Thyrotropin-releasing hormone (TRH) exerts state-dependent physiological and behavioral effects when microinjected into the dorsal hippocampus of ground squirrels (Citellus lateralis). To examine the neurochemical correlates of these changes, we used quantitative autoradiography to localize and quantify TRH receptors in the CNS of hibernating (H), winter euthermic (WE) and summer euthermic (SE) animals (n=4/grp). The pharmacological profile of [^{3}H]-MeTRH binding to brain sections was similar to that in the rat with a Kd of 6.7 ± 0.1 nM. Analysis of 82 discrete regions of the brain revealed statistically significant differences for only eight areas ($p<0.05$-0.001). Seasonal changes (SE vs WE) were reflected by decreases in TRH receptor binding in the arcuate nucleus, dorsomedial nucleus, and the ventral pallidum of WE animals. Increased binding in WE animals was evident in the area surrounding the suprachiasmatic nucleus. State dependent changes (WE vs H) were characterized by decreases in TRH receptor binding in the paraventricular nucleus, medial preoptic area and the ventral tegmental area of H animals. Increased binding occurred in the anterior cortical nucleus of the amygdala in H animals. These findings indicate that seasonal and state dependent changes occur in TRH systems in the brain, and further support the hypothesis that naturally occurring changes in central TRH systems may mediate the level of arousal in this species.

CALIBRATION OF AMERSHAM HYPERFILM ß-MAX™ (HFBM) WITH [14C] STANDARDS FOR QUANTITATIVE AUTORADIOGRAPHY (QAR) WITH [125I]. Denis G. Baskin and Thomas H. Wimpy* (SPON: James W. Little). Departments of Medicine and Biological Structure, University of Washington, Seattle, WA 98195, and V. A. Medical Center, Seattle, WA 98108.

HFBM produces high contrast autoradiographic images with [125I]. In order to use HFBM for QAR, we calibrated the response of this film to [14C] plastic standards in terms of tissue-equivalent concentrations of [125I]. Plastic sections with standard concentrations of [125I] (Amersham "Microscales") and [14C] (American Radiolabeled Chemicals) were apposed to HFBM for 1, 3, 5, and 9 days, along with liver and muscle slices (20 um) labeled with increasing concentrations of [125I]-insulin. Optical densities produced on HFBM by [125I] and [14C] plastic standards were converted to equivalent tissue [125I] concentrations (DPM/mm2). The responses of HFBM to the plastic [125I] and [14C] standards (each calibrated in tissue-equivalent DPM/mm2) were similar ($p<.001$). Standard curves of tissue [125I] (DPM/mm2) vs. standard [14C] (uCi/g) concentrations fit second order polynomials ($r2 = .99$-1.0; $p<.001$): 1 day, $y = -26.8+1.0x-.00013x2$; 3 day, $y = -49.3+1.4x-.001x2$; 5 day, $y = -39.4+1.6x-.001x2$; 9 day, $y = -5.6+1.5x-.002x2$. The useful DPM/mm2 ranges for measuring tissue [125I] radioactivity with the [14C] plastic standards were: 1 day, 50-1450; 3 day, 25-675; 5 day, 10-400; 9 day, 5-210. The results indicate that [14C] plastic sections are valid standards for measuring [125I] radioactivity concentrations in tissue slices by QAR with Hyperfilm ß-Max™. GLIA IN THE CIRCUMVENTRICULAR ORGANS: A POSSIBLE ROLE IN PROTECTING THE BRAIN FROM BLOOD-BORNE PEPTIDES. M. Ian Phillips, Tammy Vittands* and Rod Casto. Department of Physiology, College of Medicine, University of Florida, Gainesville, FL. 32610.

The circumventricular organs (CVOs) have been called "windows on the brain" because their capillaries lack the tight junctions which are necessary for a blood-brain-barrier (BBB). However, such windows are not open to free flow of normally excludable proteins and peptides. Otherwise, the BBB would constantly be circumvented. Therefore, a mechanism must exist, specific to the CVOs, which prevents uncontrolled diffusion of plasma peptides into brain. We propose that glial cells effect this mechanism.

To demonstrate the presence of glia in CVOs, rats were perfused and brain sections immunocytochemically stained using GFAP antibodies for astroglia. There are numerous glia inside the body of the organ (SFO and OVLT). In the area postrema (AP) there is a border of glial cells surrounding the organ and separating it from the NTS and other brain structures. Dye injections into the AP did not flow out of the border and dye in NTS did not flow into the AP. Glia cells contain angiotensin II receptors (Raizada, Phillips et al., PNAS, 1987) and the CVOs have high affinity binding sites for Ang II. Therefore, it is proposed that CVO glia rapidly bind and metabolize blood-borne peptides arriving at CVOs. This mechanism restricts normal plasma concentrations of peptides to the CVO and prevents crossing into brain tissue. (Supported by NIH 1-R01-27334 to MIP.)

IN-SITU DEMONSTRATION THAT SUBSTANCE P RECEPTORS ARE EXPRESSED BY GLIA AFTER NEURONAL INJURY. R.P. Zimmerman, T.S. Gates*, C.G. Boehmer*, D.J. Johnson and P.W. Mantyh. Center for Ulcer Research and Education; Brain Research Institute; UCLA School of Medicine, Los Angeles, CA 90024

Previous studies have shown that glia can express receptors for various neurotransmitters in-vitro. In this report, we use quantitative receptor autoradiography to determine in-situ which receptor binding sites are expressed by the pure glial scar formed following transection of the optic nerve in the albino rabbit. After unilateral optic nerve transection, the rabbits were allowed to survive for 40-99 days. The brains were removed, embedded in Tissue-Tek, frozen to -70°C, and sectioned (30 µm). The sections were then processed for quantitative receptor autoradiography with either radiolabeled bombesin, calcitonin gene related peptide, cholecystokinin, galanin, glutamate, somatostatin, substance P (SP) and vasoactive intestinal peptide.

Specific binding sites were identified in the forebrain for each ligand, but no specific binding sites for any radioligand tested were expressed in the normal optic nerve or tract. In the lesioned optic nerve and tract, SP was the only radioligand of those tested for which specific receptor binding sites were observed in the glial scar tissue. This glial scar expresses one of the highest concentration of SP binding sites seen in the rabbit brain, and pharmacological experiments show that these binding sites have a similar pharmacological profile to SP receptors in the striatum.

This study demonstrates that presumed glia populating the scar formed after transection of the optic nerve ectopically express high concentrations of SP receptors and suggest that SP may play a role in regulating the glial response to neuronal injury.

EFFECTS OF INTRATHECAL NEUROKININ RECEPTOR AGONISTS ON THE CARDIOVASCULAR SYSTEM OF THE CONSCIOUS FREELY MOVING RAT. H. Hasséssian and R. Couture*. Dept. of Physiology, Faculty of Medicine, University of Montréal, Montréal, Qué., Canada.

This study aims to characterize the neurokinin (NK) receptor which mediates the cardiovascular responses elicited by the intrathecal (i.th.) administration of SP. In addition to SP, neurokinin A (NKA) and neurokinin B (NKB), five NK receptor subtype selective agonists: [Pro^9, $Met(O_2)^{11}$]SP, (A); [ß-Ala^4, Sar^9, $Met(O_2)^{11}$]SP (4-11), (B); [Nle^{10}]NKA (4-10) (C); [ß-Asp^4, $MePhe^7$]NKB (4-10), (D) and [Succinyl-Asp^6, $MePhe^8$]SP (6-11), (E) were studied for their effects on mean arterial pressure (MAP) and heart rate (HR). Male Wistar rats were cannulated under pentobarbital anesthesia, with two catheters: a PE-10 in the intrathecal space (T_8-T_{10} vertebral level) and a PE-50 in the caudal artery. Experiments were performed 24h later in the conscious freely moving rat. The three NK elicited a pressive effect with the following rank order of potency: SP > NKA = NKB. Only the response to SP was dose dependent (0.065-65 nmol). All NK elicited a dose dependent increase in HR with the following rank order of potency: SP > NKA > NKB. The NK-1 selective agonists (A and B) produced a maximal increase in MAP and HR greater in intensity than SP and the HR response they elicited lasted longer. The NK-2 (C) and NK-3 (D and E) selective agonists elicited MAP increases comparable to SP but produced a much weaker HR response. In conclusion, the cardiac and pressive responses elicited by the intrathecal administration of SP appear to be mediated by an NK-1 receptor subtype. (Supported by the MRC of Canada).

SYMPATHETIC NEURONS EXPRESS HIGH LEVELS OF RECEPTORS FOR SENSORY NEUROPEPTIDES T.S. Gates*, R.P. Zimmerman, C.G. Boehmer*, S.R. Vigna, J.E. Maggio, and P.W. Mantyh. Brain Res. Inst., UCLA, LA, CA 90024, Dept. Biol. Chem. and Mol. Pharm., Harvard Med. School, 02115, Dept. of Phys., Duke Univ. Med. Center, 27710

To define which sensory neurotransmitters are involved in regulating post-ganglionic sympathetic neurons we used quantitative receptor autoradiography to determine which neuropeptide receptor binding sites are expressed by neurons in the rat and rabbit superior cervical ganglion and rabbit superior mesenteric ganglion. The neuropeptides examined included bombesin, calcitonin gene related peptide, cholecystokinin, galanin, somatostatin, substance K, substance P and vasoactive intestinal peptide. High levels of receptor binding sites for cholecystokinin, galanin, somatostatin, substance P and vasoactive intestinal peptide were present in all sympathetic ganglion examined whereas specific receptor binding sites for bombesin, calcitonin gene related peptide and substance K were not detectable. These results suggest that sensory neurons use specific neuropeptides to modulate sympathetic activity.

394.16

FUNCTIONAL ROLE OF HIGH AFFINITY NEUROTENSIN (NT) BINDING SITES IN RAT BRAIN. S. Bischoff, M. Heinrich*, E. Küng*, M. F. Pozza*, M. Schaub*, W. Schilling* and A. Vassout*. Pharma. Research, CIBA-GEIGY, Basel, CH-4002 Switzerland.

High and low affinity NT binding sites were characterized with (^{125}I-Tyr^3)NT and (^{3}H)NT binding assays. (^{3}H)NT binding was displaced by 80% with levocabastine (L), a marker of low affinity NT sites. NT and a synthetic pentapeptidic analog (P) had IC_{50}'s of 21 and 39000 nM. In (^{125}I)NT binding, L exerted a maximum of 50% inhibition, in contrast to NT (IC_{50}: 2.3 nM) and P (IC_{50}: 175nM). P showed a Hill coef. of 0.6, indicating a clear-cut interaction with two sites; the appropriate curve fitting revealed IC_{50}'s of 13 and 683 nM. These data confirm that (^{125}I)NT binds to high and low affinity NT sites. They show also that L is specific for the low, and P strongly selective for the high affinity NT sites. In vitro, P activated nigral dopamine neurons (in slices) at 3 nM (maximum: 0.3 µM). L also tended to excite these neurons, but the shape was atypic, the concentration very high (3 µM) and the solution unphysiologic (DMSO). In vivo, P produced a dose-dependent hypothermia after icv injection (first effect at 0.1 µg/rat), whereas L was inactive at the highest usable dose (70 µg/rat). In conclusion, P mimicked in vitro and in vivo effects of NT, being 3-5 times more potent, whereas L was rather inactive. According to the selectivity of P for high affinity NT binding sites, these sites play a functional role.

394.17

THE CALCITONIN RECEPTOR. R.C. Dana. Dept. of Medicine, Univ. of Calif., San Diego, La Jolla, CA 92093.

Specific, high-affinity (Kd<1 nM) cell membrane receptors for calcitonin and calcitonin-gene related peptideare widely distributed throughout the central and peripheral nervous systems and also many somatic tissues. Radioiodinated salmon calcitonin was used to study the binding to receptors on isolated membranes from: neonatal rat brain, adult rat brain, kidne liver, 8 different cell lines, bovine kidney, human placenta. The highest levels of specific binding per mg of protein were found in brains from one week rat pups. Trichloroacetic acid precipitation revealed that the liver had the greatest amount of degredation activity of peptide. Cross-linking studies revealed the neonatalrat brain receptor tohave a molecular weight of 60-70K. Current research involves the purification of receptor by affinity chromatography and electrophoresis, partial amino acid sequence analysis for the eventual isolation of the receptor cDNA with oligonucs..

MULTIPLE AFFINITY STATES OF BINDING SITES FOR (+)SKF10,047 AND 1-[1-(2-THIENYL) CYCLOXYL]-PIPERDINE (TCP) IN RAT AND GUINEA PIG BRAIN MEMBRANES. G-Z.Zhou*, A.Katki*, P.Munson* & D.Rodbard* (SPON:B.Cox),LTPB,NICHD, NIH, Bethesda,MD 20892.

We employ program "LIGAND" for simultaneous analysis of self- and cross- displacement studies and of "multiligand" dose-response surfaces, with or without 10-50 nM haloperidol (HAL), (48 curves or 574 points) to characterize multiple subtypes of binding sites for (+)SKF10,047, phencyclidine (PCP), and its analogs (TCP and 3-OH-PCP) in membranes from rat and guinea pig brain. We find 3 distinct sites in rat brain ($p < 0.001$): one (+)SKF10,047 selective, HAL suppressible site and 2 TCP selective, HAL nonsuppressible sites (Table). In guinea pig, we find 4 classes of sites: 2 selective for (+)SKF10,047 (only one is suppressible with 10-50 nM HAL) and 2 are TCP selective (Table):

		Binding Capacity	Dissociation Constants, Kd (nM)	
	site	(pmol/mg prot.)	(+)[^{3}H]SKF10,047	[^{3}H]TCP
Rat	1	1.0 ± 0.3	100 ± 25	8.6 ± 1.9
	2	2.8 ± 0.4	>1000	72 ± 20
	3	0.5 ± 0.2	120 ± 47*	>1000
Guinea pig	1	1.3 ± 0.1	330 ± 29	7.4 ± 0.6
	2	2.1 ± 0.7	>10000	310 ± 100
	3	4.3 ± 0.9	620 ±140	>1000
	4	0.4 ± 0.1	12 ±2.4	95 ± 16

*suppressible with 10-50 nM HAL. The rank order of potency for 12 drugs was evaluated for the predominant sites. The apparent multiciplicity of sites may help to clarify function, localization and modulation of these receptors.

394.19

QUANTITATIVE AUTORADIOGRAPHY OF INSULIN-LIKE GROWTH FACTOR -I (IGF-I) RECEPTORS IN RAT BRAIN: THE EFFECT OF FIXATION. M.G. King*, T.H. Wimpy*, and D.G. Baskin. Depts. Biological Structure and Medicine, University of Washington, Seattle, WA 98195, and V.A. Med. Center, Seattle, WA 98108.

We evaluated the effect of paraformaldehyde (PAF) on the binding characteristics of brain IGF-I receptors in order to develop a method for localizing IGF-I receptors at the cellular level. Frozen sections (20 µm) from rat brains perfused with saline (control), 1% PAF, or 2% PAF were incubated in 0.05 nM ^{125}I-IGF-I for 20 h at 5°C, with or without unlabeled IGF-I (0.25-50 nM) or related peptides (IGF-II and insulin), and apposed to Hyperfilm ß-Max (Amersham) for 3 days. The binding of IGF-I to 10 brain regions (including median eminence, CA3, and cerebral cortex) was quantified by computer densitometry of the autoradiographic images. The 3 groups (control, 1% PAF, 2% PAF) were not significantly different for specific binding (79 ± 1.0%, 76 ± 1.0%, 82 ± 1.0%), binding specificity (IGF-I>IGF-II>insulin), and the reversibility of binding. The number (B_{max}) and affinity (K_d) of IGF-I receptors of unfixed brain (2.03 ± 0.2 pmol/mm^2, 2.41 ± 0.2 nM) was not affected by 1% PAF (1.78 ± 0.2 pmol/mm^2, 2.46 ± 0.2 nM). 2% PAF increased the B_{max} (3.71 ± 0.5 pmol/mm^2) and decreased the K_d (4.59 ± 0.5 nM), but total specific binding capacity was unchanged. These findings indicate that tissue fixed in PAF is suitable for localization and characterization of IGF-I receptors. (Supported by NIH Grant NS 24809 and the V.A.).

PEPTIDES: ANATOMICAL LOCALIZATION III

395.1

ENKAPHALINERGIC INPUT TO THE ANTERIOR THALAMUS. B.R. Rittberg*, P.L. Faris*, J.J. Sikora*, S.A. May*, and B.K. Hartman. (SPON: M. Dysken) Dept. of Psychiatry, Univ. of Minnesota, Minneapolis, MN 55455.

The rat thalamus contains a dense plexus of met-enkephalin containing nerve fibers and terminals. The cell bodies that give rise to this plexus have not been identified. This study proposes a source for this innervation based on retrograde transport and immunohistochemistry.

Small discrete injections of the retrograde tracer Fluro Gold (20nl of a 4% solution) were centered in the antero-ventral nucleus of the thalamus in adult Wistar rats. Five days later, the rats were sacrificed and serial brain sections were studied with florescence microscopy. Numerous known thalamic afferents had been labeled. These labeled nuclear groups were then compared to enkephalin-positive cells of other rats to determine overlap. This second group of rats had been pre-treated with intraventricular colchine (100 ug). Forty-eight hours later the animals were perfused with 2% parformaldehyde and the brains serially sectioned (40 micron). The sections were then incubated with anti-methionine enkephalin which was visualized either by the PAP method or immunofluoresence. Analysis of overlap indicated that the intrinsic thalamic neurons, the thalamic reticular nucleus, caudal bed nucleus of the stria terminalis and zona incerta were the most likely sources of the thalamic inputs. Verification of this hypothesis will require the simultaneous application of these two techniques. The delineation of the enkephalinergic inputs to thalamus may be an aid to the understanding of central nociceptive pathways. Supported by NS-12311 (BKH), RSDA MH-00595 (PLF).

395.2

QUALITY OF IMMUNOHISTOCHEMISTRY AS A FUNCTION OF CONCENTRATION OF REAGENTS AND INCUBATION PARAMETERS. J.J. Sikora*, P.L. Faris* B.R. Rittberg* B. Moore[1], and B.K. Hartman. (SPON: P.Santi) Dept. of Psychiatry, Univ. of Minn., Mpls., MN 55415, [1]Wash. U. Sch. Med., St. Louis, MO 63110.

Published immunohistochemical procedures vary widely in times of incubation/washes and the concentration of immunoreagents. While some differences might be expected for the primary antibodies, an optimal set of conditions should exist for the secondary detection systems. We examined the application of the PAP localization system on rat brain 40µm vibratome sections fixed by perfusion with pH 8.5 2% formaldehyde/0.05% glutaraldehyde. Localization of the glial protein S-100 was chosen as the prototype antigen because it is present in many cellular elements of varying size throughout the thickness of the section. The antiserum used was sufficiently high in titer and affinity to permit use at a 1/20,000 dilution, making it's contribution to nonspecific staining negligible. Thus S-100 is nearly an ideal marker for evaluating the quality of staining.

Concentrations of anti-rabbit IgG and PAP were varied from 1/50 to 1/5000 of the undiluted reagents and with incubation times ranging from 2h. to 72h. Excess concentrations of either linking antibody or PAP, result in marked loss of resolution in fine structures with only a modest increase in intensity. Optimal times for clear visualization of structures throughout the section were between 18 and 24 hrs. At high concentrations of immunoreagents, staining was achieved throughout the section in a shorter time (1 to 4 h.), but localization in the outer layers of the section were overstained while structures within the section were understained. No conditions could be found where short incubations approached the quality of long incubations with low reagent concentrations. These results apply to the visualization of enzymes, peptides, and other protein markers. NS-12311 (BKH), RSDA MH-00595 (PLF)

395.3

SIMULTANEOUS LOCALIZATION OF CCK AND MET-ENKEPHALIN (ENK) IN THE RAT HYPOTHALAMUS. J.P. Kettinger*, P.L. Faris*, B. Rittberg, B.K. Hartman, J. Chen, A. Nadzan and J.F. McKelvy. Departments of Psychiatry and Pathology, Univ. of Minnesota, Mpls, MN 55455, and Abbott Laboratories, Abbott Park, IL 60064.

CCK and ENK co-exist in discrete CNS regions of the rat, including several thalamic nuclei and specific cortical layers (Gall et al., Brain Research 403: 403, 1987). In light of evidence from our lab and others (e.g. Itoh et al., Eur. J. Pharm., 80: 421, 1982) that CCK may function as a physiological antagonist of opioid action, the finding that CCK and ENK are co-stored and possibly co-released suggests the antagonistic relationship between these peptides may be mediated at the post-synaptic receptor complex. However, reported incidences of co-existance is minimal at hypothalamic sites where CCK and ENK exert opposite effects on food intake. We sought to identify other cell-to-cell interactions that may underlie their behavioral effects.

Formaldehyde fixed sections were double-labeled using a mouse monoclonal antibody (AB) against CCK-8 and a rabbit polyclonal AB against ENK followed by incubation with anti-mouse (goat)-FITC and anti-rabbit (goat)-Texas Red. Mis-matching the secondary antibodies resulted in total abolition of immunostaining.

Accessory magnocellular cells were immunoreactive for CCK and ENK-containing fibers surrounded these nucleur groups with little penetration to deeper lying cells. Approximately 5% of immunolabeled ENK cells in the parvocellular periventricular region also contained CCK. The dorsal parvocellular division was innervated with fibers containing both peptides, suggesting modulation of a common post-synaptic site. These findings suggest that CCK may interact with ENK by multiple mechanisms. Supported by NS-12311 (BKH), RSDA MH-00595 (PLF).

395.4

DISTRIBUTION OF GASTRIN-RELEASING PEPTIDE (GRP) mRNA-CONTAINING CELLS IN RAT BRAIN AS SHOWN BY *IN SITU* HYBRIDIZATION. R.T.Zoeller, A.-M. Lebacq-Verheyden* and J.F. Battey*. Lab of Neurochemistry, NINCDS, NIH, Bethesda, MD 20892.

GRP is a 27 amino acid peptide representing the mammalian homolog to the amphibian peptide bombesin. Although this peptide was initially identified as a gut hormone, central effects of GRP have been described, including effects on appetite, glucose metabolism, growth hormone and prolactin secretion. Radioimmunoassay and immunocytochemical evidence support the view that GRP is synthesized in the brain. However, antisera against GRP may cross-react with a variety of related peptides. Recently, Lebacq-Verheyden et al. (*Molecular Endocrinology,* In Press) isolated and sequenced cDNA clones encoding GRP from a rat brain library, thereby demonstrating that preproGRP mRNA is synthesized in rat brain. The present study was undertaken to map the distribution of GRP mRNA-containing cells in the rat brain. Brains from male and female rats were fresh-frozen and sectioned at 12μm in a cryostat in either coronal or saggital plane. We used NTB-3 emulsion and both ^{35}S-cRNAs (tested for specificity by Northern analysis) and synthetic oligomers to visualize GRP mRNA-containing cells. Labelled cells were distributed widely throughout the brain, especially cingulate cortex, mPOA, SCN, amygdala, and dentate gyrus. We failed to detect GRP mRNA in areas such as PVN and ventral SCN which consistently exhibit bombesin/GRP-like immunostaining. These results further support a role for GRP in central function, and clarify inconsistencies in the literature relating to its distribution within the brain.

395.5

POSTNATAL CHANGES IN THE DENSITY AND DISTRIBUTION OF NEUROTENSIN-IMMUNOREACTIVE FIBERS IN THE MEDIODORSAL THALAMIC NUCLEUS OF THE RAT. J. P. Ray and J. L. Price, Department of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

A previous report (Inagaki et al., Brain Res., 260, 143-146, '83) has suggested that the peptide neurotensin is contained in neurons of the piriform cortex which project to the mediodorsal thalamic nucleus (MD) in young rats. To confirm this, we have studied the distribution of neurotensin-immunoreactive (NTIR) fibers in MD using three antisera directed at different parts of the neurotensin molecule (Emson et al., J. Neurochem., 38, 992-999, '82). In adult rats, NTIR fibers in MD are sparse, located mostly at the medial edge of MD with a few, poorly-stained NTIR fibers in the central part of MD. In contrast, during the first postnatal week, both the medial and central portions of MD stain heavily for neurotensin. The density of NTIR fibers in MD then progressively decreases until the density typical of adult rats is reached, at about 5 weeks. The number of NTIR neurons in the piriform cortex declines approximately eightfold during this period. Changes in the distribution of NTIR fibers in MD also occur. In seven day old rats, the medial and central patches of NTIR fibers are contiguous, but by ten days a non-immunoreactive zone forms between them. This non-immunoreactive zone enlarges until the medial contingent of NTIR fibers reaches its adult position at the medial edge of MD.
Supported by NIH research grant NS09518.

A LIGHT AND ELECTRON MICROSCOPIC ANALYSIS OF GABA IMMUNOSTAINING IN MONKEY SPINAL CORD. S.M. Carlton, Anat. & Neurosci. Dept., U. Texas Med. Br., Galveston, TX 77550.

The transmitter γ-aminobutyric acid (GABA) has been previously localized in rat at the light (LM) and electron microscopic (EM) levels. These studies suggest a widespread distribution of GABA neurons and terminals in the spinal cord dorsal and ventral horns. In the present study, GABA-containing profiles were immunostained and mapped at the LM level in the monkey lumbar spinal cord. EM analysis of GABAergic neurons and terminal interactions are also reported. Four animals (M. fascicularis) were perfused with mixed aldehydes and the lumbar cord removed. The tissue was sectioned at 25μm on a vibratome and immunostained with anti-GABA using the PAP technique. LM analysis demonstrated GABAergic cells concentrated in the superficial dorsal horn (DH); however, they were present in all spinal laminae except lamina IX. Small diameter oval to round cells were located in the upper laminae while larger diameter cells with visible dendrites were present in deeper layers. Punctate GABAergic profiles, presumably terminals, were scattered diffusely over the OH, lamina X and around motoneurons in the ventral horn. EM analysis demonstrated both myelinated and unmyelinated GABAergic axons. GABAergic cell bodies with large immunoreactive nuclei were seen. GABAergic terminals contained mainly round clear vesicles and often a few dense core vesicles and synapsed onto labeled and unlabeled somata, dendrites and other axon terminals. (Supported by NS11255.)

RETINAL TERMINALS IN THE LATERAL GENICULATE NUCLEUS OF THE CAT ARE IMMUNOREACTIVE FOR N-ACETYLASPARTYLGLUTAMATE. S.B. Tieman, Neurobiol. Res. Ctr., SUNY Albany, NY 12222.

We have previously identified N-acetylaspartylglutamate immunoreactivity (NAAG-IR) in the retinal ganglion cells (RGC) of the cat and in the neuropil of their targets. If NAAG serves as a transmitter for RGC, as we have suggested, then it should be found in their terminals. To determine whether these terminals contain NAAG, one adult cat was deeply anesthetized and one eye removed. The cat was reanesthetized 10 days later and perfused with PBS followed by 4% paraformaldehyde and 4% 1 ethyl 3-(3-dimethylaminopropyl) carbodiimide in 0.1 M phosphate buffer. Frozen sections of LGN were processed for NAAG-IR by the ABC method. NAAG-IR was reduced in the neuropil, but not the cell bodies, of the denervated layers, suggesting that this loss of IR was due to the degeneration of the retinal terminals. Further, an unoperated adult cat was perfused as above, and vibratome sections of LGN were processed by the PAP method, postfixed in osmium tetroxide, and processed for electron microscopy. There was label within large terminals containing round vesicles and mitochondria that were less dense than those in other profiles, and making asymmetric synapses onto dendrites. These results demonstrate that retinal terminals are immunoreactive for NAAG, which is consistent with a neurotransmitter role for this peptide.

395.8

CA2 (RESISTANT) SECTOR OF HUMAN HIPPOCAMPUS DEFINED BY CHROMOGRANIN-LIKE IMMUNOREACTIVITY. D.G. Munoz, D.H. George* and L. Kobylinski*. Dept. of Pathology, Univ. of Saskatchewan, Saskatoon, Saskatchewan, Canada. S7N 0W0

Status epilepticus and cerebral anoxia can result in the destruction of most neurons in the hippocampus, but characteristically spare a narrow sector, known as the resistant sector, that approximately correspond to the CA2 sector defined by Golgi stains. Although certain enzymes show distribution gradients among the hippocampal sectors, there has been no reports of specific CA2 markers. Here we show that such sector can be sharply defined by the perikaryal chromogranin-like immunoreactivity of its pyramydal neurons. The monoclonal antibody (LK2H10) produced against a human pheochromocytoma (Wilson BS & Lloyd RV, AM J Path 115: 458, 1984) recognizes the human chromogranin A molecule as well as an array of polypeptides (chromogranins) with MW down to 28,000. Vibratome sections of 6 normal human hippocampi fixed for 24 hours in PPG fixative (Neuroscience 7:1779-1783, 1982) were immunocytochemically stained with LK2H10 by the ABC method. In all cases there was intense staining of the mossy fibers, as well as granular cytoplasmic staining of all pyramidal neurons in a sector corresponding to CA2, stretching from the termination of the mossy fibers to a sharp wedge-shaped lateral limit. No other neurons in the hippocampus proper were stained, although there was weak immunostaining of a subset of neurons in the dentate gyrus and the hilum.

395.9

A PROPOSED MIGRATORY ROUTE FOR LUTEINIZING HORMONE-RELEASING HORMONE (LHRH)-IMMUNOREACTIVE NEURONS FROM THE MEDIAL OLFACTORY PLACODE TO THE FOREBRAIN IN THE MOUSE. A STUDY USING TRITIATED THYMIDINE AND LHRH IMMUNOCYTOCHEMISTRY. Marlene Schwanzel-Fukuda and Donald W. Pfaff. Rockefeller University, New York, N.Y. 10021.

Swiss mice (two in each age group) were injected with tritiated thymidine (5 uCi/gram of body weight) on day 11, 14, 16 or 18 of pregnancy. Fetal brains were collected 1 hour later and processed for LHRH immunocytochemistry and autoradiography. LHRH-immunoreactivity was first detected in a few cells within the epithelium of the medial olfactory placode at 11 days of gestation. From days 14 to 18, cords of LHRH cells were seen in the placode, on the nasal septum in company with the nervus terminalis and vomeronasal nerves, and in the ventromedial forebrain caudal to the olfactory bulb. Some of these cells were associated with the nervus terminalis, but others (the majority) arched into the septal and preoptic areas of the developing brain. This finding, as well as relative numbers of immunolabeled cells at different ages, supports the notion of a migratory route. Observations of autoradiographic sections showed no thymidine labeling of LHRH cells: the cells of the placode appeared to have undergone division earlier. The nervus terminalis, a derivative of the medial olfactory placode, may serve to guide at least one population of LHRH cells into the forebrain. Supported by NIH grant NS 19662 and funds from the Whitehall Foundation (M.S.-F.).

NEUROPEPTIDE Y-IMMUNOREACTIVE NEURONS IN THE CORPUS CALLOSUM. B.Y.Kim*, T.Duong and A.B.Scheibel. UCLA Departments of Anatomy, Psychiatry and Brain Research Institute, Los Angeles, CA 90024.

We studied the morphology, distribution and number of neuropeptide Y-immunoreactive (NPY-IR) neurons in the corpus callosum of male and female Sprague-Dawley rats. Cryostat sections (30-50 μm) cut in the coronal, sagittal and horizontal planes were processed by peroxidase-antiperoxidase immunocytochemistry. The corpus callosum in the rat was divided into an anterior and posterior portion using the anterior border of Ammon's horn as the delineating landmark (2mm posterior to bregma). Comparisons were made between anterior and posterior portions of the corpus callosum, the right and left hemispheres, and between the male and female rats. NPY-IR neurons in the rat corpus callosum are small or medium-sized bipolar and multipolar neurons (7-15 μm in diameter). The highest concentration was observed in the forceps minor of the corpus callosum. The anterior portion of the rat corpus callosum contained about twice the number of NPY-IR neurons as the posterior portion. **There was no significant morphological, distributional or numerical difference between hemispheres nor between male and female rats.** We are presently investigating NPY-IR neurons in the corpus callosum of cats and humans. The morphology and size of the NPY-IR neurons appear similar to those in the rat. The distribution of NPY-IR neurons in the human corpus callosum appears sparse.

395.11

TACHYKININS AND THEIR BINDING SITES IN THE INTERPEDUNCULAR NUCLEUS (IPN) OF THE RAT. S. Brown*, T.C. Eckenrode and M. Murray. Medical College of Pennsylvania, Phila., PA 19129.

Tachykinins, identified by an antibody that recognized both SP and SK, and the binding sites for SP and SK are densely concentrated in the habenulo-interpeduncular system. Tachykinins are synthesized in the medial habenulae and transported to the lateral and rostral subnuclei of the IPN. The habenular tachykinin system shows plasticity in response to lesions of the contralateral habenular projection. Intrinsic tachykinin-containing interneurons are present in the ventral division of the rostral subnucleus of the IPN and tachykinin of non-habenular origin is also present in the central and dorsal subnuclei. An antibody specific to SK shows a distribution of habenular and non-habenular staining identical to that of the antibody which recognized both SP and SK, this was confirmed by absorption controls, and the same plasticity was demonstrated using the SK antibody. The SP and SK projections to the IPN appear to be quantitatively and qualitatively very similar. Binding sites for SP and SK were visualized using 125I-SP and 125I-eledoisin. SP binding sites were sparce and confined to the central and rostral subnuclei. The eledoisin binding sites were much denser than the SP binding sites but were also concentrated in the subnuclei which receive only non-habenular tachykinin input. The density of the tachykinin binding sites therefore differ but their patterns are similar and are matched with non-habenular but mismatched with habenular sources of tachykinins.

Supported by NIH grant NS16556.

IMMUNOELECTRON MICROSCOPIC LOCALIZATION OF THYROTROPIN-RELEASING HORMONE PRECURSOR (pro-TRH) IN THE RAT BRAIN. N. Liao*[1], M. Bulant*[2], H. Nicholas*[2], H. Vaudry*[2] and G. Pelletier[1], [1]Mol. Endocrinol., CHUL, Québec, Canada and [2]Lab. Endocrinologie, Univ. Rouen, France.

In order to study the ultrastructural localization of pro-TRH, we have raised antibodies against a cryptic fragment corresponding to the sequence [Phe178-Glu199] of the precursor. Using preembedding immunostaining, we have investigated two groups of neurons already known to contain pro-TRH: one located in the hypothalamic paraventricular nucleus (HPV) and another one in the raphe nucleus. In the positive neurons of HPV only dense core vesicles (80-100 nm in diameter) which were very numerous were labelled. Immunostained cells, dendrites and endings were frequently observed in contact with unidentified elements. In the median eminence, numerous free endings containing labelled dense core vesicles were detected. In the raphe nucleus a different pattern of labelling was observed. The positive neurons contained only a very few dense core vesicles (60-80 nm in diameter) which were all labelled, the most proeminent labelled organelle being the Golgi apparatus. Stained cell bodies and dendrites were very frequently seen in contact with unlabelled endings. These results suggest that pro-TRH and/or fragments of pro-TRH could play a neuromodulator/neurotransmettor role in different brain areas and could also be released into the pituitary portal plexus. They also demonstrate that pro-TRH can be differently processed by neurons which have different functions.

EFFECT OF EXTRINSIC DENERVATION ON CALCITONIN GENE-RELATED PEPTIDE IMMUNOREACTIVITY (CGRP-IR) IN THE RAT HEPATOBILIARY SYSTEM. L. Goehler and C. Sternini. CURE & Depts. of Psych., Med. & Anat., UCLA, LA, CA 90024.

CGRP-IR is localized in nerve fibers innervating the rodent hepatobiliary system. These fibers are abundant in the biliary pathway, whereas in the liver they are usually restricted to the interlobular space in association with the portal triad. A rich CGRP innervation is also associated with the vena porta. In this study we have investigated the effect of chemical and surgical denervation on the CGRP-IR fibers innervating the hepatobiliary system of the rat by means of immunohistochemistry and radioimmunoassay (RIA). Neonatal treatment with the sensory neurotoxin capsaicin caused a dramatic decrease, and often a complete elimination of the CGRP-IR fibers innervating the biliary tree and hepatic vasculature as well as a marked decrease of those innervating the vena porta. Celiac and superior mesenteric ganglionectomy gave similar results as capsaicin treatment, whereas bilateral vagotomy did not modify the CGRP-IR. RIA studies demonstrated that both capsaicin treatment and ganglionectomy significantly decreased CGRP content in the vena porta and biliary ducts (up to 60 and 85%, respectively). These results suggest that the CGRP innervation of the hepatobiliary system mainly originates from extrinsic, sensory neurons which are likely located within spinal ganglia.
Supported by NIH grant DK38752 and SKB Fellowship.

395.14

DISTRIBUTION OF CHOLECYSTOKININ (CCK)-LIKE IMMUNOREACTIVITY IN THE BRAIN OF THE LITTLE BROWN BAT (MYOTIS LUCIFUGUS). L.K. Laemle and J.R. Cotter. Dept. of Anatomy, New Jersey Medical School, Newark, NJ 07103 and Dept. of Anatomical Sciences, SUNY Buffalo, Buffalo NY 14214.

CCK-like immunoreactivity was localized in the brain of the little brown bat using light microscopic immunocytochemistry. Tissue was fixed in Bouins solution, embedded in paraffin, and sectioned at 10 to 12um. Two primary antisera (Incstar, and Peninsula) and two staining procedures (PAP and avodin biotin) were used. Immunoreactive fibers traveled in three major pathways: median forebrain bundle, dorsal longitudinal fasiculus, and mammillary peduncle. Particularly dense terminal plexuses were formed in the medial septal and dorsal hypothalamic areas, medial and basal amygdaloid nuclei, dorsomedial, parabrachial, and suprachiasmatic nuclei, area postrema and nucleus tractus solitarius. Immunoreactive perikarya were present in the olfactory, amygdaloid, interpeduncular, dorsal tegmental, and suprachiasmatic nuclei; medial preoptic and anterior hypothalamic areas, hippocampus and cerebral cortex.

395.15

LOCALIZATION OF NEUROPEPTIDE Y mRNA IN CHICK BRAIN USING IN SITU HYBRIDIZATION. W.J. Kuenzel, D. Larhammar, J.B. O'Neill, R.J. Milner and J.M. Hill. Dept. of Poultry Sci., Univ. of Maryland, College Pk., MD 20742; Scripps Clinic and Res. Found., La Jolla, CA 92037; and Sect. on Brain Biochem., NIMH, ADAMHA, Bethesda, MD 20892.

Neuropeptide Y (NPY) is a very abundant peptide in the mammalian brain and significantly affects several basic physiological functions, particularly food intake. The peptide has also been shown to effect hyperphagia in chicks. Recently a cDNA clone for chick NPY has been isolated and sequenced (Larhammar, Unpublished). An in vitro transcription system was used to produce single stranded RNA probes. Antisense (experimental) and sense (control) chick NPY riboprobes were labeled with S^{35}. In situ hybridization was conducted using three chicks two weeks of age. They were deeply anesthetized with Chloropent and perfused via the heart with physiological saline. Brains were then quickly removed and frozen in dry ice. Two brains were sectioned in a cryostat at 30 um for in situ hybridization while one had its hypothalamic region dissected for later RNA extraction. A set of slides were treated with RNase to serve as additional controls. Extracted chick brain RNA was analyzed on Northern blots with one of the labeled antisense NPY riboprobes. NPY mRNA was observed in cells of the preoptic periventricular nucleus, the periventricular hypothalamic nucleus, paraventricular nucleus, median eminence, and nucleus of the basal optic root. To date the neural structures identified in the chick to contain NPY mRNA have also been shown by immunocytochemistry to contain NPY-like immunoreactivity.

CARNOSINE AND ANSERINE LOCALIZATION IN NERVE AND MUSCLE OF RODENTS AND BIRDS. S. Biffo* and F. L. Margolis. Roche Inst. Molec. Biol., Nutley, N.J. 07110

Carnosine (C) is present in olfactory receptor neurons. Two related dipeptides, homocarnosine (H) and anserine (A) are chemically found in excitable tissues (retina, CNS, muscle) but their cellular location is unknown. We raised antisera against C,H, and A. After purification we obtained antisera able to discriminate C from A, but not H from C. C co-localizes with olfactory marker protein in olfactory neurons of mouse and rat. In the mouse C-like IR is observed in an astrocyte population. Analysis suggests that the IR is due to H (Br.Rsch.94,75(1975). This is consistent with the ability of CNS glia to synthesize dipeptides (Bauer et al.J.B.C.257,3593(1982). In chick C-like IR is limited to olfactory nerve axons and terminals. A-like IR is present throughout the CNS in astrocyte-like cells consistent with HPLC evidence for A in chick CNS (Neurochem.Intl.6,207(1984). Thus, in vertebrate CNS C occurs in olfactory neurons but A and H occur in non neuronal cells. Striated muscle of many species contain high levels of C and A. They differ in ontogeny, halflife and proportions in different muscles. Initial results with these antisera indicate that the ratio of C to A varies in different fibers of the same muscle. This novel observation suggests that the amount of C and A may be functionally related to the different metabolic properties of individual muscle fibers.

BURSICON-LIKE ACTIVITY IN THORACIC PERIPHERAL NEUROSECRETORY CELLS OF ADULT CRICKETS. H.W. Honegger* and I. Garcia-Scheible* (SPON: J. Tautz). Inst. Zoology, TU Munich, D-8046 Garching, Germany.

In insects, neurosecretory neurons have been found not only in the CNS but also in the periphery along nerves. As yet no specific function or defined products could be attributed to such peripheral neurosecretory neurons (PNN).

We have identified a group of PNN in the prothoracic segment of adult crickets which, together with their processes, contains a protein with bursicon-like activity. The processes are located in the sheaths of all anterior nerves of the prothoracic ganglion and in the prothoracic median nerve, a neurohemal organ. A homologous group of PNN in the mesothorax also exhibits bursicon-like activity.

Bursicon was first described by Cotrell (1962) and Fraenkel and Hsiao (1965) as a neurohormone that triggers sclerotization of the insect cuticle. It is present in central neurons of abdominal ganglia in the tobacco hornworm (Taghert and Truman, 1982). The unexpected discovery of a protein with bursicon-like activity in PNN of adult crickets suggests that this product may trigger cuticle sclerotization also in adults. Since it is released along nerves it may have an additional function in the CNS. (Supported by DFG).

SOMATOSTATIN IMMUNOREACTIVITY IN THE BRAIN OF A GYMNOTID TELEOST FISH. E. Sas and L. Maler. Fac. Health Sci., Dept. Anatomy, Ottawa, Canada. K1H 8M5

The localization of somatostatin immunoreactive (SS ir) perikarya and fibers in Apteronotus leptorhynchus, was studied by immunohistochemistry, using an antibody against somatostatin, kindly provided by Dr. J. C. Brown (UBC).

The largest populations of SS like ir cells were observed in the diencephalon, followed by the telencephalon and rhombencephalon, and a scant amount in the mesencephalon. **I.** Telencephalic ir cells were located mainly in the ventral subdivisions, N. taenia, medial forebrain bundle, entopeduncular nuclei. **II.** Diencephalic cell groups included: the suprachiasmatic N., N. preopticus periventricularis posterior, N. anterior periventricularis, N. pretectalis, glomerular complex, central posterior N., periventricular N. of posterior tuberculum, interphase between the two latter nuclei, interphase of thalamus/hypothalamus, N. tuberis lateralis, dorsal, ventral and lateral hypothalamus, central N. of inferior lobe, N. recessus lateralis and ventral thalamic nuclei. **III.** Mesencephalic SS ir cells were seen in optic tectum, torus semicircularis and interpeduncular nucleus. **IV.** Rhombencephalic ir cells were present in the central gray, paracommissural region, descending trigeminal tract, electrosensory lateral line lobe, reticular formation, vagal N., octaval nuclei. These results will be correlated with those reported in other species, and their possible relevance in the visual and electrosensory systems will be discussed.

395.19

GALANIN-LIKE PEPTIDE IN THE TELEOST SPINAL CORD: DISTRIBUTION AND NOVEL RESPONSE TO INJURY. E. E. Black and R. L. Parsons. Dept. of Anatomy and Neurobiology, Univ. Vermont Coll. Med., Burlington, VT. 05405.

The distribution of a galanin-like peptide in the spinal cord of the molly, Poecilia latipinna, was investigated with immunohistochemical techniques. A dense galanin-like immunoreactivity (GAL-LIR) was present through the length of the spinal cord. Fine varicose fibers coursed longitudinally in the gray matter, and some fibers traversed the neuraxis. Relatively few fibers were seen in the white matter. Transection of the spinal cord at the level of the sixth preterminal vertebra resulted in the disappearance of all GAL-LIR both rostral and caudal to the lesion. In some fish this disappearance was complete as early as 2 days post lesion, and was complete in all fish by 7 days post lesion. By 30 days after transection a heavy GAL-LIR reappeared in some fish at levels rostral to the lesion. Transection of the cord at levels rostral to the sixth preterminal vertebra or at the level of the terminal vertebra also resulted in complete disappearance of GAL-LIR throughout the spinal cord. These studies indicate that a galanin-like peptide is heavily distributed in the gray matter of the teleost spinal cord. Further, injury to any part of this system causes the coordinate loss of GAL-LIR throughout the spinal cord. This response is markedly different from descending putative transmitter pathways (for example, 5-HT, NE,or NPY) we have identified in the fish spinal cord. Supported by PHS R01 19880.

395.20

IMMUNOHISTOCHEMICAL SEARCH FOR SUBSTANCE P, SEROTONIN, CALBINDIN AND LHRH IN THE PRIMARY OLFACTORY SYSTEM OF A TELEOST FISH. J.P. Denizot°, T. Szabo, S. Bläher°, M.Véron-Ravaille°, D. Rouilly°(SPON: A.Mallart), Dept.Neurophysiol Sens, Lab.Physiol.Nerveuse, CNRS, F 91190 Gif sur Yvette.

Substance P, considered as a transmitter or modulator of the nociceptive system, was also revealed in the olfactory bulb of a mammal (Kream RM et al.,JCN, 222:140,1984) and recently in the primary olfactory system of the teleost gymnotids (Szabo T et al., Neurosc.Lett.,81:245,1987).Standard immunohistochemical treatment of paraffin sections with anti-substance P antiserum (1/8000) shows an intense sP-like immunoreactivity (SPLI) in the olfactory epithelium, nerve and olfatory bulb as well as in several tel- di- and mesencephalic areas. Section of the olfactory nerve causes a reduction (in 15 d) or complete depletion in 35d, in all these sites. Identical depletion is obtained 15 d after application of capsaicin (sP antagonist) to the olfactory nerve for 15 min. In contrast, application of colchicin (25%) to the olfactory nerve for 24h produces no depletion of SPLI. Anti-5HT antiserum (1/1000) labeled the primary olfactory projection in the olfactory bulb but not in the other brain areas. No immunoreactivity was obtained with anti-calbindin (CaBP28K) antiserum (provided by M Thomasset). Anti-LHRH antiserum labeled the olfactoretinal ganglion located at the anterior basal part of the olfactory bulb but not the olfactory system.

ULTRASTRUCTURAL LOCALIZATION OF SUBSTANCE P-LIKE IMMUNOREACTIVITY IN THE BRAIN OF LIMULUS. J. K. Johnson and S. C. Chamberlain. Inst. Sens. Res., Syracuse Univ., Syracuse, NY 13244-5290.

Light and electron microscope studies have shown the corpora pedunculata (CP) in Limulus to be synaptically complex and morphologically diverse (Fahrenbach, Tiss. & Cell, 9:157-166, 11:163-200). These anatomical studies have been complemented and extended with immunohistochemical methods in a survey of neuropeptide activity in Limulus brain including a positive reaction for substance P-like immunoreactivity (SPLI) (Chamberlain and Engbretson, J. Comp. Neurol., 208:304-315). Here we report the first demonstration of SPLI in the brain of Limulus at the ultrastructural level.

In the present study a monoclonal antibody against substance P raised in rat (Accurate Chemical) was used to bind substance P-like antigenic sites. Visualization of labelled sites was effected by indirect enzymatic staining with the PAP/DAB procedure (Eldred *et al.*, J. Histochem. & Cytochem., 31:285-292). This technique was used to identify neuron types in the CP that had a substance P-like positive reaction. Results suggest that only the type D afferent fibers possess SPLI in the Kenyon cell layer. In contrast possible type E afferent fibers display a somewhat weaker label in the peduncles and regions of Kenyon cell telodendra, often in close proximity to more heavily labelled type D afferent fibers.

These results are an additional line of evidence suggesting the presence of substance P in Limulus. This technique allows the specific neural circuitry of substance P-like fibers to be elucidated from populations of neurons containing other neuroactive compounds. Continued application of this technique should lead to a detailed understanding of the specific connectivity in the brain and lateral eye of Limulus at the EM level. Supported by EY03446 and EY06064.

395.22

LOCALIZATION OF LEU-ENKEPHALIN-LIKE IMMUNOREACTIVITY IN THE BRAIN OF *LIMULUS POLYPHEMUS*. T. J. Lewandowski*, A. M. Strong*, and S. C. Chamberlain. Institute for Sensory Research and Departments of Bioengineering and Biology, Syracuse University, Syracuse, New York 13244.

Antibodies raised in rabbit against Leu-Enkephalin-bovine thyroglobulin glutaraldehyde conjugate (Incstar) were used to label immunoreactive neurons in the brain of *Limulus polyphemus*. Bound primary antibodies were visualized using FITC labeled secondary antibodies. Labeled sections were photographed using epifluorescence illumination. We present here those neurons displaying Leu-Enkephalin-like immunoreativity using the nomenclature of the *Limulus* brain atlas (Chamberlain and Wyse, *J. Morph.* **187**:363).

Small-diameter fibers were sparsely labeled in the laminar neuropil and richly labeled in the medullar neuropil. Dense populations of small-diameter and large-diameter fibers were labeled in the mottled and large fiber layers of the central body neuropil respectively. A moderate population of small-diameter, varicose fibers labeled in the central neuropil of the brain.

Only two neuronal groups contained labeled somata. Approximately 20 somata labeled in the ventral region of the medullar group, adjacent to the ventral poles of the central body and the optic tract. Two groups of approximately 4 and 8 somata labeled in the dorsal region of the dorsal medial group. Supported by NIH grants and the Department of Bioengineering.

395.23

AN ATRIAL NATRIURETIC-LIKE SUBSTANCE IN THE MARINE MOLLUSK APLYSIA. V.F. Castellucci and J. Gutkowska*. Neurobiology Lab., IRCM Clinical Research Institute of Montreal, Montreal, CANADA, H2W 1R7.

The atrial natriuretic factor (ANF) is a member of a family of peptides that have been first isolated and purified from mammalian atria. It is also detected in plasma, in the peripheral and central nervous systems of vertebrates. Since ANF seems to be related to the water balance and the cardiovascular system of an organism, we were curious to see if this peptide could be detected in APLYSIA and what was its biological role.

We were able to detect ANF-like immunoreactivity in the hemolymph of APLYSIA (5-10 pg/ml); the hemolymph extract had an HPLC profile similar to the ones obtained from vertebrates with a prohormone and a circulating hormone peaks. Significant immunoreactivity was also detected in various organs, such as the heart, the aortae, the gametolytic gland, the salivary gland and the central nervous system. The immunoreactive ANF could displaced synthetic ANF (up to 100%) in a radioreceptor assay procedure. Supported by M.R.C. MA-10047.

395.24

IMMUNOHISTOCHEMICAL STUDY ON VASOACTIVE INTESTINAL POLYPEPTIDE IN THE BUCCAL GANGLION OF APLYSIA CALIFORNICA AND PLEUROBRANCHAEA CALIFORNICA. S. Soinila and G.J. Mpitsos. Hatfield Marine Science Center, Oregon State University, Newport, OR 97365.

Vasoactive intestinal polypeptide (VIP) is a putative neurotransmitter/neuromodulator in several vertebrate and invertebrate species. The present study was undertaken to define simple experimental models that would allow us to examine the role of VIP in the nervous systems of marine molluscs.

Each buccal hemiganglion contained on the coelomic (caudal) surface a single 100 μm VIP neuron. A cluster of small VIP cells (30 μm) was observed constantly near the outlets of buccal roots 1 and 2. These neurons projected into the buccal muscles. Another group of small VIP cells was located ventrally to the commissure on each side. In Aplysia, but not in Pleurobranchaea, the buccal (rostral) surface contained a large group of VIP neurons which extended from the lateral S-region to the central region.

These results provide a morphological basis for comparative studies on the effects of VIP on Aplysia and Pleurobranchaea feeding behavior. Of particular interest is to use such biochemical and neuroanatomical methods as probes to identify groups of neurons whose group dynamics can then be analyzed to determine the principles of self-organizing activity and of the role of variability in it (e.g. see Mpitsos et al., 1988, these proceedings, and Mpitsos, G. J., and Cohan, C. S., J. Neurobiol., 17: 517, 1986).

This study was supported by the grant AFOSR-86-0076 to G.J.M.

RETINA V

396.1

THE QUANTAL NATURE OF SYNAPTIC TRANSMISSION FROM PHOTORECEPTORS TO BIPOLAR CELLS. *B.R. Maple and F.S. Werblin, Graduate Group in Neurobiology, University of California, Berkeley, CA 94720*

Bipolar cells of the Tiger Salamander retina were voltage clamped with patch electrodes in light adapted retinal slices. Transmission from photoreceptors was elicited by depolarizing rods with a second patch electrode, and bipolar cell dendritic conductances were also activated directly by pressure ejection of glutamate at the outer plexiform layer.

In some OFF bipolar cells, rod depolarization elicited responses containing miniature excitatory synaptic currents. These quantal events reversed near -5 mV, the reversal potential for the dendritic glutamate response. They represented a peak conductance change of about 150 pS, with a rise time of 1 msec and a falling time constant of about 3 msec. Insensitive to tetrodotoxin, and seen in cells with transected axons, these events may reflect the release of single transmitter vesicles as are found at photoreceptor ribbon synapses.

In other OFF bipolar cells, rod depolarization elicited a similar conductance change with no discernable quantal component. These responses also reversed near -5 mV, so they were probably not electrotonically decremented or filtered. They may reflect a form of nonquantal, nonvesicular release possibly occuring at photoreceptor basal junctions. This transmission, as well as quantal transmission, was abolished by lowering extracellular calcium to 1 uM or substituting cobalt for calcium.

No corresponding quantal events were resolved in ON bipolar cells. Responses both to rod depolarization and to glutamate (conductance decreases associated with a reversal potential near 0 mV) tended to be very small, suggesting that rod to ON bipolar cell transmission is turned off postsynaptically in light adapted slices. Relatively large light responses obtained in these cells suggest there is a cone transmitter that is not glutamate-like.

396.2

GLUTAMATE RESPONSES IN SOLITARY BIPOLAR CELLS FROM SALAMANDER RETINA. *A.A. Hirano, J.A. Hirsch, and P.R. MacLeish.* Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

We have studied the currents evoked by L-glutamate and D,L-APB in single isolated bipolar cells enzymatically dissociated with papain or dispase/ collagenase from the adult tiger salamander retina. The cells were maintained in serum-free media at 12°C for up to several weeks before use, with no obvious change in response properties. During recording, the cells were superfused with a simple salt solution. In bipolar cells, identified by their characteristic morphology and I-V curve, glutamate-induced currents were recorded using whole-cell patch clamp recording techniques. Electrodes had a tip diameter of about 1 μM and contained (in mM): D-aspartate,100; NaCl,12; NaH_2PO_4,2.5; $MgCl_2$,1; EGTA,0.05; Na_2 ATP,1; HEPES,2; sucrose,20; adjusted to a pH 7.1 with KOH. The pharmacological agents were applied by pressure ejection from a second pipette positioned near the cell. We studied 41 bipolar cells of which 14 showed no response to L-glutamate (0.1-1 mM), and the rest of the cells fell into two classes. 9/22 of the papain- and only 1/19 of the dispase/ collagenase-dissociated cells responded with a large inward current that reversed around +10mV; in addition, 3/3 of papain-dissociated cells tested showed inward currents in response to kainate (25-50 μM). In contrast, 4/22 of the papain- and 13/19 of the dispase/collagenase-dissociated cells showed a small outward current with a reversal potential of about -70mV. Similarly, 4/4 of the dispase/collagenase- dissociated cells tested showed outward currents to APB (2-amino-4-phosphono butyrate, 50 μM), a known agonist for ON-bipolar cells (Slaughter & Miller, J.Neurosci., 5:224, 1985). Multipolar cells did not show this difference depending on dissociation procedures; all of the responding cells (27/33) gave a clear inward current in response to glutamate (0.1-0.5 mM). The glutamate-evoked currents of opposite polarity we observed in the bipolar cells may underlie the physiological basis of the ON- and OFF- responses in these second-order neurons. [Supported by the Lucille P. Markey Charitable Trust, NIH EY05201, the Klingenstein Fund, and an Javits Center Award (NS-22789).]

396.3

PERMEABILITY OF GLUTAMATE-GATED CHANNELS IN RETINAL BIPOLAR CELLS. T.A. Gilbertson,*[1] R.P. Scobey[2] and M. Wilson[1] (SPON: F.A. Gorin) [1]Dept. of Zoology, [2]Dept. of Neurology, Univ. of California, Davis, CA 95616.

Retinal bipolar cells make up the second neuron layer in the visual system and provide the main link between the inner and outer retina. The probable transmitter operating at the photoreceptor-bipolar cell synapse is L-glutamate (Glu).

In the present study, we have investigated current responses to Glu and its structural analogues in isolated bipolar cells from the larval tiger salamander (*Ambystoma tigrinum*) retina under whole-cell patch clamp conditions. The cells examined were apparent hyperpolarizing bipolar cells on the basis of a conductance-increase response to Glu. The channels gated by Glu and kainate (KA) activate conductances with similar ionic selectivities. The relative permeability (P) estimates for these channels are: P_K = 1, P_{Na} = 1, P_{Ca} = 3, P_{Mg} = 0.25, $P_{N\text{-methyl-D-glucamine}}$ = 0.15, P_{Cl} = 0. The Glu analogue N-methyl-D-aspartate (NMDA) causes no conductance change in the bipolar cells. The Glu- or KA-induced current is not blocked by external Mg^{++}.

Greater than 50% of the Glu-induced current desensitizes within 20 msec of the onset of application, at Glu concentrations greater than 100 uM. Desensitization is voltage-dependent, being more pronounced at larger positive and negative potentials. The KA response does not desensitize at any concentrations tested.

396.4

ELECTRICAL COUPLING BETWEEN BIPOLAR CELLS IS UNLIKELY TO ACCOUNT FOR THE LARGE RECEPTIVE FIELD CENTERS OF THESE CELLS. S. Borges and M. Wilson. Dept. of Zoology, Univ. of California, Davis, CA 95616.

When mapped with a small, dim spot of light, the receptive field centers for bipolar cells in the dark adapted retinae of tiger salamanders have a diameter between 374 and 662μm (Borges, S. and Wilson, M., J. Neurophysiol., 58:1275,1987). This is much larger than the dendritic arborization of these cells. What accounts for the large receptive fields of these cells? Characteristically, distant spots of light evoke bipolar cell responses with very long (up to 940 msec) latencies. Modelling the bipolar cells as a two dimensional network, we show that electrical coupling between bipolar cells cannot account for the observed latency. Similarly we show that reciprocal, delayed, chemical synapses between bipolar cells are an unlikely explanation. Another cell type, possibly an amacrine cell, is likely to be involved in enlarging bipolar cell fields. We have observed clear P.S.P's, presumably resulting from amacrine cell spikes, in some bipolar cells.

APB INCREASES ELECTRICAL COUPLING BETWEEN HORIZONTAL CELLS. C.-J. Dong* and J.S. McReynolds. Department of Physiology, The University of Michigan, Ann Arbor, MI 48109.

2-amino-4-phosphonobutyrate (APB) is an agonist at a unique type of glutamate receptor thought to be restricted to depolarizing bipolar cells in the retina. We find that APB also has markedly different effects on the responses of mudpuppy horizontal cells (HC) to central and peripheral illumination. 5 μM APB caused a decrease in HC responses to small centered spots and an increase in HC responses to concentric annuli, indicating an increase in coupling. APB also caused a hyperpolarization in darkness and increased the amplitude of responses to diffuse illumination, neither of which can be explained by an increase in coupling. All of these effects were opposite to those of dopamine in fish retina (see Dowling, TINS, Apr. 1986). The effects of dopamine on mudpuppy HC were qualitatively similar to those in fish, but much weaker and often absent, even at concentrations as high as 2 mM. The above results suggest that in mudpuppy APB acts either directly on HC in a manner opposite to that of dopamine in fish, or decreases the tonic release of a transmitter with an action similar to that of dopamine. We also find that APB greatly enhances surround responses in some ganglion cells; this may be due to its effect on HC coupling. The interpretation of APB-induced changes in responses of more proximal neurons should therefore take into account its effect on lateral interactions in the outer retina. Supported by NIH Grant EY01653.

CORTICOTROPIN-RELEASING FACTOR-INDUCED CURRENTS IN ACUTELY DISSOCIATED RAT RETINAL GANGLION AND BIPOLAR CELLS. Hermes H. Yeh, Department of Neurobiology and Anatomy, Univ. Rochester School of Medicine, Rochester, NY 14642.

In the rat retina, corticotropin releasing factor(CRF)-like immunoreactivity has been localized to a subpopulation of amacrine and displaced amacrine cells. In this preliminary study, whole-cell patch clamping was used to determine whether CRF could elicit current responses in isolated ganglion and bipolar cells.

Ganglion cells were identified by the presence of rhodamine-labeled microspheres injected into the superior colliculi 2-4 days prior to enucleation. In the physiological potential range, pressure-applied pulses (50 ms-3 s) of CRF (50-100 uM) induced prompt inward currents in 3 of 5 ganglion cells. I-V relation showed a reversal potential near 0 mv and a change in CRF-induced current that is essentially linear, with a slight tendency towards rectifying at positive holding potentials. In 4 cases, prolonged and continuous application of CRF partially suppressed both inward and outward currents evoked by depolarizing voltage steps.

Many bipolar cells retain their characteristic morphology following dissociation. Held at the resting potential range, CRF induced inward (2 cases) or outward currents (3 cases) in bipolar cells. Both types of currents reversed between 0 mv and +20 mv. Whether these responses reflect differential effects of CRF on presumed hyperpolarizing and depolarizing bipolar cells has yet to be determined.

In summary, CRF exerts postsynaptic effects on retinal neurons consistent with its anatomical disposition and thus may be considered as an amacrine cell transmitter candidate. Studies are ongoing to determine the ionic selectivity underlying the CRF-induced whole cell currents.

A CELLULAR MODEL OF SELECTIVE ATTENTION Z-H. Pan* and M.M. Slaughter, Dept of Biophysics, SUNY, Buffalo, NY 14214

Recording intracellularly in the superfused tiger salamander retina, we have found that baclofen, a GABA-B receptor agonist, makes amacrine and ganglion cells respond more transiently to a step of light. In third order neurons that normally respond transiently, baclofen application enhances the amplitude of these transient responses. But in cells that normally respond in a sustained manner to a step of light, baclofen application often suppresses the sustained responses and the cells begin to respond like transient neurons. Since tonic and phasic responses can carry very different information, the action of this GABA analog suggests that response characteristics of retinal neurons could be under synaptic control. To test this, we looked at trigger features that might be induced by baclofen. One stimulus feature that we examined was orientation selectivity, but we found no effect of baclofen on this property. However, when we studied directional selectivity, we found that baclofen did modify the response properties. In some cells that showed no directional selectivity to a moving slit under control conditions, a pronounced directional selectivity became evident after baclofen treatment. This change in response properties may be a form of selective attention. If baclofen's action is related to selective attention, then it should under efferent control. Dr. S. Ball has anatomical evidence of efferent inputs to GABAergic amacrine cells, which could potentially serve this function (pers.com.). NEI EY05725

N-METHYL-D-ASPARTATE RECEPTORS MEDIATE A SLOW COMPONENT OF THE TRANSIENT EXCITATORY LIGHT RESPONSE OF TIGER SALAMANDER RETINAL GANGLION CELLS. S. Mittman and W.R. Taylor*. Dept. of Ophthalmology, UCSF, San Francisco, CA 94143.

In tight-seal, whole-cell recordings from cells of the ganglion cell layer of tiger salamander retinal slices, we observed both sustained (< 20% of cells) and transient (> 80% of cells) light-evoked excitatory responses due to increases in cation conductances. To characterize these conductances, we blocked contaminating inhibitory responses with 500 nM strychnine and 100 μM bicuculline methobromide.

Two conductances, with different time courses, mediated the transient excitatory response. A fast conductance with a linear current-voltage relationship (I-V) and a reversal potential of ≈0 mV, had a time-to-peak (t_p) of 20 - 50 ms, and a half-decay-time ($t_{\frac{1}{2}}$) of 15 - 80 ms. A second, slow conductance had the same reversal potential, a longer t_p and a $t_{\frac{1}{2}}$ of 250 - 500 ms. The slow conductance had a non-linear I-V with negative slope at potentials more hyperpolarized than -30 mV, typical of conductances gated by N-methyl-D-aspartate (NMDA). The NMDA-receptor antagonist 2-amino-7-phosphonoheptanoate completely and reversibly blocked the slow, but not the fast, conductance at a concentration of 20 μM. Eliminating external Mg^{2+} (usually 1 mM), greatly reduced the voltage-dependence of the slow conductance, as expected of a NMDA-gated conductance, but did not effect the fast conductance. Ionophoresis or bath application of NMDA and kainate (in the presence of 20 μM Cd^{2+}) evoked conductances with I-V's similar to those of the slow and fast conductances, respectively.

These results demonstrate that the transient excitatory response is mediated by a mixed population of receptors. NMDA receptors are the post-synaptic mediators of the slow component of this response, but the pharmacology of receptors underlying the fast component remains undetermined.

EFFECTS OF MUSCIMOL ON CAT RETINAL GANGLION CELL ACTIVITY. A. W. Przybyszewski, O.-J. Grüsser, M. Hagner* and N. Sucher*. Dept. of Physiology, Freie Universität Berlin, Arnimallee 22, 1 Berlin 33, Germany. [SPON: European Brain and Behavior Society].

Ibotenic acid (IBO) is metabolized into muscimol (MU), a hypothetic GABA-agonist. We investigated the effects of MU injections (0.2-2mg/eye) into the vitreous body on ganglion cell activity evoked by diffuse short flashes and moving contrast gratings. The experiments were performed in pentobarbital anesthetized cats. Single ganglion cell activity was recorded by means of microelectrodes from optic tract axons.

20-40 min after injection the spontaneous flash-evoked activity of off-center ganglion cells was reduced and disappeared after 60-90 min. In on-center ganglion cells the spontaneous activity disappeared about 30 min after MU injections and the light flash responses were reduced to 2-5 action potentials per flash. The ganglion cell responses to moving gratings were reduced 20-30 min after MU injections and disappeared 10-40 min later. The relative efficiency of MU depended on spatial frequency of the grating and on drift angular velocity. Thus spatial and/or temporal factors are variables in the MU-effects on ganglion cell activity. The effect of MU on retinal ganglion cell activity is compared with that of IBO applied in comparable doses. For both substances no significant differences in the in the sensitivity of latency class I and II neurons were found.

Supported in part by a grant of the DFG (Gr 161).

RESPONSES OF CAT RETINAL GANGLION CELLS TO EYEBALL DEFORMATION DURING DIFFERENT STATES OF DARK ADAPTATION. M. Hagner*, A.W. Przybyszewski and O.-J. Grüsser. Dept. of Physiology, Freie Universität, Arnimallee 22, 1000 Berlin 33, Germany.

Eyeball deformation presumably causes a depolarization of the horizontal cell membrane potential. This effect induces via bipolar cells an activation of on-center ganglion cells (X- and Y-type) and an inhibition of off-center ganglion cells during the deformation. In the present study we examined the effect of dark adaptation on this response pattern. Defined lateral eyeball deformation was applied in total darkness 1 to 40 minutes after the onset of dark adaptation of a previously light-adapted cat retina (1-2 $cd.m^{-2}$). Responses of on-center and off-center ganglion cells were recorded from single optic tract axons.

1) The general response pattern of on-center and off-center ganglion cells was not changed during dark adaptation.

2) During the course of dark adaptation a small decrease in on-center ganglion cell activation relative to the spontaneous activity was observed.

3) Off-center neuron activity increased slightly during dark adaptation, but the inhibiting effect of eyeball deformation remained constant.

4) Our findings indicate that processes involving the receptor outer segments are not implicated in the generation of the retinal ganglion cell deformation responses.

The work was supported in part by a grant of the DFG (Gr 161)

ARE THERE ON AND OFF ROD BIPOLARS IN THE PRIMATE RETINA? R.P. Dolan and P.H. Schiller, Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA. 02139.

Recent evidence suggests that there may be only one class of rod bipolar cells in the mammalian retina, which hyperpolarize to light (Müller et. al., J. Neurosci, in press). This contrasts with the cone system in which both hyperpolarizing (OFF) and depolarizing (ON) bipolars have been identified. We present support for the contention that rod bipolars are all depolarizing.

Adult rhesus monkeys were trained on a detection task in which they made direct saccades to achromatic stimuli appearing on a CRT; stimuli presented were either brighter (incremental) or darker (decremental) than background. Monkeys were tested under both light- and dark-adapted states. Intravitreal injections of 2-amino-4-phosophonobutyrate (APB) were made into one eye and the monkeys' performance for each eye was assessed independently.

As we have found before, for photopic vision, APB greatly impaired the monkeys' ability to detect incremental stimuli, but had little effect on the detection of decremental stimuli. For scotopic vision, APB eliminated all responses to both incremental and decremental stimuli.

These findings support the existence of a single physiological class of rod bipolars that depolarize in response to light.

NON-LINEAR SUMMATION OF M- AND L- CONE INPUTS TO PHASIC GANGLION CELLS OF THE MACAQUE. B.B.Lee, P.R.Martin*and A. Valberg* Max-Planck-Inst. Biophys. Chem. 34 Göttingen FRG.

Phasic ganglion cells in the macaque retina receive combined input from M- and L- cones to both center and surround of their receptive fields. With sinusoidal alternation (flicker) of two lights of different color but having equal luminance, the M- and L- cones can be modulated in antiphase. With a 4° stimulus field at a retinal illuminance of 1400 td, phasic cells responded at twice the flicker frequency for all frequencies between 1 and 20Hz. With different pairs of alternating lights, the amplitude of the frequency-doubled response was directly related to the degree to which M- and L- cones were stimulated in antiphase. This suggests that the response is due to a non-linearity seen on summation of M- and L- cone inputs. The response was largely abolished when a 0.5° field restricted to the center of the receptive field was used, or at low mean luminance levels. The non-linearity thus arises largely in the surround mechanism at high retinal luminances. Some of its characteristics suggested a saturating non-linearity, but detailed examination of the response histograms suggested the mechanism may be more complex.

SYNTHESIS OF RETINAL GANGLION X AND Y RECEPTIVE FIELDS WITH A COMPUTER CELL PACKING MODEL. A. Moore* and C. Koch (SPON: D. van Essen) . Computation & Neural Systems Program, California Institute of Technology, Pasadena, CA, 91125.

Retinal ganglion (RG) cells are known to have smooth, roughly gaussian excitatory centers, even though the dendritic trees upon which the receptive field (RF) is constructed have large gaps between branches. It is a challenge of neural systems modelling to explain how excitation from cones, as it passes to RG cells via bipolar (BP) and amacrine (AM) cells, is smoothed enough spatially to 'fill in' these gaps (Peichl and Wassle, J. Physiol 262, 1976, p 280). In cat, the classes of BPs that contact on-and off-center X and Y class RG are known but the classes of AM cells that contribute to their RFs are not fully known. By studying which AM cell classes are sufficient to smooth the X and Y RFs, we hope to suggest which AM classes transfer information in the X and Y pathways. Thus, by applying a functional constraint (smoothness) we can make predictions about pathway structure in the retina. Images of cells at 3mm eccentricity are captured with a video camera, converted to scaled binary images, and stored in planes of computer memory. Synthetic spots are placed in the stimulus field: where a spot contacts a cone in the adjacent plane, the cone is excited. Similarly, where excited cones contact a BP input dendrite, the BP cell is excited. The excitations from cones are summed, and the total is passed to the BP output dendrites. This simulates the convergence and divergence of excitation as it passes from the outer to inner plexiform layer. The RG dendrites and soma that contact the output BP dendrites in turn sum the BP excitation. The total excitation at the RG cell due to the cone-BP-RG path is then taken as the RG response to the spot, and is placed in register with the spot in the output (RF) plane. For X RG cells, we have found that AM intermediates are not necessary to satisfy the smoothness constraint for spot stimuli of at least 25 um in diameter. For Y cells, either larger spots or AM intermediates are necessary.

A NEURAL NETWORK MODEL OF VISUAL RECEPTIVE FIELD REGIONS AS A FUNCTION OF RESPONSE LATENCIES. L. Sun* and E. Micheli-Tzanakou. Dept. of Biomedical Engineering, Rutgers University, P.O.Box 909, Piscataway, New Jersey 08855-0909.

Last year we reported about the spatiotemporal characteristics of the frog ganglion cells (1). It was found that an anticorrelation exists between the number of responses and the latencies. A parabolic relationship was also determined between the latency and the receptive field cluster as a cluster moved toward the surround. In this paper a three dimensional neural network model of the retina has been designed and computer simulations carried out in order to duplicate the experimental results and to further understand the retinal processes. The results show that the responses reach a maximum at the beginning of stimulation and then adapt to a certain level after repeated stimulation. The responses vs. latencies show a nonlinear relationship the same as in the experimental results. If the frequency of stimulation increases then repeated stimuli do not evoke repeated responses. The stimuli used were equivalent to the receptive field organization previously used in our experiments. The implications of this retinal network will be discussed.

INTERACTION BETWEEN NEUROPEPTIDES AND GLYCINE IN THE AVIAN RETINA. T. Li*, D.M.K.Lam and Y.Y.T. Su. Center for Biotechnology, Baylor College of Medicine. Houston, TX 77030.

Previous studies from this Laboratory have demonstrated the interaction between enkephalins and GABA, glycine or dopamine in the chicken retina (Su et al., Retinal Signal Systems, Degenerations and Transplants, 9:53, 1986). In this communication we present our recent studies on the interaction between somatostatin and glycine, neurotensin and glycine in the chicken retina. Our preliminary results showed that in the presence of 2 μM of somatostatin approximately 32 ± 4% of K^+-induced ^{3}H-glycine release was inhibited, while the same dosage of neurotensin increased ^{3}H-glycine release by 36 ± 2%. This suggested these peptides and glycine are functionally related. The structural basis of these systems was studied using double-label techniques. In addition to those cells which were labelled for each marker alone, some of the cells were found to be double-labelled for both ^{3}H-glycine and somatostatin- or neurotensin-immunoreactivity. The neuropeptide- and glycine-stained processes, which may have originated from single- or double-labelled cells, overlapped extensively in the inner plexiform layer. The interaction between these systems may be confined to this layer, where somatostatin may function as a presynaptic inhibitor and neurotensin as a presynaptic activator of glycine accumulating terminals.

MUSCARINIC RECEPTORS AND SECOND MESSENGER SYSTEMS IN THE RAT RETINA. S.E. Moroi, Z.-X. Qu*, G.-Y. Le*, M. Hadjiconstantinou and N.H. Neff. Depts. Pharmacology and Pathology, The Ohio State Univ. Col. Med., Columbus, OH 43210

Receptor-mediated transmembrane signaling is modulated by interactions among second messenger systems. We investigated potential interactions among cAMP and phosphoinositide (PI) second messenger systems coupled to muscarinic receptors in rat retina. Maximal stimulation with acetylcholine (ACh) caused a 30% decrease in cAMP and a 100% increase in inositol monophosphate (IP_1). Preincubation with cyclic nucleotide analogs (8-BrcAMP, dibutyryl cAMP, and 8-BrcGMP at 1 mM) and forskolin (10 uM) had no effect on basal or stimulated IP_1 which suggests that cAMP does not modulate ACh-mediated PI hydrolysis. The phorbol ester, PMA, was used to stimulate protein kinase C (PKC). Preincubation with PMA prevented ACh stimulation of IP_1 which is consistent with down regulation of muscarinic receptor function. PMA caused a 65% increase in basal cAMP and attenuated the ACh-mediated inhibition of cAMP. This finding suggests that PMA also causes functional down regulation of muscarinic receptors coupled to cAMP. These preliminary results suggest that PKC modulates muscarinic receptors coupled to both the cAMP and PI second messenger systems.

GLYCINE STIMULATES CALCIUM INDEPENDENT RELEASE OF ^{3}H-GABA FROM XENOPUS LAEVIS RETINA. John F. Smiley* and Scott F. Basinger, Program in Neuroscience and Cullen Eye Institute Baylor College of Medicine, Houston, TX. 77030

We have previously characterized an interplexiform cell in the Xenopus laevis retina that is labeled by both glycine high affinity uptake and somatostatin antibodies. We are now looking at the function of these two putative transmitters by monitoring the release of retinal ^{3}H-GABA, presumably from horizontal cells. Retinas are incubated 10 minutes in luM ^{3}H-GABA, perfused for 32 minutes, and then drugs are added to the perfusate. In most experiments six consecutive 4 minute pulses of drug are applied, with 10 minute washes between pulses.

Micromolar concentrations of glycine or glutamate are seen to stimulate ^{3}H-GABA release with approximately equal potency. These effects are completely independent of Ca^{2+}, as seen in Ringers with 0 Ca^{2+}/20mM Mg^{2+}. One difference between these responses is that glutamate down-regulates itself, causing substantially smaller responses in consecutive pulses. In contrast the glycine response at first increases, and then only gradually decreases. These patterns of self-regulation are uneffected by Ca^{2+} concentration. The response to glycine is inhibited by strychnine. Potassium also stimulates release, but this is about 75% Ca^{2+} dependent. Somatostatin-14 or -28 have no effect at concentrations of 10nM to 2uM. (Supported by NIH grants.)

GLYCINE INDUCED REVERSIBLE BLINDNESS IN SHEEP. N. Wright, R. Hill, J. Seggie (SPON: M. Steiner). Departments of Biomedical Sciences, Psychiatry, Medicine and Pathology, McMaster University, Hamilton, Ontario L8N 3Z5.

The use of a 1.5% glycine solution as a bladder irrigant during surgical removal of the prostate has been associated with transient visual impairment. Glycine is thought to be an inhibitory retinal neurotransmitter. Adult female sheep (N=17) were infused with 0, 500, 1000, 2000 or 4000 ml of 1.5% glycine. The volume control was a solution of dextrose and saline. The pupil response to 5 seconds of bright light following dark dilation was used as an index of retinal response. Observations were made at 2, 4, 6, 12, 24, 48, 96 and 192 hours after infusion. Glycine infusion resulting in plasma levels up to 15,000 μmol/L inhibited pupil response to light is a dose dependent fashion. Inhibition of pupil response was paralleled by behavioural indices of visual impairment and blindness but not by changes in plasma sodium, chloride, potassium or osmolarity. The duration of effect was also dose dependent with visual impairment following 4000 ml of glycine being detectable up to 24 hours. Data suggest that glycine inhibits retinal responsiveness to light in a dose dependent and reversible manner.

GLYCINE AND GABA ACTION ON THE SCOTOPIC THRESHOLD RESPONSE OF THE CAT ERG. F. Naarendorp, M. Adams*, P.A. Sieving* Kellogg Eye Center, Univ. of Mich., Ann Arbor, MI 48105

The Scotopic Threshold Response (STR) is a component of the electroretinogram (ERG) recorded near rod absolute threshold. The STR appears below PII threshold, in relative isolation from other ERG components. We studied the effects of intravitreal injections of Glycine and Gaba on the STR in the optically intact eye of anesthetized cats. Glycine (10-50 uMole) reduced maximal amplitudes of the STR and PII to 20% and 70% of control values respectively; PII-threshold remained unaltered but the STR was desensitized by one log unit. The photoreceptor a-wave was unaffected. Strychnine (0.1-0.4 uMole) antagonized the effect of Glycine on the STR and PII. Gaba (20-40 uMole) suppressed the STR completely, lowered PII-threshold by 0.5 log units and enhanced its amplitude significantly across the initial 2/3 of its dynamic range without changing Vmax. Bicuculline and picrotoxin prevented enchancement of PII-amplitude by Gaba; they partially blocked the suppressive effect of Gaba on the STR. Recovery from Glycine and Gaba showed a return of PII to control amplitude but an enhancement of the STR. Although both Gaba and Glycine exert a neuromodulatory role on the cells that control STR, they may do so in different ways.

DOSE RELATED DIFFERENTIAL EFFECTS OF APOMORPHINE ON THE RABBIT SCOTOPIC ERG. P. Olivier, F.B. Jolicoeur,G Lafond*, A Drumheller and J.R. Brunette*. Departments of Ophthalmology and Psychiatry, Faculty of Medecine, Sherbrooke University, Sherbrooke, Quebec, Canada J1H 5N4.

In order to better understand dopaminergic functions in mammalian retina we initiated a series of experiments in which the effects of several doses of the well known dopamine agonist apomorphine on the rabbit scotopic ERG were examined.

The effects of 0.01,0.1,1.0 mg/Kg of the drug administered intravenously in different groups (N=10) were studied in dark adapted rabbits and compared to a control group of animals (N=10) injected with the same volume of the vehicule solution. ERG parameters investigated included amplitudes and implicit times of A- and B-waves as well as four oscillatory potentials (OP1- OP4) generated by different intensities of stimulation and recorded before and15,30,60,90 and 120 min after injections.

Results indicate that neither amplitudes nor implicit times of A-waves were affected by apomorphine. Interestingly, apomorphine produced dose related differential effects on B-wave amplitudes without affecting its implicit times. The smallest dose (0.01 mg) significantly increased amplitudes at all intensities studied. The intermediate dose (0.1 mg) was without any effects whereas the largest dose (1.0 mg) markedly decreased B-wave amplitudes, an effect more prominent at high intensities of stimulation. It is noteworthy that on oscillatory potentials, apomorphine produced an enhancement of OP2 and OP3 amplitudes only with the intermediate dose (0.1 mg). Other oscillatory potentials were not altered by the drug.

Together, our results constitute experimental evidence that retinal dopaminergic neurons implicated in the generation of the B-wave and specific oscillatory potentials amplitudes possess presynaptic inhibitory receptors which are stimulated by relatively small doses of a dopamine agonist. The fact that A-wave, OP1 and OP4 amplitudes or implicit times of all ERG parameters remained unaffected suggest that retinal dopamine autoreceptors are differentially implicated in retinal response to photic stimulation. Supported by MRC grants MT 2593 and DG 284.

397.1

THE VISUAL WULST MODULATES THE DIRECTIONAL SELECTIVITY OF ACCESSORY OPTIC UNITS IN THE PIGEON. L.R.G. Britto, D. E. Hamassaki*and O.C. Gasparotto*. Dept.Physiol.Biophys,Inst Biomed.Sci., São Paulo State Univ.,05508 São Paulo,Brazil

The visual telencephalon is known to project to accessory optic system (AOS) nuclei. In order to verify the impact of that connection upon the AOS function, we examined the directional selectivity of units within the nucleus of the basal optic root (nBOR) of the pigeon AOS , before and after visual Wulst lesions. Thirty adult pigeons (Columba livia) were urethane-anesthetized and subjected to monocular dynamic photic stimulation. Half such birds previously suffered unilateral or bilateral Wulst ablations. Directional selectivity of nBOR units recorded with tungsten electrodes was then evaluated in terms of a vector analysis. In the normal pigeon, most nBOR neurons displayed preferences to upward-temporal or downward- nasal motion. After ipsilateral or bilateral Wulst lesions, the upward response components were almost absent, with most units now preferring temporal or downward-nasal motion. The contralateral lesions generated, instead, a dramatic reduction in downward responses. Indeed, most units showed in these cases upward-temporal or upward-nasal responses. These data suggest an involvement of the visual Wulst in the elaboration of the sensitivity to vertical stimulus motion of AOS neurons.

397.2

FOURIER ANALYSIS APPLIED TO VISUAL NEURONS TO DETERMINE DIRECTIONALITY. R. SIMINOFF, UNIVERSITY OF MASSACHUSSETTS AMHERST, MA (SPONSOR J. Desmond)

A neuron displays directional symmetry (DS) if (a) there is a preferred direction (PD) to stimuli moving across the receptive field, (b) there is a null direction (ND) 180 deg out of phase, and (c) responses decrease monotonically and symmetrically from the PD to ND. Degrees of directionality of 110 neurons located in the pretectum of the frog (Fite et al., 1987) using gratings moving at 6, 15 and 25 deg/sec and 8 orientations are evaluated using Fourier Transforms. Practically all units studied show some aspects of directionality and form a continuum from DS to progressively greater asymmetries with non-directionality at the other end. Deviations from DS consist of (a) a ND less than 180 deg out of phase, and (b)responses do not decrease monotonically and/or symmetrically from the PD to ND. Even the most DS neurons do not decrease from the PD to ND as a straight line function. PD's are independent of velocity in 75% of the neurons, and are along the nasal-temporal and vertical axes in 32 and 31% of the neurons, respectively. ND's are 180 and 90 deg out of phase in 30 and 40% of the neurons, respectively. While directionality is independent of background activity, a unit that is "broadly-tuned" can become "narrowly-tuned" if background activity was to increase since the background activity sets the zero level.

397.3

DIRECTION-SELECTIVE CELLS IN THE NUCLEUS OF THE OPTIC TRACT OF THE OPOSSUM (DIDELPHIS MARSUPIALIS AURITA). E. Volchan*, C.E. Rocha-Miranda*, C.Picanço-Diniz*, B. Zinsmeisser*, R.F.Bernardes* and J.G.Franca* (SPON: I.Izquierdo) Inst. de Biofísica, UFRJ, Rio de Janeiro, 21941, Brazil.

Single-unit recordings were performed on eight adult opossums subjected to a midpontine pretrigeminal section. The electrodes were oriented to the brachium of the superior colliculus based on a previous reconstruction of notal--olivary projecting cells. Most of the units showed excitation for random dots stimuli presented to the contralateral eye in a temporo-nasal direction and/or inhibition in the opposite direction. An average of 45% of the units responded to the ipsilateral eye. With two exceptions, wich had the strongest excitatory response at opposite directions for each eye, both eyes showed the same overall pattern of directionality. Inhibiton was stronger than excitation in most ipsilaterally responding cells. Excitatory response to the ipsilateral eye was always weaker than that elicited by the contralateral but in a few cases the ipsilateral inhibitory response was strongest. Many units were excited by stimulus velocities ranging from 0.6 to 150 deg/s. Inhibitory responses were tunned to intermediate spped. The response properties of these units show similarities and discrepancies with other species that can be correlated with the differences in the performance of the optokinetic reflex.

397.4

A QUANTITATIVE ANALYSIS OF THE VISUAL RESPONSE PROPERTIES OF NEURONS IN THE NUCLEUS OF THE BASAL OPTIC ROOT (nBOR) OF THE PIGEON. D.R. Wylie* and B.J. Frost (SPON: M.B. Calford). Dept. of Psychology, Queen's Univ., Kingston, Ont. K7L 3N6.

Previous research has shown that the nBOR is involved in the processing of visual information for compensatory head and eye movements. It has also been reported that these neurons have large receptive fields and respond best to large visual stimuli moving slowly in a particular direction. Two classes have been described, those preferring movement up, and those preferring movement down along the vertical axis. The present study confirms these findings, but describes several classes of neurons. Broadly tuned neurons have high spontaneous rates, but many narrowly tuned neurons have low spontaneous rates. Subfield stimulus presentation indicates that responses are not uniform across the receptive field, that is, there is an area of maximum excitation. Furthermore, the minimal area for a directional response and the area for a maximum response vary considerably. This research was supported by MRC grant #MA 7244 to B.J.F.

CELLS IN THE TURTLE'S BASAL OPTIC NUCLEUS ARE DIRECTION SELECTIVE OVER A BROAD VELOCITY RANGE. A. F. Rosenberg and M. Ariel. Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15260

Retinal direction selective (DS) ganglion cells are thought to provide input to a neural circuit controlling optokinetic nystagmus through the BON of the accessory optic system. Since the BON is a small ventral brainstem structure lying directly above the cranial floor, in vivo recordings are difficult. In our experiments, we use a novel in vitro brain preparation (eyes attached, telencephalon removed) where the brain is inverted so that the ventral side is exposed and the BON is readily accessible. Stimulation is achieved by projecting a moving spot or random dot pattern onto the contralateral eyecup. The brain is continually perfused with oxygenated physiological media and is viable for up to 10 hours after decapitation.

Visually responsive cells were recorded extracellularly in the ventral brainstem, presumably in the BON. Using visual landmarks, recording of these BON cells was often possible in the first electrode penetration. We found that the BON contains almost exclusively DS cells. These cells lacked narrow velocity tuning in both the preferred and null directions. The direction selectivity of the cells was very pronounced for a wide range of illuminations; the ratio of preferred to null responses ranged from 4:1 to 25:1.

NEURONS OF THE MEDIAL TERMINAL ACCESSORY OPTIC NUCLEUS OF RAT ARE POORLY COLLATERALIZING. R.A. Giolli, R.J. Clarke , R.H.I. Blanks, Y. Torigoe & J.H. Fallon. Dept. Anatomy & Neurobiology, Coll. Med., Univ. Calif., Irvine, CA 92717.

Most neurons of rat medial terminal nucleus (MTN) project to the nucleus of the optic tract (NOT), but some project to other brainstem nuclei involved in contolling eye movements. The possibility that MTN-NOT neurons collateralize to innervate other MTN targets is studied with two retrograde flourescent tracers. Flourogold was injected into the NOT, and Fast blue was injected into one of the following nuclei: the ipsilateral supraoculomotor periaqueductal gray and the dorsal cap of the inferior olive and the contralateral visual tegmental relay zone, dorsolateral basal pontine nucleus and superior and lateral vestibular nuclei. The results show that nearly all MTN neurons are single-labeled in all paired injections of the NOT and each of these other nuclei. About 70% of MTN cells project to the NOT and 4-9% to each of the other nuclei. Only around 1% of MTN cells are double-labeled showing that the MTN-NOT neuron population is distinct from neuron pools projecting to the other outflow areas. These data reveal that virtually all MTN neurons are projection neurons. Supported by NSF grant BNS-8612919 and NIH grant NS-15321. RJC is a Brazilian National Research Council (CNPq) Scholar.

PROJECTIONS OF SUPRAGENICULATE PRETECTAL NUCLEUS IN RABBIT. K.M. Gregory[1], R.A. Giolli[2], R. H. I. Blanks[2], & Y. Torigoe[2], Dept. Anat. & Physiology, CSU Long Beach, CA. 90840[1], & Dept. Anat.& Neurobiology, CA. Coll. Med. U.C. Irvine, CA. 92717[2].

The suprageniculate pretectal nucleus (SGp) in the rabbit consists of large darkly stained cells located posterior to the nucleus of the optic tract (NOT). Injection of ^{3}H-leucine into the SGp of rabbits shows that it projects ipsilaterally to: str. gri. superficialis (SGS) of superior colliculus (SC), str. gri. profundum (SGP) of SC, olivary pretectal (PO), NOT, medial pretectal area, periaquaductal gray, thalamic suprageniculate, and lat. hypothalamus. The anterior pretectal nucleus was conspicuous by the absence of either fiber or terminal label. Contralateral projections are to SGS, PO, SGP and SGp. Injection of HRP into the SC confirms the SGp-SC bilateral connections of the SGp and also shows that the SC projects to the ipsilateral SGp. The only cortical label was in the temporal area and was probably due to leucine uptake in the medial geniculate. Thus the rabbit SGp is distinct from the thalamic suprageniculate nucleus which in the cat has projections to the insular cortex.

THE SPATIAL ORGANIZATION OF THE TELENCEPHALIC PROJECTION TO THE PRETECTAL LENTIFORM NUCLEUS OF THE MESENCEPHALON (LM) IN CHICKEN. Stefan R. Bodnarenko and Olivia C. McKenna. Biopsychology Program, Hunter College, N.Y., N.Y. 10021 and Biology Dept., City College, N.Y., N.Y. 10031.

The lentiform nucleus of the mesencephalon (LM) is a pretectal structure that receives its afferents, which we have shown to be spatially organized (JCN 269:3 '88), primarily from the retina. In this study we used the HRP retrograde tract tracing technique to determine whether a projection from the visual telencephalon to the LM in chickens is also spatially organized and to demonstrate the cells of origin. A single population of labeled neurons, with somata measuring 678.9 μm^2 on average, was identified after injections into the LM. These round or stellate-shaped neurons were confined to the lateralmost portion of the ipsilateral accessory hyperstriatum (HA), throughout its caudal to rostral extent, except for the rostralmost portion of HA. Partial injections into the LM revealed a spatial organization of the projection neurons. Labeled neurons in the caudal two-thirds and in more ventral portions of the projection area projected to the dorsal LM. Labeled neurons throughout the entire rostrocaudal extent of the projection area, but in more dorsal regions caudally, projected to ventral LM. Labeled neurons midway on the dorsoventral axis within the projection area projected to the middle LM.

These findings, suggest that a single population of projection neurons, which is confined to a specific portion of the HA, projects in a spatially organized manner to the LM. This study, in conjunction with electrophysiological evidence for a retinotopic organization of the HA and our recent report of the retinotopic organization of the LM, suggests that specific regions of LM receive a spatially organized projection from corresponding portions of the retina, either indirectly through the HA of the visual telencephalon or directly from the retina. The nucleus of the optic tract in mammals, which is considered homologous to the LM, also shows a spatial organization of its afferents arising from the visual cortex. (Supported by NIH EY 03613)

GABA-ERGIC INPUTS TO THE NUCLEUS ROTUNDUS IN PIGEONS (*Columba livia*). T. Shimizu, H. J. Karten, and W. Woodson*. Department of Neurosciences, M-008, School of Medicine, University of California, San Diego, La Jolla, California 92093.

The nucleus rotundus thalami (Rt) in birds plays an important role in visual information processing. Rt receives a non-topographic bilateral projection from layer 13 of the optic tectum, as well as from the subpretectalis complex (SP/IPS) and nucleus reticularis superior thalami (RS). Rt projects to the ectostriatum, a visual structure in the avian telencephalon (Benowitz and Karten, *J. Comp. Neurol.*, 167:503, 1976).

Antibodies directed against glutamic acid decarboxylase (GAD), the enzyme responsible for the synthesis of gamma-aminobutyric acid (GABA), labeled a major axonal plexus in Rt, but did not label any somata. Immunohistochemical and neuroanatomical tracing techniques were used to determine the source of input of this inhibitory neurotransmitter. GAD immunoreactivity was not found in somata of layer 13 of the tectum, but was present in somata of SP/IPS and RS. When the anterograde tracer phaseolus vulgaris leucoagglutinin (PHA-L) was injected into layer 13 of the tectum, dense PHA-L positive axons were found in Rt. These axons, however, did not express GAD immunoreactivity. When PHA-L was injected into SP/IPS, we found that some PHA-L positive axons in Rt were also GAD positive. Lesions of SP/IPS caused a significant decrease of GAD positive axons in Rt.

Thus, the source of GAD positive axons in Rt is at least partially from SP/IPS, not the optic tectum. Since SP/IPS itself is a target of the tectal efferents from layer 13, the SP/IPS-rotundal pathway may provide feed-forward inhibitory information to the tecto-rotundo-ectostriatum system.

NUCLEUS ISTHMI IN THE PIGEON: AN HRP STUDY. L. Telford, Y-C. Wang* and B.J. Frost. Departments of Psychology and Physiology, Queen's University, Kingston, Canada, K7L 3N6.

Reciprocal connections between the nucleus isthmi (NI) and the optic tectum (OT) have been reported for a variety of mammalian and nonmammalian species. As this nucleus is divided into anatomically distinct parvocellular (Ipc) and magnocellular (Imc) divisions in the pigeon, we investigated tectal projections from each subdivision. Cell bodies in the deeper tectal layers were labelled after HRP was injected into Imc, suggesting that there is a direct connection between deep tectal layers and Imc. No labelled fibres were found in superficial cell layers. Long axons were also found coursing ventromedially from Imc. towards the brachium of the superior colliculus. After injection of HRP into superficial tectal layers, labelled cell bodies were found in Ipc. Projections were localized to a small group of cells within Ipc, suggesting that inputs are topographically organized within the nucleus, as reported by Hunt et al. (1977). This corresponds to our electrophysiological data (Wang and Frost 1987) which show that retinotopic mapping is maintained from tectum to NI.

397.11

RETINOTOPOGRAPHIC ORGANIZATION OF OPTIC PROJECTIONS IN RANA PIPIENS. K. V. Fite and N. Montgomery, Neuroscience & Behavior Program, University of Massachusetts/Amherst

The retinotopic organization of the anuran visual system has been reinvestigated using anterograde and retrograde transport of HRP following small retinal lesions, as well as restricted HRP injections of tectum and pretectum.

The first nuclei to receive optic axons in the CNS are the preoptic and suprachiasmatic nuclei, innervated by the dorsal portion of the optic nerve containing axons from all retinal quadrants. Axons from each retinal quadrant enter the chiasm as bands of fibers and expand across the chiasm in the order—nasal, ventral, temporal and dorsal. Fibers destined for the optic tectum become more laterally placed, while those destined for thalamus and pretectum become more medially located. Two mesencephalic retinal projections, to the optic tectum and pretectal lentiform nucleus (nLM), are organized with the temporal quadrant located anteriorly, and the nasal quadrant located posteriorly. In the thalamus, 4 retinotopic maps, n. Bellonci, corpus geniculatum, rostral visual nucleus and posterior thalamic neuropil, are organized as mirror-image reversals of the tectal and pretectal maps. All retinal quadrants contribute to the basal optic nucleus; however, retinotopy could not be established for this nucleus, nor for the pretectal uncinate neuropil.

Such results are relevant for further understanding how retinal axons are organized prior to innervation.

MOTION SENSITIVITIES OF THE VISUAL CLAUSTRUM: INTERACTION OF SPEED AND DIRECTION. R.G. Carey and K.M. Horn. Div. Neurobiol., Barrow Neurol. Inst., Phoenix, AZ 85013 and Ctr. Vis. Sci., Univ. Rochester, Rochester, NY 14627.

The dorsal claustrum is a little known subcortical nucleus that has extensive connections with both cortical and thalamic visual areas. Our investigations of the visual characteristics of this nucleus in the ferret have shown that the vast majority of these neurons are sensitive to moving stimuli. The major features of moving stimuli are direction and speed, and many neurons within the ferret visual claustrum are sensitive to both of these features. Nearly 50% of our sample can be classified as either directional or directionally biased. These responses can be divided into two groups based upon the range of speeds where directionality is manifest. One-third of the cells demonstrate directionality across a broad range of speeds, with the average range extending from 50-1000 deg/sec. The remaining directional neurons show directionality within a narrow range of speeds. Further, the remaining neurons that were not directional when tested at the preferred speed did not show any directional preferences when tested at other speeds.

Claustral neurons respond to a broad range of speeds and appear suited for the detection of motion and not for the extraction of specific features concerning motion or stimulus form. These findings support the hypothesis of Boyapati and Henry (1985) that the claustrum is involved in motion detection. Also, those neurons that manifest directionality across a broad range of speeds may be involved in the detection of the direction of motion.

NEURONS PROJECTING TO THE RETINA: AFFERENTS AND POSSIBLE FUNCTIONS. G. Marin, S. Bodnarenko, O. McKenna, and J. Wallman, Biology Dept., City College, City University of N.Y., New York., N.Y. 10031 and Biology Dept., Ramapo College of N.J., Mahwah, N.J. 07430.

The centrifugal fibers projecting to the avian retina originate in the isthmo-optic nucleus (ION). ION neural activity is strongly driven by a retinotopically organized visual input from the ipsilateral tectum, and, we find, is also modulated by saccadic eye movements. Since degeneration studies years ago suggested an input to the ION from the ocular motor nuclei, we reinvestigated the afferent connections to the ION using the HRP technique.

The ION of four-week-old chickens was injected using KCl-HRP-filled micropipettes, after localizing the nucleus by recording its visually evoked neuronal activity. Injections were small and restricted to the ION.

We found no trace of retrogradely transported HRP in any of the ocular motor nuclei. Only cells in the ipsilateral tectum were consistently labeled. The majority of the neurons had cell bodies located in lamina h of the stratum griseum et fibrosum superficialis. The long axis of their dendritic arborizations was perpendicular to the tectal laminae, with shorter dendrites extending upward, toward lamina g, and thicker and longer ramifying branches extending downward. Because no dendrites were observed above lamina g, where retinal fibers terminate, tecto-ION cells in the chicken, as in the quail, do not receive a direct projection from the retina. Instead, their larger dendrites directed toward a deeper layer suggests that the visual input to the tectum is integrated with other signals, including ones from the saccade-generating circuitry, to form the output to the ION. Experiments addressing this possibility will be presented.

397.14

SUBCORTICAL CONNECTIONS OF INFERIOR TEMPORAL CORTEX OF OWL MONKEYS. R. E. Weller and J. H. Kaas. Dept. of Psychology, Univ. of Alabama at Birmingham, AL 35294 and Dept. of Psychology, Vanderbilt Univ., Nashville, TN 37240.

Previously we described the connections in owl monkeys of subdivisions of inferior temporal cortex (IT) with the pulvinar complex. We now describe the remaining subcortical connections of IT. Injections of ^{3}H-proline were made in caudal (IT_C) or rostral (IT_R) subdivisions of IT of eleven owl monkeys (Aotus trivirgatus). Projections found included those to the amygdala, claustrum, caudate nucleus, putamen, intralaminar nuclei, pretectal nuclei, pons, and, as described previously, subdivisions of the pulvinar complex. Many of these structures also receive input from other subdivisions of extrastriate visual cortex (Graham, J., Lin, C.-S., and Kaas, J. H., J. Comp. Neurol., 187:557, 1979). The input to the amygdala, however, was not previously seen, and distinguishes the subcortical connections of IT from those of more caudal subdivisions of visual cortex. Finally, there were differences between the connections of rostral versus caudal IT. As an example, IT_R had much stronger connections with the amygdala than did IT_C. Differences such as this one support the proposed distinction in owl monkeys between the IT_R and IT_C subdivisions (Weller, R. E. and Kaas, J. H., J. Comp. Neurol., 256:137, 1987). Supported by NIH Grants EY-07147 and EY-02686.

397.15

SOME RETINOFUGAL AXONS IN ADULT FERRETS INCREASE IN CALIBER AS THEY PASS FROM EYE TO BRAIN G.E.Baker* and R.W.Guillery University of Oxford, Dept. of Human Anatomy, Oxford, U.K.

During a study of fiber order in the ferret retinofugal pathway we have noticed that the diameters of the largest axons in the optic tract appear greater than those in the intraorbital optic nerve. We have quantified this and now show that in the optic tract there are axons with diameters greater than the largest found in the post-optic segment of nerve.

Vibratome sections (200μm) from the intraorbital nerve and optic tract were osmicated and embedded in Epon. All sections were treated identically. Semi-thin sections from nerve and tract were stained with phenylene-diamine and internal diameters of axons greater than 4μm (judged by comparison with standard circles) were drawn at x1600 and then measured using the Bioquant image analysis system.

Counting the number of fibers with inside diameter greater than 5μ (D = perimeter/π) gave the following results: Ferret 1: intraorbital nerve = 304 fibers, tract = 989 fibers. Ferret 2: intraorbital nerve = 83 fibers, tract = 462 fibers.

These large fibers in the tract must be retinofugal since 3-4 months after a monocular enucleation all the largest fibers in the contralateral tract degenerate. It remains to be determined whether these fibers taper gradually or change diameter over a short distance as they pass from one glial environment to another.

THE RELATIONSHIP BETWEEN THE PROJECTIONS FROM VISUOCORTICAL AREAS V1 AND V2 TO THE THALAMIC RETICULAR NUCLEUS IN THE RABBIT. **J.W. Crabtree*. (SPON: M. Stryker). Dept. of Human Anatomy, Univ. of Oxford, U.K.**

The traditional view of the thalamic reticular nucleus (TRN) is that adjacent areas of the overlying neocortex map onto adjacent areas within the plane of the TRN. A previous study (Crabtree, J.W. and Killackey, H.P., Neurosci., Suppl., 22: 804, 1987) showed that, in the visual sector of the rabbit's TRN, focal areas of visuocortical area V1 are represented by "slabs" that lie parallel to the borders of the nucleus in the rostrocaudal dimension. In the present study of the rabbit, injections of HRP or [^{3}H]proline were made into visuocortical area V2. The resultant anterograde labelling in thalamus was analyzed and compared with that following tracer injections into V1.

A single injection in V2 results in a single focus of label that is located in the dorsocaudal, visual sector of the TRN. Injections restricted to V1 produce slabs of label that are confined to the outer two-thirds of this sector, while those involving V2 result in slabs of label within the inner one-third of the sector. Only the outer aspect of the TRN's visual sector projects to the dLGN, as revealed by retrograde labelling in the TRN following injections of HRP in the dLGN.

These findings in the rabbit show that, contrary to the traditional view, the adjacent cortical areas V1 and V2 do not map onto adjacent TRN areas along the plane of the nucleus, but rather they map onto adjacent areas orthogonal to the plane of the nucleus. Thus, the neocortex is represented in a discontinuous fashion along the plane of the TRN. The target of the efferents from the inner aspect of the TRN's visual sector, which receives the V2 projection, remains to be defined. (Supported by the MRC, Grant No. 8324037)

ULTRASTRUCTURAL EXAMINATION OF TECTAL TERMINATIONS IN THE VENTRAL LATERAL GENICULATE NUCLEUS (LGN_V) IN THE CAT. M.D. Noseworthy* and G.D. Partlow, Department of Biomedical Sciences, University of Guelph, Guelph, Ont., N1G 2W1.

To further understand the visual process, the functional morphology of the ventral lateral geniculate nucleus (LGN_V) was investigated. Tectal input was examined using degenerative tracing methods. Unilateral ablation of the superior colliculus was performed in 7 cats with care to avoid damage to the overlying visual cortex. Following survival times of 2-12 days, euthanasia was performed, and the tissue prepared for electron microscopic examination. Thin sections were cut from the ventromedial region, described as being that area receiving tectal efferents (Graham, J., J. Comp. Neurol., 173:629-654, 1977). Electron micrographs were examined for synaptic organization.

Degenerating boutons were localized in this region. Qualitatively, they were most often axodendritic, type F connections. Type F refers to boutons containing flattened vesicles, which corresponds to an inhibitory synapse. Preliminary results would indicate that normal synaptic connections were most frequently of this classification. This conveys the possibility of an inhibitory role by the tectal efferents to the LGN_V. With combined visuomotor-vestibular function, such inhibition is yet to be functionally quantified.

397.18

FUNCTIONAL ORGANIZATION OF THE VENTRAL THALAMUS IN THE TREE SHREW. M. Conley, B. Friederich-Ecsy* and I.T. Diamond. Dept. Psychology, Duke Univ., Durham, NC 27706.

The ontogenetic and comparative cytoarchitectonic studies of Rose ('42) led him to conclude that the ventral thalamus consists of the ventral lateral geniculate nucleus (GLv) and the thalamic reticular nucleus (TRN), and that reticular portions of GLv were often confused with the TRN. In this report we have used transport and immunocytochemical methods to study the functional organization of the GLv in the tree shrew and have identified 5 subdivisions, each with specific connections, supporting Rose's view: the external segment and intergeniculate leaflet are retino- and tecto-recipient and contain numerous ChAT-immunoreactive fibers and terminals; the internal segment projects to the tectum and anterior pretectal nucleus and, with the external segment, receives projections from layer V of striate cortex. Two large medial subdivisions share a common border with the TRN and are divided into rostral compact and caudal reticular segments by a ChAT-immunoreactive fiber band. Both subdivisions are rich in calmodulin-kinase but poor in GABA immunoreactivity--the reverse of TRN. The rostral segment has reciprocal connections with the nucleus of the optic tract; the caudal segment receives projections from the cerebellum and projects to the nucleus reticularis tegmenti pontis. THE VENTRAL LATERAL GENICULATE IN A LIZARD.
Neil M. Montgomery & Robin Mergendalh*
University of Massachusetts, Amherst, Mass.01003

The term ventral lateral geniculate (VGL) is used extensivily to describe a visual nucleus in the ventral thalamus of a number of vertebrates yet the relationship between these structures is unknown. In the present study the connectivity of VGL in Anolis carolinesis has been investigated using HRP.

In lizards the VGL is a large crecent shaped structure consisting of a medial cell plate and lateral neuropil. The neurons of the cell plate have palisade-like dendritic fields while the neuropil contains stellate neurons. The neuropil receives retinal afferents while the cell plate receives tectal afferents. Further, the tectal map in VGL is topographically organized and is a 'mirror-image' of that found in the tectal lobe.

Two efferent pathways arise from the VGL cell plate. The dorsal bundle projects to the pretectum reaching the medial pretectal nucleus and the nucleus of the tectal gray. The ventral pathway projects to the accessory optic nucleus, the red nucleus and premotor cell groups lateral to the oculomotor nuclei. The relationship between these projections and those found in other vertebrates will be discussed.

CEREBRAL ISCHEMIA IV

398.1

ISCHEMIA PRODUCES A LOSS OF SOMATOSTATIN IMMUNOREACTIVITY IN ALL HIPPOCAMPAL SUBFIELDS. B. Fadeel*, J. Franck, D. Kunkel and P. Schwartzkroin. Department of Neurological Surgery, University of Washington, Seattle, WA 98195.

The CA1 and CA3 subfields of hippocampus are often necrotic following disease processes, particularly temporal lobe epilepsy. We have been interested in the effects such selective cell loss has on the physiology and restructuring of remaining hippocampal neurons and in the relevance these processes may have for the clinical population with similar damage.

Selective loss of CA1 is produced experimentally, and has been observed in humans, following transient ischemia. We used this approach, produced in adult male Wistar rats by 15 minutes of carotid artery occlusion with vertebral artery cautery, to examine the consequences of CA1 loss on remaining dentate and hippocampal neurons. We have observed that ischemia results in near-complete loss of the somatostatin immunoreactivity normally present in interneurons throughout the hippocampus and dentate gyrus. This loss was observed up to 6 weeks following ischemia and appeared to be specific in that GAD immunoreactive neurons were still apparent. Studies are currently ongoing to determine if reduced somatostatin represents selective cell death or decreased peptide expression.

Somatostatin has been proposed to play a critical role in modulating inhibitory interneuron function. Selective loss of this population of cells or of the peptide they contain, particularly in regions where principal cells remain intact, may alter the excitability of remaining hippocampus.

398.2

DELAYED DECREASE IN BRAIN MITOCHONDRIAL CYTOCHROME aa_3 CONCENTRATIONS FOLLOWING ANOXIA. K.R. Wagner, M. Kleinholz* and R.E. Myers. Research Service., VA Medical Center, Cincinnati, Ohio 45220.

Hyperglycemic cats exposed to 8 minutes of anoxia develop a delayed appearance of neurologic signs including fasciculations and focal seizures involving muscles innervated by cranial nerves. These "symptomatic" cats show elevations of brain lactate and decreases in phosphocreatine due to impairments in brain mitochondrial respiration. Impairment in mitochondrial respiration appears to be due to a decrease in electron transport chain function as demonstrated by a 50% reduction in uncoupler-stimulated respiration and a 57% decrease in cytochrome oxidase activity. In contrast, these biochemical alterations are not present following anoxia in similarly exposed normoglycemic cats or in hyperglycemic cats prior to development of neurologic signs.

In the present study, only brain mitochondria isolated during the postexposure period from cats with neurologic signs showed a significant decrease (45%) in cytochrome aa_3 concentrations. Cytochrome b levels were similar in all experimental groups. Thus, these results suggest that the impairment in cytochrome c oxidase activity in postanoxic symptomatic cats may be due to a loss of heme aa_3. (Supported by Veterans Administration Medical Research Service funds).

398.3

ROLE OF LACTIC ACID TRANSPORT IN THE CNS. W. Walz. Dept. of Physiology, Coll. of Med., Univ. of Saskatchewan, Saskatoon, S7N 0W0, Canada.

Lactate/lactic acid is thought to be a mediator of irreversible brain damage during anoxia and ischemia. Lactate release of cultured astrocytes and of cultured neurons was investigated. The internal lactate concentration remained stable at 23 mM in both cell types. A lactate/proton cotransport mechanism was found to operate in both cell types. They therefore will excrete lactic acid into the ECS. The release rate of lactic acid is about 2000 in astrocytes and 300 nmol xmg^{-1} x hr^{-1} in neurons. Block of respiration increased the neuronal rate to match glial release, confirming that astrocytes have a higher anaerobic glycolysis rate than neurons. High glucose (30 mM) increased lactic acid release only in astrocytes. K^+-induced cytotoxic glial swelling doubled the release rate, but only after swelling was accomplished. Content did not change, confirming that lactate is not involved in brain cell swelling. The action of lactate/lactic acid on neuronal transmission in the hippocampus was investigated. Lactate (30 mM) did not lead to irreversible damage. Lactic acid, however, due to a decrease in pH, damaged synaptic transmission irreversibly. Thus, lactate as an anion can be very well tolerated by the CNS. However, lactic acid will damage synaptic transmission.

The author was an MRC Scholar and is presently an MRC Scientist.

ELECTRICAL, ION TRANSPORT AND METABOLIC CHANGES DURING BRAIN ISCHEMIA IN RAT: COMPENSATORY BUT NOT THRESHOLD EVENTS. C.N. Raffin*, M. Harrison*, T.J. Sick and M. Rosenthal. *Dept of Neurology, University of Miami Medical School, Miami, Fl 33101*

Ligation of the carotid arteries after electrocoagulation of the vertebral arteries (the 4-vessel occlusion model of Pulsinelli and Brierley) produces an event sequence in rat brain that includes EEG suppression, anoxic depolarization (AD) with maximal increases in extracellular potassium ion activity (K^+o), and maximal decreases in tissue oxygenation (tPO_2) with reduction of the mitochondrial electron transport carriers. To determine whether these changes are predictive or determinate of subsequent events, and to provide insights into mechanisms of EEG suppression and AD, electrode and optical techniques were employed in rats anesthetized with pentobarbital. No threshold levels of cytochrome a,a_3 reduction, tPO_2 or K^+o could be determined for EEG suppression. Also, no threshold values of tPO_2, reduction of cytochrome a,a_3 or K^+o could be found that were predictive of AD onset. However, latency to EEG suppression was inversely correlated with latency to AD, to maximal decreases in tPO_2 and to maximal reduction of cytochrome a,a_3. In contrast, latency to AD was proportional to latency of subsequent maximal decreases in tPO_2 and cytochrome a,a_3 reduction. These data do not support the concept that EEG suppression and AD are each produced by thresholds derangements of mitochondrial function. On the contrary, they suggest that EEG suppression is a compensatory process to spare oxgyen for the production of energy for other activities such as ion transport and to avoid the consequences of the loss of ion homeostasis. The early suppression of EEG also suggests the activity of a sensor of potential energy failure, the identity of which, in ischemia, remains unknown.

CEREBRAL FOCAL ISCHEMIA ALTERS LEVELS OF MOLECULAR FORMS OF ACETYLCHOLINESTERASE (AChE). S.P. Mahadik, A. Korenovsky*, C.G. Wakade, & S.E. Karpiak (SPON: H. Laev). Div. Neuroscience, NYS Psychiatric Inst., Depts. of Psychiatry, and Biochemistry & Molecular Biophysics, Physicians & Surgeons, Columbia U., New York.

Physostigmine treatment after focal cerebral ischemia in rat was shown to increase cerebral blood flow and reverse ischemic injury. To further investigate the molecular mechanism of cholinergic dysfunction in ischemia we report here changes in levels of AChE and its molecular forms (10S, mostly membrane and 4S, mostly soluble) in the primary (parietal) and peri-infarct (frontal, occipital & temporal) areas after focal ischemia in rat. Cortical focal ischemia was produced by permanent middle cerebral & common carotid artery occlusion [MCAo+CCAo] with 1 hr temporary contralateral CCAo. AChE was determined by Ellman's assay in presence of ISO-OMPA. Compared with the contralateral side, AChE levels were reduced by 25% in the primary infacrt area, and minimally in the peri-infarct areas. Analysis of molecular forms showed the 10S form was reduced by 41% and 4S form was increased by 84% in the primary area. Results indicate that during focal ischemia membrane AChE is released and converted to 4S, probably reflecting an alteration in membrane structure, contributing to a loss of cholinergic function. Since gangliosides protect cholinergic neurons in CNS injury, we are studying their effects on cholinergic enzymes.

398.6

EVIDENCE FOR *IN VIVO* RELEASE OF N-ACETYLASPARTYLGLUTAMATE DURING CEREBRAL ISCHEMIA IN THE RAT. J.K. Deshpande, G. Tsai, R.J. Traystman* and J.T. Coyle. Depts. of Anesthesiology and Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Cerebral ischemic damage exhibits a predilection for certain brain regions such as hippocampus and may be mediated by activation of glutamatergic receptors. N-acetylaspartylglutamate (NAAG) is a neuropeptide localized to some glutamatergic pathways and may act as a neurotransmitter/modulator in hippocampus that activates NMDA receptors. To determine whether NAAG is released during transient cerebral ischemia, microdialysis probes were stereotaxically placed into hippocampal subfield CA1 and perfused with artificial CSF. Ischemia was induced in 5 rats by hypotension and carotid clamping (2 v-o model) for 30 min. Ten minute fractions of dialysate were collected prior to (-60, -40 and -10 min) and during ischemia (10, 20 and 30 min). NAAG levels were measured by a sensitive and specific radioimmunoassay (RIA). The spontaneous release of NAAG-like immunoreactivity (NAAG-LIR) was high (16.8 $\pm$ 2.3 pm/fraction) immediately after placement of the probe but declined to a stable level (3.6 $\pm$ 1.4 pm/fraction) after 60 min of perfusion. Ischemia resulted in a 4 to 6-fold increase in NAAG-LIR over preischemic levels. The results demonstrate that the RIA method is sufficiently sensitive to measure endogenous NAAG in dialysate. The NAAG release during ischemia suggests that NAAG may play a role in mediating ischemic neuronal injury.

DECREASED HIPPOCAMPAL NOREPINEPHRINE AND IMPAIRED SYNTHESIS FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA IN THE MONGOLIAN GERBIL. K.E. Moore and J.N. Davis, Depts. of Medicine (Neurology) and Pharmacology, V.A. and Duke Univ. Medical Centers, Durham, NC.

Hippocampal CA_1 pyramidal cells are selectively vulnerable to transient ischemic injury. We measured the level and rate of NE synthesis after 5 min. ischemia. Hippocampal NE fell from 0.29 ±.04 to 0.14 ±.05 ng/mg ($p<.05$) at 1 hr. following ischemia, compared to 0.21 ±.04 at 1 hr. in sham operated controls. At 24 and 48 hrs. post-surgery, NE levels had returned to baseline. To determine why NE was decreased after ischemia, the DOPA decarboxylase inhibitor NSD-1015 was used to estimate NE synthesis. DOPA is barely detectable in the normal brain, but 30 min. after NSD-1015 administration 13 ±1 pg/mg accumulates. DOPA concentrations were 19 ±2 in ischemic vs. 29 ±4 pg/mg in sham operated gerbils 1 hr. post-surgery ($p<.05$), 23 ±5 vs. 38 ±13 pg/mg at 6 hrs., and 10 ±1 vs. 17 ±6 pg/mg at 12 hrs. These data indicate that 1) after surgery there is a transient decrease in hippocampal NE; 2) NE synthesis increases in ischemic and sham operated gerbils; and 3) ischemic gerbils do not increase NE synthesis as much as sham operated controls. If ischemia causes NE release, impaired NE synthesis would result in a net loss of NE. The loss of NE may aggravate neuronal loss after transient ischemia. We speculate that transient ischemia impairs phosphorylation of tyrosine hydroxylase in noradrenergic neurons.

Supported by the V.A. and N.I.H. (NS 06233).

NOREPINEPHRINE (NE) AND SEROTONIN (5-HT) RELEASE IN THE DORSAL HIPPOCAMPUS DURING GLOBAL ISCHEMIA. L. A. Phebus*, J. A. Clemens and R. Mincy* (SPON: J. A. DiMicco). The Lilly Research Labs, Indianapolis, IN 46285.

Male Wistar rats were anesthetized, both vertebral arteries were cauterized closed and reversible clamps were loosely placed around both common carotid arteries. At the same time, a miniature dialysis probe was permanently implanted in the CA-1 area of the dorsal hippocampus. The next day, the output of the dialysis probe was directly connected to an automated microbore HPLC which assayed the brain dialysate samples of NE, 5-HT, 5-HIAA, DOPAC and HVA at fifteen minute intervals. After a baseline was established, ischemia was induced by tightening the clips around the carotids. Following thirty minutes of ischemia, the carotid clips were released and reperfusion begun. In a second experiment, after a baseline was established, CSF containing 10^{-3}M ouabain was perfused through the probe and its effects on neurotransmitter release were measured.

During ischemia there was a large increase in extracellular NE and 5-HT and a decrease in 5-HIAA, DOPAC and HVA. On reperfusion, the levels of these neurochemicals returned to near normal. Ouabain administration via the dialysis probe also released NE and 5-HT into the extracellular fluid. The release of these transmitters during cerebral ischemia may play a role in the damage produced by this insult.

EFFECTS OF DIPYRIDAMOLE AND SOLUFLAZINE, NUCLEOSIDE TRANSPORT INHIBITORS, ON THE RELEASE OF PURINES FROM RAT CEREBRAL CORTEX. M.H. O'Regan*, J.W. Phillis and G.A. Walter*. Dept. of Physiology, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Manipulation of adenosine transport as a means of enhancing adenosinergic tone has been possible using selective transport inhibitors. These agents can depress neuronal activity, induce sleep in dogs, depress locomotor activity in mice, exert anticonvulsant effects and enhance hypoxia-evoked cerebral vascular reactive hyperemia. The cortical cup technique was used to determine the effects of dipyridamole and soluflazine on cortical perfusate levels of adenosine and its metabolites, measured by HPLC, before, during and after a 5% oxygen challenge. Hypoxia-evoked adenosine, inosine, hypoxanthine and xanthine levels were suppressed following soluflazine (50 µg/kg iv), consistent with inhibition of a bidirectional transporter. In contrast, dipyridamole (0.5 mg/kg iv), which purportedly does not cross the blood-brain barrier, potentiated hypoxia-induced releases of adenosine in comparison with the saline injected controls, while hypoxanthine and xanthine levels declined. These results illustrate a potential complication in the use of these inhibitors, since the bidirectional nature of facilitated nucleoside transport in brain allows for either symetrical or assymetrical inhibitory effects leading variously to increased or decreased levels of endogenous adenosine in the interstitium.

DECREASED EXCITATORY AMINO ACID RECEPTORS IN GERBIL CAUDATE FOLLOWING 10 MIN FOREBRAIN ISCHEMIA. L.P. Miller* and T.R. Insel (SPON: J. Johannessen). Vet Adm Med Ctr, Wash D.C. 20422, Dept. Pharm., Georgetown Univ. Sch. Med., Wash D.C. 20007 & Lab. Clin. Sci., NIMH, Poolesville, Md. 20837.

Subjecting rats or gerbils to short-term (5-10 min) forebrain ischemia initiates a series of events which progresses over a period of 2-4 days to cell death in a number of brain regions. There is accumulating support for excitatory amino acid (EAA) mediated neurotransmission in hippocampal cell death including: (1) presence of a high density of EAA receptors (2). inhibitors of EAA-mediated neurotransmission attenuate the observed cell death. There is also support for EAA involvement in cell loss in the caudate, since lesioning of the cortical projection to the caudate (glutamatergic fibers) will attenuate cell death in this region following forebrain ischemia. In the present study the extent of alteration in binding to glutamate receptor subtypes in the caudate was measured post-ischemia. Ischemia in 10-12 week old female gerbil was induced by bilateral clamping of the common carotids for 10 min under 2.5% halothane anesthesia. At 7 days post-ischemia the animals were sacrificed by decapitation, brains removed and frozen. EAA receptors were characterized by N-methyl-D-aspartate (NMDA) displaceable 3H-glutamate binding to the NMDA receptor, 3H-AMPA binding to the quisqualate receptor and 3H-Kainic acid binding to the KA receptor.

	Region	Percent of Control		
		NMDA	AMPA	KA
(*sig,p<0.05)	lateral caudate	79*	86	88*
	medial caudate	84	94	94

Our results (1) show that binding to EAA receptors in the lateral but not medial caudate is altered following ischemia (2) are consistent with EAA receptor involvement in cell death observed in this region of the basal ganglia.

INHIBITION OF PYRUVATE DEHYDROGENASE FOLLOWING ISCHEMIA. F.A.Welsh and Y.Katayama*. Division of Neurosurgery, Hospital of Univ. of Pennsylvania, Philadelphia, PA 19104.

Pyruvate dehydrogenase (PDH) is a rate-controlling step in energy metabolism. Thus, loss of PDH activity following cerebral ischemia may impair the generation of high-energy phosphates. In the present experiments, cerebral ischemia was produced in pentobarbital-anesthetized gerbils, using bilateral carotid artery occlusion. Gerbils were pretreated with 20 mmol/kg glucose to induce hyperglycemia. After 20 min ischemia, the brain was reperfused for intervals up to 4 hr. PDH activity in unanesthetized, normoglycemic gerbils was 50 ± 3 mmol/kg/hr in cortex and 50 ± 8 in caudate. In anesthetized, hyperglycemic animals, PDH activity was 18 ±4 and 18 ± 3 mmol/kg/hr in cortex and caudate, respectively. Ischemia increased PDH activity to 38 ± 13 in cortex and to 39 ± 5 mmol/kg/hr in caudate. However, after 20 min reperfusion, PDH activity decreased markedly to 7 ± 3 in cortex and 5 ± 2 mmol/kg/hr in caudate. Over the next 4 hr of reperfusion, PDH activity recovered gradually to 15 ± 5 and 17 ± 5 in cortex and caudate, respectively. Tissue levels of phosphocreatine exhibited a secondary decrease in caudate, but not in cortex at 4 hr. These results indicate that PDH activity is diminished following cerebral ischemia and thus may cause a secondary failure of energy metabolism. Further, the decrease PDH activity in hyperglycemic animals may explain the known detrimental effects of hyperglycemia on ischemic brain injury.

ISCHEMIC EFFECTS ON NORADRENERGIC AND ENERGY METABOLITES IN THE CEREBRAL CORTEX OF YOUNG AND ADULT GERBILS. K. Kumami, B.B. Mrsulja, Y. Ueki, B. Djuricic and M. Spatz. Lab. of Neuropathology & Neuroanatomical Sciences, Nat. Institutes of Health, Bethesda, MD 20892

Relationship between ischemic changes in the cerebral cortical content of energy and noradrenergic metabolites was evaluated in young and adult gerbils. Groups of 3 weeks and 3 months old gerbils were subjected to 5 or 15 min of bilateral carotid artery occlusion alone or with 1 hour release. Animals were killed by microwave irradiation. Energy and monoamine metabolites were determined in the same sample of tissue. Ischemia (5 and 15 min) depleted energy metabolites but did not affect the content of either norepinephrine (NE) or homovanillic acid (HVA) in young and adults. At 1 hour of reflow after 5 and 15 min of ischemia, the levels of NE significantly decreased while those of HVA increased in adult but not in young. At this time a complete recovery of energy reserves was seen in young and adults. These results indicate that the ischemic change in homeostasis of energy metabolism is not directly associated with that of noradrenergic system in young and adult cerebral cortex. The observed disturbance in the metabolic pathway of NE during recovery period in adult but not in young animals suggests that the increased turnover rate (= release) reported in cerebral ischemia of adults may differ from that of the young brain subjected to ischemia.

THE RELATIONSHIP BETWEEN EEG AND BRAIN HIGH ENERGY METABOLITES DURING HYPOXIA. D.S. Smith, M.D., H. Miyake*, S. Nioka*, A. Zaman*, B. Chance*. Depts. of Anesthesia, Biochemistry/Biophysics, Univ.of PA., Philadelphia,PA 19104.

The relationship between brain energy and EEG was studied using 31-P Magnetic resonance spectroscopy during a gradually progressive hypoxic insult.Prior to the hypoxia, the animals were exchange transfused to hemoglobin (Hb) concentrations of 0.5-1.5 g/dl with a fluorocarbon oxygen carrier. Cats were anesthetized with ketamine, tracheotomized and mechanically ventilated, catheters were inserted in the femoral arteries and veins, and the skin and muscle of the skull were reflected. Brass screws were used for recording the EEG. Phosphorus spectra were obtained with a 2 cm coil placed on top of the skull, a 26 cm, 1.9 tesla magnet and a 90° pulse at 4 sec intervals. After the exchange transfusion, FiO_2 was lowered by increments until death occurred. Each level of FiO_2 was maintained for 12 min. The results demonstrated a distinct relationship between the change in EEG amplitude and brain levels of PCr. There was a threshold response below which EEG decreased as a linear function of PCr change. There was an increase in inorganic phosphorus, however, there was minimal change in ATP. The data demonstrates the close relationship between EEG power and level of brain energy metabolites with the strongest relationship for PCr and little change in ATP. The data provides further evidence that changes in the rate of ATP consumption or production are buffered by the conversion of PCr to ATP via creatine kinase.

CEREBRAL METABOLISM AND BLOOD FLOW III

PHASE CONTRAST MR IMAGING IN CEREBRAL ISCHEMIA AT 4.7 T. M.J. Quast*, G Ward*, R. Treaff*, T.A. Kent*. (sponsor: R.R. McKendall) Depts. of Neurology, Neurosurgery, and Marine Biomedical Institute, UTMB, Galveston, Texas.

In magnetic resonance imaging (MRI) and spectroscopic studies of the brain in the immediate post-arterial occlusion period, we noticed that heavily T_2-weighted images did not demonstrate a lesion for several hours while a perfusion deficit could be clearly seen (Kent, et al, AJNR, in press) and lactate and high energy phosphates were altered within a few minutes (Bradley, et al, AANS, 1988). We therefore have pursued other methods to image early changes. Studies indicate that fatty acid levels are increased in ischemia (Rehncrona, et al, J. Neurochem, 1982). Phase contrast imaging (Dixon, Radiology, 1984) provides a method to separate fat and water signals. We optimized the 180 refocussing pulse time shift so that maximum phase contrast occurred from signals originating at 1.3 ppm in the proton NMR spectrum. Difference images, obtained by subtracting each pixel from this and a spin echo image (TE 40, TR 1000) clearly demonstrated lesions in rats: 1) Before and after death by anesthetic overdose, in which increases in signal were observed to accumulate our time, first in cortical regions, and 2) focal ischemia by MCA occlusion, 3 cerebral vessel and single carotid artery occlusion, when lesions occurred prior to becoming visible on standard MRI. The mechanism of these changes is under investigation.

399.2

VALIDATION OF LASER-DOPPLER VELOCIMETRY IN THE CNS Lindsberg P J*, O'Neill J T*, Paakkari I*, Hallenbeck J*, Feuerstein G. (SPON:D Malcolm). Depts. of Neurology and Pediatrics, USUHS, Bethesda, MD 20814

Laser-Doppler velocimetry (LDV) is a new non-invasive method for continuous on-line monitoring of microvascular blood flow. LDV has previously been validated with more established methods in various other tissues, yet its validity and accuracy in the CNS has not been shown. We have compared LDV with the microsphere method (MS) using two independent laser probes placed dorsally on exposed lumbar (L5 laminectomy) spinal cord of anesthetized rabbits (n=7). Following baseline flow measurements spinal cord blood flow (SCBF) was increased (up to 50%) with iv infusion of phenylephrine (20-60 µg/kg/min) and decreased (up to 50%) with a bolus of chlorisondamine (10 mg/kg). The percentage changes of SCBF from the baseline obtained by LDV and MS agreed excellently ($r=.94$, $p<.0001$). The corresponding changes in tissue vascular resistance (VR) also correlated well ($r=.90$, $p<.0001$). On the contrary, there was less correlation ($r=0.38$) between the absolute SCBF values obtained by the two methods during baseline or altered SCBF. In conclusion, the validity of LDV in estimating the instantaneous SCBF (ml/100g/min) remains unproven, but is confirmed in monitoring temporal changes of SCBF and VR. Therefore, LDV proves a valuable tool for research manipulating CNS microcirculation by pharmacological or pathophysiological interventions.

ASTROGLIAL K^+ HOMEOSTASIS & LOCAL CEREBRAL BLOOD FLOW REGULATION R.P. Kraig & C. Iadecola. Department of Neurology, Cornell University Medical College, New York, N.Y. 10021

Neuronal activity is a major factor regulating local cerebral blood flow (lCBF). Increased interstitial concentration of K^+ ($[K^+]_o$) from neuronal activation was thought to influence lCBF by producing cerebrovasodilation. Recently, Paulson & Newman (Science 237:896, '87) speculated that astroglial $[K^+]$ changes may mediate the increase in lCBF. We sought to test this hypothesis by measuring changes in $[K^+]_o$ and lCBF elicited by local surface electrical stimulation (lSES) before & after reduction by Ba2+ of the rise in astroglial $[K^+]$ elicited from lSES (Canad J Physiol/Pharm 65:1038, '87). $[K^+]_o$ was measured with ion-selective microelectrodes (layers I & II, parietal cortex) and lCBF with a surface laser doppler probe in halothane anesthetized and ventilated rats (n=4). Before Ba^{2+} superfusion, lSES (10 Hz, 30 s) increased $[K^+]_o$ from 2.9 ± 0.1 (n=25) to 6.6 ± 0.3 mM (n=23) and lCBF to 173 ± 13% of control. Spreading depression (SD) increased $[K^+]_o$ to 40.8 ± 4.2 (n=5) and lCBF to 195 ± 12% of control. With Ba2+, resting $[K^+]_o$ fell to 2.3 ± 0.1 mM (n=14) but rose to 7.6 ± 0.6 (n=10) during lSES and 41.7 ± 3.0 (n=6) during SD while lCBF rose to 179 ± 9 and 180 ± 16% of control, respectively. Thus, lCBF changes are not directly correlated (duration & magnitude) to a rise in $[K^+]_o$ or (presumably) astroglial [K+]. Hence, the "coupling" between functional activity & lCBF is not based solely on changes in interstitial or astroglial $[K^+]$.

399.4

CORTICAL BLOOD FLOW DURING SEIZURES IN RATS WITH OPEN VERSUS INTACT SKULLS. E.M. Slaven*, J.C. Magee*, R.M. Zweifler*, and N.R. Kreisman. (SPON: F. Domer) Dept. of Physiol., Tulane Univ. Sch. Med., New Orleans, La 70112.

Cortical blood flow (CBF) was measured during serial seizures in rats with open or intact skulls to rule out the possibility that attenuation of ictal increases in CBF results from hemodynamic changes in the open cranium. Seizures were induced at 5-10 min intervals with pentylenetetrazol in anesthetized, paralyzed rats, and CBF was measured bilaterally by H_2 washout. Mean control CBF was faster in the right cortex and with the skull open. However, CBF rose 330-350% over control (n=20) during seizures early in the series and diminished to 120-150% over control during later seizures, regardless of whether the skull was open or intact or whether measurements were made in the right or left cortices. Although exposing the cortex results in overestimation of CBF values with the H_2 washout method, probably due to diffusion of H_2 into the atmosphere, it does not alter the percent increases in CBF measured during serial seizures. (Supported by NIH grant NS-17443)

399.5

MODIFICATION OF CEREBRAL HYPOMETABOLISM AFTER CORTICAL CONTUSION: COMPARISON OF GLUCOSE UTILIZATION RATES AND CYTOCHROME OXIDASE HISTOCHEMISTRY. M.J. Chen, T.M. Rolland*, S.A. Queen, and D.M. Feeney. Depts. of Psychol. and Physiol., UNM, Albuquerque, NM 87131.

A widespread reduction in cerebral oxidative metabolism, demonstrated by cytochrome oxidase histochemistry (CYOH) has been reported at 48 hr following right sensorimotor cortex ablation in rats (1). Amphetamine (AMPH, 2mg/kg; 24 hr post-contusion compared to vehicle controls; 24 hr pre-CYOH) significantly reversed this depression of CYOH staining in some brain areas remote from the injury. This parametric study further examined effects of right sensorimotor cortex contusion (SCC) and AMPH using both autoradiographic 2-Deoxy-D-Glucose (2-DG) and CYOH procedures. At 24 hr post-SCC or sham surgery, rats received either 2 mg/kg AMPH or saline and at 2,6, or 16 days post-injury, the 2-DG procedure was implemented. Autoradiograms were quantified by computer-assisted microdensitometry (CAM). Several authors have noted the difficulties in interpreting 2-DG data from injured brain; these problems are not present with CYOH. Therefore, we are statistically analyzing glucose utilization rates and comparing the same time points and experimental manipulations also using CAM of CYOH. (1) Sutton et al., Soc. Neurosci. Abstr. 12:1404, 1986. Supported by U.S. Army Contract No. DAMD17-86-C-6144.

399.6

MAINTENANCE OF CEREBRAL BLOOD FLOW DURING STIMULATION OF THE FASTIGIAL NUCLEUS IN RAT. D.M. Nitschke*, J.L. Williams, D.D. Heistad, and W.T. Talman. Lab of Neurobiology, VAMC and Univ. of Iowa, Iowa City, IA 52242.

Autoradiographic studies in the rat have suggested that electrical stimulation of the rostral fastigial nucleus (rFN) increases cerebral blood flow (CBF) without changing metabolism and impairs autoregulation. In contrast, using the pulsed Doppler and microsphere techniques in the cat, we have found only minimal changes in CBF during stimulation of the rFN. We have used microspheres to reassess the effects of rFN stimulation on CBF in the rat. In 7 chloralose-anesthetized rats, CBF was measured during a control period and during electrical stimulation of the rFN. Arterial blood gases were controlled and stimulus sites were confirmed histologically. Mean arterial pressure increased from 85 ± 5 to 109 ± 5 mmHg during stimulation ($p<.01$). Renal blood flow (in ml/100 gm/min) decreased from 691 ± 104 to 546 ± 100 ($p<.01$) while myocardial blood flow increased from 375 ± 36 to 579 ± 50 ($p<.01$). CBF did not change significantly (from 83 ± 13 to 99 ± 16). Cerebral vascular resistance increased by a mean of 9% (NS). This study suggests that stimulation of the rFN has a minimal effect on CBF during a moderate pressor response. The data 1) do not support the hypothesis that rFN has important effects on CBF and 2) suggest that autoregulation is maintained during rFN stimulation. Supported by HL32205, NS24621, and HL14388.

BIOLOGICAL AND METHODOLOGICAL IMPLICATIONS OF PROSTAGLANDIN INVOLVEMENT IN MOUSE BRAIN LIPID PEROXIDATION MEASUREMENTS. R. Bose*, G.R. Sutherland* and C. Pinsky* (SPON: G.B. Glavin). Depts. of Pharmacol. Therap. and Surgery*. U. of Manitoba, Winnipeg, MB, Canada R3E 0W3.

The cyclooxygenase inhibitor indomethacin [2.5 to 10 mg/kg intraperitoneally (ip)] lowered the measured values of thiobarbituric acid reactive substances (TBARS), expressed as malondialdehyde (MDA) equivalents, in mouse brain regions. At 10 mg/kg ip the inhibitor significantly reduced the estimated levels of MDA to 85% of those in saline-treated mice, in frontoparietal cortex and corpus striatum. In contrast, addition of indomethacin (50-800 ug/ml) in vitro to whole brain homogenates increased estimated TBARS in a concentration-related fashion. Such enhancement was not evident when indomethacin (200-800 ug/ml TRIS) was added to pure MDA standard solutions and must therefore reflect interaction of indomethacin with TBARS other than MDA. Hence, the contribution of prostaglandin metabolism-derived MDA, which could be as much as 15% in frontoparietal cortex and corpus striatum, should not be ignored when studying tissue lipid peroxidation.

PHARMACOLOGIC MANIPULATION OF NERVE BLOOD FLOW. D. W. Zochodne* and P. A. Low (SPON: P. J. Dyck). Neurophysiology Laboratory, Department of Neurology, Mayo Foundation, Rochester, MN 55905 USA

Peripheral nerve has both an epineurial (largely capacitative) and endoneurial (nutritive) blood supply but only the former is invested with sympathetic innervation. The importance of adrenergic control of vasa nervorum is unknown. Three techniques were used to study blood supply in the sciatic nerve of normal 300 gram Sprague-Dawley rats: NBF (nerve blood flow) by H_2 clearance with an endoneurial microelectrode; NBF by an epineurial laser doppler flowmetry probe; direct visualization and measurement of epineurial blood vessels with an integrated video-computer display system. Infusion of norepinephrine into the arterial supply of the sciatic nerve elevated systemic mean arterial pressure (MAP) but promptly shut down NBF in both the endoneurial and epineurial compartments. A preceding bolus of phentolamine blocked the fall in NBF without altering the systemic hypertensive response-NBF rose passively with the rise in MAP. Phentolamine alone significantly increased endoneurial NBF despite a fall in MAP. Epineurial norepinephrine bathing solutions had variable effects. Vasoconstriction was often confined to restricted vessel segments-other segments had arrest of the flowing RBC column. Little response was evident in presumed venules. These studies suggest that 'adrenergic tone' regulates NBF and that responsive vessel segments can adjust both nutritive and capacitative flow.

399.9

VARIATION IN THE VOLUME OF PERFUSED CAPILLARIES AND PERFUSED CAPILLARY SURFACE AREA AMONG CEREBRAL MICROVASCULAR BEDS. J. Fenstermacher, S.-Z. Lin*, A. Tajima*, and H. Nakata*. Dept. of Neurosurgery, SUNY, Stony Brook, NY 11794.

We have proposed and tested the hypothesis that the volume, surface area, and percentage of perfused capillaries varies among CNS structures. The experiments were performed on awake Sprague-Dawley rats using five radiotagged materials, quantitative autoradiography, and morphometric analysis of light micrographs. The following parameters were assessed: 1) local cerebral blood flow, 2) plasma, red cell, and blood volumes of perfused-labeled microvessels (PLM), 3) transfer rate constants and permeability-surface area (PS) products for several radiotracers, and 4) total capillary volume fraction (V_f) and surface area (S_f). Among the brain areas examined were the supraoptic nucleus (SON) and ventromedial nucleus of the hypothalamus (VMH). Based on the ratios of blood volume of PLM to capillary volume fraction, the volume percent of perfused-labeled microvessels, which are probably underestimated by this approach, ranged from 64% (SON) to 95% (VMH). Comparisons of PS products to total capillary surface area suggested that the percentage of capillary surface area perfused is least in the SON (about 35%) and greatest in the VMH (100%). Although the capillary volume and surface area percentages were somewhat different for the individual structures, the order from lowest to highest percentage was the same by both measures and supported the working hypothesis.

LACTATE-SUPPORTED SYNAPTIC FUNCTION IN THE RAT HIPPOCAMPAL SLICE PREPARATION. A. Schurr, C.A. West-Phelan* and B.M. Rigor, Department of Anesthesiology, University of Louisville School of Medicine, Louisville, KY 40292.

It is generally accepted that glucose is the primary substrate of both aerobic and anaerobic cerebral energy metabolism, while lactate is the end product of energy metabolism in the absence of oxygen. Recently, we have shown that both hyperglycemic levels of glucose and lactic acidosis not only are harmless but actually beneficial in experimental hypoxia in vitro (Brain Res. 421: 135, 1987; ibid. 438: 311, 1987). Hence, in the present study we tested the possibilty that cerebral energy metabolism can be fueled by lactate alone.

As a sole energy substrate, lactate supported evoked population spikes (synaptic function) in rat hippocampal slices for hours. Synaptically silent, glucose-depleted slices could be resuscitated with lactate to exhibit normal, glucose-like evoked population spikes. Glucose-supported synaptic function was abolished by 0.2 mM iodoacetic acid, while that supported by lactate was unaffected by the glycolytic inhibitor. Thus, under aerobic conditions lactate metabolism proceeds directly, via pyruvate, to enter the tricarboxylic acid cycle.

It is suggested that lactate accumulation as a result of certain conditions such as cerebral ischemia, could actually be beneficial to the ischemic tissue upon resuscitation, as this end product is capable of fueling energy metabolism.

399.11

GLUCOCORTICOIDS (GCs) MODULATE THE EFFECT OF PLASMA EPINEPHRINE ON REGIONAL CEREBRAL GLUCOSE UTILIZATION (rCMRgl). R.M. Bryan, Jr. and J.C. King*. Departments of Surgery (Neurosurgery) and Physiology, The M.S. Hershey Medical Center of The Pennsylvania State University, Hershey, PA 17033.

We tested the hypothesis that GCs modulate the effect of plasma epinephrine on rCMRgl. Rats were divided into four groups. In two groups, rats were adrenalectomized (ADX) three days prior to the experiment; in the remaining two groups, the adrenals remained intact (I). In one ADX and one I group, epinephrine was infused iv at a rate of 8 ug/kg/min; in the remaining ADX and I groups, an equal volume of saline was infused. Regional CMRgl was measured approximately 5 min after beginning the infusions. Mean arterial blood pressure increased from 102 mm Hg in the saline infused groups to 150 mm Hg in the epinephrine infused groups. Plasma glucose decreased as a result of ADX but was increased in both ADX and I groups that received epinephrine. Elevated plasma epinephrine had no effect on rCMRgl in the rats with intact adrenals. However, in the ADX rats, iv infusion of epinephrine increased rCMRgl in every brain region measured (13 of 17 regions statistically significant). Since the response to epinephrine was different depending on the presence or absence of GCs, we conclude that GCs can modulate the effects of plasma epinephrine on CMRgl.

GLYCOGEN ACCUMULATION IN CULTURED ASTROCYTES INDUCED BY GLUTAMATE AND METHIONINE SULFOXIMINE. R.A. SWANSON, A.C.H. YU*, F.R. SHARP, P.H. CHAN. Dept. of Neurology, VAMC and Univ. of California, San Francisco, CA 94121.

Methione sulfoximine (MSO) is known to increase brain glycogen *in vivo*, but is reported to have no effect in brain slice preparation (Folbergova J, J Neurochem 20:547, 1973). It has been proposed that the increased glycogen accumulation results from the induction of brain gluconeogenesis by MSO (Hevor TK *et al.*, J Cereb Blood Flow Metab 6:292, 1986). Using mature cultured astrocytes from rat cortex, 1 mM MSO added to the culture medium at the time of cell feeding increased glycogen content 150% measured 5 hrs later. MSO added at times after feeding had lesser effects on glycogen accumulation.

Since MSO inhibits several enzymes of glutamate metabolism, 1 mM glutamate was added to the culture medium. This also increased glycogen accumulation, with a maximal effect (100% increase) when given at the time of cell feeding. Both MSO and glutamate induced less than 50% increases in the astrocyte glucose content measured between 0 and 5 hrs after feeding.

These findings suggest that: 1) the mechanism of MSO-induced glycogen accumulation is related to its inhibition of glutamate metabolism; 2) gluconeogenesis is of insufficient magnitude to account for the glycogen accumulation (Cummins CJ *et al.*, J Neurochem 40:128, 1983); 3) it is possible that glutamate or a metabolite of glutamate may have a direct effect on glial glycogen metabolism.

399.13

GLUCOSE UTILIZATION AND LEUCINE INCORPORATION IN THE DEVELOPING RAT BRAIN. T.T. Soncrant*, H.W. Holloway*, D.M. Larson*, J.C. Miller* and S.I. Rapoport. Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892.

To study regional brain maturation, we measured local cerebral glucose utilization (LCGU) and regional leucine incorporation into brain protein (RLI) in developing male Fischer-344 rats. LCGU and RLI were measured in 80 brain regions, using quantitative autoradiography and [14C]deoxyglucose or [1-14C]leucine, in groups of 4-8 rats aged 7, 10, 15, 20, 25, 30, 35, 45, 60 and 90 days.

Whole brain glucose utilization rose progressively from 9.3±1.5 (S.E.) to 73.4±3.2 umol/100g/min between 7 and 45 days, then declined by 23% at 90 days (assuming no age change in the lumped constant). Early after birth (7-15 days), the LCGU:whole brain glucose utilization ratio was lower than the adult value in several forebrain regions (neocortex, medial cortex, caudate) and the inferior colliculus, and was higher in most other areas (hippocampus, amygdala, entorhinal cortex, globus pallidus, thalamus, hypothalamus, cerebellum, most brainstem areas). By 30 days of age, however, the pattern of LCGU approximated that of adult rats.

Whole brain leucine incorporation also increased progressively between 7 and 45 days, from 2.66±0.38 to 5.95±0.37 nmol/g tissue/min, then fell by 21% at 90 days. In many regions, the RLI:whole brain leucine incorporation ratio reached the adult value by 15 days of age. Although whole brain leucine incorporation paralleled glucose utilization during development, there was no correspondence between maturational time courses or adult values of LCGU and RLI.

The results demonstrate large and heterogeneous increases during maturation in indices of regional brain function and structure and indicate that rapid brain development continues until at least 45 days after birth in rats. Lack of correspondence between individual LCGU and RLI values suggests that they measure fundamentally different aspects of brain development.

ANOXIC TOLERANCE IN TURTLE BRAIN: LOWERED VULNERABILITY OR PREVENTION OF ENERGY FAILURE? C.P. Chih*, Z.C. Feng*, P.L. Lutz*, M. Rosenthal and T.J. Sick (SPON: R.E. Kelley). Div of BLR *RSMAS* and Dept of Neurology *Med Sch* Univ of Miami, Miami, Fl 33101

During prolonged anoxia, synaptic transmission is suppressed but ion transport activity is maintained in turtle brain. To determine whether ion homeostasis is maintained despite energy faiulre or by prevention of energy failure, high energy phosphates were measured in turtle brains subjected to anoxia and glycolytic inhibition (iodoacetic acid (IAA)). After 6 hours of anoxia, levels of ATP and extracellular K^+ were unchanged, although CrP was decreased by approximately 85% and lactate increased 9 fold. During simultaneous IAA superfusion and anoxia, ion homeostasis was lost in 1-2 hrs. Anoxic depolarization occurred when ATP was about 39% and CrP was about 25% of control. These results demonstrate that ion homeostais in turtle brain is maintained during anoxia only when ATP remains near control levels. The prolonged tolerance to brain anoxia in these animals appears due to mechanisms for avoiding energy failure rather than to lowered vulnerability to the consequences of energy failure. UREMIA PRODUCES DIALYSIS-REVERSIBLE DEPRESSION OF GENICULATE BUT NOT SUPERIOR COLLICULAR OR CORTICAL 2-DEOXY-D-GLUCOSE UPTAKE. LIPMAN JJ, LAWRENCE P*, SULSER D*, WHITE DL*, TOLCHARD S*, AND TESCHAN PE*, VANDERBILT UNIV., DEPT. OF NEPHROLOGY, NASHVILLE, TN., USA.

Acute renal failure in humans and rats engenders a uremic syndrome of progressively deranged serum chemistry and neurobehavioral deficits. There is reduced EEG power with increased visual evoked potential latency. It is believed that the syndrome is engendered by the neurotoxic action of a dialytically removable uremic solute. To survey the central metabolic correlates of the phenomenon, rats were surgically implanted with chronic EEG electrodes, a peritoneal dialysis (PD) catheter guide and a jugular catheter. Nephrectomised bilaterally (NX), these animals were assigned to the following treatments: (A) attrition, n=10, whose uremia was unrelieved; (TD) therapeutic dialysis, n=11, 8 exchanges per day; (PUD), n=7, dialyzed as above with a solution containing elevated uremic levels of phosphate, and; (C) control n=10, sham operated, undialyzed. We find that in animals sacrificed 48 hours after NX regional cerebral glucose uptake (rCGLU) of attrition animals is depressed in the geniculate nuclei but not in cortex or superior colliculi. This is correlated with reduced EEG power and is reversed, in TD animals, by dialysis. Addition of phosphate to the dialysate blocked the restorative effect of dialysis on rCGLU and the EEG implicating this solute in uremia's neurotoxic effect.

DEVELOPMENTAL CHANGES IN POSTSYNAPTIC NEURONS CAUSE LOSS OF A MONOSYNAPTIC REFLEX DURING METAMORPHOSIS IN MANDUCA SEXTA. J.C. Weeks and G.A. Jacobs. Dept. of Entomological Sciences, Univ. of California, Berkeley, CA 94720.

Manduca larvae exhibit a proleg withdrawal reflex mediated by direct synapses between proleg hair afferents and the proleg retractor motorneuron PPR. During the 4 d larval-pupal transformation ecdysteroid hormones cause PPR's dendritic arbor to regress substantially. Over the same time course the afferent-evoked excitation of PPR is severely attenuated; the compound EPSP evoked in PPR by a shock delivered to the sensory nerve is 70% smaller in pupae than in larvae. PPR's input resistance does not change significantly during this time. This decreased synaptic efficacy could be due to pre- and/or postsynaptic factors. The afferents change minimally during the larval-pupal transformation, suggesting that postsynaptic changes (e.g., PPR's regression) might be sufficient to cause loss of the reflex. This hypothesis was tested by using hormone treatments to generate heterochronic mosaic pupae which retained a larval proleg. In mosaic hemisegments the afferents remained in the larval state, while PPR regressed normally. The strength of the sensory-to-motorneuron pathway was attenuated to the same degree in mosaic hemisegments as in normal pupae. Thus, the loss of the withdrawal reflex appears due to developmental changes in postsynaptic rather than presynaptic neurons. DEVELOPMENTAL CHANGES IN PRE-ECDYSIS MOTOR PATTERNS OF THE MOTH, MANDUCA SEXTA. C.I. Miles and J.C. Weeks. Dept. of Entomol. Sci., Univ. of California, Berkeley, CA 94720.

Manduca exhibits a pre-ecdysis behavior just before ecdysis, when the old cuticle is shed at the end of a molt. Both pre-ecdysis and ecdysis behaviors are triggered by the peptide eclosion hormone (EH;1,2). Pre-ecdysis behavior consists of rhythmic compressions of the abdomen which are robust at molts between larval instars, but are no longer apparent at the larval-pupal molt. The only rhythmic movements at this time are weak dorsoventral flexions of the anteriormost abdominal segments. We have identified this behavior as a weakened version of larval pre-ecdysis by its timing, its dependence on EH, and the firing patterns of the motorneurons (MNs) which produce it. The strength of the motor pattern and the synaptic drive to pre-ecdysis MNs are greatly reduced at the larval-pupal molt. This is unlikely to be due to dendritic regression of the MNs, as they do not show significant structural changes at this time. Furthermore, the activity of these MNs during ecdysis, which immediately follows pre-ecdysis, is as robust as at larval molts. Thus, changes in the structure and/or functions of interneurons presynaptic to the pre-ecdysis MNs appear responsible for the weakening of this motor pattern at the larval-pupal molt. 1.Copenhaver & Truman '82, J. DESCENDING NEURONS RECEIVING COMMON SENSORY INPUTS DIVERGE FROM THE INSECT BRAIN TO FUNCTIONALLY DISTINCT MOTOR NEURON POOLS IN THORACIC GANGLIA. Nicholas J. Strausfeld and Jürgen J Milde. ARL Div. Neurobiol., Univ. of Arizona, Tucson, AZ 85721 and Dept. Zoology, Cologne University, Weyertal 112, D-5000 Cologne, FRG.

In *Calliphora*, intracellular fills reveal a variety of uniquely identifiable descending neurons (DNs), each distinguished by its characteristic dendritic morphology in the brain and by the morphology of its axon collaterals and terminals in segmental ganglia. Dendrites of specific DNs are structurally and functionally associated into clusters (DNCs: DN clusters), each forming the core of a discrete neuropil. A given DNC receives a characteristic set of primary mechanosensory afferents, terminals of visual interneurons, and interneurons derived from olfactory centers of the protocerebrum. In the brain, local and heterolateral interneurons appear to connect different DNCs in a fashion similar to interneurons linking groups of motor neuron dendrites in the thoracic ganglia. Although the same context-specific visual and mechanosensory stimuli can elicit responses from more than one member of a DNC, the axons of these neurons project to different targets. For example, axons from one known DNC diverge to functionally distinct groups of motor neurons belonging to the leg or the flight motor. Usually, however, the axon of any one DN gives rise to segmental collaterals which appear to invade motor neuron pools supplying segmentally homologous muscles. Examples are: branches to pro-, meso-, and metathoracic leg muscle motor neurons or branches to pro- and mesothoracic motor neurons supplying anterior dorsal neck muscles and direct flight muscles, respectively. **Supported by NIH Grant No. R01 EY07151-01**

MOTOR INNERVATION OF THE LOBSTER'S WALKING LEG MUSCLES. Theodore J. Wiens, Department of Zoology, University of Manitoba, Winnipeg, MB, Canada R3T 2N2.

The recent finding (Wiens, J. Neurobiol. 16, 183, 1985: Wiens and Rathmayer, J. Comp. Physiol. 156, 305, 1985) that the common inhibitor (CI) innervates all muscles in the walking legs of crabs and crayfish prompted a test of the same hypothesis for the much-studied Homarus americanus. Paired intracellular recordings were made from different combinations of muscles during stimulation of excitatory and inhibitory axons in various nerve branches of the leg. It was found that stimulation of CI in the efferent nerve entering the closer muscle can elicit IJP's in all nine muscles distal to the basipodite, as the hypothesis predicts (comp. Wiersma and Ripley, 1952) - but only if the leg nerve is intact distal to the coxa. Investigation of activation thresholds, IJP latencies, and effects of section suggested that CI splits into two branches in or proximal to the basipodite; one of these supplies the extensor, accessory flexor, bender, closer, and opener muscles in that order, and the other the reductor, flexor, stretcher, and rotator muscles. CI's two branches are thus disjoined in the autotomized leg. The rotator's only other efferent innervation comes from one of the flexor muscle's excitatory axons (comp. Sherman and Atwood, 1971). The opener receives a second inhibitory input from the well-described specific opener inhibitor (OI). These results resolve some questions about leg control and raise others.

I thank C.K. Govind for discussions and equipment loans.

CRAYFISH SWIMMING: DIFFERENT EMG PATTERNS IN ROSTRAL AND CAUDAL ABDOMINAL SEGMENTS. D.H.Paul and R.K.Pye* Biology Depart., University of Victoria, BC V8W 2Y2, Canada

Swimming (nongiant tailflipping) in crayfish relies on a central pattern generator (CPG) whose nature is poorly understood (Reichert et al.,1981). Previous analyses of emgs from swimming crayfish and squat lobster found no corelationbetween flexor burst latency (FBL) and extensor burst period (EBP) in rostral segments (S2-4), but S5 FBLs in squat lobster covary with EBPs (Wilson & Paul,1987). We have now found that also in crayfish S5 FBLs and EBPs covary while concurrent S3 FBLs vary inversely with EBPs (Fig). Preliminary results suggest that intersegmental coordination varies with frequency and that this arises from differences in timing of extensor bursts, flexor bursts being nearly synchronous in S3 and S5 at all frequencies.

Thus nongiant tailflipping motor patterns are similar in crayfish and squat lobster. The underlying CPG appears to be fundamentally different than CPGs for locomotion using limbs in which similar segmental motor patterns are produced by coupled segmental CPGs.

THE NEURAL BASIS OF LIGHT-EVOKED WALKING IN CRAYFISH. T.W. Simon and D.H. Edwards, Dept. of Biology, Georgia State University, Atlanta, GA 30303

The backward walking response of crayfish to illumination of the Caudal Photoreceptor neurons (CPRs) in the 6th abdominal ganglion persists in restrained upside down animals. Leg movements in this position were sufficient to turn a walking wheel, and the responses appeared qualitatively similar to those in the same free-moving animals when ventrally illuminated. A cyclic response of Tonic Flexor (TF) motoneurons associated with backward walking (Kovac, 1974a,b; Moore & Larimer, 1987) commenced simultaneously with leg movements.

High frequency activity in a single CPR, similar to its light response, excited cells in the abdominal nerve cord which are part of a pattern initiating (PI) network for the TF response. When stimulated, some of these neurons could evoke a portion of the cyclic motor pattern; however, none were sufficient to elicit the entire TF response.

Interneuron A64 (Wine & Krasne, 1982), an identified mechanosensory interneuron, is also excited during the backward walking response. A64 is excited by unknown cells in the rostral portion of the abdominal nerve cord. It can excite TF motoneurons and may contribute to their excitation during the walking response.

In addition, swimmeret motoneurons and some hitherto unidentified cells which may contribute to extensor activation were excited as part of the walking response.

Both walking and the TF response to 6th ganglionic illumination persist following ligation of both circumesophageal connectives, and we are attempting to localize where the CPRs provide input to neurons which initiate walking.

400.7

EXCITATION AND INHIBITION OF THE CRAYFISH SWIMMERET RHYTHM BY STIMULATION OF SECOND NERVES OF THORACIC GANGLIA. A.Chrachri* (SPON: H.Anderson) Dept. of Zoology, Univ. California at Davis, Davis CA 95616.

In the crayfish, *Pacifastacus leniusculus,* the swimmeret motor pattern is strongly modified by tonic stimulation of the second nerves of each thoracic ganglion. Stimulation of these nerves at low intensity provokes a long-lasting activation of the swimmeret motor output. This stimulation increases the frequency of spikes of certain motor neurones within bursts in the swimmeret motor pattern, and also increases the amplitude of their membrane potential oscillation. At high intensity of stimulation of these same nerves inhibits the swimmeret rhythm. This inhibition is partially blocked by phentolamine, a competitive blocker of octopaminergic inhibition in the swimmeret system.

Blocking chemical synapses in these thoracic ganglia with low Ca^{++}- high Mg^{++} saline does not block these effects of second nerves stimulation, and Co^{++} backfills of thoracic second nerves reveal neurons in abdominal ganglion 1. Therefore, I suggest that these effects involve cell(s) which are located in ganglion 1, and that they act via pathways within the CNS, not via the blood. From the duration of their effects, these neurons might act through a modulatory process.

CRAYFISH "BACKWARD WALKING" NEURONS INHIBIT LG COMMAND NEURON

D.H. Edwards, T.W. Simon, E.M. Leise & R.A. Fricke, Dept. of Biology, Georgia State University, Atlanta GA 30303

Tonic stimulation of individual neurons in the ventral lateral margin (VLM) of the crayfish abdominal nerve cord evokes a long-lasting discharge of abdominal tonic flexor (TF) motoneurons that is part of a backward walking response (Kovac, 1974; Moore & Larimer, 1987). We have found that stimulation of single VLM neurons, including A64, inhibits the LG command neurons for tailflip while they excite the TFs.

The VLM neurons inhibit LG by tonically depolarizing it. LG EPSPs evoked by sensory root stimulation are reduced in proportion to the level of LG tonic depolarization. LG EPSPs evoked by A64 are also reduced during the tonic depolarizing phase of the LG EPSP evoked by sensory root shock. Since many of the synapses onto LG are electrical, it is likely that LG inhibition results from the postsynaptic depolarization itself, perhaps by increasing LG membrane conductance or by back-biasing rectifying electrical synapses onto LG.

A64 produces a phasic burst followed by an 80 ms, high frequency (up to 300 Hz) spike train in response to phasic stimulation of the abdomen (Zucker, 1972). The phasic burst helps excite LG through monosynaptic electrical synapses. Our results suggest that the tonic phase of the response acts to inhibit LG by tonically depolarizing it. LG EPSPs from additional inputs would be reduced during this period, which coincides with recovery from the initial tailflip.

THORACIC OUTPUT OF CRAYFISH GIANT COMMAND NEURONES. W.J. Heitler and K. Fraser*. Gatty Marine Lab, Univ. St. Andrews, Scotland, KY16 8LB.

The crayfish escape tail-flip is initiated by 2 sets of giant command interneurones, MG and LG. The abdominal circuitry driven by these neurones has been extensively studied, but little is known about their thoracic output. We describe the anatomy and physiology of three identified segmental neurones in the 4th and 5th thoracic ganglia which receive direct input from the giant neurones.

1. Leg Promotor Motorneurone. This is driven 1:1 by the MG through a rectifying electrical synapse. It has powerful excitatory neuromuscular output, which shows initial massive antifacilitation, followed by slow facilitation. This is very similar to the output of the abdominal motor giant neurone.
2. Segmental Giant Neurone. This is driven 1:1 by the LG (TG5) and LG and MG (TG4) through rectifying electrical synapses. Its axon terminates close to the ganglion in numerous fine branches, which are located entirely within the nerve root. The SG drives fast flexor motorneurones of the trunk musculature.
3. Motor Giant Neurone. This is driven 1:1 by the LG through a rectifying electrical synapse.

All three neurones receive depolarizing IPSPs which can inhibit their input from the giant neurones.

The significance of these neurones will be discussed in relation to the possible evolution of the escape from a limb-driven to a trunk-driven behaviour.

ACTIVITY OF ABDOMINAL POSITIONING INTERNEURONS IS ALTERED BY TACTILE STIMULATION OF THE LOBSTER SWIMMERET. V.C. Kotak* and C.H. Page, Nelson Biol. Labs, Rutgers Univ., Piscataway, N.J. 08854.

We recently reported that mechanosensory stimulation of a swimmeret in lobster produces tonic abdominal extension (J.Comp.Physiol.158:225,161:695;J.Neurobiol.17:421). This includes excitation of the flexor inhibitor f5 and extensor excitor motoneurons and suppression of the extensor inhibitor e5 and the flexor excitor motoneurons. The present work characterizes interneurons that both drive (or inhibit) postural motoneurons and receive inputs from swimmeret mechanoreceptors. Flexion producing interneurons (FPIs) when current injected excited the flexor excitor motoneurons. Their activity was inhibited by mechanostimulation of feathered hairs, smooth hairs and integumentary receptors in the swimmeret, suggesting that FPI suppression by swimmeret inputs contributes in generating flexion inhibition/extension activity. However, since afferents are never inhibitory, the neural circuit for such responses must include at least one layer of interneurons between the afferents and FPIs. Extension producing (EPIs) when depolarized by current injection drive f5 and inhibit the flexor excitors. Since there was no 1:1 phase relationship between interneuronal and motoneuron responses to mechanostimulation of the swimmeret, a multisynaptic pathway between swimmeret afferents and tonic motoneurons must exist.

400.11

CHOLINERGIC / SEROTONERGIC SENSORY NEURONS HAVE BOTH CLASSICAL AND MODULATORY SYNAPTIC EFFECTS ON NEURONS IN THE CRAB STOMATOGASTRIC GANGLION. P.S. Katz, M.H. Eigg*, and R.M. Harris-Warrick. Section of Neurobiology and Behavior, Cornell University, Ithaca, N.Y. 14853.

We have found a proprioceptive cell type in the stomatogastric nervous system of the crab, *Cancer borealis*, that not only provides fast synaptic input, but also has longer lasting modulatory effects on the bursting properties of central pattern generator neurons. We previously reported the existence of the GPR cells, a set of 4 muscle receptor cells in the gastro-pyloric region of the crab stomach (Katz and Harris-Warrick, Soc. Neurosci. Abstr. 13:821, 1987; 12:1207, 1986). These cells contain serotonin as determined by immunohistochemical staining and HPLC (Beltz et al., J.Exp.Biol., 109:35, 1984). We now show that they also have choline acetyltransferase activity, suggesting that serotonin and acetylcholine are cotransmitters in these cells. The GPR cells produce a variety of rapid synaptic effects in different stomatogastric neurons, including EPSPs of different time courses that are pharmocologically blocked by nicotinic antagonists. In addition, GPR activation causes prolonged modulatory effects in specific neurons, such as the induction of bursting and plateau potentials. These effects accumulate with repetition, and can outlast the duration of the stimulation by more than a minute. The GPR cells thus provide more than just a cycle-by-cycle correction of the motor output. Our results suggest that by altering the physiological state of some of the component neurons for extended periods of time, sensory input to central pattern generators can play a modulatory and instructive role.

INTERGANGLIONIC MOTOR ACTIVATION FROM THORACIC INTERNEURONS IN THE vGI SYSTEM OF THE COCKROACH. A.J. Pollack* and R.E. Ritzmann, Dept. of Biology, Case Western Reserve Univ., Cleveland, OH 44106.

The wind-mediated escape response of the cockroach Periplaneta americana has been studied as an example of a multi-element neural circuit capable of producing a complex behavior--a directed turn and run away from a wind source. Among the elements that have been studied are several metathoracic (T_3) interneurons which receive directional wind information from ventral giant interneurons (vGIs) and activate leg motor neurons in their ganglion of origin, T_3 (Pollack and Ritzmann, 1986). Other T_3 interneurons receive vGI inputs but do not excite leg motor neurons.

A large proportion of these interneurons send projections anteriorly to the mesothoracic ganglion (T_2) and beyond. Since the escape behavior involves coordinated movements among six multi-segmented legs, it is possible that intergangliónic projections exert control over motor outputs in other thoracic ganglia. We are examining this possibilty by observing motor outputs of both T_3 and T_2 simultaneously while stimulating a T_3 interneuron intracellularly.

Initial results suggest that interganglionic T_3 interneurons that produce motor outputs in T_3 also excite motor neurons in T_2. In some cases homologous motor neurons were excited in both ganglia, while in others motor neurons that are normally active in opposite phases of walking were excited in the two ganglia. T_3 interneurons that do not excite T_3 motor neurons also fail to excite T_2 motor neurons. We are continuing to characterize the T_3 and T_2 motor outputs as a result of T_3 interneuron stimulation in an attempt to further define this system and consolidate previous data which implicate specific T_3 interneurons as directional elements in the wind-mediated escape.

INTERSEGMENTAL INTERNEURONES CONTROL THE GAIN OF LOCAL REFLEXES IN THE LOCUST. G. Laurent* and M. Burrows, Dept. of Zoology, University of Cambridge, CB2 3EJ England.

Intersegmental interneurones in a mesothoracic population receive mechanosensory inputs from a middle leg (Laurent, G. 1987 J. Neurosci. 7:2977-2989). They project ipsilaterally to the metathoracic ganglion where they make output connections (87% excitatory, 13% inhibitory) with premotor nonspiking local interneurones and with motor neurones controlling the movements of the ipsilateral hind leg. Metathoracic nonspiking local interneurones thus have receptive fields on both the ipsilateral hind and middle legs, the latter resulting from convergent excitatory and/or inhibitory inputs from several mesothoracic intersegmental interneurones. These nonspiking interneurones can gate or modulate metathoracic local reflexes when their membrane potential is manipulated experimentally. The inputs they receive from the intersegmental interneurones can have similar effects, implying that the gain of a metathoracic local reflex can be changed in accordance with information from the middle leg.

TEMPERATURE EFFECTS ON SPONTANEOUS NEURAL ACTIVITY IN THE DRAGONFLY.
M. Kliss* and L. S. Stodieck. Aerospace Engineering Sciences, University of Colorado, Boulder, Colorado 80309.

Insects have often been represented as ideal poikilotherms, yet they are able to survive and function over a wide range of temperatures. It has generally been assumed that changes in behavior from temperature effects are related to changes that occur in neural processes. Previous investigations have shown that changes in temperature affect the conduction velocities of nerve fibers, as well as the afferent patterns of activity that arise in higher centers. The way in which the output of the nervous system compensates for these temperature induced changes in input, however, is not well understood. The present work focuses on the effects that ganglion temperature has on the neural activity in the dragonfly. Spontaneous extracellular recordings in the mesothoracic ganglion were obtained from both individual cells and groups of cells over a range of approximately 25 C. Spike frequency and spike slope were characterized for individual large cells. Interspike invertal histograms were obtained as a measure of total neural activity. Results indicated alterations in large cell spike frequency and slope as a function of temperature change. Changes in small cell activity were not as pronounced. Notably, the overall pattern of total neural activity remained relatively constant. The possible significance that temperature induced changes in spike slope may have on regulating neural output is discussed.

400.15

A BIOMECHANICAL ANALYSIS OF THE HEAD WAVING RESPONSE IN *APLYSIA* F. M. Kuenzi* and T. J. Carew. Dept. of Biology, Yale Univ., New Haven, CT 06520.

The head waving response (HWR) in *Aplysia* is a complex behavior that can be modified by operant conditioning (Cook and Carew, 1984, 1987). An analysis of the HWR and its plasticity requires an understanding of how the response is mechanically produced.

The *Aplysia* body is a soft, constant-volume cylinder, consisting of a muscular body wall enclosing a fluid filled space (hemocoel). Thus biomechanically, movement can be produced either by: 1) simple contraction and relaxation of appropriate muscles, or 2) contraction coupled with modulation of hydrostatic pressure. We investigated the invlovement of hydrostatic mechanisms in freely moving animals by cannulating their hemocoel and monitoring pressure with a solid state transducer. The basal pressure of resting animals was 1-2 cm of water. Three types of responses were measured: 1) Cyclic elevations and depressions of the head (in a locomotor rhythm) were associated with cyclic increases and decreases in pressure, respectively. 2) A variety of withdrawal reflexes were also all associated with clear pressure changes. 3) However, the HWR was *not* associated with any significant pressure change, and thus was due to muscle activity alone.

We next carried out a morphological analysis of the neck body wall musculature. We found muscle fiber bundles oriented longitudinally, circularly, and obliquely in three layers distinguishable by their connective tissue content and their fiber number. Having identified these muscle groups, it will now be possible to establish the innervation patterns of identified pedal motor neurons to assess their contribution both to the HWR and its modification by learning.

MODULATION OF APLYSIA RENAL PORE ACTIVITY BY L10, THE LUQ CELLS AND AN IDENTIFIED PERIPHERAL MOTONEURON.
J. Koester. Center for Neurobiology & Behavior, NY State Psychiatric Institute, and Columbia University, New York, NY 10032

Renal excretion in *Aplysia* begins with the filtration of blood across the wall of the heart. This ultrafiltrate is swept from the pericardium into the renal sac through a cilia-lined renal pericardial pore. Within the renal sac the fluid is elaborated into urine by excretion and absorption across the epithelium of the renal sac. The urine leaves the renal sac via the muscular renal pore near the posterior base of the gill.

Neuron L10, which is located in the abdominal ganglion, increases heart rate by exciting heart excitor cell RB-HE, so it may increase the rate of renal filtration. L10 also sends its major axon to the kidney. We previously showed that L10 excites the radial (opener) muscle of the pore and inhibits the circular (closer) muscle. When L10 fires, the opener muscle fibers generate synchronous twitches that do not follow the L10 spikes 1:1. Each time a twitch is generated, four events can be discriminated in an extracellular recording from the pore, in the following sequence: (1) L10's axon spike, (2) the muscle junction potential due to L10's direct connection, (3) a small action potential, which is attributed to a peripheral motoneuron, and (4) a large muscle action potential. Events (1) and (2) occur every time that L10 fires. Events (3) and (4) occur only when a twitch is generated, and they always occur together. I have localized event (3) to a single peripheral motoneuron that is embedded in the left side of the renal pore. Dye injection shows that this bipolar peripheral neuron, called the RP cell, sends processes completely around the circumference of the pore, presumably to mediate excitation of the radial muscle of the pore. Intracellular recording shows that the RP cell receives large EPSPs from L10 that must summate before an action potential is generated.

The peptidergic LUQ cells, L2-L6, are also located in the abdominal ganglion. We have previously shown that a subset of these cells inhibit the twitches that occur during pore opening. I have found that they also block events (3) and (4). Current work addresses the issue of whether the the inhibition of the RP cell by the LUQs is pre- or post-synaptic in origin. The RP cell provides a good vantage point from which to study the interaction of the central and peripheral nervous systems of *Aplysia*. (Supported by NIH grant NS14385).

PERIPHERAL ORGANIZATION OF THE SWIMMING SYSTEM IN A PTEROPOD MOLLUSC. R.A. Satterlie. Department of Zoology, Arizona State University, Tempe, AZ 85287-1501.

Locomotory structures in the pteropod mollusc Clione limacina include a pair of wing-like parapodia. Dorsal and ventral bending of the wings is accomplished by activation of four sheets of oblique muscle bundles, two associated with dorsal wing movement, and two with ventral wing movement. Wing muscle cells are simple, spindle-shaped cells up to 1.3mm in length and 30μm in diameter.

Intracellular recordings from muscle cells during swimming activity show graded junctional potentials and overshooting spike-like responses. Inhibitory junctional potentials have not been observed. Neuromuscular contacts are monosynaptic, and evidence for a peripheral motor nerve net is lacking. No difference has been noted in the electrical activity of slow-twitch and fast-twitch muscle cells.

Serotonin-like immunoreactive varicosities and processes have been found throughout the swimming muscle bundles. Since serotonin can trigger fast swimming in Clione, its role as a peripheral neuromodulator is being investigated.

ORGANIC AND INORGANIC CA++ CHANNEL BLOCKERS SHOW DIFFERENTIAL BLOCK OF PRAZIQUANTEL INDUCED MUSCLE CONTRACTION IN SCHISTOSOMA MANSONI . K. L. Blair*, J. L.Bennett* and R. A. Pax. Zoology, MSU, E.Lansing MI 48824.

Praziquantel (PZ) caused a rapid, sustained dose dependent contraction with an EC_{50} of 120 nM and a maximal effective dose (MED) of 1 uM. The Ca^{++} channel blockers nicardipine, Mg^{++}, and Cd^{++} shifted the PZ dose response curve to the left. Carbachol shifted PZ's ED_{50} up to 420 nM but did not affect the MED.

Nicardipine (10 uM) split the response into two phases, a fast transient component and a slower developing but sustained contraction. Mg^{++} blocked the sustained component while Cd^{++} blocked the transient component. When Mg^{++} and Cd^{++} were applied together, the entire contraction could be blocked.

These results are consistent with the hypothesis that PZ is a Ca^{++} channel activator. Carbachol appears to allosterically modulate the PZ activation. The differential effects of the three blockers indicates that more than one population of channel may be involved in the PZ induced contraction.

POSTNATAL GROWTH OF ALPHA- AND GAMMA-MOTONEURONS INNERVATING THE MEDIAL GASTROCNEMIUS MUSCLE OF THE CAT. He F.*, R.D. Guthrie* and W.E. Cameron. Depts. of Neurobiology, Anatomy and Cell Science and Pediatrics, Univ. of Pittsburgh Sch.of Med., Pittsburgh, PA 15261.

Medial gastrocnemius (MG) motoneurons were retrogradely labeled with horseradish peroxidase (HRP) following soak of the muscle nerve in cats of various ages. Lumbosacral spinal cord was sectioned horizontally and reacted with tetramethyl benzidine. The cell bodies and proximal dendrites of heavily labeled motoneurons were reconstructed.

	Ave. diam.		Surf. area		Volume	
Age	alpha	gamma	alpha	gamma	alpha	gamma
3 day	27.4	20.1	2047	1112	8433	3410
1 month	35.5	23.4	3383	1465	17829	5074
2 month	39.1	24.6	4082	1616	24012	5946
Adult	50.8	29.7	6937	2338	52326	10342

All values are means, N=250 for alpha; N=150 for gamma

The most rapid period of growth in both alpha and gamma motoneurons is between birth and 1 month of age. The rate of growth of the alpha-motoneurons was consistently greater than that of the gamma-motoneurons.

Supported by NIH grant HD22703.

MOVEMENT PATTERNS AND CYCLICITY OF NEWBORN RATS. C.R. Almli, J. Miller*, I. Orup* and R. Galiano*. Lab. Develop. Neuropsychobiol., Washington Univ. Sch. Med., St. Louis, MO 63110.

Research on early neurobehavioral development of movement (motility) patterns has revealed the existence of "cyclic," spontaneous movement patterns in a variety of species. Cyclic, spontaneous movement patterns have been described prior to birth or hatching, and after birth, and range in frequency from 1-3 minutes per cycle. However, there are questions concerning the locus of neural (brain and/or spinal cord) regulation of the cyclicity, and questions regarding the degree to which the movements themselves are "random" or "organized (functional precursors)." The present study used newborn rats and a computerized movement analysis system to quantify 12 characteristics of spontaneous movement (e.g., mouth, head, limbs, trunk, posture change, ambulation). The first spontaneous movements of the newborn rat were found to share a common cycle frequency (range: 0.5-1.0 cycles/min) for all body segments measured, suggesting a "cyclicity" generator in the brain and spinal cord. However, preliminary spinal transection data indicate a brain cyclicity generator, based on the loss of movement cyclicity caudal to the transection in newborn rats. The overall results also suggest that the spontaneous movements of newborn rats may be organized, and not random as previously thought. (NIH Animal Care Guidelines followed.)

PYRAMIDAL TRACT AXONS ARE INCREASED BY PRENATAL EXPOSURE TO ETHANOL. S. Al-Rabiai* and M.W. Miller (SPON: A. Gona). Dept. of Anatomy, Sch. of Osteopathic Med. and R.W. Johnson Med. Sch., UMDNJ, Piscataway, NJ 08854.

Rats prenatally exposed to ethanol have more corticospinal projection neurons than controls (Miller, J.C.N. 257:372, 1987), hence, we examined the number of pyramidal tract axons in Et-treated rats. Pregnant rats were fed a liquid ethanol-containing diet (Et), an isocaloric liquid control diet (Ct), or a diet of chow and water (Ch). On postnatal day 30, the offspring of these rats were sacrificed and their pyramidal tracts were processed for electron microscopy. 34% of the pyramidal tract axons in each group was myelinated. The axons were smaller and the myelin was thinner in Et-treated rats than in controls. The density of myelinated and non-myelinated axons was similar among the dietary groups, however, the overall size of the pyramidal tract was 10% smaller in Et-treated rats. Thus, the estimated number of axons in the pyramidal tracts of Ch- ($3.77x10^5$) and Ct-treated rats ($3.80x10^5$) was significantly greater than that of Et-treated rats ($3.18x10^5$). Nevertheless, because the brains of Et-treated rats are microcephalic this 15% decrease in absolute numbers is, in fact, a relative increase; other data show that layer V of Et-treated rats has 29% fewer neurons than that of Ct-treated rats (Potempa & Miller, this meeting). Thus, the ethanol-induced increase in the number of corticospinal projection neurons is matched by an increase in the number of pyramidal tract axons. Funded by AA06916 and DE07734.

401.4

INTRACELLULAR STUDY OF CORTICOSPINAL PROJECTION NEURONS IN RATS PRENATALLY EXPOSED TO ETHANOL. M.W. Miller, L. Klem*, N.L. Chiaia, and R.W. Rhoades. Department of Anatomy, School of Osteopathic Medicine and Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ 08854.

The effects of prenatal exposure on the structure and function of corticospinal projection neurons in mature somatosensory cortex was examined. Recordings were made in the 3 mo. old offspring of rats fed a liquid ethanol-containing diet (Et), an isocaloric liquid control diet (Ct), or chow and water (Ch). Corticospinal neurons were identified as cortical neurons antidromically driven by a stimulating electrode placed in the pyramidal decussation. Individual corticospinal neurons were injected intracellularly with horseradish peroxidase (HRP). Rats were sacrificed and the tissue was processed by standard HRP histochemical techniques. All intracellularly labeled neurons were pyramidal neurons. In Ct- and Ch-treated rats, the cell bodies of these neurons were distributed in layer V. In Et-treated rats, however, corticospinal neurons were distributed in layers II/III and VI as well as layer V. Sholl analyses of the basal dendrites of the corticospinal neurons in layer V showed that dendritic trees were significantly ($p<0.01$) more complex and more extensive in Et-treated rats than in controls. The conduction latency was significantly ($p<0.05$) shorter in Et-treated rats than in controls. These results show that prenatal exposure to ethanol has lasting effects upon the structure and function of cortical neurons. Funded by AA06916 and DE07734.

TRANSPLANTS ALTER THE DEVELOPMENT OF SENSORIMOTOR FUNCTION AFTER NEONATAL SPINAL CORD DAMAGE E. Kunkel-Bagden and B.S. Bregman Dept. Anat., Univ. MD. Sch. of Med., Balt. MD 21201

The aim of the current study was to determine if transplants (TP) of fetal spinal cord tissue alter the development of sensorimotor function after spinal cord injury at birth. Rat pups (2dpn) were hemisected (HX) at T6 (N=10). In one-half of the animals a TP of fetal (E14) spinal cord was placed into the lesion site (HX+TP, N=5). Postural reflexes were tested daily in lesioned (HX, HX+TP) and in unlesioned control (CON) rats from birth until 4 weeks of age. Posture and locomotion were observed, recorded on videotape and analyzed. The ability of the animals to right, climb onto a platform, and place in response to contact (CP), proprioceptive, and vestibular (VP) stimuli were assessed qualitatively and quantitatively. The posture, particularly hindlimb (HL) weight support and rotation, and the pattern of HL movement during locomotion was impaired in the HX group. In contrast, in the HX+TP animals these characteristics were similar to the controls. HX delayed the onset and maturation of the the postural reflexes that were immature at birth (righting, VP, CP). The presence of the TP prevented this lesion induced delay in the development of each of these, for example, righting: CON=6dpn, HX+TP=7dpn, and HX=10dpn. Transplants shift the timecourse of development of sensorimotor function toward normal. We suggest that this behavioral alteration is due to to the anatomical plasticity elicited by the transplant. Supported by NIH grant NS19259.

REFLEX PHYSIOLOGY AND CORRELATED MOTOR PERFORMANCE IN RATS WITH MILD CONTUSION SPINAL CORD INJURY.
F.J. Thompson, P.J. Reier, G.W. Schrimsher*, L.B. Jakeman, D.L. Winialski*, & C. Lucas. Dept of Neuroscience, University of Florida, Gainesville, Fl. 32610.

Our studies were aimed at examining neurophysiological parameters associated with spinal cord injury-related motor impairment in a rat model which previously has been characterized by correlative indices of behavior and anatomy.

Contusive injuries were produced using a modification of the Allen weight drop method and motor performance was quantified by the combined behavioral scoring (CBS) method of Wrathall and coworkers. Spinal reflex excitability was tested utilizing individually recorded H-reflexes. The extent of the spinal lesions was quantified by histological analysis. At one week post-injury we have observed that animals exhibited mean CBS scores of 74.0 (s.d.=22.0; n=5). Reflex amplitudes were not significantly different from controls (H/M ratio: 39.8, s.d.=13.6; n=6 compared to 48.4, s.d.=15.6, n=8). However, the sensory input required to achieve maximal reflex amplitudes in the injured animals was significantly less than in the normal animals. In addition, recovery curves of muscle and skin afferent-elicited reflexes suggested that presynaptic inhibitory depression of reflexes in the injured animals was significantly reduced compared to intact controls.

These studies suggest that motor impairment occurring within one week after contusion-injury of the rat spinal cord is most closely correlated with interactions that depend upon interneuron-mediated changes in primary afferent and motoneuron excitability. (Supported by NINCDS #NO1-NS-7-2300).

ACTIVITY OF CORTICAL NEURONS WITH TRANSIENT COLLATERAL PROJECTIONS TO THE CEREBELLUM. D.L. Tolbert, Dept. of Anat. and Neurobiol. and Surgery (Neurosurgery), St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

The stabilization or elimination of connections in the developing brain is correlated with impulse activity in converging afferents. Pathways which are normally eliminated will persist if activity in competing afferents is silenced. The transient collateral projection from the cerebral cortex to the cerebellum in neonatal cats was studied using electrophysiological techniques. Seven to 21 day-old kittens were anesthetized with alpha-chloralose and stimulating electrodes were positioned in the cerebellum (CB), pyramidal tract (PT) and medial lemniscus. Single unit recordings were made from the primary somatosensory cortex. Units with projections in the PT or CB or with collaterals in both structures (PT-CB) were identified by their antidromic activation. PT and/or CB projection neurons were not spontaneously active but fired only in response to antidromic activation. The projection neurons were capable of following relatively high frequency antidromic activation. Some units superficial to layer V projection neurons fired spontaneously and many were activated by cutaneous stimulation. Numerous units were synaptically activated following stimulation of the medial lemniscus but could not follow stimulus frequencies >1-2 Hz. The absence of activity in PT-CB projection neurons may contribute to the elimination of the collateral projection to the cerebellum. Support: NIH Grant NS20227.

Effect of Inferior Olive Lesion on Strychnine Seizure and Cerebellar [3H]AMPA Binding, M.C. Anderson*, E. Chung and M.H. Van Woert, Graduate Program in Neurobiology, Mt. Sinai School of Medicine, New York, NY 10029

Bilateral inferior olive (IO) lesions produce a proconvulsant state specific for strychnine-induced seizure and myoclonus in rats. Glutamate antagonists, glutamate diethylester (GDEE) and MK-801, both reversed IO lesion-induced leftward shift in the strychnine seizure dose-response curve. GDEE also inhibited strychnine-induced myoclonus in IO lesioned rats, while MK-801 had no effect on strychnine myoclonus. GDEE and MK-801 had no effect on strychnine-induced seizures and myoclonus in control rats.IO lesions produced a 30% increase in quisqualate (QA) displacable [3H]AMPA binding sites in cerebellar membranes. There was no difference in [3H]AMPA binding displacable by glutamate, kainate or GDEE. THe increase in QA sensitive [3H]AMPA sites may mediate the IO lesion induced proconvulsant state specific for strychnine-induced seizures and myoclonus. THis conclusion is consistent with the observation that QA antagonist pretreatment restored the threshold for both strychnine-induced seizure in IO lesioned rats to the control level, as well as significantly reducing strychnine myoclonus.

THE MATURATION OF AFFERENT PROJECTIONS TO THE RAT CEREBELLAR NUCLEI. Claude Gravel (a), Nicole Leclerc (a), Len Eisenman (b), and Richard Hawkes (a): a) Department of biochemistry and Laboratory of Neurobiology, Laval University, Quebec, PQ, Canada b) Department of Anatomy, Thomas Jefferson University, Philadelphia PA.

The corticonuclear projection in mammals is organized in the form of parasagittal bands of Purkinje (P) cells with discrete terminal fields in the deep cerebellar nuclei (DCN) and lateral verstibular nuclei. This organization can be revealed by using the monoclonal antibody anti-zebrin I (mabQ113). The olivocerebellar projection (OCP) is superimposed on this with cell clusters in the inferior olive contacting both specific P cell bands and cells in the deep nuclear target fields in the DCN and lateral vestibular nuclei. The different terminal fields in the DCN are already differentiated by birth, prior to the arrival of afferents from the Purkinje cells.

Anti-zebrin I has been used to study the maturation of the corticonuclear projection. The input matures surprisingly late: at P10 there are very few identifiable P cell terminals in the DCN. Instead, the P cell axons swirl around the periphery of the target fields, apparently unable to enter. Identifiable P cell terminals are only common from P14 onwards. Interestingly, anterograde tracer studies of the olivocerebellar projection reveals a very similar organization, with the climbing fiber axons intermeshed with the CNP at the periphery of the DCN.

This suggests two possible models by which the OCP can contact both its correct P cell band, and its correct nuclear target field. Either, both the OCP and the projection from a Purkinje cell compartment converge upon a common target territory in the DCN, and then the OCP fasciculates on P cell axons and follows them to the cortex (DCN specified), or the OCP recognizes a subset of P cell axons and birfurcates to the DCN in one direction and the cortex in the other (P cell specified).

LOCOMOTOR ACTIVITY EVOKED BY BRAINSTEM STIMULATION OF EMBRYONIC CHICK *IN OVO*. J.I. Valenzuela*, D.W. Ethell* & J.D. Steeves. Depts. Zoology & Anatomy, UBC, Vancouver, B.C., V6T 2A9

After thoracic spinal cord transection, as late as embryonic day 11 (E11), anatomical studies have provided evidence for axonal repair of brainstem-spinal projections (Nelson & Steeves, 1987, Soc. Neurosci. Abstr. **13**:972). To assess whether this axonal repair is also indicative of synaptic connectivity and functional recovery, *in ovo* techniques for focal electrical stimulation of brainstem locomotor regions in the decerebrate embryonic chick have been developed. After saturation of the amnionic fluid with Halothane anesthesia, each E18-20 chick embryo was mounted in a stereotaxic head holder and subsequently decerebrated. Leg muscle electromyographic recordings were used to monitor any evoked locomotor activity. Monopolar electrical stimulation (40-80 uA) of the caudal reticular formation, in control E18-20 embryos, evoked alternating and synchronous leg movements, characteristic of stepping and hatching motor programs, respectively. Using identical stimulation procedures, similar motor patterns were evoked in E18-20 embryos, that had their thoracic spinal cords previously transected on E6-11. (supported by MRC, Canada)

HINDLIMB MUSCLE SYNERGIES IN SPINAL TRANSECTED CHICK EMBRYOS. N.S. Bradley and A. Bekoff, Dept. EPO Biology, University of Colorado, Boulder, CO 80309.

Previously, we examined hindlimb muscle activity in intact chick embryos at 9-10 days (Bradley, N.S. & A. Bekoff, *Neurosci Abstr.* 13:1504, 1987). We now compare corresponding activity in spinal transected embryos to assess the role of descending neural input in the development of spinal networks for spontaneous motility.

White Leghorn embryos received low thoracic transections at day 3, and on day 10, 4-channel EMG recordings were obtained from one ankle extensor/flexor pair and one hip extensor/flexor pair during spontaneous motility *in ovo*. To characterize EMG records, cycle periods and burst durations were measured for all muscles, and burst onset latencies were referenced to the ankle extensor cycle period.

Similar to findings in intact embryos, motility is characterized by cyclic bursts in one or more muscles, and there are no differences in cycle period or burst durations across muscles. When two or more muscles are active, synergist pairs (*e.g.*, ankle and hip extensors) are coactive and extensor/flexor pairs are reciprocally active. While burst onsets for synergist pairs are closely related, burst durations are not closely related to either their own cycle period or the ankle extensor cycle period, but are closely related to ankle extensor burst duration. Further, and in contrast to intact embryos, burst durations for synergist pairs are closely related to each other. Also, spinal embryos typically exhibit shorter cycle periods and more cycles/episode than intact embryos.

These findings suggest that while muscle synergies for embryonic motility develop in the absence of descending input, some temporal elements are altered. Supported by NIH grant 20310.

401.12

ISOPYCNIC CENTRIFUGATION EMPLOYING PERCOLL STEP GRADIENTS FOR THE SEPARATION OF MOUSE FETAL MOTOR NEURONS FROM SPINAL CORD HOMOGENATES. M.J.Strong*, R.M. Garruto* and D.C. Gajdusek. Lab. of Central Nerv. System Studies, Natl. Inst. Health, Bethesda, MD 20892

We have developed a technique employing the principles of isopycnic centrifugation for the rapid isolation of a choline acetyltransferase (CAT) enriched cell fraction from fetal mouse spinal cord homogenates for studies of neurofilament catabolism in motor neurons.

Pooled spinal cords of fetal NIH:Or mice aged day 12-14 are dissociated, the suspension layered onto discontinuous Percoll step gradients (densities 1.040, 1.050, 1.060) formed in polycarbonate tubes, and centrifuged at 800 rpm x 15 min at 4°C in a Sorval swing-out rotor. The distinct cell populations collected at each interface can be directly plated without a wash step, enhancing cell yields and viability (85-95%). Data will be presented to demonstrate the concentration of CAT activity in the first interface. These cells, grown on a combined gelatin-polylysine-laminin substrate in serum-free medium over muscle, rapidly adhere and extend processes, producing large (30-70 µm), predominantly unipolar neurons with the morphological features of motor neurons. The second, CAT-poor fraction, yields nerve growth factor-sensitive, small (10-25 µm), multipolar neurons which are neither laminin or muscle dependant for survival. The final interface yields a mixed population of predominantly nonneuronal cells as demonstrated by immunohistology.

401.13

A MORPHOLOGICAL COMPARISON OF CHOLINERGIC NEURONS IN MOUSE SPINAL EXPLANT CULTURES WITH THOSE OF SPINAL TISSUE TAKEN FROM INTACT ANIMALS OF THE SAME LITTER. M. S. Pidnerney, D.L. Gonzalez, M.H. Droge, Dept. of Biology, Texas Woman's Univ., Denton, TX 76204.

Our objective is to use long-term explant cultures of spinal tissue to establish a model system for investigating the cellular/network mechanisms of motor pattern generation in mammals. Experiments are being conducted on tissue explant cultures and on tissue taken from intact animals to determine how closely the explants represent the in situ circuitry. Recordings of the motor activity in tissue explants are being pursued as a separate project. The aim of the current abstract is to compare the cholinergic cell populations in the lumbar ventral horn of fetal Balb/C mice (13 - 14 day gestation) with explant cultures of such tissue taken from the same litter.

Transverse sections of lumbar tissue (200 - 500 µm) taken from 13 - 14 day gestation mice have been established as explant cultures using a roller tube technique as described by Gahwiler (J. Neurosci. Meth. 4: 329-342, 1981). After a minimum of three weeks in culture, tissue explants were removed for identification of ventral horn cholinergic neurons using Karnovsky's acetylcholinesterase (AchE) staining method as modified by Guthrie et al. (B. Res. 420: 313-323, 1987). Explants were incubated in the impermeant AchE inhibitor phospholine iodide, fixed with buffered paraformaldehyde, and incubated in acetylthiocholine iodide staining solution. A parallel series of experiments was carried out on intact lumbar tissue taken from a littermate on the same day of culturing. Total cholinergic cell counts, cell density measurements and somal size distributions are being compiled using a Zeiss Videoplan Image Analysis System to quantify the cell loss due to the explantation and culturing process.

THE DEVELOPMENT OF FAST AVOIDANCE BEHAVIOR IN XENOPUS. P. van Mier and R. Stoop, Dept. of Medical Physics & Biophysics, Univ. of Nijmegen, Nijmegen, The Netherlands.

During development, in the early swimming stage (stages 28-33) Xenopus embryos start to swim when they are either stimulated mechanically, chemically or by dimming the light. In general the direction of swimming seems random with respect to the applied stimulus. During metamorphosis larvae clearly start to show avoidance behavior and swim readily away from a given stimulus. In this study we present evidence that fast avoidance behavior develops shortly after the early swimming stage. To establish when and how this type of behavior develops in Xenopus embryos and larvae (stages 35-66) we used behavioral tests, high speed filming and electrophysiological techniques. Between stages 40 and 46 embryos and larvae started to respond to sudden external (especially vibrational) stimuli with a fast and powerful tail flip causing the animals to move away from the stimulus. It occurred that at stage 46 93% of the larvae responded as such to vibrational stimuli with a maximum sensitivity for vibrations around 1000 Hz. At stage 60 the maximum sensitivity had shifted to vibrations of approximately 25 Hz. High speed filming revealed that fast avoidance behavior usually started with an initial 'C'-shaped bending of the entire body. Simultaneous in-vitro stimulation of the lateral line nerve or the otic vesicle and electrophysiological recordings in brain stem and spinal cord suggested that the Mauthner cell might be involved in fast avoidance behavior in Xenopus larvae.

401.15

IDENTIFIED INTERNEURONS IN LARVAL AND PUPAL ABDOMINAL GANGLIA OF THE TOBACCO HORNWORM, MANDUCA SEXTA. D.J. Sandstrom and J.C. Weeks. Graduate Group in Neurobiology and Dept. of Entomological Sciences, Univ. of California, Berkeley, CA 94720.

In Manduca, the physiology, anatomy and developmental fate of many motorneurons (MNs) are known, whereas virtually nothing is known about interneurons (INs) presynaptic to the MNs. An isolated, desheathed ganglion preparation has greatly facilitated recording from small INs and has allowed pairwise recordings from INs and MNs. A number of INs presynaptic to proleg MNs have been identified by recording from the proleg motor nerve in larvae, while stimulating INs intracellularly. Many of these INs (>10) are reidentifiable based on their physiological and anatomical properties. In pairwise recordings, some INs produce unitary PSPs of short, constant latency in proleg MNs. As the larva progresses to the pupal stage, the proleg muscles degenerate and the MNs which innervate them regress dramatically. A number of the larval INs can be reidentified in pupae which, unlike the MNs, do not change drastically in morphology. We are currently comparing the physiology of the IN-to-MN synapses in larvae and pupae to gain insight into developmental changes in motor circuits. Supported by an NSF fellowship to DJS and NIH and Sloan grants to JCW.

INTERNEURONS INVOLVED IN MULTISEGMENTAL REFLEXES IN LARVAE AND PUPAE OF THE MOTH *MANDUCA SEXTA*. B.Waldrop and R.B.Levine. ARL Div. Neurobiology, Univ. of Arizona, Tucson, AZ 85721

We are studying the postembryonic development of neural circuits involved in the gin trap reflex of *Manduca*. The gin trap is a pupa-specific structure containing mechanosensory hairs which cause the trap to be closed by evoking a powerful contraction of ipsilateral muscles. The sensory neurons, motor neurons and muscles of the gin trap are retained from the larva where they mediate a different reflex. Since the terminals of the sensory neurons and the dendrites of the motor neurons are in different ganglia, there must be interganglionic interneurons carrying the sensory information. We are attempting to identify these interneurons and to determine if they are also retained and modified during metamorphosis.

The experimental preparation consists of an isolated abdominal nerve cord from either a larva or a pupa. Electrical stimulation of the sensory nerve leads to stage-specific response patterns recorded intra- and extracellularly in motor neurons. Interneurons are impaled and tested for responses to the sensory stimulus, and for their ability to evoke PSPs or changes in the spike rates of the motor neurons. We have found interneurons in the larva and the pupa which satisfy both of these criteria. Intracellular cobalt fills have revealed both dorsal and ventral dendrites and interganglionic axons, consistent with a role for these interneurons in sensory-motor integration in the gin trap reflex.

REORGANIZATION OF AN IDENTIFIED LEG MOTOR NEURON DURING METAMORPHOSIS OF THE MOTH MANDUCA SEXTA. K.S. Kent and R.B. Levine. ARL Div. Neurobiol., Univ. Ariz., Tucson, AZ 85721

Using persistent fluorescent dyes (Fluoro-Gold, DiI) we are able to retrogradely label larval thoracic leg motor neurons (MNs) so that we can locate and characterize them with intracellular methods at later stages of development. We have focused our studies on one MN, which innervates the larval femoral flexor muscle and survives metamorphosis to innervate the femoral extensor muscle of the adult. During larval stages this MN has two distinct regions of dendritic branching, one located laterally in the leg neuropil and the other more dorsal and medial. Dendrites in both regions begin to regress during prepupal stages at the same time that peripheral terminals and target muscle begin to degenerate. Peripheral terminals are reduced to a few blunt, blebby processes that appear to remain associated with remnants of larval muscle and apodemes. Dendritic regression continues for three days following pupation until the dorso-medial arborizations are lost entirely and the lateral dendrites are reduced to a few sparsely branching processes. Over the ensuing few days, new afferent inputs reach the CNS and new muscles begin to form in the adult leg. Peripheral axons sprout new terminal processes and new dendrites begin to grow in the lateral region. To determine if the growth of new dendrites is influenced by ingrowth of new sensory inputs or contact with the new target muscle, we labeled the MN with DiI and removed the larval leg several days later, so that development proceeded in the absence of a new adult leg. Under such deprived conditions, the MN survives, loses larval dendrites, and begins to grow new adult dendrites on schedule. (Supported by NIH #NS24822).

402.1

IMMUNOLOGICAL REACTIONS IN INTRAVENTRICULAR XENOGRAFTS AND ALLOGRAFTS. Maciej Poltorak and William J. Freed NIMH Neurosciences Center at St. Elizabeths, Washington, D.C. 20032

We have compared the immunological reactions to embryonic brain tissue allografts and xenografts in the lateral ventricle of the rat brain, on the basis of distribution of immunocytochemical staining with antibodies against Ia antigen and helper/inducer cells. Host animals were randomly-bred Sprague-Dawley rats. The donor cerebellar tissues were taken from C57/BL mouse embryos or from Sprague-Dawley rat embryos, and implanted into the lateral ventricle of the host brain. Indirect immunofluorescence was performed on fresh frozen sections after 2,4 and 6 weeks of survival. Massive infiltrations of both cell types were found within xenografts. Ia antigen immunoreactivity was also present in the walls of small vessels near the transplanted tissue. This reaction was associated with destruction of the xenografts. In contrast, the allografts survived but nevertheless numerous cells expressing Ia- and helper-T-cell-antigen were usually detectable. Both Ia and helper cells were found along the injection needle tract and surrounding the graft 2 weeks after implantation. Some staining was also observed in small areas within the grafts. Both Ia and helper-T immunoreactivity decreased with the time of survival. In xenografts and to a lesser extent in allografts Ia immunoreactivity was enhanced in a population of small, rod-like, oblong cells, with tiny processes. These cells were found mainly within the white matter and their appearance corresponds to that of the microglia. These results suggest that the process of implantation of tissue and the associated brain injury induces enhanced Ia immunoreactivity in brain parenchyma surrounding both allo- and xenografts. Despite this predisposition to immunological reactions, only in xenografts did this reaction proceed through all of the steps required for a graft rejection response.

STUDIES OF HUMAN FETAL NEURAL TISSUE IN CULTURE. J.N. Barrett, E.H. Kriek, D. Nonner*, J.C. Kawamoto*, C. Kruse*, S. Waldrup*, D. Bhaskaran, and C.R. Freed, Depts. of Med. and Pharm., Univ. of Colo. Sch. Med., Denver, CO 80262 and Dept. of Physiol., U. Miami Sch. Med., Miami, FL 33101.

Human fetal tissue of 8 to 19 weeks' gestation was obtained from therapeutic abortions with consent given by the mother. Tissues included dopamine cells from ventral mesencephalon, cholinergic cells from basal forebrain, dorsal root ganglia, and adrenal medullary cells. Results showed that fetal adrenal medullary tissue from all gestational ages survived in the presence of mouse NGF or in cocultures with rat hippocampus, rat cortex or mitomycin C arrested C-6 glioma cells. Processes from those clusters were extensive. Clusters and processes were tyrosine hydroxylase positive and HPLC assay showed high concentrations of norepinehprine with lower concentrations of epinephrine and dopamine. Dorsal root ganglia showed neurite outgrowth in response to mouse NGF. Dopamine cells from ventral mesencephalon could be cultured only from fetus of gestational age 12 weeks or less. Cells showed TH immunoreactivity and dopamine production could be measured by HPLC. 1/5 preparations of basal forebrain showed stimulation of choline acetyl transferase activity following mouse NGF treatment. These data indicate that human fetal neural tissue can grow in tissue culture and that cells from adrenal medulla and central cholinergic systems are responsive to NGF-like growth factors.

402.3

GNRH AXONS FROM THIRD VENTRICULAR GRAFTS DO NOT REQUIRE ARCUATE NEURONS FOR TARGET LOCATION. R. Silverman, A.J. Silverman, H.M. Charlton,* M.J. Gibson. Columbia University N.Y., N.Y. 10032

Hypogonadal mice carry a mutation in the gene for gonadotropin releasing hormone (GnRH), resulting in infertility. Preoptic area grafts containing GnRH neurons from normal fetuses placed in the third ventricle of hpg mice result in increased indices of fertility subsequent to fiber outgrowth from graft into host target tissue. Immunocytochemically identified GnRH fibers grow from graft through host arcuate nucleus (A) to median eminence, the target. Neurons of A may play a role in this outgrowth. Monosodium glutamate has been shown to destroy 60-90% of A neurons. Would GnRH fibers grow through the MSG lesioned A in their typical manner or would the pattern be disrupted? Twenty neonatal hpg mice were given i.p. injections of 4mg/kg MSG and received grafts as adults: controls received saline. Thirty days after grafting, brain sections were stained immunocytochemically for GnRH. Tyrosine hydroxylase defined the A. Despite substantial neuronal loss, GnRH axonal outgrowth in the lesioned brains was indistinguishable in both pattern and intensity from that in the control brains. Similarly, the degree of reproductive recovery did not vary between groups. The majority of A neurons are not necessary for neurite outgrowth or pathfinding in this transplant system.

EFFECTS OF CHRONIC GM_1 ADMINISTRATION ON TRANSPLANT-INDUCED REVERSAL OF MEMORY IMPAIRMENTS IN NBM LESIONED RATS. V. Haroutunian, A.C. Santucci, R. Gluck and K.L. Davis. Bronx VAMC & Mt. Sinai School of Medicine, New York, N.Y. 10468.

Both fetal cell transplants and the monosialoganglioside GM_1 aid recovery of function from several types of brain damage. We have studied the possible synergistic effects of these two approaches towards amelioration of n. basalis of Meynert (nbM) lesion-induced memory deficits. Seven to ten days after ibotenic acid-induced lesions (5ug in 1ul) of the nbM different groups of rats received either sham operations or septal area fetal (17mm) cell suspension ($2x10^7$cells) transplants (TR) into the frontal cortex. Beginning immediately after the transplant session different sub-groups then received daily IP injections of either saline or 20mg/kg GM_1 for 10 days. After the termination of the GM_1 treatments each rat was tested for the 72 hour retention of one trial passive avoidance. Saline injected nbM lesioned and nbM+TR rats performed poorly relative to sham lesioned rats ($ps<0.05$). The administration of GM_1 to nbM and nbM+TR rats normalized retention test performance to a level equivalent to sham operated rats ($ps>0.1$). Experiments now underway aim to determine the longevity and histochemical characteristics of this effect.

HOST-GRAFT INTEGRATION: RAT PERIAQUEDUCTAL GRAY AND ISOLATED BOVINE CHROMAFFIN CELL IMPLANTS J.D. Ortega*, J. Sagen, and G.D. Pappas (SPON: C.H. Anderson). Dept. of Anatomy and Cell Biology, Univ. of IL at Chicago, Chicago, IL 60612.

Previous work in this lab has demonstrated survival of rat adrenal medullary tissue following transplantation into rat periaqueductal gray (PAG), an important pain modulating center. Animals with either whole-tissue or isolated chromaffin cell transplants showed decreased pain sensitivity measured by standard analgesiometric tests following subcutaneous injection of nicotine. EM studies of the solid tissue transplants revealed heavy collagen encapsulation and gliotic shielding response at the host-graft border. Though isolation of graft from host does not appear to prevent diffusion of neuromodulatory substances into surrounding tissue, physical integration may be limited to some extent by these barriers. Furthermore, adrenal medullary tissue contains many cell types in addition to chromaffin cells which may interfere with host-graft integration. To circumvent this, isolated bovine chromaffin cell suspensions were used. Cells were grafted into the PAG of adult rats and examined morphologically at various intervals following surgery. Immunocytochemical analysis of the transplant site revealed the existence of healthy chromaffin cells which stain positive for tyrosine hydroxylase. At the host-graft border, both collagen encapsulation and gliotic shielding were virtually absent. Numerous synaptic contacts between the transplanted chromaffin cells and host processes were seen as early as two weeks following transplantation. In contrast to solid tissue transplants, lymphocytic infiltration was not observed, indicating a minimal immune response to the transplanted cells. Preliminary studies indicate increased cell survival and host-graft integration with constant intraventricular NGF infusion. (Supported by NIH grants NS25054 and GM37326).

402.6

THE EFFECT OF ADRENAL MEDULLARY TRANSPLANTS ON CSF ENKEPHALIN LEVELS AND PAIN SENSITIVITY. J.E. Kemmler* and J. Sagen, Dept. of Anatomy and Cell Biology, Univ. of IL at Chicago, Chicago, IL 60612.

Recent work in our laboratory has shown that it is possible to reduce pain sensitivity by transplanting adrenal medullary tissue into the subarachnoid space of the rat spinal cord. Chromaffin cells of the adrenal medulla store and secrete large amounts of opioid peptides and are therefore a potential reservoir for local release of these substances. The analgesia produced by stimulation of the transplanted adrenal medullary tissue was shown to be reversed by the opiate antagonist naloxone, suggesting that opioid peptides released from the transplants are important in mediating this analgesia. The aim of the present study was to more directly measure enkephalin release from the transplanted tissue using spinal cord superfusion techniques. Either adrenal medullary tissue or equal volumes of control muscle tissue was transplanted into the subarachnoid space of rat spinal cord. Pain sensitivity was assessed in transplanted animals using the tail flick, paw pinch, and hot plate tests. CSF samples were collected from transplanted animals using a push-pull superfusion apparatus. These samples were assayed for met-enkephalin using a radioimmunoassay. Basal levels of met-enkephalin release from the spinal cords of animals with control transplants was 7.8 pg/ml. This was nearly doubled to 14.8 pg/ml in animals with adrenal medullary transplants. The basal levels of met-enkephalin release were correlated with changes in pain sensitivity following adrenal medullary transplants. Nicotine stimulation further increased met-enkephalin levels in the superfusates. Results of this study indicate that adrenal medullary tranplants may serve as a locally available source of opioid peptides for the reduction of pain. (Supported in part by NIH grants NS25054 and GM37326).

402.7

CHROMAFFIN CELL GRAFTS INTO CNS PAIN MODULATORY REGIONS REDUCE PAIN SENSITIVITY IN A CHRONIC PAIN MODEL. H. Wang*, J. Sagen, and G.D. Pappas. Dept. of Anatomy and Cell Biology, Univ. of IL at Chicago, Chicago, IL 60612

Recent work in our laboratory has shown that transplants of either rat adrenal medullary tissue or isolated bovine chromaffin cell suspensions into the midbrain periaqueductal gray (PAG) or the spinal cord subarachnoid space are capable of decreasing pain sensitivity as assessed using acute analgesiometric tests (tail flick, paw pinch, and hot plate). However, therapeutic strategies effective in reducing response to these acute noxious stimuli cannot always be extrapolated to the treatment of chronic pain in humans. Therefore, the need for animal models for chronic pain which more closely represent human pain syndromes has been recognized. Currently available models include the adjuvent-induced arthritis model which results in a reversible hind-paw inflammatory arthritis in rats. Animals with hind-paw inflammation were transplanted with either solid rat adrenal medullary tissue, isolated bovine chromaffin cell suspensions, or control tissue into either the PAG or spinal cord subarachnoid space. Pain sensitivity was assessed in these animals by monitoring behavioral changes, particularly vocalizations. Baseline levels of vocalization responses were lower in animals with adrenal medullary and isolated chromaffin cell transplants than in animals with control transplants. The vocalizations were further reduced by 50% following the injection of nicotine in transplanted, but not control animals. Results of this study further suggest that the transplantation of isolated chromaffin cells into CNS pain modulatory regions may be an alternative approach toward the management of pain. (Supported in part by NIH grants NS25054 and GM37326).

THE USE OF A RETROVIRAL VECTOR TO IDENTIFY FOETAL STRIATAL NEURONES TRANSPLANTED INTO THE ADULT STRIATUM

P.C.Emson, S. Shoham, C.Feler[1], J. Price* & C.J. Wilson[1]
MRC Group, Dept. of Neuroendocrinology, AFRC Institute of Animal Physiology & Genetics Research, Cambridge CB2 4AT UK & [1]Dept. Anatomy & Neurobiology, University of Tennessee, Memphis.

The BAG retrovirus contains the E.Coli ß-galactosidase gene downstream of the viral long terminal repeat (LTR) sequence. In this study the BAG virus has been used to infect rat foetal striatal neurones before the infected neurones were transplanted into the ibotenate lesioned striatum of the adult rat.

After transplantation grafts were left in the host rat for eight months before the animals were anaesthetised, perfused and the brains processed to visualise bacterial ß-galactosidase activity. All the animals which had received infected neurones contained a number of surviving neurones some of which expressed the bacterial enzyme. The ability of foetal neurones to stably incorporate the virus and express the bacterial protein means that this method may provide a convenient route for the transfer of genetic information into neurones and would have potential in the treatment of neurological illness with transplants (Supported by a NATO collaborative research grant).

FUNCTIONAL RECOVERY OF HIGH-AFFINITY CHOLINE UPTAKE IN THE HIPPOCAMPUS FOLLOWING SEPTAL CELL SUSPENSION TRANSPLANTS IN RATS WITH FIMBRIA-FORNIX LESIONS.

Y.Kaseda*, J.R.Simon, and W.C.Low. Depts of Physiology and Biophysics, Psychiatry, and Biochemistry, Inst. Psychiat. Res., and Program in Medical Neurobiology. Indiana Univ. Sch. of Medicine, Indpls., IN 46223.

The transplantation of cholinergic cells from fetal septal-diagonal band has been shown to innervate the hippocampus of rats with fimbria-fornix lesions, and to improve impaired learning and memory. It has been reported that AChE positive fibers grow from the graft into the host hippocampus. Electrophysiological properties similar to the normal septo-hippocampal cholinergic system have been seen between the graft and the host hippocampus. ChAT activity in the host hippocampus also appears to be normal. The purpose of this study was to determine the functional integrity of the cholinergic terminals derived from the graft. Cell suspensions were prepared from the septal-diagonal band area of 15-17 day old rat embryos. The transplanted group (TP) consisted of male Sprague-Dawley rats that received bilateral injections of 2 ul of cell suspensions into the dorsal hippocampus followed by bilateral fimbria-fornix lesions. Control rats received bilateral injections of 2 ul of vehicle into the dorsal hippocampus followed by bilateral fimbria-fornix lesions (LES) or sham lesions (SHAM). Neurochemical assays were performed 9-10 weeks after surgery. High-affinity choline uptake (HACU) (pmol/mg protein) in synaptosomes from dorsal and ventral hippocampus respectively was 20.1±1.7 and 23.3±0.9 in SHAM, 5.6±0.9 and 8.8±0.9 in LES, and 17.8±3.1 and 17.3±1.8 in TP. Thus, HACU was restored to 89 % and 74 % of control in the dorsal and ventral hippocampus respectively after transplantation. In addition, it was determined that the HACU related to the transplant could be activated by an elevated K^+ concentration as in normal cholinergic terminals. Thus, following preincubation at a K^+ concentration of 48 mM, HACU was activated by 30-40 % in all three groups. We conclude that the cholinergic terminals derived from the septal cell suspension have a functional HACU system, and that the HACU related to the graft can be activated by K^+ induced depolarization as in normal cholinergic terminals. (This work was supported by NIH grant RO1-NS-24464)

402.10

FETAL CNS TRANSPLANTS FOLLOWING TRAUMATIC BRAIN INJURY IN ADULT RATS. H.D. Soares* and T.K. McIntosh. (SPON: T. Koch). Surgical Research Center, Dept. of Surgery, Univ. of Connecticut Health Center, Farmington, CT 06032.

Adult rats subjected to lateral fluid-percussion (FP) traumatic brain injury (2.4 atm) exhibit parietal motor cortex necrosis resulting in neurological motor deficits. A cavity with glia limitans forms in damaged cortex between 2 to 4 weeks post-injury. We examined the ability of fetal cortical transplants to proliferate and survive at different stages of cavity development. Male Sprague-Dawley rats (350-450g) received a stereotaxic injection of whole fetal cortical tissue (E14 to E 16) into the cavity site at either 3 days (n=4), 5 days (n=5), 1 week (n=5), or 2 weeks (n=3) post-trauma. Animals were sacrificed at three weeks post-transplant and brains were subjected to either Nissl or acetylcholinesterase (AchE) histochemistry. AchE staining showed interlinking fibers between host and transplants at all timepoints. Some transplants grew to 4x original size and exhibited centralized areas of necrosis. Proximity of transplant to the left lateral ventricle appeared to be a determining factor in eventual transplant size. Transplants had fewer connections and more AchE positive cells than surrounding host areas. These data suggest that fetal brain transplants can survive and form connections when transplanted into injured cortex following traumatic brain injury. (Supported by VA Merit Review Grant 74R).

402.11

IS PHASEOLUS VULGARIS LEUCOAGGLUTININ (PHA-L) A USEFUL MARKER FOR LABELING NEURAL GRAFTS? A.M. Bhatia*, J.N. Kott, and L.E. Westrum. (SPON: P. Swanson) Depts. Neurol. Surg. and Biol. Struct., Univ. of Wash., Seattle, WA 98195.

We are presently evaluating different methods for labeling donor cells prior to neural transplantation in the olfactory system. Incubation of cultured fetal human spinal cord cells in PHA-L has been reported to allow discrimination of donor cells grafted into pre-lesioned adult rat cerebral cortex (Kamo et al., Neurosci. Lett. 76:163, 1987). We are incubating solid fetal olfactory bulbs of rat fetuses of embryonic ages 15-18 days in 1% PHA-L prior to direct transplantation into intact or pre-lesioned neonatal rat olfactory system. In addition to sections reacted for PHA-L by the ABC method, cell and fiber stains are used on alternate frozen sections. The cell and fiber stained sections show "viable grafts" with appropriate neuronal types and with fibers traversing the host-graft interface. However, the PHA-L labeling by this method appears to be incomplete, possibly due to insufficient penetration of the fetal tissue blocks. Further, host neurons at various sites outside of the graft may show PHA-L reactivity perhaps from uptake of label from degenerating donor cells. Use of cell suspensions rather than solid tissue blocks is planned next for study. (Supported by NIH Grants NS09678 and DE04942. LEW is an affiliate of CDMRC.)

402.12

ULTRASTRUCTURAL LOCALIZATION OF GOLD PARTICLES WITHIN CENTRAL GRAFTS LABELED WITH GOLD-FILLED SENDAI VIRAL ENVELOPES. J.N. Kott, L.E. Westrum, and [1]G.W. Arendash. Depts. Neurol. Surg. and Biol. Struct., Univ. of Washington, Seattle, WA 98195 and [1]Dept. Biol., Univ. of South Florida, Tampa, FL 33620.

Ardizzoni, Michaels and Arendash (Science 239:635, 1988) have described a method using gold-filled Sendai virus envelopes to mark cell suspensions prior to transplantation. We are examining similarly labeled nucleus basalis suspension grafts by electron microscopy to determine the distribution and character of this label within transplanted cells to assess the possibility of its use in studies of synaptology in graft tissue. Preliminary examination of transplanted labeled tissue in the immediate vicinity of the graft site has revealed gold particles associated with various cytoplasmic membranes of different cell types including neurons, glia and their processes. Unexpectedly, heavy labeling was observed within the nuclei of both neurons and glia. The gold particles vary between 15 and 80 nm diameter and appear as single round profiles or aggregates of several such profiles. While gold label was found throughout the limited area we have examined, its concentration dissipates with distance from the center of the graft. Examination of sites remote from such grafts, including pre-lesioned target areas is planned. (Supported by NIH Grants NS09678 and DE04942. LEW is an affiliate of CDMRC.)

FINE STRUCTURAL CORRELATES OF NEURAL TRANSPLANTATION. W. Wu* and D.E. Scott, Dept. of Anatomy and Cell Biology, Eastern Virginia Medical School, Norfolk, VA 23501.

This investigation has focused on basic questions of vascularization, survival, and regeneration in neurites in the transplanted endocrine hypothalamus. Normal fetal hypothalamic grafts 15 days post-coitus were transplanted into the third cerebral ventricle of host rats with diabetes insipidus (DI). Blood vessels were extant in grafts within the first week following transplantation. Vasopressin (AVP) positive neurons were observed in the grafts. AVP neurons project fibers which develop three types of neuroanatomical relationships with the host brain: 1) terminate in host median eminence; 2) terminate around the blood vessels which grow from the host brain into the graft; and, 3) terminate directly into the ventricular lumen of the host brain. Fenestrated capillaries with distinct perivascular spaces were observed in the ventral regions of the graft in proximity to the host median eminence. Four weeks following transplantation, AVP-positive neurons within the graft appeared well differentiated and exhibited numerous axodendritic and axosomatic synapses. This study indicates that the morphological relationships that develop between transplanted AVP-positive neurons and host-brain recipients may allow for AVP-positive neurons to release neuropeptide hormones into both the vascular and CSF compartments. THE PRESENCE OF A BLOOD-BRAIN BARRIER IN NEURAL XENOGRAFTS IS RELATED TO THE IMMUNOLOGICAL STATUS OF THE HOST. M.J. Young*, K. Rao, and R.D. Lund (SPON: M. Bennett). Dept. Neurobiol., Anat., and Cell Sci., Univ. of Pittsburgh Sch. Med. Pgh., PA 15261.

We are investigating immunological correlates of blood-brain barrier (BBB) breakdown in retinal xenografts in rats, utilizing skin grafting to initiate a timed immune response to the transplanted neural tissue. Embryonic (E13-14) CD-1 mouse retinae were grafted into the brainstem parenchyma of neonatal (P1) Spraque-Dawley rats. 21 days after transplantation one group of animals recieved a 1 cm^2 CD-1 skin graft on the flank to provoke an immune response to the neural graft. Control animals recieved no skin graft. 2-8 days post skin-grafting (DPSG) animals were injected in the femoral vein with horseradish peroxidase (HRP). Brains were processed for Nissl, HRP-TMB, and anti-M2, -M6, -Ia, -lymphocyte, -macrophage, and -astrocyte monoclonal antibodies.

Experimental and control animals injected 2-4 DPSG showed no leakage of HRP. A small percentage of 5 DPSG animals showed isolated, patchy leakage, but little or no evidence of rejection. At 6 DPSG over 50% of the grafts showed evidence of HRP leakage and the infiltration of lymphocytes. At 7-8 DPSG massive leakage of HRP and widespread infiltration of lymphocytes, macrophages, and astrocytes was evident.

The results demonstrate that the status of the BBB is closely correlated to the immunological status of the host. They also support the presence of a BBB in neural transplants, but suggest that immunological factors should be considered in allo- and xenogenic grafts of neural tissue. (NEI EY05283 & Winters Fdn)

SELECTIVE DENTATE GRANULE CELL LESIONS BY FLUID INJECTION. B.P. Vietje*, J. Wells and P.C. Camp*
(SPON: S.L. Freedman). Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

In our previous studies involving cell suspension transplants into the dentate granule cell layer, (GCL), it was noted that the fluid volume of the injected cell suspension split open the host tissue along the hippocampal cleavage planes, particularly along the hilus/GCL interface, resulting in axotomy and subsequent death of the granule cells. The present study was undertaken to study the effects of granule cell lesions in the absence of a transplant. Reproducible GCL lesions were created by stereotaxic injections of Hank's Balanced Salt Solution into the GCL of adult rats. After survival times of 6 days to 2 months, brains were analyzed by Timm's stain, nissl stains, AChE histochemistry, and GFAP and S-100 immunoreactivity. GCL lesions resulted in a loss of granule cells, decreased mossy fiber staining thinning of the stratum moleculare, and a marked gliosis surrounding the lesion. GCL lesions contribute to the altered host environment in transplant studies and provide an important control for separating the effects due to GCL lesions from those of the tgransplanted tissue. Additionally, specific granule cell lesions can be used to study the function and connectivity of the dentate granule cells. Supported by NS23266.

AUTORADIOGRAPHIC OBSERVATIONS AFTER OLFACTORY BULB TRANSPLANTATION. T. Zigova, P.P.C. Graziadei and A.G. Monti Graziadei. Dept. of Biology, Florida State Univ., Tallahassee, FL 32306-3050 and Inst. of Neurobiology, Kosice, Czechoslovakia.

In a previous study, after removal of the olfactory bulb in neonatal rats, we have transplanted embryonic presumptive olfactory bulb to see if the embryonic tissue would have interacted with the sensory input and the brain of the host. Since the transplanted olfactory bulb quite often developed acquiring the characteristics of a normal OB, it was important to demonstrate that the entire bulb was from the donor. In this study 3H-thymidine was injected to pregnant rats at the time when the large neurons of the bulb were undergoing cellular division. The autoradiographically labeled presumptive olfactory bulb from E14-E18 embryos was transplanted to neonatal P1-P5 pups in place of the removed olfactory bulb. Observations were carried on at postoperative survival times from 20 to 45 days. The results of this study have shown that the transplanted bulbs were capable of establishing connections with both the sensory input and the brain of the host.

402.17

EFFECT OF CONCENTRATED ANTIBIOTIC SOLUTION ON SURVIVAL OF RAT FETAL DOPAMINERGIC NEURONS. J. K. Morgan*, R. J. Plunkett*, M. A. Palmatier, and E.H. Oldfield* (SPON: N. H. Spector). SNB, NINCDS, NIH, Bethesda, MD. 20892

Mesencephalon from aborted fetuses is a source of dopaminergic neurons which may be useful for implantation in Parkinsonian patients. A contraindication to the use of this tissue is the high rate of contamination with vaginal flora. We devised a technique to sterilize this tissue in a concentrated antibiotic wash. As a correlative study, we examined the possible cytotoxic effects of this concentrated antibiotic solution on cells from fetal rat mesencephalon. The ventral mesencephalon dissected from embryonic day 13 or 14 rat embryos were washed either in the concentrated antibiotic solution or PBS with 6% glucose. Cell suspensions were then prepared by papain digestion and mechanical dissociation. Initial viability was assessed by trypan blue exclusion and found to be > 80% in both groups. Survival of dopaminergic neurons in cell culture was documented by tyrosine hydroxylase immunohistochemistry. We conclude that a brief exposure of fetal tissue to the concentrated antibiotic solution has no apparent cytotoxic effect.

402.18

PHENOTYPIC SELECTION OF NEUROBLASTOMA CELLS FOR USE IN TRANSPLANTATION IN ANIMAL MODELS OF PARKINSON'S DISEASE. D.G.Walker*, B.E.Boyes*, P.L.McGeer and E.G.McGeer. Kinsmen Lab. of Neurol. Res. Univ. Brit. Col., Vancouver, B.C., Canada. V6T 1W5.

The feasibility of using differentiated neuroblastoma cells in long term neural grafting procedures has been demonstrated (Gash et al., Science,233:1420,1986). To follow up our previous work of transplantation of human fetal neurons in an animal model of Parkinson Disease (Kamo et al. Brain Res.397:372,1986), by developing a renewable cell source, subclones of IMR-32 cells with dopaminergic and adrenergic characteristics were isolated using a procedure of Breakefield and Nirenberg (PNAS,71:2530,1974). Cultures of unselected IMR-32 cells were grown in F-12 media, deficient in tyrosine, to select for cells producing tyrosine hydroxylase, tryptophan hydroxylase or phenylalanine hydroxylase. In this media, the majority of cells rapidly die, and isolated foci grow. Approximately 1 out of 8,000 uncloned IMR-32 cells can grow in tyrosine deficient media. Following three passages in tyrosine deficient media, 40 tyrosine independent subclones were isolated and established. Catecholamine and indoleamine content and specific activity of tyrosine hydroxylase in each isolate was measured by HPLC with electrochemical detection. Treatment of selected isolates with retinoic acid (10 μM) and aphidicolin (1 μg/ml) induced differentiation and neurite formation.

LONG-TERM MAINTENANCE OF ENCAPSULATED PC12 CELLS IN VITRO AND AS BRAIN IMPLANTS. C.B. Jaeger, S.R. Winn*, P. Aebischer* and L.A. Greene. Dept. Physiol. Biophys. NYU Med. Ctr., New York, NY 10016, Artificial Organ Lab. Brown University, and Dept. Pathol. Columbia University.

Replacement therapy of dopamine in the brain by tumorigenic catecholaminergic cell lines (TCL) requires enclosure and containment of such cells. We studied the survival and the presence of tyrosine hydroxylase (TH) of encapsulated TCL. One TCL, the PC12 pheochromocytoma cell line, known to synthesize high levels of dopamine, was incapsulated and implanted in the forebrain of rats, or maintained in vitro. Cell-filled permselective polyvinylchloride acrylic co-polymer capsules (Aebischer et al., ASAIO 10:96,'87) were fixed at intervals up to six months, the morphology of the cells was studied, and their enzymatic properties were examined by immunocytochemistry. PC12 cells remained healthy within the capsules. Viable cells were found adjacent to the capsule wall within a radius of 100 to 150 μm. Mitotic figures in some of the enclosed PC12 cells were taken as evidence for continued cell growth within the capsules. Mitosis was observed up to six month following capsule placement into the brain. Approximately ten layers of PC12 cells located adjacent to the capsule wall were TH positive in correspondence with the region of viable cells. We conclude that the procedure of encapsulation allows long-term implantation of TCL into the brain.

403.1

CHARACTERIZATION OF THE EFFECTS OF NUCLEUS BASALIS LESIONS IN RATS 14 MONTHS POST-LESION. R. D. Terry*[2], R.J. Mandel[1,2], G. Buzsaki[2], F.H. Gage[2] & L.J. Thal[1,2]. (Spon. R. B. Livingston). [1]Dept. Neurol. VAMC, SD, 92161, [2]Dept. Neurosci., UCSD, La Jolla, 92093.

Recently, rats with nucleus basalis magnocellularis (NBM) lesions 14 mo. previously, were reported to display neuropathology similar to that seen in human Alzheimer's brains (Arendash, et al., Science 238:952, 1987). We report that, using a similar excitotoxic lesion paradigm, we did not find similar neuropathology, although the rats were impaired on biochemical, behavioral, and electrophysiological indices.

Six F-344 male rats received bilateral ibotenate lesions of the NBM. Three weeks post-surgery lesioned and unlesioned controls (n=6) were tested in a water maze task (10 trial blocks, 1 block/day, 4 trials/day). Fourteen mo. later, 4 rats from each group were retested in the same water maze (3 trial blocks). Immediately after behavioral testing, these 8 rats were implanted with cortical electrodes for freely moving EEG recording. The rats were then sacrificed for histological examination with acetycholinesterase (AChE) histochemisty, cresyl violet, and Bielchovsky silver staining. The 4 remaining rats were sacrificed for measurement of cortical choline acetyltransferase (ChAT) activity.

The NBM lesioned rats had 22.3% depletion of cortical ChAT 14 mo. after lesioning relative to controls. The lesioned rats were impaired relative to controls on initial acquisition of the maze task but did reach equivalent levels of performance during trial blocks 6-10. Fourteen mo. later, lesioned rats were impaired relative to controls on retention and reacquisition of the maze task. Although the biochemical and behavioral deficits displayed by the lesioned rats were relatively mild, EEG recording revealed high amplitude waves which were absent in control rats. While AChE positive neurons in the NBM were reduced in the lesioned rats' brains, silver staining revealed no pathology resembling cortical plaques.

403.2

INCREASED EXTRA-ADRENAL CHROMAFFIN CELLS IN AGED FISCHER-344 RATS: AN IMMUNOCYTOCHEMICAL EVALUATION. G. Yang*, M.F. Matocha and S.I. Rapoport. Lab. of Neurosci, NIA, NIH, Bethesda, MD 20892.

The number of extra-adrenal chromaffin cells in male Fischer-344 rats is strikingly increased with age (Partanen, M. et al, Neurobiology of Aging 5:105-110, 1984). In this study, the mechanism of the senescent increase was addressed using immunocytochemical methods. A monoclonal antibody against the 5-bromo-2'-deoxyuridine was injected intraperitoneally (50mg/kg b.w., once a week for 14 weeks) into rats aged 26 months, and paraganglia were tested for incorporation of the uridine . None of the extra-adrenal chromaffin cells was labeled by the antibody, indicating that the age-related increase is not due to cell proliferation. To examine if a glucocorticoid receptor (GR) mechanism is involved in the senescent increase, the temporal pattern of GR immunoreactivity in the extra-adrenal chromaffin cells was followed and was compared with that in adrenal chromaffin cells. No detectable changes in immunoreactivity were found in extra-adrenal chromaffin cells, whereas the immunoreactivity decreased with age in adrenal chromaffin cells. The persistence of GR in extra-adrenal chromaffin cells and the correlation of GR immunoreactivity with distinct aging fates of the chromaffin cells suggest that the GR is involved in the numerical increase of extra adrenal chromaffin cells in the aging rats.

403.3

AGE-RELATED CHANGES IN ADRENAL TYROSINE HYDROXYLASE EXPRESSION AND CATECHOLAMINE CONTENT: EFFECTS OF DIETARY RESTRICTION. M.A. Moore,* C. Hale,* W.J. Burke,* H.J. Armbrecht,* and R. Strong* (SPON: D.F. Russell). Ger. Res. Ed. and Clin. Ctr., St. Louis VA Med. Ctr. and Depts. Pharmacol., Biochem., Neurol., and Med., St. Louis Univ. Schl. of Med., St. Louis, MO 63125

Dietary restriction of total calories increases both the median and maximum life span of rodents and attenuates various age-related biochemical changes. We hypothesized that dietary restriction may affect the rate of aging by altering programmed changes in gene expression. Adrenal medullary catecholamine metabolism increases markedly during aging. Therefore, we measured enzymes of catecholamine metabolism, choline acetyltransferase activity and catecholamine content in adrenal glands of food-restricted and ad lib fed rats of different ages. Tyrosine hydroxylase (TH) activity increased 2-3 fold from 2 to 23 months of age. These changes in TH were paralleled by increases in dopamine (DA) content. There were no changes in the other parameters measured. Contrary to expectations, lifelong dietary restriction failed to attenuate the effect of aging on TH or DA. In fact, food restriction increased tissue content of catecholamines and TH. Preliminary results show age-related increases in adrenal TH mRNA. We are currently evaluating dietary restriction on TH mRNA.

403.4

EFFECT OF LIPID PEROXIDATION ON GLUCOSE TRANSPORT IN ASTROCYTES: POTENTIATION BY ETHANOL. T-C Jou*[1], S-M Liu*[1], FF Ahmad*[2], DL Cowan*[3] and AY Sun[2]. [1]Institute of Neuroscience, National Yang-Ming Medical College, Taipei Taiwan, ROC, and Departments of [2]Biochemistry and [3]Physics, University of Missouri, Columbia, MO 65203.

Ethanol has been shown to enhance lipid peroxidation in vivo and in vitro. We used cell culture as a model to study the metabolic regulation of the central nervous system along with the spin trapping technique using electron spin resonance spectroscopy to directly detect free radicals in the system. In presence of low concentration of $Fe^{++}+H_2O_2$, hydroxyl free radicals were detected. Exposure of the cells to this medium caused lipid peroxidation resulting in 50% inhibition of ^{14}C-deoxyglucose (DG) transport activity. Ethanol alone also inhibited DG transport in alcohol concentration dependent manner. Addition of low concentrations of ethanol increased free radical formation and hydroxyethyl free radicals were characterized. This also increased MDA formation and DG transport activity was further inhibited. Involvement of ethanol in free radical formation may provide a useful explanation for premature aging upon chronic ethanol drinking. (Supported in part by NIH grant AA02054.)

Spatial Learning Deficits in the Aged Male Rat: Neuroanatomical and Neurochemical Correlates. Lee, J.*, Lorens, S., Gower, A.*, Ross, E.* and Wulfert, E.* Dept. Pharmacol. and Pathol., Loyola Univ., Maywood, IL 60153 U.S.A., and U.C.B.,s.a., Braine-L'Alleud, Belgium

Based on their ability to locate a hidden platform in a Morris water maze, aged Sprague-Dawley rats (20-22 mo) were divided into two groups. The "old good" group acquired the task as rapidly as young (3-6 mo) animals, whereas the "old poor" rats failed to reach criterion. Using several histological methods, including antisera directed against paired helical filaments, we found no evidence for neuritic plaque or neurofibrillary tangle formation, or for abnormal cortical or hippocampal lamination in the aged animals. Compared to the young rats, both groups of old rats evidenced a reduction in the number of choline acetyltransferase (CHAT) immunoreactive cells in the ventral subdivision of the septal complex, and a decrease in CHAT cell size in the nucleus basalis. The number of CHAT labeled cells in the pontine laterodorsal tegmental nucleus in the "old poor" rats was significantly less than in the young animals. Both groups of aged rats also evidenced decreases in dopamine (DA) levels and increases in serotonin turnover in several forebrain areas. Only the "old poor" rats showed a significant decrease in medial frontal cortical DA levels. Although aged rats evidence several neuroanatomical and neurochemical changes, few are correlated with age-related deficits in spatial learning.

403.6

GLIAL FIBRILLARY ACIDIC PROTEIN mRNA INCREASES WITH AGE IN MOUSE CORTEX. J.R.Goss*, D.G.Morgan, and C.E.Finch. (SPON: S.Hess). Andrus Gerontol. Ctr. & Dept. of Biol. Sci., Univ. of Southern Calif., Los Angeles, CA 90089-0191.

Previously, we detected a 3 fold age-related increase in GFAP RNA concentration in 3 mouse brain regions by RNA gel-blot (Northern) hybridization analysis with a small number of samples. Because of our concerns that blot-hybridization analyses are at best semi-quantitative, we have performed solution hybridization (RNase protection-titration) analyses on a more extensive series of cerebral cortical samples. Male C57BL/6J mice in 4 age groups were examined for the expression of glial fibrillary acidic protein (GFAP), glutamine synthetase (GS), THY-1 antigen and beta-tubulin RNA's.

Total RNA was prepared from four cortical pools of each age group by the guanidinium thiocyanate/CsCl centrifugation method. Solution hybridization was carried out in triplicate using six concentrations of total RNA per sample. The mass of each specific message per mass of total RNA was calculated (pg/ug).

	4mo	9-10mo	17mo	26mo
GFAP	2.13±0.20	1.89±0.47	2.29±0.34	3.90±0.16
GS	13.02±1.60	14.54±0.97	13.63±1.50	14.06±1.07
THY-1	6.09±0.42	6.11±0.25	5.92±0.77	6.10±0.35
BETA-TUB	7.40±1.10	7.98±1.50	6.87±0.88	6.40±0.73

An 80% increase in GFAP message between 4 to 26 mo is the only significant change observed. This confirms our earlier limited Northern blot analysis.

An increase in GFAP without a concomitant increase in GS, both astrocyte specific RNA's, would suggest an increase in the fibrous character of astrocytes, but not in the total number of all astrocytes (fibrous plus protoplasmic). We suggest that with age there is a shift from protoplasmic to fibrous astrocytes. Future studies will compare chemical and molecular markers for the two types of astrocytes and neurons. Supported by the John Douglas French Foundation and The Anna Greenwall Award (DGM) and the A.D.R.C. of Southern California (AG-05142 to CEF).

THE EFFECT OF ESTROGEN-INDUCED ACYCLICITY ON ESTRADIOL RECEPTOR DENSITY IN THE FEMALE C57Bl/6J MOUSE BRAIN. S.G. Kohama* and C.E. Finch (SPON: P. Gray) Andrus Gerontology Center & the Dept. of Biology, University of Southern California, Los Angeles, CA 90089-0191.

Age-related declines in the reproductive neuroendocrine axis coincide with the loss of estradiol receptors (E2r) in the rodent brain (Wise and Camp, Endo 1984). A possible mechanism may involve a detrimental impact of steroids on CNS control centers, a phenomenon that may be accelerated by exogenously administered estrogens (Finch et al., Endo Rev 1984). We examined the influence of E2-induced acyclicity in young female C57Bl/6J mice on E2r populations in the brain. Mice (4.5 mo, n=4/gp) were injected sc with oil vehicle or estradiol valerate (EV). EV-treated mice remained acyclic for 5 mo and were then ovariectomized along with oil controls. After a 2 week recovery period all mice were injected ip with [2,4,6,7,16,17-^{3}H] E2, 0.05ug/10 g body weight, then were killed after 1 h. Brains were frozen, sectioned coronally and mounted on slides, then freeze-dried and apposed to tritium-sensitive film for 5 mo, then developed.

The autoradiographs were grouped by brain regions, magnified 15.6X and optical density (OD) was evaluated using the ImageMeasure software system. Controls for the labelled steroid, 100X excess cold E2, produced no exposure images. Brain regions that were analyzed encompassed the preoptic nucleus rostrally and continued caudally to the level of the mammillary nucleus. Preliminary results showed the anterior hypothalamic region of EV-treated mice to be lower in total OD versus control animals ($p<0.05$). No differences were found at the level of the preoptic area or in the more caudal regions of the hypothalamus.

"ACCELERATED AGING" OF STRIATAL MUSCARINIC AUTORECEPTORS INDUCED BY ^{56}Fe IRRADIATION: IMPLICATIONS FOR FREE RADICAL INVOLVEMENT IN MEMBRANE ALTERATIONS IN SENESCENCE. J.A. JOSEPH, W.A. HUNT,* and T.K. DALTON* Gerontology Res. Ctr./NIA, Baltimore, MD 21224; Armd. Forces Radiobiol. Res. Inst., Bethesda, MD 20814.

Research has indicated that muscarinic enhancement of K^+-evoked release of endogenous dopamine (DA) from striatal slices is blunted in old animals and is correlated with deficits in motor performance. Subsequent research has indicated that the deficit may be the result of age-related membrane alterations in the muscarinic heteroreceptor (mHTR). The mechanism of this damage may occur through lipid peroxidation by free radicals. Thus, it was thought that it might be possible to mimic this damage using radiation. K^+-evoked release of DA was examined in striatal tissue slices obtained from young animals irradiated with 0-5 Gy of ^{56}Fe, and pre-tested on a wire suspension task (WST) (3-14 days post-irr.). Slices were superfused with a modified Krebs-Ringer medium containing 2.5 mM KCl. Later the medium was switched to one containing 30 mM KCl and 0 or 500 µM oxotremorine (OXO). Results indicated that both the OXO enhancement of K^+-evoked DA release and WST performance were lowered in all radiation groups at all times by 50 to 60%, suggesting that the mHTR membrane alterations that occur during aging may involve damage by free radicals.

THE NEURAL INFLUENCE ON FIBER TYPE TRANSFORMATION IN FAST-TWITCH MUSCLE DURING AGING. W.B. Alshuaib, K.S. Saiki* and M.A. Rehim. Andrus Gerontology Center, Univ. of Southern California, LA, CA 90089-0191.

The effective field of neural input on the extensor digitorum longus (EDL) was reduced by either partial ablation (ABL) of the muscle or by crushing the nerves (CN) of direct innervation in young and old male C57BL/6J mice, respectively. Sham operations were performed in the contralateral hindlimb as controls. Five weeks post-surgery, the muscle was surgically removed and tested for dynamic properties of contraction and relaxation. Subsequently, the tissue was then analyzed histochemically for transformational changes by ATP-ase and succinate dehydrogenase (SDH) staining. Dynamic and histochemical changes were compared with the contralateral limb. Peak tension in old-ABL and in old- CN muscle showed an attenuation of contraction. Muscle from the young mice also displayed a reduction of peak tension though of less magnitude. Further, half-relaxation time increased in old- ABL and old-CN. However, the half-relaxation time in young-ABL increased while it did not change significantly in young-CN. The number of slow-twitch fibers in old-ABL increased by 27±6% and in old-CN by 14±5%, whereas in young-ABL and young-CN, they increased by 44±7% and 26±8%, respectively. SDH staining showed a 31±5% increase in old-ABL and 18±5% increase in old-CN while young-ABL increased by 54±6% and young-CN by 32±6%. Although age-related differences in the magnitude of oxidative capacity were observed, as determined by SDH staining, the significantly greater change in oxidative capacity of ABL- and CN-EDL in either young or old mice when compared to histochemical ATP-ase transformation indicates an augmented adaptative response in oxidative enzyme activity.

403.10

ENDOGENOUS GLUTAMATE RELEASE FROM FRONTAL CORTEX SLICES OF ADULT AND AGED RATS. M.J. Meldrum, D.R. Wallace, and R. Dawson Jr. Dept. of Pharmacodynamics, College of Pharmacy, Univ. of Florida, Gainesville, FL 32610.

Endogenous excitatory amino acids have been implicated in several neurodegenerative disease states. The present studies were undertaken to determine whether basal and/or stimulated amino acid release was altered in adult or aged animals.

Frontal cortex was rapidly removed and cut into 600 micron coronal slices. Brain slices (4-5) were placed in nylon baskets and transferred to glass vials containing 1 ml of oxygenated Krebs Ringer bicarbonate buffer pH 7.4 at 37°C. After a 15 minute preincubation, tissues were transferred to fresh buffer. Amino acid release was stimulated by placement of slices in 56mM KCl. Amino acid release was measured by HPLC after OPA derivitization. KCl significantly increased calcium sensitive release of glutamate but not aspartate, glycine, or taurine. Basal and stimulated glutamate release were not different between 6 and 24 month old Fischer 344 rats (n = 7-8 per group). [^{3}H] glutamate uptake was also not different in frontal cortex slices of 6 and 24 month old Fischer 344 rats. These data suggest that endogenous glutamate release from slices of frontal cortex are not significantly altered in aged Fischer 344 rats. (Supported by a grant from the American Federation for Aging Research)

LEU-ENKEPHALIN (ENK) INHIBITS IN VITRO K$^+$-STIMULATED ENDOGENOUS DOPAMINE(DA) RELEASE FROM THE CAUDATE NUCLEUS(CN) OF YOUNG BUT NOT OLD MALE RATS.

V.D.Ramirez, N.J.Laping, D.E.Dluzen. Dept. of Physiology, University of Illinois, Urbana IL 61801.

CN were removed from young (2-3month) and old (20-25month) rats and placed in small superfusion chambers containing either KRP buffer or buffer with 10-8M or10-6M ENK and superfused at a flow rate of 10ul/min. After 50 minutes equilibration effluent samples were collected on ice every 10 minutes. During samples 5&6 the media were replaced with similar media containing 30mM K$^+$. Samples were analyzed for DA using HPLC-EC. The areas under the K$^+$ evoked DA release curves for each group were analyzed for significant differences. In young rats ENK reduced K$^+$-evoked DA release (10^{-8}M=448±103pg/mg, 10^{-6}M=295±31pg/mg*; * p<0.05 vs control 781±207). As shown previously, under control conditions old rats release significantly less DA than young rats in response to high K$^+$ (307±46pg/mg). In aged rats ENK had no effect on DA release regardless of the dose used (10^{-8}M=360±91pg/mg, 10^{-6}M=379±136pg/mg). These data suggest an important differential role of opiates in the control of DA release from the CN among young and aged animals.

AGE-RELATED CHANGES IN A SIMPLE PEPTIDERGIC NEURONAL SYSTEM SEEM TO BE RELATED TO LETHALITY IN THE MOLLUSC LYMNAEA STAGNALIS. C. Janse, W. C. Wildering, G. J. Van er Wilt and M. van der Roest. (SPON: EUROPEAN NEUROSCIENCE ASSOCIATION) Dept. Biology, Vrije Universiteit, 1007 MC Amsterdam, The Netherlands.

Lymnaea offers a suitable system to study aging processes in the CNS (Janse C. et al., Mech. Ageing Dev.35:179, 1986 and 42: 263, 1988; Slob W. and Janse C. Mech. Ageing Dev. 42: 275, 1988). Within the CNS of Lymnaea a system exists of two giant identfiable ACTH-like peptide containing neurons (ACTH-cells). The neurons branch extensively over the CNS and are electrotonically coupled.

Recently we found that the ACTH-cells mediate adaptive (cardio-respiratory) responses of Lymnaea to environmental oxygen levels and receive aminergic inhibitory synaptic input from oxygen senstive receptors in the skin (Van der Wilt G. J. et al., in prep.). Although in the isolated CNS both cells are spontaneously active only one of them contains a pacemaker. In addition they differ in other types of synaptic input. Obviously coupling of the cells assures functional integration.

Up to 12 months the mean coupling rate of the ACTH-cells decreases (due to increase of junctional resistance, Rj) with a concomittant increase of the individual variability of Rj (Janse C. et al., 1986; Wildering W. C. et al., in prep.). In the age groups between 12 and 20 months (ca. maximum age), however, coupling rate increased and individual variability of Rj decreased again with age. Consequently, in the very old groups only animals with high coupling rate and low Rj were found.

The variability in Rj between different animals might reflect individual variability in pace of aging between animals. The extremely low variability in the oldest group, however, is the result of the total absence of animals with low coupling rate in this group. This in turn might be due to a decreased vitality of old animals with low coupling (although recovery of coupling can not be excluded). The low individual variability in the oldest group also signifies in this view the importance of coupling between the ACTH-cells in old animals.

Due to asymmetry of the ACTH-cells coupling will contribute to the integrated response of both cells to changes in environmental oxygen levels. This, together with the increasing importance of coupling between the ACTH-cells in old animals, suggests that animals of about 12 months of age with relatively badly coupled ACTH-cells are highly vulnerable to changes in environmental oxygen levels.Experiments are in progress to test this hypothesis.

Subtractive Cloning Used to Investigate Age-Related Changes in Gene Expression in Rat Brain. M.J. Blake, J. Fargnoli*, A. Fornace*˜ and N.J. Holbrook*. Lab. Molecular Genetics NIA (GRC), Baltimore, MD. 21224 and ˜Radiation Oncology Branch, NCI, Bethesda, MD.

The brain provides an advantageous model to assess the contribution of the genome to the aging process due to its large diversity of gene products and several well characterized, age-related structural and physiological alterations. To investigate changes in mRNA expression that occur with aging, subtraction hybridization cloning was used to generate a cDNA library enriched for sequences in young adult (5mo.) rat brain by subtracting with RNA derived from old (24mo.) brain. Initial screening of the library demonstrates that several clones show a 5X or greater expression in brain than in liver, kidney or lung. Regional brain localization experiments indicate several common distribution patterns with over 60% of our clones showing a predominant expression in the cerebellum and striatum. Results indicate that changes in expression with aging show high individual variation and may be localized within specific brain regions.(Support: MacArthur Foundation; NRC Res. Assoc. to MJB)

REPEATED ADMINISTRATION OF α-MSH DOES NOT ALTER THE INCREASED ANTIPYRETIC EFFECT OF α-MSH IN AGED RABBITS. L. B. Deeter*, L. W. Martin* and J. M. Lipton (SPON: R. E. Dill). Dept. of Physiol., The Univ. Tex. Southwestern Med. Ctr. at Dallas, Dallas, TX 75235.

α-MSH, an endogenous neuropeptide, is a potent antipyretic when administered centrally or peripherally. The concentration of α-MSH in the brain decreases with age, and older rabbits exhibit greater sensitivity to centrally administered α-MSH. To determine whether this increased responsiveness of older rabbits is due to a modifiable hypersensitivity to the peptide, we attempted to alter the central reaction to α-MSH in aged rabbits via repeated injections.

Rabbits were assigned to one of four groups: old female (3-5+ years), young female (<2 years), old male (3-5+ years), or young male (<2 years). The rabbits were made febrile by i.v. injection of crude interleukin-1, and 500 ng α-MSH was injected into a lateral cerebral ventricle via an indwelling cannula. For 10 days, the rabbits were given either 500 ng α-MSH or saline, then the rabbits were tested again for antipyretic response to α-MSH. Neither aged nor younger rabbits showed altered responses to the peptide after prolonged treatment. These results indicate that the hypersensitivity of aged animals to α-MSH cannot be reduced to the level seen in younger animals, and that there is no development of tolerance to repeated injections of α-MSH.

Supported by NIH GRANT AG00109 and NINCDS NS10046.

AGE-RELATED DIFFERENCES IN BEHAVIORAL AND CEREBRAL METABOLIC RESPONSES TO MCPP IN THE RAT. U. Freo*, T.T. Soncrant*, K.M. Wozniak*, D.M. Larson* and S.I. Rapoport (SPON: H. Levitan). Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892.

To determine the functional significance of reported losses of brain serotonin receptors with age, we measured changes in local cerebral glucose utilization (LCGU) and behavior in young and senescent rats after treatment with m-chlorophenylpiperazine (MCPP), a preferential serotonin-1b receptor agonist. LCGU was measured with the quantitative, autoradiographic [14C]deoxyglucose method in groups of 6-8 male Fischer rats, aged 3, 12, or 24 mo, at 0, 15, or 90 min after MCPP 2.5 mg/kg i.p. Rotorod performance was assessed for 2 h after MCPP in parallel experiments. Additionally, the time course of MCPP brain concentrations was determined by HPLC analysis in 3, 12, and 24 mo rats.

Peak brain MCPP levels were reached at 15 min and were similar for all ages. The brain half-life was prolonged in older animals (75, 94, and 116 min in 3, 12, and 24 mo rats); the MCPP concentration at 90 min was 1.7 times greater in 24 mo than in 3 mo rats. MCPP impaired rotorod performance maximally at 15 min at all ages. By 90 min, 3 mo animals had completely recovered, whereas 24 mo rats remained maximally affected; 12 mo animals showed partial recovery.

LCGU was reduced ($P < 0.05$) at 15 min after MCPP in 49 of 74 brain regions of 3 mo rats (mean reduction 20%), but returned to control values by 90 min. At 15 min after MCPP in 12 and 24 mo rats, fewer regions were affected (27 and 17) and mean LCGU reductions were smaller (11 and 3%). At 90 min, LCGU showed partial recovery in 12 mo rats and minimal or no return to baseline in 24 mo animals.

These results demonstrate an age-related reduction in functional responsivity of the rat brain to serotonergic stimulation that is apparent by 12 mo of age. Prolonged effects of MCPP on behavior and LCGU in older rats probably are due to age-related changes in MCPP metabolism.

403.16

MODIFICATION OF PHORBOL ESTER BINDING AND PKC ACTIVITY IN VARIOUS BRAIN AREAS OF AGED RATS. F. Battaini, R. Del Vesco*^, S. Govoni*+, C. Lopez*^, M. Trabucchi. Chair of Toxicology, II University of Rome, ^Ist. of Pharmacol. Sci. Univ. of Milan, +Dept. of Pharmacobiology, Univ. of Bari, ITALY.

[3H]-Phorbol 12,13-dibutyrate ([3H]-PDBu) binding was investigated in various brain areas of young and aged male rats. No age-related modification in kinetic parameters were observed in cortex, hippocampus and cerebellum. In hypothalamus Bmax was decreased by 39% whereas in pituitary Bmax was almost doubled in old rats. PKC activity, measured after partial purification of the enzyme, using histone III S as substrate, was reduced in soluble fractions prepared from the cortex (61% decrease) which does not display changes in [3H]-PDBu binding. The discrepancy between binding and phosphorylating activity data could be related to an age-related modification in enzyme sensitivity to the physiological activators not involving the phorbol ester binding site. The reduced availability of PKC in soluble fraction may affect those neuronal mechanisms involving a transfer (and therefore the activation) of PKC molecules from the cytoplasmic pool to membranes.

403.17

SIMILARITIES BETWEEN RADIATION AND AGING ON THE FUNCTION OF SUBSTANTIA NIGRA DOPAMINE NEURONS. J. Frascella, J.A. Joseph, & W.E. Murray* Behavioral Sciences Dept., Armed Forces Radiobiol. Res. Inst., Bethesda, MD 20814.

The effects of radiation and aging on motor function are similar (e.g. ataxia, loss of balance and coordination), and studies have revealed that changes that take place with nigrostriatal dopamine (DA) cells in aging lead to degenerative motor disorders. A proposed mechanism for the changes produced by aging is the generation of and inability to scavenge free radicals. Because ionizing radiation is very effective in generating free radicals, the purpose of this study was to investigate the functioning of nigral DA cells in radiation-exposed and aged rats in an attempt to determine a common mechanism underlying motor deficits observed with radiation and aging.

Substantia nigra DA cells in chloral hydrate anesthetized Fischer rats were recorded extracellularly by conventional techniques. Irradiated rats were exposed to 60 Gy of either γ-photons or high-energy electrons, and aged rats were between 26 and 32 months of age. Autoreceptor-specific doses (0.5-2.0 μg/kg, i.v.) of the DA agonist, apomorphine, were administered, and results showed that compared to controls, apomorphine inhibited the firing rate of DA cells to a greater extent in the irradiated and aged animals. Also, DA cells from both groups showed a greater sensitivity (increased firing rate) to the DA antagonist, haloperidol, at low doses (50-100 μg/kg, i.v.). Thus, these results suggest that a common mechanism might produce the changes in DA cell function in both irradiated and aged animals. This mechanism could be related to increased amounts of free radicals present in the nigrostriatal pathway that would affect nigral cell function and consequently motor behavior.

Pathlength analysis of age-related dendritic regression. R. Pentney, H. Ngo, and L. Quackenbush, Dept. of Anat. Sci., State Univ. of NY, Buffalo, NY 14214

A new method for analysis of dendritic regression in the Purkinje cell (PC) network showed that age-related PC regression was confined to terminal dendritic links (TL) and that it progressed by gradual shortening of TL rather than by deletion of TL at junctions (Pentney et al, Anat. Rec. 220:79A, 1988). Subsequent application of the method to PC networks from alcoholic rats (Pentney and Quackenbush, Alcoholism: Clin and Exper Res. 12:324, 1988) suggested a need for precise localization of affected network terminals by measurement of dendritic pathlengths (dendritic lengths between soma and TL tips). The method developed and applied here to networks from aging rats will be applied subsequently to networks from aging, alcoholic cohorts. Cerebellar cortices from Fischer 344 rats, 10, 18, and 28 months of age, were prepared by the Golgi-Cox procedure. Randomly selected PC networks from coded parasagittal sections were drawn and then measured on a digitizing tablet. Pathlengths for all terminals were obtained by computer analysis of these measurements, then averaged and sorted for minimum and maximum values. The data revealed that the maximum dendritic pathlength decreased significantly in PC networks of 18 month old rats ($p<.05$). Ongoing analysis of frequency histograms of pathlengths will provide data reflecting changes in density of terminals within networks. (NIAAA grant AA 05592)

BEHAVIORAL PHARMACOLOGY: MONOAMINES

404.1

SOUND PRESSURE LEVEL AND ADRENOCEPTOR INFLUENCES ON AUDIOGENIC SEIZURES IN DBA AND PRIMED C57BL MICE. C.E. Lints, A. Mayall* and D. Capruso*. Dept. of Psychology, Northern Ill. Univ., DeKalb, IL 60115.

Experiment 1 examined the relationship between sound intensity and audiogenic seizure (AGS) activity in 21- and 30-day-old genetically seizure prone DBA mice. At both ages, and for the intensities tested, AGS activity increased as sound intensity was increased above seizure threshold. However, the higher intensities were less effective in eliciting the full AGS syndrome in the older mice. In Experiment 2, the alpha-1 antagonist prazosin produced anticonvulsant effects in 21-day-old DBA mice. The alpha-2 antagonist yohimbine failed to exert proconvulsant effects at the doses tested, although the higher doses produced anticonvulsant effects. In Experiments 3 and 4 genetically seizure resistant C57BL mice were first rendered AGS susceptible through acoustic priming at 16 days-of-age and then tested as in Experiments 1 and 2 when they were 21 days old, replicating the results with DBA mice. In addition, the beta-1 antagonist atenolol produced anticonvulsant effects in the primed mice (Experiment 4). The results suggest that primed AGS in C57BL mice may represent a neuropharmacological phenocopy of the DBA syndrome, and that the midbrain adrenoceptor hypothesis may extend to primed C57BL mice.

404.2

FOREBRAIN NOREPINEPHRINE (NE) LESIONS DO NOT ELIMINATE THE EFFECTS OF ENRICHED ENVIRONMENTS ON SPATIAL MAZE PERFORMANCE. Susan J.E. Murtha, Bruce A. Pappas, and Shankar Raman*. Dept. of Psychology, Carleton Univ., Ottawa, Ont., K1S 5B6.

Previous research has shown that neonatal systemic 6-hydroxydopamine (6-OHDA) eliminates several effects of enriched (E) vs impoverished (I) rearing. Since this treatment not only lesions forebrain NE terminals but also causes a peripheral sympathectomy, either of these effects or their combination could alter the response to E/I rearing. Accordingly, we examined the effects of lesioning only the brain by intraventricular 6-OHDA in the neonate or 6-OHDA lesion of the dorsal NE bundle in the adult.

At 24 and 48 hours after birth, buproprion pretreated (to protect dopamine terminals) rats received bilateral intraventricular injection of 12.5 ug 6-OHDA. At weaning, half the rats were raised in E or I environments respectively for 35 days. The adult treated rats received 6-OHDA (4 ug) into the dorsal tegmental bundle and were subsequently housed in E or I conditions for 42 days. Following this the rats were extensively tested in a modified Hebb-Williams maze. Both the infant and the adult E-housed control rats made fewer errors than their I-housed counterparts. Furthermore, although both the neonatal and the adult lesioned rats showed substantial and selective lesions of forebrain NE terminals, these rats also showed a performance enhancing effect of E rearing. We conclude that lesioning of forebrain NE by itself does not eliminate the beneficial effects of chronic exposure to an E environment on spatial problem solving.

404.3

EFFECTS OF CHRONIC CENTRAL VERSUS PERIPHERAL INFUSION OF A BETA-BLOCKER ON AGGRESSION. M.L. Leavitt*, J.C. Maroon*, S.C. Yudofsky*, E.J. Riley*, and M.B. Bavitz*. (SPON: W.E. Hoffman). Allegheny-Singer Research Institute, Pittsburgh, PA 15212-9986.

The lipophobic beta blocker nadolol (Nad) clinically decreases aggressive behavior following large daily oral doses. To investigate its mode of action, we have compared the effects of intraventricular (IVT) versus subcutaneous (SQ) infusion of Nad on shock-induced attack behavior (SIA). Male 6-hydroxydopamine-treated rats (IVT, 2x200 µg) had baseline SIA measured before implanting minipumps that infused either: A. IVT Nad (0.25 mg/kg/day, N=8); B. IVT Nad (0.01 mg/kg/day, N=5); C. SQ Nad (0.25 mg/kg/day, N=5); D. SQ Nad (2.5 mg/kg/day, N=6); or E. SQ saline-mock pumps (N=5). SIA was monitored every 2-3 days and averaged over consecutive 7-day periods. SIA was significantly reduced compared to baseline during IVT Nad infusion at both 0.25 and 0.01 mg/kg/day. SQ Nad also reduced SIA but only at a dose 10 times the highest IVT dose.

	Baseline	Week 1	Week 2	Week 3	Week 4
A	41.6±1.4	32.2±1.6§	30.2±1.5§	-	-
B	41.5±2.2	34.1±2.6*	31.4±2.4*	-	-
C	36.7±1.0	36.2±0.9	37.7±1.4	-	-
D	40.2±2.3	30.8±3.8*	33.4±4.2	29.6±3.8*	27.2±2.6^{+}
E	37.4±4.0	35.9±4.8	37.2±2.6	39.1±0.9	40.8±2.2

*p<.05, $^{+}$p<.005, §p<.001 vs. baseline

These results suggest that lipophobic beta blockers may reduce aggressive behavior via a central mechanism.

404.4

EXTENDED BLOCKADE OF QUIPAZINE CUE CORRELATES WITH CHANGE IN 5HT-2 RECEPTOR SENSITIVITY, BUT NOT BINDING. R.L. Smith, R.J. Barrett, and E. Sanders-Bush. Dept. of Psychology and Pharmacology, Vanderbilt Univ. and VA Medical Center, Nashville, TN 37209

The present study was conducted to investigate the duration of action of 5HT-2 antagonists. Rats were trained on a saline-quipazine (Q) (1.5 mg/kg) discrimination. Following acquisition, independent groups were injected with 2 mg/kg mianserin (M). These groups were then tested at 12 h intervals for their ability to discriminate Q. Blockade of the Q cue persisted for up to 60 h following M administration. Duration of blockade was dose-dependent. Two other 5HT-2 antagonists, pizotifen and metergoline, showed similar profiles of extended antagonism. Changes in 5HT-2 receptor density and sensitivity were investigated as possible mechanisms for M's prolonged antagonism. M (2 mg/kg) caused a decrease (52%) in the density of 5HT-2 sites at 24 h but was recovered at 36 h. 5HT-2 stimulated phosphoinositide hydrolysis was used to assess 5HT-2 receptor sensitivity. Mianserin caused a significant reduction in the maximum response that persisted for 60 h. Hence, the time course for recovery of receptor sensitivity corresponded to that of the behavior while receptor density did not. (Supported by MH34007 and Veterans' Administration.)

PHARMACOLOGICAL EVALUATION OF 5-HT$_1$ RECEPTOR MEDIATED TURNING AND BEHAVIORAL SYNDROME IN THE RAT.
E.Horváth*, J.De Vry*, T.Glaser* and J.Traber* (SPON: F.K. Pierau), Neurobiology Department, Tropon Pharmaceuticals, Neurather Ring 1, D-5000 Köln 80, F.R.G.

A substantial body of evidence points to an important role of central 5-HT receptors in various psychological processes. To study those receptors and selective ligands in vivo, suitable animal models have to be pharmacologically characterized. In rats with an unilateral lesion of the dorsal raphe nucleus potent 5-HT$_{1A}$ receptor agonists such as 8-OH-DPAT (Blackburn et al., Psychopharmacol. 83: 163-165, 1984) or BAY R 1531 induced dose-dependently contralateral turning. This behavior could be prevented by pretreatment with the non-selective 5-HT antagonist methiothepine, and partially by racemic pindolol; whereas the 5-HT$_2$ receptor antagonist ritanserin was inactive. Neither of the 5-HT antagonists induced contra- or ipsilateral turning themselves. Compounds acting on other subtypes of 5-HT receptors like TFMPP, ICS 205-930 and GR38032F were inactive when applied alone. DA agonists such as SKF 38393 and pergolide were ineffective and the DA antagonists SCH 23390 and haloperidol failed to inhibit 8-OH-DPAT induced turning. The 5-HT$_{1A}$ receptor partial agonists ipsapirone, buspirone and gepirone partially induced turning and partially blocked 8-OH-DPAT activity. In intact rats, 5-HT$_{1A}$ receptor agonists reliably induced forepaw treading, Straub's tail and locomotor activity in a dose-dependent manner. 5-HT$_{1A}$ receptor partial agonists as well as (non)selective ligands for the other 5-HT receptor subtypes failed to induce these elements of the 5-HT syndrome. These data show strong quantitative and qualitative similarities with those obtained in the turning model and also correlate well with in vitro data.

HABITUATION AND DIAZEPAM SUPPRESS NOVELTY-INDUCED ACTIVITY IN ASCENDING 5-HT SYSTEMS. S.R. Bodnoff, D.H. Aitken, M. Doherty, B.E. Suranyi-Cadotte, R. Quirion, and M.J. Meaney. Douglas Hospital Research Ctr., Dept. Psychiatry McGill Univ., Montréal H4H 1R3, Canada.

Novelty results in increased arousal and a suppression of appetitive behaviors in the rat. Repeated exposure to an innocous, novel environment (habituation learning), alleviates these responses and the effectiveness of these stimuli to inhibit appetitive behaviors. This process can be circumvented with anxiolytics: Hungry animals given food in a novel environmenteat more readily following benzodiazepine (BZ) treatment, mimicking the effects of habituation. Likewise, RO15-1788 (central BZ receptor antagonist) blocks the behavioral effects of habituation.

We then exposed food-deprived rats to food in a novel environment following 0 or 7 days of habituation, or an injection of diazepam (2 mg/kg). Both 7-days habituation and diazepam decreased the latency to begin feeding. All animals were sacrificed 5 min following exposure to the novel environment and 300 uM brain sections were processed for microdissection. Norepinepherine (NE), serotonin (5-HT), and their metabolites were measured using HPLC with electro-chemical detection. In the raphé nuclei, both habituation and diazepam decreased 5-HT content and turnover and decreased NE content compared to controls. Thus, habituation and BZ's appear to share a common mechanism of action that inhibits ascending 5-HT systems and anxiety.

5HT$_{1A}$ AGONISTS AND EXCITATORY AMINO ACID ANTAGONISTS EXHIBIT ANXIOLYTIC ACTIVITY IN THE SOCIAL INTERACTION TEST AND THE ELEVATED PLUS MAZE. R. Corbett*, R. W. Dunn*, H. M. Geyer III*, M. Cornfeldt and S. Fielding. (Spon: C. P. Smith). Department of Biological Research, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876.

In the social interaction (SI) test, anxiety is generated by the novel situation of placing unfamiliar pairs of rats together in a familar setting, while in the elevated plus maze, exposure to an elevated open alley results in an approach-avoidance conflict in rats. In the present study, two classes of compounds, namely, the 5HT$_{1A}$ agonists and NMDA antagonists, showed anxiolytic activity in these paradigms. Following intraperitoneal administration, the 5HT$_{1A}$ agonists 8-OH-DPAT (0.2-0.4 mg/kg), buspirone (1-10 mg/kg) and gepirone (2.5-10 mg/kg) significantly increased SI time by +114%, +69% and +78%, respectively, while increasing open alley exploration (AE) by +108%, 70% and 43%. Likewise, the N-methyl-D-aspartate (NMDA) antagonists, CPP (2.5-10 mg/kg), 2-amino-5-phosphonopentanoic acid (30-60 mg/kg) 2-amino-7-phosphonoheptanoic acid (20-40 mg/kg) and the noncompetitive NMDA antagonist, MK-801 (0.05-0.1 mg/kg) increased SI by +59%, +73%, +116% and +51%, respectively, while increasing AE by +88%, +92%, +30% and +88%. In summary, both 5HT$_{1A}$ agonists and NMDA antagonists were anxiolytic in two different anxiety tests, suggesting that anxiety is mediated by serotonin and excitatory amino acid systems.

ULTRASONIC VOCALISATIONS BY RAT PUPS AS AN ANIMAL MODEL FOR ANXIOLYTIC ACTIVITY. J.Mos*, P.Bevan and B.Olivier. Dept of Pharmacology, Duphar B.V., P.O.Box 2, 1380 AA Weesp, The Netherlands.

Rat pups separated from their mother and littermates produce ultrasonic calls with a frequency of 40-55 kHz. Pups were tested at an age between 9 and 12 days during a 5 min period. Ultrasonic recording equipment and counters were used to measure the effects of antidepressants under two environmental conditions, viz. a cold (18°C) and a warm (37°C) plate. The more stressful cold plate evoked considerably more calls than the warm plate.

Benzodiazepines reduced ultrasounds under both conditions thereby confirming their anxiolytic activity. The purported 5-HT$_{1a}$ ligands 8-OH-DPAT, buspirone and ipsapirone all reduced ultrasounds under both conditions. The mixed 5-HT$_{1a/b}$ agonists RU24969 and eltoprazine (DU 28853) reduced ultrasonic calling only under the cold plate condition. The same applied for the 5-HT$_{1b}$ agonist TFMPP and the mixed 5-HT$_{1/2}$ agonist quipazine. Antagonists of the 5-HT receptor -methysergide and ritanserine- were ineffective in suppressing the ultrasonic calls. Drugs affecting serotonin turnover by inhibiting reuptake, such as fluvoxamine and zimeldine reduced pup ultrasounds when tested under cold testing conditions.

As reference compounds, pentobarbital, scopolamine, d-amphetamine, pentrazol, sulpiride and haloperidol were tested, none of which affected ultrasound production in a dose-dependent way.

In this animal model, non benzodiazepine anxiolytics (5-HT$_{1a}$ ligands) are thus reliably detected. At present we view those substances that only inhibit the pups reactions at the cold plate as potentially anxiolytic, albeit weaker than the benzodiazepines and the more recently developed non-benzodiazepine anxiolytics.

NORFENFLURAMINE PROVIDES STIMULUS CONTROL: COMPARISON WITH FENFLURAMINE. D. McBurney*, J.W. Boja, and M.D. Schechter, Dept. Pharmacol. Northeastern Ohio Univ. Coll. of Med., Rootstown, OH 44272.

Male rats were trained to discriminate 1.4 mg/kg norfenfluramine (NF) from its vehicle using a two-lever, food-motivated operant discrimination task. Once trained, the rats showed a dose-dependent decrease in responding on the NF-correct lever following decreased doses of NF (ED_{50}=0.71 mg/kg). Administration of 2.0 mg/kg fenfluramine (FEN) produced 100% responding on the NF-correct lever and decreasing doses of FEN, likewise, produced a dose-dependent decrease in responding on the NF-correct lever (ED_{50}=1.30 mg/kg). Time-course data indicated that NF has a fast onset and a peak effect at 20-60 min after administration. Analysis of the time-course data provided a half-life of approximately 8 hrs. In contrast, FEN did not show the rapid onset that was observed with NF. However, FEN had a similar peak effect and half-life. These results indicate a pharmacological similarity between NF and FEN, However, the difference in onset of action suggests a possible difference between the parent drug and its metabolite.

SUBSENSITIVITY TO THE BEHAVIORAL EFFECTS OF THE TRH ANALOG MK-771 FOLLOWING TREATMENT WITH 3-ACETYLPYRIDINE (3-AP). M.S. Kreider, S. Wieland and I. Lucki.(SPON: J. Winkler). Dept. of Psychiatry, Univ. of Pennsylvania, Philadelphia, PA 19104.

Systemic administration of 3-AP to rats produces lesions of the inferior olivary complex resulting in dystonic symptoms. We studied the functional and morphological integrity of the TRH system in rats treated with 3-AP by examining the following: head shake response produced by the TRH agonist MK-771, TRH levels in 12 brain regions, and the density of TRH receptors using receptor autoradiography.

Treatment with 3-AP significantly reduced the ability of MK-771 (0.63-10.0 mg/kg) to produce the head shake response. The ED50 value for MK-771 was shifted to the right and the peak response was reduced by 50% after 3-AP. TRH levels were unchanged in all brain regions following 3-AP treatment. TRH receptor density of measured using ^{3}H-MeTRH, was significantly reduced in laminae 4-10 of the cervical spinal cord. The subsensitivity found to the behavioral effects of MK-771 following 3-AP treatment may be associated with a down-regulation of TRH receptors.

404.11

ENHANCED SENSITIVITY TO THE BEHAVIORAL EFFECTS OF SEROTONIN (5-HT) AGONISTS FOLLOWING TREATMENT WITH 3-ACETYLPYRIDINE (3-AP). S. Wieland, P. McGonigle and I. Lucki. Dept. of Psychiatry, Univ. of Pennsylvania, Philadelphia, PA 19104.

Systemic administration of 3-AP to rats produces lesions of the inferior olivary complex resulting in symptoms of dystonia. We studied the functional and morphological integrity of the 5-HT system in rats treated with 3-AP by examining the following: two behavioral responses caused by stimulating 5-HT receptors, 5-HT and 5-HIAA content in six different brain regions, and the density of 5-HT_{1A} and 5-HT_2 receptors using receptor autoradiography.

Rats treated with 3-AP were 3-fold more sensitive to the ability of the 5-HT_{1A} agonist 8-OHDPAT to produce the 5-HT syndrome. Similarly, the 3-AP treated rats were 2-fold more sensitive to the selective 5-HT_2 agonist (+)-DOB at causing the head shake response. 5-HT and 5-HIAA levels were unchanged in six brain regions following 3-AP treatment. 5-HT_{1A} receptor density measured using ^{3}H-8-OHDPAT, was unchanged in the spinal cord, the CNS area associated with the 5-HT syndrome. Presently, the supersensitivity found to the behavioral effects of 5-HT agonists following 3-AP treatment cannot be explained by direct morphological changes to 5-HT neurons or receptors.

REGIONAL CORTICAL BLOOD FLOW DURING COGNITIVE ACTIVATION IN DOWN SYNDROME. K. F. Berman, M. B. Schapiro*, R. P. Friedland, S. I. Rapoport and D. R. Weinberger. Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032, and Laboratory of Neurosciences, NIA, NIH, Bethesda, MD 20892.

Few studies of pathophysiology in young, cognitively disabled patients, such as those with Down Syndrome (DS), have been carried out. Using the xenon133 inhalation method, we measured regional cortical blood flow (rCBF) in 11 non-institutionalized physically healthy, mildly to moderately retarded trisomy 21 DS patients (three women and eight men; mean age = 28 years; mean mental age on Peabody Picture Vocabulary = Test 8 years, range 4 to 16) and 22 age- and sex-matched normal controls. Following an initial resting state rCBF study on each of two consecutive days, subjects had rCBF measured during four different cognitive activation conditions: on day 1, during Raven's Progressive Matrices (RPM), which is a posterior cortical activator, and during a nonspecific control task; and on day 2, during the prefrontally-linked Wisconsin Card Sort (WCS) and during another nonspecific control task.

Despite poor performance on the WCS, DS patients increased prefrontal rCBF during the WCS compared to baseline (mean [$\pm$ SEM] change in rCBF, 5.0 $\pm$ 1.7 IS units, $P < .02$, paired T-test) in a fashion similar to normals (4.6 $\pm$ 1.9, $p < .03$). During RPM there were no significant differences between the two groups, but DS patients did not activate posterior cortical areas as normals did (patients: 0.9 $\pm$ 1.6, $p = .57$; normals: 4.7 $\pm$ 1.4, $p < .004$). These data may suggest differential pathophysiological involvement of anterior and posterior cortical systems in DS.

NEUROMAGNETIC VISUAL EVOKED RESPONSES TO SINUSOIDAL GRATINGS. J. S. George*, C. J. Aine, and E. R. Flynn, (SPON: D. L. Arthur). Neuromagnetism Laboratory, Los Alamos National Laboratory, MS M882, Los Alamos, NM 87545.

Neuromagnetic evoked responses were recorded for visual stimuli presented in the central visual field (CVF) or 8° in the right visual field (RVF). Stimuli were high contrast, intensity-modulated vertical sinusoidal gratings of 1 (Lo) or 5 (Hi) cycles per degree, that occupied 2.0°H x 1.5°V. Neuromagnetic data were collected at 42 sensor locations over occipital and parietal regions. Field amplitudes were sampled at 10 ms intervals from continuous waveform data to produce a temporal series of neuromagnetic field maps which were then fit by a current dipole model using least squares procedures. In this presentation we focus on data from three human subjects. Calculated RVF response sources were deeper than those for corresponding CVF stimuli. Field amplitudes and calculated current moment for the initial response peak were smaller for RVF than for CVF stimuli and generally peaked earlier. Major differences in field distribution and calculated source location and orientation were observed as a function of visual field of stimulation. Smaller but apparently significant differences were observed as a function of spatial frequency in early response components for a particular stimulus location. Lo spatial frequency (SF) gratings produced larger field amplitudes and larger current moments than Hi SF for RVF stimuli.

405.3

FRONTAL EEG COHERENCE AND INTELLIGENCE--A POSITIVE CORRELATION. R.S. Hernandez, A.T. Arenander, W.D. Sheppard, R.W. Boyer, and M.C. Dillbeck. Depts. of Physiological and Biological Sciences, and Psychology, Maharishi International University, Fairfield, IA 52556.

The relation of cortical EEG coherence (COH) and measures of cognitive performance have been reported by a number of researchers. In particular, Thatcher et al. (Cognitive Processing in the Right Hemisphere, Perecman, '83, 125-146) found a negative correlation between COH during eyes-closed (EC) rest and IQ in children. In contrast, Orme-Johnson et al. (abst. 15th Winter Conf. on Brain Res.) found a positive correlation between frontal COH during Transcendental Meditation (TM) practice and IQ in adults. This study attempted to reconcile these findings and to further clarify the functional significance of cortical COH by testing COH-IQ correlations across a dynamic range of mental states. We report here an anterior-posterior gradient in the COH-IQ correlations (corr.) in children across three task conditions tested.

The WISC-R was administered to 48 children (10 to 16 years). EEG COH was calculated for 4 frequency bands across 16 scalp leads during 3 task conditions: EC rest, a mental arithmetic task, and TM practice. Polynomial regression analyses of full scale IQ regressed on each of the COH variables demonstrated significant negative corr. in posterior scalp locations across all frequency bands and all task conditions. However, a consistent trend toward positive corr. was found in frontal leads for all 4 frequency bands in all task conditons. Multiple analyses of covariance demonstrated that the differences in anterior and posterior corr. were significant in delta and theta frequencies in all task conditions. The negative posterior COH-IQ correlations reported here across task conditions indicate the robustness of previous findings. In contrast, the significant postitive frontal corr. suggest that the functional significance of COH may depend upon scalp location, with frontal COH being distinct from posterior regions. These findings also suggest that TM practice produces measurable changes in the functional activity of frontal areas of the brain.

405.4

EEG COHERENCE AND SEMANTIC PROCESSING UNDER SUBLIMINAL AND SUPRALIMINAL TASK CONDITIONS. W.D. Sheppard II and R.W. Boyer.* Dept. of Biological and Physiological Sciences, Maharishi International University, Fairfield, IA 52556.

Twenty-four subjects were presented 240 randomized trials of a Lexical Decision Task (LDT) while connected to a 16 electrode EEG montage. EEG data were acquired for two seconds prior to the onset of each LDT trial. Each LDT trial consisted of a fixation asterisk (6-12s), a prime letter string (17 or 153ms), a pattern mask (300ms), and a target letter string which remained on the monitor until the subject pressed one of two buttons, word or nonword. Following the lexical decision the subject gave a verbal report identifying the prime as word or neutral and a number estimate of the confidence of that report. Results showed significantly different relationships between coherence and semantic effects depending upon prime duration and prime-target relatedness. High pretrial coherence in left frontal areas was associated with more efficient processing in fast prime trials but less efficient processing in slow prime trials. High coherence in left temporal-parietal areas showed the opposite trend but only in related prime-target trials. The relationship between high interhemispheric coherence and semantic effect was significantly different in fast vs slow prime trials but only in the unrelated prime-target trials. A model relating flow of information during cognitive processing and coherence is discussed.

405.5

DIFFERENTIAL PROCESSING OF AUDITORY STIMULI CONTINUES DURING SLEEP Nielsen-Bohlman*, L., Knight, R. T., Woods, D. L., & Woodward*, K. Neurology Dept., U. C., Davis, V.A.M.C., 150 Muir Rd., Martinez, Ca. 94553.

The principal component of the waking auditory evoked potential (AEP) is the N1, a negative potential peaking at 100 msec. We examined N1 amplitude in waking and stage II-IV sleep, and compared it to the most prominent sleep AEP, the N2 (latency 300 msec). Eighty percent of stimuli were 1.0KHz tones (1.0 sec ISI, 60dBSL). Response to stimulus deviance was evaluated by randomly presented tones of a different frequency (1.5KHz) or complex novel sounds, each occurring in 10% of trials. The waking N1 was maximal in amplitude at frontal scalp sites, with small additional peaks at temporal sites. Deviant stimuli generated a mismatch negativity (MMN) of 4.0 uV at frontal sites. During stage II sleep N1 amplitude was reduced. MMN was present but also reduced to 1.0 uV. In stage III-IV sleep N1 was abolished at all sites. AEPs during stage II-IV sleep were dominated by a centrally distributed N2 component (latency 324 msec). N2 amplitude increased in response to deviant stimuli in all sleep stages. These data suggest that the intracranial sources of AEPs change from wakefulness to sleep. Furthermore, the augmented response to deviant sounds observed during waking and all sleep stages indicates that differential processing of auditory stimuli persists during sleep.

405.6

SEX DIFFERENCES IN THE ERPS TO VERBAL AND NONVERBAL MEMORY TASKS. M.J. Taylor*, M.L. Smith* and K. Iron* (SPON: W.J. Logan). Div. of Neurol., Hosp. for Sick Children and Dept. of Psychol., Univ. of Toronto, Toronto, Canada, M5G 1X8.

Recently it has been suggested that patterns of hemispheric specialization vary with gender. For example, studies of aphasic and apraxic patients indicate that men and women differ in terms of anterior to posterior organization of function within the left hemisphere (Kimura, 1983, 1987, Can. J. Psych.). In the present study, gender differences in the neurophysiological substrates underlying memory were investigated in normal subjects (13 women, 8 men) by recording the event related potentials (ERPs) from 19 scalp electrodes during performance on visual recognition tasks for recurring verbal items (RV) and recurring abstract figures (RF). The mean reaction times did not differ for the tasks, whereas the latencies of the memory-related components (N4 and P3) were significantly longer for RF. Significant lateral asymmetries were seen only in N4 (larger on the left in both tasks). No significant differences were found between the tasks or sexes in the reaction times or error rates. There were significant sex by task interactions in the ERPs due to larger ERPs anteriorly for females for both tasks, but slightly larger ERPs posteriorly for males in the RV task. This was found only for the cognitive components (P2, N4, P3). The differences found in normal subjects between the sexes extend the evidence from neuropsychological studies in patient populations that men and women differ in terms of anterior to posterior organization of function.

405.7

EVENT-RELATED POTENTIALS TO VISUAL "POP-OUT" STIMULI. S.J. Luck* & S.A. Hillyard (SPON: G.R. Mangun). Dept. of Neurosciences, University of California, San Diego, La Jolla, CA 92093.

When a visual display contains an item that differs from the background on the basis of a basic visual feature, that item can be discriminated by an early, preattentive stage of processing. In subjective terms, it appears to "pop out" from the rest of the display. We recorded event-related brain potentials from 12 young adults while they engaged in a task that required them to discriminate pop-out stimuli.

Subjects were presented with displays of 8 randomly located colored bars. On no-pop-out trials (p=.5) all 8 bars were blue and vertical, and on pop-out trials, 1 of the bars was either horizontal (p=.17), green (p=.17), or wide (p=.17). For each run, 1 of the 3 pop-outs was the target, while the other 2 pop-out and no-pop-out displays were non-targets. Target stimuli elicited enhanced frontal P2, posterior N2, and broad P3 components. The posterior N2 was largest at scalp sites contralateral to the side of the pop-out and may represent the operation of focal attention. Both target and non-target pop-outs elicited a frontal N2 component, suggesting an automatic orienting to discrepant items regardless of their relevance.

405.8

THE CHRONOMETRY OF SELECTIVE ATTENTION AND MISMATCH DETECTION. GP NOVAK, WR RITTER, AND HG VAUGHAN*. RF Kennedy Ctr, Albert Einstein Coll of Med, Bronx, NY 10461.

In this selective attention task, targets were rare longer (170ms) tones of a designated pitch, imbedded in a sequence of 100ms standards. An additional simple reaction time (SRT) condition required a response to an unvarying standard. Event related potentials (ERPs) were recorded from 15 sites referred to the nose.

Selective attention effects were evident in the ERPs to standards. Attended standard ERPs were closely similar for easy (1000Hz vs 2000Hz) and hard (1000Hz vs 1030Hz) pitch separations, and were more negative frontocentrally than unattended standard ERPs. Difference waveforms (attended-unattended standards) revealed a negative deflection (Nd), earlier in latency for the easy task (onset, 170ms; peak, 250ms) than for the hard task (onset, 250ms; peak, 350ms). Unlike N1, Nd did not invert in polarity posterolaterally. Attentional effects for both attended and unattended standards were seen in comparison with SRT ERPs; difference waveforms (standard-SRT) revealed a negative deflection (NA), earlier in onset (50ms post stimulus onset) but identical in topography to Nd. The speed of detection of the deviant longer tones was insensitive to the attentional processes indexed by Nd. Median reaction time did not differ between tasks (easy, 510ms; hard, 513ms). Neither attention nor task difficulty affected the latency of mismatch negativity (MMN), N2 or P3 (as identified in difference waveforms: attended or unattended longer tones minus their respective standards). MMN onset and peak latencies (140ms and 185ms, respectively) preceded those of Nd, even for the easy pitch separation. Accuracy of response was determined by attention-related selection of the relevant pitch. There were more misses (28% vs 14%) and false alarms (6.7% vs 0.3%) in the hard task, and nearly all of the latter were responses to the irrelevant longer tone. The data suggest that performance is guided by two parallel and independent processes, automatic mismatch detection of the longer tone followed by selection of response based on match to the attentional template for pitch.

405.9

BRAIN POTENTIALS PREDICTIVE OF LATER PERFORMANCE ON TESTS OF RECALL, RECOGNITION, AND PRIMING. K.A. Paller, C.C. Wood, and G. McCarthy. Neuropsychology Laboratory, VA Hospital (116B1), West Haven, CT 06516 and Depts. of Neurology and Psychology, Yale Univ.

Despite the connection established between the brain areas damaged in amnesia and *declarative memory*, the functional roles of these brain areas are currently unclear. Information derived from the electrical activity generated in these brain areas during memory tasks may be useful for understanding the brain mechanisms mediating declarative memory. Event-related potentials (ERPs) may be sensitive to such activity and can be recorded from human subjects engaged in complex verbal tasks. Correlations between ERPs and later memory performance have been reported previously. In these studies, ERPs elicited by words that were later remembered were generally more positive than ERPs elicited by words that were later forgotten.

The present experiments investigated electrophysiological correlates of memory performance in relation to retention interval and type of memory test (free recall, yes-no recognition, and stem-completion priming). In the priming test (a test of *nondeclarative memory*), 3-letter stems corresponding to some of the 200 words presented earlier were mixed with an equal number of additional stems. Subjects were instructed to complete each stem verbally with the first word to come to mind. The number of completions to presented words constituted priming performance. The recall test was given after a 15-min delay, whereas recognition and priming tests were given either after a 1-min delay or after a 15-min delay.

An average of 11% of the words were recalled. The number of words recognized did not differ as a function of delay and averaged 57% (chance=14%). Priming scores were much greater with the short delay (45%) than with the long delay (18%), and in both cases were significantly greater than chance (10%). ERPs elicited during acquisition differed as a function of later memory performance. ERPs to recalled words were relatively more positive than ERPs to unrecalled words, especially 600 ms after word onset. Similar though less consistent results were obtained for recognition and priming. Preliminary results were also obtained from epileptic patients with electrodes implanted in medial temporal and other brain regions.

405.10

VISUAL SELECTIVE ATTENTION TO LINGUISTIC STIMULI: INTRACRANIAL ERP RECORDINGS. A.C. Nobre, G. McCarthy. Neuropsychology Laboratory, VA Medical Center, West Haven, CT 06516 and Depts. of Neurology and Psychology, Yale University.

We have previously demonstrated changes in scalp event-related potentials (ERPs) associated with the differential processing of concurrent visually presented stories (Nobre & McCarthy, *Soc. Neurosci. Abstr.*, 1987). The spatio-temporal characteristics of the ERP effect suggested that it is generated by multiple neural sources. Since neural generators cannot be determinded from scalp distributions alone, intracranial ERPs were obtained from a group of patients being evaluated as candidates for surgery to relieve medically intractible seizures. Each patient had chronically implanted unilateral or bilateral posterio-temporal (PT) multi-contact depth probe(s). The first several contacts of the PT probe(s) sampled activity in extrastriate visual cortex, while the deeper contacts were in the medial temporal lobe.

Words comprising two stories were randomly intermixed and displayed briefly and successively on the center of a computer display, with words in each story displayed in a single color (red or green). Subjects were instructed to read silently either the red or green story. Comprehension of the attended story was tested immediately at the end of each run.

Like the ERPs recorded from the scalp, the intracranial ERPs recorded from the PT probes' superficial contacts showed a large attentional effect in four out of five patients. The morphology and time-course of the effect were strikingly similar to that recorded from the occipital (O_z) scalp electrode in normal subjects. The intracranial effect, however, was approximately an order of magnitude larger in amplitude and opposite in polarity from that observed in its scalp counterpart. This polarity inversion suggests that one generator of the selective attention effect recorded at the scalp may be located in the extrastriate occipital cortex.

405.11

THE EFFECTS OF SPEED-ACCURACY INSTRUCTIONS ON REACTION TIME AND P3 LATENCY IN STIMULUS-RESPONSE INCOMPATIBILITY TASKS. D. Ivkovich*, C. Christensen and K. Drake*. Department of Psychology, Vassar College, Poughkeepsie, NY 12601.

Twelve subjects were tested in an ERP paradigm to assess the effects of stimulus-response (S-R) incompatibility on reaction times (RTs) and P3 latencies. An earlier investigation (Pfefferbaum et. al., EEG clin. Neurophysiol., 64:424-437, 1986) had demonstrated that P3 latency is prolonged by S-R incompatibility, but only when the task predisposed to rapid responding. A more complex task using the same stimului but with a more complicated response rule showed no incompatibility effect on P3 latency. Slower, more deliberate responding characterized this task. To evaluate whether the P3-incompatibility effect can be manipulated by altering response strategy, subjects were tested on a simple and a complex S-R incompatibility task under three instructions emphasizing speed, accuracy, or a speed-accuracy tradeoff. The simple task consisted of compatibile trials in which the subject pressed one of two buttons as indicated by the words *RIGHT* or *LEFT* printed in upper or lower case; incompatible trials required pressing the opposite button. In the complex task, compatible responses were made to upper-case words while presentation of lower-case words required incompatible responses. As expected, RTs were influenced by task, incompatibility and instruction set, with prolongation for the more complex task, for incompatible trials, and increasing emphasis on accuracy. P3 latencies were also task dependent and influenced by instruction. Incompatibility prolonged P3 latency in the simple task. A lesser effect of incompatibility was observed in the complex task. The implications of these findings and the interaction of incompatibility and instruction in the two tasks are discussed in light of the hypothesis that the P3 S-R incompatibility effect is strategy dependent.

405.12

SHIFTS OF ATTENTION AND EVENT-RELATED POTENTIALS (ERPs) IN HUMANS: EFFECTS OF VALID AND INVALID CUEING. L. Anllo-Vento and M.R. Harter. Psychol. Dept. UNC-Greensboro, NC 27412.

A cue that indicates the most probable location of a subsequent target (valid cue) results in covert shifts of attention to that point in space. Shifts of attention, in turn, result in faster and more accurate detection at the target location. Single unit studies with monkeys and behavioral studies with human patients indicate that posterior parietal cortex is selectively involved in the directing of spatial attention. This study provides electrophysiological and behavioral measures of attention shifting in humans.

ERPs were recorded over occipital (O1-O2), parietal (P3-P4), central (C3-C4), and frontal (F3-F4) sites in response to validly and unvalidly cued targets appearing 14 degrees to the right or left of a central fixation point. The interval between the cue and the target varied randomly from 200 to 600 msec. The resulting waveforms indicate that attention can be switched within 350 msec. The amplitude of N1 to the target was modulated by the validity of the preceding cue, particularly at parietal and central sites. Amplitude of the P3 component reflected differences in probability of the valid and invalid conditions. Reaction times also revealed the costs and benefits of shifting attention to either the invalid or valid hemifield.

These results corroborate previous findings of parietal involvement in the directing of spatial attention.

HUMAN EVENT-RELATED POTENTIALS DURING SPATIAL PROCESSING: A TOPOGRAPHICAL DISTRIBUTION. G.F. Wilson, R.A. Swain* and I. Davis*. AAMRL, Wright-Patterson Air Force Base, Dayton, Oh. and SRL Inc., Dayton, Oh.

In the present experiment, we assessed the distribution and electrical characteristics of ERPs elicited during a variable demand spatial rotation task in which subjects were asked to decide whether a spatially rotated histogram was identical to an earlier template. Task difficulty was increased by incrementing both the number of bars in the histogram and the degree of rotation. Nine subjects were fitted with nylon caps containing 21 tin electrodes positioned in accord with the international 10-20 system. ERPs were recorded on a topographical mapping system (Bio-logic) and analyzed using the source derivation method developed by Hjorth (1975).

The results indicated that sensory evoked responses were evident at both central and temporal sites and that these potentials were insensitive to changes in task difficulty. Three parietal sites were associated with activity corresponding to the P200. As task difficulty increased, the activity recorded over the saggital suture showed decrements in both amplitude and latency. P300 activity was maximal at 3 parietal and 1 central (right hemisphere) sites. At all four sites, the P300 declined in amplitude as the task demand increased. Analysis of latencies indicated that the parietal peak latencies declined and that the right hemisphere central peak latency increased concurrent with cognitive demand.

INTRACRANIAL DISTRIBUTION OF HUMAN COGNITIVE POTENTIALS. M.E. Smith, E. Halgren, M. Sokolik,* P. Baudena,* A. Mussolino,* C. Liegeois-Chauvel,* and P. Chauvel.* INSERM U97, Centre Paul Broca, 75014 Paris, and VA Southwest Regional Epilepsy Center, Los Angeles.

Neocortical, limbic, and diencephalic regions have all been proposed as contributors to the P3 component of the ERP. In this study, the N2 and P3 potentials are recorded from epileptic patients undergoing SEEG. Recordings are made from parietal (n≥9 electrodes), temporal (n≥25), and frontal (n≥5) lobes. Electrodes have 5-15 contacts each, with over 700 contacts sampled. ERPs are recorded in an auditory oddball task, where the less frequently occurring of two distinct tones are counted mentally, and sometimes in a visual analogue to this task. Three main results have been obtained. The very large amplitude polarity inversions of the P3 that have been observed in the medial temporal lobe in prior studies are highly localized to the hippocampus itself, and seldom observed at more medial or lateral contacts. At neocortical sites, widespread normal polarity P3s and some small polarity-inverting P3s are observed. It is unclear to what degree these neocortical potentials are generated locally vs. volume-conducted. In contrast to the modality independent P3, recordings from superior-temporal and temporo-parietal areas reveal an N2 specific to the auditory modality.

NEUROPSYCHOLOGICAL AND ELECTROPHYSIOLOGICAL DIFFERENCES IN TURNER SYNDROME. R. Clopper*[3], M. Schachter*[1], J. Shucard*[1], D. Shucard[1,2], Depts. of Neurology[1], Pediatrics[2], and Psychiatry[3], SUNY at Buffalo School of Medicine, Buffalo NY 14203.

In order to further clarify the cognitive phenotype in Turner Syndrome (TS), electrophysiological and behavioral measures were obtained in TS girls between the ages of 8 and 14 yrs. Subjects were evaluated with subtests of the Halstead-Reitan Battery to quantify spatial and sequential processing skills. Electrophysiological measures were obtained using auditory cortical evoked potentials (EP) to probe differences in electrical activity between homologous areas of the brain during the performance of visual-spatial tasks.

Neuropsychological findings indicated that although there was a heterogeneous pattern of test scores among subjects, they uniformly showed poor performance on the localization component of the Tactual Performance Test. Electrophysiological findings showed that the patterns EP asymmetry obtained during visual task performance appeared to be related to neurocognitive measures. These data indicate that neurocognitive deficits are present in TS but may be more complex than a general disturbance in spatial processing. Further, neurocognitive deficits may be related to electrophysiological indices of brain organization. Supported in part by Genentech, Inc.

FREQUENCY DEPENDENCY OF MIDDLE LATENCY AUDITORY RESPONSES OF HUMANS. M. L. Collaer *, R. A. Johnson and J. Beatty. Department of Psychology, UCLA, Los Angeles, CA 90024.

The P1 component of middle latency auditory event related responses is modulated by state of arousal and by stimulus repetition rate in both humans and cats. The neural generator of P1 is a matter of controversy, having been hypothesized to lie either within the rostral reticular activating system or in the primary auditory cortex.

P1 is a difficult component to analyze since its amplitude is relatively small and is often contaminated by muscle artifact. For these reasons, not all subjects demonstrate reliable P1 components.

We attempted to determine whether the neural tissue generating the human auditory P1 (occurring at latencies of 55-80 msec) is frequency dependent. Frequency dependency would be suggestive of a cortical rather than reticular source. P1s were measured to 800 Hz tone bursts, 100 msec in duration, presented at either 2 sec or 0.5 sec interstimulus intervals [ISIs]. It has previously been reported that P1 amplitude is attenuated at shorter ISIs. In the critical third condition, 800 Hz tone bursts were presented at 2 sec ISIs, with three 1000 Hz tone bursts intervening. Thus, in this condition, the frequency dependent ISI was 2.0 sec, while the frequency independant ISI was 0.5 sec.

Recordings were made on 11 subjects (bandpass filter settings of 10-300 Hz, Cz to linked ear reference, averages of 250 trials). P1 was measured relative to Nb, the preceding negativity. Identifiable and consistent P1s were detected in 5 of these individuals. The results suggest that the neural generators of the human P1 are frequency dependent: the amplitude of the P1 elicited by the 800 Hz tone in the mixed sequence was similar to that obtained by the 800 Hz presented at 2 sec ISIs. These results are suggestive of a cortical generator for P1. Investigations with additional subjects are being conducted. (Research supported by NIMH 37430-07)

STIMULUS INTENSITY EFFECTS ON MONKEY EVENT-RELATED POTENTIALS (ERPs): PARALLELS TO HUMAN AUGMENTING-REDUCING. T. C. Holmes[1*], J. A. Pineda[1], D. Swick[2*], and S. L. Foote[1,3]. (SPON: L. Adams). Depts. of Psychiatry[1] and Neuroscience[2], UCSD, and Scripps Clinic and Research Foundation[3], La Jolla, CA 92093.

Stimulus intensity effects on ERPs, as characterized by augmenting-reducing (AR), have been proposed to index a central mechanism for gating sensory processing and have been correlated with levels of biogenic amines. In order to study these effects, AR characteristics in auditory ERPs were recorded in squirrel monkeys (Saimiri sciureus) from chronically implanted epidural electrodes. The relationship between stimulus intensity and ERP component amplitude was examined at frontal midline, vertex, and temporal sites. Augmenting was defined as a monotonic increase in peak-to-peak amplitude for the first two major peaks, across three of the four intensities presented (50, 60, 70, and 80 dB SPL). Additionally, the response to the highest intensity was required to have the greatest amplitude. Any other result was defined as reducing. As in humans, differences in the AR profile were seen between electrodes. Frontal sites most commonly showed an augmenting profile, while temporal sites often showed a reducing profile. Despite amplitude variations between sessions, AR profiles were found to be stable over months for individual subjects. A Spearman rank-order correlation coefficient based on all subjects' data indicated a statistically significant correlation between amplitude/intensity slopes at temporal sites and P300 component areas elicited at parietal sites using an auditory oddball paradigm ($r_s \geq 0.90$, $p < 0.05$). These results indicate parallel findings in human and monkey ERPs with regard to AR profile differences between sites and P300-AR relationships.

405.18

EFFECTS OF CLONIDINE ON P300-LIKE POTENTIALS IN SQUIRREL MONKEYS. D. Swick[1*], J. A. Pineda[2], T. C. Holmes[2*], and S. L. Foote[2,3]. Depts. of Neuroscience[1] and Psychiatry[2], UCSD, La Jolla, CA 92093 and Scripps Clinic and Research Foundation[3], La Jolla, CA 92037.

Previous experiments in this lab have shown that bilateral lesions of the noradrenergic nucleus locus coeruleus (LC) decrease the amplitude of the monkey P300. To further assess the role of LC in modulating the orienting and attentional processes indexed by the P300, we systemically administered the alpha-2-adrenergic agonist clonidine to five squirrel monkeys (Saimiri sciureus) and recorded their event-related potentials (ERPs) from chronically implanted epidural electrodes. Two animals received extensive training in a 90-10 auditory oddball paradigm. Their P300 areas remained relatively stable throughout six pre-drug sessions and showed no habituation. Three untrained monkeys were presented with tones in a passive 80-10-10 oddball paradigm. In separate sessions, all animals received injections of saline or of clonidine (0.05, 0.075, and 0.1 mg/kg I.M., thought to suppress LC firing) and their ERPs were recorded. At lateral parietal sites, where the monkey P300 is most pronounced, three of five subjects (2 active, 1 passive) showed a dose-related decrease in P300 area and exhibited recovery to control levels in post-drug sessions. The remaining passive subjects failed to show clear P300s in both pre- and post-drug sessions, and hence their clonidine data were difficult to interpret. These preliminary results support the hypothesis that the LC noradrenergic system participates in P300 production.

405.19

IN SEARCH OF THE "ODDBALL": COGNITIVE PROCESSING OF STIMULUS SEQUENCE IN THE RAT HIPPOCAMPUS R.E.Hampson, C.R.Breese*, and S.A.Deadwyler, Dept. of Phys. & Pharm., Bowman Gray Sch. of Med. of Wake Forest Univ., Winston-Salem, NC 27103.

In a continuously presented stimulus series in which the subject is instructed to detect one of two stimuli, the amplitude of the P_{300} component of the human scalp-evoked potential reflects expectancy of the stimulus as predicted by the immediately preceding sequence. The hippocampal formation has been suggested as the site of generation of the sequential dependency of P_{300}. A component of the tone-elicited hippocampal averaged evoked potential (AEP) in the rat has been identified that shows a sequential dependency in a manner similar to P_{300}. The N_1 component of the AEP can be described as an updatable buffer which stores the sequence of five preceding stimuli, but not the current stimulus (Deadwyler *et al.*, Behav. Neural Biol., 44, 1985). N_1 amplitude is maximal when preceded by a series of unrewarded (target) stimuli, and minimal when preceded by rewarded (nontarget) trials, irrespective of the current (evoking) stimulus. In contrast, P_{300} amplitude is maximal when the current stimulus is different from the preceding sequence of stimuli and does not depend upon whether the stimulus is a target or nontarget.

Recent studies from this laboratory suggest that P_{300} can not be generated in the hippocampus, but that the P_{300} process interacts with information represented by hippocampal sensory-evoked potentials (Hampson and Deadwyler, Behav. Brain Sci., 1988). This relationship provides the basis for a hypothesis that N_1 serves as a critical neurophysiological "substrate" for cognitive functions represented by P_{300}. The proposed interaction between N_1 and P_{300} will be examined using a neural modeling approach. A neural network model of serial memory reflected in N_1 amplitude and its extension to P_{300} will be discussed.

NEURAL FATTY ACID PROFILE IN WEANED RATS IS SUSCEPTIBLE TO SHORT-TERM CHANGES IN DIETARY FAT COMPOSITION. J.R. Dyer* and C.E. Greenwood (SPON: G.H. Anderson). Dept. Nutr. Sci., Fac. Med., Univ. Toronto, Toronto, Ont., Canada. M5S 1A8.

We have shown that dietary fatty acid (FA) composition, in the absence of essential fatty acid (EFA) deficiency, alters behaviour of weaned rats, including spatial memory, pain sensitivity and protein selection, within 4 weeks of feeding; i.e. neither long-term feeding for several months nor EFA deficiency were necessary to observe a functional effect of dietary fat. To determine if these behavioural changes were accompanied by altered lipid composition of brain membranes, the same 20% (w/w) soybean oil and lard diets were fed to 6 week old male Sprague Dawley rats for 4 weeks. Dietary fat influenced FA profiles of phospholipids (PL) in myelin, synaptosomes, mitochondria and microsomes; the degree of change was similar across all subcellular fractions and all PLs (PC, PS, PE, CL) except PI which was relatively unaffected. Polyunsaturated FAs, except arachidonic acid (C20:4ω6), were influenced by dietary fat more than saturated or monounsaturated FAs. The magnitude of change ranged from 5% for oleic (C18:1ω9) and 10% for docosahexaenoic (C22:6ω3) acids to 100% for linoleic (C18:2ω6) and 250% for docosapentaenoic (C22:5ω6) acids. The 22-carbon FA, C22:6ω3, characteristic of electrically excitable membranes, is believed to play a specific functional role. We hypothesized that dietary fat affects behaviour via altered neural membrane FA composition and subsequent functional changes in the membrane. (MRC).

CYTIDINE STIMULATES THE SYNTHESIS OF PHOSPHATIDYLCHOLINE IN A RAT PHEOCHROMOCYTOMA CELL LINE. I. Lopez G.-Coviella*, R. J. Wurtman, L. Robinson* (SPON: W. J. H. Nauta). Laboratory of Neuroendocrine Regulation, M. I. T., Cambridge, MA 02139.

Phosphatidylcholine, the most abundant phospholipid in cell membranes, is synthesized primarily via the CDP-choline pathway in most cell types. This route utilizes CTP and phosphocholine as its rate-limiting substrates. Thus, external factors that affect the availability of these precursors could influence phosphatidylcholine synthesis. We are investigating the effects of cytidine on cellular nucleotide content and on the incorporation of [^{14}C]-choline into phospholipids and water-soluble precursors. Rat pheochromocytoma cells (PC-12) were incubated in serum-containing D-MEM medium in the presence of [^{14}C]-choline (34 μM; 7.4 mCi/mmole), with and without cytidine (100 μM). After 15 and 30 minutes of incubation, incorporation of [^{14}C]-choline into phosphatidylcholine was increased by 55 and 42%, respectively, in cytidine-supplemented cells, while labeled phosphocholine levels were decreased (by 43% and 32%). Intracellular CTP levels were doubled after 15 minutes of incubation in the presence of cytidine, and rose even higher thereafter. In similar experiments, when cells were incubated with various concentrations of cytidine, these effects were dose and time-dependent. A pulse-chase study with labeled choline also showed that most of the radioactivity initially associated with phosphocholine was gradually converted to labeled phosphatidylcholine. In the presence of cytidine, this conversion was accelerated by 36 ± 4% at all times studied. These results suggest that cytidine could be a critical regulator of phosphatidylcholine biosynthesis; possibly by elevating intracellular levels of CTP.

406.3

MICROVESSEL MEMBRANE LIPID COMPOSITION AND AGING, W. M. Williams and T. H. McNeill, Dept. Neurology, Univ. of Rochester Sch. Med. Dent., Rochester, NY 14642.

Microvessels were isolated from the cerebral cortex and cerebellum of 10, 20 and 27-30 month old mice. Membrane lipids were extracted from both microvessel and brain parenchymal fractions, and phospholipids and cholesterol separated by thin-layer chromatography (TLC). The ethanolamine phosphoglyceride (EPG) spot was subjected to separation-reaction-separation TLC in order to separate the diacyl and plasmalogen (plasmene) fractions for analysis of fatty acids and dimethyl acetals. Methyl esters, and the aldehyde dimethyl acetals from the plasmalogen fraction were prepared and analyzed by gas-liquid chromatography (GLC). Total cholesterol was determined spectrophotometrically. The data suggests that, 1) microvessel membrane from 27-30 month old brain exhibits a marked increase in the level of unsaturation, attributable primarily to an apparent increase in arachidonic (20:4) and docosahexaenoic (22:6) acids, 2) cholesterol content increases in both microvessel and brain parenchymal membranes, and 3) in contrast to parenchyma, the relative content of the major phospholipid classes in microvessel membrane remains essentially unchanged over the age period studied. These findings suggest that microvessel endothelial membranes undergo acyl compositional changes that could potentially influence microvascular production of eicosanoids, and alter blood-brain barrier function.

406.4

ISOLATION OF THE JONES IMMUNOREACTIVE GANGLIOSIDE 9-O-ACETYL-GD3. D.M. Bonafede, L. Mecala*, M. Constentine-Paton and R.K. Yu. Dept. of Biology, Yale Univ. and Dept. of Neurology, Yale Med Sch., New Haven, CT 06511.

One of the 2 major gangliosides recognized by the monoclonal antibody JONES (Constantine-Paton et al. 1986, Nature 324: 459) is 9-O-acetyl-GD3 (Blum et al. 1987, PNAS 84: 8716). JONES immunoreactive gangliosides have been implicated in neural cell and process migration (Mendez-Otero et al. 1988, J. Neurosci. 8: 540) and intercellular interactions in vitro can modulate their expression (Mendez-Otero & Constantine-Paton; Bonafede & Constantine-Paton, 1987, Soc. Neurosci. Abstr. 455.6 &7).

We have used bovine buttermilk to isolate 9-O-acetyl-GD3 for functional studies. Our purification scheme was simplified with respect to standard procedures to minimize the number of steps required to obtain pure product. The procedure, after the initial extraction in chloroform / methanol, consists of 3 successive column chromatographies: first an ion-exchange column, then two silica gel (Iatrobeads) columns, all eluted with gradients of chloroform/methanol/ water. 9-O-acetyl-GD3 was identified on the basis of: 1) HPTLC motility between GM1 and GM2; 2) JONES immunoreactivity; 3) conversion to GD3 by mild base treatment.

Supported by grants HD22498 and BSN8616965.

406.5

BIOCHEMICAL CHARACTERIZATION OF JONES IMMUNOREACTIVE GANGLIOSIDES IN RAT. P. Mylonas*, D.M. Bonafede, R.K. Yu and M. Constantine-Paton (SPON: J. Paton) Dept. of Biology, Yale Univ. and Dept. of Neurology, Yale Med. Sch., New Haven, CT 06511.

The monoclonal antibody JONES (Constantine-Paton et al. 1986, Nature 324: 459) recognizes a small family of rare gangliosides (Schlosshauer et al. 1988, J. Neurosci. 8: 550) in the developing rat nervous system. One of the 2 major gangliosides recognized is 9-O-acetyl-GD3 (Blum et al. 1987, PNAS 84: 8716).

We obtained, by ion-exchange chromatography, a ganglioside fraction enriched for the second major JONES immunoreactive ganglioside, which has HPTLC mobility between GD3 and GD1a. Mild base treatment of this fraction abolished JONES immunoreactivity and changed the HPTLC mobility of this ganglioside to the area just below GT1b, where tetrasialogangliosides run. The appearance of this band and the disappearance of the JONES reactive band near GD3, were the only changes produced by base treatment. This new band is recognized by the mAB A2B5, which was previously shown to be specific for GQ1c (Kasai & Yu 1983, Brain Res.: 277:155).

We conclude that the second (the first one being 9-O-acetyl-GD3) major JONES immunoreactive ganglioside is a base-labile GQ1c derivative, probably 9-O-acetyl-GQ1c.

Supported by grants HD222498 and BSN8616965

406.6

GANGLIOSIDE COMPOSITION OF CHOROID PLEXUS BRAIN TUMORS IN TRANSGENIC MICE. M. ElAbbadi, A. Messing and T. N. Seyfried. Dept. of Biol, Boston College, Chestnut Hill, MA 02167 and Sch. Vet. Med, Univ, WI.

The ganglioside composition of two choroid plexus tumors (papillomas), SV(188) and SV-MK(79) was examined in the brains of transgenic mice. These papillomas are inheritable tumors that develop spontaneously in adult transgenic mice carrying integrated copies of SV40 early region genes. The ganglioside composition of these tumors was compared to that of normal mouse brain and to a chemically induced ependymoblastoma growing subcutaneously in the flank. The total ganglioside sialic acid content (μg/100 mg dry weight) of the two papillomas was 76.2μg (four SV(88) tumors pooled for a single sample) and 139.4μg (the mean of two independent SV-MK(79) tumors). These concentrations were higher than that of the ependymoblastoma 39.4±3.1 (N=6), but markedly lower than the concentration in adult mouse brain (450-500μg). Although N-acetylneuraminic acid (NANA) is the only ganglioside sialic acid in adult mouse brain, both papillomas and the ependymoblastoma contained significant amounts of N-glycolylneuraminic acid (NGNA). GM3-NANA and GM3-NGNA were the predominant ganglioside species in both papillomas and the ependymoblastoma. From thin-layer chromatography evidence, the ceramide composition of the GM3 gangliosides appears to be more structurally homogeneous in the papillomas than in the ependymoblastoma. In contrast to the ependymoblastoma, the papillomas contained significant amounts of mouse brain gangliosides (GD1a, GD1b, GT1b, and GQ1b). These gangliosides may not be native to the tumors, but represent contaminants from normal brain tissue surrounding the tumors. (Supported by NIH grants NS-23355, NS-24826, and NS-22475).

GANGLIOSIDE MODULATION OF cAMP DEPENDENT PROTEIN KINASE AND CYCLIC NUCLEOTIDE PHOSPHODIESTERASE. A.J. Yates, J.D. Walters*, C.L. Wood*, S.M. Stock* and J.D. Johnson*. Departments of Pathology, Pharmacology, and Physiological Chemistry, College of Medicine and College of Dentistry, Ohio State University, Columbus, Ohio 43210.

Phosphorylation of proteins in membranes isolated from sciatic nerve of normal adult rabbits was examined using an in vitro assay, PAGE and autoradiography. In the absence (2 mM EGTA) of Ca^{+2} there were 3 major phosphorylated proteins (21 kDa,31 kDa and 51 kDa). Catalytic subunit of cAMP dependent protein kinase (PKA) enhanced phosphorylation of 21,31,38,40 and 49 kDa proteins. GM1, GD1a, GT1b inhibited phosphorylation by PKA of 38,40 and 49 kDa proteins with half maximal inhibition at 13-32 uM. With type IIA histone as a phosphate acceptor GM1 competetively inhibited PKA with Ki=110 uM. Neutral glycolipids were much less effective and free sialic acids had no inhibitory effect. GM1 stimulated the activity of purified bovine brain calmodulin-dependent cyclic nucleotide phosphodiesterase, with activation being half maximal at 0.3 uM and maximal (32-fold) at 1 um, but had no effect on Km. These findings indicate that gangliosides may affect the activity of PKA through two mechanisms: (a) decreasing levels of cAMP by activating phosphodiesterase; (b) direct inhibition of the catalytic subunit. Supported by NIH grant NS10165, Department of Pathology and College of Medicine.

MODULATION OF GAMMA-GLUTAMYL TRANSPEPTIDASE IN GLIAL CELLS BY GLUCOSAMINE. L.E. DeBault and J.L. Flagg-Newton*. Univ. of Oklahoma Health Sci. Cntr., Oklahoma City, OK 73190.

The amino-sugar, glucosamine, is known to decrease the expression of membrane-bound glycoproteins such as tyrosinase. However, cell surface gamma-glutamyl transpeptidase (GGTP) activity was stimulated by 15mM glucosamine in cultured glial cells (C_6, rat astrocytoma) over a 48 hr period. The increase in enzyme activity was dependent upon the entry of glucosamine into the cell and not on the inhibition of glucose transport. GGTP in glucosamine-treated cells exhibited an increased sensitivity to a variety of acceptor-substrates especially cysteine, while at the same time, enzyme affinity for wheat germ agglutinin (WGA) was markedly decreased. The enzyme also exhibited an altered Vmax. Rat liver hepatocytes (2B-RL), used as a control cell, had a similar Vmax alteration but in addition had an altered Km. The data suggest that the increase in GGTP activity in glucosamine-treated cells result from the appearance on the cell surface of a functionally distinct iso-form of GGTP. To date, it can be recognized by its disproportionate response to amino acid acceptors and by its decreased affinity for WGA. (This work was supported in part by NIH Grant R01-NS 18775)

ALTERATION OF INTRACELLULAR CHLORIDE CONCENTRATION AND ITS EFFECT ON THE EXPRESSION OF AChR IN MUSCLE. R.D. Heathcote and W.J. Betz. Dept. of Physiology, Univ. of Colorado School of Medicine, Denver, CO. 80262.

The mechanism by which muscle cell activity regulates the expresssion of acetylcholine receptors (AChRs) is not known. Expression of extrajunctional (EJ) AChRs correlates well with the level of internal [Cl] under a variety of conditions. For example, in normal muscle both are relatively low, but after denervation EJ AChRs appear and, as Cl conductance falls, internal [Cl] rises owing to the continued action of an inwardly directed Cl pump. Perhaps Cl acts as a second messenger, directing the expression of EJ AChRs. We tested this hypothesis by altering internal [Cl] in rat lumbrical muscles maintained in an organ culture system. Experimentally, AChRs were measured with ^{125}I-α-bungarotoxin binding, Cl conductance with electrophysiological methods and internal [Cl] with Cl-sensitive microelectrodes. Denervated muscles were cultured in low [Cl] medium (all but 9 mM Cl replaced by isethionate) to reduce internal [Cl]. This treatment inhibited AChR expression. However, low [Cl] medium caused extensive fibrillation, and when this was blocked by addition of tetrodotoxin, AChR expression rose to control levels, or higher. In the converse experiment, the appearance of AChRs was not accelerated when normal muscles were cultured in 9AC, a drug which blocks Cl conductance and raises internal [Cl]. We also investigated the effects of electrical stimulation of denervated muscle, which can restore AChR and internal [Cl] to normal levels. Addition of 9AC (which prevented the fall of internal [Cl]) did not prevent the loss of AChRs in electrically stimulated muscles. Thus, the observed increases and decreases in AChR expression are effected by altering muscle cell activity.

406.10

DENSITY OF ^{3}H-STX BINDING SITES IN PREMYELINATED AXONAL MEMBRANE IN MAMMALIAN OPTIC NERVE S.G. Waxman, J.A. Black and J.M. Ritchie*[1]. Depts. of Neurology and Pharmacology[1], Yale University School of Medicine, New Haven, CT 06510, and V.A. Medical Center, West Haven, CT 06510.

As part of a study on membrane assembly in myelinated axons, we studied STX-binding in premyelinated optic nerves (ON) of neonatal rat and rabbit. Since virtually all their axons become myelinated in the adult, these nerves provide a model for studying precursors of myelinated axolemma.

ON from neonatal (0-2 d) rats and rabbits were excised, weighed, pooled and homogenized, and the protein content and specific ^{3}H-STX-binding curve determined. The maximal specific STX-binding for neonatal rat and rabbit ON was 14 and 38 fmol/mg wet wt, respectively. Surface density of axon membrane, derived by the line-intersection method, was 9.6 $\mu m^2/\mu m^3$ (rat) and 11.3 $\mu m^2/\mu m^3$ (rabbit). For each species, surface density of ON glial membrane was ~10% of axon membrane surface density.

These results indicate a mean density of 4-7 STX binding sites per μm^2 of axolemma in neonatal rat and rabbit ON on the basis of a uniform plasmalemmal distribution of channels. Thus, both rat and rabbit premyelinated axolemma seem to exhibit an axolemmal Na channel density considerably lower than do adult unmyelinated fibers (100-200 μm^2). Since previous studies have demonstrated that neonatal rat ON exhibits TTX-sensitive action potential electrogenesis, the present results suggest that very low channel densities are capable of supporting spike electrogenesis in premyelinated fibers. [Supported in part by the NIH, NMSS and VA].

EXPRESSION OF GP50 BY CULTURED CEREBELLAR GRANULE CELLS. T. Paladino*, S.M. Nicholson*. P.W. Beesley*. and J.W. Gurd (SPON: I.R. Brown). Dept. of Biochemistry, Univ. of Toronto, Scarborough Campus, West Hill, Ont., M1C 1A4 and Dept. of Biochemistry, Royal Holloway and Bedford New College, Egham, Surrey, U.K. TW20 OEX.

We have previously described the brain-specific glycoprotein, GP50 and shown that it is expressed by granule cells in primary tissue culture (Beesley et al,1987, Br. Res., 408, 65-78). In order to further characterize GP50 we have investigated its developmental expression and molecular properties in granule cell cultures. Immunocytochemical staining of 10 day old cultures, using the monoclonal antibody Mab GP50 was confined to the perikaryal cell surface of granule cells present in cell clusters. Neurites showed little or no reactivity with Mab GP50. Immunoblotting showed that the levels of GP50 increased throughout the time in culture. In early cultures (<2 DIV) staining was reduced and was largely restricted to cells already present in forming aggregates. GP50 was labelled following the iodination of surface proteins with lactoperoxidase and partitioned (>70%) into the detergent phase following extraction with Triton X-114. Sucrose density gradient centrifugation of Triton X-100 extracts showed that GP50 exists predominantly (80%) in a 3.6S form (calculated Mr: 40K). The results indicate that GP50 is a developmentally regulated, integral, cell surface membrane glycoprotein. (Supported by grants from NSERC and MRC to JWG).

ASTROCYTE INVASIVENESS AND NEURON-SUBSTRATE CONTACTS IN FETAL RAT CNS CULTURES. V.H. Gilad, G. Shanker and G.M. Gilad. Dept. of Neurobiology, Coriell Inst. for Med. Res., Camden, NJ, USA.

In mixed fetal CNS cultures, growing astroglia express a membrane-associated activity that disrupt neuron-substrate interactions leading to neuronal detachment. The present study demonstrates first, that this invasive activity of astroglia can be prevented by treatment with 1mM dibutyryl cyclic AMP (cAMP), an ***in vitro*** morphogen that induces stellate morphology in astroglia. Second, the sulfated glycosaminoglycan heparan sulfate (HS) was found to inhibit neuron detachment in a reversible manner without affecting the flat morphology of astroglia. The importance of HS in neuron-substrate interaction was further elucidated by examining the effects of heparitinase. This enzyme which specifically hydrolyzes HS, led to neuronal detachment in the presence or absence of astroglia, but only during the early stage (2-3 days) of neuronal growth. Established cultures were not affected by heparitinase. We conclude: 1) the expression of astroglial invasive activity can be altered and may be dependent upon the state of differentiation, and 2) HS is probably involved in the formation of neuron-substrate contacts.

REGULATION OF PHOSPHATIDYLCHOLINE SYNTHESIS BY PHOSPHATIDYLSERINE AND PHORBOL ESTERS IN INTACT HUMAN NEUROBLASTOMA CELLS. B.E. Slack*, J.K. Blusztajn* and R.J. Wurtman. Laboratory of Neuroendocrine Regulation, Massachusetts Institute of Technology, Cambridge MA 02139.

Cultured neuroblastoma (LA-N-2) cells incubated in phosphatidylserine (PS) showed increases in PS content of cell lysates, and of subcellular membrane fractions. Treatment with PS (10 to 130 μM) but not PC, caused a concentration-dependent stimulation of up to two-fold in the incorporation of [^{14}C]choline into phosphatidylcholine (PC). PC synthesis can also be stimulated in many cell types by phorbol esters and diacylglycerols, both of which activate the calcium and phospholipid-dependent enzyme, protein kinase C. Phorbol myristate acetate (PMA, 100 nM) and dioctanoylglycerol (DiC_8, 1mM) increased PC synthesis by 14% and 50%, respectively, in untreated LA-N-2 cells. In cells previously exposed to PS, PMA and DiC_8 stimulated [^{14}C]choline incorporation into PC by approximately 35% and 120%, respectively, compared to cells treated with PS alone. The effects of PMA and DiC_8 were additive; together these compounds increased [^{14}C]choline incorporation in PS-treated cells by 200% with respect to PS-treatment alone. Under these conditions, the total increase in PC synthesis with respect to untreated controls was over 4-fold. In preliminary experiments cholinephosphotransferase activity was increased in cells pretreated with PS (10 to 30 μM). It remains to be determined whether PS treatment will also stimulate the rate-limiting enzyme cytidyltransferase. The results suggest that PS may stimulate PC synthesis by potentiating the activation of protein kinase C by phorbol esters and diacylglycerols. Our findings also indicate that formation of PS within the membrane may constitute a physiologic stimulus to overall membrane biosynthesis.

EFFECT OF CHRONIC ADMINISTRATION OF DIGITOXIN ON RETINAL SYNTHESIS OF NA PUMP ISOFORMS. S.C. Specht, José Martin*, Enid Gaud* and Sonia Castro Hernández*, Dept. of Pharmacology, Univ. PR School Med. San Juan, PR 00936.

The rat posseses at least three molecular isoforms of the catalytic subunit of the Na,K-ATPase which differ in sensitivity to inhibition by cardiotonic steroids. In order to determine if synthesis of the isoforms can be independently regulated by chronic administration of the cardiotonic steroids CD rats were treated for two weeks with daily injections (1.57 ml/kg) of digitoxin suspension (10 mM) in 1% carboxymethyl cellulose (CMC). Controls received only CMC. At the end of the treatment period, retinal proteins were labeled in vivo by intravitreal injection of 35S-methionine. The rats were killed after 2 hours. Na,K-ATPase was prepared from the retinae, the subunits were separated by SDS-PAGE and the radioactivity in the protein bands containing the alpha and alpha(+) forms were analyzed by liquid scintillation counting. The ratio of radioactivity in alpha(+) to alpha increased 13-20% in the digitoxin-treated animals. Incorporation into a broad group of proteins $\leq$ 58 kD was unaffected. The results demonstrate that synthesis of the catalytic subunits can be differentially regulated and suggest that chronic administration of digitoxin in a clinical setting may alter the usual cellular composition of Na pump isoforms.

ALTERED MEMBRANE COMPOSITION AND FLUIDITY IN SEIZURE-RESISTANT (C57BL/6J), SEIZURE-SUSCEPTIBLE (DBA/2J) AND KINDLED (C57BL/6J)MICE. G.M. Furman*, C. Applegate and R.A. Schatz, Toxicology Prog., Northeastern Univ. & Dept. Neuroscience, Children's Hosp., Boston, MA 02115.

Mice of the DBA/2J(D2) strain have an inherited susceptiblity to audiogenic seizures. C57BL/6J(B6) mice, however, are generally resistant to audiogenically-evoked seizures. The biochemical parameter underlying the difference in seizure susceptibility between these two strains has yet to be elucidated. This study aims to characterize D2 vs B6 mice by comparing the phospholipid (PL) and cholesterol (CL) content as well as the microviscosity of neuronal membranes from various brain regions. Alterations in membrane composition are reflected in the microviscosity of the lipid bilayer; modification of neuronal membrane fluidity may thus modulate the ability of neurons to fire and, in turn, influence seizure susceptibility. The fluidity of neuronal membranes of brain regions from both strains of mice was studied using fluorescence polarization and the PL/CL molar ratio, a biochemical estimate of fluidity. The cortex, hippocampus, striatum and midbrain from B6 mice were less fluid than corresponding regions in D2 animals as assessed by both techniques. Kindling of B6 seizure-resistant mice increased membrane fluidity in these regions as compared to non-kindled animals of the same strain. Thus, kindling altered the viscosity of neuronal membranes from seizure-resistant B6 mice such that they appear similar to those of seizure prone D2 mice. Taken together, the data suggest that a more fluid membrane microenvironment, whether genetically or electrically induced, may predispose neuronal membranes in some areas of the brain to hyperexcitability. This decrease in neuronal membrane viscosity may also be related to generation of ectopic foci and propagation of excessive electrical discharge in brain.

DEVELOPMENT OF MONOCLONAL ANTIBODIES TO THE SYNAPTIC MEMBRANE Ca^{2+}-Mg^{2+} ATPASE. M.L. Michaelis, T.E. Kitos*, S. Schueler* and L. Reichel*, Center for Biomed. Res., Univ. of Kansas, Lawrence, KS 66046

The regulation of free intraneuronal Ca^{2+} concentrations in the 0.1 uM range partially depends on the extrusion of Ca^{2+} via a (Ca^{2+} + Mg^{2+})-ATPase located in the neuronal plasma membrane. The properties of this enzyme in brain synaptic plasma membranes and its Ca^{2+} transporting activity have been described in earlier reports from our lab (Michaelis et al., J. Biol. Chem. 1983, 258, 6101-6108 and 1987, 262, 4182-4189. We have now developed methods to solubilize the enzyme in a Lubrol PX/Glycerol solution with $CaCl_2$ and NaCl, and to preserve enzymatic activity through the purification procedure. Calmodulin affinity chromatography was used to obtain a fraction exhibiting a 30-fold enrichment in Ca^{2+}-stimulated ATPase activity relative to that in the synaptic membranes. A silver-stained protein band with an estimated M_r of 140 kDa was greatly enriched on SDS-PAGE. This fraction was used to inject Balb C mice for preparation of hybridoma cells by standard fusion techniques. We now have at least 5 cloned hybridoma lines producing antibodies which recognize the isolated (Ca^{2+} + Mg^{2+}) ATPase. Further immunological characterization of these monoclonal antibodies is in progress. (DHHS grants AG 04762, AA 04732, and RR 5606, and DAMD 17-86-G-6038.)

406.17

THREE ISOZYMES OF THE Na,K-ATPase HAVE DISTINCTLY DIFFERENT CELLULAR DISTRIBUTIONS IN RAT CNS. K.M. McGrail* and K.J. Sweadner. Neurosurgical Research, Massachusetts General Hospital, Boston, MA 02114

Multiple isozymes of the Na,K-ATPase are present in the nervous system. Three alpha subunits have been sequenced, but little is known of their functions and cellular distributions. We used specific monoclonal antibodies for indirect immunofluorescence localization in the rat CNS. Markedly different patterns of staining were seen.

Specific stain for alpha 1 was found in the apical surface of the choroid plexus, in cuboidal epithelium lining the central canal of the spinal cord, and in vertically oriented fibers in the cerebral cortex. Staining for alpha 2 was present in many gray matter structures, but nearly absent in white matter tracts. Specific staining for alpha 3 was detected in pyramidal cells of the cerebral cortex, Purkinje cells of the cerebellum, and in axons of the brainstem and spinal cord.

Many different neuroanatomic structures and cell types stained for more than one isozyme. Most notable were the pyramidal cells of the hippocampus and the anterior horn cells of the spinal cord which stained intensely for alpha 2 and alpha 3. Dissociated Muller cells from the retina had both alpha 1 and alpha 2, while corpus callosum stained for alpha 1 and alpha 3. Even when a structure or region stained with more than one antibody the pattern of staining was frequently dissimilar, suggesting complex differences in cellular localization and gene expression.

406.18

PURIFICATION OF NA,K-ATPASE FROM HUMAN BRAINSTEM. J.H. Peng* and J.C. Parker, Jr.* (SPON: S.C. Sung). Dept. of Pathology, Univ. of Missouri-Kansas City Sch. of Med., Truman Med. Ctr., Kansas City, MO 64108.

The properties, structure and function of Na,K-ATPase in animal tissues has been studied extensively, but was rarely studied in human tissues. Hence, this study was undertaken to purify Na,K-ATPase from human brainstem, which will be used for biochemical and immunochemical characterization. Na,K-ATPase was purified from axolemma prepared from autopsy human brainstem tissue according to the established procedures with some modifications. Axolemma fractions were prepared sequentially by flotation technique, osmotic shock and discontinuous sucrose gradient centrifugation. Na,K-ATPase was then purified from axolemma by selective extraction using 0.4 mg SDS per mg protein for 30 min at room temp. The treated sample was diluted with medium immediately to reduce SDS concentration and layered over discontinuous sucrose gradients consisting of 6 ml of 1.0 M, 6 ml of 0.8 M and 10 ml of 0.5 M sucrose in ultra clear tubes and centrifuged at 27,000 rpm (Beckman SW 28 rotor) for 2 hr. Purified enzyme was settled at 0.8/0.5 M interface, which was collected by aspiration. The purified enzyme from human brainstem contained α+ and α subunits, corresponding to mol. wt. of 96,000 and 92,000 d, respectively, in contrast to that from rat axolemma, which has only α+ form. The purity of our enzyme preparation is more than 95% as determined by SDS-PAGE.

407.1

EXPRESSION OF TYROSINE HYDROXYLASE(TH)-IR AND mRNA IN RAT CHOLINERGIC CILIARY GANGLION NEURONS. S. Landis, A. Acheson and R. E. Siegel. Center for Neurosciences, Case Western Reserve Univ., Cleveland, OH. 44106.

The ciliary ganglion (CG) is classified as parasympathetic based on several criteria including location, acetylcholine synthesis and cholinergic target effects. Some CG neurons, however, are immunoreactive for TH, the rate-limiting enzyme in catecholamine synthesis (J Nsci 7:3574).

To learn more about TH expression and regulation in the CG, immunoblot and in situ hybridization studies were preformed. Comparison of immunoblots of CG and sympathetic ganglia revealed a 62kd band in both tissues. Analysis of IR/neuron suggested that similar amounts of TH were present in CG and sympathetic cell bodies. A higher molecular weight band was also detected in CG. In situ hybridization of CG sections with ^{35}S-labeled oligonucleotide probes showed that approximately the same proportion of CG neurons that exhibited TH-IR possessed TH mRNA. However, the TH mRNA levels were significantly lower in CG neurons than in sympathetic. The difference in the ratio of TH protein: mRNA in the two populations may reflect the absence of TH-IR in CG axons in normal adult rats. Chronic sympathectomy increases TH-IR in CG, results in detectable axonal transport of TH-IR and causes a significant increase in both the number of CG cells that contain TH mRNA and the amount per cell. By analogy with TH regulation in sympathetic neurons, NGF and impulse activity are likely candidates to mediate these effects. Supported by NINCDS 23678.

407.2

EXPRESSION OF SUBSTANCE-P (SP) BY SENSORY NEURONS OF DEVELOPING CHICK DORSAL ROOT GANGLION (DRG): ROLE OF CENTRAL AND PERIPHERAL CONNECTIONS. E: PHILIPPE*; C. DUC* and B. DROZ. Inst. Histol. Fac. of Med. Lausanne (Switzerland)

To determine the possible role of both the peripheral target tissues and the spinal cord on the expression of SP by sensory neurons, we studied DRG under the following experimental conditions: 1) When one hindlimb was resected in ovo at E 6 prior to the formation of specialized peripheral connections, the percentage of SP-immunoreactive ganglion cells (60 %), examined 6 days later, was not different from control DRG. However the intensity of immunostaining decreased.
2) When one hindlimb was resected at E 12 after establishment of peripheral connections, the immunostained cell bodies corresponded, 6 days later, to about 25 % of the neuronal population.
3) When the lumbosacral segment of the neural tube was destroyed by cauterization, the percentage of SP-immunoreactive cells examined 6 days later, was not different from the control DRG. These results suggest that SP-expression of sensory neurons may be modulated by peripheral target tissues but not by the spinal cord. (Swiss Nat.Science Foundation 3.447.83).

COMPARISON OF NEUROTRANSMITTER APPEARANCE IN THE PARACERVICAL GANGLION AND UTERINE CERVIX OF THE FEMALE RAT DURING DEVELOPMENT. K.A.Sullivan*, R.E.Papka and H.H. Traurig, Dept. of Anat. and Neurobiol., University of Kentucky, Lexington KY.

Our lab is currently interested in the development of the innervation to the female reproductive system. Acetylcholinesterase (ACHE) a marker for cholinergic neurons, tyrosine hydroxylase (TH) a marker for noradrenergic neurons, neuropeptide tyrosine (NPY) and vasoactive intestinal polypeptide (VIP) are present in the neurons of the adult paracervical ganglion (PG) and in axons in the adult uterine cervix. ACHE,TH,NPY,and VIP cell bodies are demonstrable in the PG on postnatal day 0. At this time ACHE,TH,NPY and VIP immunoreactivity is also seen in the cervix, mainly as bundles of preterminal axons. At early stages of development varicose fibers are not apparent but appear distinct by day 36. ACHE staining appears to increase in intensity in neurons and axons from days 0 to 36. There appears to be a relative decrease in the number of TH neurons and axons from day 0 to 36. The relative number of NPY and VIP neurons appears to increase from days 0 to 16. During this time NPY and VIP axons begin to branch, and form a mature appearing plexus by day 36.(Supported by NIH Grant NS-22526).

IMMUNOCYTOCHEMICAL LOCALIZATION OF PROTEIN KINASE C ISOZYMES IN RAT BRAIN. F. L. Huang*, Y. Yoshida*, H. Nakabayashi*, W. S. Young, III, and K.-P. Huang* (SPON: R. J. Waldbillig) NIH, Bethesda, MD 20892.

Recently we isolated three protein kinase C (PKC) isozymes from rat brain (PNAS 83 8535, 1986), and have determined the relative levels of each enzyme in various regions of rat brain (JBC 262, 15714, 1987). The present study describes the cellular distributions of PKC isozymes in rat brain as determined by light microscopic immunocytochemistry. Staining with PKC antibodies revealed strong immunoreactivities in neuronal somata and their dendrites. In cerebellum, the type I PKC antibodies stained the Purkinje cell bodies and dendrites; the type II PKC antibodies stained the granule cells; and the type III PKC antibody stained both Purkinje and granule cells. In the cerebral cortex, all antibodies stained neurons resembling pyramidal cells and their apical dendrites in layers II to VI, while layer I was nearly devoid of staining. However, staining with the various isozyme-specific antibodies revealed distinct laminar distribution patterns of the positively stained neurons. In the hippocampal formation, both pyramidal cells of the hippocampus and granule cells of the dentate gyrus were stained by all PKC antibodies. Subcellularly, type III PKC appeared mostly in the cytoplasm of these neurons whereas type I and II PKC seemed to associate with both cytoplasm and nucleus. The distinct cellular and subcellular distribution of PKC isozymes suggest that each isozyme plays an unique role in various neural functions. In developing cerebellum, cell type specific stainings indicated that the expression of PKC isozymes are differentially controlled and related to the various phases of cell proliferation and synaptogenesis during brain development.

EXPRESSION OF NPY, CGRP, AND NADPH-DIAPHORASE IN NEURONS OF THE DEVELOPING MURINE BOWEL: RELATIONSHIP TO THE APPEARANCE OF MUCOSAL 5-HT T.A.Branchek and M.D. Gershon, Dept. Anat. and Cell Biol. Columbia Univ. P&S, New York, N.Y. 10032.

The mechanisms underlying the generation of phenotypic diversity in enteric neurons are unknown. Serotonergic and cholinergic neurons appear earlier in ontogeny (day E12) than those which contain substance P or VIP (day E14), although substantial stores of endogenous 5-HT and neural 5-HT receptors are acquired long after serotonergic neurons can first be recognized. Enteric neural precursors continue to divide in the presence of mature neurons. These observations have led to the hypotheses that peptidergic neurons develop later than those that utilize small molecule transmitters and that early developing neurons affect neural development. In order to test these hypotheses we studied the phenotypic expression of neurons recognized by antisera to NPY and CGRP, and by the histochemical demonstration of NADPH-diaphorase. NPY immunoreactivity (IR) appeared for the first time on day E12, when it was seen in the stomach. NADPH-diaphorase, which is co-expressed with NPY-IR in many enteric neurons, was also found at this age. By day E13, the entire length of the bowel contained NPY-IR. In contrast, CGRP-IR could not be detected anywhere in the gut until day E17, but by day E18 all regions of the gut contained CGRP-IR neurons. Endogenous 5-HT was first detected at day E16 in mucosal epithelial cells in all segments of the bowel except the stomach, where it appeared at day E18. The NPY/NADPH diaphorase set of neurons thus develop before the acquisition of a detectable level of endogenous 5-HT or enteric neural 5-HT receptors. Consequently, small molecule transmitters do not necessarily develop earlier than peptides in enteric neurons and it is unlikely that 5-HT affects the differentiation of NPY/NADPH diaphorase neurons. Nevertheless, the possibility that 5-HT (or another early-appearing transmitter) might affect the development of CGRP-containing neurons has not been excluded. Supported by NIH grants # NS 22637, NS 15547, and NS 12969.

SPATIAL AND TEMPORAL EXPRESSION OF NEUROPEPTIDE mRNAs ENCODING MET-ENK, POMC, AND TRH: MAPPING IN XENOPUS LAEVIS USING *IN SITU* HYBRIDIZATION. W. P. Hayes, R. T. Zoeller and Y. P. Loh. LNN/NICHD, LNC/NINCDS, NIH, Bethesda, MD, 20892.

Neuropeptides have recently been implicated as trophic factors in neuronal development in addition to their well-documented neuromodulatory effects. To examine this possibility in early development, we have turned to the frog as a model system. *In situ* hybridization histochemistry was used to map neuropeptide mRNA expressing cells in adult and developing Xenopus laevis. Due to low amounts and rapid turnover of neuropeptides, *in situ* hybridization is a very sensitive cytochemical method for detecting neuropeptide expressing cells. 48-mer oligonucleotide, ^{35}S-labeled probes encoding regions of Xenopus-specific met-enkephalin (met-Enk), proopiomelanocortin (POMC), and thyrotropin releasing hormone (TRH) mRNA sequences were used to screen paraformaldehyde-fixed, cryoprotected, serially-sectioned frozen material.

Discrete patterns of hybridization for met-Enk, POMC and TRH mRNA were found in preoptic and hypothalamic areas in adult brain. In addition, POMC mRNA labeling was observed in cells confined within a tegmental nucleus, whereas cells labeled for met-Enk and TRH mRNA were differentially distributed in telencephalic areas, thalamus and motor nuclei. The distribution of labeled cells found in the CNS of Stage 45-46 tadpoles was similar to that found in adults. Earlier embryonic stages are being examined to determine when cells first express these neuropeptide mRNAs and whether cells express neuropeptides transiently. (W.P.H. and R.T.Z. are supported by Associateship grants from the National Research Council.)

THE SUBSTRATUM INFLUENCES NEUROTRANSMITTER EXPRESSION IN CULTURES FROM 3-DAY-OLD CHICK EMBRYO. D. Mangoura, N. Sakellaridis and A. Vernadakis.* Depts. of Psychiatry & Pharmacology, Univ. of Co. Sch. of Med. Denver, CO 80262.

We have reported: a) the developmental profiles of glutamate decarboxylase (GAD) and choline acetyltransferase (ChAT) bio- and immunocyto-chemically, for GABAergic and cholinergic neurons respectively, in neuroblast-enriched cultures from 3-day-old chick embryo, plated on poly-L-lysine in DMEM+10% FCS; and b) collagen as culture substratum inhibited neuronal aggregation and neuritic fasciculation. In this study, assessment of the same parameters, expressed as nmoles/mg protein/hr, for cultures on collagen revealed that while ChAT was not affected by the different substrata and thus the different cell organization, GAD was always markedly higher, increasing from culture day 3 (C3) up to C17 and remaining high up to C21. Similar effect was produced by 10ng NGF/ml of culture medium for neurons grown on poly. Immunostaining for GABA and ChAT reflected the biochemical findings. Overlapping of AChE and GABA staining indicated the presence of "cholinoceptive" GABAergic neurons on collagen. Glutamine synthetase and cyclic nucleotide phosphohydrolase, markers for astro- and oligodendro-cytes, showed very low, running in parallel profiles for both substrata, not related to GAD or ChAT peaks. These differences in GAD activity are attributed to factors secreted from nonneuronal cells, present in cultures on collagen, and/or cellular contacts shifting the GABA phenotypic expression (Support: MH15442).

DISSOCIATED CELL CULTURES OF GUINEA PIG CELIAC GANGLIA: AGE-DEPENDENT EXPRESSION OF NEUROPEPTIDE IMMUNOREACTIVITIES. D.L. Kreulen, R. Gruener and S.G. Matsumoto*. Depts. Pharmacology and Physiology, Univ. Ariz. Coll. Med., Tucson, AZ. 85724

We determined the relationship between expression of neuropeptides in culture and the age of the fetuses from which the neurons were derived. Neurons derived from the celiac ganglion of adult guinea pigs or fetuses at approximately 60% of term or greater exhibit immunoreactivities (IR) for neuropeptide Y (NPY) and somatostatin (SOM). Under standard culture conditions (ie. neurons grown alone) 60-80% of the neurons display NPY-IR and 10-30% SOM-IR when examined at 6 days to over 8 weeks in culture. Over 90% of the neurons also display tyrosine hydroxylase (TH)-IR and show glyoxylic acid-induced catecholamine histofluorescence (GIF).

Cultures established from earlier developmental stages showed a greatly reduced proportion of NPY-IR (20-40%) and SOM-IR (2-5%) neurons. The number of TH-IR and GIF positive neurons remains high (>90%). Many of these neurons make cholinergic synapses upon themselves and on other neurons when they are co-cultured with cardiac myocytes in microcultures.

Supported in part by NIH HL27781, HL01136 (DLK) and NIH 25644 (SGM).

407.9

POSTNATAL DEVELOPMENT OF TYROSINE HYDROXYLASE IMMUNOREACTIVE NEURONS IN THE MOUSE CNS. J.Satoh* and K.Suzuki. Dept. of Pathology, Sch. of Med., Univ. of North Carolina, Chapel Hill, NC 27599-7525

Using polyclonal antiserum to tyrosine hydroxylase (TH, Eugene Tech, NJ), we studied expression of TH-like immunoreactivity in CNS neurons during postnatal development in the mouse. Swiss Webster albino mice (from P2 to P40) were anesthetized and perfused with 2.5% glutaraldehyde / 2% paraformaldehyde. 50μm vibratome sections were treated with 1% sodium borohydride (Kosaka et al, Neurosci 18: 957, 1986) and immunostained with avidin-biotin complex method. TH-like immunoreactive neurons (TH-IN) were detected in substantia nigra, locus ceruleus, arcuate nucleus and pyriform cortex in all age groups. In neocortex, between P8 and P18, many intensely positive TH-IN were found in the medial (anterior and posterior), frontal and temporal regions of neocortex. Intensely stained neurons were pronounced in the cingulate and the cortex lateral to the striatum. Most TH-IN were multipolar and located in the deep cortical layers. Immunoreactivity of TH-IN decreased significantly after P18 and was hardly detectable at P40. Transient enhancement of immunoreactivity was also noted in TH-IN in the inferior colliculus. Similar transient expression of TH-IN during postnatal period has been reported (Jaeger et al, Dev Brain Res 1:128, 1983; Burger et al, Dev Brain Res 3:141, 1985) in the rat. Transient "overshoot" of TH activity between P13 and P18 was reported in the mouse (Baker et al, Dev Brain Res 4:157, 1982). These observations suggest the importance of the catecholamine system in this particular period of brain development. Our preliminary observation on increased numbers and intensity of TH-IN in mice treated with disulfiram during this period suggests that perturbations of the brain catecholamine system may be expressed as changes in TH-IN.

407.10

AMOUNTS OF TYROSINE HYDROXYLASE mRNA DURING MATURATION OF RAT HYPOTHALAMUS, SUBSTANTIA NIGRA, SUPERIOR CERVICAL GANGLION AND ADRENAL. W. Kedzierski* and J.C. Porter, Dept. OB/Gyn and Physiol., Univ. of TX Southwestern Medical Center, 5323 Harry Hines Blvd. Dallas, TX 75235

The purpose of this study is to investigate the effect of age on tyrosine hydroxylase (TH) mRNA in catecholamine-secreting cells. TH mRNA was analyzed by an S1 nuclease assay utilizing a [^{32}P]-labelled RNA probe (cRNA) that is complementary to TH mRNA. TH mRNA was extracted from tissue using guanidinium thiocyanate-phenol and hybridized with [^{32}P]cRNA. The product was subjected to S1 nuclease digestion. The TH mRNA-[^{32}P]cRNA duplex was dissociated, and the protected [^{32}P]cRNA was purified by urea PAGE. An autoradiogram of the gel was analyzed by densitometry. TH sense RNA, which served as a standard, was treated similarly. TH mRNA increases five to sixfold between 4 days and 6 weeks of age in the hypothalamus, substantia nigra, and adrenal (Table 1). Further development does not change the level of TH mRNA in the brain. However, between 6 weeks and 12 weeks, TH mRNA in the adrenal increased twofold.

Table 1. TH mRNA (amoles) in maturing male rats.

Age	Hypo-thalamus	Substantia nigra	Sup.cerv. ganglion	Adrenal
4 days	7.5 ± .4	107 ± 2	--	62 ± 3
6 wks	45 ± 10	480 ± 25	215 ± 14	378 ± 21
12 wks	51 ± 8	478 ± 13	274 ± 11	865 ± 30

ADRENERGIC DIFFERENTIATION IN QUAIL DORSAL ROOT GANGLION CELLS CAN BE INITIATED BY INSULIN AND IGF-I. J. Smith*, Z.G. Xue* and N.M. Le Douarin, Institut d'Embryologie Cellulaire et Moléculaire du CNRS et du Collège de France, 94736 Nogent-sur-Marne, France.

Avian dorsal root ganglia (DRG) contain a population of cells that are able, when cultured in vitro, to express a catecholaminergic phenotype, displaying tyrosine hydroxylase (TH) immunoreactivity and synthesising noradrenaline (Xue, Z.G. et al., Proc. Natl. Acad. Sci. USA 82:8800, 1985). In situ hybridisation with a quail TH-cDNA probe (Fauquet, M. et al., J. Neurochem. 50:142, 1988) reveals that TH mRNA is first expressed on day 3 of culture, at virtually the same time as the enzyme becomes detectable immunocytochemically. Catecholaminergic differentiation in this system is highly dependent on the presence of chick embryo extract (CEE). We have used quail DRG cultures, grown without CEE, to assay various hormones and growth factors for catecholaminergic differentiation-promoting activity. EGF, FGF, NGF, hydrocortisone and tri-iodothyronine are, at best, only slightly effective. In contrast, nanomolar concentrations of insulin or IGF-I elicit the development of as many TH-positive cells as do optimal concentrations of CEE. In all respects (phenotypic characteristics of the cells, their emergence from dividing precursors, the kinetics of appearance of TH mRNA and protein), the catecholaminergic differentiation observed in the presence of insulin appears identical to that occurring in medium containing CEE. We suggest that insulin-like polypeptides are plausible candidates for a role in triggering the normal development of sympathoblast precursors in vivo.

407.12

CHARACTERIZATION OF TYROSINE HYDROXYLASE (TH)-POSITIVE CELLS CULTURED *IN VITRO* FROM EMBRYONIC CHICK SPINAL CORD. J.A. Wallace, P.C. Allgood*, R.R. Maez*, A.A. Romero*, A.J. Valleios*, I. Lopez-Colberg and A.C. Towle. Dept. of Anatomy, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131.

Numerous TH-immunoreactive cells occur in the embryonic chick spinal cord, both ventral to the central canal and along the lateral border of the dorsal horn (Wallace et al., Neurosci. Letts., 83:253, '87). While only occasional cells are detected on embryonic day 15 (E15), these cells quickly reach their full complement in numbers by E17. When examined by GA histofluorescence, these TH-positive spinal cord cells are catecholamine (CA)-negative, although in other species they have been shown to contain dopamine (DA). In the present study, we examined the development of the TH-positive cells grown in vitro. Dissociated cells from chick spinal cords from E8 or E10 embryos were incubated for varying lengths of time on collagen-coated plastic slides. When cultured for 8 days, large numbers of TH-immunostained cells are present. Cells are also detected by anti-DA immunocytochemistry, although their number represents less than 10% of TH-stained neurons found in sister cultures. When the cultures are incubated for shorter periods (approximating embryonic in ovo ages earlier than E15), very few TH-containing cells are found. Thus, the relative timing of appearance of TH-positive cells grown in vitro closely mimics that observed in vivo. This model system may allow an examination of factors influencing CA neurotransmitter phenotype expression in the developing CNS. (Funded by NSF BNS-8511079 and NIH RR-08139.)

ONTOGENY OF THE PROTHORACICOTROPES IN THE TOBACCO HORNWORM, MANDUCA SEXTA. A.L. Westbrook* and W.E. Bollenbacher. Dept. of Biology, CB# 3280, Coker Hall, University of North Carolina, Chapel Hill, NC 27599-3280.

Prothoracicotropic hormone (PTTH) is a neuropeptide regulator of insect molting and metamorphosis. The expression of PTTH during embryogenesis in Manduca sexta was examined immunocytologically using a monoclonal antibody against PTTH. The neuropeptide was first expressed by the 4 lateral cerebral neurosecretory cells (L-NSC III) between 25-30% of embryonic development. The developing axons of these NSC traversed the cerebral lobes and decussated to the contralateral lobe (approximately 45% development), and exited the brain via the nervus corporis cardiacum I+II (approximately 60% development). Growth of dendritic processes within the protocerebral neuropil began at approximately 60% development, and their complexity increased up to hatching. By approximately 75% embryonic development, the axons had reached the corpora allata and arborized forming the terminal varicosities of the neurohemal organ. In addition to the L-NSC III, transient PTTH-like immunoreactivity was observed in the frontal and subesophageal ganglia, as well as the lateral brain regions.

EARLY DEVELOPMENT OF GABA IMMUNOREACTIVE NEURONS IN CEREBRAL CORTEX OF FETAL MONKEYS. M.L. Schwartz and P.S. Goldman-Rakic. Sect. of Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510

Many features of cortical connections in monkeys are well specified by the latter third of gestation. Here we have examined the development of GABA-containing local circuit neurons in the macaque prefrontal cortex (PFC). Sections of dorsolateral PFC from 15 fetal monkeys were processed for GABA (Incstar) immunoreactivity. As early as embryonic day 55 (E55) of the 165 day gestational period, GABA immunoreactive neurons (GINs) are present within the cortical plate (CP), the underlying subplate (SP) and the intermediate zone (IZ). The majority of GINs form a band spanning lower layer VI and the upper portion of the SP/IZ. SP/IZ GINs are multipolar or have an elongated soma with leading and trailing processes, the latter resembling migrating cortical neurons. Between E55 and E72 the density of GINs increases and cells in the subplate and lower layer VI develop elaborate processes. GINs are now present throughout the CP; their density increasing from superficial to deep with the exception of the high density in the marginal zone. Between E72 and E116 their density in the IZ/SP diminishes. At E116 all GINs are non-pyramidal in morphology and are densest in layers I and VI. The E116 pattern is not fully mature in that relatively few labeled cells are found in layer II and upper layer III. Between E116 and E131 two dense bands of labeled cells emerge: one spanning layers I, II and upper layer III and the other in layer IV. GINs in the emerging white matter are now fewer in number and the overall laminar pattern is similar to that of mature monkeys. These results indicate that many neurons of the developing cortex express GABA within the first third of gestation. Further, their morphology and early appearance in the IZ and SP suggest that GABA may be expressed in some cells during migration. Supported by BNS8617585,MH38546 and NS22807

LAMINAR DISTRIBUTION OF $GABA_A$ RECEPTOR AND GABA IMMUNOREACTIVITIES DURING DEVELOPMENT OF RAT CEREBRAL CORTEX. A. Cobas*, G. Alvarez-Bolado*, A.L. DeBlas and A. Fairén* (SPON: European Neuroscience Association). Instituto Cajal, CSIC, 28006 Madrid, Spain, and Department of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

Rats aged from E16 through P33 were processed for the immunocytochemical localization of GABA (Seguela et al., 1984, PNAS, 81:3888-92) and $GABA_A$ receptor (mAb 62-3G1: de Blas et al., 1988, J. Neurosci., 8:602-14; Vitorica et al., 1988, J. Neurosci., 8:615-22). At E16, $GABA^+$ cells are abundant at the lower intermediate zone and at both sides of the cortical plate (CP), which is also outlined by two narrow bands of $GABA_A$ immunoreactivity. With advancing development, the marginal zone soon becomes the most densely immunoreactive lamina for the $GABA_A$ receptor. In perinatal animals, the neuropil between the inferior border of the CP and the superior limit of the white matter shows a pattern of $GABA_A$ immunoreactivity characterized by laminar differences in intensity. $GABA^+$ cells are most abundant at this level. The laminae of $GABA_A$ immunoreactivity gradually become less distinct during the next stages of postnatal development. At P33, the densest $GABA_A$ immunostaining is in layer I, the rest of the layers showing a rather uniform pattern of staining.

With the exception of the earliest stages, a parallelism exists between the laminar patterns of $GABA_A$ and GABA immunoreactivities observed during cortical development.

ANGIOGENESIS IN THE OPTIC TECTUM OF XENOPUS TADPOLES. C.M. Rovainen. Dept. Cell Biol. and Physiol., Washington Univ. Sch. Med., St. Louis, MO 63110

The goal of this work has been to develop an amphibian model for the growth of capillaries of the CNS. Anesthetized tadpoles of albino Xenopus laevis are sufficiently transparent that individual capillaries, blood cells, endothelial nuclei, and sprouts can be resolved on the surface of the optic tectum in vivo by conventional light microscopy.

1. Case histories indicated the pial capillaries developed by the classical mechanism of sprouting of endothelial cells from existing blood vessels (Eliot Clark, 1918).
2. "Deep sources" apparently developed from surface capillary sprouts that penetrated the basement membrane, invaded the nervous tissue, and joined more arterial vessels in the ventral brain.
3. The dorsal medial venules enlarged in diameter as they drained an increasing blood flow from the tectum into the sinuses of the caudal choroid plexus.
4. Some capillaries disappeared during development. Early signs of regression appeared to be cessation of flow, narrowing, and loss of contrast. A common site of regression was upstream from a deep source.
5. No significant differences in densities of surface vessels or of deep sources were observed after removal of one eye, rearing at 30° or 12°, or rearing at half atmospheric pressure or in high O_2.

TYROSINE HYDROXYLASE IMMUNOREACTIVITY AND DOPAMINE SYNTHESIS PRECEDE DOPAMINE UPTAKE IN MESENCEPHALIC DOPAMINERGIC NEURONS FROM RAT EMBRYOS. M.L. Fiszman*, A. Zuddas, J.L. Barker and U. di Porzio. Laboratory of NeurophysIology, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health, Bethesda, MD 20892.

In this report we show that in vivo the development of tyrosine hydroxylase (TH) immunoreactivity and dopamine (DA) synthesis in mesencephalic DA neurons from rat embryos takes place before the onset of DA uptake system. Ventral mesencephali from embryonic day 11 (E11) to 1 week after birth were dissected and either processed for determination of endogenous CA by HPLC or dissociated after papain digestion (20 units/ml, 45 min/37°C) and plated in polylysine coated dishes. Cells were allowed to adhere to the plate for five hours and either fixed (4% paraformaldehyde) for tyrosine hydroxylase immunostaining or incubated with 50nM of ^{3}H-DA for 30 min/37°C or 0°C (blanks) for uptake experiments. DA begins to be detectable by HPLC in the mesencephalic homogenates at E13-E14 (about 5% of E19 content) but could not be determined in the striatal tissue before E16-E17 (1-3 pg/mg protein). TH-immunoreactivity is already present in E12 cells (putative DA neurons) and the number of TH^+ neurons increases thereafter. Quantitative data on the development of TH^+ neurons will be presented. The DA uptake mechanism appears in these cells between E15 and E16 and its capacity increases with embryonic age. The maturation of DA uptake in DA mesencephalic neurons appears therefore coincidental with the beginning of DA innervation in the striatum thus suggesting that its development is regulated by the contact with target striatal neurons, as previously observed in culture (PNAS 76, 5387, 1979; Nature 288, 370, 1980).

407.18

GABA, NEUROPEPTIDE, AND TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE FRONTAL CORTEX OF FETAL MONKEYS. G.W. Huntley, S.H.C. Hendry, H.B. Killackey, L.M. Chalupa and E.G. Jones. Depts. of Anatomy and Neurobiology and Psychobiology, University of California, Irvine, CA. 92717 and Dept. of Psychology, University of California, Davis, CA. 95616.

The frontal lobes from six fetal rhesus monkeys (Macaca mulatta) were used to examine the morphology and distribution of immunocytochemically identified GABA and neuropeptide containing neurons and to study the distribution of tyrosine hydroxylase-immunoreactive (ir) fibers during the third trimester of gestation (E110,121,131,135,150,155). All ir-cell and fiber populations were present from the youngest age. In each of the fetuses, GABA-ir neurons were present in all layers and in the subcortical white matter, but were densest in a superficial band (layers I-II) and in a deep band (layer IV). Neurons ir for NPY and SRIF were scattered throughout layers II-VI, but were densest in the underlying white matter. SP-ir somata occupied a thin band corresponding to layer V. Proenkephalin A (BAM-18)-ir neurons were located in the upper half of layer II. TH-ir fibers were densest in layers I-III and in layer VI and the subjacent white matter. Additionally, occasional TH-ir somata were present in layer VI of the developing frontal cortex. The patterns of cell and fiber immunostaining are unlike those in the adult, and show significant changes in morphology, distribution and density over the gestational period examined. Supported by Grants EY 06432, NS 21377 and RR 00169 from the National Institutes of Health.

408.1

EFFECTS OF IONTOPHORETICALLY APPLIED U50,488H (A KAPPA OPIATE AGONIST) IN THE SUBSTANTIA NIGRA. L.A. Thompson and J.M. Walker. Department of Psychology, Brown University, Providence, RI 02912.

The presence of a prodynorphinergic striatonigral pathway and the presence of kappa opiate receptors in the substantia nigra (SN) suggest a physiological action of kappa-selective peptides in this area. In order to investigate specific kappa actions in the SN, the selective agonist, U50,488h, was applied by microiontophoresis during extracellular single unit recording of neurons in the SN pars compacta (SNC) and the SN pars reticulata (SNR) in rats.

U50,488h had no effect on dopaminergic neurons of the SNC and predominantly inhibited the spontaneous firing of neurons in the SNR. Approximately 50% of SNR neurons tested were inhibited by U50,488h, and this effect was dose dependent. U50,488h appears to differentially affect SNR neurons that are distinguished by their response to a mechanical pressure stimulus applied to the hindpaw. Cells that exhibit an increase in firing rate in response to mechanical pressure are inhibited by U50,488h more often than cells that exhibit a decrease in firing in response to the stimulus or that are unaffected. These results support previous findings from this laboratory that the systemic administration of U50,488h differentially inhibits SNR neurons that exhibit excitation in response to mechanical pressure.

408.2

RECEPTOR BINDING PATTERNS IN THE BASAL GANGLIA OF PIGEONS E.K. Richfield, R.L. Albin, A. Reiner, A.B. Young and J.B. Penney, Jr. Dept. of Neurology, Univ. of Michigan, Ann Arbor, MI and Dept. of Anatomy and Neurobiology, Univ. of Tennessee., Memphis, TN.

Recent studies have shown that the basal ganglia in birds consists of fundamentally the same neuronal populations as in mammals, with the neurons of each population being definable in terms of their connections and neurotransmitter content. These results have suggested a high degree of similarity in functional organization of the basal ganglia among birds and mammals. To further explore this similarity, we have used autoradiographic techniques to examine the pigeon basal ganglia for the presence and distribution of several different receptor types that bind neurotransmitters known to be present in avian basal ganglia and its projection systems.

The following receptor types were examined (with the radiolabeled ligand used for each in parentheses): 1) D-1 dopamine (SCH23390); 2) D-2 dopamine (spiperone); 3) muscarinic cholinergic (QNB); 4) NMDA (glutamate blocked with cold quisqualate); 5) quisqualate (QA) (glutamate blocked with cold NMDA); 6) GABA-A (GABA blocked with cold baclofen); 7) GABA-B (GABA blocked with cold isoguvacine); and 8) benzodiazepine (BDZ) (flunitrazepam). The striatum was found to be rich in D-1, D-2, muscarinic, NMDA, QA, GABA-A and BDZ receptors. Of the target areas of the striatum, the pallidum was rich in GABA-A and BDZ receptors, while the nigra contained moderate levels of D-1, D-2, muscarinic, GABA-A and BDZ receptors. These results are similar to those in mammals and are consistent with the view that neurotransmitters previously localized to the pigeon basal ganglia play roles very similar to the roles they play in mammals. Supported by NS-19620 (A.R.) and NS-19613 (A.B.Y.).

NEOSTRIATAL AND FRONTAL CORTICAL CATECHOLAMINE CELLS IN LONG-TAILED MACAQUES: INDIVIDUAL VARIATION AND LESION-INDUCED OVERDEVELOPMENT. Mark Dubach, Richard H. Schmidt, Douglas M. Bowden. Psychiatry and Behavioral Sciences, Neurological Surgery, and Regional Primate Research Center, University of Washington, Seattle WA 98195.

We have reported a population of neostriatal neurons containing tyrosine hydroxylase-like immunoreactivity (TH-LI) (Neurosci Lett 75:205). We have now found these cells to be positive for dopa decarboxylase, but not for dopamine beta-hydroxylase, suggesting dopamine as their neurotransmitter. Furthermore, we have detected a similar population of cells in the medial frontal cortex (subcallosal gyrus, gyrus rectus) distributed (as in the striatum) near the border between white and gray matter.

In some monkeys, however, we have seen fewer positive cells than in others. To examine such variability while minimizing technical variations in processing, we performed immunohistochemistry on tissues from six animals simultaneously, treating comparable sections from each of twelve hemispheres together in each container. Results indicate a wide range of variability among individuals. In several animals, including three of those treated simultaneously, we have examined these cells as they appear in striatum denervated of dopaminergic input by a lesion of the substantia nigra. Striatal TH-LI cells under these conditions appear to possess thicker and more extensively ramified processes than cells in normal striata. Analysis by densitometry and quantitative microscopy suggests that the overdevelopment is correlated with diminished nigral input. The time-course of this neuronal plasticity after 6-OHDA and electrolytic lesions is now under investigation. (USPHS grants NS25724 and RR00166).

ULTRASTRUCTURE OF THE MARGINAL DIVISION OF THE STRIATUM IN THE RAT. S.Y. Shu*, C.E. Bland, and T.M. Charles. East Carolina University, Greenville, NC 27858. U.S.A. *Department of Neurobiology, Fourth Military Medical College, Xian, China.

In our former study, a new subdivision of the striatum, the marginal division was found in the rat (Shu et al. J. of Chemical Neuroanatomy 1988). The marginal division is a narrow band located at the caudal margin of the striatum surrounding the rostral and lateral border of the globus pallidus. Neurochemically, the marginal division is lighter in acetylcholinesterase staining and more densely filled with Met-enkephalin-, substance P-, and dynorphin B- immunoreactive fibers and terminals than the other part of the striatum.

This study investigates the ultrastructure of the marginal division of the striatum in the rat. Morphologically, the neurons in the marginal division are oval with a medium amount of cytoplasm which is rich in rough endoplasmic reticulum and mitochondria. The nuclei of these neurons are also oval-shaped without indentation. There are many types of synapses in the marginal division. These are axo-dendritic (A —> D, A —> D <— A, D <— A —> D), axospinous and axo-somatic. Most of them are asymmetrical synapses. The multiplex of synapses indicates the functional complexity of the marginal division in the striatum.

DESCENDING PROJECTIONS FROM SUBSTANTIA NIGRA TO THE MEDULLARY RETICULAR FORMATION. M. von Krosigk* and A.D. Smith. MRC Anatomical Neuropharmacology Unit, University Dept. Pharmacology, South Parks Road, Oxford, OX1 3QT, UK.

Using both retrograde and anterograde neuroanatomical tracers we report a descending projection from the substantia nigra to the medullary reticular formation of the rat. The retrograde tracer Wheat Germ Agglutinin Horseradish Peroxidase (1-5%, Sigma) was injected (8-100 nl) into the medullary reticular formation. These injections revealed the presence of retrogradely labelled cells in both substantia nigra pars compacta and pars reticulata, SNc and SNr, respectively, with the majority of cells found in SNr. Within SNr the labelled cells were restricted to the caudal and lateral half of SNr. Injections of the anterograde tracer Phaseolus Vulgaris Leucoagglutinin into the caudal and lateral substantia nigra revealed a medullary projection which was restricted to the lateral parvocellular reticular formation, PCRt. This anterograde labelling ran throughout the rostrocaudal extent of the PCRt. Also labelled was the rostral region of the nucleus of the solitary tract, NTS. Caudally, the labelling in the NTS was restricted to the ventrolateral NTS, dorsally adjacent to the PCRt.

SUBTRACTIVE cDNA CLONING OF NEURONALLY EXPRESSED mRNAs ENRICHED IN RAT CAUDATE PUTAMEN. Joseph B. Watson* and J. Gregor Sutcliffe (SPON: S. Forss-Petter). Molecular Biology Department, Research Institute of Scripps Clinic, La Jolla, CA 92037.

Precise knowledge of the neuronal organization of the neostriatum (caudate nucleus, putamen) will help to better define its role in voluntary movement and may suggest hypotheses to explain striatal pathologies (e.g. Huntington's Disease). One important task is to describe the presently known striatal cell types in more molecular detail. Toward this end, we are systematically isolating cDNA clones (such as pRC3) of mRNAs with enriched expression in rat caudate putamen. RC3 detects two postnatally expressed mRNAs (1.0 kb, 1.5 kb) prevalent in striatum, cerebral cortex, hippocampus, much less abundant in olfactory bulb, pons, and undetectable in cerebellum. Translation of a full length cDNA sequence predicts a novel 9.4 kDa protein with a cysteine-rich domain at its NH_2-terminus similar to cobra venom neurotoxins and C5a anaphylatoxin, and a glycine-rich domain at the COOH-terminus similar to that found in keratin. In situ hybridization experiments show that RC3 mRNA is expressed in restricted neuronal populations of the telencephalon and diencephalon. There is elevated expression in medium-size neurons of the caudate putamen over globus pallidus suggesting that RC3 may be a marker for a class of striatal neurons. Analysis of additional cDNA clones detected by subtractive hybridization using a rat caudate putamen-enriched cDNA probe will also be presented.

408.7

EFFECTS OF INTRASTRIATAL ESTROGENS ON THE DORSAL IMMOBILITY RESPONSE IN GONADECTOMIZED MALE AND FEMALE RATS. C.Van Hartesveldt, G.A. Cottrell and M.E. Meyer*. Psychology Dept., Univ. Florida, Gainesville, FL 32611.

Previous research has shown that in OVX females, intrastriatal estradiol significantly potentiates the dorsal immobility response (DIR), a response elicited by lifting the rat off its feet by the skin at the nape of its neck. We investigated whether intrastriatal estrogens or a catecholestrogen would have the same effect in castrated male rats.

Male and female Long-Evans hooded rats were gonadectomized and implanted with guide cannulae above the anterior dorsal striatum. After 2 wk recovery, independent groups of rats were implanted in the dorsal striatum with cannulae filled with 17αestradiol, 17βestradiol, 4-hydroxyestradiol, or cholesterol 4 hr prior to testing. Rats were tested for the DIR for 3 trials with a 5 min cutoff and a 30 sec intertrial interval. In both males and females this response duration was significantly increased by both isomers of estradiol. However, only in the males did the catecholestrogen significantly increase the DIR.

Thus the striatum of male and female rats responds similarly to estradiol, but only the male striatum is sensitive to the effect of a catecholestrogen on this behavior. The effect of catecholestrogens on DA metabolism may differ in male and female rats.

408.8

POTENTIATION OF THE DORSAL IMMOBILITY RESPONSE BY HORMONES IN THE BASAL GANGLIA OF OVARIECTOMIZED RATS. M.E. Meyer,* G.A. Cottrell and C. Van Hartesveldt. Psychology Dept., Univ. Florida, Gainesville, FL 32611.

The dorsal immobility response (DIR) is a species-typical inhibitory response that is elicited by grasping the rat by the dorsal skin at the nape of the neck and lifting it off its feet. The DIR persists until the rat emits escape-like behavior. We administered hormones directly to the basal ganglia of OVX female rats to determine their specificity and site of action on this response.

Long-Evans female hooded rats were OVX, then implanted with guide cannulae directly above the anterior dorsal striatum. Two wk after surgery, injection cannulae were filled with 17βestradiol, 2-hydroxyestradiol, progesterone, or cholesterol and bilaterally implanted for 4 hr into the dorsal striatum. Each rat was tested for the DIR for 3 trials with a 5 min cutoff and a 30 sec intertrial interval. After 1 wk recovery periods, each rat was tested with each substance in a Latin square design. Only the 17βestradiol significantly increased the duration of the DIR.

In a second experiment 17βestradiol was implanted in OVX females as above for 4 hr into the dorsal striatum, nucleus accumbens, globus pallidus, or cerebral cortex. The DIR was significantly increased with implants in the dorsal striatum and nucleus accumbens.

408.9

EFFECTS OF INTRASTRIATAL ESTRADIOL ON APOMORPHINE-INDUCED STEREOTYPED BEHAVIORS. R.L. Smith and C. Van Hartesveldt. Psychology Dept., Univ. Florida, Gainesville, FL. 32611.

Previous research has shown that estradiol can alter DA-related stereotyped behaviors. This study investigated whether direct application of estradiol to several regions of the basal ganglia could differentially affect individual apomorphine (APO)-induced stereotyped behaviors.

Female Long-Evans hooded rats were ovariectomized and bilaterally implanted with guide cannulae into the anterior-dorsal striatum, nucleus accumbens or globus pallidus. Two weeks after surgery animals were implanted with either 17αestradiol or 17βestradiol, and tested 48 hours later with 0.45 mg/kg apomorphine. One week later the animals were given the reverse treatment and tested with apomorphine again. Individual stereotyped behaviors were recorded every 5 sec. for one hour.

The 17βestradiol implants in the anterior dorsal striatum and globus pallidus decreased oral behavior during portions of the test session and increased sniffing behavior. Other implants were ineffective. Therefore, the effects of estradiol on APO-induced stereotyped behaviors are specific to the estradiol stereoisomer, site of implant and the behavior.

408.10

NUCLEUS OF THE POSTERIOR COMMISSURE IN THE RED EARED TURTLE, PSEUDEMYS SCRIPTA. P. M. Bell and P. S. Ulinski, Dept. Anatomy, University of Chicago, Chicago, IL 60637.

Like the substantia nigra, the nucleus of the posterior commissure (nPC) is a link between the striatum and tectum of reptiles. We have analyzed the functional architecture of nPC to help understand its role in motor behavior. nPC extends from behind the habenula, rostrally, to the rostral pole of the tectum, caudally. It comprises a cell plate just lateral to the central grey and a cell poor zone that extends laterally to nucleus pretectalis. The cell plate contains a dorsal field of small cells with round somata and a ventral field of larger cells with fusiform somata. In Golgi material, the small celled field contains bipolar cells with dorsoventrally oriented dendrites. The ventral field contains: (1) bipolar cells; (2) "rabbit" cells whose dendrites are usually oriented laterally, like ears, away from round somata; and (3) multipolar cells whose dendrites extend in many directions. The cells have smooth dendrites that extend up to one mm from their somata in the transverse plane. HRP injections in tectum retrogradely label only cells in the ventral field, but all three types are filled. Rabbit cells are situated primarily along the medial axis of the nucleus.

408.11

THE SUBSTANTIA NIGRA OF THE RED-EARED TURTLE, PSEUDEMYS SCRIPTA ELEGANS. A. F. Chang* and P.S. Ulinski. Dept. of Anatomy, University of Chicago, Chicago, IL 60637.

The striatum of turtles projects to the substantia nigra, which projects in turn to the optic tectum. The substantia nigra gives rise to a dopaminergic projection back to the striatum, but nothing is known of its functional architecture. Thus, tyrosine hydroxylase immunohistochemistry and Golgi and Nissl preparations were used to examine the morphology of cells in the substantia nigra of turtles. The substantia nigra is divided into two zones, the pars compacta and the pars reticulata, and is situated dorsolateral to the ventral tegmental area. Cells in pars compacta have thick dendritic trunks that arise from fusiform somata and bear two to four primary branches that are smooth and branch infrequently. They resemble cells stained in tyrosine hydroxylase immunohisto-chemical preparations. The orientation of pars compacta cells varies with their position. The most ventromedial have dendrites that run ventrolaterally while those in more dorsal regions have dendrites oriented progressively more mediolaterally. Those near the external border of the pars compacta send dendrites a short distance into the pars reticulata. Cells of the pars reticulata are smaller and have dendrites with a lateral-dorsal orientation. Cells in the ventral tegmental area are fusiform with dorsoventrally oriented dendrites and also stain with antisera against tyrosine hydroxylase. The dendritic fields of cells in all regions are flat in the tranverse plane.

CALCITONIN GENE-RELATED PEPTIDE (CGRP) IMMUNOREACTIVE AXONS IN THE RAT GLOBUS PALLIDUS AND SUBSTANTIA INNOMINATA: A LIGHT AND ELECTRON MICROSCOPIC STUDY.

H. Kuo* and H.T. Chang (SPON: R.C. Foehring) Department of Anatomy & Neurobiology, The University of Tennessee, Memphis, 875 Monroe Ave., Memphis, TN 38163.

Calcitonin gene-related peptide (CGRP) has been found within both axons and cell bodies in various parts of the mammalian central nervous system. In this study, the distribution of CGRP immunoreactive (CGRP+) axons in the rat globus pallidus (GP) and substantia innominata (SI) was investigated at both light and electron microscopic levels using a rabbit anti-CGRP antiserum generously provided by Dr. C. Sternini (Dept Medicine, UCLA). CGRP+ axons ramified extensively within SI. Bundles of CGRP+ axons and terminals were also found in discrete regions in the caudal and medial parts of GP bordering the internal capsule. The distribution of CGRP+ fibers appeared to overlap partially with that of the cholinergic neurons in GP and SI. Preliminary electron microscopic analysis revealed that CGRP+ boutons formed mainly asymmetrical synapses with dendrites of GP and SI neurons. Dendrites which were postsynaptic to CGRP+ boutons also formed many symmetrical synapses with unlabeled axon terminals. Since previous studies have shown that basal forebrain cholinergic neurons formed few synapses, the present result suggests that CGRP+ axons innervate mainly non-cholinergic GP and SI neurons. (This study was supported by USPHS Grants NS21003 and AG05944)

SPINDLE ACTIVITY IN THE THALAMUS IN VITRO.
M.Serafin* and M.Mühlethaler, Dept de Physiologie CMU, 1211 Genève 4, Switzerland.

Intracellular recordings from thalamic neurons have been obtained so far in situ in the cat and in guinea pig slices. However in order to study membrane properties within a complex circuitry alternative preparations must be used. We therefore recorded from thalamic neurons in an isolated whole brain preparation(IWB) and found that they displayed all the properties already described in slices. However they displayed in addition spindle activity either spontaneously or in the presence of barbiturates. These spindles were very much the same than those recorded in the intact cat. They were indeed characterized by a spindle duration of 1-3 sec. consisting of low threshold rebounds and spikes and the interspindle interval was 10-20 sec. These spindles could be manipulated either by brainstem stimulations or by the application of drugs in the perfusion.Our studies indicate that thalamic circuits are preserved in the IWB which could thus be used for studying intrinsic thalamic mechanisms as well as brainstem-thalamic interractions.

ELECTROPHYSIOLOGY OF ENTOPEDUNCULAR NEURONS AND THEIR RESPONSES TO SUBTHALAMIC STIMULATION IN RAT BRAIN SLICE PREPARATIONS.
H. Nakanishi*, H. Kita and S. T. Kitai, (SPON. T. Kita) Dept. of Anatomy & Neurobiology, The University of Tennessee, Memphis, Memphis, TN 38163. *Dept. of Pharmacology, Faculty of Dentistry, Kyushu University, Fukuoka 812, Japan.

It is well demonstrated that single subthalamic (STH) neurons in the rat project both to the pallidum and to the substantia nigra (SN). Our previous *in vitro* study demonstrated that stimulation of the STH evoked monosynaptic EPSPs in SN neurons. In this study, we examined electrophysiology of entopeduncular (EP) neurons in the rat brain slice preparations.

Sagittal slices (thickness 400 μm) containing EP and STH were placed in a recording chamber. EP neurons were intracellularly recorded through glass microelectrodes filled with K-methylsulfate. STH was electrically stimulated through bipolar metal electrodes. EP neurons were classified into two groups based on their membrane properties. Type-I neurons, the major group, were characterized by having spontaneous repetitive firing and relatively short (less than 100 ms) spike after-hyperpolarization. Type-II neurons, in contrast, had no spontaneous firing, and the spike triggered by intracellular stimulation was followed by a long (more than 200 ms) after-hyperpolarization. In type-I neurons, stimulation of the STH evoked short latency monosynaptic EPSPs and bicuculline-sensitive monosynaptic IPSPs. In the type-II neurons, the STH stimulation evoked only EPSPs. Based on already known physiological and anatomical evidences, it is likely that these monosynaptic EPSPs originated from the STH. Supported by NIH grants NS 20702 to STK and NS 25783 to HK.

THE SUBSTANTIA NIGRA PARS RETICULATA PROJECTION TO THE SUBTHALAMIC NUCLEUS OF THE RAT.
H. Kita and S.T. Kitai, Dept. of Anatomy and Neurobiol., College of Medicine, The University of Tennessee, Memphis, Memphis, Tennessee 38163.

Projection from the substantia nigra pars reticulata (SNR) to the subthalamic nucleus (STH) was studied in rats using the PHA-L anterograde tracing technique. PHA-L was iontophoretically injected into the SNR. After two weeks of survival, animals were fixed and the brains sectioned on a vibratome. Sections were immunoreacted for PHA-L using the conventional ABC method (see J. Comp. Neurol. 260: 435-452, 1987 for more details of the technique). Injection of PHA-L into the SNR resulted in the labeling of a large number of boutons in the STH. Light microscopic analysis indicated that the size of PHA-L labeled boutons (about 1μm) is much larger than the tyrosine hydroxylase-immunoreactive (i.e., monoamine containing) boutons seen in this area. Electron microscopic analysis of the labeled terminals in the STH revealed that the labeled boutons were large and contained many spherical or ellipsoidal vesicles and a number of mitochondria. Most of them formed symmetrical synapses with dendritic shafts. These morphological features were very similar to the GAD-immunoreactive boutons in the STH. The observations indicated an existence of probably GABAergic projections from the SNR to the STH. This newly found projection may function as a negative feedback circuit of previously demonstrated excitatory STH projection to the SNR (Nakanishi et al., Brain Res.). Supported by NIH grants NS 20702 and NS 23886 to STK and NS 25783 to HK.

VOLTAGE-CLAMP ANALYSIS OF A TRANSIENT POTASSIUM CURRENT IN RAT NEOSTRIATAL NEURONS.
D.J.Surmeier, Jose Bargas* and S.T.Kitai, Dept. of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, Memphis,TN 38163.

Recent current-clamp studies have suggested that an A-like potassium current is present in rat neostriatal neurons (Galarraga et al., *Neurosci.Abstr.* 11:202,1985). In addition to its importance in a general model of neostriatal discharge, the characterization of an A-like current in neostriatal neurons may be of crucial importance to an understanding of the actions of neuromodulators, such as dopamine.

To this end, whole-cell voltage clamp recordings were made from rat neostriatal neurons grown in primary monolayer cultures. Cultures were derived from the striata of E17 rat embryos and grown in a basal medium (F12:DMEM) supplemented with serum (10%), insulin (5μg/ml), HEPES (3.574 gm/ml) and antibiotics. Cells were maintained in a humid, 5% CO2, 37 C environment. Recordings were made using conventional techniques. The normal bath solution contained (in mM): 120 NaCl, 6 KCl, 2 CaCl2, 1 MgCl2, 10 Na-HEPES, 6 glucose, pH=7.4, 300 mOsm. The intracellular solution contained (in mM): 98 K-gluconate, 20 TEA-Cl, 10 HEPES, 2 MgCl2, 2 ATP, 0.2 GTP, 5 EGTA, pH=7.2, 300 mOsm. Na currents were blocked by including 1-2 μM TTX in the bath.

All neostriatal neurons exhibited a transient outward current (N=41). In most neurons, the activation and inactivation characteristics of this outward current were similar to those described in other mammalian neurons. The current was substantially reduced by bath application of 2-5 mM 4-aminopyridine (N=6), a concentration which did not significantly reduce the sustained outward currents. The current was not blocked by bath application of inorganic Ca channel blockers Cd (up to 500 μM, N=8), Co (3 mM,N=4) or Mn (2 mM,N=4). An analysis of tail current reversals suggested that potassium was the principal charge carrier. Thus, the voltage-dependence, pharmacology and selectivity of this transient conductance suggests that it is similar to the A-channel conductance. QUINOLINATE AND KAINATE NEUROTOXICITY IN NEOSTRIATAL CULTURES IS POTENTIATED BY CO-CULTURING WITH NEOCORTICAL NEURONS.
E. Galarraga*,D.J. Surmeier and S.T. Kitai, (SPON: T.Gardiner). Dept. of Anatomy and Neurobiology, College of Medicine. The University of Tennessee, Memphis, Memphis, TN 38163.

There is a substantial loss in glutamate neurotoxicity in the neostriatum following cortical deafferentation (Biziere and Coyle, *Neurosci.Lett.* 8:303-310,1978). However, the role of cortical innervation in determining the relative sensitivity of different striatal phenotypes to glutamate excitotoxins is unclear. Because of the need to precisely control agonist concentrations and exposure time, a primary monolayer culture model of neostriatum and neocortex was used to address this role.

Cultures of embryonic (E17) rat neostriatum and neocortex were maintained with serum supplemented F12:DMEM basal media in a humid, 5% CO2, 37 C environment. After 12 days *in vitro*, cultures were exposed to concentrations of quinolinate (QUIN) or kainate (KA) ranging from 1 to 1000 uM for 5 mins. Cell counts were made from representative identified fields before and after (18-24 hr) the application of the toxins. Counts were expressed as a percentage of the number of cells originally present. In order to distinguish cortical from striatal neurons in co-cultures, cortical neurons were labeled with the fluorescent carbocyanine dye (DiI) during dissociation. Cortical neurons could be readily identified for several weeks with this procedure.

Our results indicate that QUIN and KA are neurotoxic to striatal neurons cultured in the absence of cortex. However, the neurotoxicity of both substances to neostriatal neurons was potentiated when they were co-cultured with neocortical neurons. D-2-amino-5-phosphonovalerate substantially reduced the neurotoxicity of QUIN but it failed to significantly reduce the effects of KA, suggesting that different mechanisms are responsible for the toxicity of these glutamate analogs. Preliminary immunocytochemical studies indicate that different neuronal phenotypes are affected by QUIN and KA as well.. Supported by NIH grants NS 20702 and NS23886 to STK and a Huntington's Disease Foundation grant to DJS.

MUSCARINIC RECEPTORS IN PRIMARY CULTURES OF RAT NEOSTRIATUM.
P. T. Akins*, D. J. Surmeier, S. T. Kitai(SPON: C. M. Blatteis). Dept. of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, Memphis, TN 38163.

We have characterized some pharmacological properties of the receptors expressed on intact striatal neurons. Cultures were generated from fetuses at 17 days gestation. After dissection and mechanical dissociation, cells were plated into 12 well dishes at 2000/mm^2 for neuronal cultures or 200/mm^2 for glial cultures. Cultures were fed serum-supplemented DME/F12 and maintained 13-14 days in vitro.

Binding studies were carried out in HEPES buffered Hank's balanced salt solution(HBSS) at 23 degrees C. Cultures were preincubated for 15 min. Steady state binding was achieved in 45 min. for [3H]N-methylscopolamine(NMS) at concentrations of 0.01 to 2 nM. Cultures were washed with ice-cold HBSS, scraped, and counted in Optifluor at 36% efficiency. Low levels of specific binding were measured in glial cultures, constituting less than 5% of that in neuronal cultures at equivalent NMS concentrations. Saturation data(n=5) at 12 concentrations(0.01 to 2 nM) of NMS were analyzed using the computer program LIGAND. The binding was well-characterized by a single site with a Kd of 89 ± 10 s.e.m. pM, linear Scatchard plots, and Hill plots with an average slope of 1.04 ± .05. Mean Bmax values were 10.9 ± 1.5 fmol/well, 187 ± 43 fmol/mg protein, or 32,000 ± 3000 sites/neuron. Displacement studies with pirenzepine (Boehringer Ingelheim) and carbachol using 0.1 nM NMS have EC_{50}'s of 201 nM and 72 μM, and Hill coefficients of 0.58 and 0.65, respectively. These results suggest multiple subtypes of the muscarinic receptor are expressed by striatal neurons. (Supported by U.S.P.H.S. Grants NS 20702 and NS 23886).

MEMBRANE PROPERTIES OF PEDUNCULOPONTINE NEURONS AND THEIR RESPONSES TO NIGRAL STIMULATION IN AN IN VITRO SLICE PREPARATION. Y.N.Kang*, S. Afsharpour, and S.T.Kitai. Department of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, Memphis,TN 38163.

Electrical membrane properties of neurons in rat pedunclopontine nucleus (PPN) and their responses to substantia nigra reticulata (SNr) stimulation were studied in parasagital brain slices (400-500 μm) which contained the brachium conjunctivum (BC), substantia nigra and the subthalamic nucleus (STH). Intracellular potentials were recorded using conventional techniques. SNr was stimulated by three bipolar stimulating electrodes. In someexperiments, a pair of additional stimulating electrodes was placed in STH or between STH and SNr. Twenty out of 80 recorded neurons were intracellularly injected with biocytin. Slices were fixed with 4% paraformaldehyde, immersed in 20% sucrose, frozen and sectioned at 50 μm and reacted with avidin-Texas Red for flourescent visualization. These sections were then processed immunocytochemically for ChAT or counter-stained with cresyl violet. All the injected neurons were located in PPN.

Electrical membrane properties of PPN neurons were studied by intracellular current injection through the recording microelectrode. The results indicated that PPN neurons may be classified into several types based on their electricalmembrane properties such as prominent afterhyperpolarization, TEA sensitive outward currents, TTX or cobalt sensitive slow inward currents and high threshold TTX insensitive spikes which were bloked by cobalt.

Responses to SNr stimulation were predominantly monosynaptic IPSPs. It was frequently observed that IPSPs were followed by rebound Na spikes possibly generated by two types of slow inward currents. Occasional EPSPs seen following SNr stimulation were considered to be due to the activation of passing fibers in SNr since stimulation of STH or the area between STH and SNr produced EPSPs with similar shape but with slightly longer latencies. Supported by NIH grants NS 20702 and NS 23886 to STK.

ELECTROPHYSIOLOGICAL AND DOUBLE-LABELLING IMMUNOHISTOCHEMICAL ANALYSES OF NEURONS IN THE SUBSTANTIA NIGRA ZONA COMPACTA OF THE RAT. J. Bargas*, E. Galarraga* , H. T. Chang and S. T. Kitai Department of Anatomy and Neurobiology, College of Medicine. The University of Tennessee, Memphis, Memphis, TN 38163.

Electrical membrane responses of the neurons in rat substantia nigra zona compacta (SNc) were studied in the *in vitro* slice preparation. Glass microelectrodes of DC resistances around 80-120 Megs filled with either K-acetate 3M or biocytin 4% and K-acetate 2M were used. Saline compositon was, in mM: NaCl 125, KCl 1.25, KH2PO4 1.75, CaCl2 2, MgCl2 1, HCO3Na 25, glucose 11. Temperature was between 34 and 36 C and osmolarity around 300 mOsM/l. Either coronal or sagital mesencephalic slices were used. The electrophysiology of the SNc has revealed substantial heterogeneity. A majority of SNc neurons had spontaneous low frequency firing of 0.5-9Hz. Input resistance (Rn) was strongly voltage dependent largely due to a strong time dependent anomalous rectification. Rn was 147±24 Megs (n=10) when measured at a holding potential near the spontaneous firing level (-55 mV). Depolarizing currents given at -60 mV evoked repetitive firing. However, if the same depolarizing currents were given at -80 mV, many neurons exhibited low threshold spikes (LTS) of variable amplitude during the test depolarization. The LTS could elicit a single spike or a burst of fast spikes followed by a strong post-burst hyperpolarization (PBH). In some instances, oscillatory bursting behavior (2-4Hz) was seen. This depended on the holding membrane potential and the magnitude of the depolarizations as well as on the PBH amplitude. Neurons which were intracellularly injected with biocytin had their morphology revealed by reacting with avidin conjugated to Texas Red. Subsequently, the tissue was processed for tyrosine hydroxylase immunoreactivity with secondary antibodies conjugated to FITC. Preliminary results indicate that double-labelled biocytin and TH+ neurons can be readily demonstrated with this procedure. Results also suggest that there is a significant probability of impaling non-dopaminergic neurons in the SNc. Supported by NIH grants NS20702 and NS23886 to STK

PATTERNS OF TERMINATION OF RAT BASAL GANGLIA AND CEREBELLAR EFFERENTS IN THE THALAMUS: STRICTLY SEGREGATED AND PARTIALLY OVERLAPPED PROJECTIONS. . J.M. Deniau*, H. Kita & S.T. Kitai (SPON. D. Desiderio). Dept. of Anatomy & Neurobiol. , College of Medicine, The University of Tennessee, Memphis, Memphis, TN 38163. *Lab. de Physiol. des Centres Nerveux, Univ. Pierre et Marie Curie, F-75230 Paris Cedex 05, France

There is a widely held view that basal ganglia and cerebellar outputs act independently via separate subcortical channels. In this study, the pattern of innervations provided by the deep cerebellar nuclei (CDN), entopeduncular nucleus, and the substantia nigra pars reticulata was reinvestigated in rats using the PHA-L anterograde tracing technique.

PHA-L was iontophoretically injected into these brain areas. After two weeks of survival, animals were perfuse fixed and the brains sectioned on a vibratome. Sections were immunoreacted for PHA-L using the conventional ABC method.

Light microscopic observation indicated that, in the ventrolateral and the external ring of the intralaminar thalamic nuclei, basal ganglia and CDN efferents are strictly segregated. CDN fibers in these areas were either thick or thin and formed high density of en passant and terminal boutons. In contrast, in the ventromedial and parafascicular thalamic nuclei and in the deep tectum, basal ganglia and CDN efferent sites overlap. CDN fibers in these areas were usually thin and formed relatively small en passant and terminal boutons. These observations suggest that in the rat the cerebellum and the basal ganglia have, on one hand, their own distinct pathways through the thalamus; and on the other hand, they may share some thalamic and tectal neurons in processing their information. Supported by NIH grants NS 20702 and NS 23886 to STK and NS 25783 to HK.

BASAL GANGLIA AND THALAMUS: MOTOR SYSTEMS V

PERINATAL COMPETITION BETWEEN IPSI- AND CONTRALATERAL PROJECTING NIGROSTRIATAL NEURONS ELIMINATES CONTRALATERAL PROJECTING CELLS. G. Fishell, M. Takada, T. Hattori, and D. van der Kooy. Neurobiology Research Group, Dept. of Anatomy, University of Toronto, Toronto, Canada M5S 1A8

By embryonic day 16 in the rat, separate cells in the substantia nigra have developed ipsi- and contralateral axonal projections to the striatum. Retrograde fluorescent tracer (Fast Blue (FB)) injections into the striatum during the late embryonic and early postnatal period, revealed that both the ipsi- and contralateral nigrostriatal projections undergo marked periods of perinatal cell death. However, the time courses of cell death in these two populations of dopaminergic substantia nigra neurons are surprisingly different. By postnatal day 1, 85% of the embryonic population of contralateral projecting nigrostriatal neurons die. In contrast, the number of striatal projecting neurons in the much larger ipsilateral pathway increases over the same time period, peaking in size at postnatal day 4. By postnatal day 7, cell death reduces the ipsilateral pathway by 25%, to its adult size. Comparison of short versus long term retrograde labeling of the ipsi- and contralateral pathways revealed that cell death rather than axon retraction is responsible for the postnatal decrease in both pathways. In order to test whether ipsi- and contralateral projecting nigrostriatal neurons compete for survival, we lesioned the ipsilateral nigrostriatal projection on embryonic day 19. Unilateral knife cuts were made in the ventral mesencephalon caudal to where the contralateral projection decussates. Lesioned animals received a striatal injection of FB ipsilateral to the lesion, one day prior to their sacrifice on postnatal day 7. The striatum on the lesioned side was approximately 60% of the volume of the contralateral control striatum. Success of the lesion was estimated by the reduction in the number of retrogradely labeled neurons in the ipsilateral substantia nigra. The embryonic lesions produced a 90% loss of ipsilateral nigrostriatal projections. However, the normal 85% cell death of contralateral projecting neurons was completely abrogated. These results suggest that competition between ipsi- and contralateral projection neurons is the mechanism that eliminates much of the transient contralateral projecting nigrostriatal pathway.

ULTRASTRUCTURAL CHANGES IN CAUDATE NEUROPIL FOLLOWING QUINOLINIC ACID LESIONS. R.C. Roberts and M. DiFiglia. Department of Neurology, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

In order to determine the anatomical basis of excitotoxicity in the caudate nucleus as a model of Huntington's disease (HD), the effects of injections of quinolinic acid (20ug in 0.6ul) into adult rat striatum were investigated at the light and electron microscopic level at 2 (n=4), 7 (n=2) and 30 (n=3) weeks post lesion. Neuronal and synaptic density were examined at each time point in four regions: 1) lesion (intact tissue exhibiting profound neuronal loss), 2) proximal transition ("PT"=first 125um from the edge of the lesion, 3) distal transition ("DT"=500-650um from the edge of the lesion) and 4) contralateral, uninjected side.

Neuronal vs Synaptic Density

wks post L		2	7	30
zone				
L	neurons	3*	2*	1*
	synapses	10*	15*	63
PT	neurons	52*	60*	74*
	synapses	78	85	97
DT	neurons	89*	92	98
	synapses	89	104	101

values expressed as % of control
* p<.025

Both neuronal and synaptic density were markedly reduced in the lesion zone at all time points and in the PT at 2 and 7 wks. Relative to control, synaptic density was greater than neuronal density in the lesion (7-63%) and PT zones (approx. 25%) at all time points, which may reflect a compensatory regenerative response. In the lesion zone large neurons comprised 35-55% of total neurons as compared to 2-3% in the PT zone and 1% in controls. In the lesion zone, the large neurons retained their normal ultrastructure and synaptic inputs despite the severe loss of neuronal integrity in the surrounding area. Results suggest that excitotoxic lesions cause both degenerative and regenerative changes in caudate neuropil and may parallel findings made in this laboratory in Golgi impregnated caudate tissue from HD brains. Supported by NIH grant NS-16367 to MD, a Huntington's Disease Society of America grant to RCR & a NINCDS postdoctoral grant to RCR.

SPECIFIC STRIATAL LESIONS INFLUENCE BETA, BETA - IMINODIPROPIONITRILE-INDUCED DYSKINESIAS. B.I. Diamond, R. Borison, H. Nguyen.* Department of Psychiatry, Medical College of Georgia.,Augusta, GA 30917.

It has been well documented that the administration of beta, beta-iminodipropionitrile (IDPN) to various animal species produces a hyperkinetic movement disorder resembling phasic dystonia. It was the aim of this study to investigate the role of the striatum in regulating IDPN-induced movements. Male Sprague Dawley rats (200grams) were anesthetized with pentobarbital (40 mg/kg;i.p) and stereotaxic kainic acid (3nM) lesions were placed in either the dorsal or ventral caudate nucleus. Control animals received phosphate buffer striatal injections. After 1 week animals received two daily injections of IDPN (100mg/kg;i.p) and were rated 1 week later. IDPN produced circling, retropulsion and head and neck dystonia in rats. These movements were antagonized but not abolished by ventral striatal kainic acid lesions. In contrast dorsal striatal lesions with kainic acid markedly exacerbated these hyperkinesias. Other lesioned areas of the brain did not markedly affect IDPN-induced hyperkinesias. These results suggest that the striatum modulates the movements induced by IDPN but is not the initiating site for its action.

409.4

CEREBELLAR PURKINJE CELL: ANOTHER NEURONAL BASIS OF MPTP-INDUCED PARKINSONISM. M. Takada, T. Sugimoto and T. Hattori. Dept. of Anatomy, University of Toronto, Toronto Ontario M5S 1A8, Canada. Dept. of Anatomy, Kansai Med. Univ., Moriguchi, Osaka 570, Japan.

In order to re-examine neuronal bases of MPTP-induced parkinsonism, MPTP (30 mg/kg b.w./i.p. injection) was given to mice (1-10 daily injections). One to three weeks after the last injection, nicely-fixed brain tissue was Nissl-stained and compared with control normal sections. Tremendous cell loss and degeneration were observed in the substantia nigra pars compacta. The only other brain area that showed similar marked morphological changes, was the Purkinje cell (PC) layer of the cerebellum. Especially in the flocculus/paraflocculus, more than 50% of PC exhibited cell loss and various stages of cell degeneration. We have also found that the C57 black mouse is more susceptible than the CD1 white mouse to MPTP. Moreover, in the flocculus/paraflocculus of the rat given the intraventricular or intracisternal injection of colchicine, a considerable number of PC were immunoreactive for tyrosine hydroxylase (TH), but not dopamine-beta-hydroxylase. No other cellular elements displayed TH immunoreactivity in the cerebellum. These data strongly suggest that the PC may provide another neuronal basis of MPTP-induced motor impairments.

Supported by the Medical Research Council of Canada.

STRIATAL DOPAMINE AND THE INTERFACE BETWEEN ORIENTING AND INGESTIVE FUNCTIONS. S. Hall* and T. Schallert. (SPON: E. Bigler). Department of Psychology and Institute for Neurological Science, University of Texas at Austin, Austin, TX 78712.

Recent experiments have implicated forebrain catecholaminergic projections in a unique switching mechanism that enables sensory orientation to occur during ongoing feeding behavior. Sensory-related cells identified in the striatum (Schneider et al., *Neurophysiol.*, 1985) may serve as part of a system that redirects attention away from ingestive behavior and toward external stimulation (Schallert & Hall, *Behav. Brain Res.*, 1988; Hall & Schallert, *Brain Res. Bull.*, in press). In the present study, 6-hydroxydopamine (6-OHDA, which selectively destroys dopaminergic neurons when followed by a noradrenergic uptake inhibitor) or ibotenic acid (an axon-sparing neurotoxin) were infused directly and unilaterally into the ventrolateral striatum in rats. In addition to a battery of sensory and motor tests, the animals were examined for their reactions to tactile stimulation of the vibrissae during or in the absence of eating. During non-eating trials, orienting was rapid and reliable to stimuli presented on either side of the body midline. While eating, contralateral orienting never occurred in the 6-OHDA treated rats, even when the stimulation was intense, whereas ipsilateral orienting was unaffected. In contrast, the "disengage deficit" did not occur in animals treated with ibotenic acid. In other sensorimotor tests, ibotenic acid yielded mild and/or very transient asymmetries, whereas 6-OHDA yielded severe and chronic asymmetries. It was suggested that the capacity to disengage from ingestive behavior may depend importantly and specifically on the integrity of dopaminergic input to the striatum. Supported by NS-23964.

BOTH NICOTINIC AND MUSCARINIC RECEPTORS MEDIATE THE EXCITATORY ACTIONS OF ACETYLCHOLINE ON DOPAMINERGIC A9 AND A10 NEURONS. M.G.Lacey, P.Calabresi & R.A.North. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Intracellular recordings were made from presumed dopaminergic rat midbrain neurons in a slice preparation. Acetylcholine, applied by superfusion or by pressure ejection, caused a depolarization or an inward current which was potentiated by neostigmine (1 μM). The response comprised a large transient component of rapid onset and a smaller, more slowly developing component; both were unaffected by tetrodotoxin. The fast component increased in amplitude on hyperpolarization, was accompanied by an increase in membrane conductance, blocked by hexamethonium (100 μM) and cross-desensitized to nicotine (100 μM).

The slow component was mimicked by muscarine (1-30 μM) and blocked by scopolamine (3 μM). Muscarinic depolarizations and inward currents in the range -45 to -80 mV were generally associated with a conductance decrease. Muscarinic depolarizations and inward currents persisted at potentials negative to the K^+ equilibrium potential (extracellular K^+ concentration 2.5 to 20.5 mM). Dose-response curves to muscarine were shifted to the right by pirenzepine (30-300 nM), implicating an M_1 type receptor in this effect.

409.7

MODULATION OF ANTERIOR THALAMIC (AT) CELLULAR RESPONSIVENESS BY BRAINSTEM CHOLINERGIC (Ch) AFFERENTS. D. Paré, D. Bouhassira*, M. Deschênes and M. Steriade. Lab. Neurophysiol., Sch. of Med., Univ. Laval, Québec, Canada.

In contrast with most dorsal thalamic nuclei, AT cells are devoid of input from the reticular thalamic nucleus (J. Comp. Neurol. 1984, 229: 531-547). Thus, AT cells constitute a unique model to study inhibitory processes mediated by local-circuit cells and their modulation by the Ch afferents from the brainstem laterodorsal tegmental (LDT) nucleus. In order to study this problem, 86 AT neurons, physiologically identified by their short latency (3-5 ms) activation from the mammillary bodies (MB), were recorded extracellularly in the chronically-implanted, head-restrained cats during the sleep-waking cycle. The synaptic responsiveness of AT cells was assessed by comparing their response probability to two consecutive shocks (10 to 200 ms apart) applied to the MB or cingulate cortex.

Orthodromic activation of AT cells was always followed by a short (60-70 ms) and state-independent period of decreased responsiveness, presumably due to the activation of local inhibitory interneurons. The short duration of this inhibitory period contrasted with the much longer (150 ms) period of decreased responsiveness found in intralaminar neurons during slow-wave sleep. Short conditioning trains applied to the LDT nucleus increased the response probability of AT neurons to both shocks. LDT trains did not interfere with the inhibitory period induced by the first MB shock and, in some cases, increased it. No significant differences were observed when the same tests were carried out in reserpine-treated cats (0.5 mg/kg), thus suggesting that these effects were not dependent on coactivation of monoaminergic fibers. These results indicate that activation of Ch LDT cells can improve the ability of AT cells to relay incoming signals toward the cortex and preserve the local inhibitory processes required for analytic processing. Supported by MRC Grants MT-3689 and MT-5877.

DOPAMINE AND GABA ARE TRANSMITTERS IN THE NIGROTECTAL PATHWAY TO THE PERICENTRAL INFERIOR COLLICULUS. U.E. Olazábal[1] and J.K. Moore[2], Depts. of Psychology[1] and Anatomical Sciences[2], SUNY at Stony Brook, NY 11794.

Previous studies in this laboratory have demonstrated a direct projection from the substantia nigra, pars lateralis, (SN_L) to the rostrolateral pericentral zone of the inferior colliculus (IC_R). In addition, tyrosine hydroxylase (TH) and GABA immunohistochemical analyses have shown the presence of dopaminergic and GABAergic neurons in the SN_L. In order to determine the chemical specificity of this nigrotectal system, the present experiments combined TH and GABA immunohistochemistry with retrograde transport from the IC_R. Guinea pigs received small unilateral injections of a fluorescent tracer, either rhodamine-conjugated latex-microspheres or fluorogold, into the rostrolateral pericentral inferior colliculus. Tissue sections were processed for visualization of TH or GABA using the avidin-biotin variation of the PAP technique. Results indicated that approximately 70% of tracer-labelled SN_L neurons were GABA+, while about 15% of the total number of backfilled cells were TH+. Both types of double labelled neurons were multipolar cells, 20-30μm in diameter, with three to five large dendrites. Several lines of evidence suggest that the IC_R forms part of a sensorimotor pathway. The dopaminergic and GABAergic projections from the substantia nigra may thus exert a modulatory influence on acousticomotor behavior.

409.9

THE DISTRIBUTION OF THE CEREBELLOTHALAMIC AND NIGROTHALAMIC PROJECTIONS IN THE DOG. S. T. Sakai, K. Patton* and A. Smith*, Dept. of Anatomy, Michigan State University, East Lansing, MI 48824.

A series of horseradish peroxidase (HRP) injections were made into the deep cerebellar nuclei. At the same time, tritiated amino acid injections were made into the contralateral substantia nigra in anesthetized dogs. Following survival times of 2-4 days, the brains were aldehyde fixed and processed for both HRP histochemistry and autoradiography. The cerebellothalamic projections are widespread and bilateral, filling a wide arc including the rostral and dorsal portion of the ventral lateral nucleus (VLd), VL proper and the ventromedial nucleus (VM). In contrast, the nigral efferents were more limited in distribution labeling the ventral anterior nucleus (VA), the medial portion of VL and VM. Although the double labeled regions were closely opposed within VL, careful analysis of the double stained sections revealed that the patches of nigral silver grains did not directly coincide with the HRP positive patches from the cerebellum. However, a number of HRP labeled fibers were observed in close proximity to the nigra silver grains within VM. These data suggest that the motor thalamus may be primarily involved in the parallel processing of cerebellar and nigral information. (Supported by N.I.H. Grant NS18851 and B.R.S.G. funds to the College of Human Medicine, M.S.U.)

THE ORGANIZATION OF NIGROSTRIATAL PROJECTIONS IN THE DOG. D. Tanaka, Jr., S. T. Sakai and A. Smith*, Dept. of Anatomy, Michigan State University, East Lansing, MI 48824.

Little is known regarding the detailed topography of the nigrostriatal system in the dog. In the present study, the autoradiographic method was systematically used in order to trace these projections. A series of pressure injections of tritiated amino acids was made into the rostral, caudal, lateral and medial parts of the substantia nigra (SN) in anesthetized dogs. After survival times of 3-7 days, the animals were perfused with formalin-saline and the brains processed for standard autoradiography. Nigrostriatal projections terminated in a widespread patch-like pattern in the ipsilateral striatum (St). A topographical relationship emerged whereby obliquely oriented longitudinal slabs of the St received a rostrocaudal and mediolateral inverted nigral input. The lateral portion of SN projects to the ventromedial part of the St while the medial part of SN projects to the dorsolateral St. Injections confined to the rostral half of SN primarily labeled the caudal part of St. These results suggest that the topographical organization of the canine nigrostriatal system may be more complex than that previously described in other species. (Supported by N.I.H. Grants NS16991 and NS18551 and B.R.S.G. funds to the Colleges of Human Medicine and Veterinary Medicine, M.S.U.)

SUBSTANTIA NIGRA AFFERENTS OF THE NUCLEUS TEGMENTI PEDUNCULOPONTINUS IN THE RAT. B. Spann and I. Grofova, Dept. of Anatomy, Michigan State Univ., E. Lansing, MI 48824.

Previous studies have indicated that the substantia nigra, pars reticulata(SNr) is involved in the control of certain aspects of motor behavior and may mediate these effects through projections to the nucleus tegmenti pedunculopontinus(PPN). The present light and electron microscopic study utilizes the anterograde transport of lectin Phaseolus vulgaris(PHA-L) to delineate the origin, distribution and mode of termination of nigral fibers in the PPN.

Small and large injections of the tracer in different regions of the SNR resulted in similar distribution of the terminal fibers in the PPN. Both subdivisions, the subnucleus compactus(PPNc) and dissipatus(PPNd) appeared to receive the nigral afferents. However, the overall projection to the PPNd was far more prominent than that to the PPNc. A particularly dense plexus was seen in the medial PPNd in close approximation to the superior cerebellar peduncle. Although the terminal varicosities were often seen close to the somata of PPN neurons, the electron microscopic examination revealed mostly termination on the dendrites.

The observations suggest that the nigral afferents are likely to originate from the entire SNr and do not exhibit any distinct topographical organization. They terminate throughout the PPN and may impinge on dendrites of various populations of the PPN projection neurons. (Supported by N.I.H. Grant NS25744).

PROJECTIONS FROM THE NUCLEUS TEGMENTI PEDUNCULOPONTINUS TO THE BRAINSTEM RETICULAR NUCLEI. I. Grofova and B. Spann, Dept. of Anat., Mich. State Univ., E. Lansing, MI 48824.

Previous studies have indicated that the basal ganglia may control movement through a pathway involving the nucl. tegmenti pedunculopontinus(PPN). Since there exists only a meager projection from the PPN to the spinal cord, it is presumed that the PPN is linked to the spinal motor system through the reticular formation(RF) of the brainstem. This study utilizes the anterograde transport of lectin Phaseolus vulgaris(PHA-L) to delineate the distribution of PPN efferents in the pontine and medullary RF of the rat.

Following iontophoretic injections of PHA-L involving only the PPN, a significant proportion of labeled axons course caudally through the pontine and medullary RF. Within the nucl. reticularis pontis oralis and caudalis some of the axons collateralize to form a dense terminal plexus within these nuclei. Many labeled axons terminate within the medullary RF, particularly in the ventromedial portions of the nucl. reticularis gigantocellularis and its subdivisions(GiV, Giα, PGi), paramedian reticular nucleus and the ventral reticular nucleus of the medulla.

The results provide definite evidence of a substantial PPN projection to the pontine and medullary reticular nuclei containing reticulospinal neurons. They further support the notion that the PPN may serve as a relay between the basal ganglia and lower motor system. (Supported by N.I.H. Grant NS25744).

THE AMYGDALO-NIGRAL PROJECTION: AN ANTEROGRADE STUDY WITH PHASEOLUS VULGARIS LEUCOAGGLUTININ (PHA-L). C. Gonzales* and M.-F. Chesselet. (SPON: R. Harner) Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

As part of our research to determine the pattern of innervation of extrastriatal afferents to the substantia nigra, we injected the anterograde tracer PHA-L iontophoretically (5 uA, 7 sec. on, 7 sec. off for 15 min.) into the central nucleus of the amygdala. After survival times of 11-14 days, animals were perfused transcardially, the brains were removed and 30 um thick sections were taken. The presence of PHA-L was determined immunocytochemically in these sections using the avidin-biotin system with diaminobenzidine as the chromogen.

Injection sites that encompassed most of the central nucleus as well as discrete injections of the medial subregion resulted in immunoreactively labeled axons and boutons in the medial aspect of the substantia nigra pars compacta. Injection sites that involved either the medial or medial and lateral subregions but were confined to the ventral part of the nucleus produced some labeling in the lateral aspect of the pars compacta and few if any labeled processes in substantia nigra pars lateralis. In one case, extensive labeling of axons and boutons was seen in both pars lateralis and the lateral division of pars compacta when the injection site was in the most dorsal part of the central nucleus. Immunoreactivity was not seen in the substantia nigra pars reticulata after any of these injections. The results suggest that central nucleus of the amygdala projections to the substantia nigra are more extensive than previously reported. Furthermore, subregions of the central nucleus project to different parts of the substantia nigra suggesting an heterogenous organization of the pathway. Supported by BNS 86-07645 and the Dystonia Medical Research Foundation.

STRIOSOMAL DISTRIBUTION OF NEURONS EXPRESSING HIGH LEVELS OF PREPROTACHYKININ mRNA IN THE RAT STRIATUM. E. Robbins* and M.-F. Chesselet. (SPON: M. Lewis) Dept of Pharmacology, Med. Coll. Pennsylvania, Philadelphia PA 19129.

Previous studies have shown that striatal tachykinin neurons are heterogeneously distributed, with those in the striosomes expressing a higher level of substance P-like immunoreactivity (SP-LIR). In order to determine whether this pattern is related to differences in tachykinin gene expression, we examined the distribution of neurons containing the mRNA encoding beta-preprotachykinin (PPT) in the striatum. Sets of adjacent striatal sections were processed for in situ hybridization histochemistry using a 35S-RNA probe for PPT (Affolter, Zurich) and for 3H-naloxone binding. The location of cells labelled for PPT mRNA was compared to that of patches of dense 3H-naloxone binding sites which characterize the striosomes. The very large majority of PPT mRNA-positive cells observed in the striatum after short development times were located within the boundaries of the naloxone patches. Labelled cells were seen outside the patches only after longer development times, suggesting that these cells contained a lower level of PPT mRNA. The results show that the tachykinin cells of the striosomes express high levels of PPT mRNA, suggesting that the more intense SP-LIR observed in these neurons than in those of the matrix is related to a difference in tachykinin synthesis rather than storage or transport. IMMUNOHISTOCHEMICAL DETECTION OF ENKEPHALIN AND SUBSTANCE P IN THE PALLIDUM AND SUBSTANTIA NIGRA OF THE AGED RAT. K. Yurko, E. Robbins* and M.-F. Chesselet, Dept of Pharmacology, The Med. Coll. Pennsylvania, Philadelphia, PA 19129.

Immunohistochemical studies in the brain of patients with adult onset Huntington's disease (HD) have revealed that enkephalin (ENK)-positive fibers in the external pallidum, and substance P (SP)-positive fibers in the substantia nigra pars compacta, were decreased at earlier stages of the disease than SP-positive fibers innervating the internal pallidum (Albin et al., Neurosci. Abs. '87, 1361). In order to determine whether a similar pattern of loss occurs during normal aging in the rat, we analyzed met-ENK- and SP-like immunoreactivity in sections of brain from Fisher 344 rats aged 4, 16 and 24 months. Indirect immunofluorescence immunohistochemistry still revealed a dense plexus of ENK-positive fibers in the globus pallidus, and of SP-positive fibers in both the substantia nigra and the entopeduncular nucleus in 24 month old rats. Similar ENK and SP immunostaining was also observed at all ages examined using a 125I-labelled secondary antibody and film autoradiography. Quantification of optical densities in the films using a DUMAS image analysis system revealed a slight decrease in SP-like immunoreactivity in both substantia nigra and entopeduncular nucleus in the aged rats. The results show that the pattern of alteration of striatal efferent neurons during normal aging in Fisher 344 rats does not parallel that seen in patients with HD. This further supports the hypothesis that the differential alteration of striatal efferent neurons observed during HD is related to a specific effect of the deficient gene. **Supported by BNS 86-16841.**

PHA-L STUDY OF THALAMOCORTICAL FIBERS OF THE CENTRAL LATERAL NUCLEUS. G. J. Royce. Dept. of Anatomy, Univ. of Wisconsin, Madison, WI 53706.

The PHA-L lectin was injected into the central lateral (CL) nucleus in cats. The laminar distribution and morphology of labeled fibers was observed in the cortex. The most significant finding of this study is that labeled axons are present in layer I of several cortical regions. These axons are primarily oriented parallel to the cortical surface. Some long horizontal axon segments in layer I reach up to 1 mm in length. Labeled axons are also found in the deeper layers, especially layer III, where many are oriented radially. Wherever found, labeled axons have collaterals, varicosities, and terminal boutons. Some long axons traverse the cortex to reach layer I, and resemble the "unspecific or pluriareal" axons described by Lorente de No ('38).

The topographic distribution of the PHA-L labeled axons is similar to that found in our autoradiographic cases. Labeled axons are present in the lateral and suprasylvian gyri, and presylvian, cruciate, splenial, lateral and suprasylvian sulci; and limbic areas, including the cingular and retrosplenial areas.

STUDIES ON DOPAMINERGIC PROJECTIONS ARISING IN THE DORSAL RAPHE. T. R. Stratford and D. Wirtshafter. Dept. Psych., Univ. of Illinois at Chicago, Chicago, Il. 60680.

While the serotonergic efferents of the dorsal raphe (DR) have been extensively investigated, little is known about the termination sites of non-serotonergic efferents. In the following study, adult male rats received 0.1 ul injections of the fluorescent retrograde tracer Fast Blue bilaterally into the substantia nigra (SN), the striatum (CPu) or the nucleus accumbens (Acb). Following a 5 day survival period, the brains were removed and processed for the immunocytochemical detection of tyrosine hydroxylase using a rhodamine-labeled secondary antibody. In each of the brains a population of tyrosine hydroxylase-immunoreactive (THI) neurons, apparently continuous with those in the caudal linear nucleus, was observed in the rostral aspect of the DR. Although a large number of retrogradely labeled cells projecting to the CPu or the SN were observed intermingled with the THI neurons, very few of the THI neurons were double-labeled following CPu injections and none following SN injections. In contrast, approximately 10% of the THI cells in the DR were double-labeled following injections confined to the Acb. The double-labeled cells appeared to be distributed uniformly throughout the THI cell population.

In conclusion, the projection pattern of THI cells in the DR appears to differ significantly from that of the serotonergic population and seems to resemble that of THI cells in the ventral tegmental area. (Supported by NS21350)

409.18

CHEMOARCHITECTONIC CHARACTERIZATION OF THE VENTROLATERAL AND OTHER VENTRAL TIER NUCLEI IN RAT THALAMUS. L.J. Sansone*, J.C. Hedreen, L.J. Martin*, D.L. Price, and M.R. DeLong (SPON: S.J. Herdman). Neuropathology Lab., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205-2182

To improve cyto- and chemoarchitectonic definition of ventral tier nuclei in rat thalamus, serial sections were stained for acetylcholinesterase (AChE), glutamic acid decarboxylase (GAD), cytochrome oxidase (CO), and Nissl. Ventrolateral (VL), ventromedial (VM), ventroposterolateral, ventroposteromedial, submedius, and posterior nuclei were examined. The VL complex was divisible into three zones: anterior-ventrolateral (VLA); intermediate (VLB); and caudal-dorsomedial (VLC). AChE innervation (pattern of stained fibers and puncta) was light in VLA and VLC and moderately dense in VLB. GAD innervation was generally light in VLC and denser in VLA and VLB. CO profiles were similar in all regions of VL. The VM nucleus displayed fine CO puncta (in contrast to coarser, more scattered, short fibers in VL), contained smaller neuronal perikarya than VL, exhibited AChE innervation resembling that of the adjoining VLC (except for a denser, curlicue pattern in the ventromedial third), and showed variable GAD patterns with a coarse, dark-staining plexus on the lateral border. The subdivision of VL into three chemoarchitectonically distinct regions suggests possible correspondnece with the distribution of afferent connections of VL and possible homologies with VL subdivisions in primates.

PHAL STUDIES OF THE EFFERENT CONNECTIONS OF RAT GLOBUS PALLIDUS. Wm. A. Staines, Department of Anatomy, University of Ottawa, Ottawa, ONT. K1H 8M5.

The projections of the globus pallidus of the rat were studies using anterograde tracing with Phaseolus vulgaris Leucoagglutinin (PHAL) in combination with retrograde fluorescent tracing methods and immunohistochemistry for neurotransmitter markers. Anaesthetized animals received iontophoretic injections of PHAL into various sites within the globus pallidus and were perfused at survival times of from 10 days to 2 weeks. Some animals received injections of Fluorogold into the thalamus, superior colliculus or midbrain reticular formation one day prior to perfusion.

Labelled pallidal efferent fibers and terminals were found within the caudate-putamen, reticular nucleus of the thalamus, entopeduncular nucleus, subthalamic nucleus and the substantia nigra. A single fiber morphology was found within all of these sites, consisting of large, regularly spaced varicosities en passant. A few fibers with similar morphology were found within restricted regions of the frontal cortex as well. Pallidal afferents to the substantia nigra showed a striking, perisomal clustering about the cell body and primary dendrites of GABAergic output neurons. A similar but less dramatic perisomal pattern of termination was seen around somatostatin-containing neurons of the caudate-putamen. (Supported by a grant from the MRC).

DISTRIBUTION OF CHOLINERGIC PERIKARYA WITH RESPECT TO HETEROGENEITIES IN SUBSTANCE P STAINING IN THE CAUDATE NUCLEUS OF THE CAT. M. Martone*, D. M. Armstrong, P. M. Groves. Univ. California San Diego, CA 92093.

Both substance P (SP) and choline acetyl transferase (ChAT) are known to be distributed heterogeneously in the mammalian striatum. In the present study, we examined the relationship between cholinergic perikarya and SP immunoreactivity in the caudate nucleus of adult cats using a double-label immunocytochemical protocol. Fifty micron sections were cut throughout the extent of the caudate nucleus and labeled sequentially for ChAT (antibody provided by L. Hersh) and SP (Sera Labs). To distinguish the two labels at the light microscopic level, nickel chloride ($NiCl_2$) was added as an intensifier to the diaminobenzidine (DAB) reaction for the ChAT antibody. This resulted in a purple reaction product that was clearly distinguishable from the light brown reaction product of the unintensified DAB reaction used to localize SP.

Preliminary observations suggest that ChAT-positive perikarya are more numerous in areas that also stain intensely for SP. Thus, in the dorsal striatum, ChAT-positive cell bodies appear to be associated with the SP-rich patches that are visible against a lighter staining matrix. In contrast, at more ventral levels, ChAT positive cells appear to avoid the SP-poor zones visible at this level and are more concentrated in the SP rich matrix.

SUBSTANCE P AND NEUROKININ A STIMULATION OF NIGROSTRIATAL DOPAMINE AFTER INTRANIGRAL IBOTENIC ACID LESIONS. M. Reid*, M. Herrera-Marschitz*, T. Hökfelt*, U. Ungerstedt* (SPON: B. Meister). Dept. of Pharm. and Hist., Karolinska Institute, 104 01 Stockholm, Sweden.

The striatonigral pathway contains several neurotransmitters, two of which are considered to represent excitatory regulation of nigrostriatal dopamine (DA); substance P and neurokinin A. Local injection of substance P (0.00007-7.0 nmol/0.2 µL) or neurokinin A (0.009-9.0 nmol/0.2 µL) into the substantia nigra, pars reticulata (SNR) of halothane aneasthetized male Sprague-Dawley rats produced long lasting increases in ipsilateral striatal DA as measured by in vivo microdialysis. Intranigral injections were repeated in animals with ibotenic acid lesions (5.0 µg/0.5 µL) impairing non-dopaminergic neurons of the SNR (preliminary studies show only minor damage to the tyrosine hydroxylase positive dendrites in area of lesion). In the lesioned animals substance P (0.07 nmol/0.2 µL) stimulated striatal DA (avg. max. increase: 32.4 ± 5.9%, N=4), slightly less than in non-lesioned animals (53.3 ± 13.4%, N=7), while neurokinin A (0.09 nmol/0.2 µL) stimulated striatal DA (52.4 ± 11.2%, N=4) slightly more than in non-lesioned animals (36.9 ± 3.1%, N=5). These data indicate that striatonigral substance P and neurokinin A may stimulate nigrostriatal DA via monosynaptic input onto DA cells and/or dendrites in the substantia nigra.

LEARNING AND MEMORY: PHARMACOLOGY IV

410.1

GALANIN ANTAGONIZES ACETYLCHOLINE ON A MEMORY TASK IN BASAL FOREBRAIN-LESIONED RATS. J. Mastropaolo and J.N. Crawley. NSB , NIMH, Bethesda, MD 20892.

Galanin coexists with acetylcholine in nucleus basalis magnocellularis (NBM) and medial septal (MSA) neurons projecting to the cerebral cortex and hippocampus in primates (Melander and Staines, Neurosci Lett, 1986; Walker et al., Soc. Neurosci 1987), and in MSA neurons projecting to the ventral hippocampus in rats (Melander et al., Brain Res 1985), where galanin inhibits the release of acetylcholine (Fisone, PNAS, 1987). To investigate the possible behavioral role of galanin in memory processes thought to be mediated by these pathways, male Sprague-Dawley rats were lesioned with ibotenic acid at five sites in the NBM-MSA (Helpler et al., Brain Res 1985), and trained on a delayed alternation t-maze task for a food reward. Acetylcholine, 7.5 or 10 ug ivt, or 1 ug into the ventral hippocampus, significantly reversed the performance deficit in the lesioned rats. Galanin, 100-500 ng ivt, or 200 ng into the ventral hippocampus, attenuated the ability of acetylcholine, 10 ug, to restore t-maze performance in the lesioned rats. Galanin alone, 200 ng, partially reduced performance in the lesioned rats in the t-maze alternation task with no delay. At these doses, galanin had no effect on t-maze performance in sham-lesioned control rats. These data suggest that galanin may inhibit cholinergic function in brain pathways relevant to Alzheimer's disease.

410.2

BETA-ENDORPHIN ADMINISTRATION IMPAIRS AQUISITION IN THE CHICK. E.L. Bennett, T.A. Patterson, G. Schulteis, J.L. Martinez, Jr., & M.R. Rosenzweig. Department of Psychology, University of California, Berkeley, CA 94720

Several experiments, using a one-trial taste-avoidance task, were designed to examine the effects of beta-endorphin on memory formation in the chick. Previous results indicate that 5 min pre-training injection of beta-endorphin (0.01-1.0 nmole per hemisphere) into the medial hyperstriatum ventrale (MHV) produced amnesia after training (Patterson, et al., in press).

To determine the post-training susceptibility gradient for beta-endorphin, groups of chicks were given bilateral injections into the MHV of either saline or beta-endorphin (1.0 nmole per hemisphere), 5 min before training, or at various times after training. The chicks were tested 24 hr after training. The results indicate that beta-endorphin is amnestic when given 5 min before training, but is not amnestic when given at any time after training. These results suggest that this opioid acts on an early stage of memory formation.

To examine the time course of amnesia development, chicks were given bilateral injections into the MHV of either saline or beta-endorphin (1.0 nmole per hemisphere) 5 min before training, and groups of chicks were tested at various times after training. The results indicate that beta-endorphin produces amnesia that is present by 10 sec after training; this amnesia is permanent.

These results indicate that in chicks, as in rodents, pre-training injection of beta-endorphin produces an impairment in aquisition.

Supported by NSF grant BNS-86-06938 and NIDA grant 04195.

410.3

FURTHER STUDIES ON THE ROLE OF OPIOID DELTA RECEPTORS IN THE EFFECTS OF [LEU]ENKEPHALIN ON ACTIVE AVOIDANCE CONDITIONING IN MICE. G. Schulteis & J.L. Martinez, Jr. Dept. of Psychology, University of California, Berkeley, CA 94720

We previously reported (Neurosci Abstr 13:845, 1987) that selective stimulation of opioid delta receptors with [D-Pen^2-D-Pen^5]enkephalin (DPDPE) impairs acquisition of active avoidance, as does [Leu]enkephalin (LE), and that selective blockade of these receptors with ICI 154,129 enhances acquisition. Here we determine whether the effects of LE are reversed by ICI 174,864, a delta selective antagonist, and whether DAGO (Tyr-D-Ala-Gly-NMe-Phe-Gly-ol), a mu-selective agonist, affects conditioning. Peptide effects on locomotor activity were also assessed.

Two minutes prior to training (see Neurosci Abstr 13:845, 1987), male Swiss-Webster mice received ip injections of saline, LE, ICI 174,864, DAGO, or a combination of LE and ICI 174,864. LE (30 & 100 µg/kg) significantly impaired acquisition as measured by total avoidances over 14 trials. ICI 174,864 (3 mg/kg) significantly enhanced acquisition, as did DAGO (0.92 µg/kg). The dose response curves for all peptides were U-shaped. Finally, ICI 174,864 (1 mg/kg) reversed the impairment produced by LE.

Neither avoidance-impairing doses of LE (30-100 µg/kg), nor enhancing (3 mg/kg) or reversing (1 mg/kg) doses of ICI 174,864 had any effect on shock-induced activity levels measured in the avoidance apparatus. However, DAGO (0.92 µg/kg) increased activity levels; the enhancing effect of this peptide might thus be a performance effect. These data suggest that effect of LE on acquisition of active avoidance involves delta receptor activation. (Supported by PHS grant DA #04195 [JLM] and PHS NRSA #1 F31 DA05334-01 [GS])

410.4

[LEU]ENKEPHALIN AND ITS DELTA-SELECTIVE ANALOG, D-PEN^2-[D-PEN^5]ENKEPHALIN, IMPAIR AVOIDANCE CONDITIONING IN AN AUTOMATED SHELF-JUMP TASK IN RATS. S.B. Weinberger, C. Gehrig*, and J.L. Martinez, Jr. Psych. Dept., Univ. Calif., Berkeley, CA 94720, and Chem. Dept., Univ. Ariz., Tucson, AZ 85721

We reported previously that [leu]enkephalin (LE) impairs acquisition of a one-way active avoidance response in rats and mice, and that D-pen^2-[D-pen^5]enkephalin (DPDPE), a delta opioid receptor-selective analog of LE, also impairs acquisition in mice (c.f. Behav. Neural Biol. 49:192, 1988, for review). In the present study we extend these findings to an automated shelf-jump task in rats.

Male Sprague-Dawley rats received LE, DPDPE, or saline (ip) 5 m before placement in the apparatus. After 10 s a 330 uA shock was delivered to the grid floor. Rats avoided or escaped the shock by jumping to an elevated platform, where they remained for 30 s. They were then mechanically pushed off the platform to start the next trial.

LE (1 and 3 ug/kg) impaired acquisition as measured by total avoidances over 8 trials. DPDPE impaired performance at a dose equimolar to the 1 ug/kg LE dose, but not at doses equimolar to 0.1 or 10 ug/kg of LE. U-shaped dose-response curves also are seen in mice given LE and DPDPE. These data support our suggestion of delta opioid receptor involvement in LE's effects on acquisition.

410.5

QUATERNARY FORMS OF NALOXONE AND NALTREXONE ENHANCE ACQUISITION OF ONE-WAY ACTIVE AVOIDANCE CONDITIONING IN MICE. E.A. Mendieta & J.L. Martinez, Jr. Dept. of Psych., Univ. Calif., Berkeley, CA 94720.

Pre-training ip injections of naloxonium (NXM) enhance acquisition of one-way active avoidance conditioning (Psychopharm., 87:410, 1985). However, naltrexone methyl bromide (NMB) failed to alter passive avoidance retention when administered post-training (Behav. Neural Biol., 44: 434, 1985). This apparent discrepancy may reflect: 1) differences in time of administration; 2) differences in conditioning paradigm employed; or 3) differences in pharmacological properties of NXM and NMB. The present study therefore compared the effects of pre-training injections of NXM and NMB on one-way active avoidance acquisition.

Male Swiss Webster mice were given [leu]enkephalin, NXM, NMB, or saline 2 minutes prior to training (see Neurosci. Abstr., 13:845, 1987). [Leu]enkephalin (100 ug/kg) impaired acquisition of the avoidance response. NXM (0.1, 1.0, & 10.0 mg/kg) enhanced acquisition. NMB (0.1 & 1.0 mg/kg) also enhanced acquisition, but 10 mg/kg was ineffective. These results suggest that both quaternary opioid antagonists exert similar modulatory effects on one-way active avoidance conditioning when administered prior to training. The effects of post-training injections of NXM and NMB on retention of active avoidance conditioning are currently being investigated. (Supported by PHS grant DA #04195).

410.6

EFFECTS OF CAPTOPRIL AND NALOXONE ON SHUTTLE AVOIDANCE EXTINCTION: EVIDENCE FOR OPIATE MEDIATION. A.Sudilovsky, B.A. Turnbull and L.H. Miller*. The Squibb Inst. for Med. Res., Princeton, NJ 08543 and Dept. of Biobehav. Sci., Boston Univ. Med. Ctr., Boston, MA 02118.

Earlier experiments (A. Sudilovsky et al, Abst. CINP, 397, 1984) indicated that captopril (C) delays extinction of shuttle avoidance response in the rat. In the current study, 48 male Sprague Dawley rats, 180 days old, were tested using a standard shuttle box and a 10-sec. tone as conditioned stimulus followed by the delivery of a 0.8 mA current to the chamber floor. Animals reaching at least 85% correct responses on the last 4 of 15 days of training (20 trials/day on a 30-sec. VI schedule) were randomly assigned (n=8/group) to C (10mg/kg), naloxone HCl (N, 0.25mg/kg), morphine sulfate (M, 5mg/kg), C plus N (CN), M plus N (MN) or saline (S). All solutions (1mg/ml) were given blind, i.p., on the 2 days prior to the 14-day testing period and also 1 hour prior to each daily testing (20 trials/day with no shock upon failure to shuttle) No significant differences were found post-hoc between the S and the N, M, CN, and MN groups. In contrast, C produced higher avoidance responding than N and CN (days 8-14, $p<0.01$), S and MN (days 9-14, $p<0.01$), and M (days 12-14, $p<0.01$). The finding that C-induced delay of shuttle avoidance extinction is suppressed by N indicates that the positive effects of C in this memory paradigm are, at least in part, mediated by endogenous opiates.

410.7

EFFECTS OF POSTNATAL TESTOSTERONE PROPRIONATE ADMINISTRATION ON RADIAL ARM MAZE PERFORMANCE IN RATS. R. L. Roof. Dept. of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY., 82071.

This study examined the hypothesis that sex differences in spatial ability are due in part to differential steroid hormone environments during brain development. Male and female rats were injected with either 75 ug or 150 ug testosterone proprionate (TP) or an oil vehicle on days 4 and 6 after birth. At 90+ days of age, the rats were trained to a criterion level of performance on a radial arm maze. The rats were tested once a day for 10 successive days. Rats were then tested for 24 trials on a task in which only 4 of the 8 arms were baited. Accuracy and pattern of arms entered were recorded. Female rats treated with TP reached the criterion level of performance in significantly fewer trials than did control females, while the opposite pattern was observed for males. A dose related effect was observed for females, with the higher dose producing better performance. Control rats entered significantly more adjacent arms in sequence than did rats treated with TP. Males entered fewer adjacent arms in sequence than did females. No overall sex differences for accuracy were observed once criterion levels of performance were reached. These findings support the hypothesis that steroid hormones have an organizational effect on the developing brain that subsequently influences cognitive functioning.

410.8

CHRONIC TREATMENT WITH MORPHINE OR NALTREXONE INVERSELY AFFECTS RADIAL ARM MAZE PERFORMANCE OF RATS J.W.Spain* and G.C.Newsom* (SPON: H.L.Komiskey), Dept. Biomed. Sci., Univ. Ill. Col. of Med., Rockford, IL 61107

Several reports implicate the opioid system in learning and memory processes. To further explore this relationship, we utilized an appetitive task, the radial arm maze. Moderately food-restricted rats were chronically treated with either saline, morphine (40 mg/kg) or naltrexone (5 mg/kg) i.p. twice daily (two hours prior to testing and subsequent), begun 2 days before testing. Subjective behavioral effects of treatment were not obvious during testing. After the first week of testing, the protocol changed from allowing 8 choices to allowing retrieval of 4 rewards, removal for a two min delay, then return to the maze to try for the remaining four. Score one error for each duplication of an arm during a trial. With the delay, performance of all groups fell equally to approx. 1.5 errors. One week later, performance of naltrexone treated rats had significantly improved to only 0.6 errors, not to improve further in the subsequent 5 weeks. The performance of saline treated rats improved during the first two weeks following the start of the delay but, overall, did not achieve that of naltrexone treated rats. The performance of morphine treated rats did not improve during the 5 week course of treatment. When drug treatment was discontinued, there was no change for naltrexone or saline groups, but performance of morphine treated rats improved significantly in two weeks to equal that of saline-treated.

410.9

CHOLECYSTOKININ-OCTAPEPTIDE ENHANCES LEARNING AND MEMORY IN MICE AND MONKEYS. N. Pietrusiak*, L. Rumennik*, G. P. Vincent and J. Sepinwall (SPON:A. Davidson). Neurobiology and Obesity Research, Hoffmann-La Roche Inc., Nutley, NJ 07110.

CCK-8 has been reported to alter the acquisition or retention of learned responses in animals although the nature of its effect, improvement or impairment, has varied from study to study. In the present study, sulfated CCK-8 was evaluated in 2 species to assess its effects on learning and memory. CCK-8 (1-10 mg/kg s.c.) protected CF1 mice against electrobrain shock (EBS) disruption in retrieval of an active avoidance response; CCK-8 exhibited an inverted U-shaped dose-response curve. In C57BL/10 mice, CCK-8 (0.03-0.3 mg/kg s.c.) also significantly decreased the latency to find the hidden platform in a Morris water maze; the duration of action was 30 min. In squirrel monkeys, CCK-8 improved retention on a food-rewarded delayed match-to-sample procedure by 5-11% at doses of 0.0001-0.01 mg/kg i.m. These results suggest that CCK-8, administered parenterally, may have a modulatory influence on cognitive function, although the mechanism by which this occurs remains to be identified. Furthermore, compared to the usual appetite suppressant doses, rather high doses of CCK-8 were needed to enhance cognitive performance in mice whereas low doses were efficacious in the monkey.

EFFECTS OF DELTA-9-THC ON SIGNAL DETECTION AND DELAYED MATCHING TO SAMPLE PERFORMANCE IN RATS. C.J. Heyser*, C.R. Breese*, R.E. Hampson and S.A. Deadwyler, Dept. of Phys. & Pharm., Bowman Gray Sch. of Med. of Wake Forest Univ., Winston-Salem, NC 27103

Previous reports from this laboratory showed that delta-9-tetrahydrocannabinol (THC), the psychoactive ingredient in marihuana, produced a dose-dependent disruption of tone discrimination behavior correlated with alteration of identified neural responses from the hippocampus (Campbell *et al.*, JPET 239 1986a,b). In the present study, two different behavioral conditioning tasks, delayed-matching-to-sample (DMTS) and tone detection (TD) were examined after injection of THC at previously utilized dose levels (0.5-2.0 mg/kg). In the TD task, animals were trained to respond to single tones (duration 250 msec) presented at 7 different intensities with the middle intensity set at behavioral detection threshold. Doses of THC above 0.5 mg/kg produced a dose-dependent decline in the detection of tones presented at or above threshold level ($p<0.0001$). Recordings of tone evoked potentials in hippocampus revealed differences between detect and non-detect trials. Cannabidiol, a nonpsychoactive derivative of marihuana, had no effect on these measures. In the DMTS task animals were required to perform a spatial discrimination following a 1-30 sec retention interval by selecting one of two levers (left or right) previously pressed. There was a marked dose-dependent disruption in performance ($p<0.0002$) by THC which was correlated with the length of the delay interval ($p<0.0001$). No significant disruption of performance occurred at the 1-5 sec intervals at any dose of THC. It is likely that THC had a selective effect on retention as manifested by influences on concomitantly recorded hippocampal neural activity. In comparison with previous reports (see above), the two tasks dissociate the effects of THC on detection of sensory events vs memory for trial specific information. Supported by NIDA Grants DA04441, DA03502, and DA00119 to S.A.D.

VASOPRESSIN ATTENUATES SCOPOLAMINE-INDUCED MEMORY IMPAIRMENTS IN RHESUS MONKEYS. M. Gravelle*, R.Q. Wan*, and T.G. Aigner (SPON: R. Brown). Lab of Neuropsychology, NIMH, Bethesda, MD 20892.

Arginine vasopressin (AVP) is an endogenous neuropeptide that has been reported to show reduced activity in Alzheimer's dementia (AD), a disease characterized by loss of cholinergic function and memory. AVP facilitates some retention processes in animals and humans, but attempts to reverse the memory loss of AD with analogs of AVP have been only partially successful. Because little is known about the interactions of AVP with the cholinergic system, we administered AVP alone and in combination with the anticholinergic agent scopolamine (SCOP) to 3 monkeys performing an automated memory test for food reward. The task required the animal to remember lists of graphic symbols (up to 9) that were projected onto a color monitor fitted with a touch-sensitive screen. AVP alone (1.0, 1.78, 3.2, or 5.6 ug/kg, s.c. 1 hr before test) had no effect, whereas SCOP alone (17.8 ug/kg, i.m. 20 min before test) produced a significant memory loss. When both compounds were given, AVP (1.78 and 3.2 ug/kg) significantly attenuated the SCOP-induced memory impairment, even though scores did not return to control levels. Although the mechanism for this attenuation is unknown, the results encourage further study of the possible therapeutic effects of AVP.

410.12

AVP 4-9 MODULATES MEMORY RETRIEVAL IN THE RAT AS A FUNCTION OF RETENTION INTERVAL. M.D. Bunsey* and B.J. Strupp. Dept. of Psychol., Cornell, Ithaca, N.Y. 14850.

Two recent studies in this lab have suggested that the effect of AVP4-9 on memory retrieval depends on memory strength. One study used a retention interval that produced little forgetting in controls and demonstrated impairment of retrieval with AVP4-9. In a second study, using a longer retention interval at which controls showed poor memory, pre-test AVP4-9 enhanced performance. This interaction must be viewed as tentative, however, as the AVP4-9 effects were obtained with different doses.

The present study directly examined this putative interaction using the same behavioral paradigm. It is known that if a rat is given a choice between two novel foods it will demonstrate a preference for the food that its cagemate had consumed prior to their interaction. In this experiment, rats were injected with AVP4-9 or vehicle and given a food choice after varying retention intervals (delay between cagemate interaction and food choice test).

Analysis of food preference at retention test revealed an interaction between drug condition and retention interval. AVP4-9 impaired recall at the retention interval at which memory was strongest in controls and enhanced recall at the interval at which memory was weakest in controls. These results support the hypothesis that AVP4-9's memory retrieval effects vary with memory accessability.

EPILEPSY: PEPTIDES

411.1

DIFFERENTIAL CHANGES OF THE LEVELS OF PROENKEPHALIN AND PREPRODYNORPHIN mRNAs IN RAT BRAIN DURING THE DEVELOPMENT OF DEEP PREPYRIFORM CORTEX KINDLING. P. H. K. Lee, C. W. Xie*, D. Zhao*, and J. S. Hong. Lab. of Molecular and Integrative Neuroscience, NIEHS, Research Triangle Park, NC 27709.

We have demonstrated by repeated subconvulsive electrical stimulations of the deep prepyriform cortex (DPC) led to an early increase of Met^5-enkephalin but not dynorphin in the hippocampus before the development of generalized convulsions. This study investigates whether such change is due to an increase in proenkephalin (pEK) mRNA during the development of DPC kindling. Rats were stimulated every hour until twice consecutive Stage 2 (S2) or Stage 5 (S5) occurred and were sacrificed either 5 min or 24 h later. At S2-24 h pEK mRNA in the entorhinal cortex and striatum was significantly increased. pEK mRNA was also increased in the hippocampus, frontal cortex, and entorhinal cortex 5 min after S5, whereas 24 h after S5, significant increases were found in the frontal cortex and entorhinal cortex but not in the hippocampus. Hippocampal preprodynorphin (pDYN) mRNA was significantly reduced 24 h after S5 but not at the other time periods studied. These data demonstrate that pEK and pDYN gene expressions were differentially regulated during the development of DPC kindling. The early increase in pEK mRNA content suggests that enkephalinergic system may play a role in kindling development.

411.2

ELECTROCONVULSIVE SHOCK ALTERS CONTENT OF mRNA CODING FOR PREPRODYNORPHIN AND PROENKEPHALIN IN DIFFERENT RAT BRAIN REGIONS. C. W. Xie*, P. H. K. Lee, J. Douglass[a], and J. S. Hong. Lab. of Molecular and Integrative Neuroscience, NIEHS, RTP, NC 27709 and Institute for Advanced Biomedical Research, Oregon Health Sciences University, Portland, OR[a].

The effects of single or repeated electroconvulsive shocks (ECS) on abundance of dynorphin and enkephalin mRNA in rat brain were investigated. Rats were subjected to 1, 3 or 6 daily ECS and sacrificed 24 h later. The amount of mRNA coding for preprodynorphin (DYN mRNA) and proenkephalin (EK mRNA) were measured in several brain regions using RNA blot analysis. Repeated ECS led to a progressive decrease in hippocampal DYN mRNA with maximum reduction of 51% after 6 consecutive ECS. A consistent but lesser decrease in DYN mRNA level was observed in the entorhinal cortex 24 h after 1, 3, or 6 daily ECS. In contrast, DYN mRNA level showed significant elevation (by 83%) in striatum, and a modest increase (by 33%) in hypothalamus after a single ECS, which gradually declined after 3 or 6 daily shocks. EK mRNA was found to increase in entorhinal cortex (57%) and hypothalamus (75%), whereas only a small decrease was observed in hippocampus and no change in striatum after 6 daily ECS. These data suggest that repeated ECS enhances the biosynthesis of enkephalin but inhibits that of dynorphin in the entorhinal cortex-hippocampal region.

411.3

LOCALIZATION AND QUANTIFICATION OF VIP-, SS-, AND GABA-LIKE IMMUNOREACTIVITY IN THE HIPPOCAMPUS AND AREA DENTATA OF El (EPILEPTIC) AND C57BL/6 MICE. J.J. King, Jr.*, and C.G. LaMotte. (SPON:S.Kapadia) Section of Neurosurgery, Yale Univ. Sch. Med., New Haven, CT 06510.

The El mouse, an excellent genetic model of temporal lobe epilepsy, experiences tonic-clonic seizures of hippocampal origin following rhythmic vestibular stimulation. No previous work has documented an anatomical substrate for the seizure disorder. El mice were kindled by gentle tossing at age 30, 37 and 44 days and then tested for seizures after 56 days. At sacrifice all El mice had experienced at least 10 documented seizures. Presence of VIP, SS and GABA was determined using PAP immunohistochemistry. We observed elevated VIP-LI and GABA-LI interneuron cell densities in specific hippocampal anatomical subdivisions of El mice when compared to C57BL/6 mice. Increases of VIP-LI cell densities were seen in the stratum oriens and the regio superiore stratum radiatum. GABA-LI cell densities were greater in the stratum radiatum. There was no difference in the SS-LI cell densities. Both the VIP-LI and GABA-LI changes represent alterations in either the numbers of regulatory interneurons or their levels of transmitter synthesis. These data suggest that transmitter perturbations in the cells that modify projection cell output may be indicative of altered neural circuitry related to the epileptic predisposition of El mice.

The present study found differences in relatively "young" adult El mice without an extensive documented seizure history. The development of epilepsy in immature mice and the cumulative effects of many seizures in older animals will be examined in future studies. Additional immunohistochemical work on immature and aged animals may yield further insights into the epileptic process in the El mouse.

411.4

THE TIME COURSE OF CHEMICAL CHANGES IN THE KINDLED RAT BRAIN. N.S.Nadi. NINCDS, Bethesda, Md.

The evolution of changes in amino acids, neuropeptides and catecholamines were studies in the cortex (CX) and hippocampus (H) of kindled rats at stages i,ii,iii,iv and v of seizures. The levels of the amino acids, glutamate, aspartate, GABA and glycine were unchanged throughout the evolution of seizures in CX and H. Somatostatin increased at stage ii in CX but not H and continued to increase reaching a maximum at stage v in the CX. The changes in somatostatin in the H were not as marked as those observed in the cortex. The levels of substance P, neuropeptide Y and dynorphin were unchanged. The levels of enkephalin increased in the H at stages iv and v, but were unchanged at the earlier seizure stages. Enkephaloin levels were not markedly altered in the CX. The levels of catecholamines were not altered at any of the stages in CX or H. The number of NMDA receptors was slightly increased at stage ii in the H and was significantly higher compared to sham operated animals at stages iv and v in both H and CX.At stage iv and v the release of glutamate, aspartate and norepinephrine were significantly increased in the H and CX.The dynamic interactions between these changes are currently being investigated using slice techniques.

411.5

LAMINAR DISTRIBUTION OF PEPTIDES, CHOLINE ACETYLTRANSFERASE AND RECEPTORS IN THE HUMAN EPILEPTIC CORTEX. H.H.Drucker*, A.R.Wyler* and N.S.Nadi., NINCDS Bethesda, Md., and U.Tennn Med. Ctr. Memphis, Tn. (SPON: E.Streicher).

We measured the laminar distribution of choline acetyltransferase (CAT), neuropeptide Y(NPY), somatostatin(ST), glutamate (glu), aspartate (asp) and QNB and NMDA receptors in the temporal cortex (CX) removed from 8 individuals with intractable epilepsy. The layers were defined as follows : layer A: meninges, layer B: gray matter 1 and 2, layer C: gray matter 3 and 4, layer D: gray matter 5 and 6, and white matter. Glu was elevated in layer D of spiking (S) 15.8±2.8 umol/mg prot. vs nonspiking (NS) CX 8.1±3.4 umol/mg prot.. NMDA receptors were elevated in layer D 22.8 fmol/mg prot. of S vs NS CX 12.8±2.9fmol/mg prot.. CAT increased in layer B of S(35.4±6.8 pmol/mgprot/hr vs NS CX (20.7±11.9pmol/mgprot/hr). The enzyme was also elevated in layer C. ST was elevated in layer C in S (310±200 pg/mg prot) vs NS (160±150 pg/mg prot.) CX. NPY was increased in layer B of S (565±85 pg/mg prot) vs NS (345±145 pg/mg prot.) CX. No significant gradients in the distribution of asp and QNB were observed in the layers analyzed. The different distributions of the NPY and ST alterations suggest the involvement of two different populations of neurons. The changes in glu and NMDA receptors occuring in layer D indicate the involvement of yet another group of fibers and neurons in the excitatory amino acid pathways. The relationship of these findings to seizure generation will be discussed.

411.6

CONTENT OF NEUROTENSIN, VASOACTIVE INTESTINAL POLYPEPTIDE AND CHOLECYSTOKININ IN THE HUMAN EPILEPTIC CORTEX AND THE HIPPOCAMPUS. K.Wayns*, A.R.Wyler* and N.S.Nadi. NINCDS, Bethesda, MD., U.Tenn. Med. Ctr. Memphis Tn. (SPON: E.T.Hambrecht).

The levels of the neuropeptides neurotensin (NT), vasoactive intestinal polypeptide (VIP) and cholecystokinin (CCK) were determined in the spiking and non spiking regions of the temporal lobes surgically removed from 30 intractable epileptics. CCK was lower in the spiking cortex (12.5±2.8 pg/mg prot.) vs the non spiking cortex 22.9±1.7 pg/mg prot. ,p<0.01). NT was higher in the spiking cortex when compared to the non spiking cortex, 0.82±0.2 pg/mg prot. and 0.59±0.2 pg/mg prot. respectively (p<0.01). VIP was also lower in the spiking vs non spiking cortex, 31.4±12.1 pg/mg prot. vs 62.4±10.4 pg/mg protein respectively, (p<0.01). The levels of NT in six epileptic hippocampi were 0.79±0.03 pg /mg prot.. The levels of VIP and CCK were 25.5±0.82 and 11.9±0.92 pg/mg prot. respectively. No autopsied hippocampus was available for comparison. The role for most neuropeptides in the central nervous system is unclear. NT is known to colocalize with dopamine (DA) neurons and also to be excitatory. Our previous studies have shown an increase in DA in the spiking cortex and it is possible that NT and DA may be colocalized. NT may also regulate the excitability of the region. VIP has been implicated in control of circulation and the alterations observed suggest a disorder in regional circulation.

411.7

SECOND MESSENGER SYSTEMS IN THE KINDLED CORTEX AND HIPPOCAMPUS. N. Mai* and N.S.Nadi. NINCDS, Bethesda, Md. (SPON: W.H.Theodore).

We have investigated the effects of norepinephrine (NE), increased K+, N methyl aspartate (NMA) with respect to cyclic AMP and cyclic GMP regulation in slices prepared from the cortex and the hippocampus of the stage v kindled rat. Increased K+ caused a significantly larger increase in the kindled rat hippocampus and cortex slices than in the slices from sham operated rats. The changes in cyclic AMP content were not statistically different between kindled and sham operated rat brain slices. The levels of cyclic AMP were increased in response to exposure of the cortex and the hippocampus slices to norepinephrine. These changes were not statistically different between the kindled and sham operated animals. NMA cuased a significant elevation in cyclic GMP in both the cortex and hippocampus slices in the kindled and sham operated rats. The increase in cyclic GMP in the kindled cortex and hippocampus slices was significantly higher when compared to the sham operated hippocampus and cortex. These preliminary experiments suggest that the control of the cyclic GMP pool is altered in the cortex and the hippocampus of the kindled rat brain. Such alterations in second messenger control may represent a step in explaining the molecular mechanisms of the changes underlying the kindling phenomenon. Studies are currently underway to determine the time course of these changes as well as the effect of the above compounds on the phosphotidylinositol class of second messengers.

411.8

A CHEMICAL EVALUATION OF THE EPILEPTIC FOCUS. A.R.Wyler*, N.S.Nadi. U. Tenn. Med.Ctr. Memphis Tn., and NINCDS, Bethesda Md. (SPON: W.W.Alberts).

Previous studies in our laboratory have discovered a number of alterations in neuropeptides, catecholamines amino acids, receptors and enzymes in the human epileptic focus. With results from 35 patients we have analyzed the data with respect to cross correlations between these findings as well as lateralization, correlations with anticonvulsant drug levels, male-female and age related differences and relationship to surgical outcome. The question addressed in these analyses was the usefulness of the biochemical studies of the spiking brain and what future approaches might be inferred from biochemical studies. The cross correlations of all the data revealed a statistically significant correlation between somatostatin and norepinephrine (r=0.82, p<0.001), and ST and dopamine (DA) (r=0.62, p<0.01). Neurotensin (NT) and DA were also significantly correlated (r=0.52, p<0.01). The transmitter metabolites HVA and 5HIAA were also correlated (r=0.79, p<0.01). No other statistically significant correlations were demonstrated in this study. There was no significant lateralization of the transmitters although the catecholamines tended to be slightly lower in the left temporal lobe. No significant male- female or age related differences were noted. With respect to anticonvulsant drugs the levels of ST in patients on carbamazepine alone was slightly less than in patients on phenytojn alone. The data reported here did not correlate with surgical outcome. The strong correlations between ST, NT, DA and NE is suggestive of colocalization or transynaptic regulation. Such changes in the epileptic focus are suggestive of an altered synaptic connectivity as a result of neuronal loss. The lack of correlation with outcome may reflect the fact that surgery only removes a portion of the synaptic circuitry necessary to interrupt the seizures, but that it is not always necessary to remove all of the tissue to have good outcome. The data will be discussed with respect to animal models and a chemical identification of the spiking region.

411.9

INDOLES, CATECHOLS AND TYROSINE HYDROXYLASE IN THE HUMAN EPILEPTIC CORTEX. M. Pintor*, S. Pocotte, I. Mefford*, A.R. Wyler* and N. S. Nadi (SPON: R.J.Porter) . NINCDS, Bethesda, Md, and U. Tenn. Med. Ctr., Memphis, Tn.

The levels of serotonin (5HT), dopamine (DA), and their metabolites, 5HIAA and HVA were measured in surgically resected human spiking and nonspiking temporal cortex. In 13 pairs of spiking and non spiking cortex evaluated as pmol/mg protein 5HT was 6.1±2.4 and 3.5±1.3 respectively (p<0.01), and 5HIAA was 13.8±5.2 and 7.9±5 respectively (p<0.02). In a previous study norepinephrine (NE) was found to be 1.5±0.6 in the spiking cortex and 1.06±0.4 in the nonspiking cortex(p<0.001) and dopamine was 1.0±0.5 and 0.7±0.3 (p<0.001) (Goldstein, D.S, J.Neurochem. 50:225, 1988). No difference in the levels of the indoles and the catechols were observed between the right and the left temporal lobes. The activity of tyrosine hydroxylase (TH) was also measured and no difference was detected between spiking and non spiking regions of the temporal lobe. These results do not support previously reported findings (Sherwin, A. L., Neurology, 34:927, 1984). One reason for this discrepancy may be in the observation that the TH is increased during and immediately after seizure but not in the interictal phase as shown in the case of rats given a single electroconvulsive shock. The chronically elevated content of indoles and catechols may be due to an increased turnover and altered release rate. The existence of such changes in the human brain and kindled rats is currently being investigated using in vitro slice techniques.

411.10

HIPPOCAMPAL VOLUMETRIC NEURONAL DENSITY IN TEMPORAL LOBE EPILEPSY. J. H. Kim, P.O. Guimaraes*, M.Y. Shen*, C. Deutch*, S.S. Spencer, D.D. Spencer. Dept's. of Surgery (neuropathology, neurosurgery) and Neurology, Yale Univ. School of Medicine, New Haven, CT 06510

Hippocampal sclerosis, shown in a majority of temporal lobe epilepsy cases, is histologically composed of neuronal loss and gliosis, and its exact pathogenesis is controversial. To study the relationship between the degree of neuronal loss and clinical variables, volumetric neuronal density was measured in the hippocampal fields from the mid or mid-posterior level of surgically removed hippocampal coronal sections from 24 intractable epilepsy cases. 11 age matched autopsy cases without any previous history of seizure or other neurologically significant diseases served as control. Cell counts were done in multiple unit areas on 6um thick, paraffin embedded, hematoxylin and eosin stained sections in the CA1 through CA4 and granular layer. The counts were modified with Abercrombie formula, and were expressed as mean neuronal number per mm3. Pearson's correlation showed moderate to high correlation between the age of patients at the onset of seizures and the neuronal density in CA1 and CA2 (r=0.678, p<0.001, and r=0.777, p<0.001, respectively). A similar degree of correlation was obtained between a history of febrile seizures and CA1 neuronal density (r=0.666, p<0.001). No significant correlation was seen between the cell count and other clinical variables including age at the time of hippocampectomy, sex, duration of seizures (year), seizure frequency per month, frequency of seizures per month x duration in years, family history of epilepsy, and history of other neurologic problems such as head trauma or CNS infection. Thus, early onset of seizures and a history of febrile seizures are associated with statistically significant loss of neurons in CA1 and CA2, and in CA1, respectively.

411.11

Anatomic - Pharmacologic Analysis of Benzodiazepine Receptor Binding in Human Epileptic Hippocampus. H.T. Chugani*, T.L. Babb, W.R. Kupfer* and J.K. Pretorius* (SPON: E. Rubinstein). Depts of Neurology and Pediatrics and the Brain Research Institute. UCLA School of Medicine, Los Angeles, CA. 90024.

Benzodiazepine receptor binding was measured using [^{3}H]-flunitrazepam quantitative autoradiography of the fascia dentata of 6 patients who underwent temporal lobectomy for relief of epilepsy. Quantitative estimates by Scatchard analysis of receptor densities (Bmax) and affinity constants (K_D) were compared to granule cell counts of the same region in order to relate cell loss to cell receptor binding properties when using an autoradiographic densitometric technique. Mean Bmax values were 213.5 ± 43.1 SEM and mean K_D values were 5.2 nM ± 1.5 SEM. However, Bmax values ranged from 160.0 to 425.5 fmol/mg tissue and correlated inversely with the percentage of granule cell loss (R=0.54). K_D was not correlated with granule cell loss. These results suggest that receptor density in epilepsy may be determined by cell loss alone, while K_D is unaffected by hippocampal sclerosis. However, the correlation with cell loss in these analyses were not statistically significant until the data were described by a third-order polynomial. The interpretation of ligand autoradiography using light transmission must take into account the underlying anatomy of the cell densities and dendritic processes that may be labelled. NIH Grant NS02808.

411.12

Altered Patterns of Dynorphin-like Immunoreactivity in the Hippocampal Formation of Patients with Temporal Lobe Epilepsy. C.R. Houser and J.E. Miyashiro*. VA Medical Center, West Los Angeles and Brain Research Institute, UCLA, Los Angeles, CA 90024.

Dynorphin A^{1-17} has been localized in immunocytochemical preparations of human hippocampal formation. In control autopsy specimens, dynorphin A-like immunoreactivity was present in the mossy fiber path, as demonstrated in the rat (McGinty, J.F. et al., 1983), extending through the hilus and CA3 field. Very little reaction product was evident in the molecular layer of the dentate gyrus. In contrast, in surgical specimens from patients with temporal lobe epilepsy, dynorphin-like immunoreactivity was present in the granule cell and molecular layers, sometimes extending through the inner third of the molecular layer. Reaction product was also concentrated around the limited number of neurons remaining in the hilus and CA3 field.

These findings suggest that morphological reorganization of mossy fibers has occurred in humans with temporal lobe epilepsy, as demonstrated in animal models of seizure disorders (Nadler, J.V. et al., 1980), and indicate that the reorganized fibers contain at least one of the neuroactive substances normally present in mossy fibers. Supported by VA Medical Research Funds and NIH Grant NS 21908.

411.13

GLUCOCORTICOID ANTAGONISM WITH RU 486 ENHANCES LIDOCAINE KINDLING. M. A. Kling, M. A. Demitrack*, M. DeBellis*, S. R. B. Weiss*, G. P. Chrousos*, R. M. Post, and P. W. Gold*. BPB, NIMH and DEB, NICHD, Bethesda, MD 20892.

Local anesthetics such as lidocaine are capable of producing kindled seizures in rats; i.e., initially subconvulsive doses will produce seizures when given repeatedly. The mechanism of this effect has not been definitively established; however, it may involve activation of limbic substrates based on metabolic autoradiographic data. We were interested in the potential involvement of corticotropin-releasing hormone (CRH) in this effect, since CRH causes limbic seizures which cross-sensitize with amygdala-kindled seizures, and local anesthetics stimulate CRH secretion in vitro. We report here a study of the effects of RU 486, a potent glucocorticoid antagonist expected to increase endogenous CRH levels via blockade of glucocorticoid negative feedback, on lidocaine kindling in rats. Male Sprague-Dawley rats received daily injections of either RU 486 (100 mg/kg, i.p.) or vehicle 2 hours prior to lidocaine HCl (65 mg/kg x 8 days, then 75 mg/kg X 9 days, i.p.). RU 486 significantly enhanced the development and cumulative frequency of lidocaine-induced seizures (chi-sq=14.4, p<.001). RU 486-treated rats also had significantly more mortality than controls (38.0% vs. 5.3%, chi-sq=6.2, p<.025). In 62% of the RU-treated rats, the deaths occurred following seizures. The facilitation of lidocaine kindling by RU 486 may be mediated in part by increased secretion of CRH. Alternatively, glucocorticoids, which enhance GABA-mediated chloride flux under some conditions, may be tonically inhibitory to lidocaine kindling. The increased mortality in the RU 486-treated rats may be due to diminished capacity of these rats to tolerate stressful conditions.

411.14

EFFECT OF NALTREXONE ON CRH-INDUCED SEIZURES IN RATS. G.I. Perini*, S.R.B. Weiss*, M.A. Kling, M. DeBellis*, L. Wilson*, K. Vogelsong*, G.P. Chrousos*, R.M. Post, P.W. Gold* (Spon: J. Ferguson) BPB, NIMH & DEB, NICHD, Bethesda, MD 20892

Corticotropin-releasing hormone (CRH) is a stress-related peptide which causes seizures of late onset [1-5 hour latency following intracerebroventricular (i.c.v.) administration] that involve limbic structures. In vitro, CRH causes the release of B-endorphin, a peptide which produces kindled seizures following intra-amygdaloid or hippocampal administration (Cain & Corcoran, 1984). On the other hand, endogenous opiates released during seizures may be related to post-ictal decreases in seizure susceptibility. To evaluate the role of opiate peptides in CRH-induced seizures, we administered naltrexone, an opiate antagonist (10 mg/kg, i.p.) one-half hour prior to, and 4 hours after (5 mg/kg) CRH (100 µg, i.c.v.) on 2 consecutive days. The overall effect of naltrexone was to potentiate CRH-induced seizures. Although the number of animals experiencing seizures did not differ on day 1, the number of seizures per animal tended to be greater in the naltrexone group than in the controls ($\bar{x}$ ± S.E.M.=5.71 ± 1.52 vs 2.37 ± 0.53); the latency tended to be shorter in the naltrexone-treated rats (3/7 rats had seizures within the first hour compared to 0/8 controls). On day 2, more naltrexone-treated rats tended to exhibit seizures (6/9 compared to 3/10 controls), although the overall number of seizures on this day did not differ between groups. Thus, opiate release is unlikely to be the mechanism responsible for CRH-induced seizures. The trend for an overall proconvulsant effect of naltrexone on several measures may be related to a blockade of post-ictal opiate effects which in other seizure models are inhibitory.

411.15

EFFECTS OF ESTROGENS ON EPILEPTIFORM ACTIVITY IN THE IN VITRO HIPPOCAMPAL SLICE. D. L. Pettit*, S. Veregge, D., Doherty*, and C. Dolorfo*. Dept. of Biology, San Jose State Univ., San Jose, CA 95192.

Many investigators have reported cyclic changes in seizure frequency in women with epilepsy. Increases in seizures have been observed just before menses or at ovulation, times when estrogen levels are high relative to progesterone. These observations, paired with those from in vivo animal studies, suggest that estrogens may potentiate epileptiform activity. We used the hippocampal slice as a model for investigating the direct short-latency effects of estradiol and estrone-3-sulfate, an estradiol metabolite, on epileptiform activity.

Hippocampal slices were prepared from proestrus female rats and maintained under standard incubation conditions. Epileptiform activity was produced using penicillin (3000 u/ml) in ACSF. Orthodromically evoked epileptiform field potentials were recorded from CA1 and the parameters of the field potentials (peak amplitude, duration and number of population spikes) were quantified before and after the addition of estrogens to the ACSF.

Estradiol did not modify the amplitude, duration of the epileptiform activity, or number of population spikes in either physiological (0.36-36 nM) or pharmacological (367 µM) doses. Estrone-3-sulfate modulated penicillin induced epileptiform activity in pharmacological (45-4500 µM), but not physiological concentrations. In addition, concentrations 45 µM or greater of estrone-3-sulfate produced epleptiform activity. The effects of estrone did not appear to depend on estrous stage or sex. These results suggest that estradiol does not modify epileptiform activity in the hippocampus at either physiological or pharmacological doses. Investigations of the mechanism of action of estrone and other metabolites are currently underway. Work supported by the Epilepsy Foundation of America.

DIETHYLDITHIOCARBAMATE AND DITHIZONE AUGMENT THE TOXICITY OF KAINIC ACID. C. L. Mitchell, M. I. Barnes*, and L. Grimes. Lab. of Molecular and Integrative Neuroscience, NIEHS/NIH, Research Triangle Park, NC 27709 and Toxicology Curriculum, UNC-CH, Chapel Hill, NC 27514.

Grimes et al. (J. Neurosci., 8:256-264, 1988) reported that colchicine-induced lesions of the hippocampal mossy fiber pathway eliminate kainic acid (KA)-induced wet dog shakes (WDS) but do not affect the latency to onset of seizures. Since chelation of zinc appears to result in a functional disruption of this pathway (Crawford and Connor, Orthomolec. Psychiat. 4:39, 1975) we wished to determine the effects of the zinc chelators, diethyldithiocarbamate (DEDTC) and dithizone (D) on KA-induced WDS and seizure activity. Male Fischer-344 rats were injected i.p. with DEDTC (100, 200, or 400 mg/kg) or D (12.5, 25, 50, or 100 mg/kg) 15 min. after KA (8 mg/kg, s.c.). DEDTC and D reduced both the number of WDS and the onset of seizures induced by KA. Moreover, they increased the severity of seizures and frequency of death. Doses as low as 100 mg/kg of DEDTC and 12.5 mg/kg of D were effective. For example, 7/10 animals receiving DEDTC (100 mg/kg) exhibited hind limb clonic seizures and 8/10 died following KA whereas these effects were seen in only 2/10 of the animals receiving KA plus the vehicle control. These compounds may be useful tools for investigating the role of Zn in central nervous system excitatory neurotransmission and/or convulsive phenomena.

411.17

EFFECT OF PYRIDOXINE ON THE DEVELOPMENT OF AMYGDALOID KINDLED SEIZURES IN THE RAT. L. Pao, M.A. Bixler, J.L. Meyerhoff (SPON: L.H. Hicks). Dept. of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C., 20307-5100.

Several studies implicate pyridoxine-dependent inhibitory mechanisms in a variety of seizure-inducing paradigms. Dietary pyridoxine deficiency is reported to decrease seizure latency in rats following systemic kainic acid challenge (Ruth, R.E. and Morgan, D.G., Exp. Neurol., 94:441, 1986). Pyridoxine injections 1 hour prior to insulin treatment inhibited insulin-induced seizures (Saad, S. F., Eur. J. Pharm., 17:152, 1972). Pyridoxine also increased the threshold for seizures in previously fully-kindled cats (Shouse, M.N., Exp. Neurol., 75:79, 1982). In the present study, pyridoxine injections (50 mg/kg, i.p.) were given to male Sprague-Dawley rats 1 hour prior to daily amygdaloid kindling stimulation (200 microamperes, biphasic, base-to-peak) and continued daily until fully generalized (stage 5) convulsions were obtained. The number of stimulations required to achieve the first stage 5 convulsion was not significantly different in the pyridoxine group (10.1 ± 1.08) compared to saline-injected controls (11.7 ± 1.09), t = 1.04, N = 17. Thus, despite the inhibitory effect of pyridoxine on seizures in a number of acute paradigms, it did not appear to retard the kindling process.

ANTICONVULSANT CONCENTRATIONS IN CSF AND SERUM OF RATS PROTECTED AGAINST MES BY PR934-423A. T.C.M. Wilson*, G.E. Machulskis*, G.E. Garske* and E.W. Harris (SPON: A.J. Jacobs). Analytical Chemistry & Pharmacology Departments, Pharmaceutical Div., Pennwalt Corp., Rochester NY 14603

The hydrochloride salt of PR934-423 ((+)-2-amino-N(1-methyl-1,2-diphenylethyl) acetamide.HCl; PR934-423A) is a water-soluble anticonvulsant effective in mice and rats against maximal electroshock seizures (MES), with a larger therapeutic index than carbamazepine, phenobarbital or valproate. To facilitate clinical and in vitro studies, PR934-423 concentrations were determined in serum and cerebrospinal fluid (CSF) of rats protected against MES.

Young adult male rats were dosed orally with PR934-423A at 19.7 or 86 mg free-base/Kg. At 1 or 3 hours post-dose, serum and CSF samples were taken and anti-MES efficacy was determined in separate rats. The concentration of PR934-423 metabolites was measured using 14-C-labelled drug. The total amount of drug-derived material (radiolabel, in uM) was determined 1 hour post-dose.

Only 4/12 rats were protected against MES 1 hour after 19.7mpK PR934-423, but 11/11 were protected 1 hour after 86mpK; 18/27 were still protected 3 hours after 86mpK. The corresponding CSF concentrations were 31, 153, and 53 ng/ml (0.11, 0.54 and 0.19 uM). The studies with radiolabel showed that PR934-423 accounts for approximately half of all drug-derived material in CSF.

PR934-423, or a metabolite, is a very potent anticonvulsant effective at ~0.5uM or less in CSF.

DORSAL AND VENTRAL HIPPOCAMPAL KINDLING IN FEMALE RATS WITH AND WITHOUT ESTRADIOL. J.S. Kiefer*, G.M. Hudson* and G.G. Buterbaugh (SPON:P.Monroe). Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201.

Ovariectomized female Sprague-Dawley rats were kindled by daily stimulation of the dorsal (DH) or ventral hippocampus (VH). DH rats with estradiol (E) replacement required fewer afterdischarge (AD) trials to kindle (28.3 ± 3.5) compared to rats without (nE) estradiol (42.5 ± 3.7); E rats also accumulated 35% less AD time during kindling. E altered both early and late phases of DH kindling. In E rats, two landmarks of kindling, increased AD duration and first stage 4 generalized convulsion, appeared more quickly compared to nE rats. After the first stage 4 response, E rats required substantially fewer AD trials and sec to complete kindling compared to nE rats. Estradiol also stabilized late kindling generalized seizures since E rats rarely regressed to lower seizure stages as was common in nE rats. In contrast to DH kindling, VH kindling does not appear to be sensitive to estradiol. The results add to the evidence that the interaction of E with kindled seizure acquisition is stimulation-site dependent and keyed to generalized seizures. E may interact within a limited spatial domain in concert with the recruitment of parallel kindling circuits. The results further support a complex role for estradiol in catamenial epilepsy. (Supported by NS20670)

EFFECTS ON CORTICAL NEURONS OF THE KAPPA AGONIST U-50488H, THE ANTICONVULSANT U-54494A AND RELATED NON-KAPPA 1,2 DIAMINES. M.Camacho-Ochoa, G.D.Vogelsang, P.F.VonVoigtlander, and M.F.Piercey. The Upjohn Company, Kalamazoo, MI 49001.

U-50488H, a selective agonist for opiate kappa receptors, U-54494A, a non-kappa agonist anticonvulsant, and U-63764 and U-63640, two 1,2-diamines chemically related to U-50488H and U-54494A, were tested for effects on spontaneous and glutamate evoked firing rates in cerebral cortex of urethane-anesthetized male Sprague-Dawley rats. Standard 7-barrelled microelectrodes were filled with 200 mM, pH 5.5 concentrations of 1,2-diamines (except U-63764, 150 mM), or 200 mM glutamate (pH 8.0), kainic acid (pH 8.0), procaine (pH 5.5), glutamate diethyl ester (GDEE, pH 4.0), and naloxone (pH 6.0). Iontophoretic application of 1,2-diamines, GDEE, or procaine depressed spontaneous and amino acid-induced firing of cortical neurons. With continued ejection of 1,2-diamines or procaine, firing was silenced completely, but GDEE could maintain a partial suppression. A rapid rebound of excitation followed cessation of procaine ejections, but not of other agents. Iontophoretic naloxone failed to antagonize U-50488H or other 1,2-diamines. U-54494A, in doses up to 30 mg/kg i.v., significantly depressed spontaneous firing rates in 2 of 6 cortical neurons, but only 1 of 6 hippocampal pyramidal cells were weakly depressed. It is concluded that U-50488H and other 1,2-diamines inhibit neuronal excitability by a non-kappa receptor mechanism.

EPILEPSY: GABA AND BENZODIAZEPINES

412.1

REGIONALLY SPECIFIC EFFECTS OF DIAZEPAM ON 2-DG UPTAKE DURING STATUS EPILEPTICUS IN KINDLED RATS. B.E. Jones, G.M. Hudson* and G.G. Buterbaugh. Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201.

Pilocarpine-facilitated status epilepticus (pfSE) results from a synergism between seizure activity and a nonconvulsive dose of pilocarpine (20 mg/kg) in kindled rats. The early time-course (i.e.,60 min) of pfSE is characterized by stable generalized EEG seizures with mild motor components. We examined 2-DG uptake patterns during early pfSE in rats treated after 10 min of pfSE with a dose of diazepam (12.5 mg/kg; i.p.) resulting in akinesia with no overt change in EEG seizures. ^{14}C labelled 2-DG (100 uCi/kg; i.v.) was administered 5 min later; rats were sacrificed 45 min later and brains rapidly removed and frozen sectioned for contact autoradiography. Rats receiving vehicle only showed extensive bilateral 2-DG uptake particularly in the lateral septum, hippocampus, amygdala, most thalamic nuclei, substantia nigra, medial geniculate and all cortical areas. Diazepam treated rats showed a similar uptake pattern except for a selective bilateral decrease of 2-DG uptake in the entire extent of the hippocampus and parietal neocortical areas. These results suggest that the hippocampus and some neocortical areas are not significant factors in the maintenance of seizure activity in pfSE. (Supported UMAB DRIF Grant)

412.2

EXCITATION BY GABA IN MOUSE SPINAL CORD.
G. Czéh* and G.G. Somjen,
Dept. Physiol. Duke Univ. Durham NC 27710.

Last year we reported that spontaneous activity is inducted in hemisected mouse spinal cords *in vitro* by elevated $[Ca^{2+}]_o$ (Neurosci. Soc. Abstr. 13:318, 1987). Similar activity occurs in low $[Mg^{2+}]_o$. High $[Ca^{2+}]_o$ and low $[Mg^{2+}]_o$-induced spontaneous discharges in both dorsal and ventral roots (DRs and VRs) were blocked by the GABA-antagonists picrotoxin and bicuculline. After cleaving dorsal from ventral cord quadrant, spontaneous activity ceased in VR but persisted in DR. A short latency DR reflex (DRR1) could be evoked in all spinal cords in control solution (1.2 mM $[Ca^{2+}]$ and $[Mg^{2+}]$). DRR1 and the segmental monosynaptic reflex (VRR) were depressed in low $[Ca^{2+}]_o$ and in high $[Mg^{2+}]_o$ and slightly increased in high $[Ca^{2+}]_o$ and in low $[Mg^{2+}]_o$. Varying $[Ca^{2+}]_o$ had much stronger effects on the slow dorsal root potential (DRP). A later DR reflex (DRR2) appeared in elevated $[Ca^{2+}]_o$ (threshold of 1.8 mM). DRP and DRR2, but not DRR1, were depressed by bicuculline. We conclude that high $[Ca^{2+}]_o$- and low $[Mg^{2+}]_o$-induced spontaneous activity depends on an obligatory GABA-ergic link operating in dorsal gray matter. This confirms an excitatory effect of GABA in spinal cord (see Duchen: Brain Res. 379:182, 1986).

412.3

GABA-STIMULATED CHLORIDE FLUX IN THE KINDLING MODEL OF EPILEPSY. W.M. Burnham, S.J. Kish* and W.B. Sneddon*. Dept. of Pharmacology, University of Toronto, Toronto, Ont. and Clarke Institute of Psychiatry, Toronto, Ont.

On the basis of preliminary data, Burnham et al. (1988) have recently suggested that GABA-mediated chloride flux is reduced in the brain stems of entorhinal-kindled rats. The present full-scale study confirms this finding, and indicates that significant changes may be found at both 24 hours and 28+ days after the last kindled seizure.

GABA-mediated chloride flux was assayed in the brains of entorhinal-kindled and implanted control rats, sacrificed either 24 hours or 28+ days after the 6th stage-5 kindled seizure. The assay, adapted from Hollingsworth et al., involved measurement of 36-chloride entry into synaptoneurosomes in the presence or absence of 100uM GABA. When cerebral cortex and cerebellum were assayed, no differences between kindled and control brains were found. When the brain stem was assayed, however, GABA-stimulated chloride flux was found to be greatly reduced in kindled subjects. Similar reductions were seen both at 24 hours and 28 days.

These data suggest the presence of a long-lasting deficit in GABA function in at least one area of kindled brain. They are consistent with a "GABA hypothesis" of kindling.

412.4

ALLELIC DIFFERENCES IN $GABA_A$ RECEPTORS BETWEEN SEIZURE PRONE AND RESISTANT MICE. J.C.R. Fernando and D.R. Burt. Dept. Pharmacol., U. Md. Sch. Med., Baltimore, MD 21201.

Inbred strains of mice differ markedly in their susceptibility to audiogenic seizures: juvenile DBA/2 mice are much more sensitive than C57BL/6 mice of any age. Strain differences in structure or expression of inhibitory GABA receptors may contribute to seizure susceptibility. We have looked for restriction fragment length polymorphisms (RFLPs) which distinguish genes for $GABA_A$ receptors in DBA/2 and C57BL/6 mice. Southern blots of genomic DNA extracted from the livers and cut with a variety of restriction endonucleases were hybridized at low stringency with cDNA probes based on published bovine $GABA_A$ receptor sequences (Schofield et al., Nature 328:221, 1987). Two enzymes have yielded clear RFLPs. PstI-cut DNA, when probed with a cDNA representing the N-terminal portion of the alpha subunit, gave the following pattern of bands (approx. sizes in kbp): DBA/2: 1.10, 1.87, 4.9, 6.9, 10.0; C57BL/6: 1.06, 1.80, 4.9, 6.9, 10.0. HindIII-cut DNA, when probed with a cDNA representing the C-terminal portion of the alpha subunit, gave: DBA/2: 1.2, 1.9, 3.1, 5.7; C57BL/6: 1.2, 1.9, 5.7, 8.0. The first pattern suggests small deletion(s) while the second suggests single base change(s) as strain differences in genes coding for one or more forms of the mouse $GABA_A$ receptor. The nature of these allelic differences is currently under investigation.

412.5

PERIPHERAL-TYPE BENZODIAZEPINE LIGANDS REGULATE SPECIFIC ^{3}H-PHENYTOIN BINDING TO RAT BRAIN WHOLE CORTEX MITOCHONDRIA. **J. FRANCIS and L. SPERO, Dept. of Pharmacology, University of Toronto, Toronto, Ontario, Canada M5S 1A8.**

These studies were conducted to assess specific binding sites for ^{3}H-phenytoin (^{3}H-DPH) in rat brain and the regulation of these sites in vitro. These sites, previously reported to be concentrated in the P2 fraction of rat brain homogenates, were localized in the mitochondrial fraction but not in synaptosomes. Peripheral-type benzodiazepines (P-BZD), whose receptors are found in mitochondrial outer membrane, modulated specific ^{3}H-DPH binding to mitochondrial fractions. P-BZD agonists enhanced both total and specific ^{3}H-DPH binding in the order Ro5-4864 diazepam flunitrazepam Ro5-5115. PK11195, a specific P-BZD receptor antagonist, did not significantly modulate specific ^{3}H-DPH binding except at high (10 uM) concentrations, where partial inhibition of ^{3}H-DPH binding occurred. Central-type benzodiazepine (C-BZD) agonists and antagonists also did not significantly modulate specific ^{3}H-DPH binding in mitochondria, except at high (uM) doses (clonazepam, a C-BZD agonist, partially inhibits). Similar results were found in rat cerebellum. There is an apparent association between specific ^{3}H-DPH binding sites and P-BZD binding sites in rat brain cortex mitochondria. The high (uM) P-BZD concentrations involved suggests that the P-BZD binding site involved differs from the high (nM) affinity mitochondrial P-BZD receptor.(Supported by an O.M.H.F. Studentship to J.F.)

412.6

HIPPOCAMPAL GABA AFTER SYSTEMIC KAINATE (KA). P.E. Ruth and A. Selmen*. Il. Inst. Dev. Disabil., and the Committee on Neurosci., Univ. Il., Chicago, IL 60608.

We observed an apparent potentiation of diazepam (DZP) action by KA. DZP (5 mg/kg, ip) 10 minutes prior to a high dose of KA (>19 mg/kg, ip) prevented motor seizures, but the drug interaction caused respiratory depression and death in over 50% of the rats. Also DZP (10--20 mg/kg) 30 minutes after a more typical dose of KA (12 mg/kg) caused animals to "sleep" longer than expected from DZP alone.

[GABA] is implicated in this latter phenomenon. Adult female rats injected with KA (12 mg/kg, ip) were killed 30 minutes later by cervical dislocation. Half of the carcasses (3 KA-treated, 3 control) immediately received 5 seconds of cerebral microwave irradiation: for the other half, irradiation was delayed 3 minutes to estimate post-mortem GAD "activation." Hippocampal [GABA] was measured by radioreceptor assay.

In KA-treated rats, [GABA] was 19% higher than the control level of 1.62 ± 0.26 µmol/g (wet). The rate of post-mortem GABA accumulation in KA-treated rats was 27% lower than the control rate of 0.22 µmol/g/min. Paradoxically, [GABA] is elevated by KA at a time when postsynaptic inhibition is waning. The KA-induced elevation in [GABA] may partly result from increased GAD activity.

412.7

REVERSIBLE ANTICONVULSANT DISPLACEMENT OF BENZODIAZEPINE (BZ) PHOTOLABELLING TO 65 kDa BZ BINDING PROTEIN. W.C. Taft*, A.C. Bowling* and R.J. DeLorenzo (SPON: V.T. Calabrese), Dept. Neurology, Medical College of Virginia-VCU, Richmond VA 23298.

We have identified a 65 kDa benzodiazepine binding protein (BZBP) which photolabels with photoactive BZs in concentrations that produce therapeutic effects on generalized tonic-clonic (GTC) seizures, maximal electric shock (MES)-induced seizures and limitation of spike frequency adaptation (SFA) (Eur. J. Pharm. 35, 97, 1987). BZ photolabelling to BZBP is saturable, stereoselective and displaceable with other photoactive BZs. In this study, we have examined the effectiveness of non-photoactive BZs and other anticonvulsants in displacing BZ photolabelling to BZBP. [^{3}H]Flunitrazepam ([^{3}H]FNZ) was equilibrated with BZBP in the presence or absence of non-photoactive competitor. Quantitation of [^{3}H]FNZ photolabelling to BZBP was performed by SDS-PAGE and autoradiography. Reversible, concentration-dependent displacement of [^{3}H]FNZ photolabelling was observed with diazepam, phenytoin, carbamazepine, medazepam and phenobarbital, drugs which are effective against GTC seizures, MES-induced seizures and SFA. Trimethadione and ethosuximide, drugs which are not effective against GTC seizures, MES-induced seizures and SFA, did not displace [^{3}H]FNZ photolabelling. Thus, the pattern of anticonvulsant displacement of [^{3}H]FNZ photolabelling to BZBP is similar to anticonvulsant efficacy against GTC seizures, MES-induced seizures and SFA. The results suggest that the 65 kDa BZBP may function as a general anticonvulsant binding site.

412.8

INTRACELLULAR EJECTION OF 65 kDa BENZODIAZEPINE BINDING PROTEIN (BZBP) REDUCES SPIKE FREQUENCY ADAPTATION IN AN IDENTIFIED HERMISSENDA NEURON. R.R. Forman, S. Sombati, W.C. Taft* and R. J. DeLorenzo. Dept. Neurology, Medical College of Virginia-VCU, Richmond VA 23298.

Benzodiazepine (BZ) enhancement of spike frequency adaptation (SFA), a mechanism which may underlie BZ effectiveness in suppressing tonic-clonic seizures in mammals, is not mediated by BZ binding to central GABA-BZ or peripheral BZ receptors (McLean and Macdonald, J.Pharm.Exp.Ther. 244, 789, 1988). We have isolated a 65 kDa BZBP which binds BZs in concentrations that enhance SFA (Eur.J.Pharmacol. 35, 97, 1987). In a blind study, we have injected purified BZBP (prepared from rat brain cytosol by sequential affinity chromatography) into LP1, an identified neuron on the dorsal surface of the pedal ganglion of the nudibranch mollusc, Hermissenda, and have evaluated its effects on SFA in response to depolarizing current stimuli. A single ejection of BZBP (15-20 lbs/in^2, 10 s) produced a mean 66% increase in spike frequency observed in response to a 10 s stimulus (n=6 cells). This effect peaked within 5 min of ejection and remained constant for at least 30 min. Control ejections of vehicle alone, BZ photolabelled BZBP, or heat-inactivated BZBP did not produce changes in spike frequency (n=7 cells). Ejection of either BZBP or control solutions had no effect on resting membrane potential. These results suggest that the 65 kDa BZBP may modulate SFA and that BZ binding to this protein may play a role in the regulation of SFA.

412.9

REGULATION OF THE $GABA_A$ RECEPTOR COMPLEX IN BRAIN FOLLOWING LIMBIC SEIZURES PRODUCED BY KAINIC ACID. Patricia Edgar*, Mark A. Bowe and Rochelle D. Schwartz. (SPON: T.A. Slotkin). Dept. of Pharmacology, Duke University Medical Center, Durham, NC 27710.

Systemic kainic acid (KA) was used to induce limbic epilepsy in rats. The effects of seizure activity on regulation of the GABA receptor/Cl^- channel were determined by measuring GABA receptor-gated $^{36}Cl^-$ flux in rat brain vesicles and binding of [^{35}S]TBPS to "convulsant" sites associated with the GABA receptor/ionophore. Rats were injected with KA (5-20 mg/kg, ip) and sacrificed 2 hrs later. Within this time period initial decreases in locomotor activity followed by catalepsy, wet dog shakes, and finally limbic motor seizures were observed. KA-induced seizure activity decreased maximal muscimol-activated $^{36}Cl^-$ uptake in cerebral cortical synaptoneurosomes by 12% ($p=0.0053, n=9$). The distribution of "convulsant" sites labeled by TBPS was measured using in vitro receptor autoradiography. KA-induced seizure activity caused a significant decrease in TBPS binding in fronto-parietal cortex (15%, $p < 0.02$), inferior colliculus (52%, $p<0.001$), and molecular and granular layers of cerebellum (43%, $p<0.002$, and 52%, $p < 0.001$, resp.) These data suggest that KA-induced limbic motor seizures can decrease the activity of the $GABA_A$ receptor-gated ion channel and convulsant binding to the Cl^- ionophore in specific brain regions.

412.10

INTRACELLULAR RECORDING FROM NEOCORTICAL SLICES OBTAINED DURING THE GABA WITHDRAWAL SYNDROME. C. Silva-Barrat*, J. Champagnat*, S. Brailowsky, C. Menini* and R. Naquet. Laboratoire de Physiologie Nerveuse, C.N.R.S., 91190 Gif sur Yvette, France.

The interruption of intracortical, chronic GABA infusion gives rise to an epileptogenic process, which has been named the "GABA withdrawal syndrome (GWS)" (Brain Res 442:175,1988). After induction of a GWS (EEG spikes and myoclonus) in vivo, we prepared slices and recorded neurons located in the vicinity of the infused site. Membrane potentials of more than 60mV and Na^+ action potentials of 70-110mV indicated that neurons studied were not injured by the experimental procedure. Electrical stimulation of the underlying white matter induced 15-30mV, 80-150msec paroxysmal depolarization shifts in virtually all neurons, indicative of epileptiform activity. Bath applications of GABA (0.3-10 uM) in these neurons had no effect, while the same dose range was found effective in control slices obtained from non-infused animals. In neurons unresponsive to high doses (100 uM) of GABA, voltage-dependent (non-synaptic) depolarization shifts and bursts of action potentials were induced by depolarizing current injections.

These results indicate a correlation between cortical GABAergic dysfunction and epileptiform activities at the cellular level following increased and prolonged GABA exposure in vivo.

412.11

EFFECT OF LIDOCAINE ON INHIBITION IN THE RAT HIPPOCAMPAL SLICE. B. Esplin and R. Capek. Dept. of Pharmacol. and Therapeutics, McGill University, Montreal, Quebec, H3G 1Y6, Canada.

Depression of inhibitory pathways is assumed to be responsible for the seizures induced by local anesthetics. We studied the effects of lidocaine on inhibition in the hippocampal slice using paired-pulse tests. The population spikes (PSs), evoked by orthodromic stimulation and recorded in the CA1 region, were inhibited by conditioning stimuli, either orthodromic (ortho-ortho) or antidromic (anti-ortho).

Lidocaine (50 to 300 µM) administered by perfusion produced a concentration-dependent depression of the unconditioned PSs. In the anti-ortho test, 100 µM and higher concentrations of lidocaine decreased inhibition. In the ortho-ortho test, reduced inhibition was also seen in most experiments, but 200 µM of lidocaine occasionally enhanced and prolonged the inhibition. No multiple PSs were observed during lidocaine perfusion.

Although these data do not contradict the suggestion that the hippocampus is probably not the site of origin of seizures induced by local anesthetics (Shurr et al., Anesthesiol., 64: 501, 1986), hippocampal disinhibition can play an important role in generalization of seizures induced by lidocaine *in vivo*.

BLOOD/BRAIN/NERVE BARRIER II

413.1

COMPUTER ANALYSIS OF TWO METHODS OF MEASURING BLOOD BRAIN BARRIER TRANSPORT KINETICS Richard A. Hawkins and George A. Oyler*. Dept. Anesthesia, Milton S. Hershey Medical Center, Hershey, PA 17033

A computer model of blood-brain barrier transport, was used to compare the ability of two experimental techniques, the brain uptake index technique and the in situ brain perfusion method, to accurately measure blood-brain barrier transport kinetics. The model allows the experimentally observed values of V_{max} and K_m to be predicted when kinetic parameters are assigned to both endothelial cell membranes. The model considers the effects of two membranes, blood flow, substrate concentration gradients along the length of the capillary, substrate competition, and non-steady state conditions. Two kinetically different systems, glucose and neutral amino acid transport, were evaluated. Our analysis revealed that inaccurate estimates of the K_m and V_{max} can result from both methods. The apparent kinetic constants are critically dependent on a variety of factors including the range of concentations used, the time of the experiment, the endogenous concentration of substrates and the V_{max}-to-K_m ratio. The results of neutral amino acid transport experiments are particularly sensitive experimental time and the concentration range examined. Supported by NS 16737.

413.2

TIME COURSE OF THE PENETRATION OF SYSTEMICALLY ADMINISTERED IgG INTO THE RAT NEONATAL BRAIN PARENCYMA. Roderic H. Fabian*, & Claire E. Hulsebosch+. *Department of Neurology and +Anatomy and Neurosciences and the *+Marine Biomedical Institute, University of Texas Medical Branch, Galveston, Texas, 77550.

Insight concerning CNS development has been gained by examining the effect of anti-neuronal antibodies on development. We undertook this study to determine whether or not systemically administered xenogeneic IgG crosses readily into the neonatal rat brain parenchyma. Sixteen 2 to 4 day old rat pups were compared to 12 mature rats (150 - 300g) studied previously. Rats were injected intraperitoneally with purified rabbit IgG (1.3 g/kg) or were left uninjected as controls. After 2, 6, 12, 24, and 48 hours, they were deeply anesthetized and perfused, and the neuraxis was removed and examined for the presence of rabbit IgG using a controlled immunohistochemical technique. Rabbit IgG titers were determined using an ELISA technique. Sections from pups injected with rabbit IgG stained diffusely and strongly positive for rabbit IgG after 6 hours, unlike sections from mature rats which showed no staining except for specific cell groups and the circumventricular organs. Controls showed no staining. Rabbit IgG titers in rat pup serum were maximal at 2 hours after injection. This study supports the assertion that systemically administered xenogeneic IgG reaches significantly higher concentrations in the brain parenchyma of the neonatal rat than in the mature rat. Supported by NIH grant NS 11255.

413.3

MONOCLONAL ANTIBODY CROSSING BLOOD-BRAIN BARRIER BINDS BRAIN ACETYLCHOLINESTERASE. S. Brimijoin, M. Balm, P. Hammond, and V. A. Lennon. Depts. of Pharmacology, Immunology and Neurology, Mayo Clinic, Rochester MN 55905.

As a model of autoimmunity to acetylcholinesterase (AChE) adult rats were given single i.v. injections of an equal part mixture of 7 monoclonal anti-AChE antibodies (ZR1-7). Even 2 mg of IgG caused little motor impairment or other typical signs of anticholinesterase intoxication (diarrhea, profuse salivation), but it did cause sympathetic dysfunction. For example, the antibody mixture quickly induced a pronounced and persistent bilateral ptosis. Biochemical abnormalities were also striking. AChE disappeared from plasma. Synaptic 16S and 10S AChE were depleted from diaphragm. Residual oligomeric AChE in muscle was largely complexed with IgG. Immune complexes were unexpectedly abundant in brain. Up to 65% of the AChE in cortex became antibody-bound. The binding was no postmortem artifact, as shown by the time course (steady accumulation over a 3 day period), by the preferential binding of 10S AChE, and by the 30% reduction of cortical AChE activity ($p < 0.001$). Furthermore, although individual antibodies all bound solubilized enzyme, only one bound brain AChE in vivo. This antibody clearly crossed the blood-brain barrier. Additional studies with AChE-antibodies may shed light on some poorly understood disorders of peripheral and central cholinergic systems.

EFFECTS OF Al^{3+} AND Pb^{2+} ON CEREBROMICROVASCULAR $(Na^+ + K^+)$-ATPase AND MUSCARINIC RECEPTROS. M.L. Caspers and P. Grammas*, Dept. of Chem., Univ. of Detroit, Detroit, MI 48221 and Dept. of Pathol., Wayne State Univ., Detroit, MI 48201.

The cerebromicrovasculature plays a critical role in the maintenance of the brain ionic environment and has characteristics that form the basis of the blood-brain barrier (BBB). Muscarinic receptors exist on cerebral endothelium as does the $(Na^+ + K^+)$-ATPase. Circulating neurotoxic agents, including metal ions such as Pb^{2+} and Al^{3+}, may alter receptor and enzyme function in endothelium. Experiments are performed on microvessels (capillaries) obtained from rat cerebral cortices. The effects of Pb^{2+} and Al^{3+} on $(Na^+ + K^+)$-ATPase and muscarinic receptors are evaluated using $[^3H]$-ouabain and quinuclidinyl benzilate (QNB) binding, respectively. Measurement of QNB binding at 0.094 nM and 0.25 nM (basal 206 and 315 fmol/mg, respectively) indicates a 70-85% decrease with either 100μM Pb^{2+} or Al^{3+}. At 1 mM Pb^{2+} or Al^{3+} a pronounced inhibitory effect (90%) on $[^3H]$-ouabain binding (basal 2.42 pmol/mg) is noted. However, at 1 μM Pb^{2+} or Al^{3+} a slight stimulation (20-25%) or $[^3H]$-ouabain binding is demonstrable. In summary, these data suggest that Pb^{2+} and Al^{3+} affect microvascular $(Na^+ + K^+)$-ATPase and muscarinic receptors and that these changes may constitute the underlying mechanism for CNS dysfunction associated with these metal ions. (Supported in part by USPHS HL 23603, ANR Pipeline Co., and J. Rose).

413.5

TRANSFER COEFFICIENTS FOR UPTAKE OF Ga-67, Cd-109, AND Pb-203 INTO BRAIN AND CEREBROSPINAL FLUID (CSF). V.A. Murphy, Q.R. Smith, S.I. Rapoport. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892.

Metals such as Pb and Cd have been shown in numerous investigations to be neurotoxic. However, little is known of how these metals cross the blood-brain barrier (BBB) and enter the brain. Transfer coefficients (K) for uptake of Ga-67, Cd-109 and Pb-203 into brain and CSF were determined in adult rats after i.v. administration of each tracer (J. Neurochem. 36: 1463, 1981 and 46: 1732, 1986). K's are listed for CSF, parietal cortex (PC), hippocampus (HC), midbrain-colliculi (MBC), and pons-medulla (PM) (Ca-45 K's are included for comparison):

	n	Mean (SEM) K (nl/g per s)			
		Ca-45	Pb-203	Cd-109	Ga-67
CSF	3-6	170 (10)	20.7 (1.4)	0.5 (0.1)	0.48 (0.06)
PC	8	5 (1)	23.1 (1.2)	6.0 (0.2)	0.25 (0.06)
HC	8	15 (3)	19.0 (3.5)	4.5 (0.1)	0.38 (0.04)
MBC	8	10 (1)	23.7 (4.8)	6.0 (0.3)	0.31 (0.08)
PM	8	14 (2)	28.0 (4.0)	6.3 (0.1)	0.33 (0.06)

Unbound plasma tracer (% of total) determined by ultrafiltration was 9.9% for Pb-203, 1.1 for Cd-109, and 1.1 for Ga-67 (Ca is 50). The results demonstrate restricted uptake of the metals across the BBB due to low passive permeability of the free metal or metal complexes. In addition, the rate of entry across the choroid plexus (CSF) compared to that of the cerebral capillaries (parietal cortex) varied among the metals.

KINETIC ANALYSIS FOR L-CARNITINE TRANSPORT IN THE RABBIT CHOROID PLEXUS. C.S. Kim* (SPON: C.G. Lineberry). Lab of Cellular and Molecular Pharmacology, NIEHS/NIH, Research Triangle Park, NC 27709.

All kinetic studies were conducted with the lateral or fourth ventricular choroid plexus (LVCP; FVCP) of the rabbit. At L-carnitine concentration of 10 μM, the uptake was increased linearly for the first 10 min. Steady state levels were reached by 30 min. with tissue concentrations (T/M) ranging from 20 (FVCP) to 34 fold (LVCP) greater than medium concentrations. Initial uptake rates were determined from 5 min. uptake values at 37 °C. As the L-carnitine concentration of the medium increased from 0.01mM to 1.0mM, the T/M ratios (mean ± S.D.) fell from 3.6 ± 1.2 to 1.2 ± 0.2 (FVCP) and from 6.1 ± 0.9 to 1.5 ± 0.2 (LVCP), respectively, suggesting saturation of the carrier-mediated transport process. Kinetic analysis obtained from the saturable component of the transport process yielded apparent K_m of 37 μM (FVCP) and 35 μM (LVCP) and V_{max} of 19 (FVCP) and 23 nmol/ml/min (LVCP), respectively. Ouabain inhibited the uptake by 47% (FVCP) and 42% (LVCP) and hypothermia (0 °C) produced inhibition by 96% (FVCP) and 97% (LVCP), respectively. However, neither organic acid inhibitor, probenecid nor tyrosine inhibited L-carnitine transport by the choroid plexus.

FACILITATED TRANSFER OF L-KYNURENINE ACROSS THE BLOOD-BRAIN BARRIER. S. Fukui*, R. Schwarcz, S.I. Rapoport, and Q.R. Smith. Lab. of Neurosciences, NIA, NIH, Bethesda, MD 20892 and Maryland Psychiatric Research Center, Baltimore, MD 21228.

L-Kynurenine (KYN), a tryptophan metabolite, serves as precursor to two key neuroactive substances, quinolinic acid and kynurenic acid. Although formed primarily in the periphery, KYN can cross the blood-brain barrier and be taken up into brain after peripheral administration (Gal & Sherman, 1980). To determine the mechanism of transfer, we examined the concentration dependence and sensitivity to inhibition of KYN transport across the blood-brain barrier. Transport was measured in pentobarbital-anesthetized rats using the in situ brain perfusion technique of Takasato et al. (1984). In the absence of competing amino acids, the transfer coefficient for KYN uptake into brain at tracer concentrations equaled 3 x 10^{-3} ml/s/g, a value 30-times greater than that expected for transport by passive diffusion. KYN influx into brain was saturable with a estimated Vmax of 5.9 x 10^{-4} umol/s/g and a Km of 0.19 umol/ml. Addition of 10 umol/ml leucine to perfusate containing KYN decreased KYN influx into brain by 85%. Similarly, addition of 10 umol/ml KYN to perfusate containing leucine decreased leucine influx into brain by 96%. These results show that KYN is transported into brain by the large neutral amino acid carrier at the brain capillaries. (Supported by USPHS Grant NS16102 to RS).

SELECTIVE CONTROL OF CELL WATER DURING ACUTE HYPERNATREMIA IN RAT CEREBRAL CORTEX. C. Nicholson, H.F. Cserr, M. DePasquale*, C.S. Patlak*, and M.E. Rice. Physiology and Biophysics, NYU Medical Center, NY, NY 10016.

Total brain water is regulated during acute hypernatremia based in part on tissue uptake of Na and Cl (Cserr et al., Am. J. Physiol. 253:F522, 1987). We have studied the separate regulatory responses of extracellular water (ECW) and intracellular water (ICW) to this osmotic stress in the cerebral cortex of anesthetized Sprague-Dawley rats. Plasma [Na] was elevated by a single ip injection of NaCl (1.25 M, 2 ml/100 g), and changes in plasma and cortex were monitored for 2 hours. ECW was measured in situ using TMA^+ and ion-selective microelectrodes (Nicholson & Phillips, J. Physiol. 321:225, 1981). Total tissue water and electrolytes were determined, in a separate series of experiments, as functions of plasma [Na]. ICW could then be estimated as the difference between total water and ECW. ECW and ICW (gm water/gm dry wt brain, mean +SE, N=52) in control cortex were 0.86±0.02 and 2.93±0.02, respectively. ECW decreased by an average of 60% after 2 hours of hypernatremia, whereas ICW remained stable. Plasma [Na] increased from 141 to 172 meq/liter, tissue Na content by 25%, and Cl content by 40%. The decrease in ECW, together with simultaneous increases in tissue Na and Cl content, indicate that a shift of extracellular fluid into brain cells contributes to regulation of ICW during acute hypernatremia. Supported by NIH grants NS-11050 and NS-13742.

USE OF BUMETANIDE AND FUROSEMIDE TO TEST FOR NaK2Cl COTRANSPORT IN THE ISOLATED RAT CHOROID PLEXUS. C. Johanson, D. Bairamian, J. Parmelee, S. Sweeney and M. Epstein. Dept. of Clin. Neurosci., Prog. in Neurosurg., Brown Univer. and R.I. Hosp., Providence, RI 02902.

The regulation of pH, volume and secretion in the choroid plexus-CSF system is becoming clearer as the nature of Cl transport in choroid plexus (CP) is elucidated. Cl-HCO3 exchange in the CP is established; less clear is the possible functional role of NaK2Cl cotransport. We tested for cotransport by analyzing the kinetics of Cl-36 and Rb-86 (potassium) uptake by lateral ventricle CP incubated in artificial CSF (37 C). Choroidal tissues were excised from adult Sprague-Dawley rats (Metofane anesthesia) and preincubated for 20 min in CSF (with drug but without tracer) before transfer to tracer-containing CSF. The rapidity of Cl uptake, i.e., 1-2 min for steady state, suggest carrier-mediated uptake "uphill" into the choroid epithelium. Bumetanide and furosemide, inhibitors of NaK2Cl cotransport, reduced by 25-30% the transport of Cl-36 into the plexus incubated in CSF with drugs (10^{-6} to 10^{-4} M). Over the same concentration range, these loop diuretics decreased tracer Rb (K) accumulation by up to 25%; such findings were corroborated by choroidal tissue analysis of stable K (by flame photometry). The ability of bumetanide to suppress both Cl and K transport in the CP is evidence for cotransport, and suggests its usefulness as a probe in CNS (blood-brain barrier) and CSF transport models.

THE EFFECT OF LARGE NEUTRAL AMINO ACIDS ON THE PHARMACOKINETICS OF LEVODOPA IN CSF J.P. Hammerstad, W.R. Woodward, P. Gliessman,* T. Trotman* and J.G. Nutt. Depts. of Neurology and Biochemistry, Oregon Health Sciences Univ. and The Oregon Regional Primate Research Center, Portland, OR 97201.

The transport of levodopa from blood to brain occurs via the large neutral amino acid (LNAA) carrier system. Because the Km of LNAA transport approximates the plasma concentration of LNAA's, competitive inhibition of levodopa influx into brain may result from physiologic increases in plasma levels after ingestion of protein. This may account for the effects of meals on the response to levodopa in patients with Parkinson disease (PD) who exhibit the fluctuating motor response ("on-off"). In PD patients with "on-off" an oral load of a LNAA blocks the clinical response to a therapeutic level of levodopa maintained by a constant I.V. infusion. Using a similar approach in rhesus monkeys, we examined the effect of a leucine load given I.P. on the disposition of levodopa and other amino acids in cisternal CSF as a more direct indication of the effect of LNAA's on the influx of levodopa into brain. Leucine loading produced changes in CSF levels of LNAA and levodopa as well as other amino acids. An unexpected result was a 4-6 fold increase in CSF glutamate levels.

PARAVASCULAR FLUID MOVEMENT AFTER MICROEMBOLIC DISRUPTION OF THE BLOOD-BRAIN BARRIER. **O.R. Blaumanis* and M.L. Rennels. Departments of Neurology and Anatomy, Univ. of Md. Sch. of Med., Balto., MD 21201.**

Embolization of the rat brain with polystyrene microspheres (MS) results in focal opening of the blood-brain barrier (BBB). At these sites, leakage and spread occurs of plasma constituents and tracers such as horseradish peroxidase (HRP). To elucidate the mechanisms involved, pentobarbital anesthetized rats received unilateral intracarotid injections of 15 μm MS (5,000 - 100,000). Twenty min. to 24 hrs. later, HRP was given i.v. (60 mg/kg). After 10-20 min. HRP circulation, the rats were perfused with aldehydes and brain sections were processed for tracer localization by light and electron microscopy (EM). Sites of HRP leakage were always associated with arterioles occluded by MS (even a single MS causes local BBB disruption). Around these vessels, tracer occupied enlarged perivascular spaces (PVS) and basal laminae (BL) of arterioles, capillaries and venules. Diffuse gradients of HRP reaction product extended into the parenchyma. EM confirmed the dense accumulation of tracer in BL and PVS, with variable infiltration of the local extracellular spaces. Cellular uptake of HRP was limited to perivascular macrophages and intraperenchymal microglia. In addition, there was variable swelling of astrocytic processes. Microembolization does not lead to capillary stasis and there is no ultrastructural evidence of ischemic neuronal damage. **(NIH Grant No. NS 16332).**

A RAPID, SENSITIVE METHOD FOR QUANTITATION OF ESTRADIOL CONJUGATES IN BRAIN TISSUE AFTER ADMINISTRATION OF A BRAIN-ENHANCED DELIVERY SYSTEM FOR ESTRADIOL. M. Rahimy* and J.W. Simpkins. University of Florida, Gainesville, FL 32610.

Brain-enhanced delivery of Estradiol (E_2) with an E_2 chemical delivery system [i.e. estradiol 17-(1,4-dihydrotrigonellinate)] creates a problem for separating and quantitating brain levels of the active E_2 in the presence of excess concentrations of the inactive conjugated forms of the drug. We have developed a 4-step method that permits the rapid quantitative analysis of E_2 and its conjugates. The first step uses a water:acetone (50:50, v:v) solvent system to extract the conjugate from biological tissues (e.g. rat brain); second, the conjugates are hydrolyzed in 1N NaOH; third, solid phase extraction (SPE) with C_{18} reverse phase column is used to isolate E_2; and the final step is the RIA of E_2. The application of this procedure to biological tissues was assessed using rat brain homogenates. Recovery of the E_2, after solvent extraction and SPE chromatography, is 101 ± 4.5% while recovery of the E_2 conjugate is 64 ± 2% with greater than 80% hydrolysis of the conjugate. Since the solvent extraction, hydrolysis, and SPE steps can be completed for 100 samples in one day, this procedure represents a rapid, reliable and practicable method for the quantitation of E_2 and its conjugates in tissue samples (Supported by NIH HD 22540).

413.13

CEREBROVASCULAR PERMEABILITY IN EXPERIMENTAL HYPERTENSION. P.A. Grady. Univ of Maryland Sch of Med.,Balt, MD 21201.

Cerebrovascular permeability remains unaltered in most physiological states due to an intact blood brain barrier. This barrier has been shown to be breached under conditions of acute hypertension, but what occurs in chronic hypertension is less clear. This study tests the effect of chronic hypertension on cerebrovascular permeability.

Goldblatt hypertensive rats were monitored for 3 months. Blood pressures ranged from 135-165 mm Hg systolic arterial pressure. After 3 months, these rats and controls were anesthetized with chloral hydrate 100 mg/kg ip.Horseradish peroxidase(HRP) Sigma Type II or VI was injected iv and allowed to circulate for periods of 5, 10, or 20 minutes. Animals were perfused with fixative. Brain sections were incubated with diaminobenzidine and tetramethylbenzidine and examined at the light microscopic level.

Patchy areas of reaction product were scattered diffusely across gray and white matter areas. TMB incubated sections showed increased staining over the rostral portions of the cerebral hemispheres, basal forebrain and pontine areas of brainstem predominently.

The results of this study suggest that there is an increased cerebrovascular permeability under conditions of chronic hypertension which allows for the passage of macromolecules into brain parenchyma. These findings provide a basis for longterm changes in the brain in chronic hypertension.(Supported in part by PHS NS 16332)

413.14

DUAL ROLE OF ENDOTHELIAL CELL TUBULES IN BLOOD-BRAIN BARRIER INJURY. A. S. Lossinsky and M. J. Song*. NYS Inst. for Bas. Res. in Devel. Disabil., S.I., NY 10314 and NIH Res. Cent. for HVEM, NYS Dept. of Health, Albany, NY 12201

The present studies extend our exploration of the ultrastructural features of tubular profiles manifested in endothelial cells (ECs) following blood-brain barrier (BBB) insult. We have reassessed several of our previous experimental paradigms in an attempt to understand the functional role of these tubular profiles. Previous studies have indicated that the tubules represent either: (1) lysosomal-directed structures for the metabolic requirements of the cell, or (2) serve as purported conduits for trans-EC macromolecular transport. In several experimental murine models in which the BBB was compromised, employing conventional transmission or high voltage electron microscopy, we observed horseradish peroxidase-positive, conduit-like structures, directly connecting luminal and ablumenal surfaces in the thinnest portions of the EC. In wider EC regions, tubules were observed in the proximity of, or bound to secondary lysosomes or multivesicular bodies. Inflammatory cells (ICs) by scanning microscopy were often observed attached to parajunctional EC regions. Our results suggest a dual functional role of these tubules for macromolecular transfer and transport and also implicate a possible mechanism for IC attachment and eventual migration across the injured BBB. Supported by NYS OMRDD and NIH Grant # RR01219.

413.15

REGULATION OF CEREBROVASCULAR GUANYLATE CYCLASE BY NEUROHUMORAL AGENTS. P.Grammas*, F. Giacomelli*, C. Diglio* and J. Wiener* (SPON: H. Goldman).Dept. of Pathol. Wayne State Univ., Detroit, MI 48201.

Regulation of cerebromicrovascular endothelial cell function is critical to the maintenance of the blood-brain barrier (BBB). There is evidence from peripheral tissues that atrial natriuretic factor (ANF) modulates fluid volume and that this is mediated by guanylate cyclase activity. Norepinephrine and AII have been shown to affect BBB permeability under physiologic and pathologic conditions. In the present study, control of guanylate cyclase activity in cerebral microvessels (capillaries) by ANF, angiotensin II (AII) and the β- adrenergic agonist phenylephrine (PE) was evaluated. Guanylate cyclase activity was measured in isolated rat cerebral capillaries by radioimmunoassay for cGMP. Untreated microvessels yielded 0.058 ± 0.018 pmol cGMP/mg protein. ANF (0.95μM) increased cGMP about 10 fold to 0.59 ± 0.16 pmol/mg protein. Interestingly, while incubation of microvessels with AII (1μM) or phenylephrine (1μM) did not significantly change the level of cGMP (0.06 and 0.075, respectively), both AII and PE greatly potentiated the stimulation of guanylate cyclase by ANF (1.17 ± 0.4 and 1.09 ± 0.3 pmol cGMP/mg protein,) respectively. These data suggest that interaction of neurohumoral receptors in cerebral endothelium may control cyclic nucleotide formation and that this interaction might regulate cerebrovascular permeability to ions and water.

CYCLO-PHOSPHAMIDE SHORTENS THE LATENCY FOR RADIATION INDUCED BBB BREAKDOWN M. P. Remler and W. Marcussen* (SPON: A. Gabor) Dept. of Neurology, VAMC, Univ. of California, Davis, Martinez, CA, 94553

Ionizing radiation is known to lower the blood brain barrier (BBB) after a dose dependent latency. Just prior to irradiation, the rats were treated with the radiation sensitizers Chlorpromazine 37.5 mg/kg, Cisplatin 5 mg/kg, Cyclophosphamide 100 mg/kg, Acyclovir 100 mg/kg, Bleomycin 3 mg/kg, Doxorubicin 10 mg/kg, Actinomycin 0.75 mg/kg, and Dactinomycin 0.12 mg/kg. Rats were irradiated with 20 Gy of alpha particles in a single dose focused to a volume of 0.5 cc in the center of the left hemisphere. Breakdown of the BBB was detected in the irradiated portion of the brain by the presence of staining following Evans Blue dye injection. All except cyclophosphamide showed no reduction of the latency of 220 days expected for BBB breakdown following 20 Gy. Of four rats test with cyclophosphamide, one showed no BBB breakdown at 106 days while three showed breakdown at 134, 148 and 169 days. The left hemispheres with lowered BBBs were histologically normal as were the unirradiated control right hemispheres.

This research was supported by the Veterans Administration and the USPHS NIH Grant No. NS 17777.

413.17

BLOOD-BRAIN BARRIER (BBB) CHANGES IN RATS AFTER INTRACEREBRAL INJECTION OF HUMAN RECOMBINANT INTERLEUKIN-2 (rIL-2). RG Watts*, JL Wright*, LL Atkinson* and RE Merchant* (SPON: JW Bigbee). Med Coll of VA, Richmond, VA 23298.

Clinical trials utilizing intracerebral (IC) injection of rIL-2 and lymphokine-activated killer cells to treat brain tumor have reported temporary exacerbation of neurological deficit and lethargy in most patients. The current study examined the histopathological effects of a single 5ul injection of rIL-2 (12,000 U, CETUS), its excipient or saline into the right parietal lobe of rats. Animals were sacrificed at various times up to 8 days by transcardiac aldehyde perfusion (1h following IV injection of horseradish peroxidase (HRP)) and brains were processed for light and electron microscopy. Histochemical findings at 4h, 12h and 24h post-injection showed traumatic BBB disruption with no differences between injections of rIL-2, excipient or saline. HRP extravasation persisted at 3 and 8 days only in animals injected with rIL-2. In addition, only rats receiving rIL-2 demonstrated increased cellularity at the injection site with leukocytic infiltration, perivascular cuffing and localized edema which was evident at 24h and continued to increase over an 8 day period. Our results suggest that an IC injection of rIL-2 alters the integrity of the BBB directly and/or potentiates and sustains cellular events responsible for barrier disruption following traumatic injury to the brain.

413.18

HOST BLOOD-BRAIN BARRIER PERMEABILITY IS UNALTERED BY INTRAPARENCHYMAL FETAL NEURAL GRAFTS. M.S. Grady, M.J. Geist*, D.O. Maris*. Dept. of Neurol. Surgery, U. of Washington, Seattle WA 98104.

The permeability of the blood-brain barrier (BBB) may be important in the immunologic response of the host CNS to grafted tissue. There is evidence (Rosenstein, *Science* 235:772-774, 1987) that vasculature established in block grafts of fetal neural tissue no longer maintains characteristics of normal BBB despite the fact that the barrier is mature (in terms of its permeability to certain molecules) even in the embryo. However, fetal neural cell suspensions injected into host brain parenchyma may not cause this disruption of the BBB, as vascular growth may originate from the host rather than the donor.

Anesthetized adult male Sprague-Dawley (S-D) rats received grafts of E15 S-D forebrain. The donor tissue was dispersed into a cell suspension using trypsin (Schmidt et al., *Brain Res* 218:347-356, 1981) then injected stereotactically into the rostral corpus callosum. The opposite side received a vehicle injection. Survival periods of 14 days (n = 3), 30 days (n = 2), 90 days (n = 4), and 180 days (n = 4) were studied. One hour before the animals were sacrificed, 5 mg/kg of HRP type VI (Sigma) was injected i.v., after 1 mg/kg Benadryl (diphenhydramine) was given i.v. to prevent anaphylaxis. The anesthetized animals were transcardially perfused with 1% paraformaldehyde, 1.25% glutaraldehyde, and 50 micron coronal sections taken on a vibratome. Thionin stain acetylcholinesterase (AChE) histochemistry and HRP histochemistry (Mesulam method) were performed.

HRP is normally excluded from brain parenchyma where the BBB is intact. The BBB was impermeable to HRP at the control site at all time points. No graft showed HRP leakage into the parenchyma except one 14 day graft that was contaminated by non-neural tissue. All grafts formed a solid cluster of cells and demonstrated AChE positive cells and neurons as suggested by Nissl substance. Vascular distribution in the grafts was extensive, with no apparent difference between host or graft vessels.

Vasculature established in neural cell suspension grafts maintains certain BBB qualities such as impermeability to medium molecular weight proteins such as HRP.

ANIONIC PROPERTIES OF ENDOTHELIAL CELLS AFTER MODERATE CONTUSIVE INJURY TO THE RAT SPINAL CORD. L.J. Noble (SPON: M.K. Floeter). Dept. of Neurology, School of Med., UCSF, San Francisco, CA 94122.

After spinal cord injury, abnormal barrier permeability to the tracer horseradish peroxidase (HRP) and the distribution of cationized ferritin (CF), a marker of anionic sites, were examined in the spinal cord at the ultrastructural level. In control (laminectomized) animals, vessels remained impermeable to HRP. Although the luminal surface of microvessels was evenly labelled with CF, vesicle formation along the luminal front was associated with partial thinning and/or loss of anionic sites. In initial stages of vesicle formation (prior to stalk formation) anionic sites appeared reduced along the invaginated membrane. With formation of a stalk, negative sites were present along the neck of the stalk with fewer CF molecules in the vesicle proper. CF was absent in vesicles which no longer maintained continuity with the plasma front or which contacted the abluminal front.

After injury, the distribution of anionic sites, relative to luminal vesicle formation, was similar to that observed in laminectomized animals. However, there was reduced CF binding along the luminal plasmalemma. This loss of surface charge properties was typically associated with edematous tissue as indicated by enlarged perivascular spaces, swollen astrocytic foot processes and abnormal vascular permeability to HRP.

NERVE SEGMENTS FORMED IN SILICONE TUBES RECONSTITUTE A PERINEURIAL BUT NOT A VASCULAR ENDONEURIAL PERMEABILITY BARRIER. N. A. Azzam, A. A. Zalewski and L. R. Williams. Lab. of Neuronal Growth and Regeneration, NINCDS, NIH, Bethesda, MD 20892 and CNS Diseases Research (L.R.W.), The Upjohn Co., Kalamazoo, MI 49001

Peripheral nerves fibers of adult mammals can regenerate through silicone tubes wherein they reform a new nerve segment. In the present study we examined these segments to determine whether endothelial and perineurial sheath cell permeability barriers were also reconstituted. Normally these barriers, via tight intercellular junctions, regulate the movement of macromolecules into the endoneurium from inside and around a nerve. Adult rats had their sciatic nerve cut bilaterally, and the proximal and the distal ends sutured into 10 mm long tubes that were filled with saline. One tube was removed after one month, a time when a cable of tissue extended through the entire tube. The permeability of the blood and perineurial barriers was examined, 4-9 months postoperatively, with the tracer horseradish peroxidase (HRP; M.W. 40,000). The reformed nerve segments, enclosed in or free of the tubes, contained remyelinated axons, blood vessels and perineurial-like cells. However, in contrast to normal or distal regenerated nerve, axons were mini-compartmentalized by perineurial-like cells. All the regenerated blood vessels were excluded from the endoneurium of the mini-compartments, and they were profusely permeable to HRP. The extruded HRP did not penetrate the regenerated perineurial sheaths and enter the environment of the nerve fibers. Our results indicated that a reformed nerve segment contains a perineurial but not an endoneurial vascular permeability barrier. How and why vessels were excluded from the endoneurium and why previously tight endoneurial vessels became permeable requires investigation.

414.1

ROLE OF CALCIUM DEPENDENT INFLUX IN NEURONAL DIFFERENTIATION: A PERIOD OF SPONTANEOUSLY ELEVATED INTERNAL CALCIUM IS CORRELATED WITH A PERIOD OF SENSITIVITY TO EXTERNAL CALCIUM. Janet Holliday and N.C. Spitzer. Dept. of Biology, University of California, San Diego, La Jolla, CA.

Calcium dependent action potentials (APs) can be evoked from Xenopus spinal neurons cultured from neural plate stage embryos from the time they can first be recognized in culture. As the neurons mature during the first day, the ionic dependence of this AP shifts from calcium to sodium (Spitzer and Lamborghini, 1976). Growth of cells under conditions which would prevent calcium entry produces alterations in normal patterns of differentiation (Bixby and Spitzer, 1984; Henderson, Smith and Spitzer, 1984). These studies suggest that calcium influx may have a significant role in development.

The role of spontaneous calcium influx was investigated by monitoring changes in the levels of intracellular calcium during the first day in culture using the fluorescent calcium indicator, fura-2. Spontaneous elevations in internal calcium concentration are evident in the largest percentage of cells during the 6th to12th hours in culture. This is the period during which calcium dependent APs can be evoked. This is also the period which exhibits the highest sensitivity to the removal of external calcium. When normal culture medium is exchanged for calcium free medium during this period, both neurite length and neuron-myocyte contact levels are altered in the same manner as in cultures which have developed in the absence of calcium for the entire growth period of 24 hours. Spontaneous elevations of calcium are not observed in cells bathed in hyperpolarizing medium containing calcium channel blockers or in the absence of external calcium. Thus the elevation of internal calcium is likely to be due to calcium influx. Many of the cells which score as spontaneously active proceed to develop into well differentiated neurons. JH is a fellow of the USPHS; supported by NS15918 to NCS.

IN VIVO ELECTRICAL DIFFERENTIATION OF EMBRYONIC CHICK MOTONEURONS. D.P. McCobb and K.G. Beam. Physiology Dept., Colorado State Univ., Fort Collins, CO. 80523.

We have used the patch clamp to study the development of intrinsic electrical properties of limb motoneurons isolated from embryonic chicks ranging in age from 4 days (E4, HH stage 20-21) to 11 days (E11, HH stage 37). During this important period hindlegs form from rudimentary limb primordia and 50% of the motoneuronal pool undergoes cell death. Motoneurons were identified by retrograde labelling with the carbocyanine dye DiI. Action potentials and voltage dependent currents were measured 1d after dissociation using "whole-cell" current- and voltage-clamp recordings. We report that the majority of chick limb motoneurons are able to fire overshooting action potentials by E5, and virtually all are by E11. The early develoment of excitability can be attributed at least in part to the early rise in Na+ channel expression; Ina+ increases dramatically between E4 and E6, and only moderately between E6 and E11. Ca++ channel expression is maturing over this span as well. Beginning at E4 T, N, and L -type Ca++ currents are distinguishable. By E11 N and L current expression has dramatically increased, while T current has dramatically decreased, suggesting that N and L currents will be expressed in the mature motoneuron, whereas T current expression may be restricted to early stages in differentiation. We are exploring the hypothesis that electrical differentiation of motoneurons plays a deciding role in the onset of motoneuronal cell death.

Embryonic Age	4 days	5 days	6 days	11 days
% Excitable cells	-	66.7 %	76.9 %	100 %
Mean I_{Na}+ (pA/pF)	57.8	63.3	93.1	108.0
Mean I_{Ca}++ (pA/pF)				
T -type	3.64	-	0.955	0.483
N -type	2.83	-	3.73	5.72
L -type	1.72	-	4.87	6.67

ONTOGENESIS OF CALCIUM CHANNELS IN A RODENT BRAIN UTILIZING THE XENOPUS OOCYTE ASSAY. *R.W. Cohen and C.D. Hull. Mental Retardation Research Center, University of California, 760 Westwood Plaza, Los Angeles, CA 90024.*

One method for assessing ontogeny of voltage-dependent calcium channels is by extracting mRNA from brains of different postnatal ages and injecting mRNA into oocytes of Xenopus laevis. Several investigators have shown that exogenous mRNA from rat brains leads to expression of additional Ca^{2+} channels in the oocyte, which activate calcium-dependent Cl^- channels (Leonard, et al., 1987; Umbach & Gundersen, 1987). Using voltage clamp techniques, a current record for the Ca^{2+} channel was established by clamping the oocyte at -80 mV and stepping from -40 mV to +40 mV in the presence and absence of cadmium. After subtraction of Ca^{2+} and Cd^{2+} currents, oocytes containing brain mRNA of 15-24 day old mice have current levels similar to adult rat levels of 75 nA (Umbach and Gundersen, 1987). Similarly measured currents of oocytes injected either with 1-5 day old mouse brain mRNA or water (controls) have much lower values. By applying serotonin to the oocyte bath, a transient outward current was seen only in mRNA-injected oocytes regardless of mouse age. This current has been shown (Dascal, et al., 1986) to involve Cl^- channels (probably by releasing internal Ca^{2+} stores), suggesting that Cl^- channels are present at very early ages. These observations agree with recent studies on development of Ca^{2+} channels using different assays (cf. Kazazoglou, et al., 1983).

PATTERNS OF TRANSIENTLY EXPRESSED ACETYLCHOLINESTERASE ACTIVITY IN DORSAL THALAMUS OF DEVELOPING RODENTS: SPECIES COMPARISONS. H. Poon*, R.T. Robertson and J. Yu (SPON: E. Davis). Depts.of Anatomy and Neurobiology and Physical Medicine and Rehabilitation, University of California, Irvine, CA 92717.

Previous research has demonstrated patterns of transiently expressed acetylcholinesterase (AChE) histochemical staining in the dorsal thalamus and cerebral cortex of developing rat pups. This transient AChE activity appears to be found within thalamocortical neurons of the ventral basal, dorsal lateral geniculate, and ventral medial geniculate nuclei. The temporal domain of transient AChE expression corresponds well to the time of development of thalamocortical connections, suggesting that transient AChE may play a role in thalamocortical development (Robertson, Neurosci. Lett., 75:259, 1987). The present studies were undertaken to determine whether transient expression of AChE in the thalamus is a common characteristic of developing rodents.

Experiments were performed on rats, mice, gerbils, hamsters and guinea pigs. Adult animals and infants 0-25 postnatal days of age were used. Animals were perfused with aldehydes and frozen sections were processed for AChE histochemistry.

Developing animals of all species tested showed intense and transient AChE histochemical activity of the ventral basal complex. The adult ventral basal complex of all species displayed minimal AChE activity. Infants of all species showed greater AChE activity in the ventral medial geniculate nucleus than did adults, although only the infant rat displayed very intense AChE activity. The dorsal lateral geniculate nucleus of adults of all species displays moderate AChE activity. Infant mouse and hamster show slightly more intense staining, while the infant rat shows the most intense transient AChE staining in the lateral geniculate.

These data demonstrate that transient expression of AChE activity is a phenomenon common to a variety of rodents, although aspects of the transient staining appear to vary between species.

INSULIN, INSULINLIKE GROWTH FACTOR-I, AND NERVE GROWTH FACTOR STIMULATE NEURITE FORMATION IN RAT SPINAL CORD CULTURES. G.W. Glazner* and D.N. Ishii Physiology Dept., Colorado State Univ., Ft. Collins, CO 80523.

We have previously shown that insulin and insulinlike growth factors (IGFs) (Recio-Pinto et al. J. Neurosci. 6: 1211, 1986) share with nerve growth factor (NGF) the capacity to support neuron survival and stimulate neurite growth in cultured sympathetic and sensory cells. Here we investigated whether these neurotrophic responses could be elicited in spinal cord cultures as well. Embryonic 17-day-old rat spinal cords were dissociated by gentle trypsin treatment followed by passage through several sieves. The single cell cultures were plated on polylysine coated dishes in 1:1 Ham's F-12/DMEM mix containing 4% serum. About 25-30% of the plated neurons were responsive to insulin. The neurite formation response had an ED50 of about 2 nM for insulin and 1 pM for NGF. The number of neurons with neurites and the average length of neurites were increased. High doses of insulin (1 uM) combined with NGF (0.4 nM) did not significantly increase neurite outgrowth at 3 days over insulin (1 uM) alone. IGF-I (1 nM) also enhanced neurite growth. These data indicate that insulin, IGFs, and NGF may be important physiological regulators of neurite formation and play a role in the development of the spinal cord. (Supported in part by NIH grant RO1 NS24327).

GAP JUNCTIONS DURING NEOCORTICAL DEVELOPMENT: NORTHERN BLOTTING AND IMMUNOCYTOCHEMISTRY. C.C.G. Naus, D. Feinstein and G.M. Kidder*. Departments of Anatomy and Zoology, University of Western Ontario, London, Canada; Research Institute of Scripps Clinic, La Jolla, CA.

The developmental appearance of gap junctions was examined during postnatal development of the rat neocortex. A cDNA specific for the gap junction mRNA (connexin32) was used to probe Northern blots of total RNA isolated from the neocortex of rats at postnatal day 4, 7, 11, 15, 19 and 25. From postnatal day 4 to 15, very high levels of gap junction mRNA are detectable. By postnatal day 19, a sharp decline occurs in the level of this mRNA. In order to examine the distribution of gap junctions at the cellular level, sections of neocortex at these same developmental times were immunocytochemically stained with a polyclonal antibody to connexin32. Immunoreactivity for gap junctions is more abundant in the upper layers of the developing neocortex, particularly in the marginal zone and cortical plate. The cellular distribution of the mRNA for connexin32 is being examined using in situ hybridization. In addition, Northern blot analysis of mRNA isolated from neuronal and glial cultures should reveal the cellular origin of this mRNA. These results indicate that gap junctions are regulated during neocortical development. (Supported by MRC and NSERC).

CLONING OF C. ELEGANS AND DROSOPHILA cDNA CLONES THAT HAVE HOMOLOGY TO MAMMALIAN GAP-43. S.C. Ng, L.A. Perkins, G.L. Conboy*, N. Perrimon* and M.C. Fishman. Departments of Medicine, Neurology, and Genetics, Harvard Medical School, Mass. General Hosp., and Howard Hughes Medical Institute

GAP-43 is believed to be involved in neuronal remodeling of development and regeneration. Since the human and rat cDNA sequences are nearly identical (Ng et al., Neuron 1, 1988), and there is hybridization with DNA from other species (Nedivi and Skene, Soc. Neuro. Abstr., 1987), there may be evolutionary conservation of part of the protein. In order to pursue genetic analysis of GAP-43 function, as well as to identify domains conserved through evolution, we have isolated Drosophila and C. elegans GAP-43-homologous cDNA and genomic clones by using reduced stringency hybridization with the rat GAP-43 cDNA as a probe. The nucleotide sequence of one region is especially well conserved between rat, Drosophila, and C. elegans. In Drosophila there is one prominent transcript that is developmentally regulated. By in situ hybridization to the developing fly embryo we have found diffuse expression in the cellular blastoderm, subsequent expression within specific cellular compartments, and, ultimately, at the end of embryogenesis, expression restricted to the ventral nervous system and its overlying glia. We have identified the chromosomal localization of both the Drosophila and nematode GAP-43-homologous genes in order to facilitate mutational analysis.

414.8

DEVELOPMENT OF NEUROFILAMENT IMMUNOREACTIVITY IN THE PARIETAL CORTEX OF THE MOUSE. M.E.Lickey, A.J.Sprute*, A.E. Flavell*, J.I.Espinoza*, S.C.Johnson* & R.A.BreMiller*, Inst. of Neurosci., Univ. of Ore., Eugene, OR 97403.

It has been suggested that neurofilaments (NF) contribute to the stabilization of neuron shape (Willard et al., 84; Lasek et al., 83) and that this stabilizing influence may not be fully in force until late in development after the final pattern of synaptic connections has been established (Carden et al.,87; Shaw & Weber, 82). Using immunohistochemistry, we have studied the morphological disposition of NF protein in mouse parietal cortex as the brain matures. We have used 3 monoclonal antibodies (mab) from Sternberger-Meyer, Inc. These mabs bind to the H protein or the M and H proteins of the NF triplet, and they discriminate between 2 distinct phosphorylation states of the H protein. We also used a mab against glial fibrillary acidic protein. In the adult, NF immunoreactivity occurs in white matter and in distinct layers of the cortex. In the cingulate cortex 8 layers can be counted. The layered pattern is different for antibodies that bind to different phosphorylation states. Different mabs are distinct in their affinity for the somata of pyramidal cells. Before p3 the parietal cortex shows little immunoreactivity with these mabs. The layering is not mature until well-after p14. As early as p7 bushy clusters of fibers can be seen that are probably located in the hollows of whisker barrels. (Support from the Med. Res. Found. of Ore.)

IMMMUNOCYTOCHEMICAL IDENTIFICATION OF INTERMEDIATE FILAMENT PROTEINS IN THE DEVELOPING FROG NERVOUS SYSTEM. B. G. Szaro and H. Gainer. Lab. Neurochem., NINCDS, NIH, Bethesda, MD 20892.

Intermediate filament (IF) proteins from the adult Xenopus laevis nervous system were characterized immunocytochemically and on Western blots with antibodies to mammalian IF proteins. Three of these proteins were identified as cytokeratin-like (49, 55, 58 kD), one as vimentin-like (53 kD), two as GFAP-like (60 and 67 kD), and three as neurofilament-like (NF; 73, 175 and 200 kD). These antibodies were then used to observe the expression of IF proteins in the developing Xenopus nervous system from stages 12 to 42. As early as stage 19, cytokeratin-like immunoreactivity was present in the neural tube and was restricted to its inner lining throughout early neural development. Vimentin-like immunoreactivity in radially oriented neuroepithelial cell processes appeared by stage 22 in the spinal cord and rhombencephalon, stage 29/30 in the retina, and stage 33/34 in the prosencephalon. 175 kD NF protein immunoreactivity was detected shortly after the onset of neurite outgrowth in the anterior spinal cord and rhombencephalon between stages 22 and 24, and in the retina by stage 29/30, and appeared earlier than either 73 or 200 kD NF immunoreactivity. In addition, GFAP-like immunoreactivity was found in radial cells in the neural tube by stage 24, implying that the onset of glial cell differentiation occurs relatively early in Xenopus.

THE ADULT OLFACTORY SYSTEM EXPRESSES JUVENILE FORMS OF MICROTUBULE-ASSOCIATED PROTEINS. C. Viereck*, R.P. Tucker*, and A. Matus. Friedrch Miescher Inst, Box 2543, 4002 Basel, Switzerland.

Using monoclonal tau, MAP2 and MAP5 antibodies and immunoblotting, we demonstrate that the adult olfactory bulb, unlike the adult cerebellum and cerebral cortex, expresses the juvenile forms of these cytoskeletal components. Furthermore, we show that, in the juvenile brain and adult olfactory bulb, MAP5 resolves into two distinct bands which we refer to as MAP5a and MAP5b and that MAP5a is a highly phosphorylated form of MAP5. In the adult cerebellum and cerebral cortex, both the level and abundance of MAP5a relative to MAP5b are lower than in the juvenile brain and adult olfactory bulb. Immunohistochemistry shows that anti-tau stains only a subset of the axonal bundles in the olfactory nerve as well as dendrite-like processes in the sensory epithelium. Anti-MAP2 stains dendrites in the olfactory bulb, and anti-MAP5 staining is most intense in the olfactory nerve. The continued expression of juvenile tau, MAP2 and MAP5 forms in the adult CNS, where neurite outgrowth is still taking place, suggests a role for these proteins in the regulation of neurite outgrowth.

AUTORADIOGRAPHIC ANALYSIS OF CHICK RETINAL DEVELOPMENT IN CULTURE VERSUS IN OVO. S.G. Spence* and J.A. Robson. Department of Anatomy and Cell Biology. S.U.N.Y. Health Science Center, Syracuse, NY 13210.

We have compared patterns of ^{3}H-thymidine incorporation during neurogenesis in vitro and in ovo. In ovo injections were made in embryonic day 6-10 chicks (E6-E10). At E12 the embryos were fixed and the posterior retina from each eye was embedded in epon, sectioned and processed for autoradiography. In parallel experiments, pieces of posterior retina from E6 embryos were cultured in the presence of ^{3}H-thymidine. Label was added to the medium for 24 hours on day 1 in culture (E6+0) or for 3 hours on day 2, 3 or 4 in culture (E6+1, +2 or +3). Retinas were fixed at E6+4 and processed for autoradiography as above. Results show that the patterns of ^{3}H-thymidine incorporation in culture are nearly identical to those in ovo. Ganglion cells and photoreceptors are labeled in E6+0 explants and E6 embryos while cells in the inner nuclear layer (INL) are labeled in older specimens. In E6+3 cultures most labeled cells are restricted to the outer half of the INL. The most obvious difference between retinas is a reduction in the number of ganglion cells in the explants. However, our results differ from those of Kahn (Dev. Bio. 38: 30, 1974) who reported that most ganglion cells undergo their final divisions between E3 and E5. Our results indicate that this occurs between E6 and E7. (Supported by NIH Grant EY-03940 and NATO Collaborative Research Grant 0235/87).

RETINAL DIFFERENTIATION IN THE SEA LAMPREY, PETROMYZON MARINUS, WITH A TIME-SCALE IN YEARS. K. Rubinson and H. Cain.* Dept. Physiol. and Biophysics, NYU Med. Ctr., New York, NY 10016.

The retina of the larval lamprey consists of a mature central retina and a relatively undifferentiated peripheral zone . The histological and functional differentiation of the peripheral zone is completed during metamorphosis (Rubinson, et al., '77; Rubinson and Cain, '83). Relating the premetamorphic steps in retinal differentiation to the size of the animal and, thereby to its age, indicates that differentiation of the lamprey retina spans at least five years and may not be a continuous process.

Specimens with a histologically undifferentiated peripheral retina ranged in length up to 77mm (n=5, mean=64.2). Specimens in which neuroblastic and ganglion cells are the only distinguishable peripheral elements ranged from 68 to 90mm in length (n=4, mean=77.3). The differentiation of other cells was seen in lamprey of 102 to 134mm (n=6, mean=114). Photoreceptor inner and outer segments were only seen in animals entering metamorphosis.

Thus, ganglion cells begin to appear when the lamprey are 1 to 2 years old and differentiation of the remaining neuroblasts requires a minimum of 2 additional years. Beyond 4 years of age, the mean length of unmetamorphosed lamprey does not change. As the age at metamorphosis ranges from 5 to as much as 15 years, it seems that the completion of the retina can be deferred for a number of years.

GROWTH OF THE VOMERONASAL ORGAN IN GARTER SNAKES. D. A. Holtzman* (SPON: M. Halpern). Program in Neural and Behavioral Sci., SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203.

Changes in cellular composition and in volume of the vomeronasal organs (VNO) of embryonic and neonatal garter snakes were examined. Microprojection drawings of 10 micron serial sections were used to calculate the volumes of the supporting cell (SC) and bipolar cell (BP) layers in VNO's. The SC layer decreases to a quarter of its volume from mid-gestation to the period just before birth. During the same period of time, the BP layer increases to 4 times its volume. At birth, the volume of the SC layer has not changed, but the volume of the BP layer has increased by 2.5 times. Experiments using tritiated thymidine autoradiography suggest a differential generation of cells in the SC and BP layers of the VNO.

414.14

DOES THE MOUSE BRAIN HAVE ITS OWN MACROPHAGES? Hao, C.,* Richardson, A.,* and Fedoroff, S. Department of Anatomy, University of Saskatchewan, Saskatoon, SK. Canada.

When astroglia cultures are subjected to unfavorable growth conditions, large numbers of macrophages appear. These cells are ameboid, highly phagocytic, and excrete lysozyme. In established astroglia cultures initiated from mouse embryos at Theiler stages T14(E9), T18(E11), T21(E13), T23(E15), T25(E17) and from newborn animals, when grown for an additional 10 days without medium change, macrophages were present and the medium contained lysozyme. In contrast, cultures that were fed had no, or only a few macrophages and the medium contained no, or very low concentrations of lysozyme.

Macrophages in neglected astroglia cultures were compared with macrophages from adult mouse spleen and peritoneal cavity on the basis of their growth characteristics, response to trophic factors, presence of α-naphthyl butyrate esterase, peroxidase, Mac-1, Mac-3, M1/70, Ia, DiI-ac-LDL, GFAP and vimentin. We conclude that macrophages in the neglected astroglia cultures share many macrophage-specific characteristics with spleen and peritoneal cavity macrophages, but that some notable differences exist, indicating the presence of a specific type of macrophage in mouse brain. Precursors of these macrophages are present in very early embryonic stages of brain development. This work was supported by MRC of Canada Grant MT4325.

SYMPOSIUM: DEVELOPMENT OF FUNCTIONAL HETEROGENEITY AMONG SENSORY NEURONS. S.A. Scott, SUNY Stony Brook (Chairperson), L.M. Mendell, SUNY Stony Brook, A.W. Mudge*, Univ. Coll. London, A.M. Davies, St. George's Hosp. Med. Sch., J. Dodd, Columbia Univ. CPS, E. Frank, Univ. Pittsburgh Med. Sch.

Dorsal root ganglia (DRG) contain a diversity of sensory neurons. This symposium will consider some of the characteristics that distinguish subsets of sensory neurons, and how these differences arise during embryonic development. Dr. Scott will introduce the symposium by providing a brief overview of sensory neuron heterogeneity. Dr. Mendell will present recent findings on the physiological and anatomical specialization of individual sensory neurons as correlated with peripheral receptor type. Dr. Mudge will describe the early commitment of a subpopulation of DRG neurons to the Substance P phenotype, and the role of Schwann cells in determining DRG neuron morphology. Dr. Davies will consider the specificity and cooperation of different neurotrophic factors in regulating the survival of developing sensory neurons. Dr. Dodd will describe the surface properties of functionally distinct spinal sensory neurons, and will discuss axon guidance in spinal sensory neuron development. Dr. Frank will describe the phenotypic specification of sensory neurons as revealed by their spinal projections.

417

CODING AND EXECUTION OF MOVEMENT IN THREE DIMENSIONS. B.Cohen, V.Henn, T.Raphan, A.Georgopoulos, J.Soechting, J.Hollerbach.

Previous studies of coding in motor systems have often, by necessity, been limited to analysis of movement in one or two dimensions. Nevertheless, we live in a three dimensional world embedded in a gravitational environment, and the brain has evolved to code and produce motion in this environment. The goal of this symposium is to give insight into how movement in three dimensions is coded and executed by the oculomotor and skeletal motor systems. VOLKER HENN will consider whether the mechanism that produces saccadic eye movements is organized around motion in planes of space parallel to the planes of the semicircular canals or the eye muscles. THEODORE RAPHAN will present data and a model relating the mathematical structure of the dynamical system representing the slow component of the VOR to the spatial coordinate basis determined by gravity. APOSTOLOS GEORGOPOULOS will give evidence that coding of limb movement in neurons in the motor cortex is, on average, three dimensional. JOHN SOECHTING will consider representation of sensory-motor maps, obtained from psychophysical data from humans. JOHN HOLLERBACH will consider the interface between motor performance and robotics as revealed through study of kinematic calibration. The symposium will show the importance of mathematical modelling and experimental verification in generating a unified approach to understanding and predicting the behavior of sensory motor systems in three dimensions. The experimental and modelling approaches should be of interest to physiologists working on the oculomotor and skeletal motor systems as well as to those interested in designing robots that move and perform visual-motor tasks.

HUMAN BEHAVIORAL NEUROBIOLOGY IV

418.1

DEVELOPMENT IN HUMAN INFANTS OF VISUAL RECOGNITION MEMORY. W. Overman, J. Bachevalier , P. Roland*, M. Turner*, Dept. Psychol., U.N.C.-Wilmington, Wilmington, N.C. 28401 and Lab. Neuropsychol., NIMH, Bethesda, MD 20892

Two trial-unique visual recognition memory tasks, delayed non-match or match-to-sample (DNMS or DMS), were used to assess visual recognition memory in human infants and adults. Nine females aged 12-32 months, 6 males aged 14-26 months, and 12 adults (6 females and 6 males, 19-55 years of age) were trained without verbal instructions on either DNMS or DMS tasks in a WGTA. Subjects were tested daily to a criterion of 13/15 correct responses for two consecutive days. Their recognition memory was further challenged by increasing progressively the delay intervals and the lists of objects to be remembered. For DNMS there were significant inverse correlations between age and trials to criterion in both infant females ($r=-.94$) and infant males ($r=-.83$). On DNMS females reached adult levels of performance (2.5 days and 3 errors to criterion) around 20 months of age and males did so at around 26 months of age, suggesting that at these respective ages maturational events occur that enable adult performance on non-match tasks. In contrast, on DMS adult performance was much more delayed in both infant females and males, indicating a slower maturation of behavarioral inhibition, presumably from the prefrontal cortex.

418.2

RIGHT TEMPORAL-LOBE CONTRIBUTION TO GLOBAL VISUAL PROCESSING. J. Doyon* and B. Milner. Montreal Neurological Institute, McGill University, Montreal, Canada, H3A 2B4.

The contribution of the right temporal lobe to global visual processing was investigated in 36 patients with unilateral temporal- or frontal-lobe excisions and 15 normal control subjects. The experiment used hierarchically structured stimuli, each consisting of one large abstract design (global level) created by the spatial arrangement of identical smaller abstract designs (local level). The subjects were tested under two experimental conditions (global, local) of a Stroop-type, reaction-time task. In the local condition, the subjects were asked to focus their attention on the small designs and to ignore the large design, whereas they were instructed to do the reverse in the global condition. The results showed that, in the local condition, the right temporal-lobe group was less affected than other groups by interference from the overall configuration of the stimulus. As predicted, this reduced sensitivity to the global aspect of the stimuli was unrelated to the extent of hippocampal removal. These findings support the hypothesis that the human right temporal neocortex contributes to global visual processing.

418.3

THE ROLE OF THE FRONTAL LOBES IN THE ENCODING AND RECALL OF KINESTHETIC INFORMATION.
G. Leonard* and B. Milner (SPON: M. Lassonde). Montreal Neurol. Inst., McGill Univ., Montreal, Canada H3A 2B4.

One hundred and fifty two patients with unilateral temporal- or frontal-lobe excisions and 41 normal control subjects were tested on four kinesthetic recall tasks. The first two studies required subjects to monitor peripheral feedback, in order to duplicate either the distance or the end-position of examiner-defined arm movements. In the next two tasks, the subjects selected the movements to be recalled, and hence reliance on feedback was reduced. Temporal lobectomy did not interfere with performance, except on the examiner-defined kinesthetic location task where large left or large right hippocampal resection produced an impairment following 30 s of counting. Patients with left frontal-lobe or small right frontal-lobe excisions performed all tests normally, but those with large right frontal-lobe removals were impaired on the examiner-defined tasks across all delay conditions, and with both hands. The results point to an important role played by the right frontal lobe in the monitoring of kinesthetic feedback both during the presentation of the movements and during the recall attempt.

418.4

AMNESIA FOLLOWING MEDIAL TEMPORAL LOBE DAMAGE IN MONKEYS: THE IMPORTANCE OF THE HIPPOCAMPUS AND ADJACENT CORTICAL REGIONS. S. Zola-Morgan, L.R. Squire, and D.G. Amaral. V.A. Medical Center, San Diego, CA 92161, Dept. of Psychiatry, U,C.S.D., La Jolla, CA 92093, and the Salk Institute, San Diego, CA 92138.

Monkeys with bilateral medial temporal lobe lesions that damage the hippocampal formation, amygdala, perirhinal cortex, and parahippocampal cortex (H^+A^+ lesion) are severely impaired on tasks such as delayed nonmatching to sample (DNMS), which are sensitive to human amnesia. A more restricted lesion of the hippocampal formation that includes much of the parahippocampal cortex (H^+ lesion) produces a significant but less severe deficit. To determine what damage in the larger H^+A^+ lesion accounts for the more severe memory impairment, we prepared three groups of operated animals. Animals with stereotaxic lesions limited to the amygdala demonstrated no detectable deficit on DNMS. Moreover, the addition of a selective amygdaloid lesion to the H^+ lesion did not increase the impairment associated with the H^+ lesion. However, when both the perirhinal and parahippocampal cortices were damaged bilaterally without direct involvement of the amygdala or hippocampal formation, animals were at least as severely impaired on DNMS as those with H^+A^+ lesions. Since the perirhinal and parahippocampal cortices provide the major input to the monkey hippocampal formation, these data emphasize the importance of the hippocampal system in temporal lobe amnesia.

418.5

INDEPENDENCE OF MEMORY FUNCTIONS AND EMOTIONAL BEHAVIOR: SEPARATE CONTRIBUTIONS OF THE HIPPOCAMPAL FORMATION AND THE AMYGDALA. P. Alvarez-Royo*, M. Meseches*, J. Allen*, W. Saltzmann*, L.R. Squire and S. Zola-Morgan (SPON: S.A. Hillyard). Group in Neurosciences and Dept. of Psychiatry, U.C.S.D., La Jolla, CA 92093, and V. A. Med. Ctr., San Diego, CA 92161.

Monkeys with large medial temporal lobe lesions, including the hippocampus, amygdala and surrounding cortical areas (H^+A^+ lesion), are impaired on tasks sensitive to human amnesia. However, damage to the areas included in the H^+A^+ lesion can also cause changes in emotional behavior (e.g. the Kluver-Bucy syndrome). One possibility is that memory might be affected by these changes in emotional behavior.To examine this possibility, we compared the performance of monkeys with extensive or partial lesions of the medial temporal lobe on two behavioral batteries. The first measured performance on four different memory tasks. The second measured emotional behavior by evaluating responses to a variety of inanimate objects (e.g. a model of a snake, a black rubber boot, M&M candy).

Monkeys with H^+A^+ lesions were impaired on the memory tasks, and also showed abnormally elevated emotional reactivity. Monkeys with selective and circumscribed amygdala lesions performed the memory tasks normally but showed elevated emotional reactivity. Monkeys with damage to components of the hippocampal formation but without amygdala damage were impaired on the memory tasks but showed normal emotional reactivity. This double dissociation shows that memory impairment is independent of the observed changes in emotional behavior. The implications of these findings for the function of the hippocampal formation and the amygdala will be discussed.

418.6

THE NEUROLOGY OF MEMORY: QUANTITATIVE ASSESSMENT OF RETROGRADE AMNESIA IN TWO GROUPS OF AMNESIC PATIENTS. L.R. Squire, F. Haist, A.P.Shimamura, VA Medical Center, Dept. of Psychiatry, Univ. of California, San Diego, CA

Using six tests of remote memory, we evaluated the extent, severity, and stability of retrograde amnesia in two groups of amnesic patients--seven patients with alcoholic Korsakoff's syndrome and five patients with amnesia due to an anoxic or ischemic episode. The severity and extent of retrograde amnesia was similar for the two groups and was temporally graded across a period of about 15 years. The results support the following conclusions: 1) extensive, temporally-graded retrograde amnesia, which has been observed frequently in patients with Korsakoff's syndrome, occurs rapidly in other amnesic patients as well, even when their memory impairment appears well circumscribed; 2) patients with presumed damage to either the medial temporal or the diencephalic brain structures linked to memory functions can produce a similar kind of retrograde amnesia; 3) the impairment was stable across testing occasions, and thus does not reflect difficulty accessing an intact memory store that can be overcome with sufficient retrieval opportunities; 4) very remote memory, at least for factual information, can be intact in amnesia; 5) the structures damaged in amnesia support memory storage, retrieval, or both during a lengthy period of reorganization, after which representations in memory can become independent of these structures.

418.7

TRANSIENT GLOBAL AMNESIA: CHARACTERIZATION OF RETROGRADE AMNESIA IN SIX PATIENTS: M. Kritchevsky* and L.R. Squire. (SPON: N. Butters), V.A. Medical Center, San Diego, CA, 92161, Depts. Neurosciences and Psychiatry, UCSD, La Jolla, CA.

Transient global amnesia (TGA) is a short-lasting neurological condition in which memory impairment is the prominent deficit. We studied six patients in 1987, during and after their episode. During TGA, all patients were impaired on tests of new learning ability for verbal and nonverbal material. Additionally, during the episode, patients had difficulty recalling news events from the time period 1960-1985. Recall for events from 1950-59 was similar during and after TGA. During TGA, recognition memory for news events was impaired for the time period 1980-1985 but not for more remote time periods. Memory was normal one month after TGA. Results from a personalized test of past memory given during TGA similarly suggested that retrograde amnesia, albeit patchy and variable, affected some public and personal memories which had occurred as long ago as 1960. The memory impairment exhibited by these patients will be compared to the memory impairment exhibited by other patients with chronic amnesia.

418.8

MEMORY FOR TEMPORAL ORDER IN PATIENTS WITH FRONTAL LOBE LESIONS AND PATIENTS WITH AMNESIA. A.P. Shimamura*, J.S. Janowsky*, and L.R. Squire (SPON: H. Neville). Dept. of Psychiatry, Univ. of Calif., San Diego, La Jolla, CA 92093.

Patients with frontal lobe lesions, patients with Korsakoff's syndrome, patients with amnesia due to an anoxic or ischemic episode, and control subjects were asked to remember the order in which 15 words were presented. Memory for sequential (i.e., temporal) order was assessed by correlating a subject's ordering of the words with the actual presentation order. Patients with frontal lobe lesions exhibited a deficit in temporal order memory, despite normal recognition memory for the words. Amnesic patients exhibited both impaired temporal order and word recognition memory. Importantly, patients with Korsakoff's syndrome were more impaired on the temporal order test than anxoic-ischemic patients, consistent with their known frontal lobe atrophy. Similar results were obtained in a second experiment in which subjects were asked to place in chronologoical order 15 public events that occurred between 1941 and 1985. The findings demonstrate that frontal lobe lesions particularly affects temporal order memory, whereas damage to the areas that cause amnesia (i.e., diencephalic and medial temporal areas) affects both item memory and temporal order memory.

418.9

SOURCE AMNESIA IN PATIENTS WITH FRONTAL LOBE LESIONS AND THE ELDERLY. J.S. Janowsky,* A.P. Shimamura,* and L.R. Squire. (SPON: T. Jernigan). VA Medical Center, San Diego, CA 92161 and Dept. of Psychiatry, U.C.S.D., La Jolla, CA 93093.

Information is often recalled in conjunction with its source (i.e. when or where the information was learned). Previous studies showed that some amnesic patients exhibit source amnesia: they can recall a few facts taught in a recent session but they attribute the information to some other context. This study investigated the ability of patients with frontal lobe lesions and two groups of control subjects (elderly and young) to learn new facts as well as to recall the source of the information. In two experiments, patients with frontal lobe lesions recalled facts as well as the control subjects. However, both patients with frontal lobe lesions and elderly control subjects were more likely than young subjects to attribute facts learned within a test session to an incorrect source. In addition, patients with frontal lobe lesions but not the elderly or young control subjects sometimes attributed facts to the test session itself, when these facts had actually been known to the subject prior to the test session. This study shows that source errors can occur in patients with frontal lobe lesions, as well as in healthy elderly subjects, in the absence of amnesia. The frontal lobes may play a special role in helping join information in memory to the context in which it was learned.

Amnesics' Relatively Preserved Recognition in Implicit Memory.

William Hirst,* Elizabeth A. Phelps,* Marcia K. Johnson* and Bruce T. Volpe. (SPON: F. McDowell). Graduate Faculty, New School for Social Research, NY, NY, Princeton University, Cornell University Medical College.

Several theorists have divided the memory system into a component responsible for the explicit retrieval of declarative memories and a component responsible for the implicit retrieval of procedural memories (Squire, 1986). This dichotomy is supported in part by finding that human anterograde amnesia disrupts explicit declarative memory while leaving implicit procedural memory intact. Recently, it has been reported that amnesic recognition is relatively preserved when compared with amnesic recall. In as much as recognition is an explicit declarative memory task this result could suggest that aspects of amnesic explicit memory remain intact. However, amnesics' unexpectedly good recognition could build solely on their intact implicit memory. Three experiments test this hypothesis. In two, amnesic recognition is raised to normal levels even in the absence of any signs of priming as measured by stem completion and perceptual identification. In the third, factors affecting amnesic recognition such as depth of processing are shown to have no effect on amnesic priming suggesting that amnesic recognition and priming involve different mechanisms. A model accounting for the results is discussed.

VOLUNTARY CONTROL OF ATTENTION IS IMPAIRED IN KORSAKOFF' SYNDROME. RG Mair, DB Flint,* U New Hampshire and Research Service 151C, VAMC, Brockton, MA 02401, A. Inhoff*, SUNY Binghamton, PJ Langlais, San Diego VAMC.

We compared the performace of 9 Korsakoff (K) and 9 alcoholic control (AC) subjects on a series of chronometric tasks using CRT presentation and a manual response board. Tasks included reaction times (rt) facilitated by stimulus driven, subject driven, and voluntarily controlled shifts in attention; as well as Sternberg-type short term memory retrieval and sequential finger tapping. Korsakoffs exhibited slower rt's in all tasks. Although the K's showed normal superiority of rt's to valid as opposed to invalid cues, they were significantly slower on subject driven than stimulus driven attentional tasks, a pattern opposite that observed among controls. While the AC's were able to utilize cues in the voluntarily driven attentional task at a delay of 250 msec, K's showed no such benefit until a delay of 1000 msec. On both the memory retrieval and motor sequencing tasks, K's were consistently slower for all response conditions. The speed of retrieval of items from short term memory correlated significantly with performance on the attentional tasks.

418.12

PROCEDURAL LEARNING IN SCHIZOPHRENIA: EVIDENCE FROM TOWER OF HANOI-LIKE TASKS. T. E. Goldberg*, J. A. Saint-Cyr and D. R. Weinberger. Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032.

Neuropsychological paradigms have indicated the presence of frontal lobe dysfunction in schizophrenia. However, the matter of task difficulty has not been adequately addressed; that is, patients might do worse on these tasks simply because they are harder. Also, prefrontal cognitive failure might reflect "downstream" dysfunction in the basal ganglia. We attempted to examine these issues by using variants of the Tower of Hanoi puzzle. A three disk version is thought to emphasize problem solving and has been found to be sensitive to frontal lobe lesions, while a more difficult four disk version is thought to emphasize procedural learning and is sensitive to basal ganglia disease. Relative to controls, schizophrenic patients performed as poorly on the easier three disk version as they did on the more difficult four disk version. Moreover, in repeated trials, patients were able to learn the four disk tower at a rate similar to that of normal subjects, though they learned the three disk Tower much more slowly. These results suggest that poor performance on frontal lobe tests is not simply a function of task difficulty and that certain aspects of basal ganglia function may be relatively more intact in schizophrenia than frontal lobe function.

LABELING OF TORPEDO NICOTINIC ACETYLCHOLINE RECEPTOR (AChR) WITH THE HYDROPHOBIC PHOTOREAGENT 3-(TRIFLUOROMETHYL)-3-(m-[^{125}I]IODOPHENYL)DIAZIRINE ([^{125}I]TID). **B.H. White* and J.B. Cohen (SPON: D. Frail). Dept. of Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.**

We have studied the photoincorporation of the hydrophobic probe [^{125}I]TID into the AChR of T. Californica postsynaptic membranes. [^{125}I]TID labels all four subunits of the AChR. Two regions of the α-subunit incorporate label as determined by digestion with S. aureus V8 protease: the first, defined by a 20 kDa cleavage fragment, begins at residue Ser-173 and contains the hydrophobic segments M1-M3; the second extends from Asn-339 through the hydrophobic segment M4. Two fragments, spanning most of the amino terminal region from Ser-1 to Glu-161, fail to incorporate [^{125}I]TID.

[^{125}I]TID labeling of all AChR subunits is strongly inhibited (75-95%) by the agonist carbamylcholine (100 μM), an effect that is blocked by the competitive antagonist α-bungarotoxin and is restricted, on the α-subunit, to the 20 kDa V8 fragment. The noncompetitive antagonist histrionicotoxin (30 μM) also strongly inhibits AChR labeling, but 50 μM phencyclidine does not. Non-radioactive TID also specifically inhibits [^{125}I]TID labeling of the AChR (IC_{50}=10 μM). We conclude that [^{125}I]TID acts both as a nonspecific label of AChR regions exposed to lipid, and as an affinity label for a site (or sites) on the AChR distinct from, but coupled to, the agonist and noncompetitive antagonist binding sites. (Supported in part by USPHS NS 19522 and 22828 and a NSF predoctoral fellowship to B.W.)

419.2

EXPRESSION OF AVIAN GENES ENCODING NEURONAL NICOTINIC ACh RECEPTORS. E.Cooper, C.R.Bader, D.Bertrand, D.Rungger, P.Nef, S.Couturier and M.Ballivet. *Dept of Physiol. McGill Univ. Montreal,P.Q. H3G 1Y6 and Dpt de Physiol. CMU, Dpt de Zool. and Dpt de Bioch., Université de Genève. CH-1211 Genève 4, Switzerland.*

Recently, a family of genes encoding proteins related to muscle endplate nAChR subunits has been isolated from the avian genome and sequenced (Nef et al., *EMBO J.*, 7:595,1988).These genes (and their protein products) have been termed α 2, α 3, α4 and nα (non-α) and are expressed in the central and peripheral nervous system. All neuronal alpha subunits possess the pair of vicinal cysteine residues thought to be part of the ACh binding site, whereas these cysteines are lacking in the nα subunit. In this study, we used voltage clamp and patch clamp techniques to measure the physiological properties of nicotinic ACh receptors expressed by oocytes 1-5 days after nuclear injection with cDNA for α4 and nα linked to a heat-shock promoter. The DNA injection technique was used because we found that it gave more reliable ACh receptor expression compared to oocytes injections with cRNA. Heat-treated oocytes injected with both α4 and n-α constructs expressed up to 2-3uA of ACh-induced currents that could be reversibly blocked by hexamethonium but that were insensitive to α-bungarotoxin. From dose-response experiments, we determined that the slope of log-response vs log-concentration plots up to 80nM ACh was 1.5, suggesting that the functional receptors assembled with at least two α4 subunits. Single channel measurements of receptors from outside-out patches demonstrated that these receptors had linear I-V curves, reversal potentials of about -7mV and single-channel conductances of 20pS. Interestingly, the receptors, which were stable in cell-attached patches, gradually disappeared from outside-out patches over few minutes; this suggests that intracellular factors may modulate the function of these neuronal nicotinic receptors.

419.3

DIFFERENCES IN THE PHOSPHORYLATION OF UNASSEMBLED, ASSEMBLED BUT CYTOPLASMIC, AND SURFACE ACETYLCHOLINE RECEPTORS. W.N. Green* and T. Claudio. (SPON: R. Wyman) Dept. of Cell. and Molec. Physiology, Yale Univ. Sch. of Med., New Haven, CT 06510

The *in vivo* phosphorylation of *Torpedo* nicotinic acetylcholine receptor (AChR) subunits was studied using a mouse fibroblast cell line in which the four *Torpedo* AChR subunit cDNAs had been stably integrated into the host cell genome (Claudio, et al., *Science* 238:1688, 1987). Each of the subunits is synthesized, glycosylated, assembled into AChR complexes, and the complexes are expressed on the cell surface where they display all of their proper pharmacological and physiological properties. Intact AChR-fibroblast cell lines were first incubated with ^{32}P and unlabeled α-bungarotoxin (BuTx), then solubilized, followed by sequential immunoprecipitations with BuTx-specific or subunit-specific antisera. These differential immunoprecipitations resulted in the isolation of three classes of AChR subunits: 1) unassembled, cytoplasmic subunits, 2) assembled, cytoplasmic AChR complexes, and 3) assembled, cell surface AChR complexes. The degree and pattern of AChR phosphorylation differed among these three AChR pools. Phosphorylation of the γ and δ subunits was observed in the unassembled subunits and the surface AChR complexes, whereas only the δ subunit (and possibly β) was phosphorylated in the cytoplasmic AChR complexes. No phosphorylation of the α subunit was detected in any of the AChR pools. The cAMP-dependent protein kinase stimulators forskolin, cAMP-S, and cholera toxin, increased phosphorylation of the unassembled and cell surface AChR pools with no corresponding increase in the phosphorylation of the cytoplasmic assembled AChR pool. Further analysis of the role phosphorylation may play in AChR assembly and/or function is continuing.

419.4

TEMPERATURE-SENSITIVE EXPRESSION OF ALL-*TORPEDO* AND *TORPEDO*-RAT HYBRID ACHRS IN MAMMALIAN CELLS. H.L. Paulson* and T. Claudio. (SPON: E. Manuelidis) Dept. of Cell. and Molec. Physiology, Yale Univ. Sch. of Medicine, New Haven, CT 06510

We have recently shown that mouse fibroblasts express fully functional, cell surface *Torpedo californica* nicotinic acetylcholine receptors (AChRs) after the four subunit cDNAs have been stably integrated into the host cell genome (Claudio, et al., *Science* 238:1688, 1987). Although each of the subunit polypeptides is synthesized at 37°C (normal mammalian cell growth conditions), functional AChR complexes are only expressed at temperatures lower than 37°C. The four *Torpedo* AChR subunit cDNAs have also been stably integrated into the genome of a rat muscle L6 cell. Again, we find that expression of *Torpedo* AChRs only occurs at temperatures lower than 37°C whereas expression of endogenous rat AChRs occurs at both 37°C and lower temperatures. These results demonstrate that the temperature-sensitive phenomenom is not fibroblast-specific, however it does appear to be *Torpedo*-specific. Another stable L6 muscle cell line was established in which only the *Torpedo* α subunit cDNA was integrated (L6-α). Expression of *Torpedo*-rat hybrids in L6-α cells only occurred at temperatures lower than 37°C and in addition, three classes of AChRs could be isolated. AChRs were expressed that contained two rat, two *Torpedo*, or one rat and one *Torpedo* α subunit, demonstrating that the two α subunits in an AChR complex need not originate from the same polysome.

Further analysis of the *Torpedo* temperature-sensitive phenomenom suggests that the temperature-sensitive step occurs before assembly and that it probably involves an altered polypeptide conformation. 1) Once hybrid or all-*Torpedo* AChRs are formed, they are stable at 37°C. 2) *Torpedo* α subunits show a 2- to 3-fold increase in binding to α-bungarotoxin upon shift from 37°C to 26°C.

419.5

ISOLATION OF A SECOND MUSCLE ACHR ALPHA-LIKE SUBUNIT FROM *XENOPUS LAEVIS*. D.S. Hartman* and T. Claudio. Dept. of Cell. and Molec. Physiology, Yale Univ. Sch. of Med., New Haven CT 06510.

Cloning of the muscle nicotinic acetylcholine receptor (AChR) α, γ, and δ subunit cDNAs from *Xenopus laevis* stage 17 or 22 cDNA libraries has been reported (Baldwin, T. et al., *J. Cell Biol*, 106:469, 1988). We report here, the isolation of a fourth putative AChR subunit (*Xenopus* muscle α2, xmα2) from a stage 17 embryonic *Xenopus* cDNA library. We have tentatively assigned xmα2 as an α subunit for the following reasons. Expression in a rabbit reticulocyte lysate system of *in vitro* transcribed xmα2 mRNA makes a 40 kd polypeptide that is immunoprecipitated by polyclonal antisera directed against *Torpedo* α subunit. The deduced amino acid sequence of clone xmα2 revealed that it is composed of 437 amino acids (found in all muscle-like α subunits), it contains conserved cysteine residues corresponding to amino acid residues #128, 142, 192, 193 (*Torpedo* α numbering), and it contains the one potential N-linked glycosylation site corresponding to *Torpedo* residue #141. A comparison of the amino acid similarities (identity plus conservative substitutions) among xmα2, *Torpedo* α, and the Baldwin et al. *Xenopus* α clone (xα), revealed: ~80% similarity beween xmα2 or xα and *Torpedo* α; <50% similarity between xmα2 or xα and *Torpedo* β; ~80% similarity beween xmα2 and xα. The xmα2 and xα clones show similarities throughout their entire lengths with the most divergence occuring between the amino terminus and the first putative transmembrane domain, M1. Transcripts from both xmα2 and xα are found in adult *Xenopus* muscle and appear to be coordinately expressed throughout early embryonic development (oocyte, stages 10, 17, 22, 25, 30, 35).

419.6

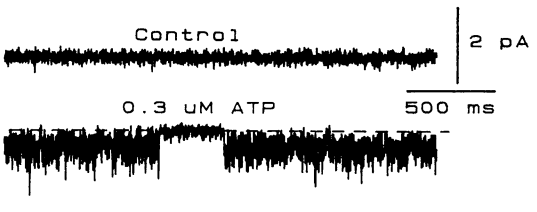
ACTIVATION AND BLOCK OF SINGLE NICOTINIC RECEPTOR CHANNELS OF THE FROG ENDPLATE BY DECAMETHONIUM. C.G. Marshall, D.C. Ogden* and D. Colquhoun*. Dept. of Pharmacology, University College, London WC1E 6BT, U.K.

Agonists which produce a small maximal effect are classically termed "partial agonists", and decamethonium (DECA) acts as such at the nicotinic receptor. Adams and Sakmann (Proc. Natl. Acad. Sci. USA (1978) 75 2994-2998) suggested that this effect derived simply from open channel block by DECA, in contrast to the view that partial agonists are inherently ineffective at receptor activation. We have used single channel recording to obtain data for DECA as an agonist and channel blocker over a wide range of concentrations (5-500μM), and data were interptreted in terms of a sequential reaction scheme. A component of the shut time distribution of mean duration 1.75-2.84 ms was identified as blockage gaps, and the blockage frequency plot gave a slope, k_{+B}, of 3.6 x 10^7 $M^{-1}s^{-1}$, intercepting the origin as expected. At 5μM DECA, the mean open time was 452μs, and a plot of reciprocal mean open time gave a slope, k_{+B}, of 3.0 x 10^7 $M^{-1}s^{-1}$, and an intercept, α, of 2076s^{-1}. We estimate the equilibrium dissociation constant for open channel block, K_B, to be 7-15μM. Our data is consistent with a simple open channel block. The maximum value of P_{open} is less than 5%, and although DECA is clearly a potent blocker, we cannot yet discriminate between a small maximal effect purely due to channel block, and a low intrinsic efficacy.

419.7

ATP-ACTIVATED CHANNELS IN RAT AND FROG SENSORY NEURONS. **B.P. Bean, C. A. Williams*, and P. W. Ceelen*. Department of Neurobiology, Harvard Medical School, Boston, MA 02115**

External ATP (Kd~3 uM) induced an increase in conductance in about 30% of bullfrog and 20% of rat DRG neurons tested. As reported by Krishtal et. al. (Neurosci. Lett. 35:41,1983), the ATP-induced current was cation-selective, inwardly-rectifying, and reversed near 0 mV. The induced current increased 3.5-4 fold for a doubling in [ATP], suggesting 2:1 binding. The rapid onset of ATP-activated current (τ ~ 300 ms at 0.3 uM ATP, τ < 15 ms at 100 uM) is nearly diffusion-limited, so that second messenger mediation is unlikely (or extraordinarily rapid). Single channels in outside-out patches flickered rapidly (τ ~ 10 usec) when activated, with a mean current of about 0.5 pA at -100 mV. The fraction of time a channel was in the activated, flickery state approached 1 at high [ATP]. Whole-cell noise showed exactly the properties expected if such channels underly the macroscopic current.



419.8

BIOPHYSICAL AND PHARMACOLOGICAL PROPERTIES OF $GABA_A$ RECEPTOR SUBUNIT CLONES EXPRESSED IN OOCYTES E.S. Levitan, L.A.C. Blair, V.E. Dionne* and E.A. Barnard*. MRC Molecular Neurobiology Unit, Cambridge, England.

The recent cloning of the bovine brain $GABA_A$ receptor α1 and β subunits (Schofield et al., 1987) has led to the further isolation of two additional α subunit RNAs (α2, α3)(Levitan et al., submitted). The properties of these clones have been determined and compared by injecting synthetic RNA into Xenopus oocytes and studying the induced GABA-sensitive currents with voltage- and patch-clamp methods. Expressing any α-β pair of subunits together produces GABA-activated Cl^- currents that are potentiated by the pentobarbital and inhibited by bicuculline and by picrotoxin. The Cl^- channels display characteristic multiple single-channel conductance states and voltage-dependent gating. A functional difference occurs when the α subunits are interchanged: the apparent sensitivity of the receptor for GABA is shifted 30-fold from 1.3 uM to 42 uM (EC_{50}). The order of sensitivity is α2,α1,α3, with α2 being most sensitive. The results suggest that functionally distinct subtypes of the $GABA_A$ receptor exist in the brain. However, these receptors are partially impaired since they fail to show the expected sensitivity to benzodiazepines and are activated by GABA with a Hill coefficient of only 1. This suggests that additional subunits or processing is required for normal $GABA_A$ receptor function. Supported by NSF (ESL) and NIH (LACB, VED).

419.9

SINGLE SUBUNITS OF THE GABAa RECEPTOR FORM ION CHANNELS WITH PROPERTIES CHARACTERISTIC OF THE NATIVE RECEPTOR.
L.A.C. Blair, E.S. Levitan, V.E. Dionne* and E.A. Barnard*
MRC Molecular Neurobiology Unit, Cambridge, England.

Alpha and beta subunits of the GABAa receptor were expressed individually in Xenopus oocytes using RNA synthesized from cloned DNAs. GABA-sensitive, chloride-selective channels were detected several days after injection with any one of three different RNAs (α_1,α_2,α_3) or with β RNA. The channels induced by each of the single subunit RNAs were indistinguishable. They had multiple conductance levels (nominally 10, 18, 28 and 44pS), and their activity was potentiated by 20μM pentobarbital and inhibited by 10μM picrotoxin indicating that the sites for these agents are present on each subunit. Based on conservative substitutions, the α and β subunits of the GABAa receptor show ~55% amino acid sequence homology. The finding that each of α and β subunits, examined separately, form GABA-sensitive ion channels with barbituate and picrotoxin regulatory sites and normal permeation properties suggests that the amino acid sequences which confer these properties in the native receptor are within the shared domains.

QUATERNARY AMMONIUM IONS BLOCK N-METHYL-D-ASPARTATE RECEPTOR-CHANNELS IN MAMMALIAN CENTRAL NEURONS IN CULTURE.
J. M. Wright* and L. M. Nowak. Dept. of Pharmacology, NYSCVM Cornell University, Ithaca, NY 14853.

Previous studies of N-methyl-D-aspartate (NMDA) activated channels indicated they were blocked in a voltage-dependent way by choline ions (Ascher et al., J. Physiol., 399:207,1988). We have examined the effects of two other quaternary ammonium ions commonly used to block voltage-gated K channels: tetraethyl- and tetrabutylammonium (TEA and TBA), on excitatory amino acid responses using patch clamp recording methods (whole cell and outside-out patches) from mammalian central neurons in cell culture. Kainate (20μM) and AMPA (5μM) whole cell currents were not affected by either TEA (5mM) or TBA (1mM). In contrast, TEA (1-10mM) and TBA (1mM) decreased NMDA (20μM) whole cell currents in a voltage-dependent manner with a greater effect at −60mV than at −40mV. Reduction of NMDA channel current amplitude by TEA was dose-dependent and qualitatively similar to the effects in choline. TBA appeared to cause a flickering block without a noticable change in conductance. Concentrations of Mg, Co, Ni and Mn ions, which might show similar effects, were found to be too low to account for the effects of TEA or TBA. Thus, the K-channel blockers TEA and TBA also block NMDA responses at similar concentrations as they affect K-channels. Detailed analysis of single channel kinetics will allow us to determine more about the mechanism of action of these blockers.
Supported by NIH grant NS24467.

419.11

STRYCHNINE AND GLYCINE-RECEPTOR INTERACTIONS IN CULTURED MEDULLARY NEURONS FROM EMBRYONIC RAT.
C.A. Lewis*, D.S. Faber and Z. Ahmed. Dept. Physiology, State Univ. of New York, Buffalo, NY 14214.

Characteristics of glycine-activated currents in 10 to 20 day old neurons were studied using the gigaseal whole-cell technique. Cells were voltage-clamped to -70 mV, and brief pulses of glycine were applied by pressure ejection from a second pipette containing 2 M glycine. Glycine produced inward currents that had a shift in reversal potential of +60 mV for a 10-fold reduction in external Cl^- concentration, indicating that the currents were due to activation of a Cl^- conductance.

Dose-response data were obtained for glycine in control saline and in saline containing different concentrations of strychnine (100 nM to 100 uM). Strychnine had mixed inhibitory actions on the glycine-induced currents in that both the maximum responses were decreased and the dose-response curves for glycine were shifted to the right. Glycine receptors with at least two different sensitivities to strychnine were found, based on the apparent inhibition constants (K_i). These two K_i values were associated with different Hill coefficients for the glycine responses; i.e. $K_i = 4.4 \pm 0.9 \times 10^{-8}$ M (± SEM, n=5), $n_{app} = 1.9 \pm 0.4$; and $K_i = 2.5 \pm 0.8 \times 10^{-6}$ M (n=6), $n_{app} = 3.8 \pm 0.7$. These differences were not related to culture conditions or age, and may reflect properties of multiple glycine receptor populations.

419.12

SINGLE CHANNEL AND SYNAPTIC CURRENTS RECORDED IN NEURONS OF MAMMALIAN BRAIN AND SPINAL CORD SLICES.
A. Konnerth, T. Takahashi, F. Edwards and B. Sakmann (SPON: European Neuroscience Association). Max-Planck-Institut für biophys. Chemie, 3400 Göttingen, FRG.

The patch clamp technique (Hamill et al., *Pflügers Archiv 391, 1981*) has been applied to neurons in thin (100-130 μm) slices of rat brain and spinal cord. In this preparation neurons can be visually identified by using Nomarski water immersion optics. In order to apply the patch clamp method, single (synaptically connected) neurons were partially exposed by removing mechanically the covering cell debris. This "cleaning" procedure did not involve the use of proteolytic enzymes.

In spinal cord slices, electrical stimulation of interneurons evoked in motoneurons large (up to 2 nA) inhibitory postsynaptic currents (i.p.s.c.s) (V_h=-50 mV, $[Cl_i]=[Cl_o]$= =140 mM, 22-24 °C). The i.p.s.c.s were reversibly blocked by strychnine (2-5 μM) and reversed at the Cl^- reversal potential and were therefore identified as being mediated by glycine. Miniature i.p.s.c.s (mean amplitude ~40 pA) recorded in the presence of TTX had a steep onset (half rise time ~0.5 ms) and a slow decay which could be fitted by the sum of two exponentials (τ_1=4.6±1.2 ms, τ_2=25.8±10.0 ms). Glycine-mediated single channel currents, registered in excised outside-out patches in the same preparation, showed multiple conductance states. The two most frequently occurring states (2.3 and 2.7 pA at -50 mV) had life-time components (τ_1=2.5±1.4 ms, τ_2=27.5±8.3 ms and τ_1=2.5±0.9 ms, 26.0±11.5 ms, respectively) comparable to those obtained for the miniature i.p.s.c.s. These results indicate that the time course of the i.p.s.c.s reflects the gating properties of glycine receptor channels and that only 15-20 channels are activated by a single packet of inhibitory transmitter.

DEGENERATIVE DISEASE: OTHER I

420.1

VASOACTIVE INTESTINAL PEPTIDE (VIP) AND CHOLECYSTOKININ (CCK) IN QUINOLINATE-LESIONED RATS AND HUNTINGTON'S DISEASE POSTMORTEM BRAIN
M.F. Mazurek, M.F. Beal, K.J. Swartz, S.F. Knowlton*, P. Patel* and J.B. Martin. McMaster Univ. Med. Ctr., Hamilton, ONT. and Mass. General Hosp., Boston, MA.

Intrastriatal injections of quinolinate (QUIN) can produce lesions which mimic many of the neurochemical and histopathological characteristics of Huntington's disease (HD). We studied levels of VIP and CCK by radioimmunoassay in chronic QUIN-lesioned Sprague-Dawley rats and in HD postmortem brain. Levels of VIP were elevated 3- to 4-fold in HD striatum, and 4- to 5-fold in QUIN-lesioned striatum. CCK was mostly normal in HD striatum as compared with a 2-fold increase in QUIN-lesioned rats. In cerebral cortex CCK immunoreactivity was elevated by 56-123% in all 13 areas that we examined, while VIP was increased to a lesser extent. There was no relationship between cortical peptide levels and the degree of striatal atrophy. QUIN-lesioned rats had normal cortical concentrations of CCK and VIP.

These results suggest that (1) a chronic QUIN lesion in the rat can produce changes in striatal VIP immunoreactivity that closely resemble those observed in HD; and (2) HD cerebral cortex contains increased levels of CCK immunoreactivity that are probably not adequately explained on the basis of abnormal feedback from the striatal-pallidal-thalamic circuit.

PATCH-MATRIX DISTRIBUTION OF CHOLECYSTOKININ AND CYTOCHROME OXIDASE ACTIVITY IN NORMAL AND HUNTINGTON'S DISEASE STRIATUM.
RJ Ferrante, NW Kowall and EP Richardson Jr. Massachusetts General Hospital and Harvard Medical School, Boston MA 02114.

The normal human striatum can be subdivided into two compartments based on the distribution of neurochemical substances and projections. In Huntington's disease (HD), acetylcholinesterase (AChE) histochemistry shows persistence of this patch-matrix pattern despite marked atrophy and neuronal loss. We examined the distribution of cholecystokinin (CCK) and cytochrome oxidase (CO) in 6 HD brains and 6 age-matched controls to further characterize patch-matrix relationships in HD striatum.

Clusters of CCK immunoreactive fiber terminals were heterogeneously distributed in both control and HD striatum. This patchy distribution has not been previously reported in human striatum. Comparison with adjacent AChE stained sections showed that CCK distribution corresponds to low AChE patches. The density of CCK patches was not altered in HD and the ratio of CCK positive patches to negatively stained matrix was increased.

In rodent striatum CO activity is patchy and enriched in spiny neuron dendrites. We found CO activity to be unevenly distributed in normal human striatum with regions of high CO activity corresponding to high AChE matrix. In HD striatum CO activity was reduced, especially in the dorsal striatum. Thus extrinsic CCK immunoreactive fiber terminals in striatal patches are preserved while striatal matrix enriched in CO is depleted. These findings confirm the relative preservation of striatal patches and striatal afferent systems and relative sensitivity of spiny neurons to destruction in HD.

A CANDIDATE CLONE FOR RAT 3-HYDROXANTHRANILIC ACID OXYGENASE. B. Navia*, M. MacDonald*, A. McClatchey*, J. Gusella, E. Okuno[1] and R. Schwarz[1](SPON: C. Kohler). [1]Neurogen. Lab., Mass. Gen. Hosp., Boston, MA 02114 and Maryland Psych. Res. Ctr, Baltimore, MD 21228.

Quinolinate (QUIN) is an endogenous brain metabolite which can cause selective excitotoxic neuronal death when introduced intracerebrally in rats. The synthetic enzyme for QUIN, 3-hydroxyanthranilic acid oxygenase (3-HAO) has been purified from rat liver and its presence has been demonstrated in the mammalian brain. In order to further elucidate the biological role of 3-HAO in the brain, we have isolated a candidate cDNA clone for rat 3-HAO. Using a polyclonal antiserum raised against purified rat 3-HAO (J. Neurochem.49,771, 1987), we screened a rat cDNA library constructed in the λgt11 expression vector. Two candidate 3-HAO cDNA clones, BN1 and BN2, were obtained. Each clone contained an approximately 1.5 kb insert which was subcloned into pUC19 for subsequent analyses. DNA sequencing revealed that the two were identical and contained only part of the putative coding region for 3-HAO. A search for DNA homology revealed the sequence to be unrelated to any previously reported genes. Efforts are under way to isolate a full-length cDNA to determine the complete structure of the 3-HAO enzyme, and to provide a critical reagent for examining the expression of this gene in the central nervous system. Supported by USPHS grants NS16102, NS20509 and NS16367.

MUSCLE WEAKNESS IN THE MDX MOUSE. C.G. Carlson, R.V. Makiejus*, J.W. Krieger*. Dept. of Biology, Purdue Univ. Calumet, Hammond, IN. 46323

The 'mdx' mouse represents an X-linked recessive myopathy (Bullfield et. al., PNAS, 81, 1189,1984) which lacks the same gene product as that lacking in Duchenne muscular dystrophy (Hoffman et. al., Cell, 51,919,1987). Using a non-invasive method for measuring 'whole body tension'(WBT) in which forward pulling tensions are averaged, we report that both male (WBT=8.6+ .6 gm tension/gm body wt.;5wks-21 mos) and female mdx mice (obtained from Roswell Park Memorial Cancer Institute and inbred;10.5+.4;5wks-9mos) are significantly weaker ($p<0.01$) than control mice (males-13.5 + .5;females-14.3+ .3;5 wks-8 mos.). In vivo (under Avertin anesthesia) twitch tension measurements in gastrocnemius showed a significant reduction in adult mdx mice (mdx-0.18 + .02 gm tension/mg wet wt.;C57-0.23+.01; $p<.05$) which was positively correlated ($r=.91$) to the WBT values. Intracellular recordings from adult mdx diaphragm fibers revealed Miniature Endplate Potential amplitude distributions characteristic of fully mature junctions which (unlike early postnatal C57 junctions) were normosensitive to elevations in extracellular potassium. These results indicate a myogenic impairment of tension generation in mdx muscle which is not associated with an inability to form fully functional mature nerve terminals. Supported by an SR Award (PUC) and an XL Summer Faculty Award (Purdue Res. Found.).

VERBAL FLUENCY IN PROGRESSIVE SUPRANUCLEAR PALSY (PSP). S. T. Smith* (SPON: W. A. Wilson). MGH Neurolinguistics Laboratory; Boston, MA 02108

Studies of cognitive processing in PSP commonly report severely impaired performance on tests of verbal fluency (production of words in a semantic or letter category in a specified time). Since these tests tap a variety of cognitive abilities (e.g., initiation, concept formation, abstract thinking, language ability and processing speed), breakdown in any of these abilities can cause impaired performance. In PSP, aspects of processing associated with frontal lobe dysfunction may be implicated.

In a case study of a 65 yr. old PSP patient with impaired fluency, an auditory recognition test designed to complement the fluency test was administered. Experimental words were tested for inclusion in their letter and semantic categories (e.g., pilot: P words; occupation). A subset of words for which the initial phoneme could be represented by more than one graphemic option was also examined in relation to a foil category (e.g., physician: F words). The same word list was repeated for each category to provide the opportunity to observe perseverations. Results indicated largely intact performance on the experimental task, and thus suggest that for this patient at least, semantic and orthographic knowledge necessary for the fluency test are preserved. Interpretations that fluency impairments in PSP are associated with frontal lobe dysfunction are thus supported by these data.

NEUROFILAMENT GENE EXPRESSION IN ANTERIOR HORN CELLS OF AMYOTROPHIC LATERAL SCLEROSIS (ALS). P.M. Tran*, A.W. Clark, I.M. Parhad. University of Calgary, Calgary, Alberta, Canada.

Studies in ALS have suggested an impaired production of RNA in surviving anterior horn cells (ahcs) and accumulation of neurofilaments (Nfs) in the proximal axons of ahcs. We evaluated the gene expression of the light neurofilament subunit (Nf-L) in 3 ALS and 3 control spinal cords. Neuronal counts showed approximately 50% loss of ahcs in the ALS cases. The area of individual ahcs was decreased in the ALS cases by approximately 25%. Total RNA recovery from the spinal cords was similar in ALS and control cases ($p>0.1$;). To date, RNase protection assays using an Nf-L riboprobe (JP Julien) have shown no difference in amount of Nf-L mRNA in ALS as compared to control cases. In situ hybridization, using the Nf-L probe revealed the expected direct correlation between neuronal size and Nf-L grain density in the control ahcs, but there was a loss of this correlation in ALS. Small ahcs in the ALS cases had an increased Nf-L grain density when compared with neurons of the same size in controls. These results suggest that Nf-L mRNA production is relatively well maintained in surviving ahcs in ALS.

THE EXPRESSION OF SPECIFIC PURKINJE CELL ANTIGENS IN TUMOR TISSUE FROM PATIENTS WITH PARANEOPLASTIC CEREBELLAR DEGENERATION. H.M. Furneaux*, D. Barbut*, F. Yee* and J.B. Posner. Dept. of Neurology, Memorial Sloan-Kettering Cancer Center, New York, N.Y. 10021

Paraneoplastic cerebellar degeneration (PCD) is a rare remote effect of cancer which is characterized clinically by subacute onset of ataxia, dysarthria, nystagmus and pathologically by a diffuse loss of Purkinje cells. The occurrence of autoantibodies which recognize two specific Purkinje cell antigens (62 kd and 34 kd) in the sera of PCD patients suggests an autoimmune etiology. The link between the generation of these autoantibodies and the occurrence of systemic cancer is not clear. We have now demonstrated (by Western blot analysis using human and rabbit antibodies) the expression of both the 62 and 34 kd PUrkinje cell antigens in tumor tissue from PCD patients. These findings therefore support the hypothesis that paraneoplastic cerebellar degeneration is caused by an immune response to cerebellar Purkinje cell antigens provoked by their inappropriate expression in tumor tissue.

A PRIMATE MODEL OF CEREBROVASCULAR DISEASE: BEHAVIORAL AND NEUROPATHOLOGICAL STUDIES. M.B. Moss, T. Kemper*, D.L. Rosene, S. Prusty* and W. Hollander*. Boston University School of Medicine, Boston, MA 02118.

The behavioral and neuropathological consequences of hypertension and atherosclerosis were assessed in male cynomolgous monkeys that received coarctation of the thoracic aorta, alone (Group Hyp, N=3) or in combination with maintenance on an atherogenic diet (Group Hyp + Ath, N=5) for 12 months prior to testing. Post-treatment performance on a visual recognition memory task was compared to that of unoperated animals maintained on an atherogenic diet (Group Ath, N=3) and unoperated control animals maintained on a normal diet (Group N, N=4). Performance by the Hyp + Ath and Hyp groups, not significantly from each other, was impaired relative to the N and Ath groups. Further, two animals in the Hyp + Ath showed disproportionate impairment. In contrast, performance by animals in Group Ath did not differ significantly from Group N on the recognition task. Initial histological assessment revealed multifocal neuropathologies in monkeys in the Hyp+Ath and Hyp groups, including perivascular hemorrhage, mineral deposits, demyelination and ischemic infarction. The data suggest that hypertension alone, and perhaps to a greater extent when combined with an atherogenic diet, can produce marked impairment in CNS function.

REGIONAL CEREBRAL BLOOD FLOW ABNORMALITIES IN EARLY AIDS DEMENTIA COMPLEX MEASURED WITH 123-I-IMP SPECT. J. M. Mountz*, N. M. Speed*, K. Adams*, J. A. Schwartz*, M. D. Gross* D. G. Ostrow*. (SPON:D. E. Kuhl). University of Michigan Medical Center, Ann Arbor, Michigan 48109.

A frequent complication of acquired immune deficiency syndrome (AIDS) is dementia. We evaluated 7 AIDS patients (age 28-55, all males) for evidence of AID dementia complex (ADC). The assessment included a psychiatric evaluation, neuropsychological(NP) testing, Computed tomography (CT), and 123-I-iodoamphetamine single photon emission computed tomography (SPECT). Six of the 7 patients exhibited cognitive (5 with memory loss) or behavioral (2 with new onset of hypomania) abnormalities on psychiatric examination. NP testing showed general deficits, but none of the cases exhibited sufficient impairment to be classified as dementia. The SPECT scans showed marked abnormality in two cases: One case demonstrating diminution of tracer uptake in the posterior temporal parietal region (posterior/anterior =.81), and the other showed marked R/L asymmetry in the subcortical region (asymmetry= 1.17). In three additional patients there was asymmetric tracer uptake in the subcortical brain region on the SPECT scan (average=1 .13). CT scans were normal in all 7 cases.In conclusion, SPECT finding showed subcortical abnormalities in 4 out of 7 patients. This finding implies functional brain imaging with SPECT may be a useful method to follow ADC progression and to evaluate therapeutic agents.

POLYAMINE DEPENDENCE OF NMDA RECEPTOR-MEDIATED Ca^{2+} FLUXES AND TRANSMITTER RELEASE FROM RAT HIPPOCAMPUS. F. Siddiqui*, Z. Iqbal and H. Koenig*. Neurology Dept., Northwestern University Medical School and Neurology Service, VA Lakeside Medical Center, Chicago, IL 60611.

The N-methyl-D-aspartate (NMDA) receptor is well characterized with respect to studies on excitatory effects of amino acids. In rat hippocampal synaptosomes,within 15 sec, 50-100 µM NMDA caused >3.5-fold increase in $^{45}Ca^{2+}$ influx, >3-fold increase in Ca^{2+} efflux and a 5-fold increase in the release of norepinephrine (NE) from synaptosomes. The NMDA-stimulated Ca^{2+} fluxes and NE release were inhibited by the specific NMDA-receptor antagonist, D-2-amino-5-phosphopentanoate, showing receptor mediation. The activity of the polyamine (PA) synthesis regulating enzyme, ornithine decarboxylase (ODC), increased 2- to 3-fold within 15-30 sec of NMDA exposure with a concomitant >1.5-fold elevation in putrescine concentration. The specific ODC inhibitor, α-difluoromethylornithine (DFMO), blocked NMDA-stimulated Ca^{2+} fluxes and NE release. DFMO inhibition was negated by the incorporation of putrescine in the incubation medium. Thus NMDA-controlled stimulation of synaptic transport functions appear to be dependent on PA which serve as messengers mediating cellular responses by enhancing Ca^{2+} fluxes needed for PA and Ca^{2+} dependent processes. (Supported by the VA and NIH grants HL 26835 and NS 18047)

EXCITATORY AMINO ACID EVOKED RELEASE OF -AMINOBUTYRIC ACID FROM CULTURED RETINAL NEURONS. H.-D. HOFMANN*, (SPON: G.B. Koelle), Max-Planck-Institut for Brain Research, 6000 Frankfurt, Fed. Rep. Germany

In dissociated neuronal cultures prepared from 8-day-old chick embryo retina, approximately 40% of the neurons accumulated ^{3}H-GABA via a high affinity uptake system. In contrast to depolarization by elevated KCl concentrations (56mM), glutamate, N-methyl-D-aspartate (NMDA), kainate and quisqualate were highly effective in eliciting the release of preloaded GABA, with half maximum effects at concentrations of 8µM, 80µM, 20µM and 2µM, respectively. Quisqualate evoked release was half of that observed in the presence of the other agonists. Autoradiographic analysis indicated that half of the ^{3}H-GABA accumulating cells did not respond to quisqualate, while glutamate, NMDA and kainate stimulated more than 95% of these cells. In agreement with electrophysiologically established characteristics of excitatory amino acid receptors, the NMDA receptor antagonists 2-amino-5-phosphonovalerat and MK 801, and high concentrations of Mg^2 (2-5mM) specifically inhibited the effects of NMDA without affecting responses to kainate and quisqualate. ^{3}H-GABA release, evoked by any of the agonists, was independent of external Ca^2 concentrations, but was abolished in the absence of Na . The results suggest that both NMDA and non-NMDA receptors that can trigger the release of preloaded GABA by a Ca^2 independent mechanism are present on the GABA accumulating retinal neurons.

421.3

GABA RELEASE EVOKED BY EXCITATORY AMINO ACID RECEPTOR ACTIVATION IN TYPE-2 ASTROCYTES IS INDEPENDENT OF cGMP FORMATION. G. Levi* and V. Gallo. (SPON: S. Denis-Donini) Neurobiology Section, Pathophysiology Laboratory, Istituto Superiore di Sanità, 00196 Roma, Italy.

Kainate (KA) (5-100 µM), quisqualate (QA) (5-50 µM) and glutamate (20-100 µM) stimulated ^{3}H-GABA release from type-2 astrocytes (AS) present in serum-containing cultures obtained from 8-day postnatal rat cerebella. Kynurenate (20-200 µM) largely antagonized the effects of KA and glutamate, but not that of QA. The releasing effects observed were totally Na^+-dependent, and partially Ca^{2+}-dependent in the case of KA. The releasing effect produced by 50 µM KA was largely prevented by an equimolar concentration of QA. However, 2 µM QA (ineffective by itself) generally potentiated the releasing action of KA. Cerebellar bipotential glial progenitor cells (precursors of type-2 AS) responded to KA and QA similarly to type-2 AS, and so did cultures enriched in type-2 AS obtained from neonatal cerebral cortex. The releasing effect of excitatory amino acid agonists did not appear to be related to a stimulation of cGMP formation. In fact, the level of cGMP was not significantly increased when cerebellar AS cultures were exposed to KA or QA. The lack of effect of these compounds was not due to the absence of guanylate cyclase. When the enzyme was activated by nitroprusside (200 µM) the level of cGMP increased up to 100 folds in cultures containing type-2 AS and much less in cultures devoid of type-2 AS, but ^{3}H-GABA release was unaffected. Immunofluorescence experiments using anti-guanylate cyclase antibodies showed a substantially stronger positivity in type-2 AS, glial precursors and oligodendrocytes than in type-1 AS. The excitatory amino acid agonists tested did not appear to interfere with the membrane carrier mediating GABA transport. It is concluded that type-2 AS and their precursors express two subtypes of excitatory amino acid receptors coupled to neurotransmitter release, but not to the synthesis of cGMP.

421.4

REGULATION OF EXCITATORY AMINO ACID(EAA)-INDUCED PHOSPHOINOSITIDES TURNOVER IN PRIMARY CULTURE OF RAT CEREBELLAR GRANULE CELLS BY γ-AMINOBUTYRIC ACID (GABA). Onnfoh Yu* and De-Maw Chuang (Sponsor: Ted H. Chiu). Lab. Preclin. Pharmacol., NIMH, St. Elizabeths Hosp., Wash., D.C. 20032.

Primary culture of 8-day-old rat cerebellar neurons consists 95% of granule cells (GC) and have EAA receptors of the the kainate (Ka), N-methyl-D-aspartate (NMDA), and quisqualate (Quis) subtypes. Activation of these receptors stimulates the hydrolysis of phosphoinositides (PI) in a Mg^{++}-sensitive (NMDA) and non-Mg^{++}-sensitive (Ka, Quis) manner. This study investigated the effect of 7-day exposure of GC to 50 µM GABA on PI hydrolysis induced by L-glutamate (L-Glu), Ka, NMDA, and Quis in Mg^{++}-free physiological saline solution with 20 mM Li^+. GABA pretreatment produced a significant increase in the efficacies of L-Glu, NMDA, and Quis to stimulate [^{3}H]-inositol monophosphate accumulation in GC prelabeled with [^{3}H]-myo-inositol. There was no increase in their EC_{50}. The PI hydrolysis induced by Ka was not affected by this GABA pretreatment. This suggested that 7-day GABA pretreatment produced a selective up-regulation of the PI response mediated by NMDA and quisqualate receptor subtypes. (This work was done while O.Y. was stationed at NIMH as a Nat. Res. Council resident Res. Assoc).

421.5

STIMULATION OF INOSITOL PHOSPHOLIPID HYDROLYSIS BY GLUTAMATE IN GLIAL CELLS: A POSSIBLE ROLE IN THE REGULATION OF GROWTH AND DIFFERENTIATION

F. Nicoletti*, D.F. Condorelli*, G. Magrì*, F. Ingrao*, V. Bruno*, M.V. Catania* and R. Avola* (SPON: F. Drago) Institutes of Pharmacology and Biochemistry, Catania Univ. Sch. of Med., Catania, Italy.

Excitatory amino acid receptor agonists added to glial cells in primary culture increased inositol phospholipid (PI) hydrolysis and reduced [^{3}H]thymidine incorporation with the following rank order of potency: quisqualate > glutamate > ibotenate > kainate >> NMDA. Twelve hour-pretreatment of glial cells with epidermal growth factor (EGF) (10 ng/ml) increased the potency of glutamate and quisqualate in enhancing PI hydrolysis and reducing [^{3}H]thymidine incorporation, respectively. After pretreatment with EGF, PI hydrolysis was maximally stimulated by concentrations of glutamate (5 uM) that were otherwise devoid of activity. In addition, it appears that activation of glutamate receptors induces changes in glutamine synthetase activity, a biochemical marker of glial differentiation. We hypothesize that activation of specific metabolotropic glutamate receptors activates inositol phospholipid hydrolysis and reduces proliferation of glial cells in primary cultures.

421.6

KYNURENIC ACID CONTENT IN THE RAT BRAIN INCREASES DURING THE DEVELOPMENT AND THE AGING PROCESSES AND AFTER THE ADMINISTRATION OF PRECURSORS.

F. Moroni, P. Russi,* V. Carla'*. Dept. of Pharmacology, Univ. of Florence, Viale Morgagni 65, 50134, Florence, Italy.

The brain content of kynurenic acid (KYNA), a tryptophan metabolite which acts as an antagonist of the excitatory amino acid receptors, was measured using an original method based on ion exchange chromatography and HPLC. (Carla' et al. Analyt. Biochem.169: 89-94, 1988). In newborn animals brain KYNA content was extremely low (15±3 pmol/g protein, mean±SE), but an increase of twenty times occurred during the first 60 days of life. After sexual maturation brain KYNA content continued to increase, reaching values of 747±116 pmol/g protein in 18 month old animals. Aging did not change KYNA content in the liver or the kydney. The brain KYNA content also significantly increased after the administration of tryptophan (50-500 mg/kg i.p.) or of its keto analogue: indolpyruvic acid (IPA 50-500mg/Kg i.p.). Indirect evidence suggests that IPA may be directly metabolised to KYNA and that IPA administration may be considered as a new approach to antagonize "in vivo" excitatory amino acid receptors. Several pharmacological actions of IPA: sedation, analgesia and anticonvulsive effects, may be explained by its metabolism to KYNA.

421.7

DIFFERENCES IN AGONIST AND ANTAGONIST RECOGNITION SITES OF THE NMDA-SENSITIVE GLUTAMATE RECEPTOR.

E. Fadda*, W. Danysz*, J.T. Wroblewski* and E. Costa (SPON: B.S. Jortner). Fidia-Georgetown Inst. for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, D.C. 20007

Several lines of evidence point at 3-(2-Carboxypiperazin-4-yl)propyl-1-phosphonic acid (CPP) as a competitive antagonist of the N-methyl-D-aspartate (NMDA)-sensitive glutamate recognition site. These include the inhibition of [^{3}H]glutamate binding, a similar distribution of [^{3}H]CPP and [^{3}H]glutamate binding in rat brain, and anticonvulsive actions of CPP. In our studies with rat brain synaptic membranes the specific binding of both [^{3}H]CPP and [^{3}H]glutamate was totally inhibited by 1 mM CPP, glutamate or 2-amino-5-phosphonovalerate (APV). However, interactions with modulatory sites present in the NMDA-sensitive receptor domain discriminate between CPP and glutamate recognition sites. Phencyclidine (PCP), a negative allosteric modulator, which fails to affect [^{3}H]glutamate binding, increases the affinity of CPP for its recognition site. D-serine, which acts at a positive modulatory site for the binding of [^{3}H]glutamate, downregulates [^{3}H]CPP binding. In both cases D-serine affects the affinity for the two ligands without changing the number of recognition sites. These data indicate that glutamate and CPP may bind to two different transitional states of the glutamate recognition site, inducing different conformations of the receptor complex.

421.8

FURTHER STUDIES WITH DEXTROMETHORPHAN AS AN N-METHYL-D-ASPARTATE (NMDA) ANTAGONIST.

M.G. Jones*, J. Church*, J. Millar*, M. Tomczyk* and D. Lodge* (SPON: B. Meldrum). Basic Vet. Sci. Dept., Royal Vet. Coll, London NW1, U.K.

Morphinans are part of a large series of compounds active at phencyclidine (PCP) receptors that are also NMDA antagonists (Church et al., Eur. J. Pharm., 111:185, 1985). Interest has been expressed in their therapeutic potential and in their mode of action. We have investigated the systemic potency and compared their in vitro actions with that of other PCP-like drugs.

An 80% reduction of NMDA excitation of rat spinal or brainstem neurones followed i.v. injection of dextrorphan (4-16mg/kg), PCP (0.2-0.5mg/kg) or ketamine (2-10mg/kg), whereas dextromethorphan (50mg/kg) only reduced NMDA excitation by about 20%. Quisqualate and kainate actions were not reduced by these drugs. Effects of dextrorphan and PCP were much longer lasting than that of ketamine.

On cortical wedges in vitro, IC50 values for reduction of NMDA were:- PCP 0.4uM, dextrorphan 3.2uM, ketamine 11uM and dextromethorphan 35uM. Compounds such as caramiphen, noscapine and phenytoin, ligands for a dextromethorphan/caramiphen binding site (Musacchio et al., Neuropharm., 26:997, 1987) were inactive as NMDA antagonists. With all four PCP-like drugs, development of the block of NMDA was agonist-dependent, a finding consistent with the view that they act at a similar site within the channel coupled to the NMDA receptor.

421.9

NMDA-COUPLED AND UNCOUPLED PCP RECEPTORS: TENTATIVE NEUROCHEMICAL EVIDENCE FOR PCP RECEPTOR SUBTYPES.

T.S. RAO* H.S. KIM, J. LEHMANN, L.L. MARTIN, P.L. WOOD. Res. Dept., Ciba Geigy Pharmaceuticals, Summit, NJ 07901 and G.D.SEARLE & CO.,CNS Dis. Res., c/o MONSANTO CO., St.Louis, MO 63198.

In vitro studies on striatal ACh release and ligand binding studies have indicated a high degree of correlation between N-methyl-D-aspartate (NMDA) and phencyclidine (PCP) receptors. In vivo electrophysiological studies and cGMP measurements also suggested a tight coupling between these two receptors, although receptor autoradiographic studies indicated that not all PCP receptors may be coupled to NMDA receptors. In the present investigation we have examined the effects of PCP-receptor agonists, (PCP, ketamine and MK-801) and of NMDA and sigma receptor agonists and antagonists (NMDA and CGS 19755, ditolylguanidine (DTG) and rimcazole respectively) on mesocortical dopamine (DA) metabolism. PCP-receptor agonists markedly increased DA metabolism and release only in mesocortical regions without changing the striatal DA metabolism. The changes in the mesocortical DA metabolism exhibited stereospecificity, dose and time-dependency. However, the agonists and antagonists of NMDA and sigma receptors were ineffective in altering mesocortical DA metabolism. These data suggest that the PCP receptors which modulate mesocortical DA release, are not coupled to NMDA or sigma receptors.

421.10

MULTISTATE MODEL OF N-METHYL-D-ASPARTATE RECEPTOR FUNCTIONING.

D.C. Javitt and S.R. Zukin Depts. of Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Phencyclidine (PCP) receptors have been shown to represent a site on the active conformation of the N-methyl-D-aspartate (NMDA) receptor complex. The interaction between PCP and NMDA receptors was studied using the selective PCP receptor ligand [^{3}H](+)-5-methyl-10,11-dihydro-5H-dibenzo[*a,d*]cycloheptene-5,10-imine maleate ([^{3}H]MK-801). Specific binding of [^{3}H]MK-801 was stimulated by excitatory amino acids (EAAs) with rank order of potency L-glutamate > NMDA > quisqualate > kainate confirming that this effect is mediated via NMDA receptors. The effect of EAAs on specific [^{3}H]MK-801 binding was blocked by the selective NMDA receptor antagonist D(-)2-amino-5-phosphonovaleric acid (D(-)AP5). D-serine and glycine increased the maximal efficacy but not the potency with which L-glutamate stimulated [^{3}H]MK-801 binding. The effect of D-serine and glycine was not inhibited by strychnine, suggesting that this potentiation is mediated via a non-strychnine-sensitive glycine receptor associated with the NMDA receptor complex. Scatchard analysis revealed two discrete components of [^{3}H]MK-801 binding. Incubation in the presence of L-glutamate or D-serine significantly altered the apparent densities but not the affinities of the high and low affinity components of binding. Under baseline conditions, more than 95% of binding sites were of low affinity. Incubation in the presence of D(-)AP5 led to a decrease in the apparent densities of this low affinity component of binding. Incubation in the presence of L-glutamate led to an dose-dependent increase in the apparent density of both high and low affinity [^{3}H]MK-801 binding vs. baseline and an apparent increase in the total number of [^{3}H]MK-801 binding sites. Incubation in the presence of combined D-serine and L-glutamate led to an increase in the apparent density of high affinity [^{3}H]MK-801 binding compared with incubation in the presence of either L-glutamate or D-serine alone but did not lead to a further increase in the apparent total number of binding sites. These data suggest a multistate model of NMDA receptor functioning in which glycine-like agents potentiate the ability of EAAs to convert receptors from closed to open conformations.

MAPPING OF A FROG BRAIN KAINIC ACID RECEPTOR WITH POLYCLONAL ANTIBODIES. Wenthold, R.J. Dechesne*, C.J., Hampson D.R., Wheaton*, K.D. and Oberdorfer*, M.D. Laboratory of Neuro-otolaryngology, NINCDS, NIH, Bethesda, MD. 20892

We have recently purified a kainic acid receptor from frog (Rana pipiens) brain using ion exchange chromatography and domoic acid affinity chromatography (Hampson and Wenthold, J. Biol. Chem. 263:2500, 1988). The purified receptor has high and low affinity components with dissociation constants and inhibition constants similar to those of the membrane-bound or crude soluble receptor. Polyclonal antibodies were made in rabbits with injections of 15-30 micrograms of the affinity purified preparation. Western analyses of antibody binding to whole frog brain showed several closely-spaced reactive bands which migrated with the purified receptor (M_r = 48,000). Analysis of frog liver, heart and muscle showed no corresponding immunoreactive bands. An antibody binding assay showed that the frog brain kainic acid receptor was strongly recognized by the antibody. However, the antibody did not recognize kainic acid receptors from several other species.

For immunocytochemical analysis frog brains were fixed by perfusion or immersion with 4% paraformaldehyde. Immunoreactivity was found throughout the brain with heaviest staining in the telencephalon and lowest in brain stem. The immunocytochemical distribution closely followed the distribution of the receptor determined autoradiographically using ^{3}H-kainic acid bound to cryostat sections. At higher magnifications, kainic acid immunoreactivity showed a punctate labeling, often appearing to follow neuronal fibers. Cell soma labeling was not present.

421.12

DIFFERENT TARGET SIZES OF THE NMDA RECEPTOR CHANNEL SITES AND THE SIGMA OPIATE SITE IN RAT BRAIN. E.H.F. Wong and M. Nielsen[1]. Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex, CM20 2QR, U.K.; [1]Psychopharmacological Research Laboratory, Sct. Hans Mental Hospital, DK-4000 Roskilde, Denmark.

It has previously been proposed that phencyclidine (PCP) and sigma opiates confer their psychotomimetic effects by acting on a common PCP/sigma site by virtue of their ability to generalise in a discriminative stimulus assay (Shannon, H.E., JPET 216: 543, 1983) and the similarity in pharmacological specificity when these sites were labelled by [^{3}H]-PCP and the prototypic sigma ligand (+)-[^{3}H]-SKF 10,047 (Mendelsohn et al, JPET 233: 597, 1985). Recent studies with more selective ligands for these two sites have highlighted a clear difference in their pharmacological specificity and regional distribution. The similarity in behavioural profile of these compounds are presumably due to their lack of selectivity.

We have investigated the two sites by measuring their molecular size utilizing the selective and potent N-methyl-D-aspartate/PCP receptor channel ligand [^{3}H]-MK-801 (Wong et al, PNAS 83: 7104, 1986) and the selective sigma ligand [^{3}H]-di-tolylguanidine (DTG) (Weber et al, PNAS 83: 8784, 1986). High energy inactivation of frozen rat cortex was used to determine the molecular target sizes of thiencyclohexylpiperidine-sensitive [^{3}H]-MK-801 binding and haloperidol-sensitive [^{3}H]-DTG binding giving values of 65900 ± 3500 daltons and 16700 ± 3700 daltons respectively.

These results have provided further evidence for a difference in the molecular characteristic of these two receptor binding sites.

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION I

422.1

SINGLE OR REPEATED MILD STRESS INCREASES SYNTHESIS AND RELEASE OF HYPOTHALAMIC CORTICOTROPIN-RELEASING FACTOR (CRF). D.A. Haas and S.R. George, Departments of Medicine and Pharmacology, University of Toronto, Toronto, Ontario M5S 1A8, Canada.

Since one of the prime mediators of the stress response is CRF, we examined the effect of a specific mild stress on CRF in hypothalamus of adult male rats. CRF immunoreactivity (CRF-ir) was determined using a rat CRF-specific RIA, and the relative contributions of synthesis and release assessed. A single 5 minute restraint significantly increased CRF-ir in the median eminence 24 hrs later compared to controls ($p<0.025$), with no change detected earlier. Plasma ACTH, an index of CRF release, was significantly elevated within 15 minutes of restraint ($p<0.025$). Repetition of a mild stress daily for 9 days ($p<0.01$), or a single episode of handling ($p<0.05$), both resulted in significantly increased CRF-ir in hypothalamus 24 hrs later. This change could be due to either increased CRF synthesis or inhibition of release. In order to investigate the mechanism involved, the 5 min restraint was repeated while protein synthesis was blocked with the protein synthesis inhibitor anisomycin. This resulted in significantly decreased CRF-ir in the median eminence 24 hrs later compared to vehicle-injected stressed ($p<0.005$) or to anisomycin-injected unstressed rats ($p<0.025$). Therefore, inhibition of protein synthesis prevented the expected post-stress increase in CRF-ir. These data show that mild stress increased net hypothalamic CRF content as a result of the balance between augmented synthesis and augmented release.

CHRONIC CORTICOTROPIN-RELEASING FACTOR (CRF) ALTERS RAT BRAIN BIOGENIC AMINE RECEPTORS. L.J. Grimm & D.C. Perry. Department of Pharmacology, George Washington Medical Center, Washington, D.C. 20037

CRF is believed to act as a CNS neurotransmitter, being released by stressful stimuli and initiating a multicomponent response to stress in the CNS and periphery. Stress is hypothesized to play an important role in depression: depressed patients often have a disrupted ability to regulate their CRF-ACTH-cortisol system, and exhibit abnormally high CSF levels of CRF. To examine effects of chronically high levels of CRF, rats were given i.c.v. CRF (5 ug in 5 ul saline) or saline twice daily for 10 days. Binding to several types of biogenic amine receptors was measured in different regions, and norepinephrine-stimulated cAMP was measured in cortical slices. Large increases were seen in 5HT-1 (but not 5HT-1a) binding in frontal cortex (64%), hippocampus (45%) and hypothalamus (19%) and in 5HT-2 binding in cortex (51%), striatum (40%) and cerebellum (50%). Alpha-1 adrenergic binding was unchanged except for an 18% increase in cortex. Beta adrenergic binding was only modestly affected, increasing in cortex (10%) and cerebellum (9%) and decreasing in pons/medulla (9%). Maximal level of norepinephrine-stimulated cAMP was increased. Thus chronic CRF leads to profound changes in binding and function of brain biogenic amine receptors, indicating a possible role for this peptide in depression. Supported by NIH 2SO7RR-05359-26.

STRESS-INDUCED FALL IN BLOOD PRESSURE IN HYPERTENSIVE RATS: STUDIES ON ENVIRONMENTAL, NEURAL AND NEUROENDOCRINE FACTORS. B.Bohus, J.M.Koolhaas, C.Nyakas and F.Hindriks (SPON: European Brain and Behaviour Society) Dept. of Anim.Physiology, Univ. Groningen, Haren, The Netherlands.

Rats proned for hypertension show a slight decrease in resting blood pressure (BP) a day after the stress of single social defeat (Fokkema, D.F. and Koolhaas, J.M., Physiol. Behav., 34: 33, 1985). The nature and mechanism of this unexpected stress response has been investigated in male rats with experimental (DOCA/salt) and genetic (spontaneous, SH) hypertension.

Stress of social defeat on 3 consecutive days led to a substantial fall of resting BP of DOCA/salt and SH rats, and a slight increase in WKy rats. This fall outlasted the stress for a few days. Stress of forced swimming, shuttle-box avoidance and escape training, unavoidable footshock or conditioned fear after a single unavoidable footshock led to a similar pattern of BP decrease in DOCA-salt hypertensives. Electrolytic destruction of the central nucleus of the amygdala prevented, while administration of the opioid antagonist before each expose to stress enhanced the fall of BP. It is concluded that the inverse cardiovascular response of hypertensive rats is (a) independent of the quality of the stressor stimulus in the dimension of controllability and predictability; (b) it involves limbic-forebrain neural mechanism, and (c) opioid system(s) play(s) a protective role in its induction. (Supported in part by the Dutch Heart Foundation, grant no. 84.002.)

OPIATES, CRH, AND OTHER NEUROMODULATORS AS MEDIATORS OF FEAR-INDUCED BEHAVIORAL RESPONSES IN THE INFANT PRIMATE. N.H. Kalin and S.E. Shelton*. Dept. of Psychiatry, VA Hospital and Univ. Wisconsin-Madison, Madison, WI 53792.

In work with separated infant rhesus monkeys tested in the presence of humans, we established that morphine attenuates and naloxone increases distress vocalizations (DVs) without affecting activity levels. Diazepam increases activity, while CRH increases behavioral inhibition without sedating the separated infants. Subsequent work showed that, depending on the environment in which a monkey is separated, fear elicits calls for help, withdrawal, or aggressive behaviors. To study neurochemical mechanisms underlying fear-induced behaviors, we established behavioral paradigms to selectively enhance withdrawal or aggressive behaviors. Infants briefly separated from their mothers were placed alone (A), in the presence of a human who did not maintain eye contact (NEC), or in the presence of a human who maintained continuous eye contact (EC). A infants showed high levels of locomotion and DVs. In comparison, EC increased and NEC decreased DVs ($p<.002$). Barking, an aggressive gesture occurring rarely in A or NEC, was evoked at high levels by EC ($p<.001$). Freezing and slowed locomotion, rare in A and EC, increased in NEC ($p<.001$). We are now assessing the role of endogenous opiate, CRH, and benzodiazepine systems in mediating fear-induced aggression elicited by EC and freezing behavior elicited by NEC.

EFFECTS OF ECT ON THE HPA AXIS: BASIC AND CLINICAL STUDIES. E.A. Young, M.K.-H. Schafer,* J. Herman, R. Day, S.J. Watson, and H. Akil. Mental Health Research Institute, University of Michigan, 205 Washtenaw Place, Ann Arbor, Michigan, 48109-0720.

Depression is accompanied by disturbance of the HPA axis. These abnormalities have been shown to normalize with effective treatment including ECT. However, ECT may have effects of its own on the HPA axis, since repeated seizures may act as a chronic stressor. Initial studies in patients compared the release of β-endorphin (βE) from the anterior pituitary with the first and last treatment. Overall, 11/17 individuals released more βE with the last treatment than with the first treatment. Those individuals who released less showed much shorter seizures with the final treatment than the first treatment. To explore the mechanism involved in HPA changes with repeated ECT, studies were undertaken in rats. In the rat, there is also a greater release with treatment #8 than with treatment #1. Measurement of the anterior pituitary content shows a 40% increase in βE in the chronic ECT rats. There is also an increase in CRF mRNA in the paraventricular nucleus of the hypothalamus. The adrenal weight is increased by 25%, and this results in a 3-fold increase in basal a.m. cortisol levels compared to unhandled control rats. There is also a shift in forms of βE-IR with repeated ECT. In rats, the 1st treatment releases βE over β-LPH in a ratio of 2:1. This is also the case in man. However, the eighth session releases predominantly β-LPH, with a ratio of β-LPH:βE of 2:1. In man, this shift in ratios does not appear to occur.

HUMAN CATECHOLAMINE RESPONSES TO STRESS AFTER DEXAMETHASONE, SCOPOLAMINE PLUS AMPHETAMINE, AND PLACEBO. R. L. Kohl. Universities Space Research Association, Space Biomedical Research Institute, Johnson Space Center, National Aeronautics and Space Administration, Houston, TX 77058.

Stress level was incrementally raised using a Staircase Profile Test (SPT) on a rotating chair assembly (Kohl, R. L., Aviat. Space Environ. Med., 58:125, 1987). Subjects made head movements out of the plane of rotation until stimulation of the vestibular system induced advanced nausea and multiple signs of autonomic system dysfunction (i.e., motion sickness). Dexamethasone (DEX) was loaded (3 mg/da) for 3 da and throughout a subsequent 5 da period of once daily SPTs. Scopolamine plus d-amphetamine (S/D, 0.4/5 mg) was administered 1.5 hr prior to 5 daily SPTs. Six blood samples were obtained prior to orally administered drug, and after drug on Monday and Friday, immediately before and after the SPT. Epinephrine (EPI) and norepinephrine (NE) levels generally rose following a SPT. DEX diminished or reversed the stress-induced rises in EPI and NE, particularly on Monday ($p<.05$). Poststress levels ranged from 30 to 65% of control. Lower pretest levels of NE in subjects receiving DEX indicated declining sympathoadrenal function ($p<.05$). S/D did not modulate catecholamine levels or responses to stressful motion. Because both drugs are effective antimotion sickness drugs, it follows that reduction of peripheral catecholamine levels or responses to stress probably does not underlie the therapeutic action of these agents.

422.7

SYMPATHETIC-ADRENAL MEDULLARY RESPONSE TO ACUTE FOOTSHOCK STRESS IN SHRs IS ASSOCIATED WITH HYPERACTIVITY TRAIT, NOT HYPERTENSION. E.D.Hendley, M.A.Cierpial* and R. McCarty*. Univ. Vermont, Burlington, VT 05405 and Univ. Virginia, Charlottesville, VA 22903.

Four genetically related, inbred Wistar-Kyoto rat strains were used to examine the sympathetic-adrenal medullary response to acute footshock stress. It had been shown previously (McCarty & Kopin, Physiol & Behav 21:567, 1978) that SHRs increase plasma catecholamines to higher levels than in WKY controls, in response to acute footshock. In this study we examined whether this sympathetic-adrenal medullary hyperreactivity is attributable to the hypertensive trait of SHRs or to the hyperactive trait that is also characteristic of SHRs. Two new inbred strains produced from a SHR X WKY cross are WK-HAs, that are hyperactive but not hypertensive, and WK-HTs, that are hypertensive but not hyperactive. These two strains plus SHR and WKY were subjected to acute footshock. Plasma catecholamines increased significantly higher in WK-HAs and SHRs than in WK-HTs and WKYs. Thus, sympathetic-adrenal medullary hyperreactivity is associated with the hyperactivity trait, common to SHR and WK-HA strains, and not to the hypertensive trait.

RELEASE OF PROLACTIN AND CORTISOL FOLLOWING COCAINE CESSATION IN MEN. E.M. Dax, W.W. Weddington*, N.S. Pilotte and J.J. Jaffe* (SPON: J.C. Fernando), Addiction Res. Ctr., Nat'l Inst. on Drug Abuse, Baltimore, MD 21224.

The use of cocaine is thought to alter the dynamics of central dopamine secretion which in turn may affect the secretion of prolactin (PRL), a hormone that is released rhythmically throughout the day. Cortisol is also released rhythmically but is not thought to be under dopaminergic control. To assess if these rhythms were altered in the same manner by cocaine, plasma PRL and cortisol levels were evaluated q 2 hr over at least two 24-hr periods following acute cessation of cocaine usage in 7 men who were known cocaine users and 3 non-abuser controls on the same research ward. The mean 24-hr PRL was significantly higher ($p < 0.05$) in abusers (14.6 ng/ml) than in controls (9.8 ng/ml) from days 2-10 after cessation. These men were mildly hyperprolactinemic. No diurnal variation in PRL levels was observed for up to 10 days. Interestingly, there was no difference between the lowest circulating levels of PRL in these two groups, but the cocaine abusers attained significantly greater ($p < 0.01$) peak levels of PRL throughout the day than did controls. Over the study period, normal cortisol levels and diurnal rhythms were present ($p < 0.001$) and invariant from day to day. Thus, PRL secretion is affected during cocaine withdrawal but whereas cortisol is not.

422.9

IV VENTRICULAR MEDIATION OF THE ACTH RESPONSE TO CENTRAL NICOTINIC STIMULATION. S.G. Matta*, K.M. McAllen*, and B.M. Sharp* (SPON: F.J. Wilson), Mpls. Med. Res. Fdn. and Dept. Med., Hennepin Cty. Med. Ctr. and Univ. Minnesota, Mpls, MN 55415.

Injection of a low dose of nicotine (N; 1 ug) into the III ventricle of the rat brain or of a relatively high dose (10ug) into the PVN rapidly elevates plasma ACTH to levels produced by peripherally administered N. To localize the site of action of N, current studies targeted the IV ventricle. Rats with chronic intracerebroventricular (icv) cannulae and chronic jugular cannulae, were given 0.5 ul N or buffer (B) icv; ACTH values (pg/ml) are mean ± sem:

	0 min	3 min	7 min	15 min
Buffer	26±5	24±6	27±10	40±13
N 0.25 ug	19±3	439±68	425±84	201±39
N 0.5 ug	17±4	680±96	902±168	403±85
N 2.5 ug	29±8	585±131	1064±126	615±69
N 5.0 ug	20±8	717±123	921±104	458±57

The N receptor antagonist mecamylamine (MEC, 1 mg/kg BW iv) significantly suppressed the ACTH response to N 0.25 ug icv by 70%; hexamethonium was ineffective. Moreover, MEC (40 ug) administered icv significantly suppressed the ACTH response to peripheral N (0.03 mg/kg iv). Therefore, sites mediating ACTH release following either central or peripheral administration of N may be found adjacent to the IV ventricle. (Supported by DA 03977).

A PERIPHERAL CORTICOTROPH STIMULATING FACTOR (PCSF) IS RELEASED FROM INFLAMED TISSUE IN RATS. K. M. Hargreaves* and A. H. Costello* (Spon: J. Hylden), NAB, NIDR, NIH, Bethesda, MD 20892

We have previously reported that circulating levels of immunoreactive beta endorphin (iB-END) are elevated during carrageenan (carra)-induced inflammation in rats (Abs. Soc. Neurosci. 12:374,1986). The present studies determined whether secretion of pituitary iB-END was due either to activation of central neuronal processes or to release of a PCSF from inflamed tissue. Inflammation was induced by sc injection of carra (3mg) into the plantar surface of hindpaws. Ninety min later subcutaneous perfusates of carra- and sal-treated hindpaws were collected (1ml/10min) in anesthetized rats using a coaxial system. Primary cultures of rat anterior lobe pituitary cultures were grown for 1 week prior to screening perfusates for releasing activity. Levels of iB-END were measured by RIA with data analyzed by ANOVA followed by Duncan's test. In an initial experiment, lesioning the sciatic and saphenous nerves one week prior to the study did not block the increase in circulating iB-END due to carra inflammation as compared to a sham surgery group (59.1±7.8 fm/ml and 40±6.0 fm/ml): both were significantly elevated over control levels (28.7±2.9 fm/ml; $p<.01$ for both). Pituitary cell culture secretion of iB-END due to the administration of carra perfusates (1318±188 fm/well) was significantly greater than secretion due to sal perfusates (328±32; $p<.01$) or to basal release (216±22 fm/well;$p<.01$). In a separate experiment, iB-END release due to carra perfusate (269±25 fm/well) was significantly greater than basal release (136±2 fm/well; $p<.01$) and was blocked in calcium-free media (130±2.6 fm/well;$p<.01$). The releasing activity was not due to a direct effect of carra or to substance P, CGRP, bradykinin or epinephrine. The results indicate that a PCSF in inflamed tissue stimulates iB-END release in the denervated rat and in cell cultures and suggests that hypothalamic and extrahypothalamic factors modulate secretion of iB-END in response to inflammation.

422.11

IDENTIFICATION OF INTERLEUKIN-1 RECEPTORS IN MOUSE PITUITARY CELL MEMBRANES AND AtT-20 PITUITARY TUMOR CELLS. Daniel E. Tracey* and Errol B. De Souza (SPON: S. R. Franklin). Hypersensitivity Diseases Res., The Upjohn Company, Kalamazoo, MI 49007 and Neuroscience Branch, NIDA, Addiction Research Center, Baltimore, MD 21224.

The cytokine interleukin-1 (IL-1) has a variety of effects in the brain, including stimulation of the hypothalamic-pituitary-adrenal axis. Whether IL-1 induces adrenocorticotropic hormone secretion by direct stimulation of cells in the pituitary or indirectly via hypothalamic stimulation of corticotropin releasing factor is controversial. We examined this question by measuring the binding of ^{125}I-labeled recombinant human IL-1α (rhIL-1α) to cell membranes from whole mouse or rat pituitary glands and brain regions. Specific binding of labeled IL-1 to pituitary membranes from C57BL/6 and other strains of mice was ten-fold higher than binding to Sprague-Dawley rat pituitary cell membranes, much higher than to mouse brain regions, including hypothalamus, and comparable to binding in mouse spleen. Labeled IL-1 also bound specifically to whole cells or membranes from the AtT-20 mouse pituitary tumor cell line and the EL-4 6.1 mouse thymoma cell line. The binding of labeled IL-1 to mouse pituitary, AtT-20 and EL-4 membranes was temperature dependent, saturable, and of high affinity with a K_D of 40-60 pM and B_{max} values of 9 (pituitary), 8 (AtT-20) and 116 (EL-4) fmoles/mg protein (570 and 6300 sites/cell for AtT-20 and EL-4 cells, respectively). Labeled rhIL-1α binding was specifically inhibited by rhIL-1α, rhIL-1β and an analog, rhIL-1β+, in parallel with their relative bioactivities, but not by an inactive IL-1 peptide or by unrelated peptides. These studies provide the first demonstration of IL-1 receptors in mouse pituitary and AtT-20 cell membranes with properties indistinguishable from the well-characterized EL-4 IL-1 receptors.

422.12

ACTIVATION OF THE "PERIPHERAL" BENZODIAZEPINE RECEPTOR INDUCES SECRETION OF RAT HYPOTHALAMIC CORTICOTROPIN-RELEASING HORMONE (CRH) IN VITRO. A.E. Calogero*, W.T. Gallucci*§, R. Bernardini, S.J. Listwak*§, P.W. Gold*§ and G.P. Chrousos DEB, NICHD and BPB§, NIMH, Bethesda, MD 20892

"Peripheral" benzodiazepine (pBZD) receptors are present in the pituitary, adrenal gland and testes. Although the role of these receptors in endocrine glands is largely unknown, it appears that pBZD receptor agonists modulate endocrine responses. Ro5-4864, a pBZD receptor agonist, inhibits β-endorphin secretion from AtT-20 cells, a mouse pituitary tumor cell line, and that the same agent increases basal and hCG-stimulated testosterone secretion in vitro. In the present study, we examined the involvement of the pBZD receptor in the secretion of immunoreactive CRH (iCRH) by explanted rat hypothalami. After explantation and overnight preincubation in medium 199 (M199), single hypothalami were incubated in M199 for 60 min, followed by a 40 min stimulation with graded concentrations of Ro5-4864 (Hoffman-LaRoche, Nutley, NJ) or Ro5-4864 plus the pBZD receptor antagonist PK 11195 (Dr. Le Fur, Pharmuka, France). The viability of each explant employed was tested, by examining the iCRH response to 60 mM KCl-induced depolarization. Ro5-4864 stimulated iCRH secretion in a dose-dependent fashion ($p<0.001$, ANOVA followed by Duncan multiple range test) with an ED_{50} of 3.5×10^{-8} M. The stimulatory effect of 10^{-7} M Ro5-4864 was completely antagonized by equimolar concentrations of PK 11195 ($p<0.001$, Student t test).

We conclude that activation of the pBZD receptors induces secretion of hypothalamic CRH in vitro. We speculate that the pBZD receptors may play a role in the in vivo regulation of the hypothalamic-pituitary-adrenal axis.

RECEPTOR MODULATION AND REGULATION III

423.1

DENERVATION TRIGGERS TRANSCRIPTIONAL ACTIVATION OF SKELETAL MUSCLE ACETYLCHOLINE RECEPTOR GENES. Huey-Jen Tsay* and Jakob Schmidt (SPON: S. Yazulla). Dept. of Biochemistry, State University of New York at Stony Brook, Stony Brook, New York 11794.

Transcriptional activity of acetylcholine receptor subunit genes was investigated in innervated and denervated chick skeletal muscle. The sciatic nerve of 3-day old White Leghorn chicks was sectioned unilaterally; after various intervals, nuclei were isolated from operated and control (sham operated) animals, and run-on assays performed. Nuclei were incubated with ^{32}P-UTP, and total RNA extracted and hybridized onto filters containing an excess of subunit-specific DNA. Specific transcripts were detected by autoradiography and quantitated densitometrically. A sharp increase in transcriptional activity was observed which began about 12 h after the operation and peaked 1.5 days later when transcriptional rates reached approximately 8; 6; and 5fold control levels for the alpha, gamma, and delta subunit genes, respectively. A substantial decline, to less than 2fold control levels was seen by the fourth day after the operation.

These results indicate that a denervation signal reaches the genome to induce receptor expression.

423.2

REPEATED RESERPINE TREATMENT UP-REGULATES D-1 RECEPTOR - ASSOCIATED ADENYLATE CYCLASE WITHOUT CHANGING THE DENSITY OF 3H - SCH 23390 BINDING. C. Missale, E. Nisoli*, S. Sigala*, M. Memo, P.F. Spano. Inst. Pharmacol. Brescia Univ. Sch. of Med., Brescia, Italy.

The present study investigates D-1 receptor plasticity using the 5 day treatment with reserpine as an experimental model. Male SD rats were given reserpine (1mg/Kg; s.c.) for 5 days and killed on the 5th day 2h after the last injection. Striatal D-1 receptors were studied both with 3H-SCH 23390 and by measuring cAMP formation in response to the selective agonist SKF 82526. The responsiveness of adenylate cyclase (AC) to D-1 receptor stimulation was markedly increased after reserpinization (EC-50 = 5μM in controls and EC-50 = 1.8μM in reserpine-treated rats); no significant changes were found in 3H-SCH 23390 binding site density (Bmax = 319±28 fmol/mg prot in controls and Bmax = 312 ± 30 fmol/mg prot in reserpinized rats). In addition, formation of cAMP induced by GppNHp was markedly enhanced in DA-depleted rats, while the responsiveness of AC to forskolin or to increasing concentrations of Mg-ATP was unchanged.

423.3

NEUROTENSIN REDUCES THE AFFINITY OF DOPAMINE D-2 RECEPTORS IN MEMBRANES FROM THE NEOSTRIATUM AND SUBCORTICAL LIMBIC AREAS OF THE RAT. G. von Euler*, K. Fuxe, L. Agnati* and F. Benfenati*. Dept. of Histology and Neurobiology, Karolinska Inst., Box 60400, S-104 01 Stockholm, Sweden, and Dept. of Human Physiology, University of Modena, Italy.

The effects of neurotensin in vitro were analyzed on the binding characteristics of 3H-N-propylnorapomorphine (3H-NPA, a D-2 agonist in vitro) in membrane preparations of neostriatum and subcortical limbic areas (mainly nucleus accumbens and tuberculum olfactorium) in the rat. Under equilibrium conditions neurotensin increased the KD-value of 3H-NPA binding in a concentration related (0.3 - 100 nM) biphasic fashion with a peak increase at 3 nM to 122 ± 9 % in neostriatal membranes and to 129 ± 12 % in subcortical limbic membranes. The Bmax-value of 3H-NPA binding was not significantly affected by neurotensin in the areas analyzed. Kinetic analysis revealed that neurotensin reduced the binding of 3H-NPA within 5 minutes of the addition of the peptide. These results indicate that the neurotensin receptor interacts with the D-2 receptor within the plane of the membrane. The dose needed to induce maximal modulation of D-2 receptors is below the dose needed to saturate the neurotensin receptors. Thus, the likelihood for inducing homeostatic mechanisms, such as down-regulation of the neurotensin receptor is highly reduced. In conclusion, the ability of neurotensin to reduce the affinity of central D-2 receptors may be of importance for the ethiology and treatment of schizophrenia and tardive dyskinesias.

423.4

DIFFERENTIAL REGULATION OF ALPHA-1 ADRENERGIC RECEPTOR SUBTYPES BY ELECTROCONVULSIVE SHOCK AND RESERPINE. J.A. Blendy, L.J. Grimm, D.C. Perry, K.J.Kellar. Depts. of Pharmacology, Georgetown and George Washington Univ., Washington, DC 20007

Repeated administration of electroconvulsive shock as well as chronic treatment with reserpine increases alpha-1-adrenergic receptors as labeled by ^{3}H-Prazosin (Vetulani, et.al., Brain Res. 275:392, 1983, Stockmeier, et.al. Eur J Pharm, 139:259,1987). Recent studies indicate that ^{3}H-Prazosin labels both alpha-1a and alpha-1b subtypes with equal affinity, while ^{3}H-WB4101 labels primarily the alpha 1a subtype (Morrow and Creese, Mol. Pharm 29:321,1986). To determine whether these subtypes could be regulated differentially by either reserpine or ECS we treated rats for 10-12 days with ECS or for 15 days with reserpine (.5mg/kg, i.p.). Quantitative in vitro autoradiography confirmed homogenate binding studies in that ECS increased ^{3}H-Prazosin binding in most regions of the cortex by 18-46% and in the medial amygdala by 60%. ^{3}H-WB4101 binding, on the other hand, was unaffected by ECS in all regions of the brain analyzed except in the medial amygdala where it remained increased by a lesser (15%) but significant extent. Chronic reserpine treatment increased ^{3}H-Prazosin binding in the frontal cortex by 50% while ^{3}H-WB4101 binding was not changed by this treatment. Hence, in both homogenate and autoradiography studies, ECS appears to increase ^{3}H-Prazosin binding more than ^{3}H-WB4101 binding; while reserpine, in homogenate studies, increased ^{3}H-Prazosin binding but not ^{3}H-WB4101 binding. These studies suggest that the two subtypes may be differentially regulated.

423.5

SELECTIVE REGULATION OF β_2-ADRENERGIC RECEPTORS BY DEXAMETHASONE. K.A. Neve. VAMC, Portland, OR 97207.

Glucocorticoids modulate the response of some tissues to ß-adrenergic receptor agonists by increasing the density of ß-adrenergic receptors. It is not known to what extent tissue-specific effects of glucocorticoids may be accounted for by variations in (1) the proportions of β_1 and β_2 receptors and the sensitivity of each subtype to glucocorticoids, (2) the presence of glucocorticoid receptors, or (3) the presence of other glucocorticoid-modulated proteins. Treatment of L6 myoblasts with 1 nM dexamethasone (DEX) increased the density of β_2 receptors by 9%, from 507 to 554 fmol/mg of protein. The effect of DEX treatment was dose-dependent, with an increase of 30% observed after treatment with 1 µM DEX. The DEX-induced receptor proliferation was maximal within 12 hr of the onset of treatment. The C_6 cell line is a glioma-derived line that expresses both subtypes of ß receptors. Treatment of C_6 cells with 1 µM DEX for 16 hr selectively increased the density of β_2-adrenergic receptors from 25 to 37 fmol/mg of protein (50%). A smaller increase was observed after treatment with 10 nM DEX (31%). The DEX-induced proliferation of receptors was prevented by cycloheximide (100 µM). DEX had no effect on the density of β_1-adrenergic receptors. Thus, tissue-specific effects of DEX on ß-adrenergic receptors may be due to receptor subtype specificity.

423.6

PHOSPHORYLATION OF PURIFIED AND MEMBRANE µ-OPIOID RECEPTORS ATTENUATE FUNCTIONAL COUPLING TO Gi, BUT NOT GTPγS-SENSITIVE AGONIST BINDING

H. Ueda[1], H. Harada[1]*, Y. Wada[1]*, T. Katada[2]*, M. Ui[3]*, H. Takagi[1] and M. Satoh[1]. [1]Dept. Pharmacol., Fac. of Pharmac. Sci., Kyoto Univ., Kyoto 606, [2]Tokyo Inst. Tech., Yokohama 227, [3]Univ. of Tokyo, Tokyo 113, Japan.

The regulatory mechanism of opioid signal transduction by phosphorylation of purified and membrane bound µ-opioid receptor by cyclic AMP-dependent kinase (A-kinase) was studied. The A-kinase phosphorylation of synaptic membranes from rat brains attenuated the µ-agonist (DAGO)-stimulation of low Km GTPase, while did not change the GTPγS-sensitive high affinity agonist ([^{3}H]DAGO) binding. In reconstituted preparations of purified Gi with purified µ-opioid receptor (or pertussis toxin-treated membranes) from rat brains, the A-kinase phosphorylation of receptor attenuated the µ-agonist-stimulation of low Km GTPase. These findings provide the evidence that µ-receptor possesses two different coupling sites involved in transducing the agonist signal to Gi and in increasing in high affinity agonist binding by coupling with Gi, and that the former is selectively inactivated by A-kinase.

423.7

OPIOID SENSITIVITY IN DIFFERENT STRAINS OF MICE CAN AFFECT OPIOID ANTAGONIST-INDUCED SUPERSENSITIVITY. B.C. Yoburn, S.P. Kreuscher*, V. Sierra*, M. Legatos* and S. Azimuddin*. College of Pharmacy, St. John's Univ., Queens, NY 11439.

Sensitivity to morphine's effects can vary with the strain of mouse employed. The ED_{50}s for morphine analgesia (tailflick) in Swiss-Webster mice from Charles River (CR) differed significantly from Taconic Swiss-Webster mice (T) and the C3H (Harlan SD) strain (ED_{50}s CR=6.2; T=3.8; C3H=2.5mg/kg). LD_{50}s in the Swiss-Webster strains differed significantly by more than 2-fold (LD_{50}s T=302; CR=707mg/kg). To determine if sensitivity to morphine affects the increase in opioid agonist potency produced by chronic naltrexone (NTX) treatment, mice were implanted subcutaneously for 8 days with NTX or placebo pellets. The pellets were removed and 24hr later ED_{50}s for morphine analgesia determined. NTX produced significant supersensitivity to morphine in the Swiss-Webster strains (morphine relative potencies for NTX-treated mice were T=2.0; CR=2.0). For the most sensitive strain, C3H, NTX produced a small, insignificant increase in potency (1.2). These data indicate that baseline sensitivity to morphine can determine the degree of the supersensitivity response, and raise the possibility that chronic opioid antagonist treatment produces minimal changes in opioid receptors in some morphine sensitive strains of mice. BINDING SITES FOR THE ANTIOPIATE TYR-MIF-1 DECREASE AFTER CHRONIC MORPHINE. J.E. Zadina, A.J. Kastin, L.J.Ge*, H.Gulden, & K.Bungart*. VA Med.Ctr. & Tulane Univ. Sch. Med. New Orleans, LA 70146.

Opiate addiction could involve a change in the activity or binding of endogenous antiopiates. Tyr-MIF-1 (Tyr-Pro-Leu-Gly-NH_2), which can antagonize exogenous and endogenous opiates (Life Sci.39:2153, 1986; Brain Res. 409:10,1987), could play such a role. Tyr-MIF-1 can bind to some opiate receptors with low affinity and to morphiceptin-labeled sites with high affinity, but its major action may be at its own high affinity binding site (Peptides 6:965,1985; Pharm. Biochem. Behav. 25:1303,1986). Rats given morphine (75mg) or placebo pellets (2 on day 1 and 4 on day 2) had reduced ^{125}I- and ^{3}H-Tyr-MIF-1 binding on day 5, when substantial tolerance and dependence are evident. In contrast, mu and delta opiate (^{3}H-DAGO, -DPDPE, or -DADLE labeled) receptors were increased. Acute injection of morphine (7.5 mg/kg), known to increase opiate receptors and analgesia, did not reduce Tyr-MIF-1 binding, indicating that chronic morphine administration is required to change Tyr-MIF-1 binding. The action of morphine on Tyr-MIF-1 binding sites could reflect a change in the activity of the tetrapeptide during the development of tolerance and dependence. These findings open new approaches to the study of addiction by focusing on antiopiate activity.

INOSITOLHEXAKISPHOSPHATE (PHYTIC ACID) ENHANCES $^{45}Ca^{2+}$ INFLUX AND ^{3}H-D-ASPARTATE RELEASE IN CULTURED CEREBELLAR NEURONS. P.L. Canonico, V. Bruno*, L. Fiore*, F. Nicoletti* and U. Scapagnini*. Institute of Pharmacology, Catania Univ. Sch. of Med., Catania, Italy.

Inositolhexakisphosphate ($InsP_6$), a putative metabolite of inositoltrisphosphate, may act as a neuromodulator in the CNS. $InsP_6$ accumulates in rat brain after in vivo labeling with ^{3}H-inositol and mimicks the action of glutamate when locally infused into the nucleus tractus solitarius (Vallejo, M. et al. Nature 330:656,1987). Here we report that addition of $InsP_6$ enhances $^{45}Ca^{2+}$ uptake and ^{3}H-D-aspartate release in cultured cerebellar granule cells, a homogeneous population of glutamatergic neurons. The action of $InsP_6$ is concentration-dependent, with an IC_{50} value in the low micromolar range. Stimulations of $^{45}Ca^{2+}$ uptake by glutamate and $InsP_6$ are additive, suggesting that $InsP_6$ does not bind to glutamate recognition sites. However, the stimulation of $^{45}Ca^{2+}$ influx by $InsP_6$ is attenuated in the presence of compounds which antagonize the action of endogenous glutamate at the Mg^{2+}-sensitive receptors. We suggest that $InsP_6$ potentiates glutamatergic transmission acting as a positive modulator at specific excitatory amino acid receptors in primary cultures of cerebellar neurons.

423.10

ACTIVATION OF PROTEIN KINASE C DECREASES GLUTAMATE SENSITIVITY OF CEREBELLAR PURKINJE CELLS. F. Crepel[X] and M. KRUPA[X](SPON:J. Hirsch). Lab.Neurobiologie et Neuropharmacologie du Développement. Université Paris-Sud, 91405 Orsay, France.

In the cerebellum, long term depression (LTD) of synaptic transmission between parallel fibres (PFs) and Purkinje cells (PCs) by concurrent activation of climbing fibres (CFs) is due to a selective desensitization of Quisqualate receptors of PCs to L-glutamate (Glu).

In the present experiments performed in 18 to 26 day old rat cerebellar slices in vitro, simultaneous activation of PCs by Glu and CFs led to a clear LTD of the responses of these neurones to Glu in 30% of the recorded cells while this effect was not observed for L-aspartate. This selective LTD of the sensitivity of PCs to Glu was also obtained in 22% of PCs by pairing Glu applications with calcium (Ca) spikes elicited by direct activation of the cells. Finally, selective LTD of Glu induced responses was obtained in all tested cells by bath application of 200 nM of phorbol esters known to activate protein kinase C (PKC).

This suggests that desensitization of Glu receptors during LTD is due to a coactivation of PKC by Ca and by diacylglycerol resulting from the stimulation of PCs through CFs and PFs respectively.

423.11

AMYGDALA KINDLING PRODUCES SPECIFIC DOWN-REGULATION OF HIPPOCAMPAL PHENCYCLIDINE RECEPTORS. R. Sircar, N. Ludvig*, S. L. Moshe* and S.R. Zukin. Departments of Psychiatry and Neuroscience, Neurology*, Albert Einstein College of Medicine, Bronx, NY 10461.

Phencyclidine (PCP) derivatives and drugs which elicit PCP-like behavioral effects, such as sigma opiates and dioxalanes, bind to specific PCP receptors. Recent findings suggest that PCP-like compounds mediate their neurobehavioral effects by non-competitive inhibition of brain N-methyl-D-aspartate (NMDA) receptors. D-(-)-2-amino-5-phosphonovaleric acid (D(-)APV), a highly selective NMDA receptor antagonist, abolishes the specific binding of PCP receptor radioligand N-(1-[2-thienyl]cyclohexyl)[^{3}H]piperidine ([^{3}H]TCP), suggesting that the PCP receptor may be localized to a site on the active conformation of a supramolecular PCP-NMDA receptor-ion channel complex. Neuroanatomical studies have demonstrated that the highest densities of both PCP and NMDA receptors are found in the CA_1 field of the hippocampus and the dentate gyrus. PCP and PCP-like drugs, including ketamine and the extremely potent PCP receptor ligand, MK-801, possess potent anticonvulsant properties. PCP raises the seizure threshold following amygdala kindling. Besides its direct applicability as a model of focal epilepsy ideal for the study of biochemical aspects of epileptogenesis, kindling has been used as a model of learning and synaptic plasticity. Here we report the effect of amygdala kindling on PCP receptor binding in specific rat brain regions. Rats were kindled from the left amygdala until they developed 3 consecutive stage 5 generalized seizures. Animals were sacrificed 72 hrs after the last stage 5 seizure. PCP receptor binding parameters were determined in specific brain areas. Among all the brain regions studied, consistent change was detected only in the hippocampus, where the density of PCP receptors was significantly decreased by 24.9% (B_{Max} = 3.31 pmol/mg protein versus 4.41 pmol/mg protein in sex-age matched naive animals). The apparent K_d values did not differ significantly between the experimental and control groups. Since the PCP receptor is an integral part of the NMDA receptor-ion channel complex, our results suggest that the NMDA receptor might be affected by kindling process, a concept also supported by others. PCP-NMDA receptor complex may play a critical role in the expression of kindling.

423.12

DIFFERENTIAL INTERACTIONS OF [^{3}H]2-OXO-QUAZEPAM BINDING WITH THE GABA RECEPTOR COMPLEX IN THE RAT BRAIN. R.T. McCabe[1], A. Barnett[2], L.C. Iorio*[2], and J.K. Wamsley[1]. [1]Dept of Psychiatry, U of UT Sch of Med, SLC, UT 84132 and [2]Schering-Plough Corp., Bloomfield, NJ 07003.

A metabolite of the hypnotic quazepam, 2-oxo-quazepam (2OXOQ), recognizes high-affinity benzodiazepine-1 (BZ_1) receptors. Interactions of subcomponents of the GABA complex are relevant physiological and pharmacological processes. Thus, [^{3}H]2OXOQ binding to BZ_1 receptors was investigated to further examine the functional significance of the association with the GABA complex. The binding of [^{3}H]2OXOQ to membranes was performed as previously described. Inhibition of [^{3}H]2OXOQ was examined with potencies in descending order: Rol5 1788, BCCE, CL 218,872, bicuculline, and picrotoxin. GABA, pentobarbital, and muscimol enhanced [^{3}H]2OXOQ binding. The presence of varying concentrations of bicuculline (10^{-3} to 10^{-9} M) did not entirely reverse the GABA and pentobarbital enhancement. Partial blockade of BZ_1 sites with BCCE or CL 218,872 eliminated the GABA and pentobarbital enhancement in the presence of variable concentrations of bicuculline. Additional analysis of BZ interactions with subcomponents of the GABA system also has been performed. These data provide greater evidence concerning the importance of the relationship of BZ sites with the GABA receptor complex and support previous studies of the heterogeneity of BZ receptor interactions.

STRUCTURAL RECOVERY IN AN INJURED CNS BY RADIATION TREATMENT. Z. Fuks*, A. Alfieri*, J.H. Kim*, and N. Kalderon¶ (SPON: J. Sparrow). The Rockefeller Univ.¶, and Dept. of Radiation Oncology, Memorial Sloan-Kettering Cancer Cnt., New York, NY 10021.

Injury of the CNS initiates a series of processes one of which is the formation of a scar that is composed primarily of reactive astrocytes. The objective of this study was to prevent glial scar formation by radiation therapy as the first step in an attempt to improve axonal regrowth and establishment of synaptic connectivity. Experiments were performed on the left olfactory bulb (OB) of rats, inflicting injury by surgical incision (top-to-bottom, cutting the projections of the mitral cells into the olfactory cortex). OBs were cryostat-sectioned and analysed by immunocytochemical and histological techniques. It was found that the low-dose rate γ-irradiation (80 cG/hr, total dose 20 Gy) of the injured CNS was effective in prevention of scar formation provided that it was given at 15-20 days postinjury. In OB samples which were severed and irradiated 16-18 days later, gliosis was reduced and partial structural continuity was restored along the site of incision and, in addition, up to 30% of the axotomized mitral cells population was rescued. In contrast, in the unirradiated samples, the severed OBs had degenerated, whereas at the site of incision in the partially cut OBs, cavitation was formed and at least 96% of the mitral cells frontal to the cut had vanished.

LOW-ENERGY HE-NE LASER IRRADIATION ENHANCES POTASSIUM-BUFFERING CAPABILITY OF GLIAL CELLS. I.E.Friedman, M.Belkin* and M.Schwartz, Dept. of Neurobiology, Weizmann Institute of Science, Rehovot 76100, Israel.

Injury to a mammalian CNS axon usually leads to irreversible degeneration of the nerve. We have recently found that low-energy He-Ne laser irradiation causes a delay in degeneration of injured rat or rabbit optic nerves, provided that treatment is initiated immediately after injury (Rosner et al. submitted). We propose that this effect on the early stages of neural degeneration may be related to the early ionic changes which result directly from the injury, such as an increased level of extracellular K^+. Since glial cells are known to be involved in regulation of extracellular K^+, we decided to study, in vitro, the effect of low-energy laser irradiation on C-6 glioma cells.

We have found that irradiating C-6 glioma cell cultures for 1 minute with 3.15 mW from a He-Ne laser resulted in a 24% increase in the rate of $^{86}Rb^+$ uptake by the cells. This elevated rate increased to 8-fold for the 5 minute period follwing irradiation, with elevated levels being maintained for up to 1 hour.

The initial rate of $^{22}Na^+$ uptake decreased by 39%. Substituting choline for Na^+ reduced the laser induced increase in $^{86}Rb^+$ uptake, although this level was still higher than that of non-lasered controls. In the presence of 1 mM ouabain, irradiation still increased $^{86}Rb^+$ uptake. $^{45}Ca^{2+}$ uptake was not affected, but the extent of efflux from preloaded cells was reduced by 20% following laser treatment.

We propose that low energy He-Ne laser irradiation increases the K^+-buffering capablity of glial cells, which can then act to reduce the spreading degeneration of nerves following trauma.

Supported by grant 0355 from the National Council for Research and Development.

CONTRASTING NEUROGLIAL RESPONSES IN THE AXOTOMIZED HYPOGLOSSAL AND RED NUCLEI OF RAT. K.D. Barron, M.P. Dentinger and R. Amundson*. Depts. of Neurology and Neurosurgery, Alb. Med. Coll. and Research Svce. (Neurology) Vet. Adm. Med. Ctr., Albany, NY 12208, USA.

Within 1-3 days of facial neurotomy, hyperplasia of resident, resting microglia of the facial nucleus is demonstrable by lectin histochemistry (Streit and Kreutzberg, 1987) and protoplasmic astrocytes, normally inapparent in stains for glial fibrillary acidic protein (GFAP), become strongly immunoreactive (Graeber and Kreutzberg, 1986) and transform into hypertrophied fibrous astrocytes. We have confirmed these data for hypoglossal nucleus (HN) of rats killed 3, 14 and 28 days after 12th nerve section. Striking microglial hyperplasia was evident 3 days postoperatively and persisted through 28 days. Concomitantly GFAP-rich, reactive astroglia appeared. All animals were killed under anesthesia by intra-aortic perfusion with buffered formaldehyde followed by ethanol-acetic acid (3:1). Paraffin sections were cut at 4 μ. In the neurotomized rats, unilateral cervical rubrospinal tractotomy was done also. The axotomy response in the magnocellular division of the red nucleus (RN) contrasted with that in HN in that there were no histochemically-definable microglial or astrocytic changes. Additionally, in contrast to the HN, there was no increase in neuroglia in the axotomized RN while tractotomy did not cause a change in the cytochemically-quantifiable RNA of rubral neuroglia. Perineuronal oligodendroglia, immunohistochemically identified by transferrin content, appeared also to behave differently in HN and RN after axotomy. Hypoglossal neurons regenerate severed axons while the centrally projecting neurons of RN fail to do so. This failure may relate to a lack of neuroglial response similar to that observed around successfully regenerating cranial motoneurons.

PERSISTENCE OF THE MORPHOLOGICAL CHANGES INDUCED BY GM_1 IN AXOTOMIZED, COERULOSPINAL, NORADRENERGIC NEURONS: A CHRONIC STUDY. J.W. Commissiong and G. Toffano. Dept. of Physiol., McGill Univ., Montreal, Canada H3G 1Y6 and Fidia Res. Lab., 35031 Abano Terme, Italy.

Based on previous results (Brain Res. 380, 205-215, 1986; Soc. Neurosci. Abs. 13: 1509, 1987), the present studies were done to test whether the morphological changes induced by GM_1 in the axotomized, coerulospinal neurons, persist after termination of treatment with GM_1. Postnatal day 14 and 21 rats were anesthetized with ether and spinalized at the middle thoracic region. The animals were treated with GM_1 (30 mg/kg, i.p.) daily for the first 3 weeks, then every other day for the next 18 weeks. Treatment was then stopped for up to 18 weeks before the animals were processed. The changes induced by GM_1 in the axotomized, coerulospinal neurons: 1) increase in the number of somatic dendrites; 2) increase in the length of the somatic dendrites; 3) increase in the fluorescent intensity of the cells, persisted for up to 18 weeks after GM_1 treatment was discontinued. Of 240 cells analyzed in five GM_1-treated animals, 141 or 60% exhibited the morphological effects listed above. Of 95 cells analyzed in saline-treated rats, 8 or < 10% exhibited the morphological changes observed. The GM_1-induced morphological changes in the cord did not persist in the chronic phase.

REESTABLISHMENT OF CENTRAL PATHWAYS AND REINNERVATION OF THE PERIPHERY BY SEROTONERGIC NEURONS IN THE SNAIL MELAMPUS BIDENTATUS. S. B. Moffett and T. A. Howard*. Dept. of Zoology, Wash. State Univ., Pullman, WA 99164.

This study focused on regeneration of neurons and axons which exhibit serotonin-like immunofluorescence. Two lesions were performed: 1) a pedal nerve was crushed, or 2) a pedal ganglion was removed. Axons were disrupted at the crush site and proximal and distal portions of the axons showed retraction bulbs (1-2 days) followed by the formation of tiny projections from the proximal ends into the crushed region (3-5 days). Subsequent growth of the proximal ends into the periphery kept pace with proximal-to-distal disintegration of distal processes (6-12 days).

A ganglion bud consists of some or all of the following: unification of the cerebropedal and pleuropedal connectives (5-7 days), growth between the intact pedal ganglion and the connectives (12-14 days), and regrowth of pedal nerves (12-21 days). Serotonergic neurons in the intact pedal ganglion, the parietal and visceral ganglia and the cerebral ganglia contribute to bud and pedal nerve formation. If the new growth fails to unite with the distal nerve stump, the distal serotonergic staining disappears (7-12 days); longer-term regeneration (1-6 mo) reveals highly variable serotonergic reinnervation. In some cases, identified cerebral neurons known to project to the missing pedal ganglion lose serotonergic immunofluorescence after pedal ganglion removal. (Supported by NIH RO1 NS 22896 to S.B.M.)

424.6

REGENERATION OF SEROTONERGIC AXONS PROJECTING TO THE PENIAL COMPLEX IN THE SALT MARSH PULMONATE SNAIL MELAMPUS. R.L. Ridgway, R.M. Bailey*, and S.B. Moffett. Dept. of Zoology, Washington State Univ., Pullman, WA 99164-4220.

The penial complex (vas deferens, penis, preputium) of Melampus bidentatus is innervated by an unpaired penial nerve that arises from the right cerebral ganglion (RCeG). Backfilling of this nerve with nickel chloride shows two clusters of small neurons: one in the RCeG (25-30 cells), the other in the right pedal ganglion (RPeG) (10-15 cells). The RPeG cluster exhibits serotonin-like immunoreactivity (SLIR). The processes of these cells project to the RCeG via the right cerebropedal connective, exit the RCeG via the penial nerve, and then terminate in the muscle layers of the penial complex. We examined the ability of these serotonergic cells to reinnervate the penial complex after RCeG removal. Distal axon stumps and terminal branches show evidence of degeneration within 3 days of lesioning and SLIR usually disappears from the penial complex by 7 days. Over the same period, regenerative growth is both rapid and specific. Proximal axon stumps sprout in the first 3 days after ganglionectomy and grow toward the penial nerve stump, reaching the penial complex in 10-15 days; in some regions SLIR approaches that of control specimens by 30 days after lesioning. Axonal growth cones of the serotonergic cells do not appear to fuse with distal axon stumps and their pattern of growth is not restricted to that of the original axons. (Funded in part by NIH RO1 NS 22896 to S.B.M.)

EARLY CHANGES IN PUTATIVE NUCLEAR PROTEINS FOLLOWING AXOTOMY. A. Buriani, M.J. Savage and D.J. Goldberg. Dept. of Pharmacology, Columbia U. Coll. of P&S, New York, NY 10032.

In the days following axotomy, neurons alter their synthesis of protein; regenerating neurons usually greatly increase the synthesis of a few proteins (GAPs), for example. Such effects are likely to be caused by early changes in the abundance or activity of certain nuclear proteins. We have thus examined early (i.e., 4-5 hours post-axotomy) changes in the incorporation of ^{35}S-methionine into nuclear proteins. Nuclei were obtained from R2 neurons of *Aplysia californica*. There were two main advantages in using this system: first, we obtained neuronal nuclei only and, second, we could clean nuclei individually under the dissecting microscope. Two-dimensional SDS-PAGE was then performed on the labeled proteins and a quantitative analysis demonstrated significant changes in the labeling of four proteins. One (m.w. 56 kD; pI 5.8) showed a 15x increase and another (41 kD; 5.3) a 9x increase. Two other proteins incorporated less label, one (47 kD; 5.2) showing a 4x and the other (77 kD; 6.0) a 2x decrease. We are now determining whether there are similarly early changes in phosphorylation of these or other putative nuclear proteins. Their probable nuclear location and rapid response to axotomy make these 4 proteins candidate factors in the triggering of later changes in protein synthesis.

CONDITIONED MEDIA OF REGENERATING FISHOPTIC NERVES MODULATE LAMININ LEVELS IN GLIAL CELLS. Cohen A.* and Schwartz M. The Weizmann Institute of Science, Dep. of Neurobiology, Rehovot, Israel.

The absence of laminin in the central nervous system of adult mammals might be a reason for their poor regenerative ability. Previously, we have shown that medium conditioned (CM) by regenerating fish optic nerves, applied *in situ* to injured optic nerves of adult rabbit, causes an increased appearance of laminin immunoreactive sites (Zak. et al. Brain Res. 408: 263 ,1987). This observetion suggests that CM can modulate laminin levels in glial cells. In the present study, we show that this CM can activate C-6-glioma cells to synthesize and accumulate laminin. The level of laminin immunoreactive sites was elevated in cells treated with CM, as revealed either by ELISA screening method for surface antigen or by immunofluorecence, by using laminin specific antibodies.The optimal effect was observed at concentration of 0.1 *ug/ml* protein and was even higher than the effect of 10% fetal calf serum. The identity of the laminin immunoreactive protein and the observed effect of CM on C-6-glioma cells was verified by metabolic labelling of these cells, followed by immunoprecipitation and gel-electrophoresis. The CM-induced effect was not unique to laminin as a similar elevetion could be observed in fibronectin level (another matrix protein). This CM-induced effect could be detected in the pool of high salt extractable proteins as well as in the medium. Boiling of the CM completely abolished it's activity, suggesting that a proteinaceous component(s) within the CM is responsible for the activation. Production of laminin may be a necessary step in the induction of regeneration. Therefor, application to injured mammalian CNS, of factor(s) originating from regenerating systems, that can modulate laminin production or accumulation in glial cells may circumvent one of the impediments to regeneration.

424.9

INCREASED TRANSFERRIN RECEPTOR EXPRESSION BY REGENERATING RAT FACIAL MOTOR NEURONS. M.B.Graeber*, G.Raivich* and G.W.Kreutzberg Dept. of Neuromorphology, Max Planck Institute for Psychiatry, Am Klopferspitz 18a, D-8033 Martinsried, F.R.Germany.

The distribution and time course of transferrin receptor expression were studied in normal and regenerating rat facial nuclei following cut lesion in the facial nerve.
1. Immunocytochemistry (Ox-26 monoclonal antibody) revealed a transient increase (days 2-14) in transferrin receptor expression on regenerating facial motor neurons reaching a peak by day 5 after operation. 2. This transferrin receptor immunoreactivity was absent from resting (unoperated facial nucleus) and reactive (axotomized facial nucleus) astrocytes and microglial cells. 3. ^{125}I-transferrin binding studies showed an approximately threefold increase in transferrin binding sites confined to the regenerating nucleus and with the same time course as observed by immunocytochemistry.
In summary, there is a dramatic increase in trans ferrin receptors on regenerating motor neurons. We suggest that this elevated capacity to take up transferrin and iron may play an important role for neuronal repair. (SPON: W. Streit)

424.10

MYELIN DEFICIENT MUTATION AS A TOOL FOR STUDYING THE NON-PERMISSIVE NATURE OF CNS REGENERATION. I.J. Kljavin, N.S. Dobratz*, A.J. Jacobs and R. Madison. Depts. of Neuropathology and Neuroscience, Harvard Medical School and Children's Hospital, Boston, MA 02115.

Regrowth of axons in the central nervous system (CNS) may be limited by the absence of necessary molecules supporting nerve growth and/or the presence of inhibitory molecules found in CNS myelin (Caroni & Schwab., Neuron., 1:85,1988). Growth of dorsal root ganglion (DRG) explants and dissociated cells was assessed on culture substrates taken from the CNS (optic nerve) and PNS (sciatic nerve), of wild type C57BL6 mice and shi/shi (an outbred stock). Shiverer is a hypomyelinated mutant lacking proteolipid and basic myelin proteins.

Cryostat sections of optic and sciatic nerves 6um thick were placed onto polylysine coated glass slides. Neuronal cultures of DRG explants and dissociated cells were prepared from E19 mouse embryos, plated onto the tissue substrates, maintained in DMEM+FCS+NGF, and examined by light and scanning electron microscopy. DRG's grew extensive fibers (more than 2X ganglion diameter; up to 10X cell diameter) onto sciatic nerves. Nerve fiber growth from explants onto normal optic nerve was rare, but a few dissociated DRG's showed limited growth (up to 3X cell diameter). Shiverer optic nerves supported more neuronal growth (at least 1X ganglion diameter; up to 5X cell diameter) but also supported noticably more non-neuronal growth compared to normal optic nerve. The potential influence of non-neuronal cells on nerve fiber outgrowth must be considered with this culture system. Supported by NS22404 to RM.

HOMOGRAFTED FETAL RAT CORTICAL ASTROCYTES MIGRATE FROM CORTICAL IMPLANTATION POCKETS THROUGHOUT ADULT HOST RAT BRAIN W.J. Goldberg and J.J. Bernstein. Laboratory of CNS Injury and Regeneration, VA Medical Center; Departments of Neurological Surgery and Physiology, George Washington University School Medicine, Washington, DC.

The cerebral cortices from 14 day gestation rat embryos were prelabeled with the lectin *Phaseolus vulgaris* leucoagglutin (PHAL) and homografted into freshly made implantation pockets in host cerebral cortex. Animals were used 30 and 60 days later. Paraffin sections were double labeled for glial fibrillary acidic protein (GFAP, astrocyte specific marker), and PHAL (graft specific marker). A PHAL-GFAP positive cell was a graft derived astrocyte. Graft derived astrocytes were found on glia limitans along the entire circumference of the brain, in the hippocampal commissure, corpus callosum, internal capsule, entopeduncular nucleus, habenular commissure, brachium of the superior colliculus, optic tract, optic chiasm and sensory root of the trigeminal nerve. Grafted astrocytes entered the spaces of Virchow-Robin, migrated along parenchymal blood vessels and between the ependymal and subependymal layers of the third and lateral ventricles. Graft derived astrocytes migrated ventrally through the gray matter at the base of the implantation pocket to enter the corpus callosum. The migration routes continued through intersecting nerve fiber bundles. Basal lamina (blood vessels, glia limitans, space between ependymal and subependymal layer) was another preferred migration route. Since a major constituent of basal lamina is laminin, these data suggest that laminin may be one of the cell surface recognition molecules for fetal astrocyte migration.

EFFECTS OF ARACHNOID-PIAL CELLS ON IN VITRO ASTROCYTIC GAP JUNCTIONAL COMMUNICATION MEASURED BY FLUORESCENCE RECOVERY AFTER LASER PHOTOBLEACHING. J.J. Anders. Anatomy Department, USUHS, Bethesda, MD 20814

Gap junctions are prevalent between astrocytic processes of the glia limitans. An interaction between astrocytes and arachnoid-pial cells may establish a regional specialization in the transfer of ions and small molecules by astrocytes at this important CSF-brain interface. The purpose of this study is to test the effect of the presence of arachnoid-pial cells on gap junctional conductance between astrocytes. A slide of rat arachnoid-pial cells was sandwiched against a glass slide on which primary rat astrocytes were grown. A 1mm thick rubber gasket separated the slides. The cells were cocultured for up to 72 hrs. The arachnoid-pial cells were removed and astrocytic gap junctional communication was examined. Fluorescent molecules (carboxyfluorescein) in the astrocytes were bleached with an argon ion laser. Fluorescence recovery due to gap junctional mediated diffusion of unbleached molecules from adjacent cells was monitored. The mean total recovery of fluorescence for control astrocytes was 25%. Astrocytes cocultured with arachnoid-pial cells for 48 hrs did not show a difference in the recovery of fluorescence. However, after 72 hrs of coculture, the mean total recovery of fluorescence increased to 62% ($P<0.001$ on T-test). These results indicate that the presence of arachnoid-pial cells increases astrocytic gap juctional conductance.

425.3

THE MOLECULAR FORMS OF PLASMINOGEN ACTIVATOR IN DIFFERENTIATING ASTROGLIA ARE DEVELOPMENTALLY REGULATED. N. Kalderon. The Rockefeller Univ., New York, NY 10021

Plasminogen activator (PA) is the key enzyme which initiates a cascade of extracellular proteolytic activities. Mammalian cells produce two distinct molecular forms of PA, the tissue-type -- t-PA and the urokinase-type -- u-PA. Recent studies show that the role of u-PA is in control of cell migration/invasion, while t-PA is involved primarily in fibrinolysis. It was established that the cellular PA activity levels of differentiating rodent astroglia are developmentally regulated (Kalderon et al., 1988 in Cur. Issues in Neural Regen. Res., Reier et al., eds., in press). This study focuses on the characterization of the molecular forms of PA which are produced by differentiating rat astroglia in cell culture. It was found that: 1) immature glial cells until the age corresponding to postnatal day 10 (P10) express mostly the u-PA form (M_r ~47K), 2) purified astroglia at cell ages P12-P24 produce both u-PA and t-PA forms, and 3) astrocytes at cell age P30 and/or older produce only the t-PA form (M_r ~81K). Since no PA activity was detected in purified oligodendroglia (P11) it is assumed that the glial PA activity is primarily of astroglia. It is concluded that the expression of PA molecular forms in astroglia is developmentally regulated. u-PA is the predominant form in the immature astrocyte. With cell maturation u-PA disappears while the t-PA type is being produced, and in the mature astrocyte t-PA seems to be the sole form.

Supported by NIH (NS23064).

ION CHANNELS IN RAT ASTROCYTES IN PRIMARY CELL CULTURE. C.L. Bowman *and* M. Sokabe*, *Department of Biophysical Sciences. SUNY - Buffalo, Buffalo, NY 14214.*

Using the single-channel recording technique in the cell-attached configuration, we are investigating several channels that exist in astrocytes (a type of glial cell) derived from neonatal rat brains. With a Mg-free Ringer's solution in both the bath and pipette, we observe several classes of channels. The first and most common (15 out of 22 cells) class consists of brief events lasting several msecs composed of several amplitudes. At depolarizing membrane potentials, the P_o and amplitude increases suggesting that this class of channel is either Cl or K selective. The second class of channel has a larger amplitude and a very long open duration (seconds) (9 of 22 cells). The third class of channel consists of spiky brief events, that occur in bursts at hyperpolarizing membrane potentials (5 of 22 cells). The fourth and final class of channel is a slow gating (10's of msecs) small amplitude event (2 of 22 cells).

With a 200 micromolar glutamate Ringer's solution in the pipette, the frequency of appearance of the slow gating channel increases (8 of 16 cells) and the spiky bursting events become observable at -60 mV, the normal membrane potential (5 of 16 cells). The reversal potential of the latter class of channel is near 0 mV.

We thank Drs. Malcolm Broderick and Mike Curran for useful suggestions. Supported by NIH grants R23 NS-24891 to CLB, Nitto Foundation to MS, and USPHS DK 37792 and USARO 22560 - LS to Frederick Sachs.

A STRETCH-ACTIVATED ION CHANNEL IN RAT ASTROCYTES IN PRIMARY CELL CULTURE. J-P.Ding*, X-C.Yang*, C.L.Bowman, and F. Sachs* (SPON: A. Auerbach). Department of Biophysical Sciences, SUNY - Buffalo, NY 14214.

Using single-channel patch-clamp recording, we have observed a stretch-activated channel (SAC) in rat astrocytes. The channel can be activated in both cell attached and inside-out excised patches and opens with 1-5 cm Hg suction applied to the pipette. The channel is present in more that 50% of the cells tested (ca. 100 cells), and is most easily observed with KCl filled pipettes. With 110 mM KCl in the pipette, the single channel conductance is about 40 pS and the I/V curve is linear, reversing at a membrane potential of approximately -60 mV. The probability of being open (Po) is voltage dependent and at 4 cm Hg ranges from 0.005 at -60 mV to 0.02 at +10 mV. The channel is blocked by 1 mM extracellular CsCl and partial blockage is visible at 10 micromolar. With NaCl or CsCl filled pipettes, an outward channel current become observable at membrane potentials more positive than +20 mV. These results suggest that the channel is K selective. The probability of the channel being open is linearly related to the square of the applied suction suggesting that gating energy is derived from elastic deformation of the channel as proposed by Guharay and Sachs (J.Physiol. 352:685, 1984) for SACs in chick muscle.

In-vivo, this channel may play a role in volume regulation of the glial cell and in the spatial buffering of potassium. Since the membrane is K permeable, elevation of extracellular K would cause the cell to swell. Swelling would open more K selective SACs thereby increasing the rate of K uptake and lowering the local extracellular levels of potassium.

EFFECT OF NIMODIPINE ON POTASSIUM (K^+) STIMULATED CALCIUM (Ca^{++}) UPTAKE IN ASTROCYTES. H.S. White*, A.S. Bender*, D.M. Woodbury, and L. Hertz*[1]. Dept. of Pharmacol. and Tox., Univ. of Utah, S.L.C., UT 84112 and [1]Dept. of Pharmacol., Univ. of Saskatchewan, Saskatoon, Canada S7N 0W0.

Previous attempts to demonstrate that K^+ stimulates $^{45}Ca^{++}$ uptake into astrocytes have been unsuccessful. Primary astrocytic cultures were incubated with serum-free media containing $^{45}Ca^{++}$ (0.5 μCi/ml) and K^+ (5.4 to 120 mM) for varying lengths of time (15 sec to 30 min). Uptake was terminated by 5 washes with 0.32 M (0-2°C) sucrose containing 2.0 mM EGTA. $^{45}Ca^{++}$ uptake was time-dependent and reached a peak steady-state level of 6 to 7 nmol/mg protein within 10 min. No increase in the 90-sec $^{45}Ca^{++}$ uptake was observed in cells simultaneously incubated with $^{45}Ca^{++}$ and depolarized with 50 mM K^+. In contrast, $^{45}Ca^{++}$ uptake into cells first loaded with $^{45}Ca^{++}$ for 60 sec and then depolarized with 50 mM K^+ for an additional 30 sec was increased 61% above unstimulated controls. This effect of K^+ was completely attenuated by the Ca^{++} channel blocker nimodipine (IC50: ≈2 nM). High concentrations (0.1 to 100 μM) of nimodipine only partially (20-30%) reduced basal uptake. Thus, under optimal conditions, $^{45}Ca^{++}$ uptake into primary astrocytes is enhanced by K^+. That nimodipine blocks this effect suggests that the utility of Ca^{++} blockers in ischemia and epilepsy may be related in part to an effect on astrocytes.

POTENT MODULATION OF POTASSIUM (K^+) UPTAKE INTO ASTROCYTES BY PROTEIN KINASE C (PKC). A.S. Bender*, L. Hertz*[1], D.M. Woodbury, and H.S. White* (SPON: J.U. Wei). Dept. Pharmacol. and Tox., U. of Utah, S.L.C., UT 84112 and [1]Dept. Pharmacol., U. of Sask., Saskatoon, Canada S7N OWO.

Within the CNS, astrocytes play an important role in the regulation of extracellular K^+. The mechanisms of this process are complex and include both active uptake and spatial buffering. The present investigation was initiated in order to assess the effect of phorbol esters on active $^{42}K^+$ uptake and passive $^{42}K^+$ permeability of cultured mouse cerebral cortical astrocytes according to the method of Hertz (Ann. N.Y. Acad. Sci. 481:318-333, 1986). The active phorbol ester 12-myristate 13 acetate (PMA) inhibited both active uptake of $^{42}K^+$ and passive $^{42}K^+$ permeability. Its effect on passive permeability was, however, significantly greater than its effect on active transport (IC50: ≈0.07 vs 81 μM). In contrast, the inactive congener 4α-phorbol 12,13-didecanoate did not exert any effect on K^+ permeability at concentrations up to 1 μM. Since it is widely recognized that phorbol esters activate PKC, the present results suggest that this enzyme plays an important role in modulating passive K^+ permeability into astrocytes. This is a novel mechanism whereby passive K^+ influx into astrocytes is regulated and may ultimately play a role in the regulation of CNS excitability. Intracellular pH regulation in cultured mammalian astrocytes. G. Boyarsky*, B.R. Ransom, W.G. Carlini, W.F. Boron* Depts. of Physiol. and Neurology. Yale Univ., Sch. of Med., New Haven, CT 06510.

Intracellular pH (pH_i) regulation was studied in single cultured rat astrocytes. pH_i was measured using the fluorescence excitation spectrum of the dye BCECF, and calibrated using the high K^+/nigericin technique. A 10-μm spot of light was focused on individual cells on an epifluorescence microscope. Cells were continuously superfused at 37°C. In HCO_3^--free, HEPES-buffered solution, the steady-state pH_i was ~6.9. Removal of external Na^+ caused an abrupt acidification. Rapid recovery to near initial pH_i followed the readdition of Na^+. Switching from a HEPES- to a HCO_3^-- buffered solution resulted in a rapid alkalinization of ~.2 pH. This rapid alkalinization was blocked by removal of external Na^+, inhibited by removal of external Cl^- (replaced by cyclamate$^-$),and partially inhibited by pretreatment with SITS, an inhibitor of HCO_3^- transport in other cells. In some experiments, removal of Cl^- in the presence of HCO_3^- elicited an alkalinization consistent with $Cl^-HCO_3^-$ exchange activity. Increasing external K^+ from 5 to 25 mM, which depolarizes these cells by ~30 mV, caused an abrupt and reversible alkalinization of ~.2 pH, both in the presence and in the absence of HCO_3^-. We have demonstrated that mammalian astrocytes, cells which have long been thought to play an important role in pH regulation in the brain, actively regulated their pH_i by an acid-extrusion process(es)that is dependent upon Na^+, HCO_3^- and Cl^-

IDENTIFICATION OF GLUCOCORTICOID REGULATED PROTEINS IN PURIFIED RAT CEREBRAL ASTROCYTES BY QUANTITATIVE 2D-GEL ELECTROPHORESIS. M. C. Bohn, A. Walencewicz*, M. Lynch* and J. deVellis Department of Neurobiology and Anatomy, Univ. of Rochester Medical Ctr., Rochester, NY 14642 and Mental Retardation Research Ctr. Univ. of California, Los Angeles, CA 90024.

Although glucocorticoids are known to act in target cells to regulate gene expression at the transcriptional level, only a few glucocorticoid regulated genes have been identified in the nervous system. Previous studies have demonstrated that glutamine synthetase is regulated at the transcriptional level in astrocytes. This study was undertaken to identify other glucocorticoid regulated proteins in astrocytes.

Astrocytes were prepared from newborn rat cerebral hemisphere and grown in DME-F12 with 10% fetal calf serum. After 2 weeks, oligodendrocytes were removed by shaking, and the astrocytes replated and grown to confluency. On day 37, the cells were shifted to serum-free medium and, a day later, 10^{-6}M hydrocortisone (HC) added for 48 hours. During the last 16 hours, cells were labeled with ^{35}S-methionine (1mCi/dish) in methionine-free medium in the presence of HC. Control cultures were run in parallel. High resolution 2D gels were run by Protein Databases, Inc (n=3).

600 and 1000 cellular proteins on 6-8, 10% and 3-10, 12.5% 2-D gels, respectively, were subjected to quantitative computer analysis. Approximately 5% of the proteins were significantly increased or decreased by HC, suggesting that protein metabolism in astrocytes is markedly affected by glucocorticoids. These data promise to lead to the identification of glucocorticoid regulated genes in the brain.

Supported by NIH grants NS20832 and HD 06576.

ASTROCYTES AS A SOURCE OF PROSTANOIDS IN THE CNS: RELEASE OF THROMBOXANE EVOKED BY ATP. S.Murphy* and B.Pearce* (SPON: W. Steele).Biology Dept., Open University, Milton Keynes MK7 6AA, England.

Using primary cultures of cells from neonatal rat brain we have shown that astrocytes can synthesise and release thromboxane (TX) and prostaglandins PGE_2 and $PGF_{2\alpha}$ (Murphy,S. et al.,Neurosci. Lett.,61:61,1985;Pearce,B. et al.,FEBS Lett.,211:73,1987;Jeremy,J. et al.,Brain Res.,419 364,1987). However, apart from calcium ionophores and phorbol esters, we have been unable to find a physiological stimulus for prostanoid release (Murphy,S. and Pearce,B. Prost.Leuk.Ess.Fatty Acids Rev.,1:1,1988) until now. Activation of P2-purinergic receptors on vessels by ATP prompts the release of prostanoids. In our astrocytes, ATP and ADP (EC_{50}=50uM), but not AMP nor adenosine, evoke TX release within 1 min, and this involves the activation of phospholipase A_2(PLA_2).This action of ATP and ADP is mediated by P2 receptors linked to the hydrolysis of inositol phospholipids and the mobilisation of intracellular calcium. When cells are calcium-depleted and then stimulated with ATP, there is a marked delay in TX release associated with the time taken for the calcium pool to re-fill.

SUBSTANCE P IMMUNOREACTIVE ASTROCYTES IN MULTIPLE SCLEROSIS PLAQUES. S.K. Kostyk, N.W. Kowall, S.L. Hauser* Neurology Service, Massachusetts General Hospital, Boston, MA 02114

The biology underlying the formation of demyelinated plaques in multiple sclerosis (MS) is not well understood. Recent studies have suggested the involvement of an autoimmune process. The neuropeptide, substance P, has been implicated in the inflammation of autoimmune rheumatoid arthritis. Substance P innervation of cerebral vessels and perivascular substance P immunoreactive astrocytes have been observed in normal tissue (Michel et al., Brain Res. 377:383, 1986). Using immunoperoxidase methods with well characterized rabbit polyclonal substance P antibody (INCstar), we examined human post-mortem brain tissue for substance P immunoreactivity in MS plaques. Preadsorbed antisera did not produce specific staining. Prominently stained astrocytes were found near the edge of the MS plaque often in association with small blood vessels. Many of the astrocytes were binucleate. Fewer substance P immunoreactive astrocytes were observed in the remainder of the plaque or surrounding tissue. These data suggest involvement of substance P immunoreactive astrocytes in the genesis of MS plaques.

TROPOMYOSIN ISOFORM EXPRESSION IN NORMAL AND NEOPLASTIC ASTROCYTES, P.G. Galloway, M.J. Likavec*, G. Perry, Case Western Reserve University, Cleveland, Ohio 44106

Tropomyosin is a protein associated with microfilaments of nonmuscle cells, having molecular weights from 29kD to 40kD. Changes in the expression of tropomyosin isoforms have been reported in transformed cells (J Biol Chem 258: 1983). We have examined tropomyosin isoform expression in human astrocytomas by immunostaining brain tumor sections and paper blots from brain tumor homogenates subjected to SDS-PAGE. Controls were normal white matter and white matter with reactive astrocytes. The tropomyosin antibodies used are listed as follows by tissue of origin and isoform recognition: platelet, 30, 32kD (PT); brain, 30, 35kD (BT); smooth muscle, 32, 36, 40kD (SM1) and smooth muscle, 30 and 32kD (SM2). Immunoreactivity of astrocytes in normal brain was present, but less intense than in neoplastic cells regardless of antibody. Immunoreactivity using BT was stronger than for PT for all degrees of anaplasia of tumors. This suggests that the 35kD isoform may be synthesized to a greater extent than the 30kD isoform in neoplastic cells. The immunoreactivity with PT and SM2 was maximal in the cytoplasm, whereas with BT and SM1 it was in cytoplasm and processes. Cytoplasmic staining by PT was smooth, but with BT it was granular. These data suggest that the different isoforms may have specific subcellular localization and organization in neoplastic cells. TRANSMITTER CONTENT AND AFFERENT CONNECTIONS OF PROGESTERONE RECEPTOR (PR) CONTAINING NEURONS IN THE PRIMATE HYPOTHALAMUS Leranth, C.[1,2], MacLusky, N. J.[1,2], Redmond, D. E.[3] and Naftolin, F.[1]*Yale U. Medical School, Depts. of Ob/Gyn.[1], Neuroanatomy[2] and Psychiatry[3].

The aims of this study were to determine [A] the anatomical location and transmitter content of PR containing neurons in the primate hypothalamus; and [B] the afferent connections to these neurons from other hypothalamic transmitter systems. Single- and double immunostaining techniques were employed in the hypothalamus of ovariectomized (OVX) and OVX - estrogen primed (estradiol valerate, EV; 4 days, 20mg/day, i.m.) adult Green monkeys (*Cercopithecus aethiops*), using antibodies directed against PR, glutamic acid decarboxylase (GAD), ACTH, tyrosine hydroxylase (TH) and 5-HT. Results: A dense population of PR immunoreactive neurons was observed in the hypothalamic infundibular and ventromedial (VM) nuclei, and in area between the VM nucleus and the fornix. PR immunostaining was confined to the cell nucleus and increased markedly in intensity after EV treatment. Staining was unaffected by injection of progesterone (4mg, s.c. 2h before sacrifice). In colchicine pretreated monkeys (560µg, icv. 48h prior to sacrifice), the perikarya of all PR immunoreactive neurons were immunoreactive for GAD, although the majority of GAD immunoreactive neurons did not exhibit PR staining. In non-colchicine pretreated animals, GAD, ACTH, TH, and 5-HT immunoreactive synaptic terminals were identified on PR-reactive cells. Conclusions: These results suggest that in the monkey 1) a subpopulation of the hypothalamic GAD immunoreactive (presumably GABAergic) neurons is estrogen-sensitive and represents the primary target for the direct genomic actions of circulating progesterone; 2) the activity of GABAergic PR containing neurons may be influenced by input from other neurons containing GABA, catecholamines, opiocortins and 5-HT. (Supported by NIH-HD135867 and St. Kitts Biomed. Res. Foundation).

426.2

TRANSMITTER CONTENT AND AFFERENT CONNECTIONS OF PROGESTERONE RECEPTOR (PR) CONTAINING NEURONS IN THE GUINEA-PIG HYPOTHALAMUS N.J. MacLusky, C. Leranth, T.J. Brown and F. Naftolin*, Dept. of Ob/Gyn, Yale University Medical School, New Haven CT06510.

The nature of the hypothalamic systems controlling female reproductive cyclicity remains poorly understood. In this study, we have examined the afferent innervation and phenotypic characteristics of PR containing neurons in the guinea-pig hypothalamus. Light and electron microscopic studies were performed using antibodies directed against PR, glutamic acid decarboxylase (GAD), ACTH, tyrosine hydroxylase (TH) and 5-HT. RESULTS: In OVX animals, PR immunoreactivity was not detectable. After estrogen priming, PR immunopositive cells were observed in the hypothalamic arcuate and ventromedial nuclei, and in the periventricular and medial preoptic area. PR immunostaining was confined to the cell nucleus, primarily associated with the dispersed euchromatin. The nucleolus remained unstained. In non-colchicine pretreated animals, numerous GAD, ACTH, TH, and 5-HT immunoreactive synaptic terminals were identified in contact with the PR-reactive cells. Colocalization of PR with these antigens in the same cell was not observed. After colchicine pretreatment (100µg, icv. 32h prior to sacrifice), however, cytoplasmic immunoreactivity for GAD was observed in the majority of PR immunopositive cells. CONCLUSIONS: These results suggest that in the guinea-pig a subpopulation of hypothalamic GABAergic neurons is sensitive to estrogen and progesterone. These GABAergic PR-positive neurons may act as integrators for synaptic input from a number of other systems, including other GABAergic neurons, as well as neurons containing catecholamines, proopiomelanocortin-derived peptides and 5-HT. (Supported by NIH grant No. HD135867).

Control of Tyrosine Hydroxylase in Sympathetic Ganglia by Testosterone. M.E. Goldstein, A.W. Tank and R.W. Hamill. Dept. of Neurology, University of Rochester/Monroe Community Hospital, Rochester, NY 14603.

The hypogastric ganglion (HG) of the rat sympathetic nervous system is dependent upon the continued presence of testosterone for normal development and maintenance of tyrosine hydroxylase (TH) activity. Previous studies reveal a progressive decrease in TH activity in HG of adult male rats 1, 2 and 4 weeks following castration, and replacement of testosterone immediately following castration prevents this decrease. The regulation of TH by testosterone has been examined further to determine whether changes in TH activity are a direct result of decreased mRNA and protein levels or a change in the level of activity of preexisting enzyme molecules. Dot blots of total RNA isolated from HG hybridized with a cDNA probe coding for TH reveal a decrease in TH-specific mRNA following castration. To determine changes in TH protein in HG in response to castration, increasing concentrations of TH antiserum has been incubated with homogenates of HG, and following centrifugation, TH activity in the supernatants was measured to determine what concentration of antiserum is required to remove 50% of the TH activity. TH protein decreases in a graded fashion following castration. The changes in TH mRNA and protein follow the decrease in TH activity suggesting that testosterone regulates TH at the level of transcription.

PREGNANCY-INDUCED ALTERATION OF GABA-A RECEPTOR SENSITIVITY IN THE BRAIN: AN ANTECEDENT OF POST-PARTUM BLUES? M.D. Majewska and G. Falkay*. NIDA, Addiction Research Center, Baltimore, MD 21224, and Dept. of Obst. and Gynecol., Univ. Med. School, Szeged, Hungary.

The GABA-benzodiazepine-chloride ionophore (GABA-A) receptor complex in the brain is regulated by several endogenous steroids, including tetrahydroprogesterone (THP); (Majewska, M. D., Biochem. Pharmacol., 36:3781 1987). Pregnancy is associated with greatly elevated levels of progesterone, whose metabolites may affect the function of the CNS.

We compared the binding of the GABA-A agonist, [^{3}H]-muscimol, in vitro, in brain synaptosomes from non-pregnant rats and those at various stages of pregnancy. At 10 nM ligand concentration, there was about 50% and 30% more muscimol binding on days 15 and 19 of pregnancy, respectively, as compared to non-pregnant rats. This effect was due to a reduction of the Kd of low affinity GABA-A receptor sites. The alterations of muscimol binding caused by pregnancy were similar to the effects of THP, in vitro, and followed the pattern of changes of progesterone levels in the plasma of pregnant rats. It is likely that these pregnancy-induced changes resulted from increased levels of GABA-A-agonistic progesterone metabolites in the CNS.

The results may have impact on the behavioral and psychological changes associated with pregnancy and post-partum period.

426.5

IDENTIFICATION OF A BRAIN SITE FOR THE ACTION OF MELATONIN IN THE FEMALE MONGOLIAN GERBIL (Meriones unguiculatus). S.A. Ferreira[s], M. DeVries[s] and J.D. Glass[s] (SPON: J. Walro) Dept. Biological Sciences, Kent State Univ., Kent, OH 44242.

The pineal, via its hormone melatonin, is the primary transducer of photic information for neuroendocrine regulation of seasonal breeding. The site of melatonin action in the brain is uncertain; however, studies in mice have implicated the anterior hypothalamus (AH). The present study was undertaken to examine this site in another species. In gerbils, the antigonadal action of short day (SD; 8L:16D) on reproductive tract weight (RTW; 81.4±8.0 mg vs. 151.8±16.0 mg for long day [$p<0.05$]) was mimicked by a constant dose of melatonin released from two large (3.1 mg) subcutaneous (sc) melatonin pellets (RTW=68.7±3.9 mg). A small (1.0 X 0.4 mm) pellet unilaterally placed in the AH (releasing 90 ng melatonin/day) caused significant reduction in RTW (82.7±6.7 mg) compared to gerbils with a small sc melatonin pellet (129.2±19.7 mg; $p<0.05$) or with a blank pellet in the AH (134.6±14.5 mg; $p<0.05$). The majority of the regressed ovaries lacked a corpus luteum and had significantly fewer mature follicles ($p<0.05$). These results are evidence for a hypothalamic site of melatonin action in this species.

3-D Mapping of Gonadotropin-Releasing Hormone (GnRH) in Human Basal Forebrain and Amygdala.

E.G. Stopa, E.T. Koh*, C.N. Svendsen*, W. Rogers, J. Schwaber, and J.C. King, (SPON: L.S. Adelman) Depts., of Path. and Anat. and Cell Bio., Tufts Univ. Sch. of Med., Boston, MA; Dept. of Anesth., Univ. of MA, Sch. of Med., Worcester, MA; E.I. Dupont Corp., Wilmington, DE; McLean Hospital, Belmont, MA.

Immunocytochemistry performed on 80um unembedded tissue sections was used to study the localization of GnRH-containing neurons and fibers in the basal forebrain and amygdala of 2 adult female human brains. Sections were subjected to computer-assisted image analysis to generate a three-dimensional map of immunoreactive structures. Cell bodies were concentrated in the preoptic area and basal hypothalamus, but were also evident in the supra-optic nuclei, septal region, anterior olfactory area, and cortical and medial amygdaloid nuclei. GnRH-containing fibers were observed within the hypothalamus (predominantly infundibular region and lamina terminalis), septum, stria terminalis and stria medularis, ventral globus pallidus, dorso-medial thalamus and medial and lateral olfactory stria. Many fibers could also be seen coursing along the base of the brain between the hypothalamus and cortical and medial amygdaloid nuclei. The localization of GnRH-containing cells and fibers in several of these areas represents new observations in the human brain, and suggests an important role for the amygdala in the regulation of gonadotropin secretion in man. (NIA:1K11AG00295)

426.7

MECHANISM OF ACUTE LH SECRETORY RESPONSE TO GNRH. J.-C. Hwan and M.E. Freeman*. Dept. Bio. Sci. Fla. St. U. Tallahassee 32306

GnRH stimulates LH release from gonadotrophs by initially binding to its receptor on the plasma membrane followed by activation of calcium channels and release of LH by exocytosis. In dispersed pituitary cells, studies of LH release in response to long term exposure to GnRH (>4h) have suggested the presence of a readily releasable pool and mechanisms for **de novo** protein synthesis. In the present study, we describe the mechanism involved in short term (<30 min) release of LH following challenge with GnRH. Within 30 min of exposure, the enzymatically dispersed rat pituitary cells release LH in two pulses. The first appeared at about 7 min while the second appeared at 17 min. This pattern was not apparent in the absence of GnRH. Although intracellular LH remained constant within the first 30 min, the ratio of LH secreted into the media versus total LH retained the biphasic pulsatile pattern. Preincubation with colchicine (7.5 uM), which inhibits the polymerization and cross-linking of microtubules, prevented both episodes of LH release within 30 min. Inhibition of protein synthesis by cycloheximide (1 mM,30 min) did not interfere with either phase of short term LH release. Release of LH by depolarization with KCl(59 mM) started only after about 17 min of exposure. Cheleating of calcium ion by EDTA(4 mM) did not interfere with either pulse of GnRH-stimulated LH release. In summary, dispersed pituitary cells responded to the challenge of GnRH with 2 pulses of LH release within 30 min. Thereafter, LH release increased linearly up to 4 hours. Though the cytoskeleton is involved in short term release, calcium ions are not required.

426.8

MECHANISM OF ACTION OF GONADOTROPIN-RELEASING HORMONE (GnRH) AS REVEALED BY STUDIES OF INTRACELLULAR CALCIUM IN SINGLE IDENTIFIED GONADOTROPES. Gary A. Shangold*, Shawn N. Murphy*, and Richard J. Miller (SPON: Morton E. Goldberg). Depts. of Pharm./Phys. and Ob./Gyn., Univ. of Chicago, Chicago, IL 60637.

Regulation of gonadotropin secretion by GnRH has been shown to involve calcium ion (Ca^{++}) influx through voltage-sensitive calcium channels (VSCCs). To elucidate the mechanisms whereby Ca^{++} participates in this stimulus-secretion coupling, we studied $[Ca^{++}]_i$ signals in single gonadotropes from 35-day old female rats, plated on etched-grid coverslips, identified via a reverse hemolytic plaque assay for luteinizing hormone (LH), and loaded with the Ca^{++}-sensitive fluorescent indicator FURA-2, with a microspectrofluorimeter.

Perifusion of cells with GnRH (100 pM) elicited an initial brisk rise in $[Ca^{++}]_i$, which then returned toward basal levels (~100-150 nM), only to rise again to a lower and more sustained secondary plateau phase. At higher concentrations (100 nM), the two phases of the response coalesced to produce a spike / plateau complex. Rapid-time analysis revealed that many cells demonstrated dramatic rapid oscillations in $[Ca^{++}]_i$. The first peak of $[Ca^{++}]_i$ was independent of extracellular Ca^{++}, and thus appeared to reflect mobilization of intracellular stores. The secondary plateau could be prevented by either removal of extracellular Ca^{++} or via VSCC blockade with nitrendipine (Ntd, 10 μM), and was enhanced in a Ntd-sensitive fashion by phorbol esters (TPA, 1μM). Multiple responses to GnRH in a single cell were dependent on intervening rises in $[Ca^{++}]_i$ via influx of extracellular Ca^{++} through VSCCs, which could be brought about either by reintroducing extracellular Ca^{++} into the perifusate, or by cell depolarization with 50 mM K^+. Thus, the secondary (plateau) phase appeared to be necessary for refilling intracellular Ca^{++} stores depleted during the initial (spike) phase.

These data are consistent with a mechanism by which GnRH induces an initial rise in $[Ca^{++}]_i$ via IP_3-mediated mobilization of intracellular Ca^{++} stores, followed by a sustained $[Ca^{++}]_i$ rise due to diacylglycerol / protein kinase C-mediated activation of VSCCs.

KINETICS OF CRF RNA LEVEL INCREASES AFTER ADRENALECTOMY. R.M. Uht and J. F. McKelvy. Department of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook N.Y. 11794.

To further characterize the role of glucocorticoids in the regulation of CRF biosynthesis, the increase in CRF RNA observed following adrenalectomy (ADX) and its attenuation by corticosterone (CORT) is being measured over time. Previously, CRF RNA has been shown to increase in the rat hypothalamus after 7 days of ADX (Jingami et al., Endocrinology 117:1314,1985), specifically in the paraventricular nucleus (Young et al., Neurosci. Letts 70:198, 1986; Kovacs et al, Neuroendo. 46:365, 1987). Here, hypothalamic CRF RNA level changes are being evaluated by Northern analyses at 1, 3, 5 and 7 days after ADX. Four groups of rats are being studied: normal, sham ADX + placebo, ADX + placebo, and ADX + corticosterone (CORT), 25 mg, s.c. Serum CORT levels, body weight changes and thymus weights are being measured. To quantitate the CRF RNA changes, total hypothalamic RNA from individual rats is hybridized to a rat CRF probe generated by a random primed reaction using a rat CRF cDNA clone (gift of Robert C. Thompson). In order to correct for the amount of RNA added per lane, Northern blots are stripped and reprobed with a v-ras probe (clone gift of Thomas Roberts). In all treatment groups, at time points evaluated so far (1,3 & 5 days), CRF RNA elutes as a single band at approximately 1.4 kb. CRF RNA is increased by 3 days of adrenalectomy, perhaps as early as by 1 day, and this increase is attenuated by the administration of CORT pellets. That an increase is observed as early as 3 days and is attenuated by CORT indicates that the effect of glucocorticoid removal is more rapid than previously described.

426.10

DIFFERENTIAL REGULATION OF ANTERIOR AND INTERMEDIATE PITUITARY LOBE POMC mRNA OCCURS BOTH AT THE TRANSCRIPTIONAL AND POST-TRANSCRIPTIONAL LEVEL. D. J. Autelitano*, M. Lopingco*, M. Blum and J. L. Roberts. Fishberg Research Center in Neurobiology, Mt. Sinai Med. Ctr., New York, NY 10029.

Although chronic treatment with CRF raises the level of anterior lobe (AL) POMC mRNA, several studies have shown an opposite effect in neurointermediate lobe (NIL). In an effort to elucidate the molecular mechanisms involved in this differential regulation we have examined changes in POMC gene transcription, levels of primary transcript and mature mRNA following in vivo treatment with CRF.

Adult female Sprague-Dawley rats (~200g) were injected s/c with 20μg r-CRF or vehicle and sacrificed after 30', 60' and 4hr for acute studies. For long term studies, rats were similarly injected, twice daily for 7 days. An antisense RNA probe spanning all of POMC exon I and part of intron A was used in solution hybridization / S1 nuclease protection assays to quantitate levels of primary transcript, nuclear mRNA and cytoplasmic mRNA. An in vitro nuclear run-on assay was used to determine POMC gene transcription rate.

In AL, POMC gene transcription rapidly increased to 130% of control after 30', and to 240% after 60' of CRF treatment. Consistent with these transcriptional changes, the level of POMC primary transcript rose rapidly, and was maintained at 200% of control from 60' to 4hrs after treatment. Associated with this increase in primary transcript was a consistent 30-40% decrease in the nuclear pool of mature POMC mRNA in AL. No changes in AL cytoplasmic POMC mRNA were observed following acute treatment with CRF. In contrast to the AL, transcription in NIL was maximally induced to 300% of control by 30', and had decreased to only 150% of control levels 60' after CRF injection. NIL POMC primary transcript was significantly elevated to 150% of control values at 30', but had returned to control levels by 60' post CRF injection.

Following 7d treatment with CRF, 2.5 - 3.0 fold increases in POMC cytoplasmic mRNA, nuclear mRNA and primary transcript were observed in AL. Although levels of POMC primary transcript and nuclear mRNA in NIL were not altered, long term CRF induced a 40 - 50% decrease in cytoplasmic levels of POMC mRNA in this tissue.

The differential effects on POMC mRNA in AL and NIL following long term CRF administration appear to be due initially to a difference in transcriptional responsiveness of the two cell types to CRF. Despite an acute stimulation of POMC transcription and primary transcript levels in NIL, repeated injection of CRF leads to a decrease in cytoplasmic mRNA in melanotrophs, which may in part be due to alterations in processing of primary transcript, and/or increased degradation of mature mRNA.

BETA-ENDORPHIN MEDIATES CLONIDINE STIMULATED GH RELEASE. T.O. Bruhn, P.A. Tresco*, G.P. Mueller and I.M.D. Jackson. Div. of Endocrinol., Brown Univ./R.I. Hospital, Providence, RI 02903

Clonidine (CLON), an α-2 adrenergic agonist, has been shown to stimulate GH secretion by releasing endogenous GRF, but the precise mechanism has been unclear. Since B-endorphin stimulates GH secretion by increasing GRF release, we explored its role in CLON stimulated GH secretion. B-endorphin antiserum (B-end-AS) as well as normal rabbit serum (NRS) and ACTH antiserum (ACTH-AS) as controls and somatostatin-AS (SRIF-AS) were infused slowly (1 ml) 2 hours before the administration of CLON (100 ug/kg BW:IV) via right atrial catheters. In addition, Naloxone (NAL; 2.5 mg/kg BW:IV) was given 15 minutes prior to CLON in some experiments. Blood samples were taken at 15 min intervals prior to and following CLON administration. CLON caused plasma GH to rise 14-fold to peak levels of 170 ± 36 ng/ml ($p<0.01$) at 30 min. Pretreatment of animals with B-end-AS significantly reduced CLON stimulated GH secretion to 87 ± 30 ng/ml ($p<.05$) at 30 min while ACTH-AS did not change GH secretion (197 ± 57 ng/ml). NAL pretreatment significantly blunted CLON stimulated GH release paralleling B-end-AS data (76 ± 20 ng/ml). Pretreatment with SRIF-AS significantly elevated basal GH secretion without changing CLON's ability to increase plasma GH. Conclusions: These results suggest that α-2 adrenergic activation stimulates GRF secretion, at least in part, via B-endorphin as a mediator.

ASSOCIATION OF SRIF BINDING SITES WITH GRF CONTAINING NEURONS IN THE RAT ARCUATE NUCLEUS. A. Beaudet, E. Moyse*, G. Tannenbaum, C. Kordon, J. Epelbaum. Department of Neurology and Neurosurgery, McGill University, Montreal, Canada; U.159 INSERM, Paris, France.

Growth hormone releasing hormone (GRF) and somatostatin (SRIF) are two neurohormones which directly control growth hormone secretion. In an attempt to clarify the relationship between SRIF receptors and GRF neurons in the brain, we have compared the radioautographic distribution of specifically labeled SRIF binding sites with the immunohistochemical distribution of GRF-containing neurons in sections of rat hypothalamus. SRIF binding sites were labeled in vitro using ^{125}I-Tyr0-DTrp8-SRIF (^{125}I-SRIF). GRF-immunoreactive neurons were visualized in a second group of rats by the PAP method. In radioautographs of sections incubated with ^{125}I-SRIF, the label was concentrated over small, round or oval neuronal perikarya clustered within the ventrolateral aspect of the arcuate nucleus. The distribution of these ^{125}I-SRIF-labeled cells was virtually identical to that of GRF-immunoreactive neurons detected in the same region. Moreover, the number of ^{125}I-SRIF-labeled cells was highly correlated with that of GRF-immunoreactive ones throughout the rostro-caudal extent of the nucleus (r=0.84). These results suggest that SRIF binding sites may be directly associated with the perikarya of arcuate GRF neurons. Such an association would provide an anatomical substrate for the physiological interactions postulated between SRIF and GRF in the hypothalamus. Supported by the MRC.

POSTNATAL CHANGES IN THE ELECTRICAL PROPERTIES OF MUSCLE-IDENTIFIED RAT MOTONEURONES: AN *IN VITRO* STUDY.

R. Navarrete*, K. D. Walton and R. Llinas. Dept. Physio. & Biophysics., New York Univ. School of Medicine, 550 First Ave., NY, NY 10016.

The functional properties of motoneurons are known to match those of the muscle fibres they innervate with remarkable precision. In order to assess the inductive role of motoneuron activity in muscle fibre differentiation, the membrane properties of identified motoneurons were studied in the *in vitro* neonatal (P0-12) rat hindlimb-spinal cord preparation. Motoneurons innervating soleus, extensor digitorum longus (EDL) and tibialis anterior (TA) muscles were tested. Action potentials recorded from young pups (P0-4) were clearly distinguishable from those of older pups (P6-12) by their marked afterdepolarization (ADP) and prolonged afterhyperpolarization (AHP), reflecting the presence of prominent Ca and K-Ca condutances. The ADP often reached spike threshold eliciting doublet firing. Compared to cells at P6-10, those at P2-4 had a higher input resistance (25 $\pm$ 3.4MΩ, n=9; 15$\pm$ 2.5MΩ, n=16), longer time constant (2.7 $\pm$ 0.3ms n=5; 1.8 $\pm$ 0.1ms n=11), and longer AHP (186 $\pm$ 22ms, n=6; 85 $\pm$ 17ms, n=13). Both in presumptive slow (soleus) and fast (EDL/TA) motoneurons a clear decrease in AHP duration was apparent with age and at this time it appears that the two populations may be separated using this parameter. The changes in membrane electrical properties are probably due to changes in channel density and distribution as well as morphological factors. The functional significance of such changes with respect to muscle differentiation and development of firing patterns will be discussed.

INTRACELLULAR RECORDINGS FROM MOTONEURONS DURING FICTIVE LOCOMOTION IN THE RAT SPINAL CORD IN VITRO.

B.J.Schmidt, J.C.Smith and J.L.Feldman. Dept of Medicine, Univ of Manitoba, Winnipeg Canada R3E 0W3, and Systems Neurobiology Lab, Dept of Kinesiology, UCLA, Los Angeles CA 90024.

Previous work has demonstrated that the *in vitro* neonatal rat brainstem-spinal cord is capable of generating rhythmic ventral root activity similar to motor output patterns recorded during locomotion in preparations with intact limbs (Smith et al, The FASEB J 2:2283-88,1988). The *in vitro* mammalian spinal cord offers the potential to explore neurochemical events underlying spinal locomotor systems which would not otherwise be feasible *in vivo*. In order to further investigate the validity of this preparation as a model of mammalian locomotion, intracellular records were obtained from lumbar motoneurons during fictive locomotion induced by the bath application of N-methyl-DL-aspartic acid or by electrical stimulation of dorsal root afferents. Rhythmic membrane potential oscillations that were phasically related to ventral root burst activity were regularly observed. Some neurons displayed bursts of firing superimposed on the depolarized phase of these drive potentials. These findings are similar to those reported in mammals during locomotion *in vivo*. The effect of intracellular chloride injection, membrane hyperpolarization and bath application of strychnine on inhibitory conductances associated with the oscillating potentials is currently being investigated. The *in vitro* spinal cord of the neonatal rat appears to be a useful model for the study of the spinal networks underlying the generation of locomotion in mammals.

DISCHARGE PATTERNS OF MEDULLARY RESPIRATORY NEURONS IN MAMMALIAN BRAINSTEM *IN VITRO*

J.C. Smith and J.L. Feldman. Systems Neurobiology Laboratory, Department of Kinesiology, UCLA, Los Angeles, CA 90024-1568.

In vitro preparations of neonatal rat brainstem-spinal cord generate respiratory motor patterns of brainstem origin (*J. Neurosci. Meth. 21*: 321, 1987). Our preliminary brainstem transection and electrophysiological mapping experiments in this preparation indicate that respiratory neuron populations distributed in the ventral half of the medulla in regions near and ventral to the nucleus ambiguus, retrofacial and facial nucleus are sufficient for motor pattern and rhythm generation *in vitro*. The temporal discharge patterns of respiratory neurons in these regions were characterized by extracellular and intracellular recording. Extracellular recordings were obtained with dye filled microelectrodes (7-10 MΩ); intracellular recordings were obtained with ultra-fine tip (100-140 MΩ) microelectrodes. Populations of inspiratory (I) and expiratory (E) neurons with the following discharge patterns were identified: (i) I neurons with spike discharge onset coincident with or immediately preceding I phase spinal motor output; (ii) neurons with spike discharge that brackets the I phase but are silent during the I phase; (iii) E neurons with early E phase or with continuous E phase discharge. Intracellular recordings show 5-10 mV rhythmic membrane potential oscillations underlying spike discharge in I neurons with temporal characteristics that in part account for the neuronal discharge patterns. Studies in progress are attempting to establish roles of the identified neuron populations in respiratory rhythmogenesis and premotor burst pattern generation.

CHARACTERISTICS OF MOTOR PATTERNS FOR LOCOMOTION GENERATED BY NEONATAL RAT SPINAL CORD IN VITRO.

S. Bodine-Fowler, J.C. Smith & R.R. Roy. Systems Neurobiology Lab, Dept. Kinesiology and Brain Research Inst., UCLA, Los Angeles, CA 90024-1568.

Rhythmic motor patterns for locomotion can be generated by chemical or sensory activation of spinal networks in neonatal rat spinal cord in vitro (Smith et al. FASEB J. 2:2283,1988). In order to more precisely characterize the locomotor patterns in vitro, the activation patterns of select flexor and extensor hindlimb muscles were determined from electromyographic recordings. Fine wire electrodes were inserted in the tibialis anterior (TA), lateral gastrocnemius (LG), vastus lateralis (VL), and rectus femoris (RF) of one hindlimb in spinal cord preparations retaining innervated hindlimbs in vitro. The spinal cord circuitry was activated by dopamine, N-methyl-D-aspartic acid, or L-aspartic acid in the presence of the excitatory amino acid uptake inhibitor dihydrokainic acid. Chemically-induced activation patterns were compared to those generated by sensory stimulation (tail-pinch). Comparisons were also made between in vitro locomotor patterns and those during treadmill locomotion in adult rats. The motor patterns in vitro consisted of multi-joint limb movements in which flexor and extensor muscles were reciprocally activated. The temporal relationships among the TA, LG, VL and RF were similar to those recorded during treadmill locomotion in the adult rat, although the cycle periods were much longer and there were variations in the chemically-induced patterns. The excitatory amino acids tended to enhance flexor muscle activity, whereas, extensor muscle activity was enhanced with dopamine suggesting a differential role of excitatory amino acid and dopaminergic mechanisms in locomotor pattern generation. These data establish that spinal motor pattern generating circuitry can be selectively activated in vitro to produce locomotor patterns resembling those generated in vivo.

CURRENTS MODULATING EXCITABILITY OF PONTINE RETICULAR NEURONS.

R.W. Greene, U. Gerber* & R.W. McCarley, (Spon. P.B. Dews), Harvard Med. Sch./VAMC, Brockton, MA 02401

There is evidence that neurons of the medial pontine reticular formation (mPRF) mediate the essential events of REM sleep. On passage to REM sleep these neurons depolarize 7-10 mV and exhibit a dramatic increase in firing rate. Thus, it is of interest to examine voltage sensitive currents modulating excitability and affected by this state dependent depolarization. Neurons from mPRF slices of young rats were recorded in the presence of TTX, employing a single electrode voltage clamp. We have described two physiological types of mPRF neurons: nonburst (NBN) and low threshold burst (LTBN). In NBNs (n=3) a transient outward current sensitive to 4-AP (500 uM) was observed with activation and inactivation voltage sensitivities similar to those described for I_A. In LTBNs (n=7) an inward current, absent in 0 mM Ca, 10 mM Mg, with voltage sensitivities similar to T current was observed (K currents blocked with Ba, 4-AP, TEA). Similar voltage sensitivities suggest an interaction between these two opposing currents in LTBNs, a point supported by the effects of 4-AP. These currents are kinetically separable because the time required for removal of inactivation of the inward current is greater than that for the transient outward current. Thus, when the membrane potential is depolarized, short duration hyperpolarizations may be followed by a rebound relative refractory period and long duration hyperpolarizations by a rebound low threshold burst.

CONVERGENCE OF INPUTS FROM THE HINDLIMB AND NECK ONTO NEURONS IN THE LUMBAR SPINAL CORD.

B.J. Yates, J. Kasper, E.E. Brink and V.J. Wilson. The Rockefeller Univ., New York, NY 10021.

We recorded extracellularly, in decerebrate cats, from spontaneously active L4 neurons whose activity was modulated by neck rotation, and studied the effects of stimulation of ipsilateral hindlimb nerves. Most units received convergent excitatory or inhibitory inputs from several nerves. The effective muscle nerves were quadriceps (37/43 units), sartorius (19/21) and tibialis anterior (17/34); stimulation of biceps posterior-semitendinosus, biceps anterior-semimembranosus, or gastrocnemius rarely influenced the firing of the neurons. Inputs from quadriceps and sartorius to about half of the neurons were short in latency (< 5ms from the arrival of the group I volley in L5) and from group I or group II afferents, with group II effects far more frequent (cf. Edgley and Jankowska, J. Physiol. 385, 1987). Muscle inputs to other neurons were long in latency and usually had thresholds in the group III range. Cutaneous and mixed nerves were very effective; the central latency was usually > 5 ms.

All of the neurons studied were located ventrally, predominantly ventromedially, in the gray matter. The locations of neurons receiving short-latency group I or II muscle inputs were not segregated from those of neurons receiving higher threshold and longer latency inputs.

RECURRENT INHIBITION OF INTERNEURONS MEDIATING VESTIBULAR EXCITATION OF LUMBAR SPINAL RENSHAW CELLS. H.-G. Ross. Department of Physiology, University Düsseldorf, F.R.G.

Dynamic natural stimulation of the maculae modulates the discharge pattern of lumbar spinal Renshaw cells (Ross, H-G & Wittrock, C, Pflügers Arch. 408; R54, 1987). The present study pursues the question how ongoing activity of motoneurons can be integrated into this vestibulospinal pathway. In precollicularly decerebrate cats (no relaxation, dorsal roots intact), motor activity was simulated by electrical shocks to cut ventral roots L7 or S1, while the discharges of individual Renshaw cells (recorded with implanted micro-electrodes) were monitored during transient (falling) or cyclic (quasi sinusoidal) vertical movements of the animals (amplitude 35-40 cm, peak velocity 70-100 cm/s). Of the two phases of modulation (facilitation and inhibition of Renshaw cells) occurring during such natural macular stimulation, only the facilitation was affected by antidromic conditioning excitation of alpha motor axons, being reduced to about 50% of its test value. As judged by its duration (up to 500 ms), this effect cannot be due to antidromic inhibition of motoneurons or to a post-excitatory depression of the Renshaw cells. Hence, it is concluded that Renshaw cells, in addition to their known connections, also form part of an inhibitory feedback loop to those interneurons through which they receive excitation from the vestibular maculae. MULTIPLICITY OF VESTIBULOSPINAL PATHWAYS TO THE UPPER CERVICAL SPINAL CORD OF THE CAT. A.H. Donevan*, M. Neuber*, and P.K. Rose, Department of Physiology, Queen's University, Kingston, Ontario, K7L 3N6.

Descriptions of the anatomical organization of the pathways linking the vestibular nuclei and the motoneurons supplying neck muscles are either incomplete or inconsistent. In the present study, we have taken advantage of the ability of the anterograde tracer, PHA-L to label axons and their collaterals in Golgi-like fashion in order to re-examine the vestibulospinal (VS) connections to the upper cervical spinal cord of the cat.

In each experiment, PHA-L was injected into a discrete region of the vestibular nuclei. These injection sites included regions of the medial, lateral and descending vestibular nuclei. In contrast to previous studies, VS axons were not restricted to the ventromedial and ventrolateral funiculi but were also stained bilaterally in the lateral funiculi, the dorsolateral funiculi and in the dorsal columns. Boutons were also found bilaterally and were located in lamina II through lamina IX. Although the projections of VS axons stained following injections in different sites overlapped, no two injections resulted in identical projections. This suggests that there may be a topographical link between the location of the injection and the distribution of axons and boutons. Regardless, VS projections are more widespread than previously recognized (supported by MRC of Canada).

THE SUPERIOR COLLICULUS AND THE TRIGEMINO-NECK REFLEXES OF THE CAT, V.C. Abrahams, E.D. Downey*, A.A. Kori*. Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

One of the most basic of head movements in the cat is reflex withdrawal. Consistent with this, a substantial discharge of neck motoneurons follows stimulation of the trigeminal nerve, the trigemino-neck reflex (TNR). The superior colliculus (SC) receives extensive connections from the trigeminal system and has long been presumed to play a role in the organisation of head aversion movements. The reported latency of the TNR is sufficient for the reflex pathway to go through the SC. The TNR has now been more extensively analysed and evidence for an SC pathway examined. In ketamine/chloralose anaesthetised cats the exposed superior colliculus was cooled while recording the TNR. No statistically significant effects either on latency, duration, peak amplitude or the form of the TNR were seen. Ablation of the superior colliculus too was without statistically significant effect on the TNR. The SC may play a role in controlling the excitability of the TNR. Microstimulation of the superior colliculus at current strengths of 20 μA was found to influence the amplitude and latency of the TNR.

THE LATERODORSAL AND PEDUNCULOPONTINE TEGMENTAL NUCLEI (LDT & PPT) SEND CHOLINERGIC PROJECTIONS TO THE PONTINE GIGANTOCELLULAR TEGMENTAL FIELD (PFTG) IN THE CAT. A.Mitani, K.Ito, Y.Mitani, A.E.Hallanger, B.H.Wainer, K.Kataoka and R.W.McCarley. Lab. Neuroscience, Dept. Psychiatry, Harvard Medical School/Brockton VAMC, Brockton, MA 02401.

Microinjection of cholinergic drugs into the pontine reticular formation of the cat activates a state with all of the components of natural REM sleep but the sites of origin of any natural cholinergic input have remained unknown. To determine these we used choline acetyltransferase (ChAT) immunohistochemistry combined with retrograde transport of horseradish peroxidase conjugated with wheat germ agglutinin (WGA-HRP) from small (10-30 nl) pressure injections in pontine PTG in 4 cats (TMB processing, 2 days survival). ChAT immunoreactivity was detected utilizing monoclonal antibody AB8 and the PAP method, with DAB as the chromogen. Cell counts showed that 10.2% of the total population of ChAT-labeled LDT neurons were double-labeled ipsilateral to the WGA-HRP injection site in PFTG and 3.7% contralateral. Of all ChAT-immunoreactive neurons in the PPT, 5.2% were double-labeled ipsilateral and 1.3% contralateral to the WGA-HRP injection site. An anterograde study employing a single iontophoretic injection of PHA-L (visualized by the PAP method after 5-8 days survival, 10 cats) showed that PHA-L-positive fibers with bouton-like varicosities were present in both ipsilateral and contralateral PFTG for both LDT and PPT injections, with greater density for LDT.

HOMOSYNAPTIC DEPRESSION IS SUBSTANTIAL IN SOLEUS BUT INFREQUENT IN VASTUS MEDIALIS. **J.D. Brooke, A.J. McComas[+], P. Yoon, M.K. Wilson and W.E. McIlroy Human Biology/Biophysics, University of Guelph and Department of Neuroscience[+], McMaster University Hamilton, Ontario Canada.**

Homosynaptic depression (HD) of soleus, from pairs of stimuli spaced 50 ms and 300 ms apart, was powerful in both young and old men (n=21). It was anticipated that a weaker heteronymous Ib reflex, exciting tonically contracted vastus medialis (VM) oligosynaptically, would be even more depressed by the repetitive stimulation. However, no such VM depression occurred. Evaluation of homonymous H reflexes in VM revealed HD insensitivity. To test whether pre-synaptic inhibition differentially evoked the soleus HD, weak and strong stimuli were presented separately and together. The proportionality of HD to size of first pulse mitigated against this pre-synaptic hypothesis. The factor differentiating the two muscles is not clear. Tonic contraction is not responsible, as in soleus it did not stop the HD. The differentiation of the muscles may be in after hyperpolarization and neurotransmitter turnover states. **Supported by The ALS Society (Canada) and NSERC grant # A0025.**

RECEPTOR IMPULSE INTERVAL PATTERNS DEFINE EQUIVALENT OLFACTORY STIMULI. R. C. Gesteland, Anatomy & Cell Biology, Univ. of Cincinnati Med. Ctr., OH 45267.

When an appropriate stimulus is presented to the frog olfactory epithelium those cells which respond do so with a brief increase in action potential (spike) rate. At low stimulus concentrations this results in a few evoked spikes followed by normal spontaneous activity. As concentration increases, the number of evoked spikes increases as does their frequency, resulting in a shorter and more vigorous response. This is followed by a period of depressed excitability which increases in duration with concentration. With some stimulus chemicals at high concentrations as few as 1 or 2 spikes are evoked before the onset of the quiet period. These phenomena are not due to adaptation in receptor-transducer processes Rather, they result from axon inactivation due to ion concentration changes in the olfactory nerve which are not rapidly reversed. There are two useful consequences of these observations. 1. Stimulus equivalents can be established for different stimuli. Equivalent stimuli are those concentrations of various substances which evoked equal spike activity and no subsequent period of suppression in an unadapted nose. 2. At higher concentrations, where suppression follows excitation, durations of suppression periods are a measure of the extent to which the stimulus evokes activity in neighboring axons. At one extreme, the stimulus affects only one cell in a local region, suppression is brief and due only to ionic changes following activity in and around that cell. At the other extreme, the stimulus activates a large proportion of the population, suppression is long lasting and is a measure of the number of cells stimulated and their sensitivities. Such measurements may allow description of cell selectivity and of population coding of olfactory information.

ACTIVITY PATTERNS IN THE RAT OLFACTORY SYSTEM REVEALED BY 3-D RECONSTRUCTION OF 2-DG AUTORADIOGRAPHS. G.A. Bell[1], A.H. Reisner[2*], H. Panhuber[1*], K.M. Easton[1*], D. Rosenfeld[3*] and K.K. Tsui[3*]. CSIRO, Divisions of [1]Food Processing and [2]Biotechnology, N. Ryde, Australia, 2113, and [3]School of Engineering, University of Sydney, Sydney, Australia, 2006.

The [14C]2-deoxyglucose method was used to produce autoradiographs from the olfactory epithelium, and forebrain of rats stimulated with clean or cage air, or known concentrations of the odorants ethyl acetoacetate, propionic acid or amyl acetate. The WIP package (Tsui and Rosenfeld, Proc.SPIE,767:654, 1987) was used to digitize images into a 256^2 array (256 grey levels). After background subtraction and calibration against autoradiographic standards, the images were aligned in a 256^3 array, using DIANA software (Hibbard et al., Science,236:1641, 1987) and utilities provided by the Fleurs Control Program package (Sch.Elec.Eng., U.Syd.). Three dimensional activity maps were deduced for various radiation thresholds using software developed for the VAX/VMS from the DISPLAY 82 package written by G.T. Herman et al. for analysis of CT scans (Proc.SPIE, 367:3, 1982). At low activity thresholds the epithelial maps closely resemble the complex morphology of the rat nasal turbinate region. At higher levels, the relationship between active zones and nasal geometry can be observed.

428.3

PROPERTIES OF THE OLFACTORY GENERATOR CURRENT. S. Firestein, F.S. Werblin and G.M. Shepherd, Section of Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510

Recordings of the generator current in olfactory sensory neurons were obtained with the whole cell patch clamp technique. The use of isolated cells (no mucus), and a technique which permitted us to monitor the magnitude and time course of a pressure ejected stimulus solution at the ciliary membrane, have allowed us to make several fundamental measurements of the odor generated current. 1) Dose-Response Relations. Odorous substance concentrations required for threshold responses were in the 10^{-5} Molar range. Dose-response curves followed a signmoidal shape and were very steep, saturating over less than a log unit of stimulus concentrations ($K_{\frac{1}{2}} = 2\times10^{-4}$ M). 2) Response latency. The mean latency from the arrival of the odorous substance to the onset of the current was 350 msec, range = 150-650 msec. The mean latency from the peak of the stimulus concentration to the peak of the current response was 650 msec. 3) Desensitization. The response to a maintained stimulus (20 sec) was transient with a decay half time of 9.4 seconds. Responses to short (100 msec) but saturating stimulus steps every 5 seconds showed only a 20% decrement after 20 consecutive stimulations. Supported by NS 07609 and NS 10174.

DEVELOPMENT OF A METHOD FOR PRIMARY RAT OLFACTORY NEURON CULTURE. J. Pevsner(1), G. Ronnett(1,2), L.D. Hester(1) and S.H. Snyder(1), Depts. of Neuroscience(1) and (2)Neurology, Johns Hopkins Medical Institutions, 725 North Wolfe Street, Baltimore, MD 21205.

The olfactory neuron has been thus far refractory to primary cell culture. We describe a method which yields a nearly pure olfactory neuronal population. Turbinates from 2-3 day neonatal rats are removed, transferred to MEM, and finely minced. The tissue is pelleted at low speed and incubated for one hr at 37°C in MEM containing digestion enzymes. Thereafter, the tissue is pushed through a wine screen, and pelleted. Cells are resuspended in MEM, pelleted, and resuspended in MEM-D-valine containing 15%/° dialyzed fetal calf serum and 10 μM Ara C. Cell clumps are removed by filtering through 50 μM Swinex filters. The resulting single-cell suspension is plated on laminin-coated dishes. After 5 days, 98%/° of cells remaining are bipolar, one process being long and unbranched while the other is short and divides into 6 to 8 branches.

These cells stain for olfactory marker protein (OMP) and vimentin, but are negative for keratin, GFAP, S-100, and neurofilament. Based on these and other markers, these cells appear to be neuronal with no evidence for glial, fibroblast and epithelial cellular contaminants. These cultures to our knowledge represent the first instance of olfactory neurons maintained in pure culture.

SINGLE-CHANNEL K^+ CURRENTS IN THE APICAL MEMBRANE OF NECTURUS TASTE CELLS. S.C. Kinnamon. Department of Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523 and Rocky Mountain Taste and Smell Center, University of Colorado Health Sciences Center,4200 E. 9th Ave., Denver, CO 80262.

Previous studies have shown that isolated mudpuppy taste receptor cells possess a voltage-dependent K^+ current which is modulated by sour taste stimuli (Kinnamon and Roper, J. Gen. Physiol. 91:351-371, 1988) and is restricted to the apical membrane (Kinnamon et al., Biophys. J. 53:11a, 1988). In this study, single-channel recordings in the cell-attached and inside-out configurations were used to identify the types and voltage-dependence of the K^+ selective channels involved in this conductance. A large number of K^+ channels was found on the apical membrane (classified by conductance values of approximately 27, 46, 55, 80, 90, 100, 110, 120, 132 and 180 pS). It is not clear if all of these represent different channels, or if some values represent variability of a single channel type. However, there are at least 5 different conductance channels because that many different channels were observed in a single patch. All channels showed a small probability of opening at the resting potential, and the smaller channels showed an increased probability of opening with depolarization. The largest channel was Ca^{++}-dependent as well as voltage-dependent. Studies are underway to determine the effects of taste stimuli on the different K^+ channels. (Supported by NIH grant NS20382).

mRNA TRANSLATION OF PUTATIVE ODORANT-GATED ION CHANNELS IN OVO. T.V. Getchell. (SPON: M. Getchell). Dept. Anat. Cell Biol., Wayne St. Univ. Sch. of Med., Detroit, MI 48201.

Total mRNA was isolated from olfactory mucosae (30 μg/130 mg tissue) of Rana pipiens and from 14 d old rat pup brains (8.2 mg/8 brains). About 150 ng olfactory mucosal mRNA/50 nl sterile water, about 50 ng rat brain mRNA/50 nl sterile water or 50 nl sterile water was microinjected into individual mature oocytes isolated from Xenopus laevis. Oocytes from each group were non-responsive to an odorant mixture and other ligands 2 d later. On the 3rd day, oocytes microinjected with Rana pipiens olfactory mucosal mRNA responded to an odorant mixture but not to other ligands; oocytes microinjected with rat brain mRNA responded to 5-hydroxytryptamine but not to an odorant mixture. The controls were non-responsive to the odorant mixture. The magnitude of the small-amplitude (10-20 nA), long-duration (2-3 min) current transients recorded in response to odorant stimulation was enhanced by preincubating the oocytes with 1 mM 8-bromo cyclic AMP for 10 min. The data suggest that odorant-gated ion channels associated with sensory transduction in olfactory receptor neurons were translated and inserted into the oocyte membrane. Further experiments will determine the usefulness of the Xenopus oocyte as a convenient and efficient translation system for mRNAs encoding membrane receptors, intermediate molecular entities and channel proteins associated with olfactory transduction. Experiments performed at Cold Spring Harbor Laboratory; supported by NIH-NS-16340.

CYTOCHEMICAL LOCALIZATION OF Na^+, K^+-ATPase IN GERBIL OLFACTORY EPITHELIUM. R.C. Kern*[1], T.P. Kerr*[1], and T.V. Getchell[2]. Depts. of Otolaryngology[1] and Anatomy & Cell Biology[2], Wayne State University, Detroit, MI 48201.

Olfactory epithelium consists of bipolar sensory neurons, sustentacular and basal cells. The apical knobs of the neurons, with appended cilia, are the presumed sites of odorant binding. Receptor potentials measured across this epithelium are sustained, at least in part, by active Na^+ transport. The identity and distribution of the sodium transport mechanism(s) therefore have significance for transduction. Since the enzyme Na^+, K^+-ATPase mediates active sodium flux in a variety of other systems, we have used a cytochemical technique (Ernst, J. Histochem. Cytochem., 1972) to identify sites of elevated Na^+, K^+-ATPase activity in olfactory epithelium. The procedure detects phosphate, which is released from an artificial substrate by enzyme catalytic activity, then converted to a product visible in the electron microscope. In tissues incubated for demonstration of Na^+, K^+-ATPase activity, reaction product was associated preferentially with the apical knobs, cilia, and dendrites of receptor neurons. In controls incubated with the specific Na^+, K^+-ATPase inhibitor ouabain, or with substrate deleted, only a small quantity of non-specific precipitate was observed. Our demonstration of elevated enzymatic activity in the apical portion of the receptor neuron extends recent biochemical data (Anholt, et al., J. Neurosci., 1986). Sodium flux in this region of the neuron, associated with odorant binding, may necessitate a high level of enzymatic activity to maintain the cation gradients required for sensory transduction. [Supported by NIH-T32-NS-07305, NIH-NS-16340 (TVG), and a Wayne State University Research Grant (TPK)].

PERIRECEPTOR EVENTS IN THE OLFACTORY ORGAN OF THE LOBSTER: EFFECTS ON THE DETECTION OF GLUTAMATE, TAURINE, AND PURINE NUCLEOTIDES. H.G. Trapido-Rosenthal, R.A. Gleeson, K.A. Cottrell, J.T. Littleton, S.L. Wachocki, and W.E.S. Carr. The Whitney Laboratory, U. of Florida, St. Augustine, FL 32086

The olfactory organ of the Florida spiny lobster, Panulirus argus, consists of an array of aesthetasc sensilla on the lateral branch of the antennule. Each sensillum is innervated by several hundred chemosensory neurons. Electrophysiological studies show that among these neurons are cells that respond specifically to glutamate, taurine, AMP, or ATP. It is presumed that each cell type has receptors on the cell surface that interact with the molecules that induce electrophysiological responses.

Biochemical studies demonstrate that perireceptor events occur in the sensilla which may affect the ability of odorants to interact with receptors. These events include specific, Na-dependent uptake systems that internalize the amino acid odorants, thus removing them from the receptor environment. The activity of the uptake system for glutamate appears to be enhanced by the presence of taurine. The excitatory nucleotides AMP and ATP are dephosphorylated by specific ectonucleotidases that require the presence of divalent cations. The sensillar 5'-ectonucleotidase converts AMP to the completely inactive nucleoside Ado, whereas the product of the ATPase, ADP, is a compound that strongly inhibits ATP-sensitive cells. We propose that these perireceptor events may play an important role in the olfactory process of this marine invertebrate.

CHEMOSPECIFIC DEFICITS IN TASTE DETECTION FOLLOWING SELECTIVE GUSTATORY DEAFFERENTATION. A. C. Spector*, G. Schwartz* and H. J. Grill (SPON: C. R. Gallistel). Dept. of Psychology and Monell Chem. Senses Ctr., Univ. of Penn., Phila., PA 19104.

Historically, most attempts to measure changes in the rat's gustatory sensibility following selective gustatory deafferentation have involved the exclusive use of intake tests. These tests are contaminated by non-taste factors. Moreover, intake tests have questionable sensitivity in the peri-threshold concentration range. It is therefore not surprising that researchers have found only modest or no deficits in intake preference exhibited toward NaCl and sucrose following rather extensive gustatory deafferentation. Using a conditioned avoidance procedure in which small volumes of taste stimuli serve as a signal for shock, we have found a significant 2 log unit increase in the NaCl threshold, but only a marginal increase in sucrose threshold following deafferentation of only 15% of the taste buds by bilaterally sectioning the chorda tympani nerve. The effect of bilateral glossopharyngeal nerve section (removes 64% of taste buds) on sucrose and NaCl thresholds is under investigation. The psychophysical data collected in these experiments, along with other behavioral data from our laboratory (Nitabach, this session) and recent electrophysiological findings from others, are consistent with the suggested existence of Na+ specific receptors that are primarily limited to the receptive field of the anterior tongue of the rat.

428.10

GUSTATORY IDENTIFICATION OF SODIUM IONS IS DEPENDENT ON THE CHORDA TYMPANI INNERVATION OF THE RAT TONGUE. M. Nitabach*, G. Schwartz* and H. Grill. Dept. of Psychology, University of Pennsylvania, Philadelphia, PA 19104.

The geniculate ganglion contains cells that are uniquely responsive to sodium ions. Behavioral data from this lab (Spector, this session) suggest that of the 2 neural inputs to this ganglion, the chorda tympani provides the exclusive input channel for the gustatory identification of sodium. The present study uses a paradigm developed by Nachman (1962) to further test this hypothesis. 24 male Sprague-Dawley rats were given a 10 min. 2-bottle preference test. The solutions presented were 0.4M NaCl and 0.2M NH_4Cl; cumulative salt preference (cum. 0.2M NaCl intake/total cum. fluid intake) was measured after each minute of the test period. At the time of testing all rats were 24 hr. water deprived. Rats were divided into 2 groups, intact (n=12) and bilateral chorda tympani sectioned (CTX, n=12). Within each of these 2 groups, intact and CTX, half of the rats were sodium replete and half were sodium deplete at the time of the preference test. For the intact group, salt preference was clearly a function of internal state. Sodium replete rats preferred the NH_4Cl solution; sodium deplete rats preferred the NaCl solution. Within each condition (replete or deplete), the preference must have been based solely on the orosensory properties of the two salt solutions; all preferences became significant within the first minute of the test, too soon for post-ingestive effects to have occurred. Results for the CTX group differed markedly; internal state did not alter salt preference. Both the sodium replete and sodium deplete rats preferred the NH_4Cl solution. This failure of the sodium deplete CTX rats to prefer the NaCl solution can best be explained by a deficit in the gustatory identification of sodium.

428.11

GENETIC FACTORS IN TASTE BUD DENSITY AND TASTE PREFERENCE. I.J. Miller, Jr. and G. Whitney*. Dept. Anat., Wake Forest Univ., Winston-Salem, NC 27103 and Dept. Psychol., Florida State Univ., Tallahassee, FL 32306-1051.

We hypothesize that some differences in taste sensitivity may be attributable to variation in taste bud density. The SWR/J strain of mice avoids the bitter substance sucrose octaacetate (SOA) at concentrations above .01 mmolar, and the C56BL/6J strain is indifferent to SOA at the same concentration. Electrophysiology yields smaller responses to SOA in the glossopharyngeal nerves of non-taster mice compared with tasters. We have undertaken a comparison of taste bud density in vallate papillae of these two strains of mice. Serial, paraffin sections were made and complete taste bud counts were compared. The SWR/J (taster) strain contained a mean of 169.4 (N=5, range 142-217) taste buds/ vallate papilla,and the C57BL/6J (non-taster) strain averaged 140.1 (N=10,range 102-179) taste buds/ vallate papilla. These distributions are probably significantly different ($t=-1.843$, $df=13$, $p<.05$). While the factors which determine taste preference in mice are probably more complicated than the density of taste buds in one population, a greater number of taste buds in tasters may produce a more intense taste response near the threshold of taste perception. THE CAROTID BODY CHEMORECEPTORS AS POLYMODAL SENSORS. J. Alcayaga*, R. Iturriaga* and P. Zapata. Lab. of Neurobiology, Catholic University of Chile, Santiago 1, CHILE.

All the sensory fibers of the carotid (sinus) nerve innervating the carotid body parenchyma respond to chemical changes of the blood (pO_2, pCO_2, pH), leading to their naming as chemosensory fibers. However, these afferents are also responsive to thermal and osmotic stimuli. We studied their possible responses to changes in flow and their interactions with oxygenation and temperature. Cat's carotid bodies were superfused with modified Tyrode's solution, buffered with HEPES-NaOH to pH 7.41 at 37.7°C. The frequency of discharges from the entire carotid nerve was determined at steady flow rates between 0.15 and 2.95 ml/min. The best fit for the regression of basal chemosensory activity on superfusion flow was provided by inverse sigmoid curves, resulting in maximal gains at about 0.78 and 0.86 ml/min, at 100% and 20% O_2 levels, respectively. The peak frequency evoked by 5 min flow interruptions was maximal and independent of previous superfusion flows, but the half-excitation time of responses to flow interruption in 100% O_2 equilibrated saline was minimal when preceded by superfusion at 0.7 ml/min. The response to flow interruption was also evoked under 100% N_2 equilibrated solutions, suggesting that a mechanism different from hypoxia participates in its generation. The changes in basal chemosensory activity in response to thermal increases in 1°C steps between 36 and 39°C were dependent on superfusion flows. It is concluded that the carotid nerve chemosensory discharge frequency may be determined by flow, when all other natural chemoreceptor stimuli are held constant. Thus, the carotid body chemoreceptors may act as detectors of steady levels and transient changes of low and temperature. Supported by DIUC, FONDECYT, and Gildemeister Foundation.

PROTEIN KINASE C ACTIVITY DURING CEREBRAL ISCHEMIA IN RAT. R.C. Crumrine*, J.C. LaManna, G. Dubyak*.(SPON: W.D. Lust). Depts. of Physiology/Biophysics and Neurology, Case Western Reserve University Medical School, Cleveland, OH 44106

Protein kinase C (PKC) can be activated by increased intracellular Ca2+, increased availability of diacylglycerol, and free arachidonic acid. All of these changes in the intracellular environment have been described in cerebral ischemia. In this study, we investigated the consequences of cerebral ischemia on activation of PKC. Cerebral cortex samples were obtained from rats at control and after 5, 10, 15, 20, and 30 minutes of irreversible cerebral ischemia produced by KCl induced cardiac arrest. Rats were frozen in situ at the times indicated. We did not observe an increase in PKC activity in the membrane over the time course studied, suggesting that PKC is not activated during ischemia. However, there was a significant increase in activator-independent activity in the membrane fraction after 5 minutes of ischemia. There was also a rising trend in the proportion of activator-independent activity in the membrane. PKC can be converted to an activator independent form known as protein kinase M by proteolytic cleavage secondary to attack by calpains. We propose that this may be occuring during ischemia. We also noted a general trend of decreasing inducable total PKC activity over the ischemic time course studied. Activator independent kinase activity did not correspondingly rise. This may reflect a change in PKC efficacy or a disappearance of the enzyme.

SELECTIVE VULNERABILITY OF NEURONS TO HYPOXIA-ISCHEMIA: ROLE OF CALCIUM-BINDING PROTEIN. G.G. Wasterlain*, W.Massarweh*, A.Sollas*, E.Rouk* and R.S.Sloviter. VA Med. Ctr., Sepulveda, CA 91343, UCLA Sch. of Med., and Coll. Phys. Surg., Columbia Univ. and H.Hayes Hospital.

In 7-day-old rats, bilateral carotid ligation and exposure to 8% O2 for 60 min causes extensive neocortical and hippocampal damage. The inner layer of hippocampal granule cells (HGC) is selectively vulnerable, while CA3 pyramids are resistant. HGC vulnerability decreases with age and after 18 days of age they are resistant to the same treatment, while CA3 becomes vulnerable. Immunocytochemical stains with polyclonal antibodies to calbindin D28K (calcium-binding protein, CABP) show that the vulnerable inner layer HGC at 7 days and the vulnerable CA3 cells of the adult lack CABP, while the resistant outer HGC and CA3 cells at 7 days contain CABP. While this association does not prove causality, it is compatible with a role of CABP as a buffer that limits rises in intracellular free calcium and protects neurons during hypoxia-ischemia. Supported by grants NS13515 and NS18201 from NIH and by the research service of the VA.

A NOVEL CALCIUM CHANNEL BLOCKER AND SEROTONIN S2 ANTAGONIST, (S)-EMOPAMIL, MARKEDLY REDUCES INFARCT SIZE IN RATS WITH MIDDLE CEREBRAL ARTERY OCCLUSION. H. Nakayama*, M.D. Ginsberg, W.D. Dietrich. Cereb. Vasc. Dis. Research Ctr., Univ. of Miami Sch. of Med., Miami, FL 33101

Reports of neuroprotection conferred by calcium channel (CC) blockers in cerebral ischemia have been variable and inconsistent. In this study we assessed (S)-emopamil (E), a highly permeable agent with both CC and serotonin S2 blocking properties. In 32 fed adult male Sprague-Dawley rats, focal cerebral ischemia was induced by electrocoagulating the proximal middle cerebral artery (MCA). In 3 groups, (S)-emopamil, 10 mg/kg in distilled water, was injected IP either 1) 30 min before, 2) immediately after, or 3) 1 hr after MCA occlusion. The same E dose was given twice a day until perfusion-fixation at 3 days. Brain infarct areas were measured by planimetry and volumes computed by integration.

INFARCT VOLUME (mm^3, mean±S.D., n=8 per group)

	Control	Pre-Rx	Post-Rx 0hr	Post-Rx 1hr
CORTEX	86±22	33±23	29±14	27±16
STRIATUM	30± 6	25±11	36± 4	27± 3

In the cortex, E reduced infarct volume to 31-38% of control ($p<0.01$) and pre- and post-ischemic regimens were equally effective. The effect was most apparent at the infarct periphery. Striatal infarct volume was not altered by E. (S)-emopamil appears to have great promise in treating focal cerebral ischemia.

RECEPTOR MEDIATED MODULATION OF HYPOXIA-INDUCED CALCIUM ACCUMULATION IN CULTURED NEURONS. A.W. Probert, M.L. Weber, and F.W. Marcoux. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

NMDA receptor mediated excitotoxicity has an important role in hypoxic neuronal injury in vitro. It has been proposed that neuronal calcium accumulation is pivotal in this process. We examined the effects of NMDA antagonists and other receptor modulators on hypoxia-induced Ca^{++} accumulation in cultured neurons. Cortical isolates of fetal rat brain were exposed to a 95% N_2/5% CO_2 atmosphere for four hours. Just prior to hypoxic exposure, maintenance medium was replaced with Hanks' balanced salt solution containing varying concentrations of test compounds. Intracellular calcium accumulation was quantitated by adding trace amounts of $^{45}Ca^{++}$ to the test medium. TTX (3 µM)/Mg++ (10 mM) controls were used to estimate hypoxic Ca^{++} accumulation in glial cells.

The competitive NMDA antagonists 7-APH and CPP blocked $^{45}Ca^{++}$ accumulation with IC50s of 10 and 4µM, respectively. The non-competitive NMDA antagonists, ketamine and MK-801 inhibited influx with IC50s of 2 and 0.03 µM, respectively. Each antagonist suppressed calcium accumulation to near TTX/Mg++ control levels. NMDA antagonists prevent hypoxia-induced Ca^{++} accumulation in cultured neurons.

MONOSIALOGANGLIOSIDE GM1 REDUCES ANOXIC NEURONAL DEGENERATION IN VITRO. S.D. Skaper, L. Facci, D. Milani* and A. Leon. Fidia Research Laboratories, Abano Terme, Italy.

Glutamate neurotoxicity (GNT) may participate in the neuronal cell losses associated with neurological insults such epilepsy, anoxia and stroke. GNT has been described in cortical and hippocampal neurons in vitro, and cell death under hypoxic conditions. In cultured cerebellar granule cells, GNT has been reported to be prevented by pretreatment with gangliosides GT1b, GD1a, and GM1 (Favaron, M. et al., FASEB J., 2:A824, 1988). We now report ganglioside effects in anoxic-exposed cultures of granule cells from day 8 rat cerebellum. Chemical anoxia, in cells between 8 and 12 days in vitro, was produced by a pulse addition of rotenone (0.1 µM for 1 hr) in the absence of Mg^{2+}. Widespread degeneration of neuronal cell bodies and their neurite network was seen the following day. This neuronal injury was abolished by the specific NMDA receptor antagonist PCP, suggesting an action of endogenous glutamate at this receptor. Pre- or concurrent treatment (>30 min) with ganglioside GM1 or its inner ester derivative largely prevented (>70%) the ensuing neuronal death, even after 4 days (ED50= 25 µM); degeneration by added glutamate was likewise reduced. These results support the observed beneficial effects of the gangliosides in ischemic brain injury in vivo.

429.6

MK-801 PROTECTS THE HIPPOCAMPAL SLICE FROM HYPOXIC INJURY IN THE ABSENCE OF EXTRACELLULAR CALCIUM. J.E. Parsons,* M.D. Fairchild,* R.A. Wallis* and C.G. Wasterlain* (SPON: N. Rosenthal). Epilepsy Res. Lab., VAMC, Sepulveda, CA 91343, Dpt. Neurology and Brain Res. Institute, UCLA Sch. of Med.

MK-801, a potent noncompetitive NMDA receptor antagonist, reduces neuronal hypoxic injury. We tested the role of extracellular calcium in this process, using hippocampal slices perfused with artificial cerebrospinal fluid (ACSF) containing (mM) CaCl2, 2.4 or 0; glucose, 4; and saturated with 95% O2/5% CO2 (normoxic) or 95% N2/5% CO2 (hypoxic). One hour after 40 min of hypoxia in 2.4 mM Ca, slices recovered 12%± 8 of the orthodromic population spike (OPS) evoked in CA1 by Schaeffer collateral stimulation. MK-801 (10 mg/l) in 2.4 mM Ca during hypoxia increased recovery to 100%. Normoxic slices in 0 Ca for 210 m. recovered 70%± 11 of OPS. 40 min hypoxia in 0 Ca yielded a recovery of 22%± 10 OPS in the absence, and 91%± 6 in the presence of MK-801 (10 mg/l). The protective effect of MK-801 in the absence of Ca in the perfusate is difficult to reconcile with its most commonly accepted mechanism of action through receptor-operated channels. Alternative hypotheses could include kinase C-mediated release of intracellular Ca stores, influx of other ions through receptor-operated channels, or modulation of metabolic rate.

429.7

HYPERGLYCEMIA PROTECTS CULTURED ASTROCYTES FROM HYPOXIA. G.A. Gregory*, A.C.H. Yu*, and P.H. Chan. Departments of Anesthesia and Neurology, University of California, San Francisco, CA 94143.

Hyperglycemia increases central nervous system (CNS) damage in animals and man, possibly by increasing lactic acidosis and decreasing pH or by increasing brain osmolarity. To determine which of these factors cause damage, we studied the effects of glucose concentration [Glc] and osmolarity on primary cultures of astrocytes that were obtained from the cerebral cortex of newborn rats. Four to six week old cultures were exposed to 0, 1.5, 3.0, 4.5, 6.0, 7.5, 15, 30, or 60 mM Glc and 95% N_2/5% CO_2 for 24 hrs at 37°C and 100% humidity. Other cultures had 7.5 mM Glc and 0, 4.5, 7.5, 15, and 30 mM mannitol added and were treated similarly to the Glc-treated cultures. After 24 hrs of hypoxia, the culture medium (MEM) was decanted, and the cells were washed with MEM and dissolved in 1 M NaOH. The concentration of lactate dehydrogenase (LDH) in the MEM from hypoxic cells was determined as an index of cell injury. Cell damage was also assessed morphologically by phase-contrast microscopy. All of the Glc disappeared in 24 hrs from the medium of cultures that initially contained 1.5, 3.0, 4.5, and 6.0 mM Glc. About 80% of the Glc disappeared when 7.5 mM Glc was added and about 2/3 disappeared when 15, 30, and 60 mM Glc was added to the MEM. Lactate progressively increased to a maximum of 16.7 ± 3.5 mmol/L (60 mM Glc added). The pH of the MEM after 24 hrs of hypoxia was 6.92 ± 0.04. The concentration of LDH in the MEM was 110-270 mmol/L in cultures containing 0-7.5 mM Glc, while that of cultures containing 15, 30, and 60 mM Glc was not different from normoxic controls (29 ± 1 mmol/L). The LDH of mannitol-treated cultures was not different from those treated with Glc alone. Hypoxic cells treated with 0-7.5 mM Glc or with Glc (7.5 mM) + mannitol appeared swollen, vacuolated, or completely disrupted, while those treated with 15-60 mM Glc appeared normal by phase-contrast microscopy. Our data suggest that neither hyperglycemia nor hyperosmolarity increased the amount of hypoxia-induced cell damage of primary cultures of astrocytes. Supported by NS-14543, NS-25372, and NS-26092.

FOCAL BRAIN ISCHEMIA REVERSES THE NORMAL INTERSTITIAL/INTRACELLULAR pH RATIO M. Nedergaard*, R.P. Kraig, J. Tanabe*, and W.A. Pulsinelli (SPON: F. PLUM). Department of Neurology Cornell University Medical College NY, NY 10021.

Intracellular pH (pH_i) is tightly regulated in all eukaryotic cells and normally is more acid compared to interstitial pH (pH_e). The purpose of this study was to examine whether focal ischemia influenced the relationship between pH_e and pH_i. Microelectrodes were used to measure pH_e and (^{14}C-5,5-dimethyl-2,4-oxazolidione (DMO)) was used to measure tissue pH in rats with focal stroke. This allowed calculation of regional pH_i where pH_e was measured. Focal cerebral ischemia was produced in 6 spontaneously hypertensive rats by occlusions of the right common carotid and middle cerebral arteries under halothane anesthesia; 15 min later, 50 uCi ^{14}C-DMO was injected and allowed to circulate for 1 hr. In the left, non-ischemic cortex the pH_e/pH_i ratio was 1.04 (7.24±0.02/ 6.98± 0.02; mean±SEM). In the area of dense cortical ischemia, the pH_e/pH_i ratio of 0.94 (6.44± 0.07/ 6.82± 0.08) was reversed and significantly different ($p<0.01$, student-t test) from normal. The one hour of focal ischemia in these brains caused histologically detectable infarction in the core ischemic zone. Results from this study suggest that 1) some population of cells in the evolving infarct remains sufficiently intact to maintain a pH_e/pH_i gradient albeit reversed and 2) cortical average pH_i may be little altered from normal in tissue undergoing infarction.

429.9

REDUCTION OF STROKE SIZE BY ELECTRICAL STIMULATION OF THE FASTIGIAL NUCLEUS OF THE CEREBELLUM IN RAT. *M. Khayata*, S. Berger, M.D. Underwood and D.J. Reis (SPON: J. Grebb).* Div. of Neurobiology, Cornell Univ. Med. Coll., New York, NY 10021

Electrical stimulation of the cerebellar fastigial nucleus (FN) elicits a global increase in regional cerebral blood flow which, in the cerebral cortex, is not associated with any change in metabolic rate (Nakai, et al., Brain Res., 260:35-49, 1983). We sought to determine whether FN stimulation produces a protective effect on cerebral ischemia. Focal cerebral ischemia was produced by unilateral occlusion of the middle cerebral artery (MCA) in forane anesthetized Sprague-Dawley rats (0.5-1% in 100% O2). The MCA was occluded by electrocautery medial to the inferior cerebral vein. Arterial pressure (AP) and blood gases were continuously monitored and maintained within a normal range. Twenty four h later the animals were sacrificed, their brains removed and frozen in freon, and sections collected through the entire lesion and stained for nissl. In unstimulated controls, MCA occlusion produced an infarction with a mean ischemic area of 241 ± 37 mm^2 (n=9). Sham operated animals had a smaller area of infarction 78 ± 9 mm^2 ($p < 0.01$; n=6). To determine whether the infarct area was reduced by FN stimulation, we electrically stimulated the FN (50 Hz; 1 sec on/1 sec off; 50-100 μA) for 1 h. FN stimulation increased AP and heart rate (threshold for 10 mmHg increase in AP = 31 ± 6 μA; maximum increase: 27 ± 2 mmHg at 100 μA). Following MCA occlusion and FN stimulation, AP was maintained within autoregulated range for CBF by blood withdrawal. FN stimulation reduced the mean ischemic area to 148.74 ± 23.42 mm^2 ($p < 0.05$; n=7). These findings suggest that FN stimulation protects against focal cerebral ischemia and results in a 38% reduction in the size of the infarct produced by MCA occlusion. This reduction in infarct size with FN stimulation may represent a rescue of the ischemic penumbra by a drop in vascular resistance and opening of collateral flow.

429.10

IMPROVING CEREBRAL BLOOD FLOW DOES NOT IMPROVE METABOLIC STATE IN PERINATAL ASPHYXIA. W.B. Stewart, L.R. Ment*, O.A.C.Petroff*, & C.C.Duncan*. (SPON: W.F. Collins, Jr) Depts. of Pediatr., Neurol., Surg., & Anat., Yale Univ. School of Medicine, New Haven, CT 06510.

During perinatal asphyxia cerebral blood flow (CBF) is markedly reduced in the gray & white matter of the telencephalon. We tested the hypothesis that a thromboxane synthesis inhibitor (TSI) would improve CBF & blunt metabolic alterations that accompany asphxyxia. Newborn beagle pups (2-7 d) were anesthetized, ventilated & randomized to insult (I = 5 min of asphyxia) or no insult (NI) & treatment with the TSI CGS 13080 (Ciba Geigy Corp) (0.06 mg/kg/hr i.v. infusion) or saline (S). Pups received TSI/S 30 min prior to I/NI. In S/I pups, CBF increased during insult in the medulla (100.9±10.7 ml/100 g/min, mean ± S.D.) but decreased elsewhere (cortex 25.0± 4.0, white 11.7±2.7). TSI/I pups increased CBF during insult in all regions (medulla 271.2±28.2, cortex 60.0± 4.0, white 25.0±7.8). In other pups, brain extracts were prepared for 1-H NMR spectral analysis of high energy phosphorylated compounds & lactate levels. In S/I pups, PCr fell from 1.6±0.2 to 0.1±0.1 mmole/kg, lactate increased from 1.2±0.5 to 4.0± 0.8 & pH fell 0.9 units. There were no differences between S/I & TSI/I. These data suggest therapeutic strategies for perinatal asphyxia must extend beyond CBF maintenance to methods which may reduce metabolic needs & prevent pathologic change.

70 KDa STRESS/HEAT SHOCK PROTEIN INDUCTION IN GERBIL BRAIN AFTER ISCHEMIA IS BLOCKED BY THE ANTICONVULSANT, MK-801. T.S. Nowak, Jr. Laboratory of Neuropathol. and Neuroanat. Sciences, NINCDS, NIH, Bethesda, MD 20892

Immunocytochemical studies have localized induction of the 70 KDa stress protein (hsp70) in gerbil brain after transient ischemia. Accumulation is most striking in CA3 neurons of hippocampus at 48 h recirculation, preceding the loss of CA1 neurons characteristic of this model. MK-801 has been suggested to block ion channels associated with glutamate receptors of the N-methyl-D-aspartate subtype and thereby protect neurons from excitotoxic cell loss. The present study examined the effect of MK-801 on hsp70 induction and CA1 damage following bilateral carotid artery occlusion in the gerbil. Pretreatment with 10 mg/kg MK-801 1 hr before 5 min ischemia prevented the appearance of hsp70 immunoreactivity in CA3 at 2 d, and posttreatment at 1 hr notably attenuated the induction. In contrast, no protection of CA1 neurons was evident after either treatment when evaluated histologically at 1 week. These results fail to support a protective effect of MK-801 on postischemic cell damage in CA1, and clearly dissociate the induction of hsp70 in CA3 from the pathophysiology of hippocampal cell loss. On the other hand these observations demonstrate that hsp70 induction is subject to pharmacological intervention, and provide a basis for further studies of the physiology resulting in such localized changes in gene expression after ischemia.

OPIOID PEPTIDES IN FOCAL CEREBRAL ISCHEMIA IN THE CAT. D.S. Baskin* and J.L. Browning (Spon: DMK Lam). Neurosurgery Department and the Center for Biotechnology, Baylor College of Medicine, Houston, TX 77025.

Opioid peptides(OP) have been implicated in the pathophysiology of stroke. Baskin etal (Nature) found that naloxone and OP can improve neurologic function and prolong survival. We measured OP concentrations following induction of focal cerebral ischemia using intracranial vascular occlusion in cats. Met enkephalin(ME), leu enkephalin(LE), dynorphin 1-17(DYN) and beta-endorphin (BE) were measured at six hours post occlusion. OP were separated using RP- HPLC were assayed using RIA. ME was increased in caudate (CAU) and cortex (CTX) and decreased in hypothalamus(HYP). LE likewise increased in CAU but also increased in hippocampus (HIP), amygdala, and thalamus with dimuition in the HYP. No significant increases were seen in DYN concentrations in any area, with decrease seen in CTX. BE levels increased in HIP, thalamus and HYP and decreased in frontal CTX. These data document changes in OP following ischemic injury, including increases in regions with a loss of cellular function. As the motor depressive effects of OP are well described, changes described here may partially explain the attenuation in motor function seen in stroke, as well as the change in motor function observed after administration of OP antagonists. This is supported by other data demonstrating that OP antagonists afford no protection from ischemic injury, despite improvement in motor function.

A NOVEL METHOD FOR TARGETING NEURONS IN A LIGHTLY FIXED STRIATAL SLICE PREPARATION. R.H. Walker*, A.M. Graybiel, R.W. Baughman and G.W. Arbuthnott*. (SPON: H. Newman-Gage) Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139; Dept. of Neurobiol., Harvard Medical School, Boston, MA 02115.

Intracellular filling of cells in the in vitro tissue slice provides detailed information about their dendritic fields. Methods have been developed for targeting specific cells by prelabeling them with transportable retrograde dyes or with nonspecific nuclear dyes such as 4,6-diamidino-2-phenylindole (DAPI). We here report a method for using a fluorescent Nissl stain (see Quinn and Weber, this meeting) that permits targeting of specific cell types according to the appearance of their perikarya, combined with injection of Lucifer Yellow, visible at the same wavelength. This method was developed in a lightly fixed striatal slice preparation. Slices 400μm thick were taken from perfused ferret brain and maintained in a bath on the stage of a microscope fitted with a 470nm epifluorescence filter. Meta-phenylene diamine was applied topically to produce a fluorescent Nissl stain. Cells with different perikaryal dimensions were targeted with a micropipette and Lucifer Yellow was injected under direct vision into the cell of choice. After a number of cells had been filled in a slice, it was post-fixed by immersion in 4% paraformaldehyde-phosphate buffer, and cut into 100μm thick sections which were then stained for cholinesterase. This method enables reconstruction of dendritic fields of striatal cells with respect to the histochemically definable striosomes, and should have broad applicability to the study of other regions of the central nervous system. *Supported by the Faculty of Medicine, Univ. of Edinburgh, the Whitaker Health Sciences Fund and NSF BNS 8720475.*

AN AFTERHYPERPOLARIZATION IN NEOSTRIATAL CELLS RECORDED IN VITRO: EFFECT OF DOPAMINE. M. Garcia-Munoz, A. Rutherford, and G.W. Arbuthnott, MRC Brain Metabolism Unit, University of Edinburgh, United Kingdom.

A slow afterhyperpolarization (AHP) following a train of action potentials has been described in mammalian central neurons. Is there an AHP in striatal cells? If so, what is the effect of dopamine (DA) on the AHP? Parahorizontal 300 μM slices of rat neostriatum were maintained at the fluid interface of a perfusion chamber at 36°C. Cells were recorded intracellularly (potassium acetate, 60-90 Mohms). No spontaneous activity was observed. The mean resting membrane potential was -83.7 ± 6.4 mV (n=82), depolarizing pulses (0.5-1 nA/80 ms) produced action potentials which overshot 0 mV. After a train of action potentials an AHP followed in cells depolarized from a holding potential of -65 to -70 mV. The input membrane resistance did not change during the course of the AHP. The estimated reversal potential at 4.5 mM external potasium was -90± 4 mV. Iontophoresis of DA (0.5 M; 25-50 nA/3-5 min) resulted in several distinct actions: 1) As already reported (Calabresi et al., 1987), it reduced the membrane resistance with depolarization increasing the quantity of injected current necessary to reach the voltage of the firing level. 2) Induced accommodation to repeated cell firing. 3) Decreased the size of the AHP with an associated increase in the number of spikes. These results may help to reconcile the excitatory versus inhibitory effects of DA previously reported in the literature.

SHIFTS IN CLASS DISTRIBUTION OF TH-LABELED CELLS IN THE SUBSTANTIA NIGRA OF THE NEUROLOGICAL MUTANT MOUSE WEAVER. D.E. Smith, M.W. Smith, III*, T.R. Cooper*, and T. H. Joh. Depts. of Anatomy & Biometry, LSU Med. Ctr., New Orleans, LA 70112 and Dept. of Neurol., Cornell Univ. Med. College, New York, NY.

The neurological mutant mouse weaver is best known for its cerebellar deficit. However, there is now evidence that tyrosine hydroxylase (TH) labeled neurons within the substantia nigra are also affected. The present study was undertaken to determine if there are specific subpopulations of TH-labeled neurons within the substantia nigra that are more severely depleted in the weaver than in the homozygous wildtype control.

Weaver and control mice were perfused with fixative. Thirty micron vibratome sections were immunocytochemically labeled with a rabbit antiserum to TH. Chi-square analyses comparing weaver with wildtype controls indicate that the number of immunocytochemically-labeled cells is significantly lower in weaver than in controls while the number of labeled cells with areal measurements of 20-74 microns and maximum diameters of 61-69 microns is significantly higher. REGIONAL EFFECTS OF THE WEAVER GENE ON PRESYNAPTIC DOPAMINE UPTAKE SITES IN STRIATUM. S. Roffler-Tarlov and A.M. Graybiel, Neuroscience Program, Tufts Univ. Sch. Med., Boston, MA 02111 AND Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

The reduction of endogenous dopamine resulting from effects of the weaver gene in mice is remarkably specific, discriminating between the nigrostriatal and mesolimbic pathways so that the nigrostriatal targets are profoundly affected and the mesolimbic targets are relatively or completely spared. We report here measurements of ^{3}H dopamine uptake, a reflection of dopamine-containing terminal function, in the three striatal regions in weavers and controls. Synaptosomes were prepared from caudoputamen (CP), nucleus accumbens (NAc) and olfactory tubercle (OT). Three animals per sample were pooled for NAc and OT. Aliquots of synaptosomes were incubated with .05 μM ^{3}H dopamine. The specificity of ^{3}H dopamine accumulation was assessed with nomifensin. The results revealed an even greater deficit in uptake capacity than in dopamine content in weaver's CP (16% vs. 31% of control) and in OT (40% vs. 52% of control). In the weaver's NAc, where dopamine content is 108% of control, accumulation of ^{3}H dopamine was reduced to 68% of control.

These results show that deficits in ^{3}H dopamine uptake exceed reduction of endogenous dopamine in the most vulnerable regions of the weaver's striatum, and that terminal function is significantly compromised also in the NAc, a mesolimbic target in which dopamine content is normal. This evidence suggests that effects on terminals may be a key feature of the action of the weaver gene on the dopamine-containing mesostriatal pathways. Supported by NS20181 and MH00655.

TOWARD A GENETIC ANALYSIS OF THE STRIOSOMAL SYSTEM: PATTERNS OF NIGROSTRIATAL LOSS IN THE MUTANT MOUSE WEAVER. A. M. Graybiel, K. Ohta* and S. Roffler-Tarlov. (SPON: D. Chikaraishi) Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139; Neuroscience Program, Tufts Univ. School of Medicine, Boston, MA 02111.

The weaver (wv) mouse carries an autosomal recessive gene leading to defects in the central nervous system. In the basal ganglia, the dopamine (DA)-containing nigrostriatal system is severely affected. With the glyoxylic acid method we have shown that the loss of DA innervation is greatest in the dorsolateral quadrant of the caudoputamen, with its ventral part least affected. We now report evidence that tyrosine hydroxylase (TH)-immunoreactive fibers are lost not only from the dorsolateral quadrant but also from striosomal regions (identified by low met-enkephalin-like immunoreactivity in serially adjoining sections) within the remaining partially affected parts of the caudoputamen.

Analysis of TH in the wv/wv midbrain suggests highly specific patterns of cell depletion in the A8-A9-A10 complex relative to cellular distributions present in littermate controls: 1) TH-positive neurons are sparse in the midlateral part of the substantia nigra pars compacta (SNpc); 2) there is marked shrinkage of cell group A8; 3) there is nearly total loss of TH-positive neurons in a caudomedially situated hypercellular zone of A9 characterized by its dense immunostaining for TH. We propose that the cellular depletion in the mid-A9 and A8 regions in the wv/wv may account for the massive loss of TH-containing fibers in the caudoputamenal matrix, whereas loss of neurons in the cell-dense caudomedial zone (putative murine densocellular zone) may account for loss in the striosomal system. *Supported by NIH 20181, The Seaver Institute and MH0655.*

DOPAMINERGIC CONTROL OF STRIATAL GABA SYNTHESIS IS REFLECTED IN THE EXPRESSION OF mRNA FOR STRIATAL GLUTAMIC ACID DECARBOXYLASE. K. Gale, J. Segovia*, N.J.K. Tillakaratne*, K. Whelan* & A.J. Tobin. Dept. of Pharmacology, Georgetown Univ. Med. Ctr., Washington, D.C. 20007 & Dept. of Biology & Brain Research Inst., UCLA, Los Angeles, CA 90024.

Lesions of dopaminergic innervation of the striatum are known to result in a marked increase in striatal GABA synthesis as measured both "in vitro" (glutamic acid decarboxylase, GAD) and "in vivo" (GABA turnover). The present study examined GAD mRNA as related to the increase in striatal GAD activity 3 months after dopaminergic denervation by 6-hydroxydopamine in the MFB. Rats were sacrificed and the striata rapidly removed and divided into 2 pieces, one to measure GAD activity using a radiochemical method, the other to assess GAD mRNA levels. A 32P labeled cloned rat GAD cDNA probe was used to detect striatal mRNA for GAD. Total mRNA was isolated using guanidine thiocynate-cesium chloride followed by electrophoresis in formaldehyde. Northern blot of RNA from striatal tissue revealed a single band at 3.7 kb. Striata from rats that were succesfully denervated showed a marked increase in GAD activity on the lesioned side when compared with the non-lesioned side (between 40 and 100% increase), or with non-lesioned controls. Similar changes could be seen in GAD mRNA levels. We suggest that the increased GAD activity observed after dopaminergic denervation of the striatum is due to a "de novo" synthesis of the enzyme and that striatal dopaminergic neurotransmission has a regulatory function on the GABAergic cells' genome expression.

TRANSPLANTS OF FETAL SUBSTANTIA NIGRA CAN REGULATE GABA SYNTHESIS IN THE STRIATA OF ADULT HOST RATS. J. Segovia*, N. Hayman* and K. Gale (SPON: S. Gobel). Dept. Pharmacology, Georgetown Univ. Med. Ctr. Washington, D.C. 20007.

The purpose of the present experiments was to determine whether transplants of fetal nigral tissue are able to reverse the alterations in host striatal GABAergic function produced by 6-hydroxydopamine (6-OHDA). Rats with unilateral 6-OHDA lesions received solid transplants of fetal mesencephalon placed into cortical cavities. 6-8 weeks after transplantation, striata were removed and a radiochemical assay was used to determine glutamic acid decarboxylase (GAD) activity. There was no difference in the GAD activity between the two striata in non-lesioned rats, whereas there was a marked increase (>40%) in striatal GAD activity homolateral to the 6-OHDA lesions in rats without transplants. In contrast, in rats with successful transplants striatal GAD activity was similar to the non-lesioned control values. Successful transplants were defined as those which reduced apomorphine- or amphetamine-induced rotational behavior by at least 50%. Unsuccessful transplants were those without significant effect on this behavior; these were also without significant effect on the lesion-induced increase in striatal GAD activity. This suggests that dopamine released from the fetal tissue graft can reverse the changes in GABAergic activity caused by the 6-OHDA lesion.

ULTRASTRUCTURAL LOCALIZATION OF MOLECULAR SUBTYPES OF NEURAL CELL ADHESION MOLECULE (NCAM) IN THE ADULT RODENT STRIATUM. M. DiFiglia, P. Marshall* and M. Yamamoto. Departments of Neurology, Massachusetts General Hospital, Boston, MA 02114 and Biochemistry, Eunice Kennedy Shriver Ctr., Waltham, MA 02254.

Neural cell adhesion molecule (NCAM) belongs to a class of integral plasma membrane glycoproteins which are thought to mediate adhesion between neuronal elements. We used immunohistochemistry (avidin-biotin-peroxidase) to examine the localization of immunoreactive (i) NCAM in the adult rodent striatum. The monoclonal antibody used in this study was raised against embryonic (E15-E17) mouse brain and identified 180, 140 kD molecular weight forms of NCAM. Light microscopic results in the adult mouse (N=4) and rat (N=4) showed that iNCAM was localized to the plasma membranes of somata and dendrites of medium and large-sized aspiny neurons throughout the caudate nucleus and to the majority of neurons in the globus pallidus. Ultrastructural analysis revealed that reaction product in aspiny somata was present in discrete, closely spaced patches along the inner face of the plasma membrane and was also prominent in somatic protrusions which were frequently apposed to synapsing axons. Distal aspiny dendrites with iNCAM received numerous synaptic inputs. Within caudate neuropil iNCAM was also present in: 1) medium spiny neurons where reaction product was localized predominantly to spines with, long thin necks and small spine heads which were postsynaptic to unlabeled axon terminals; and 2) preterminal (unmyelinated) axons and terminal boutons that issued from myelinated bundles and formed asymmetric synapses with unlabeled dendritic spines.

We speculate that the prevalence of iNCAM in medium and large aspiny caudate interneurons and in pallidal projecting cells may be involved with modulating the density of synaptic inputs, since all three types of neurons share the feature of being ensheathed by axons and terminals. The presence of iNCAM in thin spines may reveal sites of plasticity in adult spiny neurons. Supported by grants NS16367 to M.D. and NS 24726 to M.Y.

REGIONAL DISTRIBUTION AND REGULATION OF SOMATOSTATIN MESSENGER RNA (SOM mRNA) IN THE STRIATUM, AS REVEALED BY IN SITU HYBRIDIZATION HISTOCHEMISTRY (ISHH). L.T. Weiss and M.-F. Chesselet. Dept. of Pharmacology, the Medical College of Pennsylvania, Philadelphia, PA 19129.

Using ISHH, we examined the regional distribution of SOM mRNA in the striatum of the mouse. Also, because lesions of dopaminergic nigrostriatal neurons stimulate striatal SOM neurons, we determined the effects of dopamine (DA) receptor blockade on the levels of striatal SOM mRNA. Male Swiss Webster mice were injected 2 times, 8 hours apart, for 2 consecutive days with a dose of fluphenazine-N-mustard (FNM, 4 µmol/kg), which irreversibly blocks DA-D2 but not D1 receptors. The right striata were analyzed for DOPAC and DA using HPLC-EC. The DOPAC to DA ratio, an index of DA turnover, was elevated after FNM treatment, confirming effective blockade of DA-D2 receptors. The left side of the brain was processed for ISHH. Levels of SOM mRNA were quantified using light microscopy and computer-assisted grain analysis. In controls, individual neurons of the lateral striatum had higher levels of SOM mRNA than did those of the medial striatum. FNM treatment produced a decrease in SOM mRNA levels in the lateral, but not the medial striatum. The results indicate that there is a lateral to medial gradient in the levels of SOM mRNA in the striatum of control animals which is abolished by FNM treatment. Taken together with data from the literature, these results suggest that activation of the nigrostriatal pathway by sustained DA-D2 receptor blockade produces a region specific reduction in striatal SOM gene expression. PERSISTENCE OF POLYSIALYLATED ("EMBRYONIC") N-CAM IN THE SUBSTANTIA NIGRA OF ADULT RATS. M.-F. Chesselet and L.I. Aaron*, Dept of Pharmacology, Med. Coll. Pennsylvania, Philadelphia, PA, 19129.

The embryonic (E) form of the Neural Cell Adhesion Molecule (N-CAM) contains a higher amount of polysialic acid residues than adult N-CAM (A N-CAM). As a result, binding between A N-CAMs is much stronger than between the E forms of the molecule. Maturation from E to A N-CAM is believed to be a critical developmental event, but its chronology has not yet been studied at the anatomical level. We have detected the highly polysialylated N-CAM in sections of the rat brain by indirect fluorescence immunohistochemistry, using a monoclonal antibody (from G. Rougon) raised against the capsular polysaccharides of meningococcus B. This antibody reacts with the E but not the A N-CAM. In the substantia nigra (SN), the labelling was intense and homogenous in sections from 1-10 day old rats, with both cell membranes and intersomata space showing immunoreactivity. At 16 days, a ventro-dorsal gradient in the level of immunostaining appeared in the SN pars reticulata. Also, immunolabelling of cell membranes became increasingly discontinuous, taking on a more punctate appearance in sections of 3 weeks old rats. Immunostaining was still present in the SN of adult rats, but was found mostly between cell bodies. Labelling in the adult SN contrasted with the lack of immunolabelling of most other brain areas at this age. Notable exceptions in the brain stem were the periaqueductal grey and the lateral subnuclei of the interpeduncular nucleus. At all age examined, intense and widespread immunoreactivity to a polyclonal antibody recognizing both A and E N-CAM was found throughout the brain. It is proposed that highly sialylated N-CAM may play a role in neuronal plasticity in discrete areas of the adult brain, including the SN. Supported by BNS 86-07645 and the Dystonia Medical Research Foundation.

NORADRENERGIC INNERVATION OF THE RAT SUBSTANTIA INNOMINATA: A LIGHT AND ELECTRON MICROSCOPIC STUDY OF DOPAMINE ß-HYDROXYLASE IMMUNOREACTIVE AXONS. H.T. Chang, Department of Anatomy and Neurobiology, The University of Tennessee - Memphis, The Health Science Center, 875 Monroe Ave., Memphis, TN 38163.

Noradrenergic input to the rat substantia innominata (SI) was investigated in this study by immunocytochemical localization of dopamine ß-hydroxylase (DBH), the synthetic enzyme for noradrenaline. Using a rabbit anti-bovine DBH antiserum (Eugene Tech International), DBH immunoreactive (DBH+) elements were revealed by a standard avidin-biotin-HRP immunoreaction. DBH+ axons ramified extensively within SI and appeared to be contiguous with DBH+ terminal fields within the bed nucleus of stria terminalis and the amygdaloid complex. Individual DBH+ boutons in SI appeared much larger than those in the cerebral cortex, hippocampus, and thalamus. Electron microscopic analysis revealed that DBH+ boutons in SI contained many small clear synaptic vesicles (30-60 nm) and large uniformly stained vesicles (80-120 nm). DBH+ boutons formed asymmetrical synapses with mainly dendrites, but also somata and spines of SI neurons. Dendrites which were postsynaptic to DBH+ boutons also formed many symmetrical, and some asymmetrical synapses with unlabeled axon terminals. Since previous studies have shown that dendrites of SI cholinergic neurons formed few synapses, the present result suggests that noradrenergic influence of SI cholinergc neurons, if present, is through polysynaptic connections. (This study was supported by USPHS Grants NS21003, AG05944, and a grant from the Alzheimer's Disease and Related Disorders Association.)

THE HYPOTHALAMIC GnRH PULSE GENERATOR OF THE RHESUS MONKEY: THE DURATION OF PHASIC ELECTRICAL ACTIVITY AND ITS CONTROL. * C.L. Williams, *M. Nishihara, *J-C. Thalabard, *P.M. Grosser, *J. Hotchkiss, and E. Knobil. Laboratory for Neuroendocrinology, University of Texas Health Science Center, Houston, TX 77225.

The characteristic circhoral increments in multiunit activity (volleys) associated with the initiation of gonadotropic hormone pulses were studied in adult female rhesus monkeys bearing bilateral arrays of chronic recording electrodes placed in the region of the arcuate nucleus (Wilson et al., Neuroendocrinology 39:256, 1984). In the intact animal, during the follicular phase of the menstrual cycle, the duration of the volleys is 1-3 min. During the luteal phase, this is increased to 4-6 min. After ovariectomy, volley duration increases progressively to 15-25 min. Physiological estradiol replacement reverses this effect. In the intact monkey, during the follicular phase, administration of naloxone (0.3 - 1.0 mg/kg i.v.) results in volleys of increasingly longer duration, while morphine (1 - 30 µg/kg i.v.), like estradiol administration to ovariectomized animals, results in a dose-related decrease in volley duration. These findings suggest that the ovarian influence on the duration of the electrical volleys, like that on their frequency as previously described, may be mediated by endogenous opioid peptides.

431.2

THE PREPUBERTAL HIATUS IN PULSATILE GNRH RELEASE IN THE MALE RHESUS MONKEY IS NOT THE RESULT OF OPIOID INHIBITION. R. Medhamurthy*, V.L. Gay* and T.M. Plant. Dept. of Physiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

In male primates, pulsatile GnRH secretion is interrupted from shortly after birth until puberty by a mechanism of nongonadal origin. This study investigated the possible role of opioid peptides in determining the prepubertal hiatus in GnRH release in the male monkey. In order to use LH secretion as a bioassay for hypothalamic GnRH release, pituitary sensitivity was heightened in 4 castrated, prepubertal male monkeys (17-18 mo) by an iv intermittent infusion of GnRH. GnRH stimulation was discontinued 10-12h before challenging with naloxone (NAL). In one experiment, NAL was administered as an iv bolus at 4 doses (0, 0.2, 2 and 10 mg/kg BW in saline) and LH was determined in plasma collected at 10-30 min intervals before and after injection of the opioid antagonist. At the low and high NAL doses there was no increase in plasma LH levels. At the 2 mg/kg dose, however, 1 of the 4 animals showed a 2½ fold increase in plasma LH. In another experiment, monkeys were infused either with NAL (2 mg/h) or saline for 36h, and plasma was collected every h. LH levels during NAL and saline infusion were not different. In both experiments, GnRH injection after NAL administration elicited an LH discharge. These results fail to provide convincing evidence that the prepubertal hiatus in pulsatile GnRH release in male monkeys involves opioid inhibition. An additional experiment is now underway to test the effect of long-term intermittent NAL treatment on hypothalamic GnRH release in order to fully substantiate our conclusion.

431.3

PROGESTERONE IS REQUIRED FOR NALOXONE (NAL)-INDUCED LH SURGE. C. Masotto*, A Sahu* and S.P. Kalra, Dept. OB/Gyn, Univ. Fla. Col. Med., Gainesville, FL 32610

Recent studies show that continuous restraint of the hypothalamic inhibitory opioid tone produced by NAL infusion can advance the preovulatory LH surge on proestrus. We have now identified the ovarian steroid signals that facilitate this NAL-induced decrease of opioid restraint. Ovariectomized rats (7-10 days) received estradiol (E_2)-filled capsules (300 g/ml) on day 0. On day 2, saline (SAL, 0.6 ml/h) or NAL (2 mg/0.6 ml SAL/h) was infused between 1100- 1400 h through one and blood samples for LH estimations were withdrawn (between 1000-1700 h) through the other intracardiac cannula. While in SAL-infused rats plasma LH levels were unchanged, surprisingly NAL infusion in these E_2-treated rats induced only a marginal (< 2-fold) increase in plasma LH between 1600-1700 h. However, when E_2-primed rats were additionally treated with progesterone (P, 3 mg, s.c.) at 1800 on day 1, followed by similar NAL infusion on day 2 between 1100-1400 h, a robust LH surge was observed. The onset of the LH surge was advanced by 2 h (LH rise at 1130-1200 h in NAL vs 1330-1400 h in SAL-infused); LH peaks occurred earlier (NAL: 1530-1600 vs SAL: 1630-1700 h) and were of longer duration (NAL: 1530-1700 h vs SAL: 1630-1700 h). Thus, P pretreatment facilitated the neuroendocrine processes involved in induction of the LH surge by NAL in ovariectomized rats. These findings imply that expression of the hypothalamic restraint on inhibitory opioid tone, that normally precedes the proestrous LH surge, requires P action on an estrogen background and that E_2 alone may be an inadequate ovarian signal. (Supported NIH HD 08634).

431.4

PITUITARY LH RELEASE IS REFRACTORY TO NMA STIMULATION IN THE LACTATING RAT. C. R. Pohl, L.-R. Lee*, and M. S. Smith, Dept. of Physiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Whereas the suppression of LH secretion during lactation has been attributed to inhibition of GnRH release, lactating rats have a normal hypothalamic content of GnRH which is releasable by electrical stimulation. The present study was undertaken to examine whether this system can be activated by chemical stimulation of NMDA receptors, which have recently been shown to function in the control of pulsatile LH secretion in males (Arslan et al., in press).

On day 10 of lactation, OVX rats suckling 8 pups were primed for 24 hrs with GnRH pulses (5 ng iv once every 50 min) to restore pituitary GnRH receptors. Four pulses of NMA (40 mg/kg/pulse) were then infused 50 min apart, and serial blood samples were collected at 10-min intervals. Procedural controls for the NMA infusion regimen (not primed with GnRH) included gonad-intact male rats and estrous females.

LH responses (ng/ml) to 20 mg NMA/kg in males (mean peak LH/mean basal LH: 75/11) were higher than in estrous females treated with NMA at either 20 mg/kg (peak/basal: 34/18) or 40 mg/kg (peak/basal: 58/20). Whereas OVX lactating rats responded to GnRH pulses after 24 hrs of treatment (peak/basal: 51/15), LH responses to subsequent pulses of 40 mg NMA/kg were absent in these animals ("peak"/basal: 16/16). Additional efforts to stimulate LH release with NMA pulses administered over 24 hrs were similarly unsuccessful.

These data indicate a sex difference in LH responsiveness to NMA between the male and the estrous female rat and suggest that the hypothalamus of the lactating rat is refractory to NMDA receptor stimulation.

431.5

PARADOXICAL RATE OF GNRH RELEASE FROM HYPOTHALAMUS OF THE LACTATING RAT. L.-R. Lee*, C.R. Pohl, and M.S. Smith, Dept. of Physiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

During lactation in the rat, the suppression of pituitary GnRH receptors and pulsatile LH secretion can be reversed by administering pulsatile GnRH. These data suggest that the suckling stimulus suppresses endogenous GnRH secretion. To more directly test this hypothesis, we compared in vitro GnRH release rates from hypothalami of lactating rats suckling 8 pups (day 10 postpartum) and cycling diestrous rats. Individual hypothalami (POA-MBH) or median eminences (ME) were incubated and the medium was exchanged every 10-15 min during 3-5 hours of incubation.

From the ME, basal GnRH release rates (pg/min) were similar in lactation (0.47 ± 0.05) and diestrus (0.34 ± 0.07), and GnRH release rates stimulated by 55 mM K^+ (pg/ml) were about 10-fold higher in both groups: lactation, 4.9 ± 0.5; diestrus, 3.4 ± 0.9. From the POA-MBH, basal GnRH release rates did not differ between lactation (0.40 ± 0.05) and diestrus (0.53 ± 0.19), and GnRH release rates stimulated by K^+ were only 2 to 3-fold higher than basal rates (lactation, 1.3 ± 0.3; diestrus, 1.0 ± 0.4). Addition of verapamil to the medium greatly decreased both basal and stimulated GnRH release, thus the similarity in GnRH release rates between lactation and diestrus cannot be explained by a high rate of nonspecific release. Also, hypothalamic GnRH content was similar in lactating and diestrous rats.

These results are a paradox in view of in vivo studies suggesting that lactation suppresses GnRH release. One explanation is that isolation of the hypothalamus removes it from inhibitory neural input arising from other areas of the CNS activated by the suckling stimulus.

431.6

ELECTRICAL STIMULATION OF THE HYPOTHALAMUS FACILITATES LHRH RELEASE IN THE STALK-MEDIAN EMINENCE (S-ME) OF THE PERIPUBERTAL FEMALE MONKEY AS DETERMINED BY PUSH-PULL PERFUSION. L.E. Claypool, G. Watanabe', and E. Terasawa. Wisconsin Regional Primate Research Center, University of Wisconsin, Madison, WI 53715

As we have previously reported, the onset of puberty in the female rhesus monkey is heralded by an increase in LHRH release. Preliminary to studies of the mechanism underlying this increase, we have evaluated the LHRH neurosecretory system following electrical stimulation in the peripubertal female (age 25-40 months). LHRH release in the S-ME of conscious monkeys was assessed by push-pull perfusion as described previously. Modified Krebs-Ringer phosphate buffer solution was perfused at a rate of 20 µl/min, and perfusate was collected at 10-min intervals for 12 h. After 3 h of baseline perfusion, electrical stimulation (50 Hz, 0.5 msec, 500 µA) was applied 6 times for 5-10 min at 90-min intervals via a monopolar electrode, the tip of which was placed 1-2 mm rostro-dorsal to the perfusion site. **Results:** Electrical stimulation of the mediobasal hypothalamus (MBH) resulted in 1) a prompt release of LHRH which occurred within 20 min after each stimulation, and 2) a gradual increase in mean LHRH release, possibly due to long-term potentiation. Regarding the latter, mean LHRH release, 2.0±0.7 pg/ml/10 min during the 90 min prior to the first stimulation, ultimately reached 8.2±1.8 pg/ml/10 min during the 90 min after the 6th stimulation (n=8). In contrast, mean LHRH release in controls, 2.1±0.6 pg/ml/10 min prior to sham stimulation, remained stable with ultimate levels of 3.5±1.0 pg/ml/10 min (n=6). These data provide evidence that electrical stimulation of the MBH facilitates LHRH release in the peripubertal monkey by 1) depolarizing LHRH neurons and/or their terminals directly, and 2) stimulating interneurons that synapse on the LHRH neurosecretory system. (Supported by NIH grants HD11355 and HD15433.)

EFFECTS OF PRAZOSIN ON PULSATILE LUTEINIZING HORMONE (LH) RELEASE IN OVARIECTOMIZED FEMALE RHESUS MONKEYS. M. Gearing and E. Terasawa. Neuroscience Training Prog. and Wisconsin Reg. Primate Res. Ctr., Univ. of Wisc., Madison, WI 53715.

Previously, we have reported that prazosin, an α_1-adrenergic antagonist, suppressed, but did not completely block, pulsatile release of luteinizine hormone releasing hormone (LHRH; Endocrinology 122 *Suppl* #15, 1988). While our results indicating suppression of LHRH by prazosin agree with a previous report of LH suppression from another lab (Endocrinology 116:1327, 1985), the two studies disagree on the nature of the suppression. The following experiments were therefore performed to further examine the effects of prazosin on LH pulses in 8 ovariectomized female monkeys. Serial blood samples were collected from conscious monkeys at 10-min intervals through indwelling veinous catheters. After a 4 h control period, prazosin (0.2 or 0.4 mg/kg) or vehicle was injected i.v., and sampling was continued for 6 h. **Results** Both doses of prazosin induced a biphasic response: an initial period of suppression lasting up to 210 min (0.2 mg/kg) or 250 min (0.4 mg/kg), followed by a "rebound" period which lasted until the end of the experiment. During the suppression period, LH pulses were completely suppressed in only 2 of 8 (0.2 mg/kg) and 1 of 4 (0.4 mg/kg) animals; in the remaining animals, LH pulses continued with attenuated amplitude and normal frequency. During the "rebound" period, LH pulses occurred with higher amplitude and lower frequency than in the control period. No significant dose effects were observed in any aspects of the analysis. Furthermore, injection of the vehicle had no effect on pulsatile LH release. **Conclusion** Prazosin suppresses LH pulse amplitude but not frequency, indicating that an α_1-adrenergic mechanism is involved in pulsatile LH release. This finding is consonant with our previous study of pulsatile LHRH release. (Supported by NIH HD15433 and RR0169.)

IN VIVO PULSATILE LHRH RELEASE INTO THE ANTERIOR PITUITARY (AP) OF THE MALE RAT. P.S. Kalra, C.P. Phelps[1] and S.P. Kalra, Dept. OB-Gyn, Univ. FL., Gainesville, FL and [1]Dept. Anat., Univ. So. FL, Tampa, FL.

In the intact male rat, LH release is irregular with low amplitude pulses at variable intervals (30 min to >12 h). Post-castration hypersecretion of LH is characterized by an increase in frequency and amplitude driven by the putative LHRH generator. We have studied LHRH release in vivo using push-pull cannulae (PPC) placed in the AP of freely behaving adult male rats. Six rats were perfused (PERF) as intacts (day 0) and again at 1, 2 and 7 d after castration (CAST). Similarly, 12 rats were PERF on day 0 and at 3 and 7 days after CAST. Additional CAST rats were PERF at 14 (n=7) and >40 days (n=6). LHRH levels were analyzed by RIA and subjected to PULSAR analysis. Pulsatile LHRH release (0.83±0.08 pulses/h; amplitude 0.54±0.13 pg) was detected in 16 of 18 intact rats (average release rate 0.53±0.08 pg/10 min) and in 45 of 48 CAST rats; there were no significant differences in the pulse parameters of intact vs CAST rats. Although in rats subjected to repeated PERF before and after CAST there was a progressive increase in the number of rats exhibiting increased pulse amplitude and frequency, the actual levels of these parameters were not significantly different at any interval after CAST. In one group of 5 CAST rats pulse amplitude increased to 1.61±.31 pg ($p < .05$) on day 7. These results demonstrate no change after CAST in the LHRH pulse generator, indicating either a limitation of this PERF technique or that alterations in AP response to LHRH after CAST may be responsible for the increase in LH levels and pulsatility after CAST. (Supported by NIH HD 11362).

CELLULAR LEVELS OF mRNA ENCODING GONADOTROPIN RELEASING HORMONE (GnRH) IN INTACT, CASTRATED AND HYPERPROLACTINEMIC MALE RATS. M. Selmanoff, C. Shu*, S.L. Petersen, C.A. Barraclough and R.T. Zoeller, Dept. of Physiol., Univ. of Maryland, Sch. of Medicine, Baltimore, MD 21201 and LNC, NINCDS, Bethesda, MD 20892.

We quantitated single cell mRNA levels in brains of intact and castrated rats and in castrated rats bearing the 7315a PRL-secreting tumor. Nine days postcastration, rats were decapitated and 12μm sections prepared from the diagonal band of Broca through the medial preoptic nucleus (MPN). Sections were hybridized with an ^{35}S-labelled 48-base oligonucleotide probe. A single section in the region of the MPN was chosen from each brain and quantitated using darkfield optics in a Bioquant Image Analysis System IV. The average number of cells labelled/section was 8.9 ±0.5 (n=21) and the average cellular labelling intensity was 50 times background.

	Intact	Castrated	Castrated, tumor-bearing
Serum LH (ng/ml)	61 ± 8	634 ± 44	277 ± 84
Grain density	114.2 ± 5.7	130.4 ± 2.5	121.2 ± 6.1

The grain density of labelled cells was significantly increased postcastration and this increase was suppressed by the presence of a PRL-secreting tumor. The data indicate that testicular steroids and PRL affect steady state GnRH mRNA levels in cells residing in the region of the MPN. Supported by NIH grants HD-21351 and HD-02138.

DO GONADOTROPIN RELEASING HORMONE (GNRH) OR DOPAMINERGIC NEURONS IN THE SHEEP CONTAIN ESTRADIOL RECEPTORS? F.J. Karsch* and M.N. Lehman (Spon: G. Blaha). Develop. & Reprod. Biol., Univ. Mich., Ann Arbor, MI; Dept. Anat. & Cell Biol., U. Cincinnati Coll. Med., Cincinnati, OH.

Estradiol exerts a major feedback influence upon GnRH neurons which comprise a pulse generator controlling pituitary gonadotropin secretion. Using double label immunocytochemistry with a monoclonal antibody against the estradiol receptor (ER) (H222, Abbott Laboratories) we determined whether sheep GnRH neurons, or tyrosine hydroxylase (TH)-positive neurons which may be afferent to them, contain ER. Adult Suffolk ewes, either intact (n=2), ovariectomized (OVX) (n=2), or OVX with estradiol implants (OVX+E) (n=1), were perfused during anestrus with 4% paraformaldehyde. An immunoperoxidase/immunofluorescence procedure was used to visualize both ER and either GnRH or TH in the same preoptic and hypothalamic sections. Cells with nuclei immunostained for ER were concentrated in the medial preoptic area, periventricular anterior hypothalamus, and the paraventricular, ventromedial hypothalamic nucleus, and arcuate nuclei. Thus far, we have found no GnRH neurons which also contain immunoreactive ER although preoptic GnRH neurons were frequently in close proximity to ER-positive cells. We did find a small number of TH neurons which contained ER-positive nuclei in the periventricular region of the anterior hypothalamus (A14) and in the arcuate nucleus (A12). No differences between intact and OVX ewes were apparent in the distribution of cells with ER-positive nuclei. These results suggest that in sheep estradiol may not act directly upon GnRH neurons but upon cells which project to them. [Supported by NIH HD 18337 (FJK) and HD 21968 (MNL)]

ESTRADIOL INHIBITS SEPTAL NEURONS PROJECTING TO MEDIAN EMINENCE S.D. Donevan and A.V. Ferguson. Dept. of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The perikarya of luteinizing hormone releasing hormone (LHRH) immunoreactive neurons that project to the median eminence are located in a continuum from the septal region through to the anterior hypothalamus. Recordings have been obtained from neurons in the septal-preoptic area that could be antidromically identified as projecting to the median eminence and it has been suggested that these identified neurons are LHRH neurons. In the female rat, putative LHRH-containing preoptic neurons which project to the median eminence are influenced by systemic estrogen, suggesting an inhibitory role for this steroid in the control of LHRH secretion. The present study examines, in the male rat, the effect gonadal steroids on medial septal neurons identified as projecting to the median eminence.

In anesthetized male rats, extracellular recordings were obtained from 32 medial septal neurons antidromically identifed as projecting to the median eminence. Antidromic action potentials were followed by a period of inhibition (100 ms), which frequently persisted (83%) when the stimulus delivered to the median eminence was below threshold for antidromic activation. The spontaneous activity of 50% of identified septal neurons tested (n=10) was decreased following intravenous injection of 17β-estradiol (0.5-2 μg). This supports an inhibitory role for 17β-estradiol in the regulation of LHRH secretion in the male rat.

TESTOSTERONE, NOT INHIBIN, IS THE MAJOR SUPPRESSOR OF FSH SECRETION IN THE ADULT MALE RAT. M.D. Culler* and A. Negro-Vilar (SPON: W. Wetsel). Reprod. Neuroendo. Sect., LMIN, NIEHS, NIH, Research Triangle Park, NC 27709.

We have previously observed that immuno-neutralization of endogenous inhibin (I) in unanesthetized rats results in a dramatic elevation in plasma FSH in the female but not in the adult male. In order to further test the role and interaction of I and testosterone (T) in regulating FSH secretion, adult male rats were injected ip. either with ethylene dimethane sulphonate (EDS), a compound that selectively destroys the Leydig cells, or with vehicle alone. After 7 days, both groups of rats were injected iv. either with anti-I serum MC-4 or with normal sheep serum (NSS). Blood samples withdrawn 8 hrs later from the EDS-treated rats contained no detectable T as compared with a mean level of 1.34 ± 0.26 ng/ml in the vehicle-treated rats. Plasma FSH and LH levels in the EDS-treated rats were approx. 3- and 15-fold higher, respectively, than in the vehicle-treated controls. Anti-I serum treatment caused no significant changes in either gonadotropin as compared with NSS-treated rats. These results indicate that T, not I, is the major suppressor of plasma gonadotropin secretion in the adult male rat.

IMMUNOPURIFICATION OF BUTYRYLCHOLINESTERASE FROM CHICKEN SERUM: MOLECULAR PROPERTIES AND COMPARISON WITH THE MUSCLE ENZYME. K.W.K. Tsim*, W.R. Randall* and E.A. Barnard*. (SPON: M. Smith). MRC Molecular Neurobiology Unit, MRC Centre, Cambridge CB2 2QH, U.K.

Chicken serum butyrylcholinesterase (BuChE;EC 3.1.1.8) was purified sequentially on an anti-BuChE immunoaffinity column and a N-methylacridinium column. The purified enzyme has a specific activity of 125 U/mg of protein on acetylcholine as substrate, representing over 13,000-fold purification. The purified serum BuChE contains one type of catalytic subunit, apparent M_r 76,000, which can be labeled [^{3}H] diisopropylfluorophosphate; that reaction is blocked by a pretreatment with tetraisopropylpyrophosphoramide. The subunit size of serum BuChE is 4,000 daltons larger than that of chicken muscle BuChE; this difference appears to be in the carbohydrate content, since N-glycanase digestion of both enzymes leads to an identical size in SDS-PAGE. Over 95% of the purified serum BuChE is in the form of the globular tetramer which sediments at 11 S. This tetrameric BuChE consists of two disulphide-bridged dimers, each showing in SDS-PAGE an apparent M_r of 150,000 in the non-reduced state.

432.2

PHYSOSTIGMINE PROTECTS RAT HIPPOCAMPAL SLICE FROM IRREVERSIBLE DIISOPROPYL PHOSPHOROFLUORIDATE (DFP) INDUCED EPILEPTIFORM BURSTING. M. Abou-Donia, L.S. Jones, D. Lapadula*, and D.V. Lewis. Depts. of Pharmacology and Pediatrics, Duke Univ. Med. Ctr., Durham, NC 27710.

We have shown previously that DFP produces rapid, irreversible bursting in the CA3 subfield of hippocampal slices, while having little effect on the response of CA1 (Soc. Neur. Abs. 13:1354). Results with atropine suggested that the effects were partially mediated through the muscarinic cholinergic receptor; further evidence that DFP effects were cholinergic was needed. Using 625 μ slices from adult, male Sprague-Dawley rats cut in the usual manner, we have examined the ability of physostigmine (10 uM), a reversible AChE blocker, to protect the slice from the effects of DFP. Results indicate that, though the slices become somewhat hyperexcitable in the presence of physostigmine, the effect is reversible with washing. Further, when DFP is added to slices that are already bathed in physostigmine, the slices do not burst as they do in DFP alone, and the hyperexcitability is still reversible, which is not seen with DFP alone. These results point to cholinergic system activation as the primary mechanism for DFP-induced bursting in CA3.

432.3

NEUROCHEMICAL DIFFERENCES IN THE CAT VISUAL SYSTEM AFTER ANTICHOLINESTERASE AGENTS. A.W. Kirby, A.T. Townsend*, R.G. Stafford* and T.H. Harding*. U.S. Army Aeromedical Research Lab., P.O. Box 577, Ft. Rucker, AL 36362-5292.

We reported previously that the anticholinesterase agents diisopropylfluorophosphate (DFP) (Brain Res. 325: 357), and physostigmine (Science 221:1076) have similar effects on the cat visual evoked response (VER). Recent retinal release studies suggest that DFP has a direct effect on neuronal membranes (Soc. Neurosci. Abstr. 13:1057). We report here retinal and cortical neurochemical differences following administration of the two agents.

Retina and visual cortex were removed from anesthetized and paralyzed adult cats before and after physostigmine, analyzed with high performance liquid chromatography, and compared to earlier results with DFP.

Previous results with DFP suggest that cortical dopamine (DA) turnover (avg. inc. 117%) and GABA (avg. dec. 25%), as well as retinal DA (avg. dec. 28%) were linked to VER changes. Following physostigmine, there is no consistent change in DA turnover, and GABA increases in cortex (avg. 96%). Retinal DA decreases (avg. 15%). Other differences are seen in cortical glycine, aspartate (asp), epinephrine, and norepinephrine, as well as retinal asp, glutamate, and GABA.

Since the VER and cholinesterase changes are similar, the neurochemical differences following the two agents are difficult to explain. Since both have cholinergic effects, membrane effects of DFP might account for the differences.

432.4

COMPARISON OF *IN VITRO* ANTICHOLINESTERASE PROPERTIES OF PHYSOSTIGMINE AND PHYSOSTIGMINE DERIVATIVES. J.R. Atack, Q.-S. Yu, A. Brossi and S.I. Rapoport (SPON: J. Noronha). Labs of Neuroscience, NIA and Analytical Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Physostigmine (eserine), which is a carbamate ester alkaloid and a potent inhibitor of acetylcholinesterase (AChE) and butyrylcholinesterase (BChE), has recently been used in the experimental treatment of Alzheimer's disease with largely disappointing results. However, since physostigmine has a plasma half-life of less than 30 min., physostigmine derivatives with longer half-lifes may be more clinically useful than physostigmine itself. As a first step in the identification of such compounds, we synthesized two series of physostigmine analogues which were either carbamate- or N(1)-substituted derivatives. The *in vitro* potencies (IC_{50}) of these 20 compounds against human brain and erythrocyte AChE and human brain and plasma BChE were compared to that of physostigmine. For each compound, the IC_{50} against human brain and erythrocyte AChE was very similar, although the IC_{50} of human plasma BChE was consistently 5-15-fold less than for human brain BChE, suggesting that with respect to inhibitor susceptibility, human AChE is similar throughout the body whereas BChE is not. With respect to human AChE, 6 compounds (octyl-, butyl-, benzyl- and N-phenyl-carbamoyl eseroline and N(1)-nor- and N(1)-allyl-physostigmine) had IC_{50}'s (ranging from 15 ± 1 to $37\pm7\times10^{-9}$M) similar to the IC_{50} of physostigmine ($31\pm8\times10^{-9}$M). Of these compounds, only N-phenyl carbamoyl eseroline was a relatively selective inhibitor of AChE rather than BChE (IC_{50} vs. human brain AChE and BChE $=36\pm3$ and $2500\pm1100\times10^{-9}$M, respectively). Eseroline, which is presumably the major metabolite of physostigmine, was a very poor anticholinesterase.

432.5

TETRAHYDROAMINOACRIDINE (THA) EFFECTS ON BEHAVIOR IN RODENTS. D. S. Chapin* and J. A. Nielsen (SPON: L. K. Torgersen). Pfizer Central Research, Groton, CT.

Senile dementia of the Alzheimer type (SDAT) is a neurodegenerative brain disorder characterized by severe memory impairment. A decrease in neurochemical markers associated with cholinergic neurons has been found in SDAT patients. This suggests that cholinergic neurotransmission may be compromised in SDAT and that pharmacotherapy to enhance cholinergic function may be of benefit. THA, a potent cholinesterase inhibitor, produced symptomatic improvement in a limited trial with SDAT patients. To determine if the clinical findings with THA would be predicted from standard animal testing procedures, we have assessed the effect of THA in rodent models and estimated the therapeutic ratio by evaluating autonomic and behavioral side effects.

THA reversed scopolamine-induced amnesia in a T-maze procedure after i.p. (3.2 mg/kg) and p.o. (32 mg/kg) treatment in rats. The drug also improved the performance of mice in a passive avoidance model of memory function after 3.2 mg/kg, i.p. THA produced hypolocomotion at 5.6 mg/kg i.p., tremors and salivation at 17.8 mg/kg i.p. All of these side effects were prevented by scopolamine, a general muscarinic receptor antagonist, while the peripheral muscarinic antagonist glycopyrrolate inhibited only salivation.

These results suggest that THA is active in rodent models of cognition. The side effects of THA observed in rodents probably have both peripheral and central nervous system components.

432.6

STRUCTURE ACTIVITY RELATIONSHIPS FOR A SERIES OF (±)-9-AMINO-1,2,3,4-TETRAHYDROACRIDIN-1-OL (HP 029) ANALOGS. F.P. Huger, G. Bores*, G. Shutske* and D.B. Ellis*. Departments of Biological and Chemical Research, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, N.J. 08876.

Tacrine, a potent cholinesterase inhibitor, has been reported to benefit Alzheimer's disease patients. However, side effect liability may be a limiting factor. A number of HP 029 analogs were synthesized and tested for inhibition of acetylcholinesterase (AChE), butyrylcholinesterase (BChE) and biogenic amine uptake. AChE was measured in rat striatal homogenates by a modification of the Ellman method. BChE was determined similarly, except butyrylthiocholine was used as the substrate and human serum as a source of enzyme. Biogenic amine transport was measured in synaptosomal preparations from rat brain.

Whereas tacrine and the 1-hydroxyl compound (HP 029) are more potent as inhibitors of BChE than AChE, halogen substitution at the 6-position of the aromatic ring increased the potency for inhibition of AChE and reversed the selectivity of inhibition (i.e., AChE>BChE). Propyl or benzyl substitution at the 9-amino nitrogen decreased the effect on AChE. A most interesting finding was that certain benzyl-substituted analogs were also potent inhibitors of biogenic amine uptake (NE>DA>5HT). The inhibition of biogenic amine uptake by the benzyl-substituted compounds occurred at lower concentrations than the reported ion channel and NE release effects of tacrine. Compounds with combined cholinomimetic and adrenergic activity may show better efficacy in patients with multiple neurotransmitter deficits.

432.7

EFFECT OF THA ON ACH RELEASE IN ANIMALS WITH CHOLINERGIC LESIONS. P.E. Potter and S. Nitta*. Department of Anesthesiology, Albert Einstein College of Medicine, Montefiore Hospital, 111 E. 210th St., Bronx, N.Y. 10467

It has been reported that tetrahydroaminoacridine (THA), which decreases acetylcholine (ACh) release from normal brain, may enhance ACh release from brain slices of patients with Alzheimer's disease. We have lesioned cholinergic neurons in rat cortex by bilateral injection of 100 nmoles quinolinic acid into the substantia innominata, or lesioned hippocampal cholinergic terminals by intraventricular administration of 2 nmoles of ethylcholine mustard aziridinium (AF64A). The effects of THA (5 x 10^{-5} M), physostigmine (10^{-5} M), and LF-14 ([3,3-dimethyl-1-(4-amino-3-pyridyl) urea]; 5 x 10^{-5} M) were compared on electrically stimulated (2 Hz, 2 min) release of ^{3}H-ACh from hippocampal and cortical slices taken from control and lesioned rats. The slices were stimulated 3 times. Drugs were added between S_2 and S_3, and results are expressed as the S_3/S_2 ratio for fractional release. THA, like physostigmine, significantly decreased the S_3/S_2 ratio in hippocampus (Control= 0.97±0.03; THA= 0.75±0.13; physostigmine= 0.65±0.07) and cortex (Control= 0.90±0.06; THA= 0.37 ±0.09, physostigmine= 0.46±0.02). LF-14, a 3,4-diaminopyridine derivative, caused a large increase in ACh release (S_3/S_2 ratio: hippocampus= 4.51±1.35; cortex= 1.75 ±0.18). There was no significant difference in any of these values in slices from rats lesioned with AF64A or with quinolinic acid.

432.8

EFFECT OF CHOLINE ON CATECHOLAMINES SECRETION FROM THE ISOLATED PERFUSED RAT ADRENAL GLAND. İ.H.Ulus,L.Büyükuysal*and B.K.Kıran*.Dept. of Pharmacology, Uludağ University Medical Faculty,Bursa, TURKEY.

Male rats (250-320 g) were anesthetized with ether. The abdomen was opened by a mid-line incision, and the left adrenal gland and surrounding area were exposed. A cannula (PE 10) was inserted into the adrenal vein after all the small branches of the adrenal vein were ligated. A small slit was made into the adrenal cortex just opposite the entrance of the adrenal vein. Then the adrenal gland, along with the tied vessels an the cannula, was carefully removed from the animals. The gland was perfused with a buffered physiological solution (pH 7.4) at a rate about 0.4 ml/min. The solution was continously bubbled with 95% O_2+ 5% $CO_2$and was kept at 37o in a water bath. Perfusates were collected and assayed for catecholamines (CA). Addition of increasing concentrations (0.5-32 mM) of choline into the superfusion medium evoked CA secretion concentration related manner. The concentrations of choline lower than 0.5 mM failed to induce a detectable CA release into the medium. The secretion of CA induced by 5 mM of choline was blocked either by mecamylamine (1-10 µM) or by Hemicholium-3 (1 µM). Atropine (1-5 µM) was failed to alter CA secretion induced by 5 mM choline. These results show that choline has ability to induce CA secretion from the adrenal gland in vitro conditions, and the activation of nicotinic receptors via presynaptic mechanisms apparently involves in its actions.

432.9

MEASUREMENT OF ACETYLCHOLINE BY HPLC WITH ELECTROCHEMICAL DETECTION AND EFFECTS OF DOPAMINERGIC AND CHOLINERGIC AGENTS ON ACETYLCHOLINE LEVELS. F.P. Bymaster* and D.T. Wong (Spon: L. Truex). Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285

Acetylcholine (ACH) and choline (CH) are difficult to measure in tissues. Potter et al. (1983) and Bymaster et al. (1985) have reported methods for measuring ACH and CH using HPLC with electrochemical detection. CH and ACH in tissue extracts were separated, and choline oxidase and acetylcholinesterase were mixed with the eluate. The hydrogen peroxide formed was quantitatively detected. A new method allows enzyme immobilization on a column, resulting in increased sensitivity. Using this method, rats treated with the dopamine agonists pergolide (300 µg/kg), quinpirole (300 µg/kg) and LY163502 (50 µg/kg) had levels of ACH increased in striatum to 180, 212 and 228%, respectively. Dopamine antagonists haloperidol (0.3 mg/kg) and fluphenazine (1 mg/kg) lowered ACH levels to 62 and 64%, respectively. Oxotremorine (0.25 mg/kg), a cholinergic agonist, raised ACH levels in to 181%. Physostigmine (0.5 mg/kg), an acetylcholinesterase inhibitor, raised ACH levels to 202%. Cholinergic antagonists scopolamine (0.6 mg/kg) and atropine (10 mg/kg) lowered ACH levels to 56 and 23%, respectively. Thus it appears that cholinergic and dopaminergic agonists decrease ACH turnover, whereas, the antagonists increase turnover.

432.10

REGULATION OF CHOLINE ACETYLTRANSFERASE (ChAT) IN CULTURED EMBRYONIC CHICK SPINAL CORD NEURONS. C.L. Weill. Dept. of Neurology and Anatomy, Louisiana State Univ. Med. Center, New Orleans, LA 70112.

Choline acetyltransferase is induced by cAMP derivatives but not by 8-Br-cGMP in dissociated fetal mouse spinal cord-DRG cultures (J. Neurochem. **41**:1349, 1983). A re-examination of ChAT induction in cultured chick embryo spinal cord neurons revealed that ChAT was induced by cAMP derivatives and db-cGMP but not by 8-Br-cGMP. Induction by both db-cAMP and db-cGMP was dose dependent from 4 uM to 4 mM. The maximum induction effected by db-cGMP was consistently less than observed for db-cAMP, while the time course for induction by db-cGMP was different from that for db-cAMP; ChAT was maximal after 4-5 days and 2-3 days with db-cGMP and db-cAMP respectively. ChAT induction by both analogs was inhibited by both cycloheximide and actinomycin D suggesting a requirement for protein synthesis and RNA transcription. ChAT was also induced by chlorophenylthio-cAMP, an analog that is 100x more potent than cAMP at activating protein kinase A. Further, a dose dependent induction was effected by factors in embryonic muscle cytosol. No dependence on steroid hormones was observed, and insulin, somatostatin, atrial natriuretic factor, the phorbol ester, TPA, and nitroprusside were not inductive.

432.11

EFFECTS OF LANTHANUM, HIGH POTASSIUM AND α-LATROTOXIN ON INTRACELLULAR CALCIUM AND ACETYLCHOLINE IN SYNAPTOSOMES. H. W. Scheer*,1, L. Rosenthal*,2 and B. Collier3. Depts. of Pharmacology, Université de Montréal1 and McGill University3, Montreal, CANADA; Istituto Scientifico San Raffaele2, Milano, ITALY.

At the neuromuscular junction, La^{3+} has a dual effect on acetylcholine (ACh) release:basal release is augmented, stimulated release is blocked. To determine effects of La^{3+} in the CNS, rat cortex synaptosomal preparations were exposed for 10 min to La^{3+} (100µM), high K^+ (35mM) or the neurosecretagogue α-Latrotoxin (α-LTx; 2nM). ACh release and tissue contents were measured radioenzymatically; free intrasynaptosomal [Ca^{2+}] was measured by FURA-2 fluorescence. While basal [Ca^{2+}] were largely unaltered by La^{3+}, the increase in intrasynaptosomal Ca^{2+} elicited by high K^+ or α-LTx (1.6 and 4.8-fold increase resp.) was completely blocked by La^{3+}. Similarly, the increase of ACh released into medium following a 10 min incubation in high K^+ or α-LTx (2.0 and 2.8-fold increase resp.) was blocked by La^{3+}. The reduction in synaptosomal ACh content afforded by K^+ and αLTx (40% and 70% decrease resp.) was inhibited by La^{3+}. In contrast to evoked release, La^{3+} had no marked effects on either basal ACh release or contents. These results indicate that while in non-stimulated cortex synaptosomes La^{3+} does not greatly affect either ACh release or contents, La^{3+} does inhibit changes in ACh and intrasynaptosomal Ca^{2+} induced by high K^+ or α-LTx.

432.12

EFFECT OF INTERLEUKIN-2 (IL-2) ON ACETYLCHOLINE RELEASE IN RAT BRAIN: CORRELATION WITH IL-2 BINDING SITES. D.M. Araujo, P.A. Lapchak, B. Collier, and R.Quirion. Douglas Hospital Res. Ctr. and McGill Univ., Montreal, Canada.

In the present work, we characterized the distribution of IL-2-like immunoreactivity (IR) and IL-2 binding sites in rat brain, both in the adult and during ontogeny. In addition. we tested the effects of IL-2 on acetylcholine (ACh) release from brain slices. Radioimmunoassay analysis of tissue extracts showed that IL-2-like IR is present in hippocampus, striatum, and frontal cortex (0.70, 0.62, 0.12, ng/mg tissue, respectively). Using in vitro autoradiography and membrane binding techniques, specific IL-2 binding sites were detected in hippocampus (Bmax= 0.40 fmol/mg prot; Kd= 20 pM); specific binding was not apparent in either striatum or frontal cortex. In hippocampal slices, IL-2 caused a concentration-dependent inhibition of evoked ACh release; this IL-2 effect was enhanced in slices from kainate-lesioned hippocampi. In contrast, IL-2 did not significantly alter the release of ACh from either striatal or cortical slices. Furthermore, the IL-2-induced reduction of hippocampal ACh release appears to be mediated by a specific IL-2 receptor, since IL-1 (1 nM-10 uM) did not affect this measure. In summary, endogenous IL-2-like IR and specific IL-2 receptor sites are present in rat brain; activation of these sites by endogenous IL-2 may inhibit ACh release from certain brain areas. (Supported by MRC, Canada and FRSQ and FCAR, Quebec).

DIFLUNISAL ACTION ON INTESTINAL SMOOTH MUSCLE FROM THE RAT. E. Gijón*, E. Castillejos*, and X. García*.(SPON: B. Ortega-Corona). Dept. of Physiol. Sch. of Med. Universidad Nacional Autónoma de México, Ap. P. 70-250, México, D.F. 04510. MEXICO.

It has been reported that diflunisal (5-(2,4-difluorophenyl) salicilic acid) inhibits mitochondrial oxidative phosphorylation (McDougal, P., Markham, A., Cameron, I., and Sweetman, A.J. Biochem. Pharm., 32:2595-2598, 1983) and as a consecuence of the above, it induces a decrease of the mitochondrial membrane potential and therefore the release of intramitochondrial calcium and also that diflunisal behaves as an ionophore molecule (Chávez, E., Bravo, C., Gil, H.A., and Reyes, P.A. Life Sci. 37(16):1491-1498, 1985). Segments of intestine from 125 g male Wistar rat were prepared for isometric recording. It is shown that diflunisal, from Merck Sharp and Dohme de México, causes a contraction followed by a pronounced relaxation in intestinal muscle. In addition this report presents evidence that diflunisal modifies acetylcholine induced contraction. When diflunisal is applied during an acetylcholine contraction their effects are magnified. Diflunisal actions might be promoted by the release of the accumulated calcium of the mitochondria. These results also suggest an ionophoretic-like action at the muscle membrane, while a presynaptic action is not discarded, or an interaction with the acetylcholine receptor.

ENDOGENOUS ACETYLCHOLINE (ACh) RELEASE IN VIVO: MEASUREMENT BY INTRACEREBRAL MICRODIALYSIS AND GAS CHROMATOGRAPHY-MASS SPECTROMETRY (GC-MS). M.R. Marien and J.W. Richard*, Douglas Hospital Research Center, Verdun, Quebec, Canada.

Male SD rats (275-325g) were anesthetized with urethane (1.2 g/kg) and implanted with a microdialysis probe (BAS-Carnegie Medicin) terminating in the striatum. Under anesthesia, probes were perfused with Mg2+-free Ringer's solution for 8 hours, during which time drugs were administered either i.p. or via the probe. Perfusate samples (20 min, 46 ul) were mixed with internal standard (deuterated ACh) and processed for GC-MS analysis of ACh according to Wood & Peloquin (Neuropharm. 21: 349, 1982), with modifications. Assay sensitivity was 1-2 pmole ACh.

Dialyzable levels of striatal ACh (30-70 pmoles/20 min, in the presence of 75 uM physostigmine, not corrected for probe efficiencies of 10-26 %) were: (1) measureable only in the presence of physostigmine ($\geq$ 10 uM), (2) reduced by Ca2+-free Ringer's, tetrodotoxin (0.1 uM) and vesamicol (300 nM or 5 mg/kg i.p.), and (3) increased by K+ (100 mM) and haloperidol (0.75 mg/kg i.p.). Results are consistent with the known pharmacology of the striatal cholinergic system, and demonstrate the sensitivity and validity of this method for monitoring striatal ACh release in vivo. (Supported by the Douglas Hospital Research Centre).

QUANTITATIVE CHOLINERGIC EVALUATION OF SPINAL CORD IN ORGANOTYPIC CULTURES. Judith Friend, Changiz Geula, Shinji Ishimoto, and John R. Delfs. Department of Neurology, Harvard Medical School, Arnold Pain Center, New England Deaconess Hospital, and Dana Institute, Beth Israel Hospital, Boston, MA 02215

Anatomical and histological integrity of transverse sections of spinal cord in organotypic roller tube culture has been reported previously (Delfs and Saroff, Soc. Neurosci. Abst. 12:386, 1986). The purpose of this work was to determine whether cholinergic neuron morphology and biochemistry can be quantitated in these cultures. Cultures were studied after three weeks in vitro. For analysis of neuron size, intact cultures were stained for acetylcholinesterase (AChE) activity and the two-dimensional area of AChE-positive ventral horn neurons measured. Areas ranged up to 1635 with an average of 245 +/- 104 square microns, sizes comparable to reported in vivo values. Biochemically, pooled cultures showed choline acetyltransferase activity of 0.47 +/- 0.19 and AChE activity of 12.2 +/- 4.9 uMol/min/g protein (n=7), values comparable to those reported for neonatal rat spinal cord. These cultures can be used to study factors affecting ventral horn cholinergic neurons in vitro.

432.16

EFFECTS OF CHOLINOACTIVE COMPOUNDS ON AXIAL MUSCLE OF *HAEMONCHUS CONTORTUS* AND *BRUGIA PAHANGI*. M. A. Travis and D. P. Thompson. Parasitology Research, The Upjohn Company, Kalamazoo, MI 49001.

The cholinergic receptor on nematode axial muscle represents an important site for anthelmintic action. Acetylcholine is the major excitatory transmitter at neuromuscular junctions in nematodes, and two important commercial anthelmintics, levamisole and pyrantel, mimic the actions of acetylcholine in several physiological assays using *Ascaris suum* (Coles, G.C., *et al.* Gen. Pharmacol., 6:309-313, 1975; Harrow, I.D. and Gration, K.A.F., Pestic. Sci., 16:662-672, 1985). To determine the impact of cholinergic stimulation and inhibition on a nematode of importance to veterinary medicine, the effects of several nicotinic and muscarinic (ant)agonists on isolated axial muscle of adult female *Haemonchus contortus* (H.c.) were measured using a modified suction electrode-balance beam system. For comparative purposes, analogous studies were conducted using muscle strips obtained from adult female *Brugia pahangi* (B.p.), an accessible filarial nematode that is cultured in gerbils. Results of these studies support the following conclusions: (1) nicotinic agonists stimulate a spastic contraction and sustained paralysis in H.c., while in B.p., they stimulate a biphasic response (contraction, followed by flaccid paralysis); (2) neither parasite is influenced by muscarinic agonists or antagonists; (3) nicotinic antagonists exert no independent effect on parasite muscle tension, nor do they influence responses to nACh agonists; (4) B.p. desensitize to nicotinic stimulation; (5) cross-desensitization occurs among nicotine, levamisole and pyrantel. These results suggest that potentially important differences exist between nematode and mammalian nACh receptors.

432.17

CHOLINERGIC MUTANTS OF THE NEMATODE C. Elegans. James B. Rand, Aixa Alfonso-Pizarro*, and Carl D. Johnson. Dept. of Zoology, Univ. of Wisconsin, Madison, WI 53706, and Cambridge NeuroScience Research, Cambridge, MA 02139.

In order to identify genes affecting cholinergic metabolism and regulation, we have been isolating mutations that confer resistance to cholinesterase inhibitors such as the pesticide Aldicarb. Previous studies have shown that at least 12 different genes can mutate to give resistance. One of these genes is the cha-1-unc-17 complex, which we have shown to be the structural gene for choline acetyltransferase (the acetylcholine biosynthetic enzyme). Other resistance loci include unc-1, unc-10, unc-11, unc-13, unc-18, unc-32, unc-36, unc-63, unc-64, unc-65, and lan-5. We believe that many of these genes may affect acetylcholine metabolism, release, or function. We have isolated more than 400 independent spontaneious Aldicarb-resistant mutants from several starting strains known to contain active transposons; we expect that many of these mutants result from transposon insertions. Many of these mutants are severely uncoordinated or paralyzed, while others have only slight behavioral defects. Mapping experiments indicate that this set includes alleles of most or all of the known resistance loci (including at least 7 new alleles of cha-1-unc-17), plus at least one previously uncharacterized resistance locus on Linkage Group IV. (Supported by a Ford Foundation Postdoctoral Fellowship to A.A.-P. and research grants from NIGMS and MDA to J.B.R.)

432.18

AFFINITY-LABELLING AND PARTIAL CHARACTERIZATION OF THE CHOLINE CARRIER FROM TORPEDO ELECTROMOTOR NERVE TERMINALS, USING ^{3}H-CHOLINE MUSTARD. R.Jane Rylett and V.P.Whittaker Dept. Physiology, University of Western Ontario, London, Canada and Arbeitsgruppe Neurochemie, Max-Planck-Institut fur Biophys.Chemie, Gottingen, FR Germany.

Isolation and characterization of the high-affinity choline carrier is an important step towards understanding the organization of the cholinergic nerve terminal at the molecular level. The choline transporter in presynaptic plasma membranes of electric organ of Torpedo marmorata was radiolabelled with ^{3}H-choline mustard arizidinium ion, a known irreversible inhibitor of choline transport in rat brain synaptosomes. Membrane proteins were solubilized from EDTA-washed synaptic membranes with 0.6% CHAPS, then fractionated on a calibrated column of Ultrogel ACA44. The ^{3}H-labelled protein(s) were recovered as a peak with Stoke's radius of about 4.3 nm. Samples from the gel permeation chromatography were separated by equilibrium centrifugation on a 5-20% linear sucrose gradient; the ^{3}H-labelled protein was collected near the top of the gradient and had a sedimentation coefficient of about 5.5 S. Estimation of the molecular weight of the native protein-detergent-lipid complex was about 100 kDa. Separation of the ^{3}H-labelled protein by SDS-PAGE indicated that the majority of the ^{3}H was associated with a polypeptide subunit at 40-42 kDa. Labelling of the protein(s) was inhibited by hemicholinium. (Supported by the Medical Research Council of Canada, the Max-Planck Geselleschaft and EMBO).

DIFFERENCES IN OPEN FIELD BEHAVIOR IN RECOMBINANT INBRED STRAINS OF MICE. J.I. Nurnberger, Jr., J.R. Simon and J.N. Hingtgen. Inst. Psychiat. Res. and Program in Medical Neurobiol., Depts. of Psychiat. and Biochem., Indiana U. School of Med., Indianapolis, IN 46223.

Studies of recombinant inbred strains of mice may provide useful genetic data on potential relationships between cholinergic neurochemistry and behavior. Initial investigations in this laboratory on the progenitor strains, DBA/2J and C57BL/6J, indicated that DBA's have lower cholinergic activity than C57's in hippocampus and striatum (though the DBA's have higher CAT activity in striatum). DBA's also show a lower number of total crossings and center crossings than C57's in open field behavior. The cholinergic antagonist, scopolamine, and the agonist, arecoline, produced differential behavioral effects in these mice. In the present study, significant differences in open field behavior (total crossings, center crossings and rearings) were obtained when six recombinant inbred strains (phenotypic offspring of DBA and C57) were observed. Open field behaviors in these strains following arecoline and scopolamine are also being studied. In addition, high affinity choline uptake and choline acetyltransferase activity will be measured in specific brain areas of these mice. (Supported in part by Indiana Department of Mental Health grant.)

EPIDERMAL GROWTH FACTOR (EGF) BINDING SITES IN ADULT RAT BRAIN AND PITUITARY GLAND. AN IN VITRO AUTORADIOGRAPHIC STUDY. J.-G. Chabot, D.M. Araujo and R. Quirion. Douglas Hosp. Res. Ctr., Dept. of Psychiatry, McGill University, Verdun, Canada.

Recent studies have indicated that EGF may act as neurotrophic and/or neuromodulator substance in mammalian brain. Using an in vitro receptor autoradiographic method, we have studied the distribution of EGF binding sites in the rat brain and pituitary gland. Tissue sections were incubated with ^{125}I-EGF (200 pM) in the absence or presence of an excess of unlabeled EGF (200 nM) and juxtaposed against tritium-sensitive film. Autoradiographic data clearly demonstrate the discrete distribution of EGF sites in rat brain. ^{125}I-EGF binding sites are observed in several brain areas, such as cerebral cortex, striatum, hippocampal formation, certain hypothalamic nuclei, medial geniculate nucleus, ventral tegmental area, substantia nigra pars compacta and cerebellum. In the pituitary gland, EGF receptor sites are restricted to the pars distalis. Thus, EGF binding sites are present in rat brain and pituitary gland suggesting the possible involvement of this factor in the maintenance of normal CNS functions (see Quirion et al., this meeting). (Supported by MRC, Canada and FRSQ, Quebec).

432.21

GROWTH FACTOR RECEPTORS IN RAT BRAIN: LOCALIZATION AND INTERACTION WITH THE CHOLINERGIC SYSTEM. R. Quirion, D. M. Araujo, P. A. Lapchak, J.-G. Chabot, and B. Collier. Douglas Hosp. Res. Ctr. & McGill Univ., Montreal, Canada.

The present study characterized the binding of several growth factors (GFs) including insulin-like GF (IGF-1), epidermal GF (EGF), and nerve GF (NGF). Using in vitro autoradiography and membrane binding assays, we studied the ontogenetic development of GF receptor sites in the rat brain. In addition, we tested the effects of these GFs on acetylcholine (ACh) release from rat brain slices.

The results show that there is an extensive distribution of IGF-1 receptor sites in rat brain, and that these sites undergoredistribution during development and maturation. EGF sites appear to be mostly exposed during postnatal development early on (P1). In slices of hippocampus, which is highly enriched with IGF-1 sites, and some EGF sites, IGF-1 and EGF reduced the potassium-evoked (25 mM) release of ACh; this effect was evident in slices from adult, but not immature, hippocampus. In contrast, although specific NGF binding sites are present in adult rat hippocampus, NGF did not alter ACh release in either adult or immature rat hippocampus. Thus, it appears that in addition to their well-known trophic effects, IGF-1 and EGF may function as neuromodulators of ACh release in the adult rat brain. AN AGE STUDY ON THE LEVELS OF CYSTEINYLDOPAMINE AND RELATED ADDUCTS IN THE HUMAN BRAIN B. Fornstedt*, (SPON:Liljequist) Department of Pharmacology, University of Göteborg, BOX 33031, S-400 33 Göteborg, Sweden.

The cellular mechanism behind the selective degeneration of neuromelanin containing neurons in brain disorders as Parkinson's disease has been a matter of speculation for many scientists. During nonpathologic aging there is a similar but much less pronounced loss of neurons. It is well known that catecholamines undergo autoxidation to semiquinones and quinones and it is believed that further oxidation of these products with a subsequent polymerization gives rise to neuromelanin. The electron deficient quinones react readily with nucleophilic compounds, especially thiol containing substances as cysteine and glutathione which are highly concentrated in the cytosol. The higher vulnerability of catecholaminergic neurons can be explained by the reactivity of the quinones and/or the oxygen free radicals formed during the oxidation. In our method we measure the degree of autoxidation by detection of adducts with cysteine formed in vivo. So far, we have found 5-S-cysteinyldopamine, -dopa and -dopac in several mammalian brains. We are, for the time being, involved in several studies where we analyze the adduct concentrations in the brain. They include two age studies, studies on brain tissue from patients with and without degeneration of dopaminergic areas and animal studies after different pharmacological manipulations. Initial data suggest that there is an increase in cysteinyl adduct levels with age, which may be explained by a weakened cellular defense system. The results from our age studies on humans and on guinea-pigs will be discussed at the symposium.

433.2

ALTERATIONS IN TYROSINE (TYR) AND TRYPTOPHAN (TRYP) CONCENTRATIONS IN RAT BRAIN AND PLASMA BY CLENBUTEROL (CLEN). D.J. Edwards and D.A. Sorisio*. Dept. Pharmacol.-Physiol. Univ. Pittsburgh Sch. Dent. Med., Pittsburgh, PA 15261.

Recent studies in our laboratory showed that the β_2-adrenoceptor agonist salbutamol decreases plasma TYR and raises brain TRYP concentrations (Life Sci. **42**: 853, 1988). We have now examined the effects of CLEN, a β_2-agonist which more readily penetrates the blood-brain barrier. Rats were injected i.p. with either 5 mg/kg CLEN or saline and decapitated 90 min later. In some experiments, the rats were pretreated with 15 mg/kg propranolol (PROP) or saline 20 min before CLEN or saline. TYR and TRYP were assayed by HPLC with electrochemical detection. CLEN lowered both TYR and TRYP in plasma and raised them in brain. Levels of these amino acids were either unchanged or decreased in heart, lungs, spleen and liver. These changes were only partially if at all reversed by PROP. A dose-response study revealed that the reductions in plasma TYR and the elevations in brain TRYP were equal over the range of 0.5-5 mg/kg of CLEN, but the effects of the lowest dose were completely antagonized by PROP. The effects of CLEN were not blocked by the serotonin (5-HT) antagonist, methysergide, ruling out an involvement of 5-HT receptors. Preliminary results suggest that the elevations in brain TYR and TRYP levels are due to stimulation of β_2-receptors, since the effects are blocked by the β_2-antagonist ICI 118,551 but not by the β_1-antagonist betaxolol. Supported by grant #MH28340.

433.3

THE EFFECT OF NIGRAL STIMULATION ON THE ACCUMULATION OF β-PHENYLETHYLAMINE (PE) IN THE RAT STRIATUM. A.V.Juorio* and I.A.Paterson (SPON: A.A.Boulton). Neuropsychiatric Res. Unit, Univ. of Saskatchewan, Saskatoon, Sask,Canada.

PE is a neurophysiologically active compound that occurs in small concentrations in the brain where is rapidly metabolized by type B monoamine oxidase (MAO). Earlier experiments have shown that unilateral electrolytic or 6-hydroxydopamine lesion of the rat substantia nigra (SN) produced decreases in PE levels in the ipsilateral striatum but no changes were observed after raphé nuclei lesion. The object of these experiments is to determine the extent of PE accumulation following stimulation of the SN. The effect of stimulation of the SN (20 Hz, 100 µA, 1 hour with bipolar concentric electrodes) on the striatal accumulation of PE in anaesthesized (urethane 1 g/kg, i.p.) was determined in deprenyl pretreated rats (2mg/kg, i.p., 3 hours). The determination of PE was performed by a mass spectrometric technique and DA, DOPAC and HVA by HPLC with electrochemical detection. The SN stimulation produced a small but significant reduction (to 78 % of controls) in the accumulation of striatal PE at a time when the concentrations of either DOPAC or HVA were increased by about 50 % of their control levels. It may be that in MAO inhibitor treated rats, SN stimulation increases PE utilization and removal from the brain, or the increased rate of DA synthesis decreases the availability of phenylalanine for decarboxylation and synthesis of PE. Supported by Saskatchewan Health and a Saskatchewan Health Research Board Fellowship (I.A.P.).

433.4

THE RELATIONSHIP IN MANIC DISORDER OF CSF AMINE METABOLITES TO CLINICAL CHARACTERISTICS AFTER LITHIUM TREATMENT. CL Bowden, E Seleshi*, S Contreras*, MA Javors*, JW Maas. Departments of Psychiatry, The University of Texas Health Science Center, and Audie L. Murphy Memorial Veteran's Hospital, San Antonio, TX 78284.

Despite the clinical importance of manic disorder, and the general efficacy of lithium in its treatment, relatively little information is available about biological characteristics of manic disorder, or the effects of lithium on biological parameters. We studied the CSF amine metabolites MHPG, 5-HIAA and HVA in manic and bipolar depressed patients both at baseline and following four weeks treatment with lithium carbonate. Patients were diagnosed by Research Diagnostic Criteria, utilizing the Schedule for Affective Disorders and Schizophrenia. In addition to data from 18 manic patients and 20 unipolar depressed patients, baseline data were obtained from 9 healthy control subjects, and 29 patients with unipolar depression. Amine metabolite analyses were by HPLC with electrochemical detection. At baseline, CSF MHPG, but not 5-HIAA or HVA, was higher in manic patients than in healthy controls (12.0 ± 9.04 vs. 6.66 ± 2.36 pmol/ml, $\bar{x} \pm$ S.D.). After treatment, 5HIAA was higher in manic patients than in bipolar depressed patients, and the increase in 5HIAA was greater in manic patients than in bipolar depressed patients. In manic patients at baseline there was no significant correlation between MHPG and 5-HIAA. After four weeks treatment the metabolites showed a correlation of 0.77, $p = .01$. Whereas the correlation between change in MHPG and 5-HIAA was not significant for all manic patients ($r = 0.30$), when only clinically recovered cases were analyzed, the correlation was significant ($r = 0.82$). Data will also be presented with respect to the change in amine metabolites with treatment and the association of change in animal metabolites with change in symptomatology.

433.5

ORIGINS OF NOREPINEPHRINE IN RAT CEREBROSPINAL FLUID. E. Mamalaki*, L. S. Brady, D. Goldstein*, and M. Herkenham (SPON: M. A. Smith). Unit on Functional Neuroanatomy, Clinical Neuroendocrinology Branch, NIMH, and Hypertension-Endocrine Branch, NHLBI, Bethesda, MD 20892

The cerebrospinal fluid (CSF) contains informational substances whose levels fluctuate with alterations in CNS activity. Sources of catecholamines in cerebrospinal fluid (CSF) are poorly understood. The locus coeruleus is the main source of norepinephrine fibers in brain, and the superior cervical ganglion provides dense noradrenergic innervation of the choroid plexus. CSF was drawn from the cisterna magna in rats 4 days before either bilateral superior cervical ganglionectomy or electrolytic destruction of the locus coeruleus and again 4-7 days after the operations. Samples (100-200 µl) of CSF were assayed for catechols by liquid chromatography with electrochemical detection after batch alumina extraction. Ganglionectomy (N=5) did not significantly affect CSF levels of catechols, whereas locus coeruleus lesions (N=17) decreased CSF norepinephrine ($p<0.0001$) but not dihydroxyphenylalanine (DOPA), dopamine, dihydroxyphenylacetic acid (DOPAC), or dihydroxyphenylglycol (DHPG). Epinephrine was below detection limits. The decrease in CSF norepinephrine was correlated significantly ($r=0.50$, $p<0.05$) with the extent of the locus coeruleus lesions; however, total bilateral destruction decreased CSF norepinephrine by only 50%. The data indicate that the locus coeruleus is a major--but not exclusive--source of CSF norepinephrine.

433.6

A COMPARATIVE STUDY OF THE LEVELS OF MONOAMINES IN SELECTED AREAS OF THE RAT CEREBRAL CORTEX N.Kabani*, R.W.Dykes, T.A.Reader. McGill University,Universite de Montreal,Montreal, PQ.

HPLC was used to measure the levels of monoamines (MA) in the hindlimb region of the somatosensory cortex (SS), primary visual cortex (VIS), and the anterior cingulate cortex (CING) of adult male Sprague-Dawley rats.

Large, correlated changes were observed in different months of the year. A significant positive correlation ($r=0.9$) was seen between changes in 5-HT and DA in the SS whereas in the CING, a significant positive correlation was seen for all 3 primary MAs. In the VIS there was a negative correlation between NE and 5-HT ($r=0.9$). A highly significant difference was observed in the MA levels of the CING when compared to SS and VIS for all compounds except 3MT and E. Significant differences between SS and VIS were seen for NE, DA, DOPAC and HVA. Differences between the sensory corticies and CING is consistent with the functionally distinct role of the former and a difference in the levels of MAs within SS and VIS, is suggestive of a functionally different role for MAs in these two sensory corticies.

433.7

EFFECT OF MORPHINE ON EPINEPHRINE CONCENTRATION IN RAT BRAIN. M. Ota*, I. N. Mefford* and M. Linnoila. LCS, NIAAA and LCS, NIMH, Bethesda, MD 20892

Acute and chronic morphine (MO) administration affects the function of catecholamine (CA) systems within the central nervous system (CNS). Most investigators have studied effects of MO on the noradrenergic and dopaminergic systems, while only a few reports concern effects of MO on CNS epinephrine (EPI) concentration. We quantified acute and chronic effects of MO on concentrations of EPI, norepinephrine (NE), dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanilic acid (HVA) in hypothalamus (HT), medulla, locus coeruleus and frontal cortex of male Sprague-Dawley rats. HPLC with electrochemical detection was used for quantification of the analysis.

A single injection of MO sulfate (20mg/kg s.c.) reduced EPI and NE contents only in the HT, while DA, DOPAC and HVA concentrations were elevated in all areas (EPI, control 53.4±10.1, n=4, 2hrs post-injection 28.8±6.5ng/g tissue, n=4, $p<0.01$). All changes were antagonized by pretreatment with naloxone hydrochloride (NAL)(1mg/kg i.p.). This finding suggests that MO exerts its effect on metabolism through the mu opiate receptors. Repeated twice-daily MO injections for 14 days (M14) did not produce significant changes in EPI, NE or DA concentrations in any area examined 2hrs after the last MO injection. Coadministration of NAL (1mg/kg i.p.) with MO in the last injection (M14+N) induced significant depletion of EPI and NE in the HT compared to the MO only treated group (EPI, M14 51.7±8.8, n=7, M14+N 35.1±7.2ng/g tissue, n=6, $p<0.01$). These results suggest that acutely administered MO increases EPI release in the HT. Tolerance develops to this effect. Following chronic MO administration, a low dose of the opiate antagonist NAL produces an increase in EPI release.

433.8

CONTINUOUS AND INTERMITTENT LEVODOPA ADMINISTRATION DIFFERENTIALLY AFFECT BEHAVIORAL AND BIOCHEMICAL INDICES OF CENTRAL DOPAMINGERGIC ACTIVITY. T.M. Engber, J.L. Juncos*, Z. Susel*, R. Raisman*, F. Thibaut*, Y. Agid* and T.N. Chase. NINCDS, Bethesda, MD and INSERM U-289, Hopital de la Salpetriere, Paris, France.

Levodopa (LD) treatment schedules have been implicated in the pathogenesis of motor response fluctuations in Parkinson's disease. We compared continuous and intermittent LD replacement therapies in male rats with unilateral 6-hydroxydopamine lesions of the ascending dopaminergic pathways; rats were divided into 15 and 30 day treatment groups. In each, 3 subgroups of 7-9 rats were treated with either: a) continuous (cont.) saline (infused i.p. via Alzet osmotic pumps) + saline injections [all injections (inj.) given i.p., b.i.d.]; b) cont. LD (all LD doses=100 mg/kg/day) + saline inj.; or c) cont. saline + LD inj. Three days after the last treatment, contralateral rotations induced by apomorphine (0.05 or 0.5 mg/kg s.c.) were recorded. Animals were then sacrificed, and the striata dissected and analyzed for ipsilateral/contralateral D1 ([3H]SCH 23390) and D2 ([3H]spiperone) dopamine receptor binding, glutamic acid decarboxylase (GAD) and tyrosine hydroxylase (TH) enzyme activities. Only rats with 99% depletion of TH in the lesioned striatum were used. The LD injected rats exhibited a significant increase in the number of rotations during the first hour compared to the other treatment groups. GAD activity was significantly increased in the lesioned striata and in the LD inj. group compared to the other treatment groups. Rotations in the first hour correlated with the increase in GAD activity but not with alterations in D1 or D2 binding. This finding of a relationship between behavioral hypersensitivity and striatal GAD acitivity, but not with dopamine receptor binding, suggests that this behavioral hypersensitivity involves mechanisms downstream from striatal dopamine receptors.

433.9

BEHAVIORAL AND BIOCHEMICAL EFFECTS OF REPEATED APOMORPHINE TREATMENTS IN RATS. B. A. Mattingly1, J. K. Rowlett*1, J. Graff*1, M. T. Bardo2 1: Morehead State Univ. Morehead, KY 40351. 2: Dept. of Psych., Univ. of Kentucky, Lexington, KY 40506

Repeated treatments with the dopamine receptor agonist, apomorphine (APO), induces behavioral sensitization to the locomotor stimulating effects of APO. The purpose of the present study was to determine whether this behavioral sensitization effect is related to changes in dopamine receptors or metabolism. In two experiments, rats were injected SC with either apomorphine (5 mg/kg) or vehicle and tested for locomotor activity daily for 13 days. Following this chronic treatment, all rats were sacrificed, brains were removed, and striatal and mesolimbic tissue was dissected. In Exp. 1, a ^{3}H-spiroperidol receptor binding assay was performed. In Exp. 2, dopamine and DOPAC levels were measured using high pressure liquid chromatography with electrochemical detection. The results revealed no significant differences in receptor binding, dopamine levels, DOPAC levels, or DOPAC/DA ratios between the APO and vehicle pretreatment groups. These findings suggest that the development of behavioral sensitization to apomorphine is not the result of a drug-induced increase in dopamine receptors or metabolism.(This research was supported by grants from Morehead State Univ. and the KY EPSCoR committee).

433.10

DIFFERENTIAL DOPAMINE AGONIST EFFECTS ON THE INHIBITION OF ARYLSULFATASE-C. E.J. Martin* and T.J. Shickley (SPON: R.O. Warwick,Jr.), Dept. of Pharm/Tox, Philadelphia College of Pharmacy and Science, Phila., PA 19104.

We have previously shown that dopamine (DA) inhibits arylsulfatase-C (ARS-C) (Neurosci. Abstr. 13 (2),p1474, 1987). We also have shown this inhibition to be competitive (Neurosci. Abstra. 14, 1988). In the present study we examined the ability of the DA agonists apomorphine (APO), SK&F 82526 and LY-171555 to produce inhibition of ARS-C.

Partially purified ARS-C (Sigma, S-1629) was incubated in the presence of DA, APO, SK&F 82526 and LY-171555 using a modification of the spectrophotometric technic of Fowler and Rammler (Biochem. 3, p230, 1964).

The D1 agonist SK&F 82526 and the D2 agonist LY-171555 had no ability to block the desulfation of p-nitrophenyl sulfate at concentrations up to 1E-3M. The partial agonist APO produced inhibition similar to that of DA. These results suggest a structure activity relationship for the inhibition of ARS-C by DA and APO which is independent of the receptor-specific sites of the DA agonists SK&F 82526 and LY-171555.(Supported by USPHS Grant NS-26040 to T.J.S.)

433.11

ENZYME KINETICS OF DOPAMINE INHIBITION OF ARYLSULFATASE-C T.A. Cawley,Jr., E.J. Martin* and T.J. Shickley. Dept. Pharm/Tox, Philadelphia College of Pharmacy and Science, Phila. PA 19104

Arylsulfatases (EC 3.1.6.1) occur in nature in three distinct forms: A,B and C (ARS-C), all of which are found in brain. Little is known about the role of ARS-C in the CNS.

It has been previously reported that dopamine (DA) produces inhibition of ARS-C (Enyedy and Shickley. Soc. Neurosci. Abstr. 13,(2) p.1474, 1987). We have investigated the kinetics of this inhibition by DA on ARS-C.

Partially purified ARS-C (Sigma,S-1629) activity was assayed spectrophotometrically using p-nitrophenyl sulfate (p-NPS) as substrate by measuring enzymatically liberated p-nitrophenol (p-NP). Inhibition was analyzed by varying DA concentration in the presence of fixed concentrations of p-NPS.

Kinetic analysis of inhibition (Dixon Plot) revealed an apparent K_i for DA of approximately 600 uM, which is well below the DA concentration in limbic forebrain tissue (Anden et al. Acta Physiol. Scand. 67,p.306-312, 1966). This inhibition was found to fit a model for simple competitive inhibition. (Supported by USPHS Grant NS-26040 to T.J.S.)

AGE-DEPENDENT EFFECTS OF NIGROSTRIATAL LESIONS ON DOPAMINERGIC MODULATION OF ACETYLCHOLINE RELEASE. D. Jackson, S. Bernath, J.P. Bruno and M.J. Zigmond. Univ. of Pittsburgh, Pittsburgh, PA. 15260.

Adult rats are dependent upon dopamine (DA) for normal behavior: destruction of nigrostriatal bundle (NSB) results in severe behavioral deficits and, if recovery occurs, deficits can be reinstated with DA receptor antagonists. In contrast, NSB lesions produced in neonates cause no such deficits and DA antagonists have little behavioral effect. We have examined the role of residual DA in striatal function in rats lesioned during development with 6-hydroxydopamine (6-HDA). At adulthood, striatal slices were preincubated with [3H]choline, superfused with Krebs bicarbonate buffer, and exposed to electrical field stimulation (8 Hz, 1 min). The ability of sulpiride to stimulate tritium overflow was used as an index of DA inhibition of ACh release. DA in superfusates was quantified with HPLC. Although DA overflow was reduced by 6-HDA, fractional DA overflow was increased above control levels when slices were prepared from rats lesioned at 20 days of age or as adults; no such effect was seen when lesions were made at 3 or 15 days of age.Moreover, endogenous DA appeared to inhibit ACh overflow only in slices from rats lesioned at 20 days of age or greater. These results parallel our behavioral observations and suggest that if NSB injury is sustained at a young age, normal function may develop without the need for a dopaminergic influence. (Supported by NS19608)

EFFECTS OF UNILATERAL 6-HYDROXYDOPAMINE LESIONS OF SUBSTANTIA NIGRA ON DOPAMINERGIC TRANSMISSION IN RAT STRIATUM. W. Zhang*, S.J. Li*, H. Tilson, K. Nanry*, P. Hudson*, J.S. Hong, and M.K. Stachowiak.(SPON:R.H. Rech). Lab. Molecular and Integrative Neuroscience,NIEHS, P.O. Box 12233, Research Triangle Park, NC 27709.

Unilateral injection of 6-HDA (8 ug) into substantia nigra produced increases in met-enkephalin (ME) content in the ipsilateral striatum. Increase in ME immunoreactivity occurred only in striata with greater than 90% dopamine (DA) depletions suggesting that the enhanced efficiency of DA transmission may compensate for the less extensive denervation. In rats with greater than 70% DA depletion, supersensitivity of striatal dynorphin neurons to apomorphine (1 mg/kg, i.p.) was observed. Presynaptic compensations were examined by measuring extracellular concentration of striatal DA using brain dialysis. Concentration of DA in dialysates remained unchanged in striata with 60-90% DA depletions. More extensive lesions were accompanied by only 60% reduction of DA release. Increased DA release was also observed in striatum contralateral to 6-HDA lesion and was accompanied by increased DA and HVA tissue content.

In conclusion, our results indicate that DA transmission in striatum is sustained following depletion of up to 90% of striatal DA. Such synaptic homeostasis may involve increased DA release, and following more extensive lesions, increased responsiveness of striatal neurons to DA.

REDUCTION OF DOPAMINERGIC INPUT INCREASES THE EXPRESSION OF THE ENKEPHALIN GENE. G.R. Christoph, B. Burkhart*, R. G. Krause II*, J. Angulo, M.E. Lewis and L.G. Davis. Medical Products Dept., E.I. Dupont de Nemours & Co., Inc., Wilmington, DE 19898.

We have investigated the effect of dopamine receptor blockade on striatal proenkephalin mRNA levels by Northern gel analysis and in situ hybridization. Chronic haloperidol treatment resulted in a 3.5-fold increase in striatal proenkephalin mRNA. This effect could be blocked with a co-administration of apomorphine. Changes in proenkephalin mRNA levels were uniform throughout the caudate-putamen as determined by in situ hybridization. Furthermore, unilateral 6-OHDA lesions of the substantia nigra, which reduced dopaminergic input to the striatum, result in a significant ipsilateral elevation of proenkephalin mRNA. This elevation can be reversed by transplanting embryonic ventral mesencephalic tissue, which contains dopaminergic perikarya, into the denervated striatum. The results imply that altering receptor-mediated neurotransmitter activity can lead to alterations in neuronal gene expression.

To determine if the increase in proenkephalin mRNA involved transcriptional regulation, heteronuclear RNA (hnRNA) was assayed with an intron containing probe. Our data indicate that proenkephalin mRNA and hnRNA are similarly affected by dopaminergic receptor blockade, suggesting that regulation is at least partly at the level of gene transcription. Experiments in progress are aimed at understanding the biochemical mechanisms in the transduction of information from the dopamine receptor to the nucleus that leads to the alteration of the proenkephalin mRNA levels.

D-2 AGONIST QUINPIROLE INDUCES INHIBITION AND EXCITATION OF FORWARD PROGRESSION. D. Eilam and H. Szechtman. Dept. Biomedical Sciences, McMaster Univ., Hamilton, Ontario, CANADA L8N 3Z5.

The effect of the D-2 agonist quinpirole (LY171555) on forward progression was measured in 60 rats injected with either saline, 0.03, 0.125, 0.5, 2, or 8 mg/kg of the drug. The total amount of forward progression was measured continuously during the two hour observation period. Results indicate that across both dose and time, quinpirole induces inhibition and then excitation of forward progression. Thus, the 0.03 mg/kg dose of quinpirole inhibited forward progression to nil in all rats, and doses higher than 0.125 mg/kg elevated it (compared to saline). At 0.125 mg/kg, locomotion was inhibited in some rats and elevated in others, suggesting that this dose is at the threshold of the switch from inhibition to excitation. Across time, a similar profile was evident. In the first 20 minutes after injection of 0.5 mg/kg or more of quinpirole, locomotion was inhibited (compared to saline animals) and elevated dramatically from 60-120 min of testing. This behavioral profile may parallel electrophysiological findings of disinhibition and inhibition of nucleus accumbens neurons by D2 receptor stimulation [Hu & Wang, (1988) Brain Res. 444:389]. 434.2

COMBINED, BUT NOT SEPARATE, INJECTION OF D1 (SKF 38393) AND D2 (LY 171555) DOPAMINE AGONISTS INTO THE NUCLEUS ACCUMBENS INCREASES LOCOMOTOR ACTIVITY. T.J. Walsh D.F. Emerich and L.A. Taylor *. Rutgers University, Deparment of Psychology, New Brunswick, NJ 08903.

It is well established that the nucleus accumbens (NA) and its dopaminergic innervation from the ventral tegmental area (A10) are involved in the modulation of goal-directed motor behavior. The systemic and intraaccumbens administration of indirect and direct acting DA agonists such as amphetamine and apomorphine increase motor activity in a DA - dependent manner. Pharmacological and neurochemical evidence indicates that there is a duplicity of DA receptors which are designated D1 and D2 (Kebabian, J.W. Nature, 277, 93, 1979). The functional properties of these receptors in the control of motor behavior, however, have not been well characterized.

The present study demonstrated that bilateral injection of either D1 (10 or 20 ug SKF 38393) or D2 (0.5, 1.0, or 2.0 ug LY 171555) agonists into the NA of male Sprague dawley rats produced no significant increases in motor activity compared to saline injected controls. However, combined administration of the D1 and D2 agonists in a "cocktail" did significantly increase motor activity in a dose-related fashion. Combined administration of 15 ug of SKF 38393 and 1.25 ug LY 171555, or 10ug of SKF 38393 and 0.5 ug LY 171555, increased motor activity 119 % - 296% over control values for up to 90 minutes following injection.

Our results are consistent with recent electrophysiological studies that have shown that concurrent D1 and D2 receptor stimulation in the NA may be necessary to initiate and direct locomotor behavior. (Clark D. et. al., Synapse, 1, 347, 1987). These results indicate a coordinated involvement of DA receptor subtypes in the modulation of behavior.

EFFECTS OF D1 AND D2 RECEPTOR STIMULATION ON AROUSAL, ATTENTION AND INTENTION TO MOVE. A. R. Braun* and T. N. Chase (SPON: J. Walters). Experimental Therapeutics Branch, NINCDS, NIH, Bethesda, MD 20892

Dopamine appears to play a significant role in the mechanisms of arousal, selective and sustained attention, and intention to move. In order to characterize the relative roles of D1 and D2 receptors in these processes we administered the selective D1 and D2 agonists SKF38393 and LY171555 alone and in combination to male rats and evaluated responses to several categories of environmental stimuli. Both D1 and D2 receptor agonists produced dose dependent increases in arousal and in orientation to novel objects and discrete moving stimuli. Selective D2 receptor stimulation resulted in decreases in response to noxious stimuli while the D1 agonist had no significant effect. The D2 agonist produced increases in sustained exploration of a novel object and pursuit of a moving stimulus, while D1 receptor stimulation produced decreases in these behaviors. The D2 agonist produced increases in the time animals initially spent in the center of an open field, but had no significant effects upon other open field behaviors; D1 receptor stimulation did not affect time spent in the center of the field but produced dose dependent decreases in investigatory behavior and increased disorganization of open field locomotor patterns. When the agonists were administered together in varying doses, the same overall patterns persisted; concurrent D1/D2 receptor stimulation had pronounced interactive effects upon sustained attention and exploratory behavior. There was in addition an apparent functional distinction between high and low doses of the D1 agonist. When endogenous dopamine was depleted by AMPT pretreatment, D1 receptor stimulation continuted to produce an increase in orientation but did not affect other parameters. D2 receptor stimulation, on the other hand, produced dose dependent decreases in orientation, exploration, and locomotion in an open field. These data provide evidence of distinct and generally opposing roles of D1 and D2 receptor stimulation upon responses to environmental stimuli and evidence of D1/D2 receptor interaction in the generation of such responses. The data also suggest that reduction in D1 receptor tone produces sensorimotor responses following D2 receptor stimulation which are functionally the opposite of those seen in otherwise intact animals following D2 agonist administration.

CHARACTERIZATION OF RABBIT POLYCLONAL ANTI-IDIOTYPIC ANTIBODY AGAINST CONJUGATED ANTI-DOPAMINE. N. Mons*, M. Geffard, C. Messier (1), O. Mrabet (1) and C. Destrade (1). Lab. Neuroimmunology, IBCN-CNRS, 33077 BORDEAUX and (1) Lab. Psychophysiologie, UA CNRS 399, 33405 TALENCE FRANCE.

This study examined the raising of rabbit polyclonal anti-idiotypic antiserum (Ab2) that recognize dopamine (DA) receptors. Our approach to obtain this anti-idiotypic antibody (Ab) has consisted : (i) in developing polyclonal and monoclonal anti-DA conjugated antibodies which had high affinity for DA-G-lysine, (ii) in raising antibodies (Ab2) against these idiotypic antisera (Ab1). Rabbit polyclonal Ab2 was obtained after alternate immunizations with either mouse Ab or purified rabbit IgG with complete Freund's adjuvant. Then, the Ab2 were affinity chromatographed to remove anti-isotypic and anti-allotypic antibodies. The specificity of the crude anti-idiotypic was tested (1) in ELISA for their capacity to bind poly- and monoclonal idiotypic sites, (2) for its ability to inhibit 3H DA binding to DA-receptors: the 3H DA was displaced at 1/10000 dilution, (3) for its immunohistochemical visualization. Male rats were fixed with paraformaldehyde 4%-picric acid 0.2%. Fifty m sections were subjected to PAP method, using a 1/1000 dilution of Ab2. Immunoreactive product was observed in striatum, septum and substantia nigra and was abolished after preadsorption with monoclonal or polyclonal Ab1, (4) Unilateral intra-accumbens injection of the anti-idiotype in amphetamine pre-treated mice produced ipsilateral circling.

434.5

ROTATIONAL BEHAVIOR PRODUCED BY INTRA-ACCUMBENS MICROINJECTION OF CONJUGATED DOPAMINE ANTI-IDIOTYPIC ANTIBODIES. O. Mrabet*, C. Messier, N. Mons (1), M. Geffard (1) and C. Destrade. (SPON: European Brain and Behavior Society). Lab. Psychophysiologie, UA CNRS 339, TALENCE FRANCE and (1) Lab. Neuroimmunologie, IBCN-CNRS, BORDEAUX FRANCE.

Polyclonal dopamine (DA) anti-idiotype antibodies were raised in immunized rabbits with either purified polyclonal immunoglobulins or a monoclonal anti-conjugated DA antibody (Chagnaud et al., J.of Neurochem., 49, 487-494, 1987). Anti-idiotype antibody affinity and specificity were evaluated. In the present experiments, we tested the ability of the DA anti-idiotypic (AI) antibodies to change behavior through its action on a brain area rich in DA receptors. We microinjected the DA AI antibodies unilaterally into the nucleus accumbens of 2 mg/kg amphetamine pre- treated BALB/c mice. One group was injected with either 0.5, 1.5 or 3.5 µl of DA AI; a second group was injected with either 0.5, 1.5 or 3.5 µl of immunoglobulins from non-immune mice (IgG); one last group was injected with 1.5 µl of DA AI followed 45 min later by an intra-accumbens injection of apomorphine (40 ng in 2 µl). The injection of DA AI produced a locomotion bias which resulted in ipsilateral turning. No locomotion bias was observed in the mice injected with either of the IgG doses. Injection of 1.5 µl of DA AI produced ipsilateral turning which was abolished and then reversed (contralateral turning) by the intra-accumbens apomorphine injection.

ELECTROPHYSIOLOGICAL AND BEHAVIORAL STUDIES OF AMINOTETRALINS (AT) IN RAT BRAIN DOPAMINE SYSTEMS. R.J.Brooderson and F.J. White. Depts. of Pharmacol. & Psychiat. Wayne St. Univ. Sch. Med., & Neuropsychopharm. Lab., Lafayette Clinic, Detroit, MI 48207

The ATs constitute a novel class of dopamine (DA) agonist with structures similar to DA itself. These compounds have been reported to stimulate both D1 and D2 DA receptors. Given recent findings indicating the necessity of stimulating both DA receptors for the functional expression of postsynaptic D2 responses, such mixed agonists may potentially be of therepeutic utility.

We have begun to characterize the electrophysiological effects of several AT DA agonists within the mesoaccumbens DA pathway using extracellular single-unit recording techniques in chloral-hydrate anesthetized rats. Recordings from A10 DA cells indicate that the rank order of potencies at somatodendritic DA autoreceptors is: (±)-5-OHDPAT (ED_{50} 2.3 µg/kg) = (±)-7-OHDPAT (ED_{50} 2.6 µg/kg) > (±)-Dimethyl-5,6-dihydroxy-ADTN (ED_{50} 14 µg/kg) ≥ (±)-Dimethyl-6,7-dihyroxyADTN (TL-99; ED_{50} 18 µg/kg). Thus, the monohydroxylated ATs appear more potent than their dihydroxylated counterparts. Preliminary behavioral results indicate that both 5- and 7-OHDPAT (0.5mg/kg, s.c.) can reverse akinesia produced by reserpine+αMPT and induce stereotyped behaviors in rats, effects which reqiure stimulation of both D1 and D2 receptors. Thus, these ATs are potent agonists at somatodendritic DA autoreceptors and also exert both D1 and D2 agonist effects postsynaptically.

COMPLEX DOPAMINE (DA) AGONIST/ANTAGONIST EFFECTS ON SUBSTANTIA NIGRA PARS RETICULATA (SNpr) NEURONS. L.Martin* and B.L. Waszczak. Pharmacol. Sect., Northeastern Univ., Boston, MA.

Previous studies suggested that the ability of DA to increase firing and to lessen responses of SNpr neurons to GABA could be mediated by D-1 and D-2 receptors, respectively. Extracellular recordings were carried out in rats to examine the selectivity of these actions. Surprisingly, iontophoretic application (2 and 5 nA) of neither (-)sulpiride (SUL; 0.2M) nor zetidoline (ZET; 0.2M), both selective D-2 antagonists, could prevent the modulation of GABA effects by the D-2 agonist LY 171555 (LY; 0.05M, 10 nA). In fact, both drugs caused current-related agonist-like attenuations of GABA's actions, and acted additively or synergistically with LY to further depress responses to GABA (n=7-8 cells). A similar pattern was also observed for (+)SUL (0.2M; n=6) at 2 and 5 nA (enantiomeric purity was confirmed by polarimetry). At the same currents, ZET and both (-) and (+)SUL could, however, block slowing of SN DA cell firing by LY.

In related studies, analogs of cAMP (0.2M; 5-30 nA) and forskolin (FOR; 1mM; 5-15 nA) were compared with the D-1 agonist SKF 38393 (SKF). While applied FOR (n=5) and dibutyryl cAMP (n=10) acted like SKF to increase SNpr firing without lessening GABA effects, 8Br-cAMP (n=9) caused both current-related increases in firing and modulation of GABA responses, similar to D-2 agonist actions. These results confound efforts to delineate D-1 and D-2 effects on SNpr cells, and advise caution in use of these drugs by iontophoresis methods to decipher such mechanisms. Support: NS23541

EFFECTS OF SELECTIVE D1 AND D2 RECEPTOR AGONISTS ON THE ACTIVITY OF PREFRONTAL CORTEX CELLS IN FISCHER-344 RATS. A. Gratton, P. Bickford-Weimer, K.D. Parfitt. Douglas Hosp. Res. Ctr, McGill Univ., Montreal, Canada, H4H 1R3 and Dept. Pharmacol., Univ. Colorado Hlth Sci. Ctr, Denver, CO 80218.

The effects of the selective dopamine (DA) D1 and D2 receptor agonists, SKF38393 and N0437 respectively, on the firing rate of medial prefrontal cortex (MPFC) cells were studied in young (3-5 months old) Fischer-344 rats. Multibarrel glass micropipettes, filled with 1 mM SKF38393 and N0437, were lowered into the anteromedial cortical terminal field of the mesocortical DA system in urethane anesthetized animals. The drug solutions were locally applied by pressure ejection. Both drugs produced dose-dependent and reversible reductions in firing rates. However, the D2 agonist was approximately 10 times more potent than the D1 agonist in suppressing firing rate. The ED50 values for N0437 and SKF38393 were 9.9 and 118.3 psi-sec respectively. Moreover, even at the highest doses, SKF38393 rarely produced complete cessation of firing in MPFC cells. Finally no evidence of synergism was observed when the two drugs were simultaneously applied; the effects of one drug were not potentiated by the concurrent application of the other. The present data suggest that D2 agonists are far more potent than D1 agonists in MPFC.

THE D-1 SELECTIVE AGONIST SKF 38393 CAN ACTIVATE STRIATAL NEURONS IN 6-HYDROXYDOPAMINE LESIONED RATS. B.G. Weick and J.R. Walters. NINCDS, Bethesda, MD 20892.

In rats with unilateral 6-hydroxydopamine (6-OHDA)-induced lesion of the nigrostriatal dopamine (DA) pathway, some evidence suggests DA agonists may activate an inhibitory striatal input to the substantia nigra pars reticulata (SNpr). Behavioral studies with these rats have attributed contralateral turning induced by DA agonists to increased GABA-mediated inhibition of SNpr cells. It has also been shown that i.v. apomorphine and the D-1 agonist SKF 38393 inhibit SNpr single unit activity and markedly increase glucose utilization in these rats. We have utilized extracellular single unit recording techniques in locally anesthetized, gallamine immobilized, artificially respired rats 6 -8 weeks after 6-OHDA nigrostriatal lesion to examine whether i.v. SKF 38393 administration does activate striatal output cells as these observations suggest. Firing rates of 73% of striatal cells with spontaneous activity between 1 and 8 spikes/sec were significantly elevated by i.v. SKF 38393. Increases averaged 2.1±0.8 spikes/sec at 1 mg/kg (n=11), 3.1±1.0 spikes/sec at 3.4 mg/kg (n=9) and 5.2±1.7 spikes/sec at 10 mg/kg (n=7). Increased firing was reversed by SCH 23390. In addition, 3 of 5 quiescent neurons antidromically activated from the nigra began to fire after 3.4 mg/kg SKF 38393. Two neurons with spontaneous firing rates greater than 8 spikes/sec were inhibited by SKF 38393. This study supports the idea that a population of striatonigral inhibitory neurons are stimulated by systemic administration of a D-1 agonist in rats after 6-OHDA lesions.

434.10

D1 DOPAMINE RECEPTOR STIMULATION ENABLES THE POSTSYNAPTIC BUT NOT AUTORECEPTOR EFFECTS OF D2 DOPAMINE AGONISTS. S.R. Wachtel, M.P. Galloway, & F.J. White. Depts. Pharmacol. & Psychiat., Wayne State Univ. Sch. of Med., & NPPL & NPRU, Lafayette Clinic, Detroit, MI 48207

Recent electrophysiological evidence suggests that D1 dopamine (DA) receptor stimulation enables the inhibitory effects of postsynaptic D2 receptor stimulation in the rat nucleus accumbens (NAc). In the present studies we have elaborated our previous findings in the NAc and extended them to the caudate nucleus (Cd). Depletion of DA via AMPT pretreatment attenuated the inhinbitory effects of the D2 DA agonist quinpirole (QUIN), but not those of the mixed D1/D2 agonist apomorphine. The inhibition by QUIN was restored by co-iontophoresis with the D1 agonist SKF 38393 (SKF). In contrast to the enabling role of D1 stimulation on postsynaptic D2 DA receptor-mediated inhibition, removal of D1 receptor stimulation by DA depletion failed to alter the inhibition by QUIN on A9 and A10 DA cells. Moreover, co-application of either SKF or the D1 antagonist SCH 23390 (SCH) failed to alter the inhibitory effects of QUIN on A9 and A10 DA firing. Synthesis-modulating DA autoreceptors were also unaffected by manipulations of D1 receptor activation. The reversal of the GBL-induced increase in striatal and NAc DOPA accumulation by QUIN was unaffected by SKF or SCH co-administration. Thus, neither the impulse-regulating nor the synthesis-modulating D2 autoreceptor was functionally enabled by D1 stimulation, further supporting the lack of a D1 DA autoreceptor.

434.11

NEUROPHYSIOLOGICAL EFFECTS OF (+)-UH 232 and (+)-AJ 76, DOPAMINE AUTORECEPTOR ANTAGONISTS, ON DOPAMINE PRE- AND POSTSYNAPTIC RECEPTORS. D.A. Bergstrom, M. Beninato and J.R. Walters. NINCDS, Bethesda, MD 20892.

(+)-UH 232 and (+)-AJ 76 exert behavioral and biochemical effects which suggest that they can act preferentially at dopamine (DA) autoreceptors as antagonists (Svensson et al., 1986). Extracellular single unit recording techniques were used to evaluate the abilities of these drugs to interact with nigra DA autoreceptors and postsynaptic DA receptors in the basal ganglia by comparing their effects on the activity of nigra pars compacta DA neurons and globus pallidus (GP) neurons, respectively, in locally anesthetized, gallamine immobilized, artificially respired rats. At 13 μmol/kg i.v., both drugs stimulated DA cell firing rates by 28% (n=14) and increased the ED_{50} for apomorphine (APO)-induced inhibition of DA cell activity by 40-70 fold (control ED_{50}: 10±2 μg/kg, n=9). Increases in GP neuronal activity induced by 0.3 mg/kg APO were effectively blocked by pretreatment or antagonized with 13 μmol/kg UH 232 (n=4) or AJ 76 (n=7). A 10-fold lower dose of (+)-UH 232 (1.3 μmol/kg) also stimulated DA cell activity by 27±6% (n=7), increased APO's ED_{50} on DA cells to 163±36 μg/kg (n=6) and effectively reversed APO-induced increases in GP cell activity (n=5). The same 1.3 μmol/kg i.v. dose of (+)-AJ 76 stimulated DA cell activity by 16±3% (n=7), increased APO's ED_{50} on DA cells to 24±5 μg/kg (n=6) and shifted the dose-response curve of APO's effects on GP neurons (n=16) to the right. With this experimental protocol, (+)-UH 232 and (+)-AJ 76 demonstrated antagonistic effects both at DA autoreceptors and at postsynaptic receptors.

434.12

PARTIAL RECEPTOR INACTIVATION SHOWS LOW EFFICACY OF S(+)NPA. B.L. Waszczak and R.F. Cox (SPON: J.L. Neumeyer). Pharmacol. Sect., Northeastern Univ., Boston, MA 02115.

Previous studies showed that S(+)NPA had dopamine (DA) agonist potency 300-fold lower than R(-)NPA in slowing firing of nigral (SN) DA neurons. Antagonist effects were also evident since pretreatment with 40 ug/kg S(+)NPA caused a significant rightward shift of the R(-)NPA dose-response curve (drc). Such actions suggested low intrinsic efficacy for S(+)NPA. To test this, we conducted dose-response studies for slowing of rat SN DA cell firing by i.v. R(-) and S(+)NPA after partial irreversible inactivation of DA receptors with 6mg/kg EEDQ (in ethanol). EEDQ pretreatment caused a significant parallel rightward shift of the R(-)-NPA drc but no loss of maximal response relative to ethanol control rats. The same dose of EEDQ reduced the maximal response to S(+)NPA by 22% with a small shift on the dose axis. Furchgott analysis gave a steep, hyperbolic occupancy response (O-R) relationship for R(-)NPA with 50% and 100% responses at 3.5% and 28% receptor occupancies, respectively. Thus, a 72% receptor reserve exists for R(-)NPA in in this model. The O-R plot for S(+)NPA was more shallow and linear (r=0.998). Half maximal effect occurred at 65.6% occupancy; maximal response (96% inhibition) was attained at 94% occupancy. Hence, few spare receptors are present for S(+)NPA. Since a ratio of fractional occupancies at a given response is a measure of relative efficacy, at 50% response the efficacy of S(+) relative to R(-)NPA is 0.05, confirming that S(+)NPA has low efficacy. 435.1

REGIONAL DIFFERENCES IN THE BINDING OF PIRENZEPINE AND AF-DX 116 TO RAT BRAIN: COMPARISON WITH MINIMUM ENERGY CONFORMATIONS. W. Hoss, B.R. Ellerbrock*, D.A. Smith* and W.S. Messer, Jr. Dept. of Medicinal and Biological Chemistry, College of Pharmacy and Dept. of Chemistry, Univ. of Toledo, 2801 W. Bancroft St. Toledo, OH 43606

The binding of selective muscarinic receptor antagonists to regions of rat brain was examined through autoradiographic techniques. Pirenzepine and AF-DX 116 were chosen based on their selectivity for M_1 and M_2 muscarinic receptors respectively, and similarities in chemical structure. Pirenzepine displayed a higher potency than AF-DX 116 for the inhibition of [^{3}H]-l-quinuclidinyl benzilate binding to rat brain sections. Analyses of binding to brain sections revealed heterogeneous binding profiles for both antagonists, suggesting the presence of multiple receptor sites.

Quantitative autoradiographic techniques were utilized in regional analyses of pirenzepine and AF-DX 116 binding. Pirenzepine displayed the highest affinity for hippocampal, striatal and amygdaloid muscarinic receptors (IC_{50}'s < 0.4 μM), with a slightly lower affinity for cortical receptors (IC_{50}'s between 0.4 and 0.8 μM). Pirenzepine displayed the lowest affinity for thalamic and brainstem regions with IC_{50}'s generally > 1.0 μM. In contrast, AF-DX 116 bound with higher affinity to muscarinic receptors in brainstem, cerebellar and hypothalamic nuclei (IC_{50}'s < 0.5 μM) than to receptors in thalamic nuclei (IC_{50}'s between 0.5 and 2.0 μM). Binding sites with the lowest affinity for AF-DX 116 were found in cortical, striatal and hippocampal regions (IC_{50}'s > than 2.0 μM). The binding profiles of the two selective muscarinic antagonists reveal the complexity and diversity of muscarinic receptor subtypes throughout the brain. The data provide a basis for identifying muscarinic receptor subtypes with selective ligands.

Minimum energy conformations of pirenzepine and AF-DX 116 were calculated using the program MacroModel (version 1.5). Pirenzepine displayed three energy minima, differing in the relative position of the piperazine ring with respect to the tricyclic system. In contrast, the diethylaminomethyl substituent on the piperidine ring conferred a much larger set of minimum energy conformations on AF-DX 116. It is suggested that the greater conformational flexibility of AF-DX 116 allows it to achieve a conformation inaccessible to pirenzepine that can bind to M_2 receptors.

AGONIST-RECEPTOR ACTIVE CONFORMATIONS FOR CENTRAL M1 AND M2 MUSCARINIC RECEPTOR-EFFECTOR SYSTEMS. M. McKINNEY, D. ANDERSON, L. VELLA-ROUNTREE*. Neuroscience Research Division, Pharmaceutical Discovery, Dept. 47W, Abbott Laboratories, Abbott Park, IL 60064

The coupling to biochemical effector systems of central M_1 receptors (cortical phosphoinositide metabolism) and M_2 receptors (cortical and striatal cAMP inhibition) was studied in metabolically-prelabeled, mechanically-dissociated cellular preparations of the adult rat brain. Cortical [^{3}H]IP1 formation was blocked by pirenzepine with high affinity (K_i=10 nM) while this antagonist blocked cortical and striatal forskolin-elevated [^{3}H]cAMP formation with K_i values of 354 nM and 325 nM, respectively, indicating coupling of the latter response to M_2 receptors. Propylbenzilylcholine mustard (IC_{50}=6 nM) was employed to partially occlude muscarinic receptors in this preparation and the equilibrium binding constants for carbachol in mediating M_1 and M_2 responses were determined. Carbachol was bound to the M_1 receptor with a K_d value identical to its EC_{50} (104 μM), while this agonist mediated the M_2 responses in cortex and striatum with K_d values of 15 μM and 5μM, respectively. These findings indicate that the central M_1 receptor is activated by the agonist binding in a low-affinity agonist-receptor conformation, while the central M_2 receptor is activated by the agonist in a high-affinity active conformation.

435.3

ASSESSMENT OF MUSCARINIC ANTAGONIST SELECTIVITIES: RESPONSE ASSAYS IN CULTURED CELLS COMPARED WITH BRAIN M1 AND M2 BINDING POTENCIES. D.J. Anderson, L. Vella-Rountree*, D. Barnes*, and M. McKinney. Neuroscience Research Division, Pharmaceutical Discovery, Dept. 47W, Abbott Laboratories, Abbott Park, IL 60064.

M1 and M2 muscarinic receptors mediating separate biochemical responses are found in mouse neuroblastoma clone N1E-115. The M1 receptor elevates cGMP, while the M2 receptor inhibits PGE1-elevated cAMP formation. We used these receptor-effector systems to assess selectivities of muscarinic antagonists. An "equipotent molar ratio" (EPMR=IC_{50ant}/IC_{50atr}) was calculated for each of twelve antagonists relative to atropine, to compare their selectivity for blockade of carbachol-mediated M1 and M2 responses. Pirenzepine was 30-fold M1-selective, in agreement with selectivity found with Schild analysis (McKinney et al., Mol. Pharmacol. 27:223, 1985). Several other antagonists were M1 selective: trihexyphenidyl (4-fold), QNX (8-fold), and benzhexol (3-fold). Four antagonists were M2-selective in this comparison: pancuronium (7-fold), secoverine (7-fold), AF-DX 116 (4-fold), and 4-DAMP (3-fold). Central M1 and M2 receptor binding potencies were measured by blockade of [^{3}H]pirenzepine binding in the rat cortex and by blockade of [^{3}H]QNB binding in the medulla-pons, respectively. Interesting similarities and differences arose when functional selectivities were compared to those determined by binding potencies.

435.4

APROPHIT: A POTENTIAL IRREVERSIBLE ANTAGONIST FOR MUSCARINIC RECEPTORS. A.H. Newman, H. Leader, J. Covington, M. Oleshansky, P.K.Chiang. Walter Reed Army Institute of Research, Washington, DC 20307-5100.

The development of selective irreversible ligands has proven to be an invaluable technique for the characterization, isolation and purification of many receptor systems. We now report the preparation and preliminary evaluation of an isothiocyanato-derivative of aprophen (aprophit, 1) as a potential irreversible antagonist of muscarinic receptors. Aprophit inhibited the acetylcholine-stimulated release of catecholamines from isolated, perfused guinea pig adrenal glands in a dose-dependent manner. This inhibition was not reversed by perfusing the tissue with Locke's solution and was not due to a non-selective alkylation by the isothiocyanate function. This preliminary data suggests that aprophit may be binding to muscarinic receptors in an irreversible manner.

CHARACTERIZATION AND AUTORADIOGRAPHIC DISTRIBUTION OF BINDING SITES FOR [^{3}H]AF-DX116, A PUTATIVE M_2MUSCARINIC RECEPTOR PROBE. W. Regenold*, D. Araujo and R. Quirion (SPON: N.P.V. Nair) Douglas Hospital Res. Ctr., Dept. of Psychiatry, McGill Univ., Verdun, Quebec, Canada H4H 1R3.

The use of selective muscarinic antagonists in radioligand binding studies has greatly enhanced our knowledge of muscarinic receptor heterogeneity. We extend these studies through the characterization and autoradiographic depiction of [^{3}H]AF-DX116 binding sites in the rat CNS. Incubations for all experiments were in Krebs buffer at 4°C for 1 hr. Saturation experiments demonstrate binding to an apparently single class (mean n_H = 0.86) of high affinity (mean K_d = 2.8 nM) sites. Competitive inhibition experiments with 5nM [^{3}H]AF-DX116 indicate competition for a muscarinic(K_i for atropine = 1.25 nM; K_i for nicotinic drugs > 100,000 nM); non-pirenzepine/M_1 (K_i for pirenzepine = 101 nM); saturable (K_i for AF-DX116 = 0.91 nM) site. In vitro autoradiography with 10 nM [^{3}H]AF-DX116 shows an M_2 receptor-like distribution with the highest site densities seen in thalamic and brainstem nuclei. In the hippocampus, binding sites are rather diffusely distributed . In sum, [^{3}H]AF-DX116 is a useful M_2 muscarinic receptor probe. The full chemical name of AF-DX116 is 11[[2-[(diethyl-amino)-methyl]-1-piperidinyl]acetyl]-5,11-dihydro-6H-pyrido[2,3-b][1,4]-benzodiazepine-6-one.

435.6

BINDING OF A PUTATIVE M2 SELECTIVE MUSCARINIC ANTAGONIST, [3H]AF-DX 116, TO MUSCARINIC ACETYLCHOLINE RECEPTORS IS DECREASED IN THE AGED RAT BRAIN. M. Watson, X. Ming* and B. Fucigna*. Dept. of Pharmacology, University of Medicine and Dentistry of New Jersey- New Jersey Medical School, Newark, N.J. 07103-2757.

Data obtained by the use of selective antagonists such as pirenzepine (PZ) and AF-DX 116 (11-2-[[2-[(diethyl-amino) methyl]-1- piperidinyl] acetyl]-5,11-dihydro-6H-pyrido (2,3-b) (1,4) benzodiazepine-6-one) in binding and functional assays has lead to the subclassification of muscarinic acetylcholine receptors (mAChR) into subtypes (TIPS Suppl. II: 46, 1986). A senescent rat model of aging was employed to assess any age-related alterations in M2 mAChR characteristics in numerous regions of the central nervous system (CNS). Binding assays for [^{3}H]AF-DX 116, a putative M2 selective ligand, were conducted as previously described. Briefly, membrane homogenates were incubated at 25°C for 60 min. Significant reductions in binding capacity (over 20 percent) were noted in many CNS areas when 18 month old rats were compared to 3 month old controls. The cerebral cortex showed the most substantial reduction. These data directly illustrate that there is a marked and widespread age-related reduction in M2 mAChR binding in the aged rat brain. One may speculate that there is a link between this decrease and the diminished cognitive capabilities which have previously been reported to accompany the aging process. Supported in part by FUMDNJ, a BRSG from NJMS, and MH-43024.

DEVELOPMENT OF M_2 MUSCARINIC RECEPTORS IN FETAL AND NEONATAL MOUSE BRAIN AND HEART. J-X. Wang*,W. Wang*, H.I. Yamamura and W.R. Roeske Depts. of Pharmacology and Internal Medicine, Univ. of Arizona, Col. of Med. Tucson, AZ 85724.

Development of M_2 muscarinic receptor (mAChRs) has been studied in the fetal, neonatal and adult CD-1 mouse brain and heart. The total mAChRs were determined using [^{3}H](-) QNB and the M_2 receptors determined using the selective ligand [^{3}H]AF-DX 116. The total mAChRs and the M_2 receptors in both tissues reached the adult level after 42 postnatal days and half maximal value at about 14-21 postnatal days. The concentrations of total brain mAChR and the M_2 receptors, calculated based on the protein or tissue contents, increased continuously from fetal to postnatal periods. In contrast, the heart mAChR concentrations, based on either protein or tissue contents, reached the adult level as early as at the birth. The concentration of heart mAChRs kept increasing after birth with a peak level at 14 postnatal days and droped down to a lower level in the adult, suggesting a preferential development of mAChRs during early postnatal period. The percentage of M_2 receptors vs total mAChRs was constant (19-26%) in the brain while it varied (45-70%) in the heart during the development. In conclusion, the murine neuronal and cardiac M_2 receptors showed differential patterns of development.

435.8

EFFECT OF METHOCTRAMINE ON MUSCARINIC RECEPTORS IN MURINE NEUROBLASTOMA CELLS. A.D. Fryer*, N.H. Lee, E.E. El-Fakahany (SPON: N.Khazan). Dept. of Pharmacology and Toxicology, Univ. of Maryland School of Pharmacy, Baltimore, MD, 21201.

Methoctramine (Met) is an antagonist with greatest affinity for cardiac M_2 muscarinic receptors which also discriminates between muscarinic receptors in the cortex (M_1) and glands (glandular M_2), (E.J.P.; 1988, 145,61). Its antimuscarinic effects were examined using N1E-115 mouse neuroblastoma cells (NB cells). NB cells have 2 muscarinic receptor subtypes, M_1 receptors which mediate phosphoinositide (PI) turnover, and glandular M_2 receptors which inhibit cyclic AMP (cAMP) formation. Calculations were made under the assumption that Met is a competitive antagonist, since at the doses used it did not alter the rate of dissociation of bound [^{3}H]N-methyl scopolamine (NMS) from the receptors. Met displaced NMS (0.2 nM) binding from only one site in NB cells (K_D of 120 ± 11 nM, n_H close to 1.0, data showed best fit to one site using LIGAND). Met was also an equipotent antagonist for PI (stimulated by 1.0 mM carbamylcholine (CBC)) and cAMP responses (measured using 25 μM forskolin in the absence and presence of 0.1 mM CBC). The K_D values were 132 ± 19 and 155 ± 25 nM respectively, and the n_H were close to 1.0. Thus, in NB N1E-115 cells, Met does not show the obvious selectivity for muscarinic receptor subtypes reported using other tissues. (Supported in part by NIH grants 1F32HL07691-01 CLN2, NS-24158, AG-07118, AG-00344.)

435.9

SELECTIVE ANTAGONISTS REVEAL HETEROGENEITY OF RAT BRAIN MUSCARINIC RECEPTORS THAT ACTIVATE INOSITOL-PHOSPHATES METABOLISM. C. Forray, C.L. Amrhein*, O.N. Kim* and E.E. El-Fakahany. Dept. of Pharmacology and Toxicology, Univ. of Maryland School of Pharmacy, Baltimore, MD 21201.

The selectivity of muscarinic antagonists was studied in functional as well as binding studies in dissociated cell preparations from rat brain cortex. When carbachol (CBC) stimulation of [^{3}H]inositol-phosphates accumulation was assayed with increasing doses of pirenzepine (PIR) it revealed the presence of two components with an IC_{50} ratio of 1000, and 50 to 70% as high affinity sites. Competition of [^{3}H]NMS by PIR in the same preparation also showed 62% high-affinity sites with an affinities ratio of 27. Methoctramine (MET) Schild plot estimated a pA_2 of 7.03 for the CBC response at low concentrations. However in the μM range MET induced non-competitive effects. In competition binding experiments MET showed a pKi of 7.1 for 93% of the sites and 4.9 for a low-affinity site. The PIR low-affinity component of CBC response assayed in the presence of 100 nM PIR showed the following rank order of potencies: 4-DAMP> HHSiD> PIR> AF-DX 116. Our data suggest that muscarinic receptors that stimulate inositol-phosphate metabolism in rat brain cortex are of two different subtypes. Evidence obtained so far points towards the involvement of "glandular M_2" in addition to the M_1 subtype in this response. (Supported in part by NIH grants NS-24158, AG-07118 and AG-0034).

435.10

BINDING OF BM-5 (N-METHYL-N-[1-METHYL-4-PYRROLIDINO-2-BUTYNYL]-ACETAMIDE TO PUTATIVE M2 MUSCARINIC RECEPTORS IDENTIFIED BY [3H]AF-DX 116 IN THE RAT CEREBRAL CORTEX. X. Ming* and M. Watson (SPON: F. Ehlert). Dept. of Pharmacology, University of Medicine and Dentistry of New Jersey- N. J. Medical School, Newark, N.J. 07103-2757.

BM-5, an oxotremorine analog, has been demonstrated to produce muscarinic acetylcholine receptor (mAChR) agonist like effects. However, in vivo studies reveal that it is tremorolytic. We characterized the binding of this unique partial agonist in membrane preparations of the rat cerebral cortex and heart. Binding assays for [^{3}H](-)quinuclidinylbenzilate ([^{3}H](-)QNB), a highly specific but non-subtype selective antagonist of the mAChR, the M1 selective antagonist [^{3}H]pirenzepine ([^{3}H]PZ), and the M2 selective antagonist [^{3}H]AF-DX 116 were conducted as previously described. Apparent affinity (Ki) values determined by inhibition studies ranged from 2-270nM. BM-5 produced shallow Hill values in [^{3}H](-)QNB-labeled cortical membranes, reflecting its interaction with high and low affinity sites. It had low affinity (270nM) at the [^{3}H]PZ site. Similar Ki values (20-40nM) were obtained in heart and cortex vs [^{3}H]AF-DX 116. Yet, the GTP analog guanyl-5'-yl imidodiphosphate (GppNHp) caused a greater shift to lower affinity in [^{3}H]AF-DX 116-labeled cardiac (5x) vs cortical (1.5x) M2 sites. Thus BM-5 appears to have greater affinity for M2 mAChR's and shows greater GTP coupling to cardiac M2 than cortical M2 mAChRs. Supported in part by FUMDNJ, a BRSG from NJMS, and MH-43024.

435.11

HEXAHYDRODIFENIDOL DOES NOT INDICATE THAT MUSCARINIC M1-RECEPTORS ARE HETEROGENEOUS

J.L. Field*, S.B. Freedman*, M.J. Gilbert* and N.R. Newberry*, (SPON: L. Iversen), Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20 2QR, UK.

Hexahydrodifenidol (HHD) has been suggested to distinguish between muscarinic M-1 receptors in the hippocampus and ganglion with pA_2 values of 5.7 and 7.9, respectively (Lambrecht et al. TIPS suppl. 22 p82, 1988). We have studied the muscarinic antagonist properties of HHD on a variety of in vitro preparations from the rat. The pA_2 against muscarine-induced depolarisations of hippocampal CA1 cells (7.4) and superior cervical ganglia (7.6) were similar. Furthermore HHD equally displaced [^{3}H]-pirenzepine binding from hippocampal and cortical membranes (pKapp = 7.85 in each tissue). Finally, it antagonised carbachol-stimulated phosphatidyl inositol turnover in hippocampus and cortex with similar pA_2 values (7.51 and 7.52). Our results with HHD do not support the proposal of multiple M-1 receptors.

435.12

AGONISTS FOR HIPPOCAMPAL M1 MUSCARINE RECEPTORS. L. T. Potter, C. A. Ferrendelli* and H. E. Hanchett*. Dept. of Pharmacology, U. of Miami School of Medicine, Miami, FL 33101.

Most of the cholinergic receptors in the cerebral cortex and hippocampus are M1 muscarine receptors. They remain after experimental cholinergic denervation and in Alzheimer's disease; and their activation clearly promotes cerebral excitation. Direct information is needed concerning which acetylcholine analogs have the highest affinity and efficacy at these receptors, in order to design optimal M1 agonists, and to test the idea that increased cerebral excitation improves memory. The binding of agonists to M1 receptors was examined by measuring competition between each agonist and 1 nM ^{3}H-pirenzepine, using rabbit hippocampal membranes from 5 mg of tissue suspended in 1 ml of 20 mM Tris buffer - 1 mM $MnCl_2$ at 25°C (Cell. Molec. Neurobiol. 8, 1-11, 1988). Computerized analyses of binding curves showed that agonists bound to a high-affinity (K_H) and low-affinity (K_L) state of M1 receptors, and that the affinity in 0.2 mM GppNHp was similar to, although usually lower than, K_L. K_L/K_H values varied from 50 or more for cis-dioxolane, oxotremorine-M and acetylcholine, to near 1 for oxotremorine and McN-A 343. There was an excellent correlation between the K_L/K_H values for different agonists at M1 receptors, and prior data for the ability of these agonists to promote cerebral excitation and phosphoinositide turnover. Thus K_L/K_H determinations appear useful for screening agonists for high efficacy. High K_H or K_L values alone did not correlate with high efficacy. The available data show that the five cholinergic agonists which have been tested for improving memory in humans (without much success) are all weak M1 agonists.

435.13

STUDIES OF GUANINE NUCLEOTIDE-SENSITIVE AGONIST-BINDING TO M1 MUSCARINE RECEPTORS IN MEMBRANES TREATED WITH N-ETHYL MALEIMIDE. D. D. Flynn and L. T. Potter. Department of Pharmacology, University of Miami School of Medicine, Miami, FL 33101.

Studies of the agonist-binding properties of M1 muscarine receptors have been more difficult than similar studies of M2 receptors, because of the generally higher affinity of M2 receptors for agonists, and the lack of a tissue source having pure M1 receptors. Low concentrations of ^{3}H-oxotremorine-M label predominantly M2 receptors even in M1-rich tissues like the hippocampus and cortex. In order to improve assays of agonist-binding to M1 receptors, we have used rabbit hippocampal membranes treated with 0.1 mM N-ethyl maleimide (NEM), to prevent the binding of agonists to the high affinity state of M2 but not the high affinity state of M1 receptors (Mol. Pharmacol. 30, 193, 1986). Measurements of competition between oxotremorine-M and 1 nM ^{3}H-pirenzepine demonstrated that the agonist bound to high and low affinity states of M1 receptors, and that the high affinity (K_H) state was lost in 0.2 mM GppNHp. Under the conditions used (20 mM Tris-1 mM $MnCl_2$, 25°C), K_H was 20-25 nM. Under the same conditions, direct measurements of the association, dissociation and equilibrium binding of ^{3}H-oxotremorine-M revealed the same K_H for M1 receptors, and that the dissociation rate was increased 6-fold by 0.2 mM GppNHp. Thus the use of NEM-treated hippocampal membranes demonstrates an interaction between M1 receptors and an NEM-resistant G protein, and that direct measurements of agonist-binding to M1 receptors are practicable.

435.14

POSSIBLE ALLOSTERIC INTERACTION OF NICARDIPINE WITH RAT BRAIN MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES S.Katayama*, S.Kito and R.Miyoshi (SPON: Y.Yamamura) 3rd Dept. Int. Medicine, Hiroshima Univ. Sch. Med., 1-2-3 Kasumi, Minami-ku, Hiroshima, 734 Japan

The dihydropyridine (DHP) derivatives is a member of a group of compounds that have been termed 'calcium antagonists'. In this paper, effects of nicardipine, one of DHPs on muscarinic receptor (m-AChR) antagonist binding in the brain have been investigated. Experiments were done using ^{3}H-QNB, ^{3}H-PZ and ^{3}H-AF-DX116 to differentiate the effect on each subtype. Tissue homogenates were obtained from male Wistar-strain rats weighing 180-220g. We used P_2 fruction for ^{3}H-QNB and ^{3}H-PZ binding assay. For ^{3}H-AF-DX116 binding, tissue preparation and the binding assay were performed according to J.X.Wang (1987).

Nicardipine inhibited ^{3}H-QNB (0.2nM), ^{3}H-PZ (18nM) and ^{3}H-AF-DX 116 (30nM) binding comletely with Ki values and Hill coefficients $4.28X10^{-8}$ and 1.03, $7.36X10^{-8}$ and 0.80, and $7.87X10^{-7}$ and 0.75, respectively. Displacement curves of ^{3}H-QNB binding by nicardipine shifted to right as the concentration of ^{3}H-QNB increased. The inhibition curve became shallower at higher concentrations of the ligand. Schild plots yielded curvilinear functions. This deviation from linearity of Schild plots indicated possible allosteric interactions between calcium channels and muscarinic receptor. It was concluded that nicardipine had inhibitory effects on both M1 and M2 receptor binding.

435.15

POTENT ALLOSTERIC EFFECTS OF TETRAHYDROAMINO-ACRIDINE (THA) ON MUSCARINE RECEPTORS. B.D. Pearce,* C.A. Ferrendelli*, H.E. Hanchett* and L.T. Potter. (SPON: W.R. Loewenstein). Dept. of Pharmacology, University of Miami School of Medicine, Miami, FL 33101.

Clinically effective concentrations of THA (0.03-0.3 μM, Summers et al. NEJM 315, 1241, 1986) readily inhibited acetylcholinesterase from rabbit hippocampal tissue in artificial CSF at 37°C, with physiological levels of substrate. Above 1 μM, THA acted on allosteric sites on M1 and M2 receptors as an antagonist, and at 10-1000 μM THA is known to block K^+ channels. Thus THA probably acts clinically as an esterase inhibitor (Neurosci. Lett., in press). Nonetheless the allosteric effects of THA are striking. Competition curves between THA and various ^{3}H-antagonists for hippocampal M1 and brainstem M2 receptors were steeper than mass action curves, and THA fully prevented radioligand binding. Blockade was unaffected when receptors were dissociated from other proteins with GppNHp or EDTA, or with EDTA and digitonin; hence THA appears to act directly on receptors. THA markedly slowed the dissociation of ^{3}H-antagonists, and was much more potent and effective than gallamine. For example, in 20 mM Tris-1 mM $MnCl_2$, 10 μM THA made the binding of ^{3}H-pirenzepine effectively irreversible, whereas 1 mM gallamine only partially slowed its dissociation. The concentrations of THA required to reduce the binding and dissociation of antagonists were equal, suggesting that all of the effects of THA are allosteric. Curiously, THA blocked the binding of the agonist, ^{3}H-oxotremorine-M, but not its dissociation. Thus THA may recognize only low affinity conformations of muscarine receptors.

435.16

Muscarinic receptor binding properties of 1,2,3,4-tetrahydro-9-acridinamine (tacrine) and other acetylcholinesterase inhibitors. S.L. Myers*, L.L. Coughenour*, D.T. Dudley, J.H. Fergus*, C.J. Spencer*, R.D. Schwarz, and B. Berghoff*. (Spon: D.K. Boyd) Pharmacology Department, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The affinity and intrinsic activity of several acetylcholinesterase inhibitors (ACHEIs) including 1,2,3,4-tetrahydro-9-acridinamine (tacrine) were determined for muscarinic receptors in rat brain cortical membranes labeled with the muscarinic agonist ^{3}H-cismethyldioxolane (CMD) and the antagonist ^{3}H-quinuclidinyl benzilate (QNB). Ligand efficacy was indexed by the resulting antagonist/agonist (QNB/CMD) affinity ratio. In SK-N-SH cultured cells, partial to full agonists exhibited QNB/CMD values > 80. QNB/CMD ratio values for ACHEIs examined were predictive of either agonist or antagonist activity (QNB/CMD physostigmine = 1807, QNB/CMD tacrine = 8). However, all ACHEIs examined were either inactive or antagonists at stimulating PI turnover in SK-N-SH cells. The affinity of ACHEIs against ^{3}H-CMD binding correlated with their potency to inhibit acetylcholinesterase (ACHE). To determine if displacement of muscarinic binding was mediated by inhibition of ACHE, the affinities of representative ACHEIs against ^{3}H-QNB and ^{3}H-CMD binding were determined using membranes pretreated with the irreversible ACHEI, paraoxon (PAR). PAR pretreatment shifted QNB/CMD values for these ACHEIs toward 1 due to a decrease in potency to inhibit ^{3}H-CMD binding; whereas, the QNB/CMD ratio for the competitive agonist arecoline was not significantly affected. These results suggested that for those ACHEIs examined displacement of ^{3}H-CMD binding was mediated by inhibition of ACHE while displacement of ^{3}H-QNB binding was due to a direct interaction at the receptor. In addition, using this two assay binding method, PAR pretreatment distinguished ACHEI from competitive agonists.

435.17

GALLAMINE EXERTS BIPHASIC ALLOSTERIC EFFECTS AT MUSCARINIC RECEPTORS John Ellis. Neuroscience Research Unit, Department of Psychiatry, University of Vermont College of Medicine, Burlington, VT 05405.

Gallamine and a number of other compounds (verapamil, quinidine, and others) have been found to slow the rate of dissociation of labeled ligands, especially [^{3}H]N-methylscopolamine (NMS), from muscarinic receptors of heart and brain. There has been some dispute as to whether the dissociation of [^{3}H]quinuclidinyl benzilate (QNB) is subject to such allosteric regulation. We have recently found that gallamine modulates the dissociation of [^{3}H]QNB from muscarinic receptors of the heart in a biphasic manner. Low concentrations (micromolar) accelerate the rate of dissociation, while higher concentrations (millimolar) slow it; at about 0.1mM, the two effects cancel each other. Similar results are obtained with muscarinic receptors from the brainstem, but gallamine has only marginal effects on the dissociation of [^{3}H]QNB in the forebrain. On the other hand, gallamine slows the dissociation of [^{3}H]NMS to a similar extent in all three tissues (brainstem, forebrain, and heart). Furthermore, verapamil exerts only monophasic effects (slowing) on the dissociation of both [^{3}H]NMS and [^{3}H]QNB from heart receptors. The data suggest that there are multiple allosteric regulatory sites associated with muscarinic receptors. Supported by the Vermont Heart Association, the Department of Psychiatry, and the University of Vermont (BSRG).

435.18

GALLAMINE ALLOSTERICALLY MODULATES MUSCARINIC RECEPTOR BINDING AND ANTAGONIZES PHOSPHOINOSITIDE AND CYCLIC-AMP RESPONSES IN N1E-115 NEUROBLASTOMA CELLS. N.H. Lee* and E.E. El-Fakahany. Dept. of Pharmacology and Toxicology, Univ. of Maryland Sch. of Pharmacy, Baltimore, MD 21201.

Gallamine (Gall)/ 0.2 nM (^{3}H)N-methylscopolamine ((^{3}H)NMS) competition curves were shallow and best fit to a two-site model (K_H=7.6 ± 1.6 μM, R_H=40 ± 3 %; K_L=1.6 ± 0.7 mM, P<0.05). Likewise, gall/ 0.2 nM (^{3}H)N-methyl-quinuclidinyl benzilate ((^{3}H)NMeQNB) curves could be best fit to a two-site model (K_H=49 ± 4 μM, R_H=91 ± 1 %; K_L=13 ± 11 mM, P<0.05). Gall allosterically slowed the rate of dissociation of bound (^{3}H)NMS > (^{3}H)NMeQNB from muscarinic receptors (MR) in a dose dependent manner. Subtracting the allosteric component from the gall/(^{3}H)NMS and gall/(^{3}H)NMeQNB competition curves yielded a single high affinity site for gall (K_H=90 ± 8 and 62 ± 1 μM, respectively). M_1 receptor-mediated phosphoinositide hydrolysis stimulated by carbamylcholine (CBC) was antagonized by gall with a K_i value of 44 μM and a Schild slope of 1.08 ± 0.11. However, gall was less potent in antagonizing glandular M_2-mediated inhibition of cyclic-AMP formation by CBC with a K_i value of 182 μM and a Schild slope of 1.10 ± 0.08. In conclusion, gall allosterically modulates MR antagonist binding and reveals a 4-fold selectivity profile in antagonizing M_1 versus M_2-mediated responses. 436.1

THE EFFECT OF LEAD ON THE VOLTAGE ACTIVATED CALCIUM CHANNEL OF APLYSIA NEURONS. D. Buesselberg*, M.L. Evans and D.O. Carpenter. (SPON: B. Jahan-Parwar). Wads. Ctr. for Labs. & Res., NYS DOH & Sch. of Pub. Hlth., Albany NY 12201.

Despite the known neurotoxic effects of lead its locus of action is unclear. We have investigated the effects of lead on calcium currents of Aplysia neurons recorded using the two electrode voltage clamp technique. The threshold concentration for effect was 1 μM lead. At 5 μM, lead reduced the peak amplitude of the calcium current by 14.7 ± 5%, at 10 μM by 26.3 ± 2.6% and at 50 μM by 57.7 ± 4%. With washing the calcium current amplitude rapidly (within 2 to 3 min) returned to about 95% of control after lead was applied for 2 min. If lead was applied for 20 min, the calcium current amplitude did not recover. When applied for 2 min, zinc did not block the calcium current at concentrations up to 100 μM. This effect of lead appears specific for the calcium channel as lead had little effect on the delayed rectifier potassium channel at 50 μM. (Supported by NIH and DAAD).

436.2

ZINC AND LEAD INTERACTIONS IN IMMATURE GUINEA PIGS. T. Rowles, C. Womac, G. Miller, A.J. Castiglioni, Jr.,* G.R. Bratton, and E. Tiffany-Castiglioni. Dept. of Veterinary Anatomy, TAMU, College Station, TX 77843.

Studies have shown an effect of lead (Pb) on neurological function and an interaction of zinc (Zn) with Pb. We have evaluated the effects of low level Pb and its interactions with dietary Zn in 3 groups of immature guinea pigs. Group 1 received standard guinea pig chow (27 ppm Zn); group 2 received egg white based diet (5 ppm Zn); and group 3 received egg white based diet (50 ppm Zn). One third of group 1 received 10 mg Pb acetate/kg body weight and one third received 20 mg Pb acetate/kg body weight. Half of groups 2 and 3 received 20 mg Pb acetate/kg body weight. All treatments were oral and lasted 18 days beginning at 14 days of age. All groups showed increased blood and tissue Pb levels in Pb-treated animals compared to controls, but the cerebral levels of Pb were less than blood levels. Even without concentration of Pb in the cerebrum, the mean maximum diameters of the astroglia were increased in the Pb-treated animals. Neither Pb nor Zn had an effect on absolute brain weight or brain weight to body weight ratios. Dietary Zn levels did not affect levels of Cu, Zn, or Fe in the brain. Further evaluation of the significance of an increase in astroglial diameter without concentration of Pb in the cerebrum is underway. Funded by Center for Energy & Mineral Resources, TAMU and EPA R811500.

DIFFERENTIAL TOXIC EFFECTS OF CIS-PLATIN AND TRANS-PLATIN ON CHICK DORSAL ROOT GANGLION CELLS IN VITRO. K.S.Blisard and S.L. Rogers. Research Service (151), Veterans' Administration Medical Center, and Departments of Pathology and Anatomy, University of New Mexico Medical School, Albuquerque, NM 87112

Cis-diamminedichloroplatinum (II) (cis-platin) is a useful cancer chemotherapeutic agent. An important side effect of this drug in humans is the development of a peripheral neuropathy, the mechanism of which is not known. As a model system, we have administered cis-platin to cultured chick embryonic dorsal root ganglion cells. At doses of 50-100 ug/ml, the drug was toxic to cultures in 6 hours, and changess were seen in both neurons (detachment) and non-neuronal cells (vacuolation). After 24 hours, there was extensive cell death. The trans isomer of the drug, trans-platin, was much less toxic to cultures. At concentrations of 75 or 150 ug/ml, very minimal changes were seen in cultures which had been exposed to trans-platin for 6 or even 24 hours. This was significantly different from the observations with cis-platin, and suggests that a steric interaction, which is different for the two isomers of the drug, is important in the toxicity of cis-platin.

FREE AMINO ACIDS IN PLASMA AND BRAIN AFTER CHRONIC MANGANESE INTAKE. E. Bonilla, A.L.N. Prasad*, J.O. Dávila*, A. Arrieta* and R. Villalobos*. Instituto de Investigaciones Clínicas, Universidad del Zulia and INBIO-MED-FUNDACITE, Aptdo 376. Maracaibo-Venezuela.

The present study was conducted to determine the changes in the concentrations of free amino acids in plasma and brain after chronic manganese intake.

Male Sprague-Dawley rats weighing 200-250 g were treated with 1 mg of Mn per ml of drinking water. Both the manganese-treated and the control group had unrestrained water access. At eighth month, 11 animals of each group were sacrificed by decapitation. The brains were extracted immediately and placed at 4°C to dissect the striatum and frontal cortex. Prior to the sacrifice a blood sample was obtained from each rat by cardiac puncture. The analysis of the amino acids was performed by HPLC.

The growth rate of manganese intoxicated rats was normal. Brain manganese concentrations increased significantly. The means ± S.E. of the manganese content (expressed in ug/g dry weight) at the eighth month were: a) frontal cortex: 1.7 ± 0.3 in controls and 5.1 ± 0.4 in Mn-loaded rats; b) striatum: 1.8 ± 0.1 and 3.2 ± 0.2. The mean ± S.E. daily water intake during the eighth month for each rat was: 60.1 ± 0.7 ml for controls and 54.0 ± 0.5 for the Mn-treated rats. The difference was significant ($p < 0.001$).

No changes were observed in the levels of plasma amino acids in manganese-treated rats. Similar results were observed in the striatum and frontal cortex. In the light of these results it is safe to assume that the chronic manganese intake of 1 mg Mn per ml of drinking water did not affect either the gastrointestinal absorption of the amino acids nor their passage through the blood-brain barrier.

REVERSAL OF ALUMINUM-INDUCED BEHAVIORAL DEFICITS IN THE RAT BY DFO. D.J. Connor, L.E. Harrell and R.S. Jope. Dept. Psychology, Neurology and Pharmacology, Univ. of Ala., Birmingham, AL. 35294.

Administration of aluminum sulfate in the drinking water of male Sprague-Dawley rats for thirty days resulted in a reduction in the number of days to reach extinction criterion on a passive avoidance task (38% of control level). Controls yoked by fluid consumption to the treated animals demonstrated that the behavioral deficit was not due to nonspecific effects caused by lower fluid consumption. No change in vertical or horizontal open field activity was evident after the aluminum treatment. Partial improvement of the deficit was produced by replacement of the aluminum sulfate solution with tap water two weeks prior to testing ($p<0.05$). Replacement with tap water in combination with injection (i.p.) of the aluminum chelator desferoxamine (DFO: 75 mg/kg or 30 mg/kg) returned the performance of the aluminum-treated animals to control levels in a dose-dependent manner. DFO injection of control animals did not affect their activity levels or extinction on the passive avoidance task. These results indicate that the behavioral impairment is a specific, toxic effect of aluminum administration and that it can be reversed by administration of an aluminum chelator.

TRIETHYL TIN: EFFECTS ON CHOLINERGIC SYNAPTIC TRANSMISSION. R.D. Laurie*, G.P. Cooper, D.J. Minnema* and R. Greenland*. Dept. of Environ. Health, Univ. of Cincinnati Sch. Med., Cincinnati, OH 45267.

The in vitro sciatic nerve-sartorius muscle preparation of the frog (Rana pipiens) and isolated cholinergic synaptosomes obtained from rat brain were used to assess the effects of triethyltin chloride (TET) on "spontaneous" acetylcholine (ACh) release, depolarization-evoked ACh release, nerve terminal action potential (AP) latency and amplitude, and muscle resting membrane potential (Em). TET (1-100 μM) was incorporated into appropriate salt solutions and the preparations continuously superfused. In the frog TET produced a steady decline in Em, the rate and extent of which was dose-related. When tetraethylammonium chloride (TEA) was used to replace NaCl both the rate and degree of depolarization was reduced, while choline chloride replacement had little effect. TET increased the AP latency and decreased its amplitude. In both the frog and rat preparations spontaneous ACh release was initially increased but rapidly declined during TET exposure. In synaptosomes depolarization-evoked release was unaffected by TET; in the frog both the endplate potential and miniature endplate potential amplitudes were decreased more than could be accounted for by the fall in muscle Em. These studies indicate that TET has no direct effect on membrane ion channels but probably causes an increase in the muscle and nerve membrane leakiness to K^+ and possibly other monovalent ions. Support: NIEHS 03992.

MECHANISM OF TRIETHYLTIN BROMIDE-INDUCED NEUROTOXICITY. B.E. Morton, E.F. Block* and F. Taketa*, Univ. of Hawaii, Honolulu, HI 96822 & Med. Coll. of Wis. Milwaukee, WI 53226

Respiration is diminished in brain slices from rats injected with triethyltin (TET) derivatives (Biochem J. 119 95-102, 1970). Pyruvate dehydrogenase activity is also reduced in brain homogenates or mitochondria prepared from TET-intoxicated rats (FASEB J. 2 A 1373, 1988). We have now inquired whether TET affects glucose metabolism in live, conscious rats by analyzing its influence on the uptake of 2-deoxyglucose (2-DG) in brain. [14C]-2-DG (125uCi/Kg) was injected i.p. at timed intervals after i.p. injection of TET into groups of rats. Animals were sacrificed 45 min later and their brains removed for sectioning and autoradiographic analysis (J. Neurochem. 78 897-916, 1977). In addition, we investigated possible mechanisms by which TET acts by evaluating neurotransmitter receptor agonists and antagonists as potential antidotes for TET-neurotoxicity. Ligands, acting on ionophore-regulating inhibitory and excitatory receptors were administered by i.p. injection prior to TET administration and their influence on the course of development of neurotoxicity was monitored. Statistically significant reductions in global and regional uptake of 2-DG were found in brains of TET-treated rats compared with control animals. Preadministration of the putative antidotes resulted in complex changes suggesting that some of the effects of TET can be modified by ionophore regulation. [Supported by grants from the NIH (ES04005) and The Univ. of Hawaii Foundation.]

TRIETHYLTIN NEUROTOXICITY IS NOT MEDIATED BY EXTRACELLULAR CA^{2+}. Y.L.T. Ting, S.B. Fountain, T.J. Teyler. N.E. Ohio Univs. Coll of Med. Rootstown, OH 44272.

To assess the role of extracelluar Ca^{2+} in synaptic suppression by triethyltin (TET) (Fountain et al., Neurotoxicol. Teratol. in press), we exposed in vitro hippocampal slices to TET in a Ca^{2+}-free environment. Slices were prepared using standard techniques and maintained at the interface of a pool of artificial CSF and an O_2/CO_2 atmosphere. Recording and stimulating electrodes were positioned in the Schaffer collaterals. When a stable waveform was recorded, an input-output (I/O) profile was obtained by administering a series of increasing stimulus intensities. Following the baseline I/O, Ca^{2+} was removed from the pool by washout with Ca^{2+}-free medium. After 1 hr, the EPSP could no longer be evoked, and at this time any tissue-bound CA^{2+} released after the first exchange was removed with a second CA^{2+}-free washout. Following the second Ca^{2+}-free exchange, slices were exposed to 10 uM TET. Evoked responses were recorded for 2 hrs at 5 min intervals, only to be interrupted at 1 and 2 hr post-TET exchange for I/O assessments. After the I/O assessment at 2 hr postexposure, TET was washed out of the pool using Ca^{2+}-free medium, followed by an exchange of Ca^{2+}-bearing medium. Ca^{2+} replacement did not produce recovery of the EPSP. Thus, TET-induced synaptic suppression is probably not mediated through extracellular Ca^{2+}. It is possible that attenuation of evoked synaptic responses reflects TET-induced gradual depolarization of hippocampal neurons by uncoupling oxidative phosphorylation. (Supported by EPA, ONR and NIH)

TRIMETHYLTIN-INDUCED NEUROTOXICITY MAY NOT BE MEDIATED THROUGH AN EXCITOTOXIC MECHANISM. J.P. O'Callaghan, D.M. Niedzweicki, M.E. Gilbert, L.P. Miller and P. Ornstein.* U.S. EPA and Northrop Services, Res. Tri. Pk., NC 27711, VA Medical Ctr. and Georgetown University, Washington, D.C. 20422 and Eli Lilly and Co., Indianapolis, IN 46206.

Systemic administration of trimethyltin (TMT) to the rat results in a pattern of hippocampal damage similar to that seen after local or systemic administration of excitotoxic analogues of glutamate. We used agents known to inhibit glutamate receptor-mediated effects to determine the role of glutaminergic pathways in TMT neurotoxicity. Acute administration of TMT resulted in a loss of hippocampal pyramidal cells (CA1 & CA3-4). Autoradiography revealed decreased NMDA, quisqualate (QA) and kainate (KA) receptors; QA and KA receptors were most affected. Systemic or intrahippocampal (IH) injections of TMT in combination with six daily injections (s.c. or IH) of the NMDA receptor antagonists, ketamine, AP7 and MK-801, did not alter the neurotoxic effects seen after TMT alone, as evidenced by histology and assays of the neuron-specific and astrocyte specific proteins, synapsin I and GFAP. Activation of KA receptors produce seizure activity but daily IH EEG recordings failed to reveal seizure activity in TMT-treated rats. Moreover, daily administration of phenobarbital did not affect TMT-induced neurotoxicity. The data argue against a role for NMDA and KA receptors as mediators of the neurotoxic effects of TMT but do not rule out involvement of QA receptors.

AUTOMAINTAINED REVERSAL LEARNING IN RATS: PARAMETRIC ANALYSIS OF THE EFFECTS OF TRIMETHYLTIN (TMT). P.J. Bushnell. Neurotox. Div., US EPA, RTP, NC 27711.

Automaintenance involves Pavlovian conditioning in that pairing salient stimuli elicits specifiable behavior from animals. Rats received food (UCS) after a 15-sec extension of one of two levers (CS^+) into an operant chamber; extension of a second lever (CS^0) was uncorrelated with food. Responding to each lever was recorded across ten 10-trial blocks of each daily test, but did not affect food delivery. Rats responded preferentially to the CS^+, with discrimination ratios (DRs) approaching 1.0. Reversal (R) of the locations of CS^+ and CS^0 caused redirection of responding to the new CS^+. By R10, all rats reversed reliably within 100 trials. Asymptotic R performance was disrupted by TMT (7 mg/kg, iv) when a 2- or 4-sec delay separated the CS^+ from the UCS. The disruption included decreased responding to the CS^+ and increased responding to the CS^0, without change in total responding. The reduction in CS^0 responding across trials was significantly slower for TMT rats than for controls, and was highly correlated with degree of damage to the hippocampus. Hyperbolic functions fitted to R curves (ΔDR over trials) showed that hippocampal damage correlated significantly with DR asymptote but not with the trial number at which the DR was half-maximal. This procedure permits quantification and characterization of learning deficits induced by neurotoxic chemicals, and may help identify CNS substrates involved in learning.

436.11

EFFECT OF AMMONIA ON THE BENZODIAZEPINE (BZD) RECEPTOR IN CULTURED ASTROCYTES. I. Ducis*, L.O.B. Norenberg*, and M.D. Norenberg. Lab. Neuropath., Vet. Adm. Med. Ctr. & Univ. of Miami Sch. Med., Miami, FL 33101.

There is evidence that the BZD receptor may be involved in ammonia/hepatic encephalopathies. Since astrocytes appear to be critically involved in these disorders, we studied the effect of ammonia on the BZD receptor in primary astrocyte cultures. Astrocytes were obtained from neonatal rat cortices, and after 2 weeks, half of the cultures were treated with 0.5 mM dibutyryl cyclic AMP (dBcAMP). Scatchard analysis of the binding of ^{3}H-Ro5-4864 to astrocyte homogenates in the presence of 2 and 5 mM NH_4Cl showed a significant decrease in Kd: 27% and 32%, respectively ($p<.05$) in cells that had not been maintained with dBcAMP. However, no significant increase in binding affinity was observed in the presence of 10 mM NH_4Cl. No significant change in Kd nor Bmax was found at any NH_4Cl concentration when cells were maintained with dBcAMP. Homogenates from non dBcAMP-treated cells, however, showed a 14% decrease ($p<.05$) in receptor number after treatment with 10 mM NH_4Cl although no decrease was observed with 2 and 5 mM NH_4Cl. The latter results are consistent with the observation that dBcAMP has a protective effect on the ammonia-induced morphological changes observed in cultured astrocytes. Our findings furthermore suggest that some of the BZD receptor changes found in models of hepatic encephalopathy may occur on astrocytes and thus implicate the astrocyte BZD receptor in the pathogenesis of hepatic encephalopathy.

436.12

AMMONIA INDUCED DECREASE IN GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) IN CULTURED ASTROCYTES. M.D. Norenberg, L.O.B. Norenberg*, and J.T. Neary. Vet. Adm. Med. Ctr. & Univ. Miami Sch. Med., Miami, FL 33101.

Previous immunocytochemical and quantitative studies have indicated a specific reduction in GFAP in human hepatic encephalopathy (HE). Since ammonia is a prime candidate as the etiologic factor in HE and since astrocytes appear to be the principal target of ammonia toxicity, we investigated the direct effect of ammonia on GFAP in astrocytes in primary culture. Astrocyte cultures were prepared from newborn rat cortices. Some cultures were treated (day 14) and maintained in 0.5 mM dibutyryl cyclic AMP (dBcAMP). Cultures (5 to 7 weeks old) were treated with 2 and 10 mM NH_4Cl for 1 or 4 days. Cells were homogenized in SDS/EDTA/Tris buffer and supernatants were prepared. GFAP was measured by enzyme linked immunosorbent assay with porcine anti-GFAP and rabbit anti-GFAP antisera kindly supplied by Dr. L. Eng, Palo Alto, CA. No significant differences in GFAP content were observed in cultures exposed to 2 or 10 mM NH_4Cl for 1 day. However, treatment of cultures for 4 days with 10 mM NH_4Cl showed a $39\pm7\%$ decrease in GFAP (mean$\pm$SEM, n=6; $p<0.05$). The effect was dose-dependent as a smaller decrease in GFAP ($23\pm3\%$) occurred with 2 mM NH_4Cl. No significant fall in protein was noted. Astrocytes treated with dBcAMP were more resistant to ammonia; a $24\pm3\%$ decrease was observed upon treatment of these cultures with 10 mM NH_4Cl. The latter observation is consistent with the protective effect of cyclic AMP on ammonia-induced gliotoxicity. These results indicate that ammonia causes a reduction in GFAP and may be the principal factor responsible for the loss of GFAP in human HE.

AN ELECTROPHYSIOLOGICAL STUDY OF HYDROGEN SULFIDE TOXICITY IN FROG SYMPATHETIC GANGLIA. S.B. Kombian*, J. Zidichouski*, M. Kehoe* and R.J. Reiffenstein, Pharmacology Dept., Univ. of Alberta, Edmonton, AB. Canada T6G 2H7

Hydrogen sulfide (H_2S) and its alkali salts are very toxic. H_2S has caused many industrial deaths, apparently by paralysis of medullary respiratory drive. Few electrophysiological studies of its toxicity have been done (Warenycia et al., Soc. Neurosci. Abstr. 13, 94, 1987). Using sucrose gap recording, we studied the effect of NaHS (1.8 mM) on the Na^+/K^+ pump (K^+ - activated hyperpolarization), and on agonist-induced conductance changes in sympathetic ganglia of Rana pipiens. Muscarine-induced (10 μM) hyperpolarization was potentiated to 108.8 ± 5.2% of control ($p<0.05$, n=14), and the hyperpolarizing effect of 1 μM epinephrine to 117.1 ± 6.4% of control, ($p<0.05$,n=7). NaHS did not affect depolarization due to 10μM nicotine (97.2 ± 6.6% of control, $p>0.6$, n=7). The Na^+/K^+ pump activity was not initially affected by NaHS (117 ± 12% of control, $p>0.4$, n=7), but removal of NaHS potentiated the response. A consistent NaHS-induced depolarization was observed (2.75 ± 0.5 mV, $p<0.001$, n=23). The lack of significant attenuation of these diverse responses does not support a rapid anti-metabolic action of NaHS. Supported by Alberta Community and Occupational Health.

436.14

THE EFFECTS OF HYDROGEN SULFIDE EXPOSURE ON AMINO ACID LEVELS IN THE DEVELOPING RAT CEREBRUM AND CEREBELLUM. R.S. Hannah*, S.H. Roth and J. Hayden*. Depts. of Anatomy and Pharmacology and Therapeutics, University of Calgary, Calgary, Alta, Canada.

Humans can be exposed to various chronic levels of the environmental pollutant, hydrogen sulfide (H_2S). The exposure occurs both in the work place and by living in proximity to industries which produce H_2S. Since H_2S intoxication produces a variety of biochemical changes in the mature CNS of laboratory animals, it is essential to examine the effects on the developing CNS which is extremely sensitive to environmental disturbances. Timed-pregnant Sprague-Dawley rats were exposed to H_2S (75 ppm) for seven hours per day from Day 6 postcoitus until Day 21 postnatal (pn). Entire litters were euthanized on Days 7, 14 and 21 pn. The cerebrum (anterior to the optic chiasm) and cerebellum were removed and stored at -70°C. The putative amino acid neurotransmitters, aspartate, glutamate, glycine, taurine and GABA were quantitated using precolumn fluorescence derivatization with OPT and reversed-phase high performance liquid chromatography. In both regions, aspartate, glutamate and GABA were significantly reduced below control levels by Day 21 pn. Taurine which was initially elevated returned to control levels by Day 21 pn. Glycine levels were unaltered following exposure to H_2S. (Supported by Alberta Occupational Health and Safety).

BRAIN CATECHOLAMINE LEVEL ELEVATIONS AFTER H_2S. R.J. Reiffenstein, M.W. Warenycia & S.B. Kombian*. Dept., of Pharmacol., Univ. Alberta, Edmonton, Canada T6G 2H7.

H_2S intoxication leads to loss of central respiratory drive. Since catecholamines (CAs) are important for neural control of respiration, regional CA levels were examined after H_2S. Male SD rats, (≈300g) were given saline, 10 or 30mg/kg NaHS (0.66 or $2xLD_{50}$) ip. and killed at 2 min. Brainstem, cerebellum, hippocampus, striatum and cortex were weighed, sonicated in 0.1N $HClO_4$ and supernatants analyzed for CA content by HPLC with EC detection. Results are given in μg/g as the $\bar{X}$±SEM; (N=5) for dopamine(DA), noradrenaline(NA) and adrenaline(A). None changed at 10mg/kg NaHS, nor cortex or cerebellum at 30 mg/kg NaHS. *=$p<0.05$; (Duncan's Test) C=controls; T=30mg/kg NaHS.

		DA	NA	A
BRAINSTEM(B)	(C)	0.57±0.06	0.90±0.13	0.43±0.03
	(T)	1.61±0.40*	1.82±0.12*	1.26±0.08*
HIPPOCAMPUS(H)	(C)	0.81±0.19	1.09±0.10	0.51±0.07
	(T)	0.98±0.20	2.94±0.73*	1.82±0.30*
STRIATUM(S)	(C)	6.60±0.48	1.78±0.06	1.13±0.18
	(T)	6.37±0.34	2.33±0.33*	1.89±0.52*

Both NA and A increased in B, H and S; DA only in brainstem. Changes in CAs after H_2S indicate either increased synthesis or decreased catabolism, possibly by inhibition of MAO. (Supported by Alberta Community and Occupational Health).

ALZHEIMER'S DISEASE: NEUROPATHOLOGY

437.1

PREFERENTIAL LOCALISATION OF COPPER ZINC SUPEROXIDE DISMUTASE IN THE INJURED HIPPOCAMPAL NEURONS IN ALZHEIMER'S DISEASE. I.Ceballos*1, F.Agid*2, A.Delacourte*3, E.Hirsch*2, P.M.Sinet*1, and Y.Agid*2 (SPON:B.Zalc).1:CHU Necker-EM 75015 PARIS, 2:U289 INSERM CHU Pitié-Salpétrière 75013 PARIS, 3:U16 INSERM Faculté Médecine 59045 LILLE.FRANCE

The distribution of cells containing copper zinc superoxide dismutase (CuZnSOD) protein and mRNA was determined by using immunohistochemistry and in situ hybridization in hippocampi and in various cortical regions from control human brain. Results obtained with these two methods are similar and demonstrate that pyramidal neurons and granule cells of hippocampus contain high amounts of CuZnSOD protein and mRNA.

In the hippocampus of an Alzheimer's patient, successive immunostaining by antiCuZnSOD and antipaired helical filaments (PHF) antibodies show that antiPHF label the same neurons as antiCuZnSOD antibodies. Thus, pyramidal neurons which are succeptible to degenerative processes in Alzheimer's disease (AD) contain high amount of CuZnSOD protein. This might indicate that biochemical pathways leading to $O_2^{\cdot-}$ generation are specially active in these neurons, requiring a high CuZnSOD content to eliminate these radicals.

Quantitative analysis by in situ hybridization are in progress to evaluate the transcription of CuZnSOD gene in Alzheimer's disease brain.

437.2

A REEXAMINATION OF ALUMINUM IN ALZHEIMER'S DISEASE. R. W. Jacobs, T. Duong, R. E. Jones* and A. B. Scheibel, Anatomy and Psychiatry Depts. and the Brain Research Institute, UCLA Med. Center, and Geology Dept., Los Angeles, CA 90024.

This study reassesses the presence of aluminum in Alzheimer's disease (AD) as previously reported by Perl and Brody (1984) and Candy et al. (1986) using **X-ray microprobe** analysis. Hippocampal and neocortical tissue samples were obtained from six clinically diagnosed and neuropathologically confirmed cases of AD (5 females/1 male; ages 74-102 yrs) and five controls (1 female/4 males; ages 43-74 yrs) with autolysis times between 7 and 30 hrs (mean of 13.5). To demonstrate senile plaques and neurofibrillary tangles, alternating cryostat sections (40 μm) were treated with thioflavin-S, Congo red, Bielschowsky's silver stain, and by immunohistochemistry for amyloid P-component (Scheibel et al., Soc. Neurosci. Abstr., Vol. 13, Part 2, p.1152, 1987). After identification with light microscopy, these lesions and the nuclei of tangle-bearing neurons were viewed under the scanning electron microscope and microprobed (beam strengths: 10-15 KeV, 0.5-1.5 nA; probe times: ≥150 sec.; beam diameter= 1 μm) to determine their chemical composition. Control tissue was identically treated and the cytoplasm/nuclei of the neurons were similarly microprobed. Virtually **no aluminum or aluminosilicates were found in the AD cases** or in the controls. There was also no unique distribution pattern or "signature" of chemical elements to distinguish the hallmark lesions of AD. We conclude that aluminum does not appear to play a significant role in the manifestation of AD. Further investigations should settle this important question.

437.3

IDENTIFICATION OF TYPE 3 PROTEIN KINASE C IN NT2/D1 EMBRYONAL CARCINOMA CELLS. K.L.Leach*, V.A.Ruff*, E.A.Powers*, J.K.Mayo* and I.Abraham*.(SPON: D.Hyslop). Dept. of Cell Biology, The Upjohn Company, Kalamazoo, MI 49001.

Alzheimer's disease is characterized by the occurence of neurofibrillary tangles and neuritic plaques. The exact protein composition of tangles is not known, but the presence of abnormally phosphorylated proteins has been demonstrated. This suggests that changes in either kinase or phosphatase systems may be involved in the development of these neuropathological changes. There are currently no established cellular models that mimic the Alzheimer pathology. However, the human embryonal carcinoma cell line, NT2/D1, has been suggested to be a candidate for such a model (Cole, G.M. and Timiras, P.S. in Model Systems of Development and Aging of the Nervous System, 1987). Treatment with 10^{-5} M retinoic acid induces neuronal differentiation of these cells, resulting in neurite outgrowth (Andrews, P.W. Developmental Biology 103:285, 1984). We are using these cells as a potential model system for studies on the regulation of protein kinases in cells with neuronal characteristics.

We have produced type-specific antibodies to brain PKC. These monoclonal antibodies (mAbs) are specific for Type 3 PKC in both ELISA and immunoblot assays. The mAbs can be divided into 2 classes based on their ability to recognize either the 45 kDa catalytic domain or the 35 kDa regulatory domain fragment of PKC. Each of the mAbs inhibits phosphorylation of histone or lipocortin by PKC. Only those mAbs that recognize the 35 kDa regulatory domain inhibit phorbol ester binding. This functional inhibition as well as the type specificity suggests that these mAbs can be used to study the activation and regulation of Type 3 PKC. Using these mAbs, we are investigating changes in PKC expression in NT2/D1 cells. The presence of Type 3 PKC was shown on Western blots using lysates prepared from undifferentiated NT2/D1 cells. The primary reactivity of the mAbs was with the 82 kDa PKC. We did not find any evidence of PKC fragments, since we did not observe cross-reactivity with smaller molecular weight species. Our results suggest that the NT2/D1 cell line may be a good model for studying kinase regulation in neuronal differentiation.

437.4

QUANTITATIVE ASSESSMENT OF SYNAPTIC DENSITY IN ALZHEIMER'S DISEASE. S.W. Scheff, S.T. DeKosky and D. Price*. Depts. Anatomy & Neurobiology and Neurology, Lexington VAMC and Sanders-Brown Research Center on Aging, University of Kentucky, Lexington, KY 40536.

Morphological studies of the brain's of patients with Alzheimer's Disease (AD) have reported significant changes in the neuron number and the dendritic structure of cortical neurons. These data, obtained from autopsy material, suggest a decrement in the number of synaptic contacts as a consequence of the disease. The present study examined the density of synaptic contacts in the frontal cortex (Brodmann's area 9) from autopsy-proven AD patients and age-matched, post-mortem matched controls taken within 13 hours of death. The brain tissue was prepared for ultrastructural analysis using immersion fixation and standard osmium tetroxide postfixation. Stereological methods were employed to ascertain synaptic density in cortical lamina III and V. Individuals with AD exhibited a highly significant reduction in synaptic density in both laminae as compared to controls. Mean synaptic apposition length was significantly larger in AD patients and was highly correlated with individual synaptic density in both control and AD brain. This suggests a possible compensatory mechanism. These results could not be accounted for by differences in postmortem interval or by the mean age of the groups. Coupled with the reported decline of ascending (extrinsic) cortical inputs and concomitant intrinsic neuronal loss, these results indicate that AD cortex is unable to maintain normal synaptic density and shows a diminished regenerative response. (Supported by ADRDA IIRG-87042, NIH AG05119 & NS21541 and the VA Research Service.)

437.5

FOCAL SYNAPTIC LOSSES IN THE HIPPOCAMPAL COMPLEX IN ALZHEIMER'S DISEASE. J.E. Hamos, L.J. DeGennaro and D.A. Drachman. Dept. of Neurology, Univ. of Mass. Med. Ctr., Worcester, MA 01655.

To understand the extent and location of neuronal losses necessary to produce dementia in patients with Alzheimer's Disease (AD), we first studied the immunohistochemical staining of synaptic terminals in postmortem tissue. Antibodies against two proteins found in synaptic terminals - synapsin I and synaptophysin - were used to label these structures in the hippocampal complexes of 8 patients with autopsy-proven AD and 9 non-demented control subjects. All AD patients showed a striking decrease in staining in the outer half of the molecular layer of the dentate gyrus when compared with this layer in the control brains which exhibited a uniform density of staining in both inner and outer halves. The altered density of immunoreactivity, suggesting a focal synaptic loss in this area, was independent of the presence of neuritic plaques and neurofibrillary tangles in the immediate vicinity. An additional patient with progressive degenerative dementia clinically, but without plaques or tangles, also showed depleted staining in the dentate gyrus. The pathogenetic significance of these synaptic losses in producing clinical dementia remain to be determined.

SITES OF EARLY ALZHEIMER-TYPE PATHOLOGIC CHANGES IN ENTORHINAL CORTEX AND HIPPOCAMPUS VISUALIZED BY ALZ-50 IMMUNOCYTOCHEMISTRY. B.T. Hyman and G.W. Van Hoesen. Depts. of Neurology and Anatomy, Univ. of Iowa, Iowa City, IA 52242

The presence of a few neurofibrillary tangles (NFTs) in the brain of a "normal" elderly person is not an unusual pathological finding. These lesions may represent a preclinical or early stage of Alzheimer's disease (AD), and it is possible that the sites of AD pathology in these cases are the initial lesions of the disease. To explore this, we have reviewed our brain collection for cases, regardless of clinical history, in which minimal or no NFTs were present. The topography of pathologic lesions was noted using both thioflavin S and Alz-50 immunocytochemistry, an antibody that likely recognizes neurons in a "pre-NFT" stage. In these cases, NFTs and Alz-50 positive neurons were found in layer II of entorhinal cortex, the continuation of this lamina into layer III of perirhinal cortex, and the subicular/CA1 area. In some cases these specific cells were positive for Alz-50, although no NFTs were present. These are all lamina and cytoarchitectural areas that are specifically and severely affected in all cases of proven AD that we have examined. Our results are consistent with the hypothesis that these neurons are vulnerable to Alzheimer pathologic degeneration, and may be among the first sites of pathology in the brain. (We thank P. Davies for generously providing Alz-50; supported by the Mathers Foundation, and NS 14944 and PO NS 19632).

STELLATE CELLS IN LAYER II OF THE ENTORHINAL CORTEX ARE PRONE TO NEUROFIBRILLARY TANGLE FORMATION IN AGING AND ALZHEIMER'S DISEASE. T. Duong, T. Abebe* and A.B. Scheibel. UCLA Departments of Anatomy, Psychiatry and the Brain Research Institute, Los Angeles, California 90024.

We have studied the layer II neurons in the entorhinal cortex of Alzheimer's (5 female / 5 male; age = 66 - 102 years) and normal patients (5 male; age = 61 - 75 years). All clinical diagnoses of Alzheimer's disease were neuropathologically confirmed. The postmortem time varied from 7 to 15.5 hours. Cryostat sections (40 μm) were processed by routine histological stains and peroxidase-antiperoxidase immunocytochemistry directed against human amyloid P-component (Scheibel et al., Soc. Neurosci. Abstr., Vol.13, Part 2, p.1152, 1987). In man, the entorhinal cortex (Brodmann's field 28) is located in the anterior portion of the parahippocampal gyrus. Neurons in layer II of the entorhinal cortex consist of alternating clusters of small (6-12 μm) and medium (25-30 μm) neurons. The medium neurons are stellate cells and they congregate in characteristic groupings of variable size (300-600 μm in diameter). In normal aging, occasional neurofibrillary tangles (NFTs) can be demonstrated in these islands of stellate cells. The NFT formations extend from the distinctive "flame-shaped" or "whorled" neuronal somatas into the proximal dendrites. **In patients diagnosed with Alzheimer's disease, nearly all the stellate neurons in layer II of the entorhinal cortex are converted to neurofibrillary tangles. NFTs in both Alzheimer's and normal patients label positively for the antibody to human amyloid P-component.**

New Pathological Features of Alzheimer's Disease (AD) Described with the Monoclonal Antibody Tor 23. P.D. Kushner, D.T. Stephenson*, and C. Greco* Pacific Presbyterian Medical Center, San Francisco, CA 94115.

Pathological hallmarks of AD, plaques, tangles, and specific cholinergic neuronal loss, have not indicated any unusual cell surface dysfunctions. This is curious in view of recent data that the amyloid precursor gene encodes a polypeptide with a transmembrane spanning sequence. We are studying neuronal surface molecules utilizing monoclonal antibodies made to ray cholinergic nerve terminals. The antibody Tor 23 binds the apparent limiting membrane of a discrete population of neurons of the human cortex and a subpopulation of subcortical astroctytes (Stephenson et al., these abstracts). In this study we examined cortical regions from AD cases to determine if the epitope defined by Tor 23 was present, absent, or altered.

Examination of the cortex from six AD cases by immunohistochemical analyses revealed distinct differences in the distribution of Tor 23 binding relative to that of control cortex. In AD, there were fewer Tor 23 positive neurons and the immunopositive astrocyte was absent. Because a particular epitope was localized, we cannot be certain that cells were lost: they could have lost immunoreactivity. Given its pivitol surface location and its conservation within the vertebrate species, the fallout of the epitope alone may be significant. Because reactive gliosis is present in AD cortex, our finding of the loss or transformation of a glial cell is unique and warrants further examination. Funded by the Department of Health Services, California.

Tor 23 Defines a Highly Conserved Neuronal Surface Epitope Present on Rare Neurons of the Human Cortex. D.T. Stephenson*, S. Wright*, and P.D. Kushner. (SPON: L.C. Fritz) Pacific Presbyterian Medical Center, San Francisco, CA 94115.

Tor 23, a monoclonal antibody from a library made to Torpedo synaptosomes (JNC 43 775-786, 1984) binds the external membrane of a discrete set of rat CNS neurons (J. Neurosci., 1988). The epitope defined by Tor 23 is conserved in the human nervous system (Muscle & Nerve 11 10-20, 1988) and is present on the external surface of a discrete subset of neurons (Mol. Br. Res. 2 271-275, 1987).

The present in situ findings within the iso- and allocortices support the distribution of Tor 23 to the apparent limiting membrane of rare and select neurons. In the frontal, occipital, parietal and motor cortical areas Tor 23 outlined neurons of laminae 2-3. These neurons were medium to large sized, rounded, and non-pyramidal. In the hippocampus, immunopositive neurons were large and were usually located just external to the pyramidal cell layer. In addition to the stained neurons, Tor 23 bound astrocytic cells of the subcortical white matter. Co-staining with GFAP indicated that only some subcortical astrocytes were Tor 23 positive. The antigen appears to be a polypeptide by immunoblot analysis.

The conservation of an epitope from elasmobranchs to humans is evidence in favor of an important function. Its position on the neuronal external surface suggests it may play a dynamic and vital role in developing and maintaining the complex neuronal milieu of the human cortex. Its appearance on a population of astrocytes may reflect a neuronal-glial interaction among a highly specialized neural subpopulation.

437.10

A NEW MONOCLONAL ANTIBODY WHICH RECOGNIZES EXTRACELLULAR NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE (AD). C.L. Joachim,* K.S. Kosik* and D.J. Selkoe (SPON: S. Khoshbin). Center for Neurologic Diseases, Brigham and Women's Hosp. and Harvard Med. Sch., Boston, MA 02115.

A new monoclonal antibody is described. Partially purified amyloid protein isolated from AD meninges was used as immunogen in mouse. In formalin-fixed paraffin-embedded tissue sections from cases of AD, this antibody labels extracellular ("ghost") neurofibrillary tangles (NFT) but not intracellular NFT. Some amyloid plaques are very lightly labeled, and this immunostaining is enhanced by pretreatment of tissue sections with 88% formic acid. Formic acid pretreatment does not alter labeling of extracellular NFT and does not cause intracellular NFT to become immunoreactive. On frozen sections of brain tissue, this antibody labels nuclei of all cells. This antibody does not recognize bovine tau protein or purified glial fibrillary acidic protein on Western blots, nor does it recognize the 28 residue synthetic beta amyloid peptide on dot blots. No protein bands are labeled on Western blots of Triton-soluble proteins from homogenates of AD or control cerebral cortex. Studies are under way to identify the antigen(s) recognize by this antibody. Our hypothesis is that proteins immunologically cross-reactive with the beta amyloid protein may coat the filaments of extracellular tangles, and thus be recognized by this antibody.

437.11

A68 IMMUNOREACTIVITY IN BRAINS OF NONHUMAN PRIMATES. L.C. Cork*, L.C. Walker, P. Davies§, and D.L. Price. (SPON: C.S. Duchala). Neuropathology Lab., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205-2182. §Depts. of Neuroscience and Pathology, Albert Einstein College of Med., Bronx, NY 10461.

A68, an antigen enriched in the brains of individuals with Alzheimer's disease (AD), is recognized by monoclonal antibody Alz-50 [Wolozin et al., Science 232:648, 1986]. In AD, A68 immunoreactivity occurs in neurons, including neurites in plaques and neurofibrillary tangles (NFT) in perikarya. Although trace amounts of A68 immunoreactivity may occur in some control human brains, antigens in these brains may be cross-reactive proteins that differ from A68 [Wolozin & Davies, Ann. Neurol. 22:521, 1987]. To determine whether A68 appears in brains of aged nonhuman primates (which develop plaques), we used immunocytochemical methods to examine brains of New World monkeys, Old World monkeys, and great apes. In these animals, A68 immunoreactivity is present in some neurons, fibers, and abnormal neurites associated with plaques. The number of A68-immunostained elements in all nonhuman primate brains examined was significantly less than that seen in humans with AD. These findings reinforce the usefulness of nonhuman primates in the study of processes that occur in the brains of individuals with age-related degenerative diseases.

437.12

INDUCTION OF "ALZHEIMER" ANTIGENS IN CELLS FROM NORMAL SUBJECTS BY THE MITOCHONDRIAL UNCOUPLER CCCP. A.C.Baker,* L.-W. Ko,* and J.P. Blass. Dementia Research Service, Burke Rehabilitation Center, Cornell University Medical College, White Plains, NY 10605.

When grown under conditions designed to favor the expression of neuronal properties, skin cells from all of 18 Alzheimer subjects tested stained with polyclonal and/or monoclonal antibodies to paired helical filaments (PHF) and/or with the Alz-50 antibody; cells from none of the 18 carefully matched controls did so.

However, when grown in the presence of a 100 nM conc. of the mitochondrial uncoupler CCCP, control lines then stained for PHF (8 tested with polyclonal and 2 tested with monoclonal antibody). The control lines then also stained with the Alz-50 antibody (3 lines tested). CCCP was used because of published evidence that mitochondria are partially uncoupled in Alzheimer's disease brain biopsies.

Induction of a metabolic lesion comparable to that in Alzheimer brain is adequate to cause expression of typical Alzheimer antigens. This culture system appears to be convenient for studying the biology of PHF formation.

437.13

ALTERED CASEIN KINASE ACTIVITY IN ALZHEIMER BRAIN. D. Iimoto* and T. Saitoh. U.C.S.D., Sch. of Med., Neuroscience Dept., M-024, La Jolla, 92093.

Protein phosphorylation has been shown to play an important role in regulating cell functions. In Alzheimer's disease (AD), there are proteins which are abnormally phosphorylated. These include P60 (a Mr 60,000 protein), P86 (a major substrate of PK-C) and tau. Since tau is associated with AD specific neurofibrillary tangles, its overphosphorylation may have an important role in the AD pathogenesis. Therefore, there must be some kinase(s), and/or phosphatase(s) which are involved in this overphosphorylation. Since cAMP stimulates tau phosphorylation, we examined the cAMP dependent phosphorylation of tau. Using 10μM cAMP and exogenous tau, there was no difference in the kinase activity between the control and diseased samples. Furthermore, no difference was seen in tau phosphatase activities of AD and control samples in the presence of Mg^{2+}, Mn^{2+} or Ca^{2+}/calmodulin. Because we had some evidence which indicated that casein kinase might also phosphorylate tau, we studied the activity of casein kinase. Casein kinases I and II were activated with spermine (1mM) and casein kinase II was inhibited with heparin (150 units/ml). Normal cytosolic fractions contained more spermine activated kinase activity and heparin sensitive kinase activity than did the AD cytosolic fractions. This indicates that there is less casein kinase II activity in brains with AD. While the differences found are not likely to account for the excessive phosphorylation of tau in AD, altered casein kinase II activity in Alzheimer brain may be involved in the pathogenesis of disease.

437.14

NEOCORTICAL PARVALBUMIN-CONTAINING NEURONS ARE RESISTANT TO DEGENERATION IN ALZHEIMER'S DISEASE. J.H. Morrison, K. Cox*, P.R. Hof, M.R. Celio. Research Institute of Scripps Clinic, La Jolla, CA 92037, and Dept. of Anatomy, University of Kiel, FRG.

The regulation of intracellular calcium levels is critically important to neuronal viability. Therefore we investigated the distribution of the calcium-binding protein parvalbumin (PV) in human neocortex and its relationship to cellular vulnerability in Alzheimer's disease (AD). In normal human neocortex, PV-immunoreactivity was confined to the non-pyramidal cells which were present in layers II-VI, with the highest density in layers II-IV. A quantitative analysis of the superior frontal gyrus demonstrated that the mean density of labeled neurons in layers II-IV of 3 control brains was 154 ± 13 labeled cells/mm^2, whereas the mean density in 7 AD brains was 166 ± 12. Therefore, PV appears to be a marker for a subset of neurons that are resistant to pathology in AD. A second calcium-binding protein, calbindin (CaBP), labels a different subset of non-pyramidal neurons that is largely confined to layer II. In addition, pyramidal neurons in layers III and V are lightly CaBP-immunoreactive. Preliminary analysis suggests that the heavily labeled neurons are resistant to degeneration in AD, whereas the lightly labeled neurons are vulnerable. Thus, calcium-binding proteins represent interesting new markers which distinguish between neurons that are susceptible to pathology in AD from those that are resistant.

437.15

QUANTITATIVE ANALYSIS OF NON-PHOSPHORYLATED NEUROFILAMENT PROTEIN (NPNFP)-IMMUNOREACTIVE NEURONS IN NORMAL AND ALZHEIMER'S DISEASE BRAIN. P.R. Hof, K. Cox*, and J.H. Morrison. Research Institute of Scripps Clinic, BCR-1, La Jolla, CA 92037, USA.

We have postulated that pyramidal neurons that are prone to neurofibrillary tangle (NFT) formation in Alzheimer's disease (AD) contain very high somatic and dendritic levels of NPNFP in the healthy aged cortex. In addition, the intracellular concentration of NPNFP is directly correlated with the cell size. In order to further investigate the relationships between cell size, intracellular concentration of NPNFP, and NFT formation, we performed a quantitative analysis of the distribution and density of NPNFP-immunoreactive neurons in normal and AD neocortex. In the AD brains, these distribution patterns were correlated with those of plaques and NFT. The immunoreactive cells were divided into three size groups : < 250 μm^2; 250-350 μm^2; > 350 μm^2. In layer III, a significant (72 %) loss was observed only in cells > 350 μm^2, whereas in layer V, there was a moderate decrease in the intermediate-sized cells (44 %), and a dramatic loss in the large cell group (78 %). Even though cell loss was only apparent among the larger neurons, a decrease in the intracellular concentration of NPNFP (as measured by optical density) was observed in all the three size groups. In all the AD cases, there was a high number of plaques and NFT in layers III and V. These data further support the hypothesis that a chemically-identified subset of pyramidal neurons is particularly vulnerable in AD. Supported by grants from ADRDA, AG O6647 and FNRS 83.495.0.87.

SERIAL SECTION COMPARISON OF TAU HISTOCHEMISTRY WITH A HIGHLY SENSITIVE SILVER IMPREGNATION METHOD FOR SENILE PLAQUES AND NEUROFIBRILLARY TANGLES. B.J.Quigley Jr.* K.S. Kosik and N.W. Kowall. (SPON: Bruce Ekstein). Neurology Service, Mass. General Hospital, Boston MA 02114.

We compared tau immunoreactive features to argyrophilic features using the sensitive Gallyas intensified Hick's procedure developed by Campbell et al (Soc Neurosci Abs 13:678) in the CA 1 field of the hippocampal formation of 5 patients with Alzheimer's disease (AD).

Tau histochemistry showed a plexus of dystrophic neurites (DN) spanning CA 1, with greatest density near the stratum oriens and radiatum borders. A band of typical neurofibrillary tangles (NFT) and occasional senile plaques (SP) were seen in the center of CA1.

In contrast, the silver method marked NFT throughout CA1. These included typical NFT seen with tau histochemistry and a group of larger diffusely argyrophilic tangles. DN were homogeneous in distribution and longer than tau reactive DN. SP were more dense and formed a continuous band in stratum radiatum. In one case showing early changes of Alzheimer's disease, the silver method showed marked homogeneously distributed SP only whereas tau histochemistry marked occasional DN and NFT. This may reflect tau protein's predisposition to mark an earlier stage of NFT formation in A.D.

A COMPUTER METHOD FOR 3-D RECONSTRUCTION OF THE LAMINAR AND REGIONAL DISTRIBUTIONS OF PLAQUES AND TANGLES IN ALZHEIMER BRAINS. C-N Kim*, C. White III*, D. Sparkman, D. J. Woodward and M-C de Lacoste.(SPON: G. Mihailoff) Depts. of Cell Bio. & and Path., U. T. Southwestern Medical Ctr., Dallas, TX 75235

A number of previous investigators have examined the laminar and regional distributions of neurofibrillary tangles [NFT] and neuritic plaques [NP] using small blocks of tissue sampled across different regions of Alzheimer [AD] brain [e.g., *Lewis* et al., 1987]. While these studies have provided critical quantitative information, it has been difficult to conclusively determine if the spread of AD pathology in the cerebral cortex [CC] follows orthograde, retrograde or both ortho- and retrograde routes. Our aim has been to develop computer-assisted methods 1) to obtain precise 3-D reconstructions of laminar and regional distributions of NP and NFT throughout the entire extent of temporal and occipital cortices within cyto- and myeloarchitecturally defined regions and 2) to superimpose the reconstructions on a 3-D visualization of the detailed connectivity patterns for these same regions. We believe that these methods will enable us to trace the spatial course of CC degenerative changes in AD.

Formalin-fixed blocks of tissue [up to 3X4 in] were cut at 50μm with a large-stage freezing microtome. Groups of 5 sections at 1mm intervals were processed using 1) Thioflavin-S, and PHF immunocytochemistry for NP and NFT labelling and 2) cresyl violet and the Gallyas silver stain for cyto- and myeloarchitecture. CSCAN and CARP 3D were utilised for computer-assisted regional differentiations, volumetric computations, NP and NFT counting and 3-D reconstructions [*Smith, de Lacoste*, et al 1985, 1987]. These methods are proving to be effective in delineating the relationship between the distribution of AD pathology and intracortical connectivity.

MORPHOLOGIC CHANGES IN AMYGDALOID SUBREGIONS IN ALZHEIMER'S DISEASE. S.A. Scott, D.L. Sparks, C.A. Knox*, S.T. DeKosky and S.W. Scheff. Depts. Anatomy & Neurobiology and Neurology, Lexington VAMC and Sanders-Brown Research Center on Aging, University of Kentucky, Lexington, KY 40536.

The emerging picture of Alzheimer's Disease (AD) as disruption of specific cortical and subcortical structures necessitates closer examination of subregions of primary limbic structures affected by the disease. Since the amygdala is a principle limbic structure heavily involved in both the behavioral and pathological manifestations, we studied various amygdaloid subnuclei for differential alterations in AD. Three dimensional reconstructions of the entire amygdaloid complex were employed. Frozen 50 µm thick sections were obtained throughout the entire amygdala with every fifth section stained with cresyl violet.

The amygdala in subjects with AD demonstrates a striking topographical rearrangement and reduction in size. In AD the structure appears to have lost considerable volume, with secondary dilation of the inferior horn of the lateral ventricle (*ex vacuo*). The rostrocaudal extent of most nuclei, as well as the entire complex, is reduced. The nuclei reveal a distorted outline in relation to each other and to adjacent structures, most marked in the basolateral group. Volumetric changes in specific areas and nuclear groups will be discussed.

HLA-DR-POSITIVE MICROGLIA IN NORMAL AND DISEASED BRAINS. L.A. Mattiace, G. Gong* and D.W. Dickson*. Dept. Pathol., Albert Einstein College of Medicine, Bronx, NY 10461.

Several recent studies using monoclonal antibodies specific to HLA-DR, a class II major histocompatibility cell surface glycoprotein, have demonstrated HLA-DR on a small number of microglia in the normal central nervous system. Far more HLA-DR-positive microglia have been described in Alzheimer's disease (AD), raising the possibility that immune mechanisms may be operative in AD. Brains were obtained at autopsies of 2.5 to 24 hours post-mortem from 14 individuals: 1 child, 2 young adults, 2 adults with neurologic disease, and 9 cases of AD (3 early, 6 chronic). Staining of microglia with antibodies to HLA-DR was highly sensitive to duration and type of fixation. Optimal staining was obtained with short duration PLP fixation, cyropreservation with sucrose and vibratome sections. HLA-DR-positive microglia were seen in both gray and white matter of all cases. With the exception of chronic AD, microglia with delicate, highly branched processes were uniformly distributed. In chronic AD, microglia with short, stubby processes or rounded contours were clustered. Double-labeling with glial fibrillary acidic protein demonstrated that HLA-DR-positive cells were not astrocytes. With electron microscopy, labeled cells were consistent with microglia. In AD, they had prominent phagolysosomes. Double-staining with antibodies to beta-amyloid synthetic peptides showed microglia associated with amyloid deposits.

437.20

THE DISTRIBUTION AND DENSITY OF ALZHEIMER-LIKE NEUROPATHOLOGICAL MARKERS IN NON-DEMENTED AND MILDLY DEMENTED BRAINS. J.L. Price, D.L. White* and P. Davis* (SPON: W.T. Thach), Depts. of Anatomy/Neurobiology & Psychiatry, Washington Univ. School of Medicine, St. Louis, MO 63110.

As part of an ongoing study, tangles, plaques and Alz-50 immunoreactive cells (A50ic) have been mapped in the brains of cognitively unimpaired and demented subjects, 59 to 87 years in age. The cognitive status of each case was assessed by premortem testing in the Memory and Aging Project of Washington Univ., or by a structured retrospective interview with a close relative. Serial sections through the ventral forebrain were stained with the Bielschowsky silver method, or immunohistochemically with the Alz-50 antibody, and then mapped and counted with the aid of a computerized microscope digitizer. To date 7 unimpaired cases, 3 very mildly demented cases and 4 severely demented cases have been thoroughly studied.

In the unimpaired cases, the highest density of tangles and A50ic was found in the perirhinal cortex, followed (in order) by the entorhinal cortex, anterior olfactory nucleus, and hippocampal field CA1. A similar pattern is found in the mildly demented cases, although the overall density of these markers is greater. The pattern also appeared to be continued in the severely demented cases, but the high density of tangles and A50ic in many other brain structures obscured their differential distribution. These results support the concept that there is a continuum between healthy aging and Alzheimer's Disease.

However, the incidence and distribution of plaques is more selective. Almost no plaques were found in the unimpaired cases, except for one case which also had a high density of tangles, while all but one of the demented cases had a high density of plaques.

Supported by NIH grants AG05681 and NS09518.

A Case of Non-Demented Alzheimer's Disease and Hippocampal Sclerosis With Normal Cholinergic Parameters in Basal Forebrain, Neocortex, and Hippocampus. R. Zweig,* K. Schegg,* J. Peacock, and D. Melarkey* (SPON: C. Ort). Reno VA Medical Center and University of Nevada School of Medicine, Reno, NV 89520.

Maximum senile plaque (SP) density >15/mm^2 in neocortex meets the pathological criterion for Alzheimer's disease (AD), but some non-demented individuals have both high SP counts and preserved choline acetyltransferase (ChAT) in neocortex. We confirm these results for a 76 year old non-demented man and extend previous work by analysis of acetylcholinesterase (AChE) isoforms. Microscopic exam showed abundant neocortical SPs, occasionally >15/mm^2, and rare neurofibrillary tangles (NFTs) in frontal, parietal, and temporal cortices. Amygdala had highest SP counts. Despite sclerosis of CA1 region in hippocampus, neither SPs, NFTs, nor granulovacuolar degeneration were found in hippocampal gyrus, although subiculum and parahippocampal gyrus had these abnormalities. No neuronal loss or NFTs were seen in basalis or septal nuclei. ChAT activity in hippocampus, septum, and parietal cortex was similar to 3 aged control and higher than 8 AD cases. Also, the tetrameric isoform of AChE (a marker of cholinergic innervation) was not reduced. Our results suggest that pathological alterations of the basal forebrain cholinergic system do not precede SP development. ChAT activity and AChE isoform patterns in hippocampus are unaffected by severe loss of CA1 pyramidal neurons.

437.22

DISCOVERY OF HYDROXYPROLINE AND AN ACTIN DETERMINANT IN THE INSOLUBLE PAIRED HELICAL FILAMENTS OF ALZHEIMER BRAIN. G. D. Vogelsang, G. E. Dean* and F. P. Zemlan. Department of Physiology and Biophysics, Department of Microbiology and Molecular Genetics, and The Alzheimer's Research Center, University of Cincinnati College of Medicine 45267.

Neurofibrillary tangles (NFT), comprised of paired helical filaments (PHF), are the critical neuropathological feature for the differential diagnosis of Alzheimer's disease (AD). Immunological studies indicate that several antigen-specific antibodies demonstrate cross-reactivity with "purified" PHF. It has not been shown, however, that this cross-reactivity is associated with the SDS insoluble PHF core protein (PHF_i) as opposed to PHF associated proteins or contaminants of the purification process. "Purified" PHF when subjected to electrophoresis (100V) in Tris/Borate/SDS buffer resulted in the separation of solubilized PHF associated proteins (PHF_s) from PHF_i. Electronmicroscopy revealed an intact PHF structure before and after this elutrapping technique (ET). A significant difference in several amino acids characterized PHF_i from PHF_s. The percent total mass of hydroxyproline (hpr) and glycine increased in the PHF_i after ET from 30 minutes to 4-1/2 hours. The elevation of these amino acids in PHF_i remained relatively constant from 1.5 to 18 hours after ET, peaking at 22% of the total protein after 39 hours. ELISA data confirmed that our PHF_i and PHF_s fractions were reactive with several putative PHF-specific antibodies (Ab's). Cross-reactivity of PHF_i with Ab's to other cellular components which include: microtubule associated protein-tau, ubiquitin and a newly identified determinant-actin, was demonstrated. None of the purported components of PHF contain hpr. Therefore, these data suggest that inappropriate hydroxylation of proline residues in PHF protein occurs in NFT. This hydroxylation may be the catalyst for the polymerization and subsequent insolubility of PHF in brain regions affected with AD.

437.23

NEUROFILAMENT GENES AND ALZHEIMER'S DISEASE: IS THERE AN ASSOCIATION? G. Lacoste-Royal*, M. Mathieu*, J. Nalbantoglu*, M. Freire*, J.-P. Julien*, S. Gauthier and D. Gauvreau* (SPON: L. Descarries). INRS-Santé, Pointe-Claire, Canada, H9R 1G6; Institut du Cancer de Montréal, Montréal, Canada, H2L 4M1 and McGill Center for Studies in Age and Aging, Montréal, Canada, H3G 1A4.

The primary cause of Alzheimer disease (AD) remains unknown, although the implication of genetic factors has been suggested, based on autosomal dominant transmission of the disease in several pedigrees. Neurofibrillary tangles, one of the pathological lesions of AD, possess epitopes of neurofilament (NF) proteins. In order to detect a possible anomaly that might relate to the disease, we searched for an association between the NF-L gene and AD in a group of sporadic AD cases. All cases met current clinical criteria for AD; in most cases the diagnosis was confirmed at autopsy. Genotypes for a TaqI RFLP at the NF-L locus (allele 1: 3.7 kb, allele 2: 2.9 kb) were determined for a control group and for our AD group. Allelic frequencies for allele 1 and allele 2 were respectively 0.72 and 0.28 for the control and 0.60 and 0.40 for the AD group. These differences were found to be not significant for the number of samples analysed. Thus our results showed no association between the gene for the 68 kd NF protein and AD. Supported by MRC Canada grant #MA-10027.

437.24

COMPARISON OF GROWTH-ASSOCIATED PROTEIN (GAP-43) FROM RAT AND HUMAN CORTEX, AND CHANGES IN GAP-43 IN ALZHEIMER'S DISEASE. J.K. Glenn* and P.D. Coleman. Department of Neurobiology and Anatomy. University of Rochester School of Medicine and Dentistry. Rochester, NY 14642.

Using SDS polyacrylamide gel electrophoresis and western blotting we have compared GAP-43 from rat and human cortex, and examined levels of GAP-43 in normal and Alzheimer's Disease (AD) hippocampus. Gap-43 was identified in western blots using a mouse monoclonal antibody (91E12) directed against rat GAP-43 (antibody provided by J.H.P. Skene, Stanford University.) followed by blot treatment with biotinylated horse anti-mouse IgG, avidin-linked horseradish peroxidase, and peroxidase substrate.

GAP-43 was detected both in the membrane-bound and cytosolic fractions of cell extract. Triton X-100 extractions of the membrane were able to remove some GAP-43, but complete extraction required dissolving the membranes in boiling SDS. We find that the rat and human GAP-43 show the same molecular weight.

In order to determine if post-mortem delay leads to changes in GAP-43, we have examined rat brain subjected to a variety of post-mortem conditions. Our data suggest that a broad range of post-mortem delay has little effect on amount or electrophoretic pattern of GAP-43.

In paired of AD and control cases matched for age and post-mortem delay, we find lower levels of GAP-43 in SDS extracts from AD hippocampi.

When GAP-43 was analyzed from SDS gels containing urea, we observed an increase in the heterogeneity of the protein. In these gels the GAP-43 from human tissue appeared to be more heterogeneous than the rat GAP-43.

CHARACTARIZATION OF THE HUMAN GAP-43 GENE AND STUDIES OF mRNA LEVELS IN ALZHEIMER'S DISEASE. K.E. Rogers* A.B. Wadhams* N. A. Lebda* P.D. Coleman. (SPON: B. Weiss).Department of Neurobiology and Anatomy, University of Rochester, Rochester, NY, 14642.

GAP-43 is a phosphoprotein which appears to be a marker of the development, growth, and regeneration of neuronal processes. A clone containing the human GAP-43 gene was isolated from a Charon 4A genomic library provided by T. Maniatis, using a 1.4 Kb rat GAP-43 cDNA probe (pGAP) previously charactarized by P. Skene and associates. Approximately 9 x 10^5 plaques were screened with the pGAP probe and a single positivily hybridizing clone was purified through three rounds of screening. The small number of positive plaques observed from a screen of 10^5 colonies suggests a low gene copy number, while the stringency of washing subsequent to hybridization was indicitive of a high degree of homology between the rat and human coding regions. The size of the insert is 17 Kb and is consistent with the manner in which the library was constructed. Restriction mapping and sequence data for the insert will be presented. We are currently identifying non-coding regions of the gene thought to be involved the transcriptional regulation.

Studies using radioactively labelled pGAP to probe total RNA from various brain regions indicate that the levels of message for GAP-43 are similar in Alzheimer's disease (AD) and control brain hippocampus. This finding contrasts with the approximate 35-45% excess loss of neurons in AD over the loss seen in normal aging.

HEAT SHOCK PROTEINS AND UBIQUITIN IN CULTURED NERVOUS TISSUE

A.Morandi*, W.Welch, G.Perry, L.Autilio-Gambetti and P.Gambetti (SPON: P.Gambetti). Div. of Neuropathology, Case Western Reserve University, Cleveland OH 44106 and Cold Spring Harbor Laboratory, Cold Spring Harbor, NY.

We have used an in vitro system to investigate the response of the nervous tissue to stress conditions. Explants of rat dorsal root ganglia were exposed to two different types of stress conditions: aluminum intoxication and heat shock. Expression and cellular location of Heat Shock Proteins (HSPs) were analyzed on fluorograms and immunoblots after separation by one and two dimensional gel electrophoresis, and by immunocytochemistry using mono and polyclonal antibodies. Ubiquitin (Ub) conjugates were also analyzed. Both stress conditions resulted in an increase of the Ub-conjugates, with an higher increment in chronic aluminum intoxication. On the contrary, HSPs were detected only after heat shock treatment. These findings are consistent with the observation that intracytoplasmic inclusions induced by chronic administration of antimitotic drugs, which as aluminum act on cytoskeleton, react with Ub antibodies but not with antibodies to HSPs (Gambetti et al. Neuroscience 1988). However further studies are needed to determine whether the Ub and the heat shock systems can be triggered indipendently by different tipes of stress conditions. These observations may be relevant to the recent discovery that Ub is present in neuronal inclusions of Alzheimer's and other degenerative diseases, where, on the contrary HSPs have not been detected.(Supported by NIH Grants NS14503 and AG00795).

EFFECTS OF CARBACHOL and GALLAMINE ON WHOLE-CELL CURRENTS IN NEUROBLASTOMA-GLIOMA N1E-115 CELLS. D.O. Keyser, D. Doerner, and B.E. Alger, Dept. Physiol., Univ. of Maryland Sch. Med., Baltimore., MD 21201

The actions of carbachol (CCh) and gallamine were studied in mouse neuroblastoma-glioma N1E-115 cells under whole-cell voltage-clamp. Using K-filled electrodes, brief pressure-ejections of CCh (0.05-1 mM) from blunt pipettes elicited a transient inward current followed by a longer-lasting outward current. Gallamine (100-200 μM), a nicotinic and putative muscarinic M2 receptor antagonist, had no effect on resting membrane current but blocked the CCh-induced inward current without altering the outward phase. Atropine reduced the outward component, but did not affect the inward transient.

Bath application of CCh reversibly suppressed voltage-dependent K current and decreased membrane conductance. Using Cs-filled electrodes and saline containing Ba and TTX, CCh application reversibly reduced peak inward I_{Ba} elicited by depolarizing clamp steps from hyperpolarized holding potentials. This effect was inhibited by atropine but unaffected following bath application of gallamine. Characteristics of the I_{Ba} I/V relationship were unaffected by CCh.

These data suggest that nicotinic receptor activation initiates an inward current while muscarinic responses involve both activation of an outward current and modulation of voltage-gated channels.

TWO MEMBRANE CONDUCTANCE RESPONSES OF DISSOCIATED RAT SYMPATHETIC NEURONS TO MUSCARINE ARE COUPLED BY A PTX-INSENSITIVE GTP-BINDING PROTEIN. N.V. Marrion*, T.G. Smart* and D.A. Brown, MRC Neuropharmacology Research Group, Department of Pharmacology, London University School of Pharmacy, London, WC1N1AX, U.K.

Dissociated adult rat superior cervical sympathetic neurones (Marrion, N.V., Smart, T.G. & Brown, D.A. Neurosci. Lett.,77:55,1987) were whole-cell voltage-clamped using a single-electrode discontinuous amplifier. The patch pipette solution contained (mM): K aspartate, 150; KCl, 30; $MgCl_2$, 1; Na_2ATP, 1; EGTA, 0.5; HEPES, 5; NaOH, 3. (pH 6.7). This solution preserves the voltage-dependent K-current, I_M(Marrion, N.V., J.Physiol.,396:87P,1987). Cells were clamped at -30 to-45 mV and 1 sec hyperpolarizing commands applied to deactivate I_M.

Bath-application of dl-muscarine (1-10 uM) produced a reversible inward current accompanied by inhibition of I_M, as in intact adult ganglia (Constanti ,A. and Brown, D.A., Neurosci. Lett.,24:289,1981). In a proportion of cells an additional component of inward current due to an increase in a time-and voltage-insensitive conductance, reversing near 0 mV, also occured. Inclusion of the non-hydrolysable GTP-analogs, Gpp (NH)p (200 uM; n=4) or GTP- -S (500 uM; n=8) in the pipette solution mimicked both effects of muscarine. Effects of GTP-analogs were slow, requiring about 20 min to reach equilibrium. Both responses to muscarine persisted in neurons preincubated for up to 27 hr with 500 ng/ml Pertussis toxin (PTx).

We conclude that both I_M inhibition and increased conductance produced by muscarine involve activation of a PTx-insensitive GTP-binding protein.

CHOLINERGIC SUPPRESSION OF BOTH ENDOGENOUS AND ISOPROTERENOL-INDUCED M-CURRENT IN ISOLATED SMOOTH MUSCLE CELLS IS MIMICKED BY A DIACYLGLYCEROL ANALOG. Lucie H. Clapp*, Stephen M. Sims*, Joshua J. Singer, and John V. Walsh, Jr. Dept. of Physiology, U. of Mass. Med. Sch., Worcester, MA 01655

The role of the second messenger diacylglycerol [DAG] in mediating muscarinic suppression of M-current, a type of K^+ current, in gastric smooth muscle cells isolated from Bufo marinus was examined using single microelectrode voltage-clamp techniques. Extracellular application of 60 μM sn-1,2-dioctanoylglycerol [diC_8], a synthetic DAG analog, reversibly suppressed endogenous M-current in the same way as acetylcholine [ACh], causing a net inward current associated with a conductance decrease. Current relaxations which occur in response to hyperpolarizing pulses and represent the voltage-dependent turn-off of M-current were also decreased by diC_8. The suppression of M-current by diC_8 was not always as complete as it was in the case of ACh. Like ACh, diC_8, also suppressed M-current induced by isoproterenol through the mediation of cyclic AMP (Sims et al. Science 239: 190, 1988). Thus, the dual regulation of M-current by isoproterenol and ACh appears to involve two second messenger systems. Supported by NIH DK31620 and NSF DCB8511674

MUSCARINIC RECEPTORS MAY BECOME UNCOUPLED FROM ION CHANNELS IN DISSOCIATED CELL CULTURE. J. E. Freschi, Dept. of Neurology, Emory Univ. Sch. of Med, Atlanta, GA 30322.

We have found that neurons dissociated from neonatal rat superior cervical ganglia frequently lack electrophysiological responsiveness to muscarinic agonists. We have undertaken studies to determine how these neurons lose their responsiveness and how expression may be regulated. We grew neurons in F12 medium supplemented with 10% fetal bovine serum and nerve growth factor (50 ng/ml). We co-cultured some neurons with previously plated confluent brain glia, and we treated some cultures with conditioned medium from rat heart cells in culture. We used the whole cell patch technique to measure membrane potential and to voltage-clamp neurons in the single electrode switched clamp mode (Axoclamp-2). Neurons that were unresponsive to muscarine (1 uM to 1 mM) expressed voltage-sensitive K^+ currents resembling m-current (similar kinetics, voltage sensitivity, and block by barium). To examine whether the neurons expressed muscarinic receptors we measured ^{3}H-QNB binding. The cultures bound an average of 388 fmoles/mg protein (n=4). In the unresponsive neurons, phorbol esters, dibutyryl cAMP, dibutryl cGMP applied externally, and changing the GTP, ATP or Mg^{2+} levels in internal dialysis solutions did not cause an electrophysiological response or increase the responsiveness of the neurons to muscarine. Neither growing the sympathetic neurons on a layer of central glia nor exposing them to conditioned medium from heart cultures affected their sensitivity to muscarine. We suggest that certain undefined tissue culture conditions cause the muscarinic acetylcholine receptor to be uncoupled from potassium ion channels, perhaps due to the failure of expression of ntracellular messenger. This may be similar to the loss of carbachol sensitivity in cultured chick ventricular heart cells reported by Siegel and Fischbach (Devel. Biol. 101:346, 1984).

ARACHIDONIC ACID INDUCES A POTASSIUM CURRENT IN ISOLATED GASTRIC SMOOTH MUSCLE CELLS. Richard W. Ordway*, John V. Walsh, Jr., and Joshua J. Singer. Dept. of Physiology, U. of Mass. Med. Sch., Worcester, MA 01655.

Responses to externally applied arachidonic acid (AA) were measured in isolated gastric smooth muscle cells from the toad, Bufo Marinus, using patch-clamp techniques. AA was dispersed directly into aqueous solutions and delivered by either pressure ejection from a pipette or bath superfusion.

In current clamp, AA (40 μM) caused a hyperpolarization associated with a large conductance increase. Under whole-cell voltage clamp, AA (5-40 μM) induced a current as large as several nA which reversed near the calculated E_K at three different external K^+ concentrations. This current showed some outward rectification but was clearly present at very negative potentials (-100 mV). Two K^+ channels (20-25 pS and 8-10 pS in 20 mM $[K^+]_{out}$, 130 mM $[K^+]_{in}$) appear to underlie the whole-cell current. Consistent with these findings, AA was found to block acetylcholine-induced contractions in the same cells.

Our initial results indicate that this AA response can be mimicked by fatty acids which do not enter eicosanoid pathways. Thus, the mechanism of action may differ from that for "S" K^+ channel activation in Aplysia neurons (Piomelli, et al., Nature 328:38, 1987). Supported by NSF grant DCB8511674 and NIH grant DK31620.

SUBSTANCES THAT AFFECT ARACHIDONIC ACID TURNOVER IN *APLYSIA CALIFORNICA* NERVOUS SYSTEM ALSO ALTER THE INWARDLY RECTIFYING POTASSIUM CURRENT OF GIANT NEURONS. R. Q. Carlson* and I. B. Levitan, Grad. Dept. of Biochem., Brandeis University, Waltham MA 02254.

Substances, known to affect arachidonic acid (AA) metabolism in *Aplysia* nervous system, have been found to alter the magnitude of an inwardly rectifying potassium conductance (I_R) in the homologous *Aplysia* giant neurons, R2 and LP1. I_R was studied in the giant neurons using two electrode voltage clamp. Inward rectification negative to the potassium equilibrium potential, and block by 500 μM $BaCl_2$, were used to identify I_R. The phorbol ester TPA decreased I_R about 50% at 500 nM, a concentration known to maximally stimulate AA turnover from lipid storage in *Aplysia* ganglia. Para-bromophenacyl bromide (BPB), an irreversible inactivator of phospholipase A_2, increased I_R several fold irreversibly. Indomethacin at saturating dose (250 μM) increased I_R about six fold. At 50 μM, indomethacin inhibited AA turnover in ganglia.

Serotonin (5HT) has previously been shown to increase I_R in several *Aplysia* neurons through stimulation of intracellular cAMP. A saturating dose of indomethacin did not interfere with the 5HT induced increase in I_R. Also, a saturating dose of 5HT (50 μM), or forskolin and IBMX at concentrations sufficient to mimic and occlude the effect of 5HT, did not block the response of I_R to indomethacin or BPB. We conclude, therefore, the effect of BPB or indomethacin is independent of the cAMP mediated increase in I_R.

We have previously observed constitutive turnover of AA from phospholipid storage in ganglia. We propose that this turnover provides a constant supply of AA responsible for inhibiting a majority of the I_R in giant neurons. Involvement of cAMP in this inhibition seems unlikely. However, the precise molecular mechanism of AA modulation of I_R remains to be determined.

SEROTONIN DIFFERENTIALLY MODULATES TWO K^+-CURRENTS IN THE LEECH RETZIUS CELL. A.L. Kleinhaus, C.L. Sahley & J. Acosta-Urquidi, Depts. Neurol.& Bio., Yale Univ. New Haven, CT.

Bath application of 5-HT results in an increase in the interspike interval of the serotonergic Retzius (R) cell (Leake, Comp.Gen.Physiol.83:1986). In other preparations 5-HT modulates several ionic conductances. Yet, little is known about neuromodulatory mechanisms in the leech.

Therefore, we examined the effects of 5-HT on the duration of the Ca^{2+}-dependent action potential in the leech R cell. We found that 5-HT (20-100 μM) reduced the duration by about 55%, n=10, $p<.01$, suggesting that the drug acted on the underlying ionic conductances.

Using standard two-electrode voltage-clamp methods, we separated individual outward currents as previously described (Johansen & Kleinhaus, J.Neurophys.56:1986). The results show that 10 min after exposure to 5-HT I_A increased, n=9, avg 108% +/- 37(SEM), $p<.001$. No simultaneous change in inactivation kinetics occurred, $p>.1$. In contrast, I_K decreased, n=10, avg 44% +/-6(SEM), $p<.01$. In 20% of the preparations leakage slope conductance decreased, avg 32% +/- 3(SEM), $p<.02$.

Since I_A may play a role in the control of firing frequency, the results provide a plausible explanation for the increase in interspike interval seen in the R cell following exposure to 5-HT. This modulation could be one of the self-regulatory mechanisms by which the R cell titrates the amount of transmitter it releases.

NORADRENALINE (NA) INHIBITS A TRANSIENT OUTWARD CURRENT IN RAT SUPRAOPTIC (SON) NEURONS. C.W. Bourque, McGill Univ. Centre for Research in Neuroscience, Montreal, Canada, H3G 1A4

Alpha-1 adrenergic agonists depolarize rat SON neurons. This study was undertaken to characterize the ionic basis of this excitatory action.

Membrane currents were measured from 47 SON neurons in hypothalamic explants using a single electrode voltage clamp. From a holding potential of -65 mV, bath application of NA (0.5-50 μM) induced a small (<0.1 nA) but reversible inward current. This current displayed a bell-shaped voltage-dependence with a peak near -65 mV and could not be detected above -55 or below -75 mV. From a holding potential near -100 mV, NA (0.05-50 μM) also caused a dose-dependent reduction of the transient outward current (TOC) triggered by depolarizing commands. As previously reported (Bourque, 1988; J. Physiol. 397) this current is blocked by 4-Aminopyridine (4-AP) and shows an overlap of its activation and inactivation curves between ca. -75 and -55 mV. Using either voltage-clamp protocol, addition of 2 mM 4-AP could mimic and occlude the actions of NA measured in the same cell. These results strongly suggest that the depolarizing action of NA is mediated by the reduction of a steady-state "window" current carried through TOC channels.

EFFECTS OF SOMATOSTATIN-14 AND SOMATOSTATIN-28 ON POTASSIUM CURRENTS IN RAT NEOCORTICAL NEURONS. H.L. Wang, C. Bogen*, T. Reisine, and M.A. Dichter. Depts. of Neurology and Pharmacology, Univ. of PA, and Graduate Hospital, Philadelphia, PA 19104.

Somatostatin-14 (SOM-14) is a 14-amino acid cyclic polypeptide which is found widely distributed throughout the central and peripheral nervous systems as well as in a variety of nonneuronal tissues. Originally isolated from hypothalamic extracts and found to inhibit secretion of growth hormone from pituitary cells, a more general role for SOM-14 as a neurotransmitter or neuromodulator has now been proposed.

Immunoreactive-SOM (IR-SOM) has been found to be particularly abundant in rat cerebral cortical neurons, both in whole brain sections and in dispersed cortical cell cultures. In addition, cultured cortical neurons secrete IR-SOM-like material into media and have high affinity surface membrane receptors for SOM.

In the present study, SOM-14 and SOM-28 (100nM) were applied to cultured rat neorcortical neurons (12-28 days in culture) with a pressure perfusion apparatus, and responses were examined using whole cell voltage clamp technique. Cells were bathed in physiologic HEPES buffered saline containing cobalt and TTX, and potassium currents were elicited by applying step depolarizations from a holding potential of -80 mV. 16 of 24 cells responded to SOM-14 perfusion with an increase in potassium currents, while 8 of 24 showed no response. Following perfusion with SOM-28, 14 of 17 cells had a decrease in potassium currents.

Complementary receptor binding assay on membranes of cultured neurons using [^{125}I]CGP 23996 demonstrated the presence of high affinity specific binding sites for SOM-14 (IC_{50} = 0.4 nM).

A PHOSPHATASE-RESISTANT ANALOG OF IP_3 ACTIVATES A POTASSIUM CONDUCTANCE IN RAT HIPPOCAMPAL PYRAMIDAL CELLS. Madeline McCarren, Barry V.L. Potter*†, and Richard J. Miller. Univ.of Chicago, Chicago, IL 60637 and †Leicester Univ., Leicester UK LE1 7RH.

Inositol (1,4,5) trisphosphate (IP_3) is believed to function as a Ca^{+2}-mobilizing second messenger in many cell types. However, the use of the naturally occurring form of IP_3 experimentally can produce ambiguous results since IP_3 may be degraded or converted to compounds with other actions. Therefore we used a phosphorothioate analog of IP_3 (DL-IPS_3), which is resistant to phosphatase degradation (BBRC 150:626-632, 1988), to investigate the actions of IP_3 in rat hippocampal pyramidal cells using standard electrophysiological techniques.

Cells impaled with electrodes containing 25-100mM IPS_3 required more current to fire action potentials than controls, although the action potential voltage threshold was unchanged. The current-voltage relationship showed strong delayed rectification in IPS_3 cells rather than the normal inward rectification. Moreover, even subthreshold depolarizations were followed by transient afterhyperpolarizations in IPS_3 cells. These effects were not due to turning off of an inward current, as they persisted in TTX or Ca^{+2}-free solutions. The IPS_3 response was also unaffected by a reduction in extracellular Cl^- but was reduced in elevated K^+ , suggesting involvement of a K^+ conductance.

K^+ CHANNELS EVOKED BY BRADYKININ AND INOSITOL-1,4,5-TRISPHOSPHATE IN NG108-15 NEURONAL CELLS. H. Higashida[1], K. Furuya[2] & D. A. Brown[3]. [1]Department of Biophysics, Kanazawa University, Kanazawa 920, Japan, [2]National Institute for Physiological Science, Okazaki 444, Japan & [3]Department of Pharmacology, University College London, London WC1E6BT, U. K.

Activation of phosphatidylinositide breakdown in neuroblastoma x glioma (NG108-15) hybrid cells by bradykinin (BK) results in the generation of an outward K^+ current through the release of Ca^{2+} by the intermediary messenger inositol-1,4,5-trisphosphate ($InsP_3$). Channels mediating this outward current were investigated using cell-attached patch electrodes. Intracellular iontophoretic injection of InsP3 or Ca^{2+} ions, or extracellular application of BK evoked bursts of K^+ channels coincident with cell hyperpolarization measured with an intracellular recording micropipette. The most frequent channels had a mean single channel conductance of about 38 pS in symmetrical K^+ solutions; additional openings of lower conductance (18 pS)channels were also detected. The opening probability of these channels was not clearly dependent on pipette potential. Bath application of phorbol dibutyrate (PDBu, 1 uM) increased the number and opening probability of the $InsP_3$-induced channels without changing unitary conductance. The effects of PDBu suggest a possible interaction of the two products of phospatidylinositide breakdown at the level of the Ca^{2+} -dependent K^+ -channel.

RELATIONSHIP BETWEEN CALCIUM LOAD AND THE DECAY RATE OF I_{AHP} IN BULLFROG GANGLION NEURONS. Peter S. Pennefather and Joanne W. Goh, Faculty of Pharmacy, University of Toronto, Toronto, Ontario, Canada M5S 2S2.

Action potential activity in bullfrog ganglion cells induces a Ca activated K current (I_{AHP}) whose decay reflects clearance of a Ca load from the intracellular vicinity of I_{AHP} channels. We have varied the calcium load by using 2 or 50 ms current clamp steps to evoke either single action potentials or bursts of 3-4 action potentials. Trains of bursts were generated by providing 50 ms rest periods between bursts. At the end of the last current-clamp command a single electrode voltage-clamp was engaged to measure I_{AHP} and its decay. Decay rate was constant over most of the time course of the current. In 70% of cells however, distortions due to K-accumulation were apparent at early times (< 80 ms). Accordingly, decay rate was estimated only after 80 ms had elapsed and the initial amplitude of the current was estimated by extrapolation. A single burst was sufficient to produce a near maximal current. In 0.5 mM Ca, the decay rate of I_{AHP} following a single burst was 5.8 ± 0.5/s . Following a train of 10 bursts, the decay rate was 1.6 ± 0.2/s. There was a linear relation between the log of the decay rate and the log of the number of bursts (r = 0.98, slope = -0.54). A similar relation was observed in 5 mM Ca (r = 0.99; slope = -0.59) but, a third fewer bursts were needed to produce an I_{AHP} with a given decay rate; the decay rate was 3.8 ± 0.3/s following a single burst and 0.92 ± 0.07/s following a train of 10 bursts. The rate of removal of the Ca load was estimated by measuring the decay rate of I_{AHP} evoked by a single action potential and determining the degree of reduction of this parameter as a function the time from the end of a given loading procedure. In 4 mM Ca, the recovery rate was 1.01/s following a single burst and 0.40/s following a train of 20 bursts. The mean decay rates of I_{AHP} associated with the two loading procedures were 2.90/s and 0.81/s, respectively. The difference between decay rates and recovery rates suggests cooperativity in activation of the K channels by Ca. The decrease in decay rate of I_{AHP} with increasing Ca loads may be due to the presence of a rapidly equilibrating, low affinity, high capacity Ca buffer that slows diffusion of Ca away from K channels. Local saturation of such a buffer would generate intracellular domains of high free Ca levels, centered on Ca channels, that shrink only slowly after Ca channels close. In this model, the decay of I_{AHP} would reflect the mutual disposition of the Ca and K channels. Quercetin, replacement of Na by Li and caffeine had only minor effects on decay rate of I_{AHP}.

INTRACELLULAR INJECTION OF CaM KINASE II REDUCES SPIKE AFTER-HYPERPOLARIZATION IN CULTURED SPINAL CORD NEURONS. S. Sombati, R.R. Forman, B.L. Attema*, K.A. Tennes-Rees*, W.C. Taft* and R.J. DeLorenzo. Dept. Neurology, Medical College of Virginia-VCU, Richmond VA 23298.

Calcium-calmodulin-dependent protein kinase (CaM kinase II) has been shown to modulate specific K^+ and Ca^{2+} currents in invertebrate neurons (Sakakibara, et al., Biophys. J. 50:319, 1986). To investigate a possible role of this kinase in vertebrate neurons, we have intracellularly injected purified CaM kinase II into spinal cord (SC) neurons cultured from embryonic rats. Each spike in a cultured SC neuron is followed by a large (5-10 mV) and prolonged (30-50 ms) after-hyperpolarization (AHP). Injection of CaM kinase II resulted in a reduction in both amplitude and duration of AHP, and sometimes spike broadening (n=11 cells). CaM kinase II effects on AHP were observed 4 min post-injection and peaked after 5-6 min. In some neurons AHP was totally abolished. Neither vehicle nor heat-inactivated CaM kinase II injection (n=8 cells) produced these effects. Preliminary studies suggest AHP is enhanced by injection of CaM kinase II monoclonal antibody that inhibits CaM kinase II activity in vitro and labels SC neurons immunocytochemically. This observation suggests a role for endogenous CaM kinase II in modulating AHP. Characterization of AHP indicates that it is due predominantly to Ca^{2+}-dependent K^+ conductances (Zhang & Krnjevic, Neurosci. Lett. 74:58, 1986). These results indicate that CaM kinase II regulates AHP in SC neurons and are consistent with the hypothesis that the effects of CaM kinase II on K^+ and/or Ca^{2+} currents may be responsible for the effects of this kinase on AHP.

TRANSFORMED 3T3 CELLS EXHIBIT A CALCIUM-ACTIVATED K CURRENT WHICH IS ABSENT IN NONTRANSFORMED CELLS. **S.G. Rane & L.F. Fleischman*. Dept. of Physiol., Tufts U. Med. Sch., Boston, MA 02111.**

Mitogenically stimulated or oncogenically transformed cells have been reported to have augmented trans-plasma membrane cation fluxes. Using the whole cell patch clamp technique we now report that Balb 3T3 fibroblasts, stably transformed with the viral Kirsten ras oncogene, exhibit a Ca-activated K current which is either absent or unavailable for activation in their nontransformed (normal) counterparts.

3T3 cells were grown to confluence (DMEM, 10% CS), dispersed with trypsin, triturated in medium, and allowed to settle out on plastic dishes. Recording solution was (in mM): 138 NaCl, 1 CaCl , 6 KCl, 1 MgCl , 10 HEPES, and pipette solution was 100 KCl, 50 NaCl, 10 HEPES, 5 MgATP, 0.1 BAPTA, making reversal potentials for K, Cl, and Na, -70, 0, and 25 mV respectively. Cells were held at -70 mV and stepped to 0 mV for 500 msec at 1 Hz. Currents were activated either by 300 nM A23187 or by 100 nM bradykinin (BR), a Ca mobilizing peptide, applied by pressure ejection from blunt-tipped pipettes.

86% (24/28) of *ras* transformed 3T3 fibroblasts responded to A23187 with outward current at 0 mV (mean amplitude = 0.6 ± 0.11 nA) and 92% (12/13) gave identical responses to BR (1.09 ± 0.12 nA); however, only 13% (4/30) of normal fibroblasts responded to A23187 and none (0/6) responded to BR. Peak outward currents in two of the normal cells were equivalent to those in transformed cells while responses in the other two cells were only 20 and 40 pA. Both cell types responded to A23187 and BR with a very slowly activating, persistent inward current at -70 mV. This current was blocked by 5 mM BAPTA internal, suggesting that it is activated by elevation of internal Ca. This result argues against the possibility that normal cells were not being sufficiently loaded with Ca to activate the outward current. The outward current response in the transformed cells was also eliminated with 5 mM BAPTA in the pipette solution. Using voltage ramps the outward current was shown to reverse at the K reversal potential and it was fairly linear from -80 to 20 mV. This result and insensitivity to TEA block suggests that it is not the large conductance Ca-activated K current described in many other tissues. Experiments are underway in which transforming *ras* protein will be added to the patch pipette solution in an attempt to enable outward current responses in normal 3T3 cells.

ACTION POTENTIAL CHARACTERISTICS OF SEGMENTALLY DEMYELINATED OPTIC TRACT (OT) AXONS FOLLOWING POTASSIUM CHANNEL BLOCKERS. D. A. Fox, D.-Y. Ruan and Y. Blocker*. U. of Houston, College of Optometry, Houston, TX 77004.

The role of potassium channel blocking agents in altering conduction properties of demyelinated PNS axons has been examined, however, similar studies have not been conducted in CNS axons. Our in vivo studies examined the frequency-dependent effects of vehicle (baseline), 4-AP and 4-AP + TEA on compound action potential (CAP) characteristics and excitability properties in fast (t1) and middle conducting (t2) OT axons in two different models of demyelination, segmental and paranodal (see following abstract), after optic chiasm stimulation. Segmental demyelination, produced by developmental and continuous lead exposure, was confirmed in 90 day old hooded rats using electron microscopy. In t1 and t2, lead decreases conduction velocity and amplitude (AMP), and increases rise (RT) and fall time, duration (DUR), and chronaxie. In t2, lead increases absolute and relative refractory periods (RRP), decreases frequency following (FF) and produces a subnormality. Compared to baseline, 4-AP effects are generally larger in t2 than in t1 (e.g., 4-AP decreases AMP and FF, and increases DUR, FT, and RRP). TEA effects are similar to those produced by 4-AP, however, as stimulus frequency increases they are larger in t1 than in t2. Large and medium diameter axons exhibit differential frequency-dependent sensitivity to 4-AP and TEA following segmental demyelination. Supported by ES 03183 (DAF).

438.16

ACTION POTENTIAL CHARACTERISTICS OF PARANODALLY DEMYELINATED OPTIC TRACT (OT) AXONS FOLLOWING POTASSIUM CHANNEL BLOCKERS. D.-Y. Ruan, D. A. Fox and Y. Blocker*. U. of Houston, College of Optometry, Houston, TX 77004.

The role of potassium channel blocking agents in altering conduction properties of demyelinated PNS axons has been examined, however, similar studies have not been conducted in CNS axons. Our in vivo studies examined the frequency-dependent effects of 4-AP and 4-AP + TEA on compound action potential (CAP) characteristics and excitability properties in fast (t1) and middle conducting (t2) OT axons in two different models of demyelination, paranodal and segmental (see preceding abstract), after optic chiasm stimulation. Paranodal demyelination, produced by 2,5-hexanedione (2,5-HD) exposure, was confirmed in 5-7 month old hooded rats using electron microscopy. 2,5-HD decreases conduction velocity, amplitude, rheobase and frequency following and increases rise and fall time, duration, chronaxie and absolute refractory period in t1 and t2. T2 axons have supernormality and a correlated decrease in relative refractory period. The 4-AP effects are almost identical to those observed in lead-exposed rats with segmental demyelination (see preceding abstract): 4-AP effects are generally larger in t2 than in t1. In contrast, TEA effects are only observed at low stimulus frequencies and generally only in t2. Paranodally and segmentally demyelinated large and medium diameter OT axons have similar sensitivity to 4-AP and completely different sensitivity to TEA. Supported by ES 03183 (DAF).

A DIFFUSION MODEL OF $I_{Na,cAMP}$. R.-C. Huang and R. Gillette. Dept. Physiol. & Biophys. and Neural & Behav. Biol. Prog., Univ. Illinois, Urbana, IL 61801.

The cAMP-activated Na^+ current ($I_{Na,cAMP}$) in molluscan neurons is independent of phosphorylation and diffusion-limited in its kinetics. These characters permit precise calculation of cAMP diffusion coefficient and phosphodiesterase (PDE) kinetic parameters.

Use of a diffusion-limited model permits precise modelling of the $I_{Na,cAMP}$ response to pulsed intracellular injection of cAMP, including effects of relocating the point source of cAMP within the neuron soma and bath addition of PDE inhibitors. The apparent diffusion coefficient of cAMP is estimated from the relation of latency to peak response and cell radius. PDE activity is extracted as a first-order rate constant from the exponential decay of $I_{Na,cAMP}$, while Michaelis-Menten parameters (K_m, V_{max}) are obtained by curve-fitting the $I_{Na,cAMP}$ response to an explicit finite difference equation.

Justification of a diffusion-limitation assumption is provided by counter-examples of other cAMP-stimulated currents with slower kinetics.

438.18

CO-REGULATION OF $I_{Na,cAMP}$ BY cAMP AND Ca^{2+}: A COMPETITIVE BINDING MECHANISM. R. Gillette and R.-C. Huang. Dept. Physiol. & Biophys., Neural & Behav. Biol. Prog., U. of Ill., Urbana IL 61801.

Intracellular Ca^{2+} and cAMP interact to co-regulate $I_{Na,cAMP}$ in pedal ganglion neurons of the mollusk Pleurobranchaea. Activity- and voltage-induced increase in $[Ca^{2+}]_i$ suppresses the $I_{Na,cAMP}$ response to injected cAMP and confers voltage-dependence. In contrast, high levels of cAMP reduce voltage dependence and antagonize Ca^{2+}-dependent suppression of the $I_{Na,cAMP}$ response by depolarization.

Ca^{2+}-activation of phosphodiesterase in suppression of $I_{Na,cAMP}$ is not confirmed by response kinetics and pharmacology. Instead, experimental data are best fit by a unifying model of antagonistic allosteric effects of Ca^{2+} and cAMP in regulating channel activity. Bound Ca^{2+} suppresses, while cAMP stimulates, ion current. Binding of one ligand antagonizes binding of the other.

Data indicate one-to-one binding of each ligand. A competitive binding mechanism explains apparent voltage-dependence of cAMP dissociation, the IV curve for $I_{Na,cAMP}$, and antagonism of Ca^{2+} suppression effects by high levels of intracellular cAMP. Experimental results and theoretical predictions agree well.

AXON VS. TERMINAL: ANALYSIS OF STIMULATION PARAMETERS EXCITING SINGLE DORSAL ROOT FIBERS. N.C. Tkacs and R.D. Wurster. Department of Physiology, Loyola University Medical Center, Maywood, IL 60153.

The present study was designed to characterize differences in electrical stimulation responsiveness between axons and axon terminals. The experimental model is the bullfrog hemicord, in vitro . Single dorsal root fibers are isolated and action potentials recorded in response to dorsal root (DR) and dorsal horn (DH) stimulation.

The results reported here are based on experiments in which responses were elicited from DR only (n=5), from DH only (n=6) and from both DH and DR (n=2). Chronaxies to DH stimulation were significantly longer (mean = 167.5 usec, S.D. = 28.2) than to DR stimulation (mean = 108.3 usec, S.D. = 19.2) ($p<.05$, unpaired t-test). When chronaxie measurements could be made at both sites on a single fiber, DH values were almost twice DR values (Fiber 1: DR - 85 usec, DH - 160 usec; Fiber 2: DR - 110 usec, DH - 200 usec). These data may indicate a region of decreased safety factor for conduction as an action potential proceeds down an axon to the terminal region.

Further studies will use this model to evaluate the sensitivity of these two stimulation sites to agents blocking calcium and potassium channels.

439.2

SMALLER MEPP AMPLITUDE IN THE DISTAL VERSUS PROXIMAL REGION OF THE FROG NMJ USING SIMULTANEOUS INTRA AND EXTRACELLULAR RECORDING. L.P. Fortier* and J.P. Tremblay. (Spon.: L. Larochelle) Lab. of Neurobiology, Laval University, Quebec, Canada, G1J 1Z4

The present experiments were undertaken to confirm our previous observations that the MEPP amplitudes were smaller in the distal region of the frog neuromuscular junction (NMJ) than in the proximal region (near the point of contact between the axon and the muscle fiber). These results were obtained with the Spatial Decay Method using simultaneous intracellular recording with 2 electrodes (Tremblay et al. Brain Res. 328, 170, 1985). It was attributed to the presence of smaller postjunctional folds (PJFs) (Robitaille et al., Soc. Neurosci. Abstr., Vol. 13 Part 1, p. 317) and/or smaller active zones in the distal regions. To further investigate this finding, intracellular recordings were made in presence of 6-9 μM neostigmine with an electrode placed halfway between the distal end and the proximal region. During the intracellular recording period, an extracellular electrode was placed alternatively at a distal and at a proximal site. The temporal correspondence between the extracellular and intracellular signals permitted us to identify two MEPP populations originating from the distal and proximal regions. In the majority of these experiments we observed that the intracellularly recorded MEPPs originating from the distal region were significantly smaller than those produced in the proximal region of the same NMJ. This confirms Tremblay et al. observations using the Spatial Decay Method. A significant correlation was observed between the amplitude (in μV) and the area (in μV. ms) of the extracellularly recorded MEPP. In addition, for a given extracellular MEPP amplitude the area under the curve tends to be smaller for the signals coming from the distal regions. In the presence of anticholinesterase, the ACh could have rebound to multiple sites along the PJFs. Thus our observations suggest that ACh would rebind fewer times to ACh receptors in the distal region caracterized by shorter PJFs.

439.3

DIFFERENT CA^{++} SENSITIVITY OF SPONTANEOUS RELEASE ALONG THE FROG NEUROMUSCULAR JUNCTION. J.P. Tremblay and R. Robitaille. (Spon.: Radouco-Thomas, S.) Lab. of Neurobiology, Laval University, Quebec, Canada, G1J 1Z4.

Spontaneous transmitter release has been recently characterized along the frog neuromuscular junction (NMJ). Miniature endplate potentials (MEPPs) occur more frequently and are larger in proximal regions (near axon termination on muscle fibre) than in distal ones. The present experiments were done to investigate the possible roles or implications of Ca^{++} in these nonuniformity of spontaneous release. A new method (microperfusion technique) has been elaborated to apply a Ca^{++} solution at a limited portion of the nerve terminal (30 μm) and thus allowed us to study the effect of Ca^{++} on different regions of the nerve terminal. Experiments were performed on the frog cutaneous pectoris muscle placed in a 0mM Ca^{++} - 5mM Mg^{++} Ringer solution. NMJs were localized with a microscope equipped with Nomarski optics and MEPPs were recorded intracellularly. The intracellular electrode was placed at equal distance between the two regions to be microperfused with a Ca^{++} stream. This implicates that the spatial attenuation of MEPP amplitude towards the electrode is about the same and thus allows us to compare the amplitude of MEPPs produced in both regions. Another electrode (tip of 10 μm) filled with a solution of 5mM Ca^{++} and 40 mg/ml of Dextran Blue was used for the application of Ca^{++} in parallel with a high rate of bath perfusion which allows a restricted application. Several controls were performed to insure that the stain had no effects on the preparation and that the spread of the stained solution corresponds to the presence of Ca^{++}. The application of 5 mM Ca^{++} induced a larger increase of MEPP frequency which proceeds more rapidly in proximal regions than in distal ones. Moreover, MEPPs produced by the proximal regions are proportionally larger than those produced by the distal region. This confirms our previous observations using two intracellular electrodes. The present results indicate that nonuniformity of transmitter release can be related to Ca^{++}- dependant mechanisms. (Supported by MRC grant to JPT and MRC studentship to R.R.).

439.4

NONUNIFORM TRANSMITTER RELEASE EFFICACY ALONG THE FROG NEUROMUSCULAR JUNCTION R. Robitaille, and J.P. Tremblay. Lab. of Neurobiology, Laval University, Quebec, Canada, G1J 1Z4

The efficacy of the release sites has been reported to be different along the frog neuromuscular junction (NMJ). Endplate potentials (EPPs) are produced more frequently by the proximal regions than by the distal ones in conditions of reduced transmitter release probability (low extracellular Ca^{++}). Experiments discussed here deal with the efficacy of proximal and distal regions of the NMJ to evoked release in higher Ca^{++} concentrations using the microperfusion technique (see preceding abstract). Experiments were performed on the cutaneous pectoris nerve-muscle preparation placed in a 0mM Ca^{++} - 5mM Mg^{++} Ringer solution. EPPs were recorded intracellularly between the regions to be microperfused by the Ca^{++} solution. The Ca^{++} solution containing 2 mM Ca^{++} and 40 mg/ml of Blue Dextran was applied successively at the proximal and distal regions from a focal electrode (tip of 10 μm). During the microperfusion of Ca^{++}, pulse pairs (interval of 15 msec) were applied every two seconds by stimulating the nerve with a suction electrode. EPPs were subthreshold since only a reduced number of release sites participated in evoked release due to the restricted application of Ca^{++}. Quantal content was evaluated by dividing the mean amplitude of the first evoked response by the mean MEPP amplitude. EPPs evoked by the proximal regions had a larger quantal content (4.6 to 14.25, mean 8.94) than the distal regions (1.6 to 8.3, mean 5.07). In two occasions, it was impossible to evoke transmitter release in the distal region whereas the proximal regions evoked fairly large EPPs. Furthermore, failures to evoked release are less frequent in proximal regions (8%) in comparison to the distal ones (28%). The difference between EPP_2 and EPP_1 was significantly larger in proximal then in distal regions however the facilitation ($F=(EPP_2-EPP_1)/EPP_1$) was not different. All these results indicate that the proximal region of the frog NMJ is stronger and more efficient than the distal region. Supported by MRC grant (JPT) and MRC studentship (R.R.).

THE ABSENCE OF DETECTABLE NON-QUANTAL ACH RELEASE FROM ACTIVE ZONE REGIONS OF FROG NERVE TERMINALS. S.D. Meriney, S.H. Young, C.B. Gundersen, and A.D. Grinnell. Jerry Lewis Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024.

Non-quantal release of acetylcholine (ACh) from motor nerve terminals has been assumed to occur from active zone regions. However, the localization of this leakage has not been directly determined. We have used an outside-out patch of muscle membrane as a sensitive detector of ACh released from localized regions of enzymatically detached frog nerve terminals. Quantal events (EPCs and MEPCs) could be localized to 3-5 releasing sites at any one patch electrode position along the terminal. Using this method, we were unable to detect significant transmitter leakage from active zone regions of the nerve terminal. Biochemical measurements of ACh leakage did not reveal any significant difference between enzyme treated and control preparations. These results suggest that ACh leakage at adult frog terminals either is localized to a source other than the active zone region of the terminal, or is released diffusely from many sources, which may include the nerve terminal.

INHIBITORS OF VESICULAR ACETYLCHOLINE TRANSPORT AT MOUSE AND FROG NEUROMUSCULAR JUNCTIONS. S.P. Yu* and W. Van der Kloot. Dept. of Physiology & Biophysics, SUNY, Stony Brook, NY 11794.

Pretreatment in hypertonic solution increases MEPP, MEPC and uni-quantal EPP sizes roughly twofold. Responses to iontophoretic or bath applied ACh were unchanged by the pretreatment. The increases in quantal size were prevented by adding to the hypertonic solution inhibitors of active ACh transport into synaptic vesicles, like 1 μM AH5183. The inhibitors have little, short term effect on MEPP or MEPC size in untreated preparations. However, after hypertonic pretreatment, the inhibitors promptly decreased the size of mouse MEPPs and MEPCs about 50 %.

In the frog, the inhibitors had little effect except when the hypertonic solution was made with Na gluconate (replacing NaCl). Then MEPP and MEPC sizes increased about fourfold, and the inhibitors promptly decreased size about 50%. Apparently, these pretreatments add to the quantal release process a second component , which can be quickly blocked by the inhibitors. In the frog, this second component of release was also reduced by raising $[K^+]_{out}$, so it is questionable whether the additional release is by exocytosis.

UNIFYING THEORY FOR THE BASIS OF THE DIFFERENT CLASSES OF QUANTA FOUND IN THE NEUROMUSCULAR JUNCTION BASED ON SUB-UNITS. M.E. Kriebel, J. Vautrin and F. Llados. Dept. of Physiology, SUNY Health Science Ctr., Syracuse, NY 13210

There are three quantal classes normally found in the frog and mouse neuro-muscular junctions based on amplitude and different pharmacological effects. Amplitudes show bell and skew classes separated by a discontinuity in the distribution. Giant MEPPs form a skew distribution and are increased with various treatments. Day-old mice, re-innervated junctions, BTX, β-bungarotoxin poisoned junctions and those induced to release large numbers of MEPPs show mainly skew-MEPPs. Nerve stimulation releases bell-MEPP sized quanta. Integral peaks in the amplitude distributions show that both classes are composed of sub-units (sub-MEPP size) (Kriebel et al., 1982, J. Physiol.; Erxleben and Kriebel, 1988, J. Physiol.). We report slowly rising MEPPs of all 3 classes which are potentiated after high rates of release following heat, hypertonic saline and 4-amino-quinoline. Many MEPPs start with a sub-MEPP and have offsets on the rising phase. We propose that there is a counting and timing mechanism for the release of sub-units. Bell-MEPPs would be composed of 7-10 sub-units synchronously released whereas skew-MEPPs are composed of sub-units fitting a Poisson distribution. Giant MEPPs would represent two or more bell-MEPPs. Slow and irregular MEPPs of all classes result from a disruption in the sub-unit synchronization mechanism. N.S.F. 19694.

EVIDENCE FOR QUANTAL TRANSMITTER RELEASE AT A CNIDARIAN SYNAPSE. P.A.V. Anderson. Whitney Lab. and Depts. of Physiology and Neuroscience, Univ. of Florida, St. Augustine, Fl 32086.

Chemical synapses in cnidarians contain a few, large, heterogeneous, membrane-bound structures collectively termed synaptic vesicles. Given this heterogeneity of vesicle size and shape, various modes of transmitter release ranging from non-vesicular to quantal could be envisaged. Synapses in the motor nerve net of the jellyfish Cyanea were examined using patch pipettes for simultaneous intracellular recordings from the pre- and post-synaptic cells. Only cells forming a single, discrete, en passant synapse were used. Action potentials were generated (1Hz) in the pre-synaptic cell by current injection, and the EPSC recorded under voltage clamp from the post-synaptic terminal. EPSC amplitude was reduced with a high Mg^{++}, low Ca^{++} saline. EPSCs occurred in discrete, approximately 10pA size-classes. The run-down of quantal size (m) during the course of the recordings, made statistical analyses impossible, but the fact that EPSCs occurred in discrete amplitude steps strongly suggests that transmitter release at these synapses is quantal. (Supported by NSF Grant BNS 85-06193.)

BACLOFEN DECREASES SYNAPTIC INHIBITION IN CULTURED HIPPOCAMPAL NEURONS BY A PRESYNAPTIC MECHANISM THAT IS INSENSITIVE TO PERTUSSIS TOXIN

Neil L. Harrison (SPON: L.R. Skirboll).
Laboratory of Neurophysiology, NINCDS, NIH, Bethesda, MD 20892.

I have studied the actions of (-)baclofen at inhibitory synapses between rat hippocampal neurons in culture. Simultaneous whole-cell patch recordings were made from pre- and post-synaptic neurons, using an intracellular solution based on 145mM K gluconate. Individual bicuculline-sensitive IPSPs were elicited by a single electrically evoked presynaptic action potential. (-)Baclofen (1-20μM) decreased the amplitude of evoked IPSPs; under voltage-clamp at -40mV, the outward-going evoked synaptic currents (IPSCs) were reduced as expected by (-)baclofen (IC_{50}~5μM); (+)baclofen was inactive. IPSCs were reduced at all potentials by (-)baclofen, without change in E_{IPSC}. (-)Baclofen did not reduce Cl^- current responses of postsynaptic neurons to GABA, nor did it increase somatic membrane conductance. The presumed presynaptic action of (-)baclofen was not significantly antagonized by phaclofen (0.2-0.5mM); nor was it prevented by pre-incubation of the tissue with pertussis toxin (0.1-1μg/ml, 12-24h., 34-37^{o}C). I conclude that the reduction of inhibition by (-)baclofen results from its action at a presynaptic $GABA_B$ 'autoreceptor' on the terminals of GABAergic inhibitory neurons. The mechanisms by which (-)baclofen reduces GABA release appear to differ from those mediating reduction of Ca^{2+} currents in sensory neurons (Holz et al., *Nature*, 319, 670-672, 1986) and activation of K^+ conductance in adult rat neurons (Andrade et al., *Science*, 234, 1261-1265, 1986), both pertussis toxin-sensitive processes.

AN INTRACELLULAR STUDY OF PRIMARY AFFERENT DEPOLARIZATION IN THE ISOLATED BULLFROG SPINAL CORD. Y. Peng and E. Frank Depts. of Physiology and Neurobiology, Anatamy and Cell Science, Univ.of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

The neural transmitter GABA has been shown to cause primary afferent depolarization (PAD). Recently, we have shown that activation of presynaptic $GABA_A$ as well as $GABA_B$ receptors causes presynaptic inhibition of synaptic transmission between muscle spindle afferents and spinal motoneurons in the isolated bullfrog spinal cord. To demonstrate that $GABA_A$ receptors also mediate PAD, we studied the pharmocology of synaptic potentials evoked by single electrical stimuli to individual brachial nerves recorded intracellularly in primary afferent axons in the dorsal horn in 0-Mg^{+2} Ringer solution.

68 brachial muscle spindle and cutaneous afferent axons were studied. In 88.5% of the cases, a single superthreshold stimulus to a peripheral nerve evoked PAD with an amplitude $\geq$ 50 μV. The rarity of PAD evoked by a single stimulus to a peripheral nerve in the cat reported by others might have been due to the presence of Mg^{+2} ions in the extracellular milieu. 20% of the 348 examples of PAD had a monosynaptic component that could not be accounted for by extracellular field potentials. Thus, some sensory afferents have direct synaptic connections with each other. Bicuculline (50 μM), a specific competitive antagonist of $GABA_A$ receptors, inhibited PAD by 54% showing directly that a major cause of PAD is activation of presynaptic $GABA_A$ receptors. This work was supported by NS86373 to E. F.

GABA INDUCED SPATIAL CHANGES OF CALCIUM INFLUX INTO NERVE TERMINALS D.W. Tank and K. Delaney* Research Dept. Molecular Biophysics AT&T Bell Laboratories Murray Hill, NJ 07974 and Dept. Physiol.-Anat., U.C. Berkeley, Berkeley, CA 94720.

Presynaptic inhibition of excitatory transmission at crayfish opener muscle synapses is mediated by gamma amino butyric acid (GABA). We have used fluorescence imaging to measure the effect of GABA on the spatial distribution of calcium influx in excitor nerve terminals during short stimulus trains (15s, 8-10 Hz). Excitor nerve terminals were filled with fura-2 by iontophoretic injection into the axon (15-20 nA, 30-60 min.). Calcium influx into terminals located on proximal and distal sections of a nerve branch was measured while recording the excitatory junction potential (EJP) in a muscle fiber. EJP's result from the summed activity of these spatially distributed terminals. Perfusion with 100-200 μM GABA reduced the EJP in a fiber near the imaged terminal by 85-100%. During this block terminals showed no increase in calcium but secondary and tertiary branches still showed near normal increases. Extracellular stimulating current required to initiate an action potential rose 20-30%. Lower GABA concentrations (10-50 μM) reduced EJP amplitudes by 40-60%. Terminals located distal to the main or secondary axons, or on the ends of fine branches, still showed no calcium increase during stimulation. However, terminals located near the main axon or on thick branches now showed normal increases in calcium. These data suggest that failure of the action potential to invade distal portions of the axonal arbor contributes significantly to the reduction of EJP amplitude by GABA. Our methods can be easily extended to examine the spatial distribution of calcium influx in the excitor axon during normal presynatic inhibition mediated by the inhibitor axon. Supported by NIH Grant NS 15114 and AT&T Bell Labs.

IDENTIFICATION OF THREONINE-286 AS THE AUTOPHOSPHORYLATION SITE IN THE α-SUBUNIT OF CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CaM K II) RESPONSIBLE FOR THE GENERATION OF CALCIUM-INDEPENDENT ACTIVITY.

G.Thiel*, A.J. Czernik*, F. Gorelick*, A.C. Nairn and P. Greengard, Lab. of Molecular and Cellular Neuroscience, The Rockefeller Univ., New York, NY 10021.

Autophosphorylation of CaM K II converts the enzyme to a calcium-independent form. The time course for conversion correlates with the autophosphorylation of a threonine residue contained within a thermolytic phosphopeptide common to both subunits (Lai et al.,PNAS,84:5710,1987). We have directly identified this site in the α-subunit of CaM K II by sequencing ^{32}P-labeled phosphopeptides derived from cleavage of the α-subunit. After autophosphorylation for 10 sec at 0°C to produce near-maximal calcium-independent activity, the α- and β-subunits were separated by SDS-PAGE. 600 μg of α-subunit protein was cleaved with CNBr for 72 hr and the fragments separated by C-18 HPLC using gradients ofCH_3CN in 0.1% TFA. A phosphopeptide (CB-1), containing 60% of the recovered radioactivity eluted at ~30% CH_3CN. CB-1 was further purified by C-4 and C-18 HPLC with shallow gradients in the same solvent system. Phosphoamino acid analysis of CB-1 revealed only ^{32}P-phosphothreonine. Using 20 pmol of CB-1, a sequence XRQETVDXLKKFNARRKL was obtained, which represents the N-terminal 18 residues of a 26-amino acid CNBr peptide predicted from the cDNA clone of the α-subunit and contains a consensus sequence for CaM K II phosphorylation which includes Thr-286. Two peptides (CB/C-1 and CB/C-2) derived from chymotryptic digestion of CB-1 were purified by C-18 HPLC. The sequences obtained for CB/C-1 and CB/C-2, XRQ(E/A)XVDXL and XXQETVD, respectively, confirmed that Thr-286 was the phosphorylated residue.

Dopamine receptor control of 3H-dopamine and 14C-acetylcholine release: Effects of phorbol ester and forskolin. Timothy W. Lovenberg*, Pamela A. Diliberto* and Luigi X. Cubeddu. Clin. Pharm., UNC, Chapel Hill, NC 27514

The Ca^{++}-dependent release of dopamine (DA) and acetyl choline (ACH) from the striatum is modulated by DA D2-receptors. However, the mechanism of this release inhibition is unknown. We have studied 3H-DA and 14C-ACh release from superfused rabbit striatal slices in the presence of phorbol-12,13-dibutyrate (PDBu) and forskolin (FSK) to determine if protein kinase C (PKC) and cAMP may play a role in the control of neurotransmitter release. PDBu enhanced the electrically stimulated, but not basal, release of 3H-DA in a concentration-dependent manner (EC50=10nM). 14C-ACh release was unaffected. In the presence of PDBu, DA D2 receptor agonists were less potent and less effective at inhibiting 3H-DA and 14C-ACh release. Also, the DA D2-receptor antagonist sulpiride was less effective at enhancing stimulated 3H-DA and 14C-ACh release. FSK also enhanced stimulated, but not basal release of 3H-DA (EC50=100nM). 14C-ACh release was unaffected. FSK did not alter the inhibition of 3H-DA and 14C-ACh release produced by D2-agonists.

These results suggest that, a) activation of adenylate cyclase and PKC may facilitate DA release and b) D2-receptor modulation of DA and ACh release may be regulated by PKC function.

439.14

INCOMPLETE AUTOPHOSPHORYLATION OF CALMODULIN-STIMULATED PROTEIN KINASE II (CMK II) IN INTACT SYNAPTOSOMES. A.Côté*, S.M. Harrison* and P.R. Dunkley*. (SPON: R. Lasher). The Neuroscience Group, Univ. of Newcastle, NSW, 2308 Australia.

When lysed synaptosomes are incubated with [γ-^{32}P]ATP the subunits of CMK II are major phosphoproteins, however when intact synaptosomes are incubated with $^{32}P_i$ very little autophosphorylation of these subunits occurs. Solubilized CMK II is susceptible to heat inactivation. However following a 45 min. incubation at 37°C and subsequent lysis and [γ-^{32}P]ATP labelling, minimal change of synaptosomal CMK II autophosphorylation and total CMK activity assayed using an exogenous substrate was observed. These results suggest that the intracellular environment of the synaptosomes is substantially different to the conditions used in in vitro assays. We have therefore examined the effects of different buffers and observed no significant change in the autophosphorylation of CMK II or exogenous peptide labelling when either Krebs or sucrose buffers were used, relative to low ionic strength Tris buffer. However, a small (20-30%) decrease in autophosphorylation was found in the presence of K^+ glutamate buffer. Thus, the lack of phosphorylation of intrasynaptosomal CMK II is not due to thermal inactivation and is only minimally contributed to by the intracellular ionic environment. (A. Côté is supported by the FRSQ of Quebec, Canada).

IN SITU PHOSPHORYLATION OF TYROSINE HYDROXYLASE IN RAT STRIATAL SYNAPTOSOMES, BOVINE ADRENAL CHROMAFFIN CELLS, AND PC12 CELLS: DIFFERENCES IN PHOSPHOPEPTIDES. J.W. Haycock, M. Calalb* and D. Morgan*. Dept. Biochemistry and Molecular Biology, Louisiana State University Medical Center, New Orleans, LA 70119.

Incubation of catecholaminergic tissues with $^{32}PO_4$ leads to the incorporation of ^{32}P into tyrosine hydroxylase (TH), the rate-limiting and initial step in catecholamine biosynthesis. Depolarization produces a calcium-dependent increase in the phosphorylation of TH at a number of sites; and, a number of protein kinase systems are potentially involved in mediating this effect.

In the present studies we compared the HPLC elution profiles of tryptic TH phosphopeptides from three tissues after prelabeling with $^{32}PO_4$ and treatment with a depolarizing stimulus (elevated $[K^+]_o$). Limit tryptic digestion of TH from each of the three tissues produced multiple TH phosphopeptides. Elevated K^+ increased ^{32}P incorporation into more than one peptide in each of the tissues. The retention of these phosphopeptides on a C_{18} column, developed with an acetonitrile gradient in 0.1% trifluoroacetic acid, was similar for the phosphopeptides from rat synaptosomes and PC12 cells. Only one of the TH phosphopeptides from bovine chromaffin cells eluted at a retention time which approximated that for any of the phosphopeptides from rat TH. Mixing of solubilized rat and bovine tissue, prior to immunoprecipitation, failed to reveal an identity of any of the bovine and rat TH phosphopeptides. The amino acid sequences of some of the tryptic peptides, as inferred from previously published cDNA sequences, differ at only one amino acid (gln vs leu; glu vs gln). The possibility that either genetic differences or tissue-specific, post-translational modifications may account for the observed differences in retention times is currently being investigated.

PHOSPHORYLATION OF TYROSINE HYDROXYLASE IN RAT CORPUS STRIATUM *IN VIVO*: EFFECTS OF MEDIAL FOREBRAIN BUNDLE STIMULATION. Dean A. Haycock and John W. Haycock. Sterling Winthrop Res. Inst., Rensselaer, NY 12144 and Dept. Biochem. Molec. Biol., Louisiana State Univ. Med. Center, New Orleans, LA 70119

Tyrosine hydroxylase (TH), the rate-limiting enzyme in catecholamine biosynthesis, has been shown to be phosphorylated in a variety of preparations both *in vitro* and *in situ*. One essential criterion for determining the physiological significance of such findings is whether TH is phosphorylated *in vivo*. By infusing $^{32}PO_4$ (2 mCi, 5 ul, 60 min) and rapidly fixing the striata by liquid nitrogen injection (Neurosci. Abstr. (1986) 12:737), we have measured ^{32}P incorporation into TH *in vivo*. ^{32}P-TH, after immunoprecipitation and SDS-PAGE, showed no evidence of proteolysis. The TH bands were subjected to limit tryptic digestion, and the resulting phosphopeptides were separated by HPLC and analyzed with on-line radiochemical detection.

Tryptic digestion of TH labeled *in vivo* produced multiple phosphopeptides. The elution profile of these phosphopeptides was similar to that previously described for TH that was labeled *in situ* in striatal synaptosomes (Brain Res. Bull. (1987) 19:619). Electrical stimulation (biphasic square wave, 200 uA, 3 ms duration, 30 Hz, 20 min) of the medial forebrain bundle produced a change in the ratio of ^{32}P incorporation into two of the four major phosphopeptides. This change in the pattern of ^{32}P incorporation into TH phosphopeptides was different from that previously reported for TH in striatal synaptosomes depolarized with elevated $[K^+]_o$.

Thus, although similar TH phosphopeptides are observed both *in vivo* and *in situ*, the regulation of TH phosphorylation by electrical stimulation of the nigro-striatal pathway *in vivo* may differ from that produced *in situ*.

CHARACTERISTICS OF THE SPINAL CORD $5HT_{1B}$ AUTORECEPTOR DEFINED BY 5HT RELEASE INHIBITION AND [^{125}I]-IODOCYANOPINDOLOL BINDING. David J. Jones and Michelle Combs, Depts. Anesth. and Pharm., UTHSC, San Antonio, TX 78284.

Several groups have provided evidence that the 5HT autoreceptor is of the $5HT_{1B}$ type. Recent studies have used [^{125}I] - iodcyanopindolol ([^{125}I]-CYP) to label the $5HT_{1B}$ receptor in various areas of the CNS. The purpose of the present work was to pharmacologically characterize both the autoreceptor linked to 5HT release regulation and that defined by [^{125}I] - CYP binding in the spinal cord.

Synaptosomes labeled with [^{3}H]-5HT were superfused with control buffer or buffer containing 15 mM K^+ to stimulate release. [^{125}I]-CYP binding was carried out in the presence of 30 uM isoproterenol to occlude beta receptors and 100 nM 8-OH DPAT to occlude $5HT_{1A}$ receptors. Specific binding was defined in the presence of 10 uM 5HT and was 60-80% of total binding.

The rank order of potency of 5HT agonists for the inhibition of K^+ stimulated [^{3}H]-5HT release was CGS 120668 > 5HT > RU 24969 > quipazine = 2mPP > mCPP > TFMPP. The rank order of potency for displacement of specific [^{125}I]-CYP was CGS 120668 = 5HT > RU 24969 > 2 mPP > TFMPP > mCPP = quipazine. 8-OHDPAT (< 10 uM) was inactive in both systems. Based on this similar ranking, [^{125}I]-CYP binding may predict for the functional component of the $5HT_{1B}$ site in spinal cord. Supported by NIH grant NINCDS 14546.

DIFFERENTIAL EFFECTS OF d-MEDETOMIDINE ON ^{3}H-DOPAMINE RELEASE FROM RAT STRIATAL AND ACCUMBENS SYNAPTOSOMES. J.G. Csernansky, E.C.Petrie*, D. Blanchard*, D. Ott*, and R. Lammintausta*. Schizophrenia Biologic Research Center, Palo Alto VA Medical Center and Dept. of Psychiatry & Behav. Sci., Stanford Univ., Stanford, CA 94305.

DA neurons in the neostriatum (NS) possess inhibitory presynaptic receptors (heteroreceptors) stimulated by other neurotransmitters. Clonidine has been shown to inhibit potassium (K^+) stimulated ^{3}H-DA release from rat nucleus accumbens (NA) slices, suggesting the presence of alpha-2 heteroreceptors in that region as well. We assessed the effects of the alpha-2 agonist d-medetomidine on K^+ stimulated ^{3}H-DA release from rat NA and NS synaptosomes in a continuous superfusion system. In NA, control release of the total was 18.6±1.1% (mean ±SEM) of ^{3}H-DA initially present in the synaptosomes. Unlabelled DA (1.8uM) reduced release to 13.1 ± 1.4% (t=3.1, p=0.01 vs. control) consistent with an action on autoreceptors. Similarly, d-Medetomidine (1.0uM) reduced ^{3}H-DA release to 13.6±1.0% (t=3.1, p=0.013 vs. control), an effect comparable in magnitude to that produced by DA. In NS, control release of ^{3}H-DA was 25.7±0.6% and unlabelled DA (1.8uM) reduced release to 16.8±0.5% (t=11.02, p<.001 vs. control). d-Medetomidine (1.0uM) had little effect on ^{3}H-DA release in the NS, with a mean ± SEM of 25.1±0.8%, not significantly different from the control value. Our data suggest that alpha-2 heteroreceptors are present on only a subset of central DA nerve terminals and imply that it may be possible to selectively modify central DA activity with alpha-2 agonists and antagonists.

FACILITATORY AND INHIBITORY TRANSMITTERS MODULATE SPONTANEOUS RELEASE AT CULTURED APLYSIA SENSORIMOTOR SYNAPSES. N. Dale* and E.R. Kandel (SPON: C.A. Kaufmann). HHMI, Columbia CPS, New York, NY 10032

Two independent presynaptic mechanisms, one involving modulation of ionic currents and the other an increase in the availability of transmitter for release, contribute to heterosynaptic facilitation at the sensorimotor synapses of Aplysia. To study the second of these mechanisms, we observed the spontaneous miniature epsps at synapses formed between single sensory and motor cells in vitro. 1-10 uM 5-HT reversibly increased the frequency of spontaneous release 4-5 times while the inhibitory peptide FMRFa (100 nM) reversibly reduced the frequency of spontaneous release to near control values when applied simultaneously with the 5-HT. A major component of the modulation of spontaneous release does not depend on either a Ca influx or changes in the concentration of internal Ca. In salines lacking Ca or containing 1 mM Cd to block Ca currents, 5-HT still enhanced the rate of release by 3-4 times, and FMRFa when applied simultaneously reduced the rate to near control values. When BAPTA was injected into the sensory neuron to buffer the internal Ca concentration, 5-HT and FMRFa could still modulate spontaneous release. The rate of spontaneous release, and consequently the transmitter available for evoked release during presynaptic inhibition and presynaptic facilitation, can therefore be modulated by 5-HT and FMRFa directly by a mechanism which is independent of changes in internal Ca.

IMMUNOAFFINITY ISOLATION OF HIPPOCAMPAL NERVE TERMINALS BEARING [^{3}H]NICOTINE RECEPTORS. J.Irons*, G.G.Lunt, S. Wonnacott, P.Whiting† & J.M.Lindstrom†. Dept.Biochem., Univ.Bath, BATH, BA2 7AY U.K. & †Salk Inst., P.O.Box 85800, San Diego, CA92138 U.S.A.

Nicotine stimulates the release of [^{3}H]GABA and [^{3}H]ACh from hippocampal synaptosomes.The presynaptic nicotinic acetylcholine receptor (nAChR) mediating this action has a pharmacological specificity similar to that of the high affinity binding sites for [^{3}H]nicotine in brain membranes.Using monoclonal antibodies (mAbs) 270 and 290 which are specific for these nAChR, we have immunoaffinity isolated synaptosomes bearing surface [^{3}H]nicotine receptors.Synaptosomes, highly purified from rat hippocampus by isotonic Percoll density gradient centrifugation, were enriched in [^{3}H]nicotine binding sites and high affinity transport of [^{3}H]GABA and [^{3}H] choline.Synpatosomes were incubated with mAbs 270 and 290 coupled to Dynabeads M-450 (Dynal) and bound synaptosomes were separated magnetically.Up to 25% of the total nerve terminal population could be immunoisolated, as judged by measurement of lactate dehydrogenase.A differential purification of cholinergic and GABAergic terminals, assessed by CAT and GAD activities, respectively, was observed. These results suggest that nAChR are present on 25% of rat hippocampal nerve terminals, including cholinergic and GABAergic terminals, consistent with the presynaptic modulation of transmitter release by these nAChR. TRANSDUCTION OF THE MODULATORY EFFECT OF NOREPINEPHRINE ON TRANSMITTER RELEASE AT MOTOR NERVE TERMINALS. H. Chen,* W.F. Dryden and Y.N. Singh* Dept. of Pharmacol., Univ. of Alberta, Edmonton, Alberta, Canada, T6G 2H7.

There is general agreement that the enhancement of neurotransmitter release from motor nerve terminals by norepinephrine (NE) is mediated by α_1-adrenoceptors (Chen and Dryden, Neurosci. Abst. 13:68, 1987). However Miyamoto and Breckenridge (J. Gen. Physiol. 63:609, 1974) suggested that the response involved a cyclic-AMP link and this conflicted with existing concepts of transduction at the α_1-adrenoceptor. The present study was undertaken to identify the transduction mechanism involved at this site. MEPP frequency was measured at 20°C in mouse hemidiaphragms exposed to 15mM$[K^+]_0$. The enhanced release of quanta caused by 1μM NE was reduced by nonspecific kinase inhibitors (50μM clomiphene, 1.2 μM polymyxin B, 20μM auranofin) but was not affected by 50 μM H_7, an inhibitor of cyclic nucleotide dependent kinase and protein kinase C. It was reduced by 10μM W_7, an inhibitor of calcium-calmodulin dependent (CaM) kinases. The effect of NE was increased by 10mM Li, which prevents further metabolism of inositol triphosphate (IP_3), but was unaffected by pertussis toxin (2.5 μg/ml for 4 hours at 37°C). These results are consistent with transduction by IP_3 to cause intraterminal Ca^{2+} release and activation of a CaM kinase.

NORADRENALINE (NA) MEDIATES A COMPONENT OF VIP RELEASE EVOKED BY 4-AMINOPYRIDINE (4-AP) IN MOUSE NEOCORTEX. J.L. Martin and P.J. Magistretti. Département de Pharmacologie, CMU, 1211 Geneva 4, Switzerland.

In mouse cerebral cortical slices, 4-AP stimulates in a concentration-dependent manner basal VIP release (VR). VR evoked by 4-AP 1 mM is completely blocked by Co^{++} 2.5 mM and partially inhibited (74 %) by TTX 2 μM. Mepacrine, an inhibitor of phospholipase A_2, inhibits 4-AP-evoked VR (4-APVR) with an IC_{50} of 15 μM. Indomethacin, a cyclooxygenase inhibitor, and caffeic acid, an inhibitor of 5-lipoxygenase, inhibit by 35 % (at 100 μM) and 67 % (at 1 mM) respectively, 4-APVR. These inhibitors of arachidonic acid metabolites' formation act exclusively on the TTX-sensitive component of 4-APVR. NA potentiates in a concentration-dependent manner (between 1 and 100 μM) 4-APVR, while not affecting basal VR. Furthermore, 4-APVR is inhibited by the α-2-adrenergic antagonist yohimbine, but not by prazosin, an α-1-adrenergic antagonist. These results indicate that part of 4-APVR may be mediated through the release of NA. VR is also stimulated in a concentration-dependent and TTX-insensitive manner by K^+ (between 15 and 50 mM). K^+-evoked VR is completely inhibited by Co^{++} 2.5 mM and partially by Mn^{++} 1 mM (75 %) and Ni^{++} 0.1 mM (34 %) but not by Cd^{++} 20 μM. Diltiazem 20 μM, nifedipin 10 μM and ω-conotoxin 1 μM do not inhibit VR. This pharmacological profile suggests the involvement of voltage-sensitive Ca^{++}-channels of the T subtype in K^+-VR. Supported by FNRS Grant N° 3.357-0.86.

LITHIUM ENHANCES PILOCARPINE-PRODUCED EPILEPTIFORM ACTIVITY BY PRESYNAPTIC FACILITATION. M.S. Evans*, C.F. Zorumski, and D.B. Clifford. Depts. of Neurology and Psychiatry, Washington University Sch. of Med., St. Louis, MO 63110.

Pilocarpine (PILO)-injected rats develop limbic seizures; its potency is increased about 20-fold by lithium. This interaction was investigated in hippocampal slices. Slices were taken from 150-350 g rats, incubated in an oxygenated chamber and transferred as needed to a submerged-type chamber where they were perfused with oxygenated medium (NaCl 116.4, KCl 2.0, $MgSO_4$ 1.3, $CaCl_2$ 1.5, NaH_2PO_4 1.0, $NaHCO_3$ 26.2, glucose 11). Drugs were applied via the perfusate. Intracellular and field potentials were recorded in area CA1 with stimulation of Schaffer collaterals. PILO had effects like other muscarinic agonists: it increased input resistance, blocked a slow AHP, blocked accomodation to depolarizing current pulses, and depolarized the cell slightly at 100-1000 nm. Lithium 1-5 meq/l either did not change or slightly reduced these effects of PILO. Lithium increased the amplitude of dendritic field potentials (DFP) 100% at 5 meq/l, 18% at 1 meq/l, and enhanced intracellular EPSPs as well, but the response to iontophoretic glutamate pulses was unchanged or decreased, suggesting its effect is presynaptic. PILO reduced EPSPs and DFPs by presynaptic inhibition. In the presence of 500-1000 nm PILO, lithium 1 meq/l increased DFPs by 50-100%. Repetitive epileptiform spiking was routinely produced with the combination of drugs, but infrequently by PILO alone. These results suggest that lithium-PILO seizures result from an interaction at a presynaptic level, with small concentrations of lithium potently antagonizing PILO's presynaptic inhibitory effect.

INTERACTIONS OF MDMA STEREOISOMERS ON HIGH AFFINITY UPTAKE IN RAT HIPPOCAMPAL SYNAPTOSOMES. Poblete, J.C., Avdelis, B.J., Whitaker-Azmitia, P.M., Azmitia, E.C. (SPON: Feinberg, I.) Dept. Biology NYU, New York, NY 10003 and Dept. Psychiatry, SUNY, Stony Brook, Stony Brook, NY 11794.

We investigated the interactions of the (R) and (S) enantiomers of MDMA on rat hippocampal synaptosomes with respect to uptake of ^{3}H-5HT (50 nM) as previously described (Azmitia and Whitaker-Azmitia, 1987). In the first series of studies, (R) and (S) MDMA (10^{-11}M - 10^{-4}M) were added with and without Ca^{++} (incubation 37°, time = 30 min.). In our second series of tests, we performed an experiment to determine whether the enantiomers exerted their effects through the same transporter site.

The (R) isomer exhibited a more profound inhibition of 5HT uptake than the (S) isomer at identical concentrations [43% for (S) vs. 68% for (R) at 10^{-7}M]. Both isomers acted in a dose dependent manner with significant reduction at nanomolar concentration. In low Ca^{++} media, the uptake of 5HT was 50% lower after 30 minutes, and both isomers produced almost complete inhibition at 10^{-9}M. Our results from the second series of studies showed that the enantiomers of MDMA compete for the same transport site since the (S) isomer blocked the greater inhibition produced by the (R) isomer, and no evidence of cooperativity was found. These data suggest that one high affinity binding site exists for both enantiomers of MDMA, and the (R) isomer has a more potent effect of 5HT uptake in rat hippocampal synaptosomes. Supported by NIDA contract 271-87-8144.

PREVENTION OF MDMA TOXICITY TO SEROTONERGIC NEURONS IN TISSUE CULTURE BY L-TYPE CA^{++} CHANNEL ANTAGONIST. Azmitia, E.C., Murphy, R.B., Whitaker-Azmitia, P.M. Dept. Biology and Chemistry, NYU, New York, NY 10003 and Dept. Psychiatry, SUNY, Stony Brook, NY 11794.

We report that S(+)- MDMA is stimulatory at low concentrations (around 10^{-9}M) and inhibitory at high concentrations (above 10^{-6}M) on the expression of [^{3}H]-5-HT uptake on cultured serotonergic neurons. The R(-)- MDMA was inhibitory within both concentration ranges. Multiple applications of MDMA enhanced the inhibitory effects of the R enantiomer. This differential effect of the enantiomers at low concentration was confirmed with morphometric analysis of 5-HT neurons grown in normal or no Ca^{++} media. The S-MDMA enantiomer produced increases in the number of surviving 5-HT neurons, their somal area and process length. In contrast, the R-MDMA at low concentrations produced a decrease in somal area and process length of 5-HT neurons.

The specific L-channel Ca^{++} antagonist, nimodipine (2×10^{-5}M), blocked the inhibitory action of both the R and S enantiomers at high concentrations of MDMA (10^{-3} - 10^{-2}M), but did not interfere with the differential effects seen at low concentrations on the expression of reuptake by the cultured serotonergic neurons. Our results indicate that MDMA toxicity (as operationally defined) is due to an excess influx of Ca^{++} through an L-type Ca^{++} channel which appears to be independent of the biological stimulatory effects of S-MDMA on serotonergic neurons in culture. Thus, if the L-type channel mediated Ca^{++} influx is inhibited, S-MDMA appears paradoxically to function as a neuronotrophic factor since it can increase cell survival, induce process outgrowth and enhance the high affinity uptake of [^{3}H]-5-HT. The present mechanism may be of general importance in the mediation of actions of other neurotoxins. Supported by NIDA contract 271-87-8144.

440.9

MODULATION OF GLUTAMATE AND DYNORPHIN RELEASE FROM HIPPOCAMPAL MOSSY FIBER SYNAPTOSOMES. R.L. Gannon, L.T. Baty* and D.M. Terrian. Clinical Sciences Div., USAF Sch. Aerospace Med., Brooks AFB,TX 78235-5301.

The long-term potentiation (LTP) of the hippocampal mossy fiber (MF)-CA3 synaptic response is not sensitive to 2-amino-5-phosphonovalerate as is the induction of LTP at other hippocampal synapses, but this synaptic input can be selectively and potently blocked by 2-amino-4-phosphonobutyrate (APB). This effect is not accompanied by a change in postsynaptic excitability and, therefore, may be mediated by the presynaptic inhibition of transmitter release from the MF terminals. To examine this possibility we have studied the effects of APB on the K^+-evoked release of L-glutamate (Glu) and dynorphin from a subcellular fraction enriched in hippocampal MF synaptosomes. Endogenous Glu and dynorphin A(1-8) release were determined fluorometrically and by radioimmunoassay, respectively. A two minute application of 45 mM KCl to superfused guinea pig synaptosomes evoked a release of 55.7 ± 3.5 pmol Glu/min/mg protein that was partially Ca^{2+}-independent. L(+)APB, (300 µM) reduced the KCl-evoked release of dynorphin A(1-8) from 1.12 ± 0.07 to 0.53 ± 0.1 pg/min/mg protein, but had no effect on Glu release. However, after exchanging Glu out of the cytosolic pool with 50 µM D-aspartate, 300 µM L(+)APB reduced the remaining Ca^{2+}-dependent Glu release from 47.4 ± 3.1 to 29.8 ± 3.7 pmol/min/mg protein. Under the same conditions L(+)APB had no significant effect on Glu or dynorphin A(1-8) release from rat MF synaptosomes.

440.10

ADENOSINE INHIBITION OF GLUTAMATE AND DYNORPHIN RELEASE FROM HIPPOCAMPAL MOSSY FIBER SYNAPTOSOMES. P.G. Hernandez*, R.L. Gannon, M.A. Rea and D.M. Terrian. USAF School of Aerospace Medicine, Brooks AFB, TX 78235-5301.

Electrophysiological studies indicate that the anticonvulsant effect of adenosine and its analogues on hippocampal CA3 pyramidal neurons is primarily due to a presynaptic inhibition of excitatory neurotransmitter release. The hippocampal mossy fiber (MF) system provides a major excitatory synaptic input to the CA3 subfield and may represent a site of adenosine action. We have recently reported that the adenosine agonist 2-chloroadenosine (ClAdo) preferentially inhibits the Ca^{2+}-dependent component of glutamic acid released by a synaptosomal preparation enriched in hippocampal MF nerve endings. In the present experiments, we have investigated the mechanism by which adenosine modulates the MF synapse. The results demonstrate that ClAdo (0.1 µM) inhibits the 45 mM K^+-evoked release of dynorphin A(1-8), as well as glutamic acid, from superfused MF synaptosomes. Exogenous ATP (0.1 - 1.0 mM) does not mimic this effect and the order of agonist potency is ClAdo ≈ cyclohexyladenosine > 5'-N-ethylcarboxamidoadenosine. The IC_{50} for the effects of ClAdo on glutamic acid release is near 0.1 µM and this inhibition can be prevented by increasing the concentration of calcium from 0.5 to 7.0 mM. These findings suggest that adenosine presynaptically modulates the hippocampal MF synapse by interfering with calcium influx or its availability within the nerve terminal.

SENSORY SYSTEMS: AUDITORY SYSTEMS VII

AUDITORY LOCALIZATION IN THE SAW-WHET OWL. M.L. Csizy*, B.J. Frost. Queen's University, Kingston, Ontario K7L 3N6.

The Saw-whet owl (Aegolius acadicus) is a nocturnal raptor which acoustically locates its prey with great accuracy. The auditory localization abilities of this species has been studied using head orientation responses to sounds presented in a free field.

Employing the search coil technique (Robinson, 1963; Knudsen et al, 1979) permitted the tracking of lateral and vertical head motions in response to playback sounds of mice moving through leaves. Saw-whets showed the greatest accuracy for sounds emanating from a region directly in front, spanning 40 degrees in each dimension. The average error was less than 1 degree in azimuth and just above this in elevation. Acuity was reduced at the extreme limits of the sound field, the mean error for speakers positioned at 30 and -30 degrees along each axis being 6 degrees. A decline in accuracy for sounds originating from more than 10 degrees above the owl's interaural axis may be a function of the biological irrelevance of the particular stimulus at these elevations.

Testing to determine the independent contribution of interaural time and intensity differences localization is in progress. This research was supported by an NSERC grant A0353 to B.J.F.

441.2

THE REPRESENTATION OF SOUND FREQUENCY AND SPACE IN THE MIDBRAIN OF THE SAW-WHET OWL (*Aegolius Acadicus*). L.Z. Wise, B.J. Frost and S.W. Shaver. Dept. of Psychology, Queen's University, Kingston, Ont. K7L 3N6 Canada.

We studied frequency and spatial tuning of single cells in the midbrain auditory nucleus (MLD) of the ketamine-anesthetised saw-whet owl. This bird has a pronounced asymmetry in the bone structure of the ear openings, and has extremely acute sound localization ability (Csizy and Frost, *Neurosci. Abstr.*, 1988). Cells in central MLD were sharply tuned to frequencies from 200 Hz, represented dorsally, through 7 kHz, represented ventrally, and exhibited little or no sensitivity to sound source location. Cells in lateral MLD (MLD1) were broadly tuned to frequency, responded vigorously to noise stimuli, and were spatially selective. From rostral to caudal MLD1, cells preferred increasingly contralateral locations. Azimuthal spatial tuning was sharper than elevational tuning, and matched sensitivity to interaural time delay recorded in the same cells using removable headphones. Auditory responses were also recorded in the optic tectum overlying MLD. Cells responded preferentially to wide-band noise stimuli, and showed spatial selectivity in both azimuth and elevation. Supported by NSERC Grant A0353 to B.J.F.

441.3

THE RELATION BETWEEN VISION AND SOUND LOCALIZATION ACUITY IN MAMMALS. R. S. Heffner and H. E. Heffner. Dept. of Psychology, Univ. of Toledo, Toledo, OH 43606.

It has long been noted that one function of hearing is to direct the eyes to the source of a sound. Recent analysis suggests that this function may be the major source of selective pressure on sound localization acuity in mammals.

If the ears are to direct the eyes to the source of a sound, then the question arises as to how accurate the ears must be. Since humans direct their area of best vision (i.e., their fovea) to the source of a sound, we reasoned that the acuity of sound localization needed to direct the eyes might be related to the size of an animal's field of best vision.

Using retinal ganglion cell counts we defined the size of the "area of best vision" as the horizontal extent (in degrees) of the region encompassing cell densities greater than or equal to 75% of maximum density. We then correlated area of best vision with sound localization acuity in the 8 species for which both measures were available (opossum, human, gerbil, grasshopper mouse, weasel, cat, pig, cattle). The resulting correlation was 0.96 ($p<.01$).

This result suggests that the need to visually locate a sound source may be the primary source of selective pressure on sound localization acuity and may account for the wide variation in sound localization acuity in mammals.

441.4

LOCALIZATION OF UNDERWATER SOUND IN THE CLAWED FROG, XENOPUS LAEVIS. B.SCHANZ*, A.ELEPFANDT (SPON: European Brain and Behaviour Society). Fak. Biol., Univ. Konstanz, P.O.Box 5560, D-7750 Konstanz, Fed. Rep. Germany.

Localization of underwater sound was investigated in the aquatic clawed frog, Xenopus laevis. Previously, it had been argued that binaural mechanisms - such as used by terrestrial frogs - are insufficient for locating low-frequency underwater sound (van Bergeijk, W.A., in: Tavolga, W. (ed), Marine bio-acoustics. Pergamon, New York, 281,1964).

Adult females injected with gonadotropin were tested individually in a basin 4 m in diameter filled with water to a depth of 30 cm. Male mating calls were presented from various directions through underwater loudspeakers and the angles of the turning responses were measured as a function of sound direction.

The animals located sound from anterior and lateral directions with an accuracy of $\pm 19°$, which is only slightly poorer than in terrestrial frogs. Localization of posterior sound was considerably worse.

Animals with unilateral destruction of tectum and torus responded to contralateral sound by turning ipsilaterally, which indicates a lateralization of sound localization in the midbrain.

441.5

TWO-DIMENSIONAL SOUND LOCALIZATION BY HUMAN LISTENERS. J.C. Middlebrooks and J.C. Makous*. Depts. of Neuroscience and Surgery (ENT), University of Florida, Gainesville, FL 32610.

We measured the ability of human listeners to localize white noise bursts (150 msec duration) presented at horizontal and vertical locations distributed throughout nearly 360° of auditory space. Each subject reported the location of the sound source by orienting toward it while his head position was monitored with an electromagnetic device. Each sound source location was tested 5 or more times.

Subjects effectively discriminated among source locations separated by horizontal and vertical steps of 10° throughout most of the frontal half of space. Localization was most precise for midline sources (standard deviations around 2°), but the precision of localization typically fell by no more than a factor of 3 for locations in the frontal 180° within 35° of the horizontal plane. Front/back errors were infrequent. Localization precision was substantially decreased for sounds presented behind the subject; in part, this may reflect the difficulty in turning to face a sound presented from behind.
(UF award DSR-D-54 and NIH grant R29 NS25022)

441.6

GABA-MEDIATED INHIBITION CONTRIBUTES TO NEURONAL SELECTIVITY FOR INTERAURAL TIME DIFFERENCE IN THE OWL'S INFERIOR COLLICULUS. I. Fujita* and M. Konishi (SPON: D. Felleman). Biol. Div., 216-76, Calif. Inst. of Technol., Pasadena, CA 91125.

The barn owl uses interaural time differences (ITD) for localizing the azimuthal position of sounds. Neuronal selectivity for ITD first appears in the nucleus laminaris and improves in the central nucleus "core" (ICc) and the external nucleus (ICx) of the inferior colliculus. Tonal stimuli cause both ICc and ICx neurons to respond maximally not only to one particular ITD (the characteristic delay), dt, but also to dt + nT, where T is the tonal period and n an integer. This phenomenon, phase ambiguity, does not occur when ICx neurons are stimulated with noise.

Iontophoretically applied bicuculline methiodide (BMI, a selective $GABA_A$ antagonist) decreased the ITD selectivity of ICc neurons. The effects were identical for tone- and noise-evoked responses. In ICx, BMI decreased ITD selectivity to tones only in neurons tuned to frequencies below 5 kHz. BMI led to loss of ability of ICx neurons to signal uniquely their dt. The results suggest that under physiological conditions GABAergic inhibition sharpens ITD selectivity in ICc neurons and ICx neurons tuned to below 5 kHz, and eliminates phase ambiguity in ICx by interaction between the converging frequency bands. (Supported by NIH and Uehara Memorial Foundation.)

441.7

IN VITRO PHYSIOLOGICAL STUDIES OF A "PLACE MAP" IN N. LAMINARIS OF THE CHICK. E. M. Overholt*, R. L. Hyson*, and E. W Rubel (SPON: D. Sutton). Depts. of Otolaryngology and Physiology/Biophysics, Univ. of Washington School of Medicine. Seattle, WA 98195.

Third order auditory neurons in the avian n. laminaris (NL) are the first to receive binaural input. In the chick, NL consists of a monolayer of neurons with polarized dendritic arbors oriented dorsally and ventrally. Afferents from the ipsilateral 2nd order neurons in n. magnocellularis (NM) innervate the dorsal dendrites of NL while the ventral dendrites receive afferents from the contralateral NM via the crossed dorsal cochlear bundle. The arborization pattern of axons arising from contralateral and ipsilateral NM are arranged in such a way that they could provide a differential delay network creating a "place map" within NL which corresponds to the time delay of sounds arriving at the two ears (Young, S. R. and E. W Rubel, J. Neurosci., 3:1373, 1983).

We tested this possibility by analyzing evoked field potentials using an *in vitro* slice preparation containing both NL and NM. Field potentials recorded while stimulating the contralateral NM or crossed dorsal cochlear bundle demonstrated a nearly linear increase in the latency of postsynaptic potentials from medial to lateral positions in NL. Conversely, when stimulating the ipsilateral auditory nerve stump or ipsilateral NM, the latency of the post-synaptic response showed no consistent variation. This differential delay circuit provides a mechanism for converting time delay of stimuli reaching the two ears into a "place map" of simultaneous postsynaptic activation of NL cells. (Support provided by PHS grant NS 07246 and NIH grant NS 24522.)

441.8

THE EFFECTS OF SUPERIOR OLIVARY COMPLEX LESIONS ON BINAURAL INTERACTION IN THE AUDITORY CORTEX OF THE ALBINO RAT. S. L. Sally* and J. B. Kelly. Lab. of Sensory Neuroscience, Dept. of Psychology, Carleton University, Ottawa, Canada, K1S 5B6.

Cells in the superior olivary complex of the adult albino rat were selectively destroyed by micro-injections of kainic acid. Following a 2-3 week recovery period, the binaural response properties of cells in auditory cortex were examined using microelectrode mapping techniques. Rats were anesthetized with Equithesin (3.0 ml/kg i.p.), the cortical surface was exposed, and recordings were made with tungsten microelectrodes. Pure tone pulses were delivered to each ear independently through sealed loudspeakers fitted to specula inserted into the external meatus. Sound pressure levels were determined by probe tube measurements within a few mm of the tympanic membrane. Following complete unilateral ablation of the superior olivary complex, the three major binaural response types (summation, suppression and mixed) were represented at all frequencies within the rat's hearing range. The majority of neurons exhibited binaural interaction at interaural intensity differences (IIDs) which were within the normal range. Maps of auditory cortex ipsilateral or contralateral to the lesion showed the same pattern of results. Complete bilateral ablation of the superior olivary complex, however, resulted in a preponderance of cells sensitive only to monaural contralateral stimulation. There was a substantial increase in the IID thresholds of cells which did exhibit binaural interactions.

BINAURAL INTERACTION IN THE BRAINSTEM AUDITORY EVOKED RESPONSE OF THE FERRET (MUSTELA PUTORIUS). G.L. Kavanagh*, J.B. Kelly and T.W. Picton (SPON: E. Peterson). Lab. of Sensory Neuroscience, Carleton University, Ottawa, Canada, K1S 5B6 and Human Neurosciences Research Unit, University of Ottawa, Ottawa, Canada.

The effect of binaural interaction on the BAER was examined in nine adult male ferrets. Animals were anesthetized with pentobarbital sodium (35 mg/kg i.p.), placed within a sound-proof chamber, and the head was immobilized using a nontraumatic nose clamp. Clicks were produced by a 0.1 msec square wave, amplified and transduced by earphones over a broad range of intensities (34 to 104 dB peak SPL). Platinum needle electrodes were placed over the vertex and left and right mastoid. Responses were amplified 10,000 times, bandpass filtered between 0.3 Hz and 10 kHz and averaged on line at a rate of 50 kHz. The analysis epoch for each channel was 10.24 msec and all responses were based on 1,000 sweeps. The binaural interaction component of the BAER was derived using the procedure of Dobie and Berlin (1979). At each intensity the responses to left and right monaural stimulation were summed to obtain a predicted binaural response. The predicted response was then subtracted from the binaural response generated by stimulating both ears simultaneously. This yielded a difference trace containing the binaural interaction component. Binaural interaction in the ferret BAER is characterized by a prominent negative wave with a latency similar to the fourth vertex-positive potential (P4). The wave showed an increase in latency and reduction in amplitude as sound intensity was reduced over a 70 dB range.

INFLUENCE OF STIMULUS SPECTRUM ON AZIMUTH SELECTIVITY OF SINGLE UNITS IN CAT AUDITORY THALAMUS. W.A. Irons*, E.R. Samson*, T.J. Imig, Dept. of Physiology, Univ. Kansas Med. Ctr., Kansas City, KS 66103.

Single units in the ventral nucleus and Po of barbituate anesthetized cats were studied using free field stimulation. A series of tone bursts, broad band (BBN), or band pass (BPN) white noise bursts which systematically varied in level was delivered from each of several azimuths. Isorate contours were computed and plotted in SPL or spectrum level vs. azimuth coordinates. On the basis of these contour plots, three classes of response patterns were distinguished. 1) Nondirectional. These units were broadly tuned to azimuth for BBN, BPN, and tones. 2) Azimuth-selective, bandwidth-insensitive. These units were azimuth selective, and the degree of azimuthal selectivity and discharge rate was similar for BBN, BPN, and tones. Two-tone stimulation resulted in little evidence of sideband interaction. 3) Azimuth-selective, bandwidth-sensitive. These units displayed highly directional tuning to BBN with decreasing selectivity as the spectral bandwidth narrowed. Units often exhibited broad azimuthal tuning to tonal stimuli, however some units were more directionally tuned to some frequencies than others. Unit discharge rate was lowest to broad band stimulation, and highest to narrow band stimulation centered within the frequency response area suggesting the existence of inhibitory sidebands. Two-tone stimulation showed direct evidence of inhibitory and facilitory sidebands, the former being much more common. Some units displayed inhibitory sidebands on both sides of the excitatory response area, while others exhibited only one inhibitory sideband. The degree of sideband inhibition appears to be a function of both stimulus level and direction. Sideband inhibition appears to play a role not only in shaping a unit's frequency selectivity, but also its directional selectivity. (Supported by NINCDS Grant 17220 and BRSG S07RR05373)

PROCESSING OF INTERAURAL LEVEL DIFFERENCES IN THE INFERIOR COLLICULUS OF THE BARN OWL. R. Adolphs* (SPON: M. Konishi). Biology Div., 216-76, California Institute of Technology, Pasadena, CA 91125.

Barn owls use interaural differences in sound pressure level (ILD) to compute location of the source in elevation. I investigated the origin of neuronal selectivity for ILD in the medial shell of the central nucleus of the inferior colliculus (MS), a presumptive input stage to spatial elevation coding in the external nucleus (ICx).

Anatomical connectivity was demonstrated by retrograde labelling with horseradish peroxidase. Neurons of MS receive direct massive projections from the contralateral nucleus angularis, nucleus ventralis lemnisci lateralis pars posterior (VLVp), lateral region of the superior olive, and sparse projections from contralateral MS.

All above nuclei show stimulus-response curves sensitive to ILD and generally insensitive to interaural time differences (ITD), culminating in typically very sharp "EI" response curves in MS neurons: they are excited by ILD's favoring the contralateral ear, and inhibited by ILD's favoring the ipsilateral ear. Preliminary data from lidocaine injections into the projecting nuclei suggest that both VLVp and MS make inhibitory contralateral connections to MS. This is consistent with predictions made on the basis of connectivity and ILD-response character.

NEURONS IN THE INFERIOR COLLICULUS RECEIVE CONVERGENT INPUT FROM MULTIPLE BINAURAL SOURCES. R. Batra, S. Kuwada and T.R. Stanford*. Dept. of Anatomy, Univ. of Conn. Health Cntr., Farmington, CT 06032.

Several nuclei in the auditory pathways that receive input from both ears project to the inferior colliculus (IC). These include the nuclei of the superior olive, lateral lemniscus, and the auditory cortex. Several of these nuclei project to the same region of the IC, but do these projections converge on the same neurons? Here we report that single neurons in the IC which are sensitive to interaural temporal disparities (ITD's) appear to receive inputs from several binaural sources.

We recorded from neurons in the IC of the unanesthetized rabbit that were sensitive to ITD's of the waveform or the envelope. Calibrated pure and sinusoidally amplitude modulated tones were delivered dichotically. Responses were assessed at several tonal or modulation frequencies.

Neurons sensitive to ITD's are thought to arise from the convergence of phase-locked signals from the two ears along pathways which have fixed delays. Such a mechanism predicts a linear relationship between the interaural phase difference to which a neuron is most sensitive (the mean phase) and the stimulating frequency, with the slope representing the difference in delays from the two ears. We have observed significant deviations from this expected linearity in the IC. These deviations can take many forms. They can appear as oscillations of the mean phase around the regression line, or as a separation of the mean phase *vs.* frequency plot into two segments with different slopes. The two slopes indicate that the neuron receives convergent input from two sources, each of which processes a different ITD over a different range of frequency. Responses can also exhibit nulls at intermediate frequencies. All of these effects suggest convergence from two or more sources, each of which in turn receives phase-locked inputs from the two ears.

BINAURAL INTERACTION OF MIDDLE AND LONG-LATENCY AUDITORY EVOKED POTENTIALS D. L. Woods and C. C. Clayworth*, Clinical Electrophysiology Laboratory, Dept. of Neurology, U.C. Davis, VA Medical Center, Martinez, CA, 94553

We studied the binaural interaction of middle (latencies 10-70 msec) and long-latency (latencies 70-300 msec) auditory evoked potentials (AEPs). Stimuli were presented monaurally to the left and right ears and binaurally in different blocks while EEG recordings were obtained from 16 scalp sites.

The shortest latency evidence of binaural interaction was a partial occlusion of the Pa component (latency 28-30 msec) of the middle latency AEP: Pa amplitudes following binaural stimulation were about 60% larger than those following monaural stimulation. In contrast, long-latency auditory evoked potentials showed total occlusion: N1(95-120 msec) and P2 (170-200 msec) components were as large following monaural as binaural stimulation (see illustration). The results suggest that the breadth of spatial tuning of neurons generating AEPs increases at increasing latencies.

ULTRASTRUCTURE OF THE BRAINSTEM TIME CODING PATHWAYS IN THE BARN OWL. C. E. Carr and R. E. Boudreau. Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642.

In the barn owl, sensitivity to interaural time differences arises in nucleus laminaris (NL), the first recipient of binaural input. Eighth nerve afferents synapse upon the neurons of the magnocellular cochlear nucleus (NM), which in turn project bilaterally to NL. The ipsilateral axons from NM enter NL dorsally, while the contralateral axons enter ventrally. The dorso-ventral arrays created by the interdigitation of these afferents form maps of interaural time difference.

At the ultrastructural level, the owl's time coding pathway resembles that of the chick. Each neuron in NM receives two types of synaptic input. One is the calciform ending typical of eighth nerve fibers. These profiles contain round clear vesicles, and form a large number of punctate asymmetric synapses. The other type of profile is smaller and densely packed with ellipsoid vesicles. These profiles may correspond to the GAD positive terminals observed with the light microscope.

The afferent axons from NM form frequent nodes within NL, as well as many large club shaped terminals upon the dendrites and somata of NL neurons. Each NL neuron has a large oval soma, about 30μm in diameter, and short thick dendrites. As in the chick, NL neurons receive thick punctate synaptic densities from NM terminals and a second type of profile which forms narrow single densities (Parks et al., (1983) J. Comp. Neurol. 214:32-42). NL neurons lack an initial segment; the large (10μm) axon becomes myelinated at the soma, and membrane adjacent to the origin of myelination does not contain a dense undercoating.

HOW IS THE FRONTAL AUDITORY SPACE REPRESENTED IN THE AUDITORY CORTEX OF THE FM BAT, EPTESICUS FUSCUS? P.H.-S. Jen, X.D. Sun* and P.J.-J. Lin*. Div. of Biol. Sci. The Univ. of Missouri, Columbia, MO. 65211.

The spatial sensitivity of single neurons and auditory space representation in the primary auditory cortex of Eptesicus fuscus was studied under free field stimulus conditions. A 4 ms pure tone pulse was delivered from a loudspeaker placed 23 cm in front of the bat to determine the best frequency (BF) and minimum threshold (MT) of each neuron. Then an FM signal sweeping one-octave downward across the neuron's BF was delivered as the loudspeaker was moved through the frontal auditory space to determine the spatial response center at which the neuron's MT was the lowest. The stimulus was then raised 10-20 dB above each neuron's lowest MT to measure the spatial response area. All response centers are located in the contralateral frontal auditory space (0^{o} and 50^{o} in azimuth, 0^{o} and 25^{o} in elevation). Response centers tend to move toward the midline and slightly downward with increasing BF. Since high BF neurons are located anteriorly and low BF neurons posteriorly, the auditory space appears to have an orderly representation in the auditory cortex along the tonotopic axis. Thus, the lateral space is represented posteriorly and the middle space anteriorly. While the response area of cortical neurons expands asymmetrically with stimulus intensity, high BF neurons tend to have smaller spatial response areas than low BF neurons. The BFs, MTs, spatial response areas and response centers of neurons sequentially isolated from an orthogonally penetrated electrode are similar indicating columnar organization in the auditory cortex.

441.16

LOW-FREQUENCY TONE DISCRIMINATION IN THE CLAWED FROG, XENOPUS LAEVIS. A.Elepfandt, M.Hainich*. Fak. Biol., Univ. Konstanz, P.O.Box 5560, D-7750 Konstanz, Fed. Rep. Germany.

Discrimination of tones below 800 Hz, which fall into the frequency range of the amphibian papilla, was investigated in the clawed frog, Xenopus laevis. Because Xenopus is aquatic, this discrimination is of underwater sound.

In the tests, sound was presented from the bottom of a tank 65 cm in diameter filled with water to a depth of 45 cm. The frog moved on a net 7 cm below the water surface. Discrimination between trains of 6 tone pulses of constant or alternating frequency was conditioned by a go/no-go method. FFT analysis showed that the presented tones were monofrequent throughout the test area.

Most frogs learned the discrimination and remembered it for several weeks. Relative discrimination limens (DL) were 0.05-0.1, which coincides with the acuity of tone discrimination in non-mammalian vertebrates. This accuracy is considerably greater than found earlier for frequencies above 1 KHz (DL=0.45), which may reflect the fact that a tonotopic organization is found in the amphibian but not the basilar papilla of frogs.

441.17

AUDITORY DURATION DISCRIMINATION IN THE EUROPEAN STARLING (Sturnus vulgaris). E. H. Maier* and G. M. Klump*. (SPON. P. M. Narins). TU Munich, Inst. of Zoology, Lichtenbergstr. 4, D - 8046 Garching, FRG.

Three starlings were tested in a GO/NOGO-procedure on their ability to detect changes in the duration of a tone. Stimuli were pure tones at three frequencies (4 kHz, 2 kHz, 0.5 kHz) and three standard durations (800 ms, 200 ms, 100 ms). Stimulus amplitude was randomized in steps of 0.375 dB in the range of 48 to 52 dB SPL. Increments and decrements in tone duration ($\pm \triangle$ T) ranged from 5% to 90% of the standard duration. In the range of the presumed threshold they varied in steps of 5% of the standard duration. Stimuli of different durations were presented by the method of constant stimuli. Thresholds were determined using signal detection theory, threshold criterion was the discrimination measure d' of 1.8.

For an increase in duration no influence of frequency on the discrimination threshold was found (n=2). Weber fractions $\triangle$ T/T ranged from 0.12 at 800 ms standard duration to 0.23 at 100 ms standard duration. For the bird tested with a decrease in tone duration neither stimulus frequency nor standard duration had an influence on the thresholds (average $\triangle$ T/T was 0.19). The results of this animal and of one additional bird in which both thresholds for $+\triangle$ T and $-\triangle$ T were measured, suggest that it may be more difficult for the starling to detect a decrease in duration.

UNILATERAL NEONATAL DEAFENING RESULTS IN BILATERAL AUDITORY CORTICAL PATHOLOGY. Nathaniel T. McMullen, Bruce Zukerberg* and Edmund M. Glaser. Dept. of Physiology, Univ. of Maryland Sch. of Med. Balt. MD 21201.

In recent papers we have demonstrated that unilateral cochlear damage in the neonatal rabbit results in substantial alterations in presumptive target neurons in the contralateral auditory cortex (McMullen et al, JCN, 267: 92-106, 1988; McMullen & Glaser, Exp. Brain Res. 1988). Based on 3-D reconstruction and quantitative analyses of 100 Golgi-impregnated neurons obtained from 4 neonatally deafened and 2 control rabbits, we now report that spine free nonpyramidal cells ipsilateral to the neonatally damaged cochlea exhibit a nearly identical pattern of dendritic expansion (ca. 24% increase in total length) and abnormally recurved dendrites (42% of cells). The expansion was due entirely to increased branch length as there was no change in the number of dendritic branches. Recurved dendrites were almost exclusively directed tangentially or toward the white matter. These data indicate that unilateral cochlear damage results in the reorganization of both ipsilateral and contralateral ascending auditory pathways. The failure of the undamaged ear to maintain normal cortical dendritic growth bilaterally is evidence that binaural competition is an important component of auditory cortical maturation.

DEVELOPMENTAL BASIS OF CONGENITAL DEAFNESS WITH CARDIAC ARRYTHMIAS. M.J. Mulroy. Dept. Anatomy, Med. College of Georgia, Augusta, GA 30912.

The long QT syndrome is characterized by abnormal prolongation of the QT interval of the electrocardiogram, and is sometimes associated with congenital deafness. The resulting arrythmias can be life threatening. We have developed an animal model in which to study the changes in the innervation of the heart and inner ear associated with this syndrome.

Nodose and otic placodes were removed from 30-36 hour old chick embryos. ECGs were recorded on embryonic day 17. Cochlear potentials of embryos with long QT intervals were measured to assess the function of the ear. Sensory, parasympathetic and sympathetic innervation of the heart was evaluated. The cochlea was also evaluated histologically.

Data will be presented to support the hypothesis that a small lesion affecting the nodose and otic placodes during early development, when the placode are contiguous, can alter the normal innervation of the heart and cochlea resulting in cardiac arrythmias and deafness.

INDIVIDUAL NEURONAL AREA CHANGES IN THE DEVELOPING AND AGED MEDIAL NUCLEUS OF THE TRAPEZOID BODY OF HEARING IMPAIRED C57BL/6 MICE. R.H. Browner and E.R. Riedel*. Department of Anatomy, New York Medical College, Valhalla, NY 10595.

Area changes in the cells of the medial nucleus of the trapezoid body were analyzed in Nissl stained brains in 10-, 30-, and 2 year old mice. Anesthetized animals were transcardiaclly perfused with saline and then Susa's fixitive and paraffin embedded. Cross sections of 15um were measured using a F. Haer morphometric quantitative data analysis system. Measurements were made on a 100x oil planoapochromatic olympus objective. At least 2 animals (both nuclei) were measured in each survival stage. Every 4th section was measured throughout the length of the nucleus and at least 15 to 20 neurons were measured in these sections. Mean individual cell area were 10-day 139.80 um^2, 30-day 167.86 um^2, 2 year 142.58 um^2. Using T-test and ANOVA statistical methods there are significant differences between the 10- and 30-day, and 30-day and 2 year old mice; none between 10-day and two year old mice. This indicates a cyclic change in individual cell area which first increases and then decreases. This work was supported by the Culpeper and the Jurzkowski Founds and the NY Acad of Sciences.

CORTICAL DEAFNESS CANNOT ACCOUNT FOR "SENSORY APHASIA" IN JAPANESE MACAQUES. H. E. Heffner and R. S. Heffner., Dept. of Psychology, Univ. of Toledo, Toledo, OH 43606.

Bilateral ablation of the superior temporal gyrus in Japanese macaques results in a significant hearing loss (cortical deafness) as well as in an inability to discriminate between two types of their "coo" vocalizations ("sensory aphasia"). A two-part investigation was conducted to determine whether the inability to discriminate the vocalizations might simply be the result of the hearing loss itself.

First, four normal Japanese macaques were tested for their ability to discriminate coos which were attenuated to simulate the effect of a cortical hearing loss. Second, four Japanese macaques with bilateral superior temporal gyrus lesions were tested for their ability to discriminate coos which had been amplified and equalized to compensate for each animal's hearing loss.

All four normal macaques were easily able to discriminate the coos which had been attenuated to simulate a cortical hearing loss. However, amplifying the coos to compensate for the operated monkeys' hearing losses did not improve their performances.

It appears that the inability of monkeys with bilateral superior temporal gyrus lesions to discriminate conspecific vocalizations is not simply due to the accompanying hearing loss, but is a separate auditory disorder. (Supported by NIH grant NS 12992)

442.2

HISTOPATHOLOGICAL CHANGES OF THE COCHLEA AND AUDITORY NERVE FOLLOWING IMPLANTATION OF A COCHLEAR ELECTRODE IN A DEAF ANIMAL MODEL. S.A. Larsen. Dept. of Anat. Sci. & Neurobiol., Univ. of Louisville, Louisville, KY, 40292.

Histopathological changes which occur following implantation, presence and stimulation of a cochlear implant are of significant concern. Previous studies have shown that the insertion, physical presence and electrical effects of cochlear prostheses result in damage to the cochlea, auditory nerve and cochlear nuclei. Many of the published reports employed normal hearing animals or those in which the scala tympani was injected with an ototoxic drug at the time of implantation of the intracochlear electrode. In this study, monkeys were deafened using systemically delivered ototoxic drugs. Auditory brainstem responses were used to confirm the degree of deafness after which the animals were either given implants or had sham surgery. Two designs of cochlear electrodes were evaluated for their histopathologic effects. Implanted, sham surgical and deafened animals were evaluated histopathologically with scanning and transmission electron microscopy. Computer-assisted morphometric analysis was performed on cochleas and nerves. No differences in the cochleas or auditory nerves of the implanted, sham surgical and the deaf control animals were detected. These results indicate that deaf and normal-hearing animals respond differently to the presence of cochlear electrodes. Supported by a grant from the Symbion Corporation.

442.3

THE EFFECTS OF OTITIS MEDIA WITH EFFUSION INDUCED BY INOCULATION OF THE GERBIL BULLA WITH NON-VIABLE BACTERIA. M.E. Hutchings* and J.S. Kroll*. (SPON: C. Blakemore). University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, England and University Department of Paediatrics, John Radcliffe Hospital, Oxford, England.

Otitis media with effusion (OME) is the major cause of hearing disorders in children and they may suffer fluctuating auditory deprivation for months prior to surgery. The effects of OME on the auditory brainstem are being studied in the gerbil (Meriones unguiculatus) using Haemophilus influenzae, the primary bacterial pathogen associated with chronic human OME.

The right bullae of anaesthetised gerbils were inoculated with either 30ul pyrogen free saline or saline containing non-viable H. influenzae type b Eagan (1.3 x 10^9/ml). Animals were sacrificed at intervals and the temporal bones decalcified, sectioned and examined. Middle ears inoculated with bacteria were inflamed and contained serous effusions which resolved by 14 days post-operation. The round window was thickened and polymorphonuclear leucocytes were present in the scala tympani by one day post-operation and in the scala vestibuli by three days. Middle ear pathology included the formation of granulation tissue and new bone. The mucoperiosteum remained elevated one month post-operation. Saline inoculated ears developed scant effusions and the tympana were normal by 5 days post-operation.

ANIMAL MODEL OF TINNITUS: SPECIFICITY OF THE PARADIGM. P.J. Jastreboff, J.F. Brennan, C.T. Sasaki. Sect. ENT, Yale U. Sch. Med., New Haven, CT 06510; Dept. Psychology, UMASS, Boston, MA 02125.

Tinnitus, phantom auditory perception, is a widespread disorder of unknown origin. We proposed an electrophysiological and behavioral model of tinnitus, recently focusing on specificity of the behavioral paradigm. Water deprived adult pigmented rats (36), exposed to continuous noise, received lick training, acclimation to 30 s offsets of background noise used as the conditioned stimulus (CS), suppression training involving termination of CS with mild footshock, and 5 days of extinction. Previously, daily injections of salicylate starting before/after suppression training resulted in contrasting behaviors, consistent with the hypothesis of salicylate-induced tinnitus.

To address an alternative explanation based upon salicylate-induced changes in the perception of background auditory context, the noise was decreased by 20 dB starting before or after training, in place of salicylate injections. This manipulation had no behavioral effect, thus further supporting our tinnitus-based explanation. A second experiment employed 2 doses of quinine (100 and 200 mg/kg) in place of salicylate to induce tinnitus. Quinine injections resulted in changes analogous to those observed following salicylate, in a dose-dependent manner. These data further confirm the specificity of this animal model of tinnitus. (Supported by NIH NS22024 and DRF 1988)

442.5

GENERALIZATION OF CONDITIONED SUPPRESSION IN RATS FOLLOWING SALICYLATE INDUCED TINNITUS. J.F. Brennan and P.J. Jastreboff. Dept. of Psychology, University of Massachusetts at Boston, Boston, MA 02125.

The extent of auditory stimulus control of lick suppression was examined by varying the auditory environment of 36 pigmented rats exposed to daily injections of sodium salicylate, 350 mg/kg, introduced either before or after acquisition training. In successive stages, rats received lick training, acclimation exposure to the conditioned stimulus (CS), suppression acquisition sessions involving 5 onsets of 1-min 10-kHz CSi terminating with a 0.5 s, 1-mA footshock, and 5 extinction tests wherein the CS frequencies varied randomly among 7-, 8-, 9-, 10-, and 11-kHz (all at 60-dB). In Experiment I, 18 subjects were exposed continuously to a 7-kHz tone superimposed upon noise of 60-dB, except for the CS probes when only the respective tonal value occurred. In Experiment II, 18 rats were exposed to the 7-kHz background only. Stimulus control was evident in the saline injected control groups of both experiments by the sharp gradients of auditory generalization of suppression obtained within individual subjects. Both groups injected after training showed little auditory control and rapid extinction of suppression. The groups injected before training showed severe suppression and distorted gradients reflecting a summation effect. These data are readily accommodated within a model that infers the differential presence of tinnitus.

442.6

REDUCED SUSCEPTIBILITY OF THE COCHLEA TO REPEATED EXPOSURE. BL Lonsbury-Martin, DJ Franklin*, BB Stagner* and GK Martin*. Dept. Otorhinolaryngol. Communicat. Sci., Baylor Col. of Med., Houston, TX 77030.

Susceptibility of the cochlea to repeated exposure was investigated in 4 rabbits with measures of behavioral thresholds and distortion-product emissions (DPEs) from outer hair cells (OHCs). Baseline behavioral thresholds were measured at 11 frequencies (.3-22.6 kHz) representative of rabbit audibility using a conditioning task. DPEs at 2f1-f2 were measured as "audiograms" (1.5-18 kHz, 200 Hz intervals) generated by equilevel primaries (45,55,65 dB SPL) and input-output functions (5-dB steps, 9 frequencies). Following control measures, rabbits were noise-exposed (1-kHz 95-dB SPL octaveband) until a criterion reduction was detected in DPE levels generated by 45-dB primaries from 1-4 kHz. During 3 wks of recovery, DPEs were monitored at regular intervals (1,2,3,7,21 days) and compared to corresponding behavioral measures. By 3-wks postexposure, all rabbits had recovered to baseline behavioral and physiological levels. The exposure-recovery regimen was continued until a permanent 10-dB decrement in DPE level resulted for any frequency from 1-10 kHz. Using this criterion, one rabbit was exposed 2 times while each of the 3 remaining animals received 3 exposures. Following the final recovery, functional measures were evaluated at 5 wks postexposure and cochleas assessed. The major outcome was that each rabbit demonstrated an increased resistance to noise-induced dysfunction. Altered susceptibility was expressed for each successive exposure as a systematic increase in the time required to reach the criterion loss. The notion that hair cells can be "conditioned" to become less sensitive to overstimulation through repeated exposure is a relatively new concept. However, given recent evidence that the OHC system contributes dynamically to stimulus transduction, it is likely that the peripheral efferent system participates in the observed increased resistance to repeated exposure. EFFECTS OF BILATERAL ABLATION OF THE AUDITORY CORTEX AND/OR CINGULATE CORTEX ON THE BIOSONAR BEHAVIOR OF THE MUSTACHED BAT. S.J.Gaioni*, N.Suga, and H.Riquimaroux. Dept. of Biology, Washington Univ., St.Louis, MO 63130.

The mustached bat (Pteronotus parnellii) adjusts its complex biosonar signal (pulse) during orientation and insect capture: 1) it lowers pulse frequency below its resting frequency (RF) to compensate for Doppler shift in returning echoes (DSC); 2) it decreases pulse intensity as echo intensity increases; 3) it lengthens pulse CF duration when it detects a flying insect; 4) it then decreases pulse duration and increases pulse repetition rate. The mustached bat's auditory cortex (AC) has several functional subdivisions for processing different types of biosonar information. Further, its highest vocalization center, the cingulate cortex (Cg), contains a motor map representing pulse frequencies emitted during Doppler-shift compensation (Gooler & O'Neill, 1987). We conducted ablation experiments to examine the relationship between these structures and these biosonar behaviors. Quantitative measurements of the behavioral adjustments were made by placing each bat on a pendulum which was swung towards a large target. The bats were then retested following large bilateral ablations by aspiration of the Cg , Cg followed by AC, AC, or DSCF area (a part of the AC). The Cg ablations had no measurable effect on any of these behaviors. In contrast, following AC ablation, the amount and stability of DSC significantly decreased, and reaction time increased. These bats' RFs became more variable post-ablation, and the RFs also showed a large transient increase immediately following each pendulum test session. The DSCF-ablated bats showed changes in DSC similar to those displayed by the AC-ablated bats. In conclusion: 1) the AC is involved in stabilization of the RF, and its DSCF subdivision is involved in "fine-tuning" of DSC; 2) the role of the Cg in biosonar behavior is enigmatic. (Supported by AFOSR grant #86-NL-192.)

ARE THE MECHANISMS OF DELAY-DEPENDENT INTEGRATORS FOR RANGING DIFFERENT IN TWO SPECIES OF BATS, LITTLE BROWN BAT AND MUSTACHED BAT? A. Berkowitz* and N. Suga. Dept. of Biology, Washington Univ., St. Louis, MO 63130.

For echolocation, the little brown bat, *Myotis lucifugus*, emits FM pulses with no harmonics. In the auditory cortex, many neurons show a facilitated response selectively to an artificial pulse-echo pair with a particular delay between them. Many of these respond at short latency to a single weak pulse and at longer latency to a strong pulse. This paradoxical latency shift could be responsible for delay-dependent facilitation. In contrast, the mustached bat, *Pteronotus parnellii*, emits CF-FM pulses with 4 harmonics. In the auditory cortex, neurons also show delay-dependent facilitation, but each responds selectively to a pulse at the fundamental paired with an echo at one of the higher harmonics. These neurons utilize delay lines created by sub-thalamic neurons tuned to the fundamental. This study investigates whether delay-dependent integration in *Myotis* occurs through a different mechanism. Using tungsten microelectrodes on unanesthetized animals, the relationship between delay-dependent facilitation and paradoxical latency shift was examined in cortical auditory neurons. For those neurons which showed both phenomena, the magnitude of the latency shift was highly correlated with the best delay for facilitation. This suggests that pulse and echo are distinguished by intensity and that superimposition of pulse and echo inputs onto integrator neurons underlies determination of target distance in *Myotis*. Our data also suggest that high intensity pulses evoke inhibition whereas low intensity pulses do not, and this may underly paradoxical latency shift. We conclude that *Myotis* delay-dependent integrators make use of paradoxical latency shift, a mechanism different from that employed for the same function in *Pteronotus*. (Supported by NIH research grant NS17333.)

ICV INJECTION OF CARBACHOL SUPPRESSES ACOUSTIC STARTLE RELATED EMG-AMPLITUDE. M.Th. Kaltwasser*, H.U.Schnitzler* (SPON: EBBS). Dept. of Animal Physiology, Univ. of Tuebingen, Morgenstelle 28, 7400 Tuebingen, Fed. Rep. Germany.

The acoustic startle response is a simple behavioral model for studying the neural mechanism underlying the transformation of a sensory input to a motor output. Several transmitters were found to modulate this short latency reflex. Since systemic injection of acetylcholine (Ach) antagonists enhances the startle response, and since an early relay station in the startle circuit, the cochlear nucleus, is cholinergic, the present study investigated the role of Ach in modulating the startle response at the cerebral level. Microinjection of 500ng carbachol (Ach agonist) into the lateral ventricle yielded a significant suppression of the startle related EMG-amplitude of the temporalis muscle. ICV injection of 500ng atropin (Ach antagonist) showed a slight tendency for enhancing the EMG-amplitude. These results suggest that Ach modulates the motor response to a high intensity acoustic stimulus. Preliminary data indicate that the last relay station in the startle circuit, the motor trigeminal nucleus, is not the target site for this cholinergic action.

442.10

TECTAL MODULATION OF ACOUSTIC STARTLE IN THE RAT. D. S. Leitner and M. E. Cohen. Psychology Dept., Saint Joseph's Univ., Philadelphia, PA 19131 & Dept. of Psychology, Bryn Mawr Col., Bryn Mawr, PA 19010.

Sensory events which do not themselves elicit startle (prestimuli) can alter the latency or amplitude of startle depending upon the amount of time by which the prestimulus precedes the startle-eliciting stimulus. Previous work has demonstrated that the inferior colliculus (IC) plays a role in the reduction of acoustic startle amplitude in the rat by auditory prestimuli. The present study investigated the role played by the superior colliculus (SC), a visual structure, in startle amplitude reduction.

Eighteen rats were pretested for acoustic startle amplitude reduction using auditory and visual prestimuli. Seven rats were then given SC lesions, 5 were given IC lesions, and 6 served as unoperated controls. All subjects were then posttested in a manner identical to the pretest.

Data analysis showed the SC group had a reliable pre- to posttest decrease in percent startle amplitude reduction produced by the visual prestimulus but no change in that produced by the auditory prestimulus, the IC group showed a significant decrease in amplitude reduction produced by the auditory prestimulus but not the visual prestimulus, and no changes were present in the amplitude reduction produced by either prestimulus in the control group. The SC group showed reliable latency reduction to the visual prestimulus when the interstimulus interval was reduced, indicating that they were still capable of processing visual stimuli. These data replicate and extend previous findings by demonstrating that the SC plays a prominent role in amplitude reduction by visual prestimuli.

MICRODIALYSIS SHOWS INCREASED DOPAMINE TURNOVER IN THE NUCLEUS ACCUMBENS DURING LATERAL HYPOTHALAMIC SELF-STIMULATION. G. A. Hunter, L. Hernandez and B. G. Hoebel. Dept. Psychol., Princeton Univ., Princeton, NJ 08544

Extracellular dopamine (DA), and its major metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), were measured in five rats trained to lever press for a fixed current of perifornical lateral hypothalamic (PFH) stimulation. A microdialysis probe was inserted into the posterior accumbens through a previously implanted guide cannula ipsilateral to the stimulation electrode, and a series of baseline samples was taken at 20 min intervals for analysis by high pressure liquid chromatography with electrochemical detection. After DA levels had stabilized, the animals were allowed to self-stimulate for 1 hr while sampling continued. Response rates were between 2400 and 3000/hr. Extracellular levels of DOPAC and HVA increased significantly, indicating an increase in DA turnover that persisted beyond the period of self-stimulation by about 40 min. Extracellular dopamine also tended to increase. These results demonstrate an increase in DA turnover in the accumbens associated with self-stimulation in freely moving rats. Stimulation of the PFH that induces feeding has also been shown to increase extracellular DA, DOPAC and HVA in another study (1) which suggests that DA turnover in the accumbens is involved both in the reinforcement of PFH self-stimulation and the induction of food intake.

DOUBLE-LABEL DEOXYGLUCOSE AUTORADIOGRAPHIC STUDIES OF UNILATERAL AND BILATERAL MEDIAL FOREBRAIN BUNDLE SELF-STIMULATION IN RATS. R.F. Ackermann and M.E. Phelps. Division of Nuclear Medicine and Biophysics, UCLA School of Medicine, Los Angeles, CA 90024.

We are studying intracranial self-stimulation (ICSS) responding with [F-18] fluorodeoxyglucose (FDG) and [C-14] 2-deoxyglucose (2DG) double-label autoradiography in rats having chronic bilateral medial forebrain bundle (MFB) electrodes. Double-label autoradiography allows visualization of two conditions in each animal: control vs. stimulation; left stimulation vs. right stimulation; and unilateral stimulation vs. simultaneous stimulation of both left and right electrodes. The FDG/2DG data obtained thus far have confirmed that unilateral MFB stimulation produces bilateral increased-utilization patterns (cf. Porrino et al., Science, 224:306-309, 1984); simultaneous stimulation of both MFB sites enhances the already bilateralized single-stimulation utilization patterns. These patterns comprised two areas not specifically noted in previous 2DG/ICSS studies: the dorsolateral mesencephalic tegmentum, and the cerebellum. Utilization in these two structures strongly resembled that reported for motor cortex stimulation (Sharp and Evans, J. Comp. Neurol., 208: 255-287, 1982). The cerebellum itself is an ICSS site (Ball et al., Physiol. Behav., 13:123-127, 1974), and may play a greater role in integrating the sensory-motor components of ICSS behavior than previously suspected (cf. Sharp and Gonzalez, J. Comp. Neurol., 234:498-500, 1985).

443.3

TWO PROPERTIES OF THE INTEGRATOR FOR REWARDING BRAIN STIMULATION. G. Fouriezos, S. Walker* and K. Paterson*. School of Psychology, University of Ottawa, Ottawa, Canada. K1N 6N5.

Four experiments evaluated the effect on self-stimulation frequency thresholds of altering baseline activity of the directly stimulated reward substrate. Baseline activity was altered by applying a continuous, low frequency of stimulation pulses while the rats pressed a lever to earn bursts of lateral hypothalamic stimulation at the same time. Continuous stimulation (0, 2, 5, 10 or 20 Hz) decreased frequency thresholds by its own frequency when it was applied to the same electrode (Expt 1) and by frequencies predicted by empirically determined summation levels when it was applied to a contralateral electrode (Expts 1 & 2). The effect was additive over a wide range of base frequency thresholds (Expt 3) but it was completely eliminated when the continuous stimulation was restricted to times between response-triggered bursts (Expt 4). We conclude, first, that the reward integrator defends an absolute threshold in the sense that it is not sensitive to baseline activity and, second, that the integrator accepts input only for the duration of the response initiated train.

443.4

INVOLVEMENT OF DOPAMINE D2 RECEPTORS IN THE REINFORCEMENT OF OPERANT BEHAVIOUR S. Nakajima Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada

Previously I have reported that a dopamine D1 receptors are involved in the neural mechanism of reinforcement. Now the effect of dopamine D2 receptor blockade on operant behaviour was examined using raclopride.

In the rats trained to press a bar to obtain food, injection (IP) of raclopride suppressed responding in a dose related manner. Another group of rats were trained to press a bar for electrical stimulation of the ventral tegmental area. Raclopride again suppressed responding in a dose related manner. Compared with food-reinforced responses, about 10 times smaller dose was sufficient to suppress self-stimulation. Responding for stimulation at 160 Hz was more easily suppressed than responding for 60 Hz. Injection of raclopride into the nucleus accumbens suppressed self-stimulation of the ipsilateral ventral tegmental area (ED 50 = 10μg).

Blockade of dopamine D2 receptors seems to interfere with the brain mechanism of reinforcement. (Raclopride was a gift of Astra Alab AB, Sweden)

443.5

EFFECTS OF ANTERIOR MEDIAL FOREBRAIN BUNDLE LESIONS ON SELF-STIMULATION OF THE LATERAL HYPOTHALAMUS AND VENTRAL TEGMENTAL AREA. B. Murray and P. Shizgal. CSBN, Concordia University, Montreal, Quebec H3G 1M8.

Psychophysical data suggest that reward fibers directly link the lateral hypothalamus (LH) and ventral tegmental area (VTA). As a step toward identifying the nuclei from which these fibers arise, we assessed the effect on self-stimulation of both the LH and VTA of electrolytically lesioning the anterior medial forebrain bundle (MFB). Changes in the rewarding effect were inferred from lateral displacements of rate-frequency functions. Lesions in 5 of the 7 rats displaced the rate-frequency functions for the LH and/or VTA sites toward higher frequencies (26-37% above baseline), an effect consistent with a decrease in the rewarding impact of the stimulation. The ineffective lesions were restricted to compartment 'c' of the anterior MFB (Nieuwenhuys et al. J. comp. Neurol., 1982, 206, 49) while the five effective lesions invaded the more lateral compartments, 'a', 'd', and 'e'. Thus, the shifts in the rate-frequency functions may have been caused by damage to neurons projecting through compartments 'a', 'd', and 'e', or neurons with somata in the lesioned areas of the antero-lateral MFB. Although these shifts could also have resulted from damage to ascending dopaminergic fibers, it is not clear that the distribution of these fibers is consistent with the differential effect of the medial and lateral lesions.

443.6

MODULATION OF COLLISION EFFECTS BY LESIONS: IMPLICATIONS FOR IDENTIFYING NEURONS SUBSERVING BRAIN STIMULATION REWARD. P. Shizgal and B. Murray. CSBN, Concordia University, Montreal, Quebec H3G 1M8.

Lesion methods have long been used to identify the neurons responsible for the rewarding effects of electrical brain stimulation. Unfortunately, the anatomical interpretation of such data is ambiguous. A decrease in the rewarding effect could be due to damage to the directly stimulated neurons, their efferents, or neurons that modulate transmission in the reward circuit. In contrast, a collision effect inferred from psychophysical data is consistent with a clear anatomical interpretation: The tips of the two stimulation electrodes lie along the axonal trajectories of a common population of reward neurons. By combining collision tests with lesions, we hoped to render the anatomical interpretation of lesion data less ambiguous. We reasoned that if a lesion destroyed some of the reward neurons undergoing collision, then the collision effect would decrease in size.

Trains of pulse pairs were applied to the LH and VTA, with each electrode delivering either the conditioning (C) or the test (T) pulses. Collision was inferred from an abrupt decrease in stimulation effectiveness as the C-T interval was decreased. In 2 of the 4 rats, a lesion aimed 1.5 mm anterior to the LH site decreased the collision effect by 25% to 30%. The simplest interpretation of these data is that the lesions damaged reward fibers directly linking the two sites.

443.7

SMALL LESIONS IN THE ANTERIOR VENTRAL TEGMENTAL AREA (VTA) ATTENUATE THE REWARDING EFFICACY OF LATERAL HYPOTHALAMIC (LH) SELF-STIMULATION. Paul W. Glimcher and C. R. Gallistel. Department of Psychology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Male rats (350g) were implanted with monopolar stimulating electrodes in the LH (A/P -2.2 to bregma; M/L 1.5 ;D/V 8.3 to dura) and in the anterior VTA (-4.6;0.7;7.8). Animals were trained to lever press for 0.5sec trains of 0.1msec cathodal pulses at both electrodes. The frequencies of these trains were systematically varied allowing identification of the frequency of stimulation which produced half maximal rates of lever pressing at a number of currents for each electrode. Small electrolytic lesions (300uA/20sec) were made at the VTA electrode. Frequencies necessary to produce half maximal responding at the same currents were again characterized. Animals showed post-lesion shifts in the efficacy of rewarding stimulation at the LH electrode as large as 0.9 log units (as measured by the rate/frequency function (Gallistel et al. *Psych Revs.* 88, 228-273). This work, considered in light of Bielajew & Shizgal's results (*J Neurosci.* 6, 919-929) suggests that a large portion of the reinforcing signal generated by the LH electrode passes through the VTA lesion site.

This work was supported by Grant NSF BNS86-19759.

443.8

SELF-STIMULATION AND ELECTRICALLY INDUCED LOCOMOTOR ACTIVATION IN THE LATERAL HYPOTHALAMUS OF THE RAT ARE MEDIATED BY DISTINCT NEURONAL SUBSTRATES. L. Velley, C. Verney*, E.Kempf* and B. Berger*. Lab. Psychophysiologie, Univ. Bordeaux I, Avenue des Facultés 33405 Talence Cedex France.

The respective roles of intrinsic neurons and of catecholaminergic fibers in two behaviors (self-stimulation and the increase of locomotion produced by non-contingent stimulation) elicited by electrical stimulation of the lateral hypothalamus (LH), were tested. Groups of rats were injected in one LH with either ibotenic acid (4 μg/0.5 μl), 6-hydroxydopamine (2 μg/0.5 μl) or with the vehicle of each neurotoxin. Eight days later all rats were bilaterally implanted with stimulation electrodes, one in the lesioned area, the other in the contralateral LH. Whatever the lesion or the behavior tested, the response of the unlesioned LH was similar to that of vehicle-injected rats. Self-stimulation was disturbed in the ibotenic acid lesioned LH but was not modified in the 6-hydroxydopamine treated LH despite losses of catecholamines in the hippocampus and in the striatum and despite a total disruption of the catecholaminergic fibers in the lesioned area. Conversely, the locomotor increase elicited by non-contingent stimulation, measured in the open-field, was normal in the LH lesioned by ibotenic acid, but was not present following stimulation of the 6-hydroxydopamine treated LH, thus indicating distinct neuronal substrates for the expression of these two behaviors.

443.9

EXCITOTOXIN LESIONS OF LATERAL HYPOTHALAMUS FAIL TO DISRUPT SELF-STIMULATION REWARD.
J.R. Stellar, M. Waraczynski, and F.S. Hall.* Psychology Dept., Northeastern University, Boston, MA 02115

Last year, we reported (Waraczynski & Stellar Neurosci.Absts.,13:1324,1987), that microinjections of the neuronal cell body excitotoxin, ibotenic acid, into the lateral hypothalamus (LH) also may produce bleaching on Weil stain, suggestive of axon demyelination. Because demyelination impairs the effectiveness of brain stimulation in recruiting axons, studies (e.g. cited in above ref.) showing depressed LH stimulation reward after excitotoxin may have exaggerated the role of indigenous cells in LH reward.

This year, we report results of ibotenic acid and NMDA lesions of LH in 23 rats, where microinjections were placed so that the area of demyelination was away from the electrode tip, but the area of neuronal cell loss enveloped it. LH reward was assessed with a standard rate-frequency paradigm(Behav.Neur., 101:832,1987). Lesions produced no-to-small (>0.1 Log Hz) decreases in LH reward unless the demyelination zone reached the electrode tip.

EFFECTS OF NALOXONE ON REWARD INDUCED BY DORSAL RAPHE ELECTRICAL STIMULATION: A STUDY USING THE CURVE-SHIFT PARADIGM. B.A. Robinson* and P.P. Rompré (SPON: S. Amir). Department of Psychology, Concordia University, Montreal, Quebec, Canada H3G 1M8.

The present experiment examined the effects of several doses of naloxone on bar-pressing for dorsal raphe electrical stimulation. After stabilization of self-stimulation, rats were tested on different days with vehicle-saline and three doses (2, 4 and 8 mg/kg) of naloxone administered in either an ascending or descending order of dosage. Curves relating bar-pressing rates to the stimulation frequency were obtained five times just before drug injection, and repeatedly 0 to 90 min after drug injection. Naloxone shifted the curve to the right, increasing frequency thresholds for dorsal raphe stimulation. The increase in threshold was not dose-dependent, the largest shift was observed (0.15 log unit) at 4 mg/kg, 60 to 90 min after the injection. Because naloxone reduced the maximal response rates by less than 10%, we inferred that the shift in frequency threshold was due to a decrease in the rewarding effectiveness of the stimulation. No significant difference was found between shifts in threshold obtained when the drug was administered in an ascending or a descending order of dosage. These results show that like rewarding stimulation of the medial forebrain bundle, rewarding stimulation of the dorsal raphe is inhibited by blockade of opiate receptors.

443.11

NUCLEUS ACCUMBENS OPIOIDS FACILITATE BRAIN STIMULATION REWARD. T.E.G. West* and R.A. Wise. Psychol. Dept., Concordia University, Montreal, Canada H3G 1M8.

The rewarding effect of intravenous opiates and lateral hypothalamic brain stimulation are both thought to depend at least in part on activation of the mesolimbic dopamine system. Opioids have rewarding actions both near the dopamine cell bodies and near the dopamine terminals, suggesting two sites of entry into the reward circuitry. However, morphine is reported to facilitate the rewarding effects of lateral hypothalamic stimulation when injected near the dopamine cell bodies but not near the dopamine terminals. That nucleus accumbens (NAS) opiates should be rewarding in their own right but should not potentiate rewarding hypothalamic stimulation seems paradoxical, and the present study further explored the effects of NAS microinjections of morphine (5, 10 & 20 ug) and the selective mu agonist DAGO (50, 200, & 800 ng). Each opioid had robust effects. Morphine decreased BSR threshold, shifting the rate-frequency function to 0.12 log units to the left with no change in asymptote. DAGO produced similar effects. The effects of both opioids were blocked by naloxone (1 mg/kg), indicating that the effects of the central opioid injections were receptor-mediated. These data thus confirm reward-potentiating actions of opiates in the region of dopamine terminals in nucleus accumbens; however, the potency of opioids in NAS seems less than that reported for ventral tegmental morphine injections.

443.12

DEPOLARIZATION INACTIVATION OF A9 OR A10 DOPAMINE NEURONS BLOCKS BAR-PRESSING FOR ELECTRICAL STIMULATION OF THE MEDIAL FOREBRAIN BUNDLE. P.P. Rompré, T. West*, S. McGaraughty* and R.A. Wise. Department of Psychology, Concordia University, Montreal, Quebec, Canada H3G 1M8.

Previous experiments have shown that systemic pimozide and ventral tegmental area (VTA) morphine can induce dopamine depolarization inactivation; this results in a complete suppression of bar-pressing for central gray brain stimulation reward (BSR). We now report the effects of systemic pimozide and morphine injections in either VTA or substantia nigra (SN), on medial forebrain bundle BSR. Estimates of BSR threshold were obtained using the curve-shift paradigm under different drug treatments. At low doses (2.5-5 ug), morphine in either the SN or VTA induced a significant decrease in BSR threshold. Higher doses (5-10 ug) of morphine given after a systemic injection of pimozide completely blocked bar-pressing. The behavior was reinstated with either central injection of muscimol (12.5-25 ng) or systemic baclofen (0.5 mg/kg). Because similar treatment with GABA agonists is known to reverse dopamine depolarization inactivation, we infer that blockade of bar-pressing after systemic pimozide and central morphine was due to blockade of dopamine cell firing.

443.13

SCH 23390 SHIFTS THE SELF-STIMULATION RATE-FREQUENCY FUNCTION BY 0.6 LOG UNITS. R.A. Wise and P.P. Rompré (SPON: A.A. Giovino). Psychol. Dept., Concordia University Montreal, Canada H3G 1M8.

D-2 dopamine antagonists block post-synaptic dopamine receptors and can cause feedback-mediated depolarization inactivation of dopaminergic cells. To determine if such inactivation might account for the precipitous nature of extinction of responding for brain stimulation reward, we assessed the effects of the D-1 antagonist SCH 23390, which blocks the effects of post-synaptic dopamine agonists with little or no effect on dopamine feedback mechanisms. Rats were trained to bar press for MFB stimulation and were tested on different days with ascending doses of SCH 23390 (0.01 to 0.32 mg/kg). At the highest dose tested, SCH 23390 shifted rate-frequency functions by 0.6 log units before lever-pressing failed completely; this is twice the maximum shift seen with the D-2 antagonist pimozide. The more graded attenuation of response under SCH 23390 is consistent with the hypothesis that the precipitous failure of self-stimulation under pimozide results from the combination of post-synaptic dopaminergic blockade with a failure of effective transmission in the dopaminergic link in the reward pathway--such a failure of transmission has been demonstrated electrophysiologically with several D-2 antagonists.

443.14

CHRONIC NEUROLEPTIC TOLERANCE AND SENSITIZATION IN THE CURVE SHIFT BRAIN STIMULATION REWARD PARADIGM. M.R.Lynch and R.J.Carey, VA Med Ctr & SUNY HSC, Syracuse, NY 13210

Haloperidol (Hal) induced catalepsy shows a tolerance with chronic treatment rather than sensitization which would be predicted by depolarization block hypotheses of delayed onset clinical effects. The present study was conducted to examine tolerance vs sensitization of motor vs "reward" effects in the curve shift paradigm. Acute 0.07 mg/kg Hal produced reliable increases in threshold for 100 hz biphasic square wave stimulation (0.1sec pulses, 0.1sec interval, 0.2sec train) to the VTA (platinum electrodes). Stimulation was begun at maximum intensity and decreased by 50μA every 5 min, with a 2-min time-out. N=4 rats received Hal 1 hr before testing (pre) for 26 days; n=4 received Hal post and n=4 vehicle pre. The latter two showed consistent rate-intensity functions over test days. The pre group showed tolerance to the threshold increasing effect but there is a suggestion of sensitization for rate suppressing effects in the asymptotic range. Reversing pre and post conditions argued against environmentally-specific tolerance. HPLC-EC of DA and its metabolites on chronic injection days 36-37 revealed partial tolerance to acute Hal-induced stimulation of DA turnover in both pre and post drug groups. Tolerance was evident from DOPAC/DA and HVA/DA ratios but not 3MT/DA. These findings question the relevance of threshold shifts for antipsychotic efficacy and emphasize the need for assessing mechanisms of chronic adaptation processes for different behavioral effects.

443.15

MOTIVATIONAL EFFECTS OF NEUROLEPTICS. H. M. Geyer III*, M. Cornfeldt, V. Ramirez*, R. Corbett* and S. Fielding. (Spon.: S. Puri). Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876.

A progressive fixed ratio (FR) schedule of milk reinforcement for nose-poke responses was used to assess the effects of neuroleptics. It was hypothesized that motivational deficits would appear as the FR increased and motor deficits would be present across all FR's.

The rats on a restricted diet were pretreated with various compounds, placed in chambers and their nose-pokes for dippers of milk (0.02 ml) were recorded. The performance was not reduced by diazepam at 5 mg/kg or imipramine at 20 mg/kg. However, haloperidol at 0.03 mg/kg, thioridazine at 10 mg/kg, Sch 23390 at 0.005 mg/kg and chlorpromazine at 0.31 mg/kg all reduced responding. The increase in maximum FR's from 12 to 24 and 48 did not effect the performance of saline treated rats. However, chlorpromazine at 0.31 mg/kg reduced the responding at FR 48 but not at FR 12, consistant with a motivational deficit and not motor impairment. Other neuroleptics have shown similar FR dependent decrements in performance, consistant with the clinical reports of neuroleptic induced "anhedonia". The test appears to provide a method for measurement of motivational changes induced by pharmacological agents.

443.16

AMPHETAMINE, APOMORPHINE, AND CHOLECYSTOKININ MODULATION OF DOPAMINE SYSTEMS AND LATERAL HYPOTHALAMIC REWARD F.S. Hall*, J.R. Stellar, M Rice*, C. Meyers* and S. Coffey* (SPON: E. Stellar). Psychol. Dept., Northeastern Univ., Boston, MA, 02115

Dopamine (DA) is accepted as playing an important role in lateral hypothalamic (LH) self-stimulation reward, but it is unclear if DA carries or modulates this reward signal.

Using the standard rate-frequency paradigm, we have confirmed that amphetamine (indirect agonist) increases LH reward in rats and that apomorphine (direct agonist) decreases LH reward. However, the argument that apomorphine disrupts normal DA LH reward signalling by producing non-contingent DA reward signals is not supported by our recent pilot work indicating that apomorphine microinjections into the nucleus accumbens increase LH reward.

In a still more fine-grained analysis based on the rate-frequency paradigm, Cholecystokinin (CCK) microinjection in medial accumbens may increase or decrease LH reward and decrease operant motor capacity, depending on anterior/posterior microinjection locus and on CCK dose (range, 1ng - 10ug).

HYPOTHALAMICALLY ELICITED FEEDING AND SELF-STIMULATION: TWO MODES OF INTEGRATION OF THE SAME AXONAL OUTPUT. M. Waraczynski and J.M. Kaplan*. Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104

Many perifornical hypothalamic electrodes that support self-stimulation also elicit feeding. Refractory period and conduction velocity estimates for the axons supporting these behaviors appear identical (Gratton and Wise, Abst. Soc. Neurosci., 11:1176, 1986), suggesting the electrode activates a common first-stage substrate.

The present experiment generates stimulation pulse frequency-response curves for a range of current intensities for self-stimulation and for elicited feeding, using bar press rate and ingestion rate, respectively, as dependent measures. For self-stimulation, increases in intensity shift the frequency-response curves to the left without changing asymptotic performance level. For elicited feeding, increases in intensity elevate the asymptotic ingestion rate, but do not appreciably change the location of the curve along the frequency axis. The qualitatively different parametric profiles obtained uncover radically different integrative processes, acting on output from a common substrate, mediating the respective behaviors.

REWARD VERSUS PERFORMANCE EFFECTS OF INSULIN AND 2 DEOXY-D-GLUCOSE ON SELF-STIMULATION. S.A. Frutiger, Psychology Department, University of Wisconsin-River Falls, River Falls, WI 54022.

In a previous study (Frutiger, 1986) insulin and 2 deoxy-D-glucose (2DG) were noted to increase latency to initiate a self-stimulation bout and to decrease the rate of self-stimulation. Since mild activity suppression was noted during periods of noncontingent stimulation at the same lateral hypothalamic sites, these changes in latency and rate cannot be unambiguously attributed to a decrease in the rewarding effect of stimulation. This study was designed to provide a more direct dissociation of changes in self-stimulation due to reward versus performance following insulin or 2DG injections.

Anesthetized male Long-Evans rats were implanted with bilateral lateral hypothalamic electrodes, tested for stimulation-bound eating and/or drinking and self-stimulation, and trained on a fixed interval 8 sec schedule of reward. A stable rate-pulse frequency function was established for each rat at a current intensity which had sustained 50% of asymptotic response rate with a 100 pulse/sec frequency and insulin (2U/kg, sc) and 2DG (200 mg/kg, ip) were tested in counterbalanced order. Drug effects on the locus of rise and asymptotic response rate will be evaluated for the first and second half of the 8 sec inter-reinforcement interval.

444.1

THE INCENTIVE MOTIVATIONAL PROPERTIES OF FOOD AND OPIATES ARE MEDIATED BY A COMMON BRAINSTEM SUBSTRATE. A.Bechara and D.van der Kooy. Neurobiology Research Group, Anatomy Dept., Univ. of Toronto,Toronto,Canada M5S 1A8.

The reinforcing effects of opiates are dependent on both their incentive and drive reduction properties. Bilateral ibotenic acid lesions(.2 *ul* of a 4 % solution on each side) of the tegmental pedunculopontine nucleus (TPP) abolished the morphine (2-10 mg/kg s.c.) conditioned place preferences produced in opiate naive but not in opiate dependent (60 mg/kg /day for 14 days) rats. These results suggest that the TPP mediates specifically the incentive motivational properties of opiates. Moreover, the incentive motivational and aversive withdrawl properties of opiates can be measured separately by pairing a novel place only with morphine in naive rats and only with morphine withdrawl in separate dependent rats. TPP lesions blocked the place preferences for the morphine paired environment, but not the place aversions to the withdrawl paired environment.

A similar set of experiments was carried out with food (Purina lab chow) rather than morphine as the reinforcer. TPP lesions did not block the food place preferences in food deprived (23 hours) rats, nor did they block the place aversions in food deprived animals conditioned to a place paired with the lack of food. However, TPP lesions did block the place preferences produced by food in sated rats. These sated rats (TPP lesions and sham controls) did not eat the food in the training environment , but controls still showed large preferences for the place paired with the uneaten food. We suggest that reinforcers can act through two parallel motivational mechanisms in the nervous system- a circuit through the TPP that mediates the impact of incentive stimuli, and an independent drive reduction mechanism processing homeostatic signals arising from within the organism.

444.2

AVERSIVE PROPERTIES OF OPIATE RECEPTOR BLOCKADE : EXCLUSIVELY CENTRAL MEDIATION IN NAIVE AND MORPHINE-DEPENDENT RATS. T.H. HAND, G.F. KOOB, L. STINUS and M. LE MOAL. INSERM U.259 - Université de Bordeaux II, Rue Camille Saint-Saëns, 33077 Bordeaux Cedex - France. and BCR1 - Scripps Clinic, La Jolla, CA 92037, USA

The motivational effects of exclusively peripheral or central opiate receptor blockade were studied using place conditioning. Intraventricular (ICV) methylnaloxonium (MN) produced place aversions in both naive (200-1000 ng) and morphine-dependent rats (50-500 ng). Interestingly, the full withdrawal syndrome ("wet dog shakes", jumping, hyperreactivity, teeth chattering, writhing, diarrhea, weight loss) was never observed, although some of these signs were occasionally seen in the dependent group at highest dose. Subcutaneous MN (0.03-10 mg/kg) was ineffective in naive rats and produced place aversions in dependent rats only at the highest dose (a dose at which some central blockade may have occured). These data suggest that the aversive properties of opiate receptor antagonism are centrally mediated in both naive and dependent rats, and that their enhancement in dependent rats results from a sensitized central mechanism rather than from the recruitment of a peripheral component. They also suggest that the so-called "withdrawal syndrome" may not be a suitable model for these aversive effects.

444.3

ESB OF LATERAL HYPOTHALAMIC FEAR/FLIGHT SITES IN RATS PRODUCES CONDITIONED PLACE AVOIDANCE. D.S. Sacks* and J. Panksepp. (SPON: K.F. Green) Dept. of Psych., Bowling Green State University, Bowling Green, OH., 43403.

Electrical stimulation of the brain (ESB) in the anterior lateral hypothalamic area (AHA) has been shown to produce behaviors indicative of emotional states (Behav. Brain Sci., 1982, 5:407). Stimulation-induced "fear" produces species-typical defensive and escape behaviors (Neurosci. Abst., 1987, #127.1), and the present study examined whether a conditioned place aversion would develop in an environment in which the AHA -ESB was applied.

The experimental group (n=6 rats) received the AHA -ESB on their prefered side of the shuttlebox and no ESB on the other for four pairings. The control group (n=6) experienced the same procedures but with no ESB. The animals' side preference was then reassessed.

After 4 pairings of the ESB with the previously preferred side of the test chamber, a reliable decrease in side preference was exhibited on the first test after training [$F(1,10)=96.2$, $p<.001$], as well as 3 days [$F(1,10)=234.9$, $p<.001$] and 7 days [$F(1,10)=83.7$, $p=.001$] afterwards.

This research demonstrates the ESB of the AHA generates an aversive affective state that produces strong avoidance of an environment in which such stimulation was received. These results support the contention that ESB of AHA sites which yield the unconditioned response of flight does generate a true emotional state resembling fear. Therefore, the AHA may be part of a neural circuit which mediates both the behavioral manifestations and internal experience of this emotion.

IS ESCAPE FROM "REWARDING" BRAIN STIMULATION DUE TO NOCICEPTIVE PROPERTIES OF THE STIMULATION? J. Pollock, J.E.G. Williams and C. Kornetsky. Laboratory of Behavioral Pharmacology, Boston Univ. Sch. Med., Boston, MA 02118.

Prolonged electrical stimulation to rewarding brain sites will elicit escape behavior in rats. The present experiment was designed to determine if this escape behavior is reinforced by the termination of a nociceptive stimulus or reinforced by the rewarding effects of the onset of the next stimulus. If an analgesic drug having no effect on rewarding brain stimulation raises the threshold and an hyperalgesic drug, also having no effect on rewarding brain stimulation, lowers the threshold for escape from stimulation to rewarding brain areas, it would argue that such stimulation is nociceptive. In the present experiment we determined the effects of two drugs that met the above criteria, ethylketocyclazocine (EKC) and naloxone (NX) respectively, on the threshold for escape from stimulation to the medial forebrain bundle-lateral hypothalamic (MFB-LH) area. Results indicate that EKC (0.5-1.0 mg/kg) raises the escape threshold whereas NX (8.0-16.0 mg/kg) lowers the escape threshold, suggesting that aversiveness of electrical brain stimulation to the MFB-LH is the result of the nociceptive quality of stimulation and not the result of the rewarding effects of the onset of stimulation. [(Supported in part by NIDA grant DA 02326 and Research Scientist Award DA 00099 (CK) and a Culpepper Award (JP)].

SELECTIVE LESIONS OF THE DUAL OLFACTORY SYSTEM AND CAT SMELL-ATTENUATED PLAY BEHAVIOR AMONG JUVENILE RATS. L. Crepeau* & J. Panksepp (SPONSOR: J. ROSSI III). Department of Psychology, Bowling Green State University, Bowling Green, OH 43403

Juvenile rat play was measured in the presence and in the absence of cat smell in groups of rats following damage to the main, accessory or both olfactory systems, following intranasal infusions of zinc sulfate [ZINC], transections of the vomeronasal nerve [VNX], or olfactory bulbectomy [OBX], respectively. Control group animals [CON] received either sham surgery or intranasal infusions of distilled water.

During days 1-5 of testing, half of each group (CON, ZINC, VNX & OBX) were tested in clean wood chip bedding, while the other half of each group (CON_2, $ZINC_2$, VNX_2 & OBX_2) was tested in bedding containing cat odors, & conditions were reversed during days 6-10. Olfactory discrimination was also tested daily following 7-8 hours of food deprivation. Animals were allowed 3 min to find a bait buried in wood chip bedding inside a 22 X 36 X 25 cm aquarium. Both the control and VNX groups had intact smell sense, while the ZINC and OBX groups were severely impaired.

Compared to testing in clean bedding, cat smell reduced pinning levels in the CON and ZINC groups by 81 and 30 percent, respectively, and rough-and-tumble activity by 64 and 15 percent. Play levels in the VNX and OBX were unaffected by the presence of cat odors. Cat odors also suppressed pinning and activity levels in the CON_2 and $ZINC_2$ groups, an effect which persisted in clean bedding during test days 6-10, apparently from the initial cat smell experience. Rates of play in the VNX_2 and OBX_2 groups remained stable.

Disinhibition of play among VNX group animals in the presence of cat smell indicates that the AOS may elaborate behavioural inhibition in the presence of olfactory cues which indicate danger to the animal.

THE PARAMETRIC STUDY OF A TASTE AVERSION MODEL OF DRUG DISCRIMINATION (DD) LEARNING. T.V. Jaeger* and R.F. Mucha, Addiction Research Foundation, Toronto, M5S 2S1; and Dept. of Pharmacology, Univ. of Toronto, Canada.

At last year's meeting, data of Kautz etal. and Martin etal. suggested that taste aversion may provide a baseline for DD learning requiring high sensitivity, such as with naloxone in naive animals and with intracerebral drugs. Therefore, we manipulated and examined a model using SC drug to predict in thirsty rats (Sprague-Dawley males) whether or not an emetic follows presentation of 4 mls of palatable fluid. Differential consumption of the fluid was found during daily training with 0.04 mg/kg fentanyl or 20 mg/kg pentobarbital as the drug cue and 30 to 120 mg/kg LiCl as the emetic, although learning was slower using two trials per day. As DD was seen whether the drug predicted safety or discomfort, the results were not due to an acute interaction of the flavor and drug; however, learning was more rapid and in more animals with learned safety. Fentanyl dose generalization tests indicated that 0.005 mg/kg was distinguished from saline in many learned-safety rats, but 0.01 mg/kg or more was required in the learned discomfort subjects. Also, fentanyl-trained rats did not recognize pentobarbital as drug, or vice versa. Therefore, DD can, indeed, be studied with a taste aversion model, but the identification of parameters of high sensitivity may require more work.

444.7

SOMATOSENSORY REGULATION OF NURSING BEHAVIOR IN RATS. J.M. Stern and S.K. Johnson*. Psychology Dept., Rutgers University, New Brunswick, NJ 08903.

Based on pup retrieval ability, maternal behavior in rats is thought to be under multisensory control, but the sensory regulation of nursing behavior has been neglected. We assessed the dam's display of the upright crouching posture, i.e., pronounced dorsal arch, splayed legs, and immobility, following manipulations meant to reduce perioral or ventral somatosensory stimulation from pups. Dams were separated from their litter for 4-6 h prior to the crouching test; pups were placed in the nest if retrieval ability was impaired.

Before nursing begins, dams typically engage in several oral behaviors, including retrieving, licking and rearranging pups. Deprivation of perioral stimulation from pups during early lactation (day 2) via local anesthesia of the dams' mystacial pads with lidocaine or via muzzling almost completely eliminated crouching (but not maternal interest), whereas all controls crouched, as did dams deprived of licking by mouth suturing. At 2 wks postpartum, when pups leave the nest and are active in initiating nursing bouts, perioral stimulation from the pups is not essential. At all stages of lactation, active nuzzling of the dam's ventrum by pups is required to elicit crouching. This was shown by providing dams with freshly killed, but still warm pups, with live but inactive, chilled pups, and with active pups rendered incapable of rooting effectively due to mystacial pad anesthesia. Such pups are retrieved, licked, and hovered over, but the crouching posture is not assumed. (Supported by NIMH Grant MH 40459.)

MEDIAL PREOPTIC AREA AFFERENTS AND MATERNAL BEHAVIOR IN THE RAT. M. Numan, J. McSparren*, and M.J. Numan*. Dept. of Psychology, Boston College, Chestnut Hill, MA 02167.

Knife cuts severing the lateral connections of the medial preoptic area (MPOA) disrupt maternal behavior in rats. In our first experiment we found that knife cuts which severed the dorsolateral connections of the MPOA disrupted maternal behavior as effectively as did full MPOA lateral cuts, while knife cuts which severed the ventrolateral MPOA connections were ineffective.

Our second experiment examined MPOA afferents severed by the lateral cuts. Full MPOA cuts, dorsolateral MPOA cuts, and ventrolateral MPOA cuts were made with a horseradish peroxidase (HRP) coated wire knife. Nuclear groups containing HRP labeled neurons after full and dorsolateral cuts, but not after ventrolateral cuts, will suggest areas afferent to the MPOA which may be important for maternal behavior. The results obtained so far indicate the presence of HRP labeled neurons in several regions. A preliminary finding of importance is that full and dorsolateral cuts label more cells in the posteromedial nucleus of the solitary tract (NST) than do ventrolateral cuts.

The results suggest that NST input to the MPOA may influence maternal behavior.

EFFECTS OF KAINIC ACID ON EMOTIONAL AND SENSORIMOTOR BEHAVIOR IN DOMESTIC CHICKS. L. Normansell, D. Zeisloft*, and J. Panksepp. Muskingum College, New Concord, OH 43762 and Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403.

Intraventricular administration of kainic acid (KA), a conformationally-restricted analog of the excitatory amino acid glutamate, has been shown to induce vocalizations in chicks (Soc Neurosci Abstr 13: 763, 1987). This capacity of KA to increase calling is more apparent when animals are tested under environmental conditions where baseline calling rates are generally reduced.

When chicks were tested alone surrounded by mirrors, in the dark in groups of four, when exposed to loud ambient sound levels, or when held in the cupped hands of the experimenter, KA-treated animals (.1-.25 µg) vocalized more frequently than did water-treated controls, suggesting that KA may disrupt processing of the visual, auditory, and somatosensory stimuli which influences call production.

Following KA administration, other behaviors of young chicks are also affected. KA-treated chicks fail to respond to a novel object placed into their immediate environment, they exhibit abnormal approach tendencies toward the remainder of their flock, they assume a fear-like squatting posture, and they make more errors than controls on a pebble floor task of visual discrimination.

Effects of KA on the current thresholds required to produce vocalizations by electrical stimulation was also investigated after stereotaxically-guided microinjection into the Midbrain Calling Region. Two min. after KA infusion (.5 µg), stimulation thresholds were increased about 18%, whereas thresholds in control animals tended to decrease. Following surgery, KA-treated chicks showed only a slight reduction in calling frequency when they were tested in isolation. Those animals, however, did not respond to the presence of their own mirror images by a suppression of calling, suggesting a long-term disruption of visual capability.

ETHOLOGICAL STUDY OF OPEN-FIELD BEHAVIOR. P. Kabai*, A. Lajtha, G. Kobor* and C. Vadasz. Neurochem. Div., The Nathan S. Kline Inst., Orangeburg, NY 10962.

Behaviors which follow each other in the behavior sequence by higher probability than chance tend to correlate positively, thus masking underlying motivational factors. A statistical method was developed to correct for the sequential effects on correlations among behaviors in the open-field (OF) test.

OF behavior of 200 mice, a complete generation of a longterm neurogenetic study, starting from F_2 generations of 3 inbred strains (Vadasz, C. et al, J. Neurogen., 4:241-252, 1978), was monitored using an event registration software, ETHOGRAM, developed in our laboratory. Occurence of 16 behaviors was recorded. Behavior sequences were higher than second order Markov chains i.e. the probability of the occurence of a behavior is dependent at least on the two preceding acts. Factor analysis of the corrected correlation matrix yielded 6 factors which were labeled as EXPLORATION (rearing and leaning), ESCAPE (climb and jump on wall), DIRECTION CHANGE (backstep while rearing and turn), URINATION and two GROOMING factors. Defecation had a negative loading on one of the grooming factors and a small positive one on "escape".

These results demonstrate that the narrow interpretation of OF tests (in terms of EXPLORATION and EMOTIONALITY) is an oversimplification of the complexity of OF behavior.

444.11

SELECTED LINES OF RATS DIFFER IN THEIR RESPONSIVITY TO SUCCESSIVE NEGATIVE CONTRAST AND BENZODIAZEPINE TREATMENT. G.A. ROWAN & C.F. FLAHERTY. Psychology Dept, Rutgers Univ. New Brunswick, N.J. 08904

The consummatory behavior of rats shifted from 32% to 4% sucrose declines to a level substantially below that of unshifted rats that have experienced only 4% sucrose. This negative contrast effect involves a stress component (corticosterone elevation) and the decrement is attenuated by administration of the benzodiazepine tranquilizers.

The present experiments investigated the behavior of two selected lines of rats that have been shown to differ in "emotionality". The Maudsley Reactive (MR/Har) and Maudsley Nonreactive (MNRA/Har) rats and the Syracuse High and Low Avoidance rats (SHA/Bru and SLA/Bru) were both compared to a large population (N=397) of nonselected rats in terms of their negative contrast effect. The results demonstrated that the "nonemotional" rats in both selected lines (SHA and MNRA) showed reliably smaller decrements in licking when shifted from 32% to 4% sucrose than is typical in unselected rats. The SLA rats (high emotional) showed marginally larger contrast effects than the unselected rats. However, the MR rats, selected for open field defecation, showed significantly smaller contrast effects than the unselected population.

Chlordiazepoxide (8 mg/kg) was differentially effective in reducing the negative contrast in the selected lines.

EFFECTS OF ACUTE PHENYTOIN ON CORTICAL EVENT-RELATED POTENTIALS. E.S. Barratt, S.A. Shappell, M.E. Brandt*. Dept. of Psychiatry and Behavioral Sciences, University of Texas Medical Branch, Galveston, Texas 77550-2777.

Acute dosages of phenytoin have been shown to have an effect on both the early and late cortical event-related potentials while subjects observed light flashes at three intensities (Barratt, et al., Neuropsychobiology, 15:201-207, 1986). In this double-blind, placebo controlled study, phenytoin (100mg) significantly decreased the amplitude of the N100 component (reducing) and enhanced the frontal negative portion of the slow wave but did not effect the posterior portion of the P300 wave form. The current study extended this research by: (1) using 2 dosages of phenytoin (100mg and 200mg); (2) having subjects perform 2 additional tasks (oddball and go/no-go). The phenytoin related regional differences in ERP's were consistent with the previous study at both dosages. However, the 200 mg dosage had more generalized cortical effects. These experiments involved the use of a topographical analysis of EEG's (Cappola, et al., Comput Biol Med, 12:191-199, 1982). The results are consistent with the hypothesis that phenytoin effects cognition by acting on frontal cortical areas during information processing.

444.13

UNIT ACTIVITY IN THE HIPPOCAMPUS AND TEMPORO-BASAL CORTEX RELATED TO ATTENTION AND MEMORY IN THE BEHAVING MONKEY. T.R.Vidyasagar*,E.Salzmann* and O.D.Creutzfeldt(SPON:J.Kulikowski).Max Planck Institute for biophys. Chem.,Göttingen, FRG.

Single and multiunit activities were recorded from the hippocampus and temporo-basal cortex, as the monkey(Macaca fascicularis) was performing a delayed match-to-sample (DMS) task or during a variety of behaviour situations that involved attention, expectation, reward or position in egocentric space. Only a minority of neurones gave significant responses related to the DMS task. In contrast, many cells responded vigorously to situations involving the experimenter or particular emotional or motivational states of the animal. For example, many units responded (or were inhibited) during the time the monkey was shown a piece of food that was about to be given to him or while consuming it. Others were activated or inhibited when the experimenter entered or left the room, sometimes the response being dependent on the location of the event relative to the monkey. It is possible to interpret the responses in the DMS tasks as being more related to changes in motivational or attentional states of the animal during the task than to the process of memory storage itself.

444.14

THE EFFECTS OF BENZODIAZEPINES, 5HT1A AGONISTS AND ETHANOL ON NATURAL ANXIETY/DEFENSIVE BEHAVIORS OF RATS TO A CAT. R.J. Blanchard, D.C. Blanchard* and J. Rodgers. Psychology Department, Univ. of Hawaii, Honolulu, HI 96822.

Rats living in a Visible Burrow System connected to a "surface" area show a complex pattern of changes when a cat is briefly placed in the surface area, or when a cloth containing cat odor is left there. Initial patterns of withdrawal and avoidance include flight from this area to the tunnels, freezing in the tunnel/burrow system, and avoidance of openings to the surface area. These give way to a pattern of risk assessment. Nondefensive behaviors including grooming, eating, drinking and aggression are inhibited.

We are examining the effects of GABA/BZP compounds, 5HT1A agonists, and ethanol on the various behaviors measured in this situation. Results indicate that these three anxiolytic compounds produce different profiles on this task.

444.15

INFLUENCE OF TASK-COMPLEXITY AND SUBJECTIVE ESTIMATES OF INTEREST VALUE ON EVENT-RELATED POTENTIALS TO COMPLEX VISUAL STIMULI

V. Hömberg * and H. Schuhmacher*, University of Düsseldorf (SPON: European Neuroscience Association).

We have shown before that several late positive components of event-related potentials (ERP) to complex visual stimuli are systematically related to subjective experience of interest value. (Hömberg et al., Ann. NY. Acad. Sci. 425: 216-222).

This study was designed to look at the influence of difficulty of semantic processing, subjective scalings of interest value and stimulus repetition on ERPs to complex visual stimuli. 7 male volunteers were confronted with up to 500 objects presented tachistocopically for 150 ms. EEG was taken from various mid-line electrodes referred to linked mastoids. Averages were composed over tasks of various complexity and according to subjective estimates of interest value.

Principle component analyses revealed multiple partially overlapping late positive components: a parietally prepondenant P300 and a fronto-centrally dominant P800 were systematically related to demand of semantic processing as well as to psycho-physical estimates of interest value. Later prefrontally dominant positive component (LPC) was related to the difficulty of processing but not to interest value. P300, P800 and LPC simularly habituated with repetitive presentation of the same stimulus.

Multiple long latency ERP with different topography are systematically related to difficulty of semantic processing.and subjective experience of interest value.

OPIOID INJECTIONS INTO THE BED NUCLEUS OF THE STRIA TERMINALIS: EFFECTS ON FOOD INTAKE.

B.A. Gosnell. Dept. of Psychiatry, University of Michigan, Ann Arbor, MI 48109-0116.

The stria terminalis is a major efferent pathway from the amygdala, and enkephalin-containing fibers have been demonstrated in this pathway and in the bed nucleus of the stria terminalis (BNST) (e.g., Uhl et al., Brain Res. 149:223-228, 1978). In this report, the possibility was tested that the BNST may contribute to the increased feeding observed after systemic or icv injections of opioid agonists. Cannulas were implanted unilaterally into the BNST of male Sprague-Dawley rats. In a repeated measures design, the mu opioid agonist DAGO was injected into the BNST at doses of 0 (NaCl), 0.1, 0.3, and 1 nmol. In a separate group of rats, the selective delta agonist DTLET was tested at the same doses. The 1 nmol dose of DAGO caused a small but significant increase in 2 and 4 hr food intake. Intake was also increased after DTLET (1 nmol), although the effect fell just short of statistical significance. These experiments suggest participation of the BNST in the control of food intake. However, due to the proximity of the BNST to the lateral ventricle, it is possible that the effects are due to a diffusion of the peptides into the ventricle and an action at other brain sites. Studies are in progress to determine whether the BNST and stria terminalis play a role in the stimulation of intake by injections of DAGO into the amygdala (Gosnell, Neuropharmacol. 27:319-326,1988).

445.2

NEW PHENYL PIPERIDINE OPIOID ANTAGONISTS: THEIR EFFECT ON MU AND KAPPA ANALGESIA IN MICE AND ON FOOD CONSUMPTION IN THE OBESE ZUCKER RAT.

C.H. Mitch*, D.M. Zimmerman*, L.G. Mendelsohn, W. Shaw*, B.E. Cantrell*, J. Reel*, J. Snoddy* and J.D. Leander. Lilly Research Laboratories, Indianapolis, Indiana 46285. (SPON: M.J. Schmidt)

Following our initial discovery of potent pure opioid antagonist activity within the trans-3,4-dimethyl-4-phenylpiperidine series (D.M. Zimmerman, et al, Nature, 275, 332, 1978), we have greatly expanded the SAR in an effort to find new opioid antagonists with enhanced selectivity. A variety of trans-3,4-dimethyl-4-phenylpiperidines differing in the nitrogen substituent were synthesized. These were evaluated as opioid antagonists and for their effect on food consumption in the fatty Zucker rat. While several of these compounds were found to have exceptional potency as opioid antagonists and in reducing food consumption, LY255582 [(3S,4R)-1-((S)3-hydroxy-3-cyclohexylpropyl)-4-(3-hydroxy-phenyl)-3,4-dimethyl-1-piperidine) emerged as having the best overall activity profile. It has an affinity for mu and kappa receptors of 0.41 nM and 2.02 nM, respectively. In mice, it antagonizes 1.25 mg/kg (s.c.) morphine (mu) and 2.5 mg/kg (s.c.) U-50, 488 (kappa) induced analgesia with AD50 values of 0.01 mg/kg (s.c.) and 0.07 mg/kg (s.c.), respectively. In the Zucker rat, a dose of 0.05 mg/kg (s.c.) reduced 4 hour food consumption to 80% of control. LY255582 has promise as a potent opioid antagonist and appetite suppressant.

445.3

EFFECTS OF OPIATES AND THEIR ANTAGONISTS ON WATER INTAKE OF POLYDIPSIC INBRED MICE.

Y. Hattori*, T. Katafuchi*, K. Koizumi and E. Silverstein*. Departments of Physiology and Medicine, SUNY,Health Science Center at Brooklyn, Brooklyn, NY 11203

Previously we have reported that the sensitivity of neurons in the subfornical organ (SFO) and AV3V of the polydipsic strain of mice (STR/N) differs from that of controls (non-polydipsic, STR/IN and Swiss/Webster mice). The primary polydipsia, which amounted to 3 to 5 times that of controls, was greatly reduced by administration of naltrexone in polydipsic strain but not in controls. Following intracerebroventricular injection of naltrexone through minipump for 7 consecutive days, the earlier reduction in drinking was followed by a rebound in which drinking nearly doubled the amount observed in pre-injection period. This continued for more than 6 weeks after the end of the injection in this special strain. Recordings from neurons in the AV3V and the SFO in brain slice preparations showed that in all 3 groups of mice the opiates inhibited the neuronal activity, but the threshold for inhibitory action was higher in polydipsic than that found in the other two groups of mice, STR/IN and Swiss/Webster. Naltrexone or naloxone applied to the bathing medium did not change the activity of these neurons. Our results suggest the involvement of both angiotensin II and opiates in the polydipsia observed in this special strain (Supported by NIH,USPHS NS- 00847).

445.4

INTERACTION OF THE ENDOGENOUS OPIOID SYSTEM AND RADIATION IN THE SUPPRESSION OF APPETITIVE BEHAVIOR,

D.E. Morse, and G.A. Mickley, (SPON: J. McDonough) Dept. of Behavioral Sciences, AFRRI, Bethesda, MD 20814-5145

Endogenous opioids modify a wide variety of behaviors, including 'appetite'. Radiation exposure and other stressors have been reported to induce the release of endogenous opioids. Suppression of appetitive behaviors and loss of body weight are frequent consequences of radiotherapy (as used in cancer treatment). Still, the literature contains no information on the role of the endogenous opioids in postirradiation 'appetite' suppression. The present study examined interactions between the mu opioid system and radiation in post-exposure suppression of appetitive behaviors. Chronic opioid system blockade, with naltrexone, was found to partially ameliorate suppression of appetitive behaviors during the first 24 hours following radiation exposure. Post-exposure treatment with naltrexone was found to have nonsignificant effects on behavioral suppression. Administration of morphine was also found to have limited impact on the dose-effect and time-course of post-irradiation suppression of appetitive behaviors. The data suggest that changes in mu opioid system activity probably do not contribute to radiation induced 'appetite' suppression. Furthermore, the data suggest that, in clinical settings, pain control medications may not exacerbate radiotherapy induced appetite suppression.

445.5

ANTIBODIES TO DYNORPHIN A [1-8] AND [1-17] ELEVATE THRESHOLD FOR BRAIN STIMULATION-INDUCED FEEDING IN RAT. K.D. Carr, T.H. Bak* and E.J. Simon (SPON: M. Holland). Dept. of Psychiatry, NYU Med. Ctr., NY NY 10016.

We have previously reported that antibodies to DYN A [1-13] infused into the lateral ventricle (LV) produce a naloxone-like elevation in threshold for electrical brain stimulation-induced feeding (SIF) (Carr et al., Brain Res 422: 384, 1987). In the present study, antibodies to DYN A [1-8] and [1-17] were infused into the LV or meso-pontine aqueduct (AQ) to investigate the CNS level and DYN fragment that mediate SIF. LV infusions of antibodies to DYN [1-17] elevated the SIF threshold ($\bar{X}$=+23.6%; SEM=5.7; N=10) as did antibodies to DYN [1-8] ($\bar{X}$=+17.5%; SEM=7.3) when compared with the effect of normal rabbit serum ($\bar{X}$=-5.4%; SEM=3.5; N=5). AQ infusion of antibodies to DYN [1-8] produced a pronounced elevation in threshold ($\bar{X}$=+30.9%; SEM=5.9; N=5) as compared with normal serum ($\bar{X}$=+7.5%; SEM=10.6; N=5), while antibodies to DYN [1-17] did not ($\bar{X}$=+12.9%; SEM=9.7).

In our SIF paradigm, naloxone produces a marked pattern of progressive elevation in serially determined thresholds (Carr & Simon, Brain Res. 297:369, 1984). In the present study, a similarly marked pattern was produced only by DYN [1-8] antibodies infused into the AQ.

These results suggest that DYN [1-17] and [1-8] may both mediate SIF, and that DYN [1-8] activity in some caudal periventricular structure(s) may contribute prominently to the opioid mediation of feeding as revealed by naloxone antagonism. (Supported by NIDA grant DA03956 to K.D.C.)

445.6

OPPOSITE EFFECTS OF ROSTRAL AND CAUDAL VENTRICULAR INFUSION OF NOR-BINALTORPHIMINE ON STIMULATION-INDUCED FEEDING. T. Bak*, K.D. Carr, E.J. Simon and P.S. Portoghese#. Dept. of Psychiatry, NYU Med. Ctr., NY NY 10016 and #Dept. of Med. Chem., Univ. Minn. Med. School, Minneapolis, MN 55455.

The electrical brain stimulation threshold for eliciting feeding is elevated by centrally administered antibodies to the putative endogenous kappa ligand, dynorphin A (Carr et al., Brain Res. 422:384, 1987). In the present study, nor-binaltorphimine (nor-BNI), a selective kappa receptor antagonist (Portoghese et al., Life Sci. 40:1287, 1987), was used to evaluate kappa mediation of stimulation-induced feeding in the rat.

Lateral ventricular (LV) infusion of nor-BNI (50 ug) elevated mean stimulation frequency threshold from 16.5 pps (± 1.2; N=7) to 21.6 pps (± 2.6). A 25 ug dose of nor-BNI had no effect. Naloxone (100 ug) elevated threshold from 15.5 pps (± 1.2; N=6) to 18.1 pps (± 1.0).

When antagonists were delivered via the meso-pontine aqueduct (AQ), nor-BNI (50 ug) reduced the feeding threshold from 16.5 pps (± 1.4; N=4) to 13.2 pps (± 1.0), while naloxone still elevated threshold. AQ infusion of the selective kappa agonist, U50,488 (100 ug & 200 ug) produced a modest elevation in threshold [e.g. from 17.9 pps (± 1.8) to 20.4 pps (± 2.4)].

These results suggest that kappa opioid activity in rostral periventricular structures may facilitate feeding while kappa activity in caudal periventricular structures may inhibit feeding. (Supported by NIDA grant DA03956 to K.D.C.)

445.7

EFFECTS OF EXERCISE & RESTRICTED FEEDING ON WEIGHT LOSS AND BETA-ENDORPHIN LEVELS IN THE RAT: IMPLICATIONS FOR ANOREXIA NERVOSA. L.E. Doerries*, P.F. Aravich, A. Metcalf*, J.D. Wall* and T.J. Lauterio* (SPON: D.B. West). Dept. Psychology, Christopher Newport College, Newport News, VA 23606; Dept. Anatomy & Cell Biology and Dept. Internal Medicine, Eastern Virginia Medical School, Norfolk, VA 23510.

It has been proposed that exercise may be a risk factor for anorexia nervosa. It also has been proposed that anorexia nervosa is related to elevated beta-endorphin levels. We have begun a systematic examination of the phenomenon of activity-based anorexia in which exercise produces profound, voluntary anorexia in rats maintained on restricted-feeding schedules. The phenomenon also has been related to increased beta-endorphin levels. We now report that: 1) activity-based anorexia is associated with reliable elevations in circulating beta-endorphin compared to restricted feeding without exercise; 2) absolute arcuate hypothalamic beta-endorphin, although tending to be lower, is not affected reliably (beta-endorphin content relative to tissue protein will be reported later); and 3) chronic naloxone infusion (SQ) does not prevent the development of activity-based anorexia and, in fact, potentiates it. We conclude that beta-endorphin alterations are correlated with activity-based anorexia, but do not precipitate the syndrome.

445.8

EFFECTS OF EXERCISE & RESTRICTED FEEDING ON GLUCOPRIVIC EATING IN THE RAT: IMPLICATIONS FOR ANOREXIA NERVOSA. P.F. Aravich, L.E. Doerries*, E. Stanley*, A. Metcalf* & T.J. Lauterio*. Dept. Anat. & Cell Biol. and Dept. Int. Med., Eastern Virginia Med. Sch., Norfolk, VA 23510; Dept. Psychol., Christopher Newport College, Newport News, VA 23606.

Anorexia nervosa (AN) is associated with a variety of neuroendocrine and behavioral disorders, including an impaired ingestive response to 2-deoxy-D-glucose (2DG) glucoprivation. Unfortunately, it is often difficult to distinguish between the primary abnormalities of AN versus the secondary consequence of severe emaciation. Because of increased interest in the relationship between exercise and AN, we are beginning a systematic examination of "activity-based anorexia" in the rat, which is produced by superimposing exercise on a restricted-feeding schedule. We now report that activity-based anorexic rats differ from body-weight matched control rats with respect to the behavioral response to a 2DG challenge. Specifically, whereas 2DG-treated activity-based "anorexic" rats fail to increase food intake relative to saline-treated "anorexic" rats (9±1 vs. 10±2 g, respectively; p>.05), 2DG-treated body-weight matched animals reliably decrease food intake compared to saline-treated body-weight matched controls (8±1 vs. 12±1 g, respectively; p<.05). Beta-endorphin responses as a function of treatment condition will be reported later.

445.9

NALOXONE POTENTIATION OF EFFECTS OF CHOLECYSTOKININ (CCK) AND LiCl ON OXYTOCIN (OT) SECRETION, GASTRIC MOTILITY AND FEEDING. L.M. Flanagan, J.G.Verbalis, E.M. Stricker. Depts. of Behavioral Neuroscience and Medicine, University of Pittsburgh, Pittsburgh, PA 15260

Neurohypophyseal secretion of OT in response to dehydration, hypovolemia, and parturition in rats is known to be potentiated by the opioid antagonist naloxone (NX). The present studies demonstrated that stimulation of OT secretion by systemic injections of CCK and LiCl likewise is potentiated by NX. Moreover, the inhibitory effects of CCK and LiCl on gastric motility and feeding similarly were enhanced by NX. Because neurohypophyseal hormone secretion and inhibition of gastric motility are known to be mediated by oxytocinergic neurons projecting from the paraventricular nucleus of the hypothalamus, this parallel potentiation by NX of CCK- and LiCl-induced effects on OT secretion, gastric motility, and food intake suggests that: 1) OT pathways are likely involved in some aspects of central control of feeding behavior, and 2) endogenous opioid peptides are likely involved in regulation of this and other oxytocinergic neuronal systems in rat brain.

CHOLECYSTOKININ (CCK) SUPPRESSES GASTRIC MOTILITY BUT MAY NOT STIMULATE PITUITARY OXYTOCIN (OT) SECRETION IN LACTATING RATS. E. Thiels, D. L. Helmreich, J. G. Verbalis, E. M. Stricker. Departments of Behavioral Neuroscience and Medicine, University of Pittsburgh, PA 15260.

CCK is known to cause a correlated inhibition of gastric motility and stimulation of OT secretion in male rats. We report here the effects of CCK on gastric motility and OT secretion in virgin females and lactating rats 8 to 16 days postpartum. CCK given ip decreased gastric motility in both groups of female rats: by 40-60% for 10-20 min after 0.01 ug/kg CCK and by more than 60% for longer than 60 min after 10 ug/kg CCK, values comparable to those seen in male rats. In contrast, 1-10 ug/kg CCK increased plasma OT levels by 3-10 uU/ml in virgin females as in male rats, but had no effect on OT secretion in lactating rats. These results suggest that hypothalamic magnocellular neurons in lactating rats may become insensitive to the effects of systemic CCK, whereas the hypothalamic parvocellular neurons that mediate inhibition of gastric motility remain fully responsive to CCK. It is not yet clear whether this apparent dissociation between pituitary OT secretion and inhibition of gastric motility also is seen when lactating rats are given other treatments that elicit both responses in male and virgin female rats. (Supported by NIMH research grant MH-25140.)

THE EFFECT OF CHOLECYSTOKININ OCTAPEPTIDE ON FOOD INTAKE AND MATERNAL BEHAVIOR OF LACTATING AND POSTWEANING RATS. S.A. Wager-Srdar and A.S. Levine. Neuroendocrine Research Laboratory, VA Medical Center and University of Minnesota, Minneapolis, MN, 55417.

Cholecystokinin octapeptide (CCK-8) decreases food intake in a number of species. Behavioral studies have shown that CCK-8 elicits a sequence of behaviors similar to those of post-prandial satiety. It has been found that CCK-8's satiating effect is altered during lactation. We examined the effect of CCK-8 (5 ug/kg) (ip) on early dark cycle food intake and maternal behaviors of rats in early, mid and late lactation and the postweaning (PW) period. Food intake was decreased by CCK-8 during early [$F(1,99) = 4.017$] and during mid [$F(1,99) = 6.80$], but not late lactation or PW and these findings are similar to those of earlier studies. During lactation and the PW period, the rate of food consumption was decreased by CCK-8 compared to the saline group [$F(1,30) = 19.59$]. The average meal length was not altered by CCK-8. However, the latency to the first meal was increased 33-47% during lactation but not during PW. The maternal behaviors, nursing and pup interaction were not altered by CCK-8. Resting and sleeping behaviors were increased by CCK-8 [$F(1,30) = 24.04$], and exploratory behavior was decreased [$F(1,30) = 17.59$]. CCK-8 altered food intake during lactation by decreasing the rate of consumption and increasing the latency time to the first meal. Maternal behavior was not affected by CCK-8 in this study.

INSENSITIVITY OF DIABETIC (DB) RATS TO CHOLECYSTOKININ (CCK)-INDUCED SATIETY. M.A. DellaFera and B.D. Coleman*. Dept. Int.Med. Washington U. Sch.Med. St. Louis, MO 63110

Streptozotocin-induced diabetes in rats results in development of hyperphagia and changes in exocrine pancreatic and gastrointestinal function. The following study was carried out to determine the relative sensitivity of DB and control (C) rats to satiety induced by CCK-8 administered IP, and to determine changes in sensitivity over time after induction of diabetes. Male Sprague Dawley rats (6/group) were given 0, 2 and 4 ug/kg CCK-8 IP (Latin square design) after a 6 hr fast on weeks 1, 3, 5, 7, and 9 after administration of streptozotocin (S) or control (C). As early as 1 wk after S, DB rats failed to respond to CCK-8, whereas there was a clear dose-response effect in C rats. By week 9 there was still no significant decrease in food intake for DB rats, although there was trend toward a decrease; C rats still exhibited a significant dose-related decrease in intake. Diabetes results in increased rate of gastric emptying, a function partially controlled by CCK induced contraction of the pyloric sphyncter. The slowing of emptying results in distention, which may be an important signal of satiety. Defects in CCK receptor mechanisms have been identified in the pancreas of DB rats; if the same is true for pyloric CCK receptors, this could be a possible mechanism for the insensitivity to CCK's satiety effect. Supported by NIH NS20000 and Monsanto Co.

445.13

CHOLECYSTOKININ (CCK) ANALOGS AS PROBES IN ASSESSING THE SITE OF ACTION OF CCK SATIETY. T.H. Moran, T.K. Sawyer*, R.T. Jensen*, R.J. Crosby* and P.R. McHugh. Department of Psychiatry, Johns Hopkins Univ, Baltimore, MD, 21205. Biopolymer Chemistry, Upjohn Co., Kalamazoo, MI, 49001. Digestive Diseases Branch, NIH, Bethesda, MD, 20892.

Roles for both pyloric and vagal CCK receptors in the mediation of CCK satiety have been proposed. The present work examines two CCK analogs for differences in their affinity for pyloric and vagal CCK receptors, potency in stimulating in vitro pyloric contraction and in inhibiting feeding as a means to identify the site of action of CCK satiety. The analog structures are: 1) Ac-Asp-Tyr[SO_3H]-Nle-Gly-Trp-Nle-Asp-Phe-NH_2, 2) Ac-Asp-Phe[p-NH_2]-Nle-Gly-Trp-Nle-Asp-Phe-NH_2

	IC_{50} pyloric binding	IC_{50} vagal binding	EC_{50} pyloric contraction	Threshold 30 min feeding	Threshold 60 min feeding
CCK	1.1 nM	0.7 nM	0.8 nM	0.5 ug/kg	5.0 ug/kg
1	0.4 nM	0.5 nM	0.7 nM	.01 ug/kg	.01 ug/kg
2	720 nM	29 nM	>500 nM	>100 ug/kg	--

The Nle substitution does not alter the affinity for the receptor populations, but does significantly increase the satiety potency. However, the Phe[p-NH_2] substitution results in differential affinity for the receptor populations. Its lack of potency in in vitro and feeding tests is consistent with a pyloric site for CCK satiety.

HIGH DORSAL COLUMN TRANSECTION ATTENUATES BOMBESIN-INDUCED SUPPRESSION OF FOOD INTAKE. Ellen E. Ladenheim and Robert C. Ritter. Dept. of VCAPP, Washington State University, Pullman, WA 99164

The suppression of food intake after peripheral administration of bombesin (BBS) is partially mediated by spinal-visceral afferent neurons (Stuckey et al., 1985). However, sensory information from abdominal structures can utilize several different spinal pathways. In order to ascertain the importance of the dorsal column-medial lemniscal system in BBS-induced suppression of feeding we examined the ability of BBS to suppress short-term food intake in rats with high dorsal column transection. We have found that the suppression of feeding induced by peripherally administered BBS was significantly attenuated in rats with dorsal column transection compared to sham-operated controls ($p < .02$). Intraperitoneal injection of 4ug/kg BBS reduced 30 min intake of a palatable solid food (cookies) by 63.1% $\pm$ 5.8 in control rats while those with dorsal column transection reduced intake by 41.6% $\pm$ 7.5. Food intake following a baseline injection of 0.9% saline was not significantly different between groups ($p > .05$) These results indicate that high spinal cord transection of the dorsal column pathway interrupts a population of neurons which participate in BBS-induced suppression of feeding.

BUPRENORPHINE DETOXIFICATION IN OPIOID ADDICTS: DOSE EFFECTS. T.A. Kosten, J.H. Krystal, C.M. Morgan*, H.D. Kleber*, and T.R. Kosten*. Dept. of Psychiatry, Yale Univ., New Haven, CT 06519.

Pharmacological treatment of opioid addicts have used either methadone (MET), an opiate agonist, or naltrexone (NLX), an opiate antagonist. Successful detoxification from MET to NAL has been limited. Buprenorphine (BUP) is a partial opioid agonist which at higher doses can act as an opioid antagonist. An optimal treatment dose would substitute for MET without withdrawal symptoms, block opioid induced euphoria, and then allow detoxification to NLX. To determine this dose of BUP, we assigned 39 opiate addicted patients to one of three dose groups: 2, 4 or 8 mg. BUP dose was not related to treatment retention or to frequency of illicit opioid use: less than 20% of the patients left and only 22% of the urines contained opioids. Patterns of withdrawal symptoms differed across groups with the 4 mg group showing a decline in symptoms as shown by the significant effects of time ($p<.01$) and dose x time ($p<.05$). A moderate dose of BUP shows promise as a transitional agent from MET maintenance to NAL abstinence without causing serious withdrawal symptoms.

L-HISTIDINE BLOCKS THE EFFECTS OF PENTAZOCINE ON BRAIN-STIMULATION REWARD. S. Rassnick*, C. Decker* and C. Kornetsky. Laboratory of Behavioral Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Previous results indicate that the antihistamine tripelennamine potentiates the threshold lowering effects of pentazocine (PEN) (Pharm. Biochem. Behav. 21:961, 1984) on brain-stimulation reward, a model of drug-induced euphoria. To determine histamine's role in this interaction we studied the effects of the combination of L-histidine (LHIS) and PEN on the threshold for brain-stimulation reward. As in previous studies PEN alone (2.5-10.0 mg/kg) lowered the threshold for rewarding stimulation to the medial forebrain bundle-lateral hypothalamus in male F-344 rats. Also LHIS (500 and 750 mg/kg) by itself had no significant effects, yet antagonized the threshold lowering effects of PEN. This interaction may be selective for opioids with kappa receptor activity since LHIS failed to antagonize the threshold lowering effects of morphine (Fed. Proc 46(3):404, 1987). These results suggest that central histamine may be involved in the reinforcing effects of PEN. [(Supported in part by NIDA grant DA 02326 and Research Scientist Award DA 00099 (CK)].

PRECIPITATED WITHDRAWAL IN MONKEYS AFTER REPEATED DAILY ADMINISTRATION OF DIFFERENT BENZODIAZEPINES.

J. R. Martin, R. Cumin* and W. E. Haefely. Pharmaceutical Research Department, F. Hoffmann-La Roche & Co., Limited, CH-4002 Basle, Switzerland.

Relative physical dependence potential of four marketed benzodiazepines was assessed in monkeys in a flumazenil-precipitated withdrawal paradigm after the repeated oral administration of doses previously shown to be equieffective in producing a loss of righting reflex.

Squirrel monkeys received 18 daily oral administrations of 2 mg/kg alprazolam (A; N=4), 30 mg/kg diazepam (D; N=4), 1 mg/kg flunitrazepam (F; N=4), 280 mg/kg oxazepam (O; N=5) or vehicle (N=4). IV flumazenil injection 5 hours after the ninth daily treatment precipitated withdrawal (convulsions, tremor and/or vomiting were observed during a subsequent 1 hr period) in 1 A-, 4 D-, 1 F-, 4 O-, and no vehicle-treated monkeys. A second IV flumazenil injection given 5 hours after the eighteenth daily treatment resulted in withdrawal in 4 A-, 4 D-, 3 F-, 3 O-, and no vehicle-treated monkeys.

Thus, repeated oral administration of A, D, F, or O at equieffective doses produced physical dependence which was manifested as flumazenil-induced withdrawal signs in the majority of monkeys.

446.4

EFFECTS OF OPIATE AND DOPAMINERGIC DRUGS ON NOVELTY PREFERENCE BEHAVIOR.

M. T. Bardo, J. L. Neisewander and R. C. Pierce*. Dept. of Psychology, University of Kentucky, Lexington Kentucky, 40506.

Previous research has demonstrated that animals prefer a novel environment over a familiar environment. The present studies investigated the role of opioid and dopamine systems in novelty preference behavior. Rats were familiarized with a distinct environment by being confined to that environment for 30 min per day on eight consecutive days. On the ninth day, rats received either morphine sulfate (0, 0.1, 0.3, 1.0 or 3 mg/kg, s.c.), naltrexone hydrochloride (0, 0.1, 0.3 or 1.0 mg/kg, s.c.), amphetamine sulfate (0, 0.1, 0.3 or 1.0 mg/kg, s.c.) or haloperidol (0, 0.03, 0.1, 0.3 or 1.0 mg/kg, i.p.). Thirty min after injection, rats were allowed free-choice access to the familiar environment and to a novel environment for 15 min.

As expected, saline-injected control animals spent significantly more time in the novel environment than in the familiar environment. More important, the novelty preference behavior was counteracted in a dose-dependent manner by haloperidol, whereas amphetamine, morphine and naltrexone had no significant effect. These results indicate that novelty preference behavior involves a dopaminergic substrate.

STIMULUS PROFILES OF AGONIST-ANTAGONIST OPIOIDS IN A DISCRIMINATION AMONG TWO DOSES OF MORPHINE AND SALINE IN PIGEONS.

A.M. Young, M.A. Walton, and A.N. Perkins. Dept. of Psychology, Wayne State University, Detroit, MI 48202.

Experiments evaluated the discriminative stimulus profiles of selected opioids in pigeons trained to discriminate among saline and two doses of morphine (MS). Pigeons (N=15) were trained to discriminate among i.m. injections of saline (SAL), 1.8 mg/kg MS (the low dose or LD cue), and 10 mg/kg MS (the high dose or HD cue). Performance was maintained under FR 30 schedules of food delivery in 30 min sessions. After establishment of stimulus control, various doses of MS, alone and in combination with naltrexone, and doses of other opioids were tested for generalization. For MS itself, LD generalization predominated at doses of 1.0 to 3.2 mg/kg; HD generalization at doses of 5.6 to 32 mg/kg. Naltrexone pA2 values for antagonism of the LD and HD cues were similar, suggesting that the discrimination was based on quantitative differences between the LD and HD cues. The agonists etorphine and methadone and the agonist-antagonists dezocine and GPA 1657 evoked dose-dependent generalization to both the LD and HD cues. In contrast, the agonist-antagonists nalbuphine and nalorphine evoked generalization to only the LD cue and, in other experiments antagonized the HD cue. These profiles suggest that a discrimination among saline and different MS doses may provide information about the agonist efficacy of agonist-antagonist opioids. (Supported by DA03796.)

ORAL SELF-ADMINISTRATION OF ETHANOL FACILITATES REWARDING ELECTRICAL BRAIN STIMULATION.

M. Moolten, G.T. Bain and C. Kornetsky. Laboratory of Behavioral Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Many substances, including ethanol, which are readily abused in humans, have been reported to increase the sensitivity of animals to rewarding brain stimulation, a model of drug-induced euphoria. The reported effects of ethanol are less than robust, and notably variable. This variability may be due to differences in testing procedures as well as stress due to route of ethanol administration (typically intraperitoneal). In an attempt to resolve some of these ambiguities we employed a rate free threshold procedure with rats that orally self-administered ethanol.

Bipolar stainless steel electrodes were stereotaxically implanted in the medial forebrain bundle of male F-344 rats. Animals were water deprived, and then allowed to drink an ethanol-sucrose solution prior to testing. Significant threshold lowering effects were observed, which persisted throughout the testing session, at doses between 0.8 g/kg and 1.6 g/kg depending on the individual animal's sensitivity. These threshold lowering effects in animals self-administering ethanol suggest that the same pathways that subserve the reinforcing effects of other abused substances may be involved, at least in part, in the reinforcing effects of ethanol. [(Supported in part by NIAAA grant AA05950 and Research Scientist Award DA 00099 (CK)].

NALOXONE-INDUCED REDUCTION OF VOLITIONAL ETHANOL INTAKE CORRELATES WITH SPONTANEOUS PREFERENCE.

L. Pulvirenti & A.J. Kastin. VA Med. Ctr. & Tulane Univ. Sch. Med. New Orleans, LA 70146.

Recently, the possibility of a common mechanism for the reinforcing properties of ethanol and opiates has been proposed on the basis of biochemical and behavioral data. This prompted us to study the effect of the administration of naloxone (NAL), an opiate antagonist, and Tyr-MIF-1, a brain peptide with anti-opiate properties, on ethanol intake in rats with a free choice of water.

In the first study, NAL significantly reduced intake of ethanol at the doses of 1,2 and 4 mg/kg intraperitoneally. This effect was particularly evident in "high-preferring" rats (ethanol/total fluid intake > 60%) and was absent in "low-preferring" rats (ethanol/total fluid intake < 30%). Furthermore, a significant correlation ($P < 0.001$) was found between the degree of spontaneous preference (ethanol/total fluid intake ratio) and the reduction of ethanol intake induced by NAL at all doses tested ($r = -0.658$, $r = -0.742$, $r = -0.695$ for the doses of 1,2 and 4 mg/kg respectively). In the second study, Tyr-MIF-1, was ineffective in altering preference for ethanol in the free choice paradigm.

These results further support the hypothesis that the endogenous opiate system plays a role in the rewarding value of ethanol as measured by volitional drinking. The fact that a correlation was present between the degree of spontaneous preference and NAL-induced inhibition, suggests that the proposed genetic predisposition for alcoholism might involve a role for the opiate system.

446.8

THE EFFECTS OF PRENATAL, POSTNATAL AND COMBINED EXPOSURE TO ETHANOL ON LEARNING AND ON HIPPOCAMPAL CELL DENSITY IN WEANLING RATS.

T. Wigal, N.J. Lobaugh and A. Amsel. University of Texas, Austin, TX 78712.

Neonatal rats were exposed to ethanol during postnatal Days 4 to 12 by employing an artificial rearing procedure to administer either 3.0% ethanol (E) or isocaloric maltose/dextrin (C) in a milk formula. These pups were from mothers fed either a liquid ethanol (E) or a control (C) diet on gestational Days 1 to 21. This 2x2 design yielded four treatment groups: CC, CE, EC, and EE.

On postnatal Days 20 to 21 the pups learned an approach response, under either continuous (CRF) or partial (PRF) food reinforcement, which was then extinguished. The partial reinforcement acquisition effect was eliminated in CE, EC, and EE, and the partial reinforcement extinction effect was attenuated in EC and EE and was absent in CE.

Hippocampal cell density was determined at midtemporal level, showing a 12% reduction in CA1 pyramidals and an 11% reduction in mature granules after prenatal exposure to ethanol (EC and EE). The CA4 area was significantly larger after postnatal exposure (CE and EE). There was no effect on immature granule cells. Significant positive correlations were found between extinction slopes after PRF training and CA1 pyramidal-cell density in animals from Groups CC and CE. A significant negative correlation was found between extinction slopes after PRF training and CA4 area in animals from Group EE.

BIPHASIC EFFECT OF THC ON GLUCOSE UPTAKE IN RAT HIPPOCAMPUS. J. E. Margulies* and R. P. Hammer, Jr. Dept. of Anatomy & Reproductive Biology, Univ. of Hawaii, Honolulu, HI 96822.

Delta-9-tetrahydrocannabinol (THC) causes memory impairment and neurophysiologic alteration in hippocampus. We used the tritiated 2-deoxy-D-glucose (2DG) autoradiographic method to examine the effect of acute administration of THC on regional brain metabolism in hippocampus of male rats. Various doses of THC (0.2, 0.5, 2.0 and 10 mg/kg), solubilized in 5% propylene glycol and 0.5% Tween 80, were injected via intracardiac cannulae followed in 10 minutes by a pulse of 2DG (1.0 mCi/250 g). Animals were decapitated forty-five minutes after 2DG administration. Sham-operated control animals received the same dose of vehicle without THC. THC altered 2DG uptake in a biphasic manner in hippocampus and other limbic structures. The 0.2 mg/kg dose significantly increased 2DG uptake in the stratum lacunosum-moleculare (SLM) of the hippocampus, whereas doses of 2.0 and 10 mg/kg significantly decreased 2DG uptake in the SLM. THC produced differential effects on the pyramidal cell layer and stratum oriens of CA1 and CA2-3. These layers in CA2-3 responded to THC biphasically, however 2DG uptake in these regions of CA1 was unaltered at low doses of THC. Thus, certain regions of the hippocampus are more sensitive to THC. This dose sensitivity may reflect a specific effect of THC as opposed to a nonspecific effect seen at higher doses. Supported by USPHS awards RO1 DA03885 and KO4 NS01161.

Δ^9-TETRAHYDROCANNABINOL (THC) INHIBITS ARACHIDONIC ACID ACYLATION IN GUINEA PIG CEREBRAL CORTEX SLICES. M. Reichman*, W. Nen*, and L.E. Hokin* (SPON: J.L. Dahl) Dept. of Pharmacology, Univ. of Wisconsin Med. School, Madison, WI 53706

The mechanism of action of THC, the major active ingredient in marihuana, remains unclear. We have found that THC increases unesterified arachidonic acid (AA) levels in guinea pig cerebral cortex slices prelabeled with [^{14}C]AA. We report here that the mechanism underlying this rise involves an inhibition of AA acylation, rather than activation of lipolytic enzymes. The incorporation of AA into brain lipids was measured by incubating cerebral cortex slices with [^{3}H]AA for 1 hr at 37°C without and with THC. The lipids in the tissue were extracted and separated by thin layer chromatography, and the radioactivity in the individual phospholipids and neutral lipids was measured. Treatment with THC concentrations in the range of 2-32 μM elicited dose-dependent and saturable reductions in the esterified [^{3}H]AA levels in membrane lipids. The IC_{50} was on the order of 8 μM, and a maximal reduction in radioactivity of 50% occurred at 32 μM. We observed concomitant rises in the levels of unesterified [^{3}H]AA. The levels of radioactivity were significantly reduced in both the neutral lipid and phospholipid fractions, although the largest decreases in radioactivity were observed in phosphatidylinositol; the levels of [^{3}H]AA in phosphatidylcholine were not significantly affected by THC. Our results indicate that the mechanisms underlying the THC-induced elevation in unesterified AA involve an inhibition in the acylation of membrane lipids, and suggest that inositol-containing phospholipids may play an important role in the mechanisms mediating the response.

TOLERANCE STUDIES AND BRAIN NICOTINIC RECEPTORS: A COMPARISON OF CHRONIC NICOTINE TREATMENTS IN RATS. Allan C. Collins and Jeanne M. Wehner. Inst. Behav. Gen., Sch. of Pharm., Univ. of Colorado, Boulder, CO. 80309

Rats were treated for 7 days either with twice daily injections of nicotine (0.8 mg/kg), or by continuous subcutaneous infusion of nicotine (0.8 mg/kg/hr). Behavioral tolerance was assessed using open-field activity and hypothermia. Brain nicotinic receptors were evaluated using ^{3}H-nicotine (NIC) and ^{125}I-a-bungarotoxin (BTX) binding. Chronic injections resulted in tolerance and an up-regulation of NIC binding in cortex and hippocampus, but no change in BTX binding was seen. Tolerance was not lost by 8 days after withdrawal from injections, but levels of NIC binding had returned to normal. After infusion tolerance and an up-regulation of both NIC and BTX receptors was observed in five regions. Tolerance was completely lost and normal levels of NIC and BTX binding had returned in most regions by 8 days after withdrawal from infusion. These results indicate that: 1) continuous infusion produced more substantial changes in NIC and BTX binding and 2) tolerance was longer lasting after chronic nicotine injections than after nicotine infusion. We conclude that the long-lived behavioral tolerance produced after chronic injection may be confounded by other behavioral changes not directly related to nicotine tolerance. RECEPTIVE FIELD PROPERTIES AND MORPHOLOGY OF NEURONS IN THE SUPERFICIAL LAYERS OF THE SUPERIOR COLLICULUS OF NEONATALLY ENUCLEATED HAMSTERS. M.M. Nikoletseas, R.D. Mooney and R.W. Rhoades, Medical College of Ohio, Toledo, OH 43699.

Intracellular recording and horseradish peroxidase injection techniques were used to characterize 84 neurons from the stratum griseum superficiale and stratum opticum of 42 hamsters that sustained removal of both eyes on the day of birth. Of the 84 recovered cells, 90.5% (N=76) responded to somatosensory stimulation. These responses were often weaker and receptive fields were more diffuse than for somatosensory neurons recorded in the deep laminae. The vast majority (62.5%) of the recovered neurons were horizontal cells; 12.5% were widefield vertical cells, 3.1% were narrow field vertical cells, 6.3% were stellate cells, and the remainder (15.6%) could not be classified. In the superficial SC laminae of normal adult hamsters (Mooney, R.E. et al. J. Neurosci. 5:2989, 1985), horizontal cells constituted only 13.6% of a sample 59 recovered neurons; 20.3% were widefield vertical cells, 17.0% were narrow field vertical cells, 23.7% were stallate cells, 13.6% were marginal cells, and 11.9% could not be classified. These results suggest that the change in afferent input to the superficial laminae that follows neonatal enucleation may result in either dendritic remodelling or differential survival of neurons with horizontally oriented dendrites. Supported by EY 04170 and BNS 85 00142.

VIMENTIN AND GFAP EXPRESSION IN DEVELOPING HAMSTER SUPERIOR COLLICULUS. D.Wu*, S.Jhaveri*, K.L.Moya and G.E.Schneider. Dept. Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139. (Spon: J.S. Barlow)

Immunolocalization of vimentin (antibody courtesy of R.McKay) in the neonatal hamster SC reveals a radial pattern of cells fanning out from the ventricular zone. Staining of vimentin-positive cells is observed on postnatal days 1-3 (P1-P3, where P0=day of birth); it is considerably decreased on P5 and P7. However, staining of glial end feet and portions of radial cell processes attached to the pial surface persists at least until P7. A group of labelled cells around the aqueduct of Sylvius shows a tuft of processes that are positioned along the tectal midline. These cells consistently express vimentin even at later stages of development.

Immunohistochemical labelling with an antibody to GFAP (Boehringer), on the other hand, reveals little staining within the SC. The major exception to this is the group of aqueductal cells with processes along the midline, which are intensely GFAP positive. They are co-localized with vimentin-containing cells and may comprise the same population. The GFAP and vimentin-positive processes are in the same position as the "axon-refractory wedge" observed in ultrastructural studies of the tectal midline (see Poston et al., Neurosci. Abs.'88). It is known that destruction of this midline tissue in newborn hamsters which also have one eye removed is sufficient to result in abnormal crossing of the midline by axons from the remaining retina.

EARLY DEPRIVATION PRODUCES MOLECULAR AND MORPHOLOGICAL CHANGES IN CAT LATERAL GENICULATE NUCLEUS AND VISUAL CORTEX. A. Guimarães and S. Hockfield. Section of Neuroanatomy, Yale Univ. Sch. of Med., New Haven, CT 06510.

Monoclonal antibody Cat-301 recognizes a surface associated antigen on a subset of neurons in the adult mammalian CNS (Hockfield and McKay, 1983, Proc. Natl. Acad. Sci. 80: 5758). In the cat dorsal lateral geniculate nucleus (LGN) Cat-301 expression on Y-cells is sharply reduced by early visual deprivation (Sur et al., 1988, J. Neurosci. 8: 874). In order to further study experience-dependent alterations in the expression of molecular species in visual pathways, new born Balb/c mice were injected with homogenized, dissected LGN from dark-reared cats to induce an immunosuppression of antigens present in deprived tissue, and were immunized with normal cat LGN to elicit an immune response selectively to experience-dependent antigens. Monoclonal antibody Cat-304, which recognizes a surface associated antigen on neuronal cell bodies and proximal dendrites, was generated. In normal cat LGN, Cat-304 labels cells in laminae A, A1 and C, in interlaminar zones and in the medial interlaminar nucleus. In dark-reared cat LGN the number of labelled cells is markedly reduced. In cortical area 17, Cat-304 positive cells are densely distributed in two bands, in layers IV and VI. Labelled cells are also present in layers II, III and V. In area 17 of dark-reared cats, the number of antibody positive cells is reduced. The loss of antibody positive cells is most pronounced in layer VI, but layers II, III and V also contain fewer stained neurons than normal. The reduction in expression of Cat-304 antigen in dark-reared cat visual cortex is paralleled by that of Cat-301. Double-label experiments show that Cat-304 and Cat-301 recognize distinct sites on the same cell populations in LGN and area 17. These results suggest that the expression of an antigen (or antigens) recognized by Cat-304 and Cat-301 is mediated by visual experience from birth.

POSTNATAL DEVELOPMENT OF NEURONS AND OPTIC TRACT AXON ARBORS IN THE HAMSTER DORSAL LATERAL GENICULATE NUCLEUS: IN VITRO HRP STUDY. P.G. Bhide*1,2, A.R. Lieberman*2 and D.O. Frost1. 1Sect. Neuroanat., Yale Univ., New Haven, CT 06510 and 2Dept. Anat., Univ. Coll. London, WC1E 6BT.

Neurons and optic tract (OT) axons (including terminals) in the dorsal lateral geniculate nucleus (LGd) were labeled with HRP in brain slices and their morphology analyzed. On the day of birth (P0), the majority of labeled neurons resemble immature projection neurons and some resemble immature interneurons (e.g. Parnavelas et al., 1977, J. Comp. Neurol. 171:481). Their processes bear growth cones at the tips and on the trunks and are predominantly oriented towards OT. Some transiently invaginate and form synapses with OT axons and may induce the latter's collateralization. During the third week, growth cones disappear and mature dendritic patterns emerge.

The OT has 2 components: superficial optic tract (SOT) axons form a sheet on the surface of LGd, whereas fascicles of internal optic tract (IOT) axons course through LGd, parallel to SOT. In adults, only SOT axons have thalamic collaterals (Schneider & Jhaveri, 1983, Neurosci Abs. 9:809). On P0, IOT axons emit transient collaterals to the ventrobasal complex (Langdon, et al., 1987, Neurosci. Abs., 13:1023). At this stage, SOT axons are largely unbranched. A few emit collaterals restricted to the superficial LGd. Such collaterals proliferate and reach the deep border of LGd by the end of the first postnatal week. During the second week, SOT collaterals begin to form arbors which, towards the fourth week, resemble those in the adult. Thus, the development of OT axons is characterized by 3 modes of growth: elongation, collateralization and arborization

MONOCULAR ENUCLEATION AT BIRTH ALTERS THE DISTRIBUTION OF DISTINCT TYPES OF RETINO-GENICULATE TERMINALS IN THE HAMSTER. R.S. Erzurumlu, S. Jhaveri* and G.E. Schneider. Dept. Brain & Cognitive Sciences, M.I.T., Cambridge, MA, 02139.

The distribution of morphologically distinct retinogeniculate terminals was analyzed in adult hamsters which had one eye removed on postnatal day 1. Retinal terminals were labeled with HRP implants in the optic tract (OT) ipsilateral or contralateral to the remaining eye.

Normally there is a segregation of R1 and R2 terminals within the dorsal nucleus of the lateral geniculate body (LGBd) (see Jhaveri et al., Neurosci. Abs. 1988). Neonatal enucleation results in partial atrophy of the LGBd and an expansion of the territories occupied by the remaining eye. Contralaterally, the deafferented ipsilateral projection zone is occupied by R1 and R3 terminals only. Large numbers of R1 terminals are also found in the superficial zone, where they normally would not be present. Furthermore, R2 terminals, normally located superficially, now form abnormally large clusters and extend deeper into the nucleus. Ipsilateral to the remaining eye, the expanded retinal projection is comprised of R1 and R3 terminals only. In these cases R1 terminals are seen subjacent to the OT, a location normally occupied by R2 terminals from the contralateral eye. R2 terminals, on the other hand, are not present in the expanded ipsilateral projection .

These results indicate that morphology of retinofugal axon terminals may be dictated by retinal ganglion cell specificity and survival rather than by their target environment. The altered distribution of different terminal types within the LGBd, following neonatal monocular enucleation, also suggests an anomolous convergence of inputs from different types of retinofugal axons onto geniculate neurons.

ABNORMALLY PROJECTING RETINAL AXONS DISPLACE GAP-43 POSITIVE TERMINALS IN THE LATERAL POSTERIOR NUCLEUS OF THE THALAMUS. K.L.Moya, L.Carman*, L.I.Benowitz and G.E.Schneider. Dept. Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139 and Dept. of Psychiatry, Harvard Med. Sch., McLean Hosp., Belmont, MA 02178.

Lesions of the superior colliculus (SC) in neonatal hamsters are followed by regeneration of the damaged retinal ganglion cell axons over the lesioned area and the formation of abnormal, dense patch-like retinal projections in the LGN and LP. Immunocytochemical localization of GAP-43, a membrane phosphoprotein associated with neuronal growth, using a monospecific antibody has revealed that the LP shows relatively heavy staining in normal adult hamsters. We have found that in animals which had received an early lesion of the SC, GAP-43 staining was excluded from the areas of the LP that received retinal input, while the areas of LP that did not receive retinal imput showed the normal high levels of GAP-43. The source of GAP-43 positive terminals remains to be determined: lesions of the posterior cortex or SC do not diminish GAP-43 staining in the LP. In addition, shortly after ibotenic acid lesions of the LP, overall levels of GAP-43 were not reduced.

These results show that retinal ganglion cell axons, which lose their GAP-43 positive staining in the early postnatal period, do not persist in the expression of GAP-43 even when induced to project into an area normally high in this protein. Furthermore, it appears that the retinal terminals may displace GAP-43 positive axon terminals resulting in the abnormal GAP-43 negative areas in LP after early SC lesions.

MORPHOLOGICAL MATURATION OF IDENTIFIED PROJECTION NEURONS IN THE CAT'S LATERAL GENICULATE NUCLEUS (LGN). D. Raczkowski, C.-S. Lin, and W.L. Salinger. Dept. of Neurobiol., Duke Univ., Durham, NC 27710 and Dept. of Psychol., Univ. of North Carolina, Greensboro, NC 27412.

In these experiments, we examined how the adult structure of geniculocortical neurons develops by injecting rhodamine microspheres into the visual cortex of early postnatal and adult cats and, subsequently, viewing brain slices of the LGN with epi-fluorescent microscopy so that retrogradely labeled neurons could be injected intracellularly with FITC-HRP. In the adult brain slice, all three classes (1, 2, and 4) of geniculate projection neurons were recognized. In the neonate (kittens 3-5 weeks of age), neurons resembling each morphological class also could be identified. Although many class 1 and class 4 geniculate cells in the central representation of the visual field possess adult-like dendritic arbors at these ages, most class 2 neurons do not. Despite these differential rates of maturation, geniculate cells in every class at these ages exhibit morphological features not seen in the adult. These include more proximal dendrites, an increase in the number and assortment of dendritic appendages and, occasionally, exuberant intrageniculate axonal arbors. These transitory dendritic features suggest that developing neurons in the LGN actively participate in the acquisition and maintenance of synaptic interactions with their inputs. Supported by EY06951, NSF8519709, NIMH04849, and NSF8606570.

ANALYSIS OF SYNAPTOGENESIS USING MULTIPLE ULTRASTRUCTURAL CRITERIA IN THE RAT VISUAL CORTEX AND SUPERIOR COLLICULUS. B.W. Bakkum, L.A. Benevento and R.S. Cohen. Dept. of Anatomy and Cell Biology, Univ. of Illinois at Chicago, Chicago, IL 60612.

We examined the developmental patterns and time course of synaptogenesis in the developing rat visual cortex (VC) and superior colliculus (SC). The synaptic parameters measured have already been implicated as morphological correlates of plasticity but, taken together, have not been extended to deprivation studies. The VC, SC, and as a control, the temporal cortex of Sprague-Dawley rat pups, raised either in 14 hrs light/10 hrs dark or in total darkness, were fixed at postnatal days (PND) 7, 14, 21 and 28 and processed for EM analysis according to standard procedures. In the SC of light/dark-reared animals the number of synapses increased up to PND-21 and then declined. Other parameters which follow the same developmental pattern are positively curved and straight synapses, asymmetrical, dendritic, and spinous synapses. However, symmetrical synapses and negatively curved synapses peaked earlier at PND-14 and then also declined. In the VC the number of synapses at PND-7 was about equal to that found in the SC. This number also increased up to PND-21, but the number of synapses/unit area was twice as great as in the SC. This number declined to adult levels by PND-28. Asymmetrical, straight, and axospinous synapses follow a similar pattern. Symmetrical and negatively curved synapses peak at PND-14 before declining, whereas positively curved synapses increase to PND-28. There were low numbers of perforated postsynaptic densities and axosomatic synapses in the VC and SC at all stages. Dark-reared data suggest that there is little influence of sensory deprivation on the developmental patterns (i.e., trends) and time course of the aforementioned synaptic parameters. Supported by NIH Grant NS 15889.

EARLY MONOCULAR DEPRIVATION AND RAT BRAIN VISUAL SYSTEM 2-DEOXYGLUCOSE UPTAKE. R.M. Cooper and A. Jeeva.*
Psychology Dept., Univ. Calgary, Calgary, AB, T2N 1N4.

Hooded rats had one eye lid-sutured (MD) for 6 wk beginning at age 10 d. The rats were tested by binocularly exposing them to a display of stripes after the 2-DG injection. Autoradiographic analysis revealed that 2-DG uptake was greater in the LGN, VC and SC in the hemisphere lying contralateral to and primarily fed by the deprived eye. This "sensitization" effect has also been reported for dark-reared rats (Toga, A.W., Dev. Brain Res., 37: 209, 1987). Similar interhemispheric differences in 2-DG uptake, even in VC, arose when MD rats were tested with light-diffusing eye occluders. Thus the increase in 2-DG uptake may be attributed to a reduction in receptive-field specificity--normally, diffuse light has little or no effect on rat VC 2-DG uptake. But decreases in glucose utilization also occur after MD. In rats which had undergone MD for 12 wk the sensitization effect was confined to the more monocular portion of the contralateral LGN, while in the more binocular portion, 2-DG uptake was reduced. This same pattern of LGN uptake was also observed in 6 wk MD rats which were allowed 4 wk of "recovery." Thus, the deprived eye loses control in binocular regions and this process can continue even after sight is restored.

EFFECT OF MONOCULAR LID SUTURE, ENUCLEATION, AND RETINAL IMPULSE BLOCKAGE ON CYTOCHROME OXIDASE REACTIVITY IN LAMINAE II-III OF MACAQUE STRIATE CORTEX. T. C. Trusk, M. Wong-Riley, and W. Kaboord*
Dept. of Anatomy & Cellular Biology, Med. Col. of WI, Milwaukee, WI 53226.

We sought to quantify the size and numerical density of cytochrome oxidase-reactive and nonreactive neurons in control and experimental supragranular puffs (CP & EP) and intra control and experimental interpuffs (ICI & IEI) of monkeys subjected to monocular lid suture (MD), enucleation (ME), or retinal impulse blockage with tetrodotoxin (TTX). Nembutal anesthesia (30 mg/kg) was used during surgery and euthanasia. We found no cell loss in all experimental monkeys. The average size of reactive cells in CP and ICI were similar to those of normal monkeys. Numerical densities of reactive neurons were decreased in EP and IEI of all experimental monkeys. Their average size was reduced in MD and TTX. However, in a long term ME, the sparse population of remaining reactive cells were mainly medium and large in size. The average size of nonreactive neurons in EP remained similar to that found in CP. In contrast, they were consistently smaller in IEI than in ICI, and this difference was significant in adult and juvenile MD's (11 to 48 weeks). Optical densities (OD) of EP and IEI were consistently lower than those of CP and ICI. This depression was less severe in adult monkeys lid sutured for 11 weeks or given intravitreal TTX for 2 weeks; and was most severe in an adult treated with TTX for 4 weeks. Optical density of CP was within the range found in normal monkeys, while OD in ICI was consistently greater, and OD in IEI was lower than normal interpuffs. These results suggest that: a) metabolically active neurons of laminae II-III are more sensitive than less active cells to sensory deprivation in adults; and b) there is an increase in metabolic activity within the interpuff region innervated predominantly by the spared eye. EFFECTS OF VISUAL DEPRIVATION ON DENDRITIC MATURATION OF SPINY STELLATE NEURONS IN MONKEY PRIMARY VISUAL CORTEX. J.S. Lund and S.M. Holbach*. Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261.

Dendritic field extent and spine number have been compared for neurons in V1 visual cortex of age-matched visually deprived and normal macaque monkeys. Golgi rapid impregnated spiny stellate neurons from thalamic recipient layers 4Cβ and 4Cα were compared for dendritic arbor size, using a Sholl ring intersection method, and for spine number over 10μm segments taken at 20μm intervals from soma to dendritic tips; an average total spine coverage per neuron was then calculated. Rearing to 2 months with bilateral eye-lid suture from 3 days of age produced no significant difference from normal in total spine coverage per neuron. Rearing in the dark from 13 days to 3 months of age produced a 38% greater than normal total spine coverage in β but little change in total spine population in α. Rearing in the dark from 10 days of age to 6 months produced a higher than normal total spine coverage in both α (+58%) and β (+28%). Returning an animal to the light for 6 weeks after dark rearing from day 9 to 6 months produced near normal total spine coverage in α but higher than normal spine coverage (+46%) in β. Our conclusion is that visual deprivation induces a retardation in normal spine and dendritic arbor loss during the early postnatal period which is more readily reversed in α than in β by restoring normal visual input. Supported by NEI grant EY05282.

DEVELOPMENT OF LATERAL SUPRASYLVIAN VISUAL CORTICOTECTAL PROJECTIONS IN NEONATAL CATS. L.L. Bruce, J.G. McHaffie, and B.E. Stein. Dept. Anatomy, Creighton University, Omaha, NE 68178 & Dept. Physiology, Medical College of Virginia, Richmond, VA 23298.

To study the maturation of the projections from the medial bank of lateral suprasylvian (LS) sulcus to superior colliculus (SC), fast blue (FB; a long-lasting tracer) was injected into the SC at one day postnatal (dpn). At 27 dpn a nuclear yellow (NY) injection was made that encompassed the first site. Medial bank neurons that projected to SC at birth (i.e. FB labeled) were present homogeneously throughout layer V. Far fewer neurons maintained their projections at 27 dpn (i.e. double-labeled) but these had the same distribution as the FB-labeled neurons. Neurons labeled only with NY were rare.

The possibility that neurons losing corticotectal projections had 'inappropriate' targets in SC, was also evaluated. Injections of tritiated leucine were made in the medial bank of LS at 0 and 14 dpn. The terminal labeling pattern indicated that at birth, as in adulthood, the medial bank terminates topographically in the superficial laminae and dorsal aspect of the intermediate laminae of the ipsilateral SC. Therefore, although corticotectal connections from medial suprasylvian cortex are lost during maturation, their loss (like those from striate cortex) reflects refinements within the mature target zone in the SC.

VISUAL FUNCTION ALTERATIONS RESULTING FROM NEONATAL CORPUS CALLOSUM SECTION ARE LINKED TO PRIMARY VISUAL CORTEX. A.J. Elberger. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, Col. of Med., Memphis, TN 38163.

Previous studies of cats with neonatal corpus callosum section have linked behavioral alteration of perimetric visual field extent (Elberger 1979) to primary visual cortex (Elberger and Spydell 1985). When physiological studies found visual functional alterations at the cellular level, primary visual cortex was involved (Elberger 1981; Elberger and Smith 1985) while lateral suprasylvian cortex was not (Elberger and Smith 1983).

In cats with corpus callosum section at 1-6 postnatal weeks of age, three different kinds of measurements of visual function were obtained from each cat: 1)behavioral measurement of monocular and binocular visual acuity; from single striate cortical cells, physiological measurement of 2)spatial frequency threshold and 3)ocular dominance. All three measurements were significantly related to the age at which the corpus callosum section occurred, and the greatest deficits in visual function occurred in the youngest callosum sections. Compared with the results from normal cats, only the cats with callosum section during postnatal weeks 1 and 2 showed significant deficits in all measurements. From individual cats' data the three visual functions were found to be significantly interrelated. The results support the hypothesis that the most significant effect of neonatal corpus callosum section is to alter the functional capabilities of primary visual cortex. EY06362

EFFECTS OF ALTERNATING MONOCULAR OCCLUSION ON MATURATION OF FELINE VISUAL CALLOSAL CONNECTIONS. D.O. Frost[1], Y.P. Moy[1]* & D.C. Smith[2]. [1]Sect. of Neuroanatomy Yale Univ. Sch. Med., New Haven, CT 06510 and [2]Dept. of Psychology, Southern Illinois. Univ., Carbondale, Ill. 62901

In cats, neurons projecting through the corpus callosum (callosal neurons; CN's) fill areas 17 & 18 at birth; during the first 3 months of life, they narrow their distribution to the region of the 17/18 border. Rearing with strabismus (S), monocular enucleation (ME) or monocular eyelid suture (MD) stabilizes some normally transient CN's in medial area 17. Why do S, ME and MD similarly affect callosal development? Rearing with S, ME or MD all cause most neurons in areas 17 & 18 to respond predominantly to stimulation of one eye; in normal cats, most of these neurons respond well to stimulation of either eye. To test the relationship between loss of binocularity and stabilization of transient CN's, we reared cats with alternating monocular occlusion (AMO), which also makes most area 17/18 neurons monocular, but unlike S, ME and MD, lacks other physiological effects. 4 cats were raised in total darkness except that 6 d/wk they explored a normally lit room with one eye occluded; each eye was occluded on alternate days. Visual experience was gradually increased from 1 to 8 h/d. 48 h before sacrifice at age 3 months, cats received unilateral HRP injections that filled the posterolateral and lateral cortical gyri. The distribution of retrogradely labeled CN's in the opposite cortex was determined on computer reconstructions from serial, TMB-processed sections. 6 normal, adult cats were similarly treated. In AMO-reared cats, as in cats reared with S, ME or MD, normally transient CN's in medial area 17 were stabilized. This suggests that experience-dependent loss of cortical binocular responsiveness and stabilization of normally transient callosal connections are related but a causal relationship remains uncertain. Supported by EY-03465 from NIH & 5-417 from March of Dimes.

VISUAL CALLOSAL PROJECTIONS IN THE STRIATE CORTEX OF THE RABBIT FOLLOWING NEONATAL BINOCULAR ENUCLEATION. A.M. Grigonis and E.H. Murphy. Dept. of Anatomy, Hahnemann University, Phila., PA 19102, and Dept. of Anatomy, Medical College of Pennsylvania, Phila., PA 19129.

The organization of cells which comprise the projection of the corpus callosum (CC) of the rabbit are exuberant at birth and normally retract during development to become restricted to the 17/18 border in adults. Monocular enucleation (ME) on the day of birth results in an exuberant CC cell distribution in the adult similar to that observed in the neonate. Dark-rearing results in a CC cell distribution which is more sparse than normal and which extends into the medial portion of area 17 further than in the normal adult rabbit but not as far as in the neonate or the ME rabbit. In the present study we examined the effects of neonatal binocular enucleation (BE) on the CC cell distribution. Seven Dutch-Belted rabbits had BE on the day of birth. After reaching adulthood, multiple injections of HRP (Sigma VI, 20% in H_2O) were made (15 µl) throughout one entire visual cortex. Animals were perfused 24 hours later and the brains were cut and reacted with TMB. BE rabbits had a sparse CC cell distribution similar to that observed after dark-rearing. However, the CC cell distribution was not exuberant. In addition, there were fewer cells in the infragranular layers of BE rabbits compared to either normal, ME, or dark-reared rabbits. The results of the present study provide further evidence that visual experience and the presence of the primary afferent visual pathway make different contributions to the postnatal development of the corpus callosum. Supported by NIH grants EY06986 and EY02488.

447.16

DEVELOPMENT OF VISUAL THALAMOCORTICAL PROJECTIONS IN THE FETAL RAT. B.S. Reinoso and D.D.M. O'Leary, Dept of Neurosurgery & McDonnell Ctr for Studies of Higher Brain Function, Washington Univ Sch Med, St.Louis, MO 63110.

The cortical ingrowth of visual thalamic axons was studied by postmortem DiI labeling in E17-20 rats. Embryos were perfused with 10% formalin, their brains removed, transected just rostral to the colliculi, and DiI crystals placed in the region of dorsal lateral geniculate nucleus. The brains were stored in 2% formalin at 37° for 6-10 days. Sections were cut and analyzed with fluorescence and Nomarski optics. The DiI uptake site is confined to caudal dorsolateral thalamus. At all ages, anterograde labeling is most dense in the caudal portion of the thalamic radiation. Labeled axons are present in the intermediate zone (IZ) of fronto-parietal regions by E17 and within the occipital area by E19. They accumulate in more superficial IZ, but some extend into deep IZ and even into the proliferative zone. Initially, labeled axons invade deep layers of cortical plate in rostral regions, occurring on E18; this invasion then proceeds caudally. The labeled axons form branches along their trajectory; many extend out of the IZ. The presence of visual thalamic afferents to non-visual cortical areas is evidence of a transient exuberancy of thalamocortical projections. We are correlating these results with cortical neuronogenesis in mature littermates labeled with 3H-TdR in utero 2 hrs before removal of the fetuses used here for DiI labeling.

447.17

VISUAL CORTEX TRANSPLANTED TO FRONTAL REGION FORMS RECIPROCAL THALAMIC AND CALLOSAL CONNECTIONS TYPICAL OF MOTOR CORTEX. Dennis D.M. O'Leary, Dept of Neurosurgery & McDonnell Center for Studies of Higher Brain Function, Washington Univ Sch Med, St. Louis, MO 63110

In an attempt to define further the influence that the position of a developing cortical neuron in the tangential plane of the neocortex has on the connections that it will establish, pieces of E17 fetal occipital cortex, exposed to ^{3}H-thymidine in utero on E16, were transplanted to the frontal region of newborn rats. The host rats were allowed to mature (P35 to 6 mo); WGA-HRP was then iontophoresed into the transplant. 1-2 days later, the rats were perfused and their brains frozen sectioned. Alternate sections were processed for TMB histochemistry or autoradiography. In 3 of 17 rats, the injection is confined to the transplant, the borders of which can be delineated from autoradiograms. In these cases, anterograde label and retrogradely filled neurons are found within thalamic nuclei that normally have connections with motor cortex, and in the region of contralateral cortex homotopic for the location of the transplant in the host cortex. No labeling is seen in visual thalamic nuclei, nor in regions of cortex normally connected with occipital cortex. These results indicate that heterotopic neocortical transplants establish permanent thalamic and callosal connections typical of their new site in the host cortex, not of their origin.

GENERATION OF SPECIES DIFFERENCES IN EYE AND BRAIN CONFORMATION: ALLOMETRIC AND NEUROGENETIC STUDIES. G.M. Perez, D. R. Sengelaub, K. C. Wikler, and B.L. Finlay, Dept. of Psychology, Cornell University, Ithaca NY 14853

The Syrian hamster (Mesocricetus auratus) and the Mongolian gerbil (Meriones unguiculatus) are two closely related species that differ substantially in their retinal topography, visual acuity and developmental time course. The gerbil has a greater number of retinal ganglion cells, a greater center-periphery ratio of those cells, and longer gestation and maturation. In this study we have investigated the relationship between neurogenesis and allometric measurements of eye, brain and body size.

These allometric measures were compared from the initiation of neurogenesis to adulthood (hamster n=30; gerbil n=30). The body weight of gerbils is always less than hamsters. Brain size, however, is nearly identical although the duration of neurogenesis is substantially longer in gerbils. Similarly, eye size is nearly identical at the end of an extended period of neurogenesis that produces about twice as many retinal ganglion cells in the gerbil. The gerbil's eye is initially ovoid, longer on its nasotemporal axis, while the hamster eye is spherical. The gerbil eye through extended growth becomes larger and spherical which may directly contribute to the development of an asymmetric visual streak in gerbils. Thus both initial shape and developmental heterochrony contribute to the development of these species' differences. Supported NIH grants RO1 NS19245 and KO4 NS00783

EFFECT OF NGF ON TYROSINE HYDROXYLASE mRNA AND EXTRACELLULAR MONOAMINES LEVELS IN PRIMARY CULTURES OF RAT ADRENAL CHROMAFFIN CELLS. D. G. Roufa, D. R. Studelska* L. M. Pullan, S. R. Rapp*, V. W. Engleman* and **K. L. O'Malley. G. D. Searle/CNSDR, St. Louis, MO 63198 and **Anatomy/Neurobiology Dept. Washington University School of Medicine, St. Louis, MO 63110.

A subpopulation of adrenal medullary cells, obtained from neonatal rats (P7) and grown in dissociated cell culture, express NGF receptors (NGFR) as determined by immunocytochemical localization of NGFR specific mAb 192. Colocalization of NGFR with either tyrosine hydroxylase (TH) specific antibodies or TH mRNA, using in situ hybridization with ^{35}S-RNA probe, revealed two distinct cell populations. One population was both NGFR and TH positive and the other was only NGFR positive. All TH positive cells were also NGFR positive and both populations were NGF-responsive. Cells cultured in medium containing NGF had twice as much TH message (F=62.99, dt=1/100, P<0.0001) as cells grown in the absence of NGF. This increase was evident in cells from male and female animals. There was no significant effect of sex on TH message expressed and no indication of a treatment x sex interactions. Quantitative evaluation of monoamine neurotransmitters and their metabolites present in the culture medium conditioned by the adrenal medullary cells was performed using HPLC-EC system. The level of monoamine neurotransmitters and their metabolites was significantly altered when adrenal medullary cells were grown in the presence of NGF.

NGF REGULATES THE EXPRESSION OF PREPROTACHYKININ AND CGRP GENES IN ADULT RAT SENSORY NEURONS. R.M. Lindsay and A.J. Harmar, (SPON: M.Gaze), Cell Biology, Sandoz Institute for Medical Research, London, England, and MRC Brain Metabolism Unit, Edinburgh, Scotland.

Although not requiring nerve growth factor (NGF) for survival (RML, J.Neurosci., in press, 1988), adult rat dorsal root ganglion (DRG) neurons cultured with NGF show elevated levels of the neuropeptides Substance P (SP) and calcitonin gene-related peptide (CGRP) (Lindsay et al., 1987, Neurosci.Abstr. 13, 518). To confirm that the effect of NGF is due to an increase in the rate of synthesis of these two peptides, we have studied the effects of NGF on the expression of the genes encoding their precursors. After culture for periods between 4 hours - 5 days with or without NGF, total cellular RNA was isolated by incubation of adult rat DRG cultures (20-50,000 neurons) with SDS/Proteinase K followed by phenol/chloroform extraction. Messenger RNAs coding for the precursors to SP (preprotachykinin:PPT; Harmar et al., FEBS Lett. 208, 67-72, 1986) and CGRP were quantitated by northern blot analysis. In cultures deprived of NGF, PPT and CGRP mRNA levels declined with time in culture. In NGF-treated cultures, increased levels of both mRNAs were detectable within 24h and after 5 days levels of PPT and CGRP mRNA were over 20-fold higher than in control cultures. Even when cultures were initially deprived of NGF for 5 days, similar increases in the levels of both mRNAs were achieved upon NGF addition, indicating that the effects of NGF are not mediated through enhancing survival of PPT and CGRP-producing cells. These results suggest that NGF may exert a continuous trophic influence upon mature sensory neurons through regulation of specific neuronal functions such as the expression of certain neuropeptides, as shown here.

EARLY GENE REGULATION BY NERVE GROWTH FACTOR: INDUCTION OF AN INTERFERON-LIKE GENE. F.Tirone and E.M.Shooter, Department of Neurobiology. Stanford University, School of Medicine, Stanford, CA. 94305.

Nerve growth factor (NGF) is a neurotrophic molecule responsible for the maintenance and development of sympathetic and some sensory neurons in vertebrates. NGF also induces chromaffin cells, a neural crest derived tissue, to differentiate into sympathetic neurons, with a transcription-dependent mechanism. In order to gain some insight into the early steps of this differentiative process, we made a cDNA library from PC12 cells (a line derived from a chromaffin cell tumor) one hour after treatment with NGF. We identified four cDNA clones (Tirone, F., and Shooter, E.M.Soc.Neurosci.Abstr.,13(1):551,1987), PC1, PC2, PC3 and PC4, corresponding to different mRNA species highly induced by NGF as well as by epidermal growth factor and cyclic AMP (with the exception of PC4). Sequence analysis showed that PC1 corresponds to NGFI-A, recently described as an NGF-inducible cDNA coding for a transcriptional regulatory factor, while PC4 is homologous to the partial sequence of a putative mouse β interferon (Skup, D., et al., Nucleic Ac.Res. 10:3069, 1982). We cloned a full-length cDNA copy of PC4 and found that its deduced protein sequence, 449 amino acids long, is also significantly related to the entire sequence of the rat γ interferon protein. The analysis of expression in rat tissues showed that PC1, unlike the other mRNAs, is present in the adult rat brain, beginning as early as 7 days after birth, in a period related to growth and differentiation of the glial cells. PC2, PC3 and PC4 mRNAs are instead expressed in placenta and amnion - tissues rapidly proliferating and differentiating - and in the neural tube (with the exception of PC2) between 12 and 14 days of gestation, in a period related to neuroblast proliferation and, in part, differentiation. An increase (for PC1) or a decrease (for PC4) of expression was also observed during differentiation of the mouse myoblast cell line C2C12. These results suggest that the four clones could have a role in some differentiative and/or proliferative events, triggered by NGF or by other factors in the brain or in non-neuronal tissues. PC4 could exert this action, in analogy to that of interferons and lymphokines (regulators of cell proliferation and differentiation) by influencing gene expression at levels (e.g. RNA stability) other than RNA transcription (as could be for PC1).

PHORBOL MYRISTATE ACETATE (PMA) AND NERVE GROWTH FACTOR (NGF) HAVE SIMILAR EFFECTS ON ADRENAL CHROMAFFIN CELLS IN PRIMARY CELL CULTURE. M.A. Herman*#, C.A. Schulz*, I. Parada*† and P. Claude*. Wis. Reg. Primate Res. Ctr., #Dept. of Physiology and *Neurosciences Training Program, University of Wisconsin, Madison, WI, 53715.

NGF promotes survival, neuritic outgrowth and proliferation of cultured chromaffin cells from young rats (Lillien and Claude, 1985). PMA, which activates protein kinase C (PKC), mimics the action of diacylglycerol, a second messenger molecule involved in the action of some hormones (Nishizuka, 1986). PMA has been reported to mimic the effects of NGF in primary cultures of neurons (Montz et al., 1985; Wakade and Wakade, 1986). We have examined the effects of PMA, alone or in the presence of NGF, on chromaffin cells grown in dissociated cell culture for 6 days or more. Cultures were grown with or without PMA (30 ng/ml; Sigma) or NGF (10 or 100 ng/ml 7S NGF; Collaborative Research) on collagen-coated substrata in Medium 199 + 20% charcoal-stripped fetal calf serum, then scored for the proportion of cells bearing neurites or labeled by a 24 hr exposure to ^{3}H-thymidine. Some were processed for immunocytochemistry or scanning EM. **Results:** Long-term incubation with PMA produced effects similar to those produced by NGF. PMA increased cell number and proliferation, and elicited the outgrowth of neurites, although they were fewer in number and morphologically different from those elicited by NGF. In PMA + NGF, as compared to NGF alone, neuritic outgrowth was enhanced while cell proliferation was reduced, as was also observed when PMA was added for the last 2 days of a 6-day incubation in NGF (Lillien and Claude, in prep.). Cells from animals of different ages responded similarly to PMA. Thus, PMA, possibly acting through PKC, mimics or modulates long-term effects of NGF.

Supported by NIH Grant RR00167 to the WRPRC and by grants to P.C. from the NSF (BNS-8616958) and the Muscular Dystrophy Association. †Present address: Dept. of Neurology, University of Wisconsin-Madison.

DEVELOPMENTAL EXPRESSION OF NERVE GROWTH FACTOR RECEPTOR (NGF-R) mRNA IN HYPERTENSIVE AND NORMOTENSIVE RATS. K.A. Curto*, R.E. Stitzel*, R.J. Head*, J.S. Strobl*. (SPON: C.R. Craig) Dept. of Pharmacology & Toxicology, West Virginia University, Morgantown, WV 26506

NGF receptor mRNA levels were measured to examine the role of nerve growth factor receptor gene expression in the etiology of hypernoradrenergic innervation in the genetically spontaneously hypertensive rat (SHR). Total heart (H), aorta (A) and mesenteric artery (M) RNA was extracted from 10, 60 and 100 d SHR and normotensive Wistar Kyoto rats (WKY) and hybridized to P^{32}-NGF-R riboprobe. The degree of sympathetic innervation in the adult rat is A < H < M. Expression of NGF-R was developmentally regulated in all 3 tissues examined. Levels in M and A were 10-fold greater in 10 d than in the 60-100 d rats. Highest NGF-R levels in 10 d rats were seen in H and fell 2 to 3-fold at 60-100 d. Absolute levels of NGF-R mRNA in M and A of both rat strains, and in WKY H were the same in the 10 d rats. The NGF-R content in 10 d SHR H and M was 2 times that in WKY rats, but was not statistically significant.

Thus, NGF-R mRNA levels at the ages tested do not correlate with the degree of sympathetic innervation seen in the adult. Independent assays from this laboratory showed that NGF mRNA in M is 5 times greater in the 10 d SHR than WKY. Hyperinnervation of SHR M therefore correlates with elevated expression of NGF, but not NGF-R gene expression. (Supported by NIH grant HL 36885).

DISTRIBUTION OF PRO-NERVE GROWTH FACTOR-LIKE IMMUNOREACTIVITY (PRO-NGF-LI) IN THE ADULT RAT BRAIN. M.C. SENUT*, E. DICOU*, Y. LAMOUR and P. BRACHET (SPON: S. DROUVA).U161, 2, rue d'Alesia 75014 PARIS and INSERM U298, CHR, 49033 ANGERS, FRANCE.

In the adult rat, the localization of the pro-NGF has been studied in various brain and spinal cord regions, using affinity-purified sera raised against three synthetic peptides that reproduce epitopes of the pro-NGF, and immunohistochemical (IHC) methods. The three antibodies labeled similar regions, but each sera resulted, for a given structure, in a specific distribution pattern. Strong pro-NGF-LI was present in neocortex, medial septum, hippocampus, globus pallidus, some thalamic nuclei, olfactory bulb, reticular nuclei of the brain stem, whereas lateral septum, hypothalamic nuclei, cerebellum, substantia nigra, motoneurons of the ventral horns, the intermediolateral columns and dorsal horns cells showed less intense labeling. The pro-NGF-LI was mainly observed within cell bodies but some immunoreactive fibers were noticed in corpus callosum, commissura anterior, capsula interna and spinal fasciculi. To identify the pro-NGF-LI cell bodies, the IHC procedure was combined with the retrograde transport of a WGA-apoHRP-Gold complex (Basbaum and Menetrey '87) injected in thalamus, hippocampus and spinal cord; results provide evidence that the pro-NGF-LI is localized within neuronal cell bodies. Studies using antibodies against β-NGF are in progress.

NERVE GROWTH FACTOR ENHANCES SURVIVAL OF IDENTIFIED PROJECTION NEURONS IN THE RAT SEPTAL AND DIAGONAL BAND REGIONS IN VITRO. Y. Arimatsu*, M. Miyamoto*, H. Tsukui* and H. Hatanaka*. (Spon: T. Hama). Mitsubishi Kasei Inst. of Life Sci., Tokyo 194, Japan.

It has been suggested that nerve growth factor (NGF) enhances survival of cholinergic neurons in basal forebrain both in vivo and in vitro, as judged from histochemical observations for AChE and ChAT. However, previous studies did not completely rule out a possibility that NGF enhanced the expression of these enzymes and not the survival of the neurons. We here support the possibility of neuronal survival by applying NGF in vitro on rat basal forebrain neurons that had been retrogradely labeled in vivo.

Rats of 4 days of age were injected bilaterally into the hippocampus with fluorescent latex microspheres. After 20 to 24 hrs, tissue fragments were dissected out from the medial septum (MS) and vertical limb of the diagonal band (vDB) and treated by papain and DNase. The dispersed cells were cultivated for 3 days with or without 100 ng/ml 2.5S NGF. The number of cells labeled with fluorescent latex microspheres was counted under a fluorescence microscope. Some of the cultures were stained for AChE by a modified Koelle's method, and the others were stained for GABA-immunoreactivity using rabbit anti-GABA antiserum.

The number of fluorescent latex microsphere-labeled neurons in culture with NGF was much greater than that without NGF. The result clearly indicates that NGF enhances the survival of MS and vDB neurons projecting to the hippocampus. Additionally, it was shown that NGF enhanced the survival of both AChE-positive and AChE-negative neurons, and also, the survival of both GABA-positive and GABA-negative neurons. These results suggest that NGF enhances survival of not only cholinergic neurons but also GABAergic projection neurons in MS and vDB.

INJURED SENSORY NEURONS RESPOND TO DELAYED INFUSION OF NERVE GROWTH FACTOR. V.M.K. Verge, P.M. Richardson and R.J. Riopelle. Montreal General Hospital & McGill University, Montreal, Quebec, H3G 1A4 and Queen's University, Kingston, Ontario, K7L 3N6.

Approximately one half of the neurons in adult rat lumbar DRG have high-affinity receptors for NGF. To study changes in these neurons and receptors following peripheral nerve injury and subsequent infusion of NGF, radioautographs were prepared from cryostat sections of L5 DRG incubated with radioiodinated NGF. The right sciatic nerve was transected 30 days before sacrifice and in one half the animals, NGF was infused at 250ng/hr to the proximal nerve stump from the 21st to 30th days. By quantitative radioautography, the number of high-affinity sites on heavily labeled neurons was seen to fall by more than 80% after sciatic nerve transection, through loss in cell volume (50%) and receptor density (67%). For these neurons with high-affinity receptors, delayed infusion of NGF substantially reversed both receptor loss and atrophy. For neurons without high-affinity receptors, the mean volume was reduced only 25% by sciatic nerve transection and was not restored by NGF.

As part of the response to axonal injury and possibly because the cell body is deprived of NGF, fewer high-affinity receptors are displayed by sensory neurons. NGF can regulate its functional high-affinity receptor on adult mammalian neurons.

ACTIVATION OF CELL PROLIFERATION BY NERVE GROWTH FACTOR IN THE EMBRYONIC OTIC VESICLE AND COCHLEOVESTIBULAR GANGLION IN VITRO. J. Represa* and P. Bernd (SPON: J. Jakway). Dept. of Anatomy and Cell Biology, SUNY Health Science Center, Brooklyn, NY 11203.

The effects of Nerve Growth Factor (NGF) on cell proliferation and survival in inner ear primordia (otic vesicle, OV; cochleovestibular ganglion, CVG) were studied. OV and CVG were from 72 hr quail embryos (stage 19-20); a period of active proliferation for these structures. They were incubated for 24 hr at 37°C in M-199 serumless medium containing ^{3}H-thymidine (4 μM; 10 μCi/ml). Duplicate cultures also contained either 10% fetal bovine serum, 50 ng/ml NGF, or serum plus NGF. Incubation with either NGF or serum resulted in a significant increase in the TCA precipitable incorporation of ^{3}H-thymidine in OV and CVG, as compared to those cultured in serumless medium alone (3x and 11x for OV; 4x and 6x for CVG). The combination of NGF and serum resulted in an additive response (12x for OV; 10x for CVG). Antibodies to NGF (1:100) blocked the effects of NGF, but not those of serum. In subsequent experiments, OV and CVG were growth-arrested by pre-incubation in serumless medium (24 hr), prior to reactivation with NGF and/or serum, for an additional 24 hr. Any cells dependent upon NGF or serum would probably not survive this 24 hr pre-incubation. Following reactivation, NGF elicited full proliferative effects as described above (blocked by anti-NGF), while serum only elicited a full response in OV. We conclude that NGF and serum cause specific increases in ^{3}H-thymidine incorporation in both OV and CVG. For NGF, this effect appears to occur by increasing cell proliferation, and not cell survival, since NGF is still able to elicit its full response in growth-arrested OV and CVG. Supported by grants from the NSF (BNS-8896101), March of Dimes (#1-1090), and Dysautonomia Foundation.

448.10

CHARACTERIZATION AND LOCALIZATION OF NERVE GROWTH FACTOR RECEPTORS IN THE EMBRYONIC OTIC VESICLE AND COCHLEOVESTIBULAR GANGLION. P. Bernd and J. Represa*. Dept. of Anatomy and Cell Biology, SUNY Health Science Center, Brooklyn, NY 11203.

Recent findings have shown that Nerve Growth Factor (NGF) activates cell proliferation in inner ear primordia (otic vesicle, OV; cochleovestibular ganglion, CVG; see accompanying abstract), suggesting that at least some cells in these structures have receptors for NGF. OV and CVG from 72 hr quail embryos (stage 19-20) were incubated in M-199 serumless medium containing iodinated NGF (^{125}I-NGF; 15 pM to 24 nM; 1 hr; 37°C), while controls also included an excess of nonradioactive NGF (5 μg/ml). Quantitative analysis revealed specific ^{125}I-NGF binding (nonspecific binding was 25% or less of total binding), however, binding was not completely saturable even at the highest ^{125}I-NGF concentration (24 nM). Scatchard analysis indicated the presence of a single NGF receptor subtype, with dissociation constants similar to the low affinity form described in the periphery (5.2 nM, OV; 7.8 nM, CVG). OV were microdissected to determine the distribution of ^{125}I-NGF binding. The medial portion of the OV was found to contain approximately 65% of the label. Light microscopic radioautographic analysis was used to localize NGF receptors. Preliminary results reveal that ^{125}I-NGF binding is not uniform throughout either the OV or CVG. NGF receptors were concentrated in the ventromedial portion of the OV, the area adjacent to the CVG. The endolymphatic duct and lateral wall of the OV exhibited very little binding. In CVG, grain density was not homogenously distributed and all cells did not appear to have receptors for NGF. The phenotypic identity of the cells bearing NGF receptors remains to be determined. Supported by grants from the NSF (BNS-8896101), March of Dimes (#1-1090), and Dysautonomia Foundation.

Morphologically Distinct Populations of Cholinergic Neurons from the Basal Forebrain Exhibit a Differential Response to NGF or TPA. Z-W. Hua*, B. F. Alderson and L.B. Hersh. Lab. Developmental Neurobiol., NICHD, NIH, Bethesda. MD 20892.; Dept. Biochem., Univ. Texas Hlth. Sci. Ctr., Dallas. TX 75235.

Evidence from both *in vivo* and *in vitro* experiments indicate that nerve growth factor (NGF) modulates the level of choline acetyltransferase activity in cholinergic neurons of the basal forebrain. Previous reports have shown that the activation of protein kinase C by phorbol 12-myristate 13-acetate (TPA) can also increase the level of CAT activity. We have examined the effect of NGF and/or TPA on the number of CAT immunopositive cells in primary cell cultures from the basal forebrain region, in which three morphologically distinct cholinergic cell types; stellate, pyramidal, and bipolar, are evident (Nakajama et.al., PNAS, 82:6325, 1985).

Dissociated cell cultures were prepared from the basal forebrain region of 1-2 day old mouse pups and grown for 7 days following a single addition of NGF, 5-6 hours after plating. The maximal effective dose of NGF was found to be 200 ng/ml which produced a 1.9-fold increase in the total number of CAT positive cells/well and increased the number of stellate cells/well from 7±2 in the controls to 23±2. The addition of 100 ng/ml of NGF increased the number of pyramidal cells from 14±2 to 26±2 cells/well. However, no change in the number of bipolar cells was noted at any concentration of NGF tested. TPA,10.0 ng/ml, increased the total number of CAT positive cells from 27±5 to 42±4 cells/well. TPA increased the number of stellate cells from 4±2 to 12±2 and the number of pyramidal cells was increased from 11±2 to 20±3. The number of immunopositive bipolar cells was not changed by the TPA treatment. The study of the potential interaction of these two ligands is now underway.

AUTOCRINE DIFFERENTIATION OF RAT PHEOCHROMOCYTOMA PC12 CELLS USING A RETROVIRAL NGF VECTOR. M.P. Short*, M.B.Rosenberg, D. Ezzedine*, F.H. Gage, T. Friedmann* and X.O.Breakefield. E.K. Shriver Ctr., Waltham, MA 02254 and UCSD, La Jolla, CA 92093.

Rat pheochromocytoma PC12 cells have been genetically modified by use of replication-defective retroviral vectors containing, either the bacterial gene for beta-galactosidase (B-Gal) or the cDNA for mouse beta-NGF, and the bacterial gene for neomycin resistance.

Using the B-gal vector, clonal lines of PC12 cells were obtained in which almost 100% of cells stably expressed this histochemical marker. Infection of these B-gal-PC12 cells or the original PC12 cells with the NGF vector resulted in extensive neurite formation, which occurred within hours after infection and was maintained for weeks in culture. The percentage of cells expressing neurite outgrowth was comparable to that of PC12 cells treated with exogenous NGF. Neurite formation could be blocked by antibody to NGF. The amount of NGF in cells and that released into the medium was assessed by a two site radioimmunoassay and by a bioassay using "naive" PC12 cells.

Genetically modified PC12 cells are being injected stereotactically into the CNS of newborn and adult rats; their survival and effects on the brain are being assessed histologically.

448.13

THE EFFECTS OF PERTUSSIS TOXIN ON NERVE GROWTH FACTOR-STIMULATED RESPONSES IN PC12 CELLS. M.L. Contreras, K. Fujita,* P. Lelkes,* J. Shiloach, G. Guroff and P. Lazarovici. Section on Growth Factors, NICHD, and Laboratory of Cell Biology and Genetics, and Biotechnology Unit, NIDDK, NIH, Bethesda, MD 20892.

The specific events in the transmembrane signalling initiated by nerve growth factor (NGF) cells have not been identified. To test the possible involvement of a guanine nucleotide-binding protein, the effects of pertussis toxin on nerve growth factor-treated PC12 cells were examined. Incubation of PC12 membranes with pertussis toxin caused the ribosylation of a protein resembling the α-subunit of the guanine nucleotide regulatory protein, Ni. Incubation of PC12 cells with 1 μg/ml of pertussis toxin for 2 hours at 4°C inhibited both the NGF-induced increase in the intracellular concentration of free calcium and the NGF-stimulated hydrolysis of phosphoinositides. The inhibition of phosphoinositide hydrolysis was observed at concentrations of pertussis as low as 0.3 μg/ml, and was maximal at 1.8 μg/ml. When PC12 cells were treated with 1 μg/ml of pertussis toxin for two days, with fresh toxin added every 24 hours, NGF-induced neurite outgrowth was inhibited. Again, this inhibitory effect was observed at 0.3 μg/ml. The inhibitory effects were readily reversible; washing the cells to remove the toxin and readdition of NGF resulted in the production of neurites comparable to those in cells treated only with NGF. These results suggest that a pertussis-sensitive site, possibly a guanine nucleotide-binding protein, is involved in NGF receptor-linked signalling.

448.14

NGF, A DIFFERENTIATING AGENT, AND EGF, A MITOGEN, INCREASE THE ACTIVITIES OF DIFFERENT S6 KINASES IN PC12 CELLS. T. Mutoh,* B.B. Rudkin,* S. Koizumi* and G. Guroff. Section on Growth Factors, National Institute of Child Health and Human Development, NIH, Bethesda, MD 20892.

Soluble extracts from PC12 cells, prepared by the alkaline lysis method reported previously (Matsuda and Guroff, J. Biol. Chem., 262:2832, 1987), contain two S6 kinases, separable by heparin-Sepharose chromatography. As also shown in the previous study, the activity of the first of these peaks is increased in extracts from cells treated with nerve growth factor. We now report that it is the activity of the second of these peaks that is increased in cells treated with epidermal growth factor. In the presence of 80 mM β-glycerolphosphate and 20 mM EGTA, the NGF-responsive peak virtually disappeared; the EGF-responsive peak was resistant to this treatment. The EGF-responsive S6 kinase was not inhibited by the specific inhibitors of protein kinase A, H-7 and W-7. The characteristics of this EGF-responsive peak suggest that it is not protein kinase A, protein kinase C, or calcium/calmodulin-dependent kinase. It seems likely that the EGF-dependent kinase of PC12 cells is similar to the mitogen-responsive S6 kinase found in fibroblasts and other cells. The fact that NGF and EGF stimulate different S6 kinases in these cells indicates that these two peptides initiate different chains of intracellular mediators. These data open the possibility that agents inducing differentiation and those inducing proliferation produce different patterns of S6 phosphorylation, and that these, in turn, cause definable differences in S6 function.

448.15

EFFECTS OF NERVE GROWTH FACTOR ON CYTOSKELETAL GENE EXPRESSION IN AXOTOMIZED ADULT RAT DORSAL ROOT GANGLION (DRG) NEURONS. M.M. Oblinger and J.W. Wong* Dept. Cell Biology and Anatomy, Chicago Medical School, N. Chicago, IL 60064

While adult DRG neurons do not appear to be dependent on NGF for survival, NGF is thought to be important for the maintenance of normal metabolic and morphological homeostasis in these cells. In fact, the loss of trophic support from factors such as NGF as a result of axotomy has long been speculated to be involved in the injury response of sensory neurons. A very robust component of the axotomy response in DRG neurons is the cytoskeletal response. Recent studies by this and other laboratories have shown that peripheral axotomy of DRG neurons results in a downregulation of neurofilament (NF) proteins and mRNA levels and an upregulation of tubulin synthesis and mRNA levels. In the present study, we asked whether the administration of NGF to transected sciatic nerve would alter the cytoskeletal gene response in axotomized DRG neurons. To examine this question, the sciatic nerves of adult male rats were unilaterally transected at the midthigh level and placed into a silicone chamber which was connected to an implanted osmotic pump (Alzet). The transected sciatic nerves were continually infused (0.5 µl/hr) for 12 days with either NGF (0.5 mg/ml) or sterile saline. At 12 days, the axotomized and the contralateral L4 and L5 DRGs were harvested. The L4 DRGs were labeled for 1 hr *in vitro* with ^{35}S-methionine and the newly synthesized proteins analyzed by quantitative 2D gel electrophoresis/ fluorography. The L5 DRGs were embedded in paraffin, sectioned at 10 µm and hybridized with ^{35}S-labeled cDNA probes to the mRNAs of NF68 (provided by Dr. N. Cowan, NYU) and beta tubulin (provided by Dr. S. Farmer, Boston U). The quantitative results of both protein synthesis and *in situ* hybridization experiments indicated that NFG treatment did NOT alter the axotomy response with respect to the major cytoskeletal proteins. DRGs treated with NGF for 12 days after axotomy exhibited a substantial reduction in NF synthesis and NF68 mRNA levels and a substantial increase in tubulin synthesis and beta tubulin mRNA levels; the level of change in all measured parameters was not significantly different from that observed in saline treated axotomized controls. We conclude that this paradigm of administering NFG to axotomized DRG neurons does not alter the cytoskeletal component of the axotomy response.

DETECTION OF A PROTEIN KINASE ACTIVATED BY NERVE GROWTH FACTOR IN A HUMAN EWING'S OSTEOSARCOMA CELL LINE. C. **Volonté * and L.A. Greene** *Department of Pathology, Columbia University P&S, New York, N.Y. 10032.*

It has been previously found that several human Ewing's osteosarcoma cell lines possess NGF receptors (Thomson et al. [1988] Exp. Cell Res., 174: 533). One of these, the IARC-EW 1 line, responds to NGF by rapid induction of the c-*fos* proto-oncogene (Thomson et al., submitted). The present studies reveal that although this line fails to show certain responses to NGF seen in PC12 cell cultures, such as alteration of proliferation, change in morphology, survival in serum-free medium, altered glycoprotein synthesis and increased ornithine decarboxylase activity, it does share with PC12 cells the NGF-promoted activation of a serine protein kinase (PK) activity (designated PKN; Rowland et al. [1987] J. Biol. Chem., 262:7504). Partial purification of PKN from IARC-EW 1 cells by FPLC on a Mono-S column reveals at least a 10-fold activation after 10 min of NGF treatment. These findings suggest that the IARC-EW 1 line will be useful for probing the initial steps of the NGF mechanism of action. To facilitate the quantitative assessment of PKN activity (as well as the activity of other PKs) we have developed a new nitrocellulose slot-filtration assay. This assay, coupled with the rapidity and magnitude of PKN activation by NGF, may be convenient for detection of NGF responsiveness, especially in cells lacking macroscopic responses to the factor.

448.17

BEHAVIORAL AND BIOCHEMICAL EFFECTS OF NERVE GROWTH FACTOR IN RATS WITH 6-HYDROXYDOPAMINE INDUCED NIGROSTRIATAL DENERVATION. G. Pezzoli*, S. Fahn, A. Dwork*, J. de Yebenes*, V. Jackson-Lewis, J.L. Cadet. Dept. of Neurology, Columbia University, New York, New York 10032

The mechanisms by which grafts of catecholamine secreting cells alleviate the signs of experimental parkinsonism are still elusive. We undertook this study to evaluate the possibility that other factors, in addition to intracerebral transplantation of adrenal medulla, might play a role in these improvements. Aged Male Sprague-Dawley rats received 6-OHDA lesions of the substantia nigra. After several weeks during which they were evaluated for apomorphine-induced rotation, the rats were transplanted with adipose tissue and received intracerebral infusion of saline or nerve growth factor (NGF). One group received only NGF for a month period.

Behavioral studies revealed significant reduction in Apo-induced circling in the group treated with NGF + adipose tissue but not in the other groups. 6-OHDA caused significant decreases in DA, DOPAC, 5-HT, 5-HIAA in the ipsilateral striata. Adipose tissue transplantation exacerbated these changes in 5-HT and 5-HIAA. NGF significant attenuated the decreases in the 5-HT system without affecting the dopamine system. These results suggest that behavioral improvements seen after adrenal transplantation may be related to other factors in addition to the secretion of dopamine in the denervated nigrostriatal pathway.

448.18

IMMUNOREACTIVITY TO CHARACTERIZED GROWTH FACTORS IN RAT INTRASTRIATAL CELL SUSPENSION TRANSPLANTS. S.E.Loughlin, C.M. Annis* and J.H. Fallon. Dept. of Anatomy and Neurobiology, Univ. of California Irvine, Irvine, CA 92717

These studies were designed to determine whether characterized growth factors are present in the region of intrastriatal cell suspension transplants. Midbrains were removed from Sprague-Dawley rat embryos of 12 to 15 days of age. A suspension was prepared by incubation with trypsin , subsequent washing with trypsin inhibitor, DNA-ase, and MgSO4, and mechanical trituration. Suspension was injected into the caudate-putamen (CP) of adult rats which had previously received 6-hydroxy-dopamine lesions. Control animals received injections of vehicle only. Following varied survival times, animals were sacrificed by intra-aortic perfusion with fixative and brains were processed by the biotin-avidin-peroxidase immunocytochemical method. Antisera raised against tyrosine hydroxylase (TH), transforming growth factor alpha (TGF), epidermal growth factor (EGF), and fibroblast growth factor (FGF) and glial fibrillary acidic protein (GFAP) were utilized. Dense TH-immunoreactivity (IR) was observed in cells and processes within the transplant, indicating that dopamine containing neurons survived and extended processes. No FGF-IR was observed in the region of transplants. In some animals, an increase in EGF-IR was observed around successful transplants. Densely staining profiles which appeared to be astrocytes (by comparison with GFAP-IR) were immunoreactive for TGF within and around sucessful transplants. When 3 well-characterized antisera directed at defined carboxy-terminal sequences of the TGF precursor were utilized, immunoreactivity in transplants was also observed. Injections of vehicle only produced a similar, but transient, effect. These data are consistent with the hypothesis that TGF may play a role in the functional improvement observed following fetal midbrain suspension transplants.

NEURONAL DEATH II

449.1

AN APPARENT ABSENCE OF CELL DEATH AMONG SPINAL CORD INTERNEURONS IN THE CHICK EMBRYO. S.E. McKay* and R.W. Oppenheim (SPON: B.T. Troost). Dept. of Anatomy, Wake Forest Univ., Winston-Salem, NC 27103.

Although naturally occurring neuronal death has been observed in a wide variety of neurons and species, there are reports in the literature indicating that some populations of neurons exhibit little, if any, loss during development. Because casual observations have suggested that degenerating interneurons are rarely, if ever, seen in the developing chick spinal cord we have undertaken a more systematic investigation of this problem. To determine whether spinal cord interneurons degenerate during development, we have examined every fifth section of the lumbar spinal cord on embryonic days (E) 6,8,10,12 and 15. This represents the time span when synaptogenesis occurs, and thus when cell death might be expected to occur. All regions of the spinal cord intermediate zone (gray matter) were searched for dying interneurons; however, motor and sympathetic preganglionic neurons were excluded from our analysis because previous studies have already documented cell death in these populations. Four-five embryos were examined at each age. Using previously established criteria we have observed few, if any, convincing examples of degenerating interneurons at any of the ages examined. We are presently carrying out a quantitative analysis of neuronal numbers at the same ages to more directly confirm the absence of interneuronal cell death. Experiments are also underway to determine whether loss of targets or afferents results in the death of spinal cord interneurons. Understanding why some populations do not undergo naturally occurring neuronal death may help to reveal the biological role of this process. This work was supported by grant NS 20402.

449.2

MECHANISM OF ACTION OF CONDITIONING NEURONAL LESIONS. G.R. Jackson*, K. Werrbach-Perez*, C. Beck* and J.R. Perez-Polo. Dept. of Human Biol. Chem. & Gen., Univ. of Texas Med. Br., Galveston, TX 77550.

Nerve growth factor (NGF) regulates neuronal cell death during development. The PC12 line is a useful model of an NGF responsive neuron. NGF provides protection to PC12 from hydrogen peroxide, H2O2, a well known hydroxyl radical generator. Exogenous catalase also protects and NGF does induce catalase in these cells that, like most neuronal lines, have low endogenous catalase levels. NGF protection is abolished by a catalase inhibitor. Here we report on a conditioning lesion paradigm that uses a sublethal peroxidative insult to stimulate protection to subsequent peroxidative exposure. Both NGF and the conditioning lesion itself independently confer cytoprotection from H2O2; together their effect is synergistic. When treated with NGF, conditioned cells display an acceleration of neurite outgrowth compared to unconditioned cells. This is consistent with results obtained in vivo and with the hypothesis that H2O2 can result in a xenobiotic response and that NGF regulates cell death via effects on oxidant-antioxidant balance. Supported by NIH grant NS-18708.

449.3

THE EFFECTS OF ION CHANNEL MODULATORS ON HYPOXIA-INDUCED CALCIUM ACCUMULATION AND INJURY IN CORTICAL NEURONAL CULTURES. M.L. Weber, A.W. Probert, P.A. Boxer, and F.W. Marcoux. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

Hypoxic neuronal injury in culture can be ameliorated by pharmacologic blockade at the NMDA gated ion channel. It has been proposed that inhibition of neuronal calcium accumulation accounts for this neuroprotective effect. We have evaluated the effects of calcium and sodium channel modulators on hypoxia-induced neuronal calcium accumulation and injury in culture. Two week old rat cortical neuronal cultures were exposed to hypoxia (0% O_2, 95% N_2, and 5% CO_2) at 37°C for 4 hrs in the presence or absence of ion channel modulators. After the hypoxic exposure neuronal $^{45}Ca^{++}$ uptake was measured. Sister cultures were returned to a normoxic environment (95% air, 5% CO_2) at 37°C for an additional 20 hrs and were examined for morphological injury after immunocytochemical staining with HRP linked neuron-specific enolase antibody. The percentage of injured cells was calculated by comparing photographs of identical microscopic fields taken before and after hypoxic exposure. Phenytoin, tetrodotoxin, verapamil, and diltiazem were found to block Ca^{++} accumulation yet they did not prevent neuronal injury. The inorganic cations, Mg^{++} and Zn^{++}, which block both voltage dependent and NMDA gated ion channels, inhibited Ca^{++} influx and protected the cells from morphologically assessed injury.

SURVIVAL OF CORTICOSPINAL NEURONS AFTER AXOTOMY IS TEMPORALLY CORRELATED WITH GROWTH OF THEIR AXONS INTO SPINAL CORD TARGETS. M. Merline* and K. Kalil. Dept. of Anatomy and Neurosciences Training Program, University of Wisconsin, Madison, WI 53706.

A previous report (Ramirez, L.F. and Kalil, K., J. Comp. Neurol., 237:506-518, 1985) describing effects of axotomy on pyramidal tract neurons showed that lesions in young hamsters did not produce cell death as shown with Nissl staining in layer 5 of the sensorimotor cortex. A subsequent report (Tolbert, D.L., and Der, T., J. Comp. Neurol., 260:299-312, 1987) showed complete degeneration of fluorescently labeled corticospinal neurons after axotomy in newborn kittens.

To resolve these discrepancies, we retrogradely labeled hamster corticospinal neurons with bilateral injections of rhodamine beads into different levels of the spinal cord, and 24-48 hours later made unilateral pyramidal tract lesions. Labeled neurons in the contralateral cortex served as controls. Neurons projecting to the lumbar cord completely degenerated if the pyramidal tract was cut before 10 days postnatal. Lesions at 14 days or older resulted in cell survival, although they were somewhat shrunken. In contrast, neurons projecting to the cervical spinal cord survived lesions of the pyramidal tract at 9 days of age, but lesions at 7 and 5 days produced progressively greater but by no means complete cell death. Short survival times used in some of the experiments showed retrograde cell changes as early as 24 hours after axotomy.

These results show that the age at which the lesion occurs determines the ability of corticospinal neurons to survive axotomy. Since corticospinal axons begin to innervate the cervical cord at 6 days and the lumbar cord at 10 days, the ability of corticospinal neurons to survive lesions of the pyramidal tract is temporally correlated with target innervation. (Supported by NIH Grant NS-14428)

THYROXINE-POTENTIATED LATERAL MOTOR COLUMN NEURON NUMBER IN LIMB AMPUTATED TADPOLES. J.F. Goldberg* and E.D. Pollack, Inst. Study Develop. Disabil. and Dept. Biol. Sci., Univ. Illinois at Chicago, Chicago, IL. 60608

The lateral motor column (LMC) neuron population of the developing frog is under the influence of both limb and thyroid hormone. Although neuron loss is temporarily retarded following limb amputation at the onset of dramatic LMC neuron loss, by the end of the larval period a substantial reduction in neuron number occurs. Since thyroid hormone influences spinal ventricular cell proliferation, we asked how limb amputation and thyroid hormone might interact in determining the LMC neuron number outcome in Rana pipiens tadpoles. Treatment with thyroxine by immersion resulted in an LMC with somewhat more neurons than controls. When hindlimb amputation is accompanied by continual thyroxine treatment, the LMC of the amputated side exhibits extraordinary numbers of neurons at the time of metamorphic climax. In fact, the neuron counts often exceeded those present at the time of amputation, when the maximum number is normally present. This suggested that neuron loss was being inhibited as expected, though perhaps for an extended time, while the rate of ongoing proliferation as determined by ventricular mitotic counts was accelerated by thyroxine, as was overall larval development. ^{3}H-thymidine autoradiographic analysis should confirm if the LMC neuron increase, in part, is a result of the thyroxine-enhanced mitotic activity.

MORPHOMETRIC ANALYSIS OF SCIATIC NERVE MOTOR NEURONS 20 WEEKS AFTER T-9 SPINAL CORD TRANSECTION. E.R. Feringa, R.L. McBride and J.K. Williams*. V. A. Medical Center and Medical College of Georgia, Augusta, GA 30910.

Functional recovery after spinal cord injury is dependent on the condition of neurons deprived of input by the trauma. We previously reported no loss of sciatic motor neurons 10 weeks after T-9 spinal cord transection and now we extend our observations to 20 weeks after transection.

We transected the spinal cord at T-9 in 7 anesthetized seven-week old female rats. Ten weeks later, the right sciatic nerve of these rats and 11 controls was severed above the popliteal fossa and the proximal cut end soaked for one hour in a 2% solution of the retrogradely transported fluorescent dye Fluoro-Gold. The rats were perfused 4 days later. Labeled neurons were counted on every fifth 30 µm section and measured on two sections from each rat.

In contrast with some earlier reports, we found that, at least as long as 20 weeks after T-9 transection, there is no significant change in sciatic motor neurons in number or size. In addition, the transected neurons retain their ability to retrogradely transport Fluoro-Gold. Supported by the V. A. Medical Research Service.

CORTICOSPINAL AND RED NUCLEUS NEURONS TRANSPORT FLUORO-GOLD 20 WEEKS AFTER T-9 TRANSECTION. R.L. McBride, E.R. Feringa, M.K. Garver* and J.K. Williams, Jr.* V. A. Medical Center and Medical College of Georgia, Augusta, GA 30910.

Although delayed death of corticospinal and rubrospinal neurons after T-9 spinal cord transection in adult rats was indicated by reduced anterograde (proline) and retrograde (HRP) labeling, the numbers of corticospinal axons at C-1 and T-1 did not decrease. To further investigate the status of neurons axotomized far from the somata, the spinal cords of 15 anesthetized seven-week-old female rats were completely transected at T-9. Ten weeks (7 transected, 8 controls) or 20 weeks (8 transected, 9 controls) later, a cotton pellet soaked in a 2% solution of the retrogradely transported fluorescent dye Fluoro-Gold was inserted into a new transection at T-1. Four days later the rats were perfused. The mean number and size of labeled corticospinal and number of rubrospinal neurons in transected rats was not different from controls at either 10 or 20 weeks. The mean size of labeled red nucleus neurons in transected rats was decreased compared with controls in both 10 and 20 week groups ($p<.001$). We conclude that some uptake/transport mechanisms remain intact following axotomy. Supported by the V.A. Medical Research Service.

TRANSNEURONAL DEGENERATION INVOLVES ACTIVE DESTRUCTION OF RIBOSOMES. E.W Rubel, P.M. Falk* and O. Steward (SPON: W.R. Lippe). Hearing Development Labs., Univ. of Washington, Seattle, WA 98195; Neurosci. Dept., Univ. of Virginia, Charlottesville, VA 22908.

We have shown that neurons in the avian n. magnocellularis (NM) which are destined to undergo transneuronal cell death due to interruption of afferent activity can be identified autoradiographically; cessation of protein synthesis occurs within 6 hours of eliminating afferent activity (Steward, O. & E.W Rubel, J. Comp. Neurol. 231: 385, 1985). In this study we examined ultrastructural cytoplasmic changes in these neurons. Chicks, 10-15 days after hatching, were subjected to unilateral cochlea removal. Six hours later they were briefly anesthetized and given a single intracardiac injection of 0.5 mci tritiated leucine. After 1/2 hr for incorporation, the brain stems were fixed and vibratome sectioned. Sections through the middle of NM were osmicated and embedded in plastic. Adjacent thick and thin sections were taken. Thick sections were processed for emulsion autoradiography. Grain counts over all NM neurons ipsi- and contralateral to the cochlea removal were determined. Electron micrographs of the cytoplasm of each neuron were examined, scored "blind" and related to the grain density for that neuron. We observed complete destruction of ribosomes associated with the endoplasmic reticulum and could find no cytoplasmic ribosomes in unlabeled neurons. These effects were striking and never observed in labeled cells from the experimental side or in cells from the normal side of the brain. The results suggest that afferent-regulated transneuronal cell death is an active process involving activation of a "suicide factor" through gene expression or enzyme disinhibition. (Supported by PHS grants NS24518 & NS12333)

CELL DEATH IN THE INFERIOR OLIVE OF STAGGERER MICE IS AN INDIRECT EFFECT OF GENE ACTION: STUDIES OF STAGGERER CHIMERAS AND +/*sg* MICE.

H. Shojaeian*, K. Sunter*, J. Mariani, and K. Herrup. E.K. Shriver Center, Waltham, MA 02254; Lab. Neurophysiologie Ontogénétique, Univ. Pièrre. et Marie Curie, Paris

In homozygous staggerer (*sg/sg*) mice, cerebellar Purkinje cells are reduced in number by 75% due to an intrinsic effect of the mutation on Purkinje cell development. In addition, 60% of the normal number of inferior olivary neurons are lost during postnatal development. To determine whether the olivary cell death is cell-autonomous (or caused by extrinsic factors such as the loss of most of the postsynaptic Purkinje cell target) chimeras were constructed from one *sg/sg, Gus^b/Gus^b* (high ß-glucuronidase activity) embryo and one *+^{sg}/+^{sg}, Gus^h/Gus^h* (low ß-glucuronidase activity) embryo. Three adult staggerer chimeras were identified. Despite the presence of both genotypes in the olive, cell counts revealed more *sg/sg* genotype neurons present in the chimeras than in a homozygous mutant. Since *sg/sg* olive neurons can be "rescued" in the chimera, their death must be an indirect consequence of *sg* gene action. Unexpectedly, heterozygote mice (+/*sg*), while behaviorally normal, lose 30% of their olivary neurons by 6 months of age. We have performed Purkinje cell counts in 12 month old +/*sg* animals and find a 30% loss of these neurons as well. Combined with data from the chimeras, these results suggest that the pattern of staggerer gene action is the same in both the heterozygote and homozygote animals.

Supported by the NIH (NS-20591 and NS-18381), the March of Dimes Birth Defects Foundation, and a FYSSEN Foundation Fellowship to HS.

UNIDIRECTIONAL REGULATION OF CELL NUMBER FROM TARGET TO AFFERENT NEURONS DURING DEVELOPMENT.

S. Chen and D. E. Hillman. Dept. Physiol. Biophys., New York Univ. Med. Ctr., New York, NY 10016.

Interactions between target and afferent neurons (or peripheral systems) are believed to generate a relatively precise numerical ratio through transneuronal cell death. Two models of developmental dysgenesis induced by methylazoxymethanol (MAM) in rats were used to reduce the number of Purkinje cells as targets (a single injection on gestational day 14) and the number of granule cells as afferents (a single injection within 24 hours of birth). The number of granule and Purkinje cells was quantitated in the adult control and two experimental groups from area and volume of layers and cell densities.

The results revealed that prenatal MAM on the 14th day produced a deficit in the number of Purkinje cells. This was accompanied by a parallel reduction of granule cells so that their ratio remained the same. Contrarily, major deficits in the number of granule cells, generated by postnatal MAM, did not affect the number of Purkinje cells. We conclude that the number of Purkinje cells determines the maximum number of granule cells as the result of a unidirectional control of afferent cell number. ALZ-50 AS A MARKER FOR NATURALLY OCCURRING NEURONAL DEATH IN THE NEOCORTICAL SUBPLATE OF THE RAT.

W. Al-Ghoul* and M.W. Miller (SPON: R. Nagele) Department of Anatomy, School of Osteopathic Medicine and Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ 08854.

Neuronal death is a widespread phenomenon that affects many neurons in the developing nervous system. We used an immunohistochemical reaction to identify dying neurons in the subplate of the developing rat neocortex. Rats 0, 2, 5, and 30 days after birth were perfused with paraformaldehyde. Cortical tissue was reacted with a monoclonal antibody directed against Alz-50; Alz-50 is a 68K protein isolated from the brains of Alzheimer patients (Wolozin et al., Science, 232, 648 (1986)). Alz-50-immunoreactivity was visualized with a biotin-avidin-peroxidase technique. In neonates, immunoreactive neurons with round cell bodies were in the upper subplate and fusiform Alz-50-positive cells were distributed in the lower subplate. By postnatal day (P) 5 immunoreactivity in the subplate had disappeared. The time of origin of subplate neurons was determined using [^{3}H]thymidine autoradiography. These neurons were born on gestational day (G) 12. Heavily-labeled neurons were still evident on P5, but by P30 they have disappeared. Using a method which combined Alz-50 immunohistochemistry with [^{3}H]thymidine autoradiography, it was determined that many Alz-50-positive neurons were generated on G12. Thus, Alz-50 is expressed transiently and early in the process of neuronal degeneration. Funded by DE 07734, AA 06916, and AA 07568.

POST-HYPOXIC TREATMENT WITH MK-801 REDUCES HYPOXIC-ISCHEMIC NEURONAL DAMAGE IN THE NEONATAL RAT.

H. Hattori*, P.H. Schwartz, A.M. Morin, and C.G. Wasterlain*. (SPON: R. Nishimura) Epilepsy and Neurology Res. Labs., VAMC, Sepulveda, CA 91343, Dept. of Neurology, UCLA Sch. of Medicine.

We have examined the ability of post-hypoxic treatment of MK-801, a potent N-methyl-D-aspartate (NMDA) antagonist, to protect against hypoxic-ischemic brain damage in the neonatal rat. Both carotid arteries of 7-day-old rats were ligated. After 4-6 h, pups were exposed to 8% O_2 for 1 h. One group (n=8) received 10 mg/kg MK-801 (i.p.) just after the hypoxic insult. A second (n=8) received saline. Histological examination of the brains 3 days later revealed significant protective effects of MK-801. The percentage of necrotic area was scored as 0, +1 (1-25%), +2 (26-50%), +3 (51-75%) and +4 (76-100%). Post-hypoxic MK-801 reduced the degree of necrosis from +3.5±0.2 to +1.1±0.4 ($p<0.05$) in the neocortex, and from +2.1±0.3 to +0.6±0.3, ($p<0.05$) in the basal ganglia. Protection was not selective and included neocortical astrocytes. The data suggest that MK-801 has the therapeutic potential in neonates even when given after the hypoxic-ischemic insult.

THE REACTION OF GRACILE PROJECTING PRIMARY SENSORY NEURONES FOLLOWING PERIPHERAL NERVE INJURY IN THE RAT.

J. K. E. Persson*, H. Aldskogius, J. Arvidsson* and A. Holmberg*. Dept. of Anatomy, Karolinska Inst., 104 01 Stockholm, Sweden.

The purpose of this study was to analyse qualitative and quantitative morphological changes in gracile projecting primary sensory neurones following sciatic nerve transection in the rat. The possible occurence of ultrastructural changes in the gracile nucleus was examined at post-operative (p.o.) survival times ranging from one day to 32 weeks. Degenerative changes were found in the ipsilateral gracile nucleus from three days up to 32 weeks after nerve transection. These changes in terminals, preterminal axons and glial cells differed markedly from previously described transganglionic changes in other systems. Transganglionic labelling from the injured sciatic nerve with horseradish peroxidase (HRP) at the ultrastructural level showed that at least some of the altered structures were indeed the central processes of primary sensory neurones whose peripheral branches were located in the sciatic nerve. The number of dorsal root ganglion neurones in dorsal root ganglia L4 to L6 projecting to the gracile nucleus was counted 20 weeks after nerve transection. This quantitative analysis showed an ipsilateral decrease of about 30% in the number of cell bodies compared with the contralateral unoperated side. The number of axons in the gracile funiculus at C3 spinal cord level was calculated 20 weeks after ipsilateral sciatic nerve transection. The counting was restricted to an area containing axons which had been labelled with HRP from the sciatic nerve. This quantification showed a reduction of about 25% in the number of axons compared with age matched controls. In material prepared with the Marchi method to visualize degenerating myelin, a slight increase in the number of Marchi-positive structures was noted in the gracile funiculus ipsilateral to nerve transection compared with the contralateral unoperated side and age matched controls.

These findings indicate: i) that sciatic nerve transection results in prominent alterations in central terminals and axons of the injured gracile projecting ganglion cells and ii) that the occurence of these alterations are accompanied with ganglion cell death.

AGENTS WHICH PREVENT THE DEATH OF NEURONS CAUSED BY NERVE GROWTH FACTOR (NGF) DEPRIVATION

Beth K. Levy*, D.P. Martin, and E.M. Johnson, Jr. (SPON: R.E. Schmidt) Dept. of Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110

Elevated cAMP prevents neuronal death caused by NGF deprivation. Superior cervical ganglia were dissected from embryonic day-21 rats and dissociated onto collagen-coated tissue culture dishes. After one week in the presence of NGF, cultures were acutely deprived of trophic support by adding anti-NGF antiserum. Neurons treated in this manner were completely dead 48 hours after NGF deprivation. Consistent with Rydel and Greene (PNAS 85:1257-1261), chlorophenylthio-cAMP (CPT-cAMP), forskolin, cholera toxin, and isobutylmethylxanthine (IBMX) all prevented neuronal death. A concentration of IBMX too low to save by itself markedly lowered the EC_{50} of CPT-cAMP and forskolin. The ability of raised levels of cAMP to prevent neuronal death may represent a pharmacologic, rather than physiologic, effect because NGF deprivation did not decrease intracellular cAMP.

Retinoic acid prevented the death of NGF-deprived neurons as did elevated concentrations of potassium in the medium. Neither of these treatments raised intracellular levels of cAMP. We have previously shown that the death of NGF-deprived neurons requires RNA and protein synthesis. CPT-cAMP, retinoic acid, or elevated potassium did not decrease protein synthesis sufficiently to explain their saving effect, even after several days.

A variety of agents failed to alter the death of NGF deprived neurons. These included phorbol esters, polyamines, protease inhibitors, kinase inhibitors, drugs which alter the cytoskeleton, and others.

449.15

NEURONAL DEATH CAUSED BY NERVE GROWTH FACTOR (NGF) DEPRIVATION RESULTS FROM A CASCADE OF NEW RNA AND PROTEIN SYNTHESIS D.P. Martin and E.M. Johnson, Jr. Dept. of Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110

We have further characterized an in vitro model of trophic factor deprivation in which we have previously shown that neuronal death requires RNA and protein synthesis. Comparison of the dose response curves of cycloheximide for inhibition of protein synthesis and neuronal saving indicated that protein synthesis must be inhibited at least 80% to prevent neuronal death.

Inhibitors of RNA or protein synthesis prevented neuronal death only if added within about 18 hours of NGF deprivation. This time is coincident with the first observable morphologic changes associated with neuronal death, which once initiated apparently progress independent of RNA or protein synthesis. The commitment point was also determined for other agents which prevent neuronal death (NGF, CPT-cAMP, high potassium concentrations, and retinoic acid).

Neurons were deprived of NGF for 24 hours in the presence of cycloheximide, whereupon the protein synthesis block was removed without replacing NGF. These cells did not die abruptly, but rather synthesized protein for an additional 18-24 hours before beginning to die. Hence, RNA which codes for the proximate killer proteins does not accumulate during the 18 hour lag between NGF deprivation and commitment.

We believe that these data are most consistent with the hypothesis that NGF deprivation unleashes a cascade of sequential RNA and protein synthesis ending in the production of new proteins which kill the cell.

449.16

NEURONAL DEATH CAUSED BY CYTOSINE ARABINOSIDE (ARA-C) RESEMBLES DEATH CAUSED BY NERVE GROWTH FACTOR (NGF) DEPRIVATION T.L. Wallace, D.P. Martin, and E.M. Johnson Jr. Dept. of Pharmacology, Washington Univ. School of Medicine, St. Louis, MO 63110

We report here that Ara-C causes the death of rat sympathetic neurons in a fashion resembling that caused by NGF deprivation. Superior cervical ganglia were dissected from embryonic day-21 rats and dissociated onto collagen-coated tissue culture plates. After a week in the presence of NGF they were exposed to Ara-C (10^{-4}M). No changes were observable until about three days, whereupon the neurites began to thin and fragment. Over the next 24 hours the cell bodies became condensed and phase dark, such that by five days after addition of Ara-C all neurons in the dish were completely destroyed. The morphological and temporal characteristics of cell death that began around three days after adding Ara-C were very similar to those observed starting 24 hours after NGF deprivation. Although Ara-C is an antimitotic drug, its action here does not involve DNA synthesis because these neurons are postmitotic and unharmed by any other antimitotic drug (Ara-A, Ara-T, and FUDR). As with neuronal death caused by NGF deprivation, the death caused by Ara-C was prevented entirely by inhibitors of protein and RNA synthesis, agents which elevate intracellular cAMP, and elevated concentrations of potassium in the culture medium. These data suggest that Ara-C causes an active death of neurons similar to that caused by trophic factor deprivation.

RETINAL TOPOGRAPHY AND THE RETINOTECTAL PROJECTION PATTERN IN THE JUVENILE LEMON SHARK (NEGAPRION BREVIROSTRIS). R.E. Hueter. Mote Marine Laboratory, Sarasota, FL 34236.

Attention to the topography of shark retina has been hindered by the obsolete view that the elasmobranchs as a rule possess all-rod retinas. After Gruber et al. (Vision Res. 3:397, 1963) demonstrated conclusive evidence of cones in the lemon shark, at least 24 species from 10 families of elasmobranchs with duplex retinas have been described. In this study, unstained retinal wholemounts and Nomarski DIC optics were used to map the topographic organization of cones and ganglion cells in juvenile lemon shark retina. Retinal cell distribution is organized into a visual streak in register with the retinotectal streak, which is oriented within about 15° above and 15° below the horizontal meridian (Hueter, R.E., Soc. Neurosci. Abs. 12:496, 1986). Ganglion cell density ranges from a high of over 1500 cells/mm^2 inside the streak to less than 500 cells/mm^2 in the periphery. Cone density is approximately 6500 cones/mm^2 inside the streak and less than 500 cones/mm^2 in the extreme periphery. Average intercone separation is calculated to be 12.4 µm at peak cone density, which, with a posterior nodal distance of 9.398 mm in this eye, corresponds to a visual angle of 4.5'. This suggests that the visual system of the lemon shark may be specialized for certain discrimination tasks and calls for further research on spatial vision in sharks.

Supported by the Lerner-Gray Fund for Marine Research and a Sigma-Xi Grant-in-Aid.

450.2

TOPOGRAPHIC ANALYSIS OF THE GANGLION CELL LAYER AND OPTIC NERVE IN THE SANDLANCE, LIMNICHTHYES FASCIATUS (CREEIIDAE, PERCIFORMES). S.P. Collin* and H.B. Collin* (SPON: A. Hughes). Vision, Touch and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, St Lucia, Queensland 4067, Australia and School of Optometry, University of New South Wales, Kensington 2033, N. S. W. Australia.

The sandlance *Limnichthyes fasciatus* is a small teleost of the Indopacific which lives beneath the sand. Its miniscule eyes (1.04mm in diameter) are independently mobile, possess a unique cornea and a deep convexiclivate fovea on the visual axis. Examination of Nissl-stained cells within the ganglion cell layer reveal a perifoveal density of 13.0 X 10^4 cells per mm^2 counted in wholemount material compared to 15.0 X 10^4 cells per mm^2 counted in transverse sections. Peripheral densities drop to 4.5 X 10^4 cells per mm^2. To assess the proportion of cells without an axon, sections of the whole optic nerve were analysed under electron microscopy. Optic axon densities range from 2 X 10^6 axons per mm^2 in the caudal apex to over 16 X 10^6 axons per mm^2 within a specialized region of unmyelinated axons in the rostral apex. The unmyelinated axon population (26%) follows closely the topography of the total population of axons. A total of 104,452 axons were found in the optic nerve compared to 102,918 cells situated in five sublaminae within the retinal ganglion cell layer. A direct relationship is revealed between ganglion cell soma size and axon area. The corresponding topographic organization of the retina and optic nerve may reflect some functional retinotopicity.

450.3

NUMBER, DISTRIBUTION, AND RATIOS OF RODS AND CONES IN THE ADULT MACAQUE RETINA. K.C. Wikler, R.W. Williams, and P. Rakic. Section of Neuroanatomy, Yale University School of Medicine. 333 Cedar Street, New Haven, CT 06510

The photoreceptor matrix is a key determinant of visual acuity. However, the number and distribution of rod and cone photoreceptors has not yet been fully characterized in the primate retina. We have estimated total photoreceptor number, topography, and ratios in adult rhesus monkeys using differential interference contrast (DIC) optics and unstained and hydrated wholemount retinae (Curcio et al., 1987, Science, 236, 579-582).

There are 3.2 million cones (95% confidence interval (CI) ± 290,00) and 62 million rods (CI ± 500,000) in the adult monkey retina (n=7). The average density of cones in the rod-free foveola is 150,000 cells/mm^2 but values range widely from 88,000 to 213,000 cones/mm^2. Since these measures were made using identical counting procedures, the wide range of values in peak cone density may be due to difficulty in consistently visualizing the exact location of this spatially restricted rod-free zone.

The distribution of cones shows a prominent 10:1 gradient in density from central to peripheral retina. Outside of the foveola, rods are found also in higher density in central retina (5:1 center-periphery ratio). In contrast, 5 mm outside of the foveola, the ratio of rod to cone density is relatively uniform across the retinal surface. Ratios in this broad plateau region (90% of retinal area) range from 15-30:1 rods per cone. Although the density of cones per surface area decreases dramatically in the periphery, surprisingly, the number of cones per rods is stable across the retinal mosaic.

450.4

TOPOGRAPHIC ORGANIZATION OF THE GANGLION CELL LAYER IN THE RETINA OF THE ADULT BABOON (PAPIO ANUBIS) O. Fischer*, P. Wilson, and M. Kirby[1], University of California, Riverside, Riverside, CA 92521 and [1]Loma Linda University, Loma Linda, CA 92350.

The distribution of ganglion cells in the retina of the baboon, a terrestrial monkey, was determined for comparison with retinas from more arboreal primates. Retinas were immersion fixed, whole mounted and stained with cresyl violet. The retinas measured from 738 - 948mm^2 in area, and contained an estimated 1,220,000 - 1,570,000 (mean 1,430,000) ganglion cells, with a peak density of at least 18,000 cells/mm^2. Ganglion cell counts within the central 3-5% of the retinas may be underestimated because of the extreme density and thickness of the ganglion cell layer in this region.

The distribution of ganglion cells outside central retina forms a pronounced horizontal "streak." The ratios of the long to short axes of the 1000 cells/mm^2 and 2000 cells/mm^2 isodensity contours were 1.6:1 and 1.9:1 compared with ratios of 1.2:1 to 1.4:1 for comparable isodensity contours in retinae of more arboreal primate species (extrapolated from the data of: Stone, J. et al J. Comp. Neurol., 196:205, 1981; and Perry, V. H., et al. Vision Res., 25: 1795, 1985). This data is consistent with the hypothesis that the visual streak tends to be more pronounced in ground dwelling than in arboreal species (Hughes, A., Handbook of Sensory Physiology 7/5, 1977).

450.5

VISUAL ACUITY OF THE CAT: VARIATION WITH RETINAL ECCENTRICITY. *Kris Horn and Tatiana Pasternak.* University of Rochester Medical School and Center for Visual Science, University of Rochester, Rochester, NY 14627.

Anatomical and physiological studies of the cat retina provide estimates of the limits of spatial resolution at various retinal eccentricities. Estimates based on the density of ganglion cells, dendritic field diameters and receptive field center diameters suggest that X (beta) cells limit spatial resolution in the cat. Such predictions for areas outside of the central retina have never before been verified by psychophysical testing.

We developed procedures that enabled us to behaviorally measure visual function at any retinal eccentricity. We measured grating acuity in cats, whose eye position was monitored by means of a scleral search coil technique. During behavioral testing, the cat was placed in an apparatus equipped with a head restraining device and two adjacent response pedals. During each trial the cat was required to maintain fixation on a laser spot and respond to the presence or the absence of a grating by pressing the right or the left pedal. The cats readily adjusted to these training conditions and we were able to measure acuity along the horizontal and vertical meridia at eccentricities up to 12 deg in the nasal, temporal, superior and inferior retina. Acuity in area centralis reached about 4 c/deg and it declined by a factor of two at 4 deg and a factor of 3-4 at 12 deg eccentricity. The acuity was higher in the nasal than temporal retina. At all eccentricities, the behavioral acuity exceeded the resolution limit derived from Y(alpha)- cell properties, but was consistent with the values derived from the X (beta) cell properties. Supported by T32 MH18260, EY06175, EY01319.

VISUAL ACUITY ACROSS THE MACAQUE RETINA. W. H. Merigan, L. M. Katz, Dept. Ophthalmology, Univ. Roch. Med. Ctr. Rochester, N.Y. 14642.

The variation of macaque visual acuity with eccentricity was mapped behaviorally from the fovea to 30 deg eccentricity along nasal and temporal horizontal meridia. These results can be interpreted in terms of visual properties which change with eccentricity such as optical quality, cone density, ganglion cell density, and dendritic and receptive field dimensions.

Acuity was measured by the discrimination of vertical from horizontal sinusoidal gratings (17 cd/m2 mean luminance) to minimize the use of aliased information. Fixation locus was controlled behaviorally and monitored with scleral search coils. Acuity was determined at 0, 3, 6, 12, 20, and 30 deg eccentricity in an interleaved series, and stimulus size was approximately 10 cycles of a just resolved grating.

Visual acuity decreased more sharply across temporal than nasal retina, and this difference was slightly greater than that seen in humans. The rate of decline was consistent with cone density over the central 10 deg of the retina and with the density of P ganglion cells at greater eccentricities, although it has been shown that such densities cannot in themselves limit acuity.

Comparison of our acuity results with dendritic and receptive field dimensions suggest that spatial averaging may play some role in limiting visual acuity. Supported by grants NSF BNS- 8518858, ES01247, and EY01319.

SELECTIVE NEUROTOXIC DAMAGE IN THE SQUIRREL MONKEY TO THE PARVOCELLULAR RETINO-GENICULATE PATHWAY. J.J. Lynch III*, W.H. Merigan and T.A. Eskin, Environ. Hlth Sci Ctr and Depts. of Ophth. and Pathol., Univ Roch Med Ctr, Roch., NY 14642.

We have previously found, in acrylamide-exposed macaques, selective degeneration of those retinal ganglion cells that project to parvocellular layers of the lateral geniculate nucleus(dLGN)(Eskin and Merigan, 1986). While the basis of the selectivity is not yet known, this lesion provides a useful model for the study of the functional role of parallel visual pathways. We now report a similar selective lesion in the visual system of a New World monkey.

Four male squirrel monkeys (Saimiri sciureus) were given daily oral doses of 14 to 21 mg/kg (494 to 1680 mg/kg total dose) acrylamide monomer over periods of one month to several months and then allowed to recover for 3 to 4 months. Radial sections of the retina of these monkeys showed a 50 to 80% loss of ganglion cells. WGA-HRP transport from retina demonstrated a nearly complete loss of transport to all parvocellular layers of the dLGN, but largely normal transport to magnocellular layers.

Cytochrome oxidase activity was greatly decreased throughout the parvocellular layers while magnocellular layer activity was maintained. Cytochrome oxidase activity in the striate cortex was decreased in parvocellular recipient layer 4C beta, but showed little decrease in magnocellular recipent layer 4C alpha.

These results suggest that retinal ganglion cells of the parvocellular pathways of the squirrel monkey and macaque share some feature which makes them vulnerable to this chemical. The selective lesion of the parvocellular pathway reported here can be used in the squirrel monkey, as in the macaque, to examine the functional role of this pathway. Supported by EPA 812402 and ES01247.

MORPHOLOGY OF GANGLION CELL TYPES THAT PROJECT TO THE PARVOCELLULAR LAMINAE OF THE LATERAL GENICULATE NUCLEUS, PRETECTUM, AND SUPERIOR COLLICULUS OF PRIMATES. R.W. Rodieck and M.Watanabe Department of Ophthalmology, University of Washington, Seattle WA 98195

Macaque ganglion cells were retrogradely labeled following 1 µl injections of dextran-labeled fluorescent dyes to brain regions that received a direct retinal input. Following a one-week survival time the animal was sacrificed, the eyes hemisected, and the retina removed and placed in an *in vitro* chamber, where it was suprafused with Ames medium. The chamber was placed on the stage of an epifluorescence microscope and the labeled cells visualized using a water-immersion objective. The labeled cells were intracellularly injected with horseradish peroxidase, and the retinas were later reacted with DAB, and whole mounted.

The great majority of ganglion cells that project to the parvocellular laminae of the LGN are midget ganglion cells, as previously reported (Leventhal, Rodieck and Dreher, 1981). In addition, these laminae receive from ganglion cell types not previous described, including some with dendritic field diameters up to 860 µm (the largest primate ganglion cells we have yet observed). The pretectum is dominated by ganglion cells with large dendritic fields formed from dendritic processes that seldom branch. Most of the ganglion cells that project to the superior colliculus belong to one of three main groups, which we have tentatively termed thorn, maze, and sparse. Thorn cells have a thick dendritic field whose terminal processes ramify at one of two levels within the inner plexiform layer. Maze cells stratify within a narrow zone of the IPL. Sparse cells seldom branch, and have large dendritic-field diameters (~400 µm) that change little with retinal eccentricity.

FORM OF RABBIT RETINAL GANGLION CELLS PROJECTING TO LAYERS OF THE SUPERIOR COLLICULUS. J.E.G. Downing*, E. V. Famiglietti, B. Ferguson*, and T. Shaw*. Lions Sight Centre, University of Calgary, Calgary, AB, Canada T2N 4N1.

Studies were initiated to assess the organization of parallel pathways from identified retinal ganglion cells (GCs) to the superficial layers of the superior colliculus (SC) in rabbit. In cat, W-GCs provide crossed projections (Fukuda and Stone, '74) to the upper stratum griseum superficiale (SGS) (Berson,'87), while Y-GCs provide both crossed and uncrossed projections (Fukuda and Stone, '74) to the deeper portion of the SGS (Hoffman, '73; McIlwain and Lufkin,'76). In rabbit, superficial and deep SGS contain functionally different populations of neurons (Graham et al.,'81). Thus while most GCs have axonal branches in SC (Vaney et al.,'81), it is possible that different functional types of GC have different sublaminar and hence parallel, rather than strictly convergent projections. To address this possibility we have made localized deposits of HRP or rhodamine-latex beads in the superficial SC, either by pressure injection, or by a method of linear deposition (Bowling,'87), for retrograde labelling of GCs. Two days later retinas are removed and processed histologically (DAB-HRP), or placed in a perfusion chamber, and bead-labelled GCs stained with Lucifer yellow by iontophoresis. We will describe sublaminar differences in projections of GCs, identified by cell body size and dendritic branching. (Supported by the Alberta Heritage Fnd. for Med. Res. and the MRC of Canada.)

TRANSNEURONAL LABELING OF RETINAL CELLS AFTER INJECTION OF HERPES SIMPLEX VIRUS INTO OPTIC NUCLEI. R.B. Norgren, Jr.* and M.N. Lehman (SPON: G. Kokoris), Dept. of Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH 45267.

Herpes Simplex Virus, Type 1 (HSV-1) has generated great interest as a possible transneuronal tracer. We have examined the transport of HSV-1 in the optic system. 40-80 nl of HSV-1 (McIntyre strain) were injected into the hypothalamic suprachiasmatic nucleus (SCN) or superior colliculus (SC) of adult golden hamsters. After a survival period of 3 days animals were perfused with 4% paraformaldehyde, eyes and brains were removed and sectioned either on a freezing microtome or a cyrostat. HSV-1 infected cells were visualized with an antibody (Accurate) and an avidin-biotin-HRP procedure (Vectastain). Brain sections were examined to verify injection sites. In addition to damage created by the syringe, there was extensive necrosis in the vicinity of the injection as a result of viral infection. Neurons in nuclei afferent to the injected sites were heavily labeled. Examination of retinal sections revealed labeled ganglion cells in a distribution similar to that observed after injection of traditional retrograde tracers: after SCN injections, labeled ganglion cells were found dispersed throughout the retina. In contrast, the retinae of SC injected animals exhibited areas where many adjacent ganglion cells were labeled. After injections into either region, infected cells were also found in the inner nuclear layer (INL) adjacent to labeled ganglion cells; the proximity of labeled INL cells suggests that after retrograde transport of the virus to the ganglion cells, it consequently infects neurons in synaptic contact with the labeled ganglion cells. We are currently testing this hypothesis at the electron microscopic level. [Supported by NIH NS24292 to M.N.L.]

AFFERENT AND EFFERENT CONNECTIONS OF THE ISTHMO-OPTIC NUCLEUS IN PIGEON (*Columba livia*). Woodson, W.*, T. Shimizu, and H. J. Karten. Department of Neurosciences, M-008, School of Medicine, University of California, San Diego, La Jolla, CA 92093.

Previous studies (McGill et al.,'66 a,b) have shown that the isthmo-optic nucleus (ION) is the source of a projection (centrifugals) upon the retina, and receives a topographic projection from the optic tectum. The afferent and efferent connections of this nucleus were identified using Phaseolus vulgaris leucoagglutinin (PHA-L). Retrogradely labelled cells were found at the margin of layers 9-10 throughout the rostro-caudal extent of the optic tectum. The dendrites of these tectal neurons extend into the retino-recipient layers, 2-7. Efferents of ION terminate in the contralateral ION. Centrifugals to the retina arborize in layer lb and, more sparsely, in layer 5b of the inner plexiform layer (IPL). Many processes could be followed into the inner nuclear layer, forming pericellular nests and "palmate" endings around somata of medium-large sized amacrine cells. These results indicate that, in addition to direct input upon somata of amacrine and displaced ganglion cells, the centrifugals also terminate within sharply defined laminae of the IPL. Furthermore, the organization of the isthmo-optic efferents suggests that the optic tectum is able to exert bilateral control over discrete subpopulations of amacrine cells in the retina. Supported by Grants NEI-EY06890 to HJK and the Ford Foundation to WW.

AXON COLLATERALS AND/OR EFFERENT FIBERS IN THE MONKEY RETINA. C. Usai*, S. Bisti~*and S. Vallerga*.(SPON: European Brain & Behavior Society).Ist.Cib.e Biofisica,CNR, 16146 Genova and ~Ist. Neurofisiol.,CNR, 56100 Pisa, ITALY.

The presence in the monkey retina of long axons with many collaterals ending as knobbed branchlets at the surface of the inner nuclear layer (INL), has been reported by Perry et al.(*Neurosci*.12:1101,1984) after injection of HRP in the optic nerve. Those collaterals were tentatively ascribed to centrifugal fibers.

In reduced silver stained retinae of *Macaca fascicularis* we observed several fibers, branching repeatedly, often emerging from axon bundles, resembly the fibers reported in HRP material. In one instance we could trace the origin of collaterals to the axon of a small neuron with large dendritic field, located in the ganglion cell layer of the inferior nasal hemiretina. The collaterals travel for several mm. through the inner plexiform layer (IPL), keep preferentially orthogonal to axon bundles, reach on occasion the INL, and cover mostly the nasal region. Therefore both centrifugal fibers and ganglion cells originating association axon collaterals might be present in monkey retina.

INTRINSIC AXON COLLATERALS OF TURTLE RETINAL GANGLION CELLS. W. Gardiner* and D.M. Dacey (SPON: M. Koontz). Dept. of Biological Structure, The Univ. of Washington, Seattle, WA 98195

Intracellular injections of horseradish peroxidase (HRP) reveal a distinct ganglion cell type that gives rise to intrinsic axon collaterals terminating in the inner plexiform layer (IPL). Retinas from the pond turtle (*Pseudemys scripta elegans*) were dissected and placed, vitreal surface up, in a superfusion chamber mounted on the stage of an epifluorescent microscope. Application of the vital dye, acridine orange to these retinas produced a stable fluorescent staining of ganglion cell somata *in vitro*. Intracellular injections of lucifer yellow and rhodamine labelled HRP were made into the fluorescing cells under direct visual control.

The axon collateral bearing ganglion cells have large somata (~20 μm diam) and large dendritic fields (~700-1000 μm). Their dendritic tree is narrowly stratified at the outer border of the IPL (~40 μm from the soma). Dendrites are thick, wavy, moderately branched and extend radially from the soma without much overlap. The parent axon (~1-2 μm diam) arises from the soma and courses directly to the optic disc in the nerve fiber layer, issuing one or two thin axon collaterals near the soma. The primary collateral descends directly into the IPL, branching several times to form a distinct terminal arbor that is monostratified at the inner border of the IPL (~5 μm from the soma). The terminal arbor has a diameter that is approximately the same size as, and partially overlaps, the dendritic field. The axon collaterals bear distinct terminal *boutons* along their length.

Because the axon collaterals overlap the dendritic tree, they may provide recurrent feedback via amacrine or interplexiform cells. Alternatively, the difference in stratification between the dendritic tree, in the OFF-sublamina of the IPL, and the intrinsic axon collaterals, in the ON-sublamina of the IPL, suggest a synaptic pathway allowing OFF-center ganglion cells to directly influence the ON pathway.

CHARACTERIZATION OF SOMATOSTATIN-LIKE IMMUNOREACTIVE CELLS IN THE ADULT CAT RETINA. **C.A. White, D. Johnson[1], L.M. Chalupa and N.C. Brecha[1], Dept. of Psych., UCD, Davis, CA and Depts. of Med. & Anat., UCLA, L.A., CA[1]**

We have studied somatostatin-like immunoreactivity (SRIF-I) in the adult cat retina using a mouse monoclonal antibody (from Dr. A. Buchan) directed to $SRIF_{14}$. A quantitative analysis of one retina, representative of 8 others, was carried out. Two distinct groups of SRIF-I somata, both distributed preferentially in inferior retina, were found. The first group consisted of large cells with granular staining cytoplasm and poorly stained primary processes. There were 561 such cells, all in the ganglion cell layer (GCL). Their density ranged from 0-2 cells/mm^2 in superior retina to an average of 4 cells/mm^2 in inferior retina. Density peaked at 11 cells/ mm^2 in a region about 4 mm inferior to the area centralis. The average soma area of a sample from inferior nasal retina was 742 μm^2. An analysis of cell distribution in this region found the pattern to be non-random (chi square test, p<.001) with an average nearest neighbor distance of 347 μm.

The second cell type was characterized by darkly stained, small to medium somata with 2-4 primary processes. There were 1,782 such cells in the GCL and 153 in the inner nuclear layer (INL). The density of cells in the GCL averaged about 5 cells/mm^2 in inferior retina except at the retinal margins, where it increased to 43 cells/mm^2. There were very few cells in superior retina, except at the retinal margin, where density was high. The average soma size in inferior nasal retina was 237 μm^2 for cells in the GCL and 170 μm^2 for cells in the INL. An analysis of the distribution of cells in this region found the GCL cells to be distributed non-randomly (chi square test, p<.01) with an average nearest neighbor distance of 228 μm. AXON-BEARING AMACRINE CELLS OF THE PRIMATE RETINA. D.M. Dacey. Dept. of Biological Structure, Univ. of Washington, Seattle, WA 98195.

A new, and unprecedented type of retinal amacrine cell has been identified in the primate retina by intracellular injections of horseradish peroxidase (HRP). Freshly dissected macaque monkey retinas were placed in a tissue chamber mounted on the stage of a light microscope and continuously superfused with oxygenated Ames medium. Application of the vital dye, acridine orange, to these retinas produced a stable fluorescent staining *in vitro* of the somata of apparently all retinal cells in the inner nuclear layer and ganglion cell layer. Large cell bodies (~20 μm diam) were also consistently observed in the middle of the inner plexiform layer (IPL). Intracellular injections of HRP into these large cells under direct microscopic control showed that they comprise a single, morphologically distinct amacrine cell subpopulation. The dendritic tree of this cell type is moderately branched (~40-50 terminal dendrites) and broadly stratified, spanning the central ~50% of the IPL such that the soma is situated between the outermost and innermost dendritic branches. Dendritic field diameter increases from ~200 μm within 1.5 mm of the fovea to ~500 μm in the periphery. Injections of patches of the axon-bearing amacrines revealed a regular cell to cell spacing (~200-300 μm in the retinal periphery) suggesting the formation of dendritic territories and a constant coverage factor.

In addition to the dendritic tree, 2-4 axons arise from proximal dendrites (~30 μm from the soma). The axons originate as straight, smooth processes that course beyond the dendritic field. Each axon usually bifurcates into secondary branches that give rise to thin collaterals bearing distinct boutons along their length. These collaterals extend radially from the dendritic tree for 2-3 mm within the IPL without further branching. The result is a widely spreading arborization that concentrically surrounds and is morphologically distinct from the dendritic tree, increasing the cell's overall size to ~4-6 mm in diam.

The division of this cell's processes into distinct dendritic and axonal components suggests that the axon-bearing amacrine cells may, like classical neurons, use action spikes to transmit signals over long distances in the IPL. Direct synaptic input to the cell body and thick proximal dendrites would be suitably positioned to trigger action potentials in the multiple axons and would provide a functional explanation for the unusual but characteristic location of the soma in the middle of the IPL.

MORPHOLOGICAL STUDIES OF DISPLACED GANGLION CELLS IN THE CHICKEN RETINA. G. Yang*, T.J. Millar* and I.G. Morgan. Center for Visual Sciences, Research School of Biological Sciences, Australian National University, Canberra, A.C.T. 2601, Australia.

About 4000 displaced ganglion cells (DGCs) were detected in the chicken retina by back-labelling with fast blue injected into the nucleus of the basal optic root (nBOR). Densities were slightly higher in the periphery. Soma sizes varied from 12um to 20um centrally, and from 20um to 30um peripherally. After intracellular injections of Lucifer Yellow, in flat-mount preparations 4-5 primary dendrites were seen, which ramified into highly branched and varicose fine processes. The dendritic fields could be up to 600um in diameter. In transverse section, cell bodies were located on the border of the inner nuclear layer (INL) and the inner plexiform layer (IPL), and a prominent axon descended vertically through the IPL to the optic fibre layer. The dendrites of the DGCs were unstratified in the outer part of the IPL. After double labelling for AChE, the dendrites of the DGCs were found to co-laminate precisely with the outer-most AChE-positive band which co-laminates with the dendrites of the type I cholinergic amacrine cells. Interactions between the presumptive OFF-cholinergic type I amacrine cells and the DGCs may underly the responses of the OFF-directionally selective units which have been detected electrophysiologically in the chicken nBOR.

MODELS FOR THE FORMATION OF OCULAR DOMINANCE COLUMNS: COMPUTATIONAL RESULTS. K.D. Miller and M.P. Stryker. Dept. of Neuroscience, Stanford University, Stanford CA 94305, and Dept. of Physiology, UCSF, San Francisco, CA 94143.

We have previously reported on development and analysis of a simple mathematical model for formation of ocular dominance columns in mammalian visual cortex (Soc. Neur. Abs. 12:1373 (1986)). The model provides a common framework in which a variety of activity-dependent biological models, including Hebb synapses and activity-dependent release and uptake of trophic factors, can be studied.

We report here the results of simulations. LGN laminae representing each eye are represented by 25 x 25 grids, connected via 7 x 7 arbors to a 25 x 25 grid representing the cortex (a total of 61,250 modifiable connections). If afferents within one eye are correlated in their firing over at least nearest neighbor distances on the grid, and are not anticorrelated within an arbor radius, monocular cells robustly form and are organized by intra-cortical interactions into columns. Individual afferent arbors break into patches restricted to the appropriate columns, while receptive fields refine substantially in size. The more widespread the afferent correlations within one eye, the more purely monocular the resulting cortex; positive correlation over an arbor radius yields an almost perfectly monocular cortex. The width of the columns, as determined by computing the power spectra of the resulting patterns, is accurately predicted by our previous theoretical results. The effects of monocular deprivation, modelled by reducing the activity within one eye, are accurately reproduced, and a critical period is seen.

Thus, a few simple features common to many biological models of plasticity are sufficient to account for many observed features of columnar development. Most features of the model can be analytically understood, allowing predictions of the results expected under a given plasticity model from measured biological parameters.

Supported by grants from the NIH and the System Development Foundation. Computations were performed at the San Diego Supercomputer Center.

451.2

A COMPUTATIONAL MODEL FOR THE OVERALL PATTERN OF OCULAR DOMINANCE BANDS IN STRIATE CORTEX OF CAT AND MONKEY

David G. Jones, Richard C. Van Sluyters, Kathryn M. Murphy**
Department of Computer Science, Stanford University, Stanford, CA 94305
School of Optometry, University of California, Berkeley, CA 94720

In layer IV of both macaque monkey and cat primary visual cortex, geniculocortical terminals representing the two eyes are segregated into alternating zones known as ocular dominance bands. Viewed tangentially, in the monkey these bands take the form of a series of branching parallel stripes that run roughly perpendicular to the 17/18 border. On the other hand, in the cat the overall ocular dominance pattern consists of a network of irregularly branching, beaded bands, that have little if any tendency to be oriented orthogonal to the 17/18 border[1]. It has been suggested that the monkey ocular dominance pattern could result from the boundary conditions of the geniculocortical projection[2]. The present paper describes our efforts to build on this idea and formulate a single computational model that accurately predicts the quite dissimilar patterns in these two species.

Our model is based on the following observations: 1) while the LGN layers are shaped differently in these two species, the overall shape of striate cortex is the same, roughly a 2:1 ellipse; 2) in the macaque the central retina maps onto a pole of this ellipse; in the cat, it maps onto a side; 3) in both animals, neighboring points on one retina map to nearby points in the cortex, as do corresponding points from the the two retinas. Given these constraints, a computer program can generate putative cortical maps of points from the two eyes and evaluate them by computing the maximum distance between cortical representations of neighboring points (D), and the number of pairs of points that are this far apart (N). By minimizing D and N, we can determine the mapping that best meets the above constraints, and so may be called optimal. For macaque and cat boundary conditions, we obtain the following: 1) though not assumed, optimal maps invariably turn out to be retinotopic in both species; 2) in the monkey, regions representing right and left eye inputs tend to be arranged in parallel stripes, while in the cat, these regions are much less orderly and show no tendency to be oriented perpendicular to the borders of area 17.

MYELOARCHITECTURE OF FLAT-MOUNTED HUMAN OCCIPITAL LOBE: POSSIBLE LOCATION OF VISUAL AREA MT. M.I. Sereno, C.T. McDonald, and J.M. Allman. Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

Physiological and anatomical studies of extrastriate visual cortex in monkeys have uncovered a mosaic of 20 to 30 areas. The organization of these areas is remarkably similar in New and Old World monkeys, which diverged over 30 million years ago. Human extrastriate cortex is presumably organized along similar lines. However, the only visual area in humans whose borders are surely known is V1. We have therefore undertaken to describe the myeloarchitecture of human visual cortical areas using a technique for flatmounting the cortex.

Several hours after death, occipital lobes were removed and immersed in a 0.4% solution of paraformaldehyde to lightly fix the cortical grey matter but leave the unexposed white matter unfixed. The exposed surfaces of gyri in the occipital lobe were painted and numbered, and then photographed at several stages on the way to a complete flattening, which was accomplished by gently lifting off the grey matter with a blunt spatula while viewing the operation from the pial surface. The loose cortex was cut into 3 by 4 inch pieces and fixed between glass slides in 4% paraformaldehyde for several weeks before tangential 80 micron sections were cut and stained with the Gallyas silver method for myelin.

The border of striate cortex is quite apparent. A banded pattern in layer 4 of V1 with a repeat distance of about 840 microns probably represents ocular dominance columns. The rostral border of V1 is smooth except for a protruding point just dorsal to the posterior end of the lateral occipital sulcus. There is a small, ellipsoidal, coarsely-mottled, heavily myelinated area in the rostral end of the lateral extension of the parieto-occipital sulcus. This area is about 9 cm rostral to the V1/V2 border, measured on the flattened cortex, and is about 2.2 cm long dorsoventrally and 1.6 cm wide. There is no other area that is as densely myelinated within a 14 cm band surrounding the V1 border. The densely myelinated zone may correspond to area MT in non-human primates. Low contrast moving stimuli activate a similar locus as measured by PET in humans (Miezen et al., Neurosci. Abstr. 13:631). If this zone corresponds to MT, then humans have proportionally more cortex in between MT and V1 than monkeys do.

DYNAMIC PATTERNS OF ON-GOING COHERENT ACTIVITY IN NEURONAL ASSEMBLIES REVEALED BY REAL-TIME OPTICAL IMAGING IN CAT CORTEX. *A. Arieli* and A. Grinvald* The Weizmann Institute, IBM Research Division and The Rockefeller University, Lab. of Neurobiology, New York, NY 10021.

We combined real-time optical imaging, local-EEG and single unit recordings, to study the spatial organization and function of coherent neuronal assemblies. This report demonstrates a new approach to optical imaging that can be used to detect activity of neuronal assemblies rather than mixed populations, as well as to investigate the relationship between temporal patterns of activity of individual neurons and that of neuronal assemblies. We started by investigating on-going (spontaneous) activity (without a stimulus). The cat visual cortex was stained with the dye RH-795. The on-going activity in anesthetized cats was recorded continuously for 70 seconds using simultaneous optical (from 124 sites), local-EEG, and single unit (2 units) recordings. To search for spatio-temporal patterns of coherent activity from neuronal assemblies, we used spike triggered-averaging (spikes from a single neuron were used as a trigger for averaging). Analysis of the data revealed that the averaged optical signal, in a small patch of cortex, was well correlated in time course with the averaged local-EEG, indicating that the optical signal probably reflects mostly synaptic potentials. However, optical recordings offered better spatial resolution than local-EEG recordings. After subtraction of a common-mode slow depolarization, the remaining fast optical signals revealed a non-uniform spatio-temporal patterns in a cortical area of 2 x 2 mm. Most interestingly, we found that the amplitude of the on-going coherent activity recorded optically, per spike used for the averaging, was the same order of magnitude as that produced by activity evoked with an optimal visual stimulus. Analysis of segments of the data, grouped together according to the shape of the local-EEG, indicated that the patterns varied during the recording session (70 sec.). Therefore, these patterns must be dynamic over a short time scale. Finally, the spatio-temporal patterns appeared more heterogeneous with lighter anesthesia.

Since the amplitude of the on-going activity was so large and the patterns were dynamic, on-going activity is likely to interact in a dynamic nonlinear fashion with evoked activity. Therefore, it may play a significant role in cortical function of anesthetized and alert animals.

CENTER/SURROUND INHIBITORY INTERACTION IN MACAQUE V1 REVEALED BY REAL TIME OPTICAL IMAGING. *E. E. Lieke, R. D. Frostig, E. H. Ratzlaff*, and A. Grinvald.* IBM Research Division, and Laboratory of Neurobiology Rockefeller University, New York, NY 10021.

Previous reports have revealed stimulus specific long-range center/surround interactions in various cortical areas. However, the nature of these interactions as a function of multiple visual stimulus parameters and of the two dimensional functional organization of the cortex remains controversial. Real-time optical imaging can resolve some of the technical difficulties because it offers: (1) simultaneous recording of the intracellular membrane potential change from many sites with msec time resolution and (2) detection of subthreshold potentials.

We performed retinotopic imaging experiments in macaque V1, using 1° drifting gratings as stimuli. The optical signals were graded and spread over a cortical area larger than 6x6 mm, much larger than predicted from classical receptive field size, but consistent with the anatomical finding of long-range horizontal connections in cortex (Gilbert & Wiesel 1983). However, the spread of the optical signal might be due to electrotonic coupling of glial cells, rather than neuronal interaction. Furthermore, a positive optical signal can reflect either inhibition or excitation (Grinvald et al, Phsiol. Rev. 1988 *in press*).

To test whether excitation or inhibition is involved, we presented monkeys with four interlaced conditions, stimulating a small field or the surround alone, or both (the stimuli were centered with respect to the visual field by single unit recordings). In all cases activity related signals were detected in the entire cortical area (6x6 mm), and the analysis of the time course of the signals revealed that: (1) small (1-2°) gratings yielded activity in the "surround" cortical area that was delayed relative to the center and had a smaller amplitude. (2) A large grating with a bright "hole" (2.5-5°) produced the opposite result. (3) The two gratings (same orientation) presented simultaneously, but moving in opposite directions, yielded center and surround signals that were both smaller (~50%) and slower, relative to either grating alone. (4) Orthogonal orientations produced a similar result, but the effect was somewhat smaller relative to the former case. These results indicate that, on the average, the inhibitory effect is predominant. Additional experiments, employing more stimulus conditions are required to test if a net excitation exists between specific cortical sites (Nelson and Frost 1985, Ts'o et al 1986).

451.6

MAPPING OF EVOKED ELECTRICAL ACTIVITY IN NEOCORTICAL SLICES USING OPTICAL RECORDING TECHNIQUES. U. Kuhnt and L. Ehrenreich. Max-Planck-Inst. Biophys. Chem., D-3400 Göttingen.

Spatial and temporal changes of evoked neuronal activity were investigated in frontally cut, sensory neocortical slices (350 µm thick) of guinea pigs. Optical signals were recorded by a 10x10 photodiode array situated in the real image plane of an inverted microscope. Dependent on the objective, a single diode recorded optical changes from an area 110x110 or 70x70 $(\mu m)^2$ of tissue. Voltage sensitive absorption (RH155) or fluorescence (RH414) dyes were used. Stimulating electrodes were placed in layer I (L1) and in the white matter (WM). Stimulation in L1 evoked optical signals which were restricted to the upper three layers. The early, fast rising component of this response was due to antidromic and/or direct stimulation as could be shown by blocking synaptic transmission. Stimulation in WM evoked optical signals which could be detected in the lower five layers and spread laterally for 600-700 µm. 3-D reconstructions of amplitude distributions showed two stripes of increased activity after WM stimulation. The latencies of these stripes differed by 1 to 2 ms. The stripe with the shorter latency was localized perpendicular above the locus of stimulation, and was mainly due to antidromic activation. The second stripe was localized lateral to the stimulating electrode. It might be caused by activation of afferent fibres entering the neocortical grey matter and might reflect the basic functional unit in this cortical area.

CONNECTIVITY PATTERNS WITHIN RAT EXTRASTRIATE CORTEX REVEALED WITH THE AID OF VITAL TRACING OF CALLOSAL CONNECTIONS. R. Malach Neurobiology Dept., Weizmann Inst., Rehovot, Israel 76100.

It has been shown that rat extrastriate cortex can be subdivided into at least 9 separate areas. The connections among these areas were traced using localized injections of WGA-HRP. Accurate placement of injections was guided by the pattern of callosal connections which were revealed in vivo (Malach; Soc. Neurosci. Abs. 13:4). Results indicate that each area is connected to at least five other fields situated both in areas 18a and 18b. In all areas studied, the interconnections appear to relate similar representations of visual space. There seems to be a global map, within which the various fields are embedded, such that extreme rostral areas are connected more to lower field representations in striate and extra-striate cortex, while extreme posterior areas appear to over emphasize the upper visual field. Middle visual areas seem to be connected to all areas roughly equally. Thus, one factor distinguishing the various visual maps in the rat might be a systematic shift in emphasis of different locations within the visual field. SYNAPTIC ORGANIZATION OF GABA AND GABA/TACHYKININ IMMUNOREACTIVE NEURONS IN LAYER IVCB OF MONKEY AREA 17. S.H.C.Hendry and E.G. Jones. Dept. of Anatomy & Neurobiology, University of California, Irvine, Irvine, Ca 92717

GABA- and tachykinin- immunoreactive neurons were examined electron miscroscopically in layer IVCB of normal and monocularly deprived monkeys (M. fascicularis) and in monkeys in which the geniculocortical afferent axons were labeled by anterograde degeneration. The density of axosomatic and proximal axodendritic synapses was assessed in serial thin sections. Almost half the GABA neurons were sparsely innervated (10 synapses/100 um^2) and half were richly innervated (25 synapses/100um^2). Only a small proportion of GABA cells were moderately innervated (11-25 synapses/100um^2). Most tachykinin neurons were included in that subpopulation of GABA neurons which was sparsely innervated. Sparsely innervated GABA and tachykinin neurons received a relatively large proportion of their axosomatic and axodendritic synaptic contacts from geniculocortical axons. By contrast, the richly innervated GABA neurons received a very small proportion of their contracts from these afferent axons. Following injections of tetrodotoxin into one eye, half of the GABA cells and only 10-20% of the tachykinin neurons remained immunostained. These cells were richly or moderately innervated. These findings suggest that the synaptic inputs to GABA/tachykinin neurons in layer IVCB may underlie their sensitivity to changes in visually evoked activity. Supported by NEI Grants EY 06432 & EY 07193.

A GENICULO-PRESTRIATE PROJECTION SURVIVING IN LONG-TERM DESTRIATE MACAQUE MONKEYS. Anita M. Cooper* and Alan Cowey* (SPON : J. Phillips). Dept. Expt. Psychology, Oxford, OX1 3UD, U.K.

The study investigated the distribution and morphology of neurones surviving for up to 8 years in the dorsal lateral geniculate nucleus (LGNd) after total unilateral removal of the striate cortex in a group of 11 rhesus monkeys. All surviving neurones were counted and those from a sample of 5 sections through the central LGNd were drawn and measured, and distribution through the nucleus was plotted. Neurones survived in both laminar and interlaminar zones. Cells surviving within the parvocellular layers were significantly larger than those within the "parvocellular interlaminar" zones, and those within the "magnocellular interlaminar" zones. However, there were no significant differences in cell body size between the magnocellular and parvocellular layers and the two interlaminar zones. In one animal (surviving for 96 months after the striate lesion) Horseradish Peroxidase injected into the prestriate cortex retrogradely labelled neurones throughout the degenerated caudal LGNd in topographic register with the central retina and with the position of the prestriate injection sites.

HIERARCHICAL ORGANIZATION OF RAT VISUAL CORTEX. T.A. Coogan* and A. Burkhalter (SPON: G.W. Harding). Dept. Neurosurgery & McDonnell Center for Studies of Higher Brain Function, Washington University Medical School, St. Louis, MO 63110.

We have investigated the laminar pattern of connections between visual cortical areas in the hooded rat using PHA-L tracing methods, and have found evidence for two projection types. One type terminates in layer 4 (L4) as well as in L 2/3 and deeper L1. The other is predominately to L1, deep and superficial, and also projects to L 2/3, but avoids L4. The projections from area 17 to four sites in area 18a and two in 18b, are all of the first type; projections back to area 17 from those extrastriate areas are of the second type. Likewise, the projection from area 18a to 18b is of the first type, while the reciprocal projection is of the second type. Projections of the first type have also been found to temporal and cingulate cortices.

The laminar pattern of these connections are similar to those in the primate visual cortex, where projections to areas of higher processing (forward) resemble the first type, while the reciprocal, feedback connections are like the second type. This evidence suggests that areas in the rat visual cortex are hierarchically organized similar to those in primates, with area 17 at the lowest level, the visuotopic areas within 18a next, areas of 18b higher, and the areas of temporal and cingulate cortex still higher. CYTOCHROME OXIDASE TOPOGRAPHY IN STRIATE CORTEX OF NORMAL AND MONOCULARLY ENUCLEATED CEBUS MONKEYS. M.G.P.Rosa*, R.Gattass and M.Fiorani Jr.*(SPON: C.G.Gross). Instituto de Biofísica Carlos Chagas Filho, Rio de Janeiro, 21941, Brazil.

The distribuition of cytochrome oxidase (CO)-rich regions was studied in flat-mounts of primary visual cortex (V1) of 2 normal and 2 enucleated Cebus monkeys. Monocular enucleation was performed under pentobarbithal anesthesia 4 to 7 months before sacrifice. In the enucleated monkey, the topographic distribution of ocular dominance (OD) stripes in layer IV was similar to that described for macaques (Le Vay et al.'85,J.Neurosci.5:486). Stripes tend to intersect the V1/V2 border perpendicularly, and to run along isoeccentricity lines throughout the calcarine cortex. In opercular V1, stripes converge and stream medially after leaving the V1 border, except at the foveal representation, where no consistent pattern is observed. In the normal monkey, the most striking aspect of CO topography in the supragranular layers was the uniformity of CO blob density. For eccentricities ranging from foveal to 60 degrees, a constant blob density (about 4 blobs/mm^2) was observed. In monocular representation, however, the blob density fell to about 2.7 blobs/mm^2 . Mean blob area decreased towards the periphery of V1. In the enucleated monkeys, CO blobs tended to be smaller in regions overlying enucleated-eye domains, but were still visible and clearly outlined, even 7 months after enucleation.

VICIA VILLOSA LECTIN IS A SELECTIVE MARKER FOR A SUBSET OF GABA CELLS IN MACAQUE STRIATE CORTEX. K.A.Mulligan, J.F.M.van Brederode* and A.E.Hendrickson. Depts. of Biological Structure and Ophthalmology, Univ. of Washington, Seattle, WA 98195.

The lectin from *Vicia villosa* (VVA) has been shown to label GABAergic neurons in both the rat (Nakagawa et al., J. Neurocytol.15:389-396) and cat (Naegele et al., Soc. Neurosci. Abstr. 13:359) cerebral cortex. We analyzed the distribution and morphology of neurons that label specifically with VVA in the macaque striate cortex. Following incubation with peroxidase-, biotin- or FITC-conjugated VVA, a population of neurons shows fine, punctate reaction product over the surface of the soma and proximal dendrites. Small numbers of labeled cells are found in layers 2, 3A, 5 and 6, but the majority (~75%) are located in a strip of cortex overlying layers 3B to 4Ca. Layers 1 and 4Cß are devoid of labeled cells. In the supragranular layers there is no clear correlation between the distribution of VVA-labeled cells and the pattern of cytochrome oxidase staining.

Double-labeling of single sections showed that most (~78%) of the VVA-labeled cells are GABA-immunoreactive. Quantitative analysis of the distribution and cross-sectional areas of double-labeled cells indicated that they make up about 30% of the total GABAergic population and include all the large (> 160 μm^2) and many medium-sized GABAergic cells. GABAergic cells with soma areas less than 60 μm^2 were not labeled with VVA. While the soma size and laminar distribution of the VVA-labeled neurons suggest that they include the large GABAergic basket cells, intracellular injections of Lucifer Yellow into VVA-labeled cells in slices of fixed cortex reveal cells with at least three distinct types of dendritic morphology.

451.13

SIZES AND DISTRIBUTION OF GABA-IMMUNOREACTIVE NEURONS IN THE MONKEY STRIATE CORTEX. J.F.M. van Brederode*, K.A. Mulligan, R. Mehra*, and A.E. Hendrickson (SPON: C.A. Curcio). Depts. of Biol. Structure and Ophthalmol., Univ. of Washington, Seattle, WA, 98195

It has become clear that GABA-immunoreactive (GABA+) neurons in the striate cortex (SC) are not a structurally homogeneous group. In this study we describe the soma area and laminar distribution of GABA+ neurons and of a sub-population of GABA+ neurons that appear to be densely contacted by Substance P-immunoreactive terminals at the light microscopic level (GABA+/SP+). Sections of the SC were incubated in polyclonal antisera to GABA and SP, reacted with the appropriate antibodies, and visualized using different chromagens. Soma area and cell density were determined using a computer-video-microscope system. Cell density of GABA+ cells was highest in layers 2 and 4Cß. GABA+/SP+ cells were most common in layers 3, 4B, and 6, but were few in 4Cß. Soma areas (μm^2) of GABA+ cells (n=603) are shown below:

Lamina	1	2-3A	3B-4A	4B	4C	5	6
Mean	58	85	110	118	100	96	110
Range	39-90	39-181	40-198	45-265	46-269	32-218	50-265

GABA+ cells in layers 1 and 2 were smaller than those in deeper layers ($P<0.05$, Scheffe's test). Soma area variabiility was small in layers 1 and 4Cß, and large in 4B, 5, and 6. GABA+/SP+ cells were on average 1.5 times larger than GABA+/SP- cells ($P<0.05$). In conclusion, this study shows that the size of GABA+ cells in the SC varies in relation to cortical depth, and that SP+ terminals contact medium to large GABA+ cells. It is likely that GABA+/SP+ cells overlap with large GABA+ cells shown to label with the VVA lectin. This study was supported by NIH grants EY 01208, EY 04535, and EY 07031.

GAPS AND PATCHES IN VISUAL THALAMIC AND CORTICAL INPUT TO THE CLARE-BISHOP AREA. H. Vickland* and H. Sherk (SPON J. DeVito) Biol. Structure, U. of Wash., Seattle, WA 98195

Areas 17,18, and 19, as well as the LGN, all have patchy projections to the Clare-Bishop area (CB), an area of extrastriate cortex in the cat. The gaps between these patches may represent input from another source. One potential source was tested by injecting WGA-HRP into areas 17 and 18, and ^{3}H-amino acid into the lateral division of the lateral posterior nucleus (LPl), the major thalamic input to CB. There was only slight tracer spread into the medial division of LP, LPm. If input to the gaps between patches of cortical input came from LPl, we would expect the radioactive label to fall between patches of WGA-HRP. Instead, patches of the two tracers in CB were superimposed.

In a second experiment, similar but larger injections were made; both LPl and LPm were heavily involved by the ^{3}H-amino acid. While the labeled projection from areas 17 and 18 was patchy, that from LPl+LPm formed a continuous band throughout CB. The band extended beyond it, up onto the lateral bank of the suprasylvian sulcus, an area to which LPm strongly projects. This finding suggested that LPm, the tecto-recipient zone of visual thalamus, projects to the gaps between patches of input from areas 17 and 18.

RELATIONSHIP BETWEEN THE REPRESENTATION OF THE VISUAL FIELD AND THE TOPOGRAPHY OF AFFERENT CONNECTIONS TO AREA 17 OF THE CAT.

P.A. Salin*, J. Bullier and H. Kennedy. INSERM U. 94, 16 av. Doyen Lépine, 69500 BRON, FRANCE.

We have studied the topography of the afferent connections to area 17 with double retrograde label tracing techniques. A graphic method was developped to calculate the extent of the convergence and divergence of a given connection. The convergence is the extent of an afferent structure which contains neurons converging on a small region of area 17. The divergence is the extent of area 17 innervated by a small region of the afferent structure. The results show that the convergence of the projection from the LGNd to area 17 is 0.4 mm and its divergence 2 mm. The cortical afferents present much larger values of divergence. For example, the divergences of the reciprocal connections between areas 17 and 18 are 6 mm. The divergence of the projection from area 19 to area 17 is 10 mm and those from areas 20 and PMLS are close to 20 mm. Knowing divergence and convergence and the retinotopic organizations of area 17 and the LGNd, we show that the geniculo-striate projection link regions representing the same part of the visual field. Such is not the case, however, for the cortical afferents of area 17. For example, the convergence region in area 18 represents a zone 15° wide in visual field and it converges on a projection line of area 17 which represents 5° of visual angle. These results suggest that, contrary to the geniculate afferents, the connections between the visual cortical areas preserve parameters other than retinal topography.

451.16

ORIENTATION OF INTRINSIC AXONS IN TURTLE VISUAL CORTEX. C. E. Cosans* and P. S. Ulinski (SPON: D. Margoliash). Dept. Anatomy, University of Chicago, Chicago, IL 60637.

Cells in turtle visual cortex respond to small, moving stimuli anywhere in visual space. The lateral geniculate complex receives a point-to-point representation of the retina, but projects to cortex in a point-to-line fashion. A dorsal-ventral line of geniculate cells represents points along a given vertical meridian, so all cells along the corresponding medial-lateral line of the cortex receive input from all points along that vertical meridian. This abstract deals with the way in which cortical cells receive input from all points along the horizontal meridians. Axons in visual cortex of Pseudemys scripta were labeled in an in vitro wholebrain preparation with focal HRP injections. Preparations were maintained up to 10 hours in Ringers solution, flattened and reacted with diaminobenzidine. Relatively short axons radiate from the injection sites. The directions of 306 axons relative to the rostral-caudal axis were measured in 9 injection sites. Axons project in all directions, but with some preference along the representations of the vertical meridians. Thus, one part of the visual cortex projects in all directions to other nearby parts of the visual cortex; a cortical cell apparently receives input from all points along the horizontal meridians by a series of short, intracortical projections.

INTRACORTICAL AND CALLOSAL CONNECTIVITY IN THE VISUAL SYSTEM OF THE CAT. J.P. Guillemot, L. Richer*, M. Ptito, F. Leporé. Univ. du Québec and Univ. de Montréal, Québec.

Anatomical studies have shown that corpus callosum (CC) neurons connect homo- and heterotopically the visual areas such that lower order areas project to similar or higher order areas. However, the latter are also extensively interconnected intra-cortically. The present study examined with electrophysiological methods, combined with localized inactivation, the organization of these CC connections.

Neuronal activity was recorded: from CC recipient neurons in areas 17-18 or lateral suprasylvian (LS) in split-chiasm cats, from CC fibres in normal cats; from CC fibres in split-chiasm cats. Sequential inactivation of areas 17-18 and LS was obtained with topical application of Xylocaine. Recovery of areal function was confirmed by the recovery of unit response and of the VER in the area.

Results confirmed the expected predictions: cells were driven from homotopic areas via CC. However, more complex information flow was also noted: cells projecting from 17-18 to contralateral LS first synapsed in contralateral 17-18 or ipsilateral LS. Some bidirectional activity was also seen: cells projecting via CC to LS might themselves be partially activated from the other side. The latter results, which could note be predicted from the anatomy, indicates that our method can be a powerful tool to study cortico-cortical callosal connectivity.

ACTIONS OF EXCITATORY AMINO ACID ANTAGONISTS ON SYNAPTIC POTENTIALS IN THE CAT'S VISUAL CORTEX STUDIED IN VITRO. T. Shirokawa, A. Nishigori* F. Kimura* and T. Tsumoto, Dept. Neurophysiol., Biomed. Res. Ctr., Osaka Univ. Med. Sch., Kita-Ku, Osaka 530, Japan.

Excitatory amino acids (EAAs) such as glutamate and aspartate are suggested to be transmitters at least at geniculo-cortical synapses in the cat visual cortex (Tsumoto et al. J. Neurophysiol. 55, 469, 1986). EAA receptors can be classified into three types according to affinity for agonists; N-methyl-D-aspartate (NMDA), quisqualate and kainate receptors. In the present study using slice preparations of the cat visual cortex, we addressed a question of which types of receptors mediate excitatory postsynaptic potentials (EPSPs) of layer II/III cells evoked by electrical stimulation of the underlying white matter. We used 2-amino-5-phosphonovalerate (APV) as a selective antagonist for NMDA receptors and kynurenate (KYNA) as a broad-spectrum antagonist. An application of KYNA through the perfusion medium with 0.2-1.0 mM antagonized EPSPs so that slopes of their rising phase and peak amplitudes were dramatically reduced. By contrast, APV (50µM) suppressed the EPSP slopes in some of the cells but it did not in the others. In the latter group of cells the APV-sensitive EPSPs appeared when bicuculline, a γ-aminobutyric acid (GABA) antagonist, was added to the medium. There was a tendency that the APV-sensitive excitation was induced with longer latencies and often masked by GABAergic inhibition.

ELECTROPHYSIOLOGICAL INVESTIGATION OF CALLOSAL CONNECTIONS OF RAT VISUAL CORTEX IN A SLICE PREPARATION. T. J. Teyler and R. L. Berry (Spon: D. Molfese). Dept. of Neurobiology, NE Ohio Univ. College of Medicine, Rootstown, Ohio 44272.

In vitro slice techniques have proven powerful tools for the investigation of the electrophysiology of brain circuitry in many brain areas, especially those possessing a lamellar organization. In the present study the slice preparation was used to study the circuitry of the connections between right and left hemisphere visual cortical areas which are mediated by fiber tracts passing through the corpus callosum in a curved trajectory.

Visual cortical slices were obtained from Long Evans hooded rats (2-3 wk) in a standard fashion except that curved cutting blades conforming to the callosal fiber trajectories were employed to preserve these tracts. Depth profiles of field potentials in response to white matter stimulation were recorded and subjected to current source density analysis. The curved slices greatly increased the medial extent of white matter that, when stimulated, produced current sources and sinks in cortical areas OC2MM, OC2ML, OC1M and the OC1B /OC2L border--in some cases this extended into the contralateral white matter. This finding indicated that the callosal pathway mediated these effects. The patterns of current sources and sinks evoked in these cortical areas by callosal stimulation will be presented. Supported by ONR Grant #86K0664.

451.20

CALLOSALLY AND CORTICOTHALAMICALLY PROJECTING PYRAMIDAL CELLS IN CAT VISUAL CORTEX HAVE DIFFERENT SYNAPTIC DENSITY ON CELL BODIES AND AXON INITIAL SEGMENTS. Isabel Fariñas* and Javier DeFelipe. Instituto Cajal, CSIC, Velázquez 144, 28006 Madrid, Spain.

Pyramidal cells receive only symmetrical contacts on their soma and axon initial segment (AIS) from putatively inhibitory GABAergic terminals. We have studied whether there are differences in the number of these contacts between cells projecting to different targets. Callosally and corticothalamically projecting cells in area 17 were retrogradely labelled after injections of horseradish peroxidase in the contralateral cortex or in the lateral geniculate nucleus, respectively. The AIS and portions of the somata (through a depth of about 1.75 µm at their maximum diameter, MD) of labelled cells were reconstructed from electron micrographs of serial thin sections and synapses (S) counted.

	layer	MD(µm)	S_{SOMA}	S_{AIS}
Callosal	III-IV	14-30	12-33 (n=14)	16-21 (n=5)
Corticothalamic	VI	12-22	3-12 (n=13)	1-3 (n=7)

The results indicate that these two well-defined populations of projecting cells clearly differ with regard to the synaptic density on their cells bodies and AIS. This may be a clue to the differences in their functional characteristics.

451.21

MORPHOLOGICAL TYPES OF PROJECTION NEURONS IN LAYER 5 OF RAT VISUAL CORTEX. M. Hübener* and J. Bolz. Friedrich-Miescher-Labor der Max-Planck-Gesellschaft, Spemannstr. 37-39, 7400 Tübingen, FRG.

Pyramidal cells in layer 5 of the primary visual cortex (area 17) project to several subcortical targets, such as the superior colliculus (SC), the lateral posterior nucleus (LPN) and the pons. Previous studies showed that these cells can have axon collaterals to more than one subcortical site. In area 17 of the rat there is an additional projection of layer 5 neurons to the contralateral cortex. We were interested whether different cells in layer 5 project to cortical and subcortical targets. Two fluorescent tracers, fluoro-gold and rhodamine labeled latex microspheres, were injected into the SC and the contralateral cortex respectively. Retrogradely labeled cells from the SC were restricted to layer 5. Callosal projecting neurons were found in all cortical layers near the 17/18 border and in lower layer 5 and upper layer 6 throughout area 17 . No double-labeled cells were detected, indicating that the two projections arise from different cells. There was a wide variation in soma sizes of the labeled cells. Corticotectal cells had somewhat larger cell bodies than callosal cells, but there was a considerable overlap between the two populations of neurons. In order to get a more detailed view of the cells' structure, we combined retrograde labeling with intracellular staining. After injections of microspheres into the SC or the contralateral hemisphere, brain slices were prepared from area 17 and retrogradely labeled cells were injected with Lucifer Yellow. Callosal cells have 4-6 basal dendrites an an apical dendrite terminating in or below layer 3. Corticotectal cells possess 6-9 basal dendrites and a prominent apical dendrite which always forms a large tuft in layer 1. Thus, each population of neurons has a rather stereotyped dendritic branching pattern, despite the large variation in soma size. The marked morphological differences between cortical and subcortical projecting neurons in layer 5 suggests that there is an association between structure and function of these cells.

PROCESS OUTGROWTH, GROWTH CONES, AND GUIDANCE MECHANISMS VIII

452.1

IMMUNOCYTOCHEMICAL LOCALIZATION OF GAP-43 IN THE DEVELOPING RAT BRAIN. J. W. Dani, F. H. Gage, L. I. Benowitz and D. M. Armstrong. Depart. of Neurosciences, University of California, San Diego, La Jolla, CA 92093.

GAP-43 is a phosphoprotein synthesized in high concentrations during development of the mammalian CNS. Despite its prominent role during embryogenesis, relatively little is known of its anatomical distribution within the developing brain. In the present study, we employed immunocytochemical techniques using antibodies against GAP-43 and examined the distribution and cellular localization of this protein within brains of developing Sprague-Dawley rats. Numerous pre- and postnatal time points were examined.

GAP-43 was first detected in the periphery of whole mount preparations as early as E-10. Subsequently, dense fasicles of peroxidase reaction product could be detected throughout all prenatal time points in regions corresponding to major fiber tracts. By early postnatal days, the intensity of these labeled fibers decreased, thereafter GAP-43 immunoreactivity assumed its adult-like characteristics and could be detected within the neuropil of selected anatomical regions.

452.2

EXPRESSION OF GAP-43 DURING CNS DEVELOPMENT: AN IN SITU HYBRIDIZATION STUDY. R. Jacobson[1] and R. Neve[2], Depts. of [1]Neurology and [2]Genetics, Children's Hosp., Boston MA 02115

GAP-43 (aka B50, F1, pp46), a developmentally regulated neuronal phosphoprotein found in growth cones and synapses, is believed to play a role in axon growth and/or synaptic plasticity. If GAP-43 is important for process elongation in general, it should be expressed in most, if not all neurons during developmental axon growth. Alternatively, it might serve a specialized function in a subset of neurons. We are studying the distribution of GAP-43 message during development using in situ hybridization. Frozen sections of rat embryos at various stages are hybridized with an ^{35}S labelled RNA probe complimentary to the GAP-43 message; specific hybridization signal is detected autoradiographically. The 1.4 kb GAP-43 message is detectable on Northern blots by 14 days gestation (E14). With in situ, no signal is seen in the neural plate (E10) or in neural tube prior to the formation of the intermediate layer (E12). By E13, signal is seen in the primordial motor columns of the spinal cord, the sensory ganglia, retina, and intermediate lay layer of the brainstem, with especially strong signal in some clusters adjacent to the ventricular layer--presumably brainstem motor nuclei. Later (E15,16) much of the intermediate layer is labelled, with motor columns and patches of brainstem tegmentum showing stronger signal than surrounding areas. Thus, GAP-43 expression is widespread in early CNS development, but the level of its expression appears to be heterogenously distributed.

452.3

TYROSINE HYDROXYLASE AND GAP-43-LIKE IMMUNOREACTIVITIES IN THE DEVELOPING NIGROSTRIATAL AND MESOCORTICAL SYSTEMS. C.E. Adams, L. I.Benowitz and T.E. Finger. Dept. Cell. and Struc. Biol. Colo. Med. Sch., Denver, CO; Depts. Psych. and Neur., Harvard Med.Sch., Boston, MA

The 43 Kd phosphoprotein GAP-43(B50) has been implicated in axon elongation and synaptogenesis. In the present study, the development of GAP-43 was examined within a well characterized system to determine: 1) when GAP-43 is detectable relative to neuronal birth date and transmitter synthesis, and 2) how changes in the levels and distribution of GAP-43 correlate with developmental milestones such as initial axon elongation and synaptogenesis. Rat fetuses ranging in size from 9-19mm crown rump length were fixed and sectioned on a cryostat. The tissue was incubated in an antibody mixture containing mouse anti-tyrosine hydroxylase and sheep anti-GAP-43. Cells at the level of the mesencephalic flexure were labeled for both GAP-43 and TH at the earliest time examined (9mm). Labeling of GAP-43 was less intense in cells closer to the ventricular surface than in those nearer the pia at this stage. At later stages (13-19mm), fibers coursing towards the prosencephalon were immunoreactive for both TH and GAP-43.

452.4

EXPRESSION OF GROWTH-ASSOCIATED PROTEIN-(GAP)-43 IN THE DEVELOPING AVIAN NERVOUS SYSTEM. L. Baizer, S. Alkan*, and G. Ciment. Depts. of Pharmacology and Cell Biology and Anatomy, Oregon Health Sci. Univ., Portland, Or. 97201

Growth-associated protein-(GAP)-43 is a rapidly transported axonal membrane protein which is concentrated in the growth cone and expressed at markedly elevated levels during periods of axonal growth and regeneration in the nervous system. In order to analyze the involvement of GAP-43 in early neurogenesis and to obtain a more direct assessment of its phylogenetic conservation, a cDNA for chicken GAP-43 has been isolated and characterized. A cRNA probe corresponding to a short region of the cDNA for rat GAP-43 was used to screen a lambda gt10 cDNA library derived from embryonic day 10 chicken brain. Several positive clones were isolated and the longest (1.2 kb) was subcloned for further analysis. This cDNA hybridizes with an mRNA of about 1.5 kb which is restricted to nervous tissue in its expression and developmentally regulated in its abundance. DNA sequence analysis reveals that the predicted amino acid sequence for chicken GAP-43 displays 50-70% identity to that for rat.

The chicken GAP-43 cDNA has been subclone into a bacterial expression vector to generate antiserum to the protein. Specific probes for GAP-43 mRNA and protein will permit us to determine when and where GAP-43 begins to be expressed in the developing chicken nervous system.

Supported by grants from the NIH and the Oregon MRF.

452.5

GAP-43 PROMOTES AXONAL OUTGROWTH AND REGENERATION. R. J. O'Brian[1], R. L. Neve[2], L. Villa-Komaroff[3] and B. A. Yankner[3]. Dept. of Medicine[1], Massachusetts General Hospital, Depts. of Genetics[2] and Neuroscience[3], Children's Hospital, Boston, Massachusetts 02115.

The neuronal growth associated protein (GAP-43) is normally present at low levels in the rat pheochromocytoma cell line PC12 but is induced by treatment with nerve growth factor (NGF). In order to determine if GAP-43 is causally involved in neurite outgrowth, PC12 cells were transfected with GAP-43 cDNA in a DNA expression vector by the calcium phosphate method. Several clones were isolated that overexpressed GAP-43 RNA from the transfected cDNA and exhibited a marked acceleration of neurite outgrowth in response to NGF. The clones with higher GAP-43 RNA expression showed a greater neurite outgrowth response. PC12 cells transfected with the DNA expression vector alone showed the same neurite outgrowth response as untreated PC12 cells. Following mechanical shearing of neurites from differentiated PC12 cells, those cells overexpressing GAP-43 RNA showed a more rapid regeneration of neurites than controls; in addition, these cells displayed transient neurite regeneration in the absence of NGF. These results suggest the active involvement of GAP-43 in axonal outgrowth and regeneration.

452.6

POSSIBLE ROLE OF GAP-43 IN CALCIUM REGULATION / TRANSMITTER RELEASE. J. A. Freeman, A. A. Lettes, and B. Costello*. Department of Cell Biology, Vanderbilt University, Nashville, TN 37232.

Growth associated proteins (GAPs) may play an important role in neuronal growth and regeneration, yet very little is known about their function. We are currently investigating the role of GAP-43 on the regulation of intracellular calcium and on its possible modulation of neurotransmitter release. The PC12 clonal cell line provides an excellent system for these studies since exposure to nerve growth factor (NGF) markedly increases the expression of GAP-43.

In preliminary experiments, PC12 cells treated with NGF were loaded with the calcium sensitive dye FURA-2, and imaged with a high-resolution thermoelectrically cooled CCD camera. Cells were then incubated with GAP-43 antibody in the presence of 1% DMSO for 12 hrs. Labeling with a fluorescein tagged rabbit antibody showed that the GAP-43 antibody indeed penetrated the cells, and was sequestered preferentially into growth cones. When PC12 cells were exposed to 0.5 mM carbachol, FURA-2 fluorescence was markedly reduced compared to control (1% DMSO). Treatment with GAP-43 antibody decreased the carbachol induced release of (3H)NE by 50 %.

These results suggest a role for GAP-43 in the regulation of intracellular calcium which could effect calcium mediated events such as neurotransmitter release.

452.7

EVIDENCE FOR A SINGLE PHOSPHORYLATION SITE IN NEURONAL PROTEIN B50. P.J. Coggins* and H. Zwiers* (SPON: F. Quandt). Depts. of Med. Physiol. and Med. Biochem., Univ. of Calgary, Alta, T2N 4N1, Canada.

The neuronal protein B50 has a molecular weight of 24 kDa determined by direct chemical and cDNA sequencing, but has an apparent molecular weight of about 50 kDa on SDS gels. The protein contains 14 Ser and 14 Thr residues which are potential sites for kinase C mediated phosphorylation. Phosphoamino acid determination revealed the presence of [^{32}P]-Ser, but not [^{32}P]-Thr, in an acid hydrolysate of [^{32}P]labelled rat B50. [^{32}P]B50 was also digested by SAP and the reaction mixture was separated by HPLC, with UV and on-line beta radiation detection. The UV chromatogram contained numerous SAP products including four previously identified B50 fragments; S_1, S_2, S_3 and S_4 (McMaster et al 1988, in press). In contrast the beta chromatogram contained two labelled fragments which ran as 28 kDa and 14 kDa bands on SDS gels. Both are N terminally blocked and neither had the same HPLC retention times as the B50 fragments S_1 to S_4. Amino acid composition and partial sequence data indicated that S_1 is $B50_{204-226}$, S2 is $B50_{66-132}$ and that S_3/S_4 begin at residue 133 and extend to residue 203 or possibly further. A blocked N terminus suggested that the 14 kDa and 28 kDa SAP products are large N terminal fragments of B50. Therefore, we conclude that B50 contains a single phosphorylation site at Ser41, since all other Ser residues are eliminated.

REGULATION OF GAP-43, A NEURONAL GROWTH-ASSOCIATED PHOSPHOPROTEIN, IN PC12 PHEOCHROMOCYTOMA CELLS. B. Costello and J.A. Freeman (SPON: A. Lettes). Dept. of Cell Biology, Vanderbilt Medical School, Nashville, TN 37232.

The PC12 line of pheochromocytoma cell undergoes neuronal differentiation when grown in the presence of NGF. NGF also has been shown to increase levels of the growth-associated protein GAP-43 in PC12 cells. We have studied the regulation of GAP-43 expression by NGF as well as several other effectors under a variety of conditions. Induction of GAP-43, which is inhibited by methyltransferase inhibitors, is dependent on both NGF concentration and cell density, and exhibits some substrate specificity which appears to be related to the relative ability to support neurite outgrowth. In addition to NGF and dBcAMP, FGF also is an effective inducer, but EGF is not. Using FURA-2, we found that like NGF, FGF causes an increase in $[Ca]_i$, maximum in growth cones. Dexamethasone does not by itself affect GAP-43 levels, but appears to slightly decrease NGF induction. The effects of these various agents on GAP-43 levels correlate qualitatively with their reported effects on process outgrowth in PC12 cells and support the putative role of GAP-43 in neuronal growth.

SITE SPECIFIC PHOSPHORYLATION OF GAP-43. K.F. Meiri* and L.E. Bickerstaff*. (SPON: J. Covault), Dept. Pharmacology, SUNY Health Science Center, Syracuse, NY 13210.

The growth-associated protein GAP-43 is regulated in two ways: First, its synthesis and axonal transport are induced in neurons that are growing or regenerating axons. Second, its phosphorylation is regulated even in non-growing neurons. Phosphorylation of GAP-43 may further serve to regulate its interactions with other axonal proteins, specifically those of the growth cone membrane skeleton where GAP-43 is highly enriched. We are investigating whether growth cone GAP-43 is a substrate for calcium/calmodulin kinase as well as kinase C and have established that while pure GAP-43 is phosphorylatable by both kinases, the phosphorylation sites for the two enzymes are different. GAP-43, purified from neonatal rat brains by reverse phase HPLC or calmodulin affinity chromatography and incubated with ^{32}P-ATP and either pure kinase C or pure ca/cam kinase, was partially proteolysed with trypsin and the peptides separated by reverse phase HPLC. Phosphopeptides were identified by liquid scintillation counting. Pure kinase C phosphorylated one major peptide that was different from those phosphorylated by ca/cam kinase. Amino acid analysis and sequencing of these phosphopeptides allows us to locate the phosphorylation sites within the GAP-43 molecule and will enable us to determine the phosphorylation state of membrane-skeleton-associated growth cone GAP-43. Supported by NIH Grant NS 26091.

PHOSPHORYLATION OF THE PRESYNAPTIC MEMBRANE-BOUND PROTEIN B-50 (GAP-43) BY CASEIN KINASE II. M.R. Pisano*, M.G. Hegazy*, E.M. Reimann*, and L.A. Dokas (SPON: H.J. Waller). Departments of Biochemistry and Neurology, Medical College of Ohio, Toledo, OH 43699.

B-50 (GAP-43) is a presynaptic membrane-bound phosphoprotein specific to the central nervous system. The phosphorylation state of the protein may play a role in the regulation of phosphoinositide metabolism. Of several kinases tested for their abilities to phosphorylate purified B-50, including glycogen synthase kinase 3, catalytic subunit of cAMP-dependent protein kinase, protein kinase C and casein kinase II (CK-II), only protein kinase C and CK-II were able to significantly phosphorylate B-50. B-50 phosphorylation by protein kinase C has previously been established. CK-II incorporated nearly 1 mole ^{32}P/mole B-50 and this activity was almost completely inhibited by 5 µg heparin/ml. Tryptic peptide mapping of [^{32}P]B-50 phosphorylated by CK-II showed that the radioactivity was incorporated into a single peptide. Phosphoamino acid analysis indicated that ^{32}P was incorporated exclusively into serine residues. Phosphorylation of heat-treated synaptic plasma membrane preparations by CK-II resulted in phosphorylation of several proteins but the major substrate was B-50. These studies indicate that B-50 could be a physiological substrate for CK-II. Supported by NIH grants NS 23598 and DK 19231.

IDENTIFICATION OF A NOVEL NEURONAL INTERMEDIATE FILAMENT PROTEIN THAT IS PHOSPHORYLATED IN PC12 CELLS. J. M. Aletta[1], R.H. Angeletti[2], R.K.H. Liem[1], C. Purcell*[2], M.L.Shelanski[1], and L.A.Greene[1]. [1]Dept. of Pathology Columbia University N.Y.C. N.Y. 10032 [2]Div. Neuropath. Univ. of Pennsylvania, Phila. PA 19104.

NGF induces an mRNA in PC12 cells that encodes a novel neuronal intermediate filament protein that is present in PNS and certain CNS neurons (Leonard et al. J. Cell Biol. 106:181, 1988). The present results concern the identification and characterization of this protein. Partial microsequencing of the major cytoskeletal protein of PC12 cells (58 kDa; pI=5.6-5.8), derived by extraction with 1% Triton X-100, yielded a 14 residue sequence that is identical to a portion of the sequence deduced from the NGF-induced message, but not to sequences of other known proteins. Also, an antiserum raised against a 19 residue synthetic peptide corresponding to the unique C-terminus region of the protein encoded by the NGF-regulated message specifically recognizes the 58 kDa protein on Western blots and, by immunofluorescent cell staining, filamentous structures as well as a dense perinuclear cap. The protein resolves as 4 to 5 spots by IEF and is elevated in cytoskeletons from NGF-treated cells relative to those from non-treated cells. Two of these isoforms are found in the Triton-soluble fraction. Isoforms associated with the cytoskeleton are phosphorylated, but the Triton-soluble forms are not metabolically labeled with ^{32}P-orthophosphate. Relative phosphate incorporation is elevated within 2h of exposure to either NGF, TPA, a cAMP analog or 40mM K^+. This protein and its phosphorylation may be involved in NGF-mediated neurite outgrowth and/or stability.

452.12

TUBULIN TYROSINE AND SERINE PROTEIN KINASES IN RAT BRAIN GROWTH CONES. N. Cheng* and N. Sahyoun. (SPON: S. Burgess). The Wellcome Research Laboratories, 3030 Cornwallis Road, Research Triangle Park, NC 27709.

We had previously described the multi-site phosphorylation of growth cone tubulin on ser and tyr residues. We now present data pertaining to the protein kinases catalyzing these reactions. The Triton X-100-soluble fraction of growth cone membranes contained a ser protein kinase which preferentially phosphorylated the β-subunit of tubulin. The enzyme was retarded on several gel-permeation columns, displayed polydisperse behavior, and thus could be separated from the majority of growth cone polypeptides. The partially purified enzyme phosphorylated tubulin with an apparent K_m of 0.4 µM, and the corresponding values for ATP and $MgCl_2$ were about 23 µM and 2.5 mM, respectively. The presence of a tyr tubulin protein kinase in the cytoskeletal fraction of growth cones was further confirmed by the selective binding of anti-phosphotyrosine antibodies to phosphorylated cytoskeletal tubulin following electrophoretic transblotting. The cytoskeletal fraction also phosphorylated poly glu-tyr efficiently with an apparent K_m for ATP of 33 µM. Moreover, affinity labeling of the cytoskeletal enzyme preparation with (α-^{32}P) 8-azido ATP labeled specifically a unique polypeptide with M_r value of 49,000. The relationship of the ATP-binding protein to the protein kinase is under investigation.

452.13

EFFECTS OF INHIBITORS OF CA2+ -ACTIVATED NEUTRAL PROTEASE (CANP) AND PROTEIN KINASE C (PKC) ON NEURITE OUTGROWTH. L. HSU, A.Y.JENG* and K.Y.Chen*, Biol.Dept, Seton Hall Univ.,South Orange NJ 07079; Research Dept.,Ciba-Geigy Corp.,Summit,NJ 07901;Chem.Dept., Rutgers Univ.,Piscataway NJ 08854.

Upon activation by 12-0-tetradecanoylphorbol-13-acetate (TPA) or diacylglycerols, PKC is further activated by CANP to liberate a catalytic fragment which phosphorylates other cytosolic proteins to generate physiological responses. We have previously reported that activators of PKC promoted neurite outgrowth from ganglia explants. To further substantiate the involvement of PKC in this system, the effects of a selective inhibitor of CANP, leupeptin, and a potent inhibitor of PKC, staurosporine on neurite outgrowth were examined. Pretreatment with 20-500 uM leupeptin significantly reduced the formation of thick neurite fascicles induced by TPA. Leupeptin itself did not have any effect on neuronal development. Staurosporine inhibited PKC in vitro with an IC50 of 3 nM. At concentrations of 10-200 nM, it was found to exhibit neurite-promoting activities which were additive to those of TPA and were not inhibited by pretreatment with leupeptin. These results suggest that the activation of PKC by CANP is important in the induction of neurite outgrowth. While staurosporine is a potent inhibitor of PKC in vitro, its effect in vivo appears to be complicated by its non-specific nature towards other protein kinases. (Supported by NS21262,NIH).

PROTEASES IN DEVELOPING CHICK RETINA: RETINAL CELLS DIGEST SUBSTRATE BOUND GELATIN IN VITRO. J. B. Sheffield and D. Graff, Temple University, Philadelphia, PA. 19122

During retinal histogenesis, cells and their extensions migrate through the tissue to final positions. We report initial evidence that proteolytic activity might be associated with this process. Three high molecular weight bands of gelatinolytic activity can be found in zymogels of homogenates of embryonic chick and calf retinas, and in media from cultured retinal cells. Prior incubation with 0.1mM 4-aminophenyl mercuric acetate, a thiol blocking agent, enhances activity in gels and soluble assays. 5 mM 1,10 phenanthroline inhibits.

Gelatin was conjugated to rhodamine through an isothiocyanate bridge. 75 µl of a .1 mg/ml solution was applied to cleaned cover slips and allowed to dry. The slips were placed in T-25 culture flasks, and 5 ml of a suspension of 1.5 x 10^5 freshly dissociated 14 day embryonic chick retina cells/ml was added. Cultures were maintained for periods of up to one week, and samples were taken at various times for fluorescence microscopy. After periods of up to 24 hours, little change was seen. Three days after the culture was initiated, dark patches were visible in the fluorescent substrate. Two patterns were observed. The first is a restricted patch, following the path of a neuron and its growth cone. The second is more diffuse, and corresponds to the leading edge of a flat cell.

ENZYME BASED NEURITE PROMOTION BY SENSORY NEURONS IN VITRO. R.J. Riopelle and K.E. Dow. Queen's University, Depts. of Medicine, and Peds, Kingston, Canada K7L 3N6.

Enzymatic mechanisms have been proposed for neurite extension in development and consensus enzyme systems have been identified. Neural crest cells at early embryonic stages of avian development possess cell surface enzyme systems that may play a role in migration. We have recently determined that avian embryonic sensory neurons from ED 8 chick possess a cell surface galactosyltransferase (GalTase) activity that is involved in neurite formation on a laminin substrate. The acceptor substrate for GalTase is N-acetylglucosamine (GlcNac). In the presence of GlcNac or the related polymer chitotriose there was a dose dependent inhibition of neurite outgrowth by sensory neurons on the laminin substrate. Furthermore dose dependent inhibition of neurite outgrowth was also observed in the presence of a competitive acceptor substrate - alpha lactalbumin, and in the presence of the catalytic substrate for GalTase-UDP galactose (UDPgal). Since UDPgal is not normally found in the extracellular space, cell surface GalTase may provide a neurite promoting mechanism based soley on adhesion mechanisms. It remains possible however that sensory neuron GalTase enzymatic activity could modulate the extracellular milieu during the phase of patterned cell death at which time the catalytic substrate UDPgal might be released to the extracellular milieu.

THE PROTEASE TRANSIN IS INDUCED PRIOR TO NEURITE EXTENSION IN NGF-TREATED PC12 CELLS. C.M. Machida* and G. Ciment. (SPON: D. Trune). Department of Cell Biology & Anatomy and the Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

We report here that transin mRNA levels increased dramatically in rat pheochromocytoma (PC12) cells upon stimulation with nerve growth factor (NGF), reaching their maximum level within 24 hours. Although neurofilament (NF-M) mRNA levels also rose with the same time course in NGF-treated PC12 cells, the basal (uninduced) levels of mRNA for this cytoskeletal component were also high. When we compared these biochemical data with the morphological data, we found that transin mRNA levels rose prior to the initial appearance of neurites. Epidermal growth factor (EGF) and basic-heparin binding growth factor (b-HBGF) were unable to elicit both an induction in transin mRNA levels as well as a change to the neuronal phenotype. We also report that transin mRNA induction is not a primary effect of NGF, since cycloheximide was able to block the NGF induction. These data suggest that transin induction is part of the constellation of events induced upon NGF treatment, and may be involved in the process of neurite extension.

SODIUM CHANNELS ACCUMULATE ON AXOLEMMA OF HYPEREXCITABLE NEUROMA AFFERENTS M. Devor[1], C.H. Keller[*2], T. Deerinck[*3], S.R. Levinson[4] and M. Ellisman[3] [1]Life Sciences Institute, Hebrew Univ., Jerusalem 91904, Israel, [2]Scripps Institute Oceanography, and [3]Dept. Neuroscience, UCSD, LaJolla, CA. 92093, [4]Dept. Physiology, Univ. Colorado, Denver CO. 80262

Afferent axons caught in a nerve end neuroma following nerve section in vivo frequently develop ectopic impulse generating capability. We show that the emergence of such electrical hyperexcitability is associated with increased Na^+-channel content. Acute section of the lateral line nerve in the weakly electric Gymnotid fish Apternotus leptorhyncus silenced electroreceptive nerve afferents. Recordings made 10-21 days later yielded high frequency ongoing rhythmic firing independent of the electric organ discharge, which was eliminated on re-section. Single fibers microdissected from such neuromas were stained with a highly specific polyclonal antibody raised in rabbits against purified Na^+-channel protein from eel electroplax organ. Controls included deletion of primary, and use of antibody preabsorbed with purified Na^+-channel protein. Rhodamine-coupled GAR secondary antibody visualized heavy, specific labeling of preterminal demyelinated segments and terminal endstructures, and PAP immuno-electron microscopy confirmed antigen localization to the axolemma. We suggest that this Na^+-channel accumulation may account for neuroma hyperexcitability including related positive sensory symptoms in traumatic neuropathies.

L TYPE CALCIUM CHANNELS MAY REGULATE NEURITE GROWTH IN CHICK EMBRYO BRAIN NEURONS. M. Lomme,* C. Ferguson,* D. Shugarts,* J. Rosack,* P. Caracciolo,* T. Gisi,* P. Nichols,* T. Audesirk and G. Audesirk. Biology Dept., University of Colorado at Denver, 1200 Larimer St., Denver, CO 80204.

The intracellular free calcium ion concentration is thought to regulate the growth of neurites in several types of cultured neurons. Calcium influx through voltage-sensitive calcium channels increases the intracellular calcium concentration and therefore may influence the rate of neurite growth.

In vertebrate neurons, the L, T, and N calcium channels respond differently to heavy metals (Cd^{2+} and Ni^{2+}) and to organic compounds such as verapamil, the dihydropyridines, amiloride, and the aminoglycosides. In primary cultures of neurons from chick embryo brains, L channel blockers, such as Cd^{2+} (10 uM) and nifedipine, dramatically reduce neurite growth. Neither T channel blockers, such as Ni^{2+} (up to 100 uM), nor N channel blockers, such as most aminoglycosides, affect neurite growth. Streptomycin, which has been reported to block N type channels at low concentrations and L type channels at high concentrations, blocks neurite growth only at very high concentrations. Therefore, calcium influx through L type channels appears to promote neurite growth in these neurons.

Supported by grants from NIH and EPA to G. Audesirk.

PATCH-CLAMP OF CULTURED CRUSTACEAN PEPTIDERGIC NEURONS. D. Meyers, R. A. Graf, P. Ruben and I. Cooke. Békésy Laboratory of Neurobiology and Department of Zoology, University of Hawaii, Honolulu, HI 96822.

The neurosecretory cells of the crab (Cardisoma carnifex) isolated and cultured in simple, defined media, show immediate, vigorous outgrowth and retain their biochemical distinctness (Graf, et al., this vol.). We report here that they also retain the voltage-dependent currents expected from in situ studies; Na-current is lacking as expected in the absence of the axon. Membrane potentials recorded with microelectrodes are -30 to -60mV, often with random, slow fluctuations of ca. 5mV. Action potentials were not observed. Whole-cell patch electrodes at the soma were used to voltage-clamp large (>20um) cells having broad lamellipodial or radial outgrowth. During the first 5d after plating, outward currents predominate. These include a rapid-onset, time- and depolarization-inactivated current attenuated by 4AP and a slowly developing, non-inactivating outward current attenuated by TEA. Inward current recorded under regimes which minimize K and Cl currents was unaffected by TTX but rapidly blocked by Cd (0.2mM), and is thus attributed to Ca. Ca current is unchanged by V_h between -40 and -60mV, observable for steps to >-30mV and maximal at +10mV (up to 200pA). Minimum time to peak is ca. 5ms. Decay during steps to +10mV shows an initial rapid phase (<10ms) and a much slower one (>50ms); at 160ms, >50% of peak current remains. Inhibition of Ca-currents, peptide secretion and outgrowth by Cd is consistent with our suggestion that outgrowth may utilize secretory mechanisms including Ca-mediated exocytosis.

THE ORGANIZATION OF MYOSIN IN CULTURED NERVE GROWTH CONES DETECTED BY IMMUNOELECTRON MICROSCOPY. P.C. Bridgman and M.E. Dailey. Dept. of Anatomy and Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110

A postembedment labeling procedure using rapid freezing, freeze substitution and low temperature embedding in Lowicryl K11M has been adapted for the detection of myosin in cultured rat superior cervical ganglion nerve growth cones. This was necessary because conventional fixation techniques for immunoelectron microscopy either distort the structure of growth cones or destroy the antigenicity of myosin. An antiserum specific for the heavy chain of human platelet myosin was used for labeling. Rotary shadowing of purified platelet myosin/antiserum mixtures showed antibody binding at several sites along the tail and head portion of the molecule. Cross-reaction of the antiserum with the rat nerve cells was confirmed by immunoblots and immunofluorescence of frozen, freeze substituted cultures. Immunoelectron microscopy using colloidal gold showed a diffuse random distribution of label in broadly spread lamellipodia. Aggregates of label were seen at the base and along the length of filopodia and in the central region of the growth cone. The aggregates were often associated with distinct irregularly shaped areas of increased electron density. Label was not consistently associated with distinct filaments, although the relatively light staining of the sections would probably prevent detection of small filaments. The distribution of the myosin label suggests that myosin may play a role in growth cone motility.

453.1

LOCALIZATION OF 3070 IMMUNOREACTIVITY IN DEVELOPING CHICKS: RELATIONSHIP TO NEURAL EXPRESSION BY CELLS DERIVED FROM THE NEURAL CREST. H.D. Pomeranz, R.F. Payette*, N.R. Smalheiser+ and M.D. Gershon, Department of Anatomy and Cell Biology, Columbia University, P & S, New York, NY 10032 and +Department of Pediatrics, The University of Chicago, Chicago, IL 60637.

Laminin facilitates cellular attachment and neurite outgrowth. A 67 kDa laminin receptor has been implicated in attachment. Another laminin-binding protein has been identified, M_r 120 kDa ("cranin"; Smalheiser and Schwartz, 1987) or 110 kDa (Kleinman et al., 1988), which may be a neural laminin receptor. An antiserum, 3070, was raised by immunizing rabbits with the 120 kDa protein. The antiserum demonstrates the major HNK-1-immunoreactive protein of embyonic chick brain. Sites of 3070 immunoreactivity (IR) in aldehyde-fixed chick embryos were examined immunocytochemically along with markers to identify neural crest-derived cells (monoclonal antibody, NC-1) and neuronal precursors (antibodies to neurofilament-M [nf] and an associated protein [NAPA-73]). The earliest localization of 3070-IR, at stage 10, was in the neural tube. At this time, virtually all neural tube cells expressed 3070-IR, but only a small fraction expressed NC-1-IR and these did not co-express 3070-IR. No 3070-IR was found in the premigratory neural crest; however, at later stages (19-24) NC-1-immunoreactive cells that co-expressed 3070-IR were found migrating along the aorta, between the mesonephri and within the gut. The neural tube, notochord, dorsal roots and mesonephric tubules also displayed 3070-IR. Nf expression was not detected in the 3070-IR cells until stage 26. Many nf-IR cells in the branchial arches failed to express 3070-IR or NC-1-IR. At later stages in the gut 3070-IR was expressed on a subset of NC-1-IR cells and a subset of the 3070-IR cells also expressed nf-IR. These observations are consistent with the hypothesis that crest-derived cells do not acquire neural laminin receptors until they begin to differentiate as neurons. Supported by NIH grant # NS 15547.

453.2

COEXPRESSION OF AUTONOMIC AND SENSORY NEUROTRANSMITTERS BY CULTURED AVIAN NEURAL CREST CELLS. G.G. Leblanc. Developmental Biology Center, Univ. of Calif., Irvine, CA 92717.

Neural crest cells give rise to both autonomic and sensory neurons. It has been proposed that the precursors of these two kinds of neurons become segregated into separate lineages very early in development, possibly even before the onset of neural crest cell migration (Le Douarin, N. M., *Science*. 231:1515, 1986). This idea was based in part on examinations of the neurotransmitter phenotypes expressed by avian neural crest cells developing in vitro under different kinds of culture conditions. It was reported that neural crest cells grown in serum-free medium gave rise to substance P-immunoreactive cells, but not to tyrosine hydroxylase (TH)-immunoreactive cells. In contrast, neural crest explants cultured in medium containing serum and chick embryo extract contained many TH-immunoreactive cells, but were devoid of substance P containing neurons. Based on these results, it was proposed that the premigratory neural crest contains separate populations of sensory and autonomic neuron precursors which have different requirements for survival in vitro (Ziller et al., *Dev. Biol.*, 120:101, 1987). However, we have observed extensive differentiation of substance P-immunoreactive cells in cultures containing both serum and chick embryo extract by five days in vitro. Moreover, double labelling experiments showed that many of the substance P-immunoreactive cells in these cultures also contained tyrosine hydroxylase. These results indicate that individual neural crest cells can express both sensory and autonomic neurotransmitters.

DEVELOPMENTAL POTENTIAL FOR OLIGODENDROCYTES AND ASTROCYTES IN CULTURED EMBRYONAL CARCINOMA CELLS. L. Bambrick*, J. DiMichele*, J. Bell* and P. Braun. Dept. of Biochemistry, McGill University, Montreal, P.Q., H3G 1Y6 (sponsored by L. Bernier).

Embryonal carcinoma (EC) cells are pluripotent stem cells; the P19 EC cell line can be induced by treatment with retinoic acid (RA) to differentiate in vitro into CNS cells. These include neurons, fibroblasts and astrocytes (AC's). Oligodendrocytes (ODC's) have not been observed nor has it been shown that the AC's seen in RA-treated P19 EC cells include Type 2 AC's. These cells are reported to share a common bipotential O-2A progenitor with ODC's. We investigated whether the failure of P19 cells to produce ODC's was due to the absence of the O-2A progenitor and whether conditions known to stimulate ODC proliferation in vitro would affect the developmental outcome in P19 EC cells. Immunocytochemistry was used to characterize cultured cells as Type 1 AC's; $GFAP^+$; Type 2 AC's; $GFAP^+/A_2B_5^+$; ODC's; $GalC^+$. We report the presence of both Type 1 & Type 2 AC's and confirm the absence of ODC's in RA-treated P19 EC cells. Soluble rat brain extracts induced a limited differentiation of P19 EC cells into ODC's. This activity was greatest in extracts from 7 day old animals, a time of high ODC proliferation in vivo and of peak brain extract-induced ODC proliferation in vitro. Supported by the Alberta Heritage Foundation for Medical Research and the MS Society of Canada.

MULTIPOTENT PRECURSOR CELLS IN XENOPUS CILIARY MARGIN: A CELL LINEAGE ANALYSIS. Richard Wetts, George Serbedzija, and Scott E. Fraser. Dept of Physiol & Biophysics and the Developmental Biology Center, Univ Calif, Irvine, 92717.

Previously, we used cell autonomous lineage tracers to show that single Xenopus optic vesicle cells can give rise to all major cell types, including glia. We present here observations on the multipotency of ciliary margin (CM) cells. The CM is a proliferative zone that contributes new cells to the peripheral retina. It is possible that CM cells are multipotent, like optic vesicle cells, or that each cell could be committed to forming a specific type of retinal cell. Rhodamine dextran (LRD) was injected into single CM cells (St 39), and the animals were fixed (St 50).

In a prospective lineage study, the developmental potential of the injected precursor is determined by identifying the different types of cells into which its descendants have differentiated: I) In 30 of our 36 clones, the LRD-labeled cells were distributed over all 3 retinal layers; this indicates that CM cells are multipotent. II) All major cell types, identified by their morphology when the LRD filled their processes, were found within clones that included other identified cells. At least 4 clones included all major cell types, and even small clones located in 1 or 2 layers appeared to consist of multiple types. These observations indicate that CM precursor cells are not restricted in the types of cells which they can produce. Thus, our data suggest that the molecular events which regulate the commitment and differentiation of specific cell types occur relatively late in retinal lineages.

DORSAL ROOT GANGLION X NEUROBLASTOMA HYBRID CELLS EXPRESS NEURONAL ANTIGENS. R. Dingledine and L.M. Boland, Curr. Neurobiology and Dept. Pharmacology, Univ of North Carolina, Chapel Hill, NC, 27599.

Immunocytochemistry was used to study the expression of neuronal and DRG-like antigens by the F-11 hybrid cell line (Platika et.al., PNAS, 1985). F-11 cells were stained using a monoclonal antibody to neurofilament protein, but did not stain for glial fibrillary acidic protein nor fibronectin. A number of monoclonal antibodies recognize functionally distinct subpopulations of adult DRG neurons. Not all F-11 cells expressed surface carbohydrates recognized by SSEA-3, SSEA-4, or B2. Staining for each antibody was assessed by counting stained and unstained cells and classifying each cell based on its morphology. SSEA-3 stained about 20% of the hybrid cells, while 40-60% were stained by SSEA-4 or B2. The percentage of cells stained by SSEA-3 was greatest for cells that were either flat or multiform and lowest for cells that had a round cell body or a spindle shape. In contrast, the staining by SSEA-4 or B2 was more homogeneous for different morphological cell types. Staining for all antibodies used was not different for hybrid cells fed with growth medium or differentiation medium for 2-3 days. The neuroblastoma parent (N18TG-2) of the hybrid cells did not stain with any of these antibodies. These results suggest that F-11 cells are derived from a neuronal parent and express surface antigens found on sensory neurons, but do not homogeneously express characteristics of any particular subpopulation of DRG neurons. (Supported by NS23804)

GLUCOCORTICOID-INDUCED PNMT-IMMUNOREACTIVE CELLS IN THE SUPERIOR CERVICAL GANGLION OF THE RAT. H. Paivarinta[1], L. Eranko[2], V.M. Pickel[1] and T.H. Joh[1]. [1]Dept. Neurology, Cornell Univ., New York, NY 10021, [2]Dept. Anatomy, Univ. Helsinki, Helsinki, Finland

Light and electron microscopic immunocytochemistry were used to study the effect of glucocorticoids on the development of phenylethanolamine-N-methyltransferase (PNMT)-immunoreactive cells in the superior cervical ganglion of early postnatal rats. Newborn rats were daily injected with hydrocortisone acetate on postnatal days 2-6. Already 6 hours after the first glucocorticoid injection, some PNMT-immunoreactive cells and fibres were seen in the ganglion. After 5 days the number of PNMT-immunoreactive cells was increased and long processes and fibre networks were seen. Ultrastructurally, most of the PNMT-immunoreactive cells had an appearance of SIF cells: heterochromaffin clumps along the nuclear envelope and in the center of the nucleoplasm, and dense core vesicles. Also SIF cells, non immunoreactive to PNMT antiserum, were seen. Some PNMT-immunoreactive cells had the ultrastructural characteristics of nerve cells. They had a voluminous cytoplasm, dispersed nuclear hererochromaffin, and no granular vesicles. These results demonstrate that the glucocorticoids induce PNMT immunoreactivity both in SIF cells and cells with characteristics of nerve cells. Supported by NIH grant 1P01MH 42626-01.

DETERMINATION OF THE LENGTH OF THE CELL CYCLE AND THE DNA-SYNTHETIC PHASE FOR THE PROLIFERATING CELLS IN THE DENTATE GYRUS OF C57BL/6J MOUSE USING BROMODEOXYURIDINE IMMUNOHISTOCHEMISTRY. S.B. Lewin*, M.W. Miller, and R.S. Nowakowski. Dept. of Anatomy, UMDNJ-Robert Wood Johnson Medical School, and UMDNJ-School of Osteopathic Medicine, Piscataway, NJ 08854.

As part of a quantitative analysis of cell proliferation in the developing dentate gyrus, we have determined: 1) the length of the cell cycle, 2) the length of the DNA-synthetic phase (S-phase), and 3) the growth fraction (i.e., the proportion of cells in the hilus that comprise the proliferating population). A cumulative labeling procedure was used. At postnatal day 20, C57BL/6J mice were injected with bromodeoxyuridine (BUdR) at two hour intervals for a total period of 12 hours. Animals were sacrificed at selected intervals, and the brains were processed for immunohistochemistry using an antibody directed against BUdR. Sections from the approximate middle of the septo-temporal axis of the hippocampal formation were selected, and the number of BUdR-labeled and unlabeled cells in the hilus of the dentate gyrus counted. The number of BUdR-labeled cells increased linearly for 9 hours from an initial value of 12% of the total number of cells to a maximum value of 24% of the total. Calculations from these findings indicate that at this age the cell cycle is 18 hours, the S-phase is 9 hours and 24% of the cells in the dentate hilus are part of the proliferating population. In addition, the linear increase in the proportion of BUdR-labeled cells indicates that, at least in terms of the lengths of the cell cycle and the S-phase, the proliferating cells in the dentate hilus at this age comprise a single population.

Supported by NIH Grants NS 23647, AA 07568, AA 06916, DE 07734 and a grant from the UMDNJ Foundation.

IMMORTALIZATION OF AN OLIGODENDROCYTE PRECURSOR CELL VIA A RETROVIRUS CARRYING A TEMPERATURE SENSITIVE ONCOGENE. G. Almazan* and R. McKay. Departments of Biology and Brain Sciences, E25-435, Whitaker College, MIT, Cambridge, MA 02139.

Oligodendrocytes, the myelin-forming cells of the CNS, develop during the first week of postnatal life in the optic nerve of the rat. Their progenitors are bipotential cells which also give rise to type 2 astrocytes. To obtain permanent cell lines, primary cultures from the optic nerve of 3-d-old S.D. rats were infected with a retrovirus vector transducing the tsA58/U19 combination large SV40 T oncogene. At the permissive temperature, one of the derived cell lines proliferates and expresses the T antigen and small amounts of GC (galactocerebroside), a surface lipid marker for oligodendrocytes and A_2B_5 (surface gangliosides). At the non-permissive temperature, the cells lose the T antigen expression, stop proliferating, and stain very strongly with GC and A_2B_5 antibodies. In addition, the two main protein components of myelin, MBP(myelin basic protein) and PLP (proteolipid protein) are also expressed.

These results show that a precursor cell line spontaneosly differentiates into a mature oligodendrocyte when the immortalizing oncogene is inactivated. The functionality or potential use as replacement therapy of these cells will further be explored in transplantation experiments using myelin deficient mutant rodents.

RETROVIRAL VECTORS USED TO STUDY CELL LINAGE IN THE CEREBRAL CORTEX. B.P. Williams, L. Thurlow, R. Moore, J. Price, (SPON: J. Brockes) Laboratory of Embryogenesis, NIMR, Mill Hill, London, NW7 1AA, U.K.

We have developed a method for studying cell lineages which uses a retroviral vector, called BAG, to genetically mark embryonic cells in vivo (Price et al. (1987) PNAS 84: 156-160). BAG carries the bacterial β-galactosidase gene which can be detected histochemically, in infected cells, using the substrate X-gal.

We have injected BAG into the cerebral vesicles of rats in utero on embryonic day 16. The virus infects the ventricular cells of the developing cerebral cortex. The virus used is of such a titre that infection is a rare event. Analysis of the resultant clones allows us to ask two types of question. Firstly, how the different neural cell types are related; secondly, how do the progeny of a single progenitor cell expand in time and space to contribute to the cortical structure. In preliminary studies we have defined two types of progenitor cell in the developing cortex, one that gives rise to astrocytes but not neurones and one that gives rise to neurones and some types of glial cells. Further, we infected embryonic cortical cells in culture and have been able to mark clones similar to the ones we have defined in vivo. This tissue culture system allows us to ask what factors influence the fate of multipotential progenitor cells.

A STRAIN AND SPECIES SPECIFIC MONOCLONAL ANTI-NUCLEAR ANTIBODY AS A CELL MARKER FOR MOUSE CHIMERAS. R. J. Mullen and T. Cichocki*. Dept. of Anatomy, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

With the aim of producing species-specific monoclonal antibodies that could be used as cell markers in chimeric mice, BALB/c mice were immunized with cell nuclei isolated from Mus caroli brains. A monoclonal antibody (IgG) was produced that appears to bind the nuclear membrane of Mus caroli, but not BALB/c, mice. Sections of formaldehyde-fixed, polyester wax embedded brain, were immunohistochemically stained using Vector ABC with HRP. The resulting staining of nuclear membranes gives the appearance of rings, hence, the antigen has been nicknamed "ringo". The epitope recognized by this antibody was present not only in Mus caroli but also in Mus castaneus as well as in all inbred strains of laboratory mice tested including C57BL/6J, C3H/HeN, DBA/2, SWR, AKR and LPT. Since the antibody stained C57BL/6 (B6) nuclei but not BALB/c nuclei, seven CXB (i.e., BALB x B6) recombinant inbred strains were examined and the observed strain distribution pattern matched perfectly with the Gpd-1 locus on the distal end of Chromosome 4. B6 congenic mice carrying the BALB/c allele of the H-18 locus on Chromosome 4 (i.e., B6.C-H-18c) were ringo(-), suggesting the gene controlling this antigen is located on the distal end of chromosome 4 near the Gpd-1 and H-18 loci. In brain sections, the antibody appears to recognize many if not all cell types. The staining is particularly strong in the cerebellum. Preliminary observations suggest ringo may be specific to neural tissue and may first become evident sometime after postnatal day 10. We have recently examined a C3H<->BALB chimera and mosaicism was evident among cerebellar granule cells and Purkinje cells as well as in the dentate gyrus and hippocampus. CHIMERIC ANALYSIS OF LINEAGE RELATIONSHIPS AMONG MOUSE LUMBAR MOTONEURONS. M.W. Vogel, A.W. English, and K. Herrup. Dept. of Human Genetics, Yale Med. School, New Haven, CT 06510 and Dept. of Anatomy, Emory Univ., Atlanta, GA 30322.

We have analyzed mouse chimeras to address two questions about the role of lineage relationships in the development of the lumbar lateral motor column: 1) are all lumbar motoneurons descended from a defined group of progenitor cells, and 2) is motoneuron lineage related to motoneuron connectivity, as defined by muscle innervation? We have identified medial gastrocnemius motoneurons by HRP backlabeling of the muscle nerve in β-glucuronidase chimeras, and employed TMB-DAB and β-glucuronidase histochemistry to analyze both motoneuron identity and genotype. The labeled motoneuron pools in 4 chimeras contained cells of both genotypes, indicating that a motoneuron pool is not a descendent clone of a single progenitor. The genotype ratios of labeled motoneurons differed from the genotype ratios of total lumbar motoneurons, suggesting that medial gastrocnemius motoneurons are not randomly selected from an uncommitted population of lumbar motoneurons. The genotype ratios of lumbar motoneurons in the 4 labeled and 1 unlabeled chimera also varied systematically between animals and between the right and left sides of individual chimeras. This data suggests that lumbar motoneurons are descended from a smaller set of progenitor cells and that the progenitors are selected independently on the right and left sides of the spinal cord.

Supported by the NIH (MWV:NS-06789; AWE:NS-20545; KH:NS-20591 and NS-18381), and the March of Dimes Birth Defects Foundation (KH).

AN ANTIBODY TO RETINAL GANGLION CELLS RECOGNIZES PREMIGRATORY AND MIGRATING CELLS IN THE DEVELOPING CHICK RETINA. Steven C. McLoon and Roxann Severson*. Dept. of Cell Biology & Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

We have developed a monoclonal antibody, RA4, that recognizes retinal ganglion cell axons in the mature retina. Between embryonic days 3 and 9, the RA4 antigen was associated with cells in certain regions of the retina in addition to the optic fiber layer. The RA4 positive cells were of three types: an apolar cell adjacent to the ventricular surface, a bipolar cell that spanned the thickness of the retina and a monopolar cell in the ganglion cell layer. Evidence suggests that these cells are premigratory and migrating retinal ganglion cells. The expression of the RA4 antigen is the earliest indicator of ganglion cell differentiation yet reported. The existence of RA4 positive apolar cells along the outer surface of the retina suggests that the ganglion cell phenotype is expressed as soon as the cell becomes postmitotic. Approximately 20% of the migrating ganglion cells were paired. One interpretation of this observation is that ganglion cells are generated by a ganglion cell stem cell that on its ninth division undergoes a terminal division. Immunoblots and other analyses revealed the RA4 antigen to be a 140kDa cytoplasmic protein in the retina. RA4 is also expressed by many long tract axons in the brain. In the brain, the RA4 antigen was observed to have 7 different molecular weights. Evidence suggests that different cell types may express the RA4 antigen with slightly different molecular weights. Finally, the expression of the RA4 antigen in retinal axons appears to be regulated by some factor produced by the optic tectum.

IN VITRO ANALYSIS OF RADIAL GLIAL DEVELOPMENT IN EMBRYONIC RAT BRAIN. M.B. Wilkie* and J.M. Lauder, Dept. of Cell Biol. and Anat., Univ. of N.C. Sch. Med., Chapel Hill, NC 27599

A simple method for culturing relatively pure populations of radial-like glial cells was devised based on differential adhesion to a non-adhesive substrate. Dissociated cells from embryonic day 13-15 rat brain regions were plated onto glass coverslips in culture medium consisting of BME + 10% NuSerum (Collaborative Res.) + pen/strep + dextrose. Due to the initial lack of substrate adhesion, reaggregates were formed which subsequently attached and spread. Regional differences were observed in the size of aggregates and their ability to spread on the substrate, suggesting distinct cell surface properties. Most neurons did not survive after 1-2 days and the remaining cells consisted mainly of undifferentiated neuroepithelial cells or glia as determined by immunoreactivity (IR) with anti-GFAP (Accurate Chem). GFAP-IR cells initially had a radial-like appearance with long processes extending as spokes out of the aggregates. After several days, nuclei were visible within these processes, apparently moving through them to their distal ends. These cells then extended lamellipodia and retracted their proximal process which had been attached to the aggregate, forming a free-roaming GFAP-IR cell strongly resembling an astrocyte. This culture system may prove useful for investigations of the radial glial lineage.

CELL MIGRATION AFTER OLFACTORY PLACODE TRANSPLANTATION IN XENOPUS. H. Kim, A.G. Monti Graziadei and P.P.C. Graziadei. Dept. of Biological Sciences, Florida State Univ., Tallahassee, FL 32306-3050.

From stage 23-24 Xenopus laevis we transplanted the olfactory placode to same stage Xenopus borealis in place of the optic vesicle. Differential nuclear staining with quinacrine of the two animals allowed to distinguish the cells of the host from those of the donor. Chimerae were observed up to stage 52. Usually the transplanted placode fused with the one of the host producing a very large olfactory organs. In some animals the donor placode grew independently from the host's. From the transplanted placode a nerve developed and reached the diencephalon. Along this nerve many cell with the characteristics of the donor migrated and penetrated the CNS. After stage 45 these cells formed small aggregates. Attempts are under way to determine the specific nature of the migrating cells (glia versus neurons) and their significance and putative connections in the new environment.

NOTCH IS REQUIRED FOR CELL DECISIONS IN THE *DROSOPHILA* RETINA. Ross L. Cagan* and Donald F. Ready[1]. Dept. of Biology, Princeton University, Princeton, N.J. 08544, and [1]Dept. of Biol. Sci., Purdue University, West Lafayette, In. 47907.

We have examined the role of the gene *Notch* during successive stages in the developing retina of *Drosophila melanogaster*. Using flies containing the temperature-sensitive allele N^{ts1}, we shifted larvae and pupae to a non-permissive temperature for brief periods and examined the resulting defects. A diversity of abnormalities were observed, including transformation of one cell type to another. *Notch* appears to play a role in each retinal cell's choice of fate.

Shifting N^{ts1} larvae to 32°C resulted in normally uncommitted cells becoming photoreceptor cells; more posterior ommatidia showed differences in the number of cone cells. Shifts of young N^{ts1} pupae affected the number of bristles formed, while later shifts affected pigment cells. Each cell type was affected if shifts occurred at the approximate time it would normally differentiate. These changes in cell fate were at the expense of uncommitted cells and were not a result of new cell divisions. Late temperature shifts phenocopied *facet-glossy*, an allele of *Notch*. Our studies show the cells which would normally become primary pigment cells in *facet-glossy* flies develop instead as apparent secondary pigment cells. Together these defects and others suggest *Notch* has a role in allowing cells in the retina to receive information from neighboring cells, and that this information is required by cells to attain their correct fate.

DEVELOPMENT OF CELL-SPECIFIC MARKERS IN CHICK SPINAL GANGLION NEURONS. C.L. Smith, Dept of Neurobiology, Anatomy, and Cell Science, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

During development of the dorsal root ganglia, neural crest cells differentiate to form a variety of distinct types of sensory neurons that differ in their sizes, connections, and histochemical properties. I am investigating the role of peripheral targets in determining the phenotypes of sensory neurons by studying the expression of cell-specific markers by neurons in chick spinal ganglia. Four markers that label subsets of sensory neurons in mature embryos have been studied: an antibody to a calcium binding protein (CBP), a monoclonal antibody raised against chick ganglion cells (7G4; see Frank, et al., this volume), anti-substance P (SP), and soybean agglutinin (SA). The sensory neurons that express these markers are concentrated in different regions of the ganglia and differ in average size. Some neurons are both SA^+ and CBP^+ or SA^+ and $7G4^+$ but few neurons are both $7G4^+$ and CBP^+ or both $7G4^+$ and SP^+. Immunocytochemical studies in conjunction with retrograde labeling have shown that CBP^+ neurons are predominantly cutaneous afferents. 7G4 and SA label both cutaneous afferents and muscle afferents.

Some sensory neurons express 7G4 or SP immunoreactivity at E5 when few neurons have innervated their peripheral targets, suggesting that the early expression of 7G4 and SP is not target-dependent. Furthermore, sensory neurons from E5 embryos express 7G4 immunoreactivity when grown in vitro in the absence of their targets. By contrast, CBP and SA positive neurons are not observed until E10 or E12, after many sensory neurons have already innervated their targets. Sensory neurons from E5-E10 embryos do not become CBP^+ when grown in vitro for 4-6 days. Experiments are now in progress to determine whether sensory neurons grown in vitro become SA^+ or SP^+ and whether neurons can be induced to express specific markers by growing them with peripheral targets.

A MONOCLONAL ANTIBODY THAT SELECTIVELY LABELS LARGE SENSORY NEURONS IN DEVELOPING CHICK SPINAL GANGLIA. E. Frank, H. Tsuruhara*, C.L. Smith and V. Lemmon, Dept of Neurobiology, Anatomy, and Cell Science, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Studies of the development of various classes of sensory neurons within dorsal root ganglia (DRGs) would be greatly facilitated by the availability of histological markers for the different neuronal phenotypes. By generating monoclonal antibodies against lumbar DRGs in chick embryos, we have isolated one such marker, 7G4. This antibody stains approximately 50% of neuronal somata in E17 lumbar DRGs. Very few of the small DRG cells that are anti-substance P-positive stain with 7G4, while many of the larger neurons that label with anti-N-acetylaspartylglutamate (anti-NAAG, see Kowalski et al., Brain Res. 406:397) are also 7G4-positive. Axons in the dorsal and ventral roots and in the dorsal columns of the spinal cord are also labeled with 7G4. Bundles of stained axons descend from the dorsal columns through the dorsal horn to terminate in the intermediate laminae, similar to the projections of muscle sensory afferents. Although the staining pattern is qualitatively similar to that seen with RT97, which labels neurofilaments, 7G4 stains fewer axons in the spinal cord and stains some motoneuronal somata. Developmentally, sensory axons are 7G4-positive by E5, but staining of DRG neuronal somata does not appear until E10 and the number of labeled somata increases until at least E15. At E12, there is a clear division between large ventrolateral (VL) and small dorsomedial (DM) DRG cells, and 7G4 labels neurons primarily in the VL region. At later stages some 7G4-positive neurons are found throughout the DRG. The relative number of immunoreactive cells is 4-5 times greater in lumbar versus thoracic DRGs; this may be related to the smaller amount of cell death of the VL population at limb versus thoracic levels. Finally, 7G4 labels both muscle and cutaneous sensory neurons. Neurons in the mesencephalic nucleus of V, known to project largely to muscle spindles, are 7G4-positive, as are many large neurons in the opthalmic division of the trigeminal ganglion, which project primarily to skin. Similarly, DRG neurons retrogradely labeled with fluorescent latex beads from limb muscles are 7G4-positive, as are axons in cutaneous nerves in the hindlimb.

DETERMINATION OF A NEURONAL LINEAGE BY EARLY CLEAVAGE STAGES. B.C. Gallagher & S.A. Moody. Depts. Anatomy & Neuroscience, Univ. Virginia, Charlottesville, VA 22908.

In order to examine whether early interactions are necessary for the normal production of a single frog blastomere's progeny, we transplanted single labeled cells of the 16- and 32-cell stages to novel sites in unlabeled hosts. Embryos were fixed at late tailbud stages, serially sectioned, and the distribution of the labeled cells compared to normal fate maps (Moody, 1987, Dev. Biol. 119:560; 122:300). Some transplanted blastomeres took on the characteristics of their new site. For example, V1.1.2 normally is a significant contributor of Rohon-Beard neurons, but becomes a significant contributor of motoneurons after transplantation to the dorsal midline. Some blastomeres, however, continued to express their normal neuronal and non-neuronal lineages after transplantation. For example, the D1.1 clone produced after transplantation to the ventral vegetal pole was qualitatively indistinguishable from normal. In about a third of these latter experiments, and in all experiments in which V1.2 was transplanted to the ventral vegetal pole, secondary neural tubes were induced. The D1.1 clone was normally distributed in this secondary axis. Supported by Grants NS23158, NS07868, and NBBD Training Grant HD07323.

BLASTOMERE INTERACTIONS ARE NECESSARY FOR CNS LINEAGE EXPRESSION BY SOME FROG CELLS. S.A. Moody & D.W. Best. Depts. Anatomy & Neuroscience, Univ. Virginia Sch. Med., Charlottesville, VA 22908.

We investigated whether interactions between cleavage stage blastomeres are necessary for the production of their normal neuronal progeny. Single blastomeres in the third tier of the 32-cell stage (vegetal equatorial cells) were marked with a lineage dye and their anterior neighbor was removed. The dorsal midline cell normally contributes sparsely to the hindbrain and spinal cord, but after ablation it no longer contributed at all. The dorsal lateral cell normally contributes many cells to brain and spinal cord; after ablation it did not contribute to CNS in half of the embryos and contributed only a few cells in the rest. The ventral lateral cell normally contributes to dorsal hindbrain and spinal cord; after ablation its only neuronal progeny were a few Rohon-Beard neurons. The ventral midline cell normally contributes sparsely to dorsal spinal cord; after ablation it had no neuronal descendants in half of the embryos, and had the normal ones in half of them. The non-neuronal progeny of these cells were not altered by the ablations. Thus, interactions between second and third tier cells specifically influence CNS lineage expression in the frog. Supported by NS23158.

453.20

SOME NEURONAL LINEAGES ARE ALTERED BY LITHIUM TREATMENT DURING FROG CLEAVAGE STAGES. S.L.Klein and S.A.Moody. Dept. of Anatomy and Cell Biol. Univ. Virginia Sch. Med., Charlottesville, VA 22908.

Previous studies have shown that Xenopus embryos that are incubated in LiCl during cleavage stages become dorsalized and produce up to twice the normal number of neurons (Breckenridge et al., Devel., 99:353, 1987). With our methods, the critical period of Li^+-mediated dorsalization is between the 32- and 512-cell stage. We investigated whether the increase in neuronal number was caused by changes in neuronal lineages. The fates of individual blastomeres of 16-cell Li^+-treated embryos were compared to their fates in the normal embryo (Moody, Dev. Biol., 119:560, 1987). A ventral animal blastomere (V1.1), whose normal neuronal descendants are few and located only in the spinal cord, populated large amounts the forebrain, midbrain, hindbrain and spinal cord. A ventral vegetal blastomere (V2.1) and a dorsal animal blastomere (D1.1) produced significantly more progeny in regions of CNS that they normally populate. A dorsal vegetal blastomere (D2.1) produced small amounts of the CNS, as in the normal embryo. These results indicate that neuronal lineages normally are influenced by events that occur during cleavage stages and that these events are altered by Li^+ ions. Supported by HD23324 & NS23158.

NEURAL PLASTICITY IN ADULT ANIMALS: ANATOMY AND BEHAVIOR

454.1

ANATOMICAL AND BEHAVIORAL EVIDENCE FOR A TIME DEPENDENT VULNERABILITY TO LESION 2 OF 2-STAGE BILATERAL SENSORIMOTOR CORTEX LESIONS IN RATS. T.A. Jones*, T.M. Barth and T. Schallert, Dept. Psychology and Institute for Neurological Sciences, Univ. Texas, Austin, 78712

Previous research in this laboratory has shown that there may be a sensitive period following brain damage during which recovery processes are vulnerable to pharmacological manipulations (Hernandez et al., 1988). In the present study, we found that there may be a sensitive period in recovery following unilateral forelimb sensorimotor cortex (FLSMTR) lesions during which the contralateral homotopic cortex is especially vulnerable to damage. Rats were given 2-stage bilateral FLSMTR lesions with interoperative periods (IOPs) between 1 and 14 days. To compare the extent of damage incurred by Lesion 1 to Lesion 2, the volume of the intact cortex contiguous to each lesion was measured. Two-stage lesions with a 7 day IOP showed greater damage (less remaining cortical volume) in the 2nd lesioned hemisphere. However, the volume of the Lesion 1 cortex did not differ from the Lesion 2 cortex when 2-stage lesions were given with 1 or 14 day IOPs. Furthermore, sensorimotor behavioral asymmetries, as measured by a bilateral tactile stimulation test, paralleled the anatomical asymmetries. The lateralized behavior following 2-stage lesions with a 7 day IOP and the smaller cortical volume in the Lesion 2 hemisphere indicate that the cortex contiguous to the 2nd lesion may be anatomically vulnerable to damage at this stage in recovery. In other words, more extensive damage occurs to the cortex when previous damage was given in the opposite homotopic cortex. However, there appears to be a fixed stage or time period before and after which this vulnerability does not exist. Supported by NIH grant NS-23964 awarded to T.Schallert.

454.2

COMPARISONS OF INFANT AND ADULT LESIONS ON VISUOSPATIAL BEHAVIOUR IN RATS. D. Christie* and A. Cowey* (SPON: European Brain and Behaviour Society). Dept. of Experimental Psychology, University of Oxford, South Parks Road, Oxford. OX1 3UD. U.K.

Lesions of anteromedial cortex in rat produce a neglect for visual stimuli in the field contralateral to the lesion. Recovery from the gross symptoms of the neglect occurs after 2-3 weeks but subtle effects persist. It is widely believed that when lesions are made at birth there is greater recovery, or sparing, than when they are made in adult animals. This may be a reflection of the greater degree of neuroanatomical plasticity demonstrated in the neonate. The degree to which this occurs following lesions in either the anteromedial or striate cortex was examined. Unilateral lesions of anteromedial or visual cortex were made at birth (postnatal day 1) or at three months. All animals were given a three month recovery period then visuospatial behaviour was examined. The results demonstrate that the degree of recovery depends on the task as well as the age at operation. In a 2-choice spatial task (T-maze) adult-operated animals showed a bias towards the ipsilateral arm. Neonatally-operated animals did not. In an open field, containing an array of objects, all animals with lesions of anteromedial cortex directed their search behaviour initially towards the ipsilateral side of the apparatus. In contrast rats with neonatal lesion of visual cortex showed a contralateral preference whilst adult-operated animals did not show a bias. The results also suggested that the nature of the turning behaviour depended on the hemisphere damaged. Damage to the left hemisphere produced ipsilateral turning behaviour whilst identical damage to the right hemisphere caused the animals to turn contralaterally. This asymmetry was especially noticeable in the animals with lesions of anteromedial cortex.

454.3

AMPHETAMINE ENHANCES BEHAVIORAL RECOVERY FROM SENSORY-MOTOR DEFICIT RESULTING FROM INFARCTION OF PRIMARY SOMATOSENSORY CORTEX. B.E. Hurwitz, W.D. Dietrich, P.M. McCabe, B.D. Watson, M.D. Ginsberg & N. Schneiderman. Depts. of Psychology, Neurology and Cerebral Vascular Research Center., Univer. of Miami, Coral Gables, FL 33124.

The present study was undertaken to determine whether d-amphetamine (d-AMP) would differentially affect the rate of recovery of task performance after unilateral whisker cortical barrel-field infarction relative to control groups. Food-deprived adult male Wistar rats were trained in the dark to produce a right turn in a T-maze apparatus when the vibrissae on the right side of the animals' snout were deflected by a manually delivered probe. Unilateral (n=14) or sham (n=8) infarction of the left primary whisker cortical barrel-field was induced after an 80% level of correct responses was achieved during three successive sessions. Post-infarction testing was performed every other day from the third to the 35th day. All animals were tested on post-infarction day 3 to establish whether a behavioral deficit was present. Infarcted animals displayed a significant 24.3 ± 5.4 (SEM) decrease in percent correct response. Then in these infarcted animals d-AMP at 4mg/kg (n=5), d-AMP at 2mg/kg (n=5) or saline (n=4) injections were given about 24 hrs prior to testing on post-infarction days 4, 6, 9 and 11. Of the eight sham-control animals five received no injections and three received injections of d-AMP at 2mg/kg. No effect of the sham-operation or of d-AMP was observed on task performance in these control animals. However, all three infarct groups displayed a significant increasing linear trend in percentage of correct responses between post-infarction day 3 and 35. Most notably, amphetamine-enhanced recovery of performance was observed in the 4 mg/kg group, which significantly differed from the infarct-saline group from day 17 to 35. These data, provide further evidence of the facilitatory effect of d-AMP on behavioral recovery from brain injury and extend this effect to the recovery from infarction of the primary somatosensory cortex. Supported by research grants NHLBI (5 T32 HL07426-09) & USPHS (NS-05820).

454.4

ACCELERATED RECOVERY FROM LEARNED ALTERNATION DEFICITS AFTER PROGRESSIVE ENTORHINAL CORTEX LESIONS IN RATS. J.J. Ramirez*, M. Valbuena*, M. Smith* and S.T. Wallenius* (SPON: B. Fass). Dept. of Psychology, Davidson College, Davidson, NC 28036.

Sprouting by the crossed temporodentate pathway (CTD) has been implicated in the recovery of spatial alternation behavior after unilateral entorhinal cortex (EC) lesions in rats. Presumably, if sprouting contributes to behavioral recovery, systematic manipulations of the rate of sprouting should produce concomitant changes in behavior. Previously, Scheff et al. (1977) demonstrated that 2-stage (progressive) EC lesions accelerate sprouting in the dentate gyrus of rats. In the present study, we wanted to determine whether progressive unilateral EC lesions would accelerate the recovery from lesion-induced alternation deficits. Rats that sustained 1-stage or progressive lesions were tested for retention of a spatial alternation task. Whereas rats with 1-stage lesions recovered to preoperative performance levels 10 days postlesion, the progressive lesion group recovered as early as 4 days postlesion. Histological analyses indicated that the lesions of both groups were comparable. Therefore, progressive lesions accelerated behavioral recovery. This finding is consistent with the possibility that CTD sprouting contributes to recovery from alternation deficits. However, further anatomical studies are required to confirm the presumptive accelerated CTD sprouting. Supported by NIH grant 1 R15 NS24948-01.

SYNAPTIC REORGANIZATION IN THE HIPPOCAMPUS LEADS TO CHANGES IN ENERGY METABOLIZING ENZYMES. I.L. Wagman* and R.C. Collins. Dept. of Neurology, UCLA Sch. of Med., Los Angeles, CA 90024.

In the hippocampus, terminal zones of the perforant pathway from the entorhinal cortex show high levels of cytochrome oxidase (CO), whereas terminal zones of the commissural and associational fibers show high levels of lactate dehydrogenase (LDH). To study the role of afferent pathways on postsynaptic levels of energy metabolizing enzymes, we examined the distributions of CO and LDH in the dentate gyrus following lesions of the entorhinal cortex in rats. Animals received unilateral electrolytic lesions of the entorhinal cortex. After survival periods of 8 or 16 hrs. (n=1 per time point) or 1, 2, 4, 8, 16 or 30 days (n=3 per time point), serial cryostat sections were prepared and stained for cell bodies (thionin), degenerating nerve terminals (Fink-Heimer), acetylcholinesterase, or CO or LDH activity. Enzymatic changes were analyzed with densitometry. At 16 hrs. postlesion, CO staining in the deafferented outer molecular layer had decreased to 78% of contralateral control values. Levels fell to 70% of control by 8 days with no further changes up to 30 days. LDH reactivity was 88% relative to the contralateral side at 24 hrs. postlesion, decreased to 77% by 8 days and remained about the same at 30 days. A relative increase of 12-17% was observed in the inner molecular layer of the deafferented side at 24 hrs. postlesion for both CO and LDH, returning to control values by 4 days. In addition, an expansion of the band of intense staining for LDH in the inner molecular layer was observed at 8 days postlesion. At 30 days, the LDH band was 140% of its normal width. This expansion parallels that of the commissural-associational fibers following entorhinal cortex lesions. These results may reflect control of oxidative and glycolytic enzyme levels by pathway-specific synaptic input.

EARLY PLASTICITY IN THE DENTATE GYRUS FOLLOWING SURGICAL LESIONS TO THE PERFORANT PATH. D. E. Hillman and S. Chen. Dept. Physiol. Biophys., New York Univ. Med. Ctr., New York, NY 10016.

The number of synaptic sites in the dentate molecular layer begins to be restored by 5 days and returns to near normal by 60 days following lesions to afferent pathways. The source of the new sites may be from sprouting of the ipsi- and contralateral hippocampi and the septal nuclei. A surgical lesion was placed in the entorhinal cortex of the rat at the junction with the subiculum. Morphometry of the heads of spines and synaptic sites at 5 days revealed elongation of the spines so that they partially wrapped the bouton. The average size of the synaptic contact area increased by as much as 40% and additional sites occurred on the extension. Three-dimensional reconstruction revealed larger sites, irregularly shaped contact areas, and multiple sites on the same spine. We conclude that increases in the size of synaptic sites precede restoration of synaptic number following acute deafferentation of the hippocampus. These findings indicate that a significant number of the restored sites could arise from remaining synapses through dividing of the contacts and their respective spines. Supported by USPHS NS-20349 & NS-13742 from NINCDS.

Entorhinal cortical lesions are accompanied by an alteration in the expression of a ganglioside in the dentate molecular layer. S.F. Suchy, J.J. Ramirez*, M. Valbuena* and G.A. Schwarting*. Dept. of Biochemistry, E.K. Shriver Center, Waltham, MA 02154 and Dept. of Psychology, Davidson College, Davidson, NC 28036.

A ganglioside, α-galactosyl, α -fucosyl GM1, which is present in low quantities in rat brain is recognized by a monoclonal antibody, WCC4 (Suchy et al., Brain Res. 440,1988). This ganglioside is concentrated in the outer 2/3 of the molecular layer (ML) of the dentate gyrus. WCC4 antibody was used to detect changes in the distribution of α-galactosyl, α-fucosyl GM1 in the dentate ML following unilateral lesions of the entorhinal cortex (EC). Nine 90-day old male Sprague Dawley rats were administered unilateral electrolytic lesions of the EC and were sacrificied at 3 or 7 days postlesion. Immunocytochemical analysis of fresh frozen brain was performed with WCC4 antibody. The width of the immunostained portion of the ML, expressed as a fraction of the total ML width, was determined for the deafferented (ipsilateral) and contralateral ML from photographs of tissue sections. To account for time dependent "shrinkage" of the denervated ML following EC lesions, a ratio of the proportion of the immunostained ML ipsilateral/contralateral (I/C) to the lesion was calculated for each animal. At 3 days, there was no difference in immunostaining between ipsilateral and contralateral ML (I/C = 1.01 ± 0.13, n = 5). However, at 7 days postlesion there was a significant ($p<0.01$) reduction in staining in the ipsilateral EC (I/C = 0.67±0.09, n = 4). It is apparent that there is a redistribution of, or loss of, the antigen in the outer 2/3 of the molecular layer following EC lesions. The change in α-galactosyl, α-fucosyl GM1 expression in the ML corresponds to the time of expansion of commissural/associational terminal field (Lynch et al., Brain Res. 50, 1973) and the degeneration of dendrites in the deafferented zone (Caceres and Steward, J. Comp. Neurol. 214,1983). Supported by NS2494-01.

PLASTICITY IN THE CROSSED AND UNCROSSED NIGROSTRIATAL PROJECTIONS IN RELATION TO RECOVERY FROM BEHAVIORAL ASYMMETRIES INDUCED BY HEMIVIBRISSOTOMY. J.P.Huston, H.-T. Weiler*, S.Morgan* and H.Steiner*. Inst. Physiological Psychology, Univ. Düsseldorf, D-4000 Düsseldorf, F.R.G.

Unilateral removal of vibrissae (URV) in rats induces an asymmetry in facial scanning in the open-field. This behavioral asymmetry subsides after 3 days of URV. Evidence exists for plastic changes in the crossed nigrostriatal projection subsequent to URV. In this experiment we determined the time-course of this neural plasticity and compared it to that of the behavioral recovery. After URV for 1-3, 4-6, or 8-20 days rats were injected with horseradish peroxidase into the striatum (CPU) ipsilateral or contralateral to URV. Retrogradely labeled cells were counted in both substantiae nigrae. URV/1-3 rats had a greater crossed projection to the CPU ipsilateral than contralateral to URV. This asymmetry was reversed in URV/4-6 rats, and reduced in URV/8-20 rats. The latter group had a greater uncrossed projection to the CPU contralateral to URV. Thus, these results indicate a similar time-course for the neural plasticity as for the behavioral recovery after URV.

RAPID FORMATION OF NEW DOUBLE SYNAPSES IN RAT SUPRAOPTIC NUCLEUS (SON) IN RESPONSE TO INTERRUPTION OF SUBFORNICAL ORGAN EFFERENT PROJECTIONS. M.L. Weiss, C.D. Tweedle, F. Marzban*, B.K. Modney*, and G.I. Hatton. Michigan State Univeristy, Neuroscience Program, East Lansing, MI 48824-1117

Previous work at the transmission electron microscopic (TEM) level has shown that damage of the subfornical organ (SFO) produces degenerating terminals within the SON (Brain Res. 275: 365, 1983). In an attempt to replicate and extend this study, rats received damage to the SFO or its efferent pathway (SFOx) and, following a survival period of 24 hr, were prepared for TEM evaluation. In addition to finding occasional degenerating fibers, we found an increase in the percentage of cells contacted by terminals which formed synapses upon two adjacent somata in the SON (soma-somatic "double" synapses, SSD) after SFOx [mean of 41% cells with SSD after SFOx, range: 3-8 cells with double synapses per 15 cells sampled per animal (N = 5) vs. mean of 0% cells contacted by SSD after sham surgery, 0 cells with SSD per 15 cells sampled per animal (N = 3), and following sham surgery and 24 hr water deprivation: mean of 2% cells contacted by SSD, range 0-2 cells contacted by SSD in 15 cells sampled per animal, (N=3)]. It is interesting to note that the large increase in the percentage of cells contacted by SSDs after SFOx was accompanied by little increase in cell-cell apposition and that the synapses formed were morphologically similar to those found during lactation or chronic dehydration. Supported by NS 09140 and NS 16942 and NRSA Postdoctoral award 08125.

454.10

DEHYDRATION INDUCED INCREASES IN RAT SUPRAOPTIC NEURONAL CELL SIZE IS ACCOMPANIED BY ABSOLUTE INCREASES IN MULTIPLE SYNAPSES, NEURONAL MEMBRANE APPOSITION AND GLIAL CONTACT. B. K. Modney*& G. I. Hatton. (SPON: A.K. Salm) Neuroscience Program, Department of Psychology, Michigan State University, East Lansing, MI 48824.

Extensive alterations in rat SON morphology occur during chronic dehydration. Comparisons made between well-hydrated (n=6) and dehydrated rats (10 days drinking 2% saline, n=7) revealed significantly increased percentages of cell membrane contacted by adjacent cells or dendrites and multiple synapses (a single terminal forming two synaptic contacts). A significant decrease in the percentage of somatic membrane contacted by single synapses was found. No change in percentage contacted by glial processes was found. Since the neuronal surface area (SA) of these cells increases significantly with dehydration, the percentage measures listed above were multiplied by SA to determine the μm^2 per cell contacted by each cellular element. No change in the amount of somatic membrane contacted by single synapses was found. In contrast, glial contact, somatic/dendritic membrane apposition and multiple synapses were found to increase in dehydrates relative to controls. Direct membrane apposition and the formation of new double synapses may play an important role in the coordinated activity of these neurons during periods of chronic hormone release. Supported by NIH grant NS09140.

454.11

METABOLIC PLASTICITY IN THE HIPPOCAMPUS FOLLOWING SYMPATHETIC SPROUTING V. S. Yip Dept. of Anatomy, Univ. of Anatomy, Salt Lake City, UT 84132.

The invasion of the hippocampus by sprouts of peripheral sympathetic fibers following medial septal lesions provides a unique model for studying collateral sprouting in the CNS. The sympathetic sprouts are mainly restricted to the hilus and granule cell and supragranular layers of the dentate gyrus, and to the stratum lucidum and stratum radiatum of CA3 of the hippocampal formation (HF) where they replaced the lesioned septohippocampal neurons (Crutcher, K.A., Brothers, L. and Davis, J.N., Exp. Neurol., 66:778, 1979). The aim of the present experiment is to study the biochemical changes associated with the cellular events which takes place when, as the result of a medial septal lesion (loss of cholinergic fibers), the HF is invaded by noradrenergic sympathetic fibers from the superior cervical ganglion. The medial septums of rats are electrolytically lesioned under anesthesia, the brains are processed by Nissl, cholinergic and adrenergic histochemistry and quantitative microchemical analysis of two key oxidative enzymes of the citrate cycle: malate dehydrogenase (MDH) and citrate synthase (CS). The Lowry microchemical methods are used for precise localization (confirmed by histochemistry) and quantification of MDH and CS activities in the appropriate layers of the septally denervated HF. At 2 weeks after lesion, the sympathetic sprouts can be seen in the granule cell and supragranular layers of the dentate gyrus and the MDH and CS activities in the sprouted areas were depressed compare to control levels whereas the enzyme activities in the outer molecular of the HF and Layer IV of the cortex where no sprouting occurred remained unchanged. At 4 weeks post lesion, the MDH and CS levels were still low but to a lesser degree compare to the control levels. The results suggest the MDH and CS activities of sprouted sympathetic fibers are metabolically different than septohippocampal fibers and are specifically localized in the sprouted areas only.

SEROTONERGIC INNERVATION OF THE SUPERFICIAL LAMINAE OF RAT SUBNUCLEUS CAUDALIS (SpVc) FOLLOWING ADULT INFRAORBITAL (IO) NERVE TRANSECTION. B.G. Klein. Dept. of Neurosci., New York Coll. of Osteo. Med., Old Westbury, N.Y. 11568.

Serotonin immunoreactive (5-HTIR) axons which project to SpVc of the normal rat are highly concentrated in lamina I & outer lamina II, forming a dense, longitudinally oriented band. The possibility that 5-HTIR axons show a reactive alteration of this distribution following disruption of normal primary afferent input to SpVc was investigated in 4 adult rats, more than 60 days after unilateral IO nerve cut. In the IO region of SpVc, on both the normal & nerve cut sides, the superficial & deep borders of laminae I & II, as well as the dense band of 5-HTIR axons, were outlined at 113X. There was no significant change in the average width of the superficial laminae following adult IO nerve cut (normal, $\bar{X}$=98.3±15.1 u; nerve cut, $\bar{X}$=106.5±20.9 u). Mean % area of laminae I & II occupied by the dense band of 5-HTIR axons also did not change significantly (normal, $\bar{X}$=58.3%±4.7%; nerve cut, $\bar{X}$=57.7%±2.7%). The mean density of 5-HTIR varicosities (var) within the superficial laminae of the IO region of SpVc was estimated at 1111X. Again, no significant difference was observed following IO nerve cut (normal, $\bar{X}$=82599±10659 var/mm^2; nerve cut, $\bar{X}$=80887±9599 var/mm^2). Thus, adult IO nerve cut does not alter the area or terminal density of the heavy band of 5-HTIR axons within laminae I & II of the IO region of SpVc. Support:DE07734.

REINNERVATION OF SUPRAOPTIC NUCLEUS AFTER VENTRAL NORADRENERGIC/MEDIAL FOREBRAIN BUNDLE LESIONS: SOURCE OF NEW AFFERENTS. C. J. Phelps and S. W. Carlson*. Department of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

Fluorescence histochemical and physiological evidence for reinnervation of SON vasopressin-secreting neurons, after long-term neurosurgical lesion of noradrenergic afferents to the nucleus, has been reported (Phelps & Sladek, Brain Res. Bull. 13: 727, 1984). The source of this reinnervation is being studied 1) by retrograde tract-tracing methods, and 2) by eliminating contribution of peripheral vascular sympathetic sprouting by superior cervical ganglionectomy (SCGx). In intact or sham-operated rats, retrograde transport of wheat germ aggulutinin coupled to horseradish peroxidase (WGA-HRP) injected into SON consistently labelled cells in ventrolateral medulla (A1). At 4-5 days following mechanical mfb transection, retrograde transport of WGA-HRP failed to label perikarya in A1. Fluorescence microscopy showed significant loss of catecholaminergic (CA) afferents to SON after mfb "deafferentiation," but not after SCGx alone. By 14 days after combined mfb lesion + SCGx *vs.* mfb lesion alone, fluorescent innervation of SON, only in animals with intact SCG, indicated significant contribution by peripheral vascular CA afferents, although simultaneous regeneration at the lesion site was observed. Current experiments are testing the morphological significance of SCG *vs.* A1 contributions to SON after long-term deafferentation. Supported by NIH grant AG 06139 (CJP).

EVIDENCE THAT RUBROSPINAL NEURONS SURVIVE AXOTOMY IN THE ADULT OPOSSUM. G.F. Martin and X.M. Xu. Department of Anatomy and Neuroscience Program, The Ohio State University College of Medicine, Columbus, Ohio 43210.

As part of ongoing studies on rubrospinal plasticity in the opossum, we sought to determine if rubrospinal neurons survive axotomy in the adult animal. Fast-Blue (FB) was injected into the thoracic cord of 3 anesthetized animals and 4 days later they were reanesthetized and the rubrospinal tract cut 4 segments rostral to the lesion. Approximately 30 days after the lesion, the animals were anesthetized again and sacrificed by perfusion so that frozen sections of their spinal cord and brain could be examined with a fluorescence microscope. In each case, neurons were labeled in the red nucleus contralateral to the lesion. In one case, FB spread to both sides of the cord making it possible to compare the size and location of labeled rubrospinal neurons contralateral and ipsilateral to the lesion. In that case, labeled neurons on the contralateral side were smaller than those on the ipsilateral side. In 2 other animals, the rubrospinal tract was lesioned at the same level and after about 1 month the red nucleus was injected with wheatgerm agglutinin conjugated to horseradish peroxidase. Labeled axons could be traced to the lesion site where they appeared swollen, but not beyond it. We interpret our results to show that rubrospinal neurons survive axotomy for at least 1 month but their axons do not grow caudal to the lesion. (Supported by NS-25095).

RESPONSE TO SUBICULAR STIMULATION IN LAMINAE II/III AND V OF RAT CORTICAL SLICE. T.G. Hedberg Dept. Physiology Boston Univ. Sch. Med., 80 E. Concord St. Boston, MA 02118

In associative learning paradigms, subicular inflow is integral to development of neural population responses in cingulate cortex which may differ markedly between laminae. In the rat, synaptic inflow from subiculum reaches area 29c via a fiber tract with terminal field largely in lamina II/III. To investigate the response properties of pyramids in laminae II/III and V, paracoronal slices of rat cingulate cortex containing this fiber tract (SCT) were prepared. Subiculum was stimulated with square pulses lasting 0.2 msec. Intracellular responses obtained from 23/23 lamina V impalements were pure EPSPs driven at a $\bar{x}$ latency of 3.6 msec which supported 1-2 APs. In contrast, 2/27 lamina II/III impalements were not driven, 6/27 were driven with pure EPSPs, 14/27 with mixed EPSP/IPSPs and 5/27 with pure IPSPs. Lamina II/III PSP onset was >6.0 msec and EPS EPSPs and mixed EPSP/IPSPs supported 1-5 APs. Increases in stimulus amplitude (>500 uV) or frequency (>0.2 PPS) resulted in changes in PSP shape and latency indicating monosynaptic excitatory drive on lamina V neurons and polysynaptic mixed-sign drive on lamina II/III neurons.

Thus, a model SCT activation of area 29c involves: 1) monosynaptic excitation of local circuit interneurons and deep pyramids via their apical tufts, 2) polysynaptic activation of superficial units via ascending pyramidal collaterals, 3) feedback regulation of deep pyramids.

DIFFERENTIAL LAMINAR DISTRIBUTION OF ASTROCYTIC PROCESSES IN THE HIPPOCAMPAL DENTATE GYRUS. A. Marks*, K. R. Isaacs, A. M. Sirevaag, F. -L. Chang, W. T. Greenough. (Spon.:B. Oakley). Neural & Behav. Bio. Prog., Depts. of Psych and Cell & Struct. Biol. U. of Illinois, Champaign IL, 61820.

To our knowledge, no one has reported a quantitative analysis of the distribution of glial processes in the dentate gyrus of the rat. As prelude to investigating the role of glia in plasticity, it was necessary to have a reliable estimate of the pattern of glial processes. 8um frozen sections were taken from the septal end of the hippocampus of young adult male rats (60-70 days old) and labelled with antibody to GFAP, an astrocyte specific marker. Astrocyte ramifications were quantified using the method of Braendgaard and Gundersen (1986), and provided a stereologically unbiased estimate of astrocyte surface area (Sv) in the molecular layer of the dentate gyrus. The dentate gyrus molecular layer is usually divided into three approximately equal subdivisions corresponding to the inputs of the lateral and medial perforant path and the commissural /associational axons and we used this division as a template for collecting our data. A significant difference in the astrocytic Sv (in um^{-1}) was found in all 3 layers: Outer layer=72.90, Middle layer=57.70, Inner layer=41.84 ($p < 0.0001$). There were no significant differences between upper and lower blades. (Supported by NIMH, ONR and EFA).

454.17

RATS REARED IN A COMPLEX ENVIRONMENT HAVE LARGER ASTROCYTES WITH MORE PROCESSES THAN RATS RAISED SOCIALLY OR INDIVIDUALLY. A.M. Sirevaag, S. Smith, and W.T. Greenough. Depts. Psych. & Cell & Struct. Biol., & Neur. & Beh. Biol. Prog., Univ. IL, Champaign, IL 61820.

Rats raised in complex environments (EC) have larger neurons with more synapses in the occipital cortex than rats raised socially (SC) or in individual cages (IC) (e.g. Turner & Greenough, Brain Res., 1985). These results suggested that synaptic communication might be more intense in ECs than ICs. Astrocytes have been shown to be involved in ionic and neurotransmitter regulation and so may also influence the efficacy of synaptic transmission. Preliminary examination of astrocytes in the cortex of EC, SC and IC rats showed that astrocyte nuclei were larger in ECs than ICs. This implied that astrocytic arborization might also be greater in ECs than ICs. This hypothesis was tested by using indirect immunocytochemistry to label astrocytic processes with anti-GFAP and then estimating the surface area (Sv) of those processes by the stereological technique of vertical sections. This study shows that ECs have a 17% greater Sv of astrocytic process than ICs; that the density of astrocytes is 12% lower in ECs than ICs; and that the mean surface area per astrocyte is 27% greater in ECs than ICs. SCs values are intermediate on all measures. Supported by PHS 2T32GM07143 and MH 35321.

454.18

4 DAYS OF DIFFERENTIAL HOUSING ALTERS DENDRITIC MORPHOLOGY OF WEANLING RATS V.L.Kilman*, C.S.Wallace, G.S. Withers & W.T. Greenough. Neur. & Beh. Biol. Prog., Depts. Psych. & Cell & Struct. Biol., Univ. IL, Champaign, 61820.

Previous studies have demonstrated that 30 days of housing in a complex environment alters dendritic morphology of various neuron types in rat visual cortex. This study assessed these changes after a much briefer exposure to complex housing. Weanling rats were used, as exploration activity peaks at this age. 12 littermate pairs of 30 day old male Long-Evans hooded rats were randomly assigned to differential housing for 4 days. Complex housing for one littermate consisted of a large cage containing other rats and an assortment of toys (EC). EC rats spent one hour per day in a play cage while toys in the home cage were replaced. Littermates of the EC animals were housed individually (IC) for 4 days. Basilar dendrites of layer III pyramidal cells were drawn from Golgi impregnated sections. Total dendritic length and number and length of branches at each order of bifurcation were analyzed. EC rats exceeded IC rats in total dendritic length. These results indicate that the effects of exposure to a complex environment are manifest rapidly in weanling rats and are compatible with the hypothesis suggested by previous results (Turner & Greenough, Brain Research., 1985) that the effects of a complex environment on neuronal morphology involve synaptogenesis in response to environmental stimulation. COMPLEX EXPERIENCE INDUCES CAPILLARIES IN VISUAL CORTEX OF ADULT RATS. J.E.Black, A.M.Zelazny*, & W.T.Greenough, College of Medicine, Depts of Psychology and Cell & Structural Biology, and Neural & Behavioral Biology Program, University of Illinois, Urbana 61801.

Young rats reared with other rats and toys generate many new capillary branches within 30 days (Black, etal, Neurosci Lett, 83: 351), but angiogenesis in old rats provided complex experience seems to be impaired (Isaacs, etal, Soc Neur, 12: 1579). The present study examines angiogenesis in 66 3-month-old rats either given complex experience (EC) or kept in isolation (IC) for periods of 10, 30, or 60 days and then perfused. All vessels are easily seen in toluidine-stained 1 μm sections of visual cortex. The visual cortex of EC rats was significantly thicker than that of IC rats after 10, 30, and 60 days. This corresponds to previous estimates of greater synaptogenesis in EC rats (Hwang & Greenough, Soc Neur, 12: 1284) which presumably spread apart existing blood vessels. Capillary spacing was nearly identical for EC and IC rats after 10 and 30 days, however, indicating that EC rats made new capillaries. EC rats also had a smaller mean capillary diameter than IC rats after 10 days, consistent with the presence of many immature and small capillaries. These findings suggest that angiogensis in the mature cerebral cortex begins within 10 days of complex experience and requires at least 60 days to reach completion. Supported by NIMH.

BEHAVIORAL PHARMACOLOGY: ACETYLCHOLINE

EFFECTS OF SCOPOLAMINE ON A DELAYED SPATIAL MATCHING TASK IN RHESUS MONKEYS. R.F. Genovese and T.F. Elsmore*. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

We investigated the effects of scopolamine (1-32 µg/kg) on a novel spatial learning task where three rhesus monkeys were trained to interact with images on a CRT. Eight circles, arranged in a circular pattern, were presented on the screen and one circle (chosen randomly) contained a distinctive feature. Touching the featured stimulus cleared the display for .01, 4, or 16 s. A choice screen consisting of the eight circles, without the featured stimulus, was then presented. Touching the circle that had previously contained the feature, produced a food pellet and was considered a correct choice.

Under baseline conditions, accuracy was approximately 95%, 85%, and 60% for the .01-, 4-, and 16-s delay conditions, respectively. Scopolamine produced dose-dependent decreases in the number of trials completed in all three monkeys. Only small decreases in accuracy were observed at the .01-s delay. In some instances, much larger decreases in accuracy were observed at the 4- and 16-s delays. In all cases, doses of scopolamine producing decreases in accuracy also produced substantial decreases in the number of trials completed.

These results extend previous studies of cholinergic involvement in spatial learning tasks in rodents and further, suggests that the procedure may be useful for assessing the effects of a variety of compounds in primates.

455.2

SCOPOLAMNE INDUCED VISUAL MEMORY DEFICITS IN RHESUS MONKEYS. N.L. Yusuf, S.F. Sands and D.E. Moss. Departments of Neurology and Neurophysiology, University of Texas Health Science Center, 6431 Fannin, Houston, Texas 77225.

This study investigated the effects of scopolamine, a muscarinic receptor agonist, on a visual recognition task in two adult male rhesus monkeys. The monkeys were initially trained to perform on a serial probe recognition (SPR) task with a variable list length design that closely parallels tests given to humans: a simultaneous discrimination and a 1-,2-,4- and 8-item multiple retention task. A dose-dependant decline in baseline performance was observed following intramuscular injections of varying concentrations of scopolamine HBr (.003mg/kg - .025mg/kg). The scopolamine administration resulted in a significant decrease in performance on the longer list lengths indicating impaired memory function. Performance on the simultaneous discrimination, which does not involve a memory component, showed no significant change from control days. The decline in visual recognition ability in these monkeys closely resembles the decline in memory observed in humans with cholinergic insufficiencies, i.e., Alzheimer,s disease. This data suggests a strong cholinergic component in this type of visual retention task. This paradigm provides an excellent opportunity to explore new and current therapeutic approaches in memory disorders by enhancement of cholinergic transmission.

455.3

EFFECTS OF DAILY REPEATED SOMAN EXPOSURE ON TRACKING PERFORMANCE AND BLOOD CHOLINESTERASE IN RHESUS MONKEYS. D. W. Blick*†, M. R. Murphy†, G. C. Brown*†, S. Z. Kerenyi*†, & S. L. Hartgraves†. *Systems Research Laboratories, & †Radiation Sci. Div., USAF School of Aerospace Med., Brooks AFB, TX 78235-5301.

We estimated the daily dose of soman, an organophosphate that irreversibly inactivates cholinesterase (ChE), required to produce a small but reliably detectable decrement in the performance by rhesus monkeys of a well-learned compensatory tracking task, the Primate Equilibrium Platform (PEP) task. Monkeys were tested sequentially at soman dosages (0.84 - 1.06 µg/kg/day) set by the up-and-down method. The threshold dosage (ED50) for a performance decrement on or before the 5th daily exposure was found to be 0.97 µg/kg/day (95% confidence interval: 0.80 $\leq$ ED50 $\leq$ 1.18 µg/kg/day), about 40% of the single-dose acute ED50. Behavioral effects of daily repeated soman exposures are much more variable than the effects of a single, acute exposure. Blood ChE inhibition is a poor predictor of behavioral effects.

Tests for interactions between chronic ChE inhibition by pyridostigmine and performance effects of daily repeated soman exposure are in progress.

Performed under USAF Contract F33615-85-D-0659, with funding from the Naval Medical Research & Development Command under project MF4561.001.

455.4

ANTICHOLINERGIC REVERSAL OF HALOPERIDOL'S DELETERIOUS EFFECTS ON FORELIMB STEADINESS AND RESPONSE INITIATION IN RATS. S.C. Fowler, R.M. Liao, P.D.Skjoldager, C. Bass, and W.D. Brown. Depts. of Psychology and Pharmacology, University of Mississippi, University, MS 38677

Rats were trained to reach through a rectangular hole and exert downward forces on a force transducer. As long as the force on the transducer was maintained above 20 g the rats were able to drink from a dipper of sweetened condensed milk. After a two-week period of 10-min daily practice on this task, the rats were divided into 4 groups and treated with ip. injections of vehicle (V) or haloperidol (Hal, 0.04, 0.08, 0.16 mg/kg) for 17 consecutive days. On the 16th drug day each of the 4 groups received an ip. injection of atropine sulface (AS, 5mg/kg) in addition to Hal. The dependent variables were time-on-task (the amount of time the rat's forelimb force remained above 20 g) and the integrated variance ("power") of force oscillations having frequencies within a 5-to-25 hertz bandwith. Hal alone reduced time-on-task and increased the variance of force oscillations. When AS was given along with Hal, the disruptive effects of Hal on performance were significantly attenuated. These data suggest that the behavioral deficits engendered by low doses of haloperidol in rats are analogous to neuroleptic-induced parkinsonian symptoms in human beings. (Supported, in part, by MH 43429.

455.5

GLUCOSE ATTENUATES DRUG-INDUCED HYPERACTIVITY IN MICE: EFFECTS ON CENTRAL CHOLINERGIC FUNCTION. D.L. WALKER*, W.S. STONE, R.J. RUDD*, and P.E. GOLD. Dept. Psychol., Univ. Virginia, Charlottesville VA 22903.

Glucose (GLU) attenuates scopolamine (SCOP)-induced amnesia and hyperactivity, as well as atropine-induced changes in paradoxical sleep. Additionally, GLU augments the severity of physostigmine (PHYSO)-induced tremors. This study addresses the specificity of GLU interactions with cholinergic function and examines whether such effects are mediated by central or peripheral GLU actions.

Locomotor activity of mice was assessed by counting lines crossed during 10 min in a 52.5 cm^2 enclosure. 45 min prior to testing, animals were injected (IP) with saline (SAL), morphine-sulphate (MS; 10 mg/kg), or amphetamine (AMPH; 1 mg/kg). 15 min prior to test, animals received SAL, GLU (10, 50, 100, or 500 mg/kg) or PHYSO (0.01, 0.05, 0.1, or 0.2 mg/kg). GLU and PHYSO blocked MS- but not AMPH-induced hyperactivity. Because hyperactivity induced by opiates but not AMPH may be mediated by inhibition of cholinergic function, these results are consistent with a specific interaction of GLU with cholinergic systems. A second group of mice received SCOP (3 mg/kg) 45 min and fructose 15 min before testing. Fructose, which is not utilized by the CNS, did not attenuate SCOP-induced hyperactivity, suggesting that the locomotor effects of GLU are mediated centrally. (Supported by MH 31141, ONR N00014-85-KO472, the American Diabetes Association, and training grant MH18411).

CHOLINERGIC-DOPAMINERGIC INTERACTIONS IN RADIAL-ARM MAZE PERFORMANCE: ROLE OF NICOTINIC CHOLINERGIC SYSTEMS. S.R. McGurk, E.D. Levin, and L.L. Butcher. Department of Psychology, University of California, Los Angeles, CA 90024-1563.

Interference with either muscarinic-cholinergic or dopaminergic function impairs radial-arm maze performance. Paradoxically, the amnestic effect of muscarinic antagonism is significantly reduced by simultaneous dopaminergic blockade, suggesting that cognitive function is depedent upon a balance between these neurotransmitter systems. Since central nicotinic receptors are involved in cognitive functioning, and because blockade of nicotinic receptors impairs maze performance, this experiment examined the interaction of nicotinic-cholinergic and dopaminergic systems.

Rats were trained on an 8-arm radial maze. Drug testing began after asymptotic levels of performance were reached. All rats received saline, mecamylamine (2.5, 10.0 mg/kg), haloperidol (0.04, 0.08 mg/kg), or a combination of mecamylamine and haloperidol (2.5 and 0.04 mg/kg, respectively) in a counterbalanced order. Maze performance was significantly impaired by the higher doses of mecamylamine or haloperidol. Interestingly, although the lower doses of mecamylamine and haloperidol did not affect maze performance, their combination caused a significant decrease in performance.

Taken together, these results reinforce the importance of dopaminergic and nicotinic-cholinergic systems in maze performance and indicate a significant interaction of these systems. That subthreshold doses of nicotinic-cholinergic and dopaminergic antagonists summate to interfere with maze performance suggests that the circuitry underlying this behavior contains both a nicotinic and dopaminergic synapse. Finally, these data illustrate the differential involvement of muscarinic and nicotinic systems in learning. (NIH grant NS-10928 to L.L.B.).

NICOTINE ENHANCES PLAYFUL ATTACK IN THE PLAY-FIGHTING BY JUVENILE RATS. S.M. Pellis, V.C. Pellis and R.L. Lennon* Dept. of Psychology, Univ. of Florida, Gainesville, FL 32611.

Systemic (S.C.) injection of nicotinic acid produced a dose dependent increase in play-fighting in juvenile rats (30-40 days old). By using 'pinning' (ie. one animal standing over the supine partner) as the measure of play-fighting the increase was not significant over vehicle controls at 0.125 mg/kg but was so at 0.5 mg/kg. However, pinning involves both attack and defense, so that an increase in pinning could arise from an increase in either attack rate or defense rate. Therefore, attack (ie., lunge at nape) and defense (ie. rotate to supine, withdrawing nape from attacker) were measured separately for each member of each pair.

After 24h isolation sibling rats were reunited, 15 min after one animal received an appropriate injection and their behavior was videotaped under red-light for 10 min. Attack in the injected rats increased significantly with increasing dose, whereas defense remained unchanged. Neither the rate of attack or defense increased in the non-injected partners. These results show that nicotinic stimulation facilitates only one of the two components involved in play-fighting, so that overall increases in play-fighting are produced by elevated frequencies of attack, not of defense.

CONSEQUENCE OF NICOTINE TREATMENT ON A SPATIAL TEST OF MEMORY. S.A. Welner, A. Nair*, A. McNicoll*, P. Boksa and R. Quirion. Douglas Hosp. Res. Ctr., McGill Univ., Dept. of Psychiatry, Montreal, Quebec, H4H 1R53.

The consequence of a schedule of nicotine treatment to rats that is said to increase the specific binding of [^{3}H]ACh or [^{3}H]nicotine to nicotinic cholinergic sites in the cerebral cortex was tested on the acquisition and memory of platform location in a Morris water maze. Rats were treated for 5 days with saline or a low dose (0.2 mg/kg s.c.) of nicotine administered following each day's trials. Previous reports that this treatment increases locomotor activity in the first minutes following injection were confirmed. Nicotine treatment did not alter consolidation of the spatial task because the rate of task acquisition, measured as latency to find the platform, was not different in the two groups. After 2 days without treatment, at a time when nicotinic receptor up-regulation in the cortex is said still to be present, the animals were retested for their memory of the task and again, no difference was observed between the two groups. In an attempt to augment cholinergic function, tetrahydroaminoacridine (THA) at a dose of 5 mg/kg was administered 1 hr pre-test to all animals; a significant decrease in latency to find the platform from the first trial to the last trial was observed in the group treated with nicotine. (Supported by MRC Canada).

RATS DEVELOP A PREFERENCE FOR NICOTINE SOLUTIONS. F.W. Flynn and C. Ksir. Dept. of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY 82071

The responses of rats to nicotine solutions were examined using the taste reactivity (TR) test and 2-bottle 24 hr preference test. In Experiment 1, non-deprived rats were administered intraoral infusions of water, 1 µg/ml, 5 µg/ml, 10 µg/ml, 25 µg/ml, 50 µg/ml, and 100 µg/ml nicotine, and TR responses were videotaped and analyzed. Nicotine, up to 50 µg/ml, elicited ingestive TR responses. Ingestive responses significantly decreased and aversive TR responses significantly increased in response to 100 µg/ml nicotine. Next, 2-bottle preferences for water vs. 1 µg/ml, 5 µg/ml and 0 µg/ml (water control group) were measured in 3 groups of naive rats. After 16 days of exposure, rats showed a significant preference for 1 µg/ml nicotine. The preference for 5 µg/ml nicotine significantly increased during the experiment, but it remained less than that for 1 µg/ml and 0 µg/ml nicotine. Last, TR responses elicited by 1 µg/ml and 5µg/ml nicotine were measured in the rats having had the 2-bottle experience. Rats showing a 2-bottle preference for the 1µg/ml nicotine showed significantly more ingestive TR responses to 1 µg/ml and 5 µg/ml nicotine that did the control rats. These data show that prolonged voluntary access to nicotine results in an increased preference for nicotine and modifies the rats' immediate oral/gustatory reactivity to nicotine.

NICOTINE EFFECT ON LOCOMOTOR ACTIVITY IS NOT REDUCED BY DOPAMINE RECEPTOR BLOCKADE E. J. Cline and C. Ksir. Department of Psychology, University of Wyoming, Laramie, WY 82071.

Nicotine increases locomotor activity in rats, especially after several days of treatment. Evidence suggests a role for the mesolimbic dopamine system in this effect. Clarke et al (Soc Neurosci Abstr 13:406, 1987) demonstrated that nicotine increased locomotor activity and dopamine turnover in the nucleus accumbens and olfactory tubercule. Ksir and Cline (Soc Neurosci Abstr 13:447, 1987) showed that 6-OHDA lesions of the nucleus accumbens reduced nicotine-induced locomotor activity.

Rats were given daily s.c. injections of 0.2 mg/kg nicotine for seven days prior to behavioral testing. They were habituated to the test cages for one hour and then pretreated with either saline, 0.05, 0.1, or 0.2 mg/kg alpha-flupenthixol (FPT), a dopamine receptor antagonist, and returned to the test cages for 90 minutes. Rats were then tested for one hour following a dose of 0.2 mg/kg nicotine. Tests were repeated on subsequent days so that all rats received each pretreatment. Pretreatment with FPT did not reduce the number of cage crossings during the 20 min following nicotine administration.

One week later the same rats were tested for their response to 1.0 mg/kg d-amphetamine after pretreatment with either saline or 0.2 mg/kg FPT. FPT pretreatment decreased the locomotor response to d-amphetamine ($F=16.15$, $df=1,12$, $p<0.01$).

It is puzzling that blocking postsynaptic dopamine receptors does not interfere with the behavioral response to nicotine.

455.11

MAPPING OF THE EFFECT OF CARBACHOL ON LOCOMOTION IN THE BASAL FOREBRAIN OF THE RAT. S.M. Brudzynski, R.S. McLachlan and J.P. Girvin. Epilepsy Res. Lab., Dept. of Clin. Neurol. Sci., University Hospital, London, ON N6A 5A5 Canada.

Intracerebral injection of carbachol into the basal forebrain is known to decrease spontaneous locomotor activity of rats. The anatomical location of this pharmacological response is not precisely known. The goal of the present study was to quantitatively map the response to carbachol in the basal forebrain and anterior diencephalic areas. Intracerebral injections of carbachol were performed in 48 animals (total 91 brain sites) in a dose of 1 µg (5.47 nanomole - the dose close to D_{50}) and in a volume of 200 nL into different sites between the frontal planes 6.5 and 9.5 mm from the interaural plane. Locomotion, expressed as a percent of the saline control, was measured by the total distance covered by an animal and the total time of movement within 10 min after injection using an automated activity monitor. The strongest and the most consistent decrease of locomotion occurred from the medial preoptic and the anterior hypothalamic areas, particularly medial preoptic nucleus, in contrast to ventromedial hypothalamic nucleus, retrochiasmatic area, paraventricular nucleus and diagonal band where increase in locomotion was found.

THE SIZE OF THE HUMAN CORPUS CALLOSUM RELATES TO LANGUAGE LATERALIZATION AND TO VERBAL ABILITY. M. Hines[1], K. Sloan[1*], J. Lawrence[1*], J. Lipcamon[2*] and L. Chiu[2*]. [1]Dept. of Anatomy and Neuropsychiatric Institute, UCLA School of Medicine, Los Angeles, CA. 90024-1763. [2]Dept. of Radiology, Harbor/UCLA Medical Ctr., Torrance, CA. 90509.

The size of the corpus callosum and some of its subregions have been reported to vary with sex and handedness. In this study we examined relationships between callosal size and cognitive functions that vary with sex or handedness. Subjects (29 women, 20-45 years of age) completed measures of verbal fluency, visuospatial ability and language lateralization and had magnetic resonance images (MRIs) made of their brains. The midsagittal MRI was used to measure the cross-sectional surface area of the callosum and its subregions, including the posterior fifth (P5) and the posterior third minus fifth (P3-5), which have been reported to vary with sex and handedness, respectively. Verbal fluency related positively to callosal area, particularly to P5. Language lateralization related negatively to callosal area, particularly to P5 and P3-5. Visuospatial ability did not relate to callosal measures. These results suggest that individual differences in language lateralization and in verbal ability may depend on the number of the size of fibers in the corpus callosum and its subregions. A SEX DIFFERENCE IN THE STRUCTURAL ASYMMETRY OF THE CAUDATE NUCLEUS USING MRI SCANS IN HUMANS. Richard S. Lewis[1], Stephanie B. Hodson[1*], Jim Lipcamon[2*], Lee Chiu [2*] & Melissa Hines[2]. 1. Department of Psychology, Pomona College, Claremont, CA. 91711; 2. UCLA School of Medicine.

The present study investigated an anatomical asymmetry, and its variation with sex, in the volume of the left and right caudate nucleus.

Twenty six normal right-handed adults (13 males and 13 females) received inversion recovery magnetic resonance imaging (MRI) scans. The volume of the head of the caudate nucleus was traced throughout the horizontal and coronal sections and the volume of the caudate was calculated using the Bioquant Software system and an IBM PC. A laterality index was derived, (R - L)/(R + L) * 100, from the average volume values of the horizontal and coronal sections.

A significant sex difference in asymmetry was observed, $t(24) = 2.02$, $p=.055$, such that males tended to have a larger right than left caudate nucleus and females a larger left than right caudate nucleus.

456.3

STRIATE AND EXTRASTRIATE ASYMMETRIES IN JUVENILE AND ADULT HUMAN BRAINS. M-C de Lacoste, C-N Kim*, N. Smith*, & D. J. Woodward, Dept. Cell Bio., U. T. Southwestern Medical Ctr., Dallas, TX 75235

We have previously reported striking occipital regional volumetric asymmetries in a large number of primate species at all phylogenetic levels (*de Lacoste* et al., 1988). The aim of this study was to determine if, in juvenile and adult human cerebra (n=8), this "gross" asymmetry reflects an underlying asymmetry in primary visual (striate,[ST]), extrastriate [XT] , or in both ST and XT cortex.

Series of 35-50 μm Nissl and myelin stained coronal sections, obtained from both the *Yakovlev* collection and our laboratory, were videodigitized. The CSCAN utility of CARP (Computer Aided Reconstruction Package) was used for semi-automated delineations of 1) the external and internal borders of cortical gray and 2) the boundaries between ST and XT (per techniques described in [*Smith, de Lacoste* et al 1987]). CARP was also used to compute regional areas and volumes.

Preliminary results indicate that both XT and ST are highly asymmetrical in adult humans (XT: 7-122%; ST: 11-30%). In fact, occipital regional volumetric asymmetries based on cytoarchitecturally defined regions are two- to sixfold more pronounced than those we quantitated at the gross level. We believe that the reason for this is that ST and XT asymmetries favor opposite hemispheres. Our data further suggest that juvenile and adult males exhibit greater ST and XT asymmetries than their female counterparts. In sum, our results indicate that both primary and association visual areas are asymmetrically organized in the left and right hemispheres of the human brain. Future studies will assess volumetric asymmetries in subdivisions of XT i.e. visual association cortex. *Supported by HD21711 to MCL and the Biological Humanics Foundation.*

MORPHOMETRY AND OPTICAL DENSITOMETRY OF THE CORPUS CALLOSUM IN MONOZYGOTIC TWINS DISCORDANT FOR SCHIZOPHRENIA: A MAGNETIC RESONANCE IMAGING STUDY. R.D. Sanders*, M. F. Casanova*, T. Goldberg*, L. Bigelow*, G. Christison*, D. R. Weinberger and E. F. Torrey* (SPON: A. P. Oliver). Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032

Many of the symptoms, cognitive deficits and evoked potential abnormalities of schizophrenia (SC) may be due to aberrant interhemispheric communication. To test this hypothesis, several planimetric magnetic resonance imaging (MRI) and postmortem studies have analyzed the structure of the corpus callosum (CC). Results thus far have been contradictory. In the present study, we have used a computer image analysis system (LOATS) in combination with MRI's to examine the morphology and optical density of the CC in 12 pairs of monozygotic twins (5 female, 7 male) discordant for SC. No differences in CC area (anterior, middle, posterior thirds and total), length, vertical height of the CC body (at three levels) or optical density (at four points) were demonstrated by t-test comparisons of SC and their normal cotwins. Quantitative harmonic shape analyses showed no significant differences between normal and SC cotwins, but suggest effects of gender on posterior CC shape (1st harmonic $p = 0.007$, 3rd harmonic $p = 0.049$; Kruskall-Wallis), and a gender-diagnosis interaction effect on anterior CC shape ($p = 0.043$; MANOVA). These results fail to replicate prior findings of altered length, thickness and area in the schizophrenic CC, but may partially support gender-related differences in the shape of the splenium.

APPENDING SYMBOLIC INFORMATION TO GRAPHICAL REPRESENTATIONS OF NEUROANATOMICAL DATA: APPLICATIONS IN VISUAL CORTEX. W.K. Smith, N.C. Smith*, M.C. de Lacoste, D.S. Schlusselberg and D.J. Woodward. *Dept. of Cell Biology and Anatomy and Dept. of Physiology, U. Texas Southwestern Med. Ctr., Dallas, TX 75235.*

Ongoing studies in this laboratory have explored the application of computer graphics and image processing techniques to three-dimensional reconstruction from serial sections of neuroanatomical tissue. The CARP system (Computer Aided Reconstruction Package) contains software modules which allow manual tracing, morphometry, computer microscopy, C-14 2DG autoradiography analysis, three-dimensional reconstruction and image synthesis. A sophisticated hierarchical, anatomical database provides storage for varied forms of data including video images, graphical representations of tissue sections, and three-dimensional surface models. Experience has revealed a need for the ability to attach arbitrary text descriptions to graphical and image data which represent associations between the stored data and information from other sources. For example, boundaries denoting cortical regions may have appended multiple anatomical names, descriptors or lists of bibliographic references. A screen-oriented menu allows users to manipulate a LISP data structure called the *property list* which associates property-value pairs with a node in the CARP database. Once created, the property lists serve both as cross references with other information sources and as targets for searching paradigms in CARP database operations. Current applications include assigning complex descriptions to subregions of striate and extrastriate visual cortex in primate brain. *Support from DA2338, AA3901 and the Biological Humanics Foundation to DJW, HD21711 to MCL and SBIR NS25321 to WKS (Biographics, Inc.).*

HEMISPHERIC ASYMMETRIES IN LOGICAL CATEGORIES: CONVERGENT EVIDENCE FROM NORMAL AND COMMISSUROTOMY SUBJECTS. D. W. Zaidel and K. Frederick. Dept. of Psychology, UCLA, Los Angeles, Ca 90024.

In a previous study (D.W. Zaidel, Cognitive Neuropsych., 4:321-332, 1987), hemispheric asymmetry was found for retrieval of information about natural categories from long-term semantic memory. The purpose of the present study was to determine whether any asymmetries are present for logical categories. Both normal and patients with complete section of the forebrain commissures were studied. The task consisted of deciding whether or not numerals are ODD or EVEN. Stimulus numerals represented the following bins: S=<10, M=>10<20, or H=>40<50. They were flashed in the left or right visual half-fields and the answer was indicated with a key-press. Both accuracy and latency was recorded. Results showed a high accuracy rate in both visual fields. Analysis of latencies revealed significant interactions for field X parity and for field X bin (e.g.,S,M,or H). The latency results are interpreted to reflect hemispheric asymmetries in processing logical categories, where inclusion is based on necessary and sufficient conditions. This extends previous observations of hemispheric asymmetries in retrieval from long-term semantic memory for natural categoies and supports the assumption of specialized storage/retrieval even in the presence of the forebrain commissures.

456.7

HEMISPHERIC PROCESSING OF GRATINGS IN A COMMISSUROTOMY PATIENT. Robert Fendrich* and Michael Gazzaniga, Div. of Cognitive Neuroscience, Cornell Univ. Med. College, N.Y., N.Y., 10021

To test the hypothesis that the left hemisphere in humans is specialized for the processing of high spatial frequency information, while the right hemisphere is specialized for the processing of low frequency information, pairs of sinusoidal gratings were presented within the left and right visual fields of a commissurotomy patient. The gratings employed had spatial frequencies of 1, 2, 4, or 8 c/^{o}, and either horizontal or vertical orientations. The gratings were windowed by a circular Gaussian approximately 1.5^{o} across, and had a mean luminance of 31 cd/m^{2} and a maximum contrast of 66%. The two gratings in each pair were vertically aligned and flashed to the subject's left or right visual field 1.5^{o} from the vertical midline. Presentations lasted 167 msec. and were terminated by a composite grating mask. The two gratings in each pair were identical in spatial frequency but could differ in orientation. The subject reported if their orientations were the same or different.

Accuracy data provides no indication of a relative advantage for high frequencies in the RVF, or a relative advantage for low frequencies in the LVF; the data in fact shows the opposite trend. Accuracies for the 4 spatial frequencies (going from 1 to 8 c/^{o}), based on 64 trials per condition, were 81%, 83%, 77% and 63% in the RVF, and 67%, 75%, 79%, and 81% in the LVF. This suggests that at the processing levels required by the experimental task, the subject's left and right hemispheres were not specialized for the respective processing of high and low spatial frequency information.

456.8

AN INVESTIGATION OF HEMISPHERIC LATERALIZATION USING A PHOTIC PROBE PARADIGM. J.M. Rothfeld*, A.S. Zeiberg, C.W. Linebaugh, H.A. Emsellem. Depts. of Neurology and Linguistics, The George Washington Univ., Wash., DC 20037

Interhemispheric electrocortical asymmetries have been demonstrated during the processing of afferent sensory information in the human using auditory and visual evoked potential (VEP) recordings. The photic probe paradigm in conjunction with brain electrical activity mapping (BEAM, Caldwell - model 8400) of VEPs was utilized to characterize interhemispheric electrocortical responses to auditory stimuli. Pattern reversal VEPs were recorded from 20 right-handed subjects (10 males/10 females) using the standard 10-20 electrode system during inattentive and attended states to music (non-verbal) and continuous speech (verbal) stimuli.

Examination of the BEAM scans and a cross-correlation analysis generated from 8 bilateral recording sites revealed no reproducible hemispheric asymmetries associated with any of the conditions. VEPs recorded under all conditions were normal for latency and amplitude. No reproducible asymmetries were noted on separate analysis of F7-F8, T3-T4, C3-C4, O1-O2. The inability to detect previously reported electrocortical asymmetries may reflect the modality of the probe or the complex asynchronous nature of the auditory stimuli.

456.9

INDUCING EMOTION BY UNILATERAL CONTRACTION OF FACIAL MUSCLES: A LOOK AT HEMISPHERIC SPECIALIZATION AND EMOTION. B. Schiff* and M. Lamon* (Spon: I. Zucker). Dept. of Psychology, University of Toronto, Toronto, Ont. M5S 1A1.

This research investigated whether hemispheric function in emotion could be studied by arousing each hemisphere through unilateral contractions of contralateral facial muscles in the lower third of the face. We discovered that sustained contractions of the left facial muscles induced sadness. Right facial muscle contractions abolished the dysphoria produced by the left face contraction and produced a consistent but difficult to characterize mixture of positive affect and aggression. This was replicated in an objective study in which judges reliably identified the laterality of the facial contraction from transcripts of the subjects' reports. In a third experiment the performance of these facial contractions had comparable effects on the emotional tone of stories told about an ambiguous picture. These results indicate that emotions can be turned on by sustained unilateral facial muscle contractions. They are consistent with the view that the right hemisphere is implicated in negative emotional experiences and that the left hemisphere has a different but not easily specified function. They provide a method for studying hemispheric specialization for emotional experience and have implications for relations between emotion and cognition.

COGNITIVE AFFECTIVE CHANGES FOLLOWING RIGHT OR LEFT TEMPORAL LOBECTOMY FOR EPILEPSY. A.K. Collings*, R.F. Stevens*, and L. Switzman, Dept. of Psychology, Wellesley Hospital, Toronto, Canada, M4Y 1J3.

Clinical observations of epileptic patients in hospital for temporal lobectomy suggest that those with a clear and isolated L temporal epileptogenic focus have disrupted social interactions on the ward more often than those with a R focus. Consequently, we undertook to quantify this with 10 measures of cognitive-affective functioning pre- and post-surgically. Significant trends were found in 4 measures, most notable being a significant interaction in Social Imperturbability. This was higher pre-surgically in the L patients, than in the R patients, with post-surgery reduction (i.e., improved social sensitivity and awareness) in the L patients only. This variable has usually been associated with dysfunction of the frontal lobe (Lezak, 1983) not the temporal lobe. We are currently correlating this neurobehavioral finding with indices of R and L frontal and temporal cognitive dysfunction to clarify potential connections between L temporal epileptic activity and disruption of frontal lobe functions.

456.11

DICHOTIC LISTENING IN RELATION TO SEVERITY OF CLOSED HEAD INJURY. H.S. Levin, W.M. High*, D.H. Williams*, E.G. Amparo*, and H.M. Eisenberg. The University of Texas Medical Branch, Galveston, TX 77550

Eighty-two right-handed patients who sustained a closed head injury (CHI) of varying severity were characterized according to the level of the deepest lesion visualized by magnetic resonance imaging (MRI). Patients with no lesions or extradural and/or cortical lesions were grouped together (n=31) while patients with lesions extending into the subcortical white matter or deeper comprised another group (n=51). Thirteen right-handed controls were also examined. All patients and controls were screened for hearing loss and tested on dichotic listening using a computer synthesized tape which consisted of six consonant-vowel nonsense syllable pairs presented simultaneously via earphones. The subjects were instructed to repeat the syllables presented on each trial. A laterality index reflected the preference for reporting the syllables heard by the left or right ears. Nonparametric analysis of variance indicated that patients sustaining moderate to severe CHI showed a significantly greater right ear advantage in dichotic listening performance than controls. Furthermore, among the moderate to severe injuries, patients with parenchymal lesions extending into the subcortical white matter showed a greater right ear advantage as compared to controls, whereas the laterality index of patients with lesions which were higher on the neuroaxis did not differ from results in controls.

456.12

LATERALITY IN MONKEYS DISCRIMINATING INVERTED FACES. B. A. Vermeire and C. R. Hamilton. Division of Biology, California Institute of Technology, Pasadena, CA 91125.

The right hemisphere of human beings is usually found to be superior to the left in the recognition of facial identity and expression. We have shown that the right hemisphere of rhesus monkeys is superior in learning, remembering, and generalizing discriminations of monkey faces. In humans, faces are relatively more difficult to recognize when inverted than are other stimuli usually seen upright, such as houses or cars; the right hemisphere seems particularly sensitive to facial inversion. In the present experiment, 16 split-brain monkeys who had previously learned to discriminate upright faces were tested with the same discriminations inverted. While the right hemisphere was superior in discriminating the upright faces ($p<.02$), there was no significant laterality for discriminating the inverted faces. Furthermore, there was a significant difference ($p<.001$) between the laterality found for upright and inverted faces. While the interpretation of the inversion deficit is controversial, the finding that the data from monkeys is similar to that from people suggests that similar mechanisms of laterality are being examined in both species.

ANATOMICAL BRAIN ASYMMETRIES IN MONKEYS. Peter L. Heilbroner and Ralph L. Holloway. Department of Anthropology, Columbia University, New York, NY 10027.

Measurements evaluating hemispheric asymmetry were taken on the cortex of formalin-fixed brain specimens from two Old World and three New World monkey species. We found significantly greater mean length ($p<0.05$; n=20-30) for the left Sylvian fissure (SF) than for the right SF in all five of these samples. In accord with this finding, results of several behavioral studies (e.g. Petersen et al., Science 202:324,1978) suggest left-temporal-lobe dominance for auditory discrimination functions in monkeys. SF asymmetry is also characteristic in the human brain. However, other measurements on the temporoparietal area which usually suggest asymmetry in Homo brains did not reveal side differences in these monkey brain samples. Furthermore, asymmetry in the development of sulci in the cortical region homologous to Broca's area, in visual association cortices, or asymmetry in the surface area of the cingulate gyrus was not revealed. Evidence for functional lateralization involving these cortical regions in monkeys has not been reported.

456.14

ASYMMETRIES IN NEGLECT REINSTATED BY SPIROPERIDOL IN RATS RECOVERED FROM LEFT VS. RIGHT DORSOMEDIAL PREFRONTAL CORTEX LESIONS. J.M. Vargo*, M. Richard-Smith* and J.V. Corwin (SPON: B. King). Dept. of Psychology, Univ. of New Orleans, New Orleans, LA 70148.

Dopamine (DA) agonists produce acute recovery from neglect produced by unilateral destruction of medial precentral prefrontal cortex (PCm) in rats. The present study examined the role of DA mechanisms in spontaneous long-term recovery from unilateral PCm lesions.

Subjects (Ss) (male Long-Evans hooded rats) received right (RPCm) or left (LPCm) lesions or a lesion lateral to PCm (LAT). Neglect was assessed by rating the degree of head orientation to visual, auditory, or tactile stimuli. After recovery, the Ss received either 0.03, 0.05, 0.07, or 0.10 mg/kg of spiroperidol (SPIRO), or the vehicle.

SPIRO reinstated neglect dose-dependently in PCm Ss ($p<0.001$). Neglect severity also depended on the hemisphere damaged ($p=0.02$), neglect was reinstated in RPCm Ss at lower doses. As with lateralization of neglect seen postsurgery (Vargo et al., Exp. Neurol., in press), right-sided neglect was induced in both PCm groups by SPIRO. Only RPCm Ss showed bilateral dose-dependent neglect. LAT Ss were unaffected at the optimal dose of SPIRO.

The results indicate: 1) DA mechanisms may underlie spontaneous recovery from cortical neglect, and 2) these mechanisms are organized asymmetrically.

DIFFERENT BEHAVIORS INDUCED BY STIMULATION OF THE RIGHT AND LEFT STRIATUM. M. G. Ziegler and H.Szechtman. Department of Neuroscience, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Recently, animal studies have revealed left-right hemisphere asymmetries of neurotransmitter levels, dopamine receptor binding, glucose metabolism and morphology of the corpus striatum. Using a novel paradigm, the present study reveals that activation of the right striatum has a qualitatively different effect on behavior of rats than activation of the left striatum. To produce a relatively selective activation of the right and left striatum, the model of Ungerstedt was employed, where injection of apomorphine in a rat with a 6-hydroxydopamine lesion of the substantia nigra activates, preferentially, the postsynaptic dopamine receptors on the side of the lesion. By modifying the paradigm of Pisa and Szechtman (Neurosci. Letters, 64:41,1986), we assessed whether the direction of swimming in a large circular swimming pool was influenced by edges. We report here that with activation of the right striatum, rats were attracted to the edge of a pool and swam along it in a direction that was the reverse of their preferred direction in the middle of the pool. In contrast, with activation of the left striatum, rats showed little attraction to the edge and no consistent directional preference when swimming along it. These findings suggest that the right striatum controls contralateral orientation and the left striatum controls bilateral orientation.

THE DEVELOPMENT OF CEREBRAL ASYMMETRY IN THE RAT: A THYMIDINE STUDY. G.D. Rosen, A.M. Galaburda, and G.F. Sherman. Dyslexia Neuroanatomical Laboratory, Harvard Medical School and Beth Israel Hospital, Boston, MA 02215.

Hemispheric asymmetry of neocortical architectonic areas is defined as volumetric differences between homologous areas on the two sides. This asymmetry reflects side differences in the number of neurons, rather than in cell packing density (Galaburda et al., *Cortex*, 22: 151-160, 1986; *Neuropsychol.*, 25:853-868, 1987). Side differences in cell numbers could result from asymmetries present already in the germinal zones, lateral differences in cell proliferation, side differences in cell death or architectonic reassignment. The present study sought to determine which of these developmental factors underly the observed asymmetries.

Pregnant Wistar rats were injected with [^{3}H]Thymidine at various embryonic ages and the pups were sacrificed on postnatal days 5, 10, 30, and 60. The brains were embedded in paraffin, coronally sectioned at 10μ, mounted onto slides, processed for autoradiography, and counterstained with thionin. Estimations were obtained of the number of labelled and unlabelled neurons within architectonic areas 17 and 18a, as well as the architectonic volume of these areas.

The proportion of labelled to unlabelled neurons did not differ between the hemispheres over time indicating that there were no lateral differences in cell proliferation. Analysis to distinguish side differences in initial germinal zones from cell death and/or architectonic reassignment will be reported.

This research is supported, in part, by the Charles H. Hood Foundation.

MHC TYPE AND LATERALIZATION: DEGREE OF ASYMMETRY FOR HANDEDNESS AND SWIMMING ROTATION IN *H-2* CONGENIC MICE Robert L. Collins. Jackson Laboratory, Bar Harbor, ME 04609.

H-2 types were differentially distributed in lines of mice selectively bred for degree of handedness. Whereas G0 comprised six *H-2* types, strongly lateralized G24 HI line mice were predominantly *H-2*^{d}, and weakly handed LO line mice were mainly *H-2*^{b} (R. L. Collins, G. A. Carlson & J. H. Nadeau, *Society for Neuroscience Abstracts* 11:861, 1985). To further relate MHC type to degree of asymmetry, handedness and swimming rotation were examined in two panels of *H-2* congenic mice ($n = 334$): BALB/cBy (*H-2*^{d}) and C.B6-*H-2*^{b}; and C57BL/6By (*H-2*^{b}) and B6.C-*H-2*^{d}/*a* (HW19), B6.C-*H-2*^{d}/*b* (HW41), B6.C-*H-2*^{d}/*c* (HW101).

Mice were tested first for handedness in the unbiased or 'U-world' food-reaching task and then twice later in worlds biased opposite to their handedness—'U-R-R' or 'U-L-L' (R. L. Collins, *Science* 187:181-184, 1975). Data measures across tests were expressed as paw entries consistent with original hand preference. Swimming rotation for 2 minutes in a circular water maze was observed for three days. Swim measures were summed preferred rotations/total rotations.

Handedness tests yielded partial support for the research hypothesis: (BALB > C.B6) and female (HW19, HW101) > B6. However, male B6 and B6.C mice did not show the desired pattern. For degree of swimming there was no Sex × Genotype interaction: (HW19, HW41, HW101) > B6. Albino BALB and C.B6 mice swam hardly at all. Female mice of all groups tended to swim counterclockwise. For males, the directions were balanced.

Overall results support the hypothesis that *H-2*^{d} mice are more strongly lateralized than H-2^b mice. Either the *H-2* complex itself exerts pleiotropic influence on degree of lateralization, or genes affecting lateralization reside at loci located near the *H-2* complex on Chromosome 17. Results are consistent with aspects of the Geschwind hypothesis (N. Geschwind & P. Behan, *PNAS* 79:5097-5100).

SEX AND AGE DIFFERENCES IN THE DEVELOPMENTAL PATTERN OF BEHAVIORAL LATERALITY IN RATS. B. Zimmerberg, T. Eddy* and N. Horwitz*, Dept. of Psychology, SUNY-Albany, Albany, N.Y. 12222.

Rats exhibit consistent signs of behavioral laterality and can be useful in models studying the development of cerebral lateralization. Paw preferences in a reaching task were assessed at 25 and 75 days of age. There was a significant interaction between Sex and Age. The degree of paw preference did not differ by sex among weanling age rats. Among adult rats, females had a greater degree of paw preference. In addition, females increased their degree of preference with age, while males decreased their preference. In this study, subjects were chosen from one of three prenatal treatment histories: liquid diet with 35% ethanol-derived calories, pair-fed control or standard control. Prenatal undernutrition, but not prenatal alcohol exposure alone, significantly reduced the degree of paw preference. However, prenatal alcohol exposure did appear to cause a sexually dimorphic shift in a normally left-sided population bias. Morphometric analyses of hemispheric differences in hippocampal and neocortical volume are in progress. Sex and age differences in paw preferences may reflect hormonally-mediated differential growth patterns of the two hemispheres. (NIAAA AA07359)

LATERALIZED CHANGES IN 5HT$_2$ RECEPTORS AFTER FOCAL CORTICAL STROKES IN RATS. H.S. Mayberg, T.H. Moran, R.G. Robinson. Johns Hopkins Medical Institutions. Baltimore, MD 21205

PET studies in stroke patients have shown that right hemisphere lesions lead to increased ipsilateral to contralateral binding of spiperone (primarily to 5HT$_2$ receptors) while left hemisphere lesions do not. To assess whether these lateralized changes in cortical 5HT$_2$ receptors could be demonstrated in the rat, 3H-Spiperone (SP) autoradiography was performed 30 days after unilateral cortical suction lesions. Right lesions produced bilateral increases in total SP binding in frontal cortex (excluding the lesion site): 48% greater than after left lesions, and 23% greater than shams ($F=4.67$, $p=.03$). Increases in frontal binding were positively correlated with running wheel activity ($r=.79$, $p=.06$). Left lesions led to decreased SP binding in the contralateral cortex compared to both the ipsilateral cortex and to shams. The ratio of ipsilateral to contralateral binding was significantly increased in the left lesion group compared to both shams and right lesions in perirhinal (left=1.47±.35, sham=1.03±.11, right=0.84±.19; $F=10.2$, $p=.002$) and frontal cortex (left=1.27±.12, sham=0.98±.05, right=0.95±.08; $F=21.7$, $p=.0001$). These results demonstrate that there is a lateralized receptor response to focal injury in both rats and humans.

TWO-STEP MUSCLE TRANSPLANTATION TECHNIQUE TO DETERMINE THE ORIGIN OF THE DYSTROPHIC PHENOTYPE. E. Cosmos, J. Butler* and P. Cauwenbergs. Neurosciences Department, McMaster Univ. H.S.C., Hamilton, Ontario, Canada, L8N 3Z5.

During development ex ovo, avian muscles afflicted with HMD express an impaired ability to differentiate the metabolic enzymic profile characteristic of normal (N) glycolytic muscles. To determine if this ex ovo dystrophic (D) phenotype is programmed within D myogenic cells by day 2 in ovo, D somitic mesoderm was transplanted to replace N brachial somites. Due to the limited ability of embryos to hatch following somite transplantation and the fact that metabolic differentiation is completed ex ovo, a two-step procedure was necessary. Thus, the pectoralis derived from D somitic mesoderm grafted at day 2 in ovo to an N host (step 1) was then transplanted at day 16 in ovo to a newly hatched N chick (step 2). As a control, a similar two-step protocol was performed between N donors and D hosts. The degree of metabolic differentiation achieved was assessed histochemically (phosphorylase, SDH reactions) during a postoperative period of 8-16 wk ex ovo. Results indicate that the D phenotype of impaired metabolic differentiation was expressed by genotypically D muscles whereas genotypically N muscles differentiated normally. Thus, we conclude that specific D phenotypes, not overtly expressed until development ex ovo, are programmed by day 2 in ovo. Furthermore, these are uninfluenced by extramyogenic factors associated with a N environment during development in ovo and ex ovo. (MDAC, NSERC supported).

GROWTH OF AXON PROCESSES FROM TRANSPLANTED OLFACTORY NEURONS IN THE RAT BRAIN. E.E. Morrison and R.M. Costanzo. Dept. of Physiology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298-0551.

Transplantation of olfactory neurons has been successfully demonstrated in the rat brain (Morrison and Graziadei, Brain Research 279:241-245, 1983). Transplant tissue contains mitotically active basal cells and young developing olfactory neurons. As the young neurons mature they develop and grow dendrites and axon processes. In the present study, we have examined the extent to which growing axons penetrate and distribute within the host brain (parietal cortex). We observed olfactory axons originating in the transplant and growing towards the host tissue. These axons formed fascicles that penetrated deep into the host brain. However, they did not appear to form characteristic glomerular-like structures. The extent and distribution of olfactory axons within the host brain demonstrates the acceptance (plasticity) of olfactory tissue by non-olfactory regions of the CNS. These results provide further evidence that olfactory neurons may prove to be an important neural tissue in transplantation studies of the CNS.

LONG-TERM REGULATION OF β-ADRENORECEPTORS IN FETAL TRANSPLANTS AND DENERVATED HOST SOMATOSENSORY CORTEX. T.Erickson*, A.Dunn-Meynell, B.E.Levin. Neurology Service, VA Med. Ctr., E. Orange, NJ 07019.

Male Sprague-Dawley hosts had unilateral 6-hydroxydopamine locus coeruleus (LC) lesions and/or ipsilteral superior cervical ganglionectomies. Fetal (E15-16) posterior cortex (CTX) or cerebellum (CB) was transplanted into host somatosensory cortex ipsilateral to lesions or ganglionectomies with 3-6mo survivals. Specific β-receptor binding (2nm ^{125}I-iodopindolol by autoradiography) was 35% higher in host CTX layer IV (43.2+2.3fmol/mg protein) than the full cortex (layers I-VI; 33.4+1.4fmol/mg; $p<0.001$) and the β_1/β_2 ratio (ICI 118551 and ICI 89406 competitive binding) in layer IV (1.35+0.16) was the same as that in layers I-VI (1.35+0.09) in intact cortex. β_1/β_2 ratios in layer IV ipsilateral to LC lesions were reduced by 33% to 0.90+0.07 ($p<0.005$). Specific β-receptor binding in fetal CTX implants (37.4+2.7fmol/mg) was the same as ipsilateral host CTX but binding in CB implants (22.6+3.7fmol/mg) was 40% and 34% lower than CTX transplants and host CTX ($p<0.005$). The β_1/β_2 ratio in CTX implants (1.75+0.10; $p<0.05$) was 30% higher than, while CB implants had a similar ratio (1.00+0.22) to, host CTX. Neither specific binding nor subtype ratios in CTX or CB implants were affected by LC lesions or ganglionectomy. Therefore, development of transplant β-receptors was dependent upon tissue origin but not host innervation. This work was supported by VA Medical Research.

BEHAVIORAL ANALYSIS OF TRANSPLANTATION INTO THE LGN IN THE HOODED RAT. R.B.Wallace, T.Davis*, C.Haddad*, M.J.Thomas* and K.Williams*. Lab of Developmental Psychobiology, Univ. of Hartford, W.Hartford, Conn. 06117.

Past research has suggested transplantation of embryonic neocortical tissue into various brain regions of juvenile or adult host animals can be evaluated behaviorally(Wallace R.,Das,G.D.(1982) Brain Res. 243:133-139;Stein,D.G.,Micheal R.L.,Attella,J.,Rakowsky,H.(1985) Behav.Neur. Biol. 44:266-277). In an effort to further examine this issue, embryonic neocortical tissue was taken from 17 day old embryos and transplanted bilaterally into the region of the LGN in 4 mo. old male Long Evans Hooded rats. Animals receiving neocortical transplants (N=10) have been compared with animals receiving bilateral electrolytic lesions of the LGN (N=13) and with normal controls (N=16) on a battery of tests designed to assess both overall neurologic integrity and visual performance. All surgical procedures were carried out under appropriate surgical anesthesia. Following conclusion of behavioral testing, all animals were overdosed with sodium pentobarbital, transcardially perfused and the brains prepared for histology and qualitative microscopic evaluation. Behavioral examination indicates that significant differences exist on all assessments between the lesioned animals and each of the other two groups, with the control and transplant conditions being essentially comparable on the tasks examined. These results are interpreted in terms of a presumed role of the transplant tissue to allow for compensatory recovery within host animals.

SURVIVAL OF PYRAMIDAL NEURONS IN CORTICAL TRANSPLANTS GRAFTED INTO CAVITIES IN THE MOTOR/SENSORY CORTEX OF JUVENILE RATS. M.F. Gonzalez, K. Hisanaga*, J.E Loken*, J. E. Madl*, F.R. Sharp. Depts. of Neurology and Physiology, UCSF and V.A Medical Center, San Francisco, CA 94121; and Dept. of Vet. Biology, Univ. of Minnesota, Minn., MN 55455

Embryonic cortical grafts surviving in cavities made in motor/sensory cortex of adult rats contain nearly normal numbers of nonpyramidal, peptidergic interneurons (J. Neurosci. 7: 3002, 1987). However, very few retrogradely labeled pyramidal neurons are seen in similar transplants after WGA-HRP was injected into host thalamus (Exp. Neurol. 99: 154, 1987).

Juvenile rats received fetal frontal cortex transplants in motor/sensory cortex as previously described. A month later sections were processed for immunocytochemistry. A monoclonal Ab to α-tubulin was used to stain all neurons. A monoclonal to neuro-filament protein (NFP) selectively labeled pyramidal cortical neurons of layers III and V. The number of neurons in transplants and normal cortex was similar. All grafts had NFP reactive neurons but their number was less than in normal cortex. This number, however, was much greater than the number of pyramidal neurons that established connections with host thalamus in previous word. Some grafted pyramidal neurons were aligned in rows, but their processes were not perpendicular to the pial surface as in normal cortical laminae.

CROSS SPECIES TRANSPLANTS OF RODENT STRIATUM INTO A PRIMATE MODEL OF HUNTINGTON'S DISEASE: ANATOMICAL AND BEHAVIORAL EFFECTS. A.W. Deckel, D. Holmes*& W.H. Niemann*. Depts. of Psychia. and Animal Res. Facil., Univ. of Med. and Dent. of N.J., N.J. Med. Sch., 185 S. Orange Ave., Newark, N.J.

Extensive past research in our laboratory has examined the anatomical characteristics of fetal striatal transplants placed into the kainic-acid lesioned adult rodent striatum, and has suggested that these transplants have good therapeutic potential to reverse the lesion-induced behavioral deficits (for review, see Deckel and Robinson, Ann. N.Y. Aca. Sci.,.495, 556-580, 1987). This experiment reports on the effects of making similar grafts into the ibotenic acid-lesioned putamen of the primate Cynomolgus (Macaca fascicularis). Monkeys were pretrained on a rewarded alternation paradigm, requiring them to full extend their arm out of a narrow opening in their cage in order to receive a banana fixed on the end of an irregularly oscillating wire. Animals subsequently received stereotaxic IA lesions of the putamen (20ugms/2.0uls/5min). Following a two week period of recovery and post-lesion testing, animals were immunosuppressed with cyclosporin (15 mg/kg) and transplanted at 3 different sites of the lesioned putamen with day E15 rat donor striatum. Animals were subsequently behaviorally assessed for varying time periods post transplantation and examined by Nissl staining and dopaminergic/cholinergic autoradiography. This poster will discuss these results in detail.

EXPRESSION OF EXTRACELLULAR MATRIX GLYCOPROTEINS DURING ANGIOGENESIS IN NEURAL TRANSPLANTS. J.M. Krum and J.M. Rosenstein. Department of Anatomy, George Washington Univ. Sch. of Med., Washington, D.C. 20037.

Neural tissue transplants are useful models for the study of microvascular proliferation in the CNS. Transplants of both autonomic ganglia and fetal cerebral cortex are revascularized by anastomoses of host and graft vessels. The extracellular matrix molecules fibronectin (FN) and laminin (LN) form a migratory substratum for vascular endothelium in vitro; FN fragments in combination with heparin act as chemoattractants. To determine if increased amounts of these molecules are expressed in either host brain or transplant vessels during graft revascularization, 2-3 week old rats had pieces of fetal neocortex (E18-21) or mature autonomic ganglia placed in either ventricle IV or directly into the parietal cortex. After postoperative survival times of 8 hours to 1 week, 6u paraffin sections were processed for PAP immunocytochemistry using antibodies to FN or LN. There was a marked increase in FN staining in brain vessels adjacent to parenchymal grafts at 24-48 hours, when graft revascularization occurs. Fetal neocortical transplant vasculature also stained more intensely for FN during the first week. Growing CNS parenchymal vessels, whether immature or regenerating, express more FN than uninjured, mature brain vessels, while LN appears unchanged. Supported by Am. Heart Assoc. and NS-17468.

EFFECTS OF TIME OF TRANSPLANT AND FGF ON CORTICAL TRANSPLANT SURVIVAL IN CAVITIES OF NEONATAL AND JUVENILE RATS. R.P. Sandor*, M.F. Gonzalez, J.E. Loken*, P. Walicke, C. Davidson*, I. Twoomey*, F.R. Sharp. (SPON: J.W. Sharp). UCSF Dept. Neurology, V.A. Med. Ctr., S.F., CA 94121.

Many factors influence neural graft survival. We undertook an experiment to study the effects of time of transplantation, host age and fibroblast growth factor (FGF) on transplant survival in rats. FGF was used in two pulses because of its reported stimulation of angiogenesis.

Long-Evans rats were divided into Group 1 newborns and Group 2 juveniles (100-150 gms). Following anesthesia cavities were made in the forelimb motor cortex bilaterally in all rats. One cavity per rat, chosen randomly, was filled with basic FGF (500 ng/0.3 ml tris buffered saline). Each group was then subdivided as to whether they received a transplant immediately (day 0), or after 3 or 7 days. Donor frontal cortex was obtained from 16-18 day fetuses (Long-Evans). Just prior to implantation the cavities were filled a second time with basic FGF (500 ng).

Juveniles transplanted at day 0 had an overall graft survival of 30 days of 7%; those transplanted at day 7 had a survival of 76%. Grafts in newborns had survival rates of 16% and 75% at day 0 and day 7, respectively. Staining of brain sections was greater than normal with Nissl and less than normal with cytochrome oxidase and succinate dehydrogenase. Basic FGF appeared to have no effect on graft survival as used in this experiment.

SCANNING ELECTRON MICROSCOPY OF THE SURFACE OF FETAL BRAIN IMPLANTS INTO THE LATERAL VENTRICLE FOLLOWING HIPPOCAMPAL LESIONS. D.J. Paul*, R.H. Baisden and M.L. Woodruff. East Tenn. St. Univ. Col. of Med. Johnson City, TN 37614.

Mesopallium from day E-16 fetuses was implanted into cavities produced by hippocampal aspiration in rats. The implants established interfaces with the host brain parenchyma at ventricular and lesion surfaces. SEM revealed that, rather than the normal variation in ventricular surface features (dense cilia and/or microvilli), the implant surface is a matrix of interwoven cells and processes. The cells appear to give rise to the matrix of neuritic processes. Smooth oval cell bodies can be found individually and in small groups interspersed across the matrix. These cells resemble cultured ganglion cells (neurons) or oligodendroglia. Other cells are flattened and have course surfaces and resemble cells in brain aggregate culture. There are sparsely distributed regions with typical appearing cilia. Clumps of cilia can also be observed arising from shafts of some neuritic processes. In addition, there are regions of microvilli similar to regions found on the normal ventricular surface. The transplants appear to have surface features similar to those described in CNS cavities formed in response to pathological conditions such as syringomyelia. (Supported by USPHS Grant #ES04070 to MLW).

MAGNETIC RESONANCE IMAGING OF FERRITE - LABELED NEUROTRANSPLANTS. **D. Smith[1]*, L. Clarke[2]*, G. Arendash[3] (Spon: D. Cahill). Dept. of Surgery (Neurosurgery)[1], Radiology[2], Biology[3], Univ. of So. Florida, Tampa, FL 33612.**

Our laboratory has devised a technique for labeling neurotransplants with a colloidal gold marker which is apparently innocuous and persistent within grafted cells (Science, 239: 635-637, 1988). The present study employs a superparamagnetic substance as a marker to enable magnetic resonance imaging of labeled transplants in situ.

Ten-14 days after excitotoxic NBM lesioning, Sprague-Dawley rats received a 3 microliter unilateral transplant of ferrite-labeled (D-17) NBM cell suspension into the host's lesion. Animals underwent MRI scanning 1-2 mos. post-transplant, and their brains were histologically examined. The transplant was revealed as a clear region of signal void in T_1 and T_2-weighted images and was corroborated histologically. Control animals with NBM lesions alone and labeled but non-viable transplants were also examined. The results suggest the feasibility of monitoring neurotransplants in vivo with this technique.

457.11

FETAL FRONTAL CORTEX TRANSPLANTS AND GM1 GANGLIOSIDE TREATMENTS FACILITATE RECOVERY OF BRIGHTNESS AND PATTERN DISCRIMINATION IN ADULT RATS WITH VISUAL CORTEX LESIONS. D.G. Stein, E. Curran*, L. Orphanides*, B. Levin & R. Labbe* Clark U., Worcester, MA 01610 & V.A. Hosp. E. Orange, NJ 07019.

Adult rats received grafts of E19 frontal tissue into damaged occipital cortex 7 days after injury (TP). One group with lesions and transplants (TP+GM1), received injections of GM1 gangliosides (30 mg/kg) for 15 days and one group with lesions served as surgical controls (LC). These groups were compared to sham-operated rats on brightness discrimination (BD), pattern discrimination (PD) and spatial navigation (SN) performance in a water maze to assess transplant and ganglioside induced post-traumatic, behavioral recovery. We examined BD and PD learning to increasingly stringent criteria (e.g., from 9/10 successively correct to 15/16 successively correct for 2 consecutive days), and all of the injured animals were impaired with respect to sham controls; however, rats with TP & GM-1 performed better than the LC or TP groups. In contrast, we were surprised to note that on the SN task, the TP animals performed significantly better than TP & GM1 and LC groups. Uptake of C-2DG was measured during photic stimulation in area 18, 3 layers of superior colliculus, LGN and transplant. Despite behavioral recovery, no significant differences were observed in host tissue of the different groups except that shams had significantly higher uptake than brain damaged counterparts. Analysis of lesion size revealed no significant differences among the three lesion groups and rank-order correlations showed no significant relation between lesion size and behavioral performance for any of the measures employed. We conclude that under appropriate circumstances, grafts of fetal frontal tissue can partially restore visual functions in rats with severe injury to the occipital cortex. This research is supported by NIMH grant 9R01NS25685.

HOMOTYPIC FETAL TRANSPLANTS IN THE NEURON-DEPLETED SOMATOSENSORY THALAMUS : DEVELOPMENT OF GRAFTED NEURONS AND HOST MONOAMINERGIC AFFERENTS. F. Nothias*, J. Dusart*, B. Onteniente*', M. Geffard*² and M. Peschanski (spon : ENA) INSERM U 161 75014 Paris France, ' VA CNRS 339, Talence 33405 France, ² Lab. Biochimie, Bordeaux 33407 France.

Fetal thalamic neurons (E 15) implanted into the excitotoxically lesioned somatosensory thalamus grow, differentiate, and receive projections from host afferents (Peschanski and Isacson, J. Comp. Neurol, 1988). The present study was designed to analyze the time-course of development and morphological features of growing grafted neurons and ingrowing host-graft monoaminergic afferents.

Neuronal size and density were studied in Nissl-stained sections, using an image analyzer. The cross-section average area occupied by the soma of grafted neurons enlarges progressively from 65 μm^2 at day 7 post-grafting (7 dpg) to 185 μm^2 at 20 dpg, then remains constant. Neuronal density decreases in parallel to reach the adult level also around 20-25 dpg. At the EM level, most neurons exhibit various mo.rphologically immature features until 20-25 dpg, at which time myelinogenesis starts. A small number of neurons demonstrating various signs of immaturity are still observed at later stages. Synaptogenesis is almost absent at 7 dpg and the density of synapses increases rapidly over the following 2 weeks. Adult levels, however, are not reached before 60-90 dpg. Morphologically immature synapses are numerous at 10 and 15 dpg. Norepinephrin and serotonin-immunoreactive afferents originating from the adult host are already present in the transplants at 8 dpg. At this time, they have regained an immature morphology. After 15 dpg, monoaminergic afferents resemble normal adult fibers.

Compared to ontogenetic data, these results demonstrate that the development of grafted neurons and host-graft afferents resemble normal ontogenesis both morphologically and temporally.

457.13

EFFECTS OF NERVE GROWTH FACTOR (NGF) AND DEXAMETHASONE ON CATECHOLAMINE CONTENT OF RHESUS ADRENAL MEDULLA IN CULTURE. *A.C. Gore*, P. Claude & E. Terasawa.* Neurosciences Training Prog. & Wis. Reg. Primate Res. Ctr., Univ of Wisconsin, Madison, WI, 53715-1299.

Adrenal medulla is commonly used as a source of catecholaminergic tissue for neural transplantation. We thought it might be advantageous to culture medullary tissue prior to transplantation in medium containing NGF or dexamethasone (dex), since NGF, which facilitates neurite outgrowth, may shift the proportion of the 3 major catecholamines (CAs): norepinephrine (NE), epinephrine (E) and dopamine (DA); and since dex enhances cell survival. Therefore, we examined whether culturing medullary tissue in medium containing NGF, dex, both NGF + dex, or neither, affected the proportion of CAs relative to fresh tissue. Medullary tissue was dissected from adrenal cortex and cut into approximately 1 mm^3 pieces. 4-5 pieces were frozen immediately (fresh). The rest were cultured in 2.5 ml of Medium 199 plus nutrients (control), or medium containing either NGF (100 ng/ml), dex (10^{-5} M) or both for 2-3 days or 12-14 days. CAs were measured by HPLC with electrochemical detection, and total protein was measured using the Bradford method. ***Results:*** 1) CA contents in fresh tissue, expressed as CA/total protein were: E, 4.55×10^{-2}; NE, 1.98×10^{-3}; and DA, 4.62×10^{-4}. 2) Following 2-3 or 12-14 days of culture, E and NE decreased by 50-60%, although NGF tended to prevent the loss of E and NE. 3) DA content was similar in fresh and cultured tissue. Therefore, it appears that culturing medullary tissue results in a decline in E and NE but not DA. It is possible that culturing may change the content of other substances which were not examined in this study, such as opioid peptides and acetylcholine. For the purposes of neural transplantation, the use of fresh tissue seems to maximize total CA content. Supported by NIH HD-11355, HD-15433 & RR-00167.

AN EXAMINATION OF THE ABILITY OF CORTICAL TRANSPLANTS TO REVERSE MEMORY IMPAIRMENTS PRODUCED BY LESIONS OF THE NUCLEUS BASALIS IN RATS. A.C. Santucci, V. Haroutunian, R. Gluck and K.L. Davis. Bronx VAMC & Mt. Sinai School of Medicine, New York, NY 10468.

Although cortical transplants have been reported to reduce memory impairments produced by nucleus basalis of Meynert (nbM) lesions, little information is available concerning those transplant parameters that optimize recovery. Accordingly, 7-10 days after bilateral nbM lesioning, rats received fetal cell-suspension transplants (ventral forebrain) to either 0 (nbM), 2 (2TR) or 4 (4TR) frontal cortical locations. Sham-lesioned animals (SH) without transplants were also included. A spatial memory task that required subjects to find a water-filled receptacle among an array of 6x5 receptacles was employed. Animals received one trial/day and trials & errors-to-criterion served as dependent measures. Relative to the SH group, nbM and 2TR subjects required more trials and committed more errors before attaining criterion ($ps<.05$). The 4TR and SH groups exhibited statistically equivalent trial and error scores ($ps>.10$), while the 4TR and nbM groups differed on the trial measure ($p<.05$). Finally, the 2TR group did not differ from nbM animals ($ps>.20$). Experiments in progress examine the generality of this transplant-induced alleviation of lesion-induced memory impairments. Histological and neurochemical analyses will be conducted at the completion of behavioral testing.

FETAL BRAIN TRANSPLANTS ACCELERATE SPONTANEOUS RECOVERY ON PASSIVE AVOIDANCE LEARNING IN AMYGDALA LESIONED RATS. M.A. Sánchez*, J. Pérez*, S. Alvarez* and F. Bermúdez-Rattoni (SPON:R. Tapia) Instituto de Fisiología Celular. UNAM.

It has been shown that the lesions of basolateral and central nuclei of amygdala disrupt retention of passive avoidance learning. Morover, it has been reported that amygdala lesioned animals showed spontaneous recovery in a previously lost learned task. In this work we demonstrated that fetal brain transplant can accelerate the spontaneous recovery in amygdala lesioned animals. Male Wistar rats were randomly divided in five groups. Four groups sustained large amygdaloid lesions and one remained as an unoperated control group. All animal were trained to avoid foot-shock in a shuttle box, follow by five retention trials. After training two groups of lesioned rats received homotopic fetal brain transplants in the amygdala (TA), the other two groups remained as lesioned control groups (LxA). The TA and LxA animals were assigned in two pairs of groups. One pair of groups were retrained one month and the other two months later. The results showed that all animals tested aiter two months recovered the ability to learn the task. However, those grafted animals retrained one month later singnificantly improved the retention of the learned task as compared with the lesioned group. These results suggest that there are spontaneous recovery in amygdala lesioned rats in a passive avoidance learning task, and this recovery can be hastened by means of the grafted tissue.

A GOLGI AND SILVER IMPREGNATION STUDY FOR FETAL BRAIN TRANSPLANTS IN THE GUSTATORY NEOCORTEX. M.L. Escobar*, S. Díaz-Cintra, A.L. Piña-Hernández*, L. Cintra and F. Bermúdez-Rattoni. Inst. de Fisiología Celular and Inst. de Invest. Biomédicas, UNAM, México, D.F. 04510.

Recently we have demonstrated that the fetal brain transplants produced recovery of taste aversion learning in adult rats with gustatory neocortex (GN) injury (Brain Res. 416:147-152,1987). In this study we showed by Golgi and argentic histological analysis, that fetal brain transplants produced anatomical recovery. Rats previously GN lesioned, received neural tissue transplantation from fetuses of 17 days old in the lesioned area. After eight weeks of recovery all animals underwent to a Golgi and silver impregnation techniques. The silver impregnation showed astrocytes, neuronal somas and fibers in the border of the transplant as well as fiber bundles into the transplant. We found a neural reorganization in both tissues, with a more neuronal density in the transplanted tissue. With the Golgi method some neurons were well impregnated in the transplant, and was possible to identify multipolar neurons in advanced state of differentiation. We can affirm that the fetal transplant could adhere to the host tissue with abundant vascularization, a great proliferation of glial cells in the transplant's border, as well as fibers that penetrates from receptor tissue to transplant. This indicate a dynamic process of morphologic and functional interrelation between the transplant and the host tissue.

FETAL BASAL FOREBRAIN GRAFTS TO BASAL FOREBRAIN AND NEOCORTEX: EFFECTS OF DONOR AGE AND TARGET. R.J. Mandel[1,2], L.J. Thal[1,2], & F.H. Gage[2]. 1. Dept. Neurol. VAMC, SD, 92161, 2. Dept. Neurosci., UCSD, La Jolla, 92093.

Grafting of fetal basal forebrain neurons into the brains of rats with previous lesions of the nucleus basalis magnocellularis (NBM) may reverse observed learning and memory deficits. We investigated the influence of target and age of donor tissue on parameters of graft survival.

F-344 rats (n=27) were lesioned bilaterally with ibotenate in the NBM. Three weeks post-surgery rats received either, cortical injections of E-11 fetal cell suspension (n=4), cortical injections of E-16 suspension (n=5), NBM injections of E-11 suspensions (n=4), or NBM injections of E-16 suspensions (n=5). Nine lesioned rats served as lesioned controls (LC) and 5 sham rats served as unlesioned controls (C). Five weeks post-grafting, the rats were tested in a water maze paradigm (1 trial block/day, 2 trials/block, 10 total trial blocks). All the grafted animals and 2 lesioned controls were perfused transcardially and their brains processed for AChE histochemistry and cresyl-violet staining. The remainder of the LC and C rat's brains were assayed for cortical choline acetyltransferase (ChAT) activity.

The LC rats had a moderate cortical ChAT depletion (-27%) and their lesions were histologically similar to the rats with cortical grafts. All lesioned animals were impaired relative to C rats in performance of the water maze task and none of the grafting treatments affected maze behavior relative to LC rats. All grafts placed in the NBM survived (both donor ages), while less than 50% of the cortical grafts survived in either donor age group. In the NBM, E-11 suspension graft volumes were 3 times larger than E-16 suspension grafts. There was no effect of donor age on cortical graft volume but all cortical graft volumes were significantly smaller than comparable grafts to the NBM.

Both age and target are important variables for graft survival of fetal basal forebrain.

HOMOTYPIC FETAL TRANSPLANTS IN THE NEURON-DEPLETED SOMATOSENSORY THALAMUS ; ULTRASTRUCTURAL EVIDENCE OF RECONSTRUCTION OF THE DEFECTIVE CIRCUITRY. M. Peschanski, F. Nothias*, O. Isacson*[1], B. Onteniente*[2], M. Geffard*[3] and F. Roudier* INSERM U 161, 75014 Paris France, [2] Dept of Anatomy, Univ. Cambridge England, [2] UA CNRS 339 33405 Talence France, [3] Lab. Biochimie cellulaire et de neurochimie, 33407 Bordeaux France.

The neural circuitry of the somatosensory relay nucleus of the rat thalamus is relatively simple in that all afferents can be grouped in only four morphological types and each of these types correspond either mostly or exclusively to fibers originating from one source. LR (large terminals, round vesicles, assymetrical synapses) = ascending somesthetic afferents; F (flat vesicles, symmetrical synapses, GABAergic) = thalamic reticular nucleus; SR (small terminals, round vesicles, assymetrical synapses) = mostly cortico-thalamic projections; nsV (vesicle-filled non synaptic varicosities) = monoaminergic systems.

After thalamic excitotoxic lesion, the various afferents remain in the area although they undergo morphological alterations (Peschanski and Besson, JCN 1987) and all synaptic arrangements, including vesicles, disappear. When homotypic fetal neurons (E 15) are transplanted and allowed to grow and differentiate within the excitotoxically lesioned area for several months, all types of terminals (LR, F, SR, nsV) are observed in the transplant. We have labeled the main afferent systems using either the anterograde transport of WGA-HRP (for ascending somesthetic and cortico-thalamic afferents) or immunocytochemistry (for GABA, 5 HT and norepinephrin). Results demonstrate not only that all these elements of the normal somatosensory thalamic circuitry are present in the transplant but also that they have regained their usual terminal and synaptic morphology. There is, thus, a reconstruction of the defective thalamic circuitry. Additional data demonstrate, however, that other ultrastructural features are at variance from normal.

COMPARATIVE ANALYSIS OF PEP-19 AND 28-kDa Ca-BINDING PROTEIN EXPRESSION IN PURKINJE CELLS GRAFTED TO pcd MUTANT CEREBELLUM. A.C. Chang*, C.J. Alvea*, L.C. Triarhou, W.C. Low and B. Ghetti. (SPON: A.N. Siakotos). Depts. of Pathology (Neuropathology) and Physiology & Biophysics, and Program in Medical Neurobiology, Indiana Univ. Sch. of Med., Indianapolis, IN 46223 and Inst. of Neurosciences, National Yang-Ming Med. Coll., Taipei, Taiwan, R.O.C.

Cerebellar suspensions prepared from normal mouse embryos (E12) were grafted to the cerebellum of 45 day-old 'Purkinje cell degeneration' (pcd) mutant mice which, by that age, have lost virtually all of their Purkinje cells (Pc). Graft development was monitored at various times by the use of antibodies against two proteins localized selectively to Pc in normal cerebellum: 28-kDa Ca-binding protein (CaBP) and 7.6-kDa PEP-19 (gifts of M.R. Celio and J.I. Morgan respectively). CaBP immunoreactive cells were detected in the host molecular layer 9 days after transplantation (corresponding age of grafted Pc neonatal) and persisted throughout the survival time allowed (3 months). PEP-19 immunoreactivity was evident as early as 5 days after transplantation (corresponding age of grafted Pc E17) and persisted throughout the survival time allowed as well. The morphological development of immunoreactive Pc appeared very similar with both antibodies. Following grafting, somatic thorns were present at 9 days and elaborate dendritic arbors from 17 days on. These results indicate the ability of grafted Pc to retain features of normal chemical differentiation.

FETAL MEDIAL HABENULA (MH) TRANSPLANTS: INNERVATION OF INTERPEDUNCULAR NUCLEUS (IPN). N.J. Lenn & G. Raisman. Dept Neurol, Univ of Virginia, Charlottesville 22908 & Natl Inst for Medical Research, London, England.

Several protocols were tested in which important transplantation variables differed. Donor tissue was the medial-dorsal lip of III ventricle from fetuses of the same inbred rat strains as the hosts. Explants were cultured for 1-2 days, with colloidal gold conjugated to WGA (Seeley & Field, '88) to label the cells. 1-45 days later rats were anesthesized and perfused with saline for slices, formalin for LM, or mixed aldehyde for EM.

20% of 23 cases with E19 fetal explants contained donor neurons compared to 75% of 22 cases with E16 donors; the latter were markedly larger. MH neuron birthdays are E15-18, by E19 both nuclei are fully demarcated and some MH axons have reached IPN. 3 of 3 cases with HRP injected into host IPN had retrograde labeled neurons in the transplant. This occurred without deafferentation of the host MH afferents, and might be increased with deafferentation. Colloidal gold labeled macrophages, some oriented capillaries and GFAP+ processes marked the donor-host interface. Numerous synapses in the transplant were not unusual in any way.

This protocol will permit testing of hypotheses regarding the molecular bases by which the distinctive synaptology of IPN develops. Supported in part by grants NS 16882 & FO6 TW01294 (N.J.L.) & by MRC (G.R.).

QUANTIFICATION OF REACHING MOVEMENTS IN SUBJECTS WITH SPASTICITY. L.Fetters & J. Kluzik*. Department of Physical Therapy, Boston University, Boston, MA 02215.

Kinematic data were used to quantitatively describe components of reaching movements(e.g.,smoothness)traditionally described qualitatively. Five,7 to 12 year old children with spasticity and 5 aged matched controls reached to target. The WATSMART three dimensional motion analysis system and video were used for analysis.

Dependent variables included displacment of the hand and number of acceleration/decelerations during reach to target. A single accleration/deceleration combination was a movement unit (L.Fetters & J. Todd, J.Motor Behav.,19:2,1987).

Reaches of the children with spastic quadriplegia included significantly more movement units than children with normal motor abilities. In addition, the number of movement units decreased following exercise with the spastic subjects.

The analysis of movement units (stop/start action) is a viable method for characterizing reaching movements and for assessing change in subjects with motor disability.

DEPRIVED EARLY SOMATOSENSORI-MOTOR EXPERIENCE IN STUMPTAILED MONKEY NEOCORTEX: DENDRITIC SPINE DENSITY AND DENDRITIC BRANCHING OF LAYER IIIB PYRAMIDAL CELLS. Guy K. Bryan and Austin H. Riesen. Div. Biomedical Sciences and Psychology Dept., University of California, Riverside, CA 92521.

Macaca arctoides were individually raised to age 6 months in large clear cubes built into one wall of a control colony, allowing visual access to it but not tactile contact. Two deprivation conditions examined (Cond 2 and Cond 3) were equal both in physical size and with respect to partial social isolation. They differed in the amount of somatosensori-motor opportunity available during development in that the Cond 2 chamber was empty, whereas Cond 3 contained ladders, and a trapeze. Four monkeys from each of these conditions were compared with four colony-reared (Cond CR) monkeys. The neuroanatomical changes resulting from these rearing conditions were assessed by counting dendritic spines on the apical shafts of layer IIIB pyramidal cells in MI, SI, and V1 cortical regions as seen using light microscopy in Golgi-Cox stained tissue. Layer IIIB pyramidal cells with somas of medium size were selected for analysis; a sample of 10 such neurons was gathered from each cortical region and the density of apical dendritic spines determined. In addition, the basilar dendritic branches of these same neurons were traced, and dendritic branching complexity assessed in order to directly compare the sensitivity of the dendritic spine and branching measures. We found that apical dendritic spine density was significantly reduced in Cond 2 when compared with either Cond 3 or Cond CR (which did not differ from each other). This occurred in both MI and SI cortex, but did not in V1 cortex, the region used as a control for a generalized brain effect. Branching complexity on the same pyramidal neurons was reduced only in MI cortex of Cond 2. These results show spine density, a more direct measure of neuronal connectivity, to be the more sensitive measure of early environmental deprivation. Also, the enriched environment provided by Cond 3 relative to Cond 2 offset the effect of partial social isolation such that both morphometric measures were comparable to Cond CR monkeys.

458.3

POSTNATAL MATURATION OF THE PALLIDUM IN MONKEYS. J. Cano*, P. Pasik and T. Pasik. Depts. of Neurology & Anatomy, Mount Sinai Sch. Med., CUNY, N.Y.C., N.Y. 10029.

The pallidum of 20 rhesus monkeys, newborn to 4 months in age, was examined in Golgi material and ultrastructurally. All neuronal types seen in the adult are found at birth. The most common large fusiform cell shows initial signs of immaturity: blunt protrusions and dendritic dilations at bifurcation points, growth cones, filopodia and filiform processes. By 4 months, they appear fully mature save for underdeveloped terminal dendritic arborizations. The large globular cells and the interneurons are more mature than the previous type at all ages. The afferent radial fibers of striatal origin are observed from birth. They form bundles only after 8 weeks, and the density of their climbing branches increases over time reaching a mature appearance by 16 weeks. Afferents entering from the ventral surface do not show yet clusters of varicosities at 2 weeks. At this age, plexi of fine beaded fibers cover large extensions of the nucleus.

Ultrastructurally, the basic neuropil organization is present at birth albeit with immature features: incomplete covering of the dendrites with axonal boutons, low level of myelination of radial fibers, presence of growth cones and degeneration profiles. Initially, most dendrites show large varicosities and protrusions, which can be postsynaptic to multiple terminals. The other dendritic type, with only an occasional axodendritic synapse, is also seen from birth and increase in size with time. The type I axonal boutons, probably of striatal origin, are immature at birth with their interdigitations showing only after the first week. The types II-V boutons appear mature at all ages examined. Crest synapses formed by type III terminals, are observed in the later stages. Finally, postsynaptic vesicle-containing profiles are present at 4 weeks, but triadic synaptic arrangements are apparent only by 16 weeks.

Results indicate the occurrence of progressive neuronal and neuropil changes in the monkey pallidum during the first 4 postnatal months, and suggest a faster rate of maturation than that of the neostriatum, probably as a reflection of its diencephalic origin. Aided by NIH Grants #NS-22953, NS-18657 and NS 11631.

458.4

AMPHETAMINE-FACILITATED RECOVERY OF BEAM-WALKING: DIFFERENCES IN MOTOR RECOVERY ARE NOT EXPLAINED BY LESION SIZE OR DEPTH. L.B. Goldstein, K.A. Walton*, and J.N. Davis. V.A. & Duke Medical Centers, Durham, N.C. 27705.

Treatment with amphetamine increases the rate of recovery of beam-walking in rats after a unilateral suction-ablation lesion of the sensory-motor cortex. While investigating this effect, we noted that several rats which had received amphetamine unexpectedly did not recover while several controls which were not given amphetamine rapidly recovered normal beam-walking performance. The present studies were performed to determine whether the motor recovery of these outliers was related to differences in lesion anatomy. The brain lesions of four groups of selected rats were characterized: 1. Amphetamine/ recovered (n=6), 2. amphetamine/ not recovered (n=6), 3. saline/ recovered (n=6), and 4. saline/ not recovered (n=6). There were no significant differences in lesion volume index (ANOVA, p=0.8), medial cortex damage (Kruskal-Wallis H=1.9, p>.05), lesion depth overlying the striatum (Kruskal-Wallis H=5.5, p>.05), or lesion depth overlying the hippocampus (Kruskal-Wallis H=0.2, p>.05) between the groups. None of the animals had a lesion of the underlying striatum whereas two rats in groups 1, 2, and 3 and one rat in group 4 had minor lesions of the underlying regio superior of the hippocampal formation.

These data show that differences in the motor recoveries of these selected groups of rats did not correlate with lesion volume, depth, or hippocampal damage. The lack of correlation of recovery with lesion size is consistent with observations of recovery of function in man.

Supported by the N.I.H. (NS 06233 and NS 01162) and the V.A.

ELECTRICALLY INDUCED LOCOMOTION IN THE DEAFFERENTED *IN VITRO* BRAINSTEM-SPINAL CORD PREPARATION. Y. Atsuta*, E. Garcia-Rill and R.D. Skinner, Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Recently we described the ability to induce adult-like, coordinated stepping following electrical stimulation of the brainstem in the hindlimb-attached, *in vitro* brainstem-spinal cord preparation (Atsuta *et al*, Anat. Rec. 220, 1988). These findings suggest the presence at birth of supraspinal systems capable of controlling spinal locomotion pattern generators. The present study employed the hindlimb-attached *in vitro* brainstem-spinal cord preparation from 0-4 day old rats maintained in oxygenated artificial CSF. After establishing the control threshold/frequency relationship, the dorsal roots to the attached limbs were severed and the procedure repeated. No changes in threshold or qualitative differences in the locomotor pattern were observed after dorsal root section. The mean frequency of alternation induced before deafferentation was 0.37 ± 0.6 Hz and, after deafferentation, was 0.43 ± 0.12 Hz. In some cases, remarkably fast alternation was seen only after deafferentation. There was an average increase of 13% (not statistically significant) in the frequency induced at the same electrical threshold following deafferentation. These results suggest that, 1) the supraspinal control of spinal oscillators is not dependent on afferent input, and 2) afferent input, in some instances, may limit the maximal frequency of alternation of the limbs. Supported by USPHS grant NS 20246.

458.6

DENSITY OF ACETYLCHOLINE RECEPTORS IN CAT TRICEPS SURAE MUSCLES AFTER SPINAL CORD ISOLATION OR VENTRAL ROOT SECTION, L. Eldridge, L.L. Bambrick* and T. Gordon, Dept. Physiol.U.C.L.A., Los Angeles, CA 90024; Dept. Pharmacology, Univ. of Alta., Edmonton, Alta., Canada, T6G 2H7.

Comparison of numbers of ^{125}I-bungarotoxin binding sites per mg protein was made in homogenate preparations of cat triceps surae muscles, 3 weeks to 8 months after (1) spinal cord isolation and deafferentation or (2) ventral root section of the contributing motoneurones. Numbers of binding sites were significantly elevated in all muscles at 3 weeks after surgery. However they returned to normal by 8 months in the muscles with intact motor innervation (1) in contrast to the denervated muscles (2) in which the numbers remained elevated. EMG recordings showed that all muscles fibrillated within the first month after surgery but this activity ceased in the muscles with intact innervation by 2 months. These results provide evidence that acetylcholine receptors are down-regulated in inactive muscles with intact motor innervation suggesting that intact but silenced motoneurones can regulate extrajunctional receptor density in inactive muscles.

Supported by AHF and NIH Grant (5R01AG02562-03).

458.7

MUSCLE HETEROGENEITY IN MOTOR UNITS IN REINNERVATED CAT AND RAT HINDLIMB MUSCLES, V. Rafuse*, T. Gordon, T.P. Martin*, S. Erdebil* and J. Totosy de Zepetnek*. Depts. of Pharmacology and Physical Therapy, Univ. of Alberta, Edmonton, Alta., T6G 2G7.

Reinnervating motoneurones specify the force output of denervated muscle fibers after complete and partial nerve injuries to restore the normal size relationships, but whether each motoneurone fully changes properties of the muscle fibers it supplies is uncertain. In correlative electrophysiogical and quantitative histochemical studies of motor units in cat triceps surae and rat tibialis anterior muscles we have found that discrimination of fiber types according to contractile speed, "sag" and fatiguability becomes far less reliable after reinnervation. An increased proportion of units become intermediate in fatiguability and the normal property of fast units to sag during unfused tetani, is not a reliable criterion for fast units. Histochemically, muscle fibres are readily classified into types whose proportions are not changed by reinnervation but whose distribution in the muscle is clustered rather than widely distributed. Initial observations that the metabolic properties of muscle fibers within a motor unit are significantly more heterogeneous in character than they are normally may account for loss of sharper distinctions between motor unit types after reinnervation. Supported by the MDAC, MRC and AHFMR.

BILATERAL PROJECTIONS FROM MOTOR CORTEX TO THE NUCLEUS OF DARKSCHEWITSCH AFTER NEONATAL OR ADULT HEMISPHERECTOMY. R.L. Sutton and J.R. Villablanca. Depts. of Psychiatry and Anatomy, UCLA School of Medicine, Los Angeles, CA 90024.

The descending cortical pathways to the n. of Darkschewitsch (ND) were examined in cats with neonatal (N) or adult (A) left cerebral hemispherectomy (HEMI) after injection of [^{3}H]-leucine-proline into the remaining motor cortex. Computerized analyses revealed that autoradiographic grain densities in the left ND of adult cats with N-HEMI reached values ranging from 63-100% of that measured in the right ND while these values ranged from only 11-28% for A-HEMIs (vs. 3-9% for intact controls). After injection of WGA-HRP into the intact motor cortex of adult cats with N-HEMI, electronmicroscopy revealed peroxidase-labeled terminals synapsing on ND neurons bilaterally. Fibers of origin to each ND appeared to ascend through the ipsilateral red n. (RN). These age-at-lesion effects on the decussating cortical projection to the ND parallel those published for the RN and support a proposed ND-RN relationship. Supported by Grants USPHS R01 NS 25780, HD-05958, and HD-07032.

SPARED DESCENDING PATHWAYS CONTRIBUTE TO THE RECOVERY OF BIPEDAL BUT NOT MONOPEDAL MOTOR FUNCTION AFTER HEMISECTION IN THE ADULT CAT. M.E. McBride and M.E. Goldberger. Medical College of Pennsylvania, Phila., PA. 19129.

Recovery of locomotion and reflex activity following hemisection occurs in precise stages, suggesting that different pathways mediate recovery of discrete monopedal responses and bipedal activity. Spared descending pathways or primary afferent input may be responsible. To test the contribution of descending systems to the recovered behavior, a contralateral 2nd hemisection was made 4-5 segments rostral to, and 6 months after the initial hemisection. If spared descending pathways were responsible for recovery after the 1st hemisection, a decompensation of motor function would be expected after the 2nd hemisection. Threshold and kinematic measurements for postural responses showed no decompensation of monopedal responses. In fact, a significant decrease in thresholds were measured for monopedal hopping and placing on the chronic side accompanied by a progressive recovery of postural reflexes on the acute side. Kinematic analysis of conditioned overground and treadmill locomotion did decompensate but recovered again; accurate placement during precise locomotion did not recover. These results suggest that contralateral descending systems are not responsible for recovery of monopedal responses but do contribute to complex bipedal activity necessary for accurate limb placement.

ENVIRONMENTAL ENRICHMENT DURING GROWTH AFFECTED BODY SIZE AND SHAPE OF GERBILS. MaryLou Cheal, Cheryl A. Alongi*, and Mary W. Marzke*. Depts. Psychology & Anthropology, Arizona State University, Tempe, AZ 85287.

Environmental enrichment facilitated rapid growth in adolescent gerbils (Cheal, 1984). In order to maximize potential differences during earlier growth, gerbils (n = 35) were born and group reared in large cages (35 X 45 X 66 cm) with locomotor incentives, or in small rat cages (18 X 20 X 25 cm). Body weight, body length, body segment lengths, and ratios of segment length/body length were recorded on alternate days from birth to 60 day and at 8 mo of age. From 2-4 wk, when locomotion increases dramatically and pups are weaned, enriched gerbils had longer body segment lengths than controls. Between 7-9 wk, body segment lengths and forearm length/body length ratios were greater in the enriched gerbils. By 8 mo, significant differences unrelated to allometric effects remained only in forearm length/body length. It was concluded that absolute size differences due to environmental enrichment may be short-term, but forearm/body length proportions may be permanently affected.

POSTNATAL DEVELOPMENT OF DOPAMINERGIC SYSTEMS IN RAT STRIATUM; W. C. Broaddus and J. P. Bennett, Jr.;Depts. Neurosurgery, Neurology and Neuroscience, University of Virginia, Charlottesville, VA 22908.

The prominent "matrix" component of dopaminergic input to rat striatum from substantia nigra is absent at birth, and appears progressively during the first 3 to 4 weeks of life. This developmental paradigm provides a model for studying striatal cells before, during and after acquisition of afferent dopaminergic input.

Neonatal rats were sacrificed and their striata homogenized and washed twice by centrifugation. Binding studies with [3H]-SCH23390 revealed a single class of D_1 receptors (K_d 0.45 ± 0.24 nM). No significant change in K_d was noted during normal postnatal development. B_{max} increased from 17 to 80 pmol/gram(wet weight) between weeks 1 and 3, and then stabilized. [3H]-sulpiride binding revealed D_2 sites with a K_d of 3.1 ± 1.4 nM. Like the D_1 sites, B_{max} increased approximately 4-fold, to a plateau value of 7 pmol/gram at 3 weeks. Commensurate increases in B_{max} maintained a D_1 /D_2 receptor ratio of 9 to 12 throughout the postnatal period.

Specific [3H]-GppNHp binding revealed a K_d of 160 ± 10 nM, and a B_{max} which increased postnatally. Unlike D_1 and D_2 receptors however, this value continued to increase after 3 weeks of age. In adult animals the value was 10380 pmol/gram, suggesting an excess of specific guanine nucleotide sites of 130-fold relative to D_1 sites, and 1500-fold relative to D_2 sites.

Dopamine- and forskolin-dependent adenylate cyclase activities increased approximately 4-fold between 1 and 3 weeks, and then reached plateau values of 5 and 115 pmol/min/mg (wet weight), respectively. Basal, guanine nucleotide-, and Mn^{2+}-stimulated adenylate cyclase also increased postnatally, but reached plateau values earlier. An increase of only 1.5 to 2-fold was seen between 1 and 2 weeks, after which the activities stabilized close to adult levels.

Between 2 and 3 weeks a reproducible change in cyclase response to GTP was also revealed. Initially a simple sigmoidal dose-response relationship is evident, with maximal GTP levels eliciting maximal cyclase activities. Beginning at 3 weeks however, a biphasic response is seen, with maximal cyclase activity at 1 uM GTP. Above 1 uM, a progressive decline in activity is seen. Others have shown in adult rats that this biphasic effect is abolished by pertussis toxin treatment. This suggests that in neonates a transition in relative or absolute quantities of G-proteins occurs between 2 and 3 weeks of age. We speculate that this may be related to the arrival of nigrostriatal fibers, which occurs at the same time.

458.12

EFFECTS OF 6-HYDROXYDOPAMINE ON POSTNATAL DEVELOPMENT OF DOPAMINERGIC SYSTEMS IN RAT STRIATUM; J.P.Bennett, Jr. and W.C.Broaddus; Depts. Neurosurgery, Neurology, and Neuroscience; University of Virginia, Charlottesville, VA 22908.

Two protocols for intracerebroventricular injection of 6-OHDA were used to study development of the striatal dopaminergic system in neonatal rats (see also WC Broaddus and JP Bennett, accompanying abstract). One group of rats received bilateral injections once on postnatal day 3. This destroys dopaminergic input to striatal "patch" areas, but allows subsequent ingrowth of fibers to "matrix" neurons (Gerfen et al.,J Neurosci. 7, 3935, 1987). A second group of animals received injections at weeks 1, 2, 3, and 4, and were sacrificed at 7 weeks.

In the first group, striatal dopamine (DA) levels fell to 55% of control 1 week after the injection, but returned to approximately 75% of control thereafter. [3H]-Mazindol binding decreased to 30% of control at 1 week, but then rose to 130% of control, suggesting sprouting of the remaining dopaminergic terminals in response to lesioning. A 40% increase in the (DOPAC+HVA)/DA ratio was seen at 1 week, suggesting a compensatory increase in DA turnover. In the second group, DA was decreased to 32%, [3H]-mazindol binding to 70%, and (DOPAC+HVA)/DA increased to 170% of control values. Unlike the one-time injection however, these changes were persistent 3 weeks after the last (fourth) 6-OHDA injection.

Adenylate cyclase activities were characterized in each group: no changes in basal, guanine-nucleotide-, DA-, Mn^{2+}-, or forskolin-stimulated adenylate cyclase activities were found.

Dopamine receptor binding studies revealed a 50 to 60% increase in the apparent number of D_2 sites in 6-OHDA-injected animals, without any change in K_d. This change persisted in the first group of animals, despite near-normalization of other parameters. No changes were seen in D_1 receptors after 6-OHDA-injection with regard to antagonist affinity or number of sites. Agonist affinity was apparently preferentially increased however, as a 2 to 3-fold decrease in IC_{50} for SKF38393 was noted after single or multiple 6-OHDA injections. A GppNHp-dependent decrease in agonist affinity was also seen in both 6-OHDA and control animals, suggesting that these two phenomena may be independent.

Parallel behavioral studies, tissue autoradiography, and immunoblot analysis of second messenger system components are currently underway or planned to further characterize pre- and post-synaptic events in the development of nigrostriatal input.

THE ONTOGENY OF NAAG-LIKE IMMUNOREACTIVITY IN THE RAT SPINAL CORD. J. H. Neale, K. E. Miller, M. F. Humphrey and P. M. Sweetnam. Dept. of Biology, Georgetown University, Wash. D.C. 20057 and Dept. of Neurol. Surg. University of Miami School of Medicine, Miami, FL 33136.

The neuronal distribution, vesicular localization and depolarization-mediated release of N-acetylaspartylglutamate (NAAG) suggest a role for this dipeptide in transcellular communication. While the concentration of NAAG in the rat nervous system increases postnatally, the amount present in the newborn suggests the possibility of a trophic role for NAAG in prenatal development. To explore the function of this dipeptide, the development of NAAG-like immunoreactivity (LIR) was examined by immunohistochemistry in embryonic, early postnatal and adult spinal cord and dorsal root ganglia. As described previously, NAAG-LIR was present in adult spinal cord and spinal sensory neurons. Additionally, NAAG-LIR was detectable in mid and late embryonic as well as early postnatal neurons in these tissues. This relatively early appearance suggests that NAAG may have a role in development of the spinal-sensory axis. Support: DA 02297; The Miami Project to Cure Paralysis; Daniel Heuman Spinal Cord Research Foundation.

NUMBER AND SIZE OF AXONS INNERVATING THE MYSTACIAL MUSCULATURE OF THE RAT VIA THE BUCCAL BRANCH OF THE FACIAL MOTOR NERVE. P.W. Hinds*, C. Welt and J.H. Abbs (SPON: A. Weber). Speech Motor Control Labs., Waisman Center., University of Wisconsin, Madison, WI 53705-2280.

The highly ordered and behaviorally significant mystacial vibrissae system of rats provides a unique model to examine structural and functional reorganization following motor nerve damage. As a first step, electron microscopic and computer-assisted quantitative methods were used to determine the organization and fiber spectrum of axons innervating the mystacial muscles via the buccal branch (BN) of the facial nerve. In contrast to previous reports of only one branch in the BN, we consistently observed one large and two smaller branches. In five rats, the main branch had an average cross-sectional area of 52,240 µm2 and contained an average of 1543 myelinated (86%) and 260 unmyelinated (14%) axons. Fiber size (mean diameter including the myelin sheath) ranged from 1.97 to 9.67 µm, with population means of 4.61 to 6.37 µm (weighted ave.=5.35, s.d.=1.36). Axons were not arranged in separate fascicles or segregated according to size. The smaller branches showed a different quantitative profile. More than 75% of these axons were unmyelinated. The mean diameter of the myelinated fibers was smaller than in the main branch, ranging from 1.31 to 8.78 µm, with population means of 3.38 to 3.92 µm (weighted ave.=3.67, s.d.=1.63). In contrast to the normally distributed fiber sizes in the main branch, the size distributions were skewed to the smaller diameter fibers in the small branches. After applying HRP to the main branch, labeled cell bodies were found in the ipsilateral facial nucleus. In contrast, cell bodies for the small branches were in the trigeminal ganglion. These data were used to assess regeneration and recovery of function after facial nerve section. (Supported by NIH grants NS-13274 and HD-03352).

REINNERVATION OF MYSTACIAL VIBRISSAE AFTER FACIAL NERVE SECTION AND REPAIR IN RATS. C. Welt., P.W. Hinds*, M.H. Schutta* and J.H. Abbs. Speech Motor Control Labs., Waisman Center, University of Wisconsin, Madison, WI 53705-2280.

Reorganiztion of mystacial vibrissae innervation was studied in adult rats after facial n. (VII) section. Four methods, used to repair human facial n. damage, were analyzed. After cutting VII, the distal segment was (1)reattached to its proximal end, (VII-VII); (2)sutured to the proximal end of the cut hypoglossal n. (VII-XII); (3)sutured to the proximal end of the cut spinal accessory n. (VII-XI); or (4)allowed to regenerate without reattachment. After six months, HRP injections, quantitative electron microscopy of the buccal branch (BN) of VII, and observations of vibrissae movements were used to assess reorganization. Axons in the main branch of the BN regenerated and reinnervated the pad in all four groups. Two small branches, originating in the trigeminal ganglion, were unaffected by the VII n. section. HRP injections in the pad on the operated side labeled many cells ipsilaterally in the facial nucleus (FN) of VII-VII; the hypoglossal nucleus of VII-XII; the spinal cord of VII-XI, and the FN of unsutured VII. Labeled cells were not topographically arranged; neurons from all regions of each nucleus regenerated to the vibrissae. Quantitative profiles of the regenerated nerves were remarkably similar regardless of which nucleus was the source. Cross-sectional areas of the main branch were slightly smaller than normal, but they contained 2.70 to 3.25 times as many axons. Some fibers attained normal size, but mean fiber size was only 45-56% of normal, due primarily to smaller axon cylinders rather than to relative myelin thickness. Some vibrissae activity was present in all animals, but coordinated whisking did not return. At six months, however, behavioral changes and neural regenerative processes, such as remyelination, are still taking place. (Supported by NIH grants NS-13274 and HD-03352)

NIGRAL DA CELL RECRUITMENT AS A COMPENSATORY MECHANISM. J.R.Hollerman and A.A.Grace,Univ of Pittsburgh, Department of Behavioral Neuroscience, Pittsburgh, PA, 15260. Previous studies have shown that a significant proportion of nigral dopamine (DA) neurons are not spontaneously firing but can be activated by administration of a DA receptor blocker (Grace and Bunney, 1984). The present study investigates whether this population may also be recruited to compensate for 6-hydroxydopamine (6-HDA) induced striatal DA depletions.

DA depletions were produced by administration of 6-HDA bilaterally into the lateral ventricles following pargyline and DMI pretreatment. DA neurons were identified by previously established criteria (Grace and Bunney, 1983). Estimates of the relative number of active cells was made by counting spontaneously firing DA neurons using a 12 track protocol as previously described (Bunney and Grace, 1978). In DA depleted animals, this value did not differ from control unless striatal DA depletion exceeded 50%. The number of active cells after striatal DA depletions between 50 and 90% of control was also greater than the number predicted based on a linear decrease in spontaneously active cells relative to the extent of DA depletion. Although this provides evidence for the recruitment of inactive cells to compensate for the DA depletion, the actual proportion of cells activated is currently being investigated using histofluorescence techniques to establish the extent of nigral cell death relative to extent of striatal DA depletion. Supported by NS19608.

NEURONAL REORGANIZATION COINCIDE THE DEVELOPMENT OF CHEWING BEHAVIOR FROM SUCKING IN GUINEA PIGS. A. Iriki* and Y. Nakamura* (SPON: H. Asanuma). The Rockefeller University, New York, NY 10021 and Dept. Physiol., Fac. Dent., Tokyo Med. Dent. Univ., Tokyo 113, Japan.

It has been generally thought that conversion from sucking to chewing depends on a peripheral events, i.e., eruption of the teeth. However, this cannot be the case in guinea pigs which are born with mature oro-facial structures including complete permanent dentition. The conversion from sucking to chewing should therefore result from change in central mechanisms. We investigated this possibility in ketamine-anesthetized guinea pigs. To produce rhythmical jaw movements, continuous intracortical microstimulation was used. The following results were obtained: 1) Sucking was only induced in neonates, chewing only in adults. These were driven by different groups of cortico-bulbar neurons through rhythm generator in the brain stem. 2) Cortico-bulbar neurons which elicit sucking were located among the agranular cortex, while those which elicit chewing were located in the disgranular area of the granular cortex. The latter was newly formed during postnatal development. 3) During development, neurons of the agranular cortex lost their projection to the brain stem and became to activate the newly formed chewing area in the disgranular area. It is concluded that reorganizations in cortico-bulbar projections form the bases of the change in jaw movements.

EARLY METABOLIC DIFFERENTIATION OF THE RAT DIAPHRAGM. B.W.C. Rosser, R.M. Choksi*, A.M. Kelly* and P.M. Nemeth. Departments of Neurology and of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110; and Department of Pathology, University of Pennsylvania, Philadelphia, PA 19104.

The developing rat diaphragm was studied with quantitative fluorometric assays for key energy-related enzymes, with pyrophosphate gel electrophoresis for native myosins and with northern blots for myosin heavy chain (MHC) mRNA. Perinatal transitions were compared to those in rat extensor digitorum longus (EDL), gastrocnemius and soleus muscles. Whole muscle homogenates assayed for malate dehydrogenase, succinate dehydrogenase, B-hydroxyacyl-CoA dehydrogenase, 1-phosphofructokinase, lactate dehydrogenase, creatine kinase and adenylate kinase had higher activities in the diaphragm than in hindlimb muscles, from 3 days before to 7 days after birth. Individual muscle fibers in the 7 day diaphragm had enzyme activities close to adult levels for type I and IIa fibers, in contrast to the comparable maturation of the hindlimb muscles at 14 to 21 days. Consistent with this earlier development of enzymatic phenotype, mRNA for neonatal MHC was detected at 3 days prior to birth in the diaphragm as compared to 1 day prior in the gastrocnemius, and adult fast myosin was observed at 5 days after birth in the diaphragm as compared to 15 days in the EDL. The results demonstrate that contractile proteins and energy-generating enzymes of the rat diaphragm differentiate in advance of the hindlimb. This earlier timetable of differentiation appears to anticipate the vital function of the diaphragm.

DIAPHRAGM FIBER SIZE AND OXIDATIVE CAPACITY FOLLOWING PHRENIC DENERVATION OR INACTIVATION. W.Z. Zhan* and G.C. Sieck (Spon: E. Eldred). Dept. of Biomed. Eng., USC, LA, CA 90089.

The purpose of this study was to determine the changes in size and SDH activity of diaphragm fibers after denervation or blockade of phrenic nerve activity. 3 groups of rabbits were studied: 1) Controls; 2) Denervated (DNV); or 3) TTX-treated, phrenic nerve activity blocked by TTX. After 30 days, muscle sections were cut and analyzed histochemically. Fiber types were classified based on ATPase activity. Fiber SDH activity was quantified using a microdensitometric procedure implemented on an image processing system (IPS). Fiber size was also determined using the IPS. SDH activity of type I fibers was reduced in both DNV and TTX animals. SDH activity of type II fibers also decreased in DNV animals, but increased in the TTX group. In both DNV and TTX groups, the size of type I fibers increased. The size of type II fibers also increased in TTX animals, but decreased following denervation. We conclude that differences in the adaptive responses of muscle fibers following denervation vs inactivation are found primarily in type II fibers and may be related to the persistence of neurotrophic influences in the TTX group.

TRANSCELLULAR LABELING BY ORTHOGRADELY TRANSPORTED TRITIATED INTRAAXONAL MARKERS. T.Pittman* and D.Tolbert. (Spon: H. Cantor). Depts Anat., Neurobiol. and Neurosurgery, St. Louis Univ. Sch. of Med., St. Louis, MO 63104

Previous reports have documented the uptake of injected tritiated proline by glia and its subsequent translocation along axonal pathways. We report evidence of transcellular labeling of glia with secondary transport of labeled amino acids during the development of corticopontine projections in cats. A mixture of tritiated proline and leucine was injected into the primary somatosensory area of the cerebral cortex. The animals were sacrificed and their brains fixed and processed for autoradiography. Cortical axons in the ipsilateral pontine nuclei (PN) were heavily labeled. Silver grains were present over the neuropil and outlined the somatic profiles of PN neurons. Small dense clumps of silver grains were concentrated over cell bodies whose size suggested that they were glia. From the ipsilateral PN diffuse linear arrays of label could be followed through the contralateral middle cerebellar peduncle (MCP) and into the cerebellar white matter where they ended. This pattern of silver grains was strikingly different from that overlying labeled axons. Individually labeled axons were not seen in the MCP. These findings suggest the release of transported label by corticopontine synapses and the subsequent uptake of the label by glia with secondary transport, either transaxonally or through chains of glia, of labeled amino acids. This transcellular labeling was seen only in neonatal cats. Supported: NIH Grant NS20227.

EPILEPSY: SUBSTANTIA NIGRA AND AMYGDALA

459.1

MODULATION OF SEIZURE SUSCEPTIBILITY BY NEURONAL TRANSPLANTS. B.S. Meldrum, S. Patel and A.Fine# (SPON: D.Rasmusson). Dept. Neurology, Institute of Psychiatry, London SE5 8AF, U.K. and #Dept. Physiology and Biophysics, Dalhousie Univ. Med. School, Halifax, NS, Canada B3H 4H7.

Partial epilepsy, the most common form of seizure disorder, is often unresponsive to drug treatment, leaving surgical removal of the focus as the main alternative. Seizures induced in rats by i.p. administration of the muscarinic agonist pilocarpine provide a useful model of complex partial epilepsy. Susceptiblity to such seizures has been shown to be increased by destruction of the striatonigral GABA projection, and decreased by infusion of GABAergic agonists into the substantia nigra (SN), suggesting that this GABA-mediated outflow from the basal ganglia influences spread of the seizures. To test the possibility that transplantation of fetal neurons from the GABA-rich neostriatum, transplanted to the SN, could suppress pilocarpine-induced seizures, 80g male Wistar rats were given bilateral ibotenic acid lesions of the caudate-putamen, while similar animals had sham lesions. One week later, lesioned rats received either bilateral fetal striatal eminence (SE) grafts or control grafts of peripheral nerve (PN) to the SN pars reticulata;additional animals served as lesioned-only and sham-lesioned controls. Four weeks later, all received 1 mg/kg scopolamine followed by 300 mg/kg pilocarpine, and resulting seizures over 2h were scored 0-7. Lesioned-only animals had more severe seizures than sham-lesioned controls, whereas SE- as well as PN-grafted animals were not significantly different from sham-lesioned controls.

459.2

CHRONIC CAFFEINE MODULATION OF POSTICTAL PHENOMENA IN AMYGDALA KINDLED RATS. C. LUPICA*and R. BERMAN (Spon: M.M. KILBEY). Dept. Psychology and Neurosci. Prgm., Wayne State University, Detroit, MI 48202.

We have previously shown that ip and intrafocal injections of adenosine (ADO) receptor agonists can reduce the severity of kindled seizures. IP administration of these compounds can also result in an increase in the duration of postictal EEG and behavioral depression, and a decrease in postictal spiking frequency. The ADO antagonist caffeine (CAF) can block these above effects and, when given chronically, increases the number of ADO A1 binding sites. In the present experiment we reasoned that prolonged exposure to CAF would increase ADO receptor density and mimic ADO agonist effects on kindled seizures. Sixteen Long Evans rats were implanted with bipolar stimulating/recording electrodes in right amygdala. Once daily electrical stimulation was then delivered until animals were fully kindled. Eight rats were then injected ip with 35mg/kg/day CAF for 1 wk, followed by 55mg/kg/day for 2 wks. The remaining rats served as saline injected controls. One day following the final CAF injection rats were retested for seizure severity and postictal measures. Animals treated with CAF displayed less postictal spiking ($p<.05$) and extended postictal depression ($p<.05$) as compared to controls. No differences in seizure severity between groups were observed. These data support the involvement of the brain adenosine system in the postictal state. THE INTERACTIVE EFFECT OF COCAINE AND HYPERTHERMIA UPON KINDLING. G.T. Livezey and S.B. Sparber, Dept. Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

Daily cocaine injections (Post, R.M., In *Cocaine and other Stimulants*, E.H. Ellinwood, Jr. and M.M. Kilbey, eds., New York: Plenum Press, pp. 353-372, 1976) and exposure to acute hyperthermia once every 3-6 days (Klauenberg, B.J. & Sparber, S.B., Epilepsia, 25(3):292-301,1984) have produced kindling in rats. As cocaine use can be combined in some individuals with acute hyperthermia brought on by vigorous excercise, fever, or passive recreation (hottubs, sauna), and since a commonality of mechanisms has been proposed to explain kindling by a variety of stimulus classes (Post, 1976), we began a comparative study of cocaine, hyperthermia, and their combination in the production of kindling. PHASE I: Four male and four female siblings each from eight litters, were divided into groups receiving 1) hyperthermia (45°C water bath for four minutes) 2) cocaine (30mg/kg) plus hyperthermia 3) "normothermia" (37°C water bath for four minutes, procedure control) and 4) cocaine plus "normothermia". Same sex, weight matched, sibling pairs from drug and nondrug groups were run concurrently in the bath. All treatments were administered daily from 45 days of age for 16 trials. 13/18 group 2 animals convulsed early (trials 1-10) and of these 8 died. No other animals displayed convulsions through trial 16. PHASE II: Three litters of males with surviving group 2 animals that convulsed were implanted with telemetric transmitters (Data Sciences, Rosedale, MN) for body temperature and EEG data collection by computer, and their behavior plus oscilloscope monitor of EEG was taped by VCR. These animals subsequently each received one trial of treatments 1,4, and 2 in that order. Group 2 animals displayed more severe convulsions, and one animal each from group 1 and 4 convulsed upon the first trial (treatment 1) indicating kindling had occured from prior experience.Data suggest that the interaction of cocaine with hyperthermia is an enhancement of the kindling rate and severity. Supported in part by USPHS Grant T32DA07097.

Infusions of an Excitatory Amino Acid Antagonist into the Substantia Nigra Evoke an Age-dependent Effect on Seizures. J.N.D. Wurpel, E.F. Sperber & S.L. Moshé, Dept. of Neurology, Albert Einstein College of Medicine, Bronx, NY 10461

Previous studies indicate that infusions of muscimol (GABA-A agonist) in the substantia nigra (SN) are anticonvulsant in adult rats. Muscimol infusions in the SN of 16 day old rat pups produce a proconvulsant effect on flurothyl (FE) seizures. We have found differing effects with infusion of 2-amino-7-phosphono-heptanoic acid (AP7- an NMDA antagonist) into the SN of adult and 16 day old rats on FE-induced seizures.

Bilateral infusions of AP7 (22.5 pg) into the SN of adult rats increased seizure latency compared to saline infused controls [AP7 707 ± 16 sec (x ± S.E.], N=12. Sal 478 ± 17 sec, N=8; p<.0001). Infusion of AP7 dorsal to the SN had no significant effect on seizure latency [528 ± 17 sec, N=4].

Bilateral infusion of the same concentration of AP7 into the SN of 16 day old rat pups did not alter seizure latency compared with saline infused controls [AP7 497 ± 12 sec, N=11. Sal 509 ± 18 sec, N=7; p>0.05].

We hypothesize that the immature SN may exhibit altered pharmacologic response to compounds which are anti-convulsant in adult rats; related to differences in local receptor populations or nigral efferent pathways.

WIDESPREAD REGIONAL DEFICITS IN BRAIN NOREPINEPHRINE (NE) UPTAKE AND DOPAMINE β-HYDROXYLASE (DBH) ACTIVITY IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR). R.A. Browning, D.R. Wade*, G. Long*, M. Marcinczyk* and P.C. Jobe. Southern Ill. Univ. Sch. Med., Carbondale, IL and Univ. Ill. College Med., Peoria, IL.

GEPRs are known to have widespread regional deficits in brain NE and serotonin. We have shown previously that NE uptake by synaptosomes from inferior colliculus and cerebral cortex of severe seizure GEPRs (GEPR-9s) is decreased (Browning et al. Fed. Proc. 45:675, 1986). Because the Vmax for uptake in cerebral cortex was reduced while affinity was unchanged, we hypothesized that GEPR-9s have fewer noradrenergic nerve terminals than normal rats. To test this hypothesis further, we compared GEPR-9 and seizure resistant controls in terms of DBH activity (a marker for NE and epinephrine containing neurons) and synaptosomal NE uptake in various brain regions. Expressed as a percentage of the values for control rats GEPR-9 DBH activity and synaptosomal NE uptake, respectively were: cortex, 59%, 61%; hippocampus 63%, 69%; amygdala 64%, 52%; hypothalamus 75%, 71% and inferior colliculus 72%, 66%. Neither DBH activity nor synaptosomal NE uptake was altered in the cerebellum of GEPR-9 rats. The parallel reductions in DBH activity and NE uptake in GEPR-9s are consistent with our hypothesis that GEPR-9s have fewer noradrenergic nerve terminals than control rats in several brain regions. Supported by Deafness Research Foundation.

INTRANIGRAL MUSCIMOL IN ANIMAL MODELS OF PETIT-MAL SEIZURES. A. Depaulis*, O.C. Snead, M. Vergnes*, & C. Marescaux* (Spon: B. Will). Centre de Neurochimie du INSERM et CNRS U44, 67084, Strasbourg, France, and Department of Pediatrics, University of Alabama at Birmingham School of Medicine, Birmingham, Alabama 35233.

The substantia nigra (SN) has been implicated as an important structure in the propagation of generalized convulsive seizures; therefore the effect of intranigral muscimol was assessed in several models of generalized absence seizures in the rat including the pentylenetetrazole (PTZ), THIP, γ-hydroxybutyrate (GHB), and genetic model of spontaneous spike wave discharges (SWD). Preliminary results suggest that intranigral muscimol (2ng/side) significantly suppressed seizures in the PTZ, GHB, and SWD models. Further, no paroxysmal EEG discharges were observed in the SN as a result of intranigral muscimol injections.

These data suggest that low doses of muscimol in the SN suppress seizure activity in experimental models of petit mal in a manner similar to that seen in generalized convulsive seizures. However, it remains to be proven that GABAergic mechanisms in the SN are a common denominator for the generalized epilepsies in view of the proconvulsant properties of systemic GABAergic agonists in experimental absence seizures (Vergnes et al: Neurosci Lett 44:91, 1984).

459.7

AUTORADIOGRAPHIC LOCALIZATION OF REDUCED ALPHA 2 ADRENERGIC RECEPTOR BINDING IN KINDLED RATS. L.S. Chen and J.O. McNamara. Epilepsy Research Lab, Duke and VA Medical Center, Durham, NC 27705

Norepinephrine (NE) powerfully inhibits the development of kindling, an effect likely mediated through alpha 2 receptors on targets of NE neurons. McIntyre and Wong (1986) demonstrated reduced alpha 2 mediated inhibition of epileptiform bursting in amygdala-pyriform cortex slices of kindled rats. We therefore hypothesized that kindling produces a reduction of alpha 2 receptor and/or receptor coupled response. Quantitative radiohistochemical analysis of alpha 2 receptor were performed to test this idea. Male Sprague-Dawley rats were kindled by amygdaloid stimulation and sacrificed 24 hours after 3 class 5 seizures. Ten micron brain sections of kindled and control rats were thaw- mounted onto microscope slides, incubated with 2.5 nM [^{3}H]-para(3,5)-aminoclonidine ([^{3}H]- PAC) at 25°C for 45 minutes in the absence and presence of 10 μM phentolamin, rinsed, dried, apposed to Ultrafilm, exposed for 6 weeks, and viewed by computer-assisted microdensitometry. Measurements of specific [^{3}H]-PAC binding disclosed a significant reduction in the central nucleus of amygdala (26%, $p<0.05$) and pyriform cortex (24%, $p<0.05$), but no change in nucleus accumbense, pre-pyriform cortex or adjacent neocortex. The present data extend previous findings from this and other laboratories (Stanford and Jeffery 1985; Chen et al. 1987) by demonstrating a spatially specific reduction of agonist binding to alpha 2 receptors in kindled rats. This reduction may be a key molecular event underlying the attenuation of NE's inhibitory effects and might thereby contribute to the development of kindling.

459.8

NOREPINEPHRINE AND SUPPRESSED KINDLING WITH MASSED TRIALS. D. C. McIntyre, M. E. Kelly*, C. Dufresne* and N. Edson* (SPON: T. Picton). Department of Psychology, Carleton University, Ottawa, Canada, K1S 5B6.

Norepinephrine (NE) is involved in the suppression of seizure development. This effect is seen dramatically in the kindling model as rapid seizure genesis after 6-OHDA degradation of the NE system. The kindling of convulsions is optimally achieved by stimulating once per day, while massed stimulation results in retarded seizure genesis. In the present experiment, we determined the effect of the alpha-2 NE antagonist, yohimbine, and the beta antagonist, propranolol, on the suppressed seizures during massed trial kindling. This was achieved by exposing the rat amygdala to a 60 Hz sine wave stimulus once every 5 min. at an intensity immediately above the local afterdischarge threshold. This procedure was continued for 50 stimulations. The experimental (1 or 10 mg/kg yohimbine; 1 or 10 mg/kg propranolol) and vehicle groups received their i.p. injection immediately following the 15th kindling stimulation, during clear seizure suppression. The rate of kindling over the next 35 trials was then determined. Both doses of yohimbine facilitated the appearance of generalized seizures, while propranolol completely suppressed evidence of kindling over this period. These data indicate that the alpha-2 NE receptors participate in the suppression of amygdala kindling during massed stimulation, while beta receptors provide a proconvulsive profile.

459.9

EVALUATION OF ROLE OF EPINEPHRINE IN SEIZURE REGULATION IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR). P.K. Mishra, J.W. Dailey, C.E. Reigel and P.C. Jobe, **Department of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria, IL 61656.**

Sound-induced seizure susceptibility of the genetically epilepsy-prone rat (GEPR) has been partially attributed to an innate defect in indices of central noradrenergic and serotonergic function. This study was conducted to determine whether epinephrine, a possible central nervous system neurotransmitter, has any role in seizure regulation in these animals. The assay of epinephrine concentration in hypothalamus of developing and adult GEPRs as well as in peripheral organs of adult GEPRs was accomplished using high performance liquid chromatography. A significant elevation in its levels in the hypothalamus, heart and kidney of adult GEPRs was not found to be associated with the seizure intensity. Moreover, the difference in hypothalamic epinephrine content of the developing GEPRs did not correlate with their seizure intensity. LY87130, an inhibitor of the epinephrine synthesizing enzyme PNMT, reduced seizure intensity, perhaps by increasing extracellular norepinephrine. LY51614, a monoamine oxidase inhibitor which elevates intracellular epinephrine, did not alter seizure indices. Results of the present study thus indicate that epinephrine may not play a major role in the seizure regulation in GEPRs.

GEPR-9s DISPLAY A REDUCTION IN THE DISTRIBUTION AND STAINING INTENSITY OF DBH-I PROCESSES. J.C. Lauterborn and C.E. Ribak, Dept. of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

An excellent model of genetic epilepsy is the genetically epilepsy-prone rat (GEPR-9) which exhibits motor seizures in response to auditory stimuli. Biochemical studies have indicated that norepinephrine is present in lower levels in GEPR-9 as compared to non-seizing Sprague-Dawley (SD) rats. In this study, the immunocytochemical localization of dopamine β-hydroxylase (DBH), the synthesizing enzyme for norepinephrine, was compared between GEPR-9s and SD rats. Sagittal brain sections from paired GEPR-9s and SD rats were processed simultaneously using an avidin-biotin immunocytochemical technique. Brain regions caudal to the inferior colliculus, such as the cerebellum and locus ceruleus showed no differences in the distribution of dopamine β-hydroxylase-like immunoreactivity (DBH-I). However, differences in the distribution of DBH-I fibers were observed in more rostral brain regions including the central nucleus of the inferior colliculus, thalamus, hippocampus, piriform cortex, and somatosensory cortex. In these areas, the density, and often the intensity, of DBH-I processes were lower in GEPR-9s as compared to SD rats. In other cortical regions no differences were observed. These results provide anatomical data that are similar to previously described biochemical results of the norepinephrine system in the brains of GEPR-9s. (Supported by NIH Grant NS-15669).

A MEDIAN THALAMIC SYSTEM REGULATING SEIZURES AND AROUSAL J.W. Miller, C.M. Hall*, K. Holland* and J.A. Ferrendelli Departs. of Neurology and Pharmacology, Washington Univ. School of Med. St. Louis, MO 63110

The effects of small intrathalamic injections of the GABA agonist muscimol on pentylenetetrazol (PTZ) seizure thresholds and spontaneous behavior were determined in rats and compared with the effects of injections of the GABA transaminase inhibitor, gamma-vinyl GABA (GVG). Muscimol injections in the dorsal midline thalamus in the vicinity of the paraventricular, paratenial, interanteromedial and intermediodorsal nuclei, as well as the central medial nucleus facilitate PTZ myoclonic and clonic seizures, and also produce a sleep-like state. The more posterior of these midline injections also inhibited tonic seizures. Injections lateral, dorsal or ventral to this midline region had much less effect on both seizures and behavior. In contrast, GVG injections in the anterior medial thalamus elevate the threshold for all PTZ seizure types but have little behavioral effect. These results demonstrate that inhibition of descrete thalamic regions with muscimol can modify seizure expression but inhibition of larger thalamic regions, as with the GVG injections, is required for a general anticonvulsant effect. Supported by NIH Grants NS14834, NS07129, GM07200 and the Seay Neuropharmacology Research Fellowship.

DORSAL HIPPOCAMPAL STIMULATION SUPPRESSES AMYGDALOID KINDLED SEIZURES. Linda J. Burdette, Ph.D. and Marc A. Dichter, M.D., Ph.D., Department of Neurology, Graduate Hospital and the University of Pennsylvania, Philadelphia, PA

Temporal lobe epilepsy, the most prevalent form of adult seizure disorder, is also the most resistant to treatment. The efficacy of electrical stimulation as a therapeutic alternative to ablative surgery in suppressing temporal lobe seizures was investigated in this study.

Male Long Evans rats were implanted ipsilaterally with bipolar electrodes in the basolateral amygdala and the dorsal hippocampus. Rats were kindled twice daily (200 μA, 2 second train of 50 Hz, .3 ms bipolar pulses) in the amygdala until three consecutive stage 5 seizures were exhibited. Once kindled, suppressant stimulation was applied to the dorsal hippocampus. Preliminary results indicate that suppressant stimulation delivered to the dorsal hippocampus simultaneously with amygdaloid kindling stimulation dramatically reduced seizure severity from stage 5 to stage 1 in 80% of the trials. Afterdischarge duration recorded from the amygdala and hippocampus was reduced during 60% of the trials. Suppressant stimulation delivered to the dorsal hippocampus 4-8 seconds after seizure onset potentiated seizure severity and amygdaloid afterdischarge duration.

IS THE DEEP PREPYRIFORM CORTEX A CRUCIAL FOREBRAIN SITE FOR KINDLING ? D. P. Cain, M. E. Corcoran, K. A. Desborough* and D.J. McKitrick*. Depts. of Psychology, U. of Western Ontario, London N6A 5C2 & U. of Victoria, Victoria, V8W 2V2 CANADA.

Recently published data suggest that a restricted site in the deep prepyriform cortex (DPC) may be a crucial site for epileptogenesis in rat brain. To test the applicability of this idea to the kindling model, we electrically kindled different groups of rats in or near the DPC, or in pyriform cortex or amygdala (AM). In different groups of rats we also 1) kindled the AM and then tested for transfer kindling to the ipsilateral DPC, 2) made radiofrequency lesions of the DPC prior to kindling the ipsilateral AM, and 3) injected carbachol into the DPC using a syringe pump and implanted chemitrodes.

The rates of kindling in DPC (8.1 ADs), immediately surrounding areas (8.3), and pyriform cortex (8.9) were indistinguishable, and were marginally faster (Ps=0.051-0.08) than kindling in AM (11.0). The DPC lesion group kindled after 8.7 ADs, which did not differ from the AM group. Picomolar quantities of carbachol failed to evoke epileptiform spiking, but nanomolar quantities usually evoked spiking. Transfer kindling occurred after 2.8 ADs, which is consistent with the strong similarity in kindling between DPC and AM. Thus, DPC kindles readily at a rate that is similar to that of surrounding forebrain tissue, and the integrity of DPC is not necessary for normal AM kindling. INTERACTION OF SUBSTANTIA INNOMINATA AND PREPIRIFORM CORTEX IN GENERALIZED ELECTROGRAPHIC SEIZURES. R.S. McLachlan, F. Bihari* and A. Au*. Dept. Clin. Neuro. Sci. and Physiol., Univ. of West. Ont., London, Canada N6A 5C1

Stimulation of either the substantia innominata (SI) or prepiriform cortex (PPX) has been shown to induce generalized seizures. Both of these areas have widely dispersed efferents including to each other. The role of SI and PPX in generalized seizures was studied by lesioning each area respectively and stimulating the other in halothane anaesthetized Wistar rats. Since PPX has a lower seizure threshold than SI, it was postulated that SI seizures might spread via efferents to PPX and that lesioning of PPX might reduce seizures.

After a cortical penicillin spike focus was established in the ipsilateral hemisphere, unilateral bipolar stimulation of SI (0.2-0.8mA, 0.2ms, 40HZ) was carried out to induce generalized electrographic seizures. Lesioning of PPX (0.3mA, DC current x 3 minutes) had no effect on seizures induced by SI stimulation (7/7 animals). However, using the same methodology, seizures induced by electrical stimulation of PPX were abolished or decreased in duration and in amplitude after lesioning of SI (10/13 animals). Stimulation and lesion sites were histologically confirmed. Results suggest that generalized electrographic seizures from SI stimulation are not mediated via PPX but that a PPX-SI interaction does occur in seizures following PPX stimulation.

INTRA-AMYGDALOID INJECTION OF KAINIC ACID: AN ACUTE LIMBIC SEIZURE MODEL SIMILAR TO KINDLING. G.C. Yeh*, L.S. Chen, and J.O. McNamara. (SPON: S.J. Schiff). Duke Univ.& VA Med. Ctr.,Durham, NC. 27705.

Analysis of anatomical structures underling kindling is hampered by the time-consuming nature of this model. We therefore examined seizures induced by intra-amygdaloid microinjection of the convulsant, kainic acid. Behavior and EEG consequences were observed over 90 minutes. Kainic acid produced a dose-dependent (0.02-2 ug) increase in EEG and behavioral seizure intensity; the behavior mimicking that produced by electrical stimulation in kindled animals. Intra-peritoneal administration of the alpha-2 adrenergic antagonist,Idazoxan (0.5mg/kg) markedly increased the seizure response to low dose (1 ug) kainic acid. Intra-nigral muscimol (50 ng/SN) attenuated the seizure response to high dose (2 ug) kainic acid. Microinjection of low dose (0.2 ug) kainic acid in animals previously kindled by intra-amygdaloid electrical stimulation evoked intense behavioral seizure mimicking high dose kainic acid.

Together these results indicate a marked similarity in the EEG and behavioral seizures evoked by chemical and electrical stimulation of the amygdala. Both seizures are controlled by substantia nigra and by an alpha-2 antagonist. Intra-amygdaloid injection of kainic acid may aid in elucidating the anatomical framework underlying kindling.

ACTIVE CONDUCTANCES IN BASOLATERAL AMYGDALA (BLA) NEURONS ARE AFFECTED BY AMYGDALA KINDLING. P. Shinnick-Gallagher, P.W. Gean* and A.C. Anderson*. Department of Pharmacology, University of Texas Medical Branch, Galveston, TX 77550.

This study was designed to analyze changes in the electroresponsiveness of BLA neurons resulting from kindling in the BLA. Kindling was produced by applying a subconvulsive stimulus, daily, through an electrode in the BLA. Contralateral brain slices were prepared 4-6 wks after the last stage 5 seizure. In control BLA neurons, an action potential elicited with a 5 msec cathodal pulse is comprised of a fast afterhyperpolarization (f-AHP) followed by depolarizing afterpotential (DAP), a component of which is a low threshold calcium spike (lts). The f-AHP in kindled neurons (maximum value: -59.7 ± 0.9 mV; n=31) was more negative than in control (-53.1 ± 0.8 mV; n=40). The enhanced f-AHP was accompanied by an apparent loss or depression of the DAP (or lts). Rebound lts's following hyperpolarizing prepulses observed in control were not recorded in the majority of kindled BLA neurons. Control BLA neurons fire 5 to 6 spikes during 500 msec cathodal pulses whereas kindled neurons do not accommodate. In kindled neurons, the amplitude of the slow-AHP following a cathodal pulse was significantly reduced 50% and the fall-time shortened 50%. The medium-AHP was not significantly different in kindled neurones. The data suggest that calcium and potassium conductances that control cell excitability may be permanently altered in kindled BLA neurons. (Supported by NS24643)

EFFECTS OF SMALL DOSES OF KETAMINE ON SEIZURE BEHAVIOR AND 2-DEOXYGLUCOSE UPTAKE INDUCED BY AMYGDALOID STIMULATION. L.E. White*, K.M. Carnes and J.L. Price. Dept. of Anatomy & Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110.

As previously reported, graded levels of electrical stimulation of the amygdala in awake, unrestrained rats produce graded seizure activity, as manifested by behavioral effects and 2-deoxyglucose (2DG) uptake (Carnes and Price, Neurosci. Abs. 13: 125.4, 1987). Low levels of stimulation, which did not produce generalized convulsions, resulted in a pattern of 2DG uptake that reflected the majority of known primary projections of the amygdala. Higher levels of stimulation produced convulsive behaviors (e.g. "wet-dog shakes", rearing and forelimb clonus) as well as more widespread, often bilateral patterns of 2DG uptake.

Low levels of ketamine (1 to 10 mg/kg) were adminstered intravenously, in an attempt to reduce generalized convulsions, while still using high levels of stimulation to evoke widespread 2DG uptake. The effect of ketamine was to reduce both convulsive behaviors and 2DG uptake, in a dose-dependent fashion. Smaller doses of ketamine (1 to 3 mg/kg) moderated the expected pattern of 2DG uptake and reduced the intensity of the behavioral effects. Higher doses of ketamine (5 to 10 mg/kg) restricted the pattern of 2DG uptake to the heaviest primary amygdaloid targets, and prevented all but the mildest behavioral effects.

AMYGDALA KINDLED SEIZURES PRODUCE DEFICITS IN ASSOCIATIVE LEARNING WHICH DIFFER FROM THOSE PRODUCED BY PENTYLENETETRAZOL-INDUCED SEIZURES. D.B. Peele and M.E. Gilbert. Northrop Environmental Sciences, RTP, NC 27709.

The effect of seizure activity on cognitive function was examined using the long-delay flavor-aversion paradigm in rats. Previous research has demonstrated a disruption of lithium-induced flavor-aversion conditioning with pentylenetetrazol (PTZ) administered prior to lithium administration (Shaw and Webster, Psychopharm., 66:195-198, 1979). The present experiment was designed to determine whether this disruption was due associative (delay-independent) or menmonic (delay-dependent) processes, and whether the reported disruption represents a functional consequence of all (i.e., chemically- vs electrically-induced) seizure activity. Saline treated rats receiving injections of lithium (0.9mEq) after consuming saccharin flavored water later avoided saccharin ingestion: the degree of avoidance varied inversely with the time (0.5 or 6 hr) separating initial saccharin availability and lithium injection. PTZ (50 mg/kg ip), administered just prior to lithium administration, impaired conditioning at the long but not the short delays, suggesting a mnemonic deficit. Amygdala kindled seizures, elicited 2-3 min prior to lithium produced a disruption of conditioning at both the short and long delays, suggesting a more global, associative impairment. These results suggest a dissociation of the functional consequences of chemically and electrically elicited seizure activity.

BRAIN STEM MECHANISMS OF SEIZURE SUPPRESSION IN REM SLEEP.M.N. Shouse*, J.M. Siegel, and A.R. Morrison (SPON: M.B. Sterman). VA Med. Ctr., Sepulveda, CA 91343; U. of Penn. Sch. of Veterinary Med., Philadelphia, PA 19104.

The antiepileptic properties of rapid-eye-movement sleep (REMS) are well known in humans, but the mechanism is obscure. This study showed that feline epilepsy models display the same resistance to generalized EEG paroxysms and tonic-clonic convulsions (GTCs) during REMS as humans and also dissociated the REMS components responsible for these effects. Bilateral electrolytic lesions of the medial pontine tegmentum produced a syndrome of REMS without atonia. IP injections of atropine (1.5 mg/kg) produced REMS with EEG synchrony. 32 cats (12 amygdala kindled, 12 systemic penicillin epilepsy, 8 ECS) displayed minimal GTC & penicillin spike-wave (SW) activity during REMS, when compared to other sleep-waking states, before lesions or atropine. Selective loss of atonia in REMS abolished REMS protection against ECS or kindled GTCs without affecting penicillin SW. Conversely, loss of EEG desynchronization in REMS abolished REMS protection against SW without influencing GTC threshold. These results indicate that the descending brain stem pathways which mediate lower motor neuron inhibition also protect against generalized motor seizures during REMS. Protection against spread of EEG paroxysms is governed by a separate REMS mechanism, presumably the ascending brain stem pathways mediating intense thalamocortical EEG desynchronization during REMS.

460.1

AGE-RELATED MORTALITY AND MORBIDITY DIFFERENCES FOLLOWING BRAIN INJURY IN THE RAT. R.J. Hamm, B.G. Lyeth, S.E. Robinson, M. Ray, L. Doane*, L.W. Jenkins*, G.L. Clifton, & R.L. Hayes. Richard Roland Reynolds Neurosurgical Research Laboratory. Medical College of Virginia,Richmond, VA 23298.

Age is a major independent factor affecting head-injured patients; increasing age is associated with higher mortality and morbidity (J.Neurosurg.,68:409,1988). We examined age effects on mortality and behavior after traumatic brain injury in rats.

Three-month-old (young) and 20-month-old (aged) Fischer 344 rats were anesthetized with Metofane and injured at mild (1.75-1.85 atm) or moderate (2.0-2.3 atm) magnitudes of fluid percussion brain injury (J.Neurosurg., 67:110,1987). Following injury, the acute duration of reflex suppression (e.g., pinna, corneal, righting, tail flexion) and long-term motor deficits (beam-walking) were recorded.

Mild injury produced mortality rates of 50% in aged and 25% in young rats. Moderate injury produced mortality rates of 100% in aged and 20% in young rats. Recovery of reflexes was faster for young rats. Aged rats exhibited greater and longer lasting motor deficits. Our findings suggest that fluid percussion injury to the rat may be a useful model for the experimental study of aging effects on brain injury.

Supported by NIH Grant R01-NS-21458.

460.2

REDUCED URIDINE CONCENTRATION IN CSF AFTER I.C.V. BLOOD INJECTION. R.A. Mueller, T.J. McCown, R.D. Hunt,* and G.R. Breese. Departs. of Anesthesiology, Pharmacology, and Psychiatry, UNC-CH, Sch. of Med., Chapel Hill, NC 27599-7010.

Uridine in ventriculostomy cerebral spinal fluid (CSF) from adult head injury patients is less than 10% of normal.

CSF from male or female Sprague-Dawley rats was removed from the cisterna magna under light ether anesthesia at various times after neurological insults. CSF uridine, hypoxanthine and xanthine were measured by high pressure liquid chromatography.

Sublethal degrees of hypoglycemia, cerebral hypoxia or ischemia did not alter CSF uridine, but postmortem CSF uridine was unformly elevated. Injection of 200 of autologous non-heparinized blood into the lateral ventricle of rats after withdrawal of 75-100 CSF (for measurement of pre-injection CSF uridine) produced significant depression of cisternal CSF uridine 24 hrs. later, which gradually returned to normal over the next 48 hours. No similar changes were noted after serum or saline i.c.v. injection. All animals were neurologically intact after the ether effect dissipated.

It is possible that deceased uridine in head injury patients is the result of the presence of blood in the ventricular spaces. Since uridine is a potent endogenous anticonvulsant as well as an essential substrate, the sequelae of ventricular hemorrhage may be partly due to this metabolic disturbance.

460.3

TRAUMATIC BRAIN INJURY REDUCES QNB BINDING TO MUSCARINIC RECEPTORS IN RAT HIPPOCAMPUS. L.D. OLENIAK,* B.G. LYETH, T.J. MARTIN*, B.R. MARTIN, L.W. JENKINS, G.L. CLIFTON*, H.F. YOUNG* AND R.L. HAYES. Richard Roland Reynolds Neurosurgical Research Laboratories, Division of Neurosurgery, Medical College of Virginia, Richmond,VA 23298.

Our laboratories have shown muscarinic agonist-receptor interactions may contribute to the pathophysiology of traumatic brain injury (TBI) (Brain Res., 448:88,1988). One component of the pathophysiology of TBI is the characterization of abnormal neuronal information flow which may be reflected by changes in receptor binding. The present study examined muscarinic receptor binding following TBI. Male Sprague-Dawley rats (280-340g) were either sham injured or given moderate fluid percussion brain injury (2.25-2.35 atm) (J. Neurosurg., 67:110,1987). Animals were anesthetized with methoxyflurane and immersed in liquid N_2 at 5min, 3hrs and 24hrs after injury. Ten micron brain sections were mounted on subbed slides, incubated in .5nM [^{3}H]-QNB, air dried and placed against ^{3}H-Hyperfilm for 21 days. Binding was quantified using computer assisted image analysis. Preliminary data show a 30-40% decrease in binding as compared to control in the dentate gyrus and CA_1 regions of the hippocampus at 3hrs post injury. Overstimulation of muscarinic receptors may cause decreases in receptor binding. These data suggest that abnormal muscarinic agonist-receptor interactions occur following TBI. Decreased binding may possibly result from activation of intracellular second messenger systems. Supported by NIH Grant R01-NS-21458.

460.4

EFFECT OF MANNITOL-INDUCED HYPEROSMOLALITY ON BRAIN INTERSTITIAL FLUID TRANSPORT. G.A. Rosenberg, J. Barrett*, E. Estrada*, W. T. Kyner*. Neurology Service, VA Medical Center and Department of Neurology, UNM, Alb., NM 87131

Mannitol is used to treat brain edema, but its mechanism of action is controversial. Therefore, we studied the effect of mannitol-induced hyperosmolality on brain interstitial fluid (ISF) by autoradiography. Adult cats underwent intracerebral infusion of the extracellular marker, ^{14}C-sucrose. Nine animals were given 2 gms/kg of mannitol intravenously, and another 9 animals without mannitol were controls. Plasma and CSF osmolality were measured. After 2 hours the brains were removed for determination of water and electrolyte content and for preparation of the autoradiograms. Diffusion coefficients were calculated for intracerebral transport with equations for radial diffusion. Mannitol increased plasma osmolality and lowered water and potassium contents in the white matter. Diffusion was reduced in the direction of gray matter into the white matter. We conclude that low doses of mannitol control CSF pressure by selectively removing water from white matter, reducing CSF volume, and affecting molecular transport at the gray/white interface.

460.5

NEURAL NETWORK COMBINATORICS: IMPLICATION FOR RECOVERY FROM BRAIN DAMAGE. R. B. Glassman. Dept. of Psychology, Lake Forest College, Lake Forest, IL 60045.

The factors determining whether a neuron in a particular set is active include its threshold and how many connections converge onto it from neurons in another set. Consider a simplified general case of a hypothetical set of N neurons, which constitute a source of input. Each possible combination of M of these N neurons is connected to a specialized neuron in a receiving set of feature analyzers ("fa's"). The threshold of each fa is such that it will be fired if any r of its inputs are active. At a given time, a of its inputs are active. (Note that $N \geq M \geq a \geq r$.) Then the total number of fa's active is

$$\sum_{k=0}^{a-r} \left[({}_aC_{(r+k)}) \, ({}_{(N-a)}C_{(M-r-k)}) \right]$$

This formula, and more complex variants of it, have implications for restricted sizes of neuronal pools and numerosity of connections among pools. (As r decreases, the network shifts from AND- to OR-type operation.) The formulas also provide a way to estimate reliability and to estimate the sacrifice of discrimination associated with arousal or with threshold adjustments compensating for the shock or "diaschisis" component of a deficit that follows brain damage.

460.6

TIME-INTENSITY RECIPROCITY FOR MICROWAVE EXPOSURE OF MICE IN VIVO OVER EXTENDED TIME PERIODS. B. Pulford* and M.W. Luttges. Engineering Sciences, University of Colorado, Boulder, Colorado 80309.

This study is an attempt to assess the effects on the nervous system of mice of different time-intensity combinations of microwave radiation. Current microwave exposure standards in the U.S. are not time dependent, whereas many other countries do incorporate a time factor into their standards.

Carbon loaded teflon cortical screws were implanted in HS mice one week prior to exposure. Experimental mice were placed in a restraint located at an H field maximum of an S band waveguide. This precision of placement within the field allowed us to determine mid-brain SAR's accurately. "Yolked" control mice were similarly restrained and placed in a sham waveguide. The microwave signal was 2450 MHz pulsed and the specific absorption rates(SAR's) used were 1.0 and 10 mW/g. Spontaneous electrocorticograms(ECoG's) and evoked responses to a strobe light stimulus were recorded from exposed and control mice at specific times during the 8 hour recording period. The exposed animals showed a decrease in total ECoG spectral power(10-50Hz) and a depression in the amplitude of the evoked responses. In both indices, a short term(<30min) large, time-intensity reciprocity was recorded as well as a smaller, long term reciprocity. The results indicate that exposure standards need to be based on a reciprocal relation between time and intensity of microwave radiation. Further detailed studies should specify the nature of such a standard.

460.7

EFFECTS OF METHYLPHENIDATE ON RECOVERY FROM ABLATION-INDUCED HEMIPLEGIA. A.E. Kline*, T.P. Flores*, D.Y. Tso-Olivas*, M.J. Chen, and D.M. Feeney. Depts. of Psychol. and Physiol., UNM, Albuquerque, New Mexico 87131.

A single administration of d-Amphetamine (AMPH) given to rats 24 hrs after sensorimotor cortex ablation (see CRC Critical Reviews in Neurobiol., 3(2):135-197, 1987) combined with relevant experience during the period of intoxication produces an enduring acceleration of recovery of locomotion. This study tested methylphenidate (MPD) in a rat model of hemiplegia. After training rats to run a narrow elevated beam, a right sensorimotor cortex ablation or sham surgery was performed. Twenty-four hr after surgery, 3,6,8,9,10,12, or 15 mg/kg of MPD or vehicle was given (i.p.). Beam-walk testing resumed at 1,2,3, and 6 hr post-injection and every other day for 15 days. No significant effects of a single dose of MPD was obtained when compared to saline controls. The reported beneficial effects of MPD on cognitive function after brain injury (J. Clin. Exp. Neuropsychol., 9(3):297-309, 1987) may require continuous medication. Alternatively, this rat hemplegia model is inadequate for screening drugs affecting cognitive deficits. Supported by DHHS Grant NS20220-02 and by MBRS 2S06 RR08139-14.

ALPHA TOCOPHEROL-LIPOSOMES FACILITATE RECOVERY FROM FRONTAL CORTEX LESIONS IN THE RAT. S. W. Hoffman*, M. Halks-Miller, and D. G. Stein. Clark University, Worcester, MA 01610 and SRI International, Menlo Park, CA 94025.

Twenty-four male Sprague-Dawley rats approximately ninety days of age received either bilateral medial-frontal cortical lesions or sham operations. Subjects received liposomes (SRI International) with or without physiologic amounts of d-alpha tocopherol (αT) (Kodak). Following the injury, 0.1 cc of the treatment material was flushed directly into the wound cavity. The treatment was delivered directly to the lesion site by PE60 tubing attached to subcutaneously implanted Alza Alzet pumps (Model 2001). After seven days of continuous treatment, the pumps were removed and subjects were rested for seven days. Subsequently, rats were trained on a delayed-spatial alternation task for a water reward. The results of this study showed that, in comparison to sham operates, brain-injured subjects given liposomes alone were significantly impaired on this spatial task. However, rats with lesions treated with αT-containing liposomes took significantly fewer days and made fewer errors than lesion controls in attaining 9 out of 10 correct responses. Histological analyses will be described. This research is supported by NIMH Grant No. 9R01NS25685.

460.9

EXACERBATION OF TRAUMATIC BRAIN INJURY FOLLOWING CENTRAL ADMINISTRATION OF KAPPA-OPIATE RECEPTOR AGONISTS. T.K. McIntosh, R. Romhanyi*, I. Yamakami*, A.I. Faden. Dept. Surgery, Univ. of Conn. Health Ctr., Farmington, CT 06032 and Dept. Neurology, Univ. of Calif., San Francisco 94143.

We have previously suggested that endogenous κ-opioid receptor systems may be involved in the pathophysiology of traumatic brain injury. The present study examined the effect of centrally administered κ-opiate agonists dynorphin 1-17 and U50,488H on neurological outcome after fluid-percussion (FP) traumatic brain injury (2.5 atmospheres) in anesthetized male, Sprague-Dawley rats (350-450g, n=40). At 15 min postinjury, animals randomly received an intracerebroventricular (ICV) injection of either 1) dynorphin 1-17 (30nM, n=8), 2) dynorphin 2-17 (des-tyr dynorphin, inactive at opiate receptors, 30nM, n=8), 3) U-50,488H (30nM, n=8), 4) U-50,488H (100nM, n=8), or 5) artificial CSF (equal volume=5μl, n=8). Dynorphin 1-17 and U-50,488H (100nM), but not dynorphin 2-17, U-50,488H (30nM) or CSF, significantly worsened neurological outcome and increased mortality after brain trauma. Dynorphin 1-17 but not CSF exacerbated the fall in cerebral blood flow in injured cortex, measured at 1 h post-trauma using radiolabeled microspheres. These data are consistent with the hypothesis that endogenous κ-opiate receptor systems mediate certain pathophysiological sequelae of traumatic brain injury.

COGNITIVE, EMOTIONAL AND SOCIAL CHANGES IN ACUTE AND CHRONIC TRAUMATICALLY BRAIN INJURED: IT'S IMPLICATION FOR TREATMENT AND PREDICTION. D. Badillo-Martinez and M. Nelson*. DATAHR Rehabilitation Agency, Brookfield, CT 06804.

Frontal Lobe dysfunctions, new-learning problems and personality changes are frequent sequelaes to Traumatic Brain Injury (TBI). Reportedly these interfere with vocational rehabilitation efforts and return to pre-morbid functions. No systematic assessment of the concomitant impact of rehabilitation on cognitive, social and emotional functions within the same individual is reported. Moreover, the capacity for recovery is said to decline with chronicity. The cognitive-neuropsychological, emotional and social performance of two groups of severe TBI survivors, acute (1-3 years) and chronic (5 years +), were assessed at two intervals while participating in the multiple rehabilitation procedures. Findings compare the longitudinal changes in cognition, social and emotional performance within each group and between acute and chronic TBI's. Issues of critical time for rehabilitation intervention, treatment efficiency, capacity for integration and reorganization are raised.

460.11

THE BLOOD-NERVE BARRIER, NOREPINEPHRINE, PROSTACYCLIN AND MALONDIALDEHYDE IN VASCULARIZED AND NON-VASCULARIZED NERVE GRAFTS. M. Shupeck*, K. K. Ward*, J. D. Schmelzer*, P. A. Low. Neurophysiology Laboratory, Department of Neurology, Mayo Foundation, Rochester, MN 55905 USA

We compared the efficacy of vascularized (VASC) and conventional (CONV) sciatic nerve grafts in restoring nerve conduction, the blood-nerve barrier, norepinephrine (NE) and 6-keto Prostaglandin $F_{1\alpha}$ (6KPGF; the stable prostacyclin metabolite) in the rat. We also measured malondialdehyde (MDA) content. There was a statistically non-significant increase in nerve action potential amplitude in the grafted segments of vascularized nerves at 1 and 2 months post-graft. The ^{14}C-sucrose PA product was increased in both CONV and VASC at 1 and 3 mo. and not different to each other. NE and 6-KPGF, the major vasoconstrictor and dilator of nerve microvessels were better restored in VASC than CONV reaching statistical significance for 6KPGF ($p<0.001$). MDA used as an index of oxygen free radical generation was not significantly different in the 3 groups.

Group	NE (pg/mg)	6KPGF (pg/mg prot)	MDA (ng/mg) dry wt	PA (10^{-5}/sec/g) 1 mo	3 mo
CTL	2.6±0.18	8.3±0.59	5.8±0.45		
VASC	2.1±0.26	6.7±0.49	6.6±1.02	11.6±1.5	11.8±1.9
CONV	1.9±0.37	4.0±0.32	6.9±0.77	9.6±1.2	9.6±1.7

The better restoration of 6KPGF and perhaps NE suggest that vascularized grafts may be more effective in restoring vasoreactivity of peripheral nerve following graft.

460.12

PENETRATING HEAD INJURY: A RODENT MODEL OF TRAUMATIC HEMIPLEGIA. A.S. Merians, A.W. Deckel. University of Medicine and Dentistry of New Jersey, Newark, N.J. 07107.

We have developed a rodent model of unilateral penetrating brain injury manifesting persistant long term deficits, specifically sensory and motor dysfunction similar to hemiparetic characteristics evident in head injured patients. Previous studies indicated that at 1 and 3 weeks the lesioned group demonstrated decreased reaction to tactile stimulation contralateral to the lesion, decreased balance and decreased spontaneous locomotor activity. In this study the course of recovery was extended to 6 weeks.

Twenty three male rats were anesthetized with sodium pentobarbital. After administering a craniotomy 4mm in diameter over the forelimb/hindlimb representation of the motor cortex, a metal baton was inserted into a guide tube and dropped on to the dural surface. The control(10) animals received the craniotomy but not the impact.

At 6 weeks some recovery was evident, however the lesioned (13) animals demonstrated persistent deficits in vertical motor activity, tactile sensation and balance. Histological results demonstrated prominant cavitation 5mm by 3mm.

This model of traumatic hemiplegia allows for future experimentation with acute and long term treatment strategies.

460.13

PRETREATMENT WITH A-4 REDUCES BEHAVIORAL DEFICITS FOLLOWING TRAUMATIC BRAIN INJURY (TBI) IN THE RAT. S.E. Robinson, R.M. Martin*, T.R. Davis* and E.K. Enters*. Dept. Pharmacology & Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298-0613.

Activation of central cholinergic neurons has been implicated in the production of a flaccid comatose state following concussive brain injury (Saija et al., Brain Res., in press). In order to further prove the role of central cholinergic neurotransmission in the production of behavioral deficits following TBI, we studied the effect of A-4, a hemicholium-3 derivative which crosses the blood-brain barrier. Male Sprague-Dawley rats weighing 270-310 g (n=10 per group) were surgically prepared under pentobarbital anesthesia 24 h prior to injury by placing a hollow tube epidurally over a central craniotomy and were injected i.p. with either saline or A-4 (40 mg/kg) 1 h prior to TBI. This dose has previously been demonstrated to deplete central acetylcholine stores without affecting other neurotransmitter systems (Tedford et al., JPET, 240: 476, 1987). The rats received fluid percussion injury (2.2 atm) while under methoxyflurane anesthesia and were ventilated as necessary following injury. The duration of suppression of several reflexes (pinna, corneal, paw flexion, tail pinch and flexion, and righting) and responses (escape, head support, and spontaneous locomotion) were measured up to 60 min after trauma. A-4 significantly reduced the time to recovery of the corneal and righting reflexes and head support. This study lends support to the role of central cholinergic neurons in the production of transient behavioral deficits following TBI. [NS#24413 and NS#7288].

ENDOGENOUS PEROXIDATIC ACTIVITY AFTER SPINAL CORD INJURY. J.A. Ellison*, Selina C. Cortez*, and L.J. Noble. Dept. of Neurology, School of Med., UCSF, San Francisco, CA 94122.

In order to identify endogenous peroxidatic activity (EPA) after spinal cord injury, sections of cord from 0.5 to 2 cm from the injury were reacted in diaminobenzidine (DAB) in the presence of H_2O_2. At 3 h after injury reaction product (RP) was restricted to hemorrhagic areas in the dorsal column, and appeared to be primarily related to peroxidatic-like activity associated with hemoglobin. At 1 and 2 wk RP was maximal at the boundary between gray matter and dorsal column and was present up to at least 2 cm from the injury. RP was mostly confined to large conglomerates of irregularly contoured cells whose cytoplasmic processes extended into the neuropil. Frequently, these processes were closely associated with blood vessels, an observation confirmed at the ultrastructural level. Preliminary observations of sections reacted with anti-glial fibrillary acidic protein suggest that certain of these cells expressing EPA may be astrocytes.

To determine the nature of EPA, tissue was incubated with one of the following: DAB and H_2O_2; DAB; H_2O_2; 2,6 dichloro-phenolindophenol (DCPIP, a catalase inhibitor); 3,amino 1,2,4 triazole (AT, a catalase inhibitor); or potassium cyanide (KCN, a hemeprotein enzyme inhibitor). No EPA was noted with omission of either DAB or H_2O_2. KCN inhibited EPA, however, both AT and DCPIP did not.

(Supported by NIH NINCDS RO1NS23324 to L.J. Noble).

MEMBRANE LIPID CHANGES CORRELATE WITH DECREASE IN TISSUE MAGNESIUM FOLLOWING IMPACT SPINAL CORD TRAUMA IN RABBITS. M. Lemke*, P. Demediuk* and A.I. Faden (SPON: T.P. Jacobs). Dept. of Neurology, University of California, V.A. Medical Center, San Francisco, CA 94121.

Secondary neurochemical events following traumatic spinal cord injury (SCI) appear to contribute to development of tissue damage and subsequent neurological deficit. We have shown that reductions in tissue Mg^{2+} following traumatic SCI in rats are significantly correlated with the injury severity. Membrane lipid hydrolysis and eicosanoid production occur after SCI in cats and rats. In the present studies changes in water content (wet/dry weight method), tissue Na^+, K^+, and Mg^{2+} (atomic absorption spectroscopy), phospholipids (HPLC) and free fatty acids (gas chromatography) were examined in the lumbar (L-2) segment of anesthetized rabbits following moderate (40 g-cm) and severe (150g-cm) impact injury. At 4 h posttrauma decreases in tissue Mg^{2+} and phospholipids were observed associated with elevation of arachidonic acid. These changes were significantly correlated with injury severity, whereas alterations in water content, Na^+, and K^+ were not. Thus, membrane lipid hydrolysis may lead to decreased binding sites for Mg^{2+}, resulting in a reduction of tissue Mg^{2+}. Given the critical regulatory role of Mg^{2+} for essential cell functions including glycolysis, oxidative phosphorylation and receptor activity, Mg^{2+} changes after trauma may play a fundamental role in secondary tissue damage.

460.16

REGIONAL CHANGES IN GLUCOSE AND ATP CONTENTS FOLLOWING EXPERIMENTAL SPINAL CORD COMPRESSION TRAUMA IN THE RAT A.C. Nacimiento, G. Adler* and A. Mautes*
Neurosurgical Research Laboratory, Saarland University Medical School, 6650 Homburg/Saar, F.R.G.

To study regional metabolic aspects of acute posttraumatic changes in the spinal cord following compression in the model of Nacimiento et al. (J. Neurosurg., 1985, 62, 898) we applied a bioluminiscence technique described for brain tissue by Paschen et al. (J. Cereb. Bl. Flow Metabol., 1985, 5, 465). Correlation between computer-assisted measurements of optical densities in bioluminiscent images of glucose and ATP distribution in single spinal cord sections, and contents in corresponding tissue samples was highly significant. Thus, both metabolites could be quantitatively determined by image processing of the bioluminiscent sections. Two hours after compressing 60 % of dorsoventral extent of segment L4 for 50 ms, we found significant elevation in glucose and reduction of ATP content in L4 and L6 segments. Changes in L2 were not significant. This method disclosed regional differences in posttraumatic carbohydrate and energy metabolism which cannot be resolved by measurements in tissue samples.

460.17

TRAUMATIC BRAIN INJURY PRODUCES TRANSIENT REDUCTION IN BINDING TO EXCITATORY AMINO ACID RECEPTOR SUBTYPES. R.L.Hayes, L.P.Miller*, B.G.Lyeth, L.W. Jenkins*, L. Oleniak*, G.L. Clifton* and H.F. Young*. Dept of Surgery, Medical College of Virginia, Richmond, VA 23298, Vet Adm Med Ctr, Wash D.C. 20422 & Dept of Pharm, Georgetown Univ Sch. of Med.,Wash. D.C. 20007.

Abnormal agonist-receptor interactions may contribute to the pathophysiology of traumatic brain injury (TBI). Recent data have demonstrated that blockade of muscarinic (Br Res 448:88,1988) or N-methyl-D-Aspartate (NMDA) (Neurosci Abst 13:1254, 1987) receptors can attenuate behavioral deficits associated with TBI in the rat. In the present report we have examined temporal changes in excitatory amino acid (EAA) receptor subtypes following fluid percussion TBI in the rat. EAA receptors were characterized by NMDA-displaceable 3H-Glutamate binding to the NMDA receptor, 3H-AMPA binding to the quisqualate receptor, and 3H-Kainic acid (KA) to the KA receptor. Our results show that NMDA receptor binding in the strata radiatum of the hippocampus decreased to 83% of control within 3 hr post-TBI and remained significantly below control levels for up to 24 hr (90% of control). Other regions such as the dentate gyrus, outer and inner layers of the cortex showed a somewhat similar pattern for NMDA binding. 3H-AMPA binding while not significant at any time point showed a pattern toward decreased binding at both 5 min and 3 hr post-TBI, while returing to control levels by 24 hrs. 3H-KA binding decreased significantly only at 24 hrs post-TBI and only in the inner layers of the cortex. Our results suggest that NMDA receptors apparently 'down regulate' in response to TBI. This response may be related to TBI-induced rise in extracellular glutamate concentrations. These results will also be discussed in relation to the TBI-induced vulnerability to subsequent ischemia and involvement of EAA receptors.

Experimental Obstructive Hydrocephalus: Sequential MRI's of rat brains over a 10-day time course suggests an age-related differential response in ability to resolve obstructive hydrocephalus. Kathryn A. Hager,*Juan A. Cabrera, M.D.* and Michael E. Miner, M.D., Ph.D., Division of Neurosurgery, University of Texas Medical School, Houston, TX, 77030.

In producing a reliable model of hydrocephalus in rats, the question of variation of age of the animal and effect this may have on the course of hydrocephalus has not been adequately addressed. It is the purpose of this study to begin to contrast these responses. Obstructive hydrocephalus was produced in 45 and 64 day old male, Sprague Dawley rats weighing approximately 150 g. and 250 g. respectively by injections of .05 cc sterile kaoline into the cisterna magna. Each animal brain was imaged via the utilization of MRI at 2,4,7, and 10 days post-operatively to follow the progression of ventricular dilation and resolution of hydrocephalus. The younger animals exhibited progressive ventricular dilation over the 10 day time course as well as continued physical deterioration. In contrast, the older group exhibited evidence of resolution of ventricular dilation in parallel with improvement of classical symptoms of hydrocephalus. Our findings indicate that the age-related differential response represents an important variable affecting the outcome in experimental obstructive hydrocephalus studies.

AXONAL LOSS AFTER GRADED SPINAL CORD CONTUSIVE INJURY IN THE RAT. J.R. Wrathall and L. Verma*. Dept. of Anat. and Cell Biol., Georgetown Univ., Washington, D.C. 20007.

We have previously examined the development of acute pathological changes after contusive injury in axons analyzed at the light and electron microscopic level. We used stereological techniques to develop a quantitative description of axonal changes in the ventro-medial white matter at 15 min, 2, 4, 24, and 48 hrs after a standardized mild contusive injury (*Soc. Neurosci. Abstr.* 13:1500,1987). We have now extended this study to include acute axonal pathology after severe contusive injury and to compare axons in acute versus chronic injury sites 8 weeks after mild contusion. The results indicate that the time course of the development of axonal pathologies in ventro-medial white matter is similar after severe or mild contusion. By 15 mins after injury there is a significant reduction in the volume ratio of normal axoplasm that is similar in mild and severe injuries. This is further reduced between 15 mins and 2 hrs after which it remains virtually constant through 8 weeks after contusion. Thus, in both mild and severe injury the significant axonal pathological alterations that lead to axonal loss appear to have been accomplished by 2 hrs after trauma. In addition, examination of the chronic injury sites at 8 weeks also indicate a preferential loss of the larger myelinated axons and increased myelin thickness for the remaining small axons as compared to axons of similar size in the normal spinal cord. (Supported by NIH-NO1-NS-2-2310)

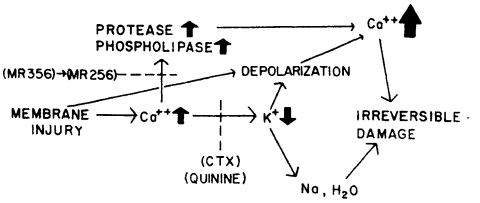
TWO NEW PHARMACOLOGIC AGENTS WHICH PROTECT THE RAT SPINAL CORD FROM CONTUSION INJURY. S. Tsuyoshi Ohnishi, Hiroaki Katagi* and Masayuki Katsuoka*. Membrane Research Institute, Phila. PA 19104.

Using the weight-drop technique (10g x 5cm), we studied the protecting effect of two new drugs in spinal cord injury of the rat. The efficacy was assessed by recovery of motor performance (Tarlov score) during 4 week period after injury.

(1) Charybdotoxin, a specific inhibitor of Ca-activated K efflux, demonstrated protective effect in pre-injury administration (0.12 mg/kg i.p.; 30 minutes before injury). Quinine also had a beneficial effect.

(2) Oligomeric derivatives of prostaglandin E_1 (6 mg/kg of either MR-256 or MR-356; i.p., post-injury administration), which may act as inhibitors for phospholipases and proteases, also had protective effect.

Possible mechanisms of protection are speculated.



460.21

INCREASE IN EXTRACELLULAR GLUTAMATE AND ASSOCIATED MASSIVE IONIC FLUXES FOLLOWING CONCUSSIVE BRAIN INJURY. Y. Katayama, M.K. Cheung, L. Gorman, T. Tamura* and D.P. Becker. Div. of Neurosurgery, UCLA, Los Angeles, CA 90024

Using microdialysis, changes in extracellular concentration of amino acids and inorganic ions ($[K^+]_e$ and $[Ca^{2+}]_e$) following concussive (fluid-percussion) brain injury were determined in the rat hippocampus. At the moment of injury, the microdialysis probe (O.D. 300 u) was temporarily withdrawn. A large increase in $[K^+]_e$ (4-5 fold baseline) occurred following the injury which produced unconsciousness lasting for more than 3 min. Moderate but significant decrease in $[Ca^{2+}]_e$, preceded by initial transient increase, was also demonstrated. Concomitantly with the $[K^+]_e$ increase, an elevation of excitatory amino acids, especially glutamate, was noted (4-5 fold baseline). Such a large increase was not observed in other amino acids. The $[K^+]_e$ increase and the $[Ca^{2+}]_e$ decrease were resistant to *in situ* administration of tetrodotoxin (10^{-4} M) through the microdialysis probe but effectively attenuated by kynurenic acid (10^{-2}M), a glutamate antagonist. These results suggest that a release of excitatory amino acids underlies the massive ionic fluxes following concussive brain injury.

460.22

ULTRA-RAPID CRYO-JET FREEZING OF MOUSE SPINAL CORD EXPLANTS. W.B. Greene* and J.D. Balentine. Dept. of Pathology and Laboratory Medicine. Medical Univ. of SC, Charleston, SC 29425.

Cryo-fixation is essential for the preservation of diffusible ions in preparation for x-ray microanalysis. Cryo-slamming has been used in our laboratory to prepare spinal cord explants. Cryo-jetting was developed for the difficult task of freezing rat spinal cord *in vivo* (Greene, W.B. & Balentine, J.D., abstract in press). The present study compared cryo-jetting with cryo-slamming of the *in vitro* spinal cord explants for a parallel *in vivo* & *in vitro* spinal cord trauma investigation. Control & traumatized explants, using techniques previously described (Balentine, J.D., Greene, W.B. & Bornstein, M., Lab. Invest. 58:93, 1988) were subjected to either slam-freezing using a Heuser type system with liquid N2 at -195°C or to jet freezing with liquid propane at -190°C and 150psi pressure. After cryo-fixation and freeze substitution, blinded assessment of sections revealed better preservation with cryo-jetting in both control and traumatized explants. The latter experiment cultures revealed clearly distinguishable focal areas of edema and axonal swelling. Cryo-jetting is a preferred method of fixation in the systems employed. (NIH Grant NS11066).

EXOGENOUS LAMININ/ARA C PROMOTES "REPAIR" OF SPINAL CORD, J. Miller and M. Politis, (C. Fischette spon.), Ortho Surg., U.B.C., Vancouver V5Z 4H4

Exogenous laminin can support axon elongation in vivo. Administration of AraC (cytosine arabinofuranoside) after CNS injury inhibits reactive gliosis. In the present study, these approaches were combined after rat spinal cord injury.

Cord were subjected to contusion lesion at T8. Elvax pellets containing laminin were inserted subdurally over dorsal columns and AraC administered by daily i.p. injection. Rats were assessed behaviorally and morphologically for 21dpo.

Behavioral studies (including inclined plane test and assessment of gait and toe spread) indicative significant "recovery" when laminin pellets were used in combination with AraC, but not when either treatment was used alone. Results were corroborated by elongating axons in dorsal columns rostral to lesion sites in laminin/AraC rats. HRP tracer studies to date suggest growth of rubrospinal and lat. vest-spinal fibers caudal to lesion site. Electrophysiological studies are in progress.

Studies are underway to determine if laminin/AraC treatment can be used in combination with other intervensions. Studies to date indicate no synergistic effects when combined with exogenous D.C. current.

ATTENUATION OF POST-TRAUMATIC SPINAL CORD ISCHEMIA BY THE LIPID PEROXIDATION INHIBITOR U74006F: COMPARISON IN A CONTUSION VS. COMPRESSION MODEL. E.D. Hall, P.A. Yonkers* and J.M. Braughler. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

The ability of the 21-aminosteroid lipid peroxidation inhibitor U74006F to attenuate the development of post-traumatic spinal cord ischemia was examined in pentobarbital anesthetized cats after either contusion (300 g-cm) or compression (180 g x 5 min.) L3 injury. Spinal cord white matter blood flow (SCBF) was measured prior to and for 4 hrs. after injury using H_2 clearance. Vehicle or drug was given as an i.v. bolus at 30 min. post-injury. Following contusion injury, there was a gradual decline in SCBF which reached -63.5% by 4 hrs. In cats receiving a 10 mg/kg i.v. dose of U74006F, the 4 hr. decrease was only 9.9% ($p<0.001$). However, lower doses (1 or 3 mg/kg) were completely ineffective. In the compression model, there was an initial hyper-perfusion (not seen in the contusion model) which abated by 30 min. followed by a decline to a level at 4 hrs. only slightly greater than that seen after contusion injury. In this model, U74006F was found to be a more potent antagonist with the 1 and 3 mg/kg doses effectively reducing the decrease in SCBF. These results point out differences between contusion and compression spinal injury and that the potency of agents as antagonists of post-traumatic ischemia is dependent upon the injury model.

PROSTHESISWARE: MICROCOMPUTER BASED COGNITIVE PROSTHETICS IN NEUROREHABILITATION. D.L. Chute and M. Hoag*. Neuropsychology Program and Software Development Group, Drexel University, Philadelphia, PA 19104.

As a prosthetic tool useful in neurorehabilitation, the microcomputer has a number of advantages that directly support cognitive functions and activities of daily living. New classes of software like HyperCard and MacLaboratory Controller are easily customized to provide "ecologically relevant" prosthetic support that does not presuppose any reorganization or restructuring of damaged neural tissue. We present case studies of traumatic brain injury patients for whom ProsthesisWare programs have been customized with the ready editing and rapid turn-around capability allowing multiple iterations and successive approximations to reach clinical goals. The speech prosthesis SpeakEasy and related programs illustrate the development model used, highlight issues in neuropsychological assessment and treatment, show features of software interface and design relevant to the head injured patient, and offer new directions for cognitive rehabilitation and the role of rehabilitation facilities. In spite of some limitations, the emergence of ProsthesisWare offers utilitarian prosthetic aids for the everyday activities of daily living for some people with cognitive impairments. This research conducted in part at Moss Rehabilitation Hospital, Philadelphia, was supported by grants from the Solon Foundation, Apple Computer Inc, Drexel University and the Ben Franklin Partnership and complies with guidelines for human subjects.

OPIATES, ENDORPHINS AND ENKEPHALINS: PHYSIOLOGICAL EFFECTS IV

461.1

NALTREXONE (NTX)-PRECIPITATED OPIATE WITHDRAWAL INCREASES LOCUS CERULEUS (LC) SPONTANEOUS DISCHARGE AND DISRUPTS LC SENSORY RESPONSES. E.F. Aulisi, R.G. Wehby* and R.J. Valentino. Dept. of Pharmacology, George Washington Univ. Med. Ctr., Washington, D.C. 20037.

LC discharge during NTX-precipitated opiate withdrawal was recorded in halothane-anesthetized rats 7 days after s.c. implantation with morphine (MOR)-containing osmotic minipumps. I.C.V. MOR (1.0 μg) had no effect on LC spontaneous discharge rates in MOR-implanted rats (n = 7). Because this dose of MOR is greater than that required to completely inhibit LC discharge of opiate-naive anesthetized rats, the results verify the development of MOR tolerance in the rats. I.C.V. administration of 1.0 μg NTX increased LC spontaneous discharge 152 ± 39% (n = 7). NTX also altered LC discharge evoked by repeated sciatic nerve stimulation such that the evoked discharge was decreased while background discharge was increased. The net effect of NTX was to decrease the ratio of evoked-to-tonic LC discharge during a block of phasic sensory stimulation. This effect is similar to that produced by certain stressors. NTX did not affect LC discharge of rats implanted with saline-containing minipumps. The present results confirm previous reports of increased LC activity during antagonist-precipitated opiate withdrawal and extend these findings by characterizing effects on LC sensory-evoked discharge. Supported by NIH Grants DA 03695 and MH 40008.

461.2

A NOVEL DECREASE IN ADENYLATE CYCLASE ACTIVITY IN THE RAT LOCUS COERULEUS IN RESPONSE TO ACUTE MORPHINE OR CLONIDINE ADIMINISTRATION. D. Beitner*, R.S. Duman, and E.J. Nestler (SPON: S.J. Strada). Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Previously, we have demonstrated two effects of morphine on adenylate cyclase activity (AC) in the rat locus coeruleus (LC): inhibition of AC by acute in vitro treatment in isolated membranes, an effect also observed in all other brain regions examined, and increased levels of AC by chronic in vivo treatment, an effect specific to the LC. In this study, we have identified a third and novel action of morphine on AC: a stable decrease in AC by acute in vivo treatment, which is retained in isolated membranes in vitro.

Rats received acute in vivo morphine treatment, after which AC was assayed in isolated brain membranes. Such morphine treatment produced a dose-dependent decrease (20-25% maximal) in enzyme activity in the LC, but not in other brain regions examined. Co-administration of naltrexone, an opiate receptor antagonist, blocked morphine's ability to produce this effect, indicating that it is mediated via the specific activation of opiate receptors. The decrease in AC in the LC is not due to morphine being retained in tissue fractions: the opiate receptor antagonist naloxone failed to reverse the effect in isolated membranes, and opiate agonists produced the same level of acute enzyme inhibition in vitro in membranes prepared from LC of control and morphine-treated rats. Interestingly, clonidine, which produces effects on the LC similar to those of morphine, also induced a decrease in AC after acute in vivo treatment, whereas diazepam, which has different actions on the LC, failed to produce this effect.

This stable decrease in AC activity may be an early step in the sequence of events that lead to the development of opiate tolerance and/or dependence in the LC.

461.3

HALOPERIDOL-SENSITIVE, SELECTIVE ELECTROPHYSIOLOGICAL EFFECTS OF SIGMA LIGANDS ON NCB-20 CELLS. J.A. Bell*, C.E. Spivak, T.-P. Su and E.D. London (SPON: L. Sharpe). Neuropharmacology Lab., NIDA Addiction Res. Center, Baltimore, MD 21224.

Although specific sigma binding sites are present in brain, studies on the effects of sigma-directed ligands on neurons have been lacking. Largent et al. (Eur. J. Pharmacol., 124:183, 1986) showed that hybrid cells (mouse neuroblastoma - Chinese golden hamster brain) of the NCB-20 line show high affinity sigma binding with a concomitant lack of phencyclidine (PCP) binding sites. We have obtained intracellular recordings from these cells with micropipettes (30 Mohm), and have studied the effects of pressure ejection of drugs on them. Sigma ligands (100 µM), (+)-3PPP, (+)-pentazocine and (+)-N-allylnormetazocine, ejected from micropipettes (3 µM tip diameter) depolarized these cells by 10-15 mV. Ejection of these drugs at 10 µM concentration produced smaller and less consistent effects. The depolarizing effect of these drugs were blocked by a bath concentration of 10 µM haloperidol. Haloperidol (10 µM) did not block the depolarizing effects of serotonin or dopamine. Morphine, l-glutamate and tetracaine (100 µM) did not depolarize NCB-20 cells. The selective PCP ligand MK-801 (100 µM) had a small depolarizing effect that was blocked by haloperidol. We conclude that NCB-20 cells may be a good neuronal model for studying sigma effects.

461.4

MPV 1440, A HIGHLY - SELECTIVE ALPHA-2 AGONIST, PREVENTS OPIATE - INDUCED MUSCLE RIGIDITY. M.B. Weinger, I.S. Segal*, and M.M. Maze*. Depts. of Anesthesiology, Univ. of California, San Diego, Stanford University, and the San Diego and Palo Alto V. A. Medical Centers.

Several studies have shown that the selective alpha-2 adrenergic agonist, MPV1440 [**M**], produces marked analgesia, muscle flaccidity and decreased sympathetic activity. Because recent work suggested that adrenergic systems might play a role in opiate-induced muscle rigidity, we studied the effects of pretreatment with **M** on muscle tone in rats given the potent short-acting opiate alfentanil [**A**]. Wistar rats had 15 minutes of baseline hindlimb electromyographic (EMG) activity recorded and were then injected with either saline [SAL], MPV1441 (the inactive stereoisomer), **M** (in several doses), or **M** and the alpha-2 antagonist, idazoxan. 15 minutes later, all rats received **A** (0.5 mg/kg s.c.) and data were collected over for 60 minutes. Data were analyzed using ANOVA and Newman-Keuls tests. There were no differences between groups in weight or baseline EMG activity. In the SAL and MPV1441 groups, **A** resulted in a marked increase in hindlimb EMG activity and the behavioral manifestations of opiate rigidity. In contrast, **M** dose-dependently prevented **A**-induced rigidity. The **M** animals were flaccid, akinetic, and lacked a startle response. The addition of idazoxan resulted in an elimination of **M**'s blockade of **A**-induced rigidity. The results of this study clearly demonstrate that pretreatment with The antagonism by idazoxan of **M**'s prevention of **A**-induced muscle rigidity supports an alpha-2 mediation of this phenomenon. The **M** doses necessary to antagonize **A** rigidity are relatively small (<1/10) compared with doses used alone reported to produce an anesthetic state. The results of these studies support a role for alpha-2 adrenergic systems in the expression of opiate-induced muscle rigidity in the rat.

461.5

OPIATE-MEDIATED BEHAVIORS AND BRAIN OPIOID PEPTIDES IN NEONATES AFTER PRENATAL ETHANOL. P. Kehoe, E. Vavrousek-Jakuba and W.J. Shoemaker. Trinity College, Hartford, CT & U Conn. Health Center, Farmington, CT.

Pregnant rats were fed either an alcohol-containing diet, an isocaloric pair--fed diet or standard chow. At birth all offspring were fostered onto control mothers, eight per litter, and tested at ten days of age. Similar groups were sacrificed at 12 days of age for brain B-endorphin levels using a specific RIA. The ten-day-old rats were isolated and monitored for ultrasonic vocalizations after naltrexone (0.5mg/kg) administration. After 10 min isolation they were tested for analgesia to heat. Chow-fed and pair-fed saline controls vocalized 200 times during isolation which doubled with naltrexone pretreatment. Alcohol-treated pups, however, vocalized significantly less after saline (75) and naltrexone (160). Additionally, these pups did not demonstrate the isolation-induced analgesia seen in controls but did show a marked increased sensitivity to heat after naltrexone administration. Prior studies have demonstrated that prenatal ethanol results in markedly increased levels of B-endorphin at birth that persists to adulthood. Our current studies confirm the earlier findings and suggest that the unusual responses of the alcohol offspring in opiate-mediated behaviors may be due to a primary defect in B-endorphin levels or, secondarily, to abnormalities of the opiate receptors.

Supported by NIAAA #06927.

461.6

HETEROGENEITY IN ENDOGENOUS OPIOID CONTROL OF FETAL OVINE CARDIOVASCULAR FUNCTION. C.E. Dunlap and N.K. Valego*. Bowman Gray Sch. Med. of Wake Forest Univ., Winston-Salem, NC 27103.

Agonists for three opioid receptor subtypes, δ (leucine-enkephalin), κ (dynorphin1-13) and μ (morphine) were studied in 3 to 7 fetal sheep 100 to 124 days gestation.

Treatment	MAP (torr)	HR (bpm)
Intact Control	45.0±1.5	179±18
Intact, 0.5mg/kg LEK	35.3±2.6	99±24
Intact, 0.5mg/kg DYN	57.9±3.1	148±36
Vagotomy Control	39.5±2.6	167±14
Vagotomy, 0.5mg/kg LEK	41.0±4.9	190±36
Vagotomy, 0.5mg/kg DYN	62.5±1.8	266±46

Morphine had no effect on mean arterial pressure (MAP) or heart rate (HR) in doses up to 10 mg/kg. Leucine-enkephalin (LEK) produced a brief, significant decrease in MAP and HR, which was abolished by vagotomy, similar to effects previously reported for met-enkephalin (LaGamma et al., Pediatr Res 17:162-67, 1983). Dynorphin1-13 (DYN) produced a significant increase in MAP which lasted up to 45 min, and was not abolished by vagotomy. DYN had no effect on HR in intact fetuses, but produced a significant increase in HR in vagotomized animals. These results suggest differential control of CV function by at least two endogenous opioid systems in developing sheep. Research Supported by NIH Grant HL34460 to CED.

461.7

DISINHIBITION OF PITUITARY LH BY INTRACEREBRAL ANTI-OPIOID TREATMENTS IN SHEEP. G.D. Weesner* and P.V. Malven. Dept. Animal Sci., Purdue Univ., W. Lafayette, IN 47907.

This research sought to determine if β-endorphin (βE) exerts a physiological inhibition on LHRH release in the CNS of sheep. Nine mature ewes were implanted with guide tubes through which matched infusion cannulae could subsequently be briefly inserted for intracerebral (ic) infusion of naloxone (NAL; 50 μg in 20 μl), normal sheep serum (NSS; 20 μl of 1:25), or sheep anti-sheep βE (SASβE; 20 μl of 1:25; Ebling and Lincoln, Endo. 120:809). To detect abrupt disinhibition of LHRH release by anti-opioid treatments, serum LH was quantified at 10-min intervals for 1-2 h before and after each ic infusion. During the luteal phases of recurring estrous cycles, complete experiments (i.e., 3 different ic infusions at each site over 27 h period) were performed 2-4 times/site. LH assays and histological analyses of CNS sites showed that SASβE consistently disinhibited LH/LHRH release when infused at the following sites: (A) rostral preoptic area/nucleus accumbens (2 ewes) and (B) anterolateral hypothalamus (1 ewe). Infusion of NAL also disinhibited LH/LHRH release at site A but not at site B. In addition, NAL disinhibited LH/LHRH release at 5 other sites (3 in areas slightly rostral to site A and 2 in mediobasal hypothalamus), but serum LH responses to SASβE were not consistently different from those to NSS. Three other sites were not responsive to either NAL or SASβE. In summary, ic immunoneutralization of endogenous βE in selected CNS sites relieved the inhibition of LHRH release. However, other opioid ligands may also be physiologically important in luteal-phase sheep since the nonspecific anti-opioid NAL was effective at more sites than SASβE.

461.8

STIMULATION OF MESOLIMBIC AND MESOCORTICAL BUT NOT NIGRO-STRIATAL DOPAMINE RELEASE BY MORPHINE. P.L. Wood and T.S. Rao*. CNS Diseases Research, G.D. Searle & Co., c/o Monsanto Co., St. Louis, MO 63198.

Previous studies have demonstrated that morphine increases dopamine (DA) synthesis and metabolism in nigrostriatal, mesolimbic and mesocortical dopaminergic projections (Kim et al., Life Sciences 39:2033, 1986). However, the effects of morphine on regional DA release have not been evaluated to date. In this report we present data concerned with the effects of morphine on steady-state 3-methoxytyramine (3-MT) levels and on 3-MT accumulation after inhibition of monoamine oxidase, both indices of DA release. Morphine (16 mg/kg, sc; 60 min) was found to increase DA release in the rat olfactory tubercle, prefrontal cortex, pyriform cortex and N. accumbens. In contrast, DA release in the striatum was unchanged after treatment with morphine.

These data support previous observations that morphine acts to uncouple DA synthesis and release in the rat striatum but that this uncoupling is not present in other DA projections to cortical and limbic terminal fields.

461.9

AUGMENTATION OF MORPHINE-INDUCED CHANGES IN CEREBRAL MONOAMINE METABOLISM IN RATS TREATED CHRONICALLY WITH NALTREXONE. L.Ahtee* and K. R. Carlson. Dept. of Pharmacy, Univ. of Helsinki, SF-00170 Finland.

Chronic naltrexone treatment enhances the antinociceptive effect of morphine as well as the binding of opioid ligands to μ- and δ-sites (Tempel, A. et al., J. Pharmac. exp. Ther. 232: 439, 1985). To investigate the role of opioid receptors in the regulation of cerebral monoaminergic neurons we studied the effects of morphine (3-30 mg/kg, 2 h, s.c.) on the concentrations of DA, NA and 5HT and their metabolites in several brain areas of male rats one day after withdrawal from 14 day treatment with naltrexone (Alzet mini-osmotic pumps). Chronic naltrexone elevated the concentration of 5HT in the limbic forebrain, the hippocampus and the lower brain stem, that of NA in the lower brain stem, and decreased that of 3MT in the striatum. In naltrexone-treated rats morphine elevated the cerebral DOPAC, HVA, MHPG and 5HIAA concentrations as well as diminished the 3MT concentrations more or in smaller doses than in control rats. Thus the opioid receptors which mediate the opioid regulation of monoaminergic neurons seem to become supersensitive during chronic naltrexone treatment.

461.10

EVIDENCE FOR MU RECEPTOR AND 5-HT LINK IN EXPRESSION OF MORPHINE INDUCED HYPERACTIVITY. S. Gurtu. Department of Pharmacology, K.G.Medical College, Lucknow,226003,INDIA.

Opioid agonist morphine, in high doses, induces hyperactivity in rodents and other species. Intraperitoneal (ip) administration of morphine (30mg/kg) consistently evokes marked enhancement of spontaneous locomotor activity (SLA) in naive mice. This naloxone antagonizable, excitatory response is of an established central origin but the opioid receptor subtype involved in this action is yet to be distinctly recognized. We tested opioid agonists and agonist-antagonists for SLA potentiating effects in naive mice, using photoactometer. Pentazocine, a mu receptor antagonist and kappa and sigma agonist, did not evoke any increase in SLA even with doses upto 60 mg/kg, ip, while a relatively selective mu agonist, fentanyl, (0.5 mg/kg, ip) produced marked hypermotility. Prior administration of pentazocine (30 mg/kg, ip) blocked morphine as well as fentanyl induced potentiation of SLA. The excitatory effects of opioid agonists on SLA thus appear to originate from an activation of mu receptors. Additionally, the manifestation of these mu receptor mediated effects requires an intact serotonergic system since both morphine and fentanyl failed to augment SLA in mice in which serotonin had been depleted by prior administration of fenfluramine.

461.11

LESION OF THE NIGROSTRIATAL DOPAMINE PATHWAY INDUCES FUNCTIONAL DOWN REGULATION OF DELTA-OPIOID AND GABA RECEPTORS IN THE GLOBUS PALLIDUS. H.S. Pan and J.R. Walters. NINCDS, NIH, Bethesda, MD 20892.

In rats, 6-hydroxydopamine (6-OHDA) lesion of the nigrostriatal pathway induces opioid and GABA receptor down regulation in the globus pallidus (GP, Pan et al., J. Neurochem., 1985). We used single unit recording techniques to examine the effects of 6-OHDA lesion on the sensitivity of GP neurons to microiontophoretically applied D-ala^2-D-leu^5-enkephalin (DADLE) and GABA 5-6 week post lesion in chloral hydrate anesthetized rats. Furthermore, the effects of chronic infusion of naloxone HCl (1.5 mg/day/rat for 2 weeks) 4 weeks after the induction of the lesion were studied. In normal rats, DADLE inhibited 45% of GP cells studied (n=29) > 80% baseline, 17% of cells > 50%, 10% of cells > 20%, and had no effects on 28% of cells. Naloxone (0.5 mg/kg, i.v.) reversed DADLE's effects. DADLE's inhibitory action on GP cells was significantly attenuated in 6-OHDA lesioned rats; 5% of GP cells studied (n=20) were inhibited >80% baseline, 40% of cells >20%, and 55% of cells were not significantly affected. Similarly, the sensitivity of GP cells to GABA was significantly decreased in lesioned rats. In naloxone treated lesioned rats, the reduced sensitivity of GP cells to DADLE was completely reversed while the cells remained subsensitive to GABA. These data show that 6-OHDA lesion causes a functional down regulation of opioid and GABA receptors in GP and that the former change is reversed by chronic naloxone treatment. The data suggest that dopamine denervation causes increased activity of striatopallidal enkephalin and GABA containing neurons.

OPIATE MODULATION OF DOPAMINE RELEASE IN THE STRIATUM AND NUCLEUS ACCUMBENS AS REVEALED WITH MICRODIALYSIS PROCEDURES. A. Mele*, P. Glue*, A. Pert (SPON: T. Bevan). BPB, NIMH and LCS, NIAAA.

Recent studies in rats, using microdialysis procedures, have demonstrated that systemically-administered mu opiate agonists enhance the release of dopamine in freely moving animals. The purpose of this study was to further localize this effect of opiates in brain using microdialysis techniques. Since opiate receptors appear to be localized on dopamine terminals in the caudate nucleus and nucleus accumbens, it was conceivable that the modulation of dopaminergic activity would take place at these levels. Unilateral concentric microdialysis probes were introduced into the caudate nucleus or nucleus accumbens of rats anesthetized with chloral hydrate. Both structures were dialyzed with artifical CSF or with various concentrations of morphine and opiate peptides. In our initial studies, racemic morphine sulfate was found to enhance the release of dopamine into the dialysate in a dose-dependent manner. DPDPE and DAGO produced similar effects. Unfortunately, however, these actions were only partially antagonized (25%) by naloxone. In addition, the (+) enantiomer of morphine was similar in potency with the (-) enantiomer. These findings suggest that opiate agonists probably do not exert their effects on dopaminergic function through dopamine terminals. Studies are underway to assess the participation of cell body regions.

THE PRESSOR RESPONSES OF CONSCIOUS RATS FOLLOWING INTRAVENOUS DYNORPHIN ADMINISTRATION ARE BLOCKED BY OPIOID, ALPHA ADRENERGIC AND VASOPRESSINERGIC RECEPTOR ANTAGONISTS. J.A. Thornhill, L.L. Gregor and Q.J. Pittman. Univ of Sask., Saskatoon, Sask. & Univ of Calgary, Calgary, Alta. Canada S7N 0W0.

Experiments were designed to determine the hemodynamic responses of conscious rats following intravenous (iv) dynorphin A_{1-13} administration and the receptor mechanisms mediating these changes. Male, Sprague-Dawley rats (≈300g body wt) were given iv bolus injections of dynorphin A_{1-13}, noradrenalin (NA), angiotensin II or sterile saline. IV administration of dynorphin A (20 nmoles/kg to 2 μmoles/kg) evoked dose-related pressor responses which were not attenuated upon repeated administration (i.e. no tachyphylaxis). Intravenous pretreatment with opioid antagonists (naloxone or MR2266) α-receptor antagonists, (yohimbine, prazosine or phentolamine)$_2$or the specific AVP-V_1 antagonist (d[$(CH_2)_5$-O-Me-(Tyr)^2, Arg^8] AVP given 10 min prior to iv dynorphin showed that all of these receptor antagonists could attenuate, or with higher concentrations, block the subsequent pressor response to iv dynorphin administration. These results suggest that in the conscious rat model the dynorphin A evokes a vasoconstrictor action, a response that can be blocked by kappa opioid as well as non-opioid (alpha adrenergic and vasopressinergic) receptor antagonists. This work was supported by the Canadian Heart Foundation.

KAPPA RECEPTOR MEDIATION OF VTA OPIOID-ELICITED FEEDING BEHAVIOR. Margaret E. Hamilton & Michael A. Bozarth. SUNY at Buffalo, Dept. of Psychology, Buffalo, NY. 14260.

The role of opioids in the ventral tegmental area (VTA) in feeding behavior was further explored. Opioid peptides were microinjected unilaterally in a volume of 0.5 μl into the VTA of non-deprived, freely moving rats and behavior was observed for 15 minutes. Dynorphin A (0--3.0 pmoles) or the Met-enkephalin analog DALA (0--3.0 nmoles), but not β-endorphin (0--100 pmoles) or the Leu-enkephalin analog DADLE (0--3.0 nmoles) elicited dose-dependent feeding. Similar to earlier findings between dynorphin(1-13) and morphine, dynorphin A was approximately 10,000 times more potent than DALA in producing feeding. This is consistent with the notion that the effect of opioids in the VTA on feeding may be mediated by kappa receptors. A role for mu receptors in the VTA in spontaneous feeding behavior remained possible, however, and kappa involvement required confirmation. The selective kappa agonist, U-50,488H (0--10 pmoles) elicited dose-dependent increases in total feeding durations. In contrast, total feeding was not significantly different from vehicle control among rats that received the mu agonist DAGO. These findings confirm that feeding elicited by opioids in the VTA is mediated by kappa receptors. It appears that kappa activation may promote the maintenance of naturally rewarding behaviors such as feeding.

ALTERATIONS IN POSTSYNAPTIC B-ADRENERGIC FUNCTION ACCOMPANY MORPHINE DEPENDENCE AND WITHDRAWAL. H.C. Moises AND C.B. Smith*+. Depts. of Physiology and Pharmacology+, University of Michigan, Ann Arbor, MI 48109.

We recently reported that B-adrenergic receptors are increased in various brain areas in rats after chronic morphine treatment and subsequently down-regulated during opiate withdrawal (Brain Res. 400, 1987). In this study, measurements of [3H]-dihydroalprenolol (3H-DHA) binding in hippocampus were carried out in conjunction with electrophysiological recording in vitro to determine whether such adjustments in receptor density might be of functional significance. Alterations in postsynaptic B-receptor function were assessed by comparing the ability of isoproterenol (ISO) to increase population spike responses and to block the calcium-dependent potassium after-hyperpolarization (AHP) in pyramidal neurons in hippocampal slices from saline and chronic morphine-treated rats.

Treatment of rats with increasing doses of morphine (up to 100mg/kg/inj., t.i.d.) for 14d resulted in a 19% in the Bmax for [3H]-DHA, whereas B-receptor density was decreased 27% in withdrawn subjects, compared to controls. No changes were found in the affinities of the receptors for [3H]-DHA or the agonists NE and ISO. Electrophysiological testing in CA1 revealed that extracellular responses to threshold (25nM) as well as maximal concentrations (500nM) of ISO were significantly enhanced in slices from dependent rats, whereas responsiveness to maximal concentrations of ISO was decreased, relative to controls, in slices from withdrawn subjects. In addition, the EC50 for ISO in reducing the AHP was significantly lower for dependent (360nM) and greater for withdrawn groups of slices (2.2uM), respectively, than for controls (820nM). These data suggest that long-term opiate administration and opiate withdrawal are accompanied by functional alterations in postsynaptic B-adrenergic systems (supported by NIDA grant DA-03365).

461.16

EFFECTS OF MONOAMINE ANTAGONISTS ON OPIOID-INHIBITION OF THE MILK-EJECTION REFLEX. G.Clarke & D.M.Wright. Dept. of Anatomy, Univ. of Bristol, & Upjohn Ltd. Crawley, U.K.

Opioids inhibit the milk-ejection reflex by suppressing the release of oxytocin, through more than one type of opioid receptor and at several sites. Monoamine and opioid systems are often interactive, therefore we examined the effect of monoamine antagonists on opioid inhibition of the milk-ejection reflex in the rat.

The opioids fentanyl (mu agonist) and U50-488H (kappa agonist) inhibited the suckling-evoked release of oxytocin. This inhibition was reversed by 1mg/kg and 10 mg/kg doses of naloxone respectively, and also by ketanserin (1mg/kg) a (S2 selective) serotonin antagonist. The β-adrenoceptor antagonist propranolol (1mg/kg) reduced the inhibition induced by U50-488H but not that of fentanyl. In contrast the other monoamine antagonists tested, phentolamine (α-adrenoceptor antagonist), haloperidol (dopamine antagonist) and cyproheptadine (non selective serotonin antagonist) were without effect.

The results suggest that: 1) Serotonin systems, acting through an S2 site, are involved in the inhibition of oxytocin secretion by both mu and kappa agonists. 2) The adrenergic system, acting through a α/β site, contributes to the kappa effect. (SPON: ENA)

461.17

MET-ENKEPHALIN STIMULATES ADRENERGICALLY-MEDIATED VASOCONSTRICTION IN RAT STRIATED MUSCLE.

J.W. Brock* and I.G. Joshua* (SPON: A. Jimenez). Dept. of Physiology and Biophysics, School of Medicine, University of Louisville, Kentucky 40292.

An endogenous opioid system may modulate peripheral vascular resistance in the rat. Small resistance vessels (6-15 μm) in rat striated muscle have demonstrated naloxone-sensitive constriction in response to topically administered methionine-enkephalin (MET). In this study, the mechanism of enkephalin-induced vasoconstriction was investigated using male, Sprague-Dawley rats, which were anesthetized with Na+ pentobarbital (50 mg/kg, i.p.). The microcirculation in the cremaster muscle (striated muscle) was observed using in vivo television microscopy. Arteriolar responses to topical application of MET (10^{-6}M) were observed before and after 1) the topical addition of phentolamine (PHE; 10^{-6}M), an alpha-adrenergic antagonist, 2) the topical addition of prazosin (PZN; 10^{-6}M), an alpha-1 adrenergic antagonist, and 3) local denervation with 6-hydroxydopamine (6HD; 10^{-6}M). MET induced vasoconstriction (66 ± 7 % of control diameter), which was abolished in the presence of PHE (101 ± 1%), PZN (108 ± 4%), and 6HD (108 ± 7%). These data suggest that met-enkephalin functions by stimulating the release of norepinephrine from sympathetic nerves supplying the striated muscle microcirculation. (Supported by grants from the Amer. Heart Assoc. and the Univ. of Louisville Med. Sch.).

OPIOID AGONISTS AND THE REGULATION OF NEUROTUMOR GROWTH.

L. Nagy*, P.J. McLaughlin and I.S. Zagon (SPON: R. Hamilton). Dept. Anatomy, Penn. State Univ. College of Medicine, Hershey, PA 17033.

Neural tumor tissue is known to possess endogenous opioids and opioid receptors. A study was conducted to determine which opioid ligand-receptor complex is most effective in modulating neuro-oncogenesis. Ajax mice were inoculated with 10^6 S20Y neuroblastoma cells and injected daily with methionine enkephalin (ME)(0.5-30 mg/kg); tumor size and appearance, and survival were monitored. On day 12, a time when 100% of control mice had a tumor, the number of mice having measurable tumors (>5 mm) was significantly reduced for mice receiving 0.5-30 mg/kg ME. At the time when 100% of control mice were dead, 10-33% of mice in the ME groups were alive. The antitumor effects of ME on tumor growth were reversed by naloxone. Study of other opioid agonists showed that daily injection (10 mg/kg) of DADLE or EKC, prototypic ligands for δ and κ receptors, respectively, had no effect on tumorigenic events. These results corroborate tissue culture studies identifying ME as a potent and natural trophic agent influencing neural cancer. Supported by NIH grant NS-20623.

461.19

PAIN PERCEPTION IN THE RAT IS MODULATED BY GONADAL STEROIDS.

L.J. Forman, Dept. of Medicine, UMDNJ-SOM, Camden, NJ 08103.

In the rat, gonadal steroids influence central and peripheral levels of the endogenous opioid peptide, beta-endorphin. As an assessment of total endogenous opioid activity, the time to respond to a noxious somatic stimulus (tail flick latency and paw lick/jump lactency) was measured in castrated and castrated gonadal steroid replaced male and female rats. Rats were castrated for two weeks prior to testing. At the end of the third week, gonadal steroid treatment was initiated and maintained for three weeks in half of the animals, while the remaining animals received the vehicle and served as castrated controls. The tail flick latency was significantly increased in castrated male rats at 1, 2 and 3 weeks of testosterone proprionate (TP) treatment. The time to paw lick or jump was greater in castrated male rats only after 3 weeks of treatment with TP. In castrated female rats the tail flick latency was increased 2 and 3 weeks after estradiol benzoate (EB) treatment was begun, while the time to paw lick or jump was reduced with 2 and 3 weeks of treatment with EB. These data indicate that gonadal steroids modulate the perception of pain in male and female rats and that the this modulation may vary according to sex and the stimulus employed.

461.20

MODIFICATION OF PERIPARTURITIONAL PAIN THRESHOLD BY INGESTION OF AMNIOTIC FLUID IN THE RAT.

M.B. Kristal, A.C. Thompson*, P. Abbott*, J.M. Di Pirro*, E.J. Ferguson*, and J.C. Doerr*. Department of Psychology, SUNY at Buffalo, Buffalo, NY 14260

Amniotic fluid (AF) and placenta contain a substance(s) (placental opioid-enhancing factor, POEF) that when ingested by nonpregnant rats, enhances (but does not cause) any opiate-mediated analgesia they are experiencing (e.g., morphine, or vaginal/cervical stimulation): 0.25 ml amniotic fluid or 1 placenta being the optimal doses for enhancement of a 3 mg/kg morphine injection.

Preliminary data suggested that opioid enhancement is a significant benefit of amniotic-fluid- (and placenta-) ingestion to the mother during the periparturitional period. Depriving parturient rats of amniotic fluid, is apparently impossible to do without interfering with delivery, stressing the mother inordinately, or interfering with the measurement of pain threshold, we have been trying to get at the answer indirectly by infusing amniotic fluid in the last few hours before the start of delivery (before the mother normally has access to it), and examining changes in enhancement of pregnancy-induced analgesia, as measured by tail-flick latency in a hot-water tail-dip test.

We assessed the effect of 3 doses of AF on pain thresholds in late-pregnant rats both with and without naloxone pre-treatment. They were assessed prepartum, after the delivery of the 1st pup, and 40 min and 2 hrs after delivery of the last.

Results: (a) larger doses produce greater enhancement; (b) the longer the Interval between the Prepartum test and the Onset of Delivery (the IPrOD), the greater the enhancement. Prepartum AF lowers pain thresholds during parturition and after delivery, if the dose of AF is low and the IPrOD is short. Naloxone pretreatment lowers pain thresholds during (a) the prepartum, parturitional, and postpartum period in AF-fed rats, (b) the prepartum period in control rats, and (c) the parturitional and postpartum period in control rats with short IPrODs.

Mother rats do show increased analgesia resulting from ingestion of amniotic fluid in the periparturitional period. The enhancement is complex, however; POEF may have a bi-phasic action, and may even enhance opioid antagonists such as naloxone.

PEPTIDES: BIOSYNTHESIS, METABOLISM AND BIOCHEMICAL CHARACTERIZATION IV

462.1

EFFECTS OF NAALADASE INHIBITORS ON [^{3}H]NAAG METABOLISM *IN VIVO*.

B.L. Stauch, M.B. Robinson, G. Forloni and J.T. Coyle. Depts. of Pharmacology and Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

The endogenous brain peptide, N-acetyl-aspartyl glutamate (NAAG), has been proposed as an excitatory neurotransmitter. Recently, a quisqualate (Quis) and phosphate-sensitive membrane bound metallopeptidase, NAALADase, which cleaves NAAG to glutamate and N-acetylaspartate, has been identified and purified. To determine whether NAALADase plays a role in the catabolism of NAAG *in vivo*, we have examined the effects of intrastriatal co-injection of NAALADase inhibitors on [^{3}H]NAAG metabolism. [^{3}H]NAAG (10 pmoles), radiolabelled on the glutamate residue, was dissolved in isotonic saline and infused by a microliter pump via a cannula stereotaxically placed in the striata of rats anesthetized with pentobarbital. The rats were decapitated 5 min after the infusion and their striata were quickly dissected on ice and extracted in ice-cold methanol. [^{3}H]NAAG and [^{3}H]glutamate were separated by ion exchange chromatography over AG1-X8 resin. The apparent $t_{1/2}$ for [^{3}H]NAAG degradation in striatum was 3.4 min. Co-injection of 25 mM phosphate (IC_{50} = 100 μM) slowed the $t_{1/2}$ of [^{3}H]NAAG to 7.8 min; the addition of 100 pmoles of Quis (IC_{50} = 0.5 μM) further inhibited metabolism by an additional 35%. To control for the potential excitatory effects of Quis, 100 pmoles of kainic acid (IC_{50} > 100 μM) and of NMDA (IC_{50} > 100 μM) were co-injected but were devoid of inhibitory effects on [^{3}H]NAAG metabolism. Co-injection of dithiothreitol (50 mM), which presumably binds the metallo-cofactor of NAALADase, inhibited [^{3}H]NAAG metabolism by 38%. Thus, co-injection of agents that inhibit NAALADase activity in three different ways prolongs NAAG catabolism *in vivo*, consistent with a role in endogenous NAAG disposition.

462.2

PURIFICATION OF N-ACETYLATED ALPHA-LINKED ACIDIC DIPEPTIDASE (NAALADASE) FROM RAT BRAIN AND KIDNEY.

M.B. Robinson, B.L. Stauch, S.S. Richards, D.A. Geller * and J.T. Coyle. Depts. of Neuroscience and Pharmacology, The Johns Hopkins University School of Medicine, Baltimore MD, 21205.

Based on electrophysiological, immunocytochemical and release studies, N-acetyl-aspartylglutamate (NAAG) is a putative excitatory neurotransmitter in the mammalian CNS. One potential mechanism for NAAG inactivation is via a dipeptidase (NAALADase), which degrades NAAG to N-acetylaspartate (NAA) and glutamate and may be coupled to sodium-dependent high affinity glutamate uptake. This peptidase is restricted to kidney and neural tissue.

We have solubilized the peptidase from both brain and kidney with Triton X-100 followed by sequential column chromatography. Both brain and kidney NAALADase are resolved into two peaks over DEAE-Sepharose. The activity of all peaks is inhibited by preincubation with EGTA or dithiothreitol, by quisqualate and phosphate, and is activated by cobalt; the inhibition or activation occurs at similar concentrations to that observed for the native membrane-bound peptidase. The first DEAE peak of brain NAALADase activity was further purified with CM- and Concanavalin A-Sepharose and Sepharose CL-6B chromatography; on each of these columns only one peak of activity was observed. We estimate that NAALADase is enriched over 5,000-fold by this purification; however, the activity is unstable after the DEAE step. Size exclusion chromatography suggests a molecular weight of approximately 190 kDa. Silver stained SDS gels of fractions surrounding the NAALADase peak of activity from CM- and size columns show enrichment of a 90 kDA band. Only 5 protein bands remain after these steps. NAALADase, defined as a quisqualate- and phosphate-sensitive metallopeptidase which degrades NAAG to NAA and Glu, is the only route of NAAG degradation observed to date.

462.3

PRODUCTION AND CHARACTERIZATION OF MONOCLONAL ANTIBODIES TO N-ACETYL-ASPARTYL-GLUTAMATE.

C. Frondoza*, S. Logan, G. Forloni and J.T. Coyle (SPON: M.E. Blue). The Johns Hopkins Medical Institutions, The Oncology Center and Dept. of Neuroscience, Baltimore, MD 21205.

N-acetyl-L-aspartyl glutamate (NAAG) is thought to be a putative neuromodulator/neurotransmitter in the mammalian nervous system. Immunohistochemical studies with polyclonal NAAG antisera have revealed immunoreactive neurons and processes in several brain regions. However, these antisera crossreacted to some degree with N-acetyl-aspartate (NAA), which is present in mM concentrations in brain, prompting the development of monoclonal antibodies more specific for NAAG.

By fusing spleen lymphocytes from a BALB/c mouse preimmunized with NAAG-bovine serum albumin conjugate with SP2/0-Ag 14 mouse myeloma cells, we produced three monoclonal IgG 2a (kappa) antibodies that specifically reacted with NAAG. These antibodies did not crossreact with NAA nor with structurally similar peptides as shown by solid phase radioimmunoassay. Antibody activity was absorbed out selectively by both NAAG-thyroglobulin conjugate and free NAAG. These monoclonal antibodies stained numerous nuclei of the medulla-pons and midbrain, mitral cells in the olfactory bulb, pyramidal neurons in sensorimotor cortex, locus coeruleus and several cholinergic cranial nuclei. The staining pattern strongly correlated with NAAG levels determined by HPLC. Monoclonal antibodies significantly enhanced sensitivity of staining, allowing visualization of dorsal horn neurons in spinal cord which were not readily detectable with polyclonal antiserum.

Availability of these monoclonal antibodies now facilitates further clarification of the role of NAAG in the brain.

462.4

CO-VARIANCE OF NAAG LEVELS AND NAALADASE ACTIVITY IN ADULT RAT CNS: A MICROPUNCH STUDY.

S.S.Richards, G.Forloni, M.B.Robinson and J.T.Coyle. Dept. of Neuroscience, The Johns Hopkins Univ. School of Med., Balto. MD, 21205.

NAAG is an acidic neuropeptide which has been implicated in excitatory neurotransmission. NAALADase is a membrane bound, quisqualate sensitive metallopeptidase specific for N-acetylated, α-linked acidic dipeptides which cleaves NAAG to N-acetyl-aspartate and glutamate. Both NAALADase and NAAG are nonuniformly distributed across rat CNS, although the correlation between their localizations is unclear. In order to elucidate the *in vivo* relationship between NAAG and NAALADase, we examined the levels of both in micropunch dissections in rat CNS. Furthermore, we examined the response of NAALADase activity to enucleation of the eye.

Micropunch dissections of 21 discrete brain nuclei and spinal cord regions were assayed for both NAALADase activity and NAAG levels. NAALADase activity was determined by the amount of [^{3}H]NAAG which was metabolized to [^{3}H]glutamate. NAAG was quantitated using a radioimmunoassay. NAALADase activity exhibited a 5-fold variation among the structures assayed. The correspondence between peptidase activity and NAAG levels was variable. Regions where both the peptidase and the neuropeptide were in relatively high amounts include locus coeruleus and dorsal raphe. A region where NAALADase activity was high while NAAG levels were low is cerebellum. Low NAALADase activity and high NAAG levels occurred in the optic tract and red nucleus. To investigate the regulation of the peptidase in response to altered levels of NAAG, rats were enucleated unilaterally with a subsequent determination of NAALADase and NAAG in the optic tract and superior colliculus at 1, 2, 3, and 4 weeks after the lesion. While NAAG levels decreased in the optic nerve ipsilateral to the lesion and in the contralateral superior colliculus, NAALADase activity increased in both regions. These results suggest that NAALADase may have another role *in vivo* in addition to the degradation of NAAG. The up-regulation of the peptidase activity in response to neuronal degeneration indicates that the peptidase may be expressed in non-neuronal cells.

462.5

CALCIUM-DEPENDENT EVOKED RELEASE OF [^{3}H]N-ACETYLASPARTYLGLUTAMATE FROM THE OPTIC TRACT.

G. Tsai, G. Forloni, M.B. Robinson and J.T. Coyle. Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

N-acetylaspartylglutamate (NAAG) is a neuropeptide localized to several glutamatergic systems, including the rodent optic pathway. To determine whether the peptide is released by depolarization, the superior colliculus of the rat was perfused with 2 μCi of [^{3}H]NAAG followed by one hour with Krebs bicarbonate buffer, using a microdialysis system. Subsequently, 10 min fractions were collected and analyzed for [^{3}H]NAAG by HPLC. Addition of 100 μM veratridine resulted in a eight-fold increase in the evoked release of [^{3}H]NAAG, which was virtually abolished by co-perfusion with Krebs buffer devoid of Ca^{2+}, containing 1mM EGTA. The basal level after labeling with [^{3}H]NAAG appears to be associated predominantly with glutamate, and veratridine depolarization has little effect on this release. Prior enucleation of the right eye reduced the basal level of [^{3}H]NAAG release by 50%, and the veratridine evoked release by greater than 85%, from the left superior colliculus. Preliminary studies indicate that [^{3}H]glutamate subjected to the same procedure of labeling, washout and evoked release results in less than two-fold increase in release of tritium associated with NAAG on HPLC. Thus, with [^{3}H]NAAG as the substrate, a more specific labeling of a discrete population of presumed nerve terminals may be accomplished than when [^{3}H]glutamate itself is used as a precursor. These results suggest that NAAG is released upon depolarization and may serve as a neurotransmitter/neuromodulator in the optic tract.

462.6

IDENTIFICATION AND PURIFICATION OF RAT BRAIN T-KININOGEN.

N. Marks, F. Stern*, L. Qui* and M.J. Berg*. Ctr.for Neurochem., N.S. Kline Inst. Ward's Island, NY, NY 10035.

T-kinin (Ile-Ser-bradykinin) present in tissues and body fluids is derived from trypsin sensitive T-kininogens, one of which is identical to plasma α$_1$-major acute protein (α$_1$-MAP). The latter increases in adjuvant treated rats or ones with experimental inflammation. In studies on cysteine proteinase inhibitors (CPI's) from rat brain, we isolated from cytosol and membrane fractions an 80 kDa glycoprotein liberating kinin(s) upon incubation with trypsin but not glandular kallikrein when assayed on the isolated rat uterus. Inhibitor was purified by alkylated papain affinity chromatography and shown by immunoblots to cross-react with a histidine-rich glycoprotein (HRG) but not anticystatin C, antilysozyme or anti-β-protein amyloid. Rat brain contained 0.5 nmol per g wet weight. The 80 kDa CPI suppressed at low concentration brain cathepsin L cleavage of Leu-enkephalin at Gly-Gly bond (to yield Tyr-Gly) with K_i 10^{-11} M. T-kininogen was present in all subcellular fractions including nuclear (P1) and microsomal (P3) particulates, post-microsomal supernatant (S3), but was the only CPI found in P2-synaptosomes. The presence of CPI's in high concentration is of interest to lysosomal regulation, protein turnover, formation of neuropeptides (T-kinins) or abnormal (amyloid) deposits.

Supported in part by grant NIDA 04178.

462.7

HUMAN DBI AND ITS PROCESSING PRODUCTS IN BRAIN AND CSF.

P. Guarneri, M.L. Barbaccia, A. Guidotti and E. Costa., FGIN, Georgetown Univ., Washington, D.C. 20007.

The structure of an 11k Da polypeptide, termed DBI (Diazepam Binding Inhibitor) purified from human brain (H-DBI) was determined by recombinant DNA technology. In rat brain DBI is processed into 3 biologically active allosteric modulators of $GABA_A$ receptor subtypes. We wanted to test whether H-DBI, which similar to rat DBI elicits a proconflict effect and inhibits beta-CCM binding, is processed in human brain into natural allosteric modulators of $GABA_A$ receptor subtypes. The technology for the purification of these H-DBI putative processing products, using specific antibodies raised in rabbits against fragment 51-70 (eikosaneuropeptide, ENP), will be reported. ENP was first obtained through tryptic digestion of purified H-DBI and shown to be as potent as H-DBI in eliciting proconflict behavior in rats. In acetic acid extracts of human brain tissues or CSF at least two peaks of ENP-like immunoreactivity were detected. While we are obtaining the amino acid sequence of these putative natural ligands, we are studying the content of DBI and its processing product in the CSF of patients suffering from various neuropsychiatric disorders.

462.8

TYROSYLPROTEIN SULFOTRANSFERASE: DISTRIBUTION AND POST-NATAL DEVELOPMENT.

S. Rens-Domiano* and J.A. Roth Dept. Pharmacology and Therapeutics, SUNY at Buffalo, Buffalo, NY 14214

Sulfation of tyrosine residues is a ubiquitous post-translational modification of biologically active peptides and proteins which is catalyzed by the golgi enzyme, TPST. The activity was measured using a filter paper assay with PAPS and Poly Glu_6,Ala_3,Tyr_1 as the sulfate donor and acceptor substrate, respectively. TPST activity was found in crude microsomal fractions prepared from livers of rabbit, rat, mouse, hamster and human. In rat, TPST activity was highest in liver, although appreciable activity was also seen in lung, spleen, heart, kidney and salivary gland. In rat brain TPST was found to be most abundant in the pituitary and cerebellum although, significant activity was also found in the hypothalamus, striatum, cerebral cortex and hippocampus. TPST activity in liver increased during post-natal development approximately five-fold from day 1 after parturition to day 5, at which time adult levels were attained. In contrast, rat cerebellar TPST activity increased only 2.5-fold from Day 1 to Day 8 at which time activity began to decline, reaching adult levels around Day 28. In neither the rat liver nor cerebellum were any significant differences in TPST activity observed during development of male or female rat pups. (Supported by NIH Grant ES20530 and by a PMAF Fellowship)

462.9

ROLE OF AN α -HELIX IN THE RECOGNITION OF DIAZEPAM BINDING INHIBITOR (DBI) FOR THE DIFFERENT TYPES OF BENZODIAZEPINE (BZ) RECOGNITION SITES.

A. Berkovich, P. Hensley*, P. McPhie*, D. Cox*, C. Wambebe, M. Campagnone*, A. Guidotti, E. Costa., FGIN, Georgetown Univ., Washington, D.C. 20007.

To interpret in structural terms interactions of rat DBI with BZ recognition sites, we used secondary structure prediction methodology (Chou, P.Y., Fasman G.D., Biochemistry-13; 222, 1974) and analysis of hydrophobicity (Kyte, J., Doolittle, R.F., J. Mol. Biol. 157; 105; 1982). We synthetized the DBI peptides(17-50),(18-50),(22-50),(26-50) and (33-50) by solid phase methodology. CD spectrum of DBI (17-50), (18-50), (22-50) demonstrated α -helical structure in MeOH. Pharmacological studies revealed that these peptides injected intraventricularly in rats causes proconflict activity. In primary cultures of cerebellar granular cells DBI peptide (33-50), displaced [^{3}H]flumazenil with K_i of $\sim$ 5 μM; the other synthetic peptides were ineffective in concentrations up to 200 μM. In primary culture of the cerebellar glial cells the peptides with stable α -helical structure DBI (17-50), (18-50), (22-50) were able to displace [^{3}H]PK11195 with K_i $\sim$ 10 uM. DBI (26-50)and (33-50) which lack the α-helical part of their structure were ineffective.

PURIFICATION FROM BRAIN OF AN ORGANIC INHIBITOR OF ^{3}H-OUABAIN BINDING.

P.S. McQuade, D.A. Stein* and F.S. LaBella. Dept. of Pharmacology, Univ. of Manitoba, Winnipeg, Manitoba, Canada R3E 0W3.

Whole rat brains were dried and defatted using separate acetone and petroleum ether extractions. After 0.2 M acetic acid extraction the peptide fraction was chromatographed on a Sephadex G-25 column and the fractions were monitored using the Lowry reaction. Those fractions of 1,000 to 5,000 daltons were rechromatographed on a Bio Rad AG-50 column to remove sodium and potassium. 100 ug of either fraction 4 or 5 reduced ouabain binding to 83% of control. These fractions did not inhibit naloxone, spiperone, verapamil or muscarinic binding. This material (5 mg) was separated using HPLC on a C_{18} uBondapak column. A linear gradient of 0.1% trifluoroacetic acid (TFA) in water to 100% 0.1% TFA in acetonitrile resolved two peaks of ouabain inhibiting activity. The smaller more hydrophobic peak produced a 10% decrease in ouabain binding. The hydrophilic peak was rechromatographed using a slower gradient (only to 50%-0.1% TFA in acetonitrile. This material weighed 1.5 mg, was 18% protein and 100 ug decreased ouabain binding to 78% of control. Ashing (600°C for 1 hr) completely abolished activity. (Supported by the Health Sciences Centre Research Foundation, the Medical Research Council of Canada and the University of Manitoba).

462.11

PURIFICATION OF L-ASPARTATE N-ACETYLTRANSFERASE FROM RAT BRAIN,

H. M. Valivullah*, M.E. Trucken-miller, G. C. Mathews*, M. A. A. Namboodiri and J. H. Neale (SPON: D. Eagles) Dept. of Biology, Georgetown University, Washington, D. C. 20057.

L-aspartate N-acetyltransferase (ANAT), a nervous system specific enzyme, mediates the acetylation of L-aspartate by acetyl-coenzyme A. The product, N-acetylaspartate, is a predominant acidic amino acid in the nervous system and may serve as a precursor in the biosynthesis of the dipeptide, N-acetylaspartylglutamate.

ANAT was solubilized from brain membranes in 1% Triton X-100 in 10 mM phosphate buffer, pH 6.8. The solubilized enzyme passed through a DEAE-anion exchange column at pH 7.0 and the unbound fraction, containing most of the enzyme, was further purified by anion exchange HPLC at pH 8.1. The active peak fractions were pooled and subjected to gel filtration HPLC followed by affinity chromatography on an L-aspartate immobilized column. The eluate showed a 600-fold increase in specific activity and 2-3% yield.

This purification will support analyses of the regulation and cellular distribution of ANAT, contributing to an understanding of the function of N-acetylaspartate. (grant DA 02297)

462.12

NEWLY SYNTHESIZED PEPTIDE IS FIRST TRANSPORTED TO RELEASE SITES: AUTORADIOGRAPHIC EVIDENCE FROM A CRAB NEUROSECRETORY SYSTEM.

E. Stuenkel, E. Gillary* and I. Cooke. Békésy Laboratory of Neurobiology, and Dept. of Zoology, University of Hawaii, Honolulu, HI 96822.

Preferential release of newly synthesized peptide has been found for all neurosecretory systems tested. This study shows that granules containing biosynthetically radiolabelled material are first transported to release sites. Later they become intermixed with non-labelled granules. The X-organ - sinus gland system of crabs (Cardisoma carnifex) was isolated and arranged to permit independent perfusion of the somata (X-organ) and terminals (sinus gland). The somata were given a pulse (5 min to 5 h) of ^{3}H-leucine in crab saline with glucose, while the terminals were continuously perfused with nutrient medium. Systems were chased for 1 - 72 h. The material was examined by light- and EM autoradiography (7 d exposures). At 1 h, exposed grains occur primarily over granules in Golgi. At 10 h, radiolabel is in the axon tract with little in the terminals. By 19 h, label is found preferentially in terminals abutting the internal hemolymph sinuses. After 72 h, label is evenly distributed throughout release and storage sites. Exocytotic profiles, indicative of release sites, have only been observed where terminals abut a hemolymph sinus (Weatherby, 1981, Cell Tissue Res. 220:293). Transported label represents hormonal peptides, and these are secreted by a Ca-dependent mechanism (Stuenkel, 1983, J. Comp. Physiol. **B153**:191; 1985, J. Physiol. **359**:163). Thus, the autoradiography provides a physical basis for preferential release of newly synthesized peptides. Supported by NSF BNS84-04459 and NIH NS 15453.

DETERMINATION OF NEUROPEPTIDES AND CYCLIC-AMP BY HIGH PERFORMANCE CAPILLARY ELECTROPHORESIS.

N. A. Guzman*, L. Hernandez and B. G. Hoebel (SPON: D. B. Nuzzio). Dept. Psychology, Princeton Univ., Princeton, NJ 08544, *Princeton Biochemicals Inc., Princeton, NJ 08543.

Radioimmunoassays for neuropeptides and cyclic-AMP are time consuming because they are based on radiolabeled compounds with segregation of a mixture performed by antibodies. Liquid chromatography can resolve a mixture of neuropeptides, but is not sensitive enough for some applications. We overcame some of these difficulties using high performance capillary electrophoresis (HPCE). Separation of a mixture of peptides and cyclic-AMP was performed in an untreated fused silica microbore tube (75 um x 100 cm) using a mobile phase of 0.05 M sodium tetraborate, pH 8.3. The test mixture contained neurotensin, met-enkephalin, leu-enkephalin, substance P, angiotensin II, sulfated cholecystokinin-8 and cyclic-AMP. Detection was performed with a modified Hitachi UV detector. Samples (4 nl) were electrokinetically loaded applying 10 KV for 15 sec, and electroosmotic flow for separation was created with 22 KV. By reversing polarity the peptide zones were run forward and backward to determine the UV-spectrum of each substance. Linearity was tested with eight different concentrations of the mixture (range 10^{-4} M to 10^{-6} M). For all compounds the regression coefficient relating concentration of the standard to absorbance units was equal to 1.00. Compounds were well separated and the retention time error was less than 2% in nine different runs. Sensitivity was between 0.1 and 0.01 picomoles, and quantification of a sample lasted about 20 min per run. These results show that HPCE is reliable for neuropeptide and cyclic-AMP analysis.

462.14

GLIAL ASSOCIATION OF ANGIOTENSINOGEN (A_0) mRNA DEMONSTRATED BY COMBINED IN SITU HYBRIDIZATION AND GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) IMMUNOCYTOCHEMISTRY.

R.L. Stornetta, P.G. Guyenet, C. Hawelu-Johnson* and K.R. Lynch*. Dept. of Pharmacol., Univ. of Virginia School of Med., Charlottesville, VA 22908

Distribution of rat brain A_0 mRNA and in particular, the cell types associated with A_0 mRNA in brain, was determined by using in situ hybridization combined with immunocytochemistry in single brain sections. Two different hybridization probes for A_0 mRNA were used: a ^{35}S-labelled 42 residue oligonucleotide and a full-length A_0 RNA (antisense or sense) labeled with tritiated UTP. Rats were anesthetized with pentobarbital (60 mg/kg, ip) and perfused transcardially with 4% paraformaldehyde. Brains were extracted, cryoprotected and sections cut 10 μm thick on a cryostat and placed into prehybridization solution for 4-18 hrs at 37° C. Either ^{35}S-labelled oligonucleotide or ^{3}H-labelled sense or anti-sense A_0 mRNA was added to the sections at a concentration of 2-3 nM. Thirty-50 fold excess unlabelled 42-mer oligonucleotide was added to some sections as a control in the ^{35}S experiments. Sections were incubated at 37° C for 18 hrs (^{35}S probe) or 72 hrs (^{3}H probe), then washed though a graded series of salt solutions of decreasing concentrations with a final wash series with RNAase (for ^{3}H- labelled RNA) at 37° C followed by a 42° C wash (both probes). Sections were postfixed in 4% paraformaldehyde and standard peroxidase-anti-peroxidase immunocytochenistry for GFAP or microtubule-associated protein-2 (MAP, a neuronal marker) was performed. Sections were then mounted onto subbed slides, dehydrated, dipped in NTB2 emulsion and exposed at 4° C for 10-14 days (^{35}S) or 4-6 weeks (^{3}H) and developed with D-19. Clusters of silver grains were seen throughout the brain with higher concentrations in ION, NTS, PBN and many hypothalamic nuclei. Grains were primarily clustered over GFAP reactive cell soma and processes. Most grain clusters were not associated with MAP reactive cells. This confirms our previous findings that the distribution of brain A_0 mRNA overlaps many of the areas reported to contain high levels of angiotensinogen and further suggests that angiotensinogen in brain is synthesized primarily by glia. ALPHA BAG CELL PEPTIDE CAUSES PARALLEL REDUCTION OF STIMULATED cAMP LEVELS AND PRO-ELH BIOSYNTHESIS IN APLYSIA BAG CELLS. R.W. Berry. Dept. Cell Biology and Anatomy, Northwestern Univ. Sch. of Med., Chicago, IL 60611.

Alpha bag cell peptide (α-BCP), one of the multiple secretory products of the precursor to the egg-laying hormone (proELH) of bag cells, has been reported to exert excitatory (Rothman, et al., PNAS, 80:5753, 1983) or inhibitory (Kauer, et al., J. Neurosci., 7:3623, 1987) feedback on the cells which secrete it. Since pro-ELH synthesis in these cells is modulated by cAMP, it was of interest to determine if α-BCP causes parallel alterations in cAMP levels and precursor synthesis. In this study, the peptide had no effect on unstimulated bag cell cAMP levels or on elevation of cAMP levels by IBMX, indicating a lack of effect on basal adenylate cyclase activity. However, it reduced the cAMP elevations induced by forskolin, high potassium, and dopamine. Consistent with the hypothesis that proELH synthesis is accelerated by cAMP, α-BCP reduced precursor synthesis and cAMP production in parallel in forskolin-stimulated preparations, but did not reverse the stimulation of peptide synthesis caused by IBMX or depletion of intracellular Ca^{++}.

C-FOS mRNA EXPRESSION IN BRAIN INDUCED BY SUBCONVULSIVE DOSES OF CAFFEINE. T. Nakajima, J.L. Daval, P.F. Morgan, and P.J. Marangos[1]. Unit on Neurochemistry, BPB, NIMH, Bethesda, MD 20892 and [1]Gensia Pharmaceuticals, San Diego, CA 92121-1207.

In several previous reports, the proto-oncogene c-fos was shown to be induced by occupation of nicotinic acetylcholine receptors and depolorization-induced calcium influx in PC12 cells. It is also induced following various seizures. Caffeine is a non-selective adenosine receptor antagonist as well as a convulsant at high doses. We examined caffeine-induced c-fos expression and its pharmacological interaction at the mRNA level in mouse brain. Caffeine administration (17.5mg, 32mg, 56mg, and 100mg/kg i.p.) increased dose-dependently c-fos mRNA levels and at the convulsive dose (175mg/kg i.p. ED50 133mg/kg) c-fos levels were highest. A time-course study revealed that after caffeine injection, c-fos levels increased rapidly to reach a maximum at 15-30 minutes and declined progressively to basal levels at 4 hours. The pharmacological profile of subconvulsive caffeine-induced c-fos expression was also investigated, and suggests that both benzodiazepines and adenosinergic mechanisms may be involved in this system.

463.2

TRANSIENT CEREBRAL ISCHEMIA (TCI) INDUCES C-FOS ONCOGENE EXPRESSION IN THE RAT BRAIN. D.R. Gehlert, M.B. Jørgensen*, J Deckert and D.C. Wright. ETB and SNB, NINCDS, N.I.H., Bethesda, Maryland 20892, Neuropatologisk Institut, Copenhagen, Denmark and Universitats-Nervenklinik, Fuchsleinstr., Wurzburg, FRG.

The c-fos protein is a cellular product that appears in neurons rapidly following neuronal stimulation. The c-fos proteins are found in the nucleus and appear to be associated with chromatin. The c-fos protein has been implicated in changes in the long term function in cells such as those which may occur in learning and memory. The basal levels of c-fos in the brain are very low but are reported to increase rapidly following sensory stimuli. Therefore, we have examined c-fos mRNA in the brain following TCI.

Under anesthesia, the vertebral arteries of male, Sprague-Dawley rats were cauterized and the common carotid arteries were isolated and exposed. Twenty-four hours later severe forebrain ischemia was induced by occluding the common carotid arteries. Animals were killed at various time periods thereafter from 3 to 72 hours. The brains were removed and sectioned at 20 microns. Following formaldehyde post fixation, the sections were hybridized using a riboprobe labelled with ^{35}S-nucleotides (Lofstrand, Gaithersburg, MD). Hybridization was detected by autoradiography using sheet film or Kodak NTB-2 emulsion.

TCI resulted in a dramatic increase in hybridization for c-fos mRNA in the brain. In general, the expression followed the distribution and time course of TCI-induced damage in the brain. High levels of expression were seen in individual neurons of the caudate-putamen, CA1 of the hippocampus and in scattered neurons in the hilus of the area dentata. These results indicate that c-fos may play a role in the damage and recovery of brain neurons following TCI.

463.3

ADRENERGIC DRUGS PROMOTE CHANGES IN C-FOS mRNA LEVELS IN BRAIN. R.M.Gubits,T.Smith*+,J.L.Fairhurst* & H.Yu* Dvsn.of Pediatric Neurology,Columbia Univ. Coll. of Phys. & Surg.,NYC, NY 10032,+Dvsn.of Analyt. Pharm.,Nathan Kline Institute, Orangeburg, NY, 10962.

The proto-oncogene c-fos encodes a nuclear phosphoprotein, which is thought to act as a transcriptional factor for other specific genes. c-fos gene expression is readily detectable in adult mammalian brain and transiently inducible in neurons by seizure activity, cholinergic receptor agonists and depolarization. To examine the in vivo effects of adrenergic drugs on c-fos mRNA expression in brain, adult male rats were injected ip as follows:1.)vehicle (V) alone,2.)yohimbine (Y) (alpha2 antagonist) alone,3.)clonidine (C) (alpha2 agonist), propranolol (P)(ß-antagonist),or prazosin (Pz) (alpha1 antagonist), alone or preceding yohimbine injection. We observed a transient induction of c-fos mRNA after vehicle injection, which was enhanced and prolonged by Y injection. Either C or P suppressed the vehicle induction,while C,P, and Pz suppressed induction of c-fos mRNA by Y. These data are consistent with the hypothesis that c-fos mRNA levels increase as a result of the interaction of norepinephrine (NE) with the post-synaptic ß-adrenergic receptor. According to this interpretation, the effects of Y and C would be due to modulation of NE release by the autoinhibitory effect of the pre-synaptic alpha2 adrenergic receptor. Supported by NIH/GM38202 and Colleen Giblin Foundation.

LOCALIZATION OF INCREASED *c-fos* mRNA CONTENT IN RAT CNS FOLLOWING RECURRENT SEIZURES. Christine Gall, Amy Arai*, and Jeffrey White, Dept. of Anatomy and Neurobiology, Univ. of California., Irvine, CA 92717 and Div. of Endocrinology, SUNY, Stony Brook, NY 11794.

The product of the cellular proto-oncogene *c-fos* has been suggested to be a regulatory factor in gene transcription. Recently, several groups, including ourselves, have demonstrated that *c-fos* protein and/or mRNA content in the CNS is increased in response to seizures. In the present study, *in situ* hybridization autoradiography was used to evaluate the correspondence between changes in the abundance of mRNAs for *c-fos* and preproenkephalin A following seizure activity.

Bilateral recurrent seizures were induced by either unilateral electrolytic lesion of the dentate gyrus hilus (HL) or perforant path stimulation in anesthetized male rats. Perfusion-fixed tissue sections through forebrain of experimental and paired control rats were processed for the localization of *c-fos* mRNA using a ^{35}S-cRNA probe. Within 15min. of electrically stimulated seizure initiation, hybridization was increased exclusively within the dentate gyrus granule cell layer, bilaterally. At 3hrs post-HL, hybridization to *c-fos* mRNA was reliably greatly elevated within dentate gyrus stratum granulosum and layer II of piriform and entorhinal cortices. Modest increases in hybridization were also generally evident throughout hippocampal stratum pyramidale, olfactory tubercle, and anterior olfactory nucleus. By 6 hrs post-HL, hybridization density had declined somewhat in stratum granulosum whereas labeling of entorhinal cortex had not diminished from the 3hr time point. These data indicate an extremely rapid increase in the abundance of *c-fos* mRNA in most, but not all, areas in which preproenkephalin A mRNA becomes elevated in the same paradigm. The data are consistent with *c-fos* gene activation in response to seizures but further work, including examination of additional time points, is needed to determine if *c-fos* transcription is elevated in all areas which exhibit seizure-induced increases in enkephalin synthesis.

REGIONAL DISTRIBUTION OF EPIDERMAL GROWTH FACTOR mRNA IN THE MAMMALIAN CENTRAL NERVOUS SYSTEM. L. M. Lazar*, J. L. Roberts and M. Blum. (SPON: David E. Wolfe) Fishberg Center for Neurobiology, Mount Sinai School of Medicine, CUNY, New York, NY 10029.

Epidermal growth factor (EGF) is a mitogenic polypeptide, originally isolated from the male mouse submaxillary gland, which has been found to exert a neurotrophic effect on primary neuronal cultures. Recent investigations into the localization of EGF within the mammalian central nervous system have identified regions of mouse and rat brain which contain relatively high levels of EGF-immunoreactive material. While such demonstrations of EGF in the CNS might reflect protein sequestration and not brain-specific protein synthesis, another study utilizing dot-blot analysis has detected preproEGF mRNA in whole mouse brain preparations suggesting local CNS synthesis. Our studies use a more sensitive RNA quantitation assay to focus on the regional distribution of EGF-specific mRNA within the central nervous system of the adult male mouse in order to further explore the brain-specific expression and potential neurotransmitter-neuromodulator functions of this neuropeptide. Using a solution hybridization S1 nuclease protection assay, we have been able to detect as well as quantitate the levels of EGF-specific mRNA in several brain regions of the adult male mouse. Our preliminary studies reveal EGF-specific mRNA at levels of approximately 50 fg per ug total RNA in mouse cerebellum and striatum with no detectable EGF mRNA in cortex. We are currently investigating the developmental pattern of expression in these tissues.

463.6

IN SITU HYBRIDIZATION ANALYSES OF CA++/CALMODULIN-DEPENDENT PROTEIN KINASE II IN DEVELOPING RAT BRAIN. K. Burgin*, M. N. Waxham* and P. Kelly (SPON: R. Yip). Dept. of Neurobiol. and Anat., and Neurology, Univ. of Tex. Med. Sch., Houston, TX 77225.

Ca++/calmodulin-dependent protein kinase II (CK-II) is a multimeric enzyme consisting of nonstoichiometric amounts of two subunits, alpha (50K) and beta (60K). Although this kinase is highly concentrated in brain tissue, immunocytochemical analyses have shown that its distribution among different brain regions is highly variable. We have recently shown that the two subunits are expressed at different times and rates during rat forebrain development. In the present study we have extended earlier findings to the mRNA level. Using oligonucleotide probes specific for each subunit we have examined changes in subunit-specific mRNA levels and their distribution during rat brain development.

While the level of alpha subunit protein is barely detectable at postnatal day 5, its mRNA is already prominent at 4 days and exhibits a distribution similar to that described for the protein in adult brain. The strongest hybridization was associated with the hippocampal formation and olfactory bulb/cortex. The neocortex and various basal forebrain and diencephalic nuclei also showed significant hybridization, which increased with postnatal age. The cerebellum displayed alpha subunit mRNA primarily in the purkinje cell layer. Hybridization to beta subunit mRNA was also strongest in hippocampal and olfactory structures, followed by neocortex and basal forebrain nuclei. Unlike alpha subunit, hybridization to beta subunit mRNA in neocortex decreased with increasing age, and in cerebellum, was detectable in the granule as well as the purkinje cell layer. These results support previous findings indicating that the expression of the two CK-II subunits are differentially regulated during rat brain development.

463.7

TRANSFORMING GROWTH FACTOR BETA IN BRAIN TUMOR BIOLOGY. Harry T. Whelan and Harold L. Moses*. Depts. of Neurology and Cell Biology, Vanderbilt Univ., Nashville, TN 37232

We studied transforming growth factor beta (TGF-beta) in several clones of a virally induced canine glioma brain tumor cell line differing in their ability to produce brain tumors in vivo after intracerebral inoculation of the cells into dogs. In vitro colony formation and TGF-beta secretion by each clone correlated with in vivo tumorogenicity. In vivo tumor growth was documented pathologically in athymic "nude" mice (immunodeficient) as well as normal adult mongrel dogs. Only some of the brain tumor cell clones were able to produce brain tumors in normal dogs, however brain tumors were produced in all "nude" mice and all dogs pretreated with Cyclosporin.

Recent data (EMBO Jnl. 6:1633, '87) suggests that TGF-beta-1-or-2 is synthesized by human glioblastoma cells in vivo, contributing to impaired immunosurveillance and allowing brain tumor growth. We thus performed Northern blot hybridization on each clone to quantify Poly A mRNA for TGF-beta-1 and beta-2. The in vivo tumorogenecity of each brain tumor cell clone correlated with the amount of mRNA for both TGF-beta-1 and beta-2.

We postulate that TGF-beta stimulates glioma cell growth and inhibits host antitumor immune surveillance.

DIFFERENTIAL REGULATION OF G-PROTEIN mRNA BY ADRENALECTOMY AND CORTICOSTERONE TREATMENT IN RAT CEREBRAL CORTEX. N. Saito*, R.S. Duman, X. Guitart*, E.J. Nestler, and J.F. Tallman. Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Previous studies have demonstrated that corticosterone (CORT) or adrenalectomy (ADX) alters the adrenergic receptor-coupled cyclic AMP generating system in the brain. The biochemical alterations responsible for these changes could involve one or all of the components of this system, which include the receptors, guanine nucleotide binding proteins (Gsα, Goα, Giα and Gβ), and the catalytic unit of adenylate cyclase. In the present study, we examined the influence of ADX and CORT on G-proteins by measuring mRNA levels for Gsα, Goα, Giα and Gβ by hybridization blot analysis using specific cDNA clones for each subunit. In addition, the total amount of Gsα, Goα and Gβ subunits was determined by immunoblotting analysis.

Giα mRNA levels in cerebral cortex were increased by ADX, and CORT replacement reversed this effect; in addition, chronic CORT administration alone decreased Giα mRNA levels. Gsα mRNA levels were increased by chronic CORT and a corresponding increase in Gsα immunolabeling was also observed; in addition, ADX tended to decrease Gsα mRNA levels. Gβ mRNA levels also tended to increase after CORT, while Goα mRNA levels and immunoreactivity were not altered by ADX or CORT treatment.

The results represent the first demonstration of differential regulation of G-protein mRNA levels and immunolabeling in the nervous system. These alterations of G-protein subunits may in part account for the influence of glucocorticoids on the adrenergic receptor-coupled cyclic AMP system in brain.

463.9

MOLECULAR CLONING OF THE HUMAN SUBSTANTIA INNOMINATA: DETERMINATION OF BRAIN REGIONALLY EXPRESSED mRNAs. B. E. Boyes*, D. G. Walker*, P. L. McGeer and E. G. McGeer. (SPON: J. R. O'Kusky) Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, B.C., Canada V6T 1W5.

In the primate brain the substantia innominata (SI) contains a group of magnocellular neurons, the majority of which are cholinergic. As such, this brain region represents a favourable source of material to characterize the genes expressed by these central cholinergic neurons. In order to examine gene expression in this region, a recombinant cDNA library has been prepared in the plasmid vector pTZ18 using SI polyadenylated RNA obtained from a neurologically normal individual. The small amount of SI RNA that can be obtained is a major difficulty in differential library screening. To identify regionally specified expressed genes, the SI library was initially screened with cerebellar cDNA. Clones which did not generate a hybridization signal with highly labelled cerebellar cDNA were further investigated by using the cDNA insert for brain regional hybridization analysis using RNA prepared from human SI, cerebellum, neocortex, corpus callosum and caudate nucleus. SI clones have been identified which correspond to genes differentially expressed in these brain regions. The sequence and cellular localization of the corresponding mRNAs are under investigation.

Supported by a grant from the ADRDA, Inc., Chicago. Brain tissues were obtained from the Alzheimer's Program, which is supported by the MRC of Canada and the B.C. Medical Services Foundation.

PHORBOL ESTERS STIMULATE APPEARANCE OF ASYMMETRIC ACETYLCHOLINESTERASE IN TTX-TREATED QUAIL MUSCLE CULTURES. C. Fernandez-Valle* and R.L. Rotundo. Dept. of Anatomy and Cell Biology, Univ. of Miami, Sch. of Med., Miami, Fl 33101

The major acetylcholinesterase (AChE) forms synthesized by tissue-cultured quail muscle are globular monomers, dimers and tetramers and asymmetric molecules, composed of three tetramers covalently linked to a collagen-like tail. Inhibition of spontaneous muscle contraction with tetrodotoxin (TTX) prevents appearance of asymmetric AChE, the predominant enzyme form at the neuromuscular junction. This does not occur via changes in synthesis, activation or degradation of newly-synthesized AChE polypeptide chains, but rather through a 2-fold increase in the fraction of total AChE activity secreted by non-contracting muscle cultures. This is suggestive of a block in assembly of tetramers with collagen-like tail subunits in the golgi apparatus. We have found that activation of protein kinase C with phorbol esters stimulates the appearance of asymmetric AChE in TTX-treated cultures. Inhibitors of PIP2 hydrolysis decrease total AChE activity to levels observed in TTX-treated cultures without affecting contractile activity. These studies suggest that regulation of synaptic components may occur through activation of second messengers in response to membrane depolarization rather than contractile activity per se. This work was supported by grants from the MDA and NIH to RLR; CFV is a State of Florida Pre-doctoral Fellow.

EXPRESSION OF MULTIPLE ACETYLCHOLINESTERASE TRANSCRIPTS IN QUAIL MYOTUBES IS REGULATED BY MUSCLE ACTIVITY. W. R. Randall*, C. Fernandez-Valle*, and R. L. Rotundo (SPON: A. Boyne). Department of Anatomy and Cell Biology, Univ. of Miami School of Medicine, Miami, Florida 33101.

Multiple oligomeric forms of acetylcholinesterase (AChE) expressed in avian and Torpedo nerves and muscle are encoded by a single gene. Using AChE-1 Torpedo cDNA as a probe (Schumacher et al., Nature 310: 407, 1986) we have isolated cDNA clones encoding quail AChE catalytic subunits. The identity of two cDNA clones was confirmed by DNA sequence analysis. Comparison of deduced amino acid sequences of Torpedo and quail AChEs so far obtained shows greater than 50% identity. One cDNA >4.5 kb is large enough to encode the entire open reading frame. Northern blot analysis of quail brain and muscle poly A+ RNA indicates the presence of multiple AChE transcripts in the range of 4.8 to 6 kb. Quail myoblasts express several AChE transcripts and synthesize membrane-bound and secreted AChE forms. The levels of AChE mRNAs, as well as rates of AChE translation, increase following myoblast fusion and subsequently decrease with the onset of spontaneous muscle contraction. Treatment of spontaneously contracting myotubes with tetrodotoxin results in a large increase in AChE mRNA. These studies show that expression of the AChE gene is developmentally regulated as well as under control by the activity state of the muscle. Supported by grants from the NIH and MDA to RLR.

cDNA CLONING OF A NOVEL NEURAL NICOTINIC RECEPTOR SUBUNIT FROM GOLDFISH RETINA. K.A. Cauley*, B.W. Agranoff and D. Goldman (SPON: K.A. Frey). Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

A way of producing changes at a synapse is to alter the properties or levels of the relevant neurotransmitter receptors. At the neuromuscular junction synaptic activity transcriptionally regulates the abundance of the nicotinic acetylcholine receptors (nAChRs). We are examining whether similar mechanisms exist for regulating nAChRs in the CNS, using the goldfish retina and regenerating optic nerve as a model system. We have screened a cDNA library prepared from RNA isolated from goldfish retina and have identified a novel nAChR subunit (GRAB-1). DNA sequence analysis shows GRAB-1 to encode a protein with structural features common to all nAChR subunits. We believe this clone is a non-alpha like subunit because it lacks the cysteines at positions 192 and 193 that are thought to constitute part of the ACh binding site in the alpha subunit. RNA blots show that GRAB-1 is expressed in the retina. S1 nuclease protection experiments indicate the presence of a second retinal mRNA identical to GRAB-1 for approximately 800 bases. In situ hybridization is being used to determine which cells in the retina are expressing this gene. (Supported by NEI Grant EY 05947.)

463.13

Appearance of a nAchR RNA Gradient Following Skeletal Muscle Denervation. J. Staple* and D. Goldman MHRI and Dept. of Biochemistry, University of Michigan, Ann Arbor MI 48109.

The neuromuscular junction (NMJ) is an excellent model system to study neural effects on synaptic organization. In adult innervated skeletal muscle, nicotinic acetylcholine receptors (nAchRs) and their RNAs are localized to the NMJ (Fontaine et al, 1988). At early times following muscle denervation a transient gradient of nAchRs exists, with receptor levels being highest in extrajunctional regions closest to the endplate (Levitt-Gilmour and Salpeter, 1986). This distribution may result from a gradient of nAchR RNA in denervated muscle.

The level of nAchR RNA in junctional and extrajunctional regions of the muscle fiber was determined by Northern blot analysis. Rat soleus muscles were denervated by cutting the sciatic nerve. At various times following denervation, muscles were removed and cut into thirds, one junctional and two extrajunctional pieces. RNA was isolated from these divided muscles and nAchR RNA levels were determined. At early times following muscle denervation we find higher levels of nAchR α, β, γ, and δ subunit RNAs in junctional versus extrajunctional regions of the muscle.

In situ hybridization was used to map the distribution of nAchR RNAs in the muscle fiber after denervation. The in situ results are consistent with those found by Northern blot analysis. At early times after muscle denervation, nAchR RNA is concentrated in the junctional region of the muscle fiber. Later, nAchR RNA levels increase in the extrajunctional regions of the muscle more distant from the endplate.

PAIN PATHWAYS: TRIGEMINAL SYSTEM

MORPHOLOGY AND PROJECTIONS OF INTRACELLULARLY LABELLED BRAINSTEM TRIGEMINAL VASCULAR CONVERGENCE NEURONS. A. Strassman, S. Potrebic*, M. Moskowitz, and R. Maciewicz. Pain Physiology Lab, Mass Gen Hosp, Boston MA 02114.

Brainstem trigeminal vascular convergence (TVC) neurons receive an excitatory, nociceptive input from cranial blood vessels as well as the periorbital skin or cornea. TVC neurons that responded to electrical stimulation of the superior sagittal sinus or middle meningeal artery as well as the cornea were identified with intracellular recording and then labelled with HRP. TVC cell somas were localized to the lateral part of lamina V in the rostral trigeminal nucleus caudalis; this distribution extended anteriorly into nucleus interpolaris, and ventrally into the trigeminal extension of the lateral cervical nucleus. Labelled neurons were typically either fusiform, with the soma and dendrites oriented along a ventromedial to dorsolateral axis, or multipolar in shape. Two patterns of TVC axonal projections were observed. The first type ascended through the spinal trigeminal complex, contributing multiple collaterals with terminations in lamina V and the adjacent medullary reticular formation. The second axon type crossed the midline to ascend in the trigeminothalamic tract. Before crossing the midline, some such axons collateralized in the dorsomedial reticular formation at the borders of the vagal and solitary nuclei. This pattern of terminations supports a role for TVC neurons in both sensory and autonomic cerebrovascular function.

MORPHOLOGICAL CHARACTERISTICS OF PHYSIOLOGICALLY DEFINED SINGLE TRIGEMINAL (V) BRAINSTEM NEURONES IN CATS. A. Yoshida*, E. Shohara*, J.G. Broton, J.O. Dostrovsky, Y. Shigenaga* and B.J. Sessle (SPON: T. Tashiro) Facs. Dentistry and Medicine, Univ. Toronto, Toronto, M5G 1G6 Canada and Hiroshima Univ., Japan.

To determine the morphological features of functionally identified V neurones, HRP-filled micropipettes were used to record and characterize the physiological properties of single neurones within V subnucleus oralis and adjacent brainstem regions. HRP was then injected intracellularly and the brainstem perfused. The 8 labelled oralis neurones had a mechanoreceptive field localized within one V division and short-latency (2-6 ms) electrically evoked inputs from skin, oral mucosa, or tooth pulp. Despite the restricted physiologically defined input, these neurones had an extensive dendritic tree: it had a mediolateral and dorsoventral span of 0.8-1.3 mm, and extended beyond the borders of the subnucleus. The thick stem dendrites averaged 6 in number and 7.8 μm in diameter and dendritic spines were abundant on the distal dendrites. The average soma diameter was 41 μm, and the axons and axon collaterals of many of these neurones could be traced out of the subnucleus to adjacent areas such as the V motor nucleus. Many of these features contrasted with those of functionally identified motoneurones labelled in the V (n=12) and VII (n=10) motor nuclei. (Supported by Can. MRC)

STIMULATION OF CRANIAL VESSELS ACTIVATES NEURONS IN THE THALAMUS OF THE CAT. A.S.Zagami*, G.A.Lambert* and J.W.Lance* (SPON: D.Tracey) Dept. of Medicine, University of New South Wales, NSW 2031, Australia.

Neurons in the ventroposteromedial (VPM) nucleus of the cat have previously been shown to be activated by noxious stimulation of orofacial structures. We have reported that electrical stimulation of the sagittal sinus (SS) and middle meningeal artery (MMA) activates neurons in VPM (Zagami,A.S. et al., Cephalalgia, 7:7-9, 1987) as have another group (Davis,K. and Dostrovsky,J., Pain, 4:S264, 1987). We now report that chemical and mechanical as well as electrical stimulation of cranial vessels activates neurons in the VPM as well as in other parts of the thalamus. The SS and MMA were stimulated electrically (40-120V,250us,0.2Hz) in chloralose anesthetized cats and single unit activity was recorded in the thalamus using glass coated tungsten electrodes. In some cases traction on the vessels was used to test for mechanical activation while in others bradykinin (BK) (10-4 to 10-5M) was applied locally. Electrical stimulation activated 44 units of which 23 were in VPM. Fifteen of these responded to SS stimulation, 5 to MMA and 3 to both. The mean latencies to SS and MMA stimulation were 18.4±2.1ms and 15.3±3ms respectively. Nine out of 10 SS linked units had receptive fields (RFs) usually periorbital and wide dynamic range in character. The mean latency for electrical stimulation of these RFs was 13.6±3ms. Traction on the SS and/or the MMA activated 4/4 units while BK was also effective in the units tested. Twelve units with a mean latency of 14.4±3.7ms to SS and/or MMA stimulation were found in the region of the posterior group of the thalamus. Some of these had facial RFs but they were often broad and sometimes bilateral. Seven responsive units were located in the zona incerta while another two were in the intralaminar complex.

SINGLE UNIT RESPONSES OF INFERIOR DENTAL NERVE TO THERMAL STIMULATION OF THE HUMAN TEETH :CORRELATION BETWEEN ELECTROPHYSIOLOGICAL DATA AND SUBJECTIVE PERCEPTION. K.IWATA*, K.TODA*, Y.TSUBOI*,J.YAGI* and R.SUMINO*(SPON:O.HIKOSAKA).Dept. Physiol. Nihon Univ. Sch. Dent. 1-8-13 Kandasurugadai, Chiyoda-KU, Tokyo 101, Japan.

Previous studies in animals have shown that thermal stimulation of teeth evokes responses in dental nerves but it is not known that the animals really receive pain sensation. However, anatomical studies reported that there were different populations in the intra-dental nerve fibers between animals and humans, suggesting that the sensory mechanisms of tooth pain to thermal stimulation were different between them. Therefore, these proposed us to study the correlation between the intra-dental responses to thermal stimulation of the tooth and the perceived sensation in man.

Young adult men were used in this study. Single fiber discharges were recorded from the inferior dental nerve with the enamel coated tungsten micro-electrodes inserted through the mental foramen. Majority of cold sensitive and heat sensitive fibers responded with bi-phasic firing (phasic and static responses) and with long lasting after discharges following thermal stimulation of the lower incisor. Almost all fibers were categolized as the slowly conducting Ao and C fibers. During the thermal stimulation of the tooth, firing rate of the fibers were correlated to the ratings of the subjective sensation. Subjects did not feel any kinds of sensation after the cessation of thermal stimuli, although, after discharges continued.

COMPARATIVE CENTRAL REPRESENTATION OF MAXILLARY AND MANDIBULAR DENTAL STRUCTURES. M.A. Henry and L.E. Westrum. Depts. of Neurol. Surg., Biol. Struct., and Restorative Dent., Univ. of Wash., Seattle, WA 98195.

The large pulpal chambers and apical foramina of permanent but immature dentition allow maximal HRP labeling of pulpal fibers and easy spread to periodontal ligament. Here we report a study of the central somatotopic organization of maxillary (Mx) as compared to mandibular dental structures (Md) following HRP injections into either a maxillary or a mandibular cuspid of a 30-week-old cat. LM shows considerable overlap between Mx and Md within dorsomedial main sensory nucleus (MSN). All spinal nuclei show a slight overlap. In pars oralis (PO) Md is most dorsal and Mx just ventral to it. In pars interpolaris (PI) Md and Mx have the same dorsal-ventral relationship as PO but occupy a more medio-ventral part of the nucleus. Pars caudalis (PC) shows a mediolateral pattern in dorsal nuclear regions with Md more medial. A pathway for primary afferent crossing to the contralateral side is demonstrated near obex and a ventral projection is seen in PI/PC. Large fibers traverse MSN/PO, enter the mesencephalic (Mes V) tract and lead to labeled cells in the Mes V nucleus. Other labeled fibers located in the motor tract show some terminal arbors. The findings show clearly separate but overlapping patterns of Mx and Md, a crossing pathway and a periobex ventral termination, (Supported by NIH Grants DE00219 and DE04942. LEW is an affiliate of CDMRC.)

464.6

CALCITONIN GENE - RELATED PEPTIDE LIKE IMMUNOREACTIVITY IN FELINE TRIGEMINAL NUCLEI. L.R. Johnson*[1], M.A. Henry[2], L.E. Westrum[2] and N.A. Nousek-Goebl*[2] (SPON: J. Loeser). [1]University of Colorado, Denver, CO 80262, [2]University of Washington, Seattle, WA 98195.

Recent studies have localized calcitonin gene - related peptide like immunoreactivity (CGRP-LI) in a variety of peripheral structures that receive trigeminal afferent innervation. The present study examines CGRP-LI in the brain stem trigeminal nuclear complex. CGRP-LI occurs in the trigeminal ganglion and all central trigeminal nuclei except the mesencephalic nucleus. In the main sensory nucleus (MSN) CGRP fibers in the ascending tract send a dense projection to the dorsomedial MSN and a sparse one to the ventrolateral MSN. CGRP positive fibers are present in the descending trigeminal tract giving off axons to all the spinal trigeminal nuclei. Pars oralis has the heaviest labeling dorsally, while pars interpolaris shows more ventral accumulations of CGRP-LI. Dense label occurs in layers I and II of the medullary dorsal horn with fibers leading to deep pockets of label in laminae V and VI. Labeled fibers cross the brain stem dorsal to the central canal. Some of these patterns are strikingly consistent with those described for dental projections. LEW is an affiliate of the CDMRC. Supported by NIH Grants DE04942, DE00219 and NS09678.

EFFECTS OF ANAESTHESIA ON RESPONSES OF TRIGEMINAL BRAINSTEM NEURONES TO TOOTH-PULP STIMULATION IN THE CAT. F.M.Boissonade* and B.Matthews, Dept. of Physiol., Univ. of Bristol, England.

Recordings of responses to stimulation of tooth-pulp and other oro-facial tissues have been made from neurones in the trigeminal main sensory and spinal (mainly pars oralis) nuclei of conscious, unrestrained cats and from the same neurones when the animals were lightly anaesthetized with alphaxalone/alphadolone (4 mg/kg, I.V.). The animals were prepared in an initial operation under general anaesthesia. A titanium chamber, which incorporated a mounting ring into which a miniature micromanipulator could be mounted, was positioned stereotaxically over a craniotomy in the posterior cranial fossa. The dura was covered with silicone elastomer and the craniotomy covered with a titanium plate. A connector block with a miniature 9-way socket and venous injection port was fixed to the skull over the frontal sinus. Leads were passed subcutaneously from this block to Ag/AgCl fillings in the right canine teeth for electrical stimulation of tooth-pulp, and to the right digastric muscle for recording its E.M.G. A cannula from the injection port was inserted into the anterior facial vein. Recordings were made with glass-insulated tungsten electrodes and began three days after the initial operation.

In a conscious animal, single tooth pulp stimuli of 0.1ms duration and up to 50X digastric reflex threshold produced no aversive behaviour. Short (~3ms) and long (~25ms) latency neuronal discharges were evoked. Light anaesthesia reduced the number of impulses in both responses, particularly the second, but had little effect on the threshold of the first. It affected responses to other forms of stimuli in only a small proportion of neurones. It reduced spontaneous activity of neurones and also the amplitude of the digastric reflex.

464.8

RESPONSE PROPERTIES OF TOOTH PULP-DRIVEN CELLS IN THE SPINAL TRIGEMINAL NUCLEUS ORALIS OF THE CAT. A.Pertovaara, T.Huopaniemi*, E.Jyväsjärvi*, S.Carlson* and F.Lindroos*. Dept.Physiol.,Univ. of Helsinki, Finland.

Tooth pulp-driven cells were recorded in the trigeminal nucleus oralis of the cat. The thresholds to monopolar electric pulses were determined using a constant current stimulator. The most sensitive oralis cells had lower thresholds and shorter latencies than the respective caudalis or interpolaris cells. In general, the thresholds were lower and the strength-duration curves flatter than those depicting liminal dental pain in man, but similar to those depicting liminal jaw reflexes. The relationship between stimulus intensity and response magnitude could well be described by power functions. The thresholds were not elevated during a noxious tail pinch. The converging input from the skin was from low-threshold mechanoreceptors. The results indicate that there are significant differences in the response properties of cells of the different spinal trigeminal subnuclei. Human pain thresholds cannot be explained by the liminal response properties of the most sensitive oralis cells but they might be important in the mediation of liminal reflex events.

464.9

IS TOOTH PULP REPRESENTED IN THE MESENCEPHALIC TRIGEMINAL NUCLEUS? N. Amano*, K. Yoshino*, H. Matsuoka*, S. Andoh* and S. Kawagishi* (SPON: T. Sugimoto). Dept. Oral Neuroscience, Kyushu Dental College, Kitakyushu, 803 Japan.

Several physiological and histological studies have shown the presence of a substantial proportion of pulpal afferent fibers with conduction velocities and diameters greater than the Aδ range in the tooth pulp of mammals including man. The purpose of this study is to examine a possible dual innervation of tooth pulp from the mesencephalic trigeminal nucleus (MTN) and trigeminal ganglion (TG) in the cat using retrograde transport of horseradish peroxidase (HRP). Great care was taken to avoid a leakage of HRP through the apical foramen into periodontal tissue and to minimize inhibition of axonal transport of HRP due to acute pulpitis in the tooth applied with HRP. Pulp chamber of each left lower canine of 8 adult cats was opened with a dental air turbine under water cooling. Following partial pulpotomy, 1–2 µl of 30% HRP in saline soaked into gelfoam was placed in each pulp chamber. The openings were sealed with dental glass-ionomer cement. Immediately after the surgery and throughout the subsequent 3-day survival period, 6 cats were subjected to systemic administration of anti-inflammatory drug, prednisolone, whereas the remaining 2 control cats were not. Histological sections were processed according to TMB technique by Mesulam. Only in 6 prednisolone-treated cats many HRP-labeled neurons were observed in both MTN and TG on the side ipsilateral to the HRP application.

SUBCORTICAL SOMATOSENSORY PATHWAYS: TRIGEMINAL SYSTEM

465.1

CHARACTERIZATION OF TRIGEMINOTECTAL AFFERENTS IN THE SUPERIOR COLLICULUS OF THE RAT. E. Gregory and W. C. Hall. Dept. of Neurobiology, Duke Univ., Durham, NC 27710.

The intermediate grey layer of the superior colliculus in the rat receives somatosensory projections from the spinal trigeminal nucleus. The present experiments were designed to characterize the terminations of this pathway as a step toward determining their contribution to the output of the various efferent pathways of this layer. We placed iontophoretic injections of 2.5% biotinylated PHA-L (Vector) in subnucleus interpolaris of the spinal trigeminal nucleus of three Long Evans rats. Six days after surgery the rats were perfused; the tissue was then processed for PHA-L immunocytochemistry and reacted in diaminobenzidene. For electron microscopy, tissue was embedded and areas containing terminations were thin-sectioned. PHA-L positive fibers are restricted to the rostral two-thirds of the superior colliculus. In the intermediate grey layer (Weiner's nomenclature), the label appears "patchy" because of variations in terminal and fiber density. The labeled axons are numerous laterally, and become sparse medially. Most axons are fine and highly branched. Many are beaded, giving the appearance of boutons en passant. Electron microscopic examination reveals that labeled terminals are filled with densely packed, small round vesicles and contact dendrites. Experiments are in progress to identify the target cells of these axons. Supported by Grant #BNS-86-07060.

WHAT'S IN A PATCH? EXAMINATION OF THE TRIGEMINAL PROJECTION TO THE SUPERIOR COLLICULUS WITH PHASEOLUS VULGARIS LEUCO-AGGLUTININ AND SINGLE FIBER LABELLING. R.W. Rhoades, R.D. Mooney, N.L. Chiaia, M.M. Nikoletseas, and W.H. Rohrer, Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Anterograde tracing with a variety of methods has demonstrated that the vast majority of the inputs to the deep laminae of the mammalian superior colliculus (SC) terminate in a discontinuous or "patchlike" fashion. There has been some disagreement as to whether these patches represent terminal arbors or bundles of preterminal axons. Anterograde tracing of the projections to the SC from trigeminal principalis (PrV) and subnucleus interpolaris (SpVi) with Phaseolus vulgaris leuco-agglutinin has allowed us to demonstrate that the patches observed with other methods are indeed terminal arborizations. Labelling of individual fibers by means of intra-axonal injection of horseradish peroxidase demonstrated further that individual trigeminotectal axons contributed to several patches across the mediolateral extent of the stratum album intermedium. We also noted that the SC projection from PrV consistently had several fibers which recrossed the midline in the SC commissure to give rise to patchy terminal arbors in the SC ipsilateral to the injection site. Supported by BNS 85-00142, BNS 85-17537, EY 04170, DE 07734.

465.3

MORPHOMETRY OF BARREL PRECURSOR PRIMARY AFFERENTS IN TRIGEMINAL NUCLEUS PRINCIPALIS. W.M. Panneton, W.E. Renehan, J. Golden* & M.F. Jacquin. Anat. & Neurobiol., St. Louis Univ. Sch. Med., MO 63104 & Anat., Univ. Louisville, KY 40292.

A neuron reconstruction system (Eutectic Elect.) was used to quantify the 3-dimensional structure of 2 electrophysiologically characterized, HRP-labeled, primary afferent fibers with collaterals in the "barrel" region of rat principalis (PrV). Each responded phasically to deflection of 1 mystacial whisker and gave rise to 6 collaterals with arbors distributed discontinuously in topographically appropriate regions of PrV. Collaterals branched 19.8±7.8 times. En passant and terminal swellings were usually 1.5um or less and were distributed unequally across branch order with most on 6th order segments or greater. Arbor envelopes of each collateral had transverse areas of 15333±14626um2 and volumes of 353380±526815um3. Arbor limits were 159±69, 173±132 and 72±38um in X,Y,Z respectively. However, one of these collaterals was unusual in having 2 second-order branches which arborized in nonoverlapping regions of PrV. Excluding this collateral, the remaining 11 collaterals had transverse areas of 11185±5187um2 and volumes of 198052 ±115077um3, while arbor limits were 154±70, 136±52 and 63±26um in X,Y,Z respectively. Thus, most of the collateral arbors had a similar geometry to that of single whisker sensitive, thalamic-projecting cells in PrV (Golden & Jacquin, this volume), but the arbors most often are larger and could contain completely one of these PrV cells. Support: NIH Grants DE07662, DE07734.

465.4

INTERSUBNUCLEAR PROJECTIONS IN THE RAT TRIGEMINAL BRAINSTEM COMPLEX. P.A. Young, R.W. Rhoades, N.L. Chiaia, P.R. Hess* & M.F. Jacquin. Anat. & Neurobiol., St. Louis Univ. Sch. Med., MO 63104 & Anat., Med. Coll. Ohio, Toledo, OH 43699.

Prior retrograde tracing and Golgi studies, primarily in cat, indicate a complex web of intersubnuclear connections within the trigeminal (V) brainstem complex. In rat, HRP-stained local circuit neurons, and some projection cells, in subnuclei caudalis, interpolaris, and oralis, have been shown to project to rostral and caudal subnuclei. In the present study, anterograde transport of Phaseolus vulgaris leukoagglutinin was used to visualize the projections and morphologies of V intersubnuclear axons. Injections restricted to caudalis (N=6) resulted in dense terminal labeling in each of the more rostral ipsilateral V subnuclei and cervical dorsal horn, and sparse label in contralateral caudalis. Interpolaris (N=4) projected heavily to ipsilateral caudalis, oralis and principalis. Principalis (N=4), on the other hand, had only a sparse projection to each of the caudal ipsilateral subnuclei. The smaller of the above injections showed axon endings in regions topographically matching their sites of origin. Individual collaterals could be reconstructed in most cases. Their morphologies were as previously described for single HRP-stained cells. Axons traveled within the deep bundles of the V brainstem complex, the V spinal tract and reticular formation. Most collaterals gave rise to circumscribed and highly branched arbors with a large number of terminal and en passant boutons. Support: NIH DE07662, DE07734, NSF BNS8515737.

465.5

MORPHOMETRY OF BARREL PRECURSOR CELLS IN TRIGEMINAL NUCLEUS PRINCIPALIS. J. Golden* & M.F. Jacquin (SPON: K. Smith). Anat. & Neurobiol., St. Louis Univ. Sch. Med., MO 63104.

A neuron reconstruction system (Eutectic Elect.) was used to quantify the 3-dimensional structure of 5 HRP-labeled cells in the "barrel" region of rat principalis. Each responded phasically to 1 mystacial whisker and projected only to thalamus. Mean latencies to V ganglion and thalamic shocks were 1.1 and 1.4 ms. Small somata gave rise to 5.6±2.3 proximal dendrites which first branched 23±14um from the soma. Similar lengths separated 19±5 subsequent branch points. All dendritic branching occurred within 100um of the soma, with the largest # of branch points between 20-30 um. 64±21 dendritic appendages (swellings, spines) were equally distributed across branch order and were most numerous on 0.4-1.2um thick branches. Total dendritic length, surface area and volume were 880±181um, 2740±597um2 and 925 ±293um3, respectively. Dendritic tree envelopes had transverse areas of 3225±863um2 and volumes of 29727±10473um3. Each tree was polarized, spanning no greater than a hemisphere around the soma; however, there was no reliable direction of polarity. Centers of dendritic area, relative to somata, were 4±23, -2±8 and -5±11um in X,Y,Z respectively. Tree limits were 68±14, 95±48 and 91±29um in X,Y,Z respectively. These small and dense dendritic trees have similar shapes to that of whisker afferent collaterals in principalis (Panneton et al., Soc. Neurosci. Abst., this volume). Their matching shapes may explain receptive field size in single-whisker principalis cells. Support:DE07662,DE07734.

465.6

CELL FORM AND FUNCTION IN TRIGEMINAL NUCLEUS PRINCIPALIS. K.L. Rossner, W.M. Panneton & M.F. Jacquin. Dept. of Anat. & Neurobiol., St. Louis Univ. Sch. Med., MO 63104.

Intracellular recording, electrical stimulation, receptive field mapping, and HRP injection techniques were used to study principalis cells in rat. 80 cells provided physiological data. They responded within 1.2±0.2 ms of trigeminal ganglion shocks and 69% were antidromically activated by thalamic shocks (1.3±0.5 ms latencies). 69% were whisker-sensitive; of these, 80% were responsive to 1 whisker (mean=1.45, range=1-8), 29% were slowly adapting, 40% were direction sensitive, 35% were spontaneously active, 2% had an inhibitory surround, and 4% also discharged to guard hairs. The rest responded to guard hairs (13%), skin (5%), teeth (1%), or nociceptors (8%), and 3% were unresponsive. 17 cells were HRP-stained. Thalamic-projecting cells with 1 whisker, guard hair, or skin receptive fields (N=12) had small somata and dendrites which extended only a short distance from the soma, where they branched extensively. Spines were rare, yet swellings were common. Axons never branched locally. Within this group, slowly adapting cells tended to have bigger dendritic trees with more swellings. As a group, however, these 12 cells had very different morphologies from those of 1 nociceptive, and 2 multi-whisker projection cells, and 2 local circuit cells. Larger somata gave rise to expansive and spiny dendritic trees, often with local, intersubnuclear, and reticular axon collaterals. These data are suggestive of structure-function correlations in principalis. Support: NIH DE07662, DE07734.

465.7

CELL FORM AND FUNCTION IN TRIGEMINAL SUBNUCLEUS ORALIS. N. Hobart*, W.M. Panneton & M.F. Jacquin (SPON: N. Connors). Anat. & Neurobiol., St. Louis Univ. Sch. Med., MO 63104

Intracellular recording, electrical stimulation, receptive field mapping, and HRP injection techniques were used to study form-function correlations in oralis of the rat. Of 15 labeled cells, 4 were local circuit neurons responsive to either an incisor, guard hairs, 1 vibrissa, or deep pressure. Their somadendritic structures most closely resembled those of V-thalamic cells in subnucleus interpolaris (Jacquin et al., Exp. Br. Res.: 61, '86); their axons had intersubnuclear and local collaterals. Thalamic- (N=6) and cerebellar-projecting (N=2) cells had response properties and morphologies which were similar to interpolaris cells with equivalent projections. 2 cells projected to spinal cord, as well as other V subnuclei; one responded to strong pressure applied to an incisor; the other was 1 whisker sensitive. Their morphologies did not differ from other oralis and interpolaris projection neurons. The remaining cell had 2 axons, one projecting to thalamus, the other to spinal cord. It responded to 15 vibrissae, guard hairs and glabrous skin. Its somadendritic morphology was similar to that of other oralis projection neurons.

The extensive dendritic trees, local and long-range axon branching, multi-whisker convergence, and functional diversity of oralis cells approximates that observed in interpolaris. Such anatomical and physiological properties are rarely seen, however, in subnucleus principalis. Support: NIH grants DE07662 and DE07734.

465.8

INNERVATION OF THE INNER CONICAL BODY IN THE RAT VIBRISSAL FOLLICLE-SINUS COMPLEX (F-SC). T.M.Mosconi,* F.L.Rice, H.Aldskogius, and J. Arvidsson. Anatomy Dept., Albany Medical College, Albany, NY 12208; Anatomy Dept., Karolinska Institute, Stockholm, Sweden.

The inner conical body (ICB) in a mystacial vibrissal F-SC is heavily innervated only in species that whisk (Rice et al., JCN 252:154). As seen in LM silver preparations of the adult rat ICB, numerous receptors are parallel to each other and encircle the vibrissal follicle in a plane perpendicular to the hair shaft. One of our goals was to determine the ultrastructure of the adult rat ICB innervation by standard TEM of thin sections and High Voltage EM of thick (0.25-0.5um) sections. Numerous endings were observed: many nearly free of surrounding structure (free nerve endings?) of which one novel type resembled grapeshot; many embedded in thick collagen matrices (?); some affiliated with collagen fibers in a "septal cell" capsule (Ruffini endings?); and a few others flattened between two satellite cells (lanceolate endings?). Another goal was to evaluate some neuropeptide LM immunoreactivity (IR) within the ICB. Numerous, but clearly not all processes expressed substance P- and CGRP-like IR. No ICB processes expressed somatostatin-, VIP-, or NPY-like IR. (Support: Swedish Medical Research Council and NIH PHS RR01219 to Drs. Donald Parsons and Min Song, NY State HVEM Facility)

PRINCIPALIS- OR PARABRACHIAL-PROJECTING SPINAL TRIGEMINAL NEURONS DO NOT STAIN FOR GABA OR GAD. J.H. Haring & M.F. Jacquin. Dept. of Anatomy & Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104.

Most low-threshold, mechanoreceptive local circuit neurons in rat spinal trigeminal (SpV) subnuclei interpolaris and caudalis have collaterals which end in more rostral subnucleus principalis (PrV). It has been hypothesized that these cells have GABA-ergic processes which serve to gate transmission of V primary afferent inputs to projection neurons in SpV and PrV. Retrograde transport of diamidino yellow (DY) and immunohistochemical double-labeling procedures were used to determine if pontine-projecting SpV cells stain positively for GAD or GABA. As expected, large bilateral injections of DY into rostral and lateral pons (N=10), inclusive of PrV and parabrachial nuclei, labeled large #'s of cells in each SpV subnucleus. Brainstems (2 colchicine pretreated) were subsequently reacted for cytoplasmic GAD or GABA immunoreactivity (Weinberg et al., Neurosci. Lett. 55:349, '85). A large # of cells throughout SpV were immunopositive (approx. 450, 200 and 160 cells per cross-section through caudalis, interpolaris and oralis, respectively), with the heaviest concentration in ventral interpolaris and laminae II of caudalis. However, none were double-labeled with DY. This result does not support the above-stated hypothesis, suggesting that SpV local circuit neurons with PrV collaterals are not GABA-ergic. These studies also indicate that parabrachial-projecting SpV cells are not GABA-ergic. Support: NIH DE07662, DE07734, NS25752.

PROGRESS ON THE CYCLIC ADENOSINE MONOPHOSPHATE RECEPTOR OF PARAMECIUM. J.L. Van Houten, J. Baez*, B. Cote*, J. Zhang*. Dept. of Zoology, Univ. of Vermont, Burlington, VT 05405

Cyclic AMP is an attractant stimulus to paramecia. As other attractants, it hyperpolarizes the cells and shows specific, saturable, albeit low affinity binding to whole cells, primarily on the cell body (not ciliary) membrane. A 48 Kd protein identified by affinity chromatography is a candidate for the cAMP receptor, as judged by its specificity for binding to the column. Although similar in molecular weight, it is not identical to the regulatory subunit of the Paramecium cAMP-dependent protein kinase on Western blots (antibody provided by M. Hochstrasser). In 2D electrophoresis, the 48 Kd protein is extreme in its pI (2.5). Con A-HRP does not appear to bind to the protein; however, it still may be a glycoprotein. Since the N terminus is blocked, microsequencing is being carried out on CNBr fragments. The sequence will be used to produce an oligonucleotide probe for clong the receptor gene. Polyclonal antibodies have been produced in New Zealand rabbits against gel slices containing the antigen. These antibodies recognize the antigen in ng amounts on slot blots and, therefore, are appropriate for screening an expression library of lambda gtll for the receptor gene. Supported by NSF.

FOLATE CHEMORECEPTOR MUTANT: ANALYSIS OF SURFACE MEMBRANE PROTEINS IN PARAMECIUM. J.M. Sasner, J.K. Isaksen, and J.L. Van Houten. Zoology Department, University of Vermont, Burlington, VT 05405.

Paramecium are attracted to folate by a chemokinetic mechanism. The cell body membrane binds folate specifically and saturably, and this binding correlates with the change in membrane potential that determines swimming behavior. We are trying to identify the receptor protein for folate by comparing the folate-binding proteins of membrane preparations of wild-type cells with those of mutants that do not normally bind or respond to folate.

We have developed a method to covalently crosslink folate to cells that specifically blocks folate chemoreception, and have developed an antibody that specifically detects the ligand. Preliminary data also shows that we can covalently crosslink iodinated folate to membrane preparations. We are using these techniques to identify membrane folate binding proteins and by comparison of wild-type and mutant folate crosslinked proteins, will identify the chemoreceptor protein.

EXPRESSION OF NEURONAL ENZYMES AND CARBONIC ANHYDRASE IN CULTURED GLOMUS CELLS OF THE RAT CAROTID BODY. C.A. Nurse, L. Farraway* and C. Vollmer*. (SPON: J. Rowe). Dept of Biology, McMaster University, Hamilton, Ontario, L8S 4K1.

We are studying neurotransmitter and transduction mechanisms in a chemosensory organ, the rat carotid body, using dissociated cell cultures (see accompanying abstract, A. Stea and C.A. Nurse). Previous studies in this laboratory indicated that single (parenchymal) glomus (type I) cells in these cultures may express both catecholamine histofluorescence as well as acetylcholinesterase (Cell Tissue Res. 250: 21-27). We now show by the use of immunofluorescence techniques that these glomus cells selectively express both tyrosine hydroxylase and neuron specific enolase immunoreactivity. In addition, histochemical staining for carbonic anhydrase (CA) indicated a selective localization in glomus cells; staining was markedly enhanced following permeabilization of the cell membranes, suggesting a predominant intracellular localization, and was abolished by the CA-inhibitor acetazolamide (10 μM). Unstained cells included sustentacular (type II) cells and fibroblasts. This finding is important since CA-localization in the carotid body is controversial and bears on the precise formulation of the acidic hypothesis, proposed to explain the organ's response to increased blood CO_2 (and H^+) levels.

Supported by the Heart and Stroke Foundation of Ontario.

SURFACE HETEROGENEITY OF HUMAN OLFACTORY EPITHELIUM. M.I. Chuah and D.R. Zheng*. Dept. of Anatomy, Chinese University of Hong Kong, Hong Kong and Dept. of Anatomy, Jinan University, Guangzhou, China.

We have conducted scanning (SEM) and transmission electron microscopic (TEM) observations on the human olfactory epithelium (OE) of the nasal septum (NS) and superior concha (SC). Our findings show that the human OE surface, hitherto assumed to be uniform, exhibits considerable heterogeneity.

In the SC, the OE surface was highly ciliated, suggesting a high density of receptor cells. For the most part, the length of the cilia was uniform. Microvilli, indicating the presence of supporting cells, were generally present in small pockets. In SEM, dendrites were observed to give rise to large numbers of cilia, more numerous than previously estimated from TEM studies. However, the usual knob-like endings of the dendrites were not apparent.

In the NS, the distribution of ciliated and microvillous surfaces was more variable than that of the SC. Generally, the ciliated regions occupied a smaller area; and patches of cilia of different lengths were often present in close proximity. Some dendrites bore radiating arrangements of cilia, which were not observed in the SC. TEM observations of young receptor cells showed that many of them possessed cilia with expanded tips (primary cilium?). Ductal openings of Bowman's glands were more numerous in the NS.

NUMERICAL RELATIONS BETWEEN OLFACTORY RELAY ELEMENTS (RECEPTOR NEURONS, GLOMERULI AND MITRAL CELLS) IN THE CAT. Tia Simms* and E. Meisami (SPON: C.L. PROSSER). Dept of Physiology, Univ. Illinois, Urbana, IL 61801

The olfactory mucosa (OM) and bulb (OB) of adult cats were analysed quantitatively for the number of primary olfactory neurons (ON), the glomeruli (GL) and mitral cells (MC) using light microscopic, numerical and morphometric methods. Complete frontal series of 10 um whole sections, stained with H&E and Nissl were employed. The results indicate that the cat possesses, on each side of the nasal cavity, about 40 million ONs which converge onto about 40,000 MCs in each OB. This gives an ON:MC convergence ratio of about 1000:1, the same as in the macrosmatic rabbit. If this convergence ratio can be considered as a neural index of olfactory sensitivity, then the cat may be as sensitive as the rabbit. The number of GL was estimated as 10,000 if the mean glomerular diameter was taken as 70 um (i.e., mean diameter of all GL per section) or 3300 if the mean diameter was taken as 105 um (i.e., average of the largest GL diameters per section). The OB volume is about 50 cu mm and MC layer surface area about 50 sq mm, giving an average of 800 MCs/sq mm. Total OM surface area is 600 sq mm, 20% covering the septum, 80% the conchae; the surface density of the ONs being about 70,000/sq mm. The OM sheet is about 50 um thick and has 9 and 3 ONs for each basal and supporting cells respectively.

LIQUID ODORANTS DELIVERED TO THE VOMERONASAL ORGAN OF GARTER SNAKES INCREASE FIRING OF CELLS IN THE ACCESSORY OLFACTORY BULB. J. Inouchi, J. L. Kubie and M. Halpern. Dept. of Anatomy and Cell Biology, SUNY Health Science Center at Brooklyn, Brooklyn, N. Y. 11203.

Most terrestrial vertebrates possess both main olfactory and vomeronasal systems with many features in common. There have been few studies using electrophysiological methods to characterize and compare the properties of these two systems. To examine the physiological properties of both systems in garter snakes (Thamnophis sirtalis parietalis), we first focused on recording electroolfactograms (EOGs) from the olfactory and vomeronasal epithelia. Using airborne odorants we were able to elicit EOG responses from the olfactory and vomeronasal epithelia although the responses from the vomeronasal epithelium were very small (less than 1 mv). It has been suggested that the vomeronasal system is normally stimulated by odorants delivered as liquids. In recordings from individually recorded accessory olfactory bulb neurons we found a variety of liquid odorants, including amyl acetate and earthworm wash, induced dramatic increases in neuronal activity. These results demonstrate that the vomeronasal system is sensitive to a variety of odorants and support the idea that under normal conditions effective stimuli arrive in a liquid medium.

EOG AMPLITUDE IS CORRELATED WITH ODOR-STIMULATED ADENYLATE CYCLASE ACTIVITY IN THE BULLFROG OLFACTORY EPITHELIUM. Graeme Lowe*, Tadashi Nakamura* and Geoffrey H. Gold. Monell Chemical Senses Center, Philadelphia, PA.

Recent work suggests that odor-stimulated adenylate cyclase (AC) activity mediates olfactory transduction in vertebrates (Pace et al., 1985; Shirley et al., 1986; Nakamura and Gold, 1987). However, stimulation of the AC by certain odorants is weak or undetectable, leading to the suggestion that the AC may not mediate transduction for all odorants (Sklar et al., 1986). An alternative explanation for these data is that differences in the magnitude of AC stimulation by various odorants may reflect differences in the number of receptor proteins or receptor cells sensitive to those odorants. If the latter hypothesis is correct, we expect the amplitude of the EOG to be correlated with the magnitude of AC stimulation by various odorants.

The EOG was recorded from excised bullfrog olfactory epithelia mounted in a perfusion chamber. Odors were applied to the apical side, dissolved in Ringer's solution at a concentration of 100 uM to approximate the conditions used in Sklar et al.'s cyclase assay. Of 35 odorants tested thus far, 31 odorants elicited a monophasic negative EOG, and 4 odorants elicited a multiphasic negative EOG. The multiphasic responses may contain contributions from currents unrelated to transduction, and therefore, were not included in the analysis below. The correlation coefficient relating the peak amplitude of the EOG to the magnitude of AC stimulation for each odorant was 0.87.

Our data show that the ability of odorants to stimulate adenylate cyclase is correlated with their ability to generate an EOG response. These results support the adenylate cyclase model of olfactory transduction.

466.8

RELATION BETWEEN NERVE FIBER TYPE AND AMILORIDE INHIBITION OF TASTE RESPONSES IN THE HAMSTER. M.E. Frank and T.P. Hettinger*. Department of BioStructure and Function, University of Connecticut Health Center, Farmington, CT 06032.

Current interest in the involvement of ion channels in taste reception and transduction is based in part on electrophysiological and behavioral effects of orally applied channel blockers in several vertebrate species. Recordings of integrated responses of the whole chorda tympani nerve have shown effects attributable to involvement of Na and K channels in taste stimulation by a variety of salts. We find in the hamster that physiologically defined classes of chorda tympani fibers respond differentially to lingual application of amiloride, a blocker of epithelial Na channels. N fibers (n = 16), those responding selectively to Na and Li salts, can be completely inhibited by 10 uM amiloride, while H fibers (n = 10), those showing a broad spectrum of response to salts and acids, are not affected. The partial inhibition seen in the whole nerve is explained by these observations. The segregation of amiloride effects according to fiber type shows that chemoreceptive mechanisms differ for the two fibers types that respond to NaCl. Amiloride presumably acts on sodium channels of the apical membrane of taste receptor cells. Thus, for N fibers, the molecular receptors for Na salts may be identical to Na channels. Receptor cell activation in this system could be achieved by direct depolarization without requiring a second messenger. Supported by NSF Grant BNS-8519638.

466.9

A SUBSET OF RAT PRIMARY OLFACTORY NEURONS AND GLOMERULI SHOWN BY ANTIBODY TO HUMAN PLACENTAL ANTIGEN COMMON TO ESTROGEN-BIOSYNTHETIC ORGANS. K. Shinoda[1]*, Y. Shiotani[1]*, J. Pearson[2] and Y. Osawa[3]*. 1. Osaka University Medical School, Japan, 2. NYU Medical Center, NY, 3. Medical Foundation of Buffalo, NY.

Primary olfactory neurons have not yet been extensively classified. A solitary, "modified glomerular complex" located caudally between the main and accessory olfactory bulbs is involved in "suckling behavior" response to nipple and amniotic fluid odors in rats. We now report localized immunoreactivity in frozen sections of paraformaldehyde fixed rat olfactory bulb using an antiserum to human placental antigen. The antiserum stains estrogen synthesizing organs (including placenta and ovary) and suppresses 73% of the activity of human placental P450 aromatase. A distinct subset of rat olfactory glomeruli forms a necklace-like pattern at the caudal end of the rat olfactory bulb and is associated with a subclass of primary olfactory receptors. Part of this subset of sensory neurons in the rat primary olfactory system appears identical with the glomerulus responsible for suckling behavior.

***CONCANAVALIN A* CYTOCHEMISTRY ON RAPIDLY-FROZEN RAT OLFACTORY EPITHELIAL SURFACES, FREEZE-ETCHED AND ROTARY-REPLICATED WITH TANTALUM/TUNGSTEN OR FREEZE-SUBSTITUTED AND EMBEDDED IN LOWICRYL K11M.** B. PH. M. Menco *Dept. of Neurobiology and Physiology, O.T. Hogan Hall, Northwestern University, Evanston, IL 60208.*

Tantalum/tungsten (Ta/W) freeze-etch replicas are considerably thinner, and hence contain more information than conventional platinum/carbon (Pt/C) replicas (1). Rat olfactory epithelial samples were incubated with the lectin Concanavalin A (Con A) conjugated to 5 nm colloidal gold particles at 0°C for 2 to 4 hours before cryo-fixation. Frozen specimens were then fractured at -140°C, etched for 30 minutes at -108°C and rotary-replicated (300-400 rpm) with Ta/W. The Ta/W replicas were, on average, about 0.2 nm to 0.3 nm thick, which is much thinner than the 2 nm to 3 nm obtained with Pt/C electron beam gun replication. Sub-populations of membrane-associated particles with ample substructure could be distinguished with Ta/W rotary-replication. For freeze-substitution the samples were after freeze-fixation kept in the substitution medium, acetone with 0.1% uranyl acetate, at -80°C for 3 days in the absence of other chemical fixatives. Specimens were then infiltrated with Lowicryl K11M for three days at -60°C and embedded in this resin for 20 days under ultraviolet polymerization, during which period the temperature was raised from -60°C to room temperature (*after* 2). The fine structural preservation is at least as good than when freeze-substitution was carried in combination with OsO_4 fixation. Lectin cytochemistry was applied on sections. Both combinations of methods, freeze-etching and Ta/W rotary-replication, and acetone freeze-substitution and Lowicryl K11M embedding of unfixed samples, can be used for lectin cytochemistry: Membranes of cellular appendices in the olfactory epithelial surface, namely those of cilia of olfactory receptor cells and of microvilli of olfactory supporting cells, contain Con A binding sites, but the density of these binding sites is higher on membranes of the latter structures than on those of the cilia. **1. SPECIFIC FUNCTIONAL MARKERS FOR GUSTATORY NEURONS AND TASTE BUD INNERVATION IN THE RAT BASED ON LECTIN, FRAP AND CGRP. J.D. Silverman & M.Zalewski*, S. Wong*, and L. Kruger. Depts. of Anatomy and Anesthesiology, and Brain Research Institute, UCLA, Los Angeles, CA 90024.

Primary gustatory neurons and their terminals were evaluated histochemically in geniculate ganglion (Gen g), taste buds of lingual fungiform papillae, the solitary nuclear complex (NS), and the area postrema (AP), using: a) calcitonin gene-related peptide-like immunoreactivity (CGRP-IR), marking mostly known peptidergic peripheral neurons and fibers; b) Griffonia Simplicifolia isolectin IB_4 reactivity (GSAR), specific for D-galactosyl residues and labelling largely non-peptidergic neurons and axons; c) fluoride-resistant acid phosphatase (FRAP) activity, also staining non-peptidergic neurons and co-localized with most GSAR(+) cells and central terminals.

CGRP-IR labeled rare somata in Gen g, while GSAR and FRAP stained the vast majority. Centrally, sparse CGRP-IR was found in the rostral NS and AP; GSAR and FRAP, however, robustly labeled this zone. Peripheral perigemmal CGRP-IR axons were abundant, but few intragemmal IR axons were seen. In contrast, GSAR labeled few perigemmal but numerous intragemmal axons directly beneath and between taste bud cells.

This work supports previous data showing abundant perigemmal, but sparse intragemmal peptidergic taste bud axons; and suggests GSAR to be a specific label for both intragemmal axons and FRAP(+) peripheral and central terminals. Prominent labeling of the Gen g, NS, as well as the AP, imply that GSAR may be a useful probe for examining the rat peripheral gustatory, and other visceral chemosensory neuronal systems. (Supported by a NIH grant NS-5685).

DEVELOPMENT OF OLFACTORY MARKER PROTEIN (OMP) IN THE RECEPTOR EPITHELIUM AND BRAIN IN THE MOUSE AS WELL AS ITS RELATIONSHIP TO TYROSINE HYDROXYLASE (TH) EXPRESSION. H. Baker. Dept. Neurology, Cornell Univ. Med. Coll, White Plain, NY 10605.

Until recently OMP was detected only in mature olfactory receptor neurons, but now has been localized in a number of brain regions in adult mouse. This observation prompted a study of the ontogeny of OMP in mouse CNS. A rostral-caudal gradient in OMP expression existed with cells found first in olfactory epithelium [embryonic (E) day 16], next in hypothalamus [postnatal day (P) 2] and lastly in spinal cord [P-15]. These experiments also demonstrated developmental relationships between OMP containing peripheral afferent fibers and expression of the catecholamine biosynthetic enzyme, TH, in juxtaglomerular neurons of main olfactory bulb. In E-18 through P-5 mice, OMP-containing fibers left the glomeruli, traversed the external plexiform layer and formed a dense plexus in the mitral cell layer where they contacted TH-containing neurons and processes. These data demonstrate, first that OMP in CNS, as in epithelium, exhibits developmental regulation, and second; that during development as in adults, peripheral afferents exert a regulatory influence on TH expression in dopamine neurons of the MOB. Supported by grant #NS23103.

MONOCLONAL ANTIBODY TO SUSTENTACULAR-LIKE CELLS OF THE FROG AND RAT OLFACTORY EPITHELIUM.
M.J. Crowe and S.K. Pixley* (SPON: P. Tornheim). Dept. of Anatomy and Cell Biology, University of Cincinnati, 231 Bethesda Ave., Cincinnati, OH 45267.

Few cell-type-specific antibodies exist for olfactory epithelial cells. In order to generate monoclonal antibody markers for olfactory cells that would cross-react with both rat and frog, unfixed nasal tissue homogenates from bullfrogs (Rana catesbeiana) or Sprague-Dawley rats were alternately injected intraperitoneally into a CB6F1/J mouse at two week intervals. Spleen cells from the mouse were fused with X-63-Ag8.653 myeloma cells, plated onto peritoneal exudate cell feeder plates in HAT selective medium and positive clones were chosen by immunocytochemistry on cryostat sections of bullfrog olfactory epithelium.

Supernatant from the 1D9.B9 clone demonstrated reactivity for sustentacular cells of bullfrog olfactory epithelium, using indirect immunofluorescence. Frog olfactory neurons and nerve tracts were negative. On 4% paraformaldehyde perfused, cryostat sections of rat olfactory epithelium, 1D9. supernatant showed binding to a subset of sustentacular-like cells. No staining of olfactory neurons or nerve bundles was observed. In cell cultures of adult rat nasal tissue, 1D9. immunocytochemical staining was observed on cells that were large, polygonal and rare in culture. The 1D9. antigen was internal and associated with the cell membrane. Further characterization is being done.

The monoclonal antibody, 1D9., promises to be a powerful *in vitro and in situ* for investigations of olfactory epithelium biology. (Supported by NIH PO1 NS23348-03, NSF BNS8544025 and NIH NS23523.)

466.14

DIFFERENTIATION OF OLFACTORY SENSORY NEURONS IN THE ABSENCE OF THEIR POSTSYNAPTIC TARGET.
J.E.Schwob, K.E.Szumowski*, and K.B.Brodie*. Dept. Anat. & Cell Biol., SUNY Health Science Ctr., Syracuse, NY 13210.

Olfactory bulb ablation causes olfactory sensory neuron (OSN) death followed by partial reconstitution of the neuronal population (Costanzo and Graziadei, 1983). Consequently, the morphological and biochemical differentiation of OSN's was studied after bulb ablation in adult rats with LM, EM and immunohistochemistry in an attempt to define which of the normal phenotypic properties require the influence of the olfactory bulb. There are three major findings. First, the OSN's on the ablated side are morphologically "immature", since the olfactory vesicles bear poorly developed, short cilia. Thus, differentiation of OSN's (or survival of fully differentiated neurons) is dependent on the bulb, paralleling observations during fetal development (Farbman and co-workers). Second, the uniquely "juvenile" phenotype of OSN's (vimentin expression, lack of neurofilaments (NF) and Thy-1) is independent of the bulb, as is the small subpopulation of OSN's that appear more "mature" and express NF or Thy-1 expression. Third, the expression of the cell surface, position-specific RB-8 antigen is restricted to neurons of the ventrolateral olfactory epithelium and their axons as on the control side and hence, does not require the continued presence of the postsynaptic target. Supported by NIH NS 19658 and BRSG 54026.

SPROUTING AND SPROUTING MECHANISMS II

467.1

INSULIN AND INSULINLIKE GROWTH FACTOR-I INCREASE NEUROFILAMENT mRNA LEVELS AND NEURITE FORMATION.
C. Wang*, B. Wible*, K. Angelides*, and D.N. Ishii (SPON: K.G. Beam) Physiology Dept., Colorado State Univ., Ft. Collins, CO 80523; Physiology and Molecular Biophysics Dept., Baylor College of Medicine, Houston, TX 77030.

Insulin and insulinlike growth factors (IGFs) can enhance neurite outgrowth in cultured sympathetic, sensory, and human neuroblastoma SH-SY5Y cells. The neurofilament (NF) proteins are major cytoskeletal macromolecules of axons and dendrites. To study the mechanism regulating neurite formation, a nick-translated cDNA clone containing the coding region of the human 68 kD NF protein was hybridized to Northern blots holding equivalent amounts of total or poly(A)+ RNA from cultured SH-SY5Y cells. Physiologically relevant concentrations of insulin and IGF-I substantially increased the relative abundance of NF mRNAs. The active concentrations were very similar to those that increased neurite formation. In the presence of actinomycin D, the relative degradation rate of 68 kD NF mRNAs was slower in insulin-treated than in untreated cultures. Insulin and IGFs can also stabilize and elevate tubulin, but not actin or histone, mRNAs in SH-SY5Y cells (Mill et al., Proc. Natl. Acad. Sci. USA 82: 7126, 1985). These results together suggest that neuritogenic polypeptides may coordinately stabilize and elevate transcripts coding for various cytoskeletal proteins during neurite formation. (Supported by NIH grants R01 NS24787 and NS24606).

467.2

DIFFERENCES IN THE ADHESIVE PROPERTIES OF ASTROCYTES IN THE LESIONED ADULT RAT OPTIC NERVE.
S. David and N. Giftochristos*, Neurosci. Unit, Mon. Gen. Hosp. Res. Inst., Montreal, Canada, H3G 1A4.

We have previously shown that the sprouting of injured axons in the intracranially transected adult rat optic nerve is associated with astrocyte containing, laminin$^-$ regions of the nerve near the site of lesion (J. Neurocytol. In Press). In the present study we have used an in vitro assay to examine the adhesive properties of the lesioned optic nerve.

The right optic nerve of adult Sprague Dawley rats were transected either intracranially or intraorbitally. After 5 days the animals were perfused with PBS, the lesioned optic nerves removed and 10 µm cryostat sections picked up on poly-L-lysine coated glass coverslips. PC-12 cells were seeded on to these sections ($5x10^3$ cells/well) in 24-well culture plates. After 7 days the cultures were fixed and labelled with Nuclear Yellow and anti-GFAP. Attachment of PC-12 cells was 5 to 10 fold greater near the site of the lesion as compared to regions away from the lesion. The cells were generally attached to GFAP+ areas of the lesioned optic nerve sections.

These results suggest that astrocytes near the site of a lesion may differ in their adhesive properties, from those located away from the lesion.

467.3

SPROUTING OF CGRP NERVE FIBERS IN RESPONSE TO DENTAL INJURIES.
P.E. Taylor* and M.R. Byers (SPON: B.R. Fink). Depts. of Endodontics; Anesthesiology; and Biol. Structure; Univ. of Washington, Seattle, WA 98195.

Calcitonin gene-related peptide (CGRP) immunocytochemistry has been used to demonstrate a large population of unmyelinated sensory nerves. Recently these nerves and the various neuropeptides that they contain have been implicated as mediators of inflammation and healing responses. The purpose of this study was to determine the response of these nerves to dental injuries.

Right first molars of 40 adult male Sprague Dawley rats received one of 3 degrees of injury: mild, outer dentin cavity; moderate, inner dentin cavity; severe, pulpal exposure. After 1 to 35 days the rats were sacrificed. The molar teeth were fixed, decalcified, sectioned and stained using standard immunocytochemistry for CGRP, then prepared for LM or EM evaluation. Control teeth showed a network of CGRP immunoreactive (IR) nerve fibers consistent with known dental sensory fiber distribution. The experimental teeth showed CGRP-IR fibers sprouting either into or around the affected tissue depending on severity of the injury. EM showed that the sprouting zone contained both CGRP-IR and unstained nerve fibers. In the milder injuries these responses were greatest 4 days post injury and recovered by 10-21 days. Preliminary studies of denervated teeth suggest that pulpal healing after severe injury is compromised in the absence of sensory nerve fibers.

This study was supported by NIH grant #DE05159.

467.4

INTERACTIONS OF NERVES AND PULP CELLS IN NORMAL AND INJURED TEETH ANALYSED BY LM AND EM IMMUNOCYTOCHEMISTRY FOR NGF-RECEPTOR.
M.R.Byers, M.A.Bothwell, K.B.Mecifi*, and G.C.Schatteman*. Anesthesiology; Physiology and Biophysics; Biol. Structure; Univ. of Washington, Seattle, WA 98195.

NGF cell surface receptor (NGFR) immunocytochemistry is useful for detecting cells or cell interactions which may be dependant on NGF. We used a monoclonal antibody to rat NGFR (Chandler et al, J.Biol.Chem 259:6882, 1984) to study its expression in axons, free nerve endings (FNE), Schwann cells (SC), odontoblasts (OD) and fibroblasts (FB) in normal rat molars or ones injured by drilling superficial dentin 4d prior to fixation. LM and EM preembedment methods were used with the avidin-biotin-peroxidase-DAB reaction. Normal Molars: NGFR-immunoreactivity (IR) was found on cell membranes of unmyel.axons and their SC; on FB in peripheral coronal pulp; and on many FNE. NGFR-IR was absent from myel. axons, some of their unmyel. terminal branches, and some FNE. OD were not stained except at contacts with labeled FB, axons or FNE. Injured 4d: FB stain was gone. Unmyel. axons and their SC were more numerous and had increased NGFR-IR. OD were proliferating and making reparative dentin; they had no NGFR-IR except at contacts with stained nerve fibers. Our results suggest that there may be NGF-dependant interactions in teeth that involve unmyel. axons, SC, some FNE, FB, and possibly OD at sites of contact with FB and nerves. NGF-immunoreactivity is also being studied in these teeth. (Supported by NIH grants #DE05159 and NS23343.)

LAMININ PROMOTES MOTOR NERVE SPROUTING IN VIVO. W.C. Yee*, A. Postronk and A.F. Hahn*(SPON:F.LaBella). Univ. of Man., Winnipeg, Canada; Johns Hopkins Sch. of Med., Baltimore,MD, 21205; Univ. of Western Ontario, London, Canada.

Extracellular matrix proteins have been reported to promote neurite outgrowth in vitro. We studied the effect of administered laminin and fibronectin on an in vivo model of motor nerve sprouting. Nerve terminal sprouting was induced at neuromuscular junctions(NMJs) of soleus muscles of adult Swiss mice by direct injection of botulinum toxin.Following botulinum treatment, daily injections of laminin or fibronection, 1mg/ml in Ringer's solution, were given directly into the muscles. Bovine serum albumin(BSA) in Ringer's or Ringer's solution alone was injected into control muscles. Muscles were removed on the 7th day. Thick longitudinal cryostat sections of muscles were stained with a combined silver-cholinesterase technique to demonstrate nerve terminals and sprouts. Tissue fixed in 3% gluteraldehyde was processed for electronmicroscopy(EM). In laminin injected muscles stained with the silver-cholinesterase technique, with botulinum induced sprouting, nerve terminals showed unusual nodular or tufted expansions. EM demonstrated multiple nerve sprouts and Schwann cell processes crowded into primary postsynaptic folds, accounting for the expansions on light microscopy. Nerve terminal expansions and multiple sprout crowding were not seen in muscles injected with fibronectin, BSA or Ringer's. Our findings suggest that administration of laminin promotes the proliferation of sprouts during motor nerve sprouting in vivo.

467.6

5-HT IMMUNOCYTOCHEMISTRY AND FRAP HISTOCHEMISTRY DEMONSTRATE NEURONAL PLASTICITY OF TWO CONVERGENT SYSTEMS IN THE ADULT RAT SPINAL CORD. D.C. Polistina and M.E. Goldberger. Medical College of Pennsylvania, Phila., PA 19129.

In a normal adult rat spinal cord, the superficial dorsal horn receives 5-HT projections from the midline raphe' nucleus and FRAP projections from the dorsal root ganglion and each of these converging projections are symmetrical from side to side. After unilateral partial deafferentation (sparing L5) the chronic (>30 days) spared root side shows an increase in 5-HT immunoreactivity in the superficial dorsal horn in segments rostral and caudal but not at the spared root's segment of entry (L5). In control bilateral spared root animals the distribution of the L5 dorsal root is symmetrical in lamina II of the dorsal horn as demonstrated by FRAP histochemistry. In experimental bilateral spared root animals, the chronic (>30 days) spared root side shows an increase in FRAP labeling within its normal distribution compared to the acute (4 days) spared root side. These results are similar to the results obtained by McNiel and Hulsebosch (1987) except that the spread of FRAP beyond the spared root's normal distribution was not seen in the present study. These data suggest that a projection may increase in response to partial deafferentation. In the case of converging projections the pathway more closely related to the one removed, in this case the spared dorsal root, prevents the increase of the 5-HT projection within the spared root's normal projection area.

467.7

THE RESPONSE OF SPARED DORSAL ROOT AFFERENT COLLATERALS FOLLOWING DORSAL FUNICULUS LESIONS IN JUVENILE XENOPUS LAEVIS. H.L. Campbell, M.S. Beattie, and J.C. Bresnahan. Dept. of Anat., Div. Neurosurg., and Neurosci. Program, Ohio State Univ. Coll. Med., Columbus, OH 43210.

The response to axotomy of dorsal root axons travelling in the dosal columns [DC] was studied in xenopus juveniles to determine the effects of 'pruning' rostral DC collaterals on segmental innervation patterns. Unilateral DC lesions just rostral to the lumbar enlargement were made in juvenile frogs. 3 days to 13 weeks later, axons of the tenth spinal nerve were filled with HRP. Axons extending into the lesion site appeared disorganized and often exhibited large swellings. Axons were not observed to extend through or around the lesion sites. Caudal to the lesion site, in the region of the tenth root entry zone, several phenomenon were noted: the area and density of the dorsal and ventral terminal fields [DTF and VTF respectively] increased significantly; the number of axons crossing the midline at the tenth segment and the extent of their contralateral arborizations increased and the diameter of axonal swellings located in the VTF appeared to increase. (Supported by NS-10165)

EVIDENCE FOR SPROUTING OF DORSAL ROOT TERMINAL FIELDS AFTER SPINAL CORD HEMISECTION IN JUVENILE **XENOPUS** FROGS. D. Norris*, M.S. Beattie, and J.C. Bresnahan. Depts. of Anatomy and Surgery, Ohio State Univ., Columbus, OH., 43210.

Complete spinal cord hemisections result in the removal of descending inputs to the spinal gray, and also axotomize the ascending collaterals of dorsal root axons innervating the cord caudal to the lesion.

Hemisections were made just rostral to the lumbar enlargement in juvenile Xenopus laevis frogs anesthetized with MS 222. Five weeks later, the tenth spinal nerves were labelled with HRP bilaterally to visualize the density and distribution patterns of dorsal root afferents caudal to the lesion. Tissue was processed using the CoCl-enhanced DAB procedure.

Six of seven cases were judged blind by two independent observers to have a greater innervation density and terminal field size on the side of the lesion for both dorsal and ventral terminal fields. Volumetric image/density analysis is underway to substantiate these observations. Hemisection appears to induce sprouting of dorsal root afferents in Xenopus. (Supported by NS-10165).

SPROUTING IN THE ELECTROSENSORY LATERAL LINE LOBE OF TELEOSTS FOLLOWING RICIN ABLATION. M.J. Lannoo* and L. Maler (SPON: W. Hendelman). Anat. Dept., University of Ottawa, Ottawa, Ontario, K1H 8M5.

Sprouting of primary electrosensory afferents occurs in the electrosensory lateral line lobe (ELL) of the teleost Apteronotus following ablation of peripheral nerve branches with Ricinus communis. We injected 2 ul of 2 ug/ml ricin diluted with fast green (Wiley and Oeltmann, '86) into a single nerve branch. Anterior lateral line ganglion cells became pyknotic 3-5 days following ricin injection. At two week intervals up to four months we double-labelled two of the remaining three nerve branches using the HRP-Cobalt technique (Ebbesson and Bazer, '87) and examined preparations for sprouting. The ELL is composed of four, somatotopic maps. Following supraorbital nerve branch ablation, infraorbital fibers sprouted from terminal arbors into this denervated area by two weeks in the medial and centromedial maps of the ELL. By four weeks sprouting from the infraorbital nerve had begun in all four maps; by six weeks sprouting was robust. Because adjacent segments are mirror-image oriented, sprouting fibers in adjacent segments coursed in opposite directions. Sprouting also occurred in ventral fibers to deeper parts of the ELL; these sprouting fibers coursed dorsally and probably originated from nodes of Ranvier. At four weeks, sprouting fibers from the trunk nerve also invaded the denervated supraorbital regions. Competition probably occurs between the infraorbital and trunk nerves for synaptic space.

MORPHOLOGICAL AND ELECTROPHYSIOLOGICAL CHANGES ELICITED IN MOUSE MOTOR NERVE TERMINALS BY IN VIVO INJECTION OF BOTULIN A TOXIN. D. Angaut-Petit* and J. Molgo* (SPON: Y. Padel). Lab. Neurobiol. Cell. and Molec. CNRS, 91190 Gif sur Yvette, France.

A sublethal dose of Botulinum A neurotoxin administered locally, *in vivo*, on the levator auris longus muscle of the mouse causes paralysis of the muscle and triggers the growth of motor nerve terminals. Between 12 and 20 days after the injection, these terminal sprouts stained by silver impregnation or by fluorescent mitochondrial dyes appeared as thin and long (100μm) filaments oriented parallel to the muscle fibres. An *in vitro* study of ionic permeabilities of the membrane of preexisting motor endings and newly formed sprouts was performed with the aid of specific channel blockers. The results revealed that: 1) the sprout growth is accompanied by the appearance of net inward current along the preexisting nerve terminal membrane, 2) the newly formed membrane also conducts impulses. Labelling of muscle acethylcholine receptors with rhodamine-conjugated α-bungarotoxin suggests their presence along the terminal outgrowth.

AGE-RELATED CHANGES IN ULTRATERMINAL SPROUTING WITHIN* DIFFERENT MUSCLES. J.L. Rosenheimer, L.A. Trotter and D.O. Smith. Dept. of Physiology, Univ. of Wisconsin, Madison, WI 53706.

End plates from extensor digitorum longus (EDL), soleus and diaphragm muscles of 10- and 25-mos rats were examined for the effect of aging on ultraterminal sprouting, a form of terminal sprouting usually associated with muscle denervation. There was a significant age-related increase in the fraction of end plates exhibiting ultraterminal sprouting in the EDL muscle; the number increased from 5.5% to 23.0%. There were comparatively fewer end plates with ultraterminal sprouts (< 3.0%) in the soleus and diaphragm muscles of 10-mos rats, and this number did not change significantly with age. Sprout length did not exhibit an age-related change in any of the muscles, although sprouts were consistently longer in the EDL. End plates from muscles of 25-mos animals that had been chronically stressed or exercised were also analyzed. These extrinsic factors did not alter the number of end plates exhibiting ultraterminal sprouting in any of the muscles. It is concluded that in certain muscles, aging may be accompanied by changes in the relationship between the nerve and muscle that may induce the expression of denervation-like characteristics which are not influenced by extrinsic factors previously shown to affect terminal number. PRAGMATIC LANGUAGE SKILLS IN CHILDREN WITH SCHIZOPHRENIA. J.G. FOY* and R. CAPLAN. 48-241 Neuropsychiatric Ins., UCLA, 760 Westwood Plaza, Los Angeles, CA 90024

Pragmatic language skills have been found to be impaired in adult schizophrenics (e.g., Rochester & Martin,1979) The purpose of this study was to investigate the pragmatic skills of children with schizophrenia and to elucidate the nature of these deficits.

15 schizophrenic children aged 7 -12.5 years were matched by sex, MA and SES to normal children. The schizophrenic children were recruited from UCLA's Neuropsychiatric Institute Inpatient and Outpatient Children's Services and from 2 L.A. schools for the emotionally disturbed. They were independently diagnosed with the Interview for Childhood Disorders and Schizophrenia (ICDS) by the Diagnostic Unit of the Childhood Psychosis Clinical Research Center. Language samples were obtained from videotapes of the Kiddie Formal Thought Disorder Story Game (SG) developed by Caplan (1988). The transcribed videotapes were rated with the Pragmatic Skills Scale (PSS) by 2 trained, blind raters. This instrument was adapted from Halliday and Hasan (1976) and operationalized for use with children.

Preliminary results indicate that the schizophrenic children differ from normal children in their use of endophora and unknown ties. The relationship of these behaviors to age and diagnosis will be presented in detail.

MONOAMINE OXIDASE ABSENT IN NORRIE DISEASE PATIENTS WITH DELETION IN CHROMOSOMAL REGION Xp11.3. M.Utterback,K.Sims*,A.dela Chapelle*, R.Norio*,E.Sankila*,Y-P.Hsu*,J.Powell*,J.Gusella X.Breakefield. Neurogenetics Div.,Shriver Ctr., Waltham, MA; Neurogenetics Lab, Mass.Gen.Hosp.; Med.Gen.Div.,Univ.Helesinki; Endocrin.Res.Unit, Harrow,England; Clin.Sci.Lab, NIMH.

Moroamine oxidase (MAO), in its two forms MAO-A and MAO-B, is the enzyme primarily responsible for degradation of amine neurotransmitters. A complementary DNA (cDNA) clone for human MAO-A has been used to establish the deletion of its corresponding gene in two male cousins with Norrie disease. No MAO-A activity was detected in their fibroblasts.MAO-B activity in platelets and fibroblasts from these patients was also non-detectable. Moreover, major catecholamine metabolites, including vanillylmandelic acid (VMA), homovanillic acid (HVA) and 3-methoxy-4-hydroxyphenylglycol (MHPG), were reduced substantially in their urine. These findings indicate that gene(s) necessary for MAO-A and MAO-B activities are deleted in these patients and that the gene loci are near each other in Xp11.3. This is the first report of absent MAO activity in humans; at least some of the clinical features of these patients may reflect this deficiency.

CORRELATION OF MORPHOLOGICAL, BIOCHEMICAL AND CBF CHANGES IN EXPERIMENTAL INFANTILE HYDROCEPHALUS. U.A. Vasthare*, R.F. Tuma*, I.A. Van Orden*, L.C. Wright*, S.D. Katz*, T.J. Lovely*, R.H. Rosenwasser* and J.P. McAllister. (SPON:J.A. Kenning). Depts. of Anatomy, Physiology and Neurosurgery, Temple U. Sch. Med., Philadelphia, PA 19140.

Our previous studies have shown that pyramidal cells degenerate and monoamine levels are reduced in cerebral cortex of hydrocephalic kittens. The present study sought to determine the relationship between these morphologic and biochemical changes and cerebral blood flow (CBF). Hydrocephalus was induced in 4-10 day old kittens by intracisternal injections of 25% kaolin and verified with ultrasound; control animals received similar injections of sterile saline. The isotope labelled microsphere method was used to measure CBF 15-20 days post-injection. Significant ($p<0.05$) decreases in CBF were detected Areas 4 (55%), 22 (56%) and 17 (58%) of cortex, as well as thalamus (46%), midbrain and pons (55%), cerebellum (50%) and caudate nucleus (61%). A Cushing response was evidenced by decreases in heart rate (22%) and cardiac output (70%), and a 221% increase in total peripheral resistance. The changes in cortical CBF did not follow the rostrocaudal gradient of neuronal degeneration and monoamine changes. Thus, these data suggest that reductions in cortical CBF may not be the only factor mediating the neurologic deficits or the neuronal deterioration that accompany hydrocephalus. Supported by NIH Grant SO RR05417 to JPM.

INTERREGIONAL CORRELATIONS OF GLUCOSE UTILIZATION AMONG BRAIN REGIONS IN YOUNG DOWN SYNDROME (DS) ADULTS. B. Horwitz, M. Schapiro*, C. Grady, and S. I. Rapoport. Laboratory of Neurosciences, National Institute on Aging, National Institutes of Health, Bethesda, MD 20892.

Correlations between regional cerebral metabolic rates for glucose (rCMRglc), determined by positron emission tomography using [^{18}F]fluorodeoxyglucose provide a measure of the functional associations between pairs of brain regions (Horwitz et al., J. Cereb. Blood Flow Metabol., 4, 484-499, 1984). We applied this method to healthy, trisomy 21 DS adults (23-33 yrs) and to 24 age-matched healthy controls (20-35 yrs).

Correlations were obtained between ratios of resting rCMRglc to global brain metabolism (Q-values). Most Q-values had group means that did not differ significantly ($p > 0.05$) between DS subjects and controls. However, many correlations between regions within and between the frontal and parietal lobes had significantly ($p < 0.01$) lower values in the DS group than in controls, with some being large and negative in the DS group that were large and positive in the controls. One region so affected was the left inferior frontal gyrus that includes Broca's area.

The decreased values of correlations associated with Broca's region are consistent with the relatively greater language impairment seen in subjects with DS. The reduced values of frontal-parietal correlations in the DS group are similar to that found in adult autistic patients (Horwitz et al., Arch. Neurol., in press), and can be interpreted as indicating a disruption of neural systems associated with directed attention.

MICROGLIA RESPONSES DURING DEVELOPMENT IN DOWN'S SYNDROME. L.C. Stanley*, L.J. Perrot, and W.S.T. Griffin (SPON: D.L. Davies). Depts. of Anat. and Pediat., Univ. Arkansas Med. Sci., Little Rock, AR 72205

Recently, we noted a profound astrogliosis characterized by elevated S100 immunoreactivity present in Down's syndrome (DS) as early as 2 days postnatal. As microglia produce factors, including Interleukin 1 (Il-1), that stimulate astrocytes in culture, we postulated that during development microglia become reactive and produce Il-1 which may contribute to the reactive astrogliosis we show in DS. Rabbit-anti-human Il-1 (1:500) was immunoreacted with sections of formalin-fixed, paraffin-embedded temporal lobe from cases of DS (ages 18-19 weeks gestational, 2 days and 3.5 months postnatal) and age-matched controls (AMC). Diaminobenzidine was used to stain immunoreactive products. There were greater numbers of Il-1 immunoreactive glia present in DS compared to AMC, and Il-1 immunoreactivity was dramatically elevated in what were morphologically identified as reactive microglia in the DS tissue. Because of the ability of Il-1 to initiate the release of corticotropin releasing factor, adrenocorticotropic hormone, and hydrocortisone and thereby cause immunosuppression, the elevation of glia-derived Il-1 may also contribute to the systemic immunodepression syndrome that accompanies DS.

468.6

ASTROCYTIC RESPONSE IN DEVELOPMENT DURING DOWN'S SYNDROME. W.S.T. Griffin, L.J. Perrot, and L.C. Stanley*. Depts. of Pediat. and Anat., Univ. Arkansas Med. Sci., Little Rock, AR 72205.

Neuropathology similar to that in Alzheimer's disease is present in Down's syndrome (DS) after age thirty (Wisniewski, K.E., Ann. Neurol., 17:278, 1985). Recently, the S100 gene was localized to chromosome 21 (Allore, R., Science, 239:1311, 1988). Since S100 is induced in reactive astrocytes, the age-related presence of reactive astrocytes in DS may be related to the gene duplication in trisomy 21. We postulated that during development, astrocytes become reactive and produce elevated levels of S100 in DS. Rabbit-anti-cow S100, diluted 1:300, was immunoreacted with sections of formalin-fixed, paraffin-embedded temporal lobe from cases of DS (ages 18-19 wk. gestational; 2 d. and 3.5 mo. postnatal) and age-matched controls (AMC). The specific astrocyte marker, glial fibrillary acidic protein (GFAP), diluted 1:500, was similarly immunoreacted. Diaminobenzidine was used to stain immunoreactive products (IR). We found greater numbers of GFAP-IR and S100-IR reactive astrocytes in DS compared to AMC, and the immunoreactivity per cell was dramatically elevated. Besides its relationship to astrocyte reactivity suggested here, overexpression of the S100 gene in DS may contribute to microtubule assembly dysfunction since S100 inhibits ATPase activity needed for microtubule assembly [Fujii, T., Chem. Pharm. Bull., 35(10)4324, 1987].

EXPRESSION OF (1) A CELL ADHESION MOLECULE (N-CAM) AND (2) A NEURITE PROMOTING MOLECULE (LAMININ) IN POST-MORTEM BRAIN TISSUE FROM ALZHIEMER'S DISEASE AND DOWN SYNDROME PATIENTS. S-J. Richards & P. Liesi*, Dept, of Biochemistry & Molecular Genetics, St. Mary's Hospital Medical School, London W2 1PG, UK and *Recombinant DNA Laboratory, University of Helsinki, Valimotie 7, Helsinki.

Down syndrome is a genetic disorder in which affected persons have a karyotype of either trisomy 21 or a translocation of the long arm of chromosome 21, in particular the region 21q22.1-21q22.2. It is the altered expression of the genes within this 'pathological' region of chromosome 21 that is thought to account for the increased incidence of Alzheimer's disease observed.

Previous neurological studies have reported that the increase in genetic material associated with the extra copy or portion of chromosome 21 causes neuronal cytoskeletal abnormalities and which may be causally related to the development of Alzheimer's disease.

We have speculated that the neurological abnormalities may be related to the over-expression of a gene(s) involved in embryogenesis, and further suggest this gene(s) could be a growth factor, cell adhesion molecule or a molecule involved in neuronal migration and axonal guidance.

To date we have examined levels of expression of N-cam and laminin in post-mortem brain material using Northern blot analysis. We are unable to report a significant variation in expression of either of these two genes within control and experimental brain tissues.(SPON: R.C.A. Pearson)

VOLTAGE DEPENDENCY ON ELECTRICAL MEMBRANE PROPERTIES IN TRISOMY 16 AND NORMAL MOUSE DORSAL ROOT GANGLIA NEURONS IN CULTURE. **J. Hidalgo,* B. Ault* and S. I. Rapoport (Spon. Anne E. Schaffner)**
NIH, NIA Lab. of Neurosciences. Bethesda MD 20892

Our laboratory has reported that trisomy 16 dorsal root ganglia (DRG) embryonic mouse neurons in culture present several electrical properties that differ from paired litter controls. Since some of these properties have a strong voltage dependency, experiments were performed to establish to what extent differences in the membrane potential could account for them.

Primary cultures of DRG neurons were kept for 2 to 4 weeks. The whole cell variation of patch clamp recording was used in current clamp mode. Standard solutions of K^+ and Na^+ for internal and external mediums were used. Current was applied to hold the membrane potential at levels between -45 and -65 mV. Suprathreshold current pulses of 10 msec were used to elicit action potentials.

The resulting data was digitized, analyzed and tabulated. In trisomy 16 neurons, the time for peak during hyperpolarizing after potential (HAP) is more sensitive to voltage and the rate of repolarization is less sensitive to voltage than in control neurons. The calcium and potassium conductances that could be underlying these differences are being studied at the single channel level.

ULTRASTRUCTURAL CHARACTERISTICS OF PERIPHERAL VISUAL AND AUDITORY SYSTEMS IN CAPRINE β-MANNOSIDOSIS. **J. A. Render*, K. L. Lovell and M. Z. Jones. Dept. Pathology, Mich. State Univ., East Lansing, MI 48824.**

Caprine β-mannosidosis, an autosomal recessive defect of glycoprotein catabolism associated with a deficiency of tissue and plasma lysosomal β-mannosidase, is expressed at birth by severe neurological deficits, including deafness. Affected kids have normal light reflexes. In the present study, ultrastructural abnormalities of the peripheral visual and auditory systems in affected goats were defined in order to further investigate the expression of the disease in peripheral sensory organs and the correlation between morphological changes and sensory function. With respect to the visual system, many types of ocular cells contained intracytoplasmic vacuoles; vacuolated retinal cells included photoreceptor cells, cells within the inner nuclear layer, and ganglion cells. Ultrastructurally these vacuoles were membrane bound, occasionally coalescing and principally electronlucent. In the optic nerve, vacuolated glial cells and ovoidal axonal spheroids composed mainly of dense bodies were present. These lesions and severe myelin deficits in optic nerve apparently do not interfere substantially with visual function. Otic morphologic abnormalities involved the external, middle and inner ears. Alterations involving the cochlea included cytoplasmic vacuolation of most cells. Through continued research on β-mannosidosis, we hope to understand the correlation between morphological changes and function of the special senses in storage diseases. A PERFORMANCE DEFICIT IN THE ADULT OFFSPRING OF C57 MICE EXPOSED TO ETHANOL DURING EARLY GESTATION. R. Dumas* and E. A. Sersen* (SPON: G.Y. Wen). NY State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

Although the deleterious effects of a brief exposure to a large dose of alcohol on the morphological development of the mouse fetus have been delineated, the subsequent functional consequences of such an exposure are not known. Previous work in our laboratory indicated deficits in climbing behavior of mice with normal external morphology born to C57Bl/6J dams gavaged with 5.8 g/kg of ethanol on E9. Recently, a larger sample of 3 groups of pregnant mice (E, ethanol; D, isocaloric dextrose; C, untreated) were allowed to come to term. Neonatal mortality and hydrocephaly, developing within the first 3 weeks, reduced the E offspring by 30%. The remaining E mice and their controls were tested on a wire bar vertical plane at 28 d and then weekly for a total of 13 weeks. The E offspring displayed essentially normal activity and motor coordination, but their movements were slower than those of the controls in traversing the apparatus. They showed a marked and significant ($p<.005$) failure to negotiate a small drop at the bottom of the plane to return to the home cage. This finding suggests a persisting functional impairment in adult normal-appearing mice who had been briefly exposed to ethanol during a critical stage of embryonic development.

THE RAT WITH METHYLAZOXYMETHANOL-INDUCED MICRENCEPHALY - A MODEL FOR DEVELOPMENTAL ABNORMALITIES OF THE VISUAL SYSTEM. A. Rabe, M. H. Lee and P. Wang*. NY State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

The micrencephalic rat with its hypoplasia of the forebrain is a useful model for the study of developmental brain defects. The two most consistently seen behavioral changes of this rat are maze learning deficits and hyperactivity. Both are unspecific since each may arise from morphological and neurochemical alterations in several different brain regions. The markedly reduced occipital region, as well as neuron loss throughout the subcortical visual system of the micrencephalic rat (Ashwell, 1987), suggest that modality-specific (visual) deficits should also exist. Indeed, Pereira et al. (1985) showed micrencephalic Wistar rats to be markedly impaired in visual pattern, but not brightness, discrimination. We have now replicated their results with Long-Evans rats. Mature rats learned to discriminate between two visual stimuli to escape a mild footshock. A black and white discrimination was given to 7 micrencephalic (M) and 8 normal (C) rats, and a discrimination of horizontal vs vertical 6 mm black and white stripes was administered to other groups of 15 M and 14 C rats. The M rats were impaired in learning the pattern, but not brightness, discrimination. The scores for pattern discrimination M vs C, were: total correct trials in 10 d, 157$\pm$ 21 vs 174 $\pm$ 10, $p < .011$; total errors 59 $\pm$ 26 vs 31 $\pm$ 12, $p < .001$.

OVERPRODUCTION OF PROTEASE NEXIN I (PNI) IN RAT BRAIN TUMORS IN VIVO. J.S. Rao*, J.B. Baker*[1], and B.W. Festoff (SPON: L.T. GIRON). Neurobiol. Res. Lab (151), V.A. Med. Ctr., Kansas City, MO 64128; [1]Dept. of Biochem., Univ. of Kansas, Lawrence, KS 66045.

PNI is identical to glial derived nexin (GDN), a neurite outgrowth promotor found in rat and human glial cells. The 9L rat brain tumor is a gliosarcoma and a model of human brain tumors. Our previous results showed that these cells secrete both PNI and PAI-1 (endothelial cell-type PA inhibitor). We studied these inhibitors in normal brain and 9L tumor in vivo. A PNI-type inhibitor formed a 92 Kd and 78 Kd complex with ^{125}I-urokinase and ^{125}I-thrombin, respectively, in the absence of SDS. In the 9L tumor, the PNI complexes were increased threefold when compared to normal brain. In addition, in contrast to studies with 9L in vitro, in the presence of SDS we found another complex at 88 Kd with ^{125}I-thrombin, but no complex with ^{125}I-urokinase. Brain tumor pathogenesis may involve increased gene expression with protease nexin I and decreased PAI-1. Such studies are in progress.

FUNDAMENTAL MECHANISMS OF TUMORIGENESIS IN THE HUMAN NERVOUS SYSTEM. B.R.Seizinger*, G.A.Rouleau*, G.E.Farmer*, A.H.Lane*, R.L.Martuza* and J.F.Gusella*. (SPON: L.Jacoby). Depts.of Neurology and Neurosurgery, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

One way of gaining insights into the normal function of the human nervous system is to study its dysfunction in specific disorders. Neurofibromatosis (NF), one of the most common inherited disorders affecting the human nervous system, is typically associated with Schwann cell-derived tumors which can lead to serious neurological complications and death. Two genetically and clinically distinct forms of NF have been described, NF1 and NF2. Using a molecular genetic approach, we have provided conclusive evidence that the defective genes causing NF1 and NF2 map to chromosome 17 and chromosome 22, respectively. This provides the basis for the isolation and characterization of the NF genes, which might eventually lead to the development of effective therapies for these serious neurological disorders. We have shown that different tumor types in NF2 are specifically associated with deletions on chromosome 22 suggesting a common pathogenetic mechanism for meningiomas, acoustic neuromas, and possibly certain types of astrocytic tumors. The same gene defect reponsible for the inherited tumors in NF2 may also cause their sporadic counterparts which constitute a considerable portion of neoplasias in the human brain. The NF2 gene seems to belongs to a class of cancer-related genes, so called tumor suppressor genes, whose loss, deletion or inactivation leads to tumor formation.
We have recently provided strong evidence that a similiar mechanism of tumorigenesis, loss of a tumor suppressor gene on the short arm of chromosome 3, underlies VHL. VHL is a devastating cancer syndrome, associated with endothelial-derived tumors in the brain and spinal cord, phaeochromocytomas, and renal cell carcinoma. The isolation and characterization of these tumor suppressor genes may not only provide insights into one of the most fundamental mechanisms of cancer development in humans, but could also elucidate key mechanisms regulating the normal development and differentiation of the human nervous system.

HYPOXIA DISRUPTS NEURONAL MIGRATION IN THE RAT. J.H. Jennings*, A.W. Deckel, and M.C. Yu. (SPON: J.A. Liederman). Depts. of Psychiatry and Anatomy, Univ. of Med. and Dent., N.J. Med. Sch., 185 S. Orange Ave, Newark, N.J., 07103.

Previous work indirectly suggested that the hypermyelination found in the striatum and thalamus in individuals with cerebral palsy was secondary to an arrest of neurons migrating from the ganglionic eminence to late forming telencephalic structures, with subsequent myelination of these neurons as they differentiated (Deckel and Robinson, Exp. Neur., 91, 212-218, 1986). This experiment directly tested that hypothesis by exposing pregnant rat dams at 14, 16, or 19 days post conception to 48 hours of a 10% oxygen/90% nitrogen environment. Controls were left at room air. Animals were given an injection of tritiated thymidine (5 uCi/g; specific activity= 6.7 Ci/mMol) immediately before placement into the hypoxic environment; rat pups were sacrificed at 21 days post birth, perfused, and examined by autoradiography and Nissl histology. Cell counts indicated increase numbers of labeled neurons in the striatum and layer III of the neocortex of hypoxic animals, and decreased numbers of cells in neocortical layer VI. The effect was greatest for the animals of gestational ages E14-E16. In addition, a hypermyelination was found within the striatum of the hypoxic animals. These results indicate that perinatal rodents exposed to a hypoxic environment (1) have a disruption of neuronal migration in the striatum and neocortex, and (2) evidence a status marmoratus-like effect within the striatum. Implications of these findings for cerebral palsy are discussed.

468.15

QUANTITATIVE MORPHOLOGIC ANALYSIS OF THE EFFECT OF MILD PERINATAL ASPHYXIA ON RAT STRIATAL CHOLINERGIC NEURONS. RE Burke, RI Stark. Columbia Univ. Coll. P&S, NYC 10032.

Little is known of the effect of perinatal asphyxia on the neurochemical anatomy of the brain. Neurochemical studies show that striatal cholinergic (ACh) markers are selectively diminished in a rodent model (Johnston, 1983), but morphologic studies show preservation of striatal ACh neurons (Johnston & Hudson, 1987). We examined the effect of mild injury on the total number of these neurons, determined by counting in 8 serial planes through the striatum. We used a model of unilateral asphyxia (ligation of one carotid artery; exposure to 8% O_2). ACh neurons were stained by the immunoperoxidase method using a monoclonal antibody to CAT (B-M). Brains were fixed by immersion, because perfusion (in the presence of a ligation) led to asymmetries of staining, visible in control nuclei and ligation-alone controls. At 3 weeks, normal controls fixed by immersion were symmetrical in total striatal ACh neurons (R=5393+266 (SEM); L=5388+280; N=8) (Abercrombie corrected). Rats with unilateral (left) asphyxia unexpectedly showed a trend for an increased number of ACh neurons on the affected side (R=4371+347; L=4659+339; N=6; p=0.1). An increase was also seen in 8 week rats (R=4036+222; L=4635+193; N=7; p=.01). The increase on the asphyxiated side was uniform rostro-caudally. Striatal ACh neurons are not only resistant to asphyxial injury, but possibly increased in number by an as yet undefined mechanism.

HIPPOCAMPAL ANOMALIES IN THE NEW ZEALAND BLACK MOUSE: A GOLGI STUDY. A.M. Galaburda, W.E. Kaufmann and N. Jaskowiak*. Dyslexia Neuroanatomical Laboratory, Harvard Medical School and Beth Israel Hospital, Boston, MA 02215.

It is reported that NZB mice show hippocampal anomalies by the Golgi-Stensaas method (Nowakowski, R.S., *Soc. Neurosci. Abs.* 13:1117, 1987). They consist of ectopic neurons, which show abnormal dendritic arborization, in the molecular layer and in the limit between the molecular and the granule cell layer. We examined by the Nissl and Golgi-Cox-Sholl methods the hippocampal formations of 14 NZB and 6 DBA mice, and describe here neurons from CA1 and CA2 of Ammon's Horn.

No pyramidal cell layer abnormalities were noted in the Nissl-stained sections. The distribution of neurons stained by the Golgi method was more regular in the DBA than in the NZB. The apical dendrites in the NZB, but not in the DBA, were straighter and lacked the tortuosity characteristic of this region (Banker, G.A. and Cowan, W.M., *J. Comp. Neurol.*, 187:469, 1979). There was more variability in the degree of basal dendritic arborization in the NZB than in the DBA, and the general pattern of branching in the former tended to adopt the axial, rather than the more typical laminar, distribution. Some of the NZB neurons exhibited basal dendrites directed toward the *stratum oriens*. Some of the pyramidal cell changes are reminiscent of earlier hippocampal developmental stages and others suggest developmental deviance. Quantitative analysis is currently in progress and will be discussed.

NEOCORTICAL ANOMALIES IN THE NEW ZEALAND BLACK MOUSE: A GOLGI STUDY. W.E. Kaufmann, N. Jaskowiak* and A.M. Galaburda. Dyslexia Neuroanatomical Laboratory, Harvard Medical School and Beth Israel Hospital, Boston, MA 02215.

Some NZB mice show neocortical molecular layer ectopias and laminar dysplasias (Sherman, G.F. et al., *PNAS* (USA), 82: 8072, 1985). We compared over 500 cells from 3 NZB mice with 4 anomalies (NZBw), 8 without anomalies (NZBw/o), and 8 DBA controls for Golgi characteristics (Golgi-Stensaas). We made planimetric analyses of cell populations in the superficial portion of layer ii (iis), the deep portion of layer ii (iid), and pyramidal neurons in layers iii, v, and vi. We quantitated basal dendritic length (*bdl*), total number of basal dendritic branches (*btn*) and of 1st (*b1*), 2nd (*b2*), and 3rd (*b3*) order branches, number of terminal basal dendritic branches (*tbdb*), apical dendritic length (*adl*), cell body surface area, average length per basal dendritic branch (*bdl/btn*), and ratio of apical to basal dendritic development (*adl/bdl*).

NZBw/o showed greater *bdl, btn, b2, b3* than DBA in all layers except vi, greater *adl* in iii and v, and larger *bdl/btn* in iis and iii. NZBw had greater *tbdb* than DBA in iii. Also, DBA showed significant interlaminar differences in most parameters, whereas only some interlaminar differences were seen in NZBw/o and no differences were demonstrated in NZBw, reflecting lesser laminar differentiation in the latter. NZBw/o had a greater *bdl/btn* than NZBw in iis, greater *b1* and *b2* in iid, and tended to have greater *btn* and *tbdb*. Ectopic neurons in i differed less from ii neurons than from iii-vi neurons (but no difference was significant), and exhibited features of both iis and iid neurons. Qualitative differences in the ectopic neurons and implications of the findings will be discussed.

STRUCTURE & NATURE OF MEGANEURONS IN CORTICAL (MARGINAL) HETEROTOPIAS: A GOLGI STUDY. M. Marin-Padilla. Dept. Pathology, Dartmouth Med. Sch. Hanover, NH 03756.
Meganeurons have been described in cortical (marginal) heterotopias of human porencephalies (M. Marin-Padilla et al. Soc. Neurosc. Abs. 5:631, 1979; R.F. Mervis et al. Soc. Neurosc. Abs. 6:738,1980). A Golgi study of these neurons has demonstrated that most, if not all, of them represent transformed interneurons that have responded to the local alterations of the circuitry caused by the heteropia. Most pyramidal neurons within the heterotopia are not affected and their size remain within normal limits. All (45) meganeurons studied are stellate cells located within layer II or at the border between layers II and III. They are characterized by a large irregular soma from which several long dendrites originate. The dendrites extend throughout the territory of layer II and penetrate into layers I and III. All dendrites as well as the soma of these meganeurons are covered by dendritic spines. The axon arises from one of the dendrites (often at a considerable distance from the soma), is frequently ascending, and gives off many collaterals that are distributed within the territories of layers II and upper III, and some collaterals even penetrate into layer I. The nucleus of these meganeurons is quite large (as large as that of layer V pyramidal neurons) suggesting polypoidy and hence (acquired) cell hypertrophy. The presence of transformed hypertrophic interneurons in cortical heterotopias could resulted in local functional alterations. Local functional alterations could explain the brain dysfunction which is associated with dyslexias, minimal brain damage and/or epilepsy.

CAUDAL NERVE CONDUCTION IN THE DEVELOPING TWITCHER MOUSE AND ITS AGING HETEROZYGOUS AND NORMAL LITTERMATES.
Charles E. Olmstead. UCLA Sch. of Med., Mental Retardation Res. Center Group at Lanterman Dev. Center, Pomona, CA 91769.

The murine mutant "twitcher" is an enzymatically authentic model for the recessively transmitted human globoid cell (Krabbe) leukodystrophy. In addition to the progressive debilitation of the affected (twi/twi) animal, we have described (Behav. Brain Res. 25(1987) 143-153) subtle neurobehavioral differences between the developing heterozygous (twi/+) and normal (+/+) littermates which suggested this mutant might also be a model for heterozygote risk during life span development.

Genotype was determined by assay of galactosyloeramidase from short segments of tail. Caudal nerve sensory and motor conduction velocities were recorded with pairs of needle electrodes placed at the base, center and tip of the tail. The animals ranged in age from 10 to 590 days and were studied under Nembutal anesthesia while immobilized on a temperature-controlled platform.

As previously reported (Soc. Neurosci. Abstr. 11, 1985) the three genotypes were clearly different by 21 days of age, when at least three conduction velocity populations could be identified. As might be expected the faster NCVs were the first to go in the (twi/twi) animals, all of which were dead by 50 days of age. At 75 days of age the twi/+ mice were not significantly different than the +/+. Twi/+ animals studied at >500 days of age showed significantly more variability than their +/+ littermates.

THE RELATIONSHIP OF IMMUNE STATUS TO NEUROPATHOLOGY IN AUTOIMMUNE MICE. G. F. Sherman, P.O. Behan*, G.D. Rosen, and A.M. Galaburda. Department of Neurology, Beth Israel Hospital and Harvard Medical School, Boston, MA 02215 and Southern General Hospital, Glasgow, Scotland.

Previous studies have shown that the New Zealand Black (NZB) and BXSB mouse strains have a high prevalence of developmental cerebral anomalies (Sherman et al., *PNAS*, 82: 8072,1985, and *Acta Neuropathol.*, 74: 239,1987). These consist of ectopic collections of neurons in layer I and underlying laminar dysplasia. The anatomical characteristics of these anomalies (dated to the late stages of neuronal migration) have lead us to propose these mice as models for the similar anomalies seen in the brain of male dyslexics (Galaburda et al., *Ann. Neurol.*, 18: 222, 1985). The present study was conducted to determine whether the anatomical anomalies were seen in other immune-dysfunctional strains, to assess for immunological differences between strains possibly related to the presence of brain anomalies, and to evaluate intra-strain differences between mice with and without brain anomalies. At least 10 male and 10 female mice from strains suspected to have immune abnormalities (MRL/Mp*lpr lpr*, MRL/Mp+/+, NZB/W, DW, AKR, CBA, C58, SJL, BALB/cBy-*nu*, C57BL/6-*nu*, and additional BXSB mice) or no immune problems (BALB/c, DBA/2, and C57BL/6) were tested on a battery of immune tests (including measurements of autoantibodies, IgG, IgA, IgM, T and B lymphocyte subsets, killer cell function, and complement activation). The brains of these mice were processed in celloidin and coronal sections were cut at 35µm and stained with cresyl violet. The sections were examined under a light microscope and the incidence of anomalies was noted and the relationship to immune abnormalities analyzed. (Supported by NIH grant 20806).

NEUROENDOCRINE CONTROLS: OTHER III

COCAINE EFFECTS ON RENIN SECRETION IN CONSCIOUS RATS. J.M.Lakoski, R.E.Halpern*, K.A.Cunningham, K.Kunimoto*, and L.D.Van De Kar (SPON:G.H.Greeley). Dept. Pharmacol., Univ. Texas Med. Branch, Galveston, TX 77550.

Our present knowledge of the neuroendocrine profile of cocaine is limited. In view of the role of serotonin (5-HT) in the regulation of renin secretion and the marked effects of cocaine on spontaneous activity of 5-HT neurons recorded in the dorsal raphe nucleus, we have investigated the effects of systemic cocaine exposure on plasma renin activity (PRA) and concentration (PRC).

Male Sprague-Dawley rats received cocaine (15mg/kg, i.p.) or saline 15 min prior to decapitation. Trunk blood was collected, plasma separated, stored at -80°C, and assayed for PRA and PRC by radioimmunoassay of generated angiotensin I. Acute administration of cocaine (COC) significantly ($p<0.01$) decreased PRA and PRC as compared to saline controls (COC 5.6±0.5 vs SAL 11.0±1.0 and COC 9.5±1.2 vs SAL 16.2±0.7, respectively). Examination of the time course of this cocaine effect revealed a maximal suppression of renin secretion at 15 min in a dose-dependent manner. PRC was also evaluated in animals sacrificed 24 hr following repeated exposure to cocaine (15mg/kg, 2x daily, i.p. for 7 days) or saline. Animals treated with cocaine had elevated PRC levels as compared to saline controls (COC 9.8±1.0 vs SAL 6.1±0.6) without changes in plasma corticosterone. These observed changes in renin secretion may result from potent effects of cocaine on 5-HT neuronal systems. Supported by DA 04296.

SEROTONIN-INDUCED NATRIURESIS IS MEDIATED BY RENAL NERVES AND ANP IN THE UNANESTHETIZED RAT. R. Montes* and A.K. Johnson (SPON: I. Gormezano). Depts. of Psychology and Pharmacology and The Cardiovascular Center, University of Iowa. Iowa City, Iowa 52242.

Central serotonin (5-HT) has been proposed to be involved in the control of sodium excretion. We studied the role of renal nerves and atrial natriuretic peptide (ANP) on natriuresis induced by intraventricularly-administered (IVT) 5-HT. Animals were bilaterally renal or sham denervated and implanted with lateral ventricular cannulae. One week later, they were instrumented with femoral venous and arterial catheters and a bladder cannula. The next day, rats were infused (i.v.) continuously with a hydrating hypotonic solution, and mean arterial pressure, heart rate, diuresis, Na^+ and K^+ excretion were determined. After 150 min., 5-HT (20 µg free base) or vehicle was injected IVT. In a second experiment, plasma ANP levels were determined 15 min. after 5-HT (5, 20 µg) or vehicle. Intraventricular 5-HT produced a decrease in sodium reabsorption, consistent with a withdrawal of sympathetic tone. Renal denervation significantly attenuated the natriuretic response to 5-HT. Both doses of 5-HT caused a significant elevation of plasma ANP levels. These results suggest that the natriuretic effect produced by centrally administered 5-HT may involve neural- as well as ANP-related mechanisms.

MONOAMINE RELEASE FROM THE VENTROMEDIAL HYPOTHALAMUS OF FREELY MOVING FEMALE RATS. I. Vathy and A.M. Etgen. Depts. Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Our previous study employing microdialysis in urethane-anesthetized female rats demonstrated that ovarian steroids may modulate norepinephrine (NE) release in the ventromedial hypothalamus (VMH). The present experiments measured NE release in the VMH of awake rats that were ovariectomized and steroid-treated. One day after rats were fitted with a loop-type microdialysis probe, samples were collected at 25 min intervals for 4-5 hr to measure baseline monoamine levels in a hormone-free state. Animals then received an injection of 3 ug of estradiol benzoate (EB), and two additional samples were collected to monitor possible stress effects on NE release. Twenty-four hr after EB injection, sample collection resumed for 4-6 hr; some animals received KCl stimulation in the dialysate to induce depolarization-evoked release of monoamines. During sample collection on the following day (48 hr after EB), rats were injected with 200 ug of progesterone (P) and were tested for estrous behavior with stimulus males 3.5 hr later. Preliminary results show that animals chronically implanted with dialysis probes in the VMH exhibit robust, hormone-dependent estrous behavior. We are able to detect NE in VMH dialysates of freely moving female rats, and we will present data correlating NE release with EB and P activation of estrous behavior.

ELECTRICAL COUPLING IN PRIMARY CULTURES OF ADULT RAT PINEALOCYTES. J.C. Saez*, V.M. Berthoud*, R. Dermietzel*[1], and M.V.L. Bennett (SPON: H. Buschke). Dept. Neurosci., A. Einstein Coll. Med., Bronx, NY 10461, [1]Inst. Anatomy, Univ. Essen, Essen, W. Germany

Gap junctions (GJs) mediate electrotonic and metabolic coupling. Extensive morphological studies have shown gap junctions between pinealocytes in diverse species. Here we characterize their physiological, pharmacological and biochemical properties. Female Sprague-Dawley rats (ca. 200g) were used. Anaesthetized rats were decapitated, and the pineal gland was dissected out and placed in Dulbecco's saline. After decapsulation, 2-3 glands were minced and incubated with 0.5% trypsin and 0.06% collagenase (0.17 U/mg) in nutrient medium (RPMI/F12, 1:1 Gibco) for 1 h at 37°C. The tissue was then triturated in RPMI/F12 with 10% FCS, and dissociated cells were plated on polylysine coated coverslips. After an hour, electrical coupling was evaluated in cell pairs under double current clamp. Dye coupling was evaluated by injecting Lucifer yellow into one cell of a pair or a cluster. The incidence of electrical coupling was 35%. Mean junctional conductance was 113.4 nS, range 2-400 nS, n=75. Dye coupling was seen in 30% of injected pairs (n=28) and in multiple cells of clusters. Octanol (0.4mM) rapidly and reversibly uncoupled the cells. Physiological saline also uncoupled reversibly, but more slowly consistent with removal of a nutrient factor. No immuno-labelling was seen with antibodies to the rat liver 27 kDa GJ protein, but immunoreactivity was found with an antibody specific for mouse liver 21 kDa protein. The labelling showed a spidery pattern, which is consistent with published freeze fracture micrographs of pineal GJs. Modulation of Gjs between pineal cells may be important in controlling secretion and synchronizing their circadian rhythm.

CIRCANNUAL VARIATIONS IN PINEALOCYTE SYNAPTIC RIBBONS IN THE 13-LINED GROUND SQUIRREL. J.A. McNulty*, W.A. Spurrier* and L.M Fox* (SPON: F. Lavelle). Depts. of Anatomy and Neurosurgery, Loyola Univ. Stritch School of Medicine, Maywood, IL 60153.

The synaptic ribbon (SR) is a pinealocyte organelle that is believed to play a role in the photoperiodic synthesis of melatonin. In this study, SR numbers were quantified at monthly intervals over a yearly cycle (except July) in the hibernating and seaonally reproductive ground squirrel, Citellus tridecemlineatus. Glands (4/month) of both sexes were collected during the middle of the photoperiod, processed for routine TEM and SR counted in 3 grid spaces (300 mesh) from 1 section per grid. SR numbers were high in active animals from May to Oct (35-45/10,000 um^2). During the months of Nov and Dec when squirrels were hibernating, SR frequency markedly declined (6-7 fold). There was a gradual increase in SR numbers during the period of late hibernation (Jan, Feb) and sexual maturation (Mar-May). Numerical changes in SR were due to changes in both ribbons and spherules both of which occurred either singly or in pairs. Although ribbon fields of up to 9 SR were observed, there were no consistent seasonal differences in fields comprising 3 or more SR. The winter decline in SR frequency is consistent with reports of a decrease in pineal melatonin during hibernation and supports the hypothesis that pinealocyte SR play an important role in neurotransduction of melatonin biosynthesis.

469.6

IS RHYTHMICITY IN CHICK PINEAL SYNAPTIC RIBBONS DETERMINED BY AN EXTRAPINEAL OSCILLATOR? G.N. Robertson*, D.H. Dickson*, P.C. Jackson Department of Anatomy, Dalhousie University, Halifax, N.S. B3H 4H7

In our preliminary work, 10 day old chicks yielded a 4:1 night:day difference in SR numbers, suggesting rhythmicity with a phase common to that of melatonin. To confirm rhythmicity, SRs were counted in 7-14 day old chicks (14L:10D) sampled at mid-light and mid-dark. To test for circadian rhythmicity, on day 8 of one experiment, lights were turned off for the remainder of the experiment and pineals taken on days 9 and 10. In these experiments, SR population fluctuations were found to occur only in the day 14 birds (3.4:1 night:day). We conclude that SR rhythmicity begins on, or near, day 10 post-hatch and is not directly related to the melatonin rhythm. To determine if the invasion of sympathetic fibers from the superior cervical ganglion may initiate the SR rhythm, we employed tyrosine hydroxylase immunochemistry to reveal the distribution of sympathetic fibers in the chick pineal. The percentage of innervated follicles increased markedly (day 7 - 46%, day 14 - 87%) over the critical day 10 period, suggesting that chick SR rhythmicity may be initiated and/or maintained by the sympathetic fibers (a possible reflection of an extrapineal oscillator) rather than the independent oscillators responsible for the melatonin rhythm in the chick pineal. Supported by MRC to DHD PCJ.

EPILEPTIC CONVULSIONS IN PINEALECTOMIZED MALE GERBILS. T.H. Champney. Dept. of Medical Anatomy, Texas A&M University, College Station, TX 77843.

Pinealectomy (PX) of male gerbils produces grand mal type seizures and declines in cortical norepinephrine (NE) levels within 45 minutes of the surgery. The present studies determined the role of the pineal stalk in pineal mediated convulsions, measured catecholamine levels in numerous brain regions and examined the role of PX on the sensitivity of gerbils to pentylenetetrazole (PTZ)-induced seizures. Nine week old male gerbils were PX, sham-PX or had their pineal stalk cut under metofane anesthesia. After arousal from anesthesia, stalk transection produced convulsive activity and depressions ($p<0.01$) in cortical NE levels (measured 4 hrs after surgery) to the same degree as observed in PX gerbils when both were compared to sham-PX. Depressions in NE were only observed in the parietal cortex with no alterations observed in the hippocampus, amygdala or hypothalamus. Gerbils were also PX and sham-PX under pentobarbital anesthesia (which prevents convulsive activity), allowed to recover for two weeks and injected with one of 4 doses of PTZ (15, 30, 45 or 60 mg/kg). PTZ produced increasing convulsive activity with increased dosage, and was equally effective in PX, sham-PX or control gerbils. Therefore, PX does not alter the gerbils' responsiveness to another convulsant agent, PTZ. Also, PX-induced convulsions appear to be due to an interruption of fiber tracts within the pineal stalk with a concommitant decline in cortical NE levels.

469.8

ANXIOLYTIC-LIKE ACTIONS OF MELATONIN ON A CONFLICT PROCEDURE. E.B. Naranjo-Rodríguez* and C. Reyes Vázquez. Farmacología Conductual, ENEP-Iztacala and Depto. de Farmacología, Facultad de Medicina, U.N.A.M. México 04510, D. F.

Some neuropharmacological effects exerted by melatonin, such as hypnotic, sedative and anticonvulsive actions, are very similar to those effects induced by GABAergic substances. Additionally, electrophysiological studies showed that melatonin reduces the electrical activity of several brain nuclei, also similarly to GABAergic drugs. Several of these GABAergic agents, like benzodiazepines, also induces antianxiety effects. So, if melatonin activates or produces GABAergic actions, then it also exert ansiolytic effects. Male Wistar rats were deprived of water for 48 h before testing in a licking behavior procedure. A dinkometer circuit was connected between the drinking tube of a water bottle an a grid located in the floor a plexyglass box; in such a way, that the rat completed the circuit whenever it licked the tube. Each time the subject closed the circuit, an electrical pulse of 0.5 mA and 0.1 msec, was delivered. The total number of shocks delivered in periods of 3 min, were counted electronically. Melatonin effects (1, 2 mg/kg) were compared with chlorodiazepoxide (5, 10 mg/kg), diazepam (2, 4 mg/kg) and pentobarbital (5, 10 mg/kg) effects on such procedure. Both chlorodiazepoxide and melatonin treated rats, showed the highest scores, followed by diazepam and pentobarbital, respectively. These results indicate the melatonin exert anti-anxiety effects.

469.9

EFFECTS OF MELATONIN AND IMIPRAMINE ON BRAIN SEROTONIN AND 5-HIAA OF MALE SYRIAN HAMSTERS . M. R. McCashin* and J. Vriend* (SPON: G. K. W. Cheng). Department of Anatomy, Univ. of Manitoba, Winnipeg, MB, Canada R3E 0W3.

In the present study the effects of melatonin and imipramine administration on serotonin and 5-HIAA levels were determined (by HPLC-EC) in selected brain regions of the Syrian hamster. Melatonin (25 ug sc), imipramine (0.75 mg ip), both melatonin and imipramine, or saline were administered daily for 8 weeks to male hamsters assigned to groups of 12. At the end of 8 weeks the animals were killed. Testicular weights were recorded at this time. Four animals of each group were treated with pargyline (20 mg sc) 4 hours prior to sacrifice. Serotonin levels were significantly depressed by melatonin in brain stem and in hypothalamus. Imipramine administration significantly increased 5-HIAA levels of brain stem. A small decrease in serotonin content ($p < .01$) after pargyline administration was observed only with melatonin. Melatonin administration also resulted in significant increases in hypothalamic content of the dopamine metabolites, DOPAC and HVA. Imipramine administration did not prevent the melatonin induced gonadal involution or the melatonin induced inhibition of gonadotropins. The effects of imipramine on the serotonergic system are interpreted as increased metabolism by MAO concurrent with inhibition of the reuptake mechanism.

469.10

EFFECTS OF MELATONIN AND IMIPRAMINE ON CIRCULATING LEVELS OF PROLACTIN AND THYROXIN IN PARGYLINE TREATED HAMSTERS. J. Vriend* and M. R. McCashin* (Spon J. A. Paterson). Department of Anatomy, Univ. of Manitoba, Winnipeg, MB., Canada R3E 0W3

The present study was designed to determine the effects of imipramine and pargyline on the melatonin-induced inhibition of circulating levels of prolactin (PRL) and of the melatonin-induced inhibition of circulating levels of thyroxine (T4).

Melatonin was administered daily (25 ug sc for 8 weeks) to male Syrian hamsters (N=12) alone, or in combination with imipramine (5 mg/kg ip). Additional groups of hamsters were treated with imipramine alone or with saline alone. All injections were administered 1 - 2 hrs before lights out in an animal room maintained on a 14L/10D schedule. At the end of 8 weeks the animals were killed. Four animals of each group were treated with pargyline (20 mg sc) four hours prior to sacrifice. Serum was collected for assay of T4 and PRL by RIA. As in previous studies melatonin significantly reduced circulating levels of these hormones. Four hours after pargyline a 5-fold increase in PRL was observed in imipramine treated hamsters, but not in saline or melatonin injected hamsters, nor in hamsters treated with both imipramine and melatonin. Pargyline also resulted in an increase in T4 in imipramine treated hamsters, but not in hamsters treated with imipramine and melatonin.

469.11

ZINC CONCENTRATIONS IN RHESUS BRAIN, PINEAL, AND PITUITARY. M.E. MCNEILL, J.S. MANGUM*, S.J. FIN*, S.L. LUCAS* AND J.T. BRAY*. Dept. of Anat. and Cell Biology and Shared Resources Lab. East Carolina Univ. School of Medicine, Greenville, NC 27858-4354.

Zinc (Zn) is an essential trace element in man. The requirement for Zn stems partly from its role in a variety of enzymes including those required for DNA and RNA synthesis. In the central nervous system (CNS) Zn is sequestered in specific regions, e.g., the mossy fiber pathway of the hippocampus where it appears to be associated with neurotransmission. In addition, intracranial endocrine tissue has a higher concentration of Zn than the brain as a whole, and recent studies implicate Zn as a modulator of hormone secretion. At physiological concentrations Zn suppresses the output of prolactin from dispersed pituitary cells in vitro (Judd et al., Brain Res. 294: 190, 1984). Further study of the role of Zn in endocrine-CNS interaction is warranted. Identifying regions rich in Zn is a first step to that end.

In this study brain and endocrine tissues were obtained from 7 male rhesus monkeys and freeze-dried at -38°C. Zinc concentration was determined by flame atomic absorption spectrophotometry. Concentrations in ug Zn/g dry tissue are: Temporal lobe 70 ± 4, Neurohypophysis 84 ± 30, Adenohypophysis 137 ± 59 and Pineal 162 ± 88. Endocrine tissues were found to have significantly higher concentrations than the temporal lobe, and, in addition, the adenohypophysis had a significantly higher concentration than the neurohypophysis.

469.12

SIGMA AND PHENCYCLIDINE (PCP) RECEPTORS IN RAT ENDOCRINE ORGANS. S.A. Wolfe, Jr., S.G. Culp and E.B. De Souza. Neuroscience Branch, National Institute on Drug Abuse, Addiction Research Center, Baltimore, MD 21224.

PCP and the prototypic sigma agonist N-allylnormetazocine (NANM) have been reported to alter neuroendocrine functions (stimulation of ACTH and corticosterone release and suppression of prolactin and lutenizing hormone secretion in rats). The aim of the present study was to survey endocrine organs and to identify, characterize and localize σ and PCP receptors in rat pituitary, adrenal, testis, ovary and placenta. Sigma receptors were labeled with [^{3}H]-haloperidol in the presence of 25 nM spiperone or with 1,3-di(2-[5-^{3}H]tolyl)guanidine (^{3}H-DTG), and PCP receptors were labeled using [^{3}H]-(1-[1-(2-thienylcyclohexyl)]piperidine) (^{3}H-TCP) or (+)-5-methyl-10,11-dihydro-[5-^{3}H]-dibenzo-[a,d]cyclohepten-5,10-imine (^{3}H-MK-801).

Sigma and PCP receptors were identified in endocrine tissues with kinetic and pharmacological characteristics similar to those previously reported in brain. The density of both σ and PCP receptors was highest in the testis. Pituitary, ovary and placenta had densities of σ receptors (30-70% of testis) comparable to that of cerebellum. The adrenal gland had the lowest density of σ receptors (10-20% of testis). In contrast, the density of PCP receptors, while detectable, was much lower in endocrine tissues (10-20%) than in brain. In vitro autoradiography and endocrine manipulations (e.g., hypophysectomy) are currently being used to localize and identify the cells containing PCP and σ receptors.

While the sites of action of PCP and NANM in altering hormone secretion remain to be determined, our demonstration of high densities of PCP and σ receptors in target endocrine organs provides support for peripheral sites of action of these drugs.

469.13

EVIDENCE FOR DENDRITIC AND AXONAL HORMONE RELEASE IN THE RAT HYPOTHALAMO-NEUROHYPOPHYSIAL SYSTEM. C.D. Tweedle, K.G. Smithson, & G.I Hatton. Neuroscience Program, Depts. of Anatomy & Physiology, College of Osteopathic Medicine, Michigan State University, East Lansing, MI 48824.

In order to ultrastructurally localize hormone release sites in the rat neurohypophysis the tannic acid-Ringer technique of Buma and Nieuwenhuys (*Neurosci. Lett.* 74: 151, 1987) was utilized. Three rats with normal levels of K^+ in the perfusion mixture showed only rare exocytotic figures, while 4 rats with 50 mM K^+ (substituted for Na^+) in the perfusion mixture showed frequent exocytotic figures. Of 20 such figures per rat, 86.3 ± 2.4 % were at morphologically identified neurosecretory endings containing microvesicles and contacting the basal lamina. This supports our contention that the observed changes in the size and number of such endings are relevant to hormone release.

Upon examination of the supraoptic nuclei from the same animals it was found that in the rats with high K^+ occasional exocytotic figures of dense core granules occurred in dendrites, but not in somata. This apparent dendritic release could accomplish local information transfer and/or be a source of the oxytocin and vasopressin found in the CSF. Current experiments are underway to see if similar findings are obtained with more physiological stimulation of hormone release. Supported by NIH grant NS09140 and by a MSTP fellowship to KGS.

ß-ADRENERGIC STIMULATION DECREASES GLIAL, AND CONCOMITANTLY INCREASES NEURAL, CONTACT WITH THE BASAL LAMINA IN RAT NEUROINTERMEDIATE LOBES INCUBATED *IN VITRO*. K.G. Smithson, I. Suarez* & G.I. Hatton. Neuroscience Program & Physiology Dept., College of Osteopathic Medicine, Michigan State University, East Lansing, MI 48824

Isoproterenol induces a change from flattened to stellate morphology in cultured adult pituicytes. We sought to determine if similar changes could also be observed in the isolated neural lobe. Neurointermediate lobes from adult male rats were isolated and placed in chambers containing artificial CSF at 37°C. Treatment consisted of a 15 min. incubation with CSF containing either 0.2% ascorbate or isoproterenol (10^{-7} or 10^{-8} M) with 0.2% ascorbate. Tissue was then prepared for conventional electron microscopy after which morphometric evaluation of the percent of, pituicyte and neurosecretory, membrane contact with the basal lamina was performed. Isoproterenol stimulation resulted in a significant decrease in pituicyte and increase in neural contact with the basal lamina, as compared to control. These changes are similar to that observed during conditions which require increased hormone release (e.g. dehydration or lactating). These results suggest that ß-agonist mediated changes in pituicyte morphology may represent a mechanism underlying these phenomena. Supported by NIH grant NS09140 and by a MSTP fellowship to KGS.

INHIBITORY EFFECT OF NOREPINEPHRINE (NE) ON THE ELECTRICAL ACTIVITY OF CAUDALLY-PROJECTING PARAVENTRICULAR (PVN) NEURONS IN RAT. Y.I.Kim, C.A. Dudley and R.L. Moss. Dept. of Physiology, Univ. of Texas Southwestern Medical Center, Dallas, Texas 75235.

Utilizing conventional extracellular single unit recording techniques, the effect of iontophoretically applied NE on the activity of caudally-projecting PVN neurons was assessed in male Sprague-Dawley rats anesthetized with urethane. These PVN neurons were identified antidromically by electrical stimulation (50 uA - 1.5 mA) of the caudal ventrolateral medulla (mean ± SEM antidromic latency: 34.7 ± 2.4 ms). In 15 of 19 identified PVN neurons (mean ± SEM baseline firing rate: 2.7 ± 0.6 impulses/s), NE was demonstrated to be inhibitory. No excitatory NE effect was observed. Five of those 15 neurons were also antidromically identified as projecting to the posterior pituitary (mean ± SEM antidromic latency: 15.0 ± 2.5 ms). The inhibitory action of NE was selectively blocked by the alpha antagonist, phentolamine (n=7) that was co-iontophoresed with NE, but not by the beta antagonist, timolol (n=9). In contrast to the inhibitory action of NE on the caudally-projecting PVN neurons, an excitatory action of NE was frequently observed in the PVN neurons projecting only to the posterior pituitary: out of 20 such neurons tested, 15 were excited and 3 were inhibited by NE.

The present results strongly suggest that NE exerts an alpha-receptor-mediated, specific inhibitory effect on the PVN neurons projecting to or passing through the caudal ventrolateral medula. These PVN neurons include a subpopulation of neurons which also project to the posterior pituitary. Supported by HD09988-V.

PARABRACHIAL NUCLEUS INVOLVEMENT IN THE INHIBITION OF DEHYDRATION-INDUCED VASOPRESSIN RELEASE BY WATER INTAKE. L.E. Ohman, R.E. Shade and J.R. Haywood. Dept. of Pharm., The Univ. of TX Hlth. Sci. Ctr., San Antonio, TX.

High circulating levels of vasopressin (pAVP) induced by water deprivation (WD) decrease within minutes of water ingestion. The lateral parabrachial nucleus (LPBN), known to be involved in the regulation of water intake and AVP release, may contribute to this inhibition of WD-induced pAVP. Rats were given either bilateral electrolytic or sham tract lesions of the LPBN. Water was removed for 48 hr, after which the rats were allowed to drink for 1 hr. Plasma osmolality (Osm) and AVP were determined prior to WD, before access to water, and 10 min after the onset of drinking. Plasma Osm increased from 289±3 to 298±2. mOsm in lesioned rats and from 288±3 to 296±2 mOsm in sham lesioned rats in response to 48 hr WD. Plasma AVP levels also increased in both groups (Lesion: 1.0±.3 to 13.5±2.4 μU/ml; Sham: 0.7±0.2 to 15.4±3.4 μU/ml). Lesioned rats drank significantly more water (18.6±1.5 ml) than sham rats (11.5±0.6 ml), but pOsm decreased to a similar value in both groups (Lesion: 284±5 mOsm; Sham: 291±2 mOsm). Plasma AVP decreased 10.6±1.4 μU/ml (75%) in sham lesioned rats after water intake, while the pAVP decrease in lesioned rats, 5.7±1.5 μU/ml (45%), was significantly less. These data suggest that the LPBN partially mediates the inhibition of dehydration-induced pAVP release by water intake. (Supported by HL32977).

IMPAIRED GLUCAGON SECRETION IN DIABETIC AND GALACTOSEMIC RATS MAY INVOLVE VAGAL-CHOLINERGIC NEUROPATHY. K.A. Skau & D.G. Patel*. Div. Pharmacol. & Med.Chem., U. Cincinnati, Cincinnati, OH 45267.

Glucagon secretion in response to insulin hypoglycemia is impaired in diabetic patients and rats and this impairment correlates with diabetic neuropathy. We have recently shown that glucagon is secreted in response to direct vagal nerve stimulation and that this response is also impaired in diabetic rats (FASEB J. 2: A1594, 1988). The present study expands on the characteristics of vagal-stimulated glucagon secretion in galactosemia and diabetes. Rats were anesthetized with chloral hydrate (350 mg/kg i.p.) and the carotid artery was cannulated for blood sampling. Vagus nerves were stimulated via silver electrodes for varying times at fixed frequency (20 Hz). Hypoglycemia-induced glucagon secretion was produced by constant infusion of insulin, via the jugular vein, until plasma glucose levels dropped to 40 mg/dl. Plasma glucose and glucagon levels were determined by glucose oxidase and RIA respectively. Plasma glucagon levels increased with increasing durations of vagal stimulation. This vagal-stimulated, as well as hypoglycemia-induced, secretion was totally prevented by atropine pretreatment (2 mg/kg i.v.). Furthermore, carbachol infusion resulted in elevated plasma glucagon. Glucagon secretion was increased by either right or left vagus stimulation. Although insulin-induced glucagon secretion was prevented by atropine it was not eliminated by acute bilateral vagotomy. In addition to diabetes, galactose-fed rats exhibited a similar impairment of glucagon secretion. It is concluded that glucagon secretion is regulated, in part, by cholinergic influences that may involve the vagus nerve, but may also involve other systems. (Supported by U. Cincinnati Research Council.)

METABOLIC MAPPING OF THE DORSAL VAGAL COMPLEX IN DEHYDRATED RATS. S. Shaver, M. Kadekaro[1] and P.M. Gross. Neurosurg. Res. Unit, Queen's Univ., Kingston, Ont. and [1]Div. Neurosurg., Univ. Texas Med. Branch, Galveston, TX.

Receptors and immunoreactive perikarya for angiotensin II (AII) are populated densely in neurally-linked subunits of the medullary dorsal vagal complex (DVC) - the area postrema (AP), nucleus of the solitary tract (NTS), and dorsal motor nucleus of the vagus nerve (DMN). We hypothesized that metabolic activity in DVC would be stimulated by dehydration associated with high systemic AII. We applied the [^{14}C]deoxyglucose method in conscious Sprague-Dawley (SD) rats, SD rats deprived of water (WD) for 120 h, Long-Evans (LE) rats, Brattleboro (DI) rats, and DI rats WD for 18 h. Values for glucose metabolism (GM) in control SD rats were AP (.69±.03 umol/g/min), NTS (.60±.04), and DMN (.56±.04); similar values were found in LE rats. WD in SD rats increased GM of AP, NTS, and DMN by 38%, 35% and 21%, respectively. In DI and WD-DI rats, GM increased by 12 to 39% in AP and NTS; no change occurred in DMN. WD-DI rats had higher GM in AP and NTS than water-sated DI rats. We speculate that AII-enriched regions within DVC are activated by circulating AII via the AP in these rat models of dehydration.

TOPOGRAPHY OF CAPILLARIES AND GLUCOSE METABOLISM WITHIN SUBREGIONS OF RAT AREA POSTREMA AND SUBFORNICAL ORGAN. J.J. Pang*, N.M. Sposito*[1], S.W. Shaver, M. Kadekaro[2] and P.M. Gross (SPON: F.A. Kutyna) Neurosurg. Res. Unit, Queen's Univ., Kingston, Ont., [1]Dept. Neurosurg, SUNY-Stony Brook, NY, and [2]Div. Neurosurg., Univ. Texas Med. Branch, Galveston, TX.

Neuronal circumventricular organs (CVOs; eg, area postrema, AP, subfornical organ, SFO) are organized in subregions defined by cytoarchitecture, afferent terminals, and distribution of neuroactive substances. In adult albino rats, we examined whether capillary density (CD) and parenchymal glucose metabolism (GM), which are closely coupled in nervous tissue, conformed topographically in these CVOs. CD was assessed by computer processing of micrographic sections (x240) from aldehyde-fixed brains. [^{14}C]deoxyglucose and image analysis were used to measure GM. In coronal sections (obex - 0.25 mm), AP subdivided into 3 zones having CDs of 200/mm^2 (dorsal) to 407/mm^2 (medial) for vessels ≤ 7.5 um; corresponding GMs were 0.52 to 0.69 umol/g /min, respectively. In SFO dorsal and ventromedial zones, CD and GM correlated directly throughout the rostrocaudal axis. Differential CD and GM within neuronal CVOs further identify subregions that may be distinct functionally.

HYPOTHALAMIC MODULATION OF PERIPHERALLY-INDUCED JAW CLOSURE IN THE CAT. S. Weiner*, A.B. Shaikh* and A. Siegel. Depts. of Restorative Dentistry and Neurosciences, UMDNJ, Newark, New Jersey 07103.

The lateral hypothalamus can modulate jaw closure, but little is known of the interaction between peripheral receptors and hypothalamus in regulating this response. We observed the effects of peripheral stimulation of the periodontal ligament upon the magnitude of masseteric EMG activity in the presence of hypothalamic stimulation.

Hypothalamically elicited quiet biting attack (QBA) and affective defense (AD) sites were identified and bipolar surface electrodes were attached bilaterally over the masseter muscles. EMG recordings were compared under conditions involving paired trials of tooth probing alone and in combination with hypothalamic stimulation. Tooth probing alone predominantly increased ipsilateral EMG activity. In contrast, dual stimulation involving tooth probing coupled with activation of contralateral QBA sites predominantly increased EMG activity on the side contralateral to tooth probing. Stimulation of AD sites did not show this effect. Moreover, stimulation of QBA and AD sites elevated overall EMG activity in comparison with non-behavioral (control) sites in the hypothalamus.

We suggest that this experimental paradigm can serve as a model for further study of the mechanisms by which the hypothalamus regulates jaw muscle activity. **[Supported by the Foundation of UMDNJ and NIH Grant NS07941-19].**

IMMUNOHISTOCHEMICAL DIFFERENTIATION OF ELECTROPHYSIOLOGICALLY DISTINCT NEURONS IN THE REGION OF THE RAT PARAVENTRICULAR NUCLEUS. N.W. Hoffman*, J.G. Tasker and F.E. Dudek. Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024

Neurons with low-threshold calcium spikes (LTS) have been found immediately lateral to the hypothalamic paraventricular nucleus (Poulain, P. and Carette, B., Brain Res. Bull. 19:453, 1987). These neurons are distinguishable from non-LTS neurons in the nucleus, not only by the presence of LTS potentials, but also by their afterhyperpolarizations, current-voltage relations and baseline synaptic activity (Tasker, J.G. and Dudek, F.E. Soc. Neurosci. Abstr. 13:1370, 1987). After electrophysiological characterization, LTS and non-LTS neurons were injected with Lucifer yellow and neurophysin immunohistochemistry was performed. Preliminary results showed that 7 of 7 Lucifer-labeled LTS neurons were neurophysin-negative and that 1 of 1 non-LTS neuron was neurophysin-positive. LTS neurons were found to surround the nucleus. From electrical and immunohistochemical data, non-LTS neurons appear to be magnocellular neuropeptidergic cells, whereas LTS neurons probably are not. These preliminary findings support the hypothesis that the two cell types are both physiologically and anatomically distinguishable. Supported by AFOSR-87-0361, BNS 87-96288 and NS 8049.

470.3

LOCAL CIRCUIT INTERACTIONS BETWEEN NEURONS IN THE REGION OF THE RAT PARAVENTRICULAR NUCLEUS. J.G. Tasker and F.E. Dudek, Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024

Local synaptic interactions in the supraoptic and paraventricular nuclei (PVN) have been postulated on the basis of electrophysiological studies using electrical stimulation to activate presynaptic neurons. This technique stimulates not only local neurons, but also axons projecting from other parts of the brain. We have used glutamate microapplication to stimulate presynaptic neuronal somata and dendrites without activating axons of passage. Neurons in the PVN were recorded intracellularly while glutamate drops (10-100 mM, 50-250 μm in diameter) were pressure-applied to several locations around the PVN. Saline drops were applied through a second barrel of the stimulating pipette to control for mechanical effects of drug application. Preliminary results showed that glutamate application, when effective, elicited an increase of EPSP's and/or IPSP's in the recorded neuron. Higher concentrations of glutamate caused trains of PSP's lasting up to several seconds. Picrotoxin (50 μM) blocked the IPSPs, suggesting they were mediated by $GABA_A$-receptors. These findings provide electrophysiological evidence for local synaptic interactions in the region of the PVN with a technique that is unlikely to involve activation of axons of passage. Supported by AFOSR-87-0361, BNS 87-96288 and NS 8049.

470.4

KYNURENATE ANTAGONISM OF FAST EPSPs IN PARAVENTRICULAR NEURONS. J.-P. Wuarin* and F.E. Dudek (SPON: W.B. Macklin). Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024

Excitatory amino acids (EAAs) may play a major role in fast synaptic transmission within the hypothalamus. Electrophysiological evidence for their involvement in the rat supraoptic nucleus has been provided (Gribkoff, V.K. and Dudek, F.E., Brain Res. 442:152, 1988). We have undertaken preliminary studies in the paraventricular nucleus (PVN) to test this hypothesis. Intracellular recordings (n=4) were obtained from guinea-pig hypothalamic slices in 50 μM picrotoxin. Electrical stimuli dorsal to the fornix evoked excitatory postsynaptic potentials (EPSPs). The EAA antagonist, kynurenate, was bath applied; EPSPs were averaged every 5 min for 20-30 min in steady state. The mean decrease was 5% for 100 μM, 44% for 300 μM and 68% for 1 mM (n=2 each). The effects were reversible (recovery within 45 min after 300 μM). From the electrophysiological properties, one neuron appeared to be a magnocellular neuropeptidergic cell, but three others had low-threshold calcium spikes (Poulain, P. and Carette, B., Brain Res. Bull. 19:453, 1987). These data support the hypothesis that EAAs are an important class of transmitter for fast synaptic actions throughout the hypothalamus. Supported by AFOSR-87-0361 and BNS 87-96288.

IN VIVO MICRODIALYSIS STUDIES OF NOREPINEPHRINE (NE), 3,4-DIHYDROXYPHENYLETHYLENEGLYCOL (DOPEG), VASOPRESSIN (VP) AND OXYTOCIN (OT) IN THE ANTERIOR HYPOTHALAMUS. D. Nakahara*†, E. Kogosov*, F. Ross-Cisneros*, M. Morris*#, T. Nagatsu*† and N. Alexander. †Nagoya Sch. of Med., Nagoya, Japan, #Bowman Grey Sch. of Med., Winston-Salem, NC 27103 and Univ. of So. Calif. Sch. of Med., Los Angeles, CA 90033.

Brain microdialysis is a technique for sampling extracellular fluid components from freely moving rats (Amer. J. Physiol. 254:R396, 1988). For the present study, a dialysis probe was inserted into the anterior hypothalamus through a guide tube implanted stereotaxically 1 week earlier (n=14). A small dialysis bag (2 mm long, 0.2 mm diam., 5000 mw cutoff) at the tip of the probe, was perfused with Ringer's solution (2 ul/min) and molecules from surrounding tissue diffused into the bag. Dialysate samples were collected at 30 minute intervals for 5 hours as the rat moved or slept. Recovery, measured in vitro, is about 20% and is independent of concentrations outside the bag. Basal dialysate concentrations were (pg/ml): NE, 80.6±15 and DOPEG, 425±57. Pargyline, added to perfusate (0.1 mM and 1.0 mM) produced a dose-related effect on DOPEG and NE. The maximum effects equaled those of I.P. pargyline (100 mg/kg), namely, a reduction of 50% in DOPEG and a 4-fold increase in NE in the dialysate. VP and OT, in pooled samples extracted on Sep Pak, showed a dose-related immuno-reactivity; their average levels were 2.5 and 4.7 pg/ml, respectively. Basal levels of VP, measured directly in 100 ul dialysate samples was 2.0±0.38 pg/ml (n=9). These findings show that brain microdialysis can provide new information on mechanisms regulating neurotransmitter and neuropeptide processes in the anterior hypothalamus.

470.6

ASYMMETRIC HYPOTHALAMIC MONOAMINE METABOLISM IS RELATED TO SIDE OF OVULATION IN LIZARD. P.H.Desan, R.E.Jones*, K.H.Lopez* and H.B.Austin*. Dept. of Neurology, Stanford Med. Ctr., Stanford, CA 94305, and Dept. of EPO Biology, Univ. of Colorado, Boulder, CO 80309.

The American chameleon (Anolis carolinensis), like certain other lizards, apes and humans, alternates ovulation between the left and right ovaries. We measured NE, MHPG, DHPG, DA, DOPAC, 5HT and 5HIAA using HPLC with serial oxidative-reductive electrochemical detection in microdissected left and right diencephalon from 15 lizards collected during their first spring ovulation cycle (8 had a maturing follicle on the right side and 7 on the left). Of the calculated neurotransmitter metabolite/parent neurotransmitter ratios, only DOPAC/DA and 5HIAA/5HT were significantly different between the two sides, being lower on the maturing follicle side than on the quiescent side: DOPAC/DA = 0.49 ± 0.06 vs. 0.61 ± 0.05, and 5HIAA/5HT = 1.14 ± 0.10 vs. 1.32 ± 0.10; paired t-test significance for both comparisons $p < 0.05$). On an individual basis 13 of 15 animals showed a lower DOPAC/DA ratio on the maturing follicle side than on the quiescent side, and 11 of 15 showed a lower 5HIAA/5HT ratio. These observations indicate that an asymmetry of hypothalamic monoamine metabolism controls or is controlled by the side of the follicle growth, perhaps via hypothalamo-medullary interconnections and the vagal innervation of the ovaries.

PROPERTIES OF ORGANUM VASCULOSUM LAMINA TERMINALIS (OVLT) NEURONS IN THE RAT. L.P. Renaud, R. Nissen* and C.W. Bourque, McGill Univ. Centre for Research in Neuroscience, Montreal, Canada H3G 1A4.

The OVLT, a circumventricular structure involved in hydromineral homeostasis, contains cells anatomically linked with the nucleus medianus (NM), supraoptic (SON) and paraventricular (PVN) nuclei. However, there is scant information as to their electrical properties. Intracellular recordings obtained from 42 OVLT neurons in slices and superfused explants of rat basal forebrain revealed average resting membrane potentials near -65mV, input impedances of 80-280 MΩ, linear V-I plots below resting membrane potentials and low threshold calcium spikes. Antidromic activation from the region of NM, PVN and/or SON agreed with axon branching and their trajectories as visualized in Lucifer-yellow filled cells. The latter also revealed a simple cellular morphology (soma 10-15 µm, 0-1 dendrites). Each of 17 tested cells depolarized in hyperosmotic (+15 mosmol) media. These data suggest an intimate relationship of OVLT neurons with forebrain areas regulating body fluid balance. Supported by FCAR, QHA and MRC.

GASTROINTESTINAL PATHOLOGIES INDUCED IN RATS BY HYPOTHALAMIC LESIONS. **N.I. Wiener, P. Wright*, J. Andersen*. Department of Psychology, York University, Toronto, Canada, M3J 1P3.**

Gastrointestinal pathologies were measured in rats as a consequence of bilateral anodal electrolytic and bilateral neurotoxic kainic acid lesions of the paraventricular nucleus of the hypothalamus. Both manipulations induced a high level of gastric ulceration within 24 hours. However, kainic acid also produced severe duodenal ulceration. The kainic acid induced duodenal ulcers appeared similar to those produced by cysteamine and other duodenal ulcerogens. The duodenal ulcers were located on the anterior and/or posterior wall of the proximal duodenum near the pylorus.

Subcutaneous injection of phentolamine and propranolol facilitated the development of gastric ulcers. Subcutaneous injection of haloperidol facilitated duodenal ulceration.

These data support the hypothesis that gastric ulcers result from depletion of central noradrenergic stores and duodenal ulcers from a reduction in dopaminergic activity in or near the paraventricular nucleus of the hypothalamus.

470.9

CHARACTERISTICS OF THERMOSENSITIVE AND OSMOSENSITIVE NEURONS IN THE RAT DIENCEPHALON. K.A. Travis* and J.A. Boulant, Department of Physiology, College of Medicine, The Ohio State University, Columbus, Ohio 43210.

Hypothalamic neurons respond to various homeostatic challenges, including changes in temperature and osmolarity. This study evaluated diencephalic neuronal thermosensitivity and osmosensitivity in Sprague Dawley, Wistar-Kyoto, and spontaneously hypertensive rats. In vitro neuronal activity was recorded from several nuclei in horizontal tissue slices perfused with control (300 mOsm/kg), hyposmotic (280 mOsm/kg) and hyperosmotic (320 mOsm/kg) media. The majority of neurons responded to at least one test medium. Temperature sensitive neurons showed no specific pattern of response to the two test media. Temperature insensitive neurons tended to be unresponsive in the hyperosmotic medium, and either increased or showed no change in the hyposmotic medium. While there were no differences in the responses of hypertensive and normotensive rats, there were differences in the responses of temperature sensitive and insensitive neurons to changes in osmolarity. (Supported in part by NSF, AHA and NIH grants.)

POSTNATAL MSG TREATMENT ALTERS PROSTAGLANDIN INDUCED FEVER IN RATS. S.M. Martin, T.J. Malkinson, L. Bauce, W.L. Veale and Q.J. Pittman. Biology Dept, Mt.St.Vincent Univ, Halifax, NS B3M 2J6 and Neurosci. Res. Group, Univ of Calgary, Calgary, AB, T2N 4N1 Canada.

Alpha-melanocyte stimulating hormone (α-MSH) has been implicated as an endogenous antipyretic active during the rising phase of fever. Since brain α-MSH is synthesized in the arcuate region, we hypothesized that lesioning of this area, with monosodium glutamate (MSG), would reduce the levels of α-MSH and alter the fever response induced by central injections of prostaglandin (PGE_1). Wister pups were given randomly either ip injections of MSG (4 mg/kg body wt) or equal volumes of saline on days 2,4,6,8,10 after birth. At maturity, male rats were implanted with intraventricular (ICV) cannulae and abdominal temperature transmitters. After recovery from surgery, the animals were given ICV injections (PGE_1, (20 ng) and body temperature data were computer collected every 5 min for 2 h before and 4 h following injections. After completion of the experiments brain tissue was assayed for α-MSH. The results show that the fever in the MSG treated animals rose faster and was higher ($p<0.05$) than fever in the saline group during the first 20 mins. As MSG pretreatment decreases α-MSH levels in brain, the enhanced fever in the MSG treated animals supports the hypothesis that α-MSH is an endogneous antipyretic. (supported by Mt.St.Vincent and the MRC).

PERFUSATE PO_2 AND NEURONAL THERMOSENSITIVITY IN PREOPTIC AREA (POA) SLICES. M. Shibata and C.M. Blatteis. University of Tennessee, Memphis, TN 38163.

In electrophysiological studies, it is usual to gas the perfusates of brain slices with $95\%O_2/5\%CO_2$, whereas $21\%O_2/5\%CO_2$ is normally used to maintain brain tissue cultures. To determine whether $95\%O_2$ might be needlessly high, possibly affecting neuronal excitability, we compared the effects of the 2 gases on the firing rates (FR) of thermosensitive neurons in 350-µm thick slices from guinea pigs POA perfused at 1 ml/min with artificial cerebrospinal fluid (ACSF) gassed with $95\%O_2$/ or $21\%O_2$/ $5\%CO_2$. Thermosensitivity (Q_{10}) was assessed by FR changes with perfusate temperatures (T_p=32-42°C), according to established criteria. Results: 1) Within 1.5 h, incubation chamber perfusate P_{O_2} at T_p 37°C reached 300-350 mmHg when gassed with $95\%O_2$, and 130-160 mmHg with $21\%O_2$. 2) Of 7 thermosensitive units initially characterized in $21\%O_2$-ACSF, 4 units lost their thermosensitivity completely, 2 decreased their Q_{10} greatly, and 1 ceased spontaneous firing when $95\%O_2$-ACSF was substituted. 3) By contrast, the Q_{10} of 6 thermosensitive units originally identified in $95\%O_2$-ACSF was not affected when the perfusate was switched to $21\%O_2$-ACSF. 4) Generally, initial Q_{10} values measured in $21\%O_2$- were higher than in $95\%O_2$-ACSF. These findings suggest that oxygenating with $95\%O_2/5\%CO_2$ increases the perfusate P_{O_2} to an unphysiological range and may cause impairment of POA neuronal responses to thermal stimuli.

HYPOTHALAMIC REGULATION OF MALE REPRODUCTIVE BEHAVIOR AND ANALGESIA IN THE RAT. M.R. Sharpe*, R.A. Leslie and D.M. Nance. Anatomy Dept., Dalhousie Univ., Halifax, N.S., B3H4H7, Canada.

Responses to noxious and sexual stimuli have visceral components which are modulated by opiates. Although the VMH is known to be involved in the control of both pain and male sexual behaviour, the role of the PVN has not been tested despite its role in autonomic function. Therefore we examined the role of the ventromedial hypothalamus (VMH) and the paraventricular nucleus (PVN) in the dual control of analgesia and sexual behavior. Bilateral lesions were made in the VMH or PVN of male rats with ibotenic acid and the effects of saline, naloxone (4 mg/kg) and morphine (10 mg/kg) on the analgesic threshold to heat (tail-flick test) and pressure (pressure algometer) were tested. Drug treatments were repeated and the effects on male sexual behavior tested. There was a significant and modality-specific effect of the lesions on analgesia. The PVN group was hyperalgesic to heat whereas the VMH group was hypoalgesic to heat, relative to controls. The PVN group was hyper-sensitive to morphine and naloxone on the tail-flick test and the VMH group was hypo-sensitive to these drugs. There was a modest reduction in mounting behavior in the PVN group and a small increase in the VMH group, relative to controls. Morphine reduced male sexual behavior in all groups, but the effect was smaller in the PVN rats. The PVN group showed a dramatic increase in mounting behavior following naloxone treatment, whereas naloxone had no effect on the VMH and control rats. Thus lesions in the VMH and PVN have opposite effects on both male sexual behavior and pain and the effects on analgesia are modality-specific. The drug effects indicate that the lesions produce an alteration in opioid systems, and these alterations in turn exert opposite effects on both sexual behavior and pain. The results after PVN lesions further suggest that the ANS may play a role in the regulation of male sexual behavior and the response to pain. Supported by M.R.C.

Developmental Regulation of Hypothalamic and Pituitary Aromatase Activity in the Male Rat. E.D. Lephart*, and S.R. Ojeda (Spon: S. Kiser). Dept Physiol, Univ TX SW Med Ctr, Dallas, TX 75235, and Div Neurosci, OR Reg Pri Res Ctr (SRO), Beaverton, OR 97006.

In the adult male rat brain aromatase activity is regulated by androgens. We have investigated whether dihydrotestosterone (DHT) regulates hypothalamic and/or pituitary aromatase activity prior to puberty. Two-, 5 and 8-wk- old male rats were divided into three groups: intact controls, castrated for 2 weeks, and castrated-treated with 20 mg DHT/kg body wt. At 28-(juvenile), 48- (peripubertal) and 68- (post-pubertal) days of age the hypothalamus and anterior pituitary were incubated with [1α, 1β-^{3}H] testosterone (T). Aromatase activity was estimated by measuring the release of [1β-^{3}H] from T into water. The enzyme activity decreased markedly in the pituitary and hypothalamus of postpubertal rats. Castration increased the activity in the pituitary at all ages tested and DHT treatment suppressed the increase. The response of hypothalamic aromatase to castration and castration plus DHT replacement was opposite to that of the pituitary. The results indicate that aromatase activity is regulated differently by androgens in the hypothalamus and pituitary during sexual development and suggest that the post-pubertal decrease in pituitary enzyme activity can be attributed to androgens while the decline in hypothalamic enzyme activity is androgen-independent.

SUPRACHIASMATIC NUCLEUS EXPRESSION OF GENE PRODUCT INDUCED BY NGF IN PC12 CELLS. A.N.van den Pol, C.Decavel*, A. Levi*, B.Paterson*. Sect.Neurosurgery, Yale Med. Sch.,New Haven,Ct.06510; Lab Biochem. NCI,NIH, Bethesda, 20892.

NGF induces in PC12 cells a 50 fold enhancement of mRNA coded for by the VGF gene (Science,229:393). Two different restriction fragments from a VGF cDNA clone were fused into the beta-galactosidase (B-gal) bacterial gene. Antisera made in rabbits against each of the two fusion products stained neurons in the rat suprachiasmatic nucleus (SCN) intensely. In addition to diffuse cytoplasmic staining, intrinsic and projection axons of the SCN were labeled. The expression of the VGF related protein was found in the dorsomedial area of the SCN where cells also contain vasopressin, and in SCN of Brattleboro rats lacking the vasopressin gene. Perikarya, but not axons, of the magnocellular paraventricular and supraoptic nucleus showed some weaker positive immunostaining. A low level of immunoreactivity was also seen in some other non-hypothalamic brain areas. SCN immunostaining was not blocked by bacterial B-gal lysate absorption; different antisera made against the product of an unrelated cDNA fusion to B-gal showed no SCN immunostaining. Adult SCN expressed no immunoreactivity for NGF-receptor, while control cells of the medial septum did. These results indicate that a previously unidentified protein coded by the VGF gene is strongly expressed in a subpopulation of SCN cells and axons, and that this protein may not require NGF for a strong expression in the CNS.

470.15

INTRACELLULAR LABELING OF ELECTROPHYSIOLOGICALLY IDENTIFIED NEURONS IN THE TUBERAL PORTION OF THE SUPRAOPTIC NUCLEUS. B. Smith* and W.E. Armstrong. Dept of Anat. Neurobiol., Univ. Tenn., Memphis, The Health Science Center, Memphis, TN, 38163.

The tuberal, or retrochiasmatic, portion of the supraoptic nucleus (SONt) consists largely of vasopressin neurons whose dendritic and axonal morphologies have not been described. SONt neurons impaled in hypothalamo-neurohypophysial explants in vitro were filled with biocytin (Horikawa and Armstrong, J. Neurosci. Meth, in press) and reconstructed in serial sections. All injections were made into neurons from which stable recordings were obtained and whose input resistance (mean = 124 MΩ) and response to neural stalk stimulation (mean constant latency = 6.75 msec) had been recorded.

SONt neurons possessed 2-4 sparsely branching, varicose dendrites which were largely oriented in the horizontal plane. Spines were occasionally observed, emitting from both somata and dendrites. The beaded axon arose from either the soma or a primary dendrite, and coursed in a wide dorsomedial arc before turning caudally into the neurohypophysial tract. In some cases axons were traced as far as 2 mm from the soma, almost reaching the neural stalk. Short, hair-like appendages arising from axonal dilatations were fairly common, but long collaterals were not observed. SONt neurons displayed a prominent afterhyperpolarization and firing frequency adaptation which distinguished them from a more dorsal group of neurons which fired rapidly and displayed low-threshold, slow action potentials, but which could not be stimulated antidromically. Supported by NIH grant NS23941 (WEA).

470.16

FLOW CYTOMETRIC ANALYSIS OF STIMULUS-INDUCED DEPOLARIZATION IN DISSOCIATED EMBRYONIC RAT HYPOTHALAMIC NEURONS S. M. O'Connell*, J. P. Grierson, R. E. Petroski and H. M. Geller. (SPON: G. S. F. Ling) Department of Pharmacology, U.M.D.N.J. - Robert Wood Johnson Medical School and The Graduate School, Rutgers University, 675 Hoes Lane, Piscataway, NJ 08854.

Two classes of voltage-sensitive fluorescent dyes are known which respond to changes in the cell membrane potential by varying their intensity of emission. In the case of the cyanine dye $DiOC_5(3)$, cell depolarization produce a drop in fluorescent output. We have used this dye to examine stimulus-induced depolarization in fetal hypothalamic neurons, obtained from embryonic day 17 rats. Neurons were dissociated by enzymatic treatment followed by mechanical dispersion and the cells loaded with 20 nM $DiOC_5(3)$ at a concentration of 10^6 cells/ml. The addition of KCl (25 - 100 mM) and veratridine (50-100 uM) depolarized the majority of these cells. Analysis of fluorescence with time revealed that a large proportion of cells begin to repolarize after 5-6 minutes, bringing their mean resting membrane potential close to pre-stimulation levels. The glutamate analog, NMDA (10 uM), also depolarized 40-50% of cells. An interesting corollary to these experiments is a K^+-induced cell swelling, which does not appear to be attributable to chloride concentration nor changes in osmolality. Parallel studies of stimulus-induced calcium mobilization with these cells will be presented in another presentation (Grierson et al). Supported by NIH NS25168 and a grant from the UMDNJ Foundation.

HYPOTHALAMUS II

471.1

LIGHT- AND ELECTRON MICROSCOPIC STUDY OF BASAL FOREBRAIN NEURONS PROJECTING TO NUCLEI GEMINI AND THEIR RELATION TO VENTRAL PALLIDUM AS DEMONSTRATED BY SP-IMMUNOHISTOCHEMISTRY. L. Heimer and D. S. Zahm. Departments of Otolaryngology and Neurosurgery, University of Virginia, VA 22908 and Dept. of Anatomy, St. Louis University, MO 63104.

Basal forebrain neurons were retrogradely labeled with WGA-HRP or Fluoro-Gold following injection of the tracer in the nuclei gemini of the posterolateral hypothalamus. The labeled cells are located among the heavily myelinated medial forebrain bundles deep to the multiform layer of the olfactory tubercle. The distribution of labeled cells extends from the rostral pole of the olfactory tubercle into the nucleus of the horizontal limb of the diagonal band at the caudal pole of the tubercle, and in a plane approximately parallel to the ventral surface of the brain. Where this plane intersects the ventral pallidum, the labeled neurons freely mingle with ventral pallidal elements. The labeled cells are large and polygonal with large radiating dendrites which are related, at least along their proximal segments, to a moderately large and heterogenous population of boutons making symmetrical or asymmetrical synaptic contacts.

471.2

CYTOARCHITECTURE AND EFFERENT CONNECTIONS OF THE VENTROMEDIAL NUCLEUS OF THE HYPOTHALAMUS OF SYRIAN HAMSTERS. Robert L. Meisel, Mark R. Sterner, and Vickie R. Luttrell. Dept. of Psychological Sciences, Purdue Univ., West Lafayette, IN 47907.

The ventromedial nucleus of the hypothalamus (VMH) is fundamental to the hormonal regulation of sociosexual behaviors in the female Syrian hamster. Nonetheless, little is known about the organization or connectivity of the VMH in the hamster. In the coronal plane, we find the VMH to be roughly spherical in shape, with most of the nucleus staining in a homogeneous pattern. In the rostral half of the nucleus there is a medial subdivision seen as a compact cluster of cells, and a lateral subdivision that is crescent-shaped with a long dorsal-ventral axis.

Efferent projections of VMH neurons were mapped following iontophoretic injections of the plant lectin, Phaseolis vulgaris leucoagglutinin. VMH efferents in the Syrian hamster are similar to those reported for the rat, with primary forebrain projections to the lateral septum, bed nucleus of the stria terminalis, medial preoptic area, anterior hypothalamus, several amygdaloid nuclei, and the paraventricular thalamus. Efferent projections to the midbrain include the central gray and several tegmental fields. Unlike the rat, innervation of the pretectum and deep layers of the rostral superior colliculus is also apparent. We are currently studying possible differences in efferent connectivity of the subdivisions of the VMH. Supported by NIH grant HD21478.

471.3

LOCALIZATION OF TYROSINE HYDROXYLASE IMMUNOREACTIVE (TH-ir) NEURONS IN THE HYPOTHALAMUS OF CATS AND RHESUS MONKEYS.

A. Jayaraman, H. Hu* and J.K. Rao*. Depts of Neurology and Pediatrics, Louisiana State Univ. Sch. of Med, New Orleans, La. 70112.

Immunocytochemical studies suggest that the distribution pattern of TH-ir neurons in the hypothalamus may vary in different species of animals and even within the same strains of mice. The organization of catecholaminergic neurons in the monkey hypothalamus has not been studied in detail. Our study of the distribution pattern of TH-ir neurons in cats and monkeys with the avidin-biotin immunohistochemical method showed numerous TH-ir neurons in the paraventricular nucleus and in zona incerta of the dorsal hypothalamus; in the periventricular nucleus and the posterior hypothalamic areas of the intermediate regions of the hypothalamus. In the ventral hypothalamus TH-ir cells were clustered in the infundibular nucleus. These patterns of localization of hypothalamic catecholaminergic neurons were similar to those described in cats and monkeys using fluorescence histochemical methods. In addition to these regions, TH-ir neurons were also noted prominently in the preoptic, supraoptic, and the dorsomedial hypothalamic areas. These areas were not recognized in earlier studies to contain catecholaminergic cells. The distribution pattern of TH-ir cells in hypothalamus of cats and monkeys show many similarities to the pattern described in mouse using immunohistochemical methods (Ruggiero et al., JCN.223:556,1984). The TH-ir neurons in the preoptic hypothalamus (along with their interactions with neurotensin) may provide the anatomical substrate for the thermoregulatory role of dopamine. Supported by the Scottish Rite program for Schizophrenia Research.

471.4

MONOAMINERGIC INNERVATION OF PEPTIDERGIC NEURONS IN THE RAT HYPOTHALAMUS: A DOUBLE IMMUNOENZYMATIC STAINING.

C.Decavel* and A.Calas. Lab.de Physiol.des Interact.Cell., UA CNRS 339, Univ.de Bordeaux I, 33405 Talence, France.

The monoaminergic (MA) innervation of magnocellular hypothalamic neurons was studied with a double immunocytochemical technique using two different substrates for peroxidase:diaminobenzidine and benzidine dihydrochloride. The greater input to vasopressinergic (VP) cells was by far the noradrenergic (NA) one, with fibers surrounding the VP cell bodies. In the contrary, only a few dopaminergic (DA) varicosities contacted VP perikarya, most often in the more anterior parts of the supraoptic (SON) and paraventricular (PVN) nuclei. The serotonergic (5HT) innervation appeared to contact subpopulations of VP cells, both in the SON and in the peripheral parts of the posterior magnocellular PVN. None of these three transmitters innervated the whole oxytocinergic (OX) population. They appeared to be directed toward groups of OX neurons. The NA and 5HT fibers contacted a greater number of OX perikarya than did the DA ones in both nuclei.
Except for the NA afferents on VP neurons, each type of MA fibers seems to innervate only certain subpopulations of VP or OX cell bodies. It remains to be determined if the information carried by these three sets of afferents are sent to separate groups of magnocellular peptidergic neurons, or if a same cell can integrate the different synaptic events of these MA systems.

471.5

FUNCTIONAL AND MORPHOLOGICAL STUDIES ON PUTATIVE INTERACTIONS BETWEEN NEUROPEPTIDE Y AND LUTEINIZING HORMONE RELEASING HORMONE IN RATS AND MONKEYS.

C.W. Coen[1], M.-C. Ruiz de Elvira[1]*, K. Maclachlan[1]*, C. Montagnese[1]*, M.J.D. Andrews[1]*, K.T. O'Byrne[2]*, I.J. Clarke[3]* and Zs. Liposits[4]*. [1]Department of Anatomy & Human Biology, King's College London, UK; [2]MRC Reproductive Biology Unit, Edinburgh, UK; [3]Prince Henry's Hospital, Melbourne, Australia; [4]Dept. Anatomy, Pecs, Hungary.

Ovariectomized rats treated with oestrogen and progesterone show an increased release of luteinizing hormone (LH) following intraventricular (i.c.v.) neuropeptide Y (NPY; 1 ug). Prior treatment (-10 min i.p.) with the α_2-adrenergic antagonists piperoxane (50 mg/kg) or idazoxone (2 mg/kg) prevents this stimulation. In contrast, the pulsatile release of LH occurring in ovariectomized rats which have not been treated with steroids is suppressed by i.c.v. NPY (1 ug) and this effect is unaffected by piperoxane. NPY may also be involved in the hypothalamic control of LH release in primates since 1 ug given i.c.v. to oestrogen-treated ovariectomized marmosets results in a stimulation of LH comparable to that induced by i.v. administration of 100 ng LH releasing hormone (LHRH). Immunohistochemical studies on adjacent sections from the rat, marmoset or macaque show a strong correspondence between LHRH perikarya and presumptive terminal fields containing NPY. With double-label immmohistochemistry (using the conventional DAB reaction product together with the nickel- or silver-intensified version in the same section) we have found NPY varicosities in putative approximation to LHRH perikarya in each of the three species studied. Confirmation of a synaptic relationship underlying the functional effects awaits completion of studies at the EM level.

471.6

MEDULLARY PROJECTIONS TO THE LUTEINIZING HORMONE RELEASING HORMONE FORMATION OF THE RAT: STUDIES INVOLVING RETROGRADE TRACING AND IMMUNOHISTOCHEMISTRY FOR NEUROPEPETIDE Y AND PHENYLETHANOLAMINE N-METHYLTRANSFERASE.

A. Castaneyra-Perdomo*, M. Bennett* and C.W. Coen (SPON: N.H.K. Holder). Dept. Anatomy & Human Biology, King's College London, U.K.

Retrograde tracing and immunohistochemical techniques have been used to identify cells in the medulla oblongata which project to the region of the luteinizing hormone releasing hormone (LHRH) perikarya in the preoptic area of the rat hypothalamus. Wheatgerm agglutinin-horseradish peroxidase was injected into the LHRH formation by iontophoresis. Three days later the rats were treated with i.c.v. colchicine (105 ug) and on the following day they were perfused transcardially with 5% acrolein. Sections through the preoptic area were reacted using the conventional DAB method to reveal the injection site. These sections were then processed for LHRH immunoreactivity using the nickel-intensified reaction. Thus, success in the placement of the micropipette was indicated by the presence of the dark blue LHRH perikarya within the brown injection site. Sections through the medulla were reacted for the retrogradely transported lysosomal peroxidase using the nickel-intensified method and these sections were subsequently processed for immunoreactivity for neuropeptide Y (NPY) or the adrenaline synthesizing enzyme phenylethanolamine N-methyltransferase (PNMT) using the DAB method. Many cells within the areas corresponding to the ventrolateral and dorsomedial adrenaline/NPY cell groups (C1 and C2) were found to contain the retrograde tracer; a minority of the cells also contained NPY- or PNMT-immunoreactivity as revealed by dark blue lysosomes within a brown perikaryon.

471.7

PROJECTIONS FROM THE TUBEROMAMMILLARY NUCLEUS OF THE HYPOTHALAMUS TO PRIMARY AFFERENT NEURONS IN THE MESENCEPHALIC NUCLEUS OF THE TRIGEMINAL NERVE.

J.I. Nagy T. Yamamoto, S. Shiosaka*, and P.E. Daddona*, Dept. of Physiology, Fac. of Med., Univ. of Man., Winnipeg, Manitoba, CANADA, R3E 0W3.

The somas of primary afferent neurons in the mesencephalic nucleus of the trigeminal nerve (Mes V) in rat are surrounded by a dense plexus of adenosine deaminase-immunoreactive (ADA-IR) axons which originate, in part, from ADA-IR neurons located in the tuberomammillary nucleus (TM) [Nagy et al., (1986) Neuroscience 17, 141-156]. Projections of TM to Mes V were investigated by ultrastructural, anterograde tracing and immunohistochemical techniques. After injections of Phaseolus vulgaris-leucoagglutinin (PHA-L) into the region of TM, PHA-L-labelled ADA-IR fibers were seen around Mes V neurons. Ultrastructurally, ADA-IR axons were varicose and contained ADA-IR vesicles 45 to 70 nm in diameter. Occasionally, thin axons could be traced back to local ADA-positive neurons. Synaptic junctions were sometimes seen between Mes V somas and ADA-IR terminals. It is suggested that the hypothalamus, via a direct action on Mes V neurons which convey proprioceptive input from jaw muscles, may exert autonomic control over jaw movements related to aggressive attack, defensive or feeding behavior.

471.8

POTENTIAL TARGET NEURONS OF A SEXUALLY DIMORPHIC ENKEPHALINERGIC FIBER SYSTEM IN THE PREOPTIC AREA.

R.E. Watson, Jr., M.C. Langub, Jr.*, S.J. Wiegand, and G.E. Hoffman. Dept. of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536, Dept. of Neurobiology and Anatomy, Univ. of Rochester, Rochester, NY 14642, and Dept. of Physiology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

A sexually dimorphic enkephalinergic fiber system, in which expression is governed by the gonadal steroids in both an organizational and activational manner, is present in the periventricular preoptic nucleus (pePOA) of the rat in only the female. In previous electron microscopic studies, we have identified abundant enkephalinergic terminals and synapses in the pePOA. Thus, in an effort to determine its functional significance, it is important to identify the target neurons of this system. Colchicine treated and untreated female Sprague-Dawley rats were perfused and sections were processed for the immunocytochemical localization of met-enkephalin (m-ENK), neurotensin (NT), substance P (SP), cholecystokinin (CCK), somatostatin (SS), corticotropin releasing factor (CRF), luteinizing hormone releasing hormone (LHRH), vasoactive intestinal polypeptide (VIP), oxytocin (OXY), vasopressin (VP), and tyrosine hydroxylase (TH). No LHRH, VIP, OXY, VP, or CRF cells were detected in the pePOA. Only widely scattered m-ENK, NT, SP, and SS cells were present, while greater numbers of these cells were detected immediately lateral or posterior to it. A comparatively higher density of CCK positive cells was present in the pePOA at the level of the sexually dimorphic m-ENK system. However, much greater numbers of these cells were present at a posterior position in the pePOA, immediately caudal to the region where the m-ENK system is maximally expressed. A relatively large number of TH positive cells are present in the pePOA at the level of the dense m-ENK fiber plexus. Double labelling studies using nickel-enhanced DAB (for m-ENK fibers) in conjuction with DAB (for TH immunoreactivity) indicate close apposition between m-ENK varicosities and TH positive cells, suggesting potential synaptic interactions between these systems. {Supported by NS-23591}

CHARACTERISTICS OF PARASYMPATHETIC SECRETOMOTOR NEURONS STUDIED IN VITRO. T.A. Harrison and R.M. Bradley. Sch. Dent., Univ. Michigan, Ann Arbor, MI 48109.

We are investigating the secretomotor control of von Ebner's lingual salivary glands in the rat. These glands secrete directly into the clefts of the circumvallate and foliate papillae and provide the microenvironment for lingual taste buds contained in the epithelium lining these clefts. The secretomotor cells controlling von Ebner's glands are closely associated with the second order gustatory relay nucleus in the brainstem (solitary nucleus), suggesting interactions between gustatory afferent information and secretomotor activity. Because it is difficult to record from the parasympathetic cells in vivo, we have developed a brain slice preparation of the medulla that contains both the gustatory and parasympathetic nuclei. Horizontal brain slices were prepared in a conventional manner and cut at a 20° angle. Such slices included not only the entire solitary nucleus but also the stump of the glossopharyngeal nerve, which can be electrically stimulated to activate both the solitary tract and the secretomotor cells. Using this preparation we have successfully recorded spontaneous activity from neurons in the caudal and rostral solitary nucleus for up to 5 hours. Rhythmically active neurons were recorded in the caudal solitary nucleus whereas neurons in the gustatory, rostral solitary nucleus showed a highly irregular pattern of activity. Successful stimulation of the solitary tract to activate solitary nucleus neurons has been accomplished using a bipolar stimulating electrode placed on the glossopharyngeal nerve stump. (Supported by NIH Grant NS21764.)

472.2

ADENOSINE INVOLVEMENT IN A LONG-LASTING BRAINSTEM-MEDIATED INHIBITION OF PHRENIC ACTIVITY FOLLOWING HYPOXIA. E.A. Gallman and D.E. Millhorn. Dept. of Physiology, Univ. of North Carolina, Chapel Hill, North Carolina 27599.

Among the long-lasting responses of central respiratory control network is an inhibition of phrenic nerve output, evoked by brief exposure to hypoxia, which lasts at least one hour and requires the presence of the midbrain (J. Physiol. 395:333, 1988). These studies were done to investigate the neurochemical basis for this inhibition. All studies were performed in cats which were anaesthetized, peripherally chemo-denervated, paralyzed, and artificially ventilated with 100% O_2. End-tidal PCO_2 and temperature were servo-controlled. Central respiratory drive was determined as the product of peak integrated phrenic nerve activity and phrenic rate. Cats were decerebrated above the midbrain and then exposed to hypoxia (F_IO_2 = .10 to .15) for 10 min to elicit long-lasting phrenic inhibition. Theophylline, an adenosine receptor antagonist, was then introduced (13.6 mg/kg i.a + 13.6 mg/kg/hr i.v.) and exposure to hypoxia repeated. In the presence of theophylline, the phrenic inhibition following hypoxia was prevented. In another series of cats, adenosine, pressure injected into the nucleus tractus solitarus (NTS) of the medulla elicited inhibition of phrenic activity. These results implicate adenosine in the long-lasting post-hypoxic inhibition of phrenic activity. This work was supported by USPHS Grant HL-33831.

472.3

CHOLINESTERASE-NEGATIVE VAGAL EFFERENTS PROJECTING TO THE ABDOMEN IN THE RAT. E.K.Tayo* and R.G.Williams* (SPON: G.J.Dockray). Dept. Phys.Pharm., The Univ., Southampton, SO9 3TU, UK.

Vagal parasympathetic preganglionic neurones innervating the abdominal viscera, arise from the Dorsal Motor Nucleus of the Vagus (DMN). These neurones are generally regarded as cholinergic, but a number of other transmitter candidates have been suggested.

As a first step towards assessing the relative proportions of different neurochemical types of vagal efferents present, we have examined the distribution of cholinesterase positive cells in the DMN of the rat.

Efferents projecting to the abdomen were identified by retrograde tracing of True Blue (TB) from the stomach wall, and the proportions containing acetylcholinesterase (AChE) assessed.

The distribution of TB cells was similar to that of the AChE cells and reflected the general shape of the DMN. However, only a proportion, less than 40%, of the TB cells were AChE positive.

CONCLUSION: It follows that, either the majority of abdominal vagal efferents are non-cholinergic or that at least two populations of cholinergic cells exist within the DMN.

472.4

EVIDENCE FOR A SOMATOSTATINERGIC PROJECTION FROM THE NUCLEUS OF THE SOLITARY TRACT TO THE NUCLEUS AMBIGUUS IN THE RAT. E.T. Cunningham, Jr.,[1,2] R. Benoit,[3] and P.E. Sawchenko.[2] The Univ. of Calif.[1] and The Salk Institute[2], La Jolla, CA. and Mont. Gen. Hosp.[3], Montreal, Canada.

Axonal transport and immunocytochemical methods were used to investigate the anatomical and biochemical organization of projections from the nucleus of the solitary tract (NTS) to the compact, esophageal part (see Beiger and Hopkins, JCN 262:546, '87) of the nucleus ambiguus (NA) in the rat. Iontophoretic deposits of the retrograde tracer fluorogold (FG) were placed in the compact NA. These deposits labeled a column of cells just medial to the solitary tract and rostral to the obex, which we term the central part of NTS (after Ross, et. al., JCN 242:511, '85). Iontophoretic deposits of the anterograde tracer Phaseolus vulgaris-leucoagglutinin (PHA-L) placed in the central part of NTS gave rise to dense and topographically restricted projections to the compact NA. More caudal and ventral aspects of the NA did not receive a prominent input from the central part of NTS, and deposits that spared the central part of NTS gave rise to only sparse projections to the compact NA. Antisera against somatostatin-28 (SS-28) revealed immunoreactive cell bodies within the central part of NTS. In addition, an immunocytochemical double-labeling procedure, capable of co-localizing both PHA-L and endogenous peptides to single fibers and/or varicosities, demonstrated an appreciable number of SS-28-immunoreactive terminals within the compact NA that arose from the NTS. These data provide evidence for a discrete somatostatinergic projection from the central part of NTS to the compact NA. Studies implicating the central part of NTS and the compact NA in esophageal function suggest that this pathway may be involved in the reflexive control of esophageal motility.

472.5

CONTRIBUTION OF THE ROSTRAL VENTROLATERAL (RVLM) AND ROSTRAL VENTROMEDIAL (RVMM) MEDULLA TO MAINTENANCE OF SYMPATHETIC NERVE ACTIVITY (SNA). K.J. Varner, C.L. Grosskreutz* and M.J. Brody. Dept. of Pharmacol. and CV Center, University of Iowa, Iowa City, IA 52242

Studies from this laboratory showed that rostral ventral medulla (RVM) contains distinct subregions which differentially regulate vasomotor function. The purposes of this study were to determine 1) the contribution of these subregions to maintenance of sympathetic tone and 2) whether RVLM (and/or RVMM) is the sole source of sympathetic outflow. Rats were prepared for measurement of heart rate, arterial pressure (AP) and renal SNA and were artificially ventilated. Reversible inactivation of RVLM (2 mm) and RVMM (1mm) lateral to midline was achieved by bilateral microinjection of lidocaine (LIDO) (200 nl, 4%). Residual SNA and neurogenic cardiovascular tone after LIDO into RVLM and RVMM was estimated by iv administration of trimethaphan (TRIM). Administration of LIDO into RVMM decreased SNA 39±10% and AP 51±12 mmHg to 59±5 mmHg. Administration of LIDO into RVLM decreased SNA 41±15% and AP 51±11 mmHg to 62±3 mmHg. After LIDO into all four sites (RVLM + RVMM) SNA fell 56±10% and AP fell 58±6 mmHg to 51±4 mmHg. TRIM produced additional falls in SNA of 41±10 % and AP of 8±3 mmHg. We conclude that 1) RVMM and RVLM contribute equally to SNA and vasomotor tone and 2) a substantial fraction of SNA appears to be generated outside of RVM but has a limited role in vasomotor control. (Supported by HLB-14388 and Berlex Labs.)

472.6

EFFERENT AND AFFERENT CONNECTIONS OF THE ROSTRAL VENTROLATERAL MEDULLA OF THE RABBIT. D.R. Liskowsky, P.L Vera, R.W. Winters*, P.M. McCabe, C.G. Markgraf, N.Schneiderman. Dept. of Psychology, Univ. of Miami, Coral Gables, FL. 33124.

The rostral ventrolateral medulla (RVLM), which encompasses the C1 noradrenergic cell group, is known to play an important role in cardiovascular regulation. Activation of this region in the rabbit, with either electrical or chemical stimulation, produces a profound pressor response, usually accompanied by bradycardia. It is thought that this region is essential to the mediation of the pressor component of the 'defence' response elicited by electrical stimulation of the hypothalamus and midbrain.

Using the retrograde fluorescent tracer Fluorogold (FG), and the retrograde and anterograde tracer horseradish peroxidase conjugated with wheat germ agglutinin (HRP) both the afferent and efferent connections of the RVLM in the rabbit were mapped. In New Zealand albino rabbits either FG or HRP (20-50 nl) were injected using glass micropipettes (tip o.d. 20-40μ) connected to a micro-pressure injection system. To facilitate placement of the tracers, pulsed electrical current (25-75μA) was passed through the pipette to elicit a pressor response from RVLM.

Injection of FG or HRP into the RVLM led to cell body labelling in several mesencephalic and diencephalic structures, including the periaqueductal grey region of the midbrain, the parabrachial nucleus, and the paraventricular nucleus and perifornical region of the hypothalamus. Retrograde labelling was also seen in the dorsal medial medulla, including the nucleus tractus solitarius. HRP histochemistry also revealed anterograde labelling in many of the same structures which showed retrograde labelling, thereby suggesting reciprocal fucntional connections. Anterograde labelling of HRP was also observed in the intermediolateral cell column of the spinal cord. Supported by NIH Grants HL07426 and HL 36588.

472.7

AN ANTEROGRADE AND RETROGRADE ANATOMICAL ANALYSIS OF RETICULO-RETICULAR CONNECTIONS IN THE RAT. R.P. Vertes. Mercer University, School of Medicine, Macon, GA 31207.

In previous analyses of ascending reticular formation (RF) projections in the rat using tritiated amino acids (Vertes et al., Neuroscience 19:873, 1986; Vertes and Martin, JCN, in press), we described pronounced RF projections to adjacent reticular fields. It was difficult, however, to unequivocally determine that ascending RF fibers terminated in, rather than coursed through, rostral levels of the RF. The present study was designed to answer this question and to determine the major inputs to the medullary (mRF), pontine (PRF) and midbrain (MRF) reticular formation.

WGA-HRP retrograde and PHA-L anterograde techniques were used. The major findings were as follows: (1) the major inputs to all levels of the brainstem RF were from other regions of the RF; (2) the PRF and mRF received pronounced projections from the contralateral PRF and mRF, respectively, but the MRF received relatively few contralateral MRF projections; (3) each level of the RF received significantly more projections from adjacent caudal as opposed to rostral levels of the RF such that nucleus gigantocellularis (NGC) received major inputs from nuclei reticularis dorsalis and ventralis of the lower medulla, nuclei pontis caudalis and oralis from NGC, and the MRF from the PRF; (4) both PRF and MRF received very few projections from lateral parvocellular regions of the RF; the mRF received moderate to heavy parvocellular projections; and (5) the PRF and mRf received heavy projections from an area of the MRF that is co-extensive with mesencephalic locomotor region. The results indicate extremely pronounced reticulo-reticular interconnections and suggest a hierarchical arrangement such that each level sends its major projection to the next rostral level.

472.8

RESPONSES OF NEURONS IN THE PONTINE SWALLOWING NUCLEUS OF LAMBS TO MULTIMODAL STIMULATION OF THE ORAL CAVITY AND LARYNX. R.D. Sweazey and R.M. Bradley. Sch. Dent., Univ. Michigan, Ann Arbor, MI 48109.

We have investigated the responses of neurons in a region of the lamb pons termed the pontine swallowing nucleus. Neurons were characterized by their responses to oral cavity and laryngeal stimulation with chemical, mechanical and thermal stimuli, by response latency, and receptive field location and size. Responsive neurons were found medial to the dorsomedial tip of the sensory trigeminal nucleus. These pontine neurons had a high spontaneous rate and over 50% responded exclusively to only one stimulus modality. The order of effective stimuli was mechanical, chemical, thermal. The remaining neurons showed multimodal responses, with the majority of these cells responding to both chemical and thermal stimuli. Responses to mechanical stimuli were observed with moving and stationary stimuli, the moving stimulus being more effective. Chemosensitive neurons in the lamb pons had responses similar to those previously observed in the nucleus of the solitary tract. Responses to thermal stimuli were observed more frequently to cooling than to warming. The receptive fields of neurons which responded to mechanical and/or thermal stimuli were larger than the receptive fields of neurons which responded to chemical stimuli. Furthermore, neurons responsive to mechanical stimuli had shorter response latencies than those responsive to chemical stimuli. Analysis of response latencies suggests that these pontine neurons receive direct afferent input from the oral cavity and larynx. (Supported by NIH grant DE05727.)

AFFERENT PROJECTIONS TO THE MEDIAN RAPHE NUCLEUS IN THE RAT. Joseph M. Paris and Stanley A. Lorens. Behavioral Pharmacol. Lab., Dept. Pharmacol., Loyola Univ. Med. Cnt., Maywood, IL 60153 USA.

The efferent projections of the midbrain raphe nuclei in the rat have been studied by many investigators. However, the afferent projections to these nuclei, in particular, the median raphe nucleus (MR) have not been thoroughly examined. Male Sprague-Dawley rats received an iontophoretic application of the fluorescent retrograde dye, Fluoro-Gold^{R}, into the MR. The rats were anesthetized and transcardially perfused 7-14 days post-injection. Coronal (18-24 μm) sections were obtained at 0.1 mm intervals throughout the brain and spinal cord.

Several regions of the neuroaxis project to the MR. In terms of the number of retrogradely labelled cell bodies, the major sources of afferent fibers are: medial frontal cortex, vertical limb of the diagonal band of Broca, lateral habenula, lateral hypothalamus, interpeduncular nucleus, reticular formation, and the lateral dorsal tegmental nucleus. Other sources of afferent fibers include: lateral septum, zona incerta, ventral tegmental area, central grey, dorsal raphe nucleus, caudal raphe nuclei, medial nucleus of the cerebellum, and the spinal cord. Thus the activities of both the serotonergic and non-serotonergic cell bodies in the MR can be modulated by fibers which originate in several distinct regions of the central nervous system.

PROJECTIONS FROM THE RAPHE ONTO MEDULLARY CATECHOLAMINERGIC NEURONS. A.P. Nicholas* and M.B. Hancock. Department of Anatomy and Neurosciences, University of Texas Medical Branch, Galveston, Texas 77550.

Phaseolus vulgaris-leucoagglutinin (PHA-L) was iontophoretically deposited into the nucleus raphe magnus, nucleus raphe obscurus and nucleus reticularis gigantocellularis pars alpha of anesthetized Sprague-Dawley rats. Following survival times of 3-5 days, the rats were anesthetized and perfused with 4% paraformaldehyde. The medulla was removed and sectioned (30 μm) with a Vibratome. PHA-L-immunoreactive (PHA-LI) elements were immunostained black with the PAP technique and nickel-intensified diaminobenzidine (Ni/DAB), while phenylethanolamine N-methyl transferase-immunoreactive (PNMTI) neurons or tyrosine hydroxylase-immunoreactive (THI) neurons were immunostained amber with the PAP technique and DAB alone. Black-stained PHA-LI cells were present at the deposition sites in the raphe and PHA-LI terminal fields were present among amber-stained PNMTI cells in the rostral medulla or THI cells in the caudal medulla. Varicose PHA-LI fibers were observed coursing along the surface of PNMTI and THI dendrites, and PHA-LI boutons were contiguous with somata of PNMTI and THI cells. These results indicate that medullary adrenergic and noradrenergic neurons are influenced by projections from the medullary raphe nuclei. These raphe projections are a likely source for 5HT-immunoreactive endings that have been shown to be contiguous with medullary catecholamine cells. ENHANCEMENT OF THE PERFORANT PATH POPULATION SPIKE BY STIMULATION OF LOCUS COERULEUS: EVIDENCE FOR TWO SEPARATE MECHANISMS. C.W.Harley, J.S. Milway* and S.Evans*. Dept of Psychology, MUN, St. John's, Nfld. A1B 3X9

Electrical stimulation in the vicinity of locus coeruleus (LC) has been shown to produce reliable and significant enhancement of the perforant path (PP) evoked population spike in the dentate gyrus of urethane-anesthetized rats. Microejection of glutamate in or near LC also induces significant enhancement of the PP evoked population spike. Both forms of enhancement appear similar in that the main effect is on population spike amplitude and enhancement can be long-lasting. We had assumed that both forms of enhancement were mediated by the release of norepinephrine (NE) in the dentate gyrus since NE can induce both short and long-lasting enhancement of the PP evoked population spike when applied to the hippocampus in vivo or in vitro. These effects of NE depend on activation of a beta receptor. In agreement with this assumption we were able to block the glutamate-induced enhancement of the population spike by administering propranolol. We were not able to block the enhancement effect produced by electrical stimulation of LC. In some experiments both glutamatergic and electrical LC activation were produced by a convergent pipette and electrode assembly. Propranolol blocked the enhancement produced by glutamate stimulation but not that produced by electrical activation.

These results suggest there are two systems in the vicinity of LC capable of producing both short- and long-lasting enhancement of the PP evoked population spike. One of the systems appears to be the LC whose effects are mediated by beta receptors in the hippocampus. The other system has not been identified pharmacologically and it is unlikely that the cell bodies of this system occur in the vicinity of LC.

EFFECTS OF STIMULUS INTENSITY AND REPETITION RATE ON BRAIN STEM AUDITORY EVOKED POTENTIALS (BAEPs) IN AWAKE MONKEY. J. A. Pineda[1], T. C. Holmes[1*], D. Swick[2*], and S. L. Foote[1,3]. Depts. of Psychiatry[1] and Neuroscience[2], UCSD, and Scripps Clinic and Research Foundation[3], La Jolla, CA 92093.

While an extensive database of knowledge exists concerning human BAEPs, there is a limited amount of non-human primate data, especially from unanesthetized animals. In this study, BAEPs were recorded in nine unanesthetized squirrel monkeys (Saimiri sciureus) from a chronically implanted epidural electrode in vertex, referenced to an inion electrode. The effects of 30, 50, 60, and 70 dB SPL clicks or repetition rates of 5, 10, 20, 40, and 80 Hz were analyzed in different sessions. Monkey waveforms resembled human BAEPs in morphology, number of components, polarity, latency variability, and inter-peak conduction times. They consisted of seven components (I-VII), six exhibiting positive polarity, some exhibiting multiple peaks, and all exhibiting similar latencies in different sessions. Additionally, slow potentials (SN, SP) recorded during the second half of the epoch provided a substratum for waves IV through VII. Systematic decreases in latency with increasing intensity were significant for most components, while increases in repetition rate increased latencies only in some components. Inter-peak conduction times resembled human data while differing from those reported for anesthetized monkeys. These similarities in conduction latencies suggest that times required for impulses to reach different brain stem areas involved in acoustical processing may be conserved across species and sizes of brain. Thus, given the similarities to human potentials, BAEPs in awake monkey may be valuable for investigations into the origins of these components.

472.13

BRAIN STEM INHIBITION IN ADAPTATION

J. Zabara. Temple Univ. Sch. of Med., Phila., PA 19140

A vestibular model of adaptation is utilized to test the hypothesis that inhibitory processes in the brain stem determine the extent and rapidity of adaptation to a changing environment. Brain stem inhibition is initiated by a vagal afferent mechanism which is activated by electrical stimulation of specific nerve groups. Four conscious and unrestrained adult male and female squirrel monkeys of Bolivian origin were exposed to 30 rpm horizontal rotation in a transparent plastic test chamber for up to 2 hours/day for 6 to 12 days. Rotation was sustained for the entire session lasting from 15 to 120 minutes with multiple vomiting episodes permitted. Vomiting latency and frequency were measured in both stimulated and non-stimulated animals. Implantation of a vagal cuff is performed on monkeys anesthetized with sodium pentobarbital IV (35 mg/kg). A pair of adjacent contacts is used for bipolar stimulation at 1-10 ma amplitude, 4-100 Hz frequency and 0.3-0.6 msec. duration. Electrode connections are made with contacts housed in a nylon receptable cemented to the top of the skull. Each monkey had a substantial reduction in emetic response to rotation during vagal activation. The percentage reduction in each of the four animals was 81% (#1), 88% (#2), 72% (#3) and 83% (#4). The average percent reduction for all animals was 81%. Thus, adaptation can be enhanced by a vagal afferent mechanism incorporating inhibitory transmitters.

472.14

PATHWAYS DESCENDING FROM SUBSTANTIA NIGRA AND VENTRAL TEGMENTAL AREA SHOWN BY PHASEOLUS VULGARIS LEUCOAGGLUTIN. M.R. Park. Dept. Anatomy & Neurobiology, Univ. Tennessee, Memphis, The Health Science Center, Memphis, TN 38163.

Injections of the anterograde tracer phaseolus vulgaris leucoagglutinin (PHAL) in substantia nigra (SN) or ventral tegmental area (VTA) produces labeling of extensive descending pathways. Injections in VTA can fill the entire mesencephalon, as seen in coronal section, with anterogradely labeled varicose axons and terminal fields. In sagittal section, terminal fields can be seen throughout the midline raphe nuclei and as far caudal as the pontine reticular nuclei. A more discrete distribution to the forebrain projecting raphe nuclei, dorsal and median raphe, as well as to raphe pontis, is seen when the injection site is in lateral VTA and medial SN. Anterogradely labeled axons are in the order of 0.5 μm in diameter. Few descending projections are seen in tegmentum from SN pars reticulata injections although ipsilateral superior colliculus is extensively labeled with axons arranged in a pattern of pillars and laminae that surround blank holes.

The extent of labeling from SN and VTA is greater than that reported for dopaminergic connections, implying that a substantial portion of these descending axons are non-dopaminergic. It should be born in mind, however, that these injections have been made in areas that carry heavy descending traffic and so test to the fullest extent possible the assertion that PHAL does not label fibers of passage.

IMMUNOHISTOCHEMICAL LOCALIZATION OF GABA IN THE RAT INTERPEDUNCULAR NUCLEUS (IP). J.C. Pearson. Dept. of Anatomy, Wright State Univ. Sch. of Med., Dayton, OH 45435.

Evidence for glutamic acid decarboxylase and GABA receptors within rat IP suggests a neurotransmitter role for GABA in this nuclear complex. In the present study, antiserum against GABA-glutaraldehyde-keyhole limpet hemocyanin was used to localize GABA-like immunoreactivity (GABA-LI) in rat IP. Rats were colchicinized and perfusion fixed (4% paraformaldehyde, 0.5% glutaraldehyde, 0.5% $K_2Cr_2O_7$ in 0.05M PO_4 buffer, pH 6.5). Vibratome sections (50μm) were processed by the avidin-biotin-peroxidase method. Staining was blocked by 100μM GABA-glutaraldehyde conjugate but not by 500μM conjugated glutamate, glutamine, or taurine. GABA-LI neuronal somata were abundant in rostral (R), dorsomedial (DM), central (C), intermediate (I), and dorsal lateral (DL) subdivisions of IP, but, found infrequently in the rostral lateral (RL) and lateral (L) nuclei and absent from the apical (A) subnucleus. GABA-LI processes were present in all IP subnuclei but prominent in IP-RL, -L and -A. Quantitative evaluation of soma cross-sectional areas indicated that GABA-LI somata were among the largest of all neurons in IP-DM and -R, but among the smallest of cells in the remaining subnuclei. Results are consistent with the hypothesis that GABA has a neurotransmitter role in IP function, and suggest that the influence of IP GABA-LI cells may be extrinsic as well as intrinsic to this nuclear complex.

Mesopontine Tegmental Projections to the Nucleus Basalis of Meynert: An Ultrastructural Study. A.E. Hallanger, S.D. Price*, T. Steininger, and B.H. Wainer. The University of Chicago, Committee on Neurobiology. Chicago, IL 60637.

The existence of a cholinergic projection from the pedunculopontine tegmental nucleus (PPT) in the midbrain to the cholinergic nucleus basalis of Meynert in the forebrain has been suggested (Woolf and Butcher, '86; Semba et al., '88). In order to determine whether the cholinergic neurons of the nucleus basalis receive input from a cholinergic source such as the PPTor the laterodorsal tegmental nucleus (LDT), or from nocholinergic neurons in the mesopontine tegmentum, we used rats treated with the following combinations of techniques: (1) ChAT immunocytochemistry only, (2) anterograde transport of PHA-L from the region of PPT to label midbrain afferent terminals in the forebrain, combined with ChAT immunocytochemistry to label cholinergic nucleus basalis neurons, and (3) anterograde transport of PHA-L from the region of the PPT, with retrograde transport of WGA-HRP from the cerebral cortex to label cortically-projecting nucleus basalis neurons. Tissue from all types of cases was examined in the electron microscope. We found that: (1) Cholinergic somata and dendrites (both distal and proximal) in the nucleus basalis of Meynert did not receive synaptic input from ChAT-immunoreactive synaptic terminals. However, numerous non-ChAT-immunoreactive terminals did contact cholinergic dendrites, and cholinergic terminals did contact noncholinergic dendrites; (2) Axons labelled with PHA-L from the mesopontine tegmentum did not form synaptic contacts onto cholinergic somata or dendrites in the basal forebrain, but did contact noncholinergic neurons in this region; and (3) PHA-L labelled axons did not form synaptic contacts onto somata retrogradely labelled from the cerebral cortex, but did synapse onto non-retrogradely labelled neurons in the basal forebrain. These results suggest that there is little, if any, cholinergic input from the PPT or LDT onto the cholinergic basal forebrain neurons. CONDITIONED TASTE AVERSIONS AFFECT GUSTATORY EVOKED ACTIVITY IN THE NTS OF CHRONIC DECEREBRATE RATS. G. P. Mark and T. R. Scott. Dept. Psychol., Princeton Univ., Princeton, NJ 08544, and Dept. Psychol. & Inst. Neurosci., Univ. Delaware, Newark, DE 19716

Decerebrate rats exhibit satiety and normal oro-facial reactions to tastants, but do not respond to the challenges of dehydration or sodium depletion. Nor do they exhibit the ability to acquire or maintain conditioned taste aversions (CTA's). To explore the possibility that taste cell activity is modified by CTA learning in these preparations, responses were recorded from 42 single neurons in the nucleus tractus solitarius (NTS) of chronic decerebrate rats in which ingestion of 2.5 mM saccharin (CS) was paired with LiCl-induced malaise. Results were compared with those reported previously for unconditioned decerebrates (Mark et al., 1988) and also to data from conditioned intact rats (Chang & Scott, 1984). When neurons were categorized into sweet and non-sweet responsive groups, responses evoked by the CS from sweet-sensitive cells were shown to be increased by 16%. Post-stimulus time histograms revealed that this increase was due largely to a spike of activity, three times greater than unconditioned decerebrate levels, which peaked 950 msec after stimulus onset. Multidimensional scaling analyses, however, did not reveal a shift in the coding of the CS following conditioning. Whereas stimulus profiles evoked by the CS and quinine became more similar with CTA development in intact animals, these profiles remained distinct in decerebrates. These results demonstrate that a subset of NTS neurons are functionally altered as a result of CTA learning independent of forebrain influences. The absence of a change in coding of the CS in decerebrates, however, may account for the fact that these animals do not demonstrate CTA learning behaviorally.

CHRONIC RECORDING IN AND AROUND THE HYPOGLOSSAL NUCLEUS DURING INGESTION AND REJECTION OF SAPID STIMULI IN THE RAT. J.B. Travers and L.M. Jackson*. Dept. Oral Biology, Ohio State Univ., Columbus, OH 43210

The neural substrate for ingestion and rejection is organized in the caudal brain stem (Grill & Norgren, '78). Gustatory stimuli influence the motoneurons producing ingestion and rejection primarily over polysynaptic pathways (Travers & Norgren, '83). We have begun to examine the neural circuitry underlying these responses by examining gustatory elicited responses of ingestion and rejection in single cells of the hypoglossal nucleus and the adjacent reticular formation. Under Nembutal anesthesia, rats were implanted with fine wires in the anterior digastric (AD), styloglossus (STY) and thyropharyngeus (PHA) muscles. In addition, a chronic microdrive was positioned over the hypoglossal nucleus and secured to the cranium. Wires were brought to an Amphenol connector for subsequent attachment to the instrumentation. Intra-oral cannulas were also implanted for the delivery of gustatory stimuli. Rats were tested in a Plexiglass observation chamber. Unit activity was recorded in response to the delivery of a battery of gustatory stimuli. During an ingestion response, rhythmic bursts of unit activity were either in phase with the anterior digastric (protruder type activity) or out of phase with the AD and in phase with STY (retractor type activity). During rejection responses to QHCl, some neural responses showed a decrement, in contrast to the peripheral musculature.

SODIUM DEPRIVATION PRODUCES ALTERATIONS OF CHORDA TYMPANI TERMINAL FIELDS IN THE NUCLEUS OF THE SOLITARY TRACT IN ADULT RATS.
Camille Tessitore* and David L. Hill (SPON: P. Lasiter). University of Virginia, Charlottesville, VA.

Recordings from rat chorda tympani (CT) nerves have demonstrated that sodium deprivation on or before 8 days postconception and continued throughout development reliably produces a suppressed taste response to NaCl while taste responses to NH_4Cl and KCl are unaffected. In order to investigate whether the alteration of the peripheral response in the deprived rat is anatomically reflected in the first order synapse in the CNS, we examined terminal fields of the CT in Na deprived and Na replete animals. HRP was applied to cut nerves and the tissue was processed according to a modified TMB technique after 24 hour survival. Results indicate that while the fields of both control and deprived animals were located in the rostral pole of the NTS, control CT terminal fields were confined in a discrete ovoid configuration, while terminal fields of Na deprived animals were in a diffuse circular configuration. Preliminary results indicate that the total volume of terminal fields is increased in Na deprived animals as compared to controls. These findings indicate that the central projection areas of the gustatory system are sensitive to environmental manipulations. (Supported by NIH NS24741 & NS01215).

PARABRACHIAL NEURAL ACTIVITY DURING GUSTATORY STIMULATION IN AWAKE RATS. H. Nishijo* and R. Norgren Department of Behavioral Science, College of Medicine, The Pennsylvania State University, Hershey, PA 17033.

Rats were adapted to receiving water while in a plastic restrainer. Under anesthesia, cranioplastic acrylic was attached to their skulls and formed around 4 pins that were bolted to the stereotaxic earbars. Two intraoral catheters also were implanted. Ten days later the animals resumed a deprivation regimen in which they received their water while restrained and with their heads held securely by the acrylic cap. Single neurons were isolated in the dorsal pons with microelectrodes introduced via a previously prepared skull opening. Data were collected from 46 cells in two animals while they responded to standard sapid stimuli consisting of 0.05 ml of 0.1 M NaCl, 0.3 M sucrose, 0.003 or 0.01 M citric acid, and 0.0001 M quinine HCl, as well as to water. For a subsample of neurons, concentration response functions were generated for some (n=7) or all (n=9) of the sapid chemicals. When compared with equivolume infusions of distilled H_2O, 40 neurons responded differentially to one or more of the sapid stimuli. The remainder responded equivalently to both water and taste stimuli. Based upon their responses to the standard stimulus concentrations, the majority of neurons were most sensitive to NaCl (n=26) or to sucrose (n=9). Within these categories, 7 cells responded to a single sapid chemical (Na=4; S=3). Responses to citric acid and quinine were less frequent, sometimes confounded with apparent water responses, and except at highest concentrations, generally of lower amplitude. ORAL SENSORY RESPONSES IN THE NUCLEUS OF THE SOLITARY TRACT. S.P. Travers & R. Norgen. College of Dentistry, Ohio State University, Columbus, OH 43210 & College of Medicine, Pennsylvania State University, Hershey, PA 17033.

The rostral two-thirds of the nucleus of the solitary tract (NST) receives primary afferent terminations from at least 6 separate gustatory receptor subpopulations, as well as somatosensory structures in both the rostral and caudal oral cavity. Single-unit responses were recorded from an extensive area of NST to ascertain the organization of responses arising from all oral gustatory receptor subpopulations and from mechanical stimulation of oral structures. We recorded from 17 gustatory-and 14 mechanically-responsive NST neurons; it is unclear whether any gustatory cells responded to mechanical stimulation, but none of the mechanical neurons were gustatory-sensitive. Seven gustatory cells received information from a single gustatory receptor subpopulation, such as the foliate papillae, whereas 7 others were activated by stimulating multiple receptor groups; e.g., the soft palate and foliate papillae. The remaining taste cells were sensitive only to stimulation of the entire oral cavity. Similarly, some mechanosensitive neurons were activated only by stimulating a specific region on the tongue (e.g., the circumvallate) whereas others were sensitive to both lingual and palatal stimulation. There was an orotopic map of both gustatory and somatosensory responses, with the somatosensory representation lateral and/or caudal to the gustatory.

ANTERIOR TONGUE TASTE AND TACTILE PROJECTIONS TO NUCLEUS OF THE SOLITARY TRACT (NST) IN SHEEP FETUSES AND LAMBS. C. M. Mistretta. Univ. of Michigan, Ann Arbor, MI 48109.

To determine whether there is a functional microorganization for salt taste and tactile projections from fungiform papillae on the anterior tongue to second order neurons, and whether the organization changes during development, multiunit recordings were made in the NST of sheep. Six fetuses at 130 days of gestation (term = 147 days), six perinatal animals (5 days before or after birth), and six postnatal lambs (30 to 60 days) have been studied. With an initial location in the anterior tongue taste projection, neural activity was recorded at 0.2 mm steps throughout rostral-caudal and medial-lateral coordinates. Within each electrode track, responses were recorded at 0.1 mm steps. Stimuli were 0.25 and 0.50 M NH_4Cl, NaCl, and KCl, and light touch with a glass probe. At all ages there was a trend for NaCl to elicit larger responses, relative to NH_4Cl, at more rostral NST coordinates. However, a well defined chemotopy for salts was not observed. Responses from papillae on the tongue tip contributed proportionately more to the taste response at more rostral NST locations. Throughout the nucleus, responses to salts were recorded most dorsally, then responses to salts and touch, and then, most ventrally, responses to touch only. For tactile responses, the posterior tongue was represented most dorsally and the anterior tongue most ventrally. These data indicate some somatotopy for anterior tongue taste and tactile projections in NST that is established early in development, and the absence of any well defined chemotopy for salts. (Supported by NIH Grant NS 25825.)

473.7

TASTE RESPONSES IN THE PARABRACHIAL PONS OF OVARIECTOMIZED RATS. P.M. Di Lorenzo, S. Monroe* and J. Levine*. Dept. of Psychology, SUNY at Binghamton, Binghamton, N.Y. 13901.

Since the early 1970s it has been known that female rats prefer higher concentrations of sweet stimuli compared with males. Recent data from our lab (Di Lorenzo & Monroe, in preparation) have revealed that units in the parabrachial nucleus of the pons (PbN) of diestrus female rats showed larger responses to sweet stimuli compared with PbN units in males. Because it has been shown that ovariectomized rats have lowered preferences for saccharin compared with intact females, it is possible to predict that responses to sweet stimuli in the PbN of ovariectomized rats might be of lower magnitude compared with those in intact females. To investigate this latter hypothesis, electrophysiological responses to representatives of the 4 basic taste qualities were recorded in the PbN of ovariectomized rats. Gustatory stimuli included 3 concentrations of each of the following: NaCl, HCl, saccharin, sucrose and quinine. Preliminary analysis of 32 PbN units in ovariectomized rats showed that responses to sweet stimuli were of comparable magnitude to those in female rats. However, responses of PbN units to quinine appeared to be elevated in ovariectomized rats compared with male and female rats. Multidimensional scaling analyses of PbN unit responses to the stimuli constructed a "taste space" that closely resembled that constructed by similar analyses of PbN responses in males. These results suggest that decreased saccharin prefence in ovariectomized rats may reflect a greater sensitivity to the bitter components of the taste of saccharin. Moreover, these data provide evidence that taste responses in the PbN are influenced by both the activational and organizational actions of ovarian hormones. Further analyses will focus on this issue in greater detail.

473.8

MULTIMODAL CONVERGENCE WITHIN AND BEYOND THE SECONDARY TASTE CORTEX IN PRIMATES. L.L.Wiggins, E.T.Rolls and T.Chisholm*. Dept. of Exptl. Psychology, University of Oxford, England.

It has been found that there is a secondary cortical taste area in the caudolateral orbitofrontal cortex (clOFC) of the primate (Macaca fascicularis) (Rolls et al., 1985 Chem. Senses 10: 442). This area receives projections from the primary taste cortex in the frontal operculum and insula (Wiggins et al., 1987 Chem. Senses 12: 206). In this study we investigated whether the neurons in this area, and in the more medial caudal orbitofrontal cortex (OFC) which also contains taste responsive neurons (Thorpe et al., 1983 Exp. Brain Res. 49: 93), are multimodal, and receive visual and/or olfactory inputs as well as gustatory inputs. Of the neurons tested for multimodal inputs, some were found which responded to visual as well as to gustatory stimuli. The majority of these had corresponding sensitivities in the two modalities, in that they responded best to sweet tastes (e.g. 1M glucose), and responded more in a visual discrimination task to the visual stimulus which signified sweet fruit juice than to that which signified saline. In addition some neurons were found which responded to visual and to olfactory stimuli. These results show that there are regions in the orbitofrontal cortex where the sensory modalities of taste, vision, and olfaction converge; and that in the majority of cases the neurons have corresponding sensitivities across modalities.

473.9

MENTHOL ALTERS PERIPHERAL AND CENTRAL NEURAL CODING OF RAT LINGUAL TEMPERATURE SIGNALS. G.J. Schwartz* and E. Kosar (SPON.: B. Bryant) Monell Chemical Senses Center, 3500 Market Street, Philadelphia, PA 19104.

The rat tongue is sensitive to both thermal and chemical stimulation. Peripheral nerve studies have revealed that neural activity may be elicited by chemical and thermal stimuli in peripheral tongue temperature fibers. To elucidate the neural coding of these chemical and thermal signals, we examined both peripheral nerve fiber and cortical single unit responses to warm water (WW) (40°C), cold water (CW) (18°C), 0.02% Menthol (M), and 0.001% capsaicin (C). Electrolytic lesions were used to determine the cytoarchitectural and laminar position of cortical cells responding to thermal and chemical stimulation. Peripheral nerve recordings revealed two distinct groups of fiber types; Type I, restricted to chorda tympani nerve fibers, responded with increased activity to CW stimulation, yet spontaneous activity was not altered by WW, M or C. Type II, restricted to trigeminal lingual nerve fibers, responded to CW stimulation, but this CW excitation was dramatically and significantly reduced by prior exposure to menthol. In addition, some Type II fibers were inhibited by WW and unaffected by M or C alone. Two distinct classes of cortical neurons were identified which had response patterns similar to the two types of peripheral nerve fibers found. Thus it appears that the peripheral organization of some lingual thermal input is maintained at the level of the cortex. However, other patterns of cortical responses not observed in the periphery, were also identified, revealing more complex processing of oral thermal and chemical signals.

SINGLE UNIT ACTIVITY IN RAT GUSTATORY CORTEX. E. Kosar and G. J. Schwartz Monell Chemical Senses Center, 3500 Market Street, Philadelphia, PA 19104

Present knowledge about neural coding of taste information in gustatory cortex is very limited. The cytoarchitectural definition of this zone has been established only recently (Kosar et al. '86). To date only a restricted number of taste stimuli have been tested for their ability to evoke cortical activity in the rat. In order to determine whether distinct populations of gustatory neurons exist at the cortical level and to more clearly establish what stimulus features they encode, it is necessary to determine the effectiveness of a wider range of chemical stimuli. In these experiments, single unit activity was recorded in the agranular insular cortex of the rat in response to stimulation of the anterior oral cavity. The stimulus set included 24 different chemicals (plus additional concentrations of some of these stimuli), as well as warm water (40°C), cold water (18°C) and tactile stimulation. The purpose of these experiments was 1) to determine the range of sensitivities of each single cortical unit recorded, and 2) to ascertain whether adjacent cortical units share similar response properties as would be predicted by a modular or columnar pattern of organization. In general, cortical units tend to be broadly tuned, responding to several categories of chemical stimulation (for example, salts and acids). Adjacent cortical neurons can differ in their responsiveness to individual tastants. Some overlap in taste sensitivities is usually observed; the most effective stimulus for eliciting a response is often the same for adjacent neurons.

473.11

GUSTATORY RESPONSES OF SINGLE NEURONS TO AN EXTENDED STIMULUS ARRAY IN GUSTATORY CORTEX OF THE ALERT MACAQUE MONKEY. T.R. Scott, and V.L. Smith*, Dept. Psychology and Inst. Neurosci., Univ. Delaware, Newark, DE 19716.

Models of gustatory neural coding have been based primarily on recordings from the hindbrains of anesthetized rodents. Where these models fail to predict human psychophysical data, three levels of ambiguity must be addressed: species differences (rodent vs human), relevant neural level (hindbrain vs cortex) and anesthetic effects. We have developed the capacity to record from single gustatory neurons in the insular-opercular cortex of the alert macaque. We now report on the responses of 41 of these cells in two monkeys to a representative array of 16 salts, acids, sugars and alkaloids, all at moderate-high concentrations. The mean spontaneous rate was 5.4±4.4 s/s (range=0.5-25.5 s/s). Of 656 trials (16 stimuli x 41 neurons), 234 (36%) elicited excitation, 19 (3%) inhibition and 403 (61%) no response. The mean breadth-of-tuning coefficient was 0.80 (range=0.38-0.99). Correlations between pairs of stimulus profiles generally confirmed expected similarities ($r_{MgCl-CaCl}$=+0.95) and dissimilarities ($r_{gluc-NaCl}$=+0.29) of taste quality. There was no compelling evidence for the segregation of taste cells into functionally discrete classes. While compromises in the precision of stimulus application and recording stability must be made these data demonstrate the feasibility of obtaining reliable records from the alert monkey.

Supported by research grant BNS 8514202 from the NSF.

473.12

ACTIVITY OF GUSTATORY CORTEX IN THE HAMSTER STUDIED WITH VOLTAGE SENSITIVE DYES. J.A. London (SPON: M. McPheeters). Dept. Bio-Structure & Function, Univ. CT Health Ctr, Farmington, CT 06032.

Optical recording methods were used to detect hamster cortical activity in response to electrical stimulation (ES) of the anterior and posterior tongue. Following a craniotomy over the gustatory cortex, a fluorescent dye, RH795, (a gift from Drs. L.B. Cohen and A. Grinvald) which changes its fluorescence with changes in membrane potential, was externally applied to the cortex. Fluorescence changes were recorded by a photodiode array. Anterior tongue ES resulted in activation of a small, (900 x 900 u) discrete cortical area. Posterior tongue ES activated a separate, more caudally located cortical area. There was also a temporal difference; cortical activity latency following anterior tongue ES was 25-60 msec, as compared to a latency of 90-150 msec following posterior tongue ES. Surrounding brain areas were not activated by anterior or posterior tongue ES. Bilateral destruction of the chorda tympani eliminated cortical activity in response to anterior tongue ES but not to posterior tongue ES. In conclusion, it appears that a discrete area of the hamster cortex which responds to tongue ES has been identified with voltage sensitive dyes. This area is bounded ventrally by the rhinal fissure and bounded dorsally by the somatosensory cortex. This area can functionally be divided into two parts: an area activated by anterior tongue ES and an area activated by posterior tongue ES. These results suggest that information to the rostral cortical area is carried by the chorda tympani. Supported by NIH grant NS16993.

474.1

NORADRENERGIC MODULATION OF OLFACTORY BULB GLYCOGEN METABOLISM. R. Coopersmith and M. Leon. Dept. Psychobiology, Univ. California, Irvine CA 92717

The rat olfactory bulb has high levels of glycogen phosphorylase, the enzyme which mobilizes glucose from glycogen. In cortex, phosphorylase is activated by norepinephrine. We therefore examined the role of norepinephrine in the control of olfactory bulb glycogen breakdown.

Olfactory bulb slices were incubated with tritiated glucose, resulting in tritiated glycogen formation. Slices were then treated with test drug, homogenized, and glycogen was extracted and measured.

Norepinephrine induced a concentration-dependent breakdown of glycogen with an ED50 of approximately 300 pM. The published value of the ED50 for norepinephrine-induced glycogenolysis in cortical slices is three orders of magnitude higher, suggesting that the olfactory bulb is an extremely sensitive target tissue for this amine.

We will also present data concerning the adrenergic receptor sub-type(s) underlying this effect. In particular, we will test the hypothesis that the sensitivity of olfactory bulb phosphorylase to norepinephrine is the result of an alpha-receptor mediated potentiation of a beta-receptor mediated response.

474.2

HISTAMINE EFFECTS ON EEG AND EVOKED POTENTIALS IN THE RAT OLFACTORY BULB. B. K. Rhoades, P. B. Cook and W. J. Freeman III. Dept of Physiology & Anatomy, Univ. of Cal. at Berkeley, Berkeley, CA 94720.

Histochemical and electrophysiological evidence has established histamine as a neuromodulator in the CNS. Histaminergic fibers originating in the tuberomammillary nuclei of the hypothalamus travel in the medial forebrain bundles and radiate widely through the forebrain. The olfactory bulbs, as cortical structures whose cytoarchitecture and electrophysiology are well characterized, are logical targets for investigation of histaminergic action.

Rats were prepared for electrophysiological recording by pentobarbital anesthesia supplemented with analgesia at surgical and stereotaxic sites. The lateral bulbar surface, primary olfactory nerve (PON) fiber bundles of the olfactory mucosa, and the lateral olfactory tract (LOT) were unilaterally surgically exposed. The PON and LOT were stimulated via bipolar electrodes. EEG and evoked potentials (EPs) were recorded from a linear array of surface electrodes oriented dorso-ventrally on the lateral bulbar surface, while the EEG of the contralateral bulb was recorded via an electrode on its dorsal surface. EPs in response to PON and LOT stimulation were recorded for near threshold stimulus intensities and averaged over 50-100 trials. Histamine at .05-5mM in an artificial cerebrospinal fluid vehicle was administered locally to the bulbar surface in the vicinity of the recording array via a push-pull cannula system.

Following histamine application EEG of the treated bulb showed a marked increase in sinusoidal burst activity. Averaged PON EPs showed an attenuation of the damped sinusoidal component and a marked attenuation of the negative slow wave component. Averaged LOT EPs showed a marked decrease in damping and a slight decrease in oscillation frequency. These effects are similar to those previously observed on administration of mecholyl with prostigmine and may be attributed to a steady state increase in periglomerular cell activity. This would attenuate PON glomerular throughput, as well as tonically increasing the excitability of the mitral-tufted cells. Current research is focused on identification and localization of the relevant histamine receptor type(s) as well as elucidation of the ionic mechanisms involved.

EVIDENCE FOR GABA-MEDIATED INHIBITION IN THE SALAMANDER OLFACTORY BULB. K.A. HAMILTON, S.R. NEFF and J.S. KAUER. Neuroscience Program and Dept. of Neurosurgery, Tufts-New England Medical Center, Boston, MA 02111.

In the olfactory bulb, GABAergic interneurons, many of which are granule cells, exert powerful control over the excitability of mitral/tufted output cells. In response to electrical and odor stimulation, this control is manifest as feedback inhibition mediated through reciprocal dendro-dendritic synapses. As a first step toward understanding how odor responses are generated in the olfactory bulb, we have used a variety of techniques to examine how GABAergic, granule-layer cells might control mitral/tufted cell excitability in the salamander.

Intracellular recordings obtained from mitral/tufted cells in the salamander have shown that a prolonged biphasic IPSP, similar to that in the rabbit and turtle, follows electrical stimulation (Hamilton and Kauer, J. Neurophys. 59: 1988). Immunocytochemical staining has also provided evidence that granule-layer cells, as well as other interneurons, are GABAergic. The effects of these cells on mitral/tufted cell activity has also been assessed using GABA blockers during video-rate imaging of voltage-sensitive dye fluorescence (Kauer, Nature 331:166, 1988). We are now applying the combination of these methods to the analysis of how other components of the olfactory bulb circuits might contribute to the generation of responses elicited by odor and electrical stimulation. Supported by grants NS-22035, NS-20003 and the Dept. of Neurosurgery.

EARLY AND LATE RESPONSES IN SLICES OF SALAMANDER OLFACTORY BULB: OPTICAL RECORDING OF ELECTRICAL EVENTS THAT DEPEND UPON CA^{++}. A.R. Cinelli* and B.M. Salzberg. Univ. of Penn., Phila., PA 19104.

Fast and slow extrinsic optical signals have been reported in several olfactory bulb preparations. The former reflects the compound action potential, but the origin of the slow signal is less certain. Optical recordings (RH-155; 0.3 - 0.5 mg/ml) from tiger salamander slices exhibited similar depolarizing responses to orthodromic stimulation. Moderate stimuli often generated an additional long-latency optical signal.

The slow signal that followed stimulation of the glomerular layer was reduced in size by Cd^{++} (50-100 μM), and in the presence of low Ca^{++}, while replacement of Ca^{++} by Sr^{++} increased its size and duration. Neither the fast nor the slow optical signals observed at the level of the mitral cell and granular dendrites, were abolished by TTX (5 μM) or 0 $[Na^{+}]_o$. These observations, together with the results of experiments using GABA, Baclofen, and APV, suggest the presence of a longlasting excitation at mitral cell dendrites which depends upon Ca^{++}, and which gives rise to the slow optical signals.

HIGH RESOLUTION VIDEO IMAGING OF ODOR RESPONSES IN THE SALAMANDER OLFACTORY SYSTEM. J.S.KAUER and S.R. NEFF Neuroscience Program and Dept. of Neurosurgery. Tufts-New England Medical Center, Boston, MA. 02111.

Global events simultaneously occuring in neuronal elements that have been activated in parallel can be measured by video-rate imaging of voltage-sensitive dye fluorescence (Kauer, Nature, 1988). Using this method, patterns of electrically-elicited activation in the tiger salamander olfactory bulb have been observed. In the present study, we show an improvement in temporal resolution from 33 to better than 16 ms/video-frame and report an analysis of responses obtained after odor stimulation of the olfactory receptors. Stimulation with one-half second pulses of odor elicits widespread, temporal patterns of depolarization and hyperpolarization in different bulbar layers which are similar to those seen in the same layers using intracellular recording. The distribution of activity within the layers is distinctively different for different odors. These data provide additional evidence that odor information is encoded by patterns of activity distributed in time and space across the cells at each level of the olfactory pathway and have begun to allow a quantitative assessment of the stability of the patterns across animals. Initial experiments are in progress in which we have imaged activity in the olfactory receptor cell population after both odor and electrical stimulation.

NEUROBEHAVIORAL CORRELATES OF POSTNATAL OLFACTORY CONDITIONING: TEMPORAL CONSTRAINTS ON THE CS - UCS RELATIONSHIP. R.M. Sullivan, D.A. Wilson and M. Leon, Dept. Psychobiology, University of California at Irvine, 92717.

Acquisition of conditioned responding and learned odor preferences during olfactory classical conditioning in rat pups requires forward pairings of the conditioned stimulus (CS) and the unconditioned stimulus (UCS), i.e., the CS must precede and overlap temporally with the UCS [Sullivan & Hall, 1988]. Other temporal relationships between the CS and UCS do not result in learning. The present study was an examination of the influence of CS - UCS temporal relationship on the acquisition of modified olfactory bulb neural responses to the CS.

Wistar rat pups were trained (PN1 - PN18, 10 min/day) with either forward (odor and stroking) or backward (stroking then odor) CS-UCS pairings. On PN19, pups were tested for a behavioral odor preference to the CS, or for olfactory bulb ^{14}C 2-DG uptake or single-unit responses to the CS.

Only pups with forward CS-UCS pairings demonstrated modified behavioral and neural responses to the CS. Thus, these results suggest that, as for the behavioral responses, modified olfactory bulb neural responses are changes specific to associative learning. Formation of this neural association requires temporal constraints on the CS - UCS relationship. [Supported by NS26100 to RMS, BNS8606786 to DAW and ML, and MH00371 to ML]

MODIFICATION OF OLFACTORY BULB PHYSIOLOGY FOLLOWING EARLY OLFACTORY DEPRIVATION. K.M. Guthrie, D.A. Wilson and M. Leon, Dept. Psychobiology, Univ. California at Irvine 92717.

Olfactory deprivation during postnatal development results in profound structural and neurochemical modification of the olfactory bulb. The present report is a description of the neurophysiological effects of this olfactory deprivation.

Wistar rat pups had a single naris occluded at 2 days after birth. At postnatal day 20-22, animals were anesthetized, the occluded naris was reopened, and the previously opened naris was closed. The functioning of the primary output neurons of the deprived bulb, mitral/tufted cells, and of the major inhibitory interneurons, granule cells, was assayed using paired-pulse stimulation of the lateral olfactory tract. Paired-pulse stimulation provides a measure of granule cell-mediated inhibition of mitral cells. In addition, olfactory bulb responses to odor were assessed using both single-unit recording from mitral/tufted cells and ^{14}C 2-deoxyglucose autoradiography. Following neurophysiological recordings, olfactory bulbs were processed for tyrosine hydroxylase immunoreactivity, to ensure that the bulb had been deprived. Olfactory deprivation has been previously shown to reduce TH-IR in juxtaglomerular neurons.

The results suggest that although levels of granule cell-mediated inhibition appear immature after early deprivation, the deprived bulb is functionally capable of responding to odors.

SPATIAL PATTERNS OF MITRAL/TUFTED CELL RESPONSES TO ODORS INVESTIGATED WITH COMBINED SINGLE-UNIT, HRP AND ^{14}C-2-DG TECHNIQUES IN THE RAT. D.A. Wilson and M. Leon, Dept. Psychobiology, Univ. California at Irvine 92717.

Odor-specific spatial patterns of radiolabeled 2-DG uptake can be observed in the olfactory bulb glomerular layer. The present study attempted to correlate these spatial patterns of metabolic activity with activity of olfactory bulb output neurons, mitral/tufted (M/T) cells.

Extracellular single-unit recordings were made from M/T cells in regions typically associated with 2-DG uptake to peppermint odor. Responses to peppermint and isoamyl acetate at 2 different intensities were monitored. After the recording session, HRP (4% in 0.5M KCl) was iontophoresed from the recording pipette. The animal was allowed to recover 24 hr, and was then injected with ^{14}C-2-DG and exposed to peppermint odor for 45 min. Alternate sections of the olfactory bulb were processed for 2-DG autoradiography (20 um sections) or HRP histochemistry (60 um sections; Hanker-Yates or TMB histochemistry). Apical dendrites of M/T cells near the recording site were reconstructed into the glomerular layer and compared with regions of focal glomerular 2-DG uptake.

Preliminary evidence suggests that response characteristics of M/T cells vary with spatial location in the bulb. This spatial pattern of M/T cell responses appears to correspond with spatial patterns of glomerular layer 2-DG uptake. [Supported by BNS-8606786 to DAW and ML.]

CSD ANALYSIS OF OSCILLATORY RESPONSES IN RAT PIRIFORM CORTEX REVEALS STEREOTYPED CYCLICAL COMPONENTS MEDIATED BY AFFERENT AND INTRINSIC ASSOCIATION FIBERS. K.L.Ketchum* and L.B.Haberly. Dept. of Anatomy, Univ. of Wisconsin, Madison, WI 53706.

CSD analysis was performed on the posterior piriform (olfactory) cortex of urethane anaesthetized rats. The response to high strength lateral olfactory tract (LOT) shocks was similar to that observed in the opossum (Haberly, Chem. Senses 10:219). CSD analysis during period 1 (initial surface negative component) of the field potential evoked by high strength shocks revealed a sequence of inward membrane currents correlated in depth with afferent and intrinsic fiber systems. The first inward current (sink) occurred at the depth of afferent fiber terminals on the distal apical dendrites of superficial pyramidal cells (SP cells). Then, two successively deeper sinks appeared in layer Ib at the depths of the intrinsic association fiber terminals on the mid and proximal segments of SP cell apical dendrites. During this time, a small sink usually occurred in layer III at the depth of SP cell basal dendrites and deep cells.

Low strength shocks evoked damped oscillatory field potentials with a period of approximately 20ms, lasting 200-300ms. These oscillations superficially resemble those recorded in response to odor stimulation. CSD analysis of these responses to low strength shocks revealed a stereotyped sequence of events that recurred during each cycle of the oscillation. Within each cycle a sink occurred in layer Ia, followed by two successively deeper sinks in layer Ib. These sinks occurred at the same depths as in the high strength shock responses and with similar latency, but were of shorter duration. This result raises the possibility that a stereotyped sequence of synaptic events, evoked by afferent and intrinsic association fiber systems, occurs repetitively at approximately 50Hz during the oscillatory response to natural odor stimulation. Supported by NINCDS grants NS08328 to KLK and NS19865 to LBH.

INTEGRATION OF COMPUTER SIMULATIONS AND MULTIUNIT RECORDING IN THE RAT OLFACTORY SYSTEM U.S.Bhalla*, M.A.Wilson*, J.M.Bower. Division of Biology, Caltech, Pasadena CA 91125 (SPON. R. Sinsheimer)

For the last several years we have been developing a component-level model of piriform cortex based on electrophysiological and neuroanatomical data. The model replicates neural responses obtained from experimental manipulations (e.g. shock stimulation of the LOT). We are now exploring the capabilities of this network for learning and classification of olfactory stimuli. These studies require information concerning the representation of information at the level of the olfatory bulb. We are using recordings of multiple single neuron activities during behavioral tasks to provide data about network-level processing within the bulb, and about the form of the output to higher processing areas like the piriform cortex. To obtain this type of data we have implanted multiple glass-coated platinum-iridium electrodes in the olfactory bulb. We are also developing methods for implantation of multi-channel silicon electrodes developed in our lab (Nelson, Rasnow, Banik and Bower, Soc. Neurosci. Abs. this volume). This multi-cell data, in conjuction with structural simulations of the bulb and piriform cortex, is being used to make predictions about the network properties of these areas and to elucidate the processing tasks carried out by them. DEPENDENCE OF PARTITIONING BEHAVIOR OF AN ANATOMICAL MODEL OF PIRIFORM CORTEX ON PHYSIOLOGICAL VARIABLES. M.W.Jung*, G.Lynch, R.Granger* (SPON: Y.Torigoe). Center for the Neurobiology of Learning and Memory, Univ. of Calif., Irvine, CA. 92717.

Coherent aggregate behavior of a biological simulation of piriform (olfactory) cortex, based strictly on its macro- and microanatomical architecture, cell biophysics, physiology, and synaptic transmission and synaptic modification rules corresponds to unsupervised partitioning of simulated input cues into similarity-based clusters (Lynch and Granger, *Psych.Learn. & Motiv.*, 1988). Experimental manipulation of physiological features comprising the simulation identifies their effects on its partitioning behavior; the resulting predictions of values of these biological parameters are directly testable physiologically. Initial investigations (see, e.g., Granger et al., IEEE NIPS Proceedings, 1987) showed that formation of robust clusters depends on incremental potentiation step size in the range of 5% of distance between naive and potentated synaptic weights. In an experiment investigating the effects of varying this distance, the distance was set at values ranging from 25%–100% increase. The major effect was in the breadth of partitions that could be formed by the network: smaller weight distance led to broader clusters. Average angle ϕ between input cue vectors within a learned cluster measures the breadth of the cluster: smaller ϕ indicates that more similarity among cues was necessary for clustering. Average angle ϕ is a monotonically increasing function (within the range $0° - 90°$) of the ratio of potentiated to naive synaptic weights ω_2/ω_1. A related experiment investigated the effect of altering the relative efficacy of naive and potentiated synapses during learning episodes. Potentiated synapses do not contribute significantly more conductance then naive synapses when activated in the theta-burst mode necessary for inducing synaptic change; with this feature in the network, multiple categories are learned with little interference; otherwise, interference appears among learned categories due to 'attractor' effects of potentiated cells during learning of inputs in different categories from those cells. These and related experiments with this simulation have led to a deeper understanding of the direct relationships between biological variables and aggregate network behavior, and have permitted simplification of the network to tractable form, leading to theoretical analysis that has identified deep relations among physiological variables (Granger, Ambros-Ingerson and Lynch, 1988, in press).

CIRCUITRY AND SYNAPTIC MECHANISMS UNDERLYING SELECTIVE LONG-TERM POTENTIATION IN PYRIFORM CORTEX: A HYPOTHESIS. D. K. Patneau and J. S. Stripling. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Previous research in our laboratory has demonstrated a long-term potentiation (LTP) of the pyriform cortex (PC) potential evoked by olfactory bulb (OB) stimulation which is selective to late components of the evoked potential and appears to be functionally inhibitory (Soc. Neurosci. Abstr. 11: 780, 1985). This selective potentiation can be produced by repeated high-frequency stimulation of the OB or the association fiber system in the PC, but not by direct activation of the lateral olfactory tract, the major afferent pathway from the OB to the PC. This, and other evidence to be presented, strongly implicates the association fiber system in the PC as the pathway mediating selective LTP. Further evidence indicates that production of selective LTP requires the activation of NMDA receptors.

A model of the circuitry and synaptic mechanisms underlying selective LTP will be presented. Discussion will focus on the ability of the model to account for the characteristics of selective LTP as documented by research in our laboratory and the potential involvement of this form of plasticity in information processing in the olfactory forebrain.

474.13

ROLE OF ASSOCIATION FIBERS IN SELECTIVE LONG-TERM POTENTIATION IN THE PYRIFORM CORTEX. J. S. Stripling and D. K. Patneau. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Electrical stimulation of the olfactory bulb (OB) or lateral olfactory tract (LOT) elicits an evoked potential in the pyriform cortex (PC) whose initial wave (period 1) reflects activation of PC pyramidal cells via the LOT and subsequent excitation within the PC. This is followed by period 2, which is associated with inhibition of PC pyramidal cells. Repeated high-frequency stimulation of the OB produces a selective long-term potentiation (LTP) of period 2 (Brain Research 441: 281-291, 1988), while stimulation restricted to the LOT does not (Soc. Neurosci. Abstr. 12: 508, 1986).

In the present experiment male Long-Evans rats with chronically implanted electrodes received repeated high-frequency stimulation of either the LOT, layer Ib, or layer III of the PC. Stimulation of either layer Ib or layer III produced a selective LTP of period 2 in the PC similar to that produced by OB stimulation in previous studies. Stimulation of the LOT produced minimal effects. These results suggest that activation of the association fiber system which runs in layers Ib and III of the PC is critical for the production of LTP. An accompanying presentation (Patneau and Stripling) will present a model of LTP in the PC which incorporates these findings. (Supported by NSF Grant BNS 85-19700.)

Symposium. FORM AND SYNAPTIC FUNCTION IN RETINAL GANGLION CELLS. E.V. Famiglietti, University of Calgary (Chairperson); R.W. Rodieck, University of Washington (Co-chairperson); J.I. Simpson, New York University; H. Wässle*, Max Planck Institute (Frankfurt); N.W. Daw, Washington University.

Recent advances in anatomical, physiological and pharmacological techniques have converged in the study of retinal ganglion cells (GCs). As a result, strong hypotheses have emerged concerning the neural circuitry underlying well defined physiological responses. Some investigations have included "identified" GCs with input to well-studied visual centers of the brain. The intent of this symposium is to focus on recent work in mammals, bringing together evidence on functional circuits obtained via several different approaches. Bob Rodieck will describe the relationship between dendritic form and central projections in intracellularly stained cat and monkey GCs. Jerry Simpson will explain the functional role of directionally selective (DS) information in the accessory optic system, innervated by morphologically and physiologically identified rabbit GCs. Ted Famiglietti will describe ultrastructural studies on the organization of synaptic inputs to identified DS GCs in rabbit. Heinz Wässle will present structural and pharmacological evidence on control of the rod pathway to GCs in cat, and Nigel Daw will outline the effects of 4 major groups of neurotransmitters upon physiological properties of rabbit GCs, and the neural circuits involved.

SYMPOSIUM. NEUROPEPTIDES, STEROIDS AND BEHAVIOR. G.F. Koob, Scripps Clinic (Chairperson); L.W. Swanson, Salk Inst.; P.M. Plotsky, Salk Inst.; D.W. Pfaff, Rockefeller Univ.; A.N. Epstein, Univ. of Pennsylvania.

This symposium will discuss neuropeptides, steroids and their interactions in functions of the CNS. We will address roles of brain neuropeptides in mediating steroid effects, and mechanisms for steroids to alter brain functions, including behavior. Specific presentations will include CRF, LHRH and preproenkephalin as they control pituitary function and extra-hypothalamic circuits.

ENDOCRINE CONTROL AND DEVELOPMENT IV

478.1

ORGANIZATION OF ARGININE VASOPRESSIN AND OXYTOCIN CELLS AND FIBERS IN THE HYPOTHALAMUS AND ANTERIOR PITUITARY OF THE FETAL SHEEP LATE IN GESTATION. G.E. Hoffman, T. McDonald, J.P. Figueroa and P.W. Nathanielsz, Department of Physiology, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261 and Lab. for Preg. and Newborn Res., Cornell Univ., NYS Coll. of Vet. Med., Ithaca, NY 14853.

Arginine vasopressin (AVP) and oxytocin (OXY) participate along with corticotropin releasing factor (CRF) in the hypothalamic-pituitary-adrenal axis. In the fetal sheep, adrenal stimulation can induce premature delivery and adrenal activity increases after 130 days gestation (d GA). This suggests that changes in the adrenal axis during the latter part of gestation dictate the onset of parturition. The aim of the present study was to examine the organization of vasopressin and oxytocin-immunoreactive structures in the fetal sheep hypothalamus at this critical period.

Six Rambouillet-Columbia sheep fetuses, delivered by cesarian section under Bio-Tal anesthesia at 134 to 145 d GA., were perfused with Zamboni's fixative and their brains processed for localization of AVP, OXY, or neurophysin (NP) using the ABC method. AVP and OXY within the magnocellular hypothalamic nuclei and the hypothalamo-neurohypophyseal tract were well developed. There were fewer OXY cells than AVP neurons and they were often segregated. Projections from the PVN joined the fibers from the SON and accessory nuclei in the hypothalamo-neurohypophyseal tract to the median eminence and posterior pituitary. AVP and OXY fibers of the internal zone of the median eminence continued into the neural lobe of the posterior pituitary. The median eminence contact zone contained a dense plexus of AVP axons and scattered OXY axons. Some AVP and OXY fibers extended into the pars tuberalis. A few AVP fibers could be further traced into the pars distalis, where they appeared to terminate in association with ACTH cells. Within the pituitary stalk, scattered AVP and OXY axons extended into the intermediate lobe. The roles of adenohypophyseal AVP and OXY are uncertain, but these axons within the adenohypophysis may provide an alternative or synergistic mechanism in the control of ACTH secretion apart from the neural-hemal route. Supported by NIH Grants RO-1 HD 18418, PO-1 HD 21350 and RO-1 AM 16166.

478.2

ORGANIZATION OF CORTICOTROPIN RELEASING FACTOR CELLS AND FIBERS IN THE HYPOTHALAMUS OF THE FETAL SHEEP LATE IN GESTATION. P.W. Nathanielsz*, T. McDonald*, J.P. Figueroa* and G.E. Hoffman (SPON: A. Humphrey). Laboratory for Pregancy and Newborn Res., Cornell Univ., N.Y. State Coll. of Vet. Med., Ithaca, NY 14853 and Department of Physiology, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

Corticotropin releasing factor (CRF) is present in fetal sheep neurons as early as 90 days gestation (d GA) and projections to the external zone of the median eminence are dense by 132 d GA (Levidiotis et al, Neuroendocrinology 46: 453, 1987). Activity of the adrenal axis shows dramatic changes after 130 d GA, suggesting that further maturation of the CRF system takes place. The aim of the present study was to examine the organization of corticotropin releasing factor (CRF) immunoreactive structures in the fetal sheep hypothalamus at this critical period of development.
