LEVATOR UNITS AND A COMMON UNIT SERVING COXAL AND BASAL MUSCLES. Daniel P. Yox\* and Stacia Moffett, Dept. of Biological Sciences, SUNY, Buffalo, New York 14260 and Dept. of Zoology, Washington State University, Pullman, WA 99164. The innervation of muscles in proximal segments of crustacean limbs has not received the intensive study accorded the more distal segments. Our interest in crab basi-ischiopodite levator muscle control relates to the dual role of these two muscles in routine limb elevation and autotomy (Moffett: 1975, J. Comp. Physiol 96, 285) Physiol. <u>96</u>, 285). Nerve trunk recordings and electrical stimulation showed

that three axons innervate the smaller, more posterior levator muscle (PL). The two units which generate the largest and intermediate-sized action potentials exit the ganglion through the RLD (remoter-levator-depressor) nerve bundle and the third small-spike unit joins the RLD nerve through an anastomosis small-spike unit joins the RLD nerve through an anastomosis from the CB (coxa-basal) nerve. The basi-ischiopodite depressor, coxal promotor, anterior remotor and the anterior levator are also innervated by this common unit. It produces very small, depolarizing ejp's, but the possibility that it is a common inhibitor has not been ruled out. The larger anterior levator muscle (AL) consists of three heads. The deep anterior head (AL<sub>a</sub>) and the more superficial posterior head (AL<sub>c</sub>) originate in the thorax, whereas the small coxal head (AL<sub>c</sub>) originates in the coxa close to the origins of some PL fibers.

some PL fibers.

some PL fibers. The nerves that innervate  $AL_a$  and  $AL_p$  branch separately from the CB nerve trunk and  $AL_c$  receives its innervation via a short nerve branch which emerges from  $AL_p$ . We were interested in determining if all heads of AL receive the same innervation. We found that  $AL_c$  and  $AL_p$  are innervated by the same six motoneurons. Dual muscle fiber recordings (Yox and Moffett: 1982, Am. Zool. 52, 950) support the extracellular nerve recording data in showing that four of the six neurons that innervate  $AL_p$  are shared with Al<sub>a</sub> (one being the common unit) and  $AL_a$  has at least one additional unit (with medium-sized spike height) that does not innervate  $AL_p$ . Thus there is a limited potential for independent action by the two major of autotomy. The shared and unshared units have been different-ially stained by backfilling one nerve with NiCl<sub>2</sub> and the other with CoCl<sub>2</sub> and developing the stains with rubeanic acid (Quicke and Brace: 1979, J. Microsc. <u>115</u>, 161). Supported by NSF Grant BNS-8022762 to S. Moffett.

114.8 REFLEX ENHANCEMENT OF MUSCLE STIFFNESS IN HERMIT CRAB ABDOMEN. <u>William D. Chapple</u>. Physiology Section, Biological Sciences Group, University of Connecticut, Storrs, CT. 06268 The longitudinal muscle layer of the ventral

The longitudinal muscle layer of the ventral superficial muscles (VSM) is the major group of muscle fibers in the abdomen of the hermit crab, <u>Pagurus</u> <u>pollicarus</u>, that is involved in the support of the shell above the substrate. Longitudinal stretch of the posterior abdomen or abduction of the uropods elicits a phasic reflex discharge in the three excitor motoneurons that innervate the muscle in each segment on each side. To determine what muscle variable is controlled in this system, the right VSM and first and third roots of the fourth abdominal segment together with the abdominal nerve cord were isolated. The muscle was mounted in an oxygenated temperature controlled bath between a force transducer and a computer controlled muscle stretcher. It was subjected to ramp stretches of different amplitudes and velocities. Individual motoneuron frequencies were recorded with a floating electrode and interspike intervals, muscle force, and muscle length were stored for off line analysis. Tonic frequency of the motoneurons was not correlated with muscle length. Motoneuron frequency was a function of stretch velocity and the initial length of the muscle, but, above a threshold value, not of stretch amplitude. Static transverse stretch of the underlying cuticle increased frequency during stretch, and transverse stretch of the euticle was as function of the rate of cyticular stress. Since abolition of the reflex with 10 M atropine sulphate (which blocks acetylcholine, the sensory transmitter) reduces muscle stiffness. The reflex appears to compensate for muscle yield but does not control or regulate muscle stiffness. 114.9 LATERALIZATION OF THE NERVOUS SYSTEM TO THE PAIRED ASYMMETRIC CHELIPEDS OF MALE FIDDLER CRABS. C.K. Govind and R.E. Young. Boston Univ. Marine Pgm., Marine Biol. Lab., Woods Hole, MA. 02543 The paired chelipeds in the adult male fiddler crab, Uca

pugnax, are asymmetric consisting of a major cheliped which is used for defence and courtship and is about 30X larger than the minor cheliped which is used for cleaning, grooming and feeding. Correspondingly the 1st thoracic ganglion and its nerve root (which serve the chelipeds) is much larger on the side of the major cheliped than on the side of the minor cheliped. (In adult female fiddler crabs the paired chelipeds are symmetrical and of the minor type and there is a corresponding symmetry of their hemiganglia and nerve roots). The asymmetry in size of the hemiganglia in male fiddler crabs was explored by cobalt backfilling of their motoneurons which revealed a constancy in the number and distribution of the somata on the two sides but a significant hypertrophy of the somata and dendritic fields on the major side compared to the minor side. The somata on the major side were approximately 50% larger than their counterparts on the minor side. The asymmetry in the size of the paired nerve roots was explored by sampling the number and diameters of axon profiles from cross-sectional montages of the entire nerve roots which revealed that the major root was 2.3% larger in surface area than the minor root. In random samples, scaled accordingly, the major side had a significantly greater (3.7X) number of axon profiles than the minor side. Conversely in random but equal area (un-scaled) samples there was no significant difference in axonal numbers between major and minor sides suggesting a similarity in axonal size between the two sides. This was confirmed directly by measuring axonal diameters which gave almost identical size distribution histograms for major and minor nerve roots. (In both roots the majority (70%) of the axons were less than 1  $\mu$ m in diameter). Since the number of motoneurons are bilaterally constant in crustacean ganglia, the greater size of the major nerve root must be due to an increase in the number of sensory axons. Neural asymmetry in male fiddler crabs therefore involves hypertrophy of the motoneuron somata in the hemiganglion and hyperplasia of sensory neurons in the nerve root associated with the major cheliped. This demonstration of lateralization in specified neuronal types is a step towards unravelling its ontogeny in the male fiddler crab which displays one of the most flamboyant examples of cheliped asymmetry in crustaceans. Supported by grants from the Univ. of West Indies to R.E.Y., by NSERCC and MDA of Canada to C.K.G. and by the Grass Fdn. to Boston Univ. Marine Pgm.

114.10 CONSERVATION AND CHANGE IN A DECAPOD CRUSTACEAN GANGLION DURING EVOLUTION. D. H. Paul, A. M. Then\* and D. S. Magnuson\*. Biology Department, University of Victoria, Victoria, B.C. V&W 2Y2.

Our research concerns identification of the sites of evolutionary change in the nervous system that accompanied the acquisition of a new locomotory behavior in the Hippid sand crab Emerita (Crustacea, Anomura). Emerita's use of only the uropods for swimming appears to have evolved from Macruran tailflipping, a behavior in which the entire abdomen is alternately extended and flexed (Paul, J.exp.Biol. 94, 159). The significant differences between Emerita and Macrurans with respect to the different modes of swimming are in the tailfan (TP) and terminal abdominal ganglion (GG). Based on comparisons of the functional morphology of TF neuromusculature in sand crabs and crayfish (a Macruran), muscles in sand crabs have been categorized as 1) conserved, with conserved function in 2) conserved, with altered function and 3) new, with no Macruran homolog (Paul, 169 and unpublished). We have focussed our attention on a conserved muscle with hew function in Emerita that is innervated by the 6th root of G6; in crayfish this root contains motor neurons (MN) that are part of the set of setially homologous fast flexor MNS mediating the power stroke of the tailflip (Dumont and Wine, pers. com.). Preliminary data, tabulated as percentage of neurons in <u>Emerita</u> compared to crayfish, reveal that there are fewer 6th root MNS in <u>Emerita</u>, but that this does not reflect a uniform reduction in numbers of all kinds of neurons in G6.

	G6 neurons	Projection interneurons	MNs, root 7 excluded	MNs in 6th root
Emerita	0.50+.05	0.50	0.75	0.38
crayfish*	-	1		

\*crayfish data from Reichert et al., J. comp. Physiol. <u>149</u>, 145 To control for the possibility that some of the differences between G6 of <u>Emerita</u> and crayfish may not be specifically related to the newly evolved function of the TF in Hippids, we are examining the TF and G6 in two tailflipping Anomurans, <u>Munida</u> and <u>Calliannassa</u>. Of interest in each animal are 1) the total number of neurons and the numbers of MNs, projection interneurons and local interneurons in G6, and 2) characteristics of the individual MNs in the 6th root (their central morphology and peripheral distribution and physiology). Comparison of these data from the different genera should reveal to what extent ganglionic architecture and ccell numbers are conserved in tailflipping Anomurans, and thus allow recognition of which of the differences between <u>Emerita</u> and crayfish are specifically associated with new functions of the muscles in the TF of <u>Emerita</u>. 114.11 SEGMENTAL HOMOLOGIES IN THE FAST FLEXOR MOTOR SYSTEM IN THE ABDOMEN OF THE CRAYFISH. J.P.C. Dumont<sup>4</sup> and J.J. Wine (SPON: T. Kilduff). Depts. of Biol. and Psychol., Stanford Univ., Stanford, CA 94305. Insights into the evolution of neural circuits can be gained

Insights into the evolution of neural circuits can be gained by comparing serially homologous ganglia in a segmental animal such as the crayfish. In the abdomen, identified motor neurons innervate the powerful fast flexor muscles used during swimming. The motor neurons in turn receive input from both intra- and intersegmental interneurons, e.g. the Lateral and Medial giants. This pattern is repeated with minor variation through the anterior five segments of the abdomen (Mittenthal, J. and Wine, J., J. comp. Neurol., 177:311-334, 1978). We have extended the study of this system into the sixth segment, the tailfan (telson and uropods), which differs from the anterior segments in that it is capable of a more complex range of movements and is thought to be the fused product of two segments.

We have now identified, by morphology and physiology, all eleven of the motor neurons innervating the fast flexor muscles of the telson, as well as three premotor interneurons. All but one of the motor neurons can be shown (with varying degrees of confidence) to be homologous with motor neurons in anterior ganglia. In particular, two highly idiosyncratic motor neurons have been identified as homologues of Motor Giants on the basis of their limited dendritic branching, soma size and position, axon diameter, input from identified interneurons and size and plasticity of EJP. Since only one pair of Motor Giants exists in each anterior ganglion, their doubling, and the doubling of other similarly identifiable neurons, adds to the evidence that this ganglion was formed by fusion. The pattern of connections between the premotor interneurons

The pattern of connections between the premotor interneurons and the other motor neurons shows much more differentiation in the terminal ganglion than in the anterior ganglia. In addition to the previously documented differences between LG and MG (Larimer, J. and Kennedy, D., <u>J. exp. Biol.</u>, <u>51</u>:119-133, 1969; Kramer, A., Krasne, F. and Wine, J., <u>J. Neurophysiol.</u>, <u>45</u>, 550-574, 1981), we find that within the set of motor neurons that are excited by the MGs some are excited at short latency while others are not, and only the directly excited cells produce suprathreshold EJPs in the telson flexor muscles. Supported by NSF grant BNS 81-12431 (J.J.W.).

EFFECTS OF INSULIN DEPLETION AND REPLETION UPON INSULIN RECEPTOR 115.1 BINDING IN DISCRETE CNS REGIONS. D.J.Steel\*, R.J.Waldbillig\*, and M.S.Kappy\* (SPON: G. Hope). Depts. of Psychology and Pedia-trics, Univ. of Florida, Gainesville, FL 32611.

Recently much attention has been paid to the action of insulin in the brain. Early reports indicated that the CNS insulin binding system was independent of pancreatic insulin, because CNS insulin binding did not change in streptozotocin-induced diabetes. However, the earlier analysis was performed on whole brain homogenate, and more recent work in this laboratory, using a microdissection technique, revealed that streptozotocin treatment produces regionally specific changes in insulin binding. More specifically it was demonstrated that streptozotocin-induced diabetes leads to an up-regulation of insulin binding in circumventricular brain areas (medial hypothalamus, MH and area postrema, AP) and a down-regulation of binding in the olfactory bulb (OLF). In the lateral hypothalamus (LH) specific binding of  $I^{125}$  insulin was unaffected by diabetes. The purpose of the present study was to determine whether the

diabetes-induced changes in specific binding were the result of changes in binding site capacity or affinity. A Scatchard analysis was conducted by incubating brain parts (MH, OLF, AP, LH) from control and streptozotocin-treated (65 mg/kg, I.V.) diabetic male Long-Evans rats with  $\rm I^{125}$  porcine insulin and various concentrations of unlabelled porcine insulin. The results of this work replicated our earlier findings and indi-cated that streptozotocin treatment induces changes in both I<sup>125</sup> insulin binding site number and affinity. However, these changes are site specific with some brain areas showing changes in binding affinity and not number while other sites changed in both binding site number and affinity.

A second study was conducted to determine whether the changes in specific binding produced by streptozotocin-induced diabetes were reversible with insulin therapy. Diabetic animals were injected with long-acting (PZI) porcine insulin (6 U/Ks) and plasma glucose levels were measured. Approximately 6 hours following the insulin injection, animals had recovered from a hypoglycemia, and plasma glucose levels were in the normal range. At this time animals were sacrificed by decapitation. I<sup>225</sup> insulin binding in the above brain regions was compared to the binding in untreated diabetic and normal control animals. Preliminary results from this work indicate that 6 hours exposure to plasma insulin is sufficient to normalize diabetes-induced changes in CNS insulin binding. The findings presented above indicate that plasma insulin levels are an important determinant of insulin binding in areas both with and without direct exposure to blood-borne insulin.

MODULATION OF HEPATIC GLUCOSE PRODUCTION BY INSULIN-SENSITIVE 115.2 NEURONS IN THE AREA POSTREMA. R.J.Waldbillig\* and D.J.Steel\* (SPON: W.Dawson). Dept. of Psychology, Univ. of Florida, Gainesville, FL 32611.

It is now known that in the area of the ventromedial hypothalamus blood-borne insulin crosses the vascular wall and suppresses neural activity. Work from our laboratory has shown that in food-deprived rats low-dose ( $100\mu$ D) insulin infusions into this area produce increases in food intake and reductions in plasma glucose (Weider and Waldbillig, Soc. Neurosci. Abst. 8:144, 1982). Because the hypoglycemic effect of these infusions can be blocked by selective hepatic vagotomies, it was suggested the autonomic influences on hepatic glucose output may be modu-lated by the binding of blood-borne insulin to neurons in the VMH. More recently it has been demonstrated that pancreatic

insulin also binds in the area postrema (van Houten and Posner, Endocrinology, 109:853, 1981). The work presented here investigated the possibility that this region is also involved in modulation of parasympathetic control over hepatic glucose out-Eighteen hour food-deprived, male Long-Evans rats were put. anesthesized and infused (1)1) in the area postrema with porcine insulin (100µU) or vehicle. Blood samples for plasma glucose determination were collected from the hepatic vein before and 2,5,10,15 and 30 minutes after the infusion.

The results of this work indicated that insulin infusions into the area postrema produced a rapid (latency < 2 min) and long-lasting (duration > 30 min) decrease in plasma glucose levels. This data in conjunction with our previous report indicates that there are multiple sites at which pancreatic insulin can influence plasma glucose levels, by altering the activity in the circumventricular-autonomic axis.

To further examine the conditions under which hepatic glucose output can be modulated by insulin in the area postrema, 12 male Long-Evans rats were tested in the absence of food deprivation. Under these conditions, area postrema insulin infusions were ineffective in changing hepatic vein glucose concentration. The finding that food deprivation is a prerequisite for the hypo glycemia suggests that metabolic state may be an important deter-minant of insulin's effect in the brain. We suggest that the importance of food deprivation arises from the fact that it places the liver in a glucose-production mode, which is then suppressed by infusions of insulin into the area postrema.

In our current work we are using selective hepatic vagotomies to investigate the role of the parasympathetic nervous system in the circumventricular-hepatic interaction.

BEHAVIORAL ANALYSIS OF CHOLECYSTOKININ-DOPAMINE INTERACTIONS IN 115.3 THE NUCLEUS ACCUMBENS, L. K. Blumstein☆ and J. N. Crawley (SPON: J. Carnahan). Neurobiology Program, E. I. Du Pont Co., Glenolde PA 19036 and National Institute of Mental Health, Bethesda, MD Glenolden, 20205.

Co-localization of cholecystokinin and dopamine in mammalian brain has been extensively characterized using immunohistological and electrophysiological techniques (Skirboll, et al., Neurosci., 6:2111, 1981). A large percentage of neurons with CCK-DA co-Tocalizations were described in the ventral tegmental area, which contains projections to the medial nucleus accumbens. This dopaminergic pathway has been implicated in several behavioral paradigms, including apomorphine-induced stereotypy and locomotor hypoactivity. The following study was designed to test the hypothesis that CCK modulates the behavioral actions of dopa-minergic agents in this region of the nucleus accumbens.

Male Sprague Dawley rats, 200-250 g, were implanted with 24 gauge stainless steel hypodermic tubing bilaterally at 3.4 mm 0ne anterior, 1.2 mm lateral and 5.7 mm ventral to bregma. anterior, 1.2 mm lateral and 5.7 mm ventral to bregma. One week later, behavioral testing began. Animals were first pre-treated with either saline or apomorphine 0.1, 0.2 or 0.4 mg/kg i.p., doses which are active postsynaptically. Ten minutes later, saline or CCK<sub>k</sub> (Bachem, Torrance, CA) 20 pg-200 ng was administered bilaterally through a 31 gauge injection tube 0.5 mm below the ventral tip of the guide cannulae. They were injected, with a Sage infusion pump, in a volume of 0.2 Ll over a period of 1 minute. Stereotyped behavior was recorded every 60 seconds over the next 15 minutes using a standard scoring. 60 seconds over the next 15 minutes using a standard scoring system.

 $\ensuremath{\texttt{CK}}_{\$}$  20 pg-2 ng into the n. accumbens significantly increased the stereotypy score for systemic abomorphine 0.2 mg/kg. Furthermore, CCK: shifted the dose-response curve for apomorphine to the More, LCK: shifted the dose-response curve for appmorphine to the left. CCK alone did not induce stereotypy at doses ranging from 20 pg to 200 ng. These results suggest that CCK potentiates docamine-mediated behaviors at sites of putative co-existence in the n. accumbens. Further studies on the role of CCK in modulating hypoactivity, induced by a low dose of appmorphine active at the presynaptic dopamine autoreceptor, are in progress.

STRUCTURE-ACTIVITY ANALYSIS OF CHOLECYSTOKININ FRAGMENTS ON SATIETY-RELATED EXPLORATORY BEHAVIORS. J. N. Crawley, S. St-Pierre, and P. Gaudreau. Clinical Neuroscience Branch, National Institute of Mental Health, Bethesda, MD 20205, and Dept. Pharmacol., Univ. Sherbrooke, Scherbrooke, Canada. Cholecystokinin octapeptide-sulfate (CCK8) binds to a peripheral site to stimulate gall bladder contraction, the melace of parceratic avulcace and to initiate a sequence of 115.4

release of pancreatic anylase, and to initiate a sequence of behavioral events analogous to an underlying state of satiety<sup>1,2,3</sup>. Autoradiographic and receptor binding studies suggest that smaller CCK peptide sequences may possess many of the properties of the octapeptide4,5. To identify the peptide

the properties of the octapeptide 4,5. To identify the peptide sequence necessary for initiation of the satiety-related behavioral actions of CCKg, a series of C-terminal and N-terminal fragments were tested in a previously-described exploratory paradigm specific for CCKg<sup>3</sup>. Male Swiss-Webster mice were administered N-terminal CCK 7,6,5,4,3,2 and C-terminal CCK 7,6,5,4,3,2 in 0.9% saline, intraperitoneally, immediately before behavioral testing, in doses from  $10^{-7}$  to  $10^{-3}$  moles/kg. Number of investigatory approaches to a novel object, number of pauses of behavioral inactivity, and total pause duration over a five-minute session were recorded. The seven amino acid peptide was active only at much higher concentrations than CCKg, with smaller fragments showing minimal activity on this behavioral paradigm. There was no evidence for antagonist activity by any Smaller fragments showing minimal activity on this behavior and paradigm. There was no evidence for antagonist activity by any of the fragments tested. Addition of a tert-butyl-oxycarbonyl (Boc) group to the N-terminal reduced the potency of CCKg one-hundred fold. Unsulfated fragments were inactive at doses as high as  $10^{-3}$  moles/kg.

Comparison of the mouse exploratory behavior bioassay with Comparison of the mouse exploratory behavior bloassay with the pancreatic amylase secretion bloassay reveals major differ-ences in the biological activity of CCK fragments. It is inter esting to speculate that the behavioral actions of CCK are mediated through a separate receptor subtype, e.g., the CCK It is interreceptors recently localized on the vagus nerve.

115.5 EFFECTS OF SINGLE AND REPEATED ELECTROCONVULSIVE SHOCK (ECS) ON REGIONAL BRAIN THYROTROPIN-RELEASING HORMONE (TRH) AND NEURO-TENSIN (NT). A. Sattin, J.L. Meyerhoff, G.P. Mueller and M.J. Kubek. Depts. of Psychiat. and Anat., Indiana U. Sch. Med. and VAMC, Indianapolis, IN 46223; Dept. Med. Neurosci., Walter Reed Army Inst. Res., Washington, DC 20012; Dept. Physiol. Unif. Ser. U. Health Sciences, Bethesda, MD 20814.

We have previously observed large increases of TRH in amygdala-pyriform and hippocampus two days after five alternate-day ECS. In contrast, no effect was seen in subconvulsively shocked compared to sham ECS rats (Neurosci. Abst. 8: 982, 1982). In order to examine the onset of this effect we have now assayed TRH in brain regions following 1, 3 and 5 ECS given on alternate days. Since NT may act physiologically opposite to some effects of TRH we assayed this peptide in similar regions following 5 daily ECS. Tonic-clonic ECS was induced in male S-D rats (150-180g) with 35-60 millicoulombs (a.c.). Sham ECS rats received identical handling but no current. All rats were decapitated 48+ 3 hrs after last treatment. Brains were removed immediately, dissected, weighed and frozen on solid CO<sub>2</sub>. TRH and NT were assayed by specific RIA following HAc extraction and results expressed as pg/mg tissue (mean + SEM). Student t-tests (2-tailed) were performed following log transformation of original data. No changes in TRH content were observed following a single ECS and none were seen in septum or s. nigra following 3 or 5 ECS. Significant increases following 3 ECS were seen in pyriform cortex (PFM; 13.1+4.9 vs. 29.2+6.8, p < 0.005), amygdala (AY; 34.1+3.9 vs. 47.2+3.T, p < 0.01), hippocampus (HC; 9.0+1.4 vs. 18.3+T.2, p < 0.001) and hypothalamus (HY; 212.2+7.9 vs. 243.0+6.6, p < 0.01). Similar results were observed following 5 ECS except for HY where no significant change was seen as reported previously. Five daily ECS had no significant effect on NT in all regions examined. These results are clinically significant since the antidepressant effect of electroconvulsive treatment (ECT) requires repetitive application and is rarely seen after a single treatment. Furthermore, during ECT significant psychobehavioral improvement is usually seen following 3 to 5 alternate-day treatments. Our failure to detect any prolonged alteration in NT, another behavioraly active peptide, following repeated ECS implies some degr 115.6 COMPARISON OF THE PHARMACOLOGICAL EFFECTS OF THYROTROPIN-RELEAS-ING HORMONE (TRH) AND BICUCULLINE. <u>G. R. Breese, T. McCown, G.D.</u> <u>Frye, and R. A. Mueller</u>. Biological Sciences Research Center and Center for Alcohol Studies, UNC School of Medicine, Chapel Hill, NC 27514.

Previous studies have shown that both TRH and bicuculline will antagonize ethanol-induced depression when introduced into brain (Cott, et. al., J.P.E.T., 196:594, 1976; Frye, et. al., J.P.E.T., 233:750, 1982). Based upon observations that GABA-mimetics reduce the effects of TRH against ethanol-induced sleep, Cott and Engel (Psychopharmacology 52:145, 1977) proposed that the effects of TRH were due to inhibition of GABA function. However, the fact that intracisternal administration of the GABA antagonist, bicuculline, results in seizures whereas TRH treatment does not, suggests a difference in their basic mechanism of action. In order to examine the possibility that TRH might antagonize GABAergic transmission, TRH and bicuculline were microinjected into two brain sites where bicuculline produces distinctive behaviors not associated with seizures, as well as into a site where bicuculline induces convulsive activity. When injected into the medial septum, bicuculline methiodide (0.45 to 1.9  $\mu$ g) increased locomotor activity, induced hyperthermia and produced a short duration (30 minute) antagonism of ethanol-induced locomotor taxia did not alter locomotor activity or body temperature in ethanol-naive rats. Stereotyped behaviors (head bobbing, smiffing, gnawing) and wild running observed when bicuculline (0.6  $\mu$ g) was bilaterally microinjected into the substantia nigra were not observed when TRH (1  $\mu$ g) was administered into this site. Bicuculline (10 ng) produced seizure activity when bilaterally injected into the inferior colliculus (see Frye, et. al., Neuroscience Abstracts, 1983), but again behavior was not affected when TGH (1  $\mu$ g) was administered into the site

when TRH (1 µg) was administered into this site. These data are consistent with the view that the medial septum is a critical brain site for the analeptic action of TRH (Kalivas and Horita, J.P.E.T., 212:203, 1980) and may also be an important site of action for bicuculline to antagonize ethanol-induced depression of CNS function. However, differences in the pharmacological profile of bicuculline and TRH suggests that TRH probably does not inhibit GABA function to produce its analeptic action against ethanol. (Supported by USPHS grants AA-02334, AA-05713, NS-17509, and HD-03110 and grants from the N.C. Alcoholism Research Authority.)

115.7 EFFECTS OF CORTICOTROPIN RELEASING FACTOR (CRF) AND GROWTH HORMONE RELEASING FACTOR (GRF) ON PATTERNS OF LOCOMOTION AND BRAIN MONO-AMINES IN RATS. <u>E.H.Y. Lee\*</u>, <u>M.A. Geyer and A.J. Mandell</u>, Dept. of Psychiatry, Univ. of California at San Diego, La Jolla CA 92093 CRF produces electrophysiological and behavioral activation in rats (Ehlers, C., et al., 1982) in contrast to GRF, which produces sedation. Analysis of their amino acid sequences reveals that CRF exposes more hydrophobic groups to the membrane solvent, with the expectation of higher instability (Davidson & Fasman, 1967), while GRF manifests less exposed hydrophobicity and more potential stability. To test the hypothesis that CRF and GRF would likewise produce opposite effects on the variability of behavior (Mandell, A.J., Int. Rev. Neurobiol. 24, 1983), spatial patterns of rat locomotion were examined using a behavioral pattern monitor.

Sixteen male Sprague-Dawley rats (300-350 g) were implanted with guide cannulae in the right lateral ventricle. The experimental chamber was a  $122\times15-in$ . box with a 4x8 perpendicular array of photobeams 3/4 in. above the floor. Animals were adapted to the chamber on 2 days and then monitored during continuous infusions of saline (N=5), 0.1 µg/µl CFF (N=6) or 1.0 µg/µl CFF (N=6) at the rate of 20 µl/hr for 30 min. Animals were sacrificed 75 min later, and caudate nucleus and hippocampus were collected for HPLC determination of brain monoamines. Neither peptide significantly affected the amount of locomotor activity, although both group means were below that of controls. However (see figure) animals infused with CRF showed more randomized locomotor patterns; those infused with GRF exhibited reduced variability in their patterns. These differences were confirmed by a statistical measure of the degree of variability in the 5-10 measure of the degree of variability in the 5-10 measure of the degree of variability in the spatial patterns. CFF elevated 5-HLAA in caudate

cerns. CRF elevated 5-HLAA in caudate and hippocampus. Caudate DA and DOPAC were also increased by CRF. Without significantly altering hippocampal NE,

both pepcides increased hippocampal DA. These behavioral results support the hypothesis and suggest a possible relationship between dynamics involving sequences of amino acid hydrophobicity in CRF and GRF and the spatial patterns of locomotor behavior under their influences. The monoaminergic system may also play a modulatory role in the physiological functions of the peptides. Supported by a grant from the W. M. Keck Foundation.

Fig. 1 Top views of representative locomotor patterns induced by saline (top), GRF (center), and CRF (bottom). 115.8 INFLUENCE OF SUBSTANCE P AND FRAGMENTS ON PASSIVE AVOIDANCE BEHAVIOR. O. Gaffori, J.M. Stewart and D. De Wied. (Spon: European Neuroscience Association). Rudolf Magnus Institute for Pharmacology, Uni. of Utrecht, Vondellaan 6, 3521 GD Utrecht, The Netherlands. Health Sci. Center, Uni. of Colorado, Denver, Colorado, USA.

Brain peptides are precursor molecules of neuropeptides with different, opposite and selective CNS activities. Recently, Hall and Stewart (Abstr. Soc. for Neurosci., 8: 369, 1982) reported that the N-terminal SP-(1-7) and C-terminal pyroglutamy1-SP-(7-11) fragments of substance P exert opposite effects in several behavioral paradigms. Glowinski et al. (The Reticular Formation <u>Revisited</u>, Eds. Hobson, J.A. and Brazier, M.A.B., New York, 1980) showed that substance P neurones could play a role in the regulation of the activity of the mesocorticoprefrontal DA pathway. On the basis of these data, the effect of substance P and these pragments was studied in a step through passive

P and these fragments was studied in a step through passive avoidance paradigm after micro-injection in the nucleus accumbens It was found that both SP and SP-(7-11) attenuated passive avoidance behavior, while SP-(1-7) facilited passive avoidance behavior following injections of picogram amount into the nucleus accumbens 1 h prior to the first retention test. The lowest active dose of SP was 3 pg/rat. A dose of 10 pg/rat had a stronger effect. The fragment SP-(7-11) was less potent than SP. SP-(1-7) at a dose of 10 pg/rat attenuated passive avoidance behavior. All 3 peptides showed a U-shaped dose response curve.

The present results agree with observations summarized by Hall and Stewart (<u>Abstr. Soc. for Neurosci.</u>, 8: 369, 1982) showing that SP and SP-(1-7) have opposite effects than SP-(7-11). The C-terminal peptide generally acts excitatory while the N-terminal peptide is inhibitory. The present study shows the opposite in that the C-terminal acted inhibitory in passive avoidance behavior. The fact that SP and SP-(7-11) exert the same effect as  $\delta$ -type endorphins (Kovacs and al, J. Neurosci., <u>2</u>: S121, 1982) suggests that these peptides also may interact with DA-auto-receptors in the nucleus accumbens. The biotransformation of  $\beta$ -endorphin and vasopressin have been shown to generate powerfull neuropeptides with different, opposite and more potent effects (Burbach et al., Nature, 28: 96, 1980). It is possible that SP requires processing by enzymatic cleavage to activate moieties which elicite the opposite behavioral effects found in the present experiments and those reported by Stewart et al. (<u>Peptides</u>, <u>3</u>: 851, 1982).

- 115.9 INTRACRANIAL SUBSTANCE P AND SUBSTANCE P FRAGMENTS: EFFECTS ON MOTOR BEHAVIOR IN MICE. <u>M. E. Hall\* and J. M. Stewart</u>. Dept. of Biochemistry, Univ. of Colo. Med. Sch., Denver, CO 80262. Intracranial administration of substance P (SP) has been
  - Biochemistry, Univ. of Colo. Med. Sch., Denver, CO 80262. Intracranial administration of substance P (SP) has been shown to alter motor behavior in rats and mice. We have examined the effects of SP, SP analogs and SP fragments on motor behavior following freehand intraventricular injection. SP itself produced a dose-dependent increase in grooming behavior, with peak activity at a dose of lug (0.6nmoles)/mouse. Doses above lug led to impairment of motor function and subsequent reduction in ability to engage in coordinated grooming. We also observed reciprocal hindlimb scratching (RHS), a unique response to SP first described by Rackham and Share (S. N. abstr. 5:2092, 1979). RHS exhibited a dose-response curve similar to that for grooming. SP did not significantly alter rearing and leaning behavior (RL), although a trend toward enhanced RL was seen with 100ng/mouse of SP. SP-enhanced grooming and RHS lasted about 3-6min. All behaviors were normal at 15 and 30min after injection. All other peptides were tested at a dose of 0.6nmole/mouse. SP sulfoxide was as active as SP in enhancing grooming (10.3 vs 9.9 grooming bouts/min) and inducing RHS (3.7 vs 3.3 reciprocal scratches/min). The 7-tyrosine analog of SP showed reduced activity (1.7 RHS/min) as did 9-D-alanine-SP (1.6 RHS/min). The free acid of SP and 1-tyrosine-11-norleucine-SP were completely inactive. C-terminal fragments of SP were also tested: Pyroglutamy1-SP(7-11) (abbreviated <E-SP(7-11)) was more potent than SP on RHS (5.0/min) and grooming (13.2/min); pyroglutamy1-SP(6-11) was also quite active. SP(4-11) increased grooming only slightly above controls and produced some RHS (0.6/min), while SP(8-11) was completely inactive. The N-terminal fragments SP(1-4), SP(1-6), SP(1-7) and SP(1-8) failed to induce grooming or RHS. A non-significant trend toward enhanced RL was seen. SP(1-7)-amide did enhance RL behavior (p<0.03). To avoid effects of trauma, studies with SP(1-7) and SE-97(7-11) were repeated in mice with
- 1.15.11 SYNTHETIC SCP<sub>B</sub> ELICITS PATTERNED NEURAL FEEDING ACTIVITY FROM THE BUCCAL GANGLIA OF TRITONIA. <u>A.O. Dennis Willows</u>, and <u>P.E. Lloyd\*</u>. Friday Harbor Laboratories, Friday Harbor WA 98250, and Division of Neurobiology and Behavior, Columbia University C.P.&S., New York, NY 10032. The neuron pair Bll in the buccal ganglia of the

The neuron pair Bil in the buccal ganglia of the mudibranch mollusc Tritonia contains both the peptide SCP<sub>p</sub> which has been isolated, sequenced, and synthesized, and also ACh (P.E. Lloyd, Fed. Proc. 41:2948, 1982; Morris, H.R. et al., Nature, 300:643, 1982). We have reported also that one identified pair of buccal ganglion motor neurons (B5), generates a motor output pattern which is part of the feeding behavior of the intact animal (Willows, A.O. D. Willows, J. Neurophysiol. 44:849, 1980) and which can be modulated by electrical stimulation of Bll or by ganglionic superfusion with SCP<sub>p</sub>.

with SCP<sub>B</sub>. We now report the action of a peptide synthesized according to a sequence derived from Aplysia tissue and compare the responses it produces to those of the native peptide as extracted from B11 in Tritonia. It is an amidated nonapeptide and its structure is H-Met-Asn-Tyr-Leu-Ala-Phe-Pro-Arg-Met-NH2. The synthetic peptide co-elutes on HPLC with SCP<sub>B</sub> extracted from Tritonia. Superfusion of the isolated buccal ganglia with the

Superfusion of the isolated buccal ganglia with the peptide (either pure synthetic, or extracted and purified from Bli in Tritonia), for 1-2 m. elicits 2-5 m. of cyclic motor output from the motor pattern generator. The dose-response relationship for the peptide perfusion indicates a threshold response below 10-6M. As the peptide concentration is increased, the output of motor neurons increases both in terms of the rate of bursting and the spike frequency during each burst.

Our evidence supports the view that under normal circumstances, Bll modulates the output of the swallowing motor pattern generator by releasing the peptide both from central terminals and onto the esophagus, to co-ordinate and enhance both the central and peripheral aspects of ingestive behavior (Lloyd, P.E., Soc. Neurosci. Abstr. 252, 1979; Lloyd, P.E. and Willows A.O.D., Soc. Neurosci. Abstr. 240.9, 1980). Additionally, we find no differences in the physiological effects produced by superfusion of the synthetic (Aplysia derived) peptide, or extracted from the neurons Bll of Tritonia. 115.10 THE EFFECT OF CALCITONINS ON AMPHETAMINE-STIMULATED ACTIVITY AND SPONTANEOUS BEHAVIOR. <u>M.J. Twery, C.W.</u> <u>Cooper\*, M.H. Lewis and R.B. Mailman</u>. Depts. of Pharmacology & Psychiatry and Biological Sciences Research Center, Univ. of North Carolina, Chapel Hill, NC 27314.

Centrally administered calcitonins (CT) have been shown to suppress food intake and water consumption. We have previously reported that salmon CT also produces a long-lasting suppression of the locomotor activity stimulated by low doses of amphetamine and the daily spontaneous activity of rats in a vertical running wheel. This study describes an effect of salmon CT on spontaneous behavior, the effect of human and eel CTs on amphetamine-induced locomotor activity, and presents evidence that the effect is not due to gross impairment of motor function. <u>METHODS</u>: Synthetic eel (4100 MRC U/mg), human (100U/mg), or salmon (4200U/mg) CT (Bachem Corp., Torrace, CA) was administered to male Sprague-Dawley rats intracerebroventricularly (ICV, 600ng). Doughut-shaped cages equipped with photocell detectors were used to estimate the locomotor activity induced by IP administration of 1.5 mg/kg d-amphetamine sulfate. In other experiments, the incidence of amphetamine-induced locomotion, rearing, sniffing, and nose poking was systematically recorded for one hour by observers unaware of treatment assignments. Salmon CT (300 ng) or vehicle was administered two hours prior to treatment with amphetamine. Interobserver reliability, corrected for chance agreements, was greater than 80% for all categories. <u>RESULTS</u>: Amphetamine treatment increased the average number of photocell counts over four fold. Human, eel, or salmon CT decreased the total number of photocell counts produced by amphetamine treated rats 35, 50, and 70%, respectively. The systematic observation of rats revealed that salmon CT reduced the incidence of amphetaminestimulated locomotor and rearing activity, but failed to block amphetamine-induced locomotor activity. The dyskinesias observed before and after administration of amphetamine. <u>DISCUSSION</u>: This comparison suggests that centrally administered salmon CT is more potent than other forms of the hormone in suppressing amphetamine-simulated behavior. Since the incidence of specific behavioral topographies we

DIFFERENTIAL REGULATION OF TWO NEUROPEPTIDES IN CULTURED 116.1 CHROMAFFIN CELLS. <u>R. E. Siegel\*, L. E. Eiden\*, and R. M. Pruss</u>\* (SPON: J. Takahashi). Laboratory of Cell Biology, NIMH, Bethesda, MD 20205.

Previous work from this laboratory has shown that boyine chrorrevious work from this laboratory has shown that bovine chro-maffin cells in culture contain two neuropeptides, vasoactive intestinal polypeptide (VIP) and met-enkephalin (L.E. Eiden, et al., <u>Life Sci.</u>, in press). In this study, we have used techniques of radioimmunoassay and immunohistochemistry to both quantitate and localize these neuropeptides and to determine signals important in controlling their expression.

After four days in culture, the level of met-enkephalin in the chromaffin cells was approximately 10-fold greater than the level of VIP. A difference in the number of cells containing the two neuropeptides was also found in immunohistochemical studies. neuropeptides was also found in immunohistochemical studies. While 80-90% of the chromatfin cells expressed enkephalin-like immunoreactivity, a maximum of 3% of the cells were positive for VIP. When the cells were examined simultaneously for both VIP and enkephalin immunoreactivity, at least 80% of the VIP positive cells were also stained for the enkephalin. Thus, the two neuro-

peptides coexist in a small population of the chromaffin cells. The expression of the two neuropeptides was differentially affected by treatment with veratridine. Addition of 10  $\mu$ M veratridine to the chromaffin cell cultures produced a 10-fold elevation in the amount of VIP within 24 hours. This treatment also caused an increase in the number of cells possessing VIP immunoreactivity; a maximum of 10% of the treated cells appeared The veratridine-induced effect on VIP was both positive. positive. The veratriaine-induced effect on VIP was both time-and dose-dependent. Surprisingly, it was not blocked by 1.0 µM tetrodotoxin, suggesting that the effect is not mediated by the voltage-sensitive sodium channels. In contrast to the changes in VIP expression, the level of met-enkephalin was virtually unaltered by veratridine. Thus, the levels of neuropeptides in chromaffin cells can be controlled independently. The mechanism underlying the action of veratridine on VIP and the effects of other environmental signals on neuropeptide expression are currently under investigation.

116.2 EVALUATION OF SAPONIN-SKINNED CHROMAFFIN CELLS BY SCANNING ELEC-TRON MICROSCOPY. S.W. Carmichael and J.C. Brooks. Mayo Med. Sch, Mayo Clinic, Rochester, MN 55905 and Marquette Univ. Sch. of Dent., Milwaukee, WI 53233.

Dent., Milwaukee, WI 53233. We have previously described a method for chemically skinning (permeabilizing) cultured adrenal medullary chromaffin cells by brief exposure to the detergent saponin (<u>J Neurochem</u> 40:468, 1983). The skinned cells appeared normal by light microscopy but lost membrane-dependent functions. Cytoplasmic enzymes leaked from the cells and catecholamines were released in an apparently exocytotic fashion in the presence of exogenous MgATP and calcium. Both the biochemical evidence and light microscopy indicated limited damage to the cells by the saponin treatment. However, the extent of the membrane discontinuities could not be deter-mined by these methods. Therefore, untreated cells and saponin-skinned cells were examined by scanning electron microscopy to detect changes in surface morphology.

skinned cells were examined by scanning electron microscopy to detect changes in surface morphology. The cells used for these experiments were cultured on poly-ester film and prepared for microscopy by routine methods. Neither the saponin treatment nor preparation for electron micro-scopy had an effect on adhesion of the cells to the polyester film. The surface membrane of untreated cells had a globular appearance and nearly complete continuity. The membrane of saponin-treated cells also had a globular appearance but con-tained holes ranging in size from one micron down to 100mm. The overall morphology otherwise resembled that of the unskinned cells. Skinned cells treated with calcium and ATP to elicit secretion were morphologically indistinguishable from unstimulated, skinned cells. We conclude that the skinning process causes holes in the

plasmalemma of sufficient size for the exchange of large mole-cules with the cell interior. Either these holes are visualized directly or weaken the membrane and cause the larger holes seen in this study. It also appears that sufficient membrane remains to support an exocytotic mechanism for catecholamine secretion. Access to the cell interior provided by this technique should permit us to identify the components of the secretory system and their role in secretion. Supported in part by a grant from Marquette University Committee on Research, and NIMH grant MH37937-01

116.3 IRREVERSIBLE INHIBITION OF CATECHOLAMINE SECRETION BY THIOPHOS-PHORYLATION OF SAPONIN SKINNED CHROMAFFIN CELLS. J.C. Brooks and <u>S. Treml</u>\* Marquette Univ. Sch. of Dent., Milwaukee, WI 53233 We have previously described a method for permeabilizing chromaffin cells with the detergent saponin (J. Neurochem. 40, 468-473, 1983). This treatment disrupts the continuity of the plasma membrane and gives direct access of exogenous substances to the secretory apparatus. The secretory system of these cells is fully competent, dependent only upon exogenous calcium and ATP to elicit secretion.

There is increasing evidence that protein phosphorylation plays a pivotal role in the control of neurosecretion. We have used chemically skinned chromaffin cells to examine the role of protein phosphorylation in catecholamine scretion using the AATP analog, Adenosine-5'-0-(3-thiotriphosphate)(ATPYS). This analog can be used by cellular kinases to thiophosphorylate a proteins. However the thiophosphoproteins are then resistant to dethiophosphorylation by cellular phosphatases. Therefore, use of ATPYS should make it possible to "lock" a phosphorylation dependent process in the thiophosphorylated state.

Skinned cells incorporated thiophosphate from ATPy( $^{35}$ S) in a calcium-dependent reaction. Thiophosphorylation could be initiated by either calcium or ATP as long as the other was already present in the medium. Use of MgATP $\gamma$ S in place of MgATP abolished secretion. Inhibition of secretion was proportional to the ratio of ATPYS/ATP in the medium. Moreover, cells treated with only ATPYS were subsequently unable to secrete when presented with their normal substrate, MgATP, suggesting that the secretory system was locked in the thiophosphorylated state.

secretory system was locked in the thiophosphorylated state. We offer the hypothesis that protein phosphorylation is an obligatory control event in catecholamine secretion by chromaffin cells. Our data suggests that a calcium-dependent protein phosphorylation primes the system for secretion while dephosphorylation is the event required for exocytosis. Supported in part by a grant from the Marquette University Committee on Research.

RELATIONSHIP BETWEEN OPIOID PEPTIDE LEVELS AND STORAGE VESICLE 116.5

RELATIONSHIP BETWEEN OPIOID PEPTIDE LEVELS AND STORAGE VESICLE SYNTHESIS IN ADRENAL MEDULLARY CHROMAFFIN CELLS. S. P. Wilsonl, O. H. Viveros<sup>2</sup> and N. Kirshner<sup>\*1</sup>. <sup>1</sup>Department of Pharmacology, Duke University Medical Center, Durham, NC 27710 and <sup>2</sup>Wellcome Research Laboratories, Research Triangle Park, NC 27709. Catecholamines (CAS), opioid peptides (OPs) including met-and leu-enkephalin, and larger enkephalin-containing peptides (ECPs) which are inactive at opiate receptors are co-stored in the secretory vesicles of adrenal medullary chromaffin cells and are co-secreted upon stimulation of the gland. Addition of CA-depleting drugs such as reserpine or tetraben-azine to the medium of bovine chromaffin cell cultures produces an exponential loss of cellular CAs (t<sub>2</sub>=1.0-1.5 d) and a 1 to 2-fold increase in OPs over 2-3 d via increased enkephalin synthe-sis (Proc. Natl. Acad. Sci. <u>77</u>: 4364, 1980). These increased OP stores are released in response to secretagogues, establishing their vesicular localization (J. Neurosci. <u>2</u>: 1150, 1982). If their vesicular localization (J. Neurosci. 2: 1150, 1982). If the increase in OPs following treatment with these drugs reflects the increase in OPs following treatment with these drugs reflects new vesicle synthesis, then other chromaffin vesicle components including ECPs and dopamine *B*-hydroxylase (DBH) should increase concomitantly. Analysis of ECP levels, as well as those of membrane-bound and soluble DBH activity, however, showed no such increases preceeding or during the drug-induced increase in OPs. These data suggest that an increase in the net number of vesicles is not required to obtain the increase in OP stores induced by CA-denleting drugs.

vesicles is not required to obtain the increase in OP stores induced by CA-depleting drugs. ' Chromaffin cells stimulated by exposure to nicotine to secrete a portion of their CA, OP, ECP and soluble DBH stores recovered all of the lost OPs, ECPs and norepinephrine over the following 3 d. Only 35% of the lost epinephrine was recovered, however, and no recovery of secreted soluble DBH activity was observed. Membrane-bound DBH activity was not altered by exposure of the cells to nicotine and did not change during the following 3 d. These results further suggest that OP and ECP levels may increase independently of other chromaffin vesicle components. In contrast. addition of insulin (1 nM-1  $\mu$ M) to chromaffin

independently of other chromaffin vesicle components. In contrast, addition of insulin (1 nM-1  $\mu$ M) to chromaffin cell cultures produced concomitant increases in DBH activity and ECP levels from 1-6 d of treatment. Increases in OP and CA contents, however, were not apparent until 3-4 d following insulin addition. Hence, chromaffin cells in culture are capable of an increased rate of vesicle synthesis, although this appears to be part of a general increase in protein synthesis produced by inculin by insulin.

INDUCTION OF ADRENAL TYROSINE HYDROXYLASE (TH) BY APOMORPHINE IN 116.6 RATS RECEIVING  $\alpha$ -DIFLUOROMETHYLORNITHINE (DFMO). M. Ekker T.L. Sourkes. Departments of Biochemistry and Psychiatry, McGill University, Montreal, Quebec, Canada, H3A 1A1. Rats exposed to stressors such as cold or bodily restraint, or given the drugs apomorphine or 2-deoxyglucose, exhibit large

increases of adrenal ornithine decarboxylase (ODC) and of the putrescine content of that gland. Spermidine is also increased by immobilization (31%), apomorphine (60%), and 2-deoxyglucose (28%). Adrenal spermine is not affected by any of these treatments. The amines are measured fluorometrically after dansylation and separation by reverse-phase HPLC. Pretreatment of the animals with the irreversible ODC inhibitor DFMO, given orally (2% in drinking water) or s.c. (200 mg/kg), almost totally prevents the increase of ODC after apomorphine or immobilization; blocks the increase of putrescine after either treatment; and prevents the increase of spermidine after immobilization, but not apomorphine. This last result suggests that decarboxylation of S-adenosyl methionine, the second step in polyamine biosynthesis, S-adenosyl methionine, the second step in polyamine biosynthesis, may be rate-limiting. To determine whether the increases in ODC and/or polyamines are necessary for the induction of TH in response to the same type of stimuli, rats were given DFMO in their drinking water for several days during which they also received repeated injections of apomorphine. Administration of DFMO again resulted in effective inhibition of ODC during the experimental period, and blocked the increase in the putrescine content of the durable. The induction of TH was redefineted content of the adrenals. The induction of TH was not affected. These results question whether increases of ODC activity and of putrescine content are crucial to the induction of TH in the adrenal.

 $\alpha$ -ADRENERGIC BINDING IN THE RAT ADRENAL MEDULLA: A PUTATIVE SITE FOR THE MODULATION OF EPINEPHRINE SECRETION. M. Bouvier\*, J. de Champlain, J. LeGuerrier\* and D. Papin\* (SPON: L. Descarries). Centre de Recherche en Sciences Neurologiques, Dept of Physiology Université de Montréal, Montréal, Québec, Canada. Presynaptic regulation of the sympathetic activity has been extensively studied. The existence of  $\alpha$  and  $\beta$  adrenergic presy-naptic receptors modulating norepinephrine release by sympathetic fibers has been demonstrated "in vivo" and "in vitro". The pre-sence of a similar autoregulatory mechanism in the modulation of adrenal medulla secretion has been recently suggested by "in vi-tro" experiments. In the present study, plasma epinephrine (E) adrenal medulla secretion has been recently suggested by "in vi-tro" experiments. In the present study, plasma epinephrine (E) concentration was used as an index of adrenal medulla secretion to evaluate the functional significance of such a modulatory me-chanism "in vivo". Acute administration of the  $\alpha_2$  antagonist Yo-himbine (YOH, 0.5 mg/kg i.v.) or of the  $\alpha_2$  agonist Clonidine (CLO 15 µg/kg i.v.) did not modify basal E plasma levels in anestheti-zed rats. However, YOH potentiated by more than three folds the E increase induced by a bilateral carotid occlusion of one minute in vagotomized animals. Moreover, Clonidine completely abolished the E response to baroreflex stimulation, thus suggesting the in-volvement of an  $\alpha_2$  adrenergic mechanism in the modulation of adrenal secretion. To determine if that regulatory mechanism adrenar sectors. To determine if that regulatory mechanism could be mediated by an  $\alpha_2$  autoreceptor located on chromaffin cells, binding experiments with tritiated YOH were carried out. These studies demonstrated the presence of a high affinity bin-ding site (Kd  $\approx$  1mM) for YOH in rat adrenal medulla. The speci-fic binding of YOH to adrenal medulla membranes, observed at 4°C, is saturable, and it is linear over a wide range of tissue con-centration (up to 30 mg of tissue). The existence of this high affinity binding site suggests the presence of an  $\alpha_2$  receptor that could be at least partially responsible for the modulation of E release. Since the membrane pellets were prepared from cruof E release. de adrenal medulla homogenates, it was not possible to determine with certainty whether the binding site is located on chromaffin with certainty whether the binding site is located on chromatin cells or on pre-ganglionic sympathetic terminals. These studies lead to the conclusion that  $\alpha_2$  receptors presumably located on chromaffin cells can mediate a functional negative feedback on the epinephrine scretion by the adrenal medulla. Supported by Medical Research Council of Canada and Québec Heart Foundation.

- SEROTONIN-IMMUNOREACTIVITY IN THE ADRENAL MEDULLA OF THE RAT. 116.7
  - M. A. Holzwarth and M. S. Brownfield', Department of Anatomical Sciences, University of Illinois, Urbana, IL 61801 and School of Veterinary Medicine, Univ. of Wisconsin, Madison, WI 53715. The adrenal medulla is reported to contain predominently norepinephrine and epinephrine as well as a variety of putative peptide transmitters including substance-P, somatostatin, neurotensin, VIP and met-enkephalin. In this study, we have evidence for the presence of impressive amounts of serotonin-immunoreactivity which is distributed in epinephrine-containing cells of the rat adrenal medulla.

Adrenal glands were stained for serotonin-immunoreactivity using antiserum to serotonin-BSA conjugate (Rabbit) from Immuno-nuclear (dilutions of 1:1000 and greater) or PNMT (1:5000) and nuclear (dilutions of 1:1000 and greater) or PNMT (1:5000) and PAP immunocytochemical techniques. Albumin-reactive antibodies were removed from the serotonin antiserum by preabsorption with BSA. We observed serotonin-immunoreactivity distributed in the cytoplasm of clusters of medullary chromaffin cells. PNMT stain-ing in adjacent sections suggests co-localization of serotonin and epinephrine in the same cell. To test the specificity of the serotonin antiserum, preabsorption control studies were run by first incubating antiserum with serotonin, serotonin-BSA conju-gate, norepinephrine, epinephrine, dopamine, 5 hydroxyindole-3-acetic acid or 5 hydroxytrytophan (1.0 to 2000 µM). Only the preabsorption with serotonin-BSA conjugate completely blocked staining; a slight reduction was observed with 5-hydroxyindole-3-acetic acid. serotonin. and 5-hydroxytrytophan at concentrations acetic acid, serotonin, and 5-hydroxytryptophan at concentrations of 100 uM and greater.

The following procedures were tested to determine if the serotonin-immunoreactivity could be altered. The adrenals of rats pretreated with a serotonin synthesis inhibitor, parachlorophenylalanine (i.p., 300 mg/kg at 72 and 48 hr prior to sacrifice) showed a reduction in serotonin staining. Splanchnic nerve ligation also resulted in a decreased serotonin staining. Acute stress or reserpine (i.p., 5 mg/kg, 18 hr previously) also re-duced immunostaining. To elevate serotonin, rats were preloaded with L-tryptophan (i.p., 200 mg/kg) 4 hrs previously; this did not increase observable staining, possibly because normal staining was already so intense.

These results provide immunocytochemical evidence for the presence of serotonin-immunoreactivity in adrenal medullary cells of the rat. This immunoreactive serotonin appears to be local-ized in the catecholamine-containing cells and can be altered by treatments known to affect serotonin levels. (Supported in part by NSF Grant PCM-810-9756.)

117.1 IMMUNOCYTOCHEMICAL LOCALIZATION OF GROWTH HORMONE-RELEASING HORMONE (GHRH) IN HUMAN AND RAT HYPOTHALAMI. I. Merchenthaler\*, S. Vigh\*, A.V. Schally\*, P. Petrusz\*, F. Okazaki\* and R.V. Randall (SPON: J.D. Mann). Dept. of Anatomy, University of North Carolina, Chapel Hill, NC 27514, Endocrine and Polypeptide Laboratories, V.A. Medical Center and Dept. of Medicine, Tulane University School of Medicine, New Orleans, LA 70146, and Depts. of Endocrinology, Internal Medicine and Pathology, Mayo Clinic, Rochester, MN 55905.

Recent isolation, structural identification and synthesis of human pancreatic GHRH has made possible the generation of specific antibodies against this peptide. Synthetic GHRH, coupled to bovine serum albumin with glutaraldehyde, was used as immunogen. The resulting anti-human pancreatic GHRH serum (SV #96) crossreacted with rat hypothalamic GHRH. Using this antiserum and vibratome immunocytochemistry we report the presence of GHRH immunoreactive structures in human and rat hypothalamic tissue. All immunostaining was completely blocked by preincubation of the primary antiserum with synthetic GHRH (10 µg/ml). Absorption with glucagon, GIP, VIP, secretin, ACTH,  $\alpha$ -MSH,  $\gamma$ -endorphin, GH, PRL, anglotensin, Metenkephalin, neurotensin, somatostatin, GnRH or TRH had no affect on the intensity and distribution of the staining. Immunoreactive GHRH was present in perikarya, neuronal processes and terminals in the hypothalamus of both species. Colchicine treatment in rats dramatically increased the number of GHRH-positive perikarya and terminals as well as the intensity of their staining. Medium-sized bi- or multipolar GHRH-containing neurons were observed in the arcuate and ventromedial nuclei and in the perifornical regions of the anterior and lateral hypothalamus. The number of cells in a 50 µm thick section was 50-60 in rat, and 80-100 in human tissue. Dense accumulation of GHRHcontaining terminals was found in the external layer of the media eminence (ME). GHRH-immunoreactive fibers with regularly spaced varicosities were found throughout the hypothalamus, but were most abundant in the dorsomedial nucleus and in the regions where cell bodies were seen. The distribution of GHRH immunoreactivity as reported here is different from that of other neuropeptides or transmitters and is consistent with the results of earlier bioassay studies (Antoni et al., J. Endocr. 91:415, 1981). The localization of GHRH in the ME in both species suggests that human pancreatic GHRH is similar or identical to rat hypothalamic G

117.2 INDUCTION OF GROWTH HORMONE SYNTHESIS BY GROWTH HORMONE RELEASING FACTOR AND DEXAMETHASONE. <u>S.A. Edwards and W.W.</u> <u>Vale</u>, Peptide Biology Laboratory. The Salk Institute. La Jolla, CA 92037.

Human pancreatic tumor growth hormone releasing factor (hpGRF) was isolated on the basis of its acute effect on growth hormone (GH) secretion. We have now studied the effect of this peptide on de novo synthesis of GH in cultured, dissociated pituitaries taken from 15-day-old, female Sprague-Dawley rats. Cells were incubated for 24 hours under serum free conditions with either 10 nM hpGRF, hpGRF plus 5 nM dexamethasone (DEX), DEX alone, or with no treatment. Postincubation, cells were analyzed by SDS polyacrylamide gel electrophoresis and fluorography. 3H incorporation into the GH band was quantitated by densitometric scanning of the fluorogram. 3H incorporation into GH was increased 13.2  $\pm$  2.5-fold over that of untreated cells by co-incubation with hpGRF and DEX, 1.86  $\pm$ .34-fold by hpGRF alone, and 1.27  $\pm$ .23-fold by DEX alone.

co-incubation with hpGRF and DEX, 1.86  $\pm$ .34-fold by hpGRF alone, and 1.27  $\pm$ .23-fold by DEX alone. GH was determined by radioimmunoassay for the cell extracts, and for the 24 hour incubation medium. Total (cells plus medium) GH was increased 1.72  $\pm$ .06-fold over untreated cells by co-incubation with hpGRF and DEX, 1.47  $\pm$ .04-fold with hpGRF alone, while treatment with DEX alone had no significant effect. DEX significantly increased hpGRF mediated GH release. A 72-hour incubation with hpGRF and DEX resulted in a 2.8-fold increase in GH concentration over cultures treated with DEX alone. When initial GH content is accounted for, this represents a 7-fold increase in nt GH accumulation. Analysis of the time course indicates that the effects of hpGRF on GH synthesis can be maintained over time. Similar results, although smaller in magnitude, were obtained with picultaries from adult rats.

Incubation of pituitary cells with hpGRF in the absence of DEX or serum results in a dose-dependent general increase in the incorporation of 3H-leucine or 35S-methionine after 24 hours, an effect that was more prominent in cells taken from adult rats. SDS gel analysis indicates that most major proteins synthesized by the cells were affected. The effects of hpGRF on general amino acid incorporation were similar but not additive to the effects of serum or DEX.

We conclude that incubation of rat pituitary cells with hpGRF results in increased GH synthesis and that this effect is potentiated by DEX.

117.3 HUMAN PANCREATIC GROWTH HORMONE RELEASING FACTOR [hpGRF(1-40)OH] STIMULATES ANTERIOR PITUITARY ADENYLATE CYCLASE ACTIVITY, CYCLIC AMP ACCUMULATION AND GROWTH HORMONE RELEASE IN A CALMODULIN-DEPENDENT MANNER. <u>G. Schettini,\* M.J. Cronin, E.L. Hewlett\* and R.M. MacLeod</u>. Depts. of Med., Physiol. & Pharmacol., Univ. of Va. School of Med., Charlottesville, VA 22908. The synthetic hpGRF(1-40)OH stimulates growth hormone (GH)

The synthetic hpGRF(1-40)OH stimulates growth hormone (GH) release both in vivo and in vitro and is associated with enhanced cyclic AMP (cAMP) accumulation in pituitary cells. Ca<sup>2+</sup> involvement in stimulus-secretion coupling and in the activation of the cAMP generating system is often mediated via the Ca<sup>2+</sup> binding protein calmodulin (CaM). We investigated the role of CaM in the effect of hpCRF(1-40)OH on anterior pituitary adenylate cyclase activity, cAMP accumulation and CH release. hpCRF(1-40)OH stimulates adenylate cyclase activity in a dose-dependent manner (3, 10, 30, 100, 300 nM) both in male and female rat anterior pituitary gland membrane preparations. The inclusion of 100 nM somatostatin reduced 3, 10 and 30 nM hpCRF(1-40)OH stimulation of adenylate cyclase activity, we used a CaM blocker, the naphthalenesulfonamide derivative W7 and the less potent dechlorinated analog W5. W7 (50 and 100 uM) but not W5 (50 and 100 uM) inhibited hpCRF(1-40)OH-stimulate adenylate cyclase activity ( $\sigma < 0.00$  0.01) without offortion becal manner activity ( $\sigma < 0.00$  0.01) without offortion becal manner activity ( $\sigma < 0.00$  0.01) without offortion becal manues activity

Initiated provides the set of th

hpGRF(1-40)OH-stimulated cAMP accumulation and GH release. These results indicate that hpGRF(1-40)OH stimulates pituitary adenylate cyclase activity and that somatostatin reduces this effect. CaM participates in the hpGRF(1-40)OH stimulation of adenylate cyclase, cAMP accumulation and GH release.

ademylate cyclase, cAMP accumulation and CH release. [Supported by Fogarty Fellowship 1 F05 TW03707 (CS), USPHS CA-07535-21 (R.M.M.), and RCOA 1K04N500601, NS 18409, AM 22125 (M.J.C.); ROL AI 18000 (E.L.H.).] 17.4 HIGH DOSES OF HEPARIN SUPPRESS PULSATILE GROWTH HORMONE SECRETION IN THE MALE RAT. M.C. Obonsawin\* and S.H. Shin\* (SPON: H. Dinsdale). Dept. of Physiology, Queen's University, Kingston, Ontario, Canada K7L 3N6. Growth hormone (GH) is secreted in intermittent bursts at approximately every 3 h. We have noticed that the peak plasma concentrations of GH in our male rats (Sprague Dawley, Charles Buind COD Candian Breading Farms and Laboratories) (Life Soit

River, CD, Canadian Breeding Farms and Laboratories) (Life Sci: 31: 547, 1982) was much lower than those obtained by other GH (half-life of 5-7 min), we collected blood by a high frequency sequential blood sampling technique. When we encountered difficulties in collecting blood because of clotting, we administered an extra amount of heparin to the rats. Bursts of GH secretion in these rats occured less frequently and were of lower amplitude. Because the administration of heparin is a common practice when sampling blood sequentially at small intervals, we felt that it was important to clarify the relationship between the secretion of GH and the dose of heparin. We therefore decided to systematically examine the effects of heparin on GH release. Two days before blood collection, a cannula (Silastic tubing, 0.025" i.d., 0.047" o.d.) was inserted into the right atrium of ether anesthetized rats. On the day of the experiment, polyethylene tubing (PE-60) was connected to the outer end of the cannula, and blood samples (70  $\mu l)$  were collected from the cannula every 2 min in heparinized microhematocrit tubes. In order not to disrupt the gentle flow pattern of blood in the cannula, there was no backflushing. We tested 4 doses of heparin. First, we injected heparin (200 U/100 g B.Wt., or more) one hour before collection. Most rats did not show any major bursts of GH secretion. Second, we decreased the heparin dose to 150 U/100 g B.Wt. We saw bursts that increased the plasma GH concentration to 200-300 ng/ml. Third, we decreased the heparin dose again to 50 U/100 g B.Wt. We saw greater plasma GH concentration to 200-300 ng/ml. Third, we decreased the heparin dose again to 50 U/100 g B.Wt. We saw greater variation in GH secretion between individual rats, with some bursts as high as 800 ng/ml. In the fourth experiment, we did not inject any heparin into the rats on the day of collection, and used heparin-coated PE-60 tubing to prevent clotting. Peak plasma concentrations of GH rose as high as 1200 ng/ml. The mechanism by which heparin reduces the amplitude of the bursts of GH secretion remains to be elucidated. 117.5 HUMAN PANCREATIC GROWTH HORMONE-RELEASING FACTOR-40 STIMULATES GROWTH HORMONE SECRETION AND POTENTIATES THYROTROPIN-RELEASING HORMONE EFFECTS ON GROWTH HORMONE SECRETION IN VITRO. J. L. C. Borges\*, D. R. Uskavitch\*, D. L. Kaiser\*, W. S. Evans\* and M. O. Thorner\* (SPON: J. A. Jane). Dept. of Internal Medicine, Univ. of Virginia School of Medicine, Charlottesville, VA 22908. The effects of synthetic hpGRF-40 (courtesy of J. Rivier, J. Spiess,

The effects of synthetic hpGRF-40 (courtesy of J. Rivier, J. Spiess, and W. Vale) on GH release from continuously perifused male rat anterior pituitary cells were studied. Pulses (2.5 min.) of hpGRF-40 stimulated GH release in a linear-log dose response relationship. Random hpGRF-40 pulses at doses of 0.03, 0.1, 0.3, 1.0, 3.0, 10.0, 30.0, and 100.0 nM elicited a GH response above baseline of 1.2+0.3, 2.4+0.4, 2.8+0.2, 4.3+0.2, 6.2+0.7, 7.0+1.0, 8.7+1.7, and 10.8+0.8 (ug/min/107 cells; mean+SEM; n=3), respectively; r=0.93. During a 6 h hpGRF-40 infusion, maximal GH stimulation was seen within 5 min and GH levels then waned to near basal by the end of the sixth h. The integrated GH response to 0.03, 0.1, and 0.3 nM of hpGRF-40 were 37.6+7.4, 52.9+8.5, and 66.7+8.2 (ug/min/107 cells; mean+SEM; n=3), respectively. There was a linear-log dose response relationship with r=0.72. The interaction of TRH and GRF in the control of GH secretion was studied to investigate the mechanism of TRH stimulation of GH seen in GH excess states in humans. Dispersed cells were perifused with either 100 nM TRH for 0.5 h, or 5nM hpGRF-40 for 4 h, or 5 nM hpGRF-40 alone stimulated GH release. When TRH was added to hpGRF-40 GH levels rose from 1.4+0.06 to 4.0+1.0; ug/min/107 cells; n=4 (p=0.03). In summary, the dispersed cell system allows comparison of effective doses of hpCRF-40 when given in short pulses and long term infusions. The GH response to TRH seen in acromegaly associated with ectopic GRF secretion as well as the TRH potentiation of hpCRF-40 stimulated GH release. TRH seen in acromegaly associated with ectopic GRF secretion as well as the TRH potentiation of hpCRF-40 stimulated GH release in vitro suggest that GRF is involved in the "paradoxical" GH response to TRH seen in vivo in human GH excess states.

117.6 GABA (γ aminobutyric acid) NOT ADRENERGIC MECHANISMS IN ANTERIOR HYPOTHALAMUS FACILITATE GROWTH HORMONE (GH) SECRETION. J.O. Willoughby, P. Jervois\*, M. Menadue\*. Centre for Neuroscience, Flinders University of South Australia, Bedford Park, South Australia 5042.

Hypothalamic peptidergic neurons regulating GH are influenced by adrenergic mechanisms as well as by GABA, acetylcholine and serotonin, as judged by pharmacologic studies which indicate facilitatory roles for these neurotransmitters in GH regulation. Somatostatin neurons which are inhibitory for GH have been shown by immunohistochemical studies to be located in the periventricular preoptic-anterior hypothalamic area (PO/AHA). The present study examined whether pharmacological agents when injected into the PO/AHA adjacent to a possible site of action on somatostatin neurons, could influence GH secretion, in unanaesthetised unrestrained rats.

Male Porton rats were prepared with indwelling chronic venous cannulae and with bilateral stereotaxic intracerebral guide cannulae directed at the PO/AHA, at co-ordinates A 6200, L  $\pm$ 0.5 mm (Konig & Klippel). Seven to ten days post-operatively, 15 min serial blood samples for radioimmunoassay of GH (NIADDK) were removed for 90 min after PO/AHA injections. All drugs were administered in 0.5 µl saline via 30 gauge needles inserted through the guide cannulae to a depth of 8.3 mm below brain surface. Animals were accustomed to the injection procedure which necessitated gentle restraint. Drug doses were 0.016, 0.16, 1.6 and 16 nanomoles.

Saline injection resulted in transient inhibition of GH. The effects of epinephrine and salbutamol were no different from saline, extending previous evidence that PO/AHA norepinephrine and dopamine are also without an effect on GH. Acetylcholine, serotonin, glycine and glutamate were without apparent effect. Only muscimol evoked a brisk consistent dose-related GH secretory response (saline 107.5  $\pm$  23.2 ng/ml; muscimol 1.6 nmol, 551.2  $\pm$  81.0 ng/ml; muscimol 0.16 nmol, 561.9  $\pm$  75.7 ng/ml; muscimol 0.016 nmol, 278.3  $\pm$  82.9 ng/ml; p < .01 vs saline). Bicuculline was no different from saline in having a slight suppressive effect on GH.

It is concluded that GABAergic mechanisms in the PO/AHA have a facilitatory action in GH regulation, possibly by inhibiting somatostatinergic neurons. Such a possibility is consistent with published GABA immunohistochemical and iontophoretic studies. The site of the facilitatory action of adrenergic mechanisms in GH regulation remains elusive, because neither somatostatin- nor somatocrinin-containing regions of the hypothalamus mediate GH secretion in response to injections of adrenergic agents in the rat. Supported by the National Health & Medical Research Council of Australia.

- PERTUSSIS TOXIN ALTERS GROWTH HORMONE RELEASING FACTOR, PROSTAGLAN-117.8 PERIUSSIS TOXIN ALTERS GROWTH HORMONE RELEASING FACTOR, PROSTAGLAN-DIN E<sub>2</sub> AND SOMATOSTATIN INFLUENCES ON GROWTH HORMONE RELEASE AND CYCLIC AMP ACCUMULATION. M.J. Cronin, A.D. Rogol\*, G.A. Myers\* and E.L. Hewlett\*. Depts. Physiology, Pediatrics & Internal Medicine, Univ. Virginia Sch. Medicine, Charlottesville, Virginia 22908. Pertussis toxin (PT) protein, released by the <u>Bordetella per-tussis</u> bacterium, has a specific effect on target cells to ADP-ri-bosylate a cell membrane protein involved in coupling hormone re-contart to adaput the curdicase. We have ghap that PT affects set ceptors to adenylate cyclase. We have shown that PT affects se-veral hypothalamic releasing and inhibiting hormones at the level of the anterior pituitary gland; PT blocks the inhibition of prolactin release by gonadotropin releasing hormone. Last year at these meetings (abstract 18.57), we reported on the properties of the crude, native human pancreatic growth hormone (GH) releasing factor (GRF) which was subsequently isolated as a peptide, sequenced and synthesized. This year we report on the action of PT relative to synthetic GRF(1-44) as well as another secretagogue, relative to synthetic GRP(1-44) as well as another secretagoue, prostaglandin  $E_2$  (PGE<sub>2</sub>), and the physiological inhibitor of GH, somatostatin. Primary cultures of male rat anterior pituitary cells were pretreated for 24 hr with or without 70 ng/ml PT. An acute treatment period ( $\pm$  secretagogues,  $\pm$  somatostatin) was ter-minated by removing the medium for GH determination and extract-ing cellular cyclic AMP for radioimmunoassay. GRF and PGE<sub>2</sub> rapid-ly stimulated cyclic AMP levels and CH release in a dose dependent manner, whereas somatostatin inhibited secretagogue-stimulated cyclic AMP accumulation and CH release. PT amplified the ability of both GRF and PGE<sub>2</sub> to enhance, and reduced the ability of soma-tostatin to inhibit, these two parameters. Although a low concen-tration of PGE<sub>2</sub> (1  $\mu$ M) often had no additive effect on GRF-stimulated cyclic AMP levels, PT treatment induced a synergism between GRF and PGE<sub>2</sub> to markedly increase cellular cyclic AMP. Somatostatin inhibition of basal GH release was blocked by PT and somato-Somatostastatin inhibition of GRF- and PGE2-induced effects was attenuated In a time course study using 10 nM GRF, cyclic AMP levels by PT. were significantly greater (p < 0.01) in the PT-treated vs. control group at the earliest time studied (i.e., 10 min). This PT-induced difference was maintained for at least 6 hr after GRF adminis-tration, a time at which the cyclic AMP values were falling back to control (i.e., no GRF) levels. GH release was stimulated by GRF at 10 min and was 3.6-fold greater than control at 2 hr. PT had little or no effect on GRF-stimulated GH release, perhaps due to a maximal GRF stimulation at 10 nM. We conclude that PT modi-fies a component involved in the transduction of signals from stimulatory (GRF,  $PGE_2$ ) and inhibitory (somatostatin) receptors that affect cyclic AMP metabolism in the anterior pituitary gland. (The GRF was a gift of Drs. Guillemin and Ling. Supported by RCDA 1K04NS00601, NS18409, AM22125 and 5 S07 RR5431 21)
- IMMUNOREACTIVE SOMATOSTATIN IN THE HYPOTHALAMUS OF OBESE AND LEAN 117.7 ZUCKER RATS. L.L. Don Carlos\*, R.H. Ho, M. Berelowitz\* and J.A. Finkelstein. Northeastern Ohio Univs. Col. Med., Rootstown; Ohio State Univ., Columbus; Univ. Cincinnati, Cincinnati, Ohio. The content of hypothalamic immunoreactive somatostatin (SOM) has been reported to be significantly lower in the genetically obese vs. lean Zucker rat as measured by radioimmunoassay (RIA) (Sheppard et. al., 1980; Voyles et.al., 1982). Because neuropep-tides play a role in the control of food intake and nutrient reg-ulation, altered SOM levels may contribute to abnormal energy homeostasis in obese animals. In the first experiment, we com-pared immunocytochemical (ICC) localization of hypothalamic SOM in five obese (fa/fa) and lean (Fa/-) littermate pairs of 60 day old male Zucker rats in an attempt to determine if there is a neuroanatomical correlate of the reported decrease in SOM content. Brain sections from each pair were processed simultaneously, using anti-SOM and the PAP technique. The localization of immunoreactive cell bodies in the hypothalamus corresponded closely to previous reports. Appropriate controls confirmed the specificity of immunoreactive staining. SOM-containing neurons in the periventricular area were counted and analyzed at four hypothalamic levels (1: anterior to the suprachiasmatic nucleus [SCN]; 2: through SCN; 3: between SCN and the ventromedial hypothalamic nucleus [VMH]; 4: through VMH). No significant differences in mean number of cells were seen at any level as shown in the table. Level: 1 2

Fa/- 31 + 5 126 + 21 294 + 14 31 + 6fa/fa 38 + 4 145 + 18 293 + 8 20 + 4Fiber density and overall staining intensity in the median eminence did not appear to be different in the two groups of rats. In a second experiment, we used RIA to compare hypothalamic SOM in groups of obese and lean Zucker rats. The difference between groups was not significant. The level of SOM in hypothalamus of obese rats was 1054 + 115 ng/g wet wt, whereas the level for lean rats was 959 + 48. Thus, our ICC and RIA data are in agreement and indicate no differences in hypothalamic SOM between obese and lean male rats. The discrepancy between these findings and published reports may be due to variables such as sex, age or antibodies. Supported in part by grants from Sigma Xi, NS14344, 17080, AM30686 and CDA of JDF.

CORTICOTROPIN RELEASING FACTOR (CRF) BINDING SITES IN RAT 117.9 CORTICOTROPIN RELEASING FACTOR (CRF) BINDING SITES IN RAT PITUITARY GLAND: AUTORADIOGRAPHIC LOCALIZATION. <u>Errol B.</u> <u>De Souza, Marilyn H. Perrin\*, Jean E. Rivier\*, Wylie W. Vale and</u> <u>Michael J. Kuhar</u>. Department of Neuroscience, Johns Hopkins Univ., Sch. Med., Baltimore, MD 21205 and Peptide Biology Lab., Salk Institute for Biological Studies, La Jolla, CA 92138 Recently a 41 amino acid peptide that fulfills many of the criteria of a physiological CRF has been isolated from ovine hypothalamic extracts, characterized and synthesized (Vale et al., Science 213:1394, 1981). This peptide is a potent stimulus to the release of ACTH and beta-endorphin/beta-lipotropin from the anterrelease of ACTH and beta-endorphin/beta-lipotropin from the anter ior pituitary, both in vivo and in vitro. In the present study, we have used the radioiodinated CRF analog, NLe<sup>21</sup>, Tyr<sup>32</sup>-CRF-1<sup>125</sup> (<sup>125</sup>I-CRF), to localize specific binding sites for CRF in rat pituitary by an in vitro light microscopic autoradio-graphic method (Young and Kuhar, Brain Res. 179:255, 1979).

Before beginning autoradiographic studies in rat pituitary sections, some preliminary biochemical experiments were carried out in slide-mounted bovine pituitary sections in order to determine the optimal binding parameters and to characterize the binding of  $^{125}I-CRF$  in pituitary. The binding of  $^{125}I-CRF$  to binding of 1/21-CRF in pituitary. The binding of 1/21-CRF to bovine pituitary sections was saturable and of high affinity, with an approximate K<sub>D</sub> of 0.5 X 10<sup>-9</sup>M. Ovine CRF and its biologically equipotent analog, NLe<sup>21</sup>, Tyr<sup>32</sup>-CRF inhibited 1/251-CRF binding with 1C<sub>50</sub>'s of 1.5 and 0.9 nM, respectively. The weak biologically active analog, CRF(1-41)-OH displaced 1/251-CRF binding with an 1C<sub>50</sub> of 1 µM and the unrelated peptide, arginine vasopressin did not inhibit  $1^{25}$ I-CRF binding.

In autoradiographic studies, slide-mounted sections of rat pituitary were incubated with 0.1  $\rm nM$   $^{125}I-CRF$  to label CRF binding sites. Adjacent slide-mounted pituitary sections were coincubated with 1 µM ovine CRF in order to determine nonspecific binding. Rat pluitary autoradiograms showed specific binding sites for CRF in anterior lobe and in intermediate lobe; no specific binding sites for CRF were apparent in the posterior lobe. The relative concentrations of specific CRF binding sites (grains/500  $\mu m^2$ ; mean + SEM) in the anterior and intermediate lobes of rat pituitary were  $34.2 \pm 1.7$  and  $21.0 \pm 1.4$ , respectively. Of interest, the CRF binding sites occurred in clusters in anterior lobe whereas a relatively uniform distribution was observed in intermediate lobe of rat pituitary.

In summary, the results of our investigation confirm the existence of CRF receptors in anterior lobe and demonstrate, for the first time, the presence of specific CRF binding sites in intermediate lobe of rat pituitary. Supported by grants MH00053, MH25951 and a grant from the

McKnight Foundation.

117.10 COLOCALIZATION OF BIOTINYLATED CORTICOTROPIN RELEASING FACTOR

COLOCALIZATION OF BIOTINYLATED CORTICOTROPIN RELEASING FACTOR (CRF) and ACTH. K. N. Westlund, S. Chmielowiec\*, T. J. Collins\*, and G. V. Childs\* Dept. of Anatomy, The University of Texas Medical Branch, Galveston, Texas 77550. We have produced a biologically active biotin conjugate of CRF (Biotinyl-CRF) using biotinyl-N-hydroxysuccinimide ester (Bayer et al., Methods in Enzymology, 62: 308-315, 1979). CRF-stimulated ACTH release of the Biotinyl-CRF was compared with CRF using three day old dispersed pituitary cell cultures. Biotinyl-CRF was found to be equipotent with CRF producing a 400% increase in secretion of ACTH ( $ED_{50}$  5 x 10<sup>-10</sup>M). We have also developed stains for the bound Biotinyl-CRF on pituitary cultured cells incorporating the avidin-biotin peroxidase complex and ACTH. Both stains were followed through time with exposure to 10<sup>-10</sup>M Biotinyl-CRF (1,3,10,30,60 min) and after four hours exposure to various doses of Biotinyl-CRF. The cells were fixed in 1% glutar-aldehyde and stained with the avidin-biotin peroxidase complex using nickel intensified diaminobenzidine (black) as the sub-strate. The cells were subsequently stained immunocytochemically with 1:20,000 anti ACTH using 3-amino-9-ethyl-carbazole as the subusing interim interimined diamober is tained (black) us the constant of the cells were subsequently stained immunocytochemically with 1:20,000 anti ACTH using 3-amino-9-ethyl-carbazole as the peroxidase substrate. Both the black Biotinyl-CRF and the bright red ACTH stains were visible in the cells. The percentage of double labeled cells increased with the dose in four hour exposures (7.5 - 14.1%). Greater than 99% of the Biotinyl-CRF stained cells also double labeled for ACTH. The distribution of both the biotinyl-CRF and the ACTH stains in the corticotropes varied with time. Controls displayed only diffuse, light staining for ACTH (8.6% of cells). After one minute exposure to Biotinyl-CRF (10<sup>-10</sup> M), more intense stain for ACTH attaining pattern was compartmentalized in "blebs" and "ruffles" in 12.7% of the cells. The black Biotinyl-CRF stain in either a broad band, cap, or punctate membrane localization or a diffuse pattern appearing to be within the blebs. Ten minutes after exposure, both stains again appear diffusely over 8.5% of diffuse pattern appearing to be within the blebs. Ien minutes after exposure, both stains again appear diffusely over 8.5% of the cells. By thirty min to one hour all variations of the above stains appear in addition to a granular black intracellular stain for Biotinyl-CRF. At thirty min, 7.5% of the cells are double labeled and 11.1% of the cells are double labeled after one hour. The staining patterns and cell percentages suggest a cycling re-lease of ACTH. These studies demonstrate that affinity cytochem-istry combined with immunecutechemictry can provide valuable istry combined with immunocytochemistry can provide valuable information about cellular events such as interaction of releas-ing hormones with their target cells and that the CRF described by Vale et al. (Science 213: 1394-1397, 1981) binds specifically to anterior lobe corticotropes. Supported by the Kempner Foundation and RCDA HD00395.

- ANGIOTENSIN II INCREASES ACTH RELEASE IN THE ABSENCE OF ENDOGENOUS ARGININE-VASOPRESSIN (AVP). Eduardo Spinedi\* and <u>Andres Negro-Vilar</u>. Department of Physiology, University of Texas Health Science Center at Dallas, Dallas, TX 75235. Angiotensin II can increase ACTH release <u>in vivo</u> and this effect may possibly occur by two different mechanisms: a) a direct action at the apterior pituitary (AP) leave combined 117.11 effect may possibly occur by two different mechanisms: a) a direct action at the anterior pituitary (AP) level, combined with possible additive effects with the corticotrophin re-leasing activity (CRA) of other peptides such as AVP and CRF and/or b) by a central mechanism, increasing the release of other neural peptides, such as AVP and/or CRF. Recent studies from our laboration. (Some and and Norre Viler in publication) leasing activity (CRA) of other peptides such as AVP and CRF and/or b) by a central mechanism, increasing the release of other neural peptides, such as AVP and/or CRF. Recent studies from our laboratory (Spinedi and Negro-Vilar, in publication) indicate that adult male rats centrally-blocked with chlorpromazine-morphine-nembutal do not show increased ACTH release in response to different i.v. doses of AII, evidence which suggests a primary central site of action of the peptide. To determine the involvement of AVP in the ACTH response to AII, the present studies were designed to test whether AII is able to release ACTH in vivo in a similar fashion in intact, cannulated, freely moving Long-Evans (LE) or AVP-deficient, Brattleboro (DI) female rats. The in vivo response to AII was compared with that elicited by synthetic CRF. Also, the CRA of AII, AVP and CRF was evaluated in vitro using dispersed an-terior pituitary cells obtained from both adult female LE and DI donor rats. AII injected i.v. (0.4 or 2 µg 100 g BW) in-duced a significant, dose-related increase in plasma ACTH values 5 and 15 min after injection. Moreover, ACTH levels after CRF in DI rats were significantly greater (p<0.05) than those obtained in LE controls. The in vitro results indicate that the response of cells from either LE or DI rats to AII or AVP (both at 10 and 10 M) was similar. On the other hand, cells from DI donors were hyperresponsive to CRF (2x10 and 10 M) in terms of ACTM release when compared with the re-sponse of cells from LE rats. Taken together with our previous studies, the present results suggest that: 1) the most im-portant site of action of AII to increase ACTH output is at the central level; 2) the presence of AVP is not essential to mediate the central response to AII and 3) AII may act cen-trally to stimulate CRF release from the hypothalamus in vivo, which would then enhance ACTH output. The results in the DI rat indicate that the increased response to CRF may be an important compensatory mechanism involved in the
- 117.12 CENTRAL MODULATION OF CORTICOTROPIN RELEASING FACTOR-LIKE IMMUNOREACTIVITY SECRETION BY ARGININE VASOPRESSIN. P.M. Plotsky, T.O. Bruhn<sup>a</sup> and W. yale. Peptide Biology Laboratory, The Salk Institute, La Jolla, CA 92037. Adenohypophysial secretion of ACTH is considered to be pre-

dominantly under the control of the recently characterized 41-amino acid corticotropin releasing factor (CRF). Arginine vasopressin (AVP), which may participate in regulation of ACTH vasoretisin (AFF), which may participate in regulation of Acim secretion, has been shown to have direct stimulatory effects on the corticotrope and to potentiate the ACTH-releasing pro-perties of synthetic CRF. A central effect of AVP on hypo-thalamic CRF secretion has also been suggested. Due to the interactions between these putative releasing agents, it has proven difficult to determine the site of action of AVP in yivo. We now report direct measurements of CRF-like immunore-(CRF-LI) present in the hypophysial portal circulaactivity tion following ventricular injection of AVP and an antagonist. Hypophysial portal blood was collected in sequential 45 min

Hypophysial portal blood was collected in sequential 45 min periods from urethane anesthetized male rats by the para-pharyngeal technique of Porter. Rats had been implanted with third ventricular guide cannulas 3-6 days prior to portal blood collection. Ventricular injection (1  $\mu$ l) of one of the following solutions occurred immediately after initiation of the second collection period: (1) 0.1 M phosphate buffered saline, pH 7.4 (PBS); (2) PBS containing 90 pmole AVP; or (3) PBS containing 100 pmole 1-deaminopenicillamine. 2-(0-methyl) typosime.AVP a protent antagonist of the vasoressor and ACTHtyrosine-AVP, a potent antagonist of the vasopressor and ACTH-releasing properties of AVP. CRF-LI was determined in extracted plasma by RIA. Reported values are not corrected for recovery (60-65%).

The mean concentration of CRF-LI in portal plasma (n=10) was  $125.2 \pm 19.9$  pM (mean  $\pm$  S.E.M.), while peripheral plasma (n-10) was (30 pM). Ventricular injection of AVP significantly reduced (p<0.05) portal plasma CRF-LI concentration by 50%. In contrast, injection of AVP antagonist resulted in a 15% increase in portal blood CRF-LI concentration. Vehicle alone had no effect on portal plasma CRF-LI concentration. These observations suggest that AVP is capable of modu-

lating hypothalamic CRF release in an inhibitory manner. physiological relevance of this effect is unknown. However, the observed weak facilitation of CRF-LI secretion by AVP antagonist supports a physiological tonic inhibitory action of AVP on hypothalamic CRF secretion into the portal circulation. Higher doses of this antagonist, other antagonists or antibody to AVP may have more clearly expressed effects. (Supported by grants from the Mellon Foundation, the DFG (BR 794/1-1), and NIH grant AM26741.)

117.13 PARAVENTRICULAR LESIONS AND ACTH SECRETION IN NORMAL AND ADRENALECTOMIZED RATS. <u>T.O. Bruhn<sup>a</sup></u>, <u>P.M. Plotsky</u>, <u>R.S. Sutton<sup>a</sup> and <u>W.W. Vale</u> (SPON: C. Rivier). Peptide Biology Laboratory, The Salk Institute. La Jolla, CA 92037. Neurons containing CRF-like immunoreactivity have been lo-</u>

Neurons containing CRF-like immunoreactivity have been localized in the paraventricular nucleus (PVN) of the rat. These neurons project to the median eminence via the paraventriculo-infundibular tract. In this report, we investigate the effect of PVN lesions on CRF-like immunoreactivity in the stalk-median eminence (SME) and on pituitary ACTH secretion.

Normal male rats received bilateral PVN-lesions (1 mA anodal ourrent) 4-6 days prior to experiment. Adrenalectomized rats were lesioned 2 weeks after ADX and used 6 days after the second surgery. Animals were fitted with indwelling femoral artery catheters and blood was collected under low stress conditions. CRF and ACTH were measured by RIA as previously reported. Proopiomelanocortin mRNA levels were quantitated by solution hybridization using a 32P-labeled POMC cDNA probe (in collaboration with N. Birnberg and R. Evans, Molecular Biology Virology Laboratory. The Salk Institute).

PVN ablation caused a 90% reduction of CRF-LI in the SME of normal rats (from control levels of 2040.9 <u></u> 148.5 pg/SME, n=7) and an 80% reduction in the SME of adrenalectomized rats.

Ether stress-induced ACTH secretion was greatly attenuated by 80% in FVN-lesioned normal rats. When these rats were challenged with 0.15 mmol (i.v.) ovine CRF the ACTH response was dramatically increased by 320% at 15 minutes after injection when compared to sham animals.

In adventation of the VN caused an 80% reduction of resting ACTH levels. Proopiomelanocortin messenger RNA levels in the anterior pituitary were attenuated by 50% indicating a reduction of ACTH synthesis due to PVN ablation.

These data suggest that CRF is an important regulator of ACTH secretion and sythesis in normal and adrenalectomized rats. Pituitary hyperresponsiveness to exogenous CRF results from removal of endogenous CRF. Supported by grants from the Mellon Foundation, the DFG (BR

117.14 SECRETION OF PROOPIOMELANOCORTIN-DERIVED PEPTIDES IS INHIBITED BY A STRESS-INDUCED RATE-SENSITIVE GLUCOCORTICOID FEEDBACK SIGNAL. G. R. Van Loon and E. B. DeSouza. VA Medical Center and Dept. of

A STRESS INCOME AND E. B. DESOUZA. VA Medical Center and Dept. of Medicine, University of Kentucky, Lexington, KY 40511 Stress produces concomitant secretion of proopiomelanocortinderived peptides, and their stress-induced secretion is regulated by two distinct phases of glucocorticoid negative feedback inhibi-tion which have been termed fast or rate-sensitive and delayed or level-sensitive feedback respectively. Evidence for rate-sensitive feedback inhibition has been based almost entirely on studies using exogenous glucocorticoid, and the significance of these data has been disputed. In this study, we present physiological evidence for rate-sensitive, fast feedback inhibition of secretion of ACTH and  $\beta$ -endorphin-related pertides. We used a 2 min restraint stress to physiologically increase plasma corticosterone in adult male rats, then examined the plasma responses of immuno-reactive ACTH and  $\beta$ -endorphin plus  $\beta$ -lipotroph ( $\beta$ END/ $\beta$ LPH) to a subsequent restraint stress. After onset of this stress, plasma corticosterone increased from 2.5 to 10 min, then remained at a peak from 10 to 15 min. The rate-rise of plasma corticosterone was 120 nMmin<sup>-1</sup>, a rate consistent with literature reports using infusions of exogenous glucocorticoids as sufficient to inhibit the pituitary-adrenocortical response to stress during this period. A single 2 min restraint stress produced peak plasma levels of ACTH and BEND/BLPH 2.5 min after onset of the stress, and these plasma concentrations declined after this initial stress at rates of 2.7 and 7.4  $pMmin^{-1}$  respectively. Application of a second restraint stress at the time of the peak corticosterone response produced plasma ACTH and  $\beta END/\beta LPH$  responses identical to those following the first stress. Thus, at this time elevated glucocorticoid concentration did not appear to provide a negative feedback signal to inhibit ACTH or  $\beta END/\beta LPH$  secretion. reedoack signal to infinit Affin of pEND/pErh sected of a Application of a second stress during the period of significant rate-rise of corticosterone in plasma did not result in decreased incremental responses of plasma ACTH or  $\beta$ END/ $\beta$ LPH. However, the rates of decline of plasma ACTH and  $\beta$ END/ $\beta$ LPH of 7.6 and 32.0 pMmin from peak levels were significantly greater (p<0.01 using analysis of covariance) after this second stress applied during the period of significant increase in corticosterone than during the period of significant increase in controlstenoie that the corresponding rates of decline observed after the initial stress or after a subsequent stress applied at the peak of plasma corticosterone. In contrast to these data from intact rats, initial and subsequent stresses did not show different rates of decline of plasma ACTH or  $\beta \text{END}/\beta \text{LPH}$  in adrenalectomized rats. In conclusion, the stress-induced rate-rise of glucocorticoid provides a negative feedback signal which serves to terminate and limit the duration but not the peak of the responses of proopiomelanocortin-derived peptides to subsequent stress.

117.15 INHIBITION BY CHOLINERGIC MUSCARINIC RECEPTOR ACTIVATION OF CYCLIC AMP FORMATION AND ACTH SECRETION IN MOUSE PITUITARY TUMOR CELLS. S. Heisler\*, L. Larose\*, J. Morisset\* (SPON: F. Garcin). Unité de Biorégulation cellulaire et moléculaire, Centre hospitalier de l'Université Laval, Québec GIV 4G2 and Centre de Recherche sur les Mécanismes de Sécrétion, Faculté de Sciences, Université de Sherbrooke, Sherbrooke JIK 2Rl (L.L., J.M.)

The AtT-20/D16-16 (AtT-20) mouse pituitary tumor cell line secretes immunoreactive ACTH in response to a wide variety of secretagoues whose activity appears mediated in part by the intracellular accumulation of cyclic AMP. These include corticoropin releasing factor (CRF),  $\beta_2$ -adrenergic agonists, vaso-active intestinal peptide (VIP), and direct activators of the adenylate cyclase complex such as forskolin and cholera toxin. Muscarinic cholinergic receptors are believed to be coupled negatively to adenylate cyclase and in initial studies, using receptor binding techniques, cholinergic muscarinic receptors were identified on AtT-20 cell membranes. The density of muscarinic creceptors averaged 120 fmol/mg protein and their affinity constant for [<sup>3</sup>H]quinuclidinyl benzilate (QNB) was 1.9 X 10<sup>-10</sup>M. [<sup>3</sup>H]QNB binding was inhibited completely by atropine (K<sub>i</sub> = 1.5 X 10<sup>-5</sup>M). The effects of carbachol were subsequently investigated on basal and stimulated cyclic AMP formation and ACTH secretion in AtT-20 cells. Carbachol reduced forskolin-stimulatory effect of forskolin on both cyclic AMP formation and ACTH secretion. The stimulatory effects of (-) isoproterenol on cyclic AMP synthesis and ACTH secretion were blocked non-competitively by carbachol. The ability of carbachol to antagonize (-) isoproterenol-elevated cyclic nucleotide levels and ACTH release was minicked by oxotremorine, another muscarinic agent. The carbachol effect on the (-) isoproterenol stimulated mucleotide and secretory responses was reversed by the muscarinic antagonist atropine, but not by the nicotinic antagonist gallamine. These findings are consistent with the belief that ACTH secretion from AtT-20 cells may be regulated by activation of cholinergic muscarinic receptors which are negatively coupled to adenylate cyclase.

117.16 LONG-TERM ENDOCRINOLOGICAL CHANGES IN SUBJECTS PRACTICING THE TRANSCENDENTAL MEDITATION AND TM-SIDHI PROGRAM. O. R. Werner\*, R. K. Wallace, E. Arnold\*, B. Charles\* and R. A. Chalmers\*. Dept. of Medicine, Maharishi European Research University, Seelisberg, Switzerland CH6446, and Dept. of Neuroscience and Biology, Maharishi International University, Fairfield, Iowa 52556. In order to extend previous physiological and biochemical in-

In order to extend previous physiological and biochemical investigations on the TM and TM-Sidhi program, a longitudinal study of a number of hormones was undertaken. Eleven male subjects were examined before and (over three years ) after starting the TM-Sidhi program. Measurements of TSH, T3, T4, cortisol, prolactin and growth hormone in serum were performed by radioimmunoand prolactin levels occurred over three years with almost no change in cortisol, T3 and T4 levels. Furthermore, there was a significant decrease in day to day variation (mean coefficient of variation) in cortisol, prolactin, T3 and T4 levels. These data suggest that the TM-Sidhi program results in an increase in sensitivity of the thyroid-to-pituitary TSH stimulation, and affects the regulation of the pituitary gland. These longitudinal changes are of particular interest in the light of other studies showing beneficial effects of the TM and TM-Sidhi program on health and aging.

117.17 BOVINE SERUM ALBUMIN-GABA-HIS-PRO-NH<sub>2</sub>: AN IMMUNOGEN FOR PRODUCTION OF HIGHER AFFINITY ANTISERA FOR TRH, <u>W. W. Youngblood\*, L. J.</u> <u>Moray\*, W. H. Busby\* and J. S. Kizer\*</u> (SPON: C. Lifieberry). The Biological Sciences Research Center and the Neurobiology Program, UNC School of Medicine, Chapel Hill, North Carolina 27514. Dissatisfaction with current methods for the production of immunogens for raising antisera to TRH stimulated us to synthesize the hapten, GABA-his-pro-NH<sub>2</sub>. Coupling of this hapten to bovine serum albumin at a molar ratio of 18:1 by means of a water soluble carbidiimide produced an immunogen which stimulated the rapid production in New Zeeland white raphts of antisera with an affinity

Disscription with current methods for the production of immunogens for raising antisera to TRH stimulated us to synthesize the hapten, GABA-his-pro-NH<sub>2</sub>. Coupling of this hapten to bound serum albumin at a molar ratio of 18:1 by means of a water soluble carbidimide produced an immunogen which stimulated the rapid production in New<sub>2</sub>Zealand white rabbits of antisera with an affinity  $(2.42\pm.3\times10^{-1}$  liter/mole) for TRH, some 8-fold higher than that of antisera (.33±.03 x 10^{-1} liter/mole) raised by immunization with a conjugate produced by the currently accepted bis-diazotized benzidine bridging technique. These higher affinity antibodies when used in a standard TRH radioimmunoassay permitted the detection of less than 1 picogram of TRH per assay tube. Application of this newer radioimmunoassay to the measurement of TRH in brain tissue yielded measurements of TRH content similar to those determined by current RIA methods. Chromatography of whole crude brain extracts revealed one major immunoractive peak corresponding to authentic TRH. We conclude that immunization of rabbits with hapten rapidly produces antisera with a high affinity for TRH suitable for the development of a very sensitive TRH radioimmunoassay. This work was supported by NICHE grant HD-14005 and NIMH grant MH-00114. J. S. Kizer is recipient of RSCDA from NIMH.

117.19 RELEASE OF IMMUNOREACTIVE LUTEINIZING HORMONE AND THYROID-STIMULATING HORMONE FROM RAT HYPOTHALAMUS. N. Emanuele\*, J. Anderson\*, G. Baker\*, D. McDonald\*, L. Kirsteins\* and A. M. Lawrence\* (SPON: J. A. McLane). Biochem. Neuroendocrinol. Lab., VA Hospital, Hines, IL 60141, and Biochem. Dept., Loyola Univ.

Anderson\*, G. Baker\*, D. McDonald\*, L. Kirsteins\* and A. M. Lawrence\* (SPON: J. A. McLane). Biochem. Neuroendocrinol. Lab., VA Hospital, Hines, IL 60141, and Biochem. Dept., Loyola Univ. Stritch Sch. of Med., Maywood, IL 60153. We have previously validated the wide distribution of luteinizing hormone (LH), thyroid-stimulating hormone (TSH), and growth hormone (GH) in the rodent brain. The presence of LH has been determined by radioimmunoassay (RIA), radioreceptor assay (RRA), <u>in vivo</u> bioassay, and <u>in vitro</u> bioassay; TSH by RIA and <u>in vivo</u> bioassay; and GH by RIA, RRA, and <u>in vivo</u> bioassay. All are present in brain for up to 7 months after hypophysectomy suggesting <u>in situ</u> origin. In these studies we have examined release of immunoreactive LH and TSH from adult male rat whole hypothalamic parts including thalamus, amygdala, caudate, cerebral cortex, cerebellum, hippocampus, pons and medulla. High medium potassium (60 mM) promoted a significant increase in the release rate of both hypothalamics/30 minutes (p < .001), and LH increased from 5 ± 0.8 ng/hypothalamus/30 minutes (p < .001), and LH increased from 5 ± 0.8 ng/hypothalamus/30 minutes to 11 ± 1.6 ng/hypothalamus/30 minutes (p < .001). In each case, the potassium-induced release was significantly blunted by the omission of calcium from the medium revealed that most of the immunoassayable materials co-eluted with pituitary LH and TSH, respectively. In contrast, high potassium was not able to stimulate hormone release from any of the extrahypothalamic brain parts. <u>Conclusions</u>: 1) LH and TSH-11ke peptides are released can be significantly augmented with a depolarizing stimulus such as high potassium concentration and this effect appears to be calcium dependent, 3) The potassium-induced release of brainbased LH seems to be unique to the hypothalamus as it does not occur in any of the extrahypothalamic areas that were studied, and 4) As we have previously shown that brain-based LH and TSH are synaptosomally associated, the data from these studies 117.18 REGIONAL HYPOTHALAMIC DISTRIBUTION OF 5' MONODEIODINASES IN THE RAT. P.N. Riskind, J. Kolodny<sup>\*</sup>, J.B. Martin, and P.R. Larsen<sup>\*</sup>. Dept. of Neurol., Massachusetts General Hospital, Boston, MA 02114 and Howard Hughes Med. Institute, Brigham and Women's Hospital, Boston. MA 02115.

and noward mognes here. Instruct, bright and women's hospital, Boston, MA 02115. The 5' monodeiodinases are enzymes which convert thyroid hormones into their less-iodinated forms. Type I enzyme is widespread in its distribution, while Type II (PTU-insensitive) appears to be mainly restricted to the brain and anterior pituitary. Both can convert thyroxine(T4) into the more potent hormone triiodothyronine (T3), and both enzymes vary in activity with changes in the level of thyroid hormones. These enzymes are thought to perform at least two functions: a) insure a "critical" level of T3 is present for metabolic purposes, and b) provide a mechanism of monitoring the level of T4 in blood. We now report a discrete localization of both Type II and total(Type I + Type II) enzyme activity within the hypothalamus, and characteristic regional responses of enzyme activity to hypothyroidism.

Euchymcoid (EU) and longterm hypothyroid (HYPO) adult male Sprague-Dawley rats weighing 250-340 g were decapitated and their brains quickly removed and frozen on CO2, Brain tissue was kept at -30° until microdissection and assay within 3 weeks. Brains were sliced coronally in 1 mm thick sections, and specific brain areas were dissected with a 1 mm diameter punch; All dissection was done over CO2. Punches were homogenized and assayed for monodeiodinase activity (reverse T3 to ~1) as previously reported (Science 214: 571, 1981). Results are expressed as femtomoles/mg/hour + SEM.

5/1, 1961). Result	ts are expres	sed as remto	mores/mg/nour +	SEri.
Region	Eu: Total	Type II	Hypo: Total	Type II
preoptic area	0	0	5+5	9+5
paraventricular n.	0	0	0	ō
arcuate-median em.	103+6	10+10	256+120	249+78
dorsomedial n.	ō	ō	7+7	ō
ventromedial n.	14+2	0	29+8	17 + 12
lateral hypoth.	ō	0	15+6	9+5
cerebral cortex	27+2	0	81+11	67+8
hippocampus	62+7	0	99+2	59+10
amygdala	19+1	0	54+11	34+4

These results demonstrate that high levels of Type II enzyme are present in the arcuate-median eminence area in hypothyroid rats; furthermore, the increase in activity of Type II enzyme and decrease in activity of Type I (Total minus Type II) in that area in hypothyroid rats is considerably greater than in any other brain region measured thus far. Subsequent studies will investigate the source of deiodinase activity within the arcuate-median eminence punch, and the probable role of thyroid hormones in modifying release and/or synthesis of releasing hormones.

117.20 EFFECT OF THYROXINE (T4) ON HYPOTHALAMIC, EXTRAHYPOTHALAMIC, AND PITUITARY THYROTROPIN-RELEASING HORMONE (TRH). M.J. Kubek, J.L. Meyerhoff, T.G. Hill, and A. Sattin. Depts. of Anatomy and Psychiatry, Indiana Univ. School of Med. and VAMC, Indianapolis, IN 46223 and Dept. of Med. Neurosciences, Walter Reed Army Inst. of Res., Washington, D.C. 20012

A 46223 and bept. of Med. Neurosciences, waiter Keed Army Inst. of Res., Washington, D.C. 20012 T4 is known to modulate TSH responses to TRH at the pituitary level. However, its effects on TRH in specific hypothalamic and extrahypothalamic loci have not been clearly elucidated. We therefore sought to examine this question through alteration of the pituitary-thyroid axis.

therefore sought to examine this question through alteration of the pituitary-thyroid axis. Male S-D rats were sham (S) or surgically thyroidectomized (Tx) at 4 weeks of age (Tx rats were given 2% Ca lactate daily to drink). Four days after surgery, shams were given NaCl (0.2cc, 0.9% ip) while Tx animals received either NaCl (Tx + S), 0.2ug T4 (Tx + 0.2), or 20ug T4 (Tx + 20) per 100g BW (ip) for 21 days. All rats were decapitated and blood collected  $24 \pm 3$  hrs after the last injection. Brains were removed, immediately dissected, weighed, and frozen on dry ice. Tissues were: anterior (AP) and posterior (PP) pituitary; median eminence (ME); anterior (AHy), middle (MHy) and posterior (PHy) hypothalamus; amygdala (Ay); pyriform (PFM); midbrain (MB); lateral (LM) and medial (MM) medulla; septum; striatum; thalamus; frontal ctx; entorhinal ctx; hippocampus and the n. diagonal band. TRH was assayed by specific RIA following MeOH extraction and the results expressed as pg/mg protein (mean + SEM). Data were log-transformed and analyzed by t-tests (2-taiTed). Serum thyroid indices (T4 and TSH) were assessed by specific RIA's.

middle (MHy) and posterior (PHy) hypothalamus; amygdala (Ay); pyriform (PFM); midbrain (MB); lateral (LM) and medial (MM) medulla; septum; striatum; thalamus; frontal ctx; entorhinal ctx; hippocampus and the n. diagonal band. TRH was assayed by specific RIA following MeOH extraction and the results expressed as pg/mgprotein (mean + SEM). Data were log-transformed and analyzed by t-tests (2-taiTed). Serum thyroid indices (T4 and TSH) were assessed by specific RIA's. Thyroidectomy (S vs Tx + S) had no demonstrable effect on TRH except in MB wherein a small (p<0.05) decrease was observed. Hyperthyroidism (S vs Tx + 20) however produced marked TRH decreases in AP (198.4 + 66.1 vs 36.4 + 22.2, p<0.02), AHy (1326.5 + 103.1 vs 981.9 + 71.7, p<0.02), and PHy (2357.5 + 195.9 vs T280.9 + 204.2, p<0.005). No significant change was observed in either MHy or ME. Of equal importance was the finding of TRH decreases in AY (187.0 + 12.9 vs 128.5 + 9.4, p<0.005), PFM (40.3 + 3.5 vs 26.2 + 2.8, p<0.01), and MM (364.9 + 23.2 vs 254.7 + T7.1, p<0.02). Partial T4 replacement (S vs Tx + 0.2) also produced TRH decreases in two loci; AP (p<0.02) and AHy (p<0.005). These results suggest: 1) Hypothyroidism has no significant effect on hypothalamic, pituitary or extrahypothalamic TRH with the possible exception of MB; 2) Experimental hyperthyroidism induced marked decreases in TRH content in specific hypothalamic and extrahypothalamic loci; and 3) The AP and AHy appear to be the sites most sensitive to T4 modulation. The mechanism whereby T4 influences TRH in specific regions is unclear but may include either decreased synthesis or increased metabolism. Supported by NIH AM-28260 (MJK) and VA Research (MJK, AS).

COPTICAL SPREAD PATTERNS OF THE INTERICTAL SPIKE COMPLEX IN HUMANS ARE REVEALED BY MAGNETOENCEPHALOGRAPHY (MEG). D.S. Barth, W. Sutherling, J. Engel Jr. and J. Beatty, Depts. of Psychology 118.1 CONTICAL and Neurology, U.C.L.A., Los Angeles, CA 90024. Interictal spikes recorded in the electroencephalogram (EEG) of

Interictal spikes recorded in the electroencephalogram (EEG) of patients with complex partial seizure disorders also produce small extracranial magnetic fields. These fields may now be measured using a highly sensitive magnetic sensor, the Superconducting QUantum Interferance Device (SQUID), coupled to superconducting gradiometer coils. To map the magnetic field produced by interictal spikes, the magnetic probe is sequentially positioned at a series of closely spaced measurement points in a rectangular matrix on the scale over the discharging context. matrix on the scalp over the discharging cortex. At each point, the probes output is averaged over at least 20 interictal spikes. Computer generated magnetic field maps may then be constructed and used to locate the source of the averaged interictal spike in three dimensions (Barth, D.S., et al., <u>Science</u>, <u>218</u>: 891-894, 1982).

Neuromagnetic recording has frequently revealed the magnetic spike complex to be composed of more than one underlying source. A systematic temporal discharge pattern may often be discerned, revealing a primary source with activity preceding that of secondary sources. In these patients, it has not been possible to adequately characterize these spread patterns in the scalp EEG, probably due to smearing of the electrical potential field by surrounding tissue and the highly resistive skull. In contrast, the MEG is relatively uninfluenced by these factors and thus provides an improved spatial resolution. Work is now under way to determine the importance of these spread patterns in the production of interictal spikes, the manner in which they may influence the timing and morphology of the scalp EEG, their selective susceptibility to antiepileptic drugs, and finally, their relationship to the ictal EEG focus.

Single unit activity in non-specific and specific thalamic nuclei during generalized spike-wave discharges in feline generalized penicillin epilepsy. R.McLachlan\*, M.Avoli and P. Gloor. Montreal Neurological Institute, Dept.Neurology & Neurosurgery, McGill University, Montreal, 118.2 Québec, Canada, H3A 2B4.

Quebec, Canada, H3A 2B4. Cats given i.m. penicillin develop absence seizures with generalized spike-wave (SW) discharges similar to those in human primary generalized epilepsy. Penicillin alters the cortical response to thalamocortical volleys from one of spindles to SWs as a result of increased excitability of cortical neurons. Furthermore, neurons in specific thalamic nuclei (lateralis posterior - pulvinar, LP), are entrained to fire in synchrony with the cortical activity and in turn seem to gate this activity. Since stimulation studies suggest that nonseem to gate this activity. Since stimulation studies suggest that non-specific thalamic nuclei are most intimately involved in thalamo-cortical mechanisms of SW genesis, the EEG and single unit activity in cortex (anterior middle suprasylvian gyrus), specific (LP) and non-specific (nucleus centralis medialis, NCM; centrum medianum, CM; centralis lateralis, CL), thalamic nuclei were recorded simultaneously from cats given i.m. penicillin and the results analyzed by computer. During SW bursts all cortical neurons exhibited periods of maximum

During SW bursts all cortical neurons exhibited periods of maximum firing probability during the spike of the SW complex alternating with absence of firing with the wave. The same pattern occurred in 91% of the LP neurons, the other 9% firing predominantly during the wave. In NCM only 43% of the neurons fired preferentially during the spike while 20% fired during the wave. The others did not alter their pre-penicillin firing patterns. In CM and CL, 90% fired during the spike and none during the wave while 10% were unaffected. Rhythmic fluctuations in firing neurophylitic water much large preprior to the neurophylitic firing probability were much less prominent in the non-specific thalamus than in cortex and LP. Furthermore, those non-specific thalamic neurons which did participate in the SW rhythm always did so well after similar activity had developed in cortex and LP. Unit activity in non-specific thalamic nuclei correlated more with cortical

activity in a with that in specific thalamic nuclei. Specific thalamic nuclei activity in both non-specific and specific thalamic nuclei during SW discharge is usually a rhythmic pattern of "excitation" alternating with "inhibition", similar to that seen in the cortex. However, neurons in specific thalamic nuclei seem to be more involved in proceeding of the other there is a proceeding of the other there is a second se in generalized SW activity than those in non-specific thalamic nuclei.

Inhibitory mechanisms in feline generalized penicillin epilepsy. <u>D.</u> <u>Giaretta\*, M. Avoli, P. Gloor, G. Kostopoulos and R. McLachlan\*</u> (SPON: D.W. Baxter). Montreal Neurological Institute and Dept. of Neurology & Neurosurgery, McGill Univ., Montreal, PQ, Canada, H3A 118.3 284.

Generalized epilepsy with brief periods of "absence" and 4-5 Hz spike and wave (SW) discharges can be induced in the cat by large amounts of i.m. penicillin (300,000 - 350,000 I.U./Kg). Previous work from this laboratory has suggested that the "wave" of the SW complex may result from the activation of an intracortical feedback inhibitory mechanism (Exp.Neurol., 73: 43-71, 1981). Furthermore we also showed that cortical recurrent inhibition (RI) induced in pericruciate neurons by single shock stimulation of cerebral peduncles is not antagonized by these small concentrations of penicillin and thus could participate in this mechanism (Brain Res., 1983, in press). The aims of the present experiments were: (a) to analyze the extracellular responses of pericruciate neurons to single shock cortical stimulation and compare in the same neuron this type of inhibition (Exp. Brain Res., 9: 137-154, 1969) with RI during the development of SW discharges (after i.m.

1969) with RI during the development of SW discharges (arter 1.m. penicillin); (b) to study in intracellular recordings of pericruciate neurons performed with 3M KCI filled glass microelectrodes the hyperpolarization associated with the "wave" of the SW complex. The extracellular data, studied as peristimulus time histograms, showed that: (a) the duration of the periods of decreased firing probability induced by cortical since shock stimulation as well as RI did not change after i.m. penicillin up to and including the stage of SW discharges (b) both types of inbibition vanished as EEG train-colonic discharges; (b) both types of inhibition vanished as EEG tonic-clonic seizures appeared. In the intracellularly recorded neurons we found that: (a) intracellular injections of chloride ions decreased and inverted the early component (first 50-80ms) of the hyperpolarization (duration: 150-200ms) associated with the "wave" of SW complex, but did not clearly affect the late phase of this hyperpolorizing potential; (b) a similar response to chloride injection was observed both before and after penicillin when studying the hyperpolarization (duration: 150-200ms) induced by repetitive stimulation (4-6Hz) of n. ventralis lateralis of the thalamus.

These data demonstrate that at the concentrations of penicillin present in the cortex in feline generalized epilepsy two inhibitory mechanisms (namely those evoked by cortical and cerebral peduncle stimulation) are still preserved during SW discharges. Furthermore, they also show that the early component of the hyperpolarization associated with the "wave" of SW complex of feline generalized penicillin epilepsy results from a mechanism which is chloride-sensitive and thus enableble. CAB Associate is notware and thus probably GABAergic in nature.

TOPICAL COLCHICINE AND FOCAL EXPERIMENTAL EPILEPSY: AN INTRA-1184 CELLULAR STUDY, A. F. Reynolds, J. C. Oakley. Neurophysiology Lab, Tucson, VAMC, Tucson, AZ 85723. This is a follow up study to an extracellular study in rat

on the generation of experimental focal epilepsy after colchicine application (Oakley, J.C., Neurosci Abstr 7:206.12, 1981). The present study investigates the intracellular events underlying neuronal bursts coincident with surface electrocorticographic (ECoG) spikes. ECoG spikes developed 8-33 minutes following the (ELOG) spikes. ELOG spikes developed  $o_{-3}$  minutes following the application of 10<sup>-1</sup>M colchicine to sigmoid cortex in the locally anesthetized, paralyzed cat. The bursts were coincident with depolarizing potentials (HPs). Membrane potential oscillated 4-5 minutes with very slow depolarization between bursts. These events were seen in a zone 0.5-2 mm away from the point of colchicine application. At the point of application there was electrical silence coincident with the ECoG spike and if the ECoG spikes were frequent additive depolarization was seen.

118.5 CHANGES IN FREE Ca<sup>2+</sup> RECORDED INSIDE HIPPOCAMPAL PYRAMIDAL NEURONS IN RESPONSE TO FIMBRIAL STIMULATION. M.E. Morris, K. Krnjević & <u>N. Ropert</u>, Depts. Anaesthesiology & Pharmacology, University of Toronto, Toronto MSS 1A8, Ont., and Depts. Anaesthesia Research & Physiology, McGill University Montréal H3G 1Y6, Québec. In rats, mostly under urethane anaesthesia, double-barrelled microelectrodes that include a Ca<sup>2+</sup>-sensitive channel (Morris & McDorold 1982, Sca Neurosci abrt e 000) unreured Morris &

In rats, mostly under urethane anaesthesia, double-barrelled microelectrodes that include a  $Ca^{2+}$ -sensitive channel (Morris & MacDonald, 1982, Soc. Neurosci. Abst. 8, 909) were used to record simultaneously the membrane potential  $(V_m)$  and free  $Ca^{2+}([Ca]_1)$ inside CA1 and CA3 pyramidal neurons. In 11 cells with Vm better than -50 mV (mean -58.3 mV, S.D. 4.14), mean [Ca] was 3.6 µM, S.D. 1.64, equivalent to a  $Ca^{2+}$  <u>activity</u> of about 1.4 µM. Although higher levels of  $[Ca]_i$  were often seen in cells with poorer Vm, there was no simple correlation between Vm and  $[Ca]_i$ , a remarkably low and stable  $[Ca]_i$  often being recorded for several minutes after almost complete decay of Vm. This is in contrast to the generally good correlation between Vm and  $[K]_i$  that we observed in the same animals when recording with K<sup>+</sup>-sensitive microelectrodes, and presumably reflects the high efficacy of  $Ca^{2+}$ -buffering by neuronel extender.

There was stable [Ca]; often being recorded for several minutes after almost complete decay of Vm. This is in contrast to the generally good correlation between Vm and [K]; that we observed in the same animals when recording with K<sup>+</sup>-sensitive microelectrodes, and presumably reflects the high efficacy of Ca<sup>2+</sup>-buffering by neuronal cytoplasm (Baker & Schlaepfer, 1978, J. Physiol. 276, 103). Repetitive stimulation of the fimbria (10-20 Hz, for 30-60 s), at an intensity sufficient to generate firing in bursts in CA1 and after-discharges in CA3, had the following effects. In the majority of cells there was a moderate fall in [Ca]; (by 10-50%) that was probably a passive reflection of the sharp fall in extracellular [Ca] frequently evoked by such stimulation (Krnjevic et al., 1980, Can. J. Physiol. Pharmacol. 58, 579). In some cells, a small and progressive increase in [Ca]; (by 5-20%) was evident during the tetanus and at the onset of the phase of post-tetanic hyeroplarization. In 34 tests on 22 cells, there was a far more conspicuous rise in [Ca]; - by 2-800  $\mu$ M (with a median value of 22  $\mu$ M) - which either started during the stimulation and reached its peak near the end of the tetanus, or was delayed for 10-60 s after the end of the tetanus. The onset was usually marked by increased firing and afterdischarges; but during the 20-60 s period of raised [Ca]; there was a temporary depression or disappearance of evoked potentials, corresponding to various degrees of post-ictal or spreading depression. These effects were usually fully reversible and sometimes could be evoked repeatedly, even by much briefer tetanic stimulation (100 Hz for 1 second). Thus, strong activation of hippocampal pyramidal cells can cause a remarkably large rise in [Ca]; could be detrimental for the long-term survival of pyramidal neurons.

118.7 PENICILLIN-INDUCED EPILEPTIFORM DISCHARGES IN CA3 HIPPOCAMPAL PYRAMIDAL CELLS: A CURRENT SOURCE DENSITY ANALYSIS. J.W. Swann, R.J. Brady\*, R.J. Friedman\* and E.J. Smith\*. Ctr. for Labs & Research, NYS Dept. of Health, Albany, NY 12201 Current source density (CSD) analysis is a procedure which

Current source density (CSD) analysis is a procedure which utilizes extracellular field potential recordings to estimate the anatomical location at which neurophysiological events are generated. We have performed a one dimensional analysis of epileptiform events in CA3 region of hippocampal slices using CSD methods. Slices from rats 25-35 days of age were exposed to 1.7 mM penicillin. Extracellular epileptiform field events, evoked by orthodromic activation of stratum oriens or radiatum were examined. Tips of 3 recording microelectrodes in a triple array were aligned perpendicular to the pyramidal cell body layer and spaced 100µm apart. This array was moved perpendicular to the cell body layer at 25µm intervals across both dendritic trees. For each location of the electrode array, two different types of recordings were averaged (7-10 responses) and analysed on-line with a computer: 1) the field potential recorded by the center electrode in the array and 2) the CSD at that location. Recordings from the three electrodes in the array were used to determine the CSD by an electronic processing system (Nicholson and Llinas, Brain. Res. 100(1975), 418-424).

Cell body layer recordings of penicillin-induced epileptiform bursts consist of a slow positive field potential. Multiple negative-going population spikes ride on the envelope of the slower positive potential. The intracellular correlate of this positive field is a large slow depolarization shift (DS). Our CSD analysis clearly indicates that there are two large current sinks associated with DS generation. These were recorded 75-150µm from the center of the cell body layer in stratum oriens and 100-250µm into stratum radiatum.

Previous studies in our laboratory have shown that when hippocampal slices from rats, 9-19 days of age, are exposed to penicillin, they generate epileptiform bursts each of which is followed in cell body layer recordings by a prolonged negative field potential. Afterdischarges ride on the envelope of this slow field. In slices taken between postnatal days 25-35 afterdischarges were rarely observed. However, a small slow negative field potential was recorded in the cell body layer following the burst. A single current sink for this slow field was recorded 25-75µm from the center of the cell body layer in stratum oriens. Taken together our data suggest that the depolarization shift is not only dendritic in origin but is generated in both the basilar and apical dendrites. In contrast the subsequent slow field potential has its origin close to the cell body layer in stratum oriens. Leung\*, I. Mody, and J.J.</u> <u>Miller</u> (SPON: J. Weinberg). Department of Physiology, University of British Columbia, Vancouver, B. C., V6T 1W5. Several studies have shown that norepinephrine (NE) produces

sity of British Columbia, Vancouver, B. C., V6T 1M5. Several studies have shown that norepinephrine (NE) produces a slight but significant inhibitory effect on CAI pyramidal neurons. Following 6-hydroxydopamine depletion of hippocampal catecholamines, NE induces an enhancement of the stratum radiatum (SR)-evoked population spike response and multiple spike discharges characteristic of epileptiform activity. It was suggested that NE, in addition to exerting a direct effect on pyramidal cells, may also act upon recurrent inhibitory interneurons to produce a disinhibition of pyramidal cells (Mody, <u>et al.</u>, Can. J. Physiol. Pharmacol., 1983, in press). The present study was undertaken to examine the effect of NE on alveus-evoked inhibition, presumed to be mediated by basket cell interneurons innervating the CAI pyramidal cells. Experiments were carried out on the <u>in vitro</u> hippocampal slice preparation and inhibition was assessed by the percent reduction of the SR-evoked population spike when preceded by a conditioning pulse applied to the alveus to activate the inhibitory interneurons via the recurrent collaterals of the pyramidal cells. Paired pulse stimulation resulted in inhibition of the SR-evoked test response with conditioning-test intervals up to 60 msec. In order to assess the effect of NE on this inhibition, independent of its influence on the SR-evoked population spike response, the test pulse stimulus intensity was adjusted to maintain a similar amplitude to the pre-NE control response. NE (50  $\mu$ M) perfusion resulted in a significant and reversible reduction of the alveus-evoked recurrent inhibition (average: 75%; range: 50-90%). These data suggest the possibility that NE may result in a disinhibition of hippocampal CAl pyramidal cells due to a direct effect on recurrent inhibitory interneurons.

118.8 ADENOSINE BLOCKS NEURAL AFTERDISCHARGES GENERATED IN THE PRESENCE AND ABSENCE OF ACTIVE CHEMICAL SYNAPSES, <u>K.S. Lee</u>, <u>P. Schubert</u>\*, Max Planck Institute for Psychiatry, Munich, F.R.G.

Adenosine is a potent depressant in the central nervous system which has recently been shown to exhibit anticonvulsant activity in the hippocampus. The depressive action of adenosine on spontaneous and evoked neuronal activity is generally ascribed to its capacity to depress the release of excitatory neurotransmitters, an effect thought to be mediated by a reduction of calcium influx into the presynaptic terminal. The cellular locus of adenosine's anticonvulsant effect, however, remains unclear. In the present study, extracellularly-recorded afterdischarges elicited in the presence of either pentcillin (Pen-G 2,000-5,000 units per ml) or low calcium (0.2 mM Ca++; 4.0 mM Mg++) were examined in the CA1 region of the hippocampal slice. In normal medium (2.2 mM Ca++; 2.0 mM Mg++), antidromic stimulation via an electrode located in the alveus evokes a single negative spike recorded in the pyramidal cell layer. In contrast, in medium containing penicillin or low concentrations of calcium, one or more additional negative deflections are observed which are usually smaller in amplitude than the initial spike. Superfusion of adenosine or certain other adenosine analogues resulted in a reduction or elimination of the secondary negative deflections while apparently not affecting the amplitude of the first spike. The second wave (i.e the first afterdischarge) was reduced by 50% in the presence of 2-5  $\mu$ M adenosine with the subsequent waves being progressively more sensitive. L-phenyisopropyladenosine (L-PIA) in attenuating the afterdischarges (IC50s of 60 nM and 2  $\mu$ M respectively), characteristic of an A1 type adenosine receptor. When adenosine was introduced by pressure microinjections, the proximal apical dendritic region was the most sensitive zone for the reduction of afterdischarges. Again in these experiments the initial antidromic spike was not affected by adenosine. The effect of adenosine (either microinjected or in the medium) was antagonized by the addition of theophylline (50-200  $\mu$ M) to the bathing m

The present studies suggest that the anticonvulsant action of adenosine ocuurs at a postsynaptic site and that this effect is most potent in the apical dendrites. Furthermore the stereospecificity of the actions of L-PIA and D-PIA indicates that this effect may be mediated by an A1 type adenosine receptor.

- 118.9 KAINIC ACID MODIFIES SOME INPUT-OUTPUT RELATIONSHIPS IN THE IN VITRO RAT HIPPOCAMPUS. P. Aitken. Dept. of Physiology, Duke Univ. Med. Center, Durham, NC 27710.
  - Slices of rat hippocampus were cut at  $400\mu$  and maintained in an interface chamber at 35-36°C in a perfusion medium with ionic composition similar to that of rat extracellular brain fluid (with potassium = 3.5mM and calcium = 1.2mM). Extracellular recording electrodes were placed in the cell body and apical dendrite layers of the CAl region, and a tungsten stimulating elec-trode in the stratum radiatum. Trains of 4 constant-current stimulus pulses ( $100\mu$ sec, 0.5Hz,  $20-150\mu$ A) were delivered and the resulting responses averaged and stored on computer; a series of 10 such stimulus trains, at different intensities, was delivered every 15 minutes before, during, and after a 1 or 2 hour per-fusion with medium containing kainic acid (KA: 0.05, 0.1, or 0.2µM). Presynaptic volley and postsynaptic population spike amplitudes were measured as peak-to-peak voltages; population epsp magnitude was measured as maximum slope during the initial stage magnitude was measured as maximum slope during the initial stage of the deflection. Input-output (i-o) curves were generated for each stimulation series by plotting (1) The prevolley amplitude vs. the epsp magnitude, and (2) The epsp magnitude vs. the popu-lation spike amplitude. For both types of i-o curve, the slope of the linear portion of the curve was determined by a leastsquares fit, and taken as a measure of the effectiveness of i-o transfer.

KA had no effect on the slope of either type of i-o curve. There were, however, reversible changes in several other i-o re-lationships: (1) A decrease in the epsp magnitude required to evoke both single and multiple population spikes, (2) An in-crease in the prevolley amplitude evoked by a given stimulus in-

crease in the prevolley amplitude evoked by a given stimulus in-tensity, and (3) An increase in the epsp magnitude evoked by a given prevolley amplitude. The first 2 findings are consistent with suggestions made by others that KA's convulsant action is the result of an increase in the excitability of nerve membranes; the last finding may in-dicate that KA also has an effect on synaptic function. EXTRACELLULAR POTASSIUM CONTROLS THE FREQUENCY OF SPONTANEOUS 118.10

EXTRACELLULAR POTASSIUM CONTROLS THE FREQUENCY OF SPONTANEOUS INTERICTAL DISCHARGES IN HIPPOCAMPAL SLICES. Paul A. Rutecki\* and Daniel Johnston (SPON: F. Pirozzolo). Neurol. Dept. and Neurosci. Prog., Baylor Coll. of Med., Houston, TX 77030. When applied to hippocampal slices <u>in vitro</u>, many convulsant agents (e.g. penicillin, picrotoxin, bicuculline) produce spon-taneous, interictal-burst discharges, which occur at a relatively constant frequency (between 0.05 and 0.5 Hz depending on the agent). The parameters that control the frequency of spontaneous interictal discharges are unknown. The concentration of extra-cellular potassium ([K]) has been shown to increase during the interictal discharge, and this increase has been implicated in the transition from interictal to ictal states. The purpose of this study is to test the hypothesis that the frequency of this study is to test the hypothesis that the frequency of

this study is to test the hypothesis that the frequency of spontaneous interictal discharges is dependent on [K] and to quantify the relationship between frequency and [K]. 400-600  $\mu$ m thick transverse hippocampal slices were prepared in conventional manner from Sprague-Dawley rats. With [K] less than about 4 mM, 10  $\mu$ M bicuculline methiodide (BMI) in the bath saline produced only irregularly-occurring interictal discharges. The BMI-induced, spontaneous-discharge rate did not become regular until [K] was increased to 5 mM or greater. Increasing [K] from 5 through 10 mM increased the frequency from about 0.1 to 0.5 Hz, a five-fold change in frequency for a two-fold change in [K]. The spontaneous-discharge rate, for any given [K], was quite consistent and independent of the preceding [K]. The pooled results from a number of experiments suggest a Sigmoidal relationship between the frequency of spontaneous interictal discharges and log ([K]\_).

ictal discharges and log ([K]). In the absence of BMI, increasing [K] to a value greater than about 6 mM also produced regularly-occurring interictal discharges. Varying [K] from 6.5 to 11 mM, increased the frequency from about 0.3 to greater than 1 Hz. At any given

frequency from about 0.3° to greater than 1 Hz. At any given  $[K]_{(\geq 6.5 \text{ m})}$ , the frequency of spontaneous interictal discharges was less with BMI present. These results support the hypothesis that the frequency of spontaneous interictal discharges is dependent on  $[K]_{.}$  If changes in frequency are important for transitions to the ictal state, then these results would suggest a role for  $[K]_{.}$  in those transitions. Our results show that  $[K]_{.}$  levels within the range that have been measured in vivo during Seizures or interictal activity can cause interictal type bursting in vitro in the absence of a convulsant agent. The cellular events that are being altered by increases in  $[K]_{.}$  and that are important for controlling frequency are currently being investigated. (Supported by the Grass Foundation and NIH grants NS11535 and ported by the Grass Foundation and NIH grants NS11535 and NS18295).

118.11 INITIATION OF SYNCHRONIZED BURSTING IN NEOCORTEX. <u>C.P. George\*</u> and <u>B.W. Connors</u>. Dept. of Neurology, Stanford Univ. Sch. of Med., Stanford, CA 94305. Isolated slices of neocortex, when exposed to GABA antagonists, display paroxysmal burst discharges which are similar to epilep-togenic interictal events recorded <u>in vivo</u> (Gutnick et al., <u>J.</u> <u>Neurophysiol</u>. 48:1321, 1982). Paroxysmal discharges arise from uniquely large excitatory synaptic conductances which occur syn-chronously in each neuron of a local population. We have now in-

uniquely large excitatory synaptic conductances which occur syn-chronously in each neuron of a local population. We have now in-vestigated the initiation of synchronized bursts in greater detail. <u>In vitro</u> slices (500  $\mu$ m thick, 35°C) of guinea pig somatosen-sory cortex were exposed to bicuculline (5-50  $\mu$ M)-containing me-dia. Low intensity electrical stimuli to the white matter elici-ted all-or-none paroxysmal extracellular field potentials (PFPs) which occurred in synchrony with intracellularly recorded neuronal bursts. Each PFP was also correlated with a glial depolarization (10-15 mV) and an increase in extracellular [K<sup>T</sup>] (2-5 mM) in the middle cortical layers. The PFP consisted of an early, brief (15-20 msec) negative spike followed by a more prolonged negative wave (10-13 mV) and an increase in excracefular [x] [2-3 mV] in the middle cortical layers. The PFP consisted of an early, brief (15-20 msec) negative spike followed by a more prolonged negative wave which decayed over several seconds. The amplitude was greatest (1-4 mV) at a depth of 400-800 µm from the pial surface. Once initiated, the PFP propagated laterally (0.1-0.3 m/sec), without decrement, to encompass the entire slice. Although spontaneous PFPs were rare in slices treated with low bicuculline concentra-tions, their frequency was greatly enhanced by high bicuculline levels, addition of 4-aminopyridine (4-AP) or repeated glutamate ejections. Groups of spontaneous PFPs were occasionally followed by spreading depression, which propagated at 4 mm/min. We hypothesized that synchronized bursts were initiated by a spatially discrete subpopulation of cortical neurons. To test this notion PFPs were evoked by short (5-200 msec), focal pressure ejections of the excitatory amino acid L-glutamate. Thresholds for discharge initiation (i.e. the minimal amount of glutamate evoking a PFP) were measured at various cortical laminae. Thres-hold minima were consistently centered on layer IV, as determined

evoking a PFP) were measured at various cortical laminae. Ihres-hold minima were consistently centered on layer IV, as determined from histological reconstruction. Conversely, focal GABA was most effective in preventing electrically evoked PFPs when it was applied to the same lamina. Finally, in slices bathed in normal medium, ejection of small amounts of bicuculline yielded evoked PFPs only when applied to the middle cortical layers. We conclude that neocortical slices contain the circuitry

we conclude that mecorrical sinces contain the circuity necessary for generating evoked and spontaneous epileptic dis-charges and spreading depression. The data suggest that certain cellular elements in layer IV, when disinhibited, have a rela-tively low threshold for burst generation. These cells act as initiators of a synchronous, synaptically driven network burst in other cortical layers. Supported by RS grant RP 5353 and NS 06477 from the NIH

## EFFECTS OF CONVULSANT AND ANTICONVULSANT DRUGS ON POTASSIUM 118.12 INACTIVATION D. Doerner and L.D. Partridge. Physiol. Dept., Univ. of New Mexico, Albuquerque, N.M., 87131.

Spike broadening, a phenomenon common to many repetitively firing neurons, is characterized by the development of a shoulder on the falling phase of successive action potentials. Aldrich <u>et al.</u> (J.P.L. 291:507-530,1979) have shown that broadening is due to cumulative potassium inactivation in the

broadening is due to cumulative potassium inactivation in the presence of a maintained calcium current. We have observed that spike broadening is affected by certain convulsant and anticonvulsant drugs. The convulsant drug Pentylenetetrazol (PTZ) causes a slight decrease in the total amount of broadening but decreases the time taken to reach maximal broadening. The anticonvulsant diphenylhydantoin (DPH) significantly depresses the amount of broadening. Both of these effects persist when calcium currents have been blocked suggesting that they result from an effect on potassium inactivation.

inactivation.

Voltage clamp studies were performed in order to assess the effect of these drugs on potassium currents. Two experimental paradigms were used, one being a 6 second maintained pulse and the other a series of 600 msec, pulses at a frequency of 1.5 Hz. Similar results were obtained with both experimental procedures. Potassium currents, in the presence of PTZ, inactivated less but exhibited a shorter time constant of inactivation. DPH caused a marked reduction is total petersium inactivitien but expended marked reduction in total potassium inactivation but showed no

marked reduction in total potassium inactivation but showed no apparent change in time constant. Since transmitter release can be a function of spike duration, spike broadening is a possible mechanism by which synaptic efficacy could be increased. The depression of potassium inactivation by DPH is one possible explanation for this drug's anticonvulsant effects. The more rapid onset of potassium inactivation in the presence of PTZ might facilitate synaptic transmission during short bursts of action potentials. PTZ causes repetitively firing neurons to produce short high-frequency bursts. high-frequency bursts.

118.13 MECHANISMS UNDERLYING PICROTOXIN-INDUCED EPILEPTIFORM ACTIVITY IN THE HIPPOCAMPUS. John J. Hablitz, Department of Neurology, Baylor College of Medicine, Houston, Texas 77030 During studies concerning the mechanism of GABA antagonism by various convulsant agents, it was noticed that paroxysmal depola-

During studies concerning the mechanism of GABA antagonism by various convulsant agents, it was noticed that paroxysmal depolarizing shifts (PDSs) induced by picrotoxin were qualitatively different from those seen after exposure of slices to penicillin. Since PTX had been shown previously to block a Cl- sensitive afterhyperpolarization (AHP), that persisted after penicillin exposure, it was used here for the investigation of spontaneous and evoked PDSs in the absence of demonstrable inhibition. Intracellular recordings were made in the CA3 region of guinea

Intracellular recordings were made in the CA3 region of guinea pig hippocampal slices during the bath application of PTX (50-200uM). Neither the resting potential, input resistance nor the ability of depolarizing current pulses to trigger instrinsic burst responses was affected by addition of the convulsant agent. In contrast, the EPSP-IPSP sequence elicited by mossy fiber stimulation was markedly altered. Within 1-2 minutes PTX reduced the amplitude of the IPSP, which was associated with the appearance of multiple late depolarizations followed by a prolonged hyperpolarization. The initial IPSP then decreased further with concomitant increases in the amplitude of the Initial EPSP and late depolarizations. By 5 minutes each depolarizing component was of sufficient amplitude to trigger action potentials, and they gradually merged to form a single epileptiform response consisting of a typical PDS, followed by one or more rhythmic afterdischarges (ADS). Simultaneous intracellular recordings from pairs of CA3 the PDS, suggesting that ADs were synaptic in origin and might result from recurrent excitatory inputs. PDSs could occasionally be triggered by activation of neuronal pairs. Extracellular recordings from the CA3 areas and subsequently appeared in CA1. In many cases, a late secondary discharge was seen in CA3, suggesting a reverberation of excitation between the regions. To better understand the origin of this complex series of events, the two regions were surgically isolated. In contrast to penicillin treated slices, spontaneous PDSs were recorded from both regions. PDSs occurred with remarkable regularity in isolated CA3 sections, while an almost random pattern of significantly longer interburst intervals was seen in CA1. PDSs in both regions were generally followed by an AHP. The AHP duration was not correlated with the interval between bursts.

Further investigation of PTX induced activity should prove useful in studying the mechanism of AD generation and testing the generality of theories developed from the penicillin model. (Supported by NS-11535 and the Epilepsy Foundation of America) 118.14 INTRACELLULAR STUDIES OF THE EFFECTS OF BACLOFEN ON BICUCULLINE-INDUCED EPILEPTIFORM ACTIVITY IN CA3 PYRAMIDAL CELLS. Robert J. Brady\* and John W. Swann (SPON: M. Pierson), Center for Laboratories and Research, NYS Dept. of Health, Albany, NY 12201 Intracellular recordings were obtained from the CA3 neurons in

Tories and Research, Wis Dept. of heatin, Albday, Wis 12201 Intracellular recordings were obtained from the CA3 neurons in rat hippocampal slices. A second extracellular microelectrode was placed in the cell body layer, close to the intracellular recording site, to simultaneously monitor field potentials. Epileptiform activity was induced by bath application of bicuculline methiodide (BIC) at a concentration of 25, 50 or 100µm. Depolarization shifts (DS) were recorded intracellularly and were coincident with epileptiform bursts in the extracellular field. Our recordings demonstrate that bath application of 10 or 100µm (+) baclofen rapidly (<10 min) blocked all spontaneous epileptiform discharges in CA3 pyramidal cells. The threshold at which stratum radiatum stimulation elicited epileptiform activity rose in response to baclofen application in a concentration dependant manner. A concentration of 10µm baclofen increased the DS threshold approximately 2 fold while 100µm baclofen had little effect on DS strengths. In contrast, 1µm baclofen had little effect on DS stimulation threshold and did not alter the frequency of spontaneous epileptiform activity in slices. The time course and extent of baclofen's effect were insensitive to changes in BIC concentration.

Intracellular recordings revealed that application of baclofen at concentrations of 10 or 100µm resulted in a large increase in the conductance of the CA3 pyramidal cell membrane and an associated hyperpolarization of the cell of up to 10mV. These latter effects persisted in slices treated with tetrodotoxin (TTX) which indicate they are mediated by a post-synaptic mechanism. Application of BIC to slices treated with TTX and baclofen did not reverse the conductance change or the hyperpolarization. The effects of baclofen were reversed when the drug was washed from the experimental chamber. Intracellular and field recordings were obtained from CA3 pyramidal cells of slices treated with BIC (25 and 100µm) and subsequently exposed to the GABA agonist, muscimel, (100µm). In contrast to the action of baclofen, muscimol did not block BIC-induced epileptiform activity. We have also bath applied GABA to slices treated with 25 or 100µm BIC. At concentrations of 100µM or ImM GABA had no apparent effect. At a concentration of 100µM and subsequently (<10 min) blocked spontaneous and evoked epileptiform activity and brought about a conductance increase in individual CA3 neurons. This effect seems to be BIC insensitive. Increasing the bath concentration of BIC from 25 to 100µm did not change the time course or magnitude of GABA's effects. Supported by Grants from the Epilepsy Foundation of America and NINCDS (NS 18309).

118.15 EPILEPTIFORM ACTIVITY INDUCED BY BATH APPLICATION OF GABA TO IMMATURE HIPPOCAMPAL SLICES. Thomas J. Chesnut, John W. Swann and David O. Carpenter. Center for Laboratories and Research, NY State Dept. of Health, Albany, NY 12201 Swann and Brady (Soc. Neurosci. Abstr. 8:1016, 1982) reported that repetitive orthodromic stimulation of immature CA3 hippo-

Swann and Brady (Soc. Neurosci. Abstr. 8:1016, 1982) reported that repetitive orthodromic stimulation of immature CA3 hippocampal pyramidal cells can lead to the development of afterdischarges. Ben-Ari <u>et al.</u> (Can. J. <u>Physiol</u>., 57:1462-1466, 1979) reported that tetanic stimulation can result in a loss of efficacy of CABA inhibition in mature hippocampus and suggested that this disinhibition may be due to desensitization. Consequently, we performed the following experiments to test if GABA desensitization can cause seizure activity in the immature hippocampus. Extracellular field recordings in response to stimulation of

Extracellular field recordings in response to stimulation of stratum radiatum were obtained from the cell body layers of areas CA<sub>2</sub> and CA<sub>3</sub> of transverse slices obtained from hippocampi of immature (10-18 day old) rats. Addition of 1-10 mM GABA to the perfused Ringer induced multiple population spikes and also the appearance of spontaneous seizures culminating in spreading depression. The appearance or augmentation of a slow negative field potential previously reported by Brady and Swann (Soc. Neurosci. Abstr. 8:1016, 1982) to be associated with epileptiform activity in penicillin treated slices was also observed. The amplitude of the population spike was increased as was that of the field positivity recorded in the cell body layer. The positivity occasionally was prolonged to 1000 msec or more in duration. Recordings of the field EPSP from stratum radiatum reflected this prolonged time course. However, the effects at these GABA concentrations were not observed in every slice. The addition of  $(\pm)$ -nipecotic acid alone occasionally elicited epileptiform activity but less often and not to the same degree as when GABA was present. These observations are consistent with disinhibition and consequently for the epileptiform activity means a possibility. (Supported by NIH Postdoctoral Fellowship NS06930 to Thomas J. Chesnut and NIH grats NS18309 to John W. Swann and NS18435 to David 0. Carpenter.)

18.16 ORGANOPHOSPHATE-INDUCED EPILEPTIFORM ACTIVITY IN RAT HIPPOCAMPAL NEURONS. <u>F.J. Lebeda</u>, P.A. Rutecki\* & D. Johnston. Dept. of Neurol. & Prog. in Neurosci., Baylor Col. of Med., Houston, TX 77030.

77030. Previous in vitro studies have shown that certain convulsants (i.e., bicuculline, picrotoxin, penicillin and curare) produce regularly occurring, paroxysmal depolarizing shifts (PDSs) in hippocampal neurons, which are due to large, excitatory postsynaptic potentials (Johnston & Brown, <u>Science 211</u>:294, 1981; Lebeda <u>et al.</u>, J. <u>Neurophysiol</u>. 48:622, <u>1982</u>). The amplitudes of these waveforms are monotonic functions of membrane potential and reverse in polarity near 0 mV. Concomitantly, these agents appear to abolish spontaneously occurring inhibitory postsynaptic potentials (IPSPs), which suggests that interference by these compounds with the putative GABAergic system is involved in generating the PDSs. The question we addressed was whether disinhibition is a general mechanism of action for other convulsants. Rat hippocampal slices were prepared in a standard manner and continuously perfused with physiological media. Extracellular

continuously perfused with physiological media. Extracellular and intracellular recordings were made from the CA3 subfield. Bath application of the organophosphorus anticholinesterase

Bath application of the organophosphorus anticholinesterase (anti-ChE), diisopropyl phosphorofluoridate (DFP), at 10  $\mu$ M, produced spontaneously occurring (.1-.3 Hz) field discharges, which resemble those events caused by the other agents. This DFP-induced activity was not antagonized by the ChE reactivator, pralidoxime (10-100  $\mu$ M), and ceased upon washout. At higher concentrations of DFP (25-50  $\mu$ M), these events were accompanied (ca. every 30 sec) by prolonged discharges (1-2 sec). Occasionally, these events were replaced by large (10-20 mV), long lasting (1-2 min), negative-going field potentials during which evoked responses could not be elicited, a phenomenon reminiscent of spreading depression (SD).

of spreading depression (SD). Other anti-ChE agents tested (physostigmine, pyridostigmine, 10-200  $\mu$ M) did not produce repetitive field activity. Two putative K-channel blockers, 4-aminopyridine (4AP, 1-50  $\mu$ M) and tetraethylammonium (TEA, 1-10 mM), however, were found to generate repetitive and SD waveforms similar to those seen with DFP. Intracellular recordings in the presence of 4AP or DFP revealed that spontaneously occurring IPSPs were prominent and that the comparent reuterial of the DFD was more near

Intracellular recordings in the presence of 4AP or DFP revealed that spontaneously occurring IPSPs were prominent and that the apparent reversal potential of the PDS was more negative than with the previously examined convulsants, a finding that is also consistent with the idea that an inhibitory synaptic input is still functional. These results further suggest that DFP, 4AP and TEA represent a class of convulsants whose principle mode of action is not disinhibition, but instead may involve the modulation of K-currents or some other process. (Supported by USAMRDC DAMD-17-82-C-2254, the Grass Foundation, and NIH grants NS11535 and NS18295). 118.17 EFFECT OF VALPROIC ACID ON CHOLINERGIC TRANSMISSION. <u>Karim A.</u> <u>Alkadhi</u>. Department of Pharmacology, University of Houston, Houston, TX 77004.

Valproic acid (VPA) is an anticonvulsant drug chemically unrelated to other anticonvulsant agents. The mechanism by which VPA exerts its antiepileptic effect has not been established. Although numerous studies have shown that VPA raises gama-aminobutyri acid (CABA) level, others presented evidence that cast some doubt on the CABA hypothesis (e.g. Anlezark et al. Biochem. Pharmacol. <u>25</u>:413, 1976). The aim of the present experiments was to obtain information on possible effects of VPA on cholinergic synaptic transmission using frog neuromuscular junction as a model.

In magnesium-blocked intact cutaneous pectoris muscles, VPA in clinically relevant concentrations produced a concentration-dependent decrease in the quantal content of the endplate potential EPP). No apparent change in the resting membrane potential of the muscle fiber was observed. There was a slight decrease (about 20%, ImM VPA) in the amplitude of miniature EPP (MEPP) but no apparent change in the frequency of MEPP was seen. The effects of VPA were not readily reversible on washing and residual effects of the drug were still present after 20-30 min of continuous superfusion with drug-free Ringer's solution.

Preliminary testing of VPA on release parameters during low frequency facilitation (Maeno and Edwards. J. Neurophysiol. <u>32</u>: 785, 1969) suggested a parallel downward shift in the frequency facilitation curve.

In voltage-clamped transected cutaneous pectoris muscle fibers, preliminary experiments suggested that VPA ( <0.1 mM) had no effect on the time constant of decay ( $\tau$ ) of the endplate current. Investigation of higher, clinically relevant, concentrations is planned.

Supported by a grant from the Epilepsy Foundation of America.

118.18 EFFECTS OF CONVULSANT AGENTS ON CULTURED NEUROBLASTOMA CELLS. J. Davenport and R. Rumpf\*. VA Hospital and Dept. Neurology, U. Missouri, Columbia, MO 65201.

> The synapse-free soma membrane effects of standard experimental epileptogenic agents were studied in cultures of mouse neuroblastoma clone NIE-115. Cells were grown to confluency in DMEM (high glucose, no pyruvate) with 10% FCS, streptomycin and 20 mM Hepes. Morphological differentiation was achieved with 2% DMSO added to growth media in final subculture. After 2-4 weeks, differentiated cells of 65-150 um diameter and possessing 2-9 major neurites were penetrated with 2M KCl-filled micropipettes having DC resistance 15-40 MΩ, using inverted phase microscopy. Standard single-electrode current-clamping techniques yielded reproducible data of somatic resting potential, DC input resistance, Na<sup>+</sup>, k<sup>+</sup>, and Ca<sup>2+</sup> currents and repetitive firing behavior. Intracellular recordings were made during constant superfusion with phosphate-buffered saline solution (Tuttle, Richelson. Brain Res 1975;84:129), to which convulsants were added: penicillin 25 mM; picrotoxin 100 uM; pentylenetetrazol 100 mM; bicuculline 100 mM; strychnine 200 uM in final concentration. Specific ionic current behaviors were examined by the use of TTX, TEA and calcium exclusion.

Stable resting membrane potential was 40  $\pm$  16 mV, input resistance was 27  $\pm$  15 MΩ; no repetitive firing was observed in the absence of applied current, which induced decrementing action potentials in 28% of studied cells. Penicillin, picrotoxin, pentylenetetrazol and strychnine had no effect on any examined cell function. Bicuculline produced small changes in action potential shape most consistent with reduced or delayed K<sup>+</sup> currents.

The epileptogenic effects of these standard experimental agents appear to require neuronal mechanisms not present in cultured neuroblastoma soma membranes, possibly including preor post-synaptic sites, specially differentiated dendritic trees, or more complex neuronal interactions.

118.19 PHENYTOIN AND CARBAMAZEPINE SELECTIVELY LIMIT SUSTAINED HIGH FREQUENCY REPETITIVE FIRING OF CULTURED MOUSE NEURONS. <u>M. J.</u> <u>McLean\* and R. L. Macdonald</u> (SPON: G. Siegel). Dept. of Neurology, University of Michigan, Ann Arbor. MI 48109.

ogy, University of Michigan, Ann Arbor, MI 48109. The effect of the anticonvulsant drugs phenytoin,carbamazepine, valproic acid and ethosuximide on sustained high frequency repetitive firing of action potentials was studied.

Nouse spinal cord neurons in primary dissociated cell culture were maintained <u>in vitro</u> for 4-6 weeks prior to experiments. For experiments, the cell cultures were bathed in protein-free buffered salt solutions with elevated magnesium (10 mM) to abolish spontaneous activity. Standard electrophysiological techniques were used to record transmembrane potentials of cells impaled with high resistance (20-50 MR) glass microelectrodes filled with 4M potassium acetate. Using the bridge technique to allow simultaneous current passage and recording of potential, long depolarizing pulses (0.5-2.0 sec) were applied to the impaled neurons. In control solution, progressively greater depolarizing pulses evoked sustained trains of action potentials firing at increasing frequency. Anticonvulsant drugs were then introduced by adding alignots of concentrated stock solution or by superfusion of solutions containing drugs at known concentrations. The range of drug concentrations studied included values equivalent to cerebrospinal fluid concentrations of patients with therapeutic serum levels.

Phenytoin and carbamazepine limited firing to a few action potentials in a concentration-dependent manner. For phenytoin, the effect commenced at 1.0  $\mu$ g/ml and was maximal at about 2-3  $\mu$ g/ml. For carbamazepine the effect commenced at about 0.8  $\mu$ g/ml and was maximal at about 1.5-2.0  $\mu$ g/ml. The effect was rapid in onset and could be reversed by returning to drug-free solution. Ethosuximide (25-100  $\mu$ g/ml) and valproic acid (8-25  $\mu$ g/ml)

did not effect the ability to sustain rapid firing. Repetitive firing in the presence of these drugs did not differ significantly from that in control solution. Selective limitation of the ability of neurons to sustain high

Selective limitation of the ability of neurons to sustain high frequency repetitive firing of action potentials at concentrations effective against clinical seizures may represent an important cellular mechanism of anticonvulsant activity of phenytoin and carbamazepine but not for valproic acid or ethosuximide. 118.20 INTERACTIONS OF FLURAZAPAM WITH GLUTAMATE EVOKED EXCITATORY RESPONSES OF CEREBELLAR PURKINJE NEURONS, J.-T. Cheng and B.D. Waterhouse, Dept. of Cell Biology, U. Tx. Hith. Sci. Ctr., Dallas, TX 75235.

Previous studies from this laboratory have demonstrated that norepinephrine (NE) can enhance both excitatory and inhibitory responses of cerebellar Purkinje (P) cells evoked by microiontophoretic application of glutamate (GLU) and GABA, respectively. Flurazapam (FUI), an anticonvulsant drug, has also been shown to potentiate the inhibitory action of GABA on P-neurons; possibly via a mechanism shared in common with NE. The present investigation was conducted to examine the action of FUU on GLU-evoked excitation of P-neurons and compare these effects with those of NE.

Extracellular activity of cerebellar P-cells was recorded from halothane anesthetized hooded rats. Excitatory responses of P-cells (n=19) to iontophoretic pulses of GLU (13-56 nA) were examined before, during and after FLU microiontophoresis (5-13nA). FLU-induced changes in GLU evoked and spontaneous P-cell discharge were quantitatively assessed by computer based analysis of drug response histograms. In 9 P-neurons, GLU-evoked excitations were attenuated during

In 9 P-neurons, GLD-evoked excitations were attenuated during FLU application at ejection currents which had little or no effect on spontaneous firing rate. In 2 of these 9 cases, GLD-induced excitations were preserved when FLU began to exert a marked depressant effect on background firing, such that there was a net enhancement of the GLU response. In 7 additional cells, FLU produced a similar net facilitation of the GLU-induced response, when spontaneous discharge was suppressed by 13% or more. FLU had no effect on GLU excitation in 3 cases. Iontophoretic administration of FLU also revealed or potentiated a post-GLU depression of firing in 7 P-cells at doses which suppressed spontaneous discharge. In summary, these results suggest that flurazapam has a

Goese which suppresses spontaneous discharge. In summary, these results suggest that flurazapam has a twofold, dose dependent action on P-neuron responsiveness to GLU. At low doses, FLU attenuates GLU-induced excitation. At higher doses which suppress background firing, FLU enhances GLU-induced excitation relative to spontaneous discharge and facilitates post-excitatory depression of activity. A combination of such effects in intact neuronal circuits may contribute to the anticonvulsant actions of this compound. The facilitating actions of FLU on GLU excitation and post-excitatory depression as reported here are similar to those observed for NE; thus the possibility must be considered that these agents share a common mechanism to augment P-cell responsiveness to GLU. 119.1 INNATE ABNORMALITIES IN CNS SEROTONIN CONCENTRATIONS IN GENETI-CALLY EPILEPSY-PRONE RATS (GEPRs). Phillip C. Jobe, Hugh E. Laird, II and John W. Dailey. Departments of Pharmacology and Psychiatry, LSU Medical Center, Shreveport, LA 71130 and Department of Pharmacology and Toxicology, University of Arizona, College of Pharmacy Turscon 27, 85721

Psychlatry, LSD Medical Lenter, Shreveport, LA 7130 and Department of Pharmacology and Toxicology, University of Arizona, College of Pharmacy, Tucson, AZ 85721. Drug studies support the concept that CNS serotonergic transmission attenuates seizure intensity in the GEPR and that a serotonergic deficit is one determinant of seizure susceptibility in this model. Pathophysiological studies of non-drug treated GEPRs with moderately severe seizures show that, after exposure to a seizure provoking stimulus, deficits in serotonin levels exist in the telencephalon, hypothalamus, midbrain and ponsmedulla. The purpose of the present investigation was to determine: (1) whether these deficits exist in GEPRs not exposed to the seizure provoking stimulus; and (2) whether GEPRs with severe seizure provoking stimulus; and (2) whether GEPRs with severe seizures have greater deficits than those with moderate seizures. Both the severe seizure and moderate seizure GEPRs were characterized by abnormally low serotonin concentrations in the telencephalon. In midbrain, pons-medulla and cerebellum there were no statistically significant differences in the serotonin concentration when moderate and severe seizure GEPRs were compared with control. In the hypothalamus-thalamus the serotonin concentration that was highly significantly lower than that of control and of the moderate seizure GEPRs. When taken together with the pharmacologic data these pathophysiologic data suggest an innate seizure regulatory role for serotonin in the GEPR (Supported in part by 1RO1 NS 16829). 119.2 NEURONAL PROTEIN PHOSPHORYLATION IN A GENETIC MODEL OF EPILEPSY. J.G. Bajorek\* and A.V. Delgado-Escueta (SPON:P.Lomax).Dept.of Neurology,Univ. Calif. Los Angeles, and V.A. Hospital Wadsworth,Los Angeles,Calif. The phosphorylation of specific membrane phosphorylation of specific membrane

Angeles,Calif. The phosphorylation of specific membrane proteins has been related to several systems which control excitability in neuronal elements. Such proteins including receptors , ionic pump enzyme components and proteins involved in synaptic transmitter release could under conditions which alter their phosphorylative state influence excitability in such a way as to allow epileptic phenomena to be expressed. The approach which we have taken to verify the hypothesis that such proteins are involved in epileptic disorders is to evaluate the state of phosphorylation of specific brain proteins in genetic models of epilepsy. The most important advantage of the models is that they allow differentiation between the effects of seizures from any genetically determined differences in susceptibility.Endogenous phosphorylation was measured in an in vitro assay using P32-ATF incubated for 90 sec. with cortical neuronal membranes. The membrane proteins were separated on SDS-PAGE electrophoresis, and the gels autoradiographed on X-ray film. In the seizure sensitive mongolian gerbil we found that proteins at 16,000,55,000,and 80,000 dalton molecular weight had an increased level of endogenous phosphorylation as compared to seizure resistant control animals. The seizure sensitive animals had been tested in an interictal state. If they were allowed to seize and the phosphorylative state measured, the 16K and 55K values returned to control levels, while the 80K value remained elevated. Other phosphoproteins at 41K,45K,50K,and 65K did not exibit any differences in endogenous phosphorylation using this method. The significance of these changes is being determined by identifying the proteins and evaluating how their phosphorylation is altered by regulatory systems. The genetic differences could be a result of alterations in linked groups of events(such as receptor-depolarization coupling) which may be mediated through phosphorylative steps.

119.3 Ca<sup>2+</sup> ATPase ACTIVITY IN SUBCELLULAR BRAIN FRACTIONS FROM MICE SUSCEPTIBLE TO AUDIOGENIC SEIZURES. <u>S.T. Palayoor\* and</u> <u>T.N. Seyfried</u>, Dept. of Neurology, Yale Univ. Sch. Med., New Haven, CT 06510.

Audiogenic seizure (AGS) susceptible DBA/2J (D2) mice have a significant reduction in brain  $Ca^{2+}$  ATPase activity compared to AGS resistant C57BL/6 (BG) mice. We recently showed that this reduction was genetically associated with differences in AGS susceptibility among 2I day-old C57 X DBA recombinant inbred strains (Trans. Amer. Soc. Neurochem. 14: 154, 1983). No genetic association was found, however, between AGS susceptibility and the activity of other ATPase, i.e., total, Na<sup>+</sup>-K<sup>+</sup>, or Mg<sup>2+</sup>. Hence, reduced Ca<sup>2+</sup> ATPase may be one of the underlying mechanisms responsible for AGS susceptibility in mice. The Ca<sup>2+</sup> ATPase activity (µ mol Pi/hr/mg protein) was characterized further in several subcellular fractions prepared from fresh whole brain homogenates of 2I day-old B6 and D2 mice. The mean ( $\pm SEM$ ) specific Ca<sup>2+</sup> ATPase activities in the total homogenate and in the microsomol, synaptosomal, and mitochondrial fractions of B6 (n=3) were 8.16 ± 0.25, 19.98 ± 0.88, 11.80 ± 0.48, and 5.98 ± 0.11, respectively. The Ca<sup>2+</sup> ATPase activities of the D2 mice (n=4) were 5.47 ± 0.44, 11.39 ± 0.43, 6.00 ± 0.38, and 5.15 ± 0.28, respectively. The Ca<sup>2+</sup> ATPase activities of the D2 mice were significantly lower than those of the B6 mice in all fractions except the mitochondrial. The Ca<sup>2+</sup> ATPase activity was enriched by only 10% in the D2 synaptosomes. When the enzyme activity was assayed at pH 9.0 instead of pH 7.4, a two-fold elevation of Ca<sup>2+</sup> ATPase activity occurred in the microsomal and synaptosomal fractions of both mouse strains. The high pH stimulated mitochondrial Ca<sup>2+</sup> ATPase activity in various subcellular brain fractions. Supported by USPHS Grant (R01NS17704).

119.4 BENZODIAZEPINE RECEPTOR BINDING DEFICIT IN MIDBRAIN OF SEIZURE-SENSITIVE GERBILS. R.W. Olsen, A.M. Snowman\*, J.K. Wamsley, R. Lee\*, and P. Lomax\*, University of California, Riverside, CA 292521; University of Utah School of Medicine, Salt Lake City, 84132; and UCLA School of Medicine, Los Angeles 90024.

CA 92521; University of Utah School of Medicine, Salt Lake City, 84132; and UCLA School of Medicine, Los Angeles 90024. Benzodiazepine and GABA receptor binding were compared in blind studies of brain regions of seizure-sensitive (SS) and seizure-resistant (SR) Mongolian gerbils (Meriones unguiculatus). High affinity (3H)GABA or (3H)muscimol binding to specific synaptic GABA receptors in homogenates showed no difference between SS and SR (6 animals each) in cortex, cerebellum, thalamus/midbrain, or pons/medulla. (3H)Diazepam binding to brain-specific benzodiazepine receptors was similar in cortex, cerebellum, pons/medulla, hypothalamus, and hippocampus, but 25% lower in thalamus/midbrain of SS vs. SR gerbils. Subdivision of this region in another series of animals showed 13%, 17%, and 28% lower binding in membrane homogenates of SS thalamus, midbrain tegmentum and midbrain tectum, respectively. Brain slice autoradiography on (3H)sensitive film revealed a 20% lower grain density for specific (3H)flunitrazepam binding in substantia nigra zona reticulata of SS vs. SR, 14% in nigral zona compacta, and 12% in the periaqueductal gray area. No differences in nigral pars lateralis, superior colliculus, or hippocampus, and 19% higher binding in SS interpeduncular nucleus were observed. SS animals showed lower benzodiazepine binding in midbrain whether or not animals had seizures just before sacrifice, but binding increased slightly in some regions after seizures. Since benzodiazepine receptor binding may reflect a functional GABA deficit. This could be part of the phenotypic expression of seizure sensitivity in this genetic model of human epilepsy. Such a conclusion would be consistent with recent literature describing a high potency of GABA-related anticonvulsants against gerbil seizures (W. Loscher, personal communication) and a role for the substantia nigra both in the action of anticonvulsants against gerbil seizures (W. Loscher, personal communication) and a role for the substantia nigra both in the action of sei

Supported by NIH Grant NS 12422.

119.5

NORADRENERGIC ABNORMALITIES IN THE GENETICALLY EPILEPSY-PRONE RAT: DO THEY CAUSE OR RESULT FROM SEIZURES? John W. Dailey and Phillip C. Jobe. Depts. of Pharmacology and Psychiatry, LSU Medical Center, Shreveport, LA 71130. The genetically epilepsy prone rat (GEPR) exhibits seizures in response to stimuli that do not cause seizures in normal ani-mals. For example, the GEPR is susceptible to seizures induced by hyperthermia and by acoustic stimulation. In addition, the GEPR exhibits abnormally low electroshock, pentylenetetrazol and bicuculline seizure thresholds. Pharmacologic studies show that drug-induced increments or decrements in noradrenergic transmis-sion cause reciprocal changes in seizure intensity in the GEPR. Some pathophysiologic evidence suggests that the GEPR has innate abnormalities in noradrenergic neuronal tracts. Because most animals used in the pathophysiologic studies have been exposed to a seizure-provoking stimulus in order to ascertain their seizure characteristics, it has not always been possible to ascribe abnormalities in indices of noradrenergic function to the seizure-prone state. That is, the possibility exists that some

seizure-prone state. That is, the possibility exists that some observed abnormalities are due to the seizure provoking stimulus or to the seizure itself rather than to the seizure prone state. The purpose of the present study was to determine if selected indices of noradrenergic function in the GEPR represent corre-lates of the seizure-prone state or if they result from a seizure or the seizure-provoking stimulus. The two indices selected for study were tyrosine hydroxylase activity and norepinephrine con-centration. These indices were evaluated in: (1) GEPRs with moderate seizures (GEPR-3) that had been exposed to an acoustic stimulus and had a seizure on three orcasions and (2) naive animals whose parents had both been either GEPR-3 or GEPR-9 (severe seizures) and whose previous litters had more than 90% of (severe seizures) and whose previous litters had more than 90% of progeny exhibiting seizures of the same characteristics as the parents. These naive animals were not subjected to a seizure-provoking stimulus and were not known to have had a seizure. In the stimulated GEPRs tyrosine hydroxylase activity was indistin-guishable from control in all brain areas except the midbrain where it was significantly elevated. In the non-stimulated progeny of GEPR parents, midbrain tyrosine hydroxylase activity was significantly reduced when compared with control and the mean enzyme activity was lower in the GEPR-9 progeny than in the GEPR-3 progeny. In both stiulated and non-stimulated animals, midbrain progeniperine was lower than control in the GEPP-3. midbrain norepinephrine was lower in the GEPR-3. These data suggest that some noradrenergic abnormalities in the GEPR Īn may be substrates for seizure-prone state whereas others appar-ently are induced by the seizure provoking stimulus and/or the seizure itself (Supported in part by NIH grant #1 RO1 NS16829).

ABNORMALITIES OF THE AUDITORY RESPONSES OF NEURONS IN THE INFERIOR COLLICULUS OF GENETICALLY EPILEPSY PRONE RATS. C.L. Faingold, M.A. Travis\*, P.C. Jobe and H.E. Laird, Dept. of Pharmacology, So. III. Univ. Sch. Med., Springfield, IL 62708, LSU Med. Sch., Shreveport, LA 71130 and Univ. Arizona Coll. 119.6

Pharmacology, So. III. Univ. Sch. Med., Springfield, IL 62708, LSU Med. Sch., Shreveport, LA 71130 and Univ. Arizona Coll. Pharmacy, Tucson, AZ 85721. The genetically epilepsy prone (GEP) rat is highly susceptible to seizures especially those induced by high intensity sounds. The inferior colliculus (IC) has been reported to be an important site of epileptogenesis for audiogenic seizures in the GEP rat based on lesion and electrical stimulation studies. Therefore, this study examined the response properties of neurons in this nucleus to pure tone burst stimuli (100 msec duration, 5 msec rise/fall) in locally anesthetized paralyzed or ketamine anesthe-tized rats. The analysis of IC neuronal responses involved determination of frequency selectivity (tuning curves), charac-teristic frequency (CF), thresholds (at CF), Q-values and, evalu-ation of binaural responsiveness. Poststimulus time histograms at CF and at 12 kHz (which will induce seizures in behaving GEP rats) were also examined. Preciseness of tuning was compared for pairs of IC neurons from GEP and normal animals with the same or similar CFs using Q values. The Q values of GEP rats were significantly smaller than normal indicating that they were more broadly tuned. Thresholds at CF were significantly elevated in GEP rats showed a 19% incidence of responses with both an onset and offset peak in response to 80 dB tone bursts. The incidence of this pattern was significantly greater than the 2% level observed in normal rats. This onset-offset pattern may constitute an afterdischarge-like response similar to that observed in many types of seizures. The percentage of neurons responding with an excitatory response to binaural stimulation was significantly higher in IC neurons of GEP rats than that in normals. A recent study (Penny et al., Acta Otolaryngol., 95:1, 1982) has reported that cochlear damage is observed in the GEP rat which may subserve the reduced cochlear microphonic and abnormal auditory nerve responses previously reported and the rat which may subserve the reduced cochlear microphonic and abnormal auditory nerve responses previously reported and the abnormal auditory nerve responses previously reported and the increased response thresholds observed in the present study. These findings taken with the present data suggest that IC neurons in the GEP rat show patterns of response consistent with hyperexcitability to intense acoustic stimuli which may be the result of compensatory mechanisms to a significant loss of hearing. (Supported by NIH grant NS 13849 and CRC grant 2-40100-71.)

EVIDENCE FOR GABA IMBALANCE IN SEIZURE-PRONE MUTANT CHICK. 119.7 Firman\* and M.M. Beck. Dept. of Animal Science, Univ. of Nebraska, Lincoln, NE 66583.

Female chicks carrying the sex-linked recessive paroxysmal (px) gene are susceptible to spontaneous and audiogenic seizures similar to those of Grand Mal epilepsy. Seizure activity begins at 7-9 days posthatching, with anorexia following, and death occurring several weeks later. A dysfunction in the GABA pathway is postulated as a possible cause of the px syndrome. While serum levels of Vitamin B<sub>6</sub>, an essential coenzyme of GABA synthesis, are not different (P>.05) between px and normal chicks, GABA levels in px brain tissue are elevated considerably over those of normal siblings (P<.05). The possibility exists that the increased GABA is not part of the neurotransmitter pool and therefore several anticonvulsants, which are thought to act via the GABA pathway, were administered in order to determine their effects on px seizures and GABA levels. Sodium valproate (300 mg/kg body wt) was Female chicks carrying the sex-linked recessive paroxysmal (px) ures and GABA levels. Sodium valproate (300 mg/kg body wt) was administered i.p. to  $\underline{p_X}$  and normal chicks. Protection against electrically-induced seizures was 100% effective in the  $\underline{p_X}$ , although GABA levels increased only moderately. Valproic acid (50 and 100 mg/kg) did not affect seizures or GABA levels, indicating that this form of the drug is not effective. Gamma-vinyl-GABA (1500 mg/kg) doubled the  $\underline{p_X}$  GABA levels, appeared not to affect seizure threshold, but transiently increased duration of stimulation necessary to elicit seizures. Sodium phenytoin (4 mg/kg) did not affect GABA levels, but increased electrical threshold by 60V (to normal level) in 50% of the  $\underline{p_X}$  chicks. Our results indicate that the  $\underline{p_X}$  seizures are at least in part the result of a GABA ince, but whether through the transmitter pool or the energy shunt remains unclear. energy shunt remains unclear.

AGONISTS AND ANTAGONISTS OF THIP INDUCED SPIKE AND WAVE IN RATS. R. G. Fariello, G. T. Golden (SPON: L. A. Marco). Dept. of Neurology and Research, Jefferson Medical College, Philadelphia, PA 19107 and VA Medical Center, Coatesville, PA 19320. Systemic injections of Muscimol and THIP induce a transient model of Petit Mal epilepsy in rodents. In the present study we 119.8

have investigated possible agonists and antagonists of the elec-trobehavorial response to these direct GABA agonists. Male Male Sprague Dawley albino rats were prepared for chronic EEG recor-dings under general anesthesia. Ten days after recovery they dings under general anesthesia. Ten days after recovery they received i.p. injection of 7.5 mg/kg THIP which induced paroxysmal bursts of S-W discharges lasting 3-5 hours. Either prior to THIP or after the THIP effect on the EEG was evident, several centrally acting drugs were i.p. administered. EEG effects of THIP were remarkably potentiated by Valproic Acid

and Baclofen and suppressed by Diazepam, Clonazepam and Etho-suximide. Other drugs such as Clutamate, Aspartate, Homocysteic acid, GDEE, 2-amino-7-phosphonoheptanoic acid, Atropine, Haloperidol, Naloxone, Bicuculline, Picrotoxin and DABA did not effect the electrobchavioral pattern. An interaction between the possibly presynaptic bicuculline

insensitive GABA receptor and the BZP linked low affinity receptor may be involved in the generation of the observed EEG abnormalities.

GABA EXACERBATES PETIT MAL LIKE SEIZURES PRODUCED BY 119.9 γ-HYDROXYBUTYRATE. O.C. Snead. Department of Pediat-rics and The Neuroscience Program, University of Alabama in Birmingham School of Medicine, Birmingham, Al. 35233.

Gamma-hydroxybutyric acid (GHB) is a naturally oc-curring, epileptogenic metabolite of  $\gamma$ -aminobutyric acid (GABA). When administered systemically to aniacid (GABA). When administered systemically to ani-mals, GHB produces seizures which bear electrical, be-havioral, and pharmacologic resemblance to petit mal epilepsy (Snead, Neurology 28:643, 1978). Because of the structural similarity of this compound to, and its intimate metabolic relation with GABA, it has been postulated that GHB produces seizures via GABAergic mechanisms. Therefore, the object of these everimechanisms. Therefore, the object of these experi-ments was to ascertain what role, if any, GABA might

play in the genesis and propagation of GHB seizures.  $\gamma$ -butyrolactone (GBL), the prodrug of GHB was used to induce seizures. The model was standardized by staging EEG changes at various dosages and determin-ing the brain pharmacokinetics of GHB with each dose of GBL. A dose of 100 mg/kg GBL produced a predict-able sequence of electrical and behavioral events in able sequence of electrical and behavioral events in terms of morphology of seizure, time of onset, and duration. Animals were then given either GABA-T inhi-bitors  $\gamma$ -vinyl GABA,  $\gamma$ -acetylenic GABA, and aminooxy-acetic acid, the GABA agonist muscimol, intracerebro-ventricular GABA, or the GABA antagonists bicuculline, picrotoxin, and DL Allylglycine and the behavioral and electrical response to 100 mg/kg GBL determined. The effect of these compounds on the brain pharmacokinet-ics of GHB was also determined. Muscimol, GABA and all the GABA-T inhibitors pro-duced no EEG changes themselves but resulted in a sig-

Muscimol, GABA and all the GABA-T inhibitors pro-duced no EEG changes themselves but resulted in a sig-nificant prolongation of GBL induced seizure with mus-cimol being the most potent in this regard. The GABA-T inhibitors prolonged the half life of GHB in brain but muscimol did not. GBL potentiated bicuculline seizures, protected against picrotoxin seizures, and had no effect on seizures produced by DL-Allylglycine. These data suggest that GABAergic mechanisms may well play a role in the petit mal-like seizures seen in GBL treated animals although such mechanisms are probably not solely responsible for this phenomenon.

119.10 DIAZEPAM PREVENTS LITHIUM-PILOCARPINE NEUROTOXICITY IN RATS.

DIAZEPAM PREVENTS LITHIUM-PILOCARPINE NEUROTOXICITY IN RATS. John W. Olney, Michael P. Honchar and William R. Sherman\*, Washington Univ, Dept of Psychiatry, St. Louis, MO 63110. Treatment of adult rats with the cholinergic agonist pilo-carpine (Pilo) (30 mg/kg sc) or the cholinesterase inhibitor physostigmine (0.4 mg/kg sc) 24 hr after a single sc injection of lithium chloride (Li) (3 meq/kg) results in an acute seizure-related brain damage (SRBD) syndrome (Honchar et al., Science 200, 323, 1983). At the above doses Li alone or Pilo alone results in a 3-5 fold elevation of brain myoinositol-1-phosphate (M1P) which is potentiated to a 40-fold elevation by Li + Pilo treatment. The repetitive seizures induced by Li + Pilo may contribute to but does not explain the massive MIP elevation since a high dose of Li (10 meq/kg sc) by itself produces a 40-fold elevation of brain MIP in the absence of seizures. The action of Li on MIP is thought to be cholinergically mediated as it is prevented by co-administration of the muscarinic antagonaction of Li on MIP is thought to be cholinergically mediated as it is prevented by co-administration of the muscarinic antagon-ist, atropine. Moreover, in Li-pretreated rats, administration of atropine (150 mg/kg sc) immediately prior to Pilo prevents all aspects of the Li/cholinotoxic syndrome (MIP elevation, seizures, bra'n damage). Here we have compared atropine and the anticonvulsant diazepam (Dz) for their ability to modify the MIP elevating activity of Li or to either prevent or arrest the SRBD effects of Li + Pilo treatment. Although atropine, when administered 1 hr after Pilo.

Although atropine, when administered 1 hr after Pilo, substantially reduced the MIP elevation, it did not modify the seizure activity or accompanying brain damage. Dz (20 mg/kg) had no influence on the MIP elevating action of Li, but attenuated the MIP elevating action of Li + Pilo and prevented Li + Pilo from inducing either seizures or brain damage. Moreover, Dz treatment 1 hr following Pilo arrested the seizure activity and decreased the severity of brain damage. The ability of atropine but not Dz to modify the MIP elevating action of Li further supports the assumption that this action is cholinergically mediated. The ability of atropine to block the SRBD syndrome when administered before but not after commencement of seizures probably reflects the confinement of atropine's action to cholinoceptive circuits involved in initiating seizures. The efficacy of Dz when administered initiating seizures. The efficacy of Dz when administered either before or after seizures suggests a more general influence of Dz over circuits concerned with the propagation and maintenance as well as initiation of seizure activity. Supported in part by USPHS Grants MH-14677, NS-05159 and RSA MH-38894 (JWO).

- THE ROLE OF SEIZURE ACTIVITY IN THE ACUTE HIPPOCAMPAL PATHOLOGY 119.11 PRODUCED BY TRIMETHYLITIN. C. Becker\*, T.J. Walsh and R.S. Sloviter. Neurology Ctr., Helen Hayes Hospital, W. Haverstraw, N.Y. 10993; U.S. E.P.A., Research Triangle Park, N.C. 27710 N.Y. 1099; U.S. E.P.A., Research Triangle Park, N.C. 27/10 Trimethyltin (TMT) causes convulsions and brain damage in experimental animals. The present study was undertaken to evaluate the role of TMT-induced seizure activity in the brain damage caused by this compound and to evaluate the acute hippocampal pathology caused by TMT. Male Sprague-Dawley rats received TMT (7mg base/Kg ip)or saline. Rats were sacrificed at different times after injection (5,7,10,30 days). Brains ware embedded in parafin for subservent evaluation by light were embedded in paraffin for subsequent evaluation by light microscopy. Approximately half of the TMT-treated rats microscopy. Approximately half of the TMT-treated rats displayed convulsions, usually within one week of injection. The latency to seizure onset was 2-3 days. Rats which did not develop convulsions did not exhibit obvious hippocampal damage. In addition, there was a general positive correlation between the severity and frequency of seizures and the severity of hippocampal damage. However, TMT induced different patterns of hippocampal damage in different rats despite the use of the same dose of TMT in one group of rats treated identically. same dose of TMT in one group of rats treated identically. Although some rats displayed acutely necrotic or missing hilar and CA3 pyramidal cells only, other rats displayed damage to the CA1 cells, with or without CA3 damage. Granule cells appeared normal in all rats. A major feature of the TMT-induced hippocampal damage was the appearance of clear, round profiles in many of the dendritic fields of the hippocampus and area dentata during the active seizure state. These profiles have been identified in kainic acid-treated and perforant path-stimulated rats as massively swollen dendritic segments which occur at the sites of excitatory innervation. In severely affected TMT-treated rats, these dendritic. In severely affected TMT-treated rats, these dendritic swellings were commonly present throughout st. oriens and st. radiatum of CA1 and CA3. This area of altered morphology stopped abruptly at the st. radiatum/moleculare border of CA1 where the commissural/associational input stops. In other rats, dendritic swellings were present only in area dentata. In these rats, the altered morphology was restricted to the inner third of the dentate molecular layer which receives a laminar input from the hilar cells of both hippocampi. These results suggest that: 1)the seizure activity produced by TMT results suggest that: 1) the seizure activity produced by TMT probably mediates the hippocampal pathology induced by this compound; 2) TMT does not produce a highly reproducible pattern of hippocampal damage (as does kainic acid); and 3) the varying patterns of dendritic swelling seen in the hippocampi of TMT-treated rats are the result of seizure activity induced in different excitatory hippocampal pathways. The mechanism by which TMT initiates seizure activity remains to be elucidated.
- 119.12 SEIZURE THRESHOLDS IN RATS AFTER ACUTE METAL CHELATION OR CHRONIC ZINC DEFICIENCY. John D. Connor, Dept. Pharmacology, Pennsylvania State Univ. Col. of Medicine, Hershey, PA 17033. Granule cells in the dentate gyrus of the hippocampus have in their terminal boutons high concentrations of divalent metals,

mostly zinc with lesser quantities of lead and copper. Responses of granule cells to electrical stimuli via the perforant path have been reported as unchanged after metal chelator injections. This report deals with the functional implications of acute zinc chel-ation or chronic zinc deficiency on responses to convulsant drugs. Male Sprague-Dawley rats (325-375 gm) were used throughout.

Doses of chelators below threshold for overt sedation or ataxia were as follows: 1,10 phenanthroline (o-phenanthroline), 40 mg/ kg i.p.; 2,9 dimethyl-1,10 phenanthroline (neocuproine), 60 mg/kg i.p.; and diethyldithiocarbamate (DEDTC), 1 gm/kg i.p. Vehicle containing PEG and saline was used for controls. Zinc deficient male rats were obtained by feeding a diet low in zinc (0.7 ppm) for 6 weeks. Pair-fed controls were given the same diet, plus 30 ppm zinc in their water.

One hour after chelator injections, 3 rats from each group were taken for Timm's reaction as modified by Sloviter (Brain Res. Bull.  $\underline{8}$ :771, 1982). Brain slices from control and treated rats were run simultaneously in the same staining solutions. Zinc deficient Tas were treated in the same way, except the right femur was also taken for atomic absorption analysis of bone zinc. After 1,10 phenanthroline, the apex of the hilus and the most lateral mossy fibers showed very light staining. The rest of the histochemical reaction was greatly diminished compared to controls. With neocuproine, no Timm's product could be detected. In DEDTC treated rats, metal deposits were discernable in all areas usually re-active, but the intensity was less. Timm's reactions in zinc de-ficient rats were indistinguishable from pair-fed, zinc supplemented controls. Femur concentrations of zinc in deficient rats were half those of controls.

Controls and treated rats were challenged simultaneously with flurothyl, a convulsant vapor. Clonic convulsion onsets after 1,10 phenanthroline and neocuproine (means of 38 and 52 sec) were significantly different from controls (means of 80 and 98 seconds) as determined by one-way anova at  $\alpha = 0.01$ . DEDTC and zinc deficient convulsion times (92 and 78 sec) were not significantly different from controls.

Although phenanthroline chelators lower seizure thresholds, results with DEDTC suggest that factors other than simple reduction of hippocampal metal concentrations are involved in the epileptiform response.

ZINC BINDING PROTEINS IN BRAINS OF ZINC TREATED AND SEVERILY ZINC 119.13 DEFICIENT RATS. <u>M. Ebadi, J.C. Vallvork\*, S. Swanson\* and C.</u> hebus\*. Department of Pharmacology, University of Febraska Col-Lecuis. Department of Frammacology, University of Febraska Col-lege of Medicine, Omaha, Nebraska 68105 and Agricultural Research Service, United States Department of Agriculture (J.C.w.), Human Nutrition Research Center, Grand Forks, Forth Dakota 58202. Evelallothioneins, low molecular weight, cystein-rich, metal binding proteins, have been isolated from tissues such as kidney

and liver. These metallothioneins are inducible following administration of  $Zn^{++}$  and other ions. By using Sephadex G-75 column chromatography calibrated with proteins of known molecular weights and by using other techniques, three separate zinc bind-ing proteins with estimated apparent molecular weights ranging from 15,000 to 210,000 daltons were isolated from rat brain (Itoh and Ebadi, J. Neurochem., in press). The zinc binding proteins in brains of rats after 30 days of zinc deficiency remained unaltered in each of the three major proteins studied. It is inter-esting that zinc deficiency state, did not alter zinc levels in most areas of brain studied with the exception of olfactory lobe (Wallwork, et al., Fed. Proc. 42:3090, 1983). Thus, the steady state concentration of zinc in the brain is firmly regulated. To test this hypothesis further, two other biochemical parameters, one of which is stimulated by zinc and the other is inhibited by one of which is stimulated by zinc and the other is inhibitor of glutamic acid decarboxylase (GAD) in vitro and in vivo. On the other hand, pyridoxal kinase, which synthesizes pyridoxal phosphate, is preferentially stimulated by free zinc in vitro and in vivo. These parameters were measured in brain of zinc deficient and pair fed rats. The activities of GAD in the brain of zinc defi-cient and pair fed rats were  $581 \pm 47$  and  $567 \pm 63$  nmoles/CO2/mg protein/30 mins respectively. The concentrations of pyridoxal phosphate in the brain of zinc deficient and pair fed rats were 1.27  $\pm$  0.04 and 1.31  $\pm$  0.74 µg/g wet tissue respectively. Thus, in the brain, zinc binding proteins not only may function as physiological donors of zinc to zinc-apometalloenzymes, but also may play a decisive role in preventing CKS toxicity by preventing the rise of free zinc ions. Consistent with these views are observations by Itoh and Ebadi (Neurochem. Res. 7:1287-1298, 1982) that intracerebroventricular injection of 0.30 µmol zinc caused epileptic seizures, including tonic-clonic convulsions; whereas the administration of huge doses of zinc (up to 100 mg/kg), either intravenously or intraperitoneally, produced no convulsive seizures or other behavioral abnormalities. (Supported in part from a grant from Am. Eps. Fdn. - ME.)

119.14 ACUTE AND CHRONIC EPILEPTIFORM ACTIVITY INDUCED BY INJECTION OF

ACUTE AND CHRONIC EPILEPTIFORM ACTIVITY INDUCED BY INJECTION OF IONIC COBALT INTO THE RAT NEOCORTEX. S. Veregge\* and J.D.Frost,Jr.\* (SPON: Y.Clement-Cormier). Program in Neuroscience and Section of Neurophysiology, Department of Neurology, Baylor College of Medicine and The Methodist Hospital, Houston, TX 77030. The placement of metallic cobalt onto or into the brain of an experimental animal produces epileptiform activity that lasts for days to weeks. In recent studies, however, the iontophoresis of ionic cobalt onto the neocortex of cats produced only short-duration (24 hours or less) epileptiform activity. This observa-tion lead Schwartzkroin et al. (1977) to suggest that the chronic effects of cobalt metal may be due to the continuous release of ionic cobalt from the metallic reservoir, and not to any long-term effects of cobalt itself. The objective of the present study was to further examine the duration and nature of the epi-leptiform activity produced by ionic cobalt using both surface leptiform activity produced by ionic cobalt using both surface EEG and single unit recording.

EEG and single unit recording. Injection of .2 ul (29 ug) of cobaltous chloride into the right sensorimotor cortex of Sprague-Dawley rats produced interictal spike activity with a rapid onset (less than 2 hours) and a dura-tion of up to 23 days. Seizure activity was also produced and was most frequent during the first week post-injection. In 8 rats, seizures were studied in more detail during this first week and were found to assume a bimodal time-distribution with an early peak of seizure activity on day 1 and a late peak on day 6. Sei-zures rarely occurred on day 4. The percent of neocortical units that exhibited bursting activity was also bimodally distributed with early and late peaks corresponding to those of seizure activity. activity.

activity. Early and late seizures were quite different. Although both types were focal motor and involved the body musculature contra-lateral to the cobalt-induced focus, most early seizures were short in duration, lasting less than 60 seconds, while most late seizures were continuous, lasting up to 48 hours. Also, electro-corticographic waves accompanying early seizures were shorter in duration and had a charter interwave interval than those accomduration and had a shorter interwave interval than those accom-

duration and had a shorter interwave interval than those accom-panying late seizures. These results suggest that, in the rat, ionic cobalt produces both acute and chronic epileptiform activity. The acute activity may, as Schwartzkroin et al. (1977) suggested, be due to the acute presence of the cobalt ion. The chronic activity, however, is more likely due to long-term effects of ionic cobalt, for example, selective neuronal death, gliosis, or changes in neurotransmitter synthesizing enzymes. The distinctly different characteristics of early and late seizures also lends support to the hypothesis that cobalt is producing these two types of seizures by different modes of action. of action.

119.15 ELECTRON MICROSCOPY AND X-RAY ANALYSIS OF RAT CEREBRAL CORTEX ELECTRON MICROSCOFT AND X-RAT ANALISIS OF RAT CEREBRAL CORTEA EXPOSED TO COBALT AND COPER. R.G. Frederickson\*, C.R. Craig\*, J.L. Culberson\* and B.K. Colasanti\*. Depts. of Anatomy and Pharmacology and Toxicology, West Virginia University Medical Center, Morgantown, WV 26506 Metallic cobalt (Co) is epileptogenic when applied to cerebral

cortex; copper (Cu) does not share this property although it evokes a significant gliotic response. The present study compares the structural changes in response to, and the subcellular localization of, these metals. Very small cortical implants of Co wire (10 mil x 0.2 mm) evoke EEG evidence of seizures in 30-35% of treated rats while implants of similar-sized pieces of Cu or glass have no such effects. At 7 to 21 days after implant-Cu or glass have no such effects. At / to 21 days after implant-ing Co, swollen neuronal cell bodies are seen in areas devoid of necrosis. Enlarged electron-lucent apical dendrites of pyramidal cells extend through layers II and III. The character-istic feature of the glial response is the appearance of specific granular inclusions within glial cells in paraneuronal, paravascular and subpial locations. These spherical granules appear alone or in clusters and each contains a centrally-placed electron-lucent core. Within the dense rim of each granule, profiles of smaller, electron-lucent bodies are observed. In non-necrotic cortex adjacent to the Cu implants, glia

contain different types of inclusion bodies. These granules are uniformly electron-dense and possess irregular ragged peri-meters. Cortex from animals with glass implants shows inflamed and necrotic tissue but no inclusions. Cu can be identified within the specific glial inclusions of

Cu can be identified within the specific glial inclusions of Cu-exposed animals by accumulating X-ray spectra. However, X-ray spectra obtained from the inclusions observed in glial cells of Co-exposed animals, have not yet confirmed the presence of elemental Co. The possibility of identifying Co by other pre-paratory techniques is suggested by the fact that this element can be demonstrated within subarachnoid macrophages by X-ray spectra and dot mapping following subdural injection of colloidal cobalt. (This research was supported by the WVU Medical Corporation and by NHB Riomedical Research Grant #SS07-Medical Corporation and by NIH Biomedical Research Grant #5807-RR 05433-18).

119.16 CORTICAL ISCHEMIA CAUSES EPILEPTIFORM DISCHARGES. A. Basil Harris, Dept. of Neurological Surgery, University of Washington, Seattle, WA 98195.

A neuronal differential vulnerability to ischemia has long been suggested. Ischemia can cause seizures in man and has been invoked as a possible cause of experimental epilepsy. Neurons in cortical layers 3, 5 and 6, hippocampal cells and Purkinje cells cortical layers 3, 5 and 6, hippocampal cells and Purkinje cells are thought to be more susceptible. Ischemia studies have pri-marily used whole brain insult. The present experiments were conducted on the suprasylvian gyrus of the cat. Ischemia was produced in this gyrus by a modification of the technique to iso-late the gyrus as described by Gruner, Hirsch and Sotelo (J Comp Neurol 154:1-28, 1974). Cortical ischemia was achieved using the operating microscope and bipolar coagulation to cut free the anterior and posterior limb of the gyrus into the white matter. A vascular clamp was then applied, with the animal heparinized, across the middle cerebral and pial blood supply of the ectosylacross the middle cerebral and pial blood supply of the ectosyl-vian gyrus and another vascular clamp placed across the pial blood supply coming from the marginal gyrus. This produced com-plete ischemia of the suprasylvian gyrus. Following a selected period of ischemia the heparin was reversed with protamine. Ischemia of this gyrus was 10, 13, 20 and 30 minutes duration in different animals. All animals had normal EEGs prior to in-clusion in the study. Thirty days following the ischemic event electricial activity in the cortax was investigated using ECoC electrical activity in the cortex was investigated using ECoG under phenobarbital anesthesia followed by perfusion fixation of the brain. Representative blocks of tissue were prepared for Golgi and light microscopic examination. Thirty minutes of ischemia produced a fibrotic scar without surviving neuronal or gial elements and without abnormal electrical discharges. Ten o 13 minutes of ischemia produced spiking, spontaneous epileptic activity in the suprasylvian gyrus. Histological examination showed preservation of cortical volume and cortical cell layers. Golgi studies of this gyrus suggest a reduction in small to medium sized cortical interneurons. A reduction in these sparse-ly spinous and aspinous neurons, which are thought to be GABAergic and may be more susceptible to ischemia, could result in a decreased GABA content which could lead to spontaneous spiking activity.

120.1 BINDING OF <sup>3</sup>H-DMCM TO BENZODIAZEPINE RECEPTORS; CHLORIDE DEPENDENT ALLOSTERIC REGULATORY MECHANISMS. <u>T. Honoré\*<sup>1</sup></u>, <u>M. Nielsen\*<sup>2</sup> and</u> <u>C. Braestrup\*<sup>1</sup>,<sup>2</sup></sub> (SPON: P. Roland). <sup>TA/S</sup> Ferrosan, Research</u> Division, Sydmarken 5, DK-2860 Soeborg, <sup>2</sup>Sct. Hans Hospital, DK-4000 Roskilde. Benzodiazepine (BZ) receptor ligands comprise a continuum of

Benzodiazepine (BZ) receptor ligands comprise a continuum of agents with pharmacological effects ranging from compounds with anxiolytic and anticonvulsant actions via pharmacological neutral compounds to compounds with anxiogenic and convulsant action; tentatively termed agonists-antagonists-inverse agonist. Specific binding of  $^{3}$ H-DMCM at 37 $^{0}$ C (a benzodiazepine receptor

Specific binding of  ${}^{3}\text{H-DMCM}$  at  $37^{\circ}\text{C}$  (a benzodiazepine receptor ligand with inverse agonistic properties) was influenced by compounds presumed to interact with chloride ionophors associated with the BZ/GABA-receptor complex. Chloride ions (200 mM) enhanced the specific binding of  ${}^{3}\text{H-DMCM}$  four-fold. The effect of chloride ions on specific  ${}^{3}\text{H-DMCM}$  binding was parallel to the observed increase in specific  ${}^{3}\text{H-diazepam}$  binding by the presence of chloride ions (Costa, T., Rodbard, D. and Pert, C.B., <u>Nature</u>, <u>277</u>:315, 1979; Martin, I.L. and Candy, J.M., <u>Neuropharmacol.</u>, <u>199</u>:175, 1980). On the other hand, iodide ions, which also penetrate chloride ionophors and enhance specific  ${}^{3}\text{H-diazepam}$  binding, have no effects on specific  ${}^{3}\text{H-DMCM}$  binding. In addition specific binding of  ${}^{3}\text{H-DMCM}$  was enhanced by picrotoxinine in the absence of chloride ions.

(+)-Etomidate and pentobarbital reduced the specific <sup>3</sup>H-DMCM binding in a partially chloride ion dependent and picrotoxinine sensitive manner. The reduction in specific <sup>3</sup>H-DMCM binding is opposite to the observed increase in the binding of BZ-receptor agonists in the presence of (+)-etomidate or pentobarbital (Ashton, D., Geerts, R., Waterkeyn, C. and Leysen, J.E., Life sci., 29:2631, 1981; Ehlert, F.J., Ragan, P., Chen, A., Roeske, W.R. and Yamamura, H.I., Eur. J. Pharmacol., 78:249, 1982). The results obtained are consonant with a chloride dependent

The results obtained are consonant with a chloride dependent allosteric regulatory mechanism within the BZ/GABA-receptor chloride ionophor complex. Furthermore, the results suggest that the regulation of <sup>3</sup>H-DMCM binding by compounds active on chloride ionophor reflect the pharmacological efficacy of DMCM. On the other hand, regulation of <sup>3</sup>H-DMCM binding by anions that penetrate chloride ionophors, seems not to be correlated with the pharmacological efficacy of DMCM.

120.3 DIFFERENTIAL INTERACTIONS OF DEPRESSANT AND CONVUL-SANT DRUGS WITH THE COMPONENTS OF BENZODIAZEPINE-GABA RECEPTOR-IONOPHORE COMPLEX. <u>R. Ramanjaneyulu\* and</u> <u>M.K. Ticku</u> (SPON: V.S. Bishop). Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284.

The picrotoxinin site of the benzodiazepine-GABA receptor-ionophore complex is an important regulatory site, where several classes of convulsant, depressant and anxiolytic drugs appear to interact. In this study, we have investigated the effect of several dapessant and convulsant drugs with the [<sup>35</sup>S]-t-butylbicyclophosphothionate [TBPT], a ligand that binds to the picrotoxinin site. TBPT binds to whole rat brain membranes, to a single site, with an apparent K<sub>D</sub> of 25 nM and a B max of 1.404 pmol/mg protein. TBPT binding was displaced by "convulsants like anisatin ( $1C_{50} = 0.1 \ \mu$ M), isopropylbicyclophosphate ( $1C_{50} =$ 0.16 \ \muM), picrotoxinin ( $1C_{50} = 0.40 \ \mu$ M) and pentamethylenetterazole (PTZ;  $1C_{50} = 700 \ \mu$ M). TBPT binding was also inhibited potently by GABA, etazolate and stereoisomers of barbiturates. Eleven tetrazole analogues inhibited TBPT binding much more potently than diazepam binding. Inhibition of TBPT binding by tetrazoles was competitive and correlated well with their convulsant potencies. Picrotoxinin also inhibits TBPT binding competitively, whereas GABA inhibits TBPT binding noncompetitively. In contrast, depressants like pentobarbital and (+)etomidate gave a mixed competitive, noncompetitive inhibition of TBPT binding in whole rat brain membranes. Furthermore, convulsants like picrotoxinin, PTZ and cage convulsant bicyclophosphate esters were equipotent in inhibiting TBPT binding in cortex and cerebellum. In contrast, GABA and depressants like pentobarbital and (+)etomidate were 3- to 6-fold more potent inhibitors of TBPT binding in cerebellum relative to cortex. This difference is not due to differential affinities of TBPT in these regions, since TBPT had similar K<sub>D</sub> values in cortex. and cerebellum: We have recently demonstrated that pentobarbital and (+)etomidate enhance both GABA and diazepam binding in cortex, to a much greater extent than in cerebellum (Thyagarajan et al, J. <u>Neurochem.</u>, in press, [983). These results further suppor the notion that

120.2 EFFECT OF PENTYLENETETRAZOL ON MUSCIMOL- AND BARBITURATE-STIMULATED [3H]FLUNITRAZEPAM RECEPTOR BINDING IN MOUSE BRAIN. A. Y. Chweh,\* E. A. Swinyard,\* and H. H. Wolf\* (Spon: J. W. Woodbury). Department of Biochemical Pharmacology and Toxicology, College of Pharmacy, University of Utah, Sait Lake City, UT 84112.

by, contege of Phanhacy, onlyersity of otan, sait take tity, UT 84112. The inhibitory activity of pentylenetetrazol (PTZ) on muscimol- and barbiturate-stimulated [3H]flunitrazepam ([3H]FLU) receptor binding was compared with the inhibitory activity of PTZ on unstimulated (basal) [3H]FLU receptor binding in mouse forebrain and cerebellum. In forebrain, PTZ inhibited both barbiturate-stimulated and basal [3H]FLU receptor binding; however, the inhibitory activity of PTZ on barbiturate-stimulated [3H]FLU receptor binding was greater than that on basal binding. The inhibitory potency of PTZ on barbiturate stimulated [3H]FLU receptor binding was reduced to the basal level by 20 µM picrotoxinin and by the exclusion of chloride ions. PTZ had no effect on muscimol-stimulated [3H]FLU receptor binding in forebrain. In cerebellym, barbiturate had relatively little stimulatory effect on [3H]FLU receptor binding. Therefore, PTZ inhibited barbiturate-stimulated [3H]FLU receptor binding to about the same extent as seen under basal conditions. Although this study does not reveal the exact site at which

Although this study does not reveal the exact site at which PTZ inhibits [3H]FLU receptor binding, the results presented indicate that a chloride ionophore sensitive to barbiturate but not to GABA participates in the PTZ inhibitory activity of benzodiazepine receptor binding. (Supported by NIH Contract No. NO1-NS-1-2347)

120.4 EFFECTS OF CHRONIC TREATMENT WITH SOME DIRECT GABA AGONISTS ON GABA RECEPTOR BINDING. M.K. Ticku, R.G. Fariellio and G.T. Golden. Dept. Pharm., UTHSC, San Antonio, TX 78284; Dept. Neurology, Jefferson College, Phila, PA, 19107; Research and Neurology, V.A. Med. Ctr., Coatesville, PA, 19520. The effects of chronic treatment (12 days) with the direct GABA agonists <u>THIP</u> (4,5,6,7-tetrahydroisoxazolo (5,4-c)-pyridine-3-ol), <u>Progabide</u> (4-((chlorophenyl)(5-fluro-2-hydroxyphenyl) methylene) amino)-butanamide and <u>3-APS</u> (3,Amino-propanesulfonic acid) on GABA and benzodiazepine binding was investigated. A total of 35 male Sprague-Dawley rats (250-300 g) were administered one of three direct GABA agonists or a control vehicle. Nine aminals received THIP (7.5 mg/kg SC) in a normal saline vehicle, eight animals received 9-APS (100 mg/kg SC) in a DMSO vehicle and nine animals received 0.2 cc DMSO as a vehicle control. Injections were administered twice a day (9 AM and 4PM)

A total of 35 male Sprague-Dawley rats (250-300 g) were administered one of three direct GABA agonists or a control vehicle. Nine aminals received THIP (7.5 mg/kg SC) in a normal saline vehicle, eight animals received Progabide (50 mg/kg SC) in a DMSO vehicle and nine animals received 3-APS (100 mg/kg) in a DMSO vehicle and nine animals received 0.2 cc DMSO as a vehicle control. Injections were administered twice a day (9 AM and 4PM) for 12 consecutive days; on the 13th day, animals received the 9 AM injection only. Between I and 5 PM, all animals were sacrificed by decapitation, brains removed immediately and dissected on ice into the following areas: cerebellum, brain stem, thalamus, forebrain, occipital cortex and midbrain. Individual areas (bilateral areas pooled where appropriate) were placed in 0.32 M sucrose and immediately frozen in dry ice. Tissue was stored at  $-80^{\circ}$ C

until analysis. The effect of chronic GABA-agonist treatment was investigated on GABA and benzodiazepine binding in six brain regions. The equilibrium binding of GABA to its receptor sites was measured by using [<sup>3</sup>H]GABA (4 nM) and [<sup>3</sup>H]muscimol (10 nM). Benzodiazepine binding was measured using 0.2 nM [<sup>3</sup>H]flunitrazepam and GABA enhancement of [<sup>3</sup>H]flunitrazepam was compared using 10<sup>4</sup> M GABA. All the binding data was compared to vehicle treated controls. THIP treatment decreased GABA binding in forebrain and midbrain, while progabide decreased GABA binding in cerebellum, forebrain, midbrain and thalamus. Thus, the effects of chronic GABA agonist treatment on GABA receptor binding varied with different agonists. Likewise, THIP, Progabide and 3-APS treatments affected [<sup>3</sup>H]flunitrazepam binding differently in various brain regions, which did not correlate with their effects on GABA binding. None of the treatments altered the enhancing effect of GABA on benzodiazepine agonist binding. These results indicate that chronic treatment with different GABA agonists may not produce identical neurochemical changes at the benzodiazepine-GABA-

Rostrocaudal Concentration Gradient for Conjugated GABA in Human 120.5 Thomas Jefferson Univ.

CSF, T.N. Ferraro, R.H. Gerner, T.A. Hare. Thomas Jefferson Uni Phila., PA 19107 and UCLA Sch. of Med., Los Angeles, CA 90024 Measurement of GABA in sequential aliquots of human CSF ob-tained via lumbar puncture have revealed the existence of a ros-Trocaudal concentration gradient supporting the hypothesis that CSF GABA levels reflect central GABAergic activity. Conjugated GABA, predominantly in the form of small molecular weight pep-tides, is present in CSF at levels 10-100X those of free GABA and may also provide information regarding the central GABA system.

In order to study the normal distribution of conjugated GABA in human CSF, we have determined levels of GABA before and after acid hydrolysis in sequential aliquots of CSF from thirteen neurologically normal adults. The group consisted of seven males (age,  $\chi_{\pm}$ SD: 32±11 yrs) and six females (age, 31±11: X±SD yrs). CSF was collected on ice via lumbar puncture in two fractions: lst-l2th ml (fraction A) and l5th-26th ml (fraction B). Fractions were mi (fraction b). Fractions were determined using the con-divided into aliquots and stored at  $-80^{\circ}$ C. CSF was deproteinized in 5% sulfosalicylic acid and subjected to hydrolysis in 6 N HCl at  $110^{\circ}$ C for 24 hrs. GABA levels were determined using the confirmed ion-exchange/fluorometric procedure.

firmed ion-exchange/fluorometric procedure. Results showed that levels of conjugated GABA were signifi-cantly higher in fraction B for the population as a whole (p < .005, n=13) as well as for both male and female subgroups (p < .05, n=7 and p < .02, n=-6, respectively) when compared to fraction A (paired t-test). Linear regression analysis within the male subgroup revealed a significant correlation between levels of free and conjugated GABA in both fraction A (p < .01)and fraction B (p < .05); this relationship was not observed in the female subgroup female subgroup.

Thus, the demonstration of a rostrocaudal concentration gradi-ent for conjugated GABA in CSF suggests that these neurochemicals originate in the brain and reflect metabolic pathways important in GABA system function. Additionally, the data suggests that males and females differ with respect to central GABA metabolism.

ANTIBODIES AGAINST SMALL MOLECULES : AN APPLICATION TO GABA Ph. SEQUELA, M. GEFFARD, R.M. BUIJS\* and M. LE MOAL, Lab. Neurobiol Comport., Univ. Bordeaux II, 33076 Bordeaux (France) and \*Brain Research Institute, Amsterdam (the Netherlands) (SPON. F. CLARC) The obtention of anti-catecholamine antibodies (Geffard et al.) led us to design a similar immunological system for aminoacids and their derivatives. Two complementary immunological techniques were used for the visualization of GABA by immunocytochemistry on the one hand and on the other hand for the titration of GABA by radio-immunological assay. immunological assay. Since the GABA molecule alone is unable to stimulate immune res-

Since the GABA molecule alone is unable to stimulate immune res-ponses, carriers and coupling agents have been chosen in function of the desired application of the antibodies. For immunocytochemical studies (Seguela et al., submitted for pu-blication) we described a method in which we used glutaraldehyde to couple GABA in such a way as to allow antigenic determinant to be couple GABA in such a way as to allow antigenic determinant to be correctly presented to the antibodies. To avoid surface effects specific to each protein, an alternance of immunogen was realized during immunization. Antibody specificity was tested in a RIA system by using the radiolabelled ligand (<sup>3</sup>H) GABA-G-lysine, which mimicks a structure possessed by the hapten fixed to the tissue and by the immunogen. We obtained good results in immunocytochemical application of this technique

by the humanicycle we obtained good results in humanicycetemical application of this technique. In order to measure GABA levels, another approach was tested in various biological samples. The RIA developed here used a iodinated radiolabelled ligand reproducing the GABA-succinyl structure. These highly specific antibodies were observed to be suitable for GABA measurements.

Up till now it has been difficult to use immunological approaches for the study of small molecules having a molecular weight of less than 200d. However, it is highly probable that the knowledge and experience gained from the two above-mentioned techniques will be useful for the visualization and titration of other small haptens in the central and peripheral nervous systems, as well as in other tissues.

PARTIAL PROTECLYTIC MAPPING OF THE BENZODIAZEPINE BINDING SUBUNIT OF CENTRAL BENZODIAZEPINE RECEPTORS. <u>R.R. Trifiletti</u> and <u>S.H. Snyder</u>. Johns Hopkins University, Depts. of <u>Neuroscience</u>, Pharmacology and Psychiatry, School of Medicine, 120.7

Baltimore, Maryland 21205. Partial proteolytic digestion patterns of the (<sup>3</sup>H)flunitrazepam photoaffinity-labelled benzodiazepine ("H) funitrazepam photoaffinity-labelled benzodiazepine binding subunit of central benzodiazepine receptors for the enzymes trypsin,  $\alpha$ -chymotrypsin, S. Aureus V8 protease, papain and carboxypeptidase Y were visualized by SDS/PAGE and fluorography. Preliminary photoaffinity labelling experiments on rat brain membranes indicates that ("H) flunitrazepam labels a single species of apparent moleuclar weight by SDS/PAGE of 52  $\pm$  0.5 kilodaltons. When the SDS/PAGE purified photoaffinity labelled protein is cubicted to oxpauting enzycolution. \* 0.5 kilodaltons. When the SDS/PAGE purified photoaffinity labelled protein is subjected to exhaustive proteolytic digestion and the products analyzed by reverse-phase HPLC, the radioactivity is confined to a single peak for all enzymes tested. This result suggests that the photolabelling process per se does not produce appreciable microheterogenity; the position of the label on the polypeptide chain is thus well-defined and can be used as a "reference point" for partial proteolytic dioaction expresent.

well-defined and can be used as a "reference point" for partial proteolytic digestion experiments. Using the results of the partial proteolytic digestion patterns obtained, a physical map of the benzodiazepine binding subunit is proposed. This map localizes the sites of proteolytic cleavage and the label position localization is useful in the determination of which region of the polypeptide chain might contain a portion of the drug binding site. Partial proteolytic digestion patterns may also be viewed as "one-dimensional fingerprints" and can be used to compare structure of polypeptides in different samples. Thus, we have compared the structure of the (3H)flunitrazepam-photolabelled polypeptide in different brain regions in a given species and

polypeptide in different brain regions in a given species and the same brain region in different mammalian species. Tryptic fingerprints were identical in all samples; similar findings were obtained for a-chymotryptic fingerprints. This suggests that there is considerable structural conservation of benzodiazepine binding subunit structure from brain region to brain region and among mammalian species.

120.8 LYSINE ADMINISTRATION DECREASES BRAIN ARGININE AND ORNITHINE LEVELS IN THE RAT. T. J. Maher, B. S. Glaeser and R. J. Wurtman. Laboratory of Neuroendocrine Regulation, M.I.T., Cambridge, MA 02139 and Department of Pharmacology, Mass. College of Pharmacy and Allied Health Sciences, Boston, MA 02115. The administration of tyrosine (TVR) or tryptophan (TRP), or the consumption of a meal that increases the ratios of serum TVR or TRP to the sum of the other competing large neutral amino acids, can accelerate the syntheses of the catecholamines and of serotonin, respectively. These increases are associated with behavioral and physiological functions thought to involve monoaminergic transmission, and are especially noted (for catecholamines) among neurons that are firing frequently. Less information is available about the relationships between basic amino acids in serum and brain. We examined the effects of ad-ministration of the sesential basic amino acid lysine (LYS) on brain levels of LYS, arginine (ARG) and ornithine (ORN). Groups of 5 rats were fasted overnight and, the following morning, given 0, 50, 100, 200, or 400 mg/kg LYS in saline intraperitoneally. One hour later they were decapitated and the brains collected and the odd on down interview context and the definite collected and the odd one of the set of the provention collected and the provention collected and the other complex collected and the provention collected and the other complex collected and the constant collected and the constant collected and the other constant constant constant constant constant constant collected and the constant collected and the constant collected and the constant collected and the constant collected collected constant constant constant constant constant collected and the constant collected constant con one hour later they were decapitated and the brains collected and stored on dry ice until assay for amino acid content with a Beckman Amino Acid Analyzer. Brain LYS levels increased in and stored on dry ice until assay for amino acid content with a Beckman Amino Acid Analyzer. Brain LYS levels increased in a dose dependent manner, and brain ARG and ORN decreased, as the LYS dose increased. There was a dose dependent increase in brain GABA reaching significance ( $\wp < 0.05$ ) in the 400 mg/kg LYS group. In another group of experiments animals were given saline, 100 mg/kg LYS, 100 mg/kg LYS + 100 mg/kg ARG, or 100 mg/kg LYS + 200 mg/kg LYS, 100 mg/kg LYS + 100 mg/kg LYS + 200 mg/kg ARG increased in a dose dependent fashion as did brain ORN (a 3 fold increase in brain ORN in the 100 mg/kg LYS + 200 mg/kg Group). Brain levels of LYS increased to the same extent in all groups given LYS, i.e. the uptake of LYS into the brain was not inhibited by the co-administration of ARG, whereas in the first experiment brain ARG levels were decreased by the administration of LYS (ARG levels decreased by 47% in the 400 mg/kg LYS group). We have previously shown that the consumption of a 0% protein meal and a 40% protein meal addecreases and increases, respectively, brain LYS (similar to TYR) while having no effect on brain ARG or ORN. Brain LYS levels might affect the syntheses of biologically-active metabolites.

CYCLOPYRROLONES INFLUENCE BENZODIAZEPINE RECEPTOR BINDING AT A NOVEL ALLOSTERIC SITE. J. Nye, R.O. Blaustein\*, R.R. Trifiletti and S.H. Snyder, Johns Hopkins University, Depts. of Neuroscience, Pharmacology and Psychiatry, School of Medicine, Polticence, Marvierd 2020E 120.9 Baltimore, Maryland 21205.

Neuroscience, Pharmacology and Psychiatry, School of Medicine, Baltimore, Maryland 21205. The in vitro inhibition of benzodiazepine receptor binding by several cyclopyrrolones, including the pyrrolopyrazine, zopiclone, and the dithiinopyrrole, suriclone, two novel anxiolytics whose structures differ considerably from classical benzodiazepines, has been characterized in bovine brain. While zopiclone potently (IC50 ~ 50 mM) displaces [3H]Ro-15-1788 binding in an apparent mass action fashion, suriclone and its metabolite, 35,489RP are extremely potent (IC50 ~ 250 and 500 pM, respectively) and show Hill coefficients of approximately 2.0. Similar to classical benzodiazepines, none of the drugs studied appears to display significant selectivity for Type I or Type II benzodiazepine receptors. All of the drugs studied, however, appear to differ from classical benzodiazepines in several respects: (i) the potencies of cyclopyrrolones at displacing [3H]Ro-15-1788 are unaffected by GABA, Cl-, pentobarbital/Cl-, and traaczolate/Cl-, at concentrations which elicit stimulation of classical benzodiazepine agonist binding; (ii) exhaustive photoaffinity labelling of membranes with unlabeled fluintrazepam does not reduce the potency of cyclopyrrolones at displacing residual [3H]Ro-15-1788 binding, the only exception being zopiclone, whose potency is reduced four-fol; (iii)Scatchard analysis of [3H]Ro-15-1788 in the presence of all the drugs studied reveals a non-competitive pattern of inhibition of binding in each case; (iv) dissociation of [3H]flunitrazepam from its receptors in bovine cortex is accelerated by cyclopyrrolones. Using the radiolabeled cyclopyrrolone, [3H]suriclone, we

PERIPHERAL BENZODIAZEPINE BINDING SITES: IN VIVO and Line LABELLING BY [<sup>2</sup>H]PK 11195. <u>G. Le Fur, A. Uzan, C. Guérémy× and J. Bénavides×</u>. PHARMUKA Lab., 92231 Gennevilliers, France. Peripheral type benzodiazepine binding sites differ from classical GABA coupled receptors by having a very high affinity for R05-4864, a benzodiazepine without affinity for the central search a very low affinity for clonazepam. In a search 120.11 The second seco in ventricles, in the kidney, in the medulla and in adrenals in the cortical zone. Thermodynamic studies demonstrated that In ventricles, in the Managy, in the medding and in adjust in adjustant the cortical zone. Thermodynamic studies demonstrated that binding of [H]PK 11195 was entropy driven, whereas binding of [H]PK 11195 was entropy driven. These results taken together with the antagonism by PK 11195 of the convulsions induced by RO5-4864 suggest that PK 11195 could be an antagonist of a receptor where RO5-4864 acts as an agonist. [H]nist of a receptor where R05-4864 acts as an agonist. [H]-PK 11195 could be useful to determine the physiological role of "peripheral type" benzodiazepine binding sites because besides its high affinity and specificity is "in vitro" conditions the administration of trace doses of ['H]PK 11195 allow to label specifically its binding sites "in vivo".

CHEMICAL MODIFICATIONS SUGGEST THE PRESENCE OF HISTI-DINE AND TYROSINE RESIDUES AT THE BENZODIAZEPINE AND GABA BINDING SITES, RESPECTIVELY. <u>G. Maksay\* and M.K.</u> Ticku. Dept. Pharm., Univ. Tx. Hith. Sci. Ctr., San Antonio, 120.10 <u>Ticku</u>. De TX 78284.

Chemical modification of the brain GABA-benzodiazepine (BZ) Chemical modification of the brain GABA-benzodiazepine (BZ) receptor complex by protein group-selective reagents may disclose the chemical topography of these pharmacologically important recognition sites. Selective protection from the inhibitory action of the reagent by the ligands of these sites may support that the modification proceeds at the very site of the binding. Experiments were carried out in rat cortical membrane fraction extensively washed both before and after treatment with protecting and modifying agona to the following extensive the protection from the protection for the following memory of the protection for the following memory of the following memory of the protection for the following memory of the protection for the following memory of the protection for the protection for the following memory of the protection for the protection for the protection for the protection for the following memory of the protection for the protection

both before and after treatment with protecting and modifying agents. The following reagents were used: tetranitromethane (TNM, pH = 8.1); N-acetylimidazole (pH = 7.5); p-diazobenzenesulfonic acid (DSA, pH = 7.1); and diethylpyrocarbonate (DEP, pH 6.0). a) <u>BZ binding</u> was inhibited by DEP (which modifies histidine residues), DSA and TNM (which modify tyrosine residues). Protection experiments revealed that DEP inactivation could be selectively and completely protected by its own ligands like flurazepam. In contrast, DSA and N-acetyl-imidazole inactivation could only be partially protected both by its own ligands and by allosteric modulators like GABA, muscimal, pentobarbital and etazolate. TNM inactivation could be partially protected only by GABA and muscimal but not by flurazepam. These results suggest that the BZ binding protein contains a histidine residue at the active site, whereas the data for the location of tyrosine residue were not definitive. b) <u>GABA binding</u> was inhibited by DSA, N-acetyl-imidazole and

b) <u>GBA binding</u> was inhibited by DSA, N-acetyl-imidazole and TNM, <u>but not by DEP</u>. The inhibition of GABA binding by DSA, N-acetyl-imidazole and TNM could be selectively and completely protected by GABA and muscimol but not by the allosteric ligands like flurazepam and etazolate. Since all these reagents are consi-tered to the production of the selective like flurazepam and etazolate. Since all these reagents are consi-dered to be selective for tyrosine, the GABA recognition site ap-parently contains a tyrosine residue. TNM, while having no effect on the high affinity GABA binding sites, decreased the number of the low-affinity GABA sites and also abolished enhancing effect of muscimol on BZ binding. These results are in agreement with a previous study from this laboratory on DSA (Burch <u>et al</u>, <u>Molec. Pharmacol.</u> 23:52, 1983) and support the notion that the enhancing effect of GABA agonists on BZ binding is mediated by the low af-finity. GABA sites finity GABA sites

In summary, these results suggest (1) the presence of histidine and tyrosine at the binding sites of BZ and GABA receptors, re-spectively; (11) that GABA and BZs bind to two distinct sites; (111) low affinity GABA receptor sites are involved in the stimulaaffinity GABA binding; and (IV) the topography of the high and low affinity GABA binding sites may not be identical. Supported by NIH Grant NS15339

120.12 STIMULATION OF <sup>3</sup>H-DIAZEPAM BINDING BY GABA AND SQ20009:MODULATION

STIMULATION OF <sup>3</sup>H-DIAZEPAM BINDING BY GABA AND S020009:MODULATION BY THE PERIPHERAL-TYPE BENZODIAZEPINE LIGANDS. <u>R. M. Mangano</u> <u>N. M. Spirt\* and R. A. O'Brien</u>. Department of Pharmacology II, Hoffmann-La Roche Inc., Nutley, NJ 07110. The high affinity benzodiazepine (BZ) binding site appears to be one constituent of a macromolecular complex that is function-ally linked with the gamma-aminobutyric acid (GABA) recognition site and the Cl<sup>-</sup> ion conductance channel in the mammalian brain. GABA, in  $\mu$ M concentrations, has been reported to enhance the binding of [<sup>3</sup>H]-BZs to central nervous system (CNS) recognition sites. This effect is due to an increase in affinity rather than a change in the number of binding sites (Nature, <u>274</u>:383, 1978). This GABA effect is bicuculline-sensitive, concentration depend-ent and can be observed in several brain regions. In addition to GABA, the pyrazolopyridines have been reported to facilitate the binding of BZ agonists to CNS recognition sites. The pyrazolo-pyridine etazolate (SQ 20009; SQ) enhances BZ binding through an increase in receptor affinity which is both bicuculline and picrotoxin sensitive (Pharmacol. Biochem. Behav., <u>9</u>:849, 1978). Ig a previous study, we reported that the GABA enhancement of [<sup>3</sup>H]-BZ binding in the mammalian CNS could be inhibited in a dose-dependent manner by a convulsant BZ, Ro 5-3663 (Life Sci. <u>26</u>: 1441, 1980). In the present study we have investigated the effect of Ro 5-3663 as well as several "peipheral-type" BZs on the en-hancement of [<sup>3</sup>H]-BZ binding by GABA and/or SQ. Binding studies were performed with membranes prepared from a crude <u>p</u>, fraction of rat cortex. The membranes were washed a total of five times to remove endogenous GABA and resuspended in 50 ml Tris-HCl containing 100 ml NaCl (pH 7.4 at room tempera-ture). Under these conditions, <u>GABA</u> (10  $\mu$ M) and SQ (10  $\mu$ M) enhanced

50 mm Pris-Hol Containing 100 mm Matr (privit at room temperature). Under these conditions, GABA (10  $\mu$ M) and SQ (10  $\mu$ M) enhanced specific ["H]-diazepam (DIAZ) binding by 95% and 31% respectively. GABA plus SQ (10  $\mu$ M each) enhanced specific binding in a additive manner to 131% of control values. At 10  $\mu$ M, neither Ro 5-3663, Ro 5-4864 nor Ro 5-5115 had any effect on DIAZ binding. These BZS, at 10  $\mu$ M, variably attenuated both the GABA (10  $\mu$ M) and SQ (10  $\mu$ M) enhancement of smerific binding by 10%-20% and 20%-60%. BZs, at 10 µH, variably attenuated both the GABA (10 µM) and SQ (10 µM) enhancement of specific binding by 10%-20% and 20%-60%, respectively. However, these compounds appear to have only a minor effect on the enhancement of DIAZ binding produced by the combination of 10 µM GABA plus 10 µM SQ. Although the additive nature of the enhancement of BZ binding in the presence of both GABA plus SQ indicates that these two compounds are acting at different sites, the modulation of the GABA and SQ effect by the convulsant and peripheral BZs suggests that the GABA recognition site does play some role in SQ enhancement of BZ binding.

R.A. O'Brien. Department of Pharmacology II, Hoffmann-LaRoche Inc., Nutley, N.J. 07110. Möhler et al. (PNAS 77: 1666, 1980) reported that, when irra-diated with UV light, the benzodiazepine (BZ) receptors could be photoaffinity labeled with flunitrazepam (FLU), which is then irreversibly bound. Gee and Yamamura (Eur. J. Pharmacol. 82: 239, 1982) and Thomas and Tallman (J. Neurosci. 3: 433, 1983) showed that photoaffinity labeling of BZ receptors alters agonist binding but not antagonist binding. This report presents some methodological considerations of this technique, i.e., differ-ences in results with storage time and with Na<sub>2</sub>HPO<sub>4</sub> buffer, pH 7.4 and Tris-HCl buffer, pH 7.4. Rat cerebral cortices were homogenized in cold 0.32 M sucrose and the P<sub>2</sub> pellet prepared. The pellet was resuspended in 90 vol of 50 mM Na<sub>2</sub>HPO<sub>4</sub>-HCl buffer, pH 7.4. This was either 1) stored by freezing at 220°C in aliquots for future photolabeling and binding studies or 2) was photolabeled and after 2 washes with Na<sub>4</sub>HPO<sub>4</sub> buffer or 2 washes of 50 mM Tris-HCl buffer, stored in their nespective washing buffers at -20°C for future binding studies.

studies

their respective washing buffers at -20°C for future binding studies. Photoaffinity labeling was performed by exposure of membranes to UV light at 254 nm for 20 min. at 0°C in the presence of 30 nM FLU. Filtration binding assays were performed using "H-diazepam (DIAZ) and "H-Ro-15-1788. When Na,HPO, buffer was used to store the membrane pregaration, a decling in binding activity of all of the controls for "H-DIAZ and for "H-Ro-15-1788 binding occurred rapidly, with a decrease to 80-90% of the day "0" activity in 24 hrs.; a decrease to 40-50% in 48 hrs. and to 10-15% after 7 days. The "H-DIAZ binding with photolabeled membranes showed an initial increase to 150% of day "0" results at 24 hrs.; a decrease to 90% by 48 hrs. and to 40-45% after 7 days. These results (the increase in binding) were not seen with the antagonist, "H-Ro-15-1788; only a decrease as seen with the controls was observed. Storage for 7 days in Tris-HCl buffer resulted in no signifi-cant decrease (185%) in binding was observed after 24 hrs. of freezing. After 48 hrs. the increase was only 140% of that on day "0" (unfrozen); this was also seen after 7 days of freezing. Stability of the membranes is evident with Tris-HCl buffer as compared to Na,HPO. Freezing may, however, change the available

compared to Na HPO\_4. Freezing may, however, change the available binding sites fr influence the irreversible photolabeled sites.

BIOCHEMICAL EVIDENCE THAT PK 8165 A QUINOLINE DERIVATIVE WITH 120.14 PURE ANTICONFLICT PROPERTIES IS A PARTIAL AGONIST OF BENZODIA-ZEPINE RECEPTOR. J. Bénavidès×, A. Uzan, C. Guérémys and G. Le

Fur. The atypical pharmacological profile of PK 8165, a quinoline derivative with pure anticonflict properties (Le Fur et al., Life Sci. 28:1439-1448, 1981) seems to be due to the fact that this compound interacts with benzodiazepine receptor in a difthis compound interacts with benzodiazepine receptor in a dif-ferent way that classical benzodiazepine structure ligands. PK 8165 is a competitive inhibitor of ["H fflunitrazepam bind-ing to brain cortex membranes with a Ki value of 80 nM. Inhi-bition curves by PK 8165 of ["H]flunitrazepam binding present a Hill slope close to unity. Possible discrimination by PK 8165 of BZ and BZ receptor subtypes has been tested by measuring the displacement of ["H] flunitrazepam binding to brain sections. PK 8165 presents the same potency in BZ rich areas as in BZ rich areas. These results have been confirmed by quantitative analysis of autoradiograms of the binding to tissue sections, where opposite to CL 218,872 PK 8165 is unable to discriminate between cerebellum (BZ.) and dentate gyrus (BZ\_). CABA and flunitrazepam photolabel-ling produce potency shifts which are intermediate between full and gentate gyrus (B<sub>2</sub>). GABA and fulntrazepam photologi-ling produce potency shifts which are intermediate between full agonists and antagonists. Thermodynamic analysis shows that PK 8165 binding opposite to R015-1788 is associated with a Moreover PK 8165 by itself is unable to modify the cerebellar cGMP level, but potentiates the lowering of CGMP by diazepam and does not present antagonistic properties of this effect. Thus PK 8165 pharmacological properties seem to be due to the fact that this compound is a partial agonist of benzodiazepine receptors.

120.15 SENSITIVITY OF THE GABA RECEPTOR TO CHANGES IN ANIONIC COMPOSITION OF THE BUFFER, Paul Madtes, Jr. Lab. of Vision Research, NEI, NIH, Bethesda, MD 20205.

**Γ-aminobutyric acid (GABA) has been established as a major** inhibitory neurotransmitter in the retina. Two sodium-independent binding sites for GABA are present in the retina, one of high affinity and one of low affinity. These sites are thought to represent postsynaptic GABA receptors. Little is known, however, about what regulates the sensitivity of GABA receptors to the transmitter, although <u>in vitro</u> characterization of GABA receptors in nervous tissue shows a sensitivity of the receptors to the presence of various ions. The presence of sodium, for example, masks the appearance of the high-affinity binding site; however, the addition of bicarbonate ions, in the presence of sodium, renders the site detectable again. In addition, the presence of chloride ions modulates the inhibitory action of picrotoxin on the GABA receptor complex. It is reported here that the number of high-affinity binding sites for  ${}^{3}\mathrm{H}$ -GABA is preferentially decreased in the presence of TRIS-HCl buffer, com-

pared to the values found in the presence of TRIS-citrate buffer. Bovine eyes were obtained from a local supplier and synaptosomal membranes were prepared from the retinas. The tissue was assayed for  $^{3}\mathrm{H}\text{-}GABA$  binding according to a modification of the method of Enna and Snyder (Brain Res. 100(1975) 81-97). The The tissue was samples were incubated either in 50 mM TRIS-citrate buffer, pH 7.4, or in 50 mM TRIS-HCl buffer, pH 7.4. No difference was found between the osmolaric strengths of the two buffers. Scat-chard analysis of the specific binding data showed that the samples assayed in TRIS-citrate had a high-affinity binding site samples assayed in TRIS-citrate had a high-affinity binding site (K<sub>D</sub> values ranging from 10 to 30 nM; B<sub>max</sub> values ranging from 1.3 to 1.5 pmol/mg protein) and a low-affinity binding site (K<sub>D</sub>: 50-130 nM; B<sub>max</sub>: 2.3-3.0 pmol/mg protein). The samples incubated in TRIS-HCl also had two binding sites - a high-affinity site (K<sub>D</sub>: 5-25 nM; B<sub>max</sub>: 0.3-0.5 pmol/mg protein) and a low-affinity site (K<sub>D</sub>: 60-120 nM; B<sub>max</sub>: 1.7-2.3 pmol/mg protein). There was a 3-4 fold decrease in the number of high-affinity binding sites (B<sub>max</sub>) for the samples incubated in TRIS-HCl, compared to the values for those incubated in TRIS-HCl, compared to the values for those incubated in TRIS-HCl, compared to the apparent affinities, comparing the two buffering conditions. apparent affinities, comparing the two buffering conditions. This dramatic decrease in the number of high-affinity binding sites may indicate that the GABA receptor is sensitive to the presence of anions in its environment. This finding is especially interesting in light of the well-known effect of GABA on chloride permeability.

120.16 ANALYSIS OF BENZODIAZEPINE RECEPTOR TURNOVER IN CELL CULTURE BY SDS-GEL ELECTROPHORESIS. C.M. Czajkowski\* and D.H. Farb\*. (SPON: C. Lance-Jones). Dept. of Anatomy & Cell Biology, SUNY Downstate Med. Ctr. Bklyn.,NY 11203

The results of previous experiments indicate that photoaf-finity binding of flunitrazepam(FNZM) to embryonic chick brain finity binding of flunitrazepam(FNZM) to embryonic chick brain and spinal cord cultures (prepared from 7d. embryos) is directed toward the functional benzodiazepine receptor (BZD-R): We have shown that there is a good correlation ( $r^{2-0}0.96$ ) between the binding affinities of a series of BZD's and their BC50's for potentiation of GABA conductance. Secondly, irreversible photo-affinity binding of FNZM to cells decreases by 75% both revers-ible (3H)FNZM binding and the ability of chlordiazepoxide to potentiate GABA conductance. Two rates (half-times 4 & 32 hrs) for BZD-R degradation have been measured in culture. These rates may reflect multiple receptor types or different pools of recep-tor. The purpose of this study was to investigate the molecular nature of the functional BZD-R in chick brain cultures and to determine whether receptor heterogeneity could account for the observed biphasic kinetics of degradation. In the present study, determine whether receptor heterogeneity could account for the observed biphasic kinetics of degradation. In the present study, 7 and 20 day chick brain homogenates were photolabeled by expo-sure to 5nM (3H)FNZM and UV light. Separation of the labeled proteins by SDS-PAGE revealed two labeled bands at 51K and 48K. In culture, intact neuronal cells were photolabeled and two labeled proteins of 51K & 48K were also observed. These results are consistent with those obtained in photolabeled rat brain homogenates (Nature 286: 285,1985). After photolabeling, the disappearance of the two bands was examined to determine if their degradation rates were different: Cultures were photolabeled, washed and returned to the incubator for various times. Cells were scraped, homogenized, washed and SDS-PAGE performed. The two labeled proteins disappeared concomitantly with a half-life of about 24 hrs (n=4), indicating that they are not degrading at different rates. By SDS-PAGE it is unclear whether the rate is biphasic. While the amount of radioactivity decreased the pattern of radioactivity was unchanged, suggesting that the 48K protein is not a result of processing of the 51K protein. Subsequent to photoblockade EZD-R replacement was also followed. Cultures were photoblockade (100mM FNZM), washed and then photolabeled with 5nM photoblocked (100nM FNZM), washed and then photolabeled with 5nM (3H) FNZM immediately or after a recovery period of 24 hrs. SDS-PAGE following immediate photolabeling revealed an equal decrease in the labeling of both the SLK & 48K proteins. After photolabeling at 24 hrs.there was a 30% recovery of labeling in both species compared to labeling immediately after photoblockade. The results, taken together, suggest coordinate synthesis and degra-dation of both BZD-R proteins in cell culture. (Supported by NIH NS-18536 & New York Heart).

REGULATION OF BENZODIAZEPINE RECEPTOR DEGRADATION IN EMBRYONIC BRAIN CULTURES. <u>L.A.Borden,\*</u> D.Mierlak,\* and D.H.Farb.\* (SPON: J.Jakway). Dept. of Anatomy & Cell Biology, SUNY Downstate Med. 120.17 Ctr., Brooklyn, NY 11203

High-affinity benzodiazepine binding sites have been iden-tified in brain membrane homogenates, and probably represent the functional benzodiazepine receptor (BZD-R). To investigate the mechanisms involved in receptor regulation we have examined BZD-R turnover in living cell cultures derived from 7d. embryonic chick brains. BZD-R appearance and degradation can be monitored in cells maintained in culture for 7d. by using flunitrazepam (FNZM) as a photoaffinity label. Half-times for BZD-R degradation of 4 and 32 hrs have been determined (submitted). In an attempt to gain an understanding of the mechanisms involved in BZD-R degradation, we have examined a number of drugs and conditions for their ability to alter the fast component of BZD-R degradation. Brain cultures were photolabeled with (3H)FNZM (5MM,  $\emptyset^{OC}$ , UV 1 hr), washed, and returned to the incubator (37°C) following the addition of complete medium. Medium was removed at various times and the radioactivity determined. BZD-R degradation was inhibited 20% by the inhibitors of ox. phos. NaNa and 2,4-DNP(5mM) and by 2-deoxyglucose(10mM). When degradation was carried out under step down conditions in Earle's BSS, a 20% decrease in degradation down conditions in Earle's BSS, a 20% decrease in degradation rate was also observed. BZD-R degradation was acutely dependent on temperature, as greater than 90% inhibition was observed when degradation was conducted at 0°C. Degradation appears to occur via a non-lysosomal pathway, as the lysosomal protease inhibitors E-64, pepstatin, chymostatin, and bestatin (each 50µg/ml) and the lysosomotropic agent NH<sub>2</sub>Cl (10mM) were without effect. These results are similar to those obtained for the insulin receptor in cultured hepatocytes (J.B.C.257:1372, 82), but unlike those ob-tained on the 20th recenter in muchanes (J.Cell Phys. 107:185-191) tained on the ACh receptor in myotubes (J.Cell.Phys.107:185, 81). To determine if BZD-R degradation and synthesis are coordi-

To determine if BZD-R degradation and synthesis are coordi-nately regulated, we examined the effect of protein synthesis in-hibitors on BZD-R levels and degradation. Cycloheximide (CH, 20µg/ ml) inhibits protein synthesis 95%, and blocks BZD-R recovery following photoinactivation. A 5 hr incubation with CH decreased BZD-R levels 11% but did not affect degradation. However, tunicamycin (Tm. 0.5µg/ml,5hr) decreased protein synthesis 38% and BZD-R levels 44%. The large decrease in BZD-R levels compared to CH probably results from Tm's ability to inhibit glycosylation (44% inhibition of (3H)mannose incorporation into TCA precipi-table material). No effect of Tm on BZD-R degradation as well as protein synthesis in the maintenance of BZD-R levels and success that BZD-R synthesis and degradation can be separately est that BZD-R synthesis and degradation can be separately modified. (Supported by NIH NS-18536 & New York Heart).

[ $^{35}$ ]TBPS) TO SPECIFIC SITES COUPLED TO RECEPTORS OF  $\gamma$ -MANNQ-BUTYRIC ACID (GABA). D. T. Wong<sup>1</sup> and R. F. Squires<sup>2</sup>. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285 and <sup>2</sup>Rockland Research Institute, Orangeburg, NY 10962. Specific binding of a new ligand, [ $^{35}$ ]TBPS (Squires et al, Mol. Pharmacol. 23, 326, 1983), is demonstrated in membrane fractions of rat cerebral cortex and accounted for 84 to 94 percent of total binding dependent upon concentrations (1-40 nM) of [ $^{35}$ ]TBPS. The optimal temperature for [ $^{35}$ S]TBPS binding is near 25°C, with none at 0°C and 60°C. [ $^{35}$ S]TBPS binding is near 25°C, with none at 0°C and 60°C. [ $^{35}$ S]TBPS binding seffectively substituted with sodium iodide or fluoride, suggesting the dominating role of anion. GABA agonists, including GABA and muscimol, inhibit 50 percent of [ $^{35}$ S]TBPS binding (IC<sub>50</sub>) at 1700 and 565 nM, respectively, while GABA antagonist, picrotoxin, but not bicuculline, inhibits with IC<sub>50</sub> of 257 nM. The diaryltriazine LY81067 (F. P. Bymaster et al, Neurosci. Abst. 1982, p. 579) and the two pyrazolopyridines cartazolate and tracazolate inhibit [ $^{35}$ ]TBPS binding with IC<sub>50</sub> values of 243, 500 and 2000 nM, respectively. GABA (3 uM) inhibits [ $^{35}$ S]TBPS binding in a noncompetitive fashion with decreasing the number of binding sites (B<sub>max</sub>) from a control value of 2.1 to 0.8 pmole/mg protein, whereas picrotoxin (50-250 nM) inhibits competitively by increasing the dissociation constant (K<sub>D</sub>) from 32.4 to 49.8 nM. LY81067 at 500 nM inhibits in a pseudocompetitive way by increasing the K<sub>D</sub> value from 29.8 to 52.4 nM and lowering the B<sub>max</sub> value from 1.79 to 1.36 pmole/mg protein. Based on these findings, GABA appears to interact allosterically with [ $^{35}$ ]TBPS binding sites while picrotoxin appears to occupy at least a portion of these sites (Squires et al, 1983). We, therefore, conclude that [ $^{35}$ , S]TBPS binds to specific sites which are coupled to GABA and ion recognition sites in the macromo

DETERMINATION OF AMINO ACID NEUROTRANSMITTERS IN BRAIN VIA PRE-120.18 DETERMINATION OF AMINO ACID NEOROTRANSMITTERS IN BRAIN VIA PRE-COLUMN DERIVATIZATION AND LIQUID CHROMATOGRAPHY WITH ELECTRO-CHEMICAL DETECTION (LCEC). <u>R. D. Greenland\*, S. M. Lasley, and</u> <u>I.A. Michaelson</u>. Dept. Environ. Health, Univ. Cinti. Coll. Med., <u>Cincinnati, Ohio</u> 45267

1.A. Michaelson. Dept. Environ. Health, Univ. Cinti. Coll. Med., Cincinnati, Ohio 45267 Recent studies have demonstrated that the reaction of o-phthaldialdehyde (OPA) with free amino acids forms fluorescent compounds that are also electrochemically active (Joseph and Davis, J. Liq. Chromatogr., in press). Experiments were under-taken to determine the optimum conditions for measuring content of the putative amino acid transmitters in small regions of the rat brain employing LCEC. Amino acids were derivatized by mixing 25 ul of standard and 100 ul of derivatizing solution containing OPA and  $\beta$ -mercapto-ethanol at alkaline pH. Exactly 2.5 minutes later 20 ul of the mixture was injected into a liquid chromatograph consisting of a 5 um reverse-phase Biophase Clg column and a L-8A glassy carbon detector cell coupled with an LC-3 amperometric controller. Once gamma-aminobutyric acid (GABA) had been eluted, a washout was initiated by switching to 90% methanol and removing those amino acids with longer retention times. All amino acids of neurotrans-mitter interest (aspartic acid, glutamic acid, taurine, and gly-cine)were eluted prior to GABA. Plots of the peak response currents <u>vs</u>. applied potential indicated a common oxidation mechanism among the derivatives. On the basis of these curves a potential of +0.7 V was selected for subsequent work. Stan-dard curves were observed to be linear in the range up to 8 nano-moles, and limits of detection at twice background were 5-10 micromles. Breakdown of several of the amino acid therivatives moles, and limits of detection at twice background were 5-10 picomoles. Breakdown of several of the amino acid derivatives

picomoles. Breakdown of several of the amino acid derivatives occurred rapidly, resulting in decreased peak responses at longer reaction times than 2.5 minutes. Long-Evans hooded rats were sacrificed by near freezing, brains removed and sectioned at  $-15^{\circ}$ C for dissection of discrete regions. Tissue was stored at  $-80^{\circ}$ C until extraction. Brain regions were homogenized in 10 volumes of methanol, centrifuged briefly, and 25 ul of supernatant diluted with 25 ul of methanol and reacted with 200 ul of derivatizing solution before injection of 20 ul. Content values are comparable to those previously reported. This method therefore provides a simple and rapid means to assay putative brain amino acid neurotransmitters. (Supported by NIH grant ES-01566). ES-01566).

RELATIONSHIP BETWEEN <sup>3</sup>H-FLUNITRAZEPAM BINDING SITES AND DISTRI-BUTION OF GAD-LIKE IMMUNOREACTIVITY WITHIN THE RAT BRAIN. R. Miyoshi\*, S. Kito, E. Itoga and J.Y.Wu. Third Dept. of Int.Med. Hiroshima Univ. School of Med., Hiroshima, Japan 734 & Dept. of Cell Biology, Baylor College of Med., Houston, Texas 77020. There have been accumulated data on interaction between benzo-diazepine binding sites ang GABA receptors. The authors per-formed autoradiography of "H-flunitrazepam(flu) binding sites and immunohistochemistry of glutamic acid decarboxylase(GAD) alternatively on serial sections of the rat brain and thus compar-ed distribution of the GABA ed distribution of benzodiazepine receptors with that of the GABA marker

ed distribution of benzoulazepine receptors with that of the one marker. Wistar strain rats were perfusion-fixed by 0.1% paraformalde-hyde and serial cryostat sections of 10um thickness were prepard. For GAD immunohistochemistry, the indirect enzyme antibody tech-nique with use of GAD antiserum was applied(PAP method). The autoradiography of benzodiazepine binding sites was done on a fritium sensitive film after 90 min incubation at 0°C with 2 nM H-flu. As the results, distribution of GAD immunoreactivities was almost consistent with that of H-flu binding sites except in the cerebellum. Nevertheless, high density of H-flu binding sites was observed in the cerebral cortex and the density was less in the caudoputamen, while vice versa in GAD immunoreact-ivity. In the cerebellar cortex GAD immunoreactivity was richest in the Purkinje cell layer with poor distribution in the both molecular and granular layers. In contrast, H-flu bind-ing sites were evenly distributed in the whole layers of the cerebellar cortex. cerebellar cortex.

cerebellar cortex. 3 In addition, we performed combination of autoradiography of H-flu and GAD immunohistochemistry on the same section at EM level. It is an established fact that H-flu binding sites are closely related with GABA receptors on the cell membrane. Wöhler et al. pointed out that only one-third of the photolabeled benzodiazepine receptors were found to be associated with immuno-cytochemically GAD stained nerve endings. In our studies, benzodiazepine indian cites were mode hardly and widely ditting cytochemically GAD stained nerve endings. In our studies, benzodiazepine binding sites were more densely and widely distri-buted than GAD immunoreactivities especially in the cerebral and cerebellar cortices. Above-mentioned results were considered to be important as characteristics of benzodiazepine receptors in the brain.

STUDY OF GABAERGIC NON-PYRAMIDAL NEURONS IN PLEXIFORM LAYERS AND 121.2

DEEP WHITE MATTER OF RAT HIPPOCAMPUS. <u>5.G. Vickrey\*</u>, <u>0.E.</u> <u>Schmechel\*</u>, and <u>J.H. Haring</u> (SPON: A. Roses). Dept. of Medicine (Neurology), Duke University Medical Center, Durham, NC 27710. Many non-pyramidal neurons in rat hippocampus are immunoreact-ive for glutamic acid decarboxylase (GAD), the biosynthetic enzyme for gamma-aminobutyric acid (GABA), and are presumably GABAergic neurons (Ribak, C., Brain Res., 140:315, 1978). Some non-pyramid-al neurons in hippocampus are also immunoreactive for other neurotransmitter candidates such as cholecystokinin (CCK-8), enkephalin, and other neuropeptides. Not all non-pyramidal neurons are local circuit neurons since some project to medial septum (Chronister, R.B. and DeFrance, J.F., Exp. Neurol., 66:509, 1979). The purpose of the present study was to determine the proportion of GABAergic neurons in the plexiform layers and deep white matter of rat hippo-campus, their possible content of other neurotransmitters, and

whether some might project to medial septum. The proportion of GAD immunoreactive to total neurons was very easy to visualize in vibratome sections of perfusion-fixed rat hippocampus with two color double immunocytochemistry (PAP method). Non-GAD immunoreactive neurons were labeled with antiserum to the specific neuronal marker, neuron-specific enolase (NSE). Approx-imately 90% of the neurons in stratum lacunosum-moleculare, 85% of the neurons in stratum radiatum, and 2/3 of the neurons in stratum oriens and the dentate molecular layer are GAD immunoreact-ive and presumed GABAergic non-pyramidal neurons.

Double immunocytochemistry (two color) for GAD and CCK-8 showed that the high proportion of GABAergic neurons in these layers is accompanied by overlap of GAD and CCK immunoreactivity. About 3/4 of neurons immunoreactive for CCK were also GAD(+). Such cells were especially numerous in stratum radiatum as well as in the pyramidal and dentate granule cell layer. CCK pre-absorption supported the specificity of CCK immunoreactivity.

series of rats were injected with horseradish peroxidase (HRP) in the medial septum to yield a population of back-labeled non-pyramidal neurons in hippocampus, as previously reported. Using

pyramidal neurons in hippocampus, as previously reported. Using a different chromogen, GAD immunocytochemistry revealed that some of the HRP-labeled cells in stratum oriens were also GAD(+). Such presumed GABAergic neurons projecting to medial septum represented a small subgroup of both GAD(+) cells and HRP-labeled neurons. The present results show that (1) a high percentage of neurons in the superficial or deep layers of rat hippocampus are GABAergic, (2) a subset of GABAergic non-pyramidal neurons also display CCK-like immunoreactivity, and (3) a few GABAergic neurons in stratum oriens appear to project to medial septum. The relationship of these findings to development and function of hippocampus will be discussed. (Supnorted by grant from Mather Foundation). discussed. (Supported by grant from Mather Foundation).

121.3 AUTORADIOGRAPHY OF <sup>3</sup>H-FLUNITRAZEPAM BINDING IN GLOBUS PALLIDUS, ENTOPEDUNCULAR NUCLEUS AND SUBSTANTIA NIGRA AFTER STRIATAL KAINIC LESIONS IN THE RAT. H. S. Pan\*, J. B. Penney and A. B. LESIONS IN THE RAT. <u>H. S. Pan\*, J. B. Penney and A. B. Young</u>. Dept. of Neurology, University of Michigan, Ann Arbor, MI 48109. Striatal kainate lesions in the rat provide a biochemical model for Huntington's disease (HD). HD brains show marked de-creases in striatal GABA, ACh, and various peptides. Neurotransmitter receptors are also altered. In the rat model, GABA receptor changes in striatum and its projection areas parallel those observed in HD. Benzodiazepine (BDZ) and GABA receptors are linked functionally and anatomically in the basal ganglia. BDZ receptor numbers in striatum are reduced in HD and its animal model. However, this agreement does not hold for distal BDZ recep-tors. Decreased BDZ binding affinities with no change in receptor numbers have been reported in the deafferented nigra 3 to 4 weeks after striatal lesions (Biggio et al, <u>Brain Res. 220</u>, 344-9; Shibuya et al, <u>Europ. J. Pharm.</u> 62, 243-4). In HD the substantia nigra shows increased BDZ receptor numbers <u>and</u> decreased binding affinities. A major difference between HD and its animal model is chronicity. We have studied BDZ receptors in rat brain acutely

and chronically after striatal kainate lesions. Twenty micron frozen sections of brain were thaw-mounted on subbed slides. Slides were washed 3 times for 5 min in 50 mM Tris.HCl buffer (pH 7.4 @ 4°C) and incubated in 0.5-50 nM  $^{3}$ H-flunitrazepam ( $^{3}$ H-Flu) for 30 min at 37°C with or without various BDZ analogs. After incubation, sections were rinsed twice in 4°C buffer for 2 min and blown dry. GABA stimulated  ${}^{3}H$ -Flu binding was studied using similar incubation conditions and  $10^{-4}$  -  $10^{-7}$  M GABA. Nonspecific binding was determined in adjacent sections coincubated with 5 µM nonradioactive clonazepam. Autoradiograms were processed and analyzed as previously described (Pan et al, J. Neurosci., in press).

The effects of unilateral striatal kainate lesions on BDZ receptors in the striktur and its immediate projection areas in 6-8 rats were investigated 7 days and 8-12 weeks after the lesion. Acutely lesioned animals showed a 42% loss (p<.001, 2 tailed paired Student t-test) of BDZ receptors in the lesioned striatum. No changes in baseline or GABA stimulated BDZ binding were found in other areas. In chronically lesioned rats, a 53% decrease (p<(001) in BDZ receptor number was seen in lesioned striatum.  $B_{max}$  was increased in deafferented striatal projection areas globus pallidus (29%, p<.02), entopeduncular nucleus (27% p<.02), and the substantia nigra pars reticulata (33%, p<.02). Binding affinities were decreased on the deafferented side. The data suggest that BDZ receptor changes which resemble those seen in HD do

occur in chronic striatal kainate lesioned rats. Supported by NSF grant BNS-8118765, USPHS grants NS00420, NS00464 and NIMH National Research Service Award 14279.

Y-AMINOBUTYRIC ACID STIMULATES THE RELEASE OF ENDOGENOUS ASCORDIC 121.4  $\gamma$ -Aminobolitic Acid Simulates the RELEASE of ENOUGENOUS ASUMBLE ACID FROM RAT STRIATAL TISSUE. J. C. Bigelow\* and R. Mark Wightman Department of Chemistry, Indiana University, Bloomington, IN 47405  $\gamma$ -Aminobutyric acid (GABA) was found to induce the release of ascorbic acid from rat striatal homogenates and minces. This  $\gamma$ -Aminobutyric acid (GABA) was found to induce the release of ascorbic acid from rat striatal homogenates and minces. This release was studied with the use of a rapid superfusion system with an on-line amperometric detector that monitors for the presence of easily oxidized substances (i.e. ascorbate, 3,4-dihydroxypheny-lethylamine (dopamine)). Such a superfusion system allows the rapid application and removal of chemical substances to a rat striatal tissue sample. Application of GABA (10<sup>-6</sup> M) in the presence of elevated potassium (40 mM) stimulated the release of an electroactive substance while application of GABA alone (10<sup>-3</sup> M to 10<sup>-5</sup> M) had no effect. This substance has been identified to be ascorbic acid by liquid chromatography with electrochemical detection. The release was found to be calcium independent and could be replenished through nonstereospecific uptake. The releasing action of GABA an effect. These data antagonist, picrotoxin. The structural analogues of GABA,  $\beta$ -alanine and  $\gamma$ -hydroxybutyric acid had no effect. These data indicate that ascorbate release is GABA-receptor mediated and synaptically localized. The presence of a releasable pool which is resistent to depletion by the superfusion stream indicates there is a tightly bound storage compartment for ascorbate in the rat caudate. rat caudate.

IDENTIFICATION OF BINDING SITES FOR <sup>3</sup>H--Y-AMINOBUTYRIC ACID IN SCIATIC NERVE OF THE FROG. A. Barolet\*, S. J. Kish\* and M. E. Morris (SPON: O. Hornyklewicz). Departments of Pharmacology and Anaesthesia and the Human Brain Laboratory, Clarke Institute of Psychiatry, University of Toronto, Toronto, Canada. The inhibitory neurotransmitter Y-aminobutyric acid (GABA) has previously been shown to increase the excitability of myelinated fibers of the isolated, desheathed frog sciatic nerve (Morris et al., Neurosci. Abs. 4: 582, 1978; Brain Research IN PRESS, 1983). This depolarizing action (reflected by changes in the stimulus-evoked half-maximal A-fiber compound action potential) has an ED<sub>50</sub> value of 0.09 mM, is chloride-dependent and can be reversibly anevoked half-maximal A-fiber compound action potential) has an ED<sub>50</sub> value of 0.09 mM, is chloride-dependent and can be reversibly an-tagonized by bicuculline and picrotoxin. Fibers forming the dors-al roots show markedly greater sensitivity to GABA than those which contribute to the ventral roots (*Barolet & Morris, Proc. Can. Fed. Biol. Soc. 26, 1983; Morris et al., Brain Research IN PRESS, 1983*). In the comparison of potencies of agonists muscimol > 3-aminopropanesulfonic acid (S-APS) > GABA >  $\beta$ -guanidinopropionic acid (O) > miniterential coid (S-APS) = Cana - finite acid (S-A acid (B-GP) > guanidoacetic acid (GuAc) > &-aminovaleric acid

 $(\delta$ -AVA) >  $\beta$ -alanine. This initial characterization of peripheral extrasynaptic re-This initial characterization of peripheral extrasynaptic re-ceptors on myelinated sensory axons is now followed by studies which identify saturable, Na<sup>+</sup>-independent binding sites for GABA in the frog sciatic nerve. The binding of <sup>3</sup>H-GABA was carried out on ice under Na<sup>+</sup>-free conditions with fresh tissue homogenate. Incubation mixtures contained 2 mg tissue and 25 nm <sup>3</sup>H-GABA in 50 mM TRIS citrate (pH 7.6). Non-specific binding was determined in the presence of 6  $\mu$ M unlabelled GABA. Following a 20 min incu-bation, samples were centrifuged and the pellets rinsed superfic-ially and counted for radioactivity. Preliminary analysis of sat-uration data suggests the existence of a population of sites which bind  $\frac{3H-GABA}{2}$  with an apparent dissociation constant (KA) of 85 nM. uration data suggests the existence of a population of sites which bind  $^{3}$ H-GABA with an apparent dissociation constant (K<sub>d</sub>) of 85 nM. Hypotonic treatment of the sciatic nerve homogenate, followed by multiple washings with buffer, did not significantly alter the amount of specific binding. Incubation at 37°C resulted in a slight decrease in binding, whereas freezing at -80°C caused a marked decrease. The rank order of potencies of agonists that displaced bound  $^{3}$ H-GABA was muscimol > GABA >  $^{5}$ -AVA >  $^{8}$ -alanine. However 3-APS,  $\beta$ -GP, and GuAc, as well as bicuculline and picrotoxin (all in concentrations up to 0.1 mM) had no discernible effect on the binding of GABA.

Thus, under our assay conditions the <sup>3</sup>H-GABA binding site which has been identified does not appear to have characteristics similar to those of either the receptor mediating GABA's depolarizing effect in the peripheral nerve or the classical <sup>3</sup>H-GABA binding

Site present in the CNS. (Supported by the Medical Research Council of Canada. S.J.K. is a Career Scientist of the Ontario Ministry of Health).

MULTIPLE BENZODIAZEPINE BINDING SITES IN NEURONAL CULTURE: FUNC-TIONAL SIGNIFICANCE AND DEVELOPMENTAL CHANGES, <u>G.D. Schiller\*, R.</u> Romaine\* and D.H. Farb\* (SPON: M. Halpern) Dept. of Anatomy and Cell Biology, SUNY Downstate Med. Ctr., Brooklyn, NY 11203 Two binding sites of high (A) and low (B) affinity for benzo-121.8

Two binding sites of high (A) and low (B) affinity for benzo-diazepines (BZD) have been found in 7-d old chick CNS, but site-B disappears by 20-d. Electrophysiological evidence from cultured spinal neurons established a good correlation betweeen the EC50s of various BZDs for potentiation of GABA conductance and their in vitro binding affinity to site-A, but not site-B. The physiologi-cally observed EC50s are 38 and 5 fold lower affinity compared to binding at  $\emptyset$  and 37 respectively. This raises the question of whether there is a difference in binding affinities between BZD-R in membranes prepared from embryonic brain and those from brain in membranes prepared from embryonic brain and those from brain cell cultures. The present study sought to examine whether or not multiple BZD binding sites also exist in cultured neurons and if they are subject to developmental change. Homogenates were pre-Multiple B2D binding sites also exist in cultured heriois and in they are subject to developmental change. Homogenates were pre-pared from 7-d brain cultures (derived from 7-d embryos) and the binding affinities for clonazepam (CZ), flunitrazepam (FNZM), diazepam (DZ), flurazepam (FZ) and chlordiazepoxide (CDX) deter-mined by competition binding studies, Multiple binding sites similar to those of 7-d CNS were observed: The respective site-A (nM) and site-B (uM) affinities were: CZ 2 & 19.5, FNZM 2.6 & l.61, DZ 13.6 & 23, FZ 23.6 & 21.3, CDPX 103 & 13.5. A good cor-relation was found between the affinity of site-A and the EC50 determined electrophysiologically (slope-1.21, r<sup>2</sup> =0.93). This was not so for site-B (slope-0.49, r<sup>2</sup>=0.098). The former corre-lation supports the hypothesis that site-A is physiologically relevant. Site-B can be distinguished from the peripheral type BZD site since the latter binds FNZM and DZ with high affinity (<20mK; Life Sci.28,991, '80) but to site-B with low affinity. A transition from site-A and -B to only site-A also occurred with time in culture. This suggests that the factors that determine the expression of BZD binding sites also exist in culture. Compa-risons of the Bmax for FNZM binding to site-A and -B reveals that The expression of B2D binding sites also exist in culture. Compa-risons of the Bmax for FN2M binding to site-A and -B reveals that site-B predominates in a ca. 35 fold excess in 7-d cultures, be-coming ca. 5 fold by 14-d and is undetectable in 20-d cultures. Results suggest that both sites are neuronal: Thus, cultures nearly free of neurons do not exhibit irreversible photoaffiniy labelling of site-A; further, the loss of site-B with time in culture and its aburdance in young cultures (trooted with ABA C culture, and its abundance in young cultures (treated with ARA-C to inhibit growth of non neuronal cells), points to site-B also being neuronal. Future research will aim to study the relation-ship of site-B to site-A and the binding properties of BZDs to intact cultured cells with regard to the physiological significance and possible regulation by chronic BZD exposure. (Supported by NIH NS-18536 & New York Heart).

GABA AGONISTS POTENTIATE NOREPINEPHRINE-STIMULATED ADENYLATE CYCLASE ACTIVITY IN RAT BRAIN FRONTAL CORTEX SLICES. <u>E.W. Karbon\*</u> <u>and S.J. Enna</u>. Depts. Pharmacol. and Neurobiol., Univ. Texas Med. Sch., Houston, TX 77025. If has been suggested that there are at least two pharmacologi-121.7

It has been suggested that there are at least two pharmacologi-cally and functionally distinct GABA receptor populations in brain. Whereas GABAA receptors appear to be directly coupled to a chloride ion channel and are blocked by bicuculline and picro-toxin, the GABAB sites are not. Unlike some other neurotrans-mitters, there is no evidence to support a direct link between GABAA receptors and a second messanger. The present study was undertaken to determine whether the GABAB site may be associated with a cyclic nucleotide generating system. Slices of rat brain frontal cerebral cortex were incubated with 3H-adenice and adenulate cyclase activity determined hy measuring

<sup>3</sup>H-adenine and adenylate cyclase activity determined by measuring the production of <sup>3</sup>H-cAMP. Adenylate cyclase activity was increased 12-15 fold in the presence of 100  $\mu$ M norepinephrine. When creased 12-15 fold in the presence of 100  $\mu$ M norepinephrine. When the samples were incubated with baclofen, a GABA<sub>B</sub> receptor agonist, 100  $\mu$ M norepinephrine increased activity 40-fold. The EC<sub>50</sub> for baclofen to enhance the stimulated response was approximately 20  $\mu$ M. Baclofen alone produced a small (2-fold), but statisti-cally significant, increase in adenylate cyclase activity. Kojic amine and GABA, both of which are GABA<sub>A</sub> and GABA<sub>B</sub> receptor agonists, also potentiated norepinephrine-stimulated adenylate velace activity in this extern. Muscimal a velativity relactive agonists, also potentiated norepinephrîne-stimulăted adenylate cyclase activity in this system. Muscimol, a relatively selective agonist for the GABA<sub>A</sub> site, was relatively weak in comparison with baclofen. Baclofen (100  $\mu$ M) enhanced the ability of norepine-phrine to stimulate cyclase activity at all concentrations (0.1 to 100  $\mu$ M) of catecholamine studied. The selectivity of this inter-action is indicated by the finding that other amino acids, such as glycine and glutamate, had no effect on either basal or norepine-phrine-stimulate cyclase activity. These findings suggest that there may be a functional link between GABA receptors and the adrenergic receptor-coupled adenylate cyclase system in brain. The initial data suggest that this associateion may be a characteristic of  $GABA_{\rm P}$  receptors. (Supported, in part, by USPHS grants NS-00335 and GM-07405, and by NSF grant BNS-8215427).

AND BENZODIAZEPINES: INTERACTIONS 121.9 BETA-CARBOLINES BETWEEN BETA-CARBOLINES AND BERZODIAZEPINES: INTERACTIONS BETWEEN NEGATIVE AND POSITIVE MODULATORS OF GARA-INDUCED CONDUCTANCE CHANGES ON CULTURED CHICK NEURONS. <u>C.Y. Chan\* AND D.H. Farb\*</u> (SPON: D. Soifer). Dept. of Anatomy & Cell Biology, S.U.N.Y. Downstate Med. Ctr., Brooklyn, NY 11203. We have previously shown that methyl beta-carboline (BCCM) in-

hibits GABA-induced conductance increases (gGABA) and that benzodiazepines (BZD) potentiated gGABA in perfused cultures. Biochem-ical studies show that beta-carbolines (BCC) and BZD compete for for the same functional site or exhibit independent actions me-diated by separate sites or different domains of the BZD site. Thus, we examined if BZD reverse the inhibition of gGABA by BCC: Thus, we examined in BZD reverse the inhibition of gCABA by RCC: If methyl 6,7-dimethoxy-beta-carboline (DNCM) and clonazepam (CZ) act independently, then CZ would not reverse the ability of DMCM to inhibit gCABA, but would simply shift the inhibited GABA dose-response curve to the left. Drugs were applied from pressure pipets and the responses recorded intracellularly. DMCM inhibited gCABA in a Michaelis-Monton lie of shipe with a petcampu of 104 MM and an efficient of

Recticed inhibiter that is not a potency of 19 $\pm$ 4nM and an efficacy of 6648% inhibition (n=4). The inhibition of gGABA by DMCM was not surmountable by maximal GABA: 30nM DMCM inhibited gGABA at 5000M GABA (DECS0=17) $\mu$ M) by 32 $\pm$ 7% (n=2). However, the inhibition of 5000M GABA by 30nM DMCM was reversed to control by a mixture of 30 $\mu$ M C2 GABA by 30mM DMCM was reversed to control by a mixture of 30mM CZ and 30mM DMCM. No potentiation of gGABA past the control level was seen, consistent with the fact that BZD do not potentiate maximal GABA response. In experiments using 50µM GABA, DMCM inhi-bition was reversed and net potentiation was produced by 30µM CZ and 30mM DMCM, as expected for competitive interaction between the two ligands. UV-flumitrazepam photoinactivation did not seem to affect this inhibition of gGABA by DMCM. The same reversal of DMCM inhibition of the response to 500µM and 50µM GABA was obser-ved (n=2) on photoinactivated cultures; however, the CZ/DMCM mixved (n=2) on photoinactivated cultures; however, the CZ/DMCM mix-ture did not cause net potentiation of 50µM GABA responses. This result is consistent with blockade of binding and electrophysio-logical action of BZD by photoinactivation, but indicates that competition by BZD at the DMCM site was unaffected. R015-1786 caused a dose-dependent potentiation of gGABA with an EC50 of 130nM comparable to that of CZ (EC50=138nM) but a maximal poten-tiation of about 72% as compared with 450% potentiation by BZD agonists. Maximal Rol5-1788 applied with maximal BCCM also reversed the BCCM inhibition of submaximal gGABA and caused a small net potentiation, suggesting competition of the BCC site with a partial agonist. The hypothesis that BCC and BZD are negative and positive modulators at a common receptor is supported by a good correlation ( $r^{2}$ =0.97,slope 1.7) between GABA ratios (Braestrup, et al. Science 216:1241,'82) and maximal potentiation or inhibition of gGABA. (NIH NS-18536 & N.Y. Heart & NHDA Fellowship).

GABAA AND GABAB RECEPTORS IN MYENTERIC NEURONS: AN INTRACELLULAR STUDY. <u>E. Cherubini and R. A. North.</u> Neuropharmacology Laboratory, M.I.T. Cambridge, MA 02139 The effects of  $\gamma$ -aminobutyric acid (GABA) applied both by ionophoresis and perfusion to myenteric neurons of the guinea-pig ileum were investigated by intracellular recording tech-niques. Ionophoretic application of GABA (10 pC - 30 nC) caused membrane depolarization of AH neurons but not S neurons. This depolarization was associated with a conductance increase. 122.1 caused membrane depolarization of AH neurons but not S neurons. This depolarization was associated with a conductance increase, and reversed polarity at a membrane potential of -18 mV with KCl electrodes and -39 mV with K acetate, citrate or sulphate electrodes. This depolarization was antagonized by bicuculline in an apparently competitive manner. During prolonged or repeated ionophoretic application of GABA, both the depolariza-tion and conductance increase desensitized.

tion and conductance increase desensitized. Superfusion of GABA (1-100 µM) caused a membrane depolariza-tion in AH neurons, associated with an increase in membrane conductance. The increase in conductance was much smaller than that evoked by ionophoresis of GABA. Bicuculline only par-tially depressed the depolarization induced by superfusion of GABA, particularly reducing its rate of rise.  $\beta$ -p-chlorophenyl GABA (baclofen) (10 µM-1 mM) minicked the effect of GABA sper-fusion. The depolarization induced by GABA superfusion did not decline during prolonged applications. The bicuculline resistant effect of GABA superfusion was reversibly blocked by cobalt (2 mM). Since the bicuculline insensitive, noncobalt (2 mM). Since the bicuculline insensitive, non-desensitizing depolarization may result from reduction of an inward calcium current, we examined the effect of GABA on two calcium dependent events: synaptic transmission and the calcium spike in AH neurons.

GABA reduced the amplitude of the fast excitatory postsynap-tic potential (e.p.s.p.) without changing the amplitude of the nicotinic response to ionophoretic application of acetylcholine The product of the product of the product of the product of the field of the product of the pro

SUBSENSITIVITY TO GABA FOLLOWING CHRONIC BENZODIAZEPINES: ELECTROPHYSIOLOGICAL STUDIES. <u>D.W.</u> <u>Gallager</u>, <u>S.F.</u> <u>Gonsalves\*</u>, <u>S.L.</u> <u>Rauch\*</u> and <u>J.M.</u> <u>Lakoski</u>. Department of Psychiatry, Yale University School of Medicine, New Haven, CT 06508. Benzodiazepines exert many of their pharmacological effects by a selective facilitation of the postsynaptic actions of GABA. Electrophysiological studies of serotonin(5HT)- containing neurons in the dorsal raphe (DR) nucleus indicate that immediately following benzodiazepine injection, GABAergic inhibition is potentiated without altering sensitivity to other neurons in the dorsal raphe (DR) indeced immediately following benzodiazepine injection, GABAergic inhibition is potentiated without altering sensitivity to other neurotransmitter substances. While several clinical and behavioral studies have reported a reduction in drug response following chronic benzodiazepine treatment, physiological studies of neurotransmitter function following chronic exposure are looking. We now report a selective decrease in CARA in DR neurons following chlowing following classifier DR neurons following lacking. We now report a selective decrease in microiontophoretic sensitivity to GABA in DR neurons following chronic benzodiazepine administration. Microiontophoretic sensitivity to the neurotransmitters 5HT

chronic benzodiazepine administration. Microiontophoretic sensitivity to the neurotransmitters SHT Microiontophoretic sensitivity to the neurotransmitters SHT and GABA was tested in DR neurons of adult male rats treated daily for 3 to 6 weeks with either vehicle (VEH) or diazepam (DZ;2.5 or 5 mg/kg/day,ip). As is observed following acute DZ administration, chronic DZ treatment did not alter the spontaneous firing rate of DR neurons (DZ:0.8  $\pm$  0.1 vs VEH: 1.0  $\pm$  0.1 spikes/sec). Neuronal sensitivities to GABA and SHT were calculated as the product (IxT<sub>60</sub>) of the iontophoretic current (nA) and time (sec) required to decrease spontaneous firing of a recorded cell by 50% of its basal rate. DR neurons in animals chronically treated with 5 mg/kg/day DZ were significantly less sensitive to GABA (p<0.001) than their corresponding controls (DZ: IxT<sub>60</sub>=22.2 $\pm$ 2.8; VEH: IxT<sub>60</sub>=10.7 $\pm$ 1.4); a similar trend was observed in the 2.5 mg/kg/day DZ were significantly less observed in the 2.5 mg/kg/day DZ were significantly altered (DZ:IxT<sub>60</sub>=182 $\pm$ 15; VEH:IxT<sub>60</sub>=164 $\pm$ 24). To determine whether the subsensitivity to GABA was mediated through a benzodiazepine receptive site, neuronal sensitivities to GABA and SHT were selective for the range observed in vehicle-treated animals increased to the range observed in vehicle-treated animals or to significantly modify 5HT responses of DR neurons in either treatment group. These studies indicate that 5HT neurons in the DR become subsensitive to GABA following chronic exposure to diazepan. This effect may be correlated with the development of tolerance to benzodiazepines following chronic drug exposure. (Support: Klingenstein Fund, USPHS MH 14276, State of Connecticut)

SUBSENSITIVITY TO GABA FOLLOWING CHRONIC BENZODIAZEPINES: RECEPTOR BINDING STUDIES. <u>S. L. Rauch\* and D. W. Gallager</u>. Department of Psychiatry, Yale University School of Medicine, New 122.2 Haven, CT 06508.

number of clinical and behavioral studies have demonstrated

A number of clinical and behavioral studies have demonstrated reductions in drug response following chronic benzodiazepine administration. We have recently found a functional subsensitivity to GABA following chronic exposure to benzodiazepines (Gallager et al, Neurosci. Abst. 1983). In order to investigate whether receptor alterations accompany these changes in GABA sensitivity, we examined various binding-site components of the GABA postsynaptic receptor complex. As in the electrophysiological studies, adult male rats were treated daily with vehicle or diazepang (DZ; 5mg/Kg,ip) \_for 3 weeks. In these studies we utilized <sup>3</sup>H-FLU binding as probes of the GABA receptor complex. <sup>3</sup>H-muscimol was used as a measure of the high affinity GABA recognition portion of the GABA receptor complex. In agreement with a number of previous studies, our treatment regimen did not produce measurable alterations in benzodiazepine receptor number or affinity as measured by treatment regimen did not produce measurable alterations in benzodiazepine receptor number or affinity as measured by saturation binding of  $^{-1}H-EIU$  (0.5 to 16nM; 37°C) to cerebral cortical membranes (VEH: B\_max= 3932 ± 283 fmoles/mg protein, K\_D=21.8 ± 7.0nM). In addition, KABA was found to enhance  $^{-1}H-EIU$  binding in membranes from both the VEH and DZ treated animals (EC<sub>50</sub>GABA= 4µM). However, the magnitude of the GABA enhancement was found to be significantly reduced in membranes from chronic diazepam treated rats (VEH= 43.0 $\pm$ 5.0%; DZ= 21.5 ± 2.3%). These effects do not appear to be due to decreases in GABA recognition sites since neither GABA receptor number nor affinity were affected by chronic DZ treatment as measured by  $^{-1}H$ -muscimol binding (VEH: B = 1538 fmoles/mg protein, K\_n= 11.9MM; DZ: B = 1539 fmoles/mg = 1538 fmoles/mg protein, K<sub>D</sub>= 11.9nM; DZ: B<sub>max</sub>=1539 fmoles/mg

 $\rm B_{max}$  = 1538 fmoles/mg protein,  $\rm K_{D}$  = 11.9nM; DZ:  $\rm B_{max}$  =1539 fmoles/mg protein,  $\rm K_{D}$  = 8.8nM). These results suggest that rather than a change in receptor number or affinity, chronic DZ exposure may produce a more subtle change in interactions between various elements of the GABA macromolecular complex. (Supported by Klingenstein Foundation and the State of Connecticut.)

NEUROTRANSMITTER-ACTIVATED CHLORIDE CHANNELS IN CULTURED MOUSE SPINAL NEURONS ARE ALSO VOLTAGE-REGULATED. <u>R.E. Study\* and J.L.</u> Barker (SPON: R. Aldrich). Lab. of Neurophysiology, NINCDS NIH, Bethesda, MD 20205.

The inhibitory neurotransmitters GABA, glycine, and beta-alanine, as well as the anesthetic barbiturate (-)pentobarbital, alanine, as well as the anesthetic barbiturate (-)pentobarbital, have been previously shown to increase membrane chloride conductance in cultured mouse spinal neurons (Barker, J.L. and Ransom, B.R., J. Physiol. <u>280</u>, 331-354, 1978; Huang, L.Y.M. and Barker, J.L., Science <u>207</u>, 195-197, 1978). We have found that the magnitude of the conductance change produced by each of these agents is highly voltage-dependent, showing up to a 15-fold increase over the range of -90 to +10 mV, as measured using voltage steps with a two-electrode voltage clamp. The voltage-dependence is similar with all of the four agents, even though the channels activated by each differ in terms of their kinetics the channels activated by each differ in terms of their kinetics and conductance. Plots of net conductance change <u>vs.</u> potential were non-linear, with minimum slope near resting and at hyperpolarized potentials, and increasing slope at depolarized potentials. This voltage-dependence of neurotransmitter activated chloride channels appears to be the rule rather than the exception in cultured spinal neurons, although the steepness of the conductance-voltage relationship varies somewhat. or the conductance-voltage relationship varies somewhat. For GABA and glycine, the changes in chloride channel behavior underlying this voltage-dependence were studied using fluctuation analysis. For the range of -90 to +10 mV, there was no change in the average single-channel conductance for either neurotransmitter. In both cases, however, there was an increase in average channel open lifetime which was insufficient (about 2-fold) to fully account for the large increase in net conductance. This indicates that there was also an increase in one channel This indicates that there was also an increase in open channel lifetime underlying the net effect. Since the inhibitory action of the activated chloride channels is much enhanced at depolarized potentials, this behavior may be an important means by which such inhibitory transmitters stabilize the post-synaptic membrane in the presence of excitatory input.

- SOMATIC AND DENDRITIC ACTIONS OF GABA AGONISTS AND UPTAKE BLOCKERS IN THE HIPPOCAMPUS <u>IN SITU.</u> <u>C. Rovira\*, Y. Ben-Ari and</u> <u>E. Cherubini.</u> (SPON. Anthony M. Adinolfi ) Laboratoire de Physiologie Nerveuse, C.N.R.S., 91190 Gif sur Yvette, France. GABA agonists and GABA uptake blockers were ionophoretic-122.5 ally applied to the some and apical dendrities of  $CA_1$  hippocampal neurones of intact urethane anaesthetized rats. A twin set of multibarrelled pipettes was used to enable concomitant recordings of somatic and dendritic field potentials elicited by commissural stimulation and iontophoresis of drugs at either site. Application of GABA, isoguvacine or muscimol on the pyramidal layer pro-duced a biphasic effect: an inhibition of the population spike that showed a rapid "fading", followed by an enhancement with the appearance of a second and occasionally a termancement with the appearance of a second and occasionally a third population spike ("off" response). The "off" response produced by muscimol was consistently greater than that produced by isoguvacine and GABA. The "fading" and the "off" response were exclusively restricted to the immediate vicinity of the pyramidal layer and were not associated with significant changes in the concomitantly recorded dendritic field EPSP. In contrast application of GABA and its dendritic field EFSP. In contrast application of GABA and its analogs to the stratum radiatum, induced a reduction of the field EFSP and the somatic population spike. No "fading" and "off" response were observed even during long periods of application of these drugs. Somatic application of GABA uptake blockers nipeco-tic acid or guvacine consistently enhanced GABAergic inhibition, induced a decrease in its latency to peak, and an increase in the recovery time. The fading and the "off" response were completely blocked by these drugs. blocked by these drugs. Dendritic application of the uptake blockers reduced the field EPSP and the somatic population spike, but failed to produce prominent changes in the action of GABA and its analogs. Somatic application of nipecotic acid and guvacine blocked also the enhancement of the somatic population spike in-duced by increased frequency of stimulation. These data suggest that in the pyramidal layer of  $CA_1$  hippocampal neurones removal of GABA is highly efficient and may be in part responsible for the lability of inhibition.
- INTRACELLULAR RECORDINGS FROM NEURONS IN THE LATERAL SEPTAL 122.6 NUCLEUS AND THE EFFECTS OF DRUGS INTERACTING WITH GABA-RECEPTOR IONOPHORE COMPLEXES. David R. Stevens, Joel P. Gallagher and

IONDHORE COMPLEXES. David K. Stevens, Joel F. Gallagher and Patricia Shinnick-Callagher. Department of Pharmacology and Toxicology, Univ. of Texas Med. Br., Galveston, TX 77550. Intracellular recordings were made from an <u>in vitro</u> rat brain slice preparation to study inhibition at the cellular level in the lateral septal nucleus. The preparation was similar to that described previously by Miller (1981). We have recorded from over 100 neurons of the dorsolateral nucleus which had stable resting potentials averaging 67mV (range: 55-78mV). These neurons had input resistances of 40-100 megohms and long time constants ( $^{4}40$  msec) compared to other CNS neurons. Stimulation of the medial septal area resulted in antidromic action potentials (APs) with short latencies whereas stimulation of the fimbria/fornix area produced excitatory postsynaptic potentials (epsps) and/or orthodromic APs.

Fast sodium APs of 2-4 msec duration could also be elicited by direct stimulation via the intracellular microelectrode. These APs were characterized by a brief afterhyperpolarization followed by a longer lasting hyperpolarization (50-200 msec). Most cells had a depolarizing after-potential which became more evident at slightly hyperpolarized membrane potentials.

Spontaneous epsps were frequently present. Epsp amplitude were enhanced by membrane hyperpolarization. Spontaneous APs Epsp amplitudes were observed in about 50% of the cells and could usually be attributed to epsp activity. GABA superfusion (10<sup>-4</sup> M) resulted in either a small hyper-

polarization (2-5mV) or a depolarization (10mV); occasionally, large GABA-induced depolarizations (30mV) were recorded. All responses were associated with a conductance increase. Ionto-phoretic GABA application resulted in depolarizing or biphasic phoretic GABA application resulted in depolarizing or obphasic responses with concomitant conductance increases. Biphasic responses could be converted to depolarizing responses by de-creasing the GABA ejection current. Picrotoxin superfusion  $(10^{-5}M)$  resulted in an increase in AP frequency and the onset of bursting activity. The sedative/hypnotic benzodiazepine, flurazepam  $(10^{-6} - 10^{-5} M)$ , hyperpolarized the membrane potential and decreased encodrageous activity. This membrane hyperpolarand decreased spontaneous activity. This membrane hyperpolar ization was associated with a conductance increase. Flurazep Flurazepam at these concentrations converted biphasic GABA responses to monophasic depolarizing responses.

The excitation observed during picrotoxin suggests the presence of tonic, GABA-mediated inhibition. It is possible that the effects of flurazepam are due to enhancement of GABA's action.

PHYSIOLOGICAL EVIDENCE FOR TWO PHARMACOLOGICALLY DISTINCT, BICU-CULLINE-INSENSITIVE ACTIONS OF GABA IN THE RAT HIPPOCAMPAL SLICE. 122.7 Brian Ault\* and J. Victor Nadler. Dept. Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710. It has been proposed that the anti-spastic drug baclofen acts Dept. Pharmacology, Duke Univ.

a subpopulation of GABA receptors that is insensitive to bicuculline (BIC). Our previous studies demonstrated that GABA could depress synaptic responses of CA1 hippocampal pyramidal cells evoked by stimulating Schaffer collateral-commissural fibers, even in the presence of BIC, and that baclofen reproduced these ac-tions. Similar actions of the GABA analogue 3-aminopropanesul-fonic acid (3-APS), which has a low affinity for BIC-insensitive receptors, were more readily antagonized by BIC than were actions of GABA. We have now studied the effects of these compounds upon perforant path-evoked responses of dentate granule cells.

The perforant path fibers were stimulated at a rate of 2/min in vitro and just-maximal population spikes were recorded from the granule cell body layer. The lateral perforant path extracellular EPSP was recorded in the distal dendritic region of the fascia dentata, while stimulating at an intensity just below that

rascia dentata, while scimilating at an intensity just below that required to elicit a population spike. Bath-applied GABA reduced the amplitude of the perforant path population spike with an  $EC_{50}$  of  $3.5 \pm 0.4$  mM and usually abo-lished this response at a concentration of 8 mM. BIC (100 µM) rather weakly reversed the action of GABA (concentration ratio of 1.5  $\pm$  0.1). 3-APS depressed the population spike with an EC<sub>50</sub> of 138  $\pm$  5  $\mu$ M and its action was more readily reversed by BIC (concentration ratio of 14  $\pm$  3). Comparable concentration ratios for GABA and 3-APS of  $1.6 \pm 0.5$  and  $13 \pm 4$ , respectively, were obtained using the Schaffer collateral-commissural (CA1) population spike as the test response. Raising the concentration of BIC from 100  $\mu$ M to 500  $\mu$ M did not further reverse the action of GABA. Baclofen, even at a concentration of 100  $\mu$ M, did not reduce the perforant path population spike by more than 50%, although 20  $\mu$ M baclofen abolished the Schaffer collateral-commissural population barbar and barbar the schaller container commission population spike. When BIC (500 µM) and baclofen (100 µM) were superfused continuously, a 5 ml pulse of GABA (4 mM) still depressed the re-sidual population spike. GABA also depressed the lateral perfo-rant path EPSP with an EC<sub>50</sub> of 4.5 mM and 100 µM BIC only weakly reversed this action (concentration ratio of 1.5). In contrast, baclofen little affected this response at concentrations as great as 100 µM.

Thus baclofen failed to reproduce some BIC-insensitive actions of GABA in the fascia dentata, although it reproduced all such actions in the CAl area. These observations suggest that GABA exerts two types of BIC-insensitive action, only one of which is shared by baclofen. (Supported by NIH grant NS 16064.)

GABA-MEDIATED INHIBITION AT SYNAPSES FORMED BY CULTURED 122.8

GABA-MEDIATED INHIBITION AT SYNAPSES FORMED BY CULTURED RETINAL NEURONS. E. Agardh\*, H.H. Yeh and D.G. Puro (Spon: P.A. Dudley). Laboratory of Vision Research, National Eye Institute, NIH, Bethesda, Maryland 20205 A cell culture system was used to assess the effects of GABA on the release of acetylcholine at synapses formed in culture by embryonic chick retinal neurons. In our experi-mental system, striated muscle cells served as postsynaptic targets for cholinergic retinal neurons. Myotubes are useful as postsynaptic targets since they have a high density of cholinergic receptors and their large size permits prolonged intracellular monitoring of postsynaptic reposes to intracellular monitoring of postsynaptic responses to acetylcholine.

Acety(choine. We report here that microiontophoretically applied GABA could inhibit transmission at synapses between cholinergic retinal neurons and muscle cells. The GABA agonists, isoguvacine and muscimol, also inhibited cholinergic trans-mission. These inhibitory effects were blocked reversibly by the GABA antagonist, bicuculline. A benzodiazepine, fluxazone, could automot the CADA modiated inhibition of flurazepam, could augment the GABA mediated inhibition of synaptic transmission.

Synaptic transmission. It was possible, by plating a low density of retinal neurons, to study the effects of GABA on acetylcholine release from isolated, visually identified, cholinergic retinal neurons. Our results indicate that most of the cholinergic neurons examined in this culture system are responsive to GABA.

EFFECTS OF BENZODIAZEPINES AND RO 15-1788 ON INHIBITION IN THE 122.9 HIPPOCAMPAL SLICE. <u>Gregory L. King</u>, <u>Julie Johnson Knox</u>\*, and <u>Raymond Dingledine</u>, Dept. of Pharmacology and Neurobiology Curriculum, Univ. North Carolina, Chapel Hill, NC 27514. Culum, Univ. North Carolina, Chapel Hill, NC 2/514. Numerous studies have emphasized the complexity of the benzo-diazepine-GABA receptor complex in the mammalian CNS. We have examined the effect of benzodiazepines (diazepam and chlordiaze-poxide), and of Ro 15-1788, a benzodiazepine antagonist, on sever-al indices of inhibition in the CAI region of the in vitro hippocampal slice preparation: 1) orthodromic paired-pulse inhibition (PPI), 2) intracellular IPSPs evoked by either orthodomic or antidromic stimulation, and 3) the  $Cat - activated K^+$  conductance. All agents were applied either by continuous perfusion or as a small droplet (<1 nl) onto the surface of the slice. When the agents were perfused during the PPI studies, a range of inter-stimulus intervals was chosen such that drug effects could be examined on both strong (10-30 msec intervals) and weak (100-200 examined on both strong (10-30 msec intervals) and weak (100-200 msec intervals) inhibition. In some slices, inhibition was observed only at the shorter interstimulus intervals. Both chlor-diazepoxide and diazepam (0,1-1.0  $\mu$ M) enhanced PPI by as much as 40%, with a greater effect on the peak inhibition than the decay phase. When the agonists, and Ro 15-1788, were applied by the nanodrop technique, a single interstimulus interval (10-30 msec) was used. Chlordiazepoxide and diazepam (0.1-1.0  $\mu$ M) enhanced inhibition by as much as 90%, an effect which lasted 40-60 minutes. Ro 15-1788 (0.1-1.0  $\mu$ M) decreased inhibition by as much as 100%, Ro 15-1788 (0.1-1.0  $\mu$ M) decreased inhibition by as much as 100%, and in some cases facilitated the test response, with a timecourse similar to that of the agonists. In preliminary intracellular studies, application of diazepam (1.0  $\mu$ M) by the nanodrop tech-nique prolonged or enhanced the IPSP produced by orthodromic stim-ulation (n=3) with little or no effect on either the antidromic IPSP (n=2) or the afterhyperpolarization following a Ca<sup>++</sup> spike (n=1). By contrast, Ro 15-1788 (1.0  $\mu$ M) applied in a similar man-ner depressed the amplitudes of both the orthodromically activated IPSP (n=4 of 5) and the Ca<sup>++</sup>-spike afterhyperpolarization (n=2), with no effect on the antidromic IPSP (n=2). Some micropipettes contained 50-100 M(0X-314. a guaternary lidocaine derivative contained 50-100 mM QX-314, a quaternary lidocaine derivative which eliminates regenerative sodium conductances. These results which eliminates regenerative sodium conductances. These results support the hypothesis that benzodiazepines act to enhance synap-tic inhibition. They also suggest that the enhanced inhibition is not achieved solely by an action on the GABA receptor complex. In addition, if Ro 15-1788 acts as a benzodiazepine antagonist, the presence in the hippocampus of an endogenous ligand for benzodia-zepine receptors is implied. QX-314 was generously supplied by Dr. Bertil Takman of Astra Pharmaceuticals and Ro 15-1788 by Dr. J. O. McNamara. Supported by NS-06953, NS-07166 and NS-17771.

122.10

THE EFFECT OF FLURAZEPAM AND SEVERAL  $\beta$ -CARBOLINES ON SINGLE DOPAMINE CELL ACTIVITY. J. A. D'Amico<sup>+</sup> and <u>D. A. MacNeil</u>. Dept. of Pharmacology I, Hoffmann-La Roche Inc. Nutley, N.J. 07110 The activity of dopamine (DA) containing neurons of the substantia nigra pars compacta (SNC) can be modified by compounds that act at GABA receptors and at benzodiazepine (BZD) receptors (1.2.3) The present study describes the affects of flurazonam (1,2,3). The present study describes the effects of flurazepam and muscimol on DA neuronal activity in the presence or absence

and muscimol on DA neuronal activity in the presence or absence of GABA. Additionally, several  $\beta$ -carbolines, which are known to interact at BZD sites, were also studied. Sprague-Dawley rats were anesthetized (chloral hydrate, 400 mg/kg i.p.) and prepared for extracellular recordings from single DA cells in the SNC. Experimental compounds were admin-istered intravenously. Flurazepam was dissolved in saline, while muscimol and the  $\beta$ -carbolines were suspended in a 0.2% carboxymethylcellulose/0.1% Tween 80 solution. In one set of experiments, the GABA synthesis inhibitor, 3-mercaptopropionic acid (3-MPA), was administered (90.0 mg/kg i.p.) 8 mins. before (4) flurazepam or muscimol. (4) flurazepam or muscimol.

(4) Flurazepam or muscimol. Flurazepam produces a dose-dependent (0.1-1.2 mg/kg, i.v.) increase in DA neuronal activity. At 1.0 mg/kg the change in activity was greater than 200%. In rats that had been pre-treated with 3-MPA, the effect of flurazepam was blocked, while

treated with 3-MPA, the effect of flurazepam was blocked, while the increase in firing rate produced by muscimol, a direct GABA agonist, was not influenced by 3-MPA. Thus the excitatory effect of flurazepam is dependent on the presence of GABA. The  $\beta$ -carbolines ( $\beta$ -CCE,  $\beta$ -CCM, FG-7142) depressed the activity of DA cells to a limited degree (20-40%). In addition, the  $\beta$ -carbolines attenuated the facilitatory effect of flurazepam by approximately 10 fold. The data demonstrate that in a decomine out the  $\beta$ -carbolines the facilitatory effect of flurazepam dopaminergic system the  $\beta$ -carbolines act as BZD antagonists as well as inverse agonists. Well as interest References 1. MacNeil, et al., Brain Res., 154: 1978, 401. 2. Waszczak, et al., <u>Brain Res.</u>, 188; 1980, 185. 3. Ross, et al., <u>Life Sci.</u>, 31: 1982, 1025. 4. INFLUENCES OF 2 ATYPICAL BENZODIAZEPINES, RO 5-3663 and RO 5-4864, ON GABA ERGIC MECHANISMS. D. A. MacNeil, J. A. D'Amico; W. D. Horst, R. A. O'Brien and N. Spirt? Dept. of Pharmacology I, Hoffmann-La Roche Inc., Nutley, N.J. 07110. Ro 5-3663 is a convulsant benzodiazepine (BZ) which is known to interact with the BZ, GABA receptor-chloride ionophore com-plex, but has a very low affinity for either the "peripheral" or the "central" BZ binding sites. Ro 5-3663 has previously been shown to inhibit the GABA stimulation of diazepam binding (1). Ro 5-4864 is a BZ well known to have a high affinity for the "peripheral" BZ binding site (2). The present studies describe the influences of these 2 BZ's on GABA stimulated 'H-diazepam binding and on the firing rates of dopamine (DA) neurons in the binding and on the firing rates of dopamine (DA) neurons in the substantia nigra pars compacta. Experimental procedures were conducted as described elsewhere (1,3).

conducted as described elsewhere (1,3). Ro 5-3663 and Ro 5-4864, at concentrations of  $10^{-6}$ M, inhibit the GABA enhancement of H-diazepam binding to rat brain (cortex) tissue by 32 and 43% respectively. Although neither drug in-fluenced the firing rates of DA neurons when given alone, both drugs blocked the GABA mediated excitatory effects of flurazepam DA for the transformed to the transformation of t mod and go blocked the GADA mediated excitation of Pheters of the argument of the mediated excitation of the pheters of the p (i.v.). Neither drug influenced the excitatory effects of direct GABA agonist, muscimol, on DA neuron firing rates. The observations here that Ro 5-3663 and Ro 5-4864 have the

The observations here that Ro 5-3663 and Ro 5-4864 have similar properties in blocking GABA mediated mechanisms along with the previous demonstration that Ro 5-3663 has no affinity for the "peripheral" BZ site (2) suggests that Ro 5-4864 is not specific for the "peripheral" BZ site but may also interact at a site on the BZ, GABA receptor-chloride ionophore complex. This may account for the proconvulsant and convulsant properties of Ro 5-4864 recently described by others (4,5,6). References

M.W. Kalichman. Naval Health Research Center, San Diego, Calif. 92134. ANTICONVULSANT AND SEDATIVE PROPERTIES OF SOME BENZODIAZEPINES. 122.12

If the anticonvulsant and sedative properties of the benzodi-azepines are produced by the same mechanism, then one would predict that benzodiazepine relative potencies should be the same regardless of the property being studied. In order to test this hypothesis, the anticonvulsant & sedative properties of the benzodiazepines were studied in rats.

In Experiment I, the relative potencies of 6 benzodiazepines were compared as anticonvulsants against convulsions produced by 3-mercaptopropionic acid. Rats were each tested with three doses of each of 6 benzodiazepines: Chlordiazepoxide (CHLOR), Clonazepam (CLON), Diazepam (DIAZ), Flurazepam (FLUR), Lorazepam (LOR), Tri-azolam (TRI). Thirty minutes after i.p. benzodiazepine injections, subjects received 3-mercaptopropionic acid (40 mg/kg, i.p.). Based on the incidence of convulsive behaviors, the six benzodiazepines were ranked in order of decreasing potency as follows: TRI, CLON=LOR, FLUR, CHLOR, DIAZ. In estimates of relative poten-

TRI, CLON=LOR, FLUR, CHLOR, DIAZ. In estimates of relative poten-cy for three of these drugs, it was estimated that TRI was twice as potent as CLON and 60 times more potent than FLUR. In Experiment II, three benzodiazepines were tested as "seda-tive-hypotics" in rats. Rats were tested with three doses of each of three drugs: CLON, FLUR, & TRI. Thirty minutes after benzodiazepine injections, subjects were scored for movement, position, and ptosis every five minutes for a period of 60 minutes. "Sedation" was defined as immobility, prostrate position, and at least 50% eye closure. By this criterion, the three benzodiaze-pines were ranked in order of decreasing potency as follows: TRI, CLON FLUR. In a comparison of these three drugs at doses which CLON, FLUR. In a comparison of these three drugs at doses which would have produced sedation in 50% of the subjects tested, i was estimated that TRI was 10 times as potent as CLON and 400 times more potent than FLUR.

Although the orders of potency were the same in the anticonvulsant and sedative experiments, the relative potencies of the ben-zodiazepines were markedly different. If the mechanisms of the sedative and anticonvulsant properties of the benzodiazepines were the same, then the relative potencies of CLON, TRI, and FLUR should have been comparable in the two test procedures. Thus, the marked differences in relative potency are inconsistent with the hypothesis that these two properties are produced by the same mechanism.

122.13 THE ACTION OF FOOTSHOCK AND β-CARBOLINES ON GABA RECEPTORS IN THE BRAIN OF STRESSED AND UNSTRESSED RATS. G. Biggio, A. Concas\*, M. Serra\*, and M.G. Corda\*. Institute of Biology, Chair of Pharmacology, University of Cagliari, Italy.

Cerebral cortex membranes from rats habituated to the manipulations that precede sacrifice (unstressed rats) have a higher total number of H-GABA binding sites than membranes from naive rats (stressed rats) (1). Habituated and naive rats were used as a model to study the effect of  $\beta$ -carbolines, footshock and diazepam on H-GABA bin-ding sites. Diazepam (5 x 10<sup>-7</sup>M), added to cortical mem-branes from naive rats, increased H-GABA binding to the level of habituated rats, but failed to induce any further increase in membranes from the latter animals. Viceversa, foot shock delivered to habituated rats and  $\boldsymbol{\beta}\text{-}$ carbolines (FG7142,  $\beta\text{-CCE},$  DMCM) added to cortical membranes from habituated rats lowered  $^3\text{H-GABA}$  binding to the level of naive animals, but caused no further decrease in the membranes from this last group. Diazepam removed the effect of both foot shock and  $\beta$ -carbolines in cortical membranes from habituated rats. Ro15-1788 (10  $^{-}$  M) (a concentration which fails to affect  $^{3}\mathrm{H-GABA}$ binding both in habituated and naive rats) reversed both  $\beta$ -carbolines-induced decrease and diazepam-induced in-crease of <sup>3</sup>H-GABA binding. The increased capability of crease of  $^{3}$ H-GABA binding. The increased capability of H-GABA to bind to diazepam-treated membranes from naive rats returned to control level up on washing with buffer prior to binding assay. On the contrary, washings with the same buffer failed to abolish the decrease in 'н– GABA binding elicited by the in vitro addition of  $\beta$ -carbolines to membranes from habituated rats. The results suggest: a) that  $\boldsymbol{\beta}\text{-carbolines}$  elicit effects opposite to benzodiazepines by decreasing <sup>3</sup>H-GABA binding sites b) handling represents a stressful stimulus for naive animals c) stress (handling - foot shock) lowers GABA binding by releasing an endogenous ligand for benzodiazepine receptors possessing similar properties to  $\beta$ -carbolines.

122.14 INVOLVEMENT OF GABA IN THE FACILITATION OF PUNISHMENT-SUPPRESSED BEHAVIOR INDUCED BY BETA-CARBOLINES. M.G. Corda, A. Guidotti, E. Costa, Lab. Preclinical Pharmacology, Saint Elizabeths Hospital, Washington, D.C. 20032 The Vogel's conflict-punishment test for anxiolytic drugs was modified to study drugs increasing the shock-induced suppression of drinking. For

The Vogel's conflict-punishment test for anxiolytic drugs was modified to study drugs increasing the shock-induced suppression of drinking. For this paradigm, 72 h. water-deprived rats were electrically shocked after every 3 sec. of continuous licking (= 1 licking period) with a low current intensity (0.2-0.3 mA). Due to the low intensity of the current delivered through the drinking tube, the animal behavior was not significantly suppressed during the conflict session (25+3 and 22+2 licking periods/3 min. for non-conflict and conflict sessions respectively)(Corda et al., Proc. Natl. Acad. Sci. USA 80:2072, 1983).

It has been recently reported that the  $\beta$ -carboline derivatives, FG-7142 ( $\beta$ -carboline-3-carboxylic acid ethyl ester methyl amide) and  $\beta$ -CCE ( $\beta$ -carboline-3-carboxylic acid ethyl ester) are able to induce anxiety in man, while DMCM (6,7 dimethoxy-4-ethyl- $\beta$ -carboline-3-carboxylic acid methyl ester) and  $\beta$ -CCM ( $\beta$ -carboline-3-carboxylic acid methyl ester) are potent convulsants in animals (Braestrup et al., Science 216: 1241, 1982). In our experiments all these four  $\beta$ -carbolines enhanced shockinduced suppression of drinking, without modifying unpunished drinking. These results indicate a proconflict effect of  $\beta$ -carbolines, which is opposite to the anticonflict effect induced by benzodiazepines (BZ). Among the  $\beta$ -carbolines tested, the most potent in eliciting a proconflict action was  $\beta$ -CCM ( $(C_{20}, 0.1 mg/kg i.v.)$ ). The effect of  $\beta$ -carbolines was antagonized by 1 mg/kg i.v. RO 15-1788 (ethyl-8-fluoro-5-6 dihydro-5methyl-6-xox-4H-imidaco (1,50)(1,4) benzodiazepine-3-carboxylate) and by 1 mg/kg i.v. CGS 8216 (2-phenylpyrazolo (4,3c) quinolin-3(5H) one) which were ineffective by themselves. Pretreatment of rats with subconvulsive doses (150 mg/kg s.c.) of Isoniazid, an inhibitor of the glutamic amino acid decarboxylase, resulted in 5 fold increase of the proconflict effect of FG-7142. In contrast strychnine, a glycine receptor antagonizes the GABA-mediated postsynaptic inhibition by acting on the CI channel, at doses of 15 mg/kg i.p. mimicked the proconflict effect of  $\beta$ -carbolines in rats. However this effect on can be alicited by drugs acting at different sites which are operative in controlling GABA receptor function.  $\beta$ -carboline derivatives alter the GABAergic transmission by acting on the EZ recognition site. This effect is potentiated by drugs that decrease GABA content in brain and is antagonized by the specific BZ antagonist, RO 15-1788. PTZ acts at a site on the CI channel and thus its effect is not modified by RO 15-1788.

- 122.15 EFFECTS OF DIAZEPAM AND GABA-MODULATING DRUGS ON SELF-STIMULATION IN PREFRONTAL CORTEX OF RATS. <u>Charles H.K. West and Richard P.</u> <u>Michael</u>. Department of Psychiatry, Emory University School of <u>Medicine</u> and <u>Georgia</u> Mental Health Institute, Atlanta, GA 30306. The acquisition of intracranial self-stimulation (ICSS) behavior in medial prefrontal cortex (mPFC) resembles in several ways the phenomenon of seizure kindling in limbic structures. Furthermore, overt seizures may occur in animals during ICSS in mPFC. Epileptiform activity is known to be modulated by GABA neurotransmission; and diazepam, which has potent antiepileptic actions, can retard the acquisition of ICSS in mPFC as well as the development of kindling in other areas. In this study, male rats trained for ICSS with stimulating electrodes in mPFC were tested with diazepam and GABAergic drugs for effects on lever pressing rate during 15 min sessions. Stimuli consisted of 200 msec trains of square wave pulses 0.2 msec in duration at 100 Hz, and current values were chosen to give stable baseline ICSS rates but below the threshold for overt seizures. A GABA antagonist, picrotoxin the threshold for overt seizures. A GABA antagonist, picrotoxin (0.125 - 1.0 mg/kg), caused a dose-dependent decrease in the rate of ICSS that reached statistical significance at the 0.5 mg/kg  $(42 \pm 10\% \text{ vehicle})$  and 1.0 mg/kg  $(5 \pm 2\%)$  dose levels. A GABA agonist, muscimol (0.15 - 1.2 mg/kg), also caused a decrease in ICSS rate. However, unlike picrotoxin, the effect was not dosedependent since 0.3 mg/kg  $(65 \pm 13\%)$  and 0.6 mg/kg  $(68 \pm 9\%)$  reduced ICSS more than 1.2 mg/kg  $(75 \pm 5\%)$ , although all of these decreases were significant. In addition to the changes in ICSS observed 15 min after drug administration, 1.2 mg/kg muscimol produced a significant increase in ICSS rate  $(117 \pm 4\%)$  one day after its administration. In contrast to the GABAerei drugs. after its administration. In contrast to the GABAergic drugs, diazepam (0.1 - 3.0 mg/kg) produced an increase in ICSS rate at the lower 3 doses, statistically significant for the 0.3 mg/kg (129  $\pm$  6%) dose level. At the highest dose of diazepam, animals appeared sedated with a resultant decrease in response rates  $(55 \pm 22\%)$  for most animals. These results suggest that drugs that affect seizure activity can have potent effects on ICSS in mPFC. Whether cortical discharges have facilatory or only rate-limiting effects on ICSS in mPFC is unknown, but epileptiform activity should be considered in investigations of the reinforcing processes occurring in mPFC. - 122.16 RELATIONSHIP BETWEEN BENZODIAZEPINE RECEPTORS AND THE ATTENUATION OF STRESS-INDUCED CORTICOSTRONE ELEVATIONS IN RATS. J.F. McElroy and J.S. Meyer. Division of Neuroscience & Behavior, Department of Psychology, University of Massachusetts, Amherst, MA 01003, Stress is accompanied by increased blood corticosterone (CS)

Stress is accompanied by increased blood corticosterone (CS) levels and prior administration of benzodiazepines (BDZs) in relatively low doses can inhibit this response. Somewhat higher doses of BDZs however, can elevate CS concentrations in unstressed animals. Saturable, high-affinity binding sites for BDZs have been found in several mammalian tissues. Recent research has demonstrated the existence of two biochemically and pharmacologically distinct "central-type" BDZ receptors, as well as a peripheral-type BDZ receptor. Central Type I BDZ recentors are GABA-independent, display a high affinity for both BDZs and triazolopyridazines (TPZs), and are thought to mediate the anxiolytic actions of these drugs. Central Type II BDZ sources are GABA-dependent, show a high affinity for BDZs but a low affinity for TPZs, and presumably mediate the derressant side effects associated with BDZ administration. The peripheraltype BDZ receptor is characterized by the ability of the clinically inactive BDZ Ro5-4864 but not the clinically active BDZ

To establish whether the actions of BDZs on the pituitaryadrenocortical system can be related to a particular receptor type, the prototype triazolopyridazine CL218,872 was compared to chlordiazepoxide (CDP) in terms of its effects on serum CS levels in stressed and unstressed rats. Our results show that a relatively low dose of CDP (5 mg/kg i.p.) significantly attenuated the elevation of serum CS produced by a 15 min. exposure to sound stimulation (21.3 vs. 46.1 µg/100 ml in the saline-treated controls). A somewhat higher dose of CDP (15 mg/kg) when given to unstressed rats itself significantly elevated CS levels (from 11.8 to 37.3 µg/100 ml). With chronic administration (6 daily pretreatments), tolerance developed to only the latter effect of CDP. In contrast, CL218,872 (2.5 to 20 mg/kg) did not inhibit the CS elevation produced by sound stimulation and also failed to alter baseline CS levels in unstressed animals. Chronic CL218,872 pretreatment (10 mg/kg for 6 days) produced a crosstolerance to the CDP-induced elevation of CS in unstressed rats, but apparently not to its attenuation of CS secretion in sound stimulated rats.

These results suggest that BDZs are not exerting their pituitary-adrenocortical actions via stimulation of central Type I receptors. Further experiments in progress are aimed at determining whether BDZs may be acting through central Type II or via peripheral BDZ receptors.

BENZODIAZEPINE RECEPTOR MEDIATION OF GENETICALLY-DFTF.RMINED STEREOTYPE ABNORMAL BEHAVIOR OF 122.17 DETERMINED STEREOTYPE ABNORMAL BEHAVIOR OF TOTTERING MICE, <u>P.J. Syapin, J.H. Schneider\*, P. Larschied\*, and</u> J.M. Cook\*. Dept. of Neurology, University of Southern California School of Medicine, Los Angeles, CA 90033 (PJS & JHS) and Dept. Chemistry, University of Wisconsin, Milwaukee, WI 53201 (PL & JMC).

The neurologic mutation tottering (gene designation tg) is expressed phenotypically as hindlimb ataxia and a "spontaneoulsy" expressed phenotypically as hindlimb ataxia and a "spontaneoulsy" recurring stereotypic pattern of abnormal movements. The reason for the occurrence of this behavior in  $(\underline{tg}/\underline{tg})$  mice is unknown. We have shown that the stereotypic abnormal movements can be induced by a low, subconvulsant, dose of pentylenetetrazol, an effect blocked by diazepam (Syapin, <u>Pharmacol</u>, <u>Biochem</u>, <u>Behav</u>, <u>18</u>:389, <u>1983</u>). These results reasoned to the stereotypic abnormation of the stereotypic stereotypi results suggested an involvement of benzodiazepine receptors in this behavior. We now report on the effects of the benzodiazepine receptor ligand  $\beta$ -carboline-3-carboxylic acid ethyl ester (BCCE) and the specific benzodiazepine receptor blocker Ro 15-1788 on this behavior of (tg/tg) mice.

The effect of vehicle or 15 mg/kg BCCE IP on  $(\underline{tg}/\underline{tg})$  mice was studied with or without 10 mg/kg Ro 15-1788 pretreatment. Mice were observed for 20 min following the last injection and scored blind for the presence of absence of the stereotypic abnormal behavior. The results are presented in the Table.

Treatment Group	Mice Showing Behavior / Mice Tested
vehicle, BCCE	8 / 9
Ro 15-1788, BCCE	1 / 10
vehicle, vehicle	1 / 11
Ro 15-1788, vehicle	2 / 12

Statistical analysis using the Cochran Q test for related nonparametric measures revealed a highly significant (p < 0.001) difference between treatment groups. Comparisons using the Fisher exact probability test showed a significant effect of Ro 15-1788 pretreatment on the ability of BCCE to elicit abnormal behavior (p = 0.00975). Treatment with Ro 15-1788 alone did not cause stereotypic

abnormal behavior in (tg/tg) mice. BCCE is known to cause experimental "anxiety" in monkeys, a benzodiazepine receptor effect that is blocked by Ro 15-1788 (Ninan et al., <u>Science</u>, <u>218</u>:1332, 1982). Our results show that treatment with BCCE can cause a specific behavioral response in (tg/tg) mice and strongly suggest that this behavior occurs in response to "anxiety"provoking stimuli. (Supported by a research grant from the Epilepsy Foundation of America to PJS).

GABA RECEPTORS MEDIATE CEREBRAL VASODILATION IN THE 122.18 UNANESTHETIZED GOAT. C. Estrada\*, G. Torregrosa\* and E. Alborch\* (SPON: C. Avendaño). Centro de Investiga-ción, Hospital La Fe, Valencia, and Dpto. Fisiología, Facultad de Medicina, Universidad Autónoma, Madrid, Spain.

Recent evidence indicates that GABA may be involved in the regulation of cerebrovascular function. Several GABA agonists have been reported to dilate isolated pial vessels from different species (Edvinsson and plai vessels from different species (Edvinsson and Krause, Brain Res. 173:89, 1979), and gabaergic recep-tors have been biochemically characterized in bovine pial vessels (Krause et al., Brain Res. 185:51, 1980). However, the role of these GABA receptors in the over-all regulation of cerebral circulation is not yet clear.

We studied the effects of GABA and muscimol on cere-bral blood flow (CBF) of the unanesthetized goat. CBF was continuously measured by means of an electromag-netic flow probe chronically implanted on the internal maxillary artery after occlusion and thrombosis of the distributer of CDB maxillary artery after occlusion and thrombosis of the distal extracerebral vessels. Administration of GABA  $(1-100 \ \mu g)$  directly into the cerebral circulation pro-duced dose-dependent increases in CBF, without accom-panying systemic effects. Muscimol mimicked the effects of GABA at doses ten times lower. Administration of pi-crotoxin  $(1-5 \ m g)$  into the internal maxillary artery did not significantly change CBF, but inhibited in a dose-dependent manner the vasodilation induced by GABA or muscimol. Selective blockade of beta adrenergic or muscarinic cholinergic receptors by propranolol or muscarinic cholinergic receptors by propranolol or atropine, respectively, did not modify the cerebrovas-cular response to the gabaergic agonists.

These results indicate that GABA increases total CBF, acting on specific receptor sites in the cerebral blood vessels. The absence of influence of picrotoxin on resting CBF suggests that the gabaergic receptors are not tonically activated under physiological conditions.

122.19 EFFECTS OF VALPROIC ACID IN TARDIVE DYSKINESIA: H.A. Nasrallah, M.K. McCalley-Whitters\*, and F.J. Dunner\*. VA Medical Center and Dept. of Psychiatry, University of Iowa College of Medicine, Iowa City, IA.

Introduction: Sodium Valproate is an anticonvulsant drug that Increases brain GABA degradative enzymes. It has been used in Tardive Dyskinesia (TD) because of the neuro-chemical evidence Tardive Dyskinesia (TD) because of the neuro-chemical evidence that GABA may be involved in down-regulating dopaminergic activity, and thus GABAergic drugs may benefit TD. A total of four studies in the literature report good, mild, minimal or no therapeutic effects respectively. The dose was not high enough and blood levels were not monitored in two of the four studies. We present here a double-blind placebo-controlled trial of sodium valproate in TD, with blood level monitoring of the drug. Method: Ten chronic schizophrenic or schizoaffective patients with persistent TD movements of two years duration and no neurological disorders that may simulate TD, consented to participate in a con-trolled trial of sodium valproate to test its effects on TD involuntary movements. The patients were kept on the maintenance medi-cation that they were receiving (if any) at the time of referral to the study. Placebo capsules were given for 3 weeks followed by sodium valproate capsules (1000-2500 mg daily in four divided doses), and finally matching placebo capsules for 4 weeks. The patients were videotaped weekly and two raters blind to the drug or study design rated the patients' movements using the AIMS ratings on tape segments that were scrambled for sequence and edited for any cues or information. Blood for valproate serum concen-trations were drawn at the end of each phase (placebo, active drug, placebo) to determine the maximum steady state achieved during the study. Results:

The global AIMS ratings for the 10 patients showed no significant chage during treatment with valproate (Wilcoxon Rank Sum Test). The mean serum concentration of valproate at the end of the active drug period was 83.8 mcg/ml, which is the highest of the active drug period was 33.8 mcg/ml, which is the highest of any TD study using valproate (therapeutic levels=50-100 mcg/ml for seizures). Side effects such as nausea with or without vomit-ing was noted in 55% of the patients. Discussion: The study suggests that there are no therapeutic

effect of valproate in a population of TD patients. However, we observed patients who showed improvement, and others who showed worsening or no change. Thus, although there may be no overall benefit from valproate in TD, some patients may derive some benefit from it. Implications for the role of GABA agonists in TD are discussed.

122.20 RESPONSE OF RAT HIPPOCAMPAL NEURONS TO TAURINE. KATHERINE H. TABER AND ROBERT H. THALMANN. Dept. of Cell Biology and Program in Neuroscience, Baylor College of Medicine, Houston Texas 77030

Texas 77030 The response of CAl neurons to taurine was examined as part of an evaluation of taurine as a possible neurotransmitter in mammalian brain. Slices of hippocampus were maintained at 37°C by standard methods. The response to taurine (20 mM in artifi-cial CSF) applied by pressure from a glass pipette positioned on the surface of the slice was monitored by intracellular microelectrodes filled with KAc. Membrane resistance was measured with 0.5nA hyperpolarizing pulses injected through the recording electrode via a bridge circuit. Orthodromic post-synaptic potentials were elicited via stimulation of Schaffer collaterals. Within 1-5sec after application of taurine to the slice surface, there was a decrease in input resistance of up to 50% which returned to baseline within 5-60 seconds, depending on dose. When spontaneous action potentials were present, they

slice surface, there was a decrease in input resistance of up to 50% which returned to baseline within 5-60 seconds, depending on dose. When spontaneous action potentials were present, they were inhibited during the response. The taurine-induced change in membrane potential, typically a small hyperpolarization re-lative to the resting potential, had a reversal potential that ranged between -65 and -70mV. When Cl was injected into the neurons via recording electrodes filled with KCl rather than KAc, the estimated reversal potential of both the orthodromi-cally elicited IPSP and the response to taurine usually shifted to a more positive value. Similar responses to taurine were obtained after action potentials and transmitter release in response to orthodromic stimulation had been blocked by incuba-tion in TTX, reduced Ca(0.5mM), and 2mM Mn. The reversal potential, increased conductance, and sensiti-vity to transmembrane Cl gradient suggest that an increased conductance to Cl constitutes a significant component of this response during TTX and blockade of Ca influx not only indicates that taurine can act directly upon the postsynaptic membrane of these cells, but also suggests that the response does not re-quire postsynaptic Ca-activated conductances. We do not yet know whether the high concentration of taurine in the droplet was required because of factors such as uptake that might re-strict the access of taurine to the postsynaptic membrane, or rather whether taurine might produce its response by binding to the receptor for a different molecule, such as GABA. Notwith-standing, these results, indicate that taurine can produce a the receiptor for a different molecule, such as GABA. Notwith-standing, these results indicate that taurine can produce a direct inhibitory action on hippocampal neurons, probably via an increased Cl conductance. Supported by National Institutes of Health, Grant NS11535.

123.1 Neurons Projecting to the Pituitary Gland and Median Eminence of the Hamster Determined by Horseradish Peroxidase (HRP) Histochemistry. Daniel B. Michael and Jerald A. Mitchell. Department of Anatomy, Wayne State University School of Medicine, Detroit, MI 48201. Previous studies have demonstrated the presence of a suprepreduced complex of neurons (SN) in the 3rd worthight of

Previous studies have demonstrated the presence of a supraependymal complex of neurons (SEN) in the 3rd ventricle of the hamster which sends a fascicle of processes into the infundibular recess (Card & Mitchell; JCN 180: 43, '78). Retrograde transport of HRP injected into the pituitary was employed to determine what aspect of the gland is innervated by the SEN. Anesthetized female golden hamsters (58), age 8-24 weeks, body wt. 75-212g, were stereotaxically injected in the pituitary gland with 0.2 or 0.05 ul of 30% HRP (Worthington) or 0.05 ul of 1% lectin bound HRP (Sigma). After 24 hrs animals were sacrificed, brains were removed, post-fixed, and sectioned on a freezing microtome. Sections were examined for HRP labeled neurons from just caudal to the inferior colliculus to the level of the optic chiasm. Labeled cells were plotted using a camera lucida and photographed.

a camera lucida and photographed. HRP was successfully injected into the pituitary gland in 35 of 57 animals. Injections were restricted to the anterior lobe (AL) or included the neural lobe (NL) with diffusion into the intermediate lobe (IL), AL, or the external layer of the median eminence (ME). Injections which included the NL and IL resulted in labeling of neurons in the SEN. HRP positive cells were also noted in the subependymal layer of the arcuate N, and the internal, middle, and external layers of ME. Readily apparent, heavily labeled neurons in the supraoptic (SON) and paraventricular (PVN) nuclei were similar in size and shape to magnocellular neurons identified in neutral red counterstained and Nissl preparations. AL injections yielded cellular labeling in connective tissue and the external layer of ME adjacent to the injection site, but not in the SEN nor any other region of the brain examined. No labeled cells were seen in controls (uninjected or injected brains in which the pituitary was missed).

HRP retrograde labeling clearly demonstrated the classic magnocellular projections from SON and PVN to NL. This data also provides evidence for projections from neurons of the SEN, subependymal layer of the arcuate, and ME to the NL and/or IL. Such cells may give rise to a fiber system innervating the IL in the hamster, similar to that recently described in the rat (Westlund and Childs; Endorr. 111: 1761, '82). No conclusive evidence for direct neural projections to the AL was provided unless such cells are located in the external layer of ME. Labeling of these cells, however may be nonspecific due to injection site proximity.

23.3 SPECIFICITY OF METHYLTRIENOLONE (R1881) BINDING IN BRAIN AND PITUITARY. <u>K.L. Olsen and A.M. Etgen</u>. Department of Psychiatry and Behavioral Science, SUNY @ Stony Brook, NY 11794 and Department of Biology, Rutgers University, Livingston Campus, New Brunswick, NJ 08903.

Methyltrienolone (R1881=17*B*-hydroxy-1%-methyl-estra-4,9,11 -trien-3-one) is a synthetic steroid with potent androgenic activity in both peripheral and central target tissues. Unlike naturally occurring androgens, R1881 is not readily metabolized. It also binds with a higher affinity than DRT to androgen receptors. Hence, R1881 may prove useful in evaluating the role of receptors in mediating androgen-regulated behaviors. A potential problem is that R1881 binds to cytosol progestin receptors and has progestin-like behavioral effects; as little as lug of R1881 synergizes with estrogen to activate female sexual responses. Therefore we sought to evaluate the degree to which (<sup>3</sup>H)R1881 could be displaced by androgens and progestins in preoptic-hypothelamic (HDA) and nituitary (PIT) cytosols.

in preoptic-hypothalamic (HPOA) and pituitary (PIT) cytosols. Initial competition experiments used HPOA and PIT cytosols from gonadectomized (gonadx) male and female King-Holtzman rats. In HPOA, 100-fold excess of unlabeled progestins (progesterone, R5020) was 60-70% as effective as unlabeled DHT and R1881, while in PIT, the progestins were 77-87% as effective in displacing (<sup>3</sup>H)R1881 binding. These data indicate that a significant component of (<sup>3</sup>H)R1881 binding in the CNS can be attributed to progestin receptors.

Since it is well known that estrogen treatment elevates progestin receptor levels, competition experiments were carried out with estrogen primed gonadx male and female rats. Results of the one point assay with 2nM ( $^{3}$ H)R1831, indicated that estrogen priming increased total R1881 binding, but did not alter the pattern of competition by the unlabeled progestins and androgens. Scatchard analysis of ( $^{3}$ H)R1831 binding suggests the presence of two binding components. Similar competition studies were performed using <u>tfm</u> rats

Similar competition studies were performed using <u>tfm</u> rats that are deficient in the number of neural androgen receptors. R5020 and progesterone were more effective in displacing (<sup>3</sup>H)8481 binding in androgen resistant rats than in wild-type males and females. Moreover, unlabeled progestins were better inhibitors than DHT in HPOA and PIT cytosols from estrogen primed <u>tfm</u> rats and in PIT of nonprimed <u>tfm</u> rats. In HPOA, R5020 and progesterone displaced binding 98% when compared with unlabeled R1881 itself.

These studies indicate that progestins, as well as androgens, contribute significantly to R1881 binding in brain and Pit. Thus, caution should be taken when interpreting results from studies using this synthetic steroid. 123.2 FURTHER EVIDENCE FOR HYPOTHALAMIC ASYMMETRY IN NEUROENDOCRINE CONTROL. D.M. Nance, M. Bhargava\* and G.A. Myatt\*. Dept. of Anatomy, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, B3H 4H7.

Previously we have shown that the facilitory effects of hemigonadectomy (Hemi-x) on FSH release of prepubertal male rats is blocked by unilateral deafferentation of the hypothalamus on the ipsi-, but not the contralateral side (Brain Res. Bull., 8: 299, 1982). This potentially neurally mediated phenomenon was spe-cific to surgeries on the right side of the brain. Subsequently, we found that ovarian compensatory hypertrophy (OCH) in prepub-ertal female rats could be blocked by unilateral hypothalamic deafferentation on the ipsi-, but not the contralateral hypothalamic respect to the Hemi-x (Nance, et al., <u>Brain Res. Bull</u>., in press). This phenomenon was specific to surgeries on the left side of the brain. We report here the effects of unilateral kainic acid (KA) lesions (1.0 µg injected in a 1.0 µl volume) in the retrochiasmatic area on OCH in adult female rats that were Hemi-x on the ipsi- or the contralateral side. Briefly, KA or saline was infused unilaterally into the hypothalamus and the animals Hemi-x or given sham surgery on the ipsi- or contralateral side following brain surgery and percent OCH was assessed 10 days later. Brain histologies revealed a modest amount of gliosis associated with the unilateral KA lesions, however, a morphometric analysis of the hypothalamus indicated that the KA injections, relative to saline, significantly reduced the distance between the fornix and 3rd significantly reduce the distance between the trains and fit we wentricle on the injected side of the brain when compared to the uninjected side. Mean reductions in the fornix -3rd ventricle distance on the injected side of the brain were  $20.5 \pm 2.1$  and  $7.5 \pm 2.5$  percent for the KA and saline injected animals, respectively. Similar to the effects of hypothalamic knife cuts, unilateral KA infusions blocked OCH if the lesions were located on the ipsi-, but not the contralateral side of the brain with respect to Hemi-x. Likewise, this phenomenon was clearly more apparent if the lesions were located on the right side of the brain. Morphometric analysis of the brain histologies indicated comparable lesions on the two sides of the brains. Additional observations indicated that whereas Hemi-x or KA lesions alone had the incidence of estrus. However, these effects on estrous orycles were not specifically associated with lesions or Hemi-x on either side, thus excluding alterations in cyclicity as an explanation of the differences between the endocrine effects of KA on the two sides of the brain. In general, these results support the previous evidence for a direct neural contribution to endocrine control and further suggest a functional difference in the twohalves of the hypothalamus in neuroendocrine regulation. Supported by MRC.

123.4 IN VIVO MEASUREMENT OF LUTEINIZING HORMONE RELEASING HORMONE IN UNANESTHETIZED, OVARIECTOMIZED RHESUS MONKEYS USING PUSH-PULL CANNULAE. N.J. <u>Schultz\*</u>, M.D. Loose\*, and <u>E. Terasawa</u> (SPON: W.T. McKinney). Wis. Reg. Primate Research Ctr., Neurosciences Training Prog. and University of WI, Madison, WI 53715-1299.

In vivo measurements of luteinizing hormone releasing hormone (LHRH) had been limited to hypophyseal portal plasma collections until Levine and Ramirez (Endocrinol. <u>107</u>: 1782, 1980) described the use of push-pull cannulae to measure LHRH release in the medio-basal hypothalamus (MBH) of conscious rats. The present study re-ports a modified method for use of push-pull cannulae applied to rhesus monkeys that allows repeated measurements of in vivo release of LHRH in various locations of the median eminence. eral months prior to the experiment 4 ovariectomized monkeys were implanted with a cranial pedestal under halothane anesthesia. Using X-ray ventriculography the center of the pedestal was placed how the infundibular recess at the midline level and was used for a reference point. Two days before the perfusion, the animal was placed in a primate chair under ketamine anesthesia. Then a push-pull cannula composed of an outer (pull) cannula (20 ga) and inner stylet (28 ga) was inserted into the brain with a hydraulic microdrive unit, originally designed for recording experiments. This unit allowed positioning of the cannula along the X,Y,Z cordinates. Cannula placement was verified by X-ray. The cannula was left in place for 2 days to allow clearance of cellular debris to avoid potential clogs, so that collection could continue for more than 4 hrs. Although the animals were restrained, they were fully conscious and able to take food and water throughout the experiment. On the 3rd day, the stylet was replaced with an inner (push) cannula (28 ga), and artificial CSF was perfused at 20  $\mu l/$ (push) cannula (28 ga), and artificial csf was perfused at 20 f/ min by two identically calibrated peristaltic pumps. A U-tube was connected to the pull side allowing detection of a change in fluid level indicating a clog. When observed, the pumps could be stop-ped avoiding imbalancedflow and subsequent tissue damage. Ten-minute fractions were collected continuously on ice and acidified to 0.1N HCl and stored at  $-20^{\circ}$ C. Perfusate samples were neutralized and assayed for LHRH by RIA using antibody supplied by Dr. Nett. LHRH release was detected in the perfusates of all monkeys LHRH release was pulsatile with mean interpeak intervals of 30-80 min. This is consistent with reports of LHRH release patterns min. measured in hypophyseal portal plasma as well as data on pulsa-tile serum LH in monkeys. Peak LHRH release was 1.8 to 2 pg/10 min, while madir values ranged from 0.3 pg/10 min to undetectable levels (assay sensitivity was 0.2 pg). With this method perfu-sates can be obtained repeatedly from conscious animals to analyze the correlates of various biochemical and neuroendocrine functions in addition to LHRH release. (Supported by NIH grants RR00167, HD15433 and HD11355.)

REGIONAL DIFFERENCES IN NEURONAL MODULATION IN RODENT 123.5 HIPPOCAMPUS.

Nicolas L. Foy, Richard Chiaia, Michael R. Μ. and Timothy J. Teyler. Neurobiology Northeastern Ohio Universities College of Vardaris and Program. Medicine, Rootstown, Ohio 44272

Previously we have observed a gender specific modulation of hippocampal pyramidal cell excitability in rodent as measured by an increased amplitude of the monosynaptic population spike. Slices taken from male rats were facilitated following exposure to 100pm 17 beta estradiol (E2) and 10pm delta 9 tetra hydrocannabinol (THC) (Foy et al, <u>Brain Res. Bull.</u>, 1982, <u>B(4)</u>:341-345). Slices taken from females were facilitated following totatestates and isotratestates. facilitated following 100pm testosterone application (Teyler et al, <u>Science</u>, 1980, <u>209</u>: 1017-19). The effect reached peak levels in 5-7 minutes. Classical cytosol receptor kinetics do not allow for such rapid effects.

Recent E2 receptor blocker experiments suggest receptor mediated mechanism (Foy & Teyler, Brain Res. Bull., 1983, in press). If such is the case, the strength of the steroid effect should bear some relationship to receptor concentration. The present investigation attempts to examine this contention. No investigation attempts to examine this contention. No measurable cytosol E2 receptors have been observed in CA1, but significant levels were observed in the dentate gyrus (Rainbow et al., <u>J. Neuroscience</u>, 1982, 2:1439-45). the

2:1439-45). In the present investigation, no measurable effects of E2 and THC were observed in the dentate gyrus of slices taken from male rats, while CA1 showed the usual pattern of facilitation. In light of the evidence supporting a receptor mediated mechanism, these results are not consistent with the known distribution of cytoplasmic receptors. A recently described class of cell surface receptors (Towle and Star J. starvid Biochem 1983 10(2):135-43) may provide an alternative mechanism for the rapid (NINCDS Grant NS 16507)

TESTOSTERONE 5α-REDUCTASE AND 3α-HYDROXYSTEROID OXIDO-REDUCTASE IN LAMINAE OF THE RAT OLFACTORY TUBERCLE. <u>Meil R. Krieger and Robert G. Scott</u>. Departments of Pharmacology and Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA. 19104. 123.7

The enzymes that catalyze the conversion of testosterone to active and inactive metabolites in brain play key roles in determining the effects of testosterone on behavior. Yet little is known about the properties and localizations of these enzymes in brain. Here we describe the localizations of testosterone  $5\alpha$ -reductase and  $3\alpha$ -hydroxysteroid oxidoreductase (3α-OHSOR) within the laminae of the rat olfactory tubercle. Testosterone  $5\alpha$ -reductase reduces testosterone to dihydrotestosterone, and  $3\alpha$ -OHSOR inactivates dihydrotestosterone by

converting it to 3α-androstandiol. Tangential sections (16u) were cut from the frozen tubercle and pooled into three groups of 16 sections each. These were homogenized and assayed for  $5\alpha$ -reductase and  $3\alpha$ -OHSOR. Incubations were carried out with radiolabelled substrate in 35 ul volumes by methods similar to those described previously. (J. Neurochem. (1983) 40, 1460). Products were separated from substrates by TLC and quantitated by scintillation counting. 5 $\alpha$ -reductase activity was highest in the deepest layers of the tubercle and lowest in the most superficial layers.  $3\alpha$ -OHSOR was then studied with higher resolution by homogenizing and assaying each 16u section. Virtually all of the activity was confined to the outermost sections. The dominant anatomical feature visible in these sections is the pia. Perhaps  $3\alpha$ -OHSOR in the pial layer opposes the movement of dihydrotestosterone across this boundary by inactivating it. The distribution of testosterone  $5\alpha$ -reductase that we observed is consistent with a localization to the granule neurons of the islands of Calleja in the olfactory tubercle. Supported by NIH 31820.

THE AMYGDALA IS NOT INVOLVED IN THE NEURAL CONTROL OF PRECOCIOUS 123.6 PUBERTY IN CHICKS. W. J. Kuenzel\* and R. R. Gabel\* (SPON: W. Hodos). Poultry Sci. Dept., Univ. of Maryland, College Park, MD 20742

Precocious puberty has been shown to be induced by surgical manipulation of the hypothalamus in female rats (Donovan, B. T and J. van der Werff ten Bosch, <u>Nature</u>, <u>London</u> 178:745, 1956; Gellert, R. J. and W. F. Ganong, <u>Acta Endocrin</u>. 33:569, 1960). Other studies have demonstrated that the medial portion of the amygdaloid complex and stria terminalis are involved in the con-trol of sexual maturation since bilateral destruction of these structures resulted in precocious ovarian stimulation (Elwers, M. and V. Critchlow, Amer. J. Physiol. 198:381, 1960; Amer. J. Physiol. 201:281, 1961).

Recently, precocious puberty has been demonstrated in male chicks following parasagittal knife cuts of the lateral hypothalamic area, extending from the preoptic to the mamillary region. Viable sperm, capable of fertilizing eggs, was obtained when chicks were 9 weeks of age (Mass, J. H. and W. J. Kuenzel, <u>Devel</u>. <u>Brain Res.</u>, in press, 1983). Luteinizing hormone (LH) and andro-gen (A) were assayed in the plasma of chicks at weekly intervals from time of hypothalamic knife cuts. Maximum levels of LH and A from time of hypothalamic knife cuts. Maximum levels of LH and A were observed 3 and 4 weeks after surgery, respectively (Kuenzel, W. J. and P. J. Sharp, <u>Neuroendocrin.</u>, submitted, 1983). Since extrahypothalamic structures have been implicated (Elwers, M. and V. Critchlow, <u>Amer. J. Physiol.</u> <u>198</u>:381, 1960) to control the on-set of puberty by inhibiting gonadoropin secretion, a study was conducted to isolate the nucleus taeniae and archistriatum (por-tions thought to be homologous to the mammalian amygdala) from medially situated brain structures

medially situated brain structures. Two groups of chicks received bilateral knife cuts. The first group (n=24) had cuts isolating both the nucleus taeniae and archgroup (n=24) had cuts isolating both the nucleus taeniae and archistriatum from known connections to the hypothalamus (stereotaxic coordinates: Anterior (A) = 8.6-4.1 mm; Depth (D) = 3.0 mm; Lateral (L) =  $\pm$  3.5 mm). The second group (n=12) received bilateral knife cuts Tocated between cuts used to isolate the amygdala (first group) and bilateral hypothalamic cuts known to induce precocious puberty (Mass, J. H. and W. J. Kuenzel, <u>Devel. Brain Res.</u>, in press, 1983). Stereotaxic coordinates of the second group were: A = 8.2-4.2 mm; D = 3.0, 2.5, 2.0 mm; L =  $\pm$  2.0 mm). No advancement of sexual maturation occurred Tin either group. Since both experimental groups received bilateral cuts designed to sever all known connections between the amygdala and hypothalamus, it is concluded that unlike marmals, the amygdala does not appear

it is concluded that unlike mammals, the amygdala does not appear to have fibers which inhibit the onset of gonadal development in chicks. It is hypothesized that more medially placed structures, perhaps in the preoptic area or nearby medial telencephalic region contain neurons which function to effect maturation of the gonads.

SEX AND DRUGS: CAN PRIMING IN ADULTHOOD AFFECT SEXUALLY DIFFERENTIATED RESPONSE PROFILES IN RODENTS? 123.8 Michael R. Foy, Nicolas L. Chiaia, David L. Quinn\*, and Timothy J. Teyler. Northeastern Ohio Universities College of Medicine, Rootstown, Ohio 44272.

In 1978, we demonstrated the modulating effects of 100 pM concentrations of 17-beta-estradiol (E2) and testosterone (T) on in vitro hippocampal slices of normal adult rats (Vardaris and Teyler, Neurosci. Abs., 1978, 4, A1145). In 1979, we reported that the modulation of hippocampal excitability in adult rats gonadectomized two days prior to testing was similar to that seen in normal rats: E2 enhanced the amplitude of the CA1 population spike in the male and T enhanced the same response in the female (Teyler, Foy and Vardaris, <u>Neurosci</u>. <u>Abs.</u>, 1979, <u>5</u>, A1568). observed differential responsitivity to gonadal steroid may The reflect: 1) sexual differentiation in the hippocampus with respect to androgen and estrogen receptors, or 2) the priming effect of plasma gonadal steroids acting upon receptor populations.

plasma gonadal steroids acting upon receptor populations. Our present investigation features a paradigm whereby adult male rats were castrated, allowed a two week recovery period, and then primed (100 ug, i.p.) with estradiol benzoate (EB), testosterone propionate (TP), or vehicle for 7 days before testing <u>in vitro</u> with E2 or T (100 pM). The following trends were observed following addition of steroid to the bathing Ringer solution: Animals primed with EB exhibited response enhancement only when challenged with T; animals primed with TP exhibited an enhancement when challenged only with E2. These data indicate that the sexually differentiated response profiles we have previously observed can be abolished or reversed

profiles we have previously observed can be abolished or reversed by manipulation of adult circulating steroid levels, at least in the male. Since the sexually differentiated hippocampal response can be blocked in males with 17-alpha-estradiol (Foy and Teyler, <u>Brain Res. Bull</u>., 1983, in press) and tamoxifen, we suspect that <u>brain Res. Boull</u>, 1963, in press and character, we suspect that circulating steroid levels can induce heterotypic receptor elaboration that are perhaps cell surface receptors (Towle and Sze, J. <u>steroid Biochem</u>., 1983, 10(2)). In this respect, it is of interest that only the TP primed castrated males showed a response enhancement to delta-9-tetrahydrocannabinol (THC) comparable to the response of the tetrahydrocannabinol (THC) comparable to the response of tet that reported earlier (Foy, Teyler and Vardaris, <u>Brain Res. Bull</u>. 1982, 8(4)), suggesting that THC is acting at the same inducible estrogen receptor. (NINCDS Grant NS 16507)

REGIONAL VARIATION IN THE UP-REGULATION OF GLUCOCORTICOID BINDING PROTEINS IN RAT BRAIN. Barbara B. Turner. Dept. of Physiol., College of Med., East Tenn. State Univ., Johnson City, TN 37614. Increases in 3H-corticosterone binding occur in the hippocampus and other brain structures of the rat following adrenalectomy (ADX). With 123.9

the exception of the hippocampus, it is not clear whether receptor binding capacity or affinity has been increased. Post-ADX changes in 3H-corticosterone binding may also reflect alterations in tissue levels of membrane associated, "transcortin-like" binding proteins. Differential responsiveness of neural tissues to ADX is of importance since the ADX rat is the source of much of our knowledge concerning the pattern of glucocorticoid receptor distribution in the brain.

Glucocrticoid binding in four brain regions (hippocampus, hypothalamus, amygdala and cortex), pituitary, and liver was examined at 10h and 96h post-ADX. Tissues from perfused male rats, were homogenized In and so particular. These from periods made racs, were funderable (1:10 w/v) in a Tris-EDTA buffer containing glycerol and molybdate. Cytosol was incubated for 3-5h with steroid at 4C before separation of Cycosol was includated for 3-3n with steroid at 4C perfore separation or bound steroid by passage through IH-20 columns. 3H-dexamethasone (3H-dex) was used to determine the binding capcity and affinity of cytosol receptors. "Transcortin-like" binding in tissue was estimated from the amount of 3H-corticosterone specifically bound at 20 mM in the presence of excess dexamethasone.

Differences were found in the percent increase in maximal binding capacity (Bmax) among brain tissues and pituitary between 10h and 96h capacity (Bmax) among brain tissues and pituitary between 10h and 96h post-ADX. A 40% increase in Bmax was observed in both the hypothalamus (150+3 vs 213+25 fm/mg P) and the cortex (178+16 vs 250+39 fm/mg P). In the hippocampus and amygdala, a near doubling of Bmax occurred between 10h and 96h post-ADX (169+16 vs 330+24 fm/mg P, and 124+20 vs 235+47 fm/mg P, respectively). The pituitary showed only a 30% increase in 3H-dex binding (146+11 vs 194+4 fm/mg P). In several brain tissues the percent increase in transcortin-like binding exceeded by many fold the increase observed in plasma transcortin (248) by twose less than that seen in liver (4508).

(24%), but was less than that seen in liver (450%). The change in transcortin-like binding appeared to be tissue specific, being unrelated to changes in cytosol receptor number. In both the hypothalamus and cortex the increase in transcortin-like binding (191% and 171%) was far greater than the increase in 3H-dex binding. In the hipporanous, the increase in transcortin binding was 83%, less than the increase in 3H-dex No increase in transcortin-like binding occurred in the binding. amvqdala.

A portion of the transcortin produced by the liver may be intended for A portion of the distribution by plansa membranes where it may act to regulate corticoid entry into cells, thus controlling the "set-point" for receptor occupancy in the cell. If this is the case, then large increases in transcortin-like binding in a tissue following ADX, may reduce the uptake of steroid by the cell and render it relatively "blank" on autoradiographs. This might be the case with the hypothalamus and the cortex in the ADX rat. Supported by VA Grant 1A(74) 111-430108.

123.11 PLASMA CORTISOL LEVELS IN OPIATE ADDICTS BEFORE AND AFTER DETOX-FICATION, A. D. Pheterson\*, C. A. Dackis\*, M. S. Gold, D. R. Sweeney, Fair Oaks Hospital, Surmit, N.J. 07901. Anti-endorphin effects of exogenous opiates have been sug-gested and demonstrated in a preliminary study.<sup>1</sup> It has also been demonstrated that corticotropin (ACTH) and beta endorphin are secreted, stored, and released in similar sites under similar conditions.<sup>2</sup> Multiple sites for the production of pro opiomelanocortin in the pituitary and hypothalamus have recently been determined<sup>3</sup>, with suggestion of differential, varying se-Cretion presumably in an attempt to maintain toward organismic hemeostasis. To study the effect of exogenous opiates upon ACTH-Adrenal activity we determined cortisol levels in indi-viduals with prolonged and current opiate intake. The effect of subsequent opiate abstinence was then examined.

Midnight plasma cortisol levels were measured in 21 chronic opiate addicts within hours of their hospital admission and last oplate addrets within hours of their hospital admission and last drug intake. Ages ranged from 19 to 34 years with a mean of 27 years. Within 72 hours of detoxification with clonidine, a sec-ond midnight sample was drawn. Mean admission plasma cortisol was 3.85 + 2.71 µgms while mean post detoxification cortisol was 5.87 + 2.62 µgms. The rise from admission level was 52.48, which was statistically significant (t=2.86, df=20, p<.01). These data are consistent with previous reports of anti-adrenal and possibly antihypothalamic-pituitary-adrenal effects of opiates.

The clinical significance of depressed cortisol production in addicts has been previously described in a pilot study.<sup>4</sup> Effects include fatiguability, anorexia, weakness, depression, and per-haps represent a strong need to self-medicate with continued opiate use. The 'rebound' of cortisol after detoxification suggests an ACTH-adrenal resilience not previously described. The possible role of clonidine is discussed.

RESERPINE INDUCES DEPLETION OF CRF-41 IMMUNOREACTIVITY FROM THE EXTERNAL LAYER OF THE MEDIAN EMINENCE. S. Cummings, R. Elde and V. Seybold. Dept. of Anatomy, Univ. of Minnesota, Mpls. MN 55455 Passive immunization studies demonstrate that corticotropin releasing factor (CRF) secreted from hypothalamic neurons terminating in the median eminence regulates ACTH release. Brain catecholamines have been implicated in inhibition of CRF release, while vasopressin has been demonstrated to potentiate the activity of this peptide. We have previously demonstrated tonic catecholamine inhibition of vasopressin/neurophysin nerve terminals in the external layer of the median eminence using reserpine and other agents known to perturb monoaminergic function (Seybold, Elde and Hökfelt, <u>Endocrinol</u>. 108:1803, 1981.) To determine if similar mechanisms regulate CRF release, 4 rats were injected with reserpine (10 mg/kg, ip, Serpasil, Ciba), and sacrificed by vascular perfusion with buffered 4% paraformalde-hyde 24 hrs. later. Four rats were injected with reserpine vehicle to serve as controls. The median eminences of 2 reserpine-treated animals and 2 vehicle-treated animals were com-posed in a single block of mounting media and cryostat sectioned at 10 µm. Alternate sections of the tissue block were processed for indirect immunofluorescence using primary antibody directed against CRF-41 (Immuno Nuclear) or arginine vasopressin (VP)(Immuno Nuclear). Specificity of staining was determined by absorption controls. absorption controls.

Evaluation of the sections indicated a decrease in the level of immunoreactive CRF and vasopressin from the external layer of the

immunoreactive CRF and vasopressin from the external layer of the median eminence of reserpine-treated animals as compared to vehicle-treated controls. Qualitative changes were not apparent in the internal layer of the median eminence. To quantify these findings in the external layer of the median eminence, 9 observers used a blind protocol to rate, on a scale of 0-4, the intensity of fluorescence immunoreactivity of tissue sections prepared as described above. Analyses (t-tests) of the mean scores revealed decreases of 57% (p<.005) and 69% (p<.005) in CRF and VP staining intensity. respectively. compared to mean scores revealed decreases of 5/% (pr.003) and 00% (pr.002) in CRF and VP staining intensity, respectively, compared to

controls. While these results do not determine the relationship between CRF and vasopressin, they are consistent with a model for brain monoamines in inhibition of CRF and vasopressin. Further experiments to examine the pharmacology associated with reserpine-induced alterations in CRF in the external layer of the median eminence and the morphological relationship of central monoamine systems to hypothalamic CRF are currently in progress. Supported by Immuno Nuclear Corp and DA02148.

123.12 NEUROENDOCRINE AND PHYSIOLOGICAL RESPONSES TO ENDOTOXIN IN THE RAT. M.F. Mazurek, J.B. Martin and N.W. Kasting. Dept. of Neurol., Massachusetts General Hospital, Boston, MA 02114.

We have previously shown that endotoxin administered intravenously to the rat results in a prompt suppression of GH &TSH, with reversal of these effects by anti-somatostatin antiserum. We now report the dynamics of plasma vasopressin (AVP),  $\beta$ -endorphin ( $\beta$ -End) and prolactin (PRL) secretion in relation to endotoxin-induced changes in plasma volume, blood pressure, body temperature, and plasma osmolality.

Experiments were performed on freely-behaving 300-350 gm Charles River rats, housed in isolation boxes. All parameters where measured every 30 minutes from 10:00 to 17:00 on both day 1 (control) and day 2 (endotoxin given via intravenous catheter at 10:30). In 3 separate groups of rats, blood was sampled (N=5) via right atrial cannula; blood pressure was measured (N=5) via right carbtid catheter; and body temperature was followed (N=4) via probe in the carbtid sheath. Intravenous endotoxin produced a prompt increase in plasma

Intravenous endotoxin produced a prompt increase in plasma AVP in all animals (mean baseline 2.3  $\pm$  .4 pg/ml; 30 min. 7.8  $\pm$  3.3 pg/ml; 60 min 29.4  $\pm$  4.7 pg/ml), with return to baseline by 180 mins. Plasma  $\beta$ -End also rose sharply after endotoxin in all rats (mean baseline 51  $\pm$  12 pg/ml; 30 min 279  $\pm$  111 pg/ml; 60 min 1650  $\pm$  120 pg/ml), then slowly declined (390 min 102  $\pm$  14 pg/ml). Plasma PRL increased significantly after endotoxin, but not as soon as AVP and  $\beta$ -END (mean baseline 0.7  $\pm$  0.1 ng/ml; 30 min 1.1  $\pm$  0.2 ng/ml; 60 min 25.1  $\pm$  9 ng/ml), then returned to baseline by 210 mins. Plasma PRL more actions of the probability of the plasma PRL increased significantly after endotoxin. 210 mins. Plasma volume abruptly decreased about 20% following endotxin (baseline hematorit  $37.6 \pm 0.33$ ; 30 min 41.8  $\pm$  0.6%; endotoxin (baseline hematocrit 37.6  $\pm$  0.33; 30 min 41.8  $\pm$  0.65; 60 min 42.8  $\pm$  0.85), then slowly returned towards baseline. Plasma osmolality was unchanged. Blood pressure response was triphasic, with a sharp initial rise, followed by an abrupt fall (mean baseline 121  $\pm$  5 mmHg; 30 min 133  $\pm$  3mmHg; 60 min 112  $\pm$  2 mmHg), and later by prolonged hypertension (mean BP>129). Body temperature change was biphasic, with hypothermia after 1 hour (mean baseline 36.6  $\pm$  .6°C; 30 min 36.8  $\pm$  .1°; 60 min 35.5  $\pm$  .6°) followed by a later hyperthermia (mean temp > 38.2). Those results show that and response to the state of the state o

These results show that endotoxin administered intravenously These results show that endots and marked increases of plasma AVP,  $\beta$ -End and PRL. These coincide with alterations of plasma aVP, blood pressure and body temperature. The relative importance of the latter physiological changes in mediating the observed hormonal responses, and the interactions between the hormones thereafter and the interactions between the hormones themselves, are being investigated.

123.13 NEURONAL, NEUROVASCULAR AND NEUROPEPTIDE ORGANIZATION OF EMBRYONIC HYPOTHALAMIC TRANSPLANTS IN THE THIRD CEREBRAL VENTRICLE OF ADULT BRATTLEBORO RAITS. D. E. Scott, W. K. Paull\*, D. Sherman\*, and D. M. Gash. Dept. of Anatomy, Univ. of Missouri Sch. of Medicine, Columbia, MO.; and Univ. of Rochester Medical Center, Rochester, N.Y.

N.Y. Female homozygous rats with autosomal diabetes insipidus were utilized in this investigation. Circadian water consumption and urine output was recorded. Rats were anesthetized and prepared for stereotaxic surgery. Fragments of anterior hypothalami from 17 day old fetal rats were stereotaxically introduced into the third ventricle, following the technique of Gash and Sladek, 1980. Host rats were killed 60 days later and prepared for correlative scanning-transmission electron microscopy (SEM-TEM), microangiography, and correlative microangiography-immunocytochemistry. SEM analysis revealed the presence of numerous large grafts on the ventral thalamic and dorsal hypothalamic walls of the third cerebral ventricle. Numerous neuron-like cells were evident on the surface of transplants and upon the adjacent hypothalamic wall, coupled with a profusion of cell processes which formed thick feltworks underlying these cells. Subsequent TEM analysis confirmed these elements to be bonafide neurons and axons. TEM coupled with microangiography demonstrated that the grafts were routinely invaded by parenchymal vessels from the adjacent paraventricular bed as well as by fenestrated vessels from the underlying mantel plexus of portal vessels of the median emineurce. These vessels were routinely surrounded by extensive perivascular spaces. Correlative angiography and ICC with antineurophysin and antivasopressin revealed the presence of numerous immunopositive cell bodies and processes in the grafts. Neurophysin positive fibers appeared to arise from the adjacent periventricular stratum. These observations suggest an intimate neurovascular and neuroanatomical relationship between host and transplant and establishes a potential substrate for the central delivery of neuropeptide hormones between explant and host. 123.14 CHANGED VASOPRESSIN IMMUNOREACTIVITY OF SUPRAOPTIC MAGNOCELLULAR NEURONS FOLLOWING INTERRUPTION OF CATECHOLAMINE NEURONAL INPUT L.D. Wilkin, R.L. Zerbe\*, J.Z. Kiss\*, T.H. Williams, and M. Palkovits\*, Dept. of Anatomy, University of Iowa, Iowa City, IA 52242; and Neuroendocrine Unit Lab. Clin. Sci., NIH, Bethesda, MD 20205.

Recent studies have demonstrated increased vasopressin (AVP) secretion after brainstem lesions or pharmacological treatments that disrupt afferent catecholamine (CA) inputs to the hypothalamic supraoptic nucleus (SON), suggesting that this neuronal input exerts a tonic inhibitory action. In the present studies, changes in hypothalamic AVP neurons were examined by immunocytochemistry and radioimmunoassay (RIA) following disruption of CA pathways.

In the first series of experiments, rats were allowed to survive for 2, 6, or 14 days after intraventricular injections of 250 µg 6-bydroxydopamine. Following perfusion and processing for AVP immunocytochemistry, 6-OHDA-treated brains were compared with controls. Clear changes in AVP staining intensity were observed in all 6-OHDA treated brains, as summarized in the following table:

Since the Al and A2 neurons of the medulla are the main source of CA projections to the AVP neurosecretory cells of the SON, groups of rats received knife cuts that transected the ascending medullary CA fibers. Following bilateral transection, water intake decreased from 51 ml/d to 11 ml/d, and urinary output dropped sharply. After an 8-day survival period, the brains were removed and frozen, and micropunches of SON and the pituitary were assayed by RIA for AVP content. AVP content (in ng/mg protein) of the pituitary decreased from 12151 ng to 8474 ng while SON AVP increased from 95.5 ng to 153.8 ng. Following unilateral transection, water intake was also reduced and pituitary AVP dropped to 11085 ng. No changes were seen in the ipsilateral SON, but the contralateral SON showed a marked increase of AVP to 152.2 ng. This unilateral increase indicates that the observed changes were due to interruption of neural input and not to a disturbance of body fluid homeostasis.

These studies demonstrate that interruptions of catecholaminergic neuronal input to SON change the hormonal content of AVP neurons. Our results provide new evidence that brain stem CA neurons may tonically inhibit the activity of AVP-secreting neuroendocrine cells.

123.15 CONTRASTING EFFECTS OF STIMULATION OF A1 AND A2 CATECHOLAMINE CELL GROUP AREAS OF THE MEDULLA ON ACTIVITY OF PARAVENTRICULAR NEUROSECRETORY NEURONS. T.A.Day\*, A.V.Ferguson and L.P.Renaud. Montreal General Hospital Research Institute and McGill University Montreal, Quebec, Canada H3G 1A4.

The neurohypophysial hormones oxytocin (OXY) and vasopressin (VP) are synthesized in magnocellular neurons of the supraoptic (SON) and paraventricular (PVN) nuclei. Although both nuclei receive noradrenergic (NA) inputs from the Al cell group of the ventrolateral medulla, the PVN also receives substantial NA inputs from the A2 group of the dorsomedial medulla and the A6 group of the pons. Following the completion of studies which indicated that NA afferents arising from the A1 group selectively activate VP neurons in the SON, we have now begun to examine the role of NA projections from A1 and A2 in regulating the activity of PVN neurons.

Extracellular recordings of PVN neurosecretory neurons identified by antidromic invasion from the neurohypophysis were obtained in rats anaesthetized with nembutal or urethane. The effects of cathodal pulses (1-3 pulses,  $50-400\mu$ A) delivered to either the Al or A2 cell group areas via a monopolar electrode (tip exposure  $50-100\mu$ M) were examined by means of post-stimulus histograms. Following each experiment the location of the stimulating electrode relative to NA cell groups was determined using a catecholamine histofluorescence technique.

Stimulation of sites corresponding to the Al NA cell group enhanced the activity of 42% of PVN units tested (n=24), the remaining 58% being unaffected. On the basis of firing patterns and responsivity to baroreceptor activation 8 of the cells tested were classified as VP-secreting and 7 as 0XY-secreting neurons. Al stimulation excited 7 of the 8 putative VP neurons, but had no affect on any of the putative 0XY neurons.

affect on any of the putative OXY neurons. Stimulation of the A2 cell group region increased cell firing in 25% of the neurons tested (n=20) and was without effect on the remaining 75%. Eleven cells were classified as OXY-secreting, 4 of which were excited following A2 stimulation.

of which were excited following A2 stimulation. Pharmacological verification of the identity of the pathways mediating these effects remains to be obtained. Nevertheless, these preliminary data suggest that, as in the SON, NA afferents arising from the A1 cell group of the ventrolateral medulla selectively activate PVN VP neurons which project to the neurohypophysis. The influence of NA afferents from the A2 group appears to differ from that of afferents originating in A1, given the observed activation of OXY-secreting neurons following stimulation in the A2 region.

Kadekaro, M. Ito,</u> <u>P.M. Gross, L. Sokoloff</u>, Laboratory of Cerebral Metabolism, NIMH, Bethesda, MD 20205.

Perikarya for corticotropin-releasing factor (CRF) have recently been identified by immunocytochemical studies to be located in the hypothalamic paraventricular nuclear complex. Additionally, a heavy density of CRF-immunoreactive fibers is present in the median eminence. It has been suggested that CRF secretion is influenced by noradrenergic input from the locus coeruleus. We studied the energy metabolism of the locus coeruleus, paraventricular nucleus, median eminence and pituitary anterior lobe of acutely adrenalectomized conscious rats with the autoradiographic [<sup>14</sup>C]deoxyglucose method. Rats were bilaterally adrenalectomized or sham-operated under light halothane anesthesia and allowed 5 hours for recovery. Dexamethasone (0.25 mg/kg i.m.) was injected during the surgical procedure in sham-operated or adrenalectomized animals. The table shows rates of glucose utilization expressed as µmoles/100 g/min (means ± SEM).

The results demonstrate that, in the absence of steroid hormones, metabolic activity is high in the axis of structures regulating corticotropin secretion and in the locus coeruleus, which probably provides important afferent input to this regulation. Glucocorticoid replacement in adrenalectomized rats reduces the rate of glucose metabolism to normal levels in these structures.

INTERACTIONS OF SOMATOSTATINERGIC AND SOMATOCRININERGIC SYSTEMS 123 17

INTERACTIONS OF SOMATOSTATINERGIC AND SOMATOCRININERGIC SYSTEMS IN THE GENERATION OF EPISODIC GROWTH HORMONE SECRETION: STUDIES IN THE FREELY-BEHAVING MALE RAT. L.C. Terry, M. Zorza\* and N. Petersen\*. Neuroendocrine Lab., Univ. of Michigan and VA Medical Center, Ann Arbor, MI 48105. Growth hormone (GH) secretion in freely-behaving male rats is characterized by an ultradian rhythm composed of secretory epi-sodes that occur every 3-4h. The zenith and nadir of this rhythm are believed to be regulated by two hypothalamic peptides, somato-statin (SRIF), which inhibits GH secretion, and somatocrinin (growth hormone-releasing factor, GRF). The purpose of the present experiments was to determine the contribution of SRIF and GRF in the generation of this rhythm. Experiment 1: Thermal lesions were placed in hypothalamic ventromedial-arcuate nuclei bilaterally to destroy GRF-producing neurons. Animals were sub-sequently implanted with chronic indwelling intra-atrial cannulae. Two weeks later, blood samples were removed serially every 15 min for 5h and assayed for immunoreactive GH. One group received cysteamine (150 mg/kg sc), an agent known to deplete CNS and peripheral SRIF, and the other group, vehicle. Prolactin was also assayed to determine if the A12 (arcuate) dopaminergic system was disrupted. Such lesions suppressed or eliminated GH secretory episodes, but did not alter nadir levels, and caused a 12 fold increase in prolactin. Cysteamine caused a significant rise in nadir GH levels, but did not reinstitute or enhance episodic release. Experiment 2: Cannulated rats were administered hpGRF (10 ug iv) or vehicle at 1005 or 1205h. hGRF prolonged GH secretory episodes when given during a zenith (1000h), and stim-ulated GH to zenith levels if administered during a nadir (1200h). Administration of hGRF during a nadir did not alter the frequency nor synchronization of the GH rhythm. Experiment 3: The SRIF antagonist analogue cyclo [Ahep-Phe-D-Trp-Lys-Thr(Bz1)] (CPP), reported to stimulate GH secretion in nembutal-a

anesthetized group. These studies indicate the following: 1) episodic GRF release generates the rhythmic pattern of GH secretion, 2) local tonic control of GH secretion by SRIF plays a minor role in the regula-tion of this rhythm under nonstressful conditions, and 3) the somatostatin analog CPP does not have a significant antagonistic action on pituitary SRIF receptors under physiologic conditions. (Supported by AM 28443 and a VA Merit Review Grant.) 123.18 LOCAL RATES OF CEREBRAL PROTEIN SYNTHESIS IN CHRONIC

HYPOTHYROIDISM IN THE ADULT RAT. D. <u>Dow-Edwards</u>, C. <u>Smith\*, and</u> <u>L. Sokoloff</u>, Department of Neurosurgery, SUNY Downstate Medical Center, Brooklyn, NY, and Laboratory of Cerebral Metabolism, NIMH, Bethesda, MD.

Although thyroid hormones are known to regulate protein synthe-Archiving the developing brain, no effects of thyroid hormones on the average rate of protein synthesis in brain taken as a whole have been observed in mature animals. Altered thyroid function has, however, been shown to influence the activity of several brain enzymes, to alter neurotransmitter levels, and to modify behavior. In order to determine if altered thyroid function might influence rates of protein synthesis in specific regions of the brain in vivo, we employed the recently developed autoradiographic method for measuring local rates of L-leucine incorporation into protein (Smith et al., 1980, <u>Trans. Amer.Soc. Neurochem. 11</u>, 94) in chronic hypothyroid rats.

Male Sprague-Dawley rats (250 g) were surgically thyroidectomized under pentobarbital anesthesia. Body weights were recorded during the following 3 months to confirm the effectiveness of the thyroidectomy. The measurement of protein synthesis was carried out in 5 hypothyroid animals and 4 sham-operated controls. The animals were administered an intravenous pulse (100  $\mu$ Ci/kg of body weight) of L-[1- C]leucine (59 mCi/mmol). Timed arterial samples were then taken for determination of the time courses of the arterial plasma concentrations of  $[{}^{14}C]$  leucine and leucine. At 60 minutes the animals were killed, and the brains were removed, 60 minutes the animals were killed, and the brains were removed, frozen, and later sectioned for autoradiography as described by Sokoloff et al. (1977, <u>J.Neurochem.</u> 28, 897-916). The sections were fixed to remove the unincorporated [<sup>14</sup>C]leucine and auto-radiographed on Kodak MR film. Areas of interest were analyzed densitometrically to determine the local concentrations of <sup>14</sup>C in the tissues. From the local tissue C concentrations and the time courses of the plasma [<sup>14</sup>C]leucine and leucine concentrations local rates of leucine incorporation into protein were calculated by the operational equation of the method. Of the 51 brain regions examined there were significant decreases in the rates of protein synthesis in 13 structures of the hypothyroid animals. These structures included mainly components of the extrapyramidal motor system, nuclei of cranial nerves, and hypothalamic nuclei. There were no significant changes in visual or auditory pathways or in any region of the cortex. Chronic hypothyroidism, therefore, appears to decrease rates of protein synthesis in a few selected areas of brain.

A HYPOTHALAMIC PITUITARY SYSTEM STIMULATES PLASMINOGEN ACTIVATOR IN PLASMA. G. Fink, C.V. Prowse\* and R.C. Dow\*. MRC Brain Metabolism Unit and Blood Transfusion Service, Edinburgh, 123.19 Scotland.

Scotland. Plasminogen activator (PA) cleaves the proenzyme plasminogen allowing subsequent lysis of blood clots by degradation of fibrin. In man PA is released into plasma by a variety of stimuli including systemic infusion of adrenaline or l-desamino-8-D-arginine vasopressin (DDAVP). In man, adrenaline acts directly on peripheral (endothelial) stores to cause PA release, whereas DDAVP acts by way of a central receptor (Cash et al, Clin. Sci. Mol. Med., 54:403, 1978). Regional infusion of DDAVP to the head in dogs released PA suggesting that DDAVP stimulates the release of a PA-releasing factor (PARF) which releases PA from a peripheral site. We have investigated the site of production of the proposed PARF and its central nervous control by means of electrical stimulation of the hypothalamus and infusion of extracts of anterior pituitary tissue. extracts of anterior pituitary tissue. All experiments were carried out on adult male rats

All experiments were carried out on adult male rats anaesthetised with urethane. In preliminary experiments the ability of intravenous adrenaline or DDAVP to raise PA levels (measured by effect on euglobulin clot lysis times; Cash & Allan, Brit. J. Haematol., 13:376, 1967) was demonstrated. Electrical stimulation of the median eminence (ME) of the hypothalamus (Fink & Jamieson, J. Endocrinol., 68:71, 1976) in intact Wistar rats had a similar effect. The mechanism of PA release by such electrical stimulation di not depend upon either vasopressin or adrenaline since ME stimulation also caused PA release in homo-zygous Brattelboro rats (totally deficient in vasopressin) and in Wistar rats from which the adrenal glands had been removed. The zygous Brattelboro rats (totally deficient in vasopressin) and in Wistar rats from which the adrenal glands had been removed. The PA response to ME stimulation was, however, abolished by section of the pituitary stalk. The release of PA was also induced, in a dose-dependent manner, by intravenous infusion into normal Wistar rats of a saline extract of anterior pituitary tissue obtained from either normal Wistar or Brattelboro rats. The activity of the pituitary extracts was destroyed by boiling, but not by treatment with di-isopropyl fluorophosphate which inhibits PA. Infusion of the forty-one amino acid residue corticotropin Infusion of the forty-one amino acid residue corticotropin releasing factor was without effect.

These results show that the anterior pituitary gland contains a heat-labile factor which acts on peripheral stores to release PA into blood, and that the release of PARF is stimulated by a hypothalamic factor. The mechanism of action of PARF and its release does not require the presence of vasopressin, adrenaline, glucocorticoids or adrenal enkephalin.

123.PO ACTH INFLUENCE ON TYROSINE HYDROXYLASE ACTIVITY IN THE LOCUS COERULEUS. K.A. Markey and P.Y. Sze. Dept. of Biobehavioral Sciences, The University of Connecticut, Storrs, CT 06268. Our previous study shows that chronic administration of corticosterone to mice during a sensitive period of early postnatal development elicits an increase of tyrosine hydroxylase activity in the locus coeruleus (Endocrinology 111: 1519, 1982). However, in adult mice, administration of glucocorticoids does not have any effect on the enzyme activity in the noradrenergic neurons. In the present study, we found that bilateral adrenalectomy resulted in an increase rather than the expected reduction of tyrosine hydroxylase activity in the locus coeruleus, suggesting that the response of the enzyme to pituitary-adrenal influences may change as ontogenesis proceeds. The enzyme activity in the locus coeruleus rose slowly in adrenalectomized adult mice, with a maximum increase of the enzyme activity was found in dopaminergic neurons of the substantia nigra. The increase of activity in the locus coeruleus following adrenalectomy was totally prevented by corticosterone replace-mote the down of the down of the substantia nigra. Was found in dopaintiergic hearbis of the subschafta firght. The increase of enzyme activity in the locus coeruleus following adrenalectomy was totally prevented by corticosterone replace-ment. Moreover, the adrenalectomy effect was abolished by hypophysectomy, indicating the involvement of the pituitary rather than the adrenocortical function. Chronic administration of ACTH (20 I.U./kg, i.p., daily) resulted in an increase of tyrosine hydroxylase activity in the locus coeruleus, with a time course and magnitude similar to those found after adrenal-ectomy. Additionally, the effects of four ACTH analogs were determined. ACTH(1-24) and ACTH(4-10) were as effective as the whole ACTH molecule, whereas ACTH(4-10,7-D-Phe) and ACTH(11-24) were ineffective. The effect of ACTH (4-10), a peptide fragment with no adrenocorticotrophic activity, further indicates that glucocorticoids are not involved. From these data, it appears that tyrosine hydroxylase in adult locus coeruleus is under the regulatory influence of pituitary ACTH. It remains to be determined whether the hormone can be transported from its pituitary origin to the locus coeruleus and exerts a direct action on the noradrenergic neurons. Regardless of the mechanism, the response of the noradrenergic neurons to pituitary activity the response of the noradrenergic neurons to pituitary activity may be an important component in physiological adaptation of the central nervous system to chronic stress. - 124.1 THE DEVELOPMENT AND EXTINCTION OF CONDITIONED FEAR FOLLOWING \* ACUTE EXPOSURE TO TRIMETHYLTIN. H.S. Swartzwelder, C.T. Johnson, C. Robinson\*, E. Kestler\*, and C. Steinbach\*. Institute of Animal Behavior, Towson State Univ., Towson, Md.21204. Trimethyltin (TMT) is a known neurotoxin which produces deficits in learning and memory as well as a distinct limbic neuropathology (Brown et. al., 1979; Dyer et. al., 1982). Although the effects of TMT upon locomotor activity (Swartzwelder et. al., 1981), avoidance learning (Walsh et. al., 1982) and problem solving (Swartzwelder et. al., 1981), avoidance of classical conditioning and neurobehavioral toxicity (Rescorla, 1968; Nation et.al., 1982), and animals with lesions in the hippocampus show impaired development of this response (Brady, 1958; Molino, 1975). In our study, conditioned suppression was measured in the control and TMT-treated rat. TMT-treated animals were given either 5.0 or 7.0 mg/kg/ml TMT via intragastric intubation and controls received the saline vehicle in equal volumes. All rats were trained to leverpress for food reinforcers on an FR-20 schedule. Once this baseline was presented at the end of each block. Although the rate of suppression did not vary between groups, the TMT-treated rats showed less suppression than controls when the tone was presented al the end of each block. Although the rate of suppression did not vary between groups, the TMT-treated rats showed less suppression than controls when the tone was presented at the end of each block. Although the rate of suppression did not vary between groups, the TMT-treated rats showed less suppression than controls when the tone was presented al the end of each block. Although the rate of suppression did not vary between groups, the TMT-treated rats showed less suppression than controls when the tone was presented al the end of each block. Although the rate of suppression did not vary between groups, the TMT-treated rats showed lest suppression than controls when the tone was presented al t
- 124.2 TRIMETHYL TIN: BEHAVIORAL, NEUROCHEMICAL AND NEUROANATOMICAL EFFECTS. <u>C.C. Loullis, R.L. Dean, D.I. Benson\*, A.S. Lippa\*, R.I. Bartus and J. Coupet.</u> Dept. of CNS Research, Medical Research Div. of American Cyanamid, Lederle Labs, Pearl River, NY 10965.

The effects of acute administration of trimethyl tin (TMT) are distinguished from other organotin compounds by selective and persistent neuropathological changes in hippocampal pyramidal cells. This relatively selective cell destruction by TMT may provide a neurobiological probe for investigating neurochemical connections in the hippocampus. Cognitive deficits also persist following TMT administration and therefore it may also be a useful model in assessing hippocampal involvement in these deficits. The purpose of the present experiment was to investigate the behavioral neurochemical and cytological effects of TMT. Rats were intubated once with either 0.9% Saline or TMT (3.5 mg/kg). Two weeks later, following the disappearance of the acute toxic behavioral effects, animals were trained on a single trial passive avoidance task. Twenty four hours later they were tested for retention. Following this, animals were sacrificed, the hippocampus was quickly dissected on ice and stored at  $-20^\circ$  C for neurochemical analysis using  $^{\rm H}(-)0{\rm NB}$  revealed a 21% decrease in muscarinic receptor density. Histological examination al loss of pyramidal cells. These metation and the these cells and receptors are critical in mediating the passive avoidance behavior.

124.3 A NEW PROCEDURE FOR SPECIATION OF NEUROTOXIC TRIMETHYLTIN IN IN-VIVO-EXPOSED MAMMALIAN TISSUES. K.I. Hulebak, J.C. Means\*. Div. Toxicology, Dept. Environ. Hlth. Sci., The Johns Hopkins Univ., Baltimore, MD 21205, and Chesapeake Biological Lab. and Dept. of Chemistry, Univ. of Maryland, Solomons, MD 20688. Exposure to trimethyltin results in morphologically detectable damage to the CNS and possibly to the kidney. Dose-response relationships have been described, but a fast method for quantitating levels of various methyltin species in target organs has been unavailable. It is possible to measure methyltins as total tin using atomic absorption spectrometry, but speciation of methyltins has proven difficult. We present a new procedure for the quantitative analysis and speciation of methyltins, directly from

exposed tissues. Trimethyltin chloride is purged from <u>in vitro</u>- or <u>in vivo</u>exposed, freshly homogenized mouse liver, kidney, and brain using NaBH<sub>4</sub>. The volatile organotin hydrides produced are cryogenically trapped on the head of a gas chromatographic column (at -40° C). The compounds are detected using selected ion monitoring in a Hewlett Packard 5985 B mass spectrometer in either the electron impact or the chemical ionization mode. Quantitation is achieved by integration of the areas of the chromatographic peaks. Linear response is obtained over the range of 1 ng to 30 µg. Recovery of trimethyltin spiked into tissues is greater than 85%. Nanogram quantities of trimethyltin can be recovered from <u>in-vivo</u>-exposed tissues. Trimethyltin is the only methyltin detected in organs from trimethyltin-exposed mice.

124.3 ALTERATIONS IN SENSORIMOTOR FUNCTION FOLLOWING ACUTE TRIETHYL LEAD EXPOSURE: TIME AND DOSE RESPONSE ANALYSIS. T. J. Walsh \* and H. A. Tilson \* (SPON: K. Yoshikawa), Lab. Behav. Neurol. Toxicol., NIEHS Research Triangle Park, NC 27709. Triethyl lead (TEL) is a neurotoxic organometal reported to

Triethyl lead (TEL) is a neurotoxic organometal reported to produce a distinct pattern of limbic system pathology, involving the hippocampus, amygdala and pyriform cortex (Seawright et al., in Methods in Toxicology and Hazard Evaluation, 1980). Since the limbic forebrain is believed to modulate the sensitivity and/or behavioral reactivity to environmentally relevant stimuli one effect of TEL might be to disrupt sensorimotor processes. Therefore, the studies reported here examined the effects of TEL on various aspects of sensorimotor function using a neurobehavioral test battery that assesses motor activity, fore- and hindlimb grip strength, spectrally analyzed whole body movement, acoustic startle and reactivity to a noxious stimulus using the hot-plate test.

strength, spectrally analyzed whole body movement, acoustic startle and reactivity to a noxious stimulus using the hot-plate test. Adult male Fischer-344 rats were injected (s.c.) with either distilled water, or 1/4 (2.63 mg/kg), 1/2 (5.25 mg/kg) or 3/4 (7.88 mg/kg) the acute LD50 of TEL cl and tested on days 1-2, 7-8, 14-15, 21-22 and 28-29 following dosing. TEL was found to affect sensorimotor function in a time and dose-related manner. The 1/4 LD50 dose of TEL failed to affect hot-plate latencies, motor activity or forelimb grip strength at any time after dosing but did increase hindlimb grip strength (10-20 %) on post-treatment days 1, 14 and 21. The intermediate dose of TEL (1/2 LD50) increased ambulation and rearing (60-140 %) on days 7, 14 and 21 and hotplate latencies (40-60 %) up to 15 days following dosing. The highest dose of TEL (3/4 LD50) increased hot-plate latencies (26-176 %) 2, 8, 15 and 29 days after dosing. Hindlimb grip strength was increased (9 %) 1 day following dosing and there was a biphasic effect on rearing and ambulation. Both components of motor activity were decreased approximately 50 % 1 day after dosing, however, animals subsequently developed a persistent hyperactivity (ie. both measures increased 55-239 %) which was evident throughout the course of testing. Spectral analysis of movement revealed dose-related increases in power (amplitude), particularly in the 2.5 -10 Hz region. Changes in the spectral profile of activity were observed one week after dosing and persisted throughout the period of study. Acute administration of TEL affected several indices of sensori-

Acute administration of TEL affected several indices of sensorimotor function. The most sensitive endpoints for detecting TEL toxicity were reactivity to a noxious stimulus, motor activity and spectrally analyzed whole body movements. Studies are now in progress to correlate these behavioral changes with alterations in central and peripheral nervous system pathology and brain neurotransmitter and peptide systems. 124.5 SOME ASPECTS OF FEEDING AND LOCOMDTOR ACTIVITY IN RATS EXPOSED TO TETRAETHYL LEAD. D. A. Czech, E. Hoium\* and T. C. Trusk. Depts. of Psychology and Biology, Marquette Univ., Milwaukee, WI 53233 Previous research has shown that organolead compounds can lead to changes in locomotor and consumatory behavior. In addition to observing that exposure to tetraethyl lead (TEL) is followed in a dose related way by increased locomotor activity and reduced food and water intake in rats, we found that when food intake of rats in a control group was limited to that of yoked counterparts in a TEL exposed group, activity increased in both. Further, food intake and activity were significantly correlated in both groups, suggesting a possible link between reduced food intake and behavioral arousal in leaded rats. To pursue this issue, we yoked rats injected i.p. with 7 mg/kg TEL, a dose found effective for the aforementioned behaviors, with controls (peanut oil vehicle), supplementing food intake of TEL rats by stomach loading them with the difference between their voluntary daily intake and that of a yoked control. A third group, also given 7mg/kg TEL, was not food yoked, and served as control for noting lead effects without intervention. Observations were made over 3 pre- and 18 post-TEL days. Food loads were delivered to the yoked-TEL group over the initial 9 post-TEL days; other groups received sham loads over this period and all rats were sham intubated over days 10-18. Both TEL groups showed significantly higher activity(relative to pre-TEL levels) over all but the first few days of the post-TEL period. Food loads to leaded groups did not effective nutritional state may therefore have contributed in part to increased activity. However, over the last 9 days, neither body weights nor food intakes were significantly different across groups, while activity remained elevated in TEL groups. Consequently, it is unlikely that nutritional state was the sole factor for all of the variance. Periodic tests over succeeding week

and possible mechanisms are discussed. Related work in our lab also showed that TEL exposed rats will eat palatable foods, while rejecting lab chow, and may return to normal feeding levels sconer if maintained on such a diet, prompting two further studies. In the first study, a group of "recovered" TEL rats (7 mg/kg) and a control group matched for body weight were challenged with 10 U/kg insulin, 600 mg/kg 2-deoxy-D-glucose and 0.9% saline. No significant food intake differences were noted between groups to substances after both 1 and 6 hour tests. In the second, TEL and control rats were similarly challenged 3-7 days after TEL dosing. These results were complex.

124.7 EARLY ELECTROPHYSIOLOGIC CHANGES IN MAMMALIAN NERVE INDUCED BY ORGANOPHOSPHORUS AGENTS. R. J. Anderson, J. H. Carlson and C. B. <u>Dunham<sup>4</sup></u> Dept. of Pharmacol., George Washington Univ. Med. Ctr., Washington, D.C. 20037. Exposure to some organophosphorus (OP) compounds leads to the

Exposure to some organophosphorus (OP) compounds leads to the development of a delayed neuropathy, which in most cases correlates with inhibition of neurotoxic esterase (NTE). However, the steps between NTE inhibition, which occurs rapidly, and the onset of the histopathology, which usually takes more than a week, are not known. The purpose of this study was to examine the electrophysiologic changes which occur during chronic administration of several delayed neuropathy-inducing OPS. Male rats were dosed ip with trichlorfon (TCF) (200 mg/kg), DFF (1 mg/kg), or soman (0.05 mg/kg) in single daily doses for up to 45 days. At intervals rats were exitability. All three OPS induced a shift toward shorter relative refractory periods, reaching a maximum after 15 days of TCF dosing, 10 days of DFP and only 1 day of soman. Also, the nerve compound action potentials had shorter durations and faster conduction velocities than the controls. These effects correlated with a loss of plasma and acetyl cholinesterase activity. Thus, these early electrophysiologic durations, though not completely recovered at these times, nevertheless increased in activity. Thus, these early electrophysiologic changes is not activity.

The sciatic nerves of these animals were also challenged with potassium-induced depolarization using the sucrose gap technique. Chronically administered DFP lead to increased nerve sensitivity to potassium, inducing greater depolarizations than the controls. This effect was maximal after 20 days of DFP dosing, a time at which both enzyme activity and nerve conduction are almost fully recovered. The effect on potassium depolarization seems to correlate with the time course of delayed neuropathy induced by DFP and may be an index of the development of this damage. Soman produced variable changes in the sucrose gap measurements which may have been due to the small dose which was used. Prior to sacrifice none of the animals showed evidence of motor deficits using behavioral measures, and histologic examination revealed only mild evidence of neuropathic changes in some, but not all of the nerves.

These results show that electrophysiologic changes do occur in peripheral mammalian nerves after chronic exposure to OPs. Some features of nerve excitability seem to correlate better with acute toxicity (cholinesterase inhibition) while others appear to correlate with the development of delayed neuropathy. This work was supported in part by USAMRICD.

- 124.6 DEFICITS IN SPATIAL MEMORY PERFORMANCE IN EIGHT ARM MAZE FOLLOWING EARLY LEAD EXPOSURE.
  - L.L. Garten\*, C. Winder\* and P.D. Lewis\* (SPON: A.J. Patel). Department of Histopathology, Royal Postgraduate Medical School, London W12, U.K.

Behavioral alterations have been reported in clinical and experimental studies of lead neurotoxicity. Lead induced changes in development and structure of the hippocampal region have also been indicated.

Maternal rats were dosed with 300 and 1000ppm lead acetate in drinking water throughout gestation and lactation; neonates were weaned to tapwater at 21 days of age. This model has been shown to produce blood lead levels in weaned offspring equivalent to childhood clinical and subclinical levels. No body weight differences between control and lead treated animals were seen at any stage. At 100 days of age, blood lead levels of dosed rats were similar to those of controls. Adult female rats (130-160 days) perinatally exposed according to this regime were used for behavioral testing.

Performance in the elevated radial 8 arm maze has been shown to be selectively affected by hippocampal damage. Radial maze tasks involve a flexible, rather than consistent response, using working memory and cognitive mapping strategies.

than consistent response, using working memory and cognitive mapping strategies. Performance in this maze was consistently and significantly impaired in lead dosed rats. Acquisition of the task was delayed and after attainment of a criterion of one error in three consecutive trials performance continued to be inferior to that of controls. The number of errors made by animals in both dose groups was significantly increased. However, latency, or time taken to make the required eight choices, was not consistently affected.

The deficits seen in performance following perinatal low level intake suggest that the hippocampus may be susceptible to lead exposure. That changes persist into adult life implies the possibility of a long-term or even irreversible disfunction.

124.8 BEHAVIORAL TOXICITY OF CARBON DISULFIDE IN THE RAT. J.T. Concannon and M.D. Schechter. Program in Pharmacology, Northeastern Ohio Universities College of Medicine, Rootstown, Ohio 44272.

Universities College of Medicine, Rootstown, Ohio 44272. Adult rats were trained under the influence of carbon disulfide (CS\_) to perform two types of operant tasks: (a) a drug-discrimination task and (b) a nose-poke task to escape inhaled CS\_. In the first task, rats were trained to discriminate between the stimulus properties of intraperitoneally-administered CS\_ and its vehicle in a two-lever, food-motivated operant task, using either 12.5 or 25.0 mg/kg CS\_. The results of an extensive, 56-session training schedule showed that only one rat met the criterion of 9 agentappropriate lever selections out of 10 consecutive trials, but its subsequent performance deteriorated to below criterion level. Posttraining biochemical determinations, however, revealed that both doses of CS\_ reliably depleted cerebellar levels of norepinephrine (NE), without affecting "rest-of-brain" levels of dopamine (DA) or NE, when determinations were made using high-performance liquid chromatography (HPLC). These results suggest that biochemical measures of brain status may be even more sensitive indices of <u>injected</u> solvent-induced "toxicity" than is operant drug-discrimination.

The second task used a system which simultaneously delivered continuous, high levels of CS to some ("chronic") animals, while rapidly decreasing CS levels contingent upon an operant mose-poke escape response in other ("trained") animals. This computerassisted system meets the following criteria: (a) gas concentrations are protected from exposure to the irritant gas; and (c) the subject orients toward the gas source and performs a simple response to terminate the gas. Preliminary results show that trained animals can learn this task compared to "yoked-control" animals who have the same CS, exposure, in terms of intensity and duration, but who cannot terminate CS, exposure. However, the learning is a very gradual process and required extensive training. Inter-trial interval (ITI) responses also indicates that CS, escape learning is not due to simple activity-increasing effects of CS, Manipulations which increased the level of CS, escape respönding will be discussed. These results suggest that CS, is detectable and can serve as a warning stimulus for subsequent aversiveneess.

ALTERED RETROGRADE AXOPLASMIC TRANSPORT BY SINGLE 124.9

ALTERED RETROGRADE AXOPLASMIC TRANSPORT BY SINGLE DOSES OF ACRYLAMIDE. <u>Matthew S. Miller and Peter S. Spencer</u>, Institute of Neurotaxicology, Depts. of Neuroscience and Pathology, Albert Einstein College of Medicine, Bronx, New York 10461. Monomeric acrylamide (ACMD) induces central-peripheral distal axonopathy in laboratory animals and humans following repeated exposure. Little is known regarding the underlying biochemical mechanisms. Recent studies suggest that small changes in bidirectional feat expendit peripheral distal pattions of paripheral exponents. mechanisms. Recent studies suggest that small changes in bidirectional fast axonal transport in distal portions of peripheral nerve are associated with ACMD-induced axonopathy. However, it is unclear whether these changes in axonal transport precede, or occur secondary to, axonal degeneration. This study determined the effects of single doses of ACMD on retrograde axonal transport. To assess retrograde axonal transport, purified iodinated tetanus toxin (<sup>125</sup>I-TX) was unilaterally injected into the gastrocnemius muscle of male CD-1 mice (20-30 g). After <sup>125</sup>I-TX injection (2.5–12.5 hours), animals were killed, and accumulation of 1251 in ipsilateral and contralateral spinal-cord anterior horn (L3–L6) and dorsal root ganglia (L3–L6) was determined by gamma counting. The difference in <sup>125</sup>1 content of ipsilateral and contralateral tissues was considered to be the result of axonal transport. In control mice, preferential accumulation of <sup>125</sup>1 in ipsilateral anterior horn and dorsal root ganglia be the result of axonal transport. In control mice, preferential accumulation of <sup>125</sup>1 in ipsilateral anterior horn and dorsal root ganglia was detected within 5 hours and attained maximum levels approximately 7.5 hours after peripheral injection of <sup>125</sup>1-TX. The effect of single doses of ACMD and N,N<sup>-</sup>methylene-bis-acrylamide (a non-neurotoxic analog of ACMD) on retrograde axonal transport of <sup>125</sup>1-TX was then investigated. One hour after peripheral injection of <sup>125</sup>1-TX, mice received a single intraperitoneal injection of ACMD (0-100 mg/kg) or equimolar doses of N,N<sup>-</sup>methylene-bis-acrylamide. Animals were killed 5 hours later and accumulation of <sup>125</sup>1-TX to avoid a dose-dependent decrease in the transport of <sup>125</sup>1-TX to avoid potential effects of ACMD on the neuronal uptake of radiolabeled toxin. Single doses of ACMD produced a dose-dependent decrease in the transport of <sup>125</sup>1-TX to the perikarya of primary sensory neurons in dorsal root ganglia and lower motor neurons. The dose of ACMD required to inhibit sensory and motor neurons. The dose of ACMD required to inhibit no ftransport by ACMD was approximately 25 mg/kg in both sensory and motor neurons. Substantially greater doses of N,N<sup>-</sup>methylene-bis-acrylamide were required to alter the axonal transport of 1<sup>25</sup>1-TX by peripheral sensory and more neurons. It is concluded that single doses of ACMD are retrograde axonal transport of the peripheral sensory and more neurons. <sup>143</sup>I-IX by peripheral sensory and motor neurons. It is concluded that single doses of ACMD alter retrograde axoplasmic transport in peripheral sensory and motor neurons. Retrograde axoplasmic transport in primary sensory neurons is more susceptible to inhibition by single doses of ACMD than that in lower motor neurons. Alterations in axonal transport may reflect the primary biochemical lesion associated with ACMD-induced central-peripheral distal axonopathy. (Supported by NS07063 and OH00851).

124.11 BEHAVIORAL TOXICITY IN RABBITS FOLLOWING PROLONGED ALUMINUM (A1) EXPOSURE DURING DIFFERENT DEVELOPMENTAL STACES. <u>R.A. Yokel and</u> <u>M.T. Willhite</u>.\* College of Pharmacy and Graduate Center for Toxicology, University of Kentucky, Lexington, KY 40536. Al has been implicated as the causative agent in dialysis Al has been implicated as the causative agent in dialysis encephalopathy and osteomalacia and has been found to accumulate in Alzheimer diseased brains. A study (Neurobehav. Toxicol. Teratol. 5: 41-46, 1983) conducted in adult rabbits showed evi-dence of toxicity following repeated systemic Al exposure (5 se inj/wk x 4wk of 0 to 400 µmole Al/kg/inj). Body weight loss was 3% in those receiving 400 µmole Al/kg/inj whereas controls gained 46% by wk 5 after Al inj. Acquisition of a classically condi-tioned mether (classically conditioned reflex (nictitating membrane extension, NME) 2.5 wk after Al exposure showed lower terminal % conditioned responses (CR) (80 and 75% of control for the 200 and 400 µmole Al groups) and longer latencies to CR (327 and 310 vs. 261 msec for controls) indicating less well developed CR acquisition.

To assess Al toxicity in younger organisms, pregnant rabbits received 5 inj/wk x 4wk of 0, 25, 100 or 400 µmole Al/kg/inj during gestation. Weight gain was little effected in the surviving offspring (54%) of 400µmole Al exposed does. The 25 µmole Al exposed group showed facilitation of NME acquisition (higher % CR and shorter CR latency) whether conditioned at 6.5 or 10.5 wk of age. This effect may relate to the epileptogenic potential of Al. The acquisition of NME in the other Al exposed offspring was not different from controls. Treatment of lactating does with 5 inj/wk x 4wk of 0 to 800

 $\mu mole ~Al/kg/inj$  resulted in weight loss, to a low of 90% of original weight at wk 5 in 400  $\mu mole ~Al$  exposed does. Does exposed to 800 µmole Al died at 4wk. Suckling offspring of 25 µmole Al exposed does increased in body weight from control levels at wk 8 to 111% of controls by wk 12. Offspring of 400 µmole Al exposed does were 75% of control body weight from wk 1 to 6 then increased to 89% of controls by wk 12. NME acquisition was more impaired in 25  $\mu$ mole Al exposed offspring (70% of controls) when conditioned at 6.5 or 10.5 wk of age, than offspring exposed to higher Al levels.

Five inj/wk x 4wk of 400  $\mu$ mole A1, 50  $\mu$ mole Pb, or 1  $\mu$ mole Sn/kg/inj to rabbits beginning at 2 days of age produced significant inhibition of weight gain in A1 treated rabbits but no consistent effects on NME acquisition in any metal exposed groups compared to controls.

Body weight changes did not consistently correlate with behavbody weight changes and not consistently correlate with behav-ioral changes suggesting no cause-effect relationship. Although the mature rabbit seems to be more affected by Al than the imma-ture rabbit, Al does not appear to have great potential to produce behavioral toxicity in the organism with normal renal function. (Supported by NIH Grant ES 2676.)

BEHAVIORAL EFFECTS OF CHRONIC HALOTHANE EXPOSURE IN DEVELOPING 124.10

BEHAVIORAL EFFECTS OF OHRONIC HALDIHANE EXPOSURE IN DEVELOPING RATS. Edward D. Levin<sup>\*</sup>, Nellie K. Laughlin<sup>\*</sup>, Robert E. Bowman, and Etsuro Uemura. Dept. of Psychology Primate Laboratory, Univ. of Wisconsin-Madison, WI. 53715, and Dept. of Anatomy, University of Iowa, Ames, Iowa. (SPON: M. H. Weiler). Halothane, a commonly used surgical anesthetic has been found to cause neural and behavioral deficits in rats exposed to low, chronic levels during perinatal development. The present study further examined the behavioral effects and will correlate these with neuropathological studies of synaptic density and dendritic further examined the behavioral effects and will correlate these with neuropathological studies of synaptic density and dendritic branching. Rats were exposed to 100 parts per million halothane in the air during gestation and until 60 days after birth. The intermittant exposure group (N=6 litters) received halothane for 8 hours/day for 5 days/week. The continuous exposure group (N=6 litters) received halothane continually throughout the exposure period except for about one hour/day needed for animal husbandry and testing. The control group (N=4 litters) received no halo-thane but were kept in exposure chambers identical to those of the other two groups. the other two groups.

At 20, 40 and 60 days of age, the rats were tested for spon-taneous alternation in an unbaited T-maze. This classic test of taneous alternation in an unbaited l-maze. This classic test of hippocampal development was chosen to complement the neuropatho-logical studies of the hippocampus. Latency and direction of choice was measured for a series of six trials. Using ANOVA no significant halothane effects were seen with the percent alterna-tion measure although the controls did show a significant increase in contrastic to the percent of a set of the set of th the measure attribute the controls and show a significant increase in alternation with development (p<.01) while both halothane groups did not. ANOVA of the latency data revealed no main ef-fect of halothane but there were significant effects of halothane x age (p<.01), halothane x trial (p<.05) and halothane x age x trial (p<.001). These significant effects reflected a lengthening of choice latency over trials of the two halothane groups at day 20 as compared with the controls who did not change their latency over trials. This effect was no longer apparent at days 40 and 60.

An additional female and male offspring from each litter were tested in an open field for 3 consequetive days beginning at wean-ing (Day 25). ANOVA of the number of squares entered indicated that halothane treated animals were less active than controls that halo halo that the pattern of changes in active than controls (p-61) and that the pattern of changes in activity within sessions was different across groups (p<.025). The decreased activity in the open field and longer response latencies in the alternation task both may suggest a similar effect of halothane on locomotor exploration. We will also report data on social behavior and on 8-arm exploration and learning. Supported by NIH grant NS 17107.

CONDITIONED TASTE AVERSION INDUCED BY THE ORGANOPHOSPHORUS INSEC-124.12 TICIDE DICHLORVOS IN RATS. L.G.Costa\*, P.Roney\* and S.D.Murphy\* (sponsor I.J.Butler). Div. of Toxicology, Det. of Pharmacology, University of Texas Medical School and School of Public Health, Houston, Texas 77025.

Houston, Texas 77025. Conditioned taste aversion (CTA) is a behavioral paradigm that is rapidly acquired by animals when the ingestion of a novel sub-stance is followed by certain drugs, toxic chemicals or X-irra-diation. CTA has been proposed as a test for evaluating the toxic effects of chemicals on the CNS. In the present study we investi-gated the ability of the organophosphorus insecticide dichlorvos (2,2-dichloroethenyl phosphoric acid dimethyl ester; DDVP; analy-tical grade, 97%) to induce CTA. Male rats were caged individual-ly and adapted to a daily restricted (30 min) water availability schedule. When intakes had stabilized (usually after 5-7 days), rats were given simultaneous access to water and to a 0.15% (w/v) saccharin solution. Immediately after the session rats were in-jected with saline, lithium chloride (6 meq/kg, as a positive control) or DDVP (1.5, 3.0, 4.5, 6.0, 9.0 mg/kg,ip). Moderate Control) or DUVP (1.5, 3.0, 4.5, 6.0, 9.0 mg/kg, np). Moderate signs of cholinergic intoxication were observed only after admi-nistration of the 9.0 mg/kg dose. Three days later the animals were presented again with the water-saccharin choice. Saccharin consumption (as percent of total fluid intake) was 83.9 for con-trol, 18.5 for LiCl-treated rats and 70.4, 65.5, 27.5, 23.4, 24.6 for rats given increasing doses of DDVP. Values were significan-tly different from control (P < 0.05, ANOVA) at 4.5, 6.0 and 9.0 mg/kg. Total fluid consumption did not differ among groups.

mg/kg, lotal full consumption due not after the adminisgroups. Cholinesterase activity was measured 30 min after the adminis-tration of DDVP and found to be inhibited 38.2 and 67.6% (plasma), 60.3 and 76.5% (whole brain) and 51.8 and 69.4% (diaphragm) after 4.5 and 9.0 mg/kg, respectively. The 4.5 mg/kg dose of DDVP did not have any effect on either spontaneous motor activity in an open field nor on motor coordination in an inclined plane test. This dose of DDVP also did not alter pain perception in the tail-immersion and hot-plate tests. At the dose of 9.0 mg/kg, DDVP had significant effects in all these tests.

These results indicate that DDVP causes CTA at doses at which no other apparent sign of toxicity is evident and suggest that CTA may be an useful test in evaluating neurobehavioral toxicity of organophosphorus insecticides. (Supported in part by grant ES-01831 from NIEHS).

- PERSISTENT LOCOMOTOR HYPERACTIVITY IN OFFSPRING OF RHESUS MONKEYS 124.13 EXPOSED TO POLYCHLORINATED OR POLYBROMINATED BIPHENYLS. Susan L. Schantz\* and Robert E. Bowman, Dept. of Psychology Primate Laboratory, Univ. of Wisconsin, Madison, WI 53706. Locomotor activity of rhesus monkeys born to polychlorinated or polybrominated biphenyl (PCB or PBB) exposed mothers was compared with that of controls. Experimental mothers were fed diets to which either the PCB mixture Aroclor 1248 or Aroclor 1016 or the PBB mixture Firemaster FF-1 were added. Experimental diets were begun prior to breeding and continued throughout gestation and nursing of offspring. Doses were as follows: (1) Aroclor 1248: 0.5 or 1.0 ppm 3 times weekly (2) Aroclor 1016: 0.25 or 1.0 ppm daily (3) Firemaster FF-1: 0.3 ppm daily. Following weaning of their offspring, Aroclor 1248 and Firemaster FF-1 exposed mothers were maintained on their experimental diets for a second breeding round from which offspring were also studied. The experiment also included the following recovery rounds of off-spring born after experimental diets were discontinued (1) Three groups of offspring born in three successive years following termination of daily exposure to a diet containing 2.5 ppm Aroclor 1248 (2) One group of offspring born following termination of the 1.0 ppm Aroclor 1016 diet and (3) one group of off-spring born following termination of the 0.3 ppm Firemaster FF-1 diet. All infants were weaned at 4 mo. of age. Locomotor activity was assessed in an activity chamber with crossed photoactivity was assessed in an activity chamber with crossed photo-beams at approximately yearly intervals beginning when the ani-mals were 12 mo. of age. For each activity test an animal was placed in the activity chamber for a 75 min. session 5 days per week for a total of 20 sessions. Photobeam breaks were con-verted to counts per hour and averaged over blocks of 4 sessions for analysis by ANOVA. Most PCB and PBB-exposed groups consistently displayed locomotor activity levels that were ele-vated with respect to controls. Locomotor activity levels in some groups remained elevated until 36 mo. of age. In a pre-vious study we reported a transition from juvenile hyperactivity vious study we reported a transition from juvenile hyperactivity to adolescent hypoactivity in a single group of monkeys born while their mothers were being exposed to 2.5 ppm Aroclor 1248 (Bowman, R.E., & Heironimus, M.P., <u>Neurobehavioral Toxicology and Teratology</u>, 3:16-18, 1982). There were as yet no indications of such a trend in the current study. The hyperactivity seen in these offspring of PCB- and PBB-exposed mothers was more persis-tent than hyperactivity we have previously reported in offspring of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD)-exposed mothers (Schantz, S.L., & Bowman, R.E., <u>The Toxicologist</u>, <u>3</u>:1(1),68,1983). However, the dose of TCDD was very low (5 ppt in the mother's diet) in the latter study. Supported by NIEHS grant ESO 1847.
- EVALUATING THE NEUROTOXICITY OF NEW INTRATHECAL CONTRAST MEDIA. 124.15 L.A. Hayman\*, L.C. Abbate\*, E.T. Hedley-Whyte, L. Miller\*, J. Contrast Media Rsh. Lab., Mass. General Hospital, Taveras\*. Boston, MA 02114.

The rapid introduction of a number of new water-soluble intrathe all contrast agents necessitates the development of an effec-tive way to compare the neurotoxicity of these agents. Available testing methods are inadequate. Clinical trials largely measure how successful the medical team is in preventing the medium from reaching the cranial cisterns rather than intrinsic neurotoxicity. Animal models usually measure only very crude indicators of neuro-toxicity (i.e., seizures or death). <u>In vitro</u> studies fail to consider important <u>in vivo</u> differences in the CSF clearance and brain absorption of different media. This report outlines a method for quantifying neurotoxicity

by power spectral analysis of electroencephalograms (EEG) obtained after cisternal injection in awake Wistar rats. obtained after cisternal injection in awake Wistar rats. This method was used to evaluate a 100  $\mu$ l bolus of <sup>3</sup>H-labelled Iopro-mide, which is a new water soluble myelographic contrast medium. These data were correlated with: 1) the CSF clearance, 2) the CNS concentration, and 3) the regional and cellular CNS location of the lopromide. Measurements of the last two parameters were done from film and microscopic autoradiographs obtained 4, 12 and 20 hours after intrathecal injection. <sup>3</sup>H polyethylene glycol (PEC-900) was given intrathecally to provide control EFG and This and 20 hours after intrathecal injection. <sup>1</sup>H polyethylene glycol (PEG-900) was given intrathecally to provide control EEG and autoradiographic measurements. Positive and negative chemography controls were obtained for all microscopic autoradiograms.

The results of the film autoradiographs showed striking accumulation of  ${}^{3}\!H$  Lopromide within grey matter regions of the CNS with relative sparing of myelinated white matter areas. The same distribution was noted after intrathecal injection of the control compound. Accumulation of the  $^{3}\mathrm{H}$  lopromide within neurons was noted on microscopic autoradiographs done 4 hours after injection. The brain concentration diminished over time. The EEG showed periodic perturbation which began 4 hours after intrathecal injection of <sup>3</sup>H lopromide. These bursts increased in sharpness and intensity between 4-8 hours after injection. They diminished but did not disappear in EEG recordings done 8-20 hours after injection. No EEG abnormalities occurred in the control rats.

- ACUTE EFFECTS OF 2,4-DICHLOROPHENOXYACETIC ACID (2,4-D) ON NEURO-124.14 ACUTE EFFECTS OF 2,4-DICHLOROPHENOXYACETIC ACID (2,4-D) ON NEORO-MUSCULAR FUNCTION IN RATS. P. A. Bernard\*, E. Toyoshima\*, C. U. Eccles, R. F. Mayer, K. P. Johnson, and S. R. Max. (SPON:) R. A. Sjodin). Dept. of Neurol., Univ. of Md. Sch. of Med., Dept. of Pharmacol., Univ. of Md. Sch. of Pharm., and V.A. Medical
  - Center, Baltimore, MD 21201. The herbicide 2,4-D has been reported to cause abnormalities of

neuromuscular function in man and animals. To assess this possi-bility we carried out a multidisciplinary study of the effects of 2,4-D on neuromuscular function in adult male rats (Fisher 344N). We investigated the effects of injections of 2,4-D (dissolved in Emulphor/ethanol/H O; 3/2/5, v/v/v) at 200 mg/kg body weight (i.p.) at 3, 15 and 24 h.<sup>2</sup> Controls received vehicle. Spontaneous locomotor activity was monitored for 20-min periods by means of an photobeams arranged at 2-inch intervals. At 3 h after injection spontaneous locomotor activity was 9% of vehicle injected control values, and it recovered to 50% of control values at 24 h. Ace-tylcholinesterase (AChE) and choline acetyltransferase (CAT) activities were assessed in sciatic nerve as well as in white quadriceps, red quadriceps, extensor digitorum longus, soleus and diaphragm muscles. At 3 h post-injection AChE was decreased (20%, p < .05) in white quadriceps with no change in sciatic nerve or the other muscles. At 15 h AChE was decreased (20%) p < .05) in white and red quadriceps and diaphragm with no change in soleus, extensor digitorum longus or sciatic nerve. At 24 h AChE was decreased (20%, p < .05) in diaphragm. There was no change in CAT activity at any time point. Electromyographic recordings with a concentric needle electrode in awake animals showed prominent myotonic discharges (repetitive muscle action potentials with waxing and waning features) in leg and buttocks muscles 3 h after 2,4-D injection. Myotonic discharges persisted Must be a nature 2,4-D injection. Myotonic distingly persisted but were reduced in duration and had less waxing and waning 24 h after injection. These data suggest that 2,4-D causes an acute postjunctional deficit. The studies further suggest that the depost-interformation and the second state of t Veterans Administration.)

124.16 LESIONS OF VENTRAL PALLIDUM ENHANCE BEHAVIORAL RESPONSE TO NICOTINE. C. Ksir and D.M. Benson\*. Department of Psychology, University of Wyoming, Laramie, WY 82071.

> Lesions made in the region of the ventral pallidum by injection of kainic acid (KA) have been shown to produce decreases in cortical acetylcholine-related enzyme activities and histopathological changes resembling those seen in Alzheimer's disease (Coyle, Price and DeLong, <u>Science</u>, 1983). Before beginning behavioral testing, pilot studies were performed on six rats in order to ensure that similar lesions made in this laboratory would result in decreased staining for acetylcholinesterase in the cerebral cortex.

> Eighteen male albino rats were given injections of KA (0.75 ug in 1.0 ul artificial CSF) bilaterally in the region of the ventral pallidum and substantia innominata. Six other rats received similar injections of the artificial CSF vehicle alone (VEH). Eighteen unoperated control rats were also tested (UNOP). One week following surgery, and again three days later, each rat was tested in one of 16 photocell activity cages. After 2 hours of adaptation to the test cages, each rat was given a subcutaneous injection of saline or of 0.1, 0.2 or 0.4 mg/kg nicotine (base weights). Each rat received one injection of saline and one of First received one injection of same and one of the first test day. Six UNOP animals received each dose of nicotine, as did six of the KA animals. The six VEH rats all received 0.2 mg/kg nicotine. Activity was measured by breaks of the photocell beams in each cage for two hours after injection. Activity levels after saline

> injections were similar among all groups. KA rats showed significantly greater behavioral activation in response to nicotine than either the UNOP or the VEH controls. The mean number of beam breaks during the first hour after injection of 0.2 mg/kg nicotine was 249.9 for the UNOP, 217.9 for the VEH, and 839.4 for the KA group. These results suggest that decreased levels of ACh and related enzymes in the cerebral cortex, as is

> seen in Alzheimer's disease, may be accompanied by a hyperresponsiveness to the behavioral effects of nicotine or other compounds acting at nicotinic receptors.

EFFECT OF SYSTEMIC AMFONELIC ACID ON CHRONIC INTRACAUDATE INFU-SION OF AMPHETAMINE ON ROTATIONAL BEHAVIOR IN THE RAT. E. H. Ellinwood, Jr., J. K. Nishita\*, and T. H. Lee\*. Dept. of Psychiatry, Duke University Medical Center, Durham, N. C. 27710. We have studied the effects of sustained high doses of amphet-125.1 We have studied the effects of sustained high doses of amphet-amine (70 ug/hr) when unilaterally infused into the caudate for 7 days. This paradigm will induce ipsilateral rotational behav-ior to the side of the chronic treatment following systemic in-jection of amphetamine (2-5 mg/kg). Furthermore, these systemic amphetamine injections produce ipsilateral rotational behavior in a dose-dependent manner (Dougherty & Ellinwood, 1981). The behav-ioral changes that occur following chronic amphetamine infusion in the caudate appear to reflect a reduction in dopamine and/or number of terminals. number of terminals.

Recently Steranka (1982) has demonstrated that amfonelic acid (AA) can block the long-term dopamine depleting effects of system-ically administered amphetamine with iprindole, which inhibit its

(AA) can block the long-term dopamine depleting effects of system-ically administered amphetamine with iprindole, which inhibit its metabolism. We tested whether systemic injections of AA could also block the changes in ipsilateral rotational behavior in our chronic intracaudate amphetamine paradigm. Male Sprague-Dawley rats were implanted with bilateral 25 ga cannulae into the caudate nuclei. Following recovery baseline rotational behavior was measured in each rat, and a preferred di-rection for turning responses was determined. Rats were divided into three treatment groups: (1) amphetamine alone, (2) amphet-amine + AA, and (3) artificial cerebrospinal fluid (CSF). Amphet-amine and artificial CSF were continuously infused unilaterally into the caudate for 7 days at a rate of 1 ul/hr through a 32 ga cannula that was attached to an Alzet osmotic pump. On each day of infusion, the amfonelic acid group received a single daily sys-temic injections. Following pump removal, rats were injected systemically with amphetamine (5 mg/kg) and rated for rotational behavior and for intoxication effects. Four weeks after the last test, rats were sacrificed for determination of striatal dopa-mine levels using HPLC coupled with electrochemical detection. Dopamine levels in the infused caudate were compared to the con-tralateral side. tralateral side.

Rats treated with AA showed significantly lower levels of amphetamine-induced rotational behavior than controls. These results are in agreement with Steranka (1982), and demonstrate that sys-temic AA is capable of blocking the behavioral effects of chronic intracaudate amphetamine infusion.

Dougherty & Ellinwood, Biol Psychiatry, 16, 479-488, 1981. Steranka, Brain Res, 234, 123-136, 1982.

while there is well as the short-term monoadjregation eminates of ampletamines (Moore, K.E., J. Pharmacol. <u>142</u>:6, 1963; Lokice <u>et al.</u>, Eur. J. Pharmacol. <u>44</u>:391, 1977), there is a paucity of data on whether aggregation and other environmental variables influence the recently discovered long-term, apparently

groups of male albino rats weighing approximately 250 g were used: saline-isolates, saline-aggregates, METH-isolates and METH-aggregates. Isolated rats were housed in suspended wire-mesh cages measuring 7.5 x 9.5 x 7". Aggregate rats were housed 12 per cage in similar but wider cages measuring 25 x 9.5 x 7". Rats administered METH received the drug subcutaneously at a dose of 15 mg/kg every 6 hours for 24 hours. Control rats were in-jected with saline. Aggregation was begun just prior to the first injection and terminated 6 hours after the last injection.

Aggregated rats that died during the drug regimen were replaced with untreated rats. At all other times during the experiment,

Ngi cycle and the state of the form of the form the experiment, all rats were housed singly with ad libitum access to food and water. Ambient temperature was  $22 \pm 1^{\circ}C$ . Two weeks after the last injection, 8 rats were randomly selected from the surviving rats in each of the above-mentioned groups and killed for hippo-campal 5HT assay. 5HT was measured by cation-exchange liquid chromatography coupled with electrochemical detection. Aggrega-tion increased the lethal effect of METH. Mortality in the METH-isolate group was 10% (1/10) whereas in the METH-aggregate group it was 25% (6/24). Aggregation also increased the long-lasting 5HT depleting action of METH. Hippocampal 5HT was decreased by 51% in the METH-isolated group, whereas in the METH-aggregate group it was decreased by 78%. This difference was significant at the 0.01 level. Aggregation per se did not lower 5HT level. These results indicate that environmental factors such as aggre-gation can enhance the toxic effect of amphetamines on central 5HT neurons. Whether aggregation sis currently being examined.

Shi her offset, whether aggregation also enhances the barned. Finally, the mechanisms underlying this effect are also under investigation. Four

taxic, effects of ampletamines on brain monoamine-containing neurons. The purpose of this study was to determine whether aggregation increased the toxic effect of d-methamphetamine (METH) on brain serotonin (SHT) and dopamine (DA) neurons. I groups of male albino rats weighing approximately 250 g were served solice inclusion and the approximately 250 g were

- 125.2 PROGRESSIVE ALTERATIONS IN BEHAVIOR DURING TWO DOSE LEVELS OF
  - CONTINUOUS AMPHETAMINE. <u>G. Ellison</u>, <u>Fredricka Martin<sup>\*</sup></u>, and <u>Lynn Wilkinson<sup>\*</sup></u>. Dept. of Psychology, UCLA, Los Angeles CA 90024 Amphetamines, when administered continuously, reliably elicit psychoses in humans. In animals, continuous amphetamines have unique neurotoxic effects in caudate and elicit a "late-stage" of abnormal social and other behaviors.

In order to clarify the stages of behavioral alterations during continuous amphetamines, and the role of motor stereo-typies in the elicitation of these effects, rats were observed typies in the elicitation of these elicits, fats were observed repeatedly throughout 14 days of very stable levels of drug administration. Two doses of continuous amphetamines were studied: a "high" dose which elicited appreciable motor stereo-typies throughout the first 10 days after pellet implantation, and a "low" dose which resulted in minimal or no stereotypies. The animals, and controls, were observed while in their home cage using time-sample procedures. Closed-circuit TV images were scored by blind observers using 26 response categories which were directly fed into minicomputer for subsequent analysis.

The animals administered the high dose were rarely inactive throughout the first ten days following pellet implant. Their motor stereotypies progressed from sniffing the floor of the cage to biting at the floor, as has been reported with repeated injections of amphetamine. These animals showed a consistent suppression of most forms of grooming, such as body washing and scratching, but an increase in grooming of the paws which developed into mild self-mutilation in several rats. Tolerance to the activating and appetite-suppressing properties of amphetamine had developed by the 10th or 11th day after

of amphetamine had developed by the loth or lith day after pellet implantation on several measures. In contrast, the low-dose animals did not enter motor stereotypies, but did show a similar progression from initial sniffing at the ceiling of the cage, in brief but frequent bouts, to biting at the ceiling of the cage. Thus, motor stereotypies are not essential for this progression from sniffing to biting. The low dose animals also showed increased body shakes and limb-flicks during the later stages of suppressed in the high dose animals throughout pellet action. Motor stereotypies thus may have an active role in suppressing or masking "late-stage" behaviors.

AGGREGATION INCREASES LONG-LASTING SEROTONIN DEPLETION INDUCED BY d-METHAMPHETAMINE. G.A. Ricaurte\*, P. Malpas\*, L. Seiden and C.R. Schuster, Depts. Pharmacol. & Physiol. Sciences & Psychiatry, University of Chicago, Chicago, IL 60637. While there is considerable evidence that aggregation enhan-125.4

EEG STUDIES DURING TOXIC LEVELS OF AMPHETAMINE. C. C. Turbes, G. T. Schneider\* and R. J. Morgan. Dept. of Anatomy, Creighton Univ. Sch. of Med., Omana, NE b8178 These studies are carried out on 12 male and female cats using hardwire and telemetry. Chronic electrodes are placed in the basal amygdala, nucleus accumbens and anterior sigmoid gyrus. Repeated doses of d- and 1-amphetamine showed symptoms of moderate intoxication. Symptoms associated with these doseslevels are: tacnycardia, hypertension, hyperthermia, dilated pupils, muscular dyskinesia stereotypy, rapid shallow breathing, vomiting, diarrnea, and urinary retention. Hallucinatory-like behavior and confusion was apparent on the second and third days of amphetamine.

Hallucinatory-like behavior and confusion was apparent on the second and third days of amphetamine. Analog data is collected on FM tape and recordings are made on a polygraph. The data is analog to digitally converted and processed on a V-72 Varian minicomputer. Power spectral, cross correlation and coherence spectral analyses are used. Changes in the electrical activity of the amygdala, nucleus accumbens and anterior sigmoid gyrus showed desynchronization at 1 to 44 Hz with mild toxic levels of amphetamine. At moderate toxic levels of amphetamine, there is increased synchronization above 40 Hz up to 100 Hz, with increase in coherence at these frequencies. There is an increase in coherence above 250 Hz on the second to fifth day of amphetamine. In some cats this is related to confusion and hallucinatory-like behavior.

125.3

DOPAMINERGIC AND NEOSTRIATAL NEURONS: DOSE-DEPENDENT CHANGES IN 125.5 SENSITIVITY TO AMPHETAMINE FOLLOWING LONG-TERM TREATMENT. <u>Kats</u> <u>Kamata\* and George V. Rebec</u> (SPON: W.D. Neff). Dept. Psychol., Indiana Univ., Bloomington, IN 47405. Katsuo

Certain components of the behavioral response to amphetamine are enhanced with repeated injections. This augmentation may erflect, in part, a subsensitivity of autoreceptors on dopamin-ergic (DA) neurons in the substantia nigra pars compacta (SNC). According to this view, a decrease in autoreceptor sensitivity would mean less inhibition of DA neurons and, thus, an enhanced effect on postsynaptic neurons in the neostriatum (Muller, P. and Seeman, P., <u>Eur. J. Pharmacol.</u>, 55:149, 1979). Recordings of amphetamine-induced changes in SNC activity, however, have pro-duced conflicting findings. Thus, whereas a reduction in the sensitivity of inhibitory autoreceptors has been reported follow-ing long-term treatment with 4.0 mg/kg (Antelman, S.M. & Chiodo, Ing long-term treatment with 4.6 mg/kg (Anterman, 5.4. & othodo, L.A., <u>Biol. Psychiat.</u>, <u>16</u>:171, 1981), other investigators (Staunton, D.A. et al., <u>Brain Res.</u>, <u>188</u>:107, 1980) found no differences in the responsiveness of DA neurons following pretreatment with either saline or with even higher doses of amphetamine. To resolve this issue, we recorded neuronal activity simultaneously from postsynaptic neurons in the neostriatum and from DA neurons in the SNC following long-term treatment with saline or

with a wide range of amphetamine does. Adult, male rats were pretreated with saline, 1.0 or 5.0 mg/kg d-amphetamine twice daily for 6 consecutive days. Single-unit recording on the following day revealed a differential shift in the iv dose of the drug required to produce at least a 50% change in neuronal activity (ED50) depending on the pretreatment dose. In the SNC, pretreatment with the low dose significantly reduced the ED50 compared to saline controls, whereas in rats pretreated with the high dose the ED50 was significantly increased. More-over, in the high-dose group an iv challenge injection of 0.25 mg/kg d-amphetamine accelerated SNC activity--an effect that was never observed in control animals. In the neostriatum, control rats responded to increasing incremental doses of d-amphetamine with either an inhibition followed by an excitation or an excita-tion. Following pretreatment with 1.0 mg/kg neurons responded with either a depression or an excitation, whereas only amphetamine-induced excitations were recorded in the neostriatum following pretreatment with 5.0 mg/kg. Thus, although the changes in firing rate produced by repeated exposure to amphet-amine are dose-dependent in both sites, a decrease in autorecep-tor sensitivity may explain our results in the SNC following long-term treatment with high amphetamine doses.

- AMPHETAMINE TOLERANCE AND BODY WEIGHT SET POINT: A DOSE 125.6
  - RESPONSE ANALYSIS. D. L. Wolgin and J. Salisbury\*. Psychology Dept., Florida Atlantic University, Boca Raton, FL 33431. Rats given amphetamine and access to food initially eat very little. However, if the drug is given chronically, intake gradually recovers. Such recovery is generally thought to reflect tolerance to the drug. Recently, Stunkard (Life Sci., 1982, 30, 2043) has proposed that amphetamine lowers a set point for body weight regulation, and that tolerance does not develop to this effect. According to this view, the decrease and subsequent increase in food intake during chronic amphetamine administration are secondary to achieving, and then maintaining, a lower weight level. To further evaluate this hypothesis, we examined the effect of long-term exposure to

hypotnesis, we examine the effect of long-term exposure to different doses of amphetamine on food intake and body weight. Rats were given 0, 2, or 4 mg/kg of d-amphetamine sulfate 20 min before daily access to sweetened milk, which was available for 30 min. Both drugged groups were initially anorexic and lost weight. While milk intakes recovered to control levels on Days 11 and 18, respectively, body weights remained below the level of controls throughout the 48 days of drug administra-Rats given 2 mg/kg maintained their weights at 94-96% of controls. Rats given 4 mg/kg maintained their weights at 86-88% of controls for 15 days, but then increased their intakes and gradually gained weight to 94% of controls by Day 48. Thus, at the 4 mg/kg dose, partial tolerance developed to the initial weight suppressant effect of amphetamine. Drug doses were then increased to 4 and 6 mg/kg, respec-tively, for an additional 63-74 days. Intense stereotyped

movements developed in both groups of rats during this period. Milk intake was suppressed in both groups during the first month, and then recovered during the second month, although month, and then recovered during the second month, although control levels of intake were not consistently maintained. Body weights in both groups dropped to as low as 76%, but were generally maintained between 78-82% of control levels. How-ever, for individual rats, milk intake during this period of maintained body weight was extremely variable from day to day, particularly in the group given 6 mg/kg. These large fluctua-tions in intake, along with the confounding effects of drug-induced teremetry. induced stereotypy, challenge any simple interpretation of the data in terms of a lowered set point for body weight.

FOREBRAIN DOPAMINE BLOCKADE DISAPPEARS DURING 6 MONTHS OF NEUROLEPTIC ADMINISTRATION. K.J. Pittman\*, A. Jakubovic, and H.C. Fibiger (SPON: E.G. McGeer). Div. of Neurological Sciences, Univ.of British Columbia, Vancouver, B.C., Canada, V6T IWS. Although the antipsychotic properties of neuroleptic drugs have been attributed to their capacity to block dopaminergic transmission, recent studies have shown that behavioral and bio-chemical indices of DA blockade within the striatum disappear after approximately 6 months of continuous neuroleptic adminis-tration, followed in some instances by a supersensitive condition. The present study sought to determine whether a similar situation applies to terminal regions of the mesocortical/mesolimbic dopa-mine projections; whether the rate and degree of tolerance is de-pendent upon the type of neuroleptic affect striatal choline acetyl-transferase (ChAT) and glutamic acid decaboxylase (GAD) activi-ties. FOREBRAIN DOPAMINE BLOCKADE DISAPPEARS DURING 6 MONTHS OF 125.7 ties

Male Long-Evans rats received cis-flupenthixol (FLU) (.8-1.0 mg/kg/day) or trifuluperazine (TRI) (2.0-3.0 mg/kg/day) for 1 week, 1 month, 3 months, or 6 months and were compared to control animals on measures of spontaneous locomotion, amphetamine-induced locomotion, and apomorphine-induced stereotypies. The levels of DA, DOPAC, HVA, 5-HT, and HIAA in the striatum, nucleus accumbens, olfactory tubercles, and medial frontal cortex were measured by HPLC.

Although behavioral responses were attenuated to a similar Although behavioral responses were attenuated to a similar degree following one week of either drug, complete tolerance appeared by 3 to 6 months on all measures. Furthermore, animals treated with TRI showed a supersensitive response to the locomo-tor-inducing effects of amphetamine as early as 1 month which persisted to the end of the study. The neuroleptics caused a sig-nificant elevation in the levels of DOPAC and HVA in all brain regions fitter are used but this disconcered by 2.6 months. regions after one week but this disappeared by 3-6 months. Con centrations of DA, 5-HT, and HIAA were not consistently altered at any time in any area. Striatal GAD and CAT activities were not influenced by 1 week or 6 month administration of either Conneuroleptic.

neuroleptic. These results suggest functional measures of dopamine receptor blockade in the rat forebrain disappear in the course of 6 months administration of neuroleptic drugs. As these findings contrast markedly with the long-term antipsychotic efficacy of these com-pounds, a reassessment of theories concerning their mode of action may be warranted. The augmented response to amphetamine of animals treated with the phenothiazine drug TRI suggests that this class of neuroleptic may more easily elicit dyskinetic symptoms than thioxanthene drugs such as FLU. Supported by grants from MRC and AHFMR.

125.8 SENSITIZATION OF NEURONS IN THE AMYGDALOID COMPLEX TO CLOZAPINE, BUT NOT HALOPERIDOL, WITH LONG-TERM TREATMENT. <u>Glenn D.</u> <u>Anderson\* and George V. Rebec</u> (SPON: T.R. Bashore). Dep Psychol., Indiana Univ., Bloomington, IN 47405. Dept.

We have previously shown that, unlike the neostriatum and the nucleus accumbens, the amygdaloid complex is differentially responsive to cataleptogenic and non-cataleptogenic antipsychotic drugs (Rebec, G.V. et al., <u>Pharmacol. Biochem. Behav.</u>, <u>14</u>:49, 1981). Haloperidol, for example, exerts little if any effect on amygdaloid activity even at doses that produce intense catalepsy, whereas clozapine, which fails to produce this response, typically accelerates firing rate in this site. Because these drugs exert their greatest clinical effects with long-term use, we extended our investigation of the amygdaloid complex to chronically treated rats.

After receiving 2 daily injections of saline, 1.0 mg/kg haloperidol, or 10.0 mg/kg clozapine for 6 consecutive days, rats were prepared for single-unit recording on the following day and Were prepared for single-unit recording on the following day and challenged (ip) with either haloperidol or clozapine. Consistent with previous evidence, clozapine, but not haloperidol, acceler-ated amygdaloid activity in saline controls. Thus, whereas haloperidol failed to change firing rate in the amygdaloid com-plex, clozapine accelerated activity to approximately 200% of the preinjection baseline rate. Following chronic treatment, this difference become even more pronounced. Clozapine for example difference became even more pronounced. Clozapine, for example, routinely increased firing rate to beyond 700% but haloperidol, as in saline controls, was largely without effect. In fact, haloperidol failed to alter amygdaloid activity in separate groups of rats pretreated with the drug for as long as 13 days. These results suggest that whereas amygdaloid neurons remain unresponsive to haloperidol even after long-term treatment, they become progressively more responsive to repeated injections of clozapine.

APOMORPHINE-INDUCED INHIBITION OF NEOSTRIATAL ACTIVITY IS 125.9 ENHANCED BY 6-HYDROXYDOPAMINE LESIONS BUT NOT BY LONG-TERM AMPHETAMINE ADMINISTRATION. <u>Kevin D. Alloway and George V.</u> <u>Rebec</u>. Dept. Psychol., Indiana Univ., Bloomington, IN 47405. It has been suggested that the behavioral augmentation produced by long-term amphetamine treatment is mediated, at least in part, by an increase in the sensitivity of postsynaptic dopamine (DA) receptors (Klawans, H. & Margolin, D., <u>Arch. Gen. Psychiat.</u>, 32:725, 1975). We tested this hypothesis by recording the ef-fects of increasing incremental doses of apomorphine, a DA receptor agonist, on single-unit activity in the neostriatum of local-ly anesthetized, immobilized rats that were pretreated twice daily with saline, 1.0, 5.0, or 10.0 mg/kg d-amphetamine for 6 consecutive days. In addition, because depletion of neostriatal DA increases DA receptor sensitivity (Creese, I. et al., Science, 197:596, 1977), we also included a group of rats that sustained unilateral 6-hydroxydopamine (6-OHDA) lesions 2 weeks prior to

single-unit recording. Examination of the dose-response curve for neurons inhibited by apomorphine (0.0025 to 0.32 mg/kg, iv) revealed that 6-OHDA, by appoint prime (or loss to or law grag, in prevented that or only, but not long-term ampletamine administration, increased the sen-sitivity of postsynaptic DA receptors. Thus, compared to saline controls, the median effective dose for producing a 50% inhibi-tion of firing rate was significantly reduced in the neostriatum of 6-OHDA-lesioned rats but not in rats pretreated with ampletamine. In fact, whereas all the ipsilateral neurons sampled from rats with a 6-OHDA lesion were inhibited by apomorphine, this response was recorded in only 62% of control neurons and only in 44 to 62% of neurons from the 3 groups of rats pretreated with amphetamine. Moreover, neostriatal activity on the lesioned side amphetamine. Moreover, neoscritical activity on the restore state was depressed to a greater extent than in control rats for apomorphine doses ranging from 0.01 to 0.08 mg/kg. Unexpectedly, neurons from the intact side of 6-OHDA rats also responded to apomorphine (0.005 to 0.02 mg/kg) with a greater decrease in apomorphile (0.005 to 0.02 mg/kg) with a greater decrease in firing rate than in saline controls. The response of amphet-amine-pretreated rats, on the other hand, paralleled that of control animals. It appears, therefore, that long-term amphet-amine administration produces an augmentation of behavior by some mechanism other than an increase in the sensitivity of postsynaptic DA receptors.

Supported, in part, by USPHS Grant DA-02451 (GVR).

125.10 BEHAVIORAL EFFECTS OF DRUG HOLIDAYS IN CHRONIC HALOPERIDOL ADMINISTRATION. W.W. Sant III, R. Cruz\*, M. Morgan\*, and G. Ellison. Dept. Psychology, UCLA, Los Angeles, Ca. 90024

A number of clinicians have suggested that periodic drug-free intervals, drug holidays, in neuroleptic administration may decrease the incidence of tardive dyskinesia (TD) in general, or of persistent TD in particular. One retrospective clinical study found a positive relationship between drug holidays and study found a positive relationship between drug holidays and persistent TD. However, this study also reported a positive relationship between number of drug holidays and length of neuroleptic administration. We undertook an examination of the effect of drug holidays on the behavioral effects of chronic haloperidol administration in rats while controlling for total exposure to haloperidol.

Two groups of female, Sprague-Dawley albino rats received haloperidol and lactic acid in their drinking water for 12 weeks. In one group haloperidol administration was uninterrupted, while in the other group three evenly spaced, one-week-long drug-free intervals were given. A control group of animals received lactic acid in their water throughout the experiment.

Animals receiving haloperidol had a mean daily intake of about 0.8 mg/kg of the drug and showed a gradual increase in body weight while control animals did not. Daily home-cage activity was dramatically depressed to about 25% of control levels on the first day of haloperidol administration and remained unchanged for the following three weeks of drug administration. Indeed, there was no attenuation of haloperidol's depression of home-cage activity after 9 weeks of either interrupted or uninterrupted haloperidol administration. During the first drug holiday, after three weeks of halo-peridol administration, activity levels rose to control levels within two days and continued to increase, peaking on the fifth day of the holiday and then returning to control levels on days

(a) of the binds with the result of a definition of the binds of the second The time-course of these increases differed between rats served. that had received drug holidays and those that had not, indicating that drug administration regimen can alter the time-course of behaviors seen after neuroleptic withdrawal. 125.11 ROLE OF ANXIETY IN MEDIATING CHLORDIAZEPOXIDE-INDUCED REDUCTION OF CORTICOSTERONE RESPONSE TO STRESS. <u>G.B. Freeman and J.B.</u> <u>Thurmond</u>. Neuropsychopharmacology Lab., University of Louisville, Louisville, KY 40292.

Anti-anxiety drugs are effective in reducing stress-induced increases in corticosterone (CS) and emotional behavior in the mouse. It was proposed whether chlordiazepoxide (CDP) has a direct effect on the CS response or whether this drug indirectly affects CS levels by decreasing an animal's emotional respon-siveness (anxiety) to acute noise stress. The role of the monoamines in CS response regulation and the mediation of emo-tional behavior in response to stress was investigated by comwith acute CDP (5, 10, 20, 40 mg/kg). The effects of stress did not produce a behavioral profile

consistent with a model of anxiety. Exploration and locomotor activity were increased by stress. This activation enhanced the stimulatory effect of low doses of CDP and attenuated the de-pressant action of higher doses. Quipazine reduced the depres-sant effects of CDP in stressed animals. Its action failed to support an anti-serotonergic action of CDP. Clonidine antag-onized the stimulatory action of low doses of CDP and provided support for the notion that the stimulatory effect of CDP may be due to enhanced catecholamine neurotransmission, especially NE.

NE. Exposure to stress produced a two-fold increase in CS which was reduced by 5 mg/kg of CDP. An inverse relationship between behavior and CS was demonstrated for nonstressed mice. The depressant action of CDP in nonstressed mice may have stimulated the hypothalamic-pituitary system. The lack of a strong rela-tionship between CS and behavior in stressed mice suggested that postulating anxiety as a theoretical intervening variable between the depress of the hereodiagneeine of the reduction of the CC. the effect of the benzodiazepines and the modulation of the CS response may not be justified. Chlordiazepoxide may have affected the CS response in some other way than by reducing an animal's emotional responsiveness to stress. Alternatively, increases in CS levels, rather than behavioral performance, may be a more suitable index of the emotional responsiveness of an animal. Subsequent reduction of this response with low doses of CDP may be a more appropriate indication of the anxiolytic effect of the benzodiazepines. Changes in CS resulting from agonist treatment indicated that

the mechanisms controlling basal CS levels may be different and separate from those mediating the CS response to stress.

125.12 Ro15-1788 PARTIALLY BLOCKS DEVELOPMENT OF CHLORDIAZEPOXIDE NIS INCOMMENTALITY DESCRIPTION OF A STATEMENT OF of classical anxiolytic-sedative-hypnotic benzodiazepines (BNZs). R/A antagonizes BNZ actions by displacing BNZs from their recep-tors and is relatively devoid of other pharmacologic activity. Previously several laboratories including ours (Neurosci. Abstr. 396, 1982) have demonstrated that R/A can precipitate an acute withdrawal (W/D) reaction in several species of lab animals

chronically treated with various BNZs. These studies support the concept that the displacement of active BNZs from the receptor triggers the expression of W/D after dependence has been induced. To further characterize the involvement of BNZ receptors in dependence, we have studied the effects of daily R/A administration during the induction of BNZ dependence. Dependence was induced by intragastrically administered chlordiazepoxide HC1 (CDP), 75 mg/kg, bid for 5 weeks (chronic CDP group). The chronic CDP + R/A group received 25 mg/kg of R/A, p.o., 2 hours after each morning dose of CDP. Water controls (chronic H20) received equivalent volumes of H20, i.g., bid for 5 weeks. Chronic R/A controls (chronic H20 + R/A) received 25 mg/kg R/A 2 hours after each morning dose of H20. On the last day of chronic treatment, all animals received R/A 25 mg/kg, i.p., 4 hours after the last a.m. CDP or H20 dose. Precipitated W/D was measured by 4 or 5 independent experienced observers who rated the intensity of 20 W/D sirns on a scale of 0 to 3. The WD score is the mean summed rating. The W/D syndrome was qualitatively similar but less during the induction of BNZ dependence. Dependence was induced rating. The W/D syndrome was qualitatively similar but less severe for chronic CDP + R/A compared to chronic CDP. R/A pre severe for chronic CDP + R/A compared to chronic CDP. R/A pre-cipitated 12.7 ( $\pm$  1.0 S.E.) and 14.8 ( $\pm$  0.6 S.E.) sims/rat for chronic CDP + R/A and chronic CDP, respectively. Peak WD scores were 16.6 ( $\pm$  1.7 S.E.) and 24.3 ( $\pm$  1.1 S.E.), respectively. The mean peak intensity of 9 individual rarded signs was signifi-cantly less for CDP + R/A compared to the CDP group. Chronic  $H_{20}$  and chronic  $H_{20} + R/A$  controls showed negligible W/D manifestations. This study demonstrates that chronic co-administration of R/A anc CDP attenuates the precipitated W/D and suptration of R/A anc CDP attenuates the precipitated W/D and sup-ports the involvement of BNZ receptors in both induction and ex-pression of physical dependence. The incompleteness of depen-dence blockade in this study may reflect the extremely short half-life of R/A in the rat which provided only intermittent as opposed to continuous receptor blockade. Additional nonreceptor specific mechanisms may also contribute to dependence induction. (Supported in part by NIDA Grant DA-02398 and by BRSG Grant

EFFECT OF PROLYL-LEUCYL-GLYCINAMIDE (PLG) ON 17B-ESTRADIOL (E2) 125.13 SUPERSENSITIVITY OF DOPAMINE (DA) RECEPTORS. <u>G. Rajakumar\*</u>, <u>P. Chiu\*, and R.K. Mishra\*(SPON: C. R. Merril)</u>. Dept. Neurosciences, 4N52, Faculty of Health Sciences, McMaster Univ., Hamilton, Ontario Canada.

Estrogen administration to male rats has been shown to increase the density of striatal DA receptors without changing their affinity. This has been documented both from behavioural and direct binding studies. The effect of estrogen on DA receptor has potential clinical implications in view of the findings that chorea is associated with pregnancy or the use of oral contraceptives. It is also claimed that ovarectomy of guinea pigs decreased stereotypy and in rats decreased DA stimulated adeny cyclase activity, but administration of estrogen reversed late both these effects.

Earlier studies from this laboratory had shown that PLG suppressed the supersensitized DA receptors induced by neuro-leptics. We now report the results of PLG administration on

leptics. we now report the results of PLS administration on estrogen induced supersensitivity in male rats. 17B-Estradiol was administered(S.C.)20 µg/kg-5 days followed by 60 µg/kg-5 days to induce supersensitivity. PLG 20 mg/kg(S.C.) was administered prior to and concurrently with estradiol administration to separate groups of rats (6 in each group). Plantation of the second prior (7). administration to separate groups of rats (o in each group). Biochemical characterization (K<sub>4</sub> & B<sub>2</sub>) of striatal DA receptors was carried out by diffect Dinding studies with <sup>3</sup>H-spiroperidol and 1 µm (d) butaclamol as the displacing agent. E<sub>2</sub> administration produced 205% of control B<sub>2</sub> of DA receptors suggesting the development of supersensitivy. While

While re-treatment and concurrent treatment of PLG produced 69% and 92% of control B respectively. -1

### PSYCHOTHERAPEUTIC DRUGS: ANTIDEPRESSANTS

THE AMYGDALA IS A SITE OF ACTION OF IMIPRAMINE IN A SCREEN FOR ANTIDEPRESSANT AGENTS. <u>G.E.Duncan\*, G.R.Breese and W.E.Stumpf</u>. Depts. of Anatomy, Psychiatry and Pharmacology and the Biol.Sci. Res.Ctr., Univ. of North Carolina, Chapel Hill, NC 27514. Many brain regions contain specific receptor-like binding sites for imipramine (IMP), (Palkovits et al. <u>Br.Res.</u>, 210:493,1981). However, IMP's therapeutic actions and behavioral effects in ani-mal models of depression may result from the interaction of the dwo with conceific neuropatomical systems. Nowever, this is therefore a transform a behavious behavious the interaction of the drug with specific neuroanatomical systems, rather than in all areas of the CNS that contain IMP receptors. In order to determine if the action of IMP can be localized to discrete areas of the CNS, IMP was infused into different brain regions of rats and tested using a behavioral model of depression (Porsolt et al.,  $\underline{Eur, J.Pharm.47:379,1978}$ ). The Porsolt test is a "learned helplessness" paradigm in which rats are forced to swim in a cylinder containing water (25°C) on two days. The first day, rats are placed in the cylinder for 15 min. After approximately 10 min the rats become immobile and float in the water. On the second day, the rats are placed in the cylinder for a 5 min period. After one to two min of activity, saline-treated rats become immobile and float in the selectively and markedly reduce the amount of time that rats are immobile during this 5 min period even though the drugs decrease open field activity (Porsolt, et al., 1978). 1978)

even though the drugs decrease open field activity (Porsolt, et al., 1978). In the present study all rats were given 15 mg/kg IMP i.p.after the 15 min swim. On the second day of the test, IMP (0.1 to 10 ug) dissolved in 0.5 ul of 0.9% NaCl or 1.9% OF 0.9% NaCl or 0.5 ul of 0.9% NaCl or 0.9% N

126.2 ANALGESIC PROPERTIES OF MJ 13754, A NONTRICYCLIC ANTIDEPRESSANT CANDIDSTE I. D. W. Smith\*, M. S. Eison, L. A. Riblet, D.P. Taylor, J. P. Yevich, and D. L. Temple, Jr. CNS Research, Pharmaceutical Research and Development Division of the Bristol-Myers Company, Evansville, IN 47721.

Recently we identified<sup>1</sup> MJ 13754, known chemically Recently we identified<sup>4</sup> MJ 13754, known chemically as 2-(3-[4(3-chlorophenyl)-1-piperazinyl]propyl)-5-ethyl-2, 4-dihy-dro-4-(2-phenoxyethyl)-3-1,2,4-triazol-3-one, as a nontricyclic antidepressant candidate exhibiting a selective serotonergic mechanism of action. MJ 13754 was found to protect against reserpine-induced ptosis in mice, thus suggesting antidepressant activity. MJ 13754 was further distinguished by <u>in vitro</u> receptor binding data. Adrenergic ( $\alpha_1, \alpha_2, \text{ and } \beta$ ), cholinergic (muscarinic), and histaminic receptor affinities were lacking. However, MJ 13754 was found to bind with high affinity <u>in vitro</u> to the serotonin 50 receptor (ICso = 39 nM).

However, MJ 13754 was found to bind with high affinity in vitro to the serotonin S<sub>2</sub> receptor ( $IC_{50} = 39$  mM). Because many tricyclic antidepressants (TCA) enjoy analgesic properties, we have evaluated the antinociceptive properties of MJ 13754. Two models for analgesia were employed: phenyl-quinone induced writhing (PQW) in mice and shock-induced vocali-zation in the rat. The potency of MJ 13754 was compared with the following TCAs: amitriptyline, clomipramine, desimipramine, doxepin, and imipramine. Also included was the nontricyclic antidepressant trazodone; and the simple piperazines m-chloro-phenylpiperazine (MCPP) and m-trifluomethylphenylpiperazine (MTTPP); and MJ 14858 (2-(3-[4-(3-trifluoromethylphenyl)-1-piperazinyl]propyl)-5-ethyl-2,4-dihydro-4-(2-phenoxyethyl)-3H-1, 2,4-trizaol-3-one). Of the TCAs examined, only amitriptyline was (hirr), and histo ( $2^{-(3)}$ ) ( $-(2^{-(3)}$ ) ( $-(2^{-(3)}$ ) ( $-(2^{-(3)}$ ) ( $-(2^{-(3)}$ ) ( $-(2^{-(3)}$ ) ( $-(2^{-(3)}$ )) ( $-(2^{-(3)})$ ) (centrally-enhanced serotonergic transmission.

THE PREDICTION OF THERAPEUTIC NORTRIPTYLINE DOSAGE REGIMES AND 126.3 THE PREDICTION OF THERAPEUTIC NORTHIPTYLINE DOSAGE REGIMES AND RELATED PLASMA CONCENTRATIONS OF HYDROXYLATED METABOLITES IN GERLATRIC DEPRESSIVES. A. L. C. Pottash<sup>1</sup>, D. M. Martin<sup>\*1</sup>, I. Extein<sup>2</sup>, F. Mas<sup>3</sup>, A. H. Jarvis<sup>\*3</sup>, R. G. Zirk<sup>\*1</sup> and M. S. Goldl. Psychiatric Diagnostic Laboratories of America, Summit, N.J. 07901<sup>1</sup>, Falkirk Hosptial, Central Valley, N.Y. 10917<sup>2</sup> and Gracie Square Hospital, New York, N.Y. 10021<sup>3</sup>. Nortriptyline (NOR) is one of the most widely used tricyclic retiference of the measurement of and remained demographic (The

antidepressants in the management of endogenous depression. This is due in part to the extensive documentation and utility of a plasma therapeutic window (50-140 ng/ml)<sup>1</sup> and single dose prediction test.<sup>2</sup> These measures allow physicians to rapidly achieve and maintain patients at therapeutic blood levels for 21 consect tive days which provides an objective, operationally defined antidepressant trial. Yet, during chronic NOR therapy plasma levels of NOR vary greatly between individuals on identical dos levels of NOR vary greatly between individuals on identical cos-age regimes and a small group of patients within the therapeutic window have minimal clinical response. 10-hydroxynortriptyline (10-OH NOR), a biologically active metabolite of NOR, also varies as greatly if not more than NOR. 10-OH NOR metabolism can be responsible for interindividual variation of NOR levels as well as elevating active plasma levels above the therapeutic range. 10-OH-NOR is primarily cleared from the plasma compartment by renal excretion which can be greatly decreased in geriatric pop-ulations. This can result in accumulations of 10-OH-NOR and may be an important compound to therapeutically monitor and include

a mean age of 63 years was studied over two months. They were maintained on varying doses of NOR as determined by a single 50 maintained on varying doses of now as determined by a single so mg loading dose and subsequent plasma level obtained 24 hours later. Plasma levels<sup>3</sup> and clinical depression rating scales were obtained weekly. In a preliminary analysis it was noted that in all patients the presence of significant amounts of 10-OH-NOR252 + 131 ng/ml existed after steady state mean NOR concentra-tions 119 + 38 ng/ml were attained. This observed concentration to flo-0H-NOR was significantly higher (p<.001) than concentra-tions noted in an adult population (N=20) mean age 44, with therapeutic levels 128 + 22 ng/ml of NOR and 110 + 70 ng/ml of 10-0H-NOR. The incorporation of 10-0H-NOR into loading dose plasma analysis indicated patients who hypometabolized NOR 10-0H-NRR. It is this group of patients that yielded the highest 10-OH-NOR levels once therapeutic NOR plasma concentrations were attained. These and other clinical data will be presented by the authors.

INTERRELATIONSHIPS BETWEEN ADAPTATION TO STRESS AND ANTIDEPRESSANT 126.4 TREATMENT. J.E. Platt, R. Trullas\*, A.V. Slucky\*, and E.A. Stone. Dept. Psychiatry, New York Univ. Sch. Med., New York, NY 10016

Repeated stress and chronic antidepressant treatment have been shown to have similar effects on noradrenergic receptor function in rat brain in that both lead to reduced beta adrenergic receptor density and a decreased cAMP response to norepinephrine. Repeated restraint stress has also been shown to induce a positive response on a behavioral screening test for antidepressants. The present studies examined further the interrelations between adaptation to stress and antidepressant treatment.

The first study was designed to test if pretreatment with anti-depressants could mimic the effects of adaptation and thereby re-duce the adverse effects of stress. Rats were treated with DMI according to a decending dose schedule (10mg/kg b.i.d. - 7.5mg/kgonce daily). Restraint stress (5 h) was administered after 14 and 21 days of DMI. Adverse reactions to stress (anorexia, gastric ulcers and plasma corticosterone elevation) were assessed after the first and second stress sessions. DMI-treated rats showed a significantly smaller decrease in

food intake following acute stress (first stress session) than controls (14,47%  $\pm$  0.63% vs. 38.83%  $\pm$  1.3%, p<.0001). They a had significantly fewer ulcers (second stress session) (0.63  $\pm$ They also 0.42 vs. 2.00 + 0.65, p<.05, one tailed) and were more likely to be ulcer-free (Fisher Exact Test, p = .067). Plasma corticosterone levels are currently being analyzed. The second study was the converse of the first and was designed

to determine if pretreatment with chronic stress (adaptation) could mimic the effects of antidepressants on a pharmacological screening test (attenuation of clonidine (1004g/kg) or reserpine

screening test (attenuation of clonidine (1004g/kg) or reserpine (5mg/kg) hypothermia). Rats were treated for 10 days with restraint stress (2.5 h per day) or with DMI (10mg/kg i.p.). Tests were conducted 24 hours after the last stress or injection. Stressed rats showed significantly less clonidine-hypothermia than controls at 60 (p < .05, one tailed), 90 and 120 min. (p < .025 one tailed) post-clonidine and were similar to DMI-treated animals (p < .025 vs. controls, one tailed, at all time points). The reservice test is control to the processing test is control to the p reserpine test is currently under investigation.

These results indicate further parallels between adaptation to stress and antidepressant therapy involving measures of resistance to stress and of preclinical antidepressant activity. They sup-port the hypothesis that antidepressant therapy mimics the central neurochemical changes that occur during adaptation to chronic stress and that this common neurochemical alteration (noradrenergic or other) underlies the observed behavioral and physiological similarities. ENHANCEMENT OF SEROTONINERGIC NEUROTRANSMISSION BY SHORT-TERM LI-

ENHANCEMENT OF SEROTONINERGIC NEUROTRANSMISSION BY SHORT-TERM LI-THIUM TREATMENT: ELECTROPHYSIOLOGICAL STUDIES IN THE RAT. P. Blier and C. de Montigny, Centre de Recherche en Sciences Neu-rologiques, Université de Montréal, Montréal, Canada H3C 3T8. Long-term tricyclic antidepressant (TCA) drug treatment in-creases the response of forebrain neurons to microiontophoreti-cally-applied serotonin (5-HT) in the rat. Lithium (Li) addition to the regimen of most TCA-refractory patients brings within 48 h a marked reduction of the depressive syndrome. It has been pos-tulated that the rapid antidepressant effect of Li in TCA-refrac-tory patients might be due to the enhancement of the activity of 5-HT neurons by lithium. The present studies were undertaken to assess electrophysiologically the effect of Li on 5-HT neuro-transmission. transmission.

transmission. Male Sprague-Dawley rats (250-275 g) were fed with regular chow or chow containing 0.2% Li carbonate for 48 h producing plasma Li concentrations of 0.4\*1.0 mEq/L. Three rats were pretreated with 5,7-dihydroxytryptamine (5,7-DHT) (200  $\mu$ g, free base, intraventricularly) one h after desipramine (25 mg/kg, i.p.) and four weeks before Li treatment. In a first series of experiments, five-barrelled micropipettes were used to record from CA3 hippocampal pyramidal neurons under chloral hydrate anesthesia (400 mg/kg, i.p.). The response of these neurons to the electrical stimulation of the ventromedial ascending 5-HT pathway was determined from peristimulus time his-

these neurons to the electrical stimulation of the ventromedial ascending 5-HT pathway was determined from peristimulus time histograms and their responsiveness to microiontophoretic applications of 5-HT creatinine sulfate (0.5 mM in 0.2 M NaCl, pH: 4) and norepinephrine bitartrate (NE) (0.05 M, pH: 4) was estimated using the I.T<sub>50</sub> method (current x time required to obtain a 50% decrease of firing rate). The responsiveness to 5-HT and NE was not modified by the Li treatment whereas the effect of the electrical stimulation of the ascending 5-HT pathway was increased. The same stimulation failed to produce any suppression of the firing in the 5,7-DHT-pretreated animals.

firing in the 5,7-DHT-pretreated animals. In a second series, unitary recordings of 5-HT neurons were obtained from the mesencephalic dorsal raphe nucleus. Lithium pretreatment did not modify the firing rate of 5-HT neurons. In conclusion, short-term Li modifies neither the responsi-veness of postsynaptic neurons to 5-HT nor the electrical activi-ty of 5-HT neurons but enhances the efficacy of the ascending 5-HT system. This effect of Li might be due to an increased release of 5-HT from forebrain terminals (Treiser et al., <u>Science, 213:</u> 1529, 1981). The present physiological demons-tration of the presynaptic effect of Li on the 5-HT system is consistent with the hypothesis that its rapid antidepressant effect in patients treated with, but not responding to, a TCA drug might be due to an increased amount of 5-HT reaching post-synaptic neurons sensitized to 5-HT by the TCA pretreatment.

ACTIVITY OF NOREPINEPHRINE-CONTAINING NEURONS IN FREELY MOVING CATS: EFFECTS OF TRICYCLIC ANTIDEPRESSANTS. D.W. Preussler and

CATS: EFFECTS OF TRICYCLIC ANTIDEPRESSANTS. <u>D.W. Preussier</u> and <u>M.E. Trulson</u>. (SPON: D.S. Robinson). Dept, of Pharmacol. Marshall Univ. Sch. of Med., Huntington, WV 25701. Tricyclic antidepressant drugs have been hypothesized to exert their therapeutic effects via an inhibition of the uptake of nor-epinephrine (NE) and serotonin (SHT) into central nerve terminals. Antidepressants possessing a secondary amine side chain, such as desipramine and chlordesimipramine are much more potent in inhibit-ing the reuptake of NE than those with a tertiary amine side chain, such as imipramine and chlorimipramine. Since tertiary amine antidepressants are N-dealkylated in the liver to their secondary amine analogues, and the activity of the hepatic enzymes involved in these processes change with a number of factors (such as certain disease states, presence of additional drugs, etc.) we examined the disease states, presence of additional drugs, etc.) we examined th effects of these antidepressants on the activity of NE-containing neurons in freely moving cats and in cats with altered hepatic metabolism. The activity of NE neurons was recorded in the locus coeruleus (LC) of adult male and female cats by means of movable 32 and 64 µ dia. insulated nichrome wires (see Brain Res., 1979, 263, 135-150 for complete methodology). Noradrenergic neurons showed a strong positive correlation with level of behavioral arousal, as previously described (Reiner and Morrison, Soc. Neuro-eci Abetr 8, 1982, n, 392). Mean discharge rates (cnikes/sec) alousal, as pleviously described (kerner and morison, soc. Abst. 8, 1982, p. 392). Mean discharge rates (spikes/sec) for the various behavioral states were as follows: active waking,  $2.72 \pm 0.27$ ; quiet waking,  $1.69 \pm 0.20$ ; slow wave sleep,  $0.77 \pm 0.13$ ; and REM sleep,  $0.09 \pm 0.02$ . Impramine produced dose-dependent decreases in LC unit activity from no significant change at 0.1 decreases in LC unit activity from no significant change at 0.1 mg/kg (i.p.) to a nearly total suppression of activity at 5 mg/kg, as compared to quiet waking. Similarly, chlorimipramine produced dose-dependent decreases in the activity of noradrenergic neurons, from no significant change at 0.5 mg/kg, (i.p.) to a complete suppression of activity at 25 mg/kg. When pretreated with a compound that inhibits drug metabolism (SKF-525A, 40 mg/kg, i.p.) 30 min prior to tricyclic antidepressant drug administration, the  $10_{50}$  for imipramine was increased from 1.28 mg/kg in naive cats to 3.48 mg/kg in the pretreated subject, and the  $ID_{50}$  for chlorimipramine was increased from 11.1 mg/kg to 102.3 mg/kg. Conversely, when the Increased iron 11.1 mg/kg to 102.3 mg/kg. Conversely, when the animals were pretreated with a compound that increases drug metabolism (phenobarbital, 50 mg/kg/day, i.p., for 7 days) the  $ID_{5,0}$  for imfpramine was decreased significantly to 0.54 mg/kg. These data demonstrate that altered hepatic metabolism dramatically influences the effects of tricyclic antidepressants on the activity of central noradrenergic neurons. Therefore, hepatic metabolism should be monitored in patients considered for tricyclic antidepressant medication.

NORADRENERGIC DENERVATION PREVENTS TRICYCLIC ANTIDEPRESSANT-INDU-127.8

NORADRENERGIC DENERVATION PREVENTS TRICYCLIC ANTIDEPRESSANT-INDUCED SENSITIZATION OF RAT FOREBRAIN NEURONS TO SEROTONIN. P. Gravel\* and C. de Montigny. Centre de recherche en sciences neurologiques, Université de Montréal, Québec, Canada H3C 378. Green and Deakin have reported that brain norepinephrine (NE) depletion prevents ECS-induced enhancement of serotonin (5-HT)me-diated behaviour (<u>Nature</u>, 285: 232, 1980). The present experi-ments were undertaken to determine if NE depletion also prevents tricyclic antidepressant (TCA)-induced sensitization to micro-iontophoretically-applied 5-HT. Male Sprague-Dawley rats (200 g) were used. One group re-ceived an intraventricular injection of 6-hydroxydopamine (6-OHDA) (200 µg FB in 20 µl of a 0.9% NaCl and 0.1% ascorbic acid solution), one hour after zimelidine (25 mg/kg, i.p.) given to protect the 5-HT system from 6-OHDA neurotoxic action. Half of this group were subsequently treated for 14 days with 5 mg/kg q.d. of a TCA drug (imipramine or amitriptyline) administered ei-ther by an i.p. minipump (Alza) or by daily i.p. injections and of child group were subsequently treated for it days with singky g.d. of a TCA drug (imipramine or amitriptyline) administered ei-ther by an i.p. minipump (Alza) or by daily i.p. injections and the other half served as controls. Half of another group of intact animals received the same TCA treatments and the other half served as controls. Microiontophoretic experiments were carried out 15 days after the pump was installed or 24 h after the last injection under urethane anesthesia (1.25 g/kg, i.p.). Five-barrelled micropipettes were used for unitary extracellular recording of CA3 dorsal hippocampus neurons. Side barrels were filled with 5-HT creatine sulfate (0.5 mM in 200 mM NaCl, pH: 4), NE bitartrate (50 mM in 50 mM NaCl, pH: 4) and acetylcholine chloride (ACh) (20 mM in 200 mM NaCl, pH: 4). Small currents of acetylcholine (1-3 nA) were used to activate silent or slowly discharging units. Neuronal responsiveness was estimated using the I.Tso method (current x time required to obtain a 50% decrea-se of firing rate from baseline). The same micropipette was used for each pair of animals (one control and one TCAtreated rat) from intact and 6-0HDA groups in order to cancel any variation in micropipette efficacy.

from intact and 6-UHUA groups in order to cancel any variation in micropipette efficacy. The 6-UHDA pretreatment did not modify the I.T<sub>50</sub> values for NE and for 5-HT, but markedly prolonged the duration of the effect of NE, indicating adequate removal of NE terminals. The TCA treatments increased responsiveness to 5-HT in intact rats but failed to do so in 6-UHDA-denervated rats. The I.T<sub>50</sub> values for NE were modified by the TCA treatments in neither intact nor 6-OHDA rats.

6-OHDA rats. These data indicate that the central NE system must be intact for the TCA-induced sensitization to 5-HT to occur. This sug-gests that sensitization of forebrain neurons to 5-HT produced by TCA drugs might result from their action on the NE system. Supported by MRC Grant MA-6444, a Studentship to P.G. from FCAC and a Scholarship to C. de M. from FRSQ.

#### EFFECT OF PIRACETAM ON HIGH AFFINITY CHOLINE UPTAKE. Vimala H. Sethy, CNS Research, The Upjohn Company, Kalamazoo, MI 49001.

A selective reduction in cholinergic markers such as choline acetyl-transferase, high affinity cholie uptake (HACU) and acetylcholinesterase have been demonstrated in the cerebral cortex of patients with Alzheihave been demonstrated in the cerebral cortex of patients with Alzhei-mer's Disease, suggesting that a specific cholinergic deficiency may be responsible for this disorder. Physostigmine, a cholinergic agent, seems to have beneficial effects in patients with Alzheimer's Disease. If a deficiency of the cholinergic system is the cause of cognitive impair-ment in patients with Alzheimer's Disease, an impairment of cholinergic functions may be observed in old rats. This hypothesis has been investigated by studying HACU in the hippocampus and cerebral cortex Investigated by studying HACU in the hippocampus and cerebral cortex of young and old rats, and by investigating the effect of piracetain on this parameter. HACU was significantly ( $p_1^{(0,05)}$  reduced in the hippocampus of both Sprague-Dawley and Fischer 344 old (24-month) female rats as compared to young (3-month) rats. A similar effect was not observed in the cerebral cortex. Acute administratin of piracetain at a dose of 100 mg/kg significantly ( $p_1^{(0,05)}$  increased HACU in the hippocampus of both the young and old rats. Piracetain had no significant effect on the HACU in the cerebral cortex. The increase in HACU in the hippocampus was favored to be deer decorder with significant efficience of the factor in the cerear correst. The increase in HACU in the hippocampus was found to be dose-dependent with piracetam, aniracetam (3, 10, 30 and 100 mg/kg) and 3,4-diaminopyrridine (1, 3 and 10 mg/kg). The results of the present investigations suggest that old rats may have reduced cholinergic activity, and piracetam improves it by increasing HACU.

LITHIUM MODIFIES NEUROPHYSIOLOGICAL RESPONSES IN THE CAI REGION M.D. Fairchild\* & J.A. Kusske. Div. of Neurological Surgery, Univ. of Calif., Irvine, CA 92717 & V.A. Med. Ctr., Sepulveda,

CA 91343.

Lithium has been employed clinically in the treatment of a num-ber of psychiatric and neurological disorders and also appears to be helpful in the treatment of chronic alcoholism. However, the mechanisms through which lithium exerts its therapeutic effects

be helpful in the treatment of chronic alcoholism. However, the mechanisms through which lithium exerts its therapeutic effects and its actions on the CNS remain largely unexplained. The pres-ent study examines electrophysiological measures of CNS activity in tissue acutely exposed to lithium. The hippocampus was dissected from brains of male Sprague-Dawley rats, prepared as in vitro slices, and maintained in a perfusion/ recording chamber. Electrophysiological measurements were ob-tained while perfusing with normal media and with media in which LiCl was substituted for NaCl in 10, 20 and 30mM amounts. Bipolar stimulation electrodes were positioned in the Schaffer/ Commissural Projections (SCP) to the apical dendrites of CAI pyra-midal cells. Extracellular measures included assessment of the field potentials recorded from cell bodies in the s. pyramidale and from the dendritic area in the s. radiatum. Input/output (I/O) relations between the stimulus current applied to the SCP and the dendritic field potentials were determined. Field poten-tials from cell body and dendritics regions were monitored simul-taneously so that stimulus intensities required to elicit detec-table and maximal dendritic regions (in a range below threshold for elicitation of pyramidal cell discharge, could be measured. Evoked activity considered to represent the presynaptic fiber vol-ley was measured in separate experiments in which conditions were

tor elicitation of pyramidal cell discharge, could be measured. Evoked activity considered to represent the presynaptic fiber volley was measured in separate experiments in which conditions were optimized to record this response. Slices perfused in 30mM lithium were found to be unstable and often exhibited seizure activity. With perfusion of a 10mM lithium media, many slices exhibited no change. However, slices perfused in 20mM lithium for periods of from six to twenty eight minutes exhibited reliable results. 1/0 relations were affected in such a way as to produce a shift in the curves describing current/response amplitude relations suggesting that lithium produced a decrease in the current required for a particular amplitude dendritic field potential. This occurred in 11 out of 12 slices tested. Varying degrees of recovery were obtained. The same concentration of lithium appears to reduce the amplitude of the presynaptic fiber volley (n=9). These results are in agreement with other studies that have pointed to lithium effects on neural fibers, possibly mediated through lithium interaction with the sodium-potassium pump. In addition, our results point to other lithium effects, possibly on synaptic transmission. (Supported by NIAAA grant # AA 03506).

127.10 TRICYCLIC ANTIDEPRESSANT DRUGS AS HISTAMINE H<sub>2</sub> RECEPTOR ANTAGON-ISTS IN BRAIN: SPECIES DIFFERENCES. <u>Richard Straub\*, Saul Maayani</u>

ISTS IN BRAIN: SPECIES DIFFERENCES. Richard Straub\*, Sail Maayani, Julia Ayala\* and Jack P. Green. Department of Pharmacology, Mount Sinai School of Medicine of C.U.N.Y., N.Y., NY. Similar to their blockade of the histamine H<sub>2</sub> receptor in guinea pig brain (Green, et al., <u>Nature</u>, <u>269</u>:163, 1977), tricyc-lic antidepressant drugs (TA) are potent competitive antagonists of the H<sub>2</sub> receptor linked to adenylate cyclase in particulate preparations from rabbit brain. Classification of the histamine (HA) receptor in rabbit brain as the H<sub>2</sub> type was done by Schild analysis of the inhibition of HA response by antagonists (cimetid-ine, tiotidine, mepyramine) and by measuring stimulation of CAMP production by known HA agonists (HA, 4-CH<sub>3</sub>-HA, 2-CH<sub>3</sub>-HA) and partial agonists (dimaprit, impromidine). While the affinities of cimetidine and tiotidine do not differ between the two species, the TA exhibit between 2 and 25 times higher affinity for the H<sub>2</sub> receptor in the rabbit brain preparation. In contrast, the affinities of the TA for the muscarinic cholingrgic binding site as measured by competition experiments with [<sup>3</sup>H]-atropine is not species dependent. species dependent

COMPARISON OF EFFECTS OF STRESS AND ANTIDEPRESSANTS ON DRADRENERGIC RECEPTOR FUNCTION IN RAT BRAIN. <u>E.A. Stone, J.E.</u> 21att, R. Trullas and A.V. Slucky. Dept. Psychiatry, New York Univ. Sch. Med., New York, NY 10016. Previous studies have shown that repeated stress reduces the 126.11

function of noradrenergic receptors in the rat brain as evidenced by a decreased cAMP response to norepinephrine (NE) and a reduced density of beta adrenergic receptors (BARs). The present study was undertaken to investigate the generality of this effect and to compare it to the desensitization of receptors produced by tr cyclic antidepressants (TADs). The stressors employed were restraint, food deprivation and hypercapnia. The former two represent common laboratory or natural stressors whereas the latter present common laboratory or natural stressors whereas the latter occurs in certain pathological states such as emphysema. Restraint was administered for 2.5 h per day for 10 days. Food deprivation consisted of six 48 h fasts given over a 3 week period. Fasts were separated by 1-2.5 days. For hypercapnia rats were exposed to a mixture of 10% CO<sub>2</sub>, 20% O<sub>2</sub> and 70% N<sub>2</sub> for 1 h per day for 10 days. Desmethylimipramine (DMI), a TAD, was injected 10 mg/kg, i.p., b.i.d., for 10 days. Rats were killed immediately or 24 h after the last stress or injection. DMI was found to significantly reduce the cAMP response to catecholamines in hypothalamic (35-40%) and cortical (35%) slices. The same effect was found after restraint but was smaller than that produced by DMI (hypothalamus, 9-22%; cortex, currently under investigation). Food deprivation and CO<sub>2</sub> have not yet been exam

investigation). Food deprivation and CO2 have not yet been exam-ined with regard to cAMP response. A similar pattern of results was obtained for BAR density: DMI produced significant decreases in the cortex (24%) and hypothalamus (16%) whereas the stressors food deprivation, restraint and CO2 produced smaller decreases of 18, 8 and 2% respectively in the cortex and of about 5% each in the hypothalamus.

The prosent results indicate that many forms of repeated stress lower brain noradrenergic receptor function as evidenced by the effects of restraint and food deprivation on the above measures. The failure of CO<sub>2</sub> to reduce BAR density however suggests that this effect may not be general to all forms of stress. The reason that CO<sub>2</sub> was ineffective may be related to the fact that it repre-sents a milder form of stimulation than the other conditions. The present results also indicate that the reduction in receptor fun-ction caused by DMI is much greater than that caused by these stressors. The significance of this finding is not yet known although it may mean that there is a physiological limit to the extent to which stress can desensitize brain noradrenergic recep-tors, and that antidepressants may exceed this limit. If this notion is correct it may have important implications for the mode tors, and that antidepressants may exceed this limit. If this notion is correct it may have important implications for the mode of action of antidepressant agents. (Supported in part by grants MH 22768 and MH 08618 and CIRIT predoct. training grant to R. T.)

Effect of CI-844, a Cognition Performance Enhancer, on Rat Brain Biogenic Amine and Acetylcholine Turnover. <u>T. Pugsley\*</u>, S. Myers\*, Y. Shih\*, L. Coughenour\*, S. Stewart\* and <u>M. Gluckman. (SPON: R. F. BRUNS) Dept. Pharmacology Warner-Lambert/Parke-Davis Research, Ann Arbor, MI 48105. CI-844 (3-phenoxypyridine) has been shown to enhance retention for passive avoidance learning in mice (Butler et al. J. Med. Chem 1981, 24: 346-350) and to increase avoid-ance in a rat aquisition procedure at 30 mg/kg i.p. (Boff et al. Soc. Neurosci., 1982, Abst 877 p. 320). Cognitive processes have been shown to be dependent on the function of brain biogenic amines and acetycholine neuronal systems. The purpose of the present study was to examine the effects</u> The purpose of the present study was to examine the effects of behaviorally active doses of CI-844 on dopamine (DA), norepinephrine (NE) and serotonin (5-HT) turnover, rat serum prolactin, and sodium-dependent high affinity choline uptake (HACU), and to determine its in vitro affinity for various rat brain receptors.

Without altering endogenous DA levels CI-844 caused a decrease in the DA metabolite 3,4-dihydroxyphenylacetic acid in rat striatum and hippocampus at 5 and 20 mg/kg i.p. but not at 1 and 0.1 mg/kg 2 hours after dosing; striatal homovanillic acid was decreased at 20 mg/kg. These findings suggested that CI-844 was decreasing DA turnover. CI-844 decreased rat serum prolactin at 25 mg/kg i.p. 1 and 2 hours after administration. This data would tend to suggest a DA agonist action of CI-844. However this effect is unlikely to be due to a direct interaction of CI-844 with DA receptors as it did not inhibit the in vitro binding of "H-haloperidol to rat striatum DA receptors at up to 1x10" M. CI-844 (20 mg/kg i.p.) did not affect measures of NE (hippocampus) 2 hours after its administration. CI-844 (0.01 - 20 mg/kg i.p.) did not affect significantly in vitro HACU into rat 2 hours after its administration. CL-844 (0.01 - 20 mg/kg i.p.) did not affect significantly in vitro HACU into rat brain hippocampal synaptosomes 30 minutes after being given suggesting that it was not altering hippocampal cholinergic neuronal activity. CL-844 exhibited no significant in vitro affinity for either rat brain adenosine A, or muscarinic receptors. The present neurochemical findings suggest that CL-844 may be evention, its constitue enhancing effects. CI-844 may be exerting, its cognitive enhancing effects, at least in part, by increasing dopaminergic neuronal function. 126.12 DEMONSTRATION OF A GROWTH REBOUND PHENOMENON FOLLOWING CESSATION OF CHRONIC METHYLPHENIDATE TREATMENT IN THE DEVELOPING RAT. W.J. Pizzi, J.E. Barnhart\*, E.C. Rode\* and V. Hirschenbein\*. Northeastern Illinois University, Chicago, IL 60625. Whether stimulants such as the amphetamines and methylphenidate light of the stimulants with the stimulants and methylphenidate.

Whether stimulants such as the amphetamines and methylphenidat lead to growth impairment and whether there is a rebound follow-ing the cessation of drug treatment has been hotly debated in the clinical literature. To date, only a few studies have been carried out on animals demonstrating a growth impairment. Fur-thermore, to our knowledge only research conducted in this lab has studied the phenomenon of growth rebound. In previous work we demonstrated that relatively high doses of methylphenidate can result in reduced femur lengths, along with decreased weights of result in reduced femur lengths, along with decreased weights of testes, adrenal, thyroid, pituitary, and brain. In our original study all of these deficits were present in a random sample of animals immediately following drug cessation; however, these deficits were absent in a randomly selected group of animals at

deficits were absent in a randomly selected group of animals at 500 days of age. The present study was carried out to determine the time course of the growth rebound. In the present study rats were injected s.c. from days 5-24 of age according to varying injection schedules (35 mg/kg body wt. twice daily for males; 35 mg/kg body wt. once daily for females) with either methylphenidate or saline. Each housing unit con-tained one dam and a minimum of 6 and maximum of 8 pups. All animals received injections for 19 or 20 days. A group of ran-domly selected animals was necropsied within a 48-hour period following drug cessation. A second group of randomly selected animals was necropsied 30 days following drug cessation. animals was necropsied 30 days following drug cessation. Immediately following methylphenidate treatment both males and females showed decreased femur lengths, along with decreased pituitary and body weights. Further, the males showed a reduced brain weight, which was not present in the female animals treated once daily. The second necropsy carried out at 55 days of age re-vealed no significant differences in any of the above measures for either methylphenidate-treated males or females. These data confirm our earlier finding of an acute growth suppression following chronic methylphenidate treatment in the developing rat Eurther, it appears that a growth rebound

developing rat. Further, it appears that a growth rebound occurs immediately upon cessation of drug treatment in the dev-eloping rat. A review of the literature indicates that growth impairments are seldom seen in children treated with less than 20 mg/day. These findings suggest that the stimulants should be 20 mg/day. used at he lowest effective therapeutic does with frequent drug holidays when these are consistent with the treatment of the disorder.

BLOCKADE OF NOREPINEPHRINE (NE) AND DOPAMINE (DA) UPTAKE AND IN-126.14 BLOCKADE OF NOREPINEHRINE (NE) AND DOPAMINE (DA) OFTAKE AND IN-DUCTION OF NE RECEPTOR SUBSENSITIVITY BY TAMETRALINE. B. Kenneth Koe, Susan W. Koch\*, Katherine W. Minor\* and Lorraine A. Lebel\*. Central Research Division, Pfizer Inc., Groton, CT 06340 Tametraline, (+)-trans (1R,4S)-N-methyl-4-phenyl-1,2,3,4-tet-

rahydro-1-naphthylamine, was reported previously to be a potent blocker of NE uptake in rat heart in vivo (Sarges et al., 1974) and NE and DA uptake in synaptosomes of rat brain (Koe, 1976). The present study describes some neurochemical effects of tametraline present study describes some neurochemical effects of tametraine and the antidepressant, nomifensine, also a NE and DA uptake blocker. The inhibition of synaptosomal uptake of NE, DA, and serotonin (SHT) by tametraline was found to be competitive; Ki values based on Dixon plots were:  $0.018 \ \mu M(\text{DR})$ ,  $0.03 \ \mu M(\text{DA})$ , and  $0.63 \ \mu M$  (SHT). Its effects on DA uptake in synaptosomes from naive and reservinized rats suggested that tametraline does not belong to the amphetamine type of DA uptake blockers. In ex vivo studies, tametraline was one-fourth as active (ED<sub>50</sub> 8 µmol/kg) as des-ipramine (DMI) in inhibiting NE uptake, twice as active (ED<sub>50</sub> 4 µmol/kg) as nomifensine in blocking DA uptake, but less effective  $\mu$ mol/kg) as nomitensine in blocking DA uptake, but less effective (ED<sub>50</sub> >100  $\mu$ mol/kg) than chlorimipramine against 5HT uptake. NE uptake ex vivo was maximally inhibited 1-2 hr after tametraline and returned to normal by 24 hr. In vivo, inhibition of NE uptake was demonstrated in rat heart (i.v. H-NE; ED<sub>50</sub> 5  $\mu$ mol/kg, com-pared to 7 and 1  $\mu$ mol/kg for nomifensine and DML; respectively) and rat brain (intracisternal H-NE). The depletion of NE and DA levels in rat brain induced by  $\alpha$ -methyl-m-tyrosine was attenuated by tametraline, further indicating blockade of uptake of these amines in vivo. Tametraline by inhibiting DA reuptake, may in-crease DA concentrations at autoreceptors. Accordingly, tametra-line was found to decrease striatal DA synthesis in naive rats as well as in rats treated with Y-butyrolactone to block impulse flow in DA neurons.

Tametraline and nomifensine were found to induce down-regulation of central NE neurons after subacute administration. the injection of 75 µmol/kg i.p., b.i.d., for 8 days, these drugs decreased the NE response of the limbic forebrain adenylate cyclase in rats by 42% and 47%, respectively. Binding of  $_3^{-1}$ H-dihydro-alprenolot to  $\beta$ -adrenoceptors was also decreased, but H-spiperone alprenoio to p-adrenoceptors was also accreased, but n-spiperone binding to 5HT-2 receptors was not. With the same dosing regimen, tametraline was found to elicit subsensitivity of the adenylate cyclase after 4 days. Thus, both drugs elicited down-regulation, which may be predictive of clinical antidepressant activity. For nomifensine, DA uptake blockade may also contribute to the latter, since the major neurochemical property of bupropion and aminep-tine both active against depression in man appears to be inbibitine, both active against depression in man, appears to be inhibi-tion of DA uptake.

BINDING SITES FOR IMIPRAMINE AND COCAINE ON A MODEL LIPID 126.15 MEMBRANE: COMPARISON WITH CNS RECEPTORS. M.E.A. Reith\*, H

MENDARGE OWNERLISON WITH CHORECEPTORS. <u>HEAR, Kettler, n.</u> <u>Sershen\* and A. Lajtha.</u> Center for Neurochemistry, Rockand Research Institute, Ward's Island, N.Y. 10035. Many antidepressant and stimulant drugs have been shown to bind with high affinity to specific sites in the CNS. The remarkable lipophilicity of these drugs raises the question of thether load another to be being applicable and the cost of the second s whether lipid constituents of brain membranes play a role in the observed high-affinity binding. In experiments with inte-gral membranes it is difficult to disentangle interactions with proteins from those with surrounding lipids. We therefore used a pure lipid system of liposomes consisting of spherical mem-branes of phosphatidylcholine and cholesterol, and investigated its interaction with the antidepressant [<sup>3</sup>H]imipramine and the stimulant [<sup>3</sup>H]cocaine. The assays with liposomes contained concentrations of phosphatidylcholine and cholesterol similar to those calculated to be present in binding assays with brain membranes. Liposomes bound [<sup>3</sup>H]imipramine and [<sup>3</sup>H]cocaine with a dissociation constant in the micromolar range and a density close to 2 pmol/µg of phosphatidylcholine. There was a highly significant correlation (r=0.9-1.0, m=13, p < 0.001) between the potencies of various drugs in inhibiting the binding to liposomes and their lipophilicities as measured by octanol-water partition coefficients. In contrast, there was a much weaker correlation (r=0.5-0.6, n=13, 0.05 the potencies of drugs in inhibiting the binding of [<sup>3</sup>H]imipra-mine and [<sup>3</sup>H]cocaine to liposomes and their potencies in inhibiting the high-affinity binding to brain membranes. The potencies of drugs in inhibiting the binding to brain membranes were somewhat dependent (r=0.6-0.7, n=13, p < 0.05) upon their lipophilicities. These results indicate that model lipid mem-branes, devoid of proteins, can actually "bind" lipophilic sub-stances, but that such lipid sites are not likely to be the primary sites of high-affinity binding to [<sup>3</sup>H]impramine and [<sup>3</sup>H]cocaine to brain membranes. However, it is likely that lipophilicity is one of the components in the complex binding interactions between lipophilic substances and receptors attached to the lipid backbone of integral membranes. whether lipid constituents of brain membranes play a role in the observed high-affinity binding. In experiments with inte-

HIGH PERFORMANCE LIQUID CHROMATOGRAPHIC ELECTROCHEMICAL DETECTION 126.16 AND GAS LIQUID CHROWICGRAFHIC ANALYSIS OF 3-METHOXY A-HYDROXY-PHENYIGLYCOL IN HUMAN URINE. D. M. Martin<sup>\*</sup>, R. E. Petroski<sup>\*</sup>, J. Alrazi<sup>\*</sup>, R. Hahn<sup>\*</sup>, A. L. C. Pottash, M. S. Gold, Psychiatric Diagnostic Laboratories of America, Summit, N.J. 07901. 3-methoxy 4-hydroxyphenylglycol (MHPG) has been reported to be the meine university of the formation of the second sec

the major urinary metabolite of norepinephrine in man and associated with treatment response to various antidepressant medications for over 10 years. The principal methodology for the analysis of urinary MHPG has been a Gas Liquid Chromatographic (GLC) separation of a trifluroacetic anhydride derivative and quantitation by electron capture detection. GLC techniques require complex extraction, derivatization and stabilization of precarious detector response all of which may add to analytical variability of the data. This in part may explain why there exists mixed reports over the clinical application of MHPG as a predictor of medication response in depressed patients. We report a High Performance Liquid Chromatographic Electrochemical Detection technique (HPLC-ECD) which eliminates many of the sources of analytical variability and methodological error inher-ent in GLC procedures. Congugated urinary MHPG was enzymatically hydrolyzed to the free form by incubating 250 uL of the 24 hour collection with 20 uL of glusalase for 20 hours. This hydroly-sate was then basified with 50 uL of 2N NaOH and extracted into 3.6 mL of ethyl acetate. The MHPG extract was washed with 0.1M acetic acid to clean the organic phase. MHPG was then extracted from the organic into 450 uL of 8M urea/0.1M citrate and washed twice with hexane. 100 uL of the urea/citrate was injected into a reverse phase isocratic HPLC system using a mobile phase of 0.05M MPC Do 1000 MPC to the VET of the total to of the original 0.05M Naf2PO4, 10% MBCH, 0.1MM Na2EDTA adjusted to DH=3.0 flowing over a 10 micron C-18 column. Detection was amperometric using a BAS glassy carbon electrochemical detector V=+0.70 volts, range 2-20 nA. Over 100 urine samples have been analyzed using both

this technique and GLC yielded an this technique and GLC yielded an excellent and significant linear relationship (r=0.97; p<.001) be-tween the two groups of data and the day-to-day coefficient of var-iation of the assay was less than 12%. As little as 10 ng of MHPG could be detected which may allow contribution of MHPG is promoted. quantitation of MHPG in plasma as well as urine. The precision re-producibility, ease of sample preparation and simplicity of in-strumentation make this technique exceptionally well suited for rou-tine clinical measurement of MHPG.

### **PSYCHOTHERAPEUTIC DRUGS: NEUROLEPTICS**

CHOLINE IN RED BLOOD CELLS AND PLASMA IN CHRONIC SCHIZOPHRENIC INPATIENTS. W.B. Lawson, D.J. Jeste,\* B.H. Phelps,\* U. Kopp,\* L.B. Bigelow, I. Hannin. Adult Psychiatry Branch, NIMH, Saint Elizabeths Hospital, Washington, D.C., 20032 and Pittsburgh, Pennsylvania INTRODUCTION: Various measures of blood choline have been proposed as possible biological markers of central cholinergic activity. For example, elevated RBC choline concentrations have been reported in a proportion of depressed patients, associated with Tourette's syndrome, and with lithium treatment. Some indirect evidence also implicates cholinergic atbology in schizoptrenia. However, very little work has been done with 127.1 pathology in schizophrenia. However, very little work has been done with blood levels of choline in schizophrenia.

blood levels of choline in schizophrenia. METHODS: All twenty-seven patients with RDC positive schizophrenia on our Research Wards at the Adult Psychiatry Branch of NIMH were examined. Two nurses on the ward rated psychopathology with the Brief Psychiatric Rating Scale. Two other nurses independently rated movement disorders with the Abnormal Involuntary Movement Scale and Abbreviated Rockland Dyskinesia Rating Scale. Blood was drawn on the same day. Plasma and RBC samples were sent to Pittsburgh where choline estimations were done "blind". In 17 patients this process was repeated two months later. Every patient had been either neuroleptic-free or on stable doses of neuroleptics for at least a month before each test-day. RESULTS: Both RBC and plasma choline concentrations had intra-

**RESULTS:** Both RBC and plasma choline concentrations had intra-subject stability over the two month period, especially in patients whose medication status remained unchanged. No significant correlation was seen between RBC and plasma choline levels. RBC choline (mean 39 + S.D. 50 nmol/ml) had a much greater inter-subject variability than did plasma choline (8 + 3 nmol/ml). Neither measure correlated significantly with most psychopathology scores on the BPRS, including the depression subscale. A significant negative correlation was seen between neuroleptic dosage (converted to chlorpromazine equivalents) and RBC choline (Pearson's r = -.41; p < 0.04) that was independent of concomitant treatment with anticholinergics. No significant difference was seen between RBC choline levels in seven patients with tardive dyskinesia (46 + 50 nmol/ml) and nondyskinetic patients (42 + 54 nmol/ml). However, one patient with neuroleptic-induced Tourette's syndrome had a markedly elevated RBC choline concentration (130 nmol/ml). Both RBC and plasma choline concentrations had intra-**RESULTS:** elevated RBC choline concentration (130 nmol/ml).

DISCUSSION: RBC choline is a possible biological marker of central cholinergic activity that is relatively stable over time. We will discuss possible implications (and limitations) of our findings with reference to neuroleptic treatment, tardive dyskinesia, iatrogenic Tourette's syndrome, depression and cognitive functioning in schizophrenia.

127.2 INTERACTION OF PYRROLOISOQUINOLINE ANTIPSYCHOTICS WITH A D-2 DOPAMINE RECEPTOR SUBTYPE - EVALUATION BY H-RO 22-1319 BINDING. T. Nakajima\*, I. Kuruma\*, and K. Nakamura\*, Dept. of Pharmaco-logy, Nippon Roche Research Center, Kamakura, Japan, and G. Olson\*, H. Cheung\*, E. Chiang\*, L. Berger\*, G. Bautz\*, R.A. O'Brien, C. Burghardt\*, T. Mowles\*, E. Gamzu, A.B. Davidson and E. Boff\*, Depts. of Chemistry and Pharmacology, Roche Research Center, Nutley, New Jersey O7110. Ro 22-1319 is a novel, conformationally rigid pyrroloisoquino-line derivative which exhibits a potent antipsychotic-like profil in animal tests. It has weak cataleptogenic activity and does nc induce receptor supersensitivity upon chronic dosing (Davidson,

line derivative which exhibits a potent antipsychotic-like profil in animal tests. It has weak cataleptogenic activity and does nc induce receptor supersensitivity upon chronic dosing (Davidson, et al., Psychopharmacol., 79:32-39, 1983). "H-Ro 22-1319 has been found to bind in a sodium-dependent manner to a single component of rat striatal homogenates with hig (nM) affinity. The binding is saturable and highly stereo-speci-fic for the pharmacologically active 4aR,8aR-(-)-enantiomer, (-)-Ro 22-1319. The binding of Ro 22-1319 and a series of pyrro-loisoquinoline analogs to the H-spiroperidol-labelled receptor also exhibited a sulpiride-like dependence on sodium ion, suggest ing that the pyrroloisoquinoline series may be selective for a D-2 receptor subtype. Other D-2 dopamine antagonists, sulpiride, metgclopramide, and molindone are\_similarly more potent inhibitor of H-Ro 22-1319 binding than of 'H-spiroperidol binding. Structure-activity relationships indicate that changes in the lipophilicity of the basic nitrogen substituent of compounds of the pyrroloisoquinoline class can modulate their binding to the D-1 (adenylate cyclase) and D-2 (spiroperidol) receptors (Bautz, et al., Soc. Neurosci. Abstr., 7:866, 1981) via their inter-action with an auxiliary binding site identified through recep-tor modeling (Olson, et al., J. Med. Chem., 24:1026-1034, 1981; Olson, et al., in "Dopamine Receptors", in press). The affinity of pyrroloisoquinoline analogs for the 'H-Ro 22-1319 receptor is less dependent on the size and lipophilicity of the group on the basic nitrogen. These observations suggest that Ro 22-1319 and analogs bind to a distinct D-2 receptor subtype which differs at the molecular level from the 'H-spiroperidol binding site by having a greatly diminished hydrophobic character in its auxili-ary binding site.

SELECTIVE ACTIVITY OF MDL 17,214EF IN TESTS PREDICTIVE OF "ANTI-1273

SELECTIVE ACTIVITY OF MDL 17,214EF IN TESTS PREDICTIVE OF "ANTI-PSYCHOTIC" ACTIVITY. <u>Francis P. Miller and Donald L. Braun,</u> Merrell Dow Research Center, Cincinnati, Ohio 45215. Initial results with MDL 17,214EF (4-(4-(6-chlor-2-naphtha-lenyl)carbonyl-1-piperidinyl)-1-(4-fluorophenyl)-1-butanone meth-ane sulfonate (1:1)) indicated that it might possess anti-psychotic-like properties. The present experiments were carriedout to determine the profile of activity of MDL 17,214EF inseveral tests where known antipsychotic agents are active. Theresults of these studies are shown in the table below, accom-panied by comparative results with haloperidol (H) and thiori-dazine (T).

102		ED50 MDL 17,214EF	(mg/kg i.p.) H	T
А.	Amphet. Aggreg. Toxicity	1.7	0.17	0.86
в.	Pernicious Preening - Mic	e 2.16	0.51	2.65
с.	Fighting Mice	9.0	2.7	8.7
D.	Apomorph. Climbing Mice	75.8	0.15	3.2
Ε.	Apomorph. Stereotypy-Rats	> 320	0.50	30.3
F.	Amphet, Stereotypy-Rats	> 320	0.33	53.6

Although H and T are equally efficacious antipsychotic agents, it is believed that T has a much lower propensity to cause extra-It is believed that I has a much lower propensity to cause extra-pyramidal symptoms (EPS). Since both antipsychotic activity and EPS are thought to be mediated via blockade of dopamine receptors and certain animal tests used to evaluate antipsychotic agents are sensitive to dopaminergic blockers, the clinical differences between H and T should be reflected in these animals tests. observation of the data in the table above shows that, although T is 1/3-1/5 as potent as H in tests A-C, it is only 1/20-1/160 as potent in tests D-F. The relatively weak activity of T vs H in Tests D-F suggests that these tests are more reflective of liability to cause EPS, whereas the relatively more potent activity of T vs H in Tests A-C suggests that these tests are more reflective of antipsychotic activity. This interpretation is supported by data with several other antipsychotic agents with Known liability to cause EPS. For MDL 17,214EF, the selectivity of blockade in these tests

For MDL 17,214EF, the selectivity of blockade in these tests is very impressive. In Tests A-C, thought to be related to antipsychotic activity, MDL 17,214EF is 1/3-1/10 as potent as H. However, in Tests D-F, thought to be related to EPS, MDL 17,214EF is  $\underline{<1/500}$  as potent as H. We suggest that these highly selective behavioral effects of MDL 17,214EF are indicative of a highly selective dopamine blocking agent, and presumably an anti-psychotic agent with minimal, if any, liability to cause EPS.

127.5	THE AVERAGE DAILY DOSE OF ANTIPSYCHOTIC DRUGS AS CLINICALLY
	PRESCRIBED IN AN INPATIENT SETTING. D. Miller*, A. C. Andorn*,
	S. Stern*, E. Seideman* (SPON: L. Hershey). Dept. of Psychiatry,
	Case Western Reserve University School of Medicine, Cleveland,
	Ohio 44106.

Discharge medication was tabulated on a umole/kg patient weight/day basis on sequential admissions to the psychiatric ser-vice in 1979. The only patients included (N=200) were those demonstrating psychotic symptoms on admission and discharged on only one antipsychotic medication. The preliminary findings indicate that the frequency with which these drugs are prescribed is: haloperidol > trifluoperazine > thioridazine = cis-thiothixene > chlorpromazine>fluphenazine>perphenazine>mezoridazine. The range of doseages used is extensive. The doses used for each drug do not appear to distribute normally which probably accounts for the large standard deviations observed in the mean doses below. AVERAGE DAILY DOSE DRUG N

	umole/kg	
Haloperidol	0.93 +/- 0.77	51
Trifluoperazine	0.85 +/- 0.52	45
Cis-thiothixene	0.88 +/- 0.83	27
Thioridazine	15.20 +/-11.60	27
Chlorpromazine	19.94 +/-17.16	17
Fluphenazine	0.57 +/- 0.59	13

If we could use the average daily dose to compute a rank order of these drugs we would note it is different from previous literature reports, and the actual doses used are higher. Further studies will be included in an effort to determine the type of distribution of dosages. It appears the the average daily dose of antipsychotic drugs has yet to be established. Ideally, both retrospective and prospective, multi-institutional studies should be done on large numbers of patients in order to determine the actual daily dose of antipsychotic medication.

HETEROGENEOUS ROTATIONAL BEHAVIOR RESPONSES TO APOMORPHINE, SKF 127.4 38393, 3-PPF AND PERCOLIDE, H.M. Fenton\* and J.M. Liebman. Res. Dept., Pharm. Div., CIBA-GEIGY Corp., Summit, NJ 07901. After unilateral destruction of the ascending nigro-neostriatal

pathway by 6-hydroxydopamine microinjections, rats show rotational behavior (RB) when injected systemically with drugs that enhance dopaminergic neurotransmission. Postsynaptic dopamine (DA) agon-ism is inferred from contralateral RB away from the lesioned side, presumably due to the stimulation of hypersensitive striatal DA receptors. This preparation has been used to evaluate the post-synaptic DA agonist properties of the putative DA autoreceptor agonist, TL-99 (Goodale et al., <u>Science</u>, 210:1141, 1980) and 3-PPP (Hjorth et al., <u>Life Sci.</u>, 28:1225, 1981) as well as the proposed D-1 agonist, SKF 38393 (Stoof and Kebabian, <u>Nature</u>, 294:366, 1981). Two inconsistencies have emerged. First, some investiga-tions showed that TL-99 and 3-PPP are capable of inducing RB in lesioned rats (Martin et al., <u>Eur. J. Pharmacol.</u>, 76:15, 1981) but others reported little or no RB (Goodale et al., 1980; Fallon et al., <u>Fed. Proc.</u>, 41:1065, 1982). Secondly, the reported ability of TL-99, 3-PPP and SKF 38393 to induce RB was inconsistent with the absence of postsynaptic DA receptor activation in behavioral receptors. This preparation has been used to evaluate the postthe absence of postsynaptic DA receptor activation in behavioral models using normal, unlesioned animals (Martin et al., 1981; Setler et al., Eur. J. Pharmacol., 50:419, 1978). To address this controversy, we systematically compared the RB induced by various doses of apomorphine, SKF 38393, 3-PPP and pergolide in a large colony of lesioned rats.

One week after unilateral nigral microinjection of 6-hydroxy dopamine (10.8 µg in 4 µl), rats were placed (without a restrain-ing harness) inside clear Plexiglas cylinders (13.5 cm radius, 29.5 cm high) centered in Omnitech Digiscan activity monitors Each complete rotation was automatically recorded by commercially available software. Rats were tested in 30 min sessions that began 5 min after s.c. injection of the DA agonist. Forty-eight rats each completed at least 35 contralateral turns

per session in response to initial testing with 0.5 mg/kg apomor-phine, and were selected for further testing. Two subgroups one subgroup (n=28) averaged 58 contralateral rotations emerged: after 0.03 mg/kg apomorphine and showed comparable contralateral RB after 1-10 mg/kg 3-PPP, 3-10 mg/kg SKF 38393 and 0.3 mg/kg per-golide. The other subgroup (n=20) failed to rotate in response to goliae. The other subgroup (n-20) failed to rotate in response 0.03 mg/kg apomorphine or at doses as high as 30-100 mg/kg SKF 38393, 30 mg/kg 3-PPP and 0.3 mg/kg pergolide. A higher dose of apomorphine (0.25 mg/kg), however, induced RB in this subgroup that was comparable in magnitude to that in the more sensitive subgroup. Thus, careful preselection of animals is necessary to yield readily interpretable results when DA agonists are assessed in the RB model. It will be of interest to determine the basis for the differential sensitivity noted with these subgroups.

THIORIDAZINE PHARMACODYNAMICS: IN VITRO CORRELATIONS AND DEPENDENCE ON DRUG METABOLISM. Mark H. Lewis, Laura Staples\*, Donna McCorkle and Richard B. Mailman. Biological Sciences Research Center and the Departments of Psychiatry and 127.6

Research Center and the Departments of Psychiatry and Pharmacology, University of North Carolina School of Medicine, Chapel Hill, N.C. 27514. At least two metabolites of the clinically useful antipsychotic drug thioridazine (THD) (Mellaril®) are known to have dopamine receptor blocking properties and also cause clinical antipsychotic effects. Earlier in vivo and in vitro work has suggested that THD-2-sulfoxide (MES) is approximately equipotent to THD whereas THD-2-sulfone is approximately 5 times more notent than the parent drug. We have cathered evidence equipotent to THD whereas THD-2-sulfone is approximately 5 times more potent than the parent drug. We have gathered evidence demonstrating that the conversion of THD to these two active metabolites is catalyzed in large measure by the hepatic flavin containing monooxygenase (EC 1.14.13.8), an enzyme high in hamsters and humans but not in rats. Therefore, we sought to compare the <u>in vivo</u> and <u>in vitro</u> activity of THD and its metabolites in the rat vs. the hamster. THD has sometimes been termed an "atypical" neuroleptic, in part, because of its inability to antagonize appmorphine-induced stereotypies in the rat A computer supported observational scoping method was used rat. A computer supported observational scoring method was used that measured multiple behavioral topographies following apomorphine administration. In these studies, we found that appmorphine administration. In these studies, we found that although THD or MES was not a very potent antagonist of appmorphine-induced stereotypies in the rat, both were quite potent in inhibiting apomorphine stereotypies in the hamster. Moreover, THD and MES both antagonized amphetamine-induced locomotion in the rat, at much lower doses than required for inhibition of stereotypies. Despite this result, little difference was noted in the ability of THD or its metabolites to displace [24]-spiperone from striatal versus mesolimbic receptors. Despite clinical data to the contrary, we found no major difference in the potency of MES vs THD in either behavioral test. Further, we have found that in the rat both THD and MES at low doses (5-10 mg/kg) <u>potentiated</u> both amphetamine-induced locomotion and, under certain conditions, apomorphine-induced stereotypies. Whether such potentiation is a pharmacokinetic phenomenon, or represents ligand-receptor interactions, awaits further study. The present results suggest interactions, awaits further study. The present results suggest that the pharmacodynamic effects of THD appear to be determined, at least in part, by drug metabolism. Further, clinical hypotheses concerning the effects of THD might better be based on experiments conducted with species that metabolize THD in a manner similar to humans. (Supported in part by PHS grants HD/MH16834 and HD03110).

- GAMMA-VINYL GABA: GABA AGONIST TREATMENT IN TARDIVE DYSKINESIA 127.7 G.K. Thaker,\* C.A. Tamminga, T.N. Ferraro, T.A. Hare. Maryland Psychiatric Research Center, U. of Maryland, Baltimore, Md. 21228; Thomas Jefferson University, Philadelphia, Pa. 19107. Enhancement of central GABA neuronal function has been attempted in individuals with hyperkinetic motor disorders to diminish dyskinetic symptoms. Although some studies in alminism dyskinetic symptoms. Although some studies in tandive dyskinesia (TD) have been positive (<u>Arch. Gen.</u> <u>Psychiat.</u> 36:595, 1979), others have reported equivocal antidyskinetic action or prominent drug-induced side effects in response to GABA agonist treatment. Since most clinical studies have been carried out in schizophrenic individuals receiving concomitant neuroleptic treatment, the action of GABA agonists to exacerbate neuroleptic-induced Parkinsonism may obscure the primary ameliorative effect of GABA stimulation in DD. We have administered the indirect acting GABA agonist gamma vinyl GABA (GVG) to seven individuals with TD who were otherwise free from centrally active drugs. All participants were withdrawn from neuroleptic treatment at least four weeks prior to testing. The double-blind, crossover design began with a fixed two-week placebo period and was followed by three weeks of GVG or placebo. then crossed with three weeks of which a like two-week placebo period and was followed by chree weeks of GVG or placebo, then crossed with three weeks of placebo or GVG. Motor symptoms and mental status were assessed by blind live ratings twice weekly, and videotapes were done weekly and rated at the end of the protocol. Each participant received 3000 mg GVG daily during the drug period. All seven patients demonstrated a clear antidyskinetic response to GVG. The mean baseline TD score ( $\pm$ SEM) was 16.1  $\pm$  3.2; mean TD score during drug treatment was 9.5  $\pm$  2.3 compared with 15.8  $\pm$  3.6 during placebo treatment (p4.01). The average decrease in dyskinetic symptomatology was 43.9%. No clinically significant motor or cognitive side effects occurred. CSF GABA levels increased by 148% during GVG treatment (99 ± 24 pM/ml, placebo; 213 ± 23 pM/ml, GVG). Analysis of amino acid levels in CSF during placebo and drug periods demonstrated a selective increase of GABA and homomorphisms without according the selective increase in GABA and homocarnisine without concomitant increases in other amino acids. Thus, GVG may be both an effective and practical antidyskinetic agent. Substantia nigra, pars reticulata GABA-containing efferent neurons may mediate this GABA agonist effect in the described terminal areas: thalamus (VM/VL), superior colliculus, or reticular system.
- NEUROLEPTIC EFFECTS ON METHIONINE ADENOSYLTRANSFERASE 127.8 KINETICS. L. C. Tolbert, J. A. Monti, W. Walter-Ryaf and J. R. Smythies. Neurosciences Program and Dept. of Psychiatry, Univ. of Alabama in Birmingham, Birmingham, Alabama 35294. Previous reports from this lab have documented decreased activity of

Previous reports from this lab have documented decreased activity of the enzyme methionine adenosyltransferase (MAT) in erythrocytes ob-tained from either Feighner or DSM-III diagnosed schizophrenics as compared to normal subjects. Other reports in the literature such as decreased rates of oxidation of methionine to CO<sub>2</sub>, lower plasma levels of S-adenosylmethionine, and exacerbation of symptoms following methionine loading are also consistent with the general concept of abnormalities in methionine metabolism in some schizophrenic subjects. Nonetheless, one of the concerns was that the patients in both MAT studies were medicated with a variety of neuroleptics and this was possibly the source of the apparent differences in enzyme activity. For this reason studies were initiated to evaluate the effects of neuroleptics on MAT kinetics. Two approaches have been taken. One approach has been to collect a blood sample from a drug-free (at least 1 month) schizophrenic upon admission and a second blood sample after initiation of neuroleptic therapy. Due to the short-term nature of the inpatient facilities this second sample is usually obtained after two weeks of neuroleptics. Both erythrocyte samples are assayed for MAT and comparisons made between these paired samples.

The second approach has been to obtain erythrocytes from a normal subject and aliquot it into five fractions. Four fractions are incubated with high therapeutic plasma concentrations of different neuroleptics (chlorpromazine, haloperidol, fluphenazine, or thioridazine) chosen because they represent the predominant medications received by the schizophrenic subject population. The fifth fraction is incubated with water (control). Each fraction is then treated and assayed in the standard manner.

The in vitro incubation of the erythrocytes with neuroleptics resulted in a consistent increase in the Km of the enzyme with no apparent effect on the Vmax. The in vivo approach demonstrates a remarkably consis-tent increase in MAT Vmax associated with two weeks of neuroleptic therapy - all patients studied thus far have increased. The magnitude of the increase is variable depending, it seems, upon how low the Vmax is in the first sample. The effect on the Km with this approach is less consistent but most paired patient samples show an increase in the Km as well.

While still preliminary, the results, taken together, suggest that neuroleptic therapy, rather than being the cause of the observed decrease in enzyme activity in schizophrenics, may actually be minimizing the differences.

The question of the possible relationship of this neuroleptic effect to clinical efficacy of these compounds remains to be explored.

ALTERATION OF THE AMPHETAMINE RESPONSE BY ATYPICAL AND TYPICAL ALTERATION OF THE AMPETAMINE RESPONSE of ATTPICAL AND THPICAL NEUROLEPTICS IN RATS WITH AMYGDALA LESIONS. <u>A. Robertson and</u> <u>C. MacDonald\*</u>. Dept. of Psychology, McGill Univ., Montreal, <u>Quebec, Canada H3A 1B1</u>. Atypical and classical neuroleptics differ according to their

ability to block the various components of the behavioral re-sponse to dopamine agonists such as amphetamine. This effect is sponse to dopamine agonists such as ampnetamine. Inis effect is strongly correlated with their tendency to produce extrapyramidal side effects clinically or in the laboratory. Although both types of neuroleptics are dopamine antagonists, the basis for their differential effects on motor output is unclear. It has been observed, however, that atypical neuroleptics such as clozapine have selective effects on neuronal activity in the amyndala when commared to classical neuroloptics can be ar mirradia (Gelman <u>et al</u>, <u>Neurosci</u>. Abstr., 8:469, 1982). As the amygdala has efferent connections to the basal ganglia (eg Yim & Mogenson, <u>Brain Res.</u>, 239:401, 1982), it is possible that this structure mediates some of the atypical effects of such drugs. Accordingly, the effects of small electrolytic lesions, limited primarily to the central nucleus and adjacent stria terminalis, on the ability of clozapine and pimozide to alter the behavioral effects of amphetamine were studied.

Rats were injected with saline, 1 or 5 mg/kg D-amphetamine, IP, and placed in large wood and plexiglass test chambers. Their behavior was observed and categorized every 6 secfor 2 min perids, at 6 intervals during a one hr test period. In both non-lesioned control and lesioned rats, 1 mg/kg amphetamine produced a strong increase in locomotion, but did not produce any stereoa strong increase in locomotion, but did not produce any stereo-typed behavior. 5 mg/kg produced strong stereotyped behavior -primarily sniffing. In control rats, pimozide (0.25 and 0.50 mg/kg, SC) produced a dose-dependent decrease in both locomotion and stereotypy. Clozapine (10 and 20 mg/kg, SC) produced a decrease in amphetamine-induced locomotion but did not alter stereotypy. In rats with amygdaloid lesions, the effectiveness of pimozide in blocking amphetamine-induced behavior (both loco-motion and stereotyped behavior) was unchanged. Similarly, the motion and stereotyped behavior) was unchanged. Similarly, the effectiveness of clozapine in blocking amphetamine-induced loconotor activity was unaltered. However, in rats with lesions, clozapine markedly enhanced the ability of amphetamine to produce stereotypy. The results demonstrate that the amygdaloid lesions and clozapine have synergistic actions on stereotypy produced by amphetamine. by amphetamine.

# 127.10 THE EFFECT OF AMINOPYRIDINES ON THE RELEASE OF <sup>3</sup>H-ACETYLCHOLINE FROM RAT BRAIN SLICES. R. D. Schwarz, C. J. Spencer\*, A. A. Bernabei\* and T. A. Pugsley\*. Warner-Lambert/Parke-Davis Pharmaceutical Research, Ann Arbor, MI 48105.

Aminopyridines (APs) are currently under considerable investi-gation due to their suggested clinical use in such areas as anesthesia, curare poisoning, botulism and myasthenia gravis. In addition, APs may be of therapeutic use in CNS diseases which are characterized by a loss of neuronal function, e.g. Parkinsonism and senile dementia of the Alzheimer type. Treat-ment of these disorders with APs may be beneficial due to their which of these disorders with Ars may be beneficial due to the ability to increase neurotransmitter release. Since many in-vestigators have studied the effects of APs on peripheral cho-linergic function, our purpose was to examing in vitro the effect of a series of APs on the release of H-acetylcholine ( $^{4}$ H-ACh) from neurons in those brain regions with high cholinergic innervation.

ergic innervation. The rat striatum, cortex or hipgocampus was removed, sliced  $(0.3 \times 0.3 \text{ mm})$  and incubated with "H-choline (0.01 uM) for 15 min at 37°C in Krebs-Ringer Hepes buffered medium, pH 7.2. After washing, the slices were further incubated for 15 min in both low K medjum or high K medium in the presence or absence of AP (10 to 10 M). At the termination of the incubation slices were searched from medium by rapid contrifi incubation, slices were separated from medium by rapid centrifu-gation and radioactivity was determined in both fractions by scintillation counting.

scintillation counting. The APS tested were mono substituted (2-, 3-, 4-AP), di substituted (2,3-, 2,6-,  $2_{5}5$ -,  $3,4_{4}AP$ ) and the related 3-phenoxy-pryidine (CI 844). At 10 to 10 M, 3,4-, 2,3- and 4-AP significantly increased basal 3H-ACh release from striatal slices. Since 3,4-AP showed the greatest effect, it was also tested in the cortex and hippocampus. Among the three brain regions, the order of response to  $3_{4}4$ -AP was: striatum>hippo-campus>cortex. The presence of Ca was necessary for the increase in basal release from striatal slices observed with both 3.4- and 4-AP. Further\_these same APS markedly reduced increase in basal release from striatal slices observed with both 3,4- and 4-AP. Further, these same APs markedly reduced K<sup>-</sup>-stimulated release at 10<sup>-</sup> and 10<sup>-</sup> M. These latter results support the concept that APs may act in part by blockade of K<sup>-</sup> channels which would prolong repolarization of the nerve terminal. As a consequence, extracellular  $\zeta_{a}^{+}$  entry would increase and result in enhanced release of H-ACh. In summary, our results show that of eight APs tested, three caused a significant increase in the basal release of H-ACh from rat striatal slices with the order of potency being 3,4-AP> 4-AP = 2,3-AP.

RADIOIMMUNOASSAY OF FLUPHENAZINE IN HUMAN PLASMA. J. L. Brownin and C. M. Davis\*. Analytical Neurochemistry, Tex. Res. Inst. of Mental Sci., Houston, TX 77030. Browning 12711

Fluphenazine has become one of the most widely used agents in the treatment of schizophrenia. Accurate measurement of plasma levels would facilitate control of dosage and clinical management. Since fluphenazine is a very potent neuroleptic it is given in low dosages especially when given as the long acting decanoate or enanthate esters. These lower dosages result in very low plasma levels requiring either extraction of a large volume of plasma or a very sensitive assay procedure. We therefore have developed a radioimmunoassay for fluphenazine that is specific and very sensitive

sensitive. The plasma sample is extracted with 1% isoamyl in heptane with 3H fluphenazine added as internal standard. The organic phase is passed through a small (.5 ml) silica gel column which is subsequently eluted with 6 ml CH<sub>2</sub>Cl<sub>2</sub> containing 1.5% triethylamine and 2% ethanol. The eluate is dried and reconstitued in ethanol to the original plasma volume. Fifty µl aliquots are assayed for fluphenazine by RIA and 200 µl is assayed for 3H recovery. Handled in this way a technician can assay 40-50 samples per day. The sensitivity of the assay is less than 10 pg per 50 µl aliquot. Column treatment completely removes the only known metabolite which cross reacts significantly, the N-oxide. Other metabolites including 3-OH-fluphenazine, 2-OH-fluphenazine and fluphenazine sulfoxide do not cross react significantly and are

fluphenazine sulfoxide do not cross react significantly and are

fluphenazine sulfoxide do not cross react significantly and are retained on the column. Comparison of 12 patient values determined by a HPTLC method (Davis and Fenimore, *J Chromatogr 272:*157, 1982) and RIA gave a correlation coefficient of r = .974. The RIA gave values of 0.6 to 14.5 ng/ml whereas HPTLC values were 0.5 to 9.2 ng/ml. Because of the sensitivity and selectivity of this assay, accurate measurement of fluphenazine in tissue samples as well as small plasma samples is now possible.

127.12 USE OF A CLONIDINE DRUG DISCRIMINATION TASK TO IDENTIFY ALPHA<sub>2</sub> AGONIST AND ANTAGONIST PROPERTIES OF VARIOUS COMPOUNDS: A COMPARand J.M. Liebman. Res. Dept., Pharm. Div., CIBA-GEIGY Corp., Summit, NJ 07901.

It has been previously shown that the interoceptive discrimina-tive stimuli associated with clonidine (CLO-IDS) are mediated by alpha2 adrenoceptor agonism (Bennett and Lal, J. Pharmacol. Exp. Ther., 223:642, 1982). The purpose of the present experiments was to: 1) further evaluate the usefulness of CLO-IDS in identifying 1120 the alpha2 properties of reported antagonists; 2) investigate the possible alpha\_ agonist properties associated with dopamine agonists, the alpha\_ agonist ST-587 and low doses of the alpha\_ antagram onist RX 781094; and, 3) compare the suitability of two rat strains in this model.

strains in this model. Rats of both the Long Evans hooded and Sprague Dawley albino strains were trained to discriminate clonidine from saline in two-lever operant chambers. All rats learned the discrimination over a comparable time course. The discriminative cue was dose-depend-ent in both Long Evans (ED<sub>50</sub> = 0.011 mg/kg) and Sprague Dawley (ED<sub>50</sub> = 0.018 mg/kg) animals. Yohtmbine, piperoxane, RX 781094 and CGS 7525A each dose-dependently antagonized the CLO-IDS in both set tertification backward both rat strains; although in some instances, Sprague Dawley animals exhibited shallower dose-response curves than those gener-ated by Long Evans rats. Mianserin produced up to 70% antagonism in Long Evans rats but only 43% antagonism in Sprague Dawley rats. Rauwolscine ( $\alpha$ -yohimbine) was more effective than coryanthine ( $\beta$ yohimbine) in antagonizing the clonidine discrimination, consistent with its greater potency at  $alpha_2$  adrenoceptors. The  $alpha_1$  antagonists WB 4101 (1-10 mg/kg), prazosin (10 mg/kg) and phenantagonists WB 4101 (1-10 mg/kg), prazosin (10 mg/kg) and phen-tolamine (3-10 mg/kg) failed to block CLO-IDS. The putative dop-amine autoreceptor agonist, TL-99 (3-10 mg/kg) produced dose-dependent generalization to clonidine, but no generalization re-sulted from 3-PPP (3-10 mg/kg). This finding supports previous evidence that TL-99, but not 3-PPP, has alpha<sub>2</sub> agonist properties (e.g., Pastor et al., <u>Eur. J. Pharmacol., 87</u>:459, 1983). The alpha<sub>1</sub> agonist ST-587 and the peripherally acting alpha agonist DPI produced no generalization at doses up to 10 mg/kg. Low doses of the alpha<sub>2</sub> antagonist, RX 781094. were also tested for doses of the alpha<sub>2</sub> antagonist, RX 781094, were also tested for agonist effects as proposed by a previous report (Goldstein et al., <u>Neurosci. Proc.</u>, <u>8</u>:104, 1982). No generalization of RX 781094 was seen in either strain (0.0003-0.01 mg/kg). These re These re-Solicate that CLO-IDS are useful in both identifying com-pounds exhibiting a primary alpha<sub>2</sub> antagonist profile and in identifying the presence or absence of alpha<sub>2</sub> agonist potential in a variety of other compounds. Although both strains are suit-able for this discrimination, some differences were noted that favor the use of Long Evans rats.

128.1 BEHAVIORAL SEQUELAE IN CAT PRODUCED BY COMPOUNDS CLAIMED OR

BEHAVIORAL SEQUELAE IN CAT PRODUCED BY COMPOUNDS CLAIMED OR SHOWN TO BE ANXIOLYTIC AND BY RO 15-1788. <u>S. Furman\*</u>, <u>K. L.</u> Keim. (SPON. W. Schlosser) Dept. of Pharmacology I, Hoffmann-La Roche Inc., Nutley, N.J. 07110. Cats were used to ascertain a minimum effective dose (MED; all doses mg/kg I.G.) for separate endpoints which together produced an overt symptom/effect profile. Drug-experienced l yr old female cats, fasted 18 hrs, were treated with selected compounds. The onset, duration and intensity of ataxia (AT; altered gait), muscle relaxation (MR; reduced abdominal tone and extensor reflex), and change in motor activity (+MA or +MA) were recorded. were recorded.

The MED for diazepam (0.25 to 10 mg/kg, = tested dose range) was 0.5 for producing AT & MR, and 1 for +MA (15 min duration); +MA and sleep occurred post 10 mg/kg. This benzodiazepine Was 0.5 for producing Al & MK, and 1 for MMA (15 min duration); HMA and sleep occurred post 10 mg/kg. This benzodiazepine dose-dependently affected the frequency, intensity and duration of the motor impairments. Alprazolam (0.01 to 20) was 5x more potent in causing AT but 4x less active in producing MR; HMA was markedly intense and followed by HMA and very deep sleep. (We previously reported that in cat, EEG effects produced by alprazolam were phenobarbital-like rather than diazepam-like [Keim & Zavatsky, 1982. Fed Proc 41: 1067]). The MED for AT following phenobarbital or meprobamate was 10 and 80 mg/kg, respectively, and at these doses the AT duration exceeded 4 hrs; MR and loss of righting occurred at higher doses. The behavioral profiles of buspirone (0.1 to 20), fenobam (0.1 to 40), and tracazolate (0.1 to 160), differed from that of classical anxiolytics; none of these produced AT or MR. Buspirone +MA and caused miosis (MEDs = 2.5); a dose of 20 mg/kg sustained the miosis for 4+ hrs. Fenobam at 20 mg/kg caused salivation and +MA. Tracazolate at a dose of 20 mg/kg caused salivation and tMA. The triazolopyridazine CL 218,872 (5 to 40) produced marked AT, lasting 24 hr (MED 40 mg/kg); CL 218,872 at this dose also caused ptosis, emesis, and relaxation of the nictitating membrame - the latter effect typically seen with neuroleptics in cat.

neuroleptics in cat.

neuroleptics in cat. Tested at 20 mg/kg, the benzodiazepine antagonist Ro 15-1788 did not cause AT or MR but an 1MA lasting 4 hrs was recorded. That alprazolam has apparent hypnotic activity in the free-roaming cat corroborates our previous findings on the EEG. Most striking is the lack of AT or MR produced by most of the non-BZ anxiolytic substances in cat - a species known to be particularly sensitive to these measures. CL 218,872 is known to cause AT and 4MA in rodents. Therefore, these behavioral profiles differ from the more classical anxiolytics.

128.2 A PRECLINICAL EVALUATION OF BUSPIRONE IN NEUROPHARMACOLOGIC, EEG, AND ANTICONFLICT TEST PROCEDURES. J.W. Sullivan\*, K.L. Ke and J. Sepinwall, Dept. Pharmacology I, Hoffmann-La Roche Inc. Nutley, NJ 07110. K<u>ei</u>m,

Buspirone HCl (B) has been reported to produce a variety of psychotropic actions including anxiolytic, antidepressant and antipsychotic effects. It has recently been suggested that B

psychotropic actions including anxiolytic, antidepressant and antipsychotic effects. It has recently been suggested that B exerts an anxioselective effect mediated through dopamine recep-tors [Taylor et al., Pharmac Biochem Behav 17(1):25-35, 1982]. The pharmacologic effects of orally administered B were studied in several standard preclinical tests (mice, cats) and in several conflict tests (rats, squirrel monkeys). In addition, we determined the effects of B on the EEG recorded from the anterior cortex in squirrel monkeys working on a food-maintained lever pressing (VI60") schedule. In mice, B (100 mg/kg) caused ataxia and a 70% reduction in locomotor activity. B also produced ethanol-primed loss of righting reflex (EDSD = 26 mg/kg) and deficits in rotarod perfor-mance (ED50 = 144 mg/kg). In female cats, miosis and hyperactivity were seen at 2.5 mg/kg of B, but neither ataxia nor muscle relaxation were observed up to 20 mg/kg. In thirsty rats in a water-lick conflict test (shock for each 20th lick), B was inactive at 1.25-20 mg/kg. In food-deprived rats trained to bar press on a single lever during alternating compo-nents of a VI30" (food)/FRIO (food+shock) schedule, B produced a small (37% over control), significant increase in punished re-sponding at the single dose of 10 mg/kg but was without anti-prince test of the standard and the section of the standard to bar pressing the section of the standard test of the section of the section of the standard test of the section of the secti sponding at the single dose of 10 mg/kg but was without antipunishment activity at other dose levels ranging from 1.25-20 mg/kg. At 40 mg/kg, significant decreases in both punished and unpunished responding occurred. In food-deprived squirrel monkeys trained on a two lever concurrent VI1.5'(food)+VR24(shock)/VI6' (food) schedule of reinforcement, B failed to produce an anti-punishment effect at 1.25 or 2.5 mg/kg, and then produced signifi-cant decreases in both punished and unpunished responding at 5 mg/kg. Our conflict results, therefore, are in disagreement with the findings of Geller and Hartmann (J Clin Psychiat 43:12 (Sec. Dec. 1982), which indicated B to be equipotent to diazeba as an anxiolytic in rat and cynomolgus monkey. In the EEG/lever-press experiment with squirrel monkeys, B (2-

In the EEG/lever-press experiment with squirrel monkeys, b (2-16 mg/kg) also reduced food-reinforced responding while producing only minor changes in the frequency distribution of the EEG. At the higher doses, the monkeys clung to the cage (8 mg/kg), exhi-bited ataxia, tremors, and were prostrate (16 mg/kg). Thus B does not produce antianxiety effects in several conflict

paradigms or changes in EEG activity consistent with those seen with more classical anxiolytic drugs (benzodiazepines, meprobamate, phenobarbital).

drugs.

- ADAPTATION OF CONDITIONED TASTE AVERSION TO SCREENING ANXIOLYTIC 128.3 DRUGS. <u>Gregory Ervin\* and Barrett R. Cooper</u>, Department of Pharmacology, Wellcome Research Labs, Res. Triangle Park, NC 27709 When rats are exposed to a novel flavor, such as that produced by saccharin, and then made ill by injection of certain drugs, the andmals subsequently display greatly reduced consumption of solu-tions containing that flavor. This effect, "conditioned taste aversion," was used in our laboratory to develop a conflict (thirst vs taste aversion) as a screen for anxiolytic drugs. After male Long Evans rats (240-300 gm) were acclimated to a schedule of drinking for 15 min a day, they were offered 0.25% saccharin solution instead of water. Fifteen minutes after this first exposure to saccharin, rats were treated with 25 mg/kg 1-5hydroxytryptophan (5-HTP) i.p. This dose of 5-HTP was used because it produces a mild aversion which appears to be due to an action peripheral to the blood brain barrier (Ervin <u>et al</u>., unpublished data). Forty-eight hours after the initial exposure to saccharin, rats that had been treated with 5-HTP drank only 6 ml while control rats (those receiving the vehicle for 5-HTP on the initial conditioning exposure to saccharin) consumed 12 ml of saccharin solution. This 5-HTP-induced conditioned reduction in saccharin consumption could be antagonized by treatment with clinically effective benzodiazepine and non-benzodiazepine anxioclinically effective benzodiazepine and non-benzodiazepine anxio-lytic drugs l hr before the second saccharin exposure. The ED<sub>50</sub> values for representative drugs are lorazepam (ED<sub>50</sub>  $\approx$  0.3 mg/kg i.p.), diazepam (ED<sub>50</sub>  $\approx$  1 mg/kg i.p.), chlordiazepoxide (ED<sub>50</sub>  $\approx$ 5 mg/kg i.p.), oxazepam (ED<sub>50</sub>  $\approx$  6 mg/kg i.p.), phenobarbital (ED<sub>50</sub>  $\approx$  15 mg/kg i.p.), chlormezanone (ED<sub>50</sub>  $\approx$  36 mg/kg i.p.), and meprobamate (ED<sub>50</sub>  $\approx$  65 mg/kg i.p.). These ED<sub>50</sub> values are ap-proximately the same as values reported in the literature using other conflict procedures. Representative agents which do not antagonize the taste aversion are d-amphetamine, dilantin, atropine, morphine, imipramine, chlorpromazine, naloxone, muscimol, apomorphine, cyproheptadine (and others). In conclusion, the taste aversion conflict procedure appears to be as sensitive to taste aversion conflict procedure appears to be as sensitive to benzodiazepine and non-benzodiazepine anxiolytic drugs as other experimental conflict procedures, yet does not require elaborate operant equipment or programming. Its simplicity and specificity suggest that it will have application to screening for anxiolytic
- 128.4 INTERACTIONS OF THE ANXIOSELECTIVE AGENT BUSPIRONE WITH CENTRAL SEROTONIN SYSTEMS. Michael S. Eison, Cam P. VanderMaelen, G. Keith Matheson<sup>1</sup>, Arlene S. Eison, and Duncan P. Taylor. CNS Research, Pharmaceutical Research and Development Division of the Bristol-Myers Company, Evansville, IN 47721, and <sup>1</sup>Department of Anatomy, Indiana University School of Medicine, Evansville, IN 47732.

Although nonbenzodiazepine in both structure and pharmacology, buspirone (Buspar<sup>144</sup>; Mead Johnson Pharmaceutical Division) has demonstrated clinical efficacy in the treatment of anxiety neuroses comparable to diazepam and clorazepate (Goldberg & Finnerty, J. <u>Clin. Psych.</u> 43: 87,1982). While the mechanisms responsible for buspirone's anxiolytic efficacy in the absence of the ancillary pharmacological properties which characterize the benzodiazepines remains elusive, some authors have hypothesized a role for serotonin in the mediation of buspirone's effects (Hjorth & Carlsson, <u>Bur. J. Pharm.</u> 83: 299, 1981). We have therefore investigated buspirone's interactions with central serotonin systems in the rat behaviorally, neurochemically, and electrophysiologically.

Rats were made supersensitive to SHT agonists by intraventricular administration of 5,7-dihydroxytryptamine (5,7-DHT). When dosed with L-5-hydroxytryptophan, they demonstrated a SHT syndrome defined by the presence of forepaw tread, tremor, headwave, straub tail, rigidity, and abducted posture at doses 10-20 fold less than unlesioned controls. Buspirone did not induce all of these signs when administered i.p. (up to 10 mg/kg) or orally (up to 50 mg/kg). Rather, buspirone only induced mildly straub tail and a splayed, as opposed to abducted, posture. In other experiments, oral administration of buspirone to rats unilaterally lesioned in the medial forebrain bundle with 5,7-DHT did not result in consistent rotational behavior. While in binding studies buspirone is essentially devoid of activity at SHT<sub>1</sub> sites exhibiting less than 1 percent of the potency of SHT itself upon rat cortical membranes, it does displace [<sup>3</sup>H]spiperone from SHT<sub>2</sub> sites with an IC<sub>50</sub> value of 740 nM. Preliminary results from single unit recordings in chloralhydrate anesthetized rats indicate that buspirone administered i.p. (2.5 - 10 mg/kg) or orally via intragastric intubation (1.0 -10 mg/kg) causes inhibition of spontaneous firing of serotonergic dorsal raphe neurons. The role of serotonin in buspirone's anxiolytic activity as reflected in its anticonflict effects will also be discussed.

128.5 CHRONIC TREATMENT WITH BUSPIRONE DOES NOT ALTER DOPAMINE RECEPTOR BINDING. <u>Deborah K. Hyslop\*, Jerry A. Becker\*, Margaret Crane\*,</u> L. A. Riblet, and Duncan P. Taylor. Preclinical CNS Research, Pharmaceutical Research and Development Division, Bristol-Myers Company, Evansville, IN 47721. Buspirone (Buspar<sup>™</sup>, Mead Johnson Pharmaceutical Division) is

Buspirone (Buspar<sup>M</sup>, Mead Johnson Pharmaccutical Division) is a new antianxiety agent with clinical efficacy comparable to that of the benzodiazepines (Am. J. Psychiat. 136: 1184-1187, 1979; J. Clin. Psychiat. 43 12 [Sect. 2]: 81-86,  $\overline{87}$ -91, 92-94, 1982). Buspirone is not only chemically distinct from the benzodiazepines, but it also presents a clinical pharmacologic profile which is "anxioselective": it relieves anxiety but lacks the accompanying ancillary properties of benzodiazepines (sedation, muscle relaxation, seizure control). No conclusive interaction with the benzodiazepine-GABA-chloride ionophore complex has been demonstrated. Buspirone does interact with dopamine receptor binding sites in vitro, and some of its pharmacologic properties are shared either by dopamine agonists or dopamine antagonists (J. Clin. Psychiat. 43 12 [Sect. 2] 11-16, 1982). To identify potential concerns associated with long-term clinical usage, we administered anxiolytically-relevant doses (two times the MED value from Vogel conflict testing: 2 mg/kg for buspirone, 0.5 mg/kg for trifluoperazine) orally three times a day for 29 days to male Sprague-Dawley rats. One day later, regions of the brain were removed and analyzed for in vitro radioreceptor binding. The results of this study (see table below) show that buspirone did not alter dopamine receptor binding. Similar results are reported by McMillen (this volume). Unlike dopamine antagonists, buspirone does not induce catalepsy in rats. In fact, buspirone reverses catalepsy induced by dopamine antagonists. It also reduced type 2 serotonin binding in the cerebral cortex by a selective decrease in the number of binding sites. Taken together, these data suggest that buspirone will not produce extrapyramidal side effects or tardive dyskinesia following clinical use. Furthermore, the alteration in 5-HT2 binding suggests a potential mechanism for the clinically-observed decrease in symptoms of depression in patients following treatment with buspirone (see Taylor et al.,

128.6 CHRONIC TREATMENT WITH BUSPIRONE REDUCES TYPE TWO SEROTONIN BINDING SITES. Duncan P. Taylor, Jerry A. Becker,\* Margaret Crane,\* Deborah K. Hyslop,\* L. A. Riblet, and D. L. Temple, Jr. CNS Research, Pharmaceutical Research and Development Division, Bristol-Myers Company, Evansville, IN 47721. Buspirone (Buspar<sup>M</sup>, Mead Johnson Pharmaceutical Division) is a provide the second s

Buspirone (Buspar<sup>m</sup>, Mead Johnson Pharmaceutical Division) is a new antianxiety agent with clinical efficacy comparable to the benzodiazepines. However, buspirone enjoys chemical and pharmacologic distinction from this class of drugs; it is truly "anxioselective" (J. Clin. Psychiat. 43 12 [Sec. 2] 11-16, 1982). It has been suggested that antianxiety agents given in the proper therapeutic regimen may be efficacious not only in the treatment of anxiety but in the treatment of depression as well. Clinical trials with benzodiazepine anxiolytics to substantiate this suggestion have been equivocal (Feighner, Mod. Probl. Pharmaco psychiat. 18 196, 1982). In addition to its efficacy in the relief of symptoms of anxiety neurosis, clinical trials of buspirone demonstrated antidepressant effects as well (Am. J. Psychiat. 136: 1864, 1979; J. Clin. Psychiat. 43 12[Sec. 2] 81, 87, 1982). To investigate the biochemical mechanism of this clinical observation, we administered anxiolytically relevant doses (two times the MED value from Vogel conflict testing; 2 mg/kg) orally three times a day for 29 days to male Sprague-Dawley rats. One day later, cerebral cortices were removed and analyzed for in vitro radioreceptor binding. The results of this study (see table below) show that buspirone treatment decreased  $\beta$ -adrenergic and type 2 serotonin (S2) binding. This effect was due to a decrease in the number of binding sites. Chronic treatment with antidepressants has been reported to decrease either  $\beta$ -adrenergic or S2 receptors (J. Clin. Psychapharmacol. 1 [6, supplement] 17S-22S, 1981). The molecular changes observed here after chronic buspirone treatment suggest a potential mechanism for the clinically-observed antidepressant effects of this unique new drug.

INDICATIONS OF SEROTONERGIC INVOLVEMENT IN THE ACTIONS OF A POTENTIAL NONBENZODIAZEPINE ANXIOLYTIC: MJ 13805. <u>Arlene S.</u> Eison, Michael S. Eison, L. A. Riblet, and D. L. Temple, Jr. 128.7

Eison, Michael S. Eison, L. A. Riblet, and D. L. Temple, Jr. .
CNS Research, Pharmaceutical Research and Development Division of the Bristol-Myers Company, Evansville, IN 47721.
MJ 13805, known chemically as 4,4-dimethyl-1-[4-[4-(2-pyrimi-dinyl)-1-piperazinyl]butyl]-2,6-piperidimedione hydrochloride was originally synthesized by W. Lobeck and D. L. Temple, Jr. While nonbenzodiazepine in both structure and pharmacology, its potential utility as an anxiolytic drug is reflected in its potent potential utility as an anxiolytic drug is reflected in its potent anticonflict effects and inhibition of shock-elicited aggression in pairs of mice selected for their propensity to fight. Understanding the mechanism of action of potential antianxiety drugs such as MJ 13805 whose pharmacology represent dramatic departures from those of the prototypical class of anxiolytic drugs, the benzodiazepines, can add much to our understanding of the neural substrates which subserve anxiety states. Recent studies suggest that central serotonin may play an important role in MJ 13805's diverse pharmacological effects. In animals unilaterally lesioned in the medial forebrain bundle with the serotonin neurotoxin 5.7-dibydroxytryntamine and administerd

Minus difference of the second of the second relation of the second of t the direction of rotation was invariably contralateral. Meuro-chemical determinations revealed the animals to have at least 90% depletions of serotonin and 5-HIAA while dopamine turnover was relatively unaffected. MJ 13805 administration induces a sero-tonin syndrome in rats depleted of central serotonin by intra-ventricular 5,7-dihydroxytryptamine and allowed sufficient time to become supersensitive. However, the MJ 13805-induced syndrome differs somewhat in its topography from that induced by L-5-hydroxytryptophan in that it results in a splayed posture as opposed to an abducted one, minimal head weaving, but robust straub tail, tremor, treading, and rigidity. While not inherently altering vocalization threshold in rats, such lesions alter the effects of MJ 13805 upon this nociceptive measure. Whereas in unlesioned animals, MJ 13805 shifts the vocalization threshold towards hypergesia at anxiolytically relevant doses, MJ 13805 in serotonin lesioned rats is without effect upon vocalization threshold. That the serotonergic activity suggested by the above results is relevant to the anxiolytic effects of MJ 13805 is demonstrated by the loss of MJ 13805's potent anticonflict effects in animals depleted of central serotonin by these lesions. These data suggest that serotonin may play an important role in the chemical determinations revealed the animals to have at least 90% data suggest that serotonin may play an important role in the behavioral effects of this nonbenzodiazepine anxiolytic candidate.

EFFECTS OF ANTIDEPRESSANTS, ANXIOGENIC SUBSTANCES AND BENZODIAZE-128.8 PINE ANTAGONISTS ON THE SELF-REGULATION OF ICSS DURATION. S. Gerhardt\* and J.M. Liebman (SPON: M. Roffman). Res. Dept.

Pharma. Div., CIBA-GEIGY Corp., Summit, NJ 07901. Rats self-regulate the duration of intracranial self-stimulation (ICSS) when they are placed in a shuttlebox where the inter-ruption of an infrared beam initiates a continuous train of stimulation pulses through an indwelling electrode. They terminate of the stimulation by interrupting another beam at the opposite end of the shuttlebox. Latency to initiate stimulation (the ON latency) is considered to correlate inversely with reward value of stimulation. For example, it was previously found that this lat-ency was reduced by two stimulant drugs (<u>d</u>-amphetamine, pipradrol) that enhance release of dopamine (Liebman, <u>Neurosci. Biobehav.</u> <u>Rev.</u>, 7:45, 1983). The latency to terminate stimulation (the OFF latency) appears to correlate inversely with stimulation-induced latency) appears to correlate inversely with stimulation-induced aversiveness, and is preferentially elevated by anxiolytic drugs (Gerhardt et al., <u>Pharmacol. Biochem. Behav., 16</u>:795, 1982). How-ever, to date no drug has been reported to decrease the OFF lat-ency preferentially. Such an effect might suggest anxiogenic activity by analogy with the opposite effects of anxiolytics. In order to explore this hypothesis, and at the same time verify the apparent association between dopamine facilitation and ON latency decrements of mid-with the opposite effects of anxionation of the same time verify the apparent association between dopamine facilitation and ON latency decrements, a wide variety of antidepressant and psychomotor stim-ulant drugs was evaluated.

Rats with lateral hypothalamic electrodes were tested in 10 min sessions, during which ON and OFF latencies were automatically compiled. Drugs were administered intraperitoneally 30 min before testing, except that RO 15-1788 was given orally 15 min prior to testing.

Amineptine (3-30 mg/kg) and nomifensine (3 & 10 mg/kg), which block dopamine reuptake, reduced the ON latency, as does bupropion (Liebman, 1983). Caffeine (10 & 30 mg/kg), an adenosine antagonist that enhances catecholamine levels, also reduced the ON lat-ency. None of these substances reduced the OFF latency, a finding that excludes nonspecific behavioral excitation as an explanation of the observed effects. These findings strengthen the observed inverse relationship between drug-induced enhancement of dopamine neurotransmission and reduction of the ON latency. Neither vil-oxazine (10 & 30 mg/kg) nor the alpha<sub>2</sub> adrenoceptor antagonist, CGS 75254 (3-30 mg/kg), reduced either latency. Pentylenetetra-zol, an anxiogenic substance, failed to reduce the OFF latency at subconvulsive doses (2.5-15 mg/kg). The benzodiazepine antagon-ist, RO 15-1788, also failed to alter either latency at doses of 0.3-100 mg/kg; 300 mg/kg elevated both latencies non-selectively. Thus, the hypothesis that an anxiogenic substance or a benzodiaz-epine antagonist would selectively decrease the OFF latency remains to be experimentally verified.

POSITIVE CORRELATION BETWEEN SEROTONIN ANTAGONISM AND ANTICON-128.9 H.\* Res. Dept., Pharm. Div., CIBA-GEIGY Corp., Summit, NJ 07901. Previous reports have shown that certain drugs with serotonin (5HT) antagonist properties increase punished responding (Stein et al., Am. J. Psychiat., 34:665, 1977). The present study examined the relationship between the degree of selective serotonin antagonism and the degree of anticonflict effect shown by various drugs. The drugs selected were: spiperone, cyproheptadine, mian-serin, cinanserin, metitepine, methysergide, quipazine, pipamperone, pirenperone and CGS 7525A. In addition, the novel SHT agonist, 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) agonist, 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) (Hjorth et al., J. Neural Trans., 55:169, 1982), was studied for possible selective presynaptic agonist activity. All drugs were assessed for their ability to displace <sup>3</sup>H-5HT (7 nM) from mem-brane preparations of calf caudate (Bennett & Snyder, <u>Molec.</u> Pharm., 12:323, 1976). Activity in this assay was used as an index of 5HT agonism (Peroutka & Snyder, <u>Molec. Pharm.</u>, 16:687, 1979). The drugs were also assessed for their ability to dis-1979). The drugs were also assessed for their ability to displace  $^3\mathrm{H}-ketanserin~(0.4~n\mathrm{M})$  from membrane preparations of rat prefrontal cortex. Activity in this assay was used as an index of 5HT antagonism (Leysen <u>et al., Molec. Pharm., 21</u>:301, 1982). A measure of the degree of selectivity as a 5HT antagonist was obtained by calculating the ratio of the agonist and antagonist IC<sub>50</sub> values

Anticonflict effects were assessed using a lick-suppression paradigm (Vogel <u>et al.</u>, <u>Psychopharmacologia</u>, <u>21</u>:1, 1971) and/or a paradigm using alternating unpunished and punished operant schedules (Davidson & Cook, <u>Psychopharmacologia</u>, <u>15</u>:159, 1969). Rela-tive anticonflict efficacy was determined by activity in one or both tests, dose response relationships and magnitude of effect. Of the eleven drugs tested, seven showed some degree of anti-

conflict activity. These seven active compounds showed a positive correlation between degree of anticonflict effect and degree of selective 5HT antagonism. The four inactive compounds were quipazine, 8-OH-DPAT, pipamperone and spiperone. Quipazine showed only weak 5HT antagonist activity, consistent with the view that this action may be responsible for anticonflict effects. It was confirmed that 8-OH-DPAT is an agonist which did not appear to manifest selective presynaptic agonism at low doses. Both spiper Both spiperone and pipamperone are dopamine antagonists which may mask the anticonflict effect. This study confirms previous reports that 5HT antagonists can manifest anticonflict activity and extends that finding to a large number of drugs. In addition, the degree of specificity of 5HT antagonism is correlated with the degree of anticonflict effect.

128.10 INTERACTION OF ETHANOL WITH ANXIOLYTICS OR HYPNOTICS IN MICE ON THE INCLINED SCREEN: AN ANIMAL MODEL OF DRUG POTENTIATION. K. L. Keim and S. Furman\* (SPON: L.R.Klevans) Pharmacology I, Hoffmann-La Roche Inc., Nutley, N. J. 07110 Using isobolograms we demonstrated that ethanol (ETOH) potentiated the effect of diazepam or lorazepam in causing the loss of righting reflex (LRR), whereas, these interacted agents were additive when tested for impairment on the traction wire test [Davidson, Furman & Keim. Soc. Neurosci Abstr 8: 470, 1982]. We expanded these studies with the following experiments using different endpoints. As before, ETOH was given to fasted CFI male mice per os 20 min after oral administration of a test compound and performance was measured 10 min later in two procedures: rotarod (RR; 16 rpm, 5 cm dia) and inclined screen (IS; 8" x 11" wire mesh field; 70° angle). Isobols were constructed as mentioned previously [also see Loewe, S. <u>Pharmacol Rev 9</u>: 237, 1957]. We found that the diazepam-ethanol isobol for RR impairment indicated the interaction to be one of additivity, whereas, the IS impairment endpoint is one of potentiation. Therefore, selected drugs were evaluated in the latter test to estimate possible ethanol potentiation:

Compound	I IS ED50 Alone mg/kg PO	E IS ED50 with ED5 ETOH	I/E Ratio
Alprazolam	>400	0.16	>2500
Lorazepam	168	5	34
Diazepam	72	5.6	13
Phenobarbital	120	31	4
Buspirone	>200	>100	*
Fenobam	>200	>100	*
Zopiclone	>200	>260	*
Triazolam	>400	0.25	>1600
Temazepam	5	2.2	2.3
Midazolam	15	7.2	2.1
Flurazepam	200	27	7.4

A range in the degree of potentiation (I/E ratio occurred with compounds that alone impaired IS. The effect of nonbenzo-diazepines (BZ) on IS was not altered by ETOH. In contrast, IS impairment by the triazolo-BZs was markedly potentiated by ETOH. While the large I/E ratio may be a numerical artefact, alprazolam and triazolam are quite distinct from the other BZs tested in their interaction with ETOH in these and other tests.

128.11 YOHIMBINE: A BETA CARBOLINE WITH BEHAVIORAL AND NEUROCHEMICAL PROPERTIES COMMON TO ANXIOCENIC DRUGS. Harbans Lai, Gary Shearman,\* Debra Bennett,\* and Agnes Horvat\* Dep. of Pharmacology, Texas Col. Osteopathic Med., Fort Worth, TX 76107, & Univ. of Rhode Island, Kingston, R.I. 02881.

> Yohimbine is an alpha-2 adrenoreceptor-antagonist and is reported to be anxiogenic in humans. It has, therefore, been postulated that the alpha-2 adrenoreceptor modulation may be the basis of the anxiogenic activity of yohimbine. Structurally, yohimbine may be considered to be a beta carboline derivative, a class of drugs known for their anxiogenic action and for interaction with the benzodiazepine-GABA receptor system. We, therefor, investigated the possibility of yohimbine producing anxiogenic action related to its beta carboline structure, by comparing its anxiety-related pharmacological profile with those discriminable-stimuli (IDS) which generalize to those of pentylenetetrazol (PTZ) in a drug-discrimination paradigm and are selectively antagonized by anxiolytic drugs (Lal and Shearman, Ann. Rep. Med. Chem. 15: 51-58, 1980). Beta carboline-type anxiogenics resemble other anxiogenics in this respect, and also displace benzodiazepines from binding sites in the brain. In the present experiment beta carboline-3-carboxylate (BCC) methyl ester and harmane generalized to PTZ in a dose-dependent manner in rats trained to discriminate PTZ from saline. yohimbine\_ (0.16-10 mg/kg) and BCC ethyl ester also generalized to PTZ; however, BCC ethyl ester was toxic at the higher doses necessary for complete generalization and yohimbine produced a bell-shaped dose-response curve. The IDS produced by these drugs, including yohimbine, showed pharmacological characteristics related to anxiety since they were antagonized by diazepam dose-dependently. In addition, similar to the known neurochemical action of beta In addition, similar to the known heurochemical action of be carbolines, yohimbine inhibited 3H-flunitrazepam binding to cerebral cortex synaptosomes with potency similar to that of harmane (IC50, 7 uM). Clonidine was ineffective in either antagonizing PTZ-IDS or in displacing flunitrazepam from its binding site. Based upon the resemblence in structure and pharmacological profile characteristic of anxlogenic beta carbolines, we suggest that anxiogenic action of yohimbine is mediated through neurobiological mechanisms underlying the beta carboline action, i.e., interaction with benzodiazepine-GABA system. Our hypothesis is further supported by our observation that neither behavioral nor neurochemical actions described above were sensitive to a well established alpha-2 adrenoreceptor agonist.

 128.13
 INTERACTION BETWEEN HARMANE AND BETA-RECEPTORS, <u>B. Delbarre</u>,

 <u>G. Delbarre and A. Ferger</u>\*. Lab. Ch. Exp., Faculté de Médecine

 37032 TOURS, FRANCE.

Harmane is a very potent inhibitor of specific (<sup>3</sup>H)-flunitrazepam binding to rat brain and bovine retina membranes. two tissues containing brain specific BDZ receptors (Braestrup C. et al., Br. J. Psychiatr. 133 : 249, 1978). In contrast to several other B-carbolines, the CNS excitatory and convulsive properties of harmane are much more pronounced (Sigg E.B. et al., Arch. Int. Pharmacodyn. 149 : 164, 1964). Thus, if harmane acts endogenously at the BDZ receptor it elicits - rather benzodiazepine antagonistic effects. Anticonvulsivant effect of BDZ are highly correlated with their anxiolytic properties (Paul S.M., Psycho pharma. Bulletin, 16, 1 : 9, 1980). Recently V.H. Sethy and al. (Soc. Neurosci. Abstr. Vol. 8 : 376, 1982) demonstrated role of B-adrenergic receptors in the antidepressant activity of some BDZ. In harmane convulsions in mice, we have compared Diazepam and a  $\beta_2$ -stimulant agent, Clenbuterol with antidepressant activity (Delbarre G. and al., Soc. Neurosci. Abstr. Vol. 5:553, 1979). Diazepam (1  $mgkg^{-1}$  IP) and Clenbuterol (0,5  $mgkg^{-1}$  IP) antagonize harmane convulsions in mice. These results suggest that antidepressive activity of some BDZ may be correlated with their activity on harmane receptors.

128.12 ONTOGENY OF THE ANXIOLYTIC PROPERTIES OF CHLORDIAZEPOXIDE. Elizabeth Ochoa\* and Gordon A. Barr\*, Dept. of Psychology Hunter College, CUNY and Dept. of Psychiatry, Albert Einstein College of Medicine, New York, New York (SPON: W.H. Bridger). A hallmark action of benzodiazepines is to release suppressed behavior. This effect correlates well with benzodiazepine's

A hallmark action of benzodiazepines is to release suppressed behavior. This effect correlates well with benzodiazepine's anxiolytic actions in humans. Previous research has shown that the benzodiazepines interact with at least two high affinity benzodiazepine (Type 1, Type 2) receptors. Further, in the rat, the ontogenesis of these benzodiazepine receptors differs, with the Type 2 receptor present at birth and the Type 1 receptor developing during the second week. We conducted a parallel behavioral study in infant rats to those used in adult rats, to determine at what age the behavioral effects of these drugs become apparent.

Rat pups were tested with chlordiazepoxide (CDZ) at either 10 or 14 days of age in one of two conditions: milk tainted with quinine or milk only (Half & Half). Quinine, which is bitter to the taste, suppresses milk intake in rat pups. All pups were isolated from their mothers and littermates for 8 hours but kept at 33° C. Anterior tongue cannulas were implanted and the pups' weights, following voiding, were recorded. CDZ was dissolved in distilled water and one of three doses (0.3, 1.0 or 3.0 mg/kg) or the water vehicle was injected intraperitoneally in a volume of 1.0 mg/100 g body weight. Milk or the adulterated milk was infused immediately after injection for one hour. The pups were reweighed, and the increase over the hour expressed as grams or as percent of preinfusion weight.

as percent of preinfusion weight. We found that CDZ produced no significant alteration of intake of either milk or milk + quinine in the younger 10 day old pups. In the 14 day olds, however, CDZ produced a dose dependent increase in ingestion of the adulterated milk (ANOVA, p < .005) with both the 1.0 and 3.0 mg/kg doses significantly enhancing intake. In the milk only condition, the drug effect was not significant (p > .05).

Our behavioral data correspond to the ontogeny of the Type 1 but not the Type 2 benzodiazepine receptor. Prior to the development of the Type 1 receptor release from suppression was not found. However, with the rapid development of the Type 1 receptor, occurring during the second week, was found the rapid onset of release from suppression. These data provide further evidence for the role of the Type 1 receptor in the anxiolytic actions of the benzodiazepines, and offer a model for studying the physiological roles of these two receptor types. Further, the data correlate strongly with the onset of the ability of opiate antagonists to modify milk ingestion, adding support to the speculation of opiate-benzodiazepine interactions in food and water intake. 129.1

REGIONAL DISTRIBUTION OF DYNORPHIN AND NEO-ENDORPHIN PEPTIDES IN RAT BRAIN, R.I. Cone<sup>1</sup>, E. Weber\*, J.D. Barchas and A. Goldstein. Addiction Research Foundation, Palo Alto, CA 94304 and Stanford University, Stanford, CA 94305 Five products of the dynorphin gene --  $\alpha$ -neo-endorphin ( $\alpha$ -Neo),  $\beta$ -neo-endorphin ( $\beta$ -Neo), dynorphin A (Dyn A), dynorphin A-(1-8) (Dyn A-8), and dynorphin B (Dyn B) -- were measured in various regions of rat brain by RIA. Specific antisera were used, supplemented by gel permeation analysis and HPLC. Antisera directed against  $\alpha$ -Neo,  $\beta$ -Neo or Dyn A-8 recognize single classes of peptide which co-elute on HPLC with the respect-ive synthetic peptides. On the other hand, antisera directed against Dyn A or Dyn B recognize larger sized dynorphins in addition to the respective synthetic peptides. For example, in brain, there were three gel-sizing peaks of immunoreactive (ir)-Dyn A and ir-Dyn B which either overlapped (2-kDal) or coin-cided exactly(4- and 7-kDal). On HPLC, the 2-kDal ir-Dyn A and cided exactly (4- and 7-kDa). On HPLC, the 2-kDal ir-Dyn A and ir-Dyn B eluted in the same positions as synthetic Dyn A and Dyn B, respectively and the 4-kDal peaks eluted in the same position as synthetic dynorphin-32 (ie. another gene product with Dyn A at the amino terminus followed by the "processing signal" Lys<sup>18</sup> - Arg<sup>19</sup>, and then by Dyn B at the carboxyl terminus). The 7-kDal peaks were not characterized further. In order to compare tissue amounts of the five gene products, cotimetee of Dyn A and Dyn B required the author time of the 1

estimates of Dyn A and Dyn B required the subtraction of the 4estimates of Dyn A and ir-Dyn B. In whole brain, c-Neo, Dyn A-8 and Dyn B were present in greater amounts than  $\beta$ -Neo and Dyn A. Although a general parallelism was found in the regional distribution of the five peptides, there were also note-worthy exceptions, suggesting that differential processing may occur.

Some dynorphin gene products are mutually exclusive because they contain the same sequence. (i.e. one molecule of the pre-cursor, pro-dynorphin, could yield Dyn A-8 or Dyn A but not both). In some brain regions, we found a reciprocal relationship between the amounts of some mutually-exclusive products. If one assumes that the peptides are present in approximate proportion to their relative rates of production, it would follow that the pro-cessing of pro-dynorphin may take different pathways in different regions. Since the dynorphin gene products have different degrees of opiate receptor selectivity and biologic activity, differential pro-cessing might therefore be a mechanism for regulating function in the dynorphin system. Supported by NIDA grants DA-01207; DA-1199, NIH grant NS-18098 and NSF grant BNS-91-07237.

STORAGE SITE OF LOW-MOLECULAR WEIGHT MET-ENKEPHALIN IMMUNOREACTIV-129.2 ITY IN BLOOD PLATELETS. G. B. Picotti\*, A. M. Di Giulio, L. Bor-riero\*, M. D. Galva\* and M. Da Prada\*°. Dept. of Pharmacol., Univ. of Milan, I-20129 Milan, Italy and °Pharm. Res. Dept., Hoffmann-La Roche, CH-4002 Basle, Switzerland.

A met-enkephalin immunoreactive material (ME), comigrating with synthetic met-enkephalin on TLC, gel permeation and HPLC, has recently been detected in human and animal blood platelets (Di Giulio et al., Life Sci. 30, 1605, 1982). Moreover, indirect evidence has been obtained suggesting a common subcellular localization for human platelet ME and 5-hydroxytryptamine (5-HT), i.e., the 5-HT organelles.

We have further investigated the subcellular distribution of platelet ME by direct assessment of ME concentrations in subcellular fractions of rabbit platelets isolated by urographin density gradient centrifugation. The results obtained indicate that ME, like 5-HT and catecholamines, is concentrated to a much grater extent in the 5-HT organelles than in any other subcellular fraction or in intact platelets. BioGel P-2 chromatography of granular ME revealed that it behaves identically with synthetic met-enkephalin. As in intact human and rat platelets (same ref.), no highmolecular weight ME could be detected in 5-HT granules from rabbit platelets, even after trypsin and carboxypeptidase B hydrolysis, using two antisera which are able to recognize some of the putative met-enkephalin precursors present in the adrenal gland or striatum. The apparent lack of ME precursors in platelets, together with the fact that platelets do not take up met-enkephalin in vitro from plasma or physiological media might indicate either that there is a different synthetic pathway for ME from those in other tissues (e.g., the adrenal medulla), a carry over mechanism from the megakaryocyte stage, or other less-likely alternatives.

Chronic administration of the 5-HT precursor 5-hydroxytryptophan to headache patients significantly increased both 5-HT and ME platelet concentrations. A 14-day treatment with the amine-uptake inhibitor amitriptyline also increased platelet ME concentrations while decreasing 5-HT content.

Additional results provide evidence that human and animal platelets are rich in enkephalin-degrading enzymes, i.e., aminopeptidase, but also the possibly more specific enkephalinases, mainly of the B type.

IMMUNOCYTOCHEMICAL LOCALIZATION OF ACTH IMMUNOREACTIVE PERIKARYA 129.3 IN NUCLEUS TRACTUS SOLITARIUS. <u>S.A.</u> Joseph and W.H. Pilcher\*. The Neuroendocrine Unit, Univ. of Rochester, Rochester, NY 14642. To date numerous investigations have indicated that neuronal

perikarya containing opiocortin peptides including ACTH, β-endorphin,  $\beta$ -lipotropin and  $\alpha$ MSH reside within the arcuate and periarcuate region of medial basal hypothalamus. An extensive fiber distribution emanating from this hypothalamic, hereive fiber distribution emanating from this hypothalamic neuronal pool has been shown to project to forebrain, limbic diencephalic and brainstem structures. In the brainstem opiocortin immuno-reactive fibers have been observed in periaqueductal gray (PAG), various catecholamine containing regions, specific cranial nuclei and autonomic centers. Our preliminary lesion and hypothal-amic deafferentation studies suggest that the origin of immunoreactive fibers within several caudal brainstem centers may be derived from an additional pool of opiocortin containing neurons.

In this report we reveal a previously unidentified group of opiocortin containing neurons in the nucleus tractus solitarius (NTS). These immunocytochemically demonstrable ACTH-neurons are confined to the caudal medulla and reside within the commis-sural portion of NTS. This medullary neuronal pool could be visualized only in the brains of animals in which colchicine had been infused into the lateral or 4th cerebral ventricle. Using the ABC method of immunocytochemistry on Bouin's fixed Vibratome sections, these medullary perikarya were immunoreactive with antisera generated against  $ACTH^{1-39}$  and the 16K fragment (Mains and Eipper) of the pro-opiocortin molecule.

In this medullary region ACTH-ir fibers were observed within all divisions of NTS, as well as tractus solitarius throughout their rostral-caudal extent. Additional fibers were observed in the parabrachial nucleus, nucleus ambiguus and various portions of the medullary reticular nuclei.

The presence of this medullary opiocortin neuronal pool suggests that a more complex organization of the central opiocortin system exists with a separate component apparently associ-ated within the NTS brainstem autonomic center.

ENKEPHALINS IN THE PITUITARY GLAND: IMMUNOHISTOCHEMICAL AND BIOCHEMICAL CHARACTERIZATION. P. Panula\*, I. Lindberg\*, H.-Y.T. Yang and E. Costa (SPON: Joan S. McIntosh) Lab. Preclinical Pharmacology, NIMH, Saint Elizabeths Hospital, Washington, D.C. 2003, Antisera, against [Met] -enkephalin, [Met] -enkephalin-Arg-Phe', [Met] -enkephalin-Arg'-Gly'-Leu', Phe-Met-Arg-Phe-NH<sub>2</sub> and B-endorphin were used to localize these immunoreactivities in the rat pituitary gland using indirect immungfluorescence. [Met] -enkephalin-and [Met] -enkephalin-Arg'-Gly'-Leu'-like immunoreactivities (ME-LI and MEAGL-LI) were found only in nerve terminals in the perimeter of the posterior lobe (PL). [Met] -enkephalin-Arg'-Phe'-like immunoreactivity (MEAP-LI) was found in the same location in the PL. In addition, most cells in the intermediate lobe (IL) exhibited MEAP-LI. Intermediate lobe MEAP-LI was not due to cross-reactivity of the antiserum with B-endorphin, since preabsorption of the antiserum with MEAP but not with B-endorphin diminished the staining. When consecutive sections were processed for MEAP-LI and Phe-Met-Arg-Phe-NH<sub>2</sub>-like immunoreactivity, different immunofluorescence patterns were  $\text{NH}_{2}\text{-like}$  immunoreactivity, different immunofluorescence patterns were observed. Phe-Met-Arg-Phe-NH\_2-like immunoreactivity was distributed throughout the PL. The specificity of all immunocytochemical procedures was confirmed using appropriate absorption controls. Enkephalin-immunoreactive peptides were characterized in acid extracts of fresh pituitaries by gel filtration on Bio-Gel P-30. While more than 90% of ME-LI and [Leu<sup>3</sup>] enkephalin-like immunoreactivities were recovered in the L1 and [Leu<sup>5</sup>] enkephalin-like immunoreactivities were recovered in the elution positions of the authentic pentapeptides, only 17% and 25% of the MEAGL-L1 and MEAP-L1, respectively, eluted in the positions of the authentic peptides. High molecular weight peptide(s) with MEAGL-L1 eluted in a region of 8,000 daltons, while high molecular weight peptide(s) with MEAP-L1 eluted at ca. 10,000 daltons. Considerably more MEAP-L1 than MEAGL-L1 was found in extracts of rat pituitaries. Since our MEAP antiserum cross-reacts with Phe-Met-Arg-Phe (but not with Phe-Met-Arg-Phe-NH<sub>2</sub>), the possibility remains that the immunoreactivity detected in the IL is related to this tetrapeptide but does not contain MEAP. We are conducting studies to determine if the proenkephalin mRNA is present in the cells of the IL using <u>in situ</u> hybridization.

IMMUNOCYTOCHEMICAL DISTRIBUTION OF OPIOID PEPTIDERGIC NEURONS IN 129.5

RAT NEOCORTEX. J. F. McGinty. Dept. of Anatomy, East Carolina University School of Medicine, Greenville, NC 27834. Radiochemical evidence has implied the presence in the cerebral cortex of a widespread opioid peptide system to mediate a variety of opiate effects on cerebral cortical functioning. However, immunocytochemical detection of opioid peptides in the cortex has been limited. This study concerns the characterization of the regional and laminar distribution of a widespread population of murine neocortical cell bodies and fibers immunoreactive for proenkephalin-A and B.

Our preliminary observations (McGinty et al., <u>Anat. Rec. 202</u>: 1252, 1982) were limited to olfactory and medial cortical regions where clusters of neurons in layers II-III containing enkephalin immunoreactivity (ir) were revealed in colchicine-treated rats. Further analysis with anti-leu<sup>5</sup>-enkephalin as well as an antiserum raised against the proenkephalin-A fragment, bovine adrenal medullary peptide (BAM22P), in colchicine and kainic acid-treated rats has revealed a morphoheterogeneous population of neocortical cells containing proenkephalin A-ir, including bipolar and multi-polar stellate cells and pyramidal cells. These cells reside in layers II-III and V-VI of medial and lateral neocortex. The regional and laminar distribution of the neurons containing en-Replain-ir and RAM-ir was more easily detected, and thus, more extensive than that of cortical cells containing dynorphin A-ir which have been detected to date. The bimodal distribution of immunopositive neurons in layers II-III and V-VI of neocortex and layers II and III of paleocortex is similar to the distribution of mu-type opiate binding sites in rat cortex (Herkenham, M. and Pert, <u>C., J. Neurosci.</u> 2:1129, 1982). The morphoheterogeneity of cells containing pro-enkephalin-A and B immunoreactivity suggests that opioid peptides are in a position to influence the function-ing of local, commissural, and projection neurons of murine cerebral cortex.

ENKEPHALIN-LIKE AND SUBSTANCE P-LIKE IMMUNOREACTIVITY IN THE 129.6 ENERGY AND SUBSTANCE PEILS PHOLONOCCUT INTO THE FLORE CRAB, UCA PUGILATOR. M. Fingerman, M. M. Hanumante\* and tL. L. Vacca. Dept. of Biology, Tulane Univ., New Orleans, LA 70118 and tbept. of Anatomy, Univ. of Kansas Wed. Ctr., Kansas City, KS 66103. The presence and distribution of Leu-enkephalin (LE)-like,

Met-enkephalin (ME)-like and Substance P (SP)-like peptides were determined in the eyestalk neuroendocrine complex of Uca pugilator using light microscopic peroxidase-antiperoxidase immunocytochemistry. Immunoreactivity for all three substances was observed in the optic nerve, sinus gland and lamina ganglionaobserved in the optic nerve, sinus gland and lamina gangliona-ris. LE-like and ME-like immunoreactive material was also found in the portion of the neuropile of the medulla terminalis abut-ting the neurosecretory cells (NSC) in the medulla terminalis X-organ. Extensive ME-like immunoreactivity was also evident in the NSC of the medulla terminalis X-organ and in axons of NSC in the medulla externa. SP-like immunostainable material was also found in the epineurium enclosing the ganglia of the eyestalk, just proximal to the retina. Interestingly, none of the somata of the NSC in this neuroendocrine complex exhibited LE-like or of the NSC in this neuroendocrine complex exhibited LE-like or SP-like immunoreactivity.

COMPARATIVE STUDIES OF OPIOID PEPTIDES: ENKEPHALIN DISTRIBUTION COMPARATIVE STUDIES OF OPIOID PEPIDES: ENKEPHALIN DISTRIBUTION IN TURTLE CENTRAL NERVOUS SYSTEM. Anton Reiner. Dept. Anatomy and Cell Biology. Univ. of Michigan, Ann Arbor, Mich. 48109. High levels of opioid receptor binding sites have been reported in the CNS of all vertebrates studied, including reptiles (Pert et al., Brain Res., V75, 1974). Thus, opioid peptide neurotrans-mitter systems are presumably an ubiquitous feature of the verte-brate nervous system. The present study used immunohistochemical techniques to determine the distribution of enkephalin in the CNS of red-eared and nainted turtles

brate nervous system. The present study used immunohistochemical techniques to determine the distribution of enkephalin in the CNS of red-eared and painted turtles. An antiserum against leucine-enkephalin (A206, courtesy K.J. Chang) was used initially to localize enkephalin-like immunoreac-tivity (ELI). The distribution of ELI observed was similar in many respects to that observed in mammalian CNS with antiserum A206 (Sar et al., JCN, V182, 1978). Numerous ELI+ neurons were consistently found in: 1) telencephalon - "striatum", septum and superficial one-fifth of the medial half of the cortex; 2) dien-cephalon - rostral two-thirds of the hypothalamus and mammillary region; 3) midbrain - deep tectal layers, medial tegmentum and the dorsal nucleus of the posterior commissure; and 4) hindbrain and spinal cord - lateral to the caudal descending tract of the spinal cord. Dense accumulations of ELI+ fibers were observed in: 1) telencephalon - "striatum", septum, deep four-fifths of the medial half of the cortex, globus pallidus and ventral paleostri-atum; 2) diencephalon - hypothalamus, neurohypophysis, dorsomed-ial/dorsolateral thalamic nuclei and medial habenula; 3) midbrain - tectum, medial tegmentum, periventricular gray and area pretec-talis; and 4) hindbrain and spinal cord - raphe region, ventro-lateral pons and medulla, locus coeruleus, parabrachial region, nucleus of the solitary tract, vagal motor nucleus, lateral to the descending tract of the trigeminus and in the dorsal horn and Lissauer's zone of the spinal cord. Although all ELI described above could be blocked by 10µM syn-thetic leucine-enkephalin, antiserum A206 has a slight crossreac-tivity with dynorphin. Accordingly, antisera against two other proenkephalin-derived opioid peptides, methionine-enkephalin

thetic leucine-enkephalin, antiserum A206 has a slight crossreac-tivity with dynorphin. Accordingly, antisera against two other proenkephalin-derived opioid peptides, methionine-enkephalin (A900, courtesy K.J. Chang) and BAM-22P (#66-B16, courtesy S.J. Watson) were used. The distributions of ELI observed with all three antisera were highly similar and (particularly in the case of the BAM-22P antiserum) readily distinguishable from that ob-tained with a dynorphin A antiserum (3CS, courtesy A. Goldstein). With this dynorphin antiserum, dense staining was observed in the strionigral pathway and its ventrolateral tegmental terminal field. The similar staining patterns observed with the three en-kephalin antisera suggests that various enkephalin-like peptides may be present in turtle CNS and derive from a common precursor similar to proenkephalin of mammals. (Supported by NS-19620)

IN SITU HYBRIDIZATION OF OPIOID PEPTIDE CONTAINING CELLS IN NERVOUS TISSUES USING SPECIFIC cDNA PROBES. <u>S.J. Watson</u>, J. Roberts<sup>a</sup>+, R. Thompson<sup>a</sup>, S. Burke<sup>a</sup>, and H. Akil. Mental Research Institute, Univ. of Michigan, Ann Arbor, MI 48109; +Columbia Univ. New York, N.Y. 129.8 Mental Health

+Columbla Univ., New Tork, N.T. Recent advances in molecular genetics, opioid peptide biochemistry, and histochemical methods have made it possible to study the mRNA's coding for the opioid peptides, in their cells of origin. DNA sequences which are the compliment of portions of specific mRNA's (i.e. cDNA) coding for all three opioid peptide families have been produced in several laboratories. Sequence specific Jaballed DNA produces con form a study double stronded specific labelled cDNA probes can form a stable double stranded hybrid with a specific region of a particular mRNA under conditions which can allow identification of that mRNA in ar anatomical context.

We have been focusing on the several techniques and controls necessary for the use of cDNA probes as markers for their matching mRNA in their cells of origin. After the mRNA sequence has been cloned into a cDNA form (from the lab of J.R.) a sequence of cloned into a CDNA form (from the lab of J.K.) a sequence of steps are required to insert the CDNA probe into a proper bacterial phage cloning vector system, grow the phage, extract it, label the CDNA, and prepare it for use as a hybridization probe. A further series of steps are necessary to prepare tissue for <u>in</u> <u>situ</u> hybridization and then to combine the probe and tissue for visualization of the specific mRNA producing cell. Finally, before the data can be interpreted, a series of technical and located interpreted. Our use of such archa will logical issues need to be considered. Our use of such probes will be presented along with the aforementioned methods.

129.9 ANATOMICAL RELATIONSHIP OF OPIATE RECEPTORS TO  $\beta$ -ENDORPHIN, ENKEPHALIN, AND DYNORPHIN-POSITIVE NEURONAL SYSTEMS IN RHESUS MONKEY BRAIN. M.E. Lewis<sup>\*</sup>, H. Khachaturian, and S.J. Watson (SPON: C.M. Butter). Mental Health Res. Inst., Univ. of Michigan, Ann Arbor, MI 48109

The functional significance of opioid systems in primate brain is poorly understood, although some clues have been provided by previous studies of opiate receptor distribution (e.g. Lewis et al, <u>Science</u>, 211:1166-69, 1981). To obtain further information, we have compared the anatomical distribution of opiate receptors to that of the three opioid systems containing  $\beta$ -endorphin ( $\beta$ -END). [Leulenkephalin (ENK), or dynorphin A (DYN)-like peptides in rhesus monkey brain. Using adjacent section PAP immunocytochemistry and <u>in vitro</u> receptor autoradiography (with [<sup>A</sup>H]naloxone) as described for rat brain (Lewis et al., <u>Life Sci.</u>, <u>31</u>:1347-50, 1982), we have observed that binding site density varies with different opioid peptide systems in different brain regions, as summarized in the list of structures below (density: + = light, ++ = medium, +++ = heavy).

	[ <sup>3</sup> H]nal	POMC	ENK	DYN
bed nuc. stria terminalis	++	+++	+++	+
periventricular hypothal.	+++	+++	++	+
supraoptic nucleus	+++	0	+	+++
periaqueductal grey	++	++ 、	+++	+
interpeduncular nucleus	+++	0	++	+
parabrachial nuclei	+++	+	++	+
nucleus tractus solitarius	++	++	+++	++
spinal treigeminal nucleus	+++	0	++	++

This partial list reflects the complex relationships of the three opioid systems in rhesus monkey brain, as well as the difficulties in anatomically relating opiate receptors to individual opioid systems. Although it is unlikely that ['H]naloxone is binding to  $\delta$  sites (virtually all specific ['H]D-Ala', D-Leu'-enkephalin binding is abolished by perfusion fixation), we are exploring possible binding site heterogeneities which may correspond to differences in the regional distribution of the three opioid systems in brain.

129.10 ONTOGENY OF OPIOID AND RELATED PEPTIDES IN THE RAT BRAIN AND PITUITARY. H. Khachaturian, N.E. Alessi, M.E. Lewis\*, N. Munfakh\*, and S.J. Watson. Mental Health Research Institute, Univ. of Michigan, Ann Arbor, MI 48109.

The embryonic (E) and postnatal (P) development of the proopiomelanocortin (POMC) peptides (16K fragment, ACTH,  $\beta$ -endorphin, and  $\alpha$ -MSH) were compared to that of Leulenkephalin (ENK) and dynorphin A (DYN) in the Sprague-Dawley rat. Further, to determine the time of origin of neurons immunoreactive (i.r.) for each peptide, timed-pregnant rats were injected with [<sup>3</sup>H]thymidine at different stages (E11-17) and their progeny were allowed to develop into young adults prior to PAP immunocytochemistry combined with [<sup>3</sup>H]thymidine autoradiography. All postnatal animals were treated with colchicine prior to sacrifice.

The POMC peptides (except  $\alpha$ -MSH) appeared first on E12 in small i.r. perikarya in the hypothalamic ridge. At E15, a few i.r. POMC cells also appeared in the pituitary anterior lobe (AL). By E16, i.r. POMC fibers had reached brain stem and spinal cord. Also at E16, scattered i.r. POMC cells appeared in the intermediate lobe (IL). At E17, faintly i.r. 16K perikarya were seen in the nucleus tractus solitarius. By E19-21, all POMC perikarya appeared darker, and their projections more widespread. The pituitary appeared adult-like except for the intense immunoreactivity (i.r.) for all POMC peptides (especially  $\alpha$ -MSH) in AL. Postnatally, brain POMC i.r. increased gradually, reaching adult-like patterns by P21-28. Conversely,  $\alpha$ -MSH i.r. in the AL declined gradually, and appeared very faint by P28. Furthermore, the so-called " $\alpha$ -2" neurons of the lateral hypothalamus were not detectable with our  $\alpha$ -MSH antiserum during embryonic stages, but were visible starting at P1, with colonicine pretreatment.

ac-HSM antiserum during embryonic stages, but were visible starling at P1, with colchicine pretreatment. ENK and DYN i.r., on the other hand, appeared later in embryonic development. At E16, both ENK and DYN i.r. fibers could be seen in the ventral brainstem and spinal cord. By E17, diffuse DYN i.r. could be detected in the posterior pituitary. Faintly i.r. ENK perikarya were detected in the brainstem at E18-19. Also at E18-19, diffuse DYN i.r. was seen in the magnocellular supraoptic neurons. At P1, ENK i.r. perikarya were visible in many brain areas, and DYN i.r. magnocellular neurons could be seen in the hypothalamus. From P7 to P28, both ENK and DYN i.r. perikarya/fibers increased in number/density to resemble adult-like patterns.

Preliminary data gathered from [<sup>3</sup>H]thymidine autoradiographic studies of immunostained neurons indicate that a majority of arcuate (POMC) and magnocellular (DYN) hypothalamic neurons are "born" at E12-14. Accordingly, we are attempting to determine the time of origin of other DYN and ENK neuronal systems. This work was suported by NIMH grants MH15794, MH36851 to and HK and SJW.

129.11 THE IMMUNOCYTOCHEMICAL DISTRIBUTION OF ENKEPHALIN IN THE THORACO-LUMBAR SPINAL CORD OF THE RAT: COINCIDENCE WITH SYMPATHETIC PRE-GANGLIONIC NUCLEAR REGIONS. <u>M.A.Romagnano and R.W.Hamili</u>, Dept. of Neurology, Monroe Community Hospital/Strong Memorial Hospital, Rochester, N.Y. 14603

The distribution of enkephalin-like(Enk-like) immunoreactive fibers was examined in thoracolumbar segments of the spinal cord There's was examined in the factor under segments of the spinal core of adult Sprague-Dawley rats using the unlabeled antibody method of immunocytochemistry. Normal and colchicine treated rats were perfused with Zamboni's fixative. The spinal cords were removed and  $30-40\mu$  horizontal serial sections were cut on a Vibratome. Sections were incubated for 48 hours in anti-Enk serum at a dilution of 1/2000 (Sundberg et al, Endocr.Abs.106:153,1980) or 1/500-1/1000(Immunonuclear Inc,18H2T). Immunoreactive Enk-like fibers were found in the thoracolumbar spinal cord localized in nuclear regions known to contain preganglionic sympathetic neurons. Moderate to dense numbers of Enk-like fibers were inter-spersed between or outlined cells of the nucleus intermediolat-eralis thoracolumbalis, pars principalis(Ilp). Labeled fibers were localized in a thin column along the gray-white border of the lateral funiculus connecting adjacent Ilp cell nests. Moderate numbers of Enk-like fibers also were found in the nucleus intermediolateralis thoracolumbalis, pars funicularis extending laterally from Ilp to the pial surface, perpendicular to the course of lateral functulus fibers and often juxtaoposed to blood vessels. Immunoreactive fibers in moderate numbers were located in nucleus intercalatus spinalis (IC) forming a series of transverse bands linking the clusters of neurons of 11p with the more medial cen-tral autonomic areas. Labeled fibers were found both dorsal and dorsolateral to the central canal. The dorsal group of Enk-like fibers formed a continuous column running the entire rostro-cau-dal length of the thoracolumbar cord while the fibers located dorsolateral to the central canal appeared to form arches inter-connecting adjacent IC nuclear groups. These regions correspond to the dorsal commissural nucleus and the nucleus intercalatus, pars paraependymalis, respectively. At lumbar segments there is an increase in the number of Enk-like fibers found in the dorsal commissural nucleus as compared to thoracic segments. Enk-like fibers and cells were observed in the lateral funiculus, dorsal and ventral horns of thoracolumbar segments and in the cervical and sacral horn. The distribution at these locations corresponds

to previously published reports. Our results demonstrate that the distribution of Enk-like fibers in the rat thoracolumbar spinal cord parallels the distribution of autonomic nuclear regions containing sympathetic preganglionic neurons. In addition, our findings provide anatomical evidence to suggest a possible involvement of the opioid peptide, enkephalin in sympathetic functions. BRSG #5-27238. 29.12 COMPARISON OF THE DISTRIBUTION OF PRODYNORPHIN AND PROENKEPHALIN DERIVED PEPTIDES IN THE RAT CENTRAL NERVOUS SYSTEM. N. Zamir\*, M. Palkovits\* and M. J. Brownstein (SPON: M. G. Wilson). Lab. of Cell Biology, NIMH, Bethesda, Maryland 20205.

The distributions of prodynorphin derived peptides ( $\alpha$  and  $\beta$ -neo-endorphin, dynorphin A, dynorphin A (1-8), dynorphin B) and proenkephalin derived peptides (Leu-enkephalin and Metenkephalin-Arg-Gly-Leu) were determined in 100 microdissected rat brain areas and in the neurointermediate lobe of pituitary gland using highly specific radioimmunoassays. Data for selected brain nuclei will be presented. The data illustrate several points: 1) All opioid peptides have a widespread and uneven distribution in the neuraxis. a) Especially high levels of pro-dynorphin derived peptides were found in the posterior pituitary. b) Among brain nuclei the substantia nigra and the anterior lateral hypothalamus have abundant prodynorphin derived peptides except for dynorphin A. In addition, the nucleus accumbens, bed nucleus of stria terminalis, hippocampus, dentate gyrus, anterior hypothalamic nuclei are rich in  $\alpha$ -neo-endorphin and dynorphin B. High levels of dynorphin A, dynorphin A, dynorphin A (1-8) and  $\beta$ -neo-endorphin were found in hypothalamic nuclei, e.g., anterior hypothalamic, dorsomedial, ventromedial, and ventral premamillary nuclei, in the median eminence and others. 2) The molar excess of  $\alpha$  and  $\beta$ -neo endorphin over dynorphin B at their derivatives suggests that a) not all derivatives are accounted for. Indeed, Leu-enkephalin mrain areas as well as in the neurointermediate lobe. The existence of Leu-enkephalin in two separate precursors may explain why the ratio of Leu-enkephalin to Met-enkephalin-Arg-Gly-Leu, and between some prodynorphin A, dynorphin B and their derivatives in fiftherent brain regions, e.g., substantia nigra. b) selective release or degradation of dynorphin A, dynorphin B and their derivatives for and their derivatives in fiftherent brain regions, e.g., substantia nigra. b) selective release or degradation of proenkephalin derived peptides are distribution of proenkephalin derived peptides.

CO-DISTRIBUTION OF LEU-ENKEPHALIN AND SUBSTANCE P IN THE BRAIN: MAPPING WITH RADIOIMMUNOHISTOTOCHEMISTRY. <u>S. McLean, L.R.</u> Skirboll, and C.B. Pert. Sec. on Brain Biochem., NSB, NIMH, Bethesda, MD 20205. 129.13

Immunohistochemical mapping of the medulla and spinal cord has Immunohistochemical mapping of the medulla and spinal cord has demonstrated substance P-like immunoreactivity (SP) and enkephalin-like immunoreactivity (ENK) to have a similar distribu-tion (Hokfelt et al., PNAS 74:3081-3085). Although providing morphological detail, fluorescence or PAP immunohistochemistry does not provide an easy assessment of peptide distribution. Radioim-munohistochemistry, however, facilitates examination of whole brain sections without magnification, allowing one to discern with rela-tive ease the pattern of distribution of a compound throughout the brain. Using radioimmunocytochemistry the distribution of SP and ENK in more rostral structures will be reported. Spranue-Dauley rats untreated or given colchicine intraventri-

brain. Using radioimmunocytochemistry the distribution of SP and ENK in more rostral structures will be reported. Sprague-Dawley rats, untreated or given colchicine intraventri-cularly, were perfused intracardially with 4% paraformaldehyde. Every 300 µm, 2 to 4 10-µm-thick, frozen sections were cut and incubated (40 hrs) with SP antisera (diluted 1:10,000) or leu-ENK antisera (1:10,000). Control sera were absorbed with 50 µg/ml of the respective peptide. Incubation with <sup>125</sup>I goat-anti rabbit antibodies were used to label the primary antibody (McLean et al., Brain Res., submitted). Visualization of the primary antibody was carried out by autoradiography using LKB Ultrofilm or emulsion-coated slides (Herkenham and Pert, J. Neurosci. 2:1129-1149). There is a striking concordance in the distribution of SP and ENK. In almost all areas displaying ENK immunoreactivity SP could be found: medial wall of the frontal cortex, caudate, ventral pallidum, lateral septal nuclei, periventricular thalamus, hypo-thalamus, habenula, central and medial nuclei of the amygdala, and the periaqueductal gray. Some exceptions to this overlap are: 1) the olfactory bub where most of the SP is confined to the granular layer, while the strongest ENK labeling is found in the plexiform and glomerula layers; 2) the posterior portion of the lateral sep-tum exhibits SP but no ENK, 3) the ventromedial nucleus of the hypothalamus without colchicine treatment is almost devoid of SP but shows moderate staining for ENK, with colchicine treatment this difference disappears; 4) the pars compacta of the substantia nigra displays both SP and ENK but the reticulata has only SP; 5) the entopeducular nucleus shows strong SP labeling but only weak ENK labeling; 6) the CA3 and CA4 layers of the hippocampus display ENK immunoreactivity but no SP; and 7) there is a cortical labeling by ENK and little by SP. Overall, the striking neuroanatomical over-lap of SP and ENK suggests a functional interrelationship between these peptides that may be similar to tha

THE DISTRIBUTION AND ORIGIN OF PROOPIOMELANOCORTIN ( $\beta$ -END &  $\alpha$ MSH) 129 15 FIBERS AND TERMINALS IN THE CENTRAL NUCLEUS OF THE RAT AMYGDALA (CNA). T.S. Gray, M.D. Cassell\*, and J.Z. Kiss\*. Departments of Anatomy, Loyola University Medical School, Maywood, IL 60153 and University of Iowa Medical School, Iowa City, IA 52242. The central nucleus of the amygdala (CNA) appears to play a

critical role in mediating opioid-opiate influences on emotive behavior and learning and memory (Gallagher & Kapp, in Endogenous Peptides & Learning & Memory, 1981). The CNA receives a dense enkephalinergic innervation though this is differentially distri-buted relative to the four subdivisions of the CNA which represent clear cytological hodological and histochemical differences with in the nucleus (Cassell et al., in prep.). Proopiomelanocortin peptide ( $\beta$ -END,  $\alpha$ MSH) terminals have been identified in the CNA though their precise distribution is uncertain. To identify the neuronal sub-populations receiving proopiomelanocortin peptide input, we have studied the distribution and origin of  $\beta-\text{END}$  and  $\alpha MSH$  terminals in the CNA using immunocytochemistry and retrograde fluorescent dye transport.

8-END and aMSH immunoreactivity was visualized on 30 µ rat  $\beta$ -END and aMSH immunoreactivity was visualized on 30  $\mu$  rat brain sections using the avidin-biotin immunoperoxidase technique. Similar distributions of  $\beta$ -END and aMSH immunoreactive terminals and fibers were identified in the medial nucleus, CNA, and intercalated cell masses in that order of decreasing density. Within the CNA,  $\beta$ -END and aMSH fibers and terminals had very similar distributions and were confined mainly to its medial subdivision. This distribution is complementary to the distribution of enkephalinergic terminals which are densest in the lateral, ventral and central divisions. Fibers reaching the CNA and appearing to originate in the basal hypothalamus could be traced over the optic tract and, more rostrally, through the substantia innominata. In a preliminary set of experiments animals received injections of true blue into the CNA. After survival times of 6-14, animals were given intraventricular colchicine 48 hrs prior to sacrifice. Retrogradely labeled neurons were observed in the lateral and mediobasal hypothalamus, notably the arcuate nucleus. Some of the retrogradely labeled arcuate neurons were found using

an immunofluorescence technique, to be immunoreactive for  $\beta$ -END. The data demonstrate that the distributions of the propio-melanocortins  $\beta$ -END and  $\alpha$ MSH in the CNA are very similar suggest-ing terminal co-localization and possible common origin in the arcuate nucleus. The proopiomelanocortin terminals are restricted to the medial subdivision of the CNA where the bulk of CNA efferents to brain stem autonomic nuclei originate. The differential distribution of proopiomelanocortins and enkephalins may be of physiological significance.

129.14 NONESTROUS FEMALE HAMSTERS HAVE ELEVATED OPIATE RECEPTOR DENSITY IN A NUMBER OF DISCRETE BRAIN LOCI. <u>B.E. Morton<sup>1</sup>, C. Chan<sup>1</sup>, R.P.</u> <u>Hammer, Jr.<sup>2</sup>, and C.B. Pert<sup>3</sup>. <sup>1</sup>Univ Hawaii, Honolulu, HA</u> <u>96822</u>; <sup>2</sup>Lab of Neurophysiol., and Sec. on Brain Biochem., NIMH,

96822; 4Lab of Neurophysiol., and Sec. on Brain Biochem., NIMH, Bethesda, MD 20205 Brains from three groups of hamsters were processed according to Herkenham and Pert (<u>J. Neurosci</u>., <u>2</u>:1129, 1982) for visualization of type 1 opiate receptors with tritiated naloxone on tritiumor type I oplate receptors with tritiated naloxone on tritium-sensitive film. Females were characterized as sexually receptive if they produced the classical estrous stringy vaginal discharge and assumed a lordotic posture when placed briefly with a male. Nonestrous females, estrous females, and males (9 in each group) were processed in a balanced design at all stages from decapitation were processed in a balanced design at all stages from decapitation and freezing of the brain to placement of slides in cassettes for visualization on film. After 10 wks, a fiber optic densitometer (Morton et al., J. Neurosci. Methods, <u>6</u>:113, 1982) was used to quantify optical density in 86 discrete loci of hamster brains. Following normalization to the mean optical density of all (27 x 86) recorded densities, analysis of variance revealed that at all loci where a significant (p < 0.001) difference was demonstrated, nonestrous females had more opiate receptors than estrous females and males. The latter two groups were not significantly different from each other. These data are consistent with a rather large body of literature, suggesting that increased oniatergic tone from each other. These data are consistent with a rather large body of literature, suggesting that increased opiatergic tone produces inhibition of sexual activity while the administration of opiate antagonists heightens libido. Detailed analysis of the preoptic area showed a significant difference in nonestrous females vs. males and estrous females at 4 of the 6 points surveyed (medial and dorsal regions but not the lateral/ventral region). This is consistent with the fact that certain characteristics of the dorso-redial expection area in the haracter have been charm to available.

consistent with the fact that certain characteristics of the dorso medial preoptic area in the hamster have been shown to exhibit sexual dimorphism (Greenough et al., <u>Brain Res., 126</u>:63, 1977). The present study suggests that rather rapid (4 day) cyclical changes in opiate receptor density may be related to sexual recep-tivity in the female. Opiate effects could modulate sexual behavior by direct or indirect inhibition of sexual activity. The biochemical mechanism of these effects is unknown; however, the notion of steroid hormones influencing receptor density is not without precedent.

COEXISTENCE OF IMMUNOREACTIVE ENKEPHALIN (I-Enk) AND DYNORPHIN (I-Dyn) IN THE NUCLEUS OF THE SOLITARY TRACT OF THE RAT. J. Mulcahy\*, H.S. Lee\* and A.I. Basbaum. Depts. of Anatomy and Endocrinology, University of California San Francisco, CA 129.16 94143.

94143. Several studies have described significant overlap in the CNS distribution of the two endogenous opioid peptides, Enk and Dyn. Since marked and varied opiate effects are exerted in the nucleus of the solitary tract (NTS), and since Enk and Dyn are associated with different opiate receptor subtypes, we decided to examine the NTS for local differences in opioid peptide distribution. Adult rats, some pretreated with intracisternal colchicine, were perfused with 4% paraformaldehyde. Fifty micron frozen sections of the medulla were cut and reacted for immunoreactive Enk and Dyn. To identify I-Enk we used an antiserum directed against the proEnk product. met-Enk-ara-alvantiserum directed against the proEnk product, met-Enk-arg-gly-leu; for I-Dyn, we used an antiserum directed against the C-terminal proDyn peptide, dynorphin B (Weber E.). Absorption controls established that the Dyn antiserum does not cross

While there is considerable overlap in the I-Enk and I-Dyn terminal and cellular distribution in the NTS caudal to the obex (including the commissural nucleus), rostral to the obex, obex (including the commissural nucleus), rostral to the obex, there is a marked segregation. Small round I-Enk cells are found in the medial NTS, medial to the tract. Large, multipolar I-Dyn cells are concentrated lateral to the tract. To assess possible peptide coexistence in neurons caudal to the obex, we next examined serial 3-4u cryostat sections of colchicine-treated rats; this allowed staining of the same neurons in several adjacent sections. While the majority of neurons in this region stain for only one of the peptides, we found numerous examples in the caudal ventrolateral NTS in which I-Enk and I-Dyn are colocalized. Double-labelled cells were also found in areas associated with the control of pain, including the ventrolateral medulla, the midline raphe and the dorsal horn.

The medial and lateral nuclei of the solitary tract receive The medial and lateral nuclei of the solitary tract receive baroreceptor and lung stretch receptor afferents, respectively. Thus our data suggest that Enk and Dyn may exert selective actions on the different visceral afferent inputs to the rostral NTS. Our data further indicate that some CNS neurons synthesize more than one opioid peptide precursor. Since these double labelled neurons are found in that part of the NTS which receives convergent baroreceptor and lung stretch receptor input, the coexistence may underlie a dual opioid control by single medullary neurons. DYNORPHINS LOCALIZED IN SPINAL CORD AND DORSAL SENSORY 129.18 NEURONS BY IMMUNOHISTOCHEMISTRY. P.M.Sweetnam, J.R.Wrathall<sup>1</sup>, E.Weber\*<sup>2</sup>, J.D. Barchas<sup>2</sup>, A.Goldstein<sup>3</sup> and J.H. Neale. Departments of Biology and A.Goldstein and J.H. Neale, bepartments of bloody and Anatomy<sup>1</sup>, Georgetown University, Washington, D.C. 20057, Departments of Psychiatry and Behavioral Sciences<sup>2</sup> and Pharmacology<sup>3</sup>, Stanford University, Stanford, CA 94305. Using peroxidase-antiperoxidase (PAP) immunohistochemistry as well as an immunofluorescence method, we have studied the

as well as an infinite interescence metrics, we have studied the cellular distribution of dynorphin- and dynorphin B-immuno reactivity (IR) in spinal cord and dorsal root ganglion neurons. Using antibody which is specific for the midportion of dynorphin, we have previously reported (PNAS 79:6742, 1982) the presence of dynorphin-IR in both spinal and sensory neuronal cell bodies with very little, if any, PAP reaction product in neurites. We report here the detection of dynorphin B-IR and dynorphin (9-17)-IR in spinal cord cell neurites as well as perikarya, a distribution similar to that observed with enkephalin antisera. Distal neurite IR was particularly apparent when fluoresceinconjugated secondary antisera were used. The observation of dynorphin (9-17)-IR in the neurites, while the midportion dynorphin-IR is relatively absent, suggests that this peptide is split in the midregion and that the non-opioid fragment is distributed within the neurites in a manner similar to the amino terminal opioid fragment. We have followed our initial observation of dynorphin-IR

in dorsal root ganglion neurons which developed from fetal In otser indised gaugiton heatons which even pet indification is a solution of the solution of develop dynorphin-IR after several weeks in culture. Neither increased concentrations of nerve growth factor nor coculture (about 4%) of these neurons which develop high levels of dynorphin-IR. Preliminary fluorescence immunohistochemistry further suggests the presence of a small but significant number of neurons with dynorphin-IR in sections of adult mouse dorsal root ganglia.

129.PO IMMUNOREACTIVE BETA ENDORPHIN-SPECIFIC PERIKARYA IN THE SUPRA-OPTIC AND PARAVENTRICULAR NUCLEI OF THE HORSE AND PONY. K.M. Knigge, P.A. Melrose\*, and W.H. Pilcher\* (SPON: J. Paterson). The Neuroendocrine Unit, Univ. of Rochester, Roch., NY 14642. Unlabeled antibody techniques were used to map the distribution of beta-endorphin ( $\beta$ -E) in the equine diencephalon. Brains from 3 horses and 2 ponies were fixed by immersion in buffered 4% paraformaldehyde containing 0.1% picric acid. SS ial 50µm sections of the diencephalon were cut on a freezing Sersliding microtome in frontal and parasagittal planes. Immuno reactive (ir)  $\beta$ -E specific cell bodies were present in the arcuate, supraoptic, and paraventricular nuclei. The topography and cross-immunoreactivity of these cells in supraoptic and paraventricular nuclei was distinctly different from ir-cells of the arcuate opiocortin formation. Immunoreactive cells in the supraoptic and paraventricular nuclei stained with antisera generated against human and camel  $\beta$ -E but not with antisera against human ACTH 1-39, alpha-MSH, enkephalin, or dynorphin. All immunoreactivity was abolished by incubating anti-camel  $\beta-E$  antisera (1:1000) with lug/ml of camel  $\beta-E$  for 48 hrs. at 4°C. Staining was not affected when antisera was incubated in a similar manner with  $1-2\mu g/m1$  of ACTH 1-39, oxytocin, or arginine vasopressin.

Results from this study suggest that neurons in the supraoptic and paraventricular nuclei of the equine brain contain  $\beta$ -E or a  $\beta$ -E-like peptide. Further, preliminary data suggest that this population of ir-cells is separate from the oxytocin and vasopressin magnocellular cell populations.

## PEPTIDES: PHYSIOLOGICAL EFFECTS III

130.1

GASTRIC HYPOSECRETION AND HYPERGLYCEMIA INDUCED BY BOMBESIN INJECTION NEAR THE PARAVENTRICULAR NUCLEUS. <u>M.W. Gunion, Y.</u> <u>Tache, and J.H. Walsh.\*</u> Center for Ulcer Research and Education, Wadsworth V.A., Los Angeles, CA. 90073, and Department of Medicine, U.C.L.A., Los Angeles, CA. Bombesin inhibits gastric acid secretion and causes hyperglycemia when given intracisternally. Bombesin immunoreactivity is localized in the forebrain as well as the lower brainstem, with particularly numerous terminals and cell bodies in the hypothalamic paraventricular nucleus. This nucleus has direct outputs to lower brainstem autonomic centers. The possible role of this region in gastric secretory and blood glucose regulation was therefore evaluated by direct injection of glucose regulation was therefore evaluated by direct injection of bombesin into this area.

glucose regulation was therefore evaluated by direct injection of bombesin into this area. Male Sprague-Dawley albino rats (200-290 g) were used; surgery was under ether anesthesia. Simultaneous bilateral infusions of bombesin-14 (50 ng/side) or vehicle (0.1% BSA/0.9% NaCl, 1 µl/side) were made over 2 min, with the 30 g stainless steel injection cannulae left in place an additional 2 min before withdrawl. The pylorus was immediately ligated through an abdominal incision; exactly 2 hr postinjection the animals were decapitated and blood and gastric contents collected. Injections near the dorsomedial aspect of the hypothalamic paraventricular nucleus caused marked suppression of gastric acid output and pronounced hyperglycemia. Acid secretion after bombesin dropped to 2 µmol/2 hr; vehicle at the same sites gave 103 µmol/2 hr. As expected, pH and serum gastrin rose, and secretion volume dropped, after effective injections. Serum glucose levels rose to 298 mg/dl after bombesin; vehicle gave 125 mg/dl. Bombesin id not affect these measures when injected into the lateral hypothalamus (output: bombesin 91 µmol/2 hr, vehicle 129 µmol/2 hr; glucose: bombesin 137 mg/dl, vehicle 127 mg/dl). These data suggest that the paraventricular nucleus is involved in the regulation of both gastric exocrine secretion and blood glucose levels, and that bombesin may have a physiological role in these processes. Further, it appears that the linkage between gastric secretion and blood glucose seen with intracisternal injections also occurs with intrahypothalamic administration.

intracisternal injections also occurs with intrahypothalamic administration.

(Supported by AM 30110 to Y.T. We wish to thank J. Rivier for his generous donations of bombesin.)

130.2

AGE-DEPENDENT CHANGES IN LHRH NEUROSECRETORY RESPONSE OF SUPER-FUSED MALE RAT HYPOTHALAMI TO CYCLIC AMP DELIVERY. Daryl E. Hartter and V. D. Ramirez. Dept. of Physiology and Biophysics, Univ. of Illinois, Urbana, IL. 61801. Previous studies in several laboratories have suggested that the adenyl cyclase/cyclic AMP-generating system is involved in the control of in vitro release of LH-releasing hormone (LHRH) from adult rat hypothalamus. In the present study, we have in-vestigated the effect of intermittent (10-min. on, 40 min. off) delivery of dibutryl cyclic AMP (dbcAMP) on LHRH release from superfused hypothalamic fragments taken from intact male rats of 25, 30, 45 or 60-75 (adult) days (d.) of age. Animals in each experimental group were sacrificed by ether anesthesia-hemorrhage, and mediobasal hypothalamus (MBH) fragments were dissected out and prepared for superfusion as previously de-scribed (Hartter & Ramirez, Endocr. 107:375, 1980), using either 4 (in 25, 30 or 45 d. groups) or 2 MBH fragments/chamber (in adult group). Each age group was replicated 4 times, with experimental (dbcAMP, 5 x 10-8M) and control (butyrate, 5 x 10-8M) groups being run simultaneously in a single superfusion experiment (of 240-min. duration). Superfusion samples were assayed for LHRH content by duration). Superfusion samples were assayed for LHRH content by radioimmunoassay.

radioimmunoassay. Our results indicate that at 25 d. of age, male rat MBHs were quite sensitive to intermittent dbcAMP (mean post-dbcAMP infusion LHRH release = 162% of pre-infusion basal release); at 30 d., the dbcAMP effect decreased to 120% of basal. At 45 d., the effect of dbcAMP on LHRH release was inhibitory (only 78% of basal); however, by adulthood, this cyclic nucleotide exerted negligeable effect on LHRH release (92% of basal). Similar intermittent in-fusions of butyrate resulted in less dramatic modifications of in vitro LHRH release, with post-butyrate mean LHRH release of fusions of butyrate resulted in less dramatic modifications of in vitro LHRH release, with post-butyrate mean LHRH release of II6, 82, 68 and 94% of basal at 25, 30, 45 d., and adult, respec-tively. Thus, differences in relative LHRH release between dbcAMP and butyrate conditions equalled 46, 38, 10 and -2% in the 4 re-spective age groups, indicating a true age-dependent decrease in responsiveness of the LHRH apparatus to cyclic AMP. In addition, this study showed that while spontaneous basal LHRH release in-creased dramatically (over 8-fold) and in a near-linear fashion with increasing age of intact male rat donor, MBH-LHRH concentra-tion reached near-maximal levels of 175 pg/mg tissue by 45 d. of age. age.

age. In sum, it can be concluded that 1.) sensitivity of the male rat neural LHRH apparatus to cyclic AMP delivery changes in an age-dependent manner and 2.) distinct maturational changes in LHRH release from and LHRH concentration in superfused male rat MBH fragments are observed using this in vitro system.

130.3

THE ROLE OF PROSTAGLANDINS AND cAMP IN IN VITRO PROGESTERONE-STIMULATED LHRH RELEASE FROM SUPERFUSED RAT HYPOTHALAMIC FRAGMENTS. K. Kim and V. D. Ramirez. Dept. of Physiology and Biophysics, Univ. of Illinois, Urbana, IL 61801. The present studies attempt to elucidate the possible role of Prostaglandin E2 (PG-E2) and Adenosine 3',5'-monophosphate (cAMP) in in vitro Progesterone (P)-stimulated LHRH release from super-fused rat hypothalamic fragments. Immature female rats (day 28) were ovariectomized and implanted with Silastic capsules contain-ing Estradiol-178. On day 30, mediobasal hypothalamic-anterior hypothalamic-preoptic area (MBH-AHA-POA) units were removed and superfused in vitro. Effluents were collected on ice at 10 min-intervals. LHRH was determined by a specific and sensitive LHRH radioimmunoassay. Each experimental group was replicated four times. Intermittent P infusion (10 ng/ml: 10 min-on, 20 min-off) is effective in stimulating LHRH release in vitro as previously shown (Kim and Ramirez, Endocrinol., 111:750, 1982). Continuous in vitro infusion of a PG synthesis inhibitor, indomethacin (100 HM) Diocked completely P-induced LHRH release (mean post-P LHRH release between Control and Indomethacin groups: 1.09 + .07 vs .31 ± .02 pg/min/mg x 10<sup>-2</sup>; p < .01). Following a 50 min-control period, a step-wise increment in several infusion doses of PG-E2 (each dose for a 50 min-interval) evoked dose-related increases in LHRH release. PG-E2 induced significant (p<.01) increments in LHRH release. PG-E2 induced significant (p<.01) increments in LHRH release. PG-E4 induced LHRH release (HARH release in 5.7 x 10<sup>-7</sup>, 5.7 x 10<sup>-7</sup>, and 5.7 x 10<sup>-7</sup> M; 10 min-on, 20 min-off) resulted in rhythmic LHRH secretion. Fol-lowing a 50 min-control period, a dose-related increase in LHRH LHRH release at dose of 5.7 x  $10^{-5}$ , 5.7 x  $10^{-6}$ , and 5.7 x  $10^{-5}$  M respectively. Intermittent infusion of dibutyryl cAMP ( $10^{-7}$  M; 10 min-on, 20 min-off) resulted in rhythmic LHRH secretion. Fol-lowing a 50 min-control period, a dose-related increase in LHRH release was obtained when adenylate cyclase activators, such as Forskolin and Cholera Toxin were infused in a step-wise manner (each dose for a 50 min-interval). Forskolin and Cholera Toxin significantly (p<.01) stimulated LHRH release at doses of  $10^{-4}$ and 5.4 x  $10^{-10}$  M respectively. These stimulatory effects of Forskolin and Cholera Toxin on LHRH release were no longer present when hypothalamic fragments were superfused in calcium-free plus EGTA (10 mM) containing medium. It appears that PG-E<sub>2</sub> and cAMP may mediate P-stimulated LHRH release <u>in vitro</u>. It is tempting to postulate that P directly or indirectly (perhaps thru Norepinephrine stimulation) enhances PG-E<sub>2</sub> activity which then activates the adenylate cyclase system to increase cAMP level which in turn triggers the release of LHRH.

CNS ACTIVITY OF N-TERMINAL FRAGMENTS OF CHOLECYSTOKININ 130.5 CTAPEPTIDE. C.A. Tamminga, M. Knight, M. Beck, S. Cohen, \* L. Steardo, \* T.N. Chase. Maryland Psychiatric Research Center, University of Maryland, Baltimore, Maryland 21228; NINCOS, ETB, Bethesda, Maryland 20205. Biologic activity of cholecystokinin, a 33 amino acid

Biologic activity of cholecystokinin, a 33 amino acid neurally active peptide, resides in the carboxyl-terminal octapeptide sequence, CCK 26-33 (CCK8); most actions require no more than CCK 29-33. Modifications of CCK8 at the carboxyl end have been reported to eliminate or reverse peripheral activity and modify behavioral actions of CCK8. In an effort to define the structure-activity relationships of other portions of the peptide and to identify fragments of specific pharmacologic peptide and to identify fragments of specific pharmacologic interest, we have prepared and tested an N-terminal analogue and N-terminal fragments of CCK8. N-acetylated peptides of the sequences Asp<sup>26</sup> to Gly<sup>29</sup> inclusive through Asp<sup>26</sup> to Asp<sup>32</sup> amide and (Lys)<sup>31</sup> CCK 26-31 were synthesized by solid phase techniques and sulfated. Purification of the fragments phase techniques and sulfated. Purification of the fragments was carried out using countercurrent chromatography on the coil planet centrifuge and HPLC techniques. The acetylated fragments CCK 26-29, CCK 26-30 amide, CCK 26-31 amide, and CCK 26-32 amide and the  $(Ly_3)^{31}$  CCK 26-31 amalogue were tested for CCK receptor affinity and biologic activity in mammalian brain. The  $(Ly_3)^{31}$  CCK 26-31 analogue has been shown to bind to the pancreatic CCK receptor and to antagonize the action of CCKS on dispersed pancreatic actnar cells; the analogue demonstrates no affinity at the CNS CCK receptor and volar. demonstrates no affinity at the CNS CCK receptor at molar concentrations up to  $10^{-3}$ . The N-terminal CCK fragments were concentrations up to 10<sup>-2</sup>. The N-terminal CCK fragments were similarly tested for affinity at brain CCK receptors. Using  $1^{25}$ I CCK-33 and guinea pig cortical membranes, we have shown that CCK 26-32 amide displaces CCK-33 binding with an IC<sub>50</sub> of 2 x 10<sup>-5</sup>M; dibutyryl cyclic GMP in this system displaces ligand binding at a potency of 5 x 10<sup>-1</sup>M. The three shorter CCK fragments failed to displace labeled ligand binding when tested at concentrations up to 10<sup>-3</sup>M. Neither the analogue nor the fragments demonstrate CCK-like activity in rat avoidance paradiams. These fragments may provide a nor the fragments demonstrate CCK-like activity in rat avoidance paradigms. These fragments may provide a pharmacologic tool for distinguishing central from peripheral actions of CCK. In addition, once central activity of CCK 26-32 is studied, this centrally-active fragment may be of value as a specific pharmacologic probe for examining the physiologic role of CCK in brain. Results of behavioral experiments with the N-terminal fragments, testing for CCK antagonist activity will be reported will be reported.

AN ELECTROPHYSIOLOGICAL ANALYSIS OF CHOLECYSTOKININ-DOPAMINE 130.4

AN ELECTROPHYSIOLOGICAL ANALYSIS OF CHOLECYSTOKININ-DOPAMINE INTERACTION. D. Hommer\*, L. Skirboll and M. Palkovits\*. Clinical Neuroscience Branch, National Institute of Mental Health, Bethesda, MD 20205. Immunohistochemical studies have shown that there is a coexistence of dopamine(DA) and cholecystokinin (CCK) in a sub-population of mesencephalic neurons which in the rat project primarily to limbic areas (Hökfelt et al., Neurosci. 5, 2093). Previously, we have reported that these DA/CCK containing cells are excited by either systemically and iontophoretically adminis-tered CCK (Skirboll et al., Neurosci. 6, 2111). This raises the question of the functional significance of DA/CCK coexistence. To investigate this question we used extracellular single unit question of the functional significance of DA/CCK coexistence. To investigate this question we used extracellular single unit recording techniques in male albino rats. Four ug/kg of CCK or its analogue ceruletide were administered systemically and their effect on the ability of the DA agonist, apormorphine, to inhibit medial A9 neurons was evaluated. These neurons are in a region which has a high proportion of cells containing both CCK and DA. Pretreatment with either CCK or ceruletide lead to a significant shift to the left of the dose response curve for apomorphine induced inhibition of firing. The ED50 of apomorphine for both CCK and ceruletide was 4 ug/kg while the ED50 for the control group was 8 ug/kg. This suggests that systemically administered CCK-like peptides can induce a DA autoreceptor supersensitivity. Iontophoretically applied CCK also is able to potentiate the inhibitory action of iontophoretically applied DA on medial A9 neurons.

Although we have found that systemically and iontophoreti-cally administered CCK have similar effects on CCK/DA neurons several behavioral effects of systemically administered CCK are several behavioral effects of systemically administered CCK are not present in vagotomized animals (Crawley et. al., Eur. J. Pharmacol. 73, 379) suggesting that CCK's behavioral effects may be mediated by an action outside the CNS. In an effort to deter-mine whether the excititory effects of CCK on DA neurons were mediated centrally or peripherally the effect of CCK on medial A9 cells was examined in three groups of rats: 1) acutely vagoto-mized animals; 2) rats with a unilateral lesion to the nucleus tractus solitarius or 3) rats given a C-1 transection prior to recording. None of these procedures altered CCK's excititory effect on medial A-9 cells suggesting that the ability of CCK to enhance the activity of DA neurons is not mediated through a peripheral action but rather represents a central action of the peptide. peptide

We also examined DA-CCK interactions in limbic DA terminal which were inhibited by apomorphine. The effects of CCK antago-nists in pre- and post-synaptic regions will also be reported.

EVIDENCE FOR NEURON-SPECIFIC PROTEIN PHOSPHORYLATION FOLLOWING PEPTIDERGIC BAG CELL ACTIVITY IN <u>APLYSIA</u>. <u>M. Schaefer, P.H.</u> <u>Brownell, and P. Shirk</u>\*. Dept. of Zoology, Oregon State Univ., Corvallis, Oregon 97331 130.6

PEPTIDERGIC BAG CELL ACTIVITY IN APLYSIA. M. Schaefer, P.H. Brownell, and P. Shirk\*. Dept. of Zoology, Oregon State Univ., Corvallis, Oregon 97331 The peptidergic bag cell neurons in the abdominal ganglion of Aplysia californica strongly influence the activities of other ganglionic neurons for periods of minutes to hours. We are investigating the role of protein phosphorylation in mediating these long-term responses. Two types of bursting pacemaker neurons in the abdominal ganglion are affected differently by bag cell activity (BCA). The left upper quadrant (LUQ) cells L2-L6 undergo long-lasting inhibition, while burst activity in neurosecretory cell Rl5 is augmented. We reasoned that since the responses to BCA in the LUQ's and Rl5 are essentially opposite, a comparison of the protein phosphorylation patterns in these cells might allow us to identify phosphoproteins involved in long-term modulation of neuronal activity. Protein phosphogylation was, monitored by intracellular injection of  $[X^{-2}CP]$  labeled ATP (NEN, S2900 Ci/mmole) following a modification of techniques described by Lemos et al. (Nature 298, 64-65, 1982). Microelectrodes were filled with labeled ATP (1 µCi/nl) in 300 mM potassium phosphate buffer (pH 6.8), and the solution was pressure injected into a single neuron per ganglion. In control ganglia, label was incorporated for 1 hr and the ganglia were frozen in liquid nitrogen. In experimental ganglia, BCA was evoked by brief localized electrical stimulation of a bag cell cluster and a maximal response was allowed to develop prior to freezing. Ganglia were homogenized and the proteins were resolved by electrophoresis on a sodium dodecyl sulfate polyacrylamide gradient gel (8-15%) (0'Farrell, J. Biol. Chem. 250, 4007-4021, 1975). The labeled proteins were visualized by autoradiography at -70°C using a Cromex (Dow) intensifying screen. Our results indicate considerable similarity in the patterns of protein phosphorylation between neurons in the ganglion as well as neuron-specific and BCA respon

ACTIONS OF N-ACETYLASPARTYLGLUTAMATE ON MAMMALIAN NEURONS. J. M. H. ffrench-Mullen\*, R. Zaczek\*, K. J. Koller, J. T. Coyle and D. O. Carpenter, NYS Dept. of Health, Albany, New York 12201 and Johns Hopkins University, Baltimore, Maryland 21205 While L-glutamate (Glu) and L-aspartate (Asp) are considered 130.7

possible excitatory transmitters there are reasons to believe that at some sites the true transmitter is related to but disthat at some sites the true transmitter is related to but dis-tinct from either Glu or Asp (cf. Hori, et al., J. Neurophysiol. 48:1289, 1982). N-acetylaspartylglutamate (NAAG) is a dipeptide present in mammalian brain which a) demonstrates a high affinity binding (420 mH) to receptor sites labelled by H-Glu and b) is a potent convulsant (Zaczek, et al., PNAS 80:1116, 1983). We have applied NAAG by single and multiple barrel ionophoresis to neurons in both rat prepyriform and sensory-motor cortex brain clience in order to determine whether NAAC head district cleatrical slices in order to determine whether NAAG has direct electrical actions on neurons and, if so, to compare the physiological and pharmacological properties of the NAAG response to that of the natural transmitter and the excitatory amino acids. NAAG was a potent excitant of 24 of 25 neurons in prepyriform and 20 of 20 neurons in sensory-motor cortex. The response was of relativly neurons in sensory-motor cortex. The response was of relativity short latency, consisting of a high frequency burst of spikes. With higher ionophoretic currents the response was prolonged, often leading to irregular spontaneous discharge and ultimately to spike inactivation and cell death. Although it is difficult to determine precise potency in ionophoretic studies, NAAG was clearly more potent than Glu, Asp or N-methyl-D-aspartate (NMDA), but was equal to or less potent than quisqualate (Quis). NAAG caused a prolonged potentiation of the responses to the other agonists. It was more neurotoxic than Glu, NMDA and Quis but less so than kainic acid.

There are differences in the pharmacologic sensitivities of the amino acid responses in these two areas of cortex, in that the traditional Glu antangonist glutamate diethylester (GDEE) and the Asp antagonist alpha amino adipate ( $\alpha AA$ ) have the expected actions in sensory motor cortex but are both without expected actions in prepyriform cortex. Furthermore the excita-tory actions of the lateral olfactory fibers on prepyriform neurons are blocked by aminophosphonobutyric acid (ABP), but not by GDEE or  $\alpha$ AA. In preliminary studies the NAAG response in prepyriform cortex was depressed by APB but not GDEE or  $\alpha$ AA, but in sensory-motor cortex it was unaltered by any of these agents. These studies suggest the possibility of a physiological role for NAAG as a neurotransmitter in the rat central nervous system, and also indicate that there are regional differences in pharmacologic sensitivities to NAAG and other excitatory agents in the cortex.

ANGIOTENSIN II AND III IN RAT HYPOTHALAMUS AND CORTEX SHOWN BY HPLC. <u>M. Ian Phillips and Birgitta Stenstrom</u>. Department of Physiology, College of Medicine, University of Florida, Gaines-130.9 Physiology, College of Medicine, University of Florida, Gaines-ville, FL 32610. To answer the question of whether angiotensin II exists in the

ville, FL 32610. To answer the question of whether angiotensin II exists in the brain independently of peripheral angiotensin, a sensitivie radi-oimmunoassay with high recovery rates was used to measure frac-tions eluted from high pressure liquid chromotography (HPLC) assay of male adult rat brains. Twenty three rats were nephrectomized bilaterally and 24 hrs later the brains were extracted in acetic acid. The hypothalamus block had consistently higher levels of Ang II than cortex. The range of Ang II concentration measured by RIA (93% recovery) was 63 pg to 873 pg/g tissue in hypothalamus and 14-179 pg/g tissue in cortex. Fifteen HPLC assays were run with the hypothalamic and cortex tissues and in every case a clear peak was reliably found in the same fractions that authentic 5(IIe) angiotensin II migrated to. The regovery rate in the HPLC column was 90%. Further tests with the 3H-Ang II confirmed the position of the presence of a brain peptide which comigrates with the octapeptide angiotensin II. The results indicate that the antibody which was previously used in our immunocytochemical localization of angio-tensin in the hypothalamus detects authentic angiotensins. [Sup-ported by NIH and SF grants to M.I.P.]

CARDIOVASCULAR ACTIONS OF BRADYKININ INJECTED INTO SPECIFIC HYPO-THALAMIC AND PREOPTIC NUCLEI. <u>D. I. Diz\* and D. M. Jacobowitz</u>, Lab. of Clinical Science, NIMH and NIGMS, Bethesda, MD 20205. 130.8

Bradykinin-like immunoreactive neuronal cells and fibers are reported to be present throughout the rat hypothalamus (Corrêa, F.M.A. et al., Proc. Natl. Acad. Sci., 76:1489, 1979), and brady-kinin (BK) has been reported to induce changes in blood pressure (BP) when administered into the lateral cerebral ventricle or pars ventralis of the lateral septal area (Corrêa, F.M.A. and F.G. Graeff, <u>J. Pharmacol. Exp. Ther., 192</u>:670, 1975). In the present study, we monitored BP and heart rate (HR) during microinjections of BK in discrete hypothalamic (HT) nuclei in order to determine the HT sites of cardiovascular (CV) actions of the peptide. Initial BP and HR in 51 halothane-anesthetized rats was 88  $\pm$  1 mm Hg and  $352 \pm 4$  beats/min (b/m), respectively. BK (5 nmol) or saline vehicle was injected (100-300 nl) via double-barreled glass micropipettes (0.D. 20-70 µm). In the HT paraventricular nucleus micropipettes (0.D.  $20-70 \ \mu\text{m}$ ). In the HT paraventricular nucleus (PVN; n = 6), BK, but not saline, decreased HR 42 ± 10 b/m (-12%) without change in BP. In contrast, increases in HR of 9% and 13% occurred at sites within the medial preoptic nucleus (POM; n = 7) and the preoptic suprachiasmatic nucleus (POS; n = 5), respectively; BP was unchanged. In the HT dorsomedial nucleus (DNN; n = 10), BK increased both BP (13%) and HR (15%). Similarly, increases of 8% and 11% in BP and HR were observed with BK injections into the posterior HT nucleus (PH; n = 7). Variable responses occurred with BK in the anterior HT nucleus depending responses occurred with as in the anterior in indicus depending upon the rostrocaudal localization of injections. The general characteristics of all the responses include an onset of less than 1 min with peak activity occurring at  $6 \pm 1$  min and a duration of about 40 min. Tachyphylaxis to repeated BK injections was present for approximately 60 min following a prior exposure to the peptide

A preliminary study in which the CV effect of bradykinin potentiating factor (BPF; angiotension converting enzyme inhibitor) were investigated suggests BPF (5 nmol) has minimal CV actions of its own in the POS, POM or PVN and may increase BP and HR in the DMN and PH. Further experiments will evaluate the effects of BPF injections 10-15 min prior to BK injections to determine if discrete inhibition of kininase II alters the CV responses to HT injections of BK.

In summary, the data indicate that the characteristics of the CV response to BK depend upon the specific site of injection and that these CV sites of action correspond well with the previously observed localization of BK-like immunoreactive nerve cells and fibers. Bradycardic actions occur within the PVN, tachycardic and pressor actions occur within the DMN and PH, and tachycardia only occurs within the POS and POM.

130.10 EXCITATORY EFFECTS OF ANGIOTENSIN II AND INHIBITORY EFFECTS OF INSULIN ON HIPPCCAMPAL CA1 FYRAMIDAL NEURONS. R.A. Palovcik, M.I. Phillips, and M.K. Raizada\*. Department of Physiology, College of Medicine, University of Florida, Gainesville, FL, 32610.

32510. Recent immunocytochemical and receptor binding studies show that the brain contains angiotensin II (AII) and insulin and their receptors. The physiological significance of the angioten-sin system appears to be in the regulation of blood pressure and drinking responses but the role of insulin in brain function is not clearly understood. The present investigation was undertaken to study the effect of these peptides on the spontaneous firing of biprogramal neurops in brain slices. of hippocampal neurons in brain slices.

hippocampus was removed from Sprague-Dawley male

The hippocampus was removed from Sprague-Dawley male rats (150-300 g) and sectioned transversely into 0.4 mm thick slices. These were maintained in a chamber at 34°C with 95% O<sub>2</sub>, 5% CO<sub>2</sub> under continuous perfusion (30 ml/hr) of Yamamoto's solution. Robust activity could be recorded as long as 35 hours; however, all experiments were done between 2 and 10 hours post setup. Peptides were applied into the medium by slow infusion to avoid mechanical artifacts, extracellular recordings were made in most come to the come interacellular term allows and the provided as between the setup. The cases but some intracellular recordings were made in lost cases but some intracellular recordings were also used. Applica-tion of AII, into the perfusion medium resulted in the excitation of 50% of CAI pyramidal neurons, no effect in 43% and inhibition in 7%. This excitatory effect was observed over a wide dose range of AII with 3 cells responding to as low as  $10^{-15}$  M and intraced with the interview for the case of the assistance of the second secon range of All with 3 cells responding to as low as 10° M and increased with each increasing dose. Saralasin, an All receptor antagonist caused attenuation of the excitatory effect of All. Intracellular recording from CA1 pyramidal neurons showed an increase in excitatory synaptic activity at low doses of All. In contrast to All, insulin inhibited firing of CA1 pyramidal

neurons (in 38% and no effect in 62%) in a dose dependent manner, producing significant inhibition with as low as  $10^{-9}$  M. For comparison carbachol was tested. Excitatory effects occurred at  $10^{-7}$  M and above. This indicates that CAI pyramidal cells are highly sensitive to insulin and AII.

The results are the first demonstration that insulin directly These results are the first combinistration that insuffit offectry affects the electrophysiological activity of neurons. These results suggest that peptides may be effective in altering neu-ronal activity in concentrations that are comparable to those detected in <u>vivo</u> and are consistent with the existence of recep-tors for these peptides in the brain. ENALAPRIL, INTRACEREBROVENTRICULAR BUT NOT PERIPHERAL ADMINISTRA-TION, BLOCKS DRINKING EVOKED BY ANGIOTENSIN I GIVEN INTRAVENTRI-CULARLY. G.E. Martin, T. Naruse, \* N.L. Papp\* and S.L. Gaul.\* Merck Institute for Therapeutic Research, West Point, PA 19486. Blockade of the enzyme which converts angiotensin I (AI) to AII should block the dipsogenic action of centrally administered AI. Blockade of AI-induced drinking by a peripherally adminis-tered angiotensin converting enzyme (ACE) inhibitor such as enalapril would provide strong evidence for a CNS action for 130.11 enalapril would provide strong evidence for a CNS action for that compound. These experiments were conducted to determine whether enalapril given peripherally could reduce drinking pro-duced by the ICV injection of AI in normotensive rats.

All ICV injections were made via an implanted 24-gauge guide tube in male Sprague-Dawley rats. In the antagonism studies, a crossover design was used in which half of the rats were first given the vehicle and half enalapril before AL. One week later the pretreatments were alternated. Enalapril was given 10 minutes before AI when given ICV, but 30 minutes prior to AI when

utes before AI when given ICV, but 30 minutes prior to AI when given p.o. or i.p. The ICV administration of AI was found to produce a dose-related drinking response which reached asymptote at 25 ng. Pretreatment with a potent hypotensive dose (3 mg/kg) of enalapril p.o. failed to reduce the fluid consumption induced by 5, 15, or 25 ng (n=5 or 6/group) of AI given ICV. The drinking produced by the intracerebral infusion of 500 ng of AI was not signifi-capture to the the prior in p deministration of contamined to the second by the intracerebral infusion of 500 ng of AI was not signifi-cantly reduced by the prior i.p. administration of enalapril (1 mg/kg i.p.), it was significantly reduced from a mean of 11.5 + 1.1 (SEM) ml/hr to  $4.5 \pm 1.7$  ml/hr following enalapril given ICV (100 µg). Furthermore, the ICV infusion of 50 µg of enalapril significantly reduced drinking produced by 25 ng of angiotensin from 7.9 ± 0.7 to 3 ± 1 ml/hr. Although p.o. pretreatment with 9 mg/kg of enalapril did reduce fluid consumption from 9.2 ± 1.0 to 5.4 + 0.8 ml/hr, the reduction was not statistically significant.

These results in the normotensive rat corroborate those re ported previously for the spontaneously hypertensive rat (Sweet et al., Fed. Proc. 41: 1663, 1982) and suggest enalapril does not efficiently cross the blood-brain barrier to block ACE in the ventricles. One might infer from these data that enalapril's hypotensive action may be exerted primarily in the peripheral nervous system.

POTENTIATION OF APOMORPHINE-INDUCED EMESIS IN THE DOG BY 130.12 CENTRALLY ADMINISTERED ANGIOTENSIN II, <u>J. Kucharczyk, M. Wu\* and</u> <u>R.K. Harding\*</u>, Dept. of Physiology, School of Medicine, Univ of Ottawa, Ottawa, Ont. K1H 8M5.

Emesis can be induced by intravenous (Carpenter, SAM-RE-82-28) and intracerebroventricular (Wu & Kucharczyk, Proc. Can. Fed. Biol. Soc. <u>26</u>, 1983) administration of angiotensin II (AII) and other vasoactive peptides, such as neurotensin and arginine vasopressin. Ablation of the area postrema (AP) blocks the neurogenic pressor response to AII (Ferrario et al., Hypertension 1: 235, 1979) as well as emesis induced by the dopaminergic agonist, apomorphine (APO) (Borison, Life Sci. <u>14</u>: 1807, 1974).

In order to study whether APO and AII act on the same central receptors to initiate emesis, five adult mongrel dogs with chronically implanted lateral cerebroventricular (LV) cannulae received repeated injections of various doses of the drugs and their antagonists. Administration of 5  $\mu$ g APO + 500  $\mu$ g AII their antagonists. Administration of 5 µg APO + 500 µg AII induced vomiting in all four dogs tested with a mean latency of 7' 45", whereas the same dose of APO given alone was totally ineffective. Two dogs tested with LV injections of 5 µg APO + 250 µg AII and 5 µg APO + 100 µg AII also responded. At higher doses of APO (20 and 40 µg), the main effect of combined APO-AII injections was to reduce the response latency and to increase the number of bouts of vomiting. Pretreatment of the LV with the dopaminergic antagonist, spiroperidol (500 µg), blocked vomiting in three dogs tested with a combined injection of 40 µg APO + 500 µg AII delivered into the same intracranial cannula. Pretreatment of the LV site with 100-900 µg of the AII antagonist, 1-Sar, 8-AIa AII, significantly reduced the number of emetic episodes elicited by injections of 40 µg APO.

Finally, in acute blood pressure recording experiments in chloralose-anesthetized dogs, LV administration of 40  $\mu$ g APO produced a small and transient decrease in mean arterial blood pressure (MAP) (5-23 mmHg), whereas injection of 500  $\mu$ g AII produced an increase in MAP of 33 mmHg. Combined LV treatment with 40  $\mu$ g APO + 500  $\mu$ g AII, on the other hand, induced a large and sustained increase in MAP (peak increase of 78 mmHg 5 min strainistic). after injection). These data suggest that APO and AII may induce vomiting through a vasoactive mechanism in which the AP plays an important receptor or integrative function. (Supported by Govt. Canada Contract 2SU81-00190).

VASOPRESSIN RELEASE IN THE RAT SEPTUM IN RESPONSE TO SYSTEMIC STIMULI, F. Rodriguez\*, J. Demotes-Mainard\*, J. Chauveau\*, D. Poulain\* and J.D. Vincent. Unité de Neurobiologie, U.176 INSERM Domaine de Carreire, Rue Camille-Saint-Saëns, 33077 BORDEAUX-contacté de Carreire, Rue Camille-Saint-Saëns, 33077 BORDEAUX-130.13 Cedex (France).

Poulain\* and J.D. Vincent. Unité de Neurobiologie, U.172 INSERM Domaine de Carreire, Rue Camille-Saint-Saëns, 33077 BORDEAUX-Cedex (France). Immunohistochemical studies have shown that the lateral sep-tum is a main target area for arginin-vasopressin (AVP) countai-ning fibers and synapses (Buijs, R.M. and Swaab, D.F., Cell Tissue Res., 204 : 355, 1979). Furthermore, a calcium-dependent release of AVP was evoked from septal slices in vitro by potas-sium and veratridine (Buijs, R.M. and Van Heerkluize, J.J., Brain Res., 252 : 71, 1982). In order to confirm such a release in vivo and to study its physiological significance we have used push-pull cannulae implanted stereotaxically in the lateral sep-tum to mesure the local release of AVP as rats were submitted to systemic stimuli known to affect the plasma level. of AVP. Push-pull cannulae (1.4mm diameter) were implanted in the lateral septum (LS), caudate nucleus (CN) and lateral ventricule (LV) of male rats anaesthetized with urethane. The cannulae were continuously supplied with artificial cerebrospinal fluid (Iml/15min). Radioiummunological assay of AVP was then carried out on superfusate samples collected every 15 min. After 30 min of superfusion, a stable release of AVP (lpg/ml/15min) was measured in the LS and the LV. AVP was not detected in the CN. Osmotic stimulation (4ml 1P, NaCl 2M) induced a dramatic increase of AVP release from the LS (30-55pg/ml/15min) which paralleled the increase in plasma aosmotic pressure. Only a small increase (2pg/ml/15min) was observed in the LV and none was observed in the CN. The release from the LS ave calcium-dependent since it was inhibited when the cannulae were supplied with Ca-free artificial CSF. Hypovolemic stimula-tion (polyvynil-pyrrolidone 40% in NaCl 0.15M, 2ml/100g IP) also induced a dramatic increase in AVP release in plasm AVP. The fact that elevated levels of AVP in response to osmotic and hypovolemic stimulations were noted only in the LS argues against a non specific diffusion of plasma AVP. through t

Our results demonstrate that a Ca-dependent release of AVP occurs within the lateral septum. This release is affected by the same stimuli that induce the liberation of AVP into the blood, suggesting that AVP within the septum may contribute to the central regulation of body fluid homeostasis.

130.14 CENTRAL ACTION OF ARGININE VASOPRESSIN ON RENAL FUNCTION. <u>C. L. Riphagen\* and Q. J. Pittman</u>. Dept. of Pharmacology and Therapeutics, Faculty of Medicine, University of Calgary,

Therapeutics, Faculty of Medicine, University of Calgary, Calgary, Alberta, Canada. The posterior pituitary hormone, arginine vasopressin (AVP) is well known for its peripheral antidiuretic and pressor effects. Immunocytochemical studies have established the pre-sence of immunoreactive AVP in neuronal fibres within the spinal cord and evidence now suggests that AVP may function as a neuro-transmitter in the central nervous system. In the present study we have tested the hypothesis that AVP may affect renal function through a central action on neurons within the spinal cord. In inactin anaesthetized rats a polyethylene (PEIO) cannula was introduced through the cisterna magna and threaded down the

was introduced through the cisterna magna and threaded down the spinal cord in the sub-arachnoid space to the region of the  ${\rm T_{12}}$ Spinal Cord in the sub-arachnoid space to the region of the  $1_{12}$ - $T_{13}$  vertebrae. Blood pressure was monitored using a carotid cannula. A jugular infusion of 0.7% NaCl/5 mM glucose was infused at a rate of 5.1 ml/hour to maintain a stable urine flow and a cannula leading to a conductivity meter and a fraction collector drained urine from the bladder. Urine volume and osmolality were calculated over 10 minute periods. 3  $\mu$ l 10<sup>-6</sup> M to 10<sup>-7</sup> M AVP in Krebs or artificial CSF [or the same volumes of the analogues arginine vasotocin (AVT), oxytocin and DDAVP (a molecule baving artidiurcic, but not pressor activity]

the analogues arginine vasotocin (AVT), oxytocin and DDAVP (a molecule having antidiuretic, but not pressor activity)] were injected into the  $T_{12}$ - $T_{13}$  region. After the injection of 10<sup>-6</sup> M AVP or the analogue AVT into the spinal cord, urine output consistently dropped to less than 50% of the control levels and the conductivity and osmolality of the urine increased. Similar injections of 10<sup>-7</sup> M AVP or oxytocin did not produce consistent results. Spinal application of DDAVP appeared to have little effect on urine flow. The observed antidiuretic effects of the centrally applied AVP was not likely due to its diffusion into the peripheral

NEUROPEPTIDE PROFILES IN POSTPARTUM PSYCHIATRIC SYNDROMES. C.S. Sebastian\*, R.G. Nathan\*, M. Hack\*, A. Vekovius\* and A. Lassen\*. (Spon: G. Trapp). Psychiatry Research Unit, Department of 130.15 Psychiatry, Louisiana State University Medical Center, Shreveport, LA 71130.

Increased activity of the hypothalamus-pituitary-cortisol axis is found in a number of patients with primary depression. The peptides that control the discharge of the pituitary hormones are known as release or release-inhibiting hormones. Many of these peptides are considered to have effects on neurotransmission in peptides are considered to have effects on neurotransmission in other parts of the brain. For particular control peptides such as the hypothalamus releasing factor, degradation is under extensive feedback control. On this basis, it has been proposed that several psychiatric disorders may be due to a peptidase insufficiency. Increased strain on the peptidergic system regulated by such a peptidase could reach a point where peptide release would exceed breakdown, resulting in pathology and peptide excretion. Trygstad et al (1980) demonstrated a pathological carrier-protein-pattern upon Sephadex G 25 gel filtration of urine samples obtained from patients suffering from acute affective psychosis. The pathological pattern was normalized by treatment with tricyclic antidepressants.

Our prospective study was designed to investigate the patterns of urinary neuropeptides occurring in pospartum psychiatric syndromes (PPS). A minor form of PPS, characterized by mild synoromes (PPS). A minor form of PPS, characterized by mild depression, anxiety and clouding of consciousness occurs in 50-80% of the women after childbirth. Accordingly, urine samples, and responses to the Zung's Self-Rating Depression Scale (SDS) and the Depression Adjective Checklist (DACL) were obtained from 50 women during the eighth month of pregnancy (samples A), from 50 women during the eighth month of pregnancy (samples A), day one postpartum (samples B) and six weeks postpartum (samples C). Preliminary computer analyses of the psychometric data indicate that the women had started out with highest scores of depression before delivery which fell off significantly by the sixth week. Thus, contrary to popular belief, women appear to report depressive features even prior to childbirth. On the SDS (n=22), the mean scores were A=54,716; B=52,102 and C=46,40 (A and B were significantly >b oth B=12.257 and C=11.829 (p<.0180).

(p<.0180). The urinary peptides (n=27) were precipitated with benzoic acid, washed in ethanol and chromatographed on 2.5 x 97 cm Sephadex G-25 column. Optical density (280 nM) on 20 ml fractions were monitored and the elution profiles plotted. The mean peak heights in samples A & B were significantly lower than C (p<.001).

CRANIAL MOTONEURONS IN VITRO: MEMBRANE PROPERTIES AND ACTIONS OF TRANSMITTERS AND TRH. R. A. Gregg and D. O. Carpenter, New York State Department of Health, Albany, NY 12201 Antidromically identified motoneurons of the hypoglossal nucleus (XIIth) and neurons of the dorsal motor vagal (DMV) 130.17

nucleus (Xth) were studied in submerged, perfused brain stem slices of the rat at 35°C. Intracellular recordings were made Moters (Atf) were studged in submerger, perioded brain stem slices of the rat at 35°C. Intracellular recordings were made using either single or double barreled electrodes. Hypoglossal motoneurons had resting potentials averaging -57.3 + 1.68 mV and input resistances of between 40-70 MG. When antidromically activated by stimulation of the XIIth nerve as it exits from the ventral brain stem with a bipolar electrode, the motoneu-rons show clear initial segment (IS) and soma-dendritic (SD) spikes, similar to those characteristic of spinal motoneurons (Brock, et al., J. Physiol. 122:429, 1953). The SD spike followed frequencies  $\geq 100$  Hz, while the IS spike followed faithfully at frequencies  $\geq 250$  Hz. The majority of neurons penetrated in the XIIth nucleus could be antidromically acti-vated. Neurons in the DMV could not be antidromically acti-vated in the plane of the slice, but had average membrane potentials of -55.6 + 1.63 mV and input resistances similar to those of XIIth neurons. The current-voltage relations of both types of motoneuron were linear in the potential range -50 to those of XIIth neurons. The current-voltage relations of both types of motoneuron were linear in the potential range -50 to -80 mV.

L-glutamate (Glu), gamma aminobutyric acid (GABA), glycine (Gly) and thyrotropin releasing hormone (TRH) were applied to DMV and XIIth neurons by ionophoresis. Glu excited every cell, DMV and XIIth neurons by ionophoresis. Glu excited every cell, causing a rapid depolarization which was not associated with a measureable conductance change. GABA and Gly both hyperpolar-ized DMV neurons, causing a conductance increase of approxi-mately 80%. However in the XIIth nucleus both GABA and Gly depolarized the cells. The response was associated with a conductance increase of approximately 25%, and reversed in polarity with about 10 mV depolarization. In spite of the depolarization with both extra- and intracellular recordings the response to each was inhibitory. TRH elicited a direct excitatory response in approximately half of the cells in both nuclei. The response was relatively slow in onset and long in duration, and was associated with an approximately 20% decrease duration, and was associated with an approximately 20% decrease in membrane conductance. Perfusion of 4 mM BaCl elicited a response very similar to that induced by TRH, suggesting the possibility that TRH is acting through effects on "M" channels.

130.16 DIFFERENTIAL SENSITIVITY OF HOME-CAGE SEEKING BEHAVIOR OF NEONATAL RATS TO ACTH PEPTIDES. J. Berran\*, G.R. Acker\* and <u>F.L. Strand</u>. Lab. of Physiology, New York University, N.Y.C., N.Y. 10003. The role of brain neuropeptides, specifically those of the arrive of brain neuropeptides.

ACTH family, in modulating learning and memory function, has been widely investigated in the adult mammalian system, while their effects in the immature animal have had little attention. their effects in the immature animal have had little attention. Therefore, we investigated the effects of ACTH 4-10 and ACTH 4-9 (Org 2766) on learning acquisition and extinction in neonatal animals less than three weeks of age, using a home-cage seeking test as motivation and reinforcement. Animals were given (SC) either ACTH 4-10, ACTH 4-9 (Org 2766) (10 Mg/kg) or saline every day starting at birth. When the animals were 16 days of age, learning trials were given by placing one animal at a time at the start of a T maze and allowing it to run either to a left or right goal box, one of which contained the mother. After 24 hours the rats were subjected to extinction trials (running the maze without the presence of the mother as reinforcement). The number of trials needed before learning or extinction was reached, the without the presence of the mother as reinforcement). The number of trials needed before learning or extinction was reached, the number of errors made, and the time it took to reach the goal box were measured. Our results show that those animals treated with ACTH 4-10 demonstrated a significantly greater delay in ex-tinction of learning of the T maze (p(O.02), as compared to ACTH 4-9 (Org 2766) or saline. In addition, ACTH 4-10 treated animals ran the T maze more quickly, but this response was not signifi-cant. The acquisition phase was not affected by the ACTH perides at the dosage given. We conclude that, at this early stage of development, the retention of a learned task is more sensitive to the neuromodulatory action of ACTH than the initial learning itself, and perhaps this is due to ACTH acting on the organiza-tional process of the developing central nervous system. This research was partially supported by Grant BRSG RR07062 awarded by the Biomedical Research Support Grant Program Division of Research Resources, National Institutes of Health.

130.18 PROTECTIVE EFFECT OF TRH IN ANAPHYLACTIC SHOCK: SITE AND MECHANISM OF ACTION. S. Amir, A. Schachar\*, M. Harel\* and D. Samuel\*. Dept. of Isotope Res., Weizmann Inst. Sci., Rehovot, Israel. The tripeptide thyrotropin releasing hormone (TRH) has been shown to improve survival in experimental endotoxic or spinal shock. In these studies, the effect of TRH appeared to be sec-ondary to its ability to reverse the cardiovascular depression associated with endotoxin administration or spinal trauma. Her Here we report the beneficial action of TRH in another model of fatal shock, systemic anaphylaxis, and provide evidence that this effect may be mediated through central activation of the adrenal

effect may be mediated through central activation of the adrenal medulla and consequent stimulation of  $\beta$ -adenoceptive sites. Subjects were ICR mice immunized with 2 mg bovine serum albumin (BSA) in 0.2 ml aluminium hydroxide gel. Fatal shock was induced by challenging the mice IV with 25 ug BSA 10 days after immunization. Administration of 125 or 250 ug TRH IV together with the challenge dose of BSA decreased the mortality rate of shocked mice by 57 and 65%, respectively (p $\rightarrow$ 0.05). IV adminis-tration of 5 or 25 ug TRH was ineffective. Similar doses of TRH decreased the mortality rate by 55 to 70%, respectively (p $\rightarrow$ 0.05), when administered ICV 5 min after induction of anaphylaxis. 'Acid' TRH, a deamidated metabolite of TRH was ineffective. 'Acid' TRH, a deamidated metabolite of TRH was ineffective in improving survival following IV administration (125 or 250 ug); ICV 'acid' TRH, 5 ug, decreased the mortality rate by 60% (p < 0.05). The involvement of the sympatho-adrenal system in the effect of TRH was studied by evaluating the effect of TRH following pretreatment with the ganglionic blocker chlorisondamine chloride (2.5 mg/kg IP) or after bilateral adrenal gland denerva-Chloride (2.5 mg/kg IV) or after bilateral adrenal gland deheva-tion (4 weeks before experimentation). Both chlorisondamine, which diminishes sympathetic outflow, and adrenal denervation reversed the protective effect of IV (125 ug) or ICV (5 mg) TRH. Pretreatment with 6-0HDA (50 mg/kg IV), which selectively destroys sympathetic nerve endings did not block the effect of IV of ICV TRH. Finally, mice were pretreated with 2.5 mg/kg phenolamine, an  $\alpha$ -adrenergic receptor blocker or 2.5 mg/kg propranolol a  $\beta$ -adrenergic receptor blocker, or with 2.5 mg/kg domperidone, a peripherally acting dopamine antagonist, prior to TRH administra-tion. In these experiments propranolol blocked the protective effect of IV or ICV TRH whereas phentolamine or domperidone had no demonstrable effects. Collectively, these results suggest that TRH exerts its protective effect in anaphylactic shock by acting In the CNS to increase sympathetic outflow to the adrenal medulla. Released adrenal catecholamines may act through  $\beta$ -adrenoceptive sites, most probably in the heart, to improve cardiocriculatory performance and thus to increase survival.

Health Sciences, Bethesda, MD 20814. Both thyrotropin-releasing hormone (TRH) and naloxone have previously been shown to improve experimental shock due to endotoxemia, hypovolemia or spinal injury, and the beneficial actions of TRH in these models have been attributed to "physio" logic" antagonism of endogenous opioid (endorphin) systems. utilized an unanesthetized guinea pig model to examine the LI0 utilized an unanestnetized guinea pig model to examine the therapeutic effects of TRH and naloxone in four additional forms of experimental shock involving vasoactive lipids. Leukotriene  $D_4$  (LTD<sub>4</sub>) (5 µg/kg IV) and platelet-activating factor (PAF) (1 nmol IV) each produced profound hypotension in this model. Similar hypotension was produced by ovalumin-induced anaphylaxis, a condition in which endogenous LTD, and/or PAF may be implicated. In addition, the hypotension produced by 15-hydro-peroxy eicosatetraenoic acid (15-HPETE) was examined by administration of the enzyme responsible for its formation, soybean lipoxygenase (150 mg/kg IV). In all four instances, the hypotension was significantly improved by TRH (2 mg/kg IV), whereas naloxone (2 mg/kg IV) was without effect. In the LTD, and PAF models, intracerebroventricular (ICV) administration of TRH reversed the hypotension at doses which were ineffective when administered systemically (0.02 mg/kg). In these same models, the synthetic TRH analog MK 771 (2 mg/kg IV) produced a bene-ficial effect which was comparable to that of TRH. In the  $LTD_4$ model, moreover, the TRH effect was dose-dependent at doses between 0.2 mg/kg IV and 2 mg/kg IV. These data suggest that TRH may be of therapeutic benefit in naloxone-resistant, lipidrelated experimental shock models through receptor-mediated central interactions which do not involve antagonism of endorphin effects. Whether TRH exerts similar non-endorphin-related actions in naloxone-sensitive shock models remains to be determined.

## FUNCTIONS OF GLIA

131.1 ELECTROPHYSIOLOGY OF ASTROCYTES IN PRIMARY CULTURES. W. Walz and L. Hertz\*. Dept. of Pharmacology, Univ. of Saskatchewan, Saskatoon, Sask. S7N OWO Canada.

In the past 15 years there has been a growing controversy whether glial cells are involved in K homeostasis of the central nervous system and whether they function as spatial buffers (distributing K by transcelular passive K currents) or by actively accumulating K by a Na -K ATPase. We studied this problem by using pure primary cultures of mouse astrocytes and intracellular glass microelectrodes for potential recording. The membrane potential was -92 mV at 3 mM external K concentration. Reduction of the external C concentration from 125 to 9 mM for 5 min had no effect on the membrane potential. Application of 2 mM furosemide, which in our astrocytes has an inhibitory effect on Na<sup>+</sup> and Cl<sup>-</sup> fluxes, resulted in no measurable alteration of the membrane potential. Hence, these experiments reveal an exclusive K conductance of the astrocytic membrane. Application of ouabain (1 mM) caused a onephase depolarization with a linear time course of 0.7 mV/min. Washing out of ouabain led to a repolarization of the membrane with a faster time course (2.3 mV/min) but no hyperpolarization, below resting potential. The astrocytes were also exposed to K free saline which loaded the cells with intracellular Na. When the K -free saline was replaced with the normal saline, the membrane repolarized but there was, again, no transient hyperpolarization below resting potential. These experiments show that a ouabain-sensitive Na -K pump is necessary for a stable membrane otential, but they give no evidence for an electrogenic contribution during steady-state or stimulation of the pump. Nevertheless, the behavior of the membrane potential was found to deviate from a Nernst potential for K when extracellular K was changed: the slope was linear from 1.5 to 100 mM with 51 mV/tenfold change compared with 61 mV for a Nernstian behavior at 37°C. <sup>4</sup>K K measurements showed that the accumulation, respectively release of K as a function of the K<sup>+</sup> concentration showed two phases: between 1.5 and 25 mM the cells almost trippled t 131.2 FAMILIAL AND SOCIAL INTERRELATIONSHIPS OF ASTROCYTES AND OLIGODENDROCYTES. <u>M. Noble</u> (SPON: W.I.McDonald). Dept. Clinical Neurology, Institute of Neurology, Queen Sq., London WClN 3BG England.

Sq., London WCIN 3BG England. Recent studies have (i) identified protoplasmic and fibrous astrocytes as two distinct populations,with different antigenic phenotypes and seemingly not interconvertible (Raff, et.al., J. Neurosci., in press;Raff and Miller, submitted) and (ii)identified a glial progenitor cell in the optic nerve of 7d old rats which can be induced <u>in vitro</u> to differentiate into either an oligodendrocyte or a fibrous astrocyte (Raff, Miller and Noble, Nature, in press). When grown in the prescence of fetal calf serum (FCS), the bipotential oligodendrocyte-astrocyte progenitors (OAPs) all expressed Glial Fibrillary Acidic Protein (GFAP) and became fibrous astrocytes; in the absence of FCS all OAPs expressed galactocerobroside and became oligodendrocytes. In these first studies, <u>in vitro</u> differentiation of all OAPs took place in 3 days, with little or no associated cell division.

These findings present several puzzles, for it's known that, both in vivo and in other in vitro systems, oligodendrocyte differentiation takes place over a span of up to several weeks, and is associated with at least limited cell division. We have begun our investigations into regulation of OAP development by examining the effect of purified protoplasmic astrocytes on in vitro development of the OAP. We have found (1)Medium conditioned by astrocytes can maintain the OAP in an undifferentiated state for several days and (2) associated with this lack of differentiation, the OAP now divides in vitro, as judged by <sup>3</sup>H-Thymidine incorporation.

We are currently attempting to characterize the factor(s) produced by astrocytes, and to examine the effects of axons on OAP development. In addition, the ability to maintain the OAP in an undifferentiated state now allows us to investigate the possible existence of positive signals capable of promoting differentiation of the OAP into an oligodendrocyte. 131.3 REACTIVE ASTROGLIOSIS IS A FOCAL PROCESS. P.S. Fishman<sup>\*</sup>, G. Nilaver, and J.P. Kelly (SPON: C. Noback). Dept. of Neurology and VA Res. Serv., Univ. of Maryland Sch. of Med., Balt., Md. 21201 and Depts. of Neurology and Anatomy and Cell Biology, Coll. of P&S, Columbia Univ., N.Y., N.Y. 10032 Reactive astrogliosis, the sequence of changes that occurs in astrocytes after brain trauma, is characterized by the prolicontent of the secuence of the sequence of the secuence active astrogliosis, the sequence of changes that occurs in astrocytes after brain trauma, is characterized by the proliferation of intermediate cytoskeletal filaments and increased immunoreactivity with antibodies against glial fibrillary acidic protein (GFAP). There are two principal hypotheses that have been advanced to explain reactive gliosis. The first states that diffusable substances emanating from the site of injury activate astrocytes nearby eventually leading to an expanding zone of gliosis. The other hypothesis states that for an astrocyte to become reactive, it must be in direct contact with neuronal or myelin debris. We have tested these two conflicting hypotheses directly by examining the pattern of gliosis that appears in the optic chiasm of the mouse after unilateral eye enucleation. Using this model system, we could compare the responses of astrocytes to fascicles of degenerating axons or normal axons lying adjacent to one another. After survival times ranging from three days to two months following enucleation, the animals' brains were processed for immunohistochemistry. Reactive astrocytes were identified in sections by their intense immunoreactivity with anti-GFAP. Nerve fibers undergoing Walleerian degeneration were identified by their pathological appearance and by their enhanced immunoreactivity to anti-neurofilament (NF) antibody (courtesy of Dr. D. Dahl). The distribution of reactive astrocytes was compared to the distribution of degenerating axons within the optic chiasm and optic tract in alternate sections.

Following enucleation, all seven experimental animals showed an increase in anti-GFAP immunoreactivity that peaked at survival intervals of two to three weeks. The regions of increased GFAP immunoreactivity were strictly confined (usually witin 50 um) to corresponding regions of enhanced NF immunoreactivity in all animals examined. Regions containing reactive astrocytes and their processes were quite uniform in outline, so that the borders between anti-GFAP positive and negative regions were remarkably sharp. There was no spread in the distribution of anti-GFAP immunoreactivity with increasing time after enucleation. In summary, reactive astrocytes in the optic chiasm are restricted in distribution to the immediate environment of degenerating axons and myelin, and it appears that intimate contact with degenerating debris is necessary to provoke and maintain reactive astrogliosis. Supported by an Associate Investigator Award from the VA Research Service.

131.5 "PERMISSIVE EFFECTS" IN C GLIOMA CELLS. <u>H. Nakamura\*, P. E. McKeever, B. H. Smith and P. L. Kornblith.</u> Surgical Neurology Branch, NINCDS, National Institutes of Health, Bethesda, MD 20205. Glucocorticoids provide the opportunity for agents which increase cAMP to work more effectively. Since these "permissive effects" of glucocorticoids have been well documented in many tissues other than central nervous system, we wondered whether they occurred in glial cells. For this reason, the modulation of the 1-isoproterenol induction of enzyme, protein and RNA by dexamethasone in C6 glioma cells was studied. Cells pretreated with 10-6M dexamethasone for 24 hours were compared with untreated cells in assays for stimulation by 10<sup>-5</sup>M 1-isoproterenol. While 1-isoproterenol for 24 hours increased lactate hydrogenase (LDH) enzyme activity from 2247 ± 47 units/mg protein (N=3) to 4071 ± 22 units/mg (68%) in non treated cells, LDH increased from 2624 ± 40 units/mg protein to 7185 ± 29/units/mg protein (178%) in dexamethasone pretreated cells.

RNA and protein synthesis were compared at 0, 1, 2, 3, 4, 5, and 6 hr. after adding isoproterenol. Stimulation of <sup>3</sup>H leucine incorporation into protein by isoproterenol was greater (67% peak) and more prolonged (at least 6 hr.) in the dexamethasone pretreated group than in the control group (27% peak and 3 hr. stimulation). Isoproterenol increased <sup>3</sup>H uridine uptake by 107% in the dexamethasone pretreated group but did not increase uridine uptake in the group without dexamethasone. Dexamethasone has a "permissive effect" on induction of LDH in C, glioma cells by isoproterenol. This effect is associated with earlier "permissive effects" on RNA and protein synthesis.

- 131.4 AUTORADIOGRAPHY OF HIGH AFFINITY UPTAKE OF CATECHOLAMINES BY PRIMARY ASTROCYTE CULTURES. <u>D. Semenoff\* and H.K. Kimelberg</u>, Division of Neurosurgery, Albany Medical College, Albany, N.Y.
  - We have previously studied uptake of catecholamines by primary astrocyte cultures prepared from the cerebral hemispheres of 2 astrobyte cultures prepared from the ceneral hemispheres of 2 day old rats (Pelton <u>et al</u>. Life Sci. <u>28</u>:1655, 1981). Uptake of <sup>3</sup>H labelled DL-norepinephrine (<sup>3</sup>HNE) or dopamine (<sup>3</sup>HDA) at around  $10^{-7}$ M was very sensitive to inhibition by tricyclic antidepres-sants or omission of Na<sup>+</sup>. The apparent K<sub>m</sub> for the uptake of <sup>3</sup>HNE was in the range of 2-3 x  $10^{-7}$ M (Kimelberg and Pelton, J. Neurochem. 40:1265, 1983). We have now examined the cellular lo-calization of this uptake using autoradiography. Uptake of 7.5 x Calization of this uptake using autoradiography. Optake of  $75\times10^{-7M}$  3/HNE representing |LC(3/5mm diameter plastic dishes was studied at an external [K<sup>+</sup>]<sub>0</sub> of 4.5mM. The dishes were developed after 1-4 weeks exposure to emulsion. Grain density above background was seen in almost all the cells, both the flat epithelial-looking cells and cells with numerous radiating processes. In previous studies we have shown both types of cells to be glial fibrillary acidic protein (+). In about 20% of the total area the grain density was very intense, and again this high density occurred in both flat and process-bearing cells. Omission of or addition of the antidepressant desmethylimpramine  $(10^{-7}M)$ reduced the grain density of all the cells to that seen for the lowest density in the non-inhibited cultures, or to background levels. Autoradiography after exposure to <sup>3</sup>HDA, in this case at levels. Autoraligraphy after exposure to -num, in this case  $27 \rm mW~(k^+)_0$ , gave essentially the same results. Inhibitors of catechol-0-methyltransferase and monoamine oxidase were always present to prevent metabolism of catecholamines. Omission of either inhibitor, and especially both, markedly lowered grain density after exposure to <sup>3</sup>HDA. Uptake studies using <sup>3</sup>HNE resulted in continually increased uptake of <sup>3</sup>HNE as [Na<sup>+</sup>]<sub>0</sub> was increased from 0 to 140mM. Increasing  $[K^+]_0$  up to 40mM did not seem to inhibit <sup>3</sup>HNE uptake. The presence of either the  $\alpha$ - and  $\beta$ -receptor antagonists phentolamine or propranolol  $(10^{-5}M)$  did not inhibit Na<sup>+</sup>-dependent uptake indicating that we are measuring uptake and not receptor binding. These results further confirm that astrocytes in primary cultures contain a high affinity up-take system for catecholamines. The autoradiographic studies also show that astrocytes prepared from whole cerebral hemispheres show differences in uptake intensity suggesting some functional heterogeneity that may depend on the region of origin within the cerebral hemisphore, even at a relatively early age. (Supported by NIH grant NS 19492 from NINCDS to H.K.K.).

131.6 VERATRIDINE CAUSES ASTROCYTES IN PRIMARY CULTURE TO BECOME EXCITABLE. C.L. Bowman\*, C. Edwards and H.K. Kimelberg (SPON. P.A. Hanson), Neurobiology Research Center, SUNY-Albany and Albany Medical College, Albany, N.Y.

P.A. Religing, Neuropology Research center, our initial and Albany Medical College, Albany, N.Y. Astrocytes in primary culture have large negative resting membraine potentials ( $-64 \pm 10$  mV, n = 32 cells) which are predominantly K<sup>+</sup> diffusion potentials. 90% of the cells stain for glial fibrillary acidic protein . The cells are electrically silent since their current-voltage curves are approximately linear (Kimelberg et al. Neurosci. Abst. 8:238, 1982). Veratridine, or the combination of veratridine and  $\alpha$ -scorpion toxin (II) causes either a series of transient depolarizations or a single long-lasting depolarization (Bowman et al. Biophysical J. 41:386a, 1983). The depolarizations are sensitive to tetrodotoxin (TTX) (15nM) and to a reduction in the external Na<sup>+</sup> concentration (replacement with Tris, choline or arginne).

We have extended these studies to test if astrocytes become electrically excitable in the presence of veratridine. Using two microelectrodes (one to pass current and one to monitor membrane potential), the membrane of the cells was hyperpolarized to between -90mV and -150mV for at least 10 seconds. In the absence of veratridine the membrane potential returned to its resting value upon cessation of the hyperpolarization current (7 cells). In the presence of veratridine ( $10^{-4}$ M) termination of the hyperplarization produced a transient depolarization more positive than the original resting potential (amplitude 2 to 200W), lasting 5 to 15 sec., n = 7 cells). The amplitude of this transient depolarization was reduced but not completely eliminated by TTX (60nM) (4 cells). This effect of veratridine was reversible upon washout of the drug (7 cells).

These results show that astrocytes in primary cultures, which are normally electrically silent, have a chemically inducible Na<sup>+</sup> channel and voltage-sensitive gate.

Na<sup>+</sup> channel and voltage-sensitive gate. We thank Dr. G. Strichartz for helpful discussions. (Supported by NIH grant NS07681 to C.E. and by NSF grant BNS 8213873 to H.K.K.).

NOREPINEPHRINE INDUCED DEPOLARIZATION OF ASTROCYTES IN PRIMARY 131.7 CULTURE. H.K. Kimelberg, C.L. Bowman\*, H. Hirata, C. Edwards, R. S. Bourke and N.T. Slater\*. Div. of Neurosurgery, Albany Medical College; Neurobiology Research Center, SUNY-Albany and Center for Laboratories and Research, NYS Dept. of Health, Albany, N.Y.

Laboratories and Research, NYS Dept. of Health, Albany, N.Y. Astrocytes in primary monolayer cultures from the cerebral hemispheres of 2 day old rat pups have large negative membrane potentials which are predominantly K<sup>+</sup> diffusion potentials (Kimel-berg <u>et al.</u> Soc. Neurosci. Abst. <u>8</u>:238, 1982). Previous biochemi-cal studies of these cells have demonstrated the presence of both  $\alpha$ - and  $\beta$ -adrenergic receptors<sup>1</sup>,<sup>2</sup>. We have recorded from these cells using conventional intracellular techniques. Norepinephrine (NE) and the  $\alpha$ -agonist phenylephrine were applied either in the bath or by ionophoresis. Both agonists evoked depolarizing rebath or by ionophoresis. Both agonists evoked depolarizing responses in these cells. These responses were reversibly antagonized by the  $\alpha$ -antagonist phentolamine, but not by the  $\beta$ -antagonist propranolol. Repeated applications of NE by ionophoresis often resulted in a decline in the amplitude of the depolarization, suggestive of desensitization.

In an effort to determine the ionic dependence of this re In an erfort to determine the ionic dependence of this re-sponse, we have also examined the effect of ionic substitution on the amplitude of the response to bath-applied NE. In this series of studies bath application of NE  $(10^{-5})$  caused a depolarization in 17 out of 18 cells tested. The amplitudes of the depolariza-tions ranged from 4 to 30mV. Replacement of external Cl<sup>-</sup> with methanesulfonate appeared to have no effect on the NE response (1 cell), while reduction of external Na<sup>+</sup> (replaced with argin-ica) reduced but did not completely aliminate the NE response (1 cell), while reduction of external Na<sup>+</sup> (replaced with argin-ine) reduced, but did not completely eliminate, the NE response in 4 out of 7 cells tested. We have also studied the effects of long-term ( $^{-}$  10 min.) application of NE. Following the initial depolarization, there was a slow repolarization in the continued presence of NE (10 cells). The rate of repolarization ranged from 0.8 to 1.6mV/min and this rate appears to be reversibly re-duced by ouabain (0.5mM; 2 cells). However, whether this ouabainsensitive repolarization represents desensitization of the depol-arizing response, or the appearance of a slower hyperpolarizing response remains to be determined. These results demonstrate That NE evokes depolarization of astrocytes in primary culture through activation of an  $\alpha$ -adrenergic receptor. Further studies are required to determine the precise ionic basis of this response and the  $\alpha$ -receptor subtype involved. (Supported by NIH grant NS19492 and NSF grant BNS 8213873 to H.K.K. and by NIH grant NS0681 to C.E.).

CYCLIC AMP STIMULATION OF CYTOSKELETAL PROTEIN PHOSPHORYLATION AND MORPHOLOGIC ALTERATION IN INTACT CULTURED RAT ASTROCYTES. Edward T. Browning, Monica Ruina\*, and Beverly Poelstra\*, Dept. of Pharmacol., Rutgers Medical School, Piscataway, NJ 08854. Past studies of cAMP stimulated protein phosphorylation in the C-6 glioma cell line showed an increased cytoskeletal intermediate filament protein (GFA and vimentin) phosphorylation following treatment of the cultures for 5' with nor-epinephrine. Present studies with primary cultures of rat astrocytes examined the relationship between cyclic AMP content, protein phosphorylation and changes in cellular morphology following exposure of the cultures to forskolin, an activator of adenylate cyclase. Cultures were prepared from neonatal rat cerebrum and were grown in Eagles medium plus 15% fetal bovine serum. Forskolin (20 uM) produced a 250-fold increase in the cAMP in 10'; the elevation was largely maintained over 120' of treatment. Following forskolin treatment, the <sup>32</sup>P-content of GFA was increased 4-, 12- and 3-fold after 5', 30' and 120', respectively. Prior to forskolin treatment, the astrocytes were irregularly shaped and highly spread on the growth surface. Following addition of forskolin the cells retracted their cytoplasm toward the nucleus forming several well defined narrow processes. The initiation of cytoplasmic retraction was evident by phase contrast microscopy within 10 min of forskolin treatment. Therefore the period of active cytoplasmic retraction was evident by phase contrast microscopy within 10 min of forskolin treatment. Therefore the period of active cytoplasmic retraction correlated in time with the period of greatest intermediate filament protein phosphorylation. (Supported by NSF Grant BNS 81-10564.)

REACTIVE RESPONSES OF ASTROCYTES IN CULTURE TO EPILEPTOGENIC 131.8 AGENTS. E. Tiffany-Castiglioni\* and A.J. Castiglioni. Depts. o Veterinary Anatomy and Biology. Texas A&M University, College Station, TX 77843. . of

Station, TX 77843. Gliotic scar formation is a prominent characteristic of human epilepsy and is associated with subchronic or chronic models of focal epilepsy induced in animals by alumina, iron or cobalt. Reactive astrocytes form a glial scar by hypertrophy and accumu-lation of densely packed glial filaments. Although cortical gliosis accompanies pathological conditions other than epilepsy, its almost invariable presence in chronic focal epilepsy has Its almost invariable presence in chronic focal epilepsy has prompted several investigators to propose a physiological role for glia in the epileptic process. Moreover, other workers have described metabolically "activated" cortical astrocytes in the anatomical region of epileptic foci, both in humans and animal models, which are not present in gliotic scars unrelated to epilepsy. The cells have elevated levels of glutamate dehydro-genase. In cobalt-induced foci in the rat, activated astrocytes appear to be a subset of morphologically activity to the subset of the subs genase, glucose-6-phosphate dehydrogenase, and lactate dehydro-genase. In cobalt-induced foci in the rat, activated astrocytes appear to be a subset of morphologically reactive astrocytes. Since neurons and glia interact intimately on molecular and cellular levels, a deficiency of one cell type may affect the other. Thus primary damage to astrocytes could result in secon-dary lesions to the neurons. A cell culture system was used in the present study to observe primary effects of epileptogenic agents on astroglia. Objectives were: (1) to establish cultures of astroglial cells from 1-3 d old rat cortex that resemble normal, non-reactive protoplasmic astrocytes morphologically and histoenzymatically and (2) to induce cells to become reactive in response to exposure to alumina or ferrous chloride. Results will be discussed.

Supported by the Epilepsy Foundation of America and Texas A&M University grant ORR-6-83.

131.10 PC12 CELLS ARE MITOGENIC FOR RAT SCHWANN CELLS. N. Ratner, R. Bunge and L. Glaser. (SPON: F. Mithen). Departments of & Neurobiology and Biochemistry, Washington University Anatomy Sch. Med., St. Louis, MO. Previous studies from this laboratory have shown that normal

rat Schwann cells derived from primary cultures of dorsal root ganglia are stimulated to proliferate by neurites in culture (Wood, Brain Res. 115:361, 1976), that the neurite-derived mitogen is a trypsin and heat-sensitive factor on the neurite surface (Salzer et al., J. Cell Biol. 84:753, 1980) and that contact between neurite and Schwann cell is required for its action. We have now shown that the pheochromocytoma cell line (PCl2) can also stimulate Schwann cell division, as assayed by autoradiography of co-cultures of Schwann cells and PCl2 cells accoraciography of co-cultures of Schwann cells and PCI2 cells in the presence of NGF. Under these conditions PCI2 cells extend neurites and Schwann cells in contact with these neurites can be demonstrated to incorporate  ${}^3\text{H-thymidine}$ . Schwann cell cultures to which crude PCI2 membranes 60-75 kg/0.6 cm<sup>2</sup> (60-75 µg/0.25 ml) have been added show a labelling index (LI)\* of 5%; in control cultures the LI is 0.5-0.9%.

Partial purification of the PC12 cell derived mitogen has been accomplished by sucrose gradient centrifugation of a crude PC12 membrane preparations followed by 0.2 M Na<sub>2</sub>Co<sub>3</sub> extraction (pH 10-11) of gradient purified membranes. 75% of total membrane protein is extracted by  $Na_2CO_3$  treatment; the 25% residue at a concentration of 20 µg/0.6 cm<sup>2</sup> (20 µg/0.25 ml) stimulates Schwann cell division approximately 100-300 X over background. The 22%-30% LI in these cultures is equivalent to the stimulation observed with crude dorsal root ganglion neurite membranes at a concentration of 8  $\mu$ g/0.6 cm<sup>2</sup> (8  $\mu$ g/0.25 ml). The PC12 cell mitogen and the neurite mitogen are similar that both mitogens:

- 1. are inactivated by heating to 60°C for 10'
- are inactivated by incubation with 0.05% trypsin for 20' at  $37^{\circ}C$  (0.2 mg Na<sub>2</sub>CO<sub>3</sub> extracted membranes/ml or 10<sup>7</sup> intact PCl coll(ml) 2. PCl2 cells/ml)
- stimulate the production of intracellular cAMP in Schwann cells 2.5-3.5 fold 16h after addition of membranes, while heat treated membranes are neither mitogenic nor do they elevate cAMP levels

are partially inactivated by freezing overnight at -80°C The mitogens differ in that while both are active in serum-4. free media when co-cultures of neurons and Schwann cells or PC12 cells and Schwann cells are grown, membranes derived from PC12 cells are not mitogenic in serum-free media while membranes derived from neurons retain their mitogenicity under these conditions.

\*LI = % labelled cells/total cells.

ETHANOL EFFECTS ON GLIAL CELL CULTURES: CELL PROLIFERATION AND 131.11

ETHANOL EFFECTS ON GLIAL CELL CULTURES: CELL PROLIFERATION AND GLUTAMINE SYNTHETASE ACTIVITY. <u>D. L. Davies and A. Vernadakis\*</u>. Depts. of Pharmacology and Psychiatry, Univ. of Colo. School of Medicine, Denver, CO 80262. Numerically glial cells constitute the major cell type of the brain and play key roles in establishing and maintaining the microenvironment of neighboring neurons. As part of an endeavor to assess the extent of glial cell involvement in the pathogenesis of brain damage following ethanol abuse, ethanol was administered to glial-enriched cultures and glutamine synthetase (GS) enzymatic activity was determined. GS activity is a glial cell marker and has been implicated in glutamate/glutamine compartmentation. DNA content of cultures was used as a measure of cell proliferation. Glial-enriched cultures were prepared from day 15 embryonic chick cerebral hemispheres. The nutrient medium was Dulbecco's Modified Eagle Medium (DMEM) fortified with 20% fetal bovine serum. After 15 hr the medium was aspirated and replaced with fresh medium. On culture day 6 ethanol was administered at 4 dose levels (0.1% to 2%, i.e., 22 to 435 mM) in DMEM - 10% fetal bovine serum. Thereafter, control and ethanol-containing media were changed daily until the cultures were harvested on culture day 10. Cell proliferation as assessed by DNA content was lower than for controls in cultures treated with 1% or 2% ethanol; the response was dose dependent. GS activity was measured in the supernatant from cell hongenates centrifuged at 15,000 RPM for 30 min and was expressed as µmoles y-glutamylhydroxamate formed/mg protein/hr. Treatment levels of 1% and 2% ethanol markedly decreased GS activity. With regard to DNA content and GS activity, cultures exposed to 0.5% ethanol were slightly lower than controls, whereas the admothed in a dove impairs cell proliferation. Additionally, since the decrease in GS activity. Alternatively, ethanol may selectively inhibit the proliferation of a subopoulation of cells. Since primary cultures are h

- 131.12 ELEVATED STEROID LEVELS SUPPRESS THE GLIAL RESPONSE TO BRAIN
  - ELEVALED STERIOD LEVELS SUPPRESS THE GLIAR RESPONSE TO BRAIN INJURY IN THE RAT. V. K. Vijayan and C. W. Cotman. Dept. of Hum. Anat., Sch. Med., Univ. Calif., Davis, CA 95616 and Dept. of Psychobiol., Univ. Calif., Irvine, CA 92717. Previous studies have suggested that high levels of circulating glucocorticoid hormones interfere with the clearing of degenera-tion products in the rat hippocampus following an entorhinal locion. It was resculated that these steroid offsets might be

lesion. It was speculated that these steroid effects might be mediated through glial cells by decreasing their number and by

mediated through gital cells by decreasing their number and by suppressing the activation of glial lysosomes. The present study tested these hypotheses by comparing the increases in the number of glial cells and in the activity of glial lysosomal enzymes in response to a unilateral entorhinal lesion in steroid-treated and untreated adult male Sprague-Dawley lesion in steroid-treated and untreated adult male Sprague-Dawley rats. Animals (60-70 days old) were implanted subcutaneously with Alzet osmotic minipumps to deliver 200 µG hydrocortisone per day. Steroid administration started 5 days prior to the lesion and continued until sacrifice of animals on the 7th post-lesion day. Animals were perfused with buffered 4% paraformalde-hyde and frozen sections were prepared from the brains. Glial cell number and density were evaluated from sections stained with cresyl violet. Glial cell induction in the denervated dentate outer molecular layer was expressed as a ratio of the glial cell cresyl violet. Glial cell induction in the denervated dentate outer molecular layer was expressed as a ratio of the glial cell density on the ipsilateral/the contralateral side. Acid phospha-tase was stained histochemically by the method of Gomori. B-glucuronidase was examined by the method of Hayashi <u>et al</u>. In untreated animals (N=5), the glial cell density ratio was 2.34, indicating a substantial increase in the number of glial cells in the denervated zone in agreement with previous results. Treated animals (N=7), compared to the untreated, exhibited 33% reduction (P < 0.001) in the glial cell density ratio. In untreated animals, entorhinal lesion caused an enhancement in the staining of both lysosomal enzymes in the denervated zone. Steroid treat-ment reduced this enhancement. Computer-assisted quantitative cytophotometric measurements of individual, radomly sampled glial cells suggested that the reduction occurred, at least in part, due to a reduced enzyme staining intensity per cell.

cells suggested that the reduction occurred, at least in part, due to a reduced enzyme staining intensity per cell. We conclude from these results that glucocorticoid hormone treatment for brief periods prior to and following an entorhinal lesion significantly suppresses the increase in glial cell number and the activation of glial lysosomes in the rat hippocampus. It is proposed that in the steroid-treated animal, these effects slow the clearing of degeneration products after injury. Steroid hormones might exert an antagonistic effect on the neuroglial response to brain injury, much like their well-known anti-inflammatory effects on other tissues.

131.13 REACTIVE GLIOSIS OF MÜLLER CELLS IN RESPONSE TO GENETIC AND EXPERIMENTALLY PRODUCED PHOTORECEPTOR DEGENERATION. A.J. Eisenfeld\*, A.H. Bunt-Milam, and P.V. Sarthy. Dept. of Ophthalmology, University of Washington, Seattle, Washington 98195. The Müller cell is the main non-neuronal cell of the retina. It is usually classified as glial, although it does not contain glial fibrillary acidic protein (GFA). This protein is found in astrocytes and increases in brain astrocytes undergoing reactive gliosis. In this study we have demonstrated that the Müller cell expresses this protein in response to photoreceptor cell necrosis using immunofluorescence to localize GFA. In the Royal College of Surgeons (RCS) rat with

photoreceptor cell necrosis using immunofluorescence to localize GFA. In the Royal College of Surgeons (RCS) rat with inherited retinal dystrophy, the photoreceptors begin to degenerate on day 18 and very few photoreceptors remain by day 60. In the normal rat retina at all ages only astrocytes contained GFA. This staining pattern was also found in RCS rats younger than 32 days. Beginning on day 32, a few GFA positive fibers spanned the retina from the inner limiting membrane to the external limiting membrane. By day 41 and at all later ages examined, the radial fibers, as well as the somata, of Müller cells were intensely labelled throughout the retina. To determine if the presence of GFA in Müller cells was a response to photoreceptor necrosis or might be a direct effect of the mutant gene, we maintained normal, adult Sprague-Dawley rats in constant light for 5 weeks. This produced photoreceptor degeneration comparable to a 40 day-old RCS rat. The Müller cells in the retinas damaged by constant light were positive for GFA, indicating that Müller cells express GFA reac-tivity in response to experimentally produced phototivity in response to experimentally produced photo-receptor degeneration.

We conclude that Müller cells undergo reactive gliosis in response to both genetic and experi-mentally produced photoreceptor degeneration. Anti-GFA kindly provided by Larry Eng. Supported by USPHS Grants EY-07013, EY-01311, and EY-01730.

131.14 ACTIVITY-DEPENDENT SHRINKAGE OF BRAIN EXTRACELLULAR SPACE IN RAT OPTIC NERVE: A DEVELOPMENTAL STUDY. C.L. Yamate\*, B.R. Ransom, and B.W. Connors (SPON: L. Eng). Dept. of Neurology, Stanford Univ. Sch. of Med., Stanford, CA 94305.

In a previous investigation on the extracellular space (ECS) of the rat optic nerve (Connors et al., <u>Science</u> 216:1341, 1982) we noted activity-dependent shrinkage of the ECS in older animals. the rat optic nerve (Connors et al., <u>Science</u> 216:1341, 1982) we noted activity-dependent shrinkage of the ECS in older animals. We have further characterized this phenomena and report the time course of its appearance in postnatal development. Nerves were dissected free and bathed in physiological saline with [K] of 5 mM. Supramaximal stimuli (with regard to evoked field potentials) were delivered to the nerves at different fre-quencies by suction electrodes. K specific microelectrodes were used to measure [K] or monitor the concentrations of choline or tetramethylamnonium (TMA) when these cations had been added to the bathing solution. In the presence of TMA or choline, the K spe-cific microelectrode does not detect changes in [K] of from 3 to 25 mM. Since cellular membranes are impermeable to choline or TMA increases in the concentration of these ions imply a shrinkage of the volume fraction occupied by the ECS. To determine the devel-opmental sequence of activity-dependent ECS shrinkage optic nerves ranging in age from 1 to 30 days were stimulated using 10 sec. trains of different frequencies. This was done initially in nor-mal solution allowing the evoked increase in [K] to be monitored. The bathing solution was then switched to one containing choline (10 mM) or TMA (5 mM) and the same stimulus trains were repeated. Under these conditions voltage fluctuations in the ion-sensitive microelectrode could be translated into changes in the size of the ECS. The relationship between maximum activity-dependent shrink-are of ECS volume fraction and age was muchy signal scheme have with microelectrode could be translated into changes in the size of the ECS. The relationship between maximum activity-dependent shrinkage of ECS volume fraction and age was roughly sigmoid-shaped with little or no shrinkage evident between 1 to 5 days (av. = 1.8%), moderate shrinkage between 7 to 17 days (av. = 5.7%) and striking shrinkage in nerves older than 24 days (17-30%). The magnitudes of ECS shrinkage and increase in [K<sup>+</sup>], were both directly proportional to stimulus frequency in the older nerves. The time course of activity-dependent ECS shrinkage was similar but slower than the time course of the evoked increase in [K<sup>+</sup>] produced by the same stimulus train. same stimulus train.

same stimulus train. The developmental sequence described above for activity-dependent shrinkage of the ECS coincides roughly with the birth and maturational sequence of glial cells in this structure (Skoff et al., <u>J. Comp. Neur</u>, 169:201, 1976). This coincidence would be consistent with the hypothesis that activity-dependent shrinkage of the ECS depends upon K<sup>-</sup>-induced electrolyte and water transport into glial cells with tissue swelling and reduction of the ECS. Further studies are underway to test this hypothesis. Supported by NIH grants NS15589 and NS00473 from the NINCDS.

- 131.15 LACTATION-ASSOCIATED GLIAL PLASTICITY IN THE SUPRAOPTIC NUCLEUS OF THE RAT. A. K. Salm, K. C. Smithson\* and G. I. Hatton. Neurosci. Prog. and Dept. Psych., Michigan St. Univ., E. Lansing, MI 48824. Electron microscopical studies have shown an absence of astro
  - cytic glial processes from between neurosecretory cells in the supraoptic nucleus (SON) during lactation, a time when an active (Hatton and Tweedle, 1982; Theodosis et al., 1981). We sought to demonstrate changes in the glia within SON which might underlie this apparent morphological plasticity. Therefore, the distribu-tion of the cytoskeletal glial fibrillary acidic protein (GFAP) as visualized by PAP immunocytochemistry, was assessed in tissue from estrous and 10 day lactating rats. Reaction product distribution in the form of a frequency histogram of 256 staining densities was determined by computerized image analysis. All measurements were made in a random order and without knowledge of experimental group membership. A split-plot design statistical analysis of the fea-tures of the frequency histogram, i.e., mean, standard deviation, skewness, and kurtosis was then performed to ascertain effects of hormonal state, location within SON, and interactions of these variables. These analyses revealed that a redistribution of GFAP had occurred in the SON of lactating subjects. Although observed in all parts of the nucleus, the change was far more dramatic in the predominantly oxytocinergic portions of the SON. In addition, the change was to a less dense, more homogeneous distribution of the GFAP, which first, is reflective of a reduction in the high density staining characteristic of that observed in glial process-es, and second, has been previously shown <u>in vitro</u> to be associat-ed with a state of great glial plasticity (Duffy et al., 1982). Identical measurements were taken from the same material in the lateral hypothalamic area. No changes were found to occur in that part of the hypothalamus. These results are important for a num-First, by demonstrating a redistribution of a ber of reasons. glial cytoskeletal protein these data provide direct support for the hypothesis that glia actively retract their processes during lactation. Second, they show that the morphological plasticity often seen in vitro occurs in vivo as well. Third, the stimulus necessary for inducing this phenomenon was a physiological one. This implies the existence of a normal underlying mechanism that somehow goes awry in the aberrations of GFAP which have been observed in neuropathologies. Finally, the homogeneity of staining densities found in tissue from lactating subjects is similar to that observed in "undifferentiated" glia <u>in vitro</u>. The data re-ported here suggest that this morphological form may represent a functional state which an astrocyte might transiently assume in vivo.

131.17 IMMUNOCYTOCHEMISTRY OF MYELIN BASIC PROTEIN IN ADULT OLIGODENDROGLIA. <u>Constancia del Cerro\*</u>, <u>Nancy H. Sternberger\*</u>, <u>Marian W. Kies\*</u><sup>+</sup> and <u>Robert M. Herndon</u> (Spon: William H. Merigan). <u>Center for Brain Research</u>, <u>University of Rochester School of Medicine</u>, Rochester, New York 14642 and Laboratory of Cerebral Metabolism, National Institute of Mental Health, NIH, Bethesda, Maryland 20014<sup>+</sup>.

Myelin basic protein (MBP) has been found immunocytochemically in oligodendroglia of the developing rat and human central nervous system. However, reaction with MBP antiserum was detectable only prior to and during the early phase of myelination. The lack of reaction with still actively myelinating and mature oligodendroglia has been puzzling. We report here that by the use of mild fixation and puzzing. We report nere that by the use of minu fixation and modification of the staining technique previously used for detection of MBP on vibratome sections, staining of oligodendroglia in sections of adult rat brain has been achieved. Stained mature oligodendroglia had very fine, branched processes. Myelin staining was not intense and oligodendroglia could be detected in heavily myelinated tracts. very fine, branched processes. Myelin staining was not intense and oligodendroglia could be detected in heavily myelinated tracts. Oligodendroglial staining was obtained with antisera to myelin, myelin basic protein and carbonic anhydrase. Antiserum to glial fibrillary acidic protein (supplied by Dr. L. Eng) reacted with astrocytic cell bodies and processes in a pattern quite different from the staining seen with antisera to oligodendroglial proteins. Supported in part by NIH grant NS 17652, NS 15283 and a grant from the Multiple Sclerosis Society.

131.16 ISOLATION OF A FRACTION ENRICHED IN OLIGODENDROCYTES PLASMA S Szuchet, PE Polak and SH Yim, Department of MEMBRANE. ology, Pritzker School of Medicine, The University of Chicago, Chicago, Illinois 60637.

A simple procedure was developed using isolated oligodendrocytes as the starting material for the separation of oligodendrocyte plasma membrane. A plasma membrane fraction was obtained that had a 21 fold enrichment in a membrane specific marker, p-nitrophenyl phosphatase (pNPase,  $9.2 \pm 2.2 \text{ nM/min/mgP}$ ) and a 7 fold increase in an oligodendrocyte specific marker,  $2^{\prime}$ , $3^{\prime}$ ,cyclic nucleotide phosphodiesterase (41.5 ± 1.5 µM/min/mgP). The corresponding values for the cell homogenate were:  $0.43 \pm 0.08$  nM/min/mgP and  $6.0 \pm 0.2 \mu$ M/min/mgP, respectively. In addition, nuclear and mitochondrial enriched fractions were also collected. Oligodendrocytes were isolated from ovine brains by our proce-dure (Szuchet et al, J Neuroscience Meth 3:7-19,1980) and maintained in culture for 4 days to allow them to recover from the trauma of isolation. After harvesting, cells were washed free trauma of isolation. After harvesting, cells were washed free of serum, resuspended in disruption medium (20mM Tris, 0.12M NaCl, lmM MnCl<sub>2</sub>, pH 7.4) and broken by passage through a cell disrupter designed by us (Szuchet and Polak, Anal Bioch,128:1983, 453-458). Disrupted cells were collected in disruption medium containing ImM EDTA and centrifuged at 300g for 7 min. The pellet  $(P_1)$  contained mostly nuclei. The supernatant  $(SP_1)$  was applied on a self-generating gradient of 20% percoll in disruption medium + EDTA and centrifuged at 30,000g (av.) for 15 min. Three bands separated on this gradient. They were designated: F1,F2, and F3 in the centrifugal direction. F2 exhibited a 5-7 fold enrichment of pNPase whereas F3 gave a 5-7 fold enrichment in a mitochondrial marker (succinic dehydrogenase), suggesting that these fractions were enriched in plasma membrane and mitochondria, respectively. F2 was washed 3 times with 10mM Tris buffer pH 7.4, centrifuging after each wash. The final pellet was resuspended in 1 ml of 0.25M surrose, cooled to 0°C and 2.7 ml of 0.23% saponin in the same solvent were slowly added, left for 15 min. at 0°C and centrifuged at 200,000g for 2 hours. The resulting pellet was dispersed in 0.85M sucrose, applied on a linear sucrose gradient from 0.9-1.5M and centri-fuged at 200,000g (av.) for 16 hours. Three bands separated on this gradient, the middle band, F2(2), had the highest enrichment of plasma membrane markers (see above). Membrane fractions prepared in this way should prove valuable for charac-terizing oligodendrocyte plasma membrane and its changes over time in culture and for comparative studies with myelin. Supporte by grant from the National Mutliple Sclerosis Soc RG 1223-B3. Supported

MYELIN-ASSOCIATED GLYCOPROTEIN 131.18 THE AND MYELIN-

THE MYELIN-ASSOCIATED GLYCOPROTEIN AND MYELIN-FORMING SCHWANN CELL-AXON INTERACTION IN QUAKING MICE. B.D. Trapp, \* R.H. Quarles\* and K. Suzuki\*. NINCDS, NIH, Bethesda, MD and Dept. Neuropathology, Albert Einstein College of Medicine, Bronx, N.Y. (Sponsor: M. Dubois-Dalcq) The myelin-associated glycoprotein (MAG) is an integral membrane glycoprotein which represents approximately 0.7% of the total PNS myelin proteins. MAG has an apparent molecular weight of 100K and consists of approximately 30% sugar. Immunocytochemically, MAG has been localized in periaxonal membranes of PNS myelin. MAG is not present in compact portions of PNS myelin. In myelinated fibers from normal perimberal perve the Schwann cell periaxonal membrane is normal peripheral nerve, the Schwann cell periaxonal membrane is separated from the axolemma by a 12-14 nm gap or periaxonal space. Based on its periaxonal localization, MAG may play a role in maintaining contact between myelin-forming Schwann cells and axon. The bulk and polarity of MAGs oligosaccharide moieties could account The bulk and polarity of MAG's oligosaccharide moieties could account for this 12-14 nm spacing. In contrast to compact myelin, which does not contain MAG, the cytoplasmic side of the periaxonal membrane does not "fuse" with the cytoplasmic side of the inner myelin lamellae to form a major dense line. The carboxy terminal of MAG may play a role in preventing this fusion. To test these hypotheses, the immunocytochemical localization of MAG was determined in ventral roots from adult quaking mice. These roots display several pathological alterations in Schwann cells and axons including partial and total separation of myelin sheaths from their axon. We compared the immunocytochemical localization of MAG in 1µm thick Epon sections with the ultrastructure in adjacent thin sections. Where the periaxonal with the ultrastructure in adjacent thin sections. Where the periaxonal space is maintained in myelinated quaking fibers, the Schwann cell periaxonal membrane is stained intensely by MAG antiserum. MAG was not detected in periaxonal membranes in regions where this 12-14nm gap is enlarged. The cytoplasmic side of these MAG negative perigap is enlarged. The cytoplasmic side of these MAG negative peri-axonal membranes fused with the cytoplasmic side of the inner compact myelin lamellae to form a major dense line. These results support a axon contact and are consistent with the hypothesis that the carboxy terminal of MAG in maintaining myelin-forming Schwann cell-axon contact and are consistent with the hypothesis that the carboxy terminal of MAG prevents the fusion of the cytoplasmic side of Schwann cell periaxonal membranes with the cytoplasmic side of the inner compact myelin lamellae. (Supported in part by grants MS 10803 and MS 03356 awarded to K.S.).

SULFATIDE: THE REGULATION OF SYNTHESIS AND ITS ROLE IN MYELINOGENESIS, <u>G. I. Tennekoon\* and M. Zaruba\*</u> (SPON: R. T. Johnson). Dept. of Neurology, Johns Hopkins University School of 131.19

Johnson). Dept. of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD 21205. To obtain a better understanding of the assembly of myelin we undertook an investigation of the synthesis of sulfogalactosyl-ceramide (sulfatide) and of factors affecting the regulation of this process. Sulfatide is enriched in myelin and it has been postulated that this acidic lipid interacts with myelin basic protein and aids in the stabilization of the membrane. If this were the case, sulfatide would be expected to be localized at the major dense line of myelin where the basic protein is located.

which the task is build would be expected to be incalled a the major dense line of myelin, where the basic protein is located. Cerebroside sulfotransferase (CST), the enzyme catalyzing the transfer of the "active" sulfate donor 3'-phosphoadenosine 5'-phosphosulfate to the acceptor lipid galactosyl ceremide, has been localized to the Golgi apparatus and co-migrates with thiamine pyrophosphatase indicating that these two enzymes are localized to the trans-Golgi. Within the trans-Golgi, CST appears to have a luminal localization, as judged by resistance to pro-tease digestion and the fact that galactosylsphingosine covalently linked to agarose is not sulfated unless detergents are added. Our date would indicate that sulfatide was not localized to the Our date would indicate that suitatide was not localized to the cytoplasmic side but was localized to the outer half of the lipid bilayer. Moreover, the "active" sulfate donor (PAPS) is synthe-sized in the cytosol and we shall present evidence that this compound is transported into the Golgi lumen via a "carrier" mechanism. The net synthesis of sulfatide is controlled by the activity of CST and by the degradive enzyme cerebroside sulfatase. We showed that neither PAPS, its transporter, nor galactosylcera-mide played a role in regulating sulfatide accumulation. This work was supported by the Multiple Sclerosis Society Grant

- EFFECTS OF DICYCLOHEXYLCARBODIIMIDE ON THE STRUCTURE OF THE 131.20 Lees and V.S
  - MYELIN PROTECLIPID. E. Ling\*, T. Rounds\*, M.B. Lees and V Sapirstein\* Depts. of Biochem., E.K. Shriver Ctr., Waltha 02254 and Biol. Chem., Harvard Med. Sch. Boston, MA 02115. Waltham, MA The myelin proteolipid has been shown to interact covalently with dicyclohexylcarbodiimide (DCCD) when incubations are carried out either with whole myelin or the isolated proteolipid; reconstitution of the proteolipid in liposomes stimulates proton flux which is inhibited by DCCD (PNAS 79:941, 1982). We report here the effects of DCCD on the secondary and tertiary structure of this protein using circular dichroism (CD) and fluorescence energy transfer. Our data indicate that aqueous solutions of the apoprotein prepared by delipidation on Solutions of the approximation propared by derivitation of Sephadex LH-60 gives a CD spectrum consistent with a structure of  $51\% \leq \text{Melix}_{25\%} \neq \text{Melix}_{25\%} = 12\% \leq 12\%$  and 24% random coil. After incubation with with a 20 fold molar excess of DCCD for 30 minutes the helical content was reduced to 17% with a corresponding increase in random coil. However, if the proteolipid is first incorporated into asolectin liposomes, under conditions allowing for DCCD inhibitable proton flux, DCCD exerted no significant effect on the structure of the protein. Thus, the presence of lipid appears to supply sufficient constraints to retain secondary structure. Although the protein contains 4 tryptophan (Trp) residues, analysis of the Trp fluorescence in water revealed one emission peak with a maxima at 340 nm suggesting all Trp residues were in a hydrophobic environment. Addition of anilino napthol sulfonate (ANS) reduced the Trp fluorescence due to energy transfer yielding an ANS emission peak at 460 nm. By following the emission at 460 nm with serial additions of ANS a binding curve was established. The existence of two binding sites was suggested; there was one high affinity site and one low affinity site per molecule of proteolipid. Since DCCD binds to ANS, the effect of DCCD was studied after scavenging the excess DCCD with acetic acid and the protein dialyzed against water prior to fluorescence studies. Control preparations were similarly treated. Incubation with DCCD did not change the shape of the ANS titration curves but did markedly reduce the degree of energy transfer to both the high and low affinity sites. Because the energy transfer depends upon the distance between the ANS binding site and the Trp residues, these results suggest that a significant structural change had occurred after treatment with DCCD. Thus, both CD and fluorescence studies suggest that DCCD can promote structural changes in the myelin proteolipid, presumably through breaking ionic linkages resulting from the reaction of DCCD with aspartic and/or glutamic side chains. These changes would appear to be minimized when the protein is incorporated into a lipid bilayer. (Supported by NS16186, NS13649 and HD 05515)

## SYMPOSIUM AND WORKSHOP

TUESDAY PM

132 SYMPOSIUM: DEVELOPMENTAL STRATEGIES FOR SELECTIVE SYNAPSE FORMA-TION. E. Frank, Northwestern Univ., Evanston (Chairman); J.T. Schmidt, SUNY, Albany; M.P. Stryker, UC Med Sch, San Francisco; D.E. VanEssen, Calif Inst Tech, Pasadena. D. VanEssen will discuss the maturation of neuromuscular con-

nections in mammalian muscle. At birth, when polyneuronal inner-vation of muscle fibers is extensive, fast and slow motoneurons innervate largely separate populations of muscle fibers, suggesting considerable selectivity in initial formation of connections. The elimination of synapses appears to occur in two stages. During the first two postnatal weeks most polyneuronal innervation disappears. Over the next several weeks there is a substantial reor-ganization of connections. The competitive basis of synapse elim-ination will be discussed, including its relationship to neural activity and to motor unit size, spinal postion and fast versus slow muscle type.

J. Schmidt has studied the regeneration of optic axons in goldfish. These axons initially produce diffuse arbors over wide regions of tectum, then concentrate them to produce an orderly reti-notopic map recorded electrophysiologically. Correlated activity between neighboring ganglion cells is implicated in the sharpening mechanisms. Binocular projections to dually innervated tecta initially overlap, then segregate into ocular dominance patches. Binocular blockade with TTX reversibly prevents the segregation. These results can be interpreted in terms of correlated firing of neighbors within an eye versus lack of correlation between eyes. Synchronous firing may increase synaptic effectiveness (summation

of EPSPs) and thereby lead to selective synaptic effectiveness (summation M. Stryker will discuss the role of impulse activity in the pro-gressive, eye-specific segregation of geniculate afferents to the developing visual cortex of the cat. Equal vision in the two eyes during the segregation process is necessary for their afferents to partition the terminal space equally. Recent findings are consistent with the notion that information in the pattern of spontane-ous retinal impulse activity may be used in the formation of cen-tral connections: blockade of optic nerve activity prevents the segregation process; while asynchronous electrical stimulation of the two optic nerves reverses the physiological effects of the blockade.

E. Frank has studied the development of the monosynaptic stretch reflex in the spinal cord. The synaptic connections between sensory and motor neurons begin to form after these cells have contacted their peripheral targets. The synapses are highly specific from the beginning; there is no stage at which appreciable numbers of inappropriate connections are seen. Topography cannot play a key role in determining this specificity because the dendrites of appropriate and inappropriate motoneurons are intermingled with each other. Local interactions may underlie the selectivity.

HETEROGENEITY OF NEUROTANSMITTER AND DRUG RECEPTORS. 133 Henry I. Yamamura, University of Arizona, Tucson, Arizona, Solomon H. Snyder, Johns Hopkins University, Baltimore, Maryland, <u>Gavril W. Pasternak</u>, Memorial Sloan-Kettering, New York, New York, David L. Nelson, University of Arizona, Tucson, Arizona, <u>Ian Creese</u>, University of California, San Diego, California, and <u>Arnold S. Lippa</u>, Lederle Labs, Pearl River, New York. <u>In the last decade</u>, great advances have been made in the

In the last decade, great advances have been made in the understanding of neurotransmitter and drug receptors by the direct labeling of recognition sites by the use of high specific activity radioligands. Initial studies provided the identificaactivity radioligands. Initial studies provided the identifica-tion and characterization of receptor binding sites however, more recent studies have shown complexity in receptor binding. Receptor heterogeneity appears to exist for every neurotransmitter or drug receptor. This workshop will focus on several important neurotransmitter and drug receptors and will provide an up-to-det information or theapen different intransport form of date information on whether different interconvertible forms of a single receptor exists or if different molecular forms of the receptor exists.
IDENTIFICATION AND ELECTROPHYSIOLOGY OF THE PEPTIDERGIC 134.1 NEUROSECRETORY CELLS THAT CONTAIN ECLOSION HORMONE IN MANDUCA

NEUROSECRETORY CELLS THAT CONTAIN ECLOSION HORMONE IN <u>MANDUCA</u> <u>SEXTA. P. F. Copenhaver and J. W. Truman</u>. Dept. Zoology, Univ. of Washington, Seattle, WA 98195. Adult development in the moth <u>Manduca sexta</u> culminates in the pulsatile release of eclosion hormone, an 8500 dalton peptide, which triggers adult emergence and activates the adult repertoire of behaviors (Truman JW. J.exp.Biol.54, 805, 1971). During metamorphosis, eclosion hormone is transported from the brain to its accordant accurates. When a transport of the brain to its associated neurohemal organ (the corpora cardiaca) where it accumulates. The timing of its release is governed by the combined action of ecdysteroid titers and circadian input (Truman JW. <u>Am. Zool</u>, <u>21</u>,655,1981). To examine the nature of these controlling mechanisms on a cellular level, it was necessary to

identify the neurosecretory cells producing eclosion hormone. Backfilling the nerves that run from the adult brain to the corpora cardiaca with cobalt chloride revealed discrete pools of corpora cardiaca with conait chloride revealed discrete pools of neurons in the medial and lateral regions of the protocerebrum and a small cluster in the tritocerebrum. Subdissection of these regions and microdissection of individual cell groups localized the cells containing biological activity to the lateral cluster of protocerebral neurosecretory cells. Intracellular recording from the somata of these cells revealed broad (20-40 msec) action potentials that could be repeatedly elicited by current injection over the course of many hours. Intracellular iontophoresis of dye confirmed the axon trajectories determined by backfilling, and revealed a distinctive pattern of neurite arborization that is superficial to the major neuropilar regions of the brain.

A minimally dissected preparation of the pharate adult moth has been developed which exposes the brain-retrocerebral complex in a restrained animal while leaving most of the tracheation and innervation intact. By sequentially assaying the dissection bath for biological activity, we found that eclosion hormone was released at a developmentally appropriate time and that this release was followed after about two hours by eclosion behavior. Recording extracellularly from the nerve containing the neurosecretory cells' axons in such preparations revealed a marked increase in electrical activity correlated with the appearence of eclosion hormone-like activity in the surrounding bath. A combination of this viable semi-intact preparation and the long-term intracellular recording described above should per-mit an aluxidation of the collular output modelling the procise mit an elucidation of the cellular events underlying the precise timing of release of this peptide hormone.

DISTRIBUTION AND PROJECTIONS OF CHOLECYSTOKININ (CCK) IMMUNO-134.2 REACTIVE NEURONS IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS (PVN) OF RAT. J.Z. Kiss\*, M.C. Beinfeld\*, T.H. Williams, and M. Palkovits\*. Dept. of Anatomy, Univ. of Iowa, Iowa City, IA 52242; and Neuroendocrine Unit, Lab. Clin. Sci. NIH, Bethesda, MD 20205

CCK-like peptides have been demonstrated in the magnocellular hypothalamo-hypophyseal system by immunocytochemical (IC) and radioimmunoassay (RIA) techniques. CCK has been reported to coexists with oxytocin in some neurons of the PVN and supraoptic nucleus (SON) (Vanderhaegen, J.J. et al., Cell Tiss. Res., 221: 277, 1981) although the exact distribution, morphology and pro-jections of CCK-immunopositive cell bodies remains unclear. The

present study addresses these points using IC and RIA. Analysis of coronal sections from colchicine treated animals revealed that CCK-positive cells form a morphologically heterogenous group, since CCK-immunoreactive cells were found among magnocellular neurons in the PVN and also in substantial numbers in the parvocellular subdivisions. Magnocellular CCK-positive neurons were concentrated mainly in the antero-medial subdivisions, while more caudally they formed a ring around a core of unstained magnocellular neurons. Immunoreactive, typical parvo-cellular neurons predominate in the anterior, medial and, to a lesser degree the lateral parvocellular subdivisions. Efferent projections of the CCK-immunoreactive neurons were

Efferent projections of the CLK-immunoreactive neurons were studied after the following transections: piuitary stalk (ST), median eminence (ME), medial forebrain bundle (MFB), lateral retrochiasmatic area (RCAL); and also after bilateral lesions of the PVN. Since CCK-immunoreactivity of the piuitary and of ME fell 8 days after PVN lesions to 23% and 18% of normal levels fell 8 days after PVN lesions to 23% and 18% of normal levels respectively, we believe that a significant portion of the total CCK-positive cells of the PVN project into the posterior lobe of the pituitary via ME. The RCAL cut, which interrupts both PVN and SON-hypophyseal fibers, resulted in a comparable depletion, indicating that the PVN is the main source of CCK in the ME and hypophysis. Following the ME lesion, there was an accumulation of CCK-immunoreactive material in both magno- and parvocellular cells. Following the ST lesion the accumulation was seen only in magnocellular neurons. Thus magnocellular (presumed oxytocin-CCK) cells send their axons to the pituitary, whereas axons of parvo-cellular neurons most likely terminate in the ME. After the MFB cut, CCK immunoreactivity increased in transected fibers proximal to the knife cut and in a few perikarya in the PVN, indicating that some CCK cells may send descending fibers to the lower brainstem via the MFB.

These studies demonstrate that CCK-immunoreactive neurons in the PVN are a morphologically heterogenous population with efferent projections to ME, neurohypophysis and brainstem.

134.3 CHOLECYSTOKININ CONTAINING AFFERENTS TO THE VENTROMEDIAL HYPO-THALAMIC NUCLEUS IN RAT. L. Zaborszky<sup>1</sup>, M.C. Beinfeld<sup>2\*</sup>, M. Palkovits<sup>3\*</sup> and L. Heimer<sup>1</sup>. Clinical Neuroscience Research Center, University of Virginia, Charlottesville, VA 22908<sup>1</sup>, Dept. Pharmacol., St. Louis Univ. Med. Ctr., St. Louis,  ${\rm MO}^2$  and 1st Dept. Anat., Semmelweis Univ. Med. Sch., Budapest, Hungary

> The ventromedial hypothalamic nucleus (VMN) is involved in a variety of autonomic, neuroendocrine and behavioral functions, and it has been suggested (Morley, Life Sci., 30, 497, 1982) that some of its activities are dependent on the neurotrans mitter CCK, which is present in the nucleus. Since the VMN contains very few CCK-containing cells it is conceivable that the major portion of CCK is located in axon terminals of extrinsic origin. Anterograde degeneration, retrograde tracing of HRP, radioimmunoassay and immunocytochemistry were used to determine the source and topography of CCK fibers to the VMN. The biochemical studies showed that CCK content in the VMN

> decreased dramatically (shan 1.965.13 ng/mg protein, operated: 0.22±0.20) following bilateral transections of the upper brain-stem at the level of the posterior diencephalon ( $\lambda$ =3.5mm according to Konig-Klippel, 1963, Imm lateral to the midline, 2.5mm wide cut), and CK-like immunoreactivity disappeared from the ipsilateral VMN following ipsilateral transection at the same level. In addition, immunoreactive material accumulated in many of cells in the dorsal parabrachial nucleus. The location of these cells corresponded to the location of labeled cells following iontophoretic injections of HRP (20%, Sigma VI) into the core of the VMN. CCK also disappeared from the VMN  $(0.10\pm0.10 \text{ mg/mg})$  following a long parasagittal cut in the lateral part of the medial forebrain bundle (between A6.2-A3.2; 1.8mm lateral to the midline), whereas only about 60% of the CCK disappeared after a shorter parasagittal cut at the lateral edge of the fornix (A5.9-A5.0; 1mm lateral to the midline) These biochemical findings are in agreement with the topography of the ascending degenerating fibers following the above for the ascending degenerating fibers following the above mentioned brainstem transections. The ascending fiber system forms a rather well contained bundle in the dorsolateral part of the medial forebrain bundle and some fibers join the supraoptic decussation. The system fans out at the rostral half of the VMN and reach the nucleus from the lateral side. Transections of the stria terminalis or the medial corticohypo-thalamic tract did not change the CCK level of the VMN.

This work was supported in part by NIH grant R NS1774303.

DO CORTICAL CHOLECYSTOKININ NEURONS HAVE EURONS S. Loughlin, F. Lesne, of Anatomy LONG 134.4

DO CORTICAL CHOLECYSTOKININ NEURONS HAVE LONG PROJECTIONS? K.B.Seroogy, J.H.Fallon, S. Loughlin, F. Leslie, C. Kodama<sup>\*</sup>, N. Canepa<sup>\*</sup>, and Y.Kim<sup>\*</sup>, Dept's. of Anatomy and Pharmacology, University of California, Irvine, CA 92717 Recent studies suggest that cholecystokinin (CCK)- containing neurons are widely distributed throughout neo-and allocortices, as well as in the substantia nigra-ventral tegmental area of the midbrain. Although it is well-known that dorsal and ventral striatal and limbic structures receive a substantia linear from midbrain CCK neurons, it is not clear to what extent substantial input from midbrain CCK neurons, it is not clear to what extent cortical CCK neurons innervate cortical, striatal and limbic structures. Moreover, we have obtained quite paradoxical results in studying other long projections of cortical CCK neurons. In this study we present both the positive and negative results related to long CCK pathways in the forebrain.

Eighty adult female albino rats were used. Seventy animals were used Eighty dout tende dibito rats were used. Severy animals were used for double-labeling experiments and ten were used to plot the distribution of CCK fibers and terminal areas. For double-labeling experiments, animals received .04 - 0.1  $\mu$ l injections of True Blue/Granular Blue or Propidium Iodide into neocortical, allocortical, limbic, striatal or thalamic structures, followed the next day by multiple 0.2 ul injections of 1% colchicine into cortex, midbrain and ventricles, followed the next day by processing for combined CCK immunofluorescence and retrograde fluorescence tracers.

The following results were obtained: (1) When damaged by colchicine, canulae or injections, nearly all major cortical forebrain tracts (corpus callosum, internal capsule, external capsule, fornix, hippocampal commissure, anterior commissure) contained immunoreactive CCK fibers, (2) Only rarely were cortical CCK neurons double-labeled after injection of tracers into cortex, (3) Numerous frontal cortical CCK neurons were double-labeled after injections in thalamic nuclei, and (4) Midbrain CCK neurons were double-labeled after injections into striatum (especially medially), septum, amygdala, olfactory tubercle and frontal cortex.

Of particular interest in this study is a comparison of results 1 and 2, which are contradictory. Since damaged cortical tracts are CCK-positive, but commissural, associational, and corticostriatal CCK neurons are rarely found, either these neurons are refractory to retrograde labeling, or this CCK immunoreactivity is damage-related with most cortical CCK neurons CCK immunoreactivity is damage-related with most cortical CCK neurons being local circuit neurons. Because corticothalamic (result 3) and mesocortical (result 4) CCK pathways were easily demonstrated, the difficulty in double-labeling cortical CCK neurons is probably not due to the fact that they are CCK-containing, or that CCK-containing terminals in cortex cannot take up retrograde tracers. Perhaps cortical CCK neurons are primarily local circuit neurons with only minor commissural, associational and striatal projections. One possibility is that the minor collatored cannot take up neurons due to be visualized in the collaterals cannot take up enough retrograde label to be visualized in the cell body. Alternately, CCK immunoreactivity in damaged axons may be a temporary axonal response to trauma. (Supported by NIH Grants NS 15321 and 16017.

LOCALIZATION OF CHOLECYSTOKININ, SOMATOSTATIN AND VASOACTIVE 134.5 INTESTINAL POLYPEPTIDE IMUNORPACTIVITY IN RAT HIPPOCAMPUS AND AREA DENTATA. R.S. Sloviter, G. Nilaver and E.A. Zimmerman. Neurology Ctr., Helen Hayes Hospital, W. Haverstraw, N.Y. 10993 and Depts. of Pharmacology and Neurology, College of Physicians and Surgeons, Columbia University, New York, N.Y. 10032.

Recent studies have shown that cholecystokinin (CCK), somatostatin (ST) and vasoactive intestinal polypeptide (VIP) antigenicity is present in neurons of the rat hippocampal formation. The present study was undertaken to determine the precise hippocampal location of this antigenicity. Alternate precise hippocampal location of this antigenicity. Alternate 100u-thick vibratome sections of brains from aldehyde-perfused male Sprague-Dawley rats were incubated in primary rabbit antisera to CCK, ST or VIP, then in biotinylated protein A, then avidin/biotin complex followed by reaction with DAB. Staining with CCK antibody revealed the presence of antigen in scattered interneurons of all hippocampal subfields. In CA1, CCK-positive somata were present in st. radiatum with fewer compata in st. purpridele and st. CCK-positive somata were present in st. radiatum with fewer somata in st. pyramidale and st. oriens. In area dentata, CCK-positive somata were primarily those of the pyramidal-shaped "basket" cells of the granule cell layer. A small number of multipolar hilar cells near the granule cell layer were also CCK-positive. In both the granule and pyramidal cell layers, CCK-positive fibers formed a dense axo-somatic plexus thought to originate from the basket cells of each layer. In the bioregraphy and the source read in the provenue in the source of the source o the hippocampus, VIP staining was seen in interneurons in st. pyramidale and st. radiatum with fewer somata in st. oriens. VIP-positive axons were seen to ramify throughout the strata of the hipocampus but particularly in the pyramidal layer. In area dentata, VIP staining was restricted to scattered interneurons in the molecular, granular and hilar regions. Very few VIP-positive cells had the morphological characteristics of the dentate basket cells stained by CCK antibody. The VIP-positive cells gave rise to axonal plexuess in the molecular and granule cell layers but also throughout the hilus. The pattern of ST-like antigenicity was very different from that of CCK and that of VIP. In CAl, different from that of CCK and that of VIP. In CA1, ST-positive somata were mainly in st. oriens with few in st. pyramidale and few or none in st. radiatum. In CA3, ST-positive somata were present in all strata. In area dentata, most cells of the hilus were ST-positive but few, if any, pyramidal-shaped basket cells of the granule cell layer were ST-positive. Little ST-like antigenicity was seen in the dentate granular or molecular layers. These results suggest that CCK, VIP and ST are localized in distinctly different populations of interneurons in the area dentate and himpergrame. oppulations of interneurons in the area dentata and hippocampus of the rat and are probably not present in the granule or pyramidal cells of this region.

134.7

PEPTIDE INTERACTIONS OF CELLS PROJECTING TO THE CENTRAL NUCLEUS OF THE AMYGDALA. Christine H. Block, Gloria E. Hoffman, Bruce S. Kapp. Dept. of Anatomy, University of Rochester, NY 14642 and Dept. of Psychology, University of Vermont, Burlington, VT 05405. It is established that the central nucleus of the amygdala (CNA) is involved in autonomic-cardiovascular function and that it receives projections from the parabrachial nuclei (PBN) and paraventricular thalamus (PVT), two areas which, based upon afferent connections from the nucleus of the solitary tract, may also function in autonomic-cardiovascular regulation. Since CNA, PBN and PVT all contain high concentrations of a variety of neuropeptides, in the present study we sought to determine the anatomical relationships of these neuropeptides with these potential autonomic-cardiovascular related projection systems to the CNA. Twenty to 50 nanoliters of a 5% suspension of true blue was injected into the CNA of adult male rats. After a 10 day survival period, a group of the animals was treated with colchicine admin-istered intracerebroventricularly and allowed to survive an additional 24-48 hours. All of the animals were perfused transcardially with

24-48 hours. All of the animals were perfused transcardially with saline and Zamboni's fixative. The brains were cut at 30 µm on a vibrating microtome and the tissue was processed for immunocytochemistry. The tissue sections were incubated overnight (VIP), somatostatin (SS) or cholecystokini occapited Overlagit valable (CCK), methionine enkephalin (mE), vasoactive intestinal polypeptide (VIP), somatostatin (SS) or cholecystokinin occapeptide (CCK). The unlabeled antibody enzyme or immunofluorescence technique was employed.

Retrogradely labeled neurons were located in the PBN and PVT following microinjection of true blue into the CNA. In animals that were not treated with colchicine, retrogradely labeled perikarya in the PBN were observed to be in contact or close apposition with NT, CCK SP, VIP or mE immunoreactive fibers. Similarly, true blue labeled neurons in PVT were surrounded and apparently contacted by fibers containing SP, mE, SS.

In the animals treated with colchicine, a small population of NT and SP immunoreactive cells of the PBN were also labeled with true

blue. There were no immunoreactive cells in PVT that were double-labeled with true blue and neuropeptides. In summary, these data reveal that 1) neurons in the PBN and PVT that project to the CNA appear to receive neuropeptidergic input and 2) some NT and SP-containing PBN neurons project to CNA. Thus, these neutronave which have been implicated in the central of these pathways which have been implicated in the control of autonomic-cardiovascular function are, at least in part, peptidergic.

The hormones oxytocin (OT) and vasopressin (VP) have been demonstrated in different brain regions outside the hypothalamus by radioimmunoassay (RIA) and immunocytochemistry. These projections are said to arise from the paraventricular nucleus (PVN) of the hypothalamus, and have been described to be mainly VP-ergic in rostral brain areas, with OT predominating in the more caudal regions. We re-evaluated the relative content of these two peptides in the various extrahypothalamic regions of rat, employing different fixatives and improved immunocytochemical techniques. Long-Evans rat brains perfusion fixed with 1% paraformaldehyde and 0.5% glutaraldehyde containing lysine (0.1M), sodium m-periodate (0.01M) in phosphate buffer were cut at 100 um thick-ness in the coronal and sagittal planes using a Vibratome. ness in the coronal and sagittal planes using a violatome. Sections were immunocytochemically labeled for VP and OT by the pre-embedding method of staining employing biotinylated Protein A in the avidin-biotin-peroxidase (ABC) technique. The raabit anti-sera employed have been previously characterized. Contrary to previous reports, we find more OT than VP-reactive fibers even previous reports, we find more OT- than VP-reactive fibers even in the rostral brain regions, including the cerebral cortex, septum, and entorhinal areas. The OT predominance was particularly evident in the hippocampus. OT fibers were present throughout the septo-temporal axis, in all areas of the hippocampus (stratum oriens, pyramidale, radiatum, and molecular layers). The fibers were particularly numerous in the stratum oriens, with long and varicose densely staining axonal processes showing extensive branching. The OT input to the hippocampus was not organized in a laminar fashion. Relatively few VP fibers could be demonstrated in the hippocampus, despite comparable staining for the two peptides in the hypothalamus. No cell bodies containing either peptide was found in the hippocampus, we cert bours concaring either treatment, suggesting the origin of these fibers outside this brain region. The OT innervation of the hippocampus probably arises from the PVN, since the suprachiasmatic nucleus (the only other source of extrahypothalamic fibers) is exclusively VP-ergic. The precise site of entry and the cells of origin of this hippocampal input however, awaits elucidation. The relative paucity of VP in the hippocampus also needs confirmation by regional RIAs. This demonstration of OT and VP in the hippocampus may form the anatomical basis of their observed electrophysiologic effects on hippocampal neuronal activity, and their effects on memory consolidation. (Supported by NIH Grant HD13147 and a Parkinson's Disease Foundation Grant to Columbia University).

THE MEDIAL PREOPTIC NUCLEUS: PEPTIDERGIC COMPONENTS. Robert E. Watson, Jr., Gloria E. Hoffman and Stanley J. Wiegand, Department of Anatomy, University of Rochester, Rochester, NY 14642. Department of Anatomy, University of Rochester, Rochester, NY 14642. The medial preoptic nucleus (MPN) has recently been shown to exhibit a cytoarchitectonic sexual dimorphism in a number of species, including the rat (Bleier, et al., 1982). Specifically, the MPN, situated immediately posterior to the organum vasculosum of the lamina terminalis (OVLT), is slightly larger and is more densely cellular in the female than in the male. Furthermore, the MPN has been demonstrated to be indispensible for phasic gonadotropin secretion in the female (Wiegand, et al., 1980). Thus, in an effort to begin to characterize this region neurochemically, the present study was conducted in order to identify the peptides localized within the perikarya and fiber components of the MPN. Young adult male and female Sprague-Dawley rats, with or without colchicine pretreatment. were perfused with saline and without colchicine pretreatment, were perfused with saline and Zamboni's fixative and brains were processed for immunocytochemistry Zamboni's fixative and brains were processed for immunocytochemistry using the unlabeled antibody enzyme technique. Sections were subsequently counterstained with 1% methyl green to facilitate identification of the MPN. Of the peptides screened, including substance P (SP), neurotensin (NT), cholecystokinin octapeptide (CCK), LHRH, vasoactive intestinal polypeptide (VIP), met-enkephalin (m-ENK), somatostatin (SRIF), vasopressin (VP), oxytocin (OXY) and ACTH, only NT, SP, and CCK showed evidence of immunoreactivity (ir) within the common of the MPN. NI, SP, and CCK showed evidence of Immunoreactivity (if) within the perikarya of the MPN. Numerous NT-ir cells were evident in the MPN and were clearly more densely packed in this region than in surrounding periventricular regions. In contrast, SP-ir perikarya were widely scattered throughout the MPN, with a relatively dense cell population associated with lateral border regions of the nucleus. Lightly staining CCK-ir cells were only widely scattered throughout the bulk of the MPN, with a more discrete magnocellular population evident at the ventrolateral border region of the nucleus. Many LHRH-ir neurons were present anterior to the MPN near the OVLT, but at the level of the MPN, LHRH-ir cells were situated laterally. Regarding the patterns of fiber labeling, two basic trends emerged. The first consisted of relatively dense peptide-ir associated clearly with the MPN proper. Substances for which this pattern was evident included; 1) SP, in which the fiber-ir was which this pattern was evident included; I) SP, in which the fiber-it was most dense within MPN in the immediate sub-ependymal zone; 2) CCK, in which a fine plexus of ir fibers was continuous with the anterior periventricular nucleus more caudally; and 3) NT, for which the density of ir fibers in the MPN was equivalent or only marginally less than that observed in adjacent regions of the preoptic area. The second group invitience of euclidence for the herein the second group consisted in adjacent regions of the propert and in second group consisted of substances for which there was evidence of only limited fiber-ir within the MPN, and included LHRH, VIP, m-ENK, SRIF, VP, OXY and ACTH. Generally, the density of labeling was greater for these substances in regions adjacent to the MPN. No obvious sex differences in peptide distribution have been detected. DISTRIBUTION OF FMRF-AMIDE IMMUNOREACTIVITY IN THE RAT BRAIN. B.M. Chronwall\*, J.A. Olschowka, T.L. O'Donohue (SPON: R.L. Irwin). Experimental Therapeutics Branch, National Institute of 134.9 <u>Irwin</u>). Experimental Therapeutics Branch, National Institute of Neurological and Communicative Disorders and Stroke, and Labora-tory of Clinical Science, National Institute of Mental Health, National Institutes of Heath, Bethesda, MD 20205 Molluscan cardioexcitatory peptide or FMRF-amide is a tetra-

Molluscan cardioexcitatory peptide or FMRF-amide is a tetra-peptide-amide with the sequence Phe-Met-Arg-Phe-NH<sub>2</sub>. Immuno-reactive (ir) FMRF-amide is present throughout the invertebrate CNS (see Watson et al., Soc. Neurosci. Abst: 1983) and an ir FMRF-amide-like peptide has been demonstrated in mammalian CNS (Weber et al., Science 214:1248, 1981). In this study, FMRF-amide ir was anatomically mapped in the CNS using antisera generated against FMRF-amide conjugated to succinylated thyroglobulin. Twenty um frozen sections from normal or colchicine pretreated rats perfused with phosphate buffer with 0.5% sodium nitrite followed by phosphate buffered 4% formaldehyde (pH 7.4) were processed for indirect immunohistochemistry. Preabsorption with FMRF-amide totally blocks the staining, whereas preabsorption with FMRF free acid, cholecystokinin, bovine pancreatic peptide, metenkephaline proctolin or neuropeptide Y does not block the staining. proctolin or neuropeptide Y does not block the staining. The highest number of FMRF-amide staining cell bodies was found

in the nucleus (n) arcuatus. N paraventricularis, n hypothalamus, In the nonedialis and n dorsomedialis also contained high numbers. Along the third ventricle dendrites of bipolar neurons were oriented in a dorso-ventral direction. In the septal complex a distinct group of bipolar and multipolar immunoreative cells was found in the rostral part of the lateral nucleus. Another prominent group of perikarya was found in the n. tractus solitarii.

FMRF-amide positive nerve fibers and terminals were widely distributed. The septal complex contained high densities especially in n interstitialis striae terminalis. The preoptic area contained moderate to high densities and n suprachiasmaticus showed high numbers of fibers. N paraventricularis hypothalami, n paraventricularis, n hypothalamicus, n ventromedials and n dorso-medialis exhibited a high to very high degree of immunoreactivity. In myelencephalon n tractus solitarii had the densest innervation. Spinal cord had fibers primarily in lamina I and II of the dorsal horn.

The results of these studies demonstrate that a FMRF-amide-like peptide has a widespread distribution throughout the mammalian central nervous system. The particularly high densities of FMRF-amide fibers and perikarya in hypothalamic nuclei, n tractus solitarii and the dorsal horn of the spinal cord suggest roles for FMRF-amide in endocrine and autonomic regulation as well as modulation of pain.

134.10 THE EFFECTS OF LESIONING THE TRIGEMINAL, SUPERIOR CERVICAL SYM-PATHETIC, C2 AND C3 GANGLIA ON SUBSTANCE-P IN CAT CEREBRAL AR-TERIES: <u>T.V. Norregaard %</u> R.C. Weatherwax \* and M.A. Moskowitz (SPON: N.T. Zervas). Depts of Neurosurgery and Neurology, Mas-sachusetts General Hospital, Harvard Med. Sch., Boston, MA 02114

> Using horseradish peroxidase as a neuronal tracer, previous studies have demonstrated trigeminal projections to pial and dural blood vessels (Mayberg, et al, Science '81). Substance P (SP), a vasoactive neuropeptide has been measured by radioimmunoassay (RIA) in pia plus arachnoid where it is primarily located within the walls of blood vessels. Levels of iSP in pial arteries are 20-fold higher than in pia arachnoid devoid of large blood vessels (786.3 +/- 286.9 fmoles/mg protein vs 29.3 +/- 4.7 fmoles/mg protein).

> Studies were undertaken to determine the source(s) of iSP content in cat cerebral arteries. Changes in iSP content were measured by a highly sensitive and specific RIA after surgical excision of the trigeminal ganglia using an extradural approach and microsurgical techniques. Unilateral trigeminal ganglionectomies caused 40-80% decrease in iSP content in the ipsilateral anterior, middle and posterior cerebral arteries compared with levels on the unoperated side. Decreases were most marked in middle cerebral and least marked in anterior most marked in middle cerebral and least marked in anterior cerebral arteries. Unilateral excision of the superior cervical sympathetic ganglia (SCG) did not decrease the iSP levels in these arteries. The combination of unilateral trigeminal ganglionectomy and bilateral SCG removal did not further decrease iSP measured after unilateral trigeminal lesions alone. In preliminary studies, iSP levels decreased in superior cerebellar arteries in 3 of 4 cats following unilateral trigeminal lesions although this decrease did not reach statistical significance at p < 0.05. Decreases in iSP levels were not found in vertebral or anterior inferior cerebellar arteries. In other preliminary experiments, excision of dorsal arteries. In other preliminary experiments, excision of dorsal root ganglia of C2, C3 bilaterally (n=2) did not appear to de-crease the iSP content in the above noted cerebral vessels. These results indicate that 1) cat trigeminal nerves are

> responsible for the majority of iSP in supratentorial cerebral vessels located in pia arachnoid 2) sympathetic projections do not contribute to iSP content in cerebral arteries. The fact that SP is both a potent vasodilator and putative transmitter in parts of the nervous system that participate in the trans-mission of nociceptive information suggests a possible role for this trigeminovascular pathway in the pathogenesis of cerebrovascular pain syndromes.

134.11 EMBRYONIC DEVELOPMENT OF VASOPRESSINERGIC AND OXYTOCINERGIC NEUROSECRETORY CELLS: IMMUNOCYTOCHEMISTRY USING MONOCLONAL ANTI-BODIES TO THE NEUROPHYSINS. M.H. Whitnall, J. Ben-Barak, S. Key, <u>K. Orato and H. Gainer</u>. NICHD, NIH, Bethesda, MD 20205 Previous immunocytochemical (ICC) studies have shown magno-cellular neurosecretory cells in the rat hypothalamus containing neurophysin (NP) or vasopressin (VP) starting at embryonic days 16-17 (E16-E17). However, oxytocin (OT) has not been detected by ICC before birth, despite the fact that RIA studies have detected OT in the brain as early as E20-E21. As a result, des-criptions of the migration and differentiation of OT cells before birth have been lacking. We have recently generated a set of criptions of the migration and differentiation of 01 cells before birth have been lacking. We have recently generated a set of monoclonal antibodies to OT-associated NP (OT-NP) and VP-NP (Ben-Barak,J., et al., submitted) which have enabled us to study the two subsets of neurosecretory cells independently by ICC during embryonic development. The specificities of the anti-bodies were demonstrated in adult rats by ELISA and RIA, immunostaining of SDS and IEF blots, and ICC localization to the appropriate sets of hypothalamic neurons on the light microscopic level and to neurosecretory vesicles in the neurohypophysis by level and to neurosecretory vesicles in the neurohypophysis by postembedding electron microscopic ICC. Embryos and newborn pups (born on E22) from precisely timed pregnant Sprague-Dawley rats were decapitated and their brains fixed by immersion in 4% paraformaldehyde, 0.2% picric acid. 50-µm vibratome sections

rats were decapitated and their brains fixed by immersion in 4% paraformaldehyde, 0.2% picric acid. 50-µm vibratome sections were immunostained using hybridoma conditioned media and affinity-purified goat anti-mouse IgG conjugated to HRP. Neurons containing OT-NP-like immunoreactivity (OT-NP-LI) and VP-NP-LI were located in separate cells with similar distributions in the region of the future supraoptic nucleus (SON). In addition, a few OT-NP-LI cells were located in the region of the future supraoptic nucleus (SON). In addition, a few OT-NP-LI cells were located in the region between the PVN and the SON and presumably included migrating neurons. By E17, many more cells of both types were located in the PVN and SON regions, and in the internuclear area. At this stage, OT-NP-LI and VP-NP-LI cells were already beginning to assume their characteristic, different distributions in the moment of 0T-NP-LI fibers emanating from the nuclei and projecting through the median eminence was a small fraction of the number of VP-NP-LI fibers found in these located in the sequences for NP and VP or OT. We are currently investigating the possibility of a developmental delay between the synthesis of precursors and conversion to NP, VP and OT.

134.12 ONTOGENY OF SOMATOSTATIN (SOM)\* IMMUNOREACTIVE ELEMENTS IN THE RAT SPINAL CORD. R.H. HO. DEPT. OF ANAT., COLL. OF MED., OHIO STATE UNIV., COLUMBUS, OH 43210

OHIO STATE UNIV., COLUMBUS, OH 43210 Prenatal rats of gestational ages E12-22 were immersion fixed while postnatal rats were perfusion fixed by Zamboni's solution and transverse cryostat sections of their spinal cords processed by Sternberger's PAP technique. SOM was first detected in the spinal cord at E13 when it was observed within presumptive perikarya of the basal plate. In addition, at E13 and 14, SOM was demonstrable in dorsal root ganglia neurons and 14, SOM was demonstrable in dorsal root ganglia neurons whose SOM immunoreactive central processes approximated the dorsal lateral surface of the spinal cords. At E14, SOM fibers were first detectable in the ventral funiculi. At E15, SOM elements resembling cell bodies first appeared in the superficial laminae of the dorsal horn while SOM fibers were present in the lateral funiculus. By E16, the gray matter contained widely dispersed SOM perikarya of various shapes and sizes, but few SOM varicosities were present. At E18 SOM fibers were present in the dorsal funiculus. By E20, a moderate density of SOM varicosities became obvious in the superficial lamine of the dorsal function. superficial laminae of the dorsal horn. SOM was widespread in the E22 and neonatal spinal cords being most numerous within the superficial laminae of the dorsal horn. The outer portion of this region contained SOM varicosities whereas the inner portion also contained small perikarya. SOM perikarya of various shapes and sizes were widely dispersed throughout the gray matter ventral to the superficial laminae, with a slightly higher density found in the region ventrolateral to the central canal. A moderate density of SOM fibers was present in the lateral funiculus, whereas only a small number were located in the dorsal and ventral funiculi. Unlike the were located in the dorsal and ventral funiculi. Unlike the case in the prenatal spinal cords, the developmental changes in the postnatal spinal cords proceeded gradually. With increasing ages, immunostained cell body profiles were harder to distinguish. On the contary, the distribution of SOM varicosities in the gray matter increased with age. At or within the first postnatal month, SOM varicosities were further found to be present very sparsely throughout most of the gray matter inter SOM ployue in the the gray matter ventral to the dense SOM plexus in the superficial laminae of the dorsal horn. However, lamina X and superincial maminae of the dorsal horn. However, lamina X and the intermediolateral cell column exhibited a moderate density of SOM varicosities. This distribution of SOM varicosities persisted to the 1 year old spinal cord. (Supported by NIH NS-17080 and in part NIH NS-10165)

\*A substance's immunoreactivity is referred to by its name.

SYNAPTIC EFFICIENCY AND NONLINEAR INTERACTIONS BETWEEN SYNAPSES: 135.1 Koch\* (SPON: European Neuroscience Association) Dept. of Psych.

C.Koch\* (SPON: European meuroscience MIT, Cambridge, MASS 02139 Using 1-dimensional cable theory we studied the synaptic efficiency and nonlinear interactions between an excitatory and a shunting inhibitiory synapse in the dendritic tree of a retinal ganglion cell of the cat (a delta cell from Boycott & Wassle 1974) and compared the results against a very simple model of the dendritic tree, consisting of a single infinite cylinder of

constant diameter. Considering the total charge injected at a synapse, we define as synaptic efficiency C the fraction of this charge actually reaching the soma. For the infinite cable C=exp(-1) where 1 is the electrotonic distance between the position of the synapse and the soma. In the delta-cell which has a profusely branched dendritic tree, C is closely approximated by the infinite cable model.

tree, C is closely approximated by the infinite cable model. To study the nonlinear interaction between synapses using conductance changes as inputs, we introduced F as the ratio of the somatic depolarization due to excitation without inhibition to the somatic potential in the presence of inhibition. It is possible to prove (Koch, Poggio & Torre 1982) that in an arbitrary branched dendritic tree the effect of inhibition is strongest when it is placed on the direct path between excitation and soma. An inhibi-tory synapse behind excitation or situated on a branch off the direct nath will denstically reduce the effect of inhibition on direct path will drastically reduce the effect of inhibition on the somatic depolarization even for extremly high values of the membrane resistance Rm. Taking the limit Rm to infinity in a single infinite cable (i.e. there are no current losses), leads to F-values independent of the distance between both synapses as long as inhibition is placed behind the excitation. If the inhibition is on the path, F is much higher and depends linear on the distance

We conclude, that the synaptic architecture and depends fine of the ors morphology is of vital importance to determine the interaction taking place between different synapses.

- POTENTIATION OF ACETYLCHOLINE RECEPTOR-CHANNEL BLOCK ADE ΒY 135.2
  - ATROPINE AND HALLUCINOGENS AFTER IRREVERSIBLE ACETYLCHOLINES-TERASE INHIBITION WITH ORGANOPHOSPHATE AGENTS. E.G. Henderson, L.S. Reynolds\*, R.L. Volle, S. Moraski Jr.\*, and P.M. Epstein\*. Dept. of Pharmacology, Univ. of Connecticut Health Center, Farmington, CT 06032.

bept. Of Pharmacorogy, onry. Of connecticut nearth center, Farmington, CT 06032. We have previously demonstrated that, in contrast to neostig-mine, echothiophate (217MI) and its tertiary amine analogue (217A0) reduce the voltage dependence of endplate current (e.p.c.) decay ( $\alpha$ ) in frog skeletal muscle (Fed. Proc. 1983, 42:991). In transected frog cutaneous pectoris muscle endplate s, 217MI and 217A0 (1-25 $\mu$ M) caused a greater than 75% decrease of  $\alpha$ at all holding potentials ( $V_m$ 's). After prolonged washing (2 hours) in Ringer solution there was a slight reversal of the slowing of e.p.c. decay and the reduction of voltage dependence of  $\alpha$  by these agents. The addition of atropine (10 $\mu$ M) after this treatment greatly accelerated e.p.c. decay ( $\alpha_0 = \alpha$  at  $V_m = 0 = 0.266$  mscc<sup>-1</sup>, before and 0.652 mscc<sup>-1</sup> after the addition of atropine) and further reduced the voltage dependence of  $\alpha$ . In endplates in which the acetylcholinesterase was active this con-centration had no effect on  $\alpha$  (N. Schmied. Arch. Pharmacol. 1980, 312:117-121). Ketamine (50 $\mu$ M) and phencyclidine (PCP, 25 $\mu$ M) have been shown to increase  $\alpha$  approximately two-fold ( $V_m = -90mV$ , J. 312:117-121). Ketamine (50µM) and phencyclidine (PCP, 25µM) have been shown to increase a approximately two-fold ( $V_m = -90mV$ , J. Pharmacol. Exp. Ther. 1982, 221:570-576). After irreversible esterase inhibition the same concentrations of ketamine and PCP increased a 5.6 times and 5 times, respectively. In both cases the voltage dependence of a was interrupted. However, with ketamine, but not PCP, e.p.c.s were biphasic when  $V_m$  was positive, with the fast phase of e.p.c. decay faster than control and the slow phase slower. In order to determine whether irreversible esterase inhibi-

In order to determine whether irreversible esterase inhibition altered the inhibition of PCP binding by atropine and ketamine to the receptor system, we tested [3H]PCP binding to torpedo microsacs in the presence of  $10_{\mu}M$  carbachol. The IC50 for ketamine was 2 x  $10^{-6}M$  and for atropine was 3 x  $10^{-4}M$  irrespective of whether the esterase was active or inactive. These studies suggest that the increased rate of e.p.c. decay in the presence of these drugs after irreversible esterase inhibition is most likely due to increased frequency of channel opening. The results are consistent with an open channel block of the activated ionic channel by ketamine, PCP and atropine. (Supported by U.S. Army contract DAAG29-81-K-0165.)

135.3 A POSSIBLE COOPERATIVITY BETWEEN SYNAPSES SHARING A COMMON POST-A POSIBLE COUPERATIVITY BETWEEN STRAPSES SHARING A COMMON POSI-SYNAPTIC LOCUS. H. Korr and D.S. Faber, Laboratoire de Neuro-biologie Cellulaire, INSERM U261, Institut Pasteur, Paris, and Div. Neurobiology, SUNY, Buffalo, NY 14214. The teleost Mauthner (M-) cell is subjected to a now classical collateral inhibition brought about by simultaneous impulses in

at least 35 cells, each of which establishes from 6 to 91 morphologically defined synaptic units  $(m=37.7 \pm 29.5, n=12)$  on this target. About 70% of them are found in a restricted region, the so-called axon cap, where they are commonly grouped in clusters of 2 to 6 terminals (Triller, A. and Korn, H., <u>J. Neurophysiol</u>., 48:708, 1982). This arrangement might be related to evidence presented here that postsynaptic potentials due to activation of the full network cannot be accounted for simply by summation of average conductance changes calculated from individual unitary responses. The latter were obtained following intracellular stimulations of single identified presynaptic inhibitory interneurons. We have consistently found that, after iontophoretic application of strychnine in the axon cap (close to the M-cell application of strychnine in the axon cap (close to the M-cell soma), the amplitude of the (depolarizing) collateral IPSP was reduced by 26 ± 18% of its initial value (n=20) whereas mean unitary IPSPs fell by 76 ± 21%. As described earlier (Faber, D.S. and Korn, H., J. Neurophysiol., 48:654, 1982), comparison of these two requires calculations of the underlying conductances,  $g_{ipSp}$ ; this term is given by  $V_{ipSp} \cdot G_m / (E-V_{ipSp})$ , where  $V_{ipSp}$  is required to the underlying conductances. -1psp: \_\_\_\_\_\_\_ipsp'  $_{ipsp}' _{ipsp}' _{ipsp}' _{ipsp}'$ , where  $V_{ipsp}$  is response amplitude,  $G_m$  the resting input conductance, and E the IPSP driving force (which equals twice the collateral IPSP, or  $V_{coll}$  - see ref. above). Solving for any fractional reduction in conductance yields

# $g'_{ipsp}/g_{ipsp} = (V'_{ipsp}/V_{ipsp})(2V_{coll}-V_{ipsp})/(2V_{coll}-V'_{ipsp}),$

where primed terms are for altered values, e.g. following strychnine. Thus, for a unitary conductance decrease of 77%, that of the full collateral response, which would be the same in the absence of any compensation, was only 40.4% in this series. The site of the facilitatory process responsible for this dis-crepancy does not appear to be presynaptic since possible mecha-nisms, such as enhancement of transmitter release by field effects or strychnine, have not been observed with intracellular recordings. On the other hand, a postsynaptic interaction might well account for these data, as well as for the reported obser-vation (Diamond, J., Roper, S. and Yasargil, G.M., <u>J. Physiol</u>., 323:87, 1973) that responses to intophoretically applied glycin (distributed diffusely over adjacent synaptic regions) are more resistant to strychnine than are synaptic inhibitions (due to high concentrations but localized transmitter output).

QUANTAL ANALYSIS OF STRYCHNINE ACTION AT A PRESUMED GLYCINERGIC 135.4 CENTRAL SYNAPSE. D.S. Faber, H. Korn and A. Triller, Div. Neuro-biology, Dept Physiology, SUNY, Buffalo, N.Y. 14214 and INSERM U261, Institut Pasteur, France. Although glycine has been proposed as a putative transmitter at inhibitory synapses onto the teleost Mauthner (M-)cell, this

hypothesis has not been tested directly with activation of indi-vidual presynaptic neurons. Support for this postulate has now been obtained from the effects of strychnine on i) unitary inhibitory postsynaptic potentials (IPSPs) following impulses in identi-fied causal interneurons and ii) binomial release parameters, n, p and q. The latter, i.e. the quantal size, is consistently reduced, as expected for a postsynaptic receptor antagonism. Two experimen-tal approaches were employed, both involving simultaneous pre- and postsynaptic intracellular recordings, with presynaptic stimula-ting rates of no more than 2 Hz, and a binomial analysis of the response fluctuations according to methods described previously (Korn, H., Triller, A., Mallet, A. and Faber, D.S., <u>Science</u>, <u>213</u>: 898, 1981). In the first series ( $n_{2}30$ ), control data was obtained prior to applying strychnine iontophoretically from a third micro-electrode located extracellularly near the M-cell soma. Unitary IPSPs were abolished in about half the cases and were reduced to  $36.5^{+}14.4\%$  of their initial amplitudes in another 15 cells. In 6 of the latter where individual responses were large enough to detect reliably, binomial statistics showed that the major effect was on q, which dropped to  $61^{-4}$ % of the controls. In contrast, n (the number of available units) remained constant, and p (the pro-bability of release) was also unaffected, with the exception of two cases where it was reduced by about 30%. Furthermore, the ki-netic parameters of unitary IPSPs were unchanged, which is quite different from the effects of competitive blockers at other juncdifferent from the effects of competitive blockers at other junc-tions. In the second set (n=7) of experiments (in which strychnine was administered intramuscularly) each interneuron was injected with HRP and reconstructed (see ref. above) to determine if, as predicted, the binomial n still equalled the number of presynaptic boutons. Such was the case, for a range of 4 to 31 stained termi-nals (bin n/hist n=1.04 $\pm$ 0.14). Values of p and q were consistent with those above. The specific effect of strychnine on quantal si-ze rather than on the exclusively release parameters n and p is inconsistent with the proposal that this drug acts mostly at a inconsistent with the proposal that this drug acts mostly at a presynaptic level (Diamond et al., <u>J. Physiol.</u>, <u>232</u>: 87, 1973). These data not only i) strengthen the notion that glycine is an inhibitory transmitter at the supraspinal level and ii) extend the validity of the binomial model to situations of reduced postsynaptic receptor density but also provide a means for pharmacolo-gical investigations of molecular mechanisms at this central synapse. (Supported in part by NIH grant NS15335).

A SLOW EXCITATORY POSTSYNAPTIC POTENTIAL MEDIATED BY ACETYL-CHOLINE IN HIPPOCAMPAL PYRAMIDAL CELLS. A.E. Cole and R.A. 135.5 Nicoll. Depts. of Pharmacology and Physiology, University of California, San Francisco, CA 94143. Considerable biotheric 194143.

Considerable biochemical and histochemical evidence indi-cates that the hippocampus receives cholinergic input from the medial septum. Although exogenously applied acetylcholine (ACh) has been shown to activate muscarinic receptors resulting in a slow depolarization, a synaptic cholinergic potential has not been demonstrated.

been demonstrated. Using intracellular recording techniques in the in vitro rat hippocampal slice preparation, we have studied the role of ACh in synaptic transmission in CAl pyramidal cells. These cells are believed to be innervated by cholinergic fibers from the medial septum. We have found that bath application of ACh has been excitors on CAL averages 1. desploration has three actions on CAl neurons: 1) depolarization associated with an increased membrane resistance, 2) blockade of an afterwith an increased membrane resistance, 2) blockade of an after-hyperpolarization (AHP) which results primarily from a calcium-activated potassium conductance ( $\mathcal{G}_K(c_a)$ ) and 3) blockade of ac-commodation of cell discharge evoked by long (600 ms) depolariz-ing pulses. All actions were reversed by the muscarinic antag-onist, atropine. Electrical stimulation of stratum oriens in the hippocampal slice elicited a series of fast excitatory postsynaptic potential (EPSPs), followed by an inhibitory postsynaptic potential (FSP). The IPSP was followed in most cells by a slow EPSP which lasted 20-40 s and was associated with an increase in membrane resistance and cell firing. The size of the slow EPSP wery sensitive to the membrane potensize of the slow EPSP was very sensitive to the membrane potential; with membrane potentials more negative than -70mV, little depolarization could be recorded. Electrical simulation also blocked the  $G_{K(Ca)}$  and the accommodation of cell discharge. All responses were enhanced by eserine and antagonized by atropine. In addition, the sites of optimal stimulation closely paralleled the distribution of cholinergic fibers in the hippocampus. The slow depolarization was calcium-dependent since it was elimi-nated by the calcium antagonist cadmium (100uM). These findings demonstrate that electrical stimulation of sites in the hippo-campus known to contain cholinergic fibers evokes a slow muscarinic EPSP in CA1 cells which exactly mimics the postsynaptic effects of exogenously applied ACh. Thus these findings fulfill an important criterion in establishing ACh as a neurotransmitter in the CNS.

DIRECT INHIBITORY ACTION OF BACLOFEN ON HIPPOCAMPAL PYRAMIDAL CELLS. N.R. Newberry\* and R.A. Nicoll. Depts. of Pharmacology and Physiology, University of California, San Francisco, CA 135.6 94143.

The GABA analogue, baclofen, appears to act at a separate The GABA alarogue, bachlett, appears to act at a separate site (GABA<sub>B</sub>) from that mediating the classical bicuculline-sensitive, chloride-dependent GABA response (GABA<sub>A</sub>) (Bowery, N.G., <u>Trends Pharmacol.</u> Sci. 3: 400, 1982). While early studies reported a postsynaptic inhibitory effect, recent interest has focussed on its presynaptic (depressant) effect on transmitter release.

We have investigated the postsynaptic action of baclofen on rat hippocampal CAl pyramidal cells using intracellular record-ing techniques in the slice preparation. The superfusion of (+)baclofen (3 X 10<sup>-7</sup> - 10<sup>-4</sup> M) hyperpolarized the membrane with baclofen (3 X  $10^{-7} - 10^{-4}$  M) hyperpolarized the membrane with an associated reduction in the input resistance and silenced those cells which were spontaneously active. The hyperpolar-ization was primarily dependent on the (-) isomer since it was approximately 100-200 times more potent than the (+) isomer. The response resulted from a direct action on the cell, since it could be recorded after 1  $\mu$ M tetrodotoxin or 100  $\mu$ M CdCl<sub>2</sub> had blocked synaptic transmission.

had blocked synaptic transmission. The hyperpolarization could be elicited by the local iono-phoresis of (+) baclofen (25 mM, pH 3) into stratum radiatum, pyramidale or oriens. The response could be evoked from cells in which the somatic chloride reversal potential had been reversed by intracellular injection of chloride. In paired ionophoresis experiments the baclofen response was compared with the hyperpolarizing somatic GABA response. The baclofen response was slower and associated with a smaller change in input resistance than the GABA response. The reversal poten-tials for the GABA and haclofen input resistance than the GABA response. The reversal poten-tials for the GABA and baclofen responses were approximately -70 and -85 mV, respectively. While the superfusion of BaCl<sub>2</sub> (0.3 - 2 mM) depressed the baclofen response but not the GABA response, the superfusion of bicuculline (10  $\mu$ M) selectively reduced the GABA response.

These experiments indicate that baclofen hyperpolarizes hipp ocampal pyramidal cells by a direct postsynaptic action which may involve an increase in potassium conductance. This action

appears to involve sites similar to the presynaptic GABA<sub>B</sub> sites. This research was supported by NIH Grant NS-15764 NS-16485, RCDA MH00437, and the Klingenstein Fund to R.A.N. N.R.N. is grateful to the Wellcome Trust for a travel grant. We thank CIBA-GEIGY for the samples of baclofen.

**VOLTAGE-DEPENDENCE OF SYNAPTIC TIME COURSE PARTIALLY MODIFIES SYNAPTIC CHARGE TRANSFER.** Daniel <u>Gardner</u>. Dept. of Physiology and Biophysics, Cornell U. Med. Coll., New York, N. Y. 10021. Postsynaptic currents mediated by inhibitory cholinergic receptors of <u>Aplysia</u> buccal ganglia are choline-sensitive, and can be blocked by the addition of 1 mM choline to the bath. Voltage-clamping cells BL and BR7, in which monosynaptic cholinergic PSPs are diphasic, excitatory-inhibitory, reveals underlying early inward (I<sub>D</sub>) and late outward (I<sub>H</sub>) currents. Bath choline blocks only I<sub>H</sub>, as does eserine and ACh. I<sub>D</sub> revealed by choline or ACh block decays exponentially with time constant  $\tau_D = 1/\alpha_D$ . Decay is voltage-dependent:  $\alpha_D = B e_1$ , with  $A = 0.016 \pm 0.001$  mV<sup>-</sup> and  $B = 0.273 \pm 0.025$  ms<sup>-1</sup> (n=13). With eserine used to block I<sub>L</sub> and so reveal I<sub>D</sub>, decay was<sub>1</sub>longer and voltage-dependence apparently steeper:  $A^2 = 0.027$  mV<sup>-</sup>, B = 0.165 ms<sup>-1</sup>, suggesting an effect of eserine on the voltage-dependent process. The time course of I<sub>L</sub> was approximated by subtraction of I<sub>D</sub> recorded in choline from control diphasic currents in sea water. Decay was again exponential, but essentially voltage-independent:  $A = -0.003 \pm 0.002$  mV<sup>-</sup>,  $B = 0.023 \pm 0.003$  ms<sup>-1</sup>, giving  $\tau_H =$ 48 ± 5 ms. VOLTAGE-DEPENDENCE OF SYNAPTIC TIME COURSE PARTIALLY MODIFIES 135.7

48 ± 5 ms.

In order to independently verify the above, and reveal I<sub>H</sub> directly, I attempted to block I<sub>D</sub> with hexamethonium (Tauc and Gerschenfeld <u>Nature</u> 192:366-367, 1961). However, the block was

Gerschenfeld <u>Nature</u> 192:366-367, "1961). However, the block was insufficiently specific: residual I<sub>D</sub> contaminated I<sub>H</sub> time course, and partial block of I<sub>H</sub> yielded an artificially steepened voltage-dependence of I<sub>D</sub> obtained by subtraction. Peak synaptic current I<sub>D</sub> and synaptic charge transfer Q of I<sub>D</sub> were computed and plottead's. V<sub>H</sub>, in order to assess the contribution of voltage-dependent time course to synaptic efficacy. The slope of the Q-V curve decreased with depolarization in 10 of 13 cells. The Q/I<sub>D</sub> ratio was less voltage-dependent than would be predicted by the behavior of a<sub>D</sub>, with A = 0.009 for data pooled to eliminate cell-to-cell variations. Significant charge transfer during rise or peak may account for the diminished voltage dependence. Depolarization therefore diminishes the voltage dependence. Depolarization therefore diminishes the effectiveness of this synaptic component, allowing the inhibitory component to predominate, not only by reducing driving force, but also by reducing the duration of the conductance change. Although this diphasic PSP meets timing criteria of Segev and Parnas (<u>Biophys. J.</u> 41: 41-50, 1983) for maximal inhibition, it uses the additional mechanism of voltage-dependent time course to further reduce the effectiveness of the early EPSP. Supported by NIH grant NS11555.

135.8 PRELIMINARY CHARACTERIZATION OF EXCITATORY ACETYL-CHOLINE RECEPTORS IN <u>APLYSIA</u> USING THE SINGLE CHANNEL RECORDING TECHNIQUE. <u>L. Simmons</u>. Center for Neurobiology and Behavior, Columbia University, College of Physicians & Surgeons, and New York State Psychiatric Institute, New York, N.Y. 10032. Using the giga-seal patch-clamp technique of Neher and Sakmann I have made a preliminary characterization of the channels that mediate the conjustem control to the property of the participant of the channels that mediate the conjustem control to the property of the participant of the participa

the excitatory acetylcholine (ACh) response in RB cells in the abdominal ganglion of <u>Aplysia californica</u>. Cells of the RB cluster in the abdominal ganglion exhibit excitation during iontophoretic application of ACh onto their somas. After desheathing the ganglion and treating the cells with proteolytic enzymes the RB cluster still maintains a normal excitatory

proteolytic enzymes the RB cluster still maintains a normal excitatory ACh response. Following enzyme treatment the cells were maintained in 19°C HEPES-buffered artificial seawater (ASW). Single ACh channel openings were recorded with the on-the-cell patch technique, using patch electrodes containing various concentrations of ACh in ASW. With 1-3 uM ACh in the pipette the inward ACh-induced currents are qualitatively similar to those described in other preparations. At a given agonist concentration, the probability of channel opening measured across various cells varies widely. The elementary current increases linearly with hyperpolarization, and the extrapolated reversal potential is 4.5 mV. The mean conductance of these excitatory channels is 32 + 3 nS(SD)32 + 3 pS (SD). The average open time of these channels at resting potential (-45 to

-50 mV) is 3.2 msecs. Individual channel openings are often transiently interrupted by brief closings (flickering). Channel lifetime becomes progressively longer when the patch membrane is hyperpolarized. The relationship between lifetime and membrane voltage is roughly linear in the range -40 mV to -95 mV with a slope of 1 msec/10 mV and saturates around -110 to -120 mV.

Previous investigators have described the relatively nonselective behavior of excitatory ACh channels in cells in the pleural ganglion of Aplysia (Ascher et al., 1978; <u>J. Physiol.</u>, 278:177). My preliminary results suggest that the excitatory ACh channels in the RB cells also exhibit this weakly selective ionic permeation characteristic. When the ASW in the patch pipette is replaced by a solution containing 1/2 isotonic MgCl<sub>2</sub> and 1/2 ASW the ACh-induced current steps are present, though reduced to 1/3 of their normal elementary current amplitude. The average open time of channels at resting potential in this solution is average open time of channels at resting potential in this solution is increased by a factor of three.

COMPARISON OF DECREASED CONDUCTANCE SEROTONERGIC RESPONSES IN 135.9 COMPARISON OF DECREASED CONDUCTANCE SERVICINERATE RESPONSES IN INK MOTOR NEURONS AND TAIL SENSORY NEURONS IN APLYSIA. John P. Walsh and John H. Byrne, Dept. of Physiol. and Cell Biology, Univ. Texas Med. Sch. at Houston, Houston TX. 77025 Previous work has demonstrated that servicin (5-HT) produces a slow decreased conductance depolarization in both the tail

sensory neurons and L14 ink motor neurons (Byrne & Walters, 1982; Pollock et al, 1982; Walters et al, 1983; Walsh & Byrne, 1982). The present study was undertaken to analyze further the ionic

and cellular mechanisms underlying the 5-HT responses in these cells using voltage clamp and microejection techniques. Differences between L14 and the sensory neurons were found in the regional sensitivity to 5-HT and in the linearity of the voltage-dependence of the 5-HT response. Somatic application of 5-HT to L14 was relatively ineffective, while application to the neuropil underneath the soma generated a current which was the neuropil underneath the soma generated a current which was linear with respect to voltage reversing at approximately -78 mV. This response was associated with a 12% decrease in input conductance. In contrast, the cell body of sensory cells was responsive to a much lower concentration of 5-HT than that used to elicit a response in L14. 5-HT produced a large decrease in a voltage dependent conductance in the sensory neurons. The response was most pronounced at depolarized levels and absent at hyperpolarized levels. The 5-HT response in both L14 and the tail sensory neurons were sensitive to changes in extracellular K<sup>+</sup>. Addition of 30mM K<sup>+</sup> -ASW caused a depolarizing shift in the reversal potential of the 5-HT response in L14 to a level in good agreement with the predicted K<sup>+</sup> Nernst equilibrium potential. Addition of high-K<sup>+</sup> ASW also shifted the IV relation of the sensory neurons and produced a reversal of the 5-HT response sponse which was not observed in normal  $K^+$  . The 5-HT responses seen in both L14 and the sensory cells were not secondary to activation of interneurons or dependent primarily upon extra-cellular Ca<sup>++</sup> since comparable responses were obtained in ASW containing 30mM Co<sup>++</sup>.

containing 30mM Co<sup>++</sup>. To examine the role of cAMP in mediating the 5-HT responses IBMX, db cAMP, and an adenylate cyclase activator (forskolin)) were added to the bath. Each compound mimicked the 5-HT response producing an inward current with a decrease in input conductance. During application of forskolin subsequent 5-HT responses were blocked or attenuated. These studies demonstrate that 5-HT mod-ulates two types of K<sup>+</sup> conductances (differing in their vol-tage dependence and spatial distribution) in L14 and the sensory neurons, and that the changes in K<sup>+</sup> conductance are mediated by cAMP. These results are consistent with observations that 5-HT increases (MD layels in the tail sensory neurons (Pollock E-HT increases cAMP levels in the tail sensory neurons (Pollock et al, 1982; Ocorr et al, this volume).

135.11 CYTOCHEMICAL DISTRIBUTION OF CALCIUM IN THE DENTATE MOLECULAR LAVER. E. Fifková, K. Cullen-Dockstader,\* J.A. Markham and R.J. Delay.\* Dept. of Psych., Univ. of Colorado, Boulder, CO R.J. D 80309.

In search for the underlying mechanism of synaptic plasticity induced in dendritic spines of the dentate fascia by tetanic stimulation, a study of the spine internal structure was indicated. It was assumed that physicochemical properties of the spine cytoplasm , like ion composition and pH, are changed by the tetanic stimulus. It was further assumed that such a change could affect the conformational state of cytoplasmic proteins and thus change the viscosity of the neuroplasm. Under such con-ditions, actin filaments which are present in dendrites and dendritic spines (FiFková and Delay, J. Cell Biol., 95:345) could contract in association with cytoplasmic myosins and regulatory proteins similarly to other nonmuscle cells. Such an activity could induce the morphometric changes observed in the spines Could induce the morphometric changes observed in the spines during long-term potentiation. The anticipated contraction of actin filaments requires a transient elevation of free  $Ca^{2+}$ . This could be provided by the calcium current during depolariza-tion when voltage dependent  $Ca^{2+}$  sensitive channels open and/or by internal sources of calcium. Therefore, we have attempted to identify cytochemically the localization sites of  $Ca^{2+}$ . Using three optimization methods, we have demonstrated disthree calcium precipitation methods, we have demonstrated dis-crete deposits in synaptic vesicles and multivesicular bodies. Larger precipitates were regularly observed in mitochondria, astrocytic processes, and in the smooth endoplasmic reticulum of axons and axon terminals. In these locations, calcium has been previously reported in the literature. Our novel contribution is the observation of  ${\rm Ca}^{2+}$  deposits in dendrites and dendritic spines in the smooth endoplasmic reticulum and the spine apparatus, respectively. The presence of  $Ca^{2+}$  deposits in the spine apparrespectively. The presence of a deposits in the spin apparatus indicates an affinity of this organelle for, and a capacity to, sequester  $Ca^{2+}$ . Thus, the spine apparatus could regulate regional concentrations of  $Ca^{2+}$  during synaptic activity and keep it relatively high in the spine, likewise the smooth endoplasmic reticulum does in the periphery of the light stimulated visual receptors. The spine apparatus may also serve as a storage site from which  $Ca^{2+}$  could be released upon stimulation in a fashion similar to that of the muscle sarcoplasmic reticulum. A  $Ca^{2+}$ concentration gradient may build up between the spine and dendrite which would, within the spine stalk, allow for an orderly organ-ization of actin filaments that is required for a contraction to take place.

NEUROTRANSMITTER RECEPTOR-MEDIATED CYCLIC GMP FORMATION: A NEW HYPOTHESIS IMPLICATING THE INVOLVEMENT OF PHOSPHOLIPASE A2 AND ARACHIDONIC ACID METABOLITES. Elliott Richelson, R. Michael Snider, Michael McKinney\* and Carlos Forray\*. Dept. of Psychiatry and Pharmacology, Mayo Clinic & Fdn., Rochester, MM 55905. Activation of muscarinic or histamine H1 receptors on murine neuroblastoma clone NIE-115 cells results in a marked increase in GGMP formation. The mechanism for this response has been thought to be activation of receptor-operated calcium channels resulting in a rise in the intracellular free [Ca<sup>++</sup>] which stimulates guanylate cyclase. Our recent data do not support this hypothe-sis. Neuroblastoma cells loaded with the photoprotein aequorin (an indicator of intracellular free [Ca<sup>++</sup>]) responded to challenge with a calcium ionophore (X537A) or melittin by a marked and immediate increase in light production, but carbachol or his-tamine had no effect. Moreover, the cGMP accumulation time-course was much more rapid for receptor agonists than for X537A or melittin, thus clearly discriminating between the intracellular [Ca<sup>++</sup>] and cGMP stimulation. In the search for an alternate mechanism of receptor-mediated CGMP formation, we found that inhibition of either phospholipase A2 (PLA2) or lipoxygenase (LPO) metabolism of arachidonic acid (AA) attenuated the receptor or ionophore-mediated cGMP response. Quinacrine, a PLA2, inhibitor, blocked the response with an IC50 of about 100µM. Inhibition of the LPO pathway of AA metabolism with eicosatetraynoic acid or nordihydroguaiaretic acid inhibited cGMP formation, we low of the low of LO and 304M response-tively. If NEUROTRANSMITTER RECEPTOR-MEDIATED CYCLIC GMP FORMATION: 135.10

of about 100µM. Inhibition of the LPO pathway of AA metabolism with eicosatetraynoic acid or nordihydroguaiaretic acid inhibited cGMP formation with IC50 values of 10 and 30µM, respectively. If PLA2 is involved in neurotransmitter action, then activation of this enzyme should stimulate cGMP accumulation. Thrombin (1-10 nM), a serine protease involved in hemostasis and well known acti-This enzyme should stimulate camp accumulation. Informin (1-1) when the probability of t

135.12 FREE INTRACELLULAR SODIUM AND POTASSIUM IN MAMMALIAN SYMPATHETIC NEURONS DURING NEUROTRANSMITTER APPLICATION. K. Ballanyi\*, P. Grafe\* and G. ten Bruggencate. Department of Physiology, University of München, 8 München 2, Federal Republic of Germany. It is well known that carbachol and GABA depolarize mammalian sympathetic neurons. The question was, to what extent changes in intracellular free concentrations of Na or K ([Na].,[K].) occured during such cholinergic, and amino acid, agonist actions. Experiments were performed on isolated, desheathed superior cervical ganglia of rats, maintained at 30°C in Krebs solution. Double barreled ion selective microelectrodes were used to re-cord the membrane potential and the [Na]. or [K]. The ion barrel was filled with Corning 477317 ([K].) or a neutral carrier exchanger (ETH 227, [Na].;), repectively (overall tip size 0.3 µm). size 0.3 µm).

carrier exchanger (ETH 227,  $[\tilde{Ma}]_{i}$ ), respectively (overall tip size 0.3 µm). Steady state values obtained were:  $[K]_{i}$  121.7 + 9.7 mmol/1 (mean ± SD, n = 30, resting potential -45.3 ± 5.4 mV, action potential amplitude 70.7 ± 13.9 mV).  $[Ma]_{i}$  was 10.0 ± 4.3 mmol/1 (n = 21, resting potential -43.8 ± 619 mV, action poten-tial amplitude 69.5 ± 12.7 mV). Repetitive stimulation (30 Hz for 20s) of preganglionic fibers induced small increases in  $[Na]_{i}$  (about 3 mmol/1). Application of 50 µmol/1 carbachol in Krebs superfusion fluid resulted in a membrane depolarization exceeding 20 mV that was accompanied by an increase in $[Na]_{i}$ between 8 and 20 mmol. The ion changes reached their maxima during the early phase of the repolarization of the membrane; recovery to baseline levels after the end of the carbachol superfusion took several minutes and usually corresponded to the time course of the extracellular K-undershoot. No re-covery was observed in the presence of 300 µmol/1 ouabain. GABA (100 µmol/1) led to a smaller decrease in  $[K]_{i}$  as com-pared to carbachol, and  $[Na]_{i}$  did not change at all. Thus, an increase in $[Na]_{i}$  does not seem to be involved in the reup-take of potassium that takes place after GABA-application. In preliminary experiments, norepinephrine (100 µmol/1) did not change  $[Na]_{i}$  nor  $[K]_{i}$  despite a membrane hyperpolari-zation of about 5 mV. These data do not support the notion that norepinephrine may activate the sodium pump in rat sym-pathetic ganglia. On the other hand, our data on carbachol application show that the sodium pump is the main factor in-volved in the homeostasis of carbachol-induced ion changes.

135.13 PLASTICITY IN NEURONAL EXCITABILITY IN THE INFERIOR MESENTERIC GANGLION OF GUINEA PIG. B.F. King\* and J.H. Szurszewski (SPON: J.P. Whisnant). Department of Physiology, Mayo Medical School, Rochester, MN 55905. Principal sympathetic neurons in mammalian prevertebral

Principal sympathetic neurons in mammalian prevertebral ganglia express variation in their active electrical properties. For instance, action potentials elicited by these cells are followed by an afterspike hyperpolarization (ASH) which may assume one of three voltage trajectories, in terms of its rate-of-decay. Also, these cells show two patterns of discharge in response to constant depolarization; they show phasic and tonic firing patterns. In addition, a small population of these principal ganglion cells display spontaneously rhythmic firing, an oscillatory behavior which has been associated with pacemaking of other ganglion cells. In view of recent knowledge of novel potassium currents which control excitability in other systems, we have come to suspect that variation in these electrical properties is due to subtle expression of these ionic currents. From intracellular recordings from sympathetic neurons in the inferior mesenteric ganglion of the guinea pig, and by manipulation of potassium currents either pharmacologically or by ionic addition and withdrawal, plasticity in neuronal excitability can be induced. From our observations on firing patterns and the voltage trajectory of the ASH, we have reason to identify at least two potassium currents. One is susceptible to 4-aminopyridine and to barium; another is susceptible to extracellular calcium levels. Whether or not these ionic currents are under transmitter/ humoral control remains equivocal. Supported by NIH Grant AM 17632.

#### **REGULATION OF PITUITARY FUNCTION II**

136.1 THE ROLE OF CORTICOMEDIAL AMYGDALA (CMA) AND MEDIAL PREOPTIC HYPOTHALAMIC AREA (MPO) IN THE ESTROGEN-INDUCED PROLACTIN (PRL) AFTERNOON SURGE. Jenn-Tser Pan\* and R.R. Gala. Dept. of Physiol., Wayne State Univ. Sch. of Med., Detroit, MI 48201. Earlier studies from this lab have shown that local implantation of estradiol-178(E<sub>2</sub>) in the MPO but not in the cerebral cortex or ventromedial hypothalamic nuclei (VMH) can induce a significant PRL afternoon surge (Fed. Proc. 42: 575, 1983). The CMA has also been reported to have some effects on PRL secretion. Both lesion and implantation experiments were performed in this study to determine the role of CMA and MPO in the estrogeninduced PBL surge

both resion and implantation experiments were performed in this study to determine the role of CMA and MPO in the estrogeninduced PRL surge. Adult female Sprague-Dawley rats weighing approximately 250 gm were used in all studies. Animals were kept 2/cage in a light (14L:10D, with light on at 0600 h) and temperature (24°C) controlled room. Radiofrequency was used in all lesion studies using either 56°C or 60°C for 1 min. Twenty-eight gauge cannulae containing E<sub>2</sub> diluted 1:100 with cholesterol were used in all implantation studies. Intra-atrial catheters were placed through the jugular vein for serial blood sampling which was initiated on day 2 through day 5. Blood samples (0.3 ml) were obtained at 1300. 1700 and 1900 h on each day.

ady 2 through day 5. Blood samples (U.S. MI) were obtained at 1300, 1700 and 1900 h on each day. In normal cycling rats, MPO lesions on diestrus I eliminated the expected proestrous PRL afternoon surge seen in normal cycling rats, MPO lesions in long-term ovariectomized (OVX for 2 wks) polyestradiol phosphate (PEP)-treated rats also blocked the PRL surge completely. Some MPO lesions included the suprachiasmatic nuclei, while others did not. However, the results were the same. Acutely CMA lesioned (2 days) OVX + PEP-treated rats exhibited normal onset and magnitude of PRL surge. High concentration of E2(1:2 or 1:4) implanted in the CMA in-

High concentration of Eq.(1:2 or ]:4) implanted in the CMA induced a significant PRL surge, but the systemic effects of Eq. were apparent as evidenced by augmented uterine weight and the appearance of vaginal cornification. Using 1:100 diluted Eq implants, no systemic effect was observed and no PRL surge was induced. Similar results were observed previously when 1:100 diluted Eq implants were placed in either the cerebral cortex or the VMH (Fed. Proc. 42: 575, 1983). Simultaneous implantation of Eq.(1:100) in the MPO and CMA did not show an amplification effect on the PRL surge over that observed for MPO implants alone. It is concluded that the MPO is by far the most important area in the action of Eq in inducing the PRL surge, and the CMA is not necessary for the generation of the surge. However, under certain physiological conditions (e.g., pseudopregnancy) the CMA may have a modulatory role. (Supported in part by NIH Research Grant #HD 14671.

136.2 PROLACTIN SECRETION IN RESPONSE TO A NONSTEROID ESTROGENIC MYCOTOXIN, ZEARALONE G. E. Resch\* (SPON: James L. Voogt) Dept. of Biol. and Schl. of Med., Univ. of Mo.-K.C. Kansas Citv, Mo. 64110

The mycotoxin Zearalenone (F2) has been implicated in problems of reproduction and growth, that have been shown to be responsive to estrogenic stimuli. Some of these effects may be attributed to the fact that F2 acts at estradiol (E2) receptors and has been demonstrated to interfere with estrogenic feedback control of LH in some species. Previous reports by Hobson et. al. (1969) that F2 elicited increases in LH and FSH secretion in the monkey supported the notion that F2 might also mimic E2 stimulation of Prolactin (PrI) secretion. The probability that F2 could also effect E2 control of PrI secretion and in vitro continuous flow dispersed pituitary cell preparation by a modification of the method of Lowery and Jay (1974). Rat pituitaries were excised, minced, and trypsinized to obtain dispersed cells. The cells were washed in Earl's BSS containing lima bean trypsin inhibitor and mixed with a polyacrilamide gel bead support matrix. The gel-cell mixture was poured into a column and perfused with medium 199 by a proportioning pump at 1 ml/min. The concentration of F2 lacet or to the column. The Pr1 response to F2 was first tested by administration of a 10 mg bolus of F2 directly on top of the cell layer. Pr1 secretion increased over 5-fold from dopamine (DA) inhibited baseline values of 5.24 ng/ml to 32.4 ng/ml following administration of F2 bolus. Response latency, time to peak value, and duration of the P1 response data suggest that a maximum response occurs to about 40 ug doses of F2 with lower responses occuring at both 4 and 400 ug amounts. Comparison of F2 and E2 elicited increases in P1 secretion in early

136.6

136.3 GONADOTROPIN-RELEASING HORMONE (GnRH) RECEPTORS IN MALE HAMSTERS: EFFECT OF CASTRATION AND PHOTOPERIOD. <u>David R. Pieper</u>, University of Detroit, Department of Biology and Health Sciences, Detroit MI 48221

Previous studies in male rats have indicated that the number of pituitary GnRH receptors (GnRH-R) is related to GnRH secretion. For instance, the number of GnRH-R is increased by castration or by injection of exogenous GnRH into intact or hypothalamic lesion-ed rats (Endo 110:749, 1982). Other investigators have shown that male Syrian hamsters exposed to a short photoperiod for 10 weeks undergo gonadal regression due to decreased gonadotropin levels. This is thought to be mediated by an inhibitory effect of pineal melatonin on the hypothalamo-hypophyseal axis. The purpose of the present study was to determine the effect of castration and photoperiod on the number of GnRH-R in Syrian hamsters. Hamsters period on the number of GnRH-R in Syrian hamsters. Hamsters (65 days old) were placed on either an LD 14:10 or LD 6:18 light:dark cycle for 9 weeks. At this time half the animals on each photoperiod were castrated. One week later, all animals were decapi-tated. The animals on LD 6:18 had regressed testes (2.4 + 0.2 mg tated. The animals on LD 5:18 has regressed testes (2.4  $\pm$  0.2 mg paired testes with per 100 g B.W.  $\overline{X+SE}$ ) compared to hamsters on LD 14:10 (23.3 $\pm$ 1.0 mg). Serum LH levels were also lower in intact animals on LD 5:18 (29.5 $\pm$ 5 ng/ml) compared to intact hamsters on LD 14:10 (55.7 $\pm$ 5 ng/ml). Animals on both photoperiods responded to castration with increased LH secretion, although the increase in animals on LD 6:18 ( $104\pm 0$  ng/ml) was less than that of hamsters on LD 14:10 ( $470\pm 44$  ng/ml). These results show that the animals on short photoperiod underwent gonadal regression and had reduced gonadotropin secretion. The GnRH-R were assessed by the method previously described for rats (Endo 105:1069, 1979) using the D-Ala<sup>6</sup> analog of GRH. Scatchard analysis of competition curves indicated that the hamster pituitary GRH receptors have charac-Indicated that the number previously described for rats ( $K_a=6.5\times10~M^{-1}$ ). Furthermore, the affinity of the receptor was similar in hamsters on long and short photoperiod. The number of GNRH-R was determined by saturation analysis. Castration of animals on LD 14:10 resulted in an increase in the number of GNRH-R from  $83\pm7$  to  $143\pm9$  fmol/pituitary, a response similar to that of rats. Intact hamsters on LD 6:18 had a reduced number of GnRH-R (48.8±5 fmol/pit) but there was also an increase (100±8 fmol/pit) following castration in the animals on short photoperiod. In conclusion, the results show that the hamster pituitary GnRH-R have characteristics similar to the rat and respond similarly to castration. The data also suggest that part of the inhibition of re-production after maintaining hamsters on short photoperiods is due to a decrease in GnRH secretion and a decrease in the number of GnRH receptors on the pituitary gland. Supported by NSF Grant # PCM 81-21327.

136.4 ELECTROCHEMICAL MEASUREMENT OF ANTERIOR PITUITARY DOPAMINE IN THE RAT: CONTRIBUTION BY THE POSTERIOR LOBE AND ITS EFFECTS ON PROLACTIN SECRETION. J. Jeffrey Mulchahey\* and Jimmy D. Neill\* (SPON: J. Brown). Department of Physiology and Biophysics, University of Alabama in Birmingham, Birmingham, AL 35294.

Dopamine (DA), secreted by tuberoinfundibular neurons into the hypophyseal portal circulation, is widely accepted as a physiological prolactin release-inhibiting factor (PF). While DA levels in hypophyseal portal plasma are sufficient to suppress prolactin (PRL) levels, they are insufficient to account completely for the tonic inhibition of PRL secretion. The present study was designed to ascertain the relative portal and posterior lobe contributions to DA in the AP of urethane anesthetized diestrus I rats was monitored <u>in situ</u> every 10 min by electrochemical (EC) methods using differential pulse voltammetry with a carbon paste electrode which was relatively ascorbate-insensitive. Measurements were taken during control periods, after posterior lobe removal followed by hypophyseal stalk section, or after inhibition of catecholamine synthesis by  $\alpha$  methyl-p-tyrosine (AMPT) followed by DA infusion. Following EC stabilization, posterior lobe aspiration resulted in a slight rise in plasma PRL from 14.413.1 ng/ml to 22.81.0 ng/ml (meantSEM, n=7, NS) while the DA-EC output fell to 47.8t6.10% of initial levels (p<0.01). Subsequent stalk section elevated PRL to 270.8396.4 ng/ml (p<0.01). In another group of animals, after EC stabilization, PRL had risen from 47.05.84 ng/ml (mean ± SEM, n=12) to 345.2t64.9 ng/ml (p<0.05) 90 min after AMPT while the DA-EC output fell to 22.9t3.52% of initial levels. Infusion of DA at a rate of 1 µg/kg·min suppressed PRL to 174.782% of initial. Infusion of DA at a rate of 2 µg/kg·min suppressed PRL to 74.7t16.7 ng/ml (NS) and restored the DA-EC output to 102.7t7.82% of initial (NS). These data demonstrate a complex, non-linear relationship between PRL secretion and DA in the AP and support the conclusion that the posterior lobe may contribute significant amounts of DA to the AP. Thus, previous measurements of hypophyseal stalk plasma DA may have underestimated the amount of DA reaching the AP. Furthermore, infusions of DA into AMPT treated rats at a rate sufficient to mic physi

136.5 PROLACTIN (PRL) STIMULATION OF (<sup>3</sup>H)-DOPAMINE (DA) RELEASE FROM RAT MEDIAN TISSUE: DEPRESSANT EFFECT OF CHRONIC ESTROGEN TREATMENT. P.E. Gottschall,\*D.K. Sarkar,\*K. Quigley\*and J. Meites.\* (SPON: R. Bernard). Dept. of Physiology, Michigan State University, E. Lansing, MI 48824.

The effect of PRL on release of  $({}^{3}\text{H})$  from rat median eminence was studied following pre-incubation of tissue with  $({}^{3}\text{H})$ -DA. Female Wistar-Furth rats on diestrous days I or II were used at 1100h (lights on 0500h - lights off 1900h). Procedures and kinetic analysis of uptake and release have been described previously (Sarkar et al, Neuroscience, in press). Briefly, median eminence was incubated for 20min in 3.6x10<sup>-7</sup>M ( ${}^{3}\text{H})$ -DA in an incubation and superfusion Krebs-Henseleit buffer. Two median eminences were used in each superfusion chamber, and ( ${}^{3}\text{H}$ ) release was stable after 40min. Fractions were collected (0.6/Zmin) and release of ( ${}^{3}\text{H}$ ) was expressed as a fractional rate constant (FRC) per minute, calculated by dividing the amount released by double the amount of ( ${}^{3}\text{H}$ ) content in the tissue at the start of each 2min period (FRC=x10<sup>-3</sup>/ min). PRL-evoked release (PER) was expressed as the FRC in the second tube collected following infusion of PRL (consistently the maximal response).

Infusion of 0.3, 6 and 120ng rat PRL over a 2min period resulted in a PER of (3H) from the tissue which was dose-dependent (PER=12.4+1.2, 20.0+2.2, and 26.7+2.6x10<sup>-3</sup>min; respectively). Analysis of the dose-response curve (r=0.87) showed no deviation from linearity F(2,13)=3.79, p>0.05, and did not exhibit significant regression (1,2)=3.35, p>0.05. Twenty minutes following PRL stimulation, 40mW K<sup>+</sup> was infused, resulting in an evoked release similar to 120ng PRL. To test the effects of chronic E treatment and E withdrawal on the ability of PRL to release (3H)-DA in vitro, Fischer 344 rats were ovariectomized 8 wks prior to the experiments, and were divided into 3 groups 1) estradiol 17-B 100 mm silastic implant)-treated animals which received an E containing implant for the last 4 wks. 2) animals which received E only for the first 4 wks, and 3) those which received an empty capsule only for the first 4 wks. The PER in this study was calculated by subtracting the FRC from the three fractions prior to PRL infusion, from the FRC of the three fractions after infusion. The dose of rat PRL was 120ng. In vitro PRL infusion resulted in a PER of 10.4+1.8x10<sup>-3</sup>/min in C, and in chronic E animals, PER was similar to C.(12.6+1.8x10<sup>-3</sup>/min). However in animals withdrawn from E, PER increased to 18.8+2.5x10<sup>-3</sup>/min. Since it is known that tuberoinfundibular DA (TIDA) turnover is increased following short term E treatment, these results suggest 1) chronic E may depress TIDA neuronal activity, even in the presence of hyperprolactinemia, and 2) if E is removed, the increase in dopaminergic activity reappears.

6 DOPAMINE INHIBITS NEUROTENSIN-INDUCED PROLACTIN RELEA-SE BY INTERACTING WITH CALCIUM CHANNEL RATHER THAN AD-ENVLATE CYCLASE SYSTEMS. M. Memo, E. Carboni, M. Trabucchi and P.F. Spano. Institute of Pharmacology and Pharmacognosy, University of Cagliari and Milan, Italy. Neurotensin (NT) is an endogenous neuropeptide that is active in many preclinical screening tests for neuro leptic drugs. It was previously found that NT stimula ted prolactin (PRL) release from incubated rat hemipituitary (Enjalbert A. et al., Neuroendocrinol. 34, 95-98, 1982). Our study was directed to investigate the molecular mechanisms leading to the PRL release. For this porpouse we kept the same experimental conditions as those described to elicit NT-dependent PRL secretions. NT (from 10<sup>-8</sup>M to 10<sup>-6</sup>M) was not able to increase cAMP levels in lh incubated rat hemipituitary as well as to enhance adenylate cyclase activity in homo genates from rat anterior pituitary membranes. Since PRL release appears to be regulated by intracellular free Ca<sup>++</sup> concentrations in a dose-dependent manner, rea ching the maximal effect at 10<sup>-6</sup>M (+388). In addition the phenomenon was time-dependent. 15 min of  $\pm^{0-7}$ M NT pre-incubation produced 15% increase in  $\pm^{-6}$ Ca<sup>++</sup> intracellular concentrations and preincubation of 10<sup>-7</sup>M NT prof 30 min further potentiated the effect (+32%). These results suggest that NT may induce PRL release not affecting adenylate cyclase system but opening specific Ca<sup>++</sup> channels in rat anterior pituitary. Addition of 10<sup>-7</sup>M DA completely antagonized Ca<sup>++</sup> influx increase induced by NT. DA was added 30 min before NT, then incubation was continued for 30 min. The inhi bitory effect was dose-dependent and specifically anta gonized by neuroleptic drugs such as haloperidol and sulpiride. Our results suggest that DA may regulate intracellular Ca<sup>++</sup> concentrations by interacting with a subtype adenylate cyclase-independent D<sub>2</sub> dopamine receptors.

136.9

THE ROLE OF ENDOGENOUS DOPAMINE UPON THE DEPLETION-TRANSFORMA-136.7 TION PHASE OF PROLACTIN IN THE LACTATING RAT. S.W. Shyr\* and C.E. Grosvenor\* (SPON: C.M. Blatteis). Dept. Physiol. & Bio-

C.E. Grosvenor<sup>A</sup> (SPUR: C.M. Blattets). Dept. Physicl. & Blo-physics, Univ. Tenn. Ctr. Hlth. Sci., Memphis, TN 38163. It is known that suckling induces PRL depletion in rat ante-rior pituitary (AP) and transformation into a releasable form. Tonically, PRL secretion is inhibited by dopamine (DA). In an attempt to further investigate the role of endogenous DA on PRL secretion, we applied dopaminergic antagonists, haloperidol and domperidone, to measure the changes in the depletion-transformation of PRL. Also using  $\alpha$ -methyl-p-tyrosine (250 mg free base/ kg body weight), we measured the turnover rate of DA in the median eminence (ME) during different stages of PRL in response to suckling.

Primiparous lactating rats of the Sprague-Dawley strain, each with a litter of 6 pups were housed in individual cages under standard laboratory conditions (23-25°C, 14 hr light: 10 hr dark). All experiments were done on day 13-15 of lactation. PRL was measured in the AP by PAGE (pH 7.2). DA in the ME was measured by HPLC combined with electrochemical detection.

Within 10 min of suckling, the concentration of PRL in the AP rapidly and significantly fell. With continued suckling the PRL concentration eventually commenced to replete rather than con-tinue to fall and by the 90th min of suckling the AP concentra-tion had returned to near the initial presuckled level.

A single injection of 0.2 mg haloperidol after the 4-5 hr non-suckling period within 20 min resulted in a marked fall in the AP concentration of PRL in comparison with that from 20 min the AP concentration of PRL in comparison with that from 20 min of suckling. However, 40 min after the onset of suckling, i.e., during the refractory period, the dose response curve shifted to the right by about 10-fold. Similarly, domperidone caused a progressively greater depletion of PRL in the AP within a dose range of 0.001-0.1 mg after 4-5 hr of non-suckling. The dose-re-sponse curve shifted to the right during the refractory period. In the ME, the concentration of DA declined during the first 20 aim in response to suckling for the first set. In the ME, the concentration of DA declined during the first 30 min in response to suckling following the 4-5 hr non-suckling period where upon it gradually returned to its presuckled level during the subsequent 90 min. Additional 10 min period of suck-ling did not further decrease DA concentration during the re-fractory period, instead, the DA level increased. The turnover rate of DA was higher during the initial depletion-transforma-tion than during the subsequent refractory phase.

These findings suggest that: 1) a greater endogenous dopa-minergic inhibitory effectiveness occurs in the AP during the refractory period to protect PRL from further depletion, 2) the increased effectiveness does not appear to be due to an increas-ed turnover of DA in the ME. EFFECT OF ALPHA-2 ADRENERGIC AGONISTS AND ANTAGONISTS ON RAT SERUM 136.8 PROLACTIN.

H.Y. Meltzer and H.L Jackman, Dept. of Psychiatry, Univ. of Chicago

Pritzker Sch. of Med., Chicago, IL. 60637 We have previously reported that yohimbine (YOH), an alpha-2 adrenergic antagonist, stimulated rat prolactin (PRL) secretion in male Sprague-Dawley rats in vivo without inhibiting the release of hypothalamic dopamine (DA) or blocking the inhibitory effect of DA on PRL secretion from pituitary glands <u>in vitro</u> (JPET 224, 21, 1983). Clonidine, an alpha-2 agonist, produced a partial blockade of the <u>in vivo</u> effect of YOH. Phenoxybenzamine and piperoxane, two other alpha-2 antagonists had no effect by themselves on PRL secretion and did not influence the effect of YOH. We have now studied the effect of other alpha-2 adrenergic agonists and antag-onists on rat serum PRL secretion. Oxymetazoline (OXY), a mixed alpha-adrenergic agonist and antagonist, ST-91, a mixed alpha-1 and alpha-2 agonist, and an alpha-2 agonist, guanfacin, 2.5 mg/kg, i.p., all produced a 15-20 fold increase in rat serum PRL levels 30 min after injection. Two other alpha-2 adrenergic agonists, ST 600 and ST 608, did not increase rat serum PRL levels nor did CGS 7525A, an alpha-2 adrenergic antagonist. The increases in PRL  $7_{025A}$ , an alpha-2 acrenergic antagonist. The increases in FRL produced by OXY and ST-91 were completely inhibited by pretreatment with phentolamine, 5 mg/kg, an alpha-2 antagonist and by prazosin, 5 mg/kg, an alpha-1 antagonist. Preliminary data also indicate a partial inhibition of the PRL releasing effect of YOH by prazosin. These findings suggest that both intact alpha-1 and alpha-2 adrenergic receptors are necessary for alpha-2 agonists or antagonists to stimulate PRL secretion.

antagonists to stimulate PRL secretion. Pretreatment with reserpine, 5 mg/kg, i.p. or alpha-methyl-paratyrosine, 100 mg/kg i.p., both of which diminish the avail-ability of NE and DA, blocked the PRL-stimulating effect of OXY, suggesting that OXY acts presynaptically and that NE, as well as DA, may be a tonic inhibitor of PRL secretion in vivo. For NE this may be in the hypothalamus rather than at the pituitary. It is also possible that stimulation of postsynaptic alpha-2 receptors and the pituitary of the pituitary of the pituitary of the pituitary. by OXY contributes to the release of PRL in rats via release of the as yet unidentified prolactin releasing factor (PRF). The reason why some, but not all alpha-2 adrenergic agonists stimulate PRL secretion and why YOH is the only alpha-2 antagonist we have so far found which stimulates PRL secretion will require further study. Supported, in part, by USPHS MH 30938 and by the State of Illinois Department of Mental Health.

136.10 ENDOGENOUS OPIATES MODULATE ESTRADIOL FEEDBACK ON PROLACTIN SECRETION AND SEROTONIN TURNOVER. M.D. Johnson and W.R Crowley. Dept. of Pharmacol. Univ. of Tennessee Center for the Health Sciences, Memphis, TN 38163. Previously, we reported that estradiol benzoate (EB) acutely activates medial preoptic serotonergic projections stimulatory to prolactin (PRL) secretion. Because opiate agonists also stimulate both PRL release and serotonin (5-HT) turnover. the operent experiments texted whothes endemenes. opiate neurons mediate estrogen feedback effects. In exper ment 1, ovariectomized rats received either 50 µg EB or oil In experiwhich, ovan either saline or a long acting opiate receptor blocker, nalmetrene (10 mg/kg), simultaneously, 3 h prior to decapitation. The pargyline method was used to determine 5-HT turnover; hence members of each treatment group received either saline or pargyline (75 mg/kg ip) 30 min prior to decapitation. Plasma PRL and LH concentrations were deterdecaptiation. Plasma PRL and LH concentrations were deter-mined by radioimmunoassays, and serotonin concentrations from microdissected, individual brain nuclei were measured by liquid chromatography with electrochemical detection. Nalme-trene blocked both the acute elevation of PRL and the increase in 5-HT turnover in the medial preoptic nucleus and ventromedial nucleus. Nalmetrene alone enhanced LH release and 5-HT turnover in the bed nucleus of the stria terminalis, and these effects were prevented by estradiol. A second study tested whether the opiate agonist. mor-

and these effects were prevented by estradiol. A second study tested whether the opiate agonist, mor-phine, mimics estrogen effects on PRL and preoptic 5-HT turn-over. Animals received saline, morphine (10 mg/kg) and/or naloxone (5 mg/ng) ip 30 min prior to decapitation. Simulta-neously, half in each group received pargyline as above. Morphine stimulated both PRL release and medial preoptic 5-HT turnover, and naloxone prevented both effects. In addition, morphine enhanced 5-HT turnover in the central amygdala, and naloxone increased 5-HT turnover in the bed nucleus of the stria terminalis and these changes appeared to be related to stria terminalis, and these changes appeared to be related to

stria terminalis, and these changes appeared to be related to opiate-induced alterations in LH. These results suggest 1) that estradiol may acutely stimu-late PRL secretion by actions on endogenous opiate peptide systems that increase activity in serotonergic projections to the medial preoptic nucleus and 2) that opiate 5-HT interac-tions may also regulate LH secretion. Supported by NRSA HD-06445-01, NIH HD 13703 and RCDA HD

MODULATION OF LUTEINIZING HORMONE RELEASE AND HYPOTHALAMIC CATECHOLAMINE ACTIVITY BY OPIATES IN THE FEMALE RAT. B.A. <u>Adler\* and W.R. Crowley</u>. Dept. of Pharmacol. Univ. of Tennessee Center for the Health Sciences, Memphis, TN 38163. The stimulation of luteinizing hormone (LH) release by the opiate receptor blocker, naloxone, can be prevented by inhib-itors of norepinephrine (NE) and/or epinephrine (EPI) synthe-sis, suggesting opiate regulation over catecholamine release. The present study tested whether an opiate agonist or antago-nist affect the depletion of hypothalamic catecholamines observed after synthesis inhibition, a measure of catechola-mine activity, concomitant with changes in LH secretion. In one study, female rats were treated with 50  $\mu g$  estradiol benone study, female rats were treated with 50  $\mu$ g estradiol ben-zoate and two days later, rats received either saline or naloxone (10mg/kg). Half the animals in each group were also given  $\alpha$ -methyl tyrosine (amt, 400 mg/kg) to inhibit catecho-lamine synthesis, and rats were killed one hour later. LH was measured by radioimmunoassay and catecholamines were determined by radioenzymatic assays. Administration of naloxone to the estradiol primed rats increased LH release, potentiated the depletion of NE in the preoptic-anterior hypothalamus and medial basal hypothalamus and also enhanced the decline of EPI and dopamine in the medial basal hypothal-amus after gmt. suggestion increased catecholamine activity the decline of EPI and dopamine in the medial basal hypothal-amus after omt, suggesting increased catecholamine activity in these regions. In a second experiment, females were treated with estradiol, followed two days later by 2 mg pro-gesterone. Two hours after progesterone, rats were given injections of either saline vehicle, morphine (10 mg/kg), or morphine plus naloxone. Half in each group also received a-methyl tyrosine simultaneously, and animals were killed one hour later. Administration of the opiate agonist, morphine, decreased LH and decreased the depletion of catecholamines after synthesis inhibition in the above-mentioned areas. suggesting reduced activity. In most

above-mentioned areas, suggesting reduced activity. In most cases, naloxone antagonized the inhibitory effect of morphine

These findings indicate that 1) naloxone may stimulate LH release by enhancing hypothalamic catecholamine turnover and 2) that this may occur by removing the inhibitory influence of an endogenous opioid peptide that stimulates receptors on catecholamine nerve terminals controlling LH-releasing horone neurosecretion.

136.11 AFFERENT PATHWAY INVOLVED IN THE REFLEX RELEASE OF OXYTOCIN IN THE LACTATING RAT. M. Dubois-Dauphin,\* W. E. Armstrong, E. Tribollet,\* and J. J. Dreifuss. Departement de Physiologie, Centre Medical Universitaire, 1, rue Michel-Servet, 1211 Geneve (Switzerland).

In the lactating rat, suckling induces an intermittent release of oxytocin from the neurohypophysial terminals of neurons located in the paraventricular and supraoptic nuclei of the hypothalamus, causing intermittent ejection of milk. We have studied the afferent pathway of this reflex. Under pentobarbital and xylasine anesthesia, bilateral electrolytic lesions and/or unilateral injections of 10% true blue or 40% horseradish peroxidase (HRP) solutions were made separately or in tandem, the injections occasionally following the lesions in the same rats using a modified syringe. The main galactophore of one or two mammary glands was cannulated for the continuous measurement of intramammary pressure and suckling tests were performed with ten pups attached to the nipples. Bilateral lesions placed in the lateral tegmentum near the inferior colliculus nucleus reduced the milk ejections altogether. Retrogradely labelled cells were notably found in relatively large numbers within the contralateral cuneatus and gracilis nuclei as well as in the contralateral lateral cervical nucleus of the spinal cord. Consequently we have lesioned those structures. Bilateral lesioning of the lateral cervical nucleus (level C2) abolished the milk ejection reflex. Unilateral injections of HRP in the lateral cervical nucleus travel in the posterior lateral tegmentum. A similar terminal in the intercollicular nucleus. Ascending fibers of this system travel in the posterior lateral ategmentum. A similar terminal labelling was observed after large unilateral ligections of HRP in the cuneate and gracile nuclei, but bilateral lesions of the cuneate and gracile fasciculi were completely ineffective in interfering with milk ejection. These results suggest that the intercollicular projection of the lateral cervical nucleus is part of the afferent pathway involved in the reflex milk ejection. (Supported by Swiss NSF, Grant 3.875-081). 136.12 FURTHER CORRELATION OF OXYTOCIN AND PROLACTIN RELEASES: LACTATION, W.K. SAMSON, M.D. LUMPKIN AND S.M. MC CANN (SPON: J.G. Parnavelas) Dept. of Physiology, UTHSCD, Dallas, TX 75235. We have described previously the ability of synthetic oxytocin (OXY) to stimulate significantly and in a dose-related fashion prolactin (PRL) release from cultured, dispersed rat pituitary cells in vitro (Lumpkin et al., Endocrinology 112: 1711, 1983). Additionally, we have demonstrated a temporal correlation between OXY release from neuronal elements and PRL secretion induced by steroid treatment of ovariectomized rats (Samson et al., Soc Neurosci 18, 22, 1982). These data, coupled with the presence of OXY immunoreactivity in the external layer of the rat median eminence, suggest a physiological role for OXY in the hypothalamic control of PRL secretion. Therefore we attempted in this study to correlate OXY and PRL release during a condition associated with release of both, i.e., lactation. Chronic right atrial cannulae were placed in the external jugular vein of lactating Sprague Dawley rats (6-8 pups each). On the next day (day 15 or 16 of lactation) pups were removed and rats left undisturbed for 4 hr, after which time a zero time blood sample (0.8 ml) was withdrawn via an extension cannula attached to the indwelling atrial cannula. Equal volumes of 0.9% NACl were infused to replace volume loss. Pups were then replaced and additional blood samples taken at 5, 10, 15, 20 and 30 min. Plasma was analyzed for PRL content by RLA. PRL levels began to rise above prepup renin-statement levels (0 time, 20.6 ± 3.7 ngm/nl, n=8) after 5 (41.3 ± 13.0) and 10 min (110.2 ± 40.0) and attained significance at 15 (116.7 ± 40.0, p.<05), 20 (171.9 ± 53.7, pc.01) and 30 min (236.0 ± 43.1, pc.001). In another group of rats pups were similarly removed for 4 hr prior to initiating experimentation. Mothers (n=10 per time point) were sacrificed by decapitation at 0 time and 5, 10, 15, 20 and 30 min after pup reinstatement. Trunk bloods were colle

#### CHEMICAL SENSES: OLFACTION AND TASTE I

137.1 FAST AND LOOSE COVALENT BINDING OF CARBONYL-CONTAINING MOLECULES TO PROTEINS. A ROLE IN VERTEBRATE OLFACTION? <u>Thomas Hellman</u> <u>Morton</u>, Department of Chemistry, University of <u>California</u>, Riverside, CA 92521 and J. <u>Russell Mason\*</u>, Monell Chemical Senses Center, 3500 Market Street, Philadelphia, PA 19104. Olfactory receptors undoubtedly have fast rates of association rith calver relevance. If the Moneration of the street of also of the second contert relevance. The Moneration of the street of a loss of the second rith calver relevance.

Olfactory receptors undoubtedly have fast rates of association with odorant molecules. If the dissociation rate is also fast, then the dissociation constant,  $K_d$ , will be comparatively large (micromolar or greater). With such fast and loose binding, a receptor can recover function rapidly. If a loosely bound molecule is intercepted at the binding site in such a way that it becomes irreversibly attached, then the receptor will be blocked. The fraction of receptors modified in this fashion can be related to the initial concentration of substrate and the residence time,  $\underline{t}$ , of substrate molecules in the receptor region. We have derived the pertinent kinetic analysis for the case where an initial pulse of substrate. If the rate of irreversible modification depends on the concentration,  $X_0$  of a third agent, let the pseudofirst order rate constant be represented as kX. If reversible association and dissociation can be shown to be equal to

$$1 - \left(\frac{K_{d}}{K_{d}} + S_{o}\right) \frac{tkX}{t}$$

This formula has been tested using, as a model, the Schiff-base forming enzyme AAD. In this case, the substrate was a ketone (cyclohexanone or ethyl acetoacetate). Irreversible modification by treatment of protein-substrate mixtures with borohydride was monitored by incorporation of radiolabel and also by loss of catalytic efficiency. The results are consistent with the derived formula, where attack of unbound substrate by borohydride constitutes the mechanism of substrate removal.

Tiger salamanders (<u>Ambystoma tigrinum</u>) have been trained, by use of avoidance conditioning, to discriminate among reagent grade chemicals as odorant stimuli. Their olfactory epithelia are easily accesible to irrigation with chemical agents designed to derivatize receptor proteins. We have previously reported that lavage with solutions of cyclohexanone or ethyl acetoacetate (10-50 mM in normal saline) induces a selective anosmia to carbonylcontaining odorants (Mason and Morton, <u>Physiol</u>. <u>Behav</u>. 29: 709, 1982). We present here a discussion of results of this behavioral assay in terms of the above chemical model. 137.2 MEMBRANE GLYCOPROTEINS SPECIFIC TO OLFACTORY CILIA. Doron Lancet, Ammon Shapira<sup>\*</sup> and Zehava Chen<sup>\*</sup>. Dept. of Membrane Research, The Weizmann Inst. of Science, Rehovot, Israel. There is growing evidence that olfactory receptor proteins,

Research, ine Weizmann Inst. of Science, Kenovot, Israel. There is growing evidence that olfactory receptor proteins, which bind odorants and mediate membrane transduction, are localized in the cilia of the sensory neurones of vertebrate olfactory epithelium. Despite considerable effort, these proteins have not yet been isolated, and their molecular characteristics remain unknown. Ligand binding techniques, that served in the purification of many other receptor molecules, have proven less useful in the olfactory system. This is because olfactory receptors (at least in air-breathing vertebrates) may be similar to immunoglobulins, being a large group of molecules with different, partially overlapping ligand specificity spectra. Any given odorant will have measurable affinity only to a small fraction of this diverse repertoire of proteins. Thus, the difficulties encountered in the use of an odorant to isolate olfactory receptor molecules may be compared to those that would arise in an attegent to purify immunoglobulins from non-immune serum using an antigen. To circumvent this problem we adopted an alternative approach, namely the mapping of membrane proteins of olfactory cilia (compared to non-sensory cilia), in search for plausible candidates for olfactory receptors. The validity of this approach is based on the documented simple protein profiles of ciliary membranes, and on the indications that olfactory receptor s of different odorant specificities may thus manifest their common molecular properties in the appearance of one or more relatively distinct protein bands, analogous to the light and heavy chain of heterogenous immunoglobulins. Membrane proteins of isolated frog olfactory and respiratory cilia, solubilized by non-ionic detergents, were visualized on the gels by radioidination, silver. staining and concanavalin-A binding. Two major protein polytentials by the lectin concanavalin-A (E.Polak, S.Shirley and G.Dodd, Fifth European Chemoreception Research Organizatio

137.3 ELECTROPHYSIOLOGICAL RESPONSES TO PHEROMONE BLENDS IN SINGLE INSECT OLFACTORY RECEPTOR NEURONS. R.J. O'Connell. The Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

In an ever increasing number of insect species precise mixtures of chemical compounds (pheromones) have been found which modulate important species specific behaviors such as long distance attraction to potential reproductive partners. The female cabbage looper moth (<u>Trichoplusia ni</u>) synthesizes a two component sex attractant pheromone. The primary component,  $2^{-7}$ , dodecenyl acetate (2-7, l2:AC), seems to be largely responsible for the initial stages of male activation and upwind flight whereas the minor component dodecyl acetate (12:AC) significantly increases the number and duration of upwind flights and increases the number of attempted copulations with the pheromone dizenses. A third compound, not yet identified in females,  $2^{-7}$ , dodecenol ( $2^{-7}$ , 12:0H) inhibits the behavioural response elicited in males by the pheromone blend. The particular behavioural sequence modulated by  $2^{-7}$ , 12:0H in order to produce this result has not been identified.

to produce this result has not been identified. The sensory mechanisms responsible for blend perception are not known. Previous electrophysiological investigations (O'Connell, R.J., <u>et al.</u>, <u>Science</u>, 1983, In Press) utilizing purified single compounds, demonstrated two high sensitivity (effective dose, .001  $\mu$ g) olfactory receptor neurons, one specialized for Z-7,12:AC and a second specialized for Z-7,12:AC. In spite of the obvious behavioural import of small amounts of 12:AC neither of these receptor neurons responded to this substance at intensities normally experienced by the male. However, if stimulus intensity was increased 10,000 fold, responses to 12:AC could be obtained in both types of receptor neurons. This disparity between the behavioural responses to the multicomponent pheromone and the electrical activity produced in olfactory receptor neurons by individual components of the blend suggests that binary mixtures of compounds would be more appropriate stimuli for these neurons. Therefore, I compared the responses to individual compounds with the responses to their binary mixtures for the three behaviourally relevant odorants in the hopes of clarifying the electrophysiological mechanisms which underlie blend perception.

The results of experiments still in progress suggest that mixtures of pheromone elicit responses from individual olfactory receptor neurons that cannot be predicted from a knowledge of their responses to the individual compounds alone. Moreover, elevated doses of Z-7,12:AC such as those which might occur near a calling female (10  $\mu$ g), cause pronounced long lasting changes in the response properties of the receptor neurons to both single compounds and to their blends.

137.4 ISOPROTERENOL-ASSOCIATED GRANULE DEPLETION IN OLFACTORY GLANDS OF THE ADULT SALAMANDER. <u>Thomas V. Getchell and Marilyn L.</u> <u>Getchell.\*</u> Department of Anatomy, Wayne State University School of Medicine, Detroit, MI 48201. The sustentacular cells (SC) in the olfactory epithelium and

The sustentacular cells (SC) in the olfactory epithelium and the multicellular cells(SC) in the olfactory epithelium and the multicellular olfactory glands (OG) in the lamina propria are the two major secretory elements in the olfactory mucosa (OM). In the ventral OM, three layers of glands have been described (Getchell and Getchell, AChemS V, 1983 abs.). We employed morphometric analyses to characterize acinar cells of the superficial (sBG) and deep (dG) glands in control and drugtreated animals. Measurements of cell and secretory granule areas and heights were taken from cells which extended from the glandular margin to the lumen and contained a nucleus and secretory granules. A statistically significant difference (p=0.01) was found between cell areas of sBG and dG. The mean area of acinar cells in SG was  $291\pm107 \ \mum^2$  (x  $\pm$  S.D.) whereas that of acinar cells in SG was  $291\pm107 \ \mum^2$ . No significant difference was found in granule areas between cells of sBG and dG. The proportion of the area occupied by the secretory granules was significantly (p=0.01) greater in sBG (41±13\$) than in dG ( $26\pm144$ \$). Cell height was significantly greater (p=0.05) in acinar cells of dG ( $28\pm6 \ \mum$ ) than in acinar cells of sBG ( $24\pm6 \ \mum$ ). No significant difference was found in granule heights. Secretory granules occupy a significantly (p=0.01) greater proportion of the cell height in sBG ( $62\pm174$ \$) than in dG ( $47\pm16$ \$). We have examined the effects of the  $\beta$  -adrenergic agonist isoproterenol (IPR) on secretory granule content of the acinar cells. Injection of 30 mg/kg i.p. was associated with a significant (p=0.01) reduction of the areas and heights occupied by secretory granules in cells of sBG and dG. In sBG acinar cells, granule area was reduced from  $12\pm5 \ \mu$  to  $9\pm4 \ \mu$ , a 405 reduction, and in dG acinar cells from  $13\pm5 \ \mu$  to  $9\pm4 \ \mu$ , a 405 reduction. The magnitude of the effects of IPR on granule areas and heights in sBG and dG acinar cells are not statistically different; *i.e.*, acinar cells o

137.6 NA AND CA IMPULSES IN TASTE CELLS. <u>S. Roper</u>. Departments of Anatomy and Physiology, University of Colorado Health Sciences Center, Denver, CO 80262.

Cells in the taste buds of <u>Necturus maculosus</u> (mudpuppy) have recently been shown to generate action potentials in response to brief depolarizing current pulses passed through an intracellular microelectrode (Roper, 1983, Science). If chemical stimulation of taste cells produces receptor potentials which reach threshold and generate action potentials having a Ca component, the influx of Ca could trigger transmitter release at synapses between the taste cell and gustatory nerve terminals. Experiments have been conducted to characterize the ionic currents underlying action potentials in mudpuppy taste cells and to identify the cells which generate impulses. Lingual epithelium from the anterior region of the tongue was

Lingual epithelium from the anterior region of the tongue was removed with blunt dissection and mounted in a shallow chamber containing Ringer solution (<u>op. cit.</u>). Taste cells were identified with the aid of Nomarski optics and were impaled with KCl-filled microelectrodes having resistances of 50-150 megohns. In some experiments, microelectrodes were filled with 4% horseradish peroxidase (HRP) in 0.625 M KCl and 0.05 M Na cacodylate buffer (pH 7). The following experiments indicated that action potentials had a definite sodium component: (1) action potentials could be reversibly blocked by 1  $\mu$ M tetrodotoxin (TTX), (2) action potentials could be recorded in the absence of Ca, even if 5-10 mM An was present. Further, a substantial Ca component to action potentials in taste cells was demonstrated by the following: (3) impulses could be restored in the presence of 1 uM TTX if 5 mM tetraethylammonium was added, (4) impulses could be recorded in isotonic Cacl<sub>2</sub>.

Lastly, HRP was injected iontophoretically into cells after impulses were recorded. Excitability was verified after HRP injection to confirm that the microelectrode remained in the cell. To date, HRP has been localized in Dark (Type I) taste cells. Characteristics of Light (Type II) taste cells have yet to be determined.

These data indicate that at least Type I taste cells possess action potentials and that these impulses have both Na and Ca components. It is likely that the Ca component plays a pivotal role in chemosensory transduction and synaptic transmission between taste cells and gustatory axons. Supported in part by grants from the Procter & Gamble Company and NIH.

SALAMANDER OLFACTORY EPITHELIUM. <u>Gordon M. Shepherd and Britta</u> <u>Hedlund</u> (SPON: W. Cain). Section of Neuroanatomy, Yale Sch. of Medicine, New Haven CT 06510 Verv little is known about the primary molecular mechanisms

MUSCARINIC RECEPTOR-OLFACTORY RECEPTOR INTERACTIONS IN THE

Wery little is known about the primary molecular mechanisms underlying sensory transduction. The presence of muscarinic receptors on olfactory receptor cells in mouse olfactory epithelium was suggested by Hirsch and Margolis (1981). We have therefore investigated the possible role of muscarinic receptors in primary olfactory mechanisms as a part of a study correlating biochemistry and physiology of the salamander olfactory receptor cells. Muscarinic cholinergic receptors are present in the olfactory epithelium of the salamander, Ambystoma tigrinum, to an amount of 0.08 pmolgs/mg protein, measured via bighding of the muscarinic antagonist H-3-quinuclidinyl benzilate (H-3-QNB). Separation of the cilia produced a three to fivefold enrichment in muscarinic receptors, to 0.35 pmoles H-3-QNB are conlonger present in the olfactory epithelium. The results indicate that they are located on the olfactory receptor cell which are known to undergo degeneration after nerve transection. Further investigations have been initiated to analyze the possible functional role of the muscarinic acetylcholine receptors. These have included competition swides and gel electrophoresis. Diffegent dorant molecules were tested for their interaction with H-3-QNB binding. It was found that odorant molecules, in contrast to other neurotransmitter molecules, inhibit H-3-QNB binding at pharmacologically relevant concentrations (10<sup>-10</sup> M). The results suggest that the muscarinic receptor is closely related to the receptor that binds odor molecules. This suggests the possibility that acetylcholine may act to modulate the sensory transduction of odor molecules, or to affect other aspects of receptor cell function such as cell differentiation and ciliary motility. 137.7 ELECTROPHYSIOLOGICAL CHANGES IN CELLS OF THE OLFACTORY EPITHELIUM AFTER NERVE TRANSECTION. <u>Britta Hedlund, Leona</u> <u>Masukawa and Cordon Shepherd</u>, Section of Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510 The aim of these studies was to determine the normal electrophysiological properties of the cells in the olfactory epithelium and to determine what changes occur in these

characteristics after nerve transection. A unique feature of this sytem is that the receptor cells turn over continuously and therefore represents a good model to study the physiology of regeneration. We used nerve transection to intensify events occurring during regrowth of receptor cells.

Intracellular recordings from the olfactory epithelium of the tiger salamander, Ambystoma tigrinum, were taken from different cell types of the olfactory epithelium using high resistance microelectrodes. Records were from in vitro preparations of control tissue and tissue 1,2, and 4 weeks after olfactory nerve transection.

Three cell types were distinguished electrophysiologically in normal tissue. The first type is the supporting cell which gave no active response to direct current depolarization, but had a high resting membrane potential, about -90 mV, and a low input resistance, 10 Mohms. Another type of cell, the olfactory receptor cell, generated repetitive spike activity to direct current stimulus. Its resting potential was lower than the supporting cells but the resistance was often very high, 150-600 Mohms.

A third type of cell had the electrical properties of receptor cells but did not spike. These are tentatively called immature receptor cells.

In another group of animals the olfactory nerve was transected. We found two changes in the electrical properties of these cells after transection: One, the receptor cells at one and two weeks after transection show an inability to generate repetitive action potentials, and two, an altered form of the supporting cell, which we call type B, has abnormally high input resistance. Our findings indicate that the receptor cells capacity to spike may be correlated to the loss or regeneration of their axon. We tentatively conclude that changes in the electrical properties of the cells in the OE are occurring during cell degeneration and regeneration. 137.8 CULTURE AND IMMUNOCYTOCHEMICAL CHARACTERIZATION OF THE RAT OLFACTORY EPITHELIUM. J.Morgan\* and J.Hempstead\*. (SPON:A.Blume). Dept.of Physiol. Chem. and Pharmacol., Roche Institute of Molecular Biology, Nutley, N.J. 07110.

The olfactory epithelium contains a population of neuroblasts which have retained the ability to mature into terminally differentiated receptor neurons. Thus this tissue represents a unique model with which to investigate the control of neuronal development in adult mammals. Our major goal has been to develop culture conditions for the olfactory neuroblasts and there-with to define those parameters which are responsible for the regulation of their maturation. This report deals with both the characterization of olfactory epithelium cultures and the production of probes for the identification and purification of cell types from the olfactory neuroepithelium. In terms of cell identification we shall discuss the utility of two monoclonal antibodies,SUS-1 and LUM-1, which react specifically with sustentacular cells and the brush border of the epithelium respectively, as cell-specific markers. These antibodies show that while olfactory neurons degenerate following olfactory bulbectomy the sustentacular cell population is left intact. In addition to monoclonal antibodies specific plant lectins may be used to identify other cell populations both within the epithelium and in dissociated preparations of the tissue. Lectins thus present potential purification probes. Both dissociated and explant cultures of the rat olfactory

Both dissociated and explant cultures of the rat olfactory epithelium have been produced. These cultures have been examined immunocytochemically with a panel of specific antibodies for various cell types and in addition with a radioimmunoassay for the olfactory marker protein which is only present in the mature olfactory receptor neuron. Using density gradient centrifugation following mild enzymatic digestion of the rat epithelium several subpopulations of cells have been obtained and grown in culture. In conjunction with the administration of tritiated thymidine <u>in</u> <u>vivo</u> it has been possible to determine which of the various cell fractions had been actively synthesizing DNA at the time of their isolation. The ability to proliferate would be one of the predicted properties of the neuroblast.

The most common cell in culture is flat with perinuclear granulation. These cells are capable of division and migration and are also observed in cultures of cerebellum. There is a slower developing population of cells identified as fibrous astrocytes by morphology and immunocytochemical presence of glial fibrillar acidic protein (GFAP). A third class of cells are round and poorly adherent. They proliferate in early stages of culture and may be cloned by limiting dilution. After longer periods <u>in vitro</u> the cells become morphologically stellate astrocytes although they are at best weakly positive for GFAP.

A HORSERADISH PEROXIDASE STUDY OF OLFACTORY BULB CONNECTIONS IN 12-DAY-OLD RAT PUPS. <u>P.E. Pedersen, P.J. Jastreboff,</u>\* and G.M. Shepherd. Sect. of Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510.

The modified glomerular complex (MCC) is a group of distinct glomeruli situated at the dorsomedial junction of the main and accessory olfactory bulbs in the rat. It exhibits  $1^{4}\text{CO-2}$ -deoxglucose uptake when rat pups O-21 days of age suckle their dams, and has therefore been implicated in processing the odor cue(s) that mediates suckling (Greer et al., 1982). This functional evidence, in conjunction with preliminary histological evidence that the MGC matures earlier than the glomeruli of the main bulb, has led us to attempt to identify the peripheral and central origins of projections to this region in young pups.

A series of experiments using horseradish peroxidase (HRP) tract-tracing methods in 12-day-old rat pups has been conducted. Pressure injections of .01-.02 uL of 10% HRP (Type VI) were made via a glass micropipette inserted by a micromanipulator into the dorsomedial portion of the caudal aspect of the main olfactory bulb. Twenty-four to forty-eight hours later pups were perfused transcardially with aldehyde fixative. Tissue sections (40um) were analyzed by light microscopy after treatment with tetramethyl benzidine (TMB). Injection sites comprised almost the entire main olfactory bulb as well as the accessory olfactory bulb. Centrally, retrograde labeling occurred in the anterior olfactory nucleus, horizontal limb of the diagonal band, dorsal aspect of the piriform cortex, and corticomedial nucleus of the angugdala. These are well known sources of centrifugal fibers in adult rats. For localized injections, extracellular ionophoretic injections of wheat germ agglutinin HRP (.25%) were made 300u deep into the MCC by stereotaxic placement of a glass micropipette. The nasal cavities were subsequently decalcified for 2 days in .1M EDTA, sectioned, and reacted with TMB. The results have provided the first tentative evidence of retrograde labeling in olfactory epithelium following HRP injections in the olfactory bulb. We are currently analyzing the extent to which label in the epithelium represents input solely to the MGC region. Technical modifications for the use of HRP in neonates will be

137.10 TASTE BUD DEVELOPMENT IN THE HAMSTER. <u>I. J. Miller, Jr.</u> Department of Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27103 Recent experiments show that taste responses from neon

Recent experiments show that taste responses from neonatal rodents differ qualitatively from those of adult animals. The objective of this study was to examine the number of taste buds in specific regions of the oral cavity in the hamster from birth to maturity. The vallate and foliate papillae are the easiest to study because of their high density of taste buds, but other regions are examined. Animals born in the laboratory were sacrificed from the first postnatal day to 150 days of age. Tissue was excised from the region of the vallate papilla, bilateral foliate papillae, soft palate, epiglottis and from the anterior portion of the tongue containing fungiform papillae to be prepared for light microscopy. Complete serial sections were studied for each region, and taste buds were counted by the presence of a taste pore. Preliminary results show no taste buds present on the vallate papilla at birth, and the troughs of the vallate papilla are unopened. Vallate papillae of hamsters aged 10 - 26 days contained from 60 to 106 (N=5) total taste buds with a mean of 78  $\pm 4$  (SEM). Adult animals 120 - 150 days of age contained a mean total of 168  $\pm 7$  (N=4) taste buds in the vallate papilla. The foliate papillae consist of 5 or 6 troughs on each lateral side of the tongue. Hamsters 19 to 26 days totaled 115 + 2 (N=6) per side. On soft palates of 4 young hamsters aged 19 - 26 days were found a mean total of 63  $\pm 2$  taste buds, while two adult animals add 22 - 26 days, and those of 2 animals aged 120-150 days averaged 74 taste buds. Fungiform papillae contained a mean total of 67 taste buds per side. A comparison between taste bud such an verage of 67 taste buds per side. A comparison between taste bud seinenvated by the glossopharyngeal nerve will show whether the regions and nerves develop at similar or different rates. Experiments are in progress with litter mates sacrificed at staged intervals to see if the increase in taste bud totals by region is a function of age for closely related animals.

137.9

137.11 GUSTATORY RECEPTOR SUBPOPULATION STIMULATION: RESPONSES OF NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT OF THE RAT. <u>S. Travers, C. Pfaffmann, and R. Norgren.</u> The Rockefeller University, New York, N.Y. 10021. Although there are at least six gustatory receptor subpopula-

tions, virtually all central taste neurophysiology is based upon sapid stimulation of only one of these receptor groups, the anterior tongue. We have developed a preparation and modified stereotaxic apparatus that permits visualization and independent stimulation of five of the six gustatory receptor subpopulations: (SP), foliate papillae (FOL), and circumvallate papilla (CV). (Taste buds on the epiglottis are not visible in this preparation.) In our initial experiments, we have assessed the degree of receptor group convergence on and chemical sensitivity of single neurons in the nucleus of the solitary tract (NST) of the rat. Following isolation of a single cell, the AT, NID, FOL and SP were stimulated individually with a mixture of the four basic taste stimuli (1.0M sucrose, 0.3M NaCl, 0.03M HCl and 0.01M OHCl). After determining the gustatory receptive field for the neuron the receptor groups eliciting responses were tested further with each of the four basic stimuli. Responsiveness to CV stimulation was often tested last since the apparatus used to stimulate those receptors interfered with access to the other parts of the oral cavity. Electrical taste stimulation through small porous-glass tipped probes was sometimes employed to verify the location of the taste receptive field for a neuron. Forty single neurons have been tested for their responsiveness to AT, NID, SP and FOL stimulation. Nineteen of these cells were also tested for their responsiveness to the four basic taste stimuli tested for their responsiveness to the four basic tasts stimuli and 12 were tested for CV responsiveness. With the exception of cells responding to stimulation of the NID, most neurons (n=25) responded to stimulation of a single tasts receptor subpoula-tion, the AT, SP or FOL. Cells that responded to the NID (n=13) also responded to chemicals applied to the AT, but often with a also responde to chemicals applied to the AL, but often with a different chemical sensitivity. Preliminary analysis of the data indicates that sucrose is a more effective stimulus for the NID than for the AT. Multi-unit and single-unit responses to stimu-lation of the AT and NID were recorded anterior to responses to stimulation of the FOL and CV in the NST. Responses to stimulation of the SP were intermediate to the other two groups of re-sponses. Recent anatomical experiments (Hamilton and Norgren, 1983) demonstrate that the chorda tympani and greater superficial petrosal nerves, which innervate the AT and palate, respectively, distribute in the NST anterior to the distribution of the branch of the glossopharyngeal nerve that innervates the CV and FOL. Supported by NIH MH15125, NS07021, NS10150 and NSF BNS8111816.

137.12 SELECTIVE RESPONSES TO ANIMAL-PRODUCT ODORS IN THE NEOCORTICAL NEURONS. N. Onoda\* and K. Imamura\* ( SPON: K. Maekawa ). Dept. of Physiol., Sch. of Med., Gunma Univ., Maebashi, Gunma 371, Japan.

during 011., Maebashi, Odor responses of neocortical neurons were studied in a restricted area in the lateral half of the prefrontal cortex close to the frontal pole of the hemisphere in rabbits. Odor-sensitive neocortical neurons responded predominantly to biologically derived odors (urine, feces, and dry food for rabbit). Most (90%) of those same neurons failed to respond to pure chemical odors. Even in the absence of the trigeminal and/or vomeronasal inputs, some neurons were observed to respond to animal-product odors. Some odor-sensitive neurons were affected by electrical stimulation of the mediodorsal thalamic nucleus (MD). When HRP was injected into the neocortical olfactory projection area (OPA), HRP-labelled cell bodies were observed in various regions (Fig.E); the medial segment of the MD, the pyriform cortex (PC), the entorhinal cortex (EC), the olfactory tubercle (OIT), and the anterior olfactory nucleus (AON). The OPA was not overlapped by the sensory-motor cortex. When these results are compared with those obtained from other structures (Fig. A-D), the percentage of neurons responded

of neurons responded exclusively to animalproduct odors (indicated by A in abscissa of each histogram) becomes more prominent in the higher structures. We can safely conclude that selective responses to animal-product odors are to be segregated through the olfactory pathway from the lower to the higher structures.

- B: both animal-product & pure chemical odors PN: endopyriform nucleus
- LOT: lateral olfactory tract
- OB: olfactory bulb P: pure chemical odors

#### FEEDING AND DRINKING: NEUROPHARMACOLOGY

138.1 NALOXONE ANTAGONISM OF SUCKLING IN GENETICALLY OBESE AND LEAN MOUSE PUPS. <u>H. L. Sinha\* and L. M. Wilson</u>, Dept. of Psychology, Univ. of Manitoba, Winnipeg, MB R3T 2N2.

The findings that pituitaries of adult genetically obese mice (C57Bl/61, ob/ob) contain higher levels of  $\beta$ -endorphin than those of lean mice and hyperphagia in adult ob/ob's can be decreased differentially by naloxone compared to the food intake of lean mice (Margules, D.L., et al., <u>Science</u>, 202:988, 1978) suggests that endorphins play a role in overeating in this strain. Opiate systems are present before birth in rodents, and, if involved in feeding regulation, their contribution to the ob/ob's development of hyperphagia may be reflected in differential suckling behavior in preobese and lean pups. Although hyperphagia in ob/obs does not appear to develop until after weaning (Rath, E.A. & Thenen, S.W., J. Nutr., 109:840, 1979)with increased availability of food, whether hyperphagia antedates weaning when early constraints on feeding are altered remains controversial (Wilson, L.M., et al., <u>Develop. Psychobiol</u>., 14:67, 1981). In this study the effects of naloxone(donated by Endo Labs: 0 (.15M saline), 0.3, or 1.0 mg/Kg body weight) on suckling beha-

In this study the effects of naloxone(donated by Endo Labs: 0 (.15M saline), 0.3, or 1.0 mg/Kg body weight) on suckling behavior were investigated in preobese and lean mouse pups at 6, 15, and 24 days of age. Intact litters (n=36) were tested in either a fed (left with dam until testing) or fasted (20 h with a nonlactating virgin female) condition at each age. Litters of fed and fasted pups were randomly assigned to 1 of 3 injection groups, to which the experimenter was blind for the duration of the study. Before testing, litters were removed from their dams; pups were reflexively micturated and defecated, and weighed. Each pup was given its appropriate body weight dose of saline or naloxone SC. Pups were tested 15 mins. postinjection in pairs or triads on their own anesthetized dams (50 mg/Kg Nembutal IP). Latency to nipple-attach and duration of nipple attachments (secs.) were recorded during 5-min. tests. Pups' phenotypes were identified visually at 55 days.

Obese pups nipple-attached sooner (p<.03)than lean pups. Overall obese pups suckled longer than lean pups (p<.01), although obese pups suckled longer only at 15 and 24 days. Fasted pups attached sooner and suckled longer than fed pups (p<.0001). Although increasing naloxone doses tended to lengthen initial attachment latencies (p=.08) and to decrease total suckling time (p=.057), it systematically depressed suckling duration and increased attachment times only in the fed condtions (p's<.01). A significant Drug Dose X Age interaction (p<.0001) for both attachment latency and suckling duration emphasized that naloxone depressed suckling behavior at 6 days (at both doses) and at 15 days (at 1.0 mg/Kg), but didn't systematically affect pups at 24 days, when suckling no longer constitutes the chief means of ingestion. Age X Drug Dose X Phenotype effects show differences for lean and preobese pups. 138.2 THE EFFECTS OF MORPHINE SULFATE ON THE FREQUENCY, SIZE AND DURATION OF FEEDING AND DRINKING BOUTS IN THE RAT. <u>A. Riley,</u> <u>D. West, A. Sipel\*, and S. Woods</u>. Department of Psychology, University of Washington, Seattle, Washington 98195. Although rats injected with morphine sulfate typically show an intermediate of the subscript of the subscript of Newson's Richard

Although rats injected with morphine sulfate typically show an increase in feeding and drinking (Morley et al., <u>Neurosci. Biobeh.</u> <u>Rev.</u> in press; Sanger, <u>Appetite</u>, <u>2</u>, 193-208, 1981), it is unclear how this increase is effected. For example, it is not known whether the opiates increase the frequency, size or duration of feeding and drinking bouts.

To address these questions, in the present experiment food and water consumption of six free-feeding rats was monitored via a microccumputer every 5 sec for 24 hours following the administration of 40 mg/kg morphine sulfate (West et al., <u>Physiol. Behav.</u>, in press). Morphine injections were given at 1230 h each day for 14 consecutive days.

Following the first morphine injection, the frequency, size and duration of feeding and drinking bouts were significantly reduced for the entire 24-hour observation period. With repeated daily exposures to morphine, the patterns of food and water consumption changed dramatically. For example, by Day 14 all rats significantly increased the size and duration of feeding bouts in the six hours following morphine injection. The frequency of feeding bouts, however, was not affected in this interval, although over the remainder of the 24-hour observation period, the frequency of these bouts was reduced to approximately 50% of the preinjection baseline. By Day 14, all rats significantly increased the <u>frequency</u> of drinking bouts in the six hours following drug exposure, although the size and duration of these bouts were unaffected. Over the remainder of the 24-hour observation period, all rats decreased the frequency of drinking bouts to approximately 20% of their preinjection baseline. Although these patterns of feeding and drinking resulted in significant increases in food and water intake for the first six hours following morphine administration, the 24-hour food and water intake either remained below or was similar to baseline levels.

These data extend the earlier work demonstrating that opiates increase food and water intake and further indicate that the manner in which this increase occurs is different for food and water, i.e., morphine increases bout size and duration for feeding and bout frequency for drinking.

CHOLECYSTOKININ (CCK) RECEPTOR BINDING IN SHEEP BRAIN. 138.3 M. A. Della-Fera, R. N. Solomons\* and C. A. Baile. Univ. Pennsylvania Sch. Vet. Med., Kennett Square, PA 19348.

CCK peptides in brain have been implicated in several CNS-controlled functions, eg., control of feed intake, gastrointestinal function, metabolism (through intake, gastrointestinal function, metabolism (through control of secretion of such hormones as insulin and adrenal cortical steroids), thermoregulation and nociception. CCK is localized in discrete areas of the brain, particularly in periventricular areas and cortex. Specific high affinity binding sites for CCK appear to follow the same pattern of localization as CCK-containing neurons. Because of the evidence supporting a physiological role for brain CCK in satiety in sheep, it was of interest to determine 1) the pattern of localization of CCK peptides and binding sites in sheep brain, and 2) whether changes in either CCK concentration or binding affinity occur in particular brain areas during feeding and fasting. in particular brain areas during feeding and fasting. In the first experiment 10 sheep were killed within two hrs of a meal, and their brains were removed and dissected immediately. Tissue was removed bilaterally from 18 brain sites, including specific cortical, dissected immediately. Tissue was removed bilaterally from 18 brain sites, including specific cortical, hypothalamic, and brain stem areas. CCK peptides were extracted from tissues of one side of the brain, while tissues from the other side were used for CCK binding assays. In the second study groups of 12 sheep each were killed either immediately after a meal or after a 4- or 24- hr fast. Brain tissues were treated as above. Results from receptor binding studies showed regional differences in distribution of CCK receptor numbers. Frontal cortex, olfactory bulb and ventromedial hypothalamus (hth) showed greatest binding, while anterior preoptic area had moderate levels of binding, and lateral and posterior hth had very low levels of binding. There were no differences for any area in CCK receptor number or affinity between fed and fasted states. CCK content in specific brain areas and the effect of feeding and fasting on CCK content is presently being determined. On the basis of the heterogeneity in the regional distribution of CCK receptors, these results support a role for CCK as a neurotransmitter or neurohormone in sheep brain. The data do not indicate, however, that alteration in CCK receptor binding occurs in response to feeding and fasting. Supported by NIH NS17670 and Sloan Fnd. Fellowship BR2190.

## ESTROGEN-GLUCOSE SYNERGISM IN THE CONTROL OF LONG 138.5 TERM BODY WEIGHT IN RATS <u>C. Wayne Simpson\*.</u> (Spon: Thomas J. Imig ) Department of Biology and School of Medicine, University of Missouri-

Kansas City, Kansas City, Missouri 64410

Several reports have described alteration in the catecholamine levels in anterior hypothalamus when estrogen level is altered. In a previous report we demonstrated that catecholamine elicited eating from an anterior hypothalamic site was inhibited at increasing estrogen concentration. The effects however were specific to short-term feeding episodes. Catecholamine injections did not alter 24 hour food intakes or body weights. Estrogen injections above a threshold dose of 1 ug/day did significantly decrease 24 hour food intakes and 24 hour body weights. In this series of experiments we investigated the hypothesis that EB may interact with other putative satiety factors at hypothesis that EB may interact with other putative satiety factors at estrogen-sensitive brain sites to mediate body weight loss. Ovariectomized rats were implanted with a unilateral cannula in LPO, VMH or Stria medullaris sites in different groups of animals. The groups were maintained and tested on <u>ad. lib.</u> food and water conditions. In an initial dose-response experiment it was determined that 1 ug EB/day represented the threshold dose to effect 24 hour body weight. Animals were injected peripherally with lug/day EB or oil vehicle and centrally with glucose 20%/ul, CCK lug/ul, or GABA lug/ul or 10 ug/ul all in a lul volume in separate experiments. The combination of 1 ug/day EB and a 1 ul injection of glucose in all of the estrogen sensitive site resulted in significant changes in 24 hour food combination of 1 ug/day Eb and a 1 u injection of glucose in all of the estrogen sensitive site resulted in significant changes in 24 hour food intakes. The VMH group ate (p < .05), the LPO group ate significantly less (p < .05) and the SM group also ate significantly less (P = .02) in the 24 hours following the dual injections. Central injections of a 20% glucose solution in the same site without simultaneous EB injections did gue cost solution in the same site without simultaneous EB injections on to result in any significant changes in the 24 food intakes for any of the three groups. Comparison of the change in 24 hour body weights following EB and glucose compared to EB and vehicle injections revealed a significant (p < 01) reduction of body weight in the LPO injected group. In addition to long term food intakes some feeding at other time intervals was also altered by these injections. In the LPO group EB and glucose injections eignificantly reduced by the provided by the provided of group EB and glucose injections significantly reduced 1 hour (p=.05), 3 hour (p.<.05) and 6 hr. (p<.01) food intakes. Short term food intakes 1,3 and 6 hrs. were not altered by this injection series in either the SM or the VMH groups. The other satiety factors CCK and GABA produced a different pattern of results when combined with peripheral EB injections. These injections resulted in decreases in short-term intakes only in the treatment group. These data imply that the combination of a threshold dose of EB, i.e., lug/day can synergize at estrogen sensitive brain sites, with a variety of putative satiety signals to alter both short-term and long-term feeding mechanisms.

- AMYGDALIN PREVENTS ALLOXAN-INDUCED LOSS OF GLUCOPRIVIC FEEDING IN 138.4
- AMYGDALIN PREVENTS ALLOXAN-INDUCED LOSS OF GLUCOPRIVIC FEEDING IN RATS. J.M. Murnane and S. Ritter, College of Veterinary Medicine, Washington State University, Pullman, WA 99160-6520. Alloxan is a toxic substance which destroys pancreatic beta (B) cells. It is now known that intracerebroventricular alloxan also damages brain cells involved in glucoprivic feeding in rats. Al-though the mechanism of alloxan's cytotoxicity has not been estab-lished either for brain cells or B cells, a variety of substances have been identified which protect B cells against alloxan-induced damage. Previously we reported that D-glucose, which blocks the effects of alloxan on the B cell, also prevents impairment of glucoprivic feeding by alloxan. In this experiment, we tested 3 additional substances for their ability to protect the glucoprivic feeding response from alloxan-induced damage. Evaluation of the feeding response from alloxan-induced damage. Evaluation of the protective effects of these substances on this centrally-mediated protective effects of these substances on this centrally-mediated response should indicate whether the mechanism of alloxan's action on brain glucoreceptor cells is similar to its action on B-cells. L-glutamine (15 mM) and amygdalin (15 mM), which protect the B cell against alloxan, and L-glucose (3 M) which does not, were injected intraventricularly to identify direct effects of these

injected intraventricularly to identify direct effects of these agents on feeding or blood glucose. Subsequently, they were co-administered into the IV ventricle with alloxan (200 ug) in 5 ul of saline. After recovery, feeding and blood glucose responses were measured after 2-deoxy-D-glucose (206, 250 mg/kg,s.c.), 5-thioglucose (5TG, 120ug/3ul, IV ventricle) and saline. When administered alone, amygdalin raised blood glucose 35 mg% above baseline (p < .01). When coadministered with alloxan only amygdalin protected the glucoprivic feeding response from alloxan-induced damage. L-glucose and L-glutamine did not attenuate alloxan-induced deficits. Alloxan-treated rats ate 35% and 30% of control levels after 2DG and 5TG, respectively (p < .01). Alloxan/L-glucose rates ate 25% and 11% and alloxan/L-glutamine rats ate 27% and 21% of control intake after 2DG and 5TG were not impaired by any treatment. any treatment.

The effects of L-glucose and amygdalin on alloxan-induced impairment of glucoprivic feeding are consistent with results ob-tained in studies of the B cell. The fact that amygdalin, a potent free radical scavenger, protects against B cell damage has been interpreted to suggest that alloxan's cytotoxicity is due to free radical recoviding the provention of the protect and the protect of the suggest that alloxan's cytotoxicity is due to free radical scave and the protect of the prote radical peroxidation. In our experiment, however, amygdalin's pro-tective action could have been mediated indirectly by elevation of blood glucose. Furthermore, L-glutamine, which antagonizes allox-an's action on the B cell, failed to protect glucoprivic feeding even though L-glutamine increases the generation of reducing equivalents. Therefore, the cytotoxic action of alloxan which im-pairs glucoprivic feeding may not be identical to its cytotoxic mochanism in the R cell. mechanism in the B cell.

EFFECTS OF INTRAVENOUS GLUCOSE AND MANNITOL ON CATECHOLAMINE 138.6 EFFECTS OF INTRAVENOUS GLUCOSE AND MANNIPLE ON CAILCHOLARINE LEVELS OF THE RAT. E. C. Lotter and R. G. Campbell\*. Nazareth College and The University of Rochester, Rochester, N.Y. Administration of an intravenous (IV) glucose pulse is known to increase plasma concentrations of total catecholamines. Moreover, we have previously reported that an IV infusion of glucose resulted in a significant increase of plasma glucose and incuit and no charge of plasma glucose. The present and insulin and no change of plasma glucagon. The present study examines the effects of IV glucose and that of mannitol, a non-absorptive sugar, on plasma glucose, epinephrine and norepinephrine levels.

Five-hr-food-deprived male Wistar rats (n=8) with an indwelling jugular catheter were randomly injected with glucose or mannitol (20%/.5 ml) over a three-minute period and blood samples mainticol (204,5 ml) over a three-minute period and blood samples were collected over 60-minutes. Water but not food was available throughout the experiment. Glucose injections resulted in an immediate increase of plasma glucose and norepinephrine with no significant change of epinephrine. The administration of mannitol resulted in an immediate and significant decrease of plasma glucose and a small non-significant increase of plasma norepinephrine. No change in epinephrine levels was observed In both the glucose and mannitol group, plasma glucose and epinephrine returned to baseline values at the end of 60-minutes. In the glucose-infused-group, norepinephrine returned to baseline levels 5-minutes after the injection, whereafter, a second peak was observed at the end of 60-minutes. In the mannitol group, was observed at the end of 60-minutes. In the maintical group, a small bi-phasic increase of norepinephrine was observed within the first 15-minutes. At 60-minutes, norepinephrine levels were below baseline values. The bi-phasic ricrease of nor-epinephrine is similar to the bi-phasic release of insulin observed when rats eat a carbohydrate meal.

These findings are of interest in view of the inhibiting effects of catecholamines on insulin release and suggest an acute nutritional shift (i.e., increased norepinephrine turnover) and/or a fluid shift.

ALPHA-NORADRENERGIC PROJECTION BLOCKADE: EFFECTS ON DRINKING BE-138.7 HAVIOR AND CARDIOVASCULAR RESPONSES TO ANGIOTENSIN II IN THE CHRONIC AWAKE RAT. D. L. Jones. Depts. Physiology and Medicine, University of Western Ontario, London, Ontario, Canada, N6A 5Cl. Catecholaminergic projections to the forebrain have been impli-cated in the control of pressor and drinking responses. Previous studies implicated the dopaminergic projections to the striatal complex in drinking responses (Camacho & Phillips, 1981, Am. J. Physiol. 240:R106; Jones & Mogenson, 1982, Can. J. Physiol. 60: 720). The noradrenergic projections to the hypothalamus have been implicated in the pressor responses to central angiotensin II administration (Camacho & Phillips, 1981, ibid). Injections of Ang-iotensin II have also been shown to increase the synthesis (Alpers et al., 1982, Neurosc. Abstr. 8:421) and turnover (Summers & Phillips, 1983, Am. J. Physiol. 244:R257) of hypothalamic nora-drenaline. These studies could not distinguish responses associated solely with pressor responses from those involved in the drinking responses. Recently Bellin et al., (1982, Neurosc. Abstr. 8:226) found that relatively selective 6-OHDA lesions which reduced hypothalamic noradrenaline content by 70-90% blocked both drinking and pressor responses to injections of angiotensin II. A recent study (Jones, 1983, Fed. Proc. 42:1126) also found that blockade of noradrenergic projections to the rostral hypothalamus attenuated angiotensin II induced drinking in awake animals and reduced pressor responses in anaesthetized animals. These experi-ments extend the preliminary studies to investigate in the chronic awake animal the effects of pretreating the rostral hypothalamus with thetalarise on the dupling and precent recomprecision with phentolamine on the drinking and pressor responses induced by central angiotensin II administration.

Male Wistar rats were prepared with a chronic indwelling femor-al arterial cannula and guide cannulae implanted bilaterally above the lateral ventricle and rostral hypothalamus. Animals were tested on separate days for responses to saline pretreatment of the hypothalamus and one dose of phentolamine (2.5, 12.5, 25.0 or 125.0 µg) followed immediately by ventricular administration of angiotensin II (25 pM). Pretreatment of the rostral hypothalamus with phentolamine attentuated the pressor and drinking responses to central angiotensin II in a dose dependent manner. Sites lateral or posterior by 1-2 mm had greatly diminished blockade. Some animals exhibited increased activity and chewing behavior associ-ated with elevated blood pressures and heart rates but did not drink. These results sugguest that α-noradrenergic projections to the rostral hypothalamus subserve both the drinking and pressor responses elicited by central angiotensin II administration. F Further, they suggest that the region involved in the pressor res-ponse may have a more restricted distribution in the rostral hypohalamus

(Supported by the Medical Research Council of Canada).

a2-ADRENERGIC RECEPTORS IN THE PARAVENTRICULAR NUCLEUS MEDIATE 138.9 FEEDING INDUCED BY NOREPINEPHRINE AND CLONIDINE. L.A.Marino\*, M.D.DeBellis\*, and S. F. Leibowitz (SPON: D. Micco). Lab. of Neuropsychopharmacology, The Rockefeller Univ., New York, N.Y. 10021

The paraventricular nucleus (PVN) of the medial hypothalamus is The paraventricular nucleus (PVN) of the medial hypothalamus is the most effective site for feeding induced by central norepineph-rine (NE) injection. The PVN is also found to respond to the  $\alpha$ -adrenergic agonist clonidine (CLON). The present study utilized a variety of  $\alpha$ -adrenergic antagonists to determine the specific

 $\alpha\text{-adrenergic}$  receptor subtype mediating this phenomenon. Using the brain-cannula technique in satiated male albino rats, the specific  $\alpha_1$ -adrenergic antagonists corynanthine and prazosin, the specific  $\alpha_2$ -adrenergic antagonists yohimbine and rauwolscine, and the general a-adrenergic antagonist phentolamine were administered into the PVN 30-45 minutes prior to PVN injection of either NE (40 nmoles) or CLON (20 nmoles). Blocker doses of 12.5 to 100 nmoles were tested. Consistent with previous findings, the general α-adrenergic

antagonist phentolamine was found to essentially abolish (-82%) the NE eating response. Clonidine-induced feeding was also significantly attenuated by phentolamine. Tests with the specific  $\alpha_1$ antagonists, corynanthine and prazosin, failed to reveal any blocker-induced attenuation of NE and CLON feeding and, in fact, showed some enhancement of NE and CLON eating with corynanthine. In contrast, the  $\alpha_2-adrenergic$  antagonists yohimbine and rauwolscine significantly attenuated, by 50-75%, both NE- and CLONinduced feeding. In a separate experiment, it was shown that PVN injection of the  $\alpha_2$  antagonist yohimbine (25-100 nmoles) significantly suppressed the effects of systemically administered CLON (25  $\mu g/kg)$  by 40-80%.

The present study demonstrates that: 1) PVN injections of NE and CLON induce feeding via  $\alpha_2$ -adrenergic receptors located in this nucleus, and 2) feeding induced by systemically administered CLON is also mediated, at least in part, by these PVN a2-adrener gic receptors.

DORSAL PERIVENTRICULAR FIBER SYSTEM DESCENDING FROM PARAVENTRICU-138.8 LAR NUCLEUS MEDIATES FEEDING INDUCED BY NOREPINEPHRINE AND CLONI-

LAR NUCLEUS MEDIATES FEEDING INDUCED BY NOREFINEPHRINE AND CLONI-DINE. G. F. Weiss\* and S. F. Leibowitz. Lab. of Neuropsychophar-macology, The Rockefeller Univ., New York, NY 10021. Hypothalamic injection of norepinephrine (NE) is known to in-duce feeding in the satiated rat. This effect is found to be strongest in the paraventricular nucleus (PVN). Clonidne also elicits a feeding response when injected into the PVN, and is be-lieved to be acting through the PVN noradrenergic feeding system. In the present study, the objective was to map out the course taken by the PVN efferent fibers that mediate NE and clonidine feeding. This was accomplished by investigating a variety of bilateral coronal knife cuts, in various forebrain and midbrain regions, and determining their impact on PVN noradrenergic-induced eating.

Male albino Sprague-Dawley rats (n=80) with chronic brain cannulas received, on separate days, PVN injections of saline, NE (40 nmoles), and clonidine (30 nmoles. Baseline responsiveness to these drugs, relative to saline control scores, was determined prior to administering the coronal knife cut. Animals were tested 3 weeks before and 6 weeks after knife cut. Sham-operated rats showed stable drug responses throughout the testing periods. Large cuts 1 mm rostral to the PVN, extending from midline to 1.1 mm lateral, had no impact on the animals' responsiveness to NE and clonidine. Large coronal knife cuts severing most of the midbrain tegmentum, with the exception of the central grey region, also produced no significant change.

In contrast, knife cuts located in the periventricular region of the thalamus and in the midbrain central grey were bothsuccess-ful in significantly attenuating the NE and clonidine eating re-sponses, by 70% and 60%, respectively. Based on these findings, it is suggested that the PVN efferent

fibers mediating NE- and clonidine-induced eating course dorsally into the thalamic periventricular area and caudally through the midbrain central grey. Additional evidence suggests that within the pons, the fibers then radiate ventrolaterally as they course toward the dorsal medulla.

138.10 CLONIDINE EFFECT ON HYPOTHALAMIC NORADRENERGIC CLONDINE EFFECT ON HYPOTHALAMIC NORADRENERGIC MECHANIAMS: INVESTIGATIONS OF CATECHOLAMINE TURNOVER AND EATING BEHAVIOR. M. Jhanwar-Uniyal\*; J. McCabe; B.E. Levin and S.F. Leibowitz (SPON: N.E. Miller). The Rockefeller Univ., New York 10021 and Dept. of Neurosci., N.J. Med. School, Newark, N.J. 07103 07103.

A noradrenergic mechanism in the hypothalamic paraventricular A horadrenergic mechanism in the hypothalamic paraventration nucleus (PVN) is believed to be involved in the stimulation of eating behavior. Investigations in this laboratory with the a2-adrenergic agonist, clonidine (CLON) indicate that this compound is a potent stimulator of eating and that it may be acting via the PVN noradrenergic system

system. Peripheral injection of CLON produces a reliable and dose-dependent eating response in the rat, at doses ranging from 12.5 to 50  $\mu$ g/kg. This stimulatory effect of peripheral CLON, like the eating response induced by central norepinephrine (NE), is found to be abolished by discrete electrolytic lesions in the PVN. Lesions dorsal to the PVN, in the dorsomedial nucleus (DMN), or the perifornical lateral hypothalamus (PFH), produce no change in CLON's action. CLON injected directly in the PVN is also effective in stimulating eating. This PVN CLON eating response, like that induced by PVN NE injection and by peripheral CLON, is associated with a preferential increase in carbohydrate ingestion. ingestion.

Using the radioenzymatic assay as described by Levin et al. (1980), the effect of peripheral CLON administration (50  $\mu$ g/kg) on the levels and turnover of NE, epinephrine (EPI), and dopamine (DA), in five hypothalamic areas (PVN, DMN, ventromedial hypothalamus, medial preoptic nucleus, PFH) and four extrahypothalamic areas (frontal cortex, locus coeruleus, cerebellum, hippocampus), were examined. The turnover was estimated in rats pretreated with alpha-methyl-p-tyrosine. CLON affected NE levels in only one brain area, namely, the PVN, where endogenous NE was decreased by 63%. EPI levels were increased by 46% in the PFH. The turnover of NE was significantly decreased in all areas examined, with the exception of PVN and locus coeruleus, where no change was seen. In the PFH, as opposed to the other brain areas, turnover of EPI and DA, as well as NE, was reliably reduced.

These data suggest that the well-established inhibitory effect of CLON on brain NE turnover does not occur in the PVN, and therefore may not be involved in CLON's stimulatory action on feeding. One possibility is that CLON, like NE, potentiates food intake by acting upon postsynaptic a2-adrenergic receptors in the PVN. (This research was supported by grant MH22879 and by funds from the Whitehall Foundation). 138.11 THE ROLE OF ADRENERGIC AND DOPAMINERGIC SYSTEMS IN THE PERI-FORNICAL HYPOTHALAMUS IN THE DEVELOPMENT OF APPARENT ANOREXIC TOLERANCE TO D-AMPHETAMINE IN RATS. P. Bhakthavatsalam\*, A. Pourany\* and M.N. Ghosh\* (SPON: David E. Levy). Depts. of

IDLEARNE ID D-APTIFICIATIONE IN NAIS. F. DIMARCHAVAGEBALAMY, A. POURAMY and M.N. Ghosh\* (SPON: David E. Levy). Depts. of Pharmacology and Anatomy, JIPMER, Pondicherry, 605006, India. The central mechanism of the apparent anorexic tolerance to amphetamine was studied in rats by testing beta-adrenergic and dopaminergic (DA) receptor sensitivity in the perifornical lateral hypothalamus (PFH), which is reported to be the most sensitive site for catecholamine (CA) and amphetamine-induced anorexia (S.F. Leibowitz, 1975, 1978). In addition, certain presynaptic manipulations, such as CA synthesis blockade and neurotoxin lesions, have been conducted to investigate the differential influence of the dopaminergic and adrenergic mechanisms.

The tolerance pattern to PFH amphetamine injection was essentially the same as that reported earlier with s.c. amphetamine injection, i.e., a persistent anorexia with no evidence of tolerance in the first 2h of the test, whereas the second 2h exhibited overeating which increased progressively on subsequent treatments. Thus, the two 2h periods combined and plotted as a 4h measurement showed an apparent tolerance development.

Isoprenaline, adrenaline and noradrenaline (NA), which produce anorexia in the PFH via beta receptor stimulation, exhibited steady anorexic responses on all days of chronic injection. This contrasts with PFH injection of DA, which gradually lost its effectiveness. These results show a subsensitivity of anorexia-mediating DA receptors, rather than of beta-adrenergic receptors. Selective bilateral depletion of DA in the PFH, with 6-OHDA injection, resulted in a significant reduction of anorexia induced by peripheral amphetamine administration and markedly delayed the time of onset and completion of the apparent tolerance. Catecholamine synthesis blockade studies with PFH injection of alpha-methyl-p-tyrosine and Fla-63, showed that both NA and DA are necessary for the anorexia and that these two systems in some manner interact to cause the development of the observed tolerance.

This study suggests that both NA and DA systems in PFH mediate amphetamine anorexia; however, it is the DA system which appears to be predominantly responsible for the observed pattern of anorexic tolerance to amphetamine. 138.12 DOPAMINERGIC MODULATION OF CONSUMMATORY BEHAVIOR IN HUNGRY AND SATED RATS. <u>H.R. Friedman\* and E.E. Coons\*</u> (SPON: C. Bruce).

Intracranial injection of dopamine (DA) were administered to sated and 22-hour food-deprived rats to study the influence of DA upon consummatory behavior. In hungry rats, DA produced a longlasting potentiation of food intake. Feeding was elevated on the 1-hour test with food which followed the DA injection and on postdrug tests (occuring at 4 day intervals) conducted as long as 16 days after the drug injection. The longevity of this effect appeared to be temporally determined because potentiated food intake was not recorded when post-drug testing was postponed beyond 16 days. Potentiated feeding after DA was specific to the testing situation and was antagonized by DA receptor blockade.

The brain sites at which DA produced this facilitatory effect coincided with the trajectory of the medial forebrain bundle and other basal forebrain zones through which DA-containing and hedonic-afferent fibers course. Injections at other posterior diencephalic sites produced a decrease in food intake on the DA injection test date. However, on post-drug tests, food intake was somewhat elevated suggesting that brain site determined the polarity of the immediate effect of the drug whereas the longevity of this effect was, more generally, facilitatory to feeding.

In contrast, DA injections at brain zones associated with facilitated feeding in hungry rats, <u>attenuated</u> spontaneous food intake on drug and post-drug tests when injected to sated rats. Again, this suppressive effect of the drug in sated rats was specific to the testing situation because later, hungermotivated food intake was not affected. However, when DA was administered to rats at the conclusion of a test-meal after a period of food-deprivation, hunger-motivated food intake on the next post-drug test was attenuated. Additional studies showed that the magnitude and polarity of the immediate effect of DA was more dependent upon the temporal contiguity of injection and testing conditions than the longevity of the influence of DA upon feeding.

These data show that intracranial injections of DA at circumscribed brain regions potentiated the expression of the consummatory responses which were motivationally prepotent at the time of the DA injection. It is suggested that brain DA activity normally may modulate the hedonic responsiveness of the rat to consummatory stimuli.

#### **REFLEX FUNCTION I**

- DYNAMICS OF THE TONIC NECK REFLEX. V.J. Wilson and K. Ezure.\* Rockefeller University, New York, N.Y. 10021 We studied the dynamics of the tonic neck reflex of 139.1 decerebrate cats by rotating the head sinusoidally in roll and recording EMG from the medial and long heads of triceps The reflex, reciprocal in the two limbs, was bilaterally. sufficiently line refers, recipical in the two finds, was sufficiently linear for a sinusoidal analysis. One series of experiments was performed on acutely labyrinthectomized cats (frequency range studied 0.01 - 4 Hz, maximal stimulus amplitude 40°). There was a reflex in 6/11 preparations. At 0.1 Hz and below, peak modulation was approximately in phase with position and gain (% EMG modulation per degree of head rotation) was flat; gain was typically 1% per degree, or less. As frequency increased, gain increased with a slope of about 10 dB per decade and phase advanced slightly in some cats but not others: there was some sensitivity to stimulus velocity. These dynamics are different from those of reflexes evoked by the same stimulus in neck extensor muscles, either because the receptors are different or because of a difference in central processing. Compar-ison of the properties of reflexes evoked by head rotation in triceps with those of vestibular reflexes evoked by roll tilt of the whole animal (Schor and Miller, J. Neurophysiol. 1981, 46: 167) suggests that up to 0.2 Hz the two reflexes should cancel 167) suggests that up to 0.2 Hz the two reflexes should cancel (von Holst and Mittelstaedt, Naturwissenschaften 1950, 37: 464; Lindsay et al., J. Physiol. 1976, 261: 583). We tested this in another series of experiments on cats with intact labyrinths: neck or vestibular reflexes could be evoked separately or in combination at frequencies up to 0.5 Hz. Neck reflexes were present in 6/6 preparations. Dynamics were similar to those of the reflex in labyrinthectomized cats, but absolute gain was exervited bicker. somewhat higher. Neck and vestibular reflexes often had comparable gain and in such cases, as predicted, combined stimulation did not produce significant EMG modulation. Results with labyrinthectomized cats suggest that there will not be such effective cancellation at higher frequencies. Supported by NIH grants NS02619 and RR07065 and NASA grant NSG2380.
- 139.2 RESPONSE OF SPINAL INTERNEURONS TO NATURAL STIMULATION OF NECK RECEPTORS. K. Ezure\*, R.H. Schor, and V.J. Wilson (SPON: A.D. Miller). Rockefeller University, New York, N.Y. 10021 We recorded extracellularly from spinal interneurons whose

We recorded extracellularly from spinal interneurons whose activity was modulated by stimuli that evoke a tonic neck reflex. Deccrebrate cats were used. Some were acutely labyrinthectomized, and the stimulus was sinusoidal head rotation in roll. In others the labyrinths were intact: in these we evoked a neck reflex (body rotation in roll with respect to a fixed head), a vestibular reflex (roll tilt of the whole body) or both together (rotation of the head alone). Up to 3 spinal segments were exposed by dorsal laminectomy. Cats were first tested for the presence of a tonic neck reflex with EMG recording, then paralyzed and artifically respirated. Neuron sampling was from C4 to C8, and cells whose activity was modulated by stimulation of neck receptors were usually in laminae 7-8.

45 neurons were studied in labyrinthectomized cats at frequencies of 0.05-4Hz. 26 were excited by rotation of the chin to the ipsilateral side and inhibited by contralateral rotation (Type 1 neurons). 19 behaved in the opposite manner (Type 2 neurons). 28/45 neurons could be studied with at least 3 frequencies; of these, 22 behaved in a consistent manner. As is the case with modulation of muscle EMG, gain increased with frequency and phase was approximately flat. Phase was close to that of muscle measured before paralysis, but was often somewhat more advanced. In cats with intact labyrinths, 31 neurons could be tested for response to both neck and vestibular reflexes, at frequencies of 0.05 to 0.5Hz. Over this range the dynamics of the response to stimulation of neck receptors were the same as in labyrinthectomized cats. The firing of 25/31 neurons was modulated by both neck and vestibular stimulation. In every instance the responses were complementary. That is, Type 1 neurons were also excited by whole body tilt to the ipsilateral body tilt. As with muscle, head rotation alone often evoked no response. When it did, the response could be predicted from vectorial addition of neck and vestibular responses. Some of the neurons we studied could be in the reflex pathway

Some of the neurons we studied could be in the reflex pathway to motoneurons, but further experiments are required to test their projections. Supported by NIH grants NS 02619 and RR07065 and NASA grant NSG 2380.

DYNAMIC MODELING OF THE VISUAL-VESTIBULAR INTERACTION IN CHAME-139.3 LEON HEAD MOVEMENTS. <u>Martha Flanders</u>\* (SPON: James L. Zacks). Dept. of Zoology, Michigan State Univ., E. Lansing, MI 48824 In vertebrates, head movements can be caused by visual cues vestibular reflexes, or proprioceptive input, and are limited by the mechanical properties of the head-neck system. Lizard head movements, made during visual and/or vestibular stimulation, were examined in order to generate a comprehensive model to predict head position in the intact animal.

head position in the intact animal. <u>Chameleo</u> sp. was used because of the binocular head tracking exhibited by this lizard during its normal feeding behavior. Pursuit head movements are easily elicited in the chameleon by moving a cricket a few inches in front of it. The chameleon fixes on its prey with both eyes and its head follows the target to keep its tongue in line with the prey, ready to strike. Mov-ing the lizard's body also triggers a head movement processed through the vestibular system (the vestibulo-collic reflex, VCR) which keeps the head stable in space. An apparatus moved the cricket and/or the animal's body with horizontal, angular, sinusoidal motions, and the resulting head movements were filmed from above. The two types of movement were examined separately by varying the frequency of stimulation, and compared to move-ments made during combined visual and vestibular stimulation.

Gain and phase data from film analysis show a non-linear in-teraction between the stabilization and pursuit systems such that the gain of the VCR is reduced during high frequency pursuit stimulation. During equal amplitude, combined stimulation, peak acceleration, not peak velocity, controls the movement of the cricket relative to the chameleon's line of sight (the percept-able motion). Weight of the head is used to quantify forces during the various movements. The chameleon head is an ideal preparation for studying electromyographic activity of antagoidentical, but processed through different neural pathways. Scientific Research Society.)

139.4 EFFECTS OF MILD MECHANICAL CUTANEOUS STIMULATION ON THE STRETCH REFLEX. J. J. Seguin and J. D. Cooke. Dept. of Physiology, University of Western Ontario, London, Ontario, Canada.

The effects of cutaneous stimulation on tonic and phasic EMG responses to stretch of the triceps surae were studied in the unanesthetized decerebrate cat. Stretch was applied directly to the isolated tendon at the calcaneus and cutaneous stimulation was applied to the paw. This allowed the stretch of the muscle and cutaneous stimulation to be applied independently and at various intervals. EMGs were recorded from the gastrocnemius and soleus muscles through fine insulated wires or a concentric needle electrode. After amplification and full wave rectification, 20 to 40 responses were averaged and recorded on an X-Y plotter. tonic response was produced by maintained stretch of the triceps surae to 80-85% of its maximum physiological length. Mild brief mechanical stimulation (a tap) applied to the metatarsal pad of the hind foot caused a sequence of excitation-inhibition-excita-tion beginning 11 to 17 msecs after onset of stimulation.

Phasic responses were elicited by a brief ramp stretch of 1-2 mm superimposed on the maintained stretch. A brief tap, applied 0.01 to 5 msecs before the start of the ramp stretch caused a decrease in the size of the early response to the stretch and converted it to a biphasic response. Electrical stimuli (0.1 to 1 ms, 0.1 msec duration) applied to the pad produced similar results.

Ancillary experiments in man showed that a light tap on the palm of the hand also caused a sequence of excitatory and inhibitory response in the averaged EMG of the biceps muscles during a voluntary maintained contraction at a latency of about 40 msecs. In addition, a short burst (50 msec, 80 Hz) of vibration applied to the palm 35 to 50 msecs before perturbation of the biceps caused a depression of the averaged EMG responses to the perturbation.

It is suggested that innocuous mechanoreceptor stimulation may be responsible for variations in EMG activity seen during pertur-bation applied to the intact limb in man and animals. (Supported by the Medical Research Council of Canada, MT-6699).

139.5 FREE NERVE ENDINGS IN MUSCLE MEDIATE THE CLASP-KNIFE REFLEX IN THE CAT. <u>Corey Cleland and W.Zev Rymer</u>, Neuroscience Program and Department of Physiology, Northwestern University Medical

School, Chicago, IL, 60611 The clasp-knife reflex, first described in spastic human patients, also occurs in decerebrated cats that have had their dorsolateral spinal funiculi sectioned. The reflex consists of powerful autogenetic inhibition which occurs when an extensor muscle is stretched beyond a certain length. Contrary to earlier views, we believe that muscular free nerve endings(FNEs) are responsible.

We recorded from single muscle afferents in the SOL-LG and MG muscle nerves or dorsal roots of 17 anesthetized cats. Twenty-three group II and III muscle afferents were found that Wency-times group if and iff muscle afterents were found that did not originate from muscle spindles, Golgi tendon organs or paciniform corpuscles. Therefore, they presumably arose from FNEs in muscle. Many were located in the achilles tendon or aponeurosis and were extremely sensitive to light pressure. Six had irregular, spontaneous discharge at long muscle lengths.

Thermal or chemosensory properties were not investigated. Most FNEs responded to both ramp stretch and isometric force tetanus. Their response to stretch was primarily dynamic with some maintained static response during the hold phase of tetanus. FNEs stretch. All substantially adapted to repeated stretches. FNEs responded both dynamically and statically to force tetami. Several were also excited by ramp shortening or the falling phase of tetanus or twitch. The dynamics of FNE activity, dependence on both length and force, and their threshold to stretch match the analogous properties of clasp-knife inhibition. In contrast, the input-output properties of secondary spindle afferents and Golgi tendon organs are quite different form theore of alors tride inhibition. All substantially adapted to repeated stretches.

different from those of clasp-knife inhibition. The reflex effects of FNEs were studied in 8 decerebrated and dorsal spinal hemisectioned cats which showed a prominent clasp-knife reflex. Selective stimulation of FNEs by squeezing the distal portion of the achilles tendon with a pair of fine the distal portion of the achilles tendon with a pair of fine forceps powerfully inhibited extensor muscles and excited flexor muscles throughout the hindlimb. This stimulus was shown in anesthetized cats to potently excite many FNEs but not affect other muscle sensory receptors. The spatial divergence of the reflex effects also matches the spatial divergence of clasp-knife inhibition and excitation. Since FNEs have the appropriate input-output properties and potently inhibit extensor and excite flexor muscles, they must mediate at least part of the clasp-knife inhibition.

mediate at least part of the clasp-knife inhibition. Supported by NIH 14959 and NIMH 5F31MH08593.

139.6 THE STIFFNESS INCREMENT PRODUCED BY THE LATE STRETCH REFLEX DURING VOLUNTARY ELBOW MOVEMENTS IN MAN, W.A. MacKay, D.J. Crammond and J.T. Murphy. Dept. of Physiology, Univ. of Toronto, Toronto, Canada MSS 1A8.

The late stretch reflex has a significant influence on muscle stif-fness and is strongly modulated during voluntary movements. The purpose of this study was to demonstrate that the mechanical output of the reflex also varies during voluntary elbow movements. A trapezoidal torque pulse was delivered to the forearm via a DC motor-manipulandum assembly. Following the onset of the late stretch reflex in elbow assembly. Following the onset of the late stretch reflex in relative muscles, the monitored torque at the manipulandum showed a steady increase directly proportional to continuing elbow angular displace-ment, although no additional torque was being externally applied. The magnitude of this elastic restoring torque was highly correlated to the size of the late stretch reflex. Borrowing from the "stiffness servo" markhedie the order with the the control the date components for hypothesis, the late reflex output may be postulated to compensate for yield to stretch beyond the limit of short-range stiffness. The ratio of muscle stiffness observable with relatively large displacements eliciting a reflex to that with "short-range" displacements (eliciting virtually no reflex), was defined as the stiffness compensation factor of the reflex. A factor of 1 indicated 100% compensation by the reflex for muscle yield. During an elbow movement, the compensation factor altered markedly, usually exceeding 1 only at the onset of muscle contraction. In subjects with a strong reflex, compensation rose as high as 2, but for those with a weak reflex the factor did not attain 1. Muscle stiffness was not maintained at a constant level during voluntary movements. We conclude that the late reflex does compensate for muscle yield at times when loads are predictably encountered, but to a degree which varies considerably among individuals. Supported by MRC of Canada.

Torque pulse opposing forearm flexion applied 500 ms (1) and 100 ms (2) before onset of vo-luntary elbow flexion. Broken line indicates form of torque motor 150 ms input signal.

A METHOD FOR MEASURING MUSCLE STIFFNESS IN UNRESTRAINED CATS. 139.7 J.A. Hoffer, T.R. Leonard\* and N.L. Spence\*. Dept. of Clinical Neurosciences, U. Calgary Fac. Med., Calgary Alberta T2N 4N1. The original postulate that muscle stiffness is the regulated property of the stretch reflex was based on experiments involving decerebrate cats. In interpreting how these findings apply to intact animals, an important concern has been the extent to which decerebration may alter reflex gain at the segmental level. In particular, several lines of evidence have recently indicated that, in decerebrate cats, the Ib feedback pathway from Golgi tendon organs to lumbar motoneurons is virtually non-functional. Whether, and how, the gain along the Ib pathway may differ in the normal and decerebrate cases, is the ultimate focus of this study.

We have used chronically implanted transducers and electrodes (described by Hoffer & Loeb, <u>Ann. Biomed. Engng. 8</u>:351, 1980) to measure incremental stiffness of the ankle extensor muscles in intact, unrestrained cats, against a range of background forces. Cats were surgically fitted with the following devices: a force transducer implanted on the Achilles tendon; a length transducer spanning from origin to insertion of the gastrocnemii; bipolar EMG electrodes in the lateral gastrocnemius and anterior tibial muscles; and three nerve cuffs on the common peroneal nerve. I most distally located cuff contained stimulating electrodes. I The It was used to synchronously activate the ankle flexor muscles, thereby stretching incrementally the ankle extensors. The middle cuff was connected to a catheter, through which a 2% solution of xylocaine was infused to block conduction of the evoked flexor nerve volleys toward the spinal cord. The proximal cuff contained a tripolar set of recording electrodes. It was used to monitor the absence of a nerve compound action potential upon stimulation and thus verify the effectiveness of the flexor nerve blockade. Upon delivery of a stimulus, the amplitude of the stretch imposed on the ankle extensors was recorded by the length gauge, and the

on the ankle extensors was recorded by the length gauge, and the amplitude of the combined response (due to the elastic properties of muscle, plus reflex effects) was recorded by the force gauge. The ratio of these two quantities gave the incremental stiffness. The test perturbations provided by this method are of the "torque pulse" type. As predicted from muscle length-tension properties, the amplitude of stretch (and, to some extent, its duration and shape) depend markedly on the operating length of the ankle flexors, as well as on the operating force of the ankle extensors. We found that the length of the test stretch and the extensors. We found that the length of the test stretch and the magnitude of the response are quite reproducible when measured at matched operating points. In intact cats, the stiffness of the ankle extensors increases monotonically for forces from 0 to 7Kg. We are now using this method to measure stiffness and obtain a direct comparison of reflex gain before and after decerebration. (Funded by the Alberta Heritage Foundation for Medical Research.)

139.9 Prior Instruction Affects Single Motor Unit Discharge Rate During

the Stretch Reflex. <u>B. Calancie and P. Bawa</u>. Dept. of Kinestology, S.F.U., Burnaby, B.C. V5A 156. CANADA. A sudden stretch of forelimb muscles in human subjects results in two separate reflex peaks in the EMG activity of those muscles (Bawa & McKenzie, 1981). These reflex peaks in the LW activity of those muscl (SL) at 25-50 msec and the long latency (LL) at 50-90 msec, precede the earliest voluntary response to stretch. Hammond (1954, J. Physiol. 127: 23-25) reported that subjects were able to modify the EMG amplitude of the LL component of the stretch reflex, depending on what voluntary movement they produced in response to the stretch. When told to react against the stretch (compensate), a subject's LL reflex amplitude was much larger than when the subject 'let go' (no voluntary interference) in than when the subject let go (no voluntary interference) in response to the stretch. The SL reflex activity was relatively unaffected by the subject's response to stretch. We have in-vestigated in 2 adult subjects the firing pattern of single motor units (SMU) during both phases of the stretch reflex, and in particular the influence of prior instruction on this firing pattern.

Step load perturbations extending the wrist joint were pro-duced by a torque motor. Surface EMG of wrist flexor muscles and single motor unit activity of flexor carpi radialis (FCR) were recorded simultaneously. Subjects were asked to either 'let go' to the step load, or to 'compensate' for the displacements as quickly as possible. Data was used only where identification of a computer white manifest in the state of the step is a s of a given unit remained certain during the large muscle move-

In most cases the unit studied was made to fire tonically, and changes in firing probability within the SL and LL periods were thus superimposed on this background firing. For each of 10 tonically firing units studied to date, the probability of firing during the LL period following muscle stretch was significantly higher during the 'compensate' task than during the 'let go' task. That is, when the subject expected to activate his wrist flexors upon perceiving the stretch, a unit was much more likely to fire during the LL period. There were no consistent changes in either background or SL firing probabilities when comparing instruction effects.

ANALYSIS OF JAW JERK VARIABILITY. <u>B.Bishop, R.S. Hickenbottom<sup>#</sup></u> and <u>T.M. Moriarty<sup>#</sup></u>. Dept. of Physiol. and Dept. of Physical Therapy, State Univ. of NY at Buffalo, Buffalo, NY 14214. The purpose of this study was to identify and assess the 139.8

relative contributions of various extrinist and assess the relative contributions of various extrinist and intrinsic neural factors on the jaw jerk reflex (JR). Thirty five healthy adults with no oro-facial pathology were studied. Each subject (S) sat in a dental chair with the head securely stabilized with a metal halo and chin rest. Chin taps were delivered by way of a solenoid-driven plunger mounted 1 cm from the site where a tap with a reflex hammer evoked the "best" response. Tap force was measured with a piezo-transducer in series with the plunger. Response amplitude was taken as the negative phase of the compound action potential recorded from surface electrodes placed over the right masseter muscle with an earclip electrode as ground. Phases of respiration were signalled by a nasal thermistor. Five of the 35 Ss had no JR when relaxed, but a JR appeared

Five of the 35 Ss had no JR when relaxed, but a JR appeared when the S voluntarily contracted the platysma muscle and thereby stretched the masseter muscle or facilitated the motoneuron pool in some other way. The JRs in the other Ss varied from trial to trial despite a constant current activating the plunger. This variability was partially due to minute changes in tap force regardless of head and chin stabilization suggesting either a shift in jaw posture or a change in facial expression. In the majority of cases the mean amplitudes of the JR increased with these very small increases in tap force, but the standard deviations of the JRs to taps of constant force were large indicating intrinsic fluctuations in motoneuron excitability. Much of this variability in the responses to taps of constant force was respiratory related. JRs evoked in late expiration and early inspiration were significantly larger than those evoked during early expiration. When the head was stabilized in 15 degrees extension, every JR response was larger than any with the head upright. It could not be ascertained whether this facilitation was neurally or mechanically mediated.

mechanically mediated. In conclusion, the masseter monosynaptic reflex is sufficiently variable within any given S or among Ss to make the response a poor index of masseteric motoneuron excitability. It appears that branchial motoneurons innervating the masticatory muscles receive far more diverse and fluctuating inputs than do somatic motoneurons innervating the limb weedes the limb muscles. INCREASED STRETCH RESPONSIVENESS IN HUMANS DURING HYPERBARIC EXPOSURE. <u>James L. Parmentier</u> and <u>David J</u> <u>Harris</u>\*, Depts. of Anesthesiology, Univ. South Alabama, Mobile, Ala. 36617 and Duke Medical Center, 139.10 Alabama, Mobile, Ala Durham, N.C. 27710.

Durham, N.C. 27218. Hyperbaric hyperneflexia has been shown to occur in man during and after breathing a mixture of compressed helium and oxygen at 25 bars or more. This pattern may be part of the High Pressure Nervous Syndrome (HPNS) which characterizes a multiplicity of neuromuscular, EEG, and psychological disturbances associated with exposure to hyperbaric gas mixtures and appears to result from upper CNS dysfunction rather than an alteration of any peripheral mechanism. We bug studied tendoperchike and Hoffmann rather than an alteration of any peripheral mechanism. We have studied tendon-strike and Hoffmann reflexes of the soleus muscle in three subjects breathing 5% TRIMIX at various pressures to 550 bar during the experimental simulated saturation dive Atlantis IV.

We found that the peak force of contractions resulting from both the electrically stimulated Hoffmann reflex and the spindle activated Tendon strike reflex increased as much as 130% during compression and recovered to control levels when

strike reflex increased as much as 128% during compression and recovered to control levels when pressure was released. During compression the ratio of the EMG amplitudes of Hmax to Mmax, which is a measure of the excitability of the monosynaptic spinal reflex arc of the posterior tibialis nerve, was not altered. However, the amplitude of the tendon-strike EMG was increased to levels comparable to the force of contraction. The intramuscular hyperexcitability was still above control levels by the fourth day of the post-dive period. It is not possible from these non-invasive experiments to determine if the hyperflexia seen during Atlantis IV is due to increased muscle spindle sensitivity or to direct effects on muscle properties which control e-c coupling or the mechanochemistry of force production. While gamma-loop resetting cannot be ruled out these effects of pressure appear to be preipheral in origin and were not ameliorated by the presence of 5% nitrogen in the breathing mixture, a level sufficient to control HPNS in two of the three diver subjects. In order to determine the specific cellular mechanisms underlying hyperbaric hyperreflexia these experiments must be repeated on excised preparations. excised preparations.

139.11 A FICTIVE TAIL FLICK REFLEX IN THE RAT. C.L. Cargill\*, J.L. Steinman\* and W.D. Willis (SPON: F.H. Rudenberg). Marine Biomed. Inst. & Depts. of Physiol. & Biophys. & Anatomy, Univ. TX Med. Branch, Galveston, TX 77550 U.S.A.

Many tests of analgesia in the rat have been based upon the tail flick reflex (TFR). Attempts to elucidate the neural mechanisms mediating the TFR have only recently been undertaken. The purpose of the present experiments was to develop a model of the TFR in an anesthetized, paralyzed preparation. Hence, the response was termed a fictive TFR (i.e., motoneuron activity without the corresponding muscle movement).

The Irk In an anescherized, paralyzed preparation. Hence, the response was termed a fictive TFR (i.e., motoneuron activity without the corresponding muscle movement). A TFR was demonstrated in rats anesthetized with Chloropent (0.23 ml/100 g body weight). Muscles participating in the tail flick included the medial longissimus (ML) (also known as the extensor caudae lateralis), extensor caudae medialis (ECM), and the abductor caudae dorsalis (ACD) muscles. Filaments of small peripheral nerves innervating the ML were separated from the surrounding muscle and cut distally. Single and multiple motor unit discharges were recorded, simultaneously with an electromyorgram (EMG) from ML. The tail flick reflex was evoked by either heating the tail with a 500 watt quartz light bulb or by a noxious pinch to the tail. The reflex (TFR) was defined as movement of the tail in any direction away from the source of noxious input. The average TFR latency was 2.5 seconds. During a TFR, there was a dramatic increase in firing of the motor units and an EMG response. The animal was then respired (60-80 cvcles/ml) via a tracheal cannula and given intraperito-

During a TFR, there was a dramatic increase in firing of the motor units and an EMG response. The animal was then respired (60-80 cycles/min) via a tracheal cannula and given intraperitoneal injections of gallamine triethiodide (Flaxedil, 2.5 mg/kg body weight). As the cumulative amount of Flaxedil was increased to 40 mg/kg, there was a gradual decrease in the movement of the tail with a corresponding decrease in the EMG response until both disappeared completely. The motor units continued to fire following exposure of the tail to noxious heat or pinch. We regard this activity to represent a fictive tail flick reflex.

regard this activity to represent a fictive tail flick reflex. In order to determine the relevance and applicability of this model, we tested the effects of vaginal stimulation (VS) on motoneuron responses to noxious heat and pinch. VS has previously been shown to inhibit TFR or leg withdrawal in intact and spinalized rats. When applied for 5 sec prior to the onset of radiant heat or pinch, VS (200 g force) completely attenuated motor unit firing during noxious stimulation. However, spontaneous activity was not diminished, indicating that the noxious input was selectively inhibited. Future experiments will include a systematic examination of the neural basis of the TFR in rats. (Supported by grants NS 07022 (JLS), NS 09743 and NS 11255 from NIH, and a grant from the Moody Foundation.)

SPINAL CORD: SOMATOSENSORY PHYSIOLOGY AND BEHAVIOR

- 140.1 SOME ASPECTS OF THE DEVELOPMENT OF CATECHOLAMINERGIC NERVES IN THE SPINAL CORD OF THE RAT. J.M. Commissiong. Dept. of Physiol., McGill University, Montreal, Quebec, Canada H36 lY6. The development of noradrenergic and dopaminergic nerves in the whole spinal cord of the rat using fluorescence microscpical and neurochemical techniques was presented previously (Commissiong, J. Brain Res. 264, 197-208, 1983). In the present study the development of these catecholaminergic nerves in five regions of the developing rat cord from fetal day (FD) 16 to the young adult stage is presented. In terms of the normal synthesis of norepinephrine (NE), the release and metabolism of NE, the capacity to synthesize NE from exogenous L-DOPA, and the ability to metabolize the newly synthesized NE, the noradrenergic nerves in the ventral horn (VH) of the cervical and lumbar regions are quite well developed at 12 hrs after birth. An equivalent stage of development is achieved in the thoracic zona intermedia (T-ZI) and the dorsal horn (DH) several days later. In all regions, NE concentration peaked in the latter half of neonatal life and then declined to that found in the young adult. At neonatal day (ND) 15, there was a concentration of fluorescent varicosities in a narrow rostrocaudal band in the ventral horn, perhaps among the apical dendritic trees of motoneurons. There was no consistent pattern in the development of spinal dopaminergic nerves except in the dorsal horn of the cervical region (C-DH). However, in all regions, at ND 20, there was a peak of DA. The capacity of the developing cord to synthesize DA from exogenous L-DOPA is already well established as early as FD 16, and peaked in all regions at ND 4. Only 10% of DA synthesized in the cord from injected L-DOPA occurs in monoaminergic nerves. At ND 18, large numbers of small cells with large nuclei appear transiently in the thoracolumbar region of the cord and are capable of synthesized exclusively in noradrenergic nerves. At ND 18, large numbers of small cel
- 140.2 INFLUENCE OF RAT STRAIN ON CAPSAIGIN-INDUCED ANTINOCICEPTION AND DEPLETION OF SUBSTANCE P. T. R. LaHann<sup>\*</sup> and M. A. Bittner<sup>\*</sup> (SPON: A. E. Snow) Minmi Valley Laboratories, The Proter & Gamble Company, Cincinnati, Ohio 45247 In recent years, many laboratories have reported on the antinociceptive actions of capsaich (C). There is general agreement that C possesses antinociceptive activity, but there is disagreement about its relative efficacy against various forms of noxious stimuli. This disagreement may be due, in part, to species or strain differences. The object of our experiments was to determine if C-induced antinociception and substance P (SP) depletion is influenced by the strain of the animals. Adult male rats of six different strains (CD [SD], CDN [SD], CDF [F-3]41), WI, SHR/N and WKY/N) were injected sc with synthetic C or vehicle alone (10% ethanol, 10% Tween 80, 80% saline). Antinociceptive activity was assessed in the hot plate (55.0 ± 0.5°C, endpoints: paw fanning and licking) and the tail flick (response time of naive rats: 3 sec) tests. Nociceptive pressure thresholds were defort to withdraw the paw). Rats were tested for thermal and pressure antinociception 1, 3, 5, 24, and 48 hrs. after C. Antinociceptive activity against noxious chemical stimuli was measured 6 hrs after C by instilling 50 µl of 0.15 N NH<sub>0</sub>OH into one eye and counting the number of blinks occurring over the next 60 seconds. Drug solutions and/or animals were coded to eliminate investigator bias. SP determinations were made by extracting the lumbar portion of the spinal cords with 2 M acetic acid. The SP content was determined by RIA. All C-treated rats showed a decreased sensitivity to chemical pain. Similarly all rats treated with 100 mg/kg C showed a decreased sensitivity to thermal pain in both the hot plate and tail flick tests. WY/N rats were the most responsive strain. C-induced antinociception to pressure pain was marked in WI and WKY/N at 100 mg/kg C, moderate in CDF at 400 mg/kg C. Showed a decreased sensit

140.3 RESPONSE DIFFERENCES OF LAMINA-3,4 NEURONS TO INPUT FROM SAI AND GI AFFERENT FIBERS, <u>D. N. Tapper and J. Aldridge</u>\*. Dept/Sect. of Physiology, N.Y. State Coll. Vet. Med., Ithaca, NY 14853. Output neurons of the [L3,4:SA1,X] network often make monosynaptic contact with other primary afferent fiber classes, such as, Guard hair fibers (GI) in addition to Type 1 slowly adapting fibers (SA1). Using graded mechanical pulses to move individual Guard hairs, activation of single GI fibers can be controlled at the level of the single nerve impulse, similar to the control we have with SAI input. In the decerebrate-low spinal preparation in cat, the output cells of the [L3,4:SA1,GI] network respond to single impulses in single afferent fibers, either SAI or GI, in a qualitatively similar manner. The response to 100 impulses delivered one per 3 sec consists of an early time-locked discharge followed by a more dispersed late discharge which is often terminated by an inhibition of ongoing activity. With SAI input the early and late discharges last for 5 and 29 ms. This quantitative difference to the same input, a single impulse, indicates that the identity of the class of input is maintained in the organization of GI input is indicative of such organization. (Supported by USPH Grant NS-07505).

140.5 CAT SPINAL DORSAL HORN NEURONS WITH BRANCHED AXONS ASCENDING BOTH THE DORSAL AND DORSOLATERAL FUNICULI. <u>C.J. Bennett, G.-W. Lu\*,</u> <u>N. Nishikawa\* and R. Dubner</u>. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, Maryland 20205. The axons of dorsal column postsynaptic (DCPS) neurons ascend

in the dorsal columns (DC) while those of spinocervical tract (SCT) neurons ascend in the dorsolateral funiculus (DLF). In other respects, however, DCPS and SCT neurons are very similar. Retrograde labeling shows that both DCPS and SCT neurons are concentrated in laminae III-IV. Intracellular staining shows that their dendritic arbors are rostrocaudally elongated, mediolaterally narrow, and concentrated in laminae III-IV. Moreover, both are known to issue axon collaterals that arborize in the vicinity of their perikarya. These similarities suggest that a single neuron might give rise to both DCPS and SCT axons. In order to examine this possibility, we delivered antidromic search stimuli to cervical  $(C_2-C_4)$  DC and DLF that were dissected apart from one another and apart from the rest of the spinal cord. Fifty-six antidromically driven neurons were found in the lumbar dorsal horn: 23 of these were driven from both the DC and the ipsilateral DLF. Intracellular records showed that both the DCand DLF-evoked spikes were typical antidromic potentials. T antidromic conduction latencies obtained from the DC and DLF The branches of any given neuron were nearly the same (x difference = 0.26 msec), indicating either that the branches' diameters were nearly equal or that the branch point was close to the caudal margin of the dissection. Antidromic conduction velocities averaged 50 m/sec (range, 17-88 m/sec). The cells with branched axons were found at depths corresponding to laminae III-IV. Al half of the cells responded only to innocuous, tactile stimuli while the remainder responded to both innocuous and noxious About stimuli. These results suggest that the DCPS and SCT projections are not completely independent since at least some of their cells of origin may contribute to both projections.

140.4 ANATOMICAL AND PHYSIOLOGICAL STUDIES OF THE POSTSYNAPTIC DORSAL COLUMN (PSDC) PROJECTION IN THE RAT. <u>G.J. Giesler, Jr., R.L.</u> <u>Nahin and A.M. Madsen\*</u>. Dept. of Anatomy, Univ. of Minnesota, Minneapolis, MN 55455.

As one of a series of studies of the ascending spinal cord pathways thought to be involved in nociception in the rat, we have examined the projection from dorsal horn neurons to the dorsal column nuclei using both the retrograde transport of horseradish peroxidase (HRP) and single cell recording techniques. Small iontophoretic HRP injections confined to the gracile nucleus (GN) labeled, in alternate sections, more than 200 neurons within a narrow band extending across the ipsilateral dorsal horn immediately subjacent to substantia gelatinosa. Fewer than 10 labeled cells were found within the gray matter of the cervical enlargement following such injections. Small injections of HRP into the cuneate nucleus (CN) labeled more than 350 neurons in the ipsilateral nucleus proprius within segments C6-8. Fewer than 20 neurons were labeled within the lumbar enlargement by injections into CN. Labeling in lumbar neurons was totally prevented following GN injections by transection of the dorsal columns at either T10, T8 or C2. Thus, the PSDC projection to GN appears to ascend entirely within the dorsal columns. Lesions of the dorsal columns in segment C2 consistently reduced the number of labeled neurons in the cervical cord following CN injections by 90%. Combined lesions of the dorsal columns and ipsilateral dorsal lateral funciculus (DLF) reduced the number of cells abeled in the cervical enlargement by more than 95%. Thus a small component of the cervical projection to CN appears to ascend within the DLF. To compare the relative sizes of the projections to the dorsal column nuclei from PSDC neurons and the central processes of primary afferent fibers, labeled by CN injections and approximately 30% of the cells labeled by CN injections were located within the dorsal horn. The PSDC pathway is therefore capable of providing a major input to the dorsal column nuclei. We have also used antidromic activation to identify individual PSDC cells in the lumbar enlargement of unanesthetized, decerebrated animals in whi

140.6 TACTILE DISCRIMINATION IN CATS AFTER LESIONS IN DORSAL SPINAL CORD. <u>G. P. Frommer</u> (SPON: S. Curtis). Dept. of Psychology, Indiana Univ., Bloomington, IN 47405.

Sagittal lesions transecting the decussation of the spinocervicothalamic system disrupt roughness discrimination much more than do lesions in dorsal columns (DC) (Kitai & Weinberg, <u>Exp. Br. Res., 1968, 6, 234</u>). Nearly complete DC lesions are also effective (Dobry & Casey, <u>Br. Res., 1972, 44, 385</u>). The present study compares effects on roughness discriminations of lesions in DC, DLC (dorsal lateral columns, which carry the spinocervical tract) and DC+DLC at the C3-C4 level. Cats were trained 12 trials/day with correction in a darkened

Cats were trained 12 trials/day with correction in a darkened double alleyway (Grice box) with movable floors bearing different texture pairs. The first discrimination, between textured and smooth metal, started as a combined visual+tactile task. After initial mastery (usually 90% correct for 3 consecutive sessions), visual cues were faded by dimming ambient illumination to zero. The next 5 tasks were between progressively finer sandpapers and smooth Masonite. The remaining tasks were between the first 4 sandpapers and a very fine sandpaper. All cats failed the last task. Lesions were made under deep barbiturate anesthesia. Anatomical verifications available from 3 cats show complete or nearly complete destruction of DC and/ or of the dorsal 1/3 of DLC.

Six cats were trained preoperatively. After DC lesions 1 cat showed no deficit, and 1 cat showed negative savings on 3 of the more difficult tasks. After DLC lesions 2 cats showed no or mild deficits. After DC+DLC lesions 2 cats showed large negative savings on the first and easiest sandpaper-Masonite discrimination, rapid relearning of subsequent easier tasks, and negative savings on the more difficult tasks. This is suggestive of acquiring a new strategy postoperatively. Four cats were trained after lesions were made. One cat

Four cats were trained after lesions were made. One cat with DC lesions failed to learn even the initial tactile discrimination, even though it had mastered the visual+tactile discrimination. The other failed on an intermediate task. The 2 cats with DLC lesions were slow to learn the initial discrimination, but with 1 exception their later performance was within normal limits.

These data are consistent with Dobry and Casey's data. They fail to confirm Kitai and Weinberg's. Differences between the present experiment and Kitai and Weinberg's include locus of lesion (DLC vs. cervicothalamic tract decussation) and procedures in the present intended to maximize cats' performance (e.g. correction, visual fading). SPINAL CORD UNIT ACTIVITY IN THE AWAKE CAT. L. S. Sorkin,\* T.J. Morrow and K.L. Casey. Department of Physiology, Univ. of Michigan and Neurology Research Laboratories, VAMC, Ann Arbor, SPINAL CORD UNIT ACTIVITY IN THE AWAKE CAT. 140 7 MI 48105.

The response properties of somatosensory spinal cord cells have not yet been described in the intact unanesthetized animal This study examines the responses of spinal cord cells to natural and electrical somatic stimuli in the awake, partially restrained cat

cat. Cats had a chronic microelectrode recording device attached to the lower lumbar vertebral column. This implant also immobilized three segments (L3-L5) of the column. Various mechanical and electrical stimuli applied to the skin were used to characterize the units. Neurons that: 1) failed to respond to each supra-threshold driving stimulus delivered at 1-100 Hz., 2) showed a latency shift as the stimulation frequency increased or 3) dis-played a biphasic or triphasic waveform, were classified as post-synaptic elements. All other neurons were considered presynaptic. Receptive field and adequate stimuli were determined for 84 isolated cutaneously driven neurons. Twenty-nine cells were pre-synaptic, 24 were postsynaptic, and 31 were not classified because 100 Hz. stimuli sometimes elicited struggling. In addi-tion, 28 units were excited by joint position or movement and could not be electrically driven.

tion, 28 units were excited by joint position or movement and could not be electrically driven. Convergence of cutaneous and proprioceptive input was never seen. Cutaneously driven units did not fire spontaneously. In contrast, proprioceptive units discharged spontaneously at rates of 5-40 Hz. Only 5 (21%) postsynaptic cells showed evidence of input from more than one type of cutaneous receptor. Four post-synaptic and l unidentified unit showed behaviorally related at the operation of procession of the second discussion IASP Abstracts, 1981). The lack of spontaneous activity in cutaneous units, the

relatively infrequent afferent convergence and the behaviorally related response modulation found in our experiments suggest that both tonic and phasic supraspinal descending inhibitory influ-ences are active in the intact unanesthetized cat.

EFFECTS OF ATTENTION ON DETECTION OF NOXIOUS AND INNOCUOUS THERMAL 140.8 STIMULI. M.C. Bushnell, R.L. Jones\*, G.H. Duncan\* and R. Dubner. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, Marvland 20205.

Responses of some thermally sensitive medullary dorsal horn neurons are greater when a monkey is required to attend to the stimulus than when he is not (Hayes et al., <u>J. Neurophysiol</u>., <u>46</u>: 428-443, 1981). This enhancement in neuronal activity may reflect differences in sensory-discriminative aspects of a sensation or may be involved in affective or reflexive responses to the stimulus. The current study evaluates the effects of attention on the discriminative aspects of sensations evoked by innocuous and noxious thermal stimuli applied to the face of humans and monkeys.

Eight human subjects detected temperature perturbations of < 1°C from baselines of 39°C and 45°C. Two contact thermodes A form baselines of 39 C and 45 C. Two contact thermodes were positioned bilaterally above the upper lip. Upon trial ini-tiation both thermodes heated to  $39^{\circ}$ C in some sessions and  $45^{\circ}$ C in others and remained at that temperature for 3-10 sec before one thermode heated an additional step of < 1°C. Subjects responded to the second temperature change by releasing a key. On 50% of the trials a signal light occurred on the left or right side of the response namel indicating the side of the part temperature the response panel, indicating the side of the next temperature perturbation. Subjects were instructed to attend to the signaled thermode. For most trials the signal was accurate, but for  $10^{\circ}$  the trials the signal was incorrect. From both innocuous ( $39^{\circ}$ C and noxious ( $45^{\circ}$ C) baselines, detection latencies were shortest റ when the subject attended to the relevant thermode (correct signal condition) and longest when he attended to the irrelevant thermode (incorrect signal condition) (Friedman test, p < .05). When there was no location signaled. latencies were intermediate. In addition, the percentage of perturbations not detected was less for the correct than for the incorrect signal condition (Friedman test, p < .05). The shorter latencies and greater accuracy do < .05). test, p not reflect a shift in response criterion, as percentage of responses occurring before the temperature shift (false alarms) was not different among stimulus conditions at either baseline.

One monkey was trained to detect small temperature changes from a  $45^{\circ}$ C baseline or to detect the onset of a dim white light. For 50% of the trials stimulus modality was signaled by one of two red lights. The monkey detected more of the temperature shifts and produced shorter detection latencies for the signaled than for the unsignaled condition (sign rank test, p < .05). There was no difference in the percentage of false alarms.

These data show that detectability of thermal stimuli is in-fluenced by attentional factors, both within and between stimulus modalities. This alteration in sensory detection could reflect the behavioral modulation observed in the medullary dorsal horn. an early stage of central nervous system processing.

SKIN NEAR THE DORSAL AND VENTRAL MIDLINES IS REPRESENTED BILATERALLY IN THE SPINAL CORD OF THE RAT. <u>C.G.Smith\* (spon:</u> 140.9 C.B. Gundersen). Sobell Department, Institute of Neurology, Queen Square, London WC1, England. The traditional view is that the two sides of the body

are represented separately in the spinal cord. This view does not take into account the finding that some cutaneous afferents terminate bilaterally. Electrophysiological studies have shown that afferents projecting bilaterally to the thoracic spinal cord in the rat innervate tactile domes near the dorsal and ventral midlines (Smith, C.G., <u>J.Physiol.</u>, <u>334:</u> 72P 1983). A population of dorsal horn neurons with bilateral receptive fields has now been identified.

Experiments were done on rats under urethane anesthesia. Recordings were made from single units in the thoracic spinal cord with a tungsten microelectrode. Activity in peripheral nerves was monitored with wire electrodes. The skin was divided along the midlines so that afferents supplying the two sides could be activated independently by mechanical stimulation.

Units with receptive fields extending across the dorsal midline were found in the lateral dorsal horn and units with receptive fields extending across the ventral midline were found in the medial part. The contralateral part of the receptive field was restricted to skin within 5-10 mm of the midlines. The ipsilateral part was usually much larger. The units were excited by displacing hairs in tactile domes and, in some cases, also by displacing other hairs. Field potentials evoked by impulses in single cutaneous

afferents could be detected in the dorsal horn, even without averaging. Impulses in dorsal horn neurons sometimes occurred during the field potentials suggesting that they were monosynaptically evoked. Some units appeared to receive monosynaptic connections from cutaneous afferents on both sides of the body. Nost bilaterally projecting afferents encountered in this

inds officierally projecting afferents encountered in this study were slowly adapting units supplying tactile domes, in confirmation of my previous findings. However, two were rapidly adapting units. One was a typical hair follicle afferent supplying a group of hairs. The second was only excited by displacing one hair.

These findings show that the region of skin represented in each dorsal horn extends across the dorsal and ventral midlines and that inputs from skin on the two sides of the midlines are integrated within the spinal cord. This leads to the expectation that the skin near the midlines may also be represented bilaterally at higher levels of the somatosensory system by pathways independent of commissural connections in the brain.

140.10 SOMATOTOPIC ORGANIZATION OF CAT SPINAL CORD SEGMENTS WITH FUSED DORSAL HORNS. L. A. Ritz, J. L. Culberson\* and P. B. Brown. Depts. of Physiology and Anatomy, West Virginia University Medical Center, Morgantown, W. V. 26506, U.S.A.

Segments  $T_4 - T_{13}$  and  $S_3 - Ca_8$  of the cat spinal cord have fused dorsal horns; i.e., laminae I-V are continuous across the midline. We used these segments to test predictions about dorsal horn somatotopy, based on previous studies of hindlimb and forelimb regions. We predicted that dorsal skin projects laterally and ventral skin projects medially in the dorsal horn. We also predicted that the dorsal root dermatomes are tilted dorsorostral and ventrocaudal relative to segmental representations, to account for the rostrolateral/caudomedial orientation of dorsal root termination zones in the dorsal horn. To test these predictions we examined: 1) somatotopy of single units in the dorsal horn; 2) dorsal root dermatomes; 3) dorsal root projections in the dorsal horn. We hypothesize that 1) and 2) are determined by 3) (Brown and Fuchs, 1975).

As recording sites within the thoracic dorsal horn are shifted from the left edge to the right edge of the fused dorsal horns, single unit receptive fields (RFs) shift in overlapping fashion from the dorsal left trunk, ventrally across the midline, to the dorsal right trunk. Although no RFs spanned the dorsal midline, the RFs of units near the midline of the fused dorsal horns spanned the ventral midline of the trunk. Caudal and thoracic dermatomes reach, but do not cross, the dorsal and ventral midlines. The rostrocaudal dermatomal trajectory is proximodistal on the tail, with each dermatome overlapping adjacent ones but rarely reaching the edge of the second dermatome in either direction. They are not tilted relative to segmental representations, suggesting that (a) rostrolateral/caudomedial orientations of dorsal root projections do not exist in these segments, or (b) such orientations exist but are not related to somatotopy.  $S_3$  is the most rostral dermatome entirely on the tail.  ${\rm Ca}_5$  through  ${\rm Ca}_8$ dermatomes all reach the tip of the tail; the rostral borders of these dermatomes continue the rostrocaudal dermatomal trajectory. Our degeneration results suggest an anatomical substrate for ventral midline continuity of thoracic dorsal horn RFs: dorsal root projections cross the midline of the fused regions. The lack of dorsal midline continuity is consistent with the minimal observed projections to contralateral lateral dorsal horn.

CUTANEOUS INNERVATION OF THE HIND LEG OF THE RAT AND ITS SOMATO-TOPIC ORGANIZATION IN LAMINAE I AND II OF THE LUMBAR SPINAL CORD. 140.11 J.E. Swett and C.J. Woolf\*. Cerebral Functions Group, Dept. of Anatomy, Univ. Coll. London, London WC1E 6BT, U.K. From electrophysiological and anatomical experiments performed Anatomy,

on cutaneous afferent fibers in subdivisions of the femoral and sciatic nerves of the rat we have compared the relative sizes and positions of their skin territories with their terminal fields in the superficial laminae of the dorsal horn. The subdivisions were the saphenous (SA), sural (C), lateral sural (LS), superficial peroneal (SP), tibial (T), and posterior cutaneous nerve of the thigh (PC).

Skin fields were charted in anaesthetized preparations by recording multiunit action potentials in each nerve evoked by probing the skin with non-noxious mechanical stimuli. Each nerve supplied a region separate and distinct from adjacent territories innervated by other nerves.

The terminal distributions of afferent fibers in the dorsal horn were determined for each nerve by reconstructing the sites of transganglionically transported wheat-germ agglutining conjugated transgangitonically transported wheat-germ agglutining conjugated horseradish peroxidase (WGA-HRP). Each nerve was exposed under anesthesia, cut, and the proximal stump isolated from surrounding tissues with low melting-point wax. Distilled water was applied to nerve end for 10 min followed by a 30% solution of WGA-HRP in water for 3-4 hours. The nerve was rinsed in saline and the wound closed. After survival periods of 48 to 72 hours the rats were sacrificed and the tissues processed according to the TMB procedure of Mesulam (1978). The distribution of label in Lamina I and substantia gelatinosa (SG) was reconstructed from coronal  $40\mu m$  frozen sections from the L1 to S1 spinal segments. The rostral limit of the label did not extend beyond mid-L2 and the label occupied the medial portions of SG. In L3 and L4 the label broadened to occupy the medial 3/4 of SG. The caudal limit extended medially to mid or caudal L5. The longitudinal extent of the label was 7.5 to 8.4 mm: its maximum width 0.6 - 0.7 mm. In this zone each nerve labelled a separate and distinct longitudinal strip of lamina I and SG with the most dense label in the latter. The entire medial portion The most dense label in the latter. The entire medial portion bordering on the dorsal columns received afferents from T. In L2 and L3 the SA label lay lateral to T. The SP label lay lateral to SA in L3 and T in L4. The label for S and LS was more lateral and extended between rostral L5 to the L2 - L3 junction. Finally PC occupied the most lateral margin of the zone in L4 and L5.

The principal observation was that each nerve occupied discrete part of SG so that together they formed a distorted but coherent impage of the skin surface of the hind limb in a two-dimensional plane. The evidence suggests that afferent inputs to SG are highly somatotopically organized. (Supported by NINCDS Grant 17630 and the MRC).

VISUAL CORTEX: INTRINSIC ORGANIZATION I

EXPLANATION OF ORIENTATION COLUMNS IN TERMS OF A HOMOGENEOUS NET-141.1

EXPLANATION OF ORIENTATION COLUMNS IN TERMS OF A HOMOCENEOUS NET-WORK OF NEURONS IN THE VISUAL CORTEX, <u>V. Braitenberg.</u> Max-Planck-Institut für Biologische Kybernetik, Tübingen, W. Germany. We had suggested (Biol. Cybern. <u>33</u>, 179, 1979) an arrangement of oriented line detectors around centers situated 0.5 mm from each other as being compatible with the available data. Singularities with that separation were indeed found later, the cytochrome oxidase blobs, and their location appeared to be re-lated to orientation columns (Horton and Hubel, 1980). The blobs are due to the staining of mitochondria predominantly inside stellate cells (Carrol and Wong-Riley, 1982). The supposition that the blobs mark the site of inhibitory neurons leads to the that the blobs mark the site of inhibitory neurons leads to the following model, presented as a view of the cortex from the top.

The inhibitors (small circles) have dendritic fields (dashed Each inhibits the pyramidal cells (black dots) surrounding its dendritic field. The input excites both kinds of neurons. A pyr-ramidal cell is activated only if it is hit by the input within its own dendritic field (large circles) and if the dendritic fields of the nearby inhibitors are not hit. This leaves mostly elongated areas (stippled) with long axes oriented along circles surrounding the inhibitors.

These microfields measure only a few minutes of arc (in the fovea). The large receptive fields observed in single neuron recording must be compounded out of many microfields of the same orientation within a certain neighbourhood presumably by the formation of a Hebbian cell assembly. All the neurons of one assembly would have the same receptive field, and the scatter of receptive field centers relative to the recording site would naturally ensue. Since the connections subserving the assemblies are random, the formation of large and small, simple and complex re-ceptive fields is left to chance. Movement sensitivity and directionality may depend on the relative distance of a neuron from the inhibitors on either side.

RETINOTOPY AND ORIENTATION COLUMNS IN THE MONKEY: A NEW MODEL. 141.2 <u>B.M. Dow</u> and <u>R. Bauer\*</u>, Neurobiology Division, Physiology Depart-ment, School of Medicine, SUNY, Buffalo, NY 14226. The units of visuotopic localization in the retina are most

The units of visuotopic localization in the retina are most likely single cones. The units of retinotopic localization in striate cortex are at present unknown. Cone separation projected onto the cortical surface achieves values close to 300µ in the central foveal region (Dow et al., Exp. Brain Res. 44:213, 1981). This is only slightly smaller than the distance between cytochrome oxidase patches (Hendrickson et al., Nature 292:605, 1981; Horton and Hubel, Nature 292:762, 1981), suggesting that cytochrome oxi-dase patches might serve as cortical retinotopic points. Based on this idea, a model is presented in which striate cortical orientation columns are generated directly out of retinotopy. On the opercular surface except in center fovea retinotopic

On the opercular surface except in center fovea retinotopic horizontal lines follow ocular dominance stripes, and retinotopic vertical lines cross ocular dominance stripes at right angles. Cytochrome oxidase patches are located in the middle of ocular dominance stripes (Hendrickson et al., 1981; Horton and Hubel, 1981). The model proposes that iso-orientation lines are arrayed 1981). The model proposes that iso-orientation lines are array radially around cytochrome oxidase patches as nodes. The nodes form a rectangular matrix superimposed upon the map of ocular liso-orientation lines follow ret dominance stripes. Horizontal iso-orientation lines follow retin-otopic horizontal lines, running down the centers of ocular domin-ance stripes. Vertical iso-orientation lines follow retinotopic vertical lines, crossing ocular dominance stripes at right angles. Preferred orientations in the infragranular layers are reversed with percent to the curperpendent layers (Pauce et al. Even Prain

with respect to the supragranular layers (Bauer et al., Exp. Brain Res. 50:133, 1983). New data indicate that the shift in orienta-tion between upper and lower layers is minimal in zones of high monocularity, presumed to be cytochrome oxidase patches. The model proposes that inhibition radiating laterally into the supragranular layers from alternate cytochrome oxidase patches is responsible for the generation of diagonal (45° and 135°) orienta-tion preferences. Diagonal orientations are consequently repretion preferences. Diagonal orientations are consequently repre-sented as alternating iso-orientation zones at the centers of the interstices in the matrix (internodal centers). There is, in fact, a predominance of diagonal orientations in the uppermost layers of striate cortex at eccentricities greater than 30 min (Bauer et al., Exp. Brain Res. 41:54, 1980). Inhibition radiating into the infragranular layers from the other set of alternate cytochrome oxidase patches is proposed as a mechanism for the orientation shift between upper and lower layers.

The model may help to explain some previously puzzling features of the relationship between ocular dominance columns, orientation columns, and retinotopy. It is highly specific and testable. (Supported by NIH grant EY02349)

STRUCTURAL BASIS OF ORIENTATION SENSITIVITY IN CAT VISUAL SYSTEM 141.3 J.D. Schall\* and A.G. Leventhal. Dept. Anat., Univ. of Utah, Sch. Med., Salt Lake City, Utah 84132 Pronounced orientation sensitivity is a distinctive charac-

Pronounced orientation sensitivity is a distinctive charac-teristic of neurons in cat visual cortex. This property, however, does not appear to be unique to cortical cells. It has been reported recently that most cat retinal ganglion cells (Levick & Thibos, 1982, J. Physiol. (Lond.), 329:243) and most relay cells in the cat's dorsal lateral geniculate nucleus (LGNd) (Vidyasagar & Urbas, 1982, Exp. Brain Res., 46:157) are sensitive to stimulus orientation. The orientation preferences of retinal ganglion cells are related systematically to their positions. Outside of the area centralis most retinal ganglion cells respond best to stimuli oriented radially, i.e., oriented parallel to the line connecting their receptive fields to the area centralis. We investigated the structural basis of this orientation sensitivity. The dendritic fields of 840 retinal ganglion cells

sensitivity. The dendritic fields of 840 retinal ganglion cells labeled by injections of horseradish peroxidase into the LGNd or optic tracts of normal cats, Siamese cats and cats deprived of or optic tracts of normal cats, Siamese cats and cats deprived of patterned visual experience from birth by monocular lid-suture (MD) were studied. Retrogradely labeled cells were first drawn under the microscope using a 40x or 100x oil immersion objective and camera lucida. Cells were sampled along the horizontal, vertical and oblique meridians of the retina. Drawings of all cells were then traced onto a digitizing tablet interfaced to the laboratory's PDP 11/23 computer system. The Cartesian coordinates comprising the drawing were stored and the dendritic fields of all cells analyzed quantitatively. Mathematical techniques designed to analyze direction were used to find the dendritic field orientation of each cell. Statistical techniques designed for angular data were used to determine the relationship between dendritic field orientation and angular position on the retina (polar angle). Our results indicate that 88 percent of retinal ganglion cells have oriented dendritic fields and that dendritic field orientation is related systematically to retinal position. In all regions of retina more than 0.5 mm from the area centralis The dendritic fields of retinal ganglion cells are oriented radially, i.e., like the spokes of a wheel having the area centralis at its hub. This relationship was present in all animals and cell types studied and was strongest for cells located close to the horizontal meridian (visual streak) of the retinal. Retinal ganglion cells appear to be sensitive to stimulus orientation because they have oriented dendritic fields.

SYSTEMATIC RELATIONSHIP BETWEEN PREFERRED ORIENTATION AND 141.4 RECEPTIVE FIELD POSITION OF NEURONS IN CAT STRIATE CORTEX A.G. Leventhal. Dept. Anat., Univ. of Utah, Sch. Med., Salt Lake City, Utah 84132

Leventhal. Dept. Anat., Univ. of Utah, Sch. Med., Salt Lake City, Utah 84132 It has been known for two decades that neurons in mammalian visual cortex respond selectively to stimuli falling on the retina at a particular angular orientation. Recent evidence suggests that most cat retinal ganglion cells (Levick & Thibos, 1982, J. Physiol. (Lond.), 329:243) and relay cells (Vidyasagar & Urbas, 1982, Exp. Brain Res., 46:157) in the cat's dorsal lateral geniculate nucleus are also orientation selective. In the retina there is a systematic relationship between receptive field position (polar angle) and preferred orientation. Outside of the area centralis, most retinal ganglion cells have oriented den-dritic fields and respond best to stimuli oriented radially, i.e., oriented parallel to the line connecting their receptive fields to the area centralis (Levick & Thibos, 1982, J. Physiol. (Lond.), 329:243). This relationship is strongest close to the horizontal meridian (the visual streak) of the retina. To determine if a relationship between preferred orientation

329:243). This relationship is strongest close to the norizontal meridian (the visual streak) of the retina. To determine if a relationship between preferred orienta-tions and receptive field positions of 768 striate cortical neurons were studied. As in the retina a systematic relationship exists between preferred orientation and visual field position in area 17. In parts of striate cortex 15 to 80 degrees from the area centralis projection there is a strong tendency for cells to respond best to lines oriented radially. In regions 4 to 15 degrees from the area centralis projection this relationship is somewhat weaker. In regions subserving the central 4 degrees of visual angle no such relationship exists. Throughout area 17 the relationship between preferred orientation and polar angle is strongest in regions subserving the horizontal meridian. It is suggested that the systematic relationship between preferred orientation and polar angle which begins in the retina provides an intrinsic framework for the organized arrangement of orientation "columns" in visual cortex. This relationship may also be responsible for the "oblique effect" as well as the visual system's preferential response to radially oriented gratings (Rovamo et al., 1982, Invest. Opthal. Vis. Sci., 23:666).

141.5 SURFACE ORGANISATION OF FUNCTIONAL AND TOPOGRAPHIC MAPS IN CAT VISUAL CORTEX. <u>M.S.Cynader, J.Matsubara and N.V.Swindale\*</u>. Depts. of Psychology and Physiology, Dalhousie Univ., Halifax,N.S.,Canada, B3H 4J1.

We have examined the topographic organisation of functional neuronal properties in cat area 18 by making a large number of penetrations (often over 100) into the cortex and examining neuronal responses. Penetrations were spaced about 300 um apart in a regular grid pattern on the cortical surface; the depth of recording was about 400 um. At each recording site we examined 1) receptive field location, 2) ocular dominance and 3) orientation selectivity.

The results indicate that the retinotopic map is markedly anisotropic in area 18, with the magnification factor for verti-cal being at least twice that for horizontal. This anisotropy makes it clear that the mapping between the retina and the cortex is not conformal: right angles in the visual world are not, in general, mapped onto right angles on the cortical surface. The exception occurs with the cortical representation for horizontal and vertical axes. The cortical representation of retinal isoelevation and iso-azimuthal contours is a set of orthogonal contours on the cortical surface. This implies a special significance for these two directions in cortical processing.

A cortical point spread function was defined as that region of cortex likely to contain cells with receptive field centers in common: this turned out to be about 1.2 mm wide and 1.8 mm long, the elongation being in the direction in which magnification factor is a maximum.

Neurons with similar functional properties occur in patches within the cortex. The fine grain map reveals patches of cells dominated by one eye or the other. Likewise, cells responding to a given orientation were located near other cells preferring the same orientation. Yet the cortical representations of different response features varied in their orderliness, periodicity, inter-animal consistency and direction of elongation. Units pre-ferring the same orientation were in properties or the ferring the same orientation were arranged in branching stripes running posterior-medial to antero-lateral across the cortical running posterior-medial to antero-lateral across the cortical surface. The period of these bands measured by spectral analysis was  $1.26\pm0.03$  mm. By contrast, the organisation of units according to eye dominance was much less regular and the periodi-city less well defined, being in the range 1.2 - 1.8 mm. The iso-orientation domains tend to run in the same direction as the cortical representation of the iso-elevation contours of visual space. The anisotrony in the magnification factor and the

visual space. The anisotropy in the magnification factor and the elongation of the point spread function has the effect of allowing a complete set of orientation columns to fit economically into a cortical territory which represents a roughly circular region of visual space.

THE ROLE OF ORIENTATION TUNING ON THE SPECIFICITY OF LOCAL INTRA-141.6 CORTICAL CONNECTIONS IN CAT VISUAL CORTEX: AN ANATOMICAL AND PHYSIOLOGICAL STUDY. J. Matsubara & M. Cynader, Depts. of Psy-chology & Physiology, Dalhousie Univ., Halifax, N.S., Canada.

Clusters, lattices and bands of cells have been observed to participate in intra- and inter-cortical projections. Are physiological response properties of anatomically-connected cells similar or different? We address this question by combining physiological recordings and anatomical tracing techniques in physiclogical reconcings and ancomcan reaching cochine techniques in area 18 of cat visual cortex. Following fine-grain mapping (Cynader, Matsubara & Swindale, 1983) neural tracers (WGA-HRP or fluorescent dyes) are injected 700 $\mu$  below surface into areas of the cortex chosen on the basis of their response properties. After perfusion, the brain is blocked and horizontal sections cut Parallel to the cortical surface. Comparisons of the charts of labelled cells with the physiological data allow us to character-ize response properties of projection neurons. Within area 18 our results indicate the following: (1) <u>Orien</u>-

retions. Injections of WGA-HRP into iso-orientation domains result in a patchy distribution of retrogradely-filled neighbouring cells. Like the cells of the injection site, these probouring cells. Like the cells of the injection site, these pro-jection cells are also within iso-orientation domains. Further-more, the best orientation of the projection cells is <u>orthogonal</u> to the best orientation of the injection site cells: e.g. cells preferring vertically-oriented stimuli project to cells prefer-ring horizontally-oriented stimuli. We speculate that this projection is inhibitory and that it is necessary for enhance-ment of the orientation selectivity of cortical cells. (2) The area over which labelled cells are found extends further in the anterior-posterior rather than the medial-lateral direction. Thus the population of projection cells covers more cortical Thus the population of projection cells covers more cortical surface in the A-P direction (i.e. vertical in visual space). This was observed for every injection confined to an iso-First was observed for every injection continue to all iso-orientation domain regardless of the best orientation of the cells within the injection site. Due to the anisotropy in cor-tical magnification factor found for the representation of vertical and horizontal visual space, the accumulated receptive field of the population of labelled cells corresponds to a number of the injection into the second of the injection into roughly circular area in visual space. (3) An injection into one iso-orientation domain typically yields 3-5 patches of pro-jection cells. Mean distance between neighbouring patches is 1.12 ±0.2 mm(corrected for shrinkage of tissue). (4) Local connections do not appear to display any obvious relationship to ocular dominance properties.

INTRINSIC CONNECTIONS OF MACAQUE MONKEY STRIATE CORTEX. 141 7 J.S. Lund, D. Fitzparick<sup>4</sup>, G.G. Blasdel. (SPON: C.J. Wallis, Lab. of Ophthalmology Research, Medical University of South Carolina, Charleston, S.C. 29425. Orthograde and retrograde transport of horseradish peroxidase (HRP) was used to trace the inter- and intralaminar (SPON: C.J. Wallis)

projections of small populations of neurons following small iontophoretic injections of HRP into individual laminae of Striate cortex. Uptake by fibers of passage or apical dendrites did not appear to present problems in the interpretation of the results. We have been particularly interested in the relative degree of lateral spread of inter-and intralaminar intrinsic projections since they may be reflected in particular physiological properties.

The neurons of the magnocellular recipient zone  $(4C\alpha)$ The neurons of the magnocerillar recipient zone (4Ca) project in a diffuse and laterally spreading fashion upon 4B in contrast to the dense vertically organized projection of  $4C\beta$ neurons upon 4A-3B. The lateral spread of connectivity is emphasized even further in 4B itself where injections demonstrate widespread intralaminar connections with a patchy distribution of terminal fields (which include upper 4C $\alpha$ ). The neurons of laminar 6 project heavily with little lateral spread upon 4C $\alpha$  and 4C $\beta$  and can be distinguished from thalamic axons by their fine calibre.

The projection zone of upper  $4C\beta$  neurons inpinges upon 4A-3Bwhich receives direct geniculate input and also a strong vertically organized input from lamina 6 neurons. 4A-3B vertically organized input from lamina o neurons. 4A-3B projects in a diffuse spreading fashion to lamina 2-3A where a spreading projection is further emphasized by intralaminar connections with a broad and patchy distribution. This region also projects heavily to lamina 5B with an emphasis on vertical connections. Lamina 2-3A receives additional input from 4B and 5B in both a prominent, vertical fashion and a more diffuse lateral input.

Laminae 5 and 6 do not show prominent lateral intralaminar connections using the present technique and in this respect differ from lamina 4B and 2-3A.

These results indicate striking differences in the patterns of connectivity for each of the laminae in monkey striate cortex. Supported by EY03321.

- ORGANIZATION AND INTRACORTICAL CONNECTIVITY OF LAYER 4 IN 141.8

ORGANIZATION AND INTRACORTICAL CONNECTIVITY OF LAYER 4 IN MACAQUE STRIATE CORTEX. <u>Gary G. Blasdel</u>, <u>David fitzpatrick</u>, and <u>Jennifer S. Lund</u>. Departments of Anatomy and Ophthalmology, Medical University of South Carolina, Charleston, South Carolina, 29425. From previous studies it is known that most geniculate afferents terminate in layers 4A and 4C of macaque striate cortex. It is also known that striate efferents originate from neurons located outside these laminae. We have used micro-iontophoretic injections of horseradish peroxidase (HRP), in conduction with electrophysiological meconizes to active micro-iontophoretic injections of norseration performance ....., in conjunction with electrophysiological recordings, to study the comparization of the intervening connections. On the basis in conjunction with electrophysiological recordings, to study the organization of the intervening connections. On the basis of these studies we find evidence for the subdivision of layer 4C into 4 zones. In <u>upper 4C-alpha</u> we find label in multiple lateral patches (that extend into 4B) after a single injection of HRP into layers 4B and 4C-alpha. Electrophysiologically we find that upper 4C-alpha may contain orientationally selective Simple and Complex cells as well. <u>Lower 4C-alpha</u>, by contrast, does not contain laterally displaced patches of label (following HRP injections into 4B) and is observed to be composed primarily of units with small recentive fields that (following HRP injections into 4B) and is observed to be composed primarily of units with small receptive fields that lack orientation selectivity. The results of both orthogradely and retrogradely transported HRP indicate that <u>upper 4C-beta</u> has a precise, point to point, projection onto layers 4A and lower 3. Lower 4C-beta, by contrast, appears not to project to this zone since its cell bodies remain unlabeled following microinjections of HRP into 4A and lower lamina 3. The units recorded in both upper and lower 4C-beta have extremely small receptive fields and respond to all orientations of visual stimulation.

For lower 4C-alpha as well as upper and lower 4C-beta it is possible to observe precisely ordered micromaps within the dimensions of single ocular dominance columns. The progression in receptive field position that occurs with each advancement of a tangentially directed electrode is small in comparison of a tangentially directed electrode is small in comparison with the minimum response fields of the recorded units; accordingly it is best characterized as one of partially shifted overlap. From the local magnification factor it is possible to calculate the horizontal distance in striate cortex that separates regions of layer 4C that deal with separate and non-overlapping parts of visual space. In lower 4C-alpha this distance is about 660 micra and in 4C-beta it is about 290 micra. These distances correspond, within a factor of 2, to the known axonal arborizations of single geniculate afferents within each of these sublaminae. Supported by EY03321.

141.9 HORIZONTAL CONNECTIONS IN STRIATE CORTEX AS REVEALED BY CROSS-CORRELATION ANALYSIS. <u>D. Ts'o, C. Gilbert, and T.N. Wiesel</u> Dept. of Neurobiology, Harvard Medical School, Boston, MA C 02115.

Anatomical and physiological methods have been used to demonstrate the columnar organization of neurons and neuronal demonstrate the columnar organization of neurons and neuronal circuitry in the visual cortex. Intracellular filling of cells and other methods of labeling have also revealed extensive horizontal connections in the visual cortex which seem to be clustered in nature '. The functional significance of these horizontal connections and their contribution to the features of cortical receptive fields is largely unknown. The present experiments investigate the relationship between the physiologi-col cornectivity of prime of colle as shown by conses-cornelation cal connectivity of pairs of cells as shown by cross-correlation methods<sup>3</sup> and the cells' receptive field properties.

Recordings in striate cortex from two independently manipulated extracellular electrodes were processed by window discriminators and fed into a digital computer programmed to perform real-time auto- and cross-correlations with high temporal resolution. This arrangement allowed rapid assessment of the physiological connectivity of cell pairs as the electrodes were advanced from cell to cell and receptive fields were character-ized. We began our experiments in the monkey striate cortex by electrophysiologically mapping the orientation columns in a limited region of cortex. Using one roving electrode and one fixed electrode, this map provided a systematic means for study-ing connectivity between spatially separate regions of various orientation specificities.

Preliminary results in both the monkey and the cat showed that units separated by .2mm or more with overlapping receptive fields but differing in receptive field properties such as orientation or directionality had responses which tended not to be correlated. At these distances, pockets of units exhibiting correlated firing had receptive field properties that matched. However, not all regions of units with matching receptive field nowever, not all regions of units with matching receptive field properties showed correlated responses. The correlograms obtained suggest that horizontal interactions at these distances are excitatory. These findings provide physiological evidence for a functional contribution of horizontal connections and are consistant with anatomical demonstrations of the clustered nature (Supported by grants EY00606, NS16189, and EY070402.)

141.10 LATTICE-LIKE INTRINSIC NEURAL CONNECTIONS IN MACAQUE PRESTRIATE

LATTICE-LIKE INTRINSIC MEURAL CONNECTIONS IN MACAGOE PRESTRIATE VISUAL CONTEX. K.S. Rockland. Southard Lab of Neuropathology, E.K. Shriver Center, Waltham, Mass. 02154 Earlier work (Rockland and Lund, '33) described a lattice-like pattern of intrinsic connections in striate cortex (area 17) of macaque and squirrel monkeys. The lattice walls, visualized by injections of horseradish peroxidase (HRP) into area 17, contain retrogradely filled neurons and orthogradely filled axon terminals, as well as labeled fibers. The lattice interaxon terminals, as well as labeled fibers. The lattice inter-stices are crossed by labeled fibers, but are not otherwise labeled. Injections of HRP in several prestriate areas in macaque reveal complexly patterned intrinsic connections in these areas also. In area V2 (injections placed in the lunate sulcus, annectent gyrus, and ventral to the calcarine sulcus) retrogradely labeled neurons occur in layers III and V. These retrogradely labeled neurons occur in layers III and V. These neurons are in register with terminal arborizations, which are labeled in layers I-VI, but are particularly dense in layers III and V. In coronal sections, these connections appear organized in radial columns, measuring about 400u across and visualized for 2.0 - 3.0mm from the injection site. Injections in area V4 (on the prelunate gyrus) similarly reveal labeled neurons in layers III and V, in register with labeled terminations. In layers 111 and V, in register with labeled terminations. In area V4, these connections measure about 500-750u across and can be followed for 3.5 -4.0mm from an injection. Intrinsic connections in both areas V2 and V4 can also be demonstrated by injections of 3H-amino acids. When examined in the tangential plane of section, these connections, like those in area 17, are seen to have a reticular or lattice-like configuration. squirrel monkey, similarly organized periodic intrinsic con-nections occur in several prestriate areas (V2 and MT). In

In both macaque and squirrel monkeys, cytochrome oxidase preparations reveal regular inhomogeneities in area V2 that are organized in a stripelike array, running orthogonal to the border with area 17. These cytochrome oxidase stripes occur in layers III and V (measuring 1000-1500u across in macaque, 750-1000u in squirrel monkey). Preliminary data suggest that the cytochrome stripes (corresponding to pulvinocortical terminations, Livingstone and Hubel,  $^{18}2$ ) do not overlie the intrincip correctional lattice in prostricts cortex (lattice) the functional network of the intrinsic lateral context of the large tangential spread of the intrinsic lateral connections (over s.0-4.0mm) may imply that they mediate effects larger than one receptive field area. (Supported by EY04946)

141.11 TOPOGRAPHY OF CYTOCHROME OXIDASE PATTERNS IN EXTRASTRIATE CORTEX OF THE OWL MONKEY. Roger B. H. Tootell\*, Martin S. Silverman\*, and Russell L. De Valois\* (spon:D. Albrecht). Dept. of Psychology, University of California, Berkeley, California 94720.

and model i. Defaultors (spont). All bentor, percent of 4720.
The discovery of spots (blobs, puffs) in V1 and strips in V2 has prompted a number of experiments on the radial architecture of these regions in the primate. In both areas, the periodic radial landmarks allow an analysis of module structure and function, and in V2 the termination of the strips furnishes a clear anatomical marker for defining the anterior boundary of the region.

Presumably, similar anatomical analyses will be possible in any cortical area in which a distinctive topography can be demonstrated. In order to look for such areas, we flat-mounted the entire surface area of the owl monkey cortex, sectioned it tangentially, and processed the tissue for cytochrome oxidase. Alternate sections were stained for myelin or nissl substance. Distinctive cytochrome oxidase patterns are found in at

141.13 INFLUENCE OF STIMULUS VELOCITY ON MONKEY STRIATE NEURONS: CHANGES WITH ECCENTRICITY. G.A. Orban, H. Kennedy<sup>\*</sup>and J. Bullier<sup>\*</sup>. Laboratoire de Neuropsychologie Expérimentale, INSERM-U 94, Bron (France) and Laboratorium voor Neuro-en Psychofysiologie, KUL, Medical School, Leuven (Belgium).

Area 17 neurons were recorded in anesthetized and paralyzed cynomolgus monkeys. The influence of stimulus velocity of an optimal narrow slit was tested with a randomized multihistogram technique (10 to 15 velocities ranging from .2 to 800°/sec). Background illumination was 8 cd/m<sup>2</sup> and stimulus luminance 36 cd/m<sup>2</sup>. The neurons recorded in area 17 subserving central vision (0-2° eccentricity, n = 30) were compared with those subserving peripheral vision (eccentricity over 15°, n = 31). Histological verification showed that in both eccentricity classes all layers were sampled. Velocity sensitivity was measured by the half height upper cut-off velocity (Orban et al., J. Neurophysiol., 45, 1043, 1981) i.e. the velocity at which the response to slow movement, i.e. the response to .2°/sec movement expressed as percent of the maximum response. The velocity locity increased on average from 8.7°/sec to 61°/sec, while the average response to slow movement decreased from 86% to 61%. In area 17 subserving central vision most cells (80%) were velocity broad band. The proportions of velocity tuned cells and direction selective cells (as defined in Orban et al., 1981) while the majority of the cells in the periphery (68%) were small in both eccentricity classes. These results show that the dependence of velocity sensitivity and direction selective cells (as defined in Orban et al., 1981) were small in both eccentricity classes. These results show that the dependence of velocity sensitivity and direction selectivity on act and 18 where the direction selectivity changes with eccentricity.

141.12 INTERACTION DISTANCES FOR SUCCESSIVELY FLASHED STIMULI IN MACAQUE MT. <u>A. Mikami, W.T. Newsome and R.H. Wurtz</u>, Lab. of Sensorimotor Research, National Eye Institute, NIH, Bethesda, MD 20205.

Sequentially flashed stimuli have been profitably used by several investigators to study mechanisms of direction selectivity, and we have applied this method to the study of direction selectivity in extrastriate area MT of the macaque monkey (Mikami et al., <u>ARVO Absts.</u>, 1983). One of the most striking results of our experiments has been the large interflash distances for which directional interactions can be obtained. We now report that this "interaction distance" is highly correlated with the speed for which direction selectivity can be obtained with smoothly moving stimuli.

MT neurons were isolated in awake behaving macaque monkeys. Receptive field boundaries were plotted, and tuning for direction and speed of smoothly moving stimuli were quantitatively determined. We then systematically varied the spatial separation and temporal interval between flashes for sequences in the preferred and null directions to determine the maximum interaction distance and interaction interval, respectively, for each cell. The ratio of response in the preferred direction to response in the opposite direction was arbitrarily required to be 5 to 1 before interactions, the maximum interflash distance which yielded directional interactions in MT neurons ranged from .32° to 6.0° with a geometric mean of 2.1°. In recordings from a few neurons in MST (a motion-related area to which MT projects) interaction distances were as large as  $10^\circ$ . Some of these interaction in any previously studied visual structure.

in any previously studied visual structure. For 36 neurons we attempted to correlate the maximum interaction distance with the highest speed for which the neuron was direction selective to smoothly moving stimuli. Natural logs of the two measures were highly correlated (r=.82; p<.001; df=34). The maximum temporal intervals for which directional interactions could be obtained were not correlated with speed for directionality for smoothly moving stimuli. These results show that the capability of an MT neuron to discriminate direction at high stimulus speeds is a function of the <u>spatial</u> extent of directional interactions within the receptive field. Since many of the interaction distances we observed are larger than the average receptive field diameter of striate neurons at equivalent eccentricities, it seems likely that the discrimination of direction at high stimulus speeds is a functional elaboration found primarily in the large receptive fields of extrastriate visual areas.

141.14 2-D PATTERNS ARE REPRESENTED IN TEMPORALLY MODULATED ACTIVITY OF STRIATE CORTEX CELLS. B. J. Richmond, L. M. Optican\*, and M. Podell\*, Laboratory of Neuropsychology, NIMH; Laboratory of Sensorimotor Research, NEI; NIH, Bethesda, MD 20205.

Although the receptive field properties of single neurons in area 17 have been studied extensively, receptive field structure alone can not predict a cell's temporal response to 2-D patterns because it does not describe a spatial-to-temporal transformation. We wished to determine how 2-D pictures were represented in the temporal activity of single units in area 17.

represenced in the temporal activity of single units in area 1/. We used 64 black and white stimuli, 3 deg square, that formed a complete, orthogonal basis set (based on Walsh functions) for pattern representation. The monkeys were trained to fixate a spot of light. The fixation light blinked off 300ms before the 400ms stimulus presentation; 400-700ms later the fixation point returned and dimmed. Only successfully completed behavioral trials were analyzed. The receptive fields of the neurons studied were approximately 3 deg contralateral to the center of gaze.

Activity of these single units was found to differentially represent members of the stimulus set. The poststimulus spike train was convolved with a Gaussian pulse to form a probability density function of spike occurrence. An average spike density function was then computed for each of the 64 stimuli. The temporal modulation caused by each pattern was quantified by decomposing the responses into their principal components with a Karhunen-Loeve transform. Two to three components were needed to reconstruct the cell's activity well enough to preserve its ability to differentiate among stimuli. Since the KL transform requires fewer components than any other linear transform (e.g. Fourier) for a given accuracy in representing the spike density functions, no single linear measurement can adequately represent the ability of these cells to discriminate among 2-D patterns.

Some patterns which give the same response when measured with any single parameter, e.g. spike count, are differentiable when the waveform of the activity (as measured with multiple components) is considered. There was very little difference in the cell's ability to differentiate stimuli when the waveforms were analyzed over short (128ms), rather than long (384ms) periods. We conclude that single striate neurons can convey detailed information about 2-D visual features in the temporal modulation of their activity.

We have recently shown temporal modulation by 2-D patterns of cell activity in inferior temporal cortex (ARVO abstracts, 1983). These results in two visual areas suggest that temporal modulation in response to visual features is important for pattern processing in the visual system.

SEPARATION OF DIRECT AND AROUSAL-RELATED INFLUENCES ON LEARNING 142.1 AND MEMORY. <u>Rita B. Messing and Sheldon B. Sparber\*</u>. D Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455. Dept. of Many agents may act in learning and memory tests by altering arousal levels. However, little systematic attention has been given to the problem of separating neurohumoral or drug effects on

arousal levels. However, little systematic attention has been given to the problem of separating neurohumoral or drug effects on arousal from more direct actions on encoding and retrieval of information. This is most likely because it is thought to be difficult to conveniently manipulate arousal independently of drug doses and unconditioned stimulus parameters. Recently, while investigating drug effects on autoshaped behavior, we predicted that the rate of acquisition could be enhanced by increased arousal produced by injecting rats with saline shortly before testing. Accordingly, male Long Evans rats, maintained at 85% of free-feeding body weights, were trained in a discrete trial, autoshape procedure, in which they were rewarded with 45 mg food pellets for touching a retractable lever presented on a 45 s random time schedule. Retracted lever contacts (nose-pokes) and unconditioned exploratory (rearing) activity were simultaneously monitored. Groups of rats (n=5-6), subjected or not subjected to handling and injection for 10 days, were administered 1 ml/kg of 0.9% NaCl s.c. 5 or 30 min before each of 2 autoshaping sessions, 2 days apart. They received 1 block (A) of 12 trials (lever presentations) in the first session and 3 blocks (B,C,D) in the second. No significant treatment effects on basal (Block A) response rates were found for any behavior. Treatment effects on learning were evaluated by a repeated basis (block A) response rates were round for any behavior. Treatment effects on learning were evaluated by a repeated measures analysis of variance on the change in responding between block A and blocks B and C. The results indicated that handling and injection history had no effect on acquisition, but that the rats administered saline closer to testing acquired the response more rapidly (F=4.78, df=1,17, P=0.04) (see Table).

Δ	Extended Lever Touch	Responses (X ± S.E.)
Inj. Time	Block B - Block A	Block C - Block A
-5 min	4.2 ± 0.9	5.1 ± 1.2
-30 min	0.9 ± 1.0	2.6 ± 1.0

We thus propose that this procedure provides a simple method for We thus propose that this procedure provides a simple method for manipulating arousal independently of other experimental variables. Based on classical conceptions of arousal effects on learning and performance, substances which act by increasing arousal should facilitate acquisition in animals given saline more than 30 min before training, but should impair it in more highly aroused rats injected with the saline probe 5 min before. (Partially supported by USPHS Grant T32DA07097.)

- OPERANT CONDITIONING: CELLULAR OR SYSTEMS PROPERTY? 142.2 James D. Belluzzi and Larry Stein. Department of Pharmacology, College of Medicine, University of California, Irvine, Irvine, CA 92717.
  - When behavior is followed by reward, the probability of the behavior is increased by a process called positive reinforcement or operant operant conditioning. A fundamental problem is to identify the functional unit for positive reinforcement in the brain. The simplest possible unit whose behavior may be capable of operant conditioning is the single brain cell. Accordingly, we attempted to demonstrate operant conditioning at the cellular level by a procedure that resembles behavioral operant conditioning. A glass micropipette for simultaneous recording and pressure injection is filled with dopamine (1 mM in 165 mM saline) or other drugs and aimed at spontaneously active cells in whole brain or CA1 cells in hippocampal slices. The neuronal response for reinforcement ("criterion response") is defined as a half-second of relatively fast activity. The requisite number of spikes/500 ms is individually established for each neuron studied so that, prior to operant conditioning, criterion responses occur at a rate of less than 5 per minute. During conditioning, a pump is briefly activated immediately after each criterion response to deliver a 10 µ-diameter droplet of drug or saline to the cell. The FIGURE shows a complete experiment for a CA1 cell reinforced with dopamine. In the first baseline phase, two criterion responses on average are observed in each block of 100 trials. Criterion responses increased sharply following the introduction of dopamine reinforcement. A matched number of noncontingent ("free") dopamine injections had no such effect, suggesting that direct stimulation could not explain dopamine's facilitatory action — indeed, noncontingent dopamine injections generally suppress the activity of CA1 cells. A second successful reinforcement phase suggested that the preparation remained viable throughout. Positive results were obtained in 8 of 16 additional dopamine experiments and 11 of 48 cocain experiments, whereas saline, GABA, and serotonin gave negative results. These findings suggest that neuronal firing patterns can be individually conditioned by the local application of a reinforcing transmitter or drug. Since it is unlikely that a neuron would display a gratuitous capacity for positive reinforcement, we suggest that permit conditioning in a callular action the autore apportune. (Supported by NIDA 02725 and AFOSR F49620-81-K-0015).

DISSOCIATION OF CHULINERGIC DRUG EFFECTS ON SHORT-TERM AND 1424 LONG-TERM MEMORY IN MICE.

J.F. Flood, G.E. Smith and Arthur Cherkin. Center, Sepulveda, CA 91343 GRECC. VA Medical

Research on drug-induced enhancement or impairment of memory retention is plaqued by inconsistent results. Suggested sources of incomistency include variations in: behavioral paradigms; time intervals between training, drug administration and reten-tion testing; and in drug doses. We present evidence which: (1) emphasizes the importance of these variables; (2) demonstrates their impact with a supra-additive two-drug combination as well or with the simple druge where word (3) are colored additional testing). as with the single drugs alone; and (3) reveals a dissociation of drug effects upon memory retention measured 3 hours vs 168

of drug effects upon memory retention measured 3 hours vs 168 hours after training and drug injection. The drugs, arecoline hydrobromide (ARE) and edrophonium chloride (EDR; Tensilon) were injected subcutaneously immedi-ately after training. The subjects were CD-1 male mice, 8 wk of age. The paradigm was I-maze active avoidance, under two training conditions, TC1 and TC2. TC1 was adjusted so that control mice showed good retention performance 1 hour but not 3 hours of the thermal memory actives avoidance active to the state of the training. control mice snowed good retention performance i nour but not b hours after training. Under TC2, controls showed good retention 24 hours but not 168 hours after training. Dose-response was studied under both TC1 and TC2, using ARR, EDR or the ARE + EDR combination at a fixed ratio. The optimal dose (mg/kg) for maximal memory retention scores are presented in the table.

Drug	Dose - TC1 (3-h Test)	Dose - TC2 (168-h Test)	Ratio TC2/TC1
ARE	0.30	1.25	4.17
EDR	1.20	7.00	5.83
ARE + EDR	0.20 + 0.60	0.05 + 0.22	0.25; 0.37

The results indicate that the optimal dose of each single drug for 168-hour retention averages 5 times the optimal dose for 3-hour retention. Such higher doses, when used under TCL, <u>impaired</u> memory retention or impaired sensory and motor perform-ance when the mice were tested 3 hours after injection. If only a single high dose were tested under TC1, it would appear to have no effect on memory.

The results indicate that the two-drug combination permitted a substantial reduction of the dose required for optimal retention under TC2 (96% less ARE and 97% less EDR). The reductions tion under TC2 (96% less ARE and 97% less EDR). The reductions were much less under TC1 (33% less ARE and 50% less EDR). The optimal combination dose for maximal 168-hour retention had no effect upon 3-hour retention. The single drug doses which improved 168-hour retention impaired 3-hour retention or performance.

THE CHOLINERGIC NERVOUS SYSTEM AND TEMPORAL MEMORY IN RATS. Warren H. Meck<sup>\*</sup> and Russell M. Church. Department of Psych 142.3 h H. Meck<sup>\*</sup> and Russell M. Church. University, Providence, RI 02912. Department of Psychology,

The purpose was to determine if reference memory for rein-forced durations could be selectively adjusted by the pharmacoloforced durations could be selectively adjusted by the pharmacolo-gical manipulation of central cholinergic neurons. A peak proce-dure was used to study the scaling of duration by rats (e.g., Roberts, J. Exp. Psychol. Anim. Behav. Processes 7: 242, 1981). In this procedure, after an intertrial interval a signal occurs and, on some trials, food is primed after a fixed duration and the rat's next lever press is reinforced; on other trials no food is available and the trial lasts for a relatively long time after the fixed duration. As a tresult, the recence rate of the art the fixed duration. As a result, the response rate of the rat initially increases as a function of the time since signal onset, as it does during standard fixed-interval training. After the time that food is sometimes available, however, the response rate decreases in a fairly symmetrical fashion when response rate is plotted on a linear time scale. The time the response rate is maximal is called the "peak time." It occurs near the time that food is maximally expected and serves as a measure of the rat's temporal criterion which is a value stored in reference memory. Using this procedure with reinforcement sometimes following the first lever press after a white noise signal had been present for 20 sec, we demonstrated that physotramin and been piss-i.p. decreased the variability of the temporal discrimination and shifted peak times permanently leftward on the time scale in a dose-dependent fashion (0, .01, .03, & .09 mg/kg). Neostigmine, an anticholinesterase that does not readily cross the blood-brain barrier, did not produce these effects. Atropine administered i.p. <u>increased</u> the variability of the temporal discrimination and The interest of the variability of the temporal discrimination and shifted peak times permanently <u>rightward</u> on the time scale in a dose-dependent fashion (0, .05, .15, & .45 mg/kg). Methyl-atro-pine, a cholinergic receptor blocker that does not readily cross the blood-brain barrier, did not produce these effects. Applica-tion of a scalar timing model indicated that physostigmine decreased the remembered values for reinforced durations and in-creased sensitivity to time, while atropine increased the remem-bered values for reinforced durations and decreased sensitivity to time. These results extend the findings of Meck (J. Exp. Psychol. Anim. Behav. Processes 9: 171, 1983) to a different timing procedure and suggest that the effective level of brain ace-tylcholine sets memory storage speed for sound durations in the Thus, physostigmine increased memory storage speed and rats remembered clock readings as shorter than they actually were, and atropine decreased memory storage speed and rats remembered clock readings as longer than they actually were. (Supported by NIMH Grant MH 37049.)

ECT-INDUCED ANTEROGRADE AMNESIA-A POSSIBLE CHOLINERGIC 142.5 MECHANISM. B. Lerer\*, M. Stanley\*, H. Altman and I. McIntyre\*. (SPON: H. Goldman). Lafayette Clinic Wayne State University Sch. of Med., Detroit, MI 48207 Patients treated with electroconvulsive therapy (ECT) manifest an anterograde amnesia characterized by impaired delayed recall of newly learned material. The following studies were undertaken in order to elucidate a possible neurochemical basis for ECT-induced amnesia. Electroconvulsive shock (ECS) was administered daily

for 7 days to rats which were sacrificed 24 hours after the last shock. ECS was found to induce a statistically significant 15% and 13% reduction in  $^{3}$ H-QNB binding to muscarinic cholinergic receptors in rat cerebral cortex and hippocampus respectively. Scatchard analysis of binding data showed a reduction in Bmax without a change in Kd. Rats sacrificed 24 hours after a single ECS did not show a similar reduction in  $^{3}$ H-QNB binding. Concurrent adily ECS was also found to completely block a significant increase in cortical <sup>3</sup>H-QNB binding caused by chronic atropine administration (10mg per Kg ip. for 5 days). In a parallel experment groups of ECS and sham-treated rats underwent passive-avoidance training 24 hours following

the last of a series of daily ECS for 7 days (training parameters: 0.5mA for 1 sec. inescapable shock). Retention of the original avoidance habit was measured 7 days later by returning the animals to the lighted side of the shuttle-box; after a brief accommodation period (10 sec.) the door separating the lighted from the dark chamber was opened and the animal's latency to cross (step-through latency) was recorded. Highly significant impairment of delayed recall was demonstrable in the ECS-treated group. Such impairment was not present in rats trained 24 hours following a single ECS.

The parallel time-course of muscarinic receptor subsensitivity and memory impairment induced by repeated ECS suggests a possible causative relationship. This possibility will be discussed in the context of the results of further studies evaluating the effect of cholinergic agonists on the ECSinduced memory impairment.

ALLEVIATION OF FORGETTING IN RATS BY INTRAVENTRICULAR INJECTION OF 142.6 APOMORPHINE BEFORE RETENTION TEST. S.J. Sara \*, G. Grecksch \* and M. Hongenaert \* (SPON : D. Quartermain). Dept de Psychophysiologie CNPS Q 190 Gif-sur-Yvette, France and Inst für Pharmakologie und

Toxikologie, Med. Akad. Magdeburg, DDR. Rats which are trained in a maze consisting of 6 left-right choices learn the task in 5 daily trials. When tested 3 weeks later, they exhibit significant retention deficits. We have found that this forgetting can be alleviated by several pretest treat ments, the most effective beeing exposure to contextual cues of the experimental environment immediately prior to the retention test (Deweer, B. et al, <u>Anim. Learn. Behav. 8</u>:2, 1980). Systemic injections of small doses of amphetamine also facilitated performance in the same paradigm (Sara, S.J. & Dever, B., <u>Behav. Neural</u> <u>Biol.</u> 36:146, 1982), leading to the hypothesis that contextual cue reminders facilitate memory retrieval through conditioned release of catecholamines (see also Cassens, G. et al, <u>Science</u> 209:1138, 1980). The present experiments address the question of specificity of site of action (central or peripheral), by using intraventricular injections of amphetamine, which releases both dopamine and noradrenalin, and the more specific agonist, apomorphine, a dopamine receptor stimulator. The rats were trained with 5 daily trials ; one week later

they were implanted with intraventricular cannula ; they were Lety were implaited with inflaventificular cannula; they were tested for retention 3 weeks after the last training trial. Fif-teen minutes prior to retention test they were injected with am-phetamine (20 µg or 40 µg) or apomorphine (10 µg or 40 µg) or an equal volume of saline (4 µl). Saline treated rats made signifi-cantly more errors at retention test. Amphetamine-treated rats tended to make fewer errors than controls, but the results had a large variance and were nonsignificant (p < .10). A second experiment yielded the same pattern of results, despite a larger N, thus leaving open the question of whether the peripheral effects of systemic amphetamine can alone account for its facilitation of memory retrieval. Apomorphine, on the other hand clearly alleviated the forgetting (p < .001) at the smaller dose, but had no effect at the larger dose. This suggests that central dopamine systems are involved in regulating processes related to memory retrieval. However, recent discovery of ventral tegmentum dopaminergic projections to locus coeruleus (Milon, H. & Mc Rae-Degueurce, A., <u>Neurosci. Let.</u> 30:297, 1982) leaves open the possi-bility that noradrenergic regulation is involved. Neurochemical studies of the effect of apomorphine injections on various brain regions are presently underway and the results will be reported at this meeting.

SEROTONERGIC MEDIATION OF CONDITIONED BRADYCARDIA IN THE ALBINO 142.7

SEROTOMERGIC MEDIATION OF CONDITIONED BRADYCARDIA IN THE ALBINO RABBIT (Oryctolagus cuniculus). Sheryl R. Ginn\*, Linda L. Hernandez, and D. A. Powell. Neuroscience Lab., VA Hospital and University of South Carolina, Columbia, S.C. Research from our laboratory indicates that forebrain sero-tonin (5-HT) may be involved in mediating Pavlovian cardio-vascular (CV) conditioned responses (CRs). For this reason, the effects of 5-HT agonist and antagonist drugs on the cardiac component of the orienting reflex (OR) and on Pavlovian condi-tioned CV responses were investigated in rabbits. Subcutaneous injections of the central 5-HT antagonist pizotifen (BC-105; 2.5 mg/kg. 5.0 mg/kg. and 10.0 mg/kg). injections of the central 5-HT antagonist pizotifen (BC-105; 2.5 mg/kg, 5.0 mg/kg and 10.0 mg/kg), the peripheral 5-HT antagonist xylamidine tosylate (10.0 mg/kg), the central 5-HT agonist d-lysergic acid diethylamide (d-LSO; 0.03 mg/kg), d-LSD (0.03 mg/kg) in conjunction with BC-105 (5.0 mg/kg) or saline were administered to rabbits 15 min prior to OR assessment and aversive differential Pavlovian heart rate (HR) conditioning. Four sec, 75 dB tones of 1216 or 304 Hz frequency served as the stimuli during OR assessment and as the CS+ or CS- during conditioning. A 500 msec, 3 mA paraorbital electric shock train served as the US. conditioning. A served as the US.

Both the HR CR and OR consisted of bradycardia. The central Both the HK CK and UK consisted of bradycardia. The central antagonist BC-105 attenuated habituation of the OR; however, the peripheral antagonist xylamidine potentiated OR habituation. d-LSD attenuated the magnitude of the OR compared to saline administration; this attenuation was partially blocked by BC-105. ministration; this attenuation was partially blocked by BC-105. BC-105 produced a dose-related attenuation of the bradycardiac HR CR. The largest HR CRs of all groups tested occurred in those animals receiving 10 mg/kg xylamidine, suggesting that the attenuation by BC-105 of the HR CR is central, rather than peripheral, in origin. d-LSD appeared to have little effect on the CR. BC-105 in conjunction with d-LSD attenuated the deceleration to both the CS+ and CS- as well as attenuating the discrimination between CS+ and CS-. These results suggest that 5-HT neurons in the CNS may modulate the magnitude of brady-cardiac responses during orienting and aversive Pavlovian conditioning. conditioning.

CENTRAL VERSUS PERIPHERAL ACTIONS OF LEU-ENKEPHALIN ON 142.8 ACQUISITION OF A GNE-WAY ACTIVE AVOIDANCE RESPONSE, LOCOMOTOR ACTIVITY AND SHOCK SENSITIVITY. J.L. Martinez, Jr., P. Conner\*, and R.C. Dana\*. Psychobiol. Dept., Univ. of Calif., Irvine, CA 92/17.

Previously, Martinez and Rigter (<u>Neurosci</u>. Abstr. 1980, 6, 319) reported that adrenal medullectomy abolished the impairing actions of enkephalins on acquisition of a one-way active

actions of enkephalins on acquisition of a one-way active avoidance response. The present study was undertaken to investigate further whether Leu-enkephalin (LE) acts through some peripheral mechanism by directly comparing peripheral (i.p.) and intracerbrowentricular (i.c.v.) routes of administration. LE (1.0 or 10.0  $\mu$ g/kg) or saline was administered to rats (Harlan Sprague Dawley) 5 min before training. Rats were placed in the shock compartment of a two-compartment alley and given 10 sec to shuttle into the safe compartment alter 10 sec a shock (1.0 mÅ) came on which was terminated when the rats escaped. Eight trials were given; the intertrial interval was 30 sec. As shown by Dument's procedure, the rats that received 10  $\mu_0/kg$  of shown by Dunnett's procedure, the rats that received 10  $\mu$ g/kg of LE made fewer avoidances than the saline group [t(2,49)=2.19,p < .05].

The effects of a four log unit dose range of LE  $(0.00275-2.75 \mu q/rat)$  administered i.e.v. 5 min before training on acquisition do the avoidance response was investigated. The highest i.c.v. dose was approximately the same as the 10  $\mu$ g/kg dose given i.p., since the average weight of the rats was 275 g. No dose of LE No dose of LE

since the average weight of the rats was 275 g. No dose of LE given i.c.v. was found to influence acquisition of the response. The effects of either saline, LE (10 µg/kg) or d-amphetamine (3.0 ng/kg) administered i.p., or Ringer's, LE (0.00275-2.75 µg/rat) or d-amphetamine (300 µg/rat) administered i.c.v. on locomotor activity was investigated. Before being placed in the open field all rats received a 1.0 mA, 1.0 sec footshock. Only d-amphetamine [U(8,9) = 4, p < .002]. For i.c.v. administration both d-amphetamine [U(8,9) = 4, p < .002] and 0.275 µg of LE [U(5,9) = 7, p < .051 increased activity. 7, p < .05] increased activity.

Finally, the effects of either Ringer's (i.p. and i.c.v.), LE (0.0275 or 0.275  $\mu$ g/rat) or morphine (6 mg/kg, i.p. or 30  $\mu$ g/rat) were determined on shock sensitivity. The range of shock intensities was 0.1-1.0 mÅ. Morphine given i.p. or i.c.v. produced analgesia as did 0.275  $\mu$ g LE. The lowest dose of LE

(0.0275 µg) produced hyperalgesia at the lowest shock intensity. The results suggest that LE impairs conditioning through a peripheral mechanism of action, since it is ineffective if administered directly into the brain. However, LE given i.c.v. clearly affects other behaviors such as locomotor activity and shock sensitivity. (Supported by ONR contract N00014-82-K-0385 to TM ) to JLM.)

THE ROLE OF MONOAMINES IN SUBSTANCE P INDUCED MEMORY ENHANCEMENT. 142.9 M.A. Pelleymounter\* and Kurt Schlesinger\* (SPON: H. Alpern). Dept. of Psych. and the Inst. for Behavioral Genetics, Univ. of Colorado, Boulder, CO 80309.

Large concentrations of Substance P (SP) have been located in higher central nervous system areas in coexistence with axons and terminals of dopamine (DA) and serotonin (5HT), particularly in substantia nigra and the striatum. Peripheral injection of SP immediately following, but not prior to, passive avoidance training, results in increased retention of the task suggesting that SP may be involved in the consolidation phase of memory processing. This study examined the role of monoamines in a mechanism for SP-induced memory enhancement by measuring changes in nigral and striatal DA, 5HT and norepinephrine (NE) levels during different stages of memory processing in passive avoidance learning. Male HS mice were placed into the clear chamber of a passive avoidance apparatus, and their latency to enter the dark area was measured. Upon entry into the dark chamber, a 0.4 mA, 5 sec footshock was administered. Immediately following the above training session, animals were injected (s.c.) with 1 ng/g SP or with acid-ified saline. Animals were tested 24 hr later for latency to enter the dark area. Retention was defined as the difference in latencies. Animals were sacrificed either 1 hr after injection and training (lIT), 24 hr after injection and training (24IT), 1 hr after injection and training without shock (11) or 1 hr after training without injection (1T). Brains were removed, frozen and rapidly dissected into striata and substantia nigra. Sections were homogenized in butanol and analyzed for DA, 5HT and NE levels using the fluorescence technique of Jacobowitz and Richardson. A dose response measure of monoamine levels in these brain areas was also done on another group of mice 1 hr after peripheral in jection of acidified saline, 1, 10, 100, 200, or 1,000 ng/g of SP. Biochemical analysis was done in the manner described above. 5HT levels were not different in 1I and 1T groups in either brain area, but were significantly lower in 241T mice than in 1IT animals; p<.05. DA levels were similar in 1I and 1T but were significantly elevated in the 24IT group; p<.01. NE levels were higher in 1T mice than in 1I mice but were not changed in other groups. The dose response study showed that 5HT levels in both brain areas decreased in a linear manner with increasing dose of SP. DA levels, however, were increased at the 1, 100, and 1,000 mg/g doses of SP in comparison to the saline group. NE levels did not change with increasing dose of SP in either brain area. These results support the hypothesis that SP may be a cotransmitter in certain monoamine pathways and that monoamines may be involved in the memory enhancing effects of SP. (This work was supported by NIH Contract #0780.4.524 B).

142.11 A SPECIFIC HYPOTHESIS CONCERNING THE BIOCHEMICAL SUBSTRATES

A seturic introduction of the blockmine in blockmine Substrates OF MEMORY. <u>M. Baudry and G. Lynch</u>. Department of Psycho-biology, UC Irvine, Irvine, CA 92717. Despite extensive theoretical and experimental inves-tigation, specific and testable hypotheses concerning the biochemistry of learning and memory in higher vertebrates have not yet been proposed. Our studies on the regulation of synaptic efficiency and glutamate receptors suggest a new, specific, and seemingly testable hypothesis about the bio-chemical events that lead to memory storage in mammals. The chemical events that lead to memory storage in mammals. central points of the hypothesis to be discussed are as The follows:

1) intense synaptic activity causes an elevation of intra-

cellular calcium in postsynaptic structures, 2) calcium activates a membrane associated neutral thiol proteinase ("Calpain I") that degrades the spectrin-like protein fodrin and certain other peptides related to the cytoskeleton,

3) this causes a localized membrane reorganization such that normally occluded receptors are exposed. the additional receptors produce potentiated synapses,

and 5) additional episodes of intense synaptic activity cause

wide-spread activation of calpain leading to changes in the shape of dendritic spines.

The proposed mechanism satisfies certain essential re-quirements of an intermediate of memory in that it is triggered by physiologically plausible events and produces Ingelasting changes that should have physiological con-sequences. Moreover, behavioral experiments have shown that inhibition of the calcium proteinase produces a selective impairment of certain types of memory (Staubli, U., Baudry, M. and Lynch, G., this meeting). These results will be discussed in light of recent data showing that the proteinase receptor interaction is absent in non-mammalian vertebrates and in memols is constructed to forobrain etvortune. This and in mammals is restricted to forebrain structures. This raises the possibility that different forms of memory have different biochemical substrates. (Supported by NSF grant BNS81-12156 to M.B. and NIMH grant 19793 to G.L.) This

CALCIUM, LONG-TERM POTENTIATION (LTP) AND DEPRESSION OF HIPPO-CAMPAL POPULATION SPIKE. <u>B. R. Sastry, S. S. Chirwa\*, J. W.</u> <u>Goh\* and H. Maretic\*.</u> Neuroscience Research Laboratory, Depart-ment of Pharmacology, Faculty of Medicine, The University of British Columbia, Vancouver, B. C., V6T 1W5, Canada. Whether LTP is presynaptic and/or postsynaptic is still un-clear although there appears to be a concert belief that LTP is 142.10

Went of Pharmacology, Faculty of Medicine. The University of British Columbia, Vancouver, B. C., V6T LW5, Canada. Whether LTP is presynaptic and/or postsynaptic is still unclear, although there appears to be a general belief that LTP is postsynaptic. The present investigations were conducted on rat hippocampal slices to examine Ca<sup>++</sup> involvement in LTP and depression of the CA1 population spike and population "EPSP" produced by Schaffer collateral (SCH) and commissural (COM) stimulation. Exposure of Slices to a medium in which Ca<sup>++</sup> and K<sup>+</sup> concentrations were 4 mM and 3.1 mM, respectively, resulted in an increase in the size of the population spike (10.1 ± 2.1 SEM fold, n = 6), but the response rapidly returned to almost control levels after re-exposure to the control medium (Ca<sup>++</sup>: 2 mM; Mg<sup>++</sup>: 2 mK; K<sup>+</sup>: 3.1 mM; 30 min: 2.06 ± 0.67 fold, n = 6). In a medium with 4 mM Ca<sup>++</sup> and 5 mM K<sup>+</sup>, the population spike was greatly enhanced (34.44 ± 7.6 fold, n = 7) and the increase was maintained in standard medium (30 min: 9.97 ± 2.08 fold; n = 7). A high frequency tetanus (400 Hz, 200 pulses) of SCH caused LTP of the CA1 population spike (30 min post-tetanus: 2.43 ± 0.56 fold; n = 7), but had little effect on the COM input-induced population spike. A 20 Hz tetanus (200 pulses) of the SCH masked the above LTP for 5-20 min (% response 5 min: 59.2 ± 18.1; 20 min: 88.0 ± 13.4; n = 10). A 20 Hz (200 pulses) tetanus of one input produced a temporary masking, but not a permanent reversal of an established LTP of the population spike produced by the other input (n = 5). Verapamil is known to interfere with soma-dendritic Ca<sup>++</sup>-channels and not to alter transmitter release. This agent (0.33 uM; 3 min) counteracted the 20 Hz (200 pulses) tetanus during the drug application (increase 30 min post-tetanus: 4.94 ± 0.95 fold, n = 5). A 10-min exposure of slices to the medium with 4 mM Mg<sup>++</sup> and 0 mM Ca<sup>++</sup> resulted in an increase in the population spike 30 min post-treatment (1.32 ± 0.09 fold, n = 11). Ca<sup>++</sup> (2-100 nA),

EVIDENCE THAT THE NIGROTEGMENTAL GABAERGIC PROJECTION MEDIATES 143.1 EVIDENCE THAT THE NIGROTEGMENTAL GABAERGIC PROJECTION MEDIATES STEREOTYPY INDUCED BY APOMORPHINE AND INTRANIGRAL MUSCIMOL. J.A. Childs and K. Gale. Dept. of Pharmacology, Georgetown Univ. Schools of Medicine & Dentistry, Washington, D.C. 20007 The substantia nigra (SN) plays a pivotal role in the relay of output from the striatum. One neural pathway from SN projects GABAergic fibers to caudal mesencephalic tegmentum, terminating in the vicinity of the pedunculopontine nucleus (PPN). To evalu-ate the functional importance of this projection in the mediation of sterrotwood behaviors of striatal and nigral opining wo misco of stereotyped behaviors of striatal and nigral origin, we micro-injected low doses of the GABA agonist, muscimol, bilaterally in-to the vicinity of the PPN. Rats receiving long muscimol bilaterally in PPN prior to systemic apomorphine administration (lmg/kg s.c.) showed no observable differences in spontaneous behavior, relative to saline-injected controls. However, this muscimol treatment completely blocked all components of apomorphine-induced stereotyped behavior. Gnawing could not be elicited, even when probes were placed near or inside the rat's mouth. This blockade was evident for the entire duration of apomorphine acblockade was evident for the entire duration of apomorphine ac-tion. The blockade observed with PPN injections was also seen in rats in which injection of long muscimol was placed 2mm below PPN, suggesting that synapses ventral to PPN may also participate in the apomorphine stereotypy. In contrast, apomorphine-induced stereotyped behavior observed in rats receiving long muscimol placed lmm above PPN (in dorsal reticular formation) was not significantly different from that obtained in controls.

Stereotypy elicited by bilateral intranigral muscimol was blocked by injection of muscimol into PPN. Rats receiving both 15ng muscimol in PPN and 8ng muscimol in SN exhibited no stereotyped behavior of any sort; instead, they were relatively inac-tive, sitting still for 50-60 min following intranigral muscimol. We conclude from our results that there exists in the vicinity of the PPN a population of GABA-receptive neuronal elements

of the PPN a population of GABA-receptive neuronal elements which, when inhibited, are capable of blocking all commonly as-sessed components of apomorphine-induced and intranigral muscimol-induced stereotypy. Since the PPN and the region immediately ven-tral to it receive GABAergic projections from SN (1), it is like-ly that stimulation of striatal dopaminergic receptors or of nigral GABAergic receptors acts to reduce GABAergic tone in the terminal field in PPN. Our data shows that the expression of stereotyped hyperactive and dyskinetic motor activities can be provented by the application of a GABA agoint into PDN, it is prevented by the applicative and dystnetic motor activities can be prevented by the application of a GARA agonist into PPN; it is therefore reasonable to infer that net disinhibition of target neurons in this region of reticular formation is necessary for the expression of these stereotyped behaviors. 143.3 EFFECTS OF SPECIFIC DOPAMINE AND SEROTONIN UPTAKE INHIBITORS ON EFFEUIS OF SPECIFIC DUPAMINE AND SEROTOMIN UPTAKE INHIBITORS ON STRIATAL-NIGRAL SUBSTANCE P ACTIVITY. J. Ritter\*, G. Hanson, C. Schmidt and J. Gibb. Dept. Biochem. Pharmacol. & Toxicol., College of Pharmacy, Univ. of Utah, Salt Lake City, UT. 84112. The neuronal circuitry of the striatum and substantia nigra is believed to play an important role in the regulation of certain types of motor activity. A principal pathway in this system is composed of nigral dopamine (DA) neurons which project to the striatum. Some control of this dopamineneito project to the composed of nigral dopamine (DA) neurons which project to the striatum. Some control of this dopaminergic projection is thought to be exerted by feedback striatal-nigral loops. It has been suggested that the excitatory component of these loops employs the neuropeptide, substance P (SP), as its transmitter (Hong et al., <u>Neuropharm.</u> 17[1978]83). If the striatal-nigral SP neurons have a Teedback function to the dopaminergic system, changes in dopaminer-gic activity would likely influence the associated SP pathway. One method for evaluating the activity of the SP striatal-nigral neurons is to measure the concentration of substance P-like immunoreactivity (SPLI) in the substantia nigra, site of the axon

neurons is to measure the concentration of substance P-like immunoreactivity (SPLI) in the substantia nigra, site of the axon terminals of this SP pathway. We have found that subacute admin-istration of the DA agonist, methamphetamine (4X, 10 mg/kg, q6h) elevates nigral SPLI by 30%. However, because methamphetamine (METH) also significantly influences serotonin pathways associated with the striatal-nigral system (Bakhit et al., <u>Eur. J. Pharma-col.</u>, 76[1981]229), it is unclear if the METH-induced changes in figral SPLI are related to the increases in dopaminergic or serotonergic activity caused by this drug. To resolve this question, the responses of the striatal-nigral SP pathway to specific uptake blockers of dopamine and serotonin were studied. Dose-dependent increases in nigral SPLI concentrations were observed following the subacute injections (4X, q6h) of amfonelic acid, a potent dopamine uptake blocker (12% at 0.1 mg/kg; 26% at 0.5 mg/kg; 60% at 1.0 mg/kg). Increases of 34% in nigral SPLI could also be measured following a single injection of amfonelic acid (2.5 mg/kg). In contrast, subacute treatments with the specific serotonin (5-HT) uptake blockers, citalopram (5X, 2 mg/kg, q6h) and chlorimipramine (5X, 4 mg/kg, q6h) did not alter nigral SPLI concentrations. These results suggest that the METH-induced changes in the striatal-nigral SP pathway are likely dopamine-mediated. However, the possibility that the serotonergic system might also directly or indirectly influence this SP system can not be ruled out since inhibition of 5-HT synthesis 48 hours following a single dose of p-chlorophenylalanine (5D mg/kg) significantly elevated nigral SPLI concentration by 17%. 143.2

THE EFFECT OF STABLE "ANTAGONIST" ANALOGS OF SUBSTANCE P ON SUBSTANTIA NIGRA EFFERENT PATHWAYS. <u>Maria Rosaria Melis\* and</u> <u>Karen Gale.</u> Dept.of Pharmacology, <u>Georgetown Univ.</u> Schools of <u>Medicine and Dentistry</u>, Washington, D.C. 20007. Striatonigral substance P (SP) pathways have been proposed to function as an excitatory component of a neuronal loop which modu-lates the activity of nigrostriatal dopaminergic (DA) neurons. SP has also been shown to stimulate non-DA cells in pars reticulata of substantia nigra (SN). We therefore examined the effects of two SP analogs (D-Pro2,-Phe7,D-Trp9-SP and D-Pro2,D-Trp7,9-SP)with purported antagonist characteristics, on the turnover rate of neu-rotransmitters in the nigrostriatal and nigrotectal projections. In control rats, microinjection of either of the above SP ana-logs (20 ug in 1 ul) into SN did not change the Wmax or cofactor affinity of striatal tyrosine hydroxylase (TH), nor was there a change in nigral TH activity.

all inity of strata cyrosine hydroxylase (in), nor was change in nigral TH activity. When haloperidol (Hal) was injected (1 mg/kg i.p.) 10 min after the unilateral intranigral injection of the SP analogs, the Hal-induced increase in the affinity of striatal TH for its pteridine cofactor was blocked in the striatum ipsilateral to the drug microinjection. Associated with this effect was an antagonism of the Hal-induced increase of HVA levels in the striatum.

the Hal-induced increase of HVA levels in the striatum. SP analogs alone caused a small increase in striatal HVA, but unlike the antagonism of the Hal effects, this effect was not limi-ted to the ipsilateral striatum nor was it site-specific. Indeed, a similar increase in striatal HVA was found after injection of SP analogs into the median forebrain bundle (MFB), but this treatment was unable to antagonize the Hal effects on striatal TH and HVA. To examine the effect of the SP analogs on the activity of non-DA efferents from SN, we measured the turnover rate of GABA in in the terminal field of the nigrotectal GABA projections. The rate of GABA-transaminase by gamma-vinyl-GABA was used as an index of GABA turnover. Intranigral injection of either of the two SP ana-logs (20 ug in 1 ul) caused a significant (35%) decrease in the GABA turnover. Intranigral injection of either of the two SP ana-logs (20 ug in 1 ul) caused a significant (35%) decrease in the rate of GABA accumulation in the deep layers of the superior colliculus ipsilateral to the injected side. No effect was observed when the SP analogues were injected into the MFB. Our results are consistent with the possibility that the SP analogues we used have SP antagonist activity and that, as a con-sequence of blocking the excitatory influence of nigral SP, they interfere with the ability of Hal to activate dopamine turnover in the nigrostriatal pathway. Furthermore, our observation that

in the nigrostriatal pathway. Furthermore, our observation that these putative SP antagonists cause a decrease in the turnover these putative SP antagonists cause a decrease in the turnover rate of GABA in the nigrotectal projections is consistent with the proposal that nigral SP normally provides an excitatory con-trol of GABAergic efferents projecting to the superior colliculus. Supported by HHS grants MH32359 and DA02206.

TRAINED CIRCLING RATS SHOW REVERSED LATERALIZATION OF CAUDATE 143.4 DOPAMINE STNTHESIS AFTER TURNING STOPS. <u>Barbara A.</u> <u>Bennett</u> and <u>Curt R. Freed</u>. Depts. of Med. and Pharmacol., Univ. of Colorado Sch. of Med., Denver, Co. 80262

Sch. of Med., Denver, Co. 80262 Previous studies in our laboratory using the trained circling rat have revealed increased dopamine synthesis, release and turnover in caudate contralateral to the circling direction. In water deprived rats running in circles for a sucrose/water reward, there was enhanced contralateral dopamine synthesis during the first 20 min of circling when turning was most intense (10-12 rpm) while synthesis returned to baseline levels ofter 70 min of circling when turns had slowed to 2-3 mm. These Interste (10-12 fµ) while Synthesis retained to Baseline Hereis after 70 min of circling when turns had slowed to 2-3 rpm. There was no change seen in dopamine production in the side of caudate ipsilateral to the circling direction. The dopamine metabolite, dihydroxyphenylacetic acid (DOPAC), followed a similar pattern of synthesis as that seen for dopamine and was increased in contralateral caudate during the first 20 min of circling and declined toward baseline after 70 min. We have now studied caudate dopamine synthesis using a 3H-tyrosine precursor technique in the time period immediately following circling to see if the termination of circling affects caudate dopamine metabolism. Male Sprague-Dawley rats were trained to circle for a water reward. After 7 days of training, animals were cannulated in the lateral cerebral ventricle. On the next day, animals were circled for 70 min and then removed from the circling drum and infused with 250 µCi of 3H-tyrosine into 3H-dopamine and 3H-DOPAC was relatively increased in caudate ipsilateral to the circling direction. Values are Mean  $\pm$  SEM. after 70 min of circling when turns had slowed to 2-3 rpm. There

\*p <.05 different from the contralateral side. n=8.

experiments show that the cessation of circling These These experiments show that the cessation of circling is associated with increased ipsilateral synthesis of caudate dopamine. It is uncertain whether this enhanced ipsilateral dopamine synthesis represents a "stop" signal for turning behavior or whether it is simply the result of ending inhibition of synthesis on the ipsilateral side. Supported by American Parkinson's Disease Association, USPHS Grants GM07063(BAB); RCDA HL00782(CRF); NS099199; and NS18639.

LATERALIZED DOPAMINE AND SEROTONIN TURNOVER IN RAT LIMBIC STRUCTURES DURING TRAINED CIRCLING BEHAVIOR. Bryan K. Yamamoto and Curt R. Freed. Depts. Med. and Pharm., U. Colo. Sch. Med., 143.5 and Curt R. Freed. Depts. Med. and Pharm., U. Colo. Sch. Med., Denver, CO 80262 We have previously reported that the trained circling rat

has increased dopanine turnover in the caudate contrelateral to the circling direction and increased turnover in substantia nigra ipsilateral to the circling direction. We have now nigra ipsilateral to the circling direction. We have now extended these observations to the limbic system and have studied the lateral septum (LS) and the ventral tegmental area (VTA). Male Sprague Dawley rats were water deprived for 23 hr and randomly chosen to be trained to turn either left or right for sucrose/water reward (Nature 298: 467, 1982). After a one week training period, regional neurotransmitter activity was studied before, during and after circling. VTA and LS were bilaterally dissected and assayed for dopamine (DA) and DOPAC by HPLC with electrochemical detection. Results were calculated as the ratio of concentrations on the contralateral relative to the ipsilateral side. Ratios greater than 1.0 indicate increased ipsilateral side. Ratios greater than 1.0 indicate increased concentrations on the contralateral side.

C 0.96±.06 0.65±.09\* Values are Mean ± SEM, n=6 at each time point. DOPAC 0.70±.06\* \*Indicates significantly different from baseline (p<0.05). These data demonstrate increased ipsilateral DA turnover

in dopaminergic nerve terminals in LS and increased contralateral dopaminergic nerve terminals in LS and increased contralateral DA turnover in the dopamine cell bodies of VTA during circling. These findings are the opposite to those we have seen in the nigrostriatal system. Nerve terminals in caudate showed contralateral increases in DA turnover while cell bodies in substantia nigra had ipsilateral increases. This striking difference in dopamine lateralization in VTA-LS compared to the nigrostriatal system implies a functionally distinct activation of the lippin gutter compared to the cartery marked by the optimization of the lippin gutter compared to the strength of the lippin gutter compared to the strength of the lippin gutter compared to the strength of the lippin gutter compared to the strength of the strength of the strength of the lippin gutter compared to the strength of the of the limbic system compared to the extrapyramidal motor system during voluntary circling behavior. Supported by American Parkinson's Disease Assn.; NIGMS GM07063; RCDA HL00782 (CRF); NIH NS09199; and R01 NS186639.

STRIATAL NEURONAL RESPONSES TO DEXAMPHETAMINE ARE SIMILAR IN 143.7 IMMOBILIZED AND CORTICALLY ABLATED FREELY MOVING RATS. Warenycia and G. M. McKenzie\*, Dept. of Pharmacology, Dalhousie Univ., Halifax, N.S., Canada, B3H 4H7. In freely moving rats, striatal neurons respond to

In freely moving rats, striatal neurons respond to dexamphetamine (DEX) with excitation as measured by multi-unit recording (Hansen, E.L. and G. M. McKenzie, <u>Neuropharmacology</u> <u>18</u>: 547, 1979). To ascertain whether feedback from drug-induced behavior might be an important determinant in the response of striatal neurons, a two-fold approach was taken: 1) experiments were carried out in immobilized rats to record responses in the absence of behavior and, 2) experiments were carried out on freely moving cortically ablated rats, since striatal afferents from the cortex presumably mediate feedback arising from DEX-induced behavior. arising from DEX-induced behavior.

All experiments were carried out on male Long-Evans rats that had been implanted with bipolar multi-unit electrodes in the striatum 5-7 days prior to the acute experiment. Cortical ablations were performed 21-30 days prior to electrode implantation. In immobilization experiments, tracheotomy was performed during halothane anesthesia, a paralytic dose of succinylcholine given, lidocaine applied to wound surfaces and respiration maintained with 70%  $N_2O/30\%$  0<sub>2</sub>. DEX, 2.5 mg/kg i.p., was given after baseline neuronal activity was established. In freely moving, cortically ablated rats, the same dose of DEX was given once baseline neuronal activity was established.

In immobilized preparations, a multiplicity of striatal neuronal responses (N=28) was observed. Inhibitory (21%), biphasic (36%) and no change (25%) responses accounted for most biplicate (30x) and no change (32x) responses accounted for mo-of the responses to DEX with the incidence of excitation reduced to 18% compared to freely moving controls. Similar results (N=50) were seen in cortically ablated rats where excitation was observed only 24% of the time. Inhibition was most predominant (42%), followed by no change (22%) and biphasic responses (12%). Although the striatal response differed markedly between ablated and non-ablated rats, behavioural responses to DEX were essentially the same. These findings indicate that striatal neuronal responses to DEX are dependent on behaviour and that at least one of the neural substrates subserving feedback from DEX-induced behavior may be striatal afferents of cortical origin. SENSORIMOTOR ASYMMETRIES AND TACTILE EXTINCTION IN UNILATERAL 143.6 FRONTAL CORTEX DAMAGED AND STRIATAL DOPAMINE-DEPLETED RATS

FRONTAL CORTEX DAMAGED AND STRIATAL DOPAMINE-DEPLETED RATS. T. Barth\*, M. D. Lindner\*, and T. Schallert. Dept. Psychology, Univ. Texas at Austin, Austin, TX 78712. In people, the most characteristic and enduring somatosensory consequence of extensive unilateral neocortex damage is "simul-taneous extinction", which is an interhemispheric perceptual interaction that is operationally distinguishable from neglect. A cutaneous stimulus presented on the contralateral side of the height dependent of the contralateral side of the body is readily detected when presented singly, but is completely

body is reachly detected when presented singly, but is completely masked during bilateral stimulation. Analogous tests designed to calibrate sensorimotor asymmetries in rats were used to determine the immediate and chronic effects of frontal cortex damage, which were then compared to the effects of neostriatal damage. We attached small adhesive stimuli to the radial surface of each forelimb bilaterally and simultaneously and recorded the latencies to remove each stimulus.

Although the durations of recovery for each group were marked-ly different, we found first that no brain-damaged animal con-The tracted or removed the contralateral stimulus until after it removed the ipsilateral stimulus, which was removed immediately. With this test we established both the presence of an ipsilateral sensorimotor bias and the absence of contralateral neglect in every animal.

In a second study, using unremovable tactile stimuli we pro-vided strong evidence that in the presence of the ipsilateral vided strong evidence that in the presence of the ipsilateral stimulus, the contralateral stimulus was not detected, which is the measure of true extinction. A key feature of the "extinc-tion" was its complete reversibility. Simply by adjusting the sensory fields occupied by the contralateral (C) and ipsilateral (I) stimuli (specifically, by increasing the C/I ratio), the animals contacted both stimuli with equal frequency. In fact, when the C/I ratio was large enough, the sensorimotor bias was totally shifted to contralateral. Thus, extinction appeared to depend in large part on the perceived intensity of the ipsilater-al stimulus relative to that of the contralateral stimulus. In additional experiments we examined the effects of damage to other additional experiments we examined the effects of damage to other cortical and subcortical areas.

CAFFEINE DECREASES RAT CAUDATE DOPAMINE RELEASE AS MEASURED BY <u>IN</u> <u>VIVO</u> ELECTROCHEMISTRY. <u>M.E. Morgan and R.E. Vestal\*</u> Clinical Pharmacology Unit, VA Medical Center, Boise, ID 83702 and Dept. of Med., Univ. of Washington, School of Med., Seattle, WA. Caffeine (CAF), a ubiquitous dietary constituent, is perhaps the most widely used psychoactive drug in western culture. Despite well known central nervous system (CNS) stimulating effects, the mechanism of action of CAF is not well understood. Recently, several investigators have provided evidence supporting the con-cept that CAF-induced CNS activation may be due to the antagonism of adenosine at cell surface receptors which inhibit neurotrans-mitter release. It is not Clear, however, if the consequence of adenosine antagonism by CAF is always an increase in neurotrans-mitter release. Nor is it clear whether CAF affects all neuro-transmitter systems in the same manner. The behavioral effects of CAF in rodents are manifested by an alteration in motor movement which may involve the basal ganglia. For these reasons, we have studied the time dependent and dose dependent relationship between CAF and caudate dopamine (DA) release in the rat using in vivo electrochemistry. Male Sprague-Dawley rats (200-300 gm) were anesthetized with urethane (1.0-1.5 gm/kg, i.p.). A 250 $\mu$  stearic acid carbon paste electrode was inserted stereotaxically into either the left or the right caudate. Electrochemical oxidations were made with a Bioanalytical Systems DCV-5 voltammeter with the electrochemical output processed by semidifferentiation. The electrochemical output processed by semidifferentiation. The electrochemical output processed by semidifferentiation inter-action between DA (40 $\mu$ M) and CAF (40 $\mu$ M-120 $\mu$ M). After achieving a steady basal release, animals were injected with either 50mg/kg or 100mg/kg, i.p. CAF. DA release was assessed for 110 min. there-after. after.

Per Cent Control of Mean(±SEM) Baseline Peak Heights

1 me (m m. )	U	30	00	110	
Dose(mg/kg)					
50	99±1	70±4*+	82±8†	120±20	
100	100±3	42±3*	44±3*	78±2	

n = 6 experiments per dose; \* p<0.05 (30 or 60 min. vs 0 min); + p<0.05 (50 mg/kg dose vs 100mg/kg dose)

Caudate DA release was significantly decreased 30 min. after CAF. After the nadir, there was a gradual return to baseline release which was slower in high dose animals compared to low dose animals. These data indicate that there is a significant time dependent and dose dependent CAF-induced decrease in the release of DA from the rat caudate. A CAF-adenosine interaction is a possible mechanism which requires further investigation.

143.9 EFFECTS OF APOMORPHINE AND AMPHETAMINE ON ACUTE ADMINISTRATION OF 6-OHDA TO THE NIGRAL-STRIATAL PATHWAY. M. Cornfeldt\*, C. Gailums\*, M. Szewczak\* and R. Chen\* (SPON: S. Fielding). Dept. of Pharmacology, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876. Unilateral lesions in rats to the nigral (N) pathway with 6hydroxydopamine (6-OHDA) has been a valuable tool for assessing the effects of a variety of agents on motor function (Pycock, C.J. <u>Neurosci.</u>, 5:461, 1980). Typically, this method involves chronic N lesions. The acute effects of 6-OHDA on N may also have value in determining drug effects on this system. Our purpose was to measure the effects of rotational preference both before and after 6-OHDA lesion and to determine the activity of amphetamine (A) and apomorphine (APO) on rotational preference with an acute lesion. Rats were tested in a rotometer for 16 hrs with 5 mg/kg ip of A before lesion; 48 hrs later, subjects were anesthetized with halothane and 8 ug 6-OHDA in 4 ul saline and ascorbic acid was delivered to the left N at the level of the crus cerebri. After 6-OHDA, rats were immediately placed in a rotometer and given ip saline (I), 1 mg/kg APO (II), 0.5 mg/kg APO (III), 5 mg/kg A (IV) and 2.5 mg/kg A (V). The test for preference before 6-OHDA showed that group III circled left 74% and group IV circled right 61%. All other groups had no directional preference >60%. After 6-OHDA groups I, IV and V had a significant (p <0.05, paired sign rank) ipsilateral preference. APO groups (II and III) had no significant rotational preference after 6-OHDA though there was a tendency to circle ipsilaterally. Both A and APO increased total circling behavior. The postsynaptic effects of APO may have compensated for the acute imbalance to the extrapyramidal system by 6-OHDA.

143.11 INTRASTRIATAL DOPAMINE- AND AMPHETAMINE-INDUCED BEHAVIORS VARY ACROSS THE ESTROUS CYCLE. J.N.Joyce and C.Van Hartesveldt. Dept. of Psychology and the Center for Neurobiological Sciences, Univ. of Florida, Gainesville, FL 32611. Previous research has shown that exogenously administered

Previous research has shown that exogenously administered estradiol initially suppresses and later enhances several behaviors thought to be modulated by striatal dopamine (DA). Since plasma estradiol (E<sub>2</sub>) varies substantially during the estrous cycle, these behaviors should be suppressed when plasma E<sub>2</sub> is high and enhanced when it is low. However, these results have not been obtained by previous authors, at least in part because behavioral tests have not always been conducted when plasma E<sub>2</sub> peaks on the morning of proestrus. In addition, the behaviors measured may have involved several brain regions. We designed this experiment to test the effects of estrous cycle variations in plasma E<sub>2</sub> on postural deviation and rotation elicited by DA drugs injected directly into the striatum.

Unilateral intrastriatal injections of dopamine (DA; 25µg/ .25µ1) or amphetamine (AMPHET; 25µg/.25µ1) induced contralateral postural deviation and contralateral rotations, that systematically vary in magnitude across the estrous cycle of Long-Evans rats. In experiment 1 it was shown that when tested between 2-6 hours after lights ON (12:12 LD), both behavioral responses were suppressed on proestrus and were enhanced on estrus as compared to all other days of the estrous cycle. In experiment 2tit was shown that the behaviors induced by intrastriatal injections of DA or AMPHET varied independently of one another across the day of proestrus. Intrastriatal DA- and AMPHET-induced postural deviation were suppressed at 4 and 7 hours after lights ON, but were enhanced (equal to the estrus response) at 11 hours after lights ON. In contrast, intrastriatal DA- and AMPHETinduced rotations were suppressed at 4,7 and 11 hours after lights ON, but enhanced by the morning of estrus. These results suggest that striatal DA-elicited postural deviation and rotation are under independent control.

143.10 INTRASTRIATAL DOPAMINE- AND AMPHETAMINE INDUCED BEHAVIORS ARE MODULATED DIFFERENTIALLY BY ESTRADIOL BENZOATE. C.Van <u>Hartesveldt, J.N.Joyce and E.Montero\*</u>. Dept. of Psychology and the Center for Neurobiological Sciences, Univ. of Florida, Gainesville, FL 32611.

We reported in another abstract (Joyce and Van Hartesveldt, this vol.) that intrastriatal dopamine (DA)- and amphetamine (MMPHET)-induced postural deviation and rotation varied in magnitude independently of one another, when measured at several points on the day of proestrus. This suggests that the two behaviors may be under independent hormonal control. To investigate if the two striatal DA-mediated behaviors show different characteristics for estrogen-induced suppression, the following procedure was utilized. Ovariectomized (OVX) Long-Evans hooded rats were implanted with intrastriatal cannulae, then treated with 3 separate hormone regimes. After each hormone regime treatment, animals were tested for unilateral intrastriatal DAand AMPHET-induced postural deviation and rotation at 1/2,3,24, 48, and 72 hours after the last hormone treatment of any regime. The rats were treated with: (1) two treatments with EB (2)g), 48 hours apart (EB+EB); (2) two treatments with the OIL vehicle for EB (OIL, 0.2ml), 48 hours apart (OIL+OIL); (3) OIL 48 hours before EB (OIL 4B).

The results indicate, first, that the two striatal DAmediated behaviors have different requirements for suppression by EB. The hormone regimes OIL+EB or EB+EB produced a supprestion of intrastriatal DA- and AMPHET-induced postural deviation at 1/2,3, and 24 hours after the last (EB+EB) or only (OIL+EB) EB treatment. The rotational response to the same intrastriatal DA and AMPHET injections showed a reduction only when treated with EB+EB, and then the suppression was not apparent until the 24 hour test. This suggests that the striatal DA-mediated behaviors, rotation and postural deviation, are differentially sensitive to the suppressive effects of estrogen treatment. We also have evidence to believe that the changes in rotational behavior induced by EB treatment do not simply reflect changes in general activity levels of the rats. Secondly, the results indicate that, during the estrous cycle,

Secondly, the results indicate that, during the estrous cycle, the reversal from suppression to enhancement is not mediated by estrogen withdrawal. Rats given the hormone regime EB+EB do show a return to the pre-hormone baseline by 48-72 hours after the last EB treatment, but do not show an enhancement of either the postural deviation or rotational behaviors. Similarly, treatment once with EB (OIL+EB) does not produce an enhancement of either striatal DA-mediated behavior at any of the test intervals. This indicates that the reversal from suppression observed during the estrous cycle, is mediated by one or more other hormones:

143.12 PROGESTERONE REVERSES ESTROGEN SUPPRESSION OF INTRASTRIATAL DOPAMINE-INDUCED POSTURAL DEVIATION. <u>R.L.Smith, J.N.Joyce</u> <u>and C.Van Hartesveldt</u>. Dept. of Psychology and the Center for Neurobiological Sciences, Univ. of Florida, Gainesville, FL 32611.

In other abstracts (this vol.) we indicate that estrogen may mediate the suppression of striatal dopamine (DA)-elicited behaviors observed on the morning of proestrus. Since progesterone (P) can act either synergistically with or antagonistically to estrogen with regard to sexual behavior, we have investigated the effects of the interaction between P and estradiol in intrastriatal DA-postural deviation.

Female Long-Evans hooded rats were bilaterally implanted with 21 GA stainless steel guide cannulae, positioned in the dorsal anterior striatum. Unilateral injections of DA (25µg/0.25µl buffer) were made with 27 GA injection cannulae. After the injections, the animals were placed in a circular chamber and observed for 30 minutes. After completion of the first test, animals were bilaterally ovariectomized (OVX), and assigned to one of two groups. One group was given estradiol benzoate (EB, 4 g/0.2ml oil) twice a day for 7 days. The other group was given EB, as above, and P (.5 mg/.5 ml oil) 6 hours before testing, at 2 and 7 days after OVX.

Animals given EB alone for 7 days exhibited suppression of contralateral deviation at 2 and 7 days after OVX. Animals given EB+P showed significantly enhanced postural deviation at 2 days after OVX. After 7 days of EB treatment, P did not reverse the EB suppression.

These data suggest that P may be involved in estrogen-induced changes of striatal DA-mediated behaviors. P appears able to reverse the suppressive effects of short-term estrogen treatment (2 days) but not after longer treatment (7 days). This effect is similar to the sequential inhibition of estrogen-induced sexual behavior by P found in the female rat (Blaustein, <u>et al.</u> <u>JCPP</u>, 91:752, 1977). 144.1 CORTICAL DISTRIBUTION AND LOCALIZATION OF CALCIUM-BINDING PROTEIN IN RATS AND EPILEPTIC (EL) MICE. K.G. Baimbridge, I. Mody and J.J. Miller. Department of Physiology, University of British Columbia, Vancouver, B.C., V67 1W5

There is increasing evidence to suggest that many of the effects of calcium in the central nervous system are mediated by intracellular proteins which bind this cation with a high affinity (uM range). One of these, calcium-binding protein (CaBP), has been shown to be neuron specific and to be present in high and unequal concentration in different regions and cell types of the CNS. In view of its possible role as an intraneuronal  $Ca^{2+}$ -buffer, CaBP's presence or absence in certain neurons should reflect differences in their ability to regulate  $Ca^{2+}$  and consequently neuronal excitability.

Using specific radioimmunoassay (RIA) and immunohistochemical techniques for CaBP the present study was undertaken to examine: 1) the distribution and localization of this protein in cortical areas of rats and mice, and 2) the comparative distribution between different strains of mice, including epileptic (EL) mice, in an attempt to extend our previous observations of a neuronal specific loss of CaBP in kindled rats (Neurosci. Abstr., <u>8</u>:457, 1982).

1982). 1) In the rat cerebral cortex there is a clear dorso-ventral distribution of the protein with ventral areas containing three times more CaBP than dorsal regions (e.g. entorhinal cortex: 1811.9 ng/mg TSP; striate cortex: 602.5 ng/mg TSP). In dorsal cortical areas the protein is mainly localized in terminals projecting to this region, whereas more ventrally it is confined to a dense plexus of fibers and terminals in layers II-IV together with pyramidal cells and their processes. A dorsal to ventral distribution was also observed in phylogenetically older cortical areas, such as the hippocampal formation, where the ventral to dorsal ratio was 1.8:1. A similar pattern of CaBP distribution was found in cortical areas of mice.

2) When compared to control mice, the EL strain had significantly lower amounts of CaBP in the hippocampal formation and cerebral cortical samples particularly the ventral-temporal/ entorhinal cortex and dorsal occipital regions. Upon vestibular, stimulation leading to seizures a further fall in CaBP levels was observed in the hippocampal formation and ventral-temporal/ entorhinal cortex.

In summary, CaBP has an unequal dorso-ventral distribution in the cerebral cortex of the two species examined, and the reduced levels in certain cortical areas of the epileptic (EL) mouse may reflect a genetically altered state in the excitability of the neurons in these regions.

144.3 CHARACTERISTICS OF INHIBITORY PROCESSES IN THE DENTATE GYRUS FOLLOWING KINDLING-INDUCED EPILEPSY. M.W. Oliver\* and J.J. Miller. Dept. of Physiology, Univ. of British Columbia, Vancouver, Canada, V6T 1W5. Investigations of the cellular mechanisms underlying

Investigations of the cellular mechanisms underlying epileptiform activity have suggested that seizures may be attributed to inappropriate synchronous neuronal depolarization induced by a reduction or failure of inhibitory processes. The majority of these studies have assessed acute alterations in neuronal activity and have not addressed the question of long-term changes which may characterize 'epileptic' neurons. The present study was undertaken to determine whether inhibitory processes within the dentate gyrus are altered following the chronic induction of kindled seizures. In vitro hippocampal slices were prepared from either

In vitro hippocampal slices were prepared from either commissural-kindled (stage 5) or control rats. Dentate granule cell excitability was evaluated by delivering paired-pulse stimulation to the perforant pathway and determining the change in the extracellular population spike amplitude at different condition-test (C-T) pulse intervals.

The results indicate that in control slices the test response exhibits a characteristic pattern of excitability consisting of an inhibition-potentiation-inhibition sequence at C-T intervals of 20-40 msec, 40-120 msec and 120 msec-8 sec, respectively. In the presence of bicuculline or low Cl<sup>-</sup> medium, the initial inhibition is reversed and replaced by potentiation persisting up to 120 msec. The late inhibitory phase is Cl<sup>-</sup> independent and unaltered by GABA antagonists. In contrast, the population spike evoked by the test pulse in kindled slices, maintained in normal medium, is inhibited at all C-T intervals ranging from 20 msec -8 sec. Perfusion of low Cl<sup>-</sup> medium results in immediate potentiation of the test response, however this period is shortlived compared to controls (up to 60 msec) indicating that the late Cl<sup>-</sup> independent inhibition is prolonged by decreasing its latency to onset.

These data suggest that the efficacy of inhibitory systems in tissue predisposed to epileptiform activity is augmented rather than reduced, contradicting the general disinhibition hypothesis of epilepsy. The alterations in inhibitory processes appear to be specific for dentate neurons since we have previously demonstrated that inhibition within the CA-1 region remains unchanged following kindling (Neurosci. Abstract, 1982). Finally the results show that enhancement of a late non-GABA mediated inhibition is responsible for the increased inhibition observed in kindled slices in response to paired-pulse stimulation.

144.2 ALTERED <sup>45</sup>Ca UPTAKE IN HIPPOCAMPAL SLICES OF COMMISSURAL AND AMYGDALA KINDLED RATS. <u>I. Mody and J.J. Miller</u>. Department of Physiology, University of British Columbia, Vancouver, B.C., V6T 1W5

Previous observations from our laboratory have indicated that the loss of a neuron-specific calcium binding protein (CaBP) in the hippocampal formation of the rat is correlated with the kindling model of epilepsy (Neurosci. Abstr., B:457, 1982). Although the role of this protein in the CNS is not clear, it has been suggested to function as an intraneuronal Ca<sup>2+</sup> buffer.

been suggested to function as an intraneuronal car buildt. In order to examine this possibility the present study was undertaken to compare possible alterations in the kinetics of <sup>45</sup>Ca uptake in hippocampal slices obtained from control and kindled rats. Although the kinetic analysis of uptake curves does not provide an absolute measurement of intracellular calcium, the relative changes may provide useful information about pools and fluxes of calcium in the system. For our analysis we adopted the open series system model of Uchikawa and Borle (Cell Calcium, 2:173-186, 1981), and the relative pools and fluxes of calcium were derived from a double exponential equation best fitting the <sup>45</sup>Ca uptake curve.

best fitting the <sup>45</sup>Ca uptake curve. As described for other systems, hippocampal <sup>45</sup>Ca uptake exhibited a fast and a slow component. When compared to controls, hippocampal slices obtained from either commissural or amygdala kindled rats exhibited significant alterations in <sup>45</sup>Ca uptake. Derivation of the fluxes and pools of calcium from the double exponential equations (non-linear least squares analysis) indicates that the enhanced <sup>45</sup>Ca uptake in the hippocampal formation of kindled rats is presumably due to an increased intracellular pool of calcium. Similar shifts in the <sup>45</sup>Ca uptake curves were observed by Borle (Cell Calcium, 2:187-196, 1981) in kidney cells when mitochondrial Ca-buffering was inhibited by DNP. Although changes in mitochondrial function cannot be excluded in the kindled preparation, our results suggest that following kindling-induced epilepsy and the loss of cytosolic GaBP there is a decrease in the efficiency of a

suggest that following kindling-induced epilepsy and the loss of cytosolic CaBP there is a decrease in the efficiency of a Ca-buffering system resulting in the increase in  $[Ca^{2+}]_i$ . These data support the hypothesis that CaBP may have an important role in buffering intracellular calcium and further that the change in  $[Ca^{2+}]_i$  associated with a loss of the protein and altered  $^{45}Ca$  uptake may be a contributing factor to the generation of epileptiform activity.

144.4 FACILITATION OF ELECTRICAL KINDLING IN VENTRAL HIPPOCAMPUS AND LATERAL SEPTUM IN VASOPRESSIN DEFICIENT RATS (BRATTLEBORO STRAIN). Bonnie J. Gillis and Donald P. Cain, Department of Psychology, U of Western Ontario, London, Ontario, Canada N6A 5C2.

Recent investigations have demonstrated the existence of vasopressin (VP) fine fibre projections to various brain sites including dorsal and ventral hippocampus, lateral septum and several nuclei of the amygdala. The role of VP in central nervous system functioning is not yet clear, however there is some evidence to suggest that VP may play a role in seizure development using a kindling paradigm. Gillis and Cain (in press) found that homozygous Brattleboro rats that have an inherited inability to synthesize VP are severely retarded in their kindling rate when electrically stimulated in the amygdala. Marchand and Hagino (1982) reported a significant decrease in the firing rate of lateral septum neurons after iontophoresis of VP, suggesting the possible role of VP in suppression of neuronal firing in this region. The present study was an examination of electrical kindling of homozygous Brattleboro rats in the lateral septum and the ventral hippocampus.

Adult male homozygous Brattleboro (HO-BRAT) rats and normal Long Evans (N-LE) rats were implanted with bilateral electrodes in the lateral septum or the ventral hippocampus. Kindling stimulation consisted of a l-sec train of biphasic square wave pulses at 60Hz delivered once a day at 200 µA. The N-LE animals stimulated in the lateral septum reached a stage 5 generalized seizure after a mean of 28.25 afterdischarges (ADS), while the lateral septum HO-BRAT animals took a mean of just 17.33 ADS (p $\blacktriangleleft$ .01) to reach stage 5. The N-LE animals stimulated in the ventral hippocampus group had a generalized seizure after a mean of only 13.75 ADS (p $\checkmark$ .001). There was no difference between HO-BRAT and N-LE lateral septum animals with respect to AD threshold and GST for HO-BRAT animals stimulated in the ventral hippocampus were significantly higher than N-LE controls (p $\checkmark$ .01; p $\checkmark$ .05).

These data along with our previous findings suggest that VP may play a role in the kindling of seizures in normal LE rats and that this role may vary depending upon the site of stimulation. The present results favour the role of VP as a neuromodulator which may differentially affect neuronal firing in different brain regions.

The present study was conducted with the support of a grant to DPC from the Natural Sciences and Engineering Research Council of Canada and while BJG held an NSERC Postgraduate Scholarship.

EFFECT OF PARTIAL AND FULLY GENERALIZED KINDLED SEIZURES EFFECT OF PARTIAL AND FULLY GENERALIZED KINDLED SEIZURES ON THYROTROPIN RELEASING HORMONE LEVELS IN SPECIFIC CORTICAL AND SUBCORTICAL REGIONS OF RAT BRAIN. D. Walczak, J.L. Meyerhoff, V.E. Bates, T. Lynch and M.J. Kubek. Neurochemistry & Neuroendocrinology Branch, Dept. Med. Neuroscience, Div. Neuropsych., Walter Reed Army Institute of Research, Washington, DC 20307 and Dept. Anat., Indiana Univ. School of Med., Indianapolis, Indiana IN 46223. Thyrotropin Releasing Hormone (TRH) has been demonstrated to exist in extrahypothalamic sites and may have neuromodulatory roles in addition to its neuroendocrine function. In a previous study TRH was found to be elevated in amygdala-pyriform complex, hippocampus and cerebral cortex of rats 48 hours after fully generalized kindled seizures (Meverhoff, Bates & Kubek, Neurosci. Abstr. 8, 457, 1982). We have 144 5

cerebral cortex of rats 4% hours after fully generalized kindled seizures (Meyerhoff, Bates & Kubek, <u>Neurosci. Abstr.</u> 8, 457, 1982). We have extended that study to examine effects in specific cortical regions and to compare effects following partially kindled (stage 2-3) seizures vs fully kindled (stage 5) seizures. Nineteen male Sprague-Dawley rats (250-300gm) were used for the study. Rats were stereotaxically implanted bilaterally in the amygdalae with bipolar depth electrodes (250 micron twisted nichrome, coordinates from lambda: 2.2 mm posterior, 4.9mm lateral, 8.5mm ventral, using the atlas of Konig and Klippel). One week after surgery 12 implanted subjects were subjected to a standard kindling regimen of one stimulation every 24 hours (1.0sec train of 60Hz biphasic square wave pulses 0.1 msec duration, 500 µA peak to peak). Before stimulations were begun, these rats were divided into 2 groups of equal average body weight, to be kindled to stage 5 or only to stage 2-3. The remaining implanted animals were handled but not stimulated and served as sham kindled controls. Forty eight hours after five stage 2-3, or five as sham kindled controls. Forty eight hours after five stage 2-3, or five stage 5 seizures, kindled subjects and their corresponding controls were decapitated and brains were removed. The brains were dissected on ice and the regional samples were immediately frozen. Further subdivisions of cortical and subcortical regions were performed in this study, including separation of amygdaloid nuclei and pyriform cortex. TRH levels were determined in each sample by specific radioimmunoassay. In comparison to sham kindled subjects, TRH in fully kindled (stage 5) subjects was elevated 6-fold in pyriform cortex, 2.5-fold in cingulate cortex, 2-fold in frontal cortex, 3-fold in the remainder of cortex and 2-fold in both the amyedala and hippocamous. TRH was also elevated in the

fold in both the amygdala and hippocampus. TRH was also elevated in the pyriform cortex of partially kindled subjects (stage 2-3). Elevations of TRH levels in these subjects were intermediate in magnitude between 55 and sham kindled values. It appears from these data that the degree of TRH elevation observed in kindled rats may be related to the stage of kindled seizure elicited. Further studies are under way to determine if the effects of kindling on TRH levels are short term or persistent. Partially supported by N.I.H.Grant AM-28260, to M.J. Kubek.

144.7 EVIDENCE IMPLICATING SUBSTANTIA NIGRA IN SEIZURES KINDLED FROM MULTIPLE FOREBRAIN SITES. <u>M. T. Galloway\*, L. C. Rigsbee\*</u>, <u>S. Legg\*, and J. O. McNamara</u> (SPON: D. B. Sanders). Depts. of Medicine (Neurology) and Pharmacology, Duke University, and Epilepsy Centers at Duke University and VA Medical Centers, N.C. 27705. Durham.

Kindling, an animal model of epilepsy, refers to the phenomenon whereby repeated administration of initially subconvulsive stimuli results in progressively more intense limbic and motor seizures. Once established, the effect is permanent. The mechanisms underlying this phenomenon remain permanent. The mechanisms underlying this phenomenon remain poorly understood. Delineation of the underlying anatomic network is a necessary first step in understanding the basic cellular and molecular mechanisms. Our previous studies supported the hypothesis that activation of the substantia nigra (SN) was necessary for the generation of both motor and limbic components of <u>amygdala</u> kindled seizures. We sought to determine whether SN involvement was unique to seizures activated from the amygdala or was common to seizures activated from multiple forebrain sites.

To test this idea, male rats underwent stereotactic To test this idea, male rats underwent stereotactic implantation of electrodes in one of the following structures: amygdala (n = 8), lateral entorhinal cortex (LEC) (n = 3), olfactory tract (n = 2), olfactory bulb (n = 2), or anterior olfactory nucleus (n = 2). Guide cannulas were placed directed toward the subtantia nigra. Electrode and injection cannula placements were histologically verified in all animals. Electrical stimulations were administered until seizures of corrected interview points which the solution the subtantian placements were solution the solution of the solution consistent intensity were reliably elicited. Motor seizure duration was measured by behavioral observation; limbic seizure duration was quantitated from the afterdischarge recorded from the stimulating electrode.

The effects of microinjection of saline or the GABA agonist muscimol (M) on motor and limbic seizure duration were determined. Animals were gently restrained during injection. Saline injection into SN did not attenuate seizure duration. By contrast, microinjection of M (50 ng in 0.5  $\mu$ 1 of saline) bilaterally into SN markedly reduced (80-100% suppression) both motor and limbic seizures elicited from each kindling site.

motor and "indic services efficient of the ach withing sites. This M effect was highly significant (p < .001, Student's t-test). The M effect reversed completely after several hours. We conclude that the SN is a key site in the network of motor and limbic seizures elicited from multiple forebrain sites. This information should prove useful in delineating the anatomic transformer underline highled estimates structures underlying kindled seizures.

144.6 KINDLED AMYGDALOID SEIZURES: MODIFICATION BY CYCLAZOCINE AND ETHYLKETOCYCLAZOCINE. T. E. Albertson, R. M. Joy and L. G. Stark. Health Sciences Neurotoxicology Unit. School of Medicine and Veterinary Medicine, Univ. of Calif., Davis, CA 95616. Sprague-Dawley rats were implanted with chronic cortical and amygdaloid electrodes. Ten days after surgery, rats were given daily i.p. injections of DMA ( $\frac{1}{2}$  cc/kg, N=8), cyclazocine (CYC) (10 mg/kg,  $\frac{1}{2}$  cc/kg in DMA, N=9) or ethylketocyclazocine (EKC) (10 mg/kg,  $\frac{1}{2}$  cc/kg in DMA, N=7) twenty minutes before electrical stimulation of the amygdala (biphasic 60 Hz, I msec duration and 400 µAmp). After ten daily injections/-stimulated daily without drug pretreatment for another 14 days until generalized kindled amygdaloid seizures (KAS) were produced in all animals (stable rank 5). The average number of stimulations to reach the first stage 5 seizure (mean + S.E.M.) was DMA = 14 + 1.1, CYC = 17.2 + 1.4 and EKC = 16.6 + 0.9. A significant (PCO)(1) between group effect, trial effect and trial and group interaction effect was found for afterdischarge duration with CYC. A 10% weight loss occurred in both the CYC and EKC groups and a 5% loss in the control DMA treated group after ten days of daily treatment. Tolerance developed to CYC-induced tail pinch analgesia but not to the elicited stereotypic behavior by the tenth injection. Tolerance developed to a lesser extent to the analgesic and ataxic effects of EKC. Additional previously kindled rats were utilized to evaluate of EK

Additional previously kindled rats were utilized to evaluate the effects of various doses of CYC (1-10 mg/kg) and threshold (20  $\mu$ Amp increments) induced seizures. With suprathreshold stimulation, increments) induced seizures. With suprathreshold stimulation, high doses of CYC and EKC increased post-ictal behavioral arrest time and spiking frequency while reducing seizure rank. When threshold stimulation was utilized, CYC significantly increased thresholds and reduced seizure ranks and afterdischarge durations. Naloxone (10 mg/kg) did not reverse and tended to potentiate these effects. EKC reduced the seizure rank and not afterdischarge duration with threshold stimulation.

The mixed opiation with threshold Stimulation. The mixed opiate antagonist CYC has pronounced anticonvulsant actions against KAS. CYC reduces afterdischarge duration and rank during acquisition of the KAS, as well as, increasing afterdischarge thresholds in the fully KAS. The anticonvulsant properties seen with the kappa agonist EKC are much more limited

144.8 MICROINJECTION OF DYNORPHIN 1-13 INTO SUBSTANTIA NIGRA SUPPRESSES KINDLED SEIZURES. J. O. McNamara, L. C. Rigsbee\*, S. Legg\*, and M. T. Galloway\*. Depts. of Medicine (Neurology) and Pharmacology, Duke University; and Epilepsy Centers, Duke University and VA Medical Centers, Durham, N. C. 27705.

Kindling is an animal model of epilepsy produced by periodic, focal electrical stimulation of the brain. We previously demonstrated that application of either a GASA agonist or a GABA transaminase inhibitor to the substantia nigra (SN) markedly suppressed kindled seizures. This raised the question of suppressed windled services. And take the detection of whether this effect was unique to GABA or whether other putative neurotransmitters endogenous to SN could also suppress the seizures. Recent immunocytochemical studies demonstrated the presence of dynorphin (DYN) immunor stories that the presence of dynorphin (DYN) immunor stories in the second story in fibers within SN. Since the opioid peptides have prominent inhibitory actions, we sought to determine whether microinjection of DYN

actions, we sought to determine whether introdujection of bin into SN could suppress the seizures. To test this idea, male rats underwent stereotactic implantation of an electrode in the amygdala and guide cannulas overlying SN. Electrode and injection cannula placements were overlying 5%. Electrode and injection cannuls placements were histologically verified in all animals. Electrical stimulations were administered until seizures of consistent intensity were reliably elicited. Motor seizure duration was measured by behavioral observation; limbic seizure duration was quantitated from the afterdischarge recorded from the stimulating electrode. Stimulations were administered ten minutes following completion

of injection and at hourly intervals thereafter until reversal. Microinjection of DYN 1-13 (1250 picomoles in 0.5 µl of artificial cerebrospinal fluid (ACSF)) bilaterally into SN markedly suppressed both motor and limbic seizures in six of six rats. (Seizure durations in seconds are expressed as mean  $\pm$  SEM.) Motor seizure duration pre-injection:  $41 \pm 4$ ; post-injection 5  $\pm$  5; reversal 39  $\pm$  1. Limbic seizure duration pre-injection: 90  $\pm$  13; post-injection: 7  $\pm$  7; reversal 81  $\pm$  8. The dynorphin effect was highly significant (p < .001, Student's t-test). Neither ACSF injection into SN (n = 3) nor DYN injection 100 - 1,000 microns dorsal to SN (n = 4) suppressed the seizures. Pre-treatment with naloxone (10 mg/kg IP) (Seizure durations in seconds are expressed as mean +

the seizures. Freetreatment with haloxone (10 mg/kg 17) completely prevented the dynorphin effect in two animals, partly attenuated it in a third, and had no effect in a fourth. We conclude that DYN possesses anticonvulsant properties in this model. The results with naloxone suggest this action may be mediated through an opiate receptor. Endogenous reduction of dynorphinergic neurotransmission in SN could be partly reconceible for the shorrwal avoitability of kindling responsible for the abnormal excitability of kindling.

144.9 ATTENUATION OF RAT DENTATE GRANULE CELL EVOKED POTENTIALS FOLLOWING LATERAL ENTORHINAL CORTICAL KINDLING. J. L. <u>Giacchino, G. Somjen and J. O. McNamara</u>. Depts. of Medicine, (Neurology), Pharm. and Physiol., Duke Univ.; Epilepsy Centerr Duke University and VA Medical Centers. Durham. NC 27705.

<u>Glacching, C. Somjen and J. U. McNamara</u>. Depts. of Medicine, (Neurology), Pharm. and Physiol., Duke Univ.; Epilepsy Centers, Duke University and VA Medical Centers, Durham, NC 27705. Kindling is an animal model of epilepsy induced by multiple high frequency electrical stimulations of the brain. It can be elicited by stimulation of many brain areas, including the entorhinal cortex (EC). An initially subconvulsive stimulation eventually results in intense limbic and generalized motor seizures. This enhanced excitability is permanent. The cellular mechanisms responsible for kindling are unknown. One hypothesis is that long-term potentiation (ITP) of excitatory synaptic communication contributes to the kindling effect. Brief high frequency excitation of EC projections to the dentate gyrus results in ITP of granule cell evoked potentials. Therefore, potentiation of dentate granule cell responsivity to test stimuli of specific afferents should appear if LTP underlives the kindling process in these afferents.

underlies the kindling process in these afferents. LTP was examined in the monosynaptic projections from the lateral entorhinal cortex (LEC) to dentate granule cells (DG) in unrestrained, unanesthetized rats. Population excitatory post-synaptic potentials (pEPSPs) were recorded from the granule cell layer and were evoked by stimulation of permanently implanted LEC bipolar electrodes (monophasic square pulses, .2 pps, .55 mscc width). Recording was done via permanently implanted electrodes or via electrodes lowered in chronically mounted microdrives. Input/output (1/0) relationships were determined using single pulse stimulations over a range of intensities. 1/0 curves were constructed on at least typee consecutive days to establish stability of evoked pEPSPs over the range of stimulus intensities. Care was taken to record from alert animals at the same time of day to avoid the complicating influences of behavior and circadian rhythm.

From alert animals at the same time of day to avoid the complicating influences of behavior and circadian rhythm. Following the baseline I/O period, animals were kindled (400-1100 µamp, biphasic square wave pulses, 1 msec width, 60 Hz for a total train of 1 sec) via the LEC electrodes. I/O curves were then constructed on consecutive days post-kindling (kindling was considered complete after 3 Class 5 seizures). Controls were unkindled rats recorded from over the same time period as the experimental rats.

Controls were unkingled rats recorded from over the same same period as the experimental rats. Averaged responses from the 4 I/O curves for each of 5 rats post-kindling as compared to averaged pre-kindling values revealed depressed pEPSP amplitudes following kindling. Control rats exhibited no consistent change in pEPSP amplitudes during the study. Thus, the results indicate that LTP of the LEC-DG synapse is not the mechanism of kindling from the LEC. 144.10 MONOAMINERGIC AND LOCAL ANESTHETIC COMPONENTS OF COCAINE'S EFFECT ON KINDLED SEIZURE EXPRESSION. <u>R. D. Russell and</u> J. S. Stripling. Department of Psychology, University of Arkansas, Fayetteville, AR 72701. Previous research (Stripling & Hendricks, 1981) has

Previous research (Stripling & Hendricks, 1981) has indicated that cocaine (a drug with both monoaminergic and local anesthetic actions) and lidocaine (a local anesthetic) have similar effects on the expression of kindled seizures, suggesting that cocaine's effects are mediated at least in part by its local anesthetic action. The purpose of the present experiments was to explore further the relative involvement of cocaine's two major pharmacological actions on kindled seizure expression.

Male Long-Evans rats were kindled to criterion via daily electrical stimulation of the prepyriform cortex. The expression of kindled seizures was examined in 39 rats following intraperitoneal injection of saline, 20 mg/kg cocaine HCl, 20 mg/kg lidocaine HCl, or 2.5 mg/kg amphetamine sulfate (which causes release of monoamines). Each drug had a different pattern of effects on the various components of a kindled seizure. Cocaine and lidocaine produced a significant reduction in both the latency to forelimb clonus and the persistence of afterdischarge beyond the end of clonus, whereas amphetamine significantly increased the former and was without significant effect on the latter. In contrast, the duration of forelimb clonus was reduced significantly by cocaine and to a lesser (non-significant) extent by amphetamine, while lidocaine produced no decrease at all.

A second experiment further explored the possibility of monoaminergic involvement by examining the effect of cocaine on kindled seizure expression following the administration of four dose levels of the monoamine antagonists haloperidol, prazosin, yohimbine, propranolol, and metergoline (selected for their ability to block dopaminergic, alpha-!noradrenergic, alpha-2-noradrenergic, beta-noradrenergic, and serotonergic receptors, respectively). None of the antagonists blocked any of cocaine's effects on seizure expression, but prazosin significantly potentiated cocaine's reduction of clonus duration.

The results of these two experiments suggest that cocaine reduces clonus latency and afterdischarge after clonus via a local anesthetic action. Cocaine's reduction of clonus duration does not appear to be mediated by a local anesthetic mechanism but may involve alpha-noradrenergic receptors. Why cocaine (which blocks norepinephrine uptake) and prazosin (which blocks post-synaptic alpha-noradrenergic receptors) should act synergistically in reducing clonus duration is a question for which we have no answer at this time.

144.11 EFFECT OF COCAINE AND LIDOCAINE ON THE DEVELOPMENT OF KINDLED SEIZURES. J. S. Stripling, C. A. Gramlich\*, and M. G. <u>Cunningham\*</u>. Department of Psychology, University of Arkansas, Fayetteville, AR 72701. Cocaine has been reported to have a variety of effects on

Cocaine has been reported to have a variety of effects on the expression of previously kindled seizures, including a reduction in the duration of all seizure components (i.e., latency to clonus, clonus duration, and the persistence of afterdischarge beyond the end of clonus). However, its effects on the development of kindling have not yet been studied, although Racine, Livingston, and Joaquin (EEG Clin... <u>Neurophysiol.</u> 38: 355-365, 1975) have reported that the local anesthetic procaine facilitated kindling of the amygdala. The experiment reported here examined the effects of a subconvulsive dose of cocaine on the development of kindling and compared its effects with those of lidocaine, a local anesthetic without pronounced monoaminergic properties.

and compared its effects with those of fidocalle, a local anesthetic without pronounced monoaminergic properties. Male Long-Evans rats were divided into three groups which received daily intraperitoneal injections of either saline, 20 mg/kg cocaine BC1, or 20 mg/kg lidocaine BC1 15 min prior to electrical stimulation of the prepyriform cortex. When an animal reached kindling criterion the drug treatment was discontinued and the transfer of kindling to a non-drug state was assessed by the administration of test stimulations after delays of 1, 5 and 47 days. Both cocaine and lidocaine significantly accelerated the development of kindling. Furthermore, the duration of clonus at kindling criterion was significantly longer in these groups than in the saline group, and the onset of clonus occurred significantly sooner after stimulation in the cocaine group. However, this performance did not transfer fully to the non-drug state. Afterdischarge duration was higher in the two drug groups at all non-drug tests, but clonus duration was no longer significantly elevated, and the latency to clonus rose dramatically. These results indicate that a subconvulsive dose of cocaine

These results indicate that a subconvulsive dose of cocaine or lidocaine can facilitate the development of kindling when the drug is active at the time of electrical stimulation. Since Racine et al. (1975) also found facilitation of kindling with procaine, this effect appears to be due to a local anesthetic action. The kindling produced in this fashion is not entirely equivalent to kindling produced by electrical stimulation alone. In animals kindled under the influence of local anesthetics, the afterdischarge at the site of stimulation is expressed without reduction in the absence of the drugs, but seizure generalization, as reflected by the latency and duration of clonus, appears to have been artificially enhanced by the drugs and is reduced in their absence. 144.12 <sup>3</sup>H-FLUNITRAZEPAM BINDING TO AMYGDALA-KINDLED RAT BRAINS: WASHED VS. UNWASHED TISSUE. H.B. Niznik\*, S.J. Kish\* and W.M. Burnham (SPON: P.E. Garfinkel). Dept. of Pharmacol., Univ. of Toronto and the Human Brain Lab, Clarke Institute of Psychiatry, Toronto. We have recently reported (Niznik et al., 1983) that the Bmax for <sup>3</sup>H-flunitrazepam (<sup>3</sup>H-FLU) binding to crude hongenates of amygdala-kindled rat brain is decreased in the hypothalamus and ipsilateral cortex two weeks following the last seizure. Tuff et al. (1983), however, using a "well-washed" preparation, have failed to observe these changes, and have reported instead an increased Bmax for <sup>3</sup>H-FLU binding in the amygdala and hippocampus. The present study was designed to compare <sup>3</sup>H-FLU binding in both washed and unwashed membranes obtained from kindled and control animals 15 days following the 6th stage 5 convulsion. <sup>3</sup>H-FLU binding washed (7x)/hypotonically 19sed (2x)/froca (-80°C)-thawed (2x) brain membranes. Diazepam or clonazepam were used as displacers. Bmax and Kd values were estimated from Scatchard plots by linear regression analysis. In washed membranes, bilateral increases of approximately 20% were observed in the Bmax for <sup>3</sup>H-FLU binding in both the amygdala and hippocampio of kindled animals. No alterations of the Kd were sevential the grees where used as displacers. Brax and Kd values for any state the section analysis. In washed membranes, bilateral increases of approximately 20% were observed in the Bmax for <sup>3</sup>H-FLU binding in both the amygdala and hippocampic of kindled animals. No alterations of the Kd were sections of kindled animals. No alterations of the Kd were sections approximately 20% were observed in the Brax and Kd values were used sections of the kd were sections afree with the previous findling for Tuff et sections approximately 20% were observed in the Brax for <sup>3</sup>H-FLU binding in both the amygdala and hippocampic of Kindled animals. No alterations of the Kd were sections aprecesting the previous findling sect

In washed membranes, bilateral increases of approximately 20% were observed in the  $B_{max}$  for  ${}^{3}H$ -FLU binding in both the amygdalac and hippocampi of kindled animals. No alterations of the Kd were seen. These results agree with the previous findings of Tuff et al. In unwashed membranes,  ${}^{3}H$ -FLU binding was unaltered in the amygdalae and hippocampi, but was reduced by approximately 20% in the hypothalamus and right cortex. These results agree with our own previous findings. Similar results were obtained in the presence of clonazepam.  ${}^{3}H$ -ROS-4864 binding (2.5 mM) as well as GABA stimulated  ${}^{3}H$ -FLU binding was unchanged in kindled rat brain. Thus, long-term alterations in  ${}^{3}H$ -FLU binding are observed in either washed or unwashed tissue. The pattern of the binding

Thus, long-term alterations in  $^{3}\text{H-FLU}$  binding are observed in either washed or unwashed tissue. The pattern of the binding changes, however, depends on the membrane preparation used. In addition, the binding alterations appear to be restricted to the "central-type" benzodiazepine receptor. Possible interpretations of these findings will be presented.

(Supported by Grant MT 5611 from the MRC of Canada. H.B.N. was supported by the Savoy Foundation and S.J.K. is a career scientist of the Ontario Ministry of Health.) 144.13 UNCHANGED NORADRENALINE LEVELS AND TURNOVER TWO MONTHS AFTER AMYGDALA KINDLING IN THE RAT. M.M. Okazaki\*, W.M. Burnham and J.J. Warsh. Dept. of Pharmacology, University of Toronto and Section of Biochemical Psychiatry, Clarke Institute of Psychiatry, Toronto, Canada.

It has been postulated that the noradrenergic system is crucially involved in the kindling phenomenon. The present study was designed to investigate noradrenaline levels and turnover, using the a-methyl-p-tyrosine method.

48 Adult male Royal Victoria hooded rats were implanted with bipolar electrodes in the right amygdala. 24 of them were stimulated once daily (1 sec, 60 Hz, biphasic 1 msec pulses, 400 µa peak-to-peak) until six Stage 4-5 "kindled" seizures had been elicited. The other 24 served as "yoked" controls, receiving identical handling but no electrical stimulation. Each yoked pair was processed in parallel throughout the study. Two months after the completion of kindling, all subjects were treated with  $\alpha$ -methyl-p-tyrosine methyl ester (250 mg/kg i.p.). Half of them were sacrificed by decapitation immediately after injection (Time 0), the other half being sacrificed four hours later (Time 4). Immediately after decapitation, each brain was dissected into eight regions (hypothalamus, brainstem, and right and left amygdala, hippocampus and cortex) and stored at -70°C until analysis. Noradrenaline and dopamine levels were prepared for chromatography using the alumina method of prepurification and analyzed using a modification of the analytical procedure described by Warsh et al (J. Chromatogr. 228:131-141, 1982). Noradrenaline and dopamine resting levels (Time 0) were unchanged in all regions examined. Noradrenaline and dopamine resting set that there are no long-lasting presynaptic changes in the noradrenergic system after amygdala kindling.

144.15 PARALLEL ALTERATIONS IN GABA AND BENZODIAZEPINE RECEPTORS IN FASCIA DENTATA IN THE KINDLING MODEL OF EFILEPSY: A RADIOHISTOCHEMICAL STUDY. <u>C. Shin\*, H. Pedersen\*, and J. O.</u> <u>McNamara</u> (SPON: W. W. Anderson). Departments of Medicine (Neurology) and Pharmacology, Duke University; Epilepsy Centers, Duke University and VA Medical Centers, Durham, N.C. 27705 Extensive evidence suggests that benzodiazepine receptors (BZR) are coupled to GABA receptors (GABA-R) in a macromolecular complex that includes chloride ion channels. Previous work from this laboratory demonstrated an increased number of BZR in fascia dentats of hippocampal formation following repeated kindled seizures. We subsequently localized the increase to dentate granule cells. The purpose of this work was twofold: 1) to determine whether parallel alterations occurred in GABA-R's and 2) to define the time course of the alteration for both receptor populations. Radiohistochemical methods were used to quantitate GABA-R and BZR binding with radiolabeled muscimol and flunitrazepam.

Male Sprague-Dawley rats received daily stimulations from an electrode in right amygdala and were sacrificed by decapitation 24 hours, 7 days and 28 days after the third Class 5 seizure, along with electrode implanted unstimulated controls (3 pairs at each time point). Frozen sections were thaw-mounted on subbed slides. [<sup>3</sup>H] sensitive film was exposed to [<sup>3</sup>H]-ornightine standards and adjacent sections incubated in 10 nM [<sup>3</sup>H]-muscimol or 2 nM [<sup>3</sup>H]-flunitrazepam. Developed film was mounted on glass slides and densitometric measurgments were quantitated using a standard curve generated with [<sup>3</sup>H] standards. At 24 hours, there was a 20% increase in [<sup>3</sup>H]-muscimol binding in fascia dentata of kindled rats (2394 fmol/mg protein) compared to control rats (1998 fmol/mg protein) (p < 0.001; 2 tailed paired t); a 38% increase in [<sup>3</sup>H]-flunitrazepam binding was found in kindled (1719 fm/mg protein) (1246

At 24 hours, there was a 20% increase in  $[^{3}\mathrm{E}]$ -muscimol binding in fascia dentata of kindled rats (2394 fmol/mg protein) compared to control rats (1998 fmol/mg protein) (p < 0.001; 2 tailed paired t); a 38% increase in  $[^{3}\mathrm{E}]$ -flunitrazepam binding was found in kindled (1719 fm/mg protein) vs. control (1246 fm/mg protein) rats (p < 0.001; 2 tailed paired t). At 7 days and 28 days, neither  $[^{3}\mathrm{E}]$ -muscimol nor  $[^{3}\mathrm{H}]$ -flunitrazepam binding exhibited any significant difference between kindled and control rats. Examination of neocortices of kindled and control rats at 24 hours disclosed no significant difference with either ligand. Experiments are under way to differentiate change in affinity from change in number of receptors.

The transient nature of these alterations is consistent with the idea that these represent a consequence of the seizures rather than part of the molecular basis of kindling. The similarities in the time course and direction of the receptor alterations support the idea that the two receptors are coupled within the postulated macromolecular complex. 144.14 CHANGES IN A2- AND B-ADRENOCEPTOR BINDING SITES IN AMYGDALA KINDLED RAT BRAIN. John G.R. Jefferys\* and S. Clare Stanford\* (SPON P.Kirkwood). Sobell Dept, Inst. of Neurology, London WCIN 3BG, and Univ. Lab. of Physiology, Oxford OXI 3PT, U.K..

Kindling occurs when animals become progressively more susceptible to seizures on repeated stimulation of certain brain regions. Several studies have implicated the central noradrenergic system in the development of kindling, although the data have not always been consistent. We report here changes in a2- and B-adrenoceptor binding in the olfactory cortex of kindled rats. Bipolar Pt/Ir wire electrodes were implanted stereotaxically,

Bipolar Pt/Ir wire electrodes were implanted stereotaxically, under Fluothane anaesthesia, in the left amygdala of thirty 300g Sprague-Dawley rats. Two weeks after operation the rats were stimulated once an hour (100 square, biphasic 400uA, 1ms pulses at 20ms) until they had experienced 3-5 stage 5 seizures; this usually required 24-27 stimulations. Sham controls received identical treatment, but with no current. Unoperated controls from the same batches of rats were housed singly and received as little handling as possible. Experimental rats and their corresponding controls were killed by cervical dislocation 22-26h after the last stimulation, and the brains dissected on ice. A2- and B-adrenoceptor binding followed the protocol of Stanford & Nutt (Neurosci. 7, 1753; 1982), except that nonspecific binding of 3H-clonidine was measured in the presence of 15uM phentolamine and nonspecific binding of 3H-dihydroalprenolol was measured in the presence of 3uM (+/-)propranolol.

presence of 3uM (+/-)propranolol. Scatchard analysis of the binding data for the olfactory cortex showed the following. (1) The density of a2-adrenoceptors was approximately 50% greater in olfactory cortex than in the remaining cerebral cortex. (2) The numbers of both a2- and B-binding sites were higher in the sham controls than in the unoperated controls. The possibility that this represents a long lasting effect of anaesthesia is currently under investigation. (3) The numbers of both binding sites were significantly and bilaterally reduced by kindling (c.f. sham controls). These results support previous reports of a down regulation of B-adrenoceptor binding sites following amygdalar kindling;

These results support previous reports of a down regulation of B-adrenoceptor binding sites following amygdalar kindling; further, they reveal a similar down regulation of a2-binding sites. Suppression of the functional output of central noradrenergic neurones, by either drugs or lesions, has been shown to accelerate the development of kindling, while monoamine oxidase inhibitors delay it. These various observations are consistent with view that the release of noradrenaline has the effect of limiting or preventing seizures. However, the repeated release of noradrenaline and increased binding to adrenoceptors during kindling triggers their down regulation and thus impairs seizure suppression. J.J. supported by the Thorn Trust, S.C.S. by M.R.C.

144.16 ELECTROGRAPHIC AND BEHAVIORAL CONSEQUENCES OF REPEATED KAINIC ACID ADMINISTRATION. <u>Michael Gruenthal and J. Victor Nadler</u>. Dept. of Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710

Dept. of Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710 Intracerebroventricular (ICV) administration of the potent convulsant kainic acid (KA), results in a dose-dependent pattern of selective neuronal degeneration. When KA is administered to rats in doses sufficient to induce prolonged limbic status epilepticus, the resulting neuronal loss closely resembles the pattern of brain damage associated with long-standing temporal lobe epilepsy in man (Ammon's horn sclerosis). In an attempt to develop a model of this disease in the rat, as well as to shed light on the relationship between seizure activity and hippocampal cytopathology, we have studied the behavioral, electrographic and histologic consequences of repeated subthreshold ICV administration of KA. Awake, freely-moving rats received repeated (every 48 h)

Awake, freely-moving rats received repeated (every 48 h) infusions of KA through a chronically implanted cannula into the left lateral ventricle while EEG records were obtained from chronically implanted surface and depth electrodes. KA (47 pmol) dissolved in 2.5 ul of artificial CSF was infused at a rate of 0.2 ul/min. Control rats received artificial CSF alone.

The electrographic reaction to the first infusion began after 8-10 min and consisted of a pronounced increase in EEG frequency and/or amplitude recorded from the ipsilateral and/or contralateral dorsal hippocampus with occasional short (30 to 120 s) limbic seizures (i.e., involving the hippocampus and/or amygdala, but not frontal cortex). These EEG changes were typically preceded by increased locomotion, snifting and defecation. Limbic seizures were associated with reduced locomotor activity and their termination was frequently accompanied by wet dog shakes. These electrographic and behavioral changes lasted 30-60 min. With repeated infusions of KA the time to onset of an

With repeated infusions of KA the time to onset of an observable reaction increased and the duration of the reaction decreased such that by the fifth infusion no behavioral or EEG alterations were observed. After the development of tolerance to the acute effects of KA, spontaneous limbic seizures were recorded 24-48 h after exposure to KA. The rats died 24-48 h following the fifth or sixth KA infusion. Histologic examination revealed no obvious abnormalities in any limbic region. Control rats showed no observable reaction to as many as 20 infusions of artificial CSF. These results suggest that repeated ICV administration of KA

These results suggest that repeated ICV administration of KA can induce spontaneous limbic seizures and may provide a model of temporal lobe epilepsy. (Supported by NIH grant NS 17771 and postdoctoral fellowship NS 07018).

NEONATAL EXPOSURES OF RAT PUPS TO LINDANE FACILITATE THE ACQUISITION OF KINDLED AMYGDALOID SEIZURES IN THE SAME SUBJECTS WHEN ADULT. <u>R. M. Joy, T. E. Albertson and L. G.</u> Stark. Health Sciences Neurotoxicology Unit, Schools of Medicine and Veterinary Medicine, University of California, Duric, C. 0.6516 144.17 Davis, CA 95616.

Daily administration of lindane, p.o., to adult male rats facilitates the rate of acquisition of kindled amygdaloid seizures. The degree of facilitation is dose dependent, and seizures. The degree of facilitation is dose dependent, and the kindled state produced is as stable and persistent as that produced in the absence of lindane, even though it develops in a shorter time. The major mechanism involved appears to be the prolongation of afterdischarge (AD) duration during acquisition trials. Lindane does not modify the total amount of AD accrued in becoming kindled and does not lower AD thresholds. The purpose of this study was to determine whether exposure to lindane during brain development would enhance kindling once subjects were grown. Nineteen pregnant females gave birth to 104 male offspring who were randomized to mothers. Nine litters were assigned to

who were randomized to mothers. Nine litters were assigned to natal treatment groups which were gavaged daily with 40 mg/kg lindane in corn oil or corn oil for 6 days. The remaining 10 litters were assigned to maternal treatment groups where the mothers were gavaged with 20 mg/kg lindane in oil or oil alone for 10-12 days. All surviving offspring (N=65) were implanted 60 days after weaning and kindled with standard procedures 10 days later.

days later. When kindled as adults no significant effects of natal versus maternal treatments were observed, so data for lindane and control groups were combined. Neonatally lindane-exposed rats kindled faster ( $9.9 \pm 0.5$  days, N=18) than did nonexposed rats ( $11.2 \pm 0.6$  days, N=25). Lindane-exposed rats tended to have longer and more severe seizures than did nonexposed rats on each trial during acquisition. However, the total AD accrued by the groups in becoming kindled was not different (lindane treated =  $254 \pm 32$  secs. N=18; controls =  $212 \pm 24$ secs, N=25). These findings are of the same type as those observed in adult rats exposed to lindane during the kindling observed in adult rats exposed to lindane during the kindling period.

period. These data demonstrate that exposures to high concentrations of lindane during development can lead to permanent changes in the nervous system that facilitate kindling in the same subjects when adult. The types of changes are similar to those produced in adult rats kindled during concommitant lindane exposure. (Supported by the Northern California Occupational Health Center and BRS 2S07RR5457.)

144.19 ICTAL TEMPERATURE TRANSIENTS IN THE KINDLED AMYGDALOID

ICTAL TEMPERATURE TRANSIENTS IN THE KINDLED AMYGDALQID FOCUS. T. J. Lynch\* and W. J. Jackson\* (SPON: R.M. Wylie) Dept. Physiology, Medical College of Georgia, Augusta, GA 30912 Using micro-mini thermistors and voltage clamped polarography, in vivo brain temperature and  $pO_2$  were monitored in left amygdal (LA) foci of Sprague-Dawley rats throughout kindled epileptogenesis. In nine rats, ictal temperature transients were recorded during 173 seizures ranging in severity from the subclinical (stage 0) to the generalized (stage 5). In the free ranging rat, LA temperature showed an average ictal increase on the order of  $0.3^\circ$  F during seizures leading up to and including the first stage 5 convulsions. In all rats the ictal heating transients increased as stage 5 convulsions. In all rats the ictal heating transients increased as kindling progressed. However, the temperature increases in three out of four stage 5 convulsions elicited under neuromuscular block were 46 to Solutions and the state of the same rats during free ranging convulsions, indicating that warming of the blood by convulsive motor activity is a major contributor to the LA heating transient. Ictal heating transients in the unstimulated, right amygdala (RA) were observed to occur upon the first kindling stimulation of the LA in one rat and upon the first stage 2 seizure in another, indicating either that early kindling metabolic activity is similar in the two sites or that the increase in cerebral blood flow (CBF) in early kindling is not just focal. Throughout the rest of kindling, ictal heating transients in the unstimulated RA were almost identical to those in the stimulated LA. Both LA and RA often almost identical to those in the stimulated LA. Both LA and RA often underwent rapid postictal cooling to temperatures between 0.3 and 1.5° F below the pre-seizure temperature. Such cooling transients were most often seen in stage 4 and 5 convulsions, but sometimes as early as stage 3. From the consistent increases in ictal pO<sub>2</sub> seen in the kindled amygdala (Lynch and Jackson, <u>Soc. Neurosci. Abst.</u> 7: 187.10) it is inferred that global CBF increases in response to even the first kindling stimulus. From the postictal cooling transients it is inferred that the postictal relationship between focal site heat production and CBF may undergo a particularly large change starting at the stage 3 level of seizure generalization. Ictal heating and pO<sub>2</sub> maxima were well synchronized with the end of the primary AD, but no further increase in either quantity was ever observed during the occurrence of a secondary AD in the same seizure. Only a poor correlation was found between total ictal heating seizure. Only a poor correlation was found between total ictal heating and the duration of the EEG afterdischarge, while the best correlation was found between total ictal heating and the severity of motor convulsive activity. Brain temperature measurement in experimental seizures may be the best on-line index of overall seizure severity since it seems to integrate brain metabolic activation and motor convulsive activity under one measurement. (Supported by NIH grant 1-NS6-2340)

144.18 DEVELOPMENT OF HYPEREXCITABILITY IN MIRROR FOCI OF EPILEPTOGENIC DEPARTMENT OF INTERNATIONAL AND A CONTROLLED TO A DEPARTMENT OF DEFINITION OF DEFINITION OF DEPARTMENT OF Neurology and Brain Research Institute, University of California, Los Angeles, CA 90024

Department of Neurology and Brain Research Institute, University of California, Los Angeles, CA 90024 Secondary epileptogenesis is a process whereby discharges of a primary seizure focus enhance the excitability of synaptically related neuronal pools. Via electrocorticographic and evoked potential techniques, the evolution of pathophysiology was exam-ined in developing "mirror" foci of epileptogenic freeze lesions. Male Sprague-Dawley rats (250gm) were implanted with bipolar stimulating electrodes in left and right somatosensory relay nuc-lei of the thalamus. The right somatosensory area of the cortex was submitted to focal freezing for 15-30 seconds; diameter of the lesions ranged from 1.0-1.5 mm. Epidural recording elec-trodes were situated bilaterally over frontal motor and somato-sensory cortex, and over the midline of the cerebellum. Electrode leads were attached to a microconnector, and the assembly was secured with dental acrylic. After a seven-day recovery period, spontaneous and thalamically evoked electrocorticographic activ-ity was recorded on a periodic basis. Thalamic stimulation included single-pulse and paired-pulse trials. Averaged evoked potentials were obtained from both right (primary focus) and left (mirror focus) somatosensory cortex.

(mirror focus) somatosensory cortex. Focal freezing of neocortex was found to induce chronically active epileptogenic lesions, capable of generating paroxysmal discharges and occasional seizure episodes. Primary foci were abnormally responsive to thalamocortical activation; evoked responses were often followed by brief afterdischarges and, in some cases, seizures. Electrocorticographic recordings in regions contralateral to active primary foci revealed gradual development of hyperexcitability. Ten to fifteen days after induction of freeze lesions, mirror zones began to generate spontaneous epilep-tiform discharges, as well as auromented thalamocortical evoked tiform discharges, as well as augmented thalamocortical evoked tiform discharges, as well as augmented thalamocortical evoked potentials. Particularly enhanced were the long-latency compon-ents of evoked potentials, which often initiated a series of afterdischarges. Hyperexcitability was also evident in paired-pulse trials, both at long and short interpulse intervals. At intervals which initially produced inhibition in mirror foci, responses to test stimuli frequently exhibited facilitation as epileptiform activity emerged. These data suggest a reduced inhib-itory drive in mirror foci of freeze lesions, as well as enhanced cellular synchronization through complex cortical pathways.

AFTERDISCHARGE ACCUMULATION DURING AMYGDALA KINDLING IN JUVENILE 144.20 AND ADULT RATS. Gary G. Buterbaugh and Patricia A. Barditch\* (SPON: Naim Khazan). Department of Pharmacology and Toxicology,

(SPUN: Naim Khazah). Department of Pharmacology and loxicology, University of Maryland School of Pharmaco, Baltimore, MD 21201. Obtaining information relevent to a specific age of development during the kindling of young rats requires more closely spaced stimulations than in adult rats (e.g. hourly vrs. daily) and more afterdischarges (AD) to kindle. Because AD accumulation parallels the acquisition of kindling, we quantitated head the AD time during kindling in rats of different ages receiving hourly stimulation as a means of determining the potential usefulness of this kindling

protocol for studying developmental aspects of kindling. Male, Sprague-Dawley rats were implanted with bipolar electrodes in the right amygdala when 23-, 43- and 83-days-old (N = 9 per age). Five days later, kindling was started with hourly stim-ulations (1 sec of 1 msec, biphasic, square-wave pulses, 60 Hz,

ulations (1 sec of 1 msec, biphasic, square-wave pulses, 60 Hz, 1.5 x threshold), 10 - 12 hours/day, until 2 consecutive stage V convulsions were obtained. The EEG AD from the stimulated amygdala was collected with a Grass Model 7 polygraph. The three age groups did not differ in the total number of ADs and AD sec to kindle. However, 28-day-old rats accumulated a sig-nificant, 5-fold greater number of ADs during stage II. This age also accumulated 32.2% of total kindling AD time in stage II com-pared to less than 6% for 48- and 88-day-old rats. These ages accumulated more AD time in stage I (46.5 & 36.5%, respect.) than 28-day-old rats (22.3%). No significant differences were found during other stages of kindling. In a separate group of 48-dayduring other stages of kindling. In a separate group of 48-day-old rats receiving daily stimulations, there was no difference in accumulated AD time to kindle compared to hourly stimulated rats (664  $\pm$  53.3 vrs. 727  $\pm$  88.8 sec, respect.). However, they had fewer ADs (13.6  $\pm$  1.2 vrs. 23.4  $\pm$  1.5, respect.), but displayed AD durations 2-fold longer in most stages of kindling. Pretreat-Ab durations 2-fold longer in most stages of kinding, rieflatment of 28- and 48-day-old rats with reservine resulted in a  $40^{\circ}$  decrease in total ADs and AD time to kindle during hourly stimulation, distributed evenly during most stages. However, 28-day-old, but not 48-day-old rats, also showed a marked increase in ADs and AD time during stage III convulsions, a stage seldom observed in untreated rats.

The results indicate the hourly kindling protocol is a useful model for studying developmental aspects of seizure acquisition. Little differences were found in total AD time required to hourly kindle in the three age groups, and in one age compared to daily stimulation. Hourly stimulation revealed differences between 28-and 48-day-old rats, including a different effect by reserpine, during the early stages of kindling. These results suggest that the processes underlying the early acquisition of kindled amygdaloid convulsions are still maturing in rats up to 48 days of age.
INTRACELLULAR OBSERVATIONS IN IN VITRO HIPPOCAMPUS OF KINDLED RATS. <u>E.W. Kairiss, G.K. Smith and R.J.</u> <u>Racine</u>. Department of Psychology, McMaster University, Hamilton, Ontario, Canada L8S 4K1. The cellular basis of epileptiform phenomena has proven difficult to identify. Studies of acute seizures (e.g. penicillin-induced) have provided some insights into mechanisms of burst generation and neuronal synchronization associated with the epilepti-form spike, but the relevance of these findings to chronic forms of epilepsy remains uncertain. Kindling is an experimental model of epilepsy which has focal characteristics, is progressive, generalizes and eventually develops spontaneous epileptiform activity. In the present study, we have examined, in vitro, the intracellularly-recorded responses of hippocampal neurones from amygdala-kindled rats in an effort to detect abnormal cellular behaviours. 144.21

intracellularly-recorded responses of hippocampal neurones from amygdala-kindled rats in an effort to detect abnormal cellular behaviours. Male Long-Evans rats, under barbiturate anesthesia, were implanted with bipolar stimulating electrodes in the lateral amygdala. Daily kindling stimulations were applied until a class V seizure was elicited. The ani-mals were then sacrificed and hippocampal slices were prepared using standard techniques. The [X] of the incubation medium was 3mM and experiments were per-formed at 34.5 °C. Routine electrophysiological tech-niques were employed for stimulation of stratum radiatum, and recording of extra- and intracellular potentials from the CA1 region. In agreement with our previous report (Kairiss et al.,Soc. Reurosci. Abstr., 7, 584,1981), slices demonstrated no spontaneous epileptiform activity as reflected in ∩xtracellular field potentials. Neuronal recordings revealed normal membrane and spike potent-ials and spike afterhyperpolarizations could be recorded in all preparations. However, neurones in kindled slices tended to respond to depolarizing current pulses with an initial high frequency rate of firing, in contrast to the normal non-bursting mode of discharge. This is suggestive of subtle, postsynaptic alterations in excitability and contrasts sharply with the properties of penicillin-induced foci. Whether ' this behaviour is directly attributable to a kindling-induced epileptogenic process in the hippocampal focus induced epileptogenic process in the hippocampus or results from activation by an extra-hippocampal focus is unclear and will require further <u>in vivo</u> study.

144.22 ANTAGONISM BETWEEN CONCURRENTLY DEVELOPING KINDLED SEIZURE FOCI CAN SUPPRESS KINDLING. J.L. Burchfiel, K. Serpa, F.H. Duffy. Children's Hospital, Boston, MA 02115 In past work (Duchowny & Burchfiel, EEG Clin Neurophysiol.,

1982) we have shown that concurrent kindling of two limbic foci in rats is associated with a striking antagonism of motor seizure generalization; a phenomenon we call "kindling antagonism." Concurrent kindling is accomplished by electrically stimulating two limble sites (using chronically implanted electrodes and typical kindling stimulus parameters) in alternation on a trial-by-trial basis, i.e. one stimulus to one site, the next stimulus to the other site, etc. The result of this paradigm is that one focus develops typical, progressive kindling culminating in generalized seizures; whereas, kindling from the alternately stimulated site fails to occur. In the present study we addressed the question of what type

of kindled seizure development is occurring at the non-dominant focus. In general, one could imagine two possibilities. First, the underlying substrate for kindling could be developing, but the actual expression of the kindled state in terms of but the actual expression of the kindled state in terms of a generalized seizure is being suppressed. A second possibility is that the kindling process itself is being suppressed, i.e. that little or no increase of seizure susceptibility is being induced by the stimulation. To choose between these possibilities we did the following experiment. Rats were stimulated alternately in the septal area and ipsilateral entorhinal cortex until a state of kindling anatagonism was established in which one site consistently elicited generalized seizures and the other site alicited to montor seizure hebraior seizures and the other site elicited no motor seizure behavior. Then stimulation of the dominant site was halted and the non-dominant site was stimulated alone on consecutive trials We found that after alternate stimulation the mean number of additional trials required for the non-dominant site to attain generalized kindled seizures was not significantly different from that required for primary kindling. This result occurred even if a two period without stimulation was interposed at the end of alternate stimulation. These data indicate that during the state of antagonism no significant kindled seizure development occurred at the non-dominant site.

RETARDATION OF AMYGDALOID KINDLING BY TREATMENT WITH SCOPOLAMINE. 144.23

RETARDATION OF AMYGDALOID KINDLING BY TREATMENT WITH SCOPOLAMINE. V. Mesterberg\* and M. E. Corcoran. Department of Psychology, University of Victoria, Victoria, B. C., Canada V8W 2/2. Studies of the effects of atropine sulfate, a muscarinic anta-gonist, on the development of amygdaloid kindled seizures have yielded contradictory results. In some studies atropine slowed the rate of amygdaloid kindling (Albright et al., <u>Exp. Neurol.</u>, 1979, 66, 409; Arnold et al., <u>Exp. Neurol.</u>, 1973, 40, 457), whereas in others it had no effect (Blackwood et al., <u>Psychopharmacology</u>, 1982, 76, 66; Corcoran et al., <u>Exp. Neurol.</u>, 1976, 51, 271). In order to clarify this issue we decided to investigate the effects of scopolamine, a muscarinic antagonist more potent than atropine, on the rate of amygdaloid kindling. Six weeks after implantation of electrodes, male Sprayue-Dawley rats received application of unilateral amygdaloid stimulation once every 2 days. Some rats received an IP injection of scopolamine (10 mg/kg) 15 min before each stimulation, and others received injections of the distilled water vehicle. If rats failed to develop bilaterally generalized (stage 5) seizures after 22 afterdischarges (ADs) they were given a 14-day rest without stimulation and then were rekindled without the drug. Scopolamine-treated rats required significantly more total ADs (M = 22.6, SD = 9.5) than controls (M = 11.8, SD = 3.9) to develop the first stage-5 seizure. Of the 9 rats treated with scopolamine, 3 failed to develop even unilateral clonic seizures after 22 ADs and required as many additional drug-free ADs to rekindle (M = 13, SD = 2.9) as controls had required for initial kindling. This suggests that scopolamine can produce a genuine prophylactic effect, in agreement with the findings of Arnold et al. (1973) with atropine. After completion of kindling, control rats were given injec-

prophylactic effect, in agreement with the findings of Afnord et al. (1973) with atropine. After completion of kindling, control rats were given injec-tions of scopolamine. There was no effect of scopolamine on the duration or intensity of kindled seizures, suggesting that its prophylactic effects against seizure development were not due to a general antiepileptic action.

The present results support the hypothesis that cholinergic or cholinoceptive neurons play an important role in the develop-ment of kindled seizures. Because there are rats that kindled even after treatment with scopolamine, however, the participation of these neurons may not be critical for kindling.

REDUCTION OF GAD-POSITIVE CELLS AND TERMINALS AFTER ENTORHINAL-144.24 REDOCTION OF GAD-FOSITIVE CELLS AND TERMINALS AFTER ENTORHALM. DENTATE KINDLING IN RATS. T.L. Babb, W.J. Frown\*, S. Feldblum\*, J. Pretorius\* and W. Kupfer\*. Dept. of Neurology, Division of Neuropathology and Brain Research Institute, UCLA Sch. of Med., Los Angeles, CA 90024. The hippocampus is known to have an effective recurrent col-

lateral inhibitory circuit which has been shown to involve acti-vation of local inhibitory interneurons by axon collaterals of principal neurons. These interneurons inhibit the principal neurons by secreting GABA at their somata. It has been suggested that epileptogenic hippocampus develops when this GABA-mediated recurrent inhibition is reduced. The present studies were designed to test if after kindling

the hippocampus, there could be a reduction in GABA inhibition as determined by a reduction in the GABA synthesizing enzyme glutamic acid decarboxylase (GAD). GAD anti-body was obtained through the generosity of Dr. I. Kopin (Oertel et al., <u>Neurosci</u>, <u>6</u>:2689-2700, 1981), and the ABC-HRP method was used to localize GAD in inter-neurons and at terminals to verify the anatomical loci in normal nearbox and at terminate to very the anatomical loci in hormal rats. Group KEC (n=8) were kindled to an average of Stage 3 setzures by 19 stimulations of entorhinal cortex (EC). Group EC (n=8) received 19 EC stimulations each spaced 10 minutes apart and did not kindle. Densitometric analysis of GAD positive termi-nals in fascia dentata (first synapse) showed a significantlyreduced GAD in the kindled group compared to the non-kindled (p **<**.05).

In a second study kindled rats (n=8) had significantly reduced GAD compared to controls (p<.01), whether or not they were sacrificed immediately after the 19th stimulation (p<.05) or 24hours later (p $\div$ .05). These results indicate that the epilept genic process of kindling does reduce the rate of synthesis of These results indicate that the epileptorecurrent GABA-mediated inhibition.

145.1 CRIGIN OF THALAMIC INPUT TO THE SUPPLEMENTARY AND ARCUATE PREMOTOR ARRAS. G.R. <u>Schell\* and P.L. Strick</u>. V. A. Med. Ctr. and Depts. of Neurosurg. and Physiol., SUNY-Upstate, Syracuse, NY 13210.

The premotor areas which project most densely to the motor cortex are: 1) the arcuate premotor area (APA), located in and around the caudal bank of the arcuate sulcus and 2) the supplementary motor area (SMA), located on the medial wall of the hemisphere (Muakkassa and Strick, Brain Res. '79). In the present experiments we determined the origin of thalamic inputs to the SMA and APA as a step toward understanding how subcortical structures might interact with each premotor area. In 4 monkeys (Macaca mulatta), small (0.025-0.05  $\mu$ l), multiple

In 4 monkeys (Macaca mulatta), small (0.025-0.05 µl), multiple injections of 2% wheat germ agglutinin conjugated to horseradish peroxidase (WGA-HRP, Sigma) were made unilaterally into either the SMA or the APA. For the purpose of comparison, similar injections were made into the motor cortex of another animal. After a 4 day survival period, animals were anesthetized and perfused with phosphate buffered aldehydes. Tissue sections were processed using the TMB technique (Mesulam, '78). Injections into each cortical area resulted in dense, slablike accumulations of anterograde and retrograde labeling in the ventrolateral thalamus. Little or no overlap was observed

Injections into each cortical area resulted in dense, slablike accumulations of anterograde and retrograde labeling in the ventrolateral thalamus. Little or no overlap was observed in the thalamic labeling following injections into separate functional areas. APA injections resulted in thalamic labeling which was most dense in area X. In contrast, SMA injections resulted in thalamic labeling which was most dense in VLo. VPLo was most densely labeled following injections into the motor cortex. Thus, the two premotor areas and the motor cortex each received thalamic input from separate, cytoarchitectonically distinct subdivisions of the ventrolateral thalamus.

distinct subdivisions of the ventrolateral thalamus. Previous anatomical studies by others have indicated that each of the three subdivisions of the ventrolateral thalamus receives input from a separate subcortical structure. Area X receives input from caudal portions of the deep cerebellar nuclei (e.g., Stanton, '80; Kalil, '81). Uso receives input from the globus pallidus (e.g., Kim et al., '76; DeVito and Anderson, '82). VPLo receives input from rostral portions of the deep cerebellar nuclei (e.g., Stanton, '80; Kalil, '81). Based on these data and our observations, we propose a new scheme of subcortical-cortical interactions. In this scheme, the output from caudal portions of the deep cerebellar nuclei is focused on the APA; the output from rostral portions of the deep cerebellar nuclei is focused on the motor cortex. Supported by funds from the VA Medical Research Service, UPSHS-NS 02957, and the Dept. of Neurosurgery. 145.2 AFFERENT AND EFFERENT CONNECTIONS OF THE POSTARCUATE REGION OF THE MONKEY CEREBRAL CORTEX. <u>M. Godschalk\*, R.N. Lemon\* and H.G.J.M.</u> Kuypers\* (SPON: European Neuroscience Association). Dept. of Anatomy II, Faculty of Medicine, Erasmus University

<u>Ruypers</u> (SPON: European Neuroscience Association). Dept. of Anatomy II, Faculty of Medicine, Ersamus University Rotterdam, P.O. Box 1738, 3000 DR Rotterdam, The Netherlands. We have previously shown that neurons in the region of the arcuate sulcus of the macaque cerebral cortex show pronounced modulation of activity during preparation for specific movements; for some neurons, changes in activity during the preparatory period are clearly related to the trajectory of arm movement required to reach for a visible target. In an attempt to define the anatomical substrate for these characteristic properties, we have now investigated the afferent and efferent connections of the postarcuate region using both anatomical and electrophysiological techniques. For retrograde transport studies we used either HRP or a combination of fluorescent tracers. Results obtained with these experiments were then confirmed by eliciting antidromic or synaptic responses in postarcuate neurons by stimulation of different cortical areas in an esthetized monkers.

Synaptic responses in postarculate neurons by Stimulation of different cortical areas in anesthetized monkeys. <u>Efferents</u>: There is a pronounced projection from this region to area 4 (motor cortex), particularly from neurons in the posterior bank of the inferior limb of the arcuate sulcus. This projection is topographically organized such that the axonal trajectory of neurons projecting from this area is generally in a postero-medial direction. For example, neurons lying around the spur of the arcuate sulcus project to the hand representation of area 4, whereas those lying in the posterior bank of the inferior limb of the arcuate sulcus project further laterally within area 4. These neurons are concentrated in the upper cortical layers and can be antidromically activated from area 4 with latencies ranging from 0.6-2.1 ms.

and can be antidromically activated from area 4 with latencies ranging from 0.6-2.1 ms. <u>Afferents</u>: There is a powerful afferent projection to the postarcuate region from the antero-lateral part of the inferior parietal lobule (IPL), the banks around the tip of the intraparietal sulcus and the superior bank of the lateral fissure. This projection comes principally from layer III pyramidal cells, which were filled in great numbers following HRP injections in the posterior bank of the inferior limb of the arcuate sulcus.

posterior bank of the inferior limb of the arcuate sulcus. Some neurons in the postarcuate region projecting into area 4 responded synaptically to stimulation of the IPL. In contrast, no evidence was found for a direct input from the IPL into area 4. Since neurons in the IPL have been implicated in the processing of visuo-spatial information related to movement, the indirect route from the IPL to area 4 via the arcuate region may provide a means of access for this information to the motor cortex.

145.3 PRIMATE FACE MOTOR CORTEX: REPRESENTATION OF IPSILATERAL AND COMPLEX OROFACIAL MOVEMENTS. <u>M.A. Sirisko\* and B.J. Sessle</u>. Fac. of Dentistry, Univ. of Toronto, Toronto M5G 1G6, Canada.

Previous studies have reported that ipsilateral and complex masticatory-like movements as well as contralateral movements can be evoked from the primate cerebral cortex. These studies have placed the ipsilateral and masticatory-like representations in areas lateral to the contralateral representation. Since our earlier investigations of the "excitable" cortex suggested that ipsilateral and masticatory-like movements might be evoked at some loci within the motor representation of the contralateral orofacial region, we decided to investigate these representations in more detail.

The motor representation of the face, jaw and tongue was determined by examining twitch and complex masticatory-like movements and associated EMG activities evoked by intracortical microstimulation (ICMS) in four unanaesthetized monkeys (Macaca fascicularis). A series of microelectrode penetrations were made 1 mm or less apart in the sensorimotor cortex and in each penetration intracortical sites were stimulated every 250  $\mu$  or less over vertical depths of up to 5 mm in precentral cortex and 10 mm in pericentral cortex. Stimuli of less than 35  $\mu$ A were used to define the "excitable" cortex and its boundaries and the characteristics of evoked responses. Over 70 microelectrode penetrations were made in each animal, and lesions were placed at the bottom of over 20% of the penetrations to aid in the subsequent histological reconstruction.

We confirmed our earlier findings that the face, jaw and tongue representation occurred precentrally, with the facial representation forming a horseshoe around a central core of jaw and tongue movements. Included within this predominantly contralateral representation in area 4 was a region of precentral cortex within which ipsilateral movements could be evoked. This region was characterized as a mediolateral strip, approximately 2 mm wide and up to 9 mm long. Facial movements predominated in this ipsilateral representation and the ipsilateral ICMS thresholds were comparable to those noted for the contralateral movements. Also included within the face motor cortex were loci from which masticatory-like movements could be evoked by continuous ICMS currents as low as 15 µA. These loci tended to be concentrated at two sites that were several mm apart. The masticatory-like movements and a frequency of 1-3 Hz and involved contralateral or jusilateral and masticatory-like movements may be represented not only in areas lateral to the face motor cortex, as earlier studies have indicated, but also within the contralateral representation in area 4.

145.4 SENSORIMOTOR PROPERTIES OF NEURONS IN AREA 5 DURING CONDITIONED ARM MOVEMENTS IN THE MONKEY. C.E. Chapman, L. Busby\*, G. Spidalieri\* and Y. Lamarre. Centre de recherche en sciences neurologiques, Département de Physiologie, Université de Montréal, Montréal, Québec, Canada, H3C 318. Results from lesion studies of area 5, together with its known connections to nee and nostcentral cortex suggest that it has

Results from lesion studies of area 5, together with its known connections to pre- and postcentral cortex, suggest that it has an important role in sensorimotor integration. We have recorded unitary discharges from area 5 in 2 monkeys trained to perform rapid elbow movements in response to 3 different, and randomly presented, sensory cues: a light, a tone and a small  $(1-2^\circ)$ , brief (50 ms) perturbation of the elbow. The discharge of 90/157 neurons was modulated in relation to prove the performance following the performance of the sense of  $M^\circ$  activity.

The discharge of 90/157 neurons was modulated in relation to movement, the earliest change following the onset of EMG activity in 92% of the units (x=25 ms before movement onset). The pattern of discharge varied with the direction of movement in 36/38 cells tested, most often in a non-reciprocal manner (30/36). In 50% of the units which showed an excitation (28/56), the movementrelated discharge was correlated with physical parameters of the movement. The results suggested that there may be some functional differences within area 5 since units located in the upper part of the anterior bank of the intraparietal sulcus were more often, and more strongly, correlated with movement parameters than those located within the depths of the sulcus. Forty per cent of the modulated cells (n=38) had a short latency (40 ms) response to the torque pulse. These cells included withma the substantian the depth of the sulcus was correlated with movement parameters when the substantian the substantian the substantian the substantian the substantian the substantian the substantiant the sub

Forty per cent of the modulated cells (n=38) had a short latency (40 ms) response to the torque pulse. These cells included almost all of the units in which discharge was correlated with movement parameters, suggesting that the correlations could be explained by peripheral afferent feedback. The sensory response was, however, clearly dependent on the subsequent performance of the movement: it was reduced or absent when movement was extinguished by withholding the reward and it was frequently absent in trials with long reaction times. The possibility that changes in the level of alertness could explain the results was ruled out by showing that the same degree of modulation is obtained when the stimulus was repeated immediately after a successful trial: the response was present only when the animal moved to the second cue. The dependence of the sensory response on the motor response is a property which might serve as a neural substrate for stereognosis, a somesthetic function which most likely depends upon concurrent processing of information from both motor centres and peripheral receptors.

and peripheral receptors. Supported by the Canadian Medical Research Council; C.E. Chapman supported by a Canadian MRC Postdoctoral Fellowship.

HINDLIMB MOTOR CORTICAL NEURONAL PATTERNS IN MONKEYS CONDITIONED 145.5 TO A VARIETY OF TASKS. S.A. Sahrmann, M.H. Clare, E.B. Montgomery JR., W.M. Landau. Dept Neurology, Washington University School of Medicine, St. Louis, MO 63110 Normal rhesus monkeys were conditioned to perform a complex behavioral paradigm that included movements known to be particularly impained by upper motor neuron lesion. Light signals were used to direct the monkey's performance of 4 self-paced tasks that included small and large sustained forces in plantar and dorsiflexion directions and large phasic forces in both directions. Each of the pseudo-randomly delivered tasks Started from rest and required the simultaneous use of both feet. Since the ultimate purpose of the study is to compare the behavior of motor cortical neurons (MCUs) in the normal to that in the monkey with the UMN syndrome, all response patterns were analyzed to describe population characteristics.

Ninety percent of the 226 analyzed MCUs showed increased activity temporally related to force and EMG. Ten percent showed decreased activity exclusively. The 203 MCUs showing increased activity differed in their directional preference: half were active only in relation to development of force in one half were active only in relation to development of force in one direction (unidirectional) and the remainder with active forces in both directions (bidirectional). Only 28/101 of the bidirectional units were symmetric (equal activity with force in both directions). The majority were asymmetric with a greater degree of activity in one direction. Both unidirectional and bidirectional (symmetric and asymmetric) MCUs often developed increased activity not only with active agonist forces but also with relaxation of opposite "antagonistic" force (relaxing force change). Seventy-eight percent of the MCUs showing increased activity during the prolonged force holds. Thirty-eight percent of the units were more active with larger force and 14% with of the units were more active with larger force and 14% with smaller force; 48% had comparable activity with both force levels. None of these characteristics was related to directionality. The most striking finding evident with our multitask behavioral paradigm was the spectrum of MCU behaviors, ranging from units which increased or decreased discharge with force in one direction, to those responding with active and relaxing force change in both directions. The complexity of the patterns of MCU activity was not simply interpretable in terms of rigid linkage to the anterior horn cells of the final common path.

CORTICAL MECHANISMS OF TWO-DIMENSIONAL AIMED ARM MOVEMENTS. VIII. CELL DISCHARGE IN MOTOR CORTEX AND AREA 5 VARIES WITH MOVEMENT 145.6 DIRECTION, NOT WITH FINAL POSITION OF THE ARM. J.F. Kalaska, A.P. Georgopoulos and R. Caminiti. The Bard Laboratories of Neurophysi-ology, Department of Neuroscience, The Johns Hopkins University,

ology, Department of Neuroscience, The Johns Hopkins University, School of Medicine, Baltimore, MD 21205. The hypothesis was tested that the frequency of discharge of motor cortical or area 5 cells during the reaction time (RT) might predict the final position of the arm in aimed movements. Rhesus monkeys were trained to move their arm to the same endpoint in a monopy which characterise is note that and the state characterise in a two-dimensional space using an articulated manipulandum. The move-ments started from 8 different points located equidistantly on the circumference of a circle of 8 cm radius and ended on the center of the circle in a reaction time task. Thus the movement endpoint was dissociated from the movement direction since all movements ended on the same point but were made in 8 different directions. The movements exhibited a dome-shaped velocity curve with a peak value of 200-400 mm/sec in different movements. The activity of 154 motor cortical and 55 area 5 cells was studied in the task during microelectrode penetrations into 5 hemispheres of 3 monkeys. These cells were related to arm movements and changed activ-ity during the RT in the task. The relations between the changes in cell discharge during the RT and the direction of movement (variant) or the movement endpoint (invariant) were evaluated us-ing an analysis of variance. The RT discharge rate of 98% of cells in either structure varied in association with the direction of movement. Therefore, these cells were related to movement di-rection and not to its endpoint. The remaining 2% of motor cortical and area 5 cells showed uniform changes in activity for all the directions tested and could be related to the invariant final position of the arm. However, the same uniformity in the changes of cell discharge was observed when the animals moved, in a different task, from the same starting point (center of the circle) to 8 different points on the circle. This suggests that the changes in discharge rate that were observed in that small proportion of cells were related to neither the direction of movement nor to its endpoint. Similar results were obtained for the movement time. In summary, cell discharge in motor cortex and area 5 relates to the direction of movement despite the same final arm position; in-deed no cells were found that were related exclusively to the movement endpoint. It appears that if the final arm position is indeed the controlled spatial variable in aimed arm movements (cf. Polit and Bizzi, J. Neurophysiol. 42: 183, 1979), that variable is not reflected in the changes in discharge rate preceding movement in the cortical areas studied. Instead, these changes are related to the movement vector itself. (Supported by USPHS Grants NS17413 and NS07226). of cells were related to neither the direction of movement nor to and NS07226).

CORTICAL MECHANISMS OF TWO-DIMENSIONAL AIMED ARM MOVEMENTS. IX. 145.7 STATIC (POSITIONAL) FACTORS CANNOT ACCOUNT FULLY FOR MOVEMENT-RELATED CELL DISCHARGE IN MOTOR CORTEX AND AREA 5. A.P. Georgo poulos, J.F. Kalaska, J.T. Massey and R. Caminiti. The Bard Laboratories of Neurophysiology, Department of Neuroscience, The Johns Hopkins Un., School of Medicine, Baltimore, MD 21205. The frequency of discharge of arm-related motor cortical and area 5 cells varies in an orderly fashion with the direction of movement (Georgopoulos et al., J. Neurosci. 2: 1527, 1982; Kalas-ka et al., Exp. Brain Res., 1983, in press). On the other hand, the steady-state discharge rate of about 70% of these cells in either structure varies with the position of the arm in space (Caminiti et al., Soc. Neurosci. Abstr. 7: 563, 1981). (The remaining 30% of cells show changes in activity with movement in the absence of positional effects.) The positional variation is such that when the hand is held at various points in a two-dimensional space, the cell response surface describes a plane. Given that during movement the hand occupies successively different positions in space, it could be argued that the directional vari-ation in discharge observed in these cells during movement reflects simply the change in position. We examined this idea by performing the following analysis on experimental results obtained from 78 motor cortical and 63 area 5 cells which exhibited planar static (positional) response surfaces. 1) The plane equation was derived from the static data. It was of the form, d = d<sub>0</sub> + ax +  $\beta y$ , where d is the discharge rate of a cell at coordinates (x,y) , and  $d_O,\;\alpha$  and  $\beta$  are constants that differ for different cells. 2) Given two-dimensional movement trajectories made by monkeys in a reaction time task (see Georgopoulos et al., J. Neurosci. 2: 1527, 1982), we calculated, using the plane equation above, the changes in discharge rate that would have occurred during these movements based on changes of hand position alone, that is, if the movements were of infinitely low speed. The spatial trajectories, of course, would be the same under both the actual and the hypothetical conditions. 3) These predicted "positional" curves were then compared with the changes in cell discharge actually observed during movement. In most cases the ob-served changes led the predicted ones in time, differed significantly from them in magnitude and time course but were similar in the direction of change in cell activity. Moreover, brisk changes in discharge were frequently observed even when the hand moved In discharge were frequencity observed even when the hand moves perpendicularly to the axis of maximum static slope; that is, when the predicted "positional" change was zero. Finally, these "dynamic" changes in cell discharge (calculated as: actually ob-served - "positionally predicted" responses) varied in an orderly fashion with the direction of movement. (Supported by USPHS Grants NS17413 and NS07226).

## 145.8

CHANGES IN ELECTRICAL EXCITABILITY OF PRIMATE PYRAMIDAL TRACT AXONS DURING ACTIVE WRIST MOVEMENTS. <u>A. Schmied and</u> <u>E. E. Fetz</u>, Dept. of Physiology & Biophysics, and Regional Primate Research Center, University of Washington, Seattle, WA 98195. In monkeys performing alternating wrist movements the threshold for electrical activation of pyramidal tract (PT) axons was found to change systematically during the wrist movements. Tested randomly, the anti-dromic thresholds of PT neurons were usually lower during the phase of movement in which the cell discharged. Two mechanisms previously documented in anesthetized animals may explain this effect. The axonal excitability of corticofugal neurons has been shown to be transiently increased by peripheral stimulation in anesthetized cats (1,2), suggesting the possibility of presynaptic modulation of transmission in corticofugal pathways. Second, the electrical threshold of an axon fluctuates follow-ing conduction of an action potential (3). In awake, behaving primates we found evidence for both spike-related and task-related changes in axonal found evidence for both spike-related and task-related changes in axonal threshold of precentral PT neurons.

Electrical excitability of PT axons was tested in macaques performing Electrical excitability of PT axons was tested in macaques performing ramp-and-hold wrist movements against an elastic load. Antidromic action potentials were evoked by 0.2-ms biphasic stimuli via a concentric bipolar electrode placed near the medullary pyramids. The proportion of antidromic action potentials evoked by near-threshold stimuli of constant intensity (n > 100) was taken as an index of electrical excitability. (Suprathreshold stimuli invariably evoked antidromic spikes, so the failures were due to fluctuations of axonal threshold.) Delivering PT timuli at fixed delays after orthodromic spikes revealed a repeatable time course for the postspike change in excitability. After the collision interval, excitability quickly rose to a peak within several milliseconds Interval, excitability quickly rose to a peak within several milliseconds and subsequently dropped to a plateau level after 15-25 ms. The tested PT neurons all exhibited a similar time course of postspike excitability, suggesting an intrinsic membrane mechanism (3). Such an increase in excitability following an orthodromic action potential may enhance conduction of subsequent action potentials into terminal branches; indeed, the facilitation of the second of two corticomotoneuronal EPSPs has a similar time course (4).

similar time course (4). Independently of the postspike threshold changes, most PT neurons also exhibited additional excitability changes related to motor activity. Such task-related changes were not consistently related to the phase of movement in which the PT neuron fired. PT stimuli delivered at a fixed postspike latency often evoked more antidromic responses during the active movement that involved the greatest force. Such task-related threshold changes may reflect depolarization of terminals within electrotonic conduction distance of the stimulation site (1,2).

- THE PRIMARY MOTOR CORTEX OF THE OWL MONKEY: A MICROSTIMULATION 145.9 APPING STUDY OF THE LEG AND ARM AREAS. <u>E.J.</u> Neafsey, E.L. Bold\*, <u>G.F. Sievert\*, R.R. Terreberry\* and G.J. Quirk\*</u>, Dept. of Anatomy, Loyola Univ. Medical Center, Maywood, IL 60153. A number of recent studies have provided detailed maps of the visual, auditory and somatosensory cortices of the owl monkey
  - (Actus trivirgatus), revealing in each area <u>multiple</u> representa-tions of the receptor surface. The owl monkey is particularly suited for these studies since its lissencephalic brain facili-tates the mapping process. The present study sought to exploit this same advantage in an intracortical microstimulation study of the primary motor cortex. During both surgical preparation and stimulation each of the

three owl monkeys studied was anesthetized with ketamine HCl. End-expired CO<sub>2</sub>, blood pressure and body temperature were main-tained near normal values. After placing the animal in a stereotaxic frame, a wide craniotomy was made, exposing frontal and parietal cortex on one side. An acrylic dam was constructed around the opening, the dura was removed, and the dam filled with mineral oil. A photograph of the surface was used to plot the location of the 100-200 penetrations made in each experiment. The tracks were .5-1 mm apart, were perpendicular to the surface, and were made to a depth of 1.5 mm. Stimulus parameters were a 50 mese train of .25 msec constant current negative pulses at 350 Hz. The maximum current was 30  $\mu$ amps. Marking lesions were made by passing 10  $\mu$ amps DC for 10 sec at selected points. At the conclusion of the experiment the animal was perfused with formalin and the brain sectioned.

Based on histological reconstruction of electrode tracks, the primary motor cortex defined by stimulation coincides with cytoarchitectonic area 4. The leg motor area of all three monkeys appeared to contain at least two distinct areas where toe move-ments were evoked. In two animals these areaswere separated from each other by cortex where more proximal knee or hip movements were elicited. In the other animal a single large patch of cortex was devoted to toe movements; however, within this area as one moved from caudal to rostral the sequence of movements repeated itself: toes flex, toes extend, toes flex, toes extend. It was common to find zones for flexion and extension movements about a joint adjacent to each other. These same observations also held true for the digit representations in the arm area, as has been reported for the squirrel monkey by Strick and Preston (JNP 48, 1982). In both the leg and arm areas there were also multiple representations of more proximal movements, similar to the pattern seen by Murphy and his coworkers in the macaque (JNP 41, 1978). The existence of multiple representations of the same movement in primary motor cortex is well established; its significance is yet to be discovered. (Supported by NIH grant NS16146 to EJN.)

145.10 MOTOR CORTICAL MECHANISMS MEDIATING RECIPROCAL ACTIVATION AND CO-CONTRACTION OF FOREARM FLEXOR AND EXTENSOR MUSCLES IN THE PRIMATE. R.J. Kasser\* and P.D. Cheney. Departments of Anatomy and Physiology, University of Kansas Medical Center, Kansas City, Kansas. 66103. Based on their pattern of covariation during volitional motor respon-ses, the activity of flexor and extensor muscles acting at a joint can be divided into two basic types: 1) reciprocal and 2) co-activation. Re-ciprocal activation, is associated with tarks in which the activity of

ciprocal activation is associated with tasks in which the activity of antagonist muscles decreases as that of agonists increases. In contrast, co-activation involves simultaneous contraction of flexor and extensor muscles to stabilize the joint in a fixed position. The purpose of this study was to determine if separate motor cortex cells mediate these two patterns of muscle activity or if some cells participate in both. Rhesus monkeys were trained on two motor tasks: 1) an alternating movement task which involved reciprocal activation of forearm flexor and extensor muscles, and 2) a power grip task which involved co-acti-vation of forearm flexors and extensors. The activity of single motor cortex cells and EMGs of 6-12 wrist and digit forearm muscles were recorded simultaneously during task performance. Cells were isolated during both tasks. Spike-triggered averaging of rectified EMG activity was used to identify corticomotoneuronal (CM) cells and the sign (facil-itation or suppression) of their output effects on motoneurons of agonist and antagonist muscles (Cheney, P.D. et al. <u>Brain Res. 247</u>:164, 1982). Forty-eight task related motor cortex cells were recorded in two monkeys. Of these, 11 were identified as CM cells based on their postspike facilitation of agonist muscle EMG activity. Two CM cells had reciprocal output effects and 9 facilitated agonists but had no effect on antagonists (pure facilitatory cells). In all cases tested (7), stimu-lus-triggered averages computed from single 5-15 uA stimuli applied to the site where the CM cell was recorded confirmed the cell's facilita-tion of agonists. Stimulus-triggered averages also confirmed suppression of antagonist muscles at the site of both reciprocal cells. One reciprocal cell increased its activity during wrist flexion of alternating move-ments; the other during extension, but both cells decreased their activ-ity during the power grip task. These relations are consistent with the fact that suppression of antagonist muscles from these cells would infact that suppression of antagonist muscles from these cells would in-terfere with co-activation during power grip. Of the 9 pure facilitatory CM cells, 3 increased their activity only during wrist flexion, 3 only during wrist extension and 3 during both alternating movements and power grip. Of 37 task related non-CM cells, only one showed an in-crease in activity specific for power grip; 23 increased their activity only for alternating movements, and 13 showed increased activity for both alternating movements and power grip. In conclusion, these results suggest that co-activation is mediated largely by nonreciprocal facilitatory CM cells which are also involved in alternating movements.

145.11 SPATIAL DISTRIBUTION OF NEURONS WITH MONOSYNAPTIC INPUTS TO ADJACENT NEURONS IN THE PRIMATE MOTOR CORTEX. M. Matsumura\* and K. Kubota. Primate Res. Inst., Kyoto Univ., Inuyama, Aichi, 484 JAPAN How close a cortical neuron receives excitatory and inibitory monosynaptic inputs was investigated by a technique of spike triggered averaging of intracellular membrane potentials. Monkeys, sitting in a primate chair with their heads tightly fixed to the chair frame , were weakly anesthetized with 0.5% Halothane. A pair of glass micro-electrodes,one for intracellular record-ing (filled with KCl or K-acetate), the other for extra-(filled with KCl or K-acetate), the other for extraina cellular unit recording (filled with Na-glutamate), were inserted into the motor cortex (area 4) through a drill-ed hole in the skull. The horizontal distances of the two electrodes were adjusted in each recording session between 0.2 and 1.5mm. To identify pyramidal tract neurons (PTNs), a concentric bipolar electrode was im-planted in the pontine pyramid. Thirty-one intracellular recordings (14 PTNs, 6 non-

PTNs and 11 unidentified neurons) were obtained from 20 penetration tracks. Fifty-six extracellular units, satisfying a criterion of at least 100 successive spike activities (usually in a period of 10 to 30s), were simultaneously recorded at cortical depths of between 1.2 and 2.0mm (corresponding to the lower part of layer 1.2 and 2.0mm (c III to layer V).

1.2 and 2.0mm (corresponding to the lower part of layer III to layer V). Of these unit activities, twenty-two (in 5 penetration tracks) were recorded within areas of 0.2 to 0.5mm horizontally from the intracellular recording sites at a cortical depth of 1.2 to 2.0mm. In seventeen of these 22 (77%), spikes triggered averaged EPSPs with amplitudes of 96 + 35µV/spike (mean + SDs) ranging from 60 to 150µV with the shortest latency of 0.7ms. Twenty-three units(in 9 tracks) were recorded within areas of 0.6 to 1.0mm horizontally at depths of 1.2 to 2.5mm. Nine of these 23 (39%) showed averaged EPSPs with amplitudes of 83 + 44µV ranging from 60 to 140µV, and one showed IPSP of 100µV. Eleven units (in 6 tracks) with horizontal distances from the electrode tips of more than 1.1mm, however,did not show any averaged potential deflections. No significant differences of PSP amplitudes were observed in respects of horizontal and vertical differences of distances of the two recording sites. The ratio of innervating neurons was higher in neurons within 0.2 to 0.5mm of horizontal distances. These results support anatomical observations of vertical columnar organization of motor cortex.

145.12 CORTICOSTRIATE AND CORTICOTHALAMIC PROJECTIONS FROM AREA 6 IN THE RACCOON. Sharleen T. Sakai and Duke Tanaka Jr. Dept of Anatomy, Michigan State University, East Lansing, MI. 48824. Several electrophysiological studies in carnivores have shown

that area 6, located within the anterior sigmoid gyrus (ASG), contains both an eye movement area located medially and the supplementary motor area located laterally and caudally. In both the dog and raccoon, these functional subdivisions correspond in In both the dog and raccoon, these functional subdivisions correspond in location to cytoarchitectonically distinct sectors of area 6. However, the cytoarchitectonic and functional differences seen within divisions of area 6 are not reflected by topographically organized subcortical projections. For example, in the dog and raccoon, thalamic afferents to area 6aa located medially and to area 6aß located more laterally do not arise from topographically distinct bands of neurons but rather from neurons organized into wide partially overlapping bands. The purpose of this study was to determine whether neostriatal and thalamic projections from area 6 also show similar widespread termination patterns in the raccoon raccoon.

Discrete single injections of tritiated leucine and proline  $(1.0\ \mu]$ ; 50  $\mu$ Ci) were made into each of two area 6 subdivisions on the ASG in the raccoon. A comparison of matched sections showed considerable overlap between corticostriate projections arising from area fax and fact the hoth cases, patches of dense label were located bilaterally over wide areas of the caudate nucleus immediately adjacent to the internal capsule. However, after injections of area fag, the label extended slightly more dorsal in the caudate nucleus than that observed following area

dorsal in the caudate nucleus than that observed following area  $\delta a \alpha$  injections. Heavy label was also noted bilaterally over the dorsal and medial parts of the putamen. Following injections of area  $\delta a \alpha$  or  $\delta a \beta$ , bands of silver grains were located over the medial half of the ventral anterior and ventral lateral nuclei as well as over the central and ventro-lateral parts of the mediodorsal nucleus. Dense label was also present over the ventral medial nucleus and intralaminar nuclei; these nuclei also contained light contralateral label. Although the label observed after area  $\delta a \alpha$  injections was situated slightly medial to that seen after area  $\delta a \beta$  injections, extensive overlab. overlap between the two projections was noted.

These data suggest that, although the corticostriate and corticothalamic projections of areas  $6a \alpha$  and  $6a\beta$  show slight topography, they are best characterized by their widespread and overlapping termination patterns. (Supported by NS 18551, NS 16991 and BRSG funds to the College

of Veterinary Medicine).

THE INTERRELATION OF CALLOSAL AND CORTICOSPINAL NEURONS IN THE 145.13 SENSORIMOTOR REGION OF THE RAT. <u>P. Herron and J. Miller\*</u>. Div. of Neurosci. and Behavior, Dept. of Psych., Univ. of Massachusetts, Amherst, MA 01060

We utilized double-labelling techniques in order to determine the spatial interrelationship of the cells of origin for the corticospinal and callosal fiber systems in the sensorimotor region of rats. We wanted to determine the following: 1) if single cells send collateral to both target regions, and 2) if the distribution of callosal neurons were congruent with the distribution of corticospinal neurons. We used a combination of the retrograde tracers nuclear yellow and fast blue, nuclear yellow and horseradish peroxidase, or fast blue and horseradish peroxidase. Inject-ions of 0.5-1.0 ul were made in the lumbar or cervical region of the spinal cord in combination with injections in the contralater-al sensorimortor region. Survival times ranged from 1 wk (for fast blue) to 24 hr. The brain and spinal cord were removed and sect-ioned at 30 or 40 um and the HRP sections reacted with tetramethyl-benzidine. All sections were examined for fluorescent labelling using an Olympus excitation filter and reflected light attachment and the horseradish peroxidase was examined using light microscopy.

We did not observe any double-labelled neurons. Both the corticospinal and callosal systems were topographical organized. though the distribution of corticospinal and callosal neurons overlapped considerably in both the horizontal and vertical dimensions, there were regions which contained many corticospinal neu-rons and relatively few callosal neurons. The bulk of the cal-losal neurons were restricted to the agranular regions whereas the corticospinal neurons were located in both the agranular and granular regions. Consequently, the distribution of corticospinal neurons were not congruent with the distribution of callosal neurons.

The corticospinal neurons formed a well-defined lamina in the ventral part of layer V whereas the callosal cells were in all layers except layer I with the maximum concentrations in layers III and V. The density of corticospinal neurons was relatively constant throughout the area of distribution for corticospinal neurons. In contrast, the density of callosal neurons varied consider-Tons. In contrast, the density of callosal neurons varied consider-ably throughout the area of distribution for callosal neurons. The maximum density of corticospinal neurons as observed in 30 or 40um sections was between 175-225/mm<sup>2</sup> whereas the density of callosal neurons was as high as 1000/mm<sup>2</sup>. In the region of overlap between the corticospinal and callosal neurons the number of callosal neurons was generally greater than the concentration of corticospin-al neurons in layer V. We concluded that parts of the corticospin-a al and callosal neurons receive similar inputs, other parts do not.

145.15 NEOCORTICAL COMMISSURAL SIZE & SEX DIFFERENCES IN PRIMATE

NEOCORTICAL COMMISSURAL SIZE & SEX DIFFERENCES IN PRIMATE BRAIN. M. C. de Lacoste and D.J. Woodward, Dept. Cell Bio., Univ. Texas Health Science Center, Dallas, Tx Our study was undertaken (1) to delineate interspecific correlative effects of brain size (BR) on the cross-sectional surface areas of both the corpus callosum (CCAREA) and the anterior commissure (ACAREA) as well as on other callosal measurements; and (2) to determine if there is sex-linked intraspecific variation in these correlative relationships. Mid-sagittal sections (N=64) of brains of both sexes from a variety of prosimian (PRO) and anthropoid species (N=30) were photographed at the Max-Planck Inst. for Brain Research (Frankfurt). BR values ranged from 1.78g (Microcebus m.) to 570g (gorilla). The photographs were used for computer-

STOG (gorilla). The photographs were used for computer-assisted planimetric measurements of CCAREA and ACAREA and for measurements of the dorsoventral widths of the splenium (SPUW) and the body of the corpus callosum. Previous data from human material were added to the primate sample. In a preliminary material were added to the primate sample. In a preliminary analysis, we identified species with median values for ER within PRO, Ceboids (CEB), Cercopithecoids (CERCO) and pongids (PON). For each of the selected species, mean values for ER, CCAREA, ACAREA, and SFLW were calculated and then entered in log/log regression analyses of ER vs. CCAREA (R=.9989), ACAREA (R=.98), and SFLW (R=.96). Residuals (Observed values/expected values from regression equation) were used to avamine interspecific and SPLW (R=.96). Residuals (Observed values/expected values from regression equation) were used to examine interspecific patterns as well as intraspecific sexual dimorphism in a small number of species: Homo sapiens (N=14), PONO- Gorilla g. (N=10) and Pan t. (N=3), CERO- Papio h. (N=4) and Macaca m. (N=2), CEB, Saimiri s. (N=2) and Callithrix j. (N=2), and PRO-Nycticebus c. (N=4), Galago d. (N=4) and Cheirogaleus m. (N=2). Results suggest that CCAREA and ACAREA appear to follow different phylogenetic growth rates: CCAREA is on the average 1.5X larger than expected in humans while ACAREA is only .48X its expected size on the basis of brain weight. In terms of sex

its expected size on the basis of brain weight. In terms of sex differences, the above PRO species show a marked tendency, similar to that found in humans, for callosal sexual dimorphism, Similar to that found in humans, for calload setual dimographism, with observed values for CCAREA and SPLW higher than expected, and, conversely, lower than expected in respectively females and males. Similar patterns were found for CCAREA but less consistently for SPLW in CERCO and FON. CEBs are the least consistent for both CCAREA and SPLW. No distinct pattern of sexual dimorphism in ACAREA was observed in all species.

Although a complete evolutionary picture of callosal dimorphism within the primate order remains to be delineated, we can conclude that at least some non-human primates manifest sex-linked variation in CCAREA and SPLW. Supported by the Biological Humanics Foundation.

RECIPROCAL SYNAPTIC RELATIONSHIPS OF MSL PYRAMIDAL NEURONS WHICH 145.14 PROJECT TRANSCALLOSALLY IN THE MOUSE. L. L. Porter; E. L. White and G. R. Belford. Dept. of Anat., Boston Univ. Sch. Med., Boston 62118.

The vibrissal region of the mouse primary motor cortex (MsI) is The vibrissal region of the mouse primary motor cortex (MsI) is reciprocally connected with the corresponding.region in the contra-lateral hemisphere (Porter and White, J. Comp. Neurol. 214;279, 1983). The purpose of the present investigation was to study the synaptic relationships between callosal projection neurons in the motor cortex and callosal afferents from contralateral MsI. Injections of horseradish peroxidase (HRP) were placed into the vibrissal region of MsI in adult male CD-1 mice in order to ret-morandoly label colls in the contralateral

vibrissal region of MsI in adult male CD-1 mice in order to ret-rogradely label cells in the contralateral cortex. On the follow-ing day, the cortex at the injection site was aspirated to identi-fy callosal afferents by lesion-induced degeneration. Four days post-lesion, the animals were perfused with aldehydes and the MsI cortex contralateral to the lesion/injection site was tissue chopped in the coronal plane and reacted for HRP. After light microscopic analysis, labeled cells from layers II-III were prepared for electron microscopic examination. Unbroken series of thin sections were cut through the soma and the entire length of the apical shaft and spines. Electron micrographs of all labeled profiles of the spical dedite were montaged and raphically reconstructed. The and spines. Interview montaged and graphically reconstructed. The locations of all synapses with the shaft and spines of the apical dendrite were noted on the reconstruction.

dendrite were noted on the reconstruction. The callosal projection neurons were pyramidal cells whose somata were located predominately in cortical layers II-III and V. Derse HRP reaction product filled the dendrites and spines of these cells. The apical dendrites of labeled cells located in both cortic-al tiers exhibited variable concentrations of dendritic spines and extended close to the pial surface. The dendritic shaft formed both symmetric and asymmetric synapses; most synapses were symmet-ric onto spines. A small proportion of the synaptic contacts with the dendritic spines were formed by degenerating callosal axon terminals. Preliminary results from the examination of one neuron showed that callosal terminals formed 6.0% of all asymmetric axospinous synapses on the apical dendrite of this cell.

Thus, these data imply that cells in the primary motor cortex project to the homotopic area of the contralateral cortex and in turn receive synapses from the same area. Supported by NIH training grant No. ST32 NS 07152 and NSF grant No. 8202614.

145.16 CALLOSAL CONNECTIONS OF THE SUPERIOR PARIETAL LOBULE IN THE MONKEY. R. Caminiti and A. Sbriccoli\*. Institute of Human Physiology, University of Rome and Institute of Neurology, Catholic University, Rome, Italy.

> The callosal connections of the superior parietal lobule (SPL) of the monkey were studied using the axonal transport of HRP in four M. nemestrina and one M. fascicularis. In two of these animals, lectin conjugated horseradish peroxidase (HRP-WGA) was

> animals, lectin conjudated horseradish peroxidase (HRP-WGA) was used. In all cases, multiple injections of the enzyme were made in the various architectonic divisions of SPL(Pandya, D.N. and Seltzer, B., J. comp. Neurol., 204: 196, 1982). The brains were processed with tetramethyl benzidine. Callosal neurons diving rise to homotopic connections are pyramidal cells of the deeper part of layer III as well as pyramidal and fusiform cells of layer VI. They occupy the entire tangential extent of SPL. Commissural cells are present in the cortex of the dorsal and rostral part of SPL up to its posterior and apical sector, including the cortex of the medial surface of the hemisphere. This callosal zone is co-extensive with architectonic areas PE and PEc. In the ventral part of SPL callosal cells occupy, at all mediolateral levels, the cortex of

architectonic areas PE and PEc. In the ventral part of SPL callosal cells occupy, at all mediolateral levels, the cortex of the upper bank of the intraparietal sulcus (IPS), in area PEa. Commissural fibers of SPL cross the midline in the posterior half of the body of the Corpus Callosum (CC). Labeling of callosal axons extends from the level of the fornical and posterior commissures up to the rostral limit of the splenium of the CC. They enter the cortex of SPL, and terminate in radial patches or columns, of various shape and size, spanning layers I-IV. These characteristic dust-like patches are particularly evident in the cortex of the upper bank of IPS. Callosal neurons are found within as well as between these columns. Differently from the primary sensory and motor areas, where large parts of peripheral representations are free of callosal connections, the cortex of SPL projects profusely to the opposite hemisphere. This callosal projection may be important for the interhemispheric integration of sensory and/or motor information across the midline and the patches of callosal terminals may represent an anatomical substrate for the representation of the

represent an anatomical substrate for the representation of the ipsilateral periphery. The callosal system of SPL may also represent an anatomical substrate for the intermanual transfer as well as for the interhemispheric integration of sensory and/or motor inputs working in a synchronous and combined way.

STRUCTURAL CHANGES IN BRAINS OF MICE WITH AGENESIS OF THE CORPUS 145.17 CALLOSUM. <u>D. Wahlsten and G. B. Jones\*</u>. Dept. of Psychology, Univ. of Waterloo, Waterloo, Ontario, Canada N2L 3G1. From 10 to 20% of adult mice of the inbred strain BALB/cCF have either total absence or substantial deficiency of trans-cortical fibres in the corpus callosum (CC). Littermates with normal CC provide good controls for comparison with sibs having normal CC provide good controls for comparison with sibs having abnormal CC because both kinds of mice have the same genotype. It is thus possible to specify what other abnormalities of the fore-brain are associated with the CC defect and to detect unusual pathways of CC axons which are prevented from crossing midplane. Analysis of 99 littermate pairs matched for age and brain weight suggested that axons which are normally part of the CC do not reroute via the anterior commissure (CA) when CC formation is disrupted. As indicated in the table, cross-sectional areas at midplane of the anterior and posterior parts of CA (designated CAA and CAP, respectively) as well as the hippocampal commissure (CFV) did not differ significantly between sibling pairs with normal and deficient CC cross-sectional area.

Projections from cortical neurons were traced in over 100 BALB/c brains by placing small electrolytic lesions in one of ten different locations in the dorsal cerebral cortex, perfusing the mouse five days after the lesion and then staining for degenerating axons and terminals using the Giolli and Pope modification (J. <u>Comp. Neurol.</u>, <u>147</u>:129, 1973) of the Fink-Heimer silver stain. Although ipsilateral projections to cerebral cortex, caudate nucleus and thalamus were clearly revealed, no degenerating axons were found in CAA or CAP of any mouse, regardless of presence or absence of CC. Axons were traced for long distances through the longitudinal Probst bundles when CC was totally absent or very small at midplane, but in cases of moderate deficiency of CC the axons usually found their way to the contralateral cortex and the size of the Probst bundles was substantially smaller.

INVESTIGATION INTO THE ELECTRICAL EXCITABILITY OF THE CEREBRAL 145.19 INVESTIGATION INTO THE ELECTRICAL EXCITABILITY OF THE CEREBRAL CORTEX: THE FIRST HALF CENTURY. KL Tyler\* (SPON: HR Tyler). Neurology Dept., Massachusetts General Hosp., Boston, Mass. 02114 In 1870 Eduard Hitzig noted that galvanic stimulation through certain portions of the intact skull in an awake patient produced involuntary eye movements. These results led him, with the assist-ance of Gustav Fritsch to conduct a series of experiments in dogs, on the electrical excitability of the exposed brain. The resulting discovery that electrical stimulation produced muscular contractions of the opposite half of the body, "Localized to specific, strictly limited, muscle groups," and that these responses were obtained from centres in discrete brain regions; was seminal.

Within three years of Hitzig's report, David Ferrier published the first in a series of reports on cerebral localization. His the first in a series of reports on cerebral localization. His work was summarized in his Croonian and Culstonian Lectures, and in the two editions of his book, <u>The Functions of the Brain</u>. He dedicated this to Hughlings Jackson, noting that he had "Antici-pated many of the more important results of recent experimental investigation into the functions of the cerebral hemispheres." Using improved technical methods, and extending his work to the monkey, Ferrier significantly expanded knowledge of brain function. In Sherrington's words he provided a, "Solid basis of experimental fact," to the, "Hitherto disputed existence of 'localisation' of cerebral function." Ferrier explicitly extended his localisation cerebral function." Ferrier explicitly extended his localisation on schema to man by transposing it onto a map of the human brain. In 1874 Roberts Bartholow demonstrated for the first time in

man that the cortex was electrically excitable. Bartholow was aware of the experiments of Fritsch and Hitzig and Ferrier, and aware of the experiments of Fritsch and Hitzig and Ferrier, and referred to them in his paper. His patient was his housemaid, who suffered from an eroding cancer of the skull. Placing one insula-ted needle into her left 'posterior lobe' and another a 1/4 inch away, in contact with the dura, electrical stimulation produced muscular contraction and a, "Feeling of tingling," in the right arm and leg. Postmortem examination of the fixed brain showed that the stimulating electrode had penetrated over an inch into the brain in the varies of the unear protected area. the brain, in the region of the upper postcentral gyrus.

Subsequent pioneering observations on the excitable cortex in primates were conducted by Gotch, Beevor, Horsley, Grunbaum (Leyton) and Sherrington. The great German neurosurgeon Fedda Krause extended Bartholin's previous observations in man, and Accurately mapped out the "focal fields" of many linb movements on the cortex of awake patients undergoing neurosurgical procedures. These investigations set the stage for the subsequent work of Foerster and Penfield which usbered in the second half-century of investigation into the excitable cortex of man.

145.18 PHYSIOLOGICAL AND MORPHOLOGICAL PROPERTIES OF PYRAMIDAL TRACT 
 FRISTOLOGISIN THE RAT.
 P. Landry\*, C. J. Wilson and S. T. Kit.

 (SPON: M. Jones)
 Dept. of Anatomy, Mich. State Univ.
 Kitai E. Lansing, MI 48824.

Intracellularly recorded pyramidal tract (PT) neurons in rat sensorimotor cortex were identified by antidromic stimulation of the pyramidal tract and injected with horseradish peroxidase (RRP). A recurrent IPSP that lasted from 25-55 ms and that could be reversed with hyperpolarizing current was observed in most be reversed with hyperpolarizing current was observed in most neurons regardless of the occurrence of antifarmic action poten-tials. The latency of this IPSP ranged from 2.3-5.5 ms (mean = 3.2, SD = 0.8, N = 13). Antifarmic latencies from the same stimu-lation ranged from 1.1-3.3 ms (mean = 1.6, SD = 0.5, N = 25). A similar response was also observed in most layer V cells, Similar response was also observed in most layer v cells, including those not responding antifuromically. The IPSP was followed by a prolonged period of inhibition of action potentials which could be followed by a rebound excitation at latencies of about 180-200 ms. In only a few cells was there an EPSP preceding the initial IPSP. A period of excitation following the onset of the IPSP and lasting from 40-50 ms was occasionally isolated from the IPSP. In most cells a similar excitatory potential could be revealed by passing hyperpolarizing current. The earliest latency to the first spike evoked by this excitation ranged from 4-12 ms (mean = 7.9, SD = 2.2, N = 12). To insure that this excitation did not arise from stimulation of medial lemniscus, a knife was passed through the entire thalamus caudal to most of the ventroposterior nuclei and sectioning the medial lemniscus. The latencies of the IPSP and the excitatory period were not changed by this procedure. Staining by intracellular injection of HRP revealed the presence of two types of PT cells having the same conduction velocities. Most of the injected neurons (11 of 12) had extensive intracortical axonal arborizations restricted to layers IV, V and VI and extending 1-2 mm from the some horizon-tally. The axon of the second type was like that described by Donoghue and Kitai (JCN, 201:1-13, 1981). Its axon collaterals were limited to an area 0.5 mm around the cell body horizontally, but extended radially as far as layer I. Cells of both types were observed to send an axon collateral to neostriatum. An aspinous stellate cell identified after injection with HRP exhibited a large and monosynaptic EPSP with a latency of 2.8 ms evoked by pyramidal tract stimulation. The duration of this EPSP was comparable to that of the short latency IPSP in PT cells, but not the longer inhibition. (Supported by NIH Grants NS 17294 to C.J.W. and NS 14866 to

S. T. Kitai and a FRSQ Fellowship to P. L.).

PHASE-LOCKING TO AUDITORY STIMULI BY EIGHTH NERVE FIBERS OF A NEOTROPICAL TREEFROG. <u>C. M. Hillery\* and P. M. Narins</u> (SPON: C. Clemente). Department of Biology, University of California, Los Angeles, Los Angeles, CA 90024. The phase-locked response pattern of eighth nerve fibers was investigated in <u>Eleutherodactylus coqui</u>. Period histograms, triggered by the positive zero-crossing of the stimulus waveform, accumulated spike counts relative to a single cycle of a pure tone stimulus. The degree of synchronization, measured as vector strength (VS), and the phase angle (i.e. the median of the period histogram's distribution) were measured for each unit at best frequency (BF) and as many other frequencies and intensities as time permitted. We found that below 1.0 kHz, neurons showed a high degree of phase-locking to stimulus waveforms, often at sound high degree of phase-locking to stimulus waveforms, often at sound levels well below (10-15 dB) their discharge rate thresholds.

Within the frequency response range of a neuron, VS showed no systematic correlation with stimulus intensity. The VS of the response was, however, clearly frequency dependent showing the greatest synchronization at the lowest test frequencies. This correlation was independent of the neuron's BF. The frequency correlation was independent of the neuron's BF. The frequency dependence of phase-locking was described as a negative linear function that was similar for low and mid-frequency fibers deriving from the amphibian papilla (a.p.). Although fibers innervating the basilar papilla in anurans have BFs well above the frequency range for which phase-locked responses occur, initial observations suggest that these fibers exhibit phase-locked responses to sinusoidal stimuli at frequencies below 1.0 kHz. The preferred phase angle shows an increasing shift (lag) with stimulus frequency. The slope of this function is similar for all a.p. neurons studied and suggests a constant time delay for stimulation of all a.p. units.

stimulation of all a.p. units. Increasing the level of simultaneously-presented broadband noise (0.05 to 6.5 kHz) did not effect the phase angle, however noise (0.05 to 6.5 kHz) did not effect the phase angle, however, the distribution of spike occurrences broadened, thereby reducing the VS. It is notable that even at the highest noise spectrum levels tested (64 dB/Hz) phase-locking was still prominent and could, at low frequencies, provide a potential source of information about stimulus waveform structure. This could provide the animal with cues about stimulus frequency (coded temporally), sound source localization (coded by relative phase shifts) or sound source localization (coded by relative phase shifts) or overall temporal features of a stimulus. The upper frequency limit for phase-locking (1.0 kHz) corresponds to measures determined for fish and reptiles but is significantly lower than the 4 - 6 kHz cut-off frequency determined for birds and mammals.

RAPID AND SHORT-TERM ADAPTATION IN GERBIL AUDITORY 146.2 RAPID AND SHORT-TERM ADAPTATION IN GERBIL ADDITORY NERVE RESPONSES. L. A. Westerman\* and R. L. Smith (SPON: A. Ecker). Inst. Sensory Res., Syracuse Univ., Syracuse NY 13210. The firing rate of a nerve fiber in the auditory periphery declines rapidly and markedly following the initial brisk response at the onset of a constant-intensity tonal stimulus. In gerbil, this decay appears to involve two components which occur within the first several hundred milliseconds. Hence at a given intensity the decay can be characterized by the equation

## $R = A e^{-Bt} + C e^{-Dt} + E$

where R is the instantaneous response at time t after the onset peak, A and B characterize the rapid decay which occurs within the first few milliseconds, C and D characterize the short term decay, and E is the steady-state rate. In order to determine the dependence of these components on sound intensity, the equation was fitted to PST histograms by a least-squares procedure. An intensity range of 40 dB was used, with the minimum intensity for each fiber set at 3 dB above audio-visual threshold. Short-term adaptation had a time constant of c. 70 msec which

varied little with stimulus intensity. When the intensity was varied, the magnitude of the short-term component of the response varied, the magnitude of the short-term component of the response varied in proportion to the steady-state rate, and saturated over the same limited operating range (c. 20 dB re threshold). The relative magnitudes of the short-term and steady-state components varied among fibers: in our sample of 19 fibers, the ratio ranged from 0.5 to 3.5, measured at the highest intensity for each fiber.

from 0.5 to 3.5, measured at the highest intensity for each fiber. The rapid component greew more rapidly with intensity than did the steady-state rate, and continued to increase at intensities which produced saturation in the steady-state rate. In some fibers, the rapid component saturated at intensities 20-30 dB higher than did the steady-state rate. This saturation occurred at an onset rate limited by the absolute refractory period of each fiber. The saturated onset response approached the limiting probability of unity, that a spike occurred within a specified narrow window at the onset of the tone-burst stimulus. In some fibers, the onset response grew more slowly with intensity and did not reach saturation at the highest intensity tested.

At high intensities, the time constants of rapid adaptation ranged from 0.8 to 4.5 msec in our sample. The rapid time constant for most fibers declined with increasing intensity and for some individual fibers varied by more than a factor of 3 over the intensity range tested. The measured effects of intensity on the time constants of adaptation match the analytical solution to Smith and Brachman's (Biol. Cybern. 44:107-120, 1982) phenomenological model of peripheral adaptation. adaptation.

CONTINUOUS BACKGROUND NOISE AND AVERAGE DISCHARGE RATE OF AUDITORY-NERVE FIBERS IN THE CAT. J. A. Costalupes and E. D. Young. Dept. of Biomedical Engineering, Johns Hopkins University School of Medicine, Baltimore, MD 21205. This study reports that addition of broadband background noise extends the overall operating range of auditory-nerve fibers.

Average discharge rates in response to 200 ms best frequency (BF) tones in the presence of continuous noise backgrounds (noise turned on at least 15 s before tone and left on continuously while testing) and simultaneously gated noise backgrounds (noise turned on and off simultaneously with tone) were recorded from auditorynerve fibers in anesthetized cats. Inspection of BF rate versus level functions obtained in noise over a wide range of noise levels reveals two effects of continuous noise backgrounds. First, previous exposure to noise results in a decrement in average discharge rate that is independent of the level of the tone stimulus. Second, the range of tone intensities over which the fiber is sensitive to changes in tone level -- the dynamic range of the fiber -- shifts to higher tone intensities. The shift occurs at an average rate of .68 dB of shift for each 1 dB increment of noise level and is independent of the fiber's best frequency and spontaneous discharge rate. Simultaneously gated and continuous noise backgrounds at a given intensity produce the same amount of shift.

Effects of continuous noise backgrounds on discharge rate to BF tones can be summarized by expressing a fiber's rate versus level function in continuous noise,  $R_{I}(i)$ , in terms of its rate versus level function in quiet,  $R_{q}(i)$ , by the equation

$$(i) = S \begin{bmatrix} R_{g}(i-i_{H}) - R_{sp} \end{bmatrix} + R_{No} -$$

D<sub>I</sub> RI where i is the level of the BF tone,  $R_p$  is spontaneous discharge rate, I is the level of the background hoise,  $R_r$  is the driven response to the noise burst alone,  $D_I$  is the rate decrement produced by previous noise exposure, and S is the fractional response to the fiber decrement produced by the fractional spectrum state of the fiber decrement produced by previous noise exposure. response rate of the fiber in noise relative to its response rate in quiet.

This extension of operating ranges of auditory-nerve fibers will be considered in light of behavioral measures of the detection of tones in noise by cats.

MORPHOLOGY OF AUDITORY NERVE FIBER INNERVATION OF THE CAT COCHLEAR NUCLEUS IN RELATION TO SPONTANEOUS RATE ACTIVITY. E.M. Rouiller\*, R. Cronin Schreiber\*, D.M. Fekete and D.K. Ryugo (SPON: J.P. Hornung). Dept. of Anatomy, Harvard Med. Sch. and Eaton-Peabody Lab., Mass. Eye and Ear Infirmary, Boston, MA. The acoustic receptors in the cochlea contact the peripheral processes of spiral ganglion neurons; the central processes of the neurons constitute the auditory nerve (AN) and project into the cochlear nucleus (CN). We have been studying the structure-function relationships of type I AN fibers in mature cats (Ryugo et al., Anat. Rec., 205:171A, 1983). The characteristic fre-quency (CF) and spontaneous rate (SR) of single fibers were determined by intracellular recordings, and then each fiber was labelled by injecting HRP through the recording pipette. This report describes morphological characteristics of en passant swellings and terminal endings within the CN, and their rela-tionship to SR. The central innervation of 22 AN fibers, ranging in CF from 0.3-28 kHz, has been analyzed from camera lucida reconstructions of serial sections. All fibers bifurcate and form an ascending and descending branch. The number of pri-mary collaterals ranges from 12-34 (X=23), independent of CF or SR. These collaterals ramify further and display en passant swellings and terminal endings. Both have been examined by EM and exhibit synaptic specializations (membrane densities and numerous clear, round vesicles approximately 50 nm in swellings and terminal endings. Both have been examined by EM and exhibit synaptic specializations (membrane densities and numerous clear, round vesicles approximately 50 nm in diameter). In our population of fibers, the ratio of terminal endings to en passant swellings is relatively constant, being 60:40. The terminal endings grade in size and complexity from simple boutons to large endbulbs of Held; in contrast, the en passant swellings are less variable in size and shape. We have counted every swelling and terminal and measured their cross-sectional areas (magnification=1250x). Our working hypothesis is that these measures will provide an estimate of synaptic density for each fiber. Neither the number nor the size of endings and swellings is related to CF, but both are related to the SR classification scheme of Liberman (JASA, 63:442, 1978). Low and medium SR fibers have a larger number (pc0.01) of simple boutons ( $\chi_{\rm p}$ =69) and en passant swellings ( $\chi_{\rm p}$ =42) when compared to high SR fibers ( $\chi_{\rm p}$ =42). Furthermore, the simple boutons of low and medium SR fibers are smaller in size (pc0.001). In contrast to the simple boutons, A fibers of differ across SR groups. As a first approximation, AN fibers of different SR groups appear qualitatively in the number and size of endings, but differ quantitatively in the number and size of endings, but differ quantitatively in the number and size of endings of certain classes. (Supported by NIH grant NS 13126 and the Swiss Foundation for Medicine and Biology).

cytoarchitecture of the acoustic tubercle (AT) was The examined in 10 turtles. Following transcardiac perfusion in 5% buffered glutaraldehyde, 0.1 M phosphate buffer, brains were removed and processed for Golgi impregnation using the Golgi-Kopsch technique. The specimens were embedded in araldite and serial sectioned at 150 um intervals. Coronal sections of cresyl violet stained brains(3), 15 um thick, were also examined.

The AT was a superficial trinuclear complex located in the dorsomedial medulla. It contained two primary auditory nuclei, Nucleus Magnocellularis (NM) and Nucleus Angularis (NA), and a

secondary auditory nucleus, Nucleus Laminaris (NL). The NM extended from the caudal end of the NA to just inferior to the caudal posterior root fibers of the eighth nerve. This nucleus consisted of larger spherical cells (9-24 um) with eccentric nuclei among clusters of smaller round cells (6l2um) which had central round nuclei. The larger spherical cells had 3 to 5 primary dendrites. The primary dendrites of a population of larger spherical cells, exhibited only secondary branches. Some of the higher order branches were long and formed an elaborate dendritic pattern. Thorn-like spines and swellings were present on many branches of the dendritic tree. A characteristic dendritic orientation did not exist in the NM. The smaller round cells had a single dendrite which could project lane. Higher order branching was very rare. Dendritic or swellings were not on the surface of the primary in any plane. Dendritic spines dendrites.

The NA was located in the rostral end of the AT caudal to the cerebellomedullary junction. It contained medium sized spherical neurons (15-24 um) with round eccentric nuclei. The 3 The 3 5 primary dendrites were usually oriented mediolaterally. few neurons had secondary branches. Many thorn-like dendritic spines and dendritic swellings were present throughout the the dendritic tree.

The NL was located ventromedial to the NM and was populated by medium sized fusiform neurons (12-21 um). The nuclei were generally central and somewhat elongated. They exhibited smooth by medium sized fusiform neurons (12-21 um). The nuclei were generally central and somewhat elongated. They exhibited smooth single primary dendrites from each soma tip. There were only secondary branches from the distal ends of the main dendrite. Dendritic spines were rare and, when present, were distally located and thorn-like.

Supported by The Whitehall Foundation.

146.7 COCHLEAR NUCLEUS UNITS SPECIALIZED FOR ENCODING AMPLITUDE MODULA-TION ARE TUNED TO DIFFERENT MODULATION FREQUENCIES. R.D. Frisina, Research

RL. Smith, and S.C. Chamberlain. Institute for Sensory Researc Syracuse Univ., Syracuse, NY 13210. The function of certain divisions of the cochlear nucleus may include the preferential encoding of modulations in sound ampli-tude. We have studied CHOPPERS in the gerbil ventral cochlear nucleus (VCN) and found that many units show phase-locked respon-ses to amplitude modulation (AM) over an intensity range 50 dB greater than that of auditory-nerve fibers [Frisina, R.D., Smith, R.L., and Chamberlain, S.C., J. Acoust. Soc. Am., 73:S81 (1983)]. At a single modulation frequency (150 Hz) and a high average intensity level, CHOPPERS show phase-locked responses that span a 30 dB range of response amplitude. We suggest that each CHOPPER may be tuned to a different modulation frequency to which it is maximally responsive.

To test this hypothesis, we measured modulation transfer functions (MTFs) for CHOPPERS in the VCN. Analyses of the responses of 14 units, for modulation frequencies from 20 to 1000 Hz, show that CHOPPERS are tuned to frequencies between 150 and 400 Hz. At an intensity of 50 dB above threshold, the response at the peak of the MTF is approximately an order of magnitude greater than that reported for auditory-nerve fibers. The shape of the MTF changes as a function of average intensity. Near threshold, the MTF resembles a low-pass filter with a small peak near the high cutoff frequency. As the average intensity increases, the MTF takes on the shape of a band-pass filter. No relation was found between natural chopping frequency, characteristic frequency, and the frequency at the peak of the MTF.

Our findings suggest that CHOPPERS in the gerbil VCN are specialized for encoding AM over a wide dynamic range for fre-quencies between 150 and 400 Hz. Presently, we are further in-vestigating the mechanism which produces this functionally rele-vant response property. [Supported by NSF and NIH]

EXCITATION AND SUPPRESSION BOUNDARIES OF UNITS IN THE AUDITORY NERVE AND ANTEROVENTRAL COCHLEAR NUCLEUS OF THE CAT. R.A. Schmiedt and J.C. Adams, Department of Otolaryngology, Medical University of South Carolina, Charleston, SC 29425

Threshold boundaries to single- and two-tone excitation and twotone suppression were mapped for single fibers in the auditory nerve and for cells in the cochlear nucleus of the cat. The boundaries were and for certain the coefficient indicates of the cat. The boundaries were obtained with the isoresponse tracking procedure developed by Kiang and Moxon (<u>J. Acoust. Soc. Am., 55</u>:620, 1974). Three stimulus paradigms were used. One incorporated a single excitatory tone and was used to obtain a standard tuning curve at a fixed criterion response. In the second paradigm, the tuning curve was retaken in the presence of a second tone placed above the characteristic frequency (CF) of the unit at a moderate level (70 to 80 dB SPL). The second tone by itself was not excitatory. In the third paradigm, a second tone was placed at the unit's CF about 15 dB above threshold and a criterion amount of suppression of the CF tone was tracked across frequency. The same measures were made from cells in the anteroventral cochlear nucleus. Most of the cells studied responded with "chopper" or "primary-notch" types of PST histograms to CF tone bursts and had no prepotentials in their spike waveforms.

Our results indicate that there is often great similarity between the responses obtained from the first-order fibers and these secondorder cell bodies with regard to the three types of isoresponse boundaries. Tuning curve shapes associated with cells are nearly identical to those of fibers obtained with the single-tone paradigm. As Identical to those of libers obtained with the single-tone paradigm. As in the nerve, the majority of the cell bodies respond to the 2f<sub>1</sub>-f<sub>2</sub> distortion product under the excitatory two-tone condition, yielding a secondary minimum above CF in the tuning curve. Further, the second tone above CF can raise the tips and often shifts the tails of the tuning curves of the cell bodies, usually as happens with the first order fibers. fibers. However, the response boundaries of the cell bodies sometimes are not predictable from the nerve responses for two-tone stimuli. For example, CF thresholds may not be raised with the addition of the second tone above CF, even though these same cells exhibit normal suppression boundaries above CF. Finally, the absolute position of the suppression boundaries obtained with tones below CF is fairly stable for fibers in the nerve regardless of fiber CF, a result that confirms (R.A. Schmidt, <u>Hearing Res.</u>, 7:335, 1982). (Supported by NSF grants BNS 82-10233 and <u>BNS 81-10222</u>).

146.8 HIGH FREQUENCY PHASE CODING IN THE COCHLEAR NUCLEUS OF THE BARN

Mul, W. E. Sullivan and M. Konishi (SPON: K. Nakai). Div. of Biol., Calif. Inst. of Tech., Pasadena, CA 91125. Ongoing time or phase differences between the two ears are utilized by Barn owls to localize high frequency sounds (5-9 kHz) along the horizontal axis. For the auditory system to measure time differences in high frequency waveforms, waveform timing must be preserved at the monaural level. Since studies

timing must be preserved at the monaural level. Since studies of mammalian auditory systems have failed to demonstrate phase or time coding at frequencies greater than 4 to 5 kHz, we investigated phase coding in the owl's cochlear nucleus to see if waveform timing is preserved at frequencies where binaural time sensitivity can be shown. Single unit responses were obtained from output fibers of the Nucleus Magnocellularis. This nucleus is known to project bilaterally to N. Laminaris, the first brainstem site where binaural time sensitivity can be found. Best frequencies of units ranged from 2.0 to 9.0 kHz. Virtually all units with Bfs from 2 to 6 or 7 kHz showed clear phase coding. In contrast to cat and monkey data, there does not seem to be a dramatic decline in phase locking ability over this range. Further, clear examples of phase coding could be seen in the range of 7 to 9 kHz. At these frequencies, the period length is from 110 to 9 kHz. At these frequencies, the period length is from 110 to 140 microseconds. Analysis of cycle histogram peak width shows that these neurons reliably respond within a range of  $\pm 25$ to 40 microseconds about the mean response phase. These observations indicate that the owl's auditory system

These observations indicate that the owl's auditory system is capable of encoding waveform timing at frequencies over an octave higher than the maximum frequencies where phase locking is seen in mammalian acoustic nerve fibers. This observation provides a basis for the earlier finding that owls can use binaural time or phase information for localization of high frequency sounds. It also raises the question of how the auditory system is able to code stimulus timing with an accuracy in the range of tens of microseconds.

- INTRACELLULAR RECORDING AND STAINING OF CELLS IN BRAIN SLICE 146.9 PREPARATIONS OF THE MOUSE COCHLEAR NUCLEI. S.H. Wu\* and D. Oertel. Dept. of Neurophysiology, Madison, WI 53706.
  - Intracellular injections of horseradish peroxidase (HRP) were made into cells which responded to electrical stimulation of the auditory nerve in parasagittally cut brain slices of the mouse cochlear nuclei. Two conclusions can be made from the results obtained thus far. (1) The morphology of cells in brain slices resembles that of Golgi-stained cells that were fixed in situ. (2) Some stellate cells in the ventral cochlear nucleus have Type l electrical characteristics (Oertel, J. Neuroscience, in press). The morphology of HRP-filled cells in brain slice preparations is similar to the morphology of cells in Golgi-stained tissue
  - described by Webster and Trune (1982, Am. J. Anat. <u>16</u>;103-130). We have injected 2 Purkinje-like cells in the dorsal cochlear nucleus; 15 stellate cells and 1 granule cell in the anteroventral cochlear nucleus; 2 stellate cells in the glocular cell region; and 18 stellate cells, 1 bushy cell, and 3 granule cells in the posteroventral cochear nucleus. Stellate cells may comprise more than a single cell type since stellate cells way greatly in Their anatomical features. Their diameters range from 13 to 21µm. Some cells have long thick dendrites with highly branched endings whereas others have thin tapering dendrites which end with terminal beads. Some have dendrites which extend only 100 µm from the cell body while others have dendrites that extend over 300 µm in the parasagittal plane. Some dendrites that extend over parallel to the auditory nerve fiber fascicles whereas others cross the fiber bundles. Some cells have somatic and dendritic

spines while others are smooth. It was difficult to obtain good recordings with HRP-filled microelectrodes so that it was not possible to characterize most cells. Three recordings from stellate cells revealed that at least some stellate cells respond to suprathreshold depolariza-tion with large, regularly firing, action potentials and have linear current-voltage relationships in the subthreshold voltage range showing that they have Type I characteristics (Oertel, J. Neuroscience, in press). We have not yet made a good recording from a cell with Type II characteristics with HRP-filled electrodes.

146.10 INTRACELLULAR STUDIES IN CAT COCHLEAR NUCLEUS: PHYSIOLOGICAL RESPONSES OF MORPHOLOGICALLY IDENTIFIED NEURONS. <u>R.H. Britt, G.T.</u> <u>Rossi, and tD.K. Morest.</u> Div. of Neurosurgery, Stanford Univ. Sch. of Med., Stanford, CA 94305 and tDept.of Anatomy, Univ. of Conn.

Arthrong, CA 94305 and Tuept.of Anatomy, Univ. of Conn. Health Center, Farmington, CT 06032. Intracellular recording techniques were used to study the physiological responses of cochlear nucleus neurons in 32 peto-barbital anesthetized cats. Electrodes were filled with 2 to 4% horseradish peroxidase (HRP) in 0.5M KCl. Each neuron was studied

barbital anesthetized cats. Electrodes were filled with 2 to 4% horseradish peroxidase (HRP) in 0.5M KC1. Each neuron was studied extracellularly by obtaining a tuning curve. After determining the characteristic frequency (CF), a peristimulus time histogram(PSTH) was generated by averaging the respones to 40 250msec tone bursts at the CF. After intracellular penetration, the PSTH at the CF was repeated to determine if any change in response had occurred. HRP was then iontophoretically injected intracellularly. Serial transverse frozen sections were incubated using a diaminobenzidine reaction intensified by preincubation with cobalt chloride. In the anteroventral cochlear nucleus (AVCN) three HRP-filled neurons were physiologically characterized. A spherical bushy cell located in the AA region had a primarylike response at its CF of 4KHz. An elongated stellate cell in the PD region of the AVCN had a primarylike response. This unit also had tone-evoked suppression of spontaneous activity at 14-15kHz, however, no inhibitory post-synaptic potentials were observed during intracellular recordings. A small stellate cell along the medial border of PV in the AVCN showed an onset response at its CF of 4KHz. In the dorsal cochlear nucleus (DCN) a horizontal giant cell was successfully marked. Extracellular recordings (biphasic spikes) showed a change from an onset pattern (8.5KHz) to onset-sustained response (10.5KHz) at its CF (see figure below). With intracellular penetration the resting membrane level dropped to -500M, the spikes became monophasic, and there was a sustained dc spift that lasted for the duration of the tone burst.

Since the spikes became monophasic, and there was a sustained to -50mV, the spikes became monophasic, and there was a sustained to shift that lasted for the duration of the tone burst. Importantly, the response patterns remained unchanged after intracellular penetration. The second HRP-marked cell in the DCN was a small broadly tuned (7-18kHz) granule cell recorded in the molecular layer which showed a primarylike response with some suggestion of superimonsed chooser activity at its C.F. of 14kHz.

ORGANIZATION OF DESCENDING PROJECTIONS FROM THE SUPERIOR OLIVARY COMPLEX TO THE COCHLEAR NUCLEI IN THE CAT. K. S. Spangler\*1, C. K. Henkel<sup>2</sup> and Nell Cant<sup>3</sup>. Department of Anatomy, Bowman Gray School of Medicine, Winston-Salem, NC<sup>1-2</sup> and Duke University School of Medicine, Durham, NC<sup>3</sup>. Descending auditory pathways from the superior olivary complex to the cochlear nuclei were investigated in the cat using retrograde and anterograde tracing methods. Injections of HRP were made in regions of the cochlear nuclei in a large number of cats. Irrespective of the size or location of these injection sites, labeled cells were seen in all periolivary regions except the ventromedial periolivary nucleus. No retrograde labeling was found in either the lateral (LSO) or medial superior olivary nuclei (MSO). Three groups of cells were prominently labeled. The first, containing the most number of labeled cells, was the ipsilateral lateral peri-olivary region including the anterolateral, lateral and *posterior periolivary nuclei*. The labeled cells in the lateral region on the contralateral side had the same topog-raphy but were far fewer in number. The region containing the second greatest number of labeled cells was the contralateral ventral nucleus of the trapezoid body. The third largest source of efferents to the cochlear nucleus was the ipsi-lateral dorsol periolivary region No. second greatest number of labeled cells was the contralateral ventral nucleus of the trapezoid body. The third largest source of efferents to the cochlear nucleus was the ipsi-lateral dorsal periolivary region. No labeled cells were found within the dorsal hilus of LSO. Nine cats received injections of tritiated leucine in the periolivary regions. Fibers projected to the cochlear nucleus via the trapezoid body and dorsal acoustic stria in all cases. Rostral fibers in the trapezoid body entered the anternwentral cochlear Fibers projected to the cochiear nucleus Via the trapezoid body and dorsal acoustic stria in all cases. Rostral fibers in the trapezoid body entered the anteroventral cochiear nucleus directly. Fibers in AVCN terminated lightly in the anterior part of the anterior division and more heavily in the posterior and posterodorsal parts of the anterior division of AVCN. Only scattered axons were seen in the posterior divi-sion of AVCN. Most of the silver grains were found in the neuropil of AVCN although perisomatic labeling could be seen. Caudal trapezoid body fibers entered the cochiear nucleus from a ventromedial direction and fanned out to supply the poste-rior and dorsal cochiear nuclei. Axons and terminals in the posterior nucleus were sparse, but when seen were often perisomatic or peridendritic. The dorsal cochiear nucleus (DCN) was primarily labeled in the fusiform and deep cell layers, with fewer silver grains in the molecular layer. The results of both methods lead to the conclusion that the different periolivary nuclei project widely within the terri-tory of the cochiear nuclei, but in much the same pattern, not heterotopically as might have been expected. Supported by NIH Grant HS 18627-61.

146.12 THE EFFECTS OF STIMULATION OF MEDIAL OLIVOCOCHLEAR NEURONS ON IPSILATERAL AND CONTRALATERAL COCHLEAR RESPONSES. M.L. Gifford\* and J.J. Guinan. EECS Dert., M.I.T., Cambridge, MA; Eaton-Peabody Lab, Mass. Eve & Ear, 243 Charles St., Boston, MA 02114. Olivocochiear (OC) cells are divisible into two prouss conditioned of the state of according to the location of their cell bodies. The medial  $(\mbox{MOC})$  group has cell bodies medial to the medial superior olive and projects predominantly to outer hair cells of both cochleas. With an electrode in the MCC, we have stimulated MCC neurons in the cat and monitored the effect of this stimulation on auditory-nerve compound action potential ( $N_{\rm c}$ ) and sochlear microphonic (CM) in response to clicks and on endocochlear potential (EP) as measured in scala media. MCC stimulation reduced N, amplitude, increased N, latency and increased CM amplitude in both ipsilateral and contralateral ears. These effects were reduced following an intraveneous injection of strychnine sulfate. MOC stimulation also reduced EP in both At least 20 shocks at a rate of 200 to 400 shocks/s were ears. needed to produce large decreases in  $N_{\rm a}$  amplitude. Effects were maximum at the end of a train of shocks and decreased over several hundred milliseconds after the shocks. For experiments in which we feel that the stimulating electrode was well placed, MOC stimulation typically shifted N  $_1$  amplitude vs. click level functions to higher sound levels by 10 to 15 dB in the contralateral ear and 4 to 6 dB in the issilateral ear. In contrast, stimulation of the olivocochlear bundle (OCB) at the midline of the floor of the fourth ventricle typically shifted these level functions by 20 to 25 dB in both ears. MOC stimulation typi-cally increased CM amplitude by 1.5 dB in the contralateral ear and 0.5 dB in the ipsilateral ear; midline OCB stimulation typically increased CM amplitude in both ears by 2 dB. The ratio of MOC effects seen in the contralateral ear to effects seen in the ipsilateral ear is approximately equal to the ratio of MOC neu-rons projecting to the contralateral cochlea to MOC neurons projecting to the insilateral cochlea (Guinan, Warr and Norris, in prep.). In order to see if MCC effects on the insilateral ear were due to excitation (e.g. transsynartically) of contrala-teral MCC sells with crossed projections, OC fibers were cut in the floor of the fourth ventricle just medial to the left facial genua. Following this out, stimulation of the left MOC had no effect on either ear; stimulation of the right MOC had no effect on the left (contralateral) can but typical effects were present in the left (contralateral) can but typical effects were present in the right (ipsilateral) can. We conclude that the effects of MOC stimulation on responses of both ipsilateral and contralateral ears are similar to those previously reported for OCB stimulation at the midline of the floor of the fourth ventricle. OC B

DEVELOPMENTAL CHANGES IN THE DISTRIBUTION OF THE GRANULE CELL OF 146.13 THE HUMAN COCHLEAR NUCLEUS. T.D. Heiman-Patterson\* and N. L. Strominger. Department of Anatomy, Albany Medical College, Albany Strominger.

> The primate cochlear nuclear complex undergoes several characteristic morphogenetic changes during the course of primate phylogenesis from lorisidae through hominidae. The most striking al-terations occur in the organization of the dorsal cochlear nucleus in which the laminar pattern becomes progressively obscured in the adult. Granule cells form an external granule layer as well as being intermixed within the molecular and pyramidal layers in slow Joris, squirrel monkey and rhesus. While a prominent external granular layer remains in the chimpanzee, granule cells are scant granular layer remains in the chimpanzee, granule cells are scant in other portions of the nucleus. In human adult, the external granule cell layer is absent. A small number of granule cells per-sist but with inconstant distribution. The present investigation was undertaken to elucidate in greater detail the organizational variations of the active remains in device the basis. variations of the cochlear complex in developing human brains. A series of human brains of varying age, from fetus to adult

> was studied to establish whether progressive changes could be ob-served that might reflect phylogenetic trends. In the human adult, served that might reflect phylogenetic trends. In the human adult, granule cells are sparse and the superficial granule cell layer non-existent. However in the fetus a prominent superficial gra-nule cell layer is present. It occurs lateral to both the antero-ventral and dorsal divisions of the cochlear nucleus and surrounds the entire posterior end of the cochlear complex. It is continuous with a thin lamina which extends ventrally and medially around Ous with a thin familia which extends ventrally and medially anomat the entire cochlear complex. In neonatal brainstems a reduced superficial granule cell layer exists; it is markedly thinner than in the fetus. The granule cell layer along the medial aspect of the complex disappears. By 18 months the molecular layer resembles the adult form. Thus, a substantial developmental reorganization or attriction of these neurons must occur. It has been shown in the adult form. Thus, a substantial developmental reorganization or attrition of these neurons must occur. It has been shown in or attrition of these neurons must occur. It has been shown de-the rat that the granule cells of the dorsal cochlear nucleus de-velop and comigrate with those of the cerebellum (Pierce, E.T., J. Comp. Neurol., 131: 323, 1967). The presence of granule cells in the fetal dorsal cochlear nucleus and their subsequent disap-pearance suggests that a programmed cell death may be responsible for this phenomenon and would seem to preclude the possibility that a defect in migration is the principal mechanism. Additionally, evidence indicates that there is a reduction in the olivo-cochlear bundle in human brainstems (Moore, J.K. and Osen, K.K., Am. J. Anat., 154: 393, 1979) which provides afferent input into the granule cell layer. It may be that a lack of afferent input triggers the process of programmed cell death in these cells.

AN ANOMALOUS INTER-COCHLEAR NUCLEUS PATHWAY INDUCED IN CHICK 146.14 EMBRYOS BY UNILATERAL REMOVAL OF THE OTOCYST. <u>Hunter Jackson</u> and <u>Thomas N. Parks</u>. Dept. of Anatomy, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

Med., Sait Lake City, UI 34132. Neurons in nucleus magnocellularis (NM) normally receive large calycine endbulbs from the cochlear nerve. NM neurons send two branches of their axon to form sprays of boutonal endings in nucleus laminaris (NL). One branch of each NM axon innervates the dorsal dendrites of the ipsilateral NL and the other branch travels in the crossed dorsal cochlear tract (CTrX) to end on the ventral dendrites of the contralateral NL. other branch travels in the crossed dorsal cochlear tract (CTrX) to end on the ventral dendrites of the contralateral NL. Surgical removal of the otocyst on the third day of incubation (E3) in chick embryos prevents formation of the input to NM. To compare the axon arbors in NL of normal and "deafferented" NM neurons, the right otocyst was surgically destroyed on E3 in a number of embryos. Then, using an <u>in vitro</u> brain stem preparation previously described (e.g., Jackson & Parks, J. Neurosci 2:1736-1743, 1982), we iontophoretically injected horseradish peroxidase (HRP) into the CTrX in operated embryos at E11-12 (n=6), E13-14 (n=5), and E17-18 (n=4). Several normal control animals were also injected at these ages. After 2-3 hr survival periods, the brains were fixed, rinsed, cryoprotected, sectioned and reacted for HRP by a cobalt-intensified DAB method. These procedures typically result in retrogradely filled cell bodies bilaterally in NL. To our surprise, we consistently observed an anomalous branching of the CTrX axons coming from the left (normally innervated) NM in operated animals. As these fibers approach the medial margin of the right NL, the main branch continues laterally along the ventral neuropil but anomalous axon collaterals branch at right angles and ascend to end in sprays of terminal boutons around cell bodies throughout NM and in the <u>dorsal</u> NL neuropil. These anomalous branches form a dense projection to the right NM in operated animals was three fibers approach the medial margin of the right angles and ascend to end in sprays of terminal boutons around cell bodies throughout NM and in the <u>dorsal</u> NL neuropil. These anomalous branches form a dense projection to the right NM in operated animal but anomalous branches form a dense projection to the right NM in operated animals. boutons around cell bodies throughout NM and in the <u>dorsal</u> NL neuropil. These anomalous branches form a dense projection to the right NM in every operated animal but are never seen in the left NM or in normal animals. It remains possible, of course, that a small transient normal projection exists prior to E11. In electron micrographs of the right NM small boutonal endings are seen forming asymmetric junctions with neuronal cell bodies; these anomalous endings closely resemble the normal NM endings in NL (Parks et al., <u>JCN 214</u>:32-42, 1983). Preliminary electrophysiological recordings of responses in the right NM to electrical stimulation of the left NM suggest that these anoma-lous endings form functional synapses. This new afferent to NM cells deprived of their cochlear nerve input may explain why only 30% of NM cells ultimately die after otocyst removal (Parks, <u>JCN 183</u>:665-678, 1979). Supported by PHS grant #NS 17257.

- SENSITIVITY TO ELECTRICAL STIMULATION OF AUDITORY NUCLEI IS 146.15 ALTERED BY CONTINUOUS SOUND. <u>G.M. Gerken\* and S.S. Saunders\*</u> (SPON: R.D. Stillman), Callier Center for Communication Disorders, Univ. of Texas at Dallas, Dallas, TX 75235. Subjects were 4 cats with a total of 12 PtIr electrodes permanently implanted in cochlear nucleus (CN) and inferior colliculus (IC). Thresholds for the detection of cathodal electrical pulses were measured behaviorally by means of a self-paced

operant task. Using a counterbalanced design, electrical stimulation thresholds (in dB re 1.0  $\mu$ A) were measured in the presence of continuous tones (0.5, 2.0, 4.0 kHz) of 80 dB SPL and in quiet. In separate sessions, the voltage ( $\mu V$  rms) of the ongoing activity recorded from the 12 electrodes was measured during the same conditions of tone and quiet. Finally, 14 ms phase-locked tone bursts of several frequencies at 80 dB SPL were used to elicit frequency following responses.

The behaviorally-measured electrical-stimulation thresholds obtained during continuous tone. Nine instances of electrical stimulation threshold decreases (re quiet) of 10 dB or more occurred for particular combinations of electrode and tone frequency. Sixteen instances of threshold decreases between 2.0 and 9.9 dB occurred, and there were 8 instances of essentially no threshold shift (+ 1.9 dB). There were only 3 occurrences of a masking-like threshold increase of 2.0 dB or more during the continuous tone. Thus, the effect of the continuous tone on the detection of electrical stimulation was generally facilitory. The continuous tone also produced both increases and decreases in ongoing brain activity as recorded from the 12 electrodes. The correlation co-efficients for electrical-stimulation threshold-shift vs. change in ongoing activity was 0.13 for CN and 0.69 for IC. Large, neurally-based frequency-following responses were obtained for frequencies near 2 kHz from some CN electrodes but the presence of these responses did not affect electrical stimulation threshold. The results indicate that in central auditory structures a

continuous tone may produce strong, sustained effects

on certain neural populations. Work supported by grant NS 16411 from NINCDS.

146.16 SPECIALIZATIONS OF GLIAL STRUCTURE IN THE COCHLEAR NUCLEI J. K. Moore. Department of Anatomical Sciences, SUNY at Stony Brook, Stony Brook, NY 11794.
 Investigations of the density and disposition of astrocytes in

the cochlear nuclei of the cat and guinea pig, done by GFA (glial fibrillary acidic protein) immunohistochemistry and Golgi-Hortega impregnation of the nuclei, have shown two regions of specialized concentration and morphology of astrocytes in the cochlear complex. First, there is a concentration of astrocytic elements within the granule cell regions of the nuclei, including the superficial granule cell regions of the ventral nucleus, the granule-fusiform cell layer of the dorsal nucleus, and the lamina of granule cells separating the two nuclei. The increased density of astrocytic processes in these regions may be related to glial investment of glomerular synaptic complexes involving granule cell dendrites and afferent mossy terminals (Mugnaini <u>et al., J. Neurocytol., 9</u>:537-570, 1980). Secondly, there is an increased concentration of astrocytes within the molecular layer of the dorsal nucleus, with astrocytes in this area characterized by lamellate or spiny expanastrocytes in this area characterized by lamellate or spiny expan-sions similar to those seen on Bergmann glial processes of the cerebellum (Rakic, J. <u>Comp. Neurol.</u>, <u>141</u>:283-312, 1971) and radi-al astrocytes of the hippocampal formation (Duffy and Rakic, J. <u>Comp. Neurol.</u>, <u>214</u>:224-237, 1983). These lamellate expansions are demonstrated by Golgi impregnation, but not by the GFA immunohistochemical technique, indicating that they do not contain glial fibrils. In all areas where such lamellate expansions have been noted, they are believed to be related to synaptic junctions

between molecular layer axons and dendrites of related neurons. Similar investigations of the cochlear complex in the macaque monkey show that the glial structure in the simian cochlear nuclei is significantly different from what is seen in the nonprimate species. No astrocytic formations typical of granular or molecular layers are seen, though staining and impregnation of glia throughout the cochlear complex and brainstem is otherwise com pletely comparable to what is seen in other mammals. These ferences reflect the alterations in cytoarchitecture of the These difcochlear complex which accompany regression of the cochlear granule cell population and related neuronal populations in higher primates (Moore, J. <u>Comp. Neurol.</u>, <u>193</u>:609-629, 1980). A further distinctive feature in the macaque is the presences of a structure analagous to the human pontobulbar body: this superficial structure is seen to consist of a dense mass of astrocytic somas and processes.

CA SPIKE INITIATION IN THE SOMATA OF CRAYFISH GIANT MOTOR NEURON : 147.1 STUDY WITH ARSENAZO III. <u>T. Shimahara, G. Czternasty</u><sup>\*</sup>, J.Stinna-<u>kre</u> and <u>J. Bruner</u><sup>\*</sup>. Lab. de Neurobiologie Cellulaire, C.N.R.S., 91190 Gif sur Yvette and Lab. de Neurobiologie, Université de Picardie, 80039 Amiens.\*

In normal conditions, a depolarizing pulse cannot trigger a regenerative action potential in the somata of the giant motor neuron (MoG) of crayfish <u>Procambarus</u>. However a Ca<sup>2+</sup> dependent slow action potential (SAP) appears with the depolarizing pulse if it is preceded by a conditioning depolarization (Czternasty & Bruner, 1981). This may be due to the reduction of the K-outward current or to the facilitation of the Ca-current, or both, by the conditioning pulse. To answer these questions, further experiments were performed in the same preparation using the metallochromic dye Arsenazo III (AZIII). A brief current pulse  $(\bigstar 5 \text{ms})$  does not initiate neither a regenerative action potential nor is accompanied by a change in AzIII absorbance. If the test pulse is preceeded by a long depolarizing pulse (e.g. 8 second to -40 mV), the SAP appears. The plateau phase of the SAP is accom-panied by a continuous increase in AzIII absorbance. Furthermore, tetraethylammonium ions (TEA) either applied extra- or intracellularly, give the same results without the need for a conditioning depolarization. These results suggested the existence of a Ca current during the SAP. Under voltage clamp, a transient increase in AzIII absorbance is detected during a 300 ms depolarization test pulse above -30 mV. This signal increases as the voltage become more positive and peaks around + 10 mV. Above there is a slight reduction but the signal cannot be suppressed even when the membrane potential is brought up to +150 mV. When a conditioning pulse is present the absorbance transient is larger at any one membrane potential between -40 and about + 40. In this case either a suppression potential cannot be demonstrated. In the presence of TEA, the effect of conditioning pulse on the AZIII transient is no longer observed and a clear suppression potential is now obtained around +130/+140 mV. These results show that a facilitation of the Ca current does not seem to explain the appearence of the SAP, rather a reduction of the K current is an essential factor.

SPIKE DURATION AND CALCIUM COMPONENT OF ACTION POTENTIALS IN RAT SUPRAOPTIC NEUROSECRETORY NEURONS ARE ACTIVITY DEPENDENT. <u>C.W.</u> Bourque\* and L.P.Renaud. (Spon: B.Esplin)Neurosciences unit, Mon 147.2 Montreal General Hospital and McGill University, Montreal, Quebec, Canada H3G 1A4.

The magnocellular neurosecretory neurons of the mammalian hypothalamic supraoptic nucleus respond to osmotic stimuli by an increase in firing rate and/or the evolution of phasic or bursting activity patterns in-vivo and in-vitro. While the latter patterns of activity have been determined to be most efficient at inducing vasopressin release on a per-spike basis, the mechanisms underly ing such an advantage have yet to be explained. Intracellular recordings from 53 supraoptic neurons obtained in

22 intravascularly perfused explants of rat hypothalamus have re-vealed that the duration of their action potentials (APs) is activity-dependent. In any given neuron, the duration of an AP (measured at 1/3 amplitude) occurring during active firing (5-25 spikes/sec) can be as much as 150% longer  $(2.9 \pm 0.3 \text{ vs} 1.7 \pm 0.2 \text{ spikes/sec})$ msec, S.D.;n=43) than during quite periods (fewer than 0.1 spikes/ sec). Furthermore, phasic firing is characterized by the progres-sive increase in duration of the initial 15-30 APs of a burst following which spike duration is observed to correlate negatively with the duration of the preceding interspike interval (ISI), indicating that recovery from events associated with an AP can influ-ence a subsequent APs' duration. Antidromic or current evoked APs following termination of a burst retain their increased duration for as long as 10-15 seconds before full recovery of the shortest AP durations.

AP durations. Perfusion of the explant with media containing either 0 Ca<sup>++</sup> + 5mM EGTA, 2mM Co<sup>++</sup> or 0.2mM Cd<sup>++</sup> abolishes the tetrodotoxin (TTX; 0.1 uM) resistant (Ca<sup>++</sup>) spike; in the <u>absence</u> of TTX, this treat-ment causes a 5-25% reduction in spike amplitude, a decrease in spike duration and the elimination of the shoulder normally found on the repolarization phase of the AP. Under these conditions the TTX sensitive (Na<sup>+</sup>) spike fails to display either activity-depen-duration of the shoulder normation of the shoulder normation of the theorem is duration and the display either activity-depen-duration between in duration and the display either activity-depen-duration between in duration and the display either activity-depen-duration between in duration are applied by the duration of the should be the duration of the should be durated by the duration of the should be durated by the duration of the should be durated by the dur dent changes in duration or spike broadening at the onset of a burst. All of the above effects are reversible. These results indicate that in these neurons activity-dependent

changes in spike duration result in variations in the calcium com-ponent of the action potential. The high incidence of short ISIs bursting or phasic action potential. The high intraduced firing and bursting or phasic activity is therefore predicted to enhance  $Ca^{++}$  influx during the action potential. The existence of similar events at terminals of neurosecretory neurons could participate in the facilitation of hormone secretion. Supported by MRC and FRSQ.

THE ELECTROPHYSIOLOGICAL EFFECTS OF VARIOUS ALCOHOLS AND NALOXONE ON THE CA<sup>++</sup> COMPONENT OF ACTION POTENTIALS. <u>S. A.</u> <u>Eskuri\* and R. S. Pozos</u>. Dept. of Physiology, Univ. of Minn., Duluth, Sch. of Med., Duluth, MN 55812. 147.3

It has been reported that ethanol can modify Ca<sup>++</sup> movements in action potentials of neurons chemically manipulated to represent presynaptic terminals (Oakes and Pozos, Dev. Brain Res., 5 (1982), 251-255). There is also evidence that naloxone inhibits ethanol's (and to a lesser extent, other alcohols') depletion of brain Ca<sup>++</sup> (Ross, Ann. N.Y. Acad. Sci., 273 (1976), 280-294) and ethanol dependence (Blum and Futterman, Nature: 265 (1977), 49-51). Therefore, various alcohols were tested using the presynaptic model to determine if their effects compared to ethanol and whether naloxone inhibited the effects.

ethanol and whether naloxone inhibited the effects. The alcohols were made up in solutions such that their thermo-dynamic activities in water were equal. Dose response curves were constructed for each (% decrease in the duration of the Ca<sup>++</sup> plateau vs. concentration) and a concentration corresponding to an activity of  $8.04 \times 10^{-2}$  was used for the naloxone study. Electrophysiological measurements were performed using a bridge circuit to simultaneously stimulate and record from a single microelectrode. Application of the drugs was accomplished by either pressure ejection or diffusion from a micropipette. It was found that when thermodynamic activities were identical

It was found that when thermodynamic activities were identical for the alcohols, they affected  $Ca^{++}$  movement to the same degree. For the alcohols, they affected Ca movement to the same degree. The dose range of the activities corresponded to ethanol concen-trations between 3 and 110 mM. Naloxone  $(10^{-4} \text{ M})$  was found to significantly inhibit ethanol's effect. The percent decrease in Ca<sup>++</sup> movement with ethanol alone was  $38.1 \pm 2.9\%$  and with ethanol and naloxone together it was  $20.5 \pm 3.5\%$ . However, naloxone did not inhibit the other alcohols to the same degree. When naloxone

was applied alone, no effect was detected. From this study, it appears that short, straight chained alcohols  $(C_1-C_5)$  have identical effects on Ca<sup>++</sup> currents if their concentrations in water are made equivalent. Also, the data suggests that naloxone does inhibit some of the effects of back suggests that habout does initiate tools of performed as what ethanol. However, the antagonism was not as complete as what has been reported for the enkephalins (Werz and MacDonald, Brain Res., 239 (1982), 315-321) or what Ross reported for brain Ca<sup>++</sup> depletion. Further, these initial findings do support the proposal that the structure of an alcohol may determine whether its action may be antagonized by naloxone. (Supported in part by NIH grant #1506 RR08212-01-GRS)

SUPERNORMAL CONDUCTION VELOCITY IN EARTHWORM GIANT AXON: ROLE OF DIVALENT CATIONS AND NA/K PUMP. <u>B. S. Glick\* and S. A. George</u>. Neurosci. Prog., Amherst College, Amherst, MA 01002. In the giant axons of the earthworm, the second of two impulses spaced 3 to 100 msec apart travels at a higher conduction velocity (AV) the the first of the travels at a higher conduction velocity 147.4

In the giant axons of the earthworm, the second of two inpulses spaced 3 to 100 msec apart travels at a higher conduction velocity (CV) than the first. We sought to discover the mechanism of this supernormality (SN). The possibility that SN results from rever-berating synaptic activity was tested by applying saline with 20 mM Mg to the nerve. SN (defined as percent increase in second spike CV at a given interval between stimuli, usually 15 msec) was not reduced in high Mg<sup>+</sup>, indicating that synaptic activity is not involved. The accumulation of K ions around axons has been pro-posed as a possible explanation for SN, but we found that applied increases in [K<sup>+</sup>]<sub>0</sub> affected neither first spike CV nor SN. Two other possible explanations involve Ca<sup>-</sup> ions. A decrease in [Ca<sup>-</sup>]<sub>0</sub> or an increase in [Ca<sup>-</sup>]<sub>1</sub>, resulting from Ca currents dur-ing a spike, could lead to increased axon excitability via effects on membrane surface potentials; in turn, these could increase the CV of the second spike. These possibilities were tinvestigated by bathing the nerve cord in saline containing [Ca<sup>-</sup>] ranging from 0 to 15 mM (normal  $[Ca^-] = 1.8$  mM). First spike CV decreased with increasing [Ca<sup>-</sup>]<sub>0</sub>, as expected from known effects of diva-lent cations on membrane excitability. SN showed the opposite dependence on [Ca<sup>-+</sup>]<sub>+</sub> thecreasing by up to 90% in solutions con-taining very low [Ca<sup>-+</sup>]; this suggests a role for Ca currents in SN. However, SN was not reduced by lanthanum ions, suggesting that factors other than Ca<sup>-</sup> may be involved. The role of active transport in SN was then investigated by adding ouabain to the bathing solution, and by replacing Na<sup>+</sup> by lit<sup>+</sup>.

That factors other than Ca may be involved. The role of active transport in SN was then investigated by adding ouabain to the bathing solution, and by replacing Na<sup>+</sup> by Li<sup>+</sup>. Both procedures abolished SN without affecting first spike conduction velocity. In conjunction with these experiments, the Hodgkin - Huxley equations for impulses in squid axon were solved by computer in order to study the above mechanisms. A shift in the K<sup>+</sup> equilibrium potential in a depolarizing direction did not produce an increase in computed CV, in agreement with the experimental result in the earthworm axon. Changes in [Ca<sup>+</sup>] were modelled by assuming a change in the dependence of Hodgkin-Huxley parameters upon membrane voltage. A decrease in [Ca<sup>+</sup>] or an increase in [Ca<sup>+</sup>] would be expected to shift the dependence in a depolarizing direction. For a 5 mV parameter shift, the equations predict a 1% would be expected to shift the dependence in a depolarizing direc-tion. For a 5 mV parameter shift, the equations predict a 1% increase in CV in squid axon. If the equations are separately modified to include a hyperpolarizing pump current of 3.5 ua/cm<sup>2</sup>, a CV increase of 0.5% was computed. When the Ca and pump effects were combined, the predicted CV increase was 3.5%. In conclusion, both experimental and theoretical studies support a combined contribution of Ca<sup>-</sup> currents and electrogenic sumport is the apprediction of supersymptotic participants.

pumping in the generation of supernormal conduction velocity aftereffects.

147.5 A "SLOW" VOLTAGE-DEPENDENT Ca<sup>2+</sup>-DEPENDENT CONDUCTANCE IS PRESENT IN SOME CULTURED MOUSE SPINAL AND HYPOTHALAMIC NEURONS. D.G. Owen\*, M. Segal\* and J.L. Barker (Spor: P. Sonderegger), Laboratory of Neurophysiology, NINCDS, NIH, Bethesda, Md. 20205 Voltage-dependent membrane properties of neurons cultured from mouse spinal cord and rat hypothalamus were studied using single electrode current-clamp and two electrode voltage-clamp techniques. All recordings were made with KC1-filled microelectrodes in media containing micromolar TIX and 20mM TEA. Brief depolarizaing current pulses often triggered Ca<sup>2+</sup> spikes which in some cells were followed by long-lasting (up to 20 sec.) depolarizations of up to 25mV in amplitude (Fig. IA). Both rapid and delayed events were activated by depolarizing the cell to about -40mV for as little as 1 msec., and were accompanied by an increase in membrane conductance. Both events were absent in solutions nominally free of Ca<sup>2+</sup> and both were blocked by 0.2mM Cd<sup>2+</sup> (Fig. IA). Under voltage-clamp, brief commands to potentials more depolarized than -40mV evoked long-lasting inward current responses upon stepping back to the holding potential (E<sub>K</sub>+) (Fig. IB). Similar voltage-jump protocols have shown that the slow inward current response is: 1)dependent on [Ca<sup>2+</sup>]<sub>0</sub>; 2) increased in amplitude and prolonged by Ba<sup>2</sup><sub>6</sub>; 3) blocked by CO<sup>2</sup><sub>6</sub>, Ni<sup>2</sup><sub>6</sub>, and Mn<sup>2</sup><sub>6</sub>; and 4) reverses in polarity between -15mV and +15mV. We tentatively conclude that the slow inward current response observed under current-clamp. This Ca<sup>2+</sup>-dependent conductance occured in a minority ( ~10 percent) of spinal cord neurons, which were relatively large (~ 25<sub>0</sub> diameter cell body) with extensive process formation and in 4 of 9 hypothalamic neurons. Slow Ca<sup>2+</sup>-dependent conductances were noticeably absent in neurons cultured from rat hippocampus, suggesting that this membrane property may be regionally specific. Its presence in cultured neurons derived from the spinal cord and hy

147.7 THREE TYPES OF TRANSIENT OUTWARD CURRENTS ARE PRESENT IN CULTURED CENTRAL MAMMALIAN NEURONS. J.L. Barker and M. Segal, (Spon: E. Yadin), Lab. of Neurophysiology, NINCOS, NIH, Bethesda, MO. 20205 Neurons cultured from dissociated rat hippocampus (HPC) and hypothalamus (HTH) and mouse spinal cord (SC) were studied using the two-electrode voltage clamp technique. The recording medium contained 0.5µM tetrodotoxin (TTX) and 20mM tetraethylammonium (TEA) to block some of the Na<sup>+</sup> and K<sup>+</sup> conductances commonly recorded in cultured CNS neurons. Cells were impaled with KCl-filled microelectrodes, clamped at about resting potential and stepped to depolarizing and hyperpolarizing potentials for various durations. Rapid transient outward currents (TOCs) were recorded in the majority of the cells when stepping from -90mV to potentials depolarized to -45mV. These TOCs could be divided into three distinct types. Type I was identified in 13 of 19 SC, 5 of 15 HPC and 4 of 6 HTH cells. The TOC peaked in 5 msec. and decayed in 15-40 msec. Cd<sup>2+</sup> or Mn<sup>2+</sup> enhanced the TOC by up to 50 percent without changing its time constant of decay. This effect was evident when the membrane was stepped to potentials positive to -20mV, and was independent of the presence of a transient inward Ca<sup>2+</sup> current. Type II TOC had similar kinetics to that of type I. Cd<sup>2+</sup> or Mn<sup>2+</sup> blocked this TOC by up to 50 percent when the TOC was evoked from -90mV but not when the TOC was already half-inactivated (e.g., when the membrane was held at -70mV). Cd<sup>2+</sup> also slowed the time constant of decay of this TOC. Type III TOC was recorded in 5 of 19 SC and In of 15 HPC neurons. Both types of TOC were blocked by 4-aminopyridine (4-AP) and Ba<sup>2+</sup>. Type IIII TOC was found mainly in SC and in some HTH cells. Its time constant of decay mas slow, 100-200 msec. Furthermore, it was insensitive to Cd<sup>2+</sup> or 4-AP. Type IIII TOC coexisted with the more rapidly decaying TOCs and when recorded together with a faster TOC, usually accounted for 10-20% of the total

current-jump protocol to neurons current-clamped at -60mv. A transient (ca. 30 msec.) rectification of voltage responses was recorded at potentials depolarized to -45mV. These rectifications were reduced by 4-AP and/or  $Cd^{2+}$ . The results indicate that central neurons derived from both spinal and supraspinal regions of the CNS exhibit at least three different types of TOC, two of which may be regulated by  $Ca^{2+}$ . Since 4-AP- and  $Cd^{2+}$ -sensitive rectifications were observed over the membrane potential range subthreshold to action potential genera- tion, it is probable that one of the physiological roles of these rapid TOCs involves regulation of the rate of membrane potential depolarization and subsequent spike discharge in response to a rapid depolarizing stimulus.

147.6 SLOW VOLTAGE-DEPENDENT FOTASSIUM CONDUCTANCE IN SENSORY NEURONS IS MUSCARINE INSENSITIVE.

Susan R. Barry, Mary Ann Werz and Robert L. Macdonald. Dept. of Neurology, University of Michigan, Ann Arbor MI 48109 We have identified a slow voltage-dependent potassium conduc-

We have identified a slow voltage-dependent potassium conductance in mouse dorsal root ganglion (DRG) neurons in cell culture. This channel shares similar kinetics and voltage dependency to the muscarine-sensitive m-channel in spinal cord and sympathetic ganglion neurons. However, the slow potassium conductance in DRG neurons is not blocked by muscarine but is sensitive to tetracthylammonium ions (TEA<sup>+</sup>).

Intracellular and single electrode voltage-clamp recordings were made from neurons bathed in tris-buffered saline at 30-35°C. TEA and muscarine were applied to the neuronal surface by pressure pulses from blunt glass micropipettes. Application of TEA<sup>†</sup> to DRGs produced membrane depolarization

Application of TEA<sup>+</sup> to DRGs produced membrane depolarization associated with a decrease in membrane conductance. TEA<sup>+</sup> responses increased in amplitude as the membrane was depolarized from about -60 to -20 mV. At potentials more negative than -60 mV, no response to TEA<sup>+</sup> was observed. In voltage clamp experiments, TEA<sup>+</sup> evoked a net inward current which increased with depolarization of the membrane from -60 to -20 mV.

To determine further what channels were involved in the TEA<sup>+</sup> response, voltage jump experiments were performed. DRG neurons were voltage-clamped at -30 mV and then stepped to -50 mV, producing an early inward current followed by a slow inward current relaxation. Upon repolarizing the cell to -30 mV, an early outward current preceded a slow outward current relaxation. Current relations were blocked by TEA<sup>+</sup>. In high (40 mM) K<sup>+</sup> media, a voltage jump from -30 to -50 mV produced an early inward current followed by an outward current relaxation. Thus, as expected for a K<sup>+</sup> current, increasing the external K<sup>+</sup> concentration reduced the K<sup>+</sup> equilibrium potential and reversed the direction of the current relaxation. The current relaxation following the voltage jump from -30 to -50 mV may result from the closing of a voltagesensitive K<sup>+</sup> channel. Upon repolarizing the cell, this channel may be activated, causing an outward current relaxation. Since TEA<sup>+</sup> blocked the current relaxations, TEA<sup>+</sup> may block this voltagesensitive K<sup>+</sup> channel.

Muscarine at a concentration of 25  $\mu$ M, depolarized spinal cord neurons but had no effect on the membrane potential of DRG cells. Thus, DRG neurons, like sympathetic and spinal cord cells, possess a voltage-sensitive K<sup>+</sup> channel activated at potentials close to the resting potential. In contrast to sympathetic and spinal cord neurons, the slow voltage-dependent K<sup>+</sup> channel in DRG neurons was not blocked by muscarine. 147.8 EVIDENCE FOR A CALCIUM-ACTIVATED POTASSIUM CONDUCTANCE IN SERO-TONERGIC DORSAL RAPHE NEURONS. C. P. VanderMaelen and G. K. <u>Aghajanian</u>. Depts. of Psychiat. and Pharmacol., Yale Univ. Sch. of Med., New Haven, CT 06508.

Aghajanian. Depts. of Psychiat. and Pharmacol., Yale Univ. Sch. of Med., New Haven, CT 06508. Calcium-activated potassium conductances have now been demonstrated in a variety of invertebrate and vertebrate neurons. In these cells increased intracellular free Ca<sup>2</sup>, usually caused by Ca<sup>2+</sup> entry during an action potential, triggers a potassium conductance,  $g_{\rm x}$ , which causes hyperpolarization of the membrane. Since serotonergic neurons of the rat dorsal raphe (DR) nucleus exhibit pacemaker potentials during which each spike is followed by a prominent after-hyperpolarization (AHP) (Aghajanian & VanderHaelen, Brain Research, 1982, 238, 463-469), the present study was aimed at determining if a calcium-activated  $g_{\rm x}$  might be present in these neurons, and might play a role in these pacemaker potentials.

Intracellular recordings were obtained from presumed serotonergic DR neurons in rat brain slices as previously described (VanderMaelen & Aghajanian, Neurosci. Abst., 1982, 8, p.482; Brain Research, in press). Slices were maintained in flowing Ringers solution at 33° - 37 °C containing in mM: NaCl, 130; KCl, 5.0; NaH<sub>2</sub>PO<sub>4</sub>, 1.25; NaHCO<sub>3</sub>, 24.0; CaCl<sub>2</sub>, 2.5 or 4.0; MgSO<sub>4</sub>, 1.5; D-glucose, 10.0; and aerated with humidified 95% 0.2, 5% CO<sub>2</sub>. Single spikes (spontaneous or evoked) were followed by 10-20 mV AHP's which lasted 200 - 800 msec. A burst of spikes driven by an intracellularly injected depolarizing pulse was followed by

Single spikes (spontaneous or evoked) were followed by 10-20 mV AHP's which lasted 200 - 800 msec. A burst of spikes driven by an intracellularly injected depolarizing pulse was followed by 10-20 mV AHP's which lasted 200 - 800 msec. A burst of spikes driven by an intracellularly injected depolarizing pulse was followed by an AHP greater in amplitude and duration than the AHP following a single spike. The reversal potential for the AHP following a single spike. The reversal potential for the AHP following with KCl rather than K-acetate microelectrodes did not shift the AHP reversal potential in the depolarizing direction. A decrease in input resistance accompanied the AHP, and was not due to anomalous rectification. The AHP reversal potential varied with the extracellular K concentration in reasonably close agreement with the Nerns equation. The removal of calcium ions from the bath, with a concommitant increase in Mg<sup>2</sup>, resulted in reductions in the amplitude of AHP's of up to about 50%, and even greater reductions in their durations. It also resulted in an increased rate of discharge for these cells. Taken together, these results indicate that the AHP is mediated by an increase in  $g_{\rm K}$ , and that at least a good portion of this is calcium dependent.

It is concluded that a calcium activated  $g_{\mu}$ , triggered by Ca<sup>2</sup> entry during the spike, is probably an important contributor to the pacemaker potentials of serotonergic DR neurons, and plays an important role in helping to maintain the slow and steady discharge so characteristic of these neurons. 147.9 INTRACELLULAR INJECTION OF A CA<sup>++</sup>-DEPENDENT PROTEIN KINASE AMPLI-FIES CA<sup>++</sup>-MEDIATED INACTIVATION OF A TRANSIENT K<sup>+</sup> CURRENT (I<sub>A</sub>) IN <u>HERMISSENDA GIANT NEURONS. J. Acosta-Urquidi, D.L. Alkon, J.A.</u> <u>Connor and J.T. Neary.</u> Section on Neural Systems, Lab. of Biophysics, NINCDS-NIH, MBL, Woods Hole, MA 02543, and Bell Labs, Murray Hill, NJ 07974.

The early transient outward  $K^+$  current (I<sub>A</sub>) in <u>Hermissenda</u> Type B photoreceptors exhibits a Ca<sup>++</sup>-mediated inactivation [hA (Ca<sup>++</sup>)] lasting tens of seconds. Previous studies show that this inactivation persists on retention days following associative conditioning (Alkon et al., Biophys. J., and Science, 1982). To probe possible biochemical steps in the long term hA(Ca<sup>++</sup>) we have previously iontophoretically injected exogenous protein kinases into B cells. A Ca<sup>++</sup>-dependent protein kinase (viz. phosphorylase kinase, PhK) amplified, in a Ca<sup>++</sup>-dependent manner, the magnitude and duration of hA(Ca<sup>++</sup>) in Type B photoreceptors (Acosta-Urquidi et al., Soc. Neurosci. Abstr. 8, 825, 1982). We have now extended these findings to central g\_ant neurons LPI-3 in the left pedal ganglion of <u>Hermissenda</u>, which exhibit a 4-AP (5-10 mM) sensitive IA, an I<sub>K</sub>(Ca<sup>++</sup>) and other delayed I<sub>K</sub>(s). The I<sub>A</sub> exhibits hA(Ca<sup>++</sup>) comparable to that of B photoreceptors. In LPI-3 cells hA(Ca<sup>++</sup>) comparable to that of B photoreceptors. In cut-axon preparations in SW, which show little or no impulse activity. I<sub>A</sub> recovery roughly parallels the return of the elevated Ca<sup>+</sup><sub>1</sub> to pre-load levels, as measured by differential absorption reduces hA(Ca<sup>++</sup>). Iontophoretic ECTA (ca. IM, pH 7.3) injection reduces or abolishe I<sub>K</sub>(Ca<sup>++</sup>). Intophoretic PhK (Sigma and purified, courtesy of Dr. E.G. Krebs) injections (0.5-1.0 mg/ml, 3-6 nA, 1-4 min) reduced I<sub>A</sub> and potentiated hA(Ca<sup>++</sup>) (123%, N=9, P< 01); full I<sub>A</sub> recovery was abolished. PhK injection also enhanced I<sub>K</sub>(ca<sup>++</sup>) and reduced other delayed I<sub>K</sub>(s) and I<sub>K</sub>(Ca<sup>++</sup>). The possibility that PhK exerts its effects by increasing I<sub>Ca</sub><sup>++</sup> directly or by modulating its Ca<sup>++</sup>-mediated inactivation is being considered. 147.10 A COMPARISON OF THE NUMBERS OF NITRENDIPINE BINDING SITES WITH THE NUMBER OF VOLTAGE DEPENDENT CALCIUM CHANNELS OF PC12 CELLS. M.J. Hawkes, S.L. Hamilton, D.L. Kunze and A.M. Brown. (SPON: K.-W. Yau). Department of Physiology and Biophysics, University of Texas Medical Branch, Galveston, Texas 77550

Dihydropyridines such as nitrendipine block voltage dependent calcium channels in nerve and cardiac tissue. Using [H]-nitrendipine, a single class of binding sites is found in the rat pheochromocytoma (PCl2) cell line. In agreement with Toll (J. Biol. Chem. 257, 13189-13192 (1982)), nitredipine binds with a dissociation constant of 1.1 nM. The site is located on the plasma membrane, as its purification parallels the purification of ouabain sensitive Na /K ATPase activity and [H]-methyl- $\alpha$ -neurotoxin binding its per PCl2 cell. For comparison, we calculate approximately 2200  $\alpha$ -neurotoxin binding sites per PCl2 cell. Functional Ca

Functional Ca<sup>\*\*</sup> channel density was estimated electrophysiologically from single Ca channel and wholf cell Ca current recordings using the patch clamp method. Na<sup>\*</sup> and K<sup>\*</sup> currents were suppressed and 40 mM Ca was used to enhance single channel current amplitudes. At -20 mV, single channel current had a range of 0.35 to 0.45 pA and whole cell peak currents, which inactivated very slowly ranged from 150 to 200 pA. In this solution, at this potential the opening probability in Helix neurons is 0.05 (Brown, et al., J. Physiol., 1983, in press). Assuming this value for PC-12 cells, there are between 3500 to 8500 voltage-gated functional Ca channels per cell. Hence dihydropyridine receptors and functional Ca channels have similar densities in PC12 plasma membranes and we suggest tentatively that there is one receptor site per channel. (Supported by N1H grant NS-11453).

- 147.11 <sup>45</sup>Ca<sup>++</sup> UPTAKE INTO RAT WHOLE BRAIN SYNAPTOSOMES ALTERED BY DIHYDROPYRIDINE CALCIUM ANTAGONISTS. Laura C. Daniell\*, Edward M. Barr\*, and Steven W. Leslie, Division of Pharmacology, College of Pharmacy, University of Texas at Austin, Austin, Texas 78712. Voltage-dependent Ca<sup>+</sup> uptake in rat whole brain synaptosomes was measured after 3 second KCl-induced depolarization to investigate possible inhibitory effects of calcium antagonists, nitrendipine, nimodipine, and nisoldipine. Synaptosomes, isolated on Ficoll density gradients, were pre-incubated in a buffered physiological salt solution with various concentrations of Ca<sup>++</sup> and drug. Ca<sup>++</sup>, Ca<sup>+</sup>, in high or low KCl solutions, was added to each sample. Ca<sup>++</sup> uptake was stopped by the addition of an EGTA solution. When incubated in the presence of 1.2 mM Ca<sup>++</sup>, nitrendipine, in concentrations ranging from 0.1 nM to 10 uM, had no effect on <sup>+</sup>Ca<sup>+</sup> uptake. However, when the Ca<sup>++</sup> concentration contained 65 mM KCl, nitrendipine (10 uM) inhibited <sup>+</sup>Ca<sup>+</sup> uptake with 30 KCl depolarization at all Ca<sup>+</sup> concentrations examined (0.06, 0.12, 0.6, and 1.2 mM). Similarly, nimodipine and nisoldipine did not inhibit <sup>+</sup>Ca<sup>++</sup> uptake, in concentrations ranging from 0.1 nM to 10 uM, when synaptosomes were depolarized by 30 mM KCl. Our studies show that large concentrations of nitrendipine are required to demonstrate a small degree of inhibition of <sup>-</sup>Ca<sup>+</sup> uptake into synaptosomes. These results indicate that the dihydropyridine calcium antagonists are considerably less potent in brain tissue than in peripheral tissue.
- 147.12 DRUG INHIBITION OF CALCIUM UPTAKE BY RAT BRAIN SYNAPTOSOMES. <u>Wayne Hoss and Robert S. Aronstam</u> (SPON: B.D. Goldstein). Center for Brain Research, Univ. of Rochester, Rochester, NY 14642 and Dept. of Pharmacology, Medical College of Georgia, Augusta, GA 30912.

Depolarization-induced calcium uptake by rat brain synaptosomes was measured by placing synaptosomes in a high (65 mM) potassium medium containing <sup>45</sup>Ca. Uptake was terminated by filtration on glass fiber filters which were washed with 5 ml of a calcium-free medium. Synaptosomes were prepared by sucrose density centrifugation and then equilibrated in a medium containing 5 mM KCl, 130 mM NaCl, 12 mM Na,PO, 10 mM glucose and 20 mM Tris-Cl, pH 7.4. The ability of synaptosomes to exclude <sup>45</sup>Ca in the resting (i.e., nondepolarized) state increased for 2 h after final dilution, while stimulated (i.e., depolarizationinduced) uptake was stable for 4 h. Stimulated uptake was essentially complete within 20 s and was linearly related to potassium concentration between 10 and 80 mM. The level of stimulated uptake gradually declined while resting uptake increased, so that after 40 min synaptosomal calcium uptake reached a plateau at 5.4 nmoles/mg protein in the presence of 10 mM calcium. The apparent Km for this process was 0.56 mM.

Depolarization-induced calcium uptake was inhibited by tricyclic antidepressant drugs, including imipramine, desipramine, amitriptyline, norriptyline, doxepin and chloripramine, with IC50's in the micromolar range. Anti-depressant drugs which were secondary and tertiary amines were equally effective at inhibiting calcium uptake. A wide range of neuroleptic drugs, including phenothiazines, haloperidol and butaclamol, also inhibited stimulated calcium uptake in a dose-depressant manner. Certain local amesthetics (e.g., fibucaine) inhibited calcium uptake while others (e.g., lidocaine and tetracaine) were ineffective. Among the compounds which did not affect depolarization induced calcium uptake were 4-aminopyridine, phenokarbital, diphenhydramine, cyclazocine, phencyclidine, histrionicotoxin, tetraethylamonium, pentazocine, pumiliotoxin, gephyrotoxin, valproic acid and various neurotransmitters. These results suggest that inhibition of calcium transport underlies the the actions of certain classes of psychoactive drugs. (Supported by PHS grants DA-01851 and DA-03303). 147.13 EFFECTS OF DECYLTRIMETHYLAMMONIUM ON IONIC CHANNELS OF THE SQUID GIANT AXON. <u>H. HORIE, T. TAKENAKA, H. HORI\*s T. MAEDA\*</u>. Dept. of Physiol. Sch. of Med. Yokohama City Univ., Minamiku, Yokohama, 232 JAPAN

Decyltrimethylammonium chloride is an analogue of TMA<sup>+</sup> and has a hydrocarbon chain with 10 carbon atoms. This agent is very soluble in water and its effects on inward-currents and outward-currents of nerve membranes were studied by using a  $v_{\rm oltage}$  clamp in squid giant axons. When the agent was applied internally at concentrations of 0.1 mM, the resting potential of membrane was not changed but the maximum inward-current was reduced to 50% and late outward-current also decreased. These values reached steady-state at 5 min after application of the agent. The potential level at the maximum value of inward-currents scaresly shifted. These effects of the agents were reversible. When the agnet was applied externally to the axon at a concentration of more than 1 mM, the agent affected both of peak inward-current and late outward-current. However, when the agent at concentration of 5 mM was externally applied to the axon perfused intracellularly, both values of the peak inward-current and late outward-current gradually decreased and reached the steady-state value at 20-30 min after application of it. The shift of the potential level at the maximum inward-current was about 20 mV in the direction of depolarization. When the intracellular perfusion was stopped after reaching the steady state, late outward-currents decreased comparing to peak inward-currents, but the potential level at the maximum inward-current scaresly shifted. When intracellular perfusion started again, the values were recovered to those in the steady state. However, by washing externally with control solution, the potential shift recovered to the control level and the value of the maximum inward-current recovered, but the values of the late outward-current recovered little. These data show that when the agent was applied externally, it affects not only external side but also internal side of the membrane. This suggests that the agent might penetrate the membrane from outside into inside of the axon and inhibit the late outward-currents. itself has no effect on sodium and potassium currents in concentrations of 10 mM. However, the agent inhibited both sodium and potassium currents in a low concentration of 0.1 mM. This might be considered that the agent gets into the lipid layer of the membrane and attaches a TMA<sup>+</sup> site of the agent to a potassium channel.

147.14 K<sup>+</sup>-CHANNEL FROM SARCOPLASMIC RETICULUM : A STUDY OF ITS PROPERTIES IN THE NATIVE MEMBRANE. A. M. Garcia<sup>\*</sup>. (SPON: E. Marder). Biophysics Program, Dept. of Biol., Brandeis University, Waltham, MA 02254.

A contribution to the study of ionic channels has been the fusion of membrane vesicles into planar bilayers membranes. Although this technique has provided useful information about the channels studied, a question still remains: Are the properties of the channel the same in the planar as in the native membrane? The main difficulty in answering this question has been measuring ion fluxes in vesicles, in a time scale of significance. Moore and Raftery (P.N.A.S. 77:4509, 1980) have developed a method to measure fluxes on the millisecond time scale: If a fluorescent dye trapped in a vesicle is rapidly mixed with a Tl<sup>+</sup> solution, the fluorescence is quenched as Tl<sup>+</sup> enters the vesicles. We have used this method to study the K<sup>+</sup>-channel from sarcoplasmic reticulum (SR) in its native membrane. Isolated SR vesicles are loaded with the fluorescent dye pyrene tetrasulfonate (choline salt) and a "test cation". The loaded vesicles are mixed with Tl<sup>+</sup> in a stopped-flow apparatus and the fluorescence quenching monitored. It has been found that the rate of Tl<sup>+</sup>-test cation exchange follows a double exponential relaxation. The slow exponential corresponds to about 30% of the total exchange and it is independent of the test cation used. The rate of fast exchange depends on the ion present, following the same pattern of selectivity as the channel in the bilayer, namely: K<sup>+</sup>=Na<sup>+</sup>>i<sup>+</sup>>Deline<sup>+</sup>>Choline<sup>+</sup>. The rate constants found (K<sup>+</sup>.

channel in the bilayer, namely:  $K^{\pm}\cong Na^{+} \Sigma Li^{+} Diethylamine^{+} Choline^{+}$ . The rate constants found  $(K^{+}, Na^{+} 300 \text{ s}^{-1})$  Li<sup>+</sup>=40 s<sup>-1</sup>) are in good agreement with the expected values. Furthermore, blockers of the channel in the bilayer also block in the vesicle, with a lower affinity, but with the same sidedness. In conclusion, using the same ions that are known to permeate the K<sup>+</sup>-channel in the bilayer, it has been found that the channel is present in a major population of SR vesicles and that its properties are similar to those found in the bilayer.

The aminopyridines have been shown to increase transmitter output at the neuromuscular junction and to have convulsant effects on cortical tissue. Voltage clamp studies on squid axon indicate that the aminopyridines block voltage-dependent potassium conductance  $(g_n)$ . However, application of 4-AP to mature mammalian myelinated axons has minimal effect on their action potential characteristics. In contrast, young myelinated axons are exquisitely sensitive to 4-AP and they give rise to a delayed membrane depolarization and spike burst activity in the presence of 4-AP (Kocsis et al, J. Neurophysiol, in press). Thesleff (Neuro-science 5, 1980) states that the aminopyridine analog 3,4-diaminopyridine (3,4-DAP) is particularly potent in the neuromuscular junction. In this study we compared the effects of 4-AP and 3,4-DAP on young myelinated axons and on the excitability properties of the cerebellar cortex. Sciatic nerves of 6 week old rats were removed, desheathed, and placed in a sucrose gap chamber from which compound action potentials could be recorded. Intra-axonal recordings were simultaneously obtained with glass microelectrodes filled with 2M KCl. Application of either 4-AP or 3,4-DAP led to the development of burst activity as determined by intraled to the development of burst activity as determined by intra-axonal recording and from occlusion experiments carried out with whole nerve recording. The area of the compound action potential after drug application ( $A_{\rm m}$ ) over the area before application ( $A_{\rm c}$ ) was plotted versus drug concentration (10 °M to 10 °M). The in-crease in this ratio ( $A_{\rm m}/A_{\rm C}$ ) was dose-related in a similar manner for both 4-AP and 3,4-DAP. Neither compound altered resting mem-brane potential. In another set of experiments, field potentials and extracellular potassium concentrations [K<sup>+</sup>] were recorded from the molecular layer of the cerebellar cortex with ion selec-tive microelectrodes. As has been previously reported, a single tive microelectrodes. As has been previously reported, a single elicits an increase in [K'] from resting levels of 3.0 mM to above 10 mM. There is a transient cessation of presynaptic and postsynaptic components of the field potential during this period of high [K']. A similar cessation of neuronal activity after a of high [K ]. A similar cessation of neuronal activity after a single stimulus was observed in the presence of 3,4-DAP. These results indicate that the aminopyridine analogs, 4-AP and 3,4-DAP, have similar electrophysiological action on myelinated mammalian axons and on excitability properties of the cerebellar cortex. Supported by the National Multiple Sclerosis Society and the Veterans Administration.

147.15 EFFECTS OF PHOSPHOLIPID SURFACE CHARGE ON ION CONDUCTION IN THE K<sup>+</sup> CHANNEL OF SARCOPLASMIC RETICULUM, Joan Bell<sup>\*</sup> (SPON: I. Levitan) Dept. of Biochemistry, Brandels Univ. Waltham, Mass. 02254.

Single-channel currents through sarcoplasmic reticulum K channels were compared when reconstituted into planar bilayers formed from neutral or negatively charged phospholipids. In neutral bilayers the  $K^+$  conductance saturates with  $K^+$ concentration according to a rectangular hyperbola, with half-saturation at 40 mM K<sup>+</sup>, and maximum conductance of 220pS. In negatively charged bilayers, the conductance is, at a given  $K^+$  concentration, higher than in neutral bilayers. This effect of negative surface charge is increasingly pronounced at lower ionic strength. The maximum conductance at high K<sup>+</sup> approaches 220pS in negative bilayers and the K<sup>+</sup>/Na<sup>+</sup> selectivity is unaffected by lipid charge. The divalent channel blocker, "bisQll", causes discrete blocking events in both neutral and negatively charged bilayers; the apparent rate constant of blocking is sensitive to surface charge, while the unblocking rate constant is largely unaffected. Bilayers containing a positively charged phosphatidyl-choline analogue lead to  $K^+$  conductances lower than those seen in neutral bilayers. The results are consistent with a simple mechanism in which the local  $K^+$  concentration sensed by the channels entryway is determined by both the bulk  $K^+$  concentration and the bulk lipid surface potnential, as given by the Gouy-Chapman model of the electrified interface. In order to be described by this approach, the channel's entryway must be assumed to be located 1-2nm away from the lipid surface, on both sides of the membrane.

147.17 PASSIVE ELECTRICAL PROPERTIES OF PERIPHERAL MYELINATED AXONS: DUAL INTRA-AXONAL MICROELECTRODES REVEAL PROMINENT SLOW (INTERNODAL) COMPONENT. K.A. Scappaticci and E.F. Barrett. Dept. of Physiology and Biophysics, Univ. of Miami Sch. of Med., Miami, FLA 33101.

Single peripheral myelinated axons coursing through the dewlap extensor muscle of lizards (Anolis sagrei) were impaled with two separate micropipettes (50-200 MΩ, filled with 0.2 M K\_2SO<sub>4</sub>), one for recording voltage, the other for passing current. Similar recordings were made from isolated frog sciatic axons. Input resistances of fibers selected for study ranged from 35-100 MΩ in the linear (hyperpolarized) region of the current-voltage relationship. The voltage response to an injected current step showed distinct fast and slow (>20 msec) components. The fast components are due to current flow through nodal membrane and internodal series leakage resistance, while the slow component represents charging of the internodal axon membrane (see Barret', E.f. and Barrett, J.N., J. Physio1, 323:117, 1982). The magnitude and time constant of the slow component varied with membrane potential. In hyperpolarized axons the slow component accounted for 40-85% of the total voltage transient in four lizard axons (30% in one frog axon). These percentages give a lower-bound estimate of the relative contribution of the internodal axon membrane to the resting properties of the myelinated axon. The relative contribution of the slow component ranged from 90-250 msec in hyperpolarized lizard and frog axons; this time constant defeased with depolarization.

In both frog and lizard axons action potentials evoked by stimulating the nerve trunk are followed by a depolarizing afterpotential. The time constant of decay of this depolarizing afterpotential usually showed the same voltage dependence as the time constant of the slow component of the passive response, suggesting that both reflect charging of internodal membrane.

that both reflect charging of internodati memorane. When doubly impaled axons were perfused with the potassium channel blocker tetraethylammonium (TEA, 1-5 mM), axonal input resistance increased at both depolarized and hyperpolarized potentials, and the magnitude and duration of both the slow component of the passive voltage transient and the depolarizing afterpotential increased. In addition, a slow anomalous rectification seen in hyperpolarized lizard axons became more prominent in TEA.

We conclude, in agreement with Chiu's voltage clamp studies in frog (<u>Soc. Neurosci. Abs., 8</u>:253, 1982), that voltage-dependent, TEA-sensitive potassium channels in the internodal membrane make a major contribution to the resting properties, as well as to the depolarizing afterpotential, in frog and lizard myelinated axons. Supported by the Muscular Dystrophy Association and NS 12404.

147.19 ACTIVATION OF ROD OUTER SEGMENT SHEDDING: THE UNIMPORTANCE OF MEMBRANE POTENTIAL. David S. Williams\*, Chester Wilson\* and Steven K. Fisher\* (SPON: George M. Austin). Dept. of Biological Sciences, University of California, Santa Barbara, CA 93106. In the retinae of lower vertebrates, the daily shedding of rod outer segment discs is maximal following dawn, and is largely a light-evoked event (Basinger, S. et al., <u>Science 194</u>: 1074, 1976). We have been interested in the physiological changes resulting from light stimulation that might be responsible for the activation of shedding. Our first experiments were designed to test if the hyperpolarisation of rods or retinal pigment epithelial (RPE) cells by light is pertinent to the shedding response. Previous work is compatible with this hypothesis: isobutylmethylayanthine has been shown to depolarise rod photorecer-

the activation of shedding. Our first experiments were designed to test if the hyperpolarisation of rods or retinal pigment epithelial (RPE) cells by light is pertiment to the shedding response. Previous work is compatible with this hypothesis: isobutylmethylxanthine has been shown to depolarise rod photoreceptors (Lipton, S.A. et al., J. Gen. Physiol. 70: 771, 1977) and inhibit the light-evoked shedding response (Besharse, J.C. et al., J. Gen. Physiol. 79: 775, 1982). We exposed retinae to other conditions that depolarise rod and RPE cells, and to conditions that hyperpolarise them. Several hours before the usual time of the onset of light, eyecups of the frog, Xenopus laevis, were placed in a bicarbonate-buffered salt solution, supplemented with amino acids and vitamins. Twenty minutes prior to lightson, the eyecups were transferred under dim red light to either fresh normal medium (controls) or the experimental medium. Two hours after lights-on, the eyecups were fixed and processed for light microscopy. The extent of shedding was quantified by choline, and the eyecups were not exposed to light, the shedding response was significantly greater than that in control eyes kept in darkness, and almost as large as that in control eyes kept in darkness, and almost as large as that in control eyecups even exposed to light. Replacement of Na<sup>+</sup> by choline hyperpolarises that is significantly greater than that in control eyecups even exposed to light. Replacement of Na<sup>+</sup> by choline hyperpolarises the rods (Brown, J.E. and Pinto, L.H., J. Physiol. (Lond.) 236: 575, 1974), but, by inhibiting Na<sup>+</sup>, K<sup>+</sup>-ATPase activity, ouabain should quickly depolarise retinal cells, including the rod and RPE cells. Beccuse both these conditions induced shedding in darkness, we conclude that membrane potential is irrelevant to shedding. Our findings are consistent with the likelihood that Na<sup>+</sup>, K<sup>+</sup>-ATPase activity of rod inner segments and RPE apical membrane is inhibited by the onset of light: that of rods by a lowering 147.18 SPONTANEOUS OSCILLATIONS OF [K<sup>+</sup>] IN NEONATAL RAT OPTIC NERVES IN Cl<sup>-</sup> DEFICIENT SOLUTIONS. <u>B.R. Ransom and B.W. Connors</u> (SPON: M.W. Siegel). Dept. of Neurology, Stanford University Sch. of Med., Stanford, CA 94305.

Stantord, CA 94305. Neonatal rat\_optic nerves display unusally large increases in extracellular K concentration ([K<sup>T</sup>]; up to 20 mM) when stimulated repetitively (Connors et al., <u>Science</u> 216:1341, 1982). We report here that these nerves exhibit spontaneous and recurring waves of markedly elevated [K<sup>T</sup>]<sub>o</sub> when bathed in Cl<sup>-</sup>-deficient solutions.

Rat optic nerves from animals ranging in age from 1 to 25 days were maintained in a perfusion chamber at  $37^{\circ}$  in a solution with 5 mM K<sup>\*</sup>. Nerves were stimulated supramaximally with suction electrodes, and double-barrel K<sup>\*</sup>-sensitive microelectrodes were used to record [K<sup>\*</sup>] and the compound action potential. When 1-5 day old nerves were exposed to solutions in which propionate was substituted for Cl<sup>\*</sup>, [K<sup>\*</sup>] increased by 2-3 mM over several minutes. In most nerves, [K<sup>\*</sup>], then rapidly and spontaneously increased to a peak of 10-15 mM before falling more slowly toward the normal baseline level. This pattern of [K<sup>\*</sup>] oscillation, or "cycling", usually continued with a period of 1-2 min per cycle, often for more than an hour. Nerves older than 5 days did not spontaneously oscillate, but showed signs of hyperexcitability.

more than an hour. Nerves older than 5 days and hot spontaneously oscillate, but showed signs of hyperexcitability. We sought the mechanism for [K<sup>+</sup>] cycling. Tetrodotoxin (1  $\mu$ M) immediately blocked the fluctuations, indicating that action potential activity plays a critical role. Reducing the bathing [K<sup>+</sup>] to 3-4 mM slowed the oscillations; 1-2 mM blocked them completely. When 9 different anions of varying hydrated radii were substituted for Cl<sup>-</sup>, cycling of [K<sup>+</sup>] occurred only with anions the size of HCO<sub>3</sub> or larger, but not with anions the size of BrO<sub>3</sub> or smaller. The amount of spontaneous axonal firing within the nerve was estimated from the size of the maximal evoked field potential: the field was largest at the [K<sup>+</sup>] increase, was abolished during the rapid [K<sup>+</sup>]<sub>0</sub> rise and returned during the falling limb of the cycle.

We hypothesize that neonatal optic axons possess an anionselective membrane channel which is open at rest. This conductance is abolished by deleting permeant anions, rendering the membranes hyperexcitable. Spontaneous firing of some axons leads to an increase in  $[K^T]$  which facilitates the firing of adjacent axons until  $[K^T]$ , rises to very high levels. Firing eventually subsides because of Na channel inactivation and/or direct K<sup>+</sup> effects and  $[K^T]$  declines. This enhancement of axonal excitability in Cl<sup>-</sup> deficient solutions may be similar to that of myotonic muscle, which results from a genetically determined reduction in  $[1^-$  channels.

147.20 ELECTROANATOMICAL STUDIES OF A SPIKING AMACRINE CELL. R. F. <u>Miller</u>. Departments of Ophthalmology, Physiology and Biophysics, Washington University School of Medicine, St. Louis, MO 63110. Intracellular recordings obtained from the retinas of a vari-

Intracellular recordings obtained from the retines of a variety of species have demonstrated the presence of on-off amacrine cells which respond to light stimulation with large amplitude EPSPs and spikes. Two different spike mechanisms, of soma and dendritic origin have been suggested. Both types of spikes are activated by depolarization of the soma, and both are blocked by TTX. The EPSPs can be as large as 60 Mv and constitute one of the largest PSPs reported in the central nervous system. Intracellular recordings from ganglian cells sometimes reveal two types of inhibitory events, one of which includes fast IPSPs which have properties and a time course similar to the dendritic spikes seen in on-off amacrine cells. This evidence coupled with two electrode recording experiments suggests that on-off amacrines are inhibitory. HRP staining of on-off amacrine cells in the mudpupp was combined with measurements of input resistance and time constant. In addition peeled time constants were analyzed to predict electrotonic length of the dendritic structure with 3 to 6 primary dendrites. Diameter and length measurements show that these structures do not branch in a "conventional" dendritic fashion but bear a closer resemblance to some axonal branching. Computer simulations were carried out to evaluate possible sites of origin of dendritic spike activity. These studies suggest the following: Dendritic spikes are probably initiated close to the soma, and may simultaneously activate the entire dendritic tree in a centripetal direction. Consistent with this suggestion is the observation that extracellularly recordedendritic spikes are purely negative. The soma spike may help to insure that dendrite spikes are propagated in a centripetal fashion. The large amplitude PSPs together with "fast" Na dependent spikes appear to be designed for evoking powerful inhibitory influences predominately onto ganglion cells and other amacrines.

147.21 PHYSIOLOGICAL AND PHARMACOLOGICAL PROPERTIES OF CHOLINERGIC ENTER-IC NEURONS GROWN IN CELL CULTURE. <u>Alan L. Willard\* and Rae Nishi</u> (SPON: S.G.Matsumoto). Dept. of Neurobiology, Harvard Med. School, 25 Shattuck St., Boston, MA 02115.

The enteric nervous system (ENS) contains several classes of neurons that can be distinguished by electrophysiological, pharmacological, morphological and immunohistochemical criteria. We are using cell cultures of neurons dissociated from small intestines of newborn rats to correlate some of these properties in single cells. Cholinergic neurons are a major subpopulation in the ENS. They are also a major class (30-50%) in our cultures. Here we report some of the electrophysiological, pharmacological and immunohistochemical properties of cultured cholinergic enteric neurons. Neurons in cultures 2-10 weeks old were impaled with intracell-

Neurons in cultures 2-10 weeks old were impaled with intracellular electrodes and tested for their ability to cause fast nicotinic epsps in nearby neurons. After a neuron was physiologically identified as cholinergic, the ionic basis of its action potential (AP) was tested, its ability to fire repetitively was examined, its responses to putative transmitters were tested and it was then fixed and examined for VIP-Like immunoreactivity (VIP-LIR).

(AP) was tested, its ability to fire repetitively was examined, its responses to putative transmitters were tested and it was then fixed and examined for VIP-like immunoreactivity (VIP-LIR). The somata of cholinergic neurons shared electrophysiological properties with both types of neurons described in adult guinea pig ENS (e.g. North, Neurosci. 7: 315 (1982)); most had APs with both Na and Ca components but a few appeared to have totally Na dependent APs. Afterhyperpolarizations (AHs) following single APs were less than 100 msec long; prolonged AHs did not follow single APs. TTX rarely blocked APs in cell bodies but it always blocked cholinergic synaptic transmission, suggesting that the neuronal processes do not have propagating Ca dependent APs. Spontaneous synaptic activity was common, but no pacemaker drivers were observed, suggesting that the spontaneous activity was largely a network property (spontaneous epsps were often suprathreshold). No cholinergic neurons were observed to fire continuously when depolarized; rather they fired 1-10 APs at the onset of a depolarizing pulse.

Responses to putative transmitters were tested by pressure ejection of test compounds from blunt micropipets. Cholinergic neurons were excited by ACh, scrotonin, Substance P and VIP. They were inhibited by GABA, norepinephrine and Met-enkephalin.

To relocate identified neurons, dishes were marked so that they could be placed back on the microscope stage in the same position and the field of view containing the physiologically and pharmacologically characterized neuron(s) was photographed. The cultures were then fixed and processed for VIP staining. Two of 14 identified cholinergic neurons stained positively for VIP-LIR. Thus there appear to be at least 2 categories of cholinergic neurons in our cultures. Studies are currently underway to test for other classes of cholinergic enteric neurons. Support: MDA, ANA and NIH.

147.23 VOLTAGE-DEPENDENT MEMBRANE CURRENTS OF RAT PHEOCHROMOCYTOMA CELLS (PCl2). <u>G.G. Schofield and F. F. Weight</u>, Laboratory of Preclinical Studies, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

The rat pheochromocytoma (PCl2) clonal cell line has been shown to display a variety of neuronal properties. Currentclamp recordings from PCl2 cells grown in the absence of nerve growth factor (NGF) reveal a rectifiying response to depolarizing current pulses suggesting the presence of a delayed potassium conductance (Dichter et al, Nature 268: 501, 1977). The authors also reported that PCl2 cells grown in the presence of NGF developed tetrodotoxin (TTX)-sensitive action potentials. A study on large chemically-fused PCl2 cells demonstrated both a tetraethylammonium (TEA)-sensitive and a calcium-dependent potassium conductance, as well as a regenerative calcium spike in non-NGF treated cells (O'Lague et al, P.N.A.S., 77: 1701, 1980). Cells treated with NGF (200 ng/ml) displayed TTX-sensitive action potentials, in addition to conductances similar to those in non-NGF treated cells. We have studied membrane currents in PCl2 cells in the presence and absence of NGF (50 ng/ ml) using the gigaohm seal technique in the whole cell voltageclamp configuration. Untreated PCl2 cells in standard physiological solutions displayed a voltage-dependent, TEA-sensitive outward membrane current which activated at potentials more depolarized than -40 mV. Typical slope conductance was 20 nS between -30 and +30 mV. The addition of TEA (1 mM) reversiby reduced the slope conductance of this outward current during command potentials between -40 and +20 mV from a holding potential of -80 mV. This transient inward current activated and decayed in less than 10 msec. In the presence of TEA (10 mM), the net inward current was inactivated with holding potentials positive to -40 mV. These observations indicated that PCl2 cells exhibit voltage-dependent conductances that resemble conductances reported previously in various types of neurons. 147.22 PATCH CLAMP STUDIES OF RAT SYMPATHETIC NEURONS IN TISSUE CULTURE. Joseph E. Freschi. Physiology Dept., Armed Forces Radiobiol. Res. Inst., Bethesda, MD 20814

Res. Inst., Bethesda, MD 20814 Using the gigohm-seal patch clamp technique (Hamill <u>et al</u>, <u>Pflugers</u> <u>Arch 391:</u> 85, 1981) I studied electrophysiological properties of neonatal rat sympathetic neurons grown in tissue culture. I used cell-attached patch, detached patch, and whole-cell recording techniques.' Access resistances of 5-20 gigohm were usually obtained with standard salines in bath and pipette. These values reflected conductances of similar orders of magnitude through the patch membrane and through the pipettemembrane seal, for example, 17 pS through the patch and 83 pS through the seal. Because, however, many channels in the patch could be active at the resting potential of the cell (around -60 mV), the established patch resistance could vary considerably, and sudden large jumps in patch conductance could resemble loss of pipette-membrane sealing. Spontaneous action potentials (APs) frequently were seen through the passive RC elements of the patch membrane. Their shape and amplitude were functions of the patch conductance. APs were small (4-5) pA and biphasic when patch conductance was low, and were large (60-80) and monophasic when patch conductance was low, and were large (60-80) and monophasic when patch conductance was low, and were large (60-80) and monophasic when patch conductance was high. Particularly in high conductance patches, however, APs were often followed by large inward currents of 20-60 pA amplitude. Changing the potential across the patch membrane had no discernable effect on action potential frequency or configuration. This suggests that the ratio of patch to whole cell conductance is usually very small. This may not be the case, however, for high conductance patches with many channels. Whole cell recording in the current clamp mode confirmed that the total cell conductance. Cell input resistance, estimated by measuring the slope resistance near resting potential, was around 100 megohms. This value is significantly higher than the 30-50 megohm

147.24 EXPRESSION OF EXCITABLE SODIUM CHANNELS IN DEVELOPING MOUSE CEREBELUUM, <u>R.B. Rogart\*, M. Willinger\*, and G. Kuzma,\*</u> Depts. of Neuroscience and Neuropathology, Children's Hospital and Department of Medicine, Brigham & Women's Hospital, Harvard Medical School, Boston, MA 02115. (SPON: P. Mullenix) Saxitoxin (\*STX) is a radiolabeled neurotoxin which has been used as a high-affinity ligand for studying the Na\* channel in nerve and skeletal muscle membrane. The ability of this labeled ligand to bind to the channel at concentrations which correlate well with the physiological block of Na\* current, allows the characterization of membrane channels as ligand receptors. We have used this approach to study the expression of Na\* channels in the developing mouse cerebellum as a model for the development of membrane excitability in the mammalian CNS.

We observe \*STX binding to a high affinity receptor with a  $K_{\rm d}$ = 1-1.5 nM starting at postnatal day 6. The density of high affinity receptors rises most steeply between days 15 and 22. The site density increases 10-fold, from 25 to 250 fmoles \*STX bound per mg/wet weight of cerebellum. This increase in channel density occurs during a period of extensive synaptogenic activity in the cerebellum.

genic activity in the derevelum. We observe a second population of Na<sup>+</sup> channel with a low affinity receptor for \*STX, present in cerebellum from postnatal day 6 to day 14. This corresponds to a period of neurogenesis and morphogenic activity. The low affinity receptor has a K<sub>d</sub>= 12-16 nM for \*STX, and a K<sub>d</sub>= 300 nM for tetrodotoxin, a neurotoxin similar to STX. This receptor is similar to a low affinity receptor found in newborn and denervated mammalian muscle and mammalian heart. In these latter preparations, a tetrodotoxin-resistant action potential has been observed in electrophysiological studies, which we believe is accounted for by the population of Na<sup>+</sup> channels with the low affinity STX/TTX receptor. (Supported by PHS NS 16183,RBR, PHS NS 17225, MW, and Core Grant HD06276.)

THE DEVELOPMENT OF SPONTANEOUS ACTIVITY AND <sup>3</sup>H-SAXITOXIN BINDING CORRELATES WITH IMPULSE-DEPENDENT NEURONAL SURVIVAL. G.L. Westbrook, D.E. Brenneman\*, J. Baumgold, and M.J. Litzinger\* Lab. Develop. Neurobiol., NICHD, and Lab. Neurobiol., NIMH, NIH, 147.25 Bethesda, Md. 20205

Previous studies in our laboratory have shown that a critical period exists for the effect of tetrodotoxin(TIX) on neuronal survival in spinal cord (SC) cultures. TIX treatment of cultures between days 7-21 in culture results in a decrease in cell number and choline acetyltransferase activity. In order to study the development and TIX sensitivity of electrical activity in these cultures, patch electrodes were utilized to obtain intracellular recordings under current clamp from SC neurons during days 1-14 in culture. Ion channel development was studied with specific radioactive ligands on companion cultures during the same period. All cells studied (n=83) showed regenerative action potentials (APS)to depolarizing current pulses(days 1-14). However, spon-taneous APs were not seen until 4-5 days i. culture. Small syn-aptic potentials(10-30 mV) and occasional spontaneous APs were observed in all cells by day 6. The intensity of spontaneous AP activity rapidly increased between days 6-10. Despite the lack Previous studies in our laboratory have shown that a critical

observed in all cells by day 6. The intensity of spontaneous AP activity rapidly increased between days 6-10. Despite the lack of spontaneous APs on days 1-4, evoked APs with rise rates of 80-100 V/sec were blocked by miniperfusion with 1  $\mu$ M TTX. AP rise rates above 100 V/sec were not seen until after day 6. There was no apparent shift in resting membrane potential during this period, but there was a downward trend in the measured input resistance from 0.5-2 gigaohms(days 1-4) to 50-250 megaohms (days 7-14)

sistance from 0.5-2 gigaonms(Gays 1-4) to 50-200 megaonms (Gays 7-14). 3H-Saxitoxin, 125I-scorpion toxin, and 3H-nitrendipine binding were compared during development. All ligands exhibited multi-phasic increases in specific binding as the cultures matured. 3H-Nitrendipine, a putative ligand for a class of calcium chan-nels, exhibited greater binding (> 5 fold) than that obtained for the sodium channel ligands early in development (1-3 days in culture). The ratio of specific scorpion toxin to saxitoxin bind-ion varied with development. Scorpion toxin was significantly ing varied with development. Scorpion toxin was significantly greater than saxitoxin early in development (days 4-11). The onset (day 7) and duration of the critical period described above correlated best with a major increase in saxitoxin binding. The presence of TIX-sensitive APs and low levels of saxitoxin

binding precede the critical period. However, the onset of a critical period in impulse-dependent neuronal survival correlates closely with the development of spontaneous electrical activity and a period of major increase in <sup>9</sup>H-saxitoxin binding.

147.27 ELECTROPHYSIOLOGICAL STUDY OF MAMMALIAN NEURONS GROWN IN PRIMARY DISSOCIATED CELL CULTURE FROM VENTRAL MESENCEPHALON. E.J. Heyer, M.D. Yahr. Dept. Neurology, Mount Sinai School of Medicine, New York, N.Y. 10029.

ventral mesencephalon (VM) were grown in primary Neurons from Neurons from ventral mesencephaton (vm) were grown in painary dissociated cell (PDC) culture, and characterized electrophysiologically in terms of resting membrane potential (RMP), input resistance ( $K_{in}$ ), maximum rate of rise of the action potential (AP) ( $V_{max}$ ) and AP duration. PDC cultures of dissected VM were prepared from 12 to 14 day old fetal

mice. After 4 to 6 weeks in culture cells of various sizes could be seen. Using a modified glyoxylic acid method in which the cultures were preincubated with 10 uM **«**-methyl norepinephrine, the catecholaminergic nature of some of these neurons was established indicating that VM neurons were surviving in culture. The fluorescent cells were most probably were surviving in culture. The fluorescent cells were most probably dopaminergic because uptake blockers for dopamine (benztropine  $\Rightarrow$  UM) eliminated fluorescence, while uptake blockers for norepinephrine (desmethylimipramine 5 uM) did not. Without preincubating the cultures in **c**-methyl norepinephrine only occasional fluorescent neurites were seen, however, no cell bodies fluoresced.

Intracellular recordings of VM neurons bathed in Tris buffered saline solution with 5 mM calcium (TBS) were made with micropipettes filled with 4M KAc or 4M KAc plus 1% ethidium bromide (a red fluorescent dye). The 4M KAe or 4M KAe plus 1% ethidium bromide (a red fluorescent dye). The larger cells (15-25 microns in diameter) could be readily impaled. In TBS solution the neurons generated APs spontaneously. However, spontaneously occurring APs were decreased in number when 12 mM MgCL, was added to TBS solution, a condition which reduces synaptic transmitter release. Therefore, this spontaneous activity was most probably synaptically mediated. Using a modified bridge circuit to inject current, APs could be elicited with depolarizing current pulses. Thus, RMP,  $V_{max}$ ,  $R_{in}$  and AP duration could be determined for cultured neurons. In addition, the catecholaminergic nature of electrophysiologically studied neurons was assessed as follows. The recorded neuron was identified by staining the cell intracellularly with ethidium bromide (micropipette filled with KAc and ethidium bromide), and its catecholaminergic nature determined by preparing the culture with the mooified glyoxylic acid method. Since ethidium bromide fluoresced red and the catecholaminer fluoresced yellow-green, with appropriate excitation wavelengths the concurrence of these two fluorescent products or their lack could be determined. Supported by NINCDS Teacher-Investigator Development Award (NS U057) (E.J.H.), Research Grant from the American Parkinson's Disease Association (E.J.H.), NINCDS Clinical Center for Research in Parkinson's and Alijed Diseases (NS 11631-10) (E.J.H. and M.D.Y.)

147.26 EXPRESSION OF THE SODIUM CHANNEL PROTEINS DURING RAT BRAIN DEVEL-OPMENT. J. Baumgold, I. Zimmerman\* and J.R. Moskal\*<sup>+</sup>. Lab. of Neurobiol., and <sup>+</sup>Lab. of Cell Biol. NIMH, Bethesda, MD. 20205

We have previously demonstrated that in the course of development of chick skeletal muscle, the sodium channel proteins first appear in an electrophysiologically non-functional form, capable of binding <sup>125</sup>I-scorpion toxin (<sup>125</sup>I-ScTX) but not <sup>3</sup>H-saxitoxin (<sup>3</sup>H-STX), followed by a change to an electrophysiologically functional form capable of binding both of these toxins (Baumgold, et al., J. Neurosci., <u>3</u>:995-1003 and 1004-1013, 1983). We have extended these experiments using developing rat brain. <sup>3</sup>H-STX binding first became detectable in homogenates of rat brain two days before birth and reached maximal levels (1.1 + 0.1 pmoles/ mg protein) by post-natal day tventy. The density of <sup>125</sup>I-ScTX binding sites, however, was maximal by post-natal day 7 (1.9 + 0.1 pmoles/ mg protein). <sup>3</sup>H-STX binding activity from mature and immature (7 day old) rat brain was solubilized (1% Triton X-100, 150 mM choline chloride, 10 mM CaCl2, 0.02% phosphatidylcholine, 20 mM We have previously demonstrated that in the course of developline chloride, 10 mm GaG12, 0.024 phosphatidylcholine, 20 mm HEPES-TRIS pH 6.7) at a concentration of 6 mg protein/ml and chro-matographed on DEAE-Sephadex ion exchange columns. Although the <sup>3</sup>H-STX binding activity from adult rat brain bound to the column and was eluted as a single peak at 200-300 mM choline chloride, two peaks of <sup>3</sup>H-STX binding activity were found from immature rat brain: 49% of the recoverable activity appeared in the void volume and the remaining 51% of the activity was eluted as above. We also compared mature and immature sodium channel proteins for their ability to bind to various lectin columns. While greate: than 90% of the recoverable  ${}^{3}$ H-STX binding activity from adult While greater that 90% of the recoverable on-Six binding activity from adult rat brain bound specifically to wheat germ agglutinin-Sepharose, less than 25% of the  ${}^{3}$ H-STX activity from immature rat brain bound specifically to this column.  ${}^{3}$ H-STX binding activity from mature and immature brain behaved allke on several other lectin columns. The behavior of  ${}^{3}$ H-STX binding activity from 14 day columns. The behavior of  $^{2}$ H-STX binding activity from 14 day old rat brain on on ion exchange and on wheat germ agglutinin columns was found to be intermediate between that of 7 day and adult material. The behavior of the  $^{3}$ H-STX binding activity on both the ion exchange and the wheat germ agglutinin columns was dependent upon the protein concentration of the solubilized mate-rial. When solubilized at 3 mg protein/ml, the  $^{3}$ H-STX binding activity from 7 day old brains behaved like that of adult.

The binding studies and the behavior of the solubilized (at 6 mg/ml)  $^{3}$ H-STX binding protein on ion-exchange and on lectin columns, suggest the existence of different molecular forms of the sodium channel protein. However, since different chromatographic profiles were obtained on ion-exchange and on lectin columns, depending on the solubilization conditions, it is also possible that differences in protein-to-lipid-to-detergent ratios could also account for these results.

147.28 ACTION POTENTIALS OF MAMMALIAN CENTRAL SPINAL AXONS IN VITRO: DEPOLARIZING AFTER-POTENTIALS AND THE ROLE OF THE MYELIN SHEATH A. R. Blight and S. Someya\*. Depts. Neurosurgery and Physiology

and Biophysics, New York Univ. Med. Ctr., New York, NY 10016. Depolarizing after-potentials (DAP) have been recorded from vertebrate peripheral axons and attributed to the discharge of axolemmal capacitance by Barrett and Barrett (J. Physiol., 323: 117, 1982). This requires the existence of a low-impedance pathway through the myelin sheath, which seems incompatible with the classically ascribed role of myelin.

Action potentials were recorded intra-axonally in vitro in tracts isolated from the thoracic spinal cord of rats. The falling phase of the action potential could be resolved into three exponential components. The time constant of the first component was less than 0.1 ms (interpreted as the relaxation of the nodal membrane), that of the second 1.6  $\pm$  0.6 ms, and of the third 27.0  $\pm$  9.2 ms. The amplitudes of the two late components, extrapolated to the peak of the two late components, extrapolated to the peak of the action potential, were 16.0  $\pm$  4.3 mV, and 4.7  $\pm$  2.4 mV. The action potential amplitude was 80.9  $\pm$  17.8 mV, and the conduction velocity 19  $\pm$  8 m s<sup>-1</sup>. (All values: mean  $\pm$  S.D., N=32, t = 25°C.).  $19 \pm 8$  m s<sup>-1</sup>. (All values: mean  $\pm$  S.D., N=32, t = 25°C.). Similar passive time constants were observed with injection of hyperpolarizing current pulses. The amplitude and duration of the late components decreased with depolarization, and DAP were rarely seen following action potentials less than 60 mV. The longer component of the DAP appears similar to (though smaller and briefer than) the DAP in peripheral axons (op. cit.), and

is open to the same interpretation. The DAP were simulated by a computer model of the passive the DAP were simulated by a computer model of the passive electrical characteristics of the axon. The model required that the nodal leakage conductance be 5 to 10 times less than values measured from single fibers, that as much as 80% of the radial resistance of the internode be due to the axolemma, and that the electrode create an additional leakage through the myelin. The leak around the electrode accounts for the shorter component of the DAP and increases the amplitude of the longer component of the bid information of the information of the formation of the formation of the DAP are monotonic and much smaller in amplitude. This analysis agrees with the previous study in indicating

that the role of the myelin is chiefly to mask the capacitance of the axolemma, not to provide a resistive shield. We di in attributing the prominence of the DAP to an artefact of We differ recording. In future modeling of saltatory conduction and the effects of demyelination it will be important to take into account the distribution of internodal resistance. 147.29 DEVELOPMENT OF VOLTAGE-DEPENDENT CONDUCTANCES IN CULTURED AMPHI-BIAN SPINAL NEURONS. <u>Diane K. O'Dowd</u>. Department of Biology, UCSD, La Jolla, CA 92093.

The ionic dependence of the action potential (AP) in spinal neurons of <u>Xenopus laevis</u> changes during development both <u>in vivo</u> and <u>in vito</u> (Baccaglini and Spitzer, '77; Spitzer and Lamborghini, '76). Current clamp measurements reveal an AP that is initially long in duration and primarily Ca-dependent. The contribution of Na to the AP increases during development and the contribution of Ca decreases; the mature AP is primarily Na-dependent. This developmental progression could be due to changes in any of several neuronal properties, e.g. Na and Ca inward conductances and outward K-dependent conductances. To understand the molecular bases which underlie the expression of a series of developmentally changing phnotypes it is important to have a quantitative description of the differentiation of these properties. To this end the whole cell voltage clamp technique (Hamill et al., '81) has been used to identify and characterize the ionic conductances in developing spinal neurons.

Dissociated cell cultures are prepared from neural plate stage <u>Xenopus</u> embryos and grown in a defined medium. High resistance seals (5-20 gigohms) are formed between the patch electrode and the cell. A short pulse of suction ruptures the membrane separating the pipet and the cell interior, creating a low resistance pathway between the pipet and the cell. The cell is voltageclamped and internally perfused in this manner. Two inward currents have been isolated in these cells by block-

Two inward currents have been isolated in these cells by blocking outward currents with Cs in the pipet and TEA in the external solution. Na and Ca currents are present at both early and late times in development, and may be separated by ionic substitutions or addition of blocking agents to the external medium. At early times in development (<10 hours in culture), the ratio of peak amplitude Na current to peak amplitude Ca current is  $0.8 \pm .2$ , as compared to  $2.5 \pm .7$  at later times (>30 hours in culture). This data is consistent with the current clamp records previously obtained in which a developmental shift from a primarily Ca-dependent AP to a primarily Na-dependent AP has been documented. The voltage dependence for activation of the Na and Ca currents does not appear to change during this same period of development. The changes in the outward conductances as well as the inward conductances will be discussed as a function of the Na AP (Blair, '83; O'Dowd, '83). The identification of the name (Changes in various conductances will facilitate evaluation of the effects of metabolic inhibitors. Supported by NSF predoctoral fellowship, and NIH grant NS15918 to N.C. Spitzer.

147.30 ELECTRICALLY EXCITABLE MEMBRANE PROPERTIES OF CULTURED MOUSE SPINAL AND SENSORY NEURONS ARE PRESENT EARLY IN DEVELOPMENT. A. MacDermott, Laboratory of Neurophysiology, NINCOS, NIH, Bethesda, MD. 20205

The development of electrically excitable membrane properties in the mammalian CNS has proved difficult to study in vivo. Some of the technical problems have been obviated by culturing embryonic mammalian central neurons. However the small size of the cells ( 15 micron diameter cell bodies) has precluded easy application of conventional intracellular recording techniques, which often damage the cell irreversibly. Recently, another method of studying electrical activity in small-sized cells has evolved following the innovation of patch-clamp recording technique involves first isolating a small patch of surface membrane by forming a tight mechanical and electrical seal between microelectrode and cell, and then carefully rupturing the patch to gain intracellular entry. Such a technique produces a mechanically stable, lowresistance pathway for recording electrical activity in small cells.

This whole cell patch clamp method has been used to study the development of excitale membrane properties in spinal cord and sensory (dorsal root ganglion or DRG) neurons cultured from the embryonic (day 13 gestational age) mouse CNS and grown in mono-culture and coculture. Under these experimental conditions embryonic SC and DRG neurons recorded at various times up to 11 days in culture had relatively high input resistances (0.2-5.0 Gohm) at the level of the resting potential, which ranged from -73m to -45m in the 27 cells studied. (The minimum acceptable seal resistance in these studies was 1 Gohm.) Most neurons studied within two days of culturing exhibited sizable outward currents in response to adequate depolarizing commands from holding potentials of -70mV. These currents were sustained for the duration of the 100msec command and were relatively insensitive to Mn<sup>24</sup>. Some of cells studies exhibited other currents, including transient types of outward current, long-lasting outward tail current, and slowly developing inward current with hyperpolarizing commands. All of these currents have been identified in neurons cultured for much longer periods. The results suggest that many electrically excitable membrane properties develop well before birth in the mouse CNS.

147.31 CURRENT NOISE GENERATED IN PATCH AND WHOLE CELL RECORDINGS OF CULTURED NEURONS DEPENDS ON THE VOLTAGE CLAMP APPLIED. G.D. Lange, A.B. MacDermott, and J.L. Barker, Laboratory of

CD. Large, A.B. MacDermott, and J.L. Barker, Laboratory of Neurophysiology, NINCDS, NIH, Bethesda, MD. 20205 The development of excitable membrane mechanisms in spinal and sensory cells cultured from the embryonic mouse CNS has been studied using several different electrophysiological recording techniques. We are now applying the patch clamp and whole cell clamp techniques (Hamill, et al. 1981), since they are quite useful for studying ion channel mechanisms in small cells. We have also applied the conventional two-electrode voltage clamp in order to compare the properties of current variance generated in patch membrane and whole cells. In addition we have applied these voltage clamp techniques to the pituitary clone GH3/6 since these cells are electrically excitable and constitute a relatively uniform population.

In a typical experiment, a substantial increase in current variance occurred when the patch membrane was ruptured. Whole cell current variance was minimum at resting potential and increased as the membrane potential was shifted in either direction. In both the embryonic neurons and the pituitary cells the spectra from one-electrode recordings were more complex than the spectra from two-electrode recordings. They were not the compound Lorentzian spectra expected from simple two-state channel theory. A broad interpretation of the spectra indicates that there are at least two processes activated on depolarization. Using gated channel terminology, one process has mean lifetimes of 1.5-2.5 msec., while the other is much slower (ca. 15 msec.). The faster component is consistent with the presence of a voltage activated outward current seen with the voltage step method. The slower component is the predominant component of the patch noise. We do not usually see two-state gated channels in the patch records. Therefore this low frequency component may have to be explained in a different way. Comparison of patch and whole cell current variance should contribute to a better understanding of the nature of the relationship between microscopic ion channel activities in patches of membrane and macroscopic conductance mechanisms recorded at the level of the whole cell. 147.32 NEURON LP1 OF <u>HERMISSENDA</u>: ELECTROPHYSIOLOGY AND EFFECTS OF DOPAMINE, 5-HT and cAMP. <u>Jon Jacklet</u>, <u>Juan Acosta-Urquidi and Daniel L. Alkon</u>. Section on Neural Systems, Lab. of Biophysics, NINCDS-NIH, Marine Biological Laboratory, Woods Hole, MA 02543. The giant (200 µm) unpaired pedal neuron, LP1, (Jerussi and Alkon, 1981) has many of the voltage-dependent conductances found in the Type B photoreceptors. Thus, it may provide a model for analysis of biophysical (Acosta-Urquidi et al., <u>Soc. Neurosci. Abstr</u>, 1983) mechanisms underlying long-term conditioning-induced conductance changes (Alkon et al., <u>Science</u>, 1982). It may serve as a model for long-term rhythmic changes also, because it shows two quasi-stable levels of membrane potential. In normal sea water (SW), at its depolarized level (~ -42 mV) spontaneous action potentials (AP), peak to peak amplitude ~ 100

In normal sea water (SW), at its depolarized level ( $\sim -42$  mV) spontaneous action potentials (AP), peak to peak amplitude  $\sim 100$  mV, occur at  $\sim 0.5/S$ . At its hyperpolarized level ( $\sim -62$  mV) the input resistance ( $R_{1n}$ ) is reduced  $\sim 4X$  to  $\sim 10$  MΩ and it is silent. In many preparations, a positive current pulse (1 nA, 1S) will shift the membrane potential from the hyperpolarized to the depolarized level and negative current pulses will shift it to the hyperpolarized level, indicating a delicate balance between the currents responsible for maintaining LP1 at each level. It receives EPSP's and a biphasic PSP (E-ILD), which shifts the membrane to the hyperpolarized level. In 0.1 mM Ca<sup>++</sup> -200 mM Mg<sup>++</sup> ASW the PSP's are abolished but the shifts in potential may still be evoked and often occur spontaneously.

As w the rSr's are abolished but the shifts in potential may still be evoked and often occur spontaneously. APs are largely eliminated in 0 Na<sup>+</sup>SW and completely eliminated by blocking Ca<sup>++</sup> influx with 1 mM Cd<sup>++</sup>-0 Na<sup>+</sup>-SW, indicating mixed Na<sup>+</sup>/Ca<sup>++</sup> APs. AP duration ( $\sim 4-5$  ms at 1/2 amplitude) is broadened ( $\sim 30\%$ ) by conditioning depolarization. 5-HT (1 µM) and 8 BTCAMP (1 mM) cause broadening by 50% or more. Pronounced broadening (> 20 ms) is caused by 4-AP (5 mM), which blocks I<sub>K</sub>, and RO-1724 (1 mM). Unlike 4-AP, which causes broadening starting at the peak of AP, RO-1724 adds an abrupt shoulder (blocked by 1 mM Cd<sup>++</sup> SW) to the AP, which is followed by a large post-AP hyperpolarization, suggesting RO-1724 enhances I<sub>Ca</sub>++ and subsequently I<sub>K</sub>(Ca<sup>++</sup>). These currents may play a role in the observed shifts in membrane level noted above, because RO-1724 can often induce shifts of membrane potential between the depolarized and hyperpolarized levels, staying at each level for 30 S or more.

polarized levels, staying at each level for 30 S or more. Dopamine (10 mM) hyperpolarizes LP1, reduces  $R_{\rm in}$  in SW or Lo Ca<sup>++</sup>-HiMg<sup>++</sup>SW, and under voltage clamp in 0 Na<sup>+</sup> SW causes an increase in I<sub>A</sub> and I<sub>K(late)</sub>. 5-HT (1  $\mu$ M) and 8 BTcAMP (1 mM) depolarize LP1 in SW or LoCa<sup>++</sup>-HiMg<sup>++</sup>SW, and increase impulse activity. Under voltage clamp I<sub>A</sub> and I<sub>K(late)</sub> are reduced by 1  $\mu$ M 5-HT. At 10<sup>-5</sup>M and higher doses more complex changes occur, probably involving Ca<sup>++</sup> as well as K<sup>+</sup> currents.

SINCLF CHANNEL RECORDING OF  $\alpha$ -BUNGAROTOXIN RESISTANT ACETYLCHOLINE CHANNELS IN DISSOCIATED CNS NEURONS OF <u>DROSOPHILA</u>. C.-F. Wu, S.H. Young, and M.A. Tanouye. Dept. of Zoology, Univ. of Towa, Towa City, IA 52242, Dept. of Physiology, Univ. of California, Irvine, CA 92717, and Div. of Biology, California Institute of Technology, 147.33 Pasadena, CA 91125.

High efficiency of acetylcholine synthesis from choline has been shown in larval CNS of Drosophila (Wu et al., 1983, J. Neurochem. 40:1386). We examined acetylcholine-induced currents in dissociated larval CNS cells in culture with the patch clamp techninue. Using fire-polished patch electrode (1 µm opening), seal resistance of greater than 10 G $\Omega$  could be obtained with patches of membrane on intact Type I and Type III cells (Wu et al., 1983, <u>J</u>. <u>Neurosci</u>. in press). A class of channels could be activated only when the electrode was filled with saline containing 10-100 nM when the electrode was filled with saline containing 10-100 mM acetylcholine. The potential inside the patch electrode was held at different levels between -80 to +40 mV. In different patches, the current amplitude was 0.7 to 2.1 pA in outward direction when the membrane potential of the patch was held at 80 mV positive to the resting potential and it became 0.4 to 1.0 pA in inward direction. tion when the membrane potential of the patch was held at 40 mV negative to the resting potential. The current voltage relation of the single channel currents was roughly linear in the voltage range tested, giving a single channel conductance of approximately 9 to 25 pS. Currents reversed at 5-15 mV positive to the resting 9 to 25 pS. potential.

These currents were observed only when the patch electrode contained acetylcholine and persisted when the saline in the bath and in the electrode contained 3  $\mu$ M tetrodotoxin, 25 mM tetra-ethylammonium, 5 mM 4-aminopyridine and 1 mM Cd<sup>++</sup>. Moreover, they were not blocked when the cells were pre-incubated with 50 µg/ml a-bungarotoxin.

The acetylcholine-activated single channel currents displayed relatively rapid kinetics. The mean channel opening time was 2 to 3.5 msec at 20°C, showing little voltage dependency. The opening frequency varied with acetylcholine concentration and exhibited strong tendency of bursting and clustering. These properties contrast with those of voltage sensitive channels such as the K channels observed in these <u>Prosophila</u> neurons. The single K channels showed strong voltage dependency in opening frequency and mean open time but the occurrence of channel opening was random

at a constant holding potential. Supported by grants from NIH NS 18500 and NS 00675 and grant from Chicago Community Trust/Searle Scholars Program.

147.34 SINGLE MUSCIMOL-ACTIVATED ION CHANNELS SHOW VOLTAGE-SENSITIVE KINETICS IN CULTURED MOUSE SPINAL CORD NEURONS. G.A. Redmann, J. Barker and H. Lecar, Laboratories of Neurophysiology and Biophysics, NINCDS, National Institutes of Health, Bethesda, MD. J.L. 20205

Patch clamp recordings were made from the cell bodies of intact Patch clamp recordings were made from the cell bodies of intact neurons cultured for 2-4 weeks from the embryonic mouse spinal cord. The medium in the patch pipette and bathing the cell con-sisted of Hank's Balanced Salt Solution. Micromolar concentra-tions of tetrodotoxin and 20mM tetraethylammonium were routinely included in the solution to suppress voltage-dependent Na<sup>+</sup> and K<sup>+</sup> channels. In most experiments 0.5-2.0 micromolar muscimol, an agonist at GABA receptors coupled to Cl<sup>-</sup> ion channels, was included in the pipette solution to activate ion channels in the patch. Adequate singal-te-poise was obtained when the sealing paten. Adequate signal-to-noise was obtained when the sealing resistance was at least 1 Gohm. Inward-going, all-or-none, pA-sized current jumps were recorded in 16 of 20 patches. Similar events were not seen when muscimol was omitted from the patch pipette solution. The inversion potential of the current jumps pipette solution. The inversion potential of the correct jumps was in the range -40 to -60mV when the potential across the patch membrane was varied, and in the range -10mV to -20mV when the patch potential was altered in conjunction with an intracellular KCl-filled microelectrode used to inject Cl- ions. Presumably, the ionic species carrying most of the inward current-signal is Cl- Kingtia capital of current impos recorded over 50mV to the ionic species carrying most of the inward current-signal is Cl<sup>-</sup>. Kinetic analysis of current jumps recorded over -50mV to -120mV range of membrane potential revealed that in most cells the distribution of open times could be fitted by two exponentials. The two populations of current jumps had time constants of large potentials. Closed times could be described by one or two exponentials in different patches. When two closed time constants were present, the amplitude ratio of the relative numbers of fast to slow events usually differed from that for the open times. The time constant(s) of closed times increased slightly at hyperpolarized potential. ized levels.

These results show that the kinetics of muscimol-activated Cl: ion currents are sensitive to membrane voltage in such a way that ion currents are sensitive to membrane voltage in such a way that at hyperpolarized potentials less charge flows per unit time. This occurs because the rate of channel activation decreases and the rate of channel closure increases. Thus, on average, fewer channels open for less time at hyperpolarized levels. We conclude that the molecular efficacy with which muscimol activates Cl-ion currents is sensitive to membrane voltage. How these results relate to synaptically activated Cl- ion channels remains to be elumidated (supertade by CSINESTOOK 01) We conclude elucidated (Supported by F32NS07044-01).

IONIC CHANNEL DISTRIBUTIONS AND AXON-GLIA INTERACTIONS IN NERVE FIBERS OF THE CRAYFISH. P. shrager, J.G. Starkus,\* M.-V Lo,\* and C. Peracchia.\* Department of Physiology, University of Rochester Medical Center, Rochester, NY 14642. We have studied the influence of the glial cell layer on the ionic microenvironment and on the distribution of ionic channels in giant axons of the crayfish. Dissected'single fibers were voltage-clamped using an axial wire technique. The accumulation or depletion of ions in the periaxonal (Frankenhaeuser-Hodgkin) space was measured from zero-current (reversal) potentials fol-lowing prepulses to activate ionic conductances. This technique quantitatively records concentration changes of the ion under study. During outward K<sup>+</sup> current flow excess K<sup>+</sup> ions accumulate in the periaxonal space, but at a rate far below that expected from the total ionic flux and the measured thickness of the space. At the conclusion of outward current flow the periaxonal K<sup>+</sup> concentration returns to the normal bulk value with a time constant of about 2 ms. The corresponding process in squid axons occurs with kinetics about 25x slower than in the crayfish. The rapid wash-out of periaxonal K<sup>+</sup> in crayfish axons represents a change in driving force that should be reflected in the shape of K<sup>+</sup> tail (repolarizing pulse. We found that at potentials negative to about -40 mV these tail currents generally exhibit two time constants, and may pass through a maximum before approaching a final asymptotic level. The initial rapid phase may in part reflect depletion of excess K<sup>+</sup>. In an attempt to compare the geography of Na<sup>+</sup> channels in the axon membrane with that of K<sup>+</sup> channels was blocked by a brief exposure to tannic acid in the internal perfused and voltage clamped. Inactivation of Na<sup>+</sup> channels was blocked by a brief exposure to tannic acid in the internal perfused and voltage clamped. Inactivation of Na<sup>+</sup> channels were able to demonstrate accumulation and wash-out of excess Na<sup>+</sup> ions in the periaxonal 147.35 IONIC CHANNEL DISTRIBUTIONS AND AXON-GLIA INTERACTIONS IN NERVE

those of K+

We have examined crayfish glial ultrastructure both in thin and extracellular fired traying fracture. Layers of connective tissue and extracellular fluid alternate with thin layers of glial cyto-plasm. A membranous tubular lattice in the adaxonal glial layer communicates with both the periaxonal space and with the first band of connective tissue. These tubules may provide a pathway for rapid diffusion of excess ions from the axon surface. In these neurons, Na<sup>+</sup> and K<sup>+</sup> channels may thus be located preferen-tially in regions of the axon membrane with relatively unre-stricted access to bulk extracellular fluid, regions defined by glial cell structure. Supported by NIH Grant NS-17965.

SPONTANEOUS BURSTING PACEMAKER ACTIVITY IN AN IN VITRO PREPARATION OF THE ELECTROSENSORY LATERAL LINE LOBE (ELLL). W.B. Mathieson, L. Maler, Dept. of Anatomy, University of Ottawa, Ottawa, Ontario KHH 8M5. Tissue slices (300µM) through the ELLL and caudal lo-bes of weakly electric fish (gymnotidae) remained viable for up to 8 hrs in vitro. Extracellular recordings from the pyramidal cell layer revealed spontaneous activity of two characteristic patterns: 1) bursting pacemakers discharging very large bursts typically consisting of several hundred spikes, burst durations of 10 sec and interburst interval of 10 sec; 2) smaller, short inter-val bursting with 2-20 spikes per burst and variable interburst intervals of <lsec. Perfusion with Ca<sup>++</sup>free CSF or Verapamil (100µM) abolished spontaneous activity presumably via blockade of chemical synaptic transmis-sion or direct influence upon Ca<sup>++</sup>flux across dendritic membranes. Atropine (150µM) also blocked spontaneous activity while eserine (5µM) caused a gradual increase in bursting frequency with intermittent paroxysmal dis-charges suggesting muscarinic, cholinergic input may contribute to the bursting behavior. Approximately 50% of bursting pyramidal cells could be driven monosynap-tically by stimulation of their afferent fibers which evoked single action potentials of short latency. (1-5m-147.36 SPONTANEOUS BURSTING PACEMAKER ACTIVITY IN AN IN VITRO of bursting pyramidal cells could be driven monosynap-tically by stimulation of their afferent fibers which evoked single action potentials of short latency (1-5m-sec). At higher frequency stimulation (>20Hz) the phase locked stimulus response was accompanied by inhibition of spontaneous bursting. The other class of neurons re-corded from could not be stimulated but were inhibited from bursting by up to 100%. Nearly all of the units that responded monosynaptically also displayed the large long interval type burst pattern while the non-drivable units displayed small, short interval bursts. After re-cording bursting pacemaker activity, the slices were The second seco

SINGLE CALCIUM-CHANNEL CURRENT MEASUREMENTS FROM BRAIN SYNAPTOSOMES IN PLANAR LIPID BILAYERS. <u>Mark T. Nelson</u>\* (SPON: B.K. Krueger). Dept. of Physiology, University of Maryland School of Medicine, Baltimore, MD 21201 Calcium entering cells through voltage-dependent channels 148.1

activates neurotransmitter release, muscle contraction, and many other physiological processes 1 have been able to incorporate Ca<sup>+</sup>-channels (using Ba<sup>+</sup>, Ca<sup>+</sup>, and Sr<sup>+</sup> as the current carriers) from rat brain synaptosomes (a preparation enriched in pinched-off and resealed presynaptic nerve terminals) into planar lipid bilayers. Synaptosomes were made from rat whole brain and from rat median eminence, an area of the brain rich in nerve terminals. Both single channel currents and macroscopic (channel-ensemble) currents were strongly voltage-dependent.

Figure: Voltage-dependence of single Ca<sup>2+</sup>-channels from synaptosomes. Solution: symmetric 250 mM SrCl, At -120 mV, all channels were closed. Bilayer: PE:PS, 100 Aum dia., 100 Hz.

The voltage across the membrane affected the open time of the channels. However, voltage did not appear to affect single channel conductance. In 250 mM BaCl<sub>2</sub>, CaCl<sub>2</sub>, and SrCl<sub>2</sub>, the single channel conductances were about 10 pS, 5 pS, and 5 pS, respectively, suggesting that relative permeabilities of the channel to Ba:Ca:Sr are 2:1:1. These channels may contribute to voltage-dependent  $Ca^{2^+}$ -influx into presynaptic nerve terminals.

WHOLE-CELL PATCH CLAMP STUDY OF CALCIUM CURRENTS IN ADRENAL CHRO-148.2 MAFFIN CELLS. <u>T. Hoshi</u>\*, J. Rothlein and S. Smith<sup>\*</sup>. Dept. of Physiol. and Dept. of Pharmacol., Yale Univ. Sch. Med., New Haven, CT 06510

Ca<sup>++</sup> influx through voltage-dependent Ca<sup>++</sup> channels regulates many important cellular events, including exocytosis of secretory vesicles. Ca<sup>++</sup> current ( $I_{Ca}$ ) in primary cultures of calf and adult bovine adrenal chromaffin cells was studied using the wholeaddit boying addenai chromaii in cerifs was studied using the white-cell patch clamp technique.  $I_{Ca}$  was separated from other ionic currents by using zero Na<sup>+</sup>, TEA-Asp and/or Cs-Asp in the internal solution. The internal Ca<sup>++</sup> concentration was buffered to 1x10<sup>-0</sup> M with 11 mM EGTA. The peak current magnitudes ranged from 35 pA to 100 pA in 5 mM Ca<sup>++</sup>.  $I_{Ca}$  shows the following four phenomena:

nomena: 1) The internal K channel blockers affects the I-V relation of the peak I<sub>Ca</sub>. When TEA<sup>+</sup> (140 mM) but not Cs<sup>+</sup> was present inside, the peak I<sub>Ca</sub> occurred between -10 and -5 mV. When both TEA (20 mM) and Cs<sup>+</sup> (120 mM) were present inside, the peak I<sub>Ca</sub> occurred between +5 and +10 mV.

2)  $I_{Ca}$  in different cells does not have the same time-course.  $I_{Ca}$  in some cells shows apparent inactivation: the current reached the peak value and then declined to 90 to 95% of the peak value during a 60 msec depolarizing pulse (inactivating type  $I_{Ca}$ ). In other cells, however, no inactivation was observed: the current was still increasing at the end of a 60 msec pulse (non-

inactivating type  $I_{Ca}$ ). 3) The time-course of the  $I_{Ca}$  changes during wash-out in some cells.  $I_{Ca}$  in whole-cell patch-clamped cells has been found to disappear gradually in this preparation and in others (wash-out). disappear gradually in this preparation and in others (wash-out) In our experiments,  $I_{Ca}$  disappeared within 10 to 15 min after achieving the whole-cell configuration when pipettes with 1  $\mu$ m opening were used. In those cells that originally had the non-inactivating type of  $I_{Ca}$ , the time-course of the current changed from the non-inactivating type to the inactivating type during the wash-out.

4) The non-inactivating type of  $I_{Ca}$  facilitates. Two step-depolarization pulses separated by 30 to 40 msec were applied.  $I_{Ca}$  magnitudes in the second pulse were greater than those without  $I_{Ca}$  magnitudes in the second pulse were greater than those without a prepulse when the first pulse potential was more positive than 0 mV. The facilitated  $I_{Ca}$  during the second pulse was of the in-activating type. Facilitation was not observed in cells that already had the inactivating type of  $I_{Ca}$ . Facilitation in this preparation may represent an intrinsic property of  $Ca^{++}$  channels, and could be responsible for synaptic facilitation characterized in parameters.

facilitation observed in neurons.

148.3 MUTATIONAL ALTERATIONS INDICATE CHANGES IN THE Ca2+-CHANNEL STRUCTURE IN <u>PARAMECIUM</u>. Y. Saimi\* and R. D. Hinrichsen\* A. Clark). Lab. of Molecular Biology, Univ. of Wisconsin, Madison, WI 53706 (SPON:

Two of the goals in the genetic dissection of the membrane-excitation process in <u>Paramecium</u> are to identify the channel proteins and to understand their molecular mechanisms. Of the seven ion channels recognized, the  $Ca^{2+}$  channel has been most extensively studied and is known to be inactivated by internal  $Ca^{2+}$  that enters after the channel is concerd by depolariation Ca<sup>2</sup> that enters after the channel is opened by dependent we have virtually isolated the Ca<sup>2+</sup> current by inhibiting the K<sup>-</sup> currents with Cs<sup>-</sup> and TEA<sup>-</sup>. In the wild type, this Ca<sup>2+</sup> current peaks within  $^{5}$  msec and decays to a steady level by  $^{20}$ msec during a long voltage stimulation. This current inactivates exponentially in a voltage-dependent manner; the higher the step, the larger the time constant. The steady level after the inactivation is also dependent on the voltage. Because there is little inactivation of the  $Ba^{2+}$  current through this channel, there is little directly voltage-dependent inactivation.

We have recently isolated eight mutants which have stronger behavioral responses to certain stimuli and found that they behavioral responses to certain stimuli and found that they fall into one complementation group. In such mutants, the inactivation of the  $Ca^{2+}$  current is much slower and less com-plete than that of the wild type. The mutant channels also have a shifted voltage sensitivity (up to 10 mV more negative). Above two changes in the inactivation are not simple parallel shifts Above along the voltage axis. Therefore, the mutations affect at least two properties of the  $Ca^{2+}$  channels: the inactivation and the voltage sensitivity.

We have also found that the slow Ca2+-activated currents of We have also found that the slow  $Ca^{\prime}$ -activated currents of the mutant are much larger than those of the wild type. These currents indicate that there is more internal  $Ca^{\prime}$  in the mutant. Consequently, the poor inactivation of the mutant  $Ca^{2+}$  current cannot be attributed to a mutationally increased  $Ca^{2+}$ -removal mechanism. It appears that the mutation affects the  $Ca^{2+}$ -channel structure or its immediate environment. Supported by NSF BNS - 8216149 and N1H 5-R01-GM-22714 to C

148.4 PROPERTIES OF CALCIUM CHANNELS IN DORSAL ROOT GANGLION CELLS. TRUTERLIES OF CALCIUM CHANNELS IN DURSAL ROOT GANGLION CELLS. Martha C. Nowycky, Bruce P. Bean\*, and Richard W. Tsien\*. Depts. of Neuronatomy and Physiology, Yale Univ. Sch. Med., New Haven, CT 06510, and Dept. of Physiology and Biophysics, Univ. of Iowa, Iowa City, IA 52242. Dorsal root ganglion (DRG) cells were prepared from 8-12 day old chick embryos and aroum in tigour culture culture from 10 and 1

Dorsal root ganglion (DRG) cells were prepared from 8-12 day old chick embryos and grown in tissue culture conditions for a few days to several weeks. Calcium currents were studied using the whole-cell patch clamp technique combined with fluctuation analysis (Hamill et al., 1981; Sigworth, 1980). Non-Ca channel currents were suppressed by: (1) replacing external Na and K with tetraethylammonium, (2) replacing internal K with Cs, (3) including 10 mH EGTA in the internal solution. In the pres-ence of 10 mM Ca, inward currents began to activate at -40 mV, and reached a maximum amplitude at +20 mV; since they were blocked by verapamil and not by TTX, they were taken as calcium channel currents. channel currents.

Noise analysis was used to estimate the number of functional calcium channels (N), single channel current amplitude (i), and probability of channel opening (p). At 0 mV, i was 0.16 pA (n=9) which is slightly larger than the value of i we have obtained which is slightly larger than the value of i we have obtained from rat heart cells in culture (i=0.11, n=12). N was estimated for eight cells. Measuring the cell capacitance and assuming 1  $\mu$ F/cm<sup>-</sup>, we calculated an average Ca channel density of 8.7±2.9 channels/ $\mu$ m<sup>-</sup> (mean ± s.e.m.). Near +20 mV, p reached values between 0.5 and 0.7 in 6 cells. These values are somewhat higher than our estimates of channel density and p in heart cells. A further similarity between calcium channels in DRG cells and is heart cells in the law concentrations of avternel Ca blocked

in heart cells is that low concentrations of external Ca blocked Ba currents. This suggests that the single-file, multi-ion model of calcium channels which has been developed for heart cells

of calcium channels which has been developed for heart cells (Hess & Tsien, this volume) may be applicable to neurons as well. Ca currents in heart cells and DRG cells were strikingly different in their rate of inactivation. In 10 mM Ca, neuronal inward currents did not decay to half during 500 msec pulses. The slow decline was unchanged when Ca was replaced by Ba. In heart cells, inward currents decayed to half within 50 msec; inactivation was greatly slowed by replacing Ca with Ba. These results raise questions about the importance of Ca channel inactivation plays a less important role than Ca-activated K current in terminating Ca action potentials in these cells. cells.

In two preliminary, experiments we found that Ca currents were decreased by (D-Ala<sup>2</sup>,D-Leu<sup>3</sup>)-enkephalin. (Supported by NIH grants NS17868 and HL13306.)

CALCIUM CHANNEL PERMEABILITY TO DIVALENT AND MONOVALENT CATIONS. 148.5

CALCIUM CHANNEL PERMEABILITY TO DIVALENT AND MONOVALENT CATIONS. A MODEL WITH TWO ION BINDING SITES AND ION-ION INTERACTION. P. Hess<sup>\*</sup> and R. W. Tsien<sup>\*</sup> (SPON: R. J. J. Benson). Department of Physiology, Yale University, New Haven, CT<sub>2</sub>06510. Calcium channels select strongly for Ca<sup>\*</sup> but are also capable of transferring ions at rates of millions/sec. To study the mechanism of ion permeation, we recorded Ca channel currents in single heart cells from adult guinea pig ventricles, with suction pipettes for voltage clamp and internal dialysis. Measurements of the reversal potential of the D600-sensitive current ( $E_{rev}$ ) with 10 mM Ba outside and 150 mM monovalent cation inside gave with 10 mM Ba outside and 150 mM monovalent cation inside  $\frac{5}{58}$  the following selectivity sequence for the monovalents: Na > K > Cs. Similarly, with 150 mM Cs inside and various divalent cations outside, measurements of E led to the following sequence: Ca > Sr > Ba >> Mg. External Ca (Ca ) at submillimolar concentrations strongly inhibits Ba currents. In addition, an anomalous mole fraction effect was seen in mixtures where (Ca + Ba ) = 10 mM: the current in the mixtures can be substantially smaller than that in either 10 mM Ca or 10 mM Ba. This is a property of open channels since it holds for unitary Ca channel current as well as for whole-cell current.

These results suggest that Ca channels contain more than one ion binding site. We formulated a single-file energy barrier model for the Ca channel with two internal wells and repulsion between ions in doubly occupied channels. The energy barriers and wells for each ion were adjusted to fit (1) measured reversal and were store each ion were adjusted to itt (1) measured reversal potentials, (2) measured values for elementary currents with only Ca or Ba, (3) behavior in mixtures of Ca and Ba. A satisfac-tory fit to the available data was obtained with the following energy profiles: equal entry and exit barriers for Ca. Sr and Ba but energy wells which increase in depth from Ba to Sr to Ca.

The energy wells. The depret how high the solution of the sol tions.

148.7 \*NITRENDIPINE BINDING TO TWO CALCIUM CHANNEL SUBTYPES IN NOUSE BRAIN, A. de Bruyn Kops", R.B. Rogart", and V. Dzaus". Depts. of Neuroscience and Neuropathology, Children's Hospital and Dept. of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115 (SPON: A. Heller) Tritium-labeled nitrendipine (\*NTP), a new 1,4-

dihydropyridine derivative which has proved to be a potent calcium channel blocker, was used to label binding sites in mouse brain homogenates, and the results compared to those in rat cardiac and smooth muscle homogenates. Other groups have reported high-affinity binding of  $\$  NTP to brain membrane, but the relationship between the NTP binding site and the calcium channel has remained largely unestablished.

Receptor binding studies over the range of 1 - 5 nM yielded biphasic specific \*NTP binding in brain membrane, indicating two distinct populations of receptors for nitrendipine. Non-linear least squares analysis indicated a high-affinity  $K_{\rm d}$  value of 0.3 – 0.5 nM, with a corresponding uptake  $(B_{\rm max})$  of 3 – 10 fmoles/mg wet weight, in approximate agreement with other published reports.

However, in addition to high-affinity \*NTP binding, we observed a substantial component of low-affinity binding sites in brain. As these sites could not be saturated over the \*NTP concentration range (0 - 5 nM) studied, characterization of the low-affinity binding sites depended upon simultaneous analysis --- competitive displacement of \*NTP by unlabeled NTP, and yielded approximate parameters of  $K_d = 40 - 75$  nM and  $B_{max} = 75 - 200$  fmoles/mg wet. 200 fmoles/mg wet.

- 200 tmoles/mg wet. From our studies in rat cardiac and smooth muscle, we have concluded that the high-affinity binding site ( $K_d = 0.25 - 0.5$ nM) corresponded to calcium channels in smooth muscle, while the low-affinity channels ( $K_d = 40 - 75$  nM) corresponded to channels in heart, since the  $K_d$  values were in good agreement with physiological estimates of nitrendipine dose-response effects in these tissues. Comparison with brain data suggests that the reader is responsed predominant calcium channel in brain membrane may correspond with the low-affinity cardiac \*NTP binding site. Physiological studies and flux measurements of nitrendipine effects in nerve tissue will be required to firmly establish correlation between binding sites and physiologically relevant calcium channels.

 $\beta\textsc{-}Adrenergic$  modulation of the number of functional calcium 148.6 B-ADRENERGIC MODULATION OF THE NUMBER OF FUNCTIONAL CALCIUM CHANNELS IN FROG HEART CELLS. <u>B.P. Bean\*, M.C. Nowycky and</u> <u>R.W. Tsien\*</u>. (SPON: T.G. Burrage). Departments of Physiology and Neuroanatomy, Yale University, New Haven, CT 06510, and Department of Physiology & Biophysics, Univ. Iowa, Iowa City, IA COLORNAL CALCIUM CONTRACT STREAM STREAM CONTRACT STREAM S 52242

Adrenergic neurotransmitters control the rhythm and strength Adrenergic neurotransmitters control the rhythm and strength of the heartbeat through a powerful modulatory effect on voltage-gated calcium channels. The mechanism of the increase in Ca conductance at the level of single channel molecules is not entirely clear. The most popular hypothesis, an increase in the number of functional channels (N), has not been demonstrated so far. Studies of unitary Ca channel activity have shown that isoproterenol increases p, the probability of a channel being one (Reuter at a) open (Reuter et al.).

To look for possible changes in N, we studied Ca channel activity in frog ventricular cells with whole-cell recordings (Hamilt et al.). K channel currents were eliminated by external TEA and internal Cs and EGTA. With depolarization to +20 mV in 10 mM Internal of and Doral with depotatization to the form of an of an and Doral sector of  $6.2 \pm 0.6$  (mean  $\pm$  s.e.m., n = 25 cells). Ensemble fluctuation analysis (Sigworth) allowed changes in N and p to be distinguished. Isoproterenol increased variance (var) as well as distinguished. Isoproterenol increased variance (var) as well as mean current (1). When var-I plots were fitted by the parabolic function var=i1-1/N, it appeared that isoproterenol increased N from 7,870  $\pm$  2,410 to 44,480  $\pm$  16,600 and p from 0.46  $\pm$  0.04 to 0.51  $\pm$  0.06 (n=4). Thus, at +20 mV, the predominant change is in N, not p. The unitary current (i) was not significantly changed, in agreement with earlier single channel recordings. Since E was under voltage clamp, and the reversal potential E remained the same, we conclude that isoproterenol leaves single channel conductance  $\tau = i(E + E - E)$  unchanged

the same, we conclude that isoproterenol leaves single channel conductance  $\gamma = i/(E_{rev})$  unchanged. Single channel recordings from cell-attached patches gave re-sults consistent with the fluctuation analysis. Isoproterenol greatly enhanced the mean current, and also strongly increased the maximal number of simultaneous unitary openings. p increased only slightly at +20 mV. However, we found that the  $\beta$ -adrenergic enhancement of Ca channel current was more than twice as big at -40 mV than at +20 mV. Since the number of functional Ca channels is presumably voltage-independent, the implication is that p(-40 mV) more than doubled. One possibility is that the p(V) relationship is merely displaced to more negais that the p(V) relationship is merely displaced to more negative voltages. A disproportionately large increase in Ca channel activity at more negative potentials might be especially important for sympathetic modulation of cardiac pacemaker activity.

148.8 THE BINDING OF NIFEDIPINE TO THE SYNAPTOSOMAL [<sup>3</sup>H]-NITRENIPINE RECEPTOR DOES NOT CORRELATE WITH ITS INTERACTION WITH SYNAPTOSOMAL Ca<sup>4+</sup> CHANNELS. <u>T. Turner<sup>\*</sup> and S.M. Goldin</u>. Dept.of Pharmacology, Harvard Medical School, Boston, MA 02115.

Nifedipine and nitrendipine are dihydropyridine derivatives that are known to block the cardiac voltage-sensitive Ca<sup>++</sup> channel. Saturable binding of  $[^{3}H]$ -nitrendipine to rat brain Channel. Saturate which go ( $\eta$ )-intributing to ( $\eta$ )-intributing to ( $\eta$ ) at birth synaptics somes prepared by the method of Hajos (Brain Res. (1975) 93,485) was observed. The K<sub>D</sub> value obtained was 0.66 nM, with a receptor concentration of 140 fmole/mg protein. By competition for this receptor, the K<sub>1</sub> value for infedipine was determined to be 5.2 nM. These results are in qualitative agreement with the findings of Gould, Murphy and Snyder (PNAS (1982)79,3656) as well as several other laboratories that have studied [3H]-nitrendipine binding to brain tissue.

Under the same conditions as used in the above binding studies,  $^{45}Ca^{++}$  flux into synantosome sensitive Ca<sup>++</sup> channel was detected by a modification of the sensitive Ca<sup>++</sup> channel was detected by a modification of the method of Nachsen and Blaustein (Mol. Pharmacol. (1979)<u>16</u>,579). High levels of external K<sup>+</sup> in the incubation medium (75 mM vs. 5 mM for control) stimulated synaptosomal <sup>45</sup>Ca<sup>++</sup> accumulation 2-3 fold. This flux could be blocked by the Ca<sup>++</sup> channel blocker verapamil (IC<sub>50</sub> ~ 100  $\mu$ M) and by inorganic blockers such as Co<sup>+</sup> (IC<sub>50</sub> = 0.25 mM). However, nifedipine had no significant effect on K<sup>+</sup>-stimulated <sup>45</sup>Ca<sup>++</sup> uptake at concentrations as high as 0.3 mM.

These results indicate that the  $[^{3}H]$ -nitrendipine binding site is not the site that is capable of mediating the blocking effects of dihydropyridines towards this synaptosomal voltage-activated ca<sup>++</sup> channel. This synaptosomal ca<sup>++</sup> channel may be, by pharma-cological criteria, distinct from the cardiac Ca<sup>++</sup> channel. Supported by grants to SMG by the NIH (NS 15236), the McKnight Foundation, and the Searle Scholars Program.

INACTIVATION OF PERSISTENT INWARD CURRENT MEDIATES 148.9 INACTIVATION OF PERSISTENT INWARD CURRENT MEDIATES POST-BURST HYPERPOLARIZATION IN APLYSIA BURSTING PACEMAKER NEURONS. <u>Richard H. Kramer\* and Robert S. Zucker</u> Dept. Physiology-Anatomy, Univ. of Calif., Berkeley, CA 94720 The ionic conductances responsible for endogenous bursting activity in molluscan neurons have been extensively studied. A voltage-dependent Ca<sup>2+</sup> current which is activated well below threshold leads to gradual membrane depolarization. It has been thought that accumulation of intracellular Ca<sup>2+</sup> during the ensuing burst activates Ca<sup>2+</sup>-dependent K<sup>+</sup> current (I<sub>K</sub>(C<sub>a</sub>), which hyperpolarizes the cell and terminates the burst. We report here that the long post-burst hyperpolarization and corresponding slow outward the long post-burst hyperpolarization and corresponding slow outward current under voltage clamp are not due to increased  $I_{K(Ca)}$ , but probably result from a Ca<sup>2+</sup>-induced decrease in a persistent Ca<sup>2+</sup> conductance.

Aplysia abdominal ganglion bursting neurons L2-L6 which had been Appysia addominal ganginon bursting neurons L2-L0 which had been axotomized were used in all experiments. These cells exhibit slow inward and outward tail currents following voltage clamp depolarizations from various holding potentials  $(V_h)$  up to a test potential  $(V_b)$  of four. These currents have similar time courses to the depolarizing afterpotential and after-hyperpolarization which follow depotatizing alterpotential and alter-hyperpotatization which to how spontaneous bursts. The slow outward tail current does not reverse at  $V_h$  between -35 to -90mv. Increasing extracellular [ $K^+$ ] does not decrease the slow outward tail current over this range, although it shifts the reversal potential of currents elicited by intracellular Ca<sup>2+</sup> injection. When these cells are current-clamped below the ca injection, when these cells are current-clamped below the measured  $E_{\rm K}$ , a step depolarization elicits a burst of spikes, followed by a long post-burst hyperpolarization. The slow outward tail current is not decreased by 100mM TEA, although  $I_{\rm K}(\rm Ca)$  elicited by Ca<sup>2+</sup> injection is totally eliminated.

The slow outward tail current is supressed by values of  $V_t$  which result in minimal  $Ca^{2+}$  entry (near  $E_{Ca}$ ) and is blocked by extracellular use of  $Ca^{2+}$  antagonists and by intracellular injection of EGTA. The best hypothesis consistent with these results is that the slow outward tail current and the post-burst hyperpolarization are due to a Ca<sup>2+</sup>-induced decrease in a persistent Ca<sup>2+</sup> current. Supported by NIH grant NS 15114.

TIMED APPEARANCE OF CALCIUM AND POTASSIUM CURRENTS IN STARFISH 148.10 OOCYTES DURING OOCENESIS, W.J. Moody and M.M. Bosma (SPON: M.S. Letinsky). Jerry Lewis Research Center, UCLA, Los Angeles, CA, 90024 and Department of Zoology, University of Washington,

Seattle, WA 98195. Occytes of the starfish, L. hexactis develop in a two-year ogenesis cycle. By July of the second year, occytes have attained 90% of their full size and are held in the female for attained 90% of their full size and are held in the female for 6 - 8 months awaiting meiotic maturation and spawning, which occur immediately before fertilization. Oocytes which have com-pleted oogenesis display action potentials in response to depol-arization, and under voltage-clamp show three major ionic cur-rents: an inward Ca current, a transient outward K current ( A current), and an inwardly rectifying K current. It has been shown previously (Moody & Lansman, PNAS, in press) that when meiotic maturation is carried out in vitro in single oocytes by exposure to the normal hormone l-methyladenine (1-MA), each of these currents is affected. During 1 hour of 1-MA exposure, the Ca current gradually increases in amplitude while both K currents

Ca current gradually increases in amplitude while both K currents are reduced in amplitude. In addition, 1-MA causes a substantial (60%) decrease in total membrane capacitance, probably indicating a decrease in surface area caused by retraction of microvilli. We have now examined the electrical properties and hormone responses of oocytes during the final six months of oogenesis. Full size oocytes studied in July and August were found to have A currents and inwardly rectifying K currents of normal amplitude; membrane capacitance was also similar to that in oocytes which have completed oogenesis (apparent specific capacitance 3.5 uF/cm<sup>2</sup> However, Ca currents were small or completely absent in these oocytes, averaging about 15% of those found at the end of oogene-sis. Furthermore, neither the ionic currents nor the membrane capacitance showed any detectible response to 1-methyladenine. In Sept. - Dec., Ca currents have attained their final amplitude and virtually all oocytes show the characteristic electrophysio-logical changes in response to 1-MA. The appearance of full-size Ca currents and normal hormone responses coincides in time with the migration of the nucleus from a central to a peripheral the migration of the nucleus from a central to a peripheral position within the occyte. We have no evidence for a causal relationship between the appearance of hormone response, the appearance of Ca currents, and nucleus migration at this stage of oogenesis, but it is notable that the earliest detectible effect of hormone application in starfish occytes is a transient increase in cytoplasmic Ca activity, and a major end point of hormone action is the breakdown of the nucleus and the resumption of meiosis.

CALCIUM ACTION POTENTIALS IN PRIMARY SENSORY NEURONS OF 148 11 LAMPREY. J.P. Leonard and W.O. Wickelgren. Dept. of Physiology, University of Colorado Medical School, Denver, Colo. 80262.

LAMPREY. <u>J.P. Leonard and W.O. Wickelgren</u>. Dept. of Physiology, University of Colorado Medical School, Denver, Colo. 80262. Calcium action potentials (CaAPs) recorded from the somata of vertebrate neurons may provide a model for the less accessible calcium influx involved in transmitter release at the nerve terminal. Somatic CaAPs may thus be subject to modulations underlying presynaptic inhibition and facilitation. For these reasons we have pursued the characterization of CaAPs in dorsal cells, primary mechanosensory neurons of the lamprey. CaAPs revealed by K channel blockers in dorsal cells were first described by Bookman and Selzer, 1980 (Soc. for Neurosci. Abstr.). We confirm that Ca<sup>-1</sup> is the curregt carrier for these APs since they are: (1) elicited in 10<sup>-0</sup> M TTX and when all Na<sup>-1</sup> in the bath is replaced by choline or tetraethylammonium (TEA), (2) reversibly blocked by removing Ca<sup>-1</sup> from the saline<sub>2</sub> (3) blocked by Cd<sup>-2</sup> or Co<sup>-1</sup>, and (4) elicited when Ca<sup>-1</sup> is replaced by Ba<sup>+</sup>. In addition, the overshogt of these APs increases 18 mV for a 4 fold rise in external Ca<sup>-1</sup>; the minimum value predicted on the basis of the Nernst equation is 17 mV. The effects of the K channel blockers, TEA and 3,4-diaminopyridine (DAP), were examined. DAP (0.1 mM) caused an increase in AP duration (to 13.4  $\pm$  3.4 ms) which was only slightly greater at 1.0 mM (15.2  $\pm$  1.6) and 5.0 mM (17.9  $\pm$  2.0). TEA caused a large additional increase in duration at 10.0 mM (91.1  $\pm$  14.3 ms) and 15.0 mM (45.9  $\pm$ 13.8) reaching a maximum when all Na is replaced by TEA (478.2  $\pm$  70.3). It is clear that E<sub>+</sub> is a major determinant of a hyperpolarizing afterpotential which follows CaAPs in these cells, since the amplitude of the undershoot varies linearly with the log of external K<sup>+</sup>. Quite often the undershoot is obscured by "process spikes". These potentials resemble somatic CaAPs in the abruptness of repolarization but are only 1/10 as large in amplitude. Although their durations vary, they can be 2-3 times as long as t

148.12 CA<sup>2+</sup> OVERLOAD: ALTERED ELECTRICAL ACTIVITY AND MITOCHONDRIAL ULTRASTRUCTURE IN CULTURED CARDIAC CELLS. M. C. Kitzes\*, L.-H. Liaw\* and M. W. Berns\*. (SPON. H. Koopowitz). Dept. of Develop-mental and Cell Biology, University of California, Irvine, CA 92717.

Cultured neonatal myocardial cells underwent progressive membrane hyperpolarization during continuous exposure to isoprotere-nol (ISO). ISO mediates an increased  $Ca^{2+}$  influx into heart muscle. If excessive, high energy phosphate breakdown and known cellular ultrastructural alterations result. Cultured cells showed similar changes in mitochondrial ultrastructure during the period of altered electrical activity. Continuous exposure of neonatal cultured myocardial cells to ISO (5µM, 10µM, 20µM, 30.M) resulted in consistent, time dependent alterations of spontaneous electrical activity. These changes were: (1) a 30 to 40% increase in discharge frequency for a period of time that varied inversely with ISO concentration. The rate and strength of mechanical contraction increased during this period of augof mechanical constraints in the state of the period of the method discharge frequency. Resting membrane potentials remained at normal levels (ISO 5 $\mu$ m and 10 $\mu$ m) or at slightly hyperpolarized at normal levels (ISO 51m and 101m) or at slightly hyperpolarized levels (ISO 201M and 301M). However, with continued exposure to ISO a subsequent phase of marked and consistent progressive hyperpolarization ensued. As the membrane polarized, the frequency of action potential discharge progressively decreased to below the control frequency. Action potentials showed a marked afterhyperpolarization, and interspike intervals became prolonged. In 45% of the cells the frequency of action potential discharge declined to nearly zero or zero when the resting mem-brane potential had stabilized at a hyperpolarized level. Spontaneous action potentials occurred occasionally and were accompanied by a strong mechanical contraction. In the remaining cells (55%), after the decline in the normal discharge rate, 20 to 25 min of additional exposure to ISO resulted in the development of a bursting pattern of action potential discharge. Discharge of spontaneous action potentials during interburst intervals ceased and interburst intervals became more prolonged as the cells stabilized at a hyperpolarized level. Eventually,

as the cells stabilized at a hyperpolarized level. Eventually, discharge activity ceased entirely. Our concurrent electrophysiological and electron microscopic findings with ISO indicate that prolonged mitochondrial exposure to increased  $[Ca^{2+}]_i$  eventually diminishes their buffering capac-ity due to intramitochondrial  $Ca^{2+}$  overload and impairment of their normal metabolism. The loss of mitochondrial buffering capacity and the increase in  $[Ca^{2+}]_i$  to greater than physiological levels lead to a significant cell hyperpolarization. We propose that the observed polarization may be due to a  $Ca^{2+}$  solutiont that the observed polarization may be due to a  $Ca^{2+}$  activated K<sup>+</sup> conductance. (Supported by NIH RO1 HL 15740.)

149.1 MEMBRANE PROPERTIES OF PRIMARY AFFERENT AXONS: A STUDY BY INTRACELLULAR RECORDING. <u>T. Hashiguchi and A.L. Padjen</u>, Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec and Department of Physiology, Tokyo Medical College, Tokyo 160.

A method was developed to study intracellular potentials from large myelinated axons in dorsal roots of isolated frog spinal cord superfused with normal amphibian Ringer at 14°C (Padjen & Hashiguchi, Can. J. Physiol. Pharmacol. 61 (1983). Using KCl or K sulfate filled microelectrodes, it was found that these axons (conduction velocity > 10 m/s; n > 40) show an unexpected and unreported nonlinearity of their voltage-current curves (V-I; obtained by standard "current-clamp" technique). An outward rectification was present from -90 mV into the depolarizing range of membrane potential (resting membrane potential -75 mV). The V-I relationship was linear from -90 to -150 mV (effective resistance 20-200 M  $\Omega$ ). The longest time constant of a hyperpolarizing electrotonic pritential often exceeded 50 ms. We have modelled these data using standard Hodgkin-Huxley equasions. The non-linear V-I relationship could be fairly well simulated by including parameters of a slow potassium current, recently described in frog nodes (Dubois, J. Physiol. 318 (1981) 297). Although a deactivation of the slow K conductance can contribute to slow charging phase of a hyperpolarizing electrotonic potential, the observed ETP is much slower than the calculated one. Other capacitative components, such as internodal membrane, may be responsible for the slow time course of an electrotonic potential in primary afferents axons (Barrett & Barrett, J. Physiol. 323 (1982) 117). (Supported by MRC.) 149.2 BIOPHYSICAL PROPERTIES OF MEMBRANES FROM DIFFERENT AGE GROUPS OF MICE. W. G. Wood, R. Strong, H. J. Armbrecht\* and R. W. Wise\*. GRECC, VA Med. Ctr., and St. Louis Univ. Sch. of Med., St. Louis, MO 63125.

Changes in membranes (e.g., membrane order, lipid composition) have been suggested to be basic factors in the aging process. These age-related changes in membranes might affect functions such as enzymatic activity, release and uptake of neurotransmitters and receptor binding. The purpose of the experiments reported here was to determine if aging was associated with changes in membrane order as measured by electron spin resonance (ESR) and changes in lipid composition. Synaptic plasma membranes (SPM), brain microsomes and erythrocyte membranes were examined. Membranes were prepared from three different age groups of C57BL/6NNIA male mice (3-5 mo; 11-13 mo; 22-24 mo). For the ESR experiments, membranes were spin labeled with the 5-nitroxide stearic acid spin label. The 5-nitroxide spin label reports the motion of the acyl chains of phospholipids near each surface of the membrane lipid bilayer. SPM and erythrocytes also were labeled with the l6-nitroxide stearic acid spin label that reports motion deeper in the membrane. ESR spectra were recorded at 37°C. Lipid extracts from whole brain homogenate, SPM, brain microsomes and erythrocyte membranes were used for analysis of cholesterol and phospholipid content. Membrane order as measured by the 5-nitroxide spin label. There was a significantly among membranes from the three different age groups. Erythrocyte membranes from the three different age. This increase in cholesterol content with increasing age. This increase was observed for SPM, brain microsomes and whole brain homogenate. Phospholipid content also increased with age for microsomes and SPM. Membrane order did not differ with age using the 5- and 16-nitroxide spin labels. These spin labels report on the membrane order of the bulk lipid environment and represents an average of the fluid and gel phase lipids. Age differences in membrane order of the bulk lipid environment and represents an average of the fluid and gel phase lipids. Age differences in membrane order may be present in specific areas of the membr

Supported by the Medical Research Service of the Veterans Administration and the Geriatric Research, Education and Clinical Center of the VA Medical Center, St. Louis.

149.3 TWO POOLS OF CHOLESTEROL IN ACETYLCHOLINE RECEPTOR-RICH MEMBRANES FROM TORPEDO. W. Liebel\*, L. Firestone\*, L.M. Braswell\*, K.W. <u>Miller</u>\* (SPON: Roger Brett). Departments of Pharmacology and Anaesthesia, Harvard Medical School and Massachusetts General Hospital, Boston, MA 02114.

The local membrane environment of the acetylcholine (ACh) receptor-channel complex may be critical to its physiological function. Since cholesterol is a major constituent of electroplax membrane isolated from <u>Torpedo californica</u>, the role of cholesterol in modulating the functional properties of the receptor was examined by liposome-mediated depletion of receptor-rich membrane fragments. Using small unilamellar phosphotidylcholine (PC) vesicles, incubation conditions were established which allowed cholesterol depletion without phospholipid back exchange or fusion with <u>Torpedo</u> membranes. This was verified using egg PC vesicles with trace algal <sup>14</sup>C-PC(Sp. Act. 1.5 Ci/mmol). Fo Fol-PC vesicles with trace algal 'C-PC(Sp. Act. 1.5 Ci/mmol). Fol-lowing incubation, cholesterol-depleted membranes or suitable controls were separated from liposomes by velocity sedimentation centrifugation on sucrose step gradients. The optimal membrane-liposome incubation conditions (3-hr. with 10-fold excess of liposomes) achieved a maximum of 40% (C:P molar ratio) choles-toral depletion. The versing subscatterol could not be deplete terol depletion. The remaining cholesterol could not be depleted either by longer incubations or multiple sequential depletions, as confirmed both directly by chemical assay and by use of  ${}^{3}\text{H}-$  cholesterol as a radiotracer. This limiting cholesterol depletion was accompanied by a significant alteration in membrane fluidity as measured by electron spin resonance spectroscopy. For example, in one preparation of membranes which had an order For example, in one preparation of membranes which had an order parameter (S) of 0.683  $\pm$  0.002, depletion of 29% of the choles-terol reduced S by 4.7%. This marked structural change was not accompanied by change in any of the measured receptor equili-brium binding parameters ( $K_{2,}$   $n_{H,11}$ ) or kinetics. Recently, Ellena <u>et al.</u> (<u>Biophys. J.</u> 41:205a, 1983) have shown that choles-terol has a four-fold preference for the lipid annulus surroun-ding the ACb receptor relative to the bulk membrane where our ding the ACh receptor, relative to the bulk membrane where our spin probe "reported" from. This is consistant with our observa-tion of two pools of cholesterol, and suggests that there exists a cholesterol-rich region of lipid around the receptor which may serve to buffer it from changes in bulk fluidity. 149.4 DIRECT SPECTROPHOTOMETRIC DETECTION OF CESIUM FLUX IN MEMBRANE VESICLES. STOPPED-FLOW MEASUREMENTS OF ACETYLCHOLINE RECEPTOR-MEDIATED ION FLUX. Jeffrey W. Karpen\* and Elena B. Paquale\* (SPON:G.P. Hess) Section of Biochemistry, Molecular and Cell Biology, Cornell University, 270 Clark Hall, Ithaca New York 14853

A spectrophotometric stopped-flow method to measure ion flux in membrane vesicles in the mesc to min time region has been developed. The technique is based on fluorescence quenching of an entrapped fluorophore (anthracene-1,5-disulfonic acid) by Cs<sup>+</sup>. The method has been applied to the measurement of acetylcholine receptor-mediated ion flux in membrane vesicles prepared from the electric organ of both <u>Electrophorus</u> electricus and <u>Torpedo californica</u>. The method is applicable to any vesicle system in which Cs<sup>+</sup> can substitute for either Na<sup>+</sup> or K<sup>+</sup>. Loading of the vesicles with the fluorescent dye is accomplished using the routine procedure for making the vesicles. Neither the dye-loading procedure nor the presence of Cs<sup>+</sup> changes the permeability of the membrane to ions, allowing ion translocation measurements to be made in the mesc to min time region. The stopped-flow design allows two sequential mixings of solutions. Data obtained with stopped-flow and Cs<sup>+</sup> is idential to data obtained previously using a quench flow technique and  $\frac{86}{7}$  (London) 282:329 (1979)).

 $\frac{(London)}{282} \frac{282}{329} \frac{(1979)}{.}$ The method represents an improvement over two existing techniques for measuring rapid ion flux in membrane vesicles, the quench flow technique (using  $\frac{86}{Nb^+}$ ) and a stopped-flow technique developed previously which utilizes Tl<sup>+</sup> (Moore, H-P.H. & Raftery, M.A. <u>Proc.</u> Matl.Acad.Sci.U.S.A. <u>77</u>:4509 (1980)). The advantages of the present method over quench flow are as follows: (1) Stopped-flow allows measurement of an entire influx curve in one mixing event whereas quench flow allows measurement of only one time point per mixing event. Stopped-flow is therefore more rapid and requires less vesicle preparation. (2) Stopped-flow does not utilize radioactive isotopes and is therefore safer. (3) Stopped-flow data can be recorded and analyzed directly by computer. The advantages of Cs<sup>+</sup> over Tl<sup>+</sup> are that Tl<sup>+</sup> moves through vesicle membranes in a few seconds, has a toxic effect on membrane systems (e.g. Tl<sup>+</sup> makes membranes more permeable to other ions), and TlCl is only sparingly soluble in water. Cs<sup>+</sup> has none of these disadvantages. (Karpen, J.W., Sachs, A.B., Cash, D.J., Pasquale, E.B. & Hess, G.P. (1983) <u>Analyt.Biochem</u>.(in press). PROPERTIES OF EXCITABLE ARTIFICIAL CELLS FROM VARIED 149.5 POLYAMINO ACIDS

S. W. Fox, A. T. Przybylski\*, and R. M. Syren\* NFCR Lab at IMCE, Univ. of Miami, Coral Gables, FL 33134.

Objectives in studying artificial excitable membranes in microspheres assembled from thermal copolyamino acids (proteinoids) are (a) to determine Copolyamino acids (proteinoids) are (a) to determine the minimal molecular requirements for electrical behavior and (b) to explore the relationships between compositions and patterns of the discharges. The question of whether artificial cells can yield electrical properties had been answered affirmatively for thermal copolyamino acids complexed with vegetable lecithin (Ishima et al., BioSystems 13 243, 1981). The spherules display electrical polarization across the membrane (membrane Vegetable lecitinin (Ishima et al., BioSystems <u>13</u> 243, 1981). The spherules display electrical polarization across the membrane (membrane potential), and electrical discharges (oscillations and spiking resembling all-or-none action potentials). Examination by the Hodgkin-Huxley equation shows much similarity to natural cells (Stratten, 12th Ann. Mtg. Soc. for Neurosc., Abstr. 66.12). More recently, similar activities have been observed for proteinoid microspheres devoid of lecithin, some at decreased amplitude (Przybylski, et al., Naturwissenschaften <u>69</u> 561, 1982). The proteinoid itself is known to have lipid quality due to nonpolar sidechains in amino acid residues (Lehninger, <u>Biochemistry</u>, 2nd ed., 1975, p. 1047). Potentials are observed during impalement by microelectrodes containing KCl, and by metallic microelectrodes as well. Electrical activities cease on drying of microspheres, but are recovered on on drying of microspheres, but are recovered on rehydration. The microspheres of proteinoid-only are more

The microspheres of proteinoid-only are more uniform in size and have more regular patterns than those containing lecithin. Since the proteinoid contains flavin and pterin pigments formed by the heating of amino acids (Heinz and Ried, BioSystems 14 33, 1982), the microspheres are sensitive to white or ultraviolet light. A number of characteristic patterns of generation and shape of spike have been found to be repeatable within microspheres from a single type of copolyamino acid, and appear to be distinctive between types. These are being tested to differentiate effects due to pigment or polymer, different polymers, aging, size of spherule, etc. of spherule, etc.

CYANINE VOLTAGE-SENSITIVE DYES RESPOND TO CELLULAR DEPOLARIZA-149.7 CYANINE VULIAGE-SENSITIVE DYES RESPOND TO CELLULAR DEPOLARIZA-TION IN RAT HIPPOCAMPAL SLICES. R.M. Dasheiff and M. Hirvonen\*. Neurology Dept., Univ. of Wisconsin and VAH, Madison, WI 53705. Voltage-sensitive dyes (VSD) provide optical signals to changes in membrane potential. The cyanine VSD are permeant and work by a mechanism involving potential-dependent redistri-bution of the charged dye between the extracellular medium and the inside of the cell. Their response is rapid (sec) and bi-phasic (opposite signals for depolarization and hyperpolariza-tion). The amount of dye entry into rat hippocampal slices phasic (opposite signals for depolarization and hyperpolariza-tion). The amount of dye entry into rat hippocampal slices maintained in vitro is linearly proportional to incubation time, dye concentration in the artificial CSF, and protein con-tent per slice. The rate of dye entry is expressed as fem-tomoles of dye per microgram of protein per micromolar concentration of dye in bath per 10-min incubation (the 10-min period is standard and thus dropped: fm/yg/yM). The dye is extensive form each binnecempal clice by workwing in QEF (ftoW)

period is standard and thus dropped: fm/µg/µM). The dye is extracted from each hippocampal slice by vortexing in 95% EtOH, and quantitated in a spectrophotofluorometer. The RATE of entry of dye into slices depolarized with KCl is linearly related to the calculated Goldman membrane potential (Fig.). Since the cyanine VSD are positively charged, less dye enters a depolarized cell. Independent confirmation of the dye's voltage sensitivity was obtained by depolarizing with 100 µM veratrine (V), blocking this with 1 µM tetrodotoxin (TTX) and causing hyperpolarization with TTX alone: fm/µg/µM ± SEM (n=21), nl 1561±33, V 830±28, V + TTX 1724±37, TTX 1860±90. Valinomycin (1 µM) increased the effect of KCl depolarization. Ouabain induced depolarization: nl 2176±96, ouabain 1686±43 (n= 13, p<.001). Freeze-thawing the slices blocked these effects.

THALLOUS ION INTERACTIONS WITH THE CATION SELECTIVE CHANNEL OF THE SR.J.Fox\* (SPON: S.Hagiwara). Neuroscience Program, B.R.I., U.C.L.A., Los Angeles CA 90024.

Thallous ion was found to permeate the cation selective channel of the sarcoplasmic reticulum selective channel of the sarcoplasmic reticulum (SR channel), and to block current when present in mixtures with other permeant ions. Channel conductance in pure thallium acetate saturates with increasing concentration with a single dissociation constant of 18 mM and a maximum conductance of 60 pS. The permeability ratio  $P_{\rm F}/P_{\rm T1}$  is near 2 over the concentration range .01 M to 1M. These results indicate that only one thallium ion may occupy an SR channel at a time in symmetric thallium salt solutions. solutions.

When thallium is present in mixtures with  $K^+$  or NH 4 in a mole fraction dependent manner. In mixtures with Li<sup>+</sup> more current is found the in a mole fraction dependent manner. In mixtures will, the more current is found than is predicted by the model of Lauger (B.B.A. 311:423-441,1973) using the constants found from single salt solutions. The thallium block can be fit by the equation of Neher (B.B.A. 401:540-544,1975) for thallium block in gramicidin channel.

granicialn channel. The figure shows conductance in mixtures of  $K^+$ and  $T1^+$  at .1 M total salt concentration. The upper curve shows the conductance expected in this mixture without blocking, the lower that expected with thal-lium block. The data points are mean single channel conductance + one standard deviation. conductance \_ one standard deviation.

CATION DISTRIBUTION IN NONMYELINATED NERVE AFFECTED BY LICL AND PHLORETIN. E.L. Roberts, Jr.\* and D.M. Easton (SPON: P. Cancalon). Department of Biology, Florida State University, Tallahassee, FL 32306. Li\* affects nerve excitability as well as synaptic trans-mission. This research examines the distribution of Li\* in it transact approach to phloreting which properties the phase Li<sup>+</sup>-treated nerves exposed to phloretin, which reportedly blocks Na<sup>+</sup>-Li<sup>+</sup> countertransport. The distribution of Na<sup>+</sup> and K<sup>+</sup> was also noted. The olfactory nerve of the gar (Lepisosteus osseus) was used in these experiments. Cation content in the nerve was measured with flame emission spectrophotometry (FES). The tota Li<sup>+</sup> content of nerves soaked in 10 mM LiCl rose from 0 to 14 mM during 2 h. The same nerves gained Na<sup>+</sup> and lost K<sup>+</sup> to the The total L1 content of metres source that the last  $K^+$  to the during 2 h. The same nerves gained Na<sup>+</sup> and lost  $K^+$  to the extent of about 15% when compared to control levels. Increase in Na<sup>+</sup> and decreases in K<sup>+</sup> were also seen when 0.1 mM or more phloretin was present in the absence of Li<sup>+</sup>. While phloretin Increases phloretin was present in the absence of Li<sup>+</sup>. While phloretin concentrations of less than 0.1 mM did not greatly affect Na<sup>+</sup> and K<sup>+</sup> distributions, they did increase the nerve's Li<sup>+</sup> content when 10 mM LiCl was present. In the presence of 0.05 mM phloretin average total nerve Li<sup>+</sup> content increased about 10% from the control level. This result suggests that phloretin blocks Na<sup>+</sup>-Li<sup>+</sup> countertransport in the nerve. However, the rate of efflux of Li<sup>+</sup> from Li<sup>+</sup>-loaded nerves into Na<sup>+</sup>-free solutions was indistinguishable from efflux into control solutions. That result does not support Na<sup>+</sup>-dependent Li<sup>+</sup> efflux from the nerve. Thus, phloretin may block an Li<sup>+</sup> exclusion mechanism other than Na<sup>+</sup>-Li<sup>+</sup> countertransport. (Aided in part by a Grant-in-Aid of Research from Sigma Xi.)

INTRACELLULAR FREE MAGNESIUM IN HELIX ASPERSA NEURONES. 149.9 S.M. Gamiño\* and F.J. Alvarez-Leefmans (SPON: J. Villa-rreal). Department of Neuroscience. CINVESTAV del IPN Apartado Postal 14-740, México 07000,D.F. Cytoplasmic Mg<sup>2+</sup> influence important cellular func-tions. Mg<sup>2+</sup> is an essential co-factor for many intrations. Mg<sup>-1</sup> is an essential co-factor for many intra-cellular enzymes eg. those concerned with glycolisis, respiration and membrane transport. In spite of this, direct measurements of cytoplasmic free Mg concentra-tion ( $[Mg^{2+}]$ ) have been reported for only very few cell types and only recently such measurements have been performed in neurones (Alvarez-Leefmans, F.J., Gawhere the performed in neurones (Alvarez-Leetmans, F.J., Gamiño, S.M. and Rink, T.J. <u>J. Physiol</u>. in the press, 1983). Furthermore, there is evidence in the literature suggesting  $Mg^{2+}$  entry during nervous activity in squid axons. Therefore we thought it would be interesting to see if there is any difference in the basal levels of  $[Mg^{2+}]_i$  between neurones undergoi; spontaneous spike axons. Therefore we thought it would be interesting to see if there is any difference in the basal levels of  $[Mg^{2+}]_i$  between neurones undergoi: g spontaneous spike activity and those which are not spontaneously active.  $Mg^{2+}$ - sensitive microelectrodes (MgSE) having tips  $\leq lum$  were prepared with a liquid sensor based on the neutral ligand ETH-1117 (Lanter, F. et al, <u>Anal. Chem</u>. <u>52</u>: 2400, 1980). This sensor shows significant inter-ference from K<sup>+</sup>. Therefore, measurement of  $[K^+]_i$  is mandatory for adequate calibration of MgSE. Since  $[K^+]_i$ was 91 ± 2.2 mM, MgSE were calibrated in solutions con-taining (mM): K<sup>+</sup>, 91; Na<sup>+</sup>, 7.5; HEPES, 5 (pH=7.5) and variable concentrations of Mg<sup>2+</sup> (0,0.5,1,2,5,10). The bathing solution contained (mM); NaCl, 80; KCl, 4; CaCl<sub>2</sub>, 4.5; MgCl<sub>2</sub>, 5; Na-HEPES, 5; pH 7.5 (21-25°C). The largest cells of the right or the left parietal gan glion were impaled first with a 3M-KCl microelectrode (5-20 M<sub>Ω</sub>) and then the MgSE (15-40 G<sub>Ω</sub>). In 7 neurones which fulfilled stringent criteria for cell viability and electrode performance,  $[Mg^{2+}]_i$  was 0.66 ± .05 mM (mean ± S.E). No distinction was made between spiking and quiescent cells. (Alvarez-Leefmans et al, <u>J.Physiol</u>. in the press). In the present experiments the <u>basal</u>  $[Mg^{2+}]_i$  in 6 quiescent cells was 0.71 ± 0.12 mM (mean ± S.E.; range 0.50-1.29 mM), while that of cells showing sustained bursting activity was 0.80 ± .07 mM (mean ± S.E.; range 0.58 - 1.15 mM; n=8). The difference between the means was not statistically significant. Our data suggests that, even if there is a Mg<sup>2+</sup> entry, these neurones keep their  $[Mg^{2+}]_i$  quite stable.

AFTEREFFECTS OF NERVE IMPULSES ON THRESHOLD OF FROG SCIATIC FIBERS DEPEND ON pH (pCO<sub>2</sub>). <u>Stephen A. Raymond, Richard Roscoe</u>. Brigham and Women's Hospital, Dept. of Anesthesia Research Laboratories, Harvard Medical School, Boston, MA 02115. The dependence of threshold and conduction velocity on impulse activity was studied in excised frog sciatic nerve axons as pH was varied from 6.8 to 8.0. Aftereffects were examined in 2 solutions: Boyle Conway (BC) Ringer buffered with bicarbonate, and frog Ringer (FR) buffered with Hepes. Threshold was measured by adjusting the duration of current pulses delivered through Ag/AgCl electrodes. Individual axons were teased from the nerve Ag/AgCl electrodes. Individual axons were teased from the nerve and recorded (DC) using Ag/AgCl contacts and suction electrodes. The electrodes were located at least 6 cm from the region of stimulation. All experiments were done at  $18^{\circ}$  C. Axons at pH 7.2 are known to show characteristic variations of threshold and conduction velocity following single impulses, short bursts, and maintained repetitive activity. These aftereffects include the relative refractory period, a "superexcitable" phase that reaches

relative refractory period, a "superexcitable" phase that reaches its peak in 20 ms and diminishes over 1 sec, and a phase of "depression" that peaks in several seconds and diminishes over several min (Raymond, J. Physiol. 290:273-303, 1979). <u>Resting Threshold</u>: The firing threshold at "rest", measured by stimulating every 2 seconds, was stable (<1%) for a day or more at control pH 7.2. Lowering pCO<sub>2</sub> in air bubbled through BC solutions raised pH to 8.0. This lowered the resting threshold to as little as 50% of the control level. At pH 6.8, threshold rose to as high as 130% of control. Resting threshold did not change (<1%) with pH in FR buffered with 10mM Hepes adjusted between pH 6 and pH 8 using 1 M NaOH. However, bubbling FR-Hepes with CO, restored dependence of resting threshold on pH.

Afterferfects: In BC Ringer's the extent of depression depended on  $pCO_2$ . For any given rate of firing, depression was less as  $pCO_2$  was reduced (alkalization). No depression occurred in fibers bathed in unbubble FR solution with thepse (pH 6.4 to 8.0). Depression was also absent in BC solutions near pH 8.0.

As  $pCO_2$  was reduced, superexcitability also diminished. In FR with Hepes (over the entire range of pH), and in BC solution (only at high pH), some fibers showed a transient subexcitability in place of the superexcitable phase. A pH dependence existed only when pH was varied by changing

A production of the state of t conduction on the history of firing in nerve axons. This work was supported by USPHS grant 30160.

CO, INDUCED IRREVERSIBLE LOSS OF VOLTAGE-DEPENDENCE AT A RECTIFY-ING ELECTROTONIC SYNAPSE. <u>C. Giaume and H. Korn</u>, (SPON: L. Jacobs) INSERM U261, Institut Pasteur, Paris, France. At the crayfish lateral giant axon (LGA) and giant motor fiber 149.10

(GMF) rectifying synapse, conductance is increased and transmis-sion is bidirectional while the LGA is more positive than the sion is builtectional while the low is more positive that the postsynaptic GMF (Furshpan, E. and Potter, D., J. Physiol., 145: 289, 1959; Giaume, C. and Korn, H., <u>Science</u>, <u>220</u>: 84, 1983). We have examined if this voltage-dependence persists under conditions of reduced junctional permeability by lowering internal pH, (pH), with short  $CO_2$  applications. As expected, this procedure produced complete uncoupling. However, when the cells had recoupled, the synapse had become bidirectional at all levels of polarization. Methods were the same as previously (see ref. above); two microelectrodes, one for current injections and one for voltage recordings, were inserted at each side of the synapse. Resting poten-tials, which normally were  $\simeq -90$  mV and -75 mV in the pre and post fibers, respectively, ( $\Delta V = -18 \stackrel{+}{=} 6$  mV in the five complete experiments used for this report) were monitored continuously and cou-There is a same term were assessed using classical equations. A 2 to 3 minutes exposure of the preparation to CO<sub>2</sub> saturated perfusate induced rapid depolarizations of  $7 \pm 3$  mV in the LGA and  $31 \pm 19$  mV in the GMF, and the junctional resistance (measured with positive pulses injected presynaptically) increased from 1365  $\pm 180$ It is pursue injected high the single that is a set of the set of time, both positive and negative current pulses in the prefiber spread to the postsynaptic element, with k(+) and k(-) reaching  $0.19 \pm 0.03$  and  $0.21 \pm 0.03$ , respectively. This new state of bidi-rectionality was accompanied by a fall of the junctional resistan-ces to steady state values of  $372 \pm 53$  KΩ for R<sub>j</sub>(+) and  $370 \pm 37$ KΩ for R<sub>j</sub>(-), a modification which persisted for over an hour, until the experiment was discontinued. Symmetrical transmission was associated with a nearly complete loss of transjunctional vol-Was associated with a nearly complete loss of transjunctional vol-tage-dependent properties: with reversal of  $\Delta V$  to  $\simeq +35$  mV, R<sub>j</sub>(+) and R<sub>j</sub>(-) were 358  $\pm$  97 K $\Omega$  and 342  $\pm$  58 K $\Omega$ , respectively, while in the controls they were 128  $\pm$  16 K $\Omega$  and 129  $\pm$  29 K $\Omega$ . Acidifi-cation due to the well known effect of CO<sub>2</sub> could be linked to de-pletion of internal Cl<sup>-</sup> in the motor fiber: during exposures, i) high frequency of IPSPs occur spontaneously in this cell and i) the large CO\_-induced depolarization seems to be Cl-dependent. This study shows that prolonged loss of rectification can be induced by brief tissue acidification and that in this system, voltage and pH, may share a common site of action.

150.1 DIFFERENTIAL PROJECTIONS FROM LOCUS COERULEUS TO OLFACTORY BULB AND OLFACTORY TUBERTON'S FROM LOCOS CONDUCTS TO OLFACTORY BUL Solano-Flores\*, O. A. Donatti-Albartán\* and H. U. Aguilar, L. P. Solano-Flores\*, O. A. Donatti-Albartán\* and H. U. Aguilar Baturoni. Departamento de Fisiología, División de Investigación, Facultad de Medicina, U.N.A.M., Apdo-Dostal 70250, 04510-México, D.F. The microiontophoretic administration of horseradish peroxidase (HRP) to the olfactory bulb (OB) or olfactory tubercle (OT) in cats and rats yielded similar results in both species. After an OB HRP-injection ipsilateral and contralateral labelled neurons were seen in the piriform cortex, polymorphic layer of OT, magnocellular preoptic region, lateral hypothalamus, ventromedial hypothalamic nucleus and locus coeruleus (LC). In both species more labelled structures were found after an OT HRP-injection than after an OB HRP-injection. The substantia nigra in rats was more abundantly labelled after an OT injection than after an OB one. In cats the dorsal and the ventral raphe were also labelled. In either species, OT HRP-injections resulted in a highter frequency of LC labelled neurons than after OB injections. These results favor the hypothesis that the OT plays an important role as a relay station for efferent inflow from the brain stem en route to the OB.

150.3 THETA BURSTING NEURONS IN THE NUCLEUS OF THE HORIZONTAL LIMB OF THE DIAGONAL BAND, J.E. Marchand, F. Macrides and Wm. B. Forbes. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

The bursting characteristics of single units in the nucleus of the horizontal limb of the diagonal band (HDB) were studied in paralyzed hamsters which had their normally cyclic nasal airflow paralyzed hamsters which had their normally cyclic nasal airflow interrupted so as to prevent odor-evoked rhythmic activity. The relationship of this bursting activity to rhythmic slow wave acti-vity (RSA) in the main olfactory bulb (MOB) and dorsal hippocampal field CA1, and the responses of HDB units to electrical stimula-tion of the MOB and hippocampus, were analyzed. Units which pro-ject to the MOB were identified using antidromic stimulation (con-stant latency, high frequency following, and collision tests) and unit recording sites were verified using iontophoretic injections of pontamine sky blue. Antidromically driven units in the HDB, as well as units which could not be driven antidromically by MOB stimulation. exhibited periods of rhythmic bursting in the theta stimulation, exhibited periods of rhythmic bursting in the theta band (4 to 12 Hz). During such periods, RSA tended to be present in both the MOB and hippocampal recordings. The rhythmic bursting in the HOB was well correlated with individual cycles of the RSA in the MOB. This rhythmic bursting and olfactory RSA were not in-In the MUB. This rhythmic bursting and olfactory KSA were not in-variably correlated with the hippocampal RSA (e.g., could exhibit a different dominant frequency). Hippocampal stimulation did not elicit antidromic responses in the HDB but often produced suppres-sion of firing and occasionally elicited excitatory responses of variable latency. Thus, theta bursting neurons in the HDB may drive the theta rhythm in the MOB, and this rhythm can be dis-tinguished from the hippocampal theta rhythm but could be modu-lated by the sent-phippocampal system. lated by the septo-hippocampal system. Supported by NIH grants NS12344 and AG00779.

- IN THE VENTROMEDIAL HYPOTHALAMUS OF THE RAT. Y. Sakuma and T. Akaishi<sup>\*</sup>. Dept. of Physiology II, Niigata Univ. Sch. of Med., Niigata 951, Japan. The spatial spread of the extracellular antidromic action potentials was measured in 83 neurons in the ventromedial hypo-

thalamus (VMH) of the ovariectomized, estrogen-treated female rats under urethane anesthesia, following electrical stimulation of the mesencephalic central gray (CG). The positive-negative configuration of the antidromic action potentials throughout the extracellular field suggested that the potentials were generated extracellular field suggested that the potentials were generated predominantly by neuronal soma with simple geometries. The spatial spread of the extracellular field along electrode tracks ranged 25-174 µm at half the maximum spike amplitude. The fre-quency distribution for the field size was distinctively bimodal and could be divided into large and small groups at 85 µm. Antidromic action potentials with larger extracellular fields , had Antidromic action potentials with larger extracellular fields had significantly larger maximum spike amplitude with shorter duration. The pattern of changes in the amplitude of isolated initial segment spikes of the antidromic response across the field were quite different from either of the two types of the extracellular field spread. Therefore, differences in the field size could be associated with neuronal size. A full 55% of the CG projection of the VMH originated from small neurons, which scattered through the ventromedial nucleus (VMH), the retrochiasmatic area and the cell-poor zone between the VMH and the arcuate nucleus.

LARGE AND SMALL GROUPS OF NEURONS WITH MESENCEPHALIC PROJECTIONS

the VNN and the arcuate nucleus. Large neurons were located in the core of the VMN. Taking into account the sampling bias, a much greater proportion of the CG projection may arise from small neurons in the VMH.

Transsynaptic facilitation from the corticomedial amygdala Transsynaptic facilitation from the corticomedial amyggala (AMY) was observed in some cells of either size. Three large neurons were driven antidromically from the AMY as well as from the CG, and were concluded to have simultaneous projections to both sites. The lack of spontaneous activity in nearly all cells prevented analysis of inhibitory effects of AMY stimulation. The lack of systematic difference in the antidromic spike

The lack of systematic difference in the antiformic spike latencies between large and small cells indicated that axonal thickness, which varies directly with the neuronal size and critically affects the conduction velocity, is not the major factor in determining the latency of the responses of VMH neurons factor in determining the latency of the responses of VMM neurons to CG stimulation. Thus, the conduction distance, i.e. the pro-jection path, may be the contributing factor to the different sizes of the neuronal population in the VMH between the male and female rats (Sakuma & Pfaff, <u>Brain Res.</u> 225, 184), which re-sponded to CG stimulation at a particular range of antidromic spike latency.

LATERAL HYPOTHALAMIC - MEDIAL FOREBRAIN BUNDLE NEURONS: RESPONSES 150.4 LAIERAL HIPOINALARIC - MEDIAL FOREBRAIN BUNDLE NEURONS: RESPONSE TO OLFACTORY BULB, TONGUE, AND SCIATIC NERVE STIMULATION. Craig A. Velozo\* and C. Robert Almli. Washington University School of Medicine, St. Louis, Mo. 63110. The lateral hypothalamic-medial forebrain bundle (LH-MFB) area

has been implicated in the regulation of feeding and drinking behaviors via brain damage, stimulation, and electrophysiological research. Electrophysiological studies have revealed that LH-MFB neuronal activity can be modulated by changes in body fluid comneutonal activity can be moduled by changes in body item body to an even position (e.g., offactory, gustatory, tactile, visual). In pre-vious studies (Fisher, R.S. and Almli, C.R. <u>Neuroscience</u> <u>Abstracts</u>, 1979, <u>5</u>, 159.), we have shown that single neurons (LH-MFB) of neonatal rats are responsive to multimodal sensory stimulation (e.g., olfactory, gustatory, tactile, and osmotic). However, as the rat ages, there appears to be a developmental "fine-tuning" of LH-MFB neurons. That is, the proportion of "multimodal" neurons decreases with stimultaneous increases in the proportion of neurons more selectively responsive to a particular sensory system. The purpose of the present study was to systematically evaluate

the degree of sensory convergence-divergence on LH-MFB neurons of adult rats using electrical stimulation of the olfactory bulb. tongue, and sciatic nerve.

Adult male albino rats were anesthelized (Dial-Urethane or Adult male albino rats were anesthelized (Ulal-Urethane or Urethane) and surgically prepared. Stimulation electrodes were placed in the olfactory bulb, on the tongue and on the sciatic nerve. Single pulses and pulse trains were used for electrical stimulation. Extracellular single neuron activity was recorded with glass micropipettes (2-3 M NaCl). In response to stimulation of individual sites (bulb, tongue

or nerve), LH-MFB neurons showed simple and complex changes in activity patterns. In some neurons the response (spikes) was time-locked to the stimulus, while for other neurons, variable forms of spike inhibition were seen. There was no obvious rela-tion between the sensory modality stimulated and the type of LH-MFB neuronal activity change. Analysis of sensory convergence revealed that many LH-MFB neurons were responsive to one or two forms of sensory stimulation, with olfactory bulb and sciatic nerve stimulation being the most effective stimulation sites. These results indicate that many individual LH-MFB neurons of adult rats have their activity modulated by one or more sensory systems, and these results do not appear to be due to the general "activation" qualities of sensory stimulation per se. (Supported by BRSG Grant 5389).

Sakuma and

CYTOARCHITECTURE OF THE MAMMALIAN HYPOTHALAMUS: A REINTERPRETATION 150.5

Joseph N. Riley and Robert Y. Moore, Dept. Neurology, Health Sciences Center, SUNY at Stony Brook, Stony Brook, NY 11794. Traditional descriptions of the anatomical organization of the mammalian hypothalamus have emphasized the apparent diffuse nature of the cytoarchitecture of this important brain region. Whereas a number of hypothalamic functions, both neuroendocrine and autonomic, have been shown to be regulated and controlled precisely, an anatomical basis for this precise regulation has been lacking. The development and exploitation of immunohistochemical methods to characterize selected populations of hypothalamic neurons has provided evidence for anatomically and functionally related neuron groupings that are not apparent in material (e.g., Nissl stains) used for traditional cytoarchitectural analysis. Such studies have suggested that the hypothalamus is more highly organized anatomically than had been suspected. In the present study, we have used a variety of neurohisto-

logical methods to re-examine the cytoarchite. ure of the hypothalamus of adult female Sprague-Dawley rats. Immunohistochemical localization of the protease Cathepsin D (Whitaker et al., Brain Research, 216 (1981) 109) has been of particular value in defin-ing specific neuronal populations in hypothalamus. Series of adjacent sections have been processed by a number of traditional neurohistological and immunohistochemical methods, as well as several variants of these methods developed in this laboratory. Using these procedures, it is evident in our material than an extremely large number of groups of neurons may be defined in hypothalamus using standard cytoarchitectural criteria. Our results to date indicate that the apparent lack of cytoarchitec-tural organization in the hypothalamus is due in part to the extreme complexity of these different neuronal groups and that many of the cytoarchitecturally defined neuronal groups overlap

with other groups, making identification of these groups difficult. These results suggest that a reinterpretation of the anatomi-cal organization of hypothalamus may be warranted. In particular, the view that the neurons of the hypothalamus are organized dif-fusely and are dependent on stochastic processes, rather than specific and highly organized anatomical relationships, may be questioned. Examples of this approach to defining hypothalamic cytoarchitecture will be presented, with particular emphasis on the cytoarchitecture of the mediobasal hypothalamus. Supported by NIH grants NS-16814 and NS-16304.

AFFERENT PROJECTIONS OF THE MEDIODORSAL THALAMUS: 150.6 RETROGRADE COMBINED FLUORESCENT TRACERS AND III, G.F. Alheid y and Clinical IMMUNOHISTOFLUORESCENCE. W.S. Young, of Neurology Dept. of oh Center, Heimer. Dept ence Research and L. Neuroscience Univ. of Virginia,

Neuroscience Research Center, Univ. of Virginia, Charlottesville, VA 22908. The concept of a ventral striatal and pallidal system in parallel to the classic striatal-pallidal system has recently parallel to the classic striatal-pallidal system has recently been proposed and studied (Heimer and Wilson, in <u>Golgi</u> <u>Centennial Symposium: Perspectives in Neurobiology</u>, 1975; Heimer, et al., Neuroscience 7:1891, 1982). The mediodorsal n. of the thalamus (MD) is envisioned as a ventral pallidal outflow target. This possible projection to the MD as well as others have been studied using fluorescent retrograde tracers in combination with immunohistochemistry. Male Sprague-Dawley rats (110-160g) had injections of 50 nl of Fast Blue (FB), Granular Blue (GB), or a red "SITS" (courtesy Dr. Swanson; by mass spectroscopy, no disodium SITS is present. Authentic yellow disodium SITS (Schmued and Swanson, Brain Res. 249:137, 1982) does not transport.) into the MD or adjacent tissues. Some animals received 50-100ug colchicine intraventricularly 48 Some animals received 50-100ug colchicine intraventricularly 48 hrs. prior to sacrifice. Antisera directed against glutamic acid decarboxylase (GAD) was used to define ventral pallidal regions in FITC staining. Other antisera directed against met-enkephalin (ME), substance P(SP), neurotensin(NT), and cholecystokinin(CCK) were also used in this study. Tracer-positive cells in the frontal pole split into two

groups caudally: one capping the claustrum and one in the dorsomedial cingulate cortex. Approximately 30-40% were found contralaterally. Frequent cells were seen in the ipsilateral deep piring of the series were seen in the ipsilateral deep piring of these were NT-positive. In the tubercle, cells occurred in areas of GAD-positivity (ventral pallidum) only, both in association with Islands of Calleja and in deep polymorph layer. Rarely, cells were also GAD-positive. More frequently, simultaneous GAD- and tracer-positive fibers were observed. Less often, ME costained fibers were seen. Tracer-positive cells were also found in the globus pallidus, both limbs of the diagonal band, medial forebrain bundle, lateral hypothalamic area, amygdala, and thalamic reticular n. Cacasional cells were observed in these contralateral areas (except amygdala). No CCK or SP double-labelled cells or processes were observed. NT double-labelled cells and processes also were seen in the vertical limb of the diagonal band and medial ventral pallidum. Supported in part by NIH grant R NS1774303.

150.7 A RE-INVESTIGATION OF MAMMILLARY NUCLEI AXON COLLATERALS BY MEANS OF FLUORESCENT TRACERS AND TRANSNUCLEAR TRANSPORT OF WGA-HRP. D.A. Hopkins, G.V. Allen<sup>\*</sup> and Y. Takeuchi. Dept. of Anatomy, Dalhousie University, Halifax, N.S., B3H 4H7 and Hiroshima University, Hiroshima, Japan. Considerable effort has been directed towards understanding the

organization of mammillary nuclei projections to the thalamus and brain stem. In addition, the mammillary nuclei have frequently been used as a model system to study lesion effects and axonal transport. However, because of the small size of the mammillary nuclei and the existence of ascending and descending axon collat-erals, many details of the connectivity of the nuclei remain unclear and it is uncertain to what extent this lack of

information affects their use as a model system. In the present study the connections of the mammillary nuclei have been re-investigated using fluorescent tracers (Fast Blue, True Blue, Nuclear Yellow) and the transnuclear transport of wheat germ agglutinin-horseradish peroxidase conjugate (WGA-HRP) in the rat. Stereotaxic injections of fluorescent tracers were made singly or in combination into the thalamus and tegmentum and WGA-HRP was injected into the thalamus or tegmentum. After survival periods of 20 hrs to 3 days, the animals were perfused and the brains were processed according to standard procedures.

The most striking finding was that after either thalamic or tegmental injections of each of the fluorescent tracers and WGA-HRP, all ipsilateral subdivisions of the mammillary nuclei were heavily retrogradely labeled. After tegmental injections the labeling in the medial and lateral magnocellular parts of the mammillary nuclei was somewhat stronger than that in the subdivisions containing small cells. Double labeling after combined thalamic and tegmental injections was most evident in the magnocellular subdivisions. Double labeling could also be discerned in the small cells but the intense nuclear labeling by transported Nuclear Yellow tended to obscure Fast Blue labeling of the scanty cytoplasm of the small cells. The transnuclear transport of WGA-HRP demonstrated that not only do all subdivisions of the mammillary nuclei send collaterals to both thalamus and tegmentum but also that these collaterals have an extremely well-organized topographical projection. The medial mammillary nuclei project topographically with very little overlap to the ventral tegmental nucleus. The present results also suggest that under certain conditions double labeling experiments with fluorescent tracers may not account for all of the collaterals of a given nucleus. Supported by MRC of Canada, the Killam Foundation and Dalhousie Medical Research Foundation.

DIRECT PROJECTIONS FROM THE BRAINSTEM INTO ANTERIOR THALAMIC 150.8 NUCLEI OF THE RAT. <u>R.W. Sikes and B.A. Vogt</u>. Department of Anatomy, Boston University School of Medicine, Boston, MA 02118.

The anterior thalamic nuclei(ATN), a prominent group in the mammalian dorsal thalamus, projects to much of limbic cortex, particularly the medial cingulate cortex. It has long been recognized that afferents to the ATN originate in the mamillary nucleus of the hypothalamus. While direct afferents from the brainstem have been reported, no thorough investigation has examined the origins of the midbrain input.

To clarify these projections, small injections(0.02  $\mu l)$  of horseradish peroxidase conjugated to wheat germ agglutinin (HRP; 5%) were placed into the ATN in albino and hooded rats. Swy were placed into the AIM in abbino and nooded fats. In several animals, the overlying somatosensory and hippocampal cortices were removed for direct visualization and injection of the ATN. This approach obviated the problem of diffusion of HRP into these cortical regions. The injections involved all subdivisions of the ATN with limited spread into adjacent struc-tures cure are the ctric metallargie intralaginar media and region. tures such as the stria medullaris, intralaminar nuclei and rostral lateral nuclei.

In addition to previously reported afferents from the mamillary nuclei and layer VI of cingulate cortex (areas 24 and 29), labeled neurons were found in several nuclei of the brainstem. These nuclei included the pretectum, central gray, laterodorsal tegmentum, raphé, locus coeruleus, and the cuniform and lateral divisions of the mesencephalic reticular formation.

Although the function of these projections is not known, it is interesting that several of these nuclei receive sensory visceral projections from the caudal medulla (solitary and vagal nuclei) through the dorsal longitudinal fasciculus. Therefore, these projections may provide a direct route through which visceral sensations reach the ATN in addition to the projection relayed in the mamillary nucleus. Since the cingulate cortex contains many neurons which are responsive to autonomic activity, the projections described in this study may provide the morphological basis for these responses. This study was supported by NIH grants NS18745 and T32N07152.

SEX DIFFERENCES OF OPIATE RECEPTORS IN THE PREOPTIC SEXUALLY DIMORPHIC NUCLEUS. <u>Ronald P. Hammer, Jr</u>., Laboratory of Neurophy-siology, NIMH, Bethesda, <u>MD 20205</u> 150.9

The sexually dimorphic nucleus of the medial preoptic area (SDN-FOA) in the rat is a cell-dense region which is larger in males than in females. Recent neurochemical studies have shown a catecholamine innervation in the SDN-POA, particularly in the fe-male (Anat. Rec. 1983, 205: 187A), as well as neurotensin, substance P, and cholecystokini immunoreactive cells and fibers in both sexes (<u>Anat. Rec</u>. 1983, 205: 210A). The present autoradiographic study examines the density of opiate receptors in the region of the SDN-POA.

Cryostat-cut, slide-mounted sections through the region from cryoscat-cut, since-mounted sections through the region from six male and nine female (three females each in proestrus, estrus, and diestrus) brains were incubated in  $[{}^{3}\text{H}]$ naloxone, fixed in paraformaldehyde vapors, defatted in xylene, and exposed to  $[{}^{3}\text{H}]$ sensitive x-ray film. The autoradiographs were digitized and analyzed using a computer-sected in graph reduction when analyzed using a computer-assisted image processing system. The optical densities of the left and right receptor-dense SDN-POA regions and the adjacent portion of POA located laterally were regions and the adjacent portion of POA located laterally were determined, as were the areas of receptor-dense SDN-POA regions on both sides. The ratio of the optical density of SDN-POA to adjacent POA was calculated for each side in every section. Comparison of optical density ratios failed to show any dif-ference between sides in any group. In addition, no significant difference was observed between optical density ratios obtained from female brains in various estrous states. However, the SDN-DO//DOA to the state of POA/POA optical density ratio in males was significantly less than FOATON optical density fails in males was significantly less than in females (1.06 vs. 1.20, p < 0.001). Mean of areal measurements of the receptor-dense SDN-POA region in sections from males was significantly greater than that of females (0.119 mm<sup>2</sup> vs. 0.091 mm<sup>2</sup>, p < 0.001). The size of the receptor-dense region appeared to be larger than the cell-dense SDN-POA nuclear region in both sexes. Within the receptor-dense region, a gradient of labeling seems to exist, especially in females. Naloxone binding appears denser medially in the central core of the nucleus, and less dense laterally. The receptor-dense nuclear region is surrounded by a zone of low receptor density.

In summary, the SDN-POA in the female rat contains a greater density of opiate receptors than the SDN-POA in the male rat. This receptor-rich region is smaller in the female. The sex difference of oplate receptor density in the SDN-POA could relate to func-tional differences in this region between the sexes. Endogenous oplates acting in the SDN-POA could be involved in the regulation of lordosis in the female rat via oplatergic pathways from this region to the mesencephalic central gray substance.

THE SEXUALLY DIMORPHIC NUCLEUS OF THE PREOPTIC AREA (SDN-POA): 150.10

THE SEXUALLY DIMORPHIC NUCLEUS OF THE PREOPTIC AREA (SDN-POA): ULTRASTRUCTURE. <u>H.-Dieter Dellmann\* and Carol D. Jacobson</u> Dept. Vet. Anatomy, Iowa State Univ., Ames, IA 50011. The SDN-POA is a morphological marker of the process of central nervous system sexual differentiation. Since the fine structure of SDN-POA neurons and surrounding neurons in the medial preoptic area (MPOA) has not been described, the present study was conducted. The fine structure of SDN-POA and MPOA neurons in the adult male and female Sprague-Dawley rat are similar. Using 5% glutaraldehyde fixation, three basic neuron types are present: TYPE I, II and III. 74.7% of the neurons are TYPE I (mean area (X), 131.26,m<sup>2</sup>). Their nuclei (X, 53.18,m<sup>2</sup>) have sparse amounts of chromatin. The cytoplasm has few polyribosomes, and rER composed of long, branching, isolated or grouped cisternae. Either elongated, flat or short, curved stacks of cisternae associated with electron-lucent, dense core and coated vesicles comprise the Golgi complex. Lyssoomes, multivesicular bodies (MVB) and autophagic vacuoles (AV) together with mitochondria may form massive accumulations in the perikaryon or at the site of dendrite origin. Synapses may contain oblong electron-lucent vesicles, synaptic vesicles and/or dense core vesicles in varying proportions. 22.5% of the neurons are TYPE II (X, 104.18,µm<sup>2</sup>) with densely packed polyribosomes located between short, stacked, parallel and dilated cisterne of rFR. The electron-dense nuclei (X, 39.84,µm<sup>2</sup>) have multiple deep indentations. These neurons are TYPE II NEURONS are often deeply indented by synapses, large dendrites or glial perikarya gr processes. 2.7% of the neurons are TYPE III (somal X, 77.64,µm<sup>2</sup>; nuclear X, 29.20,µm<sup>2</sup>). They possess the same organelles as TYPE III NEURONS. Howver, the density is decreased. These neurons lack surface indentations as well as dendritic and glial contacts. There is a statistically significant difference in both the area of the neuronal cell body and of the nucleus for the No. 5-367 from March of Dimes Birth Defects Foundation (CDJ).

150.11 ESTROGEN-CONCENTRATING NEURONS IN THE MEDIAL PREOPTIC AREA SEND AXONS TO THE VENTRAL TEGMENTAL AREA AND AMYGDALA. S.E. Fahrbach, J.I. Morrell and D.W. Pfaff. Neurobiology and Behavior, The Rockefeller University, New York, NY 10021. The medial preoptic area (MPOA) has been shown by steroid auto-

radiography to contain large numbers of estradiol (E2)-concentrating neurons. Estrogen action on the MPOA facilitates maternal behavior in the rat, and knife cuts placed lateral to MPOA abolish this behavior. Using a method combining steroid autoradiography and fluorescent dye retrograde tracing, we asked if estrogen acts directly on any long-projection neurons of the MPOA. Microinjections of the fluorescent dyes DAPI, true blue, or granular blue were made into the ventral tegmental area (n=6), into the VTA and the midbrain central gray (n=2), or into the amygdala (n=6), known targets of MPOA neurons. After 2-3 days the rats (ovariectomized, adrenalectomized, 3 month old females) were given an i.p. injec-tion of a nuclear-saturating dose of 2,4,6,7-[3H]-estradiol (0.8 µg/250 g body weight; specific activity 151 Ci/mM) and after 2 hr perfused. Brains were frozen onto cryostat chucks; 6 and 12 µm sections were picked up onto dry emulsion-coated slides. 12 µm sections were picked up onto dry emulsion-coated sildes. The autoradiograms were developed after 2-6 months, and examined under standard bright-field conditions for nuclear silver grains and with UV light for somal fluorescent dye label. The pattern of cells labeled after retrograde transport from the VTA and amygdala was similar to that reported using HRP, but

labeled cells were more numerous than previously described. The combined method demonstrated that some cells in MPOA which send fibers to VTA also concentrate E2. The greatest number of double labeled cells was found in the caudal MPOA/anterior hypothalamic region at the level of the anterior pole of suprachiasmatic nucle-us. Scattered dye-labeled, E2-concentrating cells were also found in the lateral preoptic area and lateral hypothalamus, regions which project strongly to the VTA but contain few E2-concentrating neurons. By contrast, very few double labeled cells were seen in the bed nucleus of the stria terminalis, a region which concen-trates E<sub>2</sub> heavily and sends fibers to VTA. After amygdala injec-tions, double labeled cells were also seen but the pattern was not where located most of the dye-labeled,  $E_2$ -concentrating cells seen were located more rostrally in the MPOA. Thus, a subset of the  $E_2$ -concentrating cells of the MPOA have long axonal projections, and a subset of the MPOA neurons which project to VTA and to the amygdala are  $E_2$ -concentrating. We hypothesize that these neurons, which may be under genomic control by  $E_2$ , are involved in the control of estrogen-dependent maternal behavior in the rat. This does not exclude a role for the many  ${\rm E}_2{\rm -concentrating}$  neurons in the MPOA which have specific connections not revealed in these studies.

150.12 EFFERENT CONNECTIONS OF THE DORSAL TEGMENTAL REGION IN THE RAT. H.J. Groenewegen, N.W. Kowall\* and W.J.H. Nauta. Dept. of Anatomy, Vrije Universiteit, Amsterdam, and Dept. of Psychology, M.I.T., Cambridge, MA 02139.

The term dorsal tegmental region (DTR) here denotes the caudal central grey substance comprising the dorsal tegmental nucleus of Gudden and the nucleus tegmenti dorsalis lateralis. Earlier stud-ies have shown that DTR receives massive projections from lateral habenular (HL), interpeduncular (IP) and mammillary nuclei. Th abstract summarizes efferent connections of DTR demonstrated by This autoradiography or immunohistochemistry, using, respectively, tritiated amino acids and the lectin phaseolus vulgaris. Unilateral injections in DTR (not involving locus coeruleus)

elicit dense fiber labeling in contralateral DTR. Farther rostral-ly, the aqueduct is flanked by labeled fibers which extend to the posterior hypothalamic nucleus and deep layers of the superior colliculus (SC). However, the main projection ascending from DTR is represented by two other fiber systems: one (a) tracing a largely contralateral, paramedian course rostroventrally through the median raphe nucleus, the other (b) composed of slender, main-ly ipsilateral arcuate fascicles curving widely through the tegmentum, then returning to a paramedian position at the base as main component of the mammillary peduncle (MP). Midbrain strucmain component of the mammillary peduncle (MP). Midbrain struc-tures invaded by <u>b</u> include the peripeduncular region, deep lay-ers of SC, and both lateral-geniculate nuclei. Both <u>a</u> and <u>b</u> inner-vate the ventral tegmental area and IP. In IP, DTR efferents distribute most densely to contralateral subnuclei dorsalis parvo-cellularis, dorsalis granulocellularis, and lateralis. Rostral to IP, fiber labeling is mainly ipsilateral. Very dense terminal label fills the lateral mammillary nucleus (MB), but other labeled MP fibers bypass MB as components of the medial forebrain bundle (MER) to the supra- and premembilary nuclei lateral preontico-(MFB) to the supra- and premammillary nuclei, lateral preoptico-hypothalamic region, dorsal hypothalamic area, medial amygdaloid nucleus, nucleus of the diagonal band, medial and lateral septal nuclei, hippocampus, and frontocingulate cortex. Further labeled DTR efferents deviate from MFB dorsalward, 1. alongside the fasciculus retroflexus to the HL, parafascicular nucleus, and pre-tectal area, and 2. along the mammillothalamic tract to the thalamic nuclei reuniens, gelatinosus, centralis medius , centralis lateralis, periventricularis anterior, anteroventralis and lateralis dorsalis.

These findings indicate that DTR, caudal pole of the 'limbic midbrain area', can affect widespread forebrain regions either directly, or indirectly through the supramammillary and diagonalband nuclei which both project to extensive neo- and allocortical regions (Saper, 1981). Supported by the Dutch Organization ZWO and NSF grant BNS80-07905.

150.13 INTRACELLULAR RECORDINGS FROM TEMPERATURE-SENSITIVE SEPTAL AND HYPOTHALAMIC NEURONS. M.N. Perlmutter and J.A. Boulant (SPON: J. Curry). Dept. of Physiology, Ohio State University, Columbus, Ohio 43210.

Certain neurons within the diencephalon are notably sensi-tive to their own local temperature. These cells are believed to function as central thermoreceptors which are responsible for the control of body temperature. To investigate the mechanisms by which individual neurons may act as central thermodetectors, intracellular potentials were recorded from temperature-sensitive and temperature-insensitive neurons in the septal, preoptic and anterior hypothalamic nuclei of anesthetized male Sprague Dawley rats. Conventional intracellular recording techniques were employed using electrodes filled with 2M potassium citrate. Brain temperature was manipulated between 32-42°C by a water perfused thermode and was monitored by a fine thermocouple positioned near the recording site.

Previous extracellular studies suggest that neuronal warm-sensitivity can be maintained in the absence of synaptic input, whereas neuronal cold-sensitivity was dependent on excitatory and inhibitory synaptic input. The results of this study tend to support these findings. Warm-sensitive neurons were characterized by a significant increase in the number of subthreshold and threshold depolarizations at warmer local brain temperatures. Eighty percent of these warm cells displayed long summated depolarizations with trains of action potentials; and summated depolarizations with trains of action potentials, and there was little evidence of inhibitory synaptic input at any temperature. Cold-sensitive neurons were characterized by a significant decrease in the amount of subthreshold and threshold depolarizations at warmer local brain temperatures; and in-hibitory synaptic input was more prevalent at warmer temperatures. In most cold-sensitive cells the action potential amplitude varied inversely with brain temperature. A prominent depolarizing after-potential was common in 40% of the cold-sensitive cells. Temperature-insensitive neurons displayed a variety of electrical activity, however, in no case did the frequency or amplitude of either subthreshold or threshold activity change as a function of local brain temperature. (Supported in part by NIH grant NS - 14644 and by a Grant-in-Aid from the American Heart Association.)

CORTICAL AND SUBCORTICAL AFFERENTS TO THE PERIRHINAL CORTEX (AREA 150.14

35) IN THE RAT. K. C. KOSEL, G. W. VAN HOESEN and D. L. ROSENE. Dept. of Anatomy, Boston University, Boston, MA 02118 and Dept. of Anatomy and Neurology, University of Iowa, Iowa City, IA 52242. In the rat, the perirhinal cortex (area 35) begins in the depths of the rhinal sulcus and expands ventrolaterally for a short distance forming a narrow strip of cortex along the lateral bank of the sulcus. Previous studies in the rat have tended to focus solely on the efferent connections of the area, and have demonstrated a limited series of projections to the molecular layer of the subiculum, to all lamina and subdivisions of the entorhinal cortex, and to layer I of the contralateral perirhinal cortex. Despite the fact that considerable information now exits regarding these projections, little information is available in the literature on the afferent input to area 35. Most of the findings that have been reported to date have come from studies involving pri-

In an attempt to demonstrate the source of afferent input to the perirhinal cortex, small injections of horseradish peroxidase (HRP: 0.02-0.06µl of a 10% solution), were made throughout area 35. Following a 24-48 hour survival, the animals were sacrificed and the tissue prepared for HRP histochemistry using conventional histological methods and tetramethyl benzidine as chromagen.

In the cortex, retrogradely labeled cells were observed in the anterior most parts of the ipsilateral frontal sulcal (insular) cortex following injections in the ventral part of area 35 and in both the anterior and posterior portions of the ipsilateral pre-piriform cortex (layer II). Labeled cells were also present in the contralateral perirhinal cortex and indicated the existence of a topographically organized commissural connection between the cortices of the two hemispheres. Subcortically, retrogradely labeled cells were present ipsilaterally in the nucleus reuniens of the thalamus, the ventral claustrum and in the lateral and laterobasal nuclei of the amygdala. Both the nucleus basalis and the septal nuclei were negative. Finally, labeled cells were also observed in layer II of the medial, and layers II and III of the lateral entorhinal cortices, with a lesser number in the ventral subiculum and parasubiculum. The results of the present study demonstrate the existence of a

number of cortical and subcortical projections to the perirhinal cortex in the rat. In view of the strong efferent projections of area 35 to the entorhinal cortex and subjculum, it is plausible that the perirhinal cortex may represent an alternative route for information transfer to the hippocampal formation. (Supported by NH grants NS 14944 to G.W.VH. and NS 19416 to D.L.R.)

150.15 POSTERIOR CORTICAL ABLATIONS IN THE RAT AT 1, 7, 30, or 70 DAYS AFTER BIRTH AND PERFORMANCE ON THE MAIER 3-TABLE REASONING PROBLEM. J. M. Stahl, V. L. Stroud\*, R. A. Wingate\*, and G. C. Daniels\*. Dept. of Psychology, Morris Brown College, Atlanta University Center, Atlanta, GA 30314.

Ninety six male and female Long-Evans hooded rats received unilateral or bilateral posterior cortical abla-tions or merely had the skull lifted (operated control) at either 1, 7, 30, or 70 days following birth. At 90 days of age subjects were tested on the Maier 3-table days of age subjects were tested on the mater 3-tabil-reasoning problem which was developed to test the abil-ity of the rat to combine the essentials of 2 isolated past experiences to reach a goal (Maier, 1929). Studies have indicated that the process involved in solving this problem is different than that involved in learning tasks problem is different than that involved in learning tasks which depend upon the association of contiguous events (Campbell, 1935; Maier, 1932, 1940) and is one that is not demonstrated in rats until they reach about 60 days of age (Stahl and Ellen, 1979). Performance on this task is impaired by cortical (Maier, 1932), septal (Stahl and Ellen, 1973), and hippocampal damage (Rabe and Haddad, 1969). Thus, the purpose of this study was to investi-gate the age-dependency of recovery of function on a task which requires an ability which is age-dependent in Long-Evans hooded rats. Results clearly showed that rats receiving large cortical ablations (usually bilat-eral) at any age made significantly fewer correct choices on the Maier 3-table problem than did animals which re-ceived sham surgery at the same age or smaller lesions on the Maier 3-table problem than did animals which re-ceived sham surgery at the same age or smaller lesions (usually unilateral) at 1, 7, or 30 days of age. His-tological data showed that a significant amount of hip-pocampal damage occurred in animals which received the larger ablations at 1 or 7 days of age and subsequently did not perform well on the task. Thus, results indi-cated that the amount of cortical tissue damaged at any case is the determining forter in functional receiver. age is the determining factor in functional recovery and that no functional sparing follows even minor hip-pocampal damage at any age. Supported by an NIMH grant through the Minority Biomedical Research Support Grant Program.

ORIGIN OF PROJECTIONS TO THE SUPRACALLOSAL 150.16

ANTERIOR CINGULATE CORTEX (AREA 24) OF THE RABBIT. <u>M. L. Woodruff and R. H. Baisden</u>. Dept. of Anatomy, Quillen-Dishner Col. of Med., East Tenn. State Univ., Johnson City, TN 37614.

As an adjunct to studies of the function of the cingulatecortex in behavior, the subcortical and cortical projections to area 24 were studied in the New Zealand rabbit using retrograde HRP labeling. Thalamic projections to the retrosplenial-cingular (areas 23 and 29) regions in the rabbit have been demonstrated using both retrograde cell body degeneration (J. Rose and Woolsey, J. Comp. Neurol., 89:279, 1948) and retrograde enzyme transport approaches (Berger et al., Brain Res., 201:411, 1980), but apparently only the retrograde degeneration approach has been employed to study the source of afferents to area 24 in the rabbit (Rose and Woolsey, 1948). Horseradish peroxidase was injected into area 24 in 5 rabbits. Approximately 48 hr after the injection the brains were removed, sectioned at 50u, and the sections were processed following the cobalt chloride modification of Adams (Neurosci., 2:141, 1977) which produces an enhanced HRP reaction product. Microscopic examination of the reacted sections revealed that, with the exception of contralateral homotypic sites, labeled neuronal soma were found only ipsilateral to the injection. Labeled cortical cells were found predominately in layer 3 (although some were present in layer 5), of areas 32, 4, 29d the dorsal part of 29c. Of the thalamic nuclei containing labeled cells, the heaviest concentration was observed in the 4. 29d and ventral anterior and anteromedial nuclei. Many labeled cells were also present in the centromedial nucleus and in the rhomboid and reuniens nuclei. Fewer labeled cells were found in the dorsomedial nucleus. Additional labeled cells were also observed in the nucleus of the diagonal band, the lateral part of the medial hypothalamus, the midbrain tegmentum medial to the cerebral peduncle, and in the central tegmentum of the pons.

These results agree with the above cited degeneration subject results agree with the above ortical adgeneration subcortical areas projecting to area 24. Comparison of these results to similar studies in other species (e.g. cat, Robertson and Kaitz, J. <u>Comp. Neurol.</u>, 195:501, 1981; monkey, Baleydier and Maguiere, <u>Brain</u>, 103:525, 1980) indicate some species differences in origin of afferents to area 24. 150.17 SEPTAL UNIT ACTIVITY IN PAVLOVIAN CONDITIONING: A REGIONAL COMPARISON. <u>E. Thomas and E. Yadin</u>. Department of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010 and Isotope Department, The Weizmann Institute of Science, Rehovot 76100, Israel.

Unit activity was recorded from the ventral medial septal region of the rat during Pavlovian conditioning and was compared to our previous data obtained from the dorsal lateral septum. Unit activity was assessed under three Pavlovian paradigms, 1)food US with the animals satiated, 2) food US with the animals deprived and 3) shock US.

Male Wistar rats were implanted with fine nickel chromium wires 62.5 micrometers in diameter, enamel insulated to the tip. Recordings were made either via a monopolar derivation with the indifferent electrode attached to a stainless steel screw on the skull or via a bipolar derivation with both electrodes in the active site. All of the paradigms were differential conditioning in which one stimulus (either a tone or a light) was paired with the US and the other was presented unpair. I with the US. The CS-US interval was 10 sec. For appetitive conditioning a 1 mA footshock. Unit activity was evaluated separately for CS+ and CS-. The results were as follows:

results were as follows: 1. Good appetitive conditioning was obtained both under the deprived and the satiated conditions and the sweet chocolate milk was also able to maintain good rates of lever-pressing in the satiated animals suggesting that the hedonic properties of the US could support both Pavlovian conditioning and instrumental performance in the absence of drive.

2. In the appetitive paradigm unit activity was suppressed in the presence of CS+ compared to an equivalent baseline period. There was no consistent change in unit activity in the presence of CS-. This effect was seen both under the deprived condition and under the satiated condition, suggesting that the activity change is not related to drive, but more likely to the hedonic properties of the US.

3. In the aversive paradigm, increased activity was seen in the presence of CS+ and slightly decreased activity in the presence of CS-.

These results are virtually the opposite of those we have seen in previous experiments where the electrodes were in the anterior dorsal lateral septum. We propose a possible division within the septal region regarding the mediation of positive and negative hedonic states.

This research was performed at The Weizmann Institute of Science.

- 150.18 MECHANISMS SUBSERVING SEPTAL AREA MODULATION OF AGGRESSIVE BEHAVIOR. M.Brutus, M.B.Shaikh, H.E. Siegel and A. Siegel.
  - Dept. of Neuroscience, University of Medicine & Dentistry of N.J.-New Jersey Medical School, Newark, New Jersey 07103.

We previously demonstrated that the septal area is capable of modulating hypothalamically-elicited quiet biting attack behavior in the cat (Siegel & Skog, Br. Res., 23: 371, 1970). The present study was undertaken as part of our ongoing analysis of the mechanisms underlying limbic system control of aggressive behavior. We specifically wished to determine: (1) whether stimulation of septal sites previously shown to modulate attack could modify the trigeminal sensory fields which are essential for its occurrence, and (2) the neural pathways that are activated following stimulation of septal area modulating sites utilizing  ${}^{14}\text{C}-2\text{-deoxyglucose}$  autoradiography.

Under aseptic conditions, moveable stimulating electrodes were stereotaxically implanted into the hypothalamus from which quiet attack could be elicited and into the septal area and adjacent regions from which modulation of this response could be achieved. Following identification of a modulating site, we determined the extent of the lipline, which after probing, could elicit a jaw-opening response during stimulation of the hypothalamus alone or during concurrent stimulation of the hypothalamus plus septal area. In the final aspect of the experiment,  $^{14}\text{C-2-DC}$  was injected systemically and septal stimulation was applied for 45 min., applying a regimen of 30 sec. on and 30 sec. off. Brains were removed and processed for autoradiography.

We observed that stimulation of 18 septal area sites which significantly suppressed quiet attack also constricted either the ipsilateral or contralateral trigeminal sensory fields. However, septal stimulation did not alter the latency for jaw-opening responses. The autoradiography indicates that septal stimulation results in intense labeling of the diagonal band nuclei and hippocampal formation and less intense labeling of the preopticohypothalamus and prelimbic cortex.

The results suggest that the septal area modulates attack behavior, in part, by regulating the effective trigeminal sensory fields, utilizing a pathway which supplies the nuclei of the diagonal band.

(Supported by N.I.H. Grant NS 07941-14 and by a grant from the Harry Frank Guggenheim Foundation).

150.19 PERFORMANCE ON A LATERALIZED VISUAL DISCRIMINATION FOLLOWING NEGLECT PRODUCING UNILATERAL LATERAL HYPOTHALAMIC LESIONS IN RATS. J. E. Ackil\* and C. P. Frommer. Dept. of Psychology, Western Illinois Univ., Macomb, IL 61455 and Indiana Univ., Bloomington, IN 47405.

Several behavioral mechanisms have been proposed to account for the contralateral "neglect" that follows unilateral lateral hypothalamic lesions (LH). Hoyman et al. (Physiol. Behav., 1979, 22, 139) used a lateralized tactile discrimination to show that neglect is associated with a deficit in making responses contralateral to the lesion. We here use that design with visual discriminative stimuli (SD), which permit accurate measurement of duration of observing and latency of responding.

Twelve adult male albino rats were trained to make an observing nose poke response at a hole in the front of a small, flat black painted chamber. This turned on a green LED located just below the rat's left or right eye level. Half the rats learned to make instrumental nose poke responses in a side hole on the same side as the SD (TT group) to get water reinforcement there; half had to respond at the side hole on the side opposite to the SD (TA Group). They were also tested for turning and visual and tactile orienting. When a rat learned the discrimination ( $\leq$  4 errors on two consecutive 32-trial days), it was anesthetized with ether and received 20 sec of 2 mA anodal current through a stainless steel electrode previously implanted in LH. The rats were retested for orienting and turning and were retrained on the discrimination. Terminal anatomical verification showed that the lesions were centered in LH at the level of the ventromedial nucleus.

Both TT and TA Groups showed deficits in visual and tactile orienting and turning contralateral to the lesion. They also showed a 3X decrease in correct responses contralateral to the lesion and a 7X increase in ipsilateral incorrect responses, regardless of whether the SD was contralateral (TT) or ipsilateral (TA) to the lesion. Both groups observed the SD for contralateral responding longer than the SD for ipsilateral (TT) or was ipsilateral (TA) to the lesion. The TT Group made ipsilateral responses faster than the infrequent contralateral responses. The TA Group made both ipsilateral and (rare) contralateral correct responses faster than incorrect responses. The TT Group sometimes made correct contralateral responses and then turned to the ipsilateral hole before the programmed water reinforcement arrived. For technical reasons the TA Group could not show this behavior.

Almost all the data can be interpreted as a deficit in initiating instrumental responses directed contralateral to the lesion. The remaining data suggest that the SD could trigger automatic responses organized low in the neuraxis. 150.20 OLFACTORY CONTEXT, SPONTANEOUS ALTERNATION, SOCIAL COHESION AND SEPTAL LESIONS IN MICE. <u>M. Widmayer-York\*, C.R. Goodlett, T. Moy\*, R.G. Burright\*, and P.J. Donovick</u>. Dept. of Psychology and Center for Neurobehavioral Sciences, SUNY Binghamton, N.Y. 13901. A number of behavioral changes are associated with lesions of septal nuclei. Some of these changes have been reduced or even eliminated as a result of specific manipulations in either the training or testing environment. In a T-maze over clean bedding, group housed rats with septal lesions typically fail to spontaneously alternate between the two choice arms, preferring one arm far more than the other. However, when the testing environment is altered by placing the T-maze over the rat's home cage litter shavings, lesioned animals show spontaneous alternation comparable to that of controls. The cues from the shavings apparently minimize the perseverative deficit related to the septal damage. Familiarity and social stimuli provided by the home cage shavings have been suggested as mediators of this effect.

have been suggested as mediators of this effect. Experiment 1 was designed to demonstrate the septal spontaneous alternation effect in mice. Heterogeneous male mice 90-120 days of age were given either bilateral septal lesions or control surgery. Half of the mice from each surgical condition were given 5 consecutive trials in a T-maze over clean shavings and the remaining half over home shavings. These mice displayed the same effects noted for rats; that is, there was a lesion x test condition interaction, with controls alternating more frequently than septals when tested over clean shavings, but with no difference over home shavings. If the effect of home cage shavings on rats with septal lesions is mediated by the social aspects of the home shavings, one would expect differential responses of septals and controls to situations involving direct social contact. Several investigators have shown an increase in social cohesion in rats with septal lesions, with fever reports for mice.

in rats with septal lesions, with fewer reports for mice. Experiment 2 examined social cohesiveness in mice. Intact male mice, individually housed 1 week prior to and throughout testing were placed in pairs in an open field and social behavior was recorded. Half of the pairs then received bilateral septal lesions and half control surgery. The same pairs were retested again in the open field, pairing septals with septals and controls with controls. While the social interactions of controls remained relatively stable from pre- to post-surgical testing, septally damaged mice initially showed a marked increase in social contact post operatively. These results suggest that social cues have a different impact on lesioned animals and may be responsible for the lesion x environment effects seen in spontaneous alternation testing over clean or soiled shavings.

LABELING KNIFE CUTS USED TO LOCATE THE CELLS OF ORIGIN OF AXONS 150.21 LABELING KNIFE CUTS USED TO LOCATE THE CELLS OF ORIGIN OF AXONS NECESSARY FOR LORDOSIS BEHAVIOR. C. W. Scouten and C. W. Malsbury Dept. of Psych., Mem. Univ. of Newfoundland, St. Johns, NF, A183X9 One of the oost serious difficulties with using lesions or knife cuts to study localization of function is that, while it is possible to describe the size and location of the zone of necrosis around the lesion, this may be only the tip of the iceberg in terms of the total damage done. Most regions of the brain, es-pecially the diencephalon and brainstem, are crossed by axons from nerve other ports of the brain, when come locions in an area area many other parts of the brain. When some lesions in an area are effective and some are not, as is usually the case, it is fre-quently impossible to distinguish consistent differences in the

quently impossible to distinguish consistent differences in the lesion size or location that would explain the behavioral outcome. We have dried a small amount of HRP on the .005" blade of a retractable wire knife (Labeling knife cut technique: Scouten et al, Br. Res. Bull, 1982) prior to making unilateral hypothalamic cuts about 2.5 mm long in a sagittal plane lateral and adjacent to the MFB at the level of the supraopt.c commissures. In female hamsters, these cuts usually cause a severe deficit in lordosis in resonce to struking of the contralateral but not the insilateral response to stroking of the contralateral but not the ipsilateral flank (Ostrowski et al., Physiol. Behav., 1981). Each female was tested for such a lateralized deficit and sacrificed 5 days post surgery. The brains were reacted with TMB to visualize HRP transported by the cut axons.

Damage was even more extensive than expected. An average of 80 cell groups per brain contained cells labeled with HRP reaction product. However, all but two of these cell groups can be ruled out as the source of the axons whose destruction produces the lat-eralized deficit. This is either because they were not labeled in brains of some females which displayed the deficit, or labeled as densely in the brains of some females which did not display a lateralized deficit as in the brains of females which display a lateralized deficit as in the brains of females which did. The 2 areas in which cell labeling was related to the behav-ioral deficit were the posterior pretectal area and the deep la-yers of the superior colliculus. The posterior pretectal area has not previously been implicated in the control of lordosis. Les-ions of the deep layers of the superior colliculus block lordosis in hamsters (Muntz et al, 1980). This area contains numerous cells that respond to lordosis-inducing stimuli (Rose, 1982). The ventromedial nucleus (VMN) of the hypothalamus mediates a facilitation of lordosis by gonadal steroids. The VMN sends axons laterally through the plane of our cuts, and contained HRP labeled cells in all of our animals with behavioral deficits. However,

s in all of our animals with behavioral deficits. However, VMN contained similar numbers of labeled cells in the brains cells the VMN contained similar numbers of labeled cells in the brains of 5 of the 7 females which showed no lordosis deficits. We conclude that cutting the VMN lateral efferents alone is not sufficient to produce the lateralized lordosis deficits observed. Supported by grant #MH35599 to C.W.M.

NUTRITIONAL AND PRENATAL FACTORS IN DEVELOPMENT I

EFFECTS OF DIETARY PHOSPHATIDYLCHOLINE SUPPLEMENTATION ON 151.1 SENSORIMOTOR BEHAVIOR AND BRAIN BIOCHEMISTRY IN THE RAT, J.M. Bell\*, and P.Lundberg. (SPON: T.Slotkin) Dept. of Psychology, Washington Univ., St. Louis, Mo. 63130

Washington Univ., St. Louis, Mo. 63130 Research has shown that dietary administration of the acetyl-choline (Ach) precursor, choline, produces elevations in Ach. This precursor approach to elevate brain Ach levels has largely used massive acute doses of either choline chloride or phospha-tidylcholine (PC) in the adult. Thus, the purpose of the present investigation was to examine the effects of low level chronic PC exposure on choline acetyltransferase (CAT) activity levels, as well as a variety of behavioral and sensorimotor tasks in the developing and young rat. Prior to breeding, during gestation and lactation dams were

maintained on control (C), 2% PC enriched (2% PC), or 5% PC enriched (5% PC) diets. After weaning, offspring were maintained on their respective diets (control, 2% PC PRE/POST, 5% PC PRE/ POST), or placed on the control diet (2% PC PRE, 5% PC PRE). Pups were sacrificed at various ages and either whole brain or forebrain sections were frozen for biochemical analysis.

Preweaning results indicated that animals receiving the 5% PC enriched diet weighed more, took longer to right, and showed delays in swimming development. Postweaning activity measures showed that animals exposed to PC enrichment the longest (2% PC PRE/POST, 5% PC PRE/POST) reared less in an open field situation, and emitted fewer stabilimeter counts than other animals. Rats exposed to 5% PC (PRE/POST) also had weaker neurological respon-ses (placing and hopping) than other dietary conditions. Animals receiving long term 2% PC (PRE/POST) enrichment showed attenuated analgesia in a tail flick test, 60 and 90 minutes following morphine injection. Brain/body weight ratios were significantly reduced in animals receiving both 2% and 5% PC enrichment during preweaning life. CAT activity levels were also elevated in all animals receiving dietary PC enrichment by 42 days of age.

These data suggest dietary PC enrichment does influence off-spring reflexive and sensorimotor behavior. Moreover, the extent of the effect was greater in those animals who received either high or long term dietary supplementation. These early effects may not be persistent. Although the question remains as to whether chronic low level dietary PC enrichment can modify later emerging cholinergic deficits, the evidence presented here implies that long term, low level PC supplementation may be necessary to effect such changes, and that there are some immediate consequences of this enrichment if begun in early life.

151.2 DIFFERENCES IN PERINATAL SODIUM CHLORIDE INTAKE PRODUCE DIFFERENCES IN PERINATAL SODIUM CHLUKIDE INTAKE INCOME PERSISTENT CHANGES IN FLUID CONSUMPTION OF ADULT RATS. Edythe (SDON: Christie Sahley). Yale Univ.,

PERSISTENT CHANGES IN FLUID CONSUMPTION OF ADULT RATS. <u>Edythe</u> <u>Bird\* & Robert J. Contreras</u> (SPON: Christie Sahley). Yale Univ. Dept. of Psychol., New Haven, CT 06520 To examine further the effects of early salt intake on body weight and fluid balance, nine adult female rats were maintained on a diet containing either 0.12% (low), 1.0% (mid), or 3.0% (high) sodium chloride (NaCl) throughout pregnancy and lactation. At parturition, litters were culled to eight pups (approximately a male of 4 female) on mathematic the remainer on market. At parturition, litters were culled to eight pups (approximately 4 male and 4 female) per mother; the remaining pups were decapi-tated to obtain blood samples. This resulted in 15 males and 9 females in the low salt group, 14 males and 9 females in the mid salt group, and 13 males and 11 females in the high salt group. The offspring were weaned on day 22 but were continued on these same diets until 30 days postpartum. Thereafter for the duration of the experiment all the offspring were maintained on the mid (12) calt diat (1%) salt diet.

(1%) salt diet. At birth, the body weights and serum sodium levels of the off-spring were linearly related to dietary sodium content (males: low-6.11+.10g, mid-6.42+.17g, high-6.69+.14g; females: low-5.39 +.15g, mid-5.90+.17g, high-6.08+.14g). At weaning and at 30 days of age, both the low and high salt animals were lighter than the mids. Despite these differences, dietary salt had only an immediate effect on body weight; during maintenance on the control diet between 30 and 200 days of age, neither the body weights nor the rates of weight gain of the animals differed. Several assessments of fluid intake were made beginning at 90 days of age, including (1) measurements of 24-hr water intake, urine volume, and urine electrolyte levels, and (2) two-bottle preference tests between dejonized distilled water and one of two

urine volume, and urine electrolyte levels, and (2) two-bottle preference tests between deionized distilled water and one of two test solutions, 0.1M glucose and 0.3M NaCl. The low salt males showed greater fluid intakes and urinary sodium levels, and lower preferences for NaCl. The high salt males showed lower fluid intakes, greater urinary sodium levels, and greater preferences for NaCl. These effects were not, however, evident in females. We suggest that early consumption of a diet either low or high in NaCl suggest that early consumption of a diet either low or high

We suggest that early consumption of a diet either low or nign in NaCl causes the male offspring to respond as if the set point for osmoregulation has changed. Although this was not investiga-ted, the sex differences may be accounted for by (1) hormonal influences on fluid intake of female rats, (2) the greater suscep-tibility of male rats to environmental influences, or (3) sexual dimorphism of brain areas thought to be involved in water regulation.

NUTRITIONAL TAURINE DEFICIENCY IN THE CAT RESULTS IN RETARDED DE-151.3 VELOPMENT OF THE OFFSPRING. J. A. Sturman, H. S. Rowe\*, and R. C. Moretz\*. New York State Institute for Basic Research in Developmental Disabilities, Staten Island, New York 10314.

Taurine is an essential amino acid for cats, and if not supplied in the diet, they become taurine depleted and suffer reti-nal and tapetum degeneration. Nursing cats supply the kittens with all of their nutrition, including taurine, which comprises the major portion of the free amino acid pool of cat's milk, pre-sumably to supply this great need during development. We have examined the effect of nutritional taurine on the development of kittens in the following ways: depriving the mother of taurine for a long period of time (prior to conception); depriving the mother for a few days prior to birth; and orally supplementing the kit-tens with taurine after birth. These procedures allow the effects of taurine depletion to be examined during the whole developmental period (prenatal plus postnatal), and the prenatal and post-natal effects to be separately dissected out.

The prenatal effects are considerable, resulting in reduced growth and development of the fetuses, including malformations, and a high incidence of abortions and stillbirths. All of these consequences are associated with severely reduced tissue taurine concentrations. Postnatally, taurine deficiency results in re-duced overall growth including reduced brain growth. The cerebellum is particularly affected by nutritional taurine deficiency, having a greater growth retardation than other areas of the brain. having a greater growth retardation than other areas of the brai This growth retardation appears to be associated with a delayed migration of cerebellar granule cells. These kittens have also decreased hind limb muscle control, and easily visible kyphosco-liosis. Taurine-depleted kittens also suffer from degenerating and disorganized photoreceptors, retinal ganglion cells, and tapetal cells.

These preliminary results suggest that taurine is involved in the normal migration of cerebellar granule cells, and that a deficiency during development may retard this process and lead to a cascade of abnormalities. This constellation of signs and sym-ptoms in taurine deficient kittens resembles many of those seen in the human disease, Freidreich's Ataxia.

## 151.5 PRENATAL STRESS REDUCES HIPPOCAMPAL BENZODIAZEPINE BINDING SITES

AND ABILITY TO FUNCTION IN STRESSFUL CONDITIONS AT ADULTHOOD. E. Fride<sup>\*</sup>, M. Gavish<sup>\*</sup> and M. Weinstock<sup>\*</sup> (Spon: European Neuroscience Association). Depts. of Pharmacology, Hebrew University-Hadassah Medical School, Jerusalem and Rappaport Family Research Institute, Faculty of Medicine, Technion, Haifa,

Prenatal stress has been found to influence several behaviors of Prenatal stress has been found to influence several behaviors of the offspring as adults. Exposure of adult rats to a stressful situation has been shown to reduce the number of benzodiazepine (Bz) binding sites. In the present study we investigated the hypothesis, that prenatal stress may interfere with the development of the septo-hippocampal system, thereby impairing the ability to cope with stressful situations in adult life. Rats were exposed to noise (100 db) and flashing lights on a random Were exposed to holse (100 and flashing lights on a fandom basis, for 4 hour periods, 3 times a week throughout pregnancy. Pregnant controls were left undisturbed. The female offspring were mated at the age of 6-8 weeks and maternal behavior was assessed when their pups were 4-5 days old. 7 pups of each litter were separated from the mother in the home cage by a barrier and were separated from the mother in the home cage by a barrier and alley of 60x10 cm. The time taken for each mother to return all pups to the home cage was determined twice: under normal conditions and during stressful conditions in which the mother had to pass through an air stream in order to retrieve the pups. Under control conditions, both prenatally stressed (PS) and control (C) mothers retrieved all pups within 5 min. However, when stressed, only 50% (11/21) of the PS mothers retrieved their pups within 15 min, as opposed to 96% (26/27) of the C mothers  $(v_{c}^{-12} = 0, c(0, 001)$ (χ<sup>2</sup>=12.9; p<0.001).

The no. of specific binding sites for  $^{3}\mathrm{H}\mathchar`-flunitrazepam$  in the hippocampus of the female PS and C rats was measured at the age of 3 months. The PS offspring exhibited a significant decrease The Bmax (from 660 to 385 fmol/mg protein) with no change in k<sub>d</sub> (1.5 nM). We conclude from these results that prenatal stress reduces the number of Bz binding sites and causes a permanent alteration in hippocampal function in the female offspring. This is associated with an impaired ability to function under stressful conditions.

151.4 PRENATAL EXPOSURE TO DRUGS OF ABUSE IN HUMANS: EFFECTS ON

PRENATAL EXPOSURE TO DRUGS OF ABUSE IN HUMANS: EFFECTS ON PLACENTAL NEUROTRANSMITTER RECEPTORS Y. May, B.D. Perry, P.H. Kussie\*, D.J. Pesavento\*, S.H. Schnoll\*, and D.C. U'Prichard Depts. Pharmacology Obstetrics and Gynecology, and Psychiatry, Northwestern Univ. Med. Sch., Chicago, IL 60611 Recently the concept of behavioral teratology has evolved (e.g. Vorhees et al, Science 205: 1220, 1979). In animal models, prenatal exposure to low doses of psychotropics (e.g., methadone, diazepam) results in abnormal development of behavior. Furthermore, in animals, pre- and perinatal exposure to psychoactive drugs results in altered brain neurochemistry (e.g., Slotkin et al, Life Sci., 24: 1223, 1979). In humans, similar behavioral and neurological disruptions have been reported (e.g., Dinges et al, Science 209: 620, 1979). The mechanisms responsible for these effects are unknown; however, all of these psychotropics have high affinity, specific interactions with various neurotransmitter receptors (NRS). Furthermore, normal development of nervous tissue appears to be mediated through NRs. Disruption of normal, receptor-mediated "signals" by psychoactive agents would be expected to alter development of NKS. Disruption of normal, receptor-mediated "signals" by psychoactive agents would be expected to alter development of brain. In order to examine the regulation of NRs by centrally-acting agents, we have compared placental NRs from "control" (C) and substance-abusing (SA) women, hypothesizing that 1) placental NR regulation may mirror fetal brain NR regulation and 2) placental NRs themselves may play a role in development. Standard radioligand binding methods were employed; 5-7 concentration saturation studies resulted in the following values (recentor: radioligand and k- (rM) B. (fmo)/mo development. Scandard radioingand binding methods were employed; 5-7 concentration saturation studies resulted in the following values (receptor: radioligand, and K<sub>D</sub> (nM), B<sub>max</sub> (fmol/mg prot) values for C, caesarian, no labor (CS), opiate (0), ethanol (E), amphetamine (A), and phencyclidine (PT placentas). al: <sup>3</sup>H-prazosin, C: 0.43, 30.5; CS: 0.58, 65.5; 0: 0.48, 12.6; E: 1.0, 12.1 ag: <sup>3</sup>H-rauwolscine, C: 2.4, 24.5; CS: 1.9, 37.6; 0: 1.6, 42.0; E: 2.2, 18.0; A: 2.0, 180; P; 1.1, 61.5. g: <sup>1251</sup>-iodocyanopindolol, C, 0.065, 132; CS: 0.05, 181; 0: 0.13, 51.3, A: 0.14, 106. µ-opiate: <sup>3</sup>H-naloxone, C: 1.7, 26.9; CS: 0.66, 38.1; 0: 1.8, 57.0; E: 1.8, 33.5, A: 0.7, 90.9; P: 1.6; 51.3. Control values were relatively consistent while SA values were inconsistent with wide variation in each SA group, possibly indicative of "regulation" of NRs yet certainly complicated by other variables surrounding gestation and birth (e.g., drug dosage and schedule, length of labor). These preliminary results demonstrate 1) endogenous agonist exposure during labor may "regulate" NRs in placental NRs and developing fetal NR-neurotransmitter systems. More extensive characterization of C and <u>SA</u> placental NRs are required and are in progress. (Supported by NRSA MN 08834 to B.D.P.)

DIETARY REHABILITATION OF MALNOURISHED RATS: EFFECTS ON BRAIN LIPID CONCENTRATIONS. <u>Paula K. Lundberg, C. Robert Almli, Peter</u> J. Morgane, <u>Michel Motamedi\* and Daniel Gattegno.\*</u>Univ. of Texas, Tyler, Texas 75701, Washington Univ. Med. School, St. Louis, MO 63110 and Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545

Various methods for producing malnutrition in rats have been shown to alter the concentrations of brain cholesterol (CHOL) and phospholipid (PHOS). Although early protein restriction appears to reduce the total amounts of CHOL and PHOS present in brain, it does not consistently reduce the concentrations of these brain lipids. As part of our effort to develop animal models of the marasmic child and the small-for-gestational-age infant, we have been investigating the impact of early protein restriction upon telencephalon (TEL), CHOL and PHOS concentrations. Previously, we telencephalon (TEL), CHOL and PHOS concentrations. Previously, we have reported that combined prenatal and postnatal (PN) exposure to a 6% protein diet resulted in reduced TEL CHOL concentrations on PN day 35, but not on PN day 21 whereas TEL PHOS concentrations were reduced on PN day 21 only. The purpose of the present study was twofold; to replicate our previous findings, and more impor-tantly, to assess the effect of PN dietary rehabilitation upon TEL CHOL and PHOS concentrations.

FIL CHOL and PHOS concentrations. Prior to breeding, during gestation and lactation dams were maintained on normal (N) (25% casein) or protein-restricted (PR) (6% casein) isocaloric (4.3 kcal/g) diets. After weaning pups were maintained on their respective diets. Dietary rehabilitation (P) (R) was effected by cross-fostering, prenatally, PR pups to N dams at birth. Pups were sacrificed on PN days 1, 21, and 35, their brains removed, dissected, and frozen for lipid analysis. L were extracted during homogenization as described by Folch. Lipids CHOL was analyzed enzymatically and PHOS was analyzed using the method of Fiske and Subbarow.

Body weights and TEL weights of the PR group were reduced relative to the N group at all time points (p $\mathbf{\xi}$ .001). CHOL concentrations were actually higher in the PR group at birth (p $\mathbf{\xi}$ .001) but significantly reduced on PN21 (p $\mathbf{4.001}$ ) and PN35 (p $\mathbf{4.01}$ ). PHOS concentrations were also higher in the PR pupe at birth (p<.01) but no different from the N group on PN21 or PN35. While dietary and TEL weights (p $\checkmark$ .001) than those of the N group at both time points still less (p $\checkmark$ .001) than those of the N group at both time points TEL weights of the R group, however, were no different from N pups. Yet, in spite of ameliorating TEL weights, dietary rehabilitation did not reverse the deficits in brain CHOL or PHOS concentrations due to prenatal protein restriction. Thus, prenatal protein re-striction appears to result in significant reductions in TEL CHOL and PHOS concentrations that cannot be reversed by PN days 21 and 35 even when rehabilitation is instituted at birth.

151.7 SEX AND STRAIN DIFFERENCES IN THE DEVELOPMENTAL ACTIVITY PROFILE OF RATS PRENATALLY EXPOSED TO SODIUM SALICYLATE. J. Buelke-Sam, C.A. Kimmel\*, C.J. Nelson\* and P.A. Sullivan\*, Divisions of Teratogenesis Research and Biometry, National Center for Toxicological Research (FDA), Jefferson, AR 72079. Administration of large doses of salicylates (>250 mg/kg) to here to the sector of the sector of the back of the back of the sector.

cal Research (FDA), Jefferson, AR 72079. Administration of large doses of salicylates (>250 mg/kg) to pregnant animals during organogenesis has been shown to result in malformations of the CNS and skeleton as well as several internal organs. At lower doses, it is possible that the functional integrity of these systems may be altered in the absence of gross malformations. Perinatal exposure to a variety of agents has been shown to result in enhanced and/or prolonged juvenile hyperactivity in rodents. Therefore, as an indicator of CNS function, the developmental pattern of locomotor activity was monitored in the offspring of Sprague-Dawley (CD) and Long-Evans (LE) rats treated by gavage on days 8-10 of gestation with either 0, 125 or 175 mg/kg/day sodium salicylate (NaS). No malformations were observed in any of the offspring usea in this study. A total of 51 CD litters were tested in 3 replicates and 42 LE litters in 4 later replicates. On postnatal day (PND) 1, litters were culled to 8 pups (4+2 of each sex) following normal delivery. The apparatus and general procedure used for activity testing has been described (Buelke-Sam and Kimmel, Neurosci. Abst., 6:631, 1980). Offspring were tested for 30 min on PND 12, 16, 20, 24, 30, 60, 90 and 120. Half of each litter was tested over Clean bedding (C) and half over shavings removed from each pup's home cage (HC) through PND 24 in CD rats. At later ages all CD offspring were tested over C. The dichotomy of bedding condition (C vs HC) was maintained at all ages for LE offspring. A repeated measures ANOVA on log transformed data showed main effects on activity levels due to strain at > PND 20 (CD > LE), sex (males > females at < PND 16; females > maTes at > PND 60) and bedding condition at < Hese ages. When separate analyses were conducted for each strain, sex and bedding condition, highly significant age effects were found for all groups. A main effect due to prenatal dose of NaS was found only in LE males tested over C, with treated rats being less active than 151.8 THE EFFECTS OF PROTEIN MALNUTRITION ON SLEEP STAGE RESPONSE TO LIGHT-DARK CYCLES IN RATS OF THREE AGE GROUPS. L. Cintra, W. Forbes, S. Diaz-Cintra and P.J. Morgane. Worcester Found. for Expt. Biol., Shrewsbury, MA 01545 and Institute de Invest. Bio-Medicas. UNAM, Dpto. de Fisiologia, C.P. 04510 Mexico, D.F. In these studies we used a 12/12 light/dark cycle in rats at 60, 120 and 220 days of age fed either an 8% or 25% casein diet. We found that the vigilance states follow a clear developmental

In these studies we used a 12/12 light/dark cycle in rats at 60, 120 and 220 days of age fed either an 8% or 25% casein diet. We found that the vigilance states follow a clear developmental trend during this ontogenetic period, i.e., show a reduction of waking and REM sleep activity and an increase in slow-wave-sleep as a function of age. Malnutrition in the rat produces significant changes in the pattern of age related changes in various vigilance parameters and also affects responses of the animals to changes in the light-dark cycle. In order to obtain information on the effects of malnutrition on the distribution of the vigilance states, we analyzed several periods during 24 hours of continuous recording, i.e., 12 hours light, 12 hours dark analyzed in 4 hour blocks. We found most significant changes in the vigilance states in 8% rats in the lights-on period only at the older ages (220 days). The most striking finding in the malnourished animals is a significant reduction in waking and a significant increase in slow-wave-sleep and REM sleep at 220 days of age during the lights-on period. In the lights-off period the alnourished animals show a significant decrease in REM sleep at 220 days of age but no changes at 60 and 120 days. We also found that 8% rats at 220 days of age, studied in 4 hour blocks, show significant changes in vigilance cycles only in the first and last 4-hour block of the lights-off period indicating that malnourished rats react differently to light-dark transitions (or anticipated transitions). Light/dark ratios in 8% animals showed significant differences in slow-wave-sleep at 120 days and waking at 220 days suggesting that the amplitude of the circadian rhythms of slow-wavesleep and waking is different in 8% versus 25% rats at these two age periods. These findings indicate that malnutrition may be having an effect on the endogeneous generator mechanism of the vigilance states since the changes observed in normals vs. malnourished in the three vigilance states in th

151.9 THE EFFECT OF PROTEIN MALNUTRITION ON THE HIPPOCAMPAL EEG OF THE DEVELOPING RAT. K.B. Austin\*, C.J. Siok\*, J.D. Bronzino, O. Resnick and P.J. Morgane. (SPON: W.L. McFarland). Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Biology, Shrewsbury, MA 01545. Protein malnourished pups were born to dams fed a 6% or 8% casein diet initiated 5 weeks prior to mating. Pups born to dams fed the 8% casein diet had brain and body weights at birth that were no different from the control (25% casein) group (Porbes et al., <u>Brain Res.</u> <u>Bull.</u>, 2:131-135, 1977). Dams subjected to the 6% casein diet yielded pups with significantly lower brain (P<.05) and body weights (P<.001) than the controls (Resnick et al., <u>Neurosci. Biobehav. Rev.</u>, 6:55-75, 1982). In order to study the effects of these levels of protein malnutrition on hippocampal development, power spectral analysis was used to analyse the hippocampal EEG of animals in the three diet groups at 14, 18, 22, 30 and 45 days of age. Two indices derived from the power spectrum of the hippocampal EEG proved to be sensitive indicators of maturation. <u>Peak-Theta</u> <u>frequency</u> represents the frequency within the Theta band (4-11 Hz.) at which the power spectrum exhibits a local maximum. <u>Total spectral power</u> represents the sum of power spectral values within a frequency band. The spectrum was divided into 4 frequency bands: 1-Delta band (0.5-3.5 Hz.), 2- Tonic or low Theta band (4.0-7.0 Hz.), 3- Phasic or high Theta band (7.5-11.0 Hz.) and 4- a high frequency band (11.5-32.0 Hz.). We have previously shown that, as the normal rat develops from 14 to 45 days of age, the power spectrum of the hippocampal EEG during REM sleep becomes concentrated in the Theta band (indicated by a greater total spectral power in the 4-11 Hz. range). This is accompanied by a highly significant (P<.001) shift in peak Theta frequency from 4.4 Hz. at 14 days of age to 6.6 Hz. at 45 days of age. The concentration of power in the Theta band is marked by an increase in total power within the phasic component (7-11 Hz.). Animals reared on 6% and 8% casein diets show similar spectral concentrations during maturation, but peak Theta frequency lags behind that of control animals, with the g 151.10 THE EFFECT OF PRENATAL PROTEIN MALNUTRITION ON THE DEVELOPMENT OF THE SLEEP-WAKING CYCLES IN THE RAT.

Chester J. Slot\*, Joseph D. Bronzino, Kevin Austin<sup>#</sup> and Peter J. <u>Morgane</u>, (SPON: E. Shaskan). Trinity College, Hartford CT, 06106, and Worcester Foundation for Experimental Biology, Shrewsbury, MA, 01545.

In order to understand the implications of <u>prenatal</u> protein malnutrition on the developing rat brain, we have studied sleep behavior in normal and protein deprived rats at various ages. The present study examines the sleep-waking profile in rat pups born to dams fed either a normal diet (25% casein) or a protein deficient diet (6% or 8% casein) throughout a 5 week pregravid period, pregnancy and lactation. After weaning (22 days of age) offspring were maintained on the same diet as the mother. Animals were tested at the ages of 14, 18, 22, 30 and 45 days when chronic EEG recordings from the hippocampus and frontal cortex were monitored and used in determining the sleep-waking behavior of the animal. Our results indicate that the most significant effects of prenatal protein malnutrition occur during REM sleep. Slow-wave sleep, on the other hand, is not affected. It was found that the 8% animals (when compared to the 25% animals): (1) spent significant by exime in REM sleep (p<.01), (2) had fewer REM episodes (p<.01), (3) had shorter REM episodes (significant only at 18 days, p<.01), (4) spent more time between REM episodes (significant differences were noted. In the case of the 6% animals, tests were conducted after weaning. At 22 days of age, it was found that the 6% animals (when compared to the 25% animals, (c1), By 45 days of age, no statistically significant differences were noted. In the case of the 6% animals, tests were conducted after weaning. At 22 days of age, it was found that the 6% animals (when compared to the 25% animals and 8% animals): (1) spent less time in REM sleep (p<.08), (2) had shorter REM episodes (significant only vs. the 25% animal, p<.02) and (3) spent more time in the waking state (p<.01). By 45 days of age, no statistically significant differences were noted. These results indicate that prenatal protein malnutrition alters the vigilance profile of the rat primarily during the prevening stages of development. From this data it can be postulated that derangments in those neuronal

- COMBINED PRENATAL EFFECTS OF ETHANOL AND NICOTINE: 151.11
  - COMBINED PRENATAL EFFECTS OF ETHANOL AND NICOTINE: BRAIN MYELIN AND BEHAVIOR, F. E. Lancaster, M. F. da Cunha\* and C. Johnson\*. Biology Department, Texas Woman's University, Houston, Texas 77030 Pregnant Long Evans rats were received on day 5 of gestation and divided into four groups. Animals were group fed to control for nutritional influence as fol-lows: (1) Nicotine-Ethanol (NE) received 27% calories as ethanol from Sandra Weiner ethanol diet (1226-PR-A, Bio Serve) (days 5-15 of gestation) mixed with Dutch as ethanol from Sandra Weiner ethanol diet (1226-PR-A, Bio Serve) (days 5-15 of gestation) mixed with Dutch Chocolate Sego, and 2 mg nicotine/kg/day via Alzet minipumps (days 4-19 of gestation); (2) Nicotine (N) received Sandra Weiner Control diet (1226-PR-C, Bio Serve) mixed with Dutch Chocolate Sego (days 5-15 of gestation) and 2 mg nicotine/kg/day via Alzet minipumps (days 4-19 gestation); (3) Ethanol (ET) received 27% of calories as athanol in othanol diat and wors implarted with saline filled minipumps; (4) Controls (LQ) re-ceived control diet and saline filled minipumps. Nicoceived control diet and saline filled minipumps. Nico-tine-Ethanol animals were allowed ad libitum access to the diet; all other groups were fed diet isocaloric to NE consumption. Following day 19 of gestation, all animals received lab chow and water ad libitum. animals were observed for gross anomalies at birth; time of eye opening was recorded on days 14-16. Groups of off-spring were sacrificed at 16, 21, 30 and 52 days of age. Organ weights, myelin accumulation and levels of spermatozoa and testicular DNA were measured. A bat-tery of behavioral tests was administered days 7-20. Brain myelination in female ethanol and nicotine off-spring was significantly delayed. Eye opening and development of several behavioral parameters were delayed in offspring of nicotine and ethanol dams. Levels of spermatozoa and testicular DNA were not Levels of spermatozoa and testicular DNA were not affected.
- 151.22 SYNAPTIC MEMBRANE PHOSPHOLIPIDS IN DEVELOPING CONTROL & ETHANOL RATS. J. H. Hofteig, A.B. Noronha\*, M.J. Druse-Manteuffel and C. Keresztes-Nagy. Depts. of Biochemistry & Biophysics and

C. Keresztes-Nagy. Depts. of Biochemistry & Biophysics and Medicine, Loyola Univ. Med. Ctr., Maywood, IL. 60153. In the present study the phospholipid composition of synaptic plasma membranes (SPM) was determined in the developing offspring of rats that were pair-fed on a chronic basis (prior to and during gestation) control or isocaloric 6.6% (v/v) ethanol liquid diets, containing 21% protein (Noronha & Druse, 1982). At 17,24 and 31 days of age SPM were isolated from control and ethanol pups (Cotman & Matthews, 1973). Lipids were extracted from SPM (Folch (Rouser et al., 1957) and separated into neutral, glyco- and phospholipids (Rouser et al., 1967). Total phospholipids were quantitated

(Rouser et al., 1967). Total phospholipids were quantitated (Gottfried, 1967) and separated by 2-dimensional TLC (Horrocks & Sun, 1972, as modified by de Sousa & Horrocks, 1979). In both control and ethanol pups the major SPM phospholipid was phosphatidyl choline (PC) which accounted for > 40% of the phospho-lipid phosphorus. A small but significant developmentally-related decrease in PC concentration was observed. Choline plasmalogens were not detected. The ethanolamine phosphoglycerides comprised the second most prominent group of SPM phospholipids. Phosphatidyl ethanolamine (PE) accounted for approximately 10% of the phospholipids at all ages and ethanolamine plasmalogin accounted for 5% (17 days) to 15% (31 days) of the phospholipids. Phosphatidyl serine (PS) + phoshatidyl inositol (P1) comprised 12-16\%. Small quantities of sphingomyelin (4-7\%) and phosphatidic acid (< 2\%) were also found.

were also found. Although the yield of SPM (as assessed by protein content) was comparable in ethanol and control pups, the composition of the SPM was affected in the ethanol pups. SPM from 17 day ethanol pups had a lower concentration of total phospholipids than SPM from control rats (0.80 vs 0.96 µg phospholipid/µg protein). In addition, the normal developmentally-related increase in the proportion of ethanolamine plasmalogen was delayed in ethanol pups. proportion of ethanolamine plasmalogen was delayed in ethanol pup: Whereas the control animals demonstrated an increase in the pro-portion of ethanolamine plasmalogen between 17 and 24 days of age, the ethanol pups did not demonstrate an increase until 31 days. The results of the present study suggest that there may be a delay in the maturation of synaptic membrane phospholipids in ethanol pups.

## VESTIBULAR COMPENSATION AND BRAINSTEM PATHWAYS

- THE EFFECT OF SPINAL CORD TRANSECTION ON MEDIAL VESTIBULAR NEU-152.1 RONS OF COMPENSATED HEMILABYRINTHECTOMIZED GERBILS. T.J. Clegg\* and A.A. Perachio, Depts. Otolaryngol. and Physiol. & Biophys., Univ. of Texas Medical Branch, Galveston, TX 77550 Unilateral labyrinthectomy results in characteristic acute symptoms. Following vestibular compensation, the reappearance of those symptoms (decompensation) can be produced by spinal cord transection (Azzena, Arch. Ital. Biol. 107: 1969). Neurons of the medial vestibular nuclei (MVN) on the injured side exhibit activity changes during compensation (Precht, et al., J. Neuro-physiol. 29: 1966). Decompensation is paralleled by changes in physical 291 (966). Decompensation is paralleled by changes in neuronal activity in the lateral (Azzena, et al., Experientia 3: 1977) and descending (Jensen, Neurosci. 4: 1979) vestibular nuclei. The purposes of this study were to measure in compens-ated hemilabyrinthectomized gerbils with or without cord damage the activity of MVN neurons and their responses to sinusoidal angular acceleration. Recordings were made from MVN neurons bilaterally in 24 decerebrate gerbils from each of the following groups: 1) acute labyrinthectomized , 2) compensated , 3) com-pensated and acute spinal cord transected , 4) non-labyrinth-ectomized, and 5) non-labyrinthectomized spinal cord transected. As reported previously, acute labyrinthectomized spinal cord transected. As reported previously, acute labyrinthectomy eliminated type I neurons on the injured side. No other significant changes in spontaneous activity were observed in type I neurons on the intact side or type II neurons bilaterally. The influence of the spinal cord on type I and II MVN neurons differed for measures of spinal cord on type I and IT with hearons differed for measures of both spontaneous activity and dynamic responses to yaw angular acceleration. Sample sizes were not sufficiently large for sta-tistical comparison in all groups. The gains of the response type I neurons were significantly lower following cord damage in compensated animals than in the non-labyrinthectomized spinal cond transected group even though spontaneous activity was sta-tistically equivalent in both samples. Type II neurons on the intact side exhibited significant gain increases following cord damage or acute labyrinthectomy. In compensated animals, cord damage resulted in a gain decrease on the intact side and a gain increase on the injured side. Cord transection in non-labyrinthectomized animals produced a significant decrease in the firing activity of type II neurons but did not influence type I neurons. In compensated animals transection of the spinal cord resulted in an increase in the firing rate of type II neurons on the intact side but no statistical change in the activity of type I neurons. These results suggest a significant contribution of type II neurons to vestibular compensation.

QUANTITATIVE 2-DG STUDY OF THE BRAINSTEM OF THE RAT DURING 152.2 QUANTITATIVE 2-DG STUDY OF THE BRAINSTEM OF THE KAT DURING NYSTAGMUS PRODUCED BY LESION OF THE LATERAL SEMICIRCULAR AMPULLA. F.A. Kutyna, J.W. Patrickson<sup>\*</sup>, H.J. Bryant, M. Kadekaro and J.B. Clark<sup>\*</sup>. Depts. of Physiology and Neurosurgery, Uniformed Services University, Bethesda, MD 20814 and Lab Cerebral Metabolism, NIMH, Bethesda, MD 20205. Brain functional activity of male Sprague-Dawley rats was stud-ied using the quantitative 2-deoxy-D-glucose (2-DG) autoradiogra-

phic method. Under halothane anesthesia the left horizontal canal was exposed and a fine wire was inserted to destroy the crista am-pullaris. In sham-operated controls the canal was not opened. The bone was sealed with wax and the animals allowed to recover 2 hrs before 2-DG injection. The lesioned rats showed nystagmus with the fast phase to the right side. The animals were unrestrained during the 45 minutes following 2-DG injection and exhibited postural signs and circling movements consistent with this lesion.

FURTHER STUDIES OF OTOLITH-SPINAL REFLEX ADAPTATION TO ALTERED 152.3 GRAVITY: VISUAL CONTRIBUTIONS AND EFFECTS OF HEAD ORIENTATION. D.G.D. Watt and L.M. Tomi\*, Aviation Medical Research Unit, Dept. of Physiology, McGill Univ., Montreal, Quebec, Canada H3G 176. In previous studies, it has been shown that (1) gastrocnemius-soleus emg activity occurring 50 to 150 msec after the onset of a sudden fall is predominantly otolith-spinal in origin, (2) the size of this response is reduced by rotating the gravity vector Size of this response is reduced by rotating the gravity vector  $90^\circ$  relative to the body, and (3) the response steadily increases during prolonged exposure to the supine position. The present experiments were designed to test the contribution of vision to this otolith-spinal reflex adaptation and to measure the effects of different head angles during testing. Eight subjects were exposed to sudden, unexpected vertical

falls of 15 cm while surface emg activity was recorded from their left calf muscles. Each was then tested in the supine position every 60 mins for 8 hrs, substituting for gravity with elastic cords running from a torso harness to the wall. Finally, vertical testing was repeated immediately after leaving the supine position and every 60 mins for 4 hrs. The control, first and last hori-zontal, and first and last vertical test sessions consisted of 45 Zontal, and first and last vertical test sessions consisted of 45 drops (I drop eyes open, I drop eyes closed, I drop neck flexed forward 45° and looking 'down', all repeated 15 times). All other test sessions consisted of 15 drops with eyes open only. EMG activity was rectified, averaged for each set of 15 drops (eyes open, eyes closed or neck flexed), and the area under the result-ing curve was measured from 50-150 msec after release. All data

were then normalized with respect to the eyes open controls. All subjects demonstrated a significant (P<.001) reduction of All subjects demonstrated a significant (P<.001) reduction or the response to sudden falls on assuming the supine position (average response reduced to 28%). After 8 hrs, the response was significantly larger (P<.05), averaging 74%. Contradicting the previous, more limited experiments, the reflex was found to return to its control value immediately after re-assuming the vertical position (P>.7). Closing the eyes, or flexing the neck and looking down, had no effect on any aspect of these findings (P always <.05)

These results confirm the previous finding of adaptation of an otolith-spinal reflex to prolonged exposure to the supine posiotofilm-spinal reflex to prolonged exposure to the supine posi-tion, but do not demonstrate any residual effects on returning to the vertical position. They suggest that the increased reaction to falls after 8 hrs supine is not due to an enhanced visuo-spinal reflex, or increased visual facilitation of the otolith-spinal response. The reaction to sudden falls occurs irrespective of head orientation relative to the test acceleration, and this is maintained even during adaptation, which therefore must involve all parts of the otolith system. (Supported by M.R.C. Canada, Grant MA-5837).

152.5 A MODEL RECONCILING CENTRAL OBSERVATIONS DURING PLASTICITY OF THE VESTIBULO-OCULAR REFLEX (VOR). H.L. Galiana, Aviation Medical Research Unit, McGill Univ., Montreal, Quebec, Canada H3G 1Y6

There is evidence that some commissural pathways linking the bilateral vestibular nuclei  $\left( VN\right)$  provide a positive loop for signals between 2° vestibular cells on both sides of the brain-stem (1,2). A bilateral model of the VOR has been developed, showing that such commissural loops would contribute to the realishowing that such commissural loops would contribute to the real-zation of the VOR's central integrator during compensatory slow phases (3). Hence any changes in intervestibular coupling strength should modify both the gain and phase of the VOR. Changes in commissural efficacy have been reported after compensation for unilateral vestibular lesions (4), associated with parallel impro-vement in the VOR. It follows that commissural changes should be investigated as a possible site for long-term (days) VOR plasti-city in the health custom city in the healthy system, e.g. induced with optical devices

Analytic studies are applied to a model of the VOR including the postulated commissural loop, feedback of an efference copy of eye position to 2° VN cells, and cerebellar Purkinje cell (PJ) pathways. Results indicate that modifications at the commissural level would cause changes in the responses of PJ and VN cells level would cause changes in the responses of PJ and VN cells fully compatible with published observations: i) VOR gain, and Type I PJ cell modulation during VOR suppression, vary in parallel but not by the same factor (5); ii) a greatly reduced VOR gain can be associated with deteriorated central integration (6); (iii) measured changes in the modulation of  $2^{\circ}$  VN cells can be much smaller than expected from the VOR gain changes (6,7). Thus cross-midline coupling of the VN could be the site of the modifi-able brainstem element, postulated by Miles & Lisberger (5) to account for their observations after long-term VOR plasticity. Short-term (hours) plasticity of the VOR is more likely related to  $\frac{1}{2}$  vanitie changes on PJ cells, according to the observations of Synaptic Changes on PJ cells, according to the observations of Ito (8): here, the model predicts (as observed) that the resulting changes in VN responses would be similar to those expected from commissural modifications, but that Type I PJ cell sensitivity to head velocity would vary inversely with the VOR gain.

CROSS-MIDLINE COUPLING OF THE VESTIBULAR NUCLEI: A PUTATIVE SITE 152.4 FOR VESTIBULAR COMPENSATION. H. Flohr\*, Dept. Neurobiology, Univ. Bremen, Bremen, F.R.G., H.L. Galiana and G. Melvill Jones, Aviat. Med. Res. Unit, Dept. Physiology, McGill Univ., Montreal, Quebec, Canada H3G 1Y6 (SPON: R. Capek).

Compensation following unilateral labyrinthectomy is associated with restoration of symmetry in the activity of the vestibular nuclei (VN), and with synaptic changes along commissural pathways (e.g. 1,2). However, seen in the usual context of push-pull, (e.g. 1,2). However, seen in the usual context of push-pull, feedforward, commissural connections, these findings cannot alone explain observations in various species following a second perieffect of commissurotomy (3) in frog. Thus other processes are often postulated as being also involved, though none can satisfactorily reconcile all observations. For example, general supersensitivity of the primarily deafferented VN is often propos-ed as an explanation for the Bechterew phenomenon, but it does not explain the decompensatory effect of commissurotomy

Recent neuroneurophysiological and neuroanatomical observations indicate that some commissional and headbaland in the balance of the source of the sou thectomy, the Bechterew phenomenon and its subsequent compensation, and the loss of compensation after commissurotomy. Such a si for vestibular compensation would also be compatible with the Such a site fact that balance recovery is still possible after vestibulo-cerebellectomy (6). This is relevant to clinical diagnosis in man, since the observation of spontaneous nystagmus could result either from a central lesion, or from a peripheral lesion/recovery such that central commissural gains are no longer appropriate for the new input levels.

EFFECTS OF SEMICIRCULAR CANAL LESIONS ON SPATIAL ABILITY 152.6 H.Cohen\*and M.Potegal. (SPON: L. Marco). Teachers College, Columbia Univ., N.Y., N.Y. 10027 and N.Y.State Psychiatric Inst., N.Y., N.Y. 10032

We have developed procedures for testing the hypothesis that, as an animal moves through space, it can use vestibular informaas an animal moves through space, it can use vestibular informa-tion to monitor its distance and direction from the starting point (Potegal, <u>Spatial Abilities: Development and Physiological</u> <u>Foundations</u>, Academic Press, 1982; see Mittelstaedt and Mittel-staedt, <u>Naturwissen</u>, 1980,67,566 for behavioral evidence of a particular role of the semicircular canals in "path integration"). In earlies studies we developed a passive-transport-and-return task (PTR) in which water-deprived rats are given a brief drink of water from one of eight identical spouts bordering a visually homogenous room. The rats are then passively transported along successively longer right angle trajectories in an opaque vehicle. To obtain water upon release the rats must return to the spout from which they were transported on that trial. We found that both normal and blinded rats can perform PTR but rats with lesions of the vestibular nuclei were significantly impaired on acquisi-tion and post-operative retention of the task (Miller et al., <u>Neuroscience Abstracts</u>, 1981, 7, 484; <u>Physioll. Psych.</u>, 1983, 11, 1-10). Vestibular nuclear-lesioned rats, however, have motor deficits (e.g., head nystagmus) and increased emotionality which

Could have nonspecifically impaired task performance. We now report the results of a more selective vestibular le-sion: destruction of the lateral semicircular canals. Rats previ-ously trained on PTR received either sham operations or had both lateral canals drilled open and their ampullae reamed out with a  $0.\,lmm$  diameter wire matching the curvature of the canal. On post-operative retention testing sham rats reached criterion in 14%fewer trials than pre-operatively; canal-lesioned rats took 19% more trials than pre-operatively. There were no differences be-tween canal- and sham-operated rats in PTR return latencies or on subsequent response-to-handling tests, indicating that neither motor impairment nor emotionality accounted for the PTR deficit. By contrast, high-speed cinematographic analysis of response to whole body oscillation in the horizontal plane revealed an increased head movement phase lag in canal-operated rats, independently confirming the canal dysfunction. These data are con-gruent with the Mittelstaedts' observations and support the vestibular navigation hypothesis.

MODIFICATION OF THE VESTIBULOOCULAR REFLEX IN AROUSED CATS BEFORE AND AFTER 6-OHDA INDUCED NOREPINEPHRINE DEPLETION. <u>J.G.</u> 152.7 AND AFTER 6-OHDA INDUCED NOREFINEPHRINE DEPLETION. J.G. McElligott and W.F. Freedman. Department of Pharmacology, Temple U. Sch. of Medicine, Phila., Pa. 19140 and Electrical and Computer Engineering Dept. Drexel U., Phila., Pa. Norepinephrine (NE) has been implicated in learning and neuroplasticity, i.e., the ability of the nervous system to adapt to changing conditions by forming new or enhancing existing neural connections. Modification of the vestibuloocular reflex (VOR) has been presented as a model system for investigating neuroplasticity and adaptive motor behavior. Much work has centered around the cerebellum's role in the modifiability of the cen-VOR. Cerebellar NE has been shown to be important for the learning but not the performance of specific locomotor tasks. Previous work has also shown that VOR modification (decrease in gain) is hindered in cats whose norepinephrine was reduced by intra-cisternal injection of 6-OHDA treatment. Since an animal's arousal level during modification and testing of the VOR is of critical importance, we decided to replicate this other work but to use an increase rather than a decrease in the VOR gain. Reduction in VOR gain can be due to a reduced level of alterness in the animal brought about by the 6-OHDA lesion. Modification was accomplished by oscillating head restrained cats, fitted with preformed ocular search coils, in the horizontal plane while an optokinetic drum was oscillated 180 deg out of phase with the be of the set of the and tactile stimulation. In addition, modification of the VOR was also carried out in a heightened arousal condition following an injection of amphetamine (Smg s.c.). Assays of arousal were made by counting the number of saccades made by the animal during the modification period. The animals in both the behaviorally as well as the amphetamine aroused condition increased their gain equally to an average of 1.5x over the 4 hour period. The animals were then injected with 6-OHDA intracisternally to deplete CNS norepinephrine. Following a two week recovery period, the animals again underwent modification and testing. In behaviorally aroused animals, there was no charge in the modifiabi-lity of the VOR. However, in the amphetamine aroused situation little or no modification of the VOR took place. A possible explanation for these results is that after the 6-OHDA treatment there was insufficient depletion to effect the modifiability of the VOR. However, treatment with amphetamine caused a further release and functional inactivation of NE that rendered the animal incapable of modifying its VOR.

152.8 RESPONSES OF VESTIBULAR NEURONS FROM THE NUCLEUS VESTIBULARIS AND THE FLOCCULUS IN WILDTYPE MICE AND MUTANTS.

L. Grüsser-Cornehls\* (Spon: R.F. Schmidt), Department of Physiology, Freie Universität, Berlin, Germany. Neurons were recorded from the N. vestibularis and the floccu-

Neurons were recorded from the N. vestibularis and the floculus of wildtype mice and WEAVER mutants (BGCBA) by means of glass micropipetdes in the norizontal plane in the dark at different frequencies and amplitudes. The recording sites were localized by means of small iontophoretically applied HRP markings. The neuronal response amplitude increased with frequency and

The neuronal response amplitude increased with frequency and amplitude of the sinusoidal rotation. The average slope of the amplitude frequency response characteristics of N. vestibularis and flocculus neurons did not differ significantly between wildtype mice and mutants, but the response amplitude at a given frequency has been shifted along the ordinate. The lowest response amplitude was displayed by wildtype flocculus neurons and the highest response amplitude by mutant N. vestibularis neurons. A possible explanation for this finding would be that the flocculus exerts inhibitory influences on the N. vestibularis neurons. The mean value curve for the relative phase relationship (normalized at 0.2 Hz to 0) for floccular neurons of wildtype mice showed a strong increase in phase lead by increasing frequency of the sinusoidal rotation, while the mean value curve for the N. vestibular neurons demonstrated that the relative phase relationship was practically independent of the frequency between 0.2 and 0.5 Hz.

152.9 RETROGRADE DOUBLE-LABELING OF VESTIBULAR NEURONS THAT PROJECT TO THE OCULOMOTOR NUCLEUS AND CERVICAL SPINAL CORD. F. Fang\*, B.S. Phipps, R. Maciewicz and S.H. Wray, The Stanley Cobb Lab. and the Depts. of Neurology and Psychiatry, Mass. General Hospital and Harvard Med. School, Boston MA 02114. Using the retrograde tracers horseradish peroxidase (HRP) and

Using the retrograde tracers horseradish peroxidase (HRP) and nuclear yellow (NY), a double retrograde labeling study was performed in the cat to determine the extent of overlap of cells that give rise to vestibulo-ocular and vestibulospinal projections. Following a posterior craniotomy and aspiration of the anterior cerebellar vermis, the tip of a 'ul syringe was advanced through the floor of the exposed aqueduct into the region of the oculomotor nucleus, and 50nl of 20% HRP was pressure injected. In the same animals 1% NY was injected bilaterally at C2 and C3 levels (six 'ul injections) following a partial C1 and C2 laminectomy. After a two day survival, animals were sacrificed and processed with tetramethylbenzidine to demonstrate HRP labeling; sections were viewed using brightfield illumination and fluorescent epiillumination.

Consistent with previous studies, injection of HRP into the oculomotor complex resulted in a large number of retrogradely-labeled neurons in the vestibular complex. In rostral pontine sections, densely labeled neurons were found throughout the superior nucleus. More caudally, HRP-positive cells were found in the medial nucleus and also in the border region between the ventral part of the lateral nucleus and the rostral descending nucleus. At more caudal medullary levels a smaller number of HRP-positive cells were found scattered in the medial and descending nuclei.

In the same material, cervical injections of NY retrogradely labeled numerous vestibulospinal neurons in the medial and descending nuclei. NY-positive cells were also found in the dorsal and ventral parts of the lateral nucleus; no vestibulospinal cells were found in the superior nucleus. The major area of overlap between vestibulospinal and vestibulo-oculomotor neurons in the cat occurred in the rostral descending nucleus as it borders on the ventral part of the lateral nucleus. Within this border region, many small neurons (<24um) were found to contain both HRP and NY. The presence of such double-labeling suggests that some vestibular neurons may have axons that bifurcate to the cervical cord and the region of the oculomotor nucleus. Vestibular cells with direct projections to both of these areas may function in head-eye coordination; the pattern of termination and functional linkage of such cells at cervical and mesencephalic levels remains, however, to be determined.

152.10 CENTRAL DISTRIBUTION OF THE VESTIBULAR NERVE IN THE BULLFROG, RANA CATESBEIANA. <u>A. Kuruvilla\*, V. Honrubia\*, S. Sitko\* and I. R. Schwartz</u> (SPON: D. Strelioff). Div. of Head and Neck Surgery, UCLA Sch. of Med., Los Angeles, CA 90024. Previously we demonstrated that the thick- and thin-caliber ampullary nerve fibers in the bullfrog have different physiological characteristics and innervate different regions in the cristae. In the present study we have evaluated their central

projections using intra- and extracellular horseradish peroxidase labeling of the primary vestibular afferents. We first analyzed the central pathway of the whole VIIIth nerve by labeling it extracellularly. In order to identify the central projections of the various vestibular components of the VIIth nerve we made separate extracellular injections of the whole anterior branch, the whole posterior branch, the ampullary nerve of each of the three semicircular canals and the branch to the sacculus. Individual thick-caliber fibers from the anterior and horizontal ampullae and the sacculus were labeled intracellularly in separate animals. Fibers of the vestibular nerve innervate an ipsilateral area

Fibers of the vestibular nerve innervate an ipsilateral area which extends caudally from the rhombencephalon at the level of the XIIth nerve nucleus and rostrally up to and including the nucleus cerebelli and the cerebellum. We have identified the following vestibular nuclei by the fact that they receive primary vestibular input: the nuclei ventralis, medialis, descendens, superioris and cerebelli. The nucleus dorsalis, which receives primary auditory input, also receives afferents from the sacculus. A few vestibular fibers project to the ipsilateral superior olivary nucleus, the motor nuclei of the Vth, accessory VIth, VIIth, and IXth cranial nerves and the reticular formation. The primary vestibulo-cerebellar fibers terminate mainly among the granular cells of the lobus auricularis and of the corpus cerebelli in the caudal part of the cerebellum. Fibers from each of the three ampullary nerves project into the cerebellum. From the presently available data it appears that at the single neuron level individually labeled thick-caliber fibers project to all of the vestibular efferents, are seen in the ipsilateral reticular formation, adjacent to the facial motor nucleus.

SPONTANEOUS AND EVOKED NEURAL ACTIVITY CHANGES IN SEMICIRCULAR 152.11 CANAL AFFERENTS DURING TRANSIENT ISCHEMIA. <u>S. Sitko\* and</u> <u>V. Honrubia</u>\* (SPON: E. Decima). Div. of Head and Neck Surgery, UCLA Sch. of Med., Los Angeles, CA 90024.

In the bullfrog Rana catesbeiana we have studied the effect of impairing the blood flow in the vestibular artery on the spontaneous and evoked activity of single horizontal and anterior semi-circular canal afferents. Interruption of blood flow was produced by clamping the vestibular artery using fine forceps under microscopic visual control. The spontaneous activity, evoked response to sinusoidal rotations (typically 0.2 Hz, 60 deg/sec), and, when possible, membrane potential, action potential size, and electrical threshold for depolarizing currents were monitored continuously throughout the experiments: before, during, and after removing the arterial blockage.

In most cases we observed the spontaneous activity to increase during the initial 1-5 minutes following the occlusion, usually by 10-30% above its resting value. In all ases there was a by 10-30% above its resting value. In call large the test of a subsequent reduction of the activity to a level between 80% and less than 1% of the baseline over a period of 2-20 minutes. The physiological sensitivity of the fibers followed a similar pattern with a short period of increased sensitivity in the first 1-5 minutes after clamping, followed by a progressive loss in sensitivity and compressed dynamic range.

The changes in both spontaneous activity and physiological sensitivity were partially and in many cases totally reversible upon removal of the occlusion and resumption of arterial blood flow. In those fibers of which we were able to maintain intra-The second secon nerve hair cell synaptic complex. These results demonstrate the importance of maintaining a normal blood supply to the labyrinth when evaluating physiological experiments in the vestibular nerve of cold-blooded animals.

This study was supported by grants NS08335 and NS09823 from the National Institutes of Health and a grant from the Pauley Foundation.

152.13 SPONTANEOUS ACTIVITY AND DRIVEN RESPONSES OF SEMI-CIRCULAR CANAL PRIMARY AFFERENT NEURONS IN THE ALERT PIGEON T.J. Anastasiof M.J. Correia and A.A. Pera chio. Departments of Otolaryngology and Physiology Peraand Biophysics, University of Texas Medical Branch, Galveston, TX 77550-2778.

The properties of pooled anterior, posterior and horizontal semicircular canal (SC) primary afferents horizontal semicircular canal (SC) primary afferents were studied in a chronic, alert pigeon preparation. The average spontaneous mean firing rate (MFR) re-ported for a sample of 124 SC primary afferents from eight alert pigeons was 168 impulses per second (I/S), range 8 - 396 I/S. In contrast, the average MFR reported for a sample of 124 horizontal canal primary afferents from anesthetized pigeons was 45% less (92 I/S, range 10 - 200 I/S, Lifschitz, W.S, <u>Brain Research</u>, 63: 43-57; 1973). Coefficient of variation (CV) of the mean interspike interval (ISI) was classified as follows: regular - CV < 0.1, in-termediate - CV = 0.1 to 0.4 and irregular - CV > 0.4. The percentage of SC primary afferents in each class is similar for both alert and anesthetized pi-geons. In alert pigeons, there is a linear geons. In alert pigeons, there is a linear relationship between mean ISI and the standard devi-

relationship between mean ISI and the standard devi-ation (SD) as described by the following equation and coefficient of correlation (r): SD = 1.271 (ISI) - 6.683, r = 0.9803. Four alert pigeons were subjected to sum of sines rotational stimuli at two separate bandwidths: low bandwidth - 0.029 to 0.615 Hz and high bandwidth -0.293 to 6.152 Hz. Best-fit transfer functions, and associated mean square error (MSE) values, were de-termined for the intermediate and five irregular SC termined for ten intermediate and five irregular SC primary afferents:

int. -  $H(s) = Gs^{1.14}(9.9s+1)^{-1}(0.01s+1), MSE = 0.11;$ 

irr. -  $H(s) = Gs^{1.10}(9.2s+1)^{-1}(0.02s+1), MSE = 0.12.$ 

Best - fit transfer function for 14 anterior ampullary afferents in the anesthetized pigeon across CV classes over the bandwidth - 0.01 to 2.0 Hz was found to be (Landolt, J.P. and Correia, M.J., J. Neurophysiol., 43: 1746-1770; 1980):

 $H(s)=Gs^{1.24}(10.2s + 1)^{-1}$ 

(Supported by NGT 44-088-800 and NAS9 -14641).

152.12 PRIMARY VESTIBULAR FIBER CONNECTIONS IN THE RAT. W. R. Mehler

NASA-Ames Res. Ctr., Moffett Field, CA 94035 Trans-bullar vestibular ganglionectomies were attempted on 54 Long-Evans rats. Out of 24 that survived the required 5 to 7 days 15 were excluded because of incomplete lesions or excessive pontine tegmental infarctions. Six verified complete and 3 partial ganglionectomy experiments were serially sectioned in either the coronal, sagittal or horizontal plane. Alternate sets of uranyl nitrate (Nauta and Ebbessen, '70) and Fink and Heimer ('67) method impregnations were prepared with and without cresylectviolet counterstaining.

Analysis of complete lesion series revealed massive vestibular fiber degeneration which enveloped the interstitial nucleus and entered the lateral vestibular nucleus. A small group of fibers seperates from the caudal part of the incoming nerve and without apparent bifraction terminates in cell group Y of Brodal. The degenerating 8th nerve fibers penetrate the lateral vestibular nucleus and bifracate into ascending and descending limbs made up of many secondary fascicles. The descending limb traverses the length and breadth of the spinal vestibular nucleus issuing large numbers of small degenerating collateral bundles medially into the medial vestibular nucleus where they diffuse and terminate profusely right up to the ependyma of the IVt ventricle. No terminals appear in cell group X, f-like nuc. or the prepositus hypoglossi or parasolatary nuclei. Fiber and connections were consistently found in the solitary tract and nucleus but no reticular or contralateral vestibular endings were observed. Limited terminal degeneration was encountered in parts of the spinal and in the doral part of the lateral vestibular nuclei.

Fascicles of the ascending limb ascend chiefly in the superior nuc., which exhibits terminals throughout and these fibers issue collaterals that terminate in the oral-third of the medial nucleus. Multiple small fascicles splay out dorsal to the superior nuc., penetrate the brachium conjunction and then deflect caudalwards through or vental to the interposed and fastigial nuclei. A minor component of these vestibulo-cerebellar fibers project laterally into the flocculus and a few medially into the lingula. The majority of these fibers loop diffusely caudalwards and then assemble into intermitent concentrations restricted to the white matter in the nodulus and the ventral half of the uvula from which they enter and terminate in the granular layer. Some direct 8th nerve connections with the caudal ventral fastigial cells were evident but no ventral, parvocellular dentate connection were suggested.

SPINAL CORD POTENTIALS EVOKED BY CUTANEOUS AFFERENTS IN MAN 153.1 A.M. Sherwood, M.R. Dimitrijevic, J. Faganel\*, J.A. Halter\*, L.D. Lehmkuhl\*, Department of Clinical Neurophysiology, The Institute for Rehabilitation and Research, and Department of Rehabilitation, Baylor College of Medicine, Houston, TX, 77030. We recorded spinal cord potentials from epidural electrodes

in a group of patients with spinal cord injury or lumbosacral radiculopathy. The patients were undergoing evaluation of the effectiveness of spinal cord stimulation on spasticity or pain. The electrodes were located over the dorsal aspect of the midline of the cord, from T9 to L1 vertebral levels. Mechanical midline of the cord, from T9 to Ll vertebral levels. Mechanical stimuli supplied by an electrodynamic hammer were applied to dermatomes from T11 to S1 and tendons of the triceps surae and quadriceps muscles. Electrical stimuli were applied to sural, peroneal, tibial, and iemoral nerves with 0.5 mS duration, and intensities ranging from 50 to 150 volts, at a rate defined by the patient's EKC. 16 to 128 responses were averaged for each recording. Characteristics of spinal plentials evoked by mechanical taps have been compared with those evoked by electr-ical stimulation of peripheral nerves in the lower extremity. Tapping the toenail and skin areas within the same dermatome elicited a spinal potential with initial necative and following elicited a spinal potential with initial negative and following positive components similar to those evoked by electrical stimulation of the sural nerve when recorded from an epidural electrode at Tl2. Tapping cutaneous regions of more proximal electrode at T12. dermatomes resulted in a reduction in amplitude of the negative potential which corresponded to the distance of the segmental input from the recording electrode. In addition, the positive component was substantially reduced or eliminated. Taps applied to skin overlying the Achilles and patellar tendons elicited spinal potentials of dispersed waveform even when applied at a strength below that which was necessary to elicit a stretch reflex. Furthermore, no new features were revealed when the stimulus intensity was increased above the threshold for the stretch reflex. These findings correspond to the results of stretch reflex. These findings correspond to the results of animal studies which show that the potentials recorded from the dorsal aspect of the spinal cord following stimulation of a peripheral nerve trunk reflect primarily sensory input, which has been found to be distributed over a number of adjacent spinal cord segments.

SPINAL CORD POTENTIALS ELICITED CONCURRENTLY WITH MONOSYNAPTIC 153.2 REFLEXES IN MAN, J. Faganel\*, M.R. Dimitrijevic, J.A. Halter\*, L.D. Lehmkuhl\*, A.M. Sherwood\*, Department of Clinical Neuro-physiology, The Institute for Rehabilitation and Research, and Department of Rehabilitation, Baylor College of Medicine, Houston, TX, 77030.

Evoked potentials from the lumbosacral spinal cord (SC) were recorded with epidurally placed electrodes in response to concurrently elicited myotatic reflexes or H reflexes in triceps surae muscles. This study was done in patients who had epidur-ally placed electrodes for evaluation of the effects of SC ally placed electrodes for evaluation of the errects of so stimulation on spasticity or pain due to chronic SC injury or chronic radiculopathy. The epidural electrodes were placed over the dorsal aspect of the cord, approximately on the midline, from T9 to L1 vertebral levels. H reflexes were elicited with stimuli of 0.5 mS duration delivered to the tibial nerve at the popliteal fossa, at a rate defined by the patient's EKG. Myotatic reflexes (T-waves) were elicited by an electrodynamic harmer applied to the Achilles tendon at the same rate. Reflex responses were conditioned by the application of strong vibra-tion applied to the triceps surae muscle. 16 or 32 responses were averaged for each recording. The response to electrical stimulation consists of a negative wave in the range of 10 to stimulation consists of a negative wave in the range of 10 to 100 microvolts, with an onset latency in the range 10 to 12 mS, a peak latency of approximately 15 to 16 mS, and a duration of approximately 6 mS, followed by a slower positive wave of lower amplitude. The response to mechanical stimulation was lower in amplitude and more dispersed. These responses reflect pre- and post-synaptic events generated in the root entry zone by the electrical or mechanical stimulus. By recording SC evoked potentials during electrically and mechanically elicited monosynaptic reflexes, we examined the contribution of cutaneous and proprioceptive afterent fibers in the generation of the evoked response. These SC evoked potentials were compared to SC potentials elicited during transitory hyporeflexia or areflexia induced by vibration of the Achilles tendon and to SC potentials observed during hyperreflexia due to postvibratory potentiation. Only minor changes of amplitude and waveform of the evoked spinal cord potentials were observed. In contrast, significant changes in the H- and T-reflexes were found. This suggests that generators of the SC potentials reflect more than proprioceptive input and changes to such input due to presynaptic inhibition induced by vibration.

NEUROMUSCULAR OSCILLATIONS ABOUT THE ANKLE JOINT IN THE CHRONIC 153.3 SPINALIZED CAT. N.S. BRADLEY and J.L. SMITH. Neuromotor Control Lab., Dept. Kinesiology, UCLA, Los Angeles, CA 90024.

Rapid, rhythmical oscillations of the neuromuscular system are associated with a number of neurological diseases and lesions. In the cat, these oscillations, generally referred to as clonus or tremor, may reach frequencies up to 20 Hz. Kittens spinalized at 2 wks or 3 mos of age generally develop flexor tremors at 8-12 Hz; the extensor muscles are seldom involved (Smith et al. Exp. Neurol. 76:1982). Our preliminary observations on cats spinalized as young adults suggested that extensor muscles were more frequently involved. This study was conducted to characterize neuromuscular oscillations about the ankle joint in 4 cats

spinalized at the T-12 level as adults. The animals were tested 1-2 times weekly during the first 3 mos of recovery. EMG from 2 ankle extensors, soleus (SOL) and lateral gastrocnemius (LG), and l ankle flexor, tibialis anterior (TA), were recorded during reflex testing, including tendon taps, manual stretch, paw pinch and minute vibration of the Achilles at 60 Hz. Automatic movements, airstepping (ASTP) and the paw shake response (PSR), were also examined for epochs of oscillations. Video records of the cat's limb movement were synchronized with the EMG. A total of 163 epochs of EMG oscillations, associated with rhythmical movements at the ankle, were examined. Frequency ranges from 8 to 18 Hz were found in all animals,

with the most common periods between 10-12 Hz. In the majority of records, the extensor muscles alone exhibited oscillations with no reciprocal activity in the TA. Of the 2 extensors, the SOL was according to the the two of the two seconds, the outward was more often involved than the LG. Higher mean frquencies were associated with stretch of the extensors (15 Hz) and vibration of the Achilles with the ankle held in  $90^{\circ}$  of flexion (15 Hz).

Oscillations involving reciprocal activity of the TA and SOL/LG were rare except when the animal was held suspended. Reciprocal oscillations occurred after ASTP or PSR and ranged 10-18 Hz, with a mean of 13 Hz. Normally, TA activity was initiated 50% into the extensor cycle. The average burst durations for the SOL (32 ms) and LG (26 ms) were similar to that for the TA (35 ms). These data show that the neural input associated with reciprocal oscillations were symmetrical for ankle flexors and extensors.

Although the rapid neuromuscular oscillations may be seen more typically in flexors or extensors, depending on the cat's age at typically in flexors or extensors, depending on the cat's age at spinalization, the EMG rhythms in all age groups agree with the predicted frequencies for the ankle muscles of the cat (Nichols, et al. <u>Can. J. Physiol. Pharmacol</u>. 56:1978). Since the rhythms never exceeded 20 Hz and were abolished when muscle tension in-creased, we hypothesize that the oscillations are produced by a combination of mechanical and reflex factors, rather than a central oscillator. Supported by NIH grant NS 16333.

ANKLE JOINT STIFFNESS IN A FUNCTIONALLY DEAFFERENTED HUMAN

ANKLE JOINT STIFFNESS IN A FUNCTIONALLY DEAFFERENTED HUMAN SUBJECT P.L. Weiss, R. Forget; R.E. Kearney, I.W. Hunter and Y. Lamarre Biomedical Engineering Unit, Faculty of Medicine, McGill University and Departement de Physiologie, Universite de Montreal, Montreal, Canada, H3G 1YG The relative contributions of the passive (muscle and joint visco-elasticity) and active (reflex and voluntary muscle activation) components to dynamic joint stiffness have been investigated in a subject who can vary the level of voluntary muscle contraction from full relaxation to a moderate level of activation but who is functionally deafferented. This subject has symptoms (i.e. lack of touch, vibration, pressure and kinesthetic senses) which indicate impairment of the larger diameter (groups I and II) peripheral sensory myelinated fibers below the level of C2. The results of electrophysiological tests (H-reflex and somatosensory evoked potentials), nerve biopsies and correlation functions calculated between changes in joint angle and agonist EMGs confirm the above clinical findings. findings.

The paradigm used previously (Hunter & Kearney, J. Biomechanics, 1982), in which normal subjects were subjected to repeated stochastic ankle angular displacements during contractions of the ankle joint dorsi- or plantarflexors, was slightly modified to facilitate the investigation of dynamic

contractions of the ankle joint dorsi- or plantarflexors, was slightly modified to facilitate the investigation of dynamic stiffness at low frequencies. The results of this investigation indicate that the behaviour of the ankle joint of this subject at frequencies above 5 Hz is very similar to that of normal subjects. As in previous work, ankle joint stiffness in the intact human can be modelled by a second-order transfer function having inertial, viscous and elastic terms. The inertial term remains constant but the viscous and elastic terms increase linearly with mean torque level. In contrast, the behaviour of the ankle joint at those frequencies at which one would expect the contribution of the reflex component to be relatively important (less than 1 to 2 Hz), was quite different than that shown by normal subjects. Whereas the squared coherence (a measure which provides an estimate of the proportion of the output variance accounted for at a given frequency by a linear dynamic relation between position and torque) for normal subjects was greater than 0.9 at low frequencies, it was less than 0.5 for this deafferented subject. Low coherence values will occur if (1) the relation between the input and output is non-linear, (2) there are additional, not accounted for inputs to the system being identified and (3) the output power is reduced. Our results indicate that neither (2) nor (3) are responsible for the low coherence values. Rather, it is likely that, in the absence of the possibility for reflex modification of ankle joint and torque is non-linear.

153.5 EXCITABILITY CYCLE OF A LOW-THRESHOLD HUMAN FLEXION REFLEX, <u>K.L. Robinson\* and A.J. McComas</u> (SPON: E.S. Werstiuk). Clinical Neurosciences, McMaster University Medical Center, Hamilton, Ontario. CANADA L8N 325.

We have recently discovered a low-threshold cutaneous reflex in the human arm and have now analyzed the time-course of motoneurome excitability which follows the reflex discharge. The reflex is recorded from the posterior deltoid (PD) muscle with surface electrodes and can be elicited by single stimuli applied to digital nerve fibres or to cutaneous mechanoreceptors. Although the size of the reflex varies between trials and between subjects, a response can be recorded electromyographically in almost all normal subjects (19/20 volunteers). Using a conditioning testing paradigm, it can be shown that, after the reflex discharge, there is facilitation for 15 ms and this is succeeded by an inhibitory period lasting 180 ms. Similar results, following stimulation, can be obtained by rectifying and averaging EMG activity during steady voluntary contraction of PD. Two observations indicate that the major part of the inhibition cannot be due to recurrent inhibitory phase can be detected in the anterior deltoid without a preceding excitatory period. In previously untested individuals the inhibitory period is interrupted by a second excitatory phase at 100 ms but, interestingly, the latter is loss after repeated experimentation. The topographical organization of the excitatory components of the reflex indicate that the latter is part of a flexor withdrawal mechanism. 153.6 ISCHEMIC PRESSURE BLOCK: EFFECTS ON SECONDARY FACILITATION IN THE H-REFLEX RECOVERY FUNCTION.<sup>†</sup> R.T. Pivik and F.W. Bylsma\*. Lab. Psychophysiology, Department of Psychiatry and School of

Psychology, University of Ottawa, Ottawa, Ontario, KlH 8L6. Spinal monosynaptic reflexes in man are facilitated if preceded 100-300 msec by a conditioning reflex response. The activation of long-loop reflexes, cutaneous afferents and afferent feedback following muscle contraction have been suggested as bases for this secondary facilitation. In the present investigation an ischemic pressure block was created to evaluate the effect of reducing or eliminating afferent feedback on secondary facilitation.

Twelve normal young adult volunteers (7 male, 5 female) participated in the investigation. Motor and reflex (H1, H2) responses recorded from the gastrocnemius-soleus muscles were elicited by pericutaneous stimulation of the tibial nerve in the popliteal fossa. Pairs of equal intensity .5 msec stimuli above threshold for direct responses were delivered at inter-stimulus intervals of 100, 200, and 300 msec (5 pairs/interval). Reflex measurements were taken immediately before the pressure block was put in place, at approximately 10 minute intervals during the block and immediately after the block was removed. The block was effected for 30 minutes by a sphygmamometer cuff attached to the leg between the stimulating and recording electrodes and inflated to 300 mm HG. Reflex amplitude was not appreciably diminished until the final minutes of the ischemic period (t20-t30). By t30 the ischemic effects began to spread above the cuff to the point of tibial nerve stimulation as indicated by marked decreases in amplitude of both H1 and H2. However, although both reflex responses were affected, the reduction in H2 was slightly enhanced relative to that of H1 (5.5% average greater decrement across intervals). This decrease accounts for approximately 20% of the reflex amplitude increase associated with secondary facilitation. However, the contribution of afferent feedback from muscle contraction to secondary facilitation may be more or less than the observed 20% since the ischemic block may have activated other influences, such as disinhibition of alpha motoneurons by inactivation of cutaneous afferents. The latter possibility is supported by the observation that amplitude decrements of 50% for H1 and H2 were associated with only a slight (6.1%) reduction in secondary facilitation.

153.7 REFLEX ACTION IN AN AGONIST-ANTAGONIST MUSCLE SYSTEM IN THE DECEREBRATE CAT. <u>T.R. Nichols</u>. Dept. of Kinesiology, Univ. of Washington, Seattle, WA 98195 Force of contraction and stiffness were measured in

Force of contraction and stiffness were measured in agonist and antagonist muscles with intact reflex connections during stimulation of various peripheral nerves. A flexor (tibialis anterior or extensor digitorum longus) and an extensor (soleus or gastrocnemius) were connected via individual myographs around the pulley of a printed motor in opposite directions. Cats were decerebrated at the premammillary level. Muscle temperature was regulated at 36°C. Ramp length changes lasting 100 ms and remaining at plateau for 300 ms were applied with alternating direction by the motor.

Peripheral nerve stimulation led to changes in muscle force. Stimulation of the contralateral tibial nerve (lower leg) at 50pps activated extensors at high intensities (>2XT) but frequently caused activation of flexors or transient coactivation at lower intensities. Ipsilateral tibial nerve stimulation usually led to flexor excitation and extensor inhibition at the higher intensities, but frequently led to extensor excitation at lower intensities. Ipsilateral sural nerve stimulation usually led to excitation of extensors at low intensities (<1.4 X T) and inhibition of extensors at higher intensities. Intermediate forces could be obtained by stimulating more than one nerve simultaneously.

than one nerve simultaneously. Force responses to length change increased in a quasilinear way with ramp amplitude (0.25 - 8 mm). Stiffness ( $\Delta F / \Delta L$ ) was dependent upon initial muscle force, but relatively independent of the method of excitation. Occasionally transient decreases in stiffness were observed at the onset of stimulation. (cf. Hoffer and Andreassen, 1981. J. Neurophysiol. 45:267-285). The stiffness of extensors was usually greater than that of flexors. However, flexor stiffness ware observed to equal or surpass extensor stiffness during flexor spasms. This effect could not be explained by changes in the initial force. It is concluded that various peripheral reflexes affect

It is concluded that various peripheral reflexes affect motoneuronal excitability primarily, while stiffness is regulated by supraspinal influences.

153.8 SYSTEM IDENTIFICATION OF HUMAN STRETCH REFLEXES: TIBIALIS ANTERIOR. <u>R.E. Kearney</u>, I.W. Hunter and P.L. Weiss. Biomedical Engineering Unit, Faculty of Medicine, McGill University. Montreal. Canada. H3C 1Y6.

Biomedical Engineering Unit, Faculty of Medicine, McGill University, Montreal, Canada, H3G 1Y6. System identification methods have shown that the stretch reflex in the human ankle extensor (triceps surae, TS) may be characterized as feedback of a velocity signal through a uni-directional sensitive nonlinearity via a single short latency pathway (Kearney & Hunter, Expt Brain Res, 1983). The present work has used the same methods to examine stretch reflexes in the ankle flexor (tibialis anterior, TA).

Five normal subjects maintained a tonic contraction of TA while subjected to repeated, stochastic perturbations of ankle position. Position, torque and smoothed rectified EMG's were recorded and ensemble averaged over 25 stimulus presentations.

ensemble averaged over 25 stimulus presentations. Impulse response functions (IRF) relating TA EMG to ankle velocity accounted for 60-70% of the observed EMG variance and there was no evidence of any direction dependent nonlinearity. TA IRFs were all similar to that shown in the figure and are characterized by two distinct peaks of excitation separated by a period of inhibition. The IRF amplitude increased with increasing mean torque and decreased with displacement amplitude although the size of the effect on the two peaks was different.

LAG (ms) These results indicate that stretch reflexes in TA are subserved by two separate mechanisms: a short latency pathway probably mediating spindle primary afferents and a second, longer latency pathway perhaps mediating spindle secondary afferents. Supported by a grant from the Canadian MRC. 153.9 TESTING FOR REFLEX PARTITIONING IN THE MOTOR NUCLEUS OF THE CAT LATERAL GASTROCNEMIUS MUSCLE. <u>S. Vanden-Noven, T. M. Hamm and</u> <u>D. G. Stuart</u>. Department of Physiology, University of Arizona, Tucson, AZ 85724.

Recent studies have shown that: 1) the cat lateral gastrocnemius (LG) muscle has four anatomically separate "compartments" innervated by primary nerve branches (English and Weeks, <u>Neurosci</u>. <u>Abstr. 8</u>: 959. 1982); 2) the distribution of motoneurons supplying these nerve branches is topographically organized (Weeks and English, <u>Neurosci</u>. <u>Abstr. 8</u>: 959, 1982); and 3) the muscle compartments may be activated somewhat independently during movement (Russell et al., <u>Neurosci</u>. <u>Abstr. 8</u>: 948, 1982). These findings have prompted the present study which is designed to test the hypotheses that: 1) homonymous monorvanptic Ia EPSPs are not distributed homogeneously throughout the motor nucleus of LG, and 2) this heterogeneity is attributable to "own-branch" EPSPs being larger than "other-branch" EPSPs (Botterman et al., <u>Neurosci</u>. <u>Letters 24</u>: 35-41, 1981).

Intracellular recordings from LG motoneurons were made in anesthetized low-spinal cats during periods of electrical stimulation of the nerve branches supplying the four compartments of the LG muscle. Measurements were made of each cell's composite homonymous own- and other-branch monosynaptic Ia EFSPs evoked by stimulation of the test-nerve branches. To test the first hypothesis, the fractional EPSPs produced by the stimulation of single nerve branches (fraction of sum of EPSPs produced by all nerve branches) were normalized by the corresponding fractional dorsal-root volleys (fraction of total dorsal-root volley) for each cell. This procedure was designed to factor out variations in EPSP amplitude due to cell type (i.e., S, FR, FF) and variable afferent content among the nerve branches.

An analysis of variance of these data for all nerve branch -motoneuron combinations indicates the presence of a significant (p-0.005) non-homogeneous distribution of monosynaptic Ia EPSPs in the LG motor nucleus. However, the present motoneuron sample size (N=44) is insufficient at this time to permit conclusions to be drawn concerning our second hypothesis. Supported in part by USPHS grants NS 07888, HL 07249, and NS 17887. 153.10 STRETCH REFLEXES AFTER SPINAL LESIONS IN THE CAT. M.F. Brothers, D.A. McCrea, W.G. Tatton and R.R. Tasker, Playfair Neuroscience, University of Toronto, Toronto, Canada. (Spon: J. Sharpe). In order to provide quantitative data on the changes in reflexes following soinal lesions, we have studied the stretch

flexes following spinal lesions, we have studied the stretch reflexes obtained from ankle flexor and extensor muscles in awake, unanesthetized normal cat and several lesioned preparations: the chronic spinal (mid-thoracic cord transection, duration 3-4 months), the chronic hemisected (mid-thoracic), and the acute anemic decerebrate cat. Stretch reflexes were elicited by a torque motor which caused repeated passive ankle rotation at a variety of velocities; the evoked electromyographic activity (EMG) from medial gastrocnemius (MG) and tibialis anterior was recorded, and later digitized. Trials were sorted according to the velocity of ankle rotation; rectified EMG as well as tension and position signals were computer-averaged. Reflex EMG was quantitated through expression of its size as a percentage of the muscle's maximal electrically evoked EMG output (m-max) (Lenz, G.A., Tatton, W.G., Tasker, R.R., J. Neuroscience, 1983 (in press)). For earliest latency reflex activity, chronic spinal MG showed increased reflex "gain" (slope of EMG response vs. torque velocity), and decreased reflex threshold and latency, compared to normals. This hyperreflexia was apparent by 10 days posttransection, and at 3 months had not changed significantly. Later-latency reflex activity in MG was also increased in all lesioned animals, but with response characteristics that varied significantly amongst the preparations. Decrebrate cats displayed tonic EMG activity when the muscle was maintained in a static stretch position; in contrast, in the chronic spinal cats, reflex activity persisted only as long as movement continued (dynamic stretch reflexs), with little response to maintained stretch. Two of the chronic spinal cats were decerebrated and MG stretch reflexes were obtained immediately before and after denervation of the distal hindlimb, except the nerve to MG. The hyper-reflexia in MG was still present indicating that activity in muscle afferents alone is sufficient to evoke this increased reflex response in MG. The effect of

The effect of chronic spinal transection on tibialis anterior stretch reflex activity was opposite that of MG; both early and later latency responses were reduced in size; reflex gain was less, and latency greater. Thus the reflex changes occurring after chronic spinalization may be specific for a particular muscle group with hyper-reflexia in ankle extensors and hyporeflexia in ankle flexors.

153.11 ADAPTIVE PLASTICITY IN THE PRIMATE SPINAL STRETCH REFLEX: SLOW PROGRESSIVE CHANGE FOLLOWS IMMEDIATE SMALL CHANGE. J. R. Wolpaw. Center for Labs and Research, NYS Dept. of Health and Depts. of Neurology and Anatomy, Albany Med. Coll., Albany, N.Y. 12201. Monkeys can gradually change the amplitude of the segmentally-mediated, largely monosynaptic, spinal stretch reflex (SSR), or MI, without change in background EMG or initial muscle length [Wolpaw et. al., Br. Res. 267 (1983) 196-200]. Increase (SSR mode) or decrease (SSR mode) develops over weeks and months, survives prolonged breaks in performance, and is relatively specific to the agonist, biceps, muscle (O'Keefe & Wolpaw, this vol.). Reversal and re-development of change follow the same gradual course. This study analyzes the course of SSR amplitude change for 2 months after onset of the SSR or SSR mode. The figure below illustrates the main features of SSR change: 1) Monkeys respond within 1 day, probably within 6 hrs, with a 10% rise (SSR or OK fall (SSR or SSR amplitude change slowly and the same line of the SSR amplitude change (SSR or SSR amplitude change to the declares of SSR change).

this abrupt small change, SSR amplitude changes slowly and steadily throughout the duration of data collection. In the initial weeks, SSR\* rate exceeds SSR\* rate. 3) An equation of the form y=(a/[b+(1/x)])+c closely fits both SSR\* and SSR\* courses, which approach asymptotes of 197% and 49% respectively (Fig). The first day's abrupt change presumably indicates rapid onset of activity in descending spinal cord pathways which alters operation of the segmental arc of the SSR. The subsequent slow change, thick provides the set of activity and the set of activity of the segmental arc of the segment slow change,

of activity in descending spinal cord pathways which alters operation of the segmental arc of the SSR. The subsequent slow change, which continues for at least 2 months and survives prolonged breaks, is consistent with the hypothesis that continued presence of this descending activity produces gradually increasing persistent segmental alteration. Such segmental alteration would constitute a technically accessible substrate of memory.

Daily SSR amplitude after onset of SSR<sup>+</sup> or SSR<sup>+</sup> mode, as % of pre-onset SSR amplitude. Data are from 17 mode exposures (10 SSR<sup>+</sup>, 7 SSR<sup>+</sup>) in 9 monkeys. Lines are computer fits of the equation shown above.

153.12 ADAPTIVE PLASTICITY IN THE PRIMATE SPINAL STRETCH REFLEX: BEHAVIOR OF SYNERGIST AND ANTAGONIST MUSCLES. J. A. O'Keefe\* and J. R. Wolpaw (SPON: K. D. Barron). Center for Labs and Research, NYS Dept. of Health, and Depts. of Neurology and Anatomy, Albany Medical College, Albany, NY 12201. Monkeys can slowly increase or decrease the amplitude (amp)

Monkeys can slowly increase or decrease the amplitude (amp) of the segmentally mediated, largely monosynaptic, biceps spinal stretch reflex (SSR), without change in initial muscle length or background EMG activity [Wolpaw <u>et. al.</u>, Br. Res. 267 (1983) 196-200]. We investigated the concurrent behavior of synergist (brachialis and brachioradialis) and antagonist (triceps) muscles.

Five monkeys were implanted with chronic intramuscular EMG electrodes. Two pairs, a primary pair (biceps 1) and a secondary pair (biceps 11), were placed in the biceps, and single pairs were implanted in the brachialis, brachioradialis, and triceps. Each monkey then learned to maintain a 90° (+1.5) elbow angle against steady extension torque for a period which varied randomly from 1.2-1.8 sec and to keep the average absolute value of biceps I EMG for the final 0.2 sec of this period within a preset range. If it accomplished this two-part task, a brief additional extension torque pulse extended the elbow  $2^\circ-3^\circ$  and elicited the biceps SSR. SSR amp was measured as average absolute value of EMG 14-24 msec after pulse onset, minus background EMG. Under the Control mode, reward occurred 200 msec after the stimulus. Under the SSR+ or SSR+ mode, redward continuously. All animals worked first under the Control mode for 10-30 days, and then under either the SSR+ or SSR+ mode for 20-100 days. Under the SSR+ or SSR map) biceps I SSR amp, never on synergist SSR amp) biceps I SSR amp kas greated contingent only on biceps I SSR is for control (SSR+), or decreased to ca. 150% of control (SSR+) or decreased to

Biceps II data closely paralleled biceps I, indicating that comparable SSR change occurred throughout the biceps muscle.

Synergist background EMG remained stable despite marked change in biceps SSR amp. Triceps remained inactive throughout. Thus, biceps SSR amp change cannot be attributed to changes in synergist or antagonist background activity.

synergist or antagonist background activity. When biceps SSR amp changed under the impetus of the SSR♠ or SSR♠ mode, brachialis and brachioradialis SSR amps changed 72% and 33% as much as biceps SSR amp changed. Thus, greatest change occurred in the agonist, biceps. This relative specificity effectively eliminates a number of extra-neuronal mechanisms as potential causes of SSR amp change; and thus supports the possible value of the SSR as a system for studying the neuronal and synaptic bases of memory in a primate.

GENERAL CHARACTERISTICS OF SPINAL INTERNEURONS RESPONDING TO 153 13 GENERAL CHARACTERISTICS OF SPIRAL INTERNETIONS RESPONDING TO LONGITUDINAL TENDON VIBRATION. <u>W.T. Rainey, K.G. Buahin,</u> <u>W.Z. Rymer.</u> Dept. of Physiology, Northwestern Univ. Medical Center, Chicago, IL. 60611 Longitudinal tendon vibration is a strong, selective stimulus

for primary spindle endings in passive muscle, and a powerful although less selective stimulus to these receptors in contract-ing muscle. We have used longitudinal tendon vibration, together with muscle stretch, electrically induced muscle twitch and reflexively mediated variations in tension of triceps surae muscles to assess muscle afferent projections to interneurons located in laminae V, VI and VII in the lumbosacral cord of the unanesthetized, decerebrated cat preparation. Interneurons were identi-fied on the basis of latency of activation (typically less than 3 ms), synaptic jitter and absence of antidromic activation from muscle nerve or (in many instances) from rostral cord (T12).

Forty interneurons were activated by vibration, although not usually at the vibration frequency. Responses ranged from marked rate augmentation, to more modest responses, and down to just perceptible increases. Phase-locked discharge at a subharmonic of the vibration frequency was most common, but several inter-neurons showed more irregular, "unlocked" rate increases. Vibration sensitiye neurons responded to ramp stretch, varying considerably in their degrees of response to dynamic components considerably in their degrees of response to dynamic components of these stimuli. Superimposed ramp stretch and vibration often stabilized the rate of neuron discharge at a new firing rate, and eliminated ramp-related rate increases, suggesting that secondary ending actions were not prominent. Variations in isometric force during vibration or crossed extensor activation were not reliably

during vibration or crossed extensor activation were not reliably associated with corresponding variations in discharge rate, suggesting that tendon organ convergence was also not prominent. Most vibration-sensitive neurons responded to the cessation of vibration with a sharp reduction or even cessation of discharge. A small percentage showed considerable post-vibration discharge, which decayed in broad concordance with declining muscle tension or even adapted more slowly, over several seconds.

In summary, in the decerebrate preparation many interneurons in laminae V,VI and VII receive powerful Ia input, and appear to show little or no evidence of IB mediated activation. While we do not yet know whether the axonal projections of these neurons are excitatory or inhibitory, the location of many of these cells is dorsal to that of many identified Ia inhibitory interneurons. Those interneurons with prolonged after-discharge may function as neural integrators, contributing to the prolongation of force output after vibration offset, or during stretch reflex activation.

153.14 INPUT-OUTPUT PROPERTIES OF THE CLASP-KNIFE REFLEX IN THE CAT. W.2.Rymer,C.L.Cleland(SPON'J.J.Pysh), Neuroscience Program and Dept. of Physiology, Northwestern University, Chicago, Il, 60611 The clasp-knife reflex, first described in spastic human

The clasp-knife reflex, first described in spastic human patients, also occurs in decerebrated cats that have had their dorsolateral spinal funiculi sectioned. The reflex is characterized by powerful autogenetic inhibition which occurs when an extensor muscle is stretched beyond a certain length. We studied the input-output properties of clasp-knife inhibition in 16 cats. Reflex effects of increases in muscle length and force were measured by recording the force and eng in

the homonymous (soleus(SOL)), synergist (m.gastrocnemius(MG)) and several other extensor and flexor muscles of the hindlimb.

Autogenetic reflex inhibition could be due to increases muscle length and/or force during stretch. By measuring the reflex inhibition in a synergist(MG) instead of the homonymous reflex inhibition in a synce out ing science. By measuring the reflex inhibition in a synce out ing science of the homonymous muscle(SOL), it was possible to dissociate the effects of force and length. To dissociate the reflex effects of force from length, we tetanically stimulated the SOL muscle nerve to produce increases in muscle force without increases in muscle length. Motor output in the MG was reflexely inhibited during the SOL force tetanus. Control experiments verified that the inhibition was not due to electrical stimulation of muscle afferents, unloading of spindle afferents, or mechanical coupling between the SOL muscle and sensory receptors in the MG. The magnitude of inhibition of the MG produced by active, isometric force in the SOL was less than that due to SOL stretches that produced comparable, but passive, increases in muscle force. If the reflex actions of active and passive force are similar, then increases in both length and force in the stretched muscle contribute reflex inhibition of the synergist. The input-output properties of clasp-knife inhibition indicate that it is more accuratly thought of as a flexion withdrawal reflex rather than a specialized, regulatory or

Indicate that it is more accurately thought of as <u>a flexion</u> withdrawal reflex rather than a specialized, regulatory or <u>localized</u> proprioceptive reflex. The spatial pattern of excitation and inhibition induced by stretching the SOL muscle, excitation of flexor and inhibition of extensor muscles, corresponds to that for flexion withdrawal reflexes. Stretch of a flexor muscle, the tibialis anterior, produces autogenetic excitation rather than inhibition, and the overall spatial reflex pattern is identical to the obtended for extensor pattern is identical to that obtained for stretch of an extensor muscle. Extensor muscles are inhibited simultaneously with inhibition of all other extensor muscles and excitation of flexor muscles. Finally, the duration of reflex inhibition greatly outlasts the duration of the free nerve ending input that probably produces it. All these properties are similar to of flexion withdrawal reflexes induced by other stimuli. Supported by NIH 14959 and NIMH 5F31MH08593.

153.16 NONLINEAR VISCO-ELASTIC PROPERTIES OF THE HUMAN WRIST.

FUNCTIONAL CONSEQUENCES OF BETA-ACTION. Steve Grill\*, W. Zev 153.15 Rymer, Neuroscience Program and Department of Physiology, Northwestern University Medical School, Chicago, IL, 60611. Skeletofusimotor (beta) fibers are motor fibers which branch

innervate both intrafusal (IF) and extrafusal muscle fibers (EF). Although they are abundent in both cat and monkey muscles, functional investigations have yet to be done. There are several features of beta MN's which distinguish them from gamma MN's. Recordings from gamma neurons in monkey jaw muscles and cat

hindlimb muscles have shown them to be recruited and their rates largely saturated below extrafusal threshold. Beta fibers may extrafusal threshold. We have characterized the responses of 33 spindle afferents from triceps surae muscles in decerebrated cats to reflexively mediated increases in isometric tension. The rates of 58% of these increased in parallel with force and emg. After characterizing the afferents we anesthetized the cat and After characterizing the afferents we anesthetized the cat and searched through the ventral roots for large diameter fibers which, when electrically stimulated, enhanced the afferent response to stretch (i.e. beta fibers). We found beta fibers innervating 71% of the spindle afferents. Afferents whose rates increased in parallel with motor output were more likely to show beta innervation (P < .001, W-test) suggesting that beta-innervation may be responsible for at least part of the fusimotor activity above extrafusal threshold. To further examine this hypothesis, we used procaine to block gamma fibers on the peripheral nerve and then reexamined

gamma fibers on the peripheral nerve and then reexamined previously characterized spindle afferents. Although there was fusimotor activity during gamma blockade for about half apparent of the afferents studied, the effects were vastly diminished compared with before the block. It is possible that beta action is only significant when there is on-going gamma activity.

is only significant when there is on-going gamma activity. Another probable difference between gamma and beta MN's is that beta MN's (like alpha's) probably receive powerful excitatory feedback from spindle afferents whereas gamma's do not. Increased beta discharge will enhance spindle discharge which in turn will potentially increase further beta MN discharge, constituting a positive feedback loop. If the loop gain is significant, a component of the spindle length sensitivity would be due to the neural signals going around the loop. Interrupting the loop should remove this component and reduce the length sensitivity of spindle afferents. The length sensitivities of 9 out of the 12 afferents tested were decreased after interrupting the loop by cutting the dorsal roots. The after interrupting the loop by cutting the dorsal received after interrupting the loop by cutting the dorsal roots. The positive feedback loop through beta MN's appears to be significant. According to control theory, this may help to reduce the sensitivity of the system to variations in muscle and load properties. Supported by NIH NS17489

L.E.Miller\*,J.C.Houk,S.L.Marcus\*, C.C.A.M.Gielen\*. Northwestern Univ. Dept. of Physiology and Rehab. Inst. of Chicago, Chicago, IL 60611. Supported by the Coleman, Hearst, J.M., Joyce, Regenstein, Searle Foundations, and Mr. and Mrs. L. Lavin. Visco-elastic properties of muscle mechanics and stretch reflex actions play an important role in posture and movement. In the umparimeter properties of muscle mechanics the human wrist

experiments reported here, the visco-elasticity of the human wrist motor servo was studied with the instruction, "Do not intervene voluntarily." Since subjects often have difficulty not intervening in response to perturbations, a new procedure was used to identify unintended interventions. These interventions may vary in time and amplitude and are superimposed on the more stereotypic forces due to the muscle mechanics and stretch reflex. Based on this characteristic, a trial comparison method was developed to select the most stereotype responses from a set of non-intervention trials. The selected responses are thought to represent the mechanical properties and reflex actions of the motor servo uncontaminated by triggered reactions.

Elastic properties were studied by applying step force changes that stretched or released the muscles of the wrist. The response was basically spring-like but included a short-range ( < 0.5 cm) enhancement of stiffness that gave rise to a prominent hysteresis. As a result, end position after a force change was dependent on the path to final position as well as final force. The high stiffness was appreciably diminished when a second force step was applied 300 ms following the cessation of movement caused by a prior force step. Some minimum latency may be required in order to reset the high stiffness when the limb reaches a new position.

to reset the high stiffness when the limb reaches a new position. Viscous properties were studied by applying position ramps of different velocities to the initially active limb. Responses of DMG and force could be described by a product relationship of terms related to position and velocity similar to those described for muscle spindles (Houk,J.C., J.Neurophysiol.:46,143-166,1901). DMG and force responses showed a linear increase with wrist displacement and a fractional-power dependence on velocity. Average values of the exponents were 0.30 (SD=0.09) for BMG and force and EMG began to decay slowly. After 5 seconds force traces still had not reached a constant level. This fact made it difficult to distinguish elastic from viscous properties and may be related to the phenomenon of hysteresis. be related to the phenomenon of hysteresis.

be related to the phenomenon of hysteresis. Nonlinear feedback from muscle spindles and short range elasticity of muscles may be responsible for the observed nonlinear visco-elastic properties of the wrist. These properties may be advantageous in the damping of postural responses and movements but may be disadvantageous for the accuracy of aimed movements

153.17 LENGTH, VELOCITY AND HISTORY DEPENDENCE OF THE HUMAN STRETCH REFLEX. R.K. Powers\* and W.Z. Rymer. (SPON: B.W. Peterson). Dept. Physiol., Northwestern University, Chicago, IL 60611

Previous work on the stretch reflex (SR) of the decerebrate previous work on the stretch reliex (SK) or the decerebrate cat suggests that during the dynamic phase of a ramp and hold stretch, the firing rate trajectories of primary and secondary spindle afferents, as well as the development of reflex EMG and force, are dependent upon the product of muscle length and a low for the stretch of upon the product of muscle length and a low fractional power of velocity (Kouk et al., J. Neurophys., 46:143, 1981; Proc. Int. Congr. Physiol. Sci., 13:901, 1977). Another feature of spindle response that may be evident 1977). Another feature of spindle response that may be evident in SR behavior is the independence of spindle firing rate upon the past history of length change – after the initial burst, spindle firing rate depends only upon instantaneous length and velocity. We are attempting to determine to what extent these features are shared by the SR of human elbow flexor muscles. We have studied the torque produced about the human elbow joint in response to 0.2 to 1.0 radian displacements at different constant appular uplorities and during transitions from one

constant angular velocities, and during transitions from one velocity to another. Elbow extension was produced by a torque velocity to another. Elbow extension was produced by a to motor controlled by a velocity servo. A computer controlled presentation of stretch stimuli and the collection of position, velocity, torque and surface BVG data. Subjects were required to maintain a constant background flexion torque to initiate a trial, and were instructed not to intervene as the elbow was extended. Absence of intervention was verified by low intertrial variability for a given stimulus class (Crago et al., J. Neurophys., 39:925,1976).

Neurophys., 39:925,1976). SR torque usually rose linearly during extension, and both the slope of the torque-angle trajectory and the incremental torque developed after a given amount of extension exhibited a low fractional power dependence upon angular velocity. In contrast to muscle spindle behavior, torque-angle trajectories took from 200-400 msec to approach steady-state trajectories following an upward transition. Plots of the linear envelope of biceps and brachioradialis EMG (low-pass filtered, 7 Hz cuttoff) vs. joint and angle often showed a curvilinear relation between reflex activity and angle, reflecting a randid increase in EMG at stretch onset angle often showed a curvilinear relation between reflex activity and angle, reflecting a rapid increase in DMG at stretch onset followed by little or no further increase with further stretch. The dependence of reflex DMG upon history of length change was less obvious than that of reflex torque, particularly for downward transitions where DMG often approached control trajectories within about 500 msec. These results suggest that at least part of the transitional behavior of reflex torque depends upon the mechanical properties of active muscle. Supported by NTH 1 ROI NS19331, Coleman, Hearst, J.M., Joyce and Searle Foundations. Searle Foundations.

153.18 ANATOMY AND PHYSIOLOGY OF SEXUAL REFLEXES IN MALE RATS: SPINAL ORGANIZATION OF DORSAL PENILE NERVE PRIMARY AFFERENTS. Ramón

ORGANIZATION OF DORSAL PENILE NERVE PRIMARY AFFERENTS. <u>Ramón</u> Núñez,\* Gayle H. Gross\* and Benjamin D. Sachs. The University of Connecticut, U-20, Storre, CT 06268. The dorsal penile nerve (DPN), a sensory branch of the pudendal nerve, carries sensory information mediating penile reflexes that have been functionally related to copulatory behavior. In this study we report the spinal segmental position of the dorsal most ganglion (DBC) cells that carry the seciet of the dorsal root ganglion (DRG) cells that carry the genital afference, as well as their spinal cord projection patterns, In adult male rats prefested for strong penile reflexes, horseradish peroxidase crystals were applied to the DPN for 2 hr.

Animals were allowed to survive for 72 hr before tissue preparation.

The cells of origin of the DPN were located exclusively in DRG  $L_c$ , within which they appeared to be randomly distributed. A mean of  $642 \pm 17$  labeled DRG cells were observed, with a bimodal size distribution. Within the spinal cord these DRG cells send profuse collaterals to the substantia gelatinosa. The being periods contacterate to the substantia gratinosa. In their dorsoventral trajectory the fibers course via the medial collateral pathway, exiting to form terminals on medial dorsal horn interneurons in laminae III to VI. At the anterior commissure they join fibers from the contralateral side to form a dense plexus, as well as terminals on lamina X interneurons. Thus, a striking feature of the central projection of the DPN afferents is their extensive distribution among laminae and afferents is their extensive distribution among laminae and alternets is sements ( $r_{\rm L}$  to  $s_{\rm L}$ ). Furthermore, we report the novel observation of termination of primary afferent fibers directly onto motoneurons of lamina IX in spinal segments  $L_{\rm L}$  to  $L_{\rm L}$ , including the nuclei projecting to the strikted penile mdscles. When recording from the DPN in response to dorsal root (DR)

stimulation, only DR L, produced activity. This response had two components with conduction velocities of 32 m/sec and 7.1 two components with conduction velocities of 32 m/sec and 7.1 m/sec respectively. When the reflex activity produced by electrical stimulation of the DPN was recorded from the ventral roots, the maximal polysynaptic response was obtained from  $L_{\rho}$  and decreased in amplitude caudally. No monosynaptic response was obtained by DPN stimulation. However, stimulation of the posterior biceps muscle nerve produced a monosynaptic reflex that was the time. that was facilitated by DPN stimulation. BDS and NS-10338 to Guillermo Pilar.)

## NEUROETHOLOGY: NONAVIAN AUDITORY SYSTEM AND VOCALIZATION

CRICKET (TELEOGRYLLUS OCEANICUS) PHONOTACTIC DIRECTION IS DETER-MINED BY BOTH FREQUENCY AND TEMPORAL PATTERN. G.S. Pollack, F. Huber\* and T. Weber\*. Dept. of Biol.; McGill Univ., Montreal, Quebec and Max Planck Inst. für Verhaltensphysiol, Seewiesen, FRG 154.1 Crickets locomote in a directed fashion in response to sound Crickets locomote in a directed fashion in response to sound stimuli; they perform phonotaxis. We studied phonotaxis in T. <u>oceanicus</u>, with both a flight paradigm, in which steering attempts were signalled by postural changes, and in a walking paradigm, in which walking direction on a spherical treadmill was measured. Crickets steered toward, or walked in the direction of, a speaker broadcasting a model of the species calling song with a natural carrier frequency (5 kHz), and steered or walked away from a song model with 33 kHz carrier. Thus the frequency-dependent switch from positive to negative phonotaxis, previously reported for flight behaviour by Moiseff et al (PNAS 75: 4052; 1978) also occurs during walking. 1978) also occurs during walking. Recently, Thorson et al (J. Comp. Physiol. 146: 361; 1982)

discussed how changes in carrier frequency could, due to accus-tic properties of the ears, result in alterations of the binaural difference in sound intensity which is thought to underly the cricket's determination of sound direction; directionality might thus be inaccurate at elevated carrier frequencies. Could errors in directionality explain positive and negative phonotaxis? To answer this question we studied crickets which were unilaterally deafened by amputation of one ear. Since these crickets received all acoust information from the one remaining ear, their responses should not be affected by changes in binaural intensity difference. In the flight paradigm, one-eared crickets steered toward the intact side when a 5 kHz song model was played. In the away from the intact side when a 33 kHz model way played. In the walking paradigm, crickets turned continuously (circled) toward the intact side for the 5 kHz model, and away from the intact side for the 33 kHz model. Thus, low and high frequencies elicit opposite responses even when frequency effects on binaural intensity differences are precluded.

Low and high frequency responses had different temporal pattern requirements. A non-song pattern failed to elicit responses with 5 kHz carrier frequency, but with 33 kHz carrier it elicited negative phonotaxis in intact crickets, and orienta-tion away from the intact side in one-eared crickets, in both the tion away from the intact side in one-eard crickets, in both the flight and walking assays. At an intermediate frequency, 15 kHz, response type depended on temporal pattern. The song pattern resulted in positive phonotaxis (intact crickets) or orientation toward the intact side (one-eared), and the non-song pattern in negative phonotaxis or orientation away from the intact side. Frequency-dependent directionality errors alone cannot account for our findings. It seems likely that positive and negative theartering enclose a for fifteenet encycle whethere the phonotaxis are the products of different neural substrates.

154.2 SELECTIVITY OF MIDBRAIN NEURONS TO AMPLITUDE MODULATED WHITE NOISE: DIFFERENTIAL TUNING IN TWO SPECIES OF TOADS G. J. Rose and R. R. Capranica. Section of Neurobiology and Behavior, Division of Biological Sciences, Cornell University, Ithaca, NY 14853.

The mating calls of <u>Bufo</u> a. <u>americanus</u> and <u>Bufo</u> w. <u>fowleri</u> are very similar in terms of their frequency content but differ markedly in their temporal structure. Specifically, the call of Fowler's toad is amplitude modulated (AM) at a rate approxi-mately three times that of the American toad, and is of shorter duration. Single unit recordings from the torus semicircularis in the midbrain revealed a population of neurons in each species that are tuned to particular rates of amplitude modulated white noise; these AM tuned units comprised 34% of all of the cells recorded. The modulation rate at which a unit responded maximally was termed its "best rate of AM". The distribution of best rates of AM was shifted to higher modulation rates in Fowler's toad, relative to the American toad. Further, neurons tuned to modulation rates greater than 75 Hz were only found in Fowler's toad. The results suggest that the tuning of AM-sensitive neurons in the anuran midbrain is species-specific. (Supported by NIH Grant NS-09244 and NIMH Training Grant T32-MH15793.)

A SEX DIFFERENCE IN BASILAR PAPILLA TUNING IN THE HYLA CRUCIFER 154.3 AUDITORY SYSTEM AND ITS BEHAVIORAL SIGNIFICANCE. Wilter Wilczynski, Harold Zakon, and Eliot A. Brenowitz. Section of Neurobiol. & Behav., Cornell University, Ithaca, NY 14853. The tuning of single eighth nerve auditory fibers in the spring peeper (a small treefrog) was investigated electrophysiologically The tuning of single eighth nerve auditory fibers in the spring peeper (a small treefrog) was investigated electrophysiologically in males and females collected from breeding choruses around Itha-ca, NY. Two groups of fibers are present. One consists of low and mid frequency units with best excitatory frequencies (BEFs) ranging from 103-1200 Hz. These fibers presumably arise from the amphibian papilla (AP). There is no strong difference between males and females in AP tuning. However, a sex difference is ap-parent in the tuning of the second group of fibers, which are tuned to higher frequencies and presumably arise from the basilar papilla (BP). In both sexes, the BEFs of BP units in any individ-ual are tightly clustered, but there is variation among individu-als. In males, BP tuning is lower, 2939 Hz, and the variation in tuning among individuals is greater (range: 2100-3700 Hz). Male and female thresholds are comparable. Within females BP tun-ing is correlated with size such that as snout-vent length in-creases, BP tuning may be due to size differences between males and females: females are generally larger than males. The sex difference in BP tuning may be due to size of an average male, and had a BP tuned to 3600 Hz. Although the sex difference in BP tuning was approximately the size of an average male, ad had a BP tunet to alower frequence. In many anurans the male advertiement (main) consequences. In many anurans in BP tuning may be a passive result of male-female size differ-ences, it has important behavioral consequences. In many anurans the male advertisement (mating) call has been implicated in both female attraction and intermale agonistic interactions. <u>H. cru-cifer's</u> call is a simple, tonal "peep". Its mean dominant fre-guency in males from the Ithaca area is 2895 Hz (range: 2588-3212 Hz). Thus males call where the females are tuned, which max-imizes the distance over which females can be attracted. In doing this males become "detuned" to their own calls, although they can still detect the call frequencies with the low frequency slopes of their BP tuning curves. The high detection threshold this yields is used by the males to distribute themselves within the chorus. their BP tuning curves. The high detection threshold this yields is used by the males to distribute themselves within the chorus. The average intensity of a male's call when it reaches his nearest neighbor was measured to be 79.1 dB SPL, which is just a few dB above the threshold for detecting the call frequencies. Thus males space themselves far enough apart so that they can barely hear their pairbox. hear their neighbors. Supported by NIH Fellowship NS 06237 to WW and NIH Grant NS 09244 to Robert R. Capranica, who provided support and facilities

INTERFERENCE WITH TARGET RANGE DISCRIMINATION BY ECHOLOCATING BATS, CORRELATED WITH THE STRUCTURE OF ARTIFICIAL PULSES. <u>R. Roverud</u> \* and <u>A. D. Grinnell</u>, Depts. Biology and Physiology, UCLA, Los Angeles, CA. 90024. (SPOM: R. Barrett). Bats of the species <u>Noctilio albiventris</u> were trained to dis-criminate differences in target distance by means of echolocation. During the discrimination triels, the bats premeatedly emitted 154.5

During the discrimination trials, the bats repeatedly emitted pairs of pulses, the first a constant frequency (CF) signal ap pairs of pulses, the first a constant frequency (CF) signal ap-proximately 12 msec long and 75 kHz in frequency, followed after 20-30 msec by a CF/FM pulse composed of a 75 kHz CF component of approximately 10 msec duration terminating in a 2 msec frequency modulated (FM) component sweeping downward to about 40 kHz. Loud artificial pulses, simulating the bats' natural CF/FM echolocation sounds and presented to the bats during the behavior-al trials, interfered dramatically with distance discrimination.

Systematic modifications in the structure of the artificial pulses resulted in orderly changes in the degree of interference with the discrimination. Interference occurred when repetition rates exdiscrimination. Interference occurred when repetition rates ex-ceeded 5/sec. Artificial pulses simulating the bats' natural CF sound alone or the FM component of the CF/M pulse alone did not interfere with discrimination. 12 msec white noise pulses presented at 10 pulses/sec also had no effect, although constant white noise masked the behavior. Artificial CF/M pulses with a reduced FM bandwidth were effective in disrupting performances when the FM sweep exceeded 10 kHz.

Interference occurred when the duration of the CF component of the CF/FM signal was between 2 and 30 msec, with maximal effect at durations of 8-20 msec. Presenting a brief (0.6 msec) CF signal 2-30 msec before the isolated FM component was equivalent, in effect, to CF/FM pulses having CF components of the same duration. Therefore it is the time interval between the onset of the CF component and the FM sweep that determines the extent of inter-

ference with the bat's interpretation of echoes of its own sounds. The "jamming"effectiveness of the artificial pulses depended upon the absolute frequencies presented to the bat. Interference upon the absolute frequencies presented to the bat. Interference occurred when the CF frequency was between 77 kHz and 52 kHz, with a downward IM sweep of 25 kHz from the CF frequency. The degree of interference caused by the pulse also depended on the relative frequency of the CF and FM components. The pulses interfered with the ability of the bat to discriminate only when the CF frequency was very close to that of the beginning of the FM sweep. These findings imply the importance for range discrimination of a computer that one caloatively activated by a

of a population of neurons that are selectively activated by a combination of CF onset and FM components occurring at 10-20 msec separation, within a fairly broad frequency range, but with the requirement that the frequency of the CF and the onset of the FM sweep be nearly identical.

TEMPORARY THRESHOLD SHIFT IN FROG AUDITORY NERVE FIBERS. 154.4 <u>R. Zelick\* and P.M. Narins</u>. Dept. of Biology, UCLA Los Angeles, CA 90024.

The treefrog <u>Eleviherodactylus</u> <u>coqui</u> communicates acoustically in <u>a very loud</u> sonic environment. Similar circumstances occur for many frog species in which calling males may commonly encounter continuous background levels of 80 to 90 dB SPL from the vocalizations of neighboring 80 to 90 dB SPL from the vocalizations of neighboring individuals. This prompted us to investigate whether these animals have adaptations which render them relatively in-sensitive to the temporary threshold shift (TTS) a mammal would experience in the same environment. Under computer control, thresholds to tone bursts (50 msec duration) were determined for single fibers in the eighth cranial nerve of immobilized and topically anesthetized male

cranial nerve of immobilized and topically anesthetized male <u>E. coqui</u> before and after a three minute presentation of a monaural continuous tone stimulus (CTS). For each neuron examined, the CTS was set to the best excitatory frequency (BEF) and to a level between 10 and 50 dB above the neuron's best threshold (115 dB SPL max). Immediately following the CTS, threshold determinations were made either every 200 msec or every second for a period of three minutes at the BEF and typically one and two octaves above and below the BEF. Thresholds tracked before the CTS was presented did not

typically one and two octaves above and below the BEF. Thresholds tracked before the CTS was presented did not change over time. After CTS exposure, both low frequency (amphibian papilla) and high frequency (basilar papilla) fibers exhibited thresholds elevated by as much as 40 dB. At any BEF there was a wide range of threshold shifts (>20 dB) observed for a given CTS level above threshold. TTS was greater at the BEF than at frequencies above and below the BEF. The amount of recovery (sensitivity regained) after three minutes was variable, even for neurons with similar BEFs, although all neurons recovered to some extent. Recovery although all neurons recovered to some extent. Recovery functions were typified by a rapid initial phase (<30 sec) and a more gradual second phase. A stepwise linear regression procedure was used to determine the sources of variability for the dependent variables 'initial shift' and 'recovery'. Pre-CTS best threshold was the independent variable most highly correlated (p<.0001) with both dependent variables. CTS level above best threshold and BEF were also significantly correlated with the dependent variables. correlated with the dependent variables. Research supported by NSF grant BNS 80-05258.

154.6 A QUANTITATIVE STUDY OF VOCALIZATIONS ELICITED BY HYPOTHALAMIC STIMULATION IN THE CAT. I. Altafullah,\* C. Shipley\* & J. Buchwald (SPON: E. Eldred). Brain Res. Inst., Ment. Ret. Res. Ctr., Dept. Physiology, UCLA Med. Ctr., Los Angeles, CA 90024. Vocalizations evoked by electrical stimulation of the hypo-thalamus were studied in 6 adult unanaesthetized cats. Voiced ("Meows") and/or unvoiced ("Hisses") responses were evoked, but only the voiced calls will be discussed. The objectives of this study were: 1) to analyze quantitatively the calls evoked by elec-trical stimulation of the hypothalamus 2) to compare the evoked calls with spontaneous [solation calls of the animal and 3) to calls with spontaneous isolation calls of the animal and 3) to study the effects of parametric stimulus changes upon evoked calls. Spontaneous calls were recorded with the animal comfortably re-

strained and in isolation. Stimulation was subsequently carried out with bipolar concentric electrodes delivering stimulus trains of 5 msc biphasic square waves. Stimulus parameters of interest were, frequency (30-150 cps), intensity (0.1-0.4 mA) and train duration (0.5-3 sec). At the end of the experiment the animals were sacrificed and histological confirmation of electrode sites obtained. Calls were analysed to determine latency from stimulus onset, duration and peak intensity. Acoustic analysis was perform-ed after digitizing the call (sampling rate: 20 KHz.). The analysis program used linear prediction techniques and the fast Fourier transform. A number of acoustic parameters, including the funda-mental frequency and harmonic structure of the call, were determined, which allowed quantitative comparisons between the spon-taneous calls and calls evoked under various stimulus conditions.

A total of 297 points were stimulated along 61 electrode tracks in the hypothalamus, Vocalizations were elicited from 58 points and 470 evoked calls were recorded. Especially dense collections of responsive sites were seen in the pre-optic region, the lateral hypothalamus, the perifornical region and the area around the ventromedial nucleus of the hypothalamus. The threshold for res-ponse was, in most instances, between 0.1-0.2 mA, but varied de-pending on the animal, the site and the parameters of stimulation. Similarly, the latency from stimulus onset also varied, and ranged from 0.5 to 3 sec. Increasing the intensity of stimulation had no significant effect on the latency, intensity or duration of the evoked vocalizations. In contrast, increasing the stimulus freq-uency significantly increased the intensity and decreased the lat-ency of the calls. Preliminary results from acoustic analysis suggest that voiced calls evoked by hypothalamic stimulation are very similar to spontaneous calls emitted during isolation. A detailed quantitative comparison of the evoked and spontaneous calls will be presented.

PHYSIOLOGY AND MORPHOLOGY OF ELECTRIC ORGAN DISCHARGE COMMAND 155.1 NUCLEI IN MORMYRID FISH. <u>K. Grant\*, S. Clausse\*</u>, C. Bell. Laboratoire de Physiologie <u>Nerveuse</u>, C.<u>N.R.S., 911</u>90, Gif sur Yvette, France.

Yvette, France. The spinal motorneurons which innervate the mormyrid electric organ are driven by a descending volley from the medullary relay nucleus (MRN). A recent anatomical study by Bell et al (J <u>Comp Neurol</u>, 1983) indicates that the MRN is in turn innervated by a small nucleus, nucleus C, located imme-diately ventral to the MRN. The goal of the present study was to characterize the neurons in these two command related nuclei and the the brotheries expansion with the the present study was and test the hypothesis, suggested by the previous work, that nucleus C is the EOD command nucleus. MRN neurons and nucleus C neurons were examined with intracellular recording, and with intracellular injection of horseradish peroxidase. Morphology was studied at both light and electronmicroscopic (EM) levels.

was studied at both light and electronmicroscopic (EM) levels. MRN neurons give a two spike volley before each EOD which is followed by an after-hyperpolarization (15-40 msec). Morpho-logically, each MRN cell body gives rise to 6 or 7 primary dendrites which ramify widely within the nucleus, contacting each of the other MRN somas (~20). EM examination shows gap junctions at these dendrosomatic contact points, and shows similar app0sitions between labeled and unlabeled dendrites. The above physiological results as well as electrical coupling and morphological gap junctions between MRN cells were de-scribed previously by Bennett et al (<u>J Neurophysiol</u>, 1967). Nucleus C neurons also show a two spike volley before the EOD, with the first spike in MRN cells. Apparent synaptic noise

BOD, with the first spike of the volley occurring 100-200 µsec before the first spike in MRN cells. Apparent synaptic noise and small (1-10 mv) all-or-none spike-like events (possibly axon spikes) are also seen. A pre-potential and one of the small spikes commonly precede the two full spikes of the pre-EOD volley. The synaptic noise and small spikes are blocked by a long-lasting (50-80 msec) hyperpolarization which follows the pre-EOD volley. The somas of nucleus C cells give rise to 2 or 3 main dendrites which branch slightly and extend far beyond the confines of their nucleus. The presumed axon arises laterally from a long initial segment and turns caudo-dorsally, giving off collaterals which appear to terminate immediately ventral to the MRN. The timing of the pre-EOD volley, the subthreshold potentials which precede the volley, the synaptic noise, and the morphology of nucleus C neurons support the hypothesis that these cells form an integrating center where the EOD command originates. center where the EOD command originates.

SINGLE ELECTROCYTES PRODUCE A SEXUALLY DIMORPHIC SIGNAL IN 155.2 ELECTRIC FISH. M.M. Hagedorn\* and C.E. Carr. Scripps Institution of Oceanography, La Jolla, CA., 92093.

Electric fish produce electric signals by means of an electric organ made up of modified nerve or muscle tissue in their tails. The electric organ discharge (EOD) of several species is sexually dimorphic during the breeding season, and the electric signals can Hypopomus occidentalis, a pulse-type electric fish, produce a sex-ually dimorphic signal. The electric organ of Hypopomus is driven by spinal electromotor neurons which innervate the caudal face of large, modified muscle cells, called electrocytes; both faces of the electrocyte are excitable. When the fish fires its electric organ, the caudal, innervated face fires first producing the posi-tive-going phase of the diphasic EOD. This depolarizes the elec-trocyte and causes the rostral face to fire producing the second, negative-going phase of the EOD. The second phase of a breeding, male's EOD has a smaller amplitude and a longer duration than the first phase, while nonbreeding and mature females have a symmetric EOD (see figure).

Adult males and females injected with 5 d dihydrotestosterone (DHT)  $(5_{\mathcal{M}}g/g.b.w.)$  produce an asymmetric EOD, characteristic of a breeding male, while animals injected with saline maintain a symmetric EOD. After 1 week of treatment, the EODs of the anima symmetric EOD. After 1 week of treatment, the EODs of the animals were digitized on a PDP-11 computer and analyzed by a transient capture fast fourier program. DHT-treated animals had a low peak power frequency while saline-treated animals had a high peak power frequency. Steroid treated animals also showed an enlargement of the electrocytes in their tails.

Intracellular recordings were made from single electrocytes in animals treated with DHT and saline. Electrocytes were depolarized by an intracellular stimulating electrode and spikes were recorded across the caudal, innervated face as well as the rostral, uninnervated face. The electrocytes of saline-treated fish with symmetric EODs, produced similar spikes from both faces. The electrocytes of DHT-treated fish produced a nor-DHT Normal mal spike from the caudal, inner-vated face and a spike of longer duration and smaller amplitude from the rostral, uninnervated face. This suggests that the sex-ually dimorphic EOD found in breeding, male Hypopomus occiden- 
 Statis is produced by the action of

 steroids upon single electrocytes.

THE TORUS SEMIGIRCULARIS OF GYMNOTOID ELECTRIC FISH: THE FUNCTIONAL ORGANIZATION OF A PARALLEL PROCESSOR. W.F.Heiligenberg C.E.Carr. Scripps Institution of Oceanography, University of

California at San Diego, La Jolla, CA 92093. The torus semicircularis of gymnotoid electric fish is a richly laminated, somatoropically organized midbrain structure (Carr et al, <u>J.Comp.Neurol</u>. 203: 649-670, 1981 ). The dorsal part of the torus, consisting of laminae #1 to #9, receives electrosensory input from the electrical lateral line lobe of the hindbrain (ELL) and projects topographically to the tectum, where visual and electrosensory images of the world are superimposed (Bastian, J., J.Comp.Physiol. 147:287-297, 1982). The torus is of particular importance for the control of the

Jamming Avoidance Response (JAR) which requires parallel process-ing of information about modulations in amplitude and phase of the electric signals in different parts of the body surface. Various cell types and their functional significance have been Various cell types and their functional significance have been explored previously by extracellular recordings (Scheich, H., J.Comp.Physiol., 113: 181-255, 1977; Bastian, J. and Heiligenberg, W., J.Comp.Physiol., 136: 135-152, 1980; Partridge et al, J.Comp. Physiol., 145: 153-168, 1981). We are now in the process of anatomically identifying these cell types by intracellular recording and labelling.

Information about phase, i.e. the timing of zerocrossings of the sinusoidal electric signal, is received in lamina 6, and the difference in phase between signals arriving from different parts of the body surface is encoded by cells whose somata are located in lamina 8. Information about modulations in amplitude is received in laminae 5,7 and 8 and is then computed in reference to differential phase information. The outcome of this computation

is encoded by cells in lamina 8 which project to the tectum. Different steps in information processing are thus executed in different laminae of the torus, and, by virtue of their somatotopical organization, these laminae can readily compute spatial aspects of electric signals on the animal's body surface. 155.4

FREQUENCY TUNING OF ELECTRORECEPTORS IS LOWERED IN ANDROGEN TREATED MORMYRID FISHES. <u>A.H. Bass</u>. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853 In many species of electric fish the frequency tuning curves of electroreceptors track the peak frequency of the power spectrum (PPW) of the electric organ discharge (EOD). For mormyrids with a sex difference in the EOD, the male EOD is typically longer in duration and so has a lower PPW compared to females and juveniles. The male-type EOD can be induced in females and juveniles with gonadal steroids. Similarly, there is also a sex difference in the frequency characteristics of one class of electroreceptors (Knollenorgans) that are the putative communication sensors and are tuned lower in natural males for at least one species, Brienomyrus brachyistius triphasic. For this species, there is al-so a lowering of the best frequencies (as defined with frequency tuning curves) of Knollenorgans in androgen-treated females that coincides with the decrease in the PPW of the EOD. Androgens may exert their effects directly on Knollenorgans. Alternatively, exert their effects directly on Knollenorgans. Alternatively, changes in tuning may be induced by the power of the principal stimulus to the Knollenorgans which is the EOD itself. Such al-ternative hypotheses can be tested in mormyrids by silencing the electric organ and so removing the external EOD stimulus that may "entrain" the electroreceptor's best frequency. Silencing is ac-complished by sectioning the spinal cord just anterior to the spinal electromotor nucleus located at electric organ levels, thereby interfering with a descending medullary signal that ex-cites the electromotor nucleus and the electric organ. Silenci cites the electromotor nucleus and so the electric organ. Silenc-ing experiments are being conducted with a mormyrid fish from Nigeria that also has a triphasic EOD waveform and shows a drama-tic shift in the PDW of its EOD when treated with androgens. Pre-liminary results suggest that: (1) normal hormone treated fish show a decrease in frequency tuning that tracks the decrease in the PPW; (2) cholesterol treated fish show no change in tuning or PPW; (3) silenced fish kept in isolation and now deprived of the electrical stimulus show no drift in tuning; and (4) silenced fish treated with androgens show a partial shift in tuning. fish treated with androgens show a partial shift in tuning. Gonadal steroids may alter the morphological and physiological features that define the passive and active electrical properties of the receptor cell membranes of Knollenorgans which, as other electroreceptors, are essentially modified hair cells. Studies of the development of frequency tuning in electroreceptors may provide a better understanding of the mechanisms underlying frequency tuning in other vertebrate hair cells such as auditory econter receptors.

SEX STEROIDS INFLUENCE THE ELECTROSENSORY SYSTEM OF <u>STERNOPYGUS</u>: DIRECT EFFECT ON EOD-GENERATING CIRCUITRY, INDIRECT <u>EFFECT ON</u> RECEPTOR TUNING. <u>H.H. Zakon and J.H. Meyer</u>. Neurobiology Unit, Scripps Instit. of Oceanography, Univ. of Calif., San Diego, La 155.5 Jolla, CA 92093.

RECEPTOR TUNING. <u>H.H. Zakon and J.H. Meyer</u>. Neurobiology Unit, Scripps Instit. of Oceanography, Univ. of Calif., San Diego, La Jolla, CA 92093. Weakly electric fish detect their electric organ discharges (EOD)s via specialized receptor cells termed electroreceptors. <u>Sternopygus dariensis</u> produces a nearly sinusoidal EOD, the fre-quency of which displays an ontogenetic shift which is sexually dimorphic: juveniles discharge around 100 Hz and with age, the EOD frequencies of females increase (100-200 Hz), while those of males decrease (50-100 Hz). Systemically applied androgens de-crease and estrogen increases EOD frequency. We have previously demonstrated that the androgen, 5a-dihydrotestosterone (DHT) can influence the frequency selectivity of the electroreceptors: receptors are always most sensitive to electric fields at the frequency of an individual's EOD and, after treatment with DHT, receptors can be "retuned" to a lower frequency. However, since electroreceptors are also exposed to a new EOD frequency and the tuning properties of their afferent electroreceptive fibers from the left lateral line nerve. For each fiber, best frequency (BF), Q<sub>10dB</sub>, and threshold were measured. Then, the EOD was eliminated by a high spinal transection which disrupts de-scending input to the electric organ from a medullary pacemaker nucleus (PMN), but leaves the PMN intact. Fish were put in 2 groups, one given daily injection of DHT (5 ug/ go.w.), and the other given saline control injections. After 2 weeks of injections, receptor tuning characteristics of fibers in the right nerve and PMN discharge frequencies and threshold did not differ after DHT treatment. BFS were also not signifi-cantly lower. However, Q<sub>100B</sub> values and threshold did not differ after DHT treatment. BFS were also not signifi-cantly different in the DHT group, pMN discharge frequencies were significantly lower. However, Q<sub>100B</sub> walues and threshold did not differ after DHT treatment. BFS were also not signifi-cantly different in the DHT group,

BPECTIAL SENSITIVITY IN <u>IAPLOCHIONIE DUTIONI</u> (CICHLIDAE). <u>T. E. Allen and R. D. Pernald.</u> Inst. of Neuroscience, Univ. of Dr., Eugene, Dr. 97403 Previous investigations have shown that the African cichlid 1557

<u>Raplochronis burtoni</u> lives in a complex social system in which many of the encounters among individual fish are mediated by Saily of the encounters among individual risk are reflected in vision. Social status and motivational state are reflected in body color patterns which appear to be recognized by conspecifies (Fernald, 1977; Fernald and Hirata, 1977). The visual pigments, too, suggest that the perception of color is important to this species; while the rock contain the visual pigment 2500, cones exist which contain P455, P523, and P562, (Mernald and Liebman, 1980). In order to determine the extent of color vision, it is necessary first to measure threshold as a function of wavelength. Since these are active and adaptable animals, I chose to use an operant conditioning paradigm with food reward in order to determine spectral sensitivity. A two choice chamber was constructed which could be inserted and removed from the home tanks of individual fish with minimal disturbance to them. I then designed and built an automated apparatus to select sides for stimulus presentation, to operate timers, shutters, and feeders appropriately, and to record the data. After initial training to high levels of performance at high stimulus radiances, a method of descending staircase sessions was employed. When the performance fell below criterion level (75%) correct) the following session was conducted with an increased radiance. In this manner a stable threshold was found. The function derived from testing fish under dark adapted conditions conforms reasonably closely to the nonogram of a  $P500_1$  pigment (confirming microspectrophotometric findings), but shows unexpectedly high sensitivity at short wavelengths (Allen and Fernald, 1981). Depending on assumptions about the precise angle of view of the stimulus, threshold at 500 nm is one quantum incident per second for every 5 to 50 rods. The spectral sensitivity function obtained under light adapted conditions is much broader and does not decline nearly so steeply outside the mid-spectral region; levels near to maximum are obtained from 450 nn to 600 nn. Several piguent classes are functional under these conditions. The form of the function suggests that an opponent processing mechanism similar to that found in all known trichromats is operating here (Allen and Fernald, 1982). Under light adaptation, threshold is found to be approximately 1,000 times higher than is the case for dark adaptation. Supported in part by MIGMS grant 5T32 GH 07257 in Systems and

Integrative Biology.

ANATOMICAL EVIDENCE FOR SYNCHRONIZATION OF FAST TOADFISH 155.6 SWIMBLADDER MUSCLE, AN HRP STUDY. <u>M.L. Fine and P.J. Mosca</u>\*. Dept. of Biology, Virginia Commonwealth Univ., Richmond, Va. 23284.

Toadfish sonic muscle is a classic example of a fast vertebrate muscle, capable of contracting several hundred times a second without tetanizing. Muscle contracting second minine trans a second without tetanizing. Muscle contraction rate generates the fundamental frequency of the fish's courtship and agonistic vocalizations. In 1961 Skoglund demonstrated an 0.3 - 0.5 msec difference in onset of an action potential between the cranial and caudal ends of the muscle over a length of 40-50 mm, i.e. the muscle contracts in almost perfect synchrony. This time difference is less than would be predicted from the conduction velocity of the sonic nerve.

We looked for anatomical evidence of this synchronization by utilizing retrograde transport of horseradish peroxidase (HRP) injected into the sonic muscle. Since the muscle fibers are arranged vertically in a horizontal band along the bladder, and the sonic nerve courses horizontally (perpendicular to the fiber direction), the muscle is ideally suited for investigation of somatotopic mapping of motoneuron projections on muscle fibers. Individual 4  $\mu$ L injections of 4% HRP (Sigma VI) were placed in either the cranial, mid, or caudal regions of sonic muscles. After survival times of 7-9 days, fish were processed for HRP following the procedure of Mesulam using tetramethylbenzidine as a chromagen. Serial frozen sections were cut horizontally through the SMN at 50  $\mu{\rm m}$ . The number and percentage of labeled motoneurons was recorded in each of 5 equally marked zones in the ipsilateral SMN. With minor exceptions, the distribution of labeled neurons in each of these zones was similar regardless of injection site. Small pin injections, one of which labeled only 2% of the ipsilateral neurons, confirmed this pattern. Accordingly, we conclude that a neuron in any part of the SMN has the potential to innervate fibers in any part of the sonic muscle. This is a simple but clear solution to the problem of muscle synchronization. The arrangement of toadfish sonic muscles is sufficiently different from mammalian muscles that caution must be used in suggesting that similar mechanisms control synchronous contraction of mammalian muscle.

155.PO THE NUCLEUS ELECTROSENSORIUS: A PROCESSING STATION INVOLVED IN THE NUCLEUS ELECTROSENSORIUS: A PROCESSING STATION INVOLVED IN THE CONTROL OF THE JAMMING AVOIDANCE RESPONSE. J. Bastian and J. Yuthas Dept. of Zoology, Uhiv. of Oklahoma, Norman, Ok 73069. Weakly electric fish, <u>Eigenmannia</u>, respond to the electric organ discharges (EOD) of conspecifies having similar EOD frequencies by raising or lowering their frequency thereby reducing the deletrious effects of the summed EOD fields. Animals raise or lower their EOD frequencies in response to the sign of the difference frequency  $\Delta F$ , where  $\Delta F$  is defined as the frequency of the interferring fish, F2 minus that of the reference fish, F1,  $(\Delta F=F2-F1)$ . Positive  $\Delta F$  results in fish 1 lowering its frequency and vice versa. Previous studies of this jamming avoidance response (JAR) have shown the torus Jamming avoidance response (JAK) have shown the torus semicircularis to be a major processing station for the control of this behavior (see Heiligenberg, Naturwissenshaften <u>67</u>, 499-507 [1980] for review). Recent anatomical studies have identified a nucleus in the rostral mesencephalon, the pre-pacemaker nucleus (PPN), which projects directly to the medullary pacemaker nucleus (PN), and electrical stimulation of this nucleus worldes to the statemath of the properties of the prothis nucleus verifies that it is capable of altering PM frequency. Short term increases or decreases in PM frequency occur depending on the time of stimulation relative to the phase of the EOD cycle. It remains to be determined by what pathways the outputs of the torus affect the PM frequency, presumably via the PPN.

We performed micro-stimulation experiments to try and identify brain areas which were capable of altering the PM frequency. We found that stimulation of a diencephalic site frequency. We found that stimulation of a diencephalic site evoked increases in PM frequency having a time course similar to the EOD accelerations seen in the JAR. HRP deposition showed that the stimulation site correspondes to the recently described N. electrosensorius (Carr et al. J. Comp. Neurol. 203, 649-670, [1981]). Single unit recordings from this nucleus show two major cell types. One type is completely silent during -AF but becomes active during +AF stimuli. These cells show maximal activity with AFs ranging from 2-6 Hz. The second cell type is not active during -AF and activity is partially or completely. suppressed during +4F stimulation. The activity of these cells continues to increase with increasing -4F. These cells are probably not the final controllers of the pacemaker since short term changes in their firing frequency are not strongly correlated with changes in the PM frequency. Supported by NIH grant NS12237 to J. B.

- COCKROACH ESCAPE BEHAVIOR: EFFECTS OF LESIONING INDIVIDUAL GIANT INTERNEURONS BY INTRACELLULAR INJECTION OF PRONASE. Christopher Comer. Dept. of Biological Sciences, Univ. Illinois, Chicago 60680 The ventral nerve cord of the cockroach, Peri-planeta americana, contains 7 bilaterally paired 'giant interneurons' (GIS) which encode the direction of wind stimuli and which are believed to orient the animal's wind-triggered escape response. I was inter-ested in directly testing the role of the GIS in the normal escape response and specifically in determining how spatial sensory information in these individually identified cells is translated into directed movement. To do this, I have begun analyzing the behavioral effects of lesions of individual GIS. Cockroaches were immobilized vntral side up and the nerve cord was exposed through a small flap cut in the abdominal cuticle. GIS were impaled in the connective with glass micropipettes filled with 50mM KCl and .5% Pronase (Calbiochem). After a cell was tentatively identified from the pattern of its wind evoked activity, Fronase was pressure injected into the cell and the flap of cuticle was replaced and sealed with dental wax. Animals displayed normal activity and locomotion within 1hr. of this procedure. Histological studies revealed that the axon of a GI completely degenerates within 4%hrs. of Pronase injection. Standardized behavioral tests were con-ducted from 2-7 days after injection. In 4 cases GI-1 was destroyed unilaterally. These animals turned incorrectly toward frontal winds on the side ipsilateral to the lesion (p<.05). 3 animals with unilateral deletions of GIS 1 and 2 displayed incorrect turns toward ipsilateral wind stimuli, and this effect was more pronounce than in the case of lesioning GI-1 alone. Controls with pronase injected COCKROACH ESCAPE BEHAVIOR: EFFECTS OF LESIONING INDIVIDUAL GIANT INTERNEURONS BY INTRACELLULAR 156.1

this effect was more pronounced than in the case of lesioning GI-1 alone. Controls with pronase injected extracellularly or into non-giant interneurons showed no significant change in the orientation of escape turns.

These results provide direct evidence which impli-cates cockroach GIs in the control of directional escape behavior. Systematic study of the behavioral effects of various GI lesions should yield a descrip-tion of the processes by which sensory information in this ensemble of cells is integrated to produce directional motor output.

THE BEHAVIOR OF APLYSIA CALIFORNICA: ETHOGRAM AND ETHOLOGICAL 156.3 (SPON: W.L. Veale). Dept. of Medical Physiology, Faculty of Medicine, University of Calgary, Calgary, Alberta T2N 4N1.

Medicine, University of Calgary, Calgary, Alberta TZN 4NI. As a complement to neuroethological studies, we have developed an ethogram for <u>Aplysia californica</u>, based on laboratory observations, and made detailed observations on the behavioral sequences involved in courtship, copulation and role-switching. Development of the ethogram was aided by the use of time-lapse videotape recordings. The ethogram is composed of 35 fixed action patterns (FAFs) (Schleidt, 1974; Lorons 1921) Lorenz, 1981), most of which are used in more than one context. Most FAPs represent subtle movements of specific regions of the body, primarily the head, and occur in more than one functional

body, primarily the head, and occur in more than one functional context. Many FAPs are superimposable. The sexual behavior of <u>A. californica</u> is comparable in complexity and overall structure to that of <u>Navanax inermis</u> (Leonard and Lukowiak, 1982). <u>A. californica</u> tend to copulate in bouts, with each individual alternating between behaviorally identifiable "male" and "female" states. Courtship (= pre-copulatory behavior) is initiated when one individual (the "male") contacts a conspecific (the "female") with his head and begins exploring her body, using the FAP, Brushing. At some point after Brushing starts the male begins to show Rhinophores Laid Back. The female responds to Brushine, particularly when Laid Back. The female responds to Brushing, particularly when it is directed to her parapodia by first Flaring and then Drawing Down her parapodia. These FAPs expose the mantle and make the common genital aperture (CGA) accessible to the male. The female also stops Crawling. After Brushing the male uses the Frill Tucked posture to explore the body of the female, then begins Head-leaning. He eventually comes to rest with his head inside her anterior parapodia. He remains motionless in the Head-leaning posture during intromission. Intromission varies in durations from a few minutes to more than 3 hours. The female assumes a Tentacles Pointed posture at some point after praving Down and may show Tail Puffed. A striking feature of the sexual behavior of <u>A</u> <u>californica</u> is that the male often remains motionless in the Head-leaning posture, in contact with the anterior parapodia of the female, after he has withdrawn his penis from the CGA. At some point, usually after the male has withdrawn, the female begins to shown male behavior either to her partner or to another individual.

CHANGES IN THE TEMPORAL PATTERNING OF ESCAPE SWIMMING IN CRAYFISH AS A CONSEQUENCE OF REPEATED STIMULATION. S. du Lac\* and J. J. Wine. Dept. of Psychology, Stanford University, 156.2 and J. J. Wine. Stanford, CA 94305.

Crayfish escape swimming is an episodic rhythmic movement Crayfish escape swimming is an episodic rhythmic movement offering certain advantages for neural analysis. It was recently shown that the probability of swimming declines markedly with repeated stimulation (Reichert, H. and Wine, J.J., <u>Nature</u>, <u>296</u>:86, 1982).). We wanted to know if the patterning of swimming was independent of response probability, or if the last charged are a propult of stimulation. patterning of swimming was independent of response probability, or if it also changed as a result of stimulation. We recorded EMGs from phasic flexor and extensor muscles in 15 crayfish 5.5-9.0 cm in length, which were free to swim within the confines of a 5 gal aquarium (20 x 40 cm, 20 cm deep). Each animal was stimulated with a light tap on the adomen at one min intervals at least 20 times per day. Stimulus intensities were adjusted to hold mean responding close to 50. The first two swims of a series provided a measure of response patterning in unhabituated animals. The mean duration

response patterning in unhabituated animals. The mean duration of such swims was 1151 msec (range 250-2850 msec), mean number of non-giant flexions was 11.4 (range 3-24), and mean frequency (based on inter-flexion intervals) was 8.7 Hz (range 4.2-14.7)

of non-giant flexions was 11.4 (range 3-24), and mean frequency (based on inter-flexion intervals) was 8.7 Hz (range 4.2-14.7 Hz). We confirmed findings that extension leads flexion, and that the extension-flexion interval is neither phase nor latency constant (Schrameck, J.E., Science, 169:698, 1971). With repeated stimulation, the proportion of responses that included swimming, as opposed to single, giant axon-mediated tailflips, declined from 86% on trials 1-5 to 36% on trials 16-20, thus confirming the earlier finding that swimming is more prone to habituation than is giant-mediated tailflipping (Retchert et al., ibid., 1982). In addition, the temporal properties of the swim changed over trials. The number of flexions per swim declined from 10.9 ( $\pm$  5.4, S.D.) to 3.6 ( $\pm$ 1.0, S.D.), latency to onset of swimming increased from 140 to 180 msec, and mean frequency of swimming flexience within swims was also noticed for about half of all swims. These results are inconsistent with the hypothesis that swimming is produced by a stable oscillator which is gated by a habituation-prone switch. Supported by NIH Training grant NS-07158-04 (S.d.L.) and by NSF grant BNS 81-12431 (J.J.W.).

PHYSIOLOGICAL CONTROL OF PHEROMONE RELEASE BEHAVIOR IN FEMALE 156.4 MOTHS (MANDUCA SEXTA AND UTETHEISA ORNATRIX). Haruhiko Itagaki and William E. Conner\*. Department of Zoology, Duke University, Durham, NC 27706

The behavior associated with pheromone release in female moths is termed "calling", and consists primarily of the extrusion of the terminal abdominal segments to expose the pheromone glands located near the abdominal tip. The control of calling in female <u>Manduca sexta(Lepidoptera:Sphingidae) and Utetheisa ornatrix</u> (Lepidoptera:Arctiidae) were investigated using standard physio-located methods logical methods.

Severing the ventral nerve cord (VNC) in the abdomen between the 1st and 2nd or 2nd and 3rd ganglia stopped calling in both species. Sham operated controls were unaffected. The removal of the two pairs of neurohemal organs associated with the brain, the corpora cardiaca and the corpora allata, did not affect calling behavior, contrary to the findings in Saturniid moths (Riddiford, L.M. and C.M. Williams, <u>Biol. Bull.</u>, 140:1, 1971). Since there are other neuroendocrine organs in insects, noncalling Manduca were injected with 0.03cc of blood from calling females. Recipients of blood did not initiate calling earlier than normal. The gross electrical stimulation of the VNC in isolated abdomens of <u>Utetheisa(@60Hz</u>, 1 msec. duration, 5-40v, in 3 or 5 sec. bursts) was sufficient to induce the abdomens to extrude and retract the terminal segments in a rhythmic manner similar to normal intact females. The rhythmic extrusion and retraction could be elicited from abdomens with only the termi nal ganglion present.

The control of pheromone release behavior in the moths Manduca sexta and <u>Utetheisa</u> ornatrix appears to be under strict neural control. There is no evidence for hormonal influences which initiate or modulate calling behavior. The source(s) of neural control, and the possible existence of a central pattern generator in the torriged additional according is now under deviced. tor in the terminal abdominal ganglion is now under investigation.

- SCORPION PECTINES: SENSORS OF SAND TEXTURE ? 156.5
  - SCORPION PECTINES: SENSORS OF SAND TEXTURE ? C. J. Harrington\* and T. M. Root. Biology Dept., Mid-dlebury College, Middlebury, VT 05753. Pectines are a pair of unique, comb-like sensory appendages on the ventral surface of scorpions with unknown function. Each pectine consists of a long basal element upon which numerous "teeth" are articulated. On the basis of limited work, some workers have suggested that pectines may detect the texture of sandy substrates, which is important for spermatophore deposition during courtship, but direct evidence of this mechanoreceptive role has been evidence of this mechanoreceptive role has been lacking.

lacking. In this study, scorpions were given a choice of substrates comprised of one of four sand grain sizes, ranging from 0.5 to 2.5 mm. In diameter. Chi square analyses of their choice at five minute intervals over a thirty minute period revealed that scorpions consis-tently preferred the smaller grain sizes. When the pectimes were coated with wax however, this preference was lost was lost.

To determine if the pectines were sensitive to differences in sand texture, electrical recordings from them were made in restrained animals. The pectines were sensitive to mechanical deformation of the teeth, upon which are located a series of microscopic sensory peccedings, were subsequently made from upon which are located a series of microscopic sensory pegs. Recordings were subsequently made from freely-walking scorpions with chronically-implanted platinum wire electrodes. When a tethered animal dragged its pectines on a sandy substrate, the pectines responded phasically, with complex spike bursts involv-ing at least 9-13 separate cells. The time course and pattern of impulses from the pectine nerve suggests that they are capable of almost immediate and complex responses to mechanical deformation. This work there-fore supports the theory of Carthy (1968) that the pec-tines respond to mechanical distortion of sensory fields on individual teeth, but how the complex infor-mation from each pectine is used to provide a basis for sand selection behavior is unclear.

DOMESTICATION DID NOT AFFECT WING-FLAPPING IN 156.6 CHICKENS. <u>R. R. Provine, C. S. Abrams<sup>\*</sup> and B. J.</u> Harrison<sup>\*</sup>. Dept. of Psych., Univ. Md. Baltimore Co., Catonsville, MD 21228.

The development of wing-flapping rate, lateral flight, wing area, and the ratio of wing area to body flight, wing area, and the ratio of wing area to body weight were described in three chickens (<u>Gallus</u> <u>gallus</u>) to assess the effects of domestication. The enickens were the white Legnorn (a commercial egg producer), the Cornish X Rock (a commercial meat producer), and the Red Jungle Fowl (the probable ancestor of domestic chickens). All birds performed drop-evoked, bilaterally symmetrical wing-flapping on ancestor of domestic chickens). All birds performed drop-evoked, bilaterally symmetrical wing-flapping on the day of hatching, at least one week before lateral flight was possible. Flapping rate of chickens doubled between hatching (4-6 Hz) and 13 days (9-12 Hz), after which it leveled off. The JF and WL developed lateral flight at 7-9 days. The CM first flew 1-2 weeks later but subsequently became flightless. The WL and JF had similar ratios of wing area to body weight; the ratios increased to a peak at ll-15 days and later declined. The ratio of the very heavy, essentially flightless, CR was approximately one-half that of the flighted WL and JF. The wing-flapping frequencies of the domestic WL and UF. CR for flight, The artificial selection of the CR for flight drastically diminished its flight performance by producing an unfavorable ratio of wing area to body weight. The JF and the domestic WL both flew well and had similiar ratios. neural circuitry producing the basic, bilaterally synchronized motor pattern of wing-flapping. Previous work indicated that the neural circuitry producing Work indicated that the neural circuitry producing flight was altered during the evolutionary nistory of flightless ratites and penguins (Provine, R. R., Soc. <u>Neurosci. Abstr., 6</u>: 612, 1982) but not during short intervals of movement restriction during the lifetime of individual chickens (Provine, R. R., <u>Behav. Neur. Biol., 27</u>: 233, 1979; <u>Dev. Psychobiol.</u>, <u>14</u>: 279 and 481, 1981).

156.7 PRIMATE MODELS IN BIOMEDICAL RESEARCH. F.R. Ervin, R.M. Palmour\* and S.N. Young\*. Dept. Psychiatry, McGill Univ. Montreal PQ CANADA H3A 1A1.

The world supply of well-described primates, e.g. <u>M. mulatta</u>, has precipitously declined. Simultaneously, the importance of appropriate primate models for biomedical research has increased. In particular, biological differences between man and non-primate experimental animals suggest that the medical applicability of basic or preclinical studies carried out on rodents and carnivores may be limited. One important problem is the individual variabil-ity of primates with respect to virtually any biological or behavioral parameter. Might not the innate heterogeneity found in a primate population actually be a useful resource in developing clinically appropriate models for study? One approach to this goal would be to identify individual mon-

The approach to this goal would be to hencify interface and have formed breeding groups of high blood pressure animals and, separately, of very low blood pressure animals. Within a stable enclosure, two matrilines showing strong familial predis-position to elevated blood pressure have been identified. Studi Studies of possible biochemical and/or genetic markers in these groups

have only recently been initiated. We have further been interested in models for multifactorial human diseases. An initial step is to characterize the popula-tion genetically with respect to loci which show electrophoretition generically with respect to loci which show electrophoteric cally detectable variation in man. 12 of 60 blood proteins thus far scored show polymorphism; rare variants are present in perhaps half that number of loci. Investigation of 50 additional loci is underway, including ones on each chromosome, based on the human gene map. Of particular interest are variants at loci which may nave pharmacological or toxicological consequences--serum pseudo-

cholinesterase, «-1-antitrypsin, etc. Studies of CSF levels of catecholamines, indoleamines and their metabolites reveal that the African green monkey shares some im-portant neurochemical similarities with man, while levels of the compounds in rat CSF are quite different. Mean rates of 5-HT, DA and NE metalolism in the brain are higher in female vervets than in males. Significant relationships between amino metabo-

than in males. Significant relationships between amino metado-lites and amino acid precursors were found. The Caribbean vervet population promises to be a useful model for the continued study of basic and clinical questions. We thank Behavioral Sciences Foundation, St. Kitts, NSERC (grant A8171) and MRC (grant MA7811) of Canada for support.

157.8 NEUROANATOMICAL SUBSTRATES OF JUVENILE PLAY IN RATS. <u>S.Siviy\*, J. Panksepp and K. White\*</u>, Dept. of Psych., Bowling Green State University, Bowling Green, OH 43403. Little is known about the brain mechanisms which control juvenile play. In these experiments, we sought to identify brain areas which mediate juvenile play-fighting behavior in weanling rats. Male and female Long-Evans rats were lesioned electrolytically (age 20-23 days) and play behavior, as indexed by frequency of pinning, was followed through puberty. A social deprivation paradigm was used with pups housed individually and observed for 5 minute periods daily (as in Panksepp & Beatty, <u>Behav. Neural Biol.</u>, 1980, <u>30</u>, 197). Brain areas studied were amyqdala, septum, ventromedial hypothalamus (VMH), dorsomedial (PFA). As in previous work (Beatty, et al., <u>Physiol</u>. Behav., 1982, 28, 649), septal lesions markedly increased play, while amygdala lesions decreased play. VMH lesions decreased play, probably because of many aggressive encounters with serious biting during which protagonists became timid and defensive. DMT lesions produced a moderate 15% decrease in pinning, but pin durations were increased markedly by 120%, Suggesting possible disruption of play sequence termination factors. Lesions of the PFA decreased play markedly by 65%, and behaviorally the animals seemed less able to initiate pinning sequences. Morphine (1 mg/kg) increased pins in control and DMT

Morphine (1 mg/kg) increased pins in control and DMT lesioned animals, but not in PFA animals, suggesting areas important for opioid modulation of play (Panksepp, <u>Neurosci. Abstr.</u>, 1979, <u>5</u>, 172.) The results suggest that septal circuits normally inhibit play, while amygdala, and a dorsal diencephalic circuit running through DMT and PFA elaborate excitatory influences, with the DMT involved in the termination of play bouts and the PFA participating more in play initiation. The VMH may participating more in play initiation. The VMH manormally inhibit aggressive overtones from arising The VMH may during play.

THE IMPORTANCE OF OVIDUCTS FOR ONSET OF REPRODUCTIVE <u>BEHAVIOR IN FEMALE FROGS.</u> C. Diakow, C. Scharff\*, and L. Aronow\*. Biology Dept., Adelphi University, Garden City, NY 11530. Onset of receptivity in female frogs is associated with ovulation. As ovulation proceeds, eggs are released into the body cavity, pass through the oviducts, and are stored in the uterus. By the time ovulation is complete, there are several thousand eggs in the uterus. We hypothesized that the onset of receptivity depends on some aspect of egg passage. We 156.9

In the uterus. We hypothesized that the onset of receptivity depends on some aspect of egg passage. We injected adult, female <u>R</u>. <u>pipiens</u> with one pituitary gland each to induce ovulation, and tested for receptivity. In testing, we recorded the number of vocalizations (release calls) in 30 sec. of manual vocalizations (release calls) in 30 sec. of manual clasping. Frogs were tested twice before pituitary injection, and every 4 hrs from 16 to 72 hrs after injection. A decline in the number of calls indicates receptivity. Data are presented below as the median and range of the median number of calls per female. In Exp I, oviducts were removed from Group 1 (n=6); Group 2 was sham operated (n=9). The oviductectomized

females did not become receptive.

156.11 AFFERENTS OF SOME DORSAL RETINORECIPIENT AREAS OF THE BRAIN OF BUFO BUFO. A. Weersburger and J.-P. Ewert (Spon. C.H. Hockman). Neuroethology lab., GhK, Kassel, Federal Republic of Germany. A predominant part of the behavioural repertoire of anurans is guided visually. In toads, as in other anurans, retinofugal fibres terminate in targets distributed bilaterally in the di- and mesencephalon. The sensory analysis underlying such visually guided behaviours as prey capture and avoidance of enemies and obstacles, requires interaction between retinorecipient dorsal thalamic areas and the tectum. The following results are based placement of iontophoretic deposits of HRP in the caudal, lateral and rostral tectum, posterior nucleus, caudal thalamic neuropil, lateral anterior nucleus, and a rostral area encompassing the nucleus and neuropil of Bellonci. The rostral and lateral tectum receive input from ipsilateral medullary reticular formation. All 3 tectal regions receive bilateral input from nuclei isthmi. The A11 3 tectal regions receive bilateral input from nuclei isthmi. The nucleus profundus mesencephali, pretoral grey, pretectal grey and tegmental nuclei provide ipsilateral afferents to all 3 tectal regions with the lateral tectum receiving a contralateral input from the latter two areas. The lateral tectum also receives input from the posterior tubercle, ventral (bilateral) and lateral hypo-thalamus. Lateral, posterior (bilateral), and central nuclei project to all 3 tectal recions. The ventromedial nucleus proproject to all 3 tectal regions. The ventromedial nucleus pro-jects to the caudal tectum, whereas the suprachiasmatic, preoptic and venrolateral nuclei project to the lateral tectum. Anterior entopeduncular nucleus and nucleus of Bellonci provide input to the rostral tectum. An area at the ventral edge of the lateral ventricle projects bilaterally to the lateral tectum. Posterior nucleus receives afferents from medullary reticular formation, tegmental anterodorsal nucleus, lamellar and principal nuclei of torus, tectum, pretoral and prétectal grey, ventral hypóthalamus contralateral posterior nucleus, anterior, central, ventrolateral and -medial nuclei and nucleus of Bellonci. Injection sites confined to the caudal thalamic neuropil produced cell labelling in tectum (bilateral), posterior, central, lateral, ventromedial ord poterior and posterior actendumenter nuclei and and -lateral, anterior, and posterior entopeduncular nuclei and nucleus of Bellonci. If injection sites extended to the lateral anterior nucleus too, additional labelling was seen in the anterior nucleus too, additional labeling was seen in the tegmental anterodorsal nucleus, magnocellular nucleus of torus and ventral habenular nucleus. In both cases, anterograde fibre labelling could be followed up to the striatum via the lateral forebrain bundle. Injection sites encompassing the nucleus and neuropil of Bellonci labelled cells in tectum, ventral hypo-thalamus, and posterior (bilateral), central, ventromedial and -lateral, anterior (bilateral), and posterior entopeduncular nuclei of the central anterior and posterior entopeduncular nuclei and the contralateral nucleus of Bellonci

156.10 MODEL OF A NEURAL NET SUBSERVING WORM-ANTIWORM DISCRIMINATION IN FROGS AND TOADS.<sup>1</sup> F. Cervantes-Perez<sup>\*2</sup> and M. A. Arbib (SPON: A. Barto). COINS Dept. and the Center for Systems Neuroscience, University of Massachusetts, Amherst, MA 01003. It is well known that Anuran Amphibians use mainly visual input

to guide their interactions with the external world. In the process of adapting adequately to that world these animals present very stereotyped cognitive and motor behaviors.

Neuroethological studies (Ewert, 1980 and Ingle, 1982) have shown that there are innate mechanisms in frogs and toads that recognize key-stimuli in the environment to elicit the proper motor response. It has been shown that both the size of a moving stimu-lus and its geometry in relation of the direction of motion play an important role in the prep-catching behavior of these animals: small objects whose longitudinal axis moves parallel to the direc-tion of motion ("worm-like") are considered as prey; whereas if an "antiworm-like" stimulus (larger objects moving with their longest axis orthogonal to the direction of motion) is presented the animal does not exhibit prey-catching orienting behavior or may as-sume a freezing posture or may exhibit avoidance behavior. This worm-antiworm discrimination has been proved to be invariant to This Work-aftrive distribution has been proved to be invariant to the direction of motion and there is still debate about this pro-cess being also invariant to the velocity function of the stimu-lus. Ewert (1970) and Ingle (1975) have also shown that lesions of the dorsal pc/p1 region within the thalamus (Pretectum) dis-rupts the animal's ability to discriminate different configurarupts the animal's ability to discriminate different configura-tions of the stimulus. Furthermore, animals with pretectal le-sions snap indiscriminately to any moving object, even to those resembling the probability of fitting the predator category. We present a neural net model based on anatomical, physiological and neuroethological grounds (Szekely and Lazar, 1976; Ewert, 1980; Grusser and Grusser-Cornhels, 1976), that reises specific hypoth-eses of how the interactions among several brain regions (Retina, Optic Tectum and Pretectum), formed by multiple groups of neurons structured in layers, use a parallel distributed processing of the visual input to control the animal's motor response. The model reproduces adequately the experimental observations, and allows us reproduces adequately the experimental observations, and allows us to analyze qualitatively the neural mechanisms that might be subserving worm-antiworm discrimination, with direction invariance of this phenomenon being a consequence of the tectal architecture, size selection and changes in response latency. The two latter processes depend on the animal's motivational state.

RESPONSES TO ACOUSTIC STIMULI IN THE AVIAN TRACHEOSYRINGEAL 157.1 NERVE. H. Williams\* and F. Nottebohm. (SPON: M. Constantine-Paton). Rockefeller University, New York, N.Y. 10021. Microstimulation of the principal avian forebrain song control

nucleus, hyperstriatum ventrale pars caudalis (HVc), is known to produce evoked potentials in the tracheosyringealis branch of XII (nXIIts) which innervates the avian vocal organ (A.P. Arnold, <u>Am. Sci.</u>, <u>68</u>:165, 1980). HVe is also known to respond to acoustic stimulation (L.C. Katz & M.E. Gurney, <u>Br. Res.</u>, <u>221</u>:192, acoustic stimulation (i.e. Kat2 w W.F. othrey, <u>br. Nes.</u>, <u>cet.</u> 192, 1981). We have found that under some conditions acoustic stimula will elicit activity in nXIIts as well. The nXIIts response has a long latency (30-10C ms) and follows the HVc response with a latency of ~15 ms; this is equal to the latency see when recording from nXIIts after microstimulation of HVc. Thus, it seems possible that the pathway for this peripheral acoustic response involves HVc, a forebrain nucleus.

The response evoked in nXIIts by microstimulation of HVc is gated by respiratory activity, with more axons firing during expiration than during inspiration (K.R. Manogue & J.A. Paton, Explicitly for the first second seco

nXIIts response is underway. Clicks, pure tones, and song play back have been shown to evoke the response in zebra finches and canaries.

A similar response, the laryngeal muscle acoustic reflex, has been described in the bat (P.K.-S. Jen & N. Suga, <u>Science</u>, <u>191</u>; 952, 1976). But the response latency in the bat is 6 ms, which precludes mediation by a long pathway. Acoustic reflexes also occur in the decerebrate cat (C.G. Wright & C.D. Barnes, <u>Br. Res</u>. 36:307, 1972). However, the avian mXII's acoustic response differs from these reflexes in its much longer latency (and hence its greater potential for involvement of central processing) and in the implication that it is mediated by telencephalic nuclei. Its function, as yet undetermined, may involve such higher order behaviors as song learning and production.

QUALITY OF SONG AND DEGREE OF MASCULINIZATION OF THE BRAIN IN FEMALE ZEBRA FINCHES. G. Pohl-Apel\* (SPON: M. Gurney). Univ. of 157.3 Chicago, Dept. Pharm. Phys., Chicago, Illinois 60637.

In the Zebra finch the sexes show a marked dimorphism. In females, certain brain nuclei are reduced in size and correlated with this, females do not sing. By treating female nestlings with estradiol the song system becomes male-like and if the adult bird is subsequently treated with testosterone, she may sing. The aim of this study was to investigate the correlation between the degree of female brain masculinization, produced by varying the duration of estradiol-treatment, with the quality of song.

Sixteen female nestlings were implanted with silastic capsules filled with estradiol. Treatment started between day 2 and day 10 after hatching and ended between day 8 and day 18. The birds were raised by their Zebra finch parents. When adult (150 days) the birds were implanted with testosterone-propionate to induce song. Song was recorded 6 weeks later. Four weeks after the removal of the testosterone implant the birds were killed and their brains examined.

Song was observed in 11 out of 16 birds. Within 3 to 6 weeks birds gained their individual song quality which remained unchan-ged even after several more weeks of testosterone treatment. The song quality can be classified into 3 categories: I The song is very similar to adult male song (i.e. temporal patterning, number of elements, repetition of elements in the same manner). (n=3). II The song is similar to early juveniles song, i.e. this song is poor in structure and not crystallized (no element is repeated for post in structure and not crystallized (no element is repeated to a second time in exactly the same manner). (n=4). III In between these categories are females with an intermediate song type which is similar to late juveniles song in males. (n=3). Anatomical data show that song quality correlates with degree of masculinization of the song system. Females singing the typical masculinization of the song system. Females singing the typical male song (I) have a mean volume of Nucleus robustus archistriata-lis (RA) of 0.07 mm<sup>3</sup> (0.06 - 0.08; mean RA volume in males: 0.24; 0.22 - 0.27, n=5); females with early juveniles song (II) have a mean RA volume of 0.03 mm<sup>3</sup> (0.02 - 0.04). This volume is still larger than that of nonsinging females (mean: 0.010, 0.007 - 0.010, n=4). The volume of the females with an intermediate song type (III) is between that of category I and II (mean: 0.04, 0.03 - 0.05). 0.05).

FIBERS. A.P. Arnold and S.W. Bottjer. Dept. of Psychol., UCLA, CA 90024 157.2 VOCAL LEARNING IN ZEBRA FINCHES: THE ROLE OF HYPOGLOSSAL AFFERENT

Sensory afferent fibers originate in the vocal organ (syrinx) of zebra finches (Poephila guttata) and travel along the hypo-glossal nerve (Bottjer & Arnold, 1982). A question of great theoretical interest centers on whether feedback along these fibers contributes to vocal learning in songbirds, as does audifibers contributes to vocal learning in songDirds, as does audi-tory feedback. Neither auditory feedback nor feedback along hypoglossal afferent fibers is important for maintenance of adult song patterns (Konishi, 1965; Bottjer & Arnold, in prep). The present study was designed to investigate the role of hypoglossal afferent fibers in song learning by juvenile zebra finches. Subjects were 27 male zebra finches ranging in age from 22 to 26 days. Evacemental binds (n-14) were anethetized and the

Subjects were 27 male zerra finders ranging in age from the co-36 days. Experimental birds (n=14) were anesthetized and the anastomosis between the hypoglossal and vagal nerves was exposed. The descending branch of the vagus was teased back slightly on the left side and the XII afferents were sectioned. The same the left side and the All alterents were sectioned. The same operation was performed on the right side, except that the de-scending vagus was not teased back (thus, descending X was sec-tioned along with hypoglossal afferents). Efferent hypoglossal fibers travel separately and were not disturbed. The remaining birds underwent one of two different control treatments: All control birds were subjected to the same procedure as experiment-al subjects, but no nerves were actually cut in some birds (n=6), whereas the right descending vagus was sectioned in others (n=7). The song patterns of all birds were recorded periodically until they were 90 days old. A sound spectrograph was used to analyze recordings made for each bird at approximately 75 days of age. A blind observer listened to the songs, examined the spectrographs, and assigned a score to each bird ranging from 1 (abnormal) to 5 (normal). Songs were scored based on stereotypy and complexity of the song pattern and degree of similarity of individual notes to those of normal adult males. There were no differences in the song performance of control subjects which were therefore solid performance of control solutions where the control of collapsed into one group. The median scores were 4.00 ( $\pm$ 1.44) and 2.25 ( $\pm$ 1.76) for the control and experimental groups, resp. tively. This difference did not reach significance ( $\underline{U}$  = 63.5, respec-

tively. This difference did not reach significance ( $\underline{U} = 63.5$ ,  $\underline{p} > .10$ ). We believe these results to be highly suggestive of a significant role for feedback along hypoglossal afferent fibers in the development of learned song behavior. Although the effects obtained did not achieve significance, they may have been mitigated by regrowth of the sectioned XII afferent fibers. Our current objective is to trace the central termination site of these afferent axons and lesion this site at various stages of vocal development.

DEVELOPMENTAL CHANGES IN EFFECTS OF LESIONS IN FOREBRAIN SONG-CONTROL NUCLEI OF PASSERINE BIRDS. <u>S.W. Bottjer, E. Miesner\* and</u> <u>A.P. Arnold</u>. Dept. of Psychol., U.C.L.A., CA 90024. Male zebra finches (<u>Poephila guttata</u>) learn the song typical of their species during a "critical" period of development 157.4 (Immelmann, 1969). Song patterns become progressively more stereotyped during the period from 50 to 90 days, and do not change thereafter. Two telencephalic nuclei, HVc and RA, are known to form part of the major efferent pathway of the neural system controlling song; bilateral lesion of either HVc or RA severely disrupts vocal behavior in adult songbirds (Nottebohm, et al., 1976). Two additional nuclei in the anterior forebrain. MAN and Area X, are monosynaptically connected with HVc and/or RA, and are therefore defined as part of the song system, although little is known concerning their function. The The purpose of the present study was to determine if MAN and/or Area X are involved in vocal development.

30 zebra finches ranging in age from 35 to >90 days received bilateral lesions aimed at either MAN or Area X. Birds 50 days of age and older were recorded while singing before undergoing surgery. Electrolytic lesions were produced using monopolar stainless steel insulated electrodes to pass anodal DC current of 90 to 100 ua for 60 sec. The song patterns of all birds were recorded post-operatively at two-week intervals until the birds were at least 90 days old, at which time they were sacrificed. Their brains were fixed, embedded, sectioned at 40 um, and stained with thionin. Sections were examined using a microprojector in order to verify the exact location of the lesion. Birds which received complete bilateral lesions in either MAN

Birds which received complete bilateral lesions in either MAN or Area X when they were 35 to 50 days old produced severely abnormal vocalizations from 50 to 90 days of age. Their "songs" usually consisted of 1 or 2 highly abnormal syllables, often produced at very low volume. In contrast, birds which received "control" (i.e., off-target) lesions showed normal song development. Birds which received complete bilateral lesions in MAN or Area X after 60 days of age were affected little, if at all. Because MAN and X are quite close to each other, it is conceivable that lesions in MAN interfere with axons projecting into Area X from HVc, but preliminary neuroanatomical tracing studies argue against this possibility. Lesions in MAN and X may exert their effects by interfering

Lesions in MAN and X may exert their effects by interfering with normal neural development in HVc and RA, although preliminary examination of these brains do not support this idea. Alter-natively, these results may indicate that functions important for vocal learning are being carried out in MAN and X during a re-stricted period of development. Threafter, vocal development either becomes independent of these functions, or they are somehow "transferred" to another area of the brain.

157.5 IMPORTANCE OF THE VOCAL CONTROL NUCLEUS HYPERSTRIATUM VENTRALE, PARS CAUDALE IN REPRODUCTIVE BEHAVIOR OF THE FEMALE CANARY. J. M. Greenspon\* and D. A. Ingram\*

VENTRALE, PARS CAUDALE IN REPRODUCTIVE BEHAVIOR OF THE FEMALE CANARY. J. M. Greenspon\* and D. A. Ingram\* (SPON: D. Durham). Dept. of Psychol., Hobart and William Smith Colleges, Geneva, N.Y. 14456. Female canaries learn conspecific male songs, for the most part, during their first 30 d. post-hatching (Greenspon, J.M., East. Psychol. Assoc. Abstr., 54th Ann. Mtg., p. 75, 1983). In addition, adult female canaries are attentive to attributes of conspecific male song as evidenced by their exhibiting significant-ly more robust forms of reproductive behavior (e.g., nest-building and egg laying) when exposed to complex as opposed to simple songs (Kroodsma, D.E., Science, 192: 574, 1976).

as opposed to simple songs (Kroodsma, D.E., <u>Science</u>, <u>192</u>: 574, 1976). The hyperstriatum ventrale, pars caudale (HVc) is thought to be an important brain area for auditory memory formation in canaries (Notteb.hm, F., Stokes, T.M., and Leonard, C.M., JCN, 165: 457, 1976). There-fore either left (n=6), right (n=6) or bilateral (n=5) ablations of HVc were performed on female canaries in order to selectively create auditory memory deficits. Brain-damaged females were then exposed to complex songs while having their reproductive behaviors moni-tored. Left, right and bilaterally damaged females al songs while having their reproductive behaviors moni-tored. Left, right and bilaterally damaged females all significantly (p<.05) outperformed sham controls (n=5) on measures of total number of strings gathered and placed in nest, and in latency to lay eggs; all of which are sensitive measures of female canary repro-ductive behavior. In addition, nest-material placing behavior over the first 12 d. was most robust in the bilaterally-damaged group, with both left and right-damaged groups exhibiting slightly less and the shams even less. even less

even less. Loss of auditory memory would result in an increased probability of hearing novel sounds. That bilateral, as opposed to unilateral or sham damage to HVc resulted in increased reproductive activity in females exposed to complex male songs indicates that novel aspects of song, in contrast to learned aspects, result in increased reproductive arousal. This might be due to females being habituated to learned sounds and maxi-mally sensitive and thereby aroused by novel sounds.

BRAIN STIMULATION EVOKED VOCALIZATION IN THE DOMESTIC CHICK: A 157.7 2-DG ANALYSIS. <u>P.W. Chatfield\* and N.C. de Lanerolle</u>, Psychology, Wesleyan Univ. & Neurosurgery, Yale Univ. Sch. of Med. CT. Domestic chicks vocalize in several emotional contexts. Short calls are produced in 'pleasure' situations whereas peeps are given in 'stressful' situations. Electrical stimulation (ES) in diencephalic areas evoke peeps, whereas short peeps or trills are evoked from the midbrain nu. intercollicularis (ICO)/ area C region. ES at call sites in each of these regions was combined with the 2-deoxyglucose (2-DG) method to determine the entire spectrum of neural substrates involved in the production of these vocalizations. <u>Midbrain ES resulted in increased metabolic</u> activity in the ipsilateral caudal medulla where treacheosyringeal motoneurons and motoneurons innervating upper neck muscles are located; in midbrain area C which influences respiratory rate; in ICO; nu. tegmenti pedunculo-pontinus pars compacta (TPc) (dopamine neurons) and optic tectum. All these regions are assoc-iated with vocal pathways traced from the ICO/area C call sites by silver degeneration methods. In addition several ipsilateral lateral diencephalic areas, the ectostriatum, the lateral part of paleostriatum augmentatum (PA), paleostriatum primitivum (PP), nu. pateostriatum augmentatum (rA), pateostriatum primitivum (rF), hu-intrapeduncularis (INP) and archistriatum were active. ES at di-encephalic peep sites resulted in conspicuous ipsilateral acti-vity in all parts of the hypothalamus (with highest levels in the lateral hypothalamus) and a periventricular strip dorsal to it. ES in all of these active diencephalic areas evokes peeps (de ES in all of these active diencephalic areas evokes peeps (de Lanerolle, 1972). Hypothalamic areas were not active in midbrain stimulated birds, and tectal areas were not active with peep site stimulation. The telencephalon of peep site stimulated birds has strong uptake bilaterally in the actostriatum, and on the ipsi-lateral side similar high uptake extended into the surrounding neostriatum dorsally and ventrally in the lateral part of the PA, PP and INP. The nu, taenia of the archistriatum was also more parties or the indicatoral ofde. This active depontruce the brein Fr and INF. Ine nu. taenia of the archistratum was also mole active on the ipsilateral side. This study demonstrates the brain areas in which visual information, important in the causation of chick vocalizations, can interface with motor control pathways for vocalization. A key site in this regard is the ectostriatum, which receives visual information via the tecto-rotundal pathway. This pathway has been reported, by others, to provide the basis for attention-directing and scan initiating functions, which for actions were shown previously to be crucial in the causation of chick vocalizations (Brain Behav. Evol., <u>]0</u>:  $377f \& \underline{10}$ : 354f). Ectostriatal connections with the neostriatum intermediale may also provide access to memory functions important for emotional responsiveness. Further, a dopaminergic projection from the TPc to the PA may underlie the dopaminergic mechanisms involved in the causation of vocalization (J. Comp. Phys. Psychol., 92:416 & 94:346).

NEURAL CORRELATES OF AVIAN SONG DUETTING. F.A. Brenowitz 157.6 and A.P. Arnold (SPON: D.B. Lindsley). Dept. of Psychol. and Brain Res. Inst., UCLA, Los Angeles, CA 90024.

Studies of the neural network that controls song in canaries (Serinus canarius) and zebra finches (Poephila guttata) have demonstrated striking sexual dimorphism. The volumes of the caudal nucleus of the hyperstriatum ventrale (HVc) and the robust nucleus of the archistriatum (RA) are significantly larger in males, who sing, than in females, who do not (Nottebohm and Arnold 1976). Cell body size and dendritic field spread of cells in RA are also larger in males (DeVoogd and Nottebohm 1°81; Gurney 1981). We report here the results of a preliminary investigation of the neural correlates underlying song in the white-browed robin-chat (Cossypha heuglini), a species in which both sexes participate in complex vocal duets. In January 1983 two female and three male chats were caught in

Kenya, East Africa. Song was heard from all of these birds Neuropa, rast ATTICE. Song was near Trom all of these birds before capture. They were anesthetized and perfused with 10% formalin. Their brains were frozen-sectioned and stained with thionin. The volumes of HVc and RA were determined by standard procedures. The sizes of neuronal somas distributed throughout RA were measured in two males and two females by tracing somal perimeters through a camera lucida. Using estimates of neuronal density and volume of RA, total neuronal number in RA was calculated.

Both RA and HVc are considerably larger in males (RA: mean  $\pm$  SD=0.828  $\pm$  0.149 mm<sup>3</sup>; HVc: 3.692  $\pm$  1.190 mm<sup>3</sup>) than in females (RA: 0.325  $\pm$  0.091 mm<sup>3</sup>; HVc: 1.262  $\pm$  0.515 mm<sup>3</sup>). The density of neurons within RA is greater in females (4.6-5.7 x 10<sup>4</sup> neurons/mm<sup>3</sup>) than in males (2.6-4.0 x 10<sup>4</sup> neurons/mm<sup>3</sup>). Given the greater volume of RA in males, we estimate that RA of features that RA of female chats contains more neurons (2.2-3.3 x  $10^4$ ) than that of females (1.6-2.0 x  $10^4$ ) (not corrected for cell splitting). The second does not, however, appear to be any sexual difference within RA of maximum somal diameter (male mean  $\pm$  SD = 16.97  $\pm$  4.15 um, of married married operations (more married m other male-female pair.

It thus appears that the sex difference in the volumes of RA and FVC in chats is as large as that found in canaries, a species in which only males sing. However, cell body size within RA of the duetting chats is sexually monomorphic. These results suggest that cell size is more directly related to vocal performance than overall volume of brain regions or total number of neurons

STABILIZATION OF HEBBIAN NEURAL NETS BY INHIBITORY LEARNING. 158.1 STABLIZATION OF HEBSTAM NEUKAL NETS BT INHIBITORY LEARNING. Paul Easton\* and Peter E. Gordon\*. (SPON: Isabelle Alter). Brain Research Labs, NYU Medical Center, WY,NY, 10016 and Physics Department, U of Mass. at Boston, Boston, Mass. 02125 In Hebbian neural models synaptic reinforcement occurs when the pre- and post- synaptic neurons are simultaneously active. the pre- and post- synaptic neurons are simultaneously active. This causes an instability toward unlimited growth of excitatory synapses. The system can be stabilized by recurrent inhibition via modifiable inhibitory sysapses. When this process is included, it is possible to dispense with the non-linear normalization or cutoff conditions which were necessary for stability in previous models. The present formulation is response-linear if synaptic changes are slow. It is self-consistent because the stabilizing effects will tend to keep most neural activity in the middle range, where neural response is approximately linear. The linearized equations are tensor invariant under a class

The linearized equations are tensor invariant under a class of rotations of the state space. Using this, the response to stimulation may be derived as a set of independent modes of activity distributed over the net, which may be identified with cell assemblies. A continuously infinite set of equivalent solutions exists.

A LEARNING RULE GOVERNING WEAKENING OF NEURAL INTERCONNECTIONS 158.2 COMPLEMENTS HEBB'S RULE AND ENABLES REPRESENTATION OF CONCEPT HIERARCHIES WITHIN STRUCTURALLY HOMOGENEOUS NEURAL NETWORKS. Rolf Martin. Biochemistry Lab., Chemistry Dept., Brooklyn Coll.,

Rolf Martin. Blochemistry Lab., Chemistry Dept., Brocklyn Coll., Brocklyn, NY 11210. A photograph of a male and female lion and three cubs is frequently identified as "lions"; a photograph of a lion and tiger is very often labelled "lion and tiger"; a photo contain-ing a lion, tiger, leopard and lynx is generally identified as "cats"; a photo of a lion, tiger, leopard, zebra, antelope and buffalo is frequently labelled "cats and hoofed mammals"; and a photograph of a wolf, horse, leopard, beaver, rabbit and porpoise is very often labelled "mammals". Note the shift to more inclu-sive labels as the diversity and number of concepts within each photograph increases. This shift can be simulated in simple, photograph increases. This shift can be simulated in simple, theoretical neural networks governed by Hebb's learning rule<sup>1</sup> if, and apparently only if, a second learning postulate is added which specifies that a connection between two neurons is weakened when the presynaptic neuron discharges but the postsynaptic neu-ron does not. Other capabilities required for appropriate use of concept hierarchies can also be simulated, including: listing the names of concepts within each category, listing the defining attributes of each category, separately listing the defining attributes of each concept within each category, correct cate-gorization of novel data (which represent concepts not previously "seen" by the neural net), and automatic construction of alby seen by othe neural net), and automatic construction of ar-ternative hierarchies when appropriate. The neural nets used in these simulations are basically the same as those used previous- $ly^{2-9}$  for simulation of associative and sequential recall. Layering of neurons to provide a structural basis for represent-ing levels within hierarchies is not required (cf. 4). The proposed rule governing the weakening of neural connections also appears to be necessary for relatively accurate representation of probability relations and for risk benefit assessment.

1) D.O. Hebb postulated that connections between neurons are strengthened when they discharge concurrently, so that they be-come more likely to trigger one another in the future (The Contended The Structure of Section 2017 Section 2018 Section of Behavior, Wiley, N.Y., 1949).
2) K. Nakano (1972) I.E.E. Trans. SMC 2, 380.
3) K. Fukushima (1973) Kybernetik 12, 58.
4) J. Grinberg-Zylberbaum (1976) J. Theoret. Biol. 56, 95.

158.3 INTRANEURONAL PATTERN PROCESSING: CELLULAR AUTOMATA IN CYTO-SKELETAL LATTICES. <u>S.R. Hameroff</u>, <u>S.A. Smith</u>, <u>R.C. Watt</u>. Dept. Anesthesiology, Univ Arizona Health Sci Ctr, Tucson, AZ 85724 and Computing Division, Los Alamos National Laboratories, Los Alamos, NM 85745

Rudimentary aspects of cognition may depend on intra-neuronal information processing which subserves inter-neuronal synaptic activities. Nonlinear electrodynamic effects such as Frohlich coherent dipole oscillations (Nature 228:1093, 1970; PNAS 72: tubules (MT) have been implicated in such information processing tubules (MT) have been implicated in such information processing (J Theor Biol 98:549, 1982). Cellular automata (CA) (Sci Am 244:112, 1971) are dynamical systems which can generate and pro-cess patterns via lattice neighbor interactions in discrete time intervals. Based on MT structural geometry and Frohlich coherent oscillations of  $10^{-10}$  to  $10^{-11}$  sec, we calculated the electrosta-tic forces among MT subunit ( $\alpha$ ,  $\beta$  dimer) neighbor dipoles (Fig). n (n=7 neighbors, y="vertical"

The net forces are equal to  $\sum_{i=1}^{N}$  reighbor distance, r=direct i=1 distance) and, when solved

i=1 r<sup>3</sup> distance) and, when solved for MT lattice dimensions, lead to "rules" determining dimer state at subsequent time intervals. Lower figures represent CA patterns of an initial single  $\alpha$  state which grows (left), and

EXTRINSIC AND INTRINSIC INTERACTIONS AMONG SIMULTANEOUSLY 158.4 EXTRINSIC AND INTRINSIC INTERACTIONS AMONG SIMULTANEOUSLY RECORDED NEURONS IN THE NUCLEUS PARABRACHIALIS MEDIALIS DURING SLEEP-MAKING STATES. R. D. Frostig\*, Z. Frostig\*, G. C. Sieck and R. M. Harper (SPON: M. Nuwer). Dept. of Anatomy and the Brain Research Institute, UCLA, Los Angeles, CA 90024. Respiratory-related neurons in the nucleus parabrachialis medialis, recorded from intact, drug-free, unrestrained cats, exhibit variations in their short-term discharge correlations (40 mean) between different pleon unking stepse.

(<2 msc) between different sleep-waking states (Harper and Sieck, <u>Brain Res.</u>, 199:343-358, 1980). Variations in these correlations may arise from local intra-network functional changes or from external functional sources. In order to distinguish between these possibilities, a new analytical procedure for evaluating spike train dependencies was used. This procedure is based on filtering a subset of the presynaptic spike train which includes only spikes that are responsible for the time-locked primary effects in a cross-correlogram. Different subsets can be filtered for different parts of the Different subsets can be filtered for different parts of the primary effects (i.e., a subset for interaction effect, a subset for shared input effect, etc.) and may be compared over different sleep-waking states. All neurons were found to be strongly influenced by multiple sources of shared input that were most likely extrinsic. Both these extrinsic sources and local direct connections were excitatory. When calculated across sleep-waking states, some of the local connections showed a polarity reversal between pre- and post-synaptic neurons. A point of the state between pier and post-synaptic neurons. However, no change in parameters such as rate or coefficient of variance was demonstrated. The shared input sources showed statistically significant (pc0.05) state-related changes in these parameters. Thus, we suggest that the state-related variation in short-term correlation discharge is due to variations in the shared input to the neuronal network, rather than to intra-network interactions.

158.5 OPTICAL MONITORING OF NATURALLY EVOKED DYNAMIC PATTERNS OF NEURO-NAL ACTIVITY FROM THE INTACT FROG OPTIC TECTUM USING A PHOTODIODE ARRAY. <u>A Grinvald, L. Anglister\*, R. Hildesheim\* and J.A.Freeman</u> Dept. of Neurobiology, The Weizmann Institute of Science, Rehovot 76100, Israel.

Optical recording methods were developed in order to investigate information processing, functional organization and pharmacology of the intact vertebrate brain (see also Orbach et al., Neurosci.Abstr. 8, 936, 1982; *ibid* 9, 1983). The exposed frog's optic tectum was stained for 20 min by topical application of a Ringer solution containing 1.6mM RH-414 (a new voltage sensitive fluorescent probe). In order to record and visualize the spatiotemporal patterns of evoked activity we used a 100-elements photodiode array and a computerized optical monitor (J.Physiol. <u>333</u>, 269, 1982). Complex dynamic patterns were detected in the tectum in response to visual patterns (stationary or moving, spots, bars and annuli) presented to the eye. Each optical signal contains on the objective and varies from 10 to 400 µm. Laminar analysis can be achieved by differential optical recording of the activity at different depths. In many instances signals are sufficiently large so that signal averaging is not required, and many measurements can be made\*on a single preparation.

Simultaneous optical recording from hundred loci appears to offer some unique advantages in monitoring dynamic patterns of neuronal activity in the intact brain because it provides both electrophysiological and "anatomical" information in a single experiment. The figure shows the pattern response to a light bar stimulus presented to the contralateral eye. Supported by grants from the NIH and the US-Israel BSF.

158.7 ULTRASTRUCTURE OF SYNAPSES BETWEEN IDENTIFIED NEURONS IN THE LEECH. L.P. Tolbert and R.L. Calabrese. Dept. Anatomy, Georgetown Univ. School of Medicine, Washington, DC 20007 and Biological Laboratories, Harvard Univ., Cambridge, MA 02138.

Laboratories, Harvard Univ., Cambridge, MA 02138. The rhythmic constriction of the heart tubes in the leech <u>Hirudo medicinalis</u> is controlled by an identified set of motor neurons (HE cells) and interneurons (HN cells) (reviewed by Stent, Thompson, and Calabrese, Physiological Reviews 59:101). Electrophysiological recordings have established that the HE and HN cells interact with each other in a precise pattern. HE cells, found in ganglia 3-18, innervate the heart-tube muscle and are electrically coupled to their contralateral homologues (Peterson, Biophysical Journal, in press). They are tonically active; rhythmic inhibitory synaptic input from certain HN cells coordinates their activity to produce functional firing patterns. HN cells are found in ganglia 1-7. While some HN cells. The synaptic connections among HN cells are inhibitory and differ from ganglion to ganglion. In the present study, the synaptic framework mediating the

In the present study, the synaptic framework mediating the interactions among the HE cells and HN cells is being examined in an effort both to further our understanding of the circuitry responsible for the heartbeat and to elucidate basic cellular mechanisms of integration. The electrophysiological results described above indicate particular relationships between identified neurons. Using electron microscopy of physiologically identified, HRP-injected cells, we are examining the zones of interactions and types of contacts between specific cells. Each HE cells sends numerous fine processes to the ganglionic

Each HE cells sends numerous fine processes to the ganglionic midline, where they interdigitate with the fine processes of their contralateral homologue. In the electron microscope, the HE cells are seen to contact each other frequently. Areas of direct juxtaposition of HE-cell processes are extensive, measuring as much as 6 um in length. In much of the area of juxtaposition, the apposed membranes are rigidly parallel, as is typical of gap junctions. The membranes in these areas are spearated by an intercellular gap of 6nm, like that between S cells (Muller and Carbonetto, J. comp. Neurol. 185:485). Throughout much of the neuropil, the HE processes are wrapped by glial sheets. HN cells also contact the processes of HE cells. The HN cells in the third ganglion are known to inhibit the HE cells in that ganglion. In the electron microscope, we see synaptic contacts made by HN processes onto multiple thread-like extensions of HE-cell processes; these contacts may account for the inhibitory influence. In addition, HN and HE processes have been seen to be postsynaptic at the same synapse made by a third, unknown, neuron. We are currently investigating HN-to-HN-cell contacts.

158.6 IDENTIFICATION OF ACTIVE SINGLE NEURONS IN LOCUST NEURAL CIRCUITS USING <sup>1</sup>H-2-DEOXYGLUCOSE AUTORADIOGRAPHY. <u>Aguan Wei</u> (SPON: G. Hoyle). Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

2-Deoxyglucose (2-DG) autoradiography (ARG) has been developed as a method to screen and mark neural metabolic activity which reflects electrical activity. A modified freeze-substitution proceedure (Sejnowski, T.J., et al., <u>Nature</u>, <u>287</u>:449, 1980) minimizes label diffusion, allowing for single cell resolution. Applied to invertebrate nervous systems with large and typically located identified neurons, 2-DG ARG offers the possibility for the identification of entire behavioral circuits, including behaviorally identified interneurons. The present investigations were performed to test the applicability of this technique to the locust nervous system.

of this technique to the locust nervous system. Metathoracic Fast Extensor Tibiae (FETi) motoneuron somata were used in feasibility tests in a semi-isolated preparation in which all nerves and connectives to the meso- and metathoracic ganglia were cut, except metathoracic nerve 5. In the presence of H-2-DG (100 $\mu$ C/ml), FETi on one side was stimulated antidromically at 10 Hz, using bipolar electrodes implanted in the muscle, its contralateral homologue serving as an unstimulated control. After stimulation, for varying durations, the ganglia were dissected and washed in three changes of isotonic saline for 30 minutes to remove non-specific uptake. The tissue was then either processed for autoradiography, or individual FETi somata dissected and assayed directly for uptake by scintilation counting. Stimulated FETi somata showed significantly greater uptake of 2-DG over unstimulated controls. This stimulation of the duration for at least the first 4 hours of stimulation.

The isolated metathoracic ganglion has been demonstrated to produce ventilatory rhythmicity endogenously (Lewis, G.W., et al.,  $\underline{J}$ , e<u>sp. Biol.</u>, 59:149, 1973). Autoradiographs of isolated, unstimulated ganglia reveal a set of 17 intensely-labelled, and 13 lightly-labelled cells in the fused abdominal region of the metathoracic ganglion. The positions and numbers of the heavily-labelled cells appear to be invariant between animals. Intracellular recording and dye injection confirm the presence of bursting neurons with activity in phase with ventilation, with soma sizes and positions matched with those seen labelled. These neurons are likely to be elements of the central pattern generator for ventilation.

158.8 ASCENDING INTERNEURONS IN THE VENTILATORY SYSTEM OF THE DRAGONFLY LARVA. <u>A. Komatsu.</u> Dept. of Physiology, Tokyo Women's Med. Coll., Shinjuku-ku, Tokyo 162, Japan.

In the dragonfly larva, <u>Anax parthenope julius</u> Brauer, the main oscillator of the respiratory motor hythm is located in the terminal abdominal ganglion, gA8 (Komatsu, 1982). To bring about synchronous contraction in all abdominal segments, the existence of interneurons is necessory which convey the respiratory signal from the main oscillator located in gA8 to the segmental respiratory motor systems.

To search for interneurons 4th to 7th abdominal ganglia were penetrated by glass microelectrodes. Activity of the respiratory interneurons was recorded in the deep midline region (depth 90-110 µm from the dorsal surface of the ganglion). These interneurons produced rhythmic bursts of action potentials in phase with expiration. These action potentials are considered to be axonal spikes, because they showed no prepotentials. Their structure was determined by intracellular staining with the fluorescent dye Lucifer Yellow. These neurons had their cell body in gA8 from which an axon ascended to the anterior ganglia via the ipsilateral connective. They also sent out secondary processes bilaterally in all abdominal ganglia in which their structure was determined. I designated them the ascending expiratory interneurons (AE neurons).

expiratory interneurons (AE neurons). Intracellular recordings from the segmental respiratory motoneurons have revealed a pattern of alternating excitatory and inhibitory synaptic potentials (Komatsu, 1980). To test the possibility that the AE neurons provide some of the synaptic input to the segmental motoneurons, depolarizing current pulses were injected via the recording electrode into an AE neuron whereas activity of the respiratory motoneurons was monitored extracellularly from the peripheral nerves. The amplitude but not the timing of respiratory motor output could be altered by injecting current into an AE neuron. Some expiratory motoneurons were excited and an inspiratory motoneuron was inhibited by the evoked discharges of the AE neuron. A number of tests failed to demonstrate that the AE neurons have an innate rhythmicity, or that they are elements involved in the rhythm generating system.

Electrical stimulation of a sensory nerve of gA8 during inspiration resets the respiratory motor rhythm (Mill and Hughes, 1966). When stimulus was applied during inspiration, an expiratory burst of impulses was evoked in an AE neuron and the successive burst rhythm was reset. When stimulus was applied during expiration, the activity of the AE neuron did not show a noticiable change.

These results suggest that the AE neurons form part of the drive to the segmental respiratory motor systems and that they are under the control of the rhythm generating system.

- 158.9 FREQUENCY MODULATING INTERNEURONS IN THE VENTILATORY SYSTEM OF THE CRAB, <u>Carcinus maenas. R. A. DiCaprio</u><sup>\*</sup> and <u>C. R. Fourtner</u>. Dept. of Biological Sciences, SUNY Buffalo, Buffalo, NY 14260
  - Gill ventilation in decapod crustacea is produced by rhythmic movements of the scaphognathite (SG). The motor pattern consists of alternating bursts of action potentials in the motor neurons innervating the levator and depressor muscles of the SG. The neuronal central pattern generator, originally thought to be a single endogenously oscillating non-spiking neuron in each hemiganglion (Mendelson, M., Science <u>171</u>: 1170, 1971), has recently been demonstrated to consist of a number of non-spiking interneurons (Simmers, A. J. and B. M. H. Bush, Brain Res. <u>197</u>: 247, 1980; DiCaprio, R. A. and C. R. Fourtner, Soc. Neursci. Abst. <u>7</u>: 744, 1981). We report here on three physiological types of non-spiking interneurons which can modulate the frequency of the ventilatory rhythm.

The first type of modulatory interneuron has small amplitude (<1 mv.) membrane potential oscillations in phase with the ventilatory motor pattern. The hyperpolarizing phase of the oscillation occurs at the onset of the depressor activity. In a quiescent preparation depolarizing current applied to this interneuron will initiate the SG rhythm. In rhythmically active preparations depolarizing current increases the frequency of the rhythm, while hyperpolarizing current slows and eventually stops the motor pattern. This neuron appears physiologically identical to an interneuron described by Simmers and Bush.

The second type of modulatory interneuron also has a small membrane oscillation with the same period as the motor output but its hyperpolarizing phase occurs near the end of the levator burst slightly preceeding the hyperpolarization of the first type. Applied currents produce effects on the rhythm which are opposite to those produced by the first type; depolarization of this neuron decreases the rate of ventilation while hyperpolarization increases the ventilatory rate. The frequency modulation effect is also observed in the contralateral SG rhythm. Injection of the dye Lucifer Yellow into this neuron reveals a ventrolateral soma, a large diameter neurite which crosses the midline, and an asymetrical arborization in the ventilatory neuropile of each hemiganglion.

The third type of frequency modulating interneuron shows no oscillations during the ventilatory rhythm, but does produce alterations in the rhythm which are identical to those produced by the second type when depolarizing and hyperpolarizing currents are applied. In addition, there is some evidence that depolarizing currents stronger than those necessary to stop the rhythm may trigger bouts of reversed ventilation. The cell body of this neuron is located on the ganglionic midline and a symmetrical branching pattern overlaps both ventilatory neuropiles. (Supported by grant 1F32NS06277 to R. A. D.)

158.11 MAINTENANCE OF <u>TRITONIA</u> SWIMMING BY RECIPROCAL EXCITATION. P.A. <u>Getting and M.S. Dekin.</u> Dept. of Physiol. and Biophys., Univ. of Iowa, Iowa City, IA 52242. Escape swimming of the mollusc, <u>Tritonia</u>, consists of 2-20

Escape swimming of the moliusc, <u>Iritonia</u>, consists of 2-20 cycles of alternating dorsal and <u>ventral</u> flexions and is initiated by brief, noxious stimuli to the epithelium. Swim activity can be observed in two distinct neuronal populations; a network of 12 premotor, pattern-generator interneurons (PGI) and a large pool of motor efferent cells termed flexion neurons (FN). In all these cells, the neural correlate of swimming is a large, ramp depolarization (RAMP) which is largest just after the initiating stimulus and then dissipates slowly throughout the swim. Superimposed upon the RAMP are cyclic bursts that correspond to the dorsal or ventral flexion phases of a swim. The source of the RAMP, however, remains unknown. Two possibilities are the RAMP could be generated by long-lasting effects of sensory pathways extrinsic to the swim network by re-excitation. These possibilities were tested for each cell type by 1) preventing cyclic activity. The amplitude and time course of the membrane currents underlying the RAMP

and time course of the membrane currents underlying the RAMP were measured by voltage clamp. The RAMP in FNs was dependent upon cyclic activity of the premotor PGI and appeared to arise from the summation of long-lasting excitatory components of the monosynaptic connections from the PGI to the FN. Likewise, the RAMP in two of the three subgroups of PGI (C2 and ventral swim interneurons) was heavily dependent upon cyclic bursts within the swim network. In contrast, the RAMP in the dorsal swim interneurons (DSI) (a third subgroup of PGI) was only partially dependent upon cyclic swim activity and appeared to be generated by both long-lasting excitation from sensory sources and by excitatory connections within the swim network.

and by excitatory connections within the swim network. The DSI are coupled reciprocally via monosynaptic excitatory synapses and via a polysynaptic pathway mediated by an inhibitory interneuron. In a quiescent preparation the polysynaptic inhibition is stronger than the monosynaptic excitation so that activity in one DSI leads to inhibition of the other DSI and swimming is thereby prevented. The inhibitory interneuron, however, is inhibited by C2. During a swim when C2 is firing, the inhibitory interneuron would by inactive and the DSI will mutually excite each other contributing to the maintenance of the ramp depolarization initially set-up by the sensory stimulus. Swimming, therefore, is released and maintained in part by disinhibition as well as an initial, transient excitation. 158.10 HOW OFTEN MUST A LOCUST CATCH ITS BREATH?: EXPERIMENTAL DUPLICA-TIONS OF A MODEL OF RHYTHMIC PATTERN GENERATORS WITH RANDOM NEURAL INPUTS. Simon F. Giszter® (SPON. M. Posner), Lab. of Dr. G. Hoyle, Inst. of Neuroscience, Dept. of Biology, University of Oregon, Eugene, Oregon.

How separate oscillatory portions of cyclic central pattern generators are coupled to one another and to the environment to produce viable behaviours is an important problem for understanding rhythmic motor control systems. How much random interference an oscillator system can cope with and the arrangements which are consequently best for achieving coordination have not been examined systematically from a motor control perspective. However they must be important evolutionary 'design' factors in most rhythmic behaviours such as walking, flight, ventilation and swimming. In locust ventilation several apparently redundant phase-resetting mechanisms occur and the question arises as to their functional importance.

To examine these problems a mathematical model was constructed of relaxation oscillators with pulsed cycle to cycle phase resetting. The model was examined analytically and the results confirmed and extended using computer simulations. The effects of altering the variance of added gaussian noise, types and forms of phase transition curves, and the number of oscillators interactions, were examined.

The model showed several interesting features. Using the terminology of Winfree(1980): 1) Even master/slave arrangements with type 0 oneway phase transition curves (which always reset to a fixed phase) cannot produce complete phaselocking of two oscillators corrupted by gaussian noise. Control by a single master oscillator could not reproduce the observed ventilatory behaviour in the locust. 2) Two type 1 phase transition curves allowing feedback can produce larger, more frequent periods of phase locking than one type 0 interaction. Thus apparent coupling redundancy in the locust abdomen may be an adaptation to random variations in cycle length from various sources.

rannom variations in cycle length from various sources. These results suggest sets of biological oscillators ought to cope with random events by use of inter oscillator feedback or 'memories' of disturbances. One way to generate these adaptive properties is to reciprocally couple several simple oscillators using simple phase transition curves as described. The organization of the locust abdomen seems to be such an adaptation. Using physiological parameters and connections the frequency of loss of coordination between oscillators in the model is similar to that measured between segments in the locust.

158.12 A TRIGEMINAL COMPONENT OF THE CENTRAL PATTERN GENERATOR FOR RESPIRATION IN THE ADULT LAMPREY. <u>Carl M. Rovainen</u>, Department of Physiology and Biophysics, Washington University School of Medicine, St. Louis, Missouri 63110. Unidentified generator interneurons drive branchial moto-

Unidentified generator interneurons drive branchial motoneurons (MNs) in the isolated brain stem of the adult lamprey to produce spontaneous fictive breathing activity. In the larval lamprey the pattern generators (Gs) are present in the trigeminal region of the brain stem and drive both the velar MNs in the V motor nuclei and the branchial MNs in the IX-X motor nuclei (J. Comp. Physiol. 104: 175). After metamorphosis, the trigeminal muscles are no longer used for respiration. The question is whether the rostral pattern generators are retained in the adult lamprey.

In both larval and adult lampreys, hemisection of the brain stem behind the V motor nucleus eliminates periodic bursts in IX-X MNs on the same side. This indicates that an <u>ipsilateral</u> <u>descending pathway</u> is necessary for periodic excitation of branchial MNs. The <u>rostral medulla</u> but not the midbrain is required for fictive breathing in adult lampreys.

Fequired for liftlye breathing in adult lampreys. One site for <u>bilateral coordination</u> of generators in the adult lamprey is the <u>midline of the rostral medulla</u>. Extracellular recordings at this site show periodic spike bursts which precede those in the IX-X nerves. Electrical stimulation at the same site excites IX-X MNS, elicits bursts in the nerves, and can reset and entrain fictive breathing. Cuts along the midline which spare the rostral medulla allow synchronous bursts in MNS on both sides. Alternatively, cutting the rostral midline still allows coordination through a caudal commissural system between the IX-X motor nuclei. Complete transection of the brain stem behind the V motor nuclei silences the IX-X MNS, but <u>periodic bursts can still occur at the rostral midline</u>. Therefore, at least some of the components of the pattern generators for respiration in the adult lamprey are in the rostral medulla.

The proposed locations of the pattern generators (G) and their connections are diagrammed to the right.

RESPIRATORY PUMPING IN APLYSIA IS MEDIATED BY TWO COUPLED CLUSTERS OF INTERNEURONS. J. Koester, Center for Neurobiology & Behavior, Columbia Univ., College of Physicians & 158.13

Surgeons, and N.Y. State Psychiatric Institute, N.Y., N.Y. 10032. Respiratory pumping is a brief (3-10 sec), stereotyped all-or-none behavior that consists of synchronous gill, siphon, mantle shelf and behavior that consists of synchronous gill, sipnon, manue shell and parapodial contractions, heart inhibition and vasodilation. It occurs spontaneously at intervals ranging from several seconds to several minutes, and its frequency can be modulated by a variety of stimuli, including noxious and tactile stimuli, light, hypoxia, feeding, and copuulation (Eberly et al., 1981, <u>Behav. Neural Biol</u>.). The motoneurons that mediate this behavior have been identified previously by various investigators. Byrne (1983, <u>J. Neurophysiol.</u>) has previously identified a cluster of interneurons, called L25 cells, on the left side that mediate respiratory pumping. I describe here a second cluster of interneurons, called R25 cells, that also mediate this behavior.

The R25 cells are located in the right hemiganglion, symmetrical to the L25 cluster. They have several features in common with those previously described for the L25 cells: (1) There are as many as 7 R25 cells per ganglion; (2) The R25 cells burst during spontaneous respiratory pumping episodes; (3) Firing a single R25 cell can trigger a regenerative burst in the entire L25-R25 network; (4) Hyperpolarizing a single R25 cell can decrease the rate of spontaneous respiratory pumping; (5) The R25 cells make mutually excitatory connections to each other and to the L25 cells, mediated at least in part by electrical coupling; (6) The R25 cells are excited by tactile stimuli to the gill or siphon; (7) When respira-tory pumping occurs in a steady, rhythmic fashion, the L25 and R25 cells exhibit slow, depolarizing pacemaker-like ramps between bursts.

exhibit slow, depolarizing pacemaker-like ramps between bursts. Newly described features of the L25 and R25 cells are: (1) Individual R25 cells and L25 cells that trigger a burst when depolarized also con-nect directly to motoneurons in the abdominal ganglion; some R25 cells also connect directly to neurons in the branchial ganglion; (2) The L25 and R25 cells are non-homogeneous with regard to their synaptic pro-jections and to their synaptic input; (3) The L25 cluster can burst inde-pendently of the R25 cluster, resulting in weak, low intensity episodes of consistent publication L25 cells produce low IPSPC in path. respiratory pumping; (4) Some L25 cells produce slow IPSPs in other L25 cells and in R25 cells; (5) The L25-R25 cell network can be made to switch to the rhythmic bursting mode by exciting the R20 cells, a newly described pair of electrically coupled cells located near the R25 cluster.

These results, together with Byrne's data, indicate that: (1) Initiation and maintenance of the burst in the L25-R25 network is mediated by mutually excitatory connections that lead to reverberation within the network; (2) Burst termination is in part produced by slow inhibitory synaptic potentials generated by some of the L25 cells; (3) Some L25 and R25 cells that contribute to burst initiation within the interneuron network also project directly to motoneurons that drive the behavior. (NS19328)

158.14 GANGLIONIC BLOOD FLOW INFLUENCES THE ACTIVITY OF NEURONS REGULATING THE HEART AND VASCULATURE OF <u>APLYSIA</u>. <u>S.M. Furgal\*</u> and <u>P.H. Brownell</u>. Dept. of Zoology, <u>Oregon State Univ.</u>, <u>Corvallis</u>, <u>Oregon 97331</u>. The abdominal ganglion of the mollusk <u>Aplysia californica</u> contains several identifiable motor neurons, <u>neurosecretory</u> colls and an internuent that are known to require cardiage and

contains several identifiable motor neurons, neuroscretory cells and an interneuron that are known to regulate cardiac and vascular functioning. In previous studies, we observed that the somata of these neurons generally lie adjacent to major branches of the artery serving the ganglion, and that brief interruptions of arterial blood flow tended to excite neurons that excite the heart. Since the abdominal ganglion receives blood shortly after it leaves the heart, we reasoned that a simple mechanism for mediating feedback regulation of cardiac output might involve direct, compensatory actions of pressure, oxygen tension or other blood parameters on central neurons controlling circulation. To further investigate this possibility we manipulated

To further investigate this possibility we manipulated ganglionic blood flow and oxygen tension in a dissected preparation while simultaneously monitoring cardiac activity (pressure transducer) and intracellular electrical activity of cardiovascular-control neurons. Our results show that all neurons that act to increase cardiac output or peripheral neurons that act to increase cardiac output or peripheral vascular resistance were excited by decreases in blood flow to the ganglion. Thus, the heart excitor interneuron (L10), excitor motor neurons (RB cells), the vasoconstrictor motor neurons (LB $_{\rm VC}$ ) and neurosecretory cells (R9 - R12) were reversibly excited by decreased flow while many other ganglionic neurons were unaffected or inhibited. The response of L10 was especially strong, usually transforming this cell from tonic to bursting mode of discharge. Similarly, a decrease in pO<sub>2</sub> (<20 mmHg) of blood perfusing the ganglion excited these neurons although this stimulus was notably less effective than decreased blood flow. Together these reflexive influences of blood pressure and oxygen tension on central neurons should act to stabilize and regulate cardiac output as a function of circulatory and metabolic demand in intact animals. animals.

## CARDIOVASCULAR REGULATION: HYPERTENSION AND STRESS

MODULATION OF BARORECEPTOR REFLEX SENSITIVITY BY NALOXONE 159.1 AND CLONIDINE. Julianna E. Szilagyi. Baylor College of Medicine, Houston, Texas 77030. Central control of the cardiovascular system is now known

to be influenced by the opiate system (eg, central pressor actions of angiotensin II, development of hypertension in SHR's, various forms of shock ). Additionally, the actions of the antihypertensive agent clonidine have been linked to the release of opiates. Naloxone, an opiate antagonist, can block the reduction in blood pressure due to clonidine administration in SHR's. In fact, morphine and clonidine produce simi-lar cardiovascular effects via actions on the sympathetic and parasympathetic nervous systems. This study was designed to determine whether these effects involve an action of naloxone and clonidine on baroreflex sensitivity.

Fight dogs (18-22 kg) were anesthetized with pentobarbital (30 mg/kg) and a femoral artery and vein cannulated. Blood pressure was raised or lowered pharmacologically with phenyl-ephrine  $(20\mu g/kg)$  and sodium nitroprusside  $(100\mu g/kg)$  and heart rate was determined at several levels of pressure during the response. These variables were recorded before and after administration of low dose naloxone  $(0.04\,\mbox{mg/kg})$  and clonidine (0.01mg/kg). Baroreceptor sensitivity was determined from the slope of the regression line relating mean arterial pressure and heart period (reciprocal of heart rate,msec). In one group of animals (n=4), when compared to control slopes, naloxone reduced baroreflex sensitivity to both phenylephrine and nitroprusside. The slopes of the regression lines were reduced by -52% and -20% respectively. Peak changes were not different. In contrast, introduction of clonidine in four separate dogs markedly increased sensitivity to both drugs. In this case the slopes of the regression lines were increased by 295% (phenylephrine) and 221% (nitroprusside). When low dose naloxone was given to these same animals baroreceptor reflex sensitivity was partially normalized. Compared to clonidine responses naloxone lowered the slopes of the baroreflex sen-sitivity curves to phenylephrine by -45% and to nitroprusside by -15%. Again, when compared, peak responses were not statistically different.

These data indicate that 1) blockade of endogenous opiates can diminish baroreflex sensitivity and, 2) the actions of clonidine on baroreceptor reflex sensitivity also involve opioid modulation. (Supported by NIH-NIRA and AHA-Texas Affiliate).

159.2 INCREASED CENTRAL ALPHA2-ADRENOCEPTOR RESPONSIVITY IN GENETICALLY HYPERTENSIVE RATS. J. Marwaha, Pharmacology & Physiology, Indiana Univ. Sch. of Med., Terre Haute, IN 47809. Recent studies (1, 2) indicate that there exist some common-alities in central circuits involved in control of blood pressure and nociception. Clonidine, a clinically useful antihypertensive drug, has been shown to be effective in blocking the effects of noxious stimuli in rodents (3). In the present study, we exam-ined the antinociceptive effects of clonidine in related strains of genetically hypertensive (SHR) and normotensive (WKY) rats. Age-matched SHR (Okamoto-Aoki) and WKY (Wistar-Kyoto) rats were used. These 30-week-old male rats were purchased from

Age-matched SHR (Okamoto-Aoki) and WKY (Wistar-Kyoto) rats were used. These 30-week-old male rats were purchased from Laboratory Supply Company, Inc., Indianapolis, IN. Nociceptive thresholds were tested by the tail flick method. Tail flick was tested by placing the tail of the animal in a thermostatically-controlled water bath, set at 55°C. Cut-off time in absence of a response was 10 sec. The results were ex-pressed as the mean latency  $\pm$  S.E.M. There were no differences in baseline latency values between SHR and WKY rats. After ad-ministration of clonidine, (1 mg/kg, i.p.) tail flick latencies in spontaneously hypertensive rats (SHR) were significantly greater than those in normotensive (WKY) controls. The antino-ciceptive effect of clonidine was significantly antagonized by yohimbine, an alphap-adrenoceptor antagonist (2 mg/kg, i.p.-ad-ministered 15 min. before clonidine). Oxymetazoline (up to 6 mg/kg, i.p.), a poorly permeable alphap-adrenoceptor agonist,

ministered 15 min. before clonidine). 0xymetazoline (up to 6 mg/kg, i.p.), a poorly permeable alpha<sub>2</sub>-adrenoceptor agonist, did <u>not</u> produce antinociceptive effects in either SHR or WKY rats. Our results suggest that SHR rats differ from WKY animals the following respects: (A) SHR rats have decreased responsive-ness to pain as assessed by administration of clonidine; (B) SHR rats have increased responsiveness (increased receptors!) to alpha<sub>2</sub>-adpencentor agents as assessed by whimbing attagoniem: alpha<sub>2</sub>-adrenoceptor agents as assessed by yohimbine antagonism; (C) In SHR rats the more responsive alpha2-adrenoceptors are probably centrally located as assessed by oxymetazoline. Supported in part by USPHS Grants SO7RR 5371, AG 03737, AA 05871, and an Indiana State University Grant #6703.

LONG-TERM ENHANCEMENT OF INTRASPINAL SYMPATHETIC 159.3 TRANSMISSION FOLLOWING BRIEF PERIODS OF INTENSE ACTIVATION. Alan F. Tramposch\*, Ralph L. Myers\*, and Donald N. Franz. Dept. of Pharmacology, University of Utah, Salt Lake City, Utah 84132.

Sympathetic discharges recorded from upper thoracic preganglionic rami were evoked by stimulation of descending excitatory pathways in the cervical dorsolateral funiculus of unanesthetized, spinal cats at 0.1 Hz. At this stimulus rate, the sizes of evoked discharges, analyzed on-line by signal averaging, remained stable for more than 6 hr. Brief periods of repetitive stimulation produced long-term potentiation (LTP) of subsequent discharges evoked at 0.1 Hz. The size and the duration of LTP were dependent on frequency (10-75 Hz) and duration (5-20 sec) of tetanic stimulation. Following tetanic stimulation at 50 Hz for 10 sec, subsequent discharges reached maximal sizes of 120-600% of control values within 90 sec and thereafter slowly declined to control or higher values by about 20 min. Depression of intraspinal transmission by clonidine (20 ug/kg), 5-HTP (40 mg/kg), or morphine sulfate (1 mg/kg), which act by depressing the excitability of sympathetic preganglionic neurons (SPGNs), did not depress the absolute size or duration of LTP. In contrast, chlorpromazine HCl (4.5 mg/kg) which appears to depress intraspinal transmission by blocking the excitatory influence of descending norepinephrine pathways, almost completely prevented the development of LTP. These results suggest that enhanced release of norepinephrine is largely responsible for LTP.

Repeated tetanization of intraspinal pathways (50 Hz for 10 sec), at four, 20 min intervals produced incremental increases in steady state transmission to SPGNs in 47 of 66 experiments (average, 180%; range, 110-335% of pretetanic control values). The increases in transmission were sustained for up to 3 hr and were directly correlated with the average maximal size of LTP following the four periods of tetanization (r=0.775; 0.001). These results suggest that long-term increases in intraspinal sympathetic transmission produced by intermittent, intense activation of descending excitatory pathways to SPGNs may contribute to the development of primary hypertension. (Supported by NIH grants HL-24085 and GM-07579 and the Utah Heart Association.)

DECREASED SODIUM EXCRETION DURING BEHAVIORAL STRESS IN DOGS: ROLE OF CENTRAL BETA-ADRENOCEPTORS AND RENAL NERVES. J. P. Koepke\*, K. C. Light\*, A. Grignolo\*, and P. A. Obrist\* (SPON: C. L. Lee). Dept. of Psychiatry, University of North Carolina School of Medicine, Chapel Hill, NC 27514. 159.5

Exposure to behavioral stressors has recently been shown to reduce renal sodium excretion in saline-infused dogs and rats (1-3) and in water-loaded young men with borderline hypertension or hypertensive parents who showed evidence of high sympathetic activity during stress (4). To clarify possible neural mediating processes, further studies in dogs were performed comparing ex-

processes, further studies in dogs were performed comparing ex-cretory responses to signalled shock-avoidance before and after i.v. infusion (1 mg/kg) of three non-selective beta-adrenergic antagonists or surgical renal denervation. In 7 dogs, decreases in excretion of sodium and water shown during avoidance without propranolol (-47% and -45% from baselines of 345 µEq/min and 2.1 ml/min) were abolished with propranolol (-2% and -5% from 527 µEq/min and 3.0 ml/min). In 5 other dogs showing similar stress-induced decreases in sodium and water excretion without beta-antagonists (-48% and -40%), significant decreases in excretion remained after infusion of timolol (-38% and -36%) or oxprenolol (-25% and -19%). Timolol and oxprenolol concentrate highly in the kidney and timolol is 5-10 times as potent in beta-antagonism as propranolol, indicating that block-ade of renal beta-receptors does not prevent stress-induced changes in sodium excretion. Instead, since propranolol has been shown to cross the blood-brain barrier more readily than timolol or exprenolol (5,6), its effectiveness appears to be due to receptors within the central nervous system.

Renal excretory responses to avoidance were also compared in 10 dogs before and after surgical renal denervation or sham-denerva tion. Decreases in sodium and water excretion shown before shamdenervation (-41% and -42%) persisted and were even slightly denervation (-41/4 and -42/2) persisted and were even slightly greater after (-55% and -57%). In contrast, average decreases seen before renal denervation (-41% and -44%) were largely absent after (-14% and -11%); in fact, denervation totally abolished these changes in 4 dogs but had no effect in one. Thus, in most dogs, the decreased sodium excretion induced by this stressor appears to be mediated directly by the renal nerves.

CENTRAL EFFECTS OF ANGIOTENSIN II OPPOSE SYMPATHOINHIBITION INITIATED BY BARORECEPTORS. R.D. Stein\*, R.B. Stephenson\*, and L.C. Weaver (SPON: J.R. Hoffert). Dept. of Physiol., Mich. St. 159.4 E. Lansing MI 48824.

Central administration of angiotensin II (AII) causes in-creased arterial pressure which may be mediated, in part, by effects upon central sympathetic neurons or by interference with central or peripheral components of the baroreceptor reflex. The purposes of this investigation were to determine 1) if central excitatory effects of AII on splanchnic sympathetic activity are evident in the presence of concomitant baroreceptor activation and 2) if peripheral actions of AII decrease the sensitivity of the carotid sinus baroreceptors. Discharge rates of carotid sinus afferent and splanchnic sympathetic efferent nerves were monitored in 12 chloralose-anesthetized cats. Neural responses during increases in arterial pressure caused by intracarotid or intravenous administration of AII were compared to responses to equivalent increases in arterial pressure induced by intra-

equivalent increases in arterial pressure induced by intra-venously injected dextran or phenylephrine. Intracarotid injections of AII caused a mean increase in arterial blood pressure of 16 mm Hg and variable individual splanchnic sympathetic responses consisting of increased, decreased, or unchanged activity. Mean splanchnic nerve activity within the group remained unchanged. In contrast, sympathetic activity was consistently inhibited (-24%) during equipressor infusions (18 mm Hg) of dextran or phenylephrine. AII had no apparent effect on the transduction characteristics of the arterial baroreceptors, as carotid sinus afferent activity was increased 35% by the intracarotid AII injections and 31% by the increased 35% by the intracarotid AII injections and 31% by the intravenous dextran or phenylephrine infusions.

Splanchnic and carotid sinus nerve responses to intravenously injected AII were not significantly different from responses to dextran or phenylephrine infusions. Intravenous AII caused a pressor response of 19 mm Hg, splanchnic nerve inhibition (-21%), and carotid sinus nerve excitation (+34%). Equipressor doses of dextran or phenylephrine induced the expected decreases in sympathetic discharge (-23%) and increases in baroreceptor activity (+32%). These data demonstrate that AII can act centrally to excite sympathetic outflow or to interfere with the sympatho-inhibitory baroreceptor reflex. Through such actions, AII may contribute to the genesis and maintenance of the renal hypertensive state.

MEDIAN PREOPTIC LESIONS INTERFERE WITH REFLEX COMPENSATION 159.6 DURING HEMORRHAGE. <u>D. K. Hartle, F. Cheung\* and J. W. Manning</u>. Dept. of Physiology, Emory University, Atlanta, GA 30322.

The median preoptic nucleus (MePON) has been recently implicated in central nervous control of the circulation. It appears to be an integrative site for both neural and endocrine mecha-nisms that regulate sympathetic vasomotor activity. Destruction of the MePON eliminates the central pressor actions of angiotensin II, produces chronic deficits in vasopressin regulation and impairs baroreflex function. Destruction of the MePON has been demonstrated to both prevent and reverse many different forms of experimental hypertension. Two vasoconstrictor pathways descend from the MePON that are differentially required for the develop-ment of renin-dependent and non-renin-dependent forms of renal One pathway is activated by angiotensin II and hypertension. the other pathway is apparently activated by relief of inhibition by baroreceptor-mediated input. Animals with MePON destruction do not have these central mechanisms for increasing sympathetic nervous activity and consequently do not develop hypertension.

This experiment was designed to test whether these central control mechanisms were required for homeostatic compensation during blood volume depletion. A group of five conscious un-restrained rats with previous radiofrequency destruction of the ventral MePON were compared with a group of six sham-operated rats. The animals were hemorrhaged by 1.6% of their total body weight over a 5 min period. The MePON lesion group became hypotensive with this bleed (average 59% decrease in mean arterial pressure). The sham-operated control group had no significant change in blood pressure from control. The difference between the responses of the two groups was statistically significant, p<.01.

Bleeding was continued at the reduced rate of 1ml/7 min until irreversible shock caused death in each animal. lesion animals were significantly more susceptible to irreversi-ble shock. Death occurred in this group with 2.8% body weight blood loss compared with 4.4% in the sham group. These data suggest a role for neural circuitry involving the MePON in compensatory augmentation of sympathetic vasoconstriction and vaso-pressin release required for blood volume mobilization to main-tain blood pressure during hemorrhagic crisis. Supported by GA Heart Association.

THE EFFECT OF LESIONING THE AV3V REGION UPON THE 159.7 CENTRALLY MEDIATED PRESSOR RESPONSE TO ANGIORUSINI IN THE DOG. <u>O. Marson</u>, <u>C.L. Chernicky</u>, <u>K.L. Barnes and</u> <u>C.M. Ferrario</u>, Research Division, Cleveland Clinic Foundation, IN THE DOG. <u>O.</u> <u>C.M. Ferrario</u>, Rese Cleveland, Ohio 44106.

The administration of angiotensin II (Ang II) into either a brain ventricle or the cerebral circulation of several species causes a prominent cardiovascular hypertensive response. Although in the dog the area postrema is a receptive site for the pressor effects of Ang II given via the vertebral arteries, it is not yet known what region or

given via the vertebral drifters, it is not yet known what region or structure accounts for the activation of sympathetic vasconstrictor outflow when the hormone is given into the cerebrospinal fluid (CSF). The changes in mean arterial pressure (MAP) and heart rate (HR) due to infusions of Ang II into either a third cerebral ventricle (IVT) or the common carotial artery (ICA) were measured before and following electrolytic lesion (4 mA DC, 20 sec) of the periventricular tissue surrounding the anterior portion of the ventral third cerebral ventricle

Clearbornia the anterior portion of the ventral third cerebral ventricle (AV3V) in six dogs anesthetized with chloralose. 66 mg/kg, IV) after they were medicated with morphine (2 mg/kg, IM). In another three dogs (sham control group) an electrolytic lesion was placed at sites either rostral or caudal to the AV3V region. In both sham and AV3V lesioned groups, the pressor activity of the peptide was assessed at the tollowing dosse: 1, 10, 20 and 50 ng/kg/min for the ICA route; 50, 100 and 200 ng/kg/min for the IVT route. All infusions lasted two minutes. In all dogs smaller quantities of Ang II were needed to produce a pressor response via the ICA equivalent to that obtained when the peptide was infused IVT. In addition, the increases in pressure were always associated with tachycardia following IVT administration of Ang II; in contrast, the pressor effects of Ang II administered via a third ventricle at all doses tested (i.e.:  $14 \pm 2$  and  $22 \pm 4$  mmHg before versus  $7 \pm 3$  and  $14 \pm 3$  mmHg after AV3V lesion at the doses of 50 and 200 mg/kg/min respectively). In contrast AV3V lesioned dogs did not show

7 ± 3 and 14 ± 3 mmHg after AV3V lesion at the doses of 50 and 200 ng/kg/min respectively). In contrast AV3V lesioned dogs did not show any change in the pressor activity of Ang II given via the ICA route. These findings demonstrate that in the dog the AV3V region contributes to the pressor activity of Ang II delivered via the cerebrospinal fluid. However, it appears not to be active as a site of action for blood-borne angiotensin II. (Supported in part by NHLBI grants HL-6835 and HL-24100).

- 159.8 CARDIOVASCULAR AND APPETITIVE EFFECTS OF ESTRADIOL.
  - T.A. McCaffrey\* and John A. Czaja. Department of Psychological Sciences, Purdue University, West Lafayette, IN. 47907.
     The influence of estrogens in cardiovascular and appetitive ine influence of estrogens in cardiovascular and appetitive modulation is well documented but poorly understood. Yet, simultaneous measures of these related parameters are rarely taken. The present study documents the ability of estradiol-17beta to lower blood pressure (BP) and pressor responses (PR) to norepinephrine (NE) in conscious, unrestrained guinea pigs (GP). Female GP were ovariectomized 19 days prior to implantation of carotid artery and jugular vein catheters (PE50 and PE10, respectively). Measurement of direct arterial blood pressure and response to 30 ul of intravenous NE (52 ug/ml) was performed on 7 GP just previous to subcutaneous injection of 30 ug estradiol-17beta and on 7 GP receiving only the corn oil vehicle. Measurements of resting and NE-modified systolic, vehicle. Measurements of resting and NE-modified systolic, diastolic, and pulse pressure, and HR were quantified by a microcomputer system at hour 0 and 1, 3, 6, 12, 24, 36, 48, 60, and 72 hours post injection. Food intake, water intake and body weight were measured daily throughout the experiment. The data was expressed as a change from zero-hour and compared between groups using a Student's t-test. Results indicate that estradiol depressed resting pressures up to 12% and PR up to 20% in a period from 12 to 48 hours post-injection. Only minor changes in pulse pressure, heartrate or heartrate depression induced by NE were observed. An analysis of the average NE infusion profile indicated that estrogen produced a pressure dependent decrease in indicated that estrogen produced a pressure dependent decrease in the response to NE with no change in the half-life of the the response to NE with no change in the half-life of the response. When expressed as a change from the two days previous to the injection and compared between groups, estradiol exhibited statistically significant behavioral effects. Food intake was depressed for three days following the estradiol, body weight was depressed for two days, and water intake for one day following the estradiol. A significant correlation was observed between The estimator. A significant correlation was observed between the 24 hour change in systolic pressure and the concurrent change in water intake (r(5) = .80, p < .05). The correlation could not be easily attributed to a generalized estrogen sensitivity since the depression in systolic pressure did not correlate well with the 24 hour change in food intake (r = .42, NS), body weight (r = .20, NS), or systolic pressor response (r = -.02, NS). In a related study, total 24 hour food and water deprivation could not be shown to decrease BP or pressor response to NE. Thus, the correlation between the vascular and drinking changes following estradiol treatment implies that the reduced blood pressure and vascular tone may be indicative of systemic changes in cardiovascular stimuli for thirst.
- 159.9 BURST DURATION AS AN INDEX OF RENAL SYMPATHETIC NERVE ACTIVITY IN DOCA HYPERTENSIVE YUCATAN MINIATURE SWINE.

R. R. Notvest\*, E.J. Zambraski\* and C.D. Ciccone\* (SPON: F. E. Horvath). Physiology, Rutgers Univ., New Bruns., NJ 08901.

Absolute values for sympathetic nerve activity are difficult to obtain because of the limitations of the present methods used to quantify multiunit nerve activity (voltage integration, frequency counts). This difficulty in measuring absolute activity is especially apparent when comparing nerve activity among different animals (e.g. normotensive/hypertensive). We recently have explored a novel approach for quantifying renal nerve activity (RNA) which relies on the measurement of RNA burst duration (BD). As previously reported, renal nerves discharge in pulse-synchronous bursts. We recently observed that during a synchronous bursts. We recently observed that during a phenylephrine-evoked pressor response, RNA BD decreased as mean arterial pressure (MAP) increased. There was a direct positive correlation between the time interval of positive correlation between the time interval of individual BDs and the integrated voltage per burst (r=0.76; P<0.01). This finding suggests that the BD parameter is a valid index of total RNA. We have utilized analysis of BD to compare RNA between 9 control (CON) and 7 DOCA hypertensive anesthetized swine. MAP, which was significantly elevated in conscious DOCA animals, was reduced by pentobarbital anesthesia. Under these experimental conditions the mean BD for the CON and DOCA groups were not significantly different. The mean BD per minute (normalized for heart rate) was elevated in the DOCA group although the difference was not significant. group although the difference was not significant.

	MAP-Cons.	MAP-Anes.	HR	BD	BD/min
	(mm HG)	(mm HG)	(bts/min)	(msec)	(sec)
CON	132 + 5	135 + 6	157 + 15	196 + 22	30 + 4
DOCA	170 + 7	140 + 7	174 + 14	201 + 25	35 + 5

The lack of a significant difference between the BD parameters of CON and DOCA groups may have been due to the effects of the anesthesia on nerve activity and the reduced MAP in DOCA animals. Further studies in the conscious state will be required to determine whether BD, as an index of total RNA, is altered in DOCA hypertension.

Supported by the National Institute of Health (HL25255)

159.10 EFFECTS OF ACUTE BARODENERVATION IN NORMOTENSIVE & DOCA-SALT RATS. N. Gravel\* and J. de Champlain. Dept of Physiology, Université de Montréal, Montréal, Québec, Canada. Chronic barodenervation (BDX) of the sino-aortic nerves indu-ces significant increases of the systolic arterial pressure and of circulating catecholamines (CA) in rats (Alexander, N., Am. J. Physiol. 238:H-521, 1980). However, chronic observations of these animals reveals a lability of the blood pressure rather than a consistant increase (Norman, B., Hypertension, 3:119, 1981). Sinanimals reveals a lability of the blood pressure rather than a consistant increase (Norman, R., <u>Hypertension</u>, 3:119, 1981). Sin-ce arterial baroreceptors are involved in rapid adjustments of blood pressure, it is of interest to evaluate the acute cardiou-ascular response to BDX. Furthermore, the possibility of an asso-ciation between baroreceptor dysfunction and hypertension warrants further investigation in hypertensive animals. This study was carried out to examine the cardiovascular response of normotensi carried out to examine the cardiovascular response of normotensi-ve (NT) and DOCA-salt hypertensive (HT) rats submitted to acute carotid and aortic BDX. Plasma norepinephrine (NE) and epinephri-ne (E) concentration were used as indices of sympathetic activity. NT and HT animals were either barodenervated (BDX) or sham-opera-ted (SHAM) under fentanyl anaesthesia. Mean arterial pressure (MAP) was monitored continuously in the awaken animal and recor-ded every 5 min during 1 hour while blood samples (0.5ml) were withdrawn at 20, 40 and 60 min for measurements of plasma NE and E (ng/ml) - CA conventrations were measured by radio-enzymetic ac-

ded every 5 min during 1 hour while blood samples (0.5ml) were withdrawn at 20, 40 and 60 min for measurements of plasma NE and E (ng/ml). CA concentrations were measured by radio-enzymatic assay using thin layer chromatography for separation of amines. MAP is significantly higher in NT-BDX than in NT-SHAM animals until 20 min (127  $\cdot$  3 vs 80  $\cdot$  9 mmHg) and decreases thereafter to comparable levels 40 min later. However, plasma NE and E concentrations are consistently greater in NT-BDX (1.4  $\pm$  0.1 and 3.6  $\pm$  0.5 ng/ml) than in NT-SHAM rats (0.6  $\pm$  0.1 and 0.5  $\pm$  0.03 ng/ml). Furthermore, CA levels increase steadily until 60 min in NT-SHAM. In HT animals, MAP tends to be greater in HT-BDX (158  $\pm$  14 mmHg) than in HT-SHAM (152  $\pm$  7 mmHg) until 20 min and decreases thereafter below basal values. Plasma NE and E levels are greater in HT-BDX (1.8  $\pm$  0.2 and 4.0  $\pm$  0.9 ng/ml) than in HT-SHAM (0.97  $\pm$  0.1 ng/ml and 1.0  $\pm$  0.2 ng/ml). However, in this group of rats, CA concentrations are greatest at 20 min and decrease until 60 min in HT-BDX. These findings demonstrate a close association between arterial pressure and sympathetic response at 20 min following acute BDX. The decrease in MAP observed both in NT-BDX and HT-BDX the lexser sympathetic effect of BDX in HT animals suggest the possibility of a dysfunction at the level of baro-receptor in DOCA-salt treated rats. HYPOTHALAMIC AVP RELEASE IN THE DEVELOPMENT OF DOCA/NaCl 159.11

HYPOTHALAMIC AVP RELEASE IN THE DEVELOPMENT OF DOCA/NaC1 HYPERTENSION. Y. F. Chen, B. Stamoutsos\*, M. D. Lindheimer\* and S. Oparil\*. Cardiovascular Research and Training Center, Univ. of Alabama in Birmingham, Birmingham, AL 35294. Dept. of Medicine, Univ. of Chicago, Chicago, 1L 60637. The role of arginine-vasopressin (AVP) in the development of deoxycorticosterone-NaC1 (DOCA/NaC1) hypertension was studied by measuring plasma AVP levels and basal release of AVP from superfused hypothalami of uninephrectomized male Sprague-Dawley rats subcutaneously implanted with DOCA (100mg/kg) and drinking 1% saline and three control uninephrectomized groups (H<sub>2</sub>O, saline, and DOCA alone). Three days, 1 wk, and 3 wks after DOCA implantation, animals were sacrificed by decapitation and blood was collected for determination of plasma AVP. To measure AVP release, whole hypothalamic tissue fragments were dissected out and superfused in vitro. AVP collected in the superfusate and plasma AVP were quantified by radioimmunoassa. Plasma osmolarity and body weight increases were similar among the 4 groups. Systolic blood pressure (BP) in mmhg in DOCA/NaC1 rats was significantly (p<0.01) elevated above the H<sub>2</sub>O control group [185.4f6.3 (14) vs 129.4±4.4 (16)] at 3 wks. BP in the group treated with DOCA alone was also elevated to 158.8±3.1 (13) at 3 wks. Results [Mean ± SE (n)] of plasma AVP and basal release of AVP from superfused hypothalami are: H<sub>2</sub>O NaC1 DOCA/H<sub>2</sub>O DOCA/NaC1

The observation that both hypothalamic AVP release and plasma AVP levels are increased in D0CA/H\_Q animals suggests that D0CA alone may stimulate the release of AVP from the central nervous system. Further study is needed to determine the mechanism of this effect and the role of determined AVP melaces in the optimeration for 00C0/NCL increased AVP release in the pathogenesis of DOCA/NaCl hypertension.

159.12 ATTENUATION OF BLOOD PRESSURE IN THE SPONTANEOUSLY HYPERTENSIVE RAT (SHR) BY RAUWOLSCINE. S.J. Goldman, T.R. Hansen, G.A. Oltmans and S.A. Berenbaum. (SPON: R. WEISZ). Depts. of Pharm. Physio. and Psychol., Chicago Medical School, N. Chicago, IL 60064.

The spontaneously hypertensive rat (SHR) exhibits markedly increased systolic and diastolic blood pressure in comparison to normotensive WKY controls. The SHR is also behaviorally hyperreactive compared to the WKY, and exhibits a significant increase in locomotor activity in a novel environment. Although the mechanisms responsible for the hypertension and hyperreactivity are not known, a CNS component has been implicated in both instances. In this respect, significant Increases in central  $\alpha$ -1 receptors have been reported in the SHR (Pullen, et al. 1982) in areas believed to be involved in the regulation of blood pressure. Since receptor increases frequently are associated with decreased neurotransmitter activity, in the current study the  $\alpha$ -2 antagonist rauwolscine was administered to SHR and WKY controls in an attempt to increase central adrenergic activity. The effects on blood pressure and locomotor activity were then assessed.

Fifteen minutes after injection, rauwolscine treatment (l6mg/kg, i.p.) significantly reduced the tail artery systolic pressure of unanesthetized SHR (predrug=175.5+4.6mm Hg; postdrug=108.3+8.8; p<.01) but did not significantly change that of WKY controls (predrug=111.7+4.1; postdrug=104.0+3.5). A partial recovery of pressure occurred in the SHR during the next 15 minutes (to 139.6+7.4) and blood pressure remained at this level for the next 30 minutes. The blood pressure remained at this stream was significantly below baseline at least 60 min following rauwolscine treatment. In contrast, no significant change in blood pressure was found in the normotensive WKY controls at any of these times.

In contrast to the effects on blood pressure, rauwolscine did not affect the activity levels of either SHR or WKY rats in a novel environment. Baseline activity levels of the SHR in the novel environment. Baseline activity levels of the SHR in the novel environment were significantly higher than those of WKY controls (2193+75 counts/30 min vs 1635+118, respectively). Following rauwolscine treatment, the activity levels of drug-treated SHRs were not significantly different from those of saline-treated SHRs, and both of these groups were significantly more active than drug- or saline-treated WKY controls. The results suggest a selective hypotensive effect of rauwolscine in the SHR, and further indicate that this effect is senarable from an effect on activity. (Supnorted by RSC grant

separable from an effect on activity. (Supported by BRSG grant 5366).

159.13 ALTERATIONS IN MEDIAL LEMNISCAL FIELD POTENTIAL RESPONSES IN SPONTANEOUSLY HYPERTENSIVE AND NORMOTENSIVE WISTAR KYOTO RATS. James T. Garsik\*, Walter C. Low, and David Whitehorn. Department of Physiology and Biophysics, University of Vermont, Burlington, VT 05405.

The spontaneously hypertensive rat (SHR) is a commonly used model for human essential hypertension. Increased sympathetic activity and reactivity in the SHR compared to the normotensive Wistar Kyoto rat (WKY) has been shown to contribute to the elevated blood pressure of this strain. Recent evidence suggests that this feature of the SHR is part of a generalized hyperexcitability affecting all excitable tissue. To test this hypothesis we have directly determined the responsiveness of a sensory pathway in the SHR and WKY with electrophysiological Sensity particular in the safe and way with reflections in studies of transmission through the dorsal column nuclei (cuneate nuclei). Input-output (I-O) relationships were constructed which describe the medial lemniscal responses (output from the dorsal column nuclei) as a function of electrical stimulations applied to the animal's forepaw (input to the dorsal column). to the dorsal columns). In these experiments four groups of animals were used: SHR (uSHR), SHR maintained normotensive with hydralazine from weaning (tSHR), WKY (uWKY), and WKY given the same hydralazine treatment at tSHR (tWKY).

The USRR displayed a more rapidly rising I-O relationship than did the uWRY. This difference persisted between the tSRR and tWRY indicating that this is an inherent alteration in the SHR unrelated to blood pressure. A comparison between tSHR and uSHR demonstrated that the tSHR had an I-O relationship shift upward signifying that elevated blood pressure inhibits transmission through the dorsal column nuclei (tWHY and uWKY did not differ).

Two subsequent approaches demonstrated that acute and chronic elevations in blood pressure affect dorsal column nuclei transmission. In the acute experiments medial lemniscal evoked potentials were compared during saline or phenylephrine (PE) infusion to pre-treatment responses in individual WKY. P infused animals had a reduction in the medial lemniscal re-sponse which was not seen in the saline treated rats. The chronic experiments consisted of a comparison of the I-O relationships of sham operated and Goldblatt renal clip hyper-tensive Sprague Dawley rats. The I-O function of the hypertensive rat group was shifted downward from that of the sham operated animals.

Our results are consistent with a theory of generalized neuronal hyperexcitability in the SHR and confirm that transmission through the cuneate nuclei is inhibited by hypertension.

159.14 LIMBIC HYPOTHALAMIC ELECTRICAL ACTIVITY IN SPONTANEOUS HYPERTENSIVE RATS

R.J. Morgan, C.C. Turbes, G.T. Schneider\* and T.N. Solie\* Dept. of Biophysics and Physiology, Colorado State Univ., Ft. Collins, CO 80521. Anatomical studies have shed some light on the neural

Ft. Collins, CO 80521. Anatomical studies have shed some light on the neural mechanisms in the brain stem, hypothalamus and limpic regions that serve to integrate autonomic and neuroendocrine responses to pertubations in blood pressure. Few studies have addressed the related changes in electrical activity of these regions. Chronic electrodes are implanted in the amygdala(AMY), the preoptic area(POA), arcuate nucleus of the hypothalamus(ARC) and the hippocampus(HIP) of normal (NCR) and spontaneous hypertensive rats (SHR). The central nervous system (CNS) signals are recorded simultaneously for the first ten minutes of each half-hour for eight hours sequentially for four days. The analog recordings are analyzed using signal processing procedures including cross-correlation, coherence spectra and frequency time delay plots. This study will be concerned with female rats both NCR and SHR. Inere are differences in the cross-correlation and coherence spectra findings in the SHR rats from the NCR rats. There is a reversal of signal flow in the brain regions studied of the SHR rats from the NCR rats noted in the frequency time delay plots. The signal flow in the KR rats there is a lower correlation of the signal flow patterns that relate to the reproductive cycle. In certain prain areas of the SHR rats, the signals reversed at certain periods of the reproductive cycle as compared with the NCR rats.

15915

HISTOCHEMICAL ANALYSIS OF VASOPRESSIN-NEUROPHYSIN AND NOREPINEPHRINE IN THE SUPRAOPTIC AND PARAVENTRICULAR NUCLEI OF THE SPONTANEOUSLY HYPERTENSIVE RAT. John R. Sladek, Jr. and Celia D. Sladek, Depts. of Anatomy and Neurology, University of Rochester Sch. of Med., Rochester, NY 14642. Alterations in vasopressin (VP) and norepinephrine (NE) content of the supraoptic (SON) and paraventricular nuclei (PVN) have been reported in reportenceurly by Neurotexies rate. (SHPL) compared to parameters in the supravent of the supravent to parameters in the supravent of the supraoptic (SON) and paraventricular nuclei (PVN) have been reported in spontaneously hypertensive rats (SHRs) compared to normotensive Wystar-Kyoto (WKY) controls. The present study was initiated to evaluate whether these changes in content reflect alterations in the specific distribution of these substances within the PVN and SON. A combined histofluorescence and immunohistochemical technique was applied to the brains of 15-16 week old WKY and SHR rats, 3 of each strain. At this age blood pressure is chronically elevated in the SHRs (1989, 2 mm Hz in 1992). strain. At this age blood pressure is chronically elevated in the SHKs ( $198 \pm 2$  mm Hg vs  $142 \pm 2$  mm Hg in WKY, p. 001). Alternate sections were examined either for NE fluorescence or vasopressin-associated neurophysin (VP-NP) with comparator bridge microscopy. A marked increase was seen in the density of NE varicosities in the SON. While the ventral and caudal regions contain a maximal density of varicosities in the SHR, this density was augmented by increased density of tailors in dorsal and rostral regions also. These same animals also showed an increase in VP-NP staining in the SON; a larger proportion of neurons in the dorsal VP-NP staining in the SON; a larger proportion of neurons in the dorsal and rostral regions of the nucleus were stained. Increased VP-NP staining also was seen in the PVN; the majority of neurons appeared maximally stained in the SHR whereas in the WKY a larger proportion of the neurons were lightly stained. Unlike the SON, the PVN showed a reduced density of NE varicosities over portions of the nucleus and a reduction in the overall size of the PVN. The reduced densities appeared in the form of a pocket within the dense pattern of NE innervation. In the SON the intervent of the provide the son of the nucleus and a the SON, the increased distribution of NE varicosities in the rostral portion of the nucleus mirrors the increased representation of VP-NP cells in this area. This represents either an increase in the number of VP neurons or an increase in the staining intensity which thereby increases the number of cells visualized. In PVN, the observation of NE deficient regions in the SHR corresponds to the reports of decreased norepinephrine content in the PVN of SHRs (Saavedra et al., Circ. Res. norepinephrine content in the PVN OI SHKS (Sadveura et al., Catter et al., 2000) 42:529, 1978). The increased density of VP-NP immunoreactivity in the content of the may reflect an increase in VP SHR requires further analysis. It may reflect an increase in VP biosynthesis and turnover, because it has been reported previously that the VP content of the PVN determined by radioimmunoassay is decreased (Morris and Keeler, Br. Res. 249:173, 1982). Thus, the VP prohormone (Morris and Keeler, Br. Kes. 249:173, 1982). Thus, the VP pronormone complex may be transported away from the nucleus before processing occurs thereby preventing expression of the VP immunoreactivity. Another possibility is that there is a decrease in the number of VP producing cells in the PVN of SHRs resulting in activation of the remaining cells. These possibilities will be addressed in subsequent studies. Supported by NIH grants HL-18172 and NS-15816.

AGE, SEX AND STRAIN DIFFERENCES IN ACTIVITY AND HABITUATION 15917 Advater, J. Gellis, D. Whitehorn and W.C. Low. Dept. Physiol. Biophys., Univ. Vermont, Burlington, VT 05405. D.G. Physici. Biophys., Univ. Vermont, Burlington, VT 05405. Wistar-Kyoto derived spontaneously hypertensive (SHR) and normotensive (WKY) rats, bred at the Univ. of VT, were examined with respect to their spontaneous activity in a novel environ-ment, as well as their habituation to the activity test cage during repeated exposures over a 4 h period. The test cage consisted of a plastic cage equipped with 4 sets of light beams and photodetectors. Spontaneous activity (locomotor as well as tattice we haben of the number of here backs in and photodetectors. Spontaneous activity (locomotor as well as stationary behaviors) was taken as the number of beam breaks in a 15 min period in naive rats. Habituation was determined by re-testing the rat in 3 additional 15 min trials, at 1 h intervals between trials. A total of 197 rats of both sexes were tested at ages 4 to 56 weeks. The effects of sex, age and strain (3-way ANOVA), or of sex and age within each strain (2-way ANOVA), on activity in the first trial were determined using the SPSS computer program. These results showed a strong main effect of age on activity. as well as interactions of age main effect of age on activity, as well as interactions of age with sex and strain, therefore further analyses were done using rats divided into 3 age groups: 0-18, 19-36 and greater than 37 weeks. These analyses confirmed our earlier findings, and those of others, that SHR are more active than WKY rats, at all those of others, that SHR are more active than WKY rats, at all ages and in both sexes. Within each strain, females were more active than males. Across ages, WKY rats were more active in the middle age group than at either the young or older ages, whereas SHR showed 2 peaks in activity scores over a range of 52 weeks. One peak was from 6-15 weeks of age, and the other from 35-52 weeks. Accordingly, strain differences in activity are best detected in young (e.g. 12 weeks) or older (e.g. 40 weeks) rats in these strains. Patterns of habituation to the test cage were determined using ANOVA with repeated measures (trials 2,3,4), expressed as % of trial 1 (computer program BMPP). These analyses revealed marked strain differences in BMDP). These analyses revealed marked strain differences in pattern of habituation. WKY exhibited a marked drop in activity levels across trials, falling to about 20% of trial 1 by the fourth trial, and no differences were observed with age or sex In contrast, SHR habituated poorly, particuin this strain. larly in the older rats where trial 4 activity scores were 95% of trial 1. These findings further characterize the behavioral differences between SHR and WKY rats, and emphasize that although activity levels fluctuate with age in these strains, the patterns of habituation tend to remain fixed over at least one year of time. Supported by MH36064, PHS5429-19-18, HL24110, F32-HL06339 and VT Heart Assoc. Grants-in-Aid to EDH and DW.

159.16 VASOPRESSIN AND RENIN RESPONSE TO PLASMA VOLUME LOSS IN THE SPONTANEOUSLY HYPERTENSIVE RAT (SHR). M.L. Blair, C.D. Sladek and Y.-H. Chen. Dept. Physiol., Neurol. and Anatomy, University of Rochester Medical School, Rochester, NY 14642

Both vasopressin and renin-angiotensin may contribute to the development of hypertension in the SHR. We have evaluated the possibility that stimulation of vasopressin and renin release elicited by blood volume loss might be exaggerated in the SHR in comparison with possibility that stimulation of vasopressin and renin release elicited by blood volume loss might be exaggerated in the SHR in comparison with the normotensive Wistar-Kyoto rat (WKY). Rats were studied during the early stages of hypertension development (6 weeks old) and after hypertension was fully established (18 weeks old). Rats were sacrificed 3 hr. after IP injection of 2 ml/100 gm body weight of 0.9% saline (control group), 20% polyethylene glycol (PEG) or 30% PEG. Trunk blood was collected for radioimmunoassay of serum arginine vasopressin concentration (AVP) and serum renin activity (SRA). The magnitude of plasma volume loss was evaluated from the microhematocrit values (HCT). At 6 weeks of age systolic blood pressure was 129 ± 2 mm Hg in SHR and 87 ± 2 mm Hg in WKY (P<.001). At six weeks of age neither AVP nor HCT was different in the SHR and WKY control groups (SHR: 1.7 ± 0.6 pg/ml, n = 6 samples pooled from 11 rats; hct = 40 ± 1, n = 11). For rats which showed hemoconcentration to HCT ≥ 46 after 20 or 30% PEG injection, both SHR and WKY had AVP values which were significantly greater (p<.005) than those in the control group. However, AVP values in SHR (26.0 ± 10.1 pg/ml, n = 4 samples from 10 rats) were significantly greater (p<.025) than in WKY (6.0 ± 2.0 pg/ml, n = 9 samples from 15 rats).

SRA in control 6 week old rats was not different for SHR (1.2  $\pm$  0.2 ng AI/ml<sup>+</sup>hr, n = 6) and WKY (1.8  $\pm$  0.3 ng AI/ml<sup>+</sup>hr, n = 6). In a separate group of 5 week old rats total kidney renin content and kidney renin concentration were also the same in SHR (31.1  $\pm$  1.8 mg AI/kidney hr; 64  $\pm$  6 ng AI/ mg hr, n = 5) and WKY (31.3  $\pm$  2.1 mg AI/kidney hr, 74  $\pm$  5 ng

 $\pm$  6 ng AI/ mg hr, n = 5) and WKY (31.3  $\pm$  2.1 mg AI/kidney hr, 74  $\pm$  5 ng AI/mg hr, n = 5). SRA increased (p<.001) in both groups following PEG injection and the response was not different for SHR (15.7  $\pm$  1.6 ng AI/m1 hr; n = 5) and WKY (16.5  $\pm$  1.5 ng AI/m1 hr; n = 7) for rats with hemoconcentration to a HCT  $\geq$  46. At 18 weeks, systolic BP was 194  $\pm$  3 mm Hg in SHR and 144  $\pm$  2 mm Hg in WKY (p<.001). AVP in control, 20% PEG and 30% PEG groups was 3.2  $\pm$  0.2 (n = 7), 6.1  $\pm$  2.8 (n = 7), and 13.0  $\pm$  3.2 (n = 5; p<05) pg/m1 for WKY. Neither control nor stimulated AVP values were significantly different for SHR versus WKY. In summary, SHR show an exaggerated AVP response to plasma volume

In summary, SHR show an exaggerated AVP resus wert. In summary, SHR show an exaggerated AVP response to plasma volume loss early in development of hypertension (6 weeks) but not after hypertension is fully developed (18 weeks). In contrast, renin release is not augmented in young SHR. Supported by NIH Grant 1-R01-HL-28172 and RCDA to M.L.B. K01-HL-00966.

159.18 CARDIOVASCULAR AND SYMPATHOADRENAL RESPONSES TO SWIM AND SHOCK CARDIOVASCULAR AND SYMPATHOADRENAL RESPONSES TO SWIM AND SHOCK STRESS IN TRAINED AND UNTRAINED RATS. R. H. Cox, J. W. Hubbard, J. E. Lawler, V. P. Mitchell\* and B. J. Sanders.\* Dept. of Psychology, University of Tennessee, Knoxville, TN. 37916. Swim training in rodents has been shown to result in no

change or a reduction in chronic (resting) blood pressure (BP)--an adaptation quite different than the increase produced by re-peated exposure to tail shock. This study sought to determine if a quantitative difference exists in the acute physiological re-sponse produced by these stressors. A more intense response wight he accessible with a pathological adaptation. might be associated with a pathological adaptation. A second question of the study involved the specificity of the adaptations produced by swim training. Would the attenuation of autonomic and hormonal responses to exercise, characteristic of swim trained animals, be manifested in a different stress situation? Cardioauthorized and hormonal responses to a novel stress, viz, predict-able tail shock (.2-,4mA), were measured in swim trained and control male Long-Evans rats. Swim training, which was 5-7 weeks in duration, 5 days/week for 1 hr/day, utilized two percent of bwt attached to the tails as added resistance. Non trained (NT) bwt attached to the tails as added resistance. Non trained (NI) rats received similar handling but no exercise. The heart rate (HR), systolic (S) and diastolic (D) BP and plasma levels of norepinephrine (NE), epinephrine (E) and corticosterone were measured after 20 min of each stress in rats implanted with aortic catheters. Overall swim and shock elicited similar SBP/ DBP levels in T & NT rats, but T rats showed a lower HR to swim which was evident after the first 4 min.

			Rest	Swim	Shock
Т	(N=11)	SBP/DBP HR	140/95 338±11	167/110 406±11	162/106 433±11
NT	(N=8)	SBP/DBP HR	142/94 348±10	177/116 440±13	159/104 423±10

After 20 min of swim T rats showed lower blood levels of E After 20 min of swim 1 rats showed lower blood levels of E (332 vs 739 pg/ml), corticosterone (62 vs 32 ug/dl) and lactate (.9 vs 2.0 m moles/1) compared to NT rats. However, T & NT rats did not differ during shock on any of the measured parameters. The results support the concept of specificity of training and also suggest that the differences in adaptation produced by chronic exposure to swim and shock can not be attributed to differences in the severity of the stresses. Supported by NIH (HL-06036 & HL-19680).

OLIRASIRUCIURE OF MONOAMINERGIC SYNAPTIC VESICLES IN AN EXPERIMEN TAL MODEL OF ARTERIAL HYPERTENSION. <u>A. Pellegrino de Iraldi, C.</u> Rojas Marcos Pereda and J.P. Corazza. 159.20 H1-HISTAMINE RECEPTOR ANTAGONISTS INDUCE VASOSPASM ON INTACT AND ISOLATED CEREBRAL BLOOD VESSELS: RELATION TO SEDATIVE AND SOPORIFIC EFFECTS OF ANTIHISTAMINES. Bella T. Altura\*, Burton M. Altura and Samuel Lassoff. Dept. of Physiology.

SUNY Downstate Medical Center, Brooklyn, NY 11203 H1-histomine receptor anthistamines (e.g., diphenhydramine-DI, pyrilamine-PY. pyribenzamine-PYR. promethazine-PR, chlorpheniramine-CHL) are known to possess sedative and soporific actions. No satisfactory explanation or mechanism has been presented to explain these sideeffects. We undertook quantitative in-situ and in-vitro studies to determine the direct actions of H1-receptor antihistamines on pial terminal arterioles (PTA) and muscular venules (PMV) in the young intact rat, using quantitative high-resolution television microscopy, and on isolated canine basilar (BA) and middle cerebral arteries (MCA). Perivascular application of the H1-receptor antihistamines produced concentration-dependent constriction of PTA but not PMV; the relative order of sensitivity was: CHL  $\rightarrow$  PY  $\rightarrow$  PYR  $\cong$  PR  $\rightarrow$  DI. Dases of H<sub>1</sub>- receptor blockers from 10<sup>-6</sup> to 10-1mg reduced diameters from 5-35%. Addition of these H1-receptor antihistamines to isolated canine BA and MCA suspended in Krebs-Ringer bicarbonate solution, in concentrations of from  $10^{-7}$  to  $10^{-4} M_{\odot}$ produced dose-dependent degrees of cerebrovasospasm; maximum contractile tensions were 60-95% of maximum KCl-induced contractions. No known pharmacologic amine antagonist or opiate-receptor blocker attenuated, abrogated, or prevented the micro- or macro-vascular spasms induced by these antihistaminic drugs. In view of these new findings w conclude that: 1) H1-receptor antihistamines seem to produce cerebro-vasospasm by a direct action on cerebral vascular smooth muscle cells; and 2) the potent vasoconstriction of cerebral arterioles and arteries produced by H1-histamine receptor blockers might produce cerebral hypoxia which in turn could produce sedative and/or soporific qualities. (Supported by Research Grant HL-29600 from the USPHS.)

## CARDIOVASCULAR REGULATION: CENTRAL TRANSMITTERS I

IDENTIFICATION OF SUBSTANCE P AND CHOLECYSTOKININ IN RENAL AFFER-ENT PATHWAYS IN THE CAT. J.J.Oravitz\*, D.C.Kuo, M.G.Backes\* and W.C.deGroat, (SPON: O. Reinmuth) Department of Pharmacology, Medical School, University of Pittsburgh, Pittsburgh, PA 15261 Recent horseradish peroxidase tracing experiments in the cat identified the segmental distribution and central projections of afferent neurons innervating the kidney. In the present ex-periments we have used fluorescent dye tracing combined with immunohistochemistry to study the distribution of neuropeptides in the renal afferent pathways. The central end of the transected left renal nerve in anesthe-tized cats was exposed for one hour to true blue, a fluorescent dye. Following a transport time of 1-2 weeks colchicine was applied locally or injected into the ipsilateral upper lumbar dorsal root ganglia. After 24-48 hours the animals were perfused with saline and 4% paraformaldehyde fixative. The thoracolumbar dorsal root ganglia and sympathetic chain ganglia along with the coeliac-superior mesenteric ganglion complex were removed, sec-160.1

coeliac-superior mesenteric ganglion complex were removed, sec-tioned in a cryostat, examined for dye labelled cells and then processed by indirect immunofluorescence methods for substance P, cholecystokinin, somatostatin, and vasoactive intestinal polypeptide (VIP).

The segmental distribution of dye-labelled renal afferent and sympathetic postganglionic neurons matched the distribution of these neurons identified in previous experiments by HRP-tracing techniques. Labelled cells were present in ipsilateral sympathetic chain ganglia and dorsal root ganglia from  $T_{12}$  to  $L_4$  and in the superior mesenteric ganglion. Dye labelled dorsal root ganglion cells exhibited substance P and cholecystokinin immunoreactivity, but did not contain somatostatin or VIP. Substance P, which in comparison to cholecystokinin was present in a larger number of the lower thoracic and lumbar dorsal root ganglion cells, was also identified in a larger proportion (approximately 30%) of dye labelled renal afferent neurons. In summary, the present results suggest that both substance P and cholecystokinin may be neurotransmitters in afferent pathways from the kidney. Supported by the Western Pennsylvania Affiliate of the American Heart Association. The segmental distribution of dye-labelled renal afferent and

160.2 ROLE OF SPINAL OPIATE RECEPTORS ON THE AFFERENT COMPONENT OF THE SOMATOAUTONOMIC REFLEXES IN THE EXERCISING DOC. <u>G. Pomeroy\*</u>, <u>J. F. Ardell\* and R. D. Wurster</u> (SPON: T. Khan). Department of Physiology, Loyola University Medical Center, Maywood, IL 60153.

Muscle afferents mediate, in part, the blood pressure and heart rate changes associated with exercise. Spinal cord opiate recep-tors have been located in the dorsal horn of the spinal cord and have been implicated in modulating ascending afferent activity. We hypothesize that these opiate receptors modulate muscle afferent activity mediating the cardiovascular responses to muscle exercise.

To test this hypothesis, dogs were trained to run on a tread-To test this hypothesis, dogs were trained to run on a tread-mill on their hind legs for five minutes each at 2, 4, and 6 Km/h (10% grade), successively. Simultaneously, heart rate and blood pressure responses to non-ischemic and ischemic exercise follow-ing lumbosacral intrathecal (IT) administration of either saline, morphine, or naloxone plus morphine were recorded. Under pento barbital anesthesia to chronically instrument the dogs, skin tubes were made around the carotid arteries. This allowed for the recording of carotid arterial blood pressure by pericutaneous insertion of a needle connected to a pressure transducer and oscillograph. To produce unilateral muscle ischemia, a pneumatic occluder was placed around the iliac artery. The occlusion response was tested for 90 s at each exercise level. A silicon

response was tested for 90 s at each exercise level. A silicon rubber catheter was placed in the lumbosacral IT space via a partial laminectomy at the T12 vertebral level. Several days after recovery from instrumentation, IT adminis-tration of 0.5 ml of saline or the drugs dissolved in saline were made with at least three days between testing intervals. Exercise was initiated 10 minutes after IT injection. Elood pressure usually increased with the increment of treadmill speed. Blood pressure increased further with the 90 s occlusion and returned to preocclusion levels before the treadmill speed was returned to preocclusion levels before the treadmill speed was incremented. In a dose-dependent manner, morphine (0.1 to 1 mg, Incremented. In a dose-dependent manner, morphine (0.1 to 1 mg, IT) lowered the non-occlusion blood pressure as well as the in-crement due to muscle ischemia when compared to control IT saline injection responses. Naloxone (0.4 mg, IT) administration in-creased the blood pressure before and during ischemic exercise. The decreased responses following morphine (1 mg, IT) were blocked by prior administration of naloxone (0.4 mg, IT). The heart rate responses were much more variable although they, in general, showed the same trends.

Summary: Spinal cord opiate receptors modulate ascending afferent activity involved in cardiovascular responses to exercise suggesting a possible enkephalinergic modulation of these autonomic reflexes. (Supported by NIH Grant HL27612)

CARDIOVASCULAR REGULATION: CENTRAL TRANSMITTERS I

RESPONSE OF CENTRAL SYMPATHETIC NEURONS TO SUBSTANCE P AND ELEDDISIN RELATED PEPTIDE. Leslie P. Felpel and Ronald D. Huffman, Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284 The intermediolateral (IML) cell column receives input from numerous brainstem areas and contains a number of putative neuro-transmitters, including monoamines and substance P (SP). Descend-ing SP projections from the ventral medulla to the IML have been demonstrated in the rat (Helke et al., 1982). Because the ventral medulla may play a role in the regulation of sympathetic control of the vasculature, and SP has depolarizing action on many central neurons, we have investigated the effect of SP and eledoisin related peptide (ERP), a substance P analog, on central sympathe-tic neurons in the thoracic spinal cord. Adult female cats were anesthetized with an i.p. injection of a solution of alpha chloralose (40 mg/kg) and urethane (800 mg/kg) and all surgical procedures performed. Single IML units were recorded extracellu-larly at the seventh or eighth thoracic (T/-T8) level of the spinal cord with multiple barrel micropipettes and were identispinal cord with multiple barrel micropipettes and were identi-

Spinal cord with multiple barrel micropipetes and were identi-fied by their orthodromic response to splanchnic nerve stimula-tion. Drug containing barrels were filled with solutions of monoamines as well as SP (1 mM in 0.1M NaCl) and ERP (1-5 mM in 0.1M NaCl). Localization of units was histologically verified by placing a dye mark at the recording site through the recording barrel (2M NaCl and Fast Green). Of the twelve spontaneous or d,1-homocysteic acid-evoked IML neurons, SP and ERP excited three (25%), inhibited five (42%) and had no effect on the remaining four (33%) neurons. Excitation by both SP and ERP was slow in onset (11-74 seconds), and the dura-tion (and sometimes peak) of the excitatory effect usually extended beyond the termination of the iontophoretic application of either drug. Such an effect is in agreement with neuropharma-cological studies on other spinal (Henry et al., 1975) and central neurons (Krnjevic and Morris, 1974; Phillis and Limacher, 1974). Relatively high doses (80 nA or greater) of SP and ERP were generally required to evoke either excitation or inhibition, and the two substances were approximately equipotent. While our data generally required to evoke either excitation or inhibition, and the two substances were approximately equipotent. While our data support a possible role of SP in the regulation of blood pressure, they would suggest that SP acts more in the capacity of a modulator than as a rapid-acting and direct neurotransmitter at lower thoracic central sympathetic neurons. CATECHOLAMINES AND NEUROPEPTIDES IN THE VAGAL MOTOR 160.4

CATECHOLAMINES AND NEUROPEPTIDES IN THE VAGAL MOTOR NUCLEI: EVIDENCE FOR TOPOGRAPHICALLY ORGANIZED SUBPOPULATIONS OF CHEMICALLY SPECIFIED PREGANGLIONIC NEURONS. <u>P.E. sawchenko</u>, The Salk Institute, La Jolla, CA 92037. A combined retrograde transport-immunofluorescence method was used to identify neuroactive substances that may be contained within vagal preganglionic neurons. Fifty-100 nl of a 5% suspension of a retrograde tracer, True blue, was injected beneath the sheath of the cervical vagi, bilaterally, in adult male rats. After 3-5 days the animals were sarcificed and series of sections through the medulla were were sacrificed, and series of sections through the medulla were counterstained using antisera against the catecholamine-synthesizing enzymes tyrosine hydroxylase (TH), dopamine-B-hydroxylase (DBH) or any one of a number of neuropeptides. To enhance the staining of peptidergic perikarya, some animals were pretreated at 1, 2, or 3 days prior to sacrifice with 50 µg colchicine (icv). In non-pretreated rats, small to moderate numbers of retrogradely-

labeled neurons at the rostral and caudal poles of the dorsal motor nucleus (DMX) were found reliably to stain positively for the presence of TH or DBH, suggesting the existence of norepinephrine- (or epinephrine-) containing vagal motor neurons at these loci. Near the midextent of the DMX a prominent cluster of cells could be doubly labeled with anti-TH, but not with anti-DBH, indicating that dopaminergic preganglionic neurons occupy this region. In animals pretreated for 2-3 dops with colchicine small numbers of True blue labeled neurons in the DMX could also be shown to contain any one of several neuropeptides including neurotensin, leu-enkepholin, somatostatin, and substance P; each such subsource that does not be a substance P; each such subpopulation displayed a distinctive topography. Retrogradely labeled neurons in and around the nucleus ambiguus (NA) could be doubly labeled (in pretreated rats) only with antisera against neurotension or calcitonin gene related peptide (see <u>Nature</u>, <u>298</u>;240, 1982). In each case, however, large subpopulations of neurons in the rostral half of NA were involved. Because of questions pertaining to the validity of localizations seen in colchicine pretreated animals, a unilateral ligation of the cervical vagus was performed in 6 otherwise normal animals, which were then perfused after 1, 3, or 5 days. At 5 days post-ligation, cells in the ipsilateral vagal motor nuclei could be stained for each of the neuropeptides (except substance P) mentioned above, and displayed a distribution similar to that seen after colchicine treatment.

These results indicate that vagal motor neurons contain neuroactive substances other than, or in addition to, acetylcholine, and suggest that specificity of function in these cell groups may be chemically, as well as

topographically, encoded. Supported by the American Heart Association-California Affiliate and the Clayton Foundation for Research-California Division. I thank A. Berod, N. Brown, K. Helle, and W. Vale for generous supplies of antisera.

AN IN VITRO INVESTIGATION OF SYNAPTIC TRANSMISSION IN THE MEDIAL NUCLEUS OF THE SOLITARY TRACT. D.L. Kunze and R. Miles\* Department of Physiology and Biophysics, University of Texas Medical 160.5 Branch, Galveston, TX 77550. On entering the medulla baroreceptor afferent fibres travel

in the solitary tract and terminate to a large extent on neurones located medial to the tract. It has been suggested that significant neuronal processing including the depression of reflex effects at high stimulation frequencies (Seller and Illert, Pflug, Arch., 306: 1, 1969) may occur here. We have developed two in vitro techniques to investigate synaptic transmission in this area.

Longitudinal quinea pig medullary slices of thickness 400 µm were prepared so that the solitary tract could be stimulated while intracellular recordings were made from neurones medial to if at levels close to the obex. Cells were matching methods methods by a prominent after hyperpolarization. On stimulating the tract an epsp was evoked in all neurones tested. Often several epsp's with different latencies were apparent while in a few cases an ipsp followed the initial epsp. The amplitude of the synaptic potential was progressively depressed as the frequency of stimulation was increased above 5 Hz.

In order to examine pure postsynaptic responses to putative neurotransmitters single neurones from the area medial to the neurotransmitters single neurones from the area medial to the solitary tract were enzymatically dispersed using the technique of Numann et al (Soc. Neurosci.,  $\frac{8}{5}$ : 413, 1982). The cells obtained after 2 hrs. exposure to  $\frac{5}{5}$  papain in physiological saline and mechanical dispersion possessed a morphology similar to that of Golgi stained neurones from this area. Recordings were made with 0.150 M KCl filled electrodes of resistance 2-10 MΩ using the suction pipette technique. In voltage lamp we tested neuronal responses to pressure ejection of 10 M L-glutamate which it has been suggested may be the transmitter released by afferent fibres. A conductance increase associated with a current which was inward at negative potentials and which with a current which was inward at negative potentials and which reversed at approximately 0 mV was most commonly observed. In a proportion of cells this was followed by an outward current also associated with a conductance increase. Investigations are currently underway to determine whether postsynaptic factors such as these or presynaptic mechanisms underly high frequency depression at this synapse. (Supported by American Heart Association - Texas Affiliate and NSF PCM7823216).

160.6 INVOLVEMENT OF CENTRAL α-PRESSOR AND β-DEPRESSOR ADRENOCEPTORS IN THE CARIOVASCULAR RESPONSES TO INTRACEREBROVENTICULAR ADMINISTRATION OF CATECHOLAMINES IN THE RAT. F.M.A. Corrêa and V.L. Peres-Polon\*. Dept. Pharmacology, Sch. of Medicine and Dept. Physiology, Sch. of Pharmacy and Dentistry of Ribeirão Preto, Univ. Sao Paulo. 14100, SP, Brazil.

The effect of the intracerebroventricular administration of catecholamines on the arterial blood pressure of anesthetized and awaken rats and its modification by pharmacological antagonists were studied.

One hundred seven animals were used in acute experiments. The rat were anaesthetized with urethane and intraventricular guide cannulas ware implanted according to Corrêa, F.M.A. and Graeff, F.G. (<u>Neuropharmac. 13</u>: 65-74, 1974). Arterial blood pressure was recorded by means of a PE-50 polyethylene catheter introduced into the right carotid. A group of fifty three rats was prepared for chronic blood pressure recording under unanesthetized conditions. Intraventricular cannulas were implanted under sodium pentobarbital anaesthesia. Three days later the animals were anaesthetized with ether and a chronic polyethylene cannula implanted into the femoral artery, according to Krieger, E.M. (<u>circ. Res. 15</u>: 511-521, 1964). Blood pressure recording was undertaken six days after the initial surgery. Intracerebroventricular injection of isoprenaline (1-20  $\mu$ g) and

normetanephrine (20-100  $\nu g)$  produced, respectively, depressor and pressor responses in both anesthetized and unanesthetized animals. priorebrine (1-20  $\mu g$ ) produced predominantly depressor effects of greater intensity in anesthetized than in awaken animals, while norepinephrine (1-20  $\mu g$ ) caused depressor responses in anaesthetized animals and a predominant pressor response in the awaken rat. Intracerebroventricular pretreatment with proprano lol (40-200 µg) markedly potentiated pressor responses to nor epinephrine and epinephrine and only partially blocked the depressor response to isoprenaline.  $\alpha$ -blocking agents such as phenoxybenzamine and phentolamine potentiated depressor responses to epinephrine and isoprenaline and reduced pressor responses to to epinephrine. The involvement of central  $\alpha$ -pressor responses to norepinephrine. The involvement of central  $\alpha$ -pressor and  $\beta$ -depressor adrenoceptors, in the blood pressure responses to the intracerebroventricular administration of catecholamines, is proposed. Otherwise is also evidenced the involvement of a progranolol-insensitive mechanism in the depressor response to the intracerebroventricular injection of isoprenaline in the rat.

160.3

CENTRAL NERVOUS SYSTEM ACTIONS OF BOMBESIN ON CARDIOVASCULAR 160 7 REGULATION IN THE RAT. Laurel A. Fisher and Marvin R. Brown. Peptide Biology Laboratory. The Salk Institute, La Jolla. CA 92037.

The tetradecapeptide bombesin (BOM) acts within the central nervous system (CNS) to elevate plasma levels of catecholamines, glucagon and glucose and to inhibit regulatory heat production. The hyperglycemic effects of BOM are tory near production. The hyperglycemic effects of bow are secondary to stimulation of adrenal epinephrine secretion, whereas the thermoregulatory effects of BOM are independent The following studies indicate that BOM also acts in the CNS to modulate vagal outflow. The CNS actions of BOM to stimulate adrenomedullary sympathetic outflow and vagal activity underlie separate effects on blood pressure and heart rate.

All experiments utilized conscious, freely-moving rats instrumented with lateral cerebroventricular cannulae, and jugular venous and femoral arterial cathetars. Intracerebroventricular (icv) administration of BOM (17.1 pmoles-5.7 nmoles) produced dose-related elevations of mean arterial pressure (MAP). Maximal increases in MAP averaged 15 mm Hg and the duration of the hypertensive effect increased with dose of BOM. Heart rate (HR) decreased dramatically (50-130 beats/min) following icv injection of BOM. Reductions of HR occurred by 5-20 min post injection and remained significant for at least two hours post injection and remained significant for at least two hours post injection, BOM-induced bradycar-dia was not secondary to increased MAP as acute adrenal-ectomy blocked BOM-induced elevations of MAP but failed to prevent BOM-induced decreases of HR. The cardiovascular effects of icv BOM administration were not altered by intraeffects of 100 box auministration were not altered by intra-venous (iv) injections of [1-deaminopentillamine, 2-(0-methyl)tyrosine]-AVP (50  $\mu$ g), a selective antagonist of the pressor actions of vasopressin. Methyl atropine (1 mg/kg, iv; injected 5 min prior to and 30 min following BOM) antagonized BOM-induced bradycardia but did not modify BOMinduced increases in MAP. The cardiovascular effects of BOM were not due to leakage of the peptide into the peripheral circulation as iv administration of a wide range of doses of

circulation as iv administration of a wide range of doses of BOM (570 pmoles - 57 nmoles) elicited transient pressor effects (lasting 1-5 min) and slight tachycardia. Taken together, these results indicate that BOM acts in the CNS to stimulate vagal outflow to heart resulting in bradycardia, whereas the effects of BOM on MAP appear to be secondary to adrenal epinephrine secretion. Recent experi-ments demonstrate that icv administration of BOM suppresses cold judged tachycardia suggesting that BOM may inbihit cold-induced tachycardia, suggesting that BOM may inhibit regulatory heat production by its effects on cardiac output.

ELECTROPHYSIOLOGICAL PROPERTIES OF SPINALLY-PROJECTING A5 NOR-160.9 ADRENERGIC (NE) NEURONS IN THE RAT. <u>Christopher E. Byrum\* and</u> Patrice G. Guyenet. University of Virginia, School of Medicine, Department of Pharmacology, Charlottesville, Virginia 22908. A5 neurons projecting to the thoracic spinal cord (SC) were mapped using the sequential Faglu-HRP technique of Furness et al. (Histochem. J.  $\underline{9}$ , 745). An "A5 area" was arbitrarily defined in coronal sections as a 760 x 420 µm area of ventrolateral pons centered on the densest accumulation of NE cells. This area contained 74% of all NE cells commonly included in the A5 group (total of 870 ± 111 cells/rat). Large HRP injections in SC resulted in the labelling of up to 93% of NE-fluorescent cells in the "A5 area"; these represented 80% of all HRP + cells (N=4). Prior icv injections of 6-OHDA (2 x 200  $\mu$ g, N=3) resulted in a 47% reduction in the number of A5 NE neurons and in the total loss of NE + HRP + cells; by contrast the number of NE - HRP + cells in the "A5 area" remained virtually unchanged. Single unit recordings were made in the "A5-area" in urethane-

anesthetized, paralyzed and respirated rats. The study was restricted to cells antidromically (AD) activated from thoracic SC. The vast majority of the cells encountered in the A5 area (N=45) apparently belonged to the same type (conduction velocity ca. 2-3 m/sec; slow regular discharge rate correlated neither with cardiac nor respiratory rates; total inhibition by i.v. clonidine, partial inhibition by i.v. desmethylimipramine, activation by i.v.  $\alpha 2$  antagonists). These neurons (N=18) were inhibited by increases in mean blood pressure (mBP) beyond 110-120 mm Hg and generally silenced by mBP increases into the 150-180 mm Hg range. Identical results were obtained with NE, Angiotensin II, or Arg-Vasopressin as pressor agents. The cells were unaffected by lowering mBP 25-45 mm Hg below normal resting levels (typically 60-100) with a

As man ng below hormal resting levels (typically 00-100) with a vasodilator (SCN<sup>-1</sup>) or a ganglionic blocker (trimethaphan). The second type of AD-activated cell found in the "A5 area" consisted of a few (N=4) fast conducting units (10-15 m/sec) with a regular high discharge rate which was unaffected by either clonidine or mBP elevation up to 180 mm Hg. Finally the "A5 area" contained numerous other types of units not AD-activated from SC and therefore not characterized in this estudy.

and therefore not characterized in this study. In agreement with a previous study by Andrade and Aghajanian, (Brain Res. <u>202</u>, 125) it is concluded that the slow-firing, clonidine-sensitivg units most commonly found in the "A5 area" represent somatic dendritic action potentials generated by the NF, neurons. NF neurons. These cells are subject to feedback inhibition by BP which suggest that they may normally contribute to centrally mediated pressor responses. HL 28785

EVIDENCE FOR TWO DISTINCT SYMPATHOINHIBITORY BULBO-SPINAL 160.8

SYSTEMS: <u>P.J. Bernthal\* and M.C. Koss</u>. Dept. of Pharmacology, Univ. of Oklahoma, College of Medicine, Okla. City, Okla. 73190. Yohimbine hydrochloride (0.5 mg/kg, i.v.) caused a long lasting potentiation of electrodermal (sympathetic-cholinergic) reflexes in intact anesthetized and decerebrate non-anesthetized cats. Transection of the cervical spinal cord also resulted in increased sudomotor reflex amplitude in non-anesthetized Increased submotor reliev amplitude in non-anestnelized decerebrate preparations. Depletion of CNS monoamines by pretreatment with reservine (5 mg/kg, i.p.) and  $\alpha$ -methyl-p-tyrosine (2 x 300 mg/kg, i.p.) reduced the concentrations of norepinephrine, dopamine and servotonin to less than 93% of control levels in the thoracic spinal cord. In monoamine depleted preparations, yohimbine no longer facilitated reflex amplitude whereas the effect of spinal transection was not altered. These results suggest that there are two distinct sympathoinhibitory systems in the lower brain stem that converge on spinal sympathetic neurons, one of which is monoaminergic and one of which is not. Evidence for the baroreceptor independent nature of these descending inhibitory systems will also be presented.

The figure illustrates the effect of yohimbine (Y) hydrochloride (0.5 mg/kg, i.v.) and/or cervical spinal cord transection (S.T.) on electrodermal reflex amplitude in depleted or non-depleted non-anesthetized decerebrate cats. The first two groups demonstrate the mean increase (+ S.E.M.) in EDR amplitude following yohimbine administration (N=5) or cervical cord transection (N=13) in non-depleted cats. The third group shows the lack

of effect of yohimbine (N=5) on the EDR following catecholamine depletion and the facilitation that occurs in the same preparations subjected to subsequent cervical cord transection. Measurements are of the maximal effect observed in the first 5-10 min after the procedure. 160.10 EFFECT OF BLOOD PRESSURE AND CLONIDINE ON THE ACTIVITY OF A2 NORADRENERGIC NEURONS. <u>Scott D. Moore\* & Patrice G. Guyenet</u> (SPON: J.A. Wilson) Dept. of Pharmacology, Univ. of Virginia School of Medicine, Charlottesville, VA 22908 We have previously established that the hypotensive agent

clonidine administered systemically to rats in doses of 5 to 40  $\mu$ g/kg inhibits the discharges of A2 noradrenergic neurons. The present series of experiments were undertaken to investigate the hypothesis that cloudine inhibits A2 neurons by a direct action on the NTS. In addition the effect of pharmacological manipulations of blood pressure (BP) on the firing of A2 neurons was determined.

Single unit recordings were obtained in chloral-hydrate anesthetized rats. A2 neurons located in nuc. commissuralis were identified by antidromic activation from the median forebrain bundle as previously described (Moore & Guyenet, <u>Brain Res.</u>, <u>263</u>: 211). Iontophoretic electrodes were used for the application of neurotransmitters and drugs. All the A2 neurons sampled (n=26) were inhibited by epinephrine (EPI) or by the  $\alpha 2$  agonist clonidine (CLO). This inhibition was antagonized by the  $\alpha 2$ antagonist piperoxane (PIP) (n=12). PIP alone occasionally excited the neurons and in one case activated a silent cell. The  $\beta$ antagonist sotalol had no effect by itself and did not block the inhibition produced by EPI (n=4). In addition, A2 neurons were inhibited and excited by GABA and glutamate, respectively, but were unresponsive to serotonin.

Increases in BP were elicited by intravenous administration of Increases in BP were elected by intravenous administration of norepinephrine (10-25  $\mu g/kg$ ) or Arg-vasopressin (2-6  $\mu g/kg$ ). In-creases in mean BP to between 120 and 150 mm Hg decreased spon-taneous activity in 7 out of 9 A2 neurons. Increases in mean BP to between 150 and 180 mm Hg decreased activity in 5 out of 5 neurons and silenced 3 cells. By contrast, a control sample of six unidentified units (3 in nuc. gracilis and 3 in nuc. commis-suralis) were unaffected by elevations in mean BP in the 120-150 mm Hg range.

These experiments suggest that A2 neurons receive an inhibitory input from peripheral baroreceptors. Since these cells directly project onto the hypothalamic paraventricular nucleus, the present data suggest that BP feeds back on vasopressin-releasing cells via A2 neurons and that by inhibiting A2 cells clonidine may enhance the gain of this feedback. 160.11 A GABAERGIC MECHANISM AT THE VENTRAL MEDULLA: DIFFUSION STUDIES USING <sup>3</sup>H-BICUCULLINE METHYLCHLORIDE. <u>K.A. Yamada & A.D. Loevy</u>. Dept. of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

We have previously reported blockade of the baroreceptor reflex, in cats, by topical application of bicuculline on the ventral medullary surface (Fed. Proc. 42:1121, 1983). This effect was specific for GABAergic antagonist drugs, and was dose-dependent and reversible at lower doses. It is not known, however, exactly what anatomical substrate mediates this and other evoked responses elicited by topical drug application. Electron micrographic studies of the ventral surface (Dermietzel, R. In: H.H. Loeschcke (ed.), <u>Acid-Base Homeostasis</u> of the Brain Extracellular Fluid and the <u>Respiratory Control</u> <u>System</u>, George Thieme, Stuttgart, 1976, pp. 52-65) have revealed an extensive pore and vascular system by which drugs could easily diffuse dorsally to a site of action deeper than the suggested superficial site at the ventral surface. In order to determine what possible structures had been reached by blcuculline to cause blockade of the baroreceptor reflex, we followed the diffusion of <sup>3</sup>H-bicuculline methylchloride (BMC) in chloralose-anesthetized cats. 120-940 nCi of <sup>3</sup>H-BMC was topically applied to the intermediate area of the ventral surface via cottonoid pledges. After 6.5-11 min of drug exposure, the pledgets were removed and the brainstem was blotted, dissected out, and frozen in freon on dry ice. 20 µm horizontal sections were cut from each of three 7-mm thick brainstem pieces in a cryostat at -20°C, weighed, solubilized, and scintillation counted. 4-6% of the radiolabel applied was recovered in the surface, to no detectable <sup>3</sup>H-BMC 3.5-3.7 mm below the surface. In other experiments, 20 µm coronal sections were cut at -20°C, dried, fixed, and exposed to <sup>3</sup>H-BMC diminishing dorsally from the highest concentration (HC=2.15-2.33 nCi/mg tissue) found at the ventral surface, to 50% of HC 0.5-0.9 mm below the surface, to 10% of KC 1.8-2.5 mm below the surface, to no detectable <sup>3</sup>H-BMC 3.5-3.7 mm below the surface. In other series, However, it is still not known whether the concentrations reaching

160.14 EFFECTS OF L-TRYPTOPHAN ON BLOOD PRESSURE: ROLE OF SEROTONIN. <u>W.A. Wolf and Donald M. Kuhn</u> (SPON: M. Billingsley). Sect. Biochem. Pharmacol., NHLBI, NIH, Bethesda, MD 20205. Studies were performed to elucidate the role of serotonin (5-

Studies were performed to elucidate the role of serotonin (5-HT) in mediating the cardiovascular effects of systemically administered L-tryptophan, the amino acid precursor for 5-HT. Various doses of L-tryptophan were administered intraperitoneally in spontaneously hypertensive rats (SHR) and normotensive Wistar-Kyoto rats (KKY). Systolic blood pressure measurements were obtained at various time points in conscious rats using the indirect tail cuff method with photoelectric sensing of pressure pulses. In the SHR, low doses of Ltryptophan (25-50 mg/kg) raised blood pressure by 20 mm Hg while the highest dose tested, 100 mg/kg, significantly lowered blood pressure. In the WKY, only hypertensive effects were seen at all doses (25-100 mg/kg). Concomitant analysis of tryptophan, 5-HT and 5-hydroxyindoleacetic acid (5-HIAA) levels by HPLC in specific brain regions implicated in cardiovascular regulation (hypothalamus, dorsal raphe, nucleus tractus solitarius, medulla) suggested that the hypertensive effects, seen most prominently in the WKY, is mediated by increases in brain 5-HT while the hypotensive effect s for an equimolar dose of the dextrorotary isomer of tryptophan were compared to L-tryptophan in the SHR at a dose and time when the hypotensive effect of Ltryptophan is maximal. While D-tryptophan elevates brain 5-HT and 5-HIAA levels to the same extent as L-tryptophan, no hypotensive action was observed after 100 mg/kg of Dtryptophan. The significance of these results with respect to brain 5-HT and blood pressure regulation and possible alternative mechanisms for the antihypertensive action of Ltryptophan will be discussed. 160.12 ENDOGENOUS GABAERGIC MECHANISMS IN THE VENTROLATERAL MEDULLA AND THE REGULATION OF BLOOD PRESSURE. <u>R.N. Willette, P.P. Barcas</u>, <u>A.J. Krieger</u>, and <u>H.N. Sapru</u>. Department of Neurological Surgery and Department of Pharmacology, UMDNJ-New Jersey Medical School, Newark, NJ 07103.

The ventrolateral medulla contains a caudal group of vasodepressor neurons (VLDA) and a rostral group of vasopressor neurons (VLPA). GABA receptor stimulation in the VLDA (Al area) and VLPA (Cl area) cause neurogenic hypertension and hypotension, respectively. In the present study, the GABA receptor antagonist, bicuculline methiodide, was used to determine if GABAergic mechanisms were tonically active in both sites.

nisms were tonically active in both sites. In urethane anesthetized rats vasodepressor and vasopressor neuron pools were functionally identified by microinjecting (100 nl) of the neuroexcitatory amino acid, L-glutamate (300ng/site). The bilateral microinjection of bicuculline into the VLDA caused a dose-related (0.1-100.0ng/site) decrease in blood pressure, pulse pressure, and heart rate. Maximum decreases in blood pressure and heart rate were -  $51^{\pm}2$  mmHg and -  $245^{\pm}9$ bpm, respectively. Pretreatment with the alpha adrenergic receptor antagonist, phentolamine (3mg/kg, i.v.), completely blocked the bicuculline microinjections in the VLPA also caused a 61% reduction in the fall in blood pressure evoked by stimulation of the aortic depressor nerve ( $2v_25Hz_3mscc$ ) and a 40% increase in the blood pressure response elicited by bilateral carotid occlusion. These results suggest that GABAergic mechanisms in both the caudal and rostral ventrolateral medulla are tonically involved with the maintenance and reflex regulation of blood pressure. This medullary GABAergic system may provide a reciprocal inhibition between the rostral vasopressor and caudal vasodepressor

160.15 ATTENUATION OF SALT-INDUCED HYPERTENSION IN THE DAHL RAT MODEL OF HUMAN ESSENTIAL HYPERTENSION BY CHRONIC CHOLINERGIC BLOCKADE. James A. McCaughran, Jr. and Richard Friedman \*, Department of Psychiatry and Behavioral Science, SUNY @ Stony Brook, Stony Brook, NY 11794. Recent studies from this laboratory suggest that enhanced

Recent studies from this laboratory suggest that enhanced central cholinergic neurotransmission in the Dahl salt-sensitive rat (DS rat) is an important contributing factor to the pathogenesis of hypertension. Therefore, the present experiment was done in order to determine the effect of chronic cholinergic blockade with atropine on either the development or maintenance of salt-induced hypertension in DS rats.

To investigate the effect of cholinergic blockade on the development of salt-induced hypertension, DS and DR rats were maintained on a high salt diet (8.0% NaCl w/w) and treated with atropine sulfate for 4 weeks via indwelling miniosmotic pumps. To examine the influence that atropine might also exert on rats with established hypertension, DS and DR rats were first maintained on a high salt diet for 3 weeks. Atropine, at the same dose as above, was then chronically infused over a 4 week period.

DS rats treated with atropine displayed a mean systolic BP that was significantly lower than DS rats treated with the vehicle (156 vs 200 mmHg). BP in DS rats that received atropine also failed to increase over a 9 week period following the termination of the treatment. As a result, 8 of 10 drug-treated rats survived 13 weeks on the high salt diet whereas by week 6 of the diet all control rats had died. DS rats maintained on a high salt diet for 3 weeks prior to atropine treatment developed BPs of 160 mmHg. During the 4 weeks of atropine administration, BP in the experimental group rose to 185 mmHg while BP in the control group rose to 247 mmHg. By the sixth week on the diet, all control rats had died. In contrast, 8 of 10 experimental rats survived to the ninth week and 2 of 10 to the thirteenth week of the diet. BP in DR rats was not affected by the administration of atropine.

The results of the present study clearily suggest that the cholinergic system in the DS rat is in part responsible for the development and maintenance of salt-induced hypertension. Previous studies from this laboratory have found that DS rats have a significantly greater density of cholinergic receptor sites and higher choline acetyltransferase and acetylcholinesterase activity in the forebrain and brainstem. Furthermore, normotensive DS rats display a greater pressor response to physostigmine than normotensive DR rats. Therefore, the present effects on BP likely reflect interference with a central cholinergic mechanism.

GABA INHIBITION OF CENTRAL SODIUM-INDUCED AVP-DEPENDENT PRESSOR 160.16

GABA INHIBILION OF CENTRAL SUDIOM-INDUCED AVY-DEPENDENT PRESSOR MECHANISMS. Timothy J. Brennan\* and J.R. Haywood. Dept. of Pharmacology, UTHSCSA, San Antonio, TX 78284. We have previously demonstrated that intraventricular (IVT) gamma-aminobutyric acid (GABA) inhibits the pressor effect of artificial cerobrospinal fluid made hypertonic by the addition of codium (N.) The present cludice rung undertaken to investigate sodium (Na). The present studies were undertaken to investigate the mechanism of the hypertonic CSF pressor effect and determine its sensitivity to GABA.

In conscious rats, IVT administration of 0.64, 1.07, and 1.92 microequivalents ( $\mu$ Eq) of Na increased mean arterial pressure (MAP) 8±1, 13±1, and 19±1 mmHg, respectively. IVT injection of artificial CSF (0.42  $\mu$ Eq of Na) did not change MAP. Autonomic blockade with chlorisondamine augmented the pressor effect of Na artificial csr (0.42 µcd 01 kg) dia hol change war. Autonomic blockade with chlorisondamine augmented the pressor effect of Na so that 0.64, 1.07, and 1.92 µEq of Na increased MAP 13:3, 24:3, and 42:7 mmHg, respectively. After ganglionic blockade, pre-treatment with 100 µg of GABA reduced the pressor effect of hypertonic CSF to 7±2, 11:2, and 18:4 mmHg. In addition, follow-ing chlorisondamine pretreatment, the pressor effect of 1.92 µEq of Na was reduced from 41:5 to 8:1 mmHg by d(CH<sub>2</sub>)sTyr(Me)AVP, a vascular antagonist of arginine-vasopressin (AVP). In another series of experiments, rats were pretreated with d(CH<sub>2</sub>)sTyr(Me)AVP. The pressor effect of 0.42, 1.07, and 1.92 µEq of Na was educed approximately 50% of control to 2±1, 8±1, and 11:1 mmHg, respectively. Similarly, hypophysectomy reduced these hypertonic CSF pressor responses to 1±1, 3±1, and 8±1 mmHg. We conclude that IVT hypertonic CSF increases arterial pressure largely through the pressor effect of AVP. Following elimination of the sympathetic nervous system with ganglionic blockade, the central hypertonic CSF pressor response is sensitive to low dsses of IVT GABA. (Supported by American Heart Association,

by AVP. This AVP-dependent pressor response is sensitive to doses of IVT GABA. (Supported by American Heart Association, Texas Affiliate, and NIH HL29993.)

THE EFFECT OF CENTRALLY ADMINISTERED ARGININE VASOPRESSIN ON 160.17 BLOOD PRESSURE IN THE CONSCIOUS RABBIT. S.M. Martin, T.J. Malkinson\*, W.L. Veale and Q.J. Pittman. Departments of Medical Physiology and Pharmacology and Therapeutics, Faculty of Medicine, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

(AVP), The peptide, arginine vasopressin (AVP), is known to influence reuptake of water in the kidney and peripheral vasomotor tone. Recent studies using rabbits and rats have vasomotor tone. Recent studies using rabbits and rats have indicated that AVP may also act within the central nervous system to influence blood pressure (Martin et al., <u>Can. J.</u> <u>Physiol. Pharmacol.</u>, in press, 1983; Pittman et al., <u>Endocrinology</u>, 110: 1058, 1982). The present experiments provide further evidence that the increase in blood pressure evoked by intracerebroventricular (icv) administration of AVP is mediated centrally and not due to a peripheral action of AVP

following diffusion across the blood brain barrier. Male, New Zealand White rabbits were implanted with headplates, permitting access to a lateral cerebral ventricle, headplates, permitting access to a lateral cerebral ventricle, and a chronic intracarotid catheter. Following 5 days recovery from surgery, arterial pressure was recorded in conscious, lightly restrained rabbits given intracerebroventricular injections of AVP (10-1000 ng'100  $\mu$ 1<sup>-1</sup>). Within 1 min, blood pressure was noted to rise in a dose-dependent fashion to reach a peak approximately 1.6 min following the injection. Similar injections of AVP, given iv, caused a blood pressure increase only after the infusion of the highest dose. A further increase only after the infusion of the highest dose. A further group of eight rabbits was given an iv infusion of chlorisondamine HCl (5-10 mg kg ) after which AVP (1000 ng 100  $\mu$ l) was given icv. In these animals, whereas injection of AVP without the blocking agent initiated a rise in blood pressure of  $17.5 \pm 2.50$  mm Hg, the response following ganglionic blockade was abolished in 7 animals. Four of these animals were given an icv injection of AVP, 3 h later. In three animals were given an icv injection of AVP, 3 h later. In three animals there was still no change in blood pressure but in one rabbit, an attenuated response was seen.

These results indicate that the short latency increase in blood pressure evoked by central administration of AVP is neurally mediated and not due to an effect on the vasculature after leakage of the peptide out of the brain. (chlorisondamine HCl provided by Ciba-Geigy).

FREQUENCY-DEPENDENT CARDIOVASCULAR CHANGES ELICITED FROM THE AMYGDALA. L.K. Clarke\*, <u>R. A. Galosy</u>, and <u>C. D. Barnes</u>. Texas Tech Univ. Health Sciences Center, Sch. of Med., Lubbock, 160.18 Texas

Alterations of heart rate and systolic and diastolic blood pressure in response to basolateral amygdala stimulation were studied in 25 acutely prepared, chloralose anesthetized cats The blood pressure wave was recorded from the common carotid The block pressure wave was recorded from the common carbolic artery on a Narco Systems physiograph and digitized and stored on an Apple 2e computer. Bipolar electrode cannulae (Plastic Products) were stereotaxically placed in the basolateral awygdala and in the ventromedial hypothalamus and the amygdala was electrically stimulated for 15 seconds at 300-500  $\mu$ A and at frequencies of 10 Hz, 30 Hz, 50 Hz, and 100 Hz. Blood pressure and heat rate were computed on a beat-to-beat basis for 15 and heart rate were computed on a beat-to-beat basis for 15 seconds prior to each amygdaloid stimulation and for the 45 seconds during and following the stimulus period. The changes in cardiovascular parameters from pre to post

The changes in cardiovascular parameters from pre to post stimulus were analyzed using an analysis of variance and subsequent post hoc t-tests. The results demonstrate a pronounced frequency effect ( $F_{3,810} = 24.8 P < .001$ ) for systolic and diastolic pressure. Depressor responses predominated at all frequencies. Pre to post stimulus changes in pressure at 10 Hz were significantly greater (-9.2 mHg) than changes at all other frequencies. Pressure changes at 30 Hz and 50 Hz were not statistically different (-6.2 mHg, -6.3 mHg) and ne to post stimulus changes in pressure at 100 Hz were 50 Hz were not statistically different (-6.2 mmHg, -6.3 mmHg) and pre to post stimulus changes in pressure at 100 Hz were significantly smaller (-2.4 mmHg) than those at all other frequencies. Stimulation at 100 Hz in some animals resulted in slight pressor responses. Heart rate changes were not significant at any frequency. These results indicate the stimulation frequency effects may be responsible for the varied cardiovascular effects elicited from the amygdala in previous studies. Additional evidence suggests the involvement of certain putative neurotransmitters. specifically GABA in the certain putative neurotransmitters, specifically GABA, in the modification of these frequency dependent cardiovascular changes from the amygdala. This research was supported by NIH grant HL07474.

ELECTROLYTIC LESIONS OF THE SUBSTANTIA INNOMINATA ABOLISH THE LOCCMOTOR RESPONSE TO APOMORPHINE RESULTING FROM DENERVATION OF THE NUCLEUS ACCUMBENS. N.R. Swerdlow<sup>++</sup>, L.W. Swanson<sup>-</sup>, and G.F. Koob<sup>-</sup>. <sup>1</sup>School of Med., Univ. of Calif. San Diego, La Jolla, CA 92093 and the<sup>2</sup>Salk Institute, San Diego, CA 92138. Apomorpine-stimulated locomotion in the rat is greatly enhanced following destruction of dopamine terminals in the 161.3

nucleus accumbens (N.Acc.) with 6-hydroxydopamine(GOHDA). While this augmented response is ascribed to the action of the dopamine stimulant apomorphine on supersensitive receptors within the N.Acc., little is known regarding the mechanism by which increased receptor stimulation within the N.Acc. influences lower motor circuitry to effect changes in locomotion. Efferent projections of the N.Acc. have been described, however, and in this study we examined locomotor responses in 60HDA-infused rats following destruction of the terminal region of first-order N.Acc. efferent fibers within the substantia innominata (SI). N.Acc.

Animals (n=40) were divided into two g oups that received stereotaxic injections of either 60HDA or vehicle into the N.Acc. One week later, these groups were each divided into two subgroups With similar mean locomotor response to 0.1 mg/kg apomorphine. Within each group, one subgroup received electrolytic lesions of Within each group, one subgroup received electrolytic lesions of the SI and adjacent parts of the lateral proptic area and the other received sham lesions. The following week, we examined locomotor activity after injection of 0.05 and 0.1 mg/kg apmorphine in these animals. Lesions of the SI region greatly diminished the locomotor response to apmorphine in 60HDA-infused

animals, but did not alter locomotion in vehicle-infused animals. Destruction of dopernine terminals within the N.Acc. has also been reported to enhance the place-preference response to apomorphine in rats. In order to test the effects of lesions of the SI on this augmented response, animals from the above groups were trained on four consecutive days to associate apomorphine and saline with two distinct environments, as described previously. One day later, they were tested for their place-preference for these environments during a 10 min. test. Lesions of the SI significantly decreased the place-preference for apomorphine-paired environments in 60HDA-infused animals, but did not alter place-preference responses in vehicle-infused animals.

Our results indicate that the efferent pathway from the N.Acc. to the SI serves as an important output of mesolimbic activity into motor circuitry involved in the expression of apomorphine-stimulated locomotion and place-preference.

161.5

MODIFICATION OF APOMORPHINE-INDUCED BEHAVIORAL EFFECTS BY DESTRUCTION OF LIMBIC DOPAMINE NEURONS, <u>Robert J. Carey</u>, V.A. Medical Center, Syracuse, NY 13210. In rats, activation of postsynaptic dopamine receptors by high doses of apopmorphine can have two distinctive behavioral effects: locomotion or stereotypy. Some evidence suggests that locomotion reflects activation of limbic dopamine recep-tors whereas stereotypy is a manifestation of striatal dopamine receptor stimulation. In the present series of studies, limbic dopamine neurons were destroyed in rats pretreated with desmeth-ylimipramine (25 mg/Kg) by injections of 6-hydroxydopamine (6 OHDA) (2  $\mu$ l of 3  $\mu$ g/ $\mu$ l) into either the ventral tegmental area or the nucleus Accumbens. The effects of 6-0DHA injections were compared with vehicle injections (1.0 mg/ml) ascorbic acid) and the effects on brain monoamines determined by HPLC with electrochemical detection. By destroying limbic dopamine neu-rons, limbic dopamine receptors would presumably be increased thereby increasing the likelyhood of locomotion rather than stereotypy behavior being elicited by apomorphine. In one set of experiments, rats given 0.5 mg/Kg apomorphine exhibited intense sniffing and stereotypy with a cessation of locomotion and a complete suppression of self-stimulation. Following destruction of limbic dopamine neurons, however, the same dose of apomorphine failed to elicit stereotypy and the animals ex-hibited typical non-drug levels of both locomotion and self-stimulation. In another experiment, unilateral destruction hibited typical non-drug levels of both locomotion and self-stimulation. In another experiment, unilateral destruction of nigral striatal dopamine neurons produced intense contra-lateral turning in response to apomorphine (0.25, 0.5 and 1.0 mg/Kg) and complete suppression of self-stimulation. Subsequent destruction of limbic dopamine neurons abolished turning at the high 1.0 mg/Kg apomorphine dose level and the rats exhibited locomotion as well as self-stimulation. Thus, these studies demonstrate that the destruction of limbic dopa-mine neurons can profoundly alter the behavioral responses induced by high doses of apomorphine and suggest that limbic and striatal dopamine systems may reciprocally interact such that one system at a time predominantly affects behavior.

- BEHAVIORAL RELATIONSHIPS OF NIGROSTRIATAL UNIT ACTIVITY IN FREELY 161.4
  - BEHAVIORAL RELATIONSHIPS OF NIGROSTRIATAL UNIT ACTIVITY IN FREELY MOVING CATS. Robert E. Strecker, George F. Steinfels and Barry L. Jacobs. Dept. Fsychol., Princeton Univ., Princeton, NJ 08514. We recently reported on the behavioral relationships of dopa-minergie (DA) neuron unit activity in the substantia nigra of awake, freely moving cats (<u>Brain Res. 258</u>:217, 1983). Although the discharge rate of these cells was 20% faster during active waking than during quiet waking (3.68 vs 3.07 spikes/sec), the rate and pattern of activity of these neurons did not vary significantly across quiet waking, slow-wave sleep, and REM sleep. The firing rate of these neurons also displayed no correlation with gross motor activity. They did respond, how-ever, to the repeated presentation of a click or light flash with correlation with gross motor activity. They did respond, how-ever, to the repeated presentation of a click or light flash with excitation followed by inhibition, with no evidence of habitua-tion. The most impressive change in DA unit activity was the long suppression (1-10 seconds) of firing seen during orienting and the subsequent fixation which followed the presentation of a novel or meaningful stimulus. We concluded that these DA response novel or meaningful stimulus. We concluded that these DA neurons appear to provide tonic background activity for the neostriatum

which is lifted only under specific conditions such as orienting. In order to evaluate the functional relationship between DA unit activity and the activity of neurons in the terminal regions of DA neurons, we are examining the activity of neurons in the unit activity and the activity of neurons in the terminal regions of DA neurons, we are examining the activity of neurons in the caudate nucleus under the same conditions that we have charac-terized changes in DA unit activity. Single unit activity was recorded by means of low impedance movable microwires. Despite the large variation in baseline discharge rate across caudate neurons (range - 4 to 19 spikes/sec), as a group, their activity tends to vary in a similar manner across the sleep-waking cycle. They displayed their highest discharge rate during active waking which was approximately 50% greater than their discharge rate during quiet waking. While discharge rates decreased during both slow-wave sleep and REM sleep, to about 60% of quiet waking baseline rate, the variability between cells was much greater during REM sleep. During REM sleep the discharge rates of several cells increased somewhat, while other cells showed dramatic suppressions in firing rate relative to quiet waking baseline. Caudate units are known to exhibit a variety of re-sponses to polysensory stimuli. Under our conditions, caudate neurons responded to light flash and auditory click, typically with an excitation followed by inhibition of activity. In response to stimuli producing orienting behavior, some caudate units appeared to exhibit a slight increase in rate, especially during the first few trials. This increase habituated with repeated stimulus presentation. Since changes in caudate unit activity are often associated with specific movements it is possible that the observed changes in firing rate may be related to the phasic movements rather than the changes in arousal or attention associated with orienting behavior.

and <u>W.R. King</u>\*. Dept. of Pharmacology, Howard Univ. College of Medicine, Washington, D.C. 20059. Altered metabolism of car 161.6 SEROTONERGIC SUBSTRATES OF HYPERACTIVITY IN RAT.

Altered metabolism of one or several monoamines in the CNS has been postulated as the possible etiology of the hyperactive child syndrome. Attempts to model the human hyperkinetic syndrome have centered around altering catecholamine metabolism by administer-ing the neurotoxin 6-hydroxydopamine to neonatal rats and observing the neurotoxin 6-hydroxydopamine to neonatal rats and observ-ing the development of activity in the dopamine-depleted prepara-tion. This model has met with varying success in mimicing the cardinal features of hyperkinesis (e.g., overactivity and impaired learning); however, the paradoxical calming effect of stimulant drugs has been difficult to demonstrate. The present experiment was designed to determine if depletion of central serotonin (5-HT) would induce hyperactivity in the developing rat, and if this hyperactivity is a series of the paratemeter of the series this hyperactive could be attenuated by pharmacological or envi-

ronmental manipulation. On postnatal days 1-2 Sprague-Dawley rat pups received an in-On postnatal days 1-2 Sprague-Dawley rat pups received an in-traventricular injection of 50  $\mu$ g of 5,7-dihydroxytryptamine (5,7-DHT) either alone or in combination with 50mg/kg of pargy-line, i.p.: GI: 5,7-DHT, and GII: P+5,7-DHT, respectively. Spontaneous motor activity (SMA) was monitored at 5 day inter-vals from 5-30 days of age; pups were tested either in isolation or in a familiar environment (home cage shavings), both before and after i.p. injections of d-amphetamine (1 mg/kg) or fen-fluramine (2 mg/kg). Depletion of central 5-HT alone (GII: P+5.7-DHT) did not in-

fluramine (2 mg/kg). Depletion of central 5-HT alone (GII: P+5,7-DHT) did not in-duce hyperactivity in any of the test conditions. In contrast, pups in which both 5-HT and norepinephrine (NE) were reduced (GI: 5,7-DHT) were hypoactive. The presence of home cage shavings in the testing environment significantly attenuated the activity of only the P+5,7-DHT group. The ontogeny of SMA was examined by utilizing a curve fitting procedure to determine the age at which peak activity occurred. In general, depletion of 5-HT alone delayed the onset of peak activity; depletion of both 5-HT and NE accelerated the age at which maximum activity was 5-HT and NE accelerated the age at which maximum activity was observed.

The psychomotor stimulant d-amphetamine preferentially in-creased motor activity in the 5,7-DHT and P+5,7-DHT pups. In controls, drug-induced changes varied as a function of age.

Fenfluranine decreased activity in all groups. The results indicate that alterations in central serotonin do not induce hyperactivity in the developing rat; pups with Teduced levels of this amine were hypoactive. However, changes in the characteristic ontogenetic pattern of SMA following treat-ment with 5,7-DHT indicate that serotonin is involved in the development of motor activity. (Supported by NSF Grant #80-26765).

UNIT ACTIVITY OF SEROTONERGIC NEURONS IN N. RAPHE MAGNUS IN FREELY 161.7 MOVING CATS. <u>C. Fornal, S. Auerbach, J. Heym and B. L. Jacobs.</u> Prog. in Neurosci., Dept. of Psychol., Princeton Univ., Princeton. ŊJ 08544

The activity of serotonin-containing neurons in the dorsal raphe nucleus (DRN), n. centralis superior (NCS) and n. raphe pallidus (NRP) has been examined across different behavioral pailinus (NAF) has been examined across different behavioral states in freely moving cats (<u>Brain Res.</u> 163:135-150, 1979; <u>Brain</u> Res. 251:259-276, 1982; <u>Soc. Neurosci. Abstr. 8:896</u>, 1982). In general, these neurons display similar activity patterns across general, these neurons display similar activity patterns across the sleep-wake cycle but differ in other important aspects. We now report the characteristics of neurons recorded in the region of n. raphe magnus (NRM) of freely moving cats. Single unit activity was recorded using a microwire technique previously described in detail (<u>Brain Res.</u> 163:135-150, 1979). Briefly, movable electrode bundles consisting of 32 and 64 µm dia, insula-ted, nichrome wires were implanted in the NRM at an angle 25° ted, nichrome wires were implanted in the NRM at an angle  $25^{\circ}$  posterior to vertical. Stereotaxic coordinates for the NRM target were P 5.5, L 0.0, H -8.5. Electrodes were also implanted for recording the EEG, EOG, PGO waves and dorsal neck EMG. Serotonergic neurons were initially identified by their slow and regular spontaneous activity which was similar to that previously reported for serotonergic cells in the DRN, NCS and NRP. Discharge rates of NRM serotonergic meurons were highest during active waking (5.5 + 1.0 esther/eac ware to SEM prime alor waves and the target of the target metric of target metric of NRM serotonergic neurons were highest during active waking  $(5.5 \pm 1.0 \text{ spikes/sec}, \text{ mean } \pm \text{ SEM}, n=19)$ , decreased during slow-wave sleep  $(2.4 \pm 0.5 \text{ spkes/sec})$  and were slowest during RRM sleep  $(0.3 \pm 0.1 \text{ spikes/sec})$ . The activity of these neurons appeared unrelated to PGO waves or sleep spindles. These cells responded to administration of the specific serotonin agonist 5-methoxy-N, N-dimethyltryptamine  $(5-\text{MeoDMT}, 250 \mu g/\text{kg}, \text{ i.m.})$  with a mean decrease in activity of about 60%. Serotonergic neurons in the NRM were either unaffected or only slightly excited by phasic auditory and visual stimuli. Non-serotonergic cells in the region had either much faster or irregular firing rates. did not display auditory and visual stimuli. Non-serotonergic cells in the region had either much faster or irregular firing rates, did not display their lovest rates during REM sleep and their activity did not decrease after 5-MeoDMT. These data indicate that serotonergic neurons in the NRM more closely resemble another medullary raphe nucleus, NRP, than the two mesencephalic raphe nuclei, DRN and NCS. Thus, as compared to DRN and NCS, serotonergic neurons in the medulla have higher discharge rates during waking and slow-wave sleep, are less responsive to administrations of serotonin agonist drugs, and are generally unresponsive to phasic light and auditory stimuli. However, unlike cells in the NRP, NRM seroto-nergic neurons show a large decrease in discharge rate between augustory stimult. nowever, unlike cells in the NRP, NRM seroto-nergic neurons show a large decrease in discharge rate between waking and slow-wave sleep. In addition, most NRM serotonin-containing neurons increase their activity in response to strong arousing stimuli such as mildly painful pressure (see next abstract). 161.9 ASSESSING IMPULSIVITY IN AN ANIMAL MODEL OF THE ATTENTIONAL

ASSESSING IMPULSIVITY IN AN ANIMAL MODEL OF THE ATTENTIONAL DEFICIT DISORDER. <u>G. K. Hodge, A. E. Martin\*, M. A. Foster\*, and</u> <u>J. Salinas\*.</u> Dept. of Psychology, University of New Mexico, Albuquerque, NM 87131. The Attentional Deficit Disorder (ADD), as described in the DSM III, is characterized by inappropriate inattention, impulsiv-ity, and hyperactivity. Various attempts have been made to develop an animal model of the disorder focusing on motor activity as the measure of interest. Neonatal administration of 6-hydroxydopamine (6-OHDA) induces a transient period of hyper-activity in rats, reminiscent, perhaps, of the transient period of increased motor activity in children with ADD. <u>d-Amphetamine</u>, however, which attenuates hyperactivity in children, does not consistently attenuate the 6-OHDA-induced hyperactivity in rats (see Hodge, Neuroscience Abstr, 7:41, 1981).

Consistently attendate the 5-ond-induced hyperactivity in rats (see Hodge, Neuroscience Abstr, 7:41, 1981). Gordon (J of Abnorm Child Psych, 7:317, 1979) has assessed impulsivity in children using a DRL schedule requiring children to temporarily suppress a reinforced response. Gordon (1979) reports that the DRL schedule successfully discriminated between DR and the schedule successfully discriminated between

The temporation of the temporate of the temporate temporate temporate temporate that the DRL schedule successfully discriminated between ADD and normal children. We have developed an animal model which employs a modified DRL as a measure of impulsivity in rat pups. Following designamine pretreatment, 5-day-old rats were injected intracisternally with either 100  $\mu$ g/25  $\mu$ l of 6-0HDA or 25  $\mu$ l of the ascorbic acid/saline vehicle. Testing was conducted on postpartum days 15, 19, 22, 26, and 30, with an 18-h maternal deprivation period prior to each testing session. Pups were placed at one end of a polypropylene breeding cage with the dam restrained at the opposite end. Pups were required to refrain from approaching the dam for 15 sec on each of 40 trials. Impulsivity was operationalized as the mean number of commission errors (approaches) per trial. Thirty min prior to the start of each testing session, pups received saline or either .5 or 1 mg/kg i.p. of d-amphetamine. Neonatl administration of 6-0HDA results in a transient deficit in impulsivity impairment was attenuated with the dam pay 26. The impulsivity impairment was attenuated with the maternal operation of a-maphetamine, paralleling the response of similar pharmacological intervention with ADD children.

administration of <u>d</u>-amphetamine, paralleling the response of similar pharmacological intervention with ADD children. Because ADD is being increasingly considered as an attention rather than a motor disorder, animal models focusing solely on motor activity levels are of limited usefulness. An animal model of impulsivity, as described here, may be of value in the development of a better model of childhood hyperactivity. (Supported by NIH-MBRS grant 3506-RR08139-0751)

UNIT ACTIVITY OF SEROTONERGIC NEURONS IN N. RAPHE MAGNUS OF 161.8

UNIT ACTIVITY OF SEROTONERGIC NEURONS IN N. RAPHE MAGNUS OF FREELY MOVING CATS: RESPONSE TO MORPHINE AND NOXIOUS STIMULI. S. Auerbach, C. Fornal, J. Heym and B.L. Jacobs. Prog. Neurosci., Dept. Psychol., Princeton Univ., Princeton, NJ 08544 Analgesia produced by opiates may involve activation of de-scending pathways from n. raphe magnus (NRM) which inhibit dis-charge of nociceptive neurons in the spinal cord. Since depletion of serotonin antagonizes the analgesia induced by morphine, activation of serotonergic cells within the NRM might be important in mediating the analgesic effects of opiates. To test this in mediating the analgesic effects of opiates. To test this hypothesis, we studied the response to morphine of identified serotonergic neurons recorded in the NRM of freely moving cats. Recordings of single unit activity were made from the NRM as

previously described (Fornal et al; this meeting). All units in the area of the NRM displaying slow and regular discharge patterns, supression of activity during REM sleep, and a decrease in discharge in response to the specific serotonin agonist, 5-methoxy-N,N-dimethyltryptamine (250 µg/kg i.m.) were considered to be serotonergic. The unit activity of presumed serotonergic and non-serotonergic neurons in the NRM was studied before and after Non-service region hereins in the NeW was studied before and after the systemic injection of morphine sulfate (2 mg/kg, i.p.). This dose of morphine produced profound analgesia in cats within 30 min as determined by the tail-flick test and response to pressure. Unit activity was monitored for 60 min post-injection. Most service units responded to morphine with either no change or a decrease in unit discharge. This was also true of control cells within the NEW within the NRM. We also tested the response of serotonergic units in the NRM to

we also tested the response of servicine for mitty in the wide to two types of painful stimul: 1) radiant heat was focused on a distal shaved portion of the tail. The intensity of the heat was adjusted to induce baseline tail-flick latencies of 2-4 sec; and 2) a clamp was applied to various body regions (tail, back, ear). 2) a clamp was applied to various body regions (tail, back, ear). The force of the clamp was adjusted to induce mildly painful pressure as judged by observation of the cat's reactions (i.e. withdrawal from the stimulus but absence of rage and vocaliza-tion). Most serotonergic neurons in the NRM discharge maximally in response to mildly painful pressure but responded less con-sistently to radiant heating of the tail. When heat stimulation induced increases in unit discharge, the response seemed to be correlated with periods of increased behavioral arousal as indi-cated by increases in tonic and phasic muscle activity. Similarly, the increases in unit discharge induced by pressure seemed unrelated to application of the painful stimulus per se, but best correlated with the period of behavioral arousal. Our results do not support the hypothesis that opiate-induced analgesia is dependent upon activation of serotonergic neurons in

analgesia is dependent upon activation of serotonergic neurons in NRM. However, activation of NRM cells in response to arousing stimuli could be an important aspect of an analgesic system.

INFUSION OF A MONOAMINE OXIDASE INHIBITOR INTO THE LOCUS 161.10 Goodman, J. M. Weiss, M. J. Ambrose\*, K. A. Cardle\*, W. H. Bailey and J. M. Charry\*. Laboratory of Behavioral Biology, The Rocke-feller University, New York, NY 10021. This experiment demonstrated that micro-infusion of a monoamine

oxidase inhibitor pargyline into the region of the locus coeruleus (LC) of rats could protect against stress-induced behavioral depression. Such depression can be produced by exposing animals to a stressor which they cannot control. Previous studies in our laboratory have demonstrated that stress-induced behavioral depression is correlated with large depletions (<20%) of norepine-phrine (NE) in the LC of shocked rats and is accompanied by increased floating behavior in a swim test when compared to rats not exposed to shock (No-Shock). Furthermore, evidence suggests that such NE depletion in the LC may be an important mediating step in causing the depression. The present study determined whether be-havioral depression could be prevented by pharmacologically reduc-ing the catabolism of NE in the LC so as to eliminate the NE dep-

letion that normally occurs after acute uncontrollable shock. Animals were exposed to uncontrollable tail-shock on a schedule shown to produce behavioral depression. Immediately following shock and 90 minutes prior to the 15-minute swim test, animals were infused bilaterally in the region of the LC with pargyline or which introduce the solution of the solution of the solution pergeneration was low  $\mu g/\mu l$  and was infused at a rate of 0.1  $\mu l/min$  for 10 minutes.) The results were as follows: (1) Shocked animals infused with vehicle exhibited significantly more floating behavior than No-Shock animals infused with vehicle. (2) Infusion of pargyline into No-Shock animals had no significant effect on their activity when compared with No-Shock vehicle-infu-sed animals. (3) Infusion of pargyline into shocked animals prevented the increase in floating behavior usually seen in animals exposed to uncontrollable shock. As a consequence, the behavioral profile of these shocked animals was not significantly different

profile of these shocked animals was not significantly different from that of No-Shock animals infused with vehicle. Measurement of monoamines (NE, DA, and 5-HT) in seven brain regions after the swim showed that infusion of pargyline into the LC eliminated the large depletion of NE in the LC seen in shocked animals infused with vehicle (27% depletion relative to No-Shock vehicle-infused animals), while having no effect on NE levels in other brain regions. Pargyline infusion also raised the level of UV in the LC region back of the control of the control of the lower of lower of the lower of the lower of the lower of the lower of the lower of lower of the lower of lower of lower of the lower of lowe 5-HT in the LC region, but again had no effect on 5-HT levels elsewhere.

In conclusion, the depressant effect of uncontrollable shock on behavior was prevented by infusion of pargyline into the LC. This is consistent with the hypothesis that large stress-induced depletions of NE in the LC are an important mediating event in producing stress-induced behavioral depression.

- 161.12 PLASMA EPINEPHRINE IS A SENSITIVE INDEX OF STRESS IN RATS D. Creighton\*, R. McCarty\* and B. Natelson (SPON: B. Lubit). Dept. of Neurosci., VAMC & New Jer. Med. Sch., E. Orange NJ 07018 & Dept. of Psychol., Univ. of Virginia, Charlottesville VA 22904. For a physiological variable that is altered by stress to be
  - Dept. of Neurosci., VAMC & New Jer. Med. Sch., E. Orange NJ 07018 & Dept. of Psychol., Univ. of Virginia, Charlottesville VA 22904. For a physiological variable that is altered by stress to be clinically useful as an index or "barometer" of stress, it must be both reliable and sensitive. "Reliable" means that the variable changes whenever the animal is stressed. "Sensitive" means that changes in the variable co-vary with changes in magnitude of stress. Using groups of rats, we have shown that plasma catecholamines meet these criteria (Phys. Behav. 26:1049, 1981). But, for a test to be useful clinically, such relations must also be seen in individual animals. To test this, we subjected 8 chronically catheterized rats to a 30 sec, scrambled, constant current foot shock every other day. For this group, shock was delivered in an ascending order (0 mA on day 1, .25 mA on day 3, 1 mA on day 5 and 4 mA on fay 7). Similarly, 7 rats were subjected to the same procedure, except shock was sampled remotely without disturbing the rat before the shock and immediately thereafter. Both norepinephrine and epinephrine increased reliably after foot shock stress: levels of both increased series, norepinephrine showed monotonic increases as shock intensity increased in 7 of 8 rats. Similar epinephrine increases were seen in 6 of 8 rats. Assuming each increases occurred with a probability of 0.5, the binomial probability of seeing these distributions was significant (p < .001). Since a tendency was seen in norepinephrine data for baseline levels to increase was run to evaluate the possibility that learning was interacting with the stress response to produce the results found. Baseline levels again tended to increase. Nonetheless, monotonic decreases with decreasing shock were seen in 3 of 7 rats for norepinephrine and 6 of 7 rats for epinephrine. The binomial probability of seeing this distribution for the norepinephrine data was not significant, but the probability of seeing it for the epinephrine data was significant (p < .001)
- 161.14 CHOLINE EFFECTS IN ANIMALS WITH HIPPOCAMPAL DAMAGE. J. E. <u>Springer and R. L. Isaacson</u>. Sponsored by: <u>Carolyn Ware</u>. Department of Psychology and Center for Neurobehavioral Sciences, SUNY-Binghamton, Binghamton, NY 13901.

In rats the behavioral similarities between bilateral hippocampal destruction and the systemic administration of muscarinic antagonists include increased activity in a novel environment, difficulty in learning a successive discrimination, slowness in habituating, and in inability to inhibit a previously acquired response. These similarities suggest that hippocampal damage may produce effects on remaining neural systems that are also influenced by cholinergic systems. We examined this by giving rats hippocampal or control lesions of the neocortex, and observing their spontaneous behaviors in a novel open field 10 or 60 min following the systemic administration of choline chloride (60 mg/ kg) or saline vehicle.

Choline administration reduced locomotion and increased the duration of exploratory bouts in animals with hippocampal damage but only at the shorter injection-test interval. The behavior of the control animals was unaffected at either time interval. In another experiment we found that similar injections of choline chloride ameliorated some of the behaviors induced by administration of the muscarinic receptor antagonist scopolamine but, again, only 10 min after the choline injection. It is suggested that choline administration can benefit, in a time-dependent fashion, animals which exhibit behaviors that occur following hippocampal damage. This effect may occur through changes in acetylcholine systems since choline administration also eliminates similar behaviors seen after muscarinic antagonism. 161.13 ANTERIOR CEREBELLAR VERMAL STIMULATION AND LESION: EFFECT ON CONDITIONED FEAR AND BASAL FOREBRAIN NEUROCHEMISTRY IN RAT. T.J. Albert\*, C.W. Dempesy\*, A.E. Schlein\*, and C.A. Sorenson (spon: R.G. Heath). Neuroscience Program, Amherst College, Amherst, MA. 01002.

Electrophysiological, anatomical, behavioral, and clinical studies suggest that the anterior cerebellar vermis (ACV) modulates forebrain emotional systems, particularly those controlling fear and anxiety, perhaps via monoaminergic pathways. This study evaluates the effects of both acute electrical stimulation and lesion of the ACV on conditioned fear in rat and assesses the associated changes in monoamine neurotransmission.

associated changes in monoamine neurotransmission. The behavioral model employed is the "potentiated startle effect" (PSE) in which anxiety is inferred from an enhancement of response to a startle-eliciting tone presented during a light cue previously paired with footshock. The PSE is sensitive to drugs with anxiogenic or anxiolytic properties in man (Davis, <u>Psychopharm</u>, 1979, <u>62</u>:1).

drugs with anxiogenic or anxiolytic properties in man (Davis, <u>Psychopharm</u>, 1979, 62:1). <u>ACV stimulation applied for one hour before and 45 minutes</u> during testing produced a statistically significant increase in the PSE without affecting startle baseline. Associated reliable chemical changes in the nucleus accumbens (nAcc) consisted of a decrease in DA, an increase in DOPAC, and a decrease in SHIAA in AMPT pre-treated rats. In contrast, RF lesion of the ACV produced a statistically significant decrease in the PSE at 12 days post-lesion without affecting startle baseline, but no reliable chemical changes in the nAcc at 21 days post-lesion, although a reliable increase in SHIAA was found in the septal area.

The present data suggest that acute ACV stimulation increases both conditioned fear and nAcc DA release, consistent with the previous finding (Iversen, in <u>Psychobiology of the Striatum</u>, Amsterdam, 1977:99) that nAcc DA application is associated with hypersensitivity to threatening cues. The lesion data suggest the ACV exerts a tonic facilitatory influence on this same behavior. Serotonergic involvement is also implicated.

These data cannot be readily integrated with clinical reports of mood - and affect - normalizing changes with chronic ACV stimulation (Heath, Jour. Nerv. & Ment. Disease, 1977, 165;300). However, such stimulation is typically reported to enhance responsiveness to the environment, possibly consistent with increased transmission of DA in the mesolimbic pathway.

161.15 ATROPINE INCREASES SENSITIVITY TO STRESS IN RATS

L. Landman-Roberts\*, G.J. Kant, T. Eggleston\*, C.C. Kenion\*, G.C. Driver\* and J.L. Meyerhoff. (SPON: F.J. Manning). Neuroendocrinology and Neurochemistry Br, Dept Med Neurosciences, Div Neuropsychiatry, Walter Reed Army Institute of Research, Washington DC 20307

and Neurochemistry Br, Dept Med Neurosciences, Div Neuropsychiatry, Walter Reed Army Institute of Research, Washington DC 20307 We have previously reported that various stressors increase levels of pituitary cyclic AMP in vivo in the rat [Kant et al., Pharmacol. Biochem. Behav., <u>17</u>, 1067-1072 (1982)]. During a pilot experiment we observed that rats pretreated with 60mg/kg atropine sulfate prior to footshock demonstrated an enhanced pituitary cyclic AMP response to footshock. We therefore initiated experiments to further characterize the interaction between stress and atropine.

In the first experiment, rats were pretreated with 60 mg/kg atropine sulfate or saline 15 min prior to exposure to 15 min of either footshock, forced running, immobilization or conditioned psychological stress (rats were placed into a footshock chamber where footshock had been received the previous 4 days). Control rats were sacrificed immediately upon removal from their home cages. In a separate experiment, rats were pretreated with saline or 5, 10, 30 or 60 mg/kg atropine sulfate 15 min prior to 15 min of footshock. All animals were sacrificed immediately following each stressor by

All animals were sacrificed immediately following each stressor by high power microwave irradiation to prevent post-mortem changes in cyclic AMP levels. The pituitaries were dissected, weighed and sonicated in sodium acetate buffer and the supernatants were assayed for cyclic AMP by radioimmunoassay. Trunk blood was collected in the second experiment and the plasma assayed for prolactin.

AMP by radioimmunoassay. Trunk blood was collected in the second experiment and the plasma assayed for prolactin. I.P. injection, conditioned psychological stress, forced running, immobilization and footshock all increased levels of pituitary cyclic AMP as compared to controls. Atropine-pretreated rats demonstrated higher pituitary cyclic AMP levels than saline-pretreated rats after all five stressors with statistically significant differences found after injection, immobilization and shock stressors.

Rats pretreated with 5, 10, 30 or 60 mg/kg atropine sulfate showed an increased pituitary cyclic AMP response to footshock with statistically significant differences observed between the 30 and 60 mg/kg groups vs saline-pretreated rats subjected to footshock. Prolactin response to footshock was also increased in all atropine-pretreated rats with statistically significant differences observed between the 5, 30 and 60 mg/kg groups vs saline-pretreated rats subjected to footshock.

In a follow-up experiment examining the analgesic properties of atropine, atropine-pretreated rats exhibited a significantly decreased latency between application of heat source and tail flick as compared to saline-pretreated rats.

saline-pretreated rats. These data suggest that atropine potentiates neurochemical and neuroendocrine responses to stressors, and that this effect is partially explained by the lowering of pain threshhold by atropine.

PLASMA BETA-ENDORPHIN IMMUNOREACTIVITY IN CLINICAL STRESS. 161.16 J.L. Weiss, S.R. Hameroff, R.C. Cork, J.J. Misiaszek, Depts. Anesthesiology & Psychiatry, Univ. Arizona Health Sciences Center, Tucson, AZ 85724.

Plasma beta endorphin (β-end) has been implicated in physiological responses to stress. Peripheral  $\beta$ -end affects heart lung, immunocytes, gut, autonomic ganglia, microcirculation and other hormones. Acutely, stress responses can have both beneficial and deleterious effects in clinical medicine. We present 3 studies using plasma  $\beta$ -end immunoreactivity (New England Nuclear) as an index of patients stress response

Informed consent and Human Subjects Committee approval Methods. were obtained from patients. 1. Spinal vs. general anesthesia 15 males undergoing cystoscopic transurethral prostate resection included 6 patients selecting general anesthesia and 9 selecting subarachnoid local anesthetic (spinal). Anesthetic techniques were appropriately standardized and b ood samples (5ml) withdrawn from an indwelling catheter (Fig). 2. <u>Epidural analgesia for</u> <u>labor pain</u>. 15 term pregnant women in labor participated. 10 received local anesthetic (.25% buptvacaine) via epidural cathe-ter. 5 women declined the epidural, but served as controls. 3. Electroconvulsive therapy (ECT) 7 psychiatric inpatients meeting DSM III criteria for major depressive disorder participated who were scheduled for ECT under general anesthesia with methohexital and succinylcholine.  $\beta$ -end was also correlated with heart rate, blood pressure, and plasma catecholamines.

Results. Results from studies 1 and 2 are shown. Study 3 (not shown) revealed a sharp rise (from 30 to 60 pg/ml) in mean  $\beta$ -end immunoreactivity after ECT.

Discussion Studies 1 and 3 demonstrate that  $\beta$ -end stress respones are not ablated (and may be provoked) by general anesthe-sia. Study 2 (and the spinal group in study 1) shows that pain related stress may be inhibited by regional blockade of painful  $\beta$ -end immunoreactivity will be correlated with other stimuli. stress markers.

MUSCLE PROTEASE ACTIVITY IN NORMAL AND IMMUNOSUPPRESSED SEPTIC 161.17 RATS. D. Secrist\* and R.L. Ruff (SPON: F. Bahls). Departments of Physiology and Biophysics and Medicine (Neurology), University

of Washington, Seattle, WA 98195. Recent in vitro studies (N. Eng. J. Med. 308:545, 553, 1983) suggest that sepsis induces muscle proteolysis by a prostaglandin (PG) mediated activation of lysosomal proteases. Rats were immunosuppressed (I) by daily subcutaneous injections of dexamethasone (DEX) 1.5 mg/kg. This treatment produced muscle wasting associated with increased cathepsin (CAT) D activity but no increase in CAT B or calcium activated protease (CAP) activity. A lower dose of DEX 0.3 mg/kg did not activate CAT D. Pepstatin, a CAT D inhibitor, could partially prevent the atrophy associated with DEX 1.5 mg/kg treatment. After four weeks, I rats had reduced lymphocyte counts and spontaneously developed systemic bacterial infections. Normal rats were inoculated with Streptococcus pneumoniae to produce spontaneous sepsis (SS). Both SS and I rats developed fever, accelerated muscle wasting, and and that's developed level, acceletated muscle wasting, and depletion of intracellular potassium with increased intracellular sodium in muscle associated with a marked increase in muscle CAT B activity without activation of CAT D or CAP. Muscle wasting, but not electrolyte changes, could be partially prevented by leupeptin. Indomethacin is a potent PC inhibitor while acetamen-ophen is a weak peripheral PC inhibitor. Both acetamenophen and indomethacin reduced fever in SS and I rats, but only indomethacin prevented muscle wasting and electrolyte changes. The data indicate that muscle wasting and electrolyte changes with sepsis are PG mediated with PG activation of CAT B leading to accelera-ted proteolysis. Supported by NIH grants NS00498, NS16696, and NS18544.

MONOAMINES AND BEHAVIOR I

162.1

LEARNED HELPLESSNESS: EFFECTS ON BRAIN MONOAMINES. <u>D.H. Hellhammer, M. Bell\*, M. Ludwig\* and M.A. Rea</u>. Dept. Clinical Psychology and Max Planck Clinical Re-search Unit for Reproductive Medicine, Westf. Wilhelms-University, D-4400 Münster, F.R. Germany. We have recently discussed a biphasic model of lear-ned helplessness (Hellhammer, D.H., in: The Origins of Depression, ed. by J. Angst, Springer, Berlin-Heidel-berg-New York 1983), suggesting a functional imbalance of low noradrenergic and high sertonergic activity in response to uncontrolable aversive events. This study was designed to measure levels of monoamines and meta-bolites by HPLC/EC in nine discrete brain areas in rebolites by HPLC/EC in nine discrete brain areas in response to helplessness training.

The triadic yoked control paradigm was used, and ten triplets of adult, male rats were trained for one hour on each of five consecutive days. In each triplet one rat could escape a tail-shock (FI 20, 0.7 mA) by turnrat could escape a tail-shock (FI 20, 0.7 mA) by turn-ing a wheel (HE-animals), while it's yoked counterpart received the same amount and frequency of shock but could not end the shock by turning the wheel (HY-ani-mals). This treatment provokes in HY-animals an increase in freezing responses and a deficit in a later shuttle-box escape-learning (FR 2). The third rat of each trip-let was handled under the same experimental conditions, but did not receive any shock (HC-animals). After the last training session rats were killed by decapitation, and brains were dissected at -10 °C. Le-vels of DA, DOPAC, HVA, NE, MHPG, 5-HT and 5-HIAA were determined in each brain part. For both the HE-group and the HY-animals higher levels of 5-HIAA were found in the midbrain, suggesting an enhanced functional ac-

and the midbrain, suggesting an enhanced functional ac-tivity at serotonergic receptor sites in response to shock-induced stress. In the pons/medulla levels of 5-HT decreased in the HE-group, possibly reflecting a reduced metabolism of serotonin. On the other hand, we found a decrease of NE in the yoked animals in this brain area. These results support the idea that low noradrenergic activity in the pons/medulla is a conse-quence of behavioral suppression induced by uncontrol-able shock, while serotonin is less active in the HE-animals who coped actively with the aversive event. Moreover, levels of DA were higher in the HY-rats when compared with their HE-counterparts in the pons/medul-la and the hypothalamus, and we consider this a conse-quence of enhanced motor activity in the HE-animals. (Supported by the Deutsche Forschungsgemeinschaft). in the midbrain, suggesting an enhanced functional ac-tivity at serotonergic receptor sites in response to

162.2 ELECTROLYTIC MEDIAN RAPHE LESIONS REDUCE THE ABILITY OF HALOPERIDUL TO SUPPRESS AN INSTRUMENTAL RESPONSE. <u>A.Kozlowski</u>, <u>D. Wirtshafter and K.E. Asin. (SPON'J.D.Davis).Dept.Psychol.Univ.</u> Illinois at Chicago, Chicago, Il. 60680. A number of reports have suggested the existence of some

sort of interaction between dopaminergic neurons and the median raphe nucleus. For example, electrolytic median raphe lesions have been found to increase dopamine turnover in the nucleus accumbens (Herve et al., 1981) and to potentiate amphetamine-induced hyperactivity (Lucki & Harvey, 1979). Furthermore, electrolytic raphe lesions have been reported to reduce the ability of dopamine antagonists to produce catalepsy (Kostowski al., 1972) and impair active avoidance (Kostowski & Plaznik, 1982).

The current experiment was designed to examine the generality of the conclusion that raphe lesions are able to antagonize the ability of dopamine antagonists to disrupt behavior. Rats with electrolytic median raphe lesions, or sham operated controls, were trained to traverse a straight alley for food reward. Following eight days of training, running speeds did not differ between groups. On the next two days rats were then tested 30 min following an injection of haloperidol (0.15 mg/kg). Rats with median raphe lesions ran significantly faster than controls following haloperidol treatment. The effect of the lesions was largest in the initial segment of the alley, suggesting that median raphe damage may antagonize the ability of haloperidol to slow movement initiation.

Although it is often assumed that the behavioral effects of electrolytic raphe lesions result from serotonin depletion. recent work has indicated that many of these effects may result from damage to nonserotonergic elements within the raphe. We will, therefore, also present data of the effects of haloperidol on running speeds following specific serotonin depleting lesions produced with the neurotoxic agent 5,7-dihydroxytryptamine. 162.3 HALOPERIDOL CATALEPSY SHOWS SENSITIZATION WHICH DEPENDS ON THE PASSAGE OF TIME RATHER THAN REPEATED TREATMENT, <u>S. M. Antelman\*</u>, D. Kocan\*, D. J. Edwards, M. Fraser\*, J. Perel\* and S. Knopf\*. Depts of Psychiatry and Pharmacology-Physiology, Univ. of Pittsburgh, Schools of Medicine and Dental Medicine.

burgh, Schools of Medicine and Dental Medicine. Most animal studies of the influence of repeated neuroleptic administration have shown that tolerance develops to the initial effects of these agents. Yet the neuroleptic effects of greatest clinical interest, i.e., the antipsychotic influence and tardive dyskinesia, take weeks and months, respectively, to develop. That is, they show sensitization rather than tolerance. The same agent is often capable of displaying tolerance or sensitization depending on whether treatments are massed or high dose on the one hand or relatively low dose or intermittent on the other. Since "low" doses and intermittent treatments favor the development of sensitization, we examined whether such regimes could result in sensitization of haloperidol-induced catalepsy, a response typically associated with tolerance.

result in sensitization of haloperidol-induced catalepsy, a response typically associated with tolerance. First, we administered a single injection 0.4 mg/kg, (i.p.) of Haldol<sup>®</sup> to adult male Sprague-Dawley rats daily for 28 days and tested for catalepsy once a week. Catalepsy was defined as remaining immobile for at least 25 sec. with forepaws elevated on a platform. Two min. tests were conducted at 5,10,20,30,40, 50 and 60 min. after injection. In virtually every instance the incidence of catalepsy was greater after 7,14,21 or 28 days of treatment than it was following a single injection of Haldol (p<.002). Thus, clear evidence of sensitization was obtained. Since we have previosuly shown that sensitization after amphetamine or antidepressants depends on the passage of time

Since we have previosuly shown that sensitization after amphetamine or antidepressants depends on the passage of time rather than repeated treatments, we inquired whether sensitization of Haldol catalepsy is similarly independent of repeated treatment. We now report that a single injection of 0.4 mg/kgHaldol is sufficient to significantly sensitize the cataleptic response to a second injection of the same dose when this is tested 1,2,3 or 4 weeks later (p<.001 all second injections, week 1-4 relative to all first injections). The same results have been obtained whether animals are tested for catalepsy in novel surroundings or their home cages and are therefore unlikely to be due to conditioning factors. Also radioimmunoassay of Haldol levels in the striatum indicates that drug buildup cannot account for our results.

account for our results. These findings provide the first indication that at least some of the effects of neuroleptics may grow merely with the passage of time independent of repeated treatment. As such they raise the very provocative questions of 1) whether daily treatment with these agents is necessary for clinical efficacy in schizophrenia and 2) whether the development of tardive dyskinesia may be more a function of the passage of time rather than repeated treatment.

162.5 Effects of mesolimbic dopamine lesions on hoarding, exploratory behavior and alimentary patterns in the rat. A.E. Kelley \* and L. Stinus\* (SPON: F.Moody-Corbett) Lab. Neurobiologic des Comportements, Université de Bordeaux, Bordeaux, France. The ascending mesolimbic dopamine (DA-AIO) system, arising in the ventral tegmental area (VIA), is thought to be involved in adaptive behavior and motivational processes. We have carried out a behavioral study of animals with 6-hydroxydopamine (6-OHDA) lesions of this neuronal system. The study included the following groups: VTA lesion, Nucleus accumbens lesion (N.Acc.), and control. In a fourth group, for purposes of comparison, the forebrain noradrenaline system was lesion at the level of the superior cerebellar peduncie (PCS). Three weeks after surgery, rats were selected or discarded on the basis of their amphetamine and apomorphine responses, to retain only completely lesioned rats. In a test of hoarding behavior, in which controls hoarded nearly all 00 biscuits from an open field to the home cage in a 2-hour test, hoarding was severely diminished or abolished in VTA and N:Acc. lesioned anials.Hourding in PCS tats was not significantly affected. A series of alimentary tests were then conducted. In a 24-hr. food-intake test with no prior deprivation, parameters such as food consumption, food spillage, no. of biscuits partially eaten or untouched, were recorded. In a 30 min. test with prior deprivation, additional parameters included no. of eating bouts and duration of eating. Although no major difference in food consumption was found among groups, DA-lesioned rats showed significantly different patterns of food intake. No differences anong groups. In separate tests of exploratory behavior in an 8-hole and 4-hole box, PCS and control rats displayed similar behavior. DA-lesioned rats showed either marked exploratory deficits (VTA) or changes in patterns of investing the avoir (N.Acc.). Hoarding is a highly organized intrinsic behavior in rodents, elicited by appr

162.4 STRESS EFFECTS ON SENSITIZATION AND EXPLORATION: PRIOR EX-POSURE TO D-AMPHETAMINE OR HALOPERIDOL. <u>H. Schreiber, M.</u> Warren\*, L. Nez\*, J. Kubota\*, B. Zito\*, R. Lopez-Gaston\*, K. Wanya\*, W. Ogle\*. Neurosci. Lab., Div. Behav. Sci., Highlands Univ., Las Vegas, N.M. 87701.

A single administration of d-amphetamine (AMPH) can sensitize the response to a subsequent injection of AMPH for up to 6 days (Browne & Segal, <u>Pharmac Biochem Behav</u> 6, 545, 1977). The present experiment determined (a) whether repeated exposure to an inescapable stressor would potentiate the sensi-tization produced by prior exposure to AMPH or haloperidol (HAL) and (b) whether the decrement in exploration in a novel setting seen following repeated exposure to a stressor would be influenced by a prior injection with AMPH or HAL. Adult male rats received AMPH (12 mg/kg X 2, IP), HAL (5 mg/kg X 2, IP) or saline (SAL, IP) and were left undisturbed for the next 9 days. Then, half of each group received 3 days of cold water immersion (3 min/day,  $4.5^{\circ}$ C). On the following day, rats were observed for 5 min in a small novel chamber housed in a larger sound-attenuated environmental chamber, injected with apomorphine hydrochloride (APO, .8 mg/kg) and, 10 min later, again observed for 5 min in the small chamber by a blind observer, who recorded stereotypical and other be-haviors at 5 sec intervals in a time-sampling fashion. Before APO injection, SAL-history stressed rats showed less shifting than SAL-history non-stressed rats, t(48)=3.96, p=.01, and less shifting than AMPH-history stressed rats, t(48)=2.24, p $\angle$ .02. Previous work in our laboratory has shown that shifting is the predominant exploratory behavior seen in this apparatus upon the first few exposures. After APO injection, stressed rats showed more stereotypical gnawing/licking, F(1,48)=4.7, p=.04, and more mouthing/ licking movements, F(1,48)=5.6, p=.02, than nonstressed rats. Thus, stress sensitized (i.e. potentiated) stereotypy with little evidence of an interaction with prior drug treatment. In contrast, the exploration decrement following stress was In contrast, the exploration decrement following stress was abolished by AMPH or HAL treatment from days earlier. The results are discussed in relation to the interaction of stress and sensitization (Antelman, et al., <u>Science</u> 207:329, 1980) and the potential involvement of stimulus filtering in sensitization (Kokkinidis & Anisman, <u>Psychol. Bull</u>. 88:551, 1980). Supported by NIH-MBRS grant 2-S06-RR-08066-12.

162.6 CONDITIONED PLACE PREFERENCE FROM INTRA-ACCUMBENS BUT NOT CAUDATE OR AMYGDALA AMPHETAMINE INJECTIONS <u>Geoffrey D. Carr\* and Norman M. White</u>, Department of Psychology, McGill University, 1205 Dr. Penfield Ave., Montreal, Canada, H3A 1B1.

Amphetamine administration has been demonstrated to be rewarding in rats using both the self-administration paradigm and the conditioned place preference paradigm (conditioned reinforcement). Some studies have suggested that amphetamine-induced stimulation of dopaminergic activity in the nucleus accumbens mediates the reward. Selective lesions of the dopamine terminals in the accumbens using the neurotoxin 6-hydroxydopamine attenuate amphetamine self-administration and place preference. Further, rats are reported to lever press for amphetamine injections into the accumbens. The present study was designed to determine if injections of amphetamine directly into the accumbens are rewarding by using the conditioned place preference paradigm. We further examined whether the possibly rewarding effects are specific to the accumbens or could be obtained from other dopamine terminal areas (caudate nucleus; amygdala). Rats received an injection of amphetamine (10ug in 0.5ul) through a cannula aimed at one of the three brain sites and were then placed (randomly assigned) into one of two distinctive environments for 30 minutes. The following day, they were injected with saline and placed into the other environment. After twelve such pairing days, they were given a free choice between the environments (via an open shutle box) and the time spent in each was recorded. The rats that had received the accumbens injections showed a significant preference for the amphetamine-paired environments were counterbalanced across drug conditions). In contrast, there was no preference (or aversion) induced by either the intra-caudate (t=.57, df=8, p > .05) or intra-amygdala (t=.20, df=17, p > .05) injections. The data demonstrate that stimuli paired with amphetamine injections in the accumbens become conditioned reinforcers themselves. This is interpreted as suggesting that amphetamine-induced stimulation of dopaminergic activity in the accumbens produces some type of rewarding effect. The failure of the amygdala and caudate rats to show 162.7 STRESS PROVOKED ENHANCEMENT OF AMPHETAMINE ELICITED PERSEVERATION <u>H. Anisman, D. Hoffman\* and R. Zacharko</u> (SPON: P.E. Wainwright), Dept of Psychology, Carleton University, Ottawa, Ontario KIS 5B6, Canada.

Reexposure to a stressor or cues associated with a stressor will increase the utilization of brain norepinephrine and dopamine in selected brain regions, suggesting that the mechanisms subserving the neurochemical alterations are subject to conditioning or sensitization. The behavioral effects of amphetamine were assessed in order to determine whether previous application of stressors would likewise influence the response to the drug treatment. Following administration of d-amphetamine mice exhibit a perseverative tendency in which they tend to visit successively two arms of a symmetrical Y-maze. Exposure to acute shock immediately prior to testing resulted in an appreciable enhancement of the perseverative tendency engendered by the drug. Such an effect occurred irrespective of whether or not the shock was administered in the presence of cues similar to those present in the environment in which perseveration was assessed. Moreover, it appeared that the organism's ability to cope with the stressor through behavioral means was fundamental in provoking the subsequent perseveration. In particular, escapable shock did not enhance the perseverative tendency, while a comparable amount of inescapable shock, applied in a yoked paradigm, augmented the amphetamine-elicited perseveration. Exposure to an uncontrollable stressor was also found to enhance the amphetamine elicited peseveration when testing was conducted 72 hr following the stress session. Such an effect, however, was evident only when the environment in which shock was administered was similar to the test environment. Long-term effects of the stressor were not evident when the stress and test environments were dissimilar. It is suggested that stressful events influence the subsequent response to amphetamine owing to conditioning factors, although a potential role for sensitization cannot be definitely excluded.

162.8 A BEHAVIORAL ANALYSIS OF THE EFFECTS OF AMPHETAMINE ON PLAY ANF LOCOMOTOR ACTIVITY IN THE POST-WEANING RAT. L.A. Rashin and Mary F. Sutton\*. Dept. Psychology, Amherst College, Amherst, NA 01002. Amphetamine has been shown to canalize or direct the activity of a young rat towards ethologically relevant stimuli. In the fiveday-old, amphetamine increases the speed of approach to and attachment to the nipple of an anesthetized dam, in the 15-dayold drug-induced activity is directed towards an anesthetized adult, however in the juvenile rat amphetamine reportedly disrupts species-specific behaviors such as huddling and play. The present experiments further assessed the effects of amphetamine in the post-weaning rat by measuring drug-induced behaviors in the presence of an alert and anesthetized companion. In Experiment I subjects were videotaped in the presence of an alert nontreated, same-age rat and components of play, a predominant behavior of the post-weaning rat, were recorded. Results confirmed previous reports that low doses of amphetamine (0.5 mg/kg) disrupt play behavior, however in the present experiment higher doses of amphetamine (1.0 mg/kg) did not disrupt play. Further analysis of drug-induced behavior revealed that the 1.0 mg/kg amphetamine-injected rat did not exhibit non-directed activity around the cage but rather engaged in play with the companion, however the flexibility in motor patterns of the drug-treated animal were markedly different than controls. The second experiment confirmed that amphetarine-induced activity is directed towards ethologically relevant stimuli by observing drug-treated 32-35-day-olds either in the presence of an anesthetized same-age rat exhibited their activity around that stimulus. The present experiments suggest (a) that flexible motor patterns are disrupted following amphetamine treatrent and (b) that ethologically relevant stimuli influence amphetamineinduced behavior in the post-weaning rat.

162.9 PHARMACOLOGICAL MANIPULATIONS OF DOPAMINERGIC AND SEROTONERGIC TRANSMITTER SYSTEMS ALTER MATERNAL AGGRESSIVE BEHAVIOR OF CD-1 MICE. J. R. Ieni and J. B. Thurmond. Neuropsychopharmacology Program, Univ. of Louisville, Lou. KY 40292.

Dopamine (DA) and serotonin (5-HT) have been implicated in the regulation of several variants of male aggression. However, little is known about the involvement of these transmitters in female aggression. During the postpartum period, lactating animals display intense fighting behavior toward conspecifics (Svare, B. in D. Gubernick and P. Klopfer (Eds.) Parental Care In Mammals, 1981). This study was conducted to examine the roles of DA and 5-HT on the aggressive behavior of postpartum mice.

Mammars, FORT on the aggressive behavior of postpartum mice. Both p-chlorophenylalanine (PCPA) (200 & 400 mg/kg) and 5hydroxytryptophan (5-HTP) (100 mg/kg) inhibited fighting of postpartum mice; increasing attack latencies and reducing total number of attacks. Combined treatment with PCPA and 5-HTP also suppressed fighting behavior. In addition, mothers treated acutely with 5-HT receptor antagonists displayed less aggressive behavior than control mothers. Mianserin (2 & 4 mg/kg) and methysergide (4 mg/kg) significantly reduced number of attacks emitted by postpartum mice, but failed to alter attack latency. Methiothepin (0.25 & 0.5 mg/kg) also lowered the number of attacks emitted. Biochemically, PCPA depleted brain 5-HT and 5hydroxyindoleacetic acid (5-HIAA), whereas 5-HTP increased brain 5-HT and 5-HIAA. The receptor antagonists had minimal effects on brain 5-HT and 5-HIAA levels, but methiothepin significantly elevated brain dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA).

Catecholamine (CA) synthesis inhibition with alpha-methyl-ptyrosine (AMPT) or DA receptor antagonism with haloperidol reduced postpartum aggression. Conversely, L-dihydroxyphenylalanine (L-DOPA) (50 mg/kg) elevated maternal aggressive behavior. This L-DOPA effect could be blocked by pretreatment with haloperidol. AMPT disrupted CA synthesis; indicated by decreased brain norepinephrine, DA, DOPAC and HVA. L-DOPA elevated brain DA, DOPAC and HVA, while haloperidol elevated brain DOPAC and HVA, as well as 5-HT and 5-HIAA.

The data suggest a facilitatory role for DA, and a complex, possibly facilitatory role for 5-HT in the regulation of maternal aggressive behavior. Pharmacologic manipulations of brain DA and 5-HT affect maternal aggressive behavior and forms of male aggressive behavior (e.g., isolation and territorial) in a similar manner. Thus, transmitter regulation of aggressive behavior in males and females may be similar, although the stimuli and environmental conditions which evoke the behavior are different. 162.10 NEUROLOGICAL DEFICITS INDUCED BY 2-DEOXYGLUCOSE IN 6-HDA-TREATED RATS: EXAMINATION OF THE CRITICAL LOCUS OF DOPAMINE DEPLETION. Abigail M. Snyder\*, Michael J. Zigmond and Edward M. Stricker (SPON: David J. Kupfer). Psychobiology Program, Department of Psychology, University of Pittsburgh, Pittsurgh, PA 15260. The intraventricular administration of large doses of 6-hydroxydopamine (6-HDA) to rats pretreated with systemic desmethylimiparmine (DMI, 25 mg/kg) produces a permanent and extensive (>90%) depletion of dopamine (0A) throughout the orain. Although these animals often recover from the initial akinesia induced by the lesion, neurological deficits are temporarily reinstated by exposure to such stressors as the severe glucoprivation produced by systemic administration of 2deoxyglucose (2DG) (Snyder, Zigmond & Stricker, Soc, Neurosci. Abstr. 8: 362, 1982). The present experiments examine the locus of DA depletion responsible for this disruptive effect of stress. Adult rats (220-280 g) received (=MDA (200 or 250 ug in 20 u)

of DA depletion responsible for this disruptive effect of stress. Adult rats (220-280 g) received 6-HDA (200 or 250 ug in 20 ul, ivt) after treatment with DMI. Several weeks later, when neurological function appeared normal under basal conditions, they were injected with 2DG (500 mg/kg, ip) and were found to become akinetic and cataleptic. These deficits could be reversed acutely either with 1-dopa (60 mg/kg, ip) given after R04-4602 (50 mg/kg, ip), or with apomorphine (0.1 mg/kg, sc). If prior to the administration of 6-HDA rats were pretreated with bupropion (125 mg/kg, ip), a drug which blocks catecholamine uptake, the depletion of DA was reduced and 2DG-induced neurological deficits were prevented.

Rats showing 2DG-induced akinesia had marked DA depletions in striatum, olfactory tubercle, hypothalamus and frontal cortex. When 6-HDA (1 or 2 injections of 3 ug in 4 ul, bilaterally) was administered directly into the DA-containing cell body regions of the midbrain, or into terminal areas in striatum, nucleus accumbens or olfactory tubercle, we found the loss of DA from striatum was predictive of 2DG-induced behavioral effects while the loss of DA from mesolimbic areas was not. Finally, when 6-HDA was placed bilaterally into various portions the striatum, rats receiving lateral and central injections showed 2DG-induced neurological deficits while rats with medial injections did not. Collectively, these results suggest that the loss of DA-containing terminals in the central and/or lateral portion of the striatum may be responsible for the neurological deficits produced by 2DG in rats with 6-HDA-induced brain lesions. (Supported in part by MH-29670.)

162.11 RAPHE HYPERACTIVITY: EVIDENCE FOR A MEDIATIONAL ROLE FOR DOPAMINE. <u>L. Wing, D. Wirtshafter, and K.E. Asin</u>. Department of Psychology, University of Illinois at Chicago, Chicago, Illinois 60680. Considerable evidence indicates that electrolytic lesions of the median raphe nucleus lead to pronounced hyperactivity and more recent studies suggest that dopaminergic mechanisms may be altered following these lesions. For example, Herve et al. (1981) have reported an increase in dopamine utilization in the nucleus accumbens following electrolytic median raphe lesions, and we have reported (Wirtshafter and Asin, 1981) that dopamine antagonists are able to abolish lesion-induced hyperactivity. The current study was designed to investigate in more detail the role of dopamine in the hyperactivity produced by median raphe lesions.

Male, Sprague-Dawley derived rats were administered either the catecholamine neurotoxin 6-hydroxydopamine (-OHDA) (8 ug/4 ul) in 0.2% ascorbate vehicle, or the vehicle alone. Infusions were made into the anterolateral hypothalamus, c udal to the nucleus accumbens. Twelve days following surgery, rats were habituated to a photocell activity cage and two days later, their response to an isotonic saline injection was recorded. Two days subsequent to this, rats were injected with 1.5 mg/kg d-amphetamine, and their locomotive response to the drug was measured for 1 hour. Animals were tested for activity in the open field 2 days later,

Animals were tested for activity in the open field 2 days later, and were then either sham operated or given an electrolytic median raphe lesion. Post-operatively, rats were again tested in the photocell cage for spontaneous levels of locomotor activity and also following an injection of 0.3 mg/kg apomorphine (s.c.).

Preliminary results indicate that 6-OHDA infusions into the anterolateral hypothalamus do indeed abolish the hyperactivity induced by the administration of amphetamine and, in addition, attenuate the hyperactivity produced by electrolytic median raphe lesions. These results are compatible with a dopaminergic involvement in the median raphe hyperactivity syndrome.

162.13 INFLUENCES OF ESTROGEN ON AMPHETAMINE-INDUCED ROTATIONAL BEHAVIOR <u>Jill B. Becker and Terry E. Robinson</u>. Psychology Department and Neuroscience Laboratory, The University of Michigan, Ann Arbor, MI 48109.

> Endogenous ovarian hormones modulate striatal dopamine (DA) activity in the female rat. In behavioral and biochemical studies we have found that striatal DA activity is greatest on estrus and attenuated by ovariectomy (OVX). From these studies we have concluded that estrogen (and/or progesterone) potentiates striatal DA activity in the female rat. However, others have reported that estrogen inhibits striatal DA mediated behaviors (Bédard et al, <u>Neurosci Lett</u>, <u>17</u>, 89, 1980), or that the effect of estrogen is initially inhibitory, followed by potentiation (Cordon, <u>Brain Res Bull</u>, <u>5</u>, 679, 1980). In this study we report that the length of time between estrogen treatment and the behavioral test (amphetamine (AMPH)-induced rotational behavior] is critical to the behavioral response observed. Perhaps of greater importance, we also find that different estrogen administration schedules differentially influence the subsequent behavioral response to a second AMPH injection (i.e. sensitization; see Robinson et al, <u>Brain Res</u>, <u>253</u>, 231, 1982). Female rats received unilateral 6-OHDA lesions of the substan-

> Female rats received unilateral 6-OHDA lesions of the substantia nigra and were ovariectomized 2 weeks later. Two weeks after OVX hormone injections began. One group received oil injections (OIL). The other 3 groups received 5  $\mu$ g estradiol benzoate (EB) daily for 4 days. One of these was tested 4 h after the last EB injection (EB:4h), another 24 h after the last EB injection (EB:24h), and the third 4 days after the last EB injection (EB:4d). For the behavioral test, each animal received 2.5 mg AMPH/kg and turning was recorded for 2 h. The entire procedure was repeated 2 weeks later.

During the 1st test, there was no difference between OIL and EB:24h. However, rats with EB:4h or EB:4d turned more than animals with OIL or EB:4h. This suggests that there is a very rapid potentiation of AMPH-induced rotational behavior 4 hours after EB, as well as a long-term potentiation seen 4 days later. During the 2nd behavioral test all groups turned significantly more than they did during the 1st test, except for EB:24h. Therefore, the apparent inhibitory effect seen 24 h after EB exposure may be due to an interaction between estrogen and the effect of repeated drug injections. We conclude that estrogen can potentiate striatal DA activity and caution that the behavioral paradigm used, and especially the use of repeated drug injections, should be very carefully considered when evaluating the effects of estrogen on striatal DA activity.

- 162.12 ASYMMETRY AND SEX DIFFERENCES IN THE EFFECTS OF UNILATERAL DOPAMINE DEPLETION ON BODY WEIGHT REGULATION. Terry E. Robinson, David M. Rock\* and Jill B. Becker. Psychology Dept. and Neuroscience Program, University of Michigan, Ann Arbor, MI 48109. The aphagia, adipsia and other regulatory deficits so commonly seen after bilateral lateral hypothalamic lesions or brain dopamine (DA) depletion also occurs in a less severe form following unilateral lesions or DA depletion. However, because there is an endogenous asymmetry in the nigrostriatal DA system we suspected that the effects of unilateral DA depletion or regulatory behaviors may depend on which side of the brain is damaged. To investigate this hypothesis we screened intact rats for amphetamine (AMPH)-induced rotational behavior and then operationally defined one hemisphere as "dominant" (D) for rotational behavior (the side contralateral to the preferred direction of rotation), and the other as non-dominant (ND). The animals were then pretreated with desipramine and injected with 6-OHDA (3.5-8 µg/4 µl) into either the D or ND substantia nigra. Both male and female rats were tested. After surgery every animal was weighed daily for 25 days. At least 30 days after surgery the response to two regulatory challenges (2-deoxy-d-glucose and hypertonic saline) was assessed, as was open field behavior and AMPH-induced rotational behavior. The effects of unilateral DA depletion on body weight regulation depend on at least 3 factors: (1) whether the D or ND substantia nigra is damaged; (2) the extent of the DA depletion; and (3) the sex of the animal. For example, male rats with partial DA depletions on the D sub. KDA depletion and MD-sided lesions (X DA depletions on body weight were very different (F=7.76, pc0.02). More complete DA depletions (x=98%) resulted in a chronic weight reduction in body weight following both D and ND-sided lesions (vDA depletions (>95%) produced chronic body weight changes, and although complete DA depletions (i=0.000000000000000000
- 162.14 NEONATAL 6-HYDROXYDOPAMINE ATTENUATES THE NEURAL AND BEHAVIORAL EFFECTS OF ENRICHED REARING IN THE RAT. L. O'Shea\*, M. Saari\*, B.A. Pappas, R. Ings\* and K. Stange\*. Depts. of Psychology, Nipissing U., North Bay and Carleton U., Ottawa, Ontario.

Critical periods during which the brain is shaped by experience may require intact functioning of the noradrenergic system originating from the locus coeruleus (Kasamatsu and Pettigrew, <u>Science</u>, 194:206, 1976). Since the raising of rats in enriched environments increases their cortical weight, alters a number of measures of brain morphology and chemistry and facilitates maze learning, we determined here if the neonatal loss of forebrain norepinephrine (NE) would attenuate the effects of such rearing.

Newborn male rats were administered subcutaneous 6-hydroxydopamine (6-OHDA) so as to deplete forebrain NE. After weaning at 25 days, half of the rats were raised for 35 days in an enriched environment and the other half were raised under normal isolated conditions. Subsequently the 6-OHDA rats and their vehicle controls were trained in a Lashley type III maze and then sacrificed for assay of regional brain weights and brain catecholamines. These procedures were carried out by experimenters who were blind to the treatments to which the rats had been assigned. Enriched rearing (as compared with the normal rearing) was found to affect several variables for the vehicle injected rats. None of these effects were observed, however, in the 6-OHDA rats (whose cortical and hippocampal NE levels were reduced to 24 and 8% of normal, respectively) that enriched rearing: 1) enhanced acquisition of the maze habit, 2) increased the weight of the telencephalon, 3) decreased the weight of the hypothalamus, 4) elevated hypothalamic dopamine levels and 5) elevated dopamine levels in a posterior cortical sample which also contained the amygdala.

In general our findings for the effects of enriched rearing in the vehicle injected rats are consistent with previous reports of the consequences of environmental enrichment. The striking insensitivity of the neonatal NE depleted rats to such enrichment leads us to conclude that forebrain NE plays a permissive role in the behavioral, neurochemical and neuromorphological alterations induced by environmental manipulations early in life. This conclusion is congruent with the results of Kasamatsu and Pettigrew (op. cit.), who demonstrated that NE was essential for monocular eye occlusion to reduce binocular responsiveness of visual cortical neurons in the cat. Thus, as they suggest for the cat, the rat apparently also requires the integrity of forebrain NE innervation for at least some aspects of the shaping of the brain by early experience.

METHOD FOR THE IDENTIFICATION OF SEROTONIN-CONTAINING NEURONS IN 162.15 SINCLE UNIT STUDIES IN FREELY MOVING CATS. V.M. Trulson and M.E. Trulson. Dept. of Pharmacol., Marshall Univ., Sch. of Med.,

Recent studies have examined the physiological and pharmacological properties of single units in various raphe nuclei of freely moving cats. These cells are presumed to be serotonin (5HT)-containing neurons, since the raphe nuclei contain a large number of serotonergic units. The serotonergic nature of these units, how-ever, has not been conclusively demonstrated. The present report describes a method for identifying these neurons. A movable microdescribes a method for identifying these neurons. A movable micro-drive, consisting of 4-32 $\mu$  dia. Formvar coated nichrome wires glued to a center glass micropipette (tip dia., 2-4  $\mu$ ) was stereotaxically positioned above the nucleus raphe dorsalis (RD), nucleus raphe pallidus (RPA), or nucleus centralis superior (NCS), and cemented to the skull. The micropipette was filled with a solution of L-typto-phas  $(10^{-1}M)$ . Gross electrodes for recording the EEG, EMG and EOG were also implanted. After recovery from the anesthesia, the microelectrode bundle was advanced until a unit was isolated. Unit activity was recorded across the sleep-waking cycle, its response activity was recorded across the sleep-waking cycle, its response to phasic auditory and visual stimuli was tested, and then an injec-tion of 5-methoxy-N,N-dimethyltryptamine (5MeODMT, 50-250  $\mu$ g/kg, i. m.) a direct-acting 5HT agonist, was given, and unit activity was recorded for 1 h post-injection. The cat was anesthetized with chloral hydrate (400 mg/kg, i.p.), a tube was connected to the top of the micropipette, and for 20 min. 4 Kg/cm<sup>2</sup> of pressure was applied using a pneumatic pump, in order to eject tryptophan. A 20  $\mu$ A direct current was passed through the recording electrode to mark the recording site and the havin was removed and processed mark the recording site, and the brain was removed and processed for 5HT fluroescence histochemistry according to standard techniques. for 5HT fluroescence histochemistry according to standard techniques. Coronal brain sections containing the recording loci were examined under a fluorescence microscope at 400 nm excitation and 510 nm emission wavelengths. These studies revealed that recording loci located adjacent 5HT fluorescing neurons had the following proper-ties: They discharged in a rhythmic pattern at a rate of 2-6 spikes/ sec during waking; their activity decreased during slow-wave-sleep and showed at least a 70% decrease during REM sleep; neurons in the RD and NCS were driven by phasic auditory and visual stimuli, while RPA neurons were unresponsive to these stimuli; and the activity of RD and NCS neurons was suppressed by low doses (50 µg/kg) of 5MeO-MT while RPA neurons were inhibited only w high doses (250 µg/kg). DMT, while RPA neurons were inhibited only by high doses (250 µg/kg) of the drug. Interestingly, some neurons in the NCS displayed slow, rhythmic discharge rates and were inhibited by low doses of 5MeOMDT, Thythmic discharge rates and were inhibited by low doses of bmedual but were not excited by auditory or visual stimuli, nor was their activity significantly decreased during REM sleep. These neurons showed no 5HT fluroescence, indicating that they were non-serotoner-gic cells. Thus, not all NCS neurons that display a slow, thythmic firing rate and are inhibited by low doses of 5HT agonists are serotonergic neurons.

TRANSPLANTATION OF FETAL NORADRENERGIC NEURONS INTO DORSAL BUNDLE-LESIONED ADULT RATS: EFFECTS ON HABITUATION, LEARNING AND MEMORY. <u>Timothy J. Collier, Don M.</u> Gash, and John R. Sladek, Jr. Dept. Anatomy, Univ. Rochester Sch. of Med., Rochester, NY 14642. 162.17

Med., Rochester, NY 14642. Transplantation of fetal neurons as a form of replacement therapy for behavioral and physiological deficiencies produced by brain lesions in adult animals has yielded promising results in initial studies. One area of interest is whether neuronal grafts can influence complex cognitive functions such as learning and memory. Central noradrenergic projections to hippocampus and cortex represent one class of neurons believed to influence behavioral plasticity, possibly via modulation of arousal and attention. We studied the effects of bilateral 6-hydroxydopamine lesions (6  $\mu$ g in 1.5  $\mu$ I) of the dorsal norepinephrine system, and compensatory grafts of fetal (16 days gestation) noradrenergic neurons into the lateral ventricle/dorsal hippocampus, upon habituation, learning and memory of a T-maze rewarded alternation habit. upon habituation, learning and memory of a T-maze rewarded alternation habit. An initial series of dissections was undertaken to verify the location of locus coeruleus neurons in the 16 day gestation fetus. Using the maps of Seiger and Olsen (Z. Anat. Entwickl.-Gesch. 140, 281-318 (1973)), blocks of tissue roughly 1.5 mm on a side were dissected from the dorsal brainstem at the level of the pontine flexure. The presence of monoamine neurons in this area was verified by immersion fixation with fluorescence microscopy. With reliable location and dissection of noradrenergic neurons available, the study of behavioral effects of grafts commenced. Behavioral testing began 5 months post-surgery. Latency to eat a novel food in the novel T-maze environment was used as an index of habituation. Food-deprived subjects were exposed to the situation for a limited time each day and had to meet a criterion of situation for a limited time each day and had to meet a criterion of immediate (45 sec.) food consumption. Unoperated controls (n=3) habituated rapidly (median =5 days) compared to lesioned animals (n=3; 12 days). Lesioned animals hosting grafts (n=3) required an intermediate length of time (8 days) to habituate to the novel circumstances. Likewise, when acquisition of the alternation habit was examined, animals with grafts fell between the behavioral extremes represented by lesioned and control groups (median days to acquisition: lesioned=7, lesioned + graft=11, controls=14). No significant difference in memory performance was detected. Following completion of ongoing behavioral studies subjects will undergo histofluorescence analysis of lesion-induced denervation and the extent of reinnervation by grafted neurons. The results suggest that noradrenergic neurons transplanted near the dorsal hippocampus can partially compensate for the behavioral deficits produced by dorsal bundle lesions. Furthermore, this paradigm suggests that the dorsal noradrenergic system may participate in the behavioral adjustments associated with habituation and learning, with less influence on processing of recent memory. STATE DEPENDENT EFFECTS OF PERIPHERAL EPINEPHRINE ADMINISTRATION 162.16 ON THE EXTINCTION OF LEARNED FEAR. <u>M. A. Downen and R. A. Jensen</u>. Developmental Biopsychology Laboratory, Southern Illinois Univer-sity, Carbondale, IL 62901.

Systemic administration of epinephrine (E) and other agents that cause peripheral arousal reliably produce facilitation of the acquisition and retention of avoidance behavior. However, the effects of these agents on the extinction of avoidance behavior. However, the effects of these agents on the extinction of avoidance responses has not been extensively studied. Although there is a consider-able body of literature dealing with the effects of ACTH and other peptides on the extinction of avoidance responding, information on the effects of catecholamines on the forced extinction of learned

Fear is lacking. Earlier findings from our laboratory indicated that peripheral E administration impairs the extinction of an active avoidance response. Conversely, administration of E enhanced the extinction of an inhibitory avoidance response (<u>Neurosci. Abs.</u>, 1982, <u>8</u>, 148).

To further study these effects and to determine whether state dependency may account for some of these findings, E or saline was administered prior to training and also before the extinction trials. In the present experiment, five groups of 90 - 140 day trials. In the present experiment, five groups of 90 - 140 day-old male Long-Evans rats were injected with saline or 0.1 mg/kg E immediately prior to training in an inhibitory avoidance task with a 0.75 mA, 1.0 sec foot-shock. Twenty-four and 48 hours later, animals were again injected with either saline or E immediately animals were again injected with either saine or i immediately prior to a forced extinction trial. This extinction trial consis-ted of being placed for 6 minutes in the portion of the training apparatus in which shock had previously been delivered. Retention was measured 24 hours after the second extinction trial. On test day, the saline-treated extinguished control animals Retention

showed significantly shorter latencies to re-enter the area of the apparatus in which they previously had been shocked than did the saline-treated non-extinguished control rats. This verified the effectiveness of our extinction procedure. Animals that were treated with E prior to both the training and the extinction trials exhibited significantly longer retention latencies as com-pared to saline-treated controls. Animals that received either saline before training and E before extinction, or E before training and saline before extinction did not differ significantly from saline-treated extinguished controls.

The pattern of results seen here suggests that some of the ef-fects of epinephrine administration on the extinction of learned fear may be due to state dependency rather than through a direct effect of peripheral catecholamine systems on learning and memory processes. Current investigations are aimed at assessing the processes. Current investigations are aimed at assessing one effects of amphetamine administration and adrenal medullectomy on

LESIONS IN ASCENDING NORADRENERGIC PATHWAYS AND WHEEL-RUNNING ACTIVITY. W. E. Gladfelter, Dept. of Physiology, West Virginia University Medical Center, Morgantown, WV 26506. The placement of bilateral electrolytic lesions in the ventro-lateral hypothalamus (LH) of rats produces a marked decrease in 162.18

lateral hypothalamus (LH) of rats produces a marked decrease in wheel-running activity. Ascending noradrenergic fibers may be damaged by these lesions. An experiment was done to determine whether extra-hypothalamic damage to these fibers can produce a decrease in wheel-running activity similar to that observed after placement of electrolytic LH lesions. Male Sprague-Dawley rats (24) were housed individually in activity cages, consisting of a small living compartment, and an activity wheel with a mechanical counter. The cages were kept in a room in which temperature was maintained at 21  $\pm$  2°C and the room lights were on a 12 hour on-off cycle. Water was present at all times but food was restricted to maintain body weight at 280  $\pm$  5 grams throughout the experiment. After weekly wheel-running activity was measured for a control period of 8 weeks duration, midbrain electrolytic or chemical lesions were placed in either the ascending ventral or dorsal noradrenergic pathways, or in both The second seco content. The midbrain of each brain was placed in 10% formalin solution and prepared for histological verification of the lesion sites.

Sites. Postoperative wheel-running activity was not significantly decreased below that of controls in any of the lesion groups. But a few individual rats in each group did have a decrease in wheel-running activity that was greater than that of any control rat. However, there was no significant correlation (Spearman's rank correlation) between the magnitudes of the changes in postopera-tive wheel-running activity and the level of hypothalamic noradre-nalin or dopamine, or caudate dopamine content. CENTRAL NORADRENERGIC NEURONS: CORRELATION OF SPONTANEOUS ACTIVITY WITH SYMPATHETIC TONE. <u>P.B. Reiner and A.R. Morrison</u>, Labs of Anatomy, School of Veterinary Medicine, University of 162.19

Pennsylvania, Phila, Pa., 19104 A subpopulation of neurons scattered throughout the dorsolateral pontine tegmentum, and especially within the noradrenergic cell-rich nucleus locus coeruleus (LC), are virtually silent during paradoxical sleep (PS). We have investigated two hypoduring paradoxical sleep (PS). We have investigated two hypo-theses which might explain this phenomenon. The first is that the silence of these neurons during PS is functionally linked to the antigravity muscle atonia which characterizes that state. To test this, we have recorded LC neuronal activity in cats in which muscle tone persists during PS, the PS without atonia prepara-tion. We have found 2 cells in the LC which are silent during PS without atonia and are otherwise indistinguishable from our without atonia and are otherwise indistinguishable from our larger group of 29 PS-off cells in normals. Although pontine lesions which release muscle tone during PS may alter the firing of some neurons during PS, these data indicate that at least some central noradrenergic neurons are silent while muscle tone per-sists. Furthermore, while attemting to characterize these neurons pharmacologically with the alpha-adrenergic agonist clonidine, a potent inhibitor of central noradrenergic neurons, we noted that muscle tone persisted throughout the period of inhibition of LC neuronal activity. Thus we have identified at least two instances in which we can dissociate the silence of these neurons from muscular atonia.

We have also tested the hypothesis that the silence of LC neurons during PS is functionally linked to the reduction of sympathetic tone (SYM) which has been reported to occur during that state. We have confirmed, via tripolar nerve cuff rethat state. We have confirmed, Via tripolar herve cuit re-cordings, that there is indeed a tonic reduction of cervical SYM during normal PS. Although we have no direct recordings of SYM during PS without atonia, our indirect evidence is consistent with the notion that SYM is reduced in this state as well. For example, during both normal PS and PS without atonia, the nicti-tating membrane is prolapsed and the pupil is miotic. As noted being clunding which is thought to got as an arti-humantarism above, clonidine, which is thought to act as an anti-hypertensive agent at least partly through sympatholytic effects, inhibits the spontaneous activity of central noradrenergic neurons. Thus we have been unable to dissociate the silence of central NA neurons from reductions of SYM. These data tentatively suggest a functional link beteen the activity of central noradrenergic neurons and peripheral SYM.

HYPERKINESIS IN RATS SELECTIVELY PRODUCED BY INTERMEDIATE SIZE

CENTRAL NORADRENERGIC NEURONS: KOLLIKER-FUSE NEURONAL ACTIVITY 162.20 VARIES ACROSS BEHAVIORAL STATE. <u>T.D. Parsons</u>\*, P.B. <u>Reiner and</u> <u>A.R. Morrison</u> (SPON: R. Miselis) Labs of Anatomy, School of Veterinary Medicine, Univ. of Penn., Phila., Pa.,19104

Veterinary Medicine, Univ. of Penn., Phila., Pa., 19104 We have confirmed that neurons in both the locus coeruleus (LC) and the lateral parabrachial nucleus vary their firing rate across behavioral state, becoming virtually silent during para-doxical sleep (PS). These neurons have been presumed to be noradrenergic on the basis of physiological criteria coupled with their anatomical localization to an area containing a large, albeit heterogeneous, population of noradrenergic (NA) neurons. albeit heterogeneous, population of noradrenergie (NA) neurons. We now report that neurons located in the Kolliker-Fuse (KF) nucleus, at the far lateral edge of the cell group designated A7 by Dahlstrom and Fuxe, also vary their firing rate across beha-vioral state in a manner very similar to cells lying more medially in the pontine tegmentum.

ly in the pontine tegmentum. We have recorded 10 cells in the KF of the freely-moving, unanesthetized cat. Four cells were classified as PS-off cells using criteria identical to those used for neurons in the LC. Mean firing rates across behavioral state were: AW=42.75, QW=24, SWS=8.25, PS=0.5 spikes/min. These neurons, like PS-off cells in the LC, were easily and consistently driven by auditory stimu-li. In addition to these anatomical and physiological data, we have also begun to classify these neurons pharmacologically. Clonidine, a potent alpha-adrenergic agonist, is reported to silence central noradrenergic neurons in acute preparations, presumably through the activation of autoreceptors. In unanes-thetized cats, we have found small doses of clonidine (3-5 ug/kg,

I.V.) to inhibit the activity of 3/3 PS-off cells tested in KF. These data lend credence to the notion that the PS-off cells found both within the LC and throughout the dorsolateral pontine tegmentum are indeed noradrenergic. Furthermore, anatomical stu-dies have shown that different NA cell groups may have different therminal fields, thereby suggesting different functions. Never-theless, our electrophysiological results indicate that at least with respect to behavioral state, there appears to be functional homogeneity among some central NA neurons. 162.22 HALOPERIDOL DISRUPTS THE SPATIAL PATTERNING OF EXPLORATION BY

RATS. L.M. Adams\* and M.A. Geyer. (SPON: E. Battenberg). Dept. of Psychiatry, Univ. of Calif., San Diego, CA 92093. Despite numerous reports of the ability of haloperidol (HAL) to antagonize the behavioral effects of dopamine-agonist drugs, little is known of the effects of HAL alone, particularly in low doses.

doses. Rats were treated with saline or 15  $\mu$ g/kg HAL, returned to holding cages for 20 min, then injected with saline or 60  $\mu$ g/kg of the dopamine agonist lisuride 10 min before being placed in a 12x24" behavioral pattern monitor where crossovers, rearing and holepokes were monitored. Routes of locomotion were reconstructed from stored sequences of X-Y position changes. Fifteen  $\mu$ g/kg HAL produced a slight increase in all activity measures (significant in the last half of the hour session), yet reduced by 50% the hoveractivity induced by lisuride. HAL also reduced by 50% the hyperactivity induced by lisuride. HAL also produced a marked disruption of the normal patterning of exploration. The normal progression from circling the perimeter to traversing through the center, and finally establishing a "home" corner from which excursions are made along a small set of preferred routes was not seen in HAL-treated rats. Beyond the first 10 min, rats treated with HAL exhibited complex, contorted first 10 min, rats treated with HAL exhibited complex, contorted routes of locomotion, with an apparent disregard for distinctions between center and periphery (see below). Additionally, they failed to establish a "home" corner or preferred route of locomotion. This effect of 15  $\mu$  g/kg HAL was replicated in a subsequent dose-response study. Further, HAL's disruption of exploratory patterns was also seen at doses of 5 and 45  $\mu$  g/kg, while 135  $\mu$ g/kg HAL completely suppressed locomotion beyond the first 5 min of the session. Further data on the dose-dependency of HAL's effects on activity measures will be presented. The possibility that disruption of spatial patterns by low doses of HAT is related to nigral activation via DA autorecentors will be HAL is related to nigral activation via DA autoreceptors will be discussed. Supported by NIDA02925.

15 ug/kg HAL 40-60 min from test start

162.21 RIGHT OCCIPITAL CORTICAL SUCTION LESIONS. K.L. Kubos\*, T.H. Moran\*, K.M. Saad\*, P.R. Sanberg and R.G. Robinson (SPONS: G.D. Pearlson) Dept. of Psychiatry and Behavioral Sciences, Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205. We have previously reported that right middle cerebral artery (MCA) ligation has profound effects upon behavior, as well as catecholamine concentrations (Robinson and Coyle, 1980) and produces a fronto-cortical infarction approximately 2mm in diameter. Conversely, left lightion, while producing a comparable 2mm ischemic lesion, was without effect. A subsequent investigation (Pearlson and Robinson, 1981) found that comparably placed right hemispheric (RH) suction lesions averaging 1.25mm in diameter also induced behavioral and biochemical effects similar to those produced by the ischemic lesions. Further investigation indicated that the ability of 1.25mm RH suction lesions to induce behavioral and biochemical alterations diminished as the distance from the frontal pole increased (Pearlson, et al., 1982). The efficacy of frontal compared with posterior lesions in producing bio-behavioral alterations has been postulated to be related to the relative anterior compactness of backward coursing cortical NE fibers and the consequent greater damage to these fibers by anterior ablations. We therefore examined the effects of producing 0.7. 1, 1.5 or 2mm diameter suction lesions in rat occipital cortex The previous hypothesis predicted that posterior lesions would need to exceed the size of anterior lesions to produce comparable effects upon NE and therefore locomotor activity. In agreement with this hypothesis we found that the larger the area of aspirated tissue, the greater was the NE depletion from the ipsilateral frontal cortex. However, only the 1mm diameter lesion which produced the third largest NE depletion induced resion which produced the third largest NE depletion induced hyperactivity as measured in running wheels. Thus, while the largest (2mm) diameter lesion produced the greatest NE depletion, only the third largest (1mm) ablation studied induced hyperactivity. These results indicate that the ability of the posterior cortical lesion to produce hyperkinesis is independent of its effects on cortical NE.
THE ROLE OF NORADRENALINE IN TASTE AVERSION LEARNING IN THE RAT. L.T. Dunn\*and B.J. Everitt\* (SPON. European Neuroscience Assoc-iation) Dept. of Anatomy, University of Cambridge, Cambridge, U.K. Previous reports have inconsistently implicated cortical nor-163.1 adrenaline in the extinction but not the acquisition of learned

taste aversions, as well as in extinction in certain other instru-mental learning situations. However in these studies cortical noradrenaline was manipulated using either electrolytic lesions or, in those cases where neurochemical lesions were employed, have resulted in large depletions of hypothalamic as well as cortical noradrenaline

Consequently we undertook a series of studies using 6-hydroxydopamine lesions of either the dorsal noradrenergic bundle (DNAB) innervating primarily cortex, or the ventral moradrenergic bundle (VNAB) innervating primarily hypothalamus. Typically the DNAB lesion produces a 95% depletion of cortical moradrenaline accomp-anied by a 50% depletion in the hymothalamus whilst the VNAB lesion produces 70% depletion of hypothalamic and 20% depletion of cortical noradrenaline, as measured by high performance liquid chromatography with electrochemical detection.

The effects of these lesions were studied in a variety of paradigms using 23 hour fluid deprived male hooded rats. 0.2% Saccharin solution was used as the conditioning stimulus and 0.15 M LiCl (20ml/Kg) as the unconditioned aversive stimulus, given in a single i.p. administration immediately following the conditioning trial. Using a single bottle no choice test no differences were

observed in volume of fluid ingested following the DNAB lesion whilst a deficit in extinction was found in the VNAB lesioned animals. This effect was replicated using the more sensitive two bottle test where the animals are given a choice between saccharin and water.

These results may reflect a true extinction effect similar to that claimed to follow depletion of cortical noradrenaline. Alternatively, they could represent an enhanced acquisition of the massociation between the taste and subsequent illness, initially masked by a floor effect, due to some change in sensory processing or change in emotionality which have both been proposed to follow VNAB lesions.

BEHAVIORAL ALTERATIONS FOLLOWING REPEATED EXPOSURE TO 163.2 UNCONTROLLABLE FOOT-SHOCK OR DESMETHYLIMIPRAMINE. <u>R.M.</u> <u>Facharko, N.J. Bowers</u>, <u>C. Prince</u>, <u>and Hymie Anisma</u>. Dept of Psychology, Carleton University, Ottawa, Ontario K1S 5B6, Canada. It has been postulated that following repeated application of uncontrollable stressors several adaptive neurochemical changes occur. Among other things, the synthesis and utilization of norepinephrine (NE) are increased, and subsensitivity of  $\beta$ -NE receptors and dopamine (DA) autoreceptors have been reported. These adaptive neurochemical changes have been proposed as being responsible for the elimination of the behavioral deficits attributable to acute uncontrollable stressors. In a similar fashion, following repeated treatment with tricyclic antidepressants,  $\beta^2$ -NE receptor subsensitivity ensues, and it is thought that the alterations of receptor sensitivity are responsible for the therapeutic efficacy of the drug. Parallels have been drawn between the effects of repeated uncontrollable stressor effects and those elicited by tricyclic antidepressants. That is, both represent a neuronal adaptation which results in blunting of negative affect. In the present investigation the effects of repeated uncontrollable foot-shock and chronic treatment with desmethylimipramine were evaluated on several behavioral paradigms in mice, which are thought to be adequate models of human depressive disorders. Following application of uncontrollable footshock (360 shocks of 2 sec duration, 150 uA) performance was disrupted in a shuttle escape task, a water-swim paradigm ("behavioral despair paradigm") and in responding for electrical stimulation from the nucleus accumbens. These disturbances were not eliminated among mice that received repeated application of the uncontrollable stressor over 14 successive days, Indeed, the behavioral disturbances in each of these paradigms were greatly exacerbated. In contrast, repeated application of desmethylimipramine (5 - 10 mg/kg bid) resulted in reduction of the performance deficits seen in each of these tasks. Chronic DMI has been reported to provoke both  $^{\mathcal{S}}$  -NE receptor subsensitivity, and subsensitivity of DA autoreceptors, whereas repeated footshock results in NE neuronal alterations, without appreciable adaptation with respect to DA neuronal activity, Accordingly, the differential effects of these treatments may be attributable to the alterations of DA autoreceptors provoked by DMI. Moreover, the results suggest that the effectiveness of DMI in antagonizing behavioral disturbances are due to adaptive changes beyond those which occur following repeated stressor application.

BEHAVIORAL AND NEUROCHEMICAL SEQUELAE OF MAGNESIUM DEFICIENCIES. Behavioral Akb Melaconstral Sequence of Hamision Deficiency. K. M. Kantak, N. Hale\*, S. Izenwasser\*, A. Meyers\* and D. Zucker\*, Lab. of Behavioral Neuroscience, Dept. Psychology, Boston Univ., Boston, MA 02215.

Boston, MA 02215. In the present series of experiments, the effects of dietary magnesium (Mg), which was limited to 15%, 25%, 50%, 75% and 100% of the daily requirement, were examined in male and female adult mice for its influence on offensive aggression (using the

resident-intruder paradigm) and brain catecholamine function. The results demonstrated that after 2 weeks, there was a 50% decrease in offensive threat postures and a 55% decrease in offen-sive biting attack in male residents fed the 15% diet. After 6 weeks, these decreases in threat and attack behaviors were sus-tained. Additionally at this time, there was a 36% and 37% de-crease in threat and attack behaviors in male mice fed the 25% diet. These behaviors in male mice fed the 50% and 75% require-ments of Mg were within normal limits of the 100% control. The aggressive behavior of female residents was highly variable and thus analysis revealed no consistent dietary influences. That thus analysis revealed no consistent dietary influences. That these different deficienceis were affecting female physiological processes was evident from data on reproductive sucesses. Female residents fed the 15% diet failed to get pregnant, or after doing so, spontaneously aborted the fetuses. Of females fed the 25% diet, only half delivered live young. However, the average litter size was reduced by one half and all pups died within 2 or 3 days of birth. In the 50%, 75% and 100% diet groups, all females de-livered acreated litters which everying threadling. livered normal sized litters which survived through weanling.

An assessment of catecholamine function was made after 7 weeks on the various Mg deficient diets. To study dopamine function, the amount of stereotyped sniffing induced by 2 mg/kg apomorphine was compared in males and females across groups. A decrease in was compared in males and females across groups. A decrease in the amount of stereotyped sniffing was evident in both sexes fed the 15% and 25% diets. L-amphetamine (1.5 mg/kg) induced loco-motion and rearing was measured to study norepinephrine function. A decrease in the amount of induced motor behavior was evident in males fed the 15% and 25% diets, and in females fed the 15%, 25% and 50% diets. The behavioral changes described above were not related to alterations in the amount of food ingested or body weight level. These measures remained within normal limits throughout the experiments for all groups examined. In summary, a deficiency of Mg limited to 15% and 25% of the

daily requirement reduced offensive aggression in male mice, re-duced reproductive sucesses in female mice and reduced catecholamine function in both sexes. This reduction in catecholamine function may be the basis for the observed decline in offensive aggression.

Supported by Boston University funds for Biomedical Research.

163.4 3H-SPIROPERIDOL BINDING IN DIFFERENTIALLY HOUSED MICE. C.A.

3H-SPIROPERIDUE BINDING IN DIFFERENTIALLE ROUSED FICE. <u>U.R.</u> <u>Wilmot\* and C. VanderWende</u> (SPON: A.Feldstein). Dept. of Pharmacology, Rutgers Univ., Piscataway, NJ 08854. The social isolation of male mice for 4-8 weeks produces a behavioral syndrome characterized by heightened reactivity, increased behavioral sensitivity to central stimulants and intense fighting behavior towards conspecific males. We have previously determined that significant differences in the behavioral responsiveness to amphetamine, apomorphine and phencyclidine of group-housed (GH) and individually-housed (IH) mice were most marked within the first 2 wks of differential housing(DH). To assess whether changes in central dopamine receptor number or affinity contributed to these behavioral differences, regional spiroperidol binding experiments were conducted. Male CF-1 mice were differentially housed, individually or

in groups of 20-25, commencing at 5 wks of age. After 0,14,35,40,45,50 and 60 days, both GH and IH mice were tested for fighting behavior towards an intruder male, olfactory bulbectomized, after which the mice were decapitated, and striatal(STR), limbic(LIMB) and frontal cortex(FC) tissues were taken and pooled from 8-10 mice according to housing condition and the presence or absence of fighting behavior. Tissue samples were frozen at -70C. until used. Saturation isotherms were derived with ligand concentrations ranging from 0.05 to 8 nM.

STR tissue consistently yielded a linear Scatchard plot with no significant differences among the GH from 0-60 days DH, Bmax=  $613\pm14$  fmoles/mg protein and Kd=  $0.34\pm.06$ nM (mean+SEM), whereas the Bmax of IH STR declined to 87% of the GH by 50-60 days of DH with no change in Kd. A different trend was obtained from LIMB and FC tissues. At the onset of DH, Scatchard analysis was best fit by a single site model of lower affinity than the STR site: LIMB- Bmax 121 fmoles/mg prot., Kd 1.2nN, FC Bmax 304 fmole/ $\mathrm{Img}$  prot., Kd 1.9nN, A curvilinear plot was consistently obtained from 14-60 days DH in both GH and IH with a high-affinity site Kd .lnM and low-affinity site Kd 2-3nM. A relative increase in the number of high-affinity sites in the FC of IH mice was noted. These results suggest that the development of different behavioral responses in GH and IH may be accompanied by changes in

spiroperidol binding. JSupported by NIMH Fellowship 5F31MH08873 to C.Wilmot and Busch Foundation Grant to C. VanderWende.

AFFINITY FOR THE DOPAMINE  $D_2$  RECEPTOR PREDICTS NEUROLEPTIC POTENCY IN BLOCKING THE REINFORCING EFFECT OF MFB STIMULATION. Adam Davis\* and C.R. Gallistel (Sponsor: Dr. M. R. Kare) Department of Psychology, University of Pennsylvania, Philadel-163.5

phia, PA 19104. For each of nine neuroleptics, the dose required to block sustained responding for intracranial stimulation of the medial sustained responding for intracranial stimulation of the medial forebrain bundle was determined in the rat. To check whether the blocking of responding was due to effects on reinforcement as opposed to effects on performance factors, the rats were always tested for task-specific extinction of responding by trans-ferring them to another testing box once they refused to respond in the first testing box. With all the neuroleptics, task-specific extinction was not seen in control tests with a general anaesthetic (Chloropent) nor with picrotoxin, a drug that can produce pseudo-extinction. Affinity for the dopamine  $D_2$  receptor (from in vitro studies) predict( neuroleptic botency in blocking reinforcement, whereas affinity for other amineraic in blocking reinforcement, whereas affinity for other aminergic receptors  $(D_1, D_3, \text{the } \blacktriangleleft \text{-} \text{ adrenergic receptors, } S_1, \text{ and } S_2)$ did not.

EFFECTS OF INESCAPABLE SHOCK ON CEREBRAL BLOOD FLOW AND CEREBROVASCULAR PERMEABILITY IN RATS. <u>C.W. Hughes, T. Kent\*</u>, <u>J. Campbell\*, H. Croskell\*, and S.H. Preskorn.</u> Depts. of Psychiatry & Pharmacology, Univ. of Kansas Sch. of Med., Kansas City, KS 66103. Various inescapable shock (IS) paradigms have been suggested as animal models of human perupasershipting disorders. The beba

as animal models of human neuropsychiatric disorders. The behav-ioral deficits observed in these animals have been reproducibly ioral deficits observed in these animals have been reproducibly related to an approximately 20% reduction in norepinephrine (NE) in the locus coeruleus (Weiss et al., <u>Brain Res. Rev.</u>, 1981,3:167). What physiological consequences a depletion of thismagnitude causes is uncertain. We therefore sought to examine this issue by test-ing the effects of IS on the responsivity of the cerebral micro-circulation to metabolic demand. This responsivity appears to be in part regulated by the locus coeruleus and related adrenergic neurone neurons

neurons. A duel label isotope procedure (Irwin and Preskorn, <u>Brain Res.</u>, 1982) was used to simultaneously measure CBF and PS to water. Three groups were tested: IS studied one hour after exposure, IS controls, and untreated animals. Both IS and IS control rats were individually confined in a 15 cm(w) X 46 cm(1) X 50 cm(h) chamber with a 0.3 cm dia grid (spaced 1.5 cm center to center) floor for sixty minutes. The IS treatment consisted of alter-nation periods of 0 em control control to control (space) (10) nating periods of 0.8ma scrambled, constant-current shock (10 secs.) followed by ten seconds of no shock. Following treatment, rats were removed and placed in a holding cage until PS and CBF measurements were made.

ĺ		PS vs CBF	CBF vs PaCO <sub>2</sub>	N
ł	IS Shock	y= .8 + .54x F=119	y =56 + .06x F=90	11
i	Control*	y= .97 + .51x F= 44	y= .05 + .05x F=42	19
I	*Pooled:	no difference betwee	n naive and IS controls	

The table above is based on the average value obtained for the rostral and caudal telencephalon and diencephalon. Examination for regional changes in these individual areas as well as in the medulla-pons and cerebellum are in progress. Preliminary analysis of brain levels of the biogenic amines suggest that alterations in central catecholamines do occur with this treatment. The PS and CBF findings suggest that I treatment which produces approximately a 20% depletion of NE does not alter the regulation of the cerebral microcirculation. These parameters appear to be regulated by the central adrenergic system and such

regulation of the cerebral inferocirculation. These parameters appear to be regulated by the central adrenergic system and such neuromodulation appears to be resistant to a depletion of this magnitude. However, such regulation is undoubtably only one of many functions for this system. (Supported in part by MH-00272 and NS-17252 and the PMAF.)

PIMOZIDE AND CHLORPROMAZINE REDUCE REINFORCEMENT EFFICACY AND 163.6

PIMOZIDE AND CHLORPROMAZINE REDUCE REINFORCEMENT EFFICACY AND MOTOR CAPACITY IN THE RAT. <u>G.M. Heyman\*</u>, <u>D.L. Kinzie\*</u>, <u>L.S.</u> <u>Seiden</u>. (SPON: G. Gudelsky). Dept. Pharmacol. Physiol. Sci., University of Chicago, Chicago, IL 60637. In two experiments, rats (8 subjects per group) responded for water on a series of 5 different variable-interval reinforcement schedules. The relationship between response rate and reinforce-ment mate wate recurately decrement by the ocuration for a montant when the relationship between response rate and reinforce-ment rate was accurately described by the equation for a rectang-ular hyperbola (e.g., the Matching Law, the Michaelis-Menten equation). This equation has two parameters. One is equivalent to the asymptotic response rate, and the other is equivalent to the rate of reinforcement that maintains half-asymptotic respondto the asymptotic response rate, and the other is equivalent to the rate of reinforcement that maintains half-asymptotic respond-ing. Experimental evidence indicates that the asymptotic re-sponse rate measures motor capacity and that the rate of reinfor-cement necessary for half-asymptotic responding measures reinfor-cement effectiveness. Pinozide and chlorpromazine selectively and independently changed both parameters. A 0.1 mg/kg dose of pimozide increased the rate of reinforcement necessary for half-asymptotic responding by about 86%, and a 0.75 mg/kg dose of chlorpromazine increased this parameter by about 46%. However, at these dose levels, neither drug changed the asymptotic response rate by about 20%, and it increased the asymptotic response rate by about 20%. And it increased the reinforcement parameter by an additional 23%. A 1.5 mg/kg dose of chlorproma-zine decreased the asymptotic response rate by about 15% and it increased the reinforcement parameter an additional 63%. Higher doses of both drugs either eliminated responding or disrupted it to the extent that it was not possible to fit a rectangular hyperbola to the response rates. Since an increase in the rate of reinforcement necessary for half-asymptotic responding is equivalent to a decrease in the proportion of responding maintain-ed by a given rate of reinforcement, the lowest doses of pimozide and chorpromatic responding maintainequivalent to a decrease in the proportion of responding maintain-ed by a given rate of reinforcement, the lowest doses of pimozide and chlorpromazine selectively decreased reinforcement efficacy, and the higher doses decreased both efficacy and motor capacity. Using standard deviation scores to measure changes in the para-meters, the ratio of equally effective doses was about 1.0 and 7.5 (pimozide to chlorpromazine). This ratio approximates the ratio of EDS0 values for two different behavioral tests: inhibi-tion of shock avoidance and antagonism of amphetamine induced stereotypy. Comparisons with other experiments in our laboratory support the hypothesis that catecholamines contribute to the physiological processes that mediate reinforcement. For example, support the hypothesis that catecholamines contribute to the physiological processes that mediate reinforcement. For example, amphetamine's effect on the parameters of the matching equation is just the opposite of those of the neuroleptics. REGIONAL BRAIN MONOAMINE LEVELS AND TURNOVER IN AUDIOGENIC SEIZURE SUSCEPTIBLE AND NON-SUSCEPTIBLE MICE. <u>N. Mogharreban\*</u> and C. E. Lints. Dept. of Psychology, Northern IL Univ., DeKalb, IL 60115

DBA/2J mice are genetically prone to audiogenic seizures (ACS) and show a peak susceptibility between 19-21 days of age. Aland show a peak susceptibility between 19-21 days of age. Al-though several studies have reported that these mice have lower brain levels or norepinephrine (NE) and serotonin (5-HT) than seizure resistant strains at the age of peak AGS susceptibility, we have been unable to replicate these findings for whole brain (Lints, C.E., Willott, J.F., Sze, P.Y. and Nenja, L.H., <u>Pharmac. Biochem. & Behav.</u>, <u>12</u>:335, 1980). Because whole brain assays can mask important regional differences, this study compared seizure prone DBA with setzure resistant C57B1/6J mice for both levels and turnover of NE and 5-HT in six discrete regions of the brain. 19-21 day old DBA and C57 littermates of both sexes served as

subjects. Each subject was sacrificed by decapitation and the brain was quickly removed and dissected into brain stem (pons and brain was quickly removed and dissected into brain stem (pons and medulla), cerebellum, caudal midbrain, rostral midbrain, dienceph-alon, and telencephalon. The tissue was then weighed, frozen in liquid nitrogen, and stored in a freezer until assay within two weeks. Each sample consisted of tissue pooled from the brains of six littermates except for the telencephalon, where tissue from only two littermates was included. Following a butanol extraction the amine levels were measured fluorometrically. Turnover was detoreined by measuring the accumulation of NE and STT two hours determined by measuring the accumulation of NE and 5-HT two hours after an i.p. injection of pargyline (400 mg/kg), a monoamine oxidase inhibitor.

At the age of peak AGS susceptibility, no statistically significant differences between the seizure prone DBA and seizure resistant C57 strains of mice were found for either levels or turnover of NE and 5-HT in any of the six brain regions studied. These data support our previous observations made upon whole brain assays.

AGGRESSION AND BRAIN MONOAMINES IN DOMINANT AND SUBORDINATE PIG-163.9 BONS. <u>Irving Goodman, Rosalind Burns</u>\*, <u>Albert Azzaro & David Smith</u> Departments of Psychology, Neurology & Anesthesiology, West Virginia University, Morgantown, WV 26506.

Pairs of male pigeons, when placed in a restricted environment, tend to settle the problem of territorial control with an initial period of aggressive interaction. The resulting victor or dominant member goes on to display such behaviors as bow-cooing, chasing, shoving, wing-slapping and pecking attacks. The subordinate member typically displays avoidance and escape behavior with no apparent vocalization. These roles, once established, are mainapparent vocalization. Inese roles, once established, are main-tained over days of testing, although specific behaviors may vary in intensity and frequency. The present study tried to determine if the concentrations of monoamines (dopamine (DA), norepinephrine (NE) and serotonin (5-HT) within the telencephalon, diencephalon, and brain stem varied in relation to aggressive role and number of

days subjected to aggressive interaction. Video monitored male pairs of prescreened dominant and subord-inate pigeons were tested in a 43 x 90 x 52 cm enclosure over 2 -8 daily sessions, each lasting 15 min. Birds were sacrificed with-in 1 hr following the last observation and high performance liquid chromatographic (HPLC) assays of brain monoamines were carried out soon thereafter. Statistical comparisons of monoamine concentrations in different brain regions within dominant and subordinate tions in different brain regions within dominant and subordinate individuals with those from randomly selected controls (handled but neither screened nor aggression-tested) revealed the following significant comparisons. Subordinate groups tested for 2, 4 or 8 days had higher DA concentrations in the brain stem and higher 5-HT concentrations in the telencephalon. On the other hand, dom-inant birds had elevated NE concentrations in the telencephalon and lowered 5-HT concentrations in the diencephalon.

These findings suggest that, depending upon the aggressive role expressed, (1) monoaminergic concentration shifts affect different brain regions, (2) different combinations of monoamines show concentration changes and (3) both dominant and subordinate role ex-periences are associated with significant concentration changes in in more than one monoamine. Whether the observed levels of mono-amines in dominant and subordinate pigeons represent causal or associational relationships is unanswered by this study.

163.10 SHORT AND LONG TERM EFFECT OF LITHIU: ON ERAIN CATECHCLANINE. <u>D. Ghoshdestidar and N. K. Poddar.</u> Department of <u>Flochemistry</u>, University College of Sciences, University of Calcutta, Calcutta- 700 019, UNIV

INDIA.

Schences, only of Schencetz, Schencetz, Schences, Schences, Schences, Schences, Schenzes, Sch rate of DA and NA, using non-isotopic method, showed that lithium increased the turnover rate of both DA and NA both under short and long term exposures. These results suggest that lithium induced charges in central catecholamine metabolism may have some role at least in part to explain the psychomotor action of lithium in mania.

163.11 NEUROCHEMICAL ADAPTATION FOLLOWING CHRONIC STRESS, J. Irwin and H. Anisman. Dept Of Psychology, Carleton University, Ottawa, Ontario K15 5B6, Canada.

Acute exposure to physical or psychological insults results in increased utilization of brain norepinephrine, and may reduce concentrations of this amine in some brain regions. Following repeated exposure to a stressor a series of adaptive changes occur, including a compensatory increase in NE synthesis, such that the amine reduction is no longer evident. A series of experiments assessed amine utilization and concentrations with repeated exposure to stressors, and determined the persistence of the NE variations following termination of the stressor. A single session of inescapable shock (360 shocks of 2 sec duration, 150uA) increased Inestable shock (Soo Shocks of 2 sectoration, 1500A) increased utilization of NE in hypothalamus, hippocampus, cortex and locus coeruleus, and reduced the concentrations of this amine in some brain regions (primarily hypothalamus). Serotonin (5-HT) concentrations, in contrast, increased in most brain regions examined among mice that received acute shock. Following 14 sessions of shock administered on uncontrast, days addatation use theread acute that ME administered on successive days, adaptation was observed, such that the NE reductions were eliminated, while the 5-HT concentrations approached those of nonstressed animals. Amine concentrations were found to vary with time following chronic stressor termination. Immediately after chronic stressor termination NE concentrations were comparable to those of nonstressed animals. However, within several hours of stressor termination NE concentrations in all regions examined significantly exceeded those of nonstressed mice. The enhanced NE concentrations persisted for as long as 168 hr in hypothalmus, but in the locus coeruleus, hippocampus and cortex the increased NE concentrations were evident for only 24 hr following stressor application, Evaluation of NE utilization determined immediately after chronic stressor application revealed increased utilization of the amine. However, several hours following stressor termination NE utilization rates were reduced relative to nonstressed mice. The enhanced amine concentrations are likely attributable to increased synthesis coupled with reduced utilization of the amine. These data suggest that several adaptive changes occur following repeated stressor application. Upon exposure to the stressor among chronically shocked mice utilization of NE increases in order to contend with the immediate environmental demands. Upon termination of the stressor utilization rates decline, while increased synthesis persists, thereby resulting in greater concentrations of the amine. As a result the organism may be better prepared to deal with impending stresses,

163.12 RAPHE UNIT ACTIVITY IN FREELY MOVING CATS: LACK OF EFFECT OF DI-ETARY FACTORS. M.E. Trulson. Dept. of Pharmacol., Marshall Univ. Sch. of Med., Huntington, WV 25701. Several studies have indicated that central serotonin (5HT) met-

abolism can be influenced by dietary factors. Brain tryptophan, and consequently 5HT metabolism, is regulated by the ratio of plasma tryptophan/competitive neutral amino acids (tyrosine, phenylalanine, leucine, isoleucine and valine). Ingestion of a standard laboratory diet results in no change in brain tryptophan or 5HT metabolism, because this diet contains all of the neutral amino acids. Ingestion of a diet lacking the competitive neutral amino acids but containing tryptophan results in increased brain tryptophan levels and increased 5HT metabolism, while a tryptophan-free diet containing the competitive neutral amino acids decreases brain tryptophan and 5HT metabolism. All of these findings are based on neurochemical studies. The present report examines this issue neurochemical studies. The present report examines this issue more directly, by investigating the effects of dietary manipula-tions of the activity of single 5HT-containing neurons in the dorsal raphe nucleus of freely moving cats. Unit activity was recorded by means of movable 32 or  $64 \mu$  dia. insulated nichrome wires (see Brain Res. 163, 1979, 135-150 for complete methodology). Unit activity was recorded across the complete sleep-wakefullness-arousal continuum, and the cats were then food deprived for 24 h (water was available <u>ad lib</u>). At the end of the 24-h food depriva-tion period, the cat was presented with one of the following diets: (A) standard laboratory cat chow; (B) a diet containing normal amounts of tryptophan but lacking the competitive neutral amino acids: or (C) a tryptophan-free diet containing normal amounts of acids; or (C) a tryptophan-free diet containing normal amounts of the competitive neutral amino acids. Unit activity was minitored for 4 h after the meal. The data revealed that unit activity did not change significantly (2.46  $\pm$  0.13 spikes/sec) during the food deprivation period, as compared to baseline levels (2.59  $\pm$  0.22 depivation period, as compared to baseline levels (2.59  $\pm$  0.22 spikes/sec). Presentation of food resulted in an arousal state, which significantly, but transitly, increased unit activity (3.03  $\pm$  0.10 spikes/sec). Unit activity was not significantly changed from baseline levels following meal ingestion, for any of the three diets tested (Diet A, 2.63  $\pm$  0.18; Diet B, 2.39  $\pm$  0.20; Diet C, 66  $\pm$  0.10 optime(acc).  $2.66 \pm 0.19$  spikes/sec). Neurochemical analyses revealed the following: Diet A resulted in no significant changes in brain tryp-Following: Diet A resulted in no significant changes in brain type tophan (-2.7%), SHT (+3.8%) or SHIAA (-3.2%) from control levels. Diet B resulted in a significant increase in tryptophan (+56.4%), SHT (+12.9%) and SHIAA (+30.7%), while Diet C produced significant decreases in brain tryptophan (-48.6%), SHT (-19.1%) and SHIAA (-34.6%). These data confirm that dietary manipulations produce significant changes in brain tryptophan and SHT metabolism, but the altered SHT metabolism apparently does not change the functional activity of serotonergic neurons, since no changes in raphe unit activity were observed.

THE RELATIONSHIP BETWEEN ELECTRICALLY ELICITED SNIFFING AND 163.13 SELF-STIMULATION IN THE RAT. J. Rossi III and J. Panksepp. Department of Psychology, Bowling Green State University., Bowling Green, OH 43403

Sniffing behavior has frequently been observed to be an unconditional consequence of electrical stimulation of hypothalamic circuits which support intra-cranial self-stimulation (ICSS). The present studies analyzed the relationship between elicited sniffing and ICSS obtained from the same electrodes, and assessed how thresholds of the two measures co-varied after

food deprivation and various pharmacological manipulations Sniffing thresholds were determined by video analysis of restrained rats administered computer-controlled 2 sec, 5uA (sine wave) current steps. Thresholds were determined by 2 successive current steps eliciting sniffing responses. ICSS thresholds and rates were determined for touch responses to an intermittently illuminated aluminum tea-ball in a darkened chamber, during 10 min intervals which were initiate. following 5 rewar ded contacts (.5 sec current trains/contact @ 5uA). At the end of each 10 min period the current was incremented by 5uA. Thres-holds were defined by 80 or more contacts (i.e., pre-determined

1% confidence limit) at two successive current intensities. The average sniffing threshold current for 31 rats with elec-trode placements in the posterior lateral hypothalamus was 14.2uA, and their mean self-stimulation threshold was 16.8uA. 14.200, and their mean self-stimulation threshold was 10.804. These thresholds were reliably correlated [r=.93, p<.001]. For 16 rats with mid-lateral hypothalamic placements the mean snif-fing threshold was 17.500, the average ICSS threshold was 21.800, and these thresholds were also highly correlated [r=.87, p<.001]. There was no reliable difference between the place-

pc.0011. There was no reliable difference between the place-ments for sniffing thresholds, although ICSS thresholds from the posterior sites were found to be reliably lower. Sniffing thresholds were reliably reduced by 24 hrs food dep-rivation, but this maneuver affected neither ICSS thresholds nor rates. Both sniffing and ICSS thresholds were reliably reduced by 48 hrs deprivation. by 48 hrs deprivation, and ICSS rates were reliably elevated. Haloperidol (0.1,0.25,0.5 mg/kg) failed to reliably alter sniffing thresholds. ICSS thresholds were reliably elevated by

the .25 mg/kg dose and no ICSS behavior was observed at any current tested after the 0.5 mg/kg dose.

Demphetamine failed to reliably effect either sniffing or ICSS thresholds at any dose tested  $(\emptyset, 5, 1, \emptyset, 2, 0 \text{ mg/kg})$  although ICSS rates were reliably increased after the two highest doses. These results suggest that there is a relationship between electrically elicited sniffing and ICSS, and that the commonali-

ty of the circuits involved in the expression of each does not extend to the brain dopamine system.

NEURAL SUBSTRATES OF CONDITIONED EMOTIONAL RESPONSE (CER) J.D. 163 14 Lane, D.R. Cherekt and J.E. Smitht. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107; and \*Department of Psychiatry, LSU Medical Center, Shreveport, LA 71130.

71130. To evaluate the neurochemical changes associated with CER and its reversal by acute diazepam, groups of littermate rats were conditioned to associate a CS with footshock. These groups, which included controls for shock history, etc. received nothing, veh-icle or 5 mg/kg i.p. diazepam, and radiolabelled precursors to neurotransmitters of interest (to evaluate turnover). The binding of tritiated QNB and diazepam was also assessed in cortical total particulate membrane preparations. On testday, the presentation of CS elicited CER, suppression and collateral behaviors in the conditioned animals, while diazepam-treated animals did not attend to the CS. After 15 min exposure to the CS, all groups were tot-ally frozen, the brains removed, sectioned and microdissected into discrete regions. There were few changes in content of trans-mitters or metabolites, suggesting that small physiological funct-ional pools were being utilized; however, there were many changes in the turnover of biogenic amines (DA, NE, 5-HT) and amino acids (Glu, Asp, Gly and GABA). In addition, QNB and BZ binding was reduced by CER, and only QNB was partially reversed by diazepam administration (these changes probably represent compensatory reactions to changes in turnover of AC and endogenous BZ ligands) Changes in the CER paradigm were consistent with the activation of a neural circuit in which DA input from the ventral tegmentum and NE input from the locus corrules to the subfculum are dep-ressed, releasing tonic inhibition of Glu efferents to the hippo-campus, which in turn stimulates a Glu pathway to the septum. 5-HT input from the provant cortex is depressed which To evaluate the neurochemical changes associated with CER and ressed, releasing tonic inhibition of Glu efferents to the hippo-campus, which in turn stimulates a Glu pathway to the septum. 5-HT input from the raphe to the frontal cortex is depressed which releases tonic inhibition of Glu efferents to the amygdala, caudate-putamen and preoptic-diagonal band region, which in turn stimulate cholinergic efferents to the cortex (inferred from the QNB binding data). Five changes were related exclusively to the CER paradigm, while the remainder are related to three categories of changes in the presence of diazepam--those unique to the drug, those which reversed the effects of CER, and those which enhanced the effect of CER. The changes due to acute diazepam admini-stration were primarily activation of amino acids and mixed the effect of CER. Ine Changes due to acute drazepain adminin-stration were primarily activation of amino acids and mixed changes in the turnover of the biogenic amines. These cannot so easily be evaluated by circuits because of the potential inter-action of the three categories of changes. Neurotransmitter-specific pathways are modulating the CER paradigm and reversal by benzodiazepines. [supported in part by NIMH MH 31835 (to JDL)]

## TRANSMITTER UPTAKE, STORAGE, AND SECRETION I

[<sup>3</sup>H]MAZINDOL BINDING ASSOCIATED WITH NEURONAL DOPAMINE UPTAKE SITES IN CORPUS STRIATUM MEMBRANES. <u>Jonathan A. Javitch</u>\*, <u>Robert O. Blaustein\* and Solomon H. Snyder</u>. Johns Hopkins University, Depts. of Neuroscience, Pharmacology and Psychiatry, School of Medicine, Baltimore, Maryland 21205. Drugs which inhibit biogenic amine neuronal uptake have been employed to biologic to bool site on broin mombraneo accession

Drugs which inhibit biogenic amine neuronal uptake have been employed as ligands to label sites on brain membranes associated with uptake systems for norepinephrine and serotonin. Mazindol is a potent inhibitor of both norepinephrine and dopamine uptake and is clinically employed as an appetite suppressant. The binding of [<sup>3</sup>H]mazindol to rat corpus striatum membranes appears associated with specific neuronal dopamine uptake sites. Scatchard analysis indicates a dissociation constant (K<sub>D</sub>) of about 18 nM with a maximal number of binding sites ( $B_{max}$ ) of 7.3 pmol/mg protein. The Hill coefficient of 1.0 suggests the absence of cooperative interactions. The absolute and relative potencies of various drugs in competing for [<sup>3</sup>H]mazindol binding to striatal membranes

The absolute and relative potencies of various drugs in competing for [<sup>3</sup>H]mazindol binding to striatal membranes correlate closely with their potencies in inhibiting dopamine uptake into striatal synaptsomes. Mazindol and nomifensine are the most potent agents. By contrast desipramine and imipramine, which are highly potent inhibitors of norepinephrine and serotonin uptake respectively, are very weak inhibitors of both dopamine uptake and [<sup>3</sup>H]mazindol binding sites. Dopamine inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding less potently than it inhibits [<sup>3</sup>H]desipramine binding are less than 15<sup>7</sup> ° of those in the corpus striatum. As a further finding, in rat cerebral cortex membranes the potencies of drugs at inhibiting [<sup>3</sup>H]desipramine binding. This may indicate an association with norepinephrine as well as dopamine uptake sites. [<sup>3</sup>H]Mazindol binding to striatal membrane is dependent on sodium with no binding in the absence of sodium and an apparent Km of 250 mM. The sodium stimulation is due to a change in the affinity of the ligand for its binding site with no change in  $B_{max}$ . No other cations evaluated, including lithium, potassium, rubidium and Tris, can substitute for sodium. The ability to label sites associated with dopamine uptake utilizing [<sup>3</sup>H]mazindol provides a powerful

164.2 BINDING OF THE DOPAMINE UPTAKE INHIBITOR <sup>3</sup>H-NOMIFENSINE TO STRIATAL MEMBRANES. <u>M.L. Dubocovich and N.R. Zahniser</u>. Dept. of Pharmacology, Northwestern Univ. Med. Sch., Chicago, IL 60611 and Dept. of Pharmacology, University of Colorado Med. Sch., Denver, COLOR 2002C2 Dept. of CO 80262.

The tricyclic antidepressants desipramine (DMI) and imipramine The tricyclic antidepressants desipramine (DMI) and imipramine (IMI) appears to exert their therapeutic action by inhibiting the neuronal uptake of norepinephrine (NE) and serotonin (5MT), respectively. Nomifensine, which is also an antidepressant, is more potent than either IMI or DMI to inhibit the neuronal uptake of dopamine in the striatum. Recent studies demonstrated that radiolabeled 3H-DMI and 3H-IMI have an unique high affinity for the neuronal uptake sites of NE and SHT, respectively. In this study we have characterized in striatal membranes a binding site for 3H-nomifensine (S.A.: 45 Ci/mmol, custom synthesized by New Froland Nuclear).

site for M-nomitensine (S.A.: 45 cl/mmol, custom synthesized by New England Nuclear). Binding was determined in washed membranes prepared from rat and rabbit striatum in Tris/ClH buffer (NaCl, 120 mM; KCl, 5 mM; pH 7.4) at 0°C. Samples were incubated for 1 hour, and the and rabbit striatum in Tris/C1H buffer (NaCl, 120 mM; KCl, 5 mM; pH 7.4) at 0°C. Samples were incubated for 1 hour, and the reaction was terminated by dilution with ice-cold buffer and rapid filtration. The binding of <sup>3</sup>H-nomifensine to striatal membranes is time dependent and increased linearly with tissue concentration. Benzotropine (100  $\mu$ M), used to defined specific binding, inhibited 65% of total <sup>3</sup>H-nomifensine was not augmented by pretreatment of the membranes with 300 mM KCl. In membranes from hippocampus, structure with poor dopaminergic augmented by pretreatment of the memoranes with soor mentors in memoranes from hippocampus, structure with poor dopaminergic innervation, benzotropine (100  $\mu$ M) inhibited only 20% of total 3H-nomifensine binding.

SH-nomitensine binding. Competition experiments showed a monophasic reduction of SH-nomifensine binding by unlabeled nomifensine ( $IC_{50}$ : 0.06  $\mu$ M) and benzotropine ( $IC_{50}$ : 0.6  $\mu$ M). <sup>3</sup>H-Nomifensine labels a site in striatum with the following pharmacological profile (affinity): nomifensine > M-1 [4-0H-nomifensine] > benzotropine > M-2 [3 methoxy-4-0H nomifensine] > M-3 [3-0H-4-methoxynomi-fensine] > nortriptyline > 3PPP [3-(3-0H-phenyl)-N-n-propylpipri-dingla > Control pairon > Monopherical = 0 MI dine] - spiperone - phentolamine - dopamine - DMI - tyramine -IMI - norepinephrine - SHT. A highly significant correlation (R:0.96, p < 0.001, n=9) was found between the potency of these drugs for the inhibition of 3H-dopamine uptake in striatal synaptosomes construct in the literature - Theorem reported in the literature. These results suggest <sup>3</sup>H-nomifensine labels the recognition site for the neuronal uptake of dopamine in striatum. The regional distribution and the localization of this binding site is currently under in investigation.

- INTRANEURONAL DOPAMINE (DA) COMPARTMENTALIZATION AND AMPHETAMINE 164.3 (MPH) EVOKED RELEASE. D. Minnema\* (SPON: I.A. Michaelson) Dept. Env. Hlth., Univ. Cinti. Coll. Med., Cinti., OH 45267. Current thought is that DAergic nerve terminals preferent preferentially
  - Current thought is that DAergic nerve terminals preferentially release newly synthesized and/or recently acquired DA relative to long term stored DA, particularly when release is evoked by AMPH. This hypothesis was examined by comparing newly synthesized 14C-DA (dpm) to the total (endogenous) DA released from perfused rat striatal synaptosomes (P<sub>2</sub>). Following a 30 min incubation with 14C-tyrosine, two aliquots of incubate were separately filtered (Millipore). The DA and DOPAC retained on one of the filters required as initial DA credition with and the second s 14C-tyrosine, two aliquots of incubate were separately filtered (Millipore). The DA and DDPAC retained on one of the filters provided an initial DA specific activity (SA) value. The other filter was perfused with normal Krebs-Henseleit bicarbonate buffer (pH-7.4, 370C, flow rate = 0.5 ml/min) for 30 min (spontaneous release) followed by a 40 min perfusion with  $10^{-4M}$  AMPH in buffer. Perfusates were collected at 5 min intervals. Al203 isolated DA and DDPAC were separated by HPLC and quantified by electrochemical detection and LSC. The results show that the SA of DA released during the perfusion is greater than that contained in the P2 on the initial filter (upper graph), indicating a preferential release of newly synthesized DA during spontaneous release of DA evoked slowly declines over time despite a marked release of DA evoked by AMPH (lower graph). Preliminary studies with dual labels sug-gest that the recently taken up DA and the newly synthesized DA behave similarily. The results suggest that the DA released spontaneously or by AMPH is related to the geometry of this releasable pool, where DA closer to the membrane is released first. (Supported by ES-07073, ES01566).

THE EFFECT OF ORGANIC CALCIUM ANTAGONISTS ON RELEASE OF  $({}^{3}H)$  DOPA-MINE FROM AGGREGATE CULTURES OF MIDBRAIN NEURONS. <u>Ismail A. Sha-</u> laby, Stephen B. Freedman, \* and Richard J. <u>Miller\*</u> Dept. of Pharmacol. and Physiol. Sci., Univ. of Chicago, Chicago, IL.60637. Organic calcium antagonists known to block voltage-sensitive Ca<sup>2+</sup> channels, exhibit a greater sensitivity to cardiac and smooth 164.5 channels, exhibit a greater sensitivity to cardiac and smooth muscle as compared to nerve terminals (Nachsen & Blaustein, Mol. Pharm. 16:579, 1979). Depolarization-induced release of dopamine Pharm.<u>16</u>:3/9,19/9). Depolarization-induced release of dopamine (DA) has been shown to be a calcium-dependent process. In this study we report that the organic calcium antagonists nitrendipine, nisoldipine, D-600 and diltiazem all fail to inhibit the  $Ca^{2+}$ -de-pendent 70mM K<sup>+</sup>-induced release of (<sup>3</sup>H)DA from aggregate cultures of mesencephalic neurons. We (Shalaby et al., J. Neurosci. In press) have demonstrated a  $Ca^{2+}$ -dependent K<sup>+</sup>-induced release of (<sup>3</sup>H)DA from 3 week old cultures of neurons from the rostral mesen-pendent from M week old cultures of neurons from the rostral mesencephalic tegmentum (RMT) that had been dissociated and allowed to reaggregate and grow in rotary culture with cells from the stria-tum (CS). 3 week old aggregates of the RMT-CS were exposed to 56uM (<sup>3</sup>H)DA for 30 min at 37°C. After the excess (<sup>3</sup>H) was washed off, aggregates were incubated with 1ml aliquots of buffer for 5 off, aggregates were incubated with lml aliquots of buffer for 5 min at  $37^{\circ}$ C. After each incubation the supernatant was exchanged with fresh aliquots (a total of 20 5 min consecutive incubations). When basal efflux of (<sup>3</sup>H)DA had stabilized a 70mM K<sup>+</sup> aliquot was introduced for 5 min. The 70mM K<sup>+</sup> incubation was repeated 3 times after basal efflux stabilization, with the 2nd stimulation con-taining the Ca<sup>2+</sup> antagonists. Release of (<sup>3</sup>H) per fraction was expressed as a % of tissue (<sup>3</sup>H)/5 min fraction, and 70mM K<sup>+</sup> in-duced a release of 13.4% of tissue (<sup>3</sup>H). To assess drug effects the ratio of release during the 2nd K<sup>+</sup> stimulation to the mean of the 1st and 3rd was obtained. This ratio was subtracted from 1 and multiplied by 100 to obtain % inhibition: Percent Inhibition of 70mM K<sup>+</sup> induced Release of (<sup>3</sup>H)DA

•	~							2
Percent	Inhibit	ion of	70mM	K'-ind	uced	Release	of	( <sup>3</sup> H) DA
Drug	10-9	$10^{-8}$	10-7	10-6	10-5	10-3 <sub>M</sub>		
Nitrendipine	8	11		12				
Nisoldipine	10	7		-2				
D-600			-9	17	28			
Diltiazem		20	14	23	35			
CoCl <sub>2</sub> (3mM)						82		

Statistical analysis comparing aggregates stimulated with  ${\rm K}^{\!+}$ 

Statistical analysis comparing aggregates stimulated with K' without drugs to aggregates exposed to drugs indicated that only  $CoCl_2$  (3mM) significantly inhibited K<sup>+</sup>-induced release of (<sup>3</sup>H)DA. While these organic  $Ca^{2+}$  antagonists block voltage-dependent  $Ca^{2+}$  channels and block depolarization-induced  $Ca^{2+}$  influx in muscle, their lack of effect of  $Ca^{2+}$ -dependent depolarization-induced transmitter release suggests that separate  $Ca^{2+}$  channels might exist in nerves.

164.4 EFFECTS OF DOPAMINE AND SEROTONIN UPTAKE BLOCKERS ON SOME NEUCCHEMICAL EFFECTS OF METHAMPHETAMINE. C.J. Schmidt\* and J.W. Gibe, (SPON: W. Stevens).Dept. Biochem. Pharmacol. & Toxicol., Univ. of Utah, Salt Lake City, UT. 84112. Recent evidence suggests that the uptake of indirect agonists such as amphetamine and drug-induced monoamine release may be mediated by a common carrier also responsible for neurotransmitter reuptake (Fischer and Cho, JPET, 208:203, 1979). Inhibitors of this uptake mechanism block many of amphetamine's effects both in vitro and in vivo. We have previously shown that specific dopamineric and serotonergic systems of the rat (Hotchkiss et al., JPET, 214:257, 1980; Schmidt et al., Abs. Neurosci. 8:818, 1982). These effects are characterized by marked reductions in brain concentrations of both DA and SHT as well as by their major metabolites, and their biosynthetic enzymes. The studies describmetabolites, and their biosynthetic enzymes. The studies describ-ed here further examine the effects of inhibitors of monoamine uptake on the neurochemical effects of METH.

For in vivo studies, rats were coadministered either amfonelic acid (AFA, O.15 mg/kg) or nomifensine (NOM, 0.50 mg/kg) with METH (15 mg/kg) every 6 hrs for 5 doses. As shown previously, AFA blocked the METH-induced decrease in striatal tyrosine hydroxylase

(15 mg/kg) every 6 hrs for 5 doses. As shown previously, AFA blocked the METH-induced decrease in striatal tyrosine hydroxylase (TH) activity. At the doses used NOM did not block this effect of METH. Tryptophan hydroxylase (TpH) activity, was significantly depressed by METH in the presence of either AFA or NOM. Superfusion studies using striatal slices preloaded with [<sup>3</sup>H]-DA examined the effects of DA uptake blockers on METH-induced release. Both AFA (10<sup>-5</sup>M) agd NOM (10<sup>-5</sup>M) blocked the release of [<sup>-3</sup>H]-DA caused by METH (10<sup>-5</sup>M). The 5HT-uptake blockers, chlorimipramine (Chl-IMP) and citalo-pram (CIT), were used in in vivo experiments similar to those described above. Chl-IMP (4 mg/kg) blocked the decrease in both striatal and cerebral TpH activity seen after METH (10 mg/kg x 5) without altering the decrease in striatal TH activity. Similar results were observed at higher doses of both doses of METH on striatal TpH activity. However, at the lower dose, CIT potentiated the effect of METH on the DA system in spite of protecting the 5HT system. Striatal TH activity, DA, DOPAC and HVA were reduced to a significantly greater extent by CIT + METH compared to METH alone. These results suggest an inhibition of METH metabolism by CIT. (Supported by DA 00865 and GM 07579).

CHARACTERIZATION OF DOPAMINE AND NOREPINEPHRINE EFFLUX FROM A CRUDE PREPARATION OF STORAGE VESICLES ISOLATED FROM RAT STRIATUM. G.S. Takimoto\*, B.R. Bianchi\* and T.R. Miller\* (SPON: J. Hirsch). Dept. of Biomedical Sciences, Univ. of Illinois Coll. of Med. at Rockford, Rockford, IL 61107-1897.

Evidence has been obtained from our laboratory indicating that synaptosome-stored <sup>3</sup>H-dopamine(<sup>3</sup>H-DA) is more susceptible than <sup>3</sup>H-norepinephrine(<sup>3</sup>H-NE) to depletion by sympathomimetic than "H-norepinephrine("H-NE) to depletion by sympathomimetic amines and agents such as reserpine that inhibit catechola-mine(CA) transport into storage vesicles. This finding was further investigated in the present study by monitoring the effects of sympathomimetic amines, reserpine and ATP+Mg on the spontaneous efflux of <sup>3</sup>H-CAs from a crude preparation of stor-age vesicles isolated from rat striatum. <sup>3</sup>H-DA or <sup>3</sup>H-NE was incorporated into striatal vesicles by incubation of the ves-icle fraction for 4 min at 20°C in the presence of physical Incorporated into striatal vesicles by incubation of the ves-icle fraction for 4 min at 20°C in the presence of phosphate buffer, pH 7.4, containing  $0.05\mu$ M <sup>3</sup>H-CA, ImM ATP+Mg and 5µM iproniazid. <sup>3</sup>H-CA uptake was terminated by a 50-fold dilution of the incubation mixture with phosphate buffer (20°C). Ad-dition of the dilution buffer simultaneously initiated the efflux incubation period. A greater proportion of <sup>3</sup>H-DA (60%) than <sup>3</sup>H-NE (42%) was spontaneously depleted from the loaded striatal unsiciles following a 5 min efflux incubation period. than h-K (42%) was spontaneously depicted from the loaded striatal vesicles following a 5 min efflux incubation period. Tyramine (0.5µM) and metaraminol (0.5µM) when added to the dilution buffer had no effect upon the efflux of either <sup>3</sup>H-DA or <sup>3</sup>H-DR. Reserptine (0.1µM) and ATP+Mg (ImM) when added se parately to the dilution buffer retarded the spontaneous efflux  $^{6}$  <sup>3</sup>H-DA by 55% and 71%, respectively. If reservine and ATP+Mg were combined in the dilution buffer, the effect on  $^{3}$ H-DA efflux was additive, as the vesicular loss of  $^{3}$ H-DA was completely prevented. The spontaneous efflux of  $^{3}$ H-NE was completely prevented. The spontaneous efflux of  $^{3}\mathrm{H-NE}$  was completely inhibited when either reserpine or ATP+Mg was added to pletely inhibited when either reserpine or ATP+Mg was added to the dilution buffer, and combining these agents elicited no additional effect. If tyramine was combined with ATP+Mg in the dilution buffer, the efflux of <sup>3</sup>H-DA was greater than that obtained in the presence of ATP+Mg alone, whereas <sup>3</sup>H-ME efflux was similar in the presence of tyramine + ATP+Mg and ATP+Mg alone. Both tyramine (0.5µM) and reserpine (0.1µM) inhibited the vesicular uptake of 0.05 µM <sup>3</sup>H-DA and <sup>3</sup>H-NE by approxi-mately 45%. These data indicate that DA is retained less effectively than NE by storage vesicles prepared from rat striatum. The spontaneous depletion of vesicle-stored DA and NE was differentially affected by reserpine, ATP+Mg and tyramine + ATP+Mg, which may reflect dissimilarities in the mechanisms of outward translocation and/or intravesicular stabilization of these CAS. RELATIONSHIP BETWEEN CYCLIC AMP LEVELS AND EVOKED DO-164.7 PAMINE RFLEASE IN PC-12 PHEOCHER OMPCLEVELS AND EVOLUSIOU-TURE. L. Baizer\* and N. Weiner. (SPON: J. Caldwell). Dept. Pharmacology, Univ. Colo. Health Sci. Center, Denver, CO 80262. We have previously suggested (Fed. Proc. 4<u>2</u>: 3788, 1983) that cyclic AMP (cAMP) may be involved in the process of dopamine release from

PC-12 pheochromocytoma cells. Elevated potassium (56 mM) or nicotine (100  $\mu$ M) produces increases in cAMP levels in PC-12 cells that are well correlated, with respect to time-course, magnitude, and dependence on external calcium, with dopamine release from the cells. Forskolin causes a rapid (maximal in 5-10 minutes) and dose-related

increase in PC-12 cellular cAMP levels. Increases in cAMP by forskolin Increase in PC-12 cellular CAMP levels. Increases in CAMP by torskinn are synergistic with those caused by nicotine or elevated potassium. Forskolin has differential dose-related effects on spontaneous and evoked dopamine release in PC-12 cells. At low concentrations (50-100 nM), forskolin produces approximately a two-fold increase in K<sup>+</sup> evoked release without a significant effect on spontaneous release. At higher concentrations (1  $\mu$ M or greater) forskolin cause a significant increase in spontaneous release. However, at a concentration of 1  $\mu$ M, forskolin produces a smaller increase in K<sup>+</sup> evoked release than at 100 nM; net evoked dopamine release is 30% above control levels.

Treatment of PC-12 cells with nerve growth factor protein (NGF) causes the cells to cease dividing and differentiate into cells showing radies the clarate tristic class of thing and dimensionate into certs and the many of the charateteristics of cultured sympathetic neurons. We have found, as did Greene and Rein (Brain Res. 138: 521, 1977), that treatment of PC-12 cells with NGF increases their sensitivity to nicotine; net dopamine release in response to 100  $\mu$ M nicotine is three-fold greater in NGF-treated cells than in control cells. Correspondingly, 100 µM nicotine causes a three-fold greater increase in cAMP levels in NGF-treated cells than in control cells.

The NGF-induced increase in sensitivity to nicotine is maximal after six days of NGF treatment, a similar time-course as that seen by Jumblatt and Tischler (Nature 297: 152, 1982) for the NGF-induced increase in muscarinic cholinergic receptors in these cells. The NGFincrease in muscarinic cholinergic receptors in these cells. The NGF -induced increase in sensitivity to nicotine suggests that NGF may also produce an increase in nicotinic cholinergic receptors in these cells in Supported by USPHS grants NS 07927 and NS 09199 and GM ulture. 07635.

164.8 DIFFERENTIAL STIMULATION OF SYNAPTOSOMAL NOREPINEPHRINE UPTAKE BY HIGH SALT DIET IN DAHL RATS. J. Rho and K. Hough\*. Dept Medicine, Schools of Medicine and Pharmacy, University of Southern California, Los Angeles, CA 90033. Dept. of

Dahl salt-sensitive rats (S) become hypertensive when fed a high salt (8.94% NaCl) diet but remain normotensive on a low salt (0.94% NaCl) diet. Dahl salt-resistant rats (R) are normotensive on either diet. In order to study a possible alteration of the transmembrane norepinephrine (NE) uptake system in Dahl S rats, we have studied the uptake processes directly in the synaptosomes isolated from the hypothalamus of both Dahl S and Dahl R rats in NaCl dietsand Dahl R rats on both high and low NaCl diets. The synaptosome-enriched subfraction was prepared by flotation, employing our modification of a discontinuous Ficoll-sucrose grad-ient (Booth and Clark, Biochem. J. <u>176</u>:365, 1978). The NE uptake is highly sodium-dependent (70%) and ouabain sensitive (70%). The initial  $^{3}$ H-NE uptake by the hypothalamic synaptosomal fraction The initial  $\rightarrow N_{\rm b}$  uptake by the hypothalamic synaptosomal fraction of Dahl R and Dahl S rats on a low salt diet during the first 10 minute incubation period averages 1.04 ± 0.14 and 1.39 ± 0.21 p moles per mg protein respectively while those of Dahl R and Dahl S rats on a high salt diet were 1.92 ± 0.23 and 1.71 ± 0.20 re-spectively. There was no significant difference between sensitive and resistant rats in either the 0.94% or the 8.94% NaCl diets. and testsfair tails in factor for the 0.74% of the 0.74% which were take of 3H-NE by hypothalamic synaptosomes by both strains of rats, and that the 8.94% NaCl diet differentially enhanced the reuptake of <sup>3</sup>H-NE in sensitive strain (23% increase, not significant) as compared to resistant strain (85% increase,  $P \approx .05$ ).

ALPHA-2 ADRENERGIC REGULATION OF NOREPINEPHRINE RELEASE IN THE RAT 164.9

ALPHA-2 ADREDERGIC REGULATION OF NOREPINEPHRINE RELEASE IN THE RAT SUBMANDIBULAR GLAND AS MEASURED BY LCEC. J.T. Turner\*, D.L. Pierce\* and D.B. Bylund. Department of Pharmacology, University of Missouri, School of Medicine, Columbia, MO 65212. High performance liquid chromatography coupled with electro-chemical detection (LCEC) was used to determine endogenous norepi-nephrine (NE) release in rat submandibular gland <u>in vitro</u>. Previous studies (Filinger et al., Arch. Pharmacol. <u>304</u>:21, 1978) of NE release from salivary glands have utilized preloading of the gland with tritium-labeled NE which may not fully equilibrate with endogenous NE pools. Our modification of a plasma catecholamine assay (LCEC Note No. 14, Bioanalytical Systems, W. Lafayette, IN) overcomes this problem and allows the precise determination of NE overcomes this problem and allows the precise determination of NE levels down to at least fifty picograms. Using this method in conjunction with a minced gland preparation, we have examined the potassium-stimulated increase in NE release by the gland as well as the dose-dependent potentiation of the potassium stimulation by the alpha-2 antagonist, yohimbine. Yohimbine maximally potentiates K-induced NE release at 1.0  $\mu$ M with an ED<sub>50</sub> of 0.18  $\mu$ M. The alpha-2 nature of this effect is further evidenced by the comparatively low potency  $(ED_{50} = 2 \mu)$  of prazosin, an alpha-1 antagonist, in potentiating NE release in response to K. These data are consistent with the concept that these drugs exert their effects by consistent with the concept that these drugs exert their effects by binding to presynaptic alpha-2 receptors and thus block the inhibition of NE release by NE. Further, the ED<sub>50</sub> ratio for yohimbine compared to prazosin (about 0.1) is in agreement with the IC<sub>50</sub> ratio for these drugs in inhibiting [<sup>'</sup>H]yohimbine binding in rodent tissues. The ED<sub>50</sub> and IC<sub>50</sub> ratios of about 0.1 are markedly different from the yohimbine/prazosin IC<sub>50</sub> ratios of 0.003-0.03 vs. [<sup>'</sup>H]yohimbine seen in non-rodent tissues and cells, including human platelets (Bylund and U'Prichard, Int'l Rev. Neurobiol. 24:334, 1983). These results suggest species differences in alpha-2 adrenergic receptors. The experimental system described herein promises to be an effective tool with which to study the role of other neuromodulators, including peptides, in the regulation of neurotransmitter release. neurotransmitter release.

164.10 PRESYNAPTIC MODULATION OF RELEASE OF [<sup>3</sup>H]NORADRENALINE EVOKED FROM VARICOSITIES ISOLATED FROM GUINEA-PIG MYENTERIC PLEXUS. W. MacDonald\*, D. Fitzpatrick\* and T. D. White. Department of Pharmacology, Dalhousie Univ., Halifax, N.S., Canada, B3H 4H7.

Extrinsic noradrenergic fibres innervate the myenteric plexus of the intestine, where they exert presynaptic inhibitory actions on ACh release, possibly at reciprocal axo-axonic synapses with cholinergic terminals. In the present study, we have investigated the effects of various cholinergic and adrenergic agonists on  $[^{3}H]NA$  release from myenteric varicosities (synaptosomes) isolated from ileal longitudinal varicosities (synaptosomes) isolated from ileal longitudinal muscles of 2 adult male guinea pigs. The isolated varicosities were incubated with  $2x10^{-7}M$  [<sup>3</sup>H]NA for 15 min, washed 3 times and finally incubated in Krebs-Henseleit medium with various agents. Release of [<sup>3</sup>H]NA as dpm/mg protein/10 min was detected in the supernatant following centrifugation in a Beckman microfuge for 3 min. Veratridine ( $5x10^{-5}M$ ), KCl (increased by 24mM), nicotine ( $10^{-4}M$ ) and ACh ( $10^{-4}M$ ) all evoked Ca<sup>24</sup>-dependent release of [<sup>3</sup>H]NA, release by veratridine being much greater (5-10x) and less Ca<sup>24</sup>-dependent than release by the other agents. The muscarinic agonist, bethanechol ( $10^{-4}M$ ), and antagonist, atropine ( $10^{-7}M$ ), had no effects on resting efflux or on release evoked by veratridine, KCl, (10 °M), and antagonist, atropine (10 °M), had no effects on resting efflux or on release evoked by veratridine, KC1, nicotine or ACh. However, the  $\alpha_2$  agonist, clonidine (10<sup>-5</sup>M), reduced ACh-, nicotine-and KC1-evoked release of [<sup>3</sup>H]NA to 24%, 43% and 57% of control values respectively, but had no effect on veratridine-induced efflux of dpm's. The following conclusions can be drawn: 1) Isolated myenteric varicosities. conclusions can be drawn: 1) isolated myenteric varicosities presumably those which are noradrenergic, can take up and release [<sup>3</sup>H]NA by a Ca<sup>2+</sup>-dependent mechanism when exposed to KCl, nicotine or ACh. Veratridine evokes a large efflux of radioactivity which is only partially Ca<sup>2+</sup>-dependent. 2) Th These isolated myenteric varicosities possess presynaptic nicotinic receptors but no evidence for presynaptic muscarinic receptors was obtained. Either the muscarinic receptors which modulate NA release are located on portions of the sympathetic axon remote from the varicosities, or they are destroyed during formation of the isolated varicosities. 3) The isolated rormation of the isolated varicosities. 3) The isolated varicosities possess presynaptic  $\alpha_2$  receptors which, when stimulated, inhibit  $[{}^{3}H]NA$  release. These receptors may play a role in modulating NA release in vivo. (Supported by the MRC of Canada).

HALOPERIDOL ELEVATES EXTRACELLULAR CATECHOLAMINE METABOLITES IN 164.11 MAT STRIATUM WITHOUT AFFECTING ASCORBIC ACID OR INDOLEAMINE METABOLITE LEVELS. R. D. Blakely\*, S. A. Wages\*, J. B. Justice, J. G. Herndon\*, and D. B. Neill\* (SPON:L. Walker). Depts. of Biology, Chemistry, and Psychology, Emory Univ., Atlanta, GA 30322.

In vivo oxidation currents from carbon paste electrodes chron-ically implanted in rat striatum increase following intraperi-toneal haloperidol injections. It is unclear to what degree ascorbic acid, monoamine neurotransmitters, and their metabolites contribute to these signal increases. In order to elucidate the neurochemical components responsible for this effect, high-performance liquid chromatography with electrochemical detection performance liquid chromatography with electrochemical detection (HPLC-EC) was employed to analyze perfusates passed through the striatum of unanesthetized rats. Push-pull perfusion was con-ducted at a rate of 4uL/min. between two pulled glass micro-pipettes, sealed within the lumen (200um dia.) of a hollow, semi-permeable cellulose fiber (Spectrapor HF, pore cutoff=5000 amu). Thus, all exchange of compounds between the extracellular fluid and artificial CSF occured across the dialysis membrane, permit-ing the collection of a perfusate suitable for direct, on-line chromatographic analysis without pre-columm modification of the Ing the collection of a perfusate suitable for direct, on-line chromatographic analysis without pre-column modification of the collected fractions. 100uL samples were obtained every 30 minutes and immediately injected into a Dupont Zorbax C8 reverse phase column, with mobile phase conditions appropriate for the separation of the monoamine neurotransmitters, their metabolites, and ascorbic acid. DOPAC, HVA, 5-HIAA, and ascorbic acid could be consistently identified in the perfusates of all animals. Fractions (5 to 6) were collected until a stable baseline con-dition had been achieved. Following administration of haloperidol (lmg/kg, i.p.) perfusate concentrations of DOPAC and HVA showed (Img/kg, 1.p.) perfusate concentrations of burner and now sinned significant increases (p<.001) above predrug levels, while no alterations in ascorbic acid and 5-HIAA levels could be detected. Each of the catecholamine metabolites rose to over 200% of base-line levels. The rise in extracellular DOPAC occured 30 minutes prior to the increase in HVA. Saline administration failed to alter the conconstraints of any of these compounds. These data alter the concentrations of any of these compounds. These data support the contention that increases in striatal oxidation cur rents observed following neuroleptic administration are dependent upon increased extracellular efflux of catecholamine metabolites and demonstrate an insensitivity of extracellular ascorbic acid and 5-HIAA to dopamine receptor blockade.

IN VIVO VOLTAMMETRIC RECORDING WITH NUJOL OR SILICONE OIL CARBON 164.13 PASTE ELECTRODES. <u>K. Mueller<sup>2</sup>, C. D. Andrews and P. J. Knott.</u> Dept. of Pharmacol., Marshall Univ. School of Med., Huntington, WV 25701

In vivo voltammetry is becoming an increasing popular tool for measuring catecholamine release from selected brain areas. Interpretation of results is often complicated by use of dif-ferent electrodes by different labs. We compared carbon paste electrodes fabricated with either nujol or silicone oil and found major differences between the two. In general, nujol and silicone oil electrodes produce a very

similar response to 0.1mM dopamine and a very similar response 0.2mM ascorbate <u>in vitro</u>. That is, for each substance, peak positions and heights are virtually identical for the two types to of electrodes. <u>In vivo</u>, however, nujol and silicone oil electrodes are different in several respects.

After chronic implantation in the anterior caudate of rats silicone oil electrodes consistently record 3 peaks (during a linear sweep at 10mV/sec from -200 to +500mV) on initial testing (48 hr after implantation). Nujol electrodes, however, often do not record distinct peaks until 10 to 14 days after implantation; occasionally nujol electrodes do not record any peaks when tested intermittently up to 20 days after implantation. Furthermore, the signals (in  $Asec^{-\frac{1}{2}}$ ) recorded by nujol electrodes are the signals (in masec 7) recorded by nujol electrodes are consistently smaller than the signals recorded by silicone oil electrodes; peak heights produced by endogenous substances and ip acetaminophen are virtually always smaller for the former. Nujol electrodes often record only 2 peaks as a result of merging of peaks 1 and 2. Thus data interpretation is difficult, at best. In contrast, silicone oil electrodes record 3 peaks up to 20 days or more after implantation, although the signals tend to decrease slightly over time. We are unable to explain why the two types of electrodes are

as all an invite to explain which the topes of the electrones are so similar in vitro but so dissimilar in vivo. We conclude that carbon paste electrodes fabricated with silicone oil have several advantages over carbon paste electrodes fabricated with nujol.

ON-LINE CHROMATOGRAPHIC ANALYSIS OF STRIATAL DIALYSATE IN BEHAVING ANIMALS: COMPARISON WITH VOLTAMMETRY. Joseph B. Justice, Jr., Sherry A. Wages, Adrian C. Michael, Randy D. Blakely and Darryl B. Neill, Departments of Chemistry and Psychology, Emory University, Atlanta, CA, 30322 In order to monitor the extracellular chemistry of the 164.12 ON-LINE

um in behaving rats we have assembled a system consisting high performance liquid chromatograph with electrochemical striatum of a detection and a push-pull perfusion system in which the perfusate flows through a micro dialysis tube implanted in the striatum. The dialyzed perfusate passes through a fluid swivel and continuously flows through the sample loop of the HPLC, where it is automatically injected at present intervals. The perfusate is analyzed for ascorbic acid (AA), the dopamine metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), and the serotonin metabolite 5-hydroxyindoleacetic acid (5-HIAA). and the serotonin metabolite 5-hydroxyindoleacetic acid (5-HIAA). At a flow rate of 4 ul/min, each 100ul sample of dialysate contained approximately 40 ng of AA, 5 ng of DOPAC and HVA and 1 ng of 5-HIAA. A comparison is also made of chronoamperometric data recorded from the striatum with carbon epoxy and carbon paste electrodes and chromatographic data obtained from extracellular striatal perfusate. It is shown that the decline in oxidation current during the initial sampling period in voltammetry is due primarily to a decrease in ascorbic acid. It is also shown that different electroactive components of the is also shown that different electroactive components of the extracellular fluid in the striatum are the cause of changing oxidation currents under different stimulus conditions.

LONG TERM EFFECTS OF XYLAMINE (XYL) ON AMPHETAMINE (AMPH) INDUCED RELEASE OF NOREPINEPHRINE (NE) IN VIVO. <u>C. D. Blaha\*, S. Howard-Butcher and R. F. Lane</u>. Institute of Neuroscience, University of Oregon, Eugene, OR 97403 and Dept. of Pharmacology and MRRC, UCLA, Los Angeles, CA 90024. Xylamine (Xyl), a nitrogen mustard which is thought to specifically iphibit the NE carrier was examined with respect to 164.14

specifically inhibit the NE carrier was examined with respect to its long term effects using in vivo voltammetry.

Male Sprague-Dawley rats were injected with Xy1 (12.5 mg/kg i.p.) or saline 5 days prior to experimentation. On the 6th day, the rats were anethetized with chloral hydrate (400 mg/kg i.p.) and placed in a stereotaxic instrument. Surface modified graphite electrodes, selective for catecholamines were inserted the neostriatum and the contralateral motor cortex overlying the neostriatum.

Chronoamperometric measurements were made by applying a potential of +0.25V vs Ag/Ag Cl for 1 second to each electrode with an interval of 1 minute between measurements.

Baseline values of NE in the cortex and DA in the neostriatum were obtained. The values for NE release in the cortex were decreased by approximately 90% of normal values, while there was no effect on the release of DA in the neostriatum. Animals were then treated with Amph (1 mg/kg i.v.).

ability of Amph to produce a central nervous system stimulation appears to be dependent upon the availability of newly synthesized DA or NE.

In control animals Amph induced a 25% increase in NE release from cortex and a 31% increase in DA release in the neostriatum. However, there was no effect on the release on NE from the cortex However, there was no effect on the release on NE from the cortex in Xyl treated animals, even though tissue levels of NE are only reduced by approximately 30%.

These data suggest that Xyl produces a long lasting effect on . Xyl has been shown to block NE uptake for at least ten days NE. after administration (Dudley et al JPET 217:834, 1981). The results obtained in this study are consistent with the notion that the release mediated by AMPH is the result of an exchange

diffusion mechanism involving the NE uptake system. This work was supported by USPHS Grants HD 05615, NS 13556 and GM 07257.

164.15 DIFFERENTIAL EFFECT OF XYLAMINE ON NOREPINEPHRINE (NE) AND DIFFERENTIAL EFFECT OF XYLAMINE ON NOREPINEPHRINE (NE) AND DOPAMINE (DA) RELEASE USING <u>IN VIVO</u> VOLTAMMETRY. <u>S. Howard-</u> <u>Butcher, C. D. Blaha\* and R.F. Lane</u>. Department of Pharmacology and MRRC, UCLA, Los Angeles, CA 90024 and Institute of Neuro-science, University of Oregon, Eugene OR, 97403. Xylamine (Xyl) is a new compound which selectively inhibits the NE carrier while leaving the DA levels unaffected. (Dudley et al JPET 217:834, 1981). Using in vivo voltammetry the release of bretwerse

of both NE and DA were measured. Male Sprague - Dawley rats were injected with chloral hydrate

(400 mg/kg i.p.) and body temperature maintained with a heating (400 mg/kg i.p.) and body temperature maintained with a heating pad. Electrode implantation followed standard stereotaxic techniques. Surface modified graphite electrodes, selective for catecholamines, were inserted into the neostriatum and the contralateral cortex overlying the neostriatum. Semi-differential voltammetric measurements were performed by scanning the poten-tial linearly from-0.1V to +0.5V vs Ag/AgCl and measuring the peak current centered at  $\pm 0.13V$ . Scans were repeated once every 5 min on alternate electrodes.

After a stable baseline was obtained, animals were injected with Xyl (12.5 mg/kg i.p.). There was an initial increase in NE release followed by a decrease in release of NE in the cortex of approximately 76% over a 2 hour period. The release of DA in the neostriatum was unchanged. This decrease in NE release was maximal 2 hours after Xyl injection. In an attempt to block the effect of Xyl, in a second series

of experiments, rats were pretreated with Desmethylimipramine (DMI 20 mg/kg i.p.).

Initially DMI produced a slight increase in measured NE (26%) and had no effect on DA. Xyl was injected 1 hour after DMI pretreatment. DMI blocked the Xyl induced decrease in NE release.

These data suggest that Xyl binds specifically to the NE carrier and that DMI protects the carrier from the blocking/ depleting actions of Xyl.

This work was supported by USPHS grants HD 05615, NS 13556 and GM 07257.

## TRANSMITTER UPTAKE, STORAGE, AND SECRETION II

165.1 ANTIBODIES AGAINST BLOOD PLATELETS INFLUENCE 5-HT ANTIBODIES AGAINST BLOOD PLATELETS INFLUENCE S-HT UPTAKE AND IMIPRAMINE BINDING IN SYNAPTOSOMES. M.E. Trukenmiller, I. Angel\*+, S.M.Paul‡ and J.H. Neale. Dept. of Biology, Georgetown University, Wash. D.C. 20057 +Clinical Neuroscience Branch, NIMH, NIH, Bethesda,MD 20205 Purified human blood platelet membranes were injected

into BALB/c mice and the splencytes subsequently fused with NSI myeloma cells. A single fusion produced more than 900 hybrid cell colonies and of these, more than one hundred produced antibodies which reacted with platelet membranes in solid phase radioimmunoassay. These cell cultures were expanded and their antibodies assayed for effects on serotonin uptake and imipramine binding in freshly prepared human platelets. Antibodies which produced an effect in either or both of these assays were further tested for their ability to react with rat brain synaptosome membranes in RIA and to influence serotonin uptake and imipramine binding in fresh rat brain synaptosomes. We have found that several hybridoma cell cultures produce antibodies which react with brain synaptosomes and which influence the binding of imipramine and/or the uptake of serotonin. The specificity and mechanism of action of these antibodies are of interest inasmuch as the imipramine receptor in blood platelets and brain has been implicated in certain affective disorders and the action of tricyclic anti-depressant drugs in humans.

165.2 REGULATION OF THE RELEASE OF SEROTONIN (5 HT) BY AN AUTORECEPTOR ON SYNAPTOSOMES FROM RAT SPINAL CORD TISSUE. P. J. Monroe and D. J. Smith. Depts. Pharmacology/Toxicology and Anesthesiology, West Virginia University Med. Ctr., Morgantown, W.V. 26506. Two high affinity binding sites (5  $\text{HT}_{1a}$  + 5  $\text{HT}_{1b}$ ) for <sup>3</sup>H-5-HT have recently been demonstrated in the rat spinal cord (Monroe and have recently been demonstrated in the rat spinal cold (works and Smith, J. Neurochem, in press). A possible functional role of these sites may be the regulation of 5 HT release. Therefore, preliminary studies were done to evaluate the effect of serotoner-gic drugs on the release of 5-HT from synaptosomal tissue. A drug induced alteration in the  $K^+$  evoked release of 5-HT should suggest the existence of an autoreceptor. Synaptosomes were prepared from spinal cord tissue and were

suspended in a Tris-buffered Besson's medium. After 2-10 min. in-cubations (37°C) in the absence then in the presence of 100 nM  $^{3}$ H-5HT, an aliquot (0.4 ml) of tissue suspension (50 mg/ml) was  $^{3}\text{H}-5\text{HT}$ , an aliquot (0.4 ml) of tissue suspension (50 mg/ml) was loaded onto a bed of Sephadex G-15 and superfusion was begun. The standard procedure was to wash the tissue for 50 min., then to change to a medium containing drugs 20 min. prior to exposure of the tissue to medium containing high K<sup>+</sup> (15 mM). Tissue was lyzed at the termination of the experiment with 1N HCl. 5 HT re-lease was expressed as a percentage of total <sup>3</sup>H available. Initial experiments were done to examine the degree of metab-olism of <sup>3</sup>H-5HT that might occur during the course of the experi-ments. A significant amount of <sup>3</sup>H-5HT A forms during the initial incubation of the tissue, as <sup>3</sup>H-5HT is preloaded, but is washed from the tissue in an exponential manner. During superfusion.

quent displacement of  $^{3}\text{H-5HT}$  from vesicles by the amine.

Exogenous 5-HT in the presence of fluoxetine attenuated, in a dose-dependent manner, the K<sup>+</sup> evoked release of  ${}^{3}\text{H-5}\text{HT}$ , demonstrating the existence of an autoreceptor. Concentrations of 1,

straing the existence of an autoreceptor. Concentrations of 1, 10, 30 and 100 m SHT reduced release to  $(\bar{x} \pm SEM)$  91 ± 8, 78 ± 6, 66 ± 4, 69 ± 9 % of control, respectively. Experiments, using spiperone (a serotonergic drug for which the receptors exhibit differing affinities), are currently under-way to determine which SHT receptor subtype is associated with autoregulation.

165.3 PURIFICATION AND CHARACTERIZATION OF TWO FORMS OF SEROTONIN BIND-ING PROTEIN. Liu\*, K.P., Ehrlich, Y., Gershon, M.D. and Tamir, H., N.Y. State Psych. Inst., Univ. Vermont Coll. Med. and Univ. Columbia Coll. Med.

Serotonin binding protein (SBP) is a soluble protein found in synaptic vesicles of central and peripheral serotonergic neurons: Serotonin (5-HT) is physiologically stored as a complex with SBP in situ. Two forms of SBP were detected: 45kd and 56kd. Newly taken up  $^{3}$ H-5-HT preferentially labels 45kd SBP. In order to better understand the relationship between the two forms we purified the two proteins to homogeneity and partially characterized them. Steps of purification included: (NH<sub>2</sub>)<sub>2</sub>SO<sub>4</sub> cut, molecular sieve chromatography on Sepharose-4-B, affinity chromatography, Ca-P gel, gel electrophoresis and HPLC. Purity was established by 2 dimensional gel electrophoresis. The two forms of SBP were similar in their amino acid composition, the enhancement of 5-HT binding by Fe<sup>+2</sup> and inhibition by -SH reagents, chelators, and solutions of high salt content. Antibodies raised against the 45kd SBP cross-reacted with the 56kd form. The two forms of SBP; 2) isoelectric point, (45kd more acid); 3) binding enhancement by and biarbonate (45kd ten fold less sensitive than the 56kd form); 4) inhibition of binding by ATPA-S (45kd form is insensitive, 56kd form inhibited); 5) capacity to act as a substrate for protein kinase (45kd form does not get phosphorylated, 56kd form is phosphorylated)

We suggest that a precursor-product relationship may exist between 45kd and 56 kd SBP and that the two forms may be located within different parts of serotonergic neurons. Supported in part by NSF Grant 09335 and NIMH 37575 and NIH 12969. 165.4 PRELIMINARY CHARACTERIZATION OF THE SEROTONIN UPTAKE SYSTEM IN SPINAL CORD. K. Stauderman\*, P. Lundy\* and D. J. Jones. Depts. of Anesthesiology and Pharmacology, The Univ. of Texas Hith. Sci. Ctr., San Antonio, TX 78284 Descending serotomergic pathways have been proposed to play a

Descending serotonergic pathways have been proposed to play a regulatory role in various somatosensory, autonomic and motor functions within the spinal cord. While quantitative studies have linked the synaptosomal uptake of  $[^{3}H]$ -serotonin ( $[^{3}H]$ -5HT) to a neurotransmitter role in regional brain areas, such studies have not been performed in spinal cord. We are conducting experiments on the  $[^{3}H]$ -5HT uptake system in rat spinal cord, a partial characterization of which is presented here.

5HT uptake was measured by a modification of the procedure of Kirksey and Slotkin (Br. J.Pharmacol., 67:387-391, 1979). Spinal cords were rapidly removed and a crude synaptosomal fraction ( $\$_1$ ) prepared. Aliquots of this fraction (representing 0.25-1 mg protein) were incubated in oxygenated Krebs-Ringer bloarbonate buffer (37°C) for 5 min prior to the addition of [3H]-SHT (0.01-0.05 uM). Final reaction volume was 1 ml. The reaction proceeded for 5 additional min (except for time course studies) and was stopped by the addition of 3 ml of ice cold incubation buffer followed by rapid filtration through Gelman AC filters at reduced pressure, with two subsequent 3 ml washes. The filters were then dried and counted.

Inital studies using  $[{}^{3}H]-5HT$  concentrations of 0.01 uM and 0.05 uM demonstrated linear uptake for at least 8 min. Uptake was also concentration and temperature dependent. At a  $[{}^{3}H]-5HT$  concentration of 0.025 uM, uptake was 180 pmole/gm tissue/5 min (0°C blank corrected). Decreasing the Na<sup>+</sup> concentration from 145 to 30 mM caused a 53% decrease in this value. Finally, the system appears to be differentially sensitive to uptake inhibitors like fluoxetime (10<sup>-4</sup> M) and desmethylimipramine (10<sup>-4</sup> M) which inhibited uptake 90% and 80%, respectively.

The above studies establish an active 5HT uptake system in spinal cord which is  $Na^+$  temperature dependent and is sensitive to pharmacological blockade.

165.5 VESICULAR CALCIUM FUMPING MAY DRIVE PREFERENTIAL RELEASE OF NEWLY SYNTHESIZED NEUROFRANSMITTERS. <u>A.F. Boyne and T.E.</u> <u>Phillips</u>. Dept. of Pharmacol. and Exp. Therap., Univ. of Maryland School of Medicine, Baltimore, MD 21201. Observation of quick-frozen and freeze-substituted torpedine

Maryland School of Medicine, Baltimore, MD 21201. Observation of quick-frozen and freeze-substituted torpedine ray electric organ has suggested to us how the well established preferential release of newly synthesized acetylcholine (ACh) may occur. (1) 15-20% of the resting synaptic vesicle population is attached to the presynaptic nerve terminal in apparent active zones. Conventional aldehyde fixation appears to drive the exocytotic discharge of these vesicles. They are then unavailable for quantitation to the extent that they are incorporated into the nerve terminal membrane. (2) EGTA sensitive Ca<sup>2+</sup> deposits can be seen within synaptic vesicles. The proportion of Ca<sup>2+</sup> loaded vesicles increase with 0.1 Hz stimulation (2 experiments).

This suggests that the vesicular  $Ca^{2+}$ -ATPase drives  $Ca^{2+}$ uptake by vesicles <u>in vivo</u>. Since the active zone vesicles will be the first to be exposed to incoming  $Ca^{2+}$  and will experience the highest ambient concentration, they would be expected to concentrate  $Ca^{2+}$  preferentially.  $Ca^{2+}$  facilitates displacement of ACh from cholinergic synaptic vesicles (Michaelson, A.M., et al., <u>BERC</u>, <u>80</u>(3):547, 1978). During the action potential undischarged active zone vesicles would gain some  $Ca^{2+}$  and lose some ACh. A prediction, which becomes a test of the hypothesis, is that  $Ca^{2+}$  unloading and ACh reloading would occur between action potentials so that active zone vesicles would gradually and preferentially become filled with cytoplasmic ACh, i.e. predominately newly synthesized ACh. Those vesicles which opened and closed to the extracellular space would saturate with extracellular  $Ca^{2+}$  and may achieve equilibrium with cytoplasmic ACh more quickly.

ACh more quickly. The predicted reversal of ACh/Ca<sup>2+</sup> could occur directly once the Ca<sup>2+</sup> of the marginal cytoplasm was lowered from its high point during the action potential, or it may occur indirectly, perhaps after Na<sup>+</sup>/Ca<sup>2+</sup> exchange and subsequent operation of the original ACh loading mechanism on the partially Na<sup>+</sup> filled vesicles.

In summary, we propose that active zone vesicles undergo a  $Ca^{2+}$  driven, relatively selective, acceleration of ACh turnover which results in their preferential loading with newly synthesized ACh. If this is correct, it suggests that (1) the increase in specific gravity of recycling vesicles (<u>Zimmermann and Denston, Neurosci., 2</u>:695, 1977) is the result of an incompletely reversed Ca<sup>2+</sup> load. And (2), the generality of preferential release of newly synthesized neurotransmitter may be causally related to the generality of Ca<sup>2+</sup> pumping by the associated storage granules. (Supported by NINCDS Crant #16167).

165.6 HOW ATP PREVENTS LEAKAGE OF CATECHOLAMINE FROM SECRETORY VESICLES L. S. Kao\* and E. W. Westhead. Biochemistry Department, Univ. of Massachusetts, Amherst, MA 01003 Secretory vesicles of the adrenal medulla (chromaffin gran-

Secretory vesicles of the adrenal medulla (chromaffin granules) like those of parasympathetic neurons, contain very high catecholamine concentration. At 37°, leakage of catecholamines from isolated bovine chromaffin granules is rapid but is prevented by the presence of ATP in the suspending medium. A proton-pumping ATPase provides energy for catecholamine uptake but constant reuptake <u>in vivo</u> would be a very costly process. We have examined the mechanism of ATP inhibition of catecholamine depletion using intact isolated granules and resealed "ghosts"--vesicles that have been lysed and resealed with catecholamines inside but not nucleotides or soluble macromolecules. Within 4 hours at 37° isolated granules are depleted of catecholamines and nucleotides to about 50% and 30% respectively, with 30% of catecholamine release occurring within an hour. Epinephrine and norepinephrine are released in parallel but catecholamines are released significantly faster than nucleotides. Addition of tracer amounts of  ${}^{34}SO_4^{2}$  to the suspension during depletion showed that leakage was not through non-specific pores. ATP-Mg at 10 mM inhibits 90% of the catecholamine ralease. Atractyloside alone inhibits catecholamine, are used in place of intact granules. The mechanisms by which ATP prevents loss of catecholamine for the granules. The mechanisms by which ATP prevents loss of catecholamine for ATP, ADP or atractyloside to the nucleotide carrier inhibits arecese facts we deduce that the requirement for electrical neutrality within the granules is determining facts: (1) Binding of ATP, ADP or atractyloside to the nucleotide release. From these facts we deduce that the requirement for electrical neutrality within the granules is determining factor. Catecholamines within the granules is determining factor. The biphsic release of at least divalent anions and thus inhibits the coupled release of at least divalent anions and thus inhibits the coupled release of at least divalent anions and thus inhibits the coupled release of at

MECHANISM OF GLUTAMATE UPTAKE INTO BRAIN SYNAPTIC VESICLES: 165.7 INVOLVEMENT OF BOTH ELECTRICAL POTENTIAL AND TRANSMEMBRANE PH GRADIENT. <u>S. Naito\* and T. Ueda</u>. Mental Health Research Inst., Depts. of Pharmacology and Psychiatry, University of Michigan, Ann Arbor, MI 48109.

There is increasing evidence that glutamate plays a neurotransmitter role in the central nervous system. We have recently demonstrated that glutamate is specifically taken up into certain highly purified brain synaptic vesicles in an ATPdependent, but solum-independent manner (Naito, S. and Ueda, T., J. <u>Biol. Chem.</u> 258:696-699, 1983). Here we report that the glu-tamate uptake is driven by an electrochemical proton gradient generated by a proton translocating ATPase in the vesicle membrane. Thus, proton pump ATPase inhibitors such as DCCD and tri-methyltin caused a substantial reduction in the glutamate uptake. The glutamate uptake was also inhibited by FCCP and thiocyanate agents known to attenuate membrane potential generated by Mg-ATPase, and by proton gradient dissipators such as nigericin (in the presence of potassium ions) and ammonia. Kinetic experiments have indicated that these inhibitors reduce Vmax without signifihave indicated that these inhibitors reduce what without signifi-cantly changing Km for glutamate. The ATP-dependent uptake of glutamate was observed in a sucrose medium containing imperme-able anions (e.g., maleate). The addition of 2 mM Cl, a perme-able anion, caused a marked stimulation of the uptake; Vmax was increased 4-fold, whereas Km for glutamate was hardly affected. In the presence of excess chloride ions, the uptake was reduced in a concentration-dependent manner. These observations support the notion that the maximal driving force for glutamate uptake into synaptic vesicles is provided by the combination of an optimal membrane potential and pH gradient.

165.8 INHIBITION OF ACTIVE UPTAKE OF ACETYLCHOLINE INTO TORPEDO ELECTRIC TRAILED TO BE ACTIVE OF TAKE OF A CETTICHOLINE INTO TORPED ELECTRIC ORGAN SYMAPTIC VESICLES BY  $\beta$ -BUNGAROTOXIN. <u>D.C. Anderson and</u> <u>S.M. Parsons</u>. DEPT. OF CHEMISTRY, UNIV. OF CALIF., SANTA BARBARA, CA 93106.

The presynaptic toxin  $\beta$ -bungarotoxin ( $\beta$ -BuTX) specifically inhibits acetylcholine (ACh) release at peripheral nerve terminals with a time lag that is shortened by nerve terminal activity, suggesting the possible importance of a vesicle-associated target in the toxicity. We have found that  $\beta$ -BuTX potently blocks active transport of ACh into purely cholinergic synaptic vesicles from Torpedo californica electric organ. The inhil is Ca<sup>2+</sup>-dependent, with an apparent  $K_m$  for Ca<sup>2+</sup> of 0.4 mM. The inhibition potency of inhibition increases with preincubation of  $\beta$ -BuTX and Ca<sup>2+</sup> with vesicles. The apparent K<sub>1</sub> of  $\beta$ -BuTX decreases from 60 nM with no preincubation to 8 nM with 8 hour preincubation. The inhibition of active uptake of ACh by  $\beta\text{-BuTX}$  is correlated with activation of the vesicular Ca^2+/Mg^2+ ATPase, which we have shown is coupled to active transport of ACh <u>via</u> a proton gradient (Anderson, D.C. et al., <u>Biochemistry</u> 21, 3037, 1982). ATPase activation by  $\beta$ -BuTX has an apparent K<sub>m</sub> for Ca<sup>2+</sup> identical to that for inhibition of active transport of ACh, and shows a timedependent increase in toxin effectiveness similar to that seen with active transport of ACh.  $\beta$ -BuTX maximally activates the vesicle ATPase at 3 x  $10^{-8}\text{M}$  while blocking 91% of active ACh transport at 6 x  $10^{-8}\text{M}$ . This is consistent with  $\beta$ -BuTX acting to block ACh uptake by uncoupling the ATPase from active transport of ACh in a fashion similar to protonophoric uncouplers such as ingericin. The maximal activations of the ATPase by  $\beta$ -BuTX·Ca<sup>2+</sup> and nigericin are not additive, and neither activates triton X-100 solubilized ATPase activity. In the presence of Ca<sup>2+</sup>, phospholipase A2's (PLA2's) from cobra venom, porcine pancreas, Vipera russelli and bee venom block active uptake of ACh with apparent  $K_i$ 's of 3 nM after 1 hour preincubation. Cobra venom apparent x<sub>1</sub> so r 3 m after 1 mode predictation. Cosine volume PLA<sub>2</sub> activates the vesicular ATPase with a concentration-dependence similar to that of  $\beta$ -BuTX-Ca<sup>2+</sup>. The maximal activation of the ATPase by cobra venom PLA<sub>2</sub> is not additive with activation by nigericin or  $\beta$ -BuTX-Ca<sup>2+</sup>. Thus the PLA<sub>2</sub> activity of  $\beta$ -BuTX appears to be important for its uncoupling of the vesicular ATPase and the resulting blockade of active ACh loading by synaptic vesicles.

165.9

IS COPPER-MEDIATED OXIDATION OF THIOLS A CENERALIZED MECHANISM FOR THE RELEASE OF NEUROPEPTIDES? By G.E. Rice and A. Barnea, Depts. Ob-Cyn. and Physiol., Green Ctr. Reprod. Biol., Univ.of Texas Health Sci. Ctr., Dallas, Tx. 75235. Previously, we demonstrated that copper, in a chelated form, stimulates the release of luteinizing hormone releasing hormone (LHRH) from isolated hypothalamic granules. Since copper occurs in a chelated form and in high concentrations in the hypothalamus, copper may also affect the release of other peptides from hypothalamic storage granules. To assess the generality of the copper-stimulated release process, we have determined the effects of copper on the release of  $\alpha$ -melanocyte stimulating hormone ( $\alpha$ -MSH); another peptide which is localized in a population of neurons distinct from LHRH. We addressed two specific questions: (1) What is the active form of copper that interacts with the  $\alpha$ -MSH granule (ionic or chelated)?; and (ii) Is copper-stimulated  $\alpha$ -MSH release a result of the oxidation of thiol groups? Granules, were isolated from hypothalami of adult male rats and were then incubated at 37°C for 3-5 min in a buffered medium.  $\alpha$ -MSH contained in granules was separated from -MSH release by S14 ± 68 (mean ± 5.E.), Cu tartarate by 56 ± 48, CuBSA by 32 ± 58 and Cu histidine by 29 ± 28. Neither CuEDTA nor CuCl, stimulated  $\alpha$ -MSH release from granules incubated under air. Furthermfore, the reducing agent dithiothreitol (DTT) inhibited CuATP-stimulated  $\alpha$ -MSH release (p < 0.01), whereas oxidized DTT did not do so. Pretreatment of granules incubated under air. Furthermfore, the reducing agent dithiothreitol (DTT) inhibited CuATP-stimulated  $\alpha$ -MSH release the disting reagents iodoacetic acid or 5, 5-dithio-bis-(2-nitro-benzoic acid) inhibited CuATP-stimulated  $\alpha$ -MSH release the of the metal and the action of copper involves the oxidation of the metal and the action of copper is the active form of the metal and the action of copper involves the oxidaten of the metal and the act release by  $52 \pm 3$  and  $38 \pm 4\%$ , respectively. We conclude that chelated copper, rather than ionic copper, is the active form of the metal and the action of copper involves the oxidation of thiols. These data are similar to those observed for the copper-stimulated release of LHRH. Hence, the effects of copper on the permeability of granule membranes may be a generalized phenomenon which underlies a susceptibility of storage granules to the redox status of the cellular millieu. Such a process may modulate the responsiveness of the granules to other stimuli that initiate exocytosis. exocytosis.

165.10 THE UPTAKE AND RELEASE OF <sup>3</sup>H-GABA IN RAT CEREBELLAR CULTURES. Lisa R. Scribner and Richard W. Burry, Department of Anatomy, College of Medicine, The Ohio State University, Columbus, Ohio, 43210.

The inhibitory neurotransmitter gamma aminobutryic acid (GABA) has been shown to be released in a potassium-stimulated, calcium-dependent manner (Pearce, B.R., et al., <u>Brain Research</u>, 206:485, 1981). In order to study this K<sup>+</sup>-stimulated release, the neurons need to be first loaded with a tritiated neurotrans-mitter. Lasher (<u>Brain Research</u>, 69:235, 1974) found that the matter. Lasner (<u>Brain Research</u>, 69:235, 1974) found that the uptake of  ${}^{3}$ H-GABA into cerebellar neurons was Na<sup>+</sup> dependent and age related. With this information, the present study was de-signed to examine what levels of potassium were needed to cause release from cultured cerebellar neurons. Also noted in the study was the age dependence necessary for the K<sup>+</sup>-stimulated release of  ${}^{3}$ H-GABA.

release of  ${}^{3}$ H-GABA. Dispersed rat cerebellar cultures at 7 days in vitro were loaded with 4.24 uM  ${}^{3}$ H-GABA, washed in solutions containing different concentrations of K<sup>+</sup>, and processed according to standard autoradiographic procedure. A 3mM K<sup>+</sup> wash solution left a substantial density of silver grains over the GABA-ergic neurons. This suggests that 3mM K<sup>+</sup> concentration is not adequate for release of the  ${}^{3}$ H-GABA. However autoradiograms of 7 day in vitro cultures treated with a wash solution containing 50mM K<sup>+</sup> revealed sparsely labeled GABA-ergic neurons. Thus, a wash solution containing 50mM K<sup>+</sup> stimulated the release of the tritiated neurotransmitter.

tritiated neurotransmitter. Next the release of <sup>3</sup>H-GABA was investigated with a series of Next the release of 'H-GABA was investigated with a series of scintillation experiments. Cerebellar cultures were loaded with 4.24 uM <sup>3</sup>H-GABA and washed with 3mM K<sup>+</sup> or SOmM K<sup>+</sup> solutions. These solutions were collected and counted. Low levels of <sup>3</sup>H-GABA were detected in cultures 7 days in <u>vitro</u> in both the 3mM K<sup>+</sup> and 50mM K<sup>+</sup> wash solutions. By 14 days in <u>vitro</u>, the amount of <sup>3</sup>H-GABA released was significantly higher in the 50mM K<sup>+</sup> wash solutions than in the 3mM K<sup>+</sup> wash solution.

Soume K wash solutions than in the sime K wash solution. These data indicate that the cultures were mature enough by 7 days in vitro to take up the  ${}^{3}\text{H}$ -GABA. Upon addition of dif-ferent K<sup>+</sup> concentrations, various levels of  ${}^{3}\text{H}$ -GABA were detect-ed in the autoradiograms and liquid scintillation counts. The scintillation data suggest that the release of  ${}^{3}\text{H}$ -GABA is dependent on the age of the neurons, and that only more mature neurons were able to release  $^{3}\text{H-GABA}$  in a stimulation dependent manner. Supported by NIH Grant to R.W.B. NS-15894 and funds from the Spinal Cord Injury Research Center at The Ohio State University, NIH Grant NS-10165.

degranulation is thought to occur by exocytosis. In the mutant mouse, beige, the granules are enlarged; the average diameter is about 1.7  $\mu$ . These mice resemble the Chediak-Higashi syndrome in humans. In peritoneal mast cells, with video enhanced Nomarski humans. In peritoneal mast cells, with video enhanced Nomarski differential-interference microscopy, the granules appear to be denser than the rest of the cell. Perfusion with the ionophore A-23187 and elevated Ca<sup>-+</sup> causes the emptying of the granules, and this is accompanied by swelling. There is no evidence for flattening of the vesicles. The empty vesicles stain with ruthenium red, a marker for heparin sulfate. Supported by NIH grants NS07681 and NS13778.

CHARACTERIZATION OF NONCHOLINERGIC RECEPTORS

STRUCTURE-ACTIVITY STUDIES OF LIGANDS INTERACTING WITH RAT CORTEX PHENCYCLIDINE RECEPTOR. Laurane E. Geary, Dennis M. Zimmerman\*, J. David Leander and Vin Kalra\*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285. The ability of compounds to displace <sup>3</sup>H-phencyclidine (PCP) from rat brain membrane receptors was compared with their ability to produce PCP-type catalepsy in pigeons (Chen, G., 1965. Arch. Intern. Pharmacodyn. 157: 193-201). There was a high degree of correlation between the two tests using derivatives of the phenylcyclohexylamines, dioxolanes, and benzomorphan series previously reported to produce PCP-like effects.

I. Benz[f]isoquinolines

II. Bridged benz[f]isoguinolines

Two series, benz[f]isoquinolines (I) and bridged benz[f]-isoquinolines (II), were found to have PCP-like activities. Using these two tests, the structure-activity relationships at the PCP receptor of these series were studied. It was found that replacement of the methyl-substituted nitrogen with an allyl or methylcyclopropyl group significantly increased receptor affinity and potency in the pigeon catalepsy test. Substitution of a propyl group for methyl at R2 significantly was found to be of critical importance for maximum PCP-like activity. activity.

These studies suggest that compounds from several different classes can interact strongly with the PCP receptor and that the receptor binding and catalepsy assays described can be utilized to develop compounds with high affinity and selectivity for this receptor.

166.2 Specific Binding of [<sup>3</sup>H]-Amantadine to Dog Striatal Membranes

R. Michael Allen, M.D., VAMC and UTHSCD, Dallas, Texas

I have reported previously that amantadine can displace I have reported previously that amantadine can displaw [ $^{3}H$ ]spiperone and ADTM from striatal total particulate and crude P2 preps (Allen, Neurosci., abstr. 1981) and more recently appears to effect a change in the affinity state of the D<sub>2</sub> receptor (Allen, Neurosci., Abstr. 1982). In this experiment, binding studies were carried out using custom synthesized [ $^{3}H$ ] amantadine (ICN, inc. 25 ci/mM) to determine if a binding site for amantadine existed in the striatum. The binding assay was carried out at  $37^\circ$  in a Tris salt buffer system, pH 7.34, in a 2-5m total incubation volume with a tissue concentration of 2.5 mg/tube. The GFB filters pretreated with a 0.4% bovine serum albumin GFB filters pretreated with a 0.4% bovine serum albumin solution (found previously to markedly reduce nonspecific filter binding), and washed 3x with 5ml ice cold Tris HCl pH 7.1. Nonspecific binding was determined with  $10^{-5}$  spiperone, stereospecific binding with  $10^{-5}$  ( $\pm$ ) Butaclamol. The binding was maximally defined by spiperone with a K<sub>D</sub> of 750 pM, Bmax 180 fmol/mg prot. Butaclamol stereospecifically yielded a K<sub>D</sub> of 1.25nM and Bmax of 157 fmol/mg prot. Correlation for scatchard and Hill Plot analyses was >.96 for each. scatchard and Hill Flot analyses was 3.50 for each. Inhibition experiments were carried out with ( $\pm$ ) Butaclamol (IC<sub>50</sub> (+) But <u>3nM</u> (-) But <u>150nM</u>) Apomorphine (IC<sub>50</sub> luM); ( $\pm$ ) Sulpiride (IC<sub>50</sub>>10uM), cold amantadine (IC<sub>50</sub> luM) which was quite variable and is probably due to ternary complex formation; ketanserin (IC<sub>50</sub>>10uM), and rimantadine, a non DA active analogue of amantadine (no displacement). These results indicate that exectfic amontadine heiding is a non DA active analogue of amantadine (no displacement). These results indicate that specific amantadine binding is found in the striatum, is probably to a site related to the D<sub>2</sub> receptor (possibly the D<sub>2</sub>Lo) and not to the proposed D<sub>4</sub> site of (Sokoloff et al; in <u>Molecular Pharmacology of</u> <u>Neurotransmitter Receptors</u> 163-173, 1983) due to its resistance to sulpiride displacement. Further conclusions and methodo-logical details will be presented.

Supported by Veterans Administration research funds, and a grant from E.I. Dupont Co.

TUESDAY PM

CHARACTERIZATION OF [<sup>3</sup>H]PHENCYCLIDINE (PCP) BINDING TO RAT 166.3 HIPPOCAMPAL SECTIONS USING AUTORADIOGRAPHY. M. R. Kozlowski and L. A. Lebel\*, Department of Metabolic Diseases and General Pharmacology, Pfizer Inc., Groton, CT 06340.

Autoradiographic measurement of neurotransmitter receptor binding in brain sections offers many advantages over binding assays employing brain homogenates. These advantages include simultaneous visualization of binding in several brain regions, ease of measurement of binding in small brain areas and elimination of filtration artifacts. This technique has been used nation of filtration artifacts. This technique has been used to study the binding in brain of several ligands including H-PCP (Quirion et al., <u>PNAS 78</u>, 5881, 1981). However, H-PCP binding was quantified by scintillation counting rather than autoradiography. The present study reports the characteristics of H-PCP binding to rat brain sections measured autoradio-craphically.

graphically. H-PCP bound in a saturable fashion to rat brain sections and was displaced by excess unlabeled PCP. The areas of densest and was displaced by excess unlabeled to . The druce of control binding in the forebrain included the hippocampus, neocortex and neostriatum. Scatchard analysis of H-PCP binding to binding in the forebrain included the hippocampus, neocortex and neostriatum. Scatchard analysis of H-PCP binding to hippocampus yielded a  $K_D$  of 279.5 + 35 nM and a  $B_{max}$  of 3057 + 406 fmol/mg prot., in agreement with the results 07 homogenate assays (Vincent, et al., <u>PNAS 76</u>, 4678, 1979). Similar  $K_D$ 's were observed for H-PCP binding to neocortex, neostriatum and olfactory bulb, suggesting that each of these regions contains the same type of H-PCP binding site. SKF 10,047 and 1-(1-phenylcyclqhexyl)-3-methylpiperidine (PCMP) stereoselectively inhibited H-PCP binding to hippocampal sections with the (+)-isomers being more potent than their respective (-) isomers isomers being mnore potent than their respective (-)- isomers (Table 1). In addition, the relative potencies of SKF 10,047, PCMP, ketamine and dexoxadrol in inhibiting PCP binding agreed well with their abilities to produce PCP-like behavioral effects (Browne et al., in press).

In summary, the present study demonstrates the usefulness of autoradiographic analysis of ligand binding to brain sections not only for obtaining a global picture of specific binding but also for measuring its characteristics.

	Table I	
Compound	$K_{T}(nM)$	Relative Potency

(+)SKF 10,047	310	1.44
Dexoxadrol	683	0.65
(+)PCMP	912	0.49
(-)SKF 10,047	2,100	0.21
Ketamine	4,169	0.11
(-)PCMP	10,400	0.04

AMINE RECEPTORS ON EMBRYONIC SENSORY NEURONS. K. Dunlap and D.R. 166.5 Canfield\*. Department of Physiology, Tufts University School of Medicine, Boston, MA 02111.

Nor-epinephrine (NE) has been shown to decrease the conduc-tance of voltage-dependent Ca channels in the soma membrane of embryonic chick sensory neurons in vitro (1,2). This action of NE results in a decrease in the Ca-dependent soma action potential duration (APD). Dopamine (DA) can mimic this effect of NE on APD.

NE and DA act over a 1000-fold concentration range, with  $ED_{50}{}^{\prime}{}^{s}$  of 1.4  $\mu M$  and 0.3  $\mu M$ , respectively. Maximal concentration is 10  $\mu M$  for both; however, DA is somewhat less potent, producing a maximal 29% decrease in APD as compared to 43% for NE. Several lines of evidence suggest that these two agonists act via the same receptor. Saturating doses of the two, when applied together, do not produce any larger response than that produced by either applied alone. In addition, NE added to the bath blocks the response of the neurons to DA with an  $DD_{50}$  identical to the ED<sub>50</sub> measured for NE's agonist activity (i.e., the dose-response curves are identical for NE, whether it acts as an agonist or as a blocker of DA effects). Inhibition of NE and DA responses by antagonists also suggest

that these two amines act via the same receptor. Characteristic that these two amines act via the same receptor. Characteristic of an  $\alpha_2$  adrenergic receptor, the transmitter-induced decreases in APD are blocked by yohimbine ( $\alpha_2$ ) and phentolamine ( $\alpha$ ) but not prazosin ( $\alpha_1$ ) or propranolol ( $\beta$ ). The ID<sub>50</sub>'s for yohimbine and phentolamine are 5 nM and 160 nM, respectively. In contrast, the decrease in APD is not mimicked by clonidine or xylazine, both selective  $\alpha_2$  agonists. In fact, in higher concentration cloni-dine blocks the NE-induced decrease in APD (ID<sub>50</sub> of 5 µM). This recentor also has properties of a domainarcia recentor in that receptor also has properties of a dopaminergic receptor in that the transmitter-induced decrease in APD is blocked by haloperidol  $(ID_{50} = 10 \text{ nM}).$ 

These results show that the amine receptor which mediates the decrease in APD cannot be definitively classified as either adrenergic or dopaminergic, as it exhibits a pharmacology charac-teristic, in part, of both receptor types. (Supported by PHS Grant NS 16483).

 $\beta$ -ALANINE BINDING IN THE PRESENCE AND ABSENCE OF 166.4 SODIUM, L.M. Orensanz, M.C. Azuara\* and I. Fernández\*. Dpto. de Investigación, Centro Especial Ramón y Cajal; and Dpto. de Bioquímica, Colegio Universitario Arcos

and Dpto. de Bioquimica, colegio universitatio incom de Jalón, Madrid, Spain.  $\beta$ -Alanine binds to synaptosomal-mitochondrial prep-arations in a "specific" manner. Previous studies have indicated that this binding may be representative of interaction with synaptic receptors for this amino acid. Although much of the experimental work leading the binding synaptic profession and bicarbonate-buff. to this hypothesis was performed in a bicarbonate-buffto this hypothesis was performed in a bicarbonate-bull, ered, sodium-free medium, it has been suggested that  $\beta$ -alanine binding to synaptic receptors may be studied in the presence or absence of sodium, using very low concentrations of  $\beta$ -alanine, and strychnine to define the synaptic receptor component. This communication reports results of experiments designed to investigate the possibility of studying  $\beta$ -alanine binding in several sodium-free and sodium-containing media. Effects of antagonists and uptake inhibitors on binding as well as pharmacological and saturation characteristics of binding in the absence of sodium were also studied. Experiments were conducted in rat tissue containing

brain stem plus spinal cord. Specific binding was higher in sodium-containing than in sodium-free media and was absent when extensively frozen/thawed memand was absent when extensively frozen/thawed mem-branes were used. Binding in the presence of sodium was inhibited by strychnine and the uptake inhibitor arecaidine, whereas without sodium, it was only sensi-tive to strychnine. Using either Tris or bicarbon-ate-buffered media, binding was equally sensitive to cold  $\beta$ -alanine and strychnine and equally insensitive to arecaidine, demonstrating the existence of strychration experiments in the bicarbonate-buffered medium showed a similar affinity of  $\beta$ -alanine for the two types of sites. Present results show the need to avoid sodium when

studying β-alarine binding to its putative synaptic receptors. Binding is better detected in a bicarbon-ate-buffered medium than in Tris media, although their pharmacological specificity is identical.

THE PRESENCE OF HIGH AND LOW AFFINITY BINDING SITES FOR <sup>3</sup>H-IMIPRAMINE IN RAT CEREBRAL CORTEX. <u>P.G. Conway and D.J.</u> <u>Brunswick\*</u>, Depts. of Fsychiatry and Pharmacology, University of Pennsylvania and Veterans Administration, Phila. PA 19104. It has been demonstrated previously that the tricyclic antide-

It has been demonstrated previously that the tricyclic antide-pressant drug imipramine binds to a high affinity binding site in rat brain tissue in vitro. Our preliminary findings suggested that there may also be a low affinity binding component of H-imipramine. Thus this study was performed to further evaluate the binding characteristics of H-imipramine in rat cerebral cor-tex. Saturation experiments were performed according to the method of Raisman et al. (Eur. J. Pharmacol. <u>61</u>:373-380, 1980) by incubating fresh rat cerebral cortex membranes with a wide range of H-imipramine concentrations (0.5nM to 50nM) for 60 minutes at 0°C. Specific binding was defined as that inhibited in the pres-ence of low desirements and represented 70-802 of total binding ence of  $_3$  loud desipramine and represented 70-80% of total binding at 2nM H-imipramine. Scatchard analysis of the data revealed a biphasic, concave curve indicating that imipramine does not bind to a single population of non-interacting binding sites in the rat cortex. Additional evidence for non-homogeneous binding of The oblight product of the set o 10uM desipramine was added and the incubation was allowed to con-tinue for various lengths of time (40 sec to 60 min). When the H-imipramine specifically bound (defined using 10uM desipramine) H-impramine specifically bound (defined using four desipramine) was plotted against the time of dissociation a biphasic curve was exhibited with apparent half lives of dissociation of  $2.5\pm.42$ (mean±S.E.M.) and  $18.5\pm2.46$  min (n=3). Further support for non-homogeneous binding of H-imipramine to rat cortex was obtained from competition curves derived by incubating cerebral cortical membranes with H-imipramine (2nM) and various concentrations of unlabelled imipramine (.01mM to 100uM). These curves were shalunlabelled imipramine (.01nM to 100uM). These curves were shallow and Hill analysis gave coefficients of  $0.60\pm04$  with IC-50 values of 11+1.8M (n=3). Thus analysis of saturation, dissociation and competition curves indicate that H-imipramine binds to low (micromolar) as well as high (nanomolar) binding sites in rat cortex when specific binding is defined with 10uM desipramine. These results are similar to those of Reith and coworkers (J. Neurochem. 40:389-395, 1983), who demonstrated both high and low affinity binding sites for H-imipramine in mouse cerebral cortex. PROTEOLYTIC GENERATION AND PURIFICATION OF BENZODIAZEPINE 166.7 BINDING SITE FRACMENTS. K. L. Klotz\*, J. W. Thomas', J. H. Neale and J. F. Tallman<sup>2</sup>. Department of Biology, Georgetown University, Washington, D.C. 20057; Biological Psychiatry<sup>1</sup>, NIMH, Bethesda, MD 20205 and Department of Pharmacology<sup>2</sup>, Yale University, New Haven, CT 06510.

The high affinity, membrane bound benzodiazepine (BZ) receptor site appears to be a component of a GABA receptor-ionophore complex. We have used proteolytic enzymes to generate water soluble fragments of the BZ receptor which we have purified subsequently without the use of detergents. The BZ binding site was photolabeled with <sup>3</sup>H-flunitrazepam and subsequently digested using trypsin, chymotrypsin or a combination of these enzymes. The effects of various enzyme concentrations and digestion times upon protolysis were determined. The size of the tryptic fragments was estimated using SDS polyacrylamide gel electrophorregions and solution to the solution of the solution of the solution of the solution of the solution in the solution of the so membranes, an approximately 5K dalton radiolabeled fragment is released into the aqueous supernatant.

released into the aqueous supernatant. Receptor digestion using combined trypsin and chymotrypsin for 20 minutes at  $37^{\circ}$  C released approximately 40% of the photolabeled BZ binding sites from rat brain membranes. The receptor fragment generated by enzymatic digestion was purified by Amicon YM10 filtration, Sephadex G50 gel filtration and reverse phase octadecyl silicone HPLC. Radiolabeled peaks of material which emerged from the HPLC were further purified by varying the chromatographic conditions. Microgram quantities of photolabeled BZ receptor fragments containing the BZ binding site have been BZ receptor fragments containing the BZ binding site have been partially purified using this method.

GLUTAMATE RECEPTOR: BIOCHEMICAL IDENTIFICATION IN HOUSEFLY MUSCLE. M. T. FIIbin<sup>\*</sup>, A. T. Eldefrawi and M. E. Eldefrawi<sup>\*</sup>. Dept. of Pharmacology and Exp. Ther., University of Maryland School of Medicine, Baltimore, Maryland 21201. Thoraces of house flies (Musca domestica L.) were homogenized (10<sup>\*</sup> w/v) in Van Harreveld's Duffer, pH 7.4. The following anti-proteases were included at all stages of the preparation: PMSF, pepstatin, trypsin inhibitor, aprotinin and iodoacetamide. The homogenate was filtered through cheesecloth and centrifuged at  $50,000 \times g$  for 30 min. After resuspension of the pellet and cen-trifugation at 1,000 x g for 10 min, the supernatant was recen-trifuged at  $50,000 \times g$  for 30 min. The pellet was washed and resuspended (1 g original tissue/ml) in 50 mM Tris-HCl, pH 7.1, and was used within 1 h of preparation. The membrane preparation (75 µl, 100-800 µg prot.) was incubated for 2 h at 4°C with [5H]-L-glutamate to account for the nonspecific binding. The prepar-tion was centrifuged at 12,500 x g for 7 min, after which the pel-let was washed, and its radioactivity counted. Specific [5H]L-glutamate binding was directly proportionate to tissue concentra-tion up to 300 µg of protein per sample and saturated at concen-tertion eff. In the result of the consent of the saturated at concen-tertion of the protein per sample and saturated at concen-tertion eff. In the result of the consent of the saturated streacention up to 300  $\mu$ g of protein per sample and saturated at concentrations of L-glutamate greater than 1.2  $\mu$ M. Scatchard analysis trations of L-glutamate greater than 1.2  $\mu$ M. Scatchard analysis of the binding data revealed consistently one binding site of Kp 0.57 ± 0.09  $\mu$ M (mean of 5 expt.). The B<sub>max</sub>, however, was found to vary from 10-40 pmol/mg prot., the higher density of binding sites being apparent in those preparations in which the flies were greater than 6 days old. Preincubation of the mem-branes for 5 min at 70°C eliminated specific [<sup>5</sup>H]L-glutamate bind-ing. Furthermore, specific binding was also abolished by prein-cubation of the membranes for 1 h at 21°C with trypsin, chymo-trypsin or protease. Binding was also stereoselective as a trypsin or protease. Binding was also stereoselective as a greater sensitivity to the L- than to the D-isomer of glutamate was observed. Of the drugs tested only glutamate-like ligands were effective in inhibiting specific [5H]L-glutamate binding. The order of potency was as follows: L-glutamate-L-aspartate>> The order of potency was as follows: L-glutamate>L-aspartate>> D-glutamate=L-glutamate diethyl ester>N-methyl-D-L-aspartate>> kainate. A crude extract of the venom from the bee wolf <u>Philan-</u> thus triangulum inhibited specific binding. The following drugs at I mM had an insignificant effect: ibotenate, proctolin, d-tubocurarine,  $\gamma$ -aminobutyric acid and glycine. It is suggested that [<sup>3</sup>H]L-glutamate is binding to an L-glutamate receptor in this fly thoracic muscle membrane preparation. ANTIBODIES AGAINST THE BOVINE BRAIN GLUTAMATE BINDING PROTEIN. S. Roy and E.K. Michaelis, Dept. of Human Development and Ctr. for Biomedical Research, University of Kansas, Lawrence, KS

A small molecular weight glycoprotein that has high affinity binding sites for L-glutamic acid has been purified from rat brain synaptic membranes and from bovine brain crude membrane fraction. Based on the selectivity of the protein binding sites for various L-glutamate analogs and on protein's lack of glutamate metabolizing enzymatic activity, it was proposed that this binding protein may be the recognition macromolecule of the Legutamate receptor complex (Michaelis et al., Mol. Cell. <u>Biochem.</u> 38, 163-179, 1981). We report here on our studies of raising antibodies in rabbits against the purified bovine brain glutamate binding protein (GBP). Underivatized GBP as well as GBP derivatized with dinitro-

benzene evoked a specific immune response in immunized rabbits The antibody titler was measured by the solid phase enzyme-linked immunosorbent assay (ELISA). Our results show that antibodies against bovine GBP extensively reacted with rat brain GBP indicating thereby that both proteins are immunologically homologous. A bacterial glutamate-aspartate binding protein, homologous. A bacterial glutamate-asparate bluting plote however, did not show any cross-reaction with the anti GP antibodies. The specificities of the antibodies were also investigated by measuring their cross-reactivity with glutamate metabolizing enzymes. Glutamate dehydrogenase, glutamine synthetase and  $\gamma$ -glutamyl transpeptidase showed little or no cross-reactivity with anti GBP antibodies. A crude bacterial glutamate decarboxylase preparation gave small to moderate cross-reaction with the anti GBP antibodies. The sensitivity of the ELISA assay and the specificity of the antibodies were such that GBP levels as low as 3-10 ng could be detected. it should be possible to use these anti GBP antibolies to quantitate and localize this binding protein in the brain and other tissues and to explore the role of this binding protein in the function of the physiologic glutamate receptors. (Supported by grants AA 04732 from NIAAA, DAAG 29-79-C-0156 and DAAG 29-83-K-0065 from U.S. Army Res. Office, and Biomedical Research grant 4073-706, the University of Kansas).

166.10 STRUCTURAL REQUIREMENTS OF THE SODIUM-INDEPENDENT BINDING SITE STRUCTURAL REQUIREMENTS OF THE SODIUM-INDEPENDENT BINDING SITE OF 4-AMINOBUTANOL ACID (GABA). S.L. Early and E.K. Michaelis Dept. of HDFL, Univ. of Kansas, Lawrence, KS 66045. Studies aimed at defining the structural requirements of the sodium-independent binding site of 4-aminobutanoic acid (GABA) have depended mainly on the modification of the 3-carbon backbone and the carboxylic acid. Only recently has any attempt been made

the carboxyric action. Only recently has any attempt been hade to study the effect of modifying the amino group of GABA to study the effect of modifying the amino group of GABA on the binding of [7H]-GABA to brain tissue. We report here on the effects of some N-alkylated, N-acylated, and non-acidic derivatives of GABA on the sodium-independent binding of [7H]-GABA to bovine cerebel-

on the sodium-independent binding of  $[^{3}H]$ -GABA to bovine cerebellar synaptic plasma membranes. Under the assay conditions used in this study, GABA had a K<sub>D</sub> of 14.5 nM and a B of 2800 pmol/mg protein as determined by Scatchard analysis.<sup>Th</sup> Scatchard plot over the concentration range 7 to 112 nM appears linear. A curvilinear plot at higher concentrations of  $[^{2}H]$ -GABA was observed. Eighteen analogues with modified carboxylic acid groups, most of the manlogues of bicculline, were tested. Only 5 inhibited binding by more than 50% at 1 mM. AETS (2-aminoethyl-2-amino-ethanethiosulfonate) and kojic amine (2-aminoethyl-5-hydroxy-4-Pone) inhibited binding with 10. values of 51.2 uM and

ethanethiosulfonate) and kojic amine (2-aminoethyl-5-hydroxy-4-H-pyran-4-one) inhibited binding with  $IC_{50}$  values of 51.2 uM and 4 uM (as reported by others), respectivefly. Our results suggest that bicuculline's inhibitory potency is due to its rigid confor-mation and hydrophobicity, which allows bicuculline to interact with the GABA binding site without a free carboxylic acid group. The most potent N-monoalkylated derivative of GABA was N-benzyl GABA with an  $IC_{50}$  of 37.6 uM. Tritylation of GABA gave a very lipophilic compound with an  $IC_{50}$  of 233 uM. It was observed that N-trityl-GABA inhibition was not time dependent. However, the compound does decompose in Tris sulfate buffer, presumably to GABA and a triphenylmethane derivative. to GABA and a triphenylmethane derivative. All attempts to modify the 4-amino group of GABA via an amide/

peptide bond failed to produce a compound with any significant peptide bond rate to produce a compound with any significant ability to inhibit GABA binding. Initially, we observed potent inhibition by the derivatives. However, we found that the activities of these compounds could be attributed to the presence of 0.036%–0.236% GABA. Schiff bases formed from GABA and a ketone or aldehyde were also potent inhibitors of  $[^{2}H]$ -GABA binding the course of inhibitors was not the parameters binding. However, the source of inhibition was not the parent compound, but rather the GABA released by the hydrolysis of the Schiff bases in solution. From these data, the free amine appears to be necessary for binding to the [<sup>3</sup>H]-GABA binding site. Additionally, care needs to be exercised in data interpretation when working with compounds synthesized from GABA. Supported by Biomed. Grant 4073.
