SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 14, PART 2

18TH ANNUAL MEETING
TORONTO, ONTARIO
NOVEMBER 13-18, 1988

Made in the United States of America
International Standard Book Numbers
Part 1 ISBN 0-916110-29-X
Part 2 ISBN 0-916110-30-3
Both parts ISSN 0190-5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 14, Part 2 p. xxx, 1988.

Published by
Society for Neuroscience
11 Dupont Circle, N.W., Suite 500
Washington, D.C. 20036

CONTENTS—PART 2

*7,809 volunteer abstracts, 18 symposium and workshop abstracts.

1988 PROGRAM COMMITTEE

Richard P. Bunge, M.D., *Chairperson*
Washington University School of Medicine

David P. Corey, Ph.D., *Incoming Chairperson*
Massachusetts General Hospital

Richard W. Aldrich, Ph.D.
Stanford University Medical School

Theodore W. Berger, Ph.D.
University of Pittsburgh

Suzanne H. Corkin, Ph.D.
Massachusetts Institute of Technology

William C. deGroat, Ph.D.
University of Pittsburgh Medical School

Robert P. Elde, Ph.D.
University of Minnesota

Howard L. Fields, M.D., Ph.D.
University of California Medical School,
San Francisco

Eric Frank, Ph.D.
University of Pittsburgh Medical School

John P. Horn, Ph.D.
University of Pittsburgh Medical School

Edward G. Jones, M.D., Ph.D.
University of California College of Medicine

Robert L. MacDonald, M.D., Ph.D.
University of Michigan

Marek-Marsel Mesulam, M.D.
Beth Israel Hospital, Boston

J. Anthony Movshon, Ph.D.
New York University

Louis F. Reichardt, Ph.D.
Howard Hughes Medical Center
University of California

David L. Sparks, Ph.D.
University of Alabama

Felix Strumwasser, Ph.D.
Marine Biological Laboratory

Wylie W. Vale, Ph.D.
The Salk Institute

Stanley J. Watson, Jr., M.D., Ph.D.
University of Michigan School of Medicine

Roy A. Wise, Ph.D.
Concordia University

Barry B. Wolfe, Ph.D.
University of Pennsylvania School of Medicine

Albert J. Aguayo, M.D., *ex officio*
Montreal General Hospital

David H. Hubel, M.D., *ex officio*
Harvard Medical School

Joe Dan Coulter, Ph.D., *ex officio*
University of Iowa College of Medicine

CHRONOLOGICAL LIST OF SESSIONS

(see page xii for Thematic List of Sessions)

TUESDAY

THURSDAY

Thematic List of Sessions

(Includes slide and poster sessions, symposia, and workshops only.)

Theme A: Development and Plasticity

Session Number	Session Title	Type	Day and Time
509.	Aging: physiology	Poster	Fri AM
167.	Biochemical and pharmacological correlates of development I	Poster	Tue AM
258.	Biochemical and pharmacological correlates of development II	Poster	Wed AM
518.	Biochemical and pharmacological correlates of development III	Poster	Fri AM
132.	Cell lineage and determination I	Slide	Tue AM
359.	Cell lineage and determination II	Slide	Thu AM
453.	Cell lineage and determination III	Poster	Thu PM
416.	**Development of Functional Heterogeneity Among Sensory Neurons**	**Symp.**	**Thu PM**
39.	Differentiation and development I	Poster	Mon AM
69.	Differentiation and development II	Slide	Mon PM
171.	Differentiation and development III	Poster	Tue AM
291.	Differentiation and development IV	Poster	Wed AM
311.	Differentiation and development V	Slide	Wed PM
407.	Differentiation and development VI	Poster	Thu AM
414.	Differentiation and development VII	Poster	Thu AM
483.	Differentiation and development VIII	Slide	Fri AM
510.	Differentiation and development IX	Poster	Fri AM
112.	Endocrine control and development I	Poster	Mon PM
113.	Endocrine control and development II	Poster	Mon PM
282.	Endocrine control and development III	Poster	Wed AM
478.	Endocrine control and development IV	Slide	Fri AM
354.	Limbic system I	Poster	Wed PM
401.	Motor systems I	Poster	Thu AM
458.	Motor systems II	Poster	Thu PM
12.	Neural plasticity in adult animals: LTP I	Slide	Mon AM
225.	Neural plasticity in adult animals: LTP II	Poster	Tue PM
454.	Neural plasticity in adult animals: anatomy and behavior	Poster	Thu PM
245.	Neural plasticity in adult animals: central	Slide	Wed AM
338.	Neural plasticity in adult animals: cerebral cortex	Poster	Wed PM
197.	Neural plasticity in adult animals: induced effects I	Poster	Tue PM
334.	Neural plasticity in adult animals: induced effects II	Poster	Wed PM
277.	Neural plasticity in adult animals: neuromuscular and autonomic	Poster	Wed AM
487.	Neural plasticity in adult animals: peripheral	Slide	Fri AM
150.	Neuronal death I	Poster	Tue AM
449.	Neuronal death II	Poster	Thu PM
290.	Neurotoxicity in development I	Poster	Wed AM
352.	Neurotoxicity in development II	Poster	Wed PM
507.	Neurotoxicity: studies in tissue culture	Poster	Fri AM
122.	**New Approaches to the Functional Development of the Neocortex**	**Wksh.**	**Tue AM**
235.	Nutritional and perinatal factors in development	Poster	Tue PM
108.	Process outgrowth, growth cones, and guidance mechanisms I	Poster	Mon PM
184.	Process outgrowth, growth cones, and guidance mechanisms II	Slide	Tue PM
231.	Process outgrowth, growth cones, and guidance mechanisms III	Poster	Tue PM
240.	Process outgrowth, growth cones, and guidance mechanisms IV	Slide	Wed AM
300.	Process outgrowth, growth cones, and guidance mechanisms V	Slide	Wed PM
346.	Process outgrowth, growth cones, and guidance mechanisms VI	Poster	Wed PM

Theme B: Cell Biology

372.	Membrane composition and cell surface macromolecules I	Slide	Thu AM
406.	Membrane composition and cell surface macromolecules II	Poster	Thu AM
508.	Membrane composition and cell surface macromolecules III	Poster	Fri AM
11.	Messenger RNA regulation I	Slide	Mon AM
302.	Messenger RNA regulation II	Slide	Wed PM
350.	Messenger RNA regulation III	Poster	Wed PM
463.	Messenger RNA regulation IV	Poster	Thu PM
529.	Messenger RNA regulation V	Poster	Fri AM
62.	**Molecular Biological Approaches to Study Neuropeptide Biosynthesis**	**Symp.**	**Mon PM**
173.	Neuroglia: biology of astrocytes I	Poster	Tue AM
425.	Neuroglia: biology of astrocytes II	Slide	Thu PM
317.	Neuroglia: myelin forming cells	Poster	Wed PM
48.	Neuroglia: myelin mutants	Poster	Mon AM
219.	Staining and tracing techniques I	Poster	Tue PM
220.	Staining and tracing techniques II	Poster	Tue PM

Theme C: Excitable Membranes and Synaptic Transmission

Session Number	Session Title	Type	Day and Time
121.	**At Last! Potassium Channels: Expression and Regulation**	**Symp.**	**Tue AM**
54.	Ion channels: calcium channels I	Poster	Mon AM
55.	Ion channels: calcium channels II	Poster	Mon AM
56.	Ion channels: calcium channels III	Poster	Mon AM
363.	Ion channels: calcium channels IV	Slide	Thu AM
117.	Ion channels: cell function I	Poster	Mon PM
118.	Ion channels: cell function II	Poster	Mon PM
261.	Ion channels: chloride and other	Poster	Wed AM
260.	Ion channels: ligand-gated I	Poster	Wed AM
419.	Ion channels: ligand-gated II	Slide	Thu PM
57.	Ion channels: modulation and regulation I	Poster	Mon AM
64.	Ion channels: modulation and regulation II	Slide	Mon PM
262.	Ion channels: modulation and regulation III	Poster	Wed AM
303.	Ion channels: modulation and regulation IV	Slide	Wed PM
438.	Ion channels: modulation and regulation V	Poster	Thu PM
484.	Ion channels: potassium, chloride and other	Slide	Fri AM
241.	Ion channels: sodium channels I	Slide	Wed AM
335.	Ion channels: sodium channels II	Poster	Wed PM
358.	**Non-Uniformity of Synaptic Physiology and Implications for Plasticity in the Nervous System**	**Wksh.**	**Thu AM**
207.	Pharmacology of synaptic transmission I	Poster	Tue PM
325.	Pharmacology of synaptic transmission II	Poster	Wed PM
110.	Postsynaptic mechanisms I	Poster	Mon PM
111.	Postsynaptic mechanisms II	Poster	Mon PM
369.	Postsynaptic mechanisms III	Slide	Thu AM
186.	Potassium channels I	Slide	Tue PM
382.	Potassium channels II	Poster	Thu AM
439.	Presynaptic mechanisms I	Poster	Thu PM
486.	Presynaptic mechanisms II	Slide	Fri AM
31.	Presynaptic mechanisms: ions	Poster	Mon AM
440.	Presynaptic mechanisms: modulators	Poster	Thu PM
30.	Presynaptic mechanisms: toxins	Poster	Mon AM
44.	Synaptic structure and function I	Poster	Mon AM
252.	Synaptic structure and function II	Slide	Wed AM

Theme D: Neurotransmitters, Modulators, and Receptors

Session Number	Session Title	Type	Day and Time
432.	Acetylcholine	Poster	Thu PM
257.	Acetylcholine: basal forebrain and brainstem	Poster	Wed AM
530.	Acetylcholine: receptors and choline uptake	Poster	Fri AM
523.	Adrenergic receptor modulation and regulation	Poster	Fri AM
166.	Adrenergic receptors I	Poster	Tue AM
374.	Adrenergic receptors II	Poster	Thu AM
63.	**Afferent Regulation of the Locus Coeruleus**	**Wksh.**	**Mon PM**
71.	Amino acids: GABA and benzodiazepines I	Slide	Mon PM
143.	Amino acids: GABA and benzodiazepines II	Poster	Tue AM
144.	Amino acids: GABA and benzodiazepines III	Poster	Tue AM
183.	Amino acids: GABA and benzodiazepines IV	Slide	Tue PM
326.	Amino acids: GABA and benzodiazepines V	Poster	Wed PM
393.	Amino acids: GABA and benzodiazepines VI	Poster	Thu AM
125.	Behavioral pharmacology	Slide	Tue AM
455.	Behavioral pharmacology: acetylcholine	Poster	Thu PM
340.	Behavioral pharmacology: dopamine	Poster	Wed PM
506.	Behavioral pharmacology: miscellaneous	Poster	Fri AM
404.	Behavioral pharmacology: monoamines	Poster	Thu AM
91.	Behavioral pharmacology: psychostimulants	Poster	Mon PM
16.	Catecholamines I	Slide	Mon AM
163.	Catecholamines II	Poster	Tue AM
293.	Catecholamines III	Poster	Wed AM
376.	Catecholamines IV	Poster	Thu AM
433.	Catecholamines V	Poster	Thu PM
490.	Catecholamines VI	Poster	Fri AM
164.	Catecholamines: electrophysiology I	Poster	Tue AM
377.	Catecholamines: electrophysiology II	Poster	Thu AM
294.	Catecholamines: *in vivo* measurements	Poster	Wed AM
242.	Characterization of cholinergic receptors	Slide	Wed AM
94.	Characterization of muscarinic receptors I	Poster	Mon PM
435.	Characterization of muscarinic receptors II	Poster	Thu PM
95.	Characterization of nicotinic receptors	Poster	Mon PM
107.	Cholinergic receptor modulation and regulation	Poster	Mon PM
375.	Dopamine receptor modulation and regulation	Poster	Thu AM
165.	Dopamine receptors I	Poster	Tue AM
185.	Dopamine receptors II	Slide	Tue PM
378.	Dopamine receptors III	Poster	Thu AM
434.	Dopamine receptors IV	Poster	Thu PM
40.	Excitatory amino acids I	Poster	Mon AM
97.	Excitatory amino acids II	Poster	Mon PM
98.	Excitatory amino acids III	Poster	Mon PM
198.	Excitatory amino acids IV	Poster	Tue PM
199.	Excitatory amino acids V	Poster	Tue PM
318.	Excitatory amino acids VI	Poster	Wed PM
380.	Excitatory amino acids VII	Poster	Thu AM
381.	Excitatory amino acids VIII	Poster	Thu AM
421.	Excitatory amino acids IX	Slide	Thu PM
480.	Excitatory amino acids X	Slide	Fri AM
168.	Excitatory amino acids: excitotoxicity I	Poster	Tue AM
169.	Excitatory amino acids: excitotoxicity II	Poster	Tue AM
299.	Excitatory amino acids: excitotoxicity III	Slide	Wed PM
46.	Interactions between neurotransmitters I	Poster	Mon AM
348.	Interactions between neurotransmitters II	Poster	Wed PM
489.	Interactions between neurotransmitters III	Slide	Fri AM
2.	**Interleukin-1: Immune and Neural Modulator**	**Symp.**	**Mon AM**
182.	**Neuronal Gene Expression: Physiological Activation, Transcriptional Control and DNA Binding Proteins**	**Symp.**	**Tue PM**
218.	Opiates, endorphins and enkephalins: anatomy and chemistry I	Poster	Tue PM
280.	Opiates, endorphins and enkephalins: anatomy and chemistry II	Poster	Wed AM

18.	Opiates, endorphins and enkephalins: physiological effects I	Poster	Mon AM
162.	Opiates, endorphins and enkephalins: physiological effects II	Poster	Tue AM
191.	Opiates, endorphins and enkephalins: physiological effects III	Slide	Tue PM
461.	Opiates, endorphins and enkephalins: physiological effects IV	Poster	Thu PM
146.	Peptides: anatomical localization I	Poster	Tue AM
271.	Peptides: anatomical localization II	Poster	Wed AM
395.	Peptides: anatomical localization III	Poster	Thu AM
13.	Peptides: biosynthesis, metabolism and biochemical characterization I	Slide	Mon AM
161.	Peptides: biosynthesis, metabolism and biochemical characterization II	Poster	Tue AM
349.	Peptides: biosynthesis, metabolism and biochemical characterization III	Poster	Wed PM
462.	Peptides: biosynthesis, metabolism and biochemical characterization IV	Poster	Thu PM
58.	Peptides: physiological effects I	Poster	Mon AM
59.	Peptides: physiological effects II	Poster	Mon AM
60.	Peptides: physiological effects III	Poster	Mon AM
370.	Peptides: physiological effects IV	Slide	Thu AM
10.	Peptides: receptors I	Slide	Mon AM
145.	Peptides: receptors II	Poster	Tue AM
270.	Peptides: receptors III	Poster	Wed AM
394.	Peptides: receptors IV	Poster	Thu AM
45.	Receptor modulation and regulation I	Poster	Mon AM
229.	Receptor modulation and regulation II	Poster	Tue PM
423.	Receptor modulation and regulation III	Slide	Thu PM
43.	Regional localization of receptors and transmitters I	Poster	Mon AM
73.	Regional localization of receptors and transmitters II	Slide	Mon PM
314.	Regional localization of receptors and transmitters III	Poster	Wed PM
315.	Regional localization of receptors and transmitters IV	Poster	Wed PM
35.	Second messengers I	Poster	Mon AM
36.	Second messengers II	Poster	Mon AM
37.	Second messengers III	Poster	Mon AM
52.	Second messengers IV	Poster	Mon AM
53.	Second messengers V	Poster	Mon AM
175.	Second messengers VI	Poster	Tue AM
485.	Second messengers VII	Slide	Fri AM
129.	Serotonin receptors I	Slide	Tue AM
247.	Serotonin receptors II	Slide	Wed AM
15.	Serotonin, histamine and other biogenic amines I	Slide	Mon AM
88.	Serotonin, histamine and other biogenic amines II	Poster	Mon PM
89.	Serotonin, histamine and other biogenic amines III	Poster	Mon PM
221.	Serotonin, histamine and other biogenic amines IV	Poster	Tue PM
222.	Serotonin, histamine and other biogenic amines V	Poster	Tue PM
339.	Serotonin, histamine and other biogenic amines VI	Poster	Wed PM
99.	Transmitter uptake, storage, secretion and metabolism I	Poster	Mon PM
275.	Transmitter uptake, storage, secretion and metabolism II	Poster	Wed AM
479.	Transmitter uptake, storage, secretion and metabolism III	Slide	Fri AM
17.	Transmitters in invertebrates I	Slide	Mon AM
155.	Transmitters in invertebrates II	Poster	Tue AM
216.	Transmitters in invertebrates III	Poster	Tue PM
76.	Transmitters in invertebrates: gastropods	Slide	Mon PM
365.	Transmitters: acetylcholine	Slide	Thu AM

Theme E: Endocrine and Autonomic Regulation

Session Number	Session Title	Type	Day and Time
14.	Cardiovascular regulation I	Slide	Mon AM
82.	Cardiovascular regulation II	Poster	Mon PM
136.	Cardiovascular regulation III	Slide	Tue AM
206.	Cardiovascular regulation IV	Poster	Tue PM

250.	Cardiovascular regulation V	Slide	Wed AM
391.	Cardiovascular regulation VI	Poster	Thu AM
392.	Cardiovascular regulation VII	Poster	Thu AM
422.	Hypothalamic-pituitary-adrenal regulation I	Slide	Thu PM
514.	Hypothalamic-pituitary-adrenal regulation II	Poster	Fri AM
515.	Hypothalamic-pituitary-adrenal regulation III	Poster	Fri AM
176.	Hypothalamic-pituitary-gonadal regulation I	Poster	Tue AM
177.	Hypothalamic-pituitary-gonadal regulation II	Poster	Tue AM
431.	Hypothalamic-pituitary-gonadal regulation III	Slide	Thu PM
528.	Neural control of adrenal function	Poster	Fri AM
93.	Neural control of immune system I	Poster	Mon PM
304.	Neural control of immune system II	Slide	Wed PM
512.	Neural control of immune system III	Poster	Fri AM
513.	Neural control of immune system IV	Poster	Fri AM
209.	Neuroendocrine controls: other I	Poster	Tue PM
426.	Neuroendocrine controls: other II	Slide	Thu PM
469.	Neuroendocrine controls: other III	Poster	Thu PM
33.	Neuroendocrine controls: pituitary I	Poster	Mon AM
126.	Neuroendocrine controls: pituitary II	Slide	Tue AM
256.	Neuroendocrine controls: pituitary III	Poster	Wed AM
130.	Regulation of autonomic function I	Slide	Tue AM
217.	Regulation of autonomic function II	Poster	Tue PM
527.	Regulation of autonomic function III	Poster	Fri AM
189.	Respiratory regulation I	Slide	Tue PM
255.	Respiratory regulation II	Poster	Wed AM
379.	Respiratory regulation III	Poster	Thu AM
297.	**Specificity in the Control of Regional Sympathetic Outflow: Physiological, Neurochemical and Anatomical Approaches**	**Symp.**	**Wed PM**

Theme F: Sensory Systems

Session Number	Session Title	Type	Day and Time
473.	Chemical senses: gustatory pathways	Poster	Thu PM
474.	Chemical senses: olfactory pathways	Poster	Thu PM
428.	Chemical senses: peripheral mechanisms I	Slide	Thu PM
466.	Chemical senses: peripheral mechanisms II	Poster	Thu PM
296.	**Coding of Visual Signals at the Photoreceptor Synapse**	**Wksh.**	**Wed PM**
476.	**Form and Synaptic Function in Retinal Ganglion Cells**	**Symp.**	**Fri AM**
3.	**Functional Properties of Somatic Sensory "Barrel Field" Cortex**	**Wksh.**	**Mon AM**
153.	Invertebrate sensory systems I	Poster	Tue AM
154.	Invertebrate sensory systems II	Poster	Tue AM
341.	Pain modulation: biogenic amines	Poster	Wed PM
75.	Pain modulation: central pathways I	Slide	Mon PM
342.	Pain modulation: central pathways II	Poster	Wed PM
284.	Pain modulation: opioid mechanisms	Poster	Wed AM
134.	Pain modulation: pharmacology	Slide	Tue AM
283.	Pain modulation: stress and sensory stimulation	Poster	Wed AM
368.	Pain pathways	Slide	Thu AM
49.	Pain pathways: central mechanisms	Poster	Mon AM
224.	Pain pathways: inflammation, sensitization and hyperalgesia	Poster	Tue PM
223.	Pain pathways: long-term changes	Poster	Tue PM
464.	Pain pathways: trigeminal system	Poster	Thu PM
19.	Retina I	Poster	Mon AM
68.	Retina II	Slide	Mon PM
147.	Retina III	Poster	Tue AM
244.	Retina IV	Slide	Wed AM
396.	Retina V	Poster	Thu AM
450.	Retina VI	Poster	Thu PM
133.	Sensory systems: auditory systems I	Slide	Tue AM
200.	Sensory systems: auditory systems II	Poster	Tue PM
201.	Sensory systems: auditory systems III	Poster	Tue PM

263.	Sensory systems: auditory systems IV	Poster	Wed AM
264.	Sensory systems: auditory systems V	Poster	Wed AM
321.	Sensory systems: auditory systems VI	Poster	Wed PM
441.	Sensory systems: auditory systems VII	Poster	Thu PM
442.	Sensory systems: auditory systems VIII	Poster	Thu PM
289.	Somatic and visceral afferents	Poster	Wed AM
159.	Somatic and visceral afferents: dorsal root ganglion cells	Poster	Tue AM
285.	Somatic and visceral afferents: somesthetic afferents	Poster	Wed AM
92.	Somatosensory cortex I	Poster	Mon PM
286.	Somatosensory cortex II	Poster	Wed AM
306.	Somatosensory cortex III	Slide	Wed PM
279.	Spinal cord	Poster	Wed AM
50.	Subcortical somatosensory pathways: brainstem and thalamus	Poster	Mon AM
465.	Subcortical somatosensory pathways: trigeminal system	Poster	Thu PM
20.	Subcortical visual pathways I	Poster	Mon AM
127.	Subcortical visual pathways II	Slide	Tue AM
333.	Subcortical visual pathways III	Poster	Wed PM
397.	Subcortical visual pathways IV	Poster	Thu AM
8.	Visual cortex I	Slide	Mon AM
85.	Visual cortex II	Poster	Mon PM
187.	Visual cortex III	Slide	Tue PM
243.	Visual cortex IV	Slide	Wed AM
362.	Visual cortex V	Slide	Thu AM
451.	Visual cortex VI	Poster	Thu PM
502.	Visual cortex VII	Poster	Fri AM

Theme G: Motor Systems and Sensorimotor Integration

Session Number	Session Title	Type	Day and Time
34.	Basal ganglia and thalamus: motor systems I	Poster	Mon AM
66.	Basal ganglia and thalamus: motor systems II	Slide	Mon PM
287.	Basal ganglia and thalamus: motor systems III	Poster	Wed AM
408.	Basal ganglia and thalamus: motor systems IV	Poster	Thu AM
409.	Basal ganglia and thalamus: motor systems V	Poster	Thu AM
430.	Basal ganglia and thalamus: motor systems VI	Slide	Thu PM
417.	**Coding and Execution of Movement in Three Dimensions**	**Symp.**	**Thu PM**
400.	Invertebrate motor function	Poster	Thu AM
202.	Motor systems and sensorimotor integration: cerebellum I	Poster	Tue PM
305.	Motor systems and sensorimotor integration: cerebellum II	Slide	Wed PM
497.	Motor systems and sensorimotor integration: cerebellum III	Poster	Fri AM
9.	Motor systems and sensorimotor integration: circuitry and pattern generation I	Slide	Mon AM
104.	Motor systems and sensorimotor integration: circuitry and pattern generation II	Poster	Mon PM
67.	Motor systems and sensorimotor integration: cortex I	Slide	Mon PM
142.	Motor systems and sensorimotor integration: cortex II	Poster	Tue AM
208.	Motor systems and sensorimotor integration: cortex III	Poster	Tue PM
274.	Motor systems and sensorimotor integration: cortex IV	Poster	Wed AM
329.	Motor systems and sensorimotor integration: cortex V	Poster	Wed PM
248.	Motor systems and sensorimotor integration: oculomotor system I	Slide	Wed AM
320.	Motor systems and sensorimotor integration: oculomotor system II	Poster	Wed PM
386.	Motor systems and sensorimotor integration: oculomotor system III	Poster	Thu AM
387.	Motor systems and sensorimotor integration: oculomotor system IV	Poster	Thu AM
28.	Motor systems and sensorimotor integration: posture and movement I	Poster	Mon AM
29.	Motor systems and sensorimotor integration: posture and movement II	Poster	Mon AM

105.	Motor systems and sensorimotor integration: posture and movement III	Poster	Mon PM
106.	Motor systems and sensorimotor integration: posture and movement IV	Poster	Mon PM
192.	Motor systems and sensorimotor integration: posture and movement V	Slide	Tue PM
384.	Motor systems and sensorimotor integration: posture and movement VI	Poster	Thu AM
385.	Motor systems and sensorimotor integration: posture and movement VII	Poster	Thu AM
496.	Motor systems and sensorimotor integration: posture and movement VIII	Poster	Fri AM
74.	Motor systems and sensorimotor integration: vestibular system I	Slide	Mon PM
137.	Motor systems and sensorimotor integration: vestibular system II	Poster	Tue AM
138.	Motor systems and sensorimotor integration: vestibular system III	Poster	Tue AM
383.	Muscle: function and biochemistry	Poster	Thu AM
495.	Muscle: structural characteristics	Poster	Fri AM
319.	Reflex function: general	Poster	Wed PM
521.	Reflex function: human I	Poster	Fri AM
522.	Reflex function: human II	Poster	Fri AM
427.	Spinal cord and brainstem	Slide	Thu PM
140.	Spinal cord and brainstem: anatomy	Poster	Tue AM
78.	Spinal cord and brainstem: electrophysiology	Poster	Mon PM
139.	Spinal cord and brainstem: immunocytochemistry	Poster	Tue AM
32.	Spinal cord and brainstem: lesion studies	Poster	Mon AM
79.	Spinal cord and brainstem: motor output	Poster	Mon PM

Theme H: Other Systems of the CNS

Session Number	Session Title	Type	Day and Time
328.	Association cortex and thalamocortical relations	Poster	Wed PM
472.	Brainstem systems	Poster	Thu PM
23.	Cerebral metabolism and blood flow I	Poster	Mon AM
371.	Cerebral metabolism and blood flow II	Slide	Thu AM
399.	Cerebral metabolism and blood flow III	Poster	Thu AM
488.	Cerebral metabolism and blood flow IV	Slide	Fri AM
26.	Comparative neuroanatomy: amphibians, reptiles, birds	Poster	Mon AM
504.	Comparative neuroanatomy: cerebral cortex	Poster	Fri AM
25.	Comparative neuroanatomy: fish	Poster	Mon AM
51.	Hippocampus and amygdala I	Poster	Mon AM
100.	Hippocampus and amygdala II	Poster	Mon PM
343.	Hippocampus and amygdala III	Poster	Wed PM
470.	Hypothalamus I	Poster	Thu PM
471.	Hypothalamus II	Poster	Thu PM
373.	Limbic system II	Poster	Thu AM
181.	**New Insights into the Functions of the Basal Forebrain Cholinergic System**	**Symp.**	**Tue PM**

Theme I: Neural Basis of Behavior

Session Number	Session Title	Type	Day and Time
21.	Alcohol I	Poster	Mon AM
83.	Alcohol II	Poster	Mon PM
281.	Alcohol III	Poster	Wed AM

477.	**Neuropeptides, Steroids and Behavior**	**Symp.**	**Fri AM**
22.	Psychotherapeutic drugs I	Poster	Mon AM
87.	Psychotherapeutic drugs II	Poster	Mon PM
151.	Psychotherapeutic drugs III	Poster	Tue AM
239.	**Sex Differences and Hormonal Influences on Cognitive Brain Function**	**Symp.**	**Wed AM**
178.	Stress, hormones and autonomic nervous system I	Poster	Tue AM
179.	Stress, hormones and autonomic nervous system II	Poster	Tue AM

Theme J: Disorders of the Nervous System

Session Number	Session Title	Type	Day and Time
42.	Alzheimer's disease I	Poster	Mon AM
65.	Alzheimer's disease II	Slide	Mon PM
259.	Alzheimer's disease: amyloid	Poster	Wed AM
437.	Alzheimer's disease: neuropathology	Poster	Thu PM

ONTOGENY OF MUSCARINIC M2 RECEPTORS IN THE RAT BRAIN — AN AUTORADIOGRAPHIC STUDY OF ^{3}H-AF DX 116 BINDING SITES. R. Miyoshi, S. Kito and S. Yamashita*. Third Dept. of Internal Med., Hiroshima Univ. School of Med., Hiroshima 734, Japan.

Previously, we examined the ontogeny of muscarinic acetylcholine receptors in the rat brain through in vitro autoradiography of ^{3}H-QNB and ^{3}H-pirenzepine binding sites. In the present study, an autoradiographic investigation was done using a novel antimuscarinic drug, AF DX 116, as labelled ligand. Receptor binding assay revealed that ^{3}H-AF DX 116 had a single binding site of which Kd and Bmax values were 41.1 nM and 309.2 fmol/mg protein. Brain sections of the rat of an each developmental stage were prepared and incubated with 25 nM ^{3}H-AF DX 116. In the adult rat brain, ^{3}H-AF DX 116 binding sites were richly observed in the superior and inferior colliculi, interpeduncular nucleus, nuclei of the facial and hypoglossal nerves, and moderately in the cerebral cortex (superficial and deeper layers), hippocampus, pontine nucleus and cerebellar cortex. This distribution of ^{3}H-AF DX 116 binding sites was almost consistent with the pattern being expected from those of ^{3}H-QNB and ^{3}H-pirenzepine. From ontogenetic studies, ^{3}H-AF DX 116 binding sites first appeared at 14 days of postnatal days and clearly observed at 21 days of postnatal days. After this stage, they were increased up to 30 days of postnatal days reaching the adult level.

THREE DIMENSIONAL RECONSTRUCTION OF CHOLINERGIC CELL POPULATIONS IN THE RAT BRAIN: AN INITIAL TEST OF EFFECTS OF A CHRONIC CHOLINERGIC LIGAND K.H. Gylys*, A.P. Painchaud*, S.A. Azizi, D.J. Woodward, L.B. Hersh. (Spon: D.R. Sparkman) *Dept of Cell Biology and Anatomy, Dept of Biochemistry, University of Texas Southwestern Medical Center, Dallas, TX.*

The present study was conducted to develop a comprehensive three dimensional computer based representation of the normal cholinergic cell distribution for the entire rat brain using a goat polyclonal antiserum directed against choline acetyltransferase. A second aim was to conduct an initial test of effects of chronic nicotine administration on ChAT-containing structures. Long Evans rats received subcutaneous injections twice daily of either 1.0 mg/kg nicotine or saline for 10-14 days. Results confirm previous reports of cholinergic cell bodies in the: basal forebrain nuclei (medial septal nucleus, diagonal band of Broca, substantia innominata), corpus striatum and nucleus accumbens. More caudally, ChAT-positive cells in the lateral globus pallidus and substantia innominata merge with cells in the basal nucleus of Meynert. The pedunculopontine nucleus is visible in the midbrain. Pontine and medullary sections also display ChAT immunoreactivity in all cranial motor and papasympathetic nuclei. Chronic nicotine administration had no effect on the number of cholinergic somata ($p<.05$) nor in fiber or staining density in comparable brain regions. *Supported by the R.J. Reynolds Tobacco Co., NIDA 2938, and the Biol. Humanics Foundation.*

NEUROANATOMICALLY SELECTIVE DOWN-REGULATION OF BETA-ADRENERGIC RECEPTORS BY CHRONIC IMIPRAMINE TREATMENT: RELATIONSHIPS TO ^{3}H-IMIPRAMINE BINDING. **G.E. Duncan, I.A. Paul, J.B. Fassberg, K. Powell, W.E. Stumpf, G.R. Breese. (SPON: P.P. Rowell) Biol. Sci. Res. Ctr., School of Med., Univ. of NC at Chapel Hill, NC 27599-7250.**

The down-regulation of beta-adrenergic receptors by chronic imipramine (IMP) treatment was investigated with high resolution autoradiography of ^{125}I-pindolol binding to brain sections. Neuroanatomically selective down-regulation of ^{125}I-pindolol binding was found after chronic IMP treatment. Subdivisions of the amygdala and hippocampus were differentially affected. Significant reductions in ^{125}I-pindolol in the IMP-treated rats were found in the CA-1 stratum radiatum and dentate molecular layer, but not in the CA-3 stratum radiatum of the hippocampus. In the amygdala, the basolateral nucleus exhibited reduced ^{125}I-pindolol binding after IMP treatment but the central and medial nuclei were not affected. Chronic imipramine treatment was also associated with reduced ^{125}I-pindolol binding in layer 1 of the cingulate cortex and layer 3 of the piriform cortex but not in the ventrolateral thalamic nucleus, caudate-putamen, lateral hypothalamus, or layers 2 and 3 of the somatosensory cortex. The regionally selective down-regulation of beta adrenergic receptors by chronic IMP are compared to regional distribution of binding sites for ^{3}H-DMI and ^{3}H-IMP (MH39144 & MH33127.

THE DIFFERENTIAL BINDING OF AMITRIPTYLINE TO RAT BRAIN MUSCARINIC RECEPTORS. P.S. Goldman* and W.S. Messer, Jr. (SPON: M.E. Velasco). Dept. of Biology and Dept. of Medicinal and Biological Chemistry, College of Pharmacy, University of Toledo, 2801 W. Bancroft, Toledo, OH 43606.

The tricyclic antidepressant amitriptyline is known to inhibit the reuptake of the monoamines serotonin and norepinephrine. Amitriptyline has also been found to bind to muscarinic receptors, which may be responsible for the side effects of the drug, and possibly contribute to its therapeutic activity. The affinity of amitriptyline for muscarinic receptors in rat brain slices was studied using autoradiographic techniques including image analysis. As shown by competitive inhibition of [^{3}H]-1-quinuclidinyl benzilate binding, amitriptyline was found to be more potent than either the M_1-selective antagonist pirenzepine or the M_2-selective antagonist AF-DX 116 based on IC_{50} values.

Muscarinic receptors in the external layers of the cortex bound amitriptyline with the highest affinity (IC_{50} = 65.8 ± 2.1 nM), while the hippocampal regions had somewhat lower affinities (IC_{50} = 96.3 ± 3.4 nM). Amitriptyline bound with lowest affinity in the thalamus and various midbrain regions, such as the paraventricular nucleus of the thalamus and the superior colliculus, which had IC_{50} values of 112 ± 6.8 and 117 ± 32.6 nM respectively. Other midbrain regions displayed higher affinities (e.g., the substantia nigra had an IC_{50} value of 62.8 ± 0.9 nM). The differential binding affinities of amitriptyline suggest that it has higher affinity than either pirenzepine or AF-DX 116 for muscarinic receptors in rat brain with a unique selectivity for subtypes.

GAMMA-AMINOBUTYRIC ACID OR MU-OPIOID RECEPTOR AUTORADIOGRAPHY IN PALLIDUM AFTER LESIONS IN LATERAL ACCUMBENS AND VENTRAL STRIATUM. L. Churchill, R.P. Dilts and P.W. Kalivas, VCAPP, Wash. State Univ., Pullman, WA 99164.

Do the ventral and dorsal striatopallidal projections parallel each other? Met-enkephalin and γ-Aminobutyric acid (GABA) coexist in both of these pathways. Do the receptors (mu-opioid and GABA, respectively) in the pallidum respond in a similar fashion when the striatal projection is lesioned? Quinolinic acid or nicotinic acid (control) was pressure injected into lateral nucleus accumbens and two weeks later, the rat brains were processed for receptor autoradiography. [3H]quinuclidinylbenzilate (QNB) binding verified the extent of the lesion. [3H]Muscimol binding to GABA receptors and [125I]-Tyr-D-Ala-Gly-MePhe-Gly(ol)(DAGO) binding to mu-opioid receptors were analyzed in ventral pallidum and globus pallidus. [3H]QNB binding decreased in lateral nucleus accumbens and ventrolateral striatum. No differences were observed in [125I]DAGO binding in ventral pallidum or globus pallidus after lesions in lateral nucleus accumbens. [3H]Mus binding decreased in the ventral pallidum after lateral nucleus accumbens lesions but did not change in the lateral globus pallidus when the lesions extended into lateral striatum. These data suggest that the adaptability of GABA receptors to a loss of afferents differs between dorsal and ventral pallidum and that the mu-opioid receptors are not as responsive to loss of afferents as the GABA receptors.

QUANTITATIVE IMMUNOCYTOCHEMISTRY USING AN IMAGE ANALYZER I. IMAGE PROCESSING AND MEASUREMENT TECHNIQUES. R.R. Mize[1], L.B. Nabors[1], C.J. Jeon,[1] and R.N. Holdefer[2] (SPON: T. Bertorini). [1]Dept. of Anatomy and Neurobiology, Univ. of Tennessee Health Science Center, Memphis, TN 38163 and [2]Dept. of Physiological Optics, School of Optometry, Univ. of Alabama, Birmingham, AL 35294

We have applied image processing procedures to extract and measure immunocytochemically labeled cells and fibers using an image analyzer. Labeled tissue was imaged using a Magiscan IIA image analyzer. Immunocytochemically labeled profiles were enhanced using an edge sharpening operator and extracted using segmentation (thresholding), a procedure which isolates the labeled profiles and removes background. An erosion operator was used to separate cells or fibers that were appossed to one another. A thinning operator was used to reduce fiber width to single pixels in order to measure the length of the labeled fibers. Interactive binary editing was used to remove artifacts. Using this technique, we have measured immunoreactivity in single cells, fibers, and whole fields. The technique was especially useful for estimating the innervation density (fiber area per unit field area) of immunocytochemically labeled fibers. We have found differences in the density of anti-serotonin (5-HT) labeled fibers in different layers of the cat superior colliculus and differences in the size and labeling intensity of anti-GABA labeled neurons in the perigeniculate vs. the lateral geniculate nucleus. The image analysis procedure is a rapid method for measuring the position, geometry, and staining intensity of immunocytochemically labeled tissue.

315.3

QUANTITATIVE IMMUNOCYTOCHEMISTRY USING AN IMAGE ANALYZER. II. ESTIMATION OF GABA CONCENTRATION USING A NON-BIOLOGICAL STANDARD L.B. Nabors*, E. Songu-Mize*, and R.R. Mize, Depts. of Anatomy and Neurobiology and Pharmacology, Univ. of Tennessee Health Science Center, Memphis, TN 38163

We have developed a procedure to estimate the concentration of neurotransmitters in brain based upon the optical density of immunocytochemical labeling measured with an image analyzer. A non-biological standard was used which binds conjugated neurotransmitters. Fifty micron agar sections cut from a block were used as a matrix for the standard. The agar sections were activated with cyanogen bromide/acetonitrile to promote coupling to the antigen. We used gamma aminobutyric acid (GABA) conjugated to bovine serum albumin (BSA) as the antigen. The antibody was directed against this conjugate. Activated agar sections were incubated in serial dilutions of the tritium labeled GABA/BSA conjugate. Some sections were then used to measure the amount of coupled antigen by counting the radioactivity with a liquid scintillation counter. The remaining sections were incubated in the GABA antibody and processed for immunocytochemistry. The optical density of these sections was measured with an image analyzer. A linear relationship was found between optical density and the log concentration of GABA over a range of at least 0.01 to 1 nmol/mg of agar. These results suggest that the concentration of GABA within individual cells and processes can be estimated by comparing the optical density of their label with that of the non-biological standards. Supported by EY-02973 and RR-02800.

315.4

VISUALIZATION OF PROBABLE GABA-B RECEPTOR SITES BY MONOCLONAL ANTI-BACLOFEN ANTIBODIES. G. Holstein, G. Martinelli*, I. Zamir* and P. Pasik, Depts. Neurol., Anat. & Surg., Mount Sinai Sch. Med., CUNY, New York, N.Y. 10029.

The goal of this work was the immunocytochemical visualization of baclofen as a potential marker for GABA-B receptor sites. A series of monoclonal antibodies were raised in mice by standard hybridoma techniques against the L-enantiomer of gamma-amino-beta-(p-chlorophenyl)butyric acid (baclofen) conjugated to keyhole limpet hemocyanin (KLH) using glutaraldehyde. Nine culture supernatants from twice cloned hybrids were selected for their strong reactivity against the glutaraldehyde conjugate of baclofen to human serum albumin (HSA). None of the supernatants tested by enzyme-linked immunosorbent assays (ELISA) showed any reactivity against the glutaraldehyde conjugates of GABA, histamine or monoethanolamine to HSA, suggesting that the antibodies were specific for the baclofen moiety. To evaluate the usefulness of these antibodies, studies of the immunocytochemical localization of baclofen were conducted in rats. Experimental rats were sacrificed 90 minutes after an i.m. injection of baclofen-HCl (1 mg/kg). Both injected and uninjected control rats were sacrificed under ether anesthesia by cardiac perfusion with 2% formaldehyde/0.5% glutaraldehyde in phosphate buffer. Fifty µm sections were exposed to the monoclonal antibodies for 16 hr. The sections were further treated with a rabbit anti-mouse IgG absorbed with normal rat serum, followed by the PAP procedure. Preliminary light microscopic observations suggest the presence of fine immunoreactive elements in discrete brain regions of the baclofen-injected, but not the uninjected rats. For example, cerebellar cortex shows a granular immunostain only in sections from the baclofen-injected animals, particularly prevalent in the granule cell layer. Identically processed sections from the uninjected animals showed no immunoreactivity. Aided by NIH Grants # NS-24656, NS-22953 and NS-11631. L-baclofen was generously provided by Ciba-Geigy, Ltd.

315.5

ANALYSIS OF THE DISTRIBUTION AND DENSITY OF THE GABA/BENZODIAZEPINE/CONVULSANT COMPLEX IN THE RAT CNS. R.W. Olsen[1], R.T. McCabe[2], J.P. Yezuita*[2], and J.K. Wamsley[2]. [1]Dept. of Pharmacology and the BRI, UCLA Sch of Med, Los Angeles, CA 90024 and [2]Dept. of Psychiatry, U of UT Sch of Med, SLC, UT 84132.

The GABA receptor complex which contains pharmacologically recognizable sites that interact allosterically has been the subject of considerable interest. This complex includes GABA, benzodiazepine (BZ), barbiturate, and convulsant sites that are heterogeneously distributed throughout the brain. The binding of ligands which combine with portions of this system was investigated using autoradiographic and homogenate binding techniques. Low to intermediate densities of high-affinity $GABA_A$ receptors in the CNS were labeled with [^{3}H]muscimol. High densities of [^{3}H]bicuculline methiodide and [^{3}H]SR 95531 binding sites (low-affinity $GABA_A$) were found in many regions analyzed. These sites defined by [^{3}H]flunitrazepam binding are coupled to BZ receptors. BZ_1 sites were examined using [^{3}H]2-oxo-quazepam. Convulsant sites which were identified with [^{3}H]TBOB or [^{35}S]TBPS showed intermediate to high levels of binding density in those areas studied. Modulation of [^{35}S]TBPS was examined by including several BZ and barbiturate agents and varied with brain region. Our studies provide a regional comparison of the distribution and density of individual subcomponents of the GABA complex and information regarding relationships of receptor subtypes and GABAergic function.

315.6

DISTRIBUTION OF $GABA_A$/BENZODIAZEPINE RECEPTOR AND NAAG-LIKE IMMUNOREACTIVITY IN THE RAT CNS. P. M. Sweetnam, K. E. Miller, P. A. Gallombardo, J. F. Tallman, J. H. Neale and M. F. Humphrey. Dept. of Neurol. Surg. University of Miami School of Medicine, Miami, FL. 33136; Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508; Dept. of Biology, Georgetown University, Washington, DC 20057.

The modified amino acid GABA and a dipeptide, N-acetylaspartylglutamate (NAAG), are present in relatively high concentrations in the rat CNS. While the inhibitory actions of GABA are well documented, NAAG's role as an excitatory neurotransmitter has yet to be firmly established. However, NAAG's discreet neuronal distribution, vesicular localization and depolarization-mediated release make it an intriguing molecule to study. Using monoclonal antibody Eg, prepared against the purified $GABA_A$/benzodiazepine receptor (Sweetnam, P., et al., Mol. Brain Res., 2:222, 1987), and NAAG antiserum (Cangro, C., et al., J. Neurochem., 49:1579, 1986) we have studied the distribution of both in various regions of the CNS. Our results show that in several regions, e.g., cerebellum, a number of neuronal cell types express both $GABA_A$ receptor and NAAG-like immunoreactivity. However, in other regions, e.g., the spinal cord, the distribution of each is markedly different. These data suggest that in several regions of the rat CNS GABA and NAAG may function in the same local circuitry. Support: The Miami Project to Cure Paralysis; The Daniel Heumann Spinal Cord Research Foundation; DA 02297 to JHN; MH 38813 to JFT.

315.7

IMMUNOHISTOCHEMICAL LOCALIZATION OF GLUTAMIC ACID DECARBOXYLASE (GAD) IN THE INTERPEDUNCULAR NUCLEUS OF THE RAT: AN ELECTRON MICROSCOPE INVESTIGATION. B.A. FLUMERFELT, M.D. KAWAJA* AND A.W. HRYCYSHYN*. Dept. of Anatomy, The University of Western Ontario, London, Canada N6A 5C1

The rat interpeduncular nucleus (IPN), a component of the midbrain limbic system, is composed of an abundant population of topographically organized GAD-positive neurons and a dense plexus of GAD-stained axons. Examination of the ultrastructural localization of GAD-staining in the IPN revealed a variety of arrangements of immunoreactive axodendritic and axosomatic synapses. The lateral, central, intermediate, and rostral subnuclei exhibited numerous GAD-positive somata and dendritic processes. Unstained terminals formed numerous asymmetrical contacts with immunoreactive dendrites and somata, while GAD-stained terminals formed symmetrical axodendritic and axosomatic contacts. GAD-positive terminals were observed throughout the entire centre forming symmetrical contacts with non-immunoreactive dendrites and somata. Immunoreactive myelinated axons were present in the IPN, especially in the lateral subnucleus. This study suggests that a prominent population of GAD-positive neurons contribute to a complex intrinsic GABAergic circuit. These IPN neurons are in receipt of numerous inputs and may give rise to a small GAD-positive projection. (Supported by the Medical Research Council of Canada)

315.8

TWO CLASSES OF CORTICAL GABA NEURONS DEFINED BY DIFFERENTIAL CALCIUM BINDING PROTEIN AND PARVALBUMIN IMMUNOREACTIVITY. E.G. Jones, S.H.C. Hendry and P.C. Emson, Dept. of Anatomy and Neurobiology, University of California, Irvine, 92717 and Institute of Animal Physiology, Cambridge, U.K.

Immunoreactivity for 28kd vitamin D dependent calcium binding protein (CaBP) and parvalbumin (PV) is found in separate sub-populations of GABA immunoreactive neurons in all areas of the neocortex of M. fascicularis monkeys. Most CaBP-positive and PV-positive cells also display GABA immunoreactivity but virtually no cells display both CaBP and PV immunoreactivity. A relatively small number of GABA cells lack immunoreactivity for either peptide. CaBP positive neurons predominate in layers II and IIIA while PV positive neurons predominate in layers IIIB and IV. Both types are found in smaller numbers in deeper layers. Many CaBP positive cells are bitufted and contribute long axon-like processes ascending or descending in the radial fasciculi of the cortex. They are, thus, likely to be double bouquet cells that form GABAergic interlaminar connections. Many PV positive cells have large somata, are multipolar and their axons form pericullular terminals on pyramidal cell somata. They are, thus, likely to be GABAergic basket cells. Supported by NIH Grant NS 21377

315.9

CALCIUM-BINDING-PROTEINS IN THE RAT BRAIN: A MAPPING STUDY M.R. CELIO, Institute of Anatomy University of Kiel, Olshausenstr. 40, D-2300 Kiel

Calcium-binding-proteins (CaBP) translate the information carried by Ca2+ in a meaningful message for the neuron. We are interested in understanding why certain CaBP's occur only in subpopulations of neurons and try to deduce the function of the proteins by studying their neuroanatomical localization. This poster shows that antibodies against the two CaBP's parvalbumin (PV) and calbindin D-28k (28k) are superb new neuroanatomical markers which not only visualize known cells and pathways but even reveal as yet undescribed brain nuclei. PV and 28k occur mostly in complementary systems: the first is abundant in interneurons and the second in projection neurons. PV is preferentially found in a subclass of rapidly firing GABA-positive interneurons; 28k is associated with neurons susceptible to neurodegeneration. The relationship between the distribution of neurons containing these two CaBP's and that of receptors for calcium-regulating hormones and Ca2+-channels is complex. We assume that neurons containing these additional CaBP's are privileged for certain Ca2+-dependent processes and suggest a role of parvalbumin in the control of neuronal excitability.

315.10

NEUROTRANSMITTER PHENOTYPIC EXPRESSION BY EMBRYONIC RAT NEURONS IN DISSOCIATED CULTURE. H. M. Geller, J. P. Grierson, and H. D. Baker#. Dept. of Pharmacology, UMDNJ - Robert Wood Johnson Med. Sch., Piscataway, NJ 08854. #Dept. of Neurology, Burke Rehab. Ctr., Cornell Univ., White Plains, NY 10605

The hypothalamus is a morphologically and functionally diverse region of the brain. This laboratory utilizes dissociated cultures of embryonic rat hypothalamus to investigate the expression of phenotypic properties of hypothalamic neurons in a controlled environment. In this study, we used antibodies directed against tyrosine hydroxylase (TH), GABA and olfactory marker protein (OMP) to investigate the time course and morphological characteristics of expression of these substances. TH^+ neurons appear to form two populations: a large population of small TH^+ neurons which is only observed in young cultures, and a small population of large TH^+ neurons with extensive neuritic ramifications which are first observed at 8 days in vitro and can be identified in older cultures. The overwhelming majority of the neurons in these cultures appear to synthesize immunoreactive GABA; the morphology of these cells is quite heterogeneous. The fact that virtually all neurons are $GABA^+$ would suggest that they contain other transmitters as well. Clusters of small neurons expressing OMP can be identified in cultures as early as 5 days in vitro. One interesting observation is that neurons which express TH and OMP are often found in group rather than as isolated cells, which may suggest a clonal origin for these cells. Supported by NIH NS-25168 and a grant from the Foundation of UMDNJ.

315.11

NEUROPEPTIDE-Y PROJECTIONS FROM LOCUS COERULEUS TO CEREBRAL CORTEX IN THE RAT. B.J. Wilcox and J.R. Unnerstall. Department of Neurology, Case Western Reserve University Sch/Med, Cleveland, OH 44106.

The locus coeruleus (LC) is the sole source of norepinephrine (NE) innervation to the cerebral cortex (CC). In addition to NE, many neurons in this nucleus also contain neuropeptide-Y immunoreactivity (NPY-IR). Thus, the LC may be one source of cortical NPY. We have mapped the rostro-caudal distribution of NPY neurons within the LC by immunofluorescence. In addition, using double-labelling techniques, we have identified NPY containing LC neurons which also project to the cortex. Brains of male Sprague-Dawley rats treated first with Fluorogold, then with colchicine were fixed by perfusion. Frozen sections of LC 10 μm thick were stained for NPY-IR by indirect immunofluorescence. LC neurons labelled after cortical Fluorogold injection were found throughout the dorsal compact LC. NPY-IR neurons were distributed through the entire rostro-caudal extent of the LC including subcoeruleus. Double labelling revealed a small number of neurons containing both NPY-IR and retrograde tracer. Preliminary results show that 10% of Fluorogold labelled neurons in the rostral and caudal poles of the LC also exhibited NPY-IR. In the compact LC, a larger proportion of the Fluorogold labelled cells (up to 30%) exhibited NPY-IR. Thus, LC afferents may contribute to NPY-mediated neurotransmission in the cortex.

315.12

INCREASES IN HIPPOCAMPAL NPY BINDING SITES FOLLOWING LESIONS OF THE LOCUS COERULEUS. J.R. Unnerstall. Departments of Neurology and Pharmacology, Case Western Reserve University Sch/Med, Cleveland, OH 44106.

Neuropeptide-Y (NPY) is found in cortical and hippocampal neurons and is co-localized with epinephrine and/or norepinephrine (NE) in medullary and pontine nuclei. This experiment was designed to determine whether locus coeruleus (LC) NE projections to the forebrain may also utilize NPY. Following 6-OHDA lesions of the LC (2 weeks), rat brains were processed for receptor autoradiography of NPY binding sites using [^{125}I]-PYY (120 pM). Control animals received vehicle injections. Non-specific binding was defined in the presence of 100 nM PYY or 1.0 μM NPY. Given a KD of 60 pM for [^{125}I]-PYY (determined in rat brain sections), these conditions represent an approximate 75% occupancy of high-affinity NPY binding sites. Significant increases in binding ($p < 0.05$) were selectively observed in the CA3 region of the hippocampus (+40%, stratum moleculare; +50%, stratum oriens) in the lesioned animals. Smaller increases (20-25%, $p < 0.10$) were observed in the CA1 region of the hippocampus, subiculum and dorsal medial thalamus. Minimal increases (less than 10%) were observed in the cortex (lamina I), amygdala and dorsal or lateral hypothalamus. These preliminary findings suggest that ascending LC projections to the hippocampus may significantly contribute to NPY-mediated neurotransmission in this structure.

315.13

PNMT, NPY, AND SP-IMMUNOREACTIVE STRUCTURES IN THE MEDULLA OBLONGATA OF THE TREE SHREW. G. Flügge*, S. Behrens*, A. Mittendorf*, F. Pollano * and E. Fuchs. German Primate Center, Göttingen, FRG.

Phenylethanolamine-N-methyltransferase (PNMT), neuropeptide Y (NPY), and substance P (SP) immunoreactive structures were detected in the medulla oblongata (MO) of the tree shrew, a species which provides a model of a small primate brain. Two groups of PNMT immunopositive cells (IC) corresponding to group C1 and C2 of the rat, but no group C3 were found. Most of the IC and immunoreactive terminals (IT) were observed in the solitary tract nucleus (NTS) where they form a ring around the subnucleus gelatinosus (Sg).

In the tree shrew MO, we detected very few NPY-IC but dense patterns of IT. The distribution of NPY-IT showed a great coincidence with PNMT-immunoreactive structures (IS), revealing only some NPY-IT in the Sg.

SP neurons were only found in the raphe obscurus and the hypoglossal nucleus, but there are many SP-IT in the spinal trigeminal nucleus, the vagal nucleus, the NTS, and also in the solitary tract. Most of the SP-IT were found in the medial and intermedial subdivision of the NTS, fewer in the ventrolateral and very few in the Sg. - In summary, the coincidence between the distribution of PNMT- and NPY-IR is in accord with data obtained from the rat whereas the patterns of the IS are similar to those of the rhesus monkey.

315.14

INTRACEREBROVENTRICULAR 6-HYDROXYDOPAMINE AND 5,7-DIHYDROXYTRYPTAMINE DO NOT ALTER ANGIOTENSIN II BINDING SITES IN THE RAT BRAIN. D.E. Walters and R.C. Speth. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520

To determine if the pharmacological actions of centrally administered angiotensin II (Ang II) are mediated via specific Ang II binding sites located on presynaptic monoaminergic nerve terminals, adult male Sprague-Dawley rats (~ 300 gm body wt.) received intracerebroventricular (icv) injections of 6-hydroxydopamine (6-OHDA) or 5,7 dihydroxytryptamine. Subsequently, the pressor and dipsogenic responses to icv Ang II and the specific binding of ^{125}I-sarcosine^1, isoleucine^8 angiotensin II in the hypothalamus-thalamus-septum-midbrain (HTSM) and brainstem were determined. The respective treatments caused reductions in Norepinephrine and 5-hydroxytryptamine levels in the HTSM (62% and 44%) and brainstem (57% and 26%), but did not significantly alter the specific binding of the radioligand in either tissue. Catecholamine depletion in 6-OHDA-treated rats resulted in a 55% decrease in the pressor and drinking response to icv Ang II, although the latter was not significantly different from control. These results indicate that while the central actions of Ang II require catecholaminergic neuron integrity, Ang II does not act directly on catecholaminergic nerve terminals. AUTORADIOGRAPHIC EVIDENCE OF PORCINE BRAIN NATRIURETIC PEPTIDE BINDING SITES IN THE PORCINE AND RAT BRAIN, ADRENAL GLAND AND KIDNEY. K.Shigematsu[2]*, M.Kurihara[3]*, M.Niwa[1], K.Nakao[4]*, Y.Kataoka[1]*, T.Maeda[1]*, H.Tsuchiyama[2]*, M.Ozaki[1]*, H.Imura[4]* and H.Matsuo[5]*, Depts. of [1]Pharmacology 2, [2]Pathology 2, [3]Neurosurgery, Nagasaki Univ.Sch.Med., Nagasaki 852, [4]Second Division, Dept. of Medicine, Kyoto Univ.Sch.Med., Kyoto 606 and [5]Dept. of Biochemistry, Miyazaki Med.College, Miyazaki 889-16,Japan.

Binding sites of porcine brain natriuretic peptide (pBNP) isolated from the porcine brain by H.Matsuo and colleagues (Nature 332,78,1988) were investigated. The tissue sections were incubated with ^{125}I-pBNP and analyzed using quantitative receptor autoradiography. A comparison was made with α-atrial natriuretic peptide (ANP) binding sites. Specific pBNP binding sites were found to be localized in the kidney glomerulus and adrenal zona glomerulosa of rat and porcine. Difference in the localization of pBNP binding sites was noted in the kidney, as indicating that pBNP binding sites were far less abundant in the inner medulla and inner stripe of the outer medulla, areas which were densely labeled by ^{125}I-ANP. In the porcine brain, pBNP binding sites were concentrated in the internal plexiform layer of the olfactory bulb, preoptic medial nuclei, subfornical organ, choroid plexus and suprachiasmatic nuclei. Among areas studied, no differences in the localization were observed when compared with that of ^{125}I-ANP binding sites. As evidence on functional interrelationship between ANP and pBNP has been reported, the present finding enhances our knowledge of the physiology of the natriuretic peptides in the brain and peripheral.

STAINING OF VASOPRESSINERGIC NEURONS IN ADRENALECTOMIZED RATS USING A VASOPRESSIN ANTI-IDIOTYPE ANTIBODY. D. Berlove, D. Piekut, and K. Knigge. Neuroendocrine Unit, University of Rochester School of Medicine and Dentistry, Rochester, N.Y. 14642

A vasopressin anti-idiotype antibody was generated by immunization of a rabbit with primary anti-vasopressin IgG. This antiserum immunostains neurons in the supraoptic and paraventricular nuclei of the hypothalamus in normal and Brattleboro rats. Staining was reduced or eliminated by preincubation or coincubation of the antiserum with synthetic vaspressin or rat neural membrane in a dose-dependent manner. The anti-idiotype also inhibited binding of ^{3}H-vasopressin to the neural membrane protein in a dose-dependent manner. Preliminary characterization of this antiserum indicates that the anti-idiotype recognizes a putative vasopressin receptor associated with vasopressinergic neurons. Following adrenalectomy it has been established that parvocellular CRF-containing neurons in PVN synthesize vasopressin. We examined the presence of putative vasopressin receptors associated with these parvocellular CRF-vasopressin immunoreactive cells. Rats were adrenalectomized, following a survival period of 72 hours to 8 weeks, brains were stained with the primary anti-vasopressin and the vasopressin anti-idiotype antibody. The vasopressin antisera immunostained neurons in the parvocellular and magnocellular areas of PVN, whereas the anti-idiotypic antibody immunostained magnocellular neurons only. We therefore conclude that the putative vasopressin receptor seen by our anti-idiotype in magnocellular neurons is not present in the parvocellular vasopressin producing neurons of the adrenalectomized rat.

IMMUNOHISTOCHEMICAL STUDIES ON THE VASOACTIVE SUBSTANCES IN THE HYPOTHALAMIC MAGNOCELLULAR NUCLEI.
H. Yamada*, M. Kawata and Y. Sano*. Dept. of Anatomy, Kyoto Pref. Univ. of Med., Kyoto 602, Japan.

The distribution of such vasoactive substances as serotonin, vasopressin, endogenous digitalis-like substance (EDLS), and atrial natriuretic polypeptide (ANP) in the hypothalamus was studied. The rats and monkeys were transcardially perfused with buffered aldehydes fixatives after they were anesthetized with sodium pentobarbital. Free-floating sections obtained with a cryostat were incubated in the serotonin-, vasopressin-, digoxin- and α-ANP-antibodies, and then subjected immunohistochemically with ABC method. A few serotonin nerve fibers were seen in the paraventricular nucleus, supraoptic nucleus and its accessory nuclei. In these nuclei, EDLS-containing nerve cells were distributed. Moreover, EDLS was co-localized with vasopressin. However, ANP was observed only in the parvocellular component of the paraventricular nucleus. In the rats fed with high sodium purina chow (4 weeks), the immunoreactivities of vasopressin and ANP were increased while those of digoxin (that is, EDLS content) were decreased; however, serotonin-immunoreactivity was not changed.

DISTRIBUTION OF MONOAMINE AND NEUROPEPTIDE IMMUNOREACTIVE CELLS IN THE CAT PARABRACHIAL PONTINE AREA. K. Elisevich and J. Ciriello. Dept. of Physiology, Univ. of Western Ontario, London, Canada N6A 5C1.

The parabrachial pontine area (PPA) surrounding the brachium conjunctivum of the dorsolateral pons has been implicated in pain and cardiovascular control mechanisms. In this study the distribution of perikaraya containing the catecholamine biosynthetic enzymes tyrosine hydroxylase (TH), dopamine-beta-hydroxylase (DBH) and phenylethanolamine N-methyl-transferase (PNMT), in addition to 5-hydroxytryptamine (5-HT), and the peptides substance P (SP) and leucine enkephalin (ENK) in the PPA of the cat were studied immunohistochemically after intracisternal administration of colchicine. Fewer DBH neurons were found in nucleus subcoeruleus (SC), Kolliker-Fuse (KF) and the lateral parabrachial nucleus (PBL) than TH neurons although the nucleus locus coeruleus (LC) contained comparable numbers of both. SP neurons were found in KF with fewer neurons identified in SC, PBL and LC. 5-HT and ENK neurons were more apparent in LC. In light of the neuronal connections of the PPA and its involvement in pain and cardiovascular control, these results suggest the neurochemical substrate for the effects upon analgesia and the circulation. DIRECT PROJECTIONS FROM THE LATERAL PONTINE NUCLEUS TO THE ANTERIOR INTERPOSITUS NUCLEUS: A POTENTIAL CS PATHWAY FOR CLASSICAL CONDITIONING. J.E. Steinmetz and D.R. Sengelaub. Program in Neural Science, Department of Psychology, Indiana University, Bloomington, IN 47405.

A number of studies have suggested that the interpositus nucleus of the cerebellum is a potential site for convergence of CS and US information (i.e., is a potential site for plasticity) associated with classical eyelid conditioning. In addition, previous research has demonstrated that lateral regions of the pontine nuclei (LPN) project essential acoustic CS information to the cerebellum during conditioning (e.g., Steinmetz *et al.*, Proc. Nat. Acad. Sci., 84, 3531-3535). The present study used HRP to determine if cells in the LPN project directly to dorsal regions of the anterior interpositus nucleus.

Stereotaxically placed injections of cholera toxin bound HRP (0.3-2 µl, .2%) were made unilaterally into the region of the interpositus nucleus of rabbits. HRP-labeled cells were visualized with TMB processing.

Our results indicate: (1) Injections which include the anterior interpositus nucleus, dentate nucleus, and overlying regions of the cerebellar cortex (including Larsell's HVI) retrogradely labeled cells in the contralateral LPN and dorsolateral pontine nucleus (DLPN); (2) Injections confined to the interpositus nucleus and white matter above the nucleus also labeled cells located in the LPN and the DLPN; (3) Injections confined to the lateral edge of the anterior interpositus and the medial edge of the dentate nucleus labeled cells in the LPN but not the DLPN. All injections labeled cells in the reticular tegmental pontine nucleus and rostromedial regions of the dorsal accessory olive. These data provide evidence for a direct projection from lateral regions of the pontine nuclei to the deep cerebellar nuclei, a pathway that could be used to relay acoustic CS information to potential sites of plasticity in the cerebellum during classical eyelid conditioning.

316.2

PONTINE PROJECTIONS OF COCHLEAR NUCLEI USING ANTEROGRADE HRP OR PHA-L. J.K. Thompson, D.G. Lavond, C. Weiss and R.F. Thompson. Dept Psych/SGM 501, Univ Southern Calif, Univ Park, Los Angeles, CA 90089-1061.

Previous studies using retrograde fluorescent transport of Fluorogold or of Fast Blue suggest a direct projection from DCN and VCN to posterior aspects of lateral pontine nucleus (LPN). In other studies, field potentials and multiple unit activity can be evoked in the LPN by auditory click stimuli. Both direct electrical stimulation of the LPN as a CS and LPN lesions suggest that it projects essential auditory information to the cerebellar locus of neuronal plasticity for classical conditioning.

The present study was concerned with anatomically confirming the pathway from cochlear nuclei to the pontine region by using anterograde tracing techniques. Rabbits were injected with WGA (pressure injection of 0.1-0.2 uL of 1% or 10% iontophoresis using 14 sec square waves for 10-15 mins) or iontophorectically injected with PHA-L (2.5%) into either the dorsal cochlear nucleus (DCN) or the anteroventral cochlear nucleus (VCN). Survivals were 48 hours after HRP and 14 days after PHA-L injections. The material was processed and was later examined with both light and dark field microscopy.

UNILATERAL INFERIOR OLIVE NMDA LESION LEADS TO UNILATERAL DEFICIT IN ACQUISITION OF NMR CLASSICAL CONDITIONING. M. Mintz, Y. Yun*, D.G. Lavond and R.F. Thompson. Dept. of Psychol., SGM 501, Univ. Southern California, Los Angeles, CA 90089-1061.

A unilateral lesion of the cerebellum permanently abolishes the NMR only to US presented to the eye **ipsilateral**, but not contralateral, to the side of the lesion. This specialization of cerebellar memory sites might be related to the restricted innervation pattern of cerebellar hemispheres as indeed the climbing fibers to each hemisphere convey mainly the US from the ipsilateral eye. To test this hypothesis, we have measured the conditioning of NMR to US presented to either of the eyes after denervating one cerebellar hemisphere of its US input. The anteriomedial aspect of dorsal accessory olive was localized by antidromic stimulation of cerebellar HVI area and then injected with 40-200 nMol of the neurotoxin NM-DL-A to destroy the cells' somata while sparing fibers of passage from the contralateral olive or other fibers as well. Extensive lesions of the IO prevented acquisition of NMR to the eye ipsilateral to the denervated cerebellar hemisphere. Conditioning to the other eye was normal in all rabbits. It appears that specialization of the memory sites in the cerebellum, in respect to the left vs right US presentation, originate from the distinctive lack of divergence of sensory input from one eye to the bilateral cerebellar hemispheres.

LESION OF THE CEREBELLAR INTERPOSITUS NUCLEUS ABOLISHES BOTH NICTITATING MEMBRANE AND EYELID EMG CONDITIONED RESPONSES. D.G. Lavond, C.G. Logan, J-H. Sohn, W.D.A. Garner and R.F. Thompson. Dept Psych/SGM 501, Univ Southern California, Univ Park, Los Angeles, CA 90089-1061.

Rabbits were classically conditioned for 5 days at 108 trials per day using the repeating sequence of one CS (1 KHz, 85 dB SPL, 352 ms) alone test trial and 8 paired trials of tone CS and coterminating UCS (left corneal airpuff, 2.1 N/cm^2, 100 ms). Dependent variables were nictitating membrane (NM) extension measured with a minitorque potentiometer and eyelid EMG activity measured with a preamplifier and level discriminator.

Following this all rabbits were anesthetized and lesioned in the left interpositus nucleus of the cerebellum (2 mA, 2.5 min, anodal DC current at AP+0.5, ML-5.0 and DV-14.5 mm from lambda) and allowed 7 days of recovery.

Retesting on classical conditioning demonstrated abolition of both conditioned NM extension and eyelid closure. Averaged and individual trials are presented, demonstrating a high correlation between NM, discriminated and raw EMG before and after the lesion.

Filopodia are present in synaptic glomerulae in the tactile learning neuropils of the posterior buccal lobes of *Octopus vulgaris*. J. David Robertson, Psyche Lee and J.Z. Young. Department of Anatomy, Duke University School of Medicine, Durham, N.C.

Tactile learning and memory (L&M) can be blocked in *Octopus vulgaris* by surgical ablation of the posterior buccal (PBL) and subfrontal (SFL) lobes. We have recently found evidence that tactile L&M in *Octopus* can be retarded or blocked by injection of cytochalasin B (CB) into the neuropils of the PBL and SFL without affecting previously established tactile memories. We postulated that L&M depends critically on active extension of filopodia like those of nerve growth cones in specific regions by neurites in response to specific activity. CB is known to cause collapse of filopodia in both neurones and glia in tissue cultures, and this provided the theoretical basis for the CB experiments. We assumed that active extension of filopodia by neurites in learning neuropils is important in L&M. To verify this we have studied serial sections of the PBL neuropil by electron microscopy and found numerous filopodia. These occur in repetitive glomerulae delimited by sheets of glial cells each containing groups of 8-10 presynaptic endings 1-2μm in diameter that surround postsynaptic neurites. These are usually flattened in cross section and often measure ~0.2 x 0.5 μm across. These are connected with nerve fibers 2-3 μm in diameter with prominent neurofilaments and microtubules leading away from the glomerulae. The presynaptic endings contain the usual spherical clear vesicles ~40-60 nm in diameter, some of which are larger and pleomorphic, and groups of spherical dense core vesicles 10-15 nm in diameter. Two sets of serial sections have been analyzed in detail by a computer program for 3D analysis called PC3D (Jandel Scientific) in the laboratory of Dr. Kathleen Smith using a PC's Ltd. 286 computer. Reconstructions were plotted on a HP7475A plotter. Selected profiles of pre- and postsynaptic neurites and glia cells were reconstructed through 52 sections 70 nm thick and 48 sections 50 nm thick. Numerous filopodia like those in neural tissue culture were found in both the pre- and postynaptic neurites and also in glial cells.

NEURAL SUBSTRATES FOR LONG-TERM HABITUATION OF THE ACOUSTIC STARTLE REFLEX VISUALIZED USING 2-DEOXYGLUCOSE: REGIONAL CHANGES IN AUDITORY, RETICULAR AND CEREBELLAR SYSTEMS. F. Gonzalez-Lima, T. Finkenstädt* and J.-P. Ewert. Dept. of Anat., Coll. of Med., Texas A&M Univ., College Station, TX 77843, and Dept. of Neuroethol., Univ. of Kassel, Kassel, F.R.G.

Autoradiography with ^{14}C-2-deoxyglucose (2DG) was used to examine the functional activity of the rat brain during habituation of the acoustic startle reflex. Group 1 rats were long-term habituated for one week and injected with 2DG on the last session. Group 2 rats were not pretrained and then were injected with 2DG and stimulated for one session of short-term habituation. Group 3 rats served as unstimulated controls. Long-term habituated rats showed a significantly greater metabolic activation of the auditory system (with the exclusion of the thalamocortical pathway), the cerebellum (deep nuclei, vermian lobules 1-7, lateral hemispheres) and major cerebellar input-output structures (vestibular nuclei, inferior olive, spinal cord). The largest increase was in the lateral superior olive. In contrast, the midbrain reticular formation and its ascending thalamocortical system (anterior, medial, reticular and lateral posterior nuclei, and the frontal cortex) showed significant suppressions in 2DG uptake. The changes revealed by 2DG are the first demonstration of brain substrates with localized metabolic alterations dependent on long-term habituation.

316.7

THE BEHAVIORAL EFFECTS OF CORTICAL SYMPATHETIC INGROWTH (CSI). L. E. Harrell and D. S. Parsons*. Dept. of Neurology, VAMC and Univ. of Ala., Birmingham, AL 35294.

Following cholinergic denervation of the neocortex by nucleus basalis of Meynert lesions (NBML) peripheral noradrenergic fibers are observed to grow into neocortical regions. To ascertain the behavioral effects of cortical sympathetic ingrowth the following experiments were performed.

Sixty-six male adult Sprague-Dawley rats were divided into two Groups. G1 animals underwent training on a standard radial-8-arm maze (RAM) task (i.e., all arms baited) while G2 underwent training on a modified version (i.e., 4 arms baited). After training to a specific learning criterion the animals within each major G were further subdivided into one of three subgroups: Control (CON); NBML (ibotenic 5 ug/ul); NBML + superior cervical ganglionectomy (NBML+Gx). Following surgery, animals were retested until they again achieved learning criterion.

Prior to surgery all animals were able to acquire the task, although those assigned to G2 took longer than those in G1 (mean trials ± SEM: 39.0 ± 5.0 vs 10.2 ± 4.0). Following surgery the NBM animals (34.2 ± 12.2 G1; 59 ± 7.5 G2) took significantly longer to recovery than the NBM+Gx (13.8 ± 2.5 G1; 31 ± 7.1 G2) or CON (10.2 + 2.8 G1; 13 ± 1.6 G2) groups.

The results suggest that CSI, in a manner similar to hippocampal sympathetic ingrowth, may adversely affect behavior. The effect of this neuronal reorganization on behavior following NBML should be considered.

316.8

LOCUS COERULEUS INVOLVEMENT IN CONDITIONED BRADYCARDIA. G.C. Harris and R.D. Fitzgerald*. Dept. of Med. Psychol. Oregon Health Sci. Univ., Portland, OR 97201.

The locus coeruleus (LC) is believed to play a role in the expression of fear. Both NE α-2 agonists and μ opioid agonists are known to have similar effects in suppressing the neuronal activity of LC cells while, corticotropin releasing factor (CRF) is known to enhance the firing of LC cells. This study looked at the effects of the α-2 agonists, Clonidine (3 ug) and UK 14,304 (5 ug), a μ opioid agonist, DALA (10 ug), and the CRF antagonist, Alpha-Helical CRF (9-41) (25 ug) on the development of classically conditioned bradycardia in rats when administered into the rostral fourth ventricle in the vicinity of the LC 5 min prior to training. Conditioning consisted of a discrimination paradigm in which one 6-s tone (CS+) was paired with an aversive US, while a second tone (CS-) was presented alone. An immediate antagonist test and a non-drug test 24 hrs after training were given. All groups were then retrained and the effects of the drugs on an established response was assessed. The administration of DALA, UK 14,304, and Clonidine, were found to decrement both the learning and performance of the conditioned bradycardia. The adverse effect of these drugs on the learning of the bradycardia could be due to their inhibitory action at the LC leading to a loss of LC influences in other brain structures important in the conditioning process. Alpha-Helical CRF appeared to slightly enhance the magnitude of the bradycardia.

316.9

IBOTENIC ACID LESIONS IN THE MAGNOCELLULAR MEDIAL GENICULATE NUCLEUS PREVENT THE ACQUISITION OF CLASSICALLY CONDITIONED BRADYCARDIA TO SINGLE TONES IN RABBITS. N. Schneiderman, C.G. Markgraf, P.M. McCabe, D.R. Liskowsky, and R.W. Winters*. Dept. of Psychology, Univ. of Miami, Coral Gables, FL 33124.

Previous work in our laboratory has demonstrated that ibotenic acid lesions in the magnocellular region of the medial geniculate nucleus (mMGN) prevent the acquisition of differential classically conditioned bradycardia to acoustic stimuli in rabbits. Although lesioned animals were not able to discriminate between a tone paired with shock (CS+) and a separate tone that was not paired with shock (CS-), the animals still exhibited significant bradycardia to both stimuli. This finding suggests the possibility that mMGN is involved in the discrimination between two or more tones, but that simple one-tone conditioning is mediated at a lower level in the auditory system. In order to test this hypothesis, the present study examined the role of mMGN in classically conditioned bradycardia to a single tone.

New Zealand albino rabbits received bilateral lesions via injection of ibotenic acid into either mMGN (n=8) or into control lesion sites (n=16). Following recovery and habituation to the tone CS (560 Hz, 90dB), the CS was paired with periorbital shock (0.5 sec, 3mA) for 30 trials. In half of the control lesioned animals the tone and shock were unpaired in a standard pseudoconditioning paradigm (n=8). Control lesioned animals exhibited bradycardiac responses (mean= -11.6 beats/min) that were significantly greater than the pseudoconditioned group responses (mean= -0.7 beats/min). In contrast, mMGN lesioned animals showed no significant heart rate conditioning (mean= +4.3 beats/min). These findings suggest that neurons intrinsic to mMGN are involved in classically conditioned heart rate responses to single tones as well as in differential conditioning to more than one tone. These results are consistent with results from studies in other species that have demonstrated that MGN is critical for the development of cardiovascular and behavioral conditioned responses to aversive stimuli. LIDOCAINE INJECTIONS IN RED NUCLEUS ABOLISH NEURAL UNIT MODEL AND CONDITIONED RESPONDING IN STANDARD RABBIT EYEBLINK PARADIGM. A.J. Annala, P.F. Chapman and R.F. Thompson. Program in Neural, Informational, and Behavioral Sciences, University of Southern California, Los Angeles, CA 90089-1061.

The development of a neuronal unit "model" in the interpositus nucleus preceeding the conditioned nictitating membrane response in the rabbit is well established. A similar neuronal model develops in the red nucleus.

Under anesthesia, we inserted cannulae just above the anterior interpositus nucleus or the caudal (magnocellular) red nucleus. We also implanted recording electrodes in the red nucleus or anterior interpositus on the side contralateral to the cannula. After five days of recovery, the animals were trained and then overtrained on a standard eyeblink/nictitating membrane conditioning paradigm with tone and air puff. We then injected small amounts of lidocaine (1 ul of 4 % lidocaine) through the cannulae to produce temporary lesions of the interpositus nucleus or the red nucleus.

Injection of lidocaine in the red nucleus reversibly abolished conditioned responding but did not affect the multiple unit model in the interpositus. Injection of lidocaine in the interpositus reversibly abolished conditioned responding and the multiple unit model in the red nucleus. Control injections of saline resulted in no significant changes. The absence of changes in the interpositus neuronal model following reversible lesions of the red nucleus leads us to conclude the red nucleus is not the site of plasticity.

TRANSECTION OF THE MIDDLE CEREBELLAR PEDUNCLE ABOLISHES CLASSICALLY CONDITIONED EYELID RESPONSES IN THE RAT. R.W. Skelton, Dept. of Psychology, Univ. of Victoria, Victoria, B.C., CANADA, V8W 2Y2.

The middle cerebellar peduncle (MCP) has been shown to be essential to classical conditioning of eyelid responses in rabbits (Lewis et al., 1987). The present study tested the effects of electrolytic lesions and knife cuts to the MCP on retention of eyelid conditioned responses (CR) in rats.

Male hooded rats were prepared with subcutaneous EMG electrodes for recording CRs and transorbital electrodes for delivery of eyeshock. In addition, lesion electrodes (or guide cannulae) were implanted bilaterally into the MCP (or 1 mm dorsal to it). After recovery from surgery, each rat was trained to a criterion of 80% CRs in a Pavlovian delay paradigm which paired a 380 msec tone CS with a 100 msec eyeshock unconditioned stimulus (2-4 mA, 60 Hz). The MCP was then destroyed bilaterally by passing anodal current through the lesion electrodes or a knife through the guide cannulae.

Transection of the MCP by either means severely disrupted CRs without impairing either startle responses to the tone or unconditioned responses to the eyeshock. In most cases, the cerebellum itself was undamaged. These results confirm and extend previous evidence that the MCP is a critical afferent to the cerebellum for eyelid CRs. KAINIC ACID LESIONS OF THE CEREBELLAR CORTEX ABOLISH THE CLASSICALLY CONDITIONED NICTITATING MEMBRANE RESPONSE OF THE RABBIT. M.J. Hardiman, M. Glickstein and C.H. Yeo. Dept. Anatomy, University College London, London WC1, U.K.

Discrete aspiration lesions of cerebellar cortex abolish the classically conditioned nictitating membrane response (NMR) of the rabbit (Yeo et al, Behav. Brain Res. 13:261,1984). Thompson and his colleagues failed to replicate this finding. They concluded that the cerebellar cortex is not necessary for conditioning (Lavond et al, Exp. Brain Res. 67:569,1987) and that the cerebellar nuclei are the site of plasticity crucial for NMR conditioning (McCormick and Thompson, Science 223:296,1984).

Here we used kainic acid to make fibre-sparing lesions of cerebellar cortex. NMR conditioning, previously established by pairing light and white noise conditioned stimuli (CS) with periorbital electrical stimulation, was abolished following kainic acid lesions of lobule HVI with damage to adjacent parts of lobule HVII and V. There was no reacquisition within 4000 trials over 20 sessions. Unpaired presentation of the CS revealed no long latency conditioned responses.

These fibre-sparing lesions did not exert their effect by depriving the deep nuclei of their climbing fibre collaterals since the inferior olive was intact. We confirm that the cerebellar cortex is essential for NMR conditioning. (SPON: EBBS)

SPATIAL NAVIGATION: EVIDENCE FOR CEREBELLAR INVOLVEMENT FROM pcd NEUROLOGICAL MUTANTS. K.M. Hamre, C.R. Goodlett and J.R. West. U. of Iowa, Dept. of Anatomy, Iowa City, IA 52242.

The ability to perform spatial navigation efficiently in the Morris water maze task is known to depend on normal hippocampal function. However, we have found that early postnatal alcohol exposure in rats, which had no significant effects on hippocampal cell numbers but caused severe reductions in cerebellar Purkinje cells, resulted in impairments in spatial navigation. To examine more directly whether Purkinje cell loss may produce spatial navigation deficits, we tested Purkinje Cell Degeneration (pcd) neurological mutant mice, their littermate controls (+/?) and C57BL/6J (B6) mice in the Morris maze. Groups of mice were tested beginning at either 30, 45 or 110 days of age. At all three ages the B6 and +/? groups acquired the spatial problem. The pcd mice failed to improve performance on the hidden platform task, but had only a mild impairment on the visible platform task. To determine whether the impaired spatial performance could be due to secondary cell loss in the hippocampus, pyramidal cells were counted at a mid-temporal level in 60-day-old mice in 5 µm sections. In all of the areas counted (CA4, CA3 and CA1), no differences in cell numbers were observed among the 3 groups. These data suggest that the cerebellum may also be essential to the performance of a spatial navigation task. (Supported by NIAAA grant #AA07313 to J.R.W.)

316.14

LESIONS OF THE PARABRACHIAL NUCLEI INTERFERE WITH THE FORMATION OF CONDITIONED FLAVOUR AVERSIONS. G.M. Martin[1], M. Gans[2], and D. van der Kooy[2]. [1]Dept. of Psychology Memorial University, Newfoundland, [2] Dept. of Anatomy, University of Toronto, Toronto M5S 1A8.

Neuroanatomical data suggest that the parabrachial nuclei could serve an important role in the formation of conditioned flavour aversions since lateral portions of the parabrachial nuclei receive visceral projections and medial portions receive gustatory projections. We removed the neuronal cell bodies of the lateral or medial parabrachial nuclei with bilateral injections of 0.2 ul of 4.0% ibotenic acid. Animals were given a 0.1% saccharin solution to drink and were injected i.p. with 15mg/kg of morpine or a vehicle injection immediately after saccharin removal. Animals with lateral lesions did not form a saccharin aversion, while sham and medial lesioned animals did. During the second training session the animals were permitted access to a 2.0% vinegar solution and were injected i.p. with either 50mg/kg of LiCl, 1 mg/kg of methscopolamine or their saline vehicle after vinegar removal. The animals with lateral lesions did not form as large a conditioned flavour aversion as the sham and medial lesioned animals. Control tests showed that animals with lateral lesions could taste the flavours. These data indicate that the lateral portions of the parabrachial nuclei are important to the formation or recall of conditioned flavour aversions.

316.15

VISUAL CONCEPT OF FOOD/NON-FOOD IN PIGEONS -EFFECTS OF ECTOSTRIATAL LESIONS-
S.Watanabe. Department of Psychology, Keio Univ. Mita 2-15-45, Minato-Ku, Tokyo, Japan.

Two groups of pigeons were trained on food vs non-food objects. An experimental chamber was an operant chamber with a rectangular transparent pecking key behind which a conveyor belt was placed. The conveyor belt had 40 small cubicles each contained food or non-food object. One group was taught to peck the key when foods appeared and the other group was taught to peck when non-food objects appeared. Generalization to new objects was tested when the birds learned the task. Then the ectostriatum or neostriatum was damaged and the birds were retrained. Generalization was tested again after the relearning.

Both groups could learn the discrimination. They showed generalization to the objects which had not been presented during the discrimination training.

After the neostriatal lesion the birds maintained their discrimination, whereas the birds with ectostriatal lesion required longer training to relearn the task. The subjects with damaged neostriatum showed clear generalization after surgery but those with damaged ectostriatum showed weak generalization.

These results suggest that the ectostriatum has an important role in this concept discrimination.

316.16

FOLLOWING BRAIN LESIONS, IF EXPRESSED IN d' TERMS, MEMORY DECAYS AT NORMAL RATES.
J.L. Ringo, Department of Physiology, Univ. of Rochester Med. Ctr., Rochester, NY 14642

Data from the literature on the effect of various brain lesions on recognition memory in the monkey was examined. On the basis of percentage scores the published data can be interpreted to signify that the ability to recognize a previously seen object decays faster in macaques with brain lesions than it does in normal animals.

A re-analysis in terms of the d' of Signal Detection Theory or in terms of an arcsine transform of the percentage values shows, on the contrary, that the rate of "decay" from 0-600 sec is essentially the same in normal animals and in those with lesions. Indeed, the effect of the lesions is fully developed at the shortest times tested, and shows no differential loss as a function of delay between initial presentation and test.

An implication of this result is that the lesion effects are in initial recording or retrieval processes and not in retention or any relatively slow processes following initial presentation.

NEUROGLIA: MYELIN FORMING CELLS

317.1

CLONING AND EXPRESSION OF MYELIN ASSOCIATED GLYCOPROTEIN.
P. Johnson*, M. Tropak*, M. Arquint*, W. Abramow-Newerly*, R. Dunn* and J. Roder, Dept. of Medical Genetics, University of Toronto, Mt. Sinai Hospital Research Institute, Toronto, Ontario M5G 1X5

Myelin associated glycoprotein (MAG) is a 100 kD integral membrane protein that is thought to play a role in the neuron-glial cell interactions that precede myelination. We have cloned and sequenced MAG cDNAs from a rat brain λgt-11 library. Based on the complete cDNA sequence, MAG consists of a large extracellular domain (499 residues and a 90 residue intracellular portion with sites that are phosphorylated *in vivo*. An alternative form of MAG, differing only in the cytoplasmic domain and lacking a prominent site for tyrosine phosphorylation, arises from differential splicing. The expression of the two MAG variants is developmentally and spatially regulated. We have achieved high levels of recombinant MAG protein expression in transfected mammalian and insect cells. Recombinant MAG protein extracted from transfected NIH/3T3 cells and incorporated into liposomes was found to bind specifically to neuronal processes (collaboration with M. Schachner and R. Sadoul, Heidelberg, FRG) and we are currently mapping the binding domains by mutagenesis.

The extracellular domain of MAG contains five tandem repeats, approximately 90 residues in length, which share homology (20-30%) with the variable and constant domains of immunoglobulins and the neural cell adhesion molecule (N-CAM).

317.2

ISOLATION AND PARTIAL CHARACTERIZATION OF cDNA FOR HUMAN MYELIN-ASSOCIATED GLYCOPROTEIN (MAG).
J.R. MOLLER*, R.A. LAZZARINI* and R.H. QUARLES*. (SPON: V.L. Friedrich Jr.) NINCDS, NIH, Bethesda, MD 20892

The myelin-associated glycoprotein (MAG) is an adhesion molecule that is a member of the immunoglobulin superfamily and appears to be involved in the interaction of myelin-forming oligodendrocytes and Schwann cells with axons. There is evidence implicating MAG in the pathogenesis of human diseases such as multiple sclerosis and neuropathy associated with IgM gammopathy. Several laboratories have recently characterized cDNAs from rat brain, but there is evidence for biochemical differences in human MAG which may be relevant to human diseases. Therefore, a cDNA library obtained from the basal ganglia region of a one-day old infant was screened with a ^{32}P-labeled, full-length rat cDNA clone. A positive cDNA was identified and inserted into a pBluescript vector. Double stranded sequencing of the 3'-end of the cDNA has identified 83 bases of the non-coding region, a 16 amino acid signal sequence (D0), 122 amino acids of D1, and 45 amino acids of D2. Compared to the rat sequence, there is one amino acid difference in D0, three in D1, and none in the part of D2 so far sequenced. This corresponds to a 98% amino acid sequence homology. The arg-gly-asp cell attachment site in D1 is conserved, and there is an additional potential glycosylation site in D1 of human MAG in comparison to rat MAG.

PERIPHERAL NERVE PROTEOLIPID PROTEIN: ISOLATION AND CHARACTERIZATION OF A FULL LENGTH cDNA CLONE.
J. Kamholz*, T. Behrman* and Sandra Shuman*. (SPON. J. Cohen). Dept. of Neurology, Univ. of Pa. Sch. of Med., Phila., PA 19104

Proteolipid protein (PLP), a transmembrane protein, is the major structural protein in central nervous system (CNS) myelin. Three messenger RNAs (mRNAs) encoding PLP are found in rat brain. Two of these, 3.2 and 1.6 kb in length, share a common PLP coding sequence and differ only in their sites of polyadenylation. A third transcript of 2.4 kb, produced by alternative splicing, encodes a PLP with an altered coding region (DM-20). PLP expression has recently been demonstrated in the peripheral nervous system (PNS). The PNS PLP is localized in Schwann cells, but is not found in the myelin sheath. Northern blots of rat sciatic nerve RNA probed with a PLP cDNA reveal mRNAs of 3.2 and 1.6 kb, similar in size to those found in the CNS. In order to understand the difference in PLP localization in the PNS or CNS, we have characterized several PLP cDNA clones isolated from a rat sciatic nerve cDNA library. Two overlapping cDNA clones of 1.4 and 2.4 kb encode an approximately full length cDNA of 3.2 kb. DNA sequence analysis demonstrates that a portion of the 5' untranslated region (70 bp), the coding region (834 bp) and a portion of the 3' untranslated region (500 bp) of the PNS PLP mRNA, are identical to the rat brain PLP cDNA sequence. Restriction enzyme analysis of the remainder of the 3' untranslated region is also identical to the predicted from the rat brain PLP cDNA sequence. These date demonstrate that the PNS and CNS PLP mRNAs have the same primary sequence and suggest that the absence of PLP from PNS myelin is due to mechanisms acting at the posttranslational level.

317.4

THE ROLE OF SUGAR RESIDUES IN THE SORTING OF THE MYELIN PROTEIN, Po.
M.T. Filbin* and G.I. Tennekoon*. (SPON: R. Johnson). Department of Neurology, The Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

The decrease in Po protein of myelin after axotomy is accompanied by a change in its glycosylation pattern, from a complex to a high-mannose type glycoprotein. It has been suggested that this change results in the diversion of Po to the lysosome where it is degraded. To investigate this, we expressed Po in Chinese hamster ovary (CHO) cells, whereby changes in glycosylation could be directly correlated with changes in targeting. A plasmid containing two selectable markers and the Po-cDNA under the control of the metallothionein promoter was constructed and used to transfect CHO cells with complete glycosylation enzymes and mutant CHO cells that synthesized only high mannose type glycoproteins. Initial selection was with the neomycin analogue G418. To obtain an abundance of Po protein for analysis, cells which had co-amplified the Po-cDNA were selected for by the methotrexate/dihydrofolate reductase strategy (stepwise increase of methotrexate up to 1 μM). Western blot analysis showed several clones from both cell lines with increased Po protein (2-5 fold). Immunofluorescence studies with both cell types showed a speckled pattern resembling plasma membrane staining indicating that Po glycoprotein does reach the plasma membrane. The two cell lines permit a detailed assessment of the role of carbohydrates in intracellular sorting of Po protein.

TURNOVER OF FATTY ACIDS COVALENTLY BOUND TO PROTEOLIPID PROTEIN (PLP). M.B. Lees and O.A. Bizzozero*. E.K. Shriver Center, 200 Trapelo Rd., Waltham MA 02254.

Fatty acid acylation of PLP occurs actively in adult animals, as well as during rapid myelination, consistent with an active metabolism of the acyl groups. To determine the turnover rate of the acyl groups attached to PLP, forty day old rats were injected intracranially with [^{3}H]palmitic acid and after time intervals from 0.5h to 15 days, myelin proteins were analyzed by SDS-PAGE. Incorporation of the label into PLP reached a maximum after 2 h and declined after 48 h, with a half life of approximately 8 days. Even after 15 days, >87% of the radioactivity associated with PLP could be released with NH_2OH, indicating that it was bound in ester linkage. However, analysis of the ester-bound radioactivity revealed a high degree of fatty acid interconversion. After 1 day, 15% of the protein-bound radioactivity was present in fatty acids other than palmitic whereas after 15 days, more than 50% of the original labeled palmitate had been elongated and/or oxidized. When these values were used to correct for interconversion, the half life of palmitate attached to PLP was only 3-4 days. This rate was slightly faster than that of phosphatidylcholine acyl chains (6-8 days) and much faster than that of the protein moiety calculated under the same experimental conditions (>28 days). These results suggest that acylation of PLP is a dynamic process involved mainly in myelin maintainance and function. Supported by NIH grants NS 16945 HD 05515 and HD 04147.

317.6

IN VITRO FATTY ACID ACYLATION OF Po GLYCOPROTEIN. O.A. Bizzozero* and L. Good*. (Spon: T. Fox). E. K. Shriver Center, 200 Trapelo Rd., Waltham MA 02254.

Po glycoprotein, the major PNS myelin protein, contains 1 mol of ester bound fatty acid and acylation has been demonstrated in vivo. To determine when the fatty acid is attached during the posttranslational processing of the protein, we have studied the kinetics of Po acylation in vitro. Sciatic nerve slices from 10-day old rats were incubated with a mixture of [^{3}H]palmitate and [^{14}C]amino acids and myelin proteins were analyzed by SDS-PAGE. After incubation with [^{3}H]palmitate, most of the protein radioactivity was present in Po (28K). The label associated with Po was identified as palmitic acid bound in ester linkage. The kinetics of entry of newly synthesized and palmitoylated Po into myelin were similar, suggesting that the addition of palmitate occurs near the site of synthesis. Moreover, addition of cycloheximide immediately stopped the synthesis and acylation of total nerve Po, suggesting the absence of a large pool of unacylated Po. Inhibition of protein transport with monensin or colchicine also blocked the entry of acylated Po into myelin. The reaction is a net addition of fatty acid. Developmental studies showed that the synthesis and acylation of Po are maximal during rapid myelination. In conclusion, the results indicate that fatty acids are added to Po in the early stages of the posttranslational processing and not in myelin. Supported by NIH grants 05515 and HD 04147.

317.7

PHOSPHORYLATION OF CHARGED ISOMERS OF HUMAN MYELIN BASIC PROTEIN: EFFECT ON SECONDARY STRUCTURE J.J. Ramwani*, R.M. Epand,* T.E. Mijani* and M.A. Moscarello* (SPON. G. Rajakumar)
Res.Inst. The Hospital for Sick Children,Toronto, Ont. M5G 1X8
Dept.of Biochem., McMaster University, Hamilton, Ont. L8N 3Z5

Myelin basic protein (MBP) represents the major extrinsic protein of the myelin membrane. It can be fractionated into several charged isomers (components) on the cation exchange column. In the present study effect of phosphorylation on the secondary structure of four of these components was investigated by circular dichroism.
MBP components were phosphorylated with human brain white matter protein kinase C. The extent of phosphorylation varied considerably from 1.8 moles phosphate/mole protein in component 1 (C-1) to 6.1 moles phosphate/mole protein in component 4 (C-4). All non-phosphorylated components exhibited varying amounts of β structure, random coil and turns, but no α helix. Phosphorylation of these components induced changes in secondary structure and caused an increase in β structure to 40-45% for all components. The increase in β structure could not be reversed by removal of 50% of phosphate by acid phosphatase. The other 50% was inaccessible to the enzyme suggesting it occupies a critical site involved in the stabilization of the β structure. Isolation of the critical site is under way.
In conclusion, components of MBP are phosphorylated to a different extent and phosphorylation of a single critical site may be influencing the stabilization of β structure.

317.8

IDENTIFICATION OF THE Ca^{++}/CALMODULIN-DEPENDENT PROTEIN KINASE IN RAT BRAIN MYELIN FRACTION. Y. Huang* (SPON: M. Stanley). Div. of Neuroscience, New York State Psych. Inst., 722 West 168th Street, New York, N.Y. 10032.

The process of protein phosphorylation and dephosphorylation is considered to be an important mechanism utilized by eucaryotic cells for post-translational regulation of protein function. Many of the biological effects of Ca^{++} in central nervous system are mediated by Ca^{++}/Calmodulin (CaM) dependent protein phosphorylation. Phosphorylation process is also found in brain myelin and myelin basic protein (MBP) is a major phosphoprotein. In the course of our characterization of post synaptic densities (PSDs) in human and rat brains, we have detected the presence of a Ca^{++}/CaM-dependent protein kinase capable of phosphorylation of polypeptide doublets of 48/50 kDa and 56/58 kDa in rat brain myelin fraction. Phosphorylation of these polypeptide doublets is stimulated in the presence of the Ca^{++} ions and CaM and is inhibited by the addition of the ganglioside GM1. The phosphorylation assay included 50 mM PIPES (pH 7.0), 0.5 mM Ca^{++}, 0.2 mM EGTA, 1 mM DTT, 1 mM Mg^{++} and 13 uM $^{-32}$P-ATP, and various effectors including CaM and gangliosides (10 ug). Proteins were subjected to gradient PAGE containing SDS. Gels were then exposed to X-ray film for autoradiographic localization of phosphoprotein bands. The ratio of intensity of these phosphoprotein bands between polypeptide doublets of 48/50 kDa and 56/58 kDa is 3 : 1 while 48 kDa and 50 kDa is 1-1.5 : 1 in autoradiography. The preliminary results suggest that this may be a Ca^{++}/CaM-dependent protein kinase with multiple isoenzymatic forms and/or its location in brain myelin fraction may produce differential changes in its activity.

317.9

EXPRESSION OF TRANSFERRIN AND THE TRANSFERRIN RECEPTOR BY OLIGODENDROCYTES IN VITRO. W.P. Bartlett and J.R. Connor. Dept. Anat., M.S. Hershey Med. Ctr., Hershey, PA 17033.

Transferrin, the iron mobilization protein, has been found in oligodendrocytes in the rat, mouse, and human CNS. We have undertaken the following experiment to demonstrate 1) whether oligodendrocytes grown in vitro accumulate transferrin (Tf) and express the Tf receptor, 2) the temporal sequence of Tf and Tf receptor appearance in relation to galactocerebroside and myelin basic protein. Cells were examined immunohistochemically in dissociated mixed glial cell cultures from 3-4 day old mouse pups. Tf receptor positive cells appear before the expression of GalC immunoreactive cells; an oligodendroglial marker. These cells are small, round, process-bearing cells which lie on the surface of the astrocytic bed layer. When immunostained prior to fixation, the pattern of staining is restricted to the soma and occasionally the proximal portion of a process. The Tf receptor positive cells also immunoreact with antisera to MBP and GalC. Furthermore, MBP and GalC cells immunostain with Tf. However, while MBP and GalC positive sheets of myelin-like membrane are visible, Tf is confined mostly to the perikaryal cytoplasm. This study reveals that Tf and its receptor are present in oligodendrocytes in culture and suggests that the appearance of the Tf receptor may be an early indication of a differentiated oligodendrocyte. TRANSFERRIN AND ITS RECEPTOR ARE EXPRESSED BY MYELINATING SCHWANN CELLS. H.H. Lin*, S. Toland*, and J.R. Connor. Department of Anatomy, M.S. Hershey Medical Center, Hershey, PA 17033.

A substance from ground sciatic nerve called "sciatin" was shown to be capable of replacing the requirement for transferrin (Tf) in cultures of chicken myoblasts. This substance was later shown to be Tf, but the source of the Tf in the sciatic nerve has not been determined. In this study, we demonstrate immunohistochemically that Tf and the Tf receptor are expressed by Schwann cells in the sciatic nerve, but not by those in the thoracic sympathetic trunk or vagus nerve. Following crush of the sciatic nerve Tf, the Tf receptor and galactocerebroside (GalC) are not detectable in the distal nerve segment. By 5 weeks, post-crush some GalC and Tf receptor staining is present, but not Tf. GalC, Tf receptor, and Tf are all present by 8 weeks after the crush injury, but the immunohistochemical staining pattern is abnormal. The abnormal staining pattern continues into the 10th week post-crush. The results of the crush injury study show that the expression of the Tf receptor precedes the accumulation of Tf by Schwann cells and is at least coincident with the expression of GalC. These data support the general hypothesis that Tf accumulation by myelinating cells (oligodendrocytes and and Schwann cells) is a necessary condition for the production of myelin.

Monoclonal Antibody OLIGO Recognizes Presumptive Oligodendrocytes Prior to Myelination.

B. Friedman, M. Constantine-Paton & S. G. Waxman. Dept. Neurology, Yale Univ. Sch. Med., VA Med. Cntr., West Haven, CT 06516 & Dept. Biology, Yale Univ., New Haven, CT 06520.

Previous work has shown that the monoclonal antibody OLIGO recognizes mature oligodendrocytes, myelin sheaths and immature myelin related oligodendrocytes in tadpoles.[1] The present immunocytochemical study focuses on cells that have not formed myelin but are recognized by OLIGO. The cells formed networks of immunostained processes (Figure). These processes closely resemble processes elaborated by rat oligodendrocytes in cultures free of neurons.[2] Thus our cells may be premyelinating oligodendrocytes. The longest processes of our OLIGO stained cells had a range of 48 μm +/− 10 μm (SD) (11 cells, 2 tadpoles). Process from adjacent stained cells mingled and appeared to contact each other. The observed overlap of processes suggests that presumptive oligodendrocytes may interact during early stages of development.

THE EXPRESSION OF MYELIN ANTIGENS, GFAP, AND TRANSFERRIN AND ITS RECEPTOR IN THE DEVELOPING RAT OPTIC NERVE. J.R. Connor and H.H. Lin* (SPON: R. Bohn). Dept. of Anatomy, M.S. Hershey Medical Center, Hershey, PA 17033.

Extrinsic factors (non-neuronal) are thought to exist which influence or possibly control the process of myelination. Recently, the iron transport protein, transferrin (Tf), has been found in oligodendrocytes suggesting that iron and Tf could play a role in myelinogenesis. In the present study, the developing rat optic nerve was examined immunohistochemically with antibodies to myelin basic protein; MBP and the transferrin receptor; Tfr, galactocerebroside, Tf, and glial fibrillary acidic protein. Tfr and Tf positive cells were seen near blood vessels at PND 8. Patches of MBP and GalC positive fibers were also present. The number of Tfr positive cells peaked between PND 15-21 and were generally perivascular. The number of Tf, GalC and MBP cells continued to increase into adulthood and were found throughout the optic nerve. These results demonstrate that Tfr positive oligodendrocytes appear at the time myelin begins and are most numerous during the highest rate of myelination and then decrease thereafter. Furthermore, the presence of Tf in oligodencrocytes precedes the expression of MBP and GalC in oligodendrocytes. These data are further support of the hypothesis that Tf accumulation by oligodendrocytes is a necessary condition for the process of myelination.

In Vitro Analysis of Neuroglial Cells Isolated During Demyelination and Remyelination.

R. Armstrong*, V.L. Friedrich, Jr., K.V. Holmes*, and M. Dubois-Dalcq. NIH, Bethesda, MD 20892 and USUHS, Bethesda, MD 20854.

During development a subpopulation of neuroglial cells (O-2A progenitors, oligodendrocytes, and type-2 astrocytes) is involved in CNS myelination. To analyze the potential role of this subpopulation in the course of demyelination and remyelination we induced demyelinating lesions of the spinal cord in 28d old C57Bl/6 mice by intracerebral injection of MHV-A59 coronavirus. At 4-5 wks post-infection (p.i.) vacuoles and demyelinated axons were evident in spinal cord white matter. Remyelination was already beginning and resulted in extensive myelin repair in the following 8-12 wks.

Neuroglial cells were isolated from spinal cord by combined enzymatic and mechanical dissociation along with Percoll gradient centrifugation, cultured for 1d, and stained simultaneously for O4 antigen, galactocerebroside (GC), and glial fibrillary acidic protein (GFAP) with 3-color immunofluorescence.

Control cultures contained mainly process-bearing cells which expressed O4, a developmental marker for intermediate and mature O-2A lineage cells. The majority of O4+ cells also expressed GC, an oligodendrocyte marker. Remaining O4+ cells were either O4+GFAP+ (a phenotype of type-2 astrocytes) or O4+ only (a characteristic of an intermediary in the O-2A pathway). Cultures of lesioned spinal cord (4-5 wks p.i.) exhibited a striking increase in the number of O4+GFAP+ and O4+ only cells. More O4+GC+ cells were apparent also, however this increase was proportionally smaller than was noted for the other two phenotypes. O-2A lineage type cells labeled *in vivo* with 3H-thymidine could be isolated from lesioned but not control adult spinal cord. These findings may be explained by gliogenesis and/or phenotypic changes of O-2A lineage cells which may occur in the course of remyelination, and which can be analyzed in this *in vitro* system.

317.14

EFFECT OF HISTAMINE ON PROLIFERATION OF CULTURED SCHWANN CELLS. Brian M. Gordon* and Jun E. Yoshino. Program of Neuroscience, Dept Psychology, Colgate Univ, Hamilton, NY.

Axolemma-(AEF) and myelin-enriched (MEF) fractions stimulate the division of Schwann cells (Yoshino et al., 1984, J Cell Biol. 99:2309). The addition of ammonium chloride, phorbol esters, calcium chelators, or lithium modulates the mitogenic activities of these fractions. We examined the effect of histamine, a secretory product of mast cells, on Schwann cell proliferation, because mast cells have been identified as having possible roles in the origin of neurofibromas and during demyelinating diseases.

Cultured Schwann cells were prepared from 3d rat sciatic nerve. Schwann cells treated with histamine (0.5-2.0mM) incorporated the same levels of ^{3}H-thymidine as controls (no histamine). The amount of ^{3}H-thymidine incorporated by Schwann cells treated with 2mM histamine and the MEF was greater than the level of ^{3}H-thymidine accumulated by those cells receiving only myelin. The increase in ^{3}H-thymidine uptake ranged from 20%-50% depending upon the concentration of the MEF. By autoradiography, 2mM histamine alone did not increase the number of labelled cells. The addition of 2mM histamine to MEF treated Schwann cells resulted in a 50% increase in labelled cells. In contrast, the addition of histamine did not alter the mitogenicity of the AEF. Thus, histamine specifically enhances Schwann cell proliferation induced by MEF, and may play a role in cellular proliferation occurring in certain disease states.

DEVELOPMENTAL REGULATION OF CHANNEL EXPRESSION IN OLIGODENDROCYTES. H. Sontheimer*, J. Trotter*, M. Schachner and H. Kettenmann* (SPON: G. ten Bruggencate). Dept. of Neurobiology, Univ. Heidelberg, INF 364, 6900 Heidelberg, FRG. We characterized membrane currents in cultured brain derived murine oligodendrocytes at different developmental stages, using the patch-clamp technique. Recordings were made from O10-positive/O4-positive more mature oligodendrocytes with large somata (>15 um) and many processes, O4-positive/O10-negative immature oligodendrocytes with smaller somata (10-15 um) and less than 5 processes, and O4-negative cells which probably are precursor cells with small somata (<10 um) and 1 to 3 processes. In more mature oligodendrocytes we found no voltage activated currents, but a marked inward rectification. Currents were 4-AP insensitive. In contrast, immature oligodendrocytes expressed an inactivating and a noninactivating K^+-current which could be completely blocked by 4-AP and TEA as previously described for astrocytes. The current-voltage curve showed a strong outward rectification. In addition, we observed sodium currents which peaked at about -20 mV in 4 out of 39 immature oligodendrocytes. Precursor cells expressed K^+-currents similar to those seen in immature oligodendrocytes, but in addition sodium currents were always observed. Thus channel properties of oligodendrocytes are developmentally regulated, with sodium and voltage activated potassium currents expressed early and lost during differentiation, and with voltage insensitive currents appearing at later stages.

317.16

MYELIN PROTEIN BIOSYNTHESIS BY CERVICAL SYMPATHETIC SCHWANN CELLS IN VIVO AND IN VITRO. K. R. Brunden*, A. J. Windebank, and J. F. Poduslo. Membrane Biochem. Lab., Depts. Neuro. & Biochem./Molec. Biol., Mayo Fdn., Rochester, MN 55905

More than 99% of Schwann cells (SCs) from the cervical sympathetic trunk (CST) are non-myelinating. Immunoblot analysis of endoneurial homogenates indicates that the levels of the 28 kD P_0 glycoprotein and the 14-21 kD MBPs found in adult rat CST are very low compared to those found in the sciatic nerve. Likewise, [^{3}H]Man and [^{3}H]amino acid incorporation studies reveal that the level of P_0 biosynthesis in the CST is greatly reduced relative to that of the sciatic nerve. SCs derived from adult CST will myelinate dorsal root ganglia (DRG) neurite networks if grown in the presence of serum. Immunoblot analysis of these cultures demonstrates the presence of both P_0 and MBPs. CST SCs will not myelinate DRG neurites if grown in the absence of serum, but these SCs do synthesize a 28 kD glycoprotein at levels comparable to those seen in myelinating cultures when assayed by [^{3}H]Man incorporation. This glycoprotein co-migrates with [^{3}H]Man-labeled P_0 from myelinating cultures during SDS-PAGE, and like P_0 it shows a reduction of M_r in the absence of reducing agent. A similar glycoprotein is synthesized by SCs derived from 15-day embryonic DRG co-cultured with neurites in the absence of serum. The active biosynthesis of a putative P_0 species by the cultures grown without serum would suggest that contact with myelin-supporting axons is sufficient to induce myelin protein biosynthesis even if myelin assembly is not occurring. (NS20551)

MYELIN DEGRADATION IN SCIATIC NERVE EXPLANTS.
D.L. Novicki*, J.F. Goodrum* and T.W. Bouldin*. (SPON: E. Costantino-Ceccarini). Pathology Dept. and Biological Sciences Research Center, University of North Carolina, Chapel Hill, NC 27599-7525

Studies from several laboratories have variously attributed the phagocytosis and degradation of myelin during Wallerian degeneration solely to fibroblasts, hematogenous cells, vascular pericytes, Schwann cells, endoneurial cells that have transformed into phagocytes, or to combinations of these cell types. This controversy is unlikely to be resolved by studies based solely on morphological evaluation of degenerating nerve in vivo. We have been using explant cultures of sciatic nerve endoneurial tissue from 35-45 day old male Long-Evans rats to investigate the potential of endoneurial cells to engulf and/or degrade myelin in the absence of hematogenous cells.

Peripheral nerve explants were maintained for 1 day to four weeks and examined for myelin P_0 protein by SDS-PAGE. The P_0 levels decreased approximately 50% after 4 weeks in culture. Ultrastructural examination of explants indicated that the cellularity of the explants decreased as time in culture increased and that some myelin remained undegraded. Fibroblasts, Schwann cells and macrophage-like cells all contained myelin debris. Nonspecific esterase activity, which is a macrophage marker, was present in some Schwann cells as well as in macrophage-like cells. Autoradiography following exposure to ^{3}H-thymidine demonstrated that cells within the explant and cells which had grown out were capable of proliferating. Studies are underway to determine if the macrophage-like cells are capable of proliferation in the presence or absence of conditioned medium containing colony stimulating factor.

We conclude that rat endoneurial tissue contains cells that are capable of phagocytosis and breakdown of myelin, and that these processes can occur in nerve in the absence of infiltrating hematogenous elements. Supported by ES 01104.

THE DEVELOPMENT OF OLIGODENDROGLIA IN CULTURE.
S.E. Poduslo, K. Miller*, and C.H. Pak*. Johns Hopkins Univ. Sch. of Med., Dept. Neurology, Baltimore, MD 21205.

Oligodendroglia elaborate extensive quantities of membranes which enfold segments of axons to form the multilamellar highly compacted myelin sheath. It is possible to obtain oligodendroglia by either differential plating methods or by bulk-isolation techniques. The differential plating method involves primary cultures prepared from neonatal rat brain. The bulk-isolation technique uses brain tissue from actively myelinating adolescent rat or dissected white matter from bovine brain. The rat oligodendroglia elaborate extensive networks of processes in culture but produce no myelin. Bovine oligodendroglia in suspension cultures produce whorls of membrane which biochemically appear to be early forms of myelin. Thus the rat oligodendroglia appear to be less differentiated than bovine cells. The different stages of oligodendroglia were analyzed for the synthesis of specific lipids in the presence of various agents known to affect cell differentiation. In this study, evidence of further development in culture would be increased synthesis of cerebrosides, a myelin component. Retinoic acid and thyroid hormone appeared to have a positive effect on cerebroside synthesis, while 5-azacytidine and phorbol esters had a negative effect. Ketone bodies had a slight stimulatory effect. Other agents such as sodium butyrate had no effect. (Supported by grants from NIH NS 14577 and HD 16956).

CHANGES IN CNS MYELIN FORMATION IN RESPONSE TO A REDUCTION IN OLIGODENDROCYTE PRECURSORS. T.J. Sims and S.A. Gilmore. Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205.

Exposure of lumbosacral spinal cords of 3-day-old rats to ionizing radiation induces a marked reduction in glia. Although myelin formation is delayed in both dorsal (DF) and ventral (VF) funiculi, the axons remain healthy and increase in diameter. Reconstitution of the glial population occurs with time but differs between these funiculi. Myelin formation by oligodendrocytes and Schwann cells occurs dorsally, whereas oligodendrocytes are responsible for this delayed myelination ventrally. Differences in the pattern of oligodendrocyte myelination are observed more frequently in the DF where areas of white matter myelinated by Schwann cells are interspersed with those sparsely populated by oligodendrocytes. Myelin in these latter areas appears to be derived from two different forms of oligodendrocytes. One appeared normal in that large cytoplasmic processes extended short distances and gave rise to myelin sheaths of normal thickness. Emanating from the second form of oligodendrocyte were many small processes which extended for considerable distances amongst the axons and formed myelin sheaths that were extremely thin relative to axonal diameter. The general impression is that this oligodendrocyte process "overextended" itself in order to myelinate a sizeable number of large axons. The explanation for the two different forms of oligodendrocytes is not clear nor is the dorsal-ventral difference in their frequency. Perhaps the normal appearing one was present and involved in myelin formation prior to irradiation, whereas the second form, generated after exposure, matured in an environment of large diameter, non-myelinated axons expressing an affinity for oligodendrocytes which exceeded that existing at the usual time of myelination. (Supported by NIH Grant - NS 04761).

317.20

GENERATION OF CYTOTOXIC LYMPHOCYTES FOR HUMAN GLIAL CELLS IN CULTURE. T.C.G. Ruijs*, A. Olivier*, M.S. Freedman*, J.P. Antel. Montreal Neurological Institute, McGill Univ., Montreal, Quebec, Canada H3A 2B4.

Cellular immune mechanisms directed against the myelin-forming oligodendrocytes (OGC) could contribute to tissue injury in human demyelinating disease. We attempted to measure susceptibility of OGC to cell-mediated cytotoxicity using OGC enriched adult human glial cell cultures derived from surgically resected tissue in a ^{51}Cr release assay. In a lectin-dependent, non-MHC restricted system, Concanavalin A stimulated lymphocytes were shown to lyse glial cells (mean specific lysis 30% in 4:1 ratio). Allogeneic CD8+ lymphocytes activated in a mixed lymphocyte reaction against glial cell donor's lymphocytes also induced specific cytolysis of the donor's glial cells. The CD8+ subset comprises MHC class I restricted antigen specific cytotoxic T lymphocytes, as well as non-MHC restricted natural killer (NK) cells. OGC were not lysed by non-activated lymphocytes, the usual means to assay for NK cell activity. Immunohistochemical studies indicated that the OGC (GalC+ cells) express MHC class I but not class II antigens in vitro.

ION FLUX AND PATCH CLAMP MEASUREMENTS OF PARTIALLY PURIFIED AND RECONSTITUTED GLUTAMATE-ACTIVATED ION CHANNELS. E.K. Michaelis, A.M. Ly*, M. Uto* and T. Kuwana*. Department of Pharmacology and Centers for Biomed. and Bioanalyt. Res., Univ. of Kansas, Lawrence, KS 66046.

Treatment of rat brain synaptic membranes with the non-ionic detergents Triton X-100 or n-octylglucoside in the presence of neutral phospholipids or glycerol plus phospholipids, led to successful solubilization and subsequent reconstitution of glutamate-activated Na^+ channels into liposomes. Partial purification of glutamate-binding proteins through affinity batch chromatography as described previously (Chen et al., 1988, J. Biol. Chem. 263, 417) produced both enrichment of glutamate-sensitive ion channels in reconstituted liposomes and of the ~ 70 and 63 kDa glutamate-binding proteins. Few other proteins were also detected in a number of our preparations (e.g. 90, 47, and 32 kDa). L-Glutamate (8-10 μm) caused a transient transmembrane potential in liposomes that was detected as the uptake of the anion probe [^{14}C]SCN^-. The receptor agonists ibotenate, quisqualate and N-methyl-D-aspartate also enhanced SCN^- uptake whereas the antagonists L-glutamate diethyl ester and D-2-amino-5-phosphonopentanoic acid blocked the effect of L-glutamate on SCN^- flux. L-Glutamate-activated ion channels could be detected in membrane bilayers formed at the tip of patch pipettes from liposomes reconstituted with the partially purified glutamate-binding proteins. [Supported by grants DAAL 03-86-K-0086 and 03-88-K0017 from ARO; AA 04732 from NIAAA].

ACTIONS OF CNQX IN AREA CA1 OF RAT HIPPOCAMPAL SLICES. G.L. Collingridge*, S.N. Davies*, R. Yates*, J.F. Blake*, and M.W. Brown* (SPON: W.W. Anderson), Departments of Pharmacology and Anatomy, University of Bristol, BS8 1TD.

We have studied the effects of 6-Cyano-2,3-dihydroxy-7-nitroquinoxaline (CNQX) in hippocampal slices (in 1 mM Mg).

CNQX (1-30 µM) produced a parallel shift in the log-dose response curves and gave the following Kd values (µM): α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA), 2; kainate, 2; N-methyl-D-aspartate (NMDA), >30. Low frequency (0.033 Hz) synaptic responses, elicited by low intensity stimulation of Schaffer collateral-commissural fibres, were blocked by 10 µM CNQX. However, with high intensity or high frequency (100 Hz, 0.5-1 s) stimulation a component remained which was reversibly blocked by a selective NMDA antagonist.

Field EPSPs were evoked by stimulation of two independent sets of convergent fibres. Long-term potentiation was induced specifically in one set and the stimulus intensity adjusted so that both pathways elicited EPSPs of a similar size. CNQX blocked both the potentiated and the non-potentiated response in parallel.

We conclude (i) NMDA receptors can be synaptically activated after blockade of non-NMDA type receptors and (ii) the same type of CNQX-sensitive receptor is likely to mediate both potentiated and non-potentiated responses.

CNQX was generously provided by Dr. T. Honoré (Ferrosan).

Mg^{++}, EXCITATORY AMINO ACIDS, AND DORSAL ROOT POTENTIALS IN THE FROG SPINAL CORD. J.C. Hackman and R.A. Davidoff. Neurophysiology Lab., VAMC and Dept. of Neurology, Univ. of Miami School of Med., Miami, FL 33101.

The basis for the long duration dorsal root potentials (DRPs) in the in vitro frog spinal cord is unexplained. We investigated the role of Mg^{++} since most frog Ringer's solutions omit Mg^{++} although frog CSF contains 1mM Mg^{++}.

Rana pipiens were anesthetized on ice and the hemisected spinal cord and dorsal roots (DR) placed in a sucrose gap chamber. The peak amplitude, duration, and area of DRPs evoked by single DR stimuli were stored in a computer and analyzed using Asyst software.

DRP duration ($\bar{X}$8.6±2.1 s, HCO_3-buffered medium, 0mM Mg^{++}) and area (30.0±0.5 V/ms) were decreased by 75% and 80% in 1 mM Mg^{++}; the peak amplitude (14.1±0.7 mV) was only reduced by 24%. APV (10uM) diminished DRP amplitude and area by only 14% and 40% which suggests that 1 mM Mg^{++} has effects other than NMDA antagonism. Kynurenate (KYN, 2mM) reduced the DRP amplitude to 31±5% of control values. Further addition of bicuculline (25uM) reduced the DRP to 31±7% of the KYN amplitude suggesting that about 1/3 of the GABA-DRP is independent of excitatory amino acid transmission. 20mM Mg^{++} diminished the DRP to nearly the same level as did the combination of KYN and bicuculline.

In sum, 1 mM Mg^{++} dramatically decreases the duration and area of the amphibian DRP. In addition, synaptic release of excitatory amino acids appear to contribute to nearly 70% of the DRP generation. (Supported by VAMC Funds MRIS #1769 and #3369 and USPHS grant #17577)

318.4

COMPARISON OF CURRENTS PRODUCED BY ELECTROGENIC UPTAKE OF L-GLUTAMATE AND L-ASPARTATE IN GLIAL CELLS ISOLATED FROM TIGER SALAMANDER RETINA. H. Brew* (SPON: G. Hall) Dept. of Physiology, University College London, London, U.K.

L-glutamate evokes an inward current in whole-cell clamped retinal glial (Müller) cells, due to the activation of an electrogenic (and sodium-dependent) glutamate uptake system (Brew & Attwell, 1987). I report here that the Müller cell currents evoked by aspartate, I(asp), differ from those evoked by glutamate, I(glut).

The magnitude of currents evoked by L-aspartate (ASP) or L-glutamate (GLUT) obey Michaelis-Menten kinetics (apparent K_m is 20μM for glutamate, 3μM for aspartate, independent of voltage). The maximum currents evoked by these agonists are strongly voltage-dependent, with I(glut) having a different voltage-dependence than I(asp).

When 30μM GLUT and 30μM ASP are applied to a Müller cell simultaneously, the current produced is similar (in size and voltage-dependence) to that produced by 30μM ASP alone. This suggests that mostly ASP is binding to the carriers available and being transported, resulting in aspartate-type currents (as is predicted if ASP and GLUT are transported by the same uptake system, with K_ms as above, and differences in their cross-membrane transport).

The carrier's different affinities for these two neurotransmitters may mean that if they are ever co-released at synapses, aspartate could inhibit glutamate uptake by glia, thus enhancing glutamate's postsynaptic action. (Supported by the MRC and the Wellcome Trust)

INTRACELLULAR RECORDINGS OF A SLOW NMDA RECEPTOR MEDIATED SYNAPTIC POTENTIAL IN INFERIOR COLLICULAR SLICES. M.G. Pierson, K.L. Smith, and J.W. Swann. Wadsworth Center, N.Y. State Dept. of Health, Albany, N.Y. 12201

Using in vitro slices from immature rat brain, we have studied local current-stimulated events in disinhibited (2.5 μM bicuculline) inferior colliculus. Using extracellular electrodes (2 M NaCl) we recorded an initial field potential and a very slow (1-10 sec) field potential which was accompanied in some instances by concurrent afterdischarges. Intracellular recordings (4M KAc or 1M CsAc) revealed coincident synaptic events which included: 1) a bicuculline-sensitive ipsp (equilibrium potential, -70mV), 2) a fast voltage-independent epsp (equilibrium potential, 0mV) and 3) a strikingly large (eg. 30 to 40 mV), longlasting (up to 10 sec) synaptic potential. The latter potential was reversibly and selectively abolished by 10 μM micro-ejected droplets of D-APV, 2) exhibited voltage-dependency and 3) had an equilibrium potential of approximately 0mV. Thus we infer it to be an NMDA synaptic response. Because it was also reversibly abolished by increasing extracellular Ca^{++} (from 2 to 6 mM), it is likely that the slow synaptic potential is polysynaptic in origin. The extraordinary duration of the potential is suggestive of reverberating local circuit activity.

318.6

TWO DISTINCT QUISQUALATE RECEPTORS IN ISOLATED RETINAL GANGLION CELLS FROM RAT. Elias Aizenman, Andreas Karschin*, and Stuart A. Lipton. Div. of Neuroscience, Children's Hosp. and Harvard Med. Sch., Boston, MA 02115, and Max-Planck Inst. für Hirnforschung, D-6000 Frankfurt, FRG.

We have examined with patch electrodes the inhibitory actions of kynurenate and FG9065 (CNQX) on responses elicited by quisqualate and AMPA in isolated retinal ganglion cells from rat. In 16 of the cells (type *A* cells) in which both agonists were tested at their maximal concentrations, whole cell (V_H=-60 mV) responses produced by AMPA (60 μM) exceeded quisqualate (30 μM) induced responses by 20-130%. In these cells, responses to either of these two agonists were usually smaller than 100 pA (V_H=-60 mV). In a second group of cells (type *B* cells; n=10), quisqualate activated currents were 5-75% larger than those induced by AMPA. In most of the type *B* cells, whole-cell responses exceeded 100 pA (V_H=-60 mV) when either agonist was applied. Kynurenate (750 μM) and CNQX (10 μM) substantially (90%) and totally blocked AMPA responses, respectively, in all cells tested (*A* and *B* types) in a voltage-independent manner. In type *A* cells, kynurenate did not substantially affect (5%) quisqualate-induced currents, while CNQX blocked 35% of the response to this agonist. In type *B* cells, kynurenate inhibited 30-60% of the quisqualate-generated response, while CNQX blocked 80% of the current elicited by this drug. It is concluded that quisqualate can bind to two sites in rat retinal ganglion cells: (1) a receptor with a high affinity for quisqualate and a relatively lower affinity for AMPA; and (2) a second site which does not recognize AMPA and has a relatively low affinity for quisqualate. EFFECTS OF EXCITATORY AMINO ACIDS AND PEPTIDES ON ACUTELY-ISOLATED SPINAL DORSAL HORN NEURONS OF THE RAT. K. MURASE, P-D. RYU, M. KANEDA*, M. RANDIC and N. AKAIKE*. Dept. Vet. Physiol. Pharmacol., Iowa State Univ., Ames, Iowa 50011 USA, and Dept. Physiol., Kyushu Univ., Fukuoka 812 Japan.

Solitary spinal dorsal horn neurons of 8-15 day-old rats were obtained by mechanical dissociation following enzyme (pronase and thermolysin, R. Gray and D. Johnston, 1987, Nature 327:620-622) treatment. The isolated cells maintained some of the morphological features, and their cell types thus could be identified.

Membrane ionic current induced by excitatory amino acids was measured by the whole-cell patch-clamp technique. At the holding voltage of -70 mV, application (0.1-100 uM for 5-20 sec) of L-glutamate (Glu), kainate, quisqualate and N-methyl D-aspartate (NMDA) produced inward current (10-1000 pA) in a dose-related manner in most of the tested cells. The response to Glu and NMDA was reduced by the presence of external Mg^{2+}, and increased by glycine (<1 uM).

Calcitonin gene-related peptide (CGRP, <1 uM) augmented the Ca current and induced a small inward shift in the holding current. CGRP also enhanced the NMDA response. Substance P (<1 uM) dose-dependently produced inward current. (Supported by JMESC, NSF and USDA).

IONTOPHORETIC MAPPING OF NMDA AND NON-NMDA RECEPTORS ON INHIBITORY AND EXCITATORY CELL TYPES OF CEREBRAL CORTEX. K.A. Jones and R.W. Baughman. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115

Studies of glutamate receptors suggest many types of central neurons have both NMDA and non-NMDA receptor subtypes. In neocortex, inhibitory neurons receive excitatory input from pyramidal cells; however, it is uncertain if these neurons have both receptor subtypes. To determine the receptor profiles of inhibitory cells, neurons from the visual cortex of 7-10 day-old rat pups were dissociated and grown in culture. Intracellular voltage responses to focal, iontophoretic applications of glutamate were recorded from single cells using patch electrodes. The recording medium contained 100 uM Mg++ and 1 uM glycine to reduce the block of NMDA receptor channels at resting membrane potentials, and TTX to eliminate synaptic input. All responses to glutamate iontophoresis consisted of an NMDA-component, which was sensitive to the application of 50 uM APV, and an APV-resistant, non-NMDA component. Both presumptive inhibitory neurons, identified by their characteristically fast action potentials (McCormick and Prince, 1985; Huettner and Baughman, 1988), and excitatory neurons had non-uniform responses to glutamate applied at 20-30 um intervals along major dendritic processes. Dendritic "hot spots", 2-3 times more sensitive to glutamate than neighboring regions of dendrite, resulted from either an enhanced NMDA component, a larger non-NMDA component, or a strengthening of both components. The ratios of the two components (NMDA/non-NMDA) ranged between 1.02 to 0.34 for the cell with lowest variation, and between 4.05 to 0.15 for the cell with the highest variation. These results suggest that inhibitory and excitatory cell types have similar distributions of glutamate receptor subtypes, and that NMDA as well as non-NMDA receptors are highly localized along different regions of dendrites. PHARMACOLOGY OF EXCITATORY AMINO ACID RECEPTORS IN THE RABBIT ISOLATED RETINA. A.G. Hayes* and P.J. Birch* (SPON: I. Stolerman). Dept. Neuropharmacology, Glaxo Group Research Ltd., Ware, Herts., SG12 0DJ, U.K.

Of importance to the study of excitatory amino acid (EAA) receptors is the use of novel in vitro preparations which permit easy pharmacological characterisation. Such a preparation is described. Californian rabbits (2-2.5kg) were killed by cervical dislocation with exsanginuation and the retina removed from each eye. A wedge-shaped strip of retinal tissue encompassing the ganglion cell fibre tract, forming the beginning of optic nerve, was dissected out and placed through a greased slot in the central barrier of a two compartment bath. Each side was superfused with Mg^{2+}-free Krebs-Ringer of the following composition (mM): KCl 4.7, NaCl 118, KH_2PO_4 1.2, $NaHCO_3$ 25, $CaCl_2$ 1.25, glucose 11.1 and H_2O_2 0.0024%; equilibrated with 95% O_2/5% CO_2, pH 7.4, at room temperature (18-22°C). The potential difference which developed between the two compartments was measured using Ag/AgCl electrodes and displayed on a chart recorder. Application of the EAA agonists kainate (10-100μM), AMPA (3-30μM), and NMDA (10-100μM), evoked consistent depolarisations and semi-cumulative concentration response curves could be constructed. Preliminary pharmacological results will be discussed.

NMDA-INDUCED CURRENT IN NEONATAL RAT LATERAL HORN CELLS. N. J. Dun and T. Miyazaki*(SPON: A. G. Karczmar). Dept. of Pharmacol., Loyola Univ. Med. Ctr., Maywood, IL 60153

Lateral horn cells situated in thin transverse slices of thoracolumbar spinal cord removed from neonatal (8-16 days) rats were voltage clamped using a single electrode voltage clamp method. Pressure application of N-methyl-D-aspartate (NMDA) to lateral horn cells elicited an inward current associated with a decrease of membrane conductance at the holding potential of -30 to -90 mV. The inward current was followed in a portion of cells by an outward current associated with increased conductance. The amplitude of the outward current was generally related to the magnitude of the preceding inward current. The relationship between the amplitude of the NMDA-induced current and holding potential was V-shape, with the peak amplitude at about -60 mV in normal Krebs (1.3 mM Mg) solution. In Mg-free solution, the NMDA-induced current was substantially larger than that obtained in normal Krebs solution at all holding potentials. Further, the I-V relationship was linear in Mg-free solution. However, a decrease of membrane conductance could still be detected in a population of lateral horn cells bathed in Mg-free solution. AP5 (1-10 μM) antagonized the effects of NMDA. Cd (300 μM) consistently reduced the NMDA-induced current without affecting the holding current. The results indicate that in lateral horn cells the NMDA channels are gated by Mg ions and that influx of Ca ions is partly responsible for the inward current induced by NMDA. MECHANISMS OF EXCITATION BY THE POTENT GLUTAMATE AGONIST, QUISQUALATE, IN CEREBELLAR PURKINJE NEURONS IN CULTURE. Andrea J. Yool and Donna L. Gruol, Division of Preclinical Neuroscience and Endocrinology, Research Institute of Scripps Clinic, La Jolla, CA.

Subtypes of the CNS glutamate receptor have been identified by three agonists, quisqualate (QA), kainate (KA) and N-methyl-D-aspartate (NMDA). Using whole-cell patch clamp, we characterized the responses to agonists in the mature cerebellar Purkinje neuron (PN) *in vitro*. The PN is insensitive to NMDA; QA is the most potent agonist. QA (0.5-2 μM), applied as a brief pulse by pressure pipette, elicited a long voltage-dependent response with several distinct components. The response was blocked by 1 mM kyurenate, but not by NMDA antagonist. The rapid Na-dependent depolarization was followed by a prolonged plateau involving both Na^+ and Ca^{2+}. Na-dependence of the initial and plateau phases was evident in Na^+-free saline (isomotic sucrose) which decreased response magnitude. The more subtle contribution of Ca^{2+} to the plateau is suggested by four lines of evidence: (1) in the absence of Na^+, QA evokes only a small depolarization; (2) in bath saline with 0.1 mM EGTA and no Ca^{2+}, the plateau is reduced in amplitude (although not blocked); (3) divalent blockers (Cd^{2+}, Mg^{2+}) reduce the plateau; (4) a Ca-dependent K^+ channel is activated during the plateau. The plateau may be mediated by cationic channels permeant to both Na^+ and Ca^{2+}. Voltage-dependence for QA was evaluated using voltage-clamp, after blocking spikes and much of the resting conductance (with TTX, TEA and Cs_{in}). The QA-activated current decreased in both amplitude and duration at hyperpolarized potentials. These properties were mimicked by KA. The prolonged excitatory responses of PNs to QA are unique, and include an increase in internal Ca^{2+}, voltage-dependence, and blockade by external divalent cations. These similarities to NMDA in other CNS regions may suggest a novel homologous role for QA in cells such as the cerebellar PN. (Supported by AA06420 and AA06665 to DLG and AA07456).

FAST DESENSITISATION OF QUISQUALATE RECEPTORS BLOCKED BY CONCANAVALIN-A IN MOUSE HIPPOCAMPAL NEURONS. M.L. Mayer and L. Vyklicky Jr*. Unit of Neurophysiology & Biophysics, LDN, NICHD, NIH, Bethesda, MD 20892.

A perfusion apparatus, consisting of an array of flow pipes each of 250 μM diameter, was mounted on a stepping motor driven manipulator, and fed via latching solenoid valves and a peristaltic pump. The solution exchange time constant was ≈ 20 msec, and produced rapid responses to agonists.

This system was used to apply excitatory amino acids to cultured hippocampal neurones under voltage clamp. Quisqualic acid produced an initial inward current response which decayed rapidly to a stable plateau. With 5 μM quisqualate the time constant of desensitisation was 72 ± 20 msec (n = 5), and the ratio of peak/plateau current 1.93 ± 0.82. The initial fast response to quisqualate recovers slowly following desensitisation, and subsequent applications of quisqualate activate only the plateau current, which shows no further desensitisation with repeated applications of agonist. The rapid nature of the initial response to quisqualate hinders its study with conventional techniques, and in our previous experiments application of quisqualate from puffer pipettes frequently evoked only the plateau response.

Pretreatment of cultures with 20 μM concanavalin-A for 10 minutes, or application of concanavalin-A to single neurones from which control responses to quisqualate had been recorded, produced an irreversible block of desensitisation. Experiments are in progress to examine the effects of lectins on responses to other excitatory amino acids.

We thank Jon Johnson for advice on rapid perfusion techniques.

318.13

EXTRACELLULAR CALCIUM PROMOTES DESENSITIZATION OF THE NMDA RESPONSE. G.D. Clark, D.B. Clifford, C.F. Zorumski. Depts. of Pediatrics, Neurology & Psychiatry, Washington Univ. Medical School, St. Louis, MO, 63110.

Studies of the regulation of NMDA responses are of importance in understanding ways to protect the nervous system from damage. Using whole cell voltage clamp techniques, we have found that rat postnatal hippocampal neurons undergo a slow process of desensitization upon exposure to NMDA and calcium. Concentrations of NMDA less than 100μM produce little desensitization. Maximal rates and percents of desensitization are seen at NMDA concentrations of 1mM. In solutions containing no added Ca^{++} (<2.5μM), very little decline in NMDA current is seen. Maximal rates of desensitization are seen at Ca^{++} concentrations of 10mM, but the percent decline continues to increase depending upon Ca^{++} concentrations. Raising intracellular Ca^{++} by activating voltage dependent Ca^{++} currents, by application of Bay k 8644, or by placing free Ca^{++} in the intracellular recording solution prior to activation or during activation of NMDA responses does not promote desensitization. The rate of decay of NMDA currents is nearly 10 times greater at membrane potentials of -50 mv versus +10 mv. The attenuation of the response is best fit by a single exponential decay. Based on these experiments we conclude that calcium acts in the electric field of the NMDA associated channel to promote desensitization, probably by an open channel blockade of the current.

EARLY AND LATE EPSP COMPONENTS IN CA1 PYRAMIDAL NEURONS FROM KAINIC ACID LESIONED RAT HIPPOCAMPUS. H.V. Wheal* and D.A. Turner (SPON: J. Davenport). Dept. of Neurophysiology, Univ. of Southampton, Southampton SO9 3TU UK.

Intracellular recordings in CA1 neurons were performed in vitro 7 days after a unilateral intraventricular kainic acid lesion. Neurons (n=4) from lesioned slices demonstrated evoked bursts of 2-4 action potentials and a late subthreshold EPSP component in response to stratum radiatum stimulation. Neither the bursts of 2-4 action potentials nor the late EPSP components were observed in control neurons (n=10). An early evoked EPSP was noted in all cells and analyzed to have a peak of 0.92±0.51 mV (mean±SD), 10-90% risetime of 8.1±3.1 ms and halfwidth of 30.9±9.1 ms (n=23 responses). The late EPSP was analyzed by subtracting an adjacent response which demonstrated an early EPSP in isolation. Such subtracted responses (n=41) showed a peak of 2.93±1.0 mV, risetime of 23.7±11.9 ms and halfwidth of of 42.9±11.7 ms. Thus, the late subthreshold EPSP component exhibited a significantly longer risetime and halfwidth than the early EPSP ($P<0.001$ by t-test).

The waveform parameters of the late EPSP component suggest a different time course of generation than for the early EPSP. Preliminary experiments also show that the late EPSP is abolished by D-APV. Thus, the kainic acid lesion may lead to the the subthreshold expression of an N-methyl-D-aspartate EPSP component in the CA1 neuron.

EXCITATORY AMINO ACID PHARMACOLOGY OF CA1 HIPPOCAMPAL PYRAMIDAL CELLS STUDIED BY A GREASE-GAP METHOD. M.A. Bowe, D. Martin and J.V. Nadler. Dept. Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710.

To study the pharmacology of excitatory amino acids on CA1 hippocampal pyramidal cells, a grease-gap method was developed with use of slices that included only area CA1 and the retrohippocampal area. Longitudinal slices of 475-um thickness were cut from the caudal hippocampal formation of the rat and the regio inferior and fascia dentata were dissected away. Each slice was then transferred to a two-compartment superfusion chamber and arranged such that pyramidal cell bodies and dendrites in area CA1 were separated from their axons in the subiculum with a grease barrier. Area CA1 was exposed to 5-6 compartment volumes of each excitant concentration at 32 °C and depolarizing responses of pyramidal cells were recorded relative to their axons in the subiculum.

NMDA, AMPA, kainate and L-glutamate depolarized CA1 pyramidal cells. Tetrodotoxin (0.1 uM) little affected responses to these excitants. EC_{50} values in the absence of Mg^{2+} were 4.7, 4.6, 9.4 and 1800 uM, respectively. Phencyclidine, D-AP5 and Mg^{2+} shifted the NMDA concentration-response curve to the right in a parallel manner. pA_2 values were 5.4, 5.9 and 3.4, respectively. Similarly, pentobarbital antagonized responses to AMPA with a pA_2 value of 4.1. Schild slopes were not significantly different from unity. Mg^{2+} also reversibly reduced responses to AMPA. It appeared to be about as potent an antagonist of responses to AMPA as of responses to NMDA, but it reduced responses to AMPA by a maximum of only about one-third. Neither phencyclidine nor D-AP5 significantly altered responses to AMPA.

These results suggest the presence of a substantial NMDA receptor reserve on CA1 pyramidal cells. In addition, the activation by AMPA of the Mg^{2+}-sensitive high conductance state of the quisqualate receptor-channel appears to account for a substantial portion of its depolarizing action in this system. (Supported by NIH grant NS 16064.)

DEXTRORPHAN IS A POTENT AND SELECTIVE BLOCKER OF NMDA DEPOLARIZATIONS IN THE RAT HIPPOCAMPUS. A.E. Cole, C.U. Eccles, J.J. Aryanpur and R.S. Fisher, Dept. of Neurology, Johns Hopkins Hospital, Baltimore, MD. 21205.

Dextrorphan (DX), the O-demethylated metabolite of dextromethorphan (DM), has been shown to protect against effects of hypoxia and NMDA-mediated toxicity in CNS tissue. We examined the effect of DX on NMDA actions in rat hippocampal slices using extracellular and intracellular recording techniques. Bath application of DX (100nM-50uM) depressed NMDA-induced focal field depolarizations with an EC_{50} of 500nM. Preliminary data suggests non-competitive inhibition. DX had no effect on quisqualate-induced depolarizations. In contrast, DM showed no effect on NMDA responses at 500nM-1uM; significant block, however, was achieved with 100uM DM. Maximal block for DX and DM was reached after 60-90 min bath application and was long-lasting, with only partial recovery after 2-3 hours wash. Intracellular recordings (n=10) showed that DX (50uM) selectively blocked NMDA responses without changing RMP or input resistance. Epileptiform activity induced by bathing in zero Mg^{++} solution, an effect believed to be mediated by NMDA receptors, was blocked by bath application of 50uM DX. DX (n=3) did not demonstrate the type of use-dependent block readily observed with MK-801 (n=3). These results indicate a selective and potent action of DX to block NMDA responses in the rat hippocampus.

ALKALINE EXTRACELLULAR pH TRANSIENTS EVOKED BY ASPARTATE IONTOPHORESIS IN CEREBELLUM. M. Chesler & M.E. Rice. Depts. of Neurosurgery & Physiology & Biophysics, NYU Med. Ctr. 550 First Ave., N.Y., N.Y. 10016.

Electrical stimulation of parallel fibers causes an extracellular alkaline shift (AS) in the molecular layer (ML) (Kraig et al. J. Neurophysiol 49:831-50), which is blocked by kynurenate (Chesler et al. Soc. Neurosci. Abstr. 12:696). We have studied the AS evoked by iontophoresis of aspartate (Asp) in the *in-vitro* turtle cerebellum (Pseudemys scripta elegans). A pH-sensitive microelectrode and iontophoresis pipette containing 200 mM Na-Asp (pH 7.6) were secured with tips 60-90 μm apart. With superfusion of 40 mM HCO_3^--buffered Ringer, 40 sec., 100-200 nA currents produced an AS in the granule cell layer (GCL) of 0.04 ± .02 pH (range 0.03-0.07). Identical currents produced no AS in agar gel controls, or in the ML. This was true whether the assembly was lowered from the dorsal or ventral surface. In contrast, parallel fiber stimulation evoked a small AS (0.02 pH) in the ML. After lowering the buffering capacity using 10 mM HEPES Ringer, iontophoresis evoked an AS of 0.04 pH in the ML. Mn^{2+} (3-5 mM) abolished the late component of the peduncular-evoked field potential (indicating that synaptic transmission was blocked) and reduced the iontophoretically-evoked AS in the GCL by 50%. The predominance of the Asp-evoked AS in the GCL is consistent with the distribution of similarly evoked $[Ca^{2+}]_o$ and $[K^+]_o$ transients in turtle (Rice & Nicholson Soc. Neurosci. Abstr. 13:764) and may be related to the distribution of NMDA and kainate receptors which in rat, are most dense in the GCL (Greenamyre et al. JPET 233:254, 1985). (NS-10164 & NS-07745)

THE NMDA ACTIVATED CURRENT IN HIPPOCAMPAL NEURONS IS HIGHLY SENSITIVE TO $[H^+]_o$. Martin Morad* Marc Dichter and Cha-Min Tang*(SPON:E Kiclister). Dept. of Physiol. and Neurol., U of Pa., Phila., Pa.

The interactions of $[H^+]_o$ on ion channel behavior are complicated. In general acidification to pH 6.5-7.0 leads to only small suppression of channel currents. The NMDA activated current, however, shows a greater sensitivity to external pH. In superior collicular neurons Grantyn and Lux (Neuro Sci Let, in press) showed that the transient component of the NMDA current is highly sensitive to $[H^+]_o$. We found that in rat hippocampal neurons both the transient and the persistent components of the NMDA activated current were highly sensitive to acidification, Quisqualate, kainic acid and glutamate did not demonstrate this degree of $[H^+]_o$ sensitivity.

GLUTAMATE AUTORECEPTORS REDUCE EPSC's IN CULTURED HIPPOCAMPAL NEURONS. I.D. Forsythe and J.D. Clements. Lab. Developmental Neurobiology, NICHD, NIH, Bethesda MD 20892.

In cultured hippocampal neurones, fast excitatory monosynaptic transmission is mediated by kainate or quisqualate receptors while a slower monosynaptic epsp is mediated by NMDA receptors (Forsythe & Westbrook J. Physiol. 396: 515, 1988). The slow epsp is potentiated by an endogenous glycine-like substance (Forsythe et al., J. Neurosci. In press). Here we show that a fourth excitatory amino acid (EAA) receptor depresses excitatory synaptic transmission by a presynaptic mechanism.

Recordings were made from pairs of mouse hippocampal neurons grown in cell culture for 6-14 days, using whole-cell patch recording techniques. The postsynaptic cell was voltage clamped and evoked epscs recorded before, during and after application of drugs from puffer pipettes. Glutamate (1 μM) reversibly depressed the epsc in a sub-population of synaptic connections (15 were not depressed; 33 were depressed by an average of 30%). This depression was insensitive to 2-amino-5-phosphonovalerate (AP5), indicating that NMDA receptors were not involved. L 2-amino-4-phosphonobutyrate (L-AP4, 50 μM) mimicked the action of glutamate. Neither glutamate nor L-AP4 produced any detectable inward current at these concentrations. Statistical analysis of the fluctuations in epsc amplitude showed that both substances acted at a presynaptic site to reduce the probability of transmitter release. These observations strongly suggest that a fourth EAA receptor, which has a high affinity for glutamate and is distinct from kainate, quisqualate or NMDA receptors, functions as an autoreceptor in some synaptic pathways.

NOVEL RECOGNITION SITE FOR L-QUISQUALATE SENSITIZES NEURONS TO L-2-AMINO-4-PHOSPHONOBUTYRATE. Edward R. Whittemore and James F. Koerner. Dept. of Biochemistry and Neuroscience Grad. Program, Univ. of Minn., Minneapolis, MN 55455.

Brief exposure of rat hippocampal slices to L-quisqualate (Quis) sensitizes pyramidal neurons to depolarization by L-2-amino-4-phosphonobutyrate (L-AP4)(Robinson, et al., Br. Res., 381 (1986) 187-90). We report here further attempts to clarify the duration, pharmacology, mechanism, and pathway specificity of this 'QUIS-effect'.

The Quis-induced sensitization to L-AP4 decreases only 3-fold over a four hour period. No compound besides Quis has been found to induce the QUIS-effect, including Quis analogs and compounds known to stimulate second messenger systems in hippocampal slices. Of a large number of compounds assayed, only a small number have been shown to block the induction of the QUIS-effect. Although these blockers are also potent ligands at a chloride-dependent glutamate uptake site, the pharmacological profiles of QUIS-effect blockage and uptake site potency do not match. These results suggest that the QUIS-effect is induced thru a novel recognition site for Quis.

The QUIS-effect can be induced in the rat CA1, medial perforant path, and lateral olfactory tract, and in the guinea pig CA1. However, the QUIS-effect cannot be induced in the L-AP4-sensitive rat lateral perforant path (LPP), suggesting that the receptors for L-AP4 in the LPP may be distinct from those that are sensitized by Quis elsewhere. Supported by NIH NS 17944.

PERSISTENT BLOCK OF ADENOSINE ACTION IN THE DENTATE GYRUS FOLLOWING NMDA RECEPTOR ACTIVATION. K.R. Stratton, A.J. Cole, P.F. Worley and J.M. Baraban. Dept. Neuroscience, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205.

Adenosine has prominent neuromodulatory actions in the hippocampus. We have recently demonstrated in the rat hippocampal slice preparation that phorbol esters which activate protein kinase C (PKC) block the effects of adenosine on synaptic transmission in the dentate gyrus. Since PKC may be invoved in long-term potentiation (LTP) following n-methyl-d-aspartate (NMDA) receptor activation, we assessed whether NMDA receptor activation also blocks adenosine action in the dentate. Bath application of adenosine inhibits the extracellularly recorded population spike (PS). Removal of magnesium from the perfusion buffer for 30 minutes results in a subsequent block of adenosine inhibition of the PS. This effect persists after re-introduction of magnesium to the perfusion buffer and is due to activation of NMDA receptors, as it is blocked by 20 μM d-2-amino-5-phosphonovalerate (APV) and does not occur if the perforant path is not stimulated during the magnesium-free period. APV does not block the action of phorbol esters. Thus, activation of NMDA receptors in the dentate gyrus results in prolonged block of adenosine action, which may be mediated via PKC activation.

EXCITATORY NEUROTRANSMISSION ACTIVATES VOLTAGE-DEPENDENT PROPERTIES IN NEURONS OF THE SPINAL MOTOR SYSTEM OF THE LAMPREY. S.T. Alford and K.A. Sigvardt. Neurology Dept., U. California-Davis, VAMC, Martinez CA 94553.

Episodes of fictive locomotion can be elicited in the in vitro lamprey spinal cord-tailfin preparation by stimulation of the tailfin. Application of strychnine to this preparation changes the pattern of locomotory activity from alternation between opposite pairs of ventral roots to synchronous activation (Alford & Williams, 1987). In this preparation ventral horn neurons demonstrate regular oscillations in membrane potential, the repolarizing phase of which does not depend on inhibitory neurotransmission (Alford & Williams, 1987). Single electrode voltage clamp studies of these neurons with CsCl-filled microelectrodes (to block outward currents that would otherwise develop at depolarized holding potentials) during episodes of rhythmic coactivation reveal inward currents coincident with ventral root bursting in the same segment. The conductance associated with the peak inward current is voltage-dependent at holding potentials depolarized from rest. The voltage dependence of this inward current is eliminated by the specific NMDA receptor blocker, APV, and by removal of Mg^{++} from the bathing solution. At very depolarized potentials a long-lasting outward current that is blocked by APV can be observed. In Mg^{++}-free saline this outward current is measurable at potentials slightly positive to rest and is also blocked by APV. These results implicate involvement of NMDA receptor activation in the generation of both the depolarization and repolarization phases of this rhythmic locomotor activity.

GLUTAMATE INHIBITS THE LOW-THRESHOLD, TRANSIENT CALCIUM CURRENT IN DORSAL ROOT GANGLION NEURONS ACUTELY IOSLATED FROM ADULT RAT. D.M. Lovinger* and F.F. Weight (SPON: S.R. Ikeda). Section of Electrophysiology, Lab. of Physiol. Pharmacol. Studies, NIAAA, Rockville, MD 20852.

Glutamate can activate receptor-coupled ion channels; however, little is known about the ability of this neurotransmitter to modulate voltage-gated ion channels. We have now observed, using isolated dorsal root ganglion (DRG) neurons, that glutamate not only activated an inward current in these cells, but also induced a relatively selective inhibition of a low-threshold, transient Ca^{2+} [Ca(t)] current. Neurons were isolated from DRGs using trypsin, collagenase and mechanical dissociation. Neurons thus isolated consisted of somata without extensive processes, making them suitable for whole-cell recording. Ca(t), studied under voltage clamp conditions in media which isolated Ca^{2+} currents, was elicited by brief jumps to a membrane potential of -35mV from a -80mV holding potential. Glutamate inhibition of Ca(t) was dose-dependent with a maximum inhibition of 70.5% at 100uM, and an IC50 of 0.7uM. Excitatory amino acid receptor agonists also inhibited Ca(t) with the order of potency: kainate > NMDA > quisqualate. Glutamate produced little inhibition of the high-threshold, sustained Ca^{2+} current (15% inhibition by 1mM glutamate), elicited by brief jumps to 0mV from a -50mV holding potential. In current clamp experiments glutamate, kainate or NMDA inhibited an afterdepolarizing potential (ADP), which was elicited by depolarizing pulses from hyperpolarized membrane potentials, and is produced by Ca(t) (G. White et al. this meeting). Since synapses onto DRG neurons are thought to occur only at axon terminals, one role for glutamate inhibition of the ADP might be to regulate terminal excitability.

318.24

INHIBITION OF EXCITATORY AMINO ACID (EAA) INDUCED NEUROTRANSMITTER RELEASE FROM RAT CORTICAL (CTL) AND HIPPOCAMPAL (HPL) BRAIN SLICES BY ω-CONOTOXIN GVIA (ω-CT). R.A. Keith*, T.J. Mangano* and A.I. Salama, ICI Pharmaceuticals Group, ICI Americas, Inc., Wilmington, DE 19897.

Recent studies have shown that EAA evoke calcium-dependent neurotransmitter release. In the present study, the release of [^{3}H] norepinephrine (NE) from CTL and HPL brain slices evoked by the EAA, N-methyl-D-aspartate (NMDA) and kainic acid (KA), was pharmacologically characterized. The effects of ω-CT, an inhibitor of neuronal L- and N-type voltage-sensitive calcium channels (VSCC), and PN 200-110 (PN), an inhibitor of L-type VSCC, were also examined. The potencies of NMDA (EC_{50}'s ∿ 100μM) and KA (EC_{50}'s ∿ 200μM) were similar in both tissues. NMDA- and KA-evoked release was ∿ 2-times greater in HPL than in CTL brain slices. Mg^{++} and MK-801, selective antagonists of NMDA receptor responses, inhibited NMDA- but not KA-evoked [^{3}H]NE release in both CTL and HPL brain slices, suggesting that NMDA and KA act at distinct EAA-receptor subtypes. Glycine did not enhance NMDA-evoked release. [^{3}H]NE release evoked by both NMDA and KA was similarly inhibited by 0.1μM ω-CT (∿25%) in both CTL and HPL slices. PN caused only a slight inhibition (∿8%) of EAA-evoked release in CTL and HPL slices. The results suggest that N-type, and to a lesser extent, L-type VSCC contribute to EAA-evoked release of [^{3}H]NE in CTL and HPL brain slices.

INTRACELLULAR INJECTION OF KAINIC ACID EXCITES APLYSIA NEURONS. G.K. Rieke and S.M. Fredman. Depts. Anatomy and Physiology, Meharry Medical College, Nashville, TN 37208.

Kainic acid (KA), an excitatory neurotoxin, is thought to act via glutamate sensitive receptors. However, EM autoradiography indicates that KA enters cells. The possibility that KA might act at intracellular sites was tested using identified neurons in the abdominal ganglion of Aplysia. KA, dissolved with L-Lysine free base and 0.25 mg/ml of carboxyfluorescein (CF), final pH ~7.0, was pressure injected into identified cells. Intracellular KA depolarized the neurons and produced a long-lasting increase (>350%) in neuronal firing. Injection of L-Lysine and L-Glutamate were without significant effect. Since extracellular application of KA also dramatically increased firing rates, neurons were examined for possible leakage using fluorescence microscopy to detect CF. In all cases the label was confined to the injected neurons and their processes. Our results show that in addition to its extracellular actions, KA also has a significant excitatory effect when acting on intracellular sites. This work was supported by NSF grant BNS-8710184 (GKR), NIH grant NS20846 (SMF), RCMI grant RR03032 and MBRS grant RR08037.

AMINO ACID ANTAGONISM OF DOPAMINE EFFECTS ON NEURONS R3-R13 OF THE ABDOMINAL GANGLION OF APLYSIA. D.G. Gibson and K.A. Marquis*. Dept. of Biology and Biotechnology, Worcester Polytechnic Institute, Worcester, MA 01609.

The neurosecretory cells R3-R13 of the sea slug, Aplysia californica, were treated with 1mM concentrations of phenylalanine (Phe) and Tyrosine (Tyr), singly and in conjunction with 0.1mM dopamine (DA). DA hyperpolarized these neurons by about 7 mV; both Phe and Tyr depolarized them an average of 6 mV and caused spiking rates to increase by at least +25/min (means for Phe and Tyr not significantly different at 95% confidence). When administered with DA, Phe overpowered the DA effects and caused depolarization and spiking increases comparable to those of Phe alone. Tyr and DA together, on the other hand, caused hyperpolarization and inhibition of spiking.

Phe and Tyr compete for transport at the blood-brain barrier; high circulating levels of Phe after ingestion of the artificial sweetener Aspartame may not only impair uptake of Tyr, resulting in lowered DA synthesis, but could affect some neurons directly, if there are any neurons in the brain with the same sensitivities demonstrated in this study.

PREPULSE INHIBITION AND BACKGROUND NOISE MODULATION OF THE ACOUSTIC STARTLE REFLEX. P.K.D. Pilz* & H.-U. Schnitzler* (SPON: H.C. Diener). Dept. Animal Physiol., Univ. Tübingen, D-7400 Tübingen, FRG.

Two types of behavioral plasticity of the startle reflex have been examined in rats.

PREPULSE-INHIBITION: Startle was elicited by 10 kHz tone and broad band noise stimuli. When 100 ms prior to the startle stimulus a less intense stimulus (2.5-40 kHz, 60 dB SPL) was given - which itself does not elicit a startle response - the startle threshold was increased and the amplitude to suprathreshold stimuli decreased. The prepulse inhibition in these experiments is the more effective the more broadband or intense the startle stimulus is. Thus, the higher the activation of the auditory system, the more effective seems the prepulse inhibition.

BACKGROUND NOISE MODULATION: Amplitude and threshold of startle can be modulated by background noise. Narrow band noise (bandwidth 2 kHz, 85 dB SPL) with the center frequency beeing the stimulus frequency (13 kHz) had a masking effect. Noise with the center frequency well below (1.7 octaves) the stimulus frequency increased the startle response with little effect on the startle threshold. Noise with the center frequency well above (1.7 octaves) the stimulus frequency resulted in a decrease of the startle response and an increase of startle threshold. The high frequency noise inhibition can not be explained by simple masking, while the low frequency noise fascilitation seems to work by an enhancement of the state of the "arousal" system. Supp. by DFG: SFB 307.

BISTABLE FIRING PATTERN OF SOLEUS MOTOR UNITS DURING POSTURE IN RATS. H. Hultborn, T. Eken and O. Kiehn (Spon: J. Mogensen), Dept. of Neurophysiology, University of Copenhagen, 2200 Copenhagen, Denmark.

A bistable firing behaviour of spinal motoneurones has previously been described in the decerebrate cat (Hounsgaard et al. Progr. Brain.Res: 64, p 39, 1986). This behaviour is intrinsic to the motoneurone and generated by a plateau potential. The plateau potential causes long-lasting excitability increase and can be initiated and terminated by short-lasting synaptic excitation and inhibition.

In order to elucidate if a bistable firing pattern is present in the intact animal we have used a technique (Hennig & Lømo, Nature: 314, p 164, 1985), which allows single motor unit recording as well as nerve stimulation in freely moving rats. Most soleus motor units were tonically active for extended periods during postural activity. The distribution of interspike frequencies showed two peaks at 10-14 and 20-25 Hz respectively corresponding to two stable discharge modes. When firing at a slow tonic discharge rate maintained shifts between the two stable frequencies was initiated by short-lasting synaptic excitation (weak stimulation of the tibial nerve activating Ia afferents) or inhibition (stimulation of skin afferents). These observations demonstrate a bistable firing pattern in an intact animal during posture and suggest that plateau potentials are present under normal conditions.

319.3

SOLITARIAL DEGLUTITIVE EFFERENTS IN THE RAT. M.A. Hashim*, D. Vyas and D. Bieger. Fac. of Medicine, Memorial Univ., St. John's, NF, Canada, A1B 3V6

Efferent projections of the nucleus tractus solitarii (NTS) subnuclei containing presumptive pattern generators for swallowing were studied by means of the anterograde tracer, Phaseolus vulgaris leucoagglutinin (PHAL). Micropneumophoresis of PHAL at glutamate-responsive pharyngeal and oesophageal NTS sites in the subnucleus intermedialis (NTSint) and centralis (NTScen), respectively, gave rise to labeling of terminals within different subdivisions predominantly of the ipsilateral nucleus ambiguus. NTScen injections produced heaviest labelling in the compact formation while NTSint injections yielded diffuse labeling in the tip of the ambiguus, and the semicompact and loose formations. In addition, a projection was labeled which terminated in the ventral and dorsal parabrachial nuclei. PHAL micro-injections placed in the nondeglutitive regions of the NTS failed to produce the pattern of labeling described above. These results demonstrate that solitarial deglutitive neurons project to ambigual divisions according to the viscerotopy delineated by Bieger and Hopkins (*J. Comp. Neurol.* 262:546-562, 1987) and, in addition, suggest a deglutitive function for the parabrachial region. (Supported by MRC).

319.4

THE EFFECTS OF AN NMDA ANTAGONIST, MK-801, ON SPINAL FIXATION IN RATS. M.F. ANDERSON*and B.J. WINTERSON. Dept. of Physiol., UNE Coll. of Ost. Med., Biddeford, ME 04005.

Electrical stimulation to a hindlimb produces a maintained flexion which persists for many days and appears to be mediated by the spinal cord ("spinal fixation"). NMDA receptors are found in the spinal cord and have been implicated in long term potentiation (LTP). Similarities between LTP and spinal fixation prompted us to examine the effects of MK-801, an NMDA antagonist, on spinal fixation.

Under anesthesia, electrical stimulation (1.75-2 mA, 7 msec, 100 Hz for 60 min) of rat hindlimb iduced a flexion which was measured by applying 0.5 g weights until stimulated and contralateral legs were equal. At 72 h, rats were anesthetized and remeasured. Then the spinal cord was transected at T7 and flexion measured.

In control rats, flexion following stimulation was 24.4 g. At 72 h, controls retained 10.4 g. After transection, hindlimb flexion increased to 14.8 g. Our prior work suggests that this increase reflects the removal of descending serotonergic inhibition. Experimental rats received MK-801 (10mg/kg, i.p.) 1 hr prior to stimulation. In these rats, flexion immediately following stimulation was 15.6 g. At 72 h, MK-801 treated rats retained 10.8 g flexion and after transection, hindlimb flexion was 9.0 g.

These results indicate that NMDA receptors are involved in the development of spinal fixation and in the circuitry affected by descending serotonergic inhibition.

STRYCHNINE ENHANCES THE FACILITATION OF THE SPINAL MONOSYNAPTIC REFLEX PRODUCED BY CONDITIONING CUTANEOUS AND MUSCLE AFFERENTS. N.A. Ibrahim and B.D. Goldstein. Department of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912-2300.

Conditioning volleys in sural (SU) and medial gastrocnemius (MG) nerves were found to produce a biphasic effect on the monosynaptic reflex (MSR) evoked from the MG. An initial facilitation (FAC) of 28% and 60% above the control which peaked at 3 and 2 msec was followed by an inhibition (INH) of 32% and 74% below the control which peaked at 15 and 20 msec after conditioning the SU or MG nerves, respectively. Pharmacological properties of the FAC and the INH were studied by i.v. administration of strychnine (STR), bicuculline (BIC), mecamylamine (MEC) or atropine (ATR). STR potentiated and prolonged the FAC of the MSR produced by both conditioning volleys and blocked the INH produced by volleys in the SU nerve, while not affecting the INH caused by conditioning the MG nerve. Neither the FAC nor the INH produced by both conditioning volleys were sensitive to BIC, MEC or ATR. These data suggest that the FAC produced by either the SU or MG nerves would be the result of disinhibition of background glycinergic inhibitory action on motoneurons. Furthermore, the INH produced by the SU nerve but not by the MG nerve is glycine mediated. The recurrent collaterals may not play a role in the INH produced by conditioning the MG nerve.

319.6

BLOCKADE OF THE PHYSOSTIGMINE-INDUCED FACILITATION OF THE SPINAL MONOSYNAPTIC REFLEX BY A GLYCINE ANTAGONIST. B.D. Goldstein and N.A. Ibrahim. Department of Pharmacology & Toxicology, Medical College of Georgia, Augusta, GA 30912-2300

Recent data generated in this laboratory (Ibrahim and Goldstein, Neurosci. Abs. 13:1064, 1987) have demonstrated that physostigmine (PHY) modifies the monosynaptic reflex (MSR) evoked in the L_7 ventral root of spinal cats in a dose and time dependent manner. The low dose of PHY (0.8mg/kg, i.v.) produced a facilitation lasting for three hours, whereas, the high dose (2.0mg/kg, i.v.) was found to produce an initial depression which peaked at five minutes followed by a facilitation which was maintained for three hours after the injection. In the present study we tested the hypothesis that the actions of PHY were due to the activity in the recurrent inhibitory and facilitatory pathways. Pretreatment with strychnine (0.1mg/kg i.v.) markedly antagonized the facilitation produced by the low dose of PHY and the late facilitation but not the initial depression produced by the high dose of PHY. These findings suggest that the facilitation of the MSR induced by both doses of PHY is due to disinhibition of the glycinergic inhibitory pathway. This pathway is probably a recurrent facilitatory pathway to the motoneuron. The initial depression caused by the high dose of PHY does not seem to be glycine mediated.

319.7

SPATIAL FACILITATION OF CUTANEOUS REFLEX PATHWAYS TO TRICEPS SURAE MOTONEURONS IN UNLESIONED AND CHRONIC SPINAL CATS. LaBella L A and McCrea D, Dept. Physiology, Univ. Man., Wpg, CANADA R3E 0W3.

We previously found that excitation from the caudal sural nerve predominates specifically in MG motoneurons while inhibition predominates in LG and SOL. On the other hand, effects from the lateral sural nerve are largely inhibitory throughout the triceps surae motor nuclei (TS) (LaBella et al Neurosci. Abst. 1987). The present experiments use the technique of spatial facilitation to examine the convergence of other cutaneous nerves on interneurons in these pathways. Preliminary data in unlesioned animals reveals such spatial facilitation in both the "special" excitatory sural pathway to MG and the more general inhibitory pathway to TS. Interestingly, we have also found convergence from the lateral sural pathway upon the excitatory caudal sural pathway to MG.

In studies with chronic spinal animals, sural postsynaptic potentials (PSPs) in TS were qualitatively similar to those in unlesioned cats but were greater in amplitude and had faster rises and decays (unpublished observations; see also Baker et al, Brain Res 420, 1987). One mechanism that would account for these PSP changes is an increase in the synchrony of interneuronal firing resulting in decreased dispersal of the cutaneous PSPs (Baker et al, 1987). If this is true, spatial and temporal facilitation in sural reflex pathways may be altered after chronic spinalization. Furthermore, if the apparently "special" excitatory and more general inhibitory sural pathways to TS are under different patterns of descending control, one might predict differential changes in peripheral convergence following chronic cord transection. Experiments to test these ideas are in progress. Supported by the MRC of Canada.

CHARACTERISTICS OF HINDLIMB FLEXOR PSPs EVOKED BY ACTIVATION OF Aα OR Aα AND Aδ CUTANEOUS FIBERS IN THE SPINAL CAT. J.C. Leahy* AND R.G. Durkovic (SPON: M.M. Mozell). Dept. of Physiology, SUNY HSC at Syracuse, Syracuse, NY 13210.

This report describes the characteristics of the synaptic responses of TA and PB-ST motoneurons evoked by stimulation of the cutaneous saphenous (Saph) and superficial peroneal (SP) nerves at "Aα" and "Aαδ" intensities. Experiments were performed in spinal, ischemically decapitate cats. Saph and SP were stimulated with single pulses or with trains at "Aα" or "Aαδ" intensities while recording the cord dorsum potential and the intracellular synaptic responses of TA or PB-ST motoneurons.

Saph and SP-evoked membrane potential alterations typically consisted of up to 3 phases: an early EPSP lasting 20-30ms, followed by an IPSP and then a slowly rising EPSP. During the early EPSP, motoneurons often fired a spike to both Aα and Aαδ stimulation. Increasing the stimulus intensity resulted in a decrease in central delay and an increase in the magnitude and duration of the early EPSP. Supramaximal Aα fiber activation of either Saph or SP, produced early EPSPs with a minimum central delay that averaged 2.5 ms. In a few cases a central delay of less than 1.8 ms was indicated.

We conclude that the synaptic responses elicited in TA and PB-ST motoneurons by Saph and SP stimulation are qualitatively similar for Aα and Aαδ intensities. Our data appears to be consistent with recent reports that the minimum linkage for hindlimb cutaneous reflexes may be disynaptic (see Exp. Br. Res. 69:449). Supported by NSF grants BNS 8415917 and BNS 8808495.

319.9

RECURRENT INHIBITION TO AND FROM MOTONEURONS INNERVATING THE FLEXOR DIGITORUM LONGUS AND FLEXOR HALLUCIS LONGUS MUSCLES OF THE CAT. T.M. Hamm. Div. Of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

The cat flexor digitorum longus (FDL) and flexor hallucis longus (FHL) muscles have different activities during locomotion (O'Donovan et al., J. Neurophysiol. 47: 1126, 1982), despite being anatomical and 'Ia' synergists (Fleshman et al., Exp. Brain Res. 54: 133, 1984). Fleshman et al. (1984) found no apparent differences in the pattern of recurrent IPSPs (RIPSPs) in FDL and FHL motoneurons from other motor nuclei and found no RIPSPs from FDL to other motoneurons. A larger sample of RIPSPs was obtained in this study to determine whether the distribution of RIPSPs to and from the FDL and FHL motor nuclei is more directly related to their anatomical and Ia synergism or to their function. In unanesthetized ischemic decapitate cats, it was observed that 1) RIPSPs from plantaris, medial gastrocnemius and lateral gastrocnemius-soleus (LGS) were larger to FHL motoneurons than to FDL motoneurons; 2) RIPSPs from FHL were larger to LG-S than to FDL motoneurons; 3) RIPSPs from tibialis anterior were found to FDL, but not to FHL motoneurons; and 4) no RIPSPs were observed from FDL to other motoneurons. Thus, the pattern of RIPSPs to and from FDL and FHL motoneurons corresponds more closely to function that to anatomical and Ia synergism.

Supported by USPHS grant NS22454.

THE EFFECTS OF MUSCLE FATIGUE ON SMALL DIAMETER MUSCLE AFFERENTS IN THE ANESTHETIZED CAT. L. Hayward, U. Wesselmann and W.Z. Rymer, Dept. of Physiology, Northwestern University, Chicago, IL 60611.

Recent evidence indicates that feedback from a fatiguing muscle contributes to the decline in motor unit firing rate which occurs during fatiguing voluntary contractions (Bigland-Ritchie, B., et al., J.Physiol. 378: 451, 1986). It has been hypothesized that small diameter, group III and IV muscle afferents are responsible for mediating this fatigue-related reflex since these afferents are sensitive to thermal and metabolic changes in muscle (Mense, S. & Meyer, H., J. Physiol., 363: 403, 1985). The role of these afferents in this fatigue-related reflex was evaluated by comparing the response characteristics of group III and IV muscle afferents before and during muscle fatigue.

Small diameter, slow conducting (30-1m/s) afferents originating in the triceps surae muscles were isolated and recorded from L7 and S1 dorsal rootlets in barbiturate anesthetized cats. Muscle force, length and afferent firing rate were recorded and stored on computer during muscle stretch, twitch, tetanic contraction or surface manipulation, before and during muscle fatigue. Preliminary results from 10 afferents demonstrate that muscle fatigue does induce significant increases in group III discharge rate (paired Student's t-test, $p<0.01$). 3 afferents showed significant increases in spontaneous firing rate (118-1000%) and 3 other afferents showed significant increases in discharge rate during muscle stretch (18-300%). The remaining afferents (n=5) showed increases in their discharge rates during stretch and surface pressure that were not statistically significant. There were no reductions in afferent discharge. The time course of recovery of one group III afferent (c/v 28m/s) that began discharging spontaneously during fatigue was followed for 3 minutes during which the afferent's spontaneous firing rate gradually declined until it was silent. This time course of recovery is similar to the time reported for human motor unit firing rate to recover following fatiguing maximum voluntary contractions. These preliminary data suggest that muscle fatigue does indeed modify small diameter muscle afferent responses, supporting their hypothesized role as fatigue-sensitive muscle afferents.

MEMORY SUBSTRATES IN PRIMATE SPINAL CORD PRODUCED BY OPERANT CONDITIONING OF H-REFLEX. J.R. Wolpaw and C.L. Lee. Wadsworth Labs, NYS Dpt Hlth, Albany, NY 12201.

Monkeys can gradually increase or decrease the wholly spinal, largely monosynaptic H-reflex if reward depends on reflex amplitude (J Neurophysiol 57:443-458, 1987). To define changes conditioning causes in cord, we studied reflexes after cord transection removed supraspinal control.

In 16 animals (Macaca nemestrina) the triceps surae (TS) H-reflex in one leg was increased (8 HR↑ animals) or decreased (8 HR↓ animals) by conditioning. Animals were then deeply anesthetized, and monosynaptic reflexes to L6-S1 dorsal root stimulation were recorded from TS nerve in both legs for 3 days after thoracic cord transection. Animals remained anesthetized throughout and were then sacrificed by overdose. Two effects of conditioning were clear.

First, the conditioned reflex asymmetries seen in the awake animal persisted after transection. In HR↑ animals, reflexes remained larger in HR↑ legs than in control legs. In HR↓ animals, reflexes remained smaller in HR↓ legs than in control legs. A possible source of these persistent asymmetries is plasticity at the Ia primary afferent synapse on the alpha motoneuron.

Second, after transection reflexes were small in control legs of HR↑ animals and large in control legs of HR↓ animals. Thus, removal of supraspinal influence revealed a conditioned change in the cord that was not visible in the awake animal. This effect probably reflects compensatory plasticity that allows the awake animal to maintain required background motoneuron tone while properly altering the H-reflex.

Operant conditioning of the H-reflex produces several changes in the spinal cord, several potentially accessible memory substrates. Current physiologic and anatomic studies are exploring these modifications (Lee et al., this vol). (Supp. by NIH NS22189 and United Cerebral Palsy.)

EFFECTS OF CHRONIC SPINAL HEMISECTION ON REFLEX ORGANIZATION AMONG ANKLE EXTENSORS AND FLEXORS IN CAT. JB Munson, LA Ritz, GW Sypert & TR Nichols, Dept Neurosci, U of FL Coll of Med, Gainesville, FL, and Dept Physiol, Emory Univ Sch of Med, Atlanta, GA (TRN).

Chronic spinal hemisection leads to spasticity (Carter et al., Soc Neurosci Abstr 12: 1422, 1986) and to enhanced ventral root reflexes (ibid; Hultborn & Malmsten, Acta physiol scand 119: 405, 1983) on the lesioned side. We tested muscle-specific reflexes using mechanical inputs and outputs in acute decerebrate cats, 11 mo following chronic left low-lumbar spinal hemisection. Reflexes associated with soleus (SOL), gastrocnemius (G) and tibialis anterior (TA) were measured and compared with those of control decerebrate animals (Nichols, Soc Neurosci Abstr 12: 682, 1986).

Muscle weights were normal but slightly smaller on the lesioned side. Autogenic reflexes were sometimes larger on the lesioned side, but not consistently. Inhibition from TA to SOL was observed on both sides in lesioned as in control animals, but was larger on the lesioned side. When TA was activated, inhibition from SOL to TA was weak or absent in both control and lesioned cats. The force-dependent inhibition from G to SOL was present also on both sides, but the force threshold was consistently lower on the lesioned side. These data demonstrate that the patterns of reflex interactions following lumbar spinal hemisection are similar to those of control preparations. The principal differences from normal, both on the lesioned side, are the reduced force threshold for G-to-SOL force-dependent inhibition, and the enhanced TA-to-SOL inhibitory reflex. [Supported by NS15913 (JBM), NS23683 (LAR), MRS of VA (GWS) & NS20855 (TRN)].

REFLEX ORGANIZATION AMONG ANKLE EXTENSORS AND PRETIBIAL FLEXORS IN THE CHRONIC SPINAL CAT. T.C.Cope and T.R.Nichols Dept. of Cell Biology, Univ. of Texas Health Sciences Center, Dallas, TX 75235 and Dept. of Physiology, Emory Univ., Atlanta, GA 30322 (TRN).

The mechanisms underlying the striking changes in spinal reflexes and muscle tone observed long after complete transection of the spinal cord remain unclear. To assess the involvement of both muscular and neural components, we measured muscle-specific reflexes associated with soleus (SOL), gastrocnemius (G) and tibialis anterior (TA) muscles in terminal experiments conducted up to 11 months following low thoracic transection. Weights of TA and G were within normal limits while SOL was atrophic and pale in color. When SOL was electrically stimulated, the prominent stretch-evoked yielding behavior exhibited by normal solei was not observed. Autogenic reflex strengths were within limits for control decerebrate cats, but background force and reflex stiffness were highly variable. No consistent asymmetries in autogenic reflexes were noted beteeen homologous muscles on the two sides. The reciprocal inhibition normally observed from TA to SOL was weak or absent, and heterogenic inhibition from G to SOL, while observed in averaged responses, was not statistically significant. These results support earlier suggestions that a reduction of central inhibition contributes to reflex abnormalities in cats with transected spinal cords.

319.14

THE EFFECTS OF POSTSYNAPTIC INHIBITION ON THE MONOSYNAPTIC REFLEX OF THE CAT. **Charles Capaday* and Richard B. Stein, Department of Physiology, The University of Alberta, Edmonton, Canada T6G 2H7.**

Results of a computer simulation study (Capaday and Stein, J. Neuroscience. Meth. 21:91-104, 1987) revealed that presynaptic inhibition of the Ia-afferents projecting to a motoneuron pool was the only central mechanism that could control the size of the monosynaptic reflex when comparisons were made at the same level of recruitment. In our model, the extra excitatory current necessary to restore the recruitment level to the desired value also restores the size of the monosynaptic reflex response. We have, therefore, tested the prediction concerning the effects of postsynaptic inhibition in postmammilary precollicular, decerebrate cat. Activation of the soleus motoneurons was produced by stimulation of the contralateral common peroneal nerve or by spontaneous episodes of motor activity. The monosynaptic reflex was elicited by stimulation of the cut L7-S1 dorsal roots. Tonic post-synaptic inhibition of the soleus motoneurons was produced by activation of Renshaw cells through repetive antidromic stimulation of the LG-MG nerves. When the amplitude of the monosynaptic reflex is plotted against the isometric soleus tension, a measure of the recruitment level, the data obtained when the motoneurons were under the influence of postsynaptic inhibition falls along the same straight line as the data obtained in the control condition. Presynaptic inhibition, on the other hand, can control the amplitude of the monosynaptic reflex independently of the recruitment level.

MECHANISM OF YIELD COMPENSATION IN REFLEXIVELY ACTIVE MUSCLE DURING RAMP STRETCH. Di. Boškov* and W. Z. Rymer, Dept. of Physiol., Northwestern Univ., Chicago, IL 60611. The mechanical output of reflexively active skeletal muscle demonstrates grossly linear, springlike behavior in response to ramp and hold stretches, whereas the stiffness of areflexive electrically activated muscle falls abruptly (a condition called "yield") after the amplitude of stretch exceeds a fraction of a millimeter. The patterns of spindle afferent discharge and the subsequent increase in motoneuronal activity, manifested as increase in EMG, strongly suggest that these reflex components are primarily responsible for linearization of muscle output. However, the fact that the reflex component of EMG occurs before or near the time of yield (depending of stretch velocity) indicates that some form of predictive mechanism is involved. In this study, we modeled the behavior of muscle under a variety of activation conditions.

Computer simulations of muscle responses, based on Huxley's model with Zahalak's modification, have shown that yield can be prevented by recruiting new motor units in order of increasing size, starting shortly after the onset of stretch. Subsequent recruitment of new units improved linearity during the later phase of stretch. Step increase in motoneuronal discharge of already recruited units prevented yield to some extent, but responses during the later phase of stretch were less linear. Based on these and previous results obtained during electrical stimulation of cat triceps surae muscles (which suggested that the yield is most effectively prevented by recruiting more motor units after the onset of stretch), we produced a model of motoneuron pool. This model consisted of a group of threshold devices, each representing a group of motoneurons with similar firing thresholds in order of increasing size, with common input in form of integrator of motoneuronal input. To complete the reflex loop, we used a nonlinear model of spindle response whose output was proportional to the low power of stretch velocity. Simulations of the whole reflex loop, including conduction delays, yielded responses in good agreement with well known responses of reflexively active muscle. These results support the hypothesis of preferential role of early recruitment in yield compensation and reinforce the significance of predictive or anticipatory regulation of muscle mechanical properties by reflex pathways.

EFFECTS OF DIFFERENT SYNAPTIC INPUTS ON THE DISCHARGE PROPERTIES OF A MODEL POOL OF ALPHA MOTONEURONS. R.K. Powers, Dept. of Physiol. & Biophys., Univ. of Wash., Seattle, WA 98105

Acute partial spinal lesions produce a number of alterations in the discharge properties of cat medial gastrocneumius (MG) alpha motoneurons, including a decrease in minimum steady discharge rates and an increase in discharge synchrony (Powers and Rymer, Soc. Neurosci. Abstr. 12:465,1986). These alterations could result from changes in the pattern and magnitude of synaptic inputs to the MG pool. A computer model of a small portion of the MG motoneuron pool (20 cells) has therefore been developed to investigate the effects of different patterns of synaptic input on motoneuron discharge behavior.

The neuron model used is a modification of that described by MacGregor and Oliver (Kybernetik 16:53, 1974). Currents flowing through synaptic and spike activated conductances are summed and divided by the total cell conductance to determine their net effect on membrane potential. Spikes occur whenever this value exceeds a set threshold and are followed by exponentially decaying potassimum (K) and calcium (Ca) conductances. Values of voltage threshold, input conductance, maximal K and Ca conductances and time constants of decay were chosen so that discharge behavior matched that described for type S and FR MG motoneurons.

Preliminary simulations have focussed on the effects of Renshaw inhibition on motoneuron discharge behavior, and have indicated such effects to be rather weak. The ability of common excitatory input to synchronize motoneuron discharge is slightly reduced in the presence of high levels of Renshaw inhibition, but minimum steady discharge rates are unaffected. The dependence of motoneuron discharge behavior on the magnitude, distribution and spectral content of other common excitatory and inhibitory inputs to the pool is currently being investigated.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: OCULOMOTOR SYSTEM II

320.1

COMMISSUROTOMY IMPAIRS BIHEMISPHERIC COORDINATION OF VISUALLY GUIDED PURSUIT EYE MOVEMENTS. E.G. Keating. Dept. of Anatomy and Cell Biology, SUNY Health Science Center, Syracuse, N.Y. 13210.

Some eye movements require cooperation between the two cerebral hemispheres. For example, if a visual target appears in the right visual field and moves away from the fovea, the left hemisphere computes the retinal velocity of this target, but the motor command for rightward smooth pursuit comes primarily from the right hemisphere.

Some of this interhemispheric cooperation occurs at the level of the forebrain. Two monkeys learned to pursue step-ramp targets that appeared in the left or right visual field and moved toward or away from the animal's fixation point. The posterior half of the corpus callosum was then transected. The surgery slowed pursuit for a period of one to three weeks. Eye acceleration and peak velocity during the initial 100 ms of pursuit and also peak velocity during the maintenance phase of pursuit were abnormal. In at least one of the monkeys the deficit cannot be laid to generalized trauma, since only pursuit of targets moving away from the fovea was significantly impaired. (NSF BNS8603915).

320.2

BRAIN REGIONS IN HUMANS ACTIVATED DURING SMOOTH PURSUIT VISUAL TRACKING. F. Miezin*, C. Applegate*, S. Petersen* and P. Fox, (SPON: T.O. Videen) Caltech, Pasadena, CA 91125 and Wash. Univ. Sch. of Med., St. Louis, MO 63110.

Positron Emission Tomography (PET) was used to monitor cortical neuronal responses as reflected by increased cerebral blood flow while subjects followed a visual target. Three horizontal target motions were used: sinusoidal; constant velocity to the right with return saccade to the left; and constant velocity to the left, return to the right; and a control state where the target is stationary. Two sets of scans for each target motion were obtained during a single session from each subject (n=7). The control scan was subtracted from each of the activated scans, and the resulting difference images were averaged for each of the stimulation conditions.

The cortical areas activated during pursuit eye movements include a dorsal area in parieto-occipital cortex (PO); a lateral area in temporo-occipital cortex (TO); and a region including primary and adjacent visual cortex. Horizontal saccades elicit responses in PO, the primary and secondary visual areas, the supplementary motor area, cerebellum and the frontal eye fields. No responses were seen in TO. Area TO is near a motion-processing region that may be homologous to area MT in macaques (ARVO abstract, 1988). Since TO is activated during pursuit eye movements and is near the MT homologue, TO may be homologous to area MST, a region in macaque cortex active during pursuit eye movements.

320.3

PROJECTIONS FROM THE FRONTAL LOBE EYE FIELDS TO THE UPPER BRAIN STEM IN MONKEY. B.L. Shook, M. Schlag-Rey and J. Schlag. UCLA, Dept. Anatomy and BRI, Los Angeles, CA 90024

Do patterns of connectivity of the supplementary eye field (SEF) more closely resemble those of the arcuate frontal eye field (FEF) or other cortical motor regions ? WGA-HRP (10%; TMB histochemistry) was used to study pathways of the SEF, FEF, SMA and primary motor cortices. In 2 monkeys the SEF was defined via recording and stimulation methods.

Only SEF and FEF injections labeled pre-oculomotor nuclei. SEF as FEF projects to the ipsilateral pretectum (n. limitans and n. optic tract) and the interstitial n. of Cajal. All injections labeled the superior colliculus. SEF projects to layers I, III and IV and FEF to I-IV. SMA projects to ventral IV and motor cortex to VI. Sparse pathways were found from SEF to the raphe omnipause region and from FEF to n. olivary pretectalis.

All areas injected project to the basis pontis but the terminal nucleus varied according to the locus of the injection (e.g. FEF alone to n. dorsolateralis). The pontine tegmentum exhibited dense anterograde label in n. reticularis tegmentis pontis; dorsal injections labeled the medial, and lateral injections the lateral region of this nucleus.

320.4

RECOVERY OF EYE MOVEMENTS AFTER BILATERAL FOVEA LESIONS IN MONKEYS. S. J. Heinen* and A. A. Skavenski. Dept. Psych., Northeastern Univ., Boston, MA 02115.

This report is concerned with the characteristics of fixation and saccadic eye movements in monkeys treated by laser photocoagulation to simulate bilateral human macular degeneration. The results come from a broader study of the behavioral and neural changes that accompany this major cause of blindness. Discrete time and location of lesions uncovered differences between the eye movements not seen in disease. Monkeys were trained to fixate a small target and track it with saccades when it was stepped to randomly selected 10 deg arc eccentricities. Just after lesions, animals formed a new preferred retinal locus (PRL) where fixation was stable. This PRL did not change position over long time periods. Just after lesions, primary saccades placed eccentric targets on scotomatous fovea. Small corrective saccades moved targets to the PRL. Over a period of several months, slowly increasing percentages of primary saccades directed targets to the new PRL or other intact retina. Thus, both oculomotor systems were plastic, but the saccadic system appeared much more difficult to reprogram.

320.5

VISUAL MOTION PROCESSING IN HUMANS AFTER LOSS OF STRIATE CORTEX. L. Tychsen, M. Rizzo, R.R. Hurtig*, K.W. Stevens*, E.J. Engelken*. USAF Sch Aerosp Med, Brooks AFB TX 78235.

The striate cortex provides the major input to motion processing areas of extrastriate cortex in primates. A minor input to extrastriate cortex may also be provided directly from subcortical structures. The minor input might be evident as a weak capacity for motion processing after loss of striate cortex.

We tested motion processing after loss of striate cortex in 2 patients who had unilateral occipital lobectomies 3 and 10 years before entry. Tissue loss was documented by CT and was evident behaviorally as an absolute hemianopia. Motion processing was measured as transient pursuit eye movement evoked in 750-1500 individual trials of ramp stimulus motion, using a scleral coil to record eye movement. Motion of a high luminance spot (0.5 deg, 1400 fL He-Ne laser) at eccentricities 3-30^{o} within the hemianopic field evoked pursuit in the appropriate direction. Latencies were approximately twice as long, and pursuit accelerations one-fifth to one-half as robust, as those evoked by equivalent motion in the sighted field. Step changes of spot position in the hemianopic field did not evoke accurate saccades. Motion of a large pattern (luminance 2.5 fL) in the hemianopic field failed to evoke optokinetic nystagmus.

Our findings indicate a weak capacity for visual motion processing in humans after loss of striate cortex. It is possible that this capacity is mediated by minor inputs to extrastriate areas from structures such as colliculus.

320.6

OCULAR MOTOR DEFICITS IN RETINOTOPIC AND CRANIOTOPIC SPACE IN MONKEYS WITH UNILATERAL STRIATE AND CORPUS CALLOSUM LESIONS. R.J. Tusa, S.J. Herdman, and M. Mishkin. Johns Hopkins University, Baltimore, MD 21205, and Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892.

We examined the role of visual input from striate cortex (V1) to one cerebral hemisphere in the generation of saccades. Three rhesus monkeys with a scleral coil were trained to fixate a target light randomly stepped to 1 of 9 positions between L20° & R20°. 2 monkeys then had a one-stage unilateral V1 ablation and section of the posterior half of the corpus callosum (CC), while the third monkey had a unilateral V1 ablation followed 6 weeks later by a CC section. We tested the animals for 6-12 months post-op.

Retinotopic space. During the first 2 post-op weeks, the monkeys did not make visually-guided saccades to dim (3 ft-L) or bright (2000 ft-L) lights in the visual field contralateral to the V1 lesion. By 1 month, they made visually-guided saccades to bright and dim lights in the defective visual field, but they did not recover the ability to make express saccades (latency < 100 msec). These defects were unrelated to the craniotopic location of the target.

Craniotopic space. During the first post-op week, the 2 monkeys with the one-stage operation did not make spontaneous or target-searching saccades into craniotopic space contralateral to the V1 lesion. By 1 month this deficit resolved, but the latencies for visually-guided saccades increased progressively for targets located further in contralateral craniotopic space. The monkey with the isolated V1 lesion had similar deficits after the CC section.

In summary, we found retinotopic and craniotopic saccade deficits following unilateral V1 + CC lesions. Within 1 month of a V1 ablation, other areas can mediate the retinotopic location of visually-guided but not express saccades. The deficits related to craniotopic space are more persistent, and may be due to defects in directing visual attention, constructing an internal map of extrapersonal space, or both.

320.7

RELATIONSHIP BETWEEN CATCH-UP SACCADE FREQUENCY AND SMOOTH PURSUIT GAIN IN SCHIZOPHRENICS AND NORMALS. LA Abel, L Friedman, J Jesberger* and HY Meltzer, Biomed. Eng. Dep't, U of Akron, Akron Ohio, 44325, and Psychiat. Dep't, CWRU and University Hospitals of Cleveland.

One approach used in evaluating pursuit has been counting catch-up saccades (CUS). Since these are generated in response to a position error arising from low-gain pursuit, they seemingly should correlate with pursuit gain. But, if there is a variation in how much position error is tolerated before generation of a CUS, the same number of CUS might occur with considerably different gains. We tested 10 schizophrenics and 10 normals, plotting their pursuit gains versus number of CUS, for 3 cycles of tracking at 5^{o}/s. There was a statistically significant correlation between CUS and gain in normals (-.61, p<.05, Pearson r), but not for schizophrenics (-.03). This suggests that the neural mechanism which generates corrective saccades is less consistent in schizophrenics than normals. Some patients may have a lower threshold for position error correction. This is in contrast with the apparent increase in the velocity error threshold seen in the same group of patients (Friedman et al., this volume). CUS counting may not be a good reflection of pursuit gain in these patients; the results also suggest differences in error processing between schizophrenics and normals. Supported in part by USPHS Grant # MH41684.

320.8

INCREASE OF HYPOMETRIC SACCADES IN SCHIZOPHRENICS
A.Mackert*, C.Woyth* and M.Flechtner*
(SPON: J.Kasper). Department of Psychiatry, Free University of Berlin, 1000 Berlin 19 (West) F.R.G.

Dysfunctions of eye movements are believed to be a possible psychophysiologic correlate of schizophrenia, best known are dysfunctions of the smooth tracking system. We investigated the accuracy of saccadic eye movements in 47 schizophrenic patients having acute psychotic symptoms. Diagnostic criteria fulfilled RDC-requirements for schizophrenia. Psychopathology was assessed with the Brief Psychiatric Rating Scale, the Scale for Assessment of Negative Symptoms, and the Prognostic Scale. No patient was treated with neuroleptics at the time of the examination or showed neurological abnormalities. The age range was 17-57 years. Horizontal eye movements were recorded with DC-Electro-oculography. The patients were given the task to fixate a target that was displaced horizontally at unpredictable intervals and at random amplitudes (7.5 to 20°) in both directions.

Schizophrenics produced significantly more dysmetric, undershooting saccades than a control group of sex- and age-matched healthy volunteers. Undershooting was especially prominent for saccades with small amplitudes. The prevalence of dysmetric saccades was significantly correlated with the length of illness, poor prognosis, and motor retardation. This impairment of visuomotor performance is more likely caused by dysfunction of cortical than by subcortical structures.

320.9

NEW ASPECTS OF DEFECTIVE PURSUIT IN SCHIZOPHRENICS

L Friedman, IA Abel, J Jesberger*, HY Meltzer, Psychiat. Dep't, Case Western Reserve U and University Hospitals, Cleveland, Ohio 44106, & Biomed. Eng. Dep't, U of Akron.

There have been few quantitative studies of smooth pursuit eye movements of schizophrenics. We examined the tracking of 5°/s targets by neuroleptic-treated schizophrenics (N=10) and normals (N=10), measuring time- weighted pursuit gain, catch-up saccades (CUS), mean duration of tracking segments, linearity of those segments (average Pearson r) and right/left gain ratio.

Mean gain for the schizophrenics was lower (.81 vs .99, p<.001, Mann-Whitney U) in agreement with previous reports. CUS were also more numerous (26.2 vs 9.6, p<.002) and mean segment duration lower (450 vs 710 ms, p<.001) for 3 cycles of tracking in the schizophrenics. Both groups had symmetric (left vs right) pursuit.

The most novel finding was the significantly poorer linearity of the pursuit segments made by the schizophrenics (.947 vs .989, p<.002). Thus, tracking deviated around a straight line without causing sufficient position error to elicit a saccade. This suggests that control of eye velocity is poorer in schizophrenics. Thus, schizophrenic pursuit tracking is grossly defective as measured by average gain. It is also defective in fine control as measured by linearity. Supported in part by USPHS Grant # MH41684.

320.10

SPONTANEOUS SACCADES IN THE PIGMENTED RAT FOLLOWING INFERIOR OLIVE AND CEREBELLAR LESIONS.

P. Strata*, L. Chelazzi*, M. Ghirardi*, F. Rossi* and F. Tempia* (SPON: European Neuroscience Association). Dept. of Human Anatomy and Physiology, University of Turin, 10125 Turin, Italy.

Rat saccadic eye movements have been chosen as a model to investigate the effects of inferior olive (IO) and cerebellar lesions on motor behavior. The horizontal component of spontaneous saccades has been recorded by a coil system in 20, head-restrained, pigmented rats. 5 animals served as controls. In 5 rats the IO was bilaterally destroyed, at least 1 month before recording, by means of 3-acetylpyridine. In 5 other rats the posterior vermis (lob. VI-IX) was ablated. The flocculus and paraflocculus were bilaterally removed in the remaining 5 rats. No clear saccadic impairments were observed in vermectomized animals. On the contrary, following either IO or flocculo-parafloccular lesion, saccades were characterized by a large, backward post-saccadic drift with an exponential time course (time constant 150-200 ms). Careful analysis did not reveal any significant difference between the effects of these two lesions. Such a drift is due to a mismatch between the phasic and the tonic components (the pulse and the step) of saccadic innervation with a significant reduction of the latter. Our results show that, in the rat, the flocculus and/or paraflocculus together with the IO are essential to properly coordinate the phasic and tonic activities in saccadic eye movements.

320.11

INFLUENCE OF TEMPERATURE ON OPTOKINETIC AND VESTIBULAR EYE MOVEMENTS IN GOLDFISH.

J. G. McElligott, M. Weiser* and R. Baker (SPON: J. O'Neill). Dept. Pharmacol., Temple Univ. Sch. of Med., Philadelphia, PA 19140 and Dept. Physiol. & Biophys., NYU Med. Ctr., New York, N.Y. 10016

Temperature acclimation must be requisite for appropriate motor behavior in ectothermic vertebrates. This hypothesis was examined for visual-vestibular control of horizontal eye movements and adaptive VOR gain changes over a temperature range of 4-21°C. Goldfish acclimated to 21°C for two months were tested with sinusoidal visual and vestibular stimuli (0.032-5.0 Hz) at 16-32°/sec. Little alteration was observed in the eye movements recorded until temperature reached 11°C; however, gain modifications after visual-vestibular interaction were already significantly reduced by 16°C. Further cooling from 11 to 4°C gradually decreased both optokinetic and vestibular eye velocity as well as the ability to either suppress or increase the gain of the VOR proportional to stimulus frequency. Around 6°C the VOR noticeably decreased in amplitude; however the phase of eye velocity remained constant. Close to 4°C, stable eye position and spontaneous saccades were still observed, but the VOR exhibited nearly a complete loss of fast phases. All temperature-related effects were reversible. These data demonstrate that compensatory visual and vestibular control of eye movement, except for adaptive gain control, rapidly adjusts to large fluctuations in temperature. Supported by EY02007 and NS13742.

OPEN LOOP OPTOKINETIC NYSTAGMUS OF THE SQUIRREL MONKEY EVOKED FROM A BoTx-IMMOBILIZED EYE.

O.-J. Grüsser and F. Behrens*, Dept. of Physiology, Freie Universität, Arnimallee 22, 1000 Berlin 33, Germany

Botulinum toxin (BoTx "Oculinum", San Francisco 10-11 units) injected into the retrobulbar tissue of Squirrel monkeys (Saimiri sciureus) induces within 2 to 3 days a complete immobilization of all extraocular muscles lasting for about 10 to 12 days and recovering thereafter to normal mobility of the eye within another 10 days. This technique provides a simple method to study the open loop optokinetic nystagmus (OKN). Eye movements were recorded by means of the electromagnetic search coil technique and the recordings were performed in awake squirrel monkeys.

1) In normal squirrel monkeys gain of horizontal OKN reached values between 0.8-0.97 at stimulus angular velocities below 150 $deg.s^{-1}$ (2.37 or 15° black and white vertical stripe pattern).

2) Optokinetic stimulation of the immobilized eye led to vigorous OKN and OKAN of the other eye, whereby maximum gain was found at low retinal stimulus velocities V_r (2-5 $deg.s^{-1}$, gain above 30).

3) Increasing V_r led to a decrease in gain with a slope of about -20 dB/decade.

4) When a stripe pattern suddenly appeared, rotating at a constant angular velocity, the open loop OKN-gain increased with time and reached a maximum about 40-50 seconds after stimulus onset. Thus, open loop OKN-gain is a time dependent value.

The work was supported in part by a grant of the DFG (Gr 161).

320.13

SENSORY AND MOTOR EFFECTS OF MONOCULAR DEPRIVATION ON THE OCULOMOTOR RESPONSES IN SQUIRREL MONKEYS.

F. Behrens* and O.-J. Grüsser. (SPON: European Brain and Behavior Society). Dept. of Physiology, Freie Universität Berlin, Arnimallee 22, D-1000 Berlin 33, Germany

By means of the electromagnetic search-coil technique the optokinetic nystagmus was measured in three normal and four monocularly deprived adult squirrel monkeys. Monocular deprivation had been achieved by lid suture performed during the first 10 days of life. The duration of lid closure varied between 1.5 and 9 years. Some weeks before commencing the experiments the eyelids were opened and the lid canthus reconstructed.

Normal animals responded to horizontal optokinetic stimulus velocities up to 350-400 $degrees.s^{-1}$ (vertical stripe pattern 2.4 or 15° period). OKN-responses to monocular and binocular stimulation showed only slight differences in the upper velocity ranges and. no directional selectivity. In monocularly deprived animals OKN aroused by monocular stimulation of the non-deprived eye was similar to that in normal animals. Optokinetic stimulation of the deprived eye evoked an OKN with a reduced gain and significantly smaller maximum angular velocity as well as a much higher variability in the responses compared to the OKN evoked through the normal eye. Some directional differences (temporo-nasal/naso-temporal) were found.

Since all monocularly deprived animals exhibited squinting of the deprived eye - preferentially towards the nasal side - monocular deprivation also has an effect on the "efferent" components of the oculomotor system.

Supported in part by a grant of the DFG (Gr 161).

THEORETICAL MODELS AND COMPUTER SIMULATIONS OF THE OPTIC TECTUM OF THE BARN OWL.

J.C. Pearson*, C.D. Spence*, W.E. Sullivan, J.J. Gelfand* and R.M. Peterson*. SRI-David Sarnoff Research Center, CN5300, Princeton, NJ 08543; Dept. of Biology, Princeton Univ., Princeton, NJ 08544.

The optic tectum of the barn owl contains a map of space that registers the positions of visual/acoustic stimuli and encodes the head saccade vector needed to center the stimuli in the field of view. The sensory maps in the tectum derive from topographic projections from purely visual and acoustic maps in the retina and the external nucleus of the inferior colliculus (ICX), respectively (J. C. Neurol. 218). In young owls, loss of visual/acoustic registration produced by prisms or ear plugs is corrected by compensatory shifts in the acoustic map if visual experience is provided (Science 230). This shift could be caused by changes in the tectum itself, or could simply reflect changes in the earlier stages that produce the ICX map. Our model tests the first possibility. We assume (predict) that the ICX-to-tectum projection is topographic and anatomically broad, but is functionally sharpened through synaptic plasticity. Synapses are strengthened (weakened) if the pre-synaptic element is active (inactive) and the post-synaptic voltage is greater than the threshold value, Ts (Tw). The important parameters in the model are the values of Ts and Tw relative to the strength of the fixed visual connection strength, Cv (e.g., Tw > Cv > Ts). Fusion itself can be achieved with many different choices for these relationships, however each choice is distinguished by the way the connection strengths and the receptive fields (RFs) change in time, and by the maximum correctable separations between the visual and acoustic RFs. These maximal displacements are independent of the quadrants the RFs are in, thus calling for a re-examination of the "quadrant limit" effect (Science 230). The model is also in disagreement with extracellular HRP tracing studies that show the ICX-to-tectum projection to be fixed and point-to-point. However, if the plasticity does occur at earlier stages of acoustic processing, as this evidence suggests, it is unclear how visual experience could control it, since these stages are not known to receive direct visual input.

Recent experiments with two stimulating electrodes show that the head saccade made in response to simultaneous stimulation is roughly the average of the response made to each individually (Soc. Neuro. Abstr. 1987 112.10). We present two models of how the average positional information encoded on a neural space map could be computed. One model employs a quadratically weighted excitatory topographic projection onto another map with local lateral inhibition. The other employs linear gradients of excitatory connections of opposite slope onto separate motor pools that set the effective spring constants of the agonist/antagonist muscle groups that rotate the head.

A MODEL OF THE SMOOTH PURSUIT SYSTEM WITH REALISTIC EMERGENT PROPERTIES. R.J. Krauzlis* and S.G. Lisberger. Dept. of Physiology, Div. of Neurobiology, University of California, San Francisco, CA 94143

The primate smooth pursuit system uses visual motion information to initiate and guide tracking eye movements. Lesion and electrophysiological studies have identified several brain regions that are involved in this behavior, but it is difficult to draw conclusions about their roles, because the actual signals used by the pursuit system are not known. To assess the role of particular visual motion signals, we have used behavioral data as the basis for a computer model of the pursuit system.

We measured the initiation of pursuit in Rhesus monkeys using the scleral search coil technique. Since analysis of the first 200 ms of pursuit indicates that there are at least three components in the response to moving targets, the model contains three parallel visual pathways. The first pathway is sensitive to image velocity, the second to image acceleration, and the third to the impulse of image acceleration that accompanies the onset of target motion. The model was tuned by adjusting each pathway so that the rising phase of the response to constant velocity and acceleration targets matched the data obtained from monkeys. The model does not explicitly reconstruct target velocity; instead, eye acceleration is driven directly by different aspects of visual motion. The model has several interesting emergent properties. First, the closed loop behavior of the model closely matches closed loop data, even though the model was based strictly upon the rising phase of open loop data. Second, the model shows steady-state oscillations of the same frequency as seen during sustained tracking in the monkey. Driving either the model or the monkey's pursuit system at this resonant frequency results in a 180 degree phase shift between eye and target. Finally, increasing the delay of visual feedback in the model increases the period of oscillations just as in the experimental data. The corroboration of these emergent properties by experimental data indicates that the elements within the model capture important aspects of signal processing within the smooth pursuit system. THE LINEARIZING PROPERTIES OF BILATERAL STRUCTURES IN THE OCULOMOTOR CONTROL SYSTEM. H.L. Smith* and H.L. Galiana. Biomed. Eng. Unit, McGill University, Montreal, Que. Canada H3A 2B4.

We have explored theoretically and through model simulation, the linear operating range of bilateral motor circuits in the brainstem, controlling eye movements. We considered the vestibulo-ocular reflex (VOR), which causes conjugate eye movements opposite to angular head rotation, during the slow-phases of vestibular nystagmus. Its linear range is evaluated from the ratio peak-eye-velocity/peak-head-velocity during step or sinusoidal head rotations. In the VOR's three-neuron arc, second order neurons in the vestibular nuclei typically have half the resting rate and at least twice the sensitivity of primary vestibular neurons. Hence, the VOR should be non-linear at head velocities well below the linear range of the canal (1/4 of canal range in this example). Yet, behaviourally, it remains linear for rotations beyond the linear range of both central and primary neurons!

Simulations of a bilateral model of the VOR [JNP 51:210,'84] show that a very simple mechanism could account for the large linear range of the VOR, and possibly of all motor systems. The use of a bilateral circuit introduces two aspects to central responses: The first causes reciprocal central modulations, in response to the difference between sensory or descending inputs on the two sides, which would eventually silence neural pools on one side. The other responds to the sum of bilateral inputs and raises equally the activity on the two sides, i.e. raises the 'background resting rate' dynamically. Analysis and graphs show that these two components complement each other to linearize the canal information and avoid central cut-offs. As a result, the observed linear range of a reflex can grow automatically, or extend itself, with increasing amplitudes on the sensory inputs. This property would interact with the additional, beneficial, effects of nystagmus reported earlier [SNA 12:297.16,'86].

SHORT TERM POTENTIATION AS A MECHANISM FOR A CENTRAL INTEGRATOR L. Shen* (SPON: R. Poppele) Lab. of Neurophysiology, Univ. of Minnesota, Minneapolis, MN 55455

Neurophysiological studies in oculomotor systems suggest that a time integral operation is performed by neural circuits. Previous models of the neural integrator incorporate positive feedback to generate the required time constants. Such models are generally unsatisfactory due to stringent parameter requirements and inherent instability. A new model using presynaptic potentiation phenomena is proposed. It is shown that under certain conditions, the nonlinear relation between presynaptic input and postsynaptic output has the property of an integral operator. Unlike previous models, this model is robust and without unstable singular points. Fluctuations of the parameters involved account naturally for the observed variations in the behavior of neurons in the literature. Possible incorporation of the model in the context of the vestibular-oculomotor reflex is discussed. It is shown that the model fits within the three neuron pathway. The eye position signals commonly observed in the vestibular neurons can now be explained by synaptic interactions without the extra pathways usually assumed. Results of lesion studies on cerebellum and brain stem are also accounted for by the model. It is emphasized that the nonlinear synaptic interactions between neurons have potentially very powerful computational capacity.

SENSORY SYSTEMS: AUDITORY SYSTEMS VI

321.1

AUTOREGULATION OF COCHLEAR BLOOD FLOW IN WISTAR-KYOTO RATS. W.S. Quirk, J.K. Coleman, J.W. Wright and H.A. Dengerink. Dept. of Psychology, Washington State Univ., Pullman, WA 99164-4830.

Previous investigations in our laboratory observed changes in cochlear blood flow (CBF) in normotensive Wistar-Kyoto (WKY) rats that could be interpreted as autoregulation of CBF. To test this hypothesis WKY rats were intra-arterially infused with high doses of phenylephrine (0.02 mg/kg/min in 0.15 M NaCl) or angiotensin II (1000 pmol/kg/min in 0.15 M NaCl) for 10 minutes. The results of infusion of both vasoactive compounds showed an initial increase in CBF followed by a slow steady return to baselevel during sustained elevations in systemic blood pressure. To address the question of whether autoregulation of CBF could be induced while systemic blood pressure was maintained at baselevels, vasoactive compounds were infused into the supplying vessels of the cochlea to induce local changes in CBF independent of changes in systemic blood pressure. This was accomplished by inserting a micropipette (external diameter approximately 175 microns and internal diameter approximately 125 microns) into the vertebral vessel thus allowing slow infusions (100 nl/min) of angiotensin II, phenylephrine or vasopressin. The results showed that CBF decreases and are suggestive of local vasoconstriction caused by vascular receptor binding in the supplying vessels of the cochlea.

SINGLE CHANNEL PROPERTIES OF GOLDFISH (*Carassius auratus*) AUDITORY NEURONS *IN VITRO*. R.L. Davis, E.A. Mroz* and W.F. Sewell. Eaton-Peabody Lab., Massachusetts Eye & Ear Infirmary, Boston, MA 02114.

The goal of this work is to characterize the membrane properties of auditory neurons in culture. Single auditory nerve fibers were microdissected from the saccular nerve of the goldfish without the use of proteolytic enzymes and maintained in culture for periods of up to four weeks at room temperature.

The patch clamp procedure was used to record single channel currents from the growing ends of the neurons as well as from axonal membrane that had been acutely removed from the surrounding myelin. Experiments using the cell-attached configuration of the patch clamp technique have revealed ionic channels with conductances ranging from 16 to 120 pS in solutions that select for K^+, Cl^- or Ba^{++} currents. These channels are being systematically categorized according to voltage dependence, ionic specificity and position along the length of the neuron.

321.3

EFFECT OF CALCIUM CHANNEL BLOCKER D-600 ON NEURAL ACTIVITY IN THE LATERAL LINE OF XENOPUS. Steven L. Guth* and Dennis G. Drescher. Lab. of Bio-otology, Wayne State Univ., Detroit, MI 48201.

Previous investigations in our laboratory demonstrated that spontaneous activity of lateral line nerve fibers of X. laevis is inversely related to the concentration of divalent cation bathing the inner surface of the skin, and that suppression of spontaneous activity by Ca is greater than suppression by Mg (Guth & Drescher, Soc. Neurosci. Abstr. 13: 43, 1987). Our results suggested that transmitter can be released from hair cells in the lateral line without the influx of Ca through voltage sensitive Ca channels (VSCC), and that K-induced depolarization increases neural activity by activation of VSCC. The effect of D-600 on spontaneous activity was studied to test this hypothesis. One uM D-600 (K=2 mM; Ca=0.45, 0.9 or 1.8 mM) had no effect on spontaneous activity. At 5 uM D-600 inhibition increased with Ca concentration. In a paired comparison (n=4) of the influence of 1 mM vs 3 mM K (1.5 mM Ca) on the effect of 2.5 uM D-600, spontaneous activity in 1 mM K was 32% of spontaneous activity in 3 mM K, and D-600 inhibited spontaneous activity 30% in 1 mM K and 60% in 3 mM K. We propose that elevated K increases firing rate by depolarization of the hair cells, which increases Ca current through VSCC, producing a Ca (and D-600) sensitive release of transmitter, while in reduced K (hyperpolarizing) and/or reduced Ca, spontaneous activity is sustained by a mechanism which is less sensitive to D-600. Higher concentrations of D-600 can reduce spontaneous activity further; indeed D-600 is known to inhibit many processes unrelated to VSCC at concentrations greater than 1 uM (Miller & Freedman, Life Sci. 34: 1205-1221, 1984). ELECTROCHEMICAL ASPECTS OF MONOVALENT IONS OF THE STRIA VASCULARIS IN THE CHINCHILLA. K.Ikeda* and T.Morizono* (SPON: M.A.Ruggero). Lab. of Otophysiology, Dept. of Otolaryngology, Univ. of Minnesota Med. Sch., Minneapolis, MN 55414.

The electrochemical profile for K, Na, and Cl ions across the lateral wall of the scala media (SM) was investigated using ion-selective microelectrodes. Healthy chinchillas were anesthetized with ketamine hydrochloride (20 mg/kg). Artificial respiration was maintained and muscular relaxation was induced. After removal of the bony wall of the SM, the double-barreled ion-selective microelectrode successively impaled the spiral ligament (SL), basal cells (BC), intermediate cells or intrastrial space (I), and marginal cells (MC) to reach the SM using an autodrive manipulator at the rate of 1-2 μm/sec. The changes of the membrane potential and ion-selective electrode potential were recorded on the microcomputer at 0.5 sec intervals. The membrane potential from the SL in mV and the K, Na and Cl concentration in mM (mean±S.D.) are respectively as follows: 0 (n=30), 6.6±2.4 (n=10), 146.6±4.4 (n=10), and 109.8±4.6 (n=9) in SL; 4.8±8.5 (n=28), 100.1±16.8 (n=13), 33.9±20.2 (n=5) and 70.2±9.4 (n=6) in BC; 60.4±9.5 (n=32), 22.1±14.9 (n=10), 55.4±21.2 (n=9) and 55.1±14.3 (n=13) in I; 78.3±5.7 (n=27), 141.7±9.1 (n=10), 1.7±1.2 (n=10) and 117.6±21.5 (n=7) in MC; 78.1±4.1 (n=30), 143.0±10.3 (n=10), 1.5±0.7 (n=10), 143.3±13.9 (n=10) in SM. On the basis of the electrochemical potential gradient calculated from the present results, the transport mechanisms of monovalent ions in the stria vascularis were investigated.

DISCRETE CHARGE MOVEMENTS IN OUTER HAIR CELLS MAY DRIVE THE COCHLEAR FORCE GENERATOR. J.F.Ashmore. Dept. Physiology, Med. Sch., Bristol BS8 1TD, England.

Outer hair cells of the mammalian cochlea are the candidates for cellular generators of active mechanics within the cochlea. The cells generate potential-dependent longitudinal forces vectorially decoupled from forces acting on the apical transducer. The Cell length changes are ATP-independent and operate at acoustic frequencies, (Ashmore J.Physiol 388:323, 1987).

By summing paired pulse responses, as in gating current protocols, small asymmetric currents (<20pA) were measured in outer hair cells isolated for whole cell recording from the guinea pig organ of Corti. Experiments were conducted in bilateral Cs; Ca_i was buffered from the pipette. The currents decayed exponentially and were blocked by F_i. The results can be described by a translocated positive charge, (density about one elementary positive charge per 40nm sq.), equidistributed across the membrane at -30mV. The translocation rate matched *in vitro* rates of length change and suggests that charge movements, possibly associated with the membrane cytoskeleton, are closely linked to the force-producing step.

HAIR CELL AND PRIMARY AFFERENT RESPONSES IN AN IN VITRO PREPARATION OF THE ALLIGATOR LIZARD COCHLEA. R. A. Eatock. Dept. of Physiology, University of Rochester, Rochester NY 14642.

Understanding of stimulus processing by hair cells has benefited greatly from *in vitro* preparations that provide access to the hair cells' mechanosensitive surfaces. We have extended this kind of preparation to include the primary afferent (cochlear) neurons, using the auditory organ of the alligator lizard as a model system. The organ is excised and maintained at 20-25°C in an artificial perilymph (in mM: 168 or 164 Na^+, 2 K^+, 2 or 4 Ca^{2+}, 3 D-glucose, 5 Hepes). Hair cells are stimulated by moving individual hair bundles with stimulus probes attached to piezoelectric bimorphs (Corey and Hudspeth, J. Neurosci. Meth. 3:183, 1980). Intracellular potentials are recorded from hair cells and distal processes of the primary afferent neurons. As in other preparations, the hair cell responses may be several millivolts, saturate for large stimuli (>1 micrometer), and show frequency tuning. Postsynaptic potentials can be recorded from an afferent fiber in response to stimulation of a single hair bundle. These results suggest that this preparation will be useful for examining stimulus processing by both pre- and post-synaptic elements of the primary afferent synapse.

321.7

REGIONAL DIFFERENCES IN SACCULAR MORPHOLOGY AND EFFERENT RESPONSE IN THE TOADFISH, OPSANUS TAU A. Steinacker and D. N. Menton* Depts. Otolaryngology/ Anatomy Neurobiology, Washington University Sch. of Med., St. Louis, MO. 63110.

As part of a study of the toadfish efferent acousticolateralis system, a morphological and electrophysiological study of regional differences in the saccule was undertaken Scanning electron microscopy was used to define regional characteristics of hair cell stereocilia and kinocilia. Pronounced differences were found in these features in anterior, isthmus and posterior segment of the macula, with the longest kinocilia in rim areas of every segment. Intracellular recordings of spontaneous activity were taken from primary afferents from these 3 regions before and following electrical stimulation of the efferent nucleus in the medulla. Both inhibitory and excitatory effects of efferent activation were found, with inhibition being most prominent in the posterior saccule. Both effects were of prolonged duration following short stimulation pulses. The excitatory response often appeared only after a charateristic delay. This information correlates with the differential regional responses of saccular hair cells to acetylcholine as measured by patch clamp methods.

"BUNDLE BLOT" PURIFICATION OF HAIR CELL STEREOCILIA: ELECTROPHORETIC PROTEIN MAPPING G.M.G. Shepherd, B.A. Barres, and D.P. Corey. Neuroscience Program, Harvard Medical School; Neuroscience Group, Howard Hughes Medical Institute, and Department of Neurology, Massachusetts General Hospital, Boston MA 02114.

In search of the molecular basis of transduction and adaptation in vestibular hair cells, we have developed a method for the rapid and specific isolation of stereocilia from hair cells of the bullfrog sacculus. The sensory epithelium is stripped of its overlying otolithic membrane and the apical surface gently pressed onto nitrocellulose paper (NCP) with a force of 5-15 millinewtons. The tips of the stereocilia adhere; when the NCP is separated from the sacculus the stereocilia break at their narrow bases and are remain with the NCP. Rhodamine-phalloidin staining and scanning electron microscopy demonstrated that the yield of stereocilia is over 90% while all other cell components are virtually non-adherent.

Using this "bundle blot" method we have studied the electrophoretic pattern of stereociliary proteins. After elution in 1% SDS and 2-mercaptoethanol the proteins were separated in gradient mini-gels and silver stained. Major bands at 42 and 17 kDA co-migrated with actin and calmodulin, respectively. We have previously shown calmodulin immunoreactivity in stereocilia of dissociated hair cells. About 11 other proteins are enriched in stereocilia, at 25, 36, 51, 60, 68 (probably fimbrin), 74, 82, 90, 100, 135, and 220 kDa. A number of proteins present in the cell bodies were not in stereocilia, further indicating the specificity of the isolation. This electrophoretic map differs from that previously reported for intestinal microvilli, probably reflecting the functional differences of these structurally similar organelles. The identity of the stereociliary proteins is under investigation using Western blot analysis.

OUTER HAIR CELL MOTILITY STUDIED IN AN APPROPRIATE IONIC ENVIRONMENT. B.N. Evans*, R. Hallworth and P. Dallos, Auditory Physiology Lab. & Dept. of Neurobiol. and Physiol., Northwestern University, Evanston, IL 60208.

Several investigators have shown that isolated cochlear outer hair cells (OHCs) exhibit frequency-following motility in response to electrical stimuli. *In vivo*, OHCs exist at the interface of two different ionic media. A high potassium intracellular-like medium (endolymph) bathes the apical face, while a high sodium extracellular-like medium (perilymph) surrounds the basolateral face. In addition, the apical face is electrically polarized by approximately +80 mV. In all previous motility studies, isolated OHCs have been immersed in a high sodium medium only.

Using the approach of Baylor and colleagues (Baylor, Lamb & Yau, J. Physiol., 288, 589, 1979) we have developed a preparation in which OHC motility can be studied in an appropriate ionic and electrical environment. Isolated guinea pig OHCs prepared by conventional methods were gently aspirated into close-fitting fire-polished pipettes containing artificial perilymph. A seal was formed near the apex which was sufficient to separate the electrolytes environments inside and outside the pipette. OHC movements evoked by current applied through the pipette were measured by a photodiode placed over the cell nucleus and all responses were recorded on videotape.

When artificial endolymph was applied outside the pipette, the resting length of the cell in the pipette remained constant for up to 30 minutes. All OHCs outside the pipette rounded up in response to the potassium challenge, as has been reported previously. Under these conditions electrical motility was observable at as large or larger amplitudes than measured with conventional closely-applied pipettes. This demonstrates that OHC motility can be studied under conditions which more closely resemble those found in the intact cochlea. [Supported by NS08635 & NS07223 from NINCDS].

KAINIC ACID RECEPTOR IDENTIFIED IN THE FROG LABYRINTH USING MONOCLONAL AND POLYCLONAL ANTIBODIES. C.J. Dechesne*, K. Wheaton*, G. Goping*, D.R. Hampson and R.J. Wenthold (SPON: J. Fex) Lab. Neuro-otolaryngology, NINCDS, NIH, Bethesda, MD 20892.

As pointed out by Klinke (Hearing Res.,22:235,1986), the role of glutamate as the neurotransmitter of the synapse between the hair cells and afferent fibers in the cochlea, vestibule and other acoustico-lateralis receptors, remains to be clarified. Identifying the postsynaptic receptors of excitatory amino-acids is an option of choice for their intervention as neurotransmitters. Hampson and Wenthold (JBC,263:2500,1988) have purified a kainic acid receptor from frog brain and produced polyclonal (Wenthold et al.,1987) and monoclonal (Hampson et al., this meeting) antibodies.

Frog (Rana pipiens) vestibules were fixed in situ with 4% paraformaldehyde and .1% glutaraldehyde. Saccules were dissected, processed for cryostat (10μm thick) or vibratome (50μm thick) sectioning and stained with the avidin-biotin method. For E.M., vibratome sections were then processed for epon embedding.

Immunoreactivity with polyclonal antibodies was observed in vestibular afferent fibers from the point they reached the sensory epithelium. Myelinated afferent fibers, vestibular ganglion somata and hair cells were not stained. Electron microscopic observations showed that afferent endings contacting the sensory cells were stained with staining especially heavy at the postsynaptic membranes. Immunoreactivity patterns with a monoclonal antibody were identical to those with the polyclonal antibody, at the light level. These findings suggest that a kainic acid receptor is present at the postsynaptic site of the synapse between hair cells and afferent fibers in the frog.

TUNING PROPERTIES OF TUBEROUS ELECTRORECEPTORS. E.S. Olson* and L.D. Smullin* (SPON: L. Frishkopf). Depts. of Physics and Elec. Eng., M.I.T., Cambridge, MA 02139.

We measured the frequency dependent impedance of small areas of the electroreceptor/skin structure of two species of Gymnotid electric fish, and used the data to make an equivalent circuit model of the structure. (The qualitative form of the model was proposed by M.V.L. Bennett, in Lateral Line Detectors, P. Cahn, ed., 1967.) The quantitative model allows us to estimate the voltage across the innervated membrane of the electroreceptor cells. The electroreceptor-voltage frequency tuning that we estimate is as sharp as the selectivity that exists neurally at frequencies close to the most sensitive frequency, but the agreement decreases at high frequencies, where the electroreceptor selectivity levels off, while the neural selectivity continues a steep cut-off. Additional low-pass filtering (plausibly in the chemical synapse between the receptor cells and afferent fiber) would reconcile the difference. We show that additional low-pass filtering is also suggested by the phase-versus-frequency behavior of the nerve spike.

Our measurements usually supported the passive linear system model. However, spontaneous electroreceptor voltage oscillations were detected in some measurements, indicating that the electroreceptors sometimes operate in a regime of active nonlinearity. Nonlinear analysis of the Hodgkin-Huxley type equations that we used to describe membrane impedance showed that enough negative damping can lead to sustained oscillations. Near-cancellation of positive and negative damping terms produces strong voltage dependence in the damping at voltages close to the equilibrium voltage, leading to stimulus-level dependent "impedance." When driven with current within a frequency band around the spontaneous oscillation frequency, the oscillations entrained to the drive, suggesting that weak spontaneous oscillations do not degrade sensory reception.

321.12

THE MOUSE BRAINSTEM AUDITORY EVOKED POTENTIAL AS FUNCTIONS OF STRAIN AND AGING. M.W. Church and D.W. Shucard. Wayne State Univ., Detroit, MI and SUNY at Buffalo, NY.

Female mice from C57Bl/6, BDF1 and NZB/W strains were studied in age groups of 3-4 and 9 mo. BAEPs were recorded with from screw electrodes from unanesthetized, restrained animals. The BAEP was comprised of 4 vertex-positive components (labelled P1 through P4). There were significant effects for stimulus intensity (I), mouse strain(S), and the S x I interaction for all amplitude and latency measures. For example, latencies shortened and amplitudes increased with increasing stimulus intensity. Further, the NZB/W strain had the shortest P1 latency, the longest P4 latency, and the largest BAEP amplitudes. The P4-P1 interpeak latency (IPL) also varied significantly as functions of S, I, and the S x I interaction. Here, the BDF1 strain showed a shortening of the IPL with increasing stimulus intensity, while the other two strains showed a lengthening of the IPL between intensities of 50-90 dB, followed by a reverse trend at higher intensities. BAEP thresholds in the 3-4 mo. groups were comparable (Means = 24-31 dB). At 9 months, the NZB/W group showed the least amount of threshold elevation (+6 dB) while the BDF1 and C57Bl/6 strains showed elevations of +17 and +19 dB. These data indicate significant strain-dependent differences in BAEP latencies, amplitudes and age-related hearing loss. Also, the P4-P1 IPL is not constant across stimulus intensities (as some believe) but can vary complexly as functions of stimulus intensity and animal strain.

AUDITORY EVOKED MAGNETIC FIELDS RECORDED FROM PIGTAIL MONKEY. M. Reite, P. Teale*, J. Whalen*, M. Cox*, and B. Peterson* Dept. of Psychiatry, Univ. of Colo. School of Medicine, Denver, CO 80262.

We recorded the magnetoencephalogram (MEG) over the left hemisphere of a 16 mo old 2.2 kg female pigtail (M. nemestrina) monkey during delivery of 1 kHz 15 ms long tone pips at 75 DB SPL to the right ear. We used a second order gradiometer with 20mm coil diameter, 6 cm baseline, and DC SQUID. Recordings were made from 28 points over a 4x7 grid with 15 mm spacing between points. The subject was sedated with ketamine 10mg/kg and acetylpromazine .55mg/kg. Responses to 128 stimuli were averaged. A 50 ms latency component was identified, and amplitude values obtained with reference to a 200 ms prestimulus baseline. All amplitude values were used to construct spline interpolated mesh plots of the field. The 50 ms latency component exhibited phase reversal on a line extending from approximately the occiput to the bottom of the orbit, the point of phase reversal being approximately over the pinna of the ear. The magnetic field was outgoing anteriorly (positive extrema anterior) and ingoing posteriorly (negative extrema posterior). Both positive and negative extrema were approximately 125 fT in amplitude. Our findings indicate magnetic evoked auditory fields can be recorded from non-human primates, which accordingly may be able to model the human condition. Supported by USPHS MH41396, MH46335, and RR03259.

EFFECTS OF HEMICHOLINIUM-3 ON BRAINSTEM AUDITORY EVOKED POTENTIAL IN THE RAT. U. Knappe*, F. Wirtz-Brugger*, M. Cornfeldt* and S. Fielding. Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876.

Acetylcholine (Ach) has been implicated in the brainstem auditory pathway by the use of brainstem auditory potentials (BAEP). (F. Wirtz-Brugger, et. al., Faseb abstracts 1985).

Hemicholinium (HC-3) inhibits Ach synthesis by blocking the high affinity uptake of choline and thereby causes depletion of Ach required for cholinergic transmission (Finberg et. al., Life Sci. 25: 147-156, 1979). The purpose of the study was to provide proof for direct Ach involvement in the generation of the BAEP waveforms. BAEP's were generated in anesthesized rats using bilateral auditory click stimuli and averaged with a Pathfinder I. The following compounds were evaluated in a repeated measurement design: HC-3 @ 60 μg icv significantly decreases BAEP waveforms; Physostigmine (P) @ 0.01 mg/kg ip and carbachol (C) @ 5 μg icv both increased Wave VI significantly. C pretreated with HC-3 reversed the effects of HC-3 and significantly increased Wave VI amplitudes. P did not alter decreases caused by HC-3 suggesting a direct involvement of Ach in the BAEP.

321.15

STIMULUS DEPENDENCIES OF THE GERBIL BRAINSTEM AUDITORY EVOKED RESPONSE (BAER). H.F.Voigt and R.Burkard*. Biomed. Eng. and Com. Dis., Boston Univ., Boston, MA 02215.

Three experiments evaluating the effects of various stimulus manipulations on the click-evoked gerbil BAER are reported. Five replicable peaks (i through v) are observed within six ms of click onset. Click polarity and level were covaried in Exper. 1. There is a parallel increase in peak latencies and a decrease in peak amplitudes with decreasing click level. Exper. 2 covaried click rate and polarity. Peak latencies increased with increasing click repetition rate; this latency increase was greater for the later BAER peaks, producing an increase in the i-v interval. As rate increased, the amplitudes of waves i and v decreased monotonically, whereas the amplitudes of waves ii, iii and iv were largely uninfluenced by click rate. For both experiments, the amplitudes of waves i and v were dependent on click polarity; at high click levels and low rates, wave i was larger to rarefaction clicks and wave v was larger to condensation clicks. Exper. 3 evaluated the effects of click polarity on BAERs to high-intensity, low-rate clicks. In 8 of 10 gerbils evaluated, wave i amplitude was larger to rarefaction clicks, and in all 10 animals wave v was larger to condensation clicks. The effects of click level and rate on BAER peak amplitudes, latencies and interwave intervals are reminiscent of stimulus dependencies reported for the human BAER.

321.16

EFFECTS OF 6-CYANO-2,3-DIHYDROXY-7-NITRO-QUINOXALINE (CNQX/FG9065) ON GUINEA PIG COCHLEAR POTENTIALS. R.P. BOBBIN AND J.-L. PUEL* AND M. FALLON*. Kresge Hearing Research Lab., LSU Medical Center, New Orleans, LA 70112.

Evidence exists to suggest that the hair cell transmitter in octavolateralis systems is an excitatory amino acid such as glutamate. However there is a paucity of excitatory amino acid receptor blockers that are effective in altering the magnitude of the compound action potential of the auditory nerve (CAP). Notably without effect are the NMDA type of excitatory amino acid antagonists, but kynurenic acid, a broad spectrum blocker, is effective (Bobbin, R.P. and Ceasar, G.G., Hear. Res., 25:77, 1987). This study addresses the question of whether a new non-NMDA antagonist, 6-cyano-2, 3-dihydroxy-7-nitro-quinoxaline (CNQX/FG9065; Ferrosan), affects the CAP. Perilymph spaces of guinea pig cochleae were perfused with Ringer solutions containing up to 500 µm concentrations of CNQX at a rate of 2.5 µl/min. for 10 min. Immediately after each period of perfusion cochlear potentials were recorded from a wire inserted in the basal turn scala vestibuli. CNQX as low as 3.3 µm suppressed the CAP. CM and SP were not affected. To date, CNQX is the most potent drug tested which presumably acts at receptors which are involved in the generation of the CAP.

(Supported by an NSF research grant BNS-8419241, Kresge Foundation and the Louisiana Lions Eye Foundation.)

AGE-RELATED CHANGES IN VERTEX AND TEMPORAL COMPONENTS OF MIDDLE AND LONG LATENCY AUDITORY EVOKED POTENTIALS. A.T. Cacace* and J.R. Wolpaw (SPON: L. Nelson). Depts. of Surgery, Neurology, and Anatomy, Albany Medical College, Albany, NY 12208 and Wadsworth Center for Labs and Research, New York State Dept. of Health, Albany, New York 12201.

Anatomical and physiological changes in the auditory periphery, central pathways, and cortex occur with age. Non-invasive electrophysiological correlates of age-related changes, especially changes in auditory cortex, would enhance understanding of the normal aging process and increase ability to monitor aging and recognize abnormality.

We studied click-evoked AEP scalp topographies (20-256 ms) in 59 subjects (30 males, 29 females, 20-86 years) with no significant history of otological or neurological disease. All had pure tone audiometric evaluations. AEPs were recorded from 32 channels, all referenced to a balanced noncephalic reference. We assessed both temporal components, which are putative products of auditory cortex, and vertex components.

Combined regression analyses for both males and females showed significant age-related changes in the latency of vertex components Pa (.07 ms/yr, p<.01) and N1 (-.14 ms/yr, p<.01), and in the latency of temporal component TP41 (.04 ms/yr, p<.01). TP41 amplitude also changed significantly with age (.02 uV/yr, p=.013), and this change was greater in females than in males.

THE ROLE OF NEURAL ELEMENTS (CELLS AND NERVE FIBERS) IN THE GENERATION OF THE AUDITORY BRAINSTEM POTENTIAL. M. Zaaroor*, A. Starr, Lab of Experimental Neurophysiology, Dept. of Neurology, Univ. of Calif., Irvine, CA 92717

The neural origins of the brainstem auditory evoked potentials are still uncertain. In particular the role of various neural element (cells, fibers) in the auditory brainstem responses (ABR's) has not been decided. In order to provide information to resolve these problems we made lesions in the brainstem auditory pathway of the cat that were relatively selective for destroying cell bodies (Kianic acid) or the myelin of nerve fibers (Lysophosphatial Choline-LPC). Kianic acid (1%, 0.2-0.4 ul) for destroying nerve cells or LPC (10 mg/ml, 0.2-0.4 ul) for destroying myelin was injected to the region of the superior olivary nucleus and the trapezoid body in the brainstem of cats. The ABR's of these cats were studied preoperatively and for up to 45 - 50 days post operatively in a chronic unanesthetized condition. The effects of these selective neuronal and myelin lesions were different than those resulting from electrolytic lesions of these structures. The evidence suggests that both the nerve cells and the fibers contribute to the generation of ABR's components.

ADAPTATION AND RECOVERY OF AUDITORY NERVE NEUROPHONIC (ANN) RESPONSES. T.C. CHIMENTO*, C.E. SCHREINER, AND R.L. SNYDER*, Coleman/Epstein Laboratory, University of California, San Francisco, CA 94143

Determining the time constants of adaptation and recovery for long duration, low frequency tones in the auditory nerve is an essential part in the understanding of peripheral processing of sustained acoustic signals. ANN responses to 800Hz, 100ms tones presented at 10-30 dBSL have been recorded using bipolar platinum-iridium electrodes placed on the VIIIth N of the cat to determine if the ANN accurately reflects the characteristics of single unit responses.

Adaptation of auditory fiber responses can be fit to the equation $R(t)=(100-\sigma)e^{-t/\tau A}+\sigma$ (Eggermont, 1985 *Hear. Res.*18:57-71) where R(t) is the percent of the response at time t re: onset amplitude, σ is the percent of steady state re: onset amplitude, t is time after stimulus onset and τA is the adaptation time constant. The cat ANN data fits this equation. τA is invariant for each animal at all stimulus levels, with a range of 10-30ms across animals. Recovery of the ANN onset from a 100ms masker fits the equation $R(\Delta t)=(100-\omega)e^{-\Delta t/\tau R}$ (Harris & Dallos, 1979 *J.Neurophys.* 42:1083-1107) where R(Δt) is the percent of the masked response re: unmasked response at time Δt, ω is 100-(no masker response amp/masker response amp at Δt=0), Δt is the delay between masker offset and probe onset, and τR is the recovery time constant. For 300ms probe tones at Δt=0 the recovery of the response as a function of time after probe onset also fits the equation. In both cases τR varys with masker intensity and ranges from 35-125ms.

These results indicate that τA and τR for the ANN are comparable to those measured using single unit techniques and suggests that the ANN can be used to accurately determine the τA and τR of auditory fibers using low frequency, low amplitude, long duration tones. It has become possible to record ANN responses directly from the auditory nerve in patients undergoing surgery for removal of acoustic neuromas and transection of the vestibular nerve to relieve intractable vertigo.The physiological results can be directly related to psychophysical measures determined in the same individual.(Supported by Coleman Fund and NIH Grant NS-16361).

THE MULTIPLE GENERATORS OF THE AUDITORY MIDDLE LATENCY RESPONSE ***N. Kraus, T. McGee Michael Reese Med Ctr and Univ of Chicago, Chicago, IL 60616**

In the guinea pig and gerbil, auditory evoked middle latency (MLR) components recorded from the midline differ from those recorded over the temporal lobe. These differences are apparent with: intracortical injection of neural inactivating agents (lidocaine and kainic acid), temporal lobe ablation, electrolytic lesions, systemic anesthesia, stimulation rate, and maturation.

Data reveal that midline and temporal lobe MLR components vary independently, suggesting mediation by different generator sources. The particular orientation of the generators responsible for the MLR in the guinea pig and gerbil facilitates the identification of individual components, whereas in humans, MLR component Pa is distributed over widespread areas of the cortical surface, possibly masking the activity of the multiple generators likely to underlie the response. Our data support the existence of multiple MLR generators in laboratory animals and provide insight into the generators of the MLR in humans.

The different course of development observed in midline versus temporal lobe components may help explain why the MLR is inconsistently obtained in children. The lability of the response in humans may occur because one of the generators, presumably the temporal lobe generator, has not yet developed, although other generators may have already matured. (Supported by NIH-NINCDS RO1 NS 21150.)

322.1

MODULATION OF PROTEIN KINASE ACTIVITY IN REGENERATING GOLDFISH OPTIC NERVE. Denis Larrivee, Department of Physiology, Cornell Univ. Med. Coll., New York, NY 10021.

Two-dimensional gel electrophoresis was used to monitor ^{32}P incorporation and abundance of phosphoproteins in goldfish optic nerve during regeneration. Four proteins, including the goldfish equivalent of GAP-43, increased their ^{32}P incorporation in parallel with increases in their abundance. Three proteins showing decreased phosphorylation also showed a parallel decrease in abundance. Thus, the changes in phosphorylation of tnese proteins are likely to be due to changes in their abundance. However, 4 proteins, including a vimentin-like protein, ON2, which decreased their phosphorylation during regeneration, increased in abundance when phosphorylation levels declined. Autoradiography of the separated phosphoproteins also revealed 4 proteins that shifted their isoelectric points during regeneration, including ON2 and a protein resembling the chartin proteins by molecular weight, isoelectric point, and solubility in aqueous buffer containing 1 mM Ca^{2+}. One-dimensional peptide mapping showed that the proteins from normal nerves contained peptides identical to those in the corresponding proteins from regenerating nerves. Acid hydrolysis indicated that ^{32}P was incorporated into phosphoamino acids in all proteins. Thus, changes in phosphorylation of some proteins during regeneration are due to changes in the activity of their protein kinases.

COMBINED SUBTRACTION/DIFFERENTIAL HYBRIDIZATION SCREEN FOR GENES INDUCED IN OPTIC NERVE REGENERATION. M. E. LaBate* and J. H. P. Skene. Dept. of Neurobiology, Stanford Univ., Stanford, CA 94305-5401.

Direct analysis of axonal proteins by several laboratories has identified a small number of proteins whose synthesis is widely correlated with axon growth. To complement these protein studies, we have used combined subtractive/differential hybridization as a general screen for genes induced during optic nerve regeneration in a large-eyed goldfish, the blackmoor. Poly A^+ RNA was prepared from control retinae (C) and from "regenerating" retinae taken 10 days after optic nerve crush (R). Each of these cDNAs was then hybridized to an excess of control poly A^+ RNA to an R_0t of 800. The cDNA remaining unhybridized in each reaction ("C - C" and "R - C", respectively) was then used to probe duplicate plaque filters of a cDNA library prepared from regenerating retinae. Of 100,000 clones, 90 (0.09%) gave a moderate to strong differential signal with the subtracted "R - C" probe compared to that seen with the subtracted "C - C" probe. Work is now in progress to determine the number of different mRNA sequences represented in this group of clones.

The identity of one mRNA induced during fish optic nerve regeneration was established using a rat GAP-43 cDNA probe . A 1.4 kB fish cDNA selected with the rat GAP-43 probe hybridizes on Northern blots to a 1.4kb mRNA that is strongly induced in fish retina after optic nerve injury. Preliminary sequence analysis indicates that the amino-terminal portion of GAP-43, including a putative membrane-binding domain, are highly conserved between rat and fish.

322.3

RECAPITULATION OF THE DEVELOPMENTAL PATTERN OF GENE EXPRESSION DURING AXONAL REGENERATION: COORDINATED EXPRESSION OF GAP-43 AND A SPECIFIC ISOTYPE OF BETA TUBULIN. **Paul N. Hoffman, Don W. Cleveland* and Mark C. Fishman. Johns Hopkins School of Medicine, Baltimore, MD 21205 (PNH and DWC) and Massachusetts General Hospital, Boston, MA 02114 (MCF).**

Levels of mRNAs for the 68-kD neurofilament protein (NF68), GAP-43, and several isotypes of beta tubulin (classes I, II and IV) were measured in lumbar sensory neurons of rat using hybridization with cloned cDNA probes. During both development and regeneration mRNA levels were relatively low (compared to mature neurons) for NF68 and high for both GAP-43 and the class II isotype of beta tubulin; mRNA levels changed relatively little for the class I and class IV isotypes. The induction of GAP-43 and class II beta tubulin after axotomy followed identical time courses suggesting that the expression of these proteins is closely coordinated. Thus, the longitudinal growth of both developing and regenerating axons correlates with the expression of GAP-43, a protein undergoing rapid axonal transport, and class II beta tubulin, a cytoskeletal protein. NF expression correlates with the radial growth of maturing axons.

B50/GAP43 IN THE REGENERATING PRIMARY OLFACTORY PATHWAY. J. Verhaagen*, A.B. Oestreicher+, M. Grillo, H. Nielander+, P. Schotman+, W.H. Gispen+, and F.L. Margolis. (SPON: R. Horn). Roche Inst. Mol. Biol., Nutley, N.J. + Inst. for Mol. Biol., Utrecht, Holland.

B50/GAP43 was studied in the primary olfactory pathway following unilateral bulbectomy (UBX) or lesioning of the olfactory epithelium by intranasal irrigation with Triton X-100 (TX). In intact adult animals B50/GAP43 is exclusively present in a subset of differentiating cells adjacent to the basal cell layer of the epithelium. TX-lesioning results in an initial parallel decline of B50/GAP43 and olfactory marker protein (OMP) levels. This reflects the elimination of all mature (OMP positive) and differentiating (B50/GAP43 positive) neurons. The subsequent increase in B50/GAP43 expression during the period of reconstitution of the epithelium and the sequential rise in OMP and decline in B50/GAP43 levels is consistent with the activation of a stem cell population recapitulating normal ontogeny to reconstitute the epithelium. UBX results in ipsilateral increases in B50/GAP43 mRNA and protein. In contrast to the time course following TX (which left the bulb intact) the levels of B50/GAP43 remain elevated up to 75 days after UBX, while OMP expression is minimal. Thus, the different time courses of expression of B50/GAP43 and OMP following TX lesion or UBX demonstrate the role of the olfactory bulb as a target in the reconstitution of the neuroepithelium.

322.5

SOURCE OF GAP43 (B50)-LIKE IMMUNOREACTIVITY (GBLI) IN EXTRA-AXONAL STRUCTURES OF REGENERATING PERIPHERAL NERVE. M.A. Bisby, W. Tetzlaff and H. Zwiers*. Dept. Med. Physiol., Univ. Calgary, Alta., T2N 4N1 Canada.

We previously reported that in sciatic and facial nerves of the rat GBLI was present within newly-regenerated axons as expected, but in regions of nerve containing more mature regenerated axons GBLI was also present in extra-axonal structures, identified as Schwann cell bands of Bungner. Although isolated nerve segments incubated in vitro synthesized a protein which overlapped with GAP43 on 2-D gels, peptide mapping showed that it was not identical to B50: furthermore, it was also synthesized by regions of nerve devoid of GBLI. In situ hybridization with a cDNA probe (Basi et al, 1987) did not show detectable GAP43 mRNA in the immunoreactive nerve segments. On the other hand, pre-embedding EM immunocytochemistry using the PAP technique localized GBLI both within axons, especially to the axolemma, and on the outside of Schwann cells, with the extracellular labelling decreasing with distance from the axons. We conclude that GBLI in extra-axonal structures is not due to local synthesis of GAP43 (B50), but may be due to secretion of this protein from the regenerating axons. The extra-axonal localization of GBLI is consistent with our previous finding that only 30% of the GBLI in regenerating nerve is mobile. (Supported by MRC of Canada and AHFMR).

AXONAL TRANSPORT OF GAP-43 IN INJURED AND REGENERATING RETINAL GANGLION CELL AXONS OF ADULT RATS. S.K. Doster[1], A.M. Lozano[2], M. Willard[1] and A.J. Aguayo[2]. [1] Dept. Anatomy and Neurobiology, Washington Univ.Med.Sch., St. Louis,Mo., 63110; [2]Neuroscience Unit, Montreal General Hospital and McGill University, Montreal, P.Q., H3G 1A4.

Retinal Ganglion Cells (RGCs) of adult rats increase their immunoreactivity to GAP-43 and can regenerate into peripheral nerve (PN) grafts when their axons are interupted near the eye (Soc.Neurosci.Abst.1987,13:1389). We have now studied levels of axonally transported GAP-43 under similar experimental conditions. ^{35}S-methionine was injected intraocularly in adult Sprague-Dawley rats in which the optic nerve was cut 3 mm behind the eye and left in the orbit or cut at 1 mm and replaced with a 3 cm segment of PN graft to allow axonal regrowth (J. Neurosci. 1987, 7: 2894). Transported proteins were analyzed by two-dimensional fluorography of optic nerve (n=11) and graft samples (n=9). The amount of GAP-43 was estimated by densitometry and related to levels of other transported proteins. In axotomized non-regenerating axons, the transport of GAP-43 increased, peaking in the second week and returning to normal by the fourth week after injury. In contrast, in axons growing along grafts, the enhanced transport of GAP-43 was maintained beyond this period. The results suggest that axonal injury near the RGC soma increases the transport of GAP-43 and that this post-injury enhancement may be prolonged by axonal growth.

322.7

REGULATION OF GAP-43 GENE EXPRESSION DURING AXONAL REGENERATION IN SENSORY NEURONS. G.S. Basi* and J.H. Pate Skene (SPON: T. W. Kraft). Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

GAP-43, an abundant phosphoprotein of growth cone membranes and certain mature pre-synaptic terminals, is expressed in correlation with both regenerative, and developmental axonal outgrowth in a broad evolutionary range of organisms. In the rat, GAP-43 is encoded by a single-copy gene whose expression is regulated primarily at the level of transcription. In order to study how GAP-43 gene expression is regulated during regeneration, we have examined its induction in the sensory neurons of the L4 and L5 dorsal root ganglia (DRG) after unilateral injury of the rat sciatic nerve.

Using a rat GAP-43 cDNA clone (Basi et al., 1987, Cell 49, 785-791) to probe Northern blots of RNA isolated from crush and control DRG, we have observed that GAP-43 expression is induced within 12 -24 h in the cell bodies after an injury. GAP-43 gene expression rapidly rises to a maximum by 3 - 4 d post-injury, and is maintained at this level for at-least 28 d post-injury. Neither the magnitude, nor the timing of this induction is affected by the nature of the injury (crush versus cut), nor by removal of a 12 mm segment of the distal stump. The expression declines to control levels between 28 - 40 d post injury. However, if successful regeneration is prevented by a cut injury, or a cut in conjunction with removal of the distal stump, GAP-43 mRNA does remain elevated for a longer period of time (up to 50 d following nerve transection). Furthermore, the data analyzed thus far indicate that this timing of GAP-43 gene induction is independent of the distance of the crush site from the cell body.

The very early induction of GAP-43 gene activity is consistent with the hypothesis that it is a pre-requisite for, rather than a consequence of, axonal outgrowth. In order to more definitively address this issue we employed colchicine injection into the injury site to prevent axonal outgrowth. Using doses of colchicine which were effective in blocking retrograde transport of a fluorescent tracer, we have observed that injection of colchicine into the nerve does not: a) delay the induction of GAP-43 gene activity by an injury; b) induce GAP-43 gene activity by itself in the absence of a crush. Thus, our observations indicate that GAP-43 expression precedes axonal outgrowth.

322.8

GAP-43 INDUCTION IN REGENERATING DORSAL ROOT GANGLION CELLS: AN ANALYSIS OF SORTING IN AXONAL TRANSPORT. D.J. Schreyer and J.H.P. Skene Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305

In addition to elliciting the regenerative response of the peripheral branch of dorsal root ganglion (DRG) axons, sciatic nerve injury also enhances the propensity of the central branch of DRG axons to regenerate through sciatic nerve grafts within the spinal cord (Richardson, P.M. & Verge, V.M.K., J. Neurocytol. 15:584-594, 1986). It is of interest to determine if a cellular response to injury including the production of axonally transported 'growth-associated proteins' (GAPs) affects the growth propensity of a distant, uninjured axon branch. Thus, we have used Western blot analysis of central and peripheral branches of DRG axons to determine if increased levels of the protein GAP-43 are involved in the enhanced regenerative propensity of central axon branches in response to peripheral injury, or whether newly synthesised GAP-43 is routed exclusively to the injured peripheral axon branch.

Adult rats underwent a unilateral sciatic nerve crush below the sciatic notch and survived 2-8 days. Membrane fractions were prepared from homogenized tissue taken from three areas: the sciatic nerve distal to the L4 and L5 DRG, the L4 and L5 DRG themselves, and the dorsal roots at L4 and L5 proximal to the ganglia. Membrane fractions were solubilized, electrophoresed, electroblotted to nitrocellulose, and probed with a monoclonal antibody specific for GAP-43.

Within 2 days following sciatic nerve crush, GAP-43 immunostaining on Western blots is elevated in comparison to unlesioned control tissue in peripheral sciatic nerve, in DRG, and in central dorsal root segments. The amount of GAP-43 detected in all three areas increases in subsequent days.

The increased amount of GAP-43 synthesized in DRG cells following sciatic nerve crush is thus not exclusively transported to the axon branch sustaining the injury. Transport of induced GAPs to the central branch of DRG axons may therefore be crucial to the enhanced growth ability of central DRG axons that follows peripheral lesions.

ELEVATED GAP-43 IN SPONTANEOUSLY REGENERATING CNS AXONS OF ADULT RATS. A.P. Foerster, Department of Neurosciences, McMaster University, Hamilton, Ontario L8N 3Z5.

Evidence for a spontaneous regeneration of severed axons which formed detours around lesions (made and marked by the implantation of a fine wire cutting device in the brain), that was entirely histological (J. Comp. Neurol. 210:335, 1982), has now been extended by a correlative study with monoclonal antibodies to a neuron-specific, growth-associated protein, GAP-43 (provided by J.H.P. Skene and D.J. Schreyer) and to neurofilaments (210 kDa). (Pentobarbital anesthesia was used.) Immediately postlesion, neither an axonal detour nor elevated GAP-43 was observed. Axonal detours then increased progressively as the number of severed axons facing the lesion was reduced. Within a few days, GAP-43 was elevated in the terminal portions of severed axons, and was observable for at least 3 weeks in those pursuing a reoriented course around the lesions. Within the population of axons now curving around the lesion, GAP-43 was elevated primarily in those closest to its end, i.e. the most recent arrivals, suggesting that it increases early in the regeneration and falls thereafter. There was no evidence (swelling, varicosities) in the detouring axons of mechanical hindrance of axoplasmic transport.

These immunocytochemical findings support the anatomical evidence for the occurrence of spontaneous axonal regeneration after lesions of in the adult rat brain.

REGENERATION: OTHER GROWTH-ASSOCIATED PROTEINS

PERIPHERAL NERVE INJURY AND REGENERATION INDUCES MODIFICATIONS OF SCHWANN CELL-ASSOCIATED MOLECULES Neuberger, T.J. and Cornbrooks, C.J., Dept. of Anat. and Neurobiol., Univ. of Vt., Burlington, Vt., 05405.

After nerve transection, Schwann cells (Sc) within the distal nerve stump undergo a series of poorly characterized events which may influence neuronal regeneration. Using immunohistochemical methods, we examined the expression of known, Sc-synthesized antigens which are localized in the cytoplasm or on the membrane. The immunoreactivity of glial fibrillary acidic protein (GFAP), a cytoskeletal component specific in ensheathing Sc, diminished after injury, while that of vimentin (VIM), a cytoskeletal component in myelinating Sc, became prominent within most Sc. Upon reinnervation, GFAP-positive filaments increased in number and length within finite domains of the nerve; VIM concomitantly decreased in these same areas. In control and degenerating nerves, C4 (a cell surface protein expressed by Sc in contact with nonmyelinating Sc) closely duplicated the expression of GFAP. However, upon reinnervation, increased C4 immunoreactivity preceeded that of GFAP and was transiently associated with an undetermined component of the Sc cytoskeleton. S-100 protein, normally localized near the inner and outer membrane of myelinating Sc, was slightly diminished after axotomy, but gradually increased during reinnervation. These studies indicate that alterations in Sc-neuron contact result in modifications in the expression of Sc proteins which can in turn can influence Sc shape and function. Supported by PHS RO1 20189.

323.2

ISOLATION AND CHARACTERIZATION OF A FACTOR WHICH INHIBITS PROTEIN MODIFICATION BY LYSINE DURING NERVE REGENERATION. M. Yu*, G. Chakraborty*, S. Shyne-Athwal and N.A. Ingoglia, Dep't of Physiology, New Jersey Medical School, Newark, N. J. 07103

The posttranslational modification of proteins by amino acid addition has been demonstrated in a variety of biological systems. In our laboratory, we have found that these reactions take place in rat sciatic nerves, are greatly magnified two hours after a crush injury and that the addition of individual amino acids appears to be regulated by specific factors (Shyne-Athwal et al., 1986, Science, 231: 603-605). In the present study, we have begun to characterize the inhibitor to posttranslational lysine addition at two hours after crush injury to rat sciatic nerves.

In the first series of experiments, the inhibitor was shown to be heat stable (90°C, 5 min.), and sensitive to treatment with trypsin (0.1% trypsin caused a 50% reduction in inhibitory activity). These findings suggest that the inhibitory factor is a heat stable protein or peptide. When the inhibitor was passed through a Sephacryl S-300 column, inhibitory activity eluted with molecular weight standards of approximately 10-20k Daltons. However, following further purification on a PROTEIN PAK 125 HPLC size exclusion column, the inhibitory factor appeared to have a molecular weight of less than 4,000.

In summary, the inhibitor of posttranslational conjugation of lysine to proteins appears to be a small molecule, which is heat stable and trypsin sensitive. Further characterization of this molecule is in progress. (Supported by grants from the NIH).

323.3

EARLY AND LATE NEUROFILAMENT (NF) PHOSPHORYLATIONS IN DEVELOPMENT AND REGENERATION. D. Dahl. Harvard Medical School and VA Medical Center, West Roxbury, MA. 02132.

We previously reported on the late occurrence of NF phosphorylation in development and regeneration. Here we show that NF phosphorylation is a complex phenomenon and that individual NF phosphorylation events either occur shortly after NF expression or following a considerable delay. NF phosphorylation was studied by indirect immunofluorescence in tissue sections and in primary dissociated cultures of spinal cord and dorsal root ganglia with 16 monoclonal antibodies reacting with phosphorylated epitopes. The antibodies either decorated NFs shortly after their appearance (as indicated by double labeling experiments with NF polyclonal antibodies) or after a considerable delay, ranging from 4 to 9 days in embryonal development, from 6 to 15 days in sciatic nerve regeneration and from 12 to 27 days in primary cultures. With most (but not all) antibodies, there was a good correlation between in vivo and in vitro findings as to the early or late appearance of phosphorylated epitopes. One monoclonal antibody stained regenerated axons one month after transection with an abnormal pattern, thus suggesting differences between normal and regenerated nerves with respect to NF phosphorylation. Supported by the Veterans Administration.

IMMUNOCYTOCHEMICAL LOCALIZATION OF THE SYNAPTIC VESICLE PROTEIN SV2 IN CULTURED ADULT RETINAL NEURONS. J.W. Mandell*, E. Townes-Anderson, and P.R. MacLeish, Cornell Univ. Med. Coll. and Rockefeller Univ., New York, NY 10021

We have previously shown that mature neurons from the tiger salamander retina can be maintained *in vitro* where they regenerate processes and reform synaptic connections. To visualize the distribution of synaptic vesicles during neurite regeneration, a monoclonal antibody to the synaptic vesicle protein SV2 (Buckley and Kelly, J. Cell Biol., 100:1284 1985) was used in combination with indirect immunofluorescence. Cells were isolated by enzymatic digestion and mechanical dissociation. Rod, cone, and bipolar cells examined immediately after plating had light perinuclear fluorescence and intense staining in synaptic terminals, consistent with vesicle accumulations observed by electron microscopy. Multipolar neurons, which include horizontal, amacrine, and ganglion cells, retained only the proximal portion of their processes and showed only dim perinuclear staining. Intense staining remained in photoreceptor and bipolar terminals for at least 2 weeks; retention of SV2 staining did not depend on the development of cell contacts. In addition, process outgrowth from photoreceptor somas and bipolar axons was brightly immunoreactive. In contrast, new processes from ganglion cells, identified by retrograde labeling, stained only slightly. However, a small percentage of unidentified multipolar cells showed punctate staining in processes. Thus, retinal neurons isolated with axons retain SV2 staining in synaptic terminals and appear to regenerate SV2-rich processes. These findings suggest that synaptic vesicle accumulations in adult neurons can be maintained in the absence of postsynaptic cell contact.

323.5

CHANGES IN SPECIFIC FAST AXONALLY TRANSPORTED PROTEINS IN CRUSHED FROG AND RAT OPTIC NERVES. G-S. Perng* and G.W. Perry. Department of Physiology & Biophysics, University of Miami School of Medicine, Miami, Florida.

We have seen that the majority, but not all, of those proteins rapidly transported along frog sciatic nerve axons are also conveyed at the fast rate along frog optic nerve fibres, and that a similar pattern also exists in rat optic nerve axons. Following crush of the frog optic nerve the labelling of many of the fast transported proteins (FTPs) increases. Most notable among these changes was the large increase in labelling of a GAP-43 like protein in the regenerating frog optic nerve. Also, the labelling of another FTP, designated A1 and which is normally undetectable, increases considerably in the regenerating frog optic nerve. Shortly after crush of the rats optic nerve there is a large increase in the labelling of a transported protein of similar molecular weight and isoelectric point to GAP-43. A very interesting similarity between crushed frog optic and sciatic nerves was the appearance of a polypeptide, designated A25, seen previously to be generated specifically at the site of damage in the sciatic nerve. The precursor to A25 is most likely a fast axonally transported protein, possibly a high molecular weight precursor, designated A30, which was also present in the normal optic nerve. However, A30 but not A25 was also seen in the patterns of FTPs delivered to the terminals of the optic nerve axons, that is in the frogs optic tectum. This suggests that A25 is not present in normal optic nerve or its terminals, and its appearance in the nerve is damage specific. A polypeptide with similar molecular weight and isoelectric point to A25 was also seen in the rats optic nerve shortly after crush. The high molecular weight protein, A30, also appears to be rapidly transported in normal undamaged rat optic nerves.

LEVELS OF β-PREPROTACHYKININ (β-PPT) mRNA AND TACHYKININS CHANGE DIFFERENTIALLY IN RAT DORSAL ROOT GANGLIA (DRG) FOLLOWING SCIATIC NERVE SECTION. D.B. Henken[1], A. Tessler[1,2], M.-F. Chesselet[1] and M. Murray[1], [1]The Medical College of Pennsylvania, and the [2]VA Medical Center, Philadelphia, PA.

Localization of a peptide and the mRNA for that peptide within specific populations of DRG neurons was used to examine metabolic changes associated with axotomy and regeneration. In DRG, 15-20% of the total neuronal population contains tachykinins and the mRNA for the tachykinin precursor, β-PPT. It is known that sciatic nerve section at first reduces levels of tachykinins in DRG which later recover when regeneration is complete. We examined levels of tachykinins and β-PPT mRNA 2 weeks and 6 months following sciatic nerve section and re-apposition in order to determine whether the altered peptide production by DRG cells is regulated at the level of gene expression. mRNA containing neurons were visualized with a ^{35}S-labelled RNA probe for β-PPT and tachykinins were demonstrated immunocytochemically. Two weeks following axotomy the proportion of cells labelled for the mRNA or peptide decreased. Eight to 10% of the total neuronal population stained for the peptide, whereas only 3% labelled for β-PPT mRNA. By 6 months post-operatively, the proportion of cells labelled for both the message and the peptide returned to control levels of 15-20%. These results suggest that regulation of metabolic changes during regeneration depends at least in part on alterations in gene expression and that in situ hybridization histochemistry can be used to study this regulation. Supported by NSF grant BNS8616841, VA Medical Research Service, NIH grant NS24707 and USAMRDC grant 51930002.

323.7

REGENERATING AXONS INCORPORATE NEWLY-SYNTHESIZED CYTOSKELETAL PROTEINS. B.A. Reynolds* and M.A. Bisby. (Spon: K.E. Cooper). Dept. Med. Physiol., Univ. Calgary, Alta., T2N 4N1

The structural hypothesis of slow axonal transport (SAT) suggests that regenerating axons derive their cytoskeletal proteins from those pre-formed in the axon, and moving along it at < 4 mm/day. However, the synthesis of some of these proteins in the cell body increases within a few hours after axonal injury, which seems unnecessary if regeneration is sustained by pre-formed proteins.

The L5 DRG of anesthetized adult rats was labeled with 35S-methionine 3 days after crushing the sciatic nerve 60 mm from the DRG. Labelled proteins present in the nerve distal to the crush were analyzed two days later: these included actin and tubulin identified immunologically and by MW and pI. These cytoskeletal proteins synthesized in the cell body 3 days after injury are transported into the regenerating axons, over 60 mm distal from the cell body, at a velocity of at least 30 mm/day.

Our results demonstrate that regenerating axons do incorporate cytoskeletal proteins produced by the cell body post-injury and raise the possibility that these may be special variants of the normal cytoskeletal proteins, which are required for axonal outgrowth. (Supported by MRC and AHFMR).

CALCIUM ACTIVATED NEUTRAL PROTEASE (uCANP) ACTIVITY IN AXONS IS INCREASED PROXIMAL TO A NERVE CRUSH. D.J. Fink and M. Mata, Neurology Research Laboratory, University of Michigan and VA Medical Center, Ann Arbor, MI 48105.

CANPs are cysteine endopeptidases present in the cytosol which require calcium ions for activity. A CANP activated by millimolar Ca^{++} has been identified in peripheral nerve and degrades neurofilaments in Wallerian degeneration. uCANP, activated by micromolar Ca^{++} has also been identified in peripheral nerve, although its role is not known. We measured uCANP activity in normal nerve and in proximal axons 1 wk after distal nerve crush.

Neurofilaments (NF) were isolated using a modification of the method of Schlaepfer and the CANP activity in the supernatant determined by degradation of ^{14}C casein in the presence of 50 uM Ca^{++}. The enzyme has an apparent Vmax of 70 ug casein/mg crude CANP/30 min and a K_m of 25uM. The activity is linear for 30 minutes, and using our standard incubation conditions varies directly with the amount of CANP.

We found activity in normal nerve was 41.1 ug casein/mug CANP/30 min. The activity of crude CANP isolated from proximal sciatic nerve 1 week after distal nerve crush was 71.1 mg casein/ug CANP/30 min ($P<.05$). Incubation of tritium labeled NF with 10ug of CANP for periods ranging from 1-24 hrs confirmed that uCANP was active in degrading NF, and that the uCANP from the proximal nerve after crush degraded the NF more rapidly than the normal uCANP.

The presence of uCANP in normal nerve suggests that turnover of NF may occur within the axon during axonal transport, and agrees with the presence of NF immunoreactive breakdown products in normal axons. The increased activity of uCANP in proximal nerves after crush may be related to the changes in NF transport which occur after nerve crush.

DIFFERENTIAL EXPRESSION OF 5'-NUCLEOTIDASE ENZYME AND IMMUNOREACTIVITY IN RESTING AND REACTIVE SCHWANN CELLS OF THE RAT SUPERIOR CERVICAL GANGLION. W. Nacimiento*, M.B. Graeber* and G.W.Kreutzberg (SPON: J. Noth). Dept. of Neurology and Clinical Neurophysiology, Alfried-Krupp-Hospital, 4300 Essen, and Dept. of Neuromorphology, MPI for Psychiatry, 8033 Martinsried, F.R.G.

The cellular and subcellular distributions of the ectoenzyme 5'-nucleotidase (E.C.3.1.3.5.) were studied in Schwann cells (SC) of normal and regenerating rat superior cervical ganglia (SCG). 1. 5'-nucleotidase enzymatic activity was absent from SC of normal SCG whereas during regeneration SC exhibited strong enzymatic activity in their perikaryal plasma membranes. 2. 5'-nucleotidase immunoreactivity was present in both normal and axotomized SCG. 3. At the ultrastructural level 5'-nucleotidase immunoreactivity was confined to SC plasma membranes underlying the basal lamina. In conclusion, 5'-nucleotidase enzymatic activity is newly expressed by SC stimulated by postganglionic axotomy and may thus serve as a marker for SC activation during sympathetic nerve cell repair. The differences observed in the subcellular distributions of 5'-nucleotidase enzymatic and immunoreactivity of resting and reactive SC provide another example for the heterogeneity of glial plasma membranes and suggest that the latter is responsive and can be influenced by neuronal injury.

PLASMINOGEN ACTIVATOR ACTIVITY IS EXPRESSED IN THE REGENERATING GOLDFISH VISUAL PATHWAY. F.J. Salles*, S. Strickland* and N. Schechter (SPON: W. Quitschke). Depts. of Biochemistry, Pharmacology and Psychiatry, SUNY at Stony Brook, NY 11794

In contrast to higher vertebrates, the CNS of lower vertebrates has the capacity for functional nerve regeneration after injury. A useful model to study this phenomenon is the goldfish visual pathway which regenerates following optic nerve crush.

We have studied the possible role in optic nerve regeneration of the protease plasminogen activator (PA), which has been previously implicated in nerve growth. After unilateral optic nerve crush, PA activity appeared in crude homogenates of the crushed nerve. No activity was observed in the contralateral uninjured nerve, nor in sham operated controls. The PA activity was seen as early as one day post-crush, reaching a peak at about 10 days; by 80 days post-crush, at which time vision is restored, the activity is no longer detected. Electrophoretic zymography for PA activity revealed the presence of a major species at 75Kd with two other species of variable intensities at 65 and 36Kd. The PA activity could be partially inhibited with polyclonal antisera against either human tissue-type PA or human urokinase-type PA.

These results demonstrate that PA is present in the goldfish and its expression is correlated with the process of optic nerve regeneration. (Supported by grants EY05212 (NIH) to NS and HD17875 (NIH), BC525H (ACS) to SS.)

EXTRACELLULAR GLYCOPROTEINS OF THE GOLDFISH OPTIC TECTUM ARE LABELLED BY INTRAOCULAR INJECTION OF ^{3}H-PROLINE. Finnbogi Thormodsson, Edna Antonian* and Bernice Grafstein. Physiology Dept., Cornell U. Med. Coll., New York, NY 10021.

Two-dimensional polyacrylamide gels of goldfish brain showed a prominent group of soluble proteins, consisting of 2 main sub-groups with MW's about 33K and 38K respectively, each containing a number of isoforms with pI 5.0-5.6. The proteins were also present in a small amount in the optic nerve but not in the retina. They could be readily extracted from the tissue by soaking in isotonic medium, indicating that they are largely extracellular. Since they are glycoproteins (as indicated by ^{3}H-glucosamine labelling), we have designated them "exoglycoproteins" (XGP's). They are identical to the "ependymins" described by Shashoua (Cell. Molec. Neurobiol. 5: 183, 1985). The XGP's in the optic tectum became labelled after intraocular injection of ^{3}H-proline. The labelling was consistently higher in the tectal lobe contralateral to the injected eye, it increased during optic nerve regeneration, and it was abolished by intraocular injection of a protein synthesis inhibitor, suggesting that the XGP's might be synthesized in the retina and axonally transported to the tectum. Nevertheless, the XGP labelling was inhibited by intracranial block of protein synthesis. Antibodies to the XGP's produced prominent immunostaining in the pia, whereas neuronal structures were negative. Thus the XGP's can be synthesized in non-neuronal cells of the tectum from precursors derived from axonally transported material. [Supported by NS-09015.]

IMMUNOCYTOCHEMICAL LOCALIZATION OF A REGENERATION-ASSOCIATED PROTEIN IN THE GOLDFISH VISUAL SYSTEM. G. R. Wilmot*, T. S. Ford-Holevinski, P. A. Raymond, and B. W. Agranoff. Neuroscience Lab and Dept. of Anatomy and Cell Biology, University of Michigan, Ann Arbor, MI 48104-1687.

Retinal proteins that are synthesized in greater amounts following axotomy of the goldfish optic nerve can serve as biochemical probes for understanding the molecular mechanisms underlying CNS regeneration. Such proteins can be radiolabeled and then identified in gels of regenerating optic nerve, indicating that they originate in retinal ganglion cells (RGC's) and also that they are axonally transported. We are studying an acidic 68/70 kDa axonally transported doublet in which the incorporation of ^{35}S-methionine is increased 4-35 days after nerve crush. Here we report immunocytochemical evidence that this cytosolic doublet is indeed localized within RGC's. The 68/70 kDa doublet was purified by DEAE and lectin chromatography of a high speed supernatant of goldfish brain. Following SDS-PAGE, the proteins were electroblotted onto nitrocellulose, and strips containing the doublet were implanted subcutaneously into rabbits. Reactive antiserum, judged by Western blots, was incubated overnight (diluted 1:1000) with aldehyde-fixed cryostat sections of control and 10-15 day postcrush retinas. Bound antibody was visualized by immunofluorescence (goat antirabbit conjugated to FITC) or immunohistochemistry (avidin-biotin-peroxidase conjugate). While immunoreactivity was localized to the RGC's of both control and postcrush retinas, it was markedly increased as a result of axotomy. Pre-immune serum was non-reactive. These results indicate that the 68/70 kDa doublet is synthesized and is present in increased chemical amounts in the regenerating RGC's, and thus serves as a biochemical correlate of functional recovery in the teleost CNS. Analysis of the induction of the genes of two putative calcium binding proteins during sciatic nerve regeneration. M. De León, P. Masiakowski and E. M. Shooter. Department of Neurobiology, Stanford University Sch. of Med., Stanford, Ca 94305.

Nerve growth factor is a polypeptide neurotrophic agent that is important in the maintenance and survival of sympathetic and some sensory neurons in the peripheral nervous system. NGF may also be an important element in the series of events that lead to axon growth, and consequently, nerve regeneration. NGF may participate in the regulation of axon growth by regulating the expression of specific genes, the products of which may be important for the growth process. In order to test this hypothesis we have been studying the expression during regeneration, of two mRNAs that have been found to be induced in PC12 cells after NGF exposure. The predicted amino acid sequence of these cDNA clones correspond to the family of S100 calcium binding proteins (Masiakowski and Shooter, P.N.A.S.85:1277,1988). Sciatic nerves from adult rats were cut and allowed to regenerate for 1 to 3 days; the contralateral nerve served as control. RNA was extracted from nerve distal to the injury (or from a similar area in the contralateral nerve), and from the 4th and 5th dorsal root ganglia from both the contralateral and axotomized nerves. The RNA was separated on an 1.2 % agarose formaldehyde gel and transferred to Hybond nylon filters. The filters were probed with ^{32}P-labelled inserts. It was found that both species of RNA were present in the normal nerve and DRG. The steady state RNA levels of both 42A and 42C species are increased during sciatic nerve regeneration. The induction was observed during the first three days of regeneration in the segment distal to the injury.

323.14

CHANGES IN GENE EXPRESSION FOLLOWING AXOTOMY ARE SIMILAR IN RUBROSPINAL (CNS) AND FACIAL (PNS) NEURONS. W. Tetzlaff* and M.A. Bisby. (Spon: W.K. Stell). Dept. Med. Physiol., Univ. Calgary, Alta., T2N 4N1 Canada.

Levels of mRNAs for tubulin (Tm), actin (Am), and GAP43 increase in rat facial motoneurons after facial nerve injury, while mRNAs for neurofilament proteins (Nm) decrease. Rubrospinal neurons react to axotomy not with regeneration, but with atrophy: what effect does axotomy have on expression of these mRNAs?

2 weeks after a C3 hemisection, a-Tm levels in rubrospinal neurons were elevated, but this was no longer evident at 3 weeks. No Am increase was detectable at 2 or 3 weeks, but surprisingly some neurons showed increased GAP43m expression. As in facial motoneurons, a profound decrease in Nm occurred. Even though their axons do not regenerate, rubrospinal neurons react to axotomy with many of the same changes in gene expression as occur in facial motoneurons. We are following the time-course of these changes in more detail to determine if failure of regeneration is associated with inability to sustain them. (Supported by MRC of Canada and AHFMR).

323.15

ALTERATIONS IN CYTOSKELETAL PROTEIN mRNA LEVELS IN REGENERATING MOTOR NEURONS. N.A. Muma, P.N. Hoffman, M.D. Applegate*, C.A. Fleischman*, H.F. Hough*, and D.L. Price. Neuropathology Lab., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205-2182.

Axonal injury produces characteristic changes in cellular morphology, protein expression, and RNA metabolism. The role of the regulation of genes in regenerative processes can be explored by examining levels of specific mRNA species at various stages following nerve injury/regeneration. To this end, in situ hybridization was used to measure levels of cytoskeletal protein mRNAs in motor neurons of the L4-L5 spinal cord at several intervals following axotomy of sciatic nerve. Fourteen days postaxotomy, levels of the low molecular-weight neurofilament subunit mRNA were maximally reduced (3.5 fold). Similar changes were seen in levels of mRNA coding for other neurofilament subunits. In contrast, levels of β-tubulin mRNA in neurons were increased maximally (twofold) 14 days postaxotomy. Patterns of changes in levels of cytoskeletal protein mRNAs that result from axotomy in these spinal motor neurons of the central nervous system parallel those recognized following axotomy of sensory neurons in the peripheral nervous system. These studies in animal models of regeneration will lay the foundation for studies of cytoskeletal protein gene expression in animal models of degeneration and human neurodegenerative diseases.

323.16

A COMPARISON OF PERIPHERAL AND CENTRAL AXOTOMY ON NEUROFILAMENT AND TUBULIN GENE EXPRESSION IN RAT DORSAL ROOT GANGLION (DRG) NEURONS. J.Wong* and M.M. Oblinger (SPON: C.M. Combs) Dept. Cell Biology and Anatomy, Chicago Medical School, North Chicago, IL 60064.

The cell body of the pseudounipolar dorsal root ganglion (DRG) neuron serves as the synthetic center for both a centrally and a peripherally directed axon. The two axonal branches of DRG cells are known to differ structurally, biochemically and functionally and many previous studies have indicated that aspects of the DRG cell response to peripheral branch injury differ from those elicited by central branch axotomy. In the present study, we asked whether central branch axotomy elicits a similar or different change in cytoskeletal gene expression as does peripheral branch axotomy in adult rat DRG neurons. Unilateral crush lesions of either the L5 dorsal root (4-6 mm from the L5 DRG) or the sciatic nerve (at 50-55 mm from the L5 DRG) were made and the axotomized L5 ganglia and their contralateral controls were harvested between 1d and 8 weeks later. The DRGs were fixed in paraformaldehyde, embedded in paraffin, sectioned at 10 μm, hybridized with ^{35}S-labeled cDNA probes to the mRNAs of NF68 (provided by Dr. N. Cowan, NYU) and beta tubulin (provided by Dr. S. Farmer, Boston U) and subjected to autoradiography. Quantitative analysis of *in situ* hybridization experiments on DRG neurons that sustained a peripheral axotomy revealed that the NF68 mRNA levels were substantially reduced by 1 week after injury. The decrease was maximal 2 weeks after injury and, by 4 and 8 weeks, the NF68 mRNA levels were not significantly different from those in contralateral (control) neurons. In contrast, tubulin mRNA levels were substantially increased (over 200% of contralateral controls) at 1 and 2 weeks after peripheral branch injury and then returned to normal by 4 weeks. At one week after central branch axotomy, the mRNA levels for NF68 and tubulin in DRG neurons were not significantly different from contralateral control values. However, at 2 weeks after central axotomy, NF68 mRNA levels were reduced and tubulin mRNA levels were increased relative to contralateral controls. The overall magnitude of change in cytoskeletal protein mRNA levels was lower after central branch than after peripheral branch axotomy. We conclude that both peripheral and central branch axotomy results in a change in mRNA levels for NF proteins and tubulin. However, the response to central branch injury is of smaller magnitude and has a different time course than the response to peripheral branch injury.

MONOAMINES AND BEHAVIOR IV

324.1

NEUROCHEMICAL BASES OF SPARED INGESTIVE BEHAVIOR IN RATS DEPLETED OF DOPAMINE AS NEONATES.
B.M. Potter* and J.P. Bruno, Dept. of Psychology, The Ohio State University, Columbus, Ohio 43210.

Rats incurring near-total depletions of forebrain dopamine (DA) during development do not exhibit the ingestive and sensorimotor deficits seen when comparable depletions occur during adulthood. However, as with animals depleted as adults, the feeding behavior of rats depleted as infants is disrupted by doses of α-methyl-tyrosine (AMT), an inhibitor of catecholamine (CA) biosynthesis, that have no effect in control animals. We have begun to investigate the mechanism of this AMT effect in adult rats treated with 6-HDA at 3 days of age (Day 3).

The supersensitivity to AMT is probably not due to the drug's effect on peripheral CAs because 6-HDA (sc)-induced sympathectomy prior to AMT did not potentiate its effectiveness. Central norepinephrine (NE) is also not likely to be involved because rats depleted of only NE on Day 3 are not supersensitive to AMT and because rats depleted of both DA and NE on Day 3 are no more sensitive than rats depleted of DA alone. The role of residual DA neurons is unclear. While our previous data suggest that DA is no longer involved in ingestive behavior, we report that administration of haloperidol potentiated the effects of low doses of AMT in adults depleted of DA as infants. We are currently studying the basis of this paradoxical finding.

SELECTIVE PCP AND SIGMA RECEPTOR AGONISTS PRODUCE DIFFERENTIAL EFFECTS IN RATS WITH UNILATERAL LESIONS IN THE SUBSTANTIA NIGRA. D.J. Hepler, S.W. Tam and V.J. DeNoble. E. I. duPont Co., Med. Prod. Dept., Wilmington, DE 19898.

Phencyclidine (PCP) has been shown to induce ipsilateral turning in rats with unilateral lesions of the substantia nigra. Because PCP is a mixed sigma and PCP receptor agonist, it is unclear which mechanism is involved in modulating the observed turning behavior. In this study, rats with unilateral 6-hydroxydopamine-induced lesions in the substantia nigra were evaluated for changes in rotational behavior following administration of PCP, (+)-SKF 10,047 (N-allylnormetazocine), (+)-pentazocine, MK-801, amphetamine, and apomorphine. The rotation model provides a quantitative means for examining the effects of these compounds on pre- vs. post-synaptic dopamine (DA) neuronal activities. The mixed PCP and sigma receptor agonists PCP (0.1-4 mg/kg s.c.) and (+)-SKF 10,047 (1-20 mg/kg s.c.) produced dose-dependent ipsilateral turning, indicating a pre-synaptic DA effect. This behavior is similar to that produced by amphetamine. In addition, the highly selective PCP receptor agonist, MK-801 also produced strong dose-dependent ipsilateral turning. The potency is MK-801 > amphetamine > PCP > (+)-SKF 10,047. In contrast, apomorphine, a DA receptor agonist, produced contralateral turning behavior. The highly selective sigma receptor agonist (+)-pentazocine (3-60 mg/kg s.c.) did not produce rotation. These results suggest that PCP receptor activation produces pre-synaptic DA release.

324.3

THE SELECTIVE D1 ANTAGONIST SCH-23390 PRODUCES CATALEPSY IN YOUNG RATS. L.W. FITZGERALD* and J.H. HANNIGAN. Center for Behavioral Teratology, SUNY-Albany, Albany, NY 12222.

We assessed the cataleptogenic effects of the selective D1 receptor antagonist SCH-23390 maleate (SCH) in 13-, 17-, and 21-day-old male rat pups. Pups received either SCH (0.25,0.5, 1.0 mg/kg, s.c.) or saline vehicle and were placed in a holding chamber. The chamber for 13- and 17-day-old pups was heated to 32°C in order to simulate nest temperature. Catalepsy, defined as the latency to remove the forepaws from a raised horizontal bar, was assessed at 15,30, and 45 min post-injection. SCH produced monotonic increases in catalepsy in all of the ages tested, though the magnitude of the responses depended on age. Overall, 13-day-old pups were less responsive to SCH than 17- or 21-day-old rats, which responded equivalently to the drug. These behavioral effects coincide temporally with the ontogeny of D1 receptors which peaks to adult levels at 21 days of age (Zeng, W. et al, J. Neurochem.,50:3,1988).This study demonstrates the potent cataleptogenic properties of SCH in the preweanling rat, and may provide a significant functional correlate to the development of D1 receptors.

324.4

ROTATION INDUCED BY SELECTIVE DOPAMINE AGONISTS FOLLOWING ELECTROLYTIC SUBSTANTIA NIGRA (ESN) LESIONS. K.E. Asin, L.Bednarz and W.E.Montana, Neurosci Res Div, Pharmaceutical Discovery, D47U, Abbott Labs, Abbott Park, IL 60064.

Although selective D1 and D2 dopamine agonists produce locomotion in reserpinized (RES) rats and contralateral (CONTRA) rotation in rats with unilateral 6OHDA lesions, D1 agonists do not elicit rotation in rats with quinolinic acid striatal lesions or diencephalic hemitransections. In this study we examined the effects of D1 and D2 agonists in ESN lesioned rats before and after chronic reserpine (RES) treatment.

Rats were prepared with unilateral ESN lesions and, 2 weeks later, were tested for apomorphine-induced rotation. Those showing >90 ipsilateral (IPSI) rotations/60min were later tested in response to SKF38393 (SKF)(0-20mg/kg) or LY171555 (LY)(0-.45mg/kg). LY, but not SKF, produced dose-dependent IPSI rotation, which was blocked by SCH23390 (.01mg/kg). In another group, rats were tested with either SKF (20mg/kg) or LY (.15mg/kg) before and after chronic RES (1mg/kg over 5d). RES potentiated the IPSI rotational response to LY, and resulted in the appearance of strong CONTRA rotation in response to SKF, suggesting different output pathways for the two rotational responses. The IPSI rotation produced by LY was potentiated by SKF coadministration in both control and RES rats. These results suggest that the dopamine receptors interact, in a manner dependent on relative D1:D2 stimulation, to determine the direction of rotation and the magnitude of the response in reserpinized rats with ESN lesions.

324.5

EFFECTS OF MUSCIMOL (MUSC) ON D1 & D2 DOPAMINE (DA) RECEPTOR MEDIATED BEHAVIORS. L.M. Bednarz* and K.E. Asin, (SPON.: W. Montana), Neurosci.Res.Div., Pharmaceutical Discovery, Dept 47U, AP10, Abbott Labs, Abbott Pk, IL 60064.

Studies have demonstrated that the GABA agonist MUSC enhances amphetamine (AMP) and apomorphine (APO) stereotypy (STEREO), and that MUSC also enhances neuroleptic-induced catalepsy (CAT). To investigate possible MUSC interactions with the D1 and D2 DA receptor subtypes, we examined MUSC's effects on the STEREO and CAT produced by injections of D1 or D2 selective drugs.

Adult male rats were injected with MUSC (0-1.5mg/kg,sc) + either vehicle (VEH), the D1 agonist SKF38393 (5 or 20mg/kg,sc) or the D2 agonist LY171555 (.15mg/kg,sc). Beginning 15min later, each rat's behavior was rated on a 1-6 scale for 20sec every 15min for 90min. Our results indicate that MUSC enhanced the low level sniffing STEREO produced by D2 but not D1 receptor stimulation, suggesting that MUSC's effects on AMP and APO-induced STEREO rely on D2 DA receptor stimulation. We also examined the effects of MUSC (1mg/kg,ip) on the CAT produced by the D1 antagonist SCH23390 (.06 or .25mg/kg, sc), or the D2 antagonists haloperidol (.2mg/kg,sc) or metoclopramide (25mg/kg,sc). Beginning 15min later, catalepsy (bar test) was measured periodically for 90-120min. Our results suggest that muscimol potentiates both D1 and D2 DA receptor mediated catalepsy and that the mild stereotypy produced by injections of the selective DA agonists probably involves different neuronal substrates.

324.6

D2 AGONIST QUINPIROLE INDUCES PERSEVERATION OF MOTION BUT NO PERSEVERATION OF MOVEMENTS. H. Szechtman, D. Eilam and T. Golani* Dept. Biomedical Sciences, McMaster Univ., Hamilton, Ontario, CANADA L8N 3Z5.

The behaviour of rats injected with D2 agonist, quinpirole (2 mg/kg; n=10) and saline (n=10) was analyzed in terms of variables that measure motion and movements. Results indicate that quinpirole induces perseverative motion without, at the same time, inducing a perseveration of movement. Perseverative motion was characterized by repeated travel along specific trajectories in a limited portion of the environment. Lack of perseveration of movement was evidenced by the same distribution of movements as in saline-treated animals. In addition to these effects, quinpirole increased the total amount of motion and the total number of movements performed by each body segment along all dimensions. Thus, animals under quinpirole were hyperactive but free in their movements and yet, at the same time, stereotyped in motion through the environment. In light of our previous descriptions of the behavioral profiles under apomorphine and amphetamine, the present findings suggest that quinpirole induces perseveration of motion by affecting presynaptic release of dopamine. (Supported by MRC. HS is a Research Associate of the Ontario Mental Health Foundation.)

324.7

EFFECTS OF D_1 AND D_2 RECEPTOR ANTAGONISTS AND 5HT RECEPTOR AGONISTS AND ANTAGONISTS ON NEUROENDOCRINE FUNCTION IN RHESUS MONKEYS. G.R. Heninger, J.H. Krystal and A. Smith*, Dept. of Psychiatry, Yale Univ. Sch. of Medicine, New Haven, Ct. 06508

The dopamine (DA) and serotonin (5HT) systems play important roles in modulating prolactin (PR) release. The contributions of DA and 5HT receptor subtypes to PR regulation were studied in monkeys as a model for human neuroendocrine function.

METHODS: Eight male Rhesus monkeys were studied. D_1 and D_2 antagonists included: haloperidol (H) and SCH23390 (SC), 5HT agonists included: buspirone (B), 8-OHDPAT (8OH), ipsapirone (I), gepirone (G), MCPP (MC), mescaline (MS), and tryptophan (T) and antagonists: ritanserin (R) and metergoline (MI).

RESULTS: The relative potency (PO) (in uM/kg) for a 20 ng/ml prolactin increase and the percent antagonism is:

	H	B	SC	8OH	I	G	MC	ME	T
PO	.02	.2	.5	1	2	1	4	13	1000
R	0	0	-	0	-	0	50	90	18
MI	72	95	-	96	-	90	100	100	97

H plus G as well as SC plus G did not synergize, thus the D_2 and 5HT systems appear to function independently on PR release. D_2 antagonism is 50 times more potent than 5HT stimulation in increasing PR. Behavioral effects including sedation (and catatonia with H, SC and B) were marked and clear differences were observed between the drugs studied. (See J.H. Krystal, et.al. this volume).

324.8

THE ROLE OF SPECIFIC DOPAMINE RECEPTOR SUBTYPES IN d-AMPHETAMINE (AMPH) DISCRIMINATION F.L. Smith* and W.H. Lyness. Dept. of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

In male Sprague-Dawley rats trained to discriminate 1.0 mg/kg of AMPH from saline, substitution with the D-2 agonist quinpirole (QUIN) (0.1-2.0 mg/kg) produces drug-lever responding, whereas the D-1 agonist SKF 38393 (0.3-10.0 mg/kg) elicits only saline-lever responding. Combining either QUIN (0.05 - 0.5 mg/kg) or SKF 38393 (0.5-10.0 mg/kg) with 0.3 mg/kg AMPH results in dose-related increases in drug-lever responding. Conversely, the D-1 antagonist SCH 23390 (0.02-0.1 mg/kg) antagonizes the discrimination produced by 0.7 mg/kg AMPH. Additional studies examined the effect of DA drugs on the discrimination produced by substituting QUIN for AMPH. SKF 38393 (0.5 mg/kg) fails to increase the discriminative cues produced by either 0.05 or 0.2 mg/kg QUIN. Similarly, SCH 23390 (0.01-0.1 mg/kg) fails to antagonize the drug-lever responding produced by either 0.2 or 0.5 mg/kg QUIN. Haloperidol (0.02-0.2 mg/kg) antagonizes responding produced by QUIN substitution. The AMPH experiments indicate that stimulating D-2 receptors yields drug-lever responding, and suggests that D-1 and D-2 receptors may functionally interact to alter discrimination behavior. QUIN substitution shows insensitivity to D-1 agonism/antagonism. Partially supported by NIDA grant DA-02997.

D_2, BUT NOT D_1, RECEPTORS IN THE MPOA DECREASE EJACULATORY THRESHOLD IN MALE RATS. E. Hull, R. Warner*, T. Bazzett*, R. Eaton*, E. Pehek, J. Thompson* and M. Swain*. Dept. of Psychology, SUNY at Buffalo, Amherst, NY 14260.

We have previously shown that the classic dopamine (DA) agonist apomorphine (APO), injected into the medial preoptic area (MPOA) of male rats, facilitated several copulatory measures, including increased ejaculations per test. The DA antagonist cis-flupenthixol (FLU) blocked APO's facilitation and, in higher doses, impaired copulation. To determine whether DA facilitation of copulation is mediated by D_1 or D_2 receptors, we injected either the D_2 agonist LY163502, the D_1 agonist SKF82526, or a combination of the two into the MPOA immediately before sexual behavior tests.

In Exp. 1, 1 ug LY reduced the number of intromissions preceding ejaculation. In Exp. 2, .2 or 2 ug SKF did not affect copulation; 20 ug SKF reduced the number of ejaculations. In Exp. 3, co-administration of 1 ug LY + 2 ug SKF did not summate to facilitate behavior; both LY alone and LY+SKF decreased intromissions preceding ejaculation. In Exp. 4, 10 ug FLU failed to block the reduction in intromissions preceding ejaculation caused by 1 or 10 ug LY.

In summary, the D_2 agonist LY163502 decreased the number of intromissions preceding ejaculation (ejaculatory threshold). This effect was not enhanced by co-administration of the D_1 agonist SKF82526, nor blocked by co-administration of the DA antagonist cis-flupenthixol.

324.10

INTERACTION OF D1 AND D2 RECEPTORS IN THE EXPRESSION OF SENSORIMOTOR DEFICITS IN MPTP-TREATED MICE.

F.B. Weihmuller*, J.P. Bruno, and M. Hadjiconstantinou, (SPON: S. Tjioe), Depts. of Psychology and Pharmacology, The Ohio State University, Columbus, Ohio 43210.

MPTP is a useful tool for understanding the etiology and pharmacology of parkinsonism. We recently reported that MPTP-treated mice exhibit motor impairments and sensory neglect after small doses (0.2 mg/kg) of haloperidol that have no effect in control animals. To determine the relative contribution of dopamine (DA) D1 and D2 receptors to this effect we examined the ability of selective DA antagonists, SCH 23390 (D1) and 1-sulpiride (D2), to induce sensorimotor deficits. Small to moderate doses of SCH 23390 (0.2-0.5 mg/kg) induced only motor deficits and only in MPTP-treated mice; whereas a higher dose (1.5 mg/kg) caused motor and sensory impairments in both groups of mice. MPTP-treated mice were supersensitive to the motor, but not to the sensory, effects of high doses of 1-sulpiride (100-150 mg/kg). Moreover, combined subthreshold doses of SCH 23390 (0.2 mg/kg) and 1-sulpiride (50 mg/kg) induced pronounced sensorimotor deficits in MPTP, but not saline-treated mice. These findings suggest that D1 and D2 receptors contribute to different aspects of sensorimotor behavior and their interaction is necessary for the expression of deficits in DA-depleted mice.

324.11

FACILITATION OF SEXUAL AROUSAL IN MALE AND FEMALE RHESUS MONKEYS (*Macaca mulatta*) BY THE DOPAMINE (D2) AGONIST, LY163502. G.A. Davis, R.W. Goy*, S. Baum* and J. Johnson* Wisc. Reg. Primate Res. Ctr., University of Wisconsin-Madison, WI 53715.

Dopamine agonists have long been reported to facilitate male sexual activity in humans (H.P. Vogel & R. Schiffter, *Pharmacopsychiatria* 16:107, 1983) as well as in rats. The clearest demonstration of this action has been made recently with a new compound, LY163502 (Eli Lilly & Co.), which is a highly potent and selective agonist at D2 receptors. This drug facilitates gender specific sexual behavior in both male and female rats at very low doses (Foreman & Hall, *Psychopharmacol.*, 91:96 1987; *J. Neural Transm.* 68:153, 1987). Male and female rhesus were tested with this drug in a confined partner paradigm, in which the test animal was allowed to view a standardized stimulus animal of the opposite sex but not to contact it physically. The test was carried out for a 30 min period, and indicators of sexual arousal, such as erection or presentation, as well as other behaviors, were scored in 10 sec blocks.

At doses of 10 or 25 μg/kg, LY163502 caused a 5-fold increase over saline controls in the erection rate of male animals ($p<0.001$). A dose of 1 μg/kg was ineffective. Purselip (a putative courtship signal), groom solicit and feeding were also elevated in rate, but only at 25 μg/kg. The increases in erection and purselip, in contrast to those in feeding and groom solicit, were completely dependent on the presence of a female stimulus animal. Males that had been castrated at birth were also tested in this procedure, at a dose of 25 μg/kg. These animals had received repeated testosterone injections at various times, but all treatments ceased at least one year before the present experiment. The castrates responded behaviorally much as the intact males had, but with substantially lower erection rate and quality (on a 1 to 3 scale).

Female subjects, tested with a male stimulus animal, also displayed increased sexual behaviors when treated with LY163502 at 10 or 25 μg/kg. Solicitation signals such as hand slap, along with presentation, were significantly elevated in rate. The increases did not occur in the absence of the male stimulus animal. These results are consistent with the hypothesis that dopamine plays an important role in regulating sexual arousal in both male and female primates.

EFFECTS OF D1 AND D2 AGONISTS ON THE ACQUISITION OF RESPONDING FOR CONDITIONED REWARD (CR). R.J. Beninger. Dept. of Psychol., Queen's University, Kingston, K7L 3N6, Canada.

A stimulus that is repeatedly paired with reward can acquire the ability to act as a reward in its own right, becoming a CR. In a Skinner box with two levers, the acquisition of responding on one lever for CR is differentially affected by direct and indirect-acting DA agonists, amphetamine enhancing responding on the CR level in a dose-dependent manner and apomorphine enhancing responding on both. To determine the contribution of D1 and D2 receptors to this phenomenon, the effects of quinpirole (0.01-5.0 mg/kg), bromocriptine (0.05-10 mg/kg) and SKF 38393 (0.1-10 mg/kg) were assessed with an independent group receiving each dose. Whereas SKF 38393 was without significant effect, the two D2 agonists in a dose-dependent manner produced an amphetamine-like effect, enhancing responding on the CR lever but not the other one. The dopaminergic nature of the bromocriptine effect was confirmed by the observation that pimozide (0.4 mg/kg) shifted the dose-response function to the right. The differential effects of apomorphine and D2 agonists suggests that simultaneous direct stimulation of D1 and D2 receptors by the nonspecific agonist led to the loss of stimulus control by the CR in a manner that did not occur with direct stimulation of only D2 receptors. (Funded by the Natural Sciences and Engineering Research Council of Canada.)

324.13

THE EFFECTS OF SELECTIVE DOPAMINE D1 OR D2 RECEPTOR ANTAGONISTS ON THE ESTABLISHMENT OF AGONIST-INDUCED PLACE CONDITIONING. D.C. Hoffman and R.J. Beninger. Dept. Psychol., Queen's University, Kingston, Canada.

The reinforcing effects of dopaminergic agonists have been demonstrated using the place conditioning procedure. After receiving several pairings of a drug injection in one side of a box and not the other, the undrugged animal subsequently demonstrates a preference for the drug-paired side. At least two different dopamine receptor subtypes have been identified and recent studies have investigated the ability of selective D1 or D2 receptor agonists to produce place conditioning. The D2 agonist, quinpirole produced a place preference whereas the D1 agonist, SKF 38393 produced a place aversion. To further assess the contribution of D1 and D2 receptors to these place conditioning effects, the D1 antagonist, SCH 23390 or the D2 antagonist, metoclopramide was tested with an effective dose of either the nonselective agonist, amphetamine or the subtype-specific agonists, quinpirole or SKF 38393 in male Wistar rats. SCH 23390 and metoclopramide were effective in blocking amphetamine-induced place preference and SKF 38393-induced place aversion. At lower doses, the D1 or D2 antagonist blocked the place preference induced by quinpirole, however, higher doses were not effective. Interestingly, the high dose of the D2 antagonist, but not the D1 antagonist, produced a place preference on its own that approached significance. In general, these data suggest that stimulation of both receptor subtypes is necessary for the establishment of place conditioning with amphetamine, SKF 38393 or quinpirole. (Funded by Natural Sciences and Engineering Research Council).

DOPAMINE D1 AND D2 ANTAGONISTS DIFFERENTIALLY BLOCK CONDITIONED LOCOMOTION BASED ON NONSELECTIVE, D1 OR D2 AGONISTS. E.J. Mazurski and R.J. Beninger. Dept. Psychol., Queen's University, Kingston, Ontario, K7L 3N6 Canada.

Recent evidence suggests that two receptor subtypes exist for dopamine (DA), termed D1 and D2, and drugs are now available that preferentially stimulate or block each type. Classical conditioning of locomotor activity using nonselective DA agonists as the unconditioned stimuli has frequently been demonstrated. Thus, after pairings of (+)-amphetamine (AMPH) with a specific environment rats showed enhanced activity when later given saline and placed there in comparison to a group with the same drug history, but noncontingent drug-environment pairings. Experiment 1 examined conditioned activity with AMPH (2.0 mg/kg), the D1 agonist SKF 38393 (SKF, 10.0 mg/kg), and the D2 agonist quinpirole (QUIN, 2.5 mg/kg). Two groups of 12 rats for each drug received either the drug or saline paired with automated chambers that assessed horizontal and vertical activity for nine 2-h sessions. After every third conditioning session tests were given where both groups received saline. During pairings all drugs produced hyperactivity. On saline tests the paired AMPH group showed more horizontal and vertical activity than its control. The SKF group showed only conditioned horizontal activity and the QUIN group showed only conditioned vertical activity. Experiment 2 examined the effects of co-administration of the D1 antagonist SCH 23390 (0.05 mg/kg) or the D2 antagonist metoclopramide (10.0 mg/kg) with AMPH or QUIN, and METO with SKF during conditioning. The D1 antagonist blocked conditioning only with AMPH. The D2 antagonist blocked conditioning only with QUIN. Thus, selective agonists produce conditioned activity that is blocked by selective antagonists. (Funded by NSERC.)

PHARMACOLOGY OF SYNAPTIC TRANSMISSION II

ELECTPOPHYSIOLOGICAL EVIDENCE THAT ADENOSINE REQUIRES MAGNESIUM FOR ITS INTERACTION AT THE A1 ADENOSINE RECEPTOR J.T. Bartrup* and T.W. Stone. Department of Physiology, St George's Hospital Medical School, London SW17 0RE, UK.

Binding to the A1 adenosine receptor has been shown to be influenced by magnesium ions (Mg). Removal of Mg also induces epileptiform activity in brain slices. By studying CA1 orthodromically evoked population potentials in the rat hippocampal slice, we have looked at the effect of varying Mg concentrations on synaptic inhibition by adenosine.

In standard 1.2mM Mg, adenosine depressed the population potential with an IC50 of 37±3.4μM (n=30). When Mg was omitted from the ACSF, the depression by adenosine was significantly reduced (IC50 124.6±15μM, n=5). A similar loss of potency was observed with 2-chloroadenosine.

Removal of Mg increased the potential size (12±1.6%, n=13) but this did not account for the loss of adenosine potency. Reducing the calcium (Ca) from 2.5mM to 1.2mM reduced the potential size, but failed to restore adenosine potency. Addition of cobalt (500μM), however, did restore the adenosine inhibition.

In 0Mg/ low Ca, adenosine (50μM) occasionally gave a large increase in potential size that could be rapidly reversed by theophylline (50μM). This response could also be elicited by N-ethylcarboxamidoadenosine, 2-phenylamino-adenosine and N-(9H-fluoren-9ylmethyl)adenosine, selective A2 receptor agonists.

BACLOFEN INHIBITS GLUTAMIC ACID RELEASE FROM PRIMARY CEREBELLAR GRANULE CELLS THROUGH A PERTUSSIS TOXIN SENSITIVE GUANINE NUCLEOTIDE COUPLING PROTEIN. M. Ulivi*, W. Wojcik and E. Costa, (SPON: J. Cohen). FGIN, Georgetown Univ., Washington, D.C. 20007.

Primary cerebellar granule cell cultures were used to study the effects of the $GABA_B$ receptor agonist, baclofen, on the release of glutamic acid used by these cells in neuron to neuron signaling. Glutamate was separated from other substances by strong cation exchange HPLC and detected by post-column derivatization with OPA before fluorescence detection. During a 1 min. exposure to 60 mM K^+, the glutamate detected in the incubation buffer increased by 6 to 8 fold. This release of glutamate was calcium dependent. Baclofen attenuated the 60 mM K^+ evoked release in a concentration dependent manner (EC_{50} 20 uM) and did not affect the basal release of glutamate. Maximal concentrations of baclofen inhibited only 50% of the K^+ evoked release. In cultures that were treated with pertussis toxin (1 ug/ml, 15 hrs), the concentration dependent inhibition of glutamate release by baclofen was attenuated by 69%.

325.3

EVIDENCE THAT THE DEPRESSION OF RECURRENT INHIBITION FOLLOWING TETANIC STIMULATION IN THE RAT DENTATE GYRUS IS MEDIATED BY $GABA_B$ RECEPTORS. D.D. Mott*, D.V. Lewis, A.C. Bragdon and W.A. Wilson. Depts. of Pharmacology, Physiology, Pediatrics (Neurology) and Medicine (Neurology), Duke University and Veterans Administration Medical Centers, Durham, NC 27710.

A variety of mechanisms have been proposed to explain the depression of synaptic inhibition which follows repetitive firing. We have shown that $GABA_B$ receptor activation by baclofen reduces recurrent inhibition (RI) in the rat dentate gyrus by an action on the inhibitory interneuron (Mott and Bragdon, 1987). A similar effect has been demonstrated in cultured hippocampal neurons (Harrison et al., 1988). Here we report that tetanic mossy fiber stimulation induces transient depression of RI in the rat dentate gyrus, and that the $GABA_B$ receptor antagonist phaclofen can prevent this depression.

RI was studied in hippocampal slices from 80-200 g male Sprague-Dawley rats. Perforant path (PP) stimulation evoked an EPSP and a population spike (PS) in the dentate gyrus granule cell layer. RI was induced by a single antidromic stimulus to the mossy fibers (MF) 5 msec before PP stimulation. RI was quantified as the % reduction in the PP-evoked PS. Phaclofen (24 mM) was pressure-ejected (10 msec, 30 psi) from a pipette placed near the recording electrode in the granule cell layer. Phaclofen reduced the PP-evoked PS but had no consistent effect on RI.

Tetanic MF stimulation (50 Hz, 1-2 sec) reduced RI by about 50% (N=3) for up to 1000 msec after the stimulus train and converted the PP-evoked response to one containing multiple PS's during this period. Phaclofen reversed this stimulus train-induced loss of RI. After a stimulus train, in the presence of phaclofen, RI was increased by up to 60%. In addition, the PP-evoked PS was reduced, and no secondary PS's developed. All effects of phaclofen were reversible.

These results suggest that GABA released during repetitive firing can suppress $GABA_A$-mediated RI by acting at $GABA_B$ receptors on inhibitory interneurons.

PHARMACOLOGICAL CHARACTERIZATION OF ELECTROPHYSIOLOGICAL EFFECTS OF NICOTINE IN MOUSE HIPPOCAMPUS. R. K. Freund, D. A. Jungschaffer*, and A. C. Collins. Instit. for Behav. Genetics, Univ. of Colorado, Boulder, CO 80309

Previous studies have indicated that nicotine (Nic) induces a concentration-dependent increase in the hippocampal CA1 population spike (PS) and the induction of secondary spiking. In an attempt to characterize the receptor(s) responsible for these effects, a series of nicotinic and muscarinic antagonists were tested for their effects on CA1 PS's from DBA mice. D-tubocurarine (D-TC; 10-100 uM) and atropine (100-400 uM) increased the PS and induced secondary PS's. -Bungarotoxin (10-160 uM) had similar effects at early exposure times (< 10 min.), but then responses decreased steadily and PS's could not be recovered upon washing. Mecamylamine (Mec; 0.8-3.2 mM) gave inhibitory effects during exposure and excitatory effects after washing, but no secondary PS's were observed. Hexamethonium (Hex; 3.2 mM) had little or no effect on CA1 PS's.

Several of these antagonists have been tested for the ability to inhibit effects of Nic (800 uM), at antagonist concentrations below those which elicit effects of their own. Mec was effective for inhibiting effects of Nic, whereas Hex was not. Preliminary data indicate that D-TC is also ineffective for blocking responses to Nic. These results suggest that the pharmacology of nicotinic receptors in brain is different from that found in the periphery.

ARGIOTOXIN-636 BLOCKS GLUTAMATE-MEDIATED SYNAPTIC TRANSMISSION AND RESPONSES TO EXOGENOUS GLUTAMATE IN HIPPOCAMPAL CA1 PYRAMIDAL NEURONS. C.L.Cox, J.H.Ashe, and M.E.Adams. University of California, Riverside, CA 92521.

Synthetic argiotoxin-636 (AR-636), a toxin identified from orb weaver spider venom (Adams et.al. Biochem. Biophys. Res. Comm., 148: 678-683, 1987), was tested for effects on excitatory synaptic transmission in CA1 pyramidal neurons of the in vitro rat hippocampus. Microtopical application of AR-636 (5nM-50nM) resulted in a dose dependent suppression of the amplitude of the dendritic field EPSP recorded from the stratum radiatum and the population spike amplitude recorded from the stratum pyramidale of CA1. In contrast, the amplitude of the antidromic spike was not affected by exposure to AR-636. The maximum effect of AR-636 on the amplitude of the EPSP occurred at 15-25 minutes following application. Reversal of AR-636 induced suppression of the field EPSP was inversely related to concentration. Cellular discharge elicited by pressure ejection of l-glutamate (0.2M) was abolished by AR-636 (15-25nM), whereas responses to pressure ejection of l-aspartate (0.2M) were not significantly affected by AR-636. These data suggest that AR-636 acts as a selective antagonist of glutamate-mediated synaptic transmission in rat hippocampus.

EFFECT OF DESIPRAMINE AND AMPHETAMINE ON NORADRENERGIC SYNAPTIC TRANSMISSION: IN VIVO STUDIES IN THE RAT DORSAL HIPPOCAMPUS. O. Curet and C. de Montigny. Dept. of Psychiatry, McGill University, Montreal, Canada H3A 1A1.

The present study was undertaken to determine the effects of desipramine (DMI) and amphetamine (AMPH) on noradrenergic (NE) synaptic transmission. CA_3 hippocampus pyramidal neurons were recorded with five-barreled micropipettes. The central barrel was filled with 2 M NaCl and side barrels with NE (0.05M in 0.2M NaCl; pH 4), acetylcholine (0.02M in 0.2M NaCl; pH 4) and 2M NaCl. A bipolar stimulating electrode was positioned in the locus coeruleus (LC). 150 square pulses were delivered at 1 Hz with an intensity of 800 uA. The degree of suppression of pyramidal neurons firing activity was quantified from peristimulus time histograms.

DMI (0.5-5 mg/kg, i.v.) and AMPH (0.25-5 mg/kg, i.v.) both decreased the effect of the LC stimulation and increase the duration of the response of the same neurons to the microiontophoretic application of NE. The subsequent intravenous injection of idazoxan, an α_2-adrenergic antagonist, restored the effectiveness of the LC stimulation.

It is concluded that the acute administration of either DMI or AMPH, by increasing the concentration of NE in the synaptic cleft, results in a decreased effectiveness of the LC stimulation due to an increased activation of terminal α_2-adrenergic autoreceptors.

325.7

DIFFERENTIAL EFFECTS OF D-AMPHETAMINE MEASURED INTRACELLULARLY IN HIPPOCAMPAL DENTATE GRANULE NEURONS IN VITRO FROM PREPUBERTAL AND POSTPUBERTAL RATS. S.S. Jahromi*, P.L. Carlen and C.E. Niesen. Playfair Neuroscience Unit, Addiction Research Foundation, Departments of Physiology and Medicine (Neurology), The Toronto Western Hospital, University of Toronto, Toronto, Ontario, M5T 2S8.

The effects of d-amphetamine (10-100 uM) on hippocampal dentate granule neurons in vitro were compared in pre- and postpubertal male Wistar rats using intracellular electrophysiological recording techniques.

Amphetamine, either drop-applied or perfused, caused the following:
1) A prolonged depolarization (5 to 25 mV) with increased spontaneous activity 10/13 on neurons of postpubertal rats; 2) A prolonged hyperpolarization (-3 to -8 mV) in 9/10 of prepubertal rats. All other results are similar for neurons of either pre- or postpubertal rats; 3) Marked attenuation of the post-spike train long lasting afterhyperpolarization; 4) Decreased spike frequency adaptation during a 600 msec depolarizing current pulse; 5) Decreased spike threshold to injected current even when the membrane potential was returned to predrug control levels; 6) Increased EPSP amplitude, sometimes giving rise to multiple spikes.

These drug effects were only slightly reversed with over one hour of washout.

In prepubertal neurons from rats, the actions of hyperpolarization along with decreased spike frequency adaptation and increased EPSPs may be relevant to the use of amphetamine in the attention deficit syndrome.

Supported by the Hospital for Sick Children Foundation and MRC.

ANTIEPILEPTIFORM EFFECTS OF CYCLIC AMP IN THE CA3 REGION OF RAT HIPPOCAMPAL SLICES. *S. A. Helekar* and F. J. Lebeda* (SPON: F. Pirozzolo), Program in Neuroscience and Section of Neurophysiology, Department of Neurology, Baylor College of Medicine, Houston, Texas 77030.

We have observed that cyclic AMP (cAMP 5-80μM) produces a reversible decrease in frequency of extracellularly recorded interictal discharges induced by bethanechol (40μM) and theophylline (10-20μM) in the CA3 region of rat hippocampal slices. Since it has also been observed that 5'-AMP, adenosine and its analogs produce a similar effect, we have tested the hypothesis that cAMP acts indirectly by being converted extracellularly to adenosine by two enzymatic steps catalysed by a phosphodiesterase (PDE) and a 5'-nucleotidase (5NT). This hypothesis predicts the following: 1) blocking the breakdown of cAMP would attenuate its effects and 2) nonhydrolysable analogs of cAMP would have minimal or no reversible effects.

In contrast to the first prediction, the effect of cAMP is potentiated by coapplication of α,β-methyleneadenosine 5'-diphosphate (AMP-CP 8-16μM) or 3-isobutyl-1-methylxanthine (IBMX 10-20μM), a 5NT and a PDE inhibitor (with an additional adenosine receptor blocking action) respectively. Control experiments with these compounds suggest that they do not, by themselves, have any antiepileptiform action. Furthermore, nonhydrolysable derivatives of cAMP, dibutyryl- (10-25μM) and 8-bromo-cAMP (5-10μM) are as potent as cAMP in their discharge suppressant action. These data are not consistent with the idea that the antiepileptiform action of exogenously applied cAMP is mediated solely by metabolic conversion to adenosine and suggest an additional, possibly a direct mode of action involving extracellular sites for cAMP and its first metabolic product, 5'-AMP.

EFFECTS OF AN ANESTHETIC ALPHA-2 ADRENERGIC AGONIST, DEXMEDETOMIDINE, ON RAT HIPPOCAMPAL CA 1 NEURONS. V.A.Doze, M.B.MacIver, M.Maze, J.J.Kendig (SPON: H.Schulman). Dept. of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305-5117.

Dexmedetomidine, a highly specific alpha-2 adrenergic receptor agonist, produces a behavioral state analogous to general anesthesia in the rat. The anesthetic effect is stereospecific and blocked by alpha-2 blocking agents. The present study examined electrophysiological responses to dexmedetomidine in a rat hippocampal slice preparation.* Synaptically evoked field potentials were recorded from CA 1 neurons by standard extracellular techniques. Perfusion of dexmedetomidine (10-100 nM) produced reversible concentration-dependent increases in both population spike (PS) and field EPSP amplitudes (110-200% of controls). Higher concentrations of dexmedetomidine (>1 uM) depressed both PS and EPSP. This apparent biphasic response differs from the responses (depression of PS and EPSP) observed with volatile general anesthetics in this preparation, but resembles to some extent the effects produced by pentobarbital. *Approved by Stanford Panel on Laboratory Animal Care. Supported by NIH Grant NS13108 to JJK.

325.10

EXTRACELLULAR CESIUM INCREASES THE AMPLITUDE OF CA1 DENDRITIC RESPONSES EVOKED BY REPETITIVE STIMULATION IN HIPPOCAMPAL SLICES. D.B.Macek*, J.P.Harris*, and A.L.Padjen, Dept. of Pharmacology and Therapeutics, McGill University, Montreal, Quebec, Canada H3G 1Y6.

We have compared the effect of extracellular cesium ($[Cs]_o$, 3 mM) on the responses of rat hippocampal neurons to different patterns of repetitive stimulation. D(-)-2-amino-5-phosphonovalerate (APV, 40 μM) was present in ACSF to prevent potentiation. Dendritic field potentials of the CA1 region were evoked by unpatterned stimuli to the stratum radiatum (100 pulses at 50 Hz for 2 sec), resulting in a prolonged slow depolarization that was double the amplitude of the short depolarizing responses to patterned stimuli (100 pulses grouped in 10 bursts of 10 pulses @ 100 Hz for 2 sec). In the presence of extracellular cesium (3 mM) both responses increased in amplitude, with unpatterned >> patterned.

These results are consistent with the hypothesis that $[Cs]_o$ facilitates transmitter release, possibly by blocking anomalous rectifier in terminals. /Supported by MRC/

CNQX BIOCKS EXCITATORY SYNAPTIC TRANSMISSION, QUISQUALATE INDUCED CURRENTS AND BURSTS IN HIPPOCAMPAL SLICES. R.S. Neuman, Y. Ben-Ari, M. Gho and E.Cherubini. INSERM U29, 123 Bv. De Port-Royal, Paris, France.

The action of CNQX, a purported quisqualate antagonist (Honore et al. 1987, Soc. Neurosci. Abstr.), was studied on hippocampal slices in vitro. Bath application of CNQX (2-4uM) rapidly and reversibly blocked the Schaffer collateral and mossy fibre evoked e.p.s.p. The blockade was not associated with changes in membrane potential, membrane resistance or spike accommodation. In addition, the fast and slow GABA mediated inhibition evoked by mossy fibre stimulation was not altered by CNQX. CNQX (2-3uM) also blocked spontaneous and evoked bursts in the CA3 region induced by NMDA and kainate, as well as the persistent bursts following kainate washout, the latter with 0.5uM CNQX. The effects of CNQX were also tested on the currents induced by excitatory amino acids in the presence of TTX using the single electrode voltage clamp technique. Inward currents induced by quisqualate (10uM), kainate (200nM) and NMDLA (20uM) were reduced to 32±4%, 78±17 and 66±11 of control respectively by 10uM CNQX.

From our observations we suggest that the transmitter for the e.p.s.p. evoked by Schaffer collateral and mossy fibre stimulation acts on the quisqualate type receptor and furthermore that this same receptor plays a substantial role in burst generation.

R.S.N. received support from INSERM and MRC(C). M.G. was a fellow of the Fondation du France.

325.12

DEPRESSION OF SYNAPTIC TRANSMISSION BY ω-CONOTOXIN IN THE RAT HIPPOCAMPAL SLICE. *D.B. Jaffe* and D. Johnston*, Program in Neuroscience, Baylor College of Medicine, Houston, Texas 77030.

The release of neurotransmitters from the presynaptic terminal of a neuron is dependent on calcium ions that enter through voltage-sensitive calcium channels in the plasma membrane. ω-conotoxin GVIA (ω-CTX) is an irreversible inhibitor of synaptic transmission in a number of peripheral synapses, and it binds to synaptic plasma membranes from rat brain. ω-CTX has been shown to block both N and L-type channels while having no long-lasting effect on the T-type channel, suggesting that the N and/or L channels are responsible for regulation of synaptic transmission. We studied the effects of ω-CTX on synaptic transmission in the *in vitro* hippocampal slice preparation at both the Schaffer collateral (SC)-CA1 and mossy fiber (MF)-CA3 synapses. Transverse rat hippocampal slices, 400 μm thick, were maintained in artificial CSF (aCSF) at 34-35°C in an interface chamber. Population excitatory postsynaptic potentials (pEPSPs) were recorded either in stratum pyramidale of CA1 or in stratum lucidum of CA3b. ω-CTX (5 μM) was applied as a microdrop to the surface of either stratum radiatum of CA1 or stratum lucidum of CA3. Application of 5 μM ω-CTX to the dendritic field of CA1 or CA3 irreversibly decreased SC evoked pEPSPs 39 ± 6% (n=3) and MF evoked pEPSPs 34 ± 5% (n=6), respectively, indicating a net decrease in synaptic transmission. Microdrop application of control vehicle had no effect on synaptic transmission at either the SC-CA1 (n=3) or MF-CA3 (n=4) synapses. The decrease in synaptic transmission in the hippocampus upon administration of ω-CTX to the major excitatory inputs of both the CA1 and CA3 regions suggests involvement of the N- and/or L-type calcium channel currents in the regulation of synaptic transmission at these sites. Depression of synaptic transmission by ω-CTX was less than 50%, however, which may indicate a role for the T-type or a non ω-CTX-sensitive calcium channel subtype in synaptic transmission. Nonuniform exposure of synaptic terminals to ω-CTX could also be a factor in the magnitude of the changes observed. Modulation of the properties of these channels may alter the efficacy of synaptic transmission and may be involved in the mechanism of long-term potentiation. (NIH grants NS11535 & HL31164 and AFOSR 85-0178)

325.13

NMDA CHANNEL ACTIVATION MEDIATES PROLONGED PAIRED PULSE DEPRESSION OF POPULATION SPIKE AMPLITUDE IN RAT HIPPOCAMPUS. R.S. Goldman and C.F. Stevens. Section of Molecular Neurobiology and Department of Neurology, Yale University School of Medicine, New Haven, CT. 06510.

The effect of varying magnesium (Mg) concentrations on the population spikes of paired pulses was studied in area CA1 of rat hippocampal slices. Reduction in Mg concentration resulted in a dose dependent depression of the ratio of the spike amplitude of the second pulse to that of the first pulse. This reduction lasted for hundreds of milliseconds, and was not influenced by picrotoxin, implying that this effect was not related to an effect of Mg on inhibition. Across different Mg concentrations there was a correlation between the amount of inhibition of the second population spike and the value of the field excitatory postsynaptic potential (EPSP) at the corresponding time interval. D-amino-phosphonovaleric acid, a specific blocker of the N-methyl-D-aspartate (NMDA) channel blocked the inhibition of the second pulse. Together with the dependence upon the Mg concentration, this implies involvement of the NMDA channel in mediating the depression. The field EPSP was not depressed to a comparable extent as the population spike, implying that the paired pulse depression was due primarily to a change in the excitability of the postsynaptic cell. Evoked responses following a spontaneous firing showed a similar inhibition.

In terms of possible mechanisms, we favor the view that prolonged depolarization due to NMDA channel activation (unmasked by low Mg) results in prolonged sodium channel inactivation. However, we cannot exclude the possibility that transmission of the synaptic current to the soma is impaired due to shunting of current by activated channels in the dendrites.

DO GENERAL ANESTHETICS HYPERPOLARIZE MAMMALIAN CNS NEURONS? J.J.Kendig and M.B.MacIver. Dept. of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305-5117.

Unitary theories of anesthesia propose that all general anesthetics share a common mechanism. One suggested common action is hyperpolarization of CNS neurons through increase in potassium conductances. The present study examined whether inhalation anesthetics (halothane, enflurane, isoflurane, methoxyflurane) share this action. Synaptically evoked responses, resting potential and conductance were measured intracellularly in CA 1 neurons of rat hippocampal slices.* Agents were administered via the surface gas stream at equivalent anesthetic concentrations (1 MAC). Only halothane produced hyperpolarization (3-5 mV) accompanied by a conductance increase (10-15%). Isoflurane depolarized CA 1 neurons and decreased conductance. Enflurane also decreased conductance, but produced biphasic (hyperpolarizing/depolarizing) actions. All agents blocked the synaptically evoked population spike but were variably effective in depressing EPSP amplitude, in the order methoxyflurane > isoflurane ≥ enflurane >> halothane. These results do not support a unitary theory of anesthesia; instead, there appear to be agent-specific actions at multiple membrane sites. *Protocol approved by Stanford Laboratory Animal Care Panel. Supported by NIH Grant NS13108 to JJK.

SYNAPTICALLY EVOKED SPIKE INITIATION IN DENDRITES OF CA 1 HIPPOCAMPAL NEURONS. M.B.MacIver and J.J.Kendig. Dept. of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305-5117.

Both dendritic and somatic sites have been proposed as the spike initiation zone in synaptically activated hippocampal CA 1 neurons. The present study used fixed and roving extracellular electrodes (ACSF filled, 0.5-2 M ohm) and intracellular electrodes (K acetate filled, 80-120 M ohm) in rat hippocampal slice.* Bipolar stimulating electrodes were placed in s. radiatum. Field potentials were monitored at various levels along the axis of CA 1 neuron apical dendrites. At low stimulus intensities a negativity, corresponding to the positive EPSP recorded in the somatic region, reached maximum amplitude at the level of the activated fibers in s. radiatum. At stimulus intensities which produced a half maximal population population spike, a second larger but briefer negativity was superimposed on the first, with maximum amplitude 150-200 u closer to the somatic layer, but still well within the dendritic layer in s. radiatum. This second wave occurred 0.5 to 2 ms before the population spike at the somatic level or the action potential recorded intracellularly in the soma. These results support a dendritic site for synaptically evoked spike initiation in apical dendrites of CA 1 neurons. *Protocol approved by Stanford Laboratory Animal Care Panel. Supported by NIH Grant NS13108 to JJK.

APV BLOCKS ENFLURANE-INDUCED BURST DISCHARGE OF HIPPOCAMPAL CA 1 NEURONS. D.L.Tauck, M.B.MacIver and J.J.Kendig. Dept. of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305-5117.

Enflurane is the only clinical general anesthetic which produces seizure activity in the hippocampal cortical EEG. The present study investigated cellular mechanisms underlying this action in the rat hippocampal slice.* Synaptically evoked responses were recorded from CA 1 neurons by standard intracellular and extracellular techniques. Enflurane was administered via the surface gas stream. An anesthetic concentration of 2.0 vol % (1 MAC) hyperpolarized the cells (~5 mV), decreased conductance, depressed both population and single cell EPSP amplitudes (30% of control) and blocked synaptically evoked discharge. Threshold to intracellular current injection was unchanged. At 3-4 vol % enflurane induced high frequency burst discharges closely resembling seizure activity *in vivo*. Depolarization and increased conductance accompanied burst discharges. The NMDA receptor antagonist APV blocked enflurane-induced burst discharge with little effect on threshold, resting potential or EPSP amplitude. An increase in NMDA-gated calcium currents accounts for enflurane-induced burst discharge, depolarization and conductance increase. *Protocol approved by Stanford Laboratory Animal Care Panel. Supported by NIH Grant NS13108 to JJK.

INFLUENCE OF ETHANOL ON MUSCARINIC RECEPTOR-G PROTEIN INTERACTIONS IN RAT BRAINSTEM. R.S. Aronstam and T.K. Narayanan (SPON: B.B. Gallagher), Dept. Pharmacol. & Toxicol., Medical College of Georgia, Augusta, GA 30912

The influences of alcohols on 1) agonist binding to muscarinic acetylcholine receptors and 2) receptor coupling to guanine nucleotide-dependent transducer proteins (G proteins) were determined in membranes prepared from rat brainstem. The effects of ethanol on carbamylcholine binding (determined in competition studies with [^{3}H]methylscopolamine) were temperature-dependent: At 4° the majority of receptors were in a high affinity conformation and ethanol increased agonist affinity; at 37° the majority of receptors were in a low afffinity conformation and ethanol further decreased binding affinity. At 25°, ethanol inhibited the binding of 2 nM [^{3}H]oxotremorine-M to high affinity receptors (IC50 = 0.5±0.1%). The guanine nucleotide sensitivity of [^{3}H]Oxo-M binding (an indication of receptor interaction with G proteins) was greatly decreased by ethanol (EC50 = 0.6±0.2%). Guanine nucleotide sensitivity was also decreased by a number of other alcohols with the following order of potency: n-octanol>n-butanol>ethanol>isopropanol=methanol. In this action, alcohols resembled anesthetics (Biochem. Pharm. 26:1201, 1987), raising the possibility that interference with receptor-G protein coupling underlies depression of synaptic transmission caused by a variety of agents.

HALOTHANE INHIBITION OF ACETYLCHOLINE-STIMULATED, PERTUSSIS TOXIN-SENSITIVE GTPASE ACTIVITY IN RAT BRAIN. B.L. Anthony, R.L. Dennison, T.K. Narayanan and R.S. Aronstam. Depts. of Pharmacol. & Toxicol. and Anesthesiol., Medical College of Georgia, Augusta, GA 30912.

We have demonstrated that anesthetics interfere with the interactions of muscarinic acetylcholine receptors with transducer G proteins in both brain and heart (e.g., Biochem. Pharm. 26:1201, 1987). We studied the influence of halothane on the muscarinic receptor-mediated stimulation of GTP hydrolysis by G proteins in membranes isolated from rat striatum and cerebral cortex. Membranes were incubated with gamma-[^{32}P]GTP for 1-10 min at 37° in a regenerating buffer containing 2 uM GTP. Basal GTPase activity was 56 ± 15 pmol Pi released/mg protein/min in the striatum. ACh stimulated the low K_M GTPase activity by 40-80%, with an EC50 of 2 ± 1 uM and a maximal effect with 10-20 uM ACh. Pretreatment of the membranes with pertussis toxin under ADP-ribosylating conditions decreased both basal and receptor-stimulated GTPase activity by up to 60%. Equilibration of the membrane with halothane (0.1-4%) resulted in a decrease in ACh-stimulated, but not basal, GTPase activity. The IC50 for this action was about 0.5%. These findings suggest that halothane selectively interferes with receptor-G protein coupling. (Supported by GM-37948, AA-07698 and the Georgia Heart Association.)

ISOFLURANE STRONGLY DEPRESSES POSTSYNAPTIC POTENTIALS IN NEOCORTEX. H. El-Beheiry* and E. Puil. Depts. of Anaesthesiology and Pharmacology & Therapeutics, Univ. of British Columbia, Vancouver, Canada, V6T 1W5.

An anaesthetic enhancement of neuronal inhibition has been suggested as a possible mechanism of anaesthesia in allocortex but has not yet been demonstrated in neocortex. In the present investigations, the effects of a clinical agent, isoflurane, on excitatory and inhibitory postsynaptic potentials (EPSPs and IPSPs) were investigated intracellularly in neurons of in vitro slice preparations of anterior cingulate and sensorimotor cortex (guinea pig). The microelectrodes contained 3 M KCl, K-acetate, or Cs_2SO_4. The membrane potentials were maintained at a constant resting level (~-65 mv) by DC-current injection. Applications (1-2 MAC) of isoflurane induced a dose dependent, reversible depression of EPSPs and IPSPs evoked by subpial electrical stimulation. Bicuculline (50μM) was applied in the bath to prevent summation of GABA-ergic IPSPs with the EPSPs. With bicuculline-blockade of IPSPs, isoflurane applications (1.5 MAC) markedly depressed the EPSPs. The IPSPs were evoked in either the absence, or presence of Cs^+-blockade of K^+-channels. In the latter case, isoflurane applications (1.5 MAC) reduced the amplitudes of IPSPs by 40%. The attenuation of IPSPs can account for the excitatory phenomena observed clinically during isoflurane administration. These investigations demonstrate that applications of isoflurane depressed the excitabilities of neocortical neurons by interfering with synaptic excitation rather than by potentiating neuronal inhibition. (Supported by the MRC).

MECHANISM OF ETHANOL POTENTIATION OF GABA-INDUCED $^{36}Cl^-$-INFLUX IN CULTURED SPINAL CORD NEURONS. A.K. Mehta* and M.K. Ticku, Dept. of Pharmacology, Univ. of Tx. Hlth. Sci. Ctr., San Antonio, TX 78284-7764.

$^{36}Cl^-$-influx; while at concentrations ≥ 50 mM ethanol activated Cl^- channels directly. The effect of ethanol was specific for $GABA_A$ receptor-gated Cl^- channels, since ethanol did not potentiate glycine-induced $^{36}Cl^-$-influx in the same neurons. Ethanol (20 mM) which does not exhibit a direct effect, decreased the K_m value of GABA from 11.4 ± 0.8 μM to 4.8 ± 0.5 μM without affecting the maximal response. Both the enhancing and direct effects of ethanol on $^{36}Cl^-$-influx were blocked by GABA antagonists such as bicuculline, picrotoxinin, and inverse agonists of the benzodiazepine site such as RO15-4513 and FG-7142. Ethanol potentiating effect of GABA-induced $^{36}Cl^-$-influx was also reversed by DMCM. The effects of the inverse agonists were blocked by the benzodiazepine receptor antagonist RO15-1788. Both RO15-4513 and FG-7142 reversed direct and GABA potentiating effects of ethanol effect at concentrations lower than those that exhibit inverse agonistic activity in the $^{36}Cl^-$-influx assay in cultured neurons. These results suggest that ethanol facilitation of GABAergic events involves GABA receptor-gated Cl^- channels and that this interaction may be responsible for some of the pharmacological effects of ethanol. Supported by NIAAA grant #AA04090.

Effects of continuous benzodiazepine antagonist exposure on GABA/Bz ionophore complex. C. Heninger, M. Wilson and D. Gallager, *Dept. of Psychiatry, Yale U. Sch. Med., New Haven, Ct. 06508.*

We have previously demonstrated regionally specific decreases in GABA sensitivity following chronic bz agonist exposure. Based on evidence suggesting the existance of endogenous ligands for the bz binding site, such changes could be due either to direct agonist effects within the GABA/bz complex or to displacement of endogenously active substances at the receptor. We have therefore investigated in rats the effects of chronic exposure to a bz antagonist, Ro15-1788, which would occupy the binding site without inducing agonist effects. Chronic exposure consisted of s.c. silastic implants containing crystalline Ro15-1788 which maintained brain levels of ~20 ng/g throughout the 3 week treatment period. This level of Ro15-1788 produces receptor occupation comparable to that seen with chronic agonist exposure. Following this treatment, we examined the sensitivity of dorsal raphe (DRN) neurons to iontophoretically applied GABA. While we have documented subsensitivity to GABA following comparable chronic agonist exposure, Ro15-1788 treatment failed to alter DRN GABA sensitivity. In addition, GABA/Bz binding parameters (3H-flunitrazepam, 3H-bicuculline) in cortical membranes were unaltered by chronic antagonist exposure. Finally, no significant change in bicuculline seizure threshold was observed after chronic antagonist treatment or after agonist challenge in chronic Ro15-1788 rats as compared to control animals. Such data indicate a lack of effect of chronic antagonist exposure on functional and biochemical measures of the GABA/Bz complex.

326.3

CHRONIC DIAZEPAM ALTERS GABA-STIMULATED CHLORIDE INFLUX IN CORTEX, BUT NOT CEREBELLUM. R.J. Marley and D.W. Gallager, *Dept. of Psychiatry, Yale U. Sch. Med., New Haven, Ct. 06508.*

Clinical and behavioral studies have shown that tolerance develops to many of the therapeutic actions of benzodiazepines, however, the mechanisms responsible for the development of tolerance to benzodiazepines is unknown. Recent studies in our laboratory (Wilson and Gallager, Eur. J. Pharmacol., 136:333, 1987) have found regional differences in the effects of chronic diazepam treatment. Using diazepam-filled silastic implants to maintain pharmacologically relevant brain concentrations of diazepam, it was observed that rats exposed to diazepam for 3 weeks show a decreased responsiveness of dorsal raphe neurons to iontophoretically applied GABA. In the substantia nigra pars reticulata, however, the same treatment failed to alter GABA sensitivity. Using the same sustained release chronic treatment protocol, we have measured GABA-stimulated $^{36}Cl^-$ influx into brain membrane vesicles from rats treated chronically with diazepam or vehicle. To investigate possible regional differences in response to chronic diazepam exposure, we have analyzed vesicles prepared from cortex and cerebellum. Cortical membrane preparations from chronic diazepam-treated rats exhibited a decreased GABAergic stimulation of $^{36}Cl^-$ influx. In contrast, chronic diazepam treatment had no effect on GABA-stimulated $^{36}Cl^-$ influx in cerebellar membrane preparations. These results support the suggestion that chronic benzodiazepine treatment results in a reduction in GABA/BZ receptor function in some, but not all, brain regions.

326.4

GABA SUBSENSITIVITY OF DORSAL RAPHE NEURONS IN MIDBRAIN SLICES FROM CHRONIC DIAZEPAM-TREATED RATS. M. A. Wilson and D. W. Gallager, *Dept. Psychiatry, Yale Univ. Sch. Med., New Haven, CT 06508.*

We have previously demonstrated GABA subsensitivity in dorsal raphe neurons (DRN) following chronic BZ agonist exposure. Our prior studies analyzed *in vivo* sensitivity of DRN to iontophoretically applied GABA in anesthetized rats following prolonged exposure to diazepam-filled silastic capsules. To determine whether GABA subsensitivity was dependent upon dorsal raphe afferents, we analyzed GABA responses of DR neurons in brain slices obtained from rats exposed to diazepam-filled silastic capsules for 3 wks. Midbrain slices from vehicle and diazepam-treated rats were maintained simultaneously under the same *in vitro* conditions. Artificial cerebrospinal fluid containing 2.5 uM phenylephrine was used to induce pacemaker-like activity. Firing rates of DRN in control and diazepam-treated slices were comparable (19±1 vs 18±2 spikes/10 sec), indicating that sensitivity to phenylephrine was not altered by chronic diazepam exposure. DR neurons in slices from chronic diazepam-treated rats had reduced responses to iontophoretically applied GABA, when compared to the GABA sensitivity observed in control slices (GABA IT50s: 25±2 in controls vs 34±4 nA.sec in dz-treated). Sensitivity of DRN to iontophoretically applied 5-HT was similar in control and diazepam-treated slices (5-HT IT50s: 691±66 vs 571±75). Thus, following chronic diazepam exposure, subsensitivity to GABA is observed in DR neurons both *in vivo* and *in vitro*. This suggests that the decreased GABAergic responses induced by chronic diazepam exposure reflect changes intrinsic to the dorsal raphe nucleus.

326.5

MODULATION OF GABA-MEDIATED DEPOLARIZING SYNAPTIC RESPONSES BY NMDA IN IMMATURE HIPPOCAMPAL NEURONS R. Corradetti*, J.L. Gaiarsa*, Y. Ben-Ari and E. Cherubini (SPON : R. Adamec), INSERM U-29, 123 Bd Port-Royal, Paris 14, FRANCE.

Intracellular recordings were made from immature CA3 rat hippocampal neurons (0-8 days) in the in vitro slice preparation. In adult CA3 pyramidal neurons, stimulation of the hilus evokes at resting membrane potential (RMP) an EPSP followed by an IPSP. The EPSP is mediated by an excitatory amino acid acting on non-NMDA receptors, whereas the IPSP by GABA acting on GABA A and GABA B receptors. In newborn rats, stimulation of the same region evoked a long-lasting (400 ms) depolarizing potential which was mediated by GABA acting on GABA A receptors since it was blocked by bicuculline (10 uM). The reversal potential of this response (-29 ± 4 mV, n=9 with K Cl- and -53 ± 4 mV, n=8 : mean ± SEM with K-acetate-electrodes) was very close to the reversal of the response to exogenously applied GABA (-30 mV and -59 mV with K Cl- and K -acetate respectively). NMDA receptor antagonists (APV, AP-7 : 50 uM ; CPP : 30 uM) greatly reduced or abolished the evoked responses. In addition, in newborn but not in adult animals, spontaneous giant depolarizing potentials were recorded during the first week of life. These potentials were abolished by bicuculline or APV.

We conclude that, in immature hippocampus, evoked and spontaneous giant synaptic potentials are mediated by GABA which is depolarizing at RMP and whose release is controlled by NMDA receptors. RC is recipient of an EMBO fellowship.

326.6

INHIBITION OF GABA-STIMULATED CHLORIDE INFLUX INTO MEMBRANE VESICLES FROM RAT CEREBRAL CORTEX BY ANTIDEPRESSANTS AND NEUROLEPTICS. M.Ikeda*, E.Malatynska*, R.F.Squires[1] and H.I.Yamamura. Dept. of Pharmacology, Univ.of Arizona, Tucson, AZ 85724 and [1]Nathan Kline Inst.for Psychiatric Res. Orangeburg, NY 10962.

One of the important side-effects produced by clinically used antidepressants and neuroleptics is convulsive seizures. The pharmacological basis of the convulsive effects is not known. To elucidate the convulsive effects of antidepressants and neuroleptics, we examined the effects of amoxapine, SK&F 10810, maprotiline, (-)mianserin, chlorpromazine, haloperidol, pimozide and zotepine on GABA-stimulated $^{36}Cl^-$ uptake into membrane vesicles from rat cerebral cortex. Aliquots of membrane vesicles were preincubated with test compounds for 10 min. $^{36}Cl^-$ uptake was initiated by the addition of $^{36}Cl^-$ and GABA solution to the tubes containing membrane vesicles. After incubation for 3 sec, the uptake was terminated by the addition of ice cold buffer followed by rapid vacuum filtration through Whatman GF/C filters. Amoxapine, maprotiline and (-)mianserin inhibited GABA-stimulated $^{36}Cl^-$uptake at 1uM, 44.1+/-4.8%, 30.3+/-4.9% and 41.0+/-3.8% (% of inhibition), respectively. Some neuroleptics showed inhibition of GABA-stimulated $^{36}Cl^-$ uptake at 10uM and 100uM concentration. These findings suggest that the convulsive effects of some psychotropic drugs are related to the GABA-gated chloride influx.

ß-CCE, CGS8216 AND Ro15-1788: A COMPARISON OF ACTIVITY IN MOUSE AND RAT. L.S. Labinsky* and J.L. Vaught. Janssen Research Foundation, Spring House, PA 19477

In both mouse and rat, ß-CCE, CGS8216 and Ro15-1788 selectively block the anticonvulsant activity of diazepam (but not phenobarbital) in a metrazol seizure test. However, in the mouse, ß-CCE and CGS8216 are also potent proconvulsants. In the metrazol or electrically-induced seizure threshold tests, ß-CCE at doses <5 mg/kg i.p. and CGS8216 at doses <1 mg/kg i.p. but not Ro15-1788, potentiate convulsions [proconvulsant ED50 in electrically-induced seizures: CGS8216=0.8 (0.4-1.6) mg/kg i.p.; ß-CCE=3.8 (1.8-7.6) mg/kg i.p.]. Their proconvulsant duration of action is <2 h. Thus, in the mouse, CGS8216 and ß-CCE are more potent proconvulsants than they are BZD antagonists. Unlike ß-CCM (CD50~9 mg/kg i.p.) or DMCM (CD50=3.9 mg/kg i.p), neither ß-CCE (>100 mg/kg) nor CGS8216 (>20 mg/kg) causes convulsions. In the rat, however, ß-CCE produces weak proconvulsant activity while CGS8216 is practically devoid of proconvulsant effects in either chemical or electrical-induced convulsions. Thus, in the rat, these agents are more BZD antagonist-like than proconvulsant. These data suggest: 1) as previously reported, Ro15-1788 remains the "purest" of BZD antagonists, 2) that CGS8216 and ß-CCE are similar in their effects on seizure threshold and their relative potency is consistent with binding affinity and 3) that potential differences in the pharmacophysical characteristics of the GABA/BZD complex exist between mouse and rat.

326.8

SKF88901A AND SKF89976A (POTENT GABA UPTAKE INHIBITORS): A COMPARISON OF ANALGESIC AND ANTICONVULSANT ACTIVITY IN MOUSE AND RAT. J.L. Vaught, L.S. Labinsky and P.E. Setler. Janssen Research Foundation, Spring House, PA 19477

SKF89976A [N-(4,4-diphenyl-3-butenyl)-nipecotic acid] and its ethyl ester SKF89901A (Yunger et al., JPET 228:109, 1984) were confirmed to be potent inhibitors of the uptake of GABA in rat brain synaptosomes (K_I values = 0.4 and 10.0 µM, respectively). Administered i.p. to mice, both compounds produced atropine-sensitive, naloxone, picrotoxin and bicuculline insensitive analgesia in the mouse tail flick and hot plate (48°C) tests (ED_{50}'s ranging from 5 to 25 mg/kg). Rotorod performance was not impaired by either compound at doses as high as 50 mg/kg. Tolerance developed to the analgesic effects of SKF89976A following chronic dosing (ED_{50} naive = 13.2 mg/kg ; ED_{50} chronic drug = 148.8 mg/kg i.p. hot plate). In the rat, however, no analgesic activity was observed at doses as high as 100 mg/kg. Both compounds effectively block metrazol-induced convulsions in mouse and rat with ED_{50} values between 1 and 8 mg/kg i.p. Given the similar potency in both species as an anticonvulsant, the marked differences between these species in regard to analgesic activity and the relatively inconsistent analgesic response, we suggest that these GABA-uptake inhibitors show more promise in preclinical tests as anticonvulsants than as analgesics.

326.9

STRUCTURE ACTIVITY RELATIONSHIPS FOR STEROID POTENTIATION OF GABA RECEPTOR-MEDIATED CHLORIDE TRANSPORT IN RAT CEREBRAL CORTEX. A. L. Morrow[1], R. H. Purdy[2]* and S.M. Paul[1]*. [1]Clinical Neuroscience Branch, National Institute of Mental Health, Bethesda, MD 20892, and [2]Southwest Foundation, San Antonio. TX. 78284

Endogenous metabolites of progesterone and deoxycorticosterone have recently been shown to enhance the effect of γ-aminobutyric acid (GABA) on chloride ion flux in spinal cord neurons and in rat brain synaptoneurosomes. The ring-A reduced metabolites, tetrahydrodeoxycorticosterone (THDOC) and 3-α-hydroxy,5-α-dihydroprogesterone (3-α-OH,5-α-DHP) were found to be extremely potent (EC_{50} ~ 120 nM) modulators of muscimol-stimulated $^{36}Cl^-$ uptake *in vitro*. We, therefore, examined a series of related compounds in order to determine the structural requirements for activity on GABA receptor function. Synaptoneurosomes were prepared from cerebral cortices of adult male S.D. rats. Muscimol-stimulated $^{36}Cl^-$ uptake was measured for 5 seconds in the presence or absence of various steroids (1 µM). THDOC potentiated the effect of muscimol (3 µM) by 16.1 +/- 1.5 nmole/mg protein. THDOC-21-acetate had similiar activity increasing muscimol-stimulated $^{36}Cl^-$ uptake by 12.2 +/- 1.1 nmol/mg prot. 3-α-OH,5-α-DHP and 3-α-OH P potentiated muscimol-stimulated Cl^- flux by 10.9 +/- 2 and 10.4 +/- 1 nmol/mg protein respectively, while 3-β-OH P was inactive. Analogs of these active compounds containing unsaturated C rings were also inactive. Other inactive derivatives were 3-α-OH,5-α-DHP, 3 acetate and THDOC, 3 acetate. The glucocorticoids and mineralcorticoids were inactive at concentrations between 0.2 and 5 µM. These data define the specificity for steroid hormone metabolite activity on GABA-mediated chloride ion flux in the rat brain.

326.10

PRETREATMENT WITH ETHANOL POTENTIATES INHIBITION OF GABA-ACTIVATED CHLORIDE FLUX BY BENZODIAZEPINE INVERSE AGONISTS. K.J. Buck*, A.M. Allan, and R.A. Harris. Department of Pharmacology, Univ. Colo. Hlth. Sci. Center, Denver, CO 80262; and VA Med. Res. Serv., Denver, CO 80222.

We found that the actions of benzodiazepine (BZ) inverse agonists on muscimol-activated $^{36}Cl^-$ uptake were enhanced by pretreatment with ethanol. Ethanol pretreatment in vitro or in vivo was effective. Cortical membrane vesicles (microsacs) were prepared from acutely treated mice or microsacs were treated in vitro and then washed. Basal and muscimol-activated $^{36}Cl^-$ uptake were measured as previously described (Life Sci. 39: 2005, 1985). The BZ inverse agonists used were methyl-6,7-dimethoxy-4-ethyl-β-carboline-3-carboxylate (DMCM), ethyl 8-azido-5,6-dihydro-5-methyl-6-oxo-4H-imidizo[1,5a] [1,4]-benzodiazepine-3-carboxylate (Ro 15-4513) and N-methyl-β-carboline-3-carboxamide (FG7142).

Sensitization to DMCM was the result of a shift in the potency of DMCM, rather than an increase in the maximal inhibition. The actions of DMCM were blocked by the central benzodiazepine receptor antagonist Ro 15-1788 (10 uM).

Our results indicate that pretreatment with ethanol alters sensitivity of the benzodiazepine site to inverse agonists. This sensitization may play an important role in the development of acute tolerance to and withdrawal from ethanol, as well as the antagonism of ethanol intoxication by BZ inverse agonists. Supported by the VA and AA06399.

326.11

ONTOGENY OF GABA-STIMULATED CHLORIDE UPTAKE AND ITS ENHANCEMENT BY DIAZEPAM IN RAT BRAIN SYNAPTONEUROSOMES. C.K. KELLOGG AND G.L. PLEGER*, DEPT. OF PSYCHOLOGY, UNIV. OF ROCHESTER, ROCHESTER, NY 14627.

Late gestational exposure to diazepam (DZ) has been shown to induce selective and lasting alterations in the offspring (Kellogg, Prog. Brain Res., Vol. 73;1988). Ligand binding assays have indicated the presence of DZ at appropriate receptor sites in fetal brain following administration of the drug to the dam. The present study was undertaken to determine whether DZ occupancy of its recognition site in fetal brain could elicit an effector response. In the adult organism DZ facilitates GABA stimulation of chloride (Cl^-) flux. In the present study, the ability of DZ to enhance GABA- stimulated $^{36}Cl^-$ uptake was examined in synaptoneurosomal preparations of whole brain at 20 and 21 days of gestation and of cerebral cortex from 7 to 90 days of age. GABA-stimulated Cl^- uptake was detectable from 20 days of gestation with an increase in EC_{50} for GABA occurring from 20 to 21 days gestation (from 5.1 to 11.3 µM). Maximal stimulation of uptake during this period occurred at 50-100 µM GABA and was 4.76 ng/mg protein/10 sec at 20 days and 6.13 at 21 days. DZ decreased the EC_{50} for GABA stimulation by 28% (a magnitude similar to that observed in adult tissue) without changing the maximal stimulation of Cl^- uptake. Following birth, the EC_{50} for GABA stimulation was similar to adult values (8µM) at 7 and 14 days, but DZ induced a considerably greater shift (50%) in the EC_{50} at these ages than observed in fetal or adult tissue. At 21 days, the EC_{50} for GABA-stimulation increased to 11.25 µM, but the effect of DZ was still pronounced. By 28 days postnatal age, the EC_{50} and the response to DZ appeared adult-like. The maximal stimulation increased throughout development reaching peak values (19 ng/mgprotein/10 sec) by 21 days. These results indicate that DZ is capable of eliciting an effector response by late gestation in the rat fetus. The developmental shifts in the EC_{50} for GABA stimulation of Cl^- uptake and in the responsivity to DZ suggest underlying changes in the polymolecular complex containing the DZ and GABA recognition sites and the Cl^- ionophore. Supported by grant no.MH31850.

DIBUTYRYL ^{36}cAMP AND FORSKOLIN DECREASE $GABA_A$ RECEPTOR-MEDIATED $^{36}Cl^-$ UPTAKE IN RAT BRAIN SYNAPTONEUROSOMES. Gunter Heuschneider* and Rochelle D. Schwartz. Dept. Pharmacology, Duke Univ. Medical Center, Durham, NC.

The functional activity of the GABA receptor-coupled Cl^- channel was measured under cAMP dependent phosphorylating conditions. Pretreatment of rat cerebral cortical synaptoneurosomes (10 min, 30° C) with dibutyryl cAMP (Bt_2cAMP, 0.1-3.0 mM), produced a concentration-dependent decrease of muscimol-induced $^{36}Cl^-$ uptake (5.2 ± 1.3 - 55.5 ± 2.3%). Bt_2cAMP (1 mM) decreased the maximal effect (25.3 ± 4.0%) but not the potency of muscimol to stimulate $^{36}Cl^-$ uptake. Forskolin (FSK, 30-200 uM) also inhibited muscimol-induced $^{36}Cl^-$ uptake (18.3 ± 1.5 - 42.0 ± 3.9%). The inhibitory effect of FSK (50 uM) was near maximal by 5 sec preincubation. The same time course was observed for FSK-induced cAMP generation in the intact synaptoneurosomes. However, the inactive FSK analog, 1,9-dideoxyforskolin (20-200 uM), similarly inhibited the muscimol response (19.3 ± 4.5 - 67.5 ± 5.1%), indicating the effect of FSK might also involve mechanisms unrelated to activation of adenyl cyclase. The inhibition of the muscimol response by both Bt_2cAMP (1 mM) and FSK (50 uM) was attenuated (16.0 ± 1.2 and 12.2 ± 1.9%, respectively) in Ca^{2+}-free buffer. These data suggest that cAMP-dependent phosphorylation mechanisms regulate the activity of the GABA receptor-gated Cl^- channel in brain.

Supported by NIH grant NS 24577 and PMAF Award to RDS.

326.13

A COMPARISON BETWEEN EFFECTS OF FLURAZEPAM AND Ro07-0213 REVEALES INTRACELLULAR LOCI OF ACTION OF BENZODIAZEPINES IN ADULT RAT NEURONS. J.-I. Oka, E. Sakurai* and H. Fukuda*. Dept. Toxicol. Pharmacol., Fac. Pharma. Sci., Univ. Tokyo, Hongo, Bunkyo-ku, Tokyo 113, Japan.

It is assumed that the main effect of benzodiazepines (BZD) is potentiation of γ-aminobutyric acid (GABA) action through their binding sites. However, high lipid solubility of BZD suggests rapid penetration through the plasma membrane and responses induced intracellularly. In this study, we compared the effects of flurazepam (FLU) and Ro07-0213 on dorsal root ganglion cells which were isolated from rats (250-350g) anaesthetized with urethane/α-chloralose. Ro07-0213 is a quaternary derivative of FLU, and would not be expected to pass across the membrane (czajkowski, C. & Farb, D.H., J. Neurosci., 6:2857, 1986). FLU and Ro07-0213 showed similar potentiating effects on GABA-depolarization. Trypsin-treatment (7990u/mL) abolished the GABA action and also the BZD effects, while electrical membrane properties were not affected. These results assure that BZD binding sites related to these effects are exposed at the extracellular surface. Augmentation of the membrane resistance by FLU was long-lasting, whereas that by Ro07-0213 disappeared just after termination of its application. The effects of Ro07-0213 but not FLU were abolished by trypsin. FLU preferably depressed the steady-state outward currents, whereas Ro07-0213 modified an earlier phase of outward currents as well. These results suggest existence of intracellular loci of action of BZD as well as extracellular binding sites.

GABA DIRECTLY ACTIVATES Cl^- CHANNELS IN ASTROCYTES OF HIPPOCAMPAL SLICES. S.A. Crichton(1), B.A. MacVicar(1), F.W.Y. Tse(1) and H. Kettenmann(2) (1) Neuroscience Research Group, University of Calgary, Calgary, Alberta, T2N 4N1 and (2) Department of Neurobiology, I.M. Neuenheimer Feld 364, 6900 Heidelberg F.R.G.

Glial cells in culture have GABA activated Cl^- channels (Backus et al, Glia in press). We have used kainic acid lesioned hippocampal slices to examine the responses of astrocytes to GABA in a neuron free environment. Intracellular recordings were obtained from astrocytes in the CA3 region of slices from hippocampi which had been lesioned by an i.c.v. kainic acid injection one month previously. Membrane potential of astrocyes averaged -85 mV and neurons were never impaled. GABA perfusion depolarized glial cells (1mM, 1.6 ± 0.7 mV n = 10; 10 mM, 3.5 ± 0.9 mV n = 9) as did a GABA agonist, muscimol (1 mM, 2.7 ± 1.8 mV n = 5). Picrotoxin (10^{-4} M), a Cl^- channel antagonist, reversibly decreased the GABA depolarization by 40% whereas β-alanine, which blocks glial GABA uptake had no effect (n = 3). Pentobarbital (10^{-4} M) and flunitrazepam (10^{-5}) enhanced the GABA response by 60% (n = 9) and 50% (n = 4) respectively. These results indicate that astrocytes have GABA activated Cl^- channels which are modulated in a similar manner to neuronal $GABA_A$ receptors. GABA activated glial Cl^- currents could help regulate the extracellular milieu.

THE REVERSAL POTENTIAL FOR GABAERGIC CURRENT IS INFLUENCED BY MEMBRANE VOLTAGE. J.A. Hirsch and P.R. MacLeish. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

Recordings made in slices of visual cortex (Scharfman and Sarvey, Neurosci. 23:407-422,1987) show that GABA is hyperpolarizing when applied to cell bodies and depolarizing when applied to distal dendrites. We attempted to study this regional difference in chemosensitivity by applying GABA to the somata and processes of visual cortical neurons maintained in culture. The occipital cortex of embryonic and postnatal rats was dissociated and plated onto a lawn of flat, nonneuronal cells or an antibody to Thy-1. Cultures were maintained for 1 to 6 weeks in L-15CO_2 with 5% rat serum. With standard whole-cell, patch-clamp techniques, recordings were made from cells bathed in a modified Hank's solution warmed to ~34°C. Patch pipettes contained, in mM: K gluconate, 140 mM; EGTA, 1.1; Hepes/KOH 10; $MgCl_2$, 2; NaCl,2; Na_2ATP, 2; Na_2GTP, 0.1; glucose 10. GABA, 50-100 μM, was applied by pressure from pipettes with tip diameters of 2 -4 um positioned near the cell surface. The reversal potential for GABA applied either at the soma or at distances of 50 to 150 um along dendrites was similar and within 5 mV of the holding level when cells were clamped at -58 to -60 mV. When the membrane was depolarized, E_{GABA} began to climb and, in minutes, stabilized near the new holding value. The rate of shift in reversal potential ranged from 6 - 10 mV per 10 mV increment in membrane voltage (n=12). Displacing the holding potential below -60 mV caused smaller changes in E_{GABA}. The effects of altering the membrane voltage were completely reversible. The actions of GABA were blocked by 10 μM picrotoxin and mimicked by 100 μM muscimol but not by 500 uM baclofen. Our results suggest that synaptic transmission involving $GABA_A$ receptors may be regulated by any factor that affects the membrane voltage. If, in tissue, dendrites are maintained at potentials more depolarized than at the soma, the voltage sensitivity of E_{GABA} could account for some of the previously-observed differences in response to the transmitter. RESPONSE OF THE PERIAQUEDUCTAL GRAY (PAG) NEURONS TO GABA AND ITS ANTAGONISTS M.M. Behbehani, S.D.Chandler* and M. Ennis. Dept. of Physiology and Biophysics, U. Cincinnati College of Med. Cincinnati,OH 45267-0576.

There is indirect evidence that a tonically active inhibitory GABAergic network within the PAG plays a significant role in activation of the PAG- mediated analgesia. We examined the effect of GABA,picrotoxin (PTX) and bicuculline methiodide (BICM) on baseline activity of PAG cells in PAG slices as well as in anesthetized rats.

Recordings were made from neurons in PAG slices that were perfused with normal or calcium free $CoCl_2$ containing Krebs-Ringers solution (KRS). Drugs were applied next to the recording cell by pressure . In the in vivo experiments, drugs were applied by iontophoresis or by pressure injection to PAG neurons in choloral hydrate anesthetized 250-300 gram rats.

Response of 50 cells in PAG slices and 16 cells in intact animals were examined. Injection of GABA produced inhibition in 87% of PAG cells and its effect could be blocked by BICM and PTX. Sensitization of response to GABA was noted in 60 % of the cells. BICM increased the base line firing rate in 67% of cells in the in vitro experiments. Similar effect was also observed when the tissue was bathed in calcium free- cobalt containing KRS . In the intact preparation, application of BICM increased the base line firing rate in 62% of the cells. Application of BICM caused multiple spiking of PAG cells in both types of preparations. Neurons in all regions of the PAG were responsive to GABA and BICM and no site specificity of their effect was noted. Supported by PHS grant #20643.

GABA-EVOKED RESPONSES OF MYELINATED DORSAL AND VENTRAL ROOT FIBERS: MODULATION BY K^+ CHANNEL BLOCKERS. S. Liske and M.E. Morris. Department of Pharmacology, University of Toronto, Toronto M5S 1A8.

GABA (γ-aminobutyric acid) and THIP (4,5,6,7-tetrahydroisoxazol-(5,4-c)pyridin-3-ol) evoke multi-component changes in excitability of dorsal (DR) and ventral (VR) root fibers of isolated bullfrog sciatic nerve — reflected by changes in A-fiber 1/2-maximal compound action potential responses. Initial excitability increases evoked in both roots by GABA are enhanced by 3 mM TEA (VR>>DR); later/secondary components are depressed (DR>VR). TEA also decreases THIP-evoked DR depolarization and augments the remarkably brief VR response. 2 mM CsCl, 50 μM 4-AP and 1 mM $BaCl_2$ depress/delay GABA agonist responses. Block of $GABA_A$-evoked gK or voltage-dependent fast K^+ currents of motor fibers could explain enhancement of early VR depolarizations. Depression of the depolarizations evoked in sensory fibers may signify block of slow K^+ currents and their generation of K^+ accumulation, or of a GABA-evoked inward rectifer. Such differential effects as well as data from curve fitting — using hypothetical reconstructs of depolarizing and hyperpolarizing responses of the roots in the presence and absence of bicuculline methiodide — suggest that GABA-evoked depolarizations are mediated by not only the classical $GABA_A$ receptor but at least one additional receptor/mechanism.

EFFECTS OF BICUCULLINE METHIODIDE AND PHACLOFEN ON SPONTANEOUS AND EVOKED PSP'S IN RAT HIPPOCAMPAL ROLLERTUBE CULTURES. A.T. Malouf, C.A. Robbins* and P.A. Schwartzkroin. Dept. of Neurological Surgery, Univ. of Washington, Seattle, WA 98195

We have begun to examine the electrophysiological properties of cultured hippocampal slices prepared by the method of Gahwiler (*J. Neurosci. Methods*, 4:329-342, 1981). Cells in these slices exhibited typical properties for CA1 or CA3 hippocampal pyramidal neurons. Most cultures demonstrated a high incidence of small, fast PSP's; EPSP's could trigger action potentials at a rate of 0-5/sec. These cultures also produced spontaneous slow (up to 1 sec. duration) IPSP's. Stimulation of the stratum radiatum in CA1 or the hilus produced an EPSP followed by a biphasic IPSP, suggesting that the Schaffer collaterals and mossy fiber pathways develop the appropriate pattern of innervation. The $GABA_A$ antagonist bicuculline methiodide (BMI) and the putative $GABA_B$ antagonist phaclofen were bath applied to the cultures. BMI (10 uM) produced a reduction in the number of spontaneous PSP's and repetitive burst discharges; stimulation of the afferent fiber pathway produced a long train of action potentials even at previously subthreshold stimulus intensities. Phaclofen (1 mM) did not produce changes in spontaneous fast PSP's but dramatically reduced the amplitude of the slow IPSP following fiber pathway stimulation. No increase in burst activity or number of spikes in response to pathway stimulation was observed. Our data indicate that both $GABA_A$ and $GABA_B$ receptors contribute to the spontaneous and stimulus-evoked synaptic activity of these cultures.

(-)BACLOFEN HAS A DUAL MECHANISM OF ACTION IN RAT SPINAL DORSAL HORN IN VITRO. C A ALLERTON*, P R BODEN AND R G HILL. Parke-Davis Res Unit, Addenbrookes Hospital Site, Hills Rd, Cambridge, CB2 2QB, UK.

In dorsal root ganglia, the $GABA_B$ agonist (-) baclofen depresses inward calcium currents and reduces neurotransmitter release (Robertson, B and Taylor W R, Br J Pharmac 89:661, 1986) while in hippocampus (Newberry, N R and Nicoll, R A, Nature 308:450, 1984) it activates an outward potassium current. We have examined the action of (-)baclofen on deep dorsal horn neurones by intracellular recording from 400μM slices of 9-16 day old rat spinal cord. On all neurones studies (-)baclofen (100nM-30μM) had a post-synaptic hyperpolarizing action and reduced apparent input resistance. This response was blocked by intracellular Cs^+ and extracellular Ba^{2+} (300μM). In addition, (-)baclofen depressed both spontaneous and electrically evoked epsps in these neurones. This was not affected by intracellular Cs^+ or extracellular Ba^{2+}. Indeed Ba^{2+} itself produced additional synaptic activity which was depressed by both (-)baclofen and 20mM mg^{2+}. (-)Baclofen therefore in spinal dorsal horn both post-synaptically increases potassium conductance and pre-synaptically depresses calcium (barium) currents.

PHARMACOLOGY OF INHIBITION IN THE GLOMERULAR LAYER OF THE OLFACTORY BULB. W.T. Nickell, M.T. Shipley and H.J. Duncan. Dept. Anat. & Cell Biol., Univ. Cinti. Coll. Med., Cincinnati, OH 45267

Two different central GABA receptors have been identified: $GABA_A$ receptors are activated by muscimol, and blocked by picrotoxin and bicuculline; $GABA_B$ receptors are activated by baclofen, but not muscimol and are not blocked by picrotoxin or bicuculline. A recent autoradiographic study (Bowery, *et al.*, 1987) demonstrated a striking segregation of these receptors in the olfactory bulb of the rat: $GABA_A$ receptors are present in all layers of the bulb; $GABA_B$ receptors are almost exclusively located in the glomerular layer. We have studied the properties of $GABA_A$ and $GABA_B$ synapses in the mammalian olfactory bulb (OB).

Orthodromic responses were recorded with microelectrodes in the glomerular layer of the OB. With electrical stimulation of the olfactory nerve (ON) using double pulses with intervals of 25 to 200 msec, the magnitude of the second response decreases at shorter intervals. Both baclofen and muscimol inhibited the response to both pulses. Inhibition of the second response was not blocked by picrotoxin.

These results suggest that inhibition is mediated by both $GABA_B$ receptors and $GABA_A$ receptors in the glomerular layer. $GABA_A$ receptors mediate classic postsynaptic inhibition; $GABA_B$ receptors may be the source of GABA-mediated presynaptic inhibition. Staining with GAD antisera suggest that there are large and small GABA terminals in the glomerular layer while there are only small terminals in the infra-glomerular layer. These two classes of terminals may be related to $GABA_A$ and $GABA_B$ synaptic sites. (Supported by: NS23348, US Army DAMD 17-86-C-6005, NIH NS 23523.)

CEREBRAL ISCHEMIA III

327.1

GM1 GANGLIOSIDE PROTECTS LOSS OF PLASMA MEMBRANE FUNCTION AFTER CEREBRAL FOCAL ISCHEMIA. C.G. Wakade,V. Bharucha*, S.E. Karpiak & S.P. Mahadik. Div. Neuroscience, NYS Psychiatric Inst., Depts. of Psychiatry, and Biochemistry & Molecular Biophysics, Physicians & Surgeons, Columbia U., New York.

We have reported that ganglioside GM1 treatment protects acute injury processes (ionic imbalance, edema, loss of membrane fatty acids, Na,K-ATPase and Mg2-ATPase) indicative of plasma membrane failure after global ischemia. To understand the molecular mechanism of these protective effects in ischemia we have used a reproducible model of focal ischemia. Ischemia was produced by combined permanent medial cerebral & common carotid artery occlusion [MCAo+CCAo] with 1 hr temporary contralateral CCAo in rat. Levels of Na,K-ATPase, Mg-ATPase and tissue ions (Na+, K+ & Ca2+) in ischemic tissue (primary and peri-infarct cortical areas) were compared with the contralateral side in rats treated with saline or GM1. In the primary infarct area 72 hrs after ischemia levels of Na,K-ATPase & Mg-ATPase were reduced by 45% & 37% respectively in the saline rats, and both by only 15% in GM1 treated rats. In the peri-infarct areas losses in both enzyme levels in saline treated rats were minimal (<15%), with almost no losses in GM1 treated rats. The tissue levels of Na+ & K+ paralleled the loss of Na,K-ATPase in saline treated animals but the levels of Ca2+ increased slowly, reaching a maximum after 72hrs.

IN VITRO PROTECTION AGAINST CEREBRAL HYPOXIA BY LOCAL ANESTHETICS. C.A. West-Phelan*, L.F. Lucas*, B.M. Rigor and A. Schurr, Department of Anesthesiology, University of Louisville School of Medicine, Louisville, KY 40292,

Numerous studies have been published in recent years on potential antihypoxic drugs and their pharmacology, where many of them employed in vivo models of cerebral ischemia/hypoxia. For faster and less expensive screening of such drugs we have been using the in vitro rat hippocampal slice preparation. In a recent study we demonstrated the depressive effect of lidocaine on synaptic function using this in vitro system. If such depression is the result of metabolic arrest or ion fluxes attenuation, then lidocaine and other similar local anesthetics should exhibit antihypoxic properties.

Rat hippocampal slices were incubated with non-depressive doses of either lidocaine, 2-chloroprocaine or cocaine 60 min prior to their exposure to 15 min hypoxia. The rate of recovery of synaptic function (evoked population spike) following the hypoxic episode was used as an index of hypoxic damage. Slices treated with 0.1 mM of any of the three local anesthetics exhibited a significant increase in the recovery rate of synaptic function from hypoxia as compared to control, untreated slices.

The antihypoxic properties of local anesthetics may stem from their ability to reduce Na^+ influx (and possibly its concomitant Ca^{2+} influx), or from conservation of ATP via metabolic slow down, or both.

FREE RADICAL SCAVENGERS PROTECT AGAINST PEROXIDATIVE DAMAGE IN THE HIPPOCAMPAL SLICE. T.C. Pellmar, K.L. Neel and M.L. Moss*. Physiology Department, Armed Forces Radiobiology Research Institute, Bethesda, Maryland 20814.

Hydrogen peroxide decreases synaptic efficacy and impairs postsynaptic spike generation (Pellmar, Brain Res. 364:377). Since the damage is likely to be due in part to free radical generation, the free radical scavengers dimethylsulfoxide (DMSO) and thiourea would be expected to afford some protection.

Slices of hippocampus were prepared from brains of euthanized guinea pigs. Stimulating electrodes were positioned in the stratum radiatum to stimulate afferents to CA1 region. Recording electrodes were positioned in the stratum pyramidale and in the stratum radiatum of CA1 to record the population spike and the population synaptic potential, respectively. Input-output curves were generated by varying the stimulus intensity from 0 to 1.0 mA. DMSO or thiourea was applied for 30 min prior to peroxide exposure. The responses in scavenger were compared to the responses after 30 min in 0.005% peroxide plus scavenger.

Thiourea (0.5 mM) afforded significant protection. Higher doses of thiourea were not as effective since they directly decreased the population spike. DMSO (50 mM ≃ 0.36%) had no direct effects but protected postsynaptic spike generation from peroxide damage. Impairment of synaptic efficacy by peroxide was still present in DMSO. The data support a role for free radicals in peroxide damage of neuronal tissue.

ISCHEMIC TOLERANCE IS INCREASED IN THE CISTERNAL INFUSION MODEL OF RAISED INTRACRANIAL PRESSURE: POSSIBLE ROLE OF THE EXTRACELLULAR MICROENVIRONMENT IN THE PREVENTION OF EXCITOTOXIC DEGENERATION A.-C. Duhaime and D.T. Ross Department of Clinical Neurosciences, Brown University and Department of Neurosurgery, Rhode Island Hospital, Providence, RI 02902.

Elevation of the intracranial pressure above the mean arterial pressure has been shown to temporarily stop cerebral blood flow . In order to study the effects of raised intracranial pressure on the development of cerebral ischemia, a cerebrospinal infusion model was used to elevate intracranial pressure above mean arterial pressure for various intervals.

Male Long Evans rats were anesthetized with chloral hydrate and xylazine, orally intubated, and artificially ventilated with room air. The femoral artery was cannulated for continuous measurement of arterial blood pressure. Two 25-gauge needles were introduced into the cisternae magnae, one for measurement of intracranial pressure and the other for instillation of artificial cerebrospinal fluid. Intracranial pressure was raised above blood pressure for five to thirty minutes by cisternal infusion of artificial CSF at ~1cc/ minute. The animals were allowed to survive for one to seven days and the hippocampal formation was examined for ischemic change in 33 micron Nissl stained sections by light microscopy.

No significant behavioral or histological changes were seen unless the duration of ischemia was between 25 and 30 minutes, even when the animals survived for up to seven days. The cisternal infusion of large volumes (10-50 cc) of artificial CSF may prevent the accumulation of extrracellular potassium and excitotoxic amino acids which occur in ischemia. As a result it appears that pathological and behavioral changes occur only after periods of ischemia significantly longer than those required to produce these changes in vessel occlusion models. Studies are in progress to determines the extracellular concentration of excitatory amino acids during raised intracranial pressure.

327.5

NOREPINEPHRINE IN THE GERBIL HIPPOCAMPUS: EFFECT OF DSP4 TREATMENT ON PYRAMIDAL CELL LOSS AFTER TRANSIENT ISCHEMIA. K. Nishino*, J. K. Morse, C.-S. Lin, and J. N. Davis (SPON: F. Eldridge). V.A. Medical Center and Duke University Medical Center, Durham, N.C. 27705.

Hippocampal pyramidal cells are vulnerable to transient periods of ischemia in the Mongolian Gerbil and the rat. We measured the levels of norepinephrine (NE), the distribution of tyrosine hydroxylase-immunoreactive fibers and the effect of DSP4 pretreatment on pyramidal cell counts in ischemic Gerbils. The NE levels of were similar in the dentate gyrus and the septal, midlle and temporal portions of the hippocmapal gyrus. Dopamine was barely detectable. The laminar distribution of fibers was similar to the rat, but less fibers were present in the dentate gyrus and more were seen in stratum oriens of CA_1. Animals were pretreated with 100 mg/kg. of DSP4 14 days before undergoing 5 minutes of bilateral carotid artery occlusion and sacrificed 7 days later. There was significant worsening of pyramidal cell loss in the CA_1, CA_3, and CA_4 hippocampal regions of the DSP4-pretreated animals compared to saline-pretreated ischemic controls and unoperated animals (surviving neurons were 11 *vs.* 9%, 71 *vs.* 49%, and 80 *vs.* 66%, respectively; repeated measures ANOVA, $p<0.0001$). Cortical biopsies of the treated animals before sacrifice for cell counting showed that DSP4 treatment had lowered cortical NE (Saline *vs.* DSP4, 0.29 ±0.02, 0.10 ±0.03; $p<0.0001$, "t" test). Our data are consistent with previous reports in rats suggesting that NE neurons may modulate neuronal death in hippocampal pyramidal cells.

327.6

PHENYTOIN DECREASES THE VOLUME OF ISCHEMIC DAMAGE CAUSED BY MIDDLE CEREBRAL ARTERY OCCLUSION IN F-344 RATS. J.J. Cordon*, P.A. Boxer and F.W. Marcoux, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The anticonvulsant phenytoin has been reported to be beneficial in a number of models of global cerebral ischemia. The current experiments were designed to determine if phenytoin was also effective in reducing the damage resulting from focal ischemia. The left common carotid artery was ligated along with the ipsilateral middle cerebral artery 3 mm from its origin in F-344 rats. Phenytoin or commercially available vehicle was administered either IP or IV (via a femoral catheter) 30 min and 24 hrs post occlusion. The volume of ischemic damage was assessed morphometrically based upon extravasation of the dye Evans Blue. Phenytoin, 100 mg/kg IP or 30 mg/kg IV, significantly reduced the volume of ischemic damage by 51% and 43% respectively. When given as a single IV dose (30 mg/kg) either 30 min, 2 hr, or 24 hrs post occlusion there was no significant reduction in infarct size, although there was a 30% reduction in the 30 min group. These doses of phenytoin are approximately ten times greater than the anticonvulsant ED_{50} and produce marked ataxia. Phenytoin has been shown to modulate both sodium and calcium flux and this may account for its neuroprotective activity.

NEW PHARMACOLOGIC APPROACHES TO PROTECT THE RAT BRAIN FROM ISCHEMIA. T. Tominaga, H. Katagi*, M. Katsuoka* and S.T. Ohnishi. Membrane Res. Inst., Phila., PA 19104.

Protective effects of two new drugs against ischemic brain injury were examined using a rat focal ischemia model. They are charybdotoxin (CTX; purified from a scorpion venom), which is a specific inhibitor of the Ca^{2+}-activated potassium channel, and an oligomeric derivative of prostaglandin E_1 (MR-356).

The focal ischemic lesion was produced by permanent ligations of the middle cerebral artery and the common carotid artery (CCA) combined with temporary occlusion (for 60 min) of the contralateral CCA. CTX (0.15 mg/kg) or MR-356 (6 mg/kg) was administered 30 min before or 50 min after the induction of ischemic insult. Three days after the focal ischemia, the formation of brain edema and the changes in ion contents (Na, K and Ca) were measured. Motor deficits and memory disturbance were also evaluated by motor performance tests (which included inclined plane, balance beam and prehensile tests) and the passive avoidance test, respectively.

The brain edema and ionic derangements were reduced in the pre-ischemic treatment with CTX or in the post-ischemic treatment with MR-356. Motor deficits and memory disturbance were ameliorated in accordance with the reduction of brain edema. Possible protecting mechanisms of these new drugs in brain ischemia will be discussed.

327.8

ANOXIC HIPPOCAMPAL DAMAGE IN PRIMARY CULTURES: PROTECTIVE EFFECTS OF GLUCOSE ARE pH-DEPENDENT. G.C. Tombaugh* and R. M. Sapolsky (SPON: J.D. Barchas). Dept. of Biol. Sciences, Stanford Univ., Stanford, CA 94305.

In vivo, hyperglycemia prior to hypoxia/ischemia increases neuronal injury, probably via anaerobic lactic acid production. We have used primary neuronal cultures to study whether the same effect occurs in vitro and to examine the relationships among glucose, pH_o, and anoxia-induced cell death. Hippocampal neurons taken from 18d rat fetuses were maintained at 37°C/10% CO_2 for 14 days. Cells were made anoxic (100% N_2) for 6hr at 37°C and then refed with fresh media containing 5mM glucose. 24hr later, cell viability was measured by lactate dehydrogenase assay. Since anaerobic cell activity was unable to shift media pH significantly, experimental media were adjusted to defined pH values prior to anoxia. At pH 7.4, anoxia in the absence of glucose caused severe damage; glucose concentrations ranging from 1-30mM not only did not worsen damage, but completely prevented cell death. At pH values as low as 6.5, 5mM glucose during anoxia also prevented cell death, but at $pH_o \leq 6.0$ severe damage occurred which was independent of glucose availability. Thus, in this system an effect emerges that is somewhat different from that observed in vivo: glucose exerts a protective influence on hippocampal neurons during anoxia when pH_o is greater than that which autonomously causes cell damage. (Supported by NIH AG-06633).

327.9

(S)-EMOPAMIL: A NEW CALCIUM ANTAGONIST OF THE VERAPAMIL GROUP WITH HIGH CEREBRAL AVAILABILITY AND ANTIISCHEMIC PROPERTIES. L. Szabo*, H.P. Hofmann*, M. Raschack*, L. Unger* (SPON: R. A. O'Brien). Dept. of Neuropharmacology, Knoll AG, D-6700 Ludwigshafen, Federal Republic of Germany

Experimental studies have yielded conflicting results concerning the therapeutic effect of calcium antagonists in different models. Part of the negative findings may be related to the fact that several compounds with well-documented efficacy on the heart or peripheral vessels are unable to reach the brain in sufficient quantities.

(S)-emopamil [(2S)-2-isopropyl-5-(methylphenethylamino)-2-phenylvaleronitrile-hydrochloride] is a recently developed verapamil derivative that crosses the blood-brain barrier easily. Based on measurements of radioactivity after intravenous application of 14C-labeled substances in rats, the relative cerebral concentration of (S)-emopamil was 16 to 18 times higher than that of verapamil. (S)-emopamil was found to prolong the survival of mice in a dose-dependent fashion both during hypoxic hypoxia and global cerebral ischemia whereas verapamil showed only marginal effects.

Apart from its calcium antagonistic properties, (S)-emopamil has exhibited very high affinity to the 5-HT2 receptor in 3H-ketanserin binding test (Ki=4.4 nmol/L). In measurements on rat aortic strips (S)-emopamil's serotonin antagonistic potency was shown to be 10 times as high as verapamil's (EC50: 4.5 and 42 nmol/L, respectively).

Cerebral vascular and metabolic effects of (S)-emopamil were investigated autoradiographically in the rat. Under physiological conditions (S)-emopamil increased cerebral blood flow by up to 100% of control without changing the metabolic rate of glucose. In reversible forebrain ischemia models (S)-emopamil ameliorated postischemic cerebral hypoperfusion, accelerated energetic restitution and reduced delayed hippocampal neuronal necrosis.

These results suggest that (S)-emopamil may be a useful agent for the treatment of cerebrovascular disorders.

327.10

MONOSIALOGANGLIOSIDE EFFECTS FOLLOWING TRANSITORY GLOBAL CEREBRAL ISCHEMIA IN RODENTS. A. Leon, M.S. Seren*, R. Rubini*, A. Lazzaro*, R. Zanoni*, N. Schiavo*, C. Aldinio*, M. Fiori and G. Toffano (SPON: S. Mazzari). Fidia Research Laboratories, Abano Terme, Italy.

Monosialoganglioside (GM1) treatment of animals has consistently been shown to ameliorate outcome following a variety of CNS injuries, including cerebral ischemia. We here report the effects of the inner ester derivative of the ganglioside following transitory 4 vessel occlusion in adult rats (Pulsinelli, W.A. and Brierley, J.B., Stroke 10:267, 1979). The ganglioside was systemically administered at a dose of 20 mg/kg and its efficacy was evaluated by i) monitoring of the cortical EEG and ii) assessment of the degree of morphological damage in the CA1 area of the hippocampus. Preliminary data indicate that the ganglioside improves EEG recovery during the first 2 weeks following the ischemic episode. In addition, the ganglioside increases the percentage of animals showing less severe hippocampal CA1 neuronal loss.

These effects may perhaps be related to the ganglioside prevention of glutamate neurotoxicity observed in vitro (Favaron, M. et al., FASEB J., 2:A824, 1988; Skaper, S.D. et al., this meeting). To further validate such a hypothesis, the ganglioside capability to decrease post-ischemic selective (glutamate-related) neuronal loss is currently being evaluated in gerbils following transitory bilateral common carotid artery occlusion.

327.11

MK 801 MODULATES METABOLIC RESPONSE TO PERINATAL ASPHYXIA. L.R. Ment*, W.B.Stewart, O.A.C.Petroff* and C.C.Duncan*. Depts. Pediatr., Neurol., Surg., & Anat., Yale Univ. Sch. of Med., New Haven, CT 06510.

The N-methyl-D-aspartate (NMDA) receptor antagonist MK 801 (Merck, Sharp & Dohme) prevents neuronal degeneration following ischemia. We hypothesized that blocking the NMDA receptor would prevent the depression of cerebral high energy phosphates produced by asphyxia, & thus prevent neuropathologic damage. Newborn beagle pups (2-7 d) were anesthetized, tracheotomized, ventilated & randomized to asphyxial insult (I = discontinuation of ventilatory support for 5 min) or control (NI) & drug treatment with MK 801 (10 mg/kg i.v.) or saline (S). Pups were pretreated with MK 801 or S, 30 min prior to I/NI. After 5 min of I/NI, brain extracts were prepared for ^{1}H NMR spectral analysis of high energy phosphorylated compounds & lactate levels. MK 801 had no effect on these measures in the NI brains. Phosphocreatine levels were 1.6±0.2, 0.1±0.1, & 0.87±0.03 mmole/kg (mean ± S.D.) for the S/NI, S/I & MK 801/I pups. Cerebral glucose was 1.55±0.07, 1.20±0.07, & 1.78±0.23 for the S/NI, S/I, & MK 801/I, & lactate was 1.16±0.49, 3.94±0.06, & 2.03±0.39. The pH fell 0.9 units for the S/I animals compared to 0.4 units for the MK 801/I pups. Pretreatment with the NDMA receptor antagonist MK 801 in part protects the developing brain against severe metabolic insult & may diminish the neurologic consequences. (Sup. by NS 21946 to LRM)

EFFECTS OF LY178002 AND LY256548 ON ISCHEMIA-INDUCED BRAIN DAMAGE. J. A. Clemens, M. L. Phillips*, M. E. Roush* and J. A. Panetta*. The Lilly Research Labs, Lilly Corporate Center, Indianapolis, IN 46285.

LY178002 (5-[[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methylene-4-thiazolidinone) and its N-methyl analog, LY256548, inhibit the activity of phospholipase A_2,5'-lipoxygenase, and fatty acid cyclooxygenase. Because of these properties we decided to determine their effects on ischemia-induced brain damage. In the first experiment, a 4-vessel occlusion model of global ischemia was used. Adult, male Wistar rats were prepared for experimentation under anesthesia the day prior to compound treatment by permanent cautery of the vertebral arteries and placement of atraumatic clasps around both common carotids. Global ischemia was induced the following day by tightening the clasps for a 30 min period during which the rats became unconscious. Compounds were administered orally at a dose range of 50-500 mg/kg suspended in 2% acacia. Brains were removed 72 hrs after ischemia, sectioned, and evaluated histologically. LY178002 and LY256548 significantly reduced striatal and hippocampal CA_1 damage when given either before or 15 min after the period of ischemia. In the second experiment, oral administration of 200 mg/kg of LY256548 reduced hippocampal CA_1 damage in Mongolian gerbils subjected to 10 min of bilateral carotid occlusion. We conclude from the results of these studies that LY178002 and LY256548 may be useful in protecting against ischemia-induced damage.

DELAYED TREATMENT WITH THE NMDA-ANTAGONISTS DEXTROMETHORPHAN AND DEXTRORPHAN, REDUCES CEREBRAL DAMAGE AFTER TRANSIENT FOCAL ISCHEMIA. G.K. Steinberg*, J. Saleh, R. DeLaPaz*, D. Kunis and S.R. Zarnegar*. Division of Neurosurgery, Stanford University School of Medicine, Stanford, CA 94305.

Dextromethorphan (DM), a clinically tested antitussive medication and its major metabolite dextrorphan (DX), are N-methyl-D-aspartate (NMDA) antagonists. Both drugs attenuate hypoxic neuronal injury in culture (Goldberg, M.K., et al, Neurosci. Lett. 80:11, 1987) and we have shown that pretreatment with these agents protects against cerebral damage in a rabbit model of focal ischemia (George, C.P., et al, Brain Res. 440:375, 1988; Saleh, J., et al, Soc. Neurosci. Abstr., 1988). We tested the efficacy of post-ischemia treatment with DM and DX in our rabbit model.

Twenty-two male rabbits were anesthetized and underwent transorbital clip occlusion of the left internal carotid artery and anterior cerebral artery for one hour, followed by 4 1/2 hours of reperfusion. One hour after the onset of arterial occlusion, immediately after removing the clips, animals were blindly treated intravenously with 20 mg/kg loading dose, followed by 10 mg/kg/hr of DM (n = 7), 15 mg/kg loading dose, followed by 15 mg/kg/hr of DX (n = 7), or an equivalent volume of normal saline (NS) (n = 8). The formalin-fixed brains were analyzed blindly with magnetic resonance imaging (MRI) using coronal T2-weighted images (TR2500, TE100). Ischemic neuronal damage (IND) was assessed blindly on standard, coronal hematoxylin and eosin sections.

The area of neocortical IND was significantly reduced in the DM group (4.2%, p<.05) and DX group (6.1%, p<.05), compared with the NS controls (36.2%). MRI demonstrated significantly smaller areas of cortical edema in the DM (14.6%, p<.05) and DX (8.0%, p<.01) treated rabbits, compared with the controls (32.9%).

The present study suggests that systemic treatment with DM and DX one hour after the onset of transient focal ischemia can substantially reduce the extent of neocortical neuronal damage and protect against the development of ischemic edema in a rabbit model. These drugs may have therapeutic potential in clinical stroke.

PRETREATMENT WITH THE NMDA-ANTAGONIST DEXTRORPHAN ATTENUATES NEURONAL DAMAGE AND EDEMA IN FOCAL CEREBRAL ISCHEMIA J. Saleh, G.K. Steinberg*, R. DeLaPaz*, D. Kunis and S.R. Zarnegar* Division of Neurosurgery, Stanford University School of Medicine, Stanford, CA 94305

Dextromethorphan (DM), an N-methyl-D-aspartate (NMDA) antagonist has previously been reported to attenuate ischemic neuronal damage when administered prior to the onset of focal cerebral ischemia (George C. et al, Brain Res 440:375, 1988; Prince D. & Feeser H., Neurosci Lett 85:291, 1988). DM is rapidly O-demethylated by the liver to its major metabolite, dextrorphan (DX). DX is also an NMDA antagonist and protects neurons against hypoxic damage in culture (Goldberg, M.P. et al Neurosci Lett 80:11, 1987). We studied the efficacy of systemic pretreatment with DX in our rabbit model of transient focal cerebral ischemia.

Fourteen New Zealand male rabbits were randomized into two equal groups receiving blindly either 24 mg/kg/0.5 hr loading dose, followed by 12 mg/kg/hr intravenous DX or an equivalent volume of normal saline (NS). One and one-half hours after starting the drug, the left internal carotid and left anterior cerebral arteries were transiently occluded for one hour. After 4 hours of reperfusion, the animals were sacrificed and the brains perfused with 10% buffered formalin. The brains were analyzed blindly using magnetic resonance imaging (MRI) with T2-weighted images (TR2500, TE100). Areas of increased signal representing edema were expressed as a percentage of the total cortex. Histological measurements of ischemic neuronal damage (IND) in the cortex were performed blindly at two coronal levels on hematoxylin and eosin stained sections. The total area of IND was calculated as a percentage of total cortex.

DX treated rabbits had significantly less cortical IND (7.4%), compared with the NS group (31.5%; p = .02). The DX treated group also showed a significant decrease in ischemic edema on MRI (21.6%), as compared with the control group (46.3%; p = .03).

Our findings demonstrate the protective role of DX against ischemic neuronal damage and edema when administered before the onset of transient focal ischemia. We recommend DX be considered for use in clinical trials of stroke treatment.

ASSOCIATION CORTEX AND THALAMOCORTICAL RELATIONS

328.1

CORTICAL AND MIDBRAIN CONNECTIONS OF THE INTERMEDIODORSAL NUCLEUS IN THE RAT. T. W. Deacon. Biological Anthropology, Harvard University, Cambridge, MA 02138.

The nucleus mediodorsalis (MD) is the principle thalamic source of projections terminating in prefrontal cortex. Subnuclei within MD have been shown to project to discrete subregions of prefrontal cortex in monkey, cat and rat and to receive afferents from distinct midbrain areas. However, the afferent and efferent connections of the intermediodorsal nucleus (IMD) on the midline between the MD nuclei has not been characterized and distinguished from those of MD. Injections of WGA-HRP by micropipet were centered in IMD in a series of rat brains and the tissue was processed with TMB. In a number of cases cortex and hippocampus overlying the thalamus along the trajectory of the injection were removed by cautery to prevent uptake of tracer that might confound IMD labeled connections. Injections of tracer were also made in midbrain, MD, and cortical structures to verify IMD connections and distinguish them from connections of adjacent areas. After IMD injections labeled cells are observed bilaterally in the central gray area (CGA), raphe nuclei (RN), deep mesencephalic reticular nucleus (DpMe), intermediate gray layer of the superior colliculus (IntG) and substantia nigra (SN). Injections into DpMe or IntG, not overlapping CGA fail to label axons in IMD, but label axons in subdivisions of MD. Injections into MD that do not overlap IMD fail to label CGA. Injections centered in the dorsal or lateral part of CGA label axons in IMD and cells in PV just dorsal to it. Caudal IMD injections produce significant axonal labeling within CGA, while more rostral IMD injections do not. After IMD injection, cingulate, infralimbic, orbital, and insular areas exhibit labeled cells in layer 6 bilaterally. In infralimbic and orbital areas axonal labeling in layers 3 and 1 is also visible. Injections into these cortical areas label cells and axons in IMD. These data suggest that IMD may be a major route through which the central gray area influences prefrontal areas.

328.2

DISTRIBUTION AND MORPHOLOGY OF GABA AND GLUTAMATE IMMUNOREACTIVE NEURONS IN THE THALAMIC MEDIODORSAL NUCLEUS OF THE MONKEY. A. S. Clark, M. L. Schwartz and P.S. Goldman-Rakic. Sect. Neuroanat., Yale Univ. Sch. Med., New Haven CT 06510.

The mediodorsal nucleus of the thalamus (MD) is the principle thalamic relay to the prefrontal cortex. Using GABA(Immunonuclear) and glutamate (gamma-Glu-Glu antisera, provided by J.E. Madl), the present study examined the organization and morphology of GABA and glutamate immunopositive neurons in the adult primate MD, with the aim of providing information on the local circuit neurons and projection neurons of this nucleus.

GABA and glutamate-like neurons were found to differ on several features of their distribution and morphology. GABA positive cells were generally round or ovoid in shape, and typically had soma diameters of 10 μ. In contrast, glutamate lablelled neurons were generally larger (13 μ in diameter), and had more irregularly shaped soma. GABA-positive neurons were organized in ring-like structures, surrounding areas containing few, or no, labelled cells while glutamate immunoreactive cells were more irregularly distributed, often showing a tendency to aggregate in loose clusters.

Because the magnocellular (MDmc) and parvocellular (MDpc) subdivisions of the MD have anatomically and functionally unique cortical targets, we further examined GABA neurons of these two subdivisions to determine if these differences are also evident in their local circuit organization. GABA-positive cells in the MDmc were larger than those in MDpc and the intensity of reactivity was greater in MDmc. Comparison of the densities of GABA-immunoreactive cells revealed not only a greater density of cells in the MDpc, but also that the proportion of all cells which were GABA-positive was greater in the MDpc. These differences in the density and morphology of inhibitory local circuit neurons may contribute to the functional duality of areas of frontal cortex related to these thalamo-cortical pathways. Supported by NS 08019, MH 38546 and NS 22807.

328.3

DIFFERENCES IN THE ORGANIZATION OF GRANULAR FRONTAL ASSOCIATION CORTEX OF PROSIMIAN AND ANTHROPOID PRIMATES. Todd M. Preuss and P.S. Goldman-Rakic. Sec. Neuroanatomy, Yale Sch. of Med., New Haven, CT 06510.

The connections of granular frontal cortex in the prosimian primate *Galago crassicaudatus* were investigated by injecting WGA-HRP or [3H] amino acids in frontal and posterior association cortex of 15 hemispheres. Cyto- and myeloarchitecture (using the Gallyas myelin method) were also examined. Galago organization was compared to that of macaque monkeys (anthropoid primates).

Galagos and macaques share many features of granular frontal organization, including strong connections with posterior parietal cortex. Macaques have two tiers of parietal-recipient areas, an arcuate (Walker's areas 8b, 8a, 45) and a periprincipal ("dorsolateral") tier (9, 46, 12). Galagos possess arcuate-like cortex (Preuss & Goldman-Rakic, Soc. Neurosci. Abtr. 12: 1440, '86), but lack features indicative of periprincipal areas: (1) Individual posterior parietal areas have fewer zones of termination in galago granular frontal cortex than in macaques. (2) The AV and AM thalamic nuclei, which project to principalis cortex, are weakly labeled in galagos (light label in AM, little or none in AV). (3) Galago parietal-recipient cortex does not project densely to the deep tectum or central grey, structures which receive strong projections from macaque dorsolateral areas. (4) The insula projects only lightly to galago granular frontal cortex; macaque areas 46 and 12 have strong insular connections. (5) Several distinctively myelinated principalis zones, e.g., the very light cortex of the ventral bank of the principal sulcus (area 46), are absent in galagos. We interpret these differences as evidence that prosimian primates (such as *Galago*) are lacking some or all of the dorsolateral areas found in anthropoid ("higher") primates and that these areas are evolutionary specializations of anthropoids. Our findings suggest there are qualitative differences among primates in "prefrontal" organization.

328.4

PREFRONTAL CONNECTIONS OF THE PRINCIPAL SULCUS IN THE RHESUS MONKEY. J.F. Bates and P.S. Goldman-Rakic. Sect. of Neuroanatomy, Yale Univ. Sch. of Med., New Haven, CT 06510.

The principal sulcus of the macaque prefrontal cortex is topographically connected with numerous nonprefrontal cortical areas, including premotor, temporal, and parietal cortices. However, with the exception of the frontal eyefields (Barbas & Mesulam, 1981), the connections between the principal sulcus and other subdivisions of the prefrontal cortex have not been described in detail. We have made small injections of WGA-HRP into seven distinct cytoarchitectonic areas, as defined by Walker (1940), to systematically investigate these prefrontal interconnections.

Our findings indicate that each subdivision of prefrontal cortex examined has reciprocal, columnar connections with the principal sulcus. WGA-HRP labeled cells and terminals were distributed throughout the sulcus but tended to aggregate in two focal areas, the ventral rim of the posterior principal sulcus and a portion of the dorsal rim in the anterior half of the sulcus. Areas 8a and 9 were heavily interconnected with both banks along the entire extent of the principal sulcus, whereas areas 10, 11, 25, and 45 were connected primarily or exclusively with the lower bank. Extensive interconnections between prefrontal subdivisions and the principal sulcus provide a basis for integration of different subsystems of prefrontal cortex. (Supported by MH 38456).

328.5

ORIGINS OF AFFERENTS TO PREFRONTAL CORTEX IN THE RAT. F.Condé, E.Maire-Lepoivre, E.Audinat and F.Crépel (SPON:J-P.Vedel). Lab.Neurobiologie et Neuropharmacologie du Développement, Université Paris-XI, 91405-Orsay, France.

In order to better understand the role of the rat's prefrontal cortex (PFC), retrograde transport of fluorescent tracers was used to define the distribution of afferent neurons from the whole brain. Diamidino yellow and/or true blue were injected (0.1-0.3 ul) into one or two areas of the PFC, ipsi- or contralaterally. After 4 day of survival, perfusion and histological processing were done according to Audinat, Condé & Crépel (Exp.Brain Res. 69:439-443, 1988). Different PFC areas received projections from different parts of the n.mediodorsalis of the thalamus (MD) according to Krettek & Price (J.Comp.Neurol. 171:157-192,1977), although areas of overlap were seen, eg: neurons in centralis MD projected to both insular and prelimbic area (PL). Moreover a band-like organization of thalamo-cortical relations was evident. Areas in PFC could be distinguished on the basis of their afferents: CA1 field of hippocampus and n. paratenialis (ipsi) project massively only to PL whereas N.gelatinosus and primary olfactif cortex project to insular cortex. These results support the hypothesis that the role of insular cortex is to integrate multisensory information while that of medial PFC is to analyze information prior to motor acts.

328.6

SOME OBSERVATIONS OF THE DIFFERENTIAL THALAMIC INNERVATION OF THE RODENT LATERAL AGRANULAR AND INFRALIMBIC CORTICES. L. J. Freedman and M.D. Cassell, (SPON: Dr. Adel Afifi), Department of Anatomy, University of Iowa, Iowa City, IA 52240.

Previous studies have shown that the rat ventromedial (VM) thalamic nucleus sends projection to both the infralimbic (IL) and lateral agranular (AG_L) cortices. To determine whether these projections involve axon collateralization, we conducted a retrograde double labeling experiment with bisbenzimide and fast blue injected in these cortical areas.

Injections in AG_L strongly labeled neurons in the ventroposterolateral (VPL) nucleus, posterior nuclear group, and VM. Somewhat more lightly labeled were neurons in the zona incerta (ZI) and rhomboid nuclei (Rh). Additionally, cells in the nucleus reuniens were very sparsely labeled. Injections in IL labeled neurons in the Re, Rh, and paraventricular nuclei, and usually (but not always) neurons in the medial mediodorsal nucleus and ZI. Neurons in the ventromedial nucleus were never labeled by infralimbic injections. Double labeled neurons were observed very rarely in the Re and Rh.

The lack of labelling in VM neurons following IL injections was particularly surprising. The discrepancy between our results and Herkenham's ('78) anterograde study may be due to a lateral "tail" of the Re we observed just ventral to VM; uptake of tracer by these cells probably explains the labelling seen in IL in previous studies.

The lack of collateralization among thalamic neurons innervating the infralimbic and lateral agranular cortex suggests that the modulation by the thalamus of these two cortical areas is largely separate. The limited collateralization observed in Re and Rh is consistent with the idea (Jones '85) that these nuclei are involved in diffuse cortical activation.

328.7

FUNCTIONAL HETEROGENEITY OF THE RAT PREFRONTAL CORTEX (PFC). M. Rasmussen*, C.A. Barnes, and B.L. McNaughton (SPON: M. W. Dubin). Behav. Neurosci. Program, Dept. of Psych., Univ. of Colorado, Boulder, CO 80309.

The nature of spatial deficits found after prefrontal lesions in the rat has been obscured by the differences in procedures used across studies. Kolb, Sutherland & Whishaw (1983) found deficits on the Morris water task, which requires the use of allocentric spatial maps, after large aspiration lesions to the PFC. After, small electrolytic lesions to PFC, Rasmussen, Barnes and McNaughton (1986; 1987) found no impairment on an allocentric short-latency alternation task and only a mild impairment on the radial maze working memory problem. Egocentric short-latency alternation tasks revealed severe deficits with these lesions.

As part of a study used to assess acquisition of three tasks: reference memory (RM), working memory (WM) and short-latency alternation (SLA),we report now on the results of a comparison between two types of lesion to the PFC on the allocentric spatial tasks. In the RM and SLA tasks strategy was controlled (only allocentric solutions were useful). The WM task could be solved by a combination of strategies.

Neither PFC lesion group was impaired on the RM task; both were impaired on the WM task; and only the aspiration group was impaired on the SLA task. The results suggest that small lesions to the PFC do not disrupt allocentric maps. The mild deficit on the WM task can be attributed to impaired egocentric responding.

Since large aspiration lesions to PFC result in impairment on the WM and SLA tasks, but no deficit on the RM task, the data are consistent with a prefrontal disconnection hypothesis similar to that suggested by Gaffan (1983). i.e., the mapping functions of the hippocampus are no longer available to the complex motor programming areas of the basal ganglia. It is suggested that this disconnection becomes critical when task complexity increases and/or the memory function cannot be supplied by other brain areas which remain connected to basal ganglia.

328.8

SPATIALLY SELECTIVE DISCHARGE OF VISION AND MOVEMENT MODULATED POSTERIOR PARIETAL NEURONS IN THE RAT. L. L. Chen and B. L. McNaughton. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309

Functional properties of neurons of the posterior parietal cortex (Krieg, 1946, J. Comp. Neurol., 84, 221; Kolb et al., 1987, Brain Res. Rev., 23, 127) in freely moving rats were studied in a spatial working memory task on a radial arm maze, using the stereotrode recording technique (McNaughton, et al., 1983, J. Neurosci. Meth. 8, 391). Most of the 145 cells studied exhibited selectivity for a particular state of motion (e.g., left-turns, right-turns, straight running, still). Visual response characteristics were tested by manipulating the room light source. 24% (21/88) of neurons tested were visually responsive, exhibiting either phasic excitation or inhibition with changes in room illumination or preferentially discharging while the animal was at a particular orientation relative to the light source. Some visually responsive cells showed location selective activity reminiscent of hippocampal "place" cells (O'Keefe,1979, Prog. Neurobiol., 13, 419). At least part of this location specificity appeared to be generated by an interaction between sensorimotor and visual inputs. A few cells maintained a spatial firing bias when the light source was extinguished but showed a shift in bias corresponding to shifts in the position of the visible light source. We conclude that some cells in the posterior parietal cortex could be involved in spatial representation.

328.9

DISTRIBUTION OF CAT-301 IMMUNOREACTIVITY IN THE POSTERIOR PARIETAL, PREMOTOR AND PREFRONTAL CORTEX OF THE MACAQUE. P.K. McGuire*, S. Hockfield and P.S. Goldman-Rakic, Sect. of Neuroanatomy, Yale Univ. Sch. Med., 333 Cedar St., New Haven, CT 06510.

Monoclonal antibody Cat-301 recognizes a surface antigen on certain C.N.S neurons. It appears to label interconnected areas in the thalamus and cerebral cortex (Hendry et al, J.Neurosci. 8:518 1988), and in the magnocellular visual pathway (DeYoe et al, Soc. Neurosci. Abstr. 12:130, 1986). We have examined the distribution of Cat-301-immunoreactive neurons in regions of the primate posterior parietal and frontal cortex which are strongly and topographically interconnected.

In both, the distribution is characteristic for each cytoarchitectural area, but varies greatly between areas, with abrupt changes at their borders. In posterior parietal cortex (PPC), the most intense immunoreactivity (IR) is in the superior parietal lobule (PE), and the dorsal bank (PEa), fundus (IPd) and inner ventral bank (POa(i)) of the intraparietal sulcus. In frontal cortex (rostral to area 4), labeling is strongest in the supplementary motor and premotor cortex (area 6), and in the caudal prefrontal areas (8a, 8b and 45). Two patterns of neuronal distribution are evident: throughout PPC, and in the heavily-labeled frontal areas, immunopositive cells are concentrated in lower layer III and in layer V, and approximately 15-25% are pyramidal, the remainder being non-pyramidal. In contrast, in the more rostral prefrontal areas (which are lightly-stained), labeled cells are diffusely distributed across layers II-VI, and almost all are non-pyramidal.

The laminar distribution of immunopositive cells in heavily-labeled areas matches that of the association neurons known to project between parietal and frontal cortex, and each heavily-labeled frontal area is known to be connected (but not exclusively connected) with a heavily-labeled area in PPC. This suggests that the differential ditribution of Cat-301 IR in these regions may be related to their interconnectivity.

328.10

NORADRENERGIC AXONS DO NOT EXHIBIT TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN NEOCORTEX OF MONKEYS (*MACACA FASCICULARIS AND SAIMIRI SCIUREUS*). H. J. Noack* and D. A. Lewis (SPON: J. Puig-Antich). Depts. of Psychiatry and Behav. Neurosci., Univ. of Pittsburgh, Pittsburgh, PA 15213.

In previous studies (*J. Neurosci.* 7:279, 1987) we analyzed the regional and laminar distributions of fibers immunoreactive for tyrosine hydroxylase (TH) and dopamine-β-hydroxylase (DBH) in neocortex from normal and locus coeruleus-lesioned monkeys. These comparisons suggested that a rabbit polyclonal anti-TH antiserum and a rabbit polyclonal anti-DBH antiserum label distinct populations of axons in monkey neocortex, which presumably are dopaminergic (DA) and noradrenergic (NA), respectively. These findings have now been confirmed in dual-labeling studies using anti-TH and anti-DBH antisera raised in different species. In single- and dual-labeling studies, mouse monoclonal, sheep polyclonal and rabbit polyclonal anti-TH antisera produced similar patterns of immunoreactivity in several regions of monkey neocortex. In contrast, fibers in monkey visual, motor, somatosensory and prefrontal cortical regions labeled with rabbit anti-DBH were not visualized with a mouse anti-TH in double-labeling studies. These antisera did, however, show double-labeling of the NA neurons of the locus coeruleus. Thus, these findings indicate that anti-TH labels DA, but apparently not NA axons in monkey neocortex. Possible biological bases for this apparent selectivity will be discussed.

328.11

THE NORADRENERGIC INNERVATION OF MONKEY PREFRONTAL CORTEX. D.A. Lewis, J.H. Morrison and H.J. Noack*. Depts. of Psychiatry and Behav. Neurosci., Univ. of Pittsburgh, Pittsburgh, PA 15213 and Scripps Clinic, La Jolla, CA.

The distribution of dopamine-β-hydroxylase (DBH)-immunoreactive (IR) fibers was characterized in prefrontal cortical regions of cynomolgus (*Macaca fascicularis*) and squirrel (*Saimiri sciureus*) monkeys. The density of DBH-IR fibers was heterogeneous, both across and within cortical cytoarchitectonic regions. For example, in cynomolgus monkey, fiber density was greatest in area 8b; within this region, the medial surface had a greater density of labeled processes than the dorsal surface. Areas 9 and 24 also had a high density of DBH-IR fibers, areas 11, 12, 13 and 25 were of intermediate density, and areas 10 and 46 had the lowest density of labeled fibers. Despite these regional variations in density, the laminar distribution of labeled fibers was very similar across areas of cynomolgus prefrontal cortex. Fiber density was relatively low in layers I-IV, increased substantially in layer V, and was intermediate in layer VI. With few exceptions, the regional and laminar distributions of DBH-IR fibers in squirrel monkey prefrontal cortex were similar to those in cynomolgus monkey. Since other data suggest that anti-DBH selectively labels noradrenergic axons in monkey neocortex, the distinctive innervation patterns exhibited by DBH-IR fibers reveals the regions and layers that may be the principle sites of action of norepinephrine in exerting its effects on prefrontal cortical function.

328.12

MONKEY FRONTAL AND CINGULATE CORTEX EXHIBIT REGIONALLY HETEROGENEOUS DISTRIBUTION OF NONPHOSPHORYLATED NEUROFILAMENT PROTEIN IMMUNOREACTIVE NEURONS. M.J. Campbell, K. Cox*, P.G. Pay*, T.A. Kimber*, and J.H. Morrison. Research Institute of Scripps Clinic, La Jolla, CA

Studies in our laboratory have revealed that a distinct subpopulation of primate cortical pyramidal neurons that furnish long projections is immunoreactive to SMI-32 (Sternberger-Meyer), a monoclonal antibody that recognizes nonphosphorylated neurofilament proteins. These studies have also revealed that the size, density and laminar distribution of SMI-32-ir neurons differ substantially across cortical areas in the temporal and occipital lobe in the primate. A variation in the quantity of neurons that are likely to furnish long corticocortical projections accounts for the major differences in the distribution of SMI-32-ir neurons across cortical areas. The present study reports results of an immunohistochemical analysis of the regionally heterogeneous distribution of SMI-32-ir neurons in frontal and cingulate cortex. Ventral medial frontal and anterior cingulate areas exhibited a striking paucity of SMI-32-ir neurons in the supragranular layers and were distinguished from each other by differences in the density of SMI-32-ir neurons in their infragranular layers. In contrast, other frontal areas and posterior cingulate could be readily distinguished from each other by substantial differences in the density of SMI-32-ir neurons in their supragranular layers. These observations suggest that there are significant differences in the laminar organization of specific classes of efferent neurons in frontal and cingulate cortical areas.

328.13

THE ChAT AND GABA IMMUNOPOSITIVE NEURONS IN THE RAT FRONTAL CORTEX: DISTRIBUTIONS IN ADULT AND AGING RATS, AND SPECIES DIFFERENCES. Y. Nishimura, M. Natori and M. Mato (Spon. Y. Inoue) Dept. Anatomy, Jichi Med. Sch., Tochigi, Japan 329-04.

We have investigated the distribution of Choline acetyltransferase immunoreactivity in neuron cell bodies (ChAT-IR) and Gamma aminobutyric acid immunoreactivity (GABA-IR) in the rat frontal cortex. This paper in the mainly reports the three dimensional distribution of ChAT-IR and GABA-IR in adult and aging rats. However in addition, the immunoreactivities against ChAT or GABA were investigated in the frontal cortex of rodents, lagomorphs, insectivores and primates.

In total seven adult rats, four aging rats (older than 2.5 years) and more than two each of golden hamsters, brown rats, house mice, guinea pigs, chipmunks, rabbits, musk shrews and squirrel monkeys were examined.

In adult rats, ChAT-IR was found to be accumulated at the lateral part of the frontal pole. The ChAT-IR then diminished caudally. GABA-IR was not found in an area matching to the accumulated area of ChAT-IR in the frontal pole. However excluding this area, GABA-IR was distributed rather evenly. These results suggest that the distribution of ChAT-IR and GABA-IR may be interrelated.

In aging rats, loss of ChAT-IR was found in the caudal part in the frontal cortex. GABA-IR sites also had a tendency to diminish in number. In Nissl preparations neuron loss was not so obvious compared with the loss of ChAT-IR with aging. This therefore suggests that the loss of immunoreactivity is not caused by neuron loss but by a synthesis disability of enzymes or neurotransmitters in the neurons of aging rats.

Of the other animals examined, ChAT-IR appeared only in the cortices of brown rats, house mice, golden hamsters and guinea pigs. In contrast, the GABA-IR was found in all of animals surveyed here. As far as we know, ChAT-IR is not found in mammals other than studied rodents. And therefore it is possible that the ChAT-IR may have been acquired specifically in rodents during their evolution.

328.14

INSTRUMENTAL EYE BLINK CONDITIONED REFLEX IS INDEPENDENT OF ASSOCIATION CORTEX IN CATS. *S.Song*, J.Harrison, J.Buchwald, Brain Research Institute, Mental Retardation Research Center, Dept. of Physiol., UCLA, Los Angeles, CA 90024.*

Multimodal association cortex (anterior lateral, peri-cruciate and medial suprasylvian areas) is not essential to classical conditioning of eye blink with auditory discrimination in cats (Norman et al., Science 196: 551, 1977). In order to examine the relation between association cortex and instrumental eye blink conditioning with auditory discrimination in cats, we used a 4KHz CS+ (conditioned stimulus) tone with duration of 400-520ms, 30DB and 60DB clicks or 1KHz and 2KHz tone pulses as CS-, and a shock US(unconditioned stimulus) delivered by electrodes at the outer margin of the orbicularis oculi muscle. We scored the CR (conditioned response) as a blink occurring 100 ms after CS onset but prior to the US. Daily training sessions consisted of 4 blocks of 25 CS+ per block over 12 sessions. Nine out of 12 cats were conditioned (≥80% CR in one block for at least 2 successive blocks). Surgical ablation of some or all areas of association cortex was performed bilaterally on all 12 trained cats. The lesions were histologically verified. Twelve sessions were run postoperatively. All 9 preoperatively conditioned cats remained conditioned. Of the 3 unconditioned cats, 2 developed CRs at the criterion level, and 1 remained unconditioned. The present study demonstrates that multimodal association cortex is not essential for learning and maintaining this instrumental conditioning of the eye blink in cats. Supported by USPHS grants HD05958 and NS25400.

SUBDIVISIONS OF VISUOMOTOR AND VISUAL CORTEX IN THE FRONTAL LOBE OF PRIMATES: THE FRONTAL EYE FIELD AND THE TARGET OF THE MIDDLE TEMPORAL AREA. J. H. Kaas and L. A. Krubitzer. Department of Psychology, Vanderbilt University, Nashville, TN 37240.

Eye movements evoked by microstimulation, interconnections with the middle temporal visual area (MT), and myeloarchitecture distinguish at least two and possibly three subdivisions of visual cortex in the region of the frontal eye fields of prosimian galagos and New World owl monkeys, squirrel monkeys, and marmosets. In all of these primates, injections of WGA-HRP were placed in MT of visual cortex, the region of the frontal eye field (FEF) was explored with stimulating microelectrodes and marker lesions were placed at functional boundaries. The cortex was separated from the brain, artificially flattened, sectioned parallel to the surface, and reacted for HRP or stained for myelin. Two ovals of dense myelination were apparent rostral to motor cortex in these primates. The more caudomedial oval, the FEF, had a caudal division where bilateral eye movements toward the contralateral visual hemifield were evoked by low levels of stimulation (10-50μ amps), and a rostral division where higher levels of stimulation (50-100μ amps) were needed to evoke eye movements. Injections in MT resulted in little or no label in FEF. In contrast, the more rostrolateral oval of dense myelination, the frontal ventral visual area (FV), was densely interconnected with MT. Preliminary microstimulation studies in galagos have found that high levels of stimulation could evoke eye movements from FV. The presence of the FEF and FV in both simian and prosimian primates suggests that these fields originated early in primate or even mammalian evolution, and are common to all primates. CORTICAL–THALAMIC PROJECTIONS FROM A PHYSIOLOGICALLY IDENTIFIED MOTOR BLINK REGION IN PARA-SIV CORTEX STUDIED WITH PHA-L IMMUNOCYTOCHEMISTRY. K. Park* and R.S. Waters (SPON: R.B. Caldwell) Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, Sch. of Med., Memphis, TN 38163.

In this report we describe results of terminal labeling in the thalamus after injection of the lectin phaseolus vulgaris leucoagglutinin (PHA-L) into a physiologically identified motor blink region in the fundus of the anterior ectosylvian sulcus (AES). Clemo and Stein (1983) designated this cortical region as Para-SIV. Neurons in this region have been reported to respond to cutaneous, visual, and auditory stimuli. Our findings show that this region also contains motor output neurons that can be activated with low intensity stimulating currents to produce contractions of the orbicularis oculi muscles controlling the motor blink response.

Adult cats were prepared under inhalation anesthesia. The dura over the ectosylvian gyrus was removed, and the brain surface was exposed. The gas anesthesia was turned off, and Ketamine and Nembutal anesthetics were administered throughout the remaining part of the experiment. Tungsten-in-glass stimulating electrodes were inserted into the bank of the AES, and trains of cathodal pulses (12-13 pulses/train; 0.2ms duration, 300Hz, 40μA maximum intensity) were used to examine motor responses from this region. Once the motor map was completed, a 2.5% solution of PHA-L was iontophoresed into the center of the motor map using an anodal pulsed current of 5μA for 20-40 minutes. Following a survival time of 14-21 days, the animals were anesthetized and perfused with acetate buffer and borate fixatives. Brain sections were processed according to the method of Gerfen and Sawchenko (1984).

PHA-L injections were localized to the deeper layers of para-SIV around the stimulating electrode. The heaviest labeling was found in the posterior nucleus complex (POm and POi). Lighter labeling was seen in the lateral posterior nucleus (LP) and zona incerta. The present findings corroborate our earlier work showing that POm also receives a strong cortical projection from a cortical motor output region in area 5. Together, these studies suggest that the posterior nucleus complex may play an important role in motor control of the facial musculature.

DIRECT PROJECTIONS FROM THE TONGUE AREA OF PRIMARY SENSORIMOTOR CORTEX TO THE HYPOGLOSSAL NUCLEUS AND ADJACENT RETICULAR FORMATION IN THE MACAQUE BUT NOT IN THE CAT. A. Sokoloff and T. W. Deacon. Biological Anthropology, Harvard University, Cambridge, MA 02138.

Degeneration studies have demonstrated a direct projection from the tongue area of primary motor cortex to the hypoglossal nucleus (HGN) in the macaque but not in the cat. In order to investigate the extent of cortical projections in the macaque and cat that might terminate in the HGN, multiple injections (0.5μl each) of the sensitive anterograde tracer WGA-HRP were made into cortical regions that included the primary sensorimotor tongue areas.

Following injections in the macaque axonal label is observed bilaterally in the HGN. Axonal label in the medulla is also observed bilaterally with slight ipsilateral predominance in the spinal trigeminal complex (spV), the lateral reticular formation just medial to spV and the reticular region bordering the HGN ventrally and laterally. Following injections in the cat labeled axons are not observed in either the HGN or adjacent reticular regions. Labeled axons are observed contralaterally in the lateral reticular nucleus and spV.

The present investigation confirms previous degeneration studies which identified a direct cortico-hypoglossal projection in the macaque but not in the cat. In addition the present study demonstrates in the macaque a bilateral projection to the reticular region adjacent to the HGN. The axons of this projection may turn medially to terminate within the HGN or may directly synapse upon ventrally and laterally directed dendrites of HGN motoneurons.

AXON-COLLATERALS OF PYRAMIDAL CELLS IN LAMINAE III AND V OF AREA 4 OF MONKEY'S CORTEX, REVEALED BY INTRACELLULAR HRP. R. Porter, S. Ghosh and R.E.W. Fyffe Experimental Neurology, John Curtin School of Medical Research, Canberra, 2601, Australia

Lamina V neurons of monkey's motor cortex with axons in the pyramidal tract have been stained by intracellular injection of HRP (Hamada et.al., Neurosci.Lett., 22:233-238, 1981). Six lamina V and four lamina III pyramidal neurons in area 4 of M. fascicularis were completely reconstructed after intracellular HRP injections. The lamina III pyramidal neurons differed from those in lamina V: they lacked long basal dendrites. Although axon collateral arbors of lamina III pyramidal cells varied in the extent of their distribution, 3 to 12 collaterals arose from each axon. The largest lamina III intracortical collateral arbor sent branches to all laminae and extended for at least 3mm mediolaterally. This contrasted with the axon collateral arbors of lamina V pyramidal neurons, which consistently exhibited three to five collaterals. Although the longer of these could extend for more than 1mm, the branches of lamina V axon collaterals were confined to laminae V and VI, whether or not the lamina V neurons were demonstrated to be PTN.

IPSILATERAL CORTICAL INPUT TO PRECENTRAL MOTOR AREAS OF THE NEWBORN AND MATURE MACAQUE MONKEY: A STUDY USING FIVE RETROGRADELY TRANSPORTED FLUORESCENT TRACERS. C. Darian-Smith*, S. Cheema and I. Darian-Smith.(SPON: A.W. Goodwin) Dept. of Anat., Brain Res. Lab., Univ. of Melbourne, Victoria 3052, Australia.

Cortical afferent input to the precentral cortex provides information required for the preparation, initiation and execution of movements. We are presently investigating ipsilateral corticocortical projections to several regions of the precentral cortex in order to determine; (1) the origins and distribution of afferent neurons in the newborn and adult monkey, (2) the juxtaposition of these populations, and (3) the presence of bifurcating axons.

Retrogradely transported fluorescent tracers (Fast Blue, Rhodamine latex microspheres, Diamidino Yellow, Evans Blue, Fluorogold; 3 to 5 in each animal) were injected into medial and lateral aspects of the premotor cortex (area 6), medial and lateral aspects of the primary motor cortex and the supplementary motor area (SMA).

Data pertaining to mature animals is incomplete. Preliminary results come from two monkeys delivered by caesarian section (E147 and E142), and one four day old infant.

For injections made into the SMA, labeled soma were observed immediately surrounding the injection site, in medial and lateral rostrocaudal strips involving areas 4 and 6 of the precentral cortex, in primary somatosensory cortex (S1), area 5, 7a and also in the limbic cortex, areas 24 and 23.

An injection into medial premotor cortex resulted in labeled soma in medial and lateral area 6, in a rostrocaudal strip across medial motor cortex, in rostral SMA, areas 24, 23 and lateral 5. Lateral premotor cortex injections produced additional labeling in area 7b.

Injections into primary motor cortex, resulted in labeled soma distributed in a rostrocaudal strip across both pre- and postcentral cortex, involving areas 4, S1 and 5. Labeling was also found in area 7b and SMA.

Corticocortical projections originated primarily in laminae III and V in primary sensory motor cortex and in laminae II to V in premotor cortex. Soma populations were observed as overlapping or segregated according to their cortical location. Double-labeled soma have been observed in limbic cortex which send bifurcating axons to both medial premotor area 6 and SMA (injection separation 6mm).

Results to date demonstrate a topographically organized cortical input from the primary somatosensory cortex to the motor cortex. They indicate that all major corticocortical projections to the precentral cortex, as described in recent literature for the adult, are present at least 2 weeks prior to birth. They also illustrate the presence of diverging neuronal projections from the limbic cortex to SMA and to the medial premotor area.

329.6

SOMATOTOPICAL ORGANIZATION OF CINGULATE PROJECTIONS TO THE PRIMARY AND SUPPLEMENTARY MOTOR CORTICES IN THE OLD-WORLD MONKEY. R.J. Morecraft* and G.W. Van Hoesen (SPON: T. Ritchie). Depts. of Anatomy and Neurology, Univ. of Iowa, Iowa City, IA 52242.

Experimental and clinical studies have suggested the presence of a motor-related field within the depths and the lower bank of the anterior cingulate sulcus. Indeed, corticospinal projections arise from this cortex. Despite this, little is known about the connections of this motor field, and in particular, its relationship to other cortical motor representations. Thus, a study was undertaken to examine the ipsilateral somatotopical distribution of cingulate afferents to MI and MII. Rhesus and cynomolgus monkeys were injected with retrograde tracers fast blue, diamidino yellow and HRP into face, forelimb, and hindlimb representations of MI and MII. Somatotopically organized afferents to both MI and MII were identified in the cortex of the lower bank and fundus of the cingulate sulcus. Labeling was spatially separate from area 4 (MI) and area 6 (MII) on the basis of many criteria. Projections to the various somatotopic representations within MI and MII arise from common cingulate regions, with those projecting to face located rostrally, hindlimb caudally and forelimb between. Afferents to MI originated primarily from layer V while those to MII originated from both layers III and V. Labeling was heaviest in MII cases. The results support the fact that a spatially separate and somatotopically organized motor field resides within the cingulate cortex that has direct projections to both MI and MII. Its location and relation to the motor cortices on one hand, and limbic cortices on the other, suggest an interplay between basic drives such as motivation and cortical motor mechanisms. ORIGIN AND DENSITY OF CORTICOSPINAL (CST) PROJECTIONS FROM THE PREMOTOR AREAS OF MACAQUES. R.P. DUM and P.L. STRICK. VA Med. Ctr. and Depts. of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syracuse NY, 13210.

We examined the origin of CST projections from the premotor areas in the frontal lobe of macaques (macaca nemestrina) using retrograde transport techniques. All of the premotor areas in the frontal lobe project directly to both the primary motor cortex and the spinal cord. In particular, substantial CST projections originate from 3 separate regions on the medial wall of the hemisphere (the supplementary motor area in area 6 on the superior frontal gyrus; the caudal cingulate motor area in area 23c in the cingulate sulcus; and the rostral cingulate motor area in area 24c on the ventral bank of the cingulate sulcus) and from 2 regions within lateral area 6 (the arcuate premotor area in the caudal bank of the arcuate sulcus and the premotor area which surrounds the superior precentral sulcus).

To examine the density distribution of CST neurons, we divided layer V into bins 200 um on a side and determined the number of CST neurons in each bin. Regions of 'high' density were defined as containing greater than the 90th percentile of CST neurons per bin. There were large local variations in the density of CST neurons in each cortical area of the frontal lobe. Regions of high density were not confined to the primary motor cortex, but included substantial portions of each premotor area. These results emphasize the contribution of the premotor areas to the corticospinal system. Support: VA Med.Res.Serv. and Rehab. R&D; USPHS 24328, 2957.

EXCITABILITY OF CORTICOSPINAL NEURONS DURING TONIC MUSCLE CONTRACTIONS IN MAN. B. Brouwer*, P. Ashby, G. Midroni* (SPON: J. Murphy). Playfair Neuroscience Unit, Toronto Western Hospital, Toronto, Ont. M5T 2S8

A magnetic stimulus applied to the human scalp over the motor cortex causes a short latency contraction of contralateral limb muscles. This is presumed to result from the indirect excitation of corticospinal neurons with monosynaptic connections to motoneurons. The excitability of these cortical neurons can be estimated from the magnitude of the postsynaptic potentials produced in spinal motoneurons by magnetic stimulation. In man the characteristics of these postsynaptic potentials can be derived from changes in the firing probability of single motor units. When a subject increases the level of a sustained voluntary contraction the excitability of the corticospinal motoneurons estimated in this way become less. We conclude that the additional synaptic input to motoneurons required for a stronger sustained muscle contraction comes from fiber systems other than the population of fast corticospinal neurons activated by magnetic stimulation.

329.9

MOTOR FIELDS OF MOTOR AND PREMOTOR CORTEX NEURONS IN THE RHESUS MONKEY DURING INDEPENDENT FINGER MOVEMENTS. M.H. Schieber. Wash. U. Sch. Med., St. Louis, MO 63110.

How does the motor cortex produce independent finger movements? Microstimulation can evoke movements of a single digit (Asanuma & Rosen, 1972), but spike-triggered averaging has shown that single cortical neurons often influence more than one spinal motoneuron pool (Cheney & Fetz, 1985). To study further the processes that produce independent movements, motor and premotor cortex neurons are being examined in terms of their **motor fields**, defined here as the subset of active movements with which a given neuron discharges.

Monkeys are trained to perform relatively independent flexion and extension movements of each digit of the right hand. The monkeys insert their hand into a pistol-grip manipulandum equipped with 10 microswitches, one positioned just ventral and dorsal to each digit. Flexion or extension of a digit 2-5 mm closes the appropriate switch. Cued by an LED display, the monkey closes only one switch at a time for a liquid reward. Preliminary data are available from one monkey.

The motor fields of motor cortex neurons can be classified as: **single digit**, if the neuron discharges with movement of only one digit in one direction; **contiguous**, if discharge occurs with movement of adjacent digits in the same direction; or **broad**, if discharge occurs with movements of non-adjacent digits or with movements in opposite directions. Digits 1 (thumb), 2 and 5 have greater representations than digits 3 and 4 among neurons with single digit motor fields. But among contiguous field neurons, digit 3 is most often the field's best digit. No contiguous field neurons have been found with best digit 1 or 5. The premotor cortex, compared to the motor cortex, has relatively few neurons related to these finger movements, though all three motor field types have been observed. Support: K08-NS01150-03 to M.H. THE EFFECTS OF BILATERAL COOLING OF THE SUPPLEMENTARY MOTOR AREA ON MOVEMENT-RELATED NEURONAL RESPONSES IN AREA 4 OF CONSCIOUS MONKEYS. E.M. Schmidt and J.S. McIntosh, NIH, NINCDS, Lab. of Neural Control, Bethesda, MD 20892.

The supplementary motor area (SMA) is thought to play a role in the performance of movement. One hypothesis is that the SMA may influence the responsiveness of area 4 neurons to kinesthetic stimuli (Wiesendanger, et al., Control of Posture and Movement, 331-346, '73). Previously, we (Schmidt, et al., Soc. Neurosci. Abstr. 13: 1096, '87) reported that bilateral SMA cooling did not modify the kinesthetic responsiveness of area 4 neurons. Since then, in another animal, we have found that firing rates of some movement-related area 4 neurons are modified with SMA cooling.

A Rhesus monkey was trained to flex and extend the right wrist in response to movement of a visual target on a video monitor. The monkey's hand was held in a molded form coupled to a torque motor which produced a simulated spring load. For juice rewards, the monkey was required to match a cursor coupled to wrist-movement to a target for a period of at least one second. Halfway through the random duration hold period, a 50 ms torque pulse was applied to perturb the wrist in either the flexion or extension direction. After training, the following items were implanted under pentobarbital anesthesia and aseptic conditions: 1) six bipolar EMG leads in the right forearm muscles; 2) a recording chamber over the arm area of the contralateral precentral cortex; 3) a cooling chamber placed within the sagittal fissure overlying the territory of the SMA; and 4) a head restraint device.

Thus far, the firing patterns of 22 task related area 4 neurons were analyzed during movements, hold phases and perturbations, before, during and after SMA cooling. 77% of these neurons changed their firing patterns during cooling. Premovement burst activity was reduced during SMA cooling while low activity during a hold phase was increased. No obvious modifications of the kinematic parameters of movement or torque perturbation responses were observed with cooling.

Under the test conditions employed, cooling midline structures including the SMA appears to modifiy the movement-related firing patterns of some area 4 neurons, but the consequences of this modification on motor performance are unclear.

329.11

INTERACTIONS OF BILATERALLY DRIVEN CORTICAL OUTPUTS ON MOTOR ACTIVITY IN THE RAT. D. Asdourian, O. Hnatczuk* and S. I. Lentz*. Dept. of Psych., Wayne State Univ., Detroit, MI 48202.

The effects of bilateral electrical stimulation of the frontal cortex (Cx) on motor activity in albino rats show that the electrically driven outputs from the two hemispheres interact in ways specific to the relative intensities of stimulation of the two sides and, in some cases, to the sequence of Cx stimulation. Motor activity was recorded bilaterally from the trapezius pars cervicalis which is concerned with shoulder and forelimb movement. After the thresholds for driving activity in trapezius were established for each hemisphere in each animal, the following results were obtained: (1) When both Cxs were stimulated simultaneously with subthreshold current the effects of the stimuli summed and drove activity bilaterally, (2) When one Cx was stimulated with a suprathreshold current and the other simultaneously stimulated with a subthreshold current, summation was blocked - activity was driven only by the suprathreshold stimulation, (3) When both Cxs were stimulated with subthreshold current but stimulation was presented successively rather than simultaneously, activity was driven only from the Cx stimulated first. This last effect was seen in about 1/3 of our animals.

329.12

OLFACTION DIRECTS SKILLED FORELIMB REACHING IN THE RAT. I. Q. Whishaw and J. Tomie*. Dept. of Psychology, University of Lethbridge, Lethbridge, Alberta, Canada, T1K 3M4

Rats were trained to reach for food pellets that varied in size from 20 to 300 mg from one of 21 locations on a shelf located just outside a test cage, after a barrier was lifted. Control rats walked along the front of the cage sniffing to locate the food. Once they located a food pellet, they inserted their nose between the bars of the cage, sniffed the food for one to three respiratory cycles, raised their snout slightly, and then inserted a forepaw to grasp the food. Performance was unchanged on all measures after vision was occluded with eye patches. Following olfactory bulb removal, however, the rats no longer sniffed to locate the food or sniffed the food prior to initiating a reach. Rather they systematically moved along the length of the cage inserting their snout between the bars at each possible food location and without sniffing reached for the food "as if blind". Additional impairments were not produced when the bulbectomized rats were given visual occlusion. The study demonstrates that rats locate food and direct reaching using olfaction, and are discussed in terms of the sensory control of skilled limb use and their relevance to the evolution of the sensory guidance of limb use.

SAFETY STUDIES OF MAGNETIC AND ELECTRICAL TRANSCRANIAL STIMULATION IN MAN. J. H. Kim, W. L. Levy, J. Oro, D. Tucker. Departments of Neurological Surgery University of Miami School of Medicine, Miami, FL. 33136, and University of Missouri-Columbia, Columbia, Missouri 65212.

A device for non-noxious transcranial stimulation has been introduced using a magnetic coil to induce a current in the brain. We have evaluated the safety of this method in an ongoing study from which we report data on an initial 8 volunteers. A Novametrix stimulator was used and each volunteer was stimulated 4 times in each of 4 locations, right temporal, right frontal, left temporal, and left frontal (70uV pulse, single stimuli). APB and anterior tibial EMG was recorded. Prior to and after EEG, the following tests were done: serum prolactin and cortisol, Boston naming test, story recall test and other psychometric testing. Pre and post stimulation tests showed no abnormalities. Tests during stimulation showed a marginal effect for degradation of serial 3 counting ($p=0.03$) and a significant effect of inacurracies in naming days of the week ($p=0.007$) usually omiting a day just after the stimulus. This supports a lack of long term effects, but a possible short term effect which may be usable in neuropsychological testing. We are also evaluating electrical stimulation and object movement.

EXTRACELLULAR GLYCOPROTEINS AT ACH RECEPTOR CLUSTERS OF CULTURED RAT MYOTUBES. G.Dmytrenko*, G.Poiana* and R.Bloch. Depts. of Neurology and Physiology, Univ. of Md. Sch. of Med., Baltimore, MD 21201

Cultured neonatal rat myotubes develop clusters of ACh receptors (AChR) where they adhere to the substrate. These clusters are often linear, with domains rich in AChR ("AChR domains") alternating with AChR-poor membrane domains that are closer to the tissue culture substrate ("contact domains"). We have used sequential detergent extraction and immunofluorescence microscopy to localize extracellular matrix components at these AChR clusters. N-CAM is present at both AChR and contact domains. Laminin and collagen IV are enriched at AChR domains, but are also found at contact domains. Heparan sulfate proteoglycan and fibronectin are present almost exclusively at AChR domains. Antibodies to rat muscle cell adherons recognize components of contact domains. These results suggest that extracellular components at substrate-apposed AChR clusters are organized into distinctive domains that parallel the organization of the cluster bilayer and its associated cytoskeleton.

We thank D.Schubert, M.Lacorbiere, H.Kleinman, J.Hassell, J.Covault and C.Cornbrooks for antibodies used in this study. Supported by the MDA and NIH grants NS01255 and NS22652.

330.2

DISTRIBUTION OF ACH RECEPTORS, 43K PROTEIN AND Na^+ CHANNEL IN NEUROMUSCULAR JUNCTION AND CULTURED MYOTUBES.

B.E. Flucher* and M.P. Daniels; NHLBI, NIH, Bethesda, MD20892.

We have compared the distribution of acetylcholine receptors (AChR) the 43K protein and Na^+ channels in AChR aggregates on cultured rat myotubes and in the mature neuromuscular junction (NMJ). Ultrathin sections of rat diaphragm and embryonic brain extract treated (4-5 h) myotubes were immunogold-labeled with antibodies[1] against AChR, 43K protein and Na^+ channel for electron microscopy.

43K protein and AChR were both concentrated at the crests of the postsynaptic folds, opposite the nerve terminal. A much lower number of sites was found in deeper regions of the folds. In contrast, Na^+ channels were found at a low site density in all parts of the postsynaptic membrane, as previously suggested by immunoperoxidase staining (Heimovich et al., *J. Neurosci.* 7:2957, 1987). In rat myotubes AChR and 43K protein were colocalized in aggregates on membrane regions with a submembrane density. These aggregates were often composed of many discrete AChR rich domains. No accumulation of Na^+ channels was detected in the newly formed AChR aggregates by immunogold labeling, possibly due to lack of sensitivity of the labeling technique. Apart from the cell surface, AChRs and 43K protein were localized in concentrations similar to those in the aggregates, on a tubular cytoplasmic membrane structure within the myotubes, distinct from previously described plasma membrane invaginations. This finding suggests that the association of AChR and 43K protein is not confined to AChR aggregates on myotubes or to the postsynaptic membrane.

330.3

OPTICAL RECORDING OF SYNAPTIC INTERACTIONS BETWEEN IDENTIFIED APLYSIA NEURONS IN VITRO. T.D. Parsons, D. Kleinfeld, G.F. Raccuia*, A.L. Obaid, and B.M. Salzberg. Dept. of Physiol., U. of Penn., Phila., PA 19104 and Bell Labs., Murray Hill, NJ 07974.

The potentiometric dye RH-155 and a 12 X 12 photodiode array have provided clean optical recordings of action potentials from the somata, initial segments, and fine processes of identified Aplysia neurons in cell culture. A pair of spikes recorded from the initial segment of a LUQ cell in a single sweep is shown in A. Synaptic interactions between cultured neurons have been detected optically. The change in absorbance by the soma and neurites of a LUQ cell, co-cultured with the inhibitory presynaptic cell, L10, is seen in B. The bar indicates a 500 ms train of action potentials in the presynaptic cell. (Spike height attenuation: 44 %.) Reduction in firing frequency in the postsynaptic cell is apparent.

330.4

EARLY INNERVATION AND TRANSMITTER SENSITIVITY OF SYMPATHETIC NEURONS *IN VITRO*: EVALUATION OF SYNAPTIC TRANSMISSION BY ELECTROPHYSIOLOGY AND CYTOCHROME OXIDASE HISTOCHEMISTRY. R. Gardette*, G.M. Mawe, L. D'Agastaro* & L.W. Role, Dept of Anat. & Cell Biol., Ctr for Neurobiol. and Behav., Columbia Univ, P & S, 630 W 168th, NY, NY 10032

We are interested in the process of synapse formation and the regulation of transmitter sensitivity at synapses formed between neurons. To study the onset of synaptic transmission we have innervated sympathetic neurons *in vitro* with explants of preganglionic neurons (Role, PNAS, 1988) and monitored spontaneous synaptic currents and ACh-induced currents with standard whole cell voltage clamp recording.

Cholinergic synaptic potentials were detected within 24 hours. By 1 day of co-culture 42% of the cells were innervated based on recording of spontaneous synaptic currents occuring at a frequency of 0.25 ± 0.02 (n=20) Hz. Over the next 2-4 days the mean frequency of synaptic currents increased by 55-60%. The ACh sensitivity of innervated neurons was found to be 2.6 fold greater than that of non innervated cells within 24 hours of culture (289 ± 47 vs 764 ± 113 pA, n= 19). Thus, the onset of innervation and the increase in ACh sensitivity of sympathetic neurons both occur rapidly after co-culture with pre-ganglionic explants.

Activity of the cells was also monitored by measurement of the density of cytochrome oxidase (CO) reaction product (Mawe & Gershon J. Comp Neurol,1986). The early onset of synaptic transmission was reflected in increased reaction product within individual neurons. By 1 day of co-culture the reaction product density of innervated cells was increased by 2 fold compared with uninnervated cells. Increases in synaptic current frequency seen at 4 days correlated with an additional 2 fold increase in CO reaction product. The increase in density of reaction product was reversed by blockade of synaptic transmission with hexamethonium or d-tubocurare. Therefore, the density of CO staining may be a direct indicator of the degree of early innervation of individual neurons. *Supported by NS22061, Klingenstein and Sloan Foundations (L.W.R), NATO, FRM, & Philippe Foundation (RG) and NS07062 (GMM)*

THE PRESENCE OF A SYNAPTIC BASAL LAMINA ANTIGEN IN CULTURES OF NON-NEURONAL CELLS. A.Y.Chiu, S.Perez* and K.Rodriguez* City of Hope, Duarte, CA 91010

The synaptic portion of the basal lamina (BL) ensheathing muscle fibers can regulate pre- and postsynaptic differentiation during regeneration. Immunohistochemistry revealed the segregation of unique BL epitopes into synaptic and extrasynaptic domains. Interestingly, monoclonal antibodies (MAbs) C1 and C4 which selectively stained BL at the synaptic cleft also stained kidney glomerular BL. Using glomeruli as a source of antigens recognized by C1 and C4, we have partially purified a 185kd band which binds by C4 on immunoblots. Mice immunized with this purified material produced a new panel of MAbs which stain both glomerular and synaptic BL and bind epitopes different from those recognized by C1 or C4. Since synaptic BL is sandwiched between pre- and post-synaptic cells, the source of these extracellular molecules is unknown. We have begun to address this question using cultures of the rat muscle cell line, L6, as well as primary cultures of newborn rat astrocytes (gift of J. deVellis). Extracts of both cultures show a C4 immunoreactive band of 185kd. Astrocyte cultures also release the 185kd material into the medium. These preliminary results raise the possibility that a synaptic BL antigen may be produced by non-neuronal cells and then sequestered at synaptic sites where it may provide important cues during synaptogenesis. Supported by NSF grant #BNS8617043 and March of Dimes grant #5-608.

330.6

REGULATION OF SYNTHESIS OF THE 43kD POSTSYNAPTIC PROTEIN IN CHICK MYOTUBE CULTURES. D. L. Falls, D. A. Harris, R.M. Dill-Devor*, C. Carr*, J.B. Cohen*, and G.D. Fischbach. Dept of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, Missouri 63110.

A *Torpedo* 43kD peripheral membrane protein is localized in a distribution coextensive with the nicotinic acetylcholine receptor (AChR) and is thought to play a role in the clustering of AChRs. An antiserum developed against SDS-denatured *Torpedo* 43kD protein labels epitopes co-localizing with the AChR at the chick neuromuscular junction. We have found that this antiserum specifically immunoprecipitates a 43kD protein from chick myotubes labeled with ^{35}S-methionine. In the experiments described here, 43kD protein synthesis was measured by labeling cultures for 4 hours and determining the amount of labeled 43kD protein precipitated per culture dish. The cultures utilized are mixed myotube/fibroblast cultures; control experiments have shown no detectable 43kD protein in pure fibroblast cultures.

The amount of 43kD protein per culture dish increased from day 1 through day 4 post-plating and then decreased between day 4 and day 7. The AChR insertion rate measured with ^{125}I-α-bungarotoxin showed a similar time course. Tetrodotoxin added at 1 μM to 6 day cultures for 24 hours consistently produced a 2 to 3 fold increase in the level of 43kD protein synthesis as well as an increase in the AChR insertion rate. However, a partially purified preparation of chicken 42kD ARIA (AChR-inducing activity), a factor that also increases the rate of AChR insertion, produced little or no increase in the amount of the 43kD protein in 4 of 5 experiments performed under similar conditions; in a fifth experiment, the level was elevated several fold. Therefore, under the conditions tested, muscle inactivity consistently increased 43kD protein, but a receptor inducing factor that may function at developing synapses did not. Current experiments are directed at determining if under other conditions ARIA does regulate the level of the 43kD protein and investigating the effects of other agents on 43kD protein synthesis.

THE RELATIONSHIP BETWEEN SYNAPTOGENESIS AND MOTONEURON SURVIVAL IN CHICK LIMB MUSCLE. L.M. Dahm & L.T. Landmesser. Dept. Physiol. & Neurobiol., Univ. Connecticut, 75 N. Eagleville Rd., Storrs, CT 06268.

Activity blockade has been shown to rescue motoneurons and to increase the number of nerve side branches in the chick iliofibularis muscle. To assess the importance of synaptogenesis itself in motoneuron survival, we examined the temporospatial distribution of pre- and postsynaptic profiles in this muscle using MAb SV2 to stain synaptic vesicles and MAb35 to stain ACh-R clusters. Although this muscle contracts in response to nerve stimulation by St 28-29, co-localization of SV2 and MAb35 staining was not observed until St 32-34. The initial SV2 staining was distributed diffusely thoughout the unbranched nerve trunks. ACh-R clusters appeared within several hours after nerve ingrowth. Although clusters were located within diffusional distance of the nerve trunks, they were not co-localized to sites of SV2 staining, suggesting an early diffuse form of synaptic transmission. Co-localization was first observed following nerve side branch formation near the onset of cell death when SV2 became localized to side branches and ACh-R clusters near nerve trunks disappeared and accumulated around side branches. The incidence of co-localization, which was restricted to side branches, increased throughout the cell death period. A similar but earlier co-localization in curarized embryos suggests that this process is not activity dependent and may be required for motoneuron survival. Supported by NIH grant 5R01 NS19640.

ELECTRICAL COUPLING BETWEEN NERVE AND MUSCLE CELLS OF XENOPUS IN CULTURE.
S.H. Young, I. Chow, and A.D. Grinnell. Jerry Lewis Res. Ctr., UCLA School of Medicine, Los Angeles, CA 90024.

The reports by Fischbach (Dev.Biol. 28: 1972) and Bonner (Dev.Brain.Res.38:1988) of electrical coupling between nerve-muscle contacts of cultured chick cells and that of Allen (J.Physiol. 372: 1986) of dye coupling between nerve-muscle contacts of cultured Xenopus cells prompted us to test Xenopus cultures for electrical coupling. The whole cell patch clamp was used in conjunction with standard microelectrode techniques producing resolution high enough to record current through single gap junction channels.

We used spontaneously occurring nerve-muscle contacts, or those which we created by manipulation of the muscle cell onto the nerve cell. Electrical coupling, measured by the flow of current from the nerve to the muscle was observed in a small fraction of nerve-muscle contacts. It remains a possibility that opened gap junctions, while not ubiquitous, may participate in inductive interactions associated with synaptogenesis. Supported by grants from the MDA, NSF, and NIH.

330.9

CELL SURFACE CONTACT INTERACTION DURING INITIAL STAGES OF SYNAPTOGENESIS. I.Chow, C.Haubach* and A.D.Grinnell. Jerry Lewis Neuromuscular Research Ctr. and Dept. of Physiology, UCLA School of Medicine, Los Angeles, CA 90024.

Direct cell-cell contact is important in synaptogenesis. There is evidence that this is enhanced by interaction between specific surface molecules, eg. neural cell adhesion molecule (NCAM), developmental regulation of which influences the timing or probability of synaptogenesis.This study was directed to assay the effect of inhibition of NCAM homophilic binding on the initial establishment of neuromuscular transmission.

When anti-NCAM (kindly supplied by Dr. U. Rutishauser) was added to Xenopus nerve-muscle co-cultures for 1-3 days, MEPPs were detected in only 32% of the nerve-muscle cell pairs, whereas 60-70% of the pairs were MEPP-positive in non-immune serum treated and control cultures. When the cells were cultured in normal medium, muscle contact-induced release of ACh from isolated cholinergic neurons (normally 70%) was inhibited by brief treatment (1 h) of anti-NCAM. Only 40% of the identified cholinergic neurons released ACh upon muscle contact. These preliminary results suggest that NCAM binding may be important in the intercellular recognition and initiation of contact-induced neurotransmitter release in this system.

IN SITU HYBRIDIZATION OF TUBULIN α-1 mRNA AS A MARKER OF NEURONS PARTICIPATING IN REACTIVE SYNAPTOGENESIS. J.W. Geddes,[1,2] C.W. Cotman,[2] and F.D. Miller[3]. Depts. of [1]Surgery and [2]Psychobiology, Univ. of Calif., Irvine, CA 92717, and [3]Dept. Anatomy and Cell Biology, Univ. of Alberta, Edmonton, Alberta, Canada.

Reactive synaptogenesis requires the extension of neuritic elements from neuronal populations which contribute to the sprouting response. It has previously been demonstrated that the mRNA for one isotype of α-tubulin, tubulin-α1 (Tα1), is expressed at high levels during the developmental extension of neuronal processes. The level of expression decreases in the adult brain, but can be reinduced during regeneration of facial motor neurons following a nerve crush paradigm. In contrast, the level of expression of a second α-tubulin isotype, Tα26, is unchanged during development and regeneration (Miller, F.D. et al., *J.C.B.* 105: 3065-3073, 1987). To determine if neurons undergoing reactive synaptogenesis increase their expression of Tα1 mRNA, we examined the intensity of the *in situ* hybridization signal to Tα1 mRNA at various times following lesions of the entorhinal cortex, utilizing ^{35}S-radiolabelled anti-sense RNA probes transcribed from cDNAs cloned in pGEM4 vectors. In rats which had received a unilateral entorhinal lesion, an increased hybridization intensity was apparent in ipsilateral entorhinal neurons adjacent to the lesion. The increase in hybridization intensity was apparent as early as one day postlesion, greatest at 5-7 days postlesion, and was still apparent although much reduced at 14 days postlesion. These results demonstrate that similar molecular events may underlie neurite extension in development, regeneration, and synaptogenesis. The results further suggest that *in situ* hybridization of Tα1 mRNA may be a useful marker of synaptogenesis in human disorders including Alzheimer's disease, Down's syndrome and epilepsy. CHANGES IN DISTRIBUTION OF PEANUT AGGLUTININ-BINDING MOLECULES IN DEVELOPING FROG NEUROMUSCULAR JUNCTIONS. C.-P. Ko, D.B. Folsom*, and M.M. Junge*. Dept. of Biol. Sci., Univ. Southern California, Los Angeles, CA 90089.

Peanut agglutinin (PNA) specifically recognizes glycoconjugate(s) in the extracellular matrix at frog neuromuscular junctions (NMJs). To examine the role of these PNA-binding molecules (PNA-BMs) in synaptogenesis, rhodamine- or HRP-conjugated PNA was applied to muscles in tadpoles and bullfrogs (R. catesbeiana). In early stages of development, PNA-BMs are distributed over the myofiber surface. Light microscopy shows about 50% of junctions identified with alpha-bungarotoxin staining have no PNA staining distinct from the background. As development progresses, PNA background staining is reduced. Around metamorphosis, >80% of junctions show colocalization of alpha- bungarotoxin and PNA stains. PNA also stains nerve trunks in tadpole muscles, unlike in adult muscles. Electron microscopy reveals HRP reaction products at the synaptic cleft between developing nerve terminals and muscle fibers before Schwann cells are present. After Schwann cells appear, reaction products still are confined to the cleft, but later appear also in the extracellular matrix around Schwann cells, as in adult junctions.

Thus, in synaptogenesis, PNA-BMs initially are seen over the nerve and muscle surfaces but later are confined to NMJs, first in the cleft, then also around Schwann cells. The appearance of PNA-BM in the initial nerve-muscle contact is not dependent on Schwann cells.

SYNAPTIC DEVELOPMENT INHIBITED BY NMDA ANTAGONISM W.J. Brooks*, T.L. Petit, R. Lo *, and J.C. LeBoutillier*. Dept. of Psychology, Prgm. in Neuroscience, Univ. of Toronto, Ont., Canada M1C 1A4

Synaptic plasticity induced by neuronal activation is thought to provide a physiological basis for learning and memory. Experimental models of activity dependent enhancement in neurotransmission have reliably found alterations in a number of synaptic parameters. Recently, activation of the NMDA receptor has been shown to be a critical step in the production of a plastic response by the synapse.

Over the course of development, the rapid increase in synaptic number is thought to correspond to the expansion of behavioral repertoire in response to the postnatal environment. Therefore, developmental synaptogenesis is also a model of learning and memory. The possible involvement of the NMDA receptor in developmental synaptogenesis was investigated using the selective NMDA antagonist DL-2-amino-5-phosphonovaleric acid (APV). Fifteen day old rat pups were intracranially administered APV via osmotic pumps. The pups were sacrificed two weeks after implantation (P30), cortical sections dissected out and processed for electron microscopy. Photographic analysis revealed a decrease in the number of synapses within the molecular layer of cerebral cortex in rats administered APV. This finding suggests that developmental synaptogenesis results from a mechanism similar to that producing synaptic plasticity in the adult.

330.13

REGULATION OF NEUROMUSCULAR JUNCTION DEVELOPMENT BY MUSCLE ACTIVITY. E. Bornslaeger*, G. Marazzi*, and L.L. Rubin. (SPON: J. Adler). Rockefeller Univ., NY, NY 10021.

Three important changes that occur during neuromuscular junction development are an increase in acetylcholinesterase (AChE) levels, a decrease in the level of extrajunctional acetylcholine receptor (AChR), and an increase in AChR half-life ($t_{\frac{1}{2}}$). Previously, we found that muscle activity regulates AChE and AChR levels, apparently by increasing intracellular Ca^{2+} (Rubin, L.L., PNAS 82: 7121, 1985). Tetrodotoxin (TTX) inhibits contraction of cultured rat myotubes and prevents an increase in AChR levels; these effects are overcome by simultaneous treatment with Ca-ionophores. Veratridine, which opens sodium channels but blocks contraction, promotes an increase in AChE, probably by stimulating a plasma membrane Na/Ca exchanger. Here, we report that muscle activity also appears to regulate AChR degradation rate. Treatment with TTX decreases AChR $t_{\frac{1}{2}}$ relative to untreated cultures. Effects of TTX were overcome by the Ca-ionophores A23187 or ionomycin, which cause release of intracellular Ca and an influx of Ca through plasma membrane channels. Veratridine also increased $t_{\frac{1}{2}}$ and decreased AChR levels. Curiously, ryanodine, which releases Ca from the SR, altered AChR and AChE levels, but did not affect AChR $t_{\frac{1}{2}}$. This suggests that AChR and AChE synthesis can be modulated by Ca influx through plasma membrane channels as well as Ca release from the SR. AChR $t_{\frac{1}{2}}$, however, appears to be regulated only by the former mechanism.

330.14

INVOLVEMENT OF A 37 kD PROTEIN IN AChR CLUSTERING. G. Marazzi*, F. Bard*, L.L. Rubin. Rockefeller Univ. NY, NY 10021.

Our laboratory has shown that chick muscle cells transformed with Rous sarcoma virus are unable to cluster acetylcholine receptors (AChRs) even after treatment with a clustering factor (CF) derived from Torpedo electric tissue (Anthony et al., PNAS 1984, 81, 2265-2269). Transformed cells are missing a 37 kD protein that is recognized by an antibody against nonmuscle tropomyosins (Anthony et al., J. Cell Biol., in press). This protein is concentrated at rat neuromuscular junctions. To determine if this protein is involved in the formation and/or maintenance of AChR clusters, we microinjected a monoclonal antibody (D3-16) against it into cultured muscle cells. After injection, cells were treated with CF, incubated with rhodamine α-bungarotoxin to localize AChRs, then fixed and labeled with FITC-conjugated second antibody to identify injected cells. D3-16 injected cells had a decreased ability to form AChR clusters; the antibody did not disassemble the preexisting clusters. Cells injected with nonimmune mouse immunoglobulin (IgG) were still able to form new clusters. To further test the role of the 37 kD protein, we disrupted clusters with sodium azide before injection. After azide washout, noninjected and nonimmune IgG-injected cells could form new clusters, but D3-16 injected cells could not. These data suggest that the 37 kD protein may play an important role in the formation of AChR clusters, probably as part of a sub-cluster cytoskeletal network.

EFFECTS OF BASIC FGF AND NGF ON SEPTAL NEURONS AFTER FIMBRIA FORNIX TRANSECTION AND IN CULTURE. D. Otto*, M. Frotscher*, C. Grothe* and K. Unsicker. Depts of Anatomy and Cell Biology, Univ. of Marburg, and Anatomy, Univ. of Frankfurt, F.R.G.

Basic FGF and NGF are present in the brain and trophic functions for the maintenance and transmitter metabolism of several CNS neuron populations have been assigned to them. We report here that both NGF and bFGF are capable of reducing neuronal death in the medial septum after unilateral fimbria fornix transection (FFT) and enhance survival and choline transferase activity in cultured embryonic septal cells. Adult rats received gel foam implants containing factors or vehicle, respectively, to the FFT site. Cell counts performed on cresyl violet-stained sections after four weeks revealed dramatic neuron losses (87%) on the lesioned as compared to the unlesioned sides, which were significantly reduced by NGF-(0.3 µg: 71%; 19 µg:54%) or bFGF- (8.6 µg:68%) treatments. Both factors sustained substantial proportions of Chat-immunoreactive neurons. NGF and bFGF also significantly increased Chat activity in septal neurons cultured from E16 rat embryos. Promotion of survival was only seen in low density cultures, but comprised both cholinergic and GABA-ergic neuronal subpopulations. These data suggest a trophic role of bFGF for septal neurons in vivo and in vitro.

331.2

LOCALIZATION OF NGF RECEPTOR mRNA IN THE RAT FOREBRAIN USING IN SITU HYBRIDIZATION. R.B. Gibbs[1], J.T. McCabe[1], C.R. Buck*[2], M.V. Chao*[2], and D.W. Pfaff[1]. [1]Lab of Neurobiology and Behavior, Rockefeller University, New York, N.Y. 10021, [2]Department of Cell Biology and Anatomy, Cornell University, New York, N.Y., 10021.

The expression of nerve growth factor receptor (NGFr) mRNA was examined in the adult rat CNS through the use of in situ hybridization. Sense and antisense ^{32}P-labeled riboprobes were transcribed from a 320 bp EcoR1-BamH1 fragment of the rat NGF receptor gene inserted into a pT3/T7 transcription vector.

Adult, Sprague Dawley rats (350-450 g) were used. The brains and superior cervical ganglia (SCG) were removed, blocked, and frozen in liquid nitrogen. Eight micron frozen sections were cut and mounted onto diethylpyrocarbonate-treated, gelatin-coated slides. The sections were fixed with 4% paraformaldehyde/PBS, rinsed, dehydrated and stored in a desiccator at room temperature overnight. Sections were hybridized with 10-50 ng sense or antisense probe (5 x 10^8 cpm/µg) for 40 h at 23-50°C. Sections were then treated with RNase-A (2.5-10 µg/ml), rinsed with SSC, dehydrated, dipped in Kodak NTB3 emulsion and stored at 4°C. After 10-30 days exposure, autoradiograms were developed and counterstained with cresyl violet.

The most intense cellular labeling was observed over neurons in the SCG and in areas of the septum, diagonal band, preoptic and ventromedial nuclei of the hypothalamus, the bed nucleus of the stria terminalis, the oculomotor nucleus, and the midbrain central gray. A few scattered cells were also observed in the striatum, cerebral cortex, red nucleus, and in the retrorubral field. Cellular labeling was not observed in sections hybridized with sense probe (probe complimentary to the NGFr gene). We are currently examining other areas of the CNS while continuing to optimize hybridization conditions necessary to detect mRNAs produced in very low quantities in the brain.

Supported by NIH postdoctoral grant #NS08195.

331.3

EFFECT OF NERVE GROWTH FACTOR IN THE ELECTRICAL MEMBRANE PROPERTIES OF HUMAN FETAL DORSAL ROOT GANGLIA NEURONS IN CULTURE. P. Caviedes* and S.I. Rapoport (SPON: A. Noronha). NIH, NIA. Lab. of Neurosciences. Bethesda, MD 20892.

Nerve growth factor (NGF) is a peptide that reportedly enhances survival of embryonic mice dorsal root ganglia (DRG) neurons and affects the duration of the action potential. In PC12 cells, it has been shown to induce the production of Sodium channels.

In the present study, fetal human DRG neurons obtained from abortuses of 16 to 19 weeks of gestation, were cultured in absence and presence of 40 nM NGF. After 1 week in culture, action potentials were recorded using the whole cell patch-clamp technique, in current clamp mode. Current steps of 0.1 nAmps with durations of 2 and 100 milliseconds were employed. At similar resting potential levels, cells grown in presence of NGF showed faster maximal rates of depolarization (+55.2%), of repolarization (+54.6%) and shorter duration (-20.6%) of the action potential compared to controls. The results indicate that NGF regulates the electrical activity of human fetal DRG neurons in culture.

331.4

FURTHER ANALYSIS OF NGF EFFECTS IN RATS WITH PARTIAL FIMBRIAL TRANSECTIONS. C.N. Montero*, D.C. Mash, E.O. Junard* and F. Hefti (SPON: W.L. Strauss). Dept. of Neurology, University of Miami, Miami, FL 33101.

We have previously shown that intraventricular NGF administration to adult rats with partial fimbrial transections prevents the lesion-induced disappearance of septal cholinergic neurons. NGF treatment was now found to be equally effective in 18 months old female rats. Unilateral fimbrial transections reduced the number of ChAT and NGF receptor positive neurons in the septal area by 65% in old animals. In NGF treated old rats the decrease in cell number was only 11%. We also addressed the question whether the disappearance of cholinergic cell bodies represents morphological degeneration or simply down-regulation of cholinergic marker enzymes and NGF receptors. Septo-hippocampal neurons were retrogradly labeled with fluorogold before lesioning the fimbria. Preliminary findings indicate that the lesion reduces the number of fluorogold labeled, AChE-positive neurons in the septum, suggesting cellular death after lesioning. Long-term but not short-term NGF treatment permanently rescued the cholinergic cell bodies from lesion-induced degeneration and stimulated regrowth of cholinergic fibers into the denervated hippocampus, suggesting that, after long-term treatment, the lesioned neurons had again gained access to their source of endogenous NGF.

331.5

NERVE GROWTH FACTOR REGULATES THE ELECTROPHYSIOLOGICAL PROPERTIES OF MATURE FROG SYMPATHETIC NEURONES. P. Traynor*, W.F. Dryden & P.A. Smith, (SPON: S. Malhotra). Dept. Pharmacol., Univ. Alberta, Edmonton, Canada

Axotomy of B-cells in bullfrog sympathetic ganglia (BFSG) results in an increase in action potential (AP) duration (spike width) and a reduction in the amplitude and duration of the afterhyperpolarization (AHP) which follows the AP (Kelly et al., Neurosci. letts. 67:163, 1986). These axotomy-induced changes may be due to the loss of the retrograde transport of nerve growth factor. (NGF; Levi-Montalcini, Prog. Brain. Res. 45:235, 1976). 2.5s NGF (50 ng/ml) enhances spike width and restores AHP amplitude and duration towards control levels in explant cultures of (axotomized) BFSG neurones (Traynor et al., Soc. Neurosci Abs, 13:1441, 1987). This finding supports the hypothesis that part of the electrophysiological response to axotomy results from a loss of a retrograde supply of NGF. Schwann cells produce NGF, thus axotomized neurones may have access to some NGF (Abrahamson, Dev. Brain Res., 27, 117, 1986). When anti-NGF (affinity isolated sheep IgG, 0.5 μg/ml) was included in the culture medium of BFSG explants, in order to neutralize endogenous NGF, there was an enhancement of the electrophysiological effects of axotomy. These results suggest that the electrophysiological properties of mature, BFSG neurones is under control of NGF.

331.6

A BETTER CONTROL OF INTRAVENTRICULAR NGF INFUSION IMPROVES THE PROTECTION OF AXOTOMIZED CHOLINERGIC MEDIAL SEPTUM NEURONS. H.L. Vahlsing*, T. Hagg, S. Varon, M. Manthorpe (SPON : D.R. Brady). Dept. Biology, Univ. of California, San Diego, La Jolla, CA 92093.

Intraventricular Nerve Growth Factor (NGF) infusion prevents the disappearance of axotomized adult rat medial septum cholinergic (MSC) neurons. We had previously developed a small 33 gauge (ga) cannula device for continuous infusion of NGF or other substances into the lateral ventricle at the level of the rostral medial septum (Williams, L.R. et al., Exp.Neurol. 95:743, 1987). The device consists of a metal cannula embedded in a dental acrylic stabilization platform and connected by vinyl tubing to an Alzet 2002 minisosmotic pump. When NGF was infused during the 2 weeks following fimbria-fornix transection, protection varied between 60 and 100% in different animals. After the 2 week pumping period, the flow-rate was also found to vary and often be very low compared to the pre-implantation rate, -- raising the concern that the small inner diameter of the cannula allowed it to become progressively clogged. To secure a constant infusion, the small 33 ga cannula was replaced by a larger 30 ga one, whose outer diameter was reduced to about 32 ga by acid treatment. With this new cannula the protection by NGF of the axotomized MSC neurons was improved to a consistent 95-105%. However, the prolonged infusion at higher flow rates induced a lesion in the tissue around the cannula tip. Partial paraffin coating of the pump surface resulted in a reproducible reduction of the flow rate and an elimination of the infusion-related lesion. Using the same dosage of NGF infused through the 32 ga cannula at the reduced flow rate still resulted in the same degree of MSC neuronal protection. Supported by NIH grant NS 16349 and APA grant TC 88-01

ALPHA$_1$-ADRENERGIC RECEPTORS AND PROTEIN KINASE C STIMULATE NGF RELEASE FROM THE SUBMAXILLARY GLAND. C.L. Hix and J.N. Davis. Depts. of Pharmacology and Medicine (Neurology), V.A. and Duke Univ. Med. Centers, Durham, NC 27705.

Although much research has been done to determine the tissue distribution and biological action of NGF, very little is known about what regulates NGF release. We are testing the hypothesis that receptors which activate protein kinase C (PKC) stimulate NGF release from target tissues. We began by examining the effect of stimulating adrenergic receptors on NGF release from the male mouse submaxillary gland. NGF was measured using a one-site ELISA. Dispersed submaxillary cells show a slow release of NGF over time and increased release when stimulated with epinephrine ($p<0.003$ compared to buffer). The release stimulated by 10 μM epinephrine is completely blocked by 0.15 μM prazosin. In contrast, 1 μM yohimbine or 0.2 μM propranolol only partially blocked the release. Thus, stimulation of alpha$_1$-adrenergic (α_1) receptors causes NGF release from the male mouse submaxillary gland. The effect of stimulating PKC on NGF release was tested using phorbol 12-myristate 13-acetate (PMA). Cells incubated with 100 μM PMA for 60 min. released significantly more NGF than cells incubated with buffer. This data is consistent with the hypothesis that NGF release in this tissue is induced by stimulating α_1 receptors which activate PKC.

This work was supported by the V.A. and N.I.H. (NS06233).

331.8

NGF ACTIVATION OF PROTEIN KINASE ACTIVITY AND C-FOS TRANSCRIPTION IS INHIBITED BY K252a. Gary E. Landreth, Deanna S. Smith*, Carolyn S. King*, Eric Pearson* and Cynthia Gittinger*. Department of Neurology, Medical University of South Carolina, Charleston, SC 29425.

NGF rapidly stimulated the activity of two protein kinases, a MAP2/pp250 kinase and a kinase which phosphorylated the peptide substrate Kemptide. Preincubation of PC12 cells with K252a, a protein kinase inhibitor, specifically blocked the ability of NGF to activate both kinases while having little or no effect on the EGF-stimulability of these activities. In vivo half-maximal inhibition was observed at 20 nM K252a, however, 2-4 fold higher levels of K252a were required to half-maximally inhibit the kinases when the drug was added to the assay in vitro. The data suggest that action of the drug in vivo was not due to a direct action on these kinases. The action of K252 was similar to that observed with methyltransferase inhibitors e.g. 5'methylthioadenosine (MTA). MTA was an effective inhibitor of protein kinases in vitro (K_i 100 μM). K252a treatment of PC12 cells blocked the NGF, but not EGF or TPA-stimulated transcription of c-fos. The data demonstrate that K252a inhibits a variety of rapid effects of NGF on PC12 cells.

ANALYSIS OF DELETION MUTATIONS IN THE NERVE GROWTH FACTOR RECEPTOR. A.A. Welcher, M.J. Radeke*, C.M. Biler*, and E.M. Shooter. Dept. Neurobiology, Stanford U. Sch. Med., Stanford, CA 94305

Nerve growth factor (NGF) is a polypeptide that exerts its action by interacting with specific receptors on the surface of its target cells. Two populations of receptors exist on the surface of sensory and sympathetic neurons, as well as PC12 cells. The two receptor types exhibit different dissociation kinetics and steady state binding of NGF. The major population of receptors releases NGF rapidly ("fast" receptor) while the second population releases NGF more slowly ("slow" receptor). A cDNA clone for the rat "fast" NGF receptor was recently isolated. The protein encoded by the cDNA clone contains a signal peptide, four cysteine-rich elements, two putative N-glycosylation sites, and a hydrophobic rich region which is probably a membrane spanning region. In order to identify the amino acids needed by the receptor for NGF binding, we made mutations in the cDNA clone, transfected the mutants into mouse L cells, and determined the effect on NGF binding by the mutated receptors. The first mutant is a deletion mutant containing the first 706 nucleotides of the receptor clone, but lacking the portion encoding the hydrophobic rich region as well as the carboxyl end of the protein and the 3' untranslated region. This truncated receptor sequence was subcloned into an eukaryotic expression vector and transfected into mouse L cells. A truncated form of the receptor was secreted from the cells, and was recognized by an NGF receptor specific antibody, MC192, but was unable to bind to an NGF-sepharose column under conditons where the full length receptor would bind. These results suggest that the hydrophobic rich region is a membrane spanning region and is needed to anchor the receptor in the membrane. The membrane spanning region and the 3' end of the receptor might be directly involved in NGF binding or may influence the structure of the NGF binding domain. In order to further delineate receptor sequences neccessary for NGF binding, we have constructed a set of nested deletions that span several hundred nucleotides at the 5' end of the cDNA clone, commencing after the signal peptide, by exonuclease III digestion . The deleted receptor clones were subcloned into an expression vector for tranfection into mouse L cells. Characterization of these transfected cells in terms of NGF binding will be discussed.

331.10

PRODUCTION OF A POLYCLONAL ANTISERUM RECOGNIZING THE NGF RECEPTOR. D.L. Shelton and E.M. Shooter. Dept. Neurobiology, Stanford U. Sch. Med., Stanford, CA. 94305.

All known effects of nerve growth factor are mediated by interaction with a cell surface receptor (NGFR). Although there are monoclonal antibodies that recognize the extracellular domain of the rat (MC192) or primate (a series of monoclonal antibodies) NGFR, additional antibodies would be useful. First, the currently available antibodies recognize NGFR only from the rat or primate, limiting the use of other systems. Secondly, new antibodies to discreet epitopes would provide a stronger correlation between the presence of NGFR-like immunoreactivity and the presence of the NGFR. Finally, the monoclonal antibodies react poorly, if at all, with denatured NGFR, precluding the use of immunoblots.

In order to generate such antibodies, sequence information from the recently cloned cDNA's encoding the human and rat NGFR was used to define a peptide from a conserved intracellular domain of the NGFR. This peptide was synthesized and used to produce a serum in rabbits . The antibodies were affinity purified against the peptide and subjected to the following tests to determine if they recognized the NGFR. PC12 cells were iodinated, solubilized in NP-40, immunoprecipitated with MC192 or the anti-peptide serum and run on SDS gels. Each gave rise to a single labelled band of about 84 kd. In order to determine if the anti-peptide serum recognized denatured NGFR, various cell types were solubilized, run on SDS gels and transferred to nitrocellulose. When the transfers were probed with the anti-peptide serum, nothing was detected in proteins from L cells, whereas a single strong band of about 84 kd was detected in proteins from L cells transfected with DNA encoding the NGFR and in proteins from PC12 cells. Using immunocytochemistry, the anti-peptide sera reacted strongly with sensory and sympathetic ganglia and with cells of the basal forebrain nuclei. Taken together, these data indicate that the anti-peptide serum recognizes the NGFR in its native, denatured and fixed state.

331.11

SOLUTION HYBRIDIZATION ASSAY TO MEASURE mRNA LEVELS FOR NERVE GROWTH FACTOR RECEPTOR. J. Hartikka, F. Hefti and W. Strauss. Depts. of Neurology and Pharmacology, University of Miami School of Medicine, Miami, FL 33101.

We have reported that treatment of septal cultures with nerve growth factor (NGF) increases the staining intensity of cholinergic neurons visualized with antibodies against the nerve growth factor receptor (NGFR). These results suggest that NGF stimulates the synthesis of its own receptor. In order to study the regulation of NGFR expression, we have developed a method to quantify the amount of mRNA coding for this receptor using a solution hybridization assay.

A cDNA clone for the rat NGFR (Radeke et al., Nature 325: 593, 1987) was subcloned in pGEM-blue. A single-stranded cRNA probe (specific activity 8 X 10^5 cpm/ng) was transcribed using SP6 RNA polymerase. This probe was hybridized (RoT = 0.008) to a sense strand cRNA transcribed from the same clone using T7 RNA polymerase. After digestion with ribonucleases A and T1, the nuclease-resistant RNA was precipitated and the amount of specific mRNA was quantified. Based on this assay, the concentration of mRNA coding for NGFR is less than 0.1 ng/mg of total RNA in the basal forebrain of adult rats.

331.12

PURIFICATION OF A TRUNCATED HUMAN NERVE GROWTH FACTOR (NGF) RECEPTOR. A.A. Zupan*, P.A. Osborne*, and E.M. Johnson, Jr. Department of Pharmacology, Washington University, St. Louis, MO 63110.

Our laboratory recently described the presence of a truncated form of the nerve growth factor receptor (NGFRt) in the urine, plasma, and amniotic fluids of rats. We report here the presence of forms of NGFRt in human urine and amniotic fluid by utilizing the human-specific anti-NGFR monoclonal antibody 20.4. ^{125}I-NGF specifically bound to NGFRt was chemically crosslinked using a water-soluble carbodiimide. After immunoprecipitation, labelled receptor species were visualized by autoradiography following SDS-PAGE. Labelled species corresponded to proteins of approximate molecular weights 60, 50, and 37 KDa.

Employing human adult male urine as starting material, NGFRt was purified to near homogeneity by using a combination of ion exchange and immunoaffinity chromatographies. Typical yields were about one μg/L urine. The purified protein was NGFRt as shown by an NH_2-terminal sequence identical to that predicted by the known sequence of human NGFR. In addition, amino-acid composition analysis of the protein was consistent with it being the extracellular domain of the NGFR assuming a cut site at Arg-219. The purified protein was used as an immunogen to generate polyclonal antisera. These sera blocked ^{125}I-NGF binding to A875 human melanoma cells and to PC12 rat pheochromocytoma cells. Purified NGFRt may be useful in structural and immunological studies of the native human NGFR.

IN VIVO EFFECTS OF GM1 AND NGF, ADMINISTERED IN COMBINATION, FOLLOWING CNS RETROGRADE DEGENERATION. L. Garofalo*, D. Maysinger and A.C. Cuello. Dept. Pharmacology, McGill University, Montreal, Canada, H3G-1Y6.

Following a unilateral decortication, retrograde degenerative changes occur in the nucleus basalis magnocellularis (NBM) of mature rats which can be prevented by administering the monosialoganglioside GM1. Nerve growth factor (NGF) administered i.c.v. via minipumps (12 ug/day, 7 days) is equally effective. We have presently been examining the possibility that GM1 may exert its effects by enhancing the action of endogenously occuring neuronotrophic factor(s). NGF, at the above dose, administered i.c.v. in combination with a dose of GM1 (0.5 mg/kg/day, 7days) which is ineffective in this lesion , increases ChAT activity in the NBM (120%) and in particular in the remaining cortex (155%) above that obtained by NGF alone. Furthermore, NGF, with a dose of GM1 (5mg/kg/day, 7 days) which is effective in our model, increases ChAT activity in the NBM and in particular in the remaining cortex (247%) well over that obtained by these two agents alone. The effects of these agents in other brain areas and the morphological appearance of NBM cholinergic neurons following this lesion and treatments will also be presented.These preliminary studies support previous work in the PNS and suggest that GM1 may modulate the action of neuronotrophic factors in the CNS in vivo. Supported by MRC, FCAR and FRSQ.

331.14

RETROGRADE TRANSPORT OF NERVE GROWTH FACTOR BY MOTOR NEURONS OF DEVELOPING RATS: ASSESSMENT OF POTENTIAL NEUROTROPHIC EFFECTS. W. Snider, Q. Yan, J. Pinzone* and E.M. Johnson, Jr. Depts. of Neurology and Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Several regions of the central and peripheral nervous system transiently express receptors for nerve growth factor (NGF) as revealed by a specific monoclonal antibody to the rat NGF receptor (Yan and Johnson, J Neurosci, in press). In the spinal cord, staining clearly associated with ventral motor neurons is observed from about E15, peaking on the day of birth, and decreasing to undetectable levels by postnatal day 10. In order to assess the function of these receptors we have studied the retrograde transport of NGF by spinal motor neurons and the responses of motor neurons to pharmacologic doses of NGF in neonatal rats.

^{125}I-NGF was retrogradely transported by motor neurons from their peripheral nerve terminals in newborn animals. This transport was blocked by an excess of unlabeled NGF but not by cytochrome c. ^{125}I-cytochrome c was not transported. The monoclonal anti-rat NGF receptor antibody was also transported, but not a control antibody. Despite this ability of motor neurons to transport NGF, treatment of neonatal rats with this factor did not increase motor neuron size or synthesis of neurotransmitter enzymes and did not prevent cell death after axotomy. We conclude that NGF receptors of spinal motor neurons can bind, internalize, and retrogradely transport NGF. However, these receptors do not mediate the morphological and survival-promoting effects associated with the action of NGF on sympathetic and dorsal root ganglion cells.

331.15

ULTRASTRUCTURAL LOCALIZATION OF NGF RECEPTORS IN DEVELOPING RAT SKELETAL MUSCLE. H. B. Clark, C. Grgurich* and Q. Yan Dept. of Pathology, So. Ill. Univ. Sch. of Med./Memorial Med. Ctr., Springfield, IL 62781 & Dept. of Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

The expression of nerve growth factor (NGF) receptor was studied in embryonic rat skeletal muscle by electron microscopic (EM) and light microscopic (LM) immunocytochemistry using 192-IgG, a monoclonal antibody specific for rat NGF receptor. NGF receptor immunoreactivity (NGFRI) in skeletal muscle was seen as early as embryonic day 11 (E11) but was most intense in E15 animals. In E15 rats the NGFRI seen by EM was localized to the cell surfaces of two cell types. Myotubes both with and without clearly-defined myofibrillar cytoplasmic components had intense NGFRI. Cells that were less obviously differentiated, with a spindled, fibroblastic appearance, also were heavily immunostained. By EM the NGFRI in E18 rats was absent or only faintly present on the more well-differentiated muscle cells. At E18 there still were numerous spindle-shaped cells with intense NGFRI interspersed among the fibril-containing muscle cells. By the time of birth the NGFRI seen by LM was greatly diminished and by EM appeared to be confined to the spindle-cell population. The transient expression of NGF receptors by skeletal muscle during development appears to be correlated with the cellular differentiation of myotubes. NGF may play a role in cellular mechanisms related to the fusion of myoblasts into myotubes and subsequent myotubular differentiation into mature myocytic syncytia.

GLUCOCORTICOID REGULATION OF NERVE GROWTH FACTOR mRNA IN RAT AND MOUSE TISSUE. R. P. Hellendall*, K. E. Sheppard*, M. Blum (SPON:I. Bodis-Wollner) Fishberg Ctr. for Neurobiology, Mt. Sinai Sch. of Med., N.Y., NY 10029

We have examined the effect of glucocorticoids on nerve growth factor (NGF) gene expression in the adult rat and mouse brain. Glucocorticoids have been found to increase nerve growth factor protein content in the mouse submaxillary gland; the mechanism of action for this modulation is unknown. Our work has focused on the cortex and hippocampus, the two regions containing the highest NGF mRNA levels. Utilizing the sub-picogram sensitivity of a S1 nuclease protection assay we have found basal NGFmRNA levels in the Sprague-Dawley rat in agreement with previous studies (10 fg/ug total RNA in hippocampus, 5 fg/ug total RNA in cortex). Adrenalectomy of rats, Swiss-Webster and CB57BL mice caused a down regulation of NGF gene expression in the hippocampus whereas no consistant change was observed in cortex. One week treatment with dexamethasone (.25ug/ml in drinking water) produced an increse in NGF mRNA to a level above that of intact controls in the hippocampi of rats and CB57BL mice and in the cortex of CB57BL mice. Submaxillary tissue is currently being studied to understand the peripheral effects of the adrenalectomy/replacement paradigm. We are also examining the effects of glucocorticoids on septal NGF receptor gene regulation: preliminary data indicate adrenalectomy increases NGF-R mRNA in Sprague-Dawley rats.

331.17

THE CONSTRUCTION OF HUMAN NGF EXPRESSION VECTORS: THEIR POTENTIAL ROLE IN THE TREATMENT OF ALZHEIMER'S DISEASE. G. Bruce* and G. Heinrich, Lab. Molec. Endocrinology, Mass. Gen. Hospital, Boston, MA 02114

Nerve growth factor (NGF) has recently been implicated as a trophic agent in the survival and maintenance of the basal forebrain cholinergic neurons. Evidence from animal studies suggests that a continuous intraventricular infusion of NGF or the intracerebral grafting of NGF producing cells into the Alzheimer's brain may stop the degeneration of these neurons and improve memory function. For this purpose human NGF (hNGF) expression vectors were constructed to allow for the production of recombinant hNGF for infusion and also for the potential to transform cells for grafting. Three expression vectors were constructed containing the entire coding region for mature (13,000 MW) hNGF derived from the 3' exon (exon 4) of the hNGF gene. Vector 1, a pBR322 derived vector containing the metallothionein promoter, consists of a 780 bp Apa1-Bcl1 hNGF fragment joined to a linking oligo supplying the lacking 30 bases of the 5' end. Vector 2, a pXM derived vector containing the AV MLP promoter, consists of a 1050 bp Ava1-Apa1 hNGF fragment. Vector 3, a pGEM-3 vector containing the metallothionein promoter, consists of a 1200 bp Hind III-Bcl 1 hNGF fragment joined to a 255 bp fragment of mouse NGF cDNA. All the inserted hNGF fragments contain the two potential initiation codons at -123 and -119 with the mouse NGF cDNA fragment of vector 3 also supplying the 5' sequences up to the potential initiation codon at -187. All vectors were selected and shown to contain the respective inserts by restriction mapping and oligonucleotide hybridization. These vectors are being transiently expressed in COS, CHO and PC12 cells. Expression will be measured by analysis of the transfected cell medium for immunoreactive and bioactive NGF. It is hoped that the successful expression of hNGF may represent an important first step in the potential treatment of Alzheimer's disease.

331.18

RAT β-NGF SEQUENCE AND SITES OF SYNTHESIS IN ADULT CNS. P.L. Friedman, D. Larhammar, V.R. Holets, M. Gonzalez-Carvajal*, Z.Y. Yu*, H. Persson* and S.R. Whittemore. Dept. Neurological Surgery, Univ. Miami, Miami, FL 33176 and Dept. Medical Genetics, Univ. Uppsala, S-751 23 Uppsala, Sweden.

The nucleotide sequence of a rat β-nerve growth factor (NGF) genomic sequence encoding the entire 3' exon of preproNGF was determined. Rat NGF shows very high homology with other known NGFs in both 3' untranslated regions and the prepro-peptide. The presumptive signal sequence, cysteine residues important for tertiary structure, glycosylation sites and dibasic amino acids required for proteolytic cleavage to mature NGF are highly conserved. Comparison of hydrophobicity plots and amino acid sequences revealed an evolutionarily divergent domain on the external surface of NGF which may account for the poor immunologic cross-reactivities of the various NGFs.

In situ hybridization to brain sections with a rat-specific oligonucleotide indicated high levels of NGF mRNA synthesis in both hippocampal granule and pyramidal cell layers. These results are consistent with one role for NGF in the CNS as a neuronally-released, retrogradely transported neurotrophic factor for basal forebrain cholinergic neurons. Labelled cells were also observed in olfactory cortex and other CNS regions are presently being examined.

GENETIC MODELS II

332.1

SEVERITY OF CORPUS CALLOSUM DEFICITS IN TWO SUBSTRAINS OF BALB/cWah MICE IN RELATION TO UTERINE LOCATION OF FETUSES B. Bulman-Fleming and D. Wahlsten. Dept. of Psychology, U. of Waterloo, Waterloo, Ontario, Canada N2L 3G1.

Intrauterine position (IUP) effects were studied using fetuses at embryonic day 17.5 from two sublines of the BALB/cWah inbred mouse strain. The midline areas of adult corpora callosa (CC) of about 50% of BALB/cWah1 (line 1) and about 18% of BALB/cWah2 (line 2) mice are very small or non-existent. The prenatal hippocampal commissure (HC) development in BALB is also retarded; however, all but a very few mice do eventually develop an HC of normal midline area. Our index of abnormality for midline commissure development was a standardized (z) score which expressed the number of standard deviations by which the actual CC+HC area differed from area of CC+HC expected according to its body weight. Expected values were derived from data on normal fetuses in the weight range 0.5 to 1.0 g. The results revealed: 1) differences between the lines on mean litter size, body weight, and z score; 2) a right uterine horn advantage on z score in line 2; 3) an ovarian and cervical (vs. middle) position advantage in line 2 for body and placenta weight. Apart from the line 2 right horn effect, no other IUP factor or combination of factors contributed significantly to the variability in degree of CC+HC retardation. A runs test for randomness also provided no evidence for nonrandom placement of fetuses with respect to degree of abnormality.

332.2

STUDY OF TREMOR IN A NEUROLOGICAL MUTANT SUBLINE OF SPRAGUE DAWLEY RATS. E.C. Vega-SaenzdeMiera*, B. Holmgren* and R. Urbá-Holmgren* (SPON: O.C. Ramírez). Departamento de Ciencias Fisiológicas, Instituto de Ciencias. Universidad Autónoma de Puebla, Puebla, Pue., México.

In the Sprague Dawley rat colony of our Department a neurological mutation appeared, characterized by tremor, ataxia , cataplexy and paralysis. The syndrome begins with a fine tremor in the tail and hindlimbs which is visible by simple inspection when rats reach the age of 1 month. Other neurological symptoms appear with increasing age: ataxia at 2-3 months, cataplectic episodes at 6-8 months and hindlimb paralysis after 10 months. This hereditary syndrome is transmitted as an autosomal recessive trait.

The tremor frequency was measured in 8 or more mutant rats at the following ages: 19,21,27,30,45,60,75 and 90 days, using power spectral analysis of the current induced by the movements of a magnet, attached to the animal, on a wire coil, following a procedure similar to that described by Shinozaki(Neurosci. Res. 2:63-76,1984). In about one half of 19-day-old mutants a slight tremor was detectable with a main frequency peak of 13.4 +/- 2.8 Hz. At the age of 21 days all mutants exhibited tremor at an average frequency of 12.1 +/- 1.9 Hz. When 45- day-old a second tremor peak appeared, at 6 +/- 0.2 Hz. In two-month-old mutants, this lower frequency peak (5.7 +/- 0.6 Hz) became the main one, and at the age of three months it was the only tremor peak present (5.4 +/- 0.5 Hz), and had an intentional character.The underlying pathology of this hereditary neurological syndrome is under current study by our group.

Supported by CONACYT grant PCEXNA-050414; SEP grant C87-01-0459 reg DGICSA 861711.

332.3

A DATABASE FOR THE GENETIC ANALYSIS OF GENES OF NEUROLOGICAL INTEREST. M.H. Brilliant and M. Lennon-Pierce*. The Jackson Laboratory, Bar Harbor, ME 04609.

As part of an effort to facilitate the analysis of genes and genetic loci of neurological interest, we have developed a prototype of a highly comprehensive computerized genetic information system. Our database, which deals specifically with neurological mutants, allows us to store, retrieve, sort and analyze mapping data.

A genetic information system - Compendium Genetica (CG) - developed by the Jackson Laboratory's Genetic Information Resource, allows us to compare and position genetic loci across species in relation to total cumulative mapping data. CG contains the history, characteristics, and husbandry, of specific neurological mutants, and has an extensive bibliographic component.

Comparative maps can be superimposed to reveal homologous genetic loci from one mammalian species to the genetic linkage map of another, thus displaying both linkage and synteny conservation.

We present examples of the utility of this information system and in particular, we present the analysis of the locus encoding the gene for tyrosine hydroxylase, the rate-limiting enzyme in catecholamine biosynthesis.

332.4

RELEVANCE OF DYSTROPHIC CHICKENS AS AN EXPERIMENTAL MODEL FOR HEREDITARY MUSCULAR DYSTROPHY IN HUMANS. D.M. Riedel*, R.K. Entrikin and S.K. Bhattacharya (SPON: R.P. White). Surgical Research Lab., University of Tennessee, Memphis, TN 38163 and University of California, Davis, CA 95616.

Avian muscular dystrophy (MD) in the Davis line 413 dystrophic chickens (DC) has been used for the study of hereditary MD in humans (Muscle & Nerve, 7:130, 1984). Since excessive intracellular Ca accumulation (EICA), abnormal muscle histopathology, and elevated serum CK levels are universally accepted as the earliest detectable pathogenetic changes in Duchenne muscular dystrophy (DMD) in humans (Neurology, 34:1436, 1984) and in BIO-14.6 strain dystrophic hamsters (DH) (Muscle & Nerve, 10:168, 1987), we investigated these variants in 5-week-old and 6-month-old male DC. Muscle [Ca] and [Mg] were determined in the HNO_3 extract by flame atomic absorption techniques (Anal. Lett. 12:1451, 1979). Age and sex matched Davis line 412 normal chickens (NC) served as disease controls.

Unlike DMD and DH, EICA and gross morphological changes with profound cellular necrosis and fatty infiltration were not evident in the myocardium of DC. However, the pectoralis from DC revealed significant EICA accompanied by Mg depletion and classical dystrophic histopathology. Plasma CK activity was also elevated in DC ($p < 0.001$).

We conclude that DC exhibit dystrophic lesions in the skeletal muscle only. On the other hand, DH display both the cardiac and skeletal muscle impairments universally present in DMD. (Supported by NIH grant #AR-38540)

332.5

IMMUNOHISTOCHEMICAL LOCALIZATION OF HPRT IN THE MAMMALIAN BRAIN. H.A. Jinnah,* M.B. Rosenberg, T. Friedmann,* F.H. Gage, (SPON: E. Hess). Depts. of Neurosciences and Pediatrics, UCSD, La Jolla, CA 92093.

Hypoxanthine-guanine phosphoribosyl transferase (HPRT) is an enzyme responsible for converting the bases hypoxanthine and guanine into their respective nucleotides. Deficiency of HPRT in humans results in Lesch-Nyhan syndrome, characterized by several neurological signs including extensor spasticity, choreoathetosis, and self-injurious behavior. In mice, however, absence of HPRT causes no obvious neurological impairments. In view of this difference, it would be interesting to compare the distribution of HPRT in the brains of mice and primates.

HPRT was localized in sections from murine brain using rabbit anti-human HPRT, and visualized by standard immunoperoxidase techniques.

The regional distribution of labelled cells was quite specific; all cells were not uniformly stained. The most intensely stained cells were located in the olfactory tubercle/basal forebrain, inferior colliculus, and deep layers of the superior colliculus. Medium intensity staining was observed in specific cortical layers, amygdala, several hypothalamic nuclei, red nucleus, all brainstem motor nuclei, deep cerebellar nuclei, pontine nuclei, and nucleus of the trapezoid body.

The cellular distribution of label varied according to brain region In some areas, whole neurons were densely stained, with clearly identifiable dendrites. In other regions, staining appeared coarsely granular, not evenly dispersed within the cell cytosol. Granules often appeared clustered at the cell surface, but it remains unclear if they represent intracellular inclusions or exteriorly located synaptic puncta.

We are currently investigating the distribution of HPRT in the brains of human and non-human primates.

332.6

GENETIC MAPPING AND DEVELOPMENTAL EXPRESSION OF GENES ON MOUSE CHROMOSOME 16 IN NORMAL AND ANEUPLOID MICE. B.F. O'Hara*, R.H. Reeves*, C. Bendotti, S. Fisher*, G.T. Capone, J.T. Coyle, M.L. Oster-Granite, and J.D. Gearhart*. Departments of Physiology, Psychiatry, and Neuroscience, Johns Hopkins University Sch. of Med., Baltimore, MD. 21205.

Evolutionary conservation of a number of genes on human chromosome 21 (HSA 21) and mouse chromosome 16 (MMU 16) has led to the study of the trisomy 16 mouse (Ts16) as a model system relevant to studies of human trisomy 21 or Down Syndrome. We have further refined this model by delineating the extent and character of chromosome homology, and by examining the expression of MMU 16 specific genes during development in normal and aneuploid mice. The use of RFLPs and mating schemes involving highly polymorphic mouse subspecies has revealed that gene order has been conserved between the homologous domains of MMU 16 and HSA 21. The proximal to distal gene order on both chromosomes is *App* (Amyloid precursor protein), *Sod-1* (Superoxide dismutase-1), and *Ets-2* (a proto-oncogene sequence). In addition we report that *Gap-43* (Growth associated protein - 43Kd) is distal to *Smst* (preprosomatostatin) on the proximal portion of MMU 16. As both *Gap-43* and *Smst* reside on HSA 3 this confirms and localizes a second syntenic homology on MMU 16. We have examined the expression of genes from the two domains in both Ts16 and Ts19 mice to distinguish gene dosage effects from the generalized effects of aneuploidy *per se*. Quantitative northern blot analysis and *in situ* hybridization methods were used to compare mRNA levels in Ts16 , Ts19, and their respective littermate controls on day 15 of gestation (E15). Since several of these genes may play important roles in normal development, they were examined at other gestational ages. *Smst, Gap-43, App,* and *Ets-2* were all expressed as early as E10-12 (See also G.T. Capone et al., and S. Fisher et al., this meeting; and C. Bendotti et al., European Neuroscience Association meeting, 1988, in press). Each of these genes exhibits a characteristic temporal and spatial pattern of expression, as well as distinct elevations of message in Ts16 mice and variable alterations in Ts19 mice. These studies demonstrate that transcriptional levels of any gene in aneuploid mice cannot be predicted entirely by gene copy number. (Supported in part by HD 19920, HD 19932, HD 22262, and by the Alzheimer's Disease and Related Diseases Foundation).

332.7

EXPRESSION OF THE GENE CODING GROWTH ASSOCIATED PROTEIN-43 (GAP-43) IN THE BRAINS OF NORMAL AND TRISOMIC MICE. G.T. Capone, C. Bendotti, B.F. O'Hara *, M.L. Oster-Granite, J.D. Gearhart *, R. Reeves * and J.T. Coyle. Depts. of Physiology, Psychiatry and Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

GAP-43 (F1, B-50, pp46) is a neuronal phosphoprotein associated with axonal elongation during development, with regeneration following injury, and with synaptic modification and plasticity in the adult central and peripheral nervous systems. The levels of expression of GAP-43 increase during fetal and early postnatal life, and then decline, so that adult levels are considerably lower than those found during development in normal animals. O'Hara *et al.* (this meeting) have localized the gene encoding GAP-43 to a region of mouse chromosome 16 (MMU 16) homologous to human chromosome 3.

We have used *in situ* hybridization and Northern blot analysis to determine the developmental expression of GAP-43 mRNA in normal and aneuploid (trisomic) mouse brain. Mice trisomic for MMU 16 (Ts16) were studied to determine the effects of increased gene dosage on the expression of GAP-43 mRNA. Mice trisomic for MMU 19 (Ts19) served as controls for the generalized effects of aneuploidy on development.

As early as day 11.5 of gestation (E11.5) in normal mice, GAP-43 mRNA was detected in whole head preparations; expression increased in the brain approximately 10-fold by postnatal day 1 (PND 1), and continued to increase during the first postnatal week. GAP-43 mRNA can be detected as early as E10 in normal mouse brain by *in situ* hybridization. At E15, GAP-43 mRNA expression was increased 2-3 fold in Ts16 mouse brain, relative to euploid littermate controls, but was decreased slightly (20%) in Ts19 mouse brain, relative to their euploid littermate controls. Alteration in the expression of GAP-43 mRNA observed in these aneuploid mice may contribute to some of their CNS developmental abnormalities.

332.8

DEVELOPMENTAL EXPRESSION OF AMYLOID PRECURSOR PROTEIN IN NORMAL AND TRISOMY 16 MICE: RELEVANCE TO DOWN SYNDROME AND ALZHEIMER'S DISEASE. S. Fisher*, R.A. Morgan*, B.F. O'Hara*, J.D. Gearhart*, M.L. Oster-Granite. Developmental Genetics Lab, Johns Hopkins School of Medicine, Baltimore, MD 21205

The A4 peptide is a major component of the cerebrovascular amyloid plaques and extraneuronal senile plaques found in the brains of Alzheimer's disease patients and aged Down syndrome (DS) individuals. The gene encoding the amyloid precursor protein (APP) maps to human chromosome 21, and its homolog to mouse chromosome 16. We have cloned a full-length mouse APP cDNA, which has a 97% homology with human APP at the amino acid level. This high homology and the widespread distribution of the mRNA suggest a conserved function for APP. To better understand its function and whether its early overexpression contributes to the developmental abnormalities seen in DS, we studied its expression in normal and trisomy 16 (Ts16) mice. Northern blots of tissues from different pre- and postnatal stages were hybridized with probes from mouse APP cDNA or end-labeled synthetic oligonucleotides corresponding to the forms of APP generated by differential splicing. Western blots were done on tissues from the same ages with antibodies raised to synthetic peptides from portions of the APP sequence. APP expression was detected at gestational day 10, and attained adult levels by gestational day 13. Relative expression of the form of APP with the protease inhibitor insert was higher in non-neural tissues. At all gestational ages examined, APP expression was higher in Ts16 mice. The Western blots showed greater levels of APP in non-neural tissues than predicted by the mRNA levels; this suggests a difference in stability between the different forms, leading to a greater turn-over and lower steady state levels for the form without the insert. The early overexpression of APP in the Ts16 mouse may enable us to study the contribution of APP overexpression to the developmental abnormalities seen in DS.

OBSERVATIONS ON THE CNS OF LONGER LIVED MYELIN DEFICIENT RATS. K.F. Jackson*, I.D. Duncan, M.R. Wells and S.F. Worth*. School of Vet. Med., U. of Wisconsin-Madison, WI 53706 and VA Medical Center, Washington, D.C. 20042.

Myelin deficient (md) rats have rarely survived beyond 35 days of age. Recently, certain female carriers of this X-linked dysmyelinating disorder, derived from the original Wistar breeding stock, have produced affected male pups which survive for up to 60 days. One each of these mutants at 40 and 50 days, and 2 at 60 days of age, were perfused with aldehyde fixatives and the CNSs processed for light (LM) and electron microscopy (EM). On LM there was an apparent increase in the number of myelinated axons on the ventral columns of the spinal cords of these older md rats, compared to mutants of 30 days of age. There was an apparent decrease in the total glial cell count in the intracranial optic nerve and spinal cord. There were estimated to be only 140 cells per optic nerve section at 60 days, compared to 230 glial cells per section observed in 30 days old md rats. EM examination suggested that many of the cells were astrocytes, although there was no obvious astrogliosis in either the cord or optic nerves. Undifferentiated cells and microglia were also present in both regions, as well as some abnormal oligodendrocytes, containing distended rough ER. These observations suggest a continued decrease in the glial cell population in older md rats, with particular loss of oligodendrocytes. However, a number of these cells must be viable in the older mutants, as myelin sheaths are maintained, and even appear to increase in the spinal cord. (Supported by NIH grant NS23124 and NMSS grant RG1791).

332.10

MOLECULAR ANALYSIS OF THE SHAKING PUP MUTATION. N. Nadon*, I.D. Duncan, L. Hudson* (SPON: M. Behan). National Institutes of Health, NINCDS, Bethesda, MD 20892 and School of Vet. Med., U. of Wisconsin, Madison, WI 53706

The shaking pup is a sex-linked dysmyelinating mutant of the dog in which the myelin proteolipid protein (PLP) is reduced greater than 100-fold, while DM-20, the alternatively spliced form of the protein, is reduced only about 6-fold (Yanagisawa et al., J. Neurochem. 49:1812-1917, 1987). In order to identify the molecular defect, DNA and RNA from shaking pups was compared to that from normal littermates. Northern blot and slot blot analysis showed that the PLP mRNA, a single band of 3.2 kb, is detectable in the brain and spinal cord of both normal dogs and shaking pups by two weeks of age. The PLP mRNA is the same size in the shaking pup as in the normal dog, but is reduced to about 10% of normal levels. Southern blot analysis indicates that there are no gross deletions or rearrangements of the PLP locus in the shaking pup. Genomic DNA libraries from normal dog and shaking pup were constructed in the EMBL3 vector and screened with a human PLP cDNA. The PLP clones were mapped and sequence analysis is underway to locate the defect in the shaking pup PLP locus. (Supported by grants from the NIH (NS23124) and NMSS (RG1791) to IDD).

332.11

FREQUENCY ANALYSIS OF WHOLE BODY OSCILLATION IN SHIVERER (SHI) MOUSE. R. S. Pozos, P. Iaizzo*, and C. vonRabenau*. Univ. of Minn., Duluth, School of Medicine, Duluth, MN 55812.

Mice that are homozygous for the autosomal recessive mutation which has been called shiverer (shi) lack myelin basic protein and exhibit a range of behavior patterns, including tremors, convulsions, and death. The tremor has been called a "shiver" but no analysis of the electromyogram or motion has been reported. Wire electrodes were placed in both hind limbs of shiverer (shi) mice* and an accelerometer was placed securely on their back. The animals were allowed to walk freely and the EMGs and motion were monitored during rest as well as motion. Various 16 second portions of the EMG and motion record were analyzed using traditional spectral and cross-spectral techniques on a VAX-station II computer. Analysis indicated that there were distinct bursts of EMG activity and motion at a frequency of 12 Hz. The EMG bursts were synchronous in the hind limbs and were present at rest as well as during motion. This 12 Hz oscillation in these genetically demyelinated mice did not resemble human shivering in that it did not stop during motion nor was it abated with a rise in ambient temperature.

*Donated by Dr. H. David Shine, Center for Biotechnology, Baylor College of Medicine.

332.12

OLIGOSACCHARIDES AND ABNORMAL NEURULATION IN THE DELAYED SPLOTCH MUTANT. R.G. Higbee, J.L Fiacco,* T. Vanden Hoek,* W. Goossens,* D.G. McLone, and P.A. Knepper. Division of Neurosurgery, Children's Memorial Hospital and Northwestern University Medical School, Chicago, IL 60614.

Glycoconjugates play major roles in many cellular functions, e.g., cell migration and adherence, which are involved in neurulation. Previous studies by our laboratory have indicated correlations in the time of appearance, type and distribution of oligosaccharides with normal as well as with teratogen-induced (vitamin A) abnormal neurulation which suggest that oligosaccharides may serve as molecular participants in the process of neurulation. In the present study, a genetic model of abnormal neural tube closure, the delayed splotch mouse mutant (Sp/Sp), was studied on gestation days 12, 14, and 16 by a battery of FITC-labeled lectins using low-light intensity video-microscopy and by analysis of micro-dissected neuroepithelium (NE) using PAGE, western blots, and peroxidase-coupled lectins to detect carbohydrate moieties on specific proteins. The gestation day 16 Sp/Sp embryos exhibited varying degrees of myeloschisis of the sacral region, and concomitant changes were observed in the staining patterns of several FITC-labeled lectins. Image analysis of FITC-WGA binding by control NE in 1-um plastic sections exhibited spatial and temporal changes during neurulation, particularly in the zone of closure; FITC-WGA binding was altered in the NE of Sp/Sp embryos. Western blots demonstrated a decrease in the WGA-binding of 15-Kd and 80-Kd proteins in both the caudal and rostral NE in gestation day 16 embryos with myeloschisis compared to littermates. The protein profiles of Sp/Sp, littermates, and control embryos were similar on silver-stained gels, i.e., no changes were observed in the 15-Kd and 80-Kd proteins. The results of this study demonstrated changes in oligosaccharides in Sp/Sp embryos; these changes were similar to the abnormalities of the splotch mutant and vitamin A-induced myeloschisis in the mouse. Thus, these results indicate that oligosaccharides may serve as molecular participants in the events of abnormal neurulation and provide additional evidence for the importance of glycoconjugates and the process of neurulation.

332.13

NEW MOUSE MUTANT WITH KINKY TAIL AND SEVERE CORPUS CALLOSUM (CC) DEFECT. B. Cassells and J. V. Clifton*. Dept. of Psychology, Univ. of Waterloo, Waterloo, ON, N2L 1V8 CANADA.

A recessive incompletely penetrant mutation affecting tail and CC morphology has been detected in BALB/c mice obtained from CRBL and the gene name kc (kinky tail, CC defect enhancer) proposed. At or < 2 wks after birth, mutants show variably shortened, kinked, twisted tails. Tail length at weaning (10-90% of normal) is inversely related to kink detection age. Pre- but not post-weaning growth and survival are reduced. Female but not male mutants breed.

All BALB/c kc/kc detected at birth have mid-sagittal CC areas < 30% normal. In contrast, only a minority of kc/kc late-onset, kc/+, +/?, and +/+ BALB/c's of this line show CC defects, consistent with reports on other BALB/c stocks. The effect of kc/kc on the CC depends on its interaction with other recessive elements of BALB/c heredity. This combination of characters, though sharing some features with previously described mutations, appears to be unique and indicative of a new recessive mutation. This mutant may be useful to those studying the heredity and embryology of callosal development or behavioral and physiological functions of the CC.

AUTOMATED ANALYSIS OF CIRCADIAN BEHAVIOR AND EEG POWER SPECTRA OF ALCOHOL-PREFERRING AND -NONPREFERRING RATS. S. Morzorati, B. Lamishaw*, L. Lumeng*, T.-K. Li* and J. Clemens, Dept. Med. and Regenstrief Inst., Ind. Univ. Sch. Med. 46223 Eli Lilly & Co. 46285, Indianapolis, IN.

Low dose ethanol has been shown to produce a differential response in the behavior and EEG of rats selectively bred for alcohol-preference (P) and -nonpreference (NP). Whether these rats differ in baseline circadian behavior and EEG is the focus of the present study.

The frontocortical and hippocampal EEG and movement of P and NP rats were recorded for 24 hours. Eight-second epochs of EEG taken once every minute were subjected to power spectral analysis. Behavioral maps were constructed for each rat. Time spent in non-REM sleep, REM sleep, awake/immobile, and moving and the corresponding power spectra were compared across the two rat lines in the light and dark. While P and NP rats did not differ significantly in total time spent in any behavior, P rats did show more prolonged periods of activity in the dark. Following lights on, the latency to the first sleep cycle was markedly shorter in P than in NP rats. P rats had more power in the lower frequencies during non-REM sleep, suggesting a deeper sleep. Thus, while P and NP rats regulate sleep according to a homeostatic mechanism, they differ in their latency to and depth of sleep perhaps because of differences in activity duration during the dark. FRONTAL LOBE MATURATION IN DOWN SYNDROME: IMMUNOCYTOCHEMICAL AND STRUCTURAL STUDY OF THE CHOLINERGIC SYSTEM.
I. Kostović, A. Bunarević, L.B. Hersh, G. Bruce, A. Fučić, B. Šain. Sect. Neuroanatomy, Zagreb Univ. Sch. of Med., 41001 Zagreb, Yugoslavia and Dept. Biochemistry, Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235.

The aim of this study was to determine whether abnormalities of the cholinergic basal forebrain-cortex system in Down syndrome (DS) occur during the infancy and early childhood. We applied ChAT-immunocytochemistry (anti-human placental ChAT antibody of Hersh-Bruce), AChE-histochemistry and Nissl method, analyzing basal forebrain (BF) and frontal cortex on postmortem tissue obtained from 5 individuals with DS and age-matched controls (newborn-2,5 years). In newborn, more than 80% of BF neurons are ChAT-reactive in both DS and controls; ChAT-reactivity was enhanced in DS basal forebrain. Cortical cytoarchitectonics and AChE-patterns appear to be normal. In older group (2-2,5 years) AChE-reactive pyramidal neurons were not found but fibre staining was enhanced. Layer III pyramidal neurons showed the vacuolar degeneration. In both age groups the mean perikaryal size was not different in comparison with age-matched controls. In conclusion, basal forebrain-cortical system appears structurally normal in the newborn, with possibly increased ChAT-synthesis. At 2,5 years first abnormalities appear in cortical associative layers, indicating that cortical pathology may be a primary phenomenon. Supp. by Joint-Board No. 698 and SIZ za znanost SRH.

NOREPINEPHRINE AND MET-ENKEPHALIN CONCENTRATIONS IN SPECIFIC BRAINSTEM AND SPINAL CORD REGIONS OF THE GENETICALLY EPILEPTIC, TOTTERING (tg/tg) MOUSE. L.C. Abbott, B. Weber*, and R.H. Abhold. Dept. of VCAPP, Washington State Univ., Pullman, WA 99164-6520.

Elevated levels of norepinephrine (NE), mainly in cortical regions of the brain, have been reported to be responsible for petit mal and focal motor seizure activity in tg/tg mice. However, thorough analysis of NE levels in the brainstem and spinal cord have not been previously done. Since these CNS regions may also be important in the generation and/or maintenance of these forms of seizures, NE levels were measured via HPLC-EC in several brainstem and spinal cord regions in adult tg/tg mice relative to control (+/+) mice. Decreased NE was observed in the pons from tg/tg mice while other brainstem and spinal cord regions exhibited increased NE levels.

Methionine-enkephalin (MET-ENK), known to colocalize with and modulate the actions of NE, was also measured via RIA in the brainstem. In those areas NE was decreased in tg/tg mice, MET-ENK also was decreased, relative to +/+ mice. These data raise the possibility that decreased NE and MET-ENK may be involved in epileptogenesis and/or maintenance of seizure activity in the tottering mouse. Measurements of MET-ENK levels in spinal cord regions are in progress. Supported by NIH grants RR00515 and RR05-46525.

SUBCORTICAL VISUAL PATHWAYS III

333.1

PATTERNS OF RETINAL TERMINATIONS IN RODENT SUPERIOR COLLICULUS LABELED WITH HRP AND WGA-HRP TRACERS. S. Agarwala, J.G. May III & H.M. Petry. Dept. of Psychology, S.U.N.Y. at Stony Brook, NY 11794

Retinal projections were examined after monocular intravitreal injections of either horseradish peroxidase (HRP, 50 ul of a 30% solution) or wheat germ agglutinin conjugated HRP (WGA-HRP, 30 ul of 1% solution) in ground squirrels (Citellus tridecemlineatus) and rats (Rattus rattus). Following various survival schedules, brains were processed for TMB histochemistry.

The retinal projection patterns seen after injection of either HRP or WGA-HRP were similar for all structures except for the contralateral superior colliculus (SC). In ground squirrel, this projection exhibited a discontinuous pattern of vertical slabs throughout the superficial layers in all HRP cases and in some WGA-HRP cases. However, uniform labeling of the contralateral SC occured in other WGA-HRP cases. These tracers also produced similar differences in the pattern of label in the rat SC. The differences could not be attributed to obvious methodological factors, nor could they be adequately explained by superior WGA-HRP sensitivity or its transneuronal transport. The similarity of labeling in all other visual projections regardless of tracer, makes the differences in the SC projection very intriguing. (Supported by NSF grant BNS 8519623 to JGM and NIH grant R29-EY07113 to HMP).

333.2

EFFECT OF LESIONS INVOLVING THE PARABIGEMINAL NUCLEI ON CHOLINE ACETYLTRANSFERASE AND ACETYLCHOLINESTERASE ACTIVITIES IN RAT SUPERIOR COLLICULUS. C.D. Ross[1], W.B. Farms*[1], J.D. Dunn[2] and D.A. Godfrey[1]. Depts. of Physiology[1] and Anatomy[2], Oral Roberts University, Tulsa, OK 74171

Activities of choline acetyltransferase (ChAT), catalyzing the synthesis of acetylcholine (ACh), and acetylcholinesterase (AChE), catalyzing the destruction of ACh, are high in the superior colliculus (SC), including the superficial layers that receive substantial projections from the parabigeminal (PBG) nuclei. Activities of ChAT and AChE were assayed in samples microdissected from superior collicular layers in rats killed one week after electrolytic lesions were made to areas including the PBG. Lesions destroying PBG bilaterally produced a 60-80% decrease in ChAT activity in superficial SC layers, with a slight (about 20%) decrease in some deeper layers, but no significant change in AChE activity. Lesions of similar size, but rostral to and sparing the PBG, produced no change in activity of either enzyme. These results indicate that a substantial cholinergic projection to the superficial SC layers originates in the PBG. ChAT activity in the SC is not associated with the optic projection, since it does not decrease following enucleation. Therefore, ChAT activity remaining after PBG destruction could be related to a small projection from another source or to intrinsic cholinergic neurons in the SC. (Supported by NIH grant EY-03838)

333.3

ORIENTATION OF THE DENDRITIC ARBORS OF HORIZONTAL CELLS IN THE HAMSTER'S SUPERIOR COLLICULUS. S. Ruiz*, W.H. Rohrer, M.M. Nikoletseas, R.D. Mooney and R.W. Rhoades (SPON: S.E. Fish). Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Horizontal (H) neurons are a prominent cell type in the superficial layers of the rodent SC. The orientation of the dendritic arbors of these neurons has been the subject of some controversy. Based upon examination of Golgi material, Valverde (Z. Anat. Enwickl. Gesch., 142:117, 1973) concluded that the dendritic arbors of H cells in the mouse paralleled the frontal plane. Langer and Lund (J. Comp. Neurol., 158:405, 1974) suggested that the orientation of H cell dendrites paralleled isoazimuth and isoelevation lines of the visual field representation in the rat's SC. Tokunaga and Otani (Exp. Neurol., 52:189, 1976) concluded that H cells in rat have no preferred dendritic orientation. We used computer-aided reconstruction of horseradish peroxidase-filled neurons to determine whether H cells in hamster have a preferred dendritic orientation. In 9 of 10 H cells, the mediolateral extent of the dendritic tree exceeded its rostrocaudal dimension. The average ratio of these two dimensions was 2.1 (sd=1.2). The long axis of H cell dendritic arbors was oriented at an average angle of 20.1° (sd=13.2) to the frontal plane. Thus in hamster, H cells do have a preferred dendritic orientation and it is generally parallel to the frontal plane. Supported by BNS 85-00142, EY 04170 and NS 07229.

333.4

INTERLAMINAR PROJECTIONS IN THE HAMSTER'S SUPERIOR COLLICULUS. R.D. Mooney, S.E. Fish, M.M. Nikoletseas, W.H. Rohrer and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699 and Marshall University Medical School, Huntington, W VA 25700.

We used Phaseolus vulgaris leuco-agglutinin to trace interlaminar projections within the superior colliculus (SC) of normal hamsters. The superficial SC laminae projected to all of the deep layers and also to the periaqueductal gray. This projection terminated most heavily in the stratum griseum intermediale and stratum griseum profundum and it was topographically organized. There was also a projection from the deep to the superficial laminae, but it was relatively sparse. The trajectory of the superficial to deep projection was angled laterally from a line that extended orthogonally to the SC surface from the injection site center. We assumed such orthogonals to be the most likely trajectories of SC projection lines, i.e. lines connecting the centers of receptive fields that have constant elevation and azimuth in the visual field. Because of this apparent mismatch, we combined PHA-L tracing with receptive field mapping to determine how well the trajectory of the SC-interlaminar pathway matched actual projection lines in the superficial and deep layers. As was the case for the trajectory of the SC-interlaminar projection, visual projection lines in the hamster's SC were angled laterally from lines orthogonal to the SC surface. Supported by BNS 85 00142, EY 04170 and NS 077229.

333.5

PRESYNAPTIC TRANSFER PROPERTIES OF THE RETINOTECTAL CONDUCTION GROUPS IN THE SUPERIOR COLLICULUS BRACHIUM OF THE HOODED RAT. D.Impelman and D.Fox. Dept. of Physiol.,UTHSC, S.A.,TX AND C.of OPT.,UH, Houston, TX.

Previous electrophysiological studies have shown that the fast conducting t1/Y-like(12.5m/s) and the middle conducting t2/x-like(6.0m/s) axons branch to innervate both the superior colliculus and the dLGN(Vis.Res.8:867). HRP retinotectal studies have demonstrated that the major axonal projection to SC(63%) is comprised of the slow conducting(3.5m/s) t3/W-like axons(Z.Mikrosk.Anat.Forsch.92: 283). We are interested in the presynaptic transfer properties of retinotectal axons and have studied their functional characteristics in OT and SC brachium depth recordings. The data show that 1)the relative amplitude measurements of t1, t2 and t3 are better correlated with SC HRP estimates of the RGC conduction group projections than with unit latency histograms; 2)orthodromic t3 conduction is preferentially slowed(15-20%) in brachium recordings; 3)t2 and t3 brachium recovery functions are depressed with a timecourse which parallels the SC postsynaptic field potential response. The t3 response depression is sensitive to the 4AP K+ channel blocker suggesting K+ accumulation may contribute to the SC field potential postsynaptic depression. Supported by NIEHS Grant 03183(DAF).

LIGHT-EVOKED RESPONSES FROM SINGLE MORPHOLOGICALLY IDENTIFIED TECTAL CELLS IN THE GOLDFISH. D. M. Guthrie* and S. C. Sharma. Department of Ophthalmology, New York Medical College, Valhalla, NY 10595.

91 intracellular penetrations were made into tectal neurons of 26 adult goldfish using HRP filled microelectrodes. Resting potentials varied between 30-70mvs; action potentials ranged from 10-45mvs. A 5ms flash provided visual stimulus. Following iontophoretic injections, 36 sites were identified in histology sections. 21 identified unit injections corresponded to the following morphological types described by Meek and Schellart (1978): 4 large diameter afferent fibres; 8 type I cells (pyramids); 1 type III cell; 1 type VI cell; 7 cells with somas in the SPV - 4 type XIV and 1 type XV cell and 2 glia cells. Afferent fibers provided 'on' responses, either phasic, tonic or bursting without spontaneous background; type I cells mostly yielded 'on' dominated responses, with weak or negligible 'off' components. The spontaneous activity consisted of regular bursts. One cell provided only a weak 'off' response, and one cell did not respond to light flash. Type III cell provided delayed 'on' response, while the type VI cell produced an irregular response suggesting equally strong 'on' and 'off' components. Responses from SPV cells were very variable. Glial cells appeared silent, but type XIV and XV cells were either silent or spontaneously active at a low or high level. Responses were phasic 'on'/phasic (delayed) 'off' or tonic 'on'-'off'.

AMPHETAMINE INCREASES RECEPTIVE FIELD SIZE IN THE SUPERFICIAL LAYERS OF CAT COLLICULUS. K.L. Grasse[1], R.M. Douglas [2], and J.R. Mendelson [3]. [1]Dept of Psychology, York Univ., North York, Ontario, [2]Dept of Ophthalmology, Univ. of British Columbia, Vancouver, B.C., and [3]Dept of Physiology, Univ. of Toronto, Toronto, Ontario, Canada.

Visual response properties were examined in the superficial layers of the superior colliculus (SC) of anesthetized, paralyzed cats before and after i.v. administration of dextroamphetamine sulphate. Units were tested (through the contralateral eye only) for a number of visual response properties: receptive field (RF) size and position, direction selectivity, strength of inhibitory surround, and the incidence of "on" or "off" responses. 15 minutes to 1 hour after amphetamine injections (2ml of 10mg/ml), RF size began to gradually increase. RFs expanded by some 2-10 times (mean 4.5) over the following 1-4 hours. Subsequently (i.e., 4-7 hours post-injection), RF size returned to pre-injection dimensions. In most cases, RF size did not increase equally in all directions, but rather displayed asymmetrical patterns of expansion. In addition to changes in RF size: 1) responses to flashed stimuli became much more vigorous; 2) surround inhibition, when present, usually became much weaker; and 3) no consistent effects were noted in direction selectivity. It is possible that the elevated activity levels in the SC resulting from increases in RF size, will affect the peak velocity and/or timing of visually evoked saccades.

333.8

CONTRIBUTIONS OF THE SUPERIOR COLLICULUS OF THE MONKEY TO VISUAL SPATIAL ATTENTION. Caroline Kertzman and David Lee Robinson Laboratory of Sensorimotor Research, National Eye Institute, N.I.H., Bethesda, MD 20892.

Visual spatial attention refers to the ability to select images for special use independent of eye movements. We have trained rhesus monkeys on a task developed by Posner: the animal fixates a spot of light and contacts a bar when target lights appear. Reaction times are faster for validly cued targets than for invalidly cued ones. When we injected muscimol into the superior colliculus, the animal was slow in responding to validly cued targets in the visual field contralateral to the injection. Reaction times were substantially delayed for the same target when it was preceded by a cue in the other field. The animal behaved as if it had difficulty with visual spatial attention. In control monkeys, neurons in the superficial layers of the superior colliculus were easily driven in this task. Cells in the foveal representation responded when the fixation target was in the neuron's receptive field; there was no change in activity associated with the cue (which is hypothesized to shift attention). When the cue and/or target were positioned in the visual receptive field of a neuron, cells were driven briskly. Disregarding simple refractory effects, there were no consistent and significant changes in the response of a cell to a target dependent on cue validity. The effects of pharmacological manipulation of the superior colliculus, however, show that this structure contributes substantially to visual spatial attention. These data show that the tectum has a visual function which is independent of eye movements.

333.9

MULTIPLE VISUAL MAPS IN DEEP SUPERIOR COLLICULUS OF CATS. M. A. Meredith and B. E. Stein, Depts. Anat. and Physiol. Medical College of Virginia/VCU, Richmond, VA 23298.

Topographic register among sensory representations is thought to be a critical factor in facilitating coordinated responses to a variety of sensory cues. This sort of multisensory registry has been demonstrated in the superior colliculus (SC) by relating the superficial layer retinal map to the deep laminae maps of the body and auditory space. Yet, because of the differing afferent and efferent connections of these laminae and their differing behavioral roles, this superficial-deep layer sensory register may be of little functional significance. In the present experiments, the deep laminae visual representation was examined directly. Unimodal visual neurons (n=52) had receptive fields (RFs) of intermediate size with nasal-temporal borders varying with AP and elevation varying with ML position in SC. In contrast, visual neurons that received auditory inputs (n=76) had significantly larger RFs whose nasal-temporal borders varied with AP but whose elevation was generally insensitive to different ML locations. These data demonstrate the sharing of axes by visual and nonvisual representations in the deep laminae. In addition, the differing patterns of visual RF distribution among unimodal and multisensory neurons, coupled with their different efferent projections, suggest that multiple, and functionally distinct visual maps coexist in the deep laminae. Supported by NS-22543.

SPATIAL CHARACTERISTICS OF MULTISENSORY INTEGRATION IN BEHAVING CATS. Lawrence McDade*, M. Alex Meredith and Barry E. Stein (SPON: Karl C. Corley). Depts. of Physiology and Anatomy. Medical College of Virginia/VCU. Richmond, Virginia 23298

Our previous studies have shown that a simple spatial rule characterizes multisensory integration at the cellular (superior colliculus) and behavioral levels: coincident multisensory cues produce enhancement whereas disparate stimuli produce depression (or no effect). In the present studies, we evaluated the resolution of this system behaviorally by determining the spatial separation between stimuli necessary to convert enhancement to depression. Three cats were trained to attend, orient and approach a low intensity visual stimulus at various positions along a semicircular track. A low intensity coincident auditory stimulus enhanced correct responses whereas the same stimulus inhibited correct responses when located as little as 15 degrees medial to the visual. When the auditory stimulus was 15-60 degrees lateral to the visual, it not only failed to depress correct responses but often enhanced them. This medial-lateral difference modifies the spatial rule as applied to behavior and may be due to the large excitatory receptive fields in multisensory neurons which allow stimulus position to vary widely in the periphery and still produce excitation in the same auditory-visual cells. Supported by NIH Grant NS 22543.

333.11

INTRACELLULAR HRP STUDY OF VISUAL AND INFRARED TERMINAL AND POSTSYNAPTIC CELLS IN THE OPTIC TECTUM OF THE RATTLESNAKE CROTALUS VIRIDIS. P. H. Hartline, R. V. Stirling, and D. Berson. Eye Research Institute, Boston, MA and Brown University, Providence, R.I.

The infrared sensitive pit organ of crotaline snakes sends spatial information to the optic tectum via a specialization of the trigeminal pathway. We are interested in identifying tectal cells that integrate visual information and infrared (IR) information from the pit as a step towards describing the infrastructure of multisensory integration.

We have recorded intracellulary from visual and IR terminals and postsynaptic cells in the tectum of anaesthetized snakes using bevelled HRP-filled microelectrodes. After qualitative identification of each unit's response properties to IR and visual stimuli, HRP was ejected. Filled processes were reconstructed from serial sections after DAB processing (Adams, 1981).

The infrared afferents (from nucelus reticularis caloris in the brain stem) are large diameter fibers arborizing extensively (~500 um ant/post by 500-1000 um med/lat) in the stratum griseum centrale (SGC); smaller sizes were found rostrally. This arbor size does not seem to be reflected by IR receptive field sizes of postsynaptic cells. Terminal arbors of the much finer retinal fibers are smaller and are found above SGC in stratum fibrosum et griseum superficiale.

OR neurons, which responded to both visual and IR inputs had dendrites that arborized in both upper visual and deeper IR input layers of the tectum; several different dendritic architectures were noted. Most of these were tectal output cells with crossed or uncrossed descending axons. We recovered a few neurons responding primarily to visual or IR input whose responses were modulated (enhanced or depressed) by concurrent stimulation in the other modality; these cells arborized in both superficial and deeper tectal layers. Unimodal visual or IR cells were rarely encountered, probably because of their small size.

333.12

VISUALLY ELICITED AVOIDANCE IN THE MONGOLIAN GERBIL. C. G. Ellard. Department of Psychology, Queen's University Kingston, Ontario, CANADA.

The trajectory of escape from overhead visual stimulation is poorly predicted by the trajectory of the approaching threat (Ellard and Goodale, in press). Escape responses are usually directed toward a shelter, when one is available. In the present experiment, the power of stimulus context to modify escape responses was tested by requiring animals to run toward a threat in order to reach shelter. Animals were placed in a rectangular arena for five minutes. Time sampling methods were used to record the animals' behavior during this period. Following this, an overhead visual stimulus was presented. The immediate response to the stimulus was noted and behavior was sampled for a further five minutes. Under these conditions, escape responses were directed toward the shelter on only about half the trials and only when the animal was close to the shelter at stimulus onset. This finding distinguishes escape behavior from simple "startle". Lesions of the uncrossed descending tectal efferents abolish visually elicited escape whether shelter is available or not (Ellard and Goodale, in press). The present results suggest that this pathway might have access to information regarding the location of shelter. Alternatively, tectal output may serve as a "trigger" while the details of the response are determined by modulatory influences from other brain areas.

NEURAL PLASTICITY IN ADULT ANIMALS: INDUCED EFFECTS II

334.1

THERMAL DEPENDENCE OF NEURAL ACTIVITY IN THE HAMSTER AND RAT HIPPOCAMPAL SLICE M. P. Thomas*, M. S. Krelstein*, and J. M. Horowitz. Dept. of Animal Physiology, Univ. of Calif., Davis, CA 19616.

Previous studies have shown that the temperature just below that at which a population spike could be recorded, T_t, was 4 degrees lower in a hibernator, the chipmunk, than in a nonhibernator, the rat (Hooper et al, J. therm. Biol. 10:35, 1985). In addition to this study showing phylogenetic adapation, in a study on acclimation to cold (Thomas et al. J. therm. Biol. 11:213, 1986) showed that T_t for hibernating hamsters was 12.3 $\pm$ 0.3°C (mean $\pm$ SEM) compared with the higher T_t of 15.8 $\pm$ 0.9°C for noncold-acclimated hamsters. In this study the amplitudes of population spikes evoked by Schaffer collateral stimulation (using methods described in papers cited) were measured in noncold-acclimated hamsters and rats as bath temperature was lowered from 35°C to T_t. As temperature decreased the amplitude increased to a maximum and then decreased in both hamsters and rats. Long-term potentiation (LTP) was evoked above 22°C by pulse train stimulation (15 trains at a rate of 3.33 Hz where each train was comprised of 4 shocks with an intershock interval of 10 msec). These results suggest that above 22°C the temperature effects on selected cellular mechanisms in CA1 pyramidal cells evoked by Schaffer collateral stimulation do not markedly differ in the hamster (a hibernator) and rat (a nonhibernator). Supported by NASA grant NAG 2-341.

334.2

A COMPUTER ALGORITHM FOR SEPARATING OVERLAPPING SYNAPTIC CONDUCTANCES. **Wei Su*, G.J. Pacelli* and S.R. Kelso. Dept. of Biological Sciences and Dept. of Electrical Engineering, University of Illinois at Chicago, Chicago, IL 60680.**

The activation of an afferent synaptic input to area CA1 of the hippocampus normally results in the activation of more than one type of synapse onto a single postsynaptic neuron. The resultant composite synaptic waveform comprises contributions from each conductance which are added together, or integrated in a manner determined by the electrotonic structure of the postsynaptic cell. Various experimental, pharmacological or pathological conditions can result in changes in the shape of the synaptic waveform. In such cases it is desirable to be able to determine which of the component synaptic conductances has changed. Therefore, making certain assumptions, we have begun to develop a set of computer algorithms for unambiguously breaking a composite synaptic waveform into its individual components.

We first constructed a series of waveforms composed of two alpha functions that approximated a hippocampal EPSP and IPSP and overlapped with a short delay (Brown and Johnston, J. Neurophys. 50:487, 1983). The composite waveform was thus defined by five parameters: $Alpha_{EPSP}$, K_{EPSP}, $Alpha_{IPSP}$, K_{IPSP}, and Tau. Computer algorithms were then developed which utilized an optimal search technique to decompose these waveforms and to approximate the original parameters. Finally, the algorithms were used to fit synaptic current waveforms obtained using single electrode voltage-clamp recordings in hippocampal neurons.

Supported in part by NIH grant NS24591.

334.3

A BIOLOGICALLY PLAUSIBLE IMPLEMENTATION OF A HEBBIAN COVARIANCE ALGORITHM. E.W. Kairiss, C. L. Keenan and T. H. Brown. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

A Hebbian learning mechanism is one in which synaptic modification is governed by the conjunction or covariance between pre- and postsynaptic activity. Sejnowski (*J. Theor. Biol.*, 69:385, 1977) noted that a Hebbian conjunctive mechanism that *only* produces permanent synaptic enhancement will encounter the problem of runaway instability, due to spurious coincidences, even when pre- and postsynaptic activities are uncorrelated. This runaway instability can be avoided by assuming rapid passive decay of the synaptic enhancement.

But what about more durable information storage? A Hebbian covariance mechanism can avoid the instability problem without incorporating rapid passive decay of the synaptic modifications (Sejnowski, *ibid*). Positive correlations produce synaptic enhancement and negative correlations produce synaptic depression. A covariance-type of synaptic mechanism may account for aspects of the normal self-organization of the visual system (Linsker, R., *Proc. Nat. Acad. Sci. USA*, 83:7508, 1986) as well as certain disruptive effects of monocular occlusion (Wiesel, T.N. and Hubel, D.H., *J. Neurophysiol.*, 26:1003, 1963; Reiter, H.O. and Stryker, M.P., *Proc. Nat. Acad. Sci. USA*, in press) on visual cortical development (Brown, T.H. *et al*, *Ann. Rev. Neurosci.*, submitted).

Our simulations have suggested ways to construct, from known neurobiological phenomena, synaptic computations that share some of the desirable features of a covariance mechanism. One solution is just a sum of three identified types of synaptic plasticity--a conjunctive type of synaptic enhancement and two types of synaptic depression. This three-process synaptic mechanism avoids the instability problem and offers a biologically plausible synaptic substrate for certain of the developmental phenomena cited above (Brown, T.H. *et al, ibid).* Our results immediately raise the question as to whether these three forms of plasticity actually co-occur in the same synapses or local circuits. *(Supported by the MRC and AFOSR)*

334.4

LOW-FREQUENCY SYNAPTIC DEPRESSION IN THE IN VITRO DENTATE GYRUS FOLLOWING PICROTOXIN BLOCKADE OF GABA MEDIATED INHIBITION. P.C. Rinaldi and T.A. Leach*. Dept. of Surgery, Div. of Neurosurgery, Univ. of California at Irvine, Irvine, CA 92717.

Low-frequency synaptic depression (LFD) and habituation may play an important role in the modulation of the flow of information through adaptive neural networks. The hippocampal formation, specifically the perforant input to dentate granule cells, provides an excellent system in which to investigate LFD in mammalian brain. As part of on-going efforts to investigate LFD at this synapse, experiments have been conducted employing the GABA blocker picrotoxin to aid in determining the influence that GABA mediated inhibition may have on LFD in this network. Field potentials reflecting population spike or dendritic responses were observed during LFD and compared to the same measure obtained from the same tissue following exposure to picrotoxin.

Hippocampal slices from rats were conventionally prepared and maintained. Responses to bipolar electrode stimulation of the perforant path inputs were recorded with micropipettes and evaluated on-line. The rate of stimulation during control and recovery periods was 1 every 30 seconds; during the intervening period for LFD it was 1 Hz.

Following picrotoxin exposure of 40 to 80 minutes, lower thresholds, enhanced population spike and more synchronous firing were seen. In addition, a secondary population spike often occurred. There was less LFD under picrotoxin when comparisons were made with stimulus intensity held constant. Results with threshold held constant tended toward more depression under picrotoxin. Results are consistent with an increase in granule cell excitability through release of GABA mediated inhibition. (Supported by NIH grant NS22980-01A1 to PCR.)

RELATIONSHIP OF ELECTROGRAPHIC MEASURES TO BEHAVIOURAL SEIZURE DEVELOPMENT DURING AMYGDALOID KINDLING: A MULTIVARIATE ANALYSIS. G.C. Teskey, K.-P. Ossenkopp, and D.P. Cain. Dept. Psychology, Univ. of Western Ontario, London, Ontario, Canada, N6A 5C2.

During kindling, the most commonly employed electrographic measure used to assess seizure development has been duration of after-discharge (AD). However, several other electrographic measures can also be quantified.

Male Royal Victorian hooded rats were stimulated and AD recorded thru bilaterally implanted bipolar nichrome electrodes in the amygdala. Five different electrographic measures of AD were examined; i) duration, ii) number of spikes, iii) amplitude on stimulated side, iv) amplitude on contralateral side, and v) spike frequency. The five electrographic measures and Racine's behavioural classification of seizure stage were recorded on each session to give an indication of kindling progession. A multiple regression technique was used to assess the importance of each electrographic measure as a predictor of behavioural stage and the amount of variation which can be accounted for by each electrographic measure.

Results indicate that amplitude on the contralateral side correlates best with the behavioural seizure and can account for approximately 62% of the variation in seizure behaviour. Supported by NSERC.

ROLE OF AMYGDALOID COMPLEX IN SHORT AND LONG TERM EFFECTS OF REPEATED ELECTROCONVULSIVE SHOCK. V Leviel* C.Fayada* B.Guibert*, N.Faucon* G.Machek* and R Naquet. Lab de neurophysiologie, CNRS 91198 Gif sur Yvette, France

The short and long term effects of repeated electroconvulsive shocks were compared. To this purpose rats were submitted to a series of ten daily electroconvulsive shocks and sacrificed 24 Hr or 30 days after the last stimulation. Three different neurotransmi tory systems were investigated in discreet brain regions a)The enzyme activity of tyrosine hydroxylase (TH) and the messenger RNA (TH-mRNA) levels were measured. b)The activity of glutamic acid decarboxylase (GAD) was evaluated as well as the corresponding messenger RNA (GAD-mRNA) c)The tissue concentration of Met enkephalin and also the mRNA encoding for its precursor (PPE-mRNA) was determined

In the 24-hr group, nearly all of the parameters considered increased. TH-mRNA level increased two fold compared to the control value in the ventral tegmental area (VTA) as well as in the locus coeruleus (LC). The major effect on TH activity was in the central nucleus of amygdala (ACE) where increases of Met and PPE-mRNA were also detectable. Alterations in the enzyme or mRNA levels were not detected in the substantia nigra or in the striatum.

Analysing 30-day group, Met and PPE-mRNA remained higher than control in ACE, but, in contrast to the 24-hr group, TH activity and TH-mRNA quantities were returned to basal level in LC and were significantly decreased in VTA. Simultaneously, TH activity was also lowered in ACE

These results suggest that antidepressive therapy by repeated electroconvulsive shock could implicate an alteration in monoaminergic control of ACE from VTA and LC. The changes in TH-mRNA suggest the enzymatic induction as a possible mechanism of this alteration.

A POSSIBLE ANATOMICAL MARKER FOR ENDOGENOUS LTP. N. L Desmond and W. B Levy. Dept. Neurosurgery, Univ. Virginia Sch. of Med., Charlottesville, VA 22908.

LTP of the entorhinal cortical (EC)-dentate gyrus (DG) synaptic response correlates with morphological changes at these synapses. Previously we hypothesized that the concave spine synapses represent the population of potentiated synapses. Compared with the control synapses, a set of features is consistently associated with the potentiated synapses: a postsynaptic concavity at the synaptic interface, bigger spine heads, bigger PSD and membrane apposition surface areas, an increased number of front-line synaptic vesicles, wider spine stems, and a lower probability of a polyribosome at the base of the spine stem. In the absence of stimulation-induced LTP, this same set of synaptic features also distinguishes synapses in the DG so that EC-DG concave spine synapses normally are different from EC-DG noncon-cave spine synapses. For example, the mean membrane apposition surface area per concave spine synapse is 9.5 ± 0.7 um^2/100 um^3 while a simple spine synapse has on average 3.9 ± 0.2 um^2/100 um^3 membrane apposition surface area. Similarly, the mean number of front-line synaptic vesicles along the membrane apposition trace length is 9.3 ± 0.9 for the concave spine synapses and is 4.0 ± 0.4 for the simple spine synapses. Since the postsynaptic concavity correlates with the same set of features whether or not stimula-tion-induced LTP has occurred, we hypothesize that the concave spine syn-apses with their set of defining idiosyncratic features are markers for endogenous LTP. If true, the concavity of a spine synapse will identify associative synaptic potentiation, at least for those excitatory axospinous synapses using an acidic amino acid transmitter and possessing NMDA receptors, and can be used to identify LTP as a physiological correlate of learning. NOVEL MORPHOLOGICAL CHANGES IN HIPPOCAMPAL DENTATE GRANULE CELL PERIKARYA FOLLOWING RECURRENT LIMBIC SEIZURES. M.C.Bundman, R.M. Pico, J.Athanikar* and C.M.Gall. Departments of Anatomy and Neurobiology and Pharmacology, University of California, Irvine CA 92717

Recurrent limbic seizures stimulate increased enkephalin synthesis by the dentate gyrus granule cells and lead to changes in the synaptic vesicle populations within their mossy fiber terminal boutons which covary with alterations in enkephalin content. In the present study the influence of seizure activity on the ultrastructural morphology of the granule cell perikarya was examined.

Experimental rats received a unilateral electrolytic lesion in the dentate gyrus hilus; this treatment leads to intermittent limbic seizures which recur from 1.5 to 10 hrs postlesion. At 5 hrs postlesion, hilus lesion (HL) rats with behaviorally verified seizures and paired anesthetic-controls were sacrificed and the internal blade of dentate gyrus stratum granulosum contralateral to the lesion, was prepared for electron microscopy.

In HL rats, there was a striking increase in the number of somatic spines and points of association of the nuclear membrane (NM) with the granular endoplasmic reticulum (GER) . Granule cell somatic spines were rare in control rats (n=3; 5 spines/1,463µm plasma membrane from 62 cells) whereas in HL rats numerous well-elaborated somatic spines were easily identified (n=4; 36 spines/1,723µm plasma membrane from 73 cells). Moreover, a 3-fold increase in the number of NM/GER continuities was found in the HL rats (n=3; 170 continuities/1,074µm NM from 42 cells) as compared to controls (n=3; 57 continuities/1,038µm NM from 42 cells).

The present quantitative analyses demonstrate changes in the NM/GER association that are coincident with seizure-induced alterations in granule cell synthetic activities and indicate that hippocampal seizure activity stimulates the formation of new somatic spines on the dentate gyrus granule cells.

INCREASE IN THE RATIO OF "PERFORATED" TO "NONPERFORATED" SYNAPSES DURING HIPPOCAMPAL KINDLING IS SPECIFIC FOR THE SYNAPTIC FIELD OF STIMULATED AXONS. F. Morrell, Y. Geinisman and L. deToledo-Morrell. Depts. of Neurol. Sci. and Psychol., Rush Med. Coll. and Dept. of Cell Biol. & Anat., Northwestern Univ. Med. Sch., Chicago, IL 60612.

We recently demonstrated that an increase in the proportion of "perforated" to "nonperforated" synapses occurred in the terminal field of stimulated axons during hippocampal kindling (Morrell et al., *Epilepsia*, 1987, **28**: 617; Geinisman et al., *Proc. Natl. Acad. Sci. USA*, 1988, in press). The present study was designed to elucidate whether this structural synaptic modification was restricted to the terminal field of stimulated axons or whether neighboring but not directly stimulated regions showed the same modification. To answer this question, we performed a comparative analysis of the middle (MML) and inner (IML) molecular layer of the hippocampal dentate gyrus. The MML is a directly stimulated structure; the IML is not. The two are immediately adjacent synaptic fields likely to be equally susceptible to any generalized changes resulting from convulsions or anoxia. Rats were kindled via medial perforant path stimulation (1 msec pulses at 60 Hz for 2 sec, twice a day) and examined morphologically 4 weeks after reaching a criterion of 5 generalized seizures. Implanted but unstimulated rats served as controls. The number of synapses per neuron was assessed both in the IML and in the MML using the unbiased stereological disector technique. Axospinous synapses with continuous or discontinuous postsynaptic densities ("nonperforated" or "perforated" synaptic contacts) were differentially quantified. Results indicated that both "perforated" and "nonperforated" synapses were decreased in numbers (by 29 and 30%, respectively) in the IML of kindled rats compared with controls. Thus, there was no change in the ratio of one synaptic type to another. In the MML, on the other hand, a decrease in the number of "nonperforated" synapses was associated with a 46% increase in the ratio of "perforated" to "nonperforated" junctions in kindled animals. This finding supports the notion that the alteration in the ratio of the synaptic types during kindling is specific to the stimulated circuit. Such an alteration is not a consequence of nonspecific or generalized effects, but is rather a manifestation of neuronal plasticity tuned to the source of the synaptic drive.

"PERFORATED" SYNAPSES ON DOUBLE-HEADED DENDRITIC SPINES: A STRUCTURAL MODIFICATION INDICATIVE OF SYNAPTIC PLASTICITY. Y. Geinisman, L. deToledo-Morrell and F. Morrell. Dept. of Cell Biol. & Anat., Northwestern Univ. Med. Sch. and Depts. of Neurol. Sci. and Psychol., Rush Med. Coll., Chicago, IL 60611.

Examination of axospinous synapses in serial sections obtained from the molecular layer of the rat dentate gyrus has revealed that some of them involve double-headed dendritic spines. Such a spine is attached to a parent dendrite by a single stalk. From the stalk emanates a neck which divides into two branches, each one terminating as a complex-shaped head. Each spine head is involved in a synaptic contact, and two synapses on a double-headed spine are invariably characterized by the following distinctive features: (1) they are formed by two separate axon terminals and (2) they belong to the type of "perforated" synapses distinguished by a discontinuous postsynaptic density. The convergence of two presynaptic axon terminals on a single spine may result in summation of their actions and extensive amplification of synaptic transmission. The latter effect may be further augmented by the existence of two "perforated" synapses on a single spine, since such synaptic contacts are believed to be more efficacious than "nonperforated" ones. The validity of the assumption regarding an amplification of synaptic action was tested in an experiment using kindling to induce a long-lasting enhancement of synaptic efficacy. Rats were kindled via medial perforant path stimulation and examined 4 weeks after reaching a criterion of 5 generalized seizures. Unstimulated but implanted rats served as controls. "Perforated" synapses on double-headed spines were quantified in the middle molecular layer of the hippocampal dentate gyrus with the aid of the unbiased stereological disector technique. Estimation of the number of these synapses per neuron showed that they constitute only about 2% of the total population of "perforated" axospinous synapses in control animals; in kindled rats, however, they were significantly increased in numbers (from 3.52 per neuron in controls to 6.05 in the kindled group). These results support the notion that "perforated" synapses on double-headed dendritic spines represent a structural modification related to enhanced synaptic efficacy.

PARADOXICAL CHANGES IN SYNAPTIC TRANSMISSION IN THIAMINE DEPLETED RATS. N.W.Milgram, P.A. Nellis and G.O. Ivy. Div. of Life Sciences, Univ. of Toronto, Scarborough, Ontario, M1C1A4.

Rats were chronically prepared with stimulating electrodes in the perforant path and recording electrodes in the dentate gyrus using electrophysiological guidance to obtain evoked field potentials characteristic of this pathway. Following recovery, intensity response functions were taken and a curve fitting routine was used to quantify thresholds, rates of rise and asymptotic response levels. After establishing stability, the animals were placed on a thiamine deficient diet and treated daily with pyrithiamine (1mg/kg). The most striking effect was a dramatic potentiation in population spike amplitude (mean=75%) which only became apparent after about 10 days, coinciding with the appearance of acute neurological signs. Spike threshold, in contrast, increased gradually to an average level of 160%. In addition, the spike onset latency was either unaffected or increased. Histological analysis of the forebrain revealed a pattern of pathology encompassing the dorsal medial, ventral lateral and lateral dorsal thalamic nuclei. The concurrent increase in both amplitude and threshold is unprecedented, and may indicate that thiamine depletion affects both excitatory and inhibitory processes. Supported by NSERC.

ION CHANNELS: SODIUM CHANNELS II

335.1

DISTRIBUTION OF SODIUM CHANNELS ON DENDRITES OF IDENTIFIED VERTEBRATE NEURONS: IMMUNOCYTOCHEMISTRY AND ELECTROPHYSIOLOGY M. Ellisman, L. Maler, R.W. Turner, S.R. Levinson (UCSD, Univ. Ottawa, Univ. Colo. Boulder).

Sodium channels are responsible for initiating and propagating action potentials as well as participating in the setting of a neuron's threshold. It has been suggested that sodium channels are located primarily at nodes of Ranvier and the initial segment and that their density falls off rapidly over the proximal dendrites. We have used antibody directed against the sodium channel from electric eel electroplaque to examine the distribution of sodium channels on physiologically characterized, identifiable neurons in the brain of the related gymnotiform species, Apteronotus leptorhynchus. Our initial studies demonstrated that the sodium channel distribution is tightly controlled, being found over the somatic and dendritic surface of pacemaker cells but excluded from these regions in sensory neurons which are driven at the pacemaker frequency (Maler et al., '87). We now report on the distribution of sodium channels on pyramidal cells of the electrosensory lateral line lobe (ELL) first order sensory area for the electrosensory system. In vitro studies have shown that these neurons have, in addition to the action potential, two types of sodium dependent potentials: a slow persistent inward current and rapid small potential shifts resembling the D-spikes of hippocampal pyramids (Mathieson & Maler, in press). Immunocytochemistry (light microscopy, EM, and high voltage EM) on normal material and on physiologically characterized cells from the ELL slice filled with HRP, revealed that sodium channels were distributed in patches on both apical and basilar dendrites of the pyramidal cells, but were rarely found on the somatic surface. Purkinje cells located in the same tissue section had far fewer such patches on their dendritic surface. Localized application of TTX was employed to correlate the anatomic distribution of sodium channels and the electrical activity of these cells.

DIRECT IMMUNOGOLD LABELING OF Na^+ CHANNEL IMPs IN FREEZE-FRACTURE REPLICAS. J. E. Rash[1], T.J.A. Johnson[1*], J. E. Dinchuk[2*], D.S. Duch[3], and S.R. Levinson[4]. Depts. of Anatomy and Neurobiology[1] and Pathology[2], Col. State U., Ft. Collins, CO 80523, Dept. of Anesthesiology3, Cornell Univ. Med. Sch., NY, 10021, and Dept. of Physiology[4], U. Col. Health Sci. Center, Denver, CO 80262.

Reconstituted membrane vesicles containing purified Na^+ channels from E. electricus as their only proteins were freeze-fractured and replicated. Replicated vesicles were thawed in "labeling blocking buffer," labeled with rabbit anti-Na^+ channel polyclonal Ab, counter-labeled with affinity-purified goat anti-rabbit Ab on 10 nm gold, and rinsed carefully. In these "replica-label-whole mounts," <10% of the area was occupied by vesicles and >90% by extravesicular matrix, but >90% of gold granules were associated with vesicles. Of this "vesicle specific" labeling, ca. 25% were within 20 nm of IMPs, ca. 25% were attached to unreplicated portions of vesicles (where Na^+ channel proteins were equally likely), ca. 25% were associated with deeper (unreplicated) layers of multilamellar vesicles, and ca. 15% were not associated with IMPs. Occasionally, distinctive co-patterning of IMPs and gold granules was discerned. To estimate "labeling efficiency," we presumed that Na^+ channel proteins are oriented at random in the membrane bilayer, thereby eliminating 50% from potential labeling. Of the remaining sites, approximately 30% were labeled. Based on relative ratio of apparent specific to non-specific labeling, proximity of labels to IMPs, and "sidedness" as revealed in stereoscopic images, we conclude that Na^+ channel IMPs in a simple model system were identified by direct immunogold labeling.

IMMUNOCYTOCHEMICAL LOCALIZATION OF SODIUM CHANNEL SUBTYPES R_I AND R_{II}. R.E. Westenbroek* and W.A. Catterall . Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195.

The voltage sensitive sodium channel is a transmembrane protein responsible for the rising phase of the action potential in electrically excitable tissue. Affinity-purified anti-peptide antibodies distinguish between the α subunits of sodium channel subtypes R_I and R_{II} in rat brain, and immunoprecipitation experiments have shown that R_I and R_{II} are expressed primarily in the central nervous system with R_{II} predominant in brain and R_I predominant in spinal cord (Gordon et al, *PNAS* 84:8682-8686). These antibodies have been used in combination with the indirect peroxidase-anti-peroxidase technique to investigate the distribution of R_I and R_{II} in the brain and spinal cord of adult rats. Light microscopic studies have revealed that the overall immunoreactivity for R_{II} decreases from rostral to caudal with intense staining in several brain regions and diminished staining in the spinal cord. Throughout the extent of the substania nigra there is dense labeling of fibers. In the CA1, CA2 and CA3 regions of the hippocampus, axons, but not the somata, of pyramidal neurons are immunoreactive for R_{II}. Dense immunoreactivity is present in the molecular layer of the cerebellum containing Purkinje cell axons. However, the cell bodies of Purkinje cells, interneurons and granule cells are not labeled. In addition, punctate staining of neurons and their processes is observed in the supraoptic and paraventricular nuclei. Throughout the extent of the spinal cord, R_{II} positive fibers are present mainly in the dorsal laminae 2 and 3 with relatively little immunoreactivity observed in the ventral horn.

Immunoreactivity for R_I is most apparent in the spinal cord. There is a dense band of R_I positive fibers and/or terminals located mainly in lamina 2 and/or 3, with general immunoreactivity throughout the remainder of the dorsal and ventral horns. The somata of neurons located in the ventral horn are also labeled by R_I antibodies. Overall, our results illustrate a complex distribution of the R_I and R_{II} subtypes among individual cell groups and fiber tracts in the central nervous system.

Na CHANNELS IN FETAL DIFFERENTIATING NEURONS.
M. R. WOOD, G. STRICHARTZ*, L. ELMER**, K. ANGELIDES** and K.H. PFENNINGER, UNIV. COLORADO HEALTH SCIENCES CENTER, DENVER, CO. 80262. *HARVARD MEDICAL SCHOOL, BOSTON, MA. 02115. **BAYLOR COLLEGE OF MEDICINE, HOUSTON, TX. 77030.

Previous studies on STX/TTX binding to CNS growth cones (GCPs) from E18 fetal rats have demonstrated both high- and low-affinity Na channels (K_D 0.32, 4.0 nM). In comparable synaptosomal preparations, only a high-affinity binding site (K_D 0.76 nM) was demonstrable, but it was much more abundant than all binding sites in GCPs (Wood et al., 1987, J. Cell Biol. 105, 143a).
We now report data from competition experiments indicating that there are no TTX-resistant STX binding sites present in GCPs. Western blots of synaptosomes and GCPs were treated with polyclonal Na channel antibodies and ^{125}I-second antibody. This revealed an equally high level of immunoreactivity in GCPs compared to synaptosomes with the same protein loading. Antibodies to specific synthetic peptides of rat brain Na channels recognize polypeptides of different M_r in synaptosomes versus GCPs. This provides further evidence for a different type of Na channel in growth cone membranes. These findings are relevant to the maturation of neuronal plasmalemma and the development of its functional domains. (Supported by NIH NS-24676 grant to K.H.P.)

335.5

ANTIBODIES AGAINST A CONSERVED INTRACELLULAR SEGMENT SLOW SODIUM CHANNEL INACTIVATION. P.M. Vassilev*, T. Scheuer* and W.A. Catterall. (Spon: M. Ahlijanian) Dept. of Pharmacology, SJ-30, University of Washington, School of Medicine, Seattle, WA 98195.

The primary amino acid sequence of the α-subunits of Na channels in some excitable membranes has been defined, but the relationships between molecular structure and mechanisms of channel gating remain unclarified. The effects of four antibodies, directed against different predicted intracellular segments of the α-subunits, have been tested on whole cell sodium currents in rat skeletal muscle cells. An affinity-purified antibody (anti-SP19) directed against a highly conserved amino acid sequence in the intracellular segment between domains III and IV (residues 1540 to 1557 of R_{II}) induced a substantial slowing of the inactivation kinetics which was blocked by the corresponding peptide. At a holding potential of -110 mV the intracellular application of the antibody increased the time constant of the Na current decay from 2.28 to 4.37 ms during a test pulse to -20 mV. A similar effect was observed at a holding potential of -70 mV, but its onset following seal formation occurred at a three-fold slower rate than at -110 mV. A dependence upon the test pulse potential was also observed. Slowing of inactivation was small for pulses to -50 mV, but was more pronounced at more positive test potentials up to 90 mV. Antibodies directed against distinct amino acid sequences in other intracellular segments of the R_{II} α-subunit did not significantly affect Na channel inactivation. These results identify a highly conserved intracellular segment between domains III and IV of the α-subunit which may be involved in the channel inactivation mechanism.

335.6

MOLECULAR MAPPING AND CLONING OF THE *DROSOPHILA TIP-E* LOCUS -- A MUTATION AFFECTING VOLTAGE-SENSITIVE SODIUM CHANNELS. D. W. Gil*, D. P. Kasbekar*, P. Deak* and L. M. Hall. Dept. of Genetics, Albert Einstein College of Medicine, Bronx, NY 10461.

The *tip-E* mutation causes temperature-induced paralysis, reduces the number of saxitoxin binding sites in membrane extracts and decreases the sodium current in patch clamped embryonic neurons (O'Dowd, D. K. and Aldrich, R. W., J. Neurosci., in press). In order to understand how the *tip-E* gene product affects sodium channel properties, we are cloning the gene by chromosome walking.

We have generated chromosome rearrangements that uncover the *tip-E* phenotype and used them to localize the gene to a region (64A4-B12) on the left arm of the third chromosome. In addition to *tip-E*, this region contains several other neuronally expressed genes, including a *Drosophila ras* oncogene and an acetylcholine receptor subunit homolog. We have mapped these genes with respect to the chromosome rearrangement breakpoints by hybridizing them to genomic Southern blots and to salivary gland squashes. Using these clones as starting points for a walk through the *tip-E* region, we are identifying clones that cross the breakpoint of a translocation that results in a *tip-E* phenotype. We will then use transposon mediated transformation to rescue *tip-E* embryos with clones that span this translocation break.

CLONING AND CHATACTERIZATION OF A NOVEL VOLTAGE-GATED SODIUM CHANNEL. V. Auld+*, A. Goldin'*, D. Krafte'*, J. Marshall+*, J. Dunn+*, W. Catterall"*, H. Lester'* N. Davidson'*, and R. Dunn+*. (SPON: K. Johnston) +Dept. Medical Genetics, University of Toronto, Toronto, M5S 1A8, 'Church Chemical Laboratories, CalTech, Pasadena, CA 91125 "Dept. Pharmacology, University of Washington, Seattle, WA 98195.

We have cloned and constructed a full length cDNA encoding the rat brain Na channel ∝ subunit. The encoded ∝ subunit differs from the Rat2 ∝ subunit of Noda et al (Nature, 320:188, 1986) at six amino acid positions. RNA was transcribed in vitro from this cDNA and injected into Xenopus oocytes to produce functional sodium channels. Although the primary sequences of the two ∝ subunits were almost identical, the current-voltage relationship for channels produced from our cDNA was shifted 20-25 mV in the depolarizing direction compared to that reported for the Rat2 subunit (Stuhmer et al, Eur. Biophys. J., 14:131, 1987). It is likely that one or a combination of the six varient amino acids is responsible for this shift in the current-voltage relationship. Each of the amino acids has been altered by site directed mutagenesis to the corresponding residue found in the Rat2 ∝ subunit. Voltage clamp analysis of the channels produced from these mutants provides evidence for the location of structural domains in the sodium channel subunit which are important for the voltage dependent channel opening.

335.8

SUBTYPE-SELECTIVE BLOCK OF SODIUM CHANNELS BY ZINC STUDIED AT THE SINGLE CHANNEL LEVEL IN PLANAR BILAYERS. A. Ravindran* and E. G. Moczydlowski. Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The divalent cation, Zn, has been implicated as a subtype-specific inhibitory modulator of glutamate-activated channels in mammalian brain. In what may be an analogous situation, certain Na-channel subtypes that exhibit low affinity for tetrodotoxin (TTX) have been found to be more sensitive to Zn than TTX-sensitive subtypes. We compared the effect of Zn and other divalent cations on batrachotoxin-activated Na-channels from rat skeletal muscle (TTX-sensitive) and canine heart (TTX-insensitive) after incorporation into planar lipid bilayers. External Mg, Ca, Sr, Ba, Mn, Co and Ni induced a fast voltage-dependent block (decreased unit conductance) in both types of channels. The following values were obtained for apparent blocking K_D's (in mM) at 0 mV and symmetrical 0.2 M NaCl, pH 7.4: Mg (48), Ca (40), Sr (72), Ba (88), Mn (18), Co (13), Ni (15) for muscle and Mg (51), Ca (41), Sr (75), Ba (76), Mn (20), Co (15), Ni (13) for heart. In contrast to the similar affinity of these cations for the two subtypes, Zn blocked the muscle subtype with a low affinity (K_D =11 mM) and the heart subtype with a 120-fold higher affinity (K_D =0.09 mM) at 0 mV. In contrast to a fast block by Zn for the muscle channel, Zn induced brief closing events in the heart channel with a mean duration of about 20 ms from -60 to +60 mV. The frequency of Zn-induced blocking events was both concentration and voltage dependent, indicating a voltage-dependent association rate for Zn. (NIH AR38796)

335.9

DIFFERENTIAL SENSITIVITIES TO Na+-CURRENT BLOCKADE BY TTX AND COCAINE IN N1E-115 AND RAT DORSAL ROOT GANGLION (DRG) CELLS. **J.M. Frey, K.C. Chinn*, C.P. Bianchi and T. Narahashi. Depts. of Pharmacology and Medicine/ Div. Toxicology, Northwestern Univ. Med. Sc., Chicago, IL 60611 and Thomas Jefferson Med. Col., Philadelphia, PA 19107.**

The convulsant properties of cocaine are well known and may involve the disinhibition of neuronal pathways within brain. We have examined the effects of cocaine HCl (COC) and TTX on Na+ currents by the whole cell patch clamp technique in two cell populations, the mouse neuroblastoma cell line N1E-115 (NB) grown in cell culture and DRG neurons acutely dissociated in papain/collagenase-disp./cysteine. Peak Na^+ currents (I_{Na}) were compared in experiments conducted at room temperature with Co++ and Cs++ to eliminate Ca++ and K+ currents. Peak inward I_{Na} averaged 4.5±0.8 and 3.7±0.8(SEM)nA in NB and DRG, resp. DRG neurons were less sensitive to TTX, requiring at least 5μM and up to 10μM to eliminate I_{Na}. In NB, TTX produced complete block at 1μM. COC block was time-dependent and irreversible, shifting Na+ IV curves up and to the right with maximal effect at 20-30min in both cell populations. In NB, COC (10^{-4}M) blocked I_{Na} by 39.3±3.2% at 20 min. In DRG, the same concentration produced 89.0±1.7% block. NB cells incubated in COC at least 1 hr and then patched, exhibited I_{Na} >2.5nA, whereas I_{Na} in 70% of DRG were blocked to <1nA. I_{Na} was slower in DRG than in NB. Certain cell populations may be at risk to COC even though they may exhibit low sensitivity to classical Na+ channel blockers.

335.10

GATING OF BATRACHOTOXIN-ACTIVATED Na CHANNELS IS ALTERED BY SCORPION VENOM IN PLANAR LIPID BILAYERS. M. E. O'Leary* and B. K. Krueger, Dept. of Physiology, Univ. Maryland Sch. of Med. Baltimore, MD 21201.

The effects of *Leiurus quinquestriatus* scorpion venom (LqV) on rat brain Na channels were studied in planar bilayers. In the presence of batrachotoxin (BTX), Na channels do not inactivate, however, BTX-activated Na channels still display voltage-dependent activation with the midpoint of the open probability (P_o) vs V_m relation about -90 mV. In the presence of BTX, LqV altered channel gating so that P_o remained > 0.95 at hyperpolarized potentials to -135 mV, the most negative potential tested. The single channel conductance (25 pS in symmetrical 250 mM NaCl) was not affected by LqV, moreover, LqV+BTX-activated channels displayed normal voltage-dependent block by nanomolar external STX (e-fold change in K_i/37 mV). The LqV+BTX-activated channels were also blocked by external Ca^{2+} in a voltage-dependent manner. The results suggest that even with inactivation removed by BTX, LqV alters Na channel gating without affecting site 1 toxin binding or Na^+ permeation. Supported by NIH & USAMRDC.

PRESENCE AND SIGNIFICANCE OF TETRODOTOXIN SENSITIVE SODIUM CHANNELS IN CAROTID BODY CHEMORECEPTOR CELLS. A. Rocher*, A. Obeso*, C. Gonzalez and B. Herreros* (SPON: M. Rodrigo Angulo). Depto. Bioq. Biol. Mol. y Fisiol. Fac. Med. Universidad de Valladolid. 47005-Valladolid (Spain).

There are clues that depolarization of chemoreceptor cells is an early event in their secretory response when stimulated by low pO_2. We explored the presence in type I cells of tetrodotoxin (TTX)-sensitive Na^+ channels as devices to generate the suspected depolarization.

Rabbit carotid bodies (c.b.) were loaded with ^{3}H-dopamine (^{3}H-DA) by incubation with 20 uM ^{3}H-tyrosine. ^{3}H-DA loaded c.b. were superfused with saline solutions at different pO_2 tensions or with veratridine either with or without TTX. We found: 1) Veratridine evokes ^{3}H-DA release in a dosis-related fashion. 2) Veratridine evoked release was dependent on Na^+_o and Ca^{++}_o. 3) Veratri- (50 uM) evoked release was blocked by TTX (1 uM). 4) Low pO_2 (0-40 torr) evoked release was partially inhibited by TTX (1 uM), being greater the inhibition at lower pO_2. These findings indicate that chemoreceptor cells posseses Na^+ channels and their involvement in the physiological stimulus-secretion reaction.

CARDIOVASCULAR EFFECTS OF 1-METHYL-4-(1-NAPHTHYLVINYL) PIPERIDINE HYDROCHLORIDE T.R. Henderson, E. M. DeLorme, K. Takahashi, A. P. Gray and K. L. Dretchen. Dept. of Pharmacology, Georgetown Univ. Sch. of Med. and Dent., Washington, D.C. 20007 and the Dynamac Coproration, Rockville, MD 20852.

1-Methyl-4-(1-naphthylvinyl) piperidine (B-120), in a dose range of 1 to 10 mg/ kg, produced up to a 70% decrease in systolic, diastolic and mean blood pressure without a corresponding change in heart rate in cats. The hypotensive effects were still observed in the presence of hexamethonium and atropine. B-120 did not alter the cardiovascular response to acetylcholine or vagal stimulation. Also, it did not alter the response of the nicti tating membrane to either pre- or post-ganglionic stimulation. In a rat cortical synaptosome preparation, B-120 (100 um), diminished both potassium-stimulated and basal calcium flux by 75%. In this regard, B-120 was equipotent to verapamil. B-120 has been previously reported to reduce organophosphate toxicity (J. Med. Chem. 31:807, 1988) in mice and guinea pigs. It seems likely that the organophosphate protection seen with B-120, as well as its hypotensive effects, may be related to its capacity to block calcium channels.

INDUCTION OF STX-SENSITIVE SODIUM CHANNELS IN CULTURED ASTROCYTES. P.J. Yarowsky, D.S. Brougher* and B.K. Krueger. Depts. of Pharmacology & Experimental Therapeutics and Physiology, Univ. of Maryland Sch. of Med., Baltimore, MD 21201

Tracer flux and STX binding studies reveal a progressive change in the STX affinity of cultured neonatal rat astrocyte Na channels. Low STX affinity Na channels (K_d > 40 nM) were present from the first through the fourth week in culture. High STX affinity Na channels (K_d = 0.4 nM) were present at very low levels during the first week, but increased rapidly over the next 5 days reaching a maximum (2.2 pmol/mg protein) by the end of the second week. This spontaneous change in STX affinity was coincident with changes in morphology, from polygonal cells with few processes to stellate cells with numerous processes. Replacing standard medium (MEM + 10% FCS) with serum-free, chemically defined medium at day 7 induced morphological differentiation within 15 hr in all cells. This change in medium also rapidly increased the proportion of high STX affinity channels to 62% at a time when they normally constituted only 5%. Although serum-free medium promotes the appearance of oligodendrocytes, we found no saturable STX binding to purified cultures of oligodendrocytes. Since low STX affinity channels were still present in these chemically defined cultures, both high and low STX affinity Na channels probably exist in mature stellate astrocytes. (Support: NIH and NSF)

INTENSITY-DEPENDENT SHIFT IN THE SITE OF ORIGIN OF ORTHODROMIC ACTION POTENTIAL DISCHARGE IN CA1 HIPPOCAMPAL PYRAMIDAL NEURONS. R.W. Turner*, D.E.R. Meyers and J.L. Barker. Lab. of Neurophysiology Nat. Inst. Health, Bethesda, MD 20892 (SPON: K.C. Marshall)

Synaptic depolarization of CA1 hippocampal pyramidal cells (HPC) is thought to evoke Na^+-dependent spike discharge at both the axon hillock and one or more dendritic sites containing a high density of Na^+ channels. The present study examined the site of origin of stratum radiatum (SR)-evoked spike discharge in the rat hippocampal slice preparation. HPC somatic and dendritic spike discharge was examined by testing the sensitivity of intra- and extracellular potentials recorded in the cell body layer (soma/axon hillock) and proximal apical dendrites to local application of TTX (40 μM).

At moderate to high stimulus intensities SR stimulation evoked a fast negative population discharge in proximal dendrites with shorter peak latency than the cell body population spike. TTX ejection to the somatic region reduced the cell body population spike with little change in the proximal dendritic negativity. In contrast TTX restricted to proximal dendrites reduced both the dendritic and cell body population discharge. At threshold, SR-evoked proximal intradendritic spikes were blocked in an all-or-none manner by TTX ejection to the cell body layer. At higher intensities the same ejection abolished the cell body population spike but reduced the intradendritic spike by <20%. Blockade of the intradendritic spike occurred subsequent to diffusion of TTX to the proximal dendrites.

The results suggest that at threshold SR-evoked spike discharge originates in or near the cell body layer. Higher intensities of activation shift the site for spike initiation from the cell body layer into the proximal apical dendritic region.

[^{14}C]GUANIDINIUM ION INFLUX INTO MOUSE BRAIN SYNAPTOSOMES AS A MODEL FOR $^{22}Na^+$ ION INFLUX M.E.A. Reith. Center for Neurochemistry, Nathan S. Kline Institute for Psychiatric Research, Ward's Island, New York, NY 10035.

Voltage-dependent sodium channels are permeable to a number of small organic cations including guanidinium ions. Indeed, a recent report (Eur. J. Pharmacol. 124(1986)291) indicated similarities between [^{14}C]guanidinium ion and $^{22}Na^+$ ion influx into crude synaptosomes from rat brain. In the present study [^{14}C]guanidinium ion influx into purified synaptosomes from mouse cerebral cortex was characterized in more detail in Na^+ free medium (Mol. Pharmacol. 19(1981) 78). Veratridine-activated [^{14}C]guanidinium influx, corrected for flux unrelated to sodium channels measured in the presence of 1 μM tetrodotoxin, was linear with time up to 30 sec and with guanidinium ion concentration up to 6 mM. Activation of [^{14}C]guanidinium ion (3 mM) influx (30 sec) was half-maximal at 3 μM of veratridine. Scorpion venom (20 μg/ml) shifted the activation curve to the left (half-maximal stimulation at 0.1 μM). Local anesthetic drugs inhibited guanidinium ion influx with potencies depending upon the concentration of veratridine used for activation, and inhibition was fully overcome by increasing concentrations of veratridine, suggesting a competitive interaction in contrast to the findings reported for Na^+ ion influx. Despite this difference, [^{14}C]guanidinium ion influx appears to be a valid model for $^{22}Na^+$ ion influx.

I thank the NIDA for support (grant DA 03025) and Irma Vara-Reith for technical assistance.

LOCAL ANESTHETICS: INHIBITORY EFFECTS ON BATRACHOTOXIN-ELICITED SODIUM FLUX AND PHOSPHOINOSITIDE BREAKDOWN IN GUINEA PIG CEREBRAL CORTICAL SYNAPTONEUROSOMES. Y. Nishizawa*, F. Gusovsky and J.W. Daly. Lab. of Bioorganic Chemistry, NIDDK, NIH, Bethesda, MD 20892

Local anesthetics inhibit the sodium influx and the inositol phosphate accumulation elicited by the sodium-channel activator batrachotoxin in guinea pig cerebral cortical synaptoneurosomes. Inhibitory effects of local anesthetics on sodium influx correlate closely with inhibitory effects on binding of a tritiated batrachotoxin analog to sodium channels in synaptoneurosomes. Inhibitory effects of local anesthetics on sodium influx also correlated with inhibitory effects on inositol phosphate accumulation. Euprocin, bupivacaine, lidocaine and certain analogs were nearly equipotent with respect to inhibition of sodium influx and inositol phosphate accumulation. Local anesthetics also inhibited inositol phosphate accumulation that was induced by carbamylcholine through both a tetrodotoxin-sensitive and a tetrodotoxin-insensitive pathway. Certain local anesthetics, such as dibucaine, inhibited the tetrodotoxin-sensitive pathway with higher potency than for the tetrodotoxin-insensitive pathway, while others, such as quinacrine inhibited tetrodotoxin-sensitive and insensitive pathways with equal potency. The data support an involvement of sodium channels in regulation of phosphoinositide breakdown in synaptoneurosomes, but indicate that effects of certain local anesthetics on muscarinic receptors or on the phospholipase C system may complicate interpretations.

335.17

MODULATION BY VERATRIDINE, BATRACHOTOXIN AND MONENSIN OF PHOSPHOINOSITIDE HYDROLYSIS IN NEUROHYBRID NCB-20 CELLS. D.-M. Chuang, Lab. Preclin. Pharmacol. National Inst. of Mental Health, St. Elizabeths Hospital, Washington, D.C. 20032.

Two sodium channel activators, veratridine and batrachotoxin (BTX), and a sodium ionophore, monensin activated phosphoinositide hydrolysis measured by ^{3}H-inositol monophosphate (IP_1) accumulation in NCB-20 cells. The % stimulation by these agents was unaffected by depleting extracellular NaCl suggesting that sodium influx is not necessary for this activation. In sodium-free medium, the stimulation by BTX and monensin was apparent in the presence of 60 or 10 mM lithium. Tetradotoxin blocked effects of BTX and veratridine but not that of monensin. The effects of these agents were dependent on extracellular calcium. The BTX effect was inhibited by micromolar nimodipine, while the monensin effect was unchanged. Ouabain did not alter phosphoinositide turnover. BTX and monensin also induced greater than additive effect on carbachol-induced ^{3}H-IP_1 accumulation. In cells with a high passage number, veratridine markedly inhibited the response of carbachol with 8-10 fold increase in the EC_{50}. This inhibition is mainly due to a defect in the receptor-effector coupling rather than in the binding of agonists to cell surface muscarinic receptors.

335.18

PHOSPHOINOSITIDE HYDROLYSIS INDUCED BY SODIUM CHANNEL ACTIVATORS IN MOUSE BRAIN: ROLE OF Na^+,Ca^{2+}, AND MEMBRANE POTENTIAL. M. Benuck*, M.E.A. Reith and A. Lajtha.(SPON: L.J. Cote) Ctr. Neurochem.,NS Kline Inst.,Ward's Isl.,NY 10035.

Veratridine (VERA), batrachotoxin (BTX) and other Na^+ channel activators are known to increase phosphatidylinositol (PI) hydrolysis in brain. The present work with mouse cerebrocortical slices addresses as possible mechanisms 1) the entry of Na^+, 2) depolarization, and 3) Ca^{2+} influx through voltage-dependent Ca^{2+} channels. Release of neurotransmitters is not supported by previous results.

Depolarization by 30 mM KCl enhanced PI hydrolysis. This response was not blocked by tetrodotoxin (TTX) and not stimulated by Ca^{2+} channel agonists (10 μM Bay K 8644) or prevented by Ca^{2+} antagonists (10 μM nimodipine or PN 200-110), indicating the lack of involvement of Na^+ and Ca^{2+} channels in the KCl effect. The PI response to VERA (10 μM) was blocked by TTX but not affected by the Ca^{2+} agents. The PI response to KCl was not additive with that to VERA or BTX, suggesting a common mechanism. This could be the accumulation of intracellular Na^+ ions, in the case of KCl by means other than Na^+ channels. Consonant with this possibility is the increase in PI hydrolysis found with 3 μM monensin promoting Na^+ influx without inducing depolarization, and the lack of the PI response to 30 mM KCl, 10 μM VERA, and 10 μg/ml of ScV in sodium-free media. In the latter case, a positive response to 2 mM carbachol demonstrated the functional activity of the PI system. These results support a direct role for Na^+ in regulating PI turnover. (DA 03025)

335.19

INTERACTION OF AN INSECTICIDAL ISOBUTYLAMIDE WITH VOLTAGE-SENSITIVE SODIUM CHANNELS. J. A. Ottea*, G. T. Payne*, J. R. Bloomquist, and D. M. Soderlund. Dept. of Entomology, NYS Agric. Expt. Station, Cornell University, Geneva, NY 14456.

BTG 502 [(2*E*,4*E*)-*N*-(1,2-dimethyl)-propyl-6-(5-bromonaphth-2-yl)-hexa-2,4-dienamide] is a synthetic analog of insecticidal amides isolated from *Piper* species (Elliott, M., et al. *Agric. Biol. Chem.* 50: 1347, 1986). BTG 502 at 10 μM produced approximately 75% suppression of evoked compound action potentials in excised mouse sciatic nerves. This compound also caused a slight stimulation of $^{22}Na^+$ uptake into mouse brain synaptoneurosomes, which was increased by saturating concentrations of *Leiurus quinquestriatus* venom. In the presence of *Leiurus* venom, half-maximal stimulation was achieved at 3 μM and maximal stimulation (2.3-fold greater than nonspecific uptake) at 50 μM. In the absence of *Leiurus* venom, BTG 502 inhibited veratridine (100 μM)-dependent $^{22}Na^+$ uptake. BTG 502 also inhibited the specific binding of [^{3}H]batrachotoxinin A-20-α-benzoate (BTX-B) to sodium channels in these preparations, producing half-maximal inhibition at 2 μM and maximal inhibition at 30 μM. The slope of the Hill plot for the displacement of [^{3}H]BTX-B by BTG 502 was substantially less than 1, suggesting that the effects of BTG 502 involve a negative allosteric interaction with the activator recognition site of the sodium channel. The effects of BTG 502 on $^{22}Na^+$ uptake and [^{3}H]BTX-B binding differ from those of other lipophilic insecticides (e.g., DDT and pyrethroids) and suggest the existence of a second insecticide binding domain on the sodium channel.

VOLTAGE-DEPENDENT POTASSIUM, SODIUM AND CALCIUM CURRENTS IN SMALL-CELL LUNG CANCER CELLS. J.J. Pancrazio*, M.P. Viglione*, I. Tabbara* and Yong I. Kim. (SPON: C. Desjardins) Depts. of Neurology, Biomed. Eng. & Int. Med., U.Va. Sch. of Med., Charlottesville, VA 22908.

Small-cell carcinoma (SCC) of the lung is a highly malignant tumor associated with a variety of paraneoplastic syndromes. Little is known about the types of ion channels present in these neuroendocrine-like cells.

Using patch clamp technique, we measured whole-cell currents from NCI-H128 and H69 SCC cell lines, held at -80 mV and depolarized to -60 to +120 mV (range of cell membrane capacitance: 4.0-24.8 pF). The outward K^+ current (I_K) was most prominent and found in every cell tested. I_K, measured in the presence of TTX at +80 mV, ranged from 0.9 to 4.3 nA. Externally applied TEA (30 mM) and 4-AP (2 mM) reduced I_K by about 90%. The inward sodium current (I_{Na}) was recorded after blocking I_K with internally applied CsCl and TEA. The rapidly inactivating I_{Na}, present in 25% of the cells studied, had a peak amplitude of about 70 pA (at 0 mV). I_{Na} was sensitive to TTX and reversed its polarity at 40-50 mV. Inward Ca^{2+} current (I_{Ca}), measured with 10 mM Ca^{2+} buffer after blocking I_{Na} and I_K, was readily detectable in H128 but less obvious in H69. I_{Ca} peaked at 7-10 msec with an amplitude of 10-120 pA, partially inactivating over the 40 msec depolarization (Supported by NIH grant NS18607 and an MDA research grant).

INVERTEBRATE LEARNING AND BEHAVIOR II

336.1

INTRACELLULAR SIGNALS PRODUCING HABITUATION IN STENTOR. David C. Wood. Department of Behavorial Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

The contractile protozoan, Stentor, habituates during repeated mechanical stimulation due to a progressive decrement in receptor potential amplitude. Repetitive elicitation of action potentials and contractions is required to produce this decrement; repetitive elicitation of receptor potentials alone produces no decrement. After responding to the first 3 to 10 stimuli, an occasional animal ceased contracting despite continued elicitation of receptor and action potentials. In these cases the partially decremented receptor potential recovered to prestimulation levels. Therefore, the contractile mechanism generates an intracellular signal which modifies the mechanoreceptor channels and produces habituation.

Increased intracellular Ca^{++} triggers contractions, but this Ca^{++} is not the signal for habituation since receptor potentials decrement normally when recorded with 50 mM EGTA-filled electrodes. EGTA did prevent Ca^{++}-dependent inactivation of the voltage-dependent Ca^{++} channels.

Twenty different drugs, toxins and ions known to modify the efficacy of second messenger systems were screened for their ability to alter habituation in Stentor. Only phosphodiesterase inhibitors and dibutryl cAMP increased the animal's rate of habituation without affecting their sensitivity to photic, electrical or temporally spaced mechanical stimuli. Therefore, cAMP may serve as a second messenger in the production of habituation in Stentor.

336.2

FOOD MODULATES SPIKE ACTIVITY IN FEEDING CELLS IN THE LEECH. T. Karrer and C.L. Sahley, Psychology and Biology, Yale University, New Haven, CT 06520.

Last year we reported that a carnivorous leech, *Haemopis marmorata*, could learn to alter its food preferences as a result of associative conditioning. As a first step toward the elucidation of the neurobiological events underlying this learning, we have investigated the effects of food on the LL cell, a cerebral cell which in *Hirudo medicinalis* has been shown to play an integral part in the mediation of feeding behavior (Lent & Dickinson, 1984).

Our preparation consisted of the sub- and supra-esophageal ganglia, the two most anteriorly-projecting pairs of cephalic nerves, and a piece of lip containing putative chemosensory structures (Elliott, 1986). The lip was sealed in a separate chamber. Also attached was the dorsal portion of the nerve ring which innervates the pharynx, and the previously unreported pharyngeal ganglia, which lie at the bifurcation point of the pharyngeal ring.

The LL is usually spontaneously active, producing single spikes at a mean frequency of 0.6 Hz. Food applied to the lip results, at a mean latency of 20 min, in the spikes changing to doublets at an approximate frequency of 1 Hz. This change generally persists for about 40 min.

To determine whether this change is presynaptic, or whether it is due to an intrinsic change in LL, we bathed the CNS in high Mg++ throughout the food application. The Mg++ abolished the spontaneous activity, and evoked spikes remained single. However, after washing out the Mg++, the spikes changed to doublets. This suggests that the change is presynaptic to the LL cells.

336.3

ASSOCIATIVE LEARNING IN THE LEECH: BEHAVIORAL AND CELLULAR EFFECTS OF PREDICTABILITY. Christie L. Sahley, Dept. of Biology, Yale Univ, New Haven, CT 06511.

The pairing and the predictive relationships between stimuli have been shown to be critical variables in associative learning for both vertebrate and invertebrate species. We previously addressed the pairing dependency in the intact leech. In this study we used a semi-intact preparation to address both of these variables and their cellular correlates.

Our behavioral procedures were similar to those originally used to study contingency in vertebrates (Rescorla, 1967). We compared the learning performance of leeches in four groups. Leeches in Group (Grp) 1 received 30 CS-US pairings (touch-shock). This procedure results in a significantly enhanced response to the CS. Leeches in Grp 2 experience the same pairings and they received 12 presentations of the US alone. Grps 1 and 2 were matched for US frequency. The additional US's degraded the predictive CS-US relationship. Leeches in this group show significantly less learning. Since leeches in Grp 2 received more US's than leeches in the paired grp (1), a third grp was run which received 42 paired CS-US presentations, thus controlling the total number of US presentations. Leeches in Grp 3 showed learning comparable to the learning observed in Grp 1. Finally, leeches in Grp 4 received 30 random presentations of the CS and US. Leeches in this group showed a decrement in behavior.

Cellular experiments demonstrate that the Retzius cell (R) may be implicated in this phenomenon. First, the R cell fires in response to the US and second, the firing decrements to repeated US alone presentations. No decrement has been observed during pairings. The decrement may be mediated through autoreceptors on the Retzius cell.

336.4

HABITUATION OF THE TRITONIA ESCAPE SWIM INVOLVES MULTIPLE BEHAVIORAL MODIFICATIONS. G. Brown*, W.N. Frost and P.A. Getting (SPON: M.J. O'Donovan). Dept. Physiol. & Biophys., Univ. of Iowa, Iowa City, IA. 52242.

Previous work has shown that habituation of the *Tritonia* escape swim involves a decrease in the number of cycles per swim. We now report that habituation is associated with changes in three additional aspects of the swim. During 10 trials (2 min intertrial interval) using noxious epithelial stimuli to trigger swimming, the duration of the first cycle increased from an average of 5.9 seconds (1st trial) to 7.7 (10th trial) ($N=7$, $p<.001$). In addition, the velocity of the first full dorsal flexion decreased 27% ($N=6$, $p<.02$). To test for the possible involvement of central mechanisms, the swim motor program was elicited 10 times (2 min ITI) in isolated brain preparations by electrical stimulation of a nerve root. The duration of the first cycle, as measured by the period of interneuron C2 bursts, increased from 6.2 to 8.0 seconds ($N=7$, $p<.001$). The maximum firing frequency of dorsal flexion neurons, which control the flexion movement, decreased 14% ($N=6$, $p<.01$) in isolated brains. The similarities between behavioral and isolated brain responses suggest that central nervous system modifications are partially responsible for habituation in *Tritonia*.

To test for a change in behavioral threshhold, six animals were stimulated at 2 min intervals. After 20 to 40 stimuli, all animals failed to swim on five consecutive trials, but did swim when a higher intensity stimulus was applied to the same site, indicating that the response failure was due to an increase in behavioral threshhold. Habituation of escape swimming in *Tritonia* therefore involves changes in: number of cycles, cycle duration, flexion velocity, and threshhold.

Recent studies indicate that multiple circuit modifications may mediate habituation in *Tritonia* (Frost, W.N. and P.A. Getting, Soc. Neurosci. Abstr., 1987). We intend to explore the relationship between the multiple circuit modifications and the multiple behavioral changes reported here. Supported by NS17325 and NS07247.

336.5

ADENYLATE CYCLASE ACTIVITY IS REQUIRED FOR LONG-TERM, FACILITATION. D. Dixon* & H.L. Atwood. (SPON: J.M. Wojtowicz). Dept. of Physiology, University of Toronto; Toronto, ONT. M5S 1A8.

Long-term facilitation (LTF) at the crayfish neuromuscular junction is induced by tetanic stimulation and persists for hours. Induction of LTF has been attributed to ionic imbalances produced by the stimulation. These changes in Na^+ and Ca^{++} recover shortly after stimulation, yet facilitation persists for hours. The present study investigates second messenger involvement in LTF. Activators and potentiators of cAMP (IBMX and Forskolin) are effective in producing a long-lasting facilitation similar to the second phase of LTF. Localized pre-synaptic injection of the Walsh Inhibitor (PKI) blocks the second phase of LTF at synapses near the injection site, whereas normal LTF develops at synapses distant from the injection site within the same preparation. Localization of PKI was confirmed by flourescent tagging of the PKI. Adenylate cyclase's (AC) role in LTF is further supported by results using SQ22,536, an AC inhibitor. Localized injection of SQ22,536 blocks the second phase of LTF near the injection site, while synapses distant from the injection show normal LTF. These experiments establish a role for AC activation in producing LTF. Supported by MRC Canada and OGS scholarships.

336.6

INTRACELLULAR CORRELATES OF RESTRAINT-INDUCED MODULATION OF THE CRAYFISH LATERAL GIANT ESCAPE RESPONSE. E.T. Vu and E.B. Krasne. Neuroscience Program, Department of Psychology and Brain Research Institute, University of California, Los Angeles, CA 90024.

Restraint suppresses the lateral giant (LG)-mediated tailflip escape reflex of the crayfish. This suppression involves a tonic form of inhibition descending from thoracic and higher levels of the nerve cord. We are currently investigating the circuit sites and cellular mechanisms underlying this behavioral modulation.

A likely target for extrinsic control is the circuit's command neuron, the LG. We report here two intracellularly observed effects on the LG cell of restraining the animal: (1) A clear decrease in all early phases of the second root-elicited compound postsynaptic potential, which involves inputs from both primary afferents and sensory interneurons and consists mainly of electrical synaptic input to the LG; and (2) A hyperpolarizing shift in the membrane potential, bringing it away from an unchanged firing threshold. We are determining whether the same mechanism underlies both these effects, and whether earlier circuit elements are also modulated.

336.7

OCTOPAMINE MODULATION OF THE SENSORY SYNAPSE IN CRAYFISH LATERAL GIANT ESCAPE REACTION CIRCUIT. J. Bustamante and E.B. Krasne. Department of Psychology, University of California, Los Angeles, CA 90024.

Traumatic events cause a prolonged increase in the probability of lateral giant mediated tailflip escape responses to sudden abdominal stimuli. This behavioral sensitization is associated with increased stimulus sensitivity of first order interneurons of the tailflip reflex circuit. Octopamine mimics these effects.

Here we studied the effect of octopamine on the intracellularly recorded responses of interneuron A. Octopamine (1) increased amplitudes (18-30%), rise times (11-14%), and fall times (40-75%) of unitary EPSPs evoked by stimulation of individual tailfan mechanoreceptors, (2) caused ca 300% increases in "spontaneous" (ambient water-current caused?) firings of sensory root afferents and in size and frequency of "spontaneous" unitary EPSPs, and (3) caused no apparent changes in either resting potential or critical firing level.

Response-to-response variation in unitary EPSP amplitudes, which we believe to reflect variable quantal release, is now being used to evaluate the effects of octopamine on quantal release. Though from parallel studies in Aplysia, altered release would be expected, the altered EPSP rise and fall times seen here may suggest different mechanisms. Supported by C.S.I.C. Fellowship, Spain (JB) and N.I.H. grant NS08108 (FK).

336.8

IDENTIFICATION OF PROTEINS THAT MAY MEDIATE SENSITIZATION IN APLYSIA. A. ESKIN, J.H. BYRNE+, AND K.S. GARCIA*. Bio. Dept., Univ. Houston, +Dept. Neurobiol. & Anat., Univ. Tex. Med. School at Houston, Houston, Tx, 77004.

We investigated whether neuronal proteins of A. californica were altered by procedures that mimic those used to produce long-term sensitization. Samples for 2D-gel electrophoresis were prepared from pleural sensory neurons at the end of treatment periods. We found that exposure to serotonin (5-HT) for 2 hrs increased amino acid incorporation into protein P9 and decreased incorporation into proteins P19 and P20. Forskolin or cAMP analogs mimicked the effects of 5-HT on P9, P19, and P20. A phorbol ester, TPA, had no effect on these proteins, but it increased the amount of label associated with P24. In studies of protein phosphorylation, we found that P9 and P19 are phosphoproteins, but 5-HT did not appear to affect their phosphorylation. However, 5-HT increased phosphorylation of P21 and decreased phosphorylation of P29. Preliminary results indicate that increases in cAMP mimicked the changes in phosphorylation that were produced by 5-HT. The proteins affected by both 5-HT and changes in cAMP may be involved in the induction of short and long-term changes in the nervous system of Aplysia.

336.9

A QUANTITATIVE MODEL FOR THE KINETICS OF cAMP-DEPENDENT PROTEIN KINASE (TYPE II) ACTIVITY: LONG-TERM ACTIVATION OF THE KINASE AND ITS POSSIBLE RELEVANCE TO LEARNING AND MEMORY. J.D. Buxbaum* and Y. Dudai. Dept. of Neurobiology, Weizmann Institute, Rehovot 76100, Israel.

Evidence from *Drosophila* and *Aplysia* implicates persistent activation of the cAMP cascade in memory. Different processes in the cAMP cascade may contribute to its persistent activation, including autophosphorylation of cAMP-dependent protein kinase (PKA), in which the catalytic subunit (C) phosphorylates the regulatory subunit (R). We developed a quantitative model for the interactions between the two PKA subunits, making use of experimentally defined kinetic rate constants and assuming eight functional states for R: four involving dephosphorylated R (R·C, R·cAMP·C, R·cAMP and R), and four similar states involving phosphorylated R. Computer simulations showed that following a transient (several seconds) rise in intracellular cAMP levels, PKA can be activated for tens of minutes under appropriate physiological conditions. This long-term activation of the protein kinase is due in part to the effects of phosphorylation of the regulatory subunit, which decreases the affinity of the regulatory subunit for the catalytic subunit. We have simulated the activation of PKA in *Drosophila* learning and memory mutants, with primary or secondary defects in the cAMP cascade. Our model predicts defective kinetics of PKA in *Ddc*$^-$, *rutabaga*, *dunce* and *turnip* under physiological conditions. Based on these data, combined with previous studies, we suggest that in *Drosophila*, and possibly in other organisms: a) PKA is central to sensitization, habituation, and classical conditioning, and b) PKA may retain information in short-term memory by the process of long-term activation. (Supported by the US-Israel Binational Science Foundation, Jerusalem).

336.10

TYPE II CA^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE IN DROSOPHILA. D. S. Leonard and M. B. Kennedy. (SPON: R. J. Leonard). Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125.

We previously reported that the fruit fly Drosophila contains a protein kinase with considerable homology to the rat brain type II CaM kinase (Soc. Neurosci. Abstr. 13, 559, 1987). We now report that cDNA clones coding for both subunits of the rat kinase label homologous sequences in Southern blots of Drosophila genomic DNA. We find that one restriction fragment is labeled by both rat α and β subunit cDNA probes under different low stringency conditions. Additional, non-overlapping fragments are labeled by probes encoding only one of the two rat subunits. Therefore, like the rat kinase, the fly type II CaM kinase may be composed of related subunits encoded by distinct genes.

We have also screened fly head cDNA libraries with probes made from rat kinase α and β subunit cDNAs. A clone was recovered which hybridizes to probes made from N-terminal and C-terminal portions of both rat subunits. Bulleit et al. recently pointed out that N-terminal portions of both rat subunits include highly conserved kinase and calmodulin binding domains, whereas C-terminal portions contain sequences unique to the type II CaM kinase (Neuron 1, 63-72, 1988). Thus, this clone appears to encode a large portion of one of the fly kinase subunits. Sequencing is now underway. Supported by NIH.

LIGHT PAIRED WITH ACTIVATORS OF PROTEIN KINASE C PRODUCES SHORT-AND-LONG-TERM ENHANCEMENT OF LIGHT RESPONSES OF LATERAL B-PHOTORECEPTORS IN HERMISSENDA. T. Crow and J. Forrester*. Department of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225.

Previous results have indicated that protein kinase C (PKC) may play a role in the induction of short-term plasticity in type-B photoreceptors. We now present evidence that light paired with activation of PKC is sufficient to produce both a short-term (1hr) nonassociative and long-term (24 hrs) associative enhancement of light-evoked generator potentials recorded from lateral B photoreceptors. A light step (5 min) was paired with the direct injection of PKC activators such as 1 uM TPA or 1 uM OAG onto the exposed nervous system of otherwise intact Hermissenda. Both activators of PKC produced an enhancement of the peak amplitude of the generator potential ($\bar{X}$=42.8mV) and the amplitude at light offset ($\bar{X}$=38mV). Preparations receiving control injections exhibited normal light responses ($\bar{X}$=40.1mV and $\bar{X}$=26.1mV, respectively). The application of PKC activators when paired with light produced a pairing specific long-term change in the amplitude of the generator potential (peak amplitude; $\bar{X}$=46 mV; amplitude at light offset; $\bar{X}$=29.2mV). Unpaired controls exhibited smaller responses when tested 24 hrs after unpaired light and PKC activators ($\bar{X}$=43.3mV; $\bar{X}$=25.7mV). These results indicate that light paired with activation of PKC can mimic some of the electrophysiological effects of pairing light and 5-HT on changes in the light responses of identified B photoreceptors in Hermissenda.

336.12

PROTEIN KINASE C INHIBITION PREVENTS SHORT-TERM BUT NOT LONG-TERM LIGHT-5-HT-INDUCED ENHANCEMENT OF GENERATOR POTENTIALS IN HERMISSENDA B-PHOTORECEPTORS. J. Forrester* and T. Crow (SPON: A. Moller). Dept. of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225.

Light paired with direct application of 5-HT to the exposed nervous system of otherwise intact Hermissenda produces both short-and-long-term changes in the amplitude of light-evoked generator potentials recorded from identified photoreceptors. Previous results have suggested that activation of protein kinase C (PKC) may contribute to the induction of plasticity produced by pairing a neuromodulator with activity in B-photoreceptors. We now present evidence that an inhibitor of PKC produces different effects on short-and-long-term plasticity. Application of the PKC inhibitor H-7 (1 μM) (Hidaka, 1984) blocked the short-term enhancement of light-evoked generator potentials produced by light and 5-HT (mean control peak amplitude=41.4mV, mean amplitude at light offset=27mV; H-7 mean peak amplitude=39.2mV, mean amplitude at light offset=26.5mV; H-7 + 5-HT mean peak amplitude=38.2mV, mean amplitude at light offset=26.8mV). Light responses following the application of 5-HT without H-7 were enhanced (mean peak=43.6mV, mean amplitude at light offset =29.7mV). In contrast to the short-term effects, H-7 did not block the long-term (24 hrs) enhancement of generator potentials produced by pairing light and 5-HT (mean peak amplitude=43.3mV, mean amplitude at light offset=29.8mV). These results suggest that other messenger systems may contribute to the long-term enhancement of light responses produced by light and 5-HT.

336.13

5-HT MODULATES LIGHT-EVOKED CURRENTS AND DISCRETE WAVES IN B-PHOTORECEPTORS OF HERMISSENDA. T.Pengidore* and T. Crow (SPON: A.J. Martinez). Department of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225.

In Hermissenda type-B photoreceptors the intervals between light-evoked discrete waves follow an exponential frequency distribution. Since previous research has shown that 5-HT can modulate light responses we have examined the effects of the neuromodulator 5-HT on the interwave interval distributions of light-evoked discrete waves in axotomized type B-photoreceptors. Dim illumination evoked discrete waves that conformed to an exponential interval distribution. Following bath application of .1mM or .01mM 5-HT, dim illumination evoked a decrease in the intervals between discrete waves and the intervals again followed an exponential frequency distribution. The frequency of light-evoked discrete waves calculated from the mean of the interval distribution showed a 32% increase following the bath application of 5-HT. Chi-square analysis of the fit of the observed distribution to the expected exponential distribution revealed no significant deviation ($P>.05$). Application of 5-HT in the dark did not produce a significant change in the frequency of spontaneously occurring discrete waves. The analysis of light-evoked currents from photoreceptors voltage-clamped at their dark-adapted resting potential followed an exponential interval distribution. The average increase in the frequency of light-evoked currents in the presence of 5-HT was 28%. The analysis of discrete waves may provide insights into the action of second-messenger systems activated by neuromodulators in Hermissenda.

PROTEIN DEFICIENT DIET RETARDS LEARNING IN APLYSIA. J.M. Flinn, S. Kurtz*, D. Royall*, Department of Psychology, George Mason University, Fairfax, VA 22030.

The development of learning in juvenile aplysia takes place in clearly defined stages, with sensitization appearing during stage 12 (Rankin and Carew, 1987). To explore the effect of protein deprivation on learning, we raised animals from age 50 days to age 110+ days on two different algae, gracillaria and enteromorpha, which had different protein content. All animals were obtained from the Aplysia Mariculture Facility in Woods Hole and were full siblings. Sensitization was examined by videotaping and analyzing escape behavior following tail shock. Threshold shocks were determined for all animals. Two weak stimuli at 1.5 x threshold current were administered two mins apart, followed either by a strong sensitizing shock (4 x threshold current) or by a weak shock. Two additional test shocks were given five mins later. Animals (N=20) raised on a gracillaria whose protein content at the beginning of the study was 33% (dry weight) did show sensitization. The measure used was the number of steps taken in the two mins after each test shock. Animals receiving a sensitizing shock took sig. more steps after the sensitizing shock than the controls ($p<.006$). Animals (N=19) raised on an enteromorpha, whose protein content was 16%, did not show a significant increase in steps. These results indicate that protein deprivation during development interferes with the acquisition of sensitization in juvenile aplysia.

336.15

MODIFIABLE BEHAVIOR AND AGE-SENSITIVITY MAY BE RELATED IN APLYSIA. B. Hallahan*, B. Peretz & T. Skinner*. Dept. Physiol. & Biophys., Univ. of Ky., Lexington, KY 40536.

Peretz et al. (1984) proposed that the modifiable gill withdrawal reflex (GWR) is more age-sensitive than the periodic respiratory gill pumping movements (GPM). We based this on the age-impaired function of neuron L_7 and the age-invariant function of LDG_1; L_7 and LDG_1 are major contributors of the GWR and GPM respectively. To determine the applicability of this proposal to freely moving animals, we examined the GWR and GPM in the same mature (ca 150 days) and old (ca 250 days) animals. The GWR was elicited by artifical seawater (ASW) jets of 0.4 to 8.0 g/cm^2 to the siphon. The GWR duration was reduced in old animals, $F(4,96) = 2.51$, $p<0.05$. The GWR habituated faster in old than in mature animals to repetitive jets of 2.0 g/cm^2, $F(9,198) = 2.74$, $p<0.005$. Elevated GPM rates were elicited by placing the animals in ASW from pH 7.8 (normal ASW) to 3.0 for 5 min intervals. The GPM rates were the same in both groups. The rate did not habituate to repetitive exposure to pH 5.0. When elicited together, to test if the GWR and GPM interact, the GPM rates at pH 7.8 and 5.0 were unaffected by siphon stimulation, but the GWR duration was less in pH 5.0 than in pH 7.8. In these animals the GWR and GPM express the age effects of their respective substrates. The GWR is more modifiable by sensory input and age than the GPM, and this suggests that behavioral modifiability and vulnerability to age may be related.

PERSISTENCE OF ULTRASTRUCTURAL CHANGES AT IDENTIFIED SENSORY NEURON SYNAPSES DURING LONG-TERM SENSITIZATION IN APLYSIA. M. Chen and C.H. Bailey. Ctr. for Neurobiol. & Behav., Dept. of Anat. and Cell Biol., Neurol., & Psychiat., Columbia P&S, and NYSPI, NY, NY 10032.

The time course of changes in active zone morphology at identified sensory neuron synapses was examined at different intervals following long-term sensitization of the gill-withdrawal reflex. HRP-labeled varicosities in 20 μm slab-thick sections were re-embedded, thin sectioned, and analyzed through a blind procedure; 693 sensory neuron varicosities taken from 14 animals were treated in this fashion. As reported in an earlier study, we have found that long-term sensitized animals examined within 48 hrs following the completion of training demonstrate an increase in the incidence (0.395 ± 0.03 S.E.M. vs. 0.21 ± 0.02), length ($0.51\,\mu m \pm 0.02$ vs. $0.24\,\mu m \pm 0.01$) and vesicle complement (4.2 ± 0.19 vs. 1.65 ± 0.15) of sensory neuron active zones compared to control animals. The increase in active zone number is maintained at 1 week (0.386 ± 0.02, N=3 vs. 0.22 ± 0.02, N=2, $t=4.9$, $p < .05$) and is only partially reversed at the end of three weeks (0.27 ± 0.01, N=3 vs. 0.19 ± 0.01, N=2). In contrast, the increase in active zone size and vesicle complement is not present after 24-48 hrs. The relative permanence of changes in active zone number and their similarity in time course to both changes in varicosity number as well as the duration of the memory strengthen the evidence that alterations in the number of sensory neuron synapses may contribute to the retention of long-term sensitization.

MORPHOLOGICAL EVIDENCE THAT COMPETITION FOR POSTSYNAPTIC SPACE AND SEROTONIN STIMULATION CAN REGULATE THE GROWTH OF APLYSIA SENSORY NEURONS IN CELL CULTURE. D.L. Glanzman, E.R. Kandel and S. Schacher. Howard Hughes Med. Instit., Ctr. for Neurobiol. & Behav., Columbia P&S, and NYSPI, New York, NY 10032.

We have examined the relationship between morphological changes and long-term synaptic changes for Aplysia sensorimotor synapses in culture. After assessing the strengths of synaptic connections between sensory neurons and motor cell L7 electrophysiologically, the processes of the sensory neurons were visualized via video fluorescence microscopy. Our findings suggest that the neurites which mediate synaptic contact between a sensory neuron and its postsynaptic target are not "hard-wired." Rather, they can be regulated by modulatory transmitters, such as 5-HT, and by competitive interactions with the processes of other sensory neurons. Application of 5-HT to sensorimotor cultures causes growth of the sensory processes, particularly those contacting L7's major neurite. Also, in mature cell cultures different neurites of L7 appear to be occupied by processes from different sensory neurons. Only the major neurite of L7 is regularly colonized by processes from different sensory neurons and, in these instances, the different processes are segregated onto different regions of the neurite. These findings provide structural correlates for the functional plasticity which characterizes this synapse, as well as evidence for a previously unsuspected competitive mechanism regulating the formation of connections between Aplysia sensory and motor neurons.

INVERTEBRATE LEARNING AND BEHAVIOR III

337.1

NEW APPARATUS FOR OPTICAL RECORDING OF NEURON ACTIVITY. J.-Y. Wu,* V. Pantani,* H. Abildgaard,* L.B. Cohen, D.M. Senseman, D. Schiminovich,* A.I. Cohen,* C. Xiao,* H.-P. Hopp,* and J.A. London. Dept. of Physiology, Yale Univ. Sch. of Med., New Haven, CT, 06510, Div. of Life Sciences, Univ. of Texas at San Antonio, San Antonio, TX, 78285.

In an attempt to facilitate the implementation and increase the usefulness of optical recording methods, we are in the process of introducing a new photodiode array, associated amplifiers, and computer system. The photodiode array, made by Centronics Ltd., has 464 elements (instead of the present 144) to provide better spatial resolution. The amplifiers are expected to be similar in electronic characteristics to those presently in use but would be made with either surface mount or hybrid technology (hopefully much less expensive). The new computer system is a 32 bit computer using the VME bus and a 68020 CPU. This Motorola, VERSADOS system is both easier to program and it is multi-user. The computer includes a 16 bit, 400 kHz, 512 channel, analog-to-digital converter. While we hope that the new apparatus will be an improvement on the old, the main limitation on the usefulness of optical recording methods will still be the size of optical signals from voltage or ion sensitive dyes.

337.2

SMALL NETWORKS OF ADAPTIVE ELEMENTS THAT REFLECT THE PROPERTIES OF NEURONS IN *APLYSIA* EXHIBIT HIGHER-ORDER FEATURES OF CLASSICAL CONDITIONING. J.H. Byrne, D. Buonomano*, I. Corcos*, S. Patel* & D.A. Baxter. Dept. of Neurobiol. & Anat., The Univ. of Tex. Med. Sch., Houston, TX 77225.

Previously, we developed a single-cell mathematical model of the sensory neurons in *Aplysia* (Gingrich & Byrne, *J Neurophysiol* 53:652, 1985; *J Neurophysiol* 57:1705, 1987). This single-cell model accurately simulated many aspects of empirically observed neuronal plasticity that are believed to be cellular correlates of simple forms of nonassociative and associative learning. The present study extends our analysis by incorporating this single-cell model into small networks of adaptive elements which reflect the neuronal properties and connectivity patterns in *Aplysia*. An initial network contained two sensory neurons (SNs) both of which excited a single facilitatory interneuron (FN), that feeds back onto the SNs. An assumed property of the FN was that its output accommodated as a result of its activation (Hawkins & Kandel, *Psychol Rev* 91:375, 1984). Simulations from this network exhibited 2nd order conditioning but not asymptotic blocking when the original model of the SN was used. Both 2nd order conditioning and asymptotic blocking were simulated by modifying the model such that: 1) the synaptic strength of the conditioned SN (CS+ cell) was at least twice as large as an unconditioned SN (CS- cell), 2) the time required for complete accommodation of the FN was less then the minimum ISI necessary for conditioning in the SNs, and 3) the Ca^{2+} levels within the SNs first must surpass a threshold value before associative plasticity can occur. We also investigated how the incorporation of additional interneurons that recieve excitatory input from, and feed back to inhibit the SNs, would alter the above constraints and possibly make the network more robust. Various models proved functional, but each required specific assumptions. Supported by grant AFOSR 87-020.

Circuits with Bistable Outputs Constructed from Identified Neurons. D. Kleinfeld, G. F. Raccuia* & H. J. Chiel. AT&T Bell Laboratories, NJ 07974.

We have used identified neurons from the abdominal ganglion of the mollusc *Aplysia* to construct two circuits *in vitro*.[1] These circuits exhibit bistable outputs. The first circuit consisted of co-cultured L7 and L12 neurons; these formed reciprocal, excitatory connections. In one stable state both cells were quiescent and in the other stable state both cells were firing. A pulse of depolarizing current to either cell caused the circuit to make a transition from the quiescent to the active state. The second circuit consisted of an L10 neuron co-cultured with LUQ neurons. We blocked the calcium activated potassium channels in the L10 and the LUQs with charybdotoxin; this suppressed the normal bursting output of these cells. In one such circuit the L10 formed reciprocal, inhibitory connections with two LUQs; the LUQs were electrically coupled (Fig.). In one stable state the L10 was active and the LUQs were quiescent and in the other stable state the L10 was quiescent and the LUQs were active. Injection of a depolarizing pulse of current into the quiescent neuron(s) caused them to fire persistently, thus inhibiting the previously active neuron(s). The function of this circuit resembles that of a "flip-flop". The essential features of the bistable behavior for both circuits are believed to arise from the non-linearity of the input-output relation for the neurons and the (approximate) symmetry of the synaptic connections.

337.4

A CELLULAR ANALYSIS OF TAIL-SHOCK INDUCED INHIBITION IN THE SIPHON WITHDRAWAL REFLEX OF *APLYSIA* W.G. Wright*, E.A. Marcus, H. Thaker* and T.J. Carew, (SPON: N. Donegan), Depts. of Psychology & Biology Yale Univ, New Haven, CT 06520

Tail shock, which is known to produce facilitation of the siphon withdrawal reflex in *Aplysia*, has also recently been shown to produce behavioral inhibition of the reflex (Marcus et al, 1987; Mackey et al, 1987; Krontiris-Litowitz et al, 1987). The present study was directed at a cellular analysis of this tail-shock induced inhibition.

To mimic the behavioral studies of Marcus et al (1987), which showed a transient inhibition of siphon withdrawal 90 secs after multiple tail shocks, we used a semi-intact preparation (abdominal ganglion connected to the tail and siphon via the intact CNS) to examine the effects of tail shocks on: 1) complex EPSPs in siphon motor neurons (elicited by water-jet stimuli to the siphon); and 2) monosynaptic EPSPs (elicited by intracellular sensory neuron activation). Complex and monosynaptic EPSPs were tested twice at a non-decrementing (10 min) ISI to assess baseline. A TAIL SHOCK group (N=9) then received 4 strong shocks; a CONTROL group (N=7) received no shock. Test EPSPs were expressed as a percent of mean baseline EPSPs. The TAIL SHOCK group showed significant inhibition of the complex EPSP 90 sec after shock, (med=38%) compared both to baseline ($p<.01$) and to CONTROL (med=99%; $p<.02$). The complex EPSP recovered 10 min after shock (med=83%): it was elevated compared to the 90 sec test ($p<.02$) and was no longer different from CONTROL (med=81%). The effect of tail shock on the monosynaptic EPSP (tested at 2 min; med=136%) was significantly different from the effect on the complex EPSP at 90 sec ($p<.05$).

These results show that tail shock can produce transient inhibition of complex synaptic input to siphon motor neurons with a time course parallel to behavioral inhibition.

337.5

DEVELOPMENTAL DISSOCIATION OF DISHABITUATION AND SENSITIZATION IN THE TAIL-WITHDRAWAL REFLEX OF *APLYSIA* M. Stopfer & T.J. Carew, Dept. Psychol., Yale Univ., New Haven, CT 06520.

Dishabituation and sensitization have previously been developmentally dissociated on both behavioral and cellular levels in the siphon withdrawal reflex of *Aplysia*; dishabituation emerges early (in Stage 10) whereas sensitization emerges about 60 days later (in Stage 12) (Rankin & Carew, 1988; Nolen & Carew, 1988). To examine whether this dissociation is a general feature of development in *Aplysia*, in this study we examined another response system, tail-withdrawal.

Stage 11 animals sequentially received two types of training, so that each animal served as its own control. First, SENSITIZATION TRAINING: 3 weak water-jet pre-test stimuli to the tail at a non-decrementing (5 min) ISI, followed by either tail shock (TS, N=5) or head shock (HS, N=5), followed by 3 test stimuli (ISI = 5 min). Second, DISHABITUATION TRAINING: 15 pre-test stimuli at an habituating ISI (5 sec), followed by tail or head shock, followed by 5 test stimuli (ISI = 5 sec). For both groups, (comparing percent change in test vs pre-test) no sensitization was observed; in fact, there was a trend towards inhibition (TS $\bar{x}$ = -36.0%; HS $\bar{x}$ = -0.2%). In contrast, both groups exhibited significant dishabituation (TS $\bar{x}$ = +29.4%, $p<.01$; HS $\bar{x}$ = +53.4%, $p<.05$). Preliminary evidence from similar experiments in older animals suggests that, as in siphon withdrawal, sensitization of tail-withdrawal emerges during Stage 12.

In conclusion, dishabituation and sensitization of tail withdrawal can be developmentally dissociated in juvenile *Aplysia*. Since the tail-withdrawal reflex is well suited for a cellular analysis (Walters et al, 1983), it will now be of interest to explore the ontogeny of dishabituation and sensitization in this system on a mechanistic level.

337.6

DEVELOPMENT OF TAIL SENSORY NEURONS IN THE PLEURAL GANGLIA OF *APLYSIA* E.A. Marcus, G. Schuerman*, M. Stopfer, and T.J. Carew, Depts. of Biol. and Psych., Yale Univ., New Haven, CT 06520

Tail sensory neurons in the VC cluster of the pleural ganglion of *Aplysia* are important sites of plasticity underlying different forms of learning in the tail-withdrawal reflex (Walters et al, 1983; Scholz and Byrne, 1987). Stopfer and Carew (1988) have recently shown that dishabituation and sensitization emerge differentially in this reflex. A first step in analyzing the cellular mechanisms underlying this developmental dissociation is to define and characterize the tail sensory neurons in juvenile animals.

To examine the development of tail sensory cells, we backfilled nerve P9 (which contains axons of tail sensory and motor neurons) with Ni^{++}-lysine in 3 juvenile stages (11, E12, and L12) and 3 early adult substages (13A, 13B and 13C). As early as Stage 11, filled cells appeared in an identifiable cluster. We found that there was no increase in the number of filled cells during juvenile development (Stage 11 $\bar{x}$ number of cells=10.5; Stage 13C $\bar{x}$=12.5). However, there was a significant increase in cell diameter ($F=136$, $p<.001$), ranging from $\bar{x}$=10 μ in Stage 11 to $\bar{x}$=42 μ in Stage 13C. This increase in mean diameter reflected a selective increase in the number of large cells, and a concommitant decrease in the number of small cells, resulting in a transition from a unimodal distribution of small cells in Stage 11, to a bimodal distribution of small and large cells in Stage 13C. The gradual nature of this transition and the lack of an increase in total cell number suggests that the emergence of the subpopulation of large cells in Stage 13C is due to the growth of previously existing small cells.

Having identified a candidate population of tail sensory neurons early in development, we are now characterizing their biophysical properties to examine the development of neuromodulation in the tail withdrawal circuit.

337.7

INHIBITORY INTERNEURON PRODUCES HETEROSYNAPTIC INHIBITION OF THE SENSORY-MOTOR CONNECTION MEDIATING THE TAIL WITHDRAWAL REFLEX OF APLYSIA. D. Buonomano*, L.J. Cleary & J.H. Byrne (SPON: J. Wood). Dept. of Neurobiology and Anatomy, Univ. of Texas Med. School, Houston, TX 77225.

Modulation of synaptic efficacy between the sensory (SN) and motor neurons (MN) mediating the tail withdrawal reflex in Aplysia has been correlated with modifications of that behavior. We have identified an interneuron (InhN) that inhibits transmission at this synapse. Action potentials were elicited in a SN at 1 min intervals, producing monosynaptic EPSPs in the MN. The InhN was stimulated at high frequency just before and during the 4th spike in the series. When the InhN produced a hyperpolarization of at least 2 mV in the MN, the amplitudes of the 3rd, 4th and 5th EPSPs averaged 0.6, 0.3 and 0.5, respectively, when normalized to the 1st EPSP (n=5). This example of heterosynaptic inhibition was due, at least in part, to membrane changes in the postsynaptic cell which were associated with an increased membrane input conductance. We cannot rule out a presynaptic contribution to the inhibition, however, since InhNs also hyperpolarized SNs. These effects are probably monosynaptic since the hyperpolarization of both SNs and MNs persisted in bath solutions containing high divalent cations.

InhNs may play a role in the response to tail stimulation. They receive strong excitatory synaptic input from peripheral nerves P8 and P9, and they have axons in P9. Moreover, in one semi-intact preparation the InhN responded to mechanical stimulation of the tail with a short burst of spikes. InhNs also receive excitatory input from SNs. High frequency stimulation of SNs increased the frequency of spontaneous EPSPs in InhNs, but occasionally a single spike in a SN directly elicited a discrete EPSP. Like P116, another inhibitory pleural interneuron (Mackey et al., 1987), InhNs have axons in the pleural-abdominal connective, but they do not appear to contain the same transmitter, FMRFamide.

At present, the function of inhibitory interneurons in the response to tail stimulation is not well understood. However, these neurons could contribute to the hyperpolarization of SNs that is produced by stimulation of regions of the tail that are outside of the neuron's receptive field. They could also contribute to the transient behavioral inhibition that is produced by sensitizing stimulation of the tail.

337.8

SEROTONERGIC VARICOSITIES MAKE APPARENT SYNAPTIC CONTACTS WITH PLEURAL SENSORY NEURONS OF APLYSIA. Z. Zhang*, L.J. Cleary, D.W. Marshak, J.H. Byrne, Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77225.

The mechanisms within sensory neurons contributing to sensitization of defensive reflexes in Aplysia can be activated by the neurotransmitter serotonin. Varicosities containing serotonin are distributed among the cell bodies of sensory neurons in the pleural ganglion. To further characterize the morphology of serotonergic varicosities and their contacts with sensory neurons, we used the immunoperoxidase technique (Eldred et al., 1983) with correlated light (LM) and electron microscopy (EM).

In the LM, we observed numerous varicosities surrounding somata of sensory neurons. In favorable sections, labeling of fibers surrounding the axon hillock could also be observed. Varicosities (n=) were classified into three groups based on size: small (less than 1 μm), medium (1 to 3.5 μm), and large (3.5 to 6 μm). Individual axons can form varicosities of all three types, but branch only at those of large size.

Because the somata of sensory neurons are encapsulated by glia, it is necessary to confirm that reactive varicosities directly contact membranes of sensory neurons. In the EM, we observed these contacts on both the soma and the axon hillock. Since the electron dense reaction product obscured presynaptic ultrastructure, and there are not obvious postsynaptic specializations in Aplysia, we must assume that these contacts are synaptic structures. After measuring the shortest diameter of each varicosity (0.1 to 0.9 μm; n= 28), it appears that only small varicosities make contacts. In addition, there appear to be two types of synaptic morphologies: flat, in which the area of contact is small, and invaginated, in which the serotonergic profile is nearly surrounded by the sensory neuron.

These results suggest that under the appropriate physiological conditions, serotonin is released from varicosities directly onto perikarya of sensory neurons eliciting the cellular changes correlated with sensitization. That there are two types of synaptic contacts raises the possibility that this synapse is also a site of plasticity. An important future task is to identify the neurons that give rise to these varicosities, so that their role in behavioral modifications can be characterized more completely.

337.9

SEROTONIN BROADENS ACTION POTENTIALS IN BOTH SOMATA AND AXONS OF PLEURAL SENSORY NEURONS IN APLYSIA. M. Hammer*†, L.J. Cleary and J.H. Byrne, Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77225 and †Institut für Neurobiologie, Freie Universität, 1000 Berlin 33 FRG.

The enhanced release of transmitter from synapses between sensory and motor neurons is a cellular mechanism underlying non-associative and associative learning in Aplysia. The enhancement is believed to be due, at least in part, to broadening of action potentials in the sensory neurons. While broadening is readily observed in recordings from the cell soma, parallel broadening in the synaptic terminals has only been inferred. Therefore, an important test of this model is the direct demonstration that action potentials are broadened at or near the terminals. In the pleural ganglion, the somata of sensory neurons are located 2-3 mm away from their synaptic contacts with motor neurons in the pedal ganglion. Therefore, by recording directly from the axons of sensory neurons in the pedal ganglion, the kinetics of action potentials near synapses can be compared with those far away in the soma.

Simultaneous recordings were made from sensory and motor neuron somata and from sensory neuron axons. Application of 50-300 μM serotonin to the bath broadened action potentials in both the soma and axon and enhanced the EPSP in the motor neuron. The degree of broadening is more apparent in the soma than in the axon, however. The same effects were observed when somata of the sensory neurons were separated from distal axons by cutting the pleural-pedal connective. This suggests that modulation of membrane properties in the soma is not necessary to produce broadening in the axon.

To show that the site of axon recording was electrically close to the site of transmitter release, we altered the membrane potential from which the action potential was generated. By hyperpolarizing the axon 10 mV, we decreased the amplitude of the EPSP by an average of 25%. In contrast, hyperpolarizing the soma 10 mV did not affect the amplitude of the EPSP. An average decrease of 6% was due to homosynaptic depression. Thus, our recording sites in the axon were electrically close to synaptic terminals, whereas those in the soma were relatively far.

These experiments demonstrate for the first time that spikes near the terminals of sensory neurons in Aplysia are broadened by a neurotransmitter that alters synaptic transmission. These results support the hypothesis that spike broadening is a cellular mechanism underlying learning. Further experiments will be required to determine the quantitative extent to which this mechanism accounts for the observed changes in synaptic efficacy.

337.10

AN IDENTIFIED FMRFamide-IMMUNOREACTIVE NEURON PRODUCES PRESYNAPTIC INHIBITION OF THE SIPHON SENSORY NEURONS IN APLYSIA. R.D. Hawkins and S.A. Small* (SPON: D.W. Burmeister). Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, & NYSPI, New York, NY 10032.

Noxious stimuli such as tail shock produce transient inhibition as well as longer-lasting sensitization of the Aplysia gill- and siphon-withdrawal reflex. The inhibition is due in part to presynaptic inhibition of the siphon sensory neurons which can be mimicked by application of the peptide FMRFamide. To search for neurons which participate in mediating the inhibition, we combined FMRFamide immunofluorescence with fluorescent dye backfilling from the abdominal ganglion (the location of the siphon sensory cells). This technique revealed a single cell in the left pleural ganglion, which we have named LPL16. LPL16 is excited by strong tactile stimulation to the entire body surface, and fires a phasic burst of spikes in response to tail shock. Intracellular stimulation of LPL16 with a similar burst produces inhibition of the EPSP from a siphon sensory neuron to a motor neuron ganglion (average decrease = 52%, $p < .01$). Such stimulation also produces narrowing of the action potential in the sensory neuron in the presence of 100 mM TEA (average decrease = 26%, $p < .01$), indicating that the inhibition is in part presynaptic.

These and previous results show that tail shock excites two different populations of modulatory neurons, including serotonergic facilitatory neurons (CB1) and FMRFamide inhibitory neurons (LPL16). Further characterization of these neurons may help elucidate the organization of neuromodulation in Aplysia.

ACTIVITY-DEPENDENT ENHANCEMENT OF PRESYNAPTIC INHIBITION IN APLYSIA SENSORY NEURONS. S.A. Small*, R.D. Hawkins and E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, & NYSPI, New York, NY 10032.

The gill- and siphon-withdrawal reflex of Aplysia undergoes transient inhibition and longer-lasting sensitization following a noxious stimulus such as tail shock. The inhibition is due in part to presynaptic inhibition of the siphon sensory neurons by FMRFamide acting through arachidonic acid, and the sensitization is due in part to presynaptic facilitation by serotonin acting through cAMP. The facilitation undergoes activity-dependent enhancement contributing to classical conditioning of the withdrawal reflex. To test whether the inhibition also shows activity dependence, we puffed FMRFamide onto the cell body of a siphon sensory neuron either 0.5 seconds ("paired") or 5.5 seconds ("unpaired") after a brief train of action potentials in the sensory neuron. Paired training produced significantly larger and longer-lasting inhibition of the EPSP from the sensory neuron to a motor neuron than either unpaired training (mean decrease = 38% vs. 21%, $p < .02$) or training with FMRFamide alone (28% vs. 17%, $p < .05$). Paired training also produced significantly larger and longer-lasting narrowing of the action potential in the sensory neuron in 100 mM TEA than unpaired training (29% vs. 23%, $p < .05$ one-tail), suggesting that the effect is presynaptic.

These results indicate that activity-dependent enhancement occurs for inhibition as well as facilitation of the siphon sensory neurons, and suggest that activity-dependence may be a widespread associative cellular mechanism.

CONOPRESSIN G AND S SUPPRESS THE GILL WITHDRAWAL REFLEX IN AN IN VITRO PREPARATION OF APLYSIA CALIFORNICA. M. Martinez-Padron* and K. Lukowiak. Dept. of Medical Physiology, University of Calgary, Alberta, Canada, T2N 4N1.

Two novel peptides of the vasopressin-oxytocin family, conopressin G and S, have been isolated from the venom of fish-hunting snails, genus Conus (Cruz et al.,1987). Arginine-vasotocin (AVT), another peptide of this family, mimics the suppressed behavioral state seen in Aplysia. This state is characterized by a weaker gill withdrawal reflex evoked by siphon stimulation and a faster rate of gill reflex habituation (Thornhill et al., 1981). In addition, an AVT-like peptide is present in the Aplysia central nervous system (Moore et al.1981). In this study we have examined the effect of both conopressin G and S on gill behaviors using an in vitro gill, siphon, mantle and abdominal ganglion preparation. Superfusion of the abdominal ganglion with Conopressin G or S (1-10 μM) resulted in a decrease in the amplitude of the gill withdrawal reflex evoked by tactile stimulation of the siphon and a decrease in the synaptic input to central gill motorneurons. In addition, these peptides reduced the efficacy of the central gill motorneurons to produce a gill withdrawal response. Finally, conopressin G and S, greatly increase the frequency of spontaneous gill movements.

337.13

COMPARISON OF DISHABITUATION AND SENSITIZATION OF THE GILL-WITHDRAWAL REFLEX IN APLYSIA. S.L. Mackey*, N. Lalevic*, R.D. Hawkins and E.R. Kandel (SPON: L.P. Rowland). Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, & NYSPI, New York, NY 10032.

Noxious stimuli such as tail or mantle shocks produce an increase in the strength of the Aplysia gill- and siphon-withdrawal reflex if it has been habituated ("dishabituation") or if it is rested ("sensitization"). Marcus et al. (1987) have reported that there is dishabituation 1-2 minutes after the shock, but sensitization does not appear until 10-20 minutes after the shock. Looking at a different response measure (amplitude of gill withdrawal instead of duration of siphon withdrawal) in an isolated mantle organ preparation, we also found that there is dishabituation but no sensitization 2.5 min after a shock to the mantle (Med = 1137% vs. 91% of preshock, $p < .01$). However, dishabituation and sensitization both occur 12.5 minutes after the shock (693% vs. 450%, n.s.).

In a preliminary cellular analysis, we have found that shock produces inhibition followed by facilitation of the monosynaptic EPSP from a siphon sensory neuron to a motor neuron. These effects are approximately the same whether the EPSP is depressed (10 pretests) or rested (2 pretests). NDGA, a blocker of arachidonic acid metabolism, partially blocks the inhibition, revealing an earlier onset of facilitation. These results suggest that some of the differences between dishabituation and sensitization could be due to sculpting of the facilitation by a competing inhibitory process.

337.14

GABA MEDIATION OF VISUAL-VESTIBULAR INTERACTION IN HERMISSENDA M.L. Anderson* and D.L. Alkon. LMCN, NINCDS-NIH Bethesda, MD 20892.

Convergence of CS and UCS pathways activated during associative conditioning of the nudibranch mollusc Hermissenda involves inhibition of type B photoreceptors by hair cells caudally located in statocysts. This inhibition, manifest as IPSP's elicited in type B cells by stimulation of presynaptic hair cells, was unaffected by the bath application of agents known to act as either agonists or antagonists of identified neurotransmitters (NE, ACh, 5-HT, DA, Glu). However, the GABA-A antagonist bicuculline MeBr consistently blocked type B cell hyperpolarization induced by hair cell impulses. GABA and the GABA-A agonist muscimol hyperpolarized and altered the I-V relation of both intact Type B cells and cells isolated from synaptic interactions (axotomized). Muscimol applied in concentrations ranging from 75 uM to 450 uM hyperpolarized B cells 2.5 mV to 10.2 mV (n=5). N-propyl acetate (NPA) enhanced both the hair cell inhibition of type B cells (n=5) and the hyperpolarization of B cells in response to bath applied GABA without hyperpolarizing axotomized type B cells when applied alone (n=4). Voltage clamp studies implicate a GABA-A mediated increase in inward Cl- current during the hair cell inhibition of type B cells and a much more slowly developing, but persistent decrease of K+ currents (n=4). Both of these GABA effects may be important for generating persistent changes in ionic currents after Hermissenda conditioning.

337.15

A QUANTITATIVE MODEL OF BIOPHYSICAL MECHANISMS UNDERLYING TEMPORAL SPECIFICITY OF ASSOCIATIVE LEARNING IN *HERMISSENDA*. C.Chen*, C.Koch and D.L.Alkon (SPON: H.A.Lester). Dept. of Computation and Neural Systems, 216-76, California Institute of Technology, Pasadena, CA 91125 and Lab of Cellular and Molecular Neurobiology, NIH-NINCDS, Rockville, MD 20852.

Hermissenda is able to store predictive relationships between events if they occur in a temporally contigeous manner. This type of associative learning may be mediated by cellular interactions between neurons and be stored by neuromodulation of certain ionic channels. A quantitative model simulated on a parallel computor of the hypercube family was built to relate the temporal specificity at the behavioral level to the underlying biophysical mechanisms at cellular and molecular levels. The network consists of sensory neurons (photoreceptors and haircells), convergent loci on photoreceptors and motor neurons. Seven membrane conductances were modeled by Hodgkin-Huxley-like equations to predict the receptor potential and excitability of Type B photoreceptors. Intracellular calcium was computed by considering light-induced intracellular release, voltage-gated influx, buffer, diffusion and pumps. Haircells fire with rotation and indirectly cause calcium influx on B-photoreceptors through excitatory synapses. Phototransduction is known to cleave PIP2, thereby increasing diacylglycerol (DG). The excitability of the convergent site, located on the photoreceptor somata and the post-synaptic region on the axon, is modulated by the activation of protein kinase C, which depends on the elevation of calcium and DG. The model predicts that repetitive association of light (CS) and rotation (US) with 1 second delay will optimally increase the excitability of B-photoreceptor, which eventually can excite the motor neurons involved in foot contraction in absence of haircell inputs.

337.16

MOLLUSCAN OLFACTORY INTERNEURONS: STRUCTURAL STUDIES AND MODULATION BY INTRINSIC PEPTIDES AND EXTRINSIC AMINES. A. Gelperin, J. Flores*, P.G.Sokolove[1], D.W. Tank, and S.Curtis*[2] Molecular Biophysics Research Dept., AT&T Bell Labs, Murray Hill, NJ, 07974, [1]Dept. Biol. Sci., Univ. Maryland Baltimore County, Catonsville, MD 21228, and [2]Dept. Biophysics, East Tennessee State Univ., Johnson City, TN 37614.

The procerebrum (PC) of the terrestrial slug, *Limax maximus*, is a region of densely interconnected local olfactory interneurons within which the olfactory interneurons interconnect with (1) input fibers from the noses, (2) intrinsic modulatory fibers containing SCP_B or FMRFamide and (3) extrinsic modulatory fibers containing serotonin or dopamine.

To search for additional connections between the PC and other areas of the cerebral ganglion, localized injections of HRP were made into the cellular and synaptic zones of the PC. Fiber tracts into the olfactory nerve were seen, as were isolated single fibers connecting with the metacerebral lobe of the cerebral ganglion.

Material for fine structural analysis was fixed in glutaraldehyde and paraformaldehyde, postfixed in osmium tetroxide and stained in uranyl acetate and lead citrate. The cell mass consists of groups of very closely associated somata surrounded by bundles of axons. Within the synaptic interconnect zone fibers vary widely in size and orientation, containing both clear and electron-dense vesicles.

Dissociated PC neurons in culture are excited by serotonin and dopamine, while SCP_B and FMRFamide have little or no direct effect. Responses were assayed by whole-cell loose-patch recordings with pressure pulses of transmitter applied just upstream of the neuron being recorded.

NEURAL PLASTICITY IN ADULT ANIMALS: CEREBRAL CORTEX

338.1

RECOVERY OF FUNCTION AFTER CORTICAL DAMAGE: EFFECTS OF THE ANTICONVULSANT DRUG MK-801. T.M. Barth, M.L. Grant*, T. Schallert and S. D. Iversen*. Dept. of Psychology and Institue for Neurological Sciences, Univ. Texas, Austin, 78712

Previous research has shown that GABAergic anticonvulsant drugs retard or block recovery from sensorimotor asymmetries following unilateral cortical lesions (Watson and Kennard, 1945; Brailowsky et al., 1986; Schallert et al., 1986; Hernandez et al., 1988). Whether the detrimental effects of these drugs are due to the enhancement of GABAergic function or to their anticonvulsant properties has not yet been determined. In the present experiment we investigated the effects of MK-801, an anticonvulsant agent that is a noncompetitive antagonist at the N-methyl-D-aspartate (NMDA) receptor (Clineschmidt et al., 1982; Kemp et al., 1986; Wong et al., 1986), on recovery of behavioral function. Rats sustained unilateral electrolytic lesions in either the frontal medial (FMC) or sensorimotor cortex (SMC) and received either MK-801 (1 mg/kg) or saline injection beginning 12-16 hrs after surgery. Subsequent injections were given on days 2, 4 and 6. Behavioral tests measured sensorimotor asymmetries (i.e. a bilateral-tactile stimulation test) and forelimb placing. Unlike other anticonvulsant agents, MK-801 did not retard recovery. Indeed, results from rats sustaining FMC lesions suggested that MK-801 facilitated recovery from sensorimotor asymmetry ($p < .05$ for group; days; and the group X days interaction). A similar trend was found in rats with SMC lesions. An independent analysis of activity indicated that unlike GABAergic drugs (i.e. diazepam), MK-801 increased the percentage of time that the rats spent moving. These results are consistent with the view that the retardation of recovery observed after some anticonvulsant drugs may be due to the specific enhancement of GABAergic function. Supported by NIH grant NS-23964 awarded to T. Schallert

LC LESION ALTERS RAT SI CORTICAL PLASTICITY DUE TO ASSOCIATIVE TRAINING. C.L. Hand, R.L. Craik, and B.E. Levin. Univ. of Pa. Sch. of Vet. Med., Phila., PA 19104; Neurol. Svc., VA Med. Ctr., East Orange, NJ 17019.

Previous studies in neonatal & adult rat showed that a change in stimulus context--from a passive stroking (PS) to an associatively-paired training paradigm (AP; stroking + sugar water)--of a single vibrissa (C3) resulted in a metabolic shift in the C3 cortical barrel from a **decrease** of 5% to an **increase** of 4% from control values. Since other data suggest a role for norepinephrine (NE) in cortical plasticity, adult rats were subjected to a unilateral locus coeruleus (LC) lesion (6-hydroxydopamine) and assigned to one of 3 groups: controls (no training), PS bilaterally-trained C3 or AP bilaterally-trained C3. After 60 days training, effects were tested with 2DG, and cortical NE depletions were assayed (>60% depletion on lesioned side). Pilot data are remarkable for the differential changes in the size of the **areal representation.** While the PS rats (PS/lesioned & PS/nonlesioned sides) showed no significant areal changes, the AP rats (AP/lesioned & AP/nonlesioned sides) showed substantial increases in C3 barrel area compared to nonlesioned C3 control representations: AP/nonlesioned C3 barrel representations were 116% larger than controls. Introduction of the unilateral LC lesion (AP/lesioned) significantly ($p<0.05$) reduced the areal representation by 21% to an area only 90% larger than controls. These data suggest that NE plays a role in certain types of cortical plasticity.

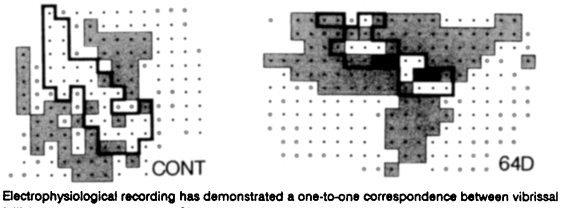
PLASTICITY IN THE BARREL CORTEX OF ADULT MOUSE: EFFECTS OF PERIPHERAL DEPRIVATION ON THE FUNCTIONAL MAP; AN ELECTROPHYSIOLOGICAL RECORDING STUDY.

E. Welker*, S.S. LeClerc*, H. Van der Loos, M. Yamakado* and R.W. Dykes
Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.
Depts. Physiol., Neurol. and Neurosur., McGill University, Montréal, Quebec, Canada H3A 1A1.



Electrophysiological recording has demonstrated a one-to-one correspondence between vibrissal follicles and barrels in mouse SI cortex. We here report on a mapping study using carbon fiber electrodes lowered into the barrel cortex under Nembutal anaesthesia. Penetrations were at 100 µm intervals. Posterior follicles of the C-row were denervated (Melzer et al., this Vol.). Maps of the barrel cortex contralateral to the lesion were made at 4 (n=1), 16 (n=4), 32 (n=2) and 64 (n=2) days after the lesion (*p.l.*), as well as from four control animals. After recording, whiskerpads and brains were processed for histology. At 16 and 32 days *p.l.* two types of maps could be distinguished: a) the C-zone was silent, i.e. no responses to whisker displacement could be elicited; b) the representations of whiskers of row B and D were enlarged, as were the receptive fields at individual penetrations; moreover, responses of affected follicles were obtained. The map of the 4 days *p.l.* mouse was of type a; those of the 64 days *p.l.* mice, of type b (see Fig; grey zones represent follicles of row B, lower left, and D; heavy line demarcates representation of follicles of row C). Recordings from affected follicles could be correlated with their reinnervation. Is the difference between type a and b depending on peripheral events, or does it reflect two modes of central adaptation to peripheral injury? Support: Swiss NSF grant 3.158.

BEHAVIORAL CONSEQUENCES OF FUNCTIONAL PLASTICITY IN RAT SI CORTEX PRODUCED BY CHRONIC SUBTOTAL VIBRISSAE DEAFFERENTATION. R.L.Craik, K.Gallo*, L.Lohwasser*, J.Lenich*, W.J. Carr*, C.L.Hand, and P.J.Hand. Beaver College, Glenside,PA 19038 and Sch. of Vet. Med., Univ. of PA., Phila,PA 19104.

Previous (^{14}C)2-deoxyglucose (2DG) studies revealed an enlarged and diffuse pattern of labeling of C3 representation in contralateral SI 90 days after neonatal follicle ablation sparing one vibrissa (C3). In a subsequent study rats kept the spared, enriched C3 vibrissa in contact with the walls of a cylindrical open field but preference dissipated with experience. Since the behavior extinguished in the open-field, this study examined behavioral changes in a more difficult task. On PND 1-3, 11 rats had follicle ablation unilaterally sparing C3; 8 animals were controls. On PND 60, rats were tested in a darkened cylindrical pen with a circular runway (5 cm wide) located against the inner wall of the cylinder 45 cm above the floor. Testing occurred 4 min per day for 5 days. It was predicted that animals with a right spared C3 would keep the vibrissa in contact with the wall traveling counterclockwise (CCW); left spared C3 animals would travel CW. (^{14}C)2DG experiments followed behavioral testing. The side of the C3 sparing affected behavior ($p<.05$) which did not extinguish; 9 of 11 spared C3 rats preferred the predicted mode unlike the control animals. The behavioral results correlate with the results of the 2DG tests suggesting that the elevated maze detects somatosensory behavioral changes and functional reorganization.

338.5

THE ROLE OF GABA IN RECOVERY OF FUNCTION AFTER CORTICAL LESIONS. T.D. Hernandez, T.A. Jones* and T. Schallert. Dept. Psychology and Institute for Neurological Sciences, Univ. of Texas, Austin 78712.

Recovery from sensorimotor asymmetries caused by unilateral damage to the cortex is disrupted by chronic administration of GABA or GABAergic drugs (Watson and Kennard, 1945; Hernandez et al., 1985, 1987, 1988; Brailowsky et al., 1986a,b, 1987; Schallert et al., 1986). Diazepam chronically delays recovery from an otherwise short-term somatosensory asymmetry caused by unilateral anteromedial cortex (AMC) lesions in rats (Schallert et al.,1986; Hernandez et al., 1987, 1988). One possible site of action for these agents is adjacent cortical tissue. Indeed, Brailowsky et al.(1986a) found that the hemiplegic syndrome produced by cannula-induced motor cortex damage is exacerbated and prolonged by chronic infusions of GABA into the surrounding motor cortex. In the present study, following unilateral AMC lesions, the GABA agonist, muscimol, was infused into the adjacent sensorimotor cortex (SMC) or, as a control, into the more remote visual cortex (VC) of the ipsilateral hemisphere. Infusions into the SMC, but not VC, retarded recovery. These data suggest that diazepam might interfere with recovery from AMC lesion-induced somatosensory asymmetry, in part, via GABA-enhancing action within the nearby SMC. In addition, we found that diazepam did not disrupt recovery from SMC lesions, which typically yield a more long-term behavioral asymmetry. These and previously reported data indicate that the vulnerability of the recovery process to GABAergic manipulations may vary depending on anatomical, neurochemical and behavioral factors.

PLASTICITY IN THE BARREL CORTEX OF ADULT MOUSE: EFFECTS OF PERIPHERAL DEPRIVATION ON THE FUNCTIONAL MAP; A DEOXY-GLUCOSE STUDY.

P. Melzer*, M. Yamakado*, H. Van der Loos, E. Welker* and J. Dörfl* (SPON: ENA).
Institute of Anatomy, University of Lausanne, Rue du Bugnon 9, 1005 Lausanne, Switzerland.

In the adult mouse whisker-to-barrel pathway, the deoxyglucose (DG) method has shown that the deflection of whiskers evokes an increase in neuronal metabolism confined to the corresponding barrels. Is this *metabolic map* in the CNS modified after denervation of whisker follicles in the periphery? In 28 adult albino mice, the branch of the infraorbital nerve which innervates the vibrissae of row C on the left muzzle was ligated and divided just distal to the ligature. At 1, 4, 8, 16, 32, 64, and 160 days post lesionem (*p.l.*), the animals were injected with [^{14}C]2-DG, and left vibrissae B1-3 & D1-3 were stimulated; all other whiskers were clipped (Melzer, P., et al., Brain Res., 348:229, 1985). Three non-injured mice underwent the same stimulation experiment. Autoradiography revealed that already one day *p.l.*, contralateral to injury and stimulation, DG uptake in barrels C1-3 was higher than normal. The increase occurred first at the borders to rows B & D and was continuous with the area of DG uptake in barrels B1-3 & D1-3, respectively. On average, the area over row B was the larger. In harmony with the increase in DG uptake in barrels C1-3, DG uptake rose in the representation of row C in the brainstem subnuclei caudalis & interpolaris ipsilateral to stimulation. In the ipsilateral barrelfield, DG uptake never differed from normal. At 4 days *p.l.*, myelinated fibers had disappeared from follicles C1-3. They re-appeared at 64 days *p.l.* In spite of this re-innervation, the increase in stimulus-evoked DG uptake over the representations of the (non-stimulated!) vibrissae C1-3 persisted and was highest at 160 days *p.l.* We attribute the observed changes to an enlargement of the metabolic representation of the whiskers neighboring those whose sensory innervation had been severed. The mechanisms underlying the alteration of the central *metabolic map* as well as the persistence of the changes upon peripheral re-innervation remain to be revealed. Support: Swiss NSF grant 3.158.

Lesions of Basal Forebrain alter Stimulus-evoked Metabolic Activity in Mouse Somatosensory Cortex. W. Ma, C.F. Hohmann, J.T. Coyle, & S.L. Juliano, USUHS, Bethesda, MD and Johns Hopkins University, Baltimore, MD.

Although the cholinergic innervation of the cerebral cortex has been reported to selectively increase the cortical response to specific stimuli, there has been little demonstration of its effect on activity patterns in sensory systems. To address this issue, we initiated experiments to study the effect of neurotoxic lesions of the basal forebrain (NBM) on stimulus-evoked metabolic activity in the barrel field of mouse somatosensory cortex. One month following a unilateral ibotenic acid lesion of the NBM, ^{14}C-2-deoxyglucose (2DG) was injected IP into 16 Balb-C mice. During the 2DG experiment, each mouse received a bilateral stimulation to the C-3 vibrissa. The lesion sites were later identified using acetylcholinesterase and cytochrome oxidase (CO) histochemistry on sections adjacent to the 2DG sections and using Nissl stains obtained from the sections which produced the 2DG autoradiograph. Comparison of the column-like label evoked after stimulation of a single whisker on each side revealed that the activity on the lesioned side was significantly reduced from that found in the normal hemisphere. On the normal side, the activated barrels averaged 638um in tangential width, were 51% above background in density, and extended from lamina II-V. On the lesioned side, the activated barrels were 470um in width, were 40% above background in density and extended from upper layer II-IV. Cortical 2DG activity outside the stimulated barrel area was the same on each side. CO activity observed on adjacent sections revealed no differences in the staining pattern for this mitochondrial enzyme in the normal and lesioned hemispheres. These experiments suggest that acetylcholine plays a significant role in the processing of somatosensory information and that its absence diminishes the stimulus-evoked activity, while the underlying metabolic activity is either not affected or recovers over time. Supported by RO7064.

Manipulation of Cortical Cholinergic Innervation Alters Stimulus-evoked Metabolic Activity in Cat Somatosensory Cortex. S.L. Juliano, W. Ma, M. Bear, and D. Eslin . USUHS, Bethesda, MD, and Brown U, Providence, RI.

Acetylcholine has (ACh) recently been reevaluated regarding its role in cerebral cortical activity. It now seems clear that this neurotransmitter is involved with increasing the specificity of cortical response. Nevertheless, little is known about the participation of ACh in processing sensory stimuli. To address this issue, we used 2 methods to manipulate the supply of ACh in the somatosensory cortex (SSC) of cats: (i) topical application of the cholinergic antagonist, atropine, (n=5) and (ii) unilateral neurotoxic lesions (using NMDA) of the basal forebrain (n=3). Twenty minutes after application of atropine and 1 week after the NMDA lesion, each animal underwent a 2-deoxyglucose experiment while the animal received identical somatic stimuli to each forepaw. The results obtained from the topical applications of atropine indicated that high doses (100u M) almost eliminated the stimulus-evoked activity in the SSC, while lower doses (40u M) reduced its density and distribution. The metabolic patterns of cortical activity were most often in the form of patches on individual sections and were reconstructed in 2 dimensions throughout the SSC. The reconstructed distributions formed strips which extended in the rostro-caudal plane & revealed that the patterns on the treated sides were similar in their overall distribution but differed in their dimension and density. For example, after a unilateral topical application of 40u M atropine, the strip width averaged 680um, while in the untreated hemisphere the strips measured 777um in width. The density of the metabolic label was 59% above background on the treated side and 79% above background on the normal side. The NMDA lesions caused similar reductions in the distribution and density of metabolic label. These changes indicate that ACh plays a significant role in the processing of sensory information and the formation of somatosensory cortical columns.

338.9

PLASTICITY IN PRIMARY SOMATOSENSORY CORTEX AFTER DIGITAL NERVE SECTION AND REGENERATION IN ADULT OWL MONKEYS. T. ALLARD, S.A. CLARK*, K.A. GRAJSKI, and M.M. MERZENICH. Coleman Lab., Depts. of Otolaryngology and Physiology, UCSF Med.Ctr., San Francisco, CA 94143; (SAC) Dept. of Plastic Surgery, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

In digital nerve section and regeneration, regenerating fibers reinnervate different peripheral sites disrupting the original topographical relationship between peripheral inputs and their central targets. The response of cortical neurons to this disruption and reassignment of peripheral inputs was measured in area 3b of adult owl monkeys. In the first study, single digital nerves were sectioned and reconnected near the metacarpal-phalangeal joint and allowed to regenerate into their original skin fields on the finger. In the second study, single digital nerves from one finger were sectioned and cross-connected to digital nerves of an adjacent finger. Highly detailed cortical maps were reconstructed from multiunit receptive fields (RFs) defined at many microelectrode penetration sites across the cortex 6 months and over a year following nerve reconnection. After final cortical mapping sessions, the skin fields of regenerating and adjacent digital nerves were mapped with the evoked potential technique. In some cases, RFs were defined in the ventral posterior lateral nucleus of the thalamus.

Both central mapping and peripheral evoked potential studies showed that denervated skin fields were completely reinnervated by cutaneous inputs. Peripheral evoked potentials showed inputs from the target skin fields were conveyed solely through fibers of the regenerating digital nerves with no observable reinnervation from adjacent nerves. In the uncrossed nerve reconnection study, the cortical representation of the regenerating nerve and adjacent skin showed normal features of map orientation and internal topography: there was a normal abrupt discontinuity in the cortical map of adjacent digits and a progressively-shifted overlap of receptive fields from the normally innervated half of the finger to the reinnervated half of the finger within the representation of a single digit. Some cortical RFs from the reinnervated skin surface were unusually large. In the crossed-nerve study, regenerating nerves were represented in their original relative position in the cortical map and in a new cortical zone near their newly-adjacent peripheral inputs.

These studies show that central RFs in adult somatosensory cortex are dynamically created and maintain an orderly internal topography following the resorting of peripheral inputs in regenerating digital nerves.

INNERVATED NEOCORTICAL GRAFTS CAN BE ACTIVATED BY ADULT HOST SOMATOSENSORY INPUTS. S.M. Lee and F.F. Ebner, Center for Neural Science, Brown University, Providence, RI 02912

Grafts of embryonic neocortex implanted in the mature barrel field become innervated by VB nucleus fibers when the appropriate peripheral nerve is transected 2 days prior to grafting (Erzurumlu and Ebner, JCN, 1988). The present experiments were carried out to determine whether innervated graft neurons show physiological responses to peripheral stimulation after the transected nerve regenerates.

The infraorbital (IO) nerve was transected unilaterally in adult male Long Evans rats (n=5) under Nembutal anesthesia. Two days later pieces of E19-20 parietal cortex were implanted in barrel field cortex contralateral to the sectioned IO nerve. The control animals (n=4) received similar transplants, without prior sensory nerve transection. From 40 to 60 days after grafting the animals were anesthetized with urethane and the barrel field cortex containing the graft was re-exposed for physiological analysis. Single unit responses to electrical stimulation of the regenerated IO nerve (0.5 µA, 200 µsec) and/or glutamate iontophoresis in cortex (0.5 M, pH 7.0, 23 nA) were recorded on-line with a 3-barrelled carbon fiber electrode (1-5 MΩ @1 kHz) and stored on a computer. Each recording site was marked with an electrolytic microlesion (1 mA, 30 sec) that could be localized following cytochrome oxidase histochemistry.

Of 72 neurons isolated by extracellular single unit recording, 45 were localized histologically within the transplant. Approximately 20% of the graft neurons analyzed were responsive at short (7-14 msec) latency to electrical stimulation of the regenerated IO nerve. Following iontophoretic application of glutamate an additional 13% could be activated by sensory nerve stimulation. In contrast, all control graft neurons isolated by glutamate application showed almost no spontaneous activity and were unresponsive to IO nerve stimulation These findings indicate that the sensory fiber ingrowth induced by peripheral nerve damage leads to functional innervation of grafted neurons.

ALTERATIONS IN DENDRITIC EXTENT OF PYRAMIDAL CELLS IN ADULT MOUSE CORTEX: A QUANTITATIVE GOLGI STUDY OF THREE AGE GROUPS. Ronald F. Mervis, Monika Bedo-Wierdl*, and Robert Dvorak*. Div. of Neuropathology, The Ohio State Univ. Med. Ctr., Columbus, Ohio 43210

In order to establish baseline lifespan parameters of neuronal morphology and assess neuroplasticity in the brains of adult rodents, we evaluated the extent of dendritic branching in cortical neurons in early- through middle-adulthood in male C57Bl/6J mice. Three ages were studied: 3, 8, and 13 months-old. Using Rapid Golgi preparations, the dendritic domain of the basilar tree of randomly selected layer V pyramidal cells from fronto-parietal cortex were quantified by Sholl analysis. Results showed that the amount of dendritic material in the 8 month-old mice was significantly reduced compared to that of the 3 month-old mice: there was a 34% decrease in dendritic material. There was no additional reduction in dendritic extent of pyramidal cells between the 8 month-old mice and the 13 month-old mice. These findings suggest that in this rodent the transition from early to middle adulthood is associated with a extensive reorganization of dendritic arbor as shown by the reduction of dendritic material. However, in the 8 to 13 month-old range the dendritic field was shown to be stabile. (Supported by Central Soya, Dept. of Pathology, and the Office of Geriatrics and Gerontology).

FLUORESCENT STAINING OF THE CEREBRAL CORTEX IN LIVING MICE. A-S. LaMantia, S.L. Pomeroy, and D. Purves, Dept. Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, Missouri 63110

We have evaluated the ability of several vital dyes to stain the superficial layer of the cerebral cortex in living mice. Young adult male mice (CF1 strain, 25-30g) were anesthetized and placed on the stage of a modified compound microscope (Purves et al., J. Neurosci 6: 1051, 1986). Following a midline incision and 3 mm occipital craniotomy, the dura was reflected to expose the cortical surface. To enhance penetration of dyes through the pia/arachnoid, 0.01% saponin in lactated Ringer's was superfused over the cortex, followed by 10 μM dye solutions, each for 3 min. Electron microscopic analysis of detergent treated, fluorescent stained cortex fixed immediately after imaging revealed only moderate disruption of cortical cytology -- most notably, swelling of dendritic profiles in layer 1.

Of 13 nuclear dyes tested, bis-benzamide (Hoechst 33342) and DAPI (Sigma) gave the brightest and most consistent staining of nuclei within the pia/arachnoid; there was little nuclear staining beneath this layer. Of 23 cytoplasmic dyes examined, three styryl pyridinium dyes (4-Di-1-ASP, 4-Di-2-ASP, and 4-Di-5-ASP; Mol. Probes Inc.) were most effective. Small bipolar cells with fine, beaded processes extending at least 200 μm were stained completely; these cells were usually directly apposed to blood vessels. Each dye also revealed a granular pattern deep to the pia which probably represents layer I neuropil. Corollary observations of styryl pyridinium staining in other regions of the CNS support this conclusion. Thus in the olfactory bulb staining is confined to the glomerulae, which contain olfactory afferent terminals, and mitral cell and peri-glomerular cell dendrites. These in vivo observations are generally consistent with standard morphological descriptions, and suggest that vital fluorescent staining and imaging may be useful techniques for monitoring the anatomy of the central nervous system over time. (NIH NS18629 and 11699.)

ONTOGENY OF NEURONAL DISCHARGE PATTERNS IN THE OCCIPITAL CORTEX OF CHLORAL-HYDRATE ANAESTHETIZED RATS. M.A. Corner and M. Mirmiran*. Netherlands Institute for Brain Research, 1105 AZ Amsterdam.

Male Wistar rats varying in postnatal age from 2 to 12 weeks were studied under chloral hydrate anaesthesia, using glass microelectrodes to record spontaneous firing in single neurons at different depths within the occipital cortex. Computerized quantification of the spike trains revealed a wide variety of complex patterns which were unrelated either to cortical depth or to fluctuations in the local EEG. Nevertheless, significant and persistent changes of interneuronal profiles occurred in an orderly fashion for different parameters at different ages:
i) at 3-4 weeks, the modal values of the interval histograms decreased from ca. 25 msec (group median) to 4-5 msec; ii) at 4-5 weeks, the long-lasting clusters of relatively intense spike activity which are characteristic for immature animals became shorter by about two-thirds; iii) between 5 and 8 weeks, slow (longer than 2-3 min) fluctuations in the mean firing rate became half as small, on the whole; iv) between 8 and 12 weeks, prominent high-frequency rhythmic components (varying from 2 to 15 cps) appeared in the spontaneous firing of many neurons.

338.14

NEONATAL 6-OHDA AND ENRICHED REARING CONDITIONS: EFFECTS ON REGIONAL BRAIN ^{14}C-2-DEOXYGLUCOSE UPTAKE ARE CRITICALLY DEPENDENT ON AROUSAL AT TEST TIME. J.N. Nobrega, M.J. Saari, J. Armstrong* & T. Reed*. Clarke Institute of Psychiatry, Toronto, Ont., M5T 1R8, Canada, and Nipissing University College, North Bay, Ont., P1B 8L7, Canada.

A preliminary investigation had suggested that relatively few brain areas show changes in ^{14}C-2-deoxyglucose (2DG) uptake as a result of norepinephrine (NE)-depleting neonatal 6-OHDA treatment and/or rearing conditions. The present study examined the possibility that 2DG profiles in these animals might vary as a function of arousal state at test time. Forty-eight newborn male Wistar rats received s.c. injections of 6-OHDA or vehicle and were reared in "isolated" or "enriched" conditions (Neurosc. Abstr., 1987, 13, 406). ^{14}C-2DG procedures were performed when the rats were three months old. Rats received the 2DG injection (100 μCi/kg i.v.) and either stayed in the home cage, or were placed in a novel environment, an open field in a separate room, for 45 min before sacrifice. Overlaying of stained sections and autoradiographic images was used to quantitate label uptake (nCi/g tissue) in 97 brain areas. Analyses of variance revealed significant Open Field X 6-OHDA interaction effects in locus coeruleus, posterior hypothalamus, and three thalamic nuclei. Twenty other areas showed significant Open Field X Enrichment interaction effects. An Enrichment main effect was seen in the anterior pretectal area, somatosensory cortex, and three thalamic nuclei. These results suggest that the effects of early NE depletion and rearing conditions on the metabolic activity of a number of brain areas may only become apparent in the presence of arousing stimulation.

5-HYDROXYTRYPTAMINE ACTS AT 5-HT$_2$ RECEPTORS TO REDUCE G_K IN RAT NUCLEUS ACCUMBEN NEURONS. N. Uchimura* and R.A. North, Vollum Institute, Oregon Health Sciences Univ., Portland, OR 97201.

Intracellular recording were made from rat nucleus accumbens neurones in brain slices. 5-hydroxytryptamine (5HT, 1-100 μM) produced depolarization associated with an increase in the input resistance. Application of 5-HT to neurons voltage-clamped caused an inward current and a decrease in the slope conductance. The current caused by 5-HT was inward at the resting potential (typically about -80 mV) and reversed to outward at the potassium equilibrium potential. This reversal potential was linearly related to the logarithm of the extracellular potassium concentration. The depolarization caused by 5-HT persisted in tetrodotoxin (1 μM). It was not abolished by a solution that contained lower levels of calcium (0.24 mM), higher levels of magnesium (5 mM), and cobalt (2 mM). The 5-HT depolarization was competitively antagonized by ketanserin and mianserin with apparent dissociation equilibrium constants of about 3 nM and 45 nM, respectively. The depolarization was not mimicked or blocked by a number of agonists and antagonists selective for the 5-HT$_1$ and 5-HT$_3$ receptor. These results show that neurons of the rat nucleus accumbens are depolarized by 5-HT acting at 5-HT$_2$ receptors to reduce to conductance of the membrane to potassium ions.

339.2

CHARACTERIZATION OF 5-HT$_2$ RECEPTORS IN THE RAT FRONTAL CORTEX: ELECTROPHYSIOLOGICAL STUDIES. E. Edwards, K. Harkins*, L.H. Jiang, R.J. Kasser, C.R. Ashby, Jr. and R.Y. Wang, Dept. of Psychiatry & Behav. Sci., SUNY at Stony Brook, Stony Brook, NY 11794.

There is strong evidence for 5-HT$_2$ involvement in the mechanism of action of hallucinogenic agents. Receptor binding autoradiography have revealed a high concentration of 5-HT$_2$ binding sites in the rat frontal cortex (FC). The aim of the present study was to characterize 5-HT$_2$ receptors using the techniques of single cell recording and microiontophoresis (ionto). Ionto-5-HT, 5-HT$_{1a}$ receptor agonist 8-hydroxy-2-[dipropyl-amino]-tetralin (8-OH-DPAT), 5-HT$_{1b}$ receptor agonist m-chlorophenylpiperazine (mCPP) and 5-HT$_2$ receptor agonist [1-4-iodo-2,5-dimethoxyphenyl]2-aminopropane (DOI) on FC cells all suppressed the neuronal activities in the FC. The 5-HT$_2$ receptor antagonist ketanserin partially blocked the depressant effect of DOI but not that induced by other 5-HT agonists. In fact, ketanserin potentiated the effect produced by 5-HT, 8-OH-DPAT and mCPP. The blockade of DOI by ketanserin cannot be due to its anti-α_1-adrenoceptor effect because α_1-adrenoceptor antagonist prazosin did block the action of DOI. To further characterize 5-HT$_2$ receptor subtypes in the FC requries more specific 5-HT$_2$ agonists and antagonists. (Supported by USPHS grants MH-41440, MH-41696 and MH-00378 to R.Y.W and BNS-8614098 and MH-44048 to E.E).

5-HT_2 RECEPTORS IN RAT PREFRONTAL CORTEX. R.C. Araneda* and R. Andrade (SPON: K. Shibata). Dept. of Pharmacology, St. Louis Univ. School of Med., St. Louis, MO 63104.

While the pharmacology, distribution and biochemistry of central 5-HT_2 receptors have been extensively investigated, little is still known about the physiological responses they mediate. Therefore we have used intracellular recordings in in vitro rat cortical slices to examine the effects of 5-HT on the prefrontal cortex, an area highly enriched in these receptors.

Bath administration of serotonin (.1 µM - 30 µM) elicited three distinct spiperone and ketanserin sensitive responses. These included a small, subthreshold depolarization associated with a conductance decrease, a reduction in the slow afterhyperpolarization which follows a burst of spikes, and a marked decrease in spike frequency accommodation. In addition, when 5-HT_{1a} and 5-HT_2 receptors coexisted on the same cell, activation of the 5-HT_2 receptors reduced or blocked the ability of the 5-HT_{1a} receptors to hyperpolarize these cells.

Thus, activation of 5-HT_2 receptors in this region elicits a set of distinct actions which interact to produce an increase in excitability to incoming stimuli while blocking the inhibitory actions of 5-HT.

EFFECTS OF KETANSERIN PRETREATMENT ON MDMA-INDUCED SEROTONIN (5-HT) DEPLETION IN THE RAT. J.F. Nash and H.Y. Meltzer, Department of Psychiatry, School of Medicine, Case Western Reserve University, Cleveland, Ohio 44106

Previous studies conducted in our laboratory have established that +3,4-methylenedioxymethamphetamine (MDMA) stimulates the secretion of corticosterone in a dose- and time-dependent manner, and that ketanserin pretreatment prevents this effect of MDMA. MDMA has been reported to deplete brain concentrations of 5-HT and its major metabolite, 5-hydroxyindoleacetic acid (5-HIAA) in a biphasic manner. The present study was undertaken to determine the effect of ketanserin pretreatment on acute (3 hr) and chronic (7 day) MDMA-induced 5-HT and 5-HIAA depletion. A single injection of MDMA (20 mg/kg, s.c.) significantly reduced the concentration of 5-HT and 5-HIAA in the following brain areas: frontal cortex > hippocampus=striatum > hypothalamus at 3 hr and 7 days. Treatment of rats with ketanserin (3 mg/kg, i.p) 1 hr prior to MDMA administration significantly attenuated MDMA-induced depletion of 5-HT and 5-HIAA at both time points. Ketanserin prevented MDMA-induced depletion most significantly in the striatum followed by the hippocampus and frontal cortex. MDMA-induced depletion of 5-HT and 5-HIAA in the hypothalamus was unaffected by ketanserin. These data suggest that reducing the acute MDMA-induced depletion of 5-HT and 5-HIAA by ketanserin pretreatment attenuates the long-term depletion. We propose that overstimulation of 5-HT_2 receptor mechanisms may, in part, account for the long-term depletion of 5-HT following a single administration of MDMA.

339.5

ARACHIDONIC ACID (AA) METABOLISM REGULATES GENERATION AND DESENSITIZATION (DEZ) OF A 5-HT_2 RECEPTOR- MEDIATED RESPONSE. B.Dalton*, J.Kaplan*, S.Maayani and R.R.Ben-Harari* (SPON: J.Goldfarb). Depts. of Pharmacology and Anesthesiology, Mt.Sinai Sch. Med., CUNY, N.Y., N.Y.10029.

Intracellular mediators, such as eicosanoids, modulate DEZ of a variety of receptor systems in smooth muscle. The response to 5-HT on guinea-pig trachea undergoes rapid DEZ and is 5-HT_2 receptor-mediated. The effect of inhibitors of eicosanoid metabolism on this response and DEZ was studied by novel kinetic procedures utilizing on-line computer digitization.

Drug(concentration; site of action)	Peak tension	DEZ rate
Indomethacin (1uM; cyclooxygenase)	↑	=
Nordihydro-guaiaretic acid (NDGA) (30uM; lipoxygenase and cytP450 oxygenase)	=	↑
Clotrimazole (Clo) (1uM; cyt P450 oxygenase)	↑	↓
Clo + NDGA	↑	↑
Arachidonic acid (AA) (10uM)	=	↓
AA + INDO	↑	↑
AA + NDGA	=	↑

We propose that the AA cascade participates both in generation and in DEZ of 5-HT_2-mediated responses. (Supported by USPH GM-34852)

339.6

SEROTONINERGIC (5-HT_2) REGULATION OF PLASMA CORTICOSTERONE AND PROLACTIN. C.Cosi, H.S.Kim and P.L.Wood. Res. Dept., Pharmaceut. Div., CIBA-GEIGY, Summit, NJ 07901.

The effect of DOI [1-(2,5-dimethoxy-4-iodophenyl-)2-aminopropane], a 5-HT_2 agonist, on plasma corticosterone and prolactin (PRL) was investigated in rats. PRL and corticosterone were detected in the same sample by radioimmunoassays. DOI (0.2-0.5 mg/kg ip) increased corticosterone to 277% and 325% of control respectively, in a dose-dependent manner. PRL was increased to 367% of control by 0.5 mg/kg DOI. In a time course experiment, DOI (0.2 mg/kg) increased corticosterone to 565% and 292% of control at 30 and 45 min respectively. DOI increased PRL to 392% of control at 30 min. At 60 min after DOI, both corticosterone and PRL had returned to control levels. Pretreatment with cinanserin (10 mg/kg ip), a 5-HT_2 antagonist, completely suppressed the action of DOI and did not affect, by itself, corticosterone or PRL. These results indicate that 5-HT_2 receptors are involved in mediating serotonin increases of plasma corticosterone and PRL.

5-HT-3 BINDING SITES IDENTIFIED IN RAT BRAIN USING [^{3}H]-ICS-205-930 A.W. Schmidt, C.J. Siok and T.F. Seeger* Pfizer Central Research, Groton, CT 06340

Serotonin receptors have been classified into multiple subtypes designated 5-HT-1, 5-HT-2 and 5-HT-3. 5-HT-1 and 5-HT-2 receptors have been extensively studied in brain, while knowledge about 5-HT-3 receptors largely has been accumulated from studies on peripheral tissues. More recently, 5-HT-3 binding sites have been identified in rat brain using [^{3}H]-GR-65630. We now report and confirm the identification of 5-HT-3 binding sites in rat brain using the tritiated form of the specific 5-HT-3 receptor antagonist ICS-205-930. Saturation experiments utilizing homogenates of rat frontal and entorhinal cortices show that binding occurs with high affinity (K_d = 1.30 nM) and a binding capacity of 29.2 fmol/mg protein. Specific 5-HT-3 antagonists inhibit [^{3}H]-ICS-205-930 with nanomolar affinity (ICS-205-930 > GR-38032F > MDL-72222). The rank order of affinity agrees well with the relative potency of these compounds as antagonists of 5-HT induced bradycardia (Bezold-Jarisch reflex), a 5-HT-3 mediated event. Agonists inhibited [^{3}H]-ICS-205-930 binding with lower affinity than antagonists (5-HT > phenylbiguanide > 2-methyl-5-HT). Other serotonergic agents (8-OH-DPAT, methysergide, cinanserin) did not significantly inhibit binding at 1 uM. Preliminary autoradiographic studies reveal a heterogeneous distribution of radiolabel in the rat brain. Highest levels of binding were found in entorhinal and frontal cortices with moderate levels of binding in limbic areas (amygdala, hippocampus, n. accumbens/olf. tub).

5-HT_3 RECEPTORS IN THE RABBIT RETINA? W.J.Brunken & N.W.Daw Dept of Biology, Boston College Chestnut Hill, MA 02167 and Dept of Cell Biology, Washington Univ. St. Louis MO 63110

We have suggested previously that both 5-HT_1 & 5-HT_2 receptors have a role in signal processing in the rabbit retina (JNS 7:1054-1065). In preliminary experiments we have employed MDL 72222 and ICS 205-903, serotonin antagonists selective for 5-HT_3 receptors in a superfused isolated eyecup preparation to test if 5-HT_3 receptors affect the visual responses of the ganglion cell, the output neuron of the retina.

These drugs had reversible effects on the visual responses of both ON and OFF center brisk cells. For all cells tested, the ON-excitation was reduced and in some cells the OFF-excitation was increased. The spontaneous activity of all classes of cell was also decreased. These effects were reversed in 10 to 30 minutes after the drugs were washed out of the perfusion bath.

The results obtained with these agents are similar in all respects as those obtained with agents selective for 5-HT_2 receptors. These results may imply either that 5-HT_3 receptors are present in the mammalian retina or that the reputed 5-HT_3 agents have actions at central 5-HT_2 receptors. Further experimentation will be necessary to confirm a functional role for 5-HT_3 receptors in the retina. (Sponsored by EY 06776 WJB and EY 00053 NWD)

SEROTONIN-3 RECEPTOR MEDIATED SPINAL ANTI-NOCICEPTION. S.R.Glaum and E.G.Anderson, Dept. of Pharmacology, U of I/Chicago. Chicago IL 60680

We recently reported that the potent and selective $5HT_3$ receptor antagonists ICS 205-930 and MDL 72222 inhibit specific ^{3}H-Serotonin binding to purified rat dorsal spinal cord synaptosomal membranes (Eur.J.Pharm.,submitted). Intrathecal (IT) administration of 5HT is known to produce significant antinociception as measured by increased tail-flick latency (TFL). We now report that the selective $5HT_3$ receptor agonist 2-methyl-5HT mimics the antinociceptive action of 5HT. Additionally, the selective $5HT_3$ receptor antagonist ICS 205-930 inhibits 5HT induced antinociception.

50,100 or 200µg IT infusions of 5HT or 2-methyl-5HT produced dose-dependent increases in TFL ($p<0.01$) at 5, 15 and 25 min post-injection. Treatment with 0.1-10µg ICS 205-930 alone produced no significant change in TFL. However, pretreatment with 0.1-1.0µg ICS 205-930 5 min prior to 200µg 5HT completely blocked anti-nociception. Furthermore, administration of 10µg ICS 205-930 prior to 200µg 5HT produced a significant decrease in TFL (hyperalgesia). These findings strongly implicate $5HT_3$ receptors in mediating spinal analgesia. PHS NS 17834-04.

5-HYDROXYTRYPTAMINE INFLUENCES RELEASE OF DOPAMINE AND ITS METABOLITES FROM RAT STRIATAL SLICES. P. Blandina* and J.P. Green. Department of Pharmacology, Mount Sinai School of Medicine, City University of New York, New York, NY 10029.

Serotonergic fibers originating from the dorsal raphe nucleus project into the striatum but the function of 5-hydroxytyptamine (5-HT) in striatum is still unclear since the neurotransmitter has been reported to have both excitatory and inhibitory effects (Chesselet M.F., Neurosci. 12, 347, 1984). The role of 5-HT in the release of endogenous dopamine (DA), dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) from superfused striatal slices was assessed. Eight week old, male Sprague-Dawley rats were decapitated, and striatal slices (400 µm thick) were superfused with artificial cerebrospinal fluid (aCSF) containing nomifensine (10 µM) to block DA reuptake. Measurements were made by high performance liquid chromatography with electrochemical detection. Spontaneous release of DA from the slices averaged 1.9 pmol/mg protein/3 min. The release of DOPAC and HVA averaged 3.5 and 1.1 pmol/mg protein/3min, respectively. Superfusion with 5-HT (10µM) resulted in a 3-fold elevation of DA release with no significant changes in the release of DOPAC and HVA. The 5-HT agonists 5-carboxyamidotryptamine (1 µM) and 2,5-dimethoxyphenylisopropylamine (10 µM) were ineffective in increasing the spontaneous release of DA, DOPAC or HVA. 2-Methyl-5-HT (10µM), an agonist of 5-HT selective for the 5-HT3 receptor, produced a 3-fold increase in spontaneous release of DA without altering the release of DOPAC or HVA. The 5-HT3 receptorshas been described in the peripheral nervous system where they appear to mediate the excitatory effects of 5-HT. These data suggest that the 5-HT3 receptor is present in brain as well. Supported by a grant (DA 01875) from the National Institute on Drug Abuse.

EXAMINATION OF THE EFFECTS OF THE 5-HT_3 RECEPTOR ANTAGONIST MDL-72222 ON PUNISHED RESPONDING IN PIGEONS. S.T. Ahlers and J.E. Barrett. Department of Psychiatry, Uniformed Services University of the Health Sciences and the Naval Medical Research Institute, Bethesda, MD 20814.

MDL-72222, a 5-HT_3 receptor antagonist, was examined for potential anxiolytic activity using a behavioral assay that, in general, has correlated well with clinically efficacious anxiolytics in humans. Pigeons were trained to key peck under a multiple fixed ratio (FR) 30-response schedule in which different components were correlated with a red or white keylight color; components alternated every 3 min. During one component, the 30th response also produced a brief electric shock which suppressed responding (punishment). MDL-72222 at doses from 0.001 to 3.0 mg/kg, i.m. administered immediately before the session produced slight increases in punished responding of some pigeons within a narrow dose range of 0.1-0.3 mg/kg. Unpunished response rates were unaffected across most of the dose response curve. Overall, the effects of MDL-72222 on punished responding were relatively weak compared to buspirone or chlordiazepoxide which have robust effects under this procedure and show potent anxiolytic activity in humans. Supported by PHS Grant DA-02873.

339.12

COMPARATIVE BEHAVIORAL EFFECTS OF SEROTONIN-3 ANTAGONISTS AND DOPAMINE ANTAGONISTS IN RODENTS. **A.E. Williams*, J.N. Wiley* and T.G. Heffner (SPON: D.A. Downs). Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor, MI 48105.**

Based on reports of possible antipsychotic utility of serotonin-3 ($5HT_3$) antagonists, we examined the effects of the reported $5HT_3$ antagonists GR 38032F (GR), MDL 72222 (MDL), and ICS 205930 (ICS) in locomotor activity tests in rodents. In mice, MDL reduced spontaneous locomotion with an ED_{50} of 5 mg/kg IP and did not cause ataxia at active doses, a profile seen with dopamine antagonists. ICS reduced locomotion at higher doses (ED_{50} = 28 mg/kg IP) in mice and also did not cause ataxia. GR did not reduce locomotor activity in mice at doses of 0.001 - 3 mg/kg IP; higher doses were lethal. In rats, MDL reduced locomotor activity after oral dosing with an ED_{50} of 8 mg/kg; GR and ICS were inactive at doses up to 10 and 100 mg/kg PO, respectively. GR failed to reduce locomotion in rats after SC or IP dosing with up to 10 mg/kg. Neither acute nor BID dosing with GR for 3 successive days reduced d-amphetamine-induced hyperactivity in mice. In contrast, both MDL and ICS antagonized amphetamine stimulation in mice. These results indicate that while the profiles of MDL 72222 and ICS 205930 in these tests share common features with those of dopamine antagonists, this activity is not seen with the other $5HT_3$ antagonist, GR 38032F.

339.13

EFFECTS OF THE SEROTONIN-3 (5HT-3) ANTAGONIST, GR38032F, ON MIDBRAIN DOPAMINE (DA) NEURONS. C.L. Christoffersen, K.A. Serpa, and L.T. Meltzer. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

GR38032F (1,2,3,9-tetrahydro-9-methyl-3-[(2-methylimidazol-1-yl)methyl]-4H-carbazole-4-one, hydrochloride) is a potent and selective 5HT-3 receptor antagonist (Brittain et al., Br. J. Pharmac. 90: 87P, 1987) that has been shown to decrease mesolimbic DA hyperactivty in behavioral and biochemical experiments (Costall et al., Br. J. Pharmac. 92:881, 1987; Hagan et al., Eur. J. Pharmac. 138: 303, 1987). In the present experiments we have begun to evaluate the effects of GR38032F on the firing activity of midbrain DA neurons, recorded extracellularly in chloral hydrate anesthetized rats. IV administration of GR38032F in cumulative doses up to 1 mg/kg had no effect on the baseline firing rate of DA neurons in either the A9 or A10 areas. Pretreatment with GR38032F (1 mg/kg IV) did not alter the inhibitory effects of d-amphetamine but did attenuate the excitatory effects of morphine (0.5 mg/kg IV) on A10 DA neurons. These preliminary electrophysiological results support the contention that GR38032F may selectively affect DA hyperactivity without altering basal activity.

339.14

TYPES OF 5-HYDROXYTRYPTAMINE (5-HT) RECEPTORS IN MOLLUSCAN HEARTS. C. D. Bruce*, M. C. Sutter* (SPON: B. R. Sastry). Department of Pharmacology & Therapeutics, The University of British Columbia, Vancouver, Canada, V6T 1W5.

It has been shown that hearts of molluscs are very sensitive to 5-HT. This study examines the contractile response of Saxidomus giganteus hearts to 5-HT, or 5-carboxamidotryptamine (5-CT) a 5-HT_1 agonist, alone and in the presence of an antagonist, methiothepin (MT), and to methysergide (UML), an antagonist with partial agonist properties. The ventricles were suspended at a resting tension of 0.5 g in aerated low Mg seawater at 16° C. Cumulative curves were constructed for force and rate in response to the agents. 5-HT produced an initial small decrease, followed by a marked increase in force (EC_{50}, 2×10^{-7} M) and rate. 5-CT produced only a marked decrease in rate and force (EC_{50}, 9×10^{-10} M) which was antagonised by 5×10^{-7} M methiothepin. UML acted as a partial agonist: an inhibitory effect on force and rate (EC_{50} 2×10^{-8} M) but reduced maximum effect. The biphasic response (initial inhibition followed by excitation) seen with 5-HT suggests that at least 2 types of 5-HT receptors are present in the hearts of Saxidomus. 5-CT produced only a potent inhibitory response (blocked by MT) while UML seems to be a partial agonist.

339.15

NEUROENDOCRINE RESPONSES DEMONSTRATING A FUNCTIONAL UP-REGULATION OF 5-HT RECEPTORS AFTER DESTRUCTION OF SEROTONERGIC NERVE TERMINALS. R.J. Maslowski*, P.A. Rittenhouse*, and L.D. Van de Kar, Loyola Univ. Chicago, Stritch Sch. Med., Dept. Pharmacology, Maywood, Il 60153.

The present studies were designed to determine whether the 5-HT receptors which increase renin and corticosterone (CORT) secretion are pre- or post-synaptic. Rats treated with nomifensine (15 mg/kg, i.p.) to protect catecholamine terminals, were injected bilaterally with 5,7-DHT (75 μg/10 μl/side i.c.v.) to destroy 5-HT nerve terminals. Two weeks later, the rats received an injection of the 5-HT agonist RU24969 (0.2, 1.0, or 5.0 mg/kg, i.p.) or saline, 30 minutes prior to sacrifice. In 5,7 DHT treated rats, there was a shift to the left in the dose-response curve for the effect of RU24969 on CORT release. The minimal dose which significantly increased CORT, decreased from 5.0 mg/kg to 1.0 mg/kg. The dose which produced a significant increase in plasma renin activity/concentration also decreased from 1.0 mg/kg in the vehicle group to 0.2 mg/kg in 5,7-DHT treated rats. In conclusion, the neuroendocrine response to the 5-HT agonist RU24969 was not blocked after the destruction of 5-HT nerve terminals, suggesting that the 5-HT receptors which mediate this response are located postsynaptically. The shift in the dose response curves suggests functional denervation supersensitivity of the 5-HT receptors.

339.16

AGING AND SEROTONIN RECEPTOR BINDING: EVALUATION IN FEMALE FISCHER 344 RATS. R.E. Halpern* and J.M. Lakoski. Dept. Pharmacol., Univ. Texas Med. Branch, Galveston, TX 77550.

An age-related decline in presynaptic 5-HT function has been identified from electrophysiologic recordings of 5-HT dorsal raphe neurons (DRN) in female rats. To identify the mechanisms which may underlie such physiological changes, we evaluated 5-HT receptor binding sites in brain tissue from aged female rats.

Female Fischer 344 rats (Young, cycling 3-4 mo and Old, acyclic 17-18 mo) were ovariectomized (7 days), vehicle implanted (sesame oil) for 48 hr and sacrificed. Brain tissue was rapidly removed, dissected and stored at -80°C until assayed. Radioligand binding studies were carried out using [^{3}H]5-HT (0.05-32 nM), with tissue diluted 1:25 in Tris-HCl buffer; nonspecific binding was determined using 10^{-4}M 5-HT. Scatchard analysis were performed using LIGAND (Elsevier; Coef. Co.> 0.90) and protein values determined by Bio-Rad assay. No alterations in receptor number (Bmax) were detected in Young vs Old prefrontal cortex (PFC; 168 vs 145 pmol/mg prot.) and DRN (166 vs 160 pmol/mg prot.). In contrast, receptor affinity apparently decreased with age (Young vs Old) in the PFC (Kd 10.9 vs 15.4 nM) but not the DRN (Kd 16.8 vs 17.2 nM). These data suggest that age related changes in 5-HT PFC but not DRN receptor binding sites occur in the female rat. Further investigations are evaluating age-induced changes in 5-HT receptor subtypes. Supported by AG 06017.

HYPERAMMONEMIA LEADS TO INCREASED BRAIN SEROTONIN METABOLISM IN UREASE INFUSED RATS. Mark L. Batshaw, Susan L. Hyman*, Melvyn P. Heyes, John Anegawa*, Joseph T. Coyle, Michael B. Robinson. (SPON: S. Logan) Dept Pediatr, Psychiat and Kennedy Inst, Johns Hopkins School of Medicine, Baltimore, MD 21205

Children with congenital hyperammonemia (HA) develop behavioral alterations including anorexia and changes in activity and sleep. Osmotic minipumps were implanted ip to deliver urease, 4.5 U/100g/d, into halothane anesthetized rats and produce HA. Behavioral alterations included anorexia and increased activity changes; a few rats seized. Mean plasma ammonium levels (n=5 each) just prior to sacrifice at 12, 24 and 48 h. after implant were 1600, 2980, 4900 uM vs sham levels of 77-130. Some nonpolar and large hydrophobic amino acids were increased in cortex. There were 2-4 fold increases in levels of tryptophan, glutamine and 5-HIAA in cortex, $p<0.05$-.001, compared to sham. There were no significant changes in quinolinic acid, the other major pathway for tryptophan metabolism nor in other biogenic amines. We conclude that urease infusion is an apt model of congenital hyperammonemia and that there is an increase in serotonin metabolism that may relate to the neurobehavioral abnormalities in these disorders.

339.18

COMPARISON OF THE ANTI-EMETIC ACTION OF TWO SUBSTITUTED BENZAMIDES, ZACOPRIDE AND BMY 25801 G.L King and V.A. Kieffer* Dept. of Physiology, AFRRI, Bethesda, MD 20814-5145.

These studies were conducted to compare the anti-emetic potency of zacopride (Z; AH Robins) with that of BMY25801 (Bristol-Myers), vs. radiation-induced emesis (RIE) in the ferret. Adult male, castrated ferrets (n = 8 - 10 per group) were given (ip) Z (0.003, 0.03 or 0.3 mg/kg), BMY (3 mg/kg) or vehicle (NaCl) prior to ^{60}Co radiation (2,4 or 6 Gy @ 1 Gy/min). The following emetic parameters were recorded for 2 hrs post-irradiation: latency to first emesis, duration of prodromal phase, duration and number of individual emetic bouts, and number of emetic expulsions (vomitus expelled). 100% of NaCl-irradiated animals vomited at all 3 radiation doses. The ED_{50} for RIE (0.77 Gy; King, Radiat. Res., in press) was increased by 0.3 Z $\geq$ 0.03 Z > 3.0 BMY, but unaffected by 0.003 Z. For each parameter, all responding (vomiting) animals were compared to NaCl-treated controls. Preliminary analysis indicates the following rank order of anti-emetic potency: 0.3 Z $\geq$ 3.0 BMY > 0.030 Z >> 0.003 Z > NaCl-irradiated controls. Depending on administration route, however, Z produced side effects of retching/emesis and defecation in the ferret (King et al., FASEB J 2:A325, 1988). We are currently evaluating BMY for similar effects.

339.19

8-OH-DPAT AND 5-HT3 ANTAGONISTS DIFFER IN EFFICACY VS. MOTION-, XYLAZINE- AND CISPLATIN-INDUCED EMESIS. J.B. Lucot and G.H. Crampton. Dept. Pharmacol., Wright State Univ., Dayton, OH 45435.

Buspirone has been reported to have broad spectrumed antiemetic efficacy in cats. Its site of action required verification by testing 8-OH-DPAT against the same emetic stimuli. 5-HT3 antagonists have been reported to prevent radiation- and cisplatin-induced emesis in ferret. The antiemetic effects of these drugs was tested against three emetic stimuli in cats and compared with 5-HT1A agonists.

The emetic stimuli were: 1) motion in a devise similar to a Ferris wheel, 2) 0.66 mg/kg xylazine SC and 3) 7.5 mg/kg cisplatin IV. 8-OH-DPAT prevented motion sickness with an ED50 of 0.011 mg/kg and xylazine-induced emesis with an ED50 of 0.056 mg/kg. The dose of 0.64 mg/kg significantly decreased the number of emetic events and increased the latency to the first vomit. ICS 205 930 (1 mg/kg SC) completely abolished cisplatin-induced emesis. However, ICS 205 930 (1 and 0.1 mg/kg), MDL 72222 (1 and 0.1 mg/kg) and zacopride (0.01-10 mg/kg) did not prevent motion sickness and ICS 205 930 and MDL 72222 did not prevent xylazine-induced emesis. 5-HT3 antagonists had greater efficacy in preventing cisplatin-induced emesis but stimulation of 5-HT1A receptors had efficacy against several stimuli. The two classes of drugs appear to act through different mechanisms.

339.20

ENDOGENOUS MELATONIN (MEL) REGULATES NORADRENERGIC ACTIVITY IN THE HYPOTHALAMUS OF C3H/HeN MICE. J. M. Fang* and M. L. Dubocovich. (SPON: C. H. Wu). Dept. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

Activation of MEL receptor sites modulates the activity of norepinephrine (NE) neurons innervating the hypothalamus of C3H/HeN mice (Fang and Dubocovich, FASEB J. 6: A1802, 1988). The role of endogenous MEL in modulating NE activity was assessed by blocking MEL receptor sites with the antagonist luzindole (LUZ, 30 mg/kg, i.p., 30 min). The levels of NE (ng/mg tissue) in the hypothalamus of C3H/HeN mice were determined following inhibition of NE synthesis with α-CH_3-p-tyrosine (α-MpT, 300 mg/kg, i.p., 2 h) by HPLC with EC detection. At noon, when the levels of endogenous MEL are low, LUZ did not affect the turnover of NE [Noon: Control: 2.82 ± 0.1 (n=10), α-MpT: 2.17 ± 0.06 (n=10), α-MpT plus LUZ: 2.14 ± 0.26 (n=4)]. 6-Cl-MEL (30 mg/kg, i.p., 30 min) reversed the α-MpT induced-depletion of NE [α-MpT plus 6-Cl-MEL: 2.69 ± 0.1 (n=10), $p<0.001$]. This effect was blocked by LUZ [α-MpT plus 6-Cl-MEL plus LUZ: 2.27 ± 0.06 (n=9), $p<0.005$]. At midnight, when the levels of MEL are high, LUZ significantly decreased the levels of NE after treatment with α-MpT, suggesting activation of MEL receptor sites by endogenous MEL [Midnight: Control: 3.39 ± 0.2 (n=10), α-MpT: 2.82 ± 0.15 (n=10), α-MpT plus LUZ: 2.38 ± 0.12 (n=7), $p<0.05$]. We conclude that the activation of MEL receptor sites in C3H/HeN mouse brain by endogenous MEL inhibits NE activity leading to decrease in NE release in the hypothalamus. Supported by grant DK 38607.

DOPAMINE AGONISTS MAINTAIN MAGNESIUM INDUCED CONDITIONED PLACE PREFERENCE. S.I. Lawley and K.M. Kantak. Lab. of Behav. Neurosci., Dept. of Psychol., Boston University, Boston, MA 02215.

Reinforcing properties of magnesium (Mg^{2+}) were studied using conditioned place preference (CPP) in mice. It is well known that stimulants will support CPP. Previous studies indicate that magnesium chloride ($MgCl_2$) will act as a reinforcer in the CPP paradigm at a dose of 15 mg/kg. We used a substitution paradigm in the CPP procedure to test the effects of various drugs on Mg^{2+} reinforced behavior. Only animals which showed a greater than 50% shift in preference were used in the substitution procedure. In these experiments 64% of the animals showed a change in preference following conditioning. The indirect dopamine (DA) agonists, amphetamine and cocaine, maintained Mg^{2+} conditioning while the DA blocker haloperidol significantly attenuated it. Pentobarbital which is known not to bind the DA receptor also maintained Mg^{2+} conditioning. Results implicate involvement of Mg^{2+} in the DA theory of reward.

THE EFFECTS OF INTRA-VTA INFUSIONS OF MORPHINE AND DYNORPHIN(1-13) ON MALE SEXUAL BEHAVIOR. J.B. Mitchell and J. Stewart, Center for Studies in Behavioral Neurobiology, Dept. of Psychology, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

Data suggests that the mesolimbic DA system is involved in mediating sexual arousal (Baum & Starr, Pharm. Biochem. & Behav., 13:175, 1980; Cagguila et al., Brain Res., 111:321, 1976). Morphine is known to increase the activity of dopaminergic cells (Matthews & German, Neurosci., 11:617, 1984; Gysling & Wang, Brain Res., 277:119, 1983), and when applied to the region of mesolimbic DA cell bodies, the VTA, increases locomotor activity (Joyce & Iversen, Neurosci. Let., 14:207, 1979; Vezina & Stewart, Pharm. Biochem. & Behav., 20:925, 1984), and feeding (Hamilton & Bozarth, Neurosci. Abs., 13:412, 1987). The opioid peptide, dynorphin, applied to the VTA also increases feeding (Hamilton & Bozarth, 1987).

Castrated males, maintained on behaviorally subthreshold doses of testosterone, were tested for sexual behaviors after intra-VTA infusions of 0.1 to 30 nmoles morphine, or of 0.03 to 3 pmoles dynorphin(1-13). Both morphine and dynorphin produced dose-dependent increases in the number of males that mounted and increased the display of female-directed behaviors, such as pursuit of the female, anogenital exploration, and partial mounts. To investigate the effect of dynorphin on mesolimbic dopamine metabolism, different groups of animals were sacrificed after intra-VTA infusions of saline, 10 nmoles morphine, or 0.3 pmoles dynorphin(1-13) and DA and DOPAC levels in the nucleus accumbens and medial frontal cortex estimated using HPLC-EC. Morphine, but not dynorphin, increased the concentration of DOPAC and the DOPAC/DA ratio in the nucleus accumbens.

These results suggest that the mesolimbic dopamine system is involved in mediating sexual arousal, but that other non-dopaminergic elements in the VTA, perhaps accessed by kappa-opioid receptors, are also involved in sexual behaviors.

PLASMA HOMOVANILLIC ACID (HVA) CHANGES DURING TESTOSTERONE OR NANDROLONE ADMINISTRATION IN HUMANS. C.J. Hannan, Jr., T.M. Kettler,* K.E. Friedl* and S.R. Plymate.* Clinical Investigation Dept, Madigan Army Med Ctr, Tacoma WA 98431.

An association of anabolic steroid administration with psychiatric symptoms prompted our examination of proposed biochemical markers of psychosis during steroid administration. Twenty-five male subjects received 6 weekly IM injections of 100 or 300 mg testosterone enanthate (Te), or 100 or 300 mg nandrolone decanoate (Nan). Two blood samples were drawn on different days before drug administration, and two were drawn during the 6th wk after the final drug dose. Serum levels of HVA and 5-hydroxyindoleacetic acid (5-HIAA) were determined by HPLC with dual electrode detection and separated with two mobile phases to confirm the purity of the eluted compounds. Increases in plasma HVA were found in both Nan groups but not in the Te subjects. Plasma HVA is an indicator of tissue dopamine turnover.

Metabolite* (ng/ml)	100 mg TE n=7	300 mg TE n=5	100 mg Nan n=6	300 mg Nan n=7
Δ HVA	0.6±1.2	-1.0±1.3	3.2±1.8†	2.0±0.6†
Δ 5-HIAA	-2.5±3.0	0.1±3.0	0.9±3.6	-3.2±4.3

*Mean changes (post-pre)±SE † = p<0.05 by Wilcoxon

The large proportion of plasma HVA which originates from CNS metabolism of dopamine has been suggested to explain its correlation with severity of psychosis in psychiatric patients. The demonstrated alteration in dopamine metabolism associated with Nan provides a mechanism to explain reported altered behavior in some anabolic steroid users.

THE PRIMING PHENOMENON IN THE EXPRESSION OF DOPAMINE RECEPTOR SUPERSENSITIVITY: DOSE AND TEMPORAL DEPENDENCY. M. Morelli & G. Di Chiara. Inst. Exp. Pharm. & Tox. Univ. Cagliari, Italy.

We have recently shown in rats unilaterally lesioned with 6-hydroxydopamine (6-OHDA) from 14 days, that the expression of D-1 receptor supersensitivity depends upon previous "priming" with a DA receptor agonist. In this study we examined the temporal and the dose-dependency characteristics of "priming". Male Sprague-Dawley rats lesioned in the left medial forebrain bundle (MFB) with 6-OHDA were used throughout all the experiments. Administration of the D-1 receptor agonist SKF38393 (2mg/kg) failed to induce contralateral turning (c.t.) in naive rats lesioned from 14 days, but produced an intense contralateral turning in naive rats lesioned from 90 days. A single administration of the D-1/ /D-2 receptors agonist apomorphine (0.1 mg/kg, 3 days before) which produced c.t. by itself, made SKF38393 very active in inducing c.t. in 14 days lesioned rats. The "priming" induced by apomorphine develops with time, in fact administration of SKF38393 three hours after apomorphine, failed to elicit c.t..Like apomorphine, also the D-2 receptor agonist LY171555 and SKF38393 itself induced "priming" in 6-OHDA lesioned rats from 14 days. This "priming" however was strictly dependent from the dose of the drug used. Moreover "priming" with any of the mentioned drugs was ineffective in rats lesioned from 7 days. The results indicate that efficacy of "priming" depends from the time of "priming" and from the dose of the drug used for "priming".

LESIONS OF THE SUBSTANTIA INNOMINATA UNMASK AN INHIBITORY EFFECT OF APOMORPHINE ON ACOUSTIC STARTLE. C.B. Sananes, J.M. Hitchcock, J.B. Rosen, M.J.D. Miserendino & M. Davis. Dept of Psychiatry, Yale University, Ribicoff Research Fac., Conn. Mental Health Ctr., New Haven, CT, 06508.

Dopamine receptor subtype agonists have opposite effects on the acoustic startle reflex. D1 agonists increase startle whereas D2 agonists depress it. The net effect of the mixed D1 and D2 agonist apomorphine is an enhancement of startle. However, this effect can be reversed into inhibition by pretreatment with the D1 antagonist SCH 23390. The present study sought to determine whether various dopamine projection areas are involved in apomorphine's effect on startle.

Rats were given bilateral electrolytic lesions of either the nucleus accumbens, the central nucleus of the amygdala, the prefrontal cortex or the substantia innominata. Following recovery, animals were tested for the effects of apomorphine (0.4 mg/ kg s.c.) and saline on acoustic startle. Half of the animals were tested with apomorphine first, and the other half with saline first. Sham-lesioned and unoperated groups were also tested.

Lesions of the nucleus accumbens, the central nucleus of the amygdala, or the prefrontal cortex had no effect on apomorphine's enhancement of startle. In contrast, lesions of the substantia innominata changed the usual excitatory effect of apomorphine into an inhibitory one. Thus, lesions of the substantia innominata,which receives dopamine projections from A8 and A10, had the same effect as pretreatment with a D1 antagonist where the D1 excitatory effect was blocked, thereby unmasking an underlying inhibitory effect of apomorphine. These data suggest that the D1and D2 effects of apomorphine on startle are independent and have different anatomical loci of action.

340.6

DIFFERENTIAL EFFECTS OF SELECTIVE DOPAMINE AGONISTS AND ANTAGONISTS ON STARTLE ELICITED ELECTRICALLY FROM THE BRAINSTEM. K.R. Melia* & M. Davis (SPON: W.P. Jordan). Dept. of Psychiatry, Yale Univ., Ribicoff Res. Fac., CMHC, New Haven, CT. 06508.

The mixed D1, D2 dopamine agonist, apomorphine, is known to increase the amplitude of the acoustic startle reflex. Pretreatment with the selective D1 antagonist, Sch 23390, reverses the usual excitatory effect of apomorphine into an inhibitory one. Pretreatment with the D2 antagonist, sulpiride, augments the excitatory effect of apomorphine. These data suggest that activation of D1 dopamine receptors increases startle whereas activation of D2 dopamine receptors decreases startle. Acoustic startle is mediated by a serial neural circuit consisting of the ventral cochlear nucleus (VCN), the ventral lateral lemniscus (VLL), the reticularis pontis caudalis (RPC), and the spinal cord. By eliciting startle electrically at different points along this pathway the present study sought to determine where D1 and D2 receptor activation ultimately alters neural transmission so as to have opposite behavioral effects.

Previous studies have shown that apomorphine increases startle elicited by an acoustic stimulus but decreases startle elicited by electrical stimulation of the VCN. In the present study the D2 agonist, Lilly 171555, was found to depress startle elicited both acoustically and electrically from the VCN. The inhibitory effect of the D2 agonist was further localized since Lilly 171555 did not depress startle elicited electrically from the RPC, the last supraspinal synapse of the startle pathway. In addition, preliminary data indicate that the D1 antagonist, Sch 23390, depresses acoustically elicted startle but not startle elicited electrically from the VCN.

These results suggest that the excitatory effect of apomorphine is mediated by its D1 activity and impinges upon the startle pathway at or before the VCN while apomorphine's inhibitory effect is mediated by its D2 activity and impinges upon the startle pathway supraspinally but downstream from the VCN.

340.7

EFFECTS OF ALPHA-METHYL-PARA-TYROSINE ON THE MAINTENANCE OF CONDITIONED PLACE PREFERENCE. N. Hiroi* and N.M. White. Department of Psychology, McGill University, Montreal, Canada.

When dopaminergic function in nucleus accumbens is disrupted on the training days in the conditioned place preference (CPP) paradigm, CPPs for amphetamine or food are not observed, suggesting that this neurochemical mediates some aspect of primary reward. The purpose of the present study was to determine if normal dopamine function is necessary on the test day to observe a preference previously conditioned with amphetamine. Rats were given 12 training days in a CPP apparatus, including 6 pairings of 2 mg/Kg d-amphetamine with one part of the apparatus and 6 pairings of saline with the other part in a counterbalanced manner. Bilateral injections of 80 ug of a-MPT into nucleus accumbens prior to testing had no effect on the CPP observed, compared to animals receiving saline or no injections. In a control experiment, bilateral injections of the same dose of a-MPT into nucleus accumbens significantly suppressed the locomotor activity produced by 2 mg/kg of d-amphetamine without causing motor impairment, suggesting that this treatment blocks dopamine release. Although there is evidence suggesting that dopamine in nucleus accumbens mediates some aspect of primary reward, the present result suggests that the memory of the primary reward, which is expressed as a place preference on the test day, is not mediated by dopamine release.

340.8

DOPAMINE D1 AND D2 RECEPTORS AND LOCOMOTOR ACTIVATION ELICITED FROM THE NUCLEUS ACCUMBENS OF RATS. J.K.Dreher and D.M.Jackson. Pharmacology Department, Sydney University, N.S.W. 2006, AUSTRALIA.

While it is well documented that the injection of DA agonists into the accumbens (Acb) of rats produces locomotor activation, it is less clear which DA receptor subtype is important and whether there is any interaction between them. Early studies suggested that D1 receptors played a role, with cholera toxin, dibutyryl cyclic-AMP and SKF38393 (SKF) producing excitation after direct injection. In the present study, (RS)-SKF (1 to 10 µg/side) produced dose-dependent long-lasting (up to 12 h) stimulation after local application, characterized by co-coordinated locomotion, sniffing and some rearing. Only the R-enantiomer was active. SKF stimulation (10 µg) was blocked by SCH23390 (0.5 mg/kg, ip) and spiperone (0.1 mg/kg), but not by ketanserin. The D1 agonist, CY208-243 (CY) was only slightly active (up to 8 µg), and the activity lasted for 2 h. Quinpirole (quin, 0.3 to 3.0 µg) also increased activity for about 2 h. DA depletion blocked the stimulant effects of SKF, CY and quin. However, stimulation was produced in these DA-depleted rats when SKF plus quin or CY plus quin was injected into the Acb. The activity consisted of coordinated forward locomotion which was generally devoid of stereotypies. The stimulation lasted for about 5 h (SKF/quin) or 2 h (CY/quin). In rats with their DA stores intact, SKF (or CY) plus quin had an at least additive effect on stimulating activity. The data clearly show that both D1 and D2 receptors play an interactive and important role in mediating stimulation elicited by DA agonists in the Acb. SUPPORTED BY THE NH & MRC.

340.9

EFFECTS OF STIMULATION AND BLOCKADE OF DOPAMINE RECEPTOR SUBTYPES ON THE DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE. R. L. Barrett* and J. B. Appel. *Behavioral Pharmacology Laboratory Department of Psychology University of South Carolina, Columbia, SC 29208 USA.*

The involvement of dopamine (DA) receptor subtypes in the behavioral (subjective) effects of cocaine was studied in rats which were trained to discriminate 10 mg/kg of this substance from saline. In substitution tests, cocaine did not generalize to the selective D_1 agonist SK&F 38393 (5.0 - 15.0 mg/kg); however, significant amounts of drug-appropriate responding did occur following relatively high doses of *d*-amphetamine (0.25 - 1.0 mg/kg) and the D_2 agonist LY 171555 (0.05 - 0.25 mg/kg). In combination tests, the D_1 antagonist SCH 23390 (0.0625 - 0.5 mg/kg) as well as the D_2 antagonists spiperone (0.25 - 0.5 mg/kg) and haloperidol (0.0625 - 1.0 mg/kg) attenuated, but did not completely block the cocaine cue. These data suggest that DA neuronal systems probably play a role in the *in vivo* effects of cocaine, but that the stimulus properties of this compound involve mechanisms that are more complex than direct activation of D_1 *or* D_2 receptors (e.g., stimulation of both D_1 *and* D_2 receptors).

340.10

DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE AND PROCAINE. P.B. Silverman. Dept. of Psychiatry, Univ. of Texas School of Medicine, Houston, TX 77030.

The abuse potential of cocaine and other psychomotor stimulants has been attributed to dopaminergic activity as has the discriminative stimulus that results from cocaine administration. Others have shown that some local anesthetics, including procaine, have stimulus properties with similarity to those of cocaine. There is, however, little evidence of dopamine agonist activity by locals. The work here compared the stimulus properties of cocaine and procaine in rats trained to discriminate one of these compounds from saline in a two lever, food reinforced operant procedure. The intent was to shed light on the apparent inconsistency concerning dopamine mediation of the stimuli.

The results to date suggest that while cocaine- and procaine-induced stimuli are, indeed, somewhat similar, only other psychomotor stimulants generalized completely to cocaine (and not to procaine) and haloperidol more effectively blocked cocaine than procaine recognition.

340.11

GENOTYPIC SEPARATION OF SUSCEPTIBILITY TO THE MOTOR ACTIVITY-STIMULATING ACTION AND REINFORCING ACTION OF COCAINE. T.W. Seale, L. Logan*, W. Landrum* and J.M. Carney*. Dept. of Pediatrics, Univ. Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK 73190 and Dept. of Pharmacology, Univ. Kentucky Sch. Medicine, Lexington, KY 40536.

Little is known about the genetic determinants influencing susceptibility to the behavioral actions of cocaine. We have utilized inbred mice as a model system to assess the role of genotype in drug-seeking behavior (DSB). Conditioned place preference (CPP) was used as a behavioral marker for cocaine-induced DSB. Conditioning to environmental cues was carried out in a chamber consisting of two compartments, one black with a wire mesh floor and cedar smell and one white with a wood chip floor and pine smell. Mice (n=10 for each treatment) were injected with vehicle or cocaine and placed in the conditioning chamber for 30 mintues. CPP was assessed 24 hours following 1 to 5 daily conditioning trials. Two strains of mice, C57BL/6J and BALB/cByJ, showed significant ($p < 0.005$), dosage dependent, trial dependent, stereospecific induction of CPP to the innately less preferred compartment. In contrast, the motor activity-stimulating effects of cocaine differed markedly in the two mouse strains. C57BL/6J showed the expected dosage-dependent stimulation of motor activity (ED_{100} about 18 mg/kg ip). Cocaine failed to induce motor activity stimulation in BALB/cByJ at any dose. These data indicate that genotype can influence the inherent behavioral responsiveness of an animal to cocaine. Relative susceptibility to its motor-activity effects does not predict inherent susceptibility to its reinforcing properties.

340.12

LEGAL STIMULANTS MIMIC AND POTENTIATE THE DISCRIMINATIVE EFFECTS OF COCAINE. R.D. Harland*, D.V. Gauvin*, and F.A. Holloway (SPON: T. Steele). Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190-3000.

The effects of caffeine and caffeine-phenylethylamine combinations upon the discriminative and rate-altering effects of cocaine were examined in rats. Twelve male Sprague-Dawley rats were trained in a two-choice, food reinforced, drug discrimination task with 10 mg/kg cocaine and saline as discriminative stimuli. Stimulus generalization tests with cocaine resulted in a dose-related increase in cocaine-appropriate responding and variable decreases in response rates. Caffeine also engendered a dose-related increase in cocaine-appropriate responding (but only partial generalization at the highest dose tested) and a biphasic dose-effect curve for response rate. Caffeine potentiated the discriminative stimulus properties of cocaine, with isobolographic analysis characterizing the interaction as simple additivity. Caffeine's effects upon the rate-reducing effects of cocaine resulted in a biphasic interaction pattern. Rats were also tested with a wide range of cocaine doses and several dose combinations of caffeine, ephedrine, and phenylpropanolamine (CEP). The CEP combinations resulted in criterion generalization at high doses. All drugs produced response rate decrements at high doses. These data indicate that certain look-alike stimulants (i.e., CEP combinations) mimic the cocaine cue.

340.13

SOME EFFECTS OF TYPICAL AND ATYPICAL NEUROLEPTICS ON NONDEPRIVED RATS LICKING SUCROSE SOLUTIONS.
S.E. Gramling*, H.F. Villanueva & J.H. Porter. (SPON: B.F. Kilpatrick). Dept. of Psych., Virginia Commonwealth Univ., Richmond, VA 23284

The stereotypic nature of the lick response has proved a useful tool in separating the motor effects from the hedonic effects of neuroleptics. The present experiment extends this research by assessing the effects of typical vs atypical neuroleptics on several measures of rats' licking.

Thirty nondeprived rats licked a 32% sucrose solution at stable rates and were then randomly assigned to one of four acute neuroleptic dosing regimes. The treatment groups were Haloperidol (HAL: 0.075, 0.15, 0.3 mg/kg, ip.) Pimozide (PIM: 0.5, 1.0, 1.5, mg/kg, ip.) Clozapine (CLOZ: 1.25, 2.5, 5.0, mg/kg, ip.) and Sulpiride (SULP: 6.25, 12.5, 25.0 mg/kg, ip.). Lick rate, duration and ILI data were collected via laboratory computer.

Overall, all four groups of rats exhibited a significant dose related decrease in response rate. Rats treated with either of the typical neuroleptics (HAL, PIM) exhibited monotonic rate decreases, whereas the CLOZ and SULP (atypical neuroleptics) treated rats exhibited a nonmonotonic pattern. The measures lick duration and ILI also differentiated these neuroleptics.

341.1

DEPLETION OF SPINAL CORD NOREPINEPHRINE ATTENUATES ANTINOCICEPTION INDUCED BY INTRATHECAL 5'-N-ETHYLCARBOXAMIDE ADENOSINE AND NUCLEUS RAPHE MAGNUS STIMULATION.
Aran, S. and Proudfit, H.K. Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, Il 60680.

We examined the capacity of spinal cord norepinephrine (NE) depletion to attenuate the antinociception produced by the interaction between intrathecal (IT) 5'-N-ethylcarboxamide adenosine (NECA) and release of endogenous NE produced by nucleus raphe magnus (NRM) stimulation.

Animals received an IT injection of either vehicle or 6-OHDA. Twenty one days after surgery baseline tail flick latencies (TFLs) were determined and a stimulus response curve was generated for electrical stimulation of the NRM. Animals were then given an IT injection of a subeffective dose of NECA. TFLs were determined 30 min after drug injection and stimulus-response curves were constructed. NRM stimulation produced significant increases in TFLs both before and after NECA injection in animals pretreated with vehicle. In animals injected with 6-OHDA, NRM stimulation failed to increase TFLs. 6-OHDA decreased NE levels to 1.1 % of control values but did not alter 5-HT levels.

These data suggest that endogenous NE, released by NRM stimulation, interacts synergistically with NECA to produce antinociception. This work was supported by USPHS Grant DA03980.

MDL 26,764, A NON-NARCOTIC ANALGESIC WITH α_2-ADRENERGIC AGONIST-LIKE PROPERTIES.
F.P. Miller, D.L. Braun, H.J. Ketteler and A.A. Carr. Merrell Dow Research Institute, Cincinnati, OH 45215.

Analgesic activity of MDL 26,764 {1-piperidineethanol,α-(4-fluorophenyl)-4-[(4-fluorophenyl)hydroxymethyl]-} was assessed against acetic acid-induced writhing in mice and rats. ED50 values, determined 30 min after sc administration, were 1.85 and 4.73 mg/kg, respectively. This activity was present for at least 4 hrs in mice (ED50 values of 8.73 mg/kg sc and 27.6 mg/kg po). MDL 26,764 also produced analgesic activity after intraventricular (ED50 19.5 µg/mouse) or intrathecal (ED50 14.7 µg/mouse) administration. In mice, MDL 26,764 increased response latency in the tail immersion test, but was ineffective in altering response latency in the hot plate test. The analgesic activity of MDL 26,764 was completely antagonized by systemic administration of the selective α_2-antagonist, idazoxan(I), whereas benextramine, an α_2-antagonist that does not cross the blood-brain barrier, and the opiate antagonist, naloxone, were ineffective. Colonic motility in mice, known to be altered by α_2-agonists, was inhibited by MDL 26,764; this inhibition was reversed by I. These results indicate that MDL 26,764 is a centrally acting, non-narcotic analgesic with a mechanism of action dependent primarily on an agonist-like effect on α_2-adrenergic receptors.

INHIBITION OF NSAID-INDUCED ANTINOCICEPTION IN MICE BY ALPHA-2 ADRENERGIC RECEPTOR BLOCKADE.
E. Baizman*, N. Beglin*, D. Koonz* and D. Luttinger. Dept. of Pharmacology, Sterling-Winthrop Research Institute, Rensselaer, NY 12144.

Central alpha-2 adrenergic blockade has been reported to attenuate antinociception produced by morphine (e.g. Camarata and Yaksh, Brain Res. 1985). We now report that the antinociceptive effects in the mouse acetylcholine-induced writhing test of two non-steroidal antiinflammatory analgesics (NSAIDs), naproxen and zomepirac, are also attenuated by alpha-2 adrenergic receptor antagonists.

Male Swiss-Webster mice were treated with receptor antagonists (s.c.) 5 min. prior to administration of an NSAID (i.v.) then challenged with acetylcholine (ACh; 3.2 mg/kg i.p.) or phenyl-p-quinone (PPQ; 1 mg/kg i.p.). S.C. administration of yohimbine (3 mg/kg) or idazoxan (RX781094; 1 mg/kg) shifted the naproxen dose-response curve to the right. Antinociceptive effects of another NSAID, zomepirac, were also inhibited by yohimbine pretreatment. The writhing response to ACh was not affected by yohimbine pretreatment, suggesting that nociceptive thresholds to ACh were not altered. Yohimbine (3 mg/kg, s.c.) did not alter the antinociceptive effects of naproxen in the PPQ writhing test.

These data suggest that alpha-2 adrenergic antagonists can modify antinociception induced by NSAIDs. However, these effects may be dependent on the nociceptive stimulus used. It is unclear whether this is due to differences in intensity of nociceptive stimulus or to mechanisms of inducing nociception.

341.4

VISCERAL NOCICEPTION: INHIBITION BY SPINAL α_2-ADRENOCEPTORS.
R.M. Danzebrink and G.F. Gebhart. Department of Pharmacology, The University of Iowa, Iowa City, Iowa, 52242.

The antinociceptive effects of the intrathecal administration of the α_2-adrenoceptor agonists clonidine, ST-91, and tizanidine, the nonselective α-adrenoceptor agonist norepinephrine, and the β-adrenoceptor agonist isoproterenol were examined in awake, unanesthetized rats. Colorectal distension, the noxious visceral stimulus employed, elicits a vigorous pressor response and contraction of abdominal and hindlimb musculature (a visceromotor response). Chronic intrathecal and arterial catheters were implanted. At the time of experimentation a distensible, latex balloon was inserted nonsurgically via the anus into the descending colon and rectum, and distensions were given 3 minutes apart. All drugs were administered in equal volumes, 7.5 µl, followed by a 7.5 µl flush of saline. Cumulative doses were given at 12 minute intervals. The α-adrenoceptor agonists produced a dose-dependent attenuation of the pressor and visceromotor responses. Pretreatment with the α_2-adrenoceptor antagonist yohimbine antagonized the effects produced by clonidine, ST-91, and tizanidine, whereas the effects produced by norepinephrine were not significantly altered. The β-adrenoceptor agonist isoproterenol did not attenuate the pressor or visceromotor response to colorectal distension. These results demonstrate that spinal α_2-adrenoceptors, and not β-adrenoceptors, mediate antinociception to noxious visceral stimulation.

DEMONSTRATION OF A UNIQUE ^{3}H-5-HT BINDING SITE IN RAT SPINAL CORD. F.P. Zemlan, E.F. Schwab and R.M. Murphy. Lab of Geriatric Research, and Dept. of Physiology, Univ. of Cincinnati Col. of Med., Cinti, OH 45267-0555.

The present studies identify a new high affinity ^{3}H-5-HT binding site in spinal cord which has a unique pharmacologic profile not observed in frontal cortex.

The density of 5-HT 1A, 1B and 1C receptors in rat frontal cortex and spinal cord was determined in saturation (^{3}H-5-HT, ^{3}H-8-OH-DPAT, ^{3}H-mesulergine) and competition (10^{-12} to 10^{-3} M) studies. In cortex, competition studies (^{3}H-5-HT) employing selective 1A masks (8-OH-DPAT, buspirone), 1B mask (RU24969) and 1C mask (mesulergine) indicated that 38±5% of ^{3}H-5-HT binding sites were of the 1A subtype, 47±5% 1B and 17±2% 1C subtypes, apparently accounting for all cortical 5-HT receptors. Competition studies in cortex confirmed these estimates. In spinal cord, the same experimental techniques identified that 25±3% of ^{3}H-5-HT binding sites were of the 1A subtype and 33±3% were 1B receptors. Subsequent competition studies indicated that the remaining 42% of specific high affinity ^{3}H-5-HT binding in spinal cord (Ki=6±1 nM) was not to 5-HT1C, 5-HT2 or 5-HT3 receptors. More extensive pharmacologic characterization of this unique ^{3}H-5-HT binding site is in progress.

SEROTONIN RELEASES ADENOSINE FROM PRIMARY AFFERENT NERVE TERMINALS IN THE SPINAL CORD: POSSIBLE INVOLVEMENT IN SPINAL ANTINOCICEPTION. M.I.Sweeney, T.D. White and J. Sawynok. Dept. of Pharmacology, Dalhousie Univ., Halifax, Nova Scotia, Canada. B3H 4H7.

Antinociception produced by intrathecal morphine and serotonin (5-HT) is blocked by adenosine receptor antagonists suggesting that adenosine release may mediate this antinociception. Morphine releases adenosine from the spinal cord in vitro and in vivo; the purpose of the present study was to determine whether 5-HT also releases adenosine from the spinal cord. Release of adenosine evoked by 5-HT from spinal cord synaptosomes was determined by HPLC with fluorescence detection of etheno-adenosine. In some cases, rats were pretreated with capsaicin either as neonates or adults and used in adenosine release studies 17-20 weeks or 1 week later, respectively. 5-HT (50 μM) increased the release of endogenous adenosine from dorsal, but not ventral, spinal cord synaptosomes. This release was reduced by the 5-HT receptor antagonist methysergide, removal of Ca^{2+} from the medium, inhibition of ecto-5'-nucleotidase, and both methods of capsaicin pretreatment. These results suggest that activation of 5-HT receptors on small diameter primary afferent terminals produces a Ca^{2+}-dependent release of a nucleotide which is converted extracellularly to adenosine. This adenosine may contribute to the spinal antinociceptive effect of 5-HT.(Supported by MRC Canada)

LAMINAR DISTRIBUTION OF RAPHESPINAL FIBERS IN THE RAT LUMBAR DORSAL HORN DEMONSTRATING SEROTONIN-LIKE IMMUNOREACTIVITY. S.L. Jones and A.R. Light. Dept. of Physiology, Univ. of N. Carolina, Chapel Hill, NC 27599.

The nucleus raphe magnus (NRM) has been implicated in the centrifugal modulation of spinal nociceptive transmission. Serotonergic raphespinal projections have been demonstrated using the retrograde tracer horseradish peroxidase in conjunction with immunohistochemistry, however, the laminar distribution of serotonin-containing raphespinal fibers and terminals within the dorsal horn has not been examined. The purpose of this study was to address this issue by using the anterogradely transported lectin, *Phaseolus vulgaris*-leucoagglutinin (PHA-L) coupled with immunohistochemistry. Male, Sprague-Dawley rats were anesthetized with an IM injection of ketamine/xylazine. Microinjections of PHA-L (10%, 0.2μl) were made into the ventromedial medulla and the rats were allowed to recover. After 4 weeks, they were perfused transcardially and the spinal cord tissue was removed and reacted with PHA-L antibody tagged with Texas Red and serotonin antibody tagged with fluorescein. The results to date, indicate that cell bodies in the medial medulla project to all laminae in the lumbar dorsal horn and ventral horn; many fibers were found labeled with PHA-L in a golgi-like fashion. A small percentage (4.8±1.3%, n=5) of PHA-L terminations labeled with serotonin immunoreactivity were found in each of the laminae I-VI, VII-X. Supported by DA04420 and DA05341

INNERVATION OF IDENTIFIED PRIMATE SPINOTHALAMIC TRACT NEURONS: ULTRASTRUCTURE OF SEROTONERGIC AND OTHER SYNAPTIC PROFILES. C.C. LaMotte, S.M. Carlton, C.N. Honda, D.J. Surmeier, and W.D. Willis. Section of Neurosurgery, Yale Univ. Sch. Med., New Haven, CT 06510 and Marine Biomed. Inst. Univ. Texas Med. Branch, Galveston, TX 77550.

We have combined intracellular staining of identified spinothalamic tract (STT) neurons with immunocytochemistry to define the terminations of primary afferent and modulating systems onto these cells in the lumbosacral cord of anesthetized monkeys (M. fascicularis). The STT cells were antidromically activated from the contralateral thalamus, and after physiological characterization were intracellularly marked with HRP. Following perfusion and post fixation with 2.5% paraformaldehyde, serial vibratome sections were reacted for HRP and then immunohistochemically labeled for serotonin (5-HT) using the PAP method. Sections were flat embedded for light microscopic reconstruction and then cut for EM.

The presently described neuron was a WDR neuron responsive to activation of low and high threshold cutaneous afferents innervating the foot. The soma was located in the lateral half of lamina V, with an extensive dendritic tree. Terminal types innervating this cell were of the same type and in closely corresponding frequency to those found on two other lamina V STT neurons we have studied previously. Over 50% were R terminals; the remaining contained large or small dense core vesicles, or flat vesicles. Most serotonergic terminals were also R type, although 5HT terminals containing either small dense cores (D) or large granular vesicles (L) were also present. L and D terminals were found on the soma of the STT cell but rarely on its proximal dendrites within lamina V. (Supported by NIH grants NS13335, NS11255).

DISTRIBUTION OF SPINOMESENCEPHALIC TRACT (SMT) CELLS AND CHEMICALLY IDENTIFIED TERMINALS IN THE RAT SPINAL CORD. R.P. Yezierski, K.E. Miller and C.M. Mendez*. Dept. of Neurological Surgery, Univ. of Miami, Sch. of Med., Miami, Fl. 33136.

Previous studies have shown that the distribution of SMT cells in the rat spinal cord overlaps with several areas receiving input from various putative neurotransmitters including serotonin (5HT), substance P (SP) and leu-enkephalin (l-enk). In the present study the technique of retrograde transport was combined with immunohistochemistry to study the relationship between SMT cells and chemically identified terminals in the rat spinal cord. Injections of fluorescent tracers (DAPI or Fluorogold) were made at different locations in the midbrain. Following survival times of 4-11 days animals were perfused sequentially with saline and 4% paraformaldehyde. Spinal cords were cut on a cryostat and processed for 5HT, SP and l-enk immunofluorescence.

Results of this study have shown 5HT, SP and l-enk varicose fibers are in close apposition with SMT cells in the superficial laminae of the dorsal horn, nucleus proprius, the lateral neck of the dorsal horn, lamina X and the lateral spinal nucleus. Close apposition of immunoreactive fibers were observed on large and small somata and on dendritic profiles.

SEROTONERGIC MEDIATION OF SPINAL ANALGESIA AND ITS INTERACTION WITH NORADRENERGIC SYSTEMS. I. Nakagawa,* K. Omote,* L.M. Kitahata and J.G. Collins. Dept. of Anesthesiology, Yale Univ. New Haven, CT 06510

Serotonin (5HT) was administered intrathecally onto cat spinal cords while recording from WDR neurons in order to evaluate its depression of noxiously evoked activity and the interaction of serotonergic and noradrenergic systems. 500ug(n=8), 1000ug(n=8) and 2000ug(n=22) of 5HT produced significant suppression of the mean noxiously evoked activity (radiant heat) of WDR neurons in the dorsal horn of the spinal cord. Intravenous administration of methyseride (nonselective 5HT antagonist, 1 or 2mg, n=5) or yohimbine (alph2-adrenergic antagonist, 0.5 or 1.0mg/kg, n=4) produced a significant antagonism of the effects of 2000ug of 5HT. In contrast to the effects of methysergide and yohimbine, intravenous administration of corynanthine (alph1-adrenergic antagonist, 0.25 or 0.5mg/kg, n=4) or naloxone (0.1 or 0.2mg, n=4) had no effect upon the antinociceptive effects of 5HT. The combination of low dose 5HT (250ug) and low dose clonidine (5ug) produced a supra-additive suppression. These data support the concept that noradrenergic systems, possibly through an alpha2-adrenergic mechanism, are involved in the modulation of spinal WDR neurons by 5HT.

INTERACTION OF SELECTIVE OPIATE RECEPTOR AGONISTS AND CLONIDINE IN ACUTE SPINAL CATS. K. Omote,* I. Nakagawa,* L.M. Kitahata, J.G. Collins. (Spon: J. Heavner) Dept. of Anesthesiology, Yale Univ. School of Medicine, New Haven, CT 06510

This study examined the potential antinociceptive activity of the combination of the mu-selective agonists DAGO or morphine or the delta selective agonist DPDPE with clonidine. We recorded extracellularly from discriminated single WDR neurons activated by noxious radiant heat in decerebrate, spinally transected cats. Following control studies, sub-effective doses of DAGO (1 or 1.5ug), DPDPE (30ug), or morphine sulfate (25ug) were applied gently onto the cord. As combination doses, each sub-effective dose described above was combined with the sub-effective doses of 5ug of clonidine. Sub-effective doses of DAGO, DPDPE, morphine or clonidine alone did not significantly suppress noxiously evoked activity. In combination, clonidine with either DPDPE or morphine demonstrated a synergistic suppression. No similar synergistic effect was seen when DAGO and clonidine were combined. Our data might suggest that although both mu and delta receptor agonists are antinociceptive, the final common pathways by which they suppress WDR neuron activity are different. The mu-selective agonist DAGO does not seem to synergize with a noradrenergic system.

THE ROLE OF SEROTONIN (5-HT) AND NOREPINEPHRINE (NE) IN THE ANALGESIC ACTION OF BETA-ENDORPHIN IN THE SPINAL CORD. T.Crisp, J.L. Stafinsky* and M. Uram*, Dept. Pharmacol., Northeastern Ohio Univ. Coll. of Med., Rootstown, OH 44272 and Dept. Anesthesiology, Western Reserve Care System, Youngstown, OH 44512.

Beta-endorphin (B-E) is an endogenous opioid peptide with antinociceptive properties (Tseng, 1985; Yaksh and Henry, 1978). In the present study, male Sprague-Dawley rats were cannulated with indwelling PE-10 catheters for intrathecal (i.t.) injections. Different doses of B-E (0.1, 1 or 10 nmol) were administered i.t. and the ability of the opioid to inhibit tail-flick latency (TFL) was tested. Spinal B-E dose-dependently elevated TFL, and the 1 nmole dose produced a strong antinociceptive response 30 min post-injection.

In order to assess the local spinal involvement of 5-HT and NE in B-E-induced spinal analgesia, serotonergic or noradrenergic receptor antagonists were administered i.t. and tested against the opioid. The various receptor selective 5-HT blockers (spiroxatrine, ritanserin or ICS 205-930) and the alpha$_2$ antagonist yohimbine reversed the spinal action of B-E. The alpha$_1$ antagonist WB-4101 failed to alter B-E-induced analgesia. These data imply a local spinal interaction between B-E, 5-HT and NE. Supported by Biomed. Res. Grant #3215

DOES INTRATHECAL SEROTONIN MIMIC THAT RELEASED ENDOGENOUSLY? D.J. Smith, J. Perrotti*, T. Crisp, and D.L. Smith*. Dept. of Anes., WVU, Morgantown, WV 26505.

Serotonin (5HT) is released from spinopetal, pain-inhibitory nerves. Large doses (μmoles) may also be administered intrathecally (i.t.) to induce analgesia (i.e. elevate the latency of the tail-flick (TFL) reflex). In 8 of 14 rats i.t. 5HT (1 μmole) increased TFL 2 S.D. above their individual mean pre-drug values within 10 m. However, it may be questioned if i.t. 5HT mimics the action of neuronally released transmitter. The dose of methysergide required to inhibit the action of i.t. 5HT is much smaller than that needed for 5HT released spinally in response to neuronal activation by i.t. morphine (ID 50 = 0.015 vs. 4.8 mg/kg, s.c. respectively). Also, i.t. 5HT causes other phenomena not observed following the release of endogenous 5HT. These include plaintive vocalization, tremors and reduced blood flow to the eye. Interestingly, these effects, as well as analgesia, may also be observed in rats whose spinal cannula are found to be malpositioned outside of the dura near the lumbar enlargement. In 6 of 11 extradurally cannulated rats, unresponsive to morphine (10 nmole), responses to 5HT were observed. These data raise the concern that some of the actions of i.t. 5HT may be peripheral to the cord (eg. changes in cord blood flow) with secondary influences on nociceptive behavior. WVU Med Corp & NIH 2507RR05433-26.

341.14

AMITRIPYTLINE AND SPINAL ANTINOCICEPTIVE MECHANISMS. G.M. Williams, D.J. Smith, R.H. Docherty*, A.J. Azzaro, L.M. Brown, D.L. Smith* and F. Perrotti*. Dept. of Anes., WVU, Morgantown, WV 26505.

The tricyclic antidepressant amitriptyline (AMT) is used for chronic pain and enhances narcotic action. This study was to determine if spinal mechanisms are involved. Rats were treated with either AMT (10 mg/kg, i.p.) or saline for 21 days. On days, 1, 10 and 17, immediately following AMT, a decrease in latency of the heat-induced nociceptive tail-flick reflex (TFL) occurred, but disappeared within 2 h. Afterwards, the response to intrathecal (i.t.) morphine was enhanced in AMT rats. These effects could result from an AMT-induced inhibition of 5HT reuptake; 1) the transient decrease, a result of the amines action to increase spinal motor neuron activity and 2) the enhanced morphine effect, related to an intensification of its 5HT component. At day 17, hot-plate reaction times did not differ in AMT and control rats nor was the hot plate-induced elevation of subsequently measured TFL changed (HP then TFL, repeated 4x, 10m between pairs). One day following AMT (d 22), baselines remained unchanged from control. Additionally, there was no apparent difference in the potency of i.t. 5HT, nor was there any alteration in the terminal autoreceptor that modulates 5HT release. Thus, AMT does not appear to directly intensify spinal antinociceptive processes.

341.15

DIFFERENTIAL ACTION OF AMITRIPTYLINE ON NEURONS IN THE TRIGEMINAL NUCLEUS. G.H. Fromm and T. Kondo*. Dept. of Neurology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

Amitriptyline (AMI) is widely used for the treatment of a variety of painful conditions. This analgesic effect has been corroborated by several controlled studies and appears to be unrelated to AMI's antidepressant effect. However, the exact mechanisms of action of AMI has not been established.

We have investigated the effect of AMI on single neurons in the trigeminal nucleus caudalis of cats anesthetized with alpha-chloralose. The i.v. administration of 1.0-4.0 mg/kg AMI markedly facilitated the periventricular inhibition of nociceptive specific and wide dynamic range neurons. Segmental inhibition was facilitated to a lesser degree. On the other hand, AMI had a mild depressant effect on the periventricular and segmental inhibition of low threshold mechanoceptive neurons.

Our experiments suggest that AMI exerts its analgesic effect by enhancing the action of endogenous inhibitory mechanisms impinging on nociceptive specific and wide dynamic range neurons, especially the inhibition descending from the periventricular gray matter. Such an effect would account for the synergistic action of AMI and opiates that has been reported in both patients and experimental animals.

341.16

COCAINE SUPPRESSION OF MEDIAL THALAMIC NOCICEPTIVE RESPONSES IN THE RAT. C.R. Belczynski Jr., A. Pertovaara, T.J. Morrow and K.L. Casey. VA Medical Center and Depts. of Neurology, Physiology and Neuroscience Program, University of Michigan, Ann Arbor, MI 48105.

Recent behavioral experiments in our laboratory have demonstrated that cocaine (25 mg/Kg, i.p.) is a rapid-onset, non-opiate analgesic in the rat. The effect has been documented using the hot-plate and the formalin tests, and appears to be independent of cardiovascular or local anaesthetic actions of the compound. Analgesic doses of cocaine do not suppress spinal nociceptive reflexes although we have shown that at supraspinal levels, cocaine simultaneously enhances spontaneous activity but reduces noxious-evoked activity of caudally and rostrally projecting medial medullary reticular neurons over a time course paralleling the behavioral analgesia. In the present study, we wished to determine whether cocaine would selectively alter nociceptively-evoked responses of neurons in the medial thalamus without affecting the mechanoreceptive responses of neurons in the lateral ventrobasal complex. Moreover, we investigated whether any observed effects were the result of thalamic or subthalamic mechanisms. Extracellular single cell recording of thalamic neurons in the anaesthetized rat demonstrated that behaviorally analgesic doses of cocaine suppress nociceptively-evoked neuronal activity in midline and intralaminar nuclei. Neuronal evoked responses to central stimulation of the medial bulboreticular formation were also suppressed. Mechanoreceptive responses of neurons in the lateral ventrobasal complex to innocuous tactile stimuli were not suppressed after cocaine administration. Unlike neurons in the medial reticular formation, there were no significant changes in levels of spontaneous activity. The effect of cocaine on neuronal responsiveness was not reversible with the opiate antagonist naloxone. The results suggest that cocaine's analgesic effect is mediated at least in part via a direct and selective suppression of medial thalamic nociceptive responses.

SEROTONIN (5-HT) AND 5-HYDROXYINDOLEACETIC ACID (5-HIAA) IN THE BRAINSTEM OF NORMAL AND ARTHRITIC RATS. F.F. Matos*, J.D. Levine* and A.I. Basbaum. Depts. of Anatomy and Medicine, Univ. California, San Francisco, CA 94143.

Previous studies have reported that forebrain, brainstem and spinal cord levels of 5-HT and 5-HIAA are increased in an animal model of chronic pain, the polyarthritic rat (Sofia and Vassar, Arch. Int. Pharm., 211:1974; Weil-Fugazza et al, Brain Res., 175: 1979). We have attempted to identify the source of the increased 5-HT and 5-HIAA, by punch-sampling different brainstem areas. Rats were made polyarthritic by tail injection of Mycobacterium butyricum in mineral oil. Three weeks later the rats were killed by decapitation and the brain rapidly removed and frozen. Only those rats with significant bilateral inflammation were used. 350μ serial crysostat sections through the brainstem were cut; from these 300μ diameter punches were collected, grouped as necessary, and homogenized in $HClO_4$. 5-HT and 5-HIAA levels per mg protein were determined by HPLC with electrochemical detection.

Although the changes previously observed in the spinal cord of the arthritic rat probably reflect activity in 5-HT groups of the rostral ventral medulla, we found no changes in 5-HT or 5-HIAA levels in the nucleus raphé magnus, pallidus or obscurus. The variability in these regions, however, was high. There was a significant increase (approximately twofold) in the level of both compounds in the midbrain dorsal raphé. The levels in various raphé target regions in the brainstem, including the lateral and dorsal periaqueductal gray and the lateral and ventrolateral medulla were unchanged. The increase of 5-HT and 5-HIAA in the dorsal raphé is consistent with the increased levels of 5-HT that have been reported in the forebrain of arthritic rats. These data indicate that changes in 5-HT synthesis in arthritic rats are not only associated with increased activity in the descending serotonergic modulation that arises from 5-HT neurons of the rostral medulla.

QUANTITATIVE STUDIES OF BULBOSPINAL SEROTONERGIC NEURONS APPOSED BY ENKEPHALIN FIBERS. W. Wu*, M. Wessendorf and R. Elde. Dept Cell Biol and Neuroanat, Univ Minnesota, Minneapolis, MN 55455

It has been suggested that met-enkephalinergic (met-enk) fibers synapsing onto bulbospinal serotonergic (5-HT) neurons are involved in the descending control of nociception. However, it has been unclear what proportion of descending 5-HT neurons might be involved in such a circuit. It was decided to determine the proportion of descending 5-HT neurons that are apposed by enkephalinergic processes.

Bulbospinal neurons were labeled by injecting the retrograde tracer Fluoro-Gold into the lumbar spinal cord of rats. Serotonin levels were increased by treatment with tryptophan and tranylcypromine prior to sacrifice. Ten μm sections of brainstems were cut and stained for 5-HT and met-enk using 2-color immunofluorescence.

In 2 rats in which the entire cross-sectional area of the lumbar spinal cord was filled with Fluoro-Gold, 3041 descending neurons were sampled in sections of the ventral medial medulla. Out of 677 5-HT neurons observed, 661 (97.6%) were retrogradely labeled with Fluoro-Gold. All of these cells were observed to have met-enk immunoreactive varicosities apposed to them. In an additional 2 rats, we evaluated 105 bulbospinal 5-HT neurons labeled after injections of Fluoro-Gold limited to the dorsal portion of the lumbar spinal cord. Again, all of these cells were apposed by met-Enk varicosites.

These experiments suggest that enkephalinergic afferents may control the activity of bulbospinal serotonergic neurons. In addition, they suggest that virtually all 5-HT neurons in this region project spinally.

These studies were supported by NS22665, DA02148, and IncStar.

ANTINOCICEPTIVE ACTIONS OF ALPHA-2 ADRENERGIC AGONISTS IN ROSTROVENTROMEDIAL MEDULLA OF THE RAT MAY BE MEDIATED BY A SELECTIVE ACTION ON A SINGLE POPULATION OF PUTATIVE NOCICEPTIVE MODULATORY NEURONS. C.M.Haws*, M.M.Heinricher and H.L. Fields. Depts of Neurol. and Physiol., Univ. CA San Francisco, San Francisco, CA 94143

Two classes of putative nociceptive modulatory neurons have been identified in the RVM of the barbiturate-anesthetized rat; the on-cell shows an increase and the off-cell a decrease in activity just prior to a tail-flick withdrawal response (TF) from noxious heat. The ability of the alpha-2 adrenergic agonist clonidine to produce antinociception following microinjection into the RVM was investigated, and a possible mechanism for this action examined using single unit recording and iontophoretic techniques.

Microinjection of clonidine (1.0-7.5 ug) into RVM produces a dose-related inhibition of the TF (10 sec cut-off) reversible by the alpha-2 receptor antagonist yohimbine but not by the alpha-1 receptor antagonist WB4101.

Iontophoretic application of clonidine produces a yohimbine-reversible suppression of the TF-related on-cell burst. Clonidine has no effect on the off-cell pause.

These results indicate that the antinociceptive effect of clonidine microinjected into the RVM is mediated by a selective action on one population of putative nociceptive-modulatory neurons, on-cells. This would be consistent with a facilitatory effect of on-cells on nociceptive transmission at the spinal level.

Supported by PHS grant NS21445 and the Migraine Foundation.

DESCENDING MODULATION OF NOCICEPTION FROM THE A5 CELL GROUP A. Burnett and G.F. Gebhart. Department of Pharmacology, College of Medicine, University of Iowa, Iowa City, Iowa 52242.

Specific brain regions supplying the spinal cord with monoaminergic innervation important to antinociception and descending inhibition have been the focus of extensive investigation. The well characterized locus coeruleus-subcoeruleus complex (A6 cell group) and the region of the superior olivary nucleus (A5 cell group) are primarily responsible for the noradrenergic innervation of the spinal cord. The present studies, conducted in rats lightly anesthetized with pentobarbital, quantitatively characterized the role of the A5 cell group in descending modulation of the spinal nociceptive tail-flick reflex. Inhibition of the tail-flick reflex was observed at low intensities of stimulation (100 Hz, 100 μs cathodal pulses) near the A5 cell group, associated with significant increases in blood pressure. Glutamate microinjections (100 mM, 0.5 ul) into the same sites as stimulation also inhibited the tail-flick reflex, but generally lowered blood pressure. Intensity-, frequency-, and pulse width-dependent effects of electrical stimulation and dose-dependent effects of chemical stimulation were studied. The possible contribution of the A5 cell group as an interface between cardiovascular and pain sensing/modulating systems was evaluated. Supported by DA02879.

PAIN MODULATION: CENTRAL PATHWAYS II

342.1

ROLE OF ANTERIOR PRETECTAL NUCLEUS (APT) IN SOMATOSENSORY CORTICAL DESCENDING MODULATION OF JAW-OPENING REFLEX (JOR) IN RATS. L.-D. Lin, C.Y. Chiang*, J.O. Dostrovsky and B.J. Sessle. Dept. Physiology, Fac. Medicine and Fac. Dentistry, Univ. of Toronto, M5S 1A8, Canada.

Since we previously noted that stimulation of the somatosensory cortex (CX) or APT produces inhibitory effects on the JOR and since the APT receives ipsilateral descending projections from CX (Wise & Jones, J. comp. Neurol., 175,129,1977), we examined whether the APT is involved in the CX descending modulation of the JOR. The digastric JOR was elicited in 60 chloralose/urethane-anaesthetized rats by test stimulation (0.1-0.3ms, 0.5Hz) of the maxillary skin or lower incisor tooth. Conditioning stimulation (8 pulses, 400Hz, 0.2ms) of CX or APT induced JOR inhibition of similar amplitude (average 60% reduction) and time course (average onset 25ms, peak at 50ms, duration 200ms). Prior lesioning of APT by ibotenic acid markedly diminished the CX-induced inhibition. Glutamate (0.2M, 200-600nl) injected into APT and adjacent ventral regions also inhibited the JOR, but electrical or glutamate-induced inhibition from APT was less than the JOR inhibition induced from caudal periaqueductal gray (PAG). Lidocaine-produced block of caudal PAG function reversibly reduced by 50% the APT-induced inhibition, whereas block of the rostral PAG had no clear effect on the inhibition. These findings suggest that the APT may at least partially mediate the CX descending modulation of JOR and that the caudal PAG may be involved in part in mediating this effect.

342.2

STIMULATION-PRODUCED ANALGESIA FROM THE NUCLEUS TRACTUS SOLITARIUS IN THE UNANESTHETIZED RAT. J.-H. Sohn, A. M. Lohof, M. M. Morgan and J. C. Liebeskind. Department of Psychology, UCLA, Los Angeles, CA 90024-1563.

Electrical or chemical activation of the commissural region of the nucleus tractus solitarius can produce analgesia in the pentobarbital anesthetized rat (Lewis et al., '87; Morgan et al.'87; Randich & Aicher, '88). Implantation of chronic indwelling electrodes into the NTS is made difficult by the caudal location of this nucleus. The present study describes a technique for implantation of chronic indwelling electrodes into the NTS, and evaluates stimulation-produced analgesia (SPA) in the conscious rat. Rats were anesthetized and placed in a stereotaxic frame. An incision was made and the trapezius muscles gently retracted from the medial occipital bone. The atlanto-occipital membrane membrane was punctured and the ventral medial part of the occipital bone removed. A tear was made in the arachnoid and a twisted bipolar electrode positioned over the obex. The electrode was bent in two places to conform to the shape of the skull. The electrode was lowered 0.8 mm into the caudal NTS and affixed to screws in the top of the skull with dental cement. One week after surgery, pain sensitivity was assessed with the tail-flick test. Brain stimulation consisted of 50 Hz monophasic pulses (0.4 ms) preceding by 20 s and remaining on during the tail-flick test. Eight of the 9 stimulation sites within the NTS supported SPA, at a mean current of 238 μA. None of the four stimulation sites located outside the NTS supported SPA. Analgesia occurred in the absence of aversive or motor reactions. These results indicate that SPA from the NTS can be obtained in unanesthetized animals and does not appear to be secondary to overt aversive or motor effects. (NIH grant NS07628)

342.3

HYPOTHALAMIC PVN STIMULATION PRODUCES ANALGESIA NOT MEDIATED BY VASOPRESSIN OR OPIOIDS. R. Yirmiya, S. Ben-Eliyahu*, Y. Shavit, P. Marek* and J.C. Liebeskind. Department of Psychology, University of California, Los Angeles, CA 90024.

The analgesic effect of hypothalamic paraventricular nucleus (PVN) stimulation and the involvement of vasopressin and opioid peptides in this process were studied in vasopressin-deficient (Brattleboro) and Long Evans rats. Rats were chronically implanted with a monopolar stimulating electrode in the PVN. Ten days after surgery, the animals were lightly anesthetized and PVN stimulation-produced analgesia (SPA) threshold was determined by the tail-flick test. Half the animals were then injected with naloxone (10 mg/kg) and half with saline. SPA threshold was determined again 20 min later. The same procedure was repeated on the following day, except that the drug assignment was reversed. PVN SPA threshold did not significantly differ between Brattleboro and Long Evans rats. Threshold was stable over the two sessions and was not significantly changed by naloxone. The result indicate that the analgesic effects of PVN stimulation are not mediated by either vasopressin or opioid peptides. Supported by NIH grant NS 07628.

342.4

ANALGESIA PRODUCED BY INJECTION OF LIDOCAINE INTO THE ANTERIOR CINGULUM. A.L. Vaccarino and R. Melzack* Dept. of Psychology, McGill University, Montreal, P.Q., Canada, H3A 1B1.

Several investigators have demonstrated thalamic involvement in pain perception. The cingulum, because of its intimate relationship between the thalamus and other limbic and cortical structures, may provide a possible mechanism by which pain signals can be processed at higher brain regions involved in emotion, cognition and motivation. In the present study, the role of the cingulum in both tests of phasic and tonic pain are examined using injections of a local anaesthetic into the cingulum region.

Male Long-Evans rats were stereotaxically implanted with unilateral cannulae aimed at the anterior portion of the cingulum. Seven to ten days following surgery the rats were infused, via an inner cannula, with 1 µl of 2% lidocaine in saline or saline alone over a 2 minute period and tested for analgesia in either the formalin or foot-flick test.

Infusions of lidocaine produced a significant reduction in formalin pain scores, but had no effect on foot-flick latencies. Furthermore, contralateral lidocaine appeared to have a greater analgesic effect than ipsilateral lidocaine. The possible additive effects of bilateral lidocaine injection are currently under investigation.

These data strongly suggest cingulum involvement in pain perception and support previous findings dissociating phasic and tonic pain mechanisms. Studies examining the involvement of other brain regions anatomically associated with the cingulum are currently in progress. Supported by NSERC grant A7891

342.5

EFFECTS OF DORSAL RAPHE, HABENULA AND EXTERNAL ELECTRICAL STIMULATIONS ON SEPTAL NUCLEUS NEURONS IN THE RAT. W.-Q. Dong, M. Skolnick and N. Dafny. The Univ. of Texas Health Sci. Center at Houston, 77225.

It was recently proposed that most CNS structures which participate in a pain modulating mechanism will respond to noxious input, and when stimulated will induce analgesia (SPA). The mechanism underlying this effect has remained an open question. Several reports have suggested that electrical stimulation applied to the septal nucleus will elicit analgesia. In order to test this hypothesis, we investigated the effects of focal stimulation of the dorsal raphe (DR) and habenula (Hab) nuclei, and pinnael (ear) electrical stimulations (PES) on the septal nucleus of the rat. Twenty-five urethane-anesthetized Sprague-Dawley rats were used. Stainless steel bipolar stimulating electrodes were placed within the DR and Hab, and external electrical stimulating electrodes were inserted into the pinnae of each animal. Micropipettes (2M NaCl) were used as recording electrodes. It was observed that the septal nucleus cells exhibit 2 types of responses to noxious stimulation (tail pinch): "nociceptive-on" and "nociceptive-off". In addition, PES was more effective as anti-nociceptive than DR and Hab stimulation."

342.6

SEROTONIN INVOLVEMENT IN ANALGESIA INDUCED BY TRANSCRANIAL ELECTROSTIMULATION. L. Hudson-Howard*, R. Warner*, C. Johnston* and M. Skolnick (Spon: B. Ho) Neurophys. Res. Cent., Univ. of Texas Health Sci. Cent., Houston, TX 77030

External transcranial electrostimulation (TE) consisting of charge-balanced, rectangular, constant current (10-15 µA) low frequency pulses has been shown to produce endorphinergic analgesia in rats. This report summarizes investigation of serotonergic involvement in TE-induced analgesia. Subjects were 200g, male, Sprague-Dawley rats naive to TE but conditioned to handling and restraint.

P-chlorophenylalanine (pCPA) was injected to block the biosynthesis of serotonin and subjects were then tested for analgesia. The rats were restrained and stimulated. Analgesia was assessed using a pressure tail flick test. Pressure (½ in. from the tip) was exerted by a metal wedge mounted on a pneumatically driven syringe plunger. Maximum pressure tolerated by the rat was read as the rat made the first coordinated motor response to move its tail. This reading was averaged over four trials to produce the tolerated peak pressure (TPP). The difference in mean TPP before and after TE was taken as a measure of analgesia. The experimenter was blind to the conditions of the experiment.

This 2x2 factorial design demonstrated a 5HT dependent analgesic effect: pCPA blocked the TE-induced analgesia. The TE treated, saline injected group shown a significant increase in mean TTP vs. all other groups--TE-pCPA, Sham-pCPA, sham-saline: N=62 $p<.01$ Tukey HSD.

342.7

ENKEPHALINASE INHIBITOR THIORPHAN POTENTIATES ANALGESIC EFFECT OF TRANSCRANIAL ELECTROSTIMULATION (TCES). J.R. Lake*, R.F. Hamilton*, M. Skolnick, and D.H. Malin (Spon: I.J. Butler) Univ. of Houston-Clear Lake, Houston, Tx 77058; Univ. of Texas Grad. School of Biomedical Sci., Houston, Texas 77030.

Naloxone-reversible analgesia is induced by bilateral ultralow current stimulation of low impedance points on the ear (TCES). The present study tested the ability of thiorphan to potentiate analgesic effects of TCES by amplifying the effects of enkephalin release. Rats (n-20) were cannulated in the 3rd ventricle and implanted with electrodes through the apex of the antihelix. Rats were pretested for latency in the 50°C wet tail flick test. Ten rats then received 30 min. of TCES (10 Hz, 10 µA, charge-balanced rectangular pulses). Ten rats received 30 min. of "sham stimulation". Half of each group received 250 µg thiorphan icv in 100 µl 3% ethanol (5 µl/min). The other half received injection vehicle alone. All rats were then retested. Analgesia scores were increases in latency (sec.s) from pretest, as shown below.

Effects of TCES and Thiorphan on Analgesia Scores M ± SEM

	TCES	SHAM STIMULATION
THIORPHAN	**3.4 ± 0.5***	**1.9 ± 0.4**
VEHICLE	**1.0 ± 0.3**	**0.1 ± 0.3**

ANOVA reveals both drug and TCES effects, $p<.01$. The thiorphan + TCES group was different, $p<.05$, from all other groups. TCES analgesia may thus be mediated by enkephalin release and intensified by enkephalinase inhibition.

342.8

MODULATION OF CORTICAL SENSORY EVOKED POTENTIALS (SEP) BY STIMULATION IN NUCLEUS RAPHE MAGNUS (NRM) IN RATS. K.A. Follett and G.F. Gebhart. Depts. of Neurosurgery and Pharmacology, Univ. of Iowa, Iowa City, Iowa, 52242.

Midbrain electrical stimulation has been reported to reduce the amplitude of SEPs. Antinociceptive effects of midbrain stimulation are mediated via nuclei of the ventral medulla, including NRM. The purpose of this study was to determine whether SEPs could also be modulated by stimulation of NRM.

A condition-test (CT) paradigm was used. Rats were anesthetized with Nembutal, N_2O and O_2, and paralyzed with pancuronium. The SEPs evoked by test stimuli (6 mA, 0.5 msec, bipolar needle electrodes) delivered to the hindpaw were recorded epidurally. Conditioning stimuli (CS) (10 pulses, 0.1 msec each) were delivered to the NRM through a monopolar electrode positioned stereotaxically.

An adequate CS preceding the test stimulus consistently reduced the amplitude of the SEP. Threshold for the effect was as low as 25 µA with near complete abolition of the SEP by CS intensities of 50-100 µA. No latency changes were observed consistently. High CS pulse frequency (400 Hz) was more effective than lower frequencies. SEP reduction was most pronounced with CT intervals of <20-50 msec.

The attenuation of SEPs by NRM stimulation may occur through depression of cortical responsiveness, blocking or occlusion at a cortical level, or by inhibition of afferent pathways at subcortical levels.

342.9

LIMBIC INFLUENCE ON INTRACELLULAR ACTIVITY OF VENTRAL MEDULLARY NEURONS. D. Borsook, S. Potrebic*, A. Strassman, R. Maciewicz. Pain Physiology Laboratory, Mass General Hospital, Boston MA 02114.

Descending projections from several limbic regions terminate in the midbrain periaqueductal gray (PAG) and nuclei of the ventromedial medulla (VM). These pathways provide a potential substrate for the analgesic effects of limbic forebrain stimulation. The present study investigated the effects of limbic stimulation on intracellular responses of VM cells in the cat. Stimulating electrodes were placed in the central amygdaloid nucleus (ACE), the anterior hypothalamus (AH), the bed nucleus of the stria terminalis (BNST), the septum, and the PAG. The final electrode placements were selected by minimizing the stimulation intensity required to suppress the tooth pulp-evoked jaw opening reflex. The majority of neurons in VM responded to PAG stimulation with a short latency, monosynaptic EPSP. Single shock or short train stimulation of ACE, the BNST, and AH also evoked mono- or oligo- synaptic EPSPs in many of these same neurons. Cells excited by ACE or BNST were intracellularly stained with HRP. Labeled cells were large multipolar or medium fusiform neurons located in raphe magnus or the adjacent magnocellular reticular formation. These results are evidence that analgesia associated with stimulation of limbic structures may be mediated by activation of antinociceptive pathways involving cells in the ventromedial medulla.

342.10

EFFECTS OF SINGLE AND CONJOINT MET-ENKEPHALIN MICRO-INJECTIONS IN RAT CENTRAL GRAY (PAG) AND NUCLEUS RETICULARIS PARAGIGANTOCELLULARIS (PGC) ON ACTIVITY OF BULBAR RAPHE (RM) AND RAPHE-SPINAL (RMS) NEURONS. J.P. Rosenfeld and L.Y. Xia*. Cresap Neuroscience Lab., Northwestern University, Evanston, IL 60208

As of submission date, 65 neurons histologically identified as being within the RM nucleus of 38 rats were studied. The rats were anaesthetized under 65 mg/kg Pentabarbitol for surgical preparation, and then maintained in light anaesthesia (with 20% initial dose per hour, IM) adequate to allow tail flick reflex in > 70% of the cases. Wound margins were locall anaesthetized with lidocaine. Rats were maintained at 36-38°C anal temperature. Neurons showing spontaneous activity were tested for spinal projection with bipolar silver ball antidromic stimulation between left T9 and right T10 dorsal surface of spinal cord, followed with collision testing. Only 8 cells satisfied the RMS criteria. Spontaneous activity of 3% of the RM cells was augmented by light touch, 2% were inhibited and most (95%) showed no response. Noxious heat enhanced spontaneous RM firing in 56% of the neurons, inhibited it in 37%, and had no effect in 3% of cases. Noxious pinch had similar effects. All body surfaces from nose to tail were tested. Effects on nose and tail were usually parallel, however in 4% of the cells, nose and tail stimulation produced different effects. (Thus 56% + 37% + 3% + 4% = 100%). Considering all 57 RM cells, single and conjoint Met-Enkephalin injections of PAG (2 min., 200 nl, 10 ug) and PGC (1 min., 100nl, 5 ug) produced enhancement of spontaneous activity (>50%) in about 1/3 of the tests and depression in 2/3 of the tests. The most significant finding was that the effect of enkephalin injection could be predicted largely by the effect of noxious stimulation: In those RM cells whose firing levels were enhanced by noxious stimulation, 100% (17 of 17) were depressed by PAG injection, 100% (18 of 18) were depressed by PGC injection, and 97% (34 of 35) were depressed by conjoint injection. In those RM neurons whose firing rates were depressed by noxious stimulation, 100% (8 of 8) of the rates were enhanced by PAG injection, 90% (9 of 10) were enhanced by PGC injection and 100% (16 of 16) were enhanced by conjoint microinjection. These patterns obtained for RMS as well as RM neurons. (Supported by NIH grant DE 07905.)

342.11

ANTINOCICEPTION INDUCED BY MICROINJECTION OF CARBACHOL IN THE VENTRAL ROSTRAL MEDULLA IS NOT MEDIATED BY ENKEPHALINERGIC NEURONS. M.A. McCartney and H.K. Proudfit. Dept. Pharmacology, Univ. Illinois at Chicago, Chicago, IL 60612.

The ventral rostral medulla (VRM) contains cholinergic terminals, muscarinic receptors, and microinjection of the cholinergic agonist, carbachol into the n. raphe magnus (NRM) produces antinociception. However, the effects of carbachol microinjected into the n. reticularis gigantocellularis pars alpha (NGCA), n. reticularis gigantocellularis (NGC), and n. reticularis paragigantocellularis (NRPG) have not been evaluated. Therefore, studies were done to determine whether microinjection of carbachol into these sites produces antinociception. In addition, the role of endogenous enkephalins in mediating carbachol-induced antinociception was examined.

Microinjection of carbachol (2.5 ug) into the NRM, NGC, NGCA, but not NRPG, produced antinociception. However, this antinociception does not appear to be mediated by enkephalins since naloxone, administered either systemically or intrathecally, failed to reverse the carbachol-induced antinociception. This work was supported by USPHS Grant DA 03980.

342.12

BEHAVIORALLY DERIVED REFRACTORY PERIOD ESTIMATES OF THE SUBSTRATES FOR ANALGESIA DERIVED FROM STIMULATION OF THE DORSAL AND VENTRAL PAG. Susan Schenk and Kim Pollard-Smith*. Texas A&M University, Dept. Psychology, College Station, TX 77843

Psychophysical methods were used to obtain refractory period estimates of the directly stimulated substrate for the analgesic effects of periaqueductal gray (PAG) stimulation. Trains of stimulation pulses (10 sec. train lengths, 0.1 msec monophasic constant current cathodal pulses) were delivered to the dorsal or ventral PAG of restrained rats. Immediately following the stimulation, the caudal 2.5 - 3.0 mm of the rat's tail was immersed in heated water (52 -54°C) and latency to tail flick was measured. Frequency threshold for analgesia was determined as the frequency of stimulation that resulted in a tail flick latency longer than 6 sec. Pairs of stimulation pulses were also delivered at intra-pulse pair intervals of 1.0 - 10.0 msec. Frequency thresholds for analgesia under this stimulation condition were compared to the threshold when only single pulses were delivered. Results indicated that the effectiveness of the paired pulse stimulation increased gradually as pulse-pair interval was increased from 1.5-7.5 msec. for both the dorsal and ventral sites. These data suggest that the analgesic properties of stimulation derived from dorsal or ventral PAG sites rely on the direct activation of similar caliber neurons.

342.13

GABA-IMMUNOREACTIVE SYNAPTIC CONTACTS ONTO PROJECTION NEURONS OF THE PERIAQUEDUCTAL GRAY MATTER AND THE NUCLEUS RAPHE MAGNUS. D. B. Reichling, H.-J. Cho* and A. I. Basbaum. Depts. Anatomy and Physiology, Univ. of California, San Franicisco, CA 94143.

GABA antagonists microinjected into the midbrain periaqueductal gray matter (PAG) or into the medullary nucleus raphe magnus (NRM) inhibit the nocifensive tail-flick reflex. Conceivably, this effect is due to the blockade of a tonic GABAergic inhibition of projection neurons from the PAG to the NRM, or from the NRM to the spinal cord. This report describes anatomical evidence for GABAergic modulation of midbrain/medullary antinociceptive pathways.

For PAG studies, WGA-apoHRP conjugated to colloidal gold was microinjected into the NRM of rats, 5 days prior to perfusion. Silver-enhanced, Vibratome sections of the PAG were embedded, thin-sectioned, and immunostained (on grids) with an anti-GABA antibody. Approximately 40% of terminals in the PAG are GABA-immunoreactive (IR). These contain round vesicles, and form symmetrical synaptic contacts with dendrites and cell bodies, but not with axons. Approximately 50% of GABA-IR profiles contain dense-core vesicles. About half of synaptic contacts onto retrogradely labelled cell bodies are GABA-IR; none of these contain dense-cored vesicles.

For NRM studies, WGA-HRP was injected into the spinal cord, and an electrolytic lesion was made in the PAG. Approximately 48% of terminals in the NRM are GABA-IR; these contain round vesicles and are presynaptic to dendrites and cell bodies. About 3% of GABA-IR terminals made asymmetrical contacts and contained flat vesicles. Degenerating PAG terminals and GABA-IR terminals converge onto raphe-spinal projection neurons. These data indicate there are multiple sites of GABAergic modulation of descending antinociceptive control. Supported by NS14627 and NS21445.

342.14

THE RELATIONSHIP OF PERIAQUEDUCTAL GRAY PROJECTIONS TO BULBOSPINAL NEURONS: A COMBINED FLUOROGOLD-PHA-L ANALYSIS. A.J. Beitz, M.A. Mullett* and N. Brandt*, Dept. of Vet. Biol., Univ. of Minnesota, St. Paul, MN 55108

The present study was designed to determine the location of brain stem neurons that receive direct input from the periaqueductal gray (PAG) and project to the spinal cord. Ten adult Sprague-Dawley rats received multiple injections of 4% Fluoro-gold into the lower cervical spinal cord and a single iontophoretic injection of phaseolus vulgaris leucoagglutinin (PHA-L) into the midbrain PAG. Following fixation, the brains were sectioned and PHA-L labeled fibers were visualized using immunofluorescence. The mean number of retrogradely labeled neurons (per 0.04 mm^2 area per nucleus per section) that were contacted by PHA-L labeled fibers were quantitated. The nuclei containing the greatest number of spinobulbar neurons, which appeared to be contacted directly by PHA-L labeled PAG projection neurons, were the gigantocellular reticular nucleus pars alpha, nucleus subcoeruleus, lateral paragigantocellular nucleus, pedunculopontine tegmental nucleus, oral pontine reticular nucleus, ventral gigantocellular reticular nucleus, ventrolateral tegmental nucleus, raphe magnus and rostroventrolateral reticular nucleus. These results suggest that several brainstem nuclei may relay PAG input to the spinal cord and quantitatively the raphe magnus does not appear to be the most significant. Supported by NSF grant BNS-8607520 and NIH grants NS 19208, DE 06682 and DA 04090.

342.15

TRIGEMINAL AND PAG MODULATION OF OPIOID PEPTIDE GENE EXPRESSION IN NUCLEUS CAUDALIS. T. Nishimori*, M. Moskowitz, D. Borsook, R. Maciewicz and G. Uhl (SPON: R.W. Kunkl). G.NSci. Unit NIDA, Depts. of Neurol. & NSci., JHU Med. School, Balto., MD 21224 & MGH, Boston, MA 02114

We have used in situ hybridization to define the expression of the preproenkephalin and preprodynorphin genes in neurons of laminae I and II of the trigeminal nucleus caudalis.

Neurons expressing preprodynorphin were more likely to be found in lamina I and the outer layer of lamina II; neurons expressing preproenkephalin were more uniformly distributed within laminae I and II.

After lesions of the trigeminal ganglion, neuronal expression of preproenkephalin decreases, due to a decline in the number of neurons expressing this gene, while the number of neurons expressing preprodynorphin increases.

0.1mA stimulation of the trigeminal ganglion increases the number of neurons expressing preproenkephalin, while preprodynorphin mRNA expression in the same animals and with electrostimulation of the PAG shows a more complex pattern of changes.

These results support specific patterns of opioid peptide gene regulation by both primary afferents and descending inputs from the PAG, and provide examples of opposite function-related changes in expression of the two principal brain opioid peptide genes.

342.16

THE MECHANISM OF INHIBITION OF SPINOTHALAMIC TRACT (STT) NEURONS BY ELECTRICAL STIMULATION OF PERIAQUEDUCTAL GRAY (PAG). D. Zhang, C.M. Owens and W.D. Willis, Dept. of Anat. & Neurosci. and Marine Biomed. Inst., Univ. of Texas Medical Branch, Galveston, TX 77550.

The activity of STT neurons can be inhibited by PAG stimulation. The present study employs extracellular and intracellular recording and horseradish peroxidase (HRP) injection to investigate the spinal mechanism involved in such inhibition. Ten anesthetized adult monkeys (M. fascicularis) were used. Extracellular recording from 7 STT neurons confirmed that PAG stimulation preferentially inhibited the responses to sural nerve C-fiber volleys regardless of cell location or type. Intracellular recording and injection of HRP into 7 STT neurons revealed a positive relationship between the response of the neurons to C-fiber volleys and the projection of dendrites into laminae I and II. PAG stimulation evoked a hyperpolarizing potential and a concomitant inhibition of discharges in 5 neurons. In 2, the resting membrane potential was altered by current injection. The amplitude of the hyperpolarization was increased with hyperpolarizing current and decreased with depolarizing current, indicating disfacilitation rather than an inhibitory postsynaptic potential. Both neurons had small responses to C-fiber volleys and one of them that was labeled with HRP had no dendrites extending to laminae I or II. (Supported by NIH grants NS 09743 and NS 11255.)

NEUROCHEMICAL LATERALITY OF THE ANALGESIC EFFECT OF PAG STIMULATION IN THE MOUSE. J. C. Liebeskind, R. Yirmiya and P. Marek* (SPON: J. Lewis). Department of Psychology, University of California, Los Angeles, CA 90024 and Institute of Genetics and Animal Breeding, Polish Academy of Sciences, 05-551 Mrokow, Poland.

The mechanisms of periaqueductal gray (PAG) stimulation-produced analgesia have been widely studied in the rat. In the present study, we compared the involvement of opioids in the analgesic effect of stimulating different regions of the PAG in mice. Swiss-Webster mice were anesthetized with pentobarbital and a monopolar stimulating electrode was stereotaxically positioned in the ventral or the dorsal lateral PAG. Nociception was assessed using the hind paw flick test (paw withdrawal from radiant heat). After determination of SPA current threshold for each paw separately, all animals received naloxone (5 mg/kg, i.p.) and SPA current thresholds were estimated again 20 min later. SPA threshold did not differ between dorsal and ventral parts of the PAG. Naloxone equally attenuated SPA threshold from both areas. The SPA threshold for the paw contralateral to the stimulation site was half that for the ipsilateral paw. Moreover, naloxone attenuation of SPA was 3 times greater for the contralateral than for the ipsilateral paw. Preexposure to analgesic neck scruff pinch almost completely abolished the antinociceptive effect of contralateral PAG stimulation, suggesting the development of functional tolerance. Naloxone administration before pinching attenuated this effect. These results suggest a contralateral organization of the opioid component of the pain inhibitory system in the PAG. Supported by NIH grant NS07628.

342.18

GENETIC MODULATION OF PAG STIMULATION PRODUCED ANTINOCICEPTION IN MICE. P. Marek*, R. Yirmiya, I. Panocka* and J. C. Liebeskind. Institute of Genetics and Animal Breeding, Polish Academy of Sciences, 05-551 Mrokow, Poland, and Department of Psychology, University of California, Los Angeles, CA 90024.

Strain differences in the analgesic effect of morphine, electroacupuncture and stress in mice indicate modulation of the endogenous pain inhibitory system by genetic factors. In the present study the antinociceptive effect of electrical periaqueductal gray (PAG) stimulation and its naloxone reversibility were compared in four genetically different strains/lines of mice: CXBK (deficient in brain opiate receptors), CXBH (rich in brain opiate receptors), LA and HA mice (selectively bred for low and high swim induced analgesia, respectively). Animals were anesthetized with pentobarbital and a monopolar stimulating electrode was stereotaxically positioned in the lateral PAG. Nociception was assessed using the hind paw flick test (paw withdrawal from radiant heat). After determination of SPA current threshold, all animals received naloxone (5 mg/kg, i.p.) and SPA current threshold was estimated again 20 min later. SPA threshold did not differ between CXBK and CXBH mice. However, naloxone caused a three-fold increase of threshold in CXBH mice, but was ineffective in CXBK mice. SPA threshold in HA mice was half that of LA mice. Naloxone significantly increased SPA threshold in HA, but not LA mice.These results indicate that genetic factors importantly affect the neurochemical mediation of endogenous analgesic processes. Supported by NIH grant NS07628 and the Polish Academy of Sciences project CPBP-04.01/6.13.

HIPPOCAMPUS AND AMYGDALA III

343.1

AMYGDALA DIRECTLY INNERVATES BRAINSTEM CATECHOLAMINERGIC CELLS IN THE RAT. T.S. Gray and D.J. Magnuson*. Dept. Anatomy, Stritch School of Medicine, Maywood, IL 60153

The present study used a combined phaseolus vulgaris leucoagluttin lectin anterograde tracer (PHA-L) and immunocytochemistry to determine whether amygdala cells directly innervated tyrosine hydroxylase, PNMT and/or dopamine beta hydroxylase immunoreactive cells within the brainstem. Iontophoretic injections of PHA-L were placed within the central nucleus of the amygdala of anesthetized 150-250g Long-Evans rats. Two weeks later animals were overdosed with sodium pentobarbital and their brains were fixed through vascular perfusion. Amygdaloid terminals were demonstrated by antibodies to PHA-L with avidin-biotin immunocytochemistry using a brown DAB reaction. Catecholaminergic cell bodies were visualized via antibodies to TH, PNMT or DBH using a glucose oxidase-nitro blue tetrazolium reaction. Amygdaloid terminals were distributed within a variety of areas that were immunoreactive to catecholamine markers. For example, amygdaloid terminals appeared to contact tyrosine hydroxylase immunoreactive cells within the substantia nigra, locus coeruleus and the A8 cell group. Amygdaloid terminals also appeared to contact TH and PNMT immunoreactive cell bodies within the nucleus of the solitary tract and the ventrolateral medulla. The results demonstrate that the amygdala can directly influence a number of subpopulations of catecholaminergic neurons within the brainstem. (Supported by NIH NS 20041)

343.2

VIDEO MICROSCOPY OF CULTURED AMYGDALA BRAIN SLICES. D.E. Stevens*, E.W. Kairiss, P.F. Chapman*, and T.H. Brown. (SPON: C.L. Keenan) Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

Long-term synaptic potentiation (LTP) was recently discovered to occur in synapses of the acute amygdala brain slice (P.F. Chapman and T.H. Brown, this meeting). To increase the accessability of this complex structure to high-resolution analysis of such synaptic phenomena, we have applied the roller tube culture procedure, which was previously developed (Gahwiler, B.H. *J. Neurosci. Meth.*, 4:329, 1981) for use on hippocampal tissue.

Horizontal slices of amygdala (including adjacent regions of cortex, fundus striati, dorsal endopiriform nucleus, lateral hypothalamus and subiculum) were prepared from the brains of 6-8 day old rat pups previously anesthetized with halothane. The slices were cultured on collagen-coated coverslips and maintained for periods of up to several weeks. Our preliminary studies have focussed on the development of the cultures and the morphological characterization of cultured amygdala neurones. The cytoarchitecture and cellular morphology were examined using video-enhanced contrast, differential-interference contrast (VEC-DIC) microscopy.

By 2 weeks *in vitro* the cultures had flattened into a 1-6 cell layer structure. Low-power (4X-10X)VEC-DIC microscopic observation of the living slices and of cresyl violet stained slices revealed the presence of recognizable amygdaloid nuclear regions as well as cortical cell layers. When viewed at higher power (40X) magnification, individual neuronal somata were readily visualized in the living tissue. Intracellular injections of lucifer yellow revealed several types of neuronal morphologies that were similar to those seen in published golgi material.

We conclude that the cultured amygdala slice preparation holds great potential for combining biophysical and neurophysiological analysis with visualization techniques such as VEC-DIC microscopy and confocal scanning laser microscopy. These combined approaches should expedite our understanding of the biophysics and microphysiology of synaptic transmission in this important but complex temporal lobe structure. *(Supported by AFOSR and Beckman Research Institute)*

STIMULATION OF THE AMYGDALOID CENTRAL NUCLEUS (ACe) FACILITATES THE NICTITATING MEMBRANE UNCONDITIONED REFLEX (NMUR) IN THE RABBIT. P.J. Whalen and B.S. Kapp. Dept. of Psychology, Univ. of Vermont, Burlington, VT 05405.

The maintenance of facilitation of the NMUR during Pavlovian conditioning appears to involve an associative learning process (Weisz and McInerney, 1987). Since the ACe (a) contributes to the modulation of various reflexes (Gary Bobo and Bonvallet, 1975; Schlor et al., 1984; Pascoe et al., 1987), (b) projects to the brainstem lateral tegmental field which contains the circuitry for the NMUR (Hopkins and Holstege, 1978) and (c) has been implicated in associative learning (Kapp et al., 1986), the present study was conducted to investigate the contribution of the ACe to facilitation of the NMUR.

New Zealand rabbits were prepared with stimulation electrodes (200um tip) in the ACe. Following recovery, the NMUR was elicited over 16 trials. Electrical stimulation of the ACe, at an intensity which influenced the brainstem as indexed by vagal bradycardia, was presented for either 400 or 100msec prior to reflex elicitation for eight of these trials (<100uamps, 100Hz). A significant increase in reflex amplitude (10-24%, ps<.05) was observed on ACe stimulation trials when compared to trials not preceded by stimulation. Stimulation of the ACe in the absence of NMUR elicitation did not induce membrane movement. These results are consistent with the notion that the ACe may contribute to associative facilitation of the NMUR.

CONNECTIONS OF THE PREFRONTAL CORTEX WITH THE HIPPOCAMPAL FORMATION IN THE CAT AND MACAQUE MONKEY. C. Cavada and F. Reinoso-Suárez. Dept. Morfología, Fac. Medicina, Univ. Autónoma, Madrid, Spain.

Injections of anterograde and retrograde tracers were made in different sectors of the prefrontal cortex (PfC) in cats and macaques, and the resulting labeling in the hippocampal formation was analyzed. Serial sections adjacent to those processed to reveal the transported tracers were stained for Acetyl Cholinesterase (AChE) histochemistry.

Our results indicate that only the dorsolateral sector of macaque PfC projects intensely to the presubiculum. In cat, the ventral PfC projects to the parasubiculum. The terminal labeling in this region is densest in the deep part of layer I, and overlaps with an intensely stained AChE band. In both cat and monkey, the subiculum projects heavily to the ventral PfC. All prefrontal sectors studied are connected with the so called caudomedial lobule in macaque and caudomedial band in cat.

These findings suggest that the connections of the PfC with the hippocampal formation exhibit notable similarities in the two species studied. This argues in favor of the existence of comparable functions of the prefronto-hippocampal loops. However, connectional differences are also present, which may entail functional implications.

BASAL FOREBRAIN AFFERENTS, MUSCARINIC RECEPTORS AND PUTATIVE PRESYNAPTIC CHOLINERGIC MARKERS IN THE HIPPOCAMPAL FORMATION AND ENTORHINAL CORTEX OF THE RHESUS MONKEY. K.J. Rhodes, D.L. Rosene, and M.B. Moss. Dept. of Anatomy, Boston Univ. Sch. Med., Boston, MA 02118.

We have compared the distribution of basal forebrain (BF) afferents with muscarinic receptors and putative presynaptic cholinergic markers in the hippocampal formation (HF) and entorhinal cortex (EC). BF afferents to the HF and EC were labeled using anterograde transport of [3H]-labeled amino acids. Muscarinic receptors were labeled with [3H]-pirenzepine (M1) and [3H]-oxotremorine (M2). Acetylcholinesterase (AChE) and [3H]-hemicholinium-3, which binds to high affinity choline uptake sites (HACU), were used as putative presynaptic markers. In the HF the distribution of BF afferents, AChE and HACU showed close correspondence except in stratum moleculare (SM) of the dentate gyrus (DG) where BF afferents and HACU were uniformly distributed but AChE reaction product was most dense in the inner 1/3. Like BF afferents, AChE and HACU were distributed densely in strata oriens and pyramidale of CA1-4 and in the prosubiculum. However, M1 and M2 sites did not follow the distribution of BF afferents, AChE, or HACU sites in several areas. For example, in SM of the DG M1 sites were very dense compared with BF afferents, AChE, M2 and HACU. In the subiculum, M2 sites were very dense compared with BF afferents, AChE, M1 and HACU. In EC, BF afferents, AChE, HACU and M1 sites showed small laminar variations in distribution but M2 sites were dense in layer III, especially in area 28S. In the HF, AChE and HACU are good markers for BF cholinergic afferents except in the inner 1/3 of SM of the DG. In the subiculum and layer III of EC, M2 sites are very dense while other cholinergic markers are not. (Supported by NS19416, AG00001, AG04321 and T32-NS07152)

DISTRIBUTION OF CORTICAL PROJECTIONS TO THE MONKEY ENTORHINAL CORTEX: AN AUTORADIOGRAPHIC STUDY. R. INSAUSTI AND D.G. AMARAL. The Salk Institute, P.O. Box 85800, San Diego, CA. and Dept. Anatomy, Univ. of Navarra, Pamplona, Spain.

Previous retrograde tracing experiments demonstrated that the macaque monkey entorhinal cortex receives several direct neocortical inputs (Insausti et al.,1987). In order to analyze the terminal distribution of these projections, discrete injections of ^{3}H amino acids were made into several of the afferent cortical areas. Orbitofrontal and temporal polar cortical regions project relatively widely within several subdivisions of the entorhinal cortex. More restricted projections were observed from the perirhinal cortex (which terminates mainly in the rostral half of the entorhinal cortex), and the superior temporal gyrus, parahippocampal gyrus, and the retrosplenial cortex (all of which preferentially innervate the caudal half of the entorhinal cortex). The lateral field of the entorhinal cortex generally receives a heavier cortical input than other entorhinal fields except when the injection involved the retrosplenial cortex. In this case, heavier labeling was located medial and caudal to the lateral subdivision. In all cases, layer I received the densest terminal innervation, followed by layers III, V and VI. These results indicate that the cortical projections to the entorhinal cortex are diffusely distributed but have a rough topographic organization.

EVIDENCE FOR A DIRECT CELL-TO-CELL INFLUENCE OF THE HIPPOCAMPUS ON MEDIAL FRONTAL "VISCERAL MOTOR" CORTEX. K.G. Ruit and E.J. Neafsey. Dept. of Anatomy, Loyola Univ. Med. Ctr., Maywood, IL 60153.

Hippocampal (HIPP) stimulation significantly decreases heart rate and blood pressure, and we hypothesize it does so via its connection with the medial frontal cortex (MFC), a region which projects directly to the solitary nucleus (NTS). The present electrophysiological and anatomical study was undertaken to determine the degree to which the HIPP projection to MFC overlaps the origin of the descending projection to NTS.

72 MFC neurons were antidromically activated by NTS stimulation with an average latency of 31 msec (SD = 10). MFC neurons also responded to HIPP stimulation, and, in a few cases, the orthodromic spike from HIPP collided with and eliminated the antidromic spike from the NTS. Following injections of wheat germ agglutinin conjugated horseradish peroxidase (WGA-HRP) into both the NTS and ipsilateral HIPP, light microscopy showed that the terminal-like labelling from HIPP appeared to overlap the retrogradely labelled cells from NTS in the MFC. Electron microscopy confirmed that HRP-labelled terminals do, in some cases, synapse on HRP-labelled cells. These results indicate that the pathway from HIPP to the MFC cells which project to NTS may be monosynaptic and, therefore, directly influence a central visceral control system. CONTRASTING EFFECTS OF STIMULATION OF AMYGDALA AND HIPPOCAMPUS ON SUBPALLIDAL OUTPUT NEURONS TO THE PEDUNCULOPONTINE NUCLEUS (PPN). C. T. Tsai*, M. Wu*, C. R. Yang* and G. J. Mogenson. Dept. of Physiology, Univ. of Western Ontario, London, Ontario, Canada N6A 5C1.

Hippocampal stimulation inhibited subpallidal(SP) output neurons to the PPN while microinjection of NMDA into the hippocampus increased locomotor activity, suggesting that signals from the hippocampus disinhibit PPN neurons to produce hypermotility (Yang & Mogenson, Neuroscience, 23:1041-1055, 1987). In contrast, microinjection of NMDA into the amygdala suppressed locomotor activity which was also mediated via the SP (Yim & Mogenson, Proc. Can. Fed. Biol. Sci., 30:120, 1987). A comparative study was made to find out whether there is contrasting effect of electrical stimulation of amygdala and hippocampus on SP-PPN neurons identified by antidromic stimulation.

In a total of 50 SP-PPN neurons, only 20 were able to be tested with single pulse stimulation of the amygdala and hippocampus. Fourteen were activated by amygdala stimulation and 6 were inhibited whereas 5 were activated by hippocampal stimulation and 13 were inhibited ($X^2=5.17$, $p<0.05$). These observations provide electrophysiological evidence that the amygdala and hippocampus have opposite effects on SP neurons projecting to the PPN.

INVOLVEMENT OF N. BASOLATERALIS AMYGDALAE IN ATTENTION IN CAT. M.F.Montaron*, J.J.Bouyer, C.Durand*, P.Delagrange*, A.Rougeul* and P.Buser*. Institut des Neurosciences, Département de Neurophysiologie comparée, CNRS-Université P.& M.Curie, 9, quai Saint Bernard, F-75005 Paris.

In cat the behavior of motionless focalized attention upon a target is accompanied by the development of rhythmic cortical activities at 36 Hz ("beta" rhythms) in the fronto-parietal cortex. Both behavior and accompanying rhythms are controlled by the ventral tegmental area (VTA): bilaterally VTA lesioned cats display hyperactivity in conditions in which normal animals would develop immobility and watching (Montaron et al., *Behav.Brain Res.*,6:129.1982). On the other hand, bilateral lesion of nucleus accumbens (Acc), a relay on the meso-limbic pathway from VTA which also projects to the striatum has the opposite effects, eliciting perseveration of motionless attentive fixation with a high rate of cortical beta rhythms (Bouyer et al., *Exp.Neurol.*,92:698,1986). The VTA is also a source for connections to the amygdala which in turn projects to Acc. With these data in mind, we have now performed bilateral kainic lesions restricted to the basolateral nucleus of the amygdala and controlled the postlesional behavior and beta activity. Both manifestations were markedly decreased after such lesions, but interestingly, no spontaneous motor hyperactivity could be noticed in this case. From this we tend to conclude that in our experimental conditions the amygdala controls the motivational component of the attentive state with no major effect upon its motor behavior component, at variance with the Acc,which being part of the striatal complex and also receiving amygdala influences, may exert a higher level control on attention.

ORGANIZATION OF HIPPOCAMPAL EFFERENT PROJECTIONS TO THE CEREBRAL CORTEX IN THE RHESUS MONKEY. G.J. Blatt and D.L. Rosene, Dept. of Anatomy, Boston University School of Medicine, Boston, MA 02118.

To identify the cells of origin of the direct hippocampal formation (HF) projection to the cerebral cortex, injections of retrograde fluorescent tracers were placed in the posterior (PPHG) and anterior (APHG) parahippocampal gyrus and the medial (MFC) and orbital frontal cortex (OFC). Injections in the medial PPHG labeled cells in the subiculum and throughout a central strip of CA1 stratum pyramidale. This strip extended longitudinally the entire anteroposterior length of the HF. Similarly an injection placed laterally in the PPHG labeled a longitudinal strip in the most lateral part of CA1 while injections in the APHG lateral to the rhinal sulcus labeled cells in a more medial strip of CA1. In contrast, MFC and OFC injections labeled cells mainly in the subiculum while in CA1 labeled cells were widely distributed but limited to the deepest part of stratum pyramidale. These results demonstrate that projections from CA1 to the PPHG and APHG originate topographically from longitudinally oriented strips of cells in contrast to projections to the MFC and OFC that originate from the deepest part of stratum pyramidale. These observations suggest a unique functional differentiation in CA1 of the monkey HF.

BASAL FOREBRAIN AFFERENTS TO THE HIPPOCAMPAL FORMATION IN THE RHESUS MONKEY. D.L. Rosene, P.L. Heilbroner and M.B. Moss Dept. of Anatomy, Boston University School of Medicine, Boston, MA 02118.

Projections from the magnocellular basal forebrain nuclei to the hippocampal formation (HF) were examined using acetylcholinesterase (AChE) histochemistry and anterograde and retrograde tracers. The medial septal nucleus (MS) and vertical limb of the diagonal band (VDB) projected strongly to uncal levels of the HF, especially to laminae of CA4, CA3, CA2, and the prosubiculum (ProS) as well as the molecular layer of the dentate gyrus (DG). This projection continued throughout the entire length of the HF but was progressively diminished caudally. Like the MS-VDB, the nucleus basalis (NB) projected most heavily to the uncal HF, although less densely. Caudally the only dense NB projection was to the border of the stratum moleculare and stratum radiatum at the junction of CA1 and ProS. These projection patterns correspond closely to the laminar pattern of AChE except in the molecular layer of the DG where the basal forebrain afferents were uniform. Injections of retrograde tracers into the HF confirmed that these projections originated from the MS, VDB and NB. AChE double-labelling demonstrated that from 30 to 50% of the retrogradely labeled neurons were likely to be cholinergic.

RESPONSES OF MEDIAL SEPTAL/DIAGONAL BAND CELLS TO ELECTRICAL STIMULATION OF THE DORSOMEDIAL-POSTERIOR HYPOTHALAMIC NUCLEI. B.H. Bland*, R.D. Ford*, L.V. Colom, (SPON:A Spira) University of Calgary, Dept. of Psychology, Calgary, Alberta T2N 1N4.

Electrical stimulation of the dorsomedial-posterior hypothalamic nuclei in the urethane anaesthetized rat produces theta (θ) in the hippocampal formation. Furthermore, increases in stimulus intensity are linearly related to increases in θ frequency. This effect is mediated by the medial septum/diagonal band nuclei since after lesions here θ can no longer be produced in the hippocampal formation by such stimulation. The purpose of this study was to investigate the effects of dorsomedial-posterior hypothalamic stimulation on the discharge properties of medial septal/diagonal band cells. Cells were classified along three dimensions, according to previously used criteria (Colom and Bland, Brain Research, 1987), as theta-on or off, phasic or tonic, linear or non-linear, during the spontaneous occurrence of θ and large amplitude irregular activity (LIA). Stimulation did not affect a cell's classification as on or off or phasic or tonic. The major effect was to change phasic non-linear theta-on cells to linear, suggesting that this ascending hypothalamic system plays an important role in increasing the number of septal cells that code the frequency shifts of hippocampal formation theta.

IDENTIFICATION OF ZINC-CONTAINING NEURONS BY RETROGRADE TRANSPORT OF ZINC-SELENIDE. G. A. Howell and C. J. Frederickson. Lab. for Neurobiology, Univ. of Texas at Dallas, Richardson, Texas 75083

We previously have shown with lesion techniques that the zinc-containing terminals in the BNST, N. terete, and VMH arise from axons of the stria terminalis and fornix/fimbria (Frederickson et al., Soc. Neurosci. Abst., 1986, 12:1532). In the present work, we used a retrograde transport marker for zinc-containing neurons (Danscher, In: Frederickson et al., The Neurobiology of Zinc, Liss, N.Y., p. 185) and sought to identify the specific cells of origin of these zinc-containing pathways.

Selenite ions (Na_2SeO_3) were infused into BNST/VMH regions in anesthetized rats, causing ZnSe to precipitate in situ in zinc-containing terminals . Twenty-four hours later, rats were sacrificed, and cryostat sections were developed in neo-Timm's, rendering the ZnSe visible by silver encapsulation.

Staining at the injection site showed characteristic labeling of the neuropil (presumably the zinc-containing boutons) with no labeling of perikarya. However, dense and selective labeling of individual perikarya was found in the ipsilateral amygdalohippocampal area, certain amygdalar nuclei, and in the ventral subiculum. These findings suggest that retrograde transport of precipitated zinc (ZnSe) is a chemospecific marker for identifying and mapping zinc-containing neuronal systems. Supported by MH 42798.

THE FUNCTION OF A ZINC METALLOTHIONEIN FROM BOVINE HIPPOCAMPUS, **V. K. Paliwal* and M. Ebadi. Dept. of Pharmacol., Univ. of Neb. Coll. of Med., 42nd St. and Dewey Ave., Omaha, NE 68105**

Mammalian hippocampi not only contain high concentrations of dithizone chelatable zinc, but also exhibit regional variation in this essential element, with concentrations being highest in the hilar region and lowest in the fimbria. For example, the concentration of zinc in the mossy fiber axons has been estimated to approach 300-350 μM. In an attempt to investigate further the dynamic metabolism of zinc, we have searched for and have identified a metallothionein-like protein in bovine hippocampus with the following properties: similar to the zinc-induced hepatic metallothionein (hep-MT), the hippocampal metallothionein-like protein exhibits an elution volume (Ve/Vo) of 2.0 on gel filtration chromatography, and produces two isoforms, which on a reverse phase high performance liquid chromatography (HPLC) show retention times of 16.72 min. (hep-MTI produces 16.53 min.) and of 17.94 min. (hep-MTII produces 18.45 min.), respectively. The hippocampal metallothionein isoform II contains a cysteine to zinc ratio of 2.8 to 1.0, and, as shown by studies involving UV spectral analysis, apparently lacks aromatic amino acids, but possesses metallomercaptide bonds. The results of these studies suggest that the metallothionein may play an essential role in regulating the transport and/or accumulation of zinc in the hippocampus. Investigations to determine the regional CNS localization, as well as the subhippocampal distribution of this metallothionein-like protein, are in progress.

COLOCALIZATION OF GABA AND PEPTIDES IN THE RAT BASOLATERAL AMYGDALA. A. J. McDonald and J. C. Pearson. Departments of Anatomy, Univ. of South Carolina Sch. of Med., Columbia, SC 29208, and Wright State University Sch. of Med., Dayton, OH 45435.

Although previous studies have shown that GABA and peptides are found in nonpyramidal neurons of the basolateral amygdala, it is not known whether these substances co-exist in the same neurons. The present study utilized a two color ABC immunoperoxidase procedure (with DAB and BDHC as chromogens) to investigate this question. The anti-GABA antiserum was raised in a guinea pig while the antibodies to peptides were raised in other species. Most somatostatin-positive and neuropeptide Y-positive neurons were also GABA-positive. All large CCK-positive neurons appeared to contain GABA while a subpopulation of small CCK cells, found mostly in the lateral nucleus, were mostly GABA-negative. Some VIP containing neurons also contained GABA. Thus, it appears that many neurons in the basolateral amygdala that contain the inhibitory transmitter GABA also contain putative peptide neuromodulators. On the other hand, most GABA-positive cells were not double-labeled. These findings are very similar to those obtained in studies of the cerebral cortex and provide further support for the notion that the cortex and basolateral amygdala share many important features. (Supported by NIH Grant NS 19733).

343.16

CHEMICAL ANATOMY OF THE AMYGDALA IN PRIMATE. A.F. Sadikot*, Y. Smith and A. Parent. Lab. of Neurobiology, Fac. of Med., Laval Univ., Québec, Canada.

Very little information is yet available on the localization of neurotransmitters in the amygdala of primates. Thus, the peroxidase-antiperoxidase immunohistochemical method was used to stain serial coronal sections of the temporal lobe of 2 squirrel monkeys (*Saimiri sciureus*) with polyclonal antibodies to tyrosine hydroxylase (TH), serotonin (5-HT) and met-enkephalin (ENK), and with a monoclonal antibody to substance P (SP). SP-immunoreactive cell bodies were noted in the basolateral nucleus and, more rarely, in the central nucleus of the amygdala. SP terminals and fibers of fine caliber occurred in the dorsal region of the medial nucleus as well as in the central and basolateral nuclei. Numerous ENK-immunoreactive fibers of the woolly type were seen in the lateral portion of the central nucleus and, to a lesser extent, in its medial portion which also contained many thinner axons and scattered terminals. 5-HT immunostaining in the amygdala was widespread with varicosed fibers being particularly prominent in the basal, lateral and central nuclei. 5-HT terminals were visualized in the central nucleus of the amygdala and the periamygdaloid cortex. TH immunoreactivity was seen mainly as scattered terminals in the central nucleus and fine varicosed fibers in the lateral and basal nuclei. The present study provides the first description of the distribution of SP, ENK, 5-HT, and TH in the amygdala of primates. These results should serve as a more rational basis for defining amygdaloid nuclei in mammals and as a framework for future studies of the chemospecific connections of the amygdala in primates. (Supported by grants of the MRC, FRSQ and FCAR).

LEARNING AND MEMORY: PHYSIOLOGY IV

344.1

MEMORY FIELDS: DIRECTIONAL TUNING OF DELAY ACTIVITY IN THE DORSOLATERAL PREFRONTAL CORTEX OF RHESUS MONKEY. S.Funahashi, C.J.Bruce, and P.S.Goldman-Rakic Sec. Neuroanatomy, Yale Univ. Sch. of Med., New Haven, CT 06510.

The prefrontal cortex (PFC) in nonhuman primates is essential for the spatial working memory processes tapped by delayed response tasks. Our previous study using an oculomotor delayed response paradigm provided evidence that PFC neurons are active (excitation or inhibition) in the delay period only when visual cues were presented at specific locations in the visual field (Funahashi et. al., Soc. Neurosci. Abstr., 12:554, 1986). We termed the area of the visual field where a neuron shows prominent delay activity as that neuron's memory field.

In the present experiment, we quantitatively analyzed the spatial tuning of these memory fields. Eight visual cues separated by 45 deg in polar direction at an eccentricity of 13 deg were presented randomly in the cue period of the oculomotor delayed response task. Tuning curves were made based on the average discharge rate during the delay period for each cue. The best directions were estimated from the parameters used to fit these experimental data to a Gaussian function. Tuning indices were defined as the departure from the best direction which reduced the response by 50% along the fitted curve.

Seventy-six PFC neurons with directional delay activity were analyzed. Although the best directions were widely distributed, a strong contralateral bias was evident: 62% of the best directions were toward the visual field contralateral to the neuron's hemisphere whereas only 26% were toward the ipsilateral field. The remaining 12% of the neuron's best directions were around the vertical meridian. The tuning indices were distributed widely (3 to 133 deg) with median of 30.4 deg; however, about half the neurons had indices between 20 and 40 deg and 9% of neurons showed tuning narrower than 10 deg.

Our results indicate that PFC neurons have a range of memory fields, with each hemisphere primarily mapping the contralateral hemifield. The findings that most memory fields are comparable to visual receptive fields and movement fields in the posterior parietal cortex or the superior colliculus suggest that the PFC is closely linked to the brain's centers for spatial vision.

344.2

CHANGES IN HAND KINEMATICS DURING A QUANTIFIABLE LEARNING PARADIGM IN PRIMATES. C.L. Ojakangas, D.K. Onstott, D.C. Tam and T.J. Ebner. Depts. Neurosurgery and Physiology, Neuroscience Grad. Prog., Univ. of MN, Mpls., MN 55455.

A paradigm involving a 2-dimensional, visually guided arm movement was developed. Monkeys moved a cursor via a manipulandum on a video screen from a start box to one of 4 randomly presented target boxes. The relationship between hand and cursor was the same for the control phase (1.0) and was varied during learning. Movement strategies during adaptation to 4 gains (.6 - 2.0) were studied via control, learning and testing phases. Results indicated that in learning a new gain monkeys scaled the velocity of their movement to match the distance the hand needed to travel (i.e. further distance, higher velocity) ($p<.01$, 2-tailed T test). Time to maximum velocity remained relatively constant over phases and across gains ($p>.01$), as did reaction time. With time constant, distance until 1st (maximum) velocity peak varied directly with gain change. During learning, the 2nd velocity peak seen initially was eliminated and hand trajectory smoothed. Total movement duration decreased ($p<.01$) although remained greater than control for smaller gains once learned ($p<.01$). Results support the hypothesis that movement duration is a free variable and invariant during the first phase of movement. The learning strategy consists of scaling hand velocity to match gain. Supported by NSF/BNS-8707572 and NIH/NS-18338.

344.3

ACTIVITY OF MONKEY HIPPOCAMPAL AND ENTORHINAL NEURONS DURING LEARNING. T. Ono, R. Tamura*, E. Tabuchi* and M. Fukuda*. Dept. Physiol., Fac. Med., Toyama Med. & Pharmaceu. Univ., Sugitani, Toyama 930-01, JAPAN

Lesion in the monkey hippocampus produces spatial memory deficit. Neuronal activity in the monkey hippocampus and entorhinal cortex was recorded during operant feeding, drinking and shock avoidance, delayed matching to sample with response-delay, and a clinical test with visual, auditory presented from various directions. Focus in the clinical test was on neuronal response selectivity to direction. Of 1075 neurons tested, 581 (54.0%) responded to some task or the clinical test and 399 (37.1%) were identified as hippocampal or entorhinal. Of these, 40 (3.7%) were direction specific and many of these were in the caudal hippocampal formation. Of these 40 neurons, 27 responded only to visual stimuli (left anterior, 4; right anterior, 22; multidirectional, 1), 8 responded only to auditory stimuli (anterior, 1; right posterior, 2; posterior, 3) and 5 responded to both visual and auditory stimulation (right anterior, 1; multidirectional, 4). The direction-selective neurons tended to respond to visual stimuli presented from the right anterior, and to auditory stimuli presented from the posterior direction. The results suggest hippocampus and entorhinal cortex involvement in central processing of directional or spatial information.

344.4

CATECHOLAMINE SENSITIVITIES OF PREFRONTAL NEURONS RELATED TO A DELAYED RESPONSE TASK OF RHESUS MONKEYS. T. Sawaguchi, M. Matsumura* and K. Kubota. Dept. of Neurophysiol., Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, Japan.

Influences of iontophoretically applied dopamine (DA) and noradrenaline (NA) on neuronal activities related to a delayed response task were examined in the prefrontal cortex. The task was started by monkeys rotating a handle to a central zone, and consisted of pre-cue (central lamp, 1 s), cue (left or right lamp, 1 s), delay (4 s), go (red lamp, rotating the handle to left or right zone within 1 s), and reward periods. Prefrontal neurons showed changes in activity during the pre-cue period (PC-types, n=18), both the cue and go periods (Cue/GO-types, n=16), the go period (GO-types, n=16), and the delay period (Delay-types, n=64). Delay-types consisted of Differential neurons (n=33) whose activity differed between left- and right-cue trials, and Non-Differential neurons (n=31). DA increased the activity of most of Cue/GO- (16/16), GO- (13/16) and Delay-types (49/64), and NA inhibited the activity of most of PC-types (13/18) and Non-Differential Delay-types (25/31). Fluphenazine and haloperidol attenuated changes in activity during the cue, delay and go periods, while sulpiride had no clear effects. Results suggest that DA auguments prefrontal neuronal activity involved in temporal integration of visual cue and motor performance, and NA inhibits prefrontal neuronal activity related to visual reception.

344.5

SELECTIVITY OF DELAY DISCHARGES TO PICTORIAL PATTERNS IN A DELAYED MATCHING-TO-SAMPLE TASK IS MAXIMIZED THROUGH LEARNING IN NEURONS OF THE PRIMATE TEMPORAL CORTEX. Y.MIYASHITA Dept.of Physiol., Univ.of Tokyo, Tokyo, Japan.

Memory of visual experience in the primate has been proposed to be stored in the neural network of the temporal cortex. Recently, shape-selective working memory neurons were found in the monkey temporal cortex (1). I report here evidence suggesting that the responsiveness of these neurons is formed through learning. Two monkeys (Macaca fuscata) were trained for 2 months to perform a modified delayed matching-to-sample task; the sample and match stimuli were presented successively on a video monitor, each for 0.2s at a 16s delay interval. A set of 100 computer-generated colored fractal patterns was used for training each monkey (learnt stimuli). When extracellular discharge of a neuron was recorded in the anterior ventral temporal cortex of these monkeys, not only the 100 learnt patterns but also another set of 100 patterns, newly generated for each neuron (new stimuli), were presented. Eighteen neurons with shape-selective sustained delay discharge were thus tested. In all of them, the maximum delay discharge among those induced by the 100 learnt stimuli was stronger than that induced by the 100 new stimuli. The stimulus-selectivity was also higher in the learnt stimuli than in the new stimuli in 17 of the 18 cells. The observations suggest that the neurons are involved in a long-term pictorial memory process.

EFFECTS OF GLUCOSE ON HUMAN MEMORY. N. P. Azari* (Spon: J. F. Masken). Psychology Dept., Colorado State University, Ft. Collins, Colorado 80523.

Animal studies have shown memory enhancement following post-trial administration of intermediate doses of glucose as well as amnesic effects resulting from glucose doses less than or greater than the optimal dose. One study has investigated memory improvement effects of glucose in elderly humans (Gonder-Fredrick, L., Hall, J. L., Vogt, J., Cox, D. J., Green, J., & Gold, P. E., Physiol. & Beh., 41, 1987). This experiment tested the hypothesis that moderate doses of glucose may improve memory in healthy humans. 18 males (18-25 yrs.) received 3 doses (0, 30, 100 g) of glucose orally (300 ml beverage) in a random, double-blind, aspartame-controlled, triple crossover design. 30 min. post-beverage subjects saw 40 nouns on a computer and took a recall and recognition test. Blood samples were drawn every 15 min. over the hour for blood glucose (BG) analysis. Data were divided according to time of peak BG change (BGC). Subjects given 30 g glucose with peak BGC at test time showed recognition memory improvement from the 0 g to 100 g treatment ($p \leq 0.05$); subjects without peak BGC at test time showed no differences. Subjects with peak BGC after test time given 30 or 100 g glucose showed negative correlations between BGC and recognition scores (r's ≥ 0.6, p's ≤ 0.05). These results confirm the importance of glucose in memory modulation.

MEMORY-SPECIFIC CHANGES IN INTERSPIKE INTERVALS IN DOMINANT HUMAN TEMPORAL LOBE. D. F. Cawthon,* E. Lettich,* O. D. Creutzfeldt,* G. A. Ojemann. Dept. Neurosurgery, Univ. of Washington, Seattle, WA 98195; Dept. Neurobiol., Max Planck Inst. of Biophys. Chem., Göttingen, F.R.G.

During epilepsy surgery, patients undergoing microelectrode extracellular recordings from dominant temporal lobe, under institutional rules for human subjects, have engaged in simple naming, reading and spatial matching tasks and a post-distractional short-term memory task. The most common neuronal firing pattern during the memory task was an increase in frequency during both silent input and overt retrieval phases (Ojemann et al. Brain, 1988, in press; Cawthon et al., in preparation), outlasting overt and presumably silent speech by several seconds. We have now examined changes in interspike intervals (ISIs) during the memory task in patients with well-isolated single cell records. In two patients, increases in the shortest band of ISIs present (5-30 msec in one, 40-120 msec in another) accompanied the increased frequency but also showed some dissociation from frequency and greater specificity to the memory task. Short ISIs increased discretely during some subdivisions of memory phases when frequency remained tonically elevated but unchanging, or when frequency actually dropped. These changes specific to short ISIs may be the mechanism for informational coding of linguistic and memory features within a task. (Supported by NIH Grants NS21724, NS20482, NS17111 and NS07289).

MODULATION OF HUMAN EVENT-RELATED POTENTIALS BY WORD REPETITION - EFFECTS OF TEMPORAL LOBE PATHOLOGY. M.D. Rugg*, M.E. Nagy*, and R.C. Roberts* (SPON: European Brain and Behaviour Society) Dept. of Psychology, University of St Andrews, U.K. and Dept. of Medicine, University of Dundee, U.K.

It has been reported that the modulation of event-related potentials (ERPs) by word repetition is attenuated after left temporal lobectomy (Halgren and Smith, Hum. Neurobiol., 6: 129-139). We provide further data concerning the relation between temporal lobe pathology and the 'ERP repetition effect'. ERPs were recorded from multiple scalp electrodes while subjects monitored a series of visually presented words for the occasional occurence of non-words. In patients with primary generalised or right-sided temporal lobe epilepsy, repeated words evoked ERPs which were typically some 5 μV more positive-going 300-600 msec post-stimulus than ERPs to non-repetitions. While some patients with left-sided temporal lobe epilepsy showed an abnormally small repetition effect, in the majority it was normal. Patients with left temporal lobectomies showed a variable pattern, ranging from abnormally small effects at all scalp sites to effects of the same size and scalp distribution as in controls. These data indicate that although abnormalities in the 'ERP word repetition effect' are associated with damage to the left temporal lobe, they are not a necessary consequence of such damage.

PREFRONTAL UNIT ACTIVITY DURING THE ASSOCIATIVE LEARNING. M. Watanabe. Dept. of Liberal Arts, Tokyo Engineering Univ. Katakura-cho, 1404 Hachioji, Tokyo, 192 JAPAN

Two monkeys were trained on a reaction time task overlapped with a classical conditioning paradigm. Sequential events of the task were as follows; (1)animal's pressing response of the lever; (2)presentation of a visual or auditory cue; (3)delay period of 1 sec.; (4)imperative stimulus presentation; (5)release of the lever by the animal. The visual or auditory cue signaled whether or not a drop of fruit juice would be given for the animal's releasing response. In this task, the animal had to release the lever even on the trial where no juice was given, to advance to the next trial.

Single unit activity was recorded from the prefrontal cortex while the animal was performing the task, in order to clarify whether prefrontal units are involved in coding the meaning or associative significance of the stimulus in relation to whether a certain cue is associated with the juice reward. Of 436 task-related units obtained, 68 units showed differential activity in relation to the associative significance of the visual or auditory cue, and 50 units showed such differential activity for both modalities of cues. The results indicate that prefrontal units are involved in coding the associative significance of the stimulus, and that in the majority of these units such coding is done in modality specific and in some units across modalities.

SHORT AND LONG LATENCY BLINK CRs ARE SUPPORTED BY ACTIVITY OF UNITS IN THE MOTOR CORTEX AND THALAMUS OF CATS. C.D. Woody, S. Aou, E. Gruen*, D. Birt, O. Melamed*, and J. Wangwongvivat*, UCLA Med. Ctr., Los Angeles, CA 90024.

Recent ablation studies suggest that long latency eyeblink conditioning depends on cerebellum and subcerebellar nuclei for its development. We examined the hypothesis that higher brain structures might support such conditioning in normal, intact animals. Recordings from the motor cortex of awake cats disclosed patterns of unit activity that increased to support performance of Pavlovian blink conditioning with four separable latency components of 8 - >112 ms onset following delivery of click CS. The components developed pari passu with those of the conditioned response, the latter measured electromyographically, and were associated with increases in unit excitability to intracellularly injected depolarizing current. Recordings from intralaminar and lateralis dorsalis thalamic nuclei also found increases in activity of short and long latency correlated with development of conditioning. Further studies demonstrated conditioning of short and long latency activation of single units of the motor cortex after pairing click CS with tap US and local iontophoretic application of glutamate. Associated with development of unit CRs were increases in neuronal excitability and input resistance and a decrease in a current resembling K_A measured by single electrode voltage clamp techniques. Ablation of the motor cortex of cats prevents short but not long latency blink conditioning. (Supported by NS25510/HD05958.)

LEARNING-RELATED CHANGES IN SINGLE-UNIT ACTIVITY IN THE MEDIAL PREFRONTAL CORTEX (PFCm) OF RABBITS. C. M. Gibbs. Neuroscience Lab., WJB Dorn Veterans' Hosp., & Dept. of Psychology, Univ. of South Carolina, Columbia, SC 29201.

Bilateral lesions of the PFCm severly disrupt the development of discriminative bradycardiac CRs in rabbits (Buchanan SL and DA Powell: JCPP 96:755), and tone (CS)-evoked multiple-unit activity in the PFCm undergoes training-induced changes that are reliably correlated with aversively conditioned changes in heart rate (Gibbs CM and DA Powell: Brain Res 442:86). Accordingly, we have begun evaluating single-unit activity in the PFCm during or following either simple Pavlovian conditioning (tone CS paired with eyeshock US), differential conditioning (one of two tones paired with eyeshock) or nonassociative training (e.g. unpaired stimuli).

Our results to date have indicated the PFCm consists of numerous, widely interspersed cell populations differing from one another with respect to the patterns of their maintained, CS- and US-evoked activity. Our data have also suggested that at least three of these functional populations show associative training-induced changes in their CS-evoked discharge that are consistent with the concomitant development/expression of bradycardiac CRs. These data thus provide further support for the suggestion that the PFCm participates in learned cardiovascular adjustments in rabbits. (Supported by VA Institutional Research funds)

INFLUENCE OF MICROIONTOPHORETIC CHOLINERGIC DRUGS ON CONDITIONED CORTICAL UNITS. K. Turco*, D. Yadon* and J. Pirch. Dept. of Pharmacology, Kirksville Coll. Osteo. Med., Kirksville, MO 63501

Microiontophoretic techniques were used to study the effects of cholinergic agents on rat frontal cortex neurons which demonstrated a differential response to reinforced (CS+) and non-reinforced (CS-) tone stimuli. Medial forebrain bundle (MFB) stimulation served as reinforcement. Cortical slow potentials were used to monitor conditioning. A current range was determined from self-stimulation testing for use in tone discrimination training. Tone duration was 2 sec, and MFB stimulation was applied at the termination of CS+. Trained animals were anesthetized with urethane, and units with a differential response to CS+ were characterized in detail. Of the 34 units in this study, 23 exhibited an excitatory response to CS+; 21 of these were excited by ACh. Atropine or tropicamide antagonized both the CS+ and ACh excitatory responses in 15 of these units, whereas in 6 units only the ACh response was antagonized. Two units that showed an excitatory response to CS+ demonstrated no response to ACh, but the CS+ was antagonized by atropine. CS+ inhibited 11 units; 10 of these were excited by ACh. Atropine or tropicamide antagonized both the CS+ and ACh responses in 6 of these units, in 3 units only the ACh response was antagonized, while in 1 unit there was no antagonism of either the ACh or CS+ response. One unit inhibited by CS+ was also inhibited by ACh; no antagonism of the CS+ was found in this unit, and antagonism of ACh was equivocal. ACh may be involved in the conditioning-related neural responses of a significant population of cortical units. Other neurotransmitters, however, may be necessary to explain the responses of units described here that demonstrate inhibitory responses and/or resistance to the effects of the cholinergic antagonists. Supported by NIH grant NS22408.

LEARNING SPECIFICALLY ALTERS FREQUENCY RECEPTIVE FIELDS IN AUDITORY CORTEX OF GUINEA PIG. J. Bakin,* C.D. Condon* and N.M. Weinberger. Cntr. Neurobio. Learning & Memory and Dept. Psychobiology, Univ. California, Irvine CA 92717.

Acquisition of the classically-conditioned pupillary dilation response in muscle-blocked cat is accompanied by specific changes in the frequency receptive fields (FRF) of single neurons in auditory cortex at the frequency of the conditioned stimulus (Diamond & Weinberger, Brain Res., 1986, 372, 356-60). The present study investigated the effects of both classical and instrumental avoidance conditioning on the FRF of clusters and single neurons in the auditory cortex of undrugged guinea pig.

FRF were determined before and following classical (body movement) or avoidance conditioning (wheel running) of male adult guinea pigs bearing chronically implanted microwires in auditory cortex. Conditioned stimuli were single tones at non-best frequency. FRF were determined in a chamber separate from the training environment. Both classical and instrumental procedures resulted in alterations of FRF for both clusters and single neurons; in most cases, changes were maximal at or immediately adjacent to the CS frequency. The findings indicate that learning-induced frequency-specific changes in tuning extend to various orders of animals, preparations and training.

THALAMOCORTICAL, HIPPOCAMPAL AND AUDITORY NEURONAL ACTIVITIES RELATED TO AUDITORY WORKING MEMORY PROCESS IN THE RAT. Y. Sakurai. Dept. of Psychology, Toyama Med. & Pharmaceu. University, Sugitani, Toyama 930-01, JAPAN.

The present study was concerned with thalamocortical, hippocampal and auditory neuronal systems underlying auditory working memory in the rat. The task was an auditory continuous nonmatching-to-sample (Sakurai, Psychobiol., 15:277, 1987). Pressing a panel (Go) was rewarded if the tone for the current trial was different than the tone for the preceding trial. A 3s of delay period was imposed between trials. In the tone-presentation period on preceding trials, the entorhinal cortical (EC) and the dorsomedial thalamic (DMT) units showed differential activation regarding type of the tone (high or low) and outcome of the next response (correct or error) respectively. In the delay period, the DMT units showed differential activity related to outcome of the next response. In the tone-presentation periods immediately prior to response, the medial geniculate body (MGB) units showed tone-differentiated activity. The MGB, CA1, CA3, EC, dentate gyrus and motor cortex had more units showing differential activation related to type of the next response (Go or No-Go). A macro neuronal model underlying the auditory working memory will be discussed. (Supported by Grant-in-Aid for Scientific Research 62710039 from the Japanese Ministry).

SHORT TERM MEMORY PROCESS IN THE PARIETAL EYE. D.J. Eder and R. K. Rader. Biological Sciences, Southern Illinois University, Edwardsville, IL 62025 and Searle Pharmaceutical, Chesterfield, MO 63198.

The lizard parietal (pineal) eye contains conelike photoreceptors that synapse directly onto ganglion cells. We have recorded characteristic electroretinographic waveforms evoked by long- and short-wavelength light stimuli in anesthetized lizards, Anolis carolinensis. Response amplitudes and waveforms evoked by identical 2-sec. blue test flashes varied depending on whether they followed either a red (589nm) or blue (460nm) 5-sec. conditioning stimulus. The conditioning effect persisted for more than 20 min. and was elicited by conditioning intensities too low to bleach quantities of photopigment sufficient to reduce quantum catch. After a red conditioning stimulus, dark recovery of the blue system progressed with a time constant of 8 min. at 24° C. The blue test stimulus itself immediately completed the recovery process by restoring full sensitivity to subsequent blue flashes. Subsequent and test flashes suppressed blue responses and "reset" the system. This eye thus seems to "remember" the wavelength of the last flash presented to it. The memory process depends on a photic "switch" and follows a time course resembling that of short term memory. We interpret the results by postulating synaptic interaction of at least two neurotransmitter systems at the ganglion cell level.

LEARNING MECHANISM FOR IDENTIFICATION OF ACOUSTIC FEATURES. B.S. Seebach* and N. Intrator*. (SPON: L. N Cooper) Center for Neural Science and Division of Applied Mathematics, Brown University, Providence, RI 02912.

A biologically-plausible neural network model is proposed which learns to identify acoustical signals by recognizing the presence or absence of various signal components, rather than by recognizing the signals as whole units. The presence of rich component structures in naturally-occurring signal sets suggests that this type of learning is common for perceptual systems.

Acoustical inputs to the network undergo pre-processing designed to mimic cochlear processing to a first approximation, using bandpass filters and zero-crossing analyzers to produce an energy vs. frequency representation of the signal for each time period. These representations are combined with the analog waveform, then input to first order neurons through a series of delay mechanisms, in a manner similar to Licklider (1951), producing a graded tonotemporal mapping of acoustical events in these neurons.

The neural network is built of Hebbian-type neurons with the modification introduced by Bienenstock, Cooper, and Munro (1982), which causes each neuron to become selective for one type of input pattern. These neurons are arranged into groups. Competition is induced by a form of global inhibition.

When the number of signals input to the system exceeds the dimensionality of the network, inter-group competition in the network causes groups to begin responding to components (or features) of the inputs in the signal set, rather than to inputs as whole units. Resulting is a demonstration of a biologically-plausible theory of learning and memory giving rise to a psychologically real phenomenon of signal component detection.

COMPUTER SIMULATIONS IN NEUROSCIENCE: PSEUDO PSEUDO-RANDOM NUMBERS. C.F. Mactutus and R.M. Booze, Dept. Physiol. Pharmacol., Bowman Gray School of Medicine, Winston-Salem, NC 27103

A reliable source of uniform random numbers is an essential building block for any computer simulation program involving a stochastic process. Many system supplied pseudo-random number generators are *linear* (or mixed) *congruential generators* (*LCG*), which generate a sequence of integers via the relation $I_{n+1} = A * I_n + C$ mod M where M is called the modulus and A and C are positive integers called the multiplier and increments, respectively. A *multiplicative congruential generator* (*MCG*) refers to the same equation, but with $C = 0$. We evaluated a *LCG* found on many personal computers running BASIC, and a *MCG*, recoded in BASIC, but more commonly found on mainframe computers. The present observations summarize three aspects of these generators on an 8 MHz computer: speed, period, and uniformity. Speed of the *LCG* was faster (0.9 msec/sample) than that of the *MCG* (1.06 msec/sample). The period of the *LCG* was 2^{24} (16,777,216 samples; 4.2 hr) relative to $2^{31} - 2$ (theoretically 2,147,483,646 samples; > 26 days) for the *MCG*. Uniformity was assessed by calculating 1000 $X^2_{(99)}$ values, each based on a 1000 number sequence generated from a different seed. A $X^2_{(99)}$ test, performed on these 1000 X^2 values indicated that reasonable proportions of large and small X^2 values were noted, as expected under "true randomness", for the *MCG* ($p < .50$), but not for the *LCG* ($p < .01$). These data 1) suggest that improvements in pseudo-random number generation quality may be obtained with modest decrements in speed, and 2) urge caution in the use of any pseudo-random number generator simply because it is readily available.

344.18

DEVELOPMENT AND CALIBRATION OF A CRYOPROBE FOR USE IN FREELY BEHAVING RATS. S. Campeau* and M. Davis. Dept. of Psychiatry, Yale University, School of Medicine, 34 Park St., New Haven, Ct 06508.

The ability to produce reversible inactivation of localized brain regions would provide an important tool for analyzing neurobehavioral function. Capitalizing on the advantages of cryogenic neural inactivation (Brooks, Rev. Physiol. Biochem. Pharmacol., 95:1-109, 1983), a cryoprobe was developed and calibrated for chronic implantation in freely behaving rats. The probe is made of 24 g stainless steel tubing enclosed within 19 g tubing. A 37 g insulated wire serves as a heating coil and is wrapped around the outer tubing except for its tip. Temperature at the tip of the probe is monitored by an internal thermocouple and controlled by circulating cold methanol at various flow rates. Initially, tissue heat loss was evaluated by acutely implanting the probe in the cerebellum of anesthetized rats. Tissue temperature, measured at various distances around the probe, was found to rise exponentially with distance. To test the effectiveness of the probe physiologically, hindlimb flexion produced by electrical stimulation of the motor cortex was examined in ketamine anesthetized rats. Reversible blockade (tested for up to 30 min and occuring within 30 sec) was observed at tissue temperatures of 5 to10 C when the probe was situated less than 0.7 mm from the pyramidal tract. Moderate hindlimb flexion disruption was obtained when the probe was further away from the pyramidal tract or with milder temperatures. To study blockade of synaptic transmission, rats were chronically implanted with the probe aimed at the ventral nucleus of the lateral lemniscus (VLL), part of the primary acoustic startle circuit. Cooling the VLL reversibly blocked the startle reflex without disrupting ongoing behavior. Startle recovered within 30 sec when cooling was turned off. These results demonstrate the specificity, reversibility, and rapidity of neural inactivation produced by a cryoprobe that can be implanted in freely behaving rats.

344.19

DISCRIMINATIVE CONDITIONING OF AUTONOMIC AND SKELETAL RESPONSES UNDER CONTINUOUS (30-90 DAY) NEUROMUSCULAR BLOCK. B.R. Dworkin and S. Dworkin*. Dept. Behavioral Science. Penn State University College of Medicine. Hershey, PA 17033.

Rats with bilateral silastic tibial n.electrode cuffs are chronically paralyzed and ventilated using a continuous infusion of alpha-bungarotoxin. They have normal blood gases, pH, Na, K, serum protein, hematocrit, blood pressure, heart rate, vasomotor tone and tibial n. activity. The physiological variables, EEG spectra and cortical EP's reflect regular sleep wakefulness cycles and responsiveness to mild stimuli. Following stabilization (3-5 days), equal-intensity auditory stimuli (2kHz; 4 kHz tones) are presented. Habituation is demonstrated within 24 hours and then one tone becomes the CS- and the other a CS+, which terminates in a brief tail shock. All rats showed differential responses of the tibial nerves, and vasoconstriction, blood pressure elevation, bradycardia and EEG desynchronization. The CS+/CS- difference was large and highly reliable ($p<.001$) for all measures. The pattern of responses to the the CS+ are similar to the responses to an aversive stimulus in a non-paralyzed animal. The preparation provides an unusual opportunity to study the physiology of conditioning in several different response systems in a stable chronic preparation.

344.20

RETENTION OF A BACKWARD CLASSICALLY CONDITIONED REFLEX RESPONSE IN SPINAL CAT. J. E. Hoover* and R. G. Durkovic (SPON: F. T. Llados). Dept. of Physiol., SUNY Health Sci. Ctr., Syracuse, NY 13210.

The purpose of this study was to conduct a specific test for retention of a backward conditioning (BC) response in the ischemically decapitate spinal cat preparation. Isometric muscle tension recordings (tibialis anticus) were used to quantify alterations in the magnitude of the flexion reflex during and after backward pairing of superficial peroneal n. stimulation (30 Hz, 0.5 sec), the US, with saphenous n. stimulation (10 Hz, 1.5 sec), the CS. Both US and CS were supramaximal for activation of A-delta fibers. Experimental animals received 30 paired trials (US preceeded CS by 0.25 sec) with an ITI of 3 min. Control animals received the same stimuli but in an explicitly unpaired manner. Following acquisition, all animals received 30 additional CS-alone trials at 5 min. intervals. Conditioned responding was monitored throughout acquisition with CS-alone "probe" trials which tested the excitability of spinal reflex circuits activated by A-alpha or A-alpha plus A-delta fibers.

In confirmation of previous results [J. Neurosci. 6: 2921], BC treatment in this preparation resulted in flexion reflex facilitation. Independent t-tests indicated that significant differences existed between the overall acquisition means of paired and unpaired groups [$t(12) = 3.337$; $p < 0.005$]. Analysis of the A-alpha CS probes yielded similar results. At intensities supramaximal for A-delta fibers, CS-alone trials, following acquisition, resulted in rapid CR decrement toward control group levels. In contrast, analysis of the overall extinction means obtained with A-alpha CS-alone probes indicated evidence of retention of the CR [$t(12) = 2.800$; $p < 0.01$]. These latter findings represent the first demonstration of retention of BC effects in this preparation. Thus, in the spinal cat, both forward conditioning (FC) [Behav. & Neural Bio. 43:12] and BC procedures result in long-term reflex potentiation. *However, unlike FC, which requires activation of A-delta pathways for retention of the CR, this study demonstrates that BC reflex alterations are limited to the spinal circuitry activated by A-alpha fibers.* These and other recent findings [J. Neurosci. 8:502] support the hypothesis that FC and BC are unique phenomena under the control of different neural processes. Supported by NSF grants BNS 8415917 and BNS 8808495.

MK-801 PREVENTS SEIZURE RELATED BRAIN DAMAGE FROM PILOCARPINE AND LITHIUM-PILOCARPINE EPIDURAL WELL INDUCED SEIZURES. D.B.Clifford, A.Benz*, J.W.Olney, C.F.Zorumski. Depts.of Neurology and Psychiatry, Washington Univ. Sch. of Med., St. Louis, MO 63110. (SPON:R.Sundermann)

Cholinergic seizures induced by systemic pilocarpine(PILO) have been used as a model of limbic seizures. They are augmented by lithium(LI) pretreatment. We have demonstrated that PILO in high doses will cause seizures and brain damage in an epidural well model. We here studied the modification of focal seizures by LI pretreatment, and the ability of the atropine or MK-801 to protect the animals from seizures or brain damage.

EEG and behavioral observations were made on rats while PILO was instilled in epidural wells. Without pretreatment (N=8) or with LI 3 mEq/kg pretreatment (N=12), the mean EEG seizure threshold dose was 47.5 or 43.4 mM PILO respectively, while the behavioral seizure threshold dose was 101.25 mM or 50 mM PILO.

MK-801, a non-competitive N-methyl-D-Aspartate antagonist was administered sc(N=7, 1mg/kg sc) one hour prior to PILO 200 mM (N=8), or LI/PILO (N=7)in a dose sufficient to cause behavioral seizures. MK-801 protected the brains from the seizure induced brain damage syndrome seen in control rats, but not electrical or behavioral seizures. Atropine 10 mM in the well or 50 mg/kg sc similarly protected the animals. We conclude that LI augments PILO action in the focal epidural well model. Atropine or MK-801 block seizure related brain damage without necessarily blocking electrical seizures. *Supported by DAMD 17-86-C-6010 (JWO). MK-801 generously supplied by Merck Sharp and Dohme.*

NMDA ANTAGONISTS AND EPILEPTIFORM BURSTS EVOKED BY BICUCULLINE METHIODIDE (BMI) IN RAT NEOCORTICAL NEURONS MAINTAINED "IN VITRO". G.G.C.Hwa* & M.Avoli (SPON: D.Baxter). MNI, McGill Univ., Montréal, Qué., Canada.

The role played by NMDA receptors in experimental epilepsy has been well documented. Here, we used intracellular recordings to study the effects of NMDA receptor antagonists on BMI (50μM)-induced bursts generated by rat neocortical neurons. The latency of the burst was inversely related to the stimulus strength and the burst duration decreased upon membrane hyperpolarization. Bath application of competitive (CPP) and non-competitive (MK-801) NMDA antagonists increased the burst latency while changing the burst induced by stimuli at threshold into a biphasic EPSP. In addition both NMDA antagonists reduced the late phase of the burst evoked by higher strength stimuli. The increase in burst latency and complete blockade at threshold intensity may reflect an action exerted by NMDA antagonists upon recurrent excitatory mechanisms. Furthermore, since the BMI bursts evoked by suprathreshold stimuli were only reduced, our data indicate that non-NMDA receptors might contribute to this type of experimental epileptiform activity.

345.3

CGP 37849 / CGP 39551: COMPETITIVE NMDA RECEPTOR ANTAGONISTS WITH POTENT ORAL ANTICONVULSANT ACTIVITY. M. Schmutz*, K. Klebs*, H.-R. Olpe*, G.E. Fagg, H. Allgeier*, R. Heckendorn*, C. Angst*, D. Brundish* and J.G. Dingwall* (Spon.: W.B. Adams), Research & Development Dept., Pharmaceuticals Division, and Central Research Labs., CIBA-GEIGY Ltd., CH-4002 Basel, Switzerland.

Evidence has accumulated that antagonists at the N-methyl-D-aspartate (NMDA) sub-type of excitatory amino acid receptor may find value for the treatment of epilepsy and ischaemic neurodegeneration. However, no competitive NMDA receptor antagonists with oral anticonvulsant properties have yet been reported.

CGP 37849 (D,L-(E)-2-amino-4-methyl-5-phosphono-3-pentenoic acid) and its ethyl ester CGP 39551 selectively inhibited ^{3}H-CPP binding with Ki values of 35 and 310 nM, respectively (for details see G.E. Fagg et al., this meeting), and exhibited potent oral anticonvulsant activity. They blocked electroshock-induced seizures in rodents with ED_{50}'s of 4-21 mg/kg po and 0.4-6 mg/kg ip and iv. The duration of action (plateau effect) exceeded 8 hr in the case of CGP 37849 and 24 hr for CGP 39551. CGP 39551 also delayed the development of overt motor seizures in rat kindling studies at 10 mg/kg po and above, whereas CGP 37849 was not effective under these conditions. The anticonvulsant activity of both compounds is likely to be mediated via blockade of NMDA receptors since orally-effective doses selectively suppressed NMDA-evoked neuronal firing in the rat hippocampus *in vivo*, but had no effect on quisqualate- or kainate-evoked responses.

CGP 37849 and CGP 39551 are the first competitive NMDA receptor antagonists with significant oral activity and, as such, are potential candidates for novel antiepileptic therapy in man.

345.4

INTERACTION BETWEEN N-METHYL-D-ASPARTATE (NMDA) AND BICUCULLINE METHIODIDE (BIC) IN VIVO IN MICE. I.M. Kapetanovic, C. Gennings*, C.D. Torchin* and H.J. Kupferberg*. Epilepsy Branch, NINCDS, NIH, Bethesda, MD 20892 and Dept. of Biostatistics, MCV, Virginia Commonwealth Univ., Richmond, VA 23298.

The balance between inhibitory and excitatory neurotransmission may be important in the pathogenesis and potential treatment of epilepsy. NMDA, agonist of excitatory glutamate receptors and BIC, antagonist of inhibitory GABA-A receptors are commonly used convulsants in experimental animal models of epilepsy. This study examined if the effects of convulsant agents which act by different mechanisms are additive, synergistic or antagonistic. NMDA and BIC were administered i.c.v., individually or as a combination, in saline to male CR:NGP(S) mice. The measured response was at least 5 sec of clonic activity during the 30 min observation period after the administration of NMDA and/or BIC. CD50 values (and 95% confidence intervals) for NMDA and BIC were estimated as 0.405 (0.386,0.425) and 0.194 (0.185,0.203) nmol, respectively. The slopes of dose response curves for NMDA and BIC alone were not parallel. The probability of clonic convulsion was modeled as a function of NMDA and BIC using the logistic regression. Results showed that the logistic model described satisfactorily the experimental data and a significant antagonistic interaction between NMDA and BIC was evident.

345.5

CONVULSANT ACTIONS OF PUTATIVE ENDOGENOUS LIGANDS FOR EXCITATORY AMINO ACID RECEPTORS UPON FOCAL INJECTION IN AREA TEMPESTAS. H. Zrebeet* and K. Gale (SPON: D. Stoff). Department of Pharmacology, Georgetown University Medical Center, Washington, DC 20007.

Quinolinic acid (QUIN), N-acetyl-aspartylglutamate (NAAG), and l-homocysteic acid (HCA) have been proposed as endogenous ligands for NMDA-preferring receptors. Since activation of NMDA receptors is critical for evoking seizures from area tempestas (AT), an epileptogenic site in the deep prepiriform cortex, we examined the effect of these three agents upon unilateral microinjection into AT in awake, freely moving rats.

QUIN (50 nmol) and HCA (160 nmol) consistently evoked bilateral clonic seizures with rearing and often falling (scores 4 or 5). These seizures started within a few minutes following the microinjection and recurred repeatedly over a 45 min period. The convulsive behavior was similar to that observed with intra-AT application of kainic acid (100 pmol), NMDA (10 nmol), aspartate (1.0 umol) and glutamate (1.0 umol). In contrast, NAAG did not evoke convulsive behavior when applied to AT in amounts up to 164 nmol; nor did this dose of NAAG modify the convulsant action of bicuculline (50 pmol) applied to AT 5 min later.

Our data indicate that QUIN and HCA, but not NAAG, produce a functional effect in AT comparable to that produced by aspartate and glutamate, but with a greater potency. As has been shown for aspartate and glutamate in AT, we expect the convulsant effects of QUIN and HCA in AT to be susceptible to blockade by focally applied NMDA receptor antagonists.

ANTICONVULSANT ACTION OF A NONCOMPETITIVE ANTAGONIST OF NMDA RECEPTORS (MK-801) IN THE KINDLING MODEL OF EPILEPSY. K.Morimoto*, K.Sato*, M.Okamoto and S.Otsuki*. Dep. of Neuropsychiatry, Okayama Univ.Med.School, Okayama, Japan.

To investigate the role of NMDA systems in kindling, the effects of systemic injection of MK-801, a novel non-competitive antagonist of NMDA receptors, were examined in kindled rats. The results were; (i) Both the seizure stage and afterdischarge (AD) duration of previously kindled seizures from the amygdala (AM) were potently suppressed following MK-801 injection (1-4 mg/kg) in a dose-dependent manner. The maximum effects were found between 2 and 4 hours after the injection. (ii) The MK-801 also showed significant anticonvulsant actions on kindled seizures from the frontal cortex and the dorsal and ventral hippocampus, while the efficacy differed between these kindled sites. (iii) Daily treatment of MK-801 (0.25 and 1 mg/kg) prior to each electrical stimulation of the AM significantly retarded kindling development. During drug sessions of the 1 mg/kg MK-801 for 19 days, all rats showed only partial seizures and the growth of ADs was strongly prevented. (iv) Pretreatment with reserpine did not antagonize the effects of MK-801 on AM kindled seizures. These results indicate that MK-801 has potent anticonvulsant actions on kindled seizures from both limbic and cortical foci, and that NMDA systems may play a critical role in the seizure-triggering mechanism of kindling.

NMDA RECEPTOR ANTAGONISTS HAVE ANTIEPILEPTOGENIC, BUT NOT ANTICONVULSANT, ACTION AGAINST IN VITRO "KINDLED" ELECTROGRAPHIC SEIZURES S. Stasheff, W.A. Wilson, S. Swartzwelder, S. Clark, and W. Anderson; Departments of Pharmacology, Medicine, and Psychology, Duke University Medical Center and the Veterans Administration Medical Center, Durham, NC

We have developed an in vitro model of epileptogenesis in the rat hippocampal slice which produces seizure-like electrographic discharges in response to kindling-like stimulations. In slices from 24-31 day-old rats, stimulus trains (60 Hz, 2 sec, twice the intensity that evokes the maximum orthodromic population spike) were delivered every ten minutes to s. radiatum of CA3. With repeated stimulations, the severity of afterdischarges (AD) recorded in s. pyramidale of CA1 and CA3 increased, until they stabilized as electrographic seizures (EGSs) with tonic and clonic components and constant durations.

The competitive NMDA receptor antagonist APV and the noncompetitive channel blocker MK801 prevented the genesis of this epileptiform activity. Slices were bathed in 20-100 uM D-APV or 10 uM MK801 prior to and during the presentation of ten stimulus trains. During this period there was no progression of AD toward characteristic EGS activity. Stimulations were then continued in artificial CSF without APV or MK801. Under these conditions, the AD progressed to yield EGSs. Finally, the antagonist was reapplied once the EGSs were established and stable. Neither APV nor MK801 had a significant suppressive effect on these established seizures.

We conclude that, in this model, the suppression of NMDA receptor activity or the opening of the associated channels is profoundly antiepileptogenic. However, once the epileptiform activity is established, NMDA antagonists have little suppressive effect. These results stand in contrast to the effects of NMDA antagonists in suppressing seizure-like activity in several other in vitro models (high K+, low Mg+), but are consistent with their effects on kindling in vivo.

345.8

SYNERGISTIC ANTICONVULSANT ACTION OF NIMODIPINE AND MK-801 IN MICE ADMINISTERED PENTYLENETETRAZOL. G.T. Bolger and S.K. O'Neill*. Division of Basic Medical Sciences, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland A1B 2V6

Both NMDA-receptor antagonists and nimodipine have been shown to possess anticonvulsant activity in mice administered the cortical convulsant pentylenetetrazol (PTZ). We have investigated the effects of i.p. administered nimodipine and the potent NMDA antagonist MK-801, either alone or in combination, on PTZ (85 mg/kg i.p.) convulsions in male CD-1 mice. PTZ produced severe clonic convulsions and posture loss in 85% of the mice (mean onset 71 $\pm$ 3 sec; mortality 23% following full tonic-clonic seizures). Nimodipine (20 mg/kg) increased the mortality (30%-50%) from PTZ convulsions. In contrast, 10 and 20 mg/kg nimodipine significantly increased (~ two fold) clonic convulsion onset time. MK-801 (0.1 and 0.5 mg/kg) neither altered the onset time nor the number of animals experiencing clonic convulsions, but did prevent death due to PTZ convulsions. Combinations of nimodipine and MK-801 at doses as low as 2 mg/kg and 0.5 mg/kg respectively, resulted in an increased onset (~ three fold) and a reduction (50%) in both the number of animals experiencing clonic PTZ convulsions and the severity of the convulsions. Furthermore, death due to PTZ convulsions was prevented at all dose combinations of nimodipine and MK-801 investigated. These results suggest that the combination of MK-801 and nimodipine may provide a safe and beneficial adjunct therapy for epilepsy.

GLYCINE POTENTIATES PHENOBARBITAL, CARBAMAZEPINE AND MK-801 IN MAXIMAL ELECTROSHOCK SEIZURES. S.L. Peterson, J.T. Trzeciakowski*, L.E. Boehnke*, and R.N. Riegel*. Dept. of Medical Pharmacology and Toxicology, Texas A & M University, College Station, Texas 77843.

The purpose of this study was to evaluate the ability of glycine to enhance the effects of clinically effective anticonvulsants in a standardized model of experimental epilepsy in rats.

Maximal electroshock seizures were induced by passing a 60 Hz, 150 mA and 0.2 sec duration current through saline soaked corneal electrodes. Seizure severity was quanitified by extension/flexion ratios. Statistical significance between anticonvulsant dose-response curves with and without glycine were determined by nonlinear regression analysis.

Glycine (30 or 40 mmol/kg, p.o.) administered 1, 2, 4 or 8 hours before the seizure test had no significant effect on seizure response. However, 40 mmol/kg glycine (p.o., 4 hours before seizure test) significantly reduced the ED50 of phenobarbital (13.2 to 10.7 mg/kg, i.p.), carbamazepine (10.1 to 6.8 mg/kg, i.p.) and MK-801 (7.0 to 3.7 mg/kg, i.p.). Glycine did not significantly affect the ED50 of divalproate or phenytoin.

Glycine potentiation of MK-801 suggests involvement of excitatory amino acid receptors in the mechanism of action of phenobarbital and carbamazepine in maximal electroshock seizures. (Supported by NIH Grant 24566)

KINDLING DEPRESSES MAGNESIUM REGULATION OF DEPOLARIZING RESPONSES TO AMINO ACID EXCITANTS. D. Martin, M.A. Bowe, J.O. McNamara and J.V. Nadler. Depts. Pharmacology and Medicine (Neurology), Duke Univ. Med. Ctr., Durham, NC 27710.

Previous reports have suggested that enhancement of NMDA receptor function may, at least in part, underlie the kindling phenomenon (Mody, I. and Heinemann, U., Nature, 326, 701 (1987); Morrisett et al., Soc. Neurosci. Abstr., 13, 946 (1987)). This idea was investigated with use of a grease-gap preparation for assaying the depolarizing responses of CA1 hippocampal pyramidal cells to amino acid excitants (Bowe et al., this volume).

Adult male rats were stimulated in the angular bundle until they experienced at least 6 class 4-5 seizures of which the last 3 were consecutive. CA1-subiculum slices were prepared from these animals either 24 h or 30-50 d after the last kindled seizure. A grease barrier was placed at the CA1-subicular border and each hippocampal region was independently superfused. Area CA1 was exposed to 5-6 compartment volumes of each excitant concentration and depolarizing responses of pyramidal cells were recorded relative to their axons in the subiculum.

When tested in the presence of 1 mM Mg^{2+} 30-50 d after the last kindled seizure, CA1 pyramidal cells from kindled rats were more sensitive to NMDA, AMPA and L-glutamate than pyramidal cells from implanted, unstimulated controls. The EC_{50} for NMDA dropped from 18.5 uM to 10.8 uM. When tested in the absence of Mg^{2+}, however, none of the concentration-response curves was affected by kindling. Hence the dose ratio for 1 mM Mg^{2+} against NMDA declined from 3.8 to 2.3. The small depressant effects of Mg^{2+} on responses to AMPA and L-glutamate were absent in slices from kindled rats. None of these changes was detected 24 h after the last kindled seizure.

These findings imply that kindling is associated with a long-lasting reduction in the ability of Mg^{2+} to regulate NMDA and quisqualate receptor function. Such a change could well underlie maintenance of the kindled state. (Supported by NIH grants NS 17771 and NS 16064.)

345.11

REGIONALLY-SPECIFIC REDUCTIONS IN KAINATE AND NMDA RECEPTOR BINDING AFTER ANGULAR BUNDLE KINDLING. M.M. Okazaki, J.O. McNamara and J.V. Nadler. Depts. Pharmacology and Medicine (Neurology), Duke Univ. Med. Ctr., Durham, NC 27710.

Previous studies have suggested that enhancement of excitatory amino acid receptor function plays a role in the kindling phenomenon. We therefore quantitated radioligand binding to kainate and NMDA receptors in brain regions of kindled rats with use of autoradiographic techniques.

Adult male rats were stimulated in the angular bundle until they experienced at least 6 class 4-5 seizures of which the last 3 were consecutive. Control animals were implanted, but not stimulated. Binding experiments were carried out on slide-mounted brain sections prepared either 24 h or 28 d after the last kindled seizure or 24 h after a single evoked afterdischarge. Kainate receptors were labeled with [^{3}H]kainate and NMDA receptors were labeled with L-[^{3}H]glutamate under conditions specific for its binding to this receptor subtype.

Kainate receptor binding had declined by 24-30% in stratum lucidum of hippocampal area CA3 and by 12-16% in the inner third of the dentate molecular layer when tested 24 h after the last kindled seizure. These effects were not detected either 28 d after the last kindled seizure or 24 h after a single evoked afterdischarge. These findings suggest that depression of kainate receptor binding represents one of many transient compensatory responses to repeated seizures and is not associated with maintenance of the kindled state.

NMDA receptor binding had declined by about 10% in stratum radiatum of the rostral hippocampal area CA1, in the rostral part of motor cortex and in layers I-IV of somatosensory cortex when tested 28 d after the last kindled seizure. No significant changes were detected in any other brain region nor in any region examined 24 h after the last kindled seizure. These findings suggest that the enhanced NMDA receptor function in kindled rats cannot be explained by an increased expression of NMDA receptors. Rather, kindling leads to a down regulation of NMDA receptor binding in selected brain regions. (Supported by NIH grants NS 16064 and NS 17771.)

345.12

DEXTROMETHORPHAN (DM) BINDING SITES: SPECIES DIFFERENCES OF ALLOSTERIC MODULATION. M. Klein*, J.J. Paturzo* and J.M. Musacchio. Dept. Pharmacology, New York Univ. Med. Ctr., New York, NY 10016.

Dextromethorphan (DM), a non-narcotic antitussive, binds in the guinea pig and rat CNS to high and low affinity sites. In the mouse, DM binds to a single high-affinity site, but two different sites can be differentiated by competing drugs. Caramiphen (CAR) and carbetapentane (CRB) displace [^{3}H]DM in the low nM range in all three species, and DM, CAR and CRB protect rats and mice against maximal electroshock seizures. Besides, DM and CRB potentiate the effect of phenytoin (PHT) (Tortella and Musacchio, Brain Res., 383:629, 1986). These reports suggested that DM sites are involved in the mediation of the anticonvulsant activity of several drugs. However, there are important species differences: in the guinea pig, 100 µM PHT and 10 µM ropizine (at pH 7.4) increase 4 fold the affinity of DM binding without changing the Bmax. By contrast, the allosteric effects are very small (pH 8.4) or undetectable (pH 7.4) in the mouse and rat brain. These results suggest that DM high affinity binding sites are part of a macromolecular complex which in some species includes allosteric modulator sites. Supported in part by USPHS grants DA-02013, MH-29591, MH-17785 and NS-23926.

DILTIAZEM ENHANCES AND FLUNARIZINE SUPPRESSES NIMODIPINE'S ANTIEPILEPTIC ACTIONS: A REFLECTION OF ALLOSTERIC BINDING INTERACTIONS AT THE DIHYDROPYRIDINE BINDING SITE? M.A. Moron, T.L. Yaksh and C.W. Stevens. Neurosurg. Res. Lab., Mayo Clinic, Rochester, MN 55905.

The dihydropyridine (DHP) calcium channel antagonist (CCA), nimodipine (NM) has antiepileptic and anticonvulsive properties that are thought to be mediated through neuronal calcium channel blockade. The DHP binding site can be positively and negatively allosterically regulated by the benzothiazepines and phenylalkylamines/piperazines, respectively. In this investigation we studied this binding interaction at the physiologic level by examining the effects of diltiazem (DLT, a benzothiazepine) and flunarizine (FLZ, a piperazine) on the antiepileptic activity of NM. Metrazol (MTZ, 30 mg/kg IP) is used to induce seizures in awake rats with chronically implanted EEG electrodes. CCAs are administered intracerebroventricularly 30 min after MTZ at 3 doses (30, 100 and 300 µg) given at 15-min intervals. DLT and FLZ alone lacked antiseizure properties. The calculated ED_{50} values for NM were: NM alone = 135.3 ± 17.2 µg; NM + DIL (100 µg) = 83.8 ± 24.2 µg. NM + FLZ (10 µg) completely suppressed NM's antiepileptic activity. These findings may reflect the interaction observed among these agents at binding sites associated with the calcium channel and supports the idea that the DHPs mediate their antiseizure actions through neuronal calcium channel antagonism. (Supported by grant NS24329.)

345.14

CARBAMAZEPINE SUPPRESSES ZERO-MAGNESIUM SEIZURES IN RAT HIPPOCAMPUS-ENTORHINAL CORTEX BRAIN SLICES. S. Clark, W.A. Wilson and A.C. Bragdon. Depts. of Pharmacology and Medicine (Neurology), Duke University and Veterans Administration Medical Centers, Durham, N.C. 27710.

Seizure activity can be studied in vitro using brain slices containing hippocampus (HC) and entorhinal cortex (EC) bathed in ACSF containing no added Mg^{++} (0 Mg^{++}). Seizures can be studied for long periods if a low concentration (0.5-5 uM) of baclofen is included in the ACSF. We have employed this model to study the actions of anticonvulsant drugs.

Slices were prepared with EC and HC connections left intact. Pairs of stimulating and recording electrodes were positioned to detect seizures in area CA3 of the HC and the ERC. To study seizure suppression, slices were exposed to 0 Mg^{++}/baclofen ASCF until stable seizure activity occurred, and then the carbamazepine was added.

Carbamazepine, at clinically relevant concentrations (2-12 uM) suppressed spontaneous seizures, increased the threshold required to trigger seizures, and shortened the duration of the seizures.

Supported by NIH grant NS 17771 and the Veterans Administration.

EFFECTS INDUCED BY THE ANTIEPILEPTIC DRUG VALPROIC ACID (VPA) UPON LOW Mg EPILEPTIFORM BURSTS. V.Tancredi, A.Siniscalchi* and M. Avoli. Dip.Med.Sper., Univ.di Roma "Tor Vergata", Rome, Italy & MNI, McGill Univ. Montréal, Qué. Canada.

Spontaneous epileptiform bursts were recorded in the CA1 subfield of rat hippocampal slices perfused with Mg-free medium. These epileptiform events occurred regularly at a frequency of 0.5-0.05Hz, each lasting 50-500ms. Addition of 2mM VPA evoked a decrease of the frequency of occurence of the epileptiform bursts and a 100-200% increase in duration of each event. In addition prolonged shifts (duration 8-20s) could appear at this stage. These changes were eventually followed by the complete disappearance of paroxysmal activity. A full recovery of the low Mg bursts was observed following VPA wash. Lower doses of VPA did not affect the occurrence or the shape of the low Mg epileptiform bursts. Furthermore in the presence of bicuculline, VPA (2mM) failed to reproduce the effects described above. These results demonstrate an action of VPA upon the low Mg epileptiform activity although the doses required for blocking these bursts appear larger than those used in other "in vitro" models of epilepsy.

345.16

IN VITRO AND IN VIVO ELECTROPHYSIOLOGICAL EFFECTS OF THE ANTICONVULSANT GABAPENTIN. C.P. Taylor, D.M. Rock, R.J. Weinkauf* and A.H. Ganong. Parke-Davis Pharm. Res., Ann Arbor, MI 48105 and Div. Neurosci., Beckman Inst. City of Hope, Duarte, CA 91010.

Gabapentin (1-(aminomethyl)cyclohexaneacetic acid) is a new anticonvulsant currently in clinical trials. Gabapentin has a novel profile of activity against experimental seizures in animals, so electrophysiological experiments were done to investigate cellular mechanisms.

In intracellular recordings from cultured mouse spinal cord neurons, gabapentin (175 μM) had no effect on sustained repetitive action potentials, spontaneous synaptic activity, or iontophoretic GABA or glutamate responses. In extracellular recordings from hippocampal slices, gabapentin (100 μM) had no effect on induction of long-term potentiation. In extracellular recordings from the hippocampal CA1 area of rats in vivo, gabapentin (≥ 1 mg/kg IP) caused a dose-dependent decrease in inhibition measured by paired-pulse stimulation. The cellular mechanism of gabapentin's action on paired-pulse inhibition is not known.

These results indicate that at relevant concentrations gabapentin does not block sodium-dependent action potentials like phenytoin, carbamazepine, or valproate. Gabapentin does not alter long-term potentiation like antagonists of the NMDA glutamate receptor subtype, but has effects similar to phenytoin on paired-pulse inhibition in vivo.

345.17

LACK OF EFFECT OF ASPARTAME ON KINDLING, ELECTROCONVULSIVE SHOCK (ECS) AND METRAZOL-INDUCED SEIZURES IN RATS. L. Thai*, H.A. Tilson, D. Zhao, T. Sobotka[a], and J.S. Hong. LMIN, NIEHS/NIH, P.O. Box 12233, Research Triangle Park, NC 27709 and [a]FDA/CFSAN, Washington, DC 20204.

Kindling was used as a model to examine the effect of aspartame on the seizure threshold. Male, Fischer rats were implanted unilaterally with bipolar electrodes to the right deep prepyriform cortex and were stimulated until 3 consecutive stage 5 convulsions were reached. If aspartame (1 g/kg, p.o.) was given 2 hrs prior to the first stimulation, which was given hourly, followed by a second dose 6 hrs later, the rate of kindling was not affected. If rats were dosed for 14 days (1 g/kg twice daily) and stimulations given hourly on the next day, aspartame had no effect. Aspartame also had no effect on the rate of kindling if rats were dosed twice daily (1 g/kg) and stimulated 2 hrs after each dose. In addition, pretreatment with aspartame (1 g/kg) 6 hr prior to ECS had no effect on the seizure threshold. Similar pretreatment with aspartame had no effect on either the seizure threshold or seizure duration in metrazol-induced convulsions. In conclusion, aspartame failed to show a proconvulsant effect in these three seizure models.

345.18

PRECLINICAL PROFILE OF ISOMERS OF THE ANTICONVULSANT, PR 934-423. G.E. Garske*, G.C. Palmer, M.L. Stagnitto*, J.J. Napier*, R.J. Gentile* and R.C. Griffith* (SPON: C.N. Latimer). Pennwalt Corporation, Pharmaceutical Division, Rochester, NY 14623.

PR 934-423 [(±)-2-amino-N-(1-methyl-1,2-diphenylethyl) acetamide·HCl] has been shown to protect rodents against maximal electroshock seizures (MES). The favorable oral efficacy/safety ratios and low toxicity led to Phase I of clinical testing. Evaluation of the isomers of PR 934-423 yielded the following results (oral doses in mg/kg)(results with the racemate are presented for comparison): ED50 MES mice, rats: PR1032-644(+) 76,33; PR 1032-646(-) 45, 20; & PR 934-423(±) 52, 19.5. Onset of MES protection at the ED98 was 30 min (all compounds) and the duration was 4 hrs for the isomers and 3 hrs for the racemate in mice while in rats these time courses were 30 min and 8 hrs. Values for neurotoxicity (TD50-inverted screen) and safety (LD50) in mice were: 647 and >1,000 for PR 1032-644(+); 598 and 723 for PR 1032-646(-); and 396 and 877 for PR 934-423(±). The resulting therapeutic indices (TD50/ED50) and safety margins (LD50/ED50) were: 8.5 and >13.2; 13.2 and 16.1; and 7.6 and 16.9 for the (+), (-), and racemate respectively. Subchronic dosing of the ED98 to mice resulted in a twofold increase in the ED50 for protection against MES. The findings indicate that in mice the (-) isomer is more potent, while in both species the (+) isomer is weaker. In addition, tolerance to MES protection occurs in mice with the racemate, as well as with the two isomers.

345.19

PR 1013-708, A POTENT ANTICONVULSANT AGAINST MAXIMAL ELECTROSHOCK SEIZURES (MES) IN RODENTS. M.L. Stagnitto*, G.C. Palmer, G.E. Garske*, J.J. Napier*, S.A. McCreedy*, R. C. Griffith* and J.C. Blosser. Pennwalt Corporation, Pharmaceutical Division, Rochester, NY 14623.

PR 1013-708 [2-amino-N-(1,2-diphenylethyl) acetamide·HCl] possesses a high degree of oral potency for protection of rodents against MES (all doses expressed as mg/kg)(ED50 for mice = 11.7, ED50 for rats = 15.5). The time course for protection reveals a 30 min onset with a duration of action of 4 hrs in mice (at the ED98) and greater than 8 hrs in the rat (at 3 x ED50). The convulsive dose 50 (CD50) is 502 in mice and 316 in rats. The toxic dose 50 (TD50) for mice using the inverted screen test is 236 and the LD50 values are 611 for mice and 421 for rats. Efficacy/safety ratios are calculated as: 1) therapeutic index (TD50/ED50), mice = 20; 2) convulsive index (CD50/ED50), mice = 43, rats = 16.2; and 3) safety margin (LD50/ED50), mice = 52, rats = 27. No tolerance to hexobarbital-induced sleep time or anti-MES actions is observed following subchronic administration of PR 1013-708 to rats or mice, respectively. PR 1013-708 is ineffective against seizures elicited by metrazol, bicuculline, strychnine or picrotoxin. No efficacy for binding of PR 1013-708 to receptors associated with GABAa, glutamate, benzodiazepine, adenosine or acetyl choline (muscarinic) is observed using synaptosomal preparations from rat brain. PR 1013-708 appears to be specific for protection against MES and would be predicted to be useful for generalized tonic/clonic seizures.

346.1

ASTROCYTE SUPPORTED NEURITE OUTGROWTH AND NEURONAL ADHESION IS REDUCED AS THE ASTROCYTE MATURES. G.M. Smith*, J. Rudge*, J. Silver and R.H. Miller* (SPON: Marcus Singer). Neuroscience Center, Case Western Reserve Univ., Sch. of Med., Cleveland, Ohio 44106.

Astrocytes have been proposed to support axon outgrowth both in vivo and in vitro. Transplant experiments indicate that astrocyte maturation either in vivo or in vitro results in a decrease in axonal outgrowth. In this study we have examined neurite outgrowth and neuronal adhesion on immature and mature astrocytes in vitro. Astrocytes were purified from newborn rat forebrains to >95% purity by differential adhesion and allowed to mature in vitro (immature <4days, mature >28days). Immature or mature astrocytes were plated onto poly-l-lysine coated coverslips at a density of 60,000 cells to form a monolayer and maintained 24 hours before the addition of neurons. Neurons were isolated from embryonic day 18 rat forebrains and seeded at a density of 5,000 neurons/coverslip to compare neurite outgrowth. Neurites were labelled with tetanus toxin 16, 28, and 40 hours after plating and their length determined. The rate of neurite outgrowth appeared linear on both immature and mature astrocytes. However, neurites were consistently 30-35% longer on immature astrocytes. For short term adhesion experiments neurons were plated at a density of $5x10^5$ neurons/well in either the presence or absence of Ca^{++} (1mM EDTA) and the number of bound cells determined. Neuron adhesion was 4 fold greater to immature astrocytes than mature astrocytes. In the absence of Ca^{++} neuron binding was substantially reduced to mature but, not to immature astrocytes. These results indicate that the capacity of astrocytes to support neurite outgrowth and neuronal adhesion is reduced as the astrocyte matures. (Supported by APA grant RC 88-02; NIH grant NS 25597-07)

CHARACTERIZATION OF A FACTOR REGULATING NEURON AND NEURITE EXCLUSION IN FRONTAL CORTEX CULTURES. R.D. Todd and P.A. Bauer (SPON: S.B. Guze). Department of Psychiatry, Washington University School of Medicine, St. Louis, MO 63110

Primary cultures of rat fetal, frontal cortex contain A2B5$^+$, GFAP$^-$, galC$^-$, immobile cells which do not support the movement of neurons or the growth of neurites across their surfaces (R. D. Todd, Soc. Neurosci. Absts. 13:257). The resulting neurite exclusion areas (NEAs) are common in cultures of E16.5 - E17.5 cortex but are rare at earlier and later times. The cells which form the NEAs die after five to seven days in vitro though the cultures as a whole are viable for at least two weeks.

To determine the mechanism of control of the expression of NEAs, we have co-cultured dissociated frontal cortex cells from different aged fetuses and have grown E17 cells in media conditioned by other age cells. The average number of NEAs present in co-cultures of E16 and E17 cells was the arithmetic mean of individual cultures. Culture of E17 cells in media conditioned by E16 cells had no effect on the number of NEAs. In contrast, co-cultured of E17 cells with E19 cells resulted in a decrease in the number of NEAs to that of E19 cells alone. Culture of E17 cells in E19 conditioned media also decreased the number of NEAs to the E19 level. These results suggested that the decrease in NEAs with increasing age is due to an active soluble factor expressed later in development. Heating of E19 conditioned media at 65°C for 15 minutes destroyed this activity. HPLC of E19 conditioned media demonstrated a high apparent molecular weight (~500,000 dalton) fraction of activity which was sensitive to protease K.

346.3

TARGET-SEEKING BEHAVIOR OF EARLY GROWING AXONS FROM RETINAL GRAFTS IN MAMMALIAN MIDBRAIN. M.H.Hankin and R.D. Lund. Dept. Neurobiol., Anat. & Cell Sci., Sch. of Med., Univ. Pittsburgh, Pittsburgh, PA 15261.

In a previous study (J Comp Neurol **263**: 455 (1987)) we showed that retinae placed on the **surface** of the midbrain preferentially project axons along the surface to reach the superior colliculus (**SC**). In contrast, retinae placed in the dorsal midbrain **parenchyma** project directly through the neuropil to innervate the SC.

Here we characterized the earliest outgrowth from these grafts to determine how retinal axons orient towards their target. Monoclonal antibody (M4/6) and normal fiber stains show that axons emerging either from surface or parenchymal grafts were highly oriented towards the SC from the earliest time they could be detected. The time of initial outgrowth from surface grafts (4d posttransplantation (**PT**)) was earlier than was seen from parenchymal grafts (6d PT). In addition, the rate of outgrowth from regions of the graft closer to the SC appeared to be greater than that seen from more distant regions.

Our observations suggest that a hierarchy of cues is involved in guiding optic axons to their targets. It appears that the surface of the brainstem is the preferred ("outgrowth-promoting") substrate. Outgrowth from parenchymal grafts suggests that the SC itself can directly influence the behavior of optic axons independent of the surface of the brainstem surface, provided the fibers are within about 1500 m. Thus the target may help to define both the polarity of elongation and the specificity of innervation. Supported by NEI grant EY05308.

PERIPHERAL OUTGROWTH OF SYMPATHETIC PREGANGLIONIC NEURITES FROM AN HETEROTOPIC THORACIC NEURAL TUBE TRANSPLANT. P. Cauwenbergs[1], J. Butler[2]* and E. Cosmos[2], Anat. Dept., CMCC[1]. Toronto, Ont. M4G 3E6 and Neurosci. Dept., McMaster University, HSC[2]., Hamilton, Ont. L8N 3Z5.

Thoracic nerves are distinct from limb-innervating nerves because (1) they do not contribute to plexus formation; (2) they alone conduct sympathetic preganglionic axons to the sympathetic trunk. Motor nerves derived from a thoracic neural tube (NT) transplanted to the brachial region of experimental (Thor-Br) chick embryos, however, form a morphologically normal brachial plexus. This occurs despite the fact that the graft develops structural characteristics of an in situ thoracic NT, notably a sympathetic column of Terni (CT); the latter (CT) is absent within the brachial region of control (Br-Br and unoperated) embryos (JEEM 95:147,1986). To determine the pattern of ectopic CT fibre outgrowth cross-sections of Thor-Br embryos were analysed using urea-silver nitrate stain.Results demonstrated that the pattern of ectopic CT fibre outgrowth in the brachial region of Thor-Br embryos duplicated that of in situ CT fibres in the thoracic region.In Thor-Br embryos, CT fibres coursed ventrolaterally within thoracic NT grafts, entered ventral motor roots and, then,diverged from the peripheral nerve to enter the brachial sympathetic trunk. This pattern was observed from day 6E to day 16E. Currently, the fate of ectopic CT fibres within the periphery is under investigation.(Supported by MDAC and NSERC).

DENTATE GRANULE NEURONS EXHIBIT ADULT NUMBER OF DENDRITIC SEGMENTS EARLY IN DEVELOPMENT. L. Rihn* and B.J. Claiborne (SPON: D. Armstrong). Division of Life Sciences, University of Texas, San Antonio, TX 78285.

Dendritic branching patterns of granule neurons from young rats were quantified and compared to those of adult granule cells described previously (Claiborne et al., *J. Comp. Neurol.*, in press). Pregnant Sprague-Dawley rats were obtained from Zivic Miller and *in vitro* hippocampal slices were prepared from pups 6 to 8 days of age. Granule neurons in the dorsal blade of the dentate gyrus were filled with horseradish peroxidase and, of six complete fills, three were analyzed in detail. As expected, the width of the dorsal molecular layer (150 um average) and the dendritic length per neuron (2003 um) were much less in the young animals than in the adults (257 um and 3478 um). In contrast, both the number of segments (33) and the transverse spread (316 um) were similar in the young and adult neurons (31 and 347 um). These data suggest that although increases in dendritic length may parallel molecular layer development over the first 3 weeks of life, establishment of adult segment number and transverse dendritic spread occur very early and are not directly correlated with molecular layer maturation.

MORPHOLOGY OF CULTURED SYMPATHETIC NEURONS WITH AND WITHOUT DENDRITES COMPARED TO NEURONS IN VIVO. M.I. Johnson and D. Higgins+. Dept. Anatomy & Pediatrics, Washington Univ. Sch. Med., St. Louis, MO 63110; +Dept. Pharm., SUNY Sch. Med., Buffalo, NY 14214.

Cultured sympathetic neurons from perinatal rat superior cervical ganglion maintained 3-4 wks in a chemically-defined medium (DM) predominantly bear one process with the characteristics of an axon. Serum in the medium or Schwann cells in the culture induce processes with dendritic morphology (Bruckenstein and Higgins, Dev. Biol., 1988). In this study the electron microscopic morphology of cultured neurons bearing only axons or those bearing in addition dendrites is compared to that of embryonic, perinatal, and postnatal neurons in vivo. Somata of unipolar neurons maintained in culture in DM contain free ribosomes surrounding a central collection of organelles, an eccentric nucleus and little rough endoplasmic reticulum (RER). The morphology of the same perinatal neurons at the time of initial dissociation is more complex including well-developed RER. With the addition of Schwann cells, cultured perinatal neurons in DM develop dendrites and the cytoplasm now has RER. However, unlike postnatal neurons in situ, the neurons contain many neurofilaments, often in bundles extending out into dendritic processes. These observations suggest that neurons cultured in DM fail to maintain the level of differentiation attained in vivo prior to dissociation. Induction of dendritic growth, particularly by Schwann cells, results in mature cytoplasmic morphology but with increased neurofilaments. (Supported by NIH NS21771, NS22126.)

COMPARISON OF NIGROSTRIATAL DOPAMINERGIC AXONS AND RADIAL GLIA IN DEVELOPING RAT BRAIN. C.W. Shults,+# R. Hashimoto,++ R.M. Brady,+* F.M. Gage,# +VA Med. Ctr., San Diego 92161, #Dept. Neurosci., UCSD, La Jolla, CA, 92093 ++Yokohama City Univ., Yokahama, Japan

The factors that control the development of the dopaminergic axons from the substantia nigra to the striatum remain unknown. Radial glia provide guidance for migrating neurons and have been suggested to guide axons during development. In the rat at ages E12, E13, E14, and E16 we compared the paths of the nigrostriatal axons and processes of radial glia using a polyclonal antiserum against tyrosine hydroxylase (TH) and a monoclonal antibody against vimentin respectively. At E12 TH-like material was not detected in the developing rat brain. However, vimentin-like material was widely distributed. At E13 TH-like cells, which later develop into the neurons of the substantia nigra and ventral tegmental nucleus, were clearly apparent at the mesencephalic flexure with projections toward the developing striatum. At E16 the TH-like cells in the mesencephalon had become more numerous and abundant axons projecting to the striatum and a few axons projecting to the developing cortex were clearly apparent. AT E16 TH-like axons emanating from the mesencephalon did not parallel vimentin-like processes. However, more rostrally the path of the developing nigrostriatal TH-like axons was similar, through not entirely overlapping with a group of vimentin-like processes.

AN ULTRASTRUCTURAL STUDY OF THE EARLIEST INTERACTIONS OF PRIMARY VESTIBULAR AFFERENTS IN THE CHICK EMBRYO MEDULLA. R. Petralia and K.D. Peusner. George Washington Univ. Sch. of Med., Washington, D.C. 20037.

The tangential nucleus (TN) is a primary vestibular nucleus which contains the principal cells (PC) that migrate at 6-6½ days and differentiate between 6½ and 8 days. Although the primary vestibular afferents enter the medulla in fascicles at 3 days, these fascicles delay forming synapses on PC until 7½ days. In fact, the very first synapses are formed at 5 days on the processes of primitive epithelial cells (PEC; PC precursors) by longitudinal fibers (LF) of unknown origins. Therefore, the present objective was to determine what ultrastructural interactions occur in the TN between 2 and 5 days.

Before the 7-8th nerve fibers grow in, the presumptive TN contains processes of PEC separated by empty spaces, or "channels". The LF appear within these channels at about the time of entrance of the 7-8th fibers. From 2 to 4 days, no synapses are apparent in the TN. However, attachment plaques and coated inpockets are present on the membranes of the components of the TN, including the primary vestibular afferents, PEC, and LF. Thus, attachment plaques and coated inpockets predate synaptogenesis in the TN. This data will provide a basis to evaluate experimental studies on TN development in the absence of the primary vestibular afferents. Supported by NIH grant R01 NS18108.

TRANSIENT GABA-IMMUNOREACTIVITY IN CRANIAL NERVES OF THE CHICK EMBRYO. C. S. Von Bartheld and E. W Rubel. Hearing Development Laboratories RL-30, Univ. of Washington, Seattle, WA 98195.

In addition to its function as a neurotransmitter, γ-aminobutyric acid (GABA) influences a variety of processes in the developing central nervous system (Redburn, D.A., and Schousboe, A., eds., Neurology & Neurobiology 32, 1986). Little is known about the distribution and function of GABA in the developing peripheral nervous system. We have investigated the distribution and time course of GABA immunoreactivity in the cranium of chick embryos from 2 to 16 days of incubation (E2-E16). GABA immunoreactivity occurs transiently in motor portions of all cranial nerves (between E4-E10), in restricted parts of the vestibular ganglion (E4.5-E9), including its central and peripheral processes, and in some early, possibly transient, projections from the brain to the spinal cord. In addition, we observed differential onset of GABA immunoreactivity in hair cells of the vestibular (E7) and cochlear endorgan (E9). Transient GABA follows "pioneer" fiber outgrowth and appears to coincide with the formation of early neuronal contacts. In the vestibular nerve, transient GABA is not restricted to portions of the ganglion thought to be of neural crest, or placodal origin. The timing of transient GABA-immunoreactivity is consistent with a change in neuronal phenotype (loss of GABA expression) as well as an elimination of GABAergic neurons (embryological cell death). Transient GABA-immunoreactivity indicates that GABA is not restricted to circuits which will be GABAergic in the adult. The function(s) of transient GABA-expression are unknown; some lines of evidence suggest that GABA may have neurotrophic functions in developing cranial nerves or their target tissue, and may be involved in the regulation of acetylcholine receptors in the developing neuromuscular junction. ELECTRON MICROSCOPIC STUDIES OF TRANSIENTLY EXPRESSED ACETYLCHOLINESTERASE ACTIVITY IN THALAMUS AND CEREBRAL CORTEX OF DEVELOPING RATS. R. T. Robertson, L. Seress and C.E. Ribak. Department of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Previous work from this laboratory has demonstrated transient patterns of acetylcholinesterase (AChE) histochemical staining in layer IV of primary sensory cortical regions of developing rats (Robertson, Neurosci. Lett., 75:259, 1987). The laminar and areal distributions of transiently expressed AChE activity correspond to the terminal fields of specific sensory thalamocortical projections, suggesting that transient AChE may serve as a marker for these thalamocortical neurons. The present studies were undertaken to determine the fine structural location of this AChE activity.

Sprague-Dawley rat pups of 8-12 postnatal days of age were perfused with aldehydes and vibratome sections were processed for AChE histochemistry. Some animals received unilateral lesions of the dorsal thalamus 36-48 hr prior to sacrifice. AChE stained sections containing the lateral or medial geniculate body or primary visual or auditory cortex were processed for electron microscopy (Seress et al., Dev. Brain Res., 36:139, 1987).

AChE histochemical reaction product was found associated with the granular endoplasmic reticulum and nuclear membranes of virtually all large projection type neurons of the lateral and medial geniculate nuclei. Glial cells were unstained. In visual and auditory cortices AChE reaction product was found associated with the plasmalemma of axon terminals, as well as with some stellate neurons. In animals that received thalamic lesions prior to sacrifice, AChE reaction product could be found associated with the plasmalemma of degenerating axon terminals in both visual and auditory cortices. The present results are consistent with previous data indicating that AChE is synthesized transiently by thalamocortical projection neurons during the early postnatal period of development.

CYTOSKELETAL INVOLVEMENT IN RESEALING OF NEURONAL MEMBRANES AFTER INJURY. X.-Y. Xie and J.N. Barrett. (SPON: D: Puro). Dept. of Physiology & Biophysics, Univ. of Miami School of Medicine, Miami, FL 33101.

Axons of cultured rat septal neurons were transected with a laser at distances of > 100 um from the soma. The transected neurons take up Lucifer Yellow and FITC-dextrans (18 kDa and 70 kDa) before, but not after, membrane resealing. Using dye exclusion as an index of membrane resealing, we found that 75% of the axons resealed within 20 min in control medium containing 2 mM Ca. Colchicine (50 uM) increased resealing to 93%, whereas taxol (20 uM) reduced resealing to 21%. Ca, Sr. and Mn (0.1 mM) enhanced resealing, whereas Mg (2 mM) reduced it. Thus it appears that agents that promote disassembly of microtubules (Ca, colchicine) enhance resealing. whereas agents that oppose disassembly (Mg, taxol) inhibit it. Resealing was reduced by the calmodulin inhibitors trifluoperazine, W7 and troponin I, and by cytochalasin E (4 uM), which inhibits F-actin assembly. These results suggest that the normal mechanism for membrane resealing is Ca-dependent and involves cytoskeletal elements and calmodulin. Surprisingly, there was 100% resealing in low ionic strength solutions (5 meq in isotonic sorbitol or sucrose) lacking divalent cations, indicating that under certain experimental conditions membrane resealing may also be achieved by a Ca-independent pathway. Supported by NIH grant NS 12207.

SERUM-FREE CELL CULTURE OF POSTNATAL RAT HYPOTHALAMIC NEURONS. K.L. Jorgenson, P.R. MacLeish and D.W. Pfaff. The Rockefeller Univ., New York, NY 10021.

We have developed a low density hypothalamic cell culture system. Medial basal hypothalamus was dissected from 2-5 day old rats, enzymatically dissociated (14 U/ml papain) and plated directly on glass coverslips coated with antibodies to Thy 1, a CNS cell surface protein. This substrate allows better neuronal attachment and survival than poly-lysine. L-15 medium supplemented with 25 mM bicarbonate, 0.3% glucose, 2 ug/ml thyroxine, insulin and transferrin, 5 mM taurine, 0.1 mg/ml gentamycin, 2.5 ug/ml Fungizone, 0.7% Methocel and 5 mg/ml bovine serum albumin was added to the cultures, which were incubated at 37 with 5% CO2. This serum-free medium increased neuronal survival and process outgrowth and decreased astrocyte proliferation (based on immunocytochemical staining for glial fibrillary acidic protein) from that observed with serum. Neurons were identified by their characteristic morphology and staining for neuron-specific enolase. Measurement of primary process outgrowth indicated a rate of about 100 microns/day, for up to 4 days in culture. The majority of neurons were unipolar, 20% and 10% had 2 and 3 primary processes, and fewer than 5% had 4 or more. A range of growth cone morphologies, from flattened membranous veils to bulbous structures, was observed. Somata were 10-20 microns in diameter. This culture system, in which individual cells can be easily studied, is suitable for testing potential growth factors.

CRUSTACEAN PEPTIDERGIC NEURONS IN PRIMARY CULTURE SHOW IMMEDIATE OUTGROWTH IN DEFINED MEDIA. R. A. Graf, S. Grau*, B. Haylett* and I. Cooke. Békésy Laboratory of Neurobiology and Department of Zoology, University of Hawaii, Honolulu, HI 96822.

Unlike most neurons in primary culture, which require conditioning factors for outgrowth, the secretory neurons of the crab (Cardisoma carnifex) and lobster (Panulirus marginatus) X-organ show immediate, vigorous outgrowth in simple, defined media (e.g. crab saline + glucose, gentamicin, pH 7.6, 25°) when isolated on a variety of substrates (routinely, Primaria). Within 18 h the morphology is established: small cells (<25 um), which include those showing RPCH immunoreactivity, have a sparsely branched major neurite extending >100 um from the axonal stump; some larger cells show similar form, but most produce a broad lamellipodium, often larger in area than the soma. These show immunoreactivity to anti-CHH, anti-MIH or anti-D sera. Growth of veiling cells ceases by 10d, while branching cells continue longer. Additional growth and altered form result from various manipulations such as brief exposure to elevated $[K]_o$ or co-culture with a sinus gland. We suggest that these cells can show immediate outgrowth by utilizing part of the secretory machinery, exocytosis without membrane reuptake, for addition of membrane. In support: a) EM's show microtubules and secretory granules in filopodia; b) growth cones and presumed Golgi are particularly immunoreactive; c) hormonal peptides are released to the media; d) cells exhibit Ca currents (Meyers, et al., this vol.); e) growth, secretion and Ca currents are blocked by Cd. We thank H. Schooneveld and R. Keller for antisera. Supported by NSF BNS84-04459 and NIH NS 15453 to I.C.

PROCESS OUTGROWTH, GROWTH CONES, AND GUIDANCE MECHANISMS VII

SEX AND THE SINGLE NEURON: GENETIC CONTROL OF SEX SPECIFIC AXONAL PROJECTIONS IN Drosophila SENSORY NEURONS. D.R. Possidente* and R.K. Murphey. Department of Biology, SUNY Albany, NY 12222.

The mechanism by which orderly axonal projections and the corresponding synaptic connections are formed during development remains an important and largely unsolved problem in neurobiology. It may be possible to bring genetic and molecular techniques to bear on this problem by examining the genetic control of axonal growth in Drosophila. We show here that gustatory axons in Drosophila are sexually differentiated and that genes involved in sex determination control the anatomy of these axons. Both males and females possess gustatory receptors on their legs and in females the axonal arborization from these receptors are exclusively unilateral. Males possess significantly more gustatory receptors, and their axonal arborizations are usually bilateral. In diplo-X "males" mutant for the genes tra or Sxl, the gustatory system is transformed toward the male phenotype both in number of receptors and in afferent projections. In order to determine the locus of this effect we examined gynandromorphs and found that the sex of the sensory neuron and apparently not the central nervous system, controls the behavior of the axons. Supported by an NIH Javits Neuroscience Investigator Award to RKM.

347.2

MODALITY SPECIFIC AFFERENT PROJECTIONS IN THE FLIES PHORMIA AND DROSOPHILIA. G.S. Pollack[1], D. Possidente*[2] and R.K. Murphey[2]. [1]Department of Biology, McGill University, Montreal, Québec H3A 1B1 and [2]Neurobiology Research Center, SUNY Albany, Albany, NY 12222.

The legs of flies bear numerous sensory hairs which serve tactile, gustatory, and proprioceptive functions. We examined the afferent projections of these sensilla and found that neurons encoding these three modalities project to distinguishable regions of thoracic neuropile. Proprioceptive neurons are associated with clusters of hairs located near joints (hair plates). Their projections are characteristically more extensive and more dorsal than those of the other two modalities. Tactile receptors are associated both with singly innervated hairs and with multiply innervated hairs, which contain one tactile neuron and four gustatory neurons. Both the tactile and gustatory neurons project to a ventral region of neuropile, but are distinguishable because (1) the gustatory neurons project more medially and posteriorly than the tactile neurons, and (2) the tactile neurons are larger in diameter.

Our findings demonstrate that there is a clear modality specific segregation of axonal arbors in the CNS. We presume that, as in other insect sensory systems, this anatomical specificity is linked to specific synaptic connectivity.

347.3

SPATIALLY RESTRICTED BINDING OF MONOCLONAL ANTIBODIES AGAINST WINGS OF DROSOPHILA MELANOGASTER. P. B. Snyder*, M. A. Murray & J. Palka. Dept. of Zoology, Univ. of Washington, Seattle, WA 98195

Because of the strong evidence that significant guidance information is provided to pioneer sensory axons in the Drosophila wing by the epithelial substrate, we have generated monoclonal antibodies against wings during the axonogenic period. 2G2 and 3C11 stain extracellular material located throughout the wing but concentrated along the veins. This distribution is similar to but not identical with that of a vein-associated antigen we have described previously (Murray, M. A. & Palka, J. Abstr. Soc. Neurosci. 13, 1143, 1987.). 1E1 shows staining exclusively along the third vein (one of two axonal tracts in the wing blade). This pattern is reminiscent of the binding distribution in Drosophila wings of INO, a monoclonal antibody that inhibits neurite outgrowth of cultured mouse neurons (Matthew, W. D. & Patterson, P. H. Cold Spring Harbor Symp. Quant Biol. 48, 625-631, 1983; Blair, S. S. & Palka, J. Abstr. Soc. Neurosci. 13, 6, 1987.). Hence, we currently have a collection of monoclonal antibodies, presumably directed against extracellular matrix components, which show overlapping but distinct distributions. We plan to analyze their binding in other Drosophila tissues and biochemically characterize the corresponding antigens. We also hope to be able to address the question of their possible role in axon growth.

347.4

A MUTATION THAT PERTURBS SELECTIVE SYNAPSES IN THE GIANT FIBER PATHWAY OF DROSOPHILA. F. Katz*, Z. Smith, W. Moats*, and M. Tanouye°. Howard Hughes Med. Inst. and Dept. Biochemistry, UT Southwestern Med. Ctr., Dallas TX, and °Dept. Biology, Cal Tech, Pasadena, CA.

The giant fiber pathway in Drosophila mediates a quick escape response. The giant fiber synapses with the TTM motoneuron (TTMm) innervating the TTM, or jump muscle. The giant fiber also innervates a postsynaptic neuron which then synapses upon the motoneurons for the DLM wing depressor muscle (Wyman et al. in: Neural Mechanisms of Startle Behavior, R.C. Eaton, ed. Plenum, 1984). A mutant was identified on the 3rd chromosome in which the pathway to the DLM is electrophysiologically normal, but the response of the TTM is aberrant, having a delayed latency much like the X-chromosome mutant bendless. Cobalt fills of the giant fiber through the antennal nerve reveal that the giant fiber is morphologically normal. Horseradish peroxidase backfills of the TTMm from the TTM indicate the TTMm is connected to the jump muscle and also appears normal. Physiological experiments are under way to pinpoint the lesion in the pathway from the giant fiber to the jump muscle. The mutation has been mapped to the proximal left portion of the third chromosome.

347.5

INTERACTIONS BETWEEN IDENTIFIED MOTONEURONS DURING PATHWAY SELECTION IN ZEBRAFISH EMBRYOS. S. Pike* and J.S. Eisen. Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

Each side of every trunk segment in the zebrafish is innervated by 3 identified motoneurons that extend axons out of the spinal cord in a stereotyped temporal and spatial pattern. The growth cones of all of these cells follow a common pathway to a region where they pause before selecting cell-specific pathways that lead to mutually exclusive muscle territories. We tested whether CaP, the first motoneuron to extend a growth cone, had a unique ability to establish the common pathway. Ablation of CaP using laser irradiation did not affect the ability of the growth cones of the other identified motoneurons, MiP and RoP, to leave the spinal cord and extend along the common pathway. We also tested whether interactions among motoneurons were required for cell-specific pathway choice. Following CaP ablation, the MiP and RoP growth cones initially selected their normal, cell-specific pathways. These results suggest that CaP is not necessary to establish the common pathway, and that interactions with CaP are not required for MiP and RoP initially to select their normal, cell-specific pathways. We are currently examining whether interactions among motor growth cones may affect later pathway choices. Supported by the NIH, NSF, Chicago Community Trust and a Patricia Roberts Harris fellowship.

347.6

MESENCHYMAL CELL DEATH DELINEATES AXON PATHWAYS IN THE HINDLIMB AND DOES SO INDEPENDENTLY OF NEURAL INTERACTIONS. S. Schroeter, J. A. Pokrzywinski* and K. W. Tosney, Biology Department, The University of Michigan, Ann Arbor, MI 48109.

We wished to know whether the mesenchyme cell death seen near growth cones in the hindlimb delineates axon pathways and, if so, whether the death was "murder" (required an interaction with growth cones) or "suicide" (independent of neural interactions and thus directly or indirectly characteristic of whatever processes generate the paths). We unilaterally deleted the lumbosacral neural tube and reconstructed the patterns of neurite outgrowth and mesenchyme cell death during the stage when neurites first colonize the thigh. In the control limbs, axonal pathways coincided with sites of cell death. Dying cells were abundant where axons ramified extensively, such as plexus regions and at foci within the muscle masses that correspond to regions where muscle nerves will form. In contrast, dying cells were not seen in adjacent non-pathway regions, such as posterior sclerotome or dorsal and ventral to the region of the plexus in which axons extend only posteriorly. In the experimental limbs, neurite outgrowth was reduced to less than one-tenth of normal (a few neurites were visible with electron microscopy) or to less than one-third of normal, extended less far distally and, in half the cases, motor innervation was completely abolished. Despite the extensive reduction in neurite outgrowth, the distribution of cell death was indistinguishable from the control side. Furthermore, it did not differ significantly in abundance. We conclude that mesenchyme cell death delineates axon pathways remarkably well and does so without an interaction with growth cones. It is an independent characteristic of axonal pathways and may in some way help to guide axons.

PEANUT AGGLUTININ (PNA) BINDS TO TISSUES THAT ACT AS BARRIERS TO AXON ADVANCE IN THE CHICK EMBRYO. R.A. Oakley & K.W. Tosney Neuroscience Program & Biol. Dept., Univ. of Michigan, Ann Arbor, MI. 48109

Several tissues in the developing chick embryo can be viewed as barriers to axon advance. These include the pelvic girdle precursor, the posterior sclerotome, and the perinotocordal mesenchyme (ventromedial sclerotome surrounding the notocord). Surgical deletion studies have shown that nerve paths expand spatially when the pelvic girdle or sclerotome are deleted and that motor axons alter their trajectory to avoid the perinotocordal mesenchyme (Tosney & Landmesser, *J. Neurosci.* 4: 2518; Tosney, *Devel. Biol.* in press). The posterior sclerotome is resistant to axon invasion and has been shown to differentially bind PNA (Stern et al., JEEM 91: 209). To determine if the binding of this lectin is typical of barrier tissues, we studied PNA binding in chick embryos in relation to the timing of axon outgrowth.

Stage 18-25 embryos were processed according to Stern et al. Frozen sections (10 μm) were stained with FITC-PNA. We found differential binding of PNA to the pelvic girdle precursor, posterior sclerotome, and to the perinotocordal mesenchyme of both posterior and anterior sclerotome. In anterior half segments, PNA binding was specifically limited to the perinotochordal mesenchyme and did not include the spinal nerve path. PNA binding in the posterior sclerotome extended more laterally, up to the myotome and to the limb base. PNA binding to the pelvic girdle precursor was detected as the earliest growth cones invade the plexus region just medial to it. PNA did not bind to nerve paths including the plexus region and the hiatuses through the girdle which normally transmit axons to the limb. Thus, a PNA binding epitope is common to several barrier tissues and may be involved in constraining the patterns of axon outgrowth. Supported by NIH #NS21308.

SPECIFICITY OF MIGRATION OF NEURAL CREST CELLS IN THE PERIPHERAL NERVE PATHWAYS OF CHICK EMBRYOS. E. M. Carpenter and M. Hollyday#. Committee on Neurobiology, University of Chicago, Chicago, IL 60637 and #Department of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

Schwann cells, the glia of the peripheral nervous system, are derived from the neural crest. In order to help clarify the role of Schwann cells in limb innervation, we have examined the distribution of neural crest-derived Schwann cells at brachial levels in the chick embryo using the chick-quail chimera technique. Chimeras were prepared by transplantation of a short segment of dorsal neural tube from a quail donor to a chick host at levels of the neural tube destined to give rise to brachial innervation. Embryos were allowed to survive to stages 22-29, then were fixed, sectioned at 4μ, and stained using the Feulgen method of staining to visualize the quail nucleolar marker. The identity of the spinal segment or segments affected by the graft and the identity of the peripheral nerves containing quail cells were determined by reconstruction using the light microscope.

As expected from the results of others, quail cells were observed in the dorsal root ganglia, the sympathetic ganglia, and in the ventral roots of spinal segments affected by the grafts. In addition, quail cells were seen in the spinal nerves and in peripheral nerves innervating the wing. Quail cells were distributed along the entire length of the nerve pathways, with increased concentrations of quail cells present in the plexus region and at nerve branch points. Quail cells were not seen in advance of the growing nerves at any of the stages examined. Quail-derived Schwann cells were distributed in the peripheral nerves in a pattern dependent on the segment or segments affected by the grafts. This pattern closely matches the pattern of innervation established by motor axons emerging from the same segmental level of the spinal cord. These results suggest that Schwann cells accompany emerging nerve fibers from the same segmental level and use these fibers as substrates to guide their migration into the periphery.

Supported by NIH grant NS 25340 to MH. EMC is supported by PHS GM 07839.

347.9

DISAPPEARANCE AND REAPPEARANCE OF FIBRONECTIN ALONG AXONAL PATHWAYS OF THE DEVELOPING PERIPHERAL NERVOUS SYSTEM OF THE CHICK. J.W. Yip and Y.P.L. Yip*. Dept. of Physiology, School of Medicine, University of Pittsburgh, Pittsburgh, PA 15261

A molecule that has been shown to modulate morphogenetic movements during gastrulation and mediate the *in vivo* and *in vitro* migration of neural crest cells is the glycoprotein fibronectin. Although fibronectin has also been shown to promote neurite growth *in vitro*, its role in the outgrowth of neurons *in vivo* is less clear. As a first step towards understanding the role of fibronectin in axonal outgrowth *in vivo*, we have examined the relationship of peripheral nerves with fibronectin at different developmental stages of the chick embryo using double immunofluorescent staining. Cryostat sections of embryos from stages 16-44 (2-18 days) were stained with EC/8 antibody against intermediate filaments in neuronal processes and with mono- or polyclonal antibodies against fibronectin. The relationship between motor, sensory and sympathetic neurons with fibronectin was examined from the earliest times they extend processes into the periphery. Prior to axonal outgrowth, fibronectin was widely distributed both within and outside of the presumptive axonal pathways. But soon after the initiation of axonal outgtowth, fibronectin began to disappear along axonal pathways. Thus during the period of active axonal growth, all neural tissues, including neuronal cell bodies and their processes, were marked by the striking absence of fibronectin. Interestingly, fibronectin immunostaining began to reappear along peripheral pathways soon after projection patterns were estahlished and increased in intensity with age. With the exception of their blood vessels, the spinal cord and peripheral ganglia remained devoid of fibronectin.

While the significance of this relationship is not known, these results indicate that growing axons are able to modify their pathways. In modifying the substrate of their pathway, neurons may alter the degree of neuron-substrate or neuron-neuron interaction. Finally, because fibronectin is distributed throughout the mesenchyme during the period of axonal outgrowth, it does not appear to be the molecule required for directing axons to their target region.

AXONAL GROWTH CONES IN EMBRYOS WITH REVERSED SPINAL CORD POLARITY. R.H. Nordlander and S.M. Bunt. Dept. Oral Biol., Case Western Reserve Univ., Cleveland, OH 44106 and Dept. Anatomy, Univ. Dundee, Scotland.

Growth cones of developing longitudinal spinal pathways were examined as they approached and entered spinal cord segments that had been rotated 180° rostrocaudally. Five segment long pieces of Xenopus embryonic neural tube were surgically reversed at stages 21-23, 15-20 hrs prior to the arrival of descending supraspinal axons and before growth of ascending fibers from caudal spinal neurons. Growth cones were visualized with HRP applied to the ventral medulla or directly to the spinal cord rostral or caudal to the rotated segment. Specimens were examined for growth cones 6-60 hrs following surgery and after 7 or 13 days for overall fiber distribution.

Many growth cones of descending axons seemed to enter and navigate the transposed segment with ease, though tangles of axons often appeared temporarily at its interface and some fibers spilled out of the prelesion segment onto surrounding tissues. Growth cones of descending pathways made immediate corrections in dorsoventral position in cases of misalignment of the reversed segment.Ascending sensory growth cones seemed to have more difficulty entering the rotated segment and in finding their appropriate position once there. By 7 days specimens looked nearly normal with few axonal tangles and ectopic fibers.

Supported by funds from NS-18773 to RHN and MRC to SMB.

PATHWAY FORMATION BY DEVELOPING SPINAL INTERNEURONS FOLLOWING PERTURBATION OF PUTATIVE GUIDANCE CUES. H. Yaginuma*, R.W. Oppenheim and O.E. Usun* (SPON: M.A. Bell). Department of Anatomy, Bowman Gray School of Medicine, Winston-Salem, NC 27103.

Invertebrate studies and studies of the vertebrate peripheral nervous system have revealed specific axonal guidance mechanisms (e.g., differential adhesion, selective fasciculation). In an attempt to determine whether guidance cues in the vertebrate CNS are similar, we have been examining the trajectories of axons comprising longitudinal intersegmental pathways in the chick embryo. Although a number of different perturbation studies are in progress, we wish to report here the effects of neural tube rotations about the dorsal-ventral (D-V) axis on pathway formation. Three segments of thoracic neural tube from stage 14-15 (day 2) embryos were rotated 90 or 180 degrees. On day 6 (stage 28) HRP was injected rostral to the rotated cord (RC). The results following 90°rotation indicate that upon contacting the rotated cord, labelled axons in both the lateral and ventral marginal zone (MZ) shift position to reach their appropriate location in the rotated MZ, a maneuver that they repeat upon reaching the opposite boundary between rotated and normal spinal cord. Similar shifts in trajectory were not observed to correct for errors in laterality of projections. Preliminary results of 180°rotations indicate that axons fail to correct their trajectories when encountering the RC. That is, axons in the ventral MZ continued to grow straight through the dorsal MZ of the RC. These results suggest that axons of spinal interneurons may utilize specific "short-range" topographic cues for maintaining their longitudinal trajectories. However, in the absence of these cues (e.g., after 180 rotation), axons can continue to extend in a "foreign" environment over relatively long distances. Supported by NSF 8707290.

EARLY AXONGENESIS AND PATHFINDING IN THE EMBRYONIC MOUSE TRIGEMINAL SYSTEM. D.Y.R. Stainier* and W. Gilbert. Bio Labs, Harvard Univ., Cambr. MA 02138

We are investigating the outgrowth and pathfinding characteristics of specific neurons in the embryonic mouse.

Wholemount preparations of E9 to E12 mouse embryos are being processed immunohistochemically with several mAb's, each with a different specificity. MAb B30 (Stainier et al., Soc. Neurosci. Abstr. 391.13, 1987) stains the surface of mesencephalic trigeminal neurons (mesV) in the CNS as well as other sensory neurons in cranial nerve and dorsal root ganglia. We focus on the trigeminal system and follow its development in both the CNS and the PNS.

MesV neurons are first defined by B30 immunoreactivity at late E9. From their midbrain location, they send axons down to the brainstem where they exit the CNS at the pontine region and mix with stained neurons and axons in the V^{th} (trig.) ganglion. At this stage, these V^{th} ganglion neurons are truly bipolar and they send short processes dorsally towards the pontine region and ventrally towards their peripheral targets. By late E10, three distinct bundles of axons leave the ventral side of the ganglion. This segregation originates within the ganglion itself. Indeed, the mandible innervating neurons form a separate entity at the caudal end of the ganglion. Single axons are also seen leaving the ganglion at other points along its circumference but they quickly join one of the three bundles. By E12 V^{th} ganglion neurons, pseudounipolar at this stage, have reached their target area where their axons branch out heavily.

RESPONSE OF REGENERATING GOLFISH RETINAL AXONS TO TECTAL CELL MEMBRANES OF ADULT FISH AND EMBRYONIC CHICK

J. Vielmetter and C.A.O. Stuermer Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft 7400 Tübingen FRG

Retinal axons from embryonic chick (E6) *in vitro* respond to position specific properties of membranes of embryonic tecta (E9 to E13), as shown by Walter et. al.(1987)

Employing their assay we pursued wether regenerating retinal axons from adult goldfish recognize differences between rostral and caudal membranes 1. of adult fish tecta and 2. of embryonic chick tecta. Cell membranes were prepared from either rostral or caudal tectum and arranged in alternating narrow stripes.

1. Fish axons from temporal retina accumulate on membranes derived from their retinotopically related rostral tectum. Nasal axons grow randomly over both types of membranes. Thus, adult fish axons from temporal retina respond to position specific differences of fish tectum in a similar mode as embryonic chick axons do on chick membranes (Walter et. al.,'87).

2. Confronted with tectal membranes from embryonic chick, temporal axons from adult fish accumulate on rostral membranes, as before. Surprisingly, fish nasal axons also choose to grow on rostral membranes of chick.

According to Walter et. al. (1987) temporal chick axons grow on rostral membranes since they avoid an inhibitory component on caudal membranes. We speculate that in fish, both the temporal and nasal axons are sensitive to the chick inhibitor.

STRUCTURAL ANALYSIS OF A FAMILY OF SENSORY AND GLIAL CELL SPECIFIC 130 KD GLYCOPROTEINS. M. L. Bajt and B. Zipser, Dept. Physiology, Michigan State University, East Lansing, MI 48824.

In the leech nervous system, a group of cell type specific 130 kD glycoproteins differentiates between specific neurons, glial cells, and connective tissue. Four of these 130 kD glycoproteins are neuronal, distinguishing between the full set of sensory afferents and 3 progressively smaller subsets. The fifth and recently isolated sixth are specific for the macroglia enveloping axons and the connective tissue that surrounds the axon tracts, respectively.

The protein cores are being compared by peptide mapping, using limited proteolysis with V8 protease and proteinase K, and analyzed by Western blotting. The two 130 kD proteins expressed by the full set and by the largest subset of sensory afferents are cleaved into identical fragments. The 130 kD proteins expressed by the small sensory subset and by the glial cells are cleaved into fewer of these same molecular weight fragments. Thus, some of the protein cores are homologous, while others are partially homologous.

In lectin affinity chromatography, the 130 kD proteins were previously shown to be mannose rich glycoproteins. Presently, we have deglycosylated the 130 kD proteins on immunoblots using N-glycanase, releasing N-linked oligosaccharides. Lack of binding to deglycosylated proteins demonstrates that the mAb specific for the full set of sensory afferents reacts with a carbohydrate epitope. Each of the 130 kD glycoproteins may have its own unique carbohydrate epitope, since only the mAb specific for the full set of sensory afferents is blocked by preincubation with alpha methyl mannoside. Thus, the same or partially homologous protein cores appear to be differentially glycosylated, thereby generating the different members of the group of 130 kD glycoproteins. Carbohydrate recognition involving the 130 kD glycoproteins may play a role in the formation of the nervous system.

347.15

130 KD LEECH PROTEINS ISOLATED WITH MABS GENERATED AGAINST N-GLYCANASE TREATED IMMUNOBLOT BANDS. I. S. Thorey* and B. Zipser. Dept. Physiology, Michigan State University, East Lansing, MI 48824.

Previously, a group of cell type specific 130 kD glycoproteins has been characterized in the leech nervous system using monoclonal antibodies (mAbs). The antibodies specifically recognize sets and subsets of sensory afferents, axon tract glia or connective tissue. They were generated against fixed CNS tissue or 130 kD gel-bands prepared from CNS tissue. Some of these mAbs were shown to react with N-linked carbohydrate moieties on the 130 kD proteins.

Presently, we have produced a new generation of mAbs by immunizing mice with 130 kD glycoproteins from immunoblots treated with N-glycanase, which cleaves N-linked carbohydrates. In the new fusion, 60 hybridoma clones where isolated, a third of which specifically bind to 130 kD proteins as analyzed on Western blots. On wholemount ganglia, the new mAbs stain components of the central and peripheral axon tracts. On cross sections of whole leech, they also stain the muscles in the body wall. While the new mAbs recognize epitopes shared by more than one cell type, their intensity of staining is generally weaker compared to the previous generation of mAbs. Thus, we might have isolated a new class of 130 kD proteins with lower abundance, and/or the stronger staining exhibited by our previous mAbs may reflect binding to repeated carbohydrate epitopes on the same protein. Conversely, our new mAbs might bind to an epitope on a more ubiquitously distributed conserved core shared by many 130 kD proteins. The core epitope might be masked in some of these 130 kD proteins, creating a lower level of antibody binding. Presently, we are characterizing further our new mAbs to determine their relationship to our first generation of mAbs specific for a group of 130 kD glycoproteins.

347.16

EARLY LABELING OF A MACROGLIAL CELL ANTIBODY IN THE EMBRYONIC LEECH, HAEMOPIS MARMORATA. R.N. Cole*, R. Morell*, and B. Zipser (SPON: S.R. Heisey). Dept. of Physiology, Michigan State Univ., East Lansing, MI. 48824.

We are studying the differentiation of macroglial cells in the developing nervous system of the leech Haemopis marmorata using monoclonal antibodies (mAbs). In the adult, the mAb Laz6-297 binds to a 130 kD surface glycoprotein expressed by macroglial cells associated with the central neuropil, interganglionic connectives, and the ganglionic roots.

Before ganglia and axon tracts are formed (5 days of development at 20C), a novel chain of cells is detected by Laz6-297 in the midline of the embryo. The chain consists of a few cell bodies confined to the posterior region of the germinal plate, with processes projecting anteriorly along the midline to the embryonic mouth. This novel cell type, which is persistent through 8 days of development (20C), demarcates the boundary between the right and left halves of the germinal plate in an arrangement similar to the more numerous midline cells detected in the leech Hirudo medicinalis by the mAb Lan3-2 (McGlade-McCulloh and Zipser, Soc. Neurosci. Abst. 13:1221, 1987).

During axon tract formation, Laz6-297 stains macroglial cells of the connectives, neuropil, commissures, and roots in an anterior-posterior temporal gradient. For example, at 10 days of development (20C) Laz6-297 stains the anterior half of the nerve cord; however, by day 11 more than two-thirds of the nerve cord is labeled. This temporal staining pattern reveals three processes exiting each side of the posterior ganglia and the apparent fusion of the two anterior processes in the anterior ganglia.

The early labeling by Laz6-297 allows us to characterize the ontogeny of glial cells and the nature of glial-neuronal interactions during development. Of particular interest to us are the interactions involving different 130 kD surface glycoproteins which distinguish glia, neurons, and connective tissue during neurogenesis.

MORPHOLOGY AND SHARED MOLECULAR PROPERTIES OF PROCESSES IN FORMING PERIPHERAL AND CENTRAL AXON TRACTS. N. Moore*, R. Morell*, and B. Zipser . Dept. Physiology, MSU,E. Lansing, MI 48824.(SPON: R.Bernard)

We are studying the formation of central and peripheral axon tracts in the leech using mAb Laz1-1 as a cell type specific marker. Centrally, the earliest processes identified in the future connective belong to the transient bipolar cells which, because of their morphology and time of appearance, were suggested to play a role in the establishment of these longitudinal pathways. Our data on the special characteristics of bipolar cells in head and tail ganglia further support this idea: (1) Bipolar cells in the head ganglia extend their processes rostrally to the edge of the germinal plate and persist late into development, until the tract between the head and supraesophageal ganglion is formed. Their extended survival is in contrast to the gradient of bipolar cell death observed in midbody ganglia. The bipolar cells in the head may persist to help form the axon tract. (2) In tail ganglia, bipolar cells deviate from their usual ipsilateral course and project contralaterally, forming a terminal loop. Thus, bipolar cells may delimit the posterior extent of the connectives. Peripherally, early stained processes belong to sensory afferents which may pioneer these peripheral tracts. Therefore, processes postulated to pioneer central and peripheral axon tracts share the earliest cytoplasmic epitopes detected in primordial ganglia and peripheral neurons.

Ten percent of the central neurons also express Laz1-1 reactive cytoplasmic proteins as they differentiate. These Laz1-1 reactive proteins are only partially Triton X-100 extractable under conditions which do not extract Lan3-8 reactive cytoskeletal proteins. The staining of large cell bodies tends to fade with detergent extraction while the staining of small cell bodies remains strong. We are trying to determine which cytoskeletal associated proteins Laz1-1 may recognize.

CYTOSKELETAL PROTEINS IN LEECH NEURONS: ACTIN, TUBULIN, NEUROFILAMENT, SPECTRIN AND TALIN. J. W. McRorie III* and B. Zipser (SPON: L. O'Kelly). Dept. of Physiology, Michigan State University, East Lansing, MI 48824

We are studying the cytoskeleton of leech (Hirudo) neurons using mAbs generated against vertebrate cytoskeletal proteins. Each antibody stains dissociated neurons with a distinct pattern and reacts with extracted leech CNS proteins on immunoblots. MAb C4 (generated against 43 kD chicken gizzard actin, Lessard,J., in press) reacts with a 42 kD band. It stains a fibrous meshwork in growth cones and veils, while in neurites it stains both a fibrous meshwork and thicker bundles. MAb 3F3 (generated against rat tubulin, Akeson, pers. com.) reacts with a 54/57 kD doublet and stains a fine fibrous network in veils and in growth cones which have a flattened morphology and numerous filopodia. Rounded neuritic terminals with few/no filopodia have a much greater intensity of fluorescent staining. MAbs 06-68 and 0240 (generated against rat neurofilament, Sternberger , L., PNAS, 80: 6126, 1983) react with major bands at 150 kD and stain fibrous patterns in all processes. Both anti-alpha-spectrin (generated against 180 and 62 kD chicken erythrocyte alpha-spectrin, Koenig, E. and Repasky, E., J. of Neuroscience, 5(3):705-714, 1985) and talin antiserum (Burridge, K., Cancer Review, 4: 18-78, 1986) react with leech proteins on immunoblots and stain dissociated neurons in culture. Talin antiserum stains a coarse, granular pattern with high intensity aggregrates on neuritic processes. We plan to characterize these leech cytoskeletal proteins at the electron microscopic level.

ROLE OF PROSTANOIDS IN THE POTENTIATION BY NORADRENALINE (NA), HISTAMINE (HIS) AND ADENOSINE (AD) OF VIP-STIMULATED cAMP FORMATION IN MOUSE NEOCORTEX. N.C. Schaad*, M. Schorderet[1] and P.J. Magistretti. Département de Pharmacologie, CMU, 1211 Geneva and [1]Ecole de Pharmacie, Lausanne, Switzerland.

We have previously shown that NA, by acting at α_1-adrenergic receptor, potentiates the accumulation of cAMP elicited by VIP in mouse cerebral cortical slices (J. Neurosci. 5, 362-368, 1985). This α_1-receptor-mediated action of NA is antagonized in a concentration-dependent manner (IC_{50} = 3 µM) by indomethacin and diclofenac, two inhibitors of cyclooxygenase, and by mepacrine and p-bromo-phenacylbromide, two inhibitors of phospholipase A_2 (Nature 368, 637-640, 1987). These observations indicate that prostanoids, formed as a result of α_1-receptor occupation, potentiate the accumulation of cAMP elicited by VIP. Among various prostanoids tested, only PGE_2 and $PGF_{2\alpha}$ mimic the action of NA. Inhibition of diacylglycerol lipase (by RHC 80267) and of protein kinase C (by H-7) are without effect on the potentiatory effect of NA, thus discarding a role of phospholipase C activation in this α_1-adrenergic effect. HIS, via H_1 receptors, and AD (at µM concentrations) also potentiate the increase in cAMP elicited by VIP in an indomethacin- and diclofenac-sensitive manner, hence indicating that prostanoids are also involved in this synergistic interaction. These results indicate a role for prostanoids in the amplification of the action of a peptide in the mammalian CNS.

348.2

BRAIN LEUKOTRIENE C4-BINDING SITES ARE S-ALKYL-GLUTATHIONE BINDING SITES. A. M. Goffinet. Positron Tomography Laboratory. Univ. Louvain Med. Sch. Louvain-la-Neuve, Belgium.

Recent studies (eg Goffinet & Nguyen, Eur P Pharmacol 140: 343) have demonstrated the presence of leukotriene C_4 (LTC4) binding sites in brain membranes and tissue sections and have been taken as evidence that LTC4 may serve some modulatory function in the central nervous system (CNS). So far, however, the nature and function of putative brain LTC4 receptors remain controversial.

In this work, we show that leukotriene C4 binding to mouse brain membranes is readily displaced by S-alkylglutathione derivatives, with the affinity of the test compound increasing as the alkyl chain lenght increases. S-methyl- and ethyl glutathione are equipotent with glutathione. S-butyl-, hexyl-, octyl-, nonyl- and decylglutathione show increasing activities. S-decylglutathione is almost as potent as leukotriene C4 itself.

These data strongly suggests that brain LTC4 binding sites are actually membrane-bound, glutathione-binding proteins such as glyoxalases I and II and/or, more likely, a microsomal form of glutathione transferase(s).

348.3

POSSIBLE OPIATE-SEROTONERGIC INTERACTIONS IN REPRODUCTIVE FUNCTION: LEVELS OF MU AND DELTA OPIATE RECEPTORS AFTER SEROTONERGIC LESIONS. D.L. Allen, V.N. Luine, B.S. McEwen, A.E. Johnson, A. Tempel, and R.S. Zukin. Rockefeller Univ., NY, NY; Hunter College, NY, NY; LCS/NIMH, Poolesville, MD; Albert Einstein Sch. of Med., Bronx, NY.

Opiate and serotonergic systems are important regulators of gonadotropin secretion and female sexual behavior. Interactions between these systems were examined by measuring levels of opiate receptors in the brain after selective lesions of serotonergic terminals by intraventricular infusion of 5,7-dihydroxytryptamine. Rats were sacrificed one week after the lesion. Levels of opiate receptors were measured by in vitro autoradiography using ^{3}H-[D-Ala^2,N-MePhe^4, Gly-ol^5]-Enkephalin (DAGO) and ^{3}H-[D-Pen^2,D-Pen^5]-Enkephalin (DPDPE) to respectively label mu and delta receptors . Lesions of serotonergic terminals decreased ^{3}H-DAGO binding in the POA and the MCG. Binding of ^{3}H-DPDPE to delta receptors was decreased in the POA and the DMN. Neither DAGO nor DPDPE binding was decreased in the VMN.

The decrease in binding of DAGO and DPDPE in the POA, DMN and MCG after the lesion provides evidence for interactions between opiates and serotonin in these areas. The decrease in opiate binding after the serotonergic lesion suggests that a subpopulation of opiate receptors is located on serotonergic terminals. This provides a basis for opiate regulation of serotonin turnover in the POA and MCG, and the lack of regulation in the VMN. Further studies are required to determine if the changes in opiate binding are due to changes in B_{max} or K_d. (Protocols in accordance with Federal and Society guidelines. Supported by GM07524, NS07080, and NS21973).

MONOCLONAL ANTIBODIES AGAINST CONJUGATED NEUROTRANSMITTERS AND THEIR IMMUNOCYTOCHEMICAL APPLICATIONS. J.L. CHAGNAUD, G CAMPISTRON, M.L. SOUAN, N. MONS, M.C. CHARRIER and M. GEFFARD.IBCN-CNRS, 33077, Bordeaux, France. For the simultaneous detection of chemical-defined neuronal pathway in rat central nervous system (CNS), we use poly and monoclonal antibodies directed against conjugated small-sized neurotransmitter (NT) molecules. The development of monoclonal antibodies required the following methodological aspects : (i)the mouse polyclonal immune response directed against each conjugated NT was carefully monitored using a modified ELISA method; (ii) according to the conjugated hapten, we used for the hybridization of spleen cells from immunized mice with myeloma cell lines (SP20/A0 or X63) either an adapted Siraganian's method (1983) or a modified Lane's method (1985); (iii) as soon as hybridomas producing specific antibodies against the conjugated NT could be discriminated from those producing antibodies against the coupling agent-carrier residue, affinity and specificity studies were carried out using conjugated NT closely related . We have recently raised monoclonal antibodies against : conjugated glutamate (10^{-7}M), conjugated Dopamine (10^{-9}M), conjugated Acetylcholine (10^{-10}M) and conjugated serotonin ($2x10^{-8}$M). Thanks to our poly and monoclonal antibodies and the immunocytochemical procedures, we have investigated the studies of the anatomical relationships between the various aminoacidergic, cholinergic and monoaminergic systems. The simultaneous incubation of aspartate antiserum and monoclonal anti-glutamate antibody on the glutaraldehyde-fixed sections from rat brain enables us to specifically visualize these two NT. Many combinations will further facilitate the understanding of the chemical relationships existing in the neuronal circuitry.

GABA AND ENKEPHALIN COLOCALIZE IN AMACRINE SYNAPTIC TERMINALS OF THE TURTLE RETINA. Charles L. Zucker & Alan R. Adolph. Eye Research Institute and Harvard Medical School, Boston, MA.

Enkephalin (Enk) and GABA have been localized in amacrine cells in retinas of turtle and other species. Both of these neuroactive substances have been shown to influence ganglion cell (GC) activity by functioning in concert to exert their effects. In the present study, we have used double-labeling techniques at both the LM and EM levels, as well as extracellular recording, in order to elucidate the circuitry which uses Enk and GABA to influence GC. Simultaneous LM localization of Enk and GAD showed that the majority of Enk-IR amacrine cells were, to varying degrees, also immunoreactive for GAD. Approximately 10% of the Enk-IR amacrine cell bodies were also intensely labeled for GAD. The remaining Enk-IR cells were also GAD-IR but of lower intensity. Combined pre- and post-embedding EM immunohistochemistry revealed that virtually all Enk-IR synaptic terminals were also GABA-IR. Most commonly, these GABA/Enk-IR terminals were seen to be presynaptic to GC and amacrine cells. These targets may receive additional synaptic input from GABA-IR (non-Enk-IR) amacrine cell processes. GABA/Enk-IR terminals receive input from bipolar and amacrine cell processes, some of which are GABA-IR. In the presence of functioning GABA synaptic transmission, met-Enk causes a net inhibition of GC. When GABA synapses are blocked, there is increased spontaneous and light-evoked activity in response to the opiate. Background spontaneous activity evoked by K^+ in the absence of all synaptic inputs (Co^{2+} block), is enhanced by focal met-Enk. Thus it appears that there is a direct, excitatory action of met-Enk on ganglion cells, as well as an indirect, synaptic inhibitory action that may be GABA mediated. Blockade of opiate action via naloxone, produces a broadening of ganglion cell receptive-field center and reduction of surround inhibition, based on changes in spatial transfer function measured using drifting square-wave gratings.

348.6

SIMULTANEOUS ULTRASTRUCTURAL DEMONSTRATION OF CHOLINE ACETYLTRANSFERASE (ChAT) AND GLUTAMIC ACID DECARBOXYLASE (GAD) IN THE RAT INPEDUNCULAR NUCLEUS. (SPON: J.G. Rutherford) M.D. KAWAJA*, B.A. FLUMERFELT AND A.W. HRYCYSHYN*. Dept. of Anatomy, The University of Western Ontario, London, Canada N6A 5C1

The ultrastructural distribution of ChAT- and GAD-immunoreactivity (IR) in the rat interpeduncular nucleus (IPN) was examined employing the sequential double antigen procedure of Levey et al. (1986). ChAT-IR was demonstrated with diaminobenzidine and GAD-IR with benzidine dihydrochloride. Each chromogen exhibited a distinct ultrastructural appearance. The central and intermediate subnuclei and the rostral half of the rostral subnucleus of the IPN possessed both ChAT-positive axons and GAD-positive somata and dendritic processes. Several types of axodendritic synapses were observed in which ChAT-positive terminals formed asymmetrical contacts on GAD-positive dendritic profiles. Symmetrical contacts between ChAT-positive terminals and GAD-positive dendrites were observed occasionally in the rostral subnucleus. Other single labeled axodendritic arrangements possessed either ChAT-positive boutons or GAD-positive dendritic processes. GAD-positive somata primarily formed contacts with non-immunoreactive terminals. This study demonstrates that the rat IPN possesses a varied array of ChAT- and GAD-positive axodendritic interactions. (Supported by the Medical Research Council of Canada)

348.7

ULTRASTRUCTURAL LOCALIZATION OF PHENYLETHANOLAMINE N-METHYLTRANSFERASE AND GABA IN THE NUCLEUS TRACTUS SOLITARIUS. V.M. Pickel, J. Chan, C. Abate and A. Towle. Dept. of Neurology, Divs. of Neurobiology and Molecular Biology, Cornell Univ. Med. Coll., New York, NY 10021.

We examined the ultrastructural localization of the adrenaline synthesizing enzyme, phenylethanolamine N-methyltransferase (PNMT) and gamma-aminobutyric acid (GABA) in the more caudaL, cardiovascular, portions of the medial nuclei of the solitary tracts (m-NTS). Peroxidase reaction for GABA and immunoautoradiographic labeling for PNMT were principally, but not exclusively, found in different populations of perikarya, dendrites and terminals. The GABAergic neurons received synaptic input from other unlabeled terminals and from terminals containing either GABA or PNMT-like immunoreactivities. Conversely, the PNMT-labeled neurons received synaptic input from unlabeled terminals and from terminals labeled for either PNMT or GABA. In some cases, the same unlabeled dendrites received synaptic input from terminals that were immunoreactive for PNMT and GABA. These results indicate that in the m-NTS adrenergic neurons (1) modulate and are modulated by other adrenergic and GABAergic neurons and (2) share common neuronal targets with GABAergic neurons. 348.8

THE RELEASE OF NEUROPEPTIDES FROM SYNAPTOSOMES PREPARED FROM THE MYENTERIC PLEXUS OF THE GUINEA PIG. F.L.Christofi*, T.J. McDonald*, and M.A. Cook. Departments of Pharmacology and Toxicology, and Medicine, University of Western Ontario, London, Ontario, N6A 5C1 Canada.

A preparation of enteric synaptosomes obtained from guinea-pig myenteric plexus was used to characterize the release of Substance P-LI (SPLI), α-neurokinin-LI (α-NKLI), Galanin-LI (GALLI), Met-enkephalin-LI (MELI) and LELI. KCl failed to evoke release of any neuropeptides in the absence of selective antagonists for endogenous inhibitors. In the presence of naloxone or atropine, clear evoked release of MELI, LELI and α-NKLI was observed. In contrast, no apparent release was seen in the presence of a selective A1 adenosine antagonist. These data support an inhibitory role for ME in the release of both the opoids and α-NK and correlates with the high content of MELI measured in this preparation. Receptor-mediated release of neuropeptides was obtained with Gastrin-Releasing Polypeptide (GRP) and bombesin in the presence of naloxone. The potency orders obtained were: For α-NKLI, GRP>>Bomb; for SPLI, GRP=Bomb; for LELI, GRP>>Bomb; and for GALLI, Bomb>>GRP. These distinct profiles are consistent with heterogeneity of GRP receptors on enteric nerve endings.It is concluded that enteric synaptosomes are a suitable system for studying both release, and modulation of release by other peptides, of several neuropeptide mediators. (Supported by MRC of Canada.)

348.9

RELEASE OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVITY (NPY-LI) FROM THE RAT HYPOTHALAMUS. A.E. Ciarleglio*, M.C. Beinfeld* and T.C. Westfall (SPON: L.W. Harris). Dept. of Pharmacol., St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Neuropeptide Y (NPY) is a tyrosine rich peptide that has been previously shown by our laboratory to attenuate the release of norepinephrine (NE) from slices of the anterior and posterior hypothalamus of the rat (Westfall et al., Synapse, in press). Studies on the distribution of NPY in the central nervous system have shown that there is a dense NPY innervation of the hypothalamus particularly in the paraventricular, arcuate, and suprachiasmatic nuclei. In addition, NPY is colocalized with NE in catecholaminergic neurons of the medulla, many of which project to nuclei in the hypothalamus. The purpose of the present study was to further elucidate the role of NPY as a modulator of noradrenergic transmission in the hypothalamus by demonstrating the release of the peptide under basal and stimulated conditions. Stimulated release of the peptide from 400 μm slices of the hypothalamus of Sprague-Dawley rats was evoked by exposing the slices to 60 mM potassium for 5 min following a 50 min equilibration period and a 5 min basal period. NPY-LI was detected by radioimmunoassay using an antibody that could detect as little as 16 picograms per tube. Both basal and stimulated release of the peptide were easily detected with average stimulated release of NPY-LI 225% over basal release. (Supported by HL26319 and HL35202.)

348.10

SUBSTANCE P-INDUCED RELEASE OF EXCITATORY AMINO ACIDS FROM THE SPINAL CORD OF FREELY MOVING RATS MONITORED BY MICRODIALYSIS. D. H. Smullin, S. R. Skilling* and A. A. Larson. Dept. of Vet. Biology, University of Minnesota, St. Paul, MN 55108.

The excitatory amino acids (EAA) glutamate and aspartate and the peptide Substance P (SP) have been proposed as primary afferent neurotransmitters involved in nociceptive transmission in the mammalian spinal cord. Microdialysis of the extracellular fluid of the dorsal lumbar spinal cord has demonstrated increased concentrations of glutamate and aspartate following formalin injection (Skilling *et al.*, J. Neurochem., 1988), and that the concentration of SP increases after electrical stimulation of the sciatic nerve (Brodin *et al.*, Neurosci. Lett., 76:357-362, 1987). In the present study, the potential interaction between SP and EAA in the rat dorsal horn was investigated using microdialysis. Male, Sprague-Dawley rats implanted transversely with dialysis tubing through the dorsal spinal cord were perfused with Ringer's solution at 5 μL/min. Samples were collected in 10 min aliquots and analyzed for amino acids using HPLC with OPA derivatization. Perfusion of SP (1mM) through the dialysis tubing for 100 min produced an immediate two-fold increase in the extracellular concentration of aspartate, but no increase in glutamate, asparagine or glycine. Aspartate concentrations remained elevated throughout the perfusion period. These results demonstrate an interaction between SP and an EAA in a region of the spinal cord associated with primary afferent neurotransmission. INTERACTIONS BETWEEN TAURINE AND EXCITATORY AMINO ACIDS: RELEASE FROM CEREBRAL CORTEX SLICES FROM ADULT AND DEVELOPING MICE. Simo S. Oja and Pirjo Kontro. Department of Biomedical Scieces, University of Tampere, Finland.

Taurine is an important inhibitor of neuronal activity, in the immature brain in particular. Spontaneous and potassium-stimulated (50 mM) release of endogenous amino acids and preloaded tritiated taurine, glutamate and D-aspartate from superfused cerebral cortex slices from adult and 3-day-old mice was now monitored for 50 min. Potassium stimulation released much more taurine but less excitatory amino acids from immature than from mature cerebral cortex, the release of preloaded glutamate being about one half of that of D-aspartate in both preparations. Taurine had no effect on the release of glutamate and D-aspartate. Glutamate, aspartate and their agonists kainate, N-methyl-D-aspartate (NMDA) and quisqualate all greatly enhanced taurine release, kainate being the most effective in 3-day-old mice. Kainate also liberated much more taurine than glutamate or aspartate from both adult and developing brain. The potassium-evoked release of taurine was potentiated by kainate and NMDA, which effects were antagonized by γ-glutamyltaurine and D-2-amino-5-phosphonovalerate, respectively. The receptors for excitatory amino acids thus modify taurine release, particularly in the immature brain.

N-methyl-D-aspartate (NMDA)-induced depolarizations and NMDA - serotonin interactions in old rat neocortex. A. Baskys, J. N. Reynolds and P. L. Carlen. Playfair Neurosci. Unit, Toronto Western Hospital, Addiction Research Foundation, Depts. of Medicine and Physiology, Univ. of Toronto, Toronto, Ont. M5T 2S8, Canada.

We examined NMDA-induced depolarizations in layer V neocortical neurons in cortical slices taken from young (4-6 mos.) and old (24-27 mos.) Fischer 344 rats. NMDA (0.5 mM) was pressure-ejected approximately 50 um dorsally from the recording site. Responses in young cells grew proportionately to the increase in the size of the NMDA droplet. In old neurons there was no correlation between the increase in the NMDA droplet size and response magnitude. Unusually large and long-lasting membrane depolarizations could be evoked in most of the old neurons by a marginal increase in NMDA droplet size. When added to the perfusate, serotonin (10 uM) significantly enhanced NMDA-induced depolarizations in young neurons but not in old. It is hypothesized that this lack of serotonin-NMDA interaction may be related to the loss of synaptic plasticity (long-term potentiation) in old rat neocortex.

THE ROLE OF ACETYLCHOLINE AND NMDA MECHANISMS IN MEDIATING THE RESPONSE TO GLYCINE IN THE NTS. W.T. Talman and S.C. Robertson* (SPON: M. Hart). Lab of Neurobiology, VAMC & Univ. of Iowa, Iowa City, IA 52242.

Glycine (GLY), glutamate (GLU), and acetylcholine (ACh) microinjected into the nucleus tractus solitarius (NTS) of rat decrease arterial pressure (AP) and heart rate (HR). GLY has been demonstrated to release ACh from central tissues and to act at the NMDA GLU receptor subtype. We, therefore, sought to determine in 55 anesthetized rats if the response to microinjection (25 nl) of GLY was mediated through ACh or GLU mechanisms. Atropine (37 pmol), but not hexamethonium (1 pmol-100 n mol), blocked the response to GLY (10 nmol); eserine (16 pmol) increased the duration of the GLY response by 31%; and GLY (100 pmol) significantly increased the response to ACh (250 pmol) from a fall of AP of 11.6 ± 2.3 mmHg before GLY to 17.8 ±3.9 mmHg after GLY. In contrast, GLY (100 pmol) decreased the AP response to NMDA by 17% and in high doses (10 nmol) blocked the response to NMDA, GLU and ACh. Direct NMDA antagonism did not significantly change the response to GLY; and strychnine, which blocked the response to GLY, did not significantly affect the response to NMDA (3 pmoles). These data suggest that GLY may elicit an excitation-like response in the NTS through release of ACh and not through action on the NMDA receptor. Supported by HL32205, HL14388, NS24621, Merit Rev. STRUCTURAL IDENTIFICATION, SUBCELLULAR LOCALIZATION AND SECRETION OF BOVINE ADRENOMEDULLARY NEUROMEDIN C (GRP-(18-27)). S. Lemaire, L. Chouinard*, D. Cecyre* and P. Mercier*. Dept. of Pharmacology, University of Ottawa, Ottawa, Ontario, Canada K1H 8M5

Bombesin-like immunoreactivity (BLI) was purified from acid (HCl) extracts of bovine adrenal medulla. High performance liquid chromatography (HPLC) on a μ-Bondapak C18 column revealed the presence of five molecular forms of BLI, one coeluting with synthetic gastrin releasing peptide (GRP), the mammalian counterpart of amphibian bombesin, one coeluting with neuromedin C and one coeluting with neuromedin B, a structurally related peptide. The two other peaks of BLI eluted at times that did not correspond with those of our synthetic standards. The material corresponding to neuromedin C was purified to homogeneity and its amino acid composition and sequence corresponded to those expected for neuromedin C. HPLC analysis on an analytical SP-5PW column of subcellular extracts of bovine adrenal medulla indicated that neuromedin C is almost exclusively localized in secretory granules. The neuropeptide function of neuromedin C and/or other BLI peptides at this level was supported by the stimulatory effect of carbamylcholine (500 μM) on the release of BLI (4.5-fold increase over the basal release of 19 fmol/5 min) from perfused bovine adrenal glands. Supported by the MRCC (PG-20).

Dopaminergic Regulation of Striatal Tachykinin Gene Expression. I. Interaction of D-1 and D-2 Dopamine Receptors. M.J. Bannon, A. Rubenstein* and D.M. Haverstick. Center for Cell Biology, Sinai Research Institute, Detroit, MI 48235.

Chronic administration of dopamine (DA) agonists and antagonists alters tachykinin (i.e. substance P and substance K) biosynthesis in the rat basal ganglia. The present experiments examined the effects of acute DA agonist treatment on striatal preprotachykinin (PPT) mRNA content. The indirect-acting DA agonist methamphetamine (METH) elicited increases in PPT mRNA which were maximal 3 hours after a single dose of 5 mg/kg. The effects of METH on PPT mRNA were prevented by concurrent administration of either the D-2 selective antagonist sulpiride (35 mg/kg) or the D-1 antagonist SCH 23390 (1 mg/kg), suggesting the involvement of both D-1 and D-2 DA receptors in this response to METH. The METH-induced increase in PPT mRNA was mimicked by the D-2 agonist quinpirole (1 mg/kg) in a SCH-reversible manner, while the D-1 agonist SKF 38393 (16 mg/kg) was without effect. These data suggest that tonic stimulation of D-1 receptors by endogenous DA is necessary for (i.e. enables) D-2 receptor activation of PPT gene expression.

349.3

Dopaminergic Regulation of Striatal Tachykinin Gene Expression. II. Mechanisms of Action. D.M. Haverstick and M.J. Bannon. Center for Cell Biology, Sinai Research Institute, Detroit, MI 48235.

Preprotachykinin (PPT) mRNA content of rat basal ganglia is acutely increased following a single i.p. injection of methamphetamine (METH). PPT mRNA contains exons encoding for both neuropeptides substance P and substance K. Nuclease/RNA protection experiments were undertaken to determine if METH treatment induced stimulus-specific alterations in the splicing of PPT mRNA and thus any changes in the ratio of substance P to substance K since tissue-specific PPT splicing has been reported for bovine tissue. The results showed that there are two major species of PPT mRNA, they increase in a parallel manner following METH, and such an increase is blocked by pretreatment with haloperidol. By determining the amount of protectable RNA in the nuclear and cytoplasmic fractions of striatal cells it was possible to show that the METH-induced increase in PPT mRNA is first evident in the nuclei and later in the cytoplasm. These results suggest that the METH-induced increase in biosynthesis of substance P is dependent upon nuclear events such as increased gene transcription, hnRNA processing or mRNA stabilization.

THE ROLE OF ENZYMATIC PROCESSING IN THE BIOLOGICAL ACTIONS OF SUBSTANCE P. J.M. Stewart and M.E. Hall*. Dept. of Biochemistry, Biophysics and Genetics, University of Colorado Health Sciences Center, Denver, CO 80262.

There is considerable evidence that substance P (SP) is a neurotransmitter mediating baroreceptor reflex activity in the nucleus of the solitary tract (NTS). Microinjection of SP into the NTS produces a reflex lowering of blood pressure and heart rate. The actions of synaptically released SP are thought to be terminated by enzymatic degradation, as there is no re-uptake system for intact SP. The endopeptidase 3.4.24.11 (endo 24.11) is thought to be the principle enzyme in SP degradation. The primary products of endo 24.11 activity are the amino-terminal fragment SP(1-7) (SP-N) and the carboxy-terminal fragment SP(8-11). Both are thought to be biologically inactive.

We have observed, however, that microinjection of SP-N into the NTS can reproduce the effects of injecting intact SP, suggesting to us that SP-N, rather than SP, may be the physiologically relevant transmitter molecule at this site. To test this, we examined the effects of intra-NTS injections of SP or SP-N immediately following inhibition of endo 24.11 by intra-NTS injection of phosphoramidon, a specific inhibitor of endo 24.11. We report that inhibition of endo 24.11 activity by phosphoramidon completely blocks the effects of SP, while the effects of SP-N are unaltered. It therefore appears that endo 24.11, rather than degrading SP, processes SP into a biologically active peptide, SP-N.

INFLUENCE OF THE CORTICOSTRIATAL PROJECTION ON SUBSTANCE P CELLS OF THE CORPUS STRIATUM. D.L. Somers* and R.M. Beckstead. Dept. of Anatomy and Cell Biology, Medical University of South Carolina, Charleston, SC 29425

An influence of the corticostriatal projection on striatonigral substance P (SP) cells was assessed by quantitative radioimmunocytochemistry (RIC). in rats. Cerebral cortex was removed by suction in one hemisphere from the frontal pole to the level of bregma. After 1 or 3 weeks (n=20), the brains were fixed, cut at 30 μm, and mounted onto slides. Sections were incubated in a monoclonal antibody to SP, followed by a biotinylated secondary antibody, an avidin bridge and, finally [^{3}H]biotin. The tissue was exposed to film for 14-21 days and was analyzed using an image analysis system. Optical densities were measured from whole substantia nigra (SN) on each side and converted to pmol [^{3}H]biotin/mg tissue equivalent by interpolation on a standard curve. SP levels were compared between the contra- and ipsilateral SN following cortical ablation and revealed an increase in ipsilateral nigral SP of 8.85% and 6.19% ($p<0.005$) at, respectively, 1 and 3 weeks survival. In a related experiment, striatal glutamate was depleted by more than 80% by 14 days of continuous intraventricular administration of methionine sulfoximine. Radioimmunoassay of SP revealed an increase in SN of 18% when compared to vehicle injected controls. The results suggest that corticostriatal (glutamate?) transmission plays a role in the regulation of SP levels in striatonigral neurons. Supported by NSF grant BNS 8504438.

OPIOID PEPTIDES AND SUBSTANCE P(SP), THEIR PRECURSORS AND PRECURSOR-PROCESSING ENZYMES IN HUMAN CEREBROSPINAL FLUID(CSF). D. Liu*, C. Dass*, G. Wood* and D. Desiderio. The Stout Neurosci. MS Lab, Dept. of Neurol., Univ. of Tenn., Memphis, TN 38163

Several opioid peptides, SP, their precursors, intermediate-sized precursors, and endogenous precursor-processing enzymes were found in human CSF using a combination of RP-HPLC, radioimmunoassay (RIA), and MS/MS. Methionine enkephalin(ME) and SP were identified by RIA, MS, and MS/MS in pooled human CSF following HPLC separation. Beta-endorphin(BE) immunoreactivity was measured in the appropriate HPLC fractions. Dynorphins and the C-terminal extension of ME were analyzed by hydrolyzing appropriate HPLC fractions followed by ME-RIA and LE-RIA. A fraction at 84 min in a 90-minute HPLC gradient was separated into 3 subfractions with a 120-min HPLC gradient. These subfractions were hydrolyzed with human CSF precursor-processing enzymes. ME-RIA and BE-RIA indicated the presence of precursors to ME and BE and of their processing enzymes. For unequivocal identification, the HPLC purified precursors were cleaved by CSF enzymes, the products were separated by HPLC; peptides in the HPLC fractions were determined by RIA and then identified by MS/MS. ME precursor and precursor-processing enzymes were proved strongly by MS/MS. The presence of a SP precursor and its processing enzymes was also established by RIA.

VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) PRECURSOR MESSENGER-RNA IN BRAIN AND PERIPHERAL TISSUE OF RATS. J-Y. Wang, Y-L. Liu*, and A. Y-C. Shum*, Dept. of Physiology, National Defense Medical Center, and Dept. of Pharmacology, National Yang-Ming Medical College, Taipei, Taiwan, R.O.C.

Vasoactive intestinal polypeptide (VIP) is a widely distributed multifunctional neuromodulator. Northern analysis and dot blot hybridization were used to examine the biosynthesis of VIP. A Bluescribe M13+ plasmid containing an insert of 1319 bp cDNA encoding rat VIP precursor (courtesy of Dr. Tim Middleton, MIT) was transfected into E. coli, which was then transformed in M9 medium. The replicated plasmid was isolated from E. coli lysates. A 1400 bp fragment was separated by agarose gel electrophoresis from Rsa I restriction digest of the plasmid and nick-translated with [α-^{32}P] dATP to serve as the probe for hybridization with pre-pro-VIP mRNA. Cytoplasmic poly(A)+ RNA was prepared from brain, heart, intestine, and kidney of adult Sprague-Dawley rats. Northern blot autoradiograms identified a single 2000-base band mRNA. For blot hybridization, 20-ug of total RNA from each tissue was dotted onto nitrocellulose by vacuum filtration, then baked in a vaccum oven and hybridized to the same probe. The dot autoradiograms were then scanned densitometrically to quantitate mRNA. The signal in brain and intestine is at least 10-20 fold more intense than in heart and 50 fold more intense than in kidney. Experiments are underway to examine the regulation of VIP biosynthesis during the hypertensive and ischemic states. (Supported by Academia Sinica, ROC)

STEROID HORMONE REGULATION OF BRAIN NEUROPEPTIDE Y mRNA LEVELS. **P Camp and JD White. Dept Medicine, Div Endo, SUNY, Stony Brook, NY 11794.**

Estradiol (E_2) and progesterone (P_4) can induce or block LH surges in ovariectomized (OVX) rats by acting within the brain. Neuropeptide Y (NPY) can also alter serum LH levels. The goal of this study is to determine if E_2/P_4 affect NPY mRNA levels in the brain. One week after OVX (day 0), E_2 Silastic capsules were placed sc at 0900. Some rats also received P_4 capsules at 0900 on either day 0, 2 or 4. Rats were sacrificed at 1500 on day 0, 1, 2, 3 and 5. Brains were dissected and rapidly frozen on dry ice. Total RNA was isolated using an SDS/urea homogenization, repeated phenol/chloroform extraction and ethanol precipitation. NPY mRNA levels were measured using solution hybridization and nuclease digestion followed by electrophoresis in acrylamide/urea gels.

Preliminary results indicate that hypothalamic NPY mRNA levels gradually decrease with time after OVX. E_2 appears to further suppress NPY mRNA while P_4 can restore hypothalamic NPY mRNA levels depending upon the duration of treatment. Currently we are examining a more detailed time course of E_2/P_4 effects on NPY mRNA. **(Supported by NIH MH-42074 and MH-09552.)**

MODULATION OF NEUROPEPTIDE Y EXPRESSION IN CULTURED SYMPATHETIC GANGLIA R.J. Lione* and J.D. White, Div. Endocrinology, SUNY Stony Brook, Stony Brook, NY 11974

Neuropeptide Y (NPY) is contained in and released from sympathetic neurons to promote vasoconstriction. In this study, the regulation of NPY expression was investigated in co-cultures of neonatal superior cervical ganglia (SCG) and cardiac myocytes.

Dispersed cardiac myocytes are obtained from 3 day old rats by mincing heart tissue and dispase/collagenase treatment. One week later SCGs are obtained from 3 day old rats, the exterior sheath cut open and two ganglia are plated as explants/ 35mm dish. One week following SCG plating, cultures are treated or not with experimental agents. PreproNPY mRNA is measured by a nuclease protection assay. NPY peptide synthesis is assessed by incubating cultures in ^{35}S-methionine and purifying radiolabeled NPY by sequential HPLC.

These cultures were found to synthesize and release NPY. Treatment of cultures with the muscarinic agonist (+)cis-dioxolane appears to result in a 35-50% reduction in preproNPY mRNA content in ganglia whereas treatment with phorbol dibutyrate appears to increase preproNPY mRNA content by approximately 1.5-2 fold. These data suggest that preproNPY mRNA is under both stimulatory and inhibitory regulation and that such regulation can be investigated in this culture system. (Supported by a fellowship to JDW from the Aaron Diamond Foundation)

CARBOXYPEPTIDASE E (ENKEPHALIN CONVERTASE) IN THE RETINA. K.M. Braas, D.R. Lynch*, and S.H. Snyder. Department of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205

Neuropeptides are commonly synthesized as precursor molecules which are flanked by dibasic amino acids; sequential action of trypsin-like and carboxypeptidase B-like enzymes releases the biologically active peptide. Carboxypeptidase E (CPE; enkephalin convertase) (EC 3.4.17.10) cleaves single basic amino acids from the carboxyl terminal of substrate peptides. CPE is found in soluble and membrane-associated forms. Enzyme activity is cobalt-stimulated and potently inhibited by guanidinoethylmercaptosuccinic acid (GEMSA). We have examined rat retina for the presence of CPE. Soluble and membrane-associated CPE enzymatic activity and [^{3}H]-GEMSA binding were identified in retina. Enzyme activity, using [^{3}H]-benzoyl-Phe-Ala-Arg as substrate, was stimulated by cobalt and inhibited by GEMSA. The enzyme had a pH optimum of 5-6. [^{3}H]-GEMSA binding was saturable with a K_D of approximately 4 nM. Inhibitor and ion effects on enzymatic activity and [^{3}H]-GEMSA binding were similar to those reported with purified bovine pituitary soluble and membrane-associated CPE. CPE messenger RNA was demonstrated by Northern analysis using cDNA probes to bovine pituitary CPE. Autoradiography using [^{3}H]-GEMSA and immunocytochemistry using anti-CPE localized highest levels in the inner plexiform layer of the retina.

DISTRIBUTION OF PEPTIDYLGLYCINE α-AMIDATING MONOOXYGENASE (PAM) IN NEURONAL AND PERIPHERAL TISSUES. V. May, K. M. Braas and B. A. Eipper. Neuroscience Dept., Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Peptidylglycine α-amidating monooxygenase (PAM; EC 1. 14.17.3) catalyzes the formation of bioactive α-amidated peptides from their glycine-extended precursors. A bovine PAM cDNA encodes a 108 kDal protein with an N-terminal signal sequence, followed by a propeptide and the catalytic domain, with a putative transmembrane domain near the C-terminus. Post-translational processing of the precursor at dibasic amino acids may yield a soluble form of PAM. The levels and forms of PAM mRNA in rat tissues were determined by Northern analysis using bovine PAM cDNA probes. In the CNS, the level of PAM mRNA was highest in the hypothalamus with moderate levels in cerebral cortex, striatum, hippocampus, brainstem, thalamus and retina; low levels were found in olfactory bulb and cerebellum. Heart atrium contained the highest level of PAM mRNA of all tissues; high levels were also identified in anterior and neurointermediate lobes of the pituitary gland, and in heart ventricle. Moderately high levels of PAM mRNA were observed in the submaxillary, sublingual and thyroid glands, while low levels were found in the ovary, adrenal gland, lung and kidney. The ratio of soluble to membrane-associated PAM enzymatic activity was tissue specific.

IN VIVO SOMATOSTATIN BIOSYNTHESIS IN THE RAT CEREBRAL CORTEX. R.P.S. Kwok and J.D. Fernstrom. Departments of Psychiatry and Behavioral Neuroscience, University of Pittsburgh School of Medicine, Pittsburgh PA 15213.

The cerebral cortex contains a major fraction of the total somatostatin (SRIF) immunoreactivity (IR) in the central nervous system. In this region, IR-SRIF is located in neurons, suggesting a neurotransmitter function. SRIF biosynthesis can be studied in vivo in rat hypothalamus following ^{35}S-cysteine administration into the third ventricle (Van Itallie & Fernstrom, ENDOCRINOLOGY 113: 1210, 1983). We have now adapted this technique to study SRIF biosynthesis in rat cerebral cortex. Anesthetized male rats (250-300 g) received 100 microCi ^{35}S-cysteine into each lateral ventricle, and were killed 5 hr later. A bilateral strip of cortex around the injection sites was removed from each rat, and prepared for HPLC separation. The samples were subjected to two sequential reversed-phase HPLC separations, to isolate labeled SRIF peptides (SRIF-14 and SRIF-28). Following this procedure, a prominent ^{35}S-cysteine peak was found corresponding to SRIF-14. Only a very small SRIF-28 peak was observed. The SRIF-14 peak was further verified by showing it to shift its retention time following reduction and carboxymethylation to that corresponding to standard carboxymethyl-SRIF-14. Labeling of SRIF-14 was also observed to be suppressed in rats pretreated with cysteamine, as it is in hypothalamus. These and other data suggest it is now possible to study in vivo the kinetics of SRIF biosynthesis in the cerebral cortex. These methods should prove useful in elucidating the role of SRIF peptides in cerebral function.

349.13

The primary neuron-enriched culture from rat brain as a model for studying somatostatin (SS) and neuropeptide Y (NPY) turnover. *J.J. Poulakos, W.J. Millard, M.K. Raizada and E.M. Meyer, Univ. of Florida, Sch. of Med., Dept.of Pharmacol. & Therapeutics, Gainesville, Fl. 32610*

We recently found that long term cholinergic hypofunction induced by bilateral lesioning of nucleus basalis induces greatly elevated NPY, SS and CRH levels in the cerebral cortex, which appear to occur concomitantly with memory-related behavioral recovery; suggesting a potential role for these peptides in memory. Since these elevations could be due to increased synthesis or reduced release, we began to investigate SS release (measured by RIA) and NPY synthesis (Northern blot analysis, probe provided by Dr. J.Allen) in neuronal cell cultures. SS was found to be synthesized (5.3±0.3ng/mg protein) and then released in a depolarization-sensitive manner. Norepinephrine (100μM) and insulin (0.1μg/ml) triggered release, while carbachol (50μM) had no effect. Atropine (1μM) however, increased release, consistent with the presence of cholinergic synapses on SS neurons. With respect to peptide synthesis, Northern blot analysis revealed high levels of NPY-mRNA in 19 day old cultures, indicating that it should be possible to characterize further NPY expression. These studies will be important in developing a unifying hypothesis to account for how changes in one ascending pathway affect three different neuropeptide-systems similarly.

349.14

ISOLATION OF A 7 KILODALTON PEPTIDE DERIVED FROM BRAIN PROSOMATOSTATIN. R.A. Benoit and G. Gravel*. Department of Medicine, Montreal General Hosp. Research Institute and McGill University, Montreal, Que. H3G 1A4.

The largest peptide product derived from mammalian prosomatostatin (proSS) is an 8 kilodalton (kD) molecule that we identified in rat brain as preproSS(25-100). We have indicated that certain tissue extracts contain an abundant molecular form related to the 8 kD peptide and now report its isolation from brain. The acid extract of 210 rat brains containing peptidase inhibitors was fractionated on Sephadex G-75 gel permeation chromatography columns and the effluent was monitored by radioimmunoassay (RIA) for the presence of peptides containing the first eight amino acids at the NH_2-terminus of prosomatostatin. A somatostatin-28(1-12) RIA was used to identify preproSS-(25-100). The two main immunoreactive peaks eluted from the column were a 7 kD material and preproSS(25-100). These two molecular forms could only be resolved by ion-exchange chromatography on carboxymethyl cellulose (CMC) at low ionic concentration. The 7 kD material from CMC was further purified by reversed-phase liquid chromatography (RPLC) using heptafluorobutyric or trifluoroacetic acid /acetonitrile as the mobile phases. Three immunoreactive components were seen by RPLC. The major one was rich in Ala and Leu and contained a single met. These results indicate that the 7 kD peptide(s) represents a major product of prosomatostatin processing in brain and that it is heterogeneous. Supported by canadian MRC and FRSQ.

A CRITICAL ANALYSIS OF THE USE OF CYSTEAMINE TO DEPLETE SOMATOSTATIN-LIKE IMMUNOREACTIVITY IN THE CENTRAL NERVOUS SYSTEM (SRIF-LI). L.L. Cook*, G. Bissette, and C.B. Nemeroff (SPON: D.L. Evans). Depts. of Psychiat. & Pharmacol., Duke Univ. Med. Center, Durham, NC 27710.

The wide CNS distribution of SRIF-LI and its reduction in Alzheimer's disease have stimulated studies of its extrahypothalamic role. The reduction of hypothalamic SRIF-LI by subcutaneously (SC) administered cysteamine (CYS) is well-documented, but reports describing effects of centrally administered CYS on SRIF-LI are discordant. SRIF-LI was measured by RIA in the frontal cortex (CTX), hypothalamus (HYP), and hippocampus (HIP) in rats following daily (x7) infusions into stereotaxically positioned, unilateral cannulae in either the lateral ventricle (LV, 300 $\mu g/2\mu l$) or the dorsal HIP (100 $\mu g/2\mu l$), and following single (300 mg/kg) or daily (100 mg/kg, x7) SC injections; rats were killed 4 or 24 hr after the last injection. Following LV infusions, SRIF-LI was reduced only in the HYP (35% at 4 hr and 27% at 24 hr; $p<0.05$). Following HIP infusions, SRIF-LI was reduced only in the HYP at 4 hr (23%) and was not changed in either the ipsi- or contra-lateral HIP or CTX. Although the depletion of SRIF-LI in the HYP was increased by repeated SC dosing, the extrahypothalamic reduction of SRIF-LI by SC CYS was negligible and was not enhanced by repeated dosing. CYS does not appear to be a particularly effective agent for the reduction of extrahypothalamic SRIF-LI following SC or CNS administration. (Supported by NIMH MH-40524 and NIA AG-05128)

ANTI-DEPRESSANT DRUGS INCREASE GLUCOCORTICOID RECEPTOR mRNA IN PRIMARY CULTURES OF RAT BRAIN NEURONS. Marie-Claude Pépin* and Nicholas Barden, Ontogénèse et Génétique Moléculaires, Le Centre Hospitalier de l'Université Laval, Ste-Foy, Québec G1V 4G2, Canada.

Hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis, indicated by elevated serum cortisol levels and a non-suppression of serum cortisol following dexamethasone (DEX) administration are frequently associated with major depressive illness. The hyper-cortisolaemia of depression is not associated with any of the physical characteristics of Cushing's syndrome and this apparent lack of sensitivity to glucocorticoids may be due to a reduction in glucocorticoid receptor (GR) number. A decreased number of GR in lymphocytes of depressed patients has been noted and, if such a decrease is also present in the CNS, this could explain the lack of feedback regulation characteristic of non-suppressors. Since non-suppressive responses of serum cortisol to DEX revert to normal during anti-depressant therapy, it is possible that anti-depressant drugs modify the GR content of brain areas involved in control of the HPA axis. To test this hypothesis, we investigated the effects of anti-depressants on GR mRNA in cultured rat brain neurons.

Hypothalamus, cerebral cortex and amygdala of 16-18 day rat embryos were excised under a dissecting microscope. Dissociated cells were cultured in serum- and antibiotic-free, chemically defined, medium (DMEM-F12). After 15 days in culture, cells were incubated with the test substance for 48 hours and their RNA content isolated and deposited on nylon filters. The filters were hybridized with a ^{32}P-labelled RNA probe complementary to a 2,2 Kb fragment of the GR cDNA. Actin mRNA concentration was used as internal standard.

Irrespective of selective inhibitory actions on reuptake of serotonin (amitriptyline, imipramine, trimipramine) or norepiniphrine (maprotiline, desipramine), all anti-depressants tested increased the GRmRNA level of hypothalamic cells. In cultures derived from cerebral cortex or amygdala, the level of GRmRNA was increased by amytriptyline and desipramine, while imipramine was without effect. These results indicate that anti-depressants can modulate the GR receptor content of brain areas involved in control of the HPA axis, and suggest a mechanism of action for their normalization of endocrinological parameters in depressive patients.

GLUCOCORTICOID AND MINERALOCORTICOID RECEPTOR mRNA EXPRESSION IN RAT BRAIN. H.M. Chao* and B.S. McEwen. (SPON: A. Miller) Lab. of Neuroendocrinology, Rockefeller Univ., N.Y.,N.Y.10021

The autoregulation of corticosterone receptors by glucocorticoids is well documented. The binding of CORT in the rat brain is mediated by two receptor types, the glucocorticoid receptor (GR) and the mineralocorticoid receptor (MR). Molecular probes for the GR and MR were used to study the regulation of these receptors at the mRNA level. GR mRNA expression was quantified using a rat GR probe (from K. Yamamoto) in a SP6 quantitative nuclease protection assay which employs RNAse T2. The levels of expression of GR mRNA are comparable in the cerebellum, hippocampus, hypothalamus, pons-medulla and striatum. Adrenalectomy (ADX) induces an increase and subsequent CORT replacement causes a decrease in cytosolic GR binding; however, no significant changes in the GR mRNA levels are seen with these treatments. We conducted similar analyses using a cDNA clone for the MR (from R. Evans). Though the MR is barely detectable in intact rats in the cytosolic receptor binding assay, the MR mRNA is readily measured and shows a higher level of expression in the hippocampus than in the other four brain regions examined. Initial indications are that the steady-state level of expression of the MR mRNA (like that of the GR mRNA) is not altered by ADX or CORT treatment. (Supported by MH41256 and NS07080.)

TWO TYPES OF GLYCINE RECEPTORS EXPRESSED IN XENOPUS OOCYTES INJECTED WITH RAT SPINAL CORD mRNA. H. Akagi* and R. Miledi, Laboratory of Cellular and Molecular Neurobiology, Department of Psychobiology, University of California, Irvine, CA 92717.

Poly(A)$^+$-messenger RNAs (mRNAs) isolated from adult and neonate (3-4d old) rat spinal cord were injected into Xenopus oocytes which were subsequently examined under voltage clamp. Messenger RNAs obtained from both sources induced the oocytes to aquire functional glycine receptors (GlyR). The glycine-induced currents reversed direction at about -20mV (close to the equilibrium potential of Cl^- in the oocytes) and the responses were blocked by strychinine (0.5μM) or picrotoxin (20μM). Thus, the GlyR encoded by two kinds of mRNAs share some common characteristics. Nevertheless, size fractionation of the GlyR-mRNAs by sucrose density sedimentation exhibited contrasting profiles; the majority of the adult cord GlyR-mRNA sedimented in heavy density fractions, close to the position of the 28S RNA, whilst the neonate GlyR-mRNA was seen mainly close to that of the 18s RNA. The properties of GlyR encoded by the adult mRNA were different from those of the receptor encoded by the neonatal mRNA in respect to dose-response relationship, time-course of desensitization and some pharmacological actions. These results suggest that in rat spinal cord there exist, at least, two molecular classes of mRNAs which code for distinct glycine receptors. Moreover, the production of the GlyR-mRNAs in the spinal cord appears to be developmentally regulated.

REGULATION OF TYROSINE HYDROXYLASE (TH), PHENYLETHANOLAMINE N-METHYLTRANSFERASE (PNMT) AND PROENKEPHALIN (pEK) mRNAs IN ADRENAL MEDULLARY CELLS BY CATECHOLAMINE DEPLETING AGENTS. ROLE OF TRANSCRIPTION AND PROTEIN SYNTHESIS. O.H. Viveros, J.S. Hong, J. Sigafoos, and M.K. Stachowiak. Borroughs Wellcome Co. and NIEHS/LMIN, RTP, NC 27709.

Depletion of catecholamines (CA) in cultured bovine adrenal medullary cells (BAMC) increases the content of TH and pEK derived peptides and modifies TH, pEK and PNMT mRNAs levels. Incubation of BAMC with tetrabenazine (TBZ), 0.1-100 μM, for 48 hr produced a dose-dependent depletion of CA and a inversely proportional increase in TH and pEK mRNA levels. Reserpine produced similar results suggesting that the levels and/or intracellular distribution of the CA regulate the expression of TH and pEK genes. The level of PNMT mRNA exhibited complex responses to TBZ and reserpine. Increases (+50 to +100%) were observed at low concentrations of the drugs but decreases (-40 to -94%) at the higher concentrations. TBZ at 100μM produced biphasic time-dependent changes in pEK mRNA; a 2-3 fold increase at 3 hours was followed by a gradual decline (-90% at 48 hours). The increase in TH mRNA (+420%) by TBZ was not affected by cycloheximide (+408%) but reduced to +82% in the presence of α-amanitin (both drugs at 10μg/ml), suggesting transcriptional regulation of TH. In contrast, both the increase in pEK and the biphasic responses of PNMT mRNA after CA-depleting drugs, were prevented by cycloheximide, indicating involvement of protein synthesis in the regulation of these two adrenomedullary proteins.

PROLONGED TREATMENT OF PC12 CELLS WITH POTASSIUM REDUCES TYROSINE HYDROXYLASE mRNA LEVELS. E.J. Kilbourne* and E.L. Sabban. Dept. of Biochem., New York Med. Coll., Valhalla, NY 10595.

To study the effect of prolonged neuronal activity, we examined the effect of long-term treatment of PC12 cells with potassium. Cells were treated for 3 days with 56 mM KCl. Morphologically, the general cellular appearance in phase contrast miroscopy was unaltered. The cellular dopamine and norepinephrine were completely depleted, as expected. Total RNA was extracted from the cells and analyzed by Northern blot analysis, and hybridized with a ^{32}P labelled cDNA to tyrosine hydroxylase (TH). The TH mRNA levels were decreased over 10 fold.

The time course of this effect showed that the TH mRNA levels was not decreased upon treatment for 1 day or less with 56 mM KCl, but from 2-5 days it went down over 10 fold. The specificity of effect was examined by assesing actin mRNA levels and total protein synthesis under these conditions. Hybridization with actin cDNA showed no decrease in actin mRNA following this treatment. Moreover, protein synthesis, measured by incorporation of ^{35}S-methionine into protein, was similar at these time points. Thus, there appears to be a large specific decrease in TH mRNA levels upon prolonged treatment of PC12 cells with 56 mM KCl. (Supported by NIH grant NS 20440)

CO-REGULATION OF TYROSINE HYDROXYLASE AND INSULIN mRNA IN PRIMARY CULTURES OF RAT PANCREATIC ISLET CELLS.
D.R. Studelska*, C.A. Marshall*, C.J. Fink*, M.L. McDaniel*, and K.L. O'Malley (SPON: R. Weinshilboum).
Anatomy/Neurobiology and Pathology Depts., Washington University School of Medicine, St. Louis, MO 63110

It has been shown that tyrosine hydroxylase (TH), the rate limiting enzyme in catecholamine production, is expressed in a subset of insulin-secreting pancreatic islet cells (Teitelman and Lee, Dev. Biol., 121: 454, 1987). We have recently shown that the human TH gene is within 2.7 kb of the insulin (INS) gene on chromosome 11. Such close linkage raises the possibility that factors which influence one gene might act upon the contiguous gene. As the first step in testing this hypothesis, we have isolated rat pancreatic islet cells, maintained them in dissociated culture and tested for TH or INS mRNA expression using in situ hybridization in conjunction with immunological techniques. Preliminary experiments suggest that both INS and TH mRNA expression are dependent on glucose concentration. Six hr after plating in media containing 16.5 mM glucose, INS-containing islet cells expressed high levels of INS mRNA. In parallel cultures, TH mRNA was detected in a subset (30%) of INS immunoreactive cells. The levels of TH mRNA in these cells ranged from 5-30% of the average amount of INS mRNA expressed under comparable conditions. Under low glucose (5.5 mM) conditions, both INS and TH message could be detected at lower levels in islet cells cultured for 1-6 hours, but after three days, fewer than 0.1% of cells expressed INS mRNA, while TH message could not be detected. In contrast, islet cells maintained in 16.5 mM glucose produced both messages after all time intervals. These data suggest that TH and INS are coordinately regulated by glucose. We are currently determining if other factors known to modulate TH gene expression also co-regulate INS levels.

IN SITU HYBRIDIZATION ANALYSIS OF THE LOCALIZATION AND REGULATION OF DARPP-32 IN THE RAT BRAIN . M. Ehrlich, M. Schalling, M. Djurfeldt*, M. Herrera-Marschitz*, H. Hallman*, T. Kurihara*, T. Hokfelt, and P. Greengard. The Karolinska Institutet, Stockholm, SW and The Rockefeller University, NY, NY.

Dopamine- and adenosine-3':5'monophosphate-regulated phosphoprotein (DARPP-32) is highly enriched in neurons bearing D1-receptors, particularly the medium spiny neurons of the caudate nucleus. We investigated the effects of dopamine-related agents on steady-state levels of DARPP-32 mRNA in rats via in situ hybridization with an ^{35}S-labelled oligonucleotide probe complementary to rat DARPP-32 mRNA. In control animals, the distribution of DARPP-32 mRNA correlated with that of the protein as previously shown by immunocytochemistry. After overnight autoradiography, a strong signal was observed in the caudate nucleus, nucleus accumbens, pyriform cortex and ependymal cells surrounding the third ventricle. The distribution in the caudate was somewhat patch-like. Longer exposure revealed labelling in two bands throughout the cerebral cortex. The various treatments had little or no effect on the level of DARPP-32 mRNA, but the specific mRNAs for substance P, dynorphin, or glutamic acid decarboxylase were markedly altered from control. We conclude that the steady-state level of DARPP-32 mRNA is more stable and is regulated by different mechanisms than are the levels of mRNA for several other molecules involved in signal transduction in the caudate nucleus.

350.8

PROTEIN SYNTHESIS INHIBITION BLOCKS THE INCREASE IN LEVELS OF TYROSINE HYDROXYLASE-mRNA INDUCED BY cAMP OR GLUCOCORTICOID IN A RAT PHEOCHROMOCYTOMA CELL LINE. L.H. Fossom*, N. Weiner and A.W. Tank, Depts. Pharmacology, Univ. Colorado HSC, Denver, CO 80262 and Univ. Rochester Med. Ctr., Rochester, NY 14642. (Sponsor: Victor G. Laties)

We have previously reported that both cAMP and glucocorticoid induce levels of tyrosine hydroxylase (TH) enzyme in PC18 cells, and that this induction is preceded by and can be accounted for quantitatively by increased synthesis rate of TH and increased levels of TH-mRNA. We and others have shown that the induction of TH-mRNA levels is due in part, if not entirely, to increased transcription of the gene for TH. In this report we show that two protein synthesis inhibitors, that work by different mechanisms, can block the induction of TH-mRNA by either cAMP or dexamethasone. Three hour treatments with either 1 mM 8Br-cAMP or 1 μM dexamethasone increased TH-mRNA levels 2.5- or 2.9-fold, respectively. Treatment with 3.7 μM cycloheximide beginning 1 hr before and continuing during induction, completely blocked these increases in TH-mRNA without altering basal levels. Protein synthesis inhibition using 37 μM puromycin also blocked induction of TH-mRNA by both inducers. These results suggest that inhibition of the synthesis of some rapidly turning over protein(s) prevents induction of TH-mRNA by cAMP and dexamethasone. We are currently working to determine whether this protein factor(s) is required for increased transcription of the TH gene or acts to stabilize TH-mRNA.

DOPAMINE DECREASES TYROSINE HYDROXYLASE mRNA IN CULTURED RAT ADRENAL MEDULLA. W.J. Burke, R. Strong, H.D. Chung, A.C. Towle, H.P. Paivarinia, G.L. Marshall and T.H. Joh. St. Louis VAMC, St. Louis Univ. Med. Sch., St. Louis, MO 63125 and Cornell Univ. Med. Coll., New York, NY 10021.

We have recently reported that dopamine (DA) reduces the activity amount and rate of synthesis of tyrosine hydroxylase in cultured rat adrenal medulla (Biochem. Pharmac. 37, 1391-1398, 1988).

In the present study we sought to determine if the decrease in TH synthesis was due to decreased levels of mRNA. Adrenal medullae from 4 month old 450g Holtzman rats were cultured in the presence or absence of 2mM (DA) for 22h. TH mRNA was determined by in situ hybridization using a [^{32}P] labelled oligonucleotide probe. Densitometric quantification of the X ray film revealed a 56% decrease in TH mRNA in DA treated medullae. In a similar experiment 2mM epinephrine resulted in a 30% decrease in TH mRNA. Northern blot analysis of medullae exposed to DA also revealed a 70% decrease in TH mRNA. Thus DA reduces TH synthesis by reducing TH mRNA in cultured adrenal medullae.

TRANSLATIONAL REGULATION OF TYROSINE HYDROXYLASE IN RAT PHEOCHROMOCYTOMA CELLS. S.A. Signs*, J.F. Bowyer and A.W. Tank, Depts. Pharmacology, Univ. Rochester Med. Ctr., Rochester, NY 14642 and Univ. Colorado Hlth. Sci. Ctr., Denver, CO 80262.

PC18 pheochromocytoma cells display 3-4 fold increase in tyrosine hydroxylase (TH) and TH-mRNA after treatment with dexamethasone (DEX) or 8-bromo-cyclic-AMP (8Br-cAMP). When PC18 cells are treated simultaneously with DEX plus 8Br-cAMP, additive amounts of TH enzyme (i.e. 6-8 fold) are synthesized, however, TH-mRNA levels are not increased additively. The synthesis of ^{3}H-TH in cell-free reticulocyte lysates directed by RNA isolated from DEX plus 8Br-cAMP treated cells is 2-fold greater than that directed by RNA containing equal amounts of hybridizable TH-mRNA from cells treated with either inducer alone (Bowyer et al., submitted for publication). In an effort to explain this increased translational activity of TH-mRNA, we have used a primer extension assay to examine whether multiple TH-mRNA transcripts are produced. ^{32}P-Labeled oligomer complementary to 20 nucleotides near the 5'-end of exon 2 of TH-mRNA was annealed to RNA isolated from each treatment condition and the RNA·DNA hybrids were extended using AMV reverse transcriptase. Oligomer-TH-mRNA hybrids from all treatments extended to the same predicted transcriptional start-site. Thus, enhanced translational activity of TH-mRNA derived from DEX plus 8Br-cAMP treated cells is not due to an alternate transcriptional start-site or to alternate splicing to form multiple first exons.

GROWTH HORMONE GENE EXPRESSION IN GENETICALLY OBESE MALE AND FEMALE RATS. I. Ahmad*, A.W. Steggles*, and J.A. Finkelstein. Depts. of Anatomy and Biochemistry, Northeastern Ohio Universities College of Medicine, Rootstown, Ohio 44272.

Pulsatile release of growth hormone (GH) is significantly decreased in male genetically obese Zucker rats (fa/fa) in comparison to lean littermates (Fa/-). In order to understand the underlying molecular mechanism of this abnormality, we have begun studying GH gene expression. Pituitaries were obtained from seven pairs of obese and lean littermates. After homogenization of the pituitaries, GH mRNA was quantified by cytoplasmic dot blot, using a 32P-labeled cDNA probe. In the male animals, GH mRNA level was 2.5 fold lower in the obese rats than in the lean controls. A similar comparison between groups of female rats of the same age showed a change in the same direction but the difference was not as pronounced as that seen in the groups of male animals. The variability within the groups of females was greater than that seen in the groups of male animals. Although obesity is as marked in the females as in the males, sex hormones may influence the observed differences in GH mRNA levels between obese and lean animals. (Supported by Ohio Board of Regents Research Challenge Funds).

DEVELOPMENTAL CHANGES IN RAT ANTERIOR AND INTERMEDIATE POMC PRIMARY RNA TRANSCRIPT AND MATURE MESSENGER RNA. R. Scott*, D.J. Autelitano, M. Blum, J.L. Roberts, and J.E. Pintar (SPON: M. Ferin). Dept. Anatomy and Cell Biology, Columbia P&S, NYC, NY 10032 and Fishberg Ctr. for Neurobiology, Mt. Sinai Medical Center, NYC, NY 10029.

Anterior and intermediate lobe proopiomelanocortin (POMC) cells are derived from a common embryological precursor, but differentiate at different times during development and are characterized by developmental changes in the extent of prohormone processing. In this study we have determined the levels of POMC primary transcript and POMC mRNA in separated anterior and neurointermediate (NIL) lobes at late prenatal and early post-natal stages of rat development using POMC intron/exon splice junction probes. Anterior and NIL lobes were dissected from fetal (e18,e21), neonatal (p1,p10,p21), and adult Sprague-Dawley rats and nuclear and cytoplasmic fractions isolated. Radiolabelled antisense cRNA probes were synthesized from an SP65 vector containing a rat genomic DNA fragment encoding all of POMC exon 1 and 60 bp of intron A. Radiolabelled probe was hybridized to ioslated nuclear and cytoplasmic RNA in solution, digested with RNAse or S1 nuclease following hybridization, and separated by gel electrophoresis. POMC RNA species were quantitated by comparison to a standard curve produced by hybridizing radiolabelled antisense RNA to unlabelled sense RNA. Although the amount of POMC primary transcript per pituitary increased in both cell populations during these ages, (e.g. 0.03 fmole/anterior pituitary (AP) at e18 to 0.17 fmole/AP in the adult), POMC mRNA levels increased by greater amounts in both lobes. Thus, the relative abundance of POMC primary transcript compared to mature POMC mRNA in both anterior and NIL was markedly higher during late gestation than in the adult, which indicates that dynamic changes in POMC transcript processing are occurring during differentiation of both POMC cell populations during development. Supported by NIH grants to JP and JLR.

EFFECT OF CHEMICAL ADRENALECTOMY ON VASOPRESSIN, CRF, AND POMC mRNA REGULATION IN THE HYPOTHALAMUS AND PITUITARY. S.P. Kwak*, E.A. Young, R. Przewlocki*, H. Akil, and S.J. Watson (SPON: M.J. Majchrzak). Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Adrenalectomy has often been used as a paradigm for studying the role of glucocorticoid negative feedback on the hypothalamo-pituitary system. However, using this procedure it is difficult to study acute effects, since confounding variables such as surgical stress and steroid release during removal of adrenals are often associated with this procedure. To observe the acute consequences of endogenous glucocorticoid removal, we have employed metyrapone as a potent inhibitor of adrenal steroid synthesis and studied the changes in mRNA levels in relevant nuclei. Rats were treated with daily injections of metyrapone (20mg/100g bw) s.c. for 3 days, sacrificed, and the brain was microdissected using a brain block. Using RNase protection assay, we observed 200% increase of POMC mRNA over controls in the anterior pituitary, confirming our previous data obtained from dot blots. Vasopressin mRNA increased by 62% in the PVN. Plasma β- endorphin levels were also elevated 3 fold over controls, suggesting that the effects produced by metyrapone resembles changes observed during adrenalectomy. Our data is in agreement with the study by Plotsky et al. (*Endocrinology*, 120(4)1987), showing 5.2 fold rise in plasma ACTH levels with concurrent increase in CRF and vasopressin staining in the PVN. We are currently assaying for CRF mRNA and plasma levels of β-endorphin over various days of treatment to compare the effects of chemical versus surgical adrenalectomy.

350.14

OXYTOCIN GENE EXPRESSION IN THE SUPRAOPTIC NUCLEUS DURING PREGNANCY AND LACTATION P.J. Brooks, P.K. Lund*, W.E. Stumpf, and C.A. Pedersen. The Curriculum in Neurobiology, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, 27514

We have investigated the regulation of oxytocin gene expression in the supraoptic nucleus on days 10,18, and 22 of pregnancy and day 5 of lactation in the rat using quantitative in situ hybridization with an I125 tailed oligonucleotide probe. For each treatment group, frequency distributions relating grain densities to percent of total labelled cells were generated by an observer unaware of treatment conditions. Examination of the frequency distribution of the lactating group compared to the pregnant groups indicated a shift to the right, i.e. an increased percentage of cells having higher grain densities in the lactating group compared to all of the pregnancy groups. The shape of the distribution of the lactating group was found to be significantly different from all other groups (Kolmogorov-Smirnov Test, $p<0.001$).

These results indicate that oxytocin mRNA levels in supraoptic nucleus cells remain relatively constant over late pregnancy, while lactation is associated with an increased percentage of cells in the supraoptic nucleus expressing higher mRNA levels. We are presently determining whether oxytocin cells in other brain regions undergo similiar changes.

350.15

REGULATION OF PROENKEPHALIN (pEK) mRNA IN RAT ADRENAL MEDULLA (AM) DURING STRESS AND AFTER ADRENAL DENERVATION. IN SITU HYBRIDIZATION STUDY. M. Sar[a]*, J.S. Hong[c], W. Stumpf[a], B.B. Kaplan[b], L. Thai[c]*, E.K. Stachowiak[a]*, and M.K. Stachowiak (SPON: G.J. Harry). University of North Carolina, Chapel Hill, NC[a], University of Pittsburgh, PA [b], NIEHS Res. Triangle Pk., NC[c] 27709.

We have examined the regulation of pEK gene expression in AM cells using a single-stranded DNA probe complementary to 30 nucleotides of the coding region of pEK gene. Cells expressing pEK mRNA were unevenly distributed in AM, and were not found in the adrenal cortex. Transection of the splanchnic nerve increased 4-8 times pEK mRNA content in the individual AM cells. Increases occured predominantly in the portion of medulla adjacent to the nerve transection. Intensity of hybridization signals was also affected by hypoglycemia. 24 hrs following 2 hrs insulin shock pEK mRNA levels in individual AM cells increased 5-10 fold. These changes were distributed throughout the medulla. No changes in the number of cells expressing pEK mRNA were detected. Taken together our results indicate that the neural regulation of pEK gene expression in AM cells is complex. Under basal condition neural input appears to have an inhibitory effect, whereas elevation of the nerve activity by hypoglycemia enhances pEK gene expression.

350.16

HALOPERIDOL AND DOMPERIDONE TREATMENTS HAVE THE OPPOSITE EFFECT ON LEVELS OF PROENKEPHALIN mRNA IN THE CAUDATE-PUTAMEN OF THE RAT BRAIN. C.S. Woolley*, J.A. Angulo and B.S. McEwen (SPON: G. Ryan). Lab of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

In situ hybridization histochemistry was used to evaluate the effects of two pharmacological agents with D2 dopamine receptor subtype antagonistic activity, haloperidol and domperidone, on levels of proenkephalin (PE) mRNA in the mid caudate-putamen (C-PU) region of the rat brain. Male Sprague-Dawley rats were treated for six days with haloperidol (1 mg/kg/day) or domperidone (0.4 and 0.8 mg/kg/day) delivered by osmotic minipump. A synthetic oligonucleotide (30mer) complementary to regions in the first and second exons of the PE message was end-labeled with ^{32}P and used as a hybridization probe to detect specific mRNA in coronal brain sections from treated and control rats. Optical density of X-ray film exposed by labeled sections was quantitated in the C-PU region by densitometry using an image analyzer and data were expressed as percent of control values. Treatment with haloperidol resulted in a 2.5 fold increase in the level of PE mRNA while treatment with domperidone resulted in decreased levels. Thus, the effect of haloperidol treatment on PE mRNA in the C-PU region of the rat brain is not equivalent to the antagonistic effect of domperidone at the D2 dopamine receptor subtype.

350.17

EFFECT OF SODIUM DEPLETION AND ALDOSTERONE TREATMENT ON ANGIOTENSINOGEN mRNA IN THE BRAIN OF THE RAT. J. Angulo, J. Schulkin* and B. McEwen, Dept. of Anatomy, University of Pennsylvania and Lab. of Neuroendocrinology, The Rockefeller University.

We have studied the effect of sodium depletion and aldosterone treatment on brain angiotensinogen mRNA by in situ hybridization histochemistry using a synthetic oligonucleotide probe corresponding to amino acids 106-115 of proangiotensinogen. The probe was radiolabelled at the 3' end by the addition of adenosine mononucleotides (32-P) by terminal deoxynucleotidyl transferase.

Sodium depletion resulted in increased levels of angiotensinogen mRNA in the preoptic area and no changes in the dorsomedial and ventromedial nuclei of the hypothalamus or the medial amygdala. Aldosterone treatment increased angiotensinogen mRNA levels in the preoptic area but not in other brain areas examined. The data suggest that sites in the preoptic area of the brain are part of a neural circuit involved in regulating the hunger for salt.

350.18

BRAIN ANGIOTENSINOGEN mRNA IN GENETICALLY HYPERTENSIVE AND NORMOTENSIVE RATS. B.G. Yongue, J. Angulo and B.S. McEwen. New York State Psychiatric Insitute and Rockefeller University, New York, NY 10021

Brain angiotensin is implicated in blood pressure (BP) control and fluid/electrolyte metabolism, via vasopressor actions and stimulation of thirst and salt consumption. Spontaneously Hypertensive rats (SHR) not only have high BP, but also consume more salt than Wistar/Kyoto rats (WKY), a normotensive strain from the same progenitor. SHR also seem to be more responsive than WKY to both the BP and salt appetite stimulating actions of the renin-angiotensin system. We are examining genotype and adrenal influences on expression of the gene coding for angiotensinogen, the angiotensin precursor, in brain of SHR and WKY. Brains of SHR and WKY, either intact or adrenalectomized, were frozen and sectioned at 16 u. Brain angiotensinogen mRNA was detected by in situ hybridization histochemistry with a synthetic oligonucleotide probe (proangiotensinogen, amino acids 106-115). The probe was radiolabelled by addition of adenosine mononucleotides (32P) at the 3' end by terminal deoxynucleotidyl transferase. Hybridization autoradiograms were quantitated by computerized densitometry. Preliminary results indicate a greater expression of angiotensinogen mRNA in circumscribed regions of SHR brain, and that this difference is enhanced after adrenalectomy.

350.19

EFFECTS OF STRIATAL DOPAMINE DEPLETION ON SOMATOSTATIN NEURONS. T.T. Lu*, M. Goldstein, R.H. Roth, F. Baldino, Jr., and A.Y. Deutch. Depts. of Pharmacol. & Psychiat., Yale Univ. Sch. Med., New Haven, CT 06510, NYU Med. Sch., New York, NY, and Cephalon, Inc., West Chester, PA.

Among the intrinsic striatal neurons is a population of cells containing both somatostatin (SOM) and neuropeptide Y (NPY). Previous studies have revealed that depletion of striatal dopamine (DA) results in changes in striatal tachykinin and enkephalin neurons, as reflected by changes in peptide mRNA levels. We have therefore examined the effects of striatal DA depletion on SOM neurons, using immunohistochemical (IHC) and in situ hybridization histochemical (ICSS) methods. Folowing unilateral 6-OHDA lesions of the midbrain DA cell groups, animals were prepared for IHC or ISHH. Striatal DA deafferentation resulted in decreased (18-25%) numbers of SOM-like immunoreactive (SOM-li) neurons (but increased SOM-li fiber staining) in the nuc. accumbens (NAS); ISHH revealed a corresponding decrease in SOM mRNA in the NAS. In contrast, the number of NPY-li neurons in the ventral striatum was increased (40-42%) on the lesioned side; studies of NPY mRNA are in progress. These data suggest that DA regulates ventral striatal SOM neurons, and further suggest that DA may differentially regulate gene expression of two coexistent peptides within striatal neurons.

CELLULAR LOCALIZATION OF SUBSTANCE P/NEUROKININ A AND NEUROKININ B mRNAs IN THE RAT RETINA. N. Brecha, C. Sternini, K. Anderson and J. E. Krause. Depts. Anat. & Med., UCLA School of Med., LA, CA 90024 & Depts. Anat. & Neurobiol., Washington Univ., St. Louis, MO 63110.

The mammalian tachykinin (TK) peptides, substance P (SP) and neurokinin A (NKA), and neurokinin B (NKB) are encoded by distinct mRNAs derived from separate SP/NKA and NKB genes. Using antibodies directed to the conserved TK C-terminal region as generalized markers for the TK family and immunohistochemistry, numerous immunoreactive cells were identified in both the ganglion cell layer (GCL) and proximal inner nuclear layer (INL) of the rat retina. In situ hybridization histochemistry with ^{35}S-labeled rat SP/NKA- or NKB-encoding antisense cRNAs showed SP/NKA-encoding transcripts in cell bodies distributed to the GCL and proximal INL, and NKB-encoding transcripts in somata located in the GCL. Northern blot analysis confirmed the presence of these mRNAs in retinal extracts. Nuclease protection experiments showed a single NKB-encoding transcript, but multiple SP/NKA-encoding transcripts (gamma-SP/NKA mRNA> beta-SP/NKA mRNA >> alpha SP mRNA). These results demonstrate that both TK genes are expressed in the rat retina. The differential localization of SP/NKA- and NKB-encoding mRNAs in the INL and GCL documents a cellular specific expression of TK-encoding mRNAs in the retina.

PREPROTACHYKININ A GENE EXPRESSION IN RAT ENTERIC AND SENSORY NEURONS. C. Sternini, K. Anderson, G. Frantz, J.E. Krause and N. Brecha. CURE & Depts. Med., Anat. & Biol., UCLA School of Med., Los Angeles, CA 90024, & Depts. Anat. & Neurobiol., Washington Univ., St. Louis, MO 63110.

The preprotachykinin (PPT) A gene generates three mature mRNAs: alpha-PPT A mRNA which encodes substance P (SP), and beta- and gamma-PPT A mRNAs encoding both SP and the related tachykinin, neurokinin A (NKA). In this study, we have used in situ hybridization histochemistry with a T7 transcribed [35]S-labeled rat PPT A antisense cRNA that recognizes alpha-, beta- and gamma-PPT A mRNAs to identify the cell bodies in which the PPT A gene is trancribed in the enteric nervous system and sensory ganglia of the rat. PPT A mRNA is localized in neurons in the myenteric plexus of the esophagus and stomach and in both the myenteric and submucosal plexuses of the small and large intestine. In the trigeminal and dorsal root ganglia, intense labeling was observed in small to medium size somata. The distribution of enteric and sensory ganglion cells expressing PPT A mRNA is comparable to the immunohistochemical pattern of SP-like immunoreactivity as shown in cryostat sections immunostained with SP antisera. These results demonstrate that the PPT A gene is transcribed in a subpopulation of enteric and sensory neurons and that the specific mRNA and the final product of RNA translation are localized in the same structures.

Cellular localization of mRNA by in situ hybridization in cultured nerve muscle contacts. S.A. Berman, S. Bursztajn, K. Tkach and W. Gilbert. Bio. Labs, Harvard Univ., Cambridge. MA.02138.

Acetylcholine receptor (AChR) synthesis is responsive to a variety of neuronal and non-neuronal factors. To determine if a correlation between innervation and AChR mRNA exists, we examined mRNA at a single cell level via in situ hybridization and autoradiography with an α subunit AChR genomic probe obtained from J.P. Changeux. Muscle cells four days after plating were cocultured with spinal cord explant, ciliary neurons or dorsal root ganglia (DRG). 7-8 days into coculture muscle cells within two explant diameters of the spinal cord explant show a higher density of silver grains than muscle cells alone. A graded decrease in the silver grain distribution is observed as distance from the explant increases. A similar gradient in AChR mRNA distribution is not evident when ciliary neurons are used. Instead, the distribution of mRNA is uniform, but at a much higher density than with muscle cells alone. Neither an increased mRNA level nor a gradient is seen when DRGs are used. We hypothesize that coculture with cholinergic neurons results in a localized increase in AChR mRNA.

351.1

HIPPOCAMPAL GLIOSIS IN A GENETIC MOUSE MODEL OF EPILEPSY. J.V. Brigande*, M. D. Albert*, and T. N. Seyfried. (Spon: G. Balkema) Dept of Biology, Boston College, Chestnut Hill, MA 02167.

El (epileptic) mice have an inherited convulsive disorder that resembles temporal lobe epilepsies in humans (T. Seyfried, and G. Glaser, Epilepsia 26: 143, 1985). The seizures in El mice begin spontaneously around 100 days of age and then persist throughout life. The immunocytochemical distribution of glial fibrillary acidic protein (GFAP) was studied in the brains of El and control C57BL/6J (B6) mice at adolescent (43 days) and adult (240-300 days) ages. GFAP was identified with an anti-GFAP polyclonal antibody (obtained from J. Goldman) using a peroxidase-antiproxidase procedure. The brain sections were counter stained with Mayer's hematoxylin. The mean number of GFAP-positive cells in the hippocampal stratum granulosum area dentatae was about 20 fold higher in the El mice (304 stained cells per square mm, N=4 mice) than in the B6 mice (13 stained cells, N = 4 mice) at adult ages. The GFAP-positive cells in El mice also differed qualitatively from those in B6 mice in having enlarged cell somas and thick, elongated processes. The gliotic reaction in the El mice was not associated with an observable neuronal loss. No differences were observed between the El and B6 mice in the cerebellum or cerebral cortex. There were also no major quantitative or qualitative differences in GFAP-positive cells between the El and B6 mice at the younger age. We conclude that the El mouse can serve as an excellent epilepsy model for studying the association between seizure activity and gliosis. (Supported by NIH grants 23355 and 24826).

TIME COURSE AND BRAIN DISTRIBUTION OF SEIZURE-INDUCED ASTROCYTE HYPERTROPHY IN RATS. W. Moore, N.W. Milgram, M. Khurgel and G.O. Ivy. Div. of Life Sciences, Univ. of Toronto, Toronto, Ontario, M1C 1A4.

Using immunohistochemical techniques, we have shown that patterns of astrocyte hypertrophy (AH) can be used to trace neural systems which undergo abnormally heightened levels of electrical activity (Neurosci. Abs. 13:1265). We now delineate the time course and more detailed brain distribution of this response. Rats were injected systemically with kainic acid (KA); both seizure time and survival time were varied. The brains were processed for immunoreactivity to glial fibrillary acidic protein (GFAP). Increased immunoreactivity to anti-GFAP was apparant in hippocampus (H) and in the outer layers of neo- and paleocortex within 5 hours after onset of seizure activity. At 24 hours, AH was extensive in these regions, and was also present in amygdala, dorsomedial (DM) and laterodorsal (LD) thalamic nuclei and nucleus reuniens (R); the deep layers of neo- and paleocortex were conspicuously devoid of heightened immunoreactivity. By 1 week following 3-5 hours of status epillepticus, H, DM, LD, R and deep layers of pyriform cortex contained necrotic cells. The relative amount and distribution of immunoreactivity was similar at 1 month but was decreased and more restricted at 4 months after the seizures. These results indicate that rapid, progressive and long lasting degenerative changes result from a single incident of seizure activity. Supported by NSERC.

EARLY MATURATION OF BRAIN DAMAGE AFTER FLUROTHYL SEIZURES. W.A. Kofke, J. Towfighi, J. Graybeal*, K. Houseman*, R.A. Hawkins. Dept. Anesthesia, Milton S. Hershey Medical Center, Hershey, PA 17033

Brain damage was studied in rats following flurothyl seizure (SZ). There were 4 groups: (1) 45 min (SZ), (2) 45 min control, (3) 45 min (SZ) with 2 h recovery, (4) 45 min control with 2 h recovery. Rats were anesthetized with isoflurane/N_2O, paralyzed, intubated and ventilated. After cannulation of the femoral vessels flurothyl was administered (5% for 1 min and 3% for 44 min) via Ethrane vaporizor. SZs were controlled by blood withdrawal. SZ was stopped with IV thiopental 15 mg/kg. Recovered rats were ventilated for 2 h. EEG power spectra were recorded by computer. Substantia nigra was examined for eosinophilic neurons. All sham brains were normal. 45 min status epilepticus produced fine nigral sponginess with 5-10 eosinophilic neurons per lesional area (PLA) on coronal sections thru the center of the lesion. After recovery nigral sponginess was considerably more course, with 20-25 eosinophilic neurons PLA. The size of nigral damage was similar in both groups. The results demonstrated that flurothyl can be given continuously and quantitatively with adequate oxygenation and control of blood gases. Damage apparent by light microscopy after 45 min SZ matures further after SZ has stopped and the convulsant is eliminated.

SYNAPTOGENESIS IN KINDLING. N. Hawrylak, F.-L. Chang, D. Treacy, K. R. Isaacs, W.T. Greenough, Neur. Beh. Bio. Prog., Coll. Med., Depts. of Psych., and Cell and Struct. Bio. Univ. of Illinois, Champaign, Il. 61820

Kindling has features that replicate certain forms of human epilepsy. The epileptiform activity induced by kindling is characterized by synchronous hyperactivity of neurons and in this respect it is similar to LTP, a model of learning/memory. Chang and Greenough (Brain Res. 309:35, 1984), have demonstrated an increase of shaft and sessile synapses, suggested intermediaries during synaptogenesis, following LTP.

We adopted an in vitro kindling model from Stasheff et al. (1985). Control or kindling stimulation was administered to the CA1 region of 5 pairs of adjacent rat hippocampal slices. We found a significant increase in the density of shaft (110%) and sessile ("stubby") spine (149%) synapses. The total number of synapses increased by only 0.9% which was not significant. The finding is comparable to those obtained with LTP.

These results support the view that kindling and LTP share a similar mechanism of modifying hippocampal circuitry. Our quantitative EM study strongly suggests that synaptogenesis occurs during kindling. These new synapses may participate in feedforward connectivity increasing synchronization.

Synaptic Reorganization of Mossy Fibers into Inner Molecular Layer in Human Epileptic Fascia Dentata. T.L. Babb, W.R. Kupfer* and J.K. Pretorius* Dept. of Neurology and Brain Research Institute. Univ. of Calif. Los Angeles 90024.

Reactive synaptogenesis ("sprouting") of recurrent excitatory mossy fibers into the inner molecular layer (IML) of fascia dentata (FD) of rats has been demonstrated to be correlated with hyperexcitability in vitro following prior in vivo kainic acid lesions of CA_3/CA_4 of the rat hippocampus (Tauck and Nadler, J. Neurosci. 1985, 5:1016). We used the Timm's sulphide procedure to stain for mossy fiber (MF) distribution and density in surgically-excised human hippocampi (n=13) known to be epileptogenic by prior in vivo recordings of focal electrographic/clinical seizure onsets. Cell counts of Niss1-stained sections demonstrated differing percents of cell loss in CA_3 and CA_4 which we correlated with the densities of increased mossy fibers sprouting into the IML. Controls (n=2) had no cell loss and no MF sprouting. IML light transmission was quantified objectively with an IBAS image analyzer by standardizing the tissue staining density for each of 6 sections/patient, and paired t-tests demonstrated statistical significance in all IML compared to MML of epileptic but not control tissue. There were no significant changes in outer ML or granule cell staining. The cell loss was correlated significantly for CA_3 ($R=.88$; $p<.01$) and a trend for CA_4 ($R=.50$; $p<.10$) with IML mossy fiber reinnervation. These results demonstrate that chronic hippocampal epilepsy may be attributed to abnormal recurrent excitation.

KAINATE INJECTION INCREASES GAD mRNA LEVELS IN HILAR NEURONS OF THE RAT HIPPOCAMPUS. S. Feldblum[1*], R.F. Ackermann[2], and A.J. Tobin[1,3,4] (SPON: S.R. Snodgrass). Departments of [1]Biology and [2]Neurology, [3]Molecular Biology Institute, and [4]Brain Research Institute, University of California, Los Angeles, CA 90024.

Decreased inhibition has often been suggested as a causal factor in focal seizure disorders. We are using in situ hybridization to investigate this hypothesis in the kainate-induced seizure model of rats. Our preliminary data suggests an increase, rather than the expected decrease in the production of the GABA synthetic enzyme, glutamate decarboxylase (GAD).

Injection of kainic acid (0.5 ug) into the CA3 pyramidal layer of the ventral hippocampus induces local neuronal damage and a long term increase in seizure susceptibility. Following kainate injection, the number of hippocampal neurons containing GAD mRNA did not change, but the hilar cells of the ipsilateral dentate gyrus showed markedly higher levels of GAD mRNA. We are now evaluating the relationship of these increases to the sprouting that follows the destruction of pyramidal cells by kainate.

MOSSY FIBER SYNAPTIC REORGANIZATION INDUCED BY REPETITIVE PENTYLENETETRAZOL SEIZURES. G. Golarai*, I. Parada* and T. Sutula, Department of Neurology, Neurosciences Training Program, University of Wisconsin, Madison, WI 53792.

Synchronous perforant path activation and limbic kindling by periodic electrical stimulation induce mossy fiber synaptic reorganization in the hippocampus as indicated by development of supragranular Timm granules in the dentate gyrus (Science 239:1147, 1988). To determine whether synaptic reorganization occurs in other models of epilepsy, the Timm method was used to study the mossy fiber pathway in rats that received pentylenetetrazol (PTZ), a convulsant that blocks GABA-mediated inhibition. Injections of PTZ (24 mg/kg IP) repeated every other day initially produced no behavioral effects, but eventually induced myoclonus followed by generalized seizures. Rats kindled to generalized seizures by PTZ demonstrated prominent supragranular Timm granules, but rats experiencing only myoclonus or no behavioral response to PTZ showed no evidence of mossy fiber synaptic reorganization. Five days after a generalized seizure evoked by a single dose of PTZ (50 mg/kg IP), there was no evidence of synaptic reorganization. As with electrical kindling, the supragranular Timm granules induced by PTZ kindling developed in the absence of overt neuronal damage. The results show that repeated activation of hippocampal pathways during PTZ seizures induces mossy fiber synaptic reorganization and demonstrate that synaptic reorganization also occurs in generalized models of epilepsy.

MOSSY FIBER SYNAPTIC REORGANIZATION DEVELOPS AND BECOMES PERMANENT IN PARALLEL WITH PROGRESSION OF KINDLING. J. Cavazos, I. Parada* and T. Sutula. Department of Neurology, University of Wisconsin, Madison, WI 53792.

Kindling induces mossy fiber synaptic reorganization as indicated by development of supragranular Timm granules in dentate gyrus (Science 239:1147, 1988). If synaptic reorganization has a role in development of kindling, supragranular Timm granules should develop in parallel with progression of evoked seizures and become permanent when long-lasting susceptibility to kindling is established (after Class V seizures). Rats received either perforant path or amygdala stimulation until 5-10 AD's, or 5, 10, 20, 30, 50 Class V seizures were evoked. Mossy fiber reorganization was classified at 18 hrs after the last seizure as follows: 0-no granules; 1-sparse granules; 2-prominent granules; 3-confluent granules. Timm granules were noted after 5-10 AD's and correlated with the number of seizures. To determine if synaptic reorganization at various stages of kindling was long-lasting, similar groups of rats were perfused 3 months after the last seizure. Supragranular Timm granules persisted at least 3 months after Class V seizures but were diminished 3 months later in the 5-10 AD group. Supragranular Timm granules develop and become permanent in parallel with the progression of kindling. Mossy fiber synaptic reorganization is reversible prior to Class V seizures, and may be a cellular mechanism of kindling.

ENHANCED ASPARTIC ACID RELEASE FROM HIPPOCAMPAL SLICES OF EPILEPTIC (El) MICE H.J. Flavin, A. Wieraszko, and T.N. Seyfried. Dept of Biology, Boston College, Chestnut Hill, MA 02167.

The Epileptic (El) mouse represents a natural , genetic model of epilepsy . An adult El mouse seizes spontaneously , but seizures can also be induced by twirling the animal by the tail . The release of putative neurotransmitters (Asp , Glu , and GABA) was studied in hippocampal slices from five El mice and five age-matched nonepileptic C57BL/6J (B6) mice . The average number of observed seizures per El mouse was 86 . Sets of hippocampal slices (400 μ thick) were incubated in a series of normal and high potassium (60 mM) buffers either in the presence or absence of calcium . The amount of transmitter released per sample was expressed as a percent of the total release from a given set of slices . For each transmitter , the basal release was subtracted from the potassium stimulated release in the presence and the absence of calcium . These differences were used to characterize the neurotransmitter release in each mouse strain . The data were expressed as the mean ± SEM . No differences were found between the El and B6 mice for the release of Glu (33.0 ± 2.6 / 34.8 ± 4.6) or GABA (25.0 ± 4.6 / 24.1 ± 4.1) . Asp release , however , was significantly higher in the El mice (39.7 ± 3.8) than in the B6 mice (21.4 ± 2.8) ($p < 0.01$) . Thus, enhanced Asp release may be related to seizures . RELEASE OF EXCITATORY AND INHIBITORY AMINO ACIDS FROM HIPPOCAMPAL SLICES IN TETANUS TOXIN CHRONIC EPILEPSY. J.G.R.Jefferys, P.Mitchell*, L.O'Hara*, J.Hardy*, S.Jordan*, M.Lynch*, J.Wadsworth*. St.Mary's Hosp.Med.Sch., London W2 1PG, UK and National Institute for Medical Research, London NW7 1AA, UK.

Injecting a minute dose of tetanus toxin into rat hippocampus causes a chronic epileptic syndrome. This has been attributed to a disruption of the release of the inhibitory transmitter, GABA. Hippocampal slices prepared from such rats during their active seizure phase retain spontaneous "interictal" and seizure-like actvity in vitro (Jefferys, 1986, J.Physiol.373,24P). Here we have prepared slices 10 to 14 days after injection in order to measure the K^+-evoked, Ca^{++}-dependent release of amino acid transmitters into the superfusate. Tetrodotoxin was included to prevent spontaneous activity. We measured the release of endogenous aspartate, glutamate and GABA by HPLC, and of preloaded radiolabeled D-aspartate and GABA by liquid scintillation counting. The effects of K^+, Ca^{++}, experiment number, and injection type were assessed using analysis of variance. Both glutamate and GABA showed a Ca^{++}-dependent, K^+-evoked release, but radiolabelled D-aspartate and endogenous aspartate did not. The release of GABA was impaired by the tetanus toxin treatment.

We conclude that: (1) radiolabelled D-aspartate is not a suitable marker for glutamate as a transmitter; (2) endogenous aspartate does not behave like a transmitter in this experiment; (3) transmitter release is impaired by the minute dose of intra-hippocampal tetanus toxin needed to induce a chronic epileptic focus.

PRESENCE OF INTRINSIC EPILEPTIFORM ACTIVITY IN HUMAN BRAIN SLICES. Steven A. Reid and Reinhard A. Palovcik, Departments of Neurological Surgery and Neuroscience, University of Florida, Gainesville, FL 32610.

We report the occurrence of spontaneous, epileptiform activity in isolated slices of human cortex, obtained in the course of surgery for epilepsy. Prior to removal, the location and extent of the epileptogenic area was mapped using arrays of electrodes placed on the cortical surface.

Tissue obtained in the operating room was quickly sliced into 400 micron thick sections and transferred to a slice transport system for removal to the laboratory. We have recorded electrophysiological activity from such slices for periods up to 20 hours following surgical removal from the patient. This tissue is part of a specimen that would normally be resected in the routine course of the neurosurgical procedure.

Slice epileptiform activity consisted of episodes of spontaneous large spikes with characteristics similar to those found on the corresponding corticogram and EEG. Slices from areas neighboring the epileptic focus showed little or no spontaneous activity and never exhibited the large spikes found in the area of the focus. During an epileptiform burst we were able to record extracellular complex spikes from layers 4 and 5 that were as large as 20 mv but were more often between one and five mv.

Evoked activity was recorded from layer five upon stimulation of layers three and four. Evoked spikes ranged from 100 microvolts to 3.65 millivolts and were between 1 and 4 msec. in duration. Evoked spikes could be completely inhibited by iontophoretic application of GABA. Application of a dilute ($5x10^{-6}M$) ferric chloride solution (a known topical epileptogenic agent) potentiated the size of evoked spikes. We have observed a similar potentiation of evoked action potentials in rat hippocampal slices with the application of iron. These findings suggest that relatively small volumes of cortical tissue are sufficient to initiate and maintain epileptic discharges in human focal epilepsy.

ELECTROPHYSIOLOGICAL PROPERTIES OF NEURONS IN THE SUPERFICIAL LAYERS OF HUMAN TEMPORAL NEOCORTEX. J.C. Lacaille, G.G.C. Hwa* and M. Avoli. MNI, McGill University and Université de Montréal, Que., CANADA

Intracellular recordings were performed in 34 neocortical neurons in slices of human tissue obtained from temporal lobe epileptic foci (n=9) or brain tumor (n=1). Cells were located within 750 um from the pia. Two neurons were of the fast spiking type but the majority (32/34) behaved like regular spiking neurons. They displayed resting membrane potential of 75 + 1.4mV, (mean + S.E.; n=31), Ri of 32 + 2.4 M (n:31), time constant of 13.8 + 1.1 ms (n=23) and action potential (AP) amplitude of 92+ 1.6 mV (n=30). In most neurons a single AP was followed by a fast afterhyperpolarization (AHP_f), a depolarizing afterpotential and a medium AHP (AHP_m). Following repetitive firing of APs, a slower AHP (AHP_s) also appeared. I-V relationships usually demonstrated inward rectification in the depolarizing direction, depolarizing sag and anomalous rectification. In 14 neurons focal electrical stimulation elicited an EPSP-IPSP sequence but did not induce burst firing. Rhythmic, spontaneous PSPs were observed occasionally (n=3). The properties of these neocortical neurons are similar to those observed in experiments performed in the neocortex of other mammalian species in normal conditions. Supported by MRC, FRSQ and Sloan Found.

INHIBITORY SYNAPTIC INPUT CORRELATES WITH INTRINSIC MEMBRANE PROPERTIES IN NEOCORTICAL PYRAMIDAL CELLS. L.R. Silva, Y. Chagnac-Amitai and B.W. Connors. Depts. of Neurology, Stanford University, Stanford, CA 94305, and Neurobiology, Brown University, Providence, RI 02912.

Layer 5b of rat SmI cortex has two types of pyramidal cells, as defined by their intrinsic membrane properties: bursting cells and regular-spiking cells. The local synaptic control of these cell types is of particular interest because many layer 5 pyramidal cells are output neurons, and bursting cells may play a key role in epileptic discharge.

Layer 5b pyramidal cells were recorded intracellularly in slices of rat SmI. PSPs were evoked by exciting nearby cells with L-glutamate (GLU) or acetylcholine (ACh) applied focally to the same layer. GLU evoked EPSPs and, often, prominent IPSPs in regular-spiking cells. In contrast, in bursting cells GLU evoked EPSPs but no apparent IPSPs. ACh applied near regular-spiking cells reliably evoked IPSPs (cf. McCormick & Prince, J. Physiol., '86). However, IPSPs evoked by ACh were very rarely observed in bursting cells.

These data demonstrate that: 1) both regular-spiking and bursting cells in layer 5b receive excitatory input from neighboring cells, and 2) regular-spiking cells, but not bursting cells, are strongly inhibited by layer 5 interneurons.

ANATOMICAL AND PHYSIOLOGICAL PROPERTIES OF BURSTING CELLS IN LAYER V_B OF SOMATOSENSORY CORTEX. Y. Chagnac-Amitai*, A. Agmon and D.A. Prince (SPON:K.L. Chow). Dept. of Neurology, Stanford Medical Center, Stanford, CA 94305.

Previous studies have shown a small population (<10%) of intrinsic bursting neurons in layers IV and superficial V of guinea-pig cortex (B.W. Connors et al. J. Neurophys. 48: 1302, 1982). We identified a second group of cells with these properties in layer V_B of brain slices from somatosensory cortex of rodents. Intracellular labelling with Lucifer Yellow and reaction with anti-Lucifer Ab's showed that these neurons are among the largest pyramids in layer V_B. Approximately 50% of the cells impaled at this specific cortical depth display bursting properties.

Spike generation of these neurons is distinguished by prominent DAPs, and directly evoked bursts of action potentials which are not blocked at membrane potentials positive to rest. More than one burst or repetitive doublets are generated during a depolarizing current pulse. Synaptic responses are characterized by a prolonged voltage-dependent depolarizing component and often by an absence of a visible fast IPSP.

TTX blocked all spiking activity and the underlying intrinsic depolarizations, while several Ca^{2+} blockers failed to block the burst generation. We speculate that layer V_B bursting pyramidal neurons function as amplifiers of cortical output under normal and epileptogenic conditions.

FURTHER STUDIES OF THE SUSTAINED DEPOLARIZATION OF SEIZURE-LIKE DISCHARGES IN IMMATURE CA3 HIPPOCAMPAL NEURONS. J.W. Swann, K.L. Smith, C. Yu. Wadsworth Ctr. for Labs & Res., NYS Dept. of Health, Albany, NY 12201

During prolonged (10-30 sec.) seizure-like discharges individual pyramidal cells undergo a sustained depolarization (SD). Synchronized afterdischarges ride the envelope of this depolarization. Previously we have shown that the SD is a separate physiologic process from the synchronized discharges and the product of localized synaptic interactions. To further examine its synaptic nature we have begun recording intracellularly with Cs microelectrodes. Whenever Cs is injected intracellularly a dramatic and unexpected 3-5 fold increase in the amplitude of the sustained depolarization is produced. Under current clamp conditions the enhanced SD uniformly reverses polarity near OmV. The amplitude of the SD is a monotonic function of membrane potential. These latter observations are consistent with the notion that the SD is a synaptic event.

Computer simulation using a membrane parallel conductance model predicts that if Cs blocks K+ conductances that are concurrent with excitatory synaptic currents a nonlinear increase in the amplitude of epsps occurs. Thus our results also suggest that a K+ conductance(s) plays an important role in limiting the degree of intracellular depolarization during seizure discharges. (Supported by NINCDS grant NS18309)

PAIRED INTRACELLULAR RECORDINGS REVEAL MONO- AND POLYSYNAPTIC EXCITATORY INTERACTIONS IN IMMATURE HIPPOCAMPUS. K.L. Smith*, J. Turner and J.W. Swann (SPON: W. Shain). Wadsworth Ctr. for Labs and Research, NYS Dept. of Health, Albany, NY 12201.

Isolated segments of CA3 subfield were taken from 10-15 day old rats. Epileptiform activity was induced by bath application of 1.7 mM penicillin. When depolarizing current was applied to single neurons, (both bursting and fast spiking) 60% of these cells initiated epileptiform discharges. Once a cell initiated seizure-like discharges a second cell was impaled. Synaptic interactions occurred in over 50% (16/30) of these pairs. One pair was electrically coupled. Two pairs had monosynaptic epsps and three pairs interacted in both directions. One cell produced a monosynaptic epsp with an amplitude of 3.14mV, a latency to onset of 1.23 msec, a latency to peak of 7.2 msec and a probability of 92%. In several respects our results differ from those obtained in the mature hippocampus. The most striking difference is the higher frequency of synaptic interaction in paired neurons. We suggest early development of local circuits is characterized by an enhanced degree of synaptic interaction. Such a maturational difference may explain why the immature hippocampus is more susceptible to seizure-like activity. The anatomical correlates of these synaptic interactions are under investigation. (Supported by NS18309; RR02984)

351.17

MOSSY FIBER LESION DOES NOT PROTECT CA3 HIPPOCAMPAL PYRAMIDAL CELLS FROM KAINIC ACID BY REDUCING KAINATE RECEPTOR DENSITY. J.P. Vicedomini, M.M. Okazaki and J.V. Nadler. Dept. Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710.

Intracerebroventricular (i.c.v.) administration of kainic acid (KA) to rats provokes limbic seizure activity associated with neuronal degeneration. CA3 hippocampal pyramidal cells are exceptionally vulnerable to i.c.v. KA. Previous studies demonstrated that the vulnerability of these neurons depends upon an intact mossy fiber innervation, because a prior lesion of this pathway protected the denervated CA3 pyramidal cells from destruction. A mossy fiber transection was effective immediately, within 10 min, suggesting that the protective effect resulted from cessation of impulse flow along the mossy fiber pathway. The present study tested an alternative hypothesis: namely, that the mossy fiber lesion led to a rapid down regulation of kainate receptors in area CA3.

The mossy fiber pathway of the rostral hippocampal formation was transected unilaterally with a Scouten wire knife and the rats were sacrificed 10 min, 2 h or 6 d later. To obtain autoradiographic images of kainate receptor binding, unfixed brain sections were incubated with [^{3}H]KA and apposed to ^{3}H-sensitive Hyperfilm for 4 weeks.

In agreement with Represa et al. (Neuroscience, 20, 739 (1987)), the mossy fiber lesion substantially reduced kainate receptor binding in stratum lucidum of area CA3 within 6 d. The reduction was observed only within that region of the rostral hippocampal formation in which CA3 pyramidal cells had been extensively denervated. Only modest effects of the transection, at most, were evident at the 10 min or 2 h survival times. Thus a rapid down regulation of kainate receptors probably does not account for the neuroprotective effect of a mossy fiber lesion. Protection most likely results from the interruption of impulse flow. This effect of the lesion might: (1) prevent KA from releasing a potentially damaging substance from the mossy fibers and/or (2) abolish a postsynaptic interaction between KA and one or more neuroactive substances released by the mossy fibers. (Supported by NIH grant NS 17771.)

SYNAPTIC INHIBITION AND THE PRODUCTION OF ICTAL DISCHARGES BY CHOLINERGIC AND ANTICHOLINESTERASE AGENTS IN RAT HIPPOCAMPUS. *F.J. Lebeda, T.H. Ton*, and P.R. Rutecki.* Sect. of Neurophysiol., Prog. in Neurosci., Dept. of Neurol., Baylor College of Medicine, Houston, TX 77030.

A variety of convulsants (*e.g.*, picrotoxin (PTX), 4-aminopyridine) produce brief (20-200 ms), synchronous, repetitive discharges in hippocampal slices whether or not the agent interferes with GABA-mediated inhibition. This study was conducted to determine the role of GABAergic transmission during the epileptiform activity induced by partial (bethanechol, oxotremorine and pilocarpine) and full (acetylcholine, muscarine and carbachol) muscarinic agonists (1-150 μM) as well as irreversible anticholinesterases (anti-ChEs; DFP or soman; 10-25 μM).

Besides producing brief (interictal) events within 30 min of exposure in the CA3 subfield, prolonged exposure (1-2 h) to these agents could produce repetitive ictal discharges — extracellularly recorded events lasting >2 s. A transition from interictal to ictal discharges also occurred within 30 min with the co-application of salines containing 7.5 mM K^+ or 5-10 mM Li^+. The ictal discharges were blocked following washout of the test agent or by the co-application of atropine (0.5-10 μM). The ictal events induced by the partial muscarinic agonists or by the anti-ChEs were converted to interictal discharges by the co-application of 10-50 μM bicuculline or PTX. In contrast, higher concentrations of PTX (200-500 μM) were required to convert the ictal events induced by full agonists. The amplitudes of the intracellular correlates of both the interictal and ictal events reversed in polarity at relatively negative potentials (*ca.* −15 mV). These results suggest that inhibitory neurotransmission plays a role in the generation of the interictal and ictal events induced by agents that modify cholinergic neurotransmission. NORADRENERGIC MODULATION OF EPILEPTIFORM ACTIVITY IN THE HIPPOCAMPUS. *P.A. Rutecki, T.H. Ton*, F.J. Lebeda.* Sect. of Neurophysiol., Dept. of Neurology, Program in Neurosci., Baylor Col. of Med., Houston, TX 77030.

Noradrenergic agonists have been characterized as having both pro- and anticonvulsant effects. We have examined the effects of norepinephrine (NE) and selective α- and β-adrenergic receptor agonists and antagonists on the frequency of epileptiform discharges that were recorded extracellularly in the CA3 region of rat hippocampal slices. The discharges were produced by the bath application of saline containing 10 μM picrotoxin (PTX) or 7.5 mM extracellular potassium (high K^+).

In high K^+ saline, coapplication of 5 μM NE increased the frequency of spontaneously occurring discharges by 37% while 30 μM NE slowed the frequency by 60%. The PTX-induced discharge frequency was significantly slowed by 10-30 μM NE (26-47%); however, at low NE concentrations there was not a statistically significant increase in frequency. In both model convulsants, isoproterenol (0.1-1 μM), a β agonist, significantly increased the frequency. The increase in frequency induced by NE or isoproterenol was blocked by timolol (0.1-1 μM), a β receptor antagonist. Timolol, however, did not block the slowing in frequency produced by 10-30 μM NE. Conversely, the frequency suppression seen with higher concentrations of NE was blocked by the α antagonist phenoxybenzamine (10 μM). Phenoxybenzamine also revealed a significant frequency enhancement of 1-10 μM NE for PTX-induced discharges (30-84%).

These results demonstrate a concentration-dependent effect of NE on the frequency of high K^+- and PTX-induced epileptiform discharges *in vitro*. At low NE concentrations the increase in frequency appeared to be a β-adrenergic effect, and the decrease in frequency seen at higher NE concentrations appeared to be mediated by α-adrenergic receptor activation. (Supported by the Klingenstein Fund, USAMRDC DAMD 17-86-C-6029, AFOSR 85-0178, and NIH grants NS11535 and NS01049.)

NEUROTOXICITY IN DEVELOPMENT II

352.1

INTERACTION OF ETHANOL WITH PHOSPHOINOSITIDES DURING BRAIN DEVELOPMENT. L. G. Costa and W. Balduini*. Dept. of Environmental Health, University of Washington, Seattle, WA 98195.

The developmental profile of muscarinic receptor (MR)-stimulated phosphoinositide (PI) metabolism in rat brain is strikingly similar to that of the rat brain growth spurt (JPET 241:421, 1987). This has led to the hypothesis that the enhanced hydrolysis of membrane PIs by cholinergic agonists during this period may have a relevant role in cell proliferation and differentiation. We have investigated whether exposure of rat pups to ethanol (ETOH) during the brain growth spurt (4 g/kg/day from day 4 to day 10) would alter MR-stimulated PI metabolism in cerebral cortex slices. ETOH caused long lasting microencephaly but did not alter the pups' body weights compared to an equally-handled, sucrose fed group of animals. MR-stimulated PI metabolism was significantly reduced in ETOH-exposed rats on day 7 but not on days 12, 20 and 45, when microencephaly was present. A similar treatment in adult rats did not cause these alterations despite similar blood ETOH concentrations (approx. 250 mg/dl). In vitro experiments indicated that ETOH (150-300 mM) inhibited MR-stimulated PI metabolism in cerebral cortex from 7 day-old, but not adult, rats. These results confirm that the developing brain is particularly sensitive to the effects of ETOH and suggest that the PI system coupled to MR could represent a relevant target for its neurotoxicity. SYNAPTOTOXIC EFFECTS OF CHRONIC PERINATAL ETHANOL EXPOSURE DEMONSTRATED In Vivo. J.L. Walewski*, M. Okamoto and R.L. DeGrandchamp* Dept. of Pharmacology, Cornell Univ. Medical College; New York, N.Y. 10021 and Neurotoxicology Lab, Rutgers Univ.; New Brunswick, N.J. 08903

We postulate that low-level Chronic Perinatal Ethanol Exposure (CPEE) selectively affects some processes involved in synapse formation. We report an animal model demonstrating the synaptotoxic effects of CPEE, using an ETOH dose below the threshold for Fetal Alcohol Syndrome. ETOH 3% v/v mixed with high-protein liquid diet (HPLD) (Bio-Serve) was the only diet source. The controls received isocaloric sucrose (HPLD). ETOH R_x began on day 8 of pregnancy. ETOH 3% v/v did not sig. reduce the body weights and diet consumption of the dams, nor the gross growth of the ETOH pups vs. controls. Blood ETOH conc., determined by NAD-NADH assay, was approx. 50 mg % in both the dams and pups throughout the treatment. Standard neuromuscular twitch preparations utilizing the sciatic nerve-gastrocnemius muscle, were done on 1,2 and 3 week old pups in vivo. The physiologic and pharmacologic functional tests indicated that: [1] the ETOH pups had a longer rise time of single twitch contraction (2 wk., 120% ; 3 wk., 122% of control). This disappeared with direct muscle stim. in a curarized prep., indicating that the deficit is neuronal. [2] 75 Hz. indirect stim. revealed faster tetanic fatigue by ETOH : T1/2 for C = 9.41 +/- 1.83 sec. vs. E = 4.51 +/- 0.23 sec.. [3] Physostigmine twitch potentiation in 3 wk. ETOH pups, was enhanced approx. 2 fold.

Light microscopic endplate morphology revealed cholinesterase and neurofilaments in situ. In the 2 and 3 wk. ETOH pups, the terminal branches were swollen and their number reduced; while endplate length was shortened by 16.3% and 23%, respectively. These data indicate a selective synaptic pathology by CPEE. IBOTENIC ACID INDUCED DEMYELINATION AND INFLAMMATORY RESPONSE. P.J. Coffey*, V.H. Perry* and J.N.P. Rawlins* (SPON: D. Gaffan). Dept. of Experimental Psychology, Oxford University, England.

Demyelination induced by ibotenic acid within the central nervous system coincided very closely with the borders of aregion containing a high density of leucocytes (Coffey et al., Neurosci Letts., 84: 178, 1988). To assess further the correlation between the extent of the recruited haemopoietic cells and demyelination after ibotenic acid injections, rats were exposed to either 700 rads, 900 rads, 900 rads with a lead shield covering the head or no irradiation, and were then given ibotenic acid injections (0.2µl of 10µg/µl) into the medial septum. The number of neuronal cells, non-neuronal cells and those expressing the CR3 antigen (microglia, macrophages and neutrophils), as revealed by OX42 immunocytochemistry, were counted in the region of the lesion. Demyelination was measured by an independent observer in ajacent sections. This study showed that there was concomitant reduction in demyelination and cell recruitment after exposure to irradiation, but no change in neuronal loss. These results support the view that demyelination following ibotenic acid injections is due to a non-specific or "bystander" effect of the inflammatory response. The integrity of the blood-brain barrier will also be discussed.

352.4

IMMUNE SYSTEM RESPONSE TO STERILE LESIONS IN RAT BRAIN. H. Akiyama*, S. Itagaki*, P.L. McGeer, and E.G. McGeer (SPON: D.D. Greenwood). Kinsmen Lab, Dept Psych, Univ of B C, Vancouver, Canada, V6T 1W5.

Expression of major histocompatibility complex (MHC) class I and class II surface glycoproteins was observed immunohistochemically in rat brain following sterile lesions. These were induced by epidural kainic acid application, lateral hypothalamic 6-hydroxydopamine injections, or intracortical needle cuts. Round to ameboid cells expressing both class I and class II MHC antigens as well as leukocyte common antigen (LCA) were observed quickly to invade the necrotic central area of the lesion. In areas peripheral to the necrosis, microglia became reactive. These microglia displayed MHC class I antigens as early as 1-2 days after lesioning, and class II antigens at 4-5 days. Class I expressing microglia outnumbered class II but many expressed both MHC classes and were also positive for LCA. MHC expression peaked in 1-2 weeks and gradually declined thereafter. After 3-6 months, the presence of these surface markers on microglial cells had almost disappeared. Reactive astrocytes proliferated near the lesion site and were still prominently expressing glial fibrillary acidic protein after 6 months. They were not observed to express either class I or class II MHC antigens. Round cells positive for the PAN-T lymphocyte marker were also observed in the lesioned area suggesting a significant role for T lymphocytes.

352.5

NEONATAL EXPOSURE TO THE LIMBIC-SYSTEM NEUROTOXIN, TRIMETHYLTIN (TMT), IMPAIRS WORKING MEMORY IN PREWEANLING RATS. C.V. Pickens* and M.E. Stanton (SPON: M.I. Gage). Northrop Services, Inc. and Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC 27711.

Neonatal exposure to TMT causes a loss of hippocampal pyramidal cells and impairs cognition in adult animals. Relatively little is known, however, about the effects of neonatal TMT on cognition in infant animals. Here we report that neonatal TMT administration prevents delayed-alternation learning in 18-day-old rat pups.

Long-Evans rat pups received an i.p. injection of either TMT (6 mg/kg) or saline vehicle on postnatal day ten (PND 10). These pups were then tested on PND 18 for their ability to learn two tasks in a T-maze. One task was discrete-trials-delayed-alternation (working memory) and the other was a simple spatial discrimination (reference memory). Testing occurred on PND 18 because this appears to be the age at which normal rat pups can first perform the alternation task (see Green and Stanton, Behavioral Neuroscience, in press, for results and methodological details). TMT transiently impaired learning, but not assymptotic performance, of spatial discrimination, but utterly abolished learning of delayed alternation.

These results indicate that TMT can be shown to impair cognition during development; and suggest a role for limbic system maturation in the ontogeny of working memory.

ENRICHED REARING ATTENUATES PERFORMANCE DEFICIT INDUCED BY NEONATAL MONOSODIUM GLUTAMATE (MSG) INJECTIONS. S. Fong*, M.J. Saari, J. Armstrong*, and A. Shivji. Neuroscience Research Unit, Nipissing Univ. Coll., North Bay, Ontario, P1B 8L7.

Recovery of function following some brain lesions can be influenced by the post-lesion rearing environment. We report here that impaired performance in the place navigation task following neonatal MSG injections is also sensitive to the consequent rearing environment.

Male Wistar rat pups were cross fostered at birth and injected daily with MSG (4g./kg.) on days 2 to 12 after birth. Control pups received an equivalent volume of saline. Following weaning at 25 days the rats were randomly allocated to enriched or isolated rearing to yield 4 treatment groups (MSG-Enriched; MSG-Isolated; Saline-Enriched; Saline-Isolated).

After 35 days in their respective rearing environments all rats were weighed and tested in an open field. Activity (grid crosses) and rearing were recorded in an open field. The rats were then tested using the place navigation task.

Multivariate analysis of variance of the mean daily latency in the place navigation task, open-field activity and rearing and body weight measures revealed a significant two way interaction of the rearing environment by MSG-Saline manipulations. Univariate F tests and associated multiple comparisons showed that the MSG-Isolated rats were profoundly impaired in the place navigation task while the MSG-Enriched rats performed nearly as well as saline injected controls. The weight measure also revealed a significant univariate F for the interaction. The open-field measures contributed significant main effects for rearing environment (the isolated rats reared less than enriched) and that neonatal MSG treatment increased open-field activity.

352.7

NEOVASCULARIZATION IN THE KAINIC ACID-INDUCED LESIONS OF RAT STRIATUM. AN IMMUNOHISTOCHEMICAL STUDY WITH LAMININ. K. Shigematsu*, H. Kamo*, I.Akiguchi*, M. Kameyama*, H. Kimura*, P.L. McGeer* and E.G. McGeer* (SPON:H. Ando). Dept. of Neurology, Faculty of Medicine, Kyoto University, Kyoto 604, JAPAN.

Vascular changes that follow stereotaxic injection into the rat striatum of kainic acid, excitatory neurotoxin, were studied at different time intervals after the lesion by laminin immunohistochemistry. 2 µg of kainic acid was dissolved in 1 µl isotonic saline and was injected into the striatum of male rats weighting approximately 300g of the Wistar strain. At various times after treatment (2, 7, 28 days and 3 months) the animals were sacrificed by transcardial perfusion with a fixative containing 4% paraformaldehyde under deep anesthesia. The brains were removed and sections 20 µm thick were prepared on cryostat. Tissues were stained for laminin, tyrosine hydroxylase(TH) and glial fibrillary acidic protein(GFA) using standard immunohistochemical procedures. Immunohistochemistry using antibodies against laminin, a basement membrane glycoprotein, revealed striking neovascularization in the lesioned striatum. The increased laminin-immunoreactivity remained at least up to 3 months after the operation. Rapid and profound changes in striatal astrocytes were demonstrated by increased GFA-immunoreactivity, whereas TH-immunoreactive axons in the injected region did not markedly differ from the control.

LONGTERM EXPOSURE TO PCBs ALTERS DOPAMINE CONCENTRATIONS IN MONKEY NEOSTRIATUM. R.F. Seegal, K.O. Brosch*, R. Okoniewski* and B. Bush*. Wadsworth Labs, N.Y.S. Dept. of Health, Albany, NY 12201.

PCBs decrease striatal dopamine (DA) concentrations in laboratory rodents (Agrawal et al., 1981; Seegal et al., 1986). However, doses used were greater than those that induce behavioral change in monkeys (Bowman et al., 1978; 1981).

To determine whether low-dose PCBs alter DA function in a species neurochemically similar to humans, we exposed adult male Macaca nemestrina (pig-tailed macaque) daily to corn-oil (controls) or corn-oil + PCBs (Aroclor 1260, 800 to 3200 ug/kg/day) for 26 weeks. Monkeys were then deeply anesthetized and sacrificed by overdose. Brains were then removed, chilled in saline, frozen in dry-ice and stored at -80°C.

Coronal 2-mm sections corresponding to plates A23 to A6 of Winter et al. (1969) were cut. Two-mm punches (mean wet weight = 8 mg) from the caudate (CA), putamen (P) and globus pallidus (GP) were homogenized in ice-cold perchloric acid + EGTA. Supernatants were analyzed by HPLC.

Monkeys remained healthy and active throughout PCB exposure. No signs of toxicity were noted. However, PCB exposure significantly altered neostriatal DA concentrations: DA concentrations increased in CA and P at the two middle doses and decreased in GP at all doses. In addition, DOPAC/DA ratios decreased, indicative of decreased neuronal activity.

Thus, exposure to PCBs alters DA-ergic function in primate neostriatum. These results may explain movement disorders in chlorinated hydrocarbon exposed humans (Klawans et al., 1987). Supported in part by NIEHS Grant #3884.

352.9

POLYCHLORINATED DIBENZOFURANS ALTER CENTRAL BIOGENIC AMINE FUNCTION IN ADULT RAT. K.O. Brosch*, R.F. Seegal and B. Bush*. (SPON: D. Martin). NYS Dept. Health, Albany, NY 12201.

Polychlorinated biphenyls (PCBs) are often contaminated with the more toxic polychlorinated dibenzofurans (PCDFs). Furthermore, municipal waste incinerators produce significant levels of PCDFs (Rizzardini et al.,1983). We recently demonstrated (NSA, 13:933, 1987) that PCDFs, at concentrations as low as 2 ppb, are capable of altering in-vitro catecholamines in pheochromocytoma (PC-12) cells. In order to determine whether similar changes take place in an intact mammalian preparation, we exposed laboratory rodents to PCDFs alone or in combination with PCBs.

PCDFs were separated from PCBs by Florisil-column chromatography; the separation was validated using GC-MS. Adult male Wistar-derived rats were given ad-lib access to adulterated chow containing 1000 ppm PCBs and/or 20 ppb PCDFs (equivalent to the PCDF contamination found in the original PCB mixture) for 28 d. Following exposure, the animals were sacrificed, their brains rapidly removed, dissected and homogenized in ice-cold perchloric acid + EGTA. Biogenic amines and metabolites were analyzed by HPLC.

Exposure to either PCBs or PCDFs significantly decreased metabolite to neurotransmitter ratios (biochemical measures of neuronal activity). In striatum and lateral olfactory tract DOPAC/DA and HVA/DA were decreased; in hippocampus, hypothalamus and brainstem 5-HIAA/5-HT ratios were decreased.

These in-vivo results confirm earlier in-vitro findings and suggest that PCDFs may prove to be neurotoxins of significant public health concern.

Supported in part by EPA Grant #8138.

352.10

AN EVALUATION OF GLUTAMATE INVOLVEMENT IN THE DEVELOPMENT OF THE SOMATOTOPIC ORGANIZATION OF THE NEOCORTEX OF THE RAT. Karl F. Jensen, Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC 27711

Neonatal administration of glutamate dramatically alters the development of the visual and auditory systems. To evaluate its effect on the developing somatosensory system, 4mg/g was administered daily from PND-0 to PND-5. On PND-7 the animals were anesthetized, perfused and the cortex was removed, flattened, tangentially sectioned and reacted for cytochrome oxidase (CO) activity. The somatotopic pattern of CO activity in glutamate treated animals appeared normal. In additional animals, CPP, a potent glutamate antagonist, was administered daily (4mg/kg) from PND-0 to PND-5. The somatotopic pattern of CO activity in CPP treated animals appeared normal. The observation that neither glutamate excitotoxicity nor glutamate antagonism alters development of somatotopic organization suggests that, in contrast to the visual and auditory systems, glutamate does not play a major role in patterning afferents in the somatosensory system.

352.11

EFFECTS OF METHYLMERCURY ON EXCITATORY AMINO ACID RECEPTORS IN THE MOUSE CEREBRUM. B. H. Choi, J. Lincoln*, P. Amodei* Neuropathology, Univ. of Calif. Irvine, Irvine, CA 92717.

Methylmercury (MeHg) is a highly neurotoxic environmental pollutant that causes selective damage to neurons of the calcarine cortex and precentral gyrus of the cerebrum and granule cells of the cerebellum in adults. However, the precise mechanism of neurotoxic damage or selective vulnerability of specific neuronal groups in MeHg poisoning remains unclear. In order to investigate the role of excitatory amino acid transmitter pathways in neurotoxic effects as well as selective neuronal damage in MeHg poisoning, we have examined the status of the N-methyl-D-aspartate (NMDA) kainate (KA) and alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors in brains obtained from MeHg poisoned young adult mice and controls by the use of in-vitro radioautographic methods, and analyzed with a microcomputer-assisted imaging system.

A significant increase in density of both AMPA and KA was observed in the parietal cortex of MeHg groups as compared to controls. Also noted was a significant decrease in NMDA density in the frontal cortex of MeHg groups. This modification in receptor density may represent excitotoxic damage and/or plastic changes following MeHg poisoning.

These results suggest that one of the pathways of MeHg neurotoxic damage may be mediated through excitatory amino acid transmitter systems.

EFFECTS OF KAINIC ACID LESIONS ON AFFERENT INPUTS TO THE LATERAL SEPTAL REGION. P.W. Nance and D. M. Nance. Depts. of Medicine and Anatomy, Dalhousie Univ., Halifax, N.S., B3H 4H7, Canada.

Kainic acid (KA) lesions of the lateral septal area block the anterograde transport of anatomical tract tracers from the lateral septal region, but have minimal effect on the retrograde transport of tracers from the lesion site (Hopkins, et al, *N.S. Abst*,**10**: 423,1984). This is consistent with the concept that toxic lesions destroy cell bodies whereas fibers of passage and axon terminals are spared. The septal area receives a variety of neurochemically specific inputs and among these, leucine enkephalin, substance P, serotonin, and neurotensin have been localized in terminals of the lateral septal region. To examine further the specificity of KA, unilateral or bilateral KA lesions were produced in the lateral septal area of rats and following a 3-10 week survival period, animals were perfused with 4.0% paraformaldehyde. Sections (40 µm thick) were agitated overnight in rabbit antibodies to either leucine enkephalin (1/10000), serotonin (1/3000), substance P (1/10000) or neurotensin (1/7500) (ImmunoNuclear, Stillwater, MN) containing 1.0% normal goat serum and 1.0% Triton-X 100 in PBS. The immunoreactivity was visualized using either the ABC technique (Vector Labs.) or PAP technique (Cappel) with DAB as the chromogen. Localization of leucine enkephalin-, substance P-, neurotensin- and serotonin-like immunoreactivity in the septal region following a KA lesion indicated that all four transmitters were present in axons and terminals within the lesion sites and the staining appeared more intense than on the unlesioned side of the septum or relative to unoperated rats. The immunoreactive fibers were compressed as though a similar number of afferent fibers were distributed throughout a much smaller neuropil. This apparent constriction of numerous axons and terminals within the compressed KA lesion site was similar for all four transmitters. Thus, KA has a toxic effect on cell bodies within the lateral septal area, but spares chemically specific afferent fibers and terminals. Supported by M.R.C. of Can.

352.13

THE EFFECTS OF ASPARTAME INGESTION ON THE DEVELOPMENT OF THE VISUAL SYSTEM IN GUINEA PIGS. D.A. Burstein*, T.H. Milhorat, L.A. Scribani *and D.L. Dow-Edwards. Laboratory of Cerebral Metabolism, Dept. of Neurosurgery, State University of N Y, Health Science Center at Brooklyn,450 Clarkson Ave., Brooklyn, N.Y. 11203.

Aspartame (Nutrasweet®) is commonly used by pregnant women as an artificial sweetener. Once ingested, aspartame is metabolized into phenylalanine, aspartic acid and methanol. Methanol is known to be toxic to the visual system in the adult guinea pig and human. Therefore, we have investigated the toxicity of aspartame with regard to the developing visual system in the guinea pig.

Virgin Duncan-Hartley guinea pigs were time mated in our laboratory. We administered aspartame at 500, 250, or 0 mg/kg body weight in sesame oil by mouth between day 1 of gestation and day of birth. A non-treated control group was also maintained.

At the 55th day of gestation some animals were sacrificed, fetal orbits were removed, fixed in buffered formalin, and sectioned for histopathological analysis. Thickness of retinal layers and alterations of cellular morphology were quantified. Other animals were allowed to give birth and the offspring were evaluated at 30 days of age for functional activity of brain structures within the visual system using the quantified deoxyglucose method (Sokoloff).

The results of the histopathological studies and brain functional activity will be correlated.

Supported by NIH Grant NS22766

352.14

DEVELOPMENTAL TOXICITY OF ASPARTAME IN THE GUINEA PIG **D.L. Dow-Edwards, L.A Scribani*, L.A Freed* D.E Adler* and T.H Milhorat; Laboratory of Cerebral Metabolism, Dept. of Neurosurgery, State University of N.Y., 450 Clarkson Avenue, Brooklyn, N.Y. 11203.**

Aspartame (eg Nutrasweet ®) is an artificial sweetening agent which is widely used by pregnant women. Previous reports have found developmental toxicity in rats only at very high doses. However, the guinea pig may be a better model for human toxicity than the rat.

Virgin Duncan-Hartley guinea pigs were time mated in our laboratory and assigned to recieve either 500 or 250mg aspartame/kg body weight in a sesame oil vehicle or the vehicle alone by mouth between day 1 of gestation and the day of birth. A nontreated control group was also maintained. On the day of birth pups were weighed, sexed and allowed to remain with their natural mother.

At 15-16 days of age, odor aversion testing was carried out using LiCl. At 30 days of age, brain glucose metabolic activity was quantified using the deoxyglucose method of Sokoloff et al. (J. Neurochem. 28: 897, 1977).

Deficits in odor aversion testing were found to be correlated with altered patterns of brain glucose metabolism in the exposed offspring compared to the controls.

Supported by NIH grant NS22766

DISSOCIATED NIGRAL CELL SUSPENSIONS GRAFTED TO WEAVER STRIATUM: A POSSIBLE ROLE FOR HETEROTOPIC DOPAMINERGIC DENDRITES? **L. C. Triarhou, P. Brundin,* G. Doucet, A. Björklund and B. Ghetti. Dept. of Pathology (Neuropathology) and Program in Medical Neurobiology, Indiana Univ. Sch. of Med., Indianapolis, IN 46223 and Dept. of Medical Cell Research, Univ. of Lund, S-223 62 Lund, Sweden.**

Nigral cell suspensions prepared from the ventral midbrain of normal mouse embryos were implanted to the striatum of adult weaver mutants. Prior to perfusion, which was carried out 80 days after grafting, host striata were deprived of the intrinsic dopamine (DA) projection through local injection of 6-OHDA into the ipsilateral substantia nigra (SN). Grafts contained 100-700 tyrosine hydroxylase (TH) immunoreactive neurons. TH axon terminals were found in synaptic contact with unlabeled spines, dendrites and somata in the grafted striatum after 6-OHDA lesions of the SN, providing evidence that innervating axons originated in the graft. TH dendrites extended from the grafts into the striatum as well; they received synaptic input from unlabeled axon terminals; further, they were apposed to unlabeled neurons of the host. In the heterotopic position DA dendrites may, through the release of DA, participate in homologous physiological functions, such as regulation of the activity of grafted DA and non-DA SN neurons and of the release of transmitter from afferent axons to the graft; one may speculate that, in addition, DA dendrites could serve heterologous functions, such as modulation of the activity of corticostriatal fibers and influence of the physiological state of host striatal neurons.

353.2

RECOVERY OF LEARNING AND MOTOR DISFUNCTIONS BY STRIATAL FETAL BRAIN TRANSPLANTS IN PREVIOUSLY LESIONED ADULT RATS. A.L. Piña-Hernández,* H.Fernández-Ortega*, M. Gómez-Chavarín*, and F. Bermúdez-Rattoni. Instituto de Fisiología Celular, UNAM. P.O. Box 70-600. 04510 México.

In this study we demonstrate that fetal striatum grafts can induce recovery of a previously disrupted retention of passive avoidance (PA) and normal motor activity. Male wistar rats were divided into an unoperated control group and a group that sustained large electrolytic lesions in the striatum (ST). All animals were trained to avoid foot shocks in a shuttle box, followed by three retention trials, they were also measured for motor-activity on stoelting boxes. Lesioned animals were divided in two groups, one group received fetal striatal grafts (STG) and the other remained as a lesioned control group (STLx). Eight weeks later all the measurments and training were repeated as mention above.Behavioral results pretransplant showed that striatal lesions produced a significant disruption on PA retention,and enhancement of motor activity. Postransplant results showed a significant improvement of the PA retention and motor activity for the STG but not the STLx group as compared with the unoperated control group. Histological (Nissl) and acetylcholinesterase histochemistry analysis revealed that the ST grafts were well integrated into the host ST, but with less acetylcholinesterase reaction than the host ST tissue. These results support the hypothesis that the fetal brain transplants can restore motor and cognitive disfuctions.

353.3

CONTRALATERAL GRAFTS OF FETAL SUBSTANTIA NIGRA, INDUCE A DECREASE IN ROTATIONAL BEHAVIOR IN NIGRO-STRIATAL LESIONED RATS. J.L. Mendoza-Ramírez*, R. Aguilar-Roblero*, J. Vera* A. Zainos-Rosales*, R. Drucker-Colín. (SPON: H. Brust-Carmona). Depto. de Neurociencias, Instituto de Fisiología Celular, UNAM. México.

This study determined whether fetal substantia nigra (SN) grafts placed on the lateral ventricle contralateral to the lesion, produces improvement in the behavioral deficits produced by unilateral substantia nigra lesions. 10 Rats were injected with 8 ug/4ul of 6-OHDA into the medial forebrain bundle (MFB). Apomorphine-induced rotation was determined 10, 20, 30 days after the lesion. On post-lesion day 34, 5 rats received fetal solid SN graft (E16) in the lateral ventricle contralateral to the lesion. Rotational behavior was determined at 10, 20, 30, 45 and 60 days after the graft and from there on each 15 days for the next 4 months. Rats were sacrificed and the tyrosine hydroxylase (TH) and dopamine-B-hydroxylase (DBH) reactivity were determined. Grafted group performed less rotational behavior (RB) (down to 50%) about 145 days after the graft, whereas the sham operated group increased rotation frequency.

We propose that humoral release of neuroactive substances produces a reduction in hypersensitive dopamine-receptors, causing them to return to a more normal level following the lesion. Spiperone-Binding tests are currently underway in our laboratory to this suggestion.

353.4

RECOVERY OF MOTOR IMPAIRMENTS AND TH-IR IN AGED RATS WITH INTRAVENTRICULAR ADRENAL TRANSPLANTS. R. Drucker-Colín, F. García-Hernández*, R. Vega-Carbajo*, M. Dávila and O. Prospéro-García. Depto. de Neurociencias, Instituto de Fisiología Celular, UNAM, México.

The motor performance of aged rats suggests dopamine deficiency, since apomorphine can transiently revert motor inabilities. This suggests that deterioration of brain dopamine (DA) neurotransmission may contribute to some of the movement disorders of advanced age. This work was carried out to determine the capacity of adrenal medullary grafts to revert such motor inabilities. The effects of the grafts on nigro-striatal tyrosine hydroxylase immunoreactivity (TH-IR) was also examined. Rats of 4 and 22 months of age were tested for swimming capacity for 15 minutes. Each aged rat was then transplanted with adrenal medullary tissue into the lateral ventricle near the caudate. The effect of the graft on swimming behavior was tested 10, 20, 50 days after the transplant. The performance of grafted aged rats was significantly improved. Aged animals adopted a more horizontal position, and swimmed more vigorously and successfully. TH-IR was also improved, since the relative optical density in the nigro-striatal pathway reached levels similar to those of young rats. These data suggest that grafting adrenal medulla in aged rats may cause a shift in the relative amounts of DA. Moreover, the improvement in motor coordination suggests that adrenal implants restore age related impairments in neurotransmission.

353.5

PARTIAL REVERSAL OF POST-LESIONAL CHANGES IN THE DOPAMINE-DENERVATED STRIATUM OF THE RAT BY DOPAMINERGIC NEURONS-ENRICHED IMPLANTS.
J.P. Herman , M. Le Moal and N. Abrous (SPON: B. Dufy). INSERM U259 - Université de Bordeaux II., 33077 Bordeaux, France.

Lesion of the nigrostriatal dopaminergic (DA) pathway induces a variety of morphological and functional changes in the denervated striatum, among others DA receptor upregulation, an increase of enkephalin (ENK) synthesis and content, of neuropeptide Y (NPY) content and -following neonatal lesion- serotoninergic (5HT) sprouting. The influence of DA-enriched mesencephalic grafts on these changes were tested.

Grafts were implanted into the denervated striatum in neonatal (PD6) or adult rats, 4 days after the unilateral destruction of the nigrostriatal DA pathway. Implanted DA neurons reinnervated the host striatum and reversed the rotational assymetry evoked by amphetamine in both age group 1 month after grafting. DA receptor hypersensitivity -as judged by apomorphine-induced rotation- was equally reversed by the grafts. Changes in ENK and NPY systems could be visualized by immunohistochemistry following the lesion in both age-group; however only the increase in NPY was antagonized by the graft, while that of ENK was unifluenced. Likewise 5HT sprouting evoke by neonatal lesion was present, irrespective of the presence of the grafts. The results suggest an unequal influence of the grafts on the different target system in the striatum.

353.6

FETAL STRIATAL TISSUE GRAFTS INTO EXCITOTOXIC-LESIONED STRIATUM: PHARMACOLOGICAL AND BEHAVIORAL ASPECTS. M. Giordano, P.R. Sanberg, S.F. Calderon and A.B. Norman. Lab. of Behavioral Neuroscience, Depts. of Psychiatry, Psychology, Neurosurgery, Physiology, and Anatomy, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267-0559.

Although fetal striatal tissue grafts reverse the functional deficits produced by excitotoxin lesions of the striatum, relatively little is known about their pharmacological properties. We investigated drug induced behaviors and dopamine receptors in rats with fetal striatal grafts. Excitotoxic lesions of the striatum abolished haloperidol and SCH23390 induced catalepsy (1). Fetal striatal grafts (E 17-19) induced a significant increase in both haloperidol and SCH23390 induced catalepsy six weeks after the graft, but this effect was not significant at 14 or 20 weeks post transplant. Fetal striatal tissue grafted into the unilaterally lesioned striatum ameliorated apomorphine- induced rotation behavior (2). However, autoradiographic analysis of fetal grafts in both bilateral and unilateral excitotoxin-lesioned striatum demonstrated the absence of both [^{3}H]SCH23390 and [^{3}H]spiperone binding to D_1 and D_2 dopamine receptors.

In conclusion, although fetal striatal grafts are capable of normalizing spontaneous behavior (3) they have differential effects on dopamine agonist and antagonist-induced behaviors, and do not appear to express dopamine receptors.

SIX MONTH NEOSTRIATAL TRANSPLANTS EXHIBIT MINIMAL CONNECTIONS WITH HOST SUBSTANTIA NIGRA. J.P. McAllister, S.R. Cober*, E.R. Schaible* and P.D. Walker. Dept. of Anatomy, Temple U. Sch. Med., Philadelphia, PA 19140.

Our previous evaluation of neostriatal grafts placed in the kainic acid lesioned neostriatum (NS) of adult rats indicated that minimal connectivity existed between the graft and the host brain at 2 months post-transplantation (Brain Res., 425: 34-44,1987). The purpose of the present study, performed at 6-8 months post-transplantation, was to determine if connectivity had changed. Five days after kainic acid lesions were made, cell suspensions of E14 neostriatal primordia were injected into the lesion site. Eight animals with grafts received unilateral injections of lectin-bound horseradish peroxidase into the ipsilateral substantia nigra. Retrograde labelling of cell bodies was conspicuous in intact regions of the host NS surrounding the graft, but no transplanted neurons were labelled. Likewise, anterograde axonal label was abundant within the intact NS and the lesion site adjacent to the transplant. However, axonal and terminal labelling was very sparse and present only in peripheral regions of the graft. Therefore, we conclude that 6-8 month old NS grafts do not make appreciable connections with the host substantia nigra. Since Pritzel et al (Exp. Brain Res. 65:112-126, 1986) have shown connections at this time with similar grafts, the possibility that differences may occur between lesioning agents will be discussed.

353.8

FETAL STRIATAL GRAFTS IN THE IBOTENATE LESIONED STRIATUM REINNERVATE THE HOST GLOBUS PALLIDUS AND RECEIVE SPECIFIC INPUTS FROM THE HOST. K. Wictorin*, O. Isacson*, R. Simerly, L.W. Swanson, C. Ouimet and A. Björklund (SPON: ENA). Dept. Med. Cell Res., Univ. of Lund, Lund, Sweden.

Graft-host connections of striatal suspension grafts in the ibotenic acid lesioned rat striatum were studied with anterograde and retrograde tracers. Injections of Phaseolus lectin into the graft labeled axons which could be traced from the graft into the host globus pallidus. Fluoro-Gold injections into the host globus pallidus labeled large numbers of graft neurons which were distributed in patches throughout the graft. Similar Fluoro Gold injections in the host substantia nigra labeled only scattered graft neurons. Immunohistochemstry of DARPP-32 (normally enriched in neurons possessing dopamine D1 receptors) revealed a patchy distribution of DARPP-32 positive neurons within the grafts, and these patches overlapped with the patches of neurons retrogradely labeled from the host globus pallidus. The DARPP-32 patches received a dense innervation of tyrosine hydroxylase positive fibers from the host substantia nigra. The grafts also received host afferents labeled by Phaseolus lectin from the frontal cortex, and these cortical afferents were seen to ramify both within and outside the DARPP-positive graft patches. The results suggest that functional graft-mediated behavioural effects may at least in part depend on a partial reconstruction of striatal circuitry.

CO-TRANSPLANTS: EFFECT OF FETAL STRIATAL TISSUE ON FETAL DOPAMINERGIC NIGRAL NEURONS. D.M. Yurek, T.J. Collier, B.F. Daley and J.R. Sladek, Jr. Department of Neurobiology & Anatomy, University of Rochester School of Medicine & Dentistry, Rochester, New York, 14642.

In the developing animal, striatal tissue provides a target for fetal nigral cells which are committed to becoming DA neurons of the nigrostiatal pathway. Several factors may contribute to the synpatic formation between these two groups of developing neurons, including guidance of axonal growth by extracellular channels, selective adhesion, and the release of chemotropic factors from the post-synaptic neurons. Menesini-Chen et al. (*Arch. Ital. Biol. 116*, 53-84, 1978) have demonstrated that intracerebral injections of nerve growth factor (NGF) can direct sympathetic fibers to project in an aberrant pathway towards the NGF injection site. This suggests that fiber outgrowth can be manipulated by the appropriate chemotropic stimuli. We examined if factors within the fetal striatal milieu serve to (1) stimulate the proliferation of fetal nigral cells with DA phenotypes, (2) if implanted proximal to the fetal nigral tissue, act as a chemotropic target and attract fiber outgrowth from fetal substantia nigra tissue grafts. Recovery of DA function was pharmacologically assessed using the rotational model.

Donor fetal striatal and nigral tissue was obtained from embryos [E15-17] of pregnant female Sprague-Dawley rats. Fetal striatal tissue was dissociated into cell suspensions. Male Sprague-Dawley rats [225-250 gm] received unilateral 6-OHDA nigral lesions, screened for amphetamine-induced rotation, and served as co-graft recepients. Fetal striatal cell suspensions were implanted 1 mm above and below the fetal nigral tissue chunk within the lateral ventricle adjacent to the DA-denervated striatum.

Tyrosine hydroxylase immunocytochemical analysis of brain slices containing the co-grafts revealed that TH-positive grafted neurons proliferated both within the nigral graft and also in the adjacent regions in which the striatal cell suspensions were located. TH-positive cells located in the region of the striatal cell suspension were robust with extensive arborization and extended processes. Moreover, some TH-positive fibers extended processes through the ependymal wall of the ventricle and innervated the adjacent DA-denervated striatum.

Pharmacological tests revealed that the co-grafts attenuated apomorphine- and amphetamine-induced rotation. Several of the co-grafted animals treated with amphetamine rotated exclusively toward the contralateral side throughout the 75 minutes of testing indicating a predominance of DA activity on the grafted side. These data indicate that fetal striatal cells may provide a neurotropic influence on the proliferation of fetal nigral grafts. This research was supported by T32 MH 18260 (DMY) and AG 00847 (JRS).

LONG-TERM SURVIVAL OF GRAFTED FETAL NIGRAL DOPAMINE CELLS AND BEHAVIOR RECOVERY IN THE RAT. H.Nishino, H.Sato*, F.Furuyama*, Y.Isobe*, T.Hashitani*, M.Kumazaki*, Y.Ishida*, R.Shibata* and T.Ono. Dept. Physiol, Nagoya City Univ., Med. Sch., 467 Nagoya and Dept. Physiol., Fac. Med., Toyama Med.& Pharmaceu. Univ., 930-01 Toyama, Japan.

Cell suspension of fetal rat substantia nigra was grafted into the ipsilateral caudate nucleus of young rats with unilateral lesion in the nigrostriatal dopamine pathway, and survival of grafted cells, recovery from motor imbalance and security for long period after the graft were investigated. The results were as follows : 1) Recovery from motor imbalance started in the 2nd week and almost fully in the 4th week after the graft. 2) Once occuring, the recovery continued for more than 2 years, although the host animals sometimes suffered from mastopathy or pituitary adenoma. 3) Morphological examination revealed that grafted cells (TH-positive cells) had spiny- and mega-neurites in the 2nd week, and developed into multigonal neurons later. 4) Animals with TH-positive cells more than 300 showed full, 50 to 300, partial, and those with less than 50, poor recovery. 5) Synaptic connections between TH-positive soma/dendrites and TH-negative soma/dendrites were detected. 6) Level of dopamine, DOPAC and HVA restored 30 to 50% of those of control level (brain dialysis, HPLC method). The data suggest that grafted cells, once survived, alleviate motor imbalance safely for more than 2 years.

353.11

HUMAN FETAL NIGRAL NEURONS GRAFTED TO DOPAMINE-DENERVATED IMMUNOCOMPROMISED RATS: HISTOCHEMICAL & ELECTROCHEMICAL INVESTIGATIONS. I. Stromberg*, P. Almquist*, M. Bygdeman*, T. Finger, G. Gerhardt, A.-C. Granholm, T. Mahalik, A. Seiger, P. Stieg*, L. Olson, B. Hoffer. Karolinska Institute and Hospital, Stockholm, Sweden; Univ. of Colorado Health Sciences Ctr., Denver, CO and Univ. of Miami Medical Ctr., Miami, FL, USA.

Human fetal substantia nigra, obtained from first-trimester elective abortions, was grafted to DA-denervated striatum of adult immunocompromised (cyclosporin-treated or athymic nude rats). The DA-denervation was made by 6-OHDA-injection into the nigrostriatal pathway and the rats were tested using apomorphine-induced rotation before grafting. The transplants were implanted intraparenchymally as small solid pieces. The survival and function of the grafts were evaluated with immunohistochemistry using antibodies against tyrosine hydroxylase (TH), laminin, 5-hydroxytryptamine (5-HT) and human-specific Thy-1. All transplants were strongly Thy-1-immunofluorescent, and weaker fluorescent processes from the grafts were seen entering the host striatum. These processes were also TH-immunoreactive. Numerous TH-positive cells were seen in the transplants. In addition, 5-HT-immunoreactive cells were often seen. Laminin-positive structures, presumably blood vessels, were widely distributed in the grafts. High-speed in vivo chronoamperometric recordings demonstrated K^+-induced monoamine overflow within and adjacent to the transplants. The ratios of oxidation to reduction currents suggested both DA and 5-HT were released. Ongoing studies will evaluate the sensitivity of the grafted human DA neurons to the neurotoxic actions of MPTP.

HUMAN XENOGRAFTS TO THE STRIATUM OF DOPAMINE-DEPLETED RATS: LIGHT AND ELECTRON MICROSCOPIC IMMUNOCYTOCHEMISTRY. Thomas J. Mahalik, Ingrid Stromberg, Thomas E. Finger, Lars. Olson, Ake. Seiger, Marc Bygdeman, and Barry J. Hoffer. U. of Colorado Medical School, Karolinska Institute, U. of Miami.

Grafts of human fetal dopaminergic neurons have been suggested as a therapy for Parkinson's disease. The purpose of our study was to use ultrastructural immunocytochemistry to characterize grafts of human fetal tissue to the striata athymic rats

Donor tissue was obtained from fragments of dead fetuses derived from elective clinical abortions during the 6 to 12th weeks of pregnancy. The tissue was placed into the lesioned striata of 7 athymic "nude" rats which were allowed to survive from 3 to 5 months before being perfused.

The grafts contained tyrosine hydroxylase-like immunoreactive (THLI) and serotonin-like (5-HTLI) immunoreactive cell bodies and fibers. THLI terminals formed symmetric and asymmetric synapses, and 5HT-LI terminals formed asymmetric synapses in the host striatum. The host neuropil also contained THLI and 5-HTLI dendrites.

Our study indicates that xenografts of human fetal material can form synapses within the catecholamine-depleted rat striatum and that the grafts may be regulated by input from the host CNS.

353.13

MESENCEPHALIC TRANSPLANTS RESTORE DOPAMINERGIC MODULATION OF STRIATAL ACETYLCHOLINE AFTER 6-HDA. R.K. Carder, D. Jackson, H.J. Morris*, R.D. Lund, M.J. Zigmond. Center for Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA. 15261

Ventral mesencephalic grafts placed into the striatum of rats depleted of dopamine (DA) as neonates, survive and send out extensive processes. These grafts appear to exert some degree of functional control over motor behavior in that these animals make contralateral rotations in response to amphetamine and stress. Biochemical examination of depleted neonates reveals a loss of inhibitory influence of endogenous DA on the release of acetylcholine (ACh) from striatal interneurons. Using an in vitro superfusion system, we sought to determine whether there was endogenous DA release from grafts, as well as what impact this DA has on ACh release.

Striatal slices were prepared from animals that had received unilateral grafts and turned at least 5 turns/min in response to amphetamine and stress. Striatal DA levels were approximately 6% of control levels as compared to 2% on the untransplanted side. Field depolarization (18 mA, 8 Hz) increased basal efflux of DA on the transplanted side as measured by HPLC while producing no change on the untransplanted side. To assess the effect of DA on ACh release, slices were preincubated with [^{3}H]choline and the efflux of tritium into the superfusate was measured in the presence or absence of the DA antagonist, sulpiride (1 um). In slices from transplanted rats, sulpride produced a 50-270% increase in ACh. In comparison, sulpiride produced no increase in ACh release from slices prepared from DA-depleted neonates and a 90% increase from normal slices. These results suggest that mesencephalic grafts are capable of releasing DA and that this released DA modulates striatal cholinergic neurons. (NIH grants EY05283 and NS19608)

353.14

EXOGENOUS D2 AGONISTS BUT NOT ENDOGENOUS DOPAMINE CONTROL ACETYLCHOLINE RELEASE IN STRIATO-STRIATAL GRAFTS. T. Wichmann*, K. Wictorin*[a], A. Björklund*[a] and K. Starke* (SPON: G. Gmelin). Inst. Pharmacol., Univ. of D-7800 Freiburg and [a]Dept. Med. Cell Res., Univ. of S-22362 Lund

Striato-striatal grafts of embryonic tissue in rats with striatal ibotenic acid lesions have dopamine D2 binding sites (Isacson et al., Neurosci. 22:481, 1987) and are invaded by host dopaminergic fibres (Clarke et al., Neurosci. 24:791, 1988). We investigated the dopaminergic control of acetylcholine (ACh) release in graft tissue 16 to 20 weeks post-transplantation.

In superfusion experiments after preincubation of tissue slices with 3H-choline the overflow of tritium upon electrical stimulation (3 Hz, 2 min), reflecting ACh release, was inhibited by the D2 agonist quinpirole (0.03 µmol/l). The inhibition was less in grafts (26%) than in controls (52%). The D2 antagonist sulpiride (1 µmol/l) enhanced ACh release in controls by 30% and after addition of the dopamine uptake inhibitor nomifensine (1 µmol/l) by 673%. Nomifensine alone and the dopamine releasing drug amphetamine (1 µmol/l) decreased ACh release in controls by 39% and 81%. However, none of these drugs had any significant effect on ACh release in grafts.

We conclude that striato-striatal grafts partly restore the impaired choline uptake in lesioned striata. Although the grafted cholinergic cells are sensitive to D2 agonists, modulation by endogeneous dopamine is almost absent.

RECOVERY FROM UNILATERAL NIGROSTRIATAL DOPAMINE DEPLETION INDUCED BY DOPAMINE-SECRETING POLYMER IMPLANTS A. Gonzalez*, P. Barton*, J. B. Becker, T. E. Robinson, A. Sintov* and R. J. Levy* (sponsor: D. Green). Dept. Psychology, Div. Pediatric Cardiology and Neuroscience Program, The University of Michigan, Ann Arbor, MI.

QUESTION: Can an intrastriatal implant of a dopamine (DA) secreting polymer matrix alleviate the effects of unilateral DA depletion (i.e., mimic the effects of tissue grafts)? In a first attempt to address this question we studied the effects of implants (6.9±0.5 mg) of a silicone polymer matrix that released DA at a slow constant rate (43.3±3.9 nmol/mg/day) on apomorphine (APO)-induced rotational behavior in male rats with a unilateral 6-OHDA lesion of the substantia nigra.

Animals that received DA-secreting implants in the medial portion of the caudate nucleus, on the denervated side, showed a 50% reduction in APO-induced rotational behavior (relative to pre-implant). This effect was significantly different from the effect of control implants and persisted unabated for 2 months (when the experiment was terminated). This reduction in rotational behavior is comparable to that seen with adrenal medulla grafts. Additional studies in progress will be reported. This study suggests that the controlled release of DA from an intracerbral polymer matrix can produce a long-lasting reduction in some of the symptoms associated with nigrostriatal DA depletion.

Adrenal medulla grafts enhance functional activity of the striatal dopamine system following substantia nigra lesions. Jill B. Becker, William J. Freed and Eileen Curran*. Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI and The National Institute of Mental Health, St. Elizabeth's Hospital, Washington, D.C.

Adrenal medulla grafts in the lateral ventricle reduce the behavioral manifestations of striatal dopamine (DA) depletion in an animal model of Parkinson's Disease. Using microdialysis in freely moving rats, the behavioral effectiveness of adrenal medulla grafts was found to be associated with changes in neurotransmitter activity. Contrary to a popular hypothesis, baseline extracellular concentrations of DA in striatum were not elevated and DA was not detectable in cerebrospinal fluid (CSF). However, adrenal medulla grafts were associated with an increase in DA turnover and amphetamine-stimulated striatal DA release was increased in animals with behaviorally effective adrenal medulla grafts. Therefore, adrenal medulla grafts increase presynaptic striatal DA release without an appeciable increase in CSF DA. Whether this striatal DA release is under feedback control is currently under investigation.

Adrenal medulla grafts also increased serum DA concentrations, and the increase in serum DA was directly correlated with the behavioral efficacy of the grafts. We conclude that DA, produced by adrenal medulla grafts, gains access to the striatum via the blood supply and then leaks out into the host striatum through permeable blood vessels adjacent to the graft. Through this mechanism, adrenal medulla grafts may increase functional dopaminergic activity in the striatum. These results may be important for understanding the mechanism through which autografts of adrenal medulla cells produce a putative alleviation of the symptoms of Parkinson's Disease. (Supported by NIH grants #NS22157 and NS01056 to JBB).

ELECTROPHYSIOLOGICAL AND ANATOMICAL DEVELOPMENT OF HUMAN HIPPOCAMPUS AS INTRAOCULAR GRAFTS IN RAT HOSTS. R. Freedman, A.-C. Granholm, B.J. Hoffer, I. Strömberg*, A. Seiger, P. Stieg, M. Eriksdotter-Nilsson*, M. Byqdeman*, L. Olson. Denver VAMC, Univ. of Miami, Karolinska Institute, and Univ. of Colorado, Denver, CO 80262.

Brain fragments derived from dead first trimester abortuses were transplanted into the anterior chamber of the eye of athymic nude rats. Transplants of hippocampus were allowed to develop in the eye for up to one year. Neuroanatomical studies showed the presence of neuronal cell bodies, which in some cases formed a layer parallel to the transplant surface. Immunocytochemical evidence for intrinsic GABA-ergic terminals, as well as cholinergic and adrenergic terminals from the iris, was obtained. Neuronal action potentials were recorded extracellularly, and laminated field potentials were seen after surface stimulation. Paired pulse inhibition was also demonstrated. Seizure-like activity was seen after treatment with penicillin, enkephalin, or tetanic stimulation. The data suggest that human hippocampal transplants develop many neurobiological features which are characteristic of hippocampus in situ, including excitatory and inhibitory neuronal circuitry.

354.2

ELECTRICAL PROPERTIES AND AMINO ACID SENSITIVITY OF IDENTIFIED POSTNATAL HIPPOCAMPAL NEURONS IN CULTURE. C.F. Zorumski, L.L. Thio, and D.B. Clifford. Depts of Psychiatry and Neurology, Washington U. Sch. Med., St. Louis, MO

To study the development of electrical properties and amino acid sensitivity of postnatal hippocampal projection neurons we have used primary cultures from neonatal albino rats injected in the fornix with latex rhodamine microspheres. In 2-10 day old animals, injections label neurons in the pyramidal layer of areas CA3 and CA1 but not the dentate gyrus. Label is greater in CA3 than CA1 and labelled neurons stain with antibodies against neuron specific enolase but not GFAP.

Over the first 10 days in culture , input resistances fall from >2000MΩ to near 450MΩ while capacitance increases from 25pf to >70pf. Membrane potentials remain stable over this time and all neurons fire action potentials (AP). AP amplitudes remain greater than 70mV but AP durations decrease from 14ms to 5ms. Membrane charging curves are well described by a monoexponential process for 87% of neurons studied within 5 days of plating. By day 10 only 39% have monoexponential curves reflecting increases in cell size and neuritic processes.

Neurons respond to all excitatory amino acids and GABA. Responses decline over the first 24 hours in culture and recover over several days. Responses to glutamate at all ages consist of two components, a rapidly activating and desensitizing phase followed by a slower decaying tail.

354.3

DENTATE GRANULE NEURONS FROM TWO POPULATIONS OF SPRAGUE-DAWLEY RATS HAVE DIFFERENT BRANCHING PATTERNS, BUT SIMILAR DENDRITIC LENGTHS. B.J. Claiborne, M. Lehman* and L. Rihn*. Division of Life Sciences, University of Texas at San Antonio, San Antonio, TX 78285.

The dendritic branching patterns of dentate granule neurons in two populations of adult Sprague-Dawley rats were compared. Dorsal blade granule neurons (n=12) in rats obtained from Harlan Sprague-Dawley Inc. were filled with horseradish peroxidase, analyzed in three dimensions and compared to granule neurons (n=30) in Sprague-Dawley rats from Zivic Miller described previously (Claiborne et al., *J. Comp. Neurol.*, in press). Results showed that the molecular layer was significantly wider in the Harlan rats (299±11 um vs. 257±7 um; M±SEM), but that neurons from the Harlan population had fewer dendritic segments (27 ± 1) and smaller transverse spreads (318 ± 24 um) than did neurons from the Zivic Miller sample (31 ± 1 and 347±14 um). Because segment number and transverse spread varied inversely with layer width, total dendritic lengths per neuron were similar in the two populations. Two representative Harlan neurons had lengths of 3148 and 3543 um; the mean dendritic length of Zivic cells was 3478±88 um. These findings suggest that neurons may vary dendritic parameters systematically in order to conserve total dendritic length.

LONG LASTING INDUCTION OF PERIODIC SYNAPTIC CURRENTS BY NMDA IN IMMATURE HIPPOCAMPAL NEURONS IN ABSENCE OF SYNAPTIC TRANSMISSION.
E. Cherubini, K. Krnjevic and Y. Ben-Ari, INSERM U-29, 123 Bd Port-Royal, 75014 Paris, FRANCE.

The single electrode voltage clamp technique was used to study the action of NMDA in CA3 immature rat hippocampal neurons (1-10 days) in the in vitro slice preparation. Slices were perfused with ACSF containing TTX (1 uM) to block fast Na^+ currents and Cs^+ (4 mM) and TEA (10 mM) or 4-AP (30 µM) to reduce outward K^+ currents. Bath application of NMDA (5-10 µM) induced a slow inward current which was blocked by APV (50 µM). In addition, after repeated (3-5) applications of NMDA, Periodic Inward Currents (PICs) developed, which were maintained for several hours after NMDA was washed out. NMDA was essential for their induction but not for their maintenance, since APV failed to block them, once they have developed. The amplitude of PICs was a monotonic function of the holding potential and their reversal was close to 0 mV. PICs were blocked by a Ca^{2+} free medium or by Ca^2 antagonists Cd^{2+} (50 µM) or Co^{2+} (2 mM). PICs were recorded with both K Cl or K-acetate containing microelectrodes, as well as with electrodes containing the calcium chelators EGTA or BAPTA. PICs were not blocked when TEA (126 mM) was substituted for external Na^+. PICs were reduced in frequency by bicuculline (10-20 µM) and completely abolished by kynurenic acid (1 mM).

We conclude that PICs represent a novel mechanism of long lasting synchronization of synaptic currents by NMDA in absence of synaptic transmission.

354.5

ONTOGENY OF EXCITATORY PROCESSES IN THE RAT CA1 HIPPOCAMPAL REGION. E.W. Lothman and H.B. Michelson. Dept. of Neurology, Univ. of Virginia Medical Center, Charlottesville, VA 22908.

Although several studies have compared hippocampal slices from young versus adult rats, a systematic in vivo characterization of the ontogeny of electrophysiologic responses in this structure has not yet been done. This and the accompanying study report responses obtained from rats of postnatal (PN) ages 7-65 days. Under urethane anesthesia, a stimulating electrode was placed in one CA3 region and a second recording electrode in the contralateral CA1 region. Stimulus intensity was then varied to generate input-output curves for CA1 population spikes (PS). In younger animals, PS were broader, smaller in amplitude, and required higher intensity stimuli. However, after PN 14, excitability (measured by voltage required for half maximal PS) and PS duration (width at one-half peak for maximum amplitude) were not different from adult values. In contrast, maximum amplitude PS did not attain adult levels until PN 35. Conduction velocities (measured from time of stimulation to peak of evoked PS) steadily increased from PN 7 to PN 65. Thus, many, but not all, aspects of excitatory responses in CA1 hippocampal region are mature by PN 14.

354.6

ONTOGENY OF PAIRED PULSE INHIBITION IN THE RAT CA1 HIPPOCAMPAL REGION. H.B. Michelson and E.W. Lothman. Dept. of Neurology, Univ. of Virginia Medical Center, Charlottesville, VA 22908.

To complement our studies on the ontogeny of excitatory processes in the hippocampus, in vivo studies on the maturation of inhibition were carried out. Paired pulse stimuli were given in CA3 and population spikes (PS) recorded in the contralateral CA1 of rats on postnatal (PN) day 7 to PN 65. Ratios of the second (test) PS [PS(T)] amplitude to that of the first (conditioning) PS [PS(C)] assessed the potency of inhibition. We systemically explored the influence of PS(C) and interpulse interval (IPI) on paired pulse inhibition. Before PN 14, no inhibition was present at any amplitude PS(C) or any IPI. At later time points, inhibition appeared for IPI of 20-100 msec, provided PS(C) amplitudes were >75% of maximum. Inhibition was first detected at PN 18 and gradually increased to adult levels between PN 42-65. These studies indicate that recurrent GABAergic inhibition in the CA1 area of the hippocampus is not functionally present for at least 2 postnatal weeks and delayed for as much as 2 months before reaching adult values. The time course for this development lags considerably behind that of "excitatory" processes outlined in the accompanying abstract.

354.7

DEVELOPMENT OF PAIRED-PULSE SYNAPTIC FACILITATION IN THE RAT HIPPOCAMPUS, AREA CA1. P.G. DiScenna & T.J. Teyler Neurobiology Department, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

We are examining the development of one measure of neuronal excitability, paired-pulse synaptic facilitation, in the rodent hippocampus, area CA1. Hippocampal slices are prepared from 2-4,6,8,10,13,15,20 and >60 day rats, and maintained using standard slice procedures (2mM Ca/2mM Mg). At least 4 animals and 8 slices have been sampled at each age. Stimulating (50um concentric bipolar) and recording electrodes (2-5mOhm) are placed, on-line, in the middle of the apical dendritic field of CA1, in order to record the evoked synaptic field potential. Homosynaptic paired pulses (conditioning pulse = 40-60% max. field EPSP) are recorded across a range of interpulse intervals (10-5000ms), delivered at .033Hz. We are comparing the initial slopes of the conditioning and test pulse field EPSPs, as well as longer latency events, both within and across ages. Preliminary analyses demonstrate the presence of PPF at the earliest day tested, PN2 (eg. 2.58% @ 20ms IPI; 16.98% @ 60ms; 12.98% @ 120ms; -9.97% @ 500ms), with gradual increases peaking in the 15 day slices (120% @ 20ms; 134.58% @ 60ms; 86.73% @ 120ms; 25.48% @ 500ms), with a slight decline in the >60 day group (87.8% @ 20ms; 96.33% @ 60ms; 63.25% @ 120ms; 18.22% @ 500ms). Excitatory processes appear to develop before inhibition, in CA1. Therefore the decreased level of PPF during the early postnatal days, provides a margin of safety for the developing hippocampus. SPROUTING OF CENTRAL AND PERIPHERAL NORADRENERGIC FIBERS INTO THE DENTATE GYRUS FOLLOWING COMBINED LESIONS OF THE ENTORHINAL AND SEPTAL AFFERENTS. G.M. Peterson, Dept. Anat. Cell Biol., East Carolina Univ. Sch. of Med., Greenville, NC 27858.

Virtually all of the afferents to the hippocampal formation (HF) undergo reactive synaptogenesis (sprouting) after removal of adjacent afferent systems. However, the noradrenergic (NA) afferents, which in other regions of the brain demonstrate a remarkable propensity for regeneration and sprouting, do not sprout in the denervated HF. In contrast, sympathetic NA axons, which do not normally invade the CNS, sprout into the HF following interruption of the septohippocampal cholinergic input. The present study was designed to determine if interruption of both entorhinal and septal inputs can alter the innervation pattern of central or peripheral NA afferents to the dentate gyrus (DG) of adult female Sprague-Dawley rats. The ipsilateral and contralateral entorhinal afferents to the right DG were removed by knife cuts through the ipsilateral perforant path and the ventral hippocampal commissure, respectively. At the same time, or 4 weeks later, the fimbria-fornix was bilaterally aspirated. Four weeks later the animals were perfused, the brains removed, and 40 um thick sections were cut in either the coronal or horizontal plane. Lesions were verified in sections stained for Nissl, Timm's silver sulfide, or acetylcholinesterase histochemistry. The noradrenergic identity of the fibers was indicated by immunoreactivity for dopamine beta hydroxylase (DBH) and peripheral sympathetic fibers were demonstrated by immunoreactivity for nerve growth factor receptor (NGFr). DBH + fibers were present in the hilus of both the left and right DG and many of these were also found to be NGFr +. The outer half of the molecular layer of the right DG had a dense plexus of DBH + fibers coursing parallel to the pial surface. However, no NGFr + fibers were present in this region, thus indicating that the DBH + fibers are of central origin. It is concluded that combined bilateral deafferentation of the entorhinal and septal inputs does not change the sprouting patterns of peripheral sympathetic fibers but results in the sprouting of central NA fibers in the molecular layer of the dentate gyrus. PEPTIDERGIC NEURONS IN THE HUMAN HIPPOCAMPUS DURING DEVELOPMENT AND AGING. F. Lotstra* and J.-J. Vanderhaeghen. Laboratory of Neuropathology and Neuropeptide Research. Brugmann and Erasme Hospitals, Université Libre de Bruxelles, Brussels, B-1070, Belgium.

The distribution of Neuropeptide Y (NPY), Neurotensin (NT) Somatostatin (SOM), Cholecystokinin (CCK), and Substance P (SP) neurons is studied in the human hippocampal formation using the peroxidase technique of Sternberger. CCK and SP interneurons are mainly represented in the hilus, CA3 and CA2. NPY and SOM are more concentrated in CA1, subiculum and entorhinal cortex. Several interstitial NPY, SP and SOM neurons are present in the angular bundle. Before three years of age, transient immunoreactivity is present in some neurons. Such transient neurons are CCK interneurons in the entorhinal cortex, NT pyramidal neurons in the subiculum and NT granular neurons in the area dentata. Althought the density of NPY neurons decreases during development, the total number of these neurons is well established at birth, stays stable until at least the age of 42 and begins to decrease at the age of 60. Similarly the total number of SP neurons in the hilus region stays stable from birth until the age of 42. Supported by Belgian FRSM 3.4523.86 and FMRE 86.

LOCALIZATION OF SYNAPTIC VESICLE PROTEIN IN DEVELOPING RAT PIRIFORM CORTEX. L.E. Westrum, R.E. Westenbroek*, N.A. Nousek-Goebl*, and W.D. Matthew[1]. Depts. of Neurol. Surg., Biol. Struct., and Pharmacol., Univ. of Washington, Seattle, WA 98195; [1]Dept. of Neurobiol., Harvard Med. Sch., Boston, MA 02115.

Antibodies to synaptic vesicle protein (J. Cell Biol. 91:257, 1981) are being used to study synaptogenesis and plasticity in piriform cortex (PC) using immuno-labeling techniques. A banding pattern which delineates sublaminae of PC is lost following olfactory bulb lesions. The ultrastructural basis for these patterns is being examined in rats of postnatal (PN) ages 3, 7, and 13 days and adults. Axon terminals, some with synaptic contact, and their preterminal axons label in the youngest animals. Greater numbers of terminals and synapses label in older ages whereas preterminal axons disappear after PN 7. In some of the adult material essentially all of the terminals label. The deeper sublamina (Ib) has more labeled terminals than superficial regions (Ia) with a transition zone. Label occurs in association with the surface of synaptic vesicles that are usually round in shape, and the contacts are mostly asymmetric. Postsynaptic elements do not label. The results explain the banding pattern, identify the precise synaptic elements and substructural localization and provide a valuable method for studying plasticity at a synaptic level. (Supported by NIH Grants NS09678 and DE04942. LEW is an affiliate of the CDMRC.)

BEHAVIORAL MATURATION AND PROTRACTED POSTNATAL PROLIFERATION OF RECURRENT MOSSY FIBER COLLATERALS IN THE GUINEA PIG HIPPOCAMPUS. D.P. Wolfer* and H.-P. Lipp. Institute of Anatomy, Univ. of Zürich, CH-8057 Zürich, Switzerland.

Behavioral maturation may depend on a protracted differentiation of neuronal circuitry long after the differentiation of sensori-motor systems (Flechsig's rule). The evidence for this rule is based on myelination cycles and protracted neurogenesis of hippocampal granule cells, but clear changes in the distribution of axonal terminals have not been observed thus far.

Fifty-six guinea pigs, precociously born animals, were studied (8 per age group) at the age of 5, 10, 20, 40, 80, 160, and 320 days. Behavioral tests measured activity in a novel environment, and responses to electrical shock in a shuttle-box. The area of a plexus formed by recurrent mossy fiber collaterals below and above the granule cell layer of the fascia dentata was assessed by means of digital image analysis. These mossy fiber collaterals proliferate till the age of 40 days, and thereafter in some but not all animals. The prepubertal proliferation (which may reflect mossy synapses overgrowing inhibitory interneurons) was coincident with an increase of shock levels required to induce locomotion. No age-related differences were found for the latency to start locomotion in a novel environment. So, Flechsig's rule applies to mossy fibers, too, and their late proliferation may have specific behavioral consequences. Supp. by SNF 3.081-0.84.

ISOLATION "STRESS": REARING EFFECTS UPON ACTIVITY, PLASMA GLUCOCORTICOIDS AND BRAIN GLUCOCORTICOID BINDING. R. Holson, P. Sullivan*, A. Scallet, S.F. Ali, and B. Turner*. Div. Reprod. & Develop. Toxicol., National Center for Toxicological Research, Jefferson, AR 72079 and *Quillen-Dishner College of Medicine, Johnson City, TN 37614.

It has been suggested that isolation rearing is a "stressor". To investigate this contention, male and female rats were reared from weaning at postnatal day (PND) 21 to adulthood (PND 100) in one of three standard laboratory conditions: three animals to a transparent acrylic cage (SOC), isolation in the same plastic cage (IPC) or isolation in smaller metal hanging cages (IHC). When tested in the open field, SOC activity was much greater if odor cues from cagemates were present in the field. IHC rats displayed profound freezing, due to lack of familiarity with the human handling provided by twice-weekly cage changes of plastic cages. IPC rats were more active than SOC rats without but not with cagemate odor cues in the field. There was no rearing effect on basal plasma glucocorticoids, on hippocampal or prefrontal type I or type II glucocorticoid receptors, or on body-weight-adjusted adrenal and thymus weights. Corticosterone levels following open field were only elevated in IHC. These data provide scant support for the position that isolation rearing is a chronic stressor. They do demonstrate that isolation rearing effects result from a complex interaction between prior experience and test circumstances.

NEW GENES FROM OLD DISEASES. X.O. Breakefield[1], F.S Collins[2], J.F. Gusella[3], R.G. Worton[4] and R.A. Weinberg[5]. [1]E.K. Shriver Ctr. and Massachusetts Gen. Hosp., Boston, MA; [2]Univ. Michigan Med. Sch., Ann Arbor, MI; [3]Harvard Med. Sch. and Massachusetts Gen. Hosp., Boston, MA; [4]Hosp. Sick Children, Toronto, Canada; [5]Whitehead Inst., M.I.T., Cambridge, MA.

Molecular genetic studies have elucidated the chromosomal location of a number of genes causing inherited neurologic and psychiatric diseases. For several of these diseases, new genes important in the function of the nervous system have been identified. This symposium will focus on genetic strategies used to find and characterize disease genes and their products. Basic recombinant DNA techniques used to proceed from linked markers to disease genes will be explained: "jumping" libraries, pulsed field gel electrophoresis, cloning in artificial yeast chromosomes, subtractive DNA libraries, and polymerase chain reaction amplification and sequencing. Xandra Breakefield will present an overview of current progress in identifying genes associated with diseases of the nervous system. Progress toward finding the genes responsible for neurofibromatosis (NF1) and Huntington disease will be presented by Francis Collins and James Gusella, respectively. Ronald Worton will discuss the structure of the X-linked gene responsible for Duchenne muscular dystrophy, and its encoded muscle protein which has homologies to alpha-actin. Robert Weinberg will describe the recessive oncogene responsible for retinoblastoma tumors and the possible role of the encoded protein in regulating gene expression in retinal cells. This symposium will alert neuroscientists to new genes important in the nervous system which need further characterization.

358

WORKSHOP. NON-UNIFORMITY OF SYNAPTIC PHYSIOLOGY: IMPLICATIONS FOR PLASTICITY IN THE NERVOUS SYSTEM. J.P. Tremblay, Laval Univ. (chairman); H. Korn, Inst. Pasteur, Inserm, Paris; A.D. Grinnell, UCLA Sch.Méd.; J.P. Tremblay and R. Robitaille, Laval Univ.; M. Wojtowicz and A. Atwood, Univ. Toronto; E. Henneman, Harvard Med. Sch.; S. Redman, John Curtin Sch. Med.

During recent years, several laboratories have presented evidence that all the synaptic contacts made by terminals of a given axon do not participate equally in the release of neurotransmitter. On the other hand, many analyses of morphological changes in central synapses have been based on the assumption that morphologically defined synapses are physiologically meaningful. Non-uniformity of synaptic physiology implies that many morphologically defined synapses are normally impotent, but may become active during adaptive or developmental changes in the nervous system. It is the purpose of this symposium to present and discuss various mechanisms that have been advanced to account for the heterogeneous behaviour of synapses; some deal with axonal properties, others raise questions about the probability of exocytosis at a given site following a propagated impulse. Korn will present evidence that synaptic noise can be reconstructed using experimental data indicating that release is quantal and well described by a simple binomial process at the level of each presynaptic interneuron. Synaptic noise than appears to be equivalent to temperature in models of neural networks. Grinnell will show that even in a relatively simple synapse (the frog NMJ), different transmitter release sites show a gradient in their participation in evoked release. He will review possible morphological and physiological explanations for these gradients. The results of Tremblay and Robitaille indicate that there are also gradients during spontaneous release and that the MEPP amplitudes produced by the distal portion of the nerve terminal are smaller. Wojtowicz and Atwood will present evidence that in the crayfish NMJ, there are variations in the number of physiologically participating synapses (n) during presynaptic inhibition and long term facilitation. These results suggest that the large number of release sites may be the substrate for such plasticity. Henneman's results suggest that impulses conducted in a single Ia afferent fiber do not necessarily activate all the synapses formed by that fiber on a motoneuron. Redman will review the evidence that different excitatory synapses arising from the same axon and contacting the same neuron can have different release probabilities, and that these probabilities are altered during PTP and presynaptic inhibition.

CELL LINEAGE AND DETERMINATION II

359.1

DIVISION PATTERN OF THE PRECURSER CELLS TO THE PERIPHERAL NERVOUS SYSTEM IN WILDTYPE AND MUTANT DROSOPHILA EMBRYOS. R. Bodmer, R. Carretto & Y.N. Jan. SPON: K. Ocorr. Howard Hughes Med. Inst., UCSF, San Francisco, CA 94143-0724.

The division patterns of the cells that give rise to the embryonic peripheral nervous system (PNS) were studied using the thymidine analog BrdU to monitor DNA synthesis (Gratzner, H.G., Science, 218: 474, 1982). It was found that cell divisions during neurogenesis of the PNS happen between ca. 6 and 9 h after fertilization. During this period, the cell divisions that occur in the epidermal cell layer of the body wall almost exclusively give rise to the PNS. Furthermore, sensory organs of different types and locations within a segment have a stereotyped pattern and time of birth. For example, the precurser cells for the external sensory (es) organs are the last ones to complete their cell divisions.

This method provides a very useful means of analyzing mutations that affect PNS development. For example: in embryos that are homozygous for mutations in the achaete-scute complex (AS-C), the PNS is reduced in that all es organs and certain other sensory neurons are absent (Dambly-Chaudiere, Ch. and Ghysen, A., Genes & Dev., 1: 297, 1987). These mutations could either be affecting the relevant precursor cells or they could disrupt the normal differentiation of their progeny. By labelling mutant embryos with BrdU it was possible to distinguish between these possibilities by showing that the precursor cells for the missing sensory organs are either absent or fail to divide. This methodology is currently being used to study other mutants that may affect the development of the embryonic PNS of Drosophila.

LOCALIZED EXPRESSION OF THE CHICKEN ENGRAILED GENE IN EARLY CHICK EMBRYOS. C.A. Gardner*#, D.Darnell*@, C.P.Ordahl*@, K.F.Barald# (SPON: M. Alpern) Dept. Anatomy & Cell Biol., U. Michigan#, Ann Arbor, MI 48109; Dept. Anatomy, U Cal San Francisco@, CA, 94143.

Engrailed (en) has been identified in Drosophila as an important developmental gene involved in the control of segmentation. A chicken gene (ChickEn) containing a region homologous to the en homeobox and to 22 additional base pairs of the fly gene has been identified [DD,CO]. A 500 bp fragment of ChickEn genomic DNA was used to make ^{35}S-labeled RNA probe [CG,KB]. In Northern analyses, the probe hybridized to 3 bands of whole cell RNA from 2 or 4 day chick embryo (5.0, 3.5, 2.2 Kb) [DD,CO,CG,KB]. In situ hybridization [CG,KB] to 4 day chick embryos (ED-4) shows heavily labeled cells in the mesencephalon. In cultured chick cranial neural crest (NC) cells (31 hr; stage 9) in situ hybridization [CG,KB] shows probe localization in a subset (<10%) of NC cells. Inv-49 is a monoclonal antibody (MCA) which Patel, Coleman, Poole, Kornberg and Goodman (ms in prep.) have shown binds to the homeo box region of the en protein product. Patel et al and we have shown that this MCA labels mesencephalon and anterior rhombencephalon of stage 9-26 chick. The MCA also stains sections of ED-4 chick in the same region of the mesencephalon in which ChickEn mRNA is localized [CG,KB]. We have found no MCA staining in chick embryos before stage 9. We are presently examining NC cells and early embryos with a variety of other antibodies for NC including CG-1 and CG-4 that label a subset of mesencephalic NC cells [KB] to determine ChickEn mRNA and MCA colocalization patterns.

359.3

NEURONAL REGULATION OF GLIAL PROGENITOR CELL DIFFERENTIATION. J.M.Levine, Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook,N.Y.,11794

Astrocytes and oligodendrocytes develop from a common precursor cell termed an O2A progenitor cell. Progenitor cells have been studied extensively in cultures of post-natal rat optic nerve which contain no neurons. We have identified cells in cultures of post-natal rat cerebellum (CBL) whose antigenic phenotype is identical to that of O2A progenitor cells. However, these CBL cells rarely develop into oligodendrocytes when grown in a chemically defined,serum-free medium.

These observations suggest that neurons may influence the choices made by developing progenitor cells. This hypothesis was tested by growing post-natal day 5-7 rat optic nerve cells in serum-free medium that was conditioned by either CBL interneurons (NCM), CBL astrocytes (GCM) or several neuronal and glial cell lines. The numbers of progenitor cells and oligodendrocytes was determined by immunofluorescence staining with cell-type specific marker antibodies 18-24hr after plating the cells and again 3-5 days later. The newly plated cells contained approximately equal numbers of progenitor cells and oligodendrocytes. After 3 additional days in unconditioned defined medium, most of the progenitor cells disappeared and 85% of the labeled cells were oligodendrocytes.In contrast, after 3 days in NCM, 60% of the labeled cells were progenitor cells and 38% were oligodendrocytes. Between 3-8% of the progenitor cells were dividing in NCM suggesting that differentiation was not delayed due to extensive cell division. Medium conditioned by glial cells had no effect on the normal differentiation of oligodendrocytes.

These results indicate that CBL interneurons secrete or shed factors into the medium that effect glial development. These factors can promote the survival of progenitor cells and prevent the development of oligodendrocytes. Thus the neuronal microenvironment may play a role in regulating the differentiation of multipotential glial precursor cells.

359.4

A FINELY VARIEGATED, HOMOGENOUS MIX OF NEURON GENOTYPES EXISTS THROUGHOUT THE CNS OF MOUSE CHIMERAS. A. Peterson1,J.P. Julien*2,I.Tretjakoff*1,P.Valera*1 and O. Mayor*1. 1 Ludwig Institute, Montréal, 2 Institut du Cancer de Montréal, Canada.

Transgenic mice containing the human neurofilament light gene (hNF-L) were used to investigate the cis sequences which confer neuron specific expression and to provide a genotype marker. The hNF-L gene is expressed in neurons, the transgene product assembles into neurofilaments and is detectable in situ with a monoclonal antibody (Julien et al., Genes. Dev. 1:1085, 1987).

To investigate the lineage/clonal relationships that are postulated to underlie the origins of phenotypically different neurons, hNF-L↔+/+ chimeras were examined for the distribution of the two neuron genotypes. Throughout the nervous system, a finely variegated pattern of mosaism exists and, in each chimera similar genotype proportions were found in all neuronal populations.

These findings require that the chimera neuroectoderm was a homogenous mix of the two genotypes and that different neuronal phenotypes do not arise clonally from small numbers of prespecified progenitors. Rather, neurons of each phenotype arise from a representative sample (i.e. a large number) of progenitors, or more likely, all progenitors contribute daughter cells to all of the neuronal subpopulations at each level of the neuroaxis.

359.5

DIVERSE NEURONAL TYPES ARISE FROM A SINGLE PROGENITOR IN CHICK OPTIC TECTUM: STUDIES USING A ROUS SARCOMA VIRUS AS A LINEAGE MARKER. G.E. Gray*[1], J. Majors*[2], and J.R. Sanes[1], Depts. of [1]Anatomy & Neurobiology, and [2]Biological Chemistry, Washington Univ. School of Medicine, St. Louis, MO 63110

We are using recombinant retroviruses to trace cell lineage in the chicken optic tectum. These replication-defective vectors insert the E. coli β-galactosidase (lacZ) gene into the genome of an infected cell; the cell's lacZ-positive progeny are detected histochemically (Sanes et al., EMBO J. 5: 3133, 1986). Previously we infected tectal progenitors during the period of active proliferation, then analyzed clones when proliferation was nearly over but before laminae formed (E7-9). We found that lineally related cells form radial arrays in the developing tectum (Glover et al., Soc. Neurosci. Abstr. 13: 183, 1987). We have now extended these studies to analyze the disposition and phenotype of clonally related cells in mature tecta. We find that some (but not all) clones remain radially organized at E19, when the tectum is fully laminated. These clones span many laminae, and individual clones contain neurons of varied (≥4) distinctive morphologies, many of which can be classified by reference to Golgi studies of Cajal and others. Thus, a single precursor can give rise to neurons of diverse types.

Our new studies benefit from a novel recombinant Rous sarcoma virus that bears the lacZ gene. The viral genes pol, env, and portions of gag and src were replaced with lacZ; the vector encodes a gag-lacZ fusion protein. The helper-free virus was grown in a cell line, made by cotransfecting a quail fibroblast line (QT6) with the gag-lacZ plasmid and a plasmid that carries viral structural genes. The resulting virus has both a higher titer and a higher level of lacZ activity per infected chicken cell than we had obtained in initial studies (op. cit.) using a Moloney murine leukemia virus.

CELL LINEAGE ANALYSIS IN THE EMBRYONIC MOUSE RETINA BY RETROVIRAL VECTOR-MEDIATED GENE TRANSFER. D. L. Turner*, E. Y. Snyder* and C. L. Cepko (SPON: D. Potter). Dept. of Genetics and Program in Neuroscience, Harvard Med. School, Boston, MA 02115.

We have previously described the use of retroviral vector-mediated gene transfer as a cell lineage marking system in the mammalian nervous system (Price et al., PNAS 84:156, 1987). The BAG vector expresses the E. coli β-galactosidase gene, which permits histochemical identification of marked clones derived from single infected progenitor cells. We have used this marking system to analyze cell lineage in the postnatal rat and mouse retinas (Turner & Cepko, Nature 328:131, 1987, and unpublished results). Labeled clones contained up to three different neuronal and/or glial cell types in various overlapping combinations. This suggested that the four cell types generated in the postnatal rodent retina (rod photoreceptors, bipolar cells, amacrine cells, and Müller glia) arise from a common progenitor.

We have now extended this analysis to the embryonic mouse retina. Using the *exo utero* surgical procedure developed by Muneoka et al. (J. Exp. Zoo. 239:289, 1986) we injected BAG virus between the retina and pigment epithelium of CD-1 mice on the 14th day of gestation (plug = day 1). Approximately 400 clones were labeled in the retinas of three animals which survived to adulthood. Clones contained from one to more than 70 cells in radial clusters. Some clones contained labeled cells of all four cell types labeled in the postnatal infections. Other clones contained rods, bipolar cells, amacrine cells, and either cone photoreceptors or ganglion cells (two cell types that only form prenatally). These results confirm the proposal that rods, bipolar cells, amacrine cells, and Müller glia can arise from a common progenitor. In addition, the same progenitor can generate cones or ganglion cells earlier in development. This suggests that lineage is probably not involved in cell type determination in the rodent retina. Supported by NEI 1 RO3 EY07331-01 and NIH RO1 NS 23021-01.

359.7

CORTICAL COLUMNS ARE NOT CLONAL BOUNDARIES. C. Walsh and C.L. Cepko. Dept. of Genetics, Harvard Med. Sch., and Dept. of Neurology, Mass. Gen. Hosp., Boston, MA.

We tested the suggestion that neurons in a cerebral cortical column share common lineage by using retroviral mediated gene transfer to mark cortical progenitors(Turner,D. and Cepko,C.L., Nature 328:131,1987) in 62 fetal rats from E14-E19. A replication-incompetent retrovirus vector carrying a histochemical marker gene, E. Coli beta-galactosidase, was injected into the lateral ventricle, and rats were killed 3-60 days later and processed for histochemistry. Infection by the defective virus stably transfers the beta-galactosidase gene to neural progenitor cells, producing groups of labelled, clonally related cells. Since the virus is replication- defective, there is no ongoing infection.

After 10-60 day survival times, labelled cells showed "Golgi like" staining, allowing easy identification of cell type in most cases. All known cell types were labelled, including neurons of diverse morphology in all cortical laminae and regions. Surprisingly, it was very rare for more than two labelled neurons to occupy the same cell column. Labelled neurons occurred in small groups after E16-17 injection, generally with 2-3 neurons in the several cortical layers, separated laterally by 25-200μm. Larger groups of labelled neurons occurred after E15 injection, with 5-10 neurons in all cortical layers, spread over a similar or larger distance across the cortex.

After 3-7 day survival times, labelled, clonally related cells were more closely grouped in the subventricular and intermediate zones, but their morphology suggested migration along several, sometimes nonadjacent, radial glial cells. Thus, the widely separated neurons seen after longer survival times appear to be clonally related. Therefore, clonally related cortical neurons migrate along different radial glial cells to achieve substantial circumferential separation in their final position. Grant support from NEI 1 RO3 EY07331-01 and NIH RO1 NS 23021-01.

359.8

A COMMON PRECURSOR FOR ASTROCYTES AND OLIGODENDROCYTES. E.F. Ryder*, C. Walsh, and C.L. Cepko. Dept. of Genetics, Harvard Med. School, and Dept. of Neurology, Mass. Gen. Hosp., Boston, MA.

Macroglia have traditionally been divided into fibrous and protoplasmic astrocytes, and perineuronal and intrafasicular oligodendrocytes. However, morphological types intermediate between these classes have also been recognized (e.g., del Rio-Hortega, Mem. de la Real Soc. Esp. de Hist. Nat.14:5, 1928). Recent in vitro work (Raff et al.,Nature 303:390,1983) suggests that fibrous astrocytes and intrafasicular oligodendrocytes share a common progenitor, while protoplasmic astrocytes derive from a separate lineage (Miller and Raff, J.Neurosci. 4:585,1984). In order to show in vivo lineage relationships directly, progenitor cells were infected with a replication defective retroviral vector carrying the beta-galactosidase gene. This gene is transmitted only to progeny of infected cells. Sixty-two rats from E14-P0 (also used in an accompanying study, Walsh,C. and Cepko,C.L., this volume) received injections into the lateral ventricle and were processed for beta-galactosidase histochemistry 3-60 days later.

Labelled cells showed intense, "Golgi-like" staining of cellular processes, which allowed identification of cell type in 80-90% of cells, following survival to P8 or longer. All four types of glia could be recognized, although some labelled glia were of intermediate morphological type. Labelled glial cells occurred in groups, presumably clonally related, of up to 180 cells. Although many smaller groups contained just one morphological cell type, other groups contained any possible combination of fibrous/protoplasmic astrocytes and perineuronal/intrafasicular oligodendrocytes. Larger groups spread over wide distances in the brain and usually contained several, sometimes all four, glial types. Thus, a common progenitor apparently produces all four major morphological types of macroglia in the rat forebrain. Grant support from NIH RO1 NS 23021-01, NIH 5 T32 GMO7196, and NEI R03 EY 07331-01.

EFFECTS OF DIBUTYRYL CYCLIC AMP ON RAT RETINAL GERMINAL NEUROEPITHELIAL CELL PROLIFERATION. T.A. Reh and M. Taylor*, Dept. Med. Physiology, Univ. Calgary, Alberta, T2N 4N1.

Little is known about the factors that regulate neuronal production during development in the mammalian CNS. The purpose of this study was to examine the role of second messenger systems, specifically the cyclic AMP (cAMP) cascade, in the regulation of cell proliferation during the pre and postnatal developmental period in the rat retina. Aggregate cultures of embryonic (E15 and E18) and postnatal (P1) retina were exposed to dibutyryl cAMP (1 mM) for 48 hours. Cell proliferation and newly synthesized protein levels in the cultures were determined by TCA precipitation following incubation with H^3-thymidine (24 hours) and S^{35}-methionine (3 hours). In cultures of E15 retina, no differences were seen between control and treated groups in cell proliferation and protein synthesis; however, in E18 and P1 cultures protein levels remained constant while cell proliferation decreased to 12-20% of the control values. Histological analysis using toluidine blue stained 4 um plastic sections confirmed that the change in H^3-thymidine incorporation in the P1 cultures was due to a decline in germinal neuroepithelial proliferation. By contrast, the dibutyryl cAMP treatment had no effect on the proliferation of germinal cells from the E15 retina. These results indicate that the regulation of germinal neuroepithelial cell proliferation involves the cAMP second messenger system after E18; however, prior to that time, the proliferation of these cells is independent of changes in cAMP.

359.10

DEVELOPMENTAL IMPLICATIONS OF THREE-DIMENSIONAL DISTRIBUTIONS OF PEPTIDERGIC PERIKARYA IN THE BRAIN OF FROGS. K.M. Conway[1] and R.T. Zoeller[1,2], [1]NINCDS and [2]NIMH, Bethesda, MD 20892.

In order to compare distributions of neurons with vasotocin (AVT), mesotocin (MT), and thyrotropin-releasing hormone (TRH) phenotypes we prepared multiple sets of semi-serial transverse sections from brains of adult Xenopus laevis and Bufo marinus frogs for in situ hybridization and immunocytochemistry. Antisense DNA oligomers were synthesized using published sequences of cDNAs for Xenopus TRH and Bufo japonicus AVT and MT. The AVT and MT probes were positive in Bufo marinus, and the TRH and MT probes were positive in Xenopus. Antibody reagants specific for Xenopus AVT- and MT- associated neurophysins were also used.

MT and AVT cells were found in the preoptic area and posteriorly over the optic chiasm along the sulcus limitans. The region of AVT cells in Bufo extended further anteriorly into the striatum and further posteriorly into the infundibulum. TRH positive cells were found in every section examined, from the granular area of the olfactory bulb anteriorly to the trigeminal motor nucleus posteriorly and including preoptic and hypothalamic regions.

In transverse sections these distributions were distinct but had many areas of overlap and intermixing. The longitudinal extent of TRH greatly exceeded that of AVT, which exceeded that of MT. A parsimonious explanation is that longitudinal columns of neural plate progenitors are specified as to permissible peptidergic phenotypes of their progeny, and that the convoluted and intermixed adult pattern derives from subsequent cell and tissue movements overlayed upon an initially simple pattern.

INDUCTION OF MITOTIC ARREST AND MORPHOLOGIC DIFFERENTIATION OF NEUROBLASTOMA CELLS BY NEOCARZINOSTATIN: CYTOLOGIC AND THERAPEUTIC IMPLICATIONS. N. F. Schor. Division of Child Neurology, Children's Hospital, Pittsburgh, PA 15213

Neocarzinostatin is a chemotherapeutic agent which consists of a chromophore noncovalently bound to a protein. We have found that, in addition to its antimitotic effect upon C1300 neuroblastoma cells in culture, neocarzinostatin induces the morphological differentiation of these cells. Unlike the case for the antimitotic effect, this process requires the intact protein-chromophore complex. Chromophore alone or protein alone are antimitotic, but do not induce morphological change. The morphology-altering effect of neocarzinostatin, coupled with its well studied chemical mode of action may provide insight into the mechanisms underlying neural differentiation.

The activity of neocarzinostatin increases with increasing intracellular sulfhydryl content. We have increased the sulfhydryl content of C1300 cells with 6-mercaptodopamine, a compound which preferentially enters cells with catecholamine receptors. This increases the potency of neocarzinostatin for these cells. No reduction in growth rate or morphological alteration is seen with 6-mercaptodopamine alone, indicating that the effect of the sulfhydryl compound is due to facilitation of neocarzinostatin efficacy. Since 6-mercaptodopamine preferentially enters cells such as neuroblastoma cells which harbor dopamine receptors, it is hoped that this approach will lead to the development of targeted therapy for neural crest tumors.

IMMUNOHISTOCHEMICAL DOUBLE-LABELING FOR GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) AND TRANSFERRIN (Tf) PERMITS THE CATEGORIZATION OF GLIAL CELLS IN SECTIONS OF RAT BRAIN. V.K. Vijayan and S.M. Martin. Dept. of Hum. Anatomy, Univ. Calif. Sch. of Med., Davis, CA 95616.

Categorization of glial cells into subclasses is a prerequisite for evaluation of properties and functions of glia in vivo. We used double-labeling immunohistochemistry for GFAP and Tf to identify subpopulations of glial cells in rat brain. Under anesthesia, rats received cortical stab wounds and were sacrificed by transcardiac perfusion with 4% paraformaldehyde (PFO), 4% periodate-lysine-paraformaldehyde (PLP) or formalin-alcohol-acetic-acid (FAA). Paraffin sections and Vibratome slices of the brain were subjected to sequential immunohistochemical staining for GFAP and Tf and counterstained with methyl green. Three subpopulations of glia were observed in the cerebral cortex adjacent to the wound: $GFAP^+,Tf^-$; $GFAP^-,Tf^+$ and $GFAP^-,Tf^-$. No double-stained cells were detected. $GFAP^+,Tf^-$ cells resembled traditional astrocytes. $GFAP^-,Tf^+$ cells exhibited Tf staining in the cytoplasm with few reactive processes. Nuclear chromatin pattern of these cells resembled that of oligodendrocytes. $GFAP^-,Tf^-$ cells were tentatively identified as microglia. Tf staining was optimal in brains fixed with FAA, satisfactory with PLP and poor with PFO. Our studies support the use of immunohistochemical double-labeling for GFAP and Tf in identifying astrocytes and oligodendrocytes in sections of rat brain. This approach may prove useful in evaluating changes in the number of these two subclasses of glia in the rat brain following injury.

SYNAPTOGENESIS III

360.1

VIDEO MICROSCOPY OF FIRST CONTACTS IN CA1 HIPPOCAMPAL CELL CULTURES. M.W. Cooper* and S.J. Smith* (SPON: P. Forscher). Section of Molecular Neurobiology, Yale University School of Medicine. 333 Cedar St., New Haven, CT 06510

We used digital video microscopy to observe neurons establishing their first contacts in newborn rat hippocampal cell cultures. Newly dissociated cells were put in a sealed chamber at times ranging from 6 to 18 hours after plating and placed under an inverted microscope equipped with computerized autofocus and auto-scanning to sample multiple fields in long term experiments. Our previous studies using immunocytochemical stains aided in the recognition of the cell types *in vitro*.

We find that: (1) the physical interactions between cells are always mediated by filipodia arising from both interacting cell surfaces. (2) Incoming growth cones can induce protrusions from cell surfaces previously devoid of filipodia. Growth cones do this by repeatedly touching the target cell surface. (3) The contact of one filipodium triggers redirection of others to the target. Filipodial interactions are followed by either: (a) retraction of the growth cone or (b) stable contact formation brought about by accelerated growth and the coalescence of filipodia, culminating in the close apposition of the two cells. (4) Cell-to-cell contacts generate tension as evidenced by the rapid shortening of the contacting processes and consequent displacement of their cell bodies. This sequence of events is necessary for the formation of stable contacts.

Neuron-astrocyte contacts are also common and the initial interactions have many similarities to those seen in neuron-neuron contacts, although astrocyte projections are lamellar in nature.

GRADUAL LOSS OF MULTIPLE INNERVATION VISUALIZED WITH A SIMPLE CONFOCAL MICROSCOPE. J.W. Lichtman, R.J. Balice-Gordon, and W.J. Sunderland. Dept. Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

It is unknown whether the competition underlying synapse elimination causes an abrupt or a gradual loss of synapses. We have addressed this question by visualizing the transition from polyneuronal to single innervation at endplates in the transversus abdominis muscle of embryonic Elaphe snakes. Using activity dependent uptake of fluorescent molecules (Nature 314: 357-359, 1985) to separately label the synapses of different axons converging on the same endplate, we studied how terminals of competing axons are interspersed as development proceeds. In embryonic muscle, the activity-dependent labelling technique gave an unsatisfactorily high background which we compensated for by building a simple confocal attachment for our fluorescence microscope. This device reduces scattered and out-of-focus light with a series of apertures inserted into the light path at a point where each aperture is used to simultaneously illuminate and view the specimen. The adaptation is straightforward and inexpensive.

At 3-4 weeks before hatching, inputs are extensively intermingled and occupy roughly equal proportions of the developing endplate. As development proceeds, however, the inputs segregate from each other and typically one axon occupies a significantly larger area within the endplate than another. By 2 weeks before birth, this segregation becomes more pronounced as one axon's terminal area continues to grow while another axon's terminal area shrinks, often to one remaining bouton. By birth all of the endplates are singly innervated. These results suggest that the competitive interactions between convergent inputs result in the gradual elimination of one axon's terminals. The axon which ultimately persists at an endplate captures a progressively larger share of the endplate territory.

360.3

ELIMINATION AND ELABORATION OF PRE- AND POSTSYNAPTIC SITES DURING SYNAPTIC COMPETITION AT DEVELOPING NEUROMUSCULAR JUNCTIONS. R.J. Balice-Gordon and J.W. Lichtman, Department of Anatomy and Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110

We have studied the sequence of pre- and postsynaptic events during the elimination of multiple innervation at developing neuromuscular junctions in mouse sternomastoid muscle. Using 4-Di-2-ASP to vitally label motor neuron terminals and a non-blocking dose of fluorescently tagged alpha-bungarotoxin to label postsynaptic acetylcholine receptors, the same junctions were repeatedly studied at short intervals during the first postnatal month.

At multiply innervated junctions, some nerve terminal branches and the postsynatpic acetylcholine receptors underlying them are rapidly eliminated, often in less than two days. At the same junctions, other terminal and receptor sites are gradually elaborated. This elaboration continues until the end of the first postnatal month, resulting in junctions that gradually become more complex. After this time, the configuration of both nerve terminals and receptors is remarkably stable, enlarging by simple expansion as muscle fibers grow.

Thus elimination and elaboration of synaptic sites are concurrent events. Interestingly, at multiply innervated junctions, the remaining axon does not elaborate terminals at sites vacated by eliminated terminals. Eliminated terminal and receptor sites therefore represent permanent alterations in the arborization pattern of the endplate.

These results suggest that axons do not compete for occupation of the same postsynaptic sites, and that competition alters not only nerve terminals but also postysynaptic acetylcholine receptors.

360.4

PHYSICAL CHARACTERIZATION OF XENOPUS NERVE-MUSCLE AND MUSCLE-MUSCLE SYNAPTIC ADHESION IN CELL CULTURE. A.M. Brown* and M.m. Poo. Section of Molecular Neurobiology, Yale Univ. School of Medicine, New Haven, CT 06511.

When a growth cone encounters a target cell stable adhesion develops between the two cell surfaces. This mechanical connection is the first event in the structural development of the mature neuromuscular junction. Similarly, when two muscle cells encounter each other they adhere and become electrically coupled. In order to understand the early recognition events in the formation of chemical and electrical synapse we have studied the kinetics of adhesion development in these two systems.

The experiments were performed by manipulating a spherical myocyte (myoball), using a suction micropipet, into contact with another myoball or a neurite adhering to the culture substrate. After waiting a specified interval the pipet is withdrawn to test the strength of the adhering bond. We have developed a qualitative assay for neuromuscular adhesion that operates by examining the morphological characteristics of the cells during separation. Four grades of adhesion were defined based on the formation of membrane filaments connecting myoball and neurite, deformation of the growth cone, and detachment of the growth cone from the substratum. Quantitative muscle-muscle adhesion experiments are accomplished by bringing two myoballs into contact using two suction pipets. By holding one cell firmly while applying stepwise increasing suction to hold the other cell, a quantitative estimate of the critical separation force is obtained.

Results from these studies indicate monotonic increases in intercellular adhesion within 10 to 15 minutes following cell contact. This time course correlated well with the observed post contact increase in synaptic efficacy and the localization of specific cell surface components at the contact sites.

LOCAL ACCUMULATION OF ACETYLCHOLINE RECEPTORS IS INSUFFICIENT TO INDUCE CLUSTERING. J. Stollberg* and S.E. Fraser. Dept. Physiology and Biophysics, UC Irvine, Irvine, CA 92717.

Acetylcholine receptors (AChRs) aggregate at the developing neuromuscular junction by mechanisms not fully understood, but at least in part *via* lateral migration. We have shown that in a simple model system - cultured *Xenopus* muscle cells exposed to external electric fields - AChRs, concentrated at the cathode-facing cell pole, continue to aggregate there after the field is terminated (Stollberg and Fraser *J. Cell Biol.* 106, 1988). This aggregation event is due to lateral migration, sensitive to trypsin digestion, and insensitive to agents disrupting microtubules and microfilaments, suggesting that the aggregation is mediated by ad- or cohesion events on the extracellular membrane surface. The simplest model accounting for these observations is that the field-induced rise in AChR concentration triggers the aggregation event. Our present results argue against this interpretation, and suggest the aggregation involves other molecule(s), a voltage-sensitive mechanism, or both.

Treatment of myoball cultures with neuraminidase changes the charge on the cell surface, and has been reported to reverse the direction of electro-osmotic migration for AChRs and concanavalin A binding sites (Orida and Poo *Nature* 275, 1978). Using digitally-analyzed fluorescence video-microscopy, we find that the field-induced distribution of AChRs is bi-modal (density is high at the anode- and cathode-facing poles), suggesting that the electro-osmotic migration and aggregation of AChRs are opposed following neuraminidase treatment. Additionally, we find that the AChR density increases at the cathode-facing pole after field termination, but decreases at the anode-facing pole - clear evidence that elevated AChR density alone does not initiate post-field clustering. As trypsin disrupts the aggregation event, we also analyzed the AChR distribution on cells pre-treated with neuraminidase and trypsin. Consistent with the above interpretation, these cells showed elevated and decreased AChR densities at the anode- and cathode-facing poles, respectively, in a manner well-explained by electro-osmotic migration and diffusion. After termination of the field, the distribution decayed back to uniformity. The kinetics of asymmetry development with time in the field, and decay post-field, give an estimated diffusion constant for the AChR of 1.2×10^{-9} cm^2/sec.

These results indicate that AChR accumulation *per se* is neither necessary nor sufficient to trigger AChR aggregation. It appears that aggregation requires the accumulation (or perhaps voltage-sensitive action) of some other molecule(s).

JS-1, A COMPONENT OF SYNAPTIC BASAL LAMINA AT THE NEUROMUSCULAR JUNCTION, Dale D. Hunter[1], John P. Merlie[2], and Joshua R. Sanes[1]. Dept. of [1]Anatomy & Neurobiology and [2]Pharmacology, Washington University School of Medicine, St. Louis, Missouri 63110

Axons preferentially reinnervate original synaptic sites in denervated muscle and differentiate there into nerve terminals. These phenomena are mediated at least in part by the synaptic portion of the muscle fiber's basal lamina sheath. Immunohistochemical studies have defined antigens concentrated in synaptic basal lamina which could mediate these interactions; we recently used immunoblotting and immunoprecipitation to identify one such antigen, JS (Junction-Specific)-1, a glycoprotein of Mr 185,000 and pI 5.5-6.0 (Soc. Neurosci. Abstr. 13: 375, 1987).

We have now purified JS-1 greater than 2000-fold to $\geq$20% purity. In addition, we have used monoclonal antibodies to JS-1 to isolate a cDNA clone from a λgt11 library which encodes a fragment of JS-1. Antisera raised against the encoded fusion protein recognize synaptic sites in skeletal muscle, supporting the classification of this fragment as part of JS-1. We are currently characterizing the purified protein and sequencing the cDNA.

To determine whether neurons can recognize JS-1, we plated ciliary ganglion cells (which form skeletal neuromuscular junctions in vivo) on dishes coated with purified or recombinant JS-1. Neurons adhere to either substrate, but do not send out neurites; on laminin, they adhere and send out neurites; on several control substrata, they do neither. This result is consistent with the hypothesis that JS-1 is a component of the synaptic basal lamina with which neurons interact. We are therefore asking whether neurites extending on laminin stop growing and/or differentiate when they encounter a deposit of JS-1. (Sponsored by MDA and NIH.)

MOTOR NEURONS CONTAIN AGRIN-LIKE MOLECULES DURING THE PERIOD OF NEUROMUSCULAR SYNAPTOGENESIS. C. Magill & U.J. McMahan. Dept. of Neurobiology, Stanford University, Stanford, CA 94305

Several lines of evidence indicate that the molecules in the synaptic basal lamina at the neuromuscular junction that direct the formation of acetylcholine receptor (AChR) and acetylcholinesterase (AChE) aggregates on regenerating muscle fibers are similar to agrin, a protein extracted from Torpedo electric organ. It has been hypothesized that the agrin-like molecules in the basal lamina are secreted by the motor neuron's axon terminal, that they are the same molecules that mediate the motor neuron-induced formation of AChR and AChE aggregates on developing myofibers in the embryo, and that they direct the maintenance of these postsynaptic specializations in the normal adult. Our previous studies have provided evidence that motor neurons in perinatal and adult animals contain agrin-like molecules, which is consistent with these hypotheses. The two experiments described here further revealed that agrin-like molecules are present in embryonic motor neurons at the times when AChR and AChE aggregates begin to form at neuromuscular junctions.

First, we stained the spinal cord of chick embryos with anti-agrin monoclonal antibodies. We detected anti-agrin labelling in the cytoplasm of motor neurons as early as stage 27, when neuromuscular synaptogenesis begins. The level of staining increased with developmental age at least until hatching, a period during which there is rapid synaptic growth. Motor neurons were the only neurons in which staining was detected at any age.

Second, we dissociated embryonic chick (stage 27-31) spinal cords, separated the cells into motor neuron-enriched and motor neuron-poor fractions, and made extracts of each. The extract of the motor neuron-enriched fraction contained AChR-aggregating activity which was specifically immunoprecipitated with anti-agrin monoclonal antibodies, whereas the extract of the non-motor neuron fraction contained little such activity.

360.8

AGRIN RELATED MOLECULES ARE EXPRESSED IN ANEURAL DEVELOPING MUSCLE. Justin R. Fallon and Celia E. Gelfman*, Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545

Molecules closely related if not identical to agrin, 'agrin-related molecules', are highly concentrated in the synaptic basal lamina of the adult neuromuscular junction and are likely to play a role in directing the regeneration of the postsynaptic apparatus at this synapse. Previous work from this laboratory has established that in developing chicks agrin-related molecules are expressed in muscle prior to synapse formation and are subsequently co-localized with >95% of AchR clusters. In the present studies two preparations were used to determine if the expression of agrin-related molecules in developing muscle is dependent upon innervation. In one set of experiments, embryos with aneural hindlimbs were generated by extirpating the lumbosacral spinal cord at stage 17 (2.5d), before motoneurons have exited the CNS. In a second series, limb buds which had not yet been innervated (stage 19-21, 3.5d), were removed from embryos and grafted onto the chorioallantoic membrane. Seven days after either manipulation the experimental limbs were examined by fluorescence microscopy of cryostat sections using antibodies against agrin and rhodamine α-bungarotoxin. In both cases agrin related molecules are present in the aneural muscles and co-localize with AchR clusters. These experiments extend our previous results which indicate that agrin-like molecules play a role in the initial events of synapse formation and also suggest that at least some of the agrin-like molecules present at the neuromuscular junction are synthesized by muscle.

TARGET RECOGNITION DURING SYNAPTOGENESIS OF CULTURED *HELISOMA* NEURONS. Zoran, M. J. and Haydon, P. G. Department of Zoology, Iowa State University, Ames, IA 50011

Cholinergic neuron B5, isolated from the buccal gangion of *Helisoma* and plated into culture, reliably forms the presynaptic element of inappropriate chemical synapses with ACh-sensitive, identified neurons P5, B19 and B5. In contrast, cholinergic neuron B19 is unable to form chemical connections with the same inappropriate, postsynaptic targets. Is recognition of an appropriate postsynaptic cell necessary for B19 to become an adequate presynaptic element?

Single supralateral radular tensor (SLT) muscle fibers, known to be the postsynaptic elements of cholinergic connections with neuron B19 *in vivo*, were dissociated into cell culture. Single muscle fibers maintain normal physiological properties in cell culture; application of ACh evokes depolarizing potentials and contractile responses. Neuron B19 was plated in cell culture with the single SLT target fibers and, after a period for neurite extension and contact, formed cholinergic chemical synapses. Thus, B19 is capable of forming appropriate chemical synapses when plated with its appropriate target.

Therefore, although both neurons B19 and B5 can form chemical synapses in culture, they utilize different synaptogenic strategies. Neuron B19 requires the recognition of an appropriate target for synapse formation; whereas, B5 forms inappropriate synapses with any ACh-receptive target.

RECEPTOR-MEDIATED REGULATION OF SYNAPTIC CONNECTIVITY IN CULTURED *APLYSIA* NEURONS. G.M. Carrow and I.B. Levitan. Graduate Department of Biochemistry, Brandeis Univ., Waltham, MA 02254.

When dissociated neurons from the mollusc, *Aplysia californica*, are placed in primary cell culture, they form electrical synapses in a specific manner. Neurons from the same ganglion form electrical synapses (homoganglionic synapses) with high coupling coefficients due to high macroscopic junctional conductance (G_j; 10-25 nS). By contrast, synapses between neurons from different ganglia (heteroganglionic synapses) exhibit low coupling coefficients as a result of low G_j (1-5 nS). Moreover, this specificity is altered by treatment of the neurons with the lectin, Concanavalin A (Con A; Carrow & Levitan, 1987; Lin & Levitan, 1987).

We have now found that the alteration in synaptic specificity induced by Con A results from its increasing the junctional conductance of heteroganglionic synapses to the level characteristic of homoganglionic synapses. Furthermore, this increase in conductance is dependent upon protein synthesis. Pairs of neurons isolated from juvenile ganglia and grown in culture in the absence of Con A were voltage clamped and perfused with 0.1 μM Con A. The G_j of heteroganglionic pairs began to increase about 2 hr after introduction of Con A and continued to increase over several hours, even after wash out of the lectin. Homoganglionic pairs treated similarly showed no change in G_j. Heteroganglionic pairs failed to show increased G_j when treated for 1 day with 0.5 μM Con A in the presence of the protein synthesis inhibitor, anisomycin (10 μM). However, this blockage was partially reversible since G_j increased several fold in the continued presence of Con A after wash out of anisomycin.

Synaptic specificity among these regenerating neurons is likely mediated by ganglion-specific cell recognition molecules. The results summarized here suggest that these molecules are or are linked to lectin receptors that regulate synthesis of gap junction channels or associated regulatory proteins.

GLUTAMATE RELEASED FROM ENTORHINAL CORTEX AXONS INHIBITS DENDRITIC OUTGROWTH AND PROMOTES SYNAPTOGENESIS IN HIPPOCAMPAL NEURONS. M. P. Mattson, R. E. Lee*, M. E. Adams*, P. B. Guthrie & S. B. Kater, Program in Neuronal Growth & Dev., Colorado State Univ., Ft. Collins, CO 80523.

A culture system of embryonic rat entorhinal cortex explants and isolated hippocampal neurons was used as a model of hippocampal development to demonstrate that endogenously-released neurotransmitters can shape neuronal circuitry. Hippocampal neuron dendrites were visualized by MAP2 immunocytochemistry on the background of nonstaining entorhinal axons; little dendritic outgrowth occurred in neurons on the axon bed. Since glutamate can inhibit dendritic outgrowth in isolated hippocampal neurons (Mattson et al., J. Neurosci. 8:2087, 1988), we hypothesized that glutamate, released from entorhinal axons, might be suppressing dendritic outgrowth. HPLC analysis of culture medium showed activity- and calcium-dependent, release of glutamate from explants. The glutamate receptor antagonist d-glutamylglycine (DGG) significantly increased dendritic outgrowth in hippocampal neurons on the axon bed. Tetrodotoxin, elevated extracellular Mg^{2+}, or removal of entorhinal cell bodies also enhanced dendritic outgrowth; apparently ongoing activity in entorhinal neurons and associated glutamate release was responsible for outgrowth inhibition. Both the geometry and synaptic organization of a neuron determine its information coding capabilities. We therefore examined synaptic correlates of glutamate's effects at the light (Timm method and protein III staining) and ultrastructural levels. In control cultures synaptic specializations associated with the soma and dendrites of hippocampal neurons were abundant and well differentiated containing numerous small (30-50 nm) vesicles. In contrast, synapses in DGG-treated cultures were reduced in numbers and were poorly developed with relatively few, large (>100 nm) and irregular-shaped vesicles. The mechanism by which glutamate inhibits outgrowth and promotes synaptogenesis apparently involves sustained elevations in intracellular calcium; DGG reduced intracellular calcium levels in hippocampal neurons on the axons. Our data indicate that neurotransmitters can shape both the neuritic architecture and specific connections of the circuits in which they participate in information coding. ALZHEIMER'S DISEASE: PROTEIN

361.1

Reduction of APP-695 Beta-Amyloid Transcript Prevalence in Alzheimer Disease (AD) Cortex. SA Johnson, GM Pasinetti and CE Finch, Andrus Gerontology Center and Dept. Biol. Sci., Univ. of So. Cal., Los Angeles CA, 90089-0191

Recent work has shown that mRNA for the beta-amyloid precursor protein (APP) exists in the brain in two differentially spliced forms (APP-695 and APP-751). APP-751 has an additional exon encoding a "Kunitz serine-protease inhibitor" peptide (Ponte et.al., Nature 331:525, 1988). We examined whether the different beta-amyloid transcripts have different prevalence in AD or control (CTL) cortex, using probes and hybridization conditions to discriminate APP-695 and APP-751 transcripts separately on poly(A)+RNA gel blots. In initial studies with pooled cortical A+RNA from AD or CTL (5 individuals per pool), two closely migrating bands were detected at 3.6 Kb & 3.4 Kb (APP-751 probe) and at 3.4 Kb & 3.2 Kb (APP-695 probe). Mixing studies showed each probe to be highly selective and consistent with alternate polyadenylation sites. Autoradiogram quantitation indicated a 65% decrease in AD for the APP-695 transcript doublet. Overall, the ratio of APP-751/APP-695 increased 2 fold in AD. Similar results were obtained with individual A+RNA samples (5 AD and 4 CTL). While the prevalence of the APP-751 full length doublet did not change in AD, the APP-695 transcripts decreased 60%. The APP-751/A-695 transcript prevalence ratio increased from 2.4 in CTL to 5.6 in AD. We also detected a new 1.6 Kb APP-695-related transcript in both AD and CTL A+RNA, whose prevalence with respect to full-length APP-695 transcripts increased 3-fold in AD. In situ hybridization experiments are in progress to determine whether different neuronal types show selective loss of these transcripts in AD. The large decrease of transcripts lacking the Kunitz serine protease inhibitor peptide could be important to AD pathogenesis by disturbing the balance of protein processing and degradation. These studies were supported by grants to CEF (AG-05142, ADRC of Southern California) and to SAJ from ADRDA.

AMYLOID PROTEIN PRECURSOR mRNAs: DIFFERENTIAL EXPRESSION IN ALZHEIMER'S DISEASE. M. Palmert*, T. Golde*, M. Cohen*, D. Kovacs*, R. Tanzi*, J. Gusella*, M. Usiak*, L. Younkin, and S. Younkin. Case Western Reserve and Harvard Schools of Medicine.

We used *in situ* hybridization (ISH) with [35]S-labeled cRNA probes to assess amyloid protein precursor (APP) mRNA in 11 sporadic Alzheimer's disease (AD) and 7 control brains well matched for age and postmortem interval. Total APP mRNA was evaluated using a 3' probe complementary to all APP mRNAs. APP mRNA containing the Kunitz protease inhibitor (KPI) domain was separately evaluated using a probe complementary to the KPI sequence. In each experiment, sets of AD and control sections from the same brain region were processed side-by-side to optimize comparison of mRNA levels in AD and control cases. In AD we observed a significant two-fold increase in total APP mRNA in nucleus basalis of Meynert (nbM) and locus ceruleus (LC) neurons, but there was no change in total APP mRNA in hippocampal subicular neurons, neurons of the basis pontis, or occipital cortical neurons. With the KPI-specific probe, we observed no change in any of the brain regions examined. Thus the increase in total APP mRNA in nbM and LC neurons was due exclusively to an increase in APP mRNA lacking the KPI domain. We are currently performing ISH with junctional probes in an effort to confirm the selective increase in the APP mRNA lacking the KPI domain, to assess the basal level of expression of this form in control cells, and to determine if there is a large percentage increase in this form in AD. (Supported by USPHS grants AG06656, MH43444, and a grant from the state of Ohio.)

361.3

THE MONKEY HOMOLOG OF THE β-AMYLOID PRECURSOR PROTEIN OF ALZHEIMER'S DISEASE: ISOLATION OF cDNAs AND DETECTION OF PRECURSOR PROTEIN. M. Berman-Podlisny,* D. Tolan* and D. Selkoe (SPON: G. Strichartz). Harvard Med. Sch., Brigham and Women's Hosp. and Boston University, Boston, MA.

Alzheimer's disease is always accompanied by the deposition of extraneuronal filaments composed of the β-amyloid protein (βAP). A similar process occurs during normal brain aging in humans and lower primates. We have shown that amyloid in aged monkey cortex contains βAP antigenically indistinguishable from that in AD. Thus, aging monkeys may prove useful for dynamic studies of the processing of the βAP precursor (βAPP) into amyloid that are not possible in humans. Human βAPP cDNAs were used to probe a cDNA plasmid library from adult monkey cortex. Of ~60 clones detected, the longest insert was ~1.9 kb. To date, we have sequenced 0.8 kb, yielding a monkey sequence that shows 97.7% nucleotide homology in the region 1279 - 2073 bp of the human sequence (Kang et al., Nature 1987). The nucleotide changes produced no amino acid substitutions within this 264-residue region that includes the βAP. Antibodies to C-terminal synthetic peptides of the human βAPP were used to probe Western blots of monkey brain. We detected proteins of ~110-135 kDa that co-migrate with polypeptides we have identified as forms of the native βAPP in human tissues. These comparative studies should enable analysis of the proteolytic processing of the βAPP in a non-human primate that undergoes cortical amyloidosis and neuritic plaque formation with age.

361.4

Isolation and expression of multiple forms of Beta Amyloid Protein pecursor cDNAs. R.J. Donnelly*, C. G. Rasool, R. Bartus, B. Beer, A.J. Blume, and M. Vitek. Molecular Neurobiology and Geriatrics, Central Nervous System Biological Research Department, Medical Research Department, Lederle Laboratories, American Cyanimid Company, Pearl River, NY 10965.

Alzheimer's Disease (AD) is associated with the extra-normal accumulation of a 42 amino acid beta-amyloid peptide (BAP) in amyloid plaques and cerebrovascular deposits. Though BAP is deposited exclusively in brains of AD and Downs syndrome patients, the mRNA encoding BAP is found in the brain and in peripheral tissues. Using an HL 60 cDNA library, we have isolated two Amyloid Peptide Precursor (APP) cDNAs with sequences that code for proteins containing 751 and 770 amino acids (APP 751 and APP 770). In addition to containing the coding region for BAP, they also contain a region homologous to the Kunitz domain of serine protease inhibitors. In order to examine the potential function of these putative precursor proteins and to study the processing of APP 751 and APP 770 into the 42 aa peptide, we have engineered the cDNA sequences into bacterial and eucaryotic expression vectors. The results of the expression of the exogenous gene in mammalian cell cultures and the characteristics of the bacterially produced protein will be discusssed with respect to a possible precursor-product relationship in AD.

361.5

THE BIOLOGICAL ACTIVITY OF ALZHEIMER'S AMYLOID. B. A. Yankner[1], L. Villa-Komaroff[1] and R. L. Neve[2]. Depts. of Neuroscience[1] and Genetics[2], The Children's Hospital, Boston, MA 02115

The rat pheochromocytoma cell line PC12 differentiates into a neuronal cell type in response to nerve growth factor (NGF). Northern blot analysis demonstrated that the amyloid precursor RNA is expressed constitutively in PC12 cells but is induced about 100-fold by treatment with NGF. cDNAs corresponding to the amyloid precursor or a fragment containing the amyloid beta protein were transfected into PC12 cells by the calcium phosphate method. Several clones were isolated that overexpressed either amyloid beta protein or amyloid precursor RNA from the transfected cDNAs. Clones overexpressing the amyloid beta protein exhibited a significant acceleration of neurite outgrowth in response to NGF. Clones overexpressing the amyloid precursor also exhibited an increased response but relatively less than cells expressing similar amounts of the amyloid beta protein fragment. Conditioned medium from transfected cells greatly potentiated neurite outgrowth when added to untreated PC12 cells or cultured dorsal root ganglion neurons. These results suggest that proteolytic cleavage of the Alzheimer's amyloid precursor may generate a peptide with potent effects on neuronal differentiation.

361.6

DEVELOPMENT OF A GENETICALLY ENGINEERED CELLULAR MODEL FOR THE AMYLOIDOSIS OF ALZHEIMER'S DISEASE. **S.B. Zain*, W.-G. Chou*, R.E. Majocha*, and C.A. Marotta (SPON: G. Hauser). Univ. Rochester Cancer Ctr., Rochester, NY 14642; Harvard Med. Sch., Massachusetts General Hosp., Boston, MA 02114; Mailman Res. Ctr., McLean Hosp., Belmont, MA 02178.**

The A4 domain of the amyloid precursor protein (APP) cloned directly from Alzheimer's Disease (AD) brain mRNA has the same structure as from non-AD sources (Zain, et al, P.N.A.S. 85:929, 1988). Local processing of the precursor may be a critical event in the formation of amyloid plaques. Therefore we prepared genetically transformed cells that overexpress the A4 domain. Transfections were carried out with synthetic vectors, originally derived from SV40, that were linked to the 1.1 kb cDNA Eco RI fragment that contains the A4 region. Successful transfection was confirmed by Southern blots and in situ hybridizations. Cells were immunostained by monoclonal antibodies to the A4 peptide. Transfectants carrying vectors in the correct reading frame for APP produced immunologically detectable amounts of the A4 epitope. The cells are being used to examine the consequences of amyloid over-production and to define conditions that interrupt this process. Supported by AG02126, CA11198, CA36432, American Health Assistance Foundation and Familial A.D. Res. Foundation.

361.7

IDENTIFICATION OF NEWLY SYNTHESIZED BETA-AMYLOID PRECURSOR PROTEINS IN RAT AND HUMAN. W. Wallace, M. Krishnamurthi J. Anderson [1], P. Mehta [2], V. Haroutunian[1], N. K. Robakis[1] Dept. of Psychiatry and Fishberg Center for Neurobiology Mt. Sinai School of Medicine, New York and [2] Institute for Basic Research in Developmental Disabilities, New York.

The amyloid core protein (ACP) likely derives from a larger protein termedthe beta-amyloid precursor protein (B-APP). Three splicing variants of the mRNA coding for B-APP have been isolated. We are using polysomes to identify and characterize the newly synthesized forms of B-APP in rat and human brain, in the absence of post-translational modifications such as those responsible for the formation of ACP. Polysomes are translated in vitro and the translation products immunoprecipitated with antibodies generated to synthetic peptides made to various portions of the putative precursor. We observe three different polypeptides (Mr 110,115,120 kD) synthesized by the polysomes, immunoprecipitated by four different antibodies, and specifically competed away by the synthetic peptides. In the human, the 115 and 120 kD species are present in considerably higher abundances relative to the 110 species compared with the rat. These same polypeptides are synthesized by cerebellar as well as cerebral cortical polysomes. All three polypeptides are made exclulsively by membrane-bound polysomes. The different newly synthesized B-APP's may be products of the mRNA splicing variants.

361.8

TAU PROTEIN IN ALZHEIMER'S DISEASE, AGED RATS AND SYSTEMIC ORGANS. S.Ch. Papasozomenos and L.I. Binder. Dept. of Pathology, Univ. of Texas Med. Sch., Houston, TX 77225 and Depts. of Cell Biol. and Neurology, Univ. of Alabama, Birmingham, AL 35294.

We have shown that in Alzheimer's disease (AD) excessive amounts of tau immunoreactivity localized not only with paired helical filaments but also with ribosomes in both neurons and astrocytes. We have also shown (Papasozomenos, S.Ch. and Binder, L.I., Cell Motil. Cytoskel. 8:210, 1987) by using two monoclonal antibodies against tau, Tau-1 and Tau-2, that phosphorylated Tau-1 epitope and the Tau-2 epitope are present on microtubules and ribosomes in the somatodendritic compartment of neurons and in astrocytes. In order to gain further insight into the physiologic functions of tau and the etiopathogenesis of AD, we have examined the tau immunoreactivity in almost every systemic organ and the CNS of several Sprague-Dawley rats 6 weeks to 25 months old. Among the systemic organs, tau immunoreactivity was detectable only in plasma cells, the islets of Langerhans and the renal medullary collecting duct epithelium. In the CNS, using the Tau-1 antibody, tau immunoreactivity was not detectable in the somatodendritic compartment of neurons and astrocytes without prior dephosphorylation of sections up to the age of 3 months, but in older rats tau non-phosphorylated at the Tau-1 epitope, and thus detectable without prior dephosphorylation of sections, appeared, besides axons, in protoplasmic astrocytes. These astrocytes were most numerous in cortical layer IV, the inferior colliculi, the granule cell layer of cerebellum, the CA3 region of hippocampus and the dorsal half of the lumbar spinal cord. Involvement of astrocytes throughout the brain and perhaps earlier than neurons was also observed in AD. These findings suggest that a disturbance of a secretory process in which tau may play a role may be involved in the pathogenesis of aging and AD.

CONCOMITANT PRESENCE OF UBIQUITIN AND TAU PROTEIN IN EXPERIMENTAL NEURONAL INCLUSIONS.

P.Gambetti, W.Welch, G.Perry, L.Autilio Gambetti and A.Morandi* (SPON: G.Perry)
Div. of Neuropathology, Case Western Reserve University, Cleveland OH, 44106 and Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

Several diseases of the nervous system, such as Alzheimer's, Pick, Parkinson and amiotrophic lateral sclerosis are charachterized by the presence of intraneuronal inclusions whose composition and mode of formation are unknown. We have induced the formation of intracytoplasmic neuronal inclusions exposing rat dorsal root ganglia to the antimitotic drug cytosin-arabinoside (5*10e-6 M), for 7 days. The inclusions are round, approximately the size of the nucleus and markedly eosinophilic. Ultrastructurally they are composed of packed filaments mixed with trapped cytoplasmic organelles. The inclusions immunoreact with antibodies to Ubiquitin, Tau proteins and phosphorilated epitopes of the 200 kDa neurofilament subunit, but not with antibodies to actin and Heat Shock Proteins 70 and 28. Antitubulin antibodies react only with some inclusions. The experimental inclusions we have obtained may provide a model to study the mode of formation of those neuronal inclusions that form in the course of human neurodegenerative conditions and that contain Ubiquitin, Tau proteins and phosphorilated epitopes of neurofilaments.

THE ALZ50 EPITOPE IS IN THE CARBOXY HALF OF TAU AND BACTERIAL SYNTHESIS OF THE SITE IS NOT SUFFICIENT FOR RECOGNITION.

K.S. Kosik,* S. Bakalis* and L.D. Orecchio* (Spon: L.M. Hemmendinger). Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115.

Alz50 is a monoclonal antibody directed against an antigen that is present at higher levels in Alzheimer versus control brain (Wolozin et al., SCIENCE 1986). Recently, we have shown that the antibody reacts with tau in all of its heterogeneous forms (Nukina et al., NEUROSCI LETT 1988). We therefore sought the epitope in tau wtih which the antibody reacts. Alz50 does not react with any of the epitopes presented to it in bacterially synthesized tau, thus suggesting the antibody is directed against a post-translational modification or a conformation not achieved in the bacterial system. Bovine tau was digested with cyanogen bromide (CNBr) and the HPLC-separated fragments tested for Alz50-reactivity. The reactive fragments eluted over a broad range with a late retention time relative to the other CNBr fragments. Tubes with Alz50-reactivity contained two tau peptides, both of which derived from the carboxy half of the molecule. The carboxy half of tau is likely to contain the microtubule binding domain. One of the peptides is likely to contain the Alz50 epitope, which may represent a site on tau that is involved in the early stages of neurofibrillary tangle formation.

IN SITU MAPPING OF pADHC-9: A POLY(A)RNA SEQUENCE OVEREXPRESSED IN ALZHEIMER'S DISEASE HIPPOCAMPUS.

P.C. May, Ph.D., S.A. Johnson, Ph.D., M.E. Lampert-Etchells, Ph.D.* and C.E. Finch, Ph.D. Andrus Gerontology Center, Dept. Biological Sciences, USC, Los Angeles, CA 90089.

Poly(A)RNA sequences with altered prevalence in Alzheimer's disease (AD) are being cloned to identify the molecular events associated with neuronal degeneration and regeneration occurring in the AD hippocampus. Clone pADHC-9 is a 0.7 Kb cDNA clone isolated from a mixed AD/Control hippocampal cDNA library by differential screening with AD and control cDNA probes. By Northern analysis, pADHC-9 hybridizes to a 2.0 Kb RNA whose prevalence was selectively increased two-fold in AD hippocampus; no increase in this RNA was detected in AD RNA samples from other brain regions which undergo degeneration (e.g., frontal, occipital or temporal cortex). To map the cellular distribution of the RNA encoded by pADHC-9, sense and antisense ^{35}S-labelled cRNA probes were hybridized to coronal sections of AD and control hippocampal formation. Direct autoradiography of tissue sections after in situ hybridization indicated a laminar distribution of the RNA encoded by pADHC-9 in the entorhinal cortex and hippocampus. Prominent labelling was observed in the granule cell layer of the dentate gyrus and along the pyramidal tract of the hippocampus. Sequence data analysis of pADHC-9 indicated no significant homology with any entry in GenBank. Additional cDNA clones nearly spanning the entire 2 Kb RNA have been obtained and are being sequenced. Provisionally we conclude that pADHC-9 represents a new marker reflecting altered gene expression in AD hippocampus. Identification of this RNA sequence and characterization of the function of its protein product will establish a new approach to basic mechanisms of pathogenesis in AD.

ALTERATION IN GLIAL FIBRILLARY ACIDIC PROTEIN mRNA CONTENT IN THE RAT HIPPOCAMPUS AFTER ENTORHINAL CORTEX LESION.

J. Poirier*, P.C. May and C.E. Finch. Department of Neurobiology/Gerontology, Univ. Southern California, Los Angeles, CA 90089.

To better reveal the role of denervation on the hippocampal expression of selected mRNA in Alzheimer's disease, we used a rodent model of hippocampal deafferentation. Electrolytic lesions of the entorhinal cortex were made in twenty 3 month old Fisher rats. After 14 days, rats were sacrificed and total hippocampal RNA was isolated by the guanidinium isothiocyanate method of Chirgwin at al. 1979. The total RNA was used for solution hybridization and northern blot hybridization. The loss of entorhinal input in the dentate gyrus in lesioned rats results in sprouting of the afferents originating from the septal area (cholinergic) and from the commissural/ associational (glutamatergic) fibers. This plastic response is very similar to what has been observed in the hippocampus of Alzheimer's patients (Geddes et al, 1985). Based on this striking similarity of response, we are studying the expression of mRNA of proteins that were shown to be increased, decreased or associated with tangles in the hippocampus of Alzheimer's disease patients. These include glial fibrillary acidic protein, beta amyloid, somatostatin and ubiquitin. Complementary RNA (cRNA) of each of these probes were synthesized and hybridized to total RNA extracted from lesioned and control rat hippocampi. These lesions had no affect effect on total and A+ RNA yield. Ubiquitin, somatostatin and beta amyloid mRNA content in the hippocampus of lesioned animals do not differ from control animals whereas GFAP mRNA shows a highly significant increase in northern blot analysis using a computer based image densitometry. Subsequent quantification of GFAP messenger by RNA-RNA solution hybridization indicate a 3.0 fold increased expression in the hippocampus of lesioned (10.8 $\pm$ 1.8 pg/ug of total RNA) versus control (3.8 $\pm$ 0.2 pg/ug of total RNA) animals. This is in agreement with a recent report that has shown a two fold increase GFAP mRNA content in the hippocampus of patients with Alzheimer's disease (May et al., 1987). By in situ hybridization with an S35-GFAP cRNA, unilaterally lesioned animals show increased signal in the outer two thirds of the molecular layer of the dentate gyrus. It is also in the same area that maximal sprouting of cholinergic septal fibers and glial proliferation have been previously observed (Scheff et al., 1980). These results indicate that this rat model of hippocampal deafferentation can effectively mimic some of the molecular responses observed in Alzheimer's disease.

VISUAL CORTEX V

362.1

STUDIES OF PRIMATE VISUAL CORTEX USING A DOUBLE-LABEL DG TECHNIQUE AND COLOR AUTORADIOGRAPHY.

R. B. H. Tootell, R. T. Born* and S. L. Hamilton*. Dept. Neurobi., Harvard Med. Sch., Boston, Ma. 02115.

Several investigators have experimented with a double-label deoxyglucose (DG) technique [Livingstone and Hubel, *Nature 291:* 554 (1981); Webster et al, *Neurosci. Lett. 40:* 281 (1983); Friedman et al, *Exp. Brain Res. 66:* 543 (1987)]. The potential advantage of such a technique is that brain activity produced by both an experimental and control condition can be labelled in the same tissue, typically with ^{3}H-DG in one condition and with ^{14}C-DG in the other. Following Kronenberg *[Anal. Biochem. 93:* 189; (1979)], who tested radioactive standards on color-negative film, we developed a double-label DG protocol incorporating color film autoradiography, in which the distributions of ^{3}H- and ^{14}C-DG can be reliably separated from each other. In this protocol, ^{3}H-DG produces a blue image on color-positive film, and the ^{14}C-DG produces a whitish image on the same film.

To validate our modified double-label technique, a paralyzed, anesthetized macaque monkey was shown a split-field visual stimulus, monocularly. Initially, ^{3}H-DG was injected while the animal viewed a black-white square wave grating (of systematically varied orientation, spatial frequency, drift rate and direction) confined to the lower visual field. After 45 minutes, when most of the ^{3}H-DG was taken up, the stimulus was reversed so that the grating was in the upper visual field, and ^{14}C-DG was injected to label its effect. Color autoradiographs from this case showed blue ocular dominance strips in dorsal striate cortex, whitish ocular dominance strips in ventral striate cortex, and a sharp retinotopic border between the two regions. By using blue and red color filters and digital subtraction routines, images of these ^{3}H- and ^{14}C-DG labelled ocular dominance strips could be unambiguously isolated. In another experiment, horizontal and vertical (blue and whitish) orientation columns were labelled in areas V1, V2 and other regions of macaque visual cortex with binocular, single-orientation stimulation. This technique should be extremely useful in studies of extrastriate cortical columns, where it is necessary to label the effect of at least two different stimulation conditions to prove the existence of functional columns.

362.2

INFRA-RED IMAGING OF FUNCTIONAL ORGANIZATION OF VISUAL CORTEX THROUGH THE INTACT DURA USING A CCD CAMERA.

R.D. Frostig, E.E. Lieke, D.Y. Ts'o and A. Grinvald. IBM Research Division, Yorktown Heights, NY 10598 and Lab. of Neurobiology, The Rockefeller University, New York, NY 10021.

We have demonstrated that activity dependent intrinsic signals can be used for optical mapping of the functional organization of the visual cortex. Exploration of the nature of the intrinsic signals useful for functional imaging revealed two major components. One component originates from changes in blood volume probably due to local capillary recruitment in an activated area. These changes are followed by an increase in hemoglobin absorption. Detailed characterization of the time course and saturation of this optical signal may help to improve the performance of PET imaging which is based on similar phenomena (Fox et. al. Nature, 323, 806-809, 1986). The other component originates from light scattering that accompanies changes in the cortical tissue after activation (e.g., ion and water movement, expansion and contraction of extracellular spaces, capillary expansion, neurotransmitter release, etc.).

The blood volume component of the intrinsic signal dominates between 500-700 nm while the light scattering component dominates in the near infra-red region above 800 nm. These two components have different time courses. Nevertheless, maps of functional organization obtained in both regions of the spectrum were identical either in area 17 of the macaque monkey or area 18 of the cat. Thus each component can be used for functional mapping (see also Ts'o et. al. this volume).

We have found that the proper control of depth of field is an important factor in optical imaging. With present optics the depth field is probably larger than 500 μm. Since near infra-red light penetrates the cortex deeper than visible light it facilitates the imaging of deeper cortical structures. Thus infra-red imaging may prove more useful for confocal three-dimensional imaging than visible light. Moreover, near infra-red light also allowed us to image, using a high resolution CCD camera, the orientation columns of the cat and the ocular dominance columns of the monkey through the intact dura, which is opaque to visible light. The obtained maps were identical to maps obtained after the dura was removed. The ability to image the functional organization through the dura will be advantageous for research on chronic animal preparations.

362.3

FUNCTIONAL ORGANIZATION OF VISUAL AREA 18 OF MACAQUE AS REVEALED BY OPTICAL IMAGING OF ACTIVITY-DEPENDENT INTRINSIC SIGNALS *D.Y. Ts'o, R.D. Frostig, E.E. Lieke, A. Grinvald. Laboratory of Neurobiology, The Rockefeller University, NY, NY 10021 and IBM Research Division, Yorktown Heights, NY 10598.*

Using a high *S/N* CCD camera, we have extended the spatial resolution of the imaging of intrinsic activity-dependent optical signals[1] (i.e. without dyes), and applied the technique to study the functional organization in the macaque visual areas 17 and 18. These methods have enabled us to directly image *in vivo* the thick and thin cytochrome oxidase-rich stripes as well as other functional features of area 18.

By presenting visual stimuli to each of the two eyes separately and subtracting the two sets of frames after averaging, the familiar pattern of ocular dominance in area 17 was obtained. However this procedure revealed no pattern in area 18. In an alternative strategy, the same two sets of frames were each compared to a set of no-visual-stimulus frames. This method revealed stripe-like cortical regions activated by each of the two monocular stimulus conditions that were overlapping in area 18 rather than interdigitating as in area 17. Comparison with cytochrome oxidase histology from the same tissue showed that these regions of higher activity imaged optically coincided with the thick and thin stripes of area 18. A similar overlapping of regions of activity with monocular stimulation of each of the two eyes has been seen using the double-label 2DG method.[2] We later discovered that frames obtained with binocular stimulation also showed the stripes in area 18. The stripes imaged optically, then, may represent a co-mingling of cells from both ocular dominance groups, or perhaps regions that have high responsivity or low stimulus selectivity.

We also used these techniques to map orientation specificity in areas 17 and 18. The resultant patterns appeared as an arrangement of patches that were, in area 17, 200-400μm in diameter, but in area 18 were 500-800μm, showing large regions with uniform orientation selectivity. This feature of the organization of orientation selectivity in area 18 has been suggested by single unit recordings in area 18.[3]

362.4

PATHWAY TRACING IN PRIMATE VISUAL CORTEX USING VOLTAGE SENSITIVE DYES IN VIVO. H. S. Orbach, D. J. Felleman and D. C. Van Essen. Div. of Biol., Caltech, Pasadena, CA 91125.

We have used voltage-sensitive dyes in conjunction with focal electrical stimulation to map connections between visual areas in the anesthetized squirrel monkey. Dorsal V1 and V2 were exposed, stained with a styryl dye (RH795, courtesy A. Grinvald and R. Hildesheim), and imaged onto a 10 x 10 photodetector array. Area V1 was stimulated with a brief train of pulses passed through a tungsten microelectrode. Large responses were seen with current pulses as low as 10 uamp x 0.2 ms (biphasic).

Within V1, local responses extended several mm. from the stimulation site; the full-width at half-height was 1-2 mm. Responses in the periphery of this zone began 4 msec or more after those in the center, which presumably reflects conduction and/or synaptic delays.

In two hemispheres, responses were seen at the expected topographic location in V2. These were well separated from the V1 stimulation site and began with a delay of 5-8 msec. The region of activation in these instances included all three cytochrome-oxidase stripes (thick, thin and inter-stripe). Thus, this paradigm should be valuable for probing the topographic (and probably compartmental) organization of cortical visual areas. Supported by the Office of Naval Research.

362.5

SPATIAL FREQUENCY ORGANIZATION OF PRIMATE STRIATE CORTEX D.H. Grosof*, M.S. Silverman*, R.L. De Valois* and S.D. Elfar*.(SPON:D. Bentley) Dept. Psychology, Univ. of California, Berkeley, CA 94720

We measured the spatial frequency (SF) tuning of cells at regular intervals along tangential probes through the supragranular layers of the monkey striate cortex, and correlated the recording sites with the cytochrome oxidase patterns, to address three questions with regard to the cortical SF organization:

1. Is there a periodic anatomical arrangement of cells tuned to different spatial frequencies? Yes. The preferred SF in successive loci changes systematically: it gradually rises and falls. The cycle repeats with a period of about 0.6 to 0.7 mm.
2. Are there just two populations of cells, low SF and high SF, at a given eccentricity, or is there a continuum? There is a continuum, with most tuned to the intermediate SFs, forming a unimodal distribution. Further, the cells with different peaks were found to be continuously and smoothly distributed across a module.
3. What is the relation between the physiological SF organization and the cytox blobs? We found cells with different spatial frequency tuning to be systematically mapped onto the modular cytox pattern, which varies continuously in staining density. Low SF cells are at the center of the blobs and cells tuned to increasingly higher SFs are at increasing radial distances.

362.6

FUNCTIONAL ORGANIZATION OF THE BLOB CELLS IN THE MONKEY STRIATE CORTEX. Charles R. Michael, Dept. of Cellular/Molecular Physiology, Yale School of Medicine, New Haven, CT. 06510.

Closely spaced, perpendicular tungsten electrode tracks were made through the cytochrome oxidase blobs in the supragranular layers of the monkey's striate cortex to examine the relationships of the various cell types to one another. Double opponent color cells seemed to be concentrated in the centers of the blobs; broad band units were found primarily at the edges; and in between, there were Type II and modified Type II neurons. Double opponent cells were maximally excited by presenting one color in the center while simultaneously illuminating the surround with the complementary color. Spectral sensitivity curves revealed that the surrounds were organized in an opponent color manner. Some of these cells, particularly in layer 2, did not respond to colored annuli. The modified Type II cells never discharged to annular stimuli. Their surrounds had broad-band spectral sensitivities, thus preventing any response to large spots or two-colored stimuli. Type II cells were often seen in layer 3 while modified Type II neurons were more prevalent in layer 2. Supported by NIH Grant EY 00568.

362.7

A COMPUTER SIMULATION OF CORTICAL ORIENTATION SELECTIVITY IN THE CAT VISUAL SYSTEM. U. J. Wehmeier and C. Koch, Division of Biology, 216-76, Caltech, Pasadena, CA 91125.

The manifestation of orientation tuned responses in cells of cat visual cortex has been addressed by models utilizing excitatory feedforward connections (Hubel & Wiesel,1961) and more recently utilizing intracortical inhibition (Heggelund,1981; Silito,1975). Recently, one of us has proposed an ecclectic model of orientation selectivity, combining aspects from all these models (Ferster and Koch, 1987). We have implemented a computer simulation of a patch of the foveal X system of the cat based on anatomical and physiological data to evaluate these different models. The simulation demonstrates responses of a 2x2 degree patch of visual angle in the retina, its projection to LGN, and its subsequent projection to layer IVc in cortical area 17. The retinal image is modeled using gaussian sensitivity profiles with different constants for center and surround fields (Linsenmeier et al., 1982), and is then sampled on a hexagonal grid of beta cells (Wässle et al., 1981).

We have found that two types of inhibitory projections, cross-orientation and inhibition among similar oriented cells with spatially displaced receptive fields, superimposed on a Hubel and Wiesel type scheme, to be effective in discriminating orientation. Due to the massive inhibitory feedback among our 2500 cortical cells, each cell can be highly orientation selective and no non-oriented interneurons are required. Simulation results indicate that presentation of low contrast bars, while not being discriminated by the classical Hubel and Wiesel feedforward model due to their lack of a gain control mechanism, elicit responses once inhibitory feedback is introduced. Inhibitory connections within orientation columns increase the sharpness of orientation tuning. In addition, our simulation produces intracellular responses in which EPSP's are maximally tuned to the optimal orientation (Ferster 1986). We will show a video of these salient responses in our computer simulation.

362.8

INHIBITORY AND EXCITATORY CONTRIBUTIONS TO ORIENTATION TUNING IN THE CAT'S STRIATE CORTEX. F. Wörgötter* and U.Th. Eysel, Institute of Physiology, Ruhr-Universität Bochum, D-4630 Bochum, F.R.G.

Orientation specificity in the visual cortex can be generated by excitatory convergence of subcortical elements, intracortical excitation and intracortical inhibition (Ferster, D. & Koch, C., TINS, 10:487,1987). Our study utilized local lateral inactivation of cortical tissue by GABA microiontophoresis to investigate the influence of intracortical mechanisms. Recordings were made from cells in layers III-VI near area centralis in the striate cortex of anesthetized cats while stimulating with moving light bars. GABA microiontophoresis was performed at different distances relative to the recorded cell and changes of the response characteristics were quantified. Orientation tuning was significantly reduced for S- and C-cells during inactivation of lateral regions. Lateral inhibition contributing to orientation selectivity was demonstrated predominantly by local inactivation at distances of about 0.5 mm. Such loss of lateral inhibition in layer IV S-cells clearly shows that intracortical inhibition is involved in the generation of orientation tuning in addition to the direct CGL input. Lateral excitatory effects were most frequently affected by inactivation at distances of about 1.0 mm. To determine the interdependence of direction and orientation tuning correlation coefficients between the strength of both specificities were calculated and only a weak coupling was found. This supports our previous evidence that different mechanisms underly direction and orientation specificity (Eysel et al., J.Physiol, 399:657, 1988). The results further suggest that both excitatory and inhibitory connections from laterally displaced cells can contribute to the generation of orientation specificity.

362.9

SIMPLE CELL BEHAVIOR IS PREDICTED BY A PUSH-PULL MODEL INCORPORATING COSPATIAL LATERAL GENICULATE (LGN) CELL INPUT. S.S. Raab*, J. McLean*, R.A. Stepnoski*, L.A. Palmer. Dept. of Anatomy, Univ. of Penn., Phila., PA 19104.

We have developed a model of simple cell receptive fields (SRF) based on the following assumptions: linearity of summation in 2D space and time, biphasic time course of rectified LGN inputs and a Hubel-Wiesel geometry of LGN inputs configured as push-pull (class B) amplifiers. By push-pull, we mean that all points in the SRF are excited by inputs of one center sign (push) and inhibited by inputs of the opposite center sign (pull). We will show that this model accounts for the following aspects of SRF function: a) structure in space-space-time b) orientation selectivity c) spatial summation d) spatial frequency selectivity e) cospatial distribution of epsps to bright (dark) and ipsps to dark (bright) stimuli f) optimal direction and velocity g) action of on-channel blockade by retinal APB and h) action of GABA blockers.

362.10

MEASUREMENT OF A SIMPLE-CELL THRESHOLD FUNCTION IN CAT'S STRIATE CORTEX. *R.C. Emerson, M.J. Korenberg*, and M.C. Citron.* Ophthalmology and Ctr. for Visual Sci., U. Rochester, Rochester, NY 14627; Electrical Engrg., Queen's U., Kingston, Ontario, Canada, K7L 3N6; and Childrens Hosp. of LA, Neurology Research, P.O. Box 54700, Los Angeles, CA 90054.

We estimated the shape of a cortical threshold curve to gain insight into the operations that such a function could perform. We measured responses in an OFF area of a simple cell that showed strong threshold nonlinearities when it was presented with an optimally oriented bar whose luminance was modulated randomly. We then characterized the dynamic behavior of the pathway from retina to cortex by calculating a family of functions that are related to Wiener kernels. These functions are used to describe linear contributions to the neural response, and also nonlinear contributions that arise from interactions in time and intensity. Because cortical transformations are difficult to measure directly, we modeled the neural pathway as a cascade of a dynamic linear, a static nonlinear, and a second dynamic linear transformation (LNL model) in which only the linear transformations showed temporal filtering. Bloch's law suggests that the first transformation should be a linear temporal filter. The unique dependence of responses on the sequence of transformations in a system with alternating dynamic-linear and static-nonlinear stages facilitates testing model hypotheses about the sequence and nature of neural events. The resolution and completeness of the measurements allowed us to identify the first linear filter as lowpass and the second as more strongly bandpass. A fourth-degree polynomial representation of the intervening static nonlinearity, which we believe to represent the threshold nonlinearity of the measured simple cell, suggests that the onset of action-potential generation is gradual. This gradual transformation is well represented by a squaring function for positive input signals, i.e., a "half-squarer," which implies that a low order of nonlinearities will suffice for an accurate representation.

Our results suggest that (1) intracellulary, simple cells carry a highly linear representation of image luminance; (2) cortical thresholds are gradual, which makes them ideal for nonlinear operations such as squaring, an operation that has been proposed for movement energy models; and (3) the action-potential generator itself may initiate the mildly periodic process that we measure as the second dynamic linear filter. 362.11

X- AND Y-LIKE RECEPTIVE FIELD PROPERTIES IN CAT AREAS 17 AND 18. B. Jagadeesh* and D. Ferster. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

In a recent abstract, Ferster (Neurosci. Abstr., **13**:1449) reported that X- and Y-mediated synaptic potentials, identified by their thresholds to stimulation of the optic nerves, are largely segregated between areas 17 and 18 of cat visual cortex. Does this apparent segregation give rise to differences in receptive fields of cells in the two areas? Movshon *et al.* (J. Physiol. **283**:101) found that preferred spatial frequencies in area 17 were on the average 3-fold higher than those in area 18; this parallels the difference in preferred spatial frequencies of X and Y cells. We report two further distinctive features of receptives fields in area 17 and 18.

1) Y-cells are identified by their phase-independent, frequency-doubled response to stationary contrast-modulated gratings, which is most evident at high spatial frequencies. Spitzer and Hochstein (J. Neurophysiol. **53**:1245) failed to find evidence for this type of nonlinear response in the cells of area 17. We have confirmed this result and report in addition that the Y-like nonlinearity is present in many cells of area 18. 2) Y-cells have on average a 3-fold higher contrast sensitivity than X-cells (Troy, Vision Res. **27**:1733). Paralleling this difference, field potentials evoked in area 18 by stationary contrast-modulated gratings have approximately 3-fold higher contrast sensitivity than field potentials recorded simultaneously in area 17.

These differences in receptive field properties support the apparent segregation of X and Y input into areas 17 and 18 found intracellularly. Since with four independent methods, evidence for Y input to area 17 cannot be demonstrated, we suggest that the Y input to area 17 differs fundamentally from that in area 18, or is minimal in its extent.

362.12

SPATIO-TEMPORAL DISTRIBUTION OF STIMULUS-SPECIFIC OSCILLATIONS IN THE CAT VISUAL CORTEX I: LOCAL INTERACTIONS. C.M. Gray*, P. König*, A. Engel* and W. Singer (SPON: J.E.Skinner). Max-Planck-Institute for Brain Research, D-6000 Frankfurt/M 71, F.R.G.

An optimal stimulus presented within the receptive field of neurons in the cat visual cortex evokes a correlated oscillation of both the multiunit activity (MUA) and the local field potential (LFP) at a frequency near 40 Hz (C.M.Gray, W.Singer, Neurosci Abs 404.3, 1987). This finding suggests that neuronal oscillations provide a mechanism by which local intracolumnar populations of neurons temporally coordinate their activity. To test this hypothesis we recorded both MUA and LFP responses simultaneously across columns within a cortical layer, and within all layers of the same column using 4-16 closely-spaced electrodes (150-400 µm separation) in areas 17 and 18 of the cat visual cortex. The results demonstrate 1) that oscillations of both the MUA and LFP can occur in precise synchrony throughout all layers of the cortex, as well as independently in upper and lower layers, and 2) that the active population of cells engaged in the synchronous oscillations can extend from 300-1500 µm. Sharp boundaries of synchronous oscillatory activity occur at the junctions of columns having orientation preferences which differ by 60-90 degrees. The results support the hypothesis that neuronal oscillations provide a mechanism by which local populations of neurons synchronize their activity in response to specific sensory stimuli.

362.13

SPATIO-TEMPORAL DISTRIBUTION OF STIMULUS-SPECIFIC OSCILLATIONS IN THE CAT VISUAL CORTEX II: GLOBAL INTERACTIONS. W.Singer, C.M.Gray*, A.Engel* and P.König* (SPON:L.Peichl). Max-Planck-Institute for Brain Research, D-6000 Frankfurt/M 71, F.R.G.

In the previous report local populations of neurons, within columnar boundaries, were shown to engage in stimulus-specific coherent oscillations throughout all cortical layers. This suggests that relations between common, but spatially separate, features in the visual field may be established by the synchronization of oscillatory responses in different parts of the visual cortex. To test this hypothesis we recorded multiunit activity (MUA) and local field potential (LFP) responses in area 17 of the cat from multiple electrodes separated by 2-8 mm in the cortex while stimulating the respective receptive fields simultaneously with moving light bars. Cross correlation and coherence analysis of the signals demonstrated 1) that significant stimulus-dependent correlations of oscillatory responses occur between columns within area 17 separated by 2-8 mm, 2) that the correlated oscillations occur in phase with a variation of phase lag in the range of ± 3 ms, and 3) that the probability for correlated activity is related to the stimulus selectivity of the respective recording sites. These data support the hypothesis that oscillatory responses in spatially separate regions of the cortex may transiently synchronize and thereby define relations between stimuli with common features.

363.1

MULTIPLE CALCIUM CURRENTS IN CULTURED EMBRYONIC AMPHIBIAN SPINAL NEURONS. M.E. Barish, Department of Physiology and Biophysics, University of California, Irvine, CA 92717.

As part of an analysis of the roles of ion channel activity in neural development, I have studied the Ca currents of cultured embryonic *Xenopus* neurons during the period of initial differentiation and neurite outgrowth.

Cultures are prepared from nerve and muscle precursor cells isolated from the spinal region of the neural plate and underlying mesoderm of late neural plate-stage embryos. Ca currents in differentiating neurons are studied using conventional whole-cell tight-seal techniques. Cells are grown on serum-coated glass coverslips to minimize neurite growth, and neurons with processes extending less than one soma diameter can be studied routinely. Ca currents show monotonic activation and rapid deactivation, indications of good spatial control of membrane voltage.

Three components of Ca current can be separated based on kinetics and pharmacology. A fast transient component shows an activation threshold of ~-40 mV, and activation and steady-state inactivation curves overlap between -40 and -30 mV. These transient currents can be blocked by 100-150 μM Ni. In the presence of Ni, currents showing incomplete slow inactivation (during 1 sec depolarizations) are recorded at voltages >-30 mV. The inactivating portion shows an activation threshold of ~-30 mV, and overlap of activation and inactivation curves (measured using 1 sec conditioning and test depolarizations) occurs between -30 and +10 mV. Shifting the holding voltage to -40 mV exposes a non-inactivating inward current that can be activated at voltages >-10 mV. These components correspond to the T-, N- and L-type Ca currents that have been described in other excitable cells.

The resting potential of these neurons is between -50 and -60 mV, and the action potential threshold is about -25 mV. Thus two of the components of Ca current observed may mediate Ca entry during subthreshold voltage excursions.

363.2

LOW-THRESHOLD Ca CHANNELS OF ISOLATED RAT HYPOTHALAMIC AND HIPPOCAMPAL NEURONS ARE DIHYDROPYRIDINE-SENSITIVE.
N. AKAIKE*, Y. OSIPCHUK*, K. MURASE, A. YOSHIDA* and Y. IKEMOTO* (SPON: R.SHINGAI). Dept. of Physiol., Fac. of Med., Kyushu Univ., Fukuoka, 812, Japan.

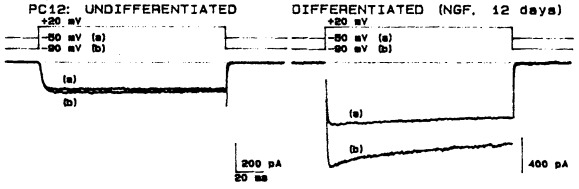
Electrical and pharmacological properties of low-threshold Ca channels have been studied in neurons isolated acutely from the hypothalamus and hippocampus of adult rats using both intracellular perfusion and concentration-clamp techniques.

In most cells a definite low-threshold inactivating component was found. The low-threshold component was activated at membrane depolarization to -60 mV from a holding potential level of -100 mV, and it inactivated exponentially in a potential dependent manner. The steady-state inactivation occurred at very negative membrane potentials, reaching 50% level at -90 mV. Low-threshold Ca channels were blocked in the order of La > Zn > Cd > Ni > Co and of flunarizine > nicardipine > nifedipine > nimodipine > D-600 > diltiazem. Substitution of Ba for Ca reduced the current by 30-50% while substitution of Sr for Ca did not produce definite changes in current amplitude.

363.3

EXPRESSION OF CA^{2+} CHANNELS IN DIFFERENTIATED PC12 CELLS. Mark R. Plummer, Diomedes E. Logothetis*, Peter Hess*. Dept. of Mol. and Cell. Physiology, Harvard Med. School, 25 Shattuck St., Boston, MA 02115.

Differentiation of PC12 cells induced by the presence of NGF for >10 days leads to a 5-fold increase in the density of Ba^{2+} current in the cell body and to a marked increase of the fraction of Ba^{2+} current which is irreversibly blocked by ω-Conotoxin. Holding potentials negative to -40 mV recruit a current component which inactivates slowly (τ=50-100 ms) and incompletely. The single channel activity underlying this component of whole cell current is similar in its main conductance (18-22pS), activation range, and mean open time to the dihydropyridine (DHP) sensitive L-type calcium channel, but it can be distinguished from the L-type channel by its lack of sensitivity to the DHP agonist (+) 202-791, inactivation rate during test depolarizations, and more negative steady-state inactivation range.



363.4

VOLTAGE-DEPENDENT CALCIUM CONDUCTANCES AND MAMMILLARY BODY NEURONS AUTORYTHMICITY: AN *IN VITRO* STUDY. A. Alonso* and R. Llinás. (SPON: D. Sanes). Dept. of Physiology. & Biophysics, NYU School of Medicine, New York, NY 10016.

Current and voltage-clamp recordings from medial mammillary and premammillary body neurons indicate the presence of three voltage-dependent Ca-conductances. In current-clamp studies, depolarization from a membrane potential of -80 mV, elicited typical low-threshold calcium spikes (LTS). These were often followed by prolonged plateau potentials (PPs), which were especially clear after TTX. Depolarizations from a more positive potential (-50 mV) could evoked PPs in isolation from the LTS, as the conductance responsible for the LTS was close to total inactivation at -50mV. After TEA, the PPs always generated high threshold Ca-spikes. Under voltage clamp from a holding potential of -85 mV a typical transient inward Ca-currents were first observed at -65 mV reaching a maximum peak at approximately -40 mV. A second inward Ca-current with slower activation and inactivaton kinetics and a higher activation voltage followed the transient ICa. Near -20 mV the voltage control was often lost as high threshold spikes were invariably evoked. These findings indicate that three Ca-conductances are present in mammillary neurons. These provide the electroresponsiveness needed to support the pacemaker authorhythmicity involved in the generation of theta rhythm in the limbic system. Supported by NIH grant NS13742 and a Fellowship to A.A. from theMinisterio de Educacion y Ciencia (Spain).

363.5

INACTIVATION OF Ca CURRENT IN ACUTELY DISSOCIATED HIPPOCAMPAL PYRAMIDAL CELLS

Alan R. Kay.* (SPON: D. Kleinfeld) Dept. Neurol., Columbia Univ. CPS.,NY,NY 10032 and AT&T Bell Labs., Murray Hill, NJ 07974.

The Ca^{2+}-current in acutely dissociated hippocampal CA1 pyramidal cells, activated rapidly (1-2 ms) on depolarizing the cell to potentials above -40 mV. The current then inactivated with a slow time course that was well characterized by the sum of 2 exponentials (time constants ~ 200 and 2000 ms) plus a constant offset. Both time constants decreased monotonically with increasing step potentials, suggesting a voltage dependent mechanism for inactivation. However, when a protocol to disclose Ca^{2+}-dependent inactivation was used (an inactivating prepulse (7s) to varying potentials, followed by a step to a constant potential to assay the amount of remaining current) the magnitude of all three components in the postpulse exhibited a minimum at the peak of the IV curve. The resulting U-shaped dependence of postpulse amplitude on voltage suggests Ca^{2+}-induced inactivation, however, contrary to the expectations of this form of inactivation, when the fast Ca^{2+}-buffer BAPTA, was included in the intracellular medium and Ba^{2+} extracellularly, the U-shape of the inactivation curve persisted. Moreover, under conditions where all current passing through the Ca^{2+} current was borne by Na+,the U-shape of the inactivation curve still persisted.

363.6

RELATIONSHIP BETWEEN CALCIUM CURRENTS, I_{Ca}, AND INTRACELLULAR CALCIUM CONCENTRATION, $[Ca^{2+}]_i$, IN SENSORY NEURONS. Stanley A. Thayer* and Richard J. Miller Dept. of Pharm. & Physiol. Sci., Univ. of Chicago, Chicago, IL 60637

Simultaneous whole cell patch clamp and fura-2 microfluorimetric recordings of I_{Ca} and $[Ca^{2+}]_i$ were made from sensory neurons grown in primary culture from the dorsal root ganglion of the rat. Cells were held at -80 mV and depolarized to 0 mV eliciting a I_{Ca} that resulted in a $[Ca^{2+}]_i$ transient which lasted long after the cell had repolarized and the current stopped. When the cell was depolarized for different test pulse durations the relation between the integrated I_{Ca} and the peak of the $[Ca^{2+}]_i$ transient saturated at long test pulse durations. Thus, there appears to be a ceiling that limits the maximum obtainable $[Ca^{2+}]_i$ resulting from Ca^{2+} influx via Ca^{2+} channels. Higher $[Ca^{2+}]_i$'s were detected when, for example, Ca^{2+} flowed into the cell from a loss of seal resistance. Calculations of the integrated I_{Ca} and the peak $[Ca^{2+}]_i$ for currents and transients elicited at different test potentials also yielded integrated I_{Ca} versus peak $[Ca^{2+}]_i$ transient curves which saturated. When neuropeptide Y, which acts via its receptor and a G protein to inhibit I_{Ca}, was applied to a cell depolarized for 320 ms at 20s intervals a marked inhibition of I_{Ca} was observed with no significant effect on the peak of the $[Ca^{2+}]_i$ transient. However, when the test pulse was shortened to 80 ms a similar inhibition of I_{Ca} resulted in a significant inhibition of the $[Ca^{2+}]_i$ transient as well. Thus, inhibition of I_{Ca} was reflected by a change in the peak $[Ca^{2+}]_i$ only when submaximal $[Ca^{2+}]_i$'s were reached, implying that modulation of $[Ca^{2+}]_i$ is dependent on the activation state of the cell.

363.7

Modulation of calcium currents by Neuropeptide Y in rat myenteric neuron cultures. Lane D. Hirning*, Aaron P. Fox*, & Richard J. Miller (SPON: M.C. Nowycky), Dept. of Pharmacological and Physiological Sciences, The University of Chicago, 947 E. 58th St., Chicago, Il. 60637.

Our previous studies showed that Neuropeptide Y (NPY), acting via a GTP binding protein, inhibited primarily the inactivating component of whole-cell calcium current. Cell-attached patch recordings, with 90 mM Ba^{2+} in the patch pipette, demonstrated the presence of two types of unitary events with different amplitudes. The smaller amplitude Ca channel ("N-type"), 14 pS single-channel slope conductance, exhibited unitary events unaffected by the dihydropyridine Ca channel agonist Bay K 8644. Holding potentials more negative than -40 mV were required to reprime most of the N-type channel activity, although some openings were apparent even after extended periods at HP = -40 mV. The second type of Ca channel ("L-type"), 27 pS slope conductance, had open times that were dramatically lengthened by Bay K 8644. Furthermore, the L-type openings were relatively insensitive to the holding potential; the channels were largely available at HP = -40 mV. In 5 large multi-channel patches, the addition of 100 nM NPY outside of the patch pipette had no effect on the Ca channel currents under the patch pipette, implying that a readily diffusible second messenger was not involved. 100 nM NPY dramatically inhibited whole-cell currents and the depolarization induced calcium influx measured by Fura-2. These preliminary data suggest that NPY acts via a GTP-binding protein that may couple directly to N-type Ca channels.

363.8

ω-CONOTOXINS AND TWO CLASSES OF VOLTAGE-SENSITIVE CALCIUM CHANNEL TARGETS. L.J. Cruz, J.S. Imperial*, G.C. Zafaralla*, J. Haack and B. M. Olivera. Dept. of Biology, University of Utah, Salt Lake City, Utah 84112 and Dept. of Biochemistry & Marine Sci. Inst., Univ. of the Philippines, Metro Manila.

The ω-conotoxins are peptide toxins which inhibit voltage-sensitive Ca channels; at least two classes of ω-conotoxin targets can be distinguished. Not all Ca channels at vertebrate neuromuscular junctions are inhibited by ω-conotoxins; ω-conotoxin GVIA blocks avian, but not murine neuromuscular junctions. However, i.c. injection of mice causes a characteristic shaker syndrome, suggesting a class of ω-conotoxin sites in the CNS that differ from neuromuscular presynaptic targets. Biochemical evidence is also consistent with two classes of ω-conotoxin targets, one with a subunit MW of 135-160 K (efficiently crosslinked using disuccinimidyl suberate), and a second class with significantly higher molecular weights (200-300 K), crosslinked with photoactivatable ω-conotoxin GVIA derivatives. Crosslinking the 135-160 K target with ω-conotoxin is correlated to neuromuscular junction block. Using ω-conotoxin affinity chromatography, the two classes can be separated. ω-conotoxins from different Conus venoms often differ in their receptor subtype specificity. We have purified and characterized three new ω-conotoxins, SVIA, SVIB and TVIA. The receptor subtype specificities of the new ω-toxins are presently being defined. (Supported by GM22737).

363.9

TRANSIENT INHIBITION OF CALCIUM CURRENT BY ω-CONOTOXIN (ω-CgTX VIA) IN RAT RETINAL GANGLION CELLS. Andreas Karschin* and Stuart A. Lipton (SPON: H. Wässle). Max-Planck Inst. für Hirnforschung, D-6000 Frankfurt, FRG, and Dept. of Neurology, Children's Hospital & Harvard Medical School, Boston, MA 02115.

Calcium currents were recorded with patch electrodes in both the whole-cell and single-channel (cell attached) configurations. Isolation of currents was achieved as described by Lipton & Tauck [*J. Physiol.* 1987;385:361]. During whole-cell recording, application of voltage protocols [Fox, Nowycky & Tsien, *J. Physiol.* 1987;394:149] suggested the presence of multiple components of calcium current. Test potentials to -40 mV from a holding potential of -90 mV activated a transient, rapidly inactivating current (τ = 10-30 ms). Stronger depolarizations (to >-20 mV) activated a more slowly decaying component (τ = 100-200 ms) as well as a substantial steady-state level; these findings persisted when the extracellular solution was changed from 10 mM Ca^{2+} to Ba^{2+}. Some cells displayed only one or two of these components (e.g., transient and sustained) while others had all three. The transient (T-type) current was nearly unchanged when equimolar Ba^{2+} was substituted for Ca^{2+}, whereas the other component(s) increased. Dihydropyridines yielded the expected results on the sustained (L-type) component. However, unlike the experience in DRG neurons [McCleskey et al., *PNAS* 1987;84:4327], 10 μM ω-CgTX VIA transiently and reversibly suppressed all components of calcium current.

363.10

CELLULAR DISTRIBUTION AND LATERAL MOBILITY OF A NEURONAL CALCIUM CHANNEL VISUALIZED WITH FLUORESCENT ANALOGS OF ω-CONOTOXIN. Owen T. Jones*, Diana L. Kunze and Kimon J. Angelides. (SPON:J.Dani). Dept. Physiol. & Mol. Biophys., Baylor College of Medicine, Houston, Texas 77030.

To determine the topography and mechanisms that regulate neuronal Ca^{2+} channel distribution during development and synaptogenesis, biologically active fluorescent analogs of ω-conotoxin (a high affinity probe for neuronal Ca^{2+} channels) were prepared. Electrophysiology and binding studies show that these analogs retain their high affinity for the Ca^{2+} channel (Kd=6nM).

Digital fluorescence imaging of rat hippocampal CA1 neurons labeled with fluorescent conotoxin analogs reveal a non-uniform distribution of the channels. The fluorescence was most intense on the cell body and was clustered in hotspots that coincided with axo-somatic synapses. Hotspots were also seen on processes and on cell bodies with no discernible synaptic contacts. Measurement of the lateral mobility of the channels on the cell body by fluorescence photobleach recovery shows that 70% are immobilized, the remaining fraction move at a rate of 5 X 10^{-10} cm^2/s. In contrast, on the cell body, Na^+ channels are diffusely distributed and rapidly mobile (10^{-9} cm^2/s). Thus, there appears to be specific mechanisms that regulate Ca^{2+} channel distribution and organize and immobilize these channels into discrete regions of the pre- and postsynaptic membranes.

363.11

EFFECTS OF Ca-CHANNEL AGONISTS AND ANTAGONISTS ON THE SPECIFIC BINDING OF [^{3}H]-NITRENDIPINE (NP) TO CANINE CEREBRAL CORTEX SYNAPTIC MEMBRANE (SPM) AND POSTSYNAPTIC DENSITY (PSD) FRACTIONS. P. Siekevitz and M. LeDoux*, Lab. Cell Biol., Rockefeller Univ., New York, NY 10021

The specific binding of the antagonist NP ($2x10^{-9}$M) to both SPM and PSD fractions was inhibited in a linear fashion by nifedipine (NF) antagonist, by BAY K8644 agonist, by Sandoz Lts. enantiomers, +(202-791) agonist and (-) 202-791 antagonist, reaching in all cases 100% inhibition at 10^{-6}M. Each of the (+) and (-) enantiomers caused a three-fold increase in the K_D for NP binding, but also decreased somewhat the Bmax. At $8x10^{-8}$M all four compounds inhibited the binding by ~50%. However, when $8x10^{-8}$M NF and $8x10^{-8}$M BAY K8644 were added together, the resultant inhibition was additive, reaching 80-100%, with both fractions. The same result obtained when the (+) and (-) enantiomers were added together each at $8x10^{-8}$M. A similar result was obtained when the ratio of NP receptors to NP conc. was changed. The binding of NP to PSDs was reversible. Thus, there occured a 25% loss of PSD-bound NP after incubation at 25°C for 40 min. Each of the enantiomers, at $8x10^{-8}$M, increased the loss to 45-50%, but when added together, the loss was additive, 100%. A possible explanation is that the binding of NP is competed for at the same site by other antagonists, such as NF and (-)202-791, and that the agonists, BAY K8644 and (+)202-791 bind to another site which allosterically interacts with the antagonist site, reducing NP binding.

363.12

ISOLATION OF A VOLTAGE-DEPENDENT CALCIUM CHANNEL FROM MAMMALIAN CNS. (SPON J. Ransohoff) B. Cherksey, M. Sugimori, B. Rudy and R.Llinás. Dept. Physiol. & Biophys., NYU Med. Ctr. New York, N.Y. 10016

A calcium channel blocking factor purified from *Agelenopsis aperta* venom was utilized to isolate voltage-dependent ion channels from central neurons. An affinity gel constructed with this factor allowed the extraction of protein from guinea pig solubilized whole brain homogenate. The functional activity of the resulting protein solution was assessed using the lipid bilayer technique. The electrical activity was measured in solutions containing: 80 mM $BaCl_2$, 10 mM HEPES pH 7.4 on the *trans* side; 150 mM KCl, 1 mM $MgCl_2$, 10 mM HEPES pH 7.4 on the *cis* side (side of potential application and vesicle addition). The most typical channel observed was characterized by a slope conductance of 15-20 pS. The I-V curves exhibited some rectification. E_{rev} was at +90- +120 mV. The channel had a mean open-probability of < 7% at -70 mV and opened with increasing frequency as the potential was made more positive. Single-channels were blocked by *trans* addition of Cd or Co at concentrations below 100 μM and by the active factor. With $MgCl_2$ absent from the *cis* solution, monovalent ions could traverse the channel. For 150 mM concentration of monovalent ions a conductance of 100 pS was determined for K^+ and 20 pS for Cs^+.

We conclude that purified factor has allowed us to isolate a CNS voltage-dependent calcium channel with properties similar to those underlying the high- threshold calcium spikes in Purkinje cells, which are also blocked by a toxin preparation derived from this venom (Sugimori&Llinás 1987 Neuroscience Abst.) Supported by NIH NS13742.

EMBRYONIC CHICK MOTONEURONS RESPOND TO NGF IN VITRO AND RETROGRADELY TRANSPORT NGF IN VIVO. D.B. Wayne* and M.B. Heaton. Dept. of Neuroscience, University of Florida, Gainesville, FL, 32610.

The role of NGF in stimulating outgrowth from neurons of the PNS has long been recognized. Here we present evidence that embryonic chick motoneurons of the brainstem and spinal cord are NGF-responsive. Brainstem trigeminal and spinal cord lumbosacral motoneurons specifically transport ^{125}I-NGF transiently early in development and respond to NGF in vitro during that time.

Trigeminal motoneurons were found to specifically transport ^{125}I-NGF following target (jaw) injections at 4 1/2 and 5 but not at 10 days of incubation. Neurons of the spinal lateral motor column (LMC) were found to specifically transport ^{125}I-NGF following target (limb) injections at 5 and 6 but not at 13 days of incubation.

Dissociates of the trigeminal basal plate (VBP) (day 4) and the ventral spinal cord (SCBP) (day 5) were cultured in the presence of NGF or in control medium. NGF did not affect survival of these populations, however, process outgrowth was enhanced. NGF significantly increased the neurite quantity of SCBP dissociates at 24 and 48 hours while neurite initiation was significantly increased in VBP dissociates after 48 hours.

364.2

STRUCTURE AND DEVELOPMENTAL EXPRESSION OF THE NGF RECEPTOR IN CHICK BRAIN . T.H. Large, G. Weskamp* and L.F. Reichardt. Howard Hughes Medical Institute and Dept. of Physiology, Univ. of California, San Francisco, CA 94143

We have determined the nucleic acid sequence of the nerve growth factor receptor from chicken. A cDNA probe containing the coding region of the low affinity (fast) NGF receptor from rat was used to isolate a 3.7 kb insert from an E13 chick brain cDNA library. Southern blots of chick genomic DNA probed with the chick cDNA or rat NGF receptor cDNA showed similar banding patterns, strongly suggesting the chick clone encodes the low affinity NGF receptor. In support of this, the deduced amino acid sequence for the chick receptor shows 70% sequence identity with the rat and human receptors. Of the two in-frame ATG sequences found upstream of the signal peptide in rat and human, only the second is conserved in chick, suggesting this site may be favored for initiation of translation. In the extracellular domain, the four cysteine-rich repeating elements show 75% sequence identity, including conservation of all 24 cysteine residues. The region surrounding the membrane-spanning domain is the most highly conserved part of the receptor (95% identical), suggesting this region may be critically important for receptor function. Within the intracellular domain (60% identical), the C-terminus is the most strongly conserved (80% identical). Northern blot analysis indicated a receptor mRNA of approximately 4.0 kb is expressed in E13 sympathetic ganglia but not adult liver. Receptor mRNA also is relatively abundant in retina, optic tectum, cortex, cerebellum and brainstem from E13 chicks, but is barely detectable in adult brain regions. Thus, the NGF receptor appears to be transiently expressed throughout the chick brain during embryonic development.

SUBSTANCE P MODULATES RELEASE OF LOCALLY SYNTHESIZED NERVE GROWTH FACTOR FROM RAT SAPHENOUS NERVE NEUROMA

U. Otten, F. Keller*, M. Hardung* and D.K. Meyer*
Dept. of Pharmacology, Biocenter of the University, CH-4056 Basel, Switzerland and Dept. of Pharmacology, University of Freiburg, D-7800 Freiburg, FRG

The most proximal segment of the transected saphenous nerve, a neuroma-like structure, was used as a model to study mechanisms in nerve growth factor (NGF) synthesis and release. In saphenous nerve neuromata of adult rats a long-term increase in NGF protein was detected by an enzyme-linked immunoassay after nerve transection. There was a rapid 3 fold increase in NGF levels 12 h after injury, which reached peak values (9 fold) after 4 days and subsequently fell to 2 fold elevated levels within 3 weeks. Quantitative Northern blots showed, that NGF mRNA levels increased rapidly in neuroma tissue, reaching a maximum about 2-4 days after transection indicating that the increase in NGF in response to injury is due to local biosynthesis.

Superfusion of the neuroma in situ revealed a continous basal release of NGF protein (2pg/min) for at least 45 min, which was drastically decreased by substance P (SP) in a dose-dependent manner. Maximum inhibition (85 ± 10%, N=8) occurred at a concentration of 0.1 µM. Neurokinin A was less potent than SP. Neurokinin B, as well as other peptides such as calcitonin gene-related peptide, somatostatin and neurotensin at concentrations up to 50 µM did not significantly affect NGF release.

These results suggest that SP may specifically modulate the availability of NGF in the microenvironment of regenerating nerve fiber endings.

364.4

THE EXPRESSION OF MESSENGER RNAS ENCODING NERVE GROWTH FACTOR AND ITS RECEPTOR IN THE EMBRYONIC HIPPOCAMPUS. **B. Lu, C. R. Buck, C. F. Dreyfus, and I. B. Black. Div. of Developmental Neurology, Cornell Univ. Med. Col., New York, N.Y., 10021**

Increasing evidence suggests that Nerve Growth Factor (NGF) plays a role in the ontogeny of the basal forebrain-hippocampal system. However, it is not known whether NGF regulates the development of the hippocampus (Hi) itself. While high levels of NGF protein in embryonic Hi have been detected and reported, RNA blot hybridization analysis failed to identify NGF message. We have employed sensitive nuclease protection assays to evaluate levels of NGF and NGF receptor (NGF-R) messages in the fetal Hi.

Using a sensitive ribonuclease protection assay, we found that NGF mRNA is expressed as early as embryonic day 16, and the message increases progressively throughout the postnatal period. Further, S1 nuclease experiments revealed that NGF-R message is also expressed in embryonic Hi. However, the receptor message declines postnatally. Thus, both NGF and NGF-R are locally synthesized in the embryonic Hi. These data suggest that NGF may play a role in the developing embryonic Hi. We are currently defining the specific cell types that express NGF and NGF-R, and studying the precise role of NGF in Hi ontogeny. (supported by NIH grant HD23315 and a grant from the Alzheimer's Disease and Related Disorders Assoc.)

364.5

LOCALIZATION OF HIGH AFFINITY NGF RECEPTORS TO GABAERGIC NEURONS IN THE CULTURED BASAL FOREBRAIN (BF). C.F. DREYFUS, P. BERND AND I.B. BLACK, Div. Devel. Neur., Cornell Med. Coll., New York, N.Y. 10021 and Dept. Anat. and Cell Biol., SUNY Health Science Center, Bklyn, N.Y. 11203.

Previous studies indicate that nerve growth factor (NGF) specifically elevates choline acetyltransferase (CAT) in BF cultures. To identify mediating mechanisms, we employed simultaneous radioautography, visualizing putative high-affinity ^{125}I-NGF receptors (NGF-R), and immunocytochemistry, detecting CAT+ cells. High-affinity NGF-R's were detected on CAT+ cells, suggesting that NGF directly regulates cholinergic neurons by binding to high-affinity receptors. Unexpectedly, we also observed a population of noncholinergic, NGF-R+ cells.

To further identify these potentially NGF receptive cells, we now have examined BF dissociates for co-localization of high-affinity NGF-R's and other transmitter traits. Gamma aminobutyric acid (GABA) cells were identified immunocytochemically using two polyclonal anitsera, one produced against a glutaraldehyde conjugate of GABA (Chemicon International, Inc.) and a second raised against GABA conjugated to bovine serum albumin (Incstar Corp.). In both cases, high-affinity NGF-R's were detected on GABA+ cells. However, only a subset of GABA+ cells exhibited NGF-R's, while other NGF-R+ cells were GABA negative. Our observations suggest that GABA+, as well as CAT+, cells express NGF-R's. Presently, we are further characterizing these diverse populations. (Supported by NS 20788, HD 23315 and the Alzheimer's Disease and Related Disorders Assoc., Inc.)

STUDY OF NGF RECEPTOR IN RAT POSTERIOR PITUITARY

Q. Yan, P. E. Lampe*, H. B. Clark and E. M. Johnson, Jr. Dept. of Pharmacology, Washington Univ. Med. Sch., St. Louis, MO 63110.

The expression of nerve growth factor (NGF) receptor was studied in rat pituitary gland by immunohistochemistry using 192-IgG, a specific anti-rat NGF receptor monoclonal antibody. The NGF receptor immunoreactivity (NGFRI) in pituitary gland started to appear diffusely at about 40 days of age. At 2-, 4- and 12-month-old, the staining was intense but became diffuse and less distinct in 17-month-old animals. The staining in pituitary was only seen in the posterior but not in the intermedial and anterior lobe. The staining formed patches in cross section and a bundle pattern in sagittal section of the posterior lobe. The staining was also seen in pituitary stalk and the outer layer of medial eminence but was not found in hypothalamus. The same staining pattern was seen in both sexes of 2-month-old rats and castration of males at 30 days did not affect the staining in the adults. ^{125}I-NGF crosslink/192-IgG immunoprecipitation followed by SDS-PAGE autoradiography, showed that the NGF receptor in pituitary gland had the same molecular weight (90 KD) as previously reported. The amount was much greater in the posterior lobe than in the anterior lobe. Preliminary double labeling results showed that the NGFRI elements in the posterior pituitary were neurophysin negative. The cellular characterization of NGFRI is now in progress by both immunofluorescent double staining and by immunoelectromicroscopy.

RETROGRADE TRANSPORT OF NERVE GROWTH FACTOR (NGF) FROM HIPPOCAMPUS TO SEPTUM IS IMPAIRED IN AGED RATS. Sookyong Koh and Rebekah Loy Dept. of Neurobiology & Anatomy, Univ. of Rochester Rochester, NY 14642

Previous work in our laboratory has demonstrated age-related loss of NGF sensitive neurons in rat basal forebrain (*Brain Research* 440). Decrease in the number of NGF receptor immunoreactive neurons appears to reflect a loss of receptor expression by a process of chronic cellular dysfunction and not primarily cell death. The present study was undertaken to determine whether this reduction in NGF receptor signifies an impairment of receptor-mediated axonal transport of NGF from target area to the cell bodies of NGF responsive neurons. Female Fisher 344 rats at 29 months of age (n=5) and 13 months of age (n=4) were used. I^{125} NGF was injected intrahippocampally into dentate gyrus/CA3 region and the brains taken out 24 hours later. Labeled neurons in the medial septal nucleus (MS) and vertical limb of diagonal band nucleus(VDB) were visualized autoradiographically. 15 coronal sections were selected from each brain and nucleus ipsilateral to the injection sites counted. Within the MS/VDB of the aged group, the mean number of radiolabeled neurons is reduced 30% compared to the young adult (255± 48 vs 369 ±39 ; $p \leq 0.005$). This loss of labeled neurons parallels reduction of 32% in the number of NGF immunoreactive neurons in aged rats previously documented. Loss of capacity of basal forebrain neurons to bind and transport NGF from their terminals in the hippocampus would result in decrease in NGF delivered to the cell bodies and may promote cellular dysfunction and death of neurons in aging. Supported by NRSA MH-09541 (SK) and ADRDA PRG-86-041(RL). Fisher 344 rats were provided by NIA for predoctoral studies (SK).

THE NERVE GROWTH FACTOR COMPLEX FROM *MASTOMYS NATALENSIS*: cDNA CLONING OF α- AND γ-LIKE MOLECULES. M. Fahnestock and R. A. Bell*. SRI International, Menlo Park, CA 94025.

Nerve growth factor (NGF) is isolated from the submaxillary glands of the mouse and of the African rat, *Mastomys natalensis*, as a high-molecular-weight complex. In the mouse, this complex consists of three subunits: βNGF, which has nerve-growth-promoting activity; the γ subunit, a member of the kallikrein family of serine proteases; and the α subunit, an inactive member of the kallikrein family. The lack of activity of the mouse α subunit may result from amino acid substitutions near the active site or from N-terminal changes that prevent zymogen activation.

The *Mastomys* NGF complex differs from the mouse complex in that in *Mastomys* the γ subunit is either missing or more loosely bound than in the mouse. We have previously isolated a cDNA clone coding for *Mastomys* βNGF whose sequence suggests reasons for the differences in subunit interactions between mouse and *Mastomys* complexes. Furthermore, like the mouse, *Mastomys* contains a large family of homologous kallikreins. We have isolated cDNA clones for a number of these kallikreins, one of which shares a high degree of sequence homology with the γ subunit of mouse 7S NGF. However, the clone contains an Arg→Leu substitution at residue -1 that might prevent zymogen activation in a manner similar to the mouse α subunit. The sequences of the isolated cDNAs provide information on conserved and variable regions of the *Mastomys* kallikreins and are important for further studies of the α and γ subunits of NGF.

EFFECTS OF NGF, CNTF, EGF, PDGF, TGF-β, INSULIN, AND RETINOIC ACID ON SEPTAL AND PEDUNCULOPONTINE CHOLINERGIC NEURONS IN CULTURE. B. Knusel* and F. Hefti (SPON: W. Sheremata), Dept. of Neurology, Univ. of Miami, Miami, FL 33101.

In order to study the trophic control of different populations of central cholinergic neurons, various known trophic factors were added to primary cultures of dissociated septal and pedunculopontine neurons of fetal rat brain. NGF, as shown previously, increased the activity of choline acetyltransferase (ChAT) in septal cultures severalfold as compared to controls. In contrast, ChAT activity of pedunculopontine cultures, which contain a second major population of centrally ascending cholinergic neurons, was not influenced by NGF. NGF did not affect protein levels in either type of culture. Retinoic acid has been reported to stimulate expression of NGF and NGF receptors in neuroblastoma cells but failed to elevate ChAT activity in both culture systems and did not affect the NGF mediated elevation of ChAT activity in septal neurons. TGFβ mildly stimulated ChAT activity in septal cultures. High concentrations of insulin increased ChAT activity in pedunculopontine and to a lesser extent in septal cultures. EGF and insulin elevated protein levels in both culture systems in a dose dependent manner. CNTF and PDGF failed to affect ChAT activity and protein levels in both septal and pedunculopontine cultures.

Interleukin-1 Regulates NGF mRNA in Rat Hippocampal Cultures. W.J. Friedman, L. Lärkfors*, T. Ebendal*, and H. Persson*, Lab. of Molecular Neurobiology, Karolinska Institute, Stockholm, Sweden, and Dept. of Developmental Biology, Uppsala University, Uppsala, Sweden

Abundant evidence indicates that nerve growth factor (NGF) is synthesized in rat hippocampus and cortex, and provides trophic support for basal forebrain cholinergic neurons. To investigate specific signals which regulate expression of this trophic factor we have examined dissociated cultures of rat hippocampus from embryonic day (E) 21.

Previous work has demonstrated increases in NGF mRNA and protein following lesions of the septo-hippocampal pathway. To determine possible underlying mechanisms, the effect of interleukin-1 on NGF in hippocampal cultures was examined. NGF mRNA was analyzed using Northern blots, and protein was detected using a highly sensitive enzyme immunoassay. Dissociates were grown at a density of one million cells per 35 mm plate for four days, at which time they were exposed to human recombinant interleukin-1 (IL-1) (10 U/ ml) for four hours. This treatment elicited a significant increase in NGF mRNA. Since IL-1 has been detected in the brain following injury, it may play a role in mediating the lesion-induced increase in NGF. Studies are now in progress to further characterize this effect.

ELECTRON MICROSCOPY OF NERVE GROWTH FACTOR RECEPTOR IMMUNOREACTIVITY IN CEREBELLAR PURKINJE CELLS OF ADULT RATS PRETREATED WITH COLCHICINE. **E.P. Pioro, A. Ribeiro-da-Silva and A.C. Cuello. Dept. of Pharmacology and Therapeutics, McGill University, Montreal, PQ, H3G 1Y6.**

Nerve growth factor receptor (NGFr) immunoreactivity (IR), as revealed by the monoclonal antibody 192-IgG (Chandler, C. *et al. J Biol Chem 259*: 6882, 1984), is present in the cerebellum of postnatal rat (Eckenstein, F., *Brain Res 446*: 149, 1988). Its apparent immunocytochemical disappearance from adult cerebellum, however, does not correspond with relatively high levels of receptor IR detected here by radioimmunoassay (Taniuchi, M. *et al. PNAS USA 83*: 1950, 1986). We have shown that pretreatment of adult rats with colchicine allows visualization of NGFr-IR in Purkinje cells (Pioro and Cuello, *Brain Res*, in press). Here we report the ultrastructural appearance of such IR in these cells of Wistar rats which had received colchicine (27.5 mg/100 g) intracerebroventricularly 40 hours prior to aldehyde perfusion and tissue processing for electron microscopic (EM) analysis. The majority of peroxidase IR was localized to the Purkinje cell membrane although NGFr reaction product was also related to Golgi apparatus, rough endoplasmic reticulum and secondary lysosomes. Rarely, immunoreactive clathrin-coated vesicles (80-90 nm dia.) were seen near the cell membrane. This is the first EM demonstration of NGFr-IR in neurons of the central nervous system with evidence of NGFr synthesis, membrane-incorporation, internalization and degradation. Supported by the Medical Research Council (Canada).

NERVE GROWTH FACTOR RECEPTOR IMMUNOREACTIVITY PRESENT IN AXONS AND EPITHELIAL CELLS OF THE RAT SKIN.

A. Ribeiro-da-Silva*, R.L. Kenigsberg* and A. Claudio Cuello.
Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec, Canada H3G 1Y6.

The distribution of nerve growth factor receptor (NGFr) was investigated immunocytochemically in the skin of the lower lip of the rat. Tissue was fixed by vascular perfusion and then processed for light or electron microscopy. NGFr immunoreactive sites were revealed with the use of IgG 192 monoclonal antibody followed by a monoclonal anti-mouse IgG/anti-horseradish peroxidase bi-specific secondary antibody. NGFr immunoreactivity was found to occur in a patchy pattern in the plasma membranes of groups of basal keratinocytes and Merkel cells of the epidermis and outer root sheaths of hair follicles. Intense immunostaining was also present in the perineural cells and in axons of small cutaneous nerves. Some of these nerves were in close contact with the immunoreactive epithelial cells. Isolated immunoreactive nerve fibers could also be seen penetrating the epidermis while other immunostained nerves were surrounding the wall of blood vessels and glands. The physiological significance of these findings will be discussed.

364.13

RABBIT ANTI-NGF IgG REDUCES CHOLINE ACETYLTRANSFERASE ACTIVITY IN THE HIPPOCAMPUS AND SEPTAL AREA OF NEONATAL RATS. G. Vantini, N. Schiavo*, M. Fabris*, L. Callegaro*, A. Di Martino*, P. Polato*, D. Guidolin* and A. Leon. Fidia Research Laboratories, Abano Terme, Italy.

Several recent observations have indirectly led to the suggestion that NGF may have a physiological role for cholinergic neurons of the basal forebrain. We here report that rabbit anti-NGF IgG decreases choline acetyltransferase (Chat) activity in the septum and hippocampus of newborn rats. In particular, the anti-NGF antibodies, intracerebrally injected (6 μg in 10 μl of phosphate buffered saline) on postnatal days (P) 2, 4, 6 and 8, produced on P9 a significant decrease (approx. 30%) of Chat activity. This decrease was less evident at P15 (15% decrease), while no significant changes were detected at P25. Furthermore, a marked reduction of Chat-positive neurons was observed in the septal area of 9-day-old rats treated with anti-NGF IgG. At all times, acetylcholine esterase activity remained unmodified.

These results provide a direct demonstration that endogenous NGF affects the function of forebrain cholinergic neurons. Thus, a lack of endogenous NGF or a reduced sensitivity to NGF may well underlie alterations and/or loss of these neurons known to occur in some neurodegenerative diseases.

TRANSMITTERS: ACETYLCHOLINE

365.1

POSTJUNCTIONAL MONITORING OF ACETYLCHOLINE RELEASE. R.J. Storella, M. Alexander[a] and S.A. Slomowitz[a]. Department of Anesthesiology, Hahnemann University, Philadelphia, PA 19102

Postjunctional monitoring is often used to assess changes in acetylcholine (ACh) release. Thus, the frequency-dependent decrease of either tension or endplate potentials during neuromuscular block suggests a decrease in ACh release. However, we hypothesized that changes in ACh release in the presence of α-bungarotoxin (αBT) would be masked from detection due to αBT's irreversible binding to ACh receceptors. The mouse phrenic-nerve diaphragm was maintained in a modified Krebs solution, aerated with O_2/CO_2 (95%/5%) at 37°C. The nerve was stimulated supramaximally and isometric tension recorded. Preparations were 70-80% blocked (0.2 Hz) with either d-tubocurarine (dTC) or αBT and tested with conditions assumed to either increase or decrease junctional ACh levels. Following either tetanus (200 Hz, 20 sec) or edrophonium (12.4 µM), dTC block was reversed. Also, $MgCl_2$ (0.3 mM) increased dTC block. In contrast, these same conditions had minimal effects on αBT block. Thus, changes in ACh release and duration during αBT block were not detected. Therefore, the minimal frequency-dependence of αBT block (observed at 2.0 Hz) may be due to an inability to detect changes in ACh release rather than an inability of αBT to cause such changes. Postjunctional monitoring of ACh release must be interpreted cautiously.

365.2

ACETYLCHOLINE ELICITS TWO TYPES OF RESPONSE IN LARGE CELLS OF BASAL FOREBRAIN CULTURES. M. Anderson, A.A. Khan and R.W. Baughman. Dept. of Neurobiology, Harvard Med. School, Boston, MA 02115.

The basal forebrain projects widely to neocortex and hippocampus, and receives cholinergic input from the pontine tegmentum. We explored the effects of acetylcholine on large neurons (20 - 30 um) of the basal forebrain in tissue cultures prepared from 7 - 10 day old Long-Evans rat pups. Neurons were enzymatically dissociated (Heuttner and Baughman '86) and plated in Eagles MEM containing 5% rat serum and 1 ug/ml 7S nerve growth factor. Whole cell patch electrodes of 4.5 - 14.5 Mohms resistance were used to record intracellularly from cells in 21 - 38 day old cultures. The cells had resting potentials of 61.8 $\pm$ 6.2 mV (n = 19) and input resistances of 243.2 $\pm$ 109.6 (n = 19). The effects of acetylcholine (ACh) were tested in cultures perfused with Hepes-buffered recording medium containing 1 uM tetrodotoxin. Puffer pipets (3 um diameter) were used to deliver 0.2 - 0.4 s pulses of recording medium alone, 10 uM ACh, 100 uM ACh, or a mixture of 10 uM ACh and 1 uM atropine. In some experiments, the bath was also perfused with 1 uM atropine. In different cells, ACh elicited either depolarizations or hyperpolarizations. In some cells, ACh elicited depolarizations up to 28 mV in amplitude with times to peak of 100 - 300 ms; the depolarizations were accompanied by a decrease in input resistance, and they were diminished in a partially reversible manner when the bath was perfused with 1 uM atropine. Pulses of control medium produced no change in membrane potential or input resistance. In other cells, ACh elicited long duration (2 - 4 s) hyperpolarizations up to 4.4 mV; the hyperpolarizations were accompanied by an increase in membrane resistance. Addition of atropine to the puffer solutions reversibly reduced the hyperpolarizations. These results suggest that ACh acts at muscarinic receptors on basal forebrain cells to produce two types of response. Supported by NIH EY03502 and ADRDA II-86-099.

MUSCARINIC EXCITATION OF INHIBITORY CIRCUITS IN NEOCORTICAL SLICES. B.W. Strowbridge and G.M. Shepherd, Departments of Neuroscience and Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510.

Acetylcholine (ACh) excites both pyramidal cells and inhibitory interneurons in the guinea pig neocortex. We have used local microapplication of ACh to probe inhibitory local circuits, measured by their postsynaptic actions on pyramidal cells.

With the excitatory M-1 response suppressed by pirenzepine, pyramidal cells responded to ACh with hyperpolarization. With low concentrations of ACh (1-5 mM), the response had several components. A slow hyperpolarization lasted 1-3 seconds, associated with increased conductance; it reversed at 85-95 mv. Superimposed on this response were 1-3 mv fast unitary-like hyperpolarizations ranging from 30-60 ms in duration and reversing at potentials 10-15 mv more depolarized than the slow response. These fast events were depolarizing in neurons impaled with KCl electrodes, suggesting they were chloride mediated. Bicuculline resistant slow events were also observed.

Our results suggest that local ACh applications can evoke several types of inhibitory responses, whose properties resemble those of fast and slow IPSPs. These responses may be mediated by the same circuit, since repeated ACh applications often showed a fast event immediately preceding the slow responses. (Supported by NIH NS-07609 and the Office of Naval Research)

CALCITONIN-GENE-RELATED-PEPTIDE ENHANCES THE RATE OF DESENSITIZATION OF THE NICOTINIC ACETYLCHOLINE RECEPTOR IN CULTURED MOUSE MUSCLE CELLS.

C. Mulle, P. Benoit and J.P. Changeux.
CNRS UA041149, Laboratoire de Neurobiologie Moléculaire, Institut Pasteur, Paris, France.

Calcitonin-gene-related-peptide (CGRP) is a neuropeptide which coexists with acetylcholine (ACh) in spinal cord motoneurons. The effects of CGRP on the functional properties of the nicotinic acetylcholine receptor (AChR) are examined by electrophysiological methods. Using the whole-cell patch-clamp technique and a mouse cell line derived from soleus muscle, we find that CGRP produces a progressive and reversible enhancement of the rapid decay phase of AChR desensitization. Single channel data further show that CGRP decreases ACh-activated channel opening frequency. This decrease takes place when CGRP and acetylcholine are applied on different areas of the cell surface and is thus most likely mediated by a second messenger system. CGRP is also shown to increase cAMP synthesis in this cell line. The effects of CGRP on macroscopic ACh-activated currents are mimicked by external application of forskolin (10µM) or by internal perfusion of the cell with cAMP (1mM). In both these cases, further application of CGRP does not produce additional enhancement of AChR desensitization. These results suggest that, on mouse muscle cells, CGRP regulates AChR desensitization by a mechanism which could involve, at least in part, cAMP-dependent phosphorylation of the AChR.

HALF-LIFE OF PHOSPHATIDYLCHOLINE IN CHOLINERGIC AND NON-CHOLINERGIC NEURONS. W.D. Blaker and A.F. Dobrenski* VA-MD Regional College of Veterinary Medicine, Va Tech, Blacksburg,VA 24061

To initiate an in vivo study of the hypothesis that choline-containing lipids in cholinergic nerve endings can serve as a source of choline for acetylcholine synthesis, we compared the apparent half-lives of labelled, axonally transported choline phospholipids in a cholinergic vs. a non-cholinergic brain pathway. [^{3}H]-choline and [^{3}H]-mevalonate were stereotaxically injected into the rat medial septum (site of cholinergic neurons projecting to the hippocampus) or the hippocampus (site of non-cholinergic neurons projecting to the contralateral hippocampus). The labelling of specific lipids in the hippocampi (septal injections) or contralateral hippocampus (hippocampal injections) was followed 1-12 weeks post-injection. The choline labelled exclusively phosphatidylcholine and sphingomyelin. The mevalonate labelled almost exclusively cholesterol, which was used to correct for injection and sample handling variability. Cutting the projection fibers post-injection was used to confirm that the hippocampal labelling was due to axonal transport rather than injected label diffusion. The half-lives of neither choline phospholipid was significantly different in the two pathways.

PEPTIDERGIC AFFERENTS TO FOREBRAIN CHOLINERGIC NEURONS. L. Zaborszky and A. Braun*. Dept. of Otolaryngology, Univ. of Virginia Sch. of Med., Charlottesville, VA 22908.

In order to determine whether peptidergic afferents innervate cholinergic forebrain neurons, sections from rat brains were processed for the simultaneous light microscopic visualization of peptidergic fibers/terminals and choline acetyltransferase (ChAT) containing neurons, using nickel enhanced DAB for peptidergic terminals and DAB for identification of ChAT containing neurons. Antibodies against the following peptides were used: neurotensin, somatostatin (14, 28), CCK, Met-enkephalin, CRF, Neuropeptide Y, beta-endorphin, alfa-MSH and CGRP. There is a differential but partially overlapping distribution of the various peptidergic fibers to the subdivisions of the cholinergic forebrain system. For example, cholinergic neurons in the ventral pallidum are surrounded by a dense neurotensin-containing fiber network, and ChAT neurons in the bed nucleus of the stria terminalis may receive alfa-MSH fibers. These neurons are supplied only occasionally by other peptidergic afferents. On the other hand, cholinergic neurons in the substantia innominata receive a heavy input from virtually all of the peptidergic systems studied. Electron microscopic studies confirmed the presence of NPY-containing terminals on ChAT cell bodies and light microscopic evidence suggests that these terminals originate at least partially from local NPY-neurons. Supported by USPHS Grant NS. 23945 and 17743.

ELECTROPHYSIOLOGY OF PUTATIVE CH6 CHOLINERGIC NEURONS IN THE LATERODORSAL TEGMENTAL NUCLEUS. S.J. Grant, D.A. Highfield* and T. Piser*. Dept. Psych., Univ. Del., Newark, DE 19716.

Ascending cholinergic pathways from the brain stem have long been associated with regulation of arousal, but the activity patterns of these neurons are unknown. This study examined the activity of putative cholinergic neurons (Ch6) in the Laterodorsal Tegmental nucleus (LDT).

Extracellular recordings from the pontine tegmentum, including the LDT, and Locus Coeruleus (LC), were made in anesthetized rats. Putative Ch6 neurons were identified in vivo by antidromic activation from the AV thalamus since 90% of this projection from the LDT is cholinergic. NADP-d staining (a positive marker for Ch5-6 neurons) indicated whether recording sites lay within clusters of cholinergic neurons. LC neurons were identified by standard neurophysiological and histological criteria.

55 neurons met standard criteria for antidromic activation from AV thalamus. 41% were within clusters of NADP-d positive neurons in the LDT, 49% were localized to the LC, while 9% were found in other areas. LDT neurons were 1) non-spontaneous (78%), or slowly firing (<1 Hz; 22%), and 2) had slow conduction velocities (0.8 $\pm$ 0.3m/s) which were nonetheless significantly faster than LC neurons (0.5 $\pm$ 0.4m/s; t=3.1, p=0.003). Studies are in progress examining the pharmacological responses of putative Ch6 neurons. Supported by NIH Biomedical Grant and UDRF (SJG), and UD Honors Program (DH).

CHOLINERGIC EXCITATION AND INHIBITION MEDIATED BY TWO DISTINCT K CONDUCTANCES IN MEDIAL PONTINE RETICULAR FORMATION. U. Gerber*, R.W. Greene, and R.W. McCarley, (Spon. J. Schildkraut), Harvard Medical School/ VAMC, Brockton, MA 02401

The best phenomenological model of REM sleep is evoked by microinjection of cholinergic compounds into the medial pontine reticular formation (mPRF) but the mechanisms responsible for these effects are unknown. Using an in vitro mPRF slice preparation from young rats we investigated the effects of the cholinergic agonist, carbachol on 27 neurons. Bath or puffer pipette applied carbachol evoked a slow depolarization associated with a conductance decrease in 75% of the cells, a hyperpolarization associated with a conductance increase in 15% and a biphasic (hyperpolarization- depolarization) response in 11% of the cells. These responses were observed in the presence of TTX. Under voltage clamp control, the reversal potential was determined to be more negative than -80mV for both the depolarizing and the hyperpolarizing responses. The I/V relationship for the depolarizing response was linear indicative of a voltage-insensitive membrane conductance. Further analysis of the hyperpolarizing response in 2 cases showed a voltage sensitivity between -100 and -50mV with inward rectification. Our results suggest that a decrease in a voltage insensitive K conductance and an increase in a voltage sensitive K conductance are responsible for the cholinergically-evoked depolarizing and hyperpolarizing response,respectively.

DEPOLARIZATION CONTROL CHOLINERGIC MUSCARINIC RECEPTORS: SELECTIVE EFFECT ON DIFFERENT NEURONAL CELL TYPES. R. Simantov and R. Levy.* Dept. of Genetics, Weizmann Inst. of Science, Rehovot 76100, Israel.

Muscarinic cholinergic neurons regulate many activities in the nervous system, including learning and memory. It is now established that cholinergic neurons degenerate in specific brain regions of patients with Alzheimer's type dementia. An abnormal behaviour may result however from changes in the activity rather than destruction of a given neuronal system. Thus, an increased expression of cholinergic phenotypes, like muscarinic receptors, may alter the function of various neuronal circuits. As neuronal activation regulates many developmental and functional processes, we have studied herein whether chemical depolarization modulates the expression of muscarinic receptors in cultured neurons. Continuous depolarization of a subclone of the NG108-15 hybrid cells (with KCl) increased the number of muscarinic receptors, monitored with ^{3}H-QNB, but short treatment had no effect. The calcium channel blocker verapamil enhanced the effect of KCl. Two rat brain cell lines, SC9 and WC5, that also bind ^{3}H-QNB, did not show an increased binding of ^{3}H-QNB upon chronic depolarization. The specificity of the receptors in the three cell types was therefore determined with the selective M-1 compound pirenzepine, and indeed SC9 and WC5 cells have higher affinity to pirenzepine than the NG108-15 cells. The physiological significance of this differential role of depolarization on the expression of different muscarinic receptors is discussed.

AF102B: A POTENTIAL DRUG FOR THE TREATMENT OF ALZHEIMER'S DISEASE (AD); FURTHER CHARACTERIZATION A. Fisher, R. Brandeis*, I. Karton*, Z. Pittel*, M. Sapir*, Y. Grunfeld*, G. Simon*, I. Rabinovitch*, S. Dachir*, A. Levy and E. Heldman*. Israel Institute for Biological Research, Ness-Ziona, ISRAEL

Cis-methyl-spiro(1,3-oxathiolane-5,3')quinuclidine (AF102B), a new centrally active M1 muscarinic agonist was suggested as a drug for the treatment of AD (Fisher et al, Soc. Neuroci., 13 Abs 184.12, 1987). Further characterization of this drug is described herein. AF102B has a ready passage through the blood-brain barrier as evidenced by its central selective effects and its pharmacokinetic profile. Whole body autoradiography in mice and tissue distribution in rats after iv injection of ^{3}H-AF102B showed that the cerebrum (rich in M1 receptors) absorbed higher radioactivity than the cerebellum (rich in M2 receptors). AF102B acts as a full agonist on the guinea-pig ileum preparation. However, unlike other full agonists, chronic administration (3 month, 5-100 mg/kg/day, po) of AF102B in rats, neither produce down-regulation of brain muscarinic receptors nor did it change its affinity towards these receptors. Central effects of AF102B were expressed in mnemonic processes in three types of animal models mimicking different aspects of AD. Thus in AF64A-treated rats, AF102B (0.2-1mg/kg, ip or po) reversed the cognitive impairments in passive avoidance (PA), or Morris water maze (MWM) and in 8-arm radial maze (1-5mg/kg) tasks. In addition, AF102B (3-5 mg/kg, ip) restored scopolamine-induced cognitive impairments in rats in the PA test, and improved the performance of old rats in the MWM task (1 mg/kg, ip) . All these new features of AF102B, together with its wide therapeutic index and its M1 selectivity as previously reported, indicate that AF102B may be an effective drug in the treatment of AD.

IMPACT OF PLASMA ANTICHOLINERGIC ACTIVITY ON COGNITIVE PERFORMANCE. O.J. Thienhaus, A. Allen*, J. Thoene*, F.P. Zemlan. Lab. of Geriatrics, Univ. of Cincinnati, College of Medicine, Cincinnati, OH 45267-0559.

An exploratory study yielded pilot data on the relationship between anticholinergic plasma activity and cognitive measures in geropsychiatric inpatients (mean age 59 years). Subjects received various psychotropic medications with known antimuscarinic properties. Plasma samples were obtained when patients were medication-free, and five to seven days after target dosage had been achieved. Samples were analyzed for total anticholinergic activity, using the tritiated quinuclidinyl benzilate ([3-H]-QNB) radio ligand binding assay (Tune, L., and Coyle, J.T., Psychopharmacology, 75:9, 1981). Results were expressed in units of atropine equivalence [pmole/ml].

Non-demented subjects (n=10) developed no cognitive dysfunction while their mean anticholinergic plasma activity reached 2314 pmole/ml (S.D.=1205). In demented patients, meeting diagnostic criteria for probable Alzheimer's disease (McKhann, G., et al., Neurology, 34: 485, 1984), aggregate cognitive rating scores revealed that cognitive performance ratings deteriorated an average of 18 percent while anticholinergic plasma activity increased to 2700 pmole/ml (S.D.=1957).

365.12

SPATIAL LEARNING IN THE WATER MAZE IS CORRELATED WITH CORTICAL ChAT IN NUCLEUS BASALIS LESIONED RATS. L.J. Thal[1,2], F.H. Gage[2], & R.J. Mandel[1,2]
1. Dept. Neurol. VAMC, SD, 92161, 2. Dept. Neurosci., UCSD, La Jolla, 92093

The degree of depletion of cortical choline acetyltransferase (ChAT) in rats with excitotoxic lesions of the nucleus basalis magnocellularis (NBM) has never been correlated with the extent of their learning and/or memory deficit. In Alzheimer's disease, the degree of dementia has been correlated with the loss of cortical ChAT. We report that acquisition and accuracy of performance in a water maze task is highly correlated with the reduction in cortical ChAT. F-344 rats (n=12) were anesthetized and bilaterally lesioned in the NBM (2 sites/side) with ibotenate in 2 stages 1 week apart. Three weeks post-surgery the 9 surviving lesioned and 8 sham control rats were tested in a water maze (1 trial block/day, 2 trials/block) for 5 consecutive days, followed by 2 days off, and then tested for 5 more days. The following week, rats were tested for 72 h retention (600s max.) of a passive-avoidance (PA) task (Jarvik 2 chamber box) after 2 initial training trials. Nine days after initial maze testing, the rats were tested for maze retention (1 trial block). The next day, after 1 trial block, the platform was removed and the rats swam for 90s for a spatial probe trial. The NBM lesioned rats had a significant reduction of cortical ChAT activity (mean 24% depletion). The NBM lesioned rats displayed a severe deficit in acquisition of the water maze task. Neither group displayed a retention deficit after a 9 day interval. The spatial probe trial revealed that the control rats remembered the spatial location far better than lesioned rats. Acquisition performance of the maze task was correlated with %ChAT depletion (r=.88). Spatial acuity, defined as the probability of being in the platform quadrant and the platform annulus during the probe trial, was correlated with %ChAT depletion (r=-.75). This is the first report of a significant correlation between a learning paradigm and degree of cortical ChAT depletion in the rat. These data suggest that the observed ChAT depletion is important for the behavioral deficit.

CHOLINERGIC NEURONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS IN THE ADULT RAT: A TOPOGRAPHICAL STUDY.
M. Piotte, P. Tagari* and A.C. Cuello.
Dept. of Pharmacology and Therapeutics, McGill University, Montreal (Quebec), Canada H3G 1Y6

We attempted to define the morphological landmarks of the rat nucleus basalis magnocellularis (NBM) based on the topographical organization and morphology of its cholinergic perikarya. The brains of 4 male Wistar rats were perfused and sequential 50 µm thick coronal sections of the entire NBM were cut, processed for choline acetyltransferase (ChAT) immunocytochemistry and studied with an image analysis system (Quantimet 920). Neuronal density as well as cell size and shape were assessed. Results indicated that in both the rostral and caudal thirds of the NBM the cholinergic neurons are distributed along a band following the ventro-medial edge of the globus pallidus. In the mid third of the nucleus cell distribution assumed a triangular outline and cell density was lower than in the other two thirds. However, cholinergic perikarya were larger in the mid NBM than in the rostral or caudal third where they were of equivalent size. Cell roundness measurements suggested that the shape of the ChAT immunoreactive nerve cell bodies remained constant throughout the entire rostro-caudal extent of the NBM. Thus the NBM can be readily identified within the rat basal forebrain based on the topographical distribution and density of its cholinergic neurons. (Supported by MRC and FRSQ).

BIOLOGICAL RHYTHMS: SYSTEMS I

366.1

ANNUAL VARIATION IN HYPOTHALAMIC LUTEINIZING HORMONE-RELEASING HORMONE, PLASMA AND PITUITARY LH, AND TESTOSTERONE PRODUCTION OF MIGRATORY GARDEN WARBLERS (Sylvia borin).
C. K. Bluhm, H. Schwabl*, E. Gwinner*, I. Schwabl*, and B.K. Follett*. Max-Planck-Institut für Verhaltensphysiologie Vogelwarte, 8138 Andechs, F.R.G., & Department of Zoology, University of Bristol, Bristol BS8 1UG England.

Garden Warblers show distinct annual cycles of testicular development and regression. Our goal was to determine how components of the hypothalamic-pituitary-gonadal system change temporally through phases of the annual cycle. We found distinct autonomous seasonal variation in hypothalamic GnRH-I content in warblers kept on constant daylength. GnRH-I content is low from December through March, but increases in April, and again from May to June. Of particular interest is the finding that GnRH-I content does vary in individuals during the 7 months preceding breeding, even in the absence of photoperiodic change.

Although pituitary LH content increased from March to April, levels varied only 2.5 fold during the study. Seasonal changes in plasma LH levels paralleled the changes in hypothalamic GnRH-I content; levels of both increased steadily from March to June. Increases in testicular mass occurred from March to April, and again from April to May. Increases in in vitro testosterone production paralleled increases in mass. Thus, in warblers a series of autonomous hormonal changes are important in regulating seasonal gonadal growth. Supported by the Alexander von Humboldt Foundation.

EFFECTS OF CHRONIC CLONIDINE ADMINISTRATION AND WITHDRAWAL ON CIRCADIAN ACTIVITY RHYTHMS IN RATS.
A.M. Rosenwasser, Dep't of Psychology, Univ. of Maine, Orono, ME 04469

The alpha-adrenergic agonist clonidine has been shown to alter mood, arousal, and activity. While acute administration is generally sedating, chronic administration can result in hyperarousal and irritability. Furthermore, a recent study showed that clonidine withdrawal results in a long-term behavioral depression. In light of the reported relationship between mood and activity disorders and circadian rhythm disturbances, I examined the effects of chronic clonidine administration and withdrawal on free-running circadian activity rhythms. After three weeks in constant dim light, female rats were treated with clonidine via the drinking water (5.0 ug/ml) for either two or three weeks, after which the drug was discontinued. During clonidine administration, free-running periods were shorter, circadian amplitudes were reduced, and overall levels of activity were lower, relative to baseline. When the drug treatment was withdrawn, animals treated for two weeks showed recovery of baseline rhythmicity, but animals treated for three weeks generally failed to recover, and continued to show altered rhythmicity for the duration of post-drug observations. These results suggest that central monoaminergic neurons may underlie the relationships between mood and activity states and circadian rhythmicity which have been previously reported.

CHRONIC CLORGYLINE DECREASES THE MAGNITUDE OF PHASE-SHIFTS IN WHEEL-RUNNING ONSET PRODUCED BY SUBSATURATING, MONOCHROMATIC LIGHT PULSES W.C. Duncan*, P.G. Sokolove, W. Orem and T.A. Wehr*(SPON: I. Wexler) Clinical Psychobiology Branch, NIMH, Bethesda, MD 20892

We have recently observed that chronic clorgyline (CLG), a monoamine oxidase inhibitor with antidepressant properties in humans, increases the period of wheel-running and alters the phase response curve to fifteen minute light pulses administered to Syrian hamsters. These experiments indicate that CLG differentially alters the response of the circadian pacemaker to light. For example, in the previous study, the magnitude of light-induced phase-delays was increased and the magnitude of light-induced phase-advances was decreased by chronic CLG treatment. The light intensity selected in the earlier study (28 μW.cm-2) was presumed sufficient to saturate the phase-shift response of drug-free hamsters; however in CLG-treated hamsters the intensity-response relationship between light and the phase-shift response is unknown. In order to examine the relationship between chronic CLG and responsivity of the circadian pacemaker to light, the phase-shift response to subsaturating, five minute pulses of monochromatic light was examined.

Group-housed hamsters were implanted with Alzet minipumps (Model 2002) containing either CLG (n=22 ; 2 mg.kg-1.day-1) or saline (n=18) for over four weeks. Individual hamsters were then transferred to cages and had free access to running-wheels, food and water. After about one week in LD 14.5:9.5, hamsters were exposed to continuous darkness(DD) for the next seven days. On day 8 hamsters were transferred to a light chamber where a five minute pulse of monochromatic light (505 nm, hb 10nm; .137 μW.cm-2) was delivered either at CT 13.5 or CT 18. Hamsters were then transferred back to individual cages and remained in DD for the remainder of the experiment. The change in the phase of wheel-running onset following the light pulse was calculated after the onset of wheel-running assumed a steady state. The magnitudes of phase-delays at CT13.5 and phase-advances at CT18 were significantly reduced by chronic CLG compared to saline. These data indicate that chronic CLG decreases the response of the circadian pacemaker to subsaturating visual stimulation of the circadian system.

DAILY INJECTIONS OF TRIAZOLAM INDUCE LONG-TERM CHANGES IN THE PERIOD OF THE CIRCADIAN ACTIVITY RHYTHM OF GOLDEN HAMSTERS. F.W. Turek and O. Van Reeth, Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL and Institute of Interdisciplinary Research, Free University of Brussels, Brussels, Belgium.

In the absence of a synchronizing light-dark cycle (i.e. during exposure to constant light or darkness), single injections of triazolam can induce permanent phase shifts in both behavioral and endocrine circadian rhythms in hamsters, and repeated injections at fixed circadian intervals can entrain the rhythm of locomotor activity. In addition to altering the phase of the circadian clock system, we have noted that following the termination of drug treatment, changes in the free-running period of the activity rhythm are often observed. In order to study this systematically, we examined the effects on period following the administration of triazolam or vehicle for up to 49 consecutive days. While daily injections of vehicle had no effect on period, daily injections of triazolam induced changes in the period of the activity rhythm that persisted for as long as 100 days following the termination of drug treatment. Thus, period as well as phase of a mammalian circadian clock can be altered by treatment with benzodiazepines.

366.5

EFFECTS OF ALPRAZOLAM ON THE CIRCADIAN SYSTEM OF GOLDEN HAMSTERS. P.C. Zee* and F.W. Turek (SPON: J. Joy). Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

The demonstration that the short-acting benzodiazepine, triazolam, can induce phase shifts of circadian rhythms, raises the possibility that alprazolam, a triazolobenzodiazepine with different therapeutic properties can also affect the circadian system of the golden hamster. Intraperitoneal injections of alprazolam 2 mg. or DMSO vehicle were administered at eight circadian times (CT) in both constant light (LL) and constant darkness (DD). Injections of vehicle alone had no consistent effect on the activity rhythm, whereas, alprazolam induced phase shifts of the activity rhythm that were a function of the CT of treatment in both LL and DD. However, the phase response curves (PRC) in LL and DD were notably different: 1. The amplitude of both phase advances and delays was of a smaller magnitude in DD compared to LL. 2. In LL, phase advances occured at CT6 and CT9, whereas in DD, advances were seen consistently only at CT9. Alprazolam induced phase delays at CT21 and CT24 in both LL and DD. The differences between the PRC's in LL and DD suggest that light plays a role in the phase shifting effects of alprazolam and these differences may prove useful in delineating the mechanism of action of the benzodiazepines on the circadian system of hamsters.

DIFFERENTIAL EFFECTS OF TRIAZOLAM ON THE CIRCADIAN CLOCK IN INBRED STRAINS OF GOLDEN HAMSTERS. M.M. Hotz and F.W. Turek. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

A single injection of the benzodiazepine, triazolam, is known to produce large phase shifts in both behavioral and endocrine circadian rhythms of an outbred stock of golden hamsters (Lak:LVG(SYR)). Some within-species variation in this response has been observed. In order to investigate the possibility of genetic sources of this variation, we have studied the response to triazolam in inbred strains of the golden hamster. Phase shifts in the locomotor activity rhythm of hamsters kept in constant light in response to injections of 2.5 mg of triazolam were determined in two strains: MHA/SsLak and LSH/SsLak. The general shape of the phase response curve to injections of triazolam in the LSH strain is similar to that of the outbred stock (both are normally pigmented), with advances at CT 3 (circadian time; CT 12 = activity onset) and CT 6, and phase delays at CT 18 and CT 21. However, the magnitude of the phase shifts are greater in the LSH strain. The albino MHA strain does not exhibit significant phase shifts when injected at any CT, although the increase in activity typically associated with triazolam injections is observed in this strain. The lack of an effect of triazolam on the circadian clock of albino MHA hamsters may prove important in elucidating the physiological mechanisms underlying the effects of benzodiazepines on circadian rhythmicity.

HYPOGLOSSAL NUCLEUS ACTIVITY DURING WAKING AND SLEEP STATES. C.A. Richard, R.R. Terreberry, R.C. Frysinger and R.M. Harper. Dept. of Anatomy and Brain Research Institute, UCLA, Los Angeles, CA 90024-1763.

Obstructive sleep apnea in humans may result from relapse of the tongue toward the posterior wall of the pharynx during REM sleep, since activity of the genioglossus muscle, the principal tongue protruder, greatly diminishes during that state. During waking and quiet sleep, genioglossal EMG activity phasically increases during each inspiratory effort. However, during REM sleep, both phasic and tonic activity decrease dramatically. The nucleus reticularis gigantocellularis (NGC) may hyperpolarize XII nerve motoneurons during REM sleep. Stimulation of the NGC causes IPSPs in somatic motor neurons only during REM periods. NGC neurons also demonstrate selectively greater activity during REM sleep. We hypothesize that hypoglossal motoneuronal activity will decrease during REM sleep and that NGC input underlies this decrease. Neuronal discharge was recorded from the hypoglossal nucleus in drug-free cats across all sleep and waking states. During REM epochs, hypoglossal activity showed periods of very low or no activity interspersed with periods of faster activity similar to rates in the awake state. Many of the faster REM firing rates coincided with phasic REM events. NGC stimulation elicited short-latency neuronal responses in the hypoglossal nucleus. The NGC may mediate state-specific effects on hypoglossal activity. (Supported by HL 22418-10)

SEX DIFFERENCES IN PARADOXICAL SLEEP IN THE RAT. J. Fang*, C. Lewis*, and W. Fishbein. Neurocognition Prog, CUNY, City College & Graduate Sch, N.Y. 10031.

Last year we reported on sex differences in the ultradian cyclicity of sleep in the mouse, and also reported that the sleep of males could be completely sex-reversed by prenatally stressing them. The findings were the first to indicate that sleep is sexually dimorphic. We have now extended our observations to the Sprague-Dawley rat.

Eight female and eight male animals were used. At 116.13 +/- 6.55 days of age, sleep-wakefulness cycles were recorded continuously over a 2-7 day period. The mean weight of the females was 65.28% of the males. Therefore, a second recording of the females at 268.63 +/- 11.26 days of age was taken. The females were then 86.45% of the male group weight.

The time spent asleep over 24 hrs. was the same in the two sexes. However, males spend significantly more time in Paradoxical Sleep (PS) than females ($F(1,14)=4.73$ $p<.05$) and this difference was most visible during the day (10am-8pm) ($F(1,14)=10.79$, $P<.005$), and even more pronounced in the 2nd run of the female group. The difference is totally accounted for by a greater number of PS episodes in the males ($F(1,14)=8.11$, $p<.01$), with the average duration of the PS episodes undiscernibly different. The greater amount of PS in males was not reflected in a significantly greater amount of Slow Wave Sleep in females.

The results are practically identical to our observations in the mouse, but the direction of the differences is just the opposite; namely, female mice have more PS than males whereas male rats have more PS than females. Thus, there are clear organizational differences in sleep between the sexes. We believe that a single hormonal agent may be responsible for the sexual differentiation of sleep, however, resolution of the differences between species will not be found in terms of a single hormone, but of androgen-receptor-mediated differences, most likely, in basal forebrain target neurons.

COMPUTER NETWORK RECONSTRUCTION OF PROJECTION POPULATIONS TO CHOLINOCEPTIVE REM SLEEP INDUCTION SITES.
J. Quattrochi, T. Hensch,* A. Mamelak* and J.A. Hobson. Laboratory of Neurophysiology, Harvard Medical School, Boston, MA 02115.

We define the precise multicellular network projecting to a discrete injection site within the anterodorsal pontine tegmentum which generates REM sleep when stimulated by carbachol fluorescent microspheres. This pharmacologically active retrograde probe and 3-D computer reconstruction of labelled cells permit the spatial dissection of afferent populations involved in the generation of REM sleep. Our observations in four adult cats indicate a labelled projection network within discrete nuclear boundaries of the gigantocellular, paralemniscal, lateral, central, pedunculopontine, and dorsolateral tegmentum, paramedian reticularis, dorsal raphe magnus, locus coeruleus, parabrachialis, and nucleus cuneiformis. Labelling intensity per unit volume and spatial topographical analysis indicate distinct patterned arrangements between anatomically defined cholinergic (Ach) and noradrenergic (NA) subgroup populations. We interpret these results within the context of whether (1) Cholinergic neurons project to the REM sleep induction site, and (2) REM sleep generation can be modeled structurally as the network intersection among Ach and NA projection populations. A TEST FOR CIRCADIAN VARIABILITY OF THE RESTLESS LEGS SYNDROME IN PATIENTS TREATED WITH OPIOIDS. W.A.Hening, A.S. Walters*, and S. Chokroverty*. Lyons VAMC, NJ 07939

Restless legs syndrome (RLS) is a sensorimotor disorder defined by paresthesias and motor restlessness. Its features include periodic movements in sleep, dyskinesias while awake (DWA), and sleep dysfunction (Walters & Hening, Clin Neuropharm 10:225). These symptoms, provoked by repose, are usually experienced at night. They may be powerfully suppressed by opioids, then reactivated by naloxone, suggesting the involvement of the endogenous opiate system in RLS (Hening et al., Neurology 36:1363). We developed a test for activation of RLS symptoms and used it to study circadian influences on symptom expression in 2 opioid-treated patients with RLS. At intervals during the day-night cycle, we required the patients to remain supine for 1/2 hour while we recorded bilateral ant. tibialis EMG. On half the trials, we gave 0.8 to 1.6 mg of naloxone I.V. This provocative test caused DWA in both patients that consisted of rapid leg flexions, most marked at hip and knee, that were sometimes quite periodic. Pt. 1, whose symptoms were poorly controlled, had DWA that were not aggravated by naloxone, while Pt. 2, who was asymptomatic on therapy, had DWA only after naloxone. In both patients, DWA appeared with shortest latency and highest frequency at night. This results suggests that RLS symptoms may be provoked by repose at all hours, but most easily at night while opioid therapy, even if it suppresses symptoms, may not change this tendency.

LOW SODIUM DIET ELEVATES PLASMA NOREPINEPHRINE (NE) AND IMPAIRS SLEEP PATTERNS IN MAN: A REPLICATION
M.V. Vitiello*, R.C. Veith*, D.D. Ralph* and P.N. Prinz. (Sponsor: K.F. Moe). Psychiatry and Behavioral Sciences and Medicine, University of Washington and Seattle and American Lake VAMC, Seattle, Washington 98195, USA.

Previously we reported that a low sodium diet significantly elevated plasma (NE) and disturbed sleep patterns in healthy young men, indicating that increased sympathetic nervous system (SNS) activity may affect sleep. In an attempt to replicate this finding, we studied the sleep and nighttime plasma NE levels of 9 healthy young men (23+.3 years) after four days of low (500mg/day) and normal (2,000mg/day) sodium diets presented in counterbalanced order. Sleep ratings and NE assays were made blind to condition. NE was significantly elevated ($p<.02$); sleep efficiency was lower ($p<.025$) with subjects awake longer ($p<.025$) and more often ($p<.01$); REM sleep was reduced ($p<.05$) and REM latency lengthened ($p<.05$) in the low compared to the normal sodium condition. Sleep latencies to Stages 1 and 2, time in bed, total sleep time and stage 3 & 4 sleep were not significantly different between conditions. NE correlated with total number of awakenings ($r=.75$, $p<.02$) and number of awakenings ≥ 1 minute ($r=.66$, $p<.05$) in the low sodium condition. These results confirm our original finding that increased SNS tone results in disturbed sleep. This may help explain the disturbed patterns of the healthy elderly, who exhibit elevated nighttime SNS activity.

CEREBRAL GLUCOSE METABOLIC STUDY OF GENERALIZED ANXIETY DISORDER AS ASSESSED BY PET
M. Vasquez*, J.C. Wu, M.S. Buchsbaum* (SPON:W.E.Bunney) Dept. of Psychiatry, UCI, Irvine, CA 92717

INTRODUCTION A study of regional cerebral metabolism of anxiety as assessed by positron emission tomography was performed. Twenty patients who met DSM-III-R criteria for generalized anxiety disorder (GAD) without panic attacks were compared with nineteen normal controls. Subjects were given 5 mCi of 18 FDG and told to fixate on a flashing light. Subjects were then scanned on a NEUROECAT II PET scanner. RESULTS There was a significant decrease of relative glucose metabolism on the left side of the cerebral cortex in GAD patients versus controls (significant hemisphere by group interaction, $F=5.41, d.f.=1,37, p=.03$). Basal ganglia structures such as the right putamen and left globus pallidus showed a significant decrease. Deep limbic structures such as amygdala, the hippocampus, and parahippocampus showed no significant change in GAD patients compared to controls. Thalamic structures showed no significant change in GAD.

SPECTRAL ANALYSIS OF PREMENSTRUAL TENSION SYMPTOMS.
A. Collins *, G.J. Coleman and L. Andersson* Deptm. Psychiatry and Psychology, Karolinska Institute, 104 01 Stockholm, Sweden and Deptm. Psychology, La Trobe Univ. Bundoora, Victoria 3083, Australia

Premenstrual tension refers to cyclic variability of mood and physical symptoms in the late luteal phase of the menstrual cycle. Characteristics include irritability, depression, breast tenderness. Forty women diagnosed as premenstrual tension sufferers were studied during one assessment cycle and nine treatment cycles using dietary supplementation with essential fatty acids in a double blind crossover design. The subjects kept daily records of mood and somatic symptoms using a visual analogue scale throughout the study. Ovulation was verified by radioimmunoassay of estrogen and progesteron in blood samples drawn in the follicular and luteal phases of the cycle. The daily ratings were analyzed using a time series technique adapted for prospective mood ratings, where the underlying pattern is identified by spectral density analysis. The results showed that both adverse and positive moods displayed 28 day cyclicity. Patients varied in the number of symptoms with significant cyclicity. Treatment with essential fatty acids did not alter the degree of cyclicity of premenstrual tension symptoms.

OLFACTORY BULBECTOMY DISRUPTS CIRCADIAN RHYTHMS AND AGGRESSION IN MALE MICE.
A. R. Lumia*, B. Possidente*, L. Delemos*, L. Sterner*, M.Y. McGinnis and Martin H. Teicher. Depts. Psychology and Biology, Skidmore College, Saratoga Springs, NY 12866 Dept. Anatomy, Mt. Sinai Sch. Med., CUNY, New York, NY 10029, and Dept. of Psychiatry, Harvard Medical School and McLean Hospital, Belmont, MA 02178.

Depression in humans is often characterized by disruption of circadian rhythms, loss of sexual libido, and irritability. In rats, we have previously shown that olfactory bulb removal (OBX) produces similar symptoms, disrupting daily activity rhythms and copulatory behavior. These disruptions can be reversed by treatment with antidepressant, amitriptyline. In the present experiment using male SWR mice we found that OBX reduced the proportion of total wheel running activity during the peak phase (from .83+ .03 in sham to .74+ .04 in OBX) of a 12:12 cycle as previously described in rats. The most interesting finding, however, was a shift of 43 min in the period of a free running circadian rhythm for activity in OBX mice (23.89+/- .05 OBX vs 23.17+/- .10 sham; $p<.0001$). Aggression against castrated males was abolished by OBX. After surgery 9 of 12 shams and 0/12 OBX mice attacked castrated males. These data combined with our previous data from rats suggest that OBX rodents may serve as a useful model for agitated depression.

LONG-TERM SENSITIZATION IN APLYSIA INCREASES THE NUMBER OF PRESYNAPTIC CONTACTS ONTO THE IDENTIFIED GILL MOTOR NEURON L7. C.H. Bailey and M. Chen. Ctr. for Neurobiol. & Behav., Dept. of Anat. & Cell Biol., Neurol., & Psychiat., Columbia P&S, and NYSPI, NY, NY 10032.

To complement our morphological studies of identified sensory neuron presynaptic terminals, we have examined the effects of long-term sensitization on the structure of an identified postsynaptic target -- the gill motor neuron L7. Individual motor cells from control (N=2) and sensitized animals (N=4) were labeled with HRP and serially reconstructed. Preliminary l.m. observations suggest an increase in focal outpocketing of finger-like processes (spines) in sensitized cells. Quantitative ultrastructural analysis of 945 labeled profiles revealed an increase in the frequency of presynaptic contacts onto L7 processes in sensitized compared to control animals (0.45 ± 0.03 S.E.M. vs. 0.198 ± 0.02, $t=5.32$, $p< 0.01$). The number of synaptic contacts/μm^2 increases (1.72 ± 0.06 vs. 0.55 ± 0.09, $t=10.54$, $p < 0.001$) as does the incidence of multiple synaptic contacts onto the same postsynaptic profile (0.06 ± 0.008 vs. 0.016 ± 0.001, $t=3.8$, $p< 0.05$). Combined, these data indicate a striking upward shift following long-term training in the percentage of L7's surface area that is occupied by synaptic contacts (0.08 ± 0.002 vs. 0.02 ± 0.006, $t=11.8$, $p < 0.001$). These results are consistent with our observations of an increase following sensitization in sensory neuron synapses and provide additional support for the notion that changes in synapse number may represent a mechanism underlying long-term memory.

367.2

SEARCH FOR ADDITIONAL MOLECULAR SITES OF STIMULUS CONVERGENCE DURING ACTIVITY-DEPENDENT FACILITATION, A MECHANISM OF CLASSICAL CONDITIONING IN *APLYSIA* SENSORY NEURONS. T.W. Abrams Dept. of Biology & Inst. of Neurological Sciences, Univ. of Penn., Phila., PA 19104.

During conditioning of the withdrawal reflex in *Aplysia*, synaptic transmission from sensory neurons (SNs) of the CS pathway is strengthened through activity-dependent presynaptic facilitation. In activity-dependent facilitation, the SNs' activity and the accompanying Ca influx, triggered by the CS, enhance the SNs' response to facilitatory transmitter released by the US. Since synaptic facilitation in SNs is mediated at least substantially by cAMP, and since paired activity enhances the rise in cAMP produced by facilitatory transmitter, it has been suggested that the calmodulin-sensitive adenylate cyclase may be a molecular site of stimulus convergence between Ca influx, the signal from the CS, and transmitter, the signal from the US. Are there additional sites of activity-dependent enhancement downstream from the synthesis of cAMP? The spike broadening response in SNs, which contributes to presynaptic facilitation, is similarly enhanced by activity that is paired with facilitatory transmitter. In an initial investigation of downstream sites of activity-dependent enhancement, we measured the spike broadening response in experiments in which we bypassed the cyclase, substituting a rise in cAMP for transmitter. Brief elevations in cAMP were achieved by photolysis of "caged" cAMP (dimethoxynitrobenzyl cAMP). A UV light flash was given either immediately after a train of 5 spikes in a SN (Paired) or 4 sec after a spike train (Unpaired). Paired activity did not increase the spike broadening response to the cAMP transient. These preliminary results suggest that the dually-regulated cyclase may be the major site of stimulus convergence during this form of associative synaptic plasticity.

367.3

SEROTONIN PAIRED WITH SPIKE ACTIVITY IN SENSORY NEURONS OF APLYSIA PROLONGS FACILITATION OF SENSORIMOTOR SYNAPSES IN CULTURE. P.G. Montarolo* and S. Schacher (SPON: G. Clark). Ctr. Neurobiol. & Behav., HHMI, Columbia P&S, & NYSPI, New York, NY 10032.

Activity-dependent enhancement of heterosynaptic facilitation at sensorimotor synapses has been proposed to be the cellular mechanism underlying classical conditioning in Aplysia. To study further the molecular mechanisms underlying this synaptic plasticity, we have examined the interaction between spike activity in sensory neurons and facilitation produced by application of serotonin (5-HT) on the reconstituted sensorimotor synapse in culture.

We measured the amplitude of the excitatory synaptic potential (EPSP) evoked in motor cell L7 and 10 min later treated the cells with either a) control treatment; b) 5-HT puff; c) tetanus to sensory neuron (20 Hz for 2 sec); or d) tetanus plus 5-HT puff at 1 sec after onset of tetanus. The EPSP was measured at 1, 5, 10, and 15 min after the respective treatments. Each treatment significantly enhanced the EPSP after 1 min compared to controls (range of +27 to +42% compared to -14%, N=10). At 15 min, the EPSP following treatment with tetanus plus 5-HT ($+7 \pm 11\%$) was enhanced relative to treatment with 5-HT ($-39 \pm 3\%$), tetanus ($-26 \pm 3\%$) or controls ($-41 \pm 2\%$). One now needs to determine whether this prolongation of synaptic enhancement requires the temporal pairing of the two stimuli, and whether other facilitatory transmitters can substitute for 5-HT.

367.4

SEROTONIN SELECTIVELY PRODUCES LONG-TERM FACILITATION OF APLYSIA SENSORIMOTOR SYNAPSES IN CULTURE. S. Schacher and P.G. Montarolo*. Ctr. Neurobiol. & Behav. & HHMI, Columbia CPS & NYS Psychiatric Inst., New York, NY 10032.

Serotonin (5-HT), an important transmitter involved with behavioral sensitization of the gill and siphon withdrawal reflex in Aplysia, can produce both short- and long-term facilitation of the connections between the sensory and motor cells in culture. This synapse can also be enhanced for a short duration following tetanic stimulation of the sensory cells or brief application of small cardioactive peptide (SCP-B). We therefore examined whether SCP-B and tetanic stimulation, as 5-HT, can evoke long-term changes in sensorimotor synapses.

We first developed a protocol in which comparable short duration synaptic enhancement was evoked by 5-HT, SCP-B, and tetanic stimulation. After testing the amplitude of the excitatory synaptic potential (EPSP) evoked in motor cell L7, each culture was given one of the treatments 4 times at 20 minute intervals. Whereas 5-HT significantly enhanced the amplitude of the EPSPs when retested 24 hrs later ($58 \pm 11\%$, N=6), treatments with SCP-B ($7 \pm 10\%$, N=6) or tetani ($6 \pm 6\%$, N=6) did not significantly affect synaptic strength and were similar to the control untreated group ($4 \pm 6\%$, N=6).

These results, which parallel those from short- and long-term synaptic depression, suggest that the long-term modulation of this identified synapse may be evoked only by a subset of the neuromodulators that can produce short-term synaptic plasticity.

367.5

SEROTONIN (5-HT) CAUSES A PERSISTENT INCREASE IN PROTEIN PHOSPHORYLATION THAT IS TRANSCRIPTION-DEPENDENT: A MOLECULAR MECHANISM CONTRIBUTING TO LONG-TERM SENSITIZATION IN APLYSIA SENSORY NEURONS. J.D. Sweatt* and E.R. Kandel (SPON: N.L. Leith). HHMI, Columbia P&S, New York, NY 10032.

We have developed an intact-cell protein kinase assay for clusters of pleural sensory neurons based on the analysis of proteins labeled with ^{32}P and run on quantitative 2-D gels. A single application to these cells of either 5-HT (40 uM, 2 min) or 8(4 chlorophenylthio)-cyclic AMP (+ isobutylmethyl-xanthine, 100 uM ea., for 10 min), which produces short-term presynaptic facilitation, caused an increase in phosphorylation of 17 proteins (ranging in m.w. from 20 kD to 50 kD, and pI from 4.5 to 7.5). The increases range from 50% to 700%. Five pulses of 5-HT or application of 5-HT or cAMP for 2-hrs, which produces electrophysiologic effects lasting 24 hrs, caused an increase in phosphorylation of the same 17 proteins, but this increase now persisted for 24 hrs after stimulus washout. Addition of 10 uM anisomycin (a protein synthesis inhibitor) or 10 uM actinomycin D (an RNA synthesis inhibitor) during the 5-HT or cAMP application blocked the increase in protein phosphorylation observed at 24 hrs, without affecting the increase in phosphorylation in response to a 2 min 5-HT treatment. These data suggest that, in addition to their role in short-term facilitation, 5-HT and cAMP can recruit a long-term mechanism for a persistent increase in protein phosphorylation that is dependent for its induction on active translation and transcription.

367.6

SEROTONIN (5-HT) CAUSES CHANGES IN PROTEIN SYNTHESIS IN PLEURAL SENSORY NEURONS FROM APLYSIA. A. Barzilai, T.E. Kennedy, E.R. Kandel and J.D. Sweatt*, HHMI, Columbia Univ. CPS, NY, NY 10032.

The long-term facilitation (LTF) induced by 5-HT in Aplysia sensory neurons is blocked by the application of anisomycin (a protein synthesis inhibitor) or actinomycin D (an RNA synthesis inhibitor) during the 1.5-hr training period. This finding suggests that genes and proteins are required for long-term facilitation that are not needed for the short-term process. We therefore studied the effect of 5-HT on total protein synthesis in the pleural sensory cells by measuring incorporation of ^{35}S-methionine (^{35}S-met) into the TCA-precipitable fractions. Application of 5 um 5-HT during the training period (1.5 hrs) induced three temporally distinct changes in overall protein synthesis as resolved by 30-min ^{35}S-met pulses: 1) a trough at 30 min (a decrease of $32\% \pm 9\%$ SEM), 2) an early peak at 1 hr ($36\% \pm 16\%$), and 3) a second peak at 3 hrs ($94\% \pm 30\%$). Beyond the effects on overall incorporation, 5-HT also changes ^{35}S-met incorporation into specific proteins. Application of 5-HT causes a selective and transient increase at 30 min in the rate of synthesis of three proteins in two-dimensional gels. At 3 hours, these early changes disappear, but two new proteins show a selective increase in labeling. Actinomycin D blocks both the early and late specific changes in protein synthesis, suggesting that these changes are mediated at the transcriptional level. Results qualitatively similar to those obtained with 5-HT were also obtained with 100 um 8-(4-chlorophenylthio) cAMP plus 100 um IBMX.

367.7

AMINO ACID SEQUENCE OF A PROTEIN WHOSE NET RATE OF SYNTHESIS INCREASES IN ASSOCIATION WITH LONG-TERM SENSITIZATION IN APLYSIA. T.E. Kennedy, E.R. Kandel, M. Knapp, and J.D. Sweatt*. Ctr. for Neurobio. & Behav., HHMI, Columbia Univ., New York, NY 10032.

Long-term sensitization of the gill and siphon withdrawal reflex in Aplysia, produced by one or four days of training, is associated with a specific increase in the incorporation of ^{35}S-methionine into four proteins (Castellucci et al., Neuron, July, 1988). One of these, Aplysia protein #407, MW 52 kD, pI 4.7, is present in sensory neurons and can be identified on coomassie blue-stained preparative 2-D gels of Aplysia total CNS extract. This protein was isolated from preparative gels and sequenced using a gas phase microsequencer. We obtained 16 residues of amino acid sequence (XPTVYFKEEFGDDXAE). A sequence homology search in protein sequence databases revealed no homologous proteins. However, we similarly isolated and sequenced a comigrating protein from a crude cell lysate of cultured rat embryo fibroblasts obtaining 15 residues of amino acid sequence (XPAXYFXEQFLDXRA). The Aplysia and rat proteins are 64% identical at the amino acid level. We have synthesized oligonucleotides which correspond to all possible coding sequences of 7 residues in the Aplysia peptide (YFKEEFG). We are currently using this oligonucleotide mixture to screen lambda gt 10 cDNA libraries prepared from both Aplysia total CNS and Aplysia abdominal ganglion sensory and motor neurons.

367.8

FACILITATING STIMULI, 5-HT, ELECTRIC SHOCK, AND PHORBOL ESTER, CAUSE TRANSLOCATION OF PROTEIN KINASE C IN APLYSIA NEURONS. T.C. Sacktor and J.H. Schwartz, HHMI and Dept. of Neurology, Columbia Univ. Col. Phys. & Surg., New York, NY 10032

The dependence on Mg^{2+} of protein kinase C (PKC) binding to membrane is complex: it is blocked by physiological Mg^{2+} concentrations, but reversed by Ca^{2+} and phorbol ester. The translocation produced by phorbol ester is maximal at 3 mM Mg^{2+}. Changes in intracellular Mg^{2+} may be important in regulating PKC in cells; in any case, the concentration of Mg^{2+} must be optimized to obtain consistent data on the role of the kinase in facilitating Aplysia neurons. We examined unilateral sensitization of the tail-withdrawal reflex (mediated by pleural sensory neurons) with the protocol of Scholz & Byrne (Science 235: 685-687, 1987), shocking one side of the animal. Facilitation of sensory cells also is produced by serotonin or phorbol ester. We find that all of these facilitating stimuli activate PKC, translocating the enzyme from cytosol to membrane.

367.9

SENSORY NEURONS IN APLYSIA EXPRESS TWO ISOZYMES OF PROTEIN KINASE C (PKC) WITH HOMOLOGY TO VERTEBRATE β_1 and β_2. K. Kruger, T.C. Sacktor and J.H. Schwartz, HHMI, Columbia Univ. Col. Phys. & Surg., NY 10032.

Serotonin activates two protein kinases in Aplysia sensory neurons, the cAMP-dependent kinase by increasing cAMP and PKC by translocation from cytosol to plasma membrane. Both enzymes modulate transmitter release (see Sacktor et al., These Abstracts). We screened a pleural ganglion sensory cell library (provided by M. Knapp, P. Goelet, and E.R. Kandel) at low stringency using rat β_1 PKC cDNA (G. Hausey and B. Weinstein) as probe. DNA sequencing of the several clones obtained revealed the two different forms of the enzyme with different 3' ends, homologous to vertebrate β_1 and β_2. The constant regions of Aplysia PKC, however, have greater than 85% homology to vertebrate PKCs. Northern blots with Aplysia clones show both isozymes are encoded by single transcripts of similar (10 kb) size. Antibodies to PKC synthetic peptides are raised to determine cell specificity and subcellular localization of the two isozymes and to study regulation of expression in short- and long-term sensitization.

367.10

ORDER DEPENDENCE IN THE ACTIVATION OF ADENYLATE CYCLASE BY SEROTONIN AND Ca^{2+}/CALMODULIN: A POSSIBLE MOLECULAR MECHANISM FOR ASSOCIATIVE LEARNING IN *APLYSIA*. Y. Yovell* and T.W. Abrams (SPON: C. Stein). Dept. of Neurobiology, Weizmann Institute, Rehovot 76100, Israel and Dept. of Biology and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Adenylate cyclase has been suggested as a molecular site of convergence for Ca^{2+} and serotonin, the cellular representations of the CS and US in classical conditioning of the gill and siphon withdrawal reflex of *Aplysia*. By modifying a recently developed, perfused membrane cyclase assay, we were able to study the temporal interactions of brief pulses of Ca^{2+}/calmodulin and serotonin in stimulating adenylate cyclase from *Aplysia* CNS. The apparatus enabled continuous monitoring of cyclase activity and rapid application and termination of ligand stimuli. We found that the magnitude of adenylate cyclase activation by 6 sec pulses of Ca^{2+} and serotonin depended on their order of presentation: cyclase activation was 25% to 50% greater when the Ca^{2+} transient immediately preceded the serotonin transient (Forward pairing) than when they were given in the reverse order (Backward pairing). The magnitude of the Forward-Backward difference depended on the concentration of Ca^{2+} used and on the presence of calmodulin in the assay. When a non-hydrolyzable GTP analog was used, no Forward-Backward difference was observed. These results suggest that adenylate cyclase may provide a molecular mechanism underlying the two requirements for contiguity detection in classical conditioning: temporal proximity and order dependence.

367.11

SEQUENTIAL CHANGES OF IONIC CURRENTS DURING CLASSICAL CONDITIONING OF HERMISSENDA. C. Collin*, I. Lederhendler* and D. L. Alkon. (SPON.: M. Bak) Lab. of Molecular and Cellular Neurobiology, NINCDS-NIH, Rockville MD 20892

Reductions of voltage-dependent K^+ currents (I_A, I_{Ca}++-K^+) and a Ca^{++} current (I_{Ca}++) in Hermissenda Type B photoreceptors persist for days after classical conditioning (Alkon et al, Science, 215:693, 1982; Collin et al, Neurosci. Abstr., 1986). Here, we studied changes in these currents which depend upon increasing numbers of training trials. After 50 trials I_A, measured in ASW 24 hours later, was reduced by 17% in conditioned compared to control animals. I_{Ca}++-K^+ and I_{Ca}++ remained unchanged in these groups. Twenty-four hrs after 100 trials I_{Ca}++-K^+ (measured as a tail current in 300 mM K^+o, 5mM 4-AP, 100 mM TEA) was reduced by 40% in paired as compared to control animals. I_{Ca}++, however, was not significantly different for conditioned animals After 200 trials, I_{Ca}++ (measured in 300 mM K^+o, 5mM 4-AP, 100 mM TEA) was reduced 20% with a further reduction to 40% after 400 trials but with no aditional change of I_A and I_{Ca}++-K^+.

These results indicate that during classical conditioning, ionic membrane currents change sequentially as well as progressively.

367.12

PROTEIN AND mRNA CHANGES INDUCED BY ASSOCIATIVE CONDITIONING OF HERMISSENDA. T.J. Nelson and D.L. Alkon, Lab. of Molec.and Cellular Neurobiology, NINCDS/NIH, Bethesda, MD 20892 (Spon.: A.Sidhu).

Protein synthesis inhibition enhances Ca2+ -mediated reduction of the K+ currents which undergo persistent reduction with classical conditioning of Hermissenda (H) (Alkon et al., PNAS (1987)). To assess the role of specific proteins in associative memory, H were trained with paired light and rotation. 24 hr after training, eyes were dissected and incubated for 6 hr with mixed 3-H amino acids and 32P-phosphate, and proteins were analyzed by HPLC. Conditioning increased a 21 kDa phosphoprotein (previously found to be a C-kinase and CaM-kinase substrate) by 1.6-fold compared with random controls receiving unpaired light and rotation ($p<0.05$), and decreased a 169 kDa phosphoprotein to 0.3x normal levels ($p<0.001$). The sp.act. of 3-H incorporation into the 169 kDa protein was increased 5-fold ($p<0.05$), while the sp.act of the 21 kDa protein was decreased to 0.47 x normal levels ($p<0.001$). No differences were observed between random and naive controls. All the above changes were significantly correlated with the degree of learning ($p<0.01$ to $p<0.05$).

In a related experiment, eyes from trained H were incubated with 32P-phosphate and mRNA was isolated and analyzed on agarose gels. The mRNA showed changes which paralleled the protein changes for the 21 and 169 kDa proteins. Thus, associative learning in H changes the synthesis rates of specific phosphoproteins within H eyes. These results are consistent with previous results demonstrating a correlation of mRNA levels with learned behavior in intact H up to 4 days after conditioning.

367.13

MODEL OF HERMISSENDA TYPE B PHOTORECEPTOR RESPONSE BASED ON PRINCIPAL SOMA CURRENTS. M. Sakakibara, S. Usui, H. Ikeno and D.L. Alkon, Dept. Inf. & Comp.Sci., Toyohashi Univ. of Tech., Toyohashi 440 JAPAN and Lab. of Molec.& Cell. Neurobiol., NINCDS, NIH, Bethesda, MD 20892.

To further understand the functional significance of persistent ionic current changes induced by Hermissenda classical conditioning, a model of the type B cell was formulated from Hodgkin-Huxley equations for three principal soma currents: I_A, ICa^{2+}-K^+, and I Na. Previous measurements demonstrated that on days after classical conditioning, but not control procedures, I_A and I Ca^{2+}-K^+ remain significantly reduced (Alkon et al.,1982, 1985),while the long-lasting depolarizing response (LLD) to light was enhanced and prolonged (West et al., Farley & Alkon, 1982). Based on the present model the observed enhancement of the LLD was shown to arise quantitatively from the observed reductions of I_A and I $Ca^{2+}K^+$ following conditioning. The model was also effective in producing quantitative estimations of actual ionic currents. Biophysical isolation of I_A and I Ca^{2+}-K^+ was predicted from differences in the activation and inactivation characteristics of these two currents. These predictions were confirmed by model responses to cycles of triangular waveform commands (±60 mv, holding potential at -60 mv). Triangular commands at 0.1 sec/cycle and 10 sec/cycle activated only I_A and I Ca^{2+}-K^+ respectively, the isolated currents closely resembling currents isolated by selective pharmacologic blockade (with 4-AP and TEA). Addition of other more minor soma ionic currents (e.g.,I Ca^{2+}) will be necessary for more exact simulation of the type B photoresponse particularly as it is progressively modified during acquisition of classically conditioned behavior.

PAIN PATHWAYS

368.1

MECHANISMS IN CENTRAL POST-STROKE PAIN (CPSP) - A CLINICAL STUDY J. Boivie, G. Leijon and I. Johansson. Depts of Neurology and Radiology, Univ. Hosp., Linköping, Sweden.

Central pain can be induced by thalamic as well as extrathalamic cerebrovascular lesions (CVL). To elucidate the mechanisms of CPSP the present study investigated to what extent the CVL engages the thalamus in patients with CPSP, which other locations of CVL can cause CPSP, if the pain differs according to the location of the CVL and which neurological symptoms and signs the patients (pts) have in addition to pain.

Patients and Methods. Examinations including quantitative sensory tests were done of 20 men and 7 women.

Results. The lesions involved the thalamus in 33 % of the pts. In 27 % and 22 %, resp., the CVL were located infratentorially and suprathalamically. The pain was usually burning, aching, pricking or lacerating with some differences due to CVL location. It was increased by various stimuli. Abnormal temperature sensibility was the only sign common to all pts. 93 % had some hypertensitivity to cutaneous stimuli. Hypaesthesia to touch and vibration was found in 52 % and 41 %, resp. 48 % had pareses.

Conclusion. The results indicate that the crucial factor for CPSP is a lesion affecting temperature (and possibly pain) sensibility. It appears likely that the spinothalamic tract or its relay or thalamocortical projections is involved. (SPON: ENA)

368.2

TOPOGRAPHY OF LATE SOMATOSENSORY EVOKED POTENTIAL COMPONENTS IN HUMANS: CUTANEOUS HEAT STIMULI VERSUS ELECTRICAL NERVE STIMULI. **R.-D. Treede*, S. Kief*, T. Hölzer*, B. Bromm*** (SPON: S.N.Raja). **Inst. Physiology, Univ. Hosp. Eppendorf,D-2000 Hamburg 20, F.R.G.**

Short cutaneous heat stimuli elicit late and intralate somatosensory evoked cerebral potentials (SEPc) correlating with first and second pain due to Aδ- and C-fiber activation (B. Bromm and R.-D. Treede, Exp. Brain Res., 67: 153, 1987). The late SEPc were compared with responses to electrical nerve stimuli (SEPn) which activate predominantly Aα- and Aβ- fibers.

In 24 subjects EEG was recorded from 14 electrodes over both hemispheres (bandpass 0.1-70 Hz). SEP were averaged over 80 stimuli each. Both hands and the left foot were tested in balanced order with CO_2-laser pulses (20 ms, 0.75-1.5 times pain threshold, hairy skin sites) and constant current stimuli (0.2 ms, 0.75-1.5 times motor threshold, median and tibial nerves).

In the upper limb both stimulus types evoked a common component sequence: a negativity N1 with a maximum over the contralateral somatosensory cortex was followed by a negativity N2 in central leads and a large positivity P2 in centro-parietal midline leads. SEPc peak latencies (170, 250, 390 ms) were about 100 ms longer than those of SEPn (70, 140, 260 ms) due to heat conduction to cutaneous receptors and slower nerve conduction velocity. N1 of SEPc was more lateral and N2 and P2 of SEPc more posterior than corresponding SEPn components. After stimulation of the lower limb all latencies were prolonged by 20-30 ms.

In spite of the different fiber spectrum activated by cutaneous heat and electrical nerve stimuli and the different projection in the spinal cord, the topography and inter-peak latencies indicated similarities in cerebral processing.

368.3

INVERSE RELATION BETWEEN HEAT PAIN THRESHOLD AND RATE OF TEMPERATURE RISE: THE REACTION TIME ARTEFACT. David Yarnitsky* and Jose Ochoa (SPON. Rose Dotson). Good Samaritan Neurological Sciences Center, Portland, Oregon, 97210 and Department of Neurology, Rambam Medical Center, Haifa, Israel.

Afferent impulse frequency varies with the rate of rise of a stimulus: the faster the increase in stimulus energy, the higher the frequency of firing for a given amount of energy (Darian-Smith et al 1979). This predicts that, for a given energy level, subjective magnitude will be higher the faster the stimulus reaches that level, and explains why the steeper the stimulus ramp the lower is the threshold for perception (Grindley, 1936; Hensel, 1952; Kenshalo et al, 1968).

However, the opposite has been reported for heat pain (HP) in man (Croze and Duclaux, 1978; Pertovaara and Kojo, 1985). We examined research reports so claiming and found that artefactual participation of reaction times (RT) might explain the paradox.

Our study compared HP thresholds through a method that involves RT participation, vs. those obtained by-passing RT. We found, in 16 volunteers, that if RTs are by-passed, thresholds decrease as the rate of temperature rise increases ($p<0.001$). A significant fall in HP threshold was demonstrated at all 3 rates used when omitting the RT artefact from threshold reading ($p=.018$, <0.001, <0.001).

SENSATIONS EVOKED BY SELECTIVE INTRANEURAL MICRO - STIMULATION OF C NOCICEPTOR FIBRES IN HUMAN SKIN NERVES. J. Ochoa and E. Torebjörk* Good Samaritan Neurological Sciences Center, Portland, Oregon, 97210 and Department of Clinical Neurophysiology, Academic Hospital, Uppsala, Sweden.

Microneurography of 36 identified C polymodal noci - ceptors supplying glabrous and hairy skin in awake human volunteers was supplemented with intraneural microstimulation (INMS). Cognitive attributes of ele - mentary sensations evoked by INMS at liminal intensity for perception were estimated psychophysically for subjective quality and localized projection.

There was excellent matching of physiological unit type (C polymodal nociceptor) with subjective quality of evoked sensation (dull pain). Further, there was remarkable spatial matching of unitary receptive field of C nocicep - tors with projected field of the elementary sensation evoked at liminal stimulus intensity.

While matching of subjective quality and localization with physiological type and receptor location gives evidence that unitary C nociceptor channels were selec - tively activated during INMS, the results also directly attest that C polymodal nociceptors from human skin evoke delayed dull pain, fairly accurately projected to a defined locus of skin.

TWO COMPONENTS OF PAIN SENSATION IN RESPONSE TO COLD STIMULATION OF HUMAN TEETH. K.-D. Kniffki, E. Jyväsjärvi*, M.K.C. Mengel* and A. Stiefenhofer*. Physiologisches Institut der Universität, D-8700 Würzburg, FRG.

In animals it has recently been demonstrated, that cold stimulation of teeth elicits quite distinct responses in intradental Aδ- and C-fibres (Jyväsjärvi, E. and Kniffki, K.-D., J. Physiol. 391: 193 - 207, 1987). The aim of the present study was to evaluate, whether these different response properties of single intradental Aδ- and C-fibres are reflected in distinguishable pain sensations in humans.

Randomly adjusted cold stimuli between +25 °C and -40 °C lasting 2.5 min were applied to 13 upper central incisors of ten volunteers. The subjects had to rate the magnitude of their pain sensations using a verbally anchored 50-point scale (category partitioning), and afterwards described their sensations qualitatively using a list of descriptors.

Almost all subjects rated two components of pain. The magnitude of both pain components was dependent on the temperature of the stimulating individually adapted thermode. The first component had a mean threshold of 11 ± 3.6 °C, a latency of less than one second, lasted only a few seconds and was described as sharp, shooting and well localized. The average peak ratings are fitted rather well by a Steven's power function: $y = 2.58 \cdot |T - T_o|^{0.71}$, (r = 0.98). The second component had a mean threshold of 5 ± 2.8 °C, a latency of 10-20 s, often lasted some minutes and was described as dull, burning and poorly localized. The average ratings are fitted by $y = 2.02 \cdot |T - T_o|^{0.62}$, (r = 0.93).

Assuming that the response behaviour of human intradental Aδ- and C-fibres is similar to that of the cat, it is concluded that the first pain component evoked by cold stimulation of teeth is elicited by activation of Aδ-, and the second pain component by C-fibres.

368.6

BRANCHED Aδ- AND C-FIBRES TO BOTH PERIODONTAL LIGAMENT AND DENTAL PULP. M.K.C. Mengel*, E. Jyväsjärvi* and K.-D. Kniffki (SPON: C. Vahle-Hinz). Physiologisches Institut der Universität, D-8700 Würzburg, FRG.

Electrophysiological experiments were performed to study the responses of afferent Aδ- and C-fibres supplying both periodontal and pulpal tissues of the cat canine teeth. Recordings were made from single fibres, isolated from the inferior alveolar nerve in anaesthetized cats. They were identified by electrical current pulses applied to the periodontal space, the dental pulp, and in some experiments also to the nerve trunk. In addition, some of the fibres were tested with heat, cold, potassium-chloride and mechanical stimuli applied to tooth and periodontium.

Fifteen of 260 identified slowly conducting periodontal fibres were also activated by electrical stimulation of the dental pulp. Eleven of them were classified as C- and four as Aδ-fibres. The response characteristics of the fibres to non-electrical stimulation of the periodontium were similar to those of slowly conducting fibres innervating the periodontium exclusively (Jyväsjärvi, E., Kniffki, K.-D. & Mengel, M.K.C., Progr. Brain Res. 74: xx - yy, 1988). But, in addition, responses were also evoked by stimulating the pulp with heat, cold, potassium-chloride and drilling. The receptive fields of single C-fibres, determined with a dental probe, were located deep in pulpal and periodontal tissues. In a few cases, after determining the branched fibre's responses, the pulp was completely removed and the responses to stimulation of the periodontal ligament were found to persist.

It is concluded, that there exist some slowly conducting fibres in the inferior alveolar nerve, that branch to innervate more than one oral tissue as it has been shown in other peripheral nerves.

368.7

ANALYSIS OF THE ACTIVITY OF PRIMARY AFFERENT NEURONS IN A MODEL OF NEUROPATHIC PAIN IN THE RAT. K.C. Kajander and G.J. Bennett. NAB, NIDR, NIH, Bethesda MD 20892.

We have developed a model of neuropathic pain in the rat for which we have reported behavioral evidence of hyperalgesia, allodynia and spontaneous pain (Bennett and Xie, Pain 33:87-108, 1988). In this model, nerve injury is produced by ligatures tied loosely around the sciatic nerve. Behavioral evidence of neuropathic pain appears by the second day after nerve injury. We have now looked for changes in the activity of primary afferent neurons one day after the injury.

Rats were anesthetized with pentobarbital and paralyzed with gallamine triethiodide (Flaxedil-FLAX). The sciatic nerve was exposed and two bipolar stimulating electrodes were placed 10 mm apart, one proximal and one distal to the injured area. Recordings were made from the dorsal rootlets of spinal segments L4-6.

More than 200 individual sciatic axons were classified according to conduction velocity as Aß, Aδ or C fibers. Approximately 90% of Aß fibers and 65% of Aδ fibers were activated only from the proximal electrode. In contrast, 85% of C fibers were activated from both the proximal and distal electrodes. The receptive field charactertistics of 19 of the Aδ and C fibers were identified (nociceptive = 14, low threshold mechanoreceptive = 5). Additionally, 44 of 185 Aß and Aδ fibers exhibited non-evoked activity. Supplemental doses of FLAX (3mg/kg) increased the discharge frequency of many fibers with ongoing activity and also activated some previously silent fibers. The incidence and duration of the FLAX effect was highly variable. These data indicate that within one day this injury preferentially affects conduction in myelinated fibers across the ligated area.

368.8

THE DEACTIVATION OF C-FIBER NOCICEPTIVE RECEPTORS FOLLOWING INTRADERMAL INJECTION OF THE CAPSAICIN ANALOGUE NE-21610. R.H. Cohen, J.N. Campbell, A.A. Khan* and R.A. Meyer, Dept. Neurosurgery, Johns Hopkins Univ., Baltimore Md 21205

The potency, specificity, and time course for excitation and deactivation of cutaneous nociceptors following i.d. injection of the capsaicin analogue NE-21610 was determined in neurophysiological experiments in anesthetized monkey. Single fiber recording techniques were used to monitor the heat and mechanical responsiveness of primary afferents before and after 30 µl injections into the receptive field (RF). Four C-fiber nociceptors received a 0.3 µg dose which resulted in: (1) a brief (10 s) discharge, (2) a period (5-120 min) of complete insensitivity, and (3) a subsequent recovery. The evoked discharge after injection of 3 µg into the RF was similarly brief, however the deactivation lasted more than 240 min. In comparison, a 3 µg injection of capsaicin (n=5) produced a deactivation that lasts from 5 to 30 min. Injections adjacent to the RF of C-fiber nociceptors resulted in a small response (10-20 discharges), but no deactivation. In addition, other C-fiber afferents whose RF could not be located with mechanical stimuli were activated by injections. These afferents could be chemospecific. A 3 µg dose of NE-21610 did not activate or alter the responsiveness of A-fiber nociceptors (n=4) or low-threshold mechanoreceptors (n=2). These results suggest that, in comparison to capsaicin, the selective deactivation of C-fibers by NE-21610 is at least 10 times more potent and long lasting.

C-FIBER NOCICEPTORS IN MONKEY ARE SENSITIZED BY BRADYKININ ANTAGONISTS. A.A. Khan*, S.N. Raja, R.A. Meyer, J.N. Campbell, & D.C. Manning*, School of Medicine and Applied Physics Lab., Johns Hopkins U., Baltimore, MD 21205. U.S.A.

We previously demonstrated that the endogenous peptide, bradykinin (BK), sensitizes C-fiber nociceptors. To determine whether the B_1 or B_2 bradykinin receptor mediates this sensitization, we examined the effects of specific B_1 and B_2 receptor antagonists on the response properties of C-fiber nociceptors. Standard single-fiber techniques were used to record from 19 cutaneous C-fiber nociceptors responsive to mechanical and heat stimuli (CMHs). A fixed dose (10^{-8} moles in 10 µl neutral saline) of BK, the B_1 antagonist [desArg^9,Leu^8]BK, or the B_2 antagonist DArg[Hyp^3,DPhe^7]BK was injected intradermally into the receptive field of the nociceptor. The response to heat of the CMHs before and after drug administration was tested with a sequence of stimuli ranging from 41 to 49°C. Both antagonists, as well as BK, sensitized the CMHs to heat stimuli. The normalized response (i.e., the total response to the heat sequence after injection divided by the response before) was 1.8 ± 0.1 (n=10), 1.5 ± 0.1 (n=4), and 1.5 ± 0.2 (n=5) for BK, and the B_1 and B_2 antagonists, respectively. The vehicle injection had no effect on the thermal response. These results indicate that BK analogs, with antagonist properties in smooth muscle preparations, sensitize nociceptors. This suggests that BK and the BK analogs tested do not sensitize nociceptors through classical B_1 or B_2 bradykinin receptors.

ALTERED PREPROTACHYKININ GENE EXPRESSION IN TRIGEMINAL AND CERVICAL DORSAL ROOT GANGLIA IN RESPONSE TO SUBARACHNOID HEMORRHAGE.

M.D. Linnik*, D.E. Sakas*, G.R. Uhl, M.A. Moskowitz
Massachusetts General Hospital, Boston, MA, 02114.

Substance P (SP)-containing projections from trigeminal and dorsal root (DRG) ganglia innervate cerebral vessels and may be involved in the transmission of pain information associated with blood in the subarachnoid space. We monitored neuropeptide levels in the cerebral arteries, trigeminal ganglia and DRG, as well as preprotachykinin mRNA levels in trigeminal ganglia, following the intracisternal injection of blood. Marked, 50% decreases in basilar artery SP levels were found within 4 h. SP in the DRG was depleted at 48 h and persisted for 7 days. The middle cerebral artery and circle of Willis were exposed to less blood and normal SP levels were maintained. In trigeminal ganglia, levels of SP were increased at 24 and 48 hrs. Preprotachykinin mRNA levels, as assessed by northern analyses, were also elevated in the trigeminal ganglia at 48 h. To investigate the pathophysiological mechanism in vitro, cultured F-11 cells (neuroblastoma x dorsal root ganglion) were exposed to hemoglobin (Hb). At 24 hrs, Hb caused a dose dependent reduction in SP in these cells. These results are consistent with blood-induced alteration of preprotachykinin gene expression in cerebrovascular sensory fibers, and implicate these fibers in the pathophysiology of subarachnoid hemorrhage. Supported by NS08166, NS10828, The McKnight, Sloan and American Parkinsons Disease Assns.

RECEPTIVE FIELD PLASTICITY OF DORSAL HORN CELLS: A COMPARISON BETWEEN MULTIRECEPTIVE AND NOCIRECEPTIVE NEURONES. J.M.A. Laird* and F. Cervero* (SPON: European Neuroscience Association) Department of Physiology, University of Bristol, Medical School, Bristol, U.K.

It is known that the receptive field (RF) size of some dorsal horn neurones can increase following a brief period of noxious stimulation. We have now investigated such RF changes of Multireceptive (Class 2) and Nocireceptive (Class 3) neurones in the sacral dorsal horn of the rat. The conditioning stimuli were 8N pinches delivered to the neurone's RF on the tail over a period of up to three hours, and/or electrical stimulation of A and C fibres from the tail. RF areas were measured and mechanical thresholds determined before, during and after these stimuli.

Following a single noxious pinch the RFs of all Class 2 neurones increased in size to include skin regions well away from the stimulated point. In addition, these cells were more excitable and their mechanical thresholds were decreased. Similar changes were seen after electrical stimulation, as has been previously described.

In contrast, Class 3 neurones exhibited much smaller increases in RF size which were restricted to the immediate area around the noxious pinch. Mechanical thresholds fell and excitability increased in some neurones but to a lesser degree than in the Class 2 cells. In about 50% of the cells several pinches were needed before changes were evident.

We conclude that RF changes in Class 3 cells following noxious stimulation can be explained by sensitisation of primary afferents whereas those observed in Class 2 neurones include an important central component. This shows fundamental differences in the processing of nociceptive information by Multireceptive and Nocireceptive cells.

368.12

SEGREGATION OF COARSE AND FINE GLOSSOPHARYNGEAL AND VAGAL AXONS IN THE NUCLEUS TRACTUS SOLITARII. F. Torrealba*, A. Claps* and F. Calderon* (SPON: N. Inestrosa). Dept. Physiol. Sci., Catholic Univ., Santiago, Chile.

In normal adult cats we studied with the Fink-Heimer method the distribution of degenerating glossopharyngeal afferents in the nucleus tractus solitarii (NTS), after the unilateral removal of the petrosal ganglion. At short survivals only a fine fiber component was present mainly in dorso-medial and commissural regions. At longer survivals fine fibers tended to disappear and a coarse component predominated, mainly in the lateral subnuclei. To support these findings we placed WGA-HRP injections in medial or lateral or commissural NTS regions and studied the distribution of sizes of the retrogradely labeled neurons in the petrosal and nodose ganglia. Medial injections produced bilateral label of small cells in both ganglia and large cells in the nodose ganglia. Lateral injections labeled small and large cells only in the ipsilateral petrosal ganglion. Commissural injections bilaterally labeled small cells in both ganglia.

These findings indicate that fine and coarse fibered inputs from visceral receptors differ in their central distribution and that they may participate in different central pathways.

POSTSYNAPTIC MECHANISMS III

369.1

INTERACTIONS AND POSSIBLE SECOND MESSENGER SYSTEMS INVOLVED IN NEUROTRANSMITTER RESPONSES IN THE THALAMUS. David A. McCormick. Yale University School of Medicine.

ACh and NE are known to both decrease a resting gK, while ACh and the $GABA_B$ agonist, baclofen, can both activate a gK, in thalamic neurons. The possibility that these actions are achieved through the same ionic channels and/or second messenger systems was investigated using intracellular recordings in relay neurons of the guinea pig lateral geniculate nucleus, in vitro. Sequential application of ACh, NE and baclofen revealed that the ACh and NE-induced inward currents, as well as the ACh and baclofen-induced outward currents, displayed non-additivity indicating that these three transmitters converge upon only two gKs. Application of the muscarinic antagonist scopolamine blocked the ACh responses, but not those of NE or baclofen. LGNd neurones exposed to pertussis toxin (in vivo) displayed (in vitro) only the inward currents in response to ACh and NE and no response to baclofen. Similarly, intracellular injection of GTP-gamma-S resulted in a large hyperpolarization and blocked the outward currents induced by ACh and baclofen, but not the inward currents induced by ACh and NE. Intracellular injection of the calcium chelating agent BAPTA blocked the medium AHP, but not the ACh and NE responses. These results indicate that ACh and GABA activate the same gK in thalamic neurones through a pertussis toxin sensitive G-protein, while NE and ACh decrease the same gK through an as of yet unknown second messenger system.

369.2

ACTIVATION OF PROTEIN KINASE C REDUCES $GABA_A$ MEDIATED CHLORIDE CONDUCTANCE. A.Stelzer* and R.K.S.Wong. Department of Neurology, Columbia University, New York, N.Y. 10032.

There is increasing evidence that ligand-gated receptor-channel complexes are regulated by protein phosphorylation. The observation that $GABA_A$ receptor function is maintained by phosphorylation factors (Neurosci. Abstr. 13, 279.7) prompted studies to identify putative protein kinases involved in the regulation of $GABA_A$ receptor function. We examined the action of phorbol 12-13 dibutyrate on GABA-mediated chloride currents in acutely isolated cells prepared from the CA1 region of the guinea-pig hippocampus (Kay and Wong, 1986). Whole-cell voltage-clamp experiments were performed at room temperature, cells were clamped at -10mV. GABA (200 μM) was applied by short pressure pulses (20-80 ms). Application of phorbol 12-13 dibutyrate (200 nM) via perfusate reduced the peak-current amplitude of the GABA-mediated outward currents to 69.5% $\pm$ 4.1 (N=10) measured 5 min following phorbol 12-13 dibutyrate application. 400 nM of phorbol 12-13 dibutyrate reduced GABA currents to 45.1 $\pm$ 7.2 (N=5) whereas 4α Phorbol had no effect on GABA responses. Following washout of phorbol 12-13 dibutyrate GABA currents recovered partially (81.5% $\pm$ 5.2, N=5, compared to 63.8 % $\pm$ 4.7 during phorbol 12-13 dibutyrate application in these 5 cells). These data indicate that activation of protein kinase C by phorbol 12-13 dibutyrate reduces $GABA_A$-mediated chloride conductance. Taken together with previous findings (Neurosci. Abstr. 13, 279.7) it may be speculated that the $GABA_A$ receptor is regulated by several protein kinases, as reported for the nicotinic Ach receptor (comp. Huganir and Greengard, TIPS, 1987).

MODULATION OF ELECTROTONIC COUPLING BETWEEN HIPPOCAMPAL NEURONS BY NMDA AND C-KINASE. **M. O'Beirne and B.A. MacVicar. Neuroscience Research Group. University of Calgary, Calgary, Alberta. T2N 4N1**

Electrotonic coupling and dye coupling has been observed between hippocampal neurons in brain slices and in dissociated tissue culture. We have previously shown dye coupling to be correlated with electrotonic coupling in tissue culture. We have examined the modulation of electrotonic coupling between hippocampal neurons by determining the extent of dye-coupling in culture and in slices in the presence of NMDA and C-kinase activators.

In control, 23% (n=35) of cultured hippocampal neurons were dye coupled. Application of NMDA(10^{-4} 10^{-3}M) abolished dye-coupling (n=28) as did TPA (50nM, n=21) a phorbol ester which activates C-kinase. In slices, dye coupling was also abolished by TPA (n=15 vs 50%, n=16 in control). Preincubation of slices in H-7 (100 µM), a C-kinase inhibitor prevented TPA uncoupling. NMDA application appeared to be toxic in brain slices so we indirectly activated NMDA receptors by incubating slices in Mg++ free solution and dye coupling was abolished (n=16). These findings indicate that electrotonic coupling between hippocampal neurons is dynamiccally modulated.

FORSKOLIN ACCELERATES DESENSITIZATION OF 5-HT_3 RECEPTORS IN MOUSE HIPPOCAMPUS AND NG108-15 CELLS. J.L. Yakel* & M.B. Jackson, Dept. of Biology, UCLA, Los Angeles, CA.

5-HT induces rapid currents in hippocampal neurons (Yakel et al, J. Neurosci. 8:1273) and NG108-15 cells (Christian et al, Brain Res. 147:261). Studies in NG108-15 cells show that this current is carried by sodium and potassium ions. ICS 205-930 (1 nM), a selective 5-HT_3 antagonist, blocked these responses. 2-methyl-5-HT, a selective 5-HT_3 agonist, partially activated these responses. The magnitude of the response produced by 2-methyl-5-HT (50 uM) was 8% of the 5-HT response (also 50 uM). This suggests that the rapid 5-HT response in both cell types is mediated through the 5-HT_3 receptor.

The response in both cell types completely desensitizes, with a biphasic time course. Quantitative analysis of the time course of desensitization in NG108-15 cells yielded average time constants of .23 $\pm$ .04 sec (mean $\pm$ SEM) and 2.6 $\pm$ .6 sec for the fast and slow components, respectively. The ratio of the current contributed by the fast versus the slow components averaged 3.28 $\pm$ .58. Forskolin, an adenylate cyclase activator, increased the rate of desensitization in both cell types. The half-time of desensitization was decreased by 38 $\pm$ 7% (n= 4 cells) in hippocampal neurons and 61 $\pm$ 3% (n= 9 cells) in NG108-15 cells following the application of 30 uM forskolin. This suggests that desensitization of the 5-HT_3 receptor may be regulated by phosphorylation.

POSTSYNAPTIC MECHANISMS OF ADENOSINE MEDIATED INHIBITION IN CA1 NEURONS, IN VITRO. H.L. Haas*, U. Gerber* & R.W. Greene, Johannes Gutenberg-Universitat, Mainz, FRG; Harvard Med. Sch./VAMC, Brockton, MA 02401

Endogenous adenosine (AD) exerts an inhibitory tone on CA1 neurons even in the absence of synaptic activity. Exposure to exogenous AD evokes a hyperpolarization probably mediated by an increase in potassium conductance. In the present study, records were obtained from CA1 neurons of adult S.D. rats in vitro, employing single electrode sample and hold voltage clamp to analyze the voltage and ionic sensitivity of AD effects. The amplitude and polarity of the AD evoked current varied with extracellular K (3.2, 6.2, 12.5, 25 mM) as predicted by the Nernst equation for a change in potassium permeability. I/V plots (membrane potential was altered from -120 to -50 mV at a rate of 1 mV/200 mS) showed an AD evoked increase in conductance that was voltage insensitive. Neither the addition of 1-5 mM CsCl nor 500 uM 4-AP to the perfusate affected the AD evoked hyperpolarization. However, the addition of 2 mM Ba reversibly blocked the AD response. Transient outward currents were also examined. I_{AHP}, a calcium dependent K current, was increased but I_A was not. We conclude that AD evoked postsynaptic inhibition is mediated by a voltage insensitive increase in steady state potassium conductance and I_{AHP}. The former is similar in its lack of voltage sensitivity and inactivation to a potassium conductance reduced by ACh (analogous to S current described in invertebrates) in CA1 neurons.

MEMBRANE POTENTIAL FLUCTUATIONS DO NOT CONTRIBUTE TO SHORT-TERM SYNAPTIC PLASTICITY IN *APLYSIA*. Daniel Gardner. Dept. of Physiology, Cornell Univ. Medical College, New York NY 10021.

At identified inhibitory synapses in the *Aplysia* buccal ganglia, both duration and amplitude of synaptic currents are alterable by manipulating presynaptic activity, producing short-term changes in synaptic efficacy. Recent theoretical reports have suggested modifications to Hebbian learning paradigms in which synaptic efficacy would be altered not by neuronal activity, but by changes in the rate of activity. In an attempt to evaluate a variability-sensing learning rule which uses a biophysically plausible mechanism, I advance and test the hypothesis that membrane potential (V_m) fluctuations themselves produce changes in postsynaptic current (PSC) strength. Fluctuations in V_m produced by complex synaptic input might plausibly ease conformational changes of membrane proteins, producing direct or indirect effects on postsynaptic channels. The hypothesis is tested by injecting excess variance (6×10^{-4} V^2 noise over 1-500 Hz range) into identified voltage-clamped postsynaptic neurons, monitoring synaptic efficacy for 60-180 min, and comparing to control synapses sharing a common pre- or postsynaptic element. Different paradigms using three-cell networks evaluate non-specific and associative effects on individual synapses.

NON-ASSOCIATIVE EFFECTS OF NOISE: PSCs were simultaneously recorded at 1 min intervals from two postsynaptic cells innervated by a common presynaptic neuron, with noise injected into one of the two between PSCs. Synaptic current amplitudes and durations varied in parallel in the two followers; normalizing by control values suggests no non-associative effects of noise injection.

ASSOCIATIVE EFFECTS OF NOISE: In a complementary protocol, a postsynaptic neuron was alternately stimulated by two presynaptic cells, with noise injected during PSCs produced by only one of the two inputs. Neither PSC amplitude nor duration was consistently altered by associative pairing with noise.

I conclude that synaptic efficacy is unaffected by 1-2 h of noise simulating complex excitatory and inhibitory synaptic input from other pathways.

AN INCREASE IN POSTSYNAPTIC CALCIUM IS SUFFICIENT TO ENHANCE SYNAPTIC TRANSMISSION IN HIPPOCAMPUS. J.A. Kauer, R.C. Malenka, R.S. Zucker, & R.A. Nicoll. UCSF, San Francisco, CA 94143 and Univ. Calif., Berkeley, CA 94720.

Using the hippocampal slice, we have performed two sets of experiments to define the importance of calcium in the induction of long term potentiation (LTP). Intracellular electrodes were filled with the photolabile calcium chelator, Nitr5, loaded with calcium. Photolysis of Nitr5 that elevates calcium to the low micromolar range markedly increased the size of the EPSP in CA1 pyramidal cells for more than 20 minutes. No effect of light exposure was observed either on the extracellularly recorded population EPSP, or in control experiments using electrodes filled with Nitr5 which was not loaded with calcium, demonstrating that the release of calcium was the factor responsible for the potentiation.

Pairing low-frequency stimuli to the presynaptic afferents with depolarization of the postsynaptic cell has been reported to produce LTP. If Ca^{++} entry is necessary for the induction of LTP, one would expect that by holding a cell near the reversal potential for calcium, one could block LTP. Using Cs^{+}-filled electrodes, pairing 10 afferent stimuli with very strong depolarization of the postsynaptic cell produced little or no potentiation of the EPSP; subsequent pairing of 10 identical stimuli with a smaller depolarization produced a large and long-lasting potentiation. Taken together, these experiments demonstrate that calcium is both necessary and sufficient to trigger postsynaptic processes involved in synaptic potentiation.

369.8

NMDA RECEPTOR ACTIVATION POTENTIATES SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS. R.C.Malenka, J.A. Kauer, & R.A. Nicoll. University of California, San Francisco, CA 94143.

To determine whether NMDA application in the absence of presynaptic fiber activity is sufficient to elicit LTP we have examined the effects on synaptic transmission of iontophoretic application of NMDA onto CA1 pyramidal cell dendrites. A large depolarizing dose of NMDA caused an initial depression of the EPSP followed by an enhancement. A small dose of NMDA, which when paired with hyperpolarizing current injection did not cause an enhancement of the EPSP, caused a pronounced potentiation of the EPSP when paired with depolarizing current injection. The NMDA-induced potentiation was occluded shortly after the induction of LTP and could be mimicked by a tetanus suggesting that LTP and NMDA-induced potentiation may activate the same intracellular mechanisms. However, NMDA-induced potentiation differed from LTP in that its average duration was 15-20 minutes.

Activation of the full complement of glutamate receptors also was not sufficient to elicit LTP since application of glutamate alone or quisqualate and NMDA together always elicited a decremental form of potentiation. It was possible to change, in the same cell, a decremental form of potentiation into a long lasting form by increasing stimulus strength during the LTP-inducing stimulus. Increasing stimulus strength would be expected to recruit smaller diameter, higher threshold fibers. From these results, we propose that what previously has been termed LTP consists of two components, a decremental component which can be mimicked by NMDA receptor activation and a long-lasting, non-decremental component which may require stimulation of small diameter, high threshold afferent fibers.

Differential distribution of acetylcholine receptor mRNA in myotube nuclei. S. Bursztajn, S.A. Berman and W. Gilbert. Bio. Labs. Harvard Univ.,Cambridge, MA. 02138.

Acetylcholine receptor (AChR) genes are differentially regulated during development. AChRs are expressed on muscle cells which are multiucleated and thus represent an interesting system in which to study nuclear activation and inactivation. We have used in situ hybridization with a genomic DNA probe to examine the distribution of AChR α subunit mRNA at the subcellular level. The α subunit genomic clone was obtained from J.P. Changeux. Cells were hybridized with the labelled AChR α subunit,or with labelled actin DNA probe or poly(U)RNA.The hybrids were detected by nuclear track emulsion autoradiography. Silver grains due to AChR α subunit probe showed a striking perinuclear localization. In contrast, myotubes labelled with an actin probe or poly(U) showed a diffuse distribution of silver grains throughout the myotube. Quantitation of myotube nuclei revealed that 71%+4% of nuclei actively express AChR mRNA,and that the other nuclei express the mRNA at low levels or are inactive. Our results show that myotube nuclei are differentially activated for the expression of AChR α subunit mRNA and possibly other synaptic proteins.

BIPHASIC CHANGES IN ACETYLCHOLINE BINDING TO POST-SYNAPTIC NICOTINIC RECEPTORS BY BARBITURATES, B.A. Dodson, R.L. Ruch*, L.L. Firestone and K.W. Miller*. Dept. of Anaesthesia, Harvard Medical School, Massachusetts General Hospital, Boston, MA 02114 USA.

Preliminary data suggest that barbiturates have a biphasic effect on equilibrium ^{3}H-acetylcholine (^{3}H-ACh) binding to Torpedo postsynaptic acetylcholine receptors (AChR). To study this effect in more detail, we examined barbiturate-dependent changes in % AChR desensitized ($\%R_{hi}$). The studies used membranes purified from Torpedo electroplaque and preincubated with DFP. To determine barbiturate-dependent changes in $\%R_{hi}$, ^{3}H-ACh (40-50nM) was added to equilibrated barbiturate-membrane (20-25nM AChR) solutions (pH 7.0). After 5 secs, ^{3}H-ACh binding was determined by filtration (^{3}H-ACh does not itself induce desensitization itself under these conditions).

At lower concentrations, barbiturates decreased $\%R_{hi}$ from control values (25-30% of AChR) in a mass action-like fashion (n_H=1). At higher concentrations, barbiturates increased $\%R_{hi}$ with slopes (n_H)>1. These findings support both a negative allosteric barbiturate-ACh interaction and a more nonspecific interaction, similar to that described for the alcohols and volatile anesthetics. Therefore, biphasic changes in equilibrium ^{3}H-ACh binding appear to represent two different mechanisms of barbiturate actions on the acetylcholine receptor.

THE DURATION OF GLYCINE ACTION AT MAUTHNER CELL INHIBITORY SYNAPSES IS DETERMINED BY DIFFUSION, NOT NA-DEPENDENT UPTAKE. M. J.Titmus, D.S. Faber, and H.Korn. Dept. Physiol., SUNY at Buffalo, Buffalo, NY ,14214 ,and Dept. Biotechnologies, Pasteur Inst. , Paris.

Recent evidence for facilitatory interactions between adjacent glycinergic synapses on the Mauthner(M-) cell suggested that diffusion, rather than an active uptake or inactivation mechanism, may account for removal of this transmitter from the synaptic cleft. To test this idea we studied the effects of blocking Na- dependent glycine uptake on the kinetics of inhibitory responses evoked by i)stimulating the collateral network, and ii) glycine iontophoresis. 75% of the extracellular Na was replaced by Li or N-methyl glucamine, using in vivo superfusion. A successful exchange was indicated by a reduction in antidromic spike height and membrane depolarization. Removal of Na had no effect on the time course of the decay of evoked synaptic responses recorded in current (n=7) or voltage (n=4) clamp, when they were compared with controls obtained at the same membrane potential. The durations of the longer lasting (1sec vs 10 msec) conductance changes produced by glycine iontophoresis were also unchanged. However, the magnitudes of these responses were enhanced in Li, with the glycine dose-response curves being shifted to the left by about 0.2 to 0.5 log units. This facilitation does not appear to be due to a change in glycine receptor properties, since the Hill coefficient, which averaged about 2, was unaltered by Li in 4 experiments. We conclude that uptake does not influence the duration of glycine action following its synaptic release but may rather act to maintain a low concentration of this transmitter in the synaptic cleft despite its high serum levels. PEPTIDES: PHYSIOLOGICAL EFFECTS IV

370.1

SUPPRESSION OF BARORECEPTOR REFLEX RESPONSE BY ENDOGENOUS ANGIOTENSIN III IN THE RAT. J.Y.H. Chan, S.H.H. Chan and C.D. Barnes. Dept. of Pharmacology, National Yang-Ming Med. Coll., Taipei 11221, Taiwan, and Dept. of VCAPP, Washington State Univ., Pullman, WA 99164-6520.

We investigated in the present study the participation of endogenous brain angiotensin III (AIII) in central cardiovascular regulation in pentobarbital sodium anesthetized rats. AIII (100 pmol) promoted an elevation in systemic arterial pressure and a reduction in the baroreceptor reflex (BRR) response. Blocking or enhancing the endogenous AIII activity respectively with its specific antagonist, Ile^7-AIII (100 nmol), or the aminopeptidase inhibitor, bestatin (200 nmol), on the other hand, augmented the loop gain of the same reflex. The suppressive action of AIII on the BRR response was attenuated, and the augmentative effect of Ile^7-AIII was potentiated, however, when these two peptides were administered simultaneously with bestatin. All these events were significantly different from their controls during the first 10-15 min following injection, parallel to the time-course of a discernible action of AIII and Ile^7-AIII on systemic arterial pressure. Furthermore, microiontophoretically applied AIII significantly blunted the responses of neurons in the nucleus tractus solitarius (NTS) to arterial pressure fluctuations. These data suggest that the endogenous AIII may participate in central cardiovascular control by tonically suppressing the BRR response, possibly at the level of the NTS.

370.2

ATTENUATION OF GUANABENZ-INDUCED CARDIOVASCULAR SUPPRESSIVE EFFECTS BY ANGIOTENSIN III IN THE RAT. S.H.H. Chan, J.Y.H. Chan and D.C. Yin*. Institute of Pharmacology, National Yang-Ming Medical College, Taipei 11221, Taiwan, R.O.C.

We evaluated in the present study the interactions between brain neuropeptides and the central catecholaminergic system, using angiotensin III (AIII) and the cardiovascular effect of the α_2-adrenoceptor agonist, guanabenz, as the respective example in rats anesthetized with pentobarbital sodium. Intracerebroventricular (i.c.v.) administration of AIII (100 or 200 pmol) significantly and dose-relatedly attenuated the hypotensive and bradycardiac effects of guanabenz (50 µg/kg, i.v.). Bilateral microinjection of AIII (20 or 40 pmol) to the nucleus reticularis gigantocellularis (NRGC), a medullary site believed to be intimately related to the antihypertensive actions of the aminoguanidine compound, produced similar results. In addition, i.c.v. administered AIII (200 pmol) altered the effects of guanabenz on the arterial pressure-related single-neurons in the NRGC, in a manner that paralleled the blunted vasodepressive and cardioinhibitory actions of the aminoguanidine compound. When applied microiontophoretically, AIII also significantly decreased the responses of NRGC neurons to guanabenz. Based on these findings, it is conceivable that AIII may lessen the antihypertensive efficacy of guanabenz by reducing the responsiveness of neurons in the NRGC to this agent, resulting in the attenuation of its cardiovascular suppressive potency. (Supported in part by NSC-76-0412-B010-23)

370.3

ENHANCED BAROREFLEX SENSITIVITY IN CAPTOPRIL(CAP) TREATED SHR IS DUE TO AN INHIBITION OF BRAIN ANGIOTENSIN II (AII) MECHANISMS. K. H. Berecek and S. WT. Cheng*, Hypertension Program, Univ. of AL. at Birmingham, AL 35294

We examined whether the increase in baroreflex sensitivity previously reported in CAPtreated SHR was due to an inhibition of brain AII mechanisms. Pregnant and lactating female SHR were given oral captopril (100 mg/kg/day). After weaning, pups were maintained on CAP (50 mg/kg) until the study (19-21 wk). Ten days prior to study CAP and control (CON) SHR were given an intracerebroventricular (ICV) infusion of AII (7.5 ng/hr), or vehicle (VEH, artificial CSF). Baroreflex control of heart rate (HR) was assessed in response to changes in mean arterial pressure (MAP) induced by phenylephrine and nitroprusside. ICV AII had no effect on MAP in CAP treated (CAPAII 124±7 vs CAPVEH 119±4) or CON (CONAII 164±7, CONVEH 157±6 mmHg) SHR. ICVAII produced a significant ($p<0.01$) rise in HR (CAPAII 378±13 vs CAPVEH 320±11, CONAII 347±9 vs CONVEH 306±10 bpm) and in water intake and a ($p<0.05$) decrease in the slope of the relationship between pulse interval and MAP but only for CAPSHR (increase in MAP: CAPAII 0.81±.08; CAPVEH 2.8±0.9 CONAII 0.57±0.1, CONVEH 0.67±0.07, decrease in MAP CAPAII 0.46±0.1 CAPVEH 0.85±0.2; CONAII 0.78±0.09, CONVEH 0.99±0.2). Our findings suggest that decreased brain AII activity induced by CAP underlies increased baroreflex sensitivity in SHR.

370.4

THE REGULATION OF OXYTOCIN AND VASOPRESSIN SECRETION BY NEUROHYPOPHYSIAL CO-PEPTIDES. C.A. Bondy* and H. Gainer, LNC, NINCDS, Bethesda, Md. 20892.

Dynorphin, which is co-localized with vasopressin(VP) in the hypothalamo-neurohypophysial system, inhibits the electrically evoked, Ca^{++} dependent secretion of oxytocin(OT) [Bondy et al, Endocrinol.122:1224, 1988]. We have examined the regulatory roles of cholecystokinin(CCK) and corticotropin releasing hormone(CRH) which are co-localized with OT in many magnocellular neurons. Both of these peptides produce significant increases in OT and VP release from rat neurohypophyses *in vitro*.

High affinity CCK receptors were demonstrated autoradiographically in the rat neural lobe(NL). We found that CCK-8 produced a large augmentation of OT and VP secretion from isolated NLs with an EC50 of 10^{-10}M. CCK's stimulatory effect was not dependent upon electrical stimulus or the presence of Ca^{++} in the incubation medium, but was blocked by staurosporine, an inhibitor of C kinase. CRH(500nM) caused a Ca^{++} dependent stimulation of OT and VP secretion from neuro-intermediate lobes(NILs) but had no effect on NLs alone. The application of α-melanocyte stimulating hormone to NLs induced a pattern of OT and VP release identical to that produced by CRH on NILs. Thus, co-peptides released with VP or OT may act locally, either directly on the NL, or via an interaction with the adjacent pars intermedia, to modulate OT and VP release from the nerve terminals of the neurohypophysis.

370.5

INTRATHECAL ARGININE^8-VASOPRESSIN PRODUCES DIFFERENT CARDIOVASCULAR RESPONSES IN CONSCIOUS AND ANESTHESIZED RATS. A. Martinez-Arizala, J. B. Long, and J. W. Holaday. Dept. of Medical Neurosciences, Walter Reed Army Inst. of Research, Washington D.C. 20307-5100.

Prior studies in our laboratories suggested that the cardiovascular changes produced by intrathecal (i.t.) arg^8-vasopressin (AVP) in conscious rats differed from those in anesthesized rats. To further characterize the differences in the responses to i.t. AVP , S-D rats were implanted with PE catheters in the tail artery, the jugular vein, and the lumbar subarachnoid space. Mean arterial pressure (MAP) and hindlimb motor function were monitored following i.t. injections of AVP (0.01 nmoles). Both conscious and anesthesized (ketamine and xylazine) rats had a pressor response to i.t. AVP and conscious rats exhibited an acute hindlimb paralysis. The pressor effect of i.t. AVP were more striking in conscious rats (mean ↑ in ' of 73 ± 3 mmHg) than in anesthesized rats (30 ± 8 mmHg). effects of i.t. AVP were mediated centrally at the V_1 recept since they were blocked by the i.t., but not the i.v. injection c the V_1-receptor antagonist d(CH$_2$)$_5$[TYR(Me)^2]AVP. In addition, the pressor effects of i.t. AVP were: a) blocked by phenoxybenzamine and hexamethonium in the anesthesized, but not in the conscious rats, and b) not blocked in conscious rats by the angiotensin II antagonist [Sar^1, Thr^8]-angiotensin II. These results indicate that sympathetic catecholaminergic mechanisms mediate the rise in MAP produced by i.t. AVP in anesthesized rats, but not in conscious rats.

370.6

OXYTOCIN-INDUCED PENILE ERECTION AND YAWNING: STRUCTURE ACTIVITY STUDIES. A. Argiolas and M.R. Melis. Department of Neurosciences, University of Cagliari, Via Porcell 4, 09100 Cagliari, Italy.

The effect of the i.c.v. injection of several oxytocin (OXY) related peptides on penile erection and yawning was studied in male rats. Substitution of two aminoacids caused marked changes in OXY effect, the rank order of potency being: OXY>Thr^4,Gly^7-OXY>Ser^4,Ile^8-OXY>vasopressin (VP) Similarly, deletion of the C-terminal glycinamide as in OXY 1-8 caused a 99% decrease in OXY potency. In contrast, permanent opening of the disulfide bridge by carboxymethylation completely abolished OXY effect. Inactive were also tocinoic acid (OXY 1-6) and the C-terminal tripeptide Pro-Leu-GlyNH$_2$ (OXY 7-9). Penile erection and yawning induced by OXY-related peptides were antagonized in a dose-dependent manner by potent and selective OXY antagonists such as d(CH$_2$)$_5$Tyr(Me)-Orn^8-vasotocin and (Pen^1,Phe(Me)^2,Thr^4 Orn^8)-OXY and, much less effectively, by the selective VP antagonist d(CH$_2$)$_5$ Tyr(Me)-Arg^8-VP. Carboxymethylated OXY, OXY 1-6 and OXY 7-9 were devoid of antagonistic activity. The present results suggest that central oxytocin receptors mediating the induction of penile erection and yawning are structurally related to those mediating OXY effects in the uterus and mammary gland.

370.7

HYPOTHALAMIC ATRIAL NATRIURETIC PEPTIDE RECEPTORS IN ADRENALECTOMIZED, HYPOPHYSECTOMIZED AND VASOPRESSIN-DEFICIENT RATS. Pero Castrén and Juan M. Saavedra, Laboratory of Clinical Science, National Institute of Mental Health.

Atrial natriuretic peptide (ANP) has receptors in supra-optic and paraventricular nucleus of the hypothalamus; these nuclei are implicated in the regulation of the hormone release from the pituitary gland. We have studied the physiological role of these receptors by measuring ANP binding in hypophysectomized (HX) and adrenalectomized (ADX) rats and in vasopressin-deficient homozygous Brattleboro rats (DI) by receptor autoradiography according to Kurihara et al. (Brain Res. 408:311-39,1987).

Following HX, ANP binding sites were increased in both supraoptic (37±6 and 20±7 mg/fmol protein for HX and controls, respectively, P<0.001) and magnocellular paraventricular nuclei (35±5 and 16±6 fmol/mg protein for HX and control, respectively, P<0.001). A similar increase was observed in DI rats (26±2 and 13±1 fmol/mg protein in SON and 13±1 and 9±1 fmol/mg protein in mPVN for DI and control rats, respectively, P<0.05). ADX did not alter ANP binding in these nuclei.

These results support the hypothesis that hypothalamic ANP receptors are mainly involved in the regulation of vasopressin release.

370.8

INTRATHECAL (I.T.) VASOACTIVE INTESTINAL POLYPEPTIDE (VIP), SUBSTANCE P (SP) AND C-FIBER STIMULATION (CS) HAVE ALTERED EFFECTS AFTER PERIPHERAL NERVE INJURY.

Z. Wiesenfeld-Hallin and R.G. Hallin, Dept. Clin. Neurophysiol., Karolinska Institute, S-141 86 Huddinge, Sweden.

VIP and SP are found in separate populations of primary afferents. After peripheral nerve section the SP content of spinal ganglion cells decreases whereas VIP level increases. Changes in spinal reflex excitability after i.t. VIP, SP and CS were compared in rats with intact or sectioned peripheral nerves.

The hamstring flexor reflex was examined in decerebrate, spinalized, unanesthetized rats. SP and VIP were injected i.t. via a catheter with its tip on the lumbar enlargement. The reflex was evoked by electric shocks (sural n., 0.5ms, 5mA, 1/min), recorded as EMG signals and integrated. In some animals the sciatic n. was sectioned unilaterally 14–21 d. before.

VIP, SP or a brief CS train (20, 1Hz) increased spinal excitability for 2–5 min. SP+CS caused a synergistic facilitation of reflex excitability, which VIP+CS did not. After nerve section SP, VIP and the CS train facilitated the reflex as in intact animals. However, synergism between SP+CS was not observed, whereas VIP+CS had a strong synergistic effect.

SP, VIP and the CS train caused similar reflex facilitation, which may indicate that the CS train releases peptides at afferent central terminals. Synergism between SP+CS train when the sciatic nerve was intact may indicate that other peptides released by the CS (e.g. calcitonin gene-related peptide) interact with SP. No such interaction occurs with VIP. The altered interaction of SP+CS train and VIP+CS train after nerve section may indicate that postinjury changes in peptide levels can be associated with changes in spinal function.

IONIC BASIS FOR SUBSTANCE P EXCITATION IN TRIGEMINAL ROOT GANGLION (TRG) NEURONS I. Spigelman and E. Puil, Dept. of Pharmacology & Therapeutics, Faculty of Medicine, University of British Columbia, Vancouver, Canada, V6T 1W5.

The slow, depolarizing responses in the perikarya of TRG neurons to substance P applications (Spigelman and Puil, Can. J. Physiol. Pharmacol., 1988) are of special interest because of possible involvement in the transmission of nociceptive impulses. Initially we proposed that substance P excitation in TRG neurons resulted from an increased Na^+-conductance (g_{Na}) in combination with a blockade of a K^+-conductance (g_K). We now provide direct evidence using single electrode voltage clamp techniques for an activation of inward current during applications of substance P (2 µM) in the presence of 4-aminopyridine (1 mM) and tetraethylammonium (10 mM). This current also was observed during internal Cs^+-blockade of K^+-channels. Because changes in g_{Na}/g_K could result from actions on the Na^+/K^+ pump, the effects of extracellular removal of Mg^{2+} were studied on the depolarizations evoked by substance P. The responses were drastically reduced in Mg^{2+}-deficient solutions. The above observations imply that the ionic mechanism of substance P action on TRG neurons is unlike that proposed in central neurons. Also, extracellular [Mg^{2+}] may modulate the substance P responses at the level of peptide-receptor interaction.

Supported by a Medical Research Council grant to E. Puil and a Canadian Heart Foundation Research Traineeship to I. Spigelman.

SYNERGISTIC EFFECTS OF β-PREPROTACHYKININ-DERIVED PEPTIDES ON SALIVARY GLAND SECRETION. Y. Takeda and J.E. Krause, Department of Anatomy & Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110

The preprotachykinin (PPT) precursors encoding Substance P (SP) and Neurokinin A (NKA) display a high degree of homology in regions that do not encode these tachykinins, and the precursors may be differentially processed post-translationally. These observations have led us to examine some biological responses due to these other peptides, and to examine whether they have coordinate actions with SP or NKA on their biological endpoints. We examined the activity of β-PPT derived peptides on salivation responses in rats, and document potent effects of Neuropeptide K [NPK; β-PPT-(72-106)-peptide amide] on the salivation response as well as its synergism with SP in inducing salivary gland secretion. The rank order of potency of femoral vein injected β-PPT-derived peptides on the salivation response was as follows: NPK > SP > NKA, and others, including β-PPT-(72-96)-peptide, were inactive. NPK-induced responses occurred at lower doses than that of SP, and the maximal response was greater. Salivation responses induced by NPK and SP were antagonized by the tachykinin antagonist ([D-Pro^2,D-Trp^{7,9}]-SP), but not by atropine. The potency of NPK (Ki=100 nM) on the displacement of ^{3}H-SP binding to the SP-P type receptor in rat submandibular gland membranes was 100-fold lower than that of SP (Ki=1.00 nM). When both NPK and SP were co-infused for 10 min at submaximal doses, these peptides greatly stimulated salivary secretion over a similar time course than either peptide alone, but the total response was some 3-fold greater than the sum total of individually infused NPK and SP.

We conclude that NPK is a potent tachykinin, and the synergistic effects of NPK and SP on the salivation response may represent an important mechanism of tachykinin cotransmission in tachykinin-elicited biological responses.

CHRONIC TREATMENT WITH THE POTENT PERIPHERAL CHOLECYSTOKININ ANTAGONIST L-364,718 PRODUCES MULTIPLE PATHOLOGICAL CHANGES IN THE RAT. RB Murphy, LH Schneider, J Sidhu#, JT Pedersen#, MR Pincus#, ES Corp#, SC Weatherford, CA Watson#, J Gibbs and GP Smith. Dept. Psychiatry, NY Hosp-Cornell Med. Ctr., White Plains, NY 10605; Dept. Chemistry and Dept. Pathology, New York Univ., and Manhattan VA Hospital, NY, NY 10032

We treated rats chronically with the potent cholecystokinin (CCK) antagonist L-364,718 for a 14-day period at a dose of 1.5 mg-kg^{-1}-day^{-1} (CA Watson et al, Soc. Neurosci. Abstr., this meeting). In the treated animals (N=9), the spleens were uniformly and grossly enlarged as compared to vehicle-treated controls (N=9) and were distinguished by a diffuse scattering of collections of histiocytes resembling small, non-necrotizing granulomas in the red pulp area. The pancreas in treated animals showed a diminution in the size of the Islets of Langerhans. Other organs, including the exocrine pancreas, were grossly normal. Enlargement of the spleen was not observed in acutely-treated (1-day) rats. Our results strongly suggest that chronic blockade of peripheral CCK receptors with large doses of L-364,718 produces multiple pathological changes. The functional changes associated with these alterations are currently under investigation.

EVIDENCE FOR ARTERY-VEIN DIFFERENCES IN RESPONSE TO NEUROPEPTIDE Y IN MESENTERY OF GUINEA PIG. T.L. Anthony* and D.L. Kreulen, Department of Pharmacology, University of Arizona, College of Medicine, Tucson, AZ. 85724.

Neuropeptide Y (NPY) is present in sympathetic nerves that innervate blood vessels. The present study was performed to determine the effects of (NPY) in vascular smooth muscle of the guinea pig mesenteric artery and vein. Membrane potentials were measured with intracellular microelectrodes and contractions were measured on isolated ring segments of the vessels. NPY (65 to 425 pmoles) was administered by pressure ejection from micropipettes placed 95 μm from the tissue surface. NPY evoked a dose-dependent depolarization in mesenteric artery and vein that resembled a slow depolarization not an excitatory junction potential (EJP). The depolarization in vein averaged 8.7 mV and in artery it averaged 2.6 mV. The duration of the depolarizations averaged 10.6 s in artery and 6.2 s in vein. If the NPY was administered at intervals less than 5 min the amplitude of the depolarizations diminished. The amplitude of the EJPs evoked with nerve stimulation was increased 12% (n=2 cells) after pressure ejection of NPY and this effect persisted after the membrane had repolarized. NPY was equipotent for producing contractions in artery and vein in isolated ring preparations. However NPY was more effective in vein than in artery when compared to the norepinephrine maximum response. These experiments demonstrate that NPY could function as an excitatory neurotransmitter in both mesenteric artery and vein to produce a slow depolarization and to potentiate neuromuscular transmission. Support DK36289.

CEREBRAL METABOLISM AND BLOOD FLOW II

371.1

ANIMATING 3D STRUCTURE-FUNCTION RELATIONSHIPS

A.W. Toga and B.A. Payne*
Laboratory of Neuro Imaging, Department of Neurology
UCLA, Los Angeles, CA 90024-1769

Recent progress in neuro imaging has extended analysis of anatomic and physiologic data from 2D to 3D. Research in our laboratory and others have concentrated on techniques for modelling, surface rendering and brain mapping. The result has been the production of accurate and realistic displays of whole brain. However, as the complexity of these models increased, static presentations have become less comprehensible. The problem has been exacerbated by extending the domain to four and five dimensions by introducing functional data, time course and statistical information.

We have addressed this problem by adding movement during the analysis of 3D reconstructions. Real time animation enables the viewer to visualize complex functional anatomic shapes and the spatial relationships between them.

Autoradiographic and histologic data from rats were reconstructed to 3D models by assembling 600 coronal sections per animal. These 3D data sets were used as the basis of an animation that illustrates the process of synthysizing spatially accurate models of structure (histology) and function (autoradiography). Each view (frame) of the 3D brain was computed, displayed and written to video tape. The tape was stopped between views, repositioned and readied for recording the next frame. A frame consisted of 1/30 sec. during tape playback. The results of our efforts are in the form of a video movie.

The movie, which will be shown during the session, illustrates the complex relationships between structure and function during focal seizures in rat. Various forms of rendering and display will be demonstrated.

371.2

STEREOTAXIC COORDINATES AND Z SCORE TRANSFORMATION SIMPLIFY GROUP METABOLIC ACTIVITY DATA ANALYSIS. H.H. Holcomb, H.L. Loats, C.A. Tamminga, J. Links*, R.F. Dannals*, H.N. Wagner* U. Md. Psych. Res. Ctr., Johns Hopkins Medical Institutes, Baltimore, Md., 21205.

Functional image analysis (positron emission tomography [PET] and deoxyglucose autoradiography [2DG-QAR]) is complicated by (1) nonhomogeneous data sets, and (2) inexact, inconsistent anatomical characterization of functional images. These two problems are partially solved by data normalization and statistical transformation (all pixels are Z score converted). Images for a given individual are normalized by dividing each pixel by the whole brain mean gray-plus-white value. Z score transformation is accomplished by subtracting each pixel value from the group mean and dividing that difference value by the sigma associated with that group mean. All functional images, PET and 2DG-QAR, are registered with their anatomical substrates. PET images are registered with integrated 3 mm thickness magnetic resonance images (MRI) and 2DG-QAR with their original tissue sections. 3 Dimensional stereotaxic coordinates are generated from orthogonal, registered MR images, using the bicommissural axis, midline, as the zero point. Image coordinates acquired from planes oblique to the AC-PC line are geometrically transformed. 2DG-QAR coordinates derive directly from stereotaxic apparatus measurements, facilitated by partitioning the brain into one centimeter blocks at known coordinates. Z score activity transformation and 3 dimensional coordinate insertion both facilitate group image analysis.

REPRODUCIBILITY OF REGIONAL CEREBRAL BLOOD FLOW MEASUREMENTS IN NORMAL SUBJECTS WITH AND WITHOUT AUDITORY STIMULATION . *E. Meyer,* R.J. Zatorre, A.C. Evans,* B. Alivisatos,* and S. Marrett**. McConnell Brain Imaging Unit, Montreal Neurological Institute, McGill University, Montreal, Canada H3A 2B4

Regional cerebral blood flow (rCBF) was measured in six normal, right-handed, young male volunteers using the intravenous $H_2{}^{15}O$ bolus technique and positron emission tomography (PET). On each subject, 5 baseline and 5 stimulation studies were carried out on different days. In both conditions, the subjects' eyes were open. During the stimulation condition, binaural broadband white noise at a sound pressure level of 75 dB was applied via miniature earphones. For each subject, matched magnetic resonance and PET images were collected which allowed precise anatomical localization of the measured rCBF distribution.

Regional CBF across each group of 5 studies was examined for reproducibility and variability. A significant gradual reduction in global CBF across the 5 studies was observed in both conditions (a 17 % drop between the first and last studies). The white noise condition did not reduce the rCBF variability with respect to the baseline condition. It did, however, produce a significant increase in the normalized rCBF value for the primary auditory cortex.

REGIONAL CEREBRAL METABOLISM OF REM AND NON-REM HUMAN SLEEP AS ASSESSED BY PET J.C. Wu(1), M.S. Buchsbaum(1)*, J.C. Gillin(2), (1)Dept of Psychiatry, UCI, Irvine, CA 92717, (2)Dept of Psychiatry, UCSD

INTRODUCTION: This is the first PET study of sleep with subjects studied under natural nighttime conditions with full polysomnographically recorded sleep. METHOD: Thirty-six normal volunteers were accommodated to the sleep lab. Subjects went to sleep at 2300. 18 FDG was infused after sleep EEG indicated the desired sleep stage. Subjects were roused 32-45 minutes after FDG injection and scanned on a NEUROECAT II scanner (FWHM=7.6mm). Twelve subjects for REM, NREM, and eyes closed awake controls, who met the criteria of spending 75% of their uptake in the desired stage, were studied. RESULTS: NREM sleep showed a significant decrease compared to waking, whereas REM sleep showed an increase (significant sleep stage group effect, $F=5.99$, $d.f=2,3$ $p<.01$). Cortical decreases in NREM were greater than subcortical (basal ganglia, thalamus) decreases. Cortical increases in REM were greater than subcortical changes.

BRAIN GLUCOSE METABOLISM DURING FASTING IN MAN STUDIED BY POSITRON EMISSION TOMOGRAPHY. *L.J. Hoffer,* C. Redies, C. Beil,* E.B. Marliss,* A.C. Evans,* F. Lariviere,* S. Marrett,* E. Meyer,* M. Diksic,* and A.M. Hakim** (SPON: *G. Karpati*). Montreal Neurological Institute and McGill Nutrition and Food Science Centre, McGill University, Montreal, Canada H3A 2B4

Positron emission tomography (PET) was used to study cerebral glucose and oxygen metabolism, blood flow, and blood volume in four hospitalized obese men (age 38±6SD years, body mass index 36±4 kg/m^2). PET studies were carried out on a control diet (10–14 hours after previous meal), and after 20–24 days of a total fast.

Cerebral metabolic rate for glucose (CMRglc) and glucose tracer rate constants (K_1^* to k_3^*) were measured using ^{18}F labeled fluorodeoxyglucose and dynamic imaging. Cerebral metabolic rate for oxygen, blood flow, blood volume, and oxygen extraction ratio were measured with ^{15}O labeled O_2, CO_2, and CO gases.

Regional CMRglc fell to 38–47% of control values ($p<0.002$). The rate constant for tracer phosphorylation (k_3^*) fell to 42–57% of control values ($p<0.002$). Both parameters decreased relatively uniformly throughout the brain. Regional blood-brain barrier transfer rate constants for tracer (K_1^* and k_2^*), metabolic rate for oxygen, blood flow, and blood volume were unchanged.

Supported by MRC grant SP-5, and fellowships from MRC, DFG (Re 616/1-1), Max-Planck Gesellschaft, and Juvenile Diabetes Foundation.

371.6

SEQUENTIAL DOUBLE-LABELING WITH 2-DEOXYGLUCOSE (2-DG): A TEST OF THE PRIMARY ASSUMPTION. D.L. McEachron, P. Hand, and C.R. Gallistel, Image Processing Center, Drexel Univ., Philadelphia, PA 19110

Double-labeling with 2-DG involves injecting a bolus of 2-DG labeled with [14]C, waiting 45 minutes, injecting a second bolus of 2-DG labeled with another radioisotope and applying a simulus during the second 45 minute period. The relative contributions from the different radioisotopes are separated using different films, when using [3]H, or utilizing the shorter half-life of [18]F. The idea behind the technique is to use each animal as its own control. The primary assumption is that original [14]C-labeled 2-DG does not relocate in response to stimulation during the second labeling period.

Preliminary results of the following experiments were reported in Science, Vol. 238 as a technical comment (McEachron, et.al. : 1586, 1988). Eight rats were prepared for self-stimulation (Gallistel, et.al., J. Neurosci. 5: 1246, 1985) and given [14]C-2-DG (80 μCi/rat) in an intraperitoneal injection. Four rats were stimulated from 0-45 minutes post-injection, 2 of which were sacrificed at 45 minutes and 2 at 90 minutes post-injection. Four animals were stimulated from 45-90 minutes post-injection and sacrificed at 90 minutes. Responses to stimulation in the ventral limb of the Diagonal Band of Broca and right posterior MFB were similar in all animals stimulated from 0-45 minutes and in 2 of four animals stimulated from 45-90 minutes.

To further assess the stability of labeled 2-DG during stimulation from 45-90 minutes post-injection, young male rats were prepared for full quantification procedures (Sokoloff, et.al., J. Neurochem. 28: 897, 1977). At time 0, 50 μCi of [14]C-2-DG was given intravenously. From 0-45 minutes post-injection, the left C3 was stimulated by tactile whisker stimulation while from 45-90 minutes, the right C3 was stimulated in exactly the same manner. Blood was collected during the entire 90 minute procedure and the autoradiograms were analyzed for local cerebral glucose utilization (LCGU) using the DUMAS imaging system.Comparison of the left and right cerebral cortices in 5 rats indicated that between 39-68% of the increase in LGCU over background levels recorded in the first 45 minutes occurred during the second period (from 45-90 minutes) This confirms the results from the self-stimulation experiment and suggests that the primary assumption in sequentail double-labeling is invalid.

371.7

DOUBLE-LABEL DEOXYGLUCOSE METHOD APPLIED TO FERRET VISUAL CORTEX. *C. Redies and M. Diksic**. Montreal Neurological Institute, McGill University, Montreal, Canada H3A 2B4

The quantitative double-label deoxyglucose method (Redies et al., Neurosci.22:601,1987) allows the separation of glucose utilization patterns in mammalian brain elicited by two sequential sensory stimulations.

The method requires the knowledge of the rate constants for transfer of tracer across the blood-brain barrier (K_1^* and k_2^*), tracer phosphorylation (k_3^*), and loss of metabolized tracer (k_4^*), and of the lumped constant (LC). These constants were determined for fluorodeoxyglucose (FDG) and 2-deoxyglucose (2-DG) in 18 ferrets killed between 2.5 and 180 min after tracer injection. Mean gray matter values for [^{14}C]2-DG are: $K_1^* = 0.19$ml/g/min, $k_2^* = 0.28$/min, and $k_3^* = 0.093$/min; and for [^{3}H]FDG: $K_1^* = 0.21$ml/g/min, $k_2^* = 0.29$/min, and $k_3^* = 0.15$/min. Results suggest that loss of metabolized tracer (k_4^*) occurs at a constant rate of 0.01/min for 180 min after injection. However, whether k_4^* is 0 or 0.01/min, has a negligible effect on calculating glucose utilization in conventional 45 min 2-DG experiments provided that the entire analysis including the determination of the LC is consistent. Assuming $k_4^* = 0.01$/min, the LC in ferret brain is 1.03±0.08SEM for FDG and 0.70±0.09 for 2-DG.

Double-label experiments in the ferret visual cortex show that the method provides layer-specific information on functional "columns" elicited by two different sequential visual stimulations in the same animal.

Supported by MRC of Canada (Grant MA-10233).

COMPARISON OF METABOLIC TRAPPING OF RADIOACTIVITY FROM (^{14}C)-2-DEOXYGLUCOSE AND (6-^{14}C)-GLUCOSE IN RAT BRAIN. W.E. Stumpf, G.E. Duncan* and G.R. Breese. Dept. Cell Biol. and Anat. Univ. of N.C., Chapel Hill, NC 27599.

The uptake and retention of radioactivity was measured in areas of rat brain at different times after i.v. injection of (^{14}C)-2-deoxyglucose (2-DG) or (6-^{14}C)-glucose (G) with nuclear emulsion autoradiography. In most brain regions the accumulation of radioactivity from the two compounds was similar using a 30 min survival period for G and a 45 min survival period for 2-DG. However, at those times, relatively more radioactivity accumulated from 2-DG in stratum lacunosum-moleculare of hippocampus and layer 4 of isocortex. In contrast, relatively more radioactivity accumulated from G in the dentate gyrus, CA-1 pyramidal cell layer of hippocampus, and layer 2 of piriform cortex. With G at 5 and 30 min survival periods, the distribution of radioactivity was identical except in layer 4 of isocortex, where more radioactivity was present at 5 min. With 2-DG at 5 and 45 min survival periods the relative and absolute amount of radioactivity was greater at 5 min compared to 45 min in the dentate gyrus, CA-1 pyramidal cell layer, and in layer 2 of piriform cortex. In other brain regions, the absolute and relative amount of radioactivity was similar or slightly greater at 45 min compared to 5 min. These results demonstrate that neuroanatomically selective loss of radioactivity occurs after injection of 2-DG during a 45 min survival period.

371.9

CENTRAL ACTION OF PSYCHOMOTOR STIMULANTS ON LOCAL CEREBRAL GLUCOSE UTILIZATION (LCGU) IN EXTRAPYRAMIDAL MOTOR AREAS. A.S. Kimes, G. Wilkerson*, C. Ori* and E.D. London. Neuropharmacol. Lab., NIDA Addiction Res. Ctr., Baltimore, MD 21224.

Psychomotor stimulants, such as l-cocaine, ±3,4-methylenedioxymethamphetamine (MDMA), d-amphetamine and phencyclidine (PCP), produce stereotyped behaviors and increase LCGU in the extrapyramidal motor system as well as other brain areas of rats. It seemed possible that LCGU effects in motor areas could be secondary to increased limb movements rather than due to primary actions in the brain. We, therefore, used the 2-deoxy-D-[1-^{14}C]glucose method to measure LCGU in paralyzed (gallamine, 60-80 mg/kg, i.v.) and artificially ventilated rats treated with the aforementioned drugs. Rats received i.p. injections of saline, cocaine (30 mg/kg) or MDMA (30 mg/kg); or i.v. injections of saline, PCP (5 mg/kg) or amphetamine (5 mg/kg) 5 min before radiotracer injection. Cocaine and MDMA stimulated LCGU in the globus pallidus, substantia nigra pars reticulata and cerebellum. Amphetamine elevated LCGU in the same areas and also the anteroventral thalamus, zona incerta, subthalamic nucleus (n.) and red n. PCP elevated LCGU in the red n., substantia nigra pars reticulata, subthalamic n., zona incerta, anteroventral thalamus, globus pallidus and caudate putamen. As these effects were seen in paralyzed rats, they were not secondary to limb movements, but rather were primary central effects.

371.10

GLUCOSE UTILIZATION IN DISCRETE BRAIN AREAS AFTER CHRONIC ADMINISTRATION OF IMINODIPROPIONITRILE IN RATS. A. Della Puppa*, J.L. Cadet and E.D. London (SPON: J. Johnson). Neuropharmacology Lab., NIDA-ARC, Baltimore, MD 21224; Dept. of Neurol. Columbia Univ., New York, NY 10032.

The chronic administration of the neurotoxin iminodipropionitrile (IDPN) to rats causes a persistent behavioral syndrome consisting of random circling, vertical head twitches and hyperactivity (Chou, S.M., Acta. Neuropath., 3:428, 1964). The 2-deoxy-D-[1-^{14}C]-glucose method was used to assay the local cerebral glucose utilization (LCGU) in discrete brain areas.

Twelve male Sprague-Dawley rats were assigned to one of two groups, receiving a single daily i.p. injection of saline or IDPN, respectively. One day after the development of the characteristic behavioral syndrome, LCGU was measured as previously described (Sokoloff et al., J. Neurochem., 2:897, 1977). Statistically significant decreases in LCGU were found within the superficial and deep layers of the superior colliculus, interpeduncular nucleus, inferior colliculus, medial and lateral geniculate nuclei and medial and lateral vestibular nuclei. Nonsignificant decrements were seen in the substantia nigra. The claustrum showed a 34% increase in LCGU.

These findings suggest that IDPN affects the nigrotectal pathways controlling head and neck movements via reticulospinal tracts. This effect may also contribute to the phenomena of IDPN-induced, persistent spasmodic dyskinesias in rats.

371.11

ACUTE COCAINE DECREASES REGIONAL CEREBRAL GLUCOSE UTILIZATION IN HUMAN SUBSTANCE ABUSERS. E.D. London, N.G. Cascella*, D.F. Wong*, M. Sano, R.F. Dannals*, J. Links*, R.I. Herning*, J.K.T. Toung*, H.N. Wagner, Jr.* and J.H. Jaffe*. Neuropharmacol. Lab. NIDA Addiction Res. Ctr. and Johns Hopkins Univ., Balto., MD.

Regional cerebral metabolic rates for glucose (rCMR-glu) provide indices of brain function under various conditions. To clarify mechanisms mediating cocaine euphoria, we initiated a double-blind, placebo-controlled, crossover study of cocaine (C) effects on rCMRglu by the PET [^{18}F]fluorodeoxyglucose (FDG) method. Subjects for the study were men, 23-38 years of age, with a history of polydrug abuse. Self reports and EEG responses to 20 or 40 mg C or placebo (P), i.v., recorded on 4 separate days before the PET study, indicated that C increased EEG *beta* activity and produced euphoria. The subjects underwent 2 FDG scans, with 40 mg C or P given simultaneously with FDG. Rates of rCMRglu were measured in 22 regions of interest. C generally reduced mean rCMRglu, particularly in parts of the parietal and occipital cortices ($\geq$ 26% of P values). Decrements in most regions were 10-19% of P. Some areas showed minimal or no C-induced changes (cerebellum, insula, lateral thalamus). The observed decreases in rCMRglu suggest that 40 mg C, i.v., selectively reduces cerebral oxidative metabolism and that C-induced euphoria is mediated by a reduction in cortical activity.

VISIBLE LIGHT AFFECTS ^{14}C-2-DEOXYGLUCOSE UPTAKE INTO RAT CEREBRAL CORTICAL TISSUE IN VITRO. P.D. Wade$^{+\ddagger}$ and P. Siekevitz^{+}, $^{+}$Rockefeller Univ., New York, NY 10021 and ‡New York College of Podiatric Medicine, NY, NY 10035

Prompted by an observation that visible light influences K^+-induced release of GABA from cortical slices, (Soc.Neurosci.Absts.11:1129,1985), we have begun to examine the generality of response to light by measuring its effect on ^{14}C-2-DG uptake into the slices. One-half mm thick cortical slices were incubated with 0.7 µM ^{14}C-2-DG in Ringer's in a dark room in a water bath at 36-37 C for 30 min. either with or without light (1.9 mW/cm^2, broad spectrum, much of the UV removed by glass). The tissue was then rinsed repeatedly with Ringer's until excess radioactivity was removed, and the acid-soluble radioactivity taken up into the tissue was measured. Normalized ratios of uptake in a light expt. to uptake in a dark expt. yielded a mean of 0.89$\pm$0.06 (SEM, n=11). Thus at the one intensity of light used, visible light caused about 10% inhibition of ^{14}C-2-DG uptake into the tissue. As a first approximation, this degree of inhibition might be considered to be in a functional range, since in some in vivo states, functional activity changes have been associated with 10% changes in 2-DG uptake into certain brain regions [Soc.Neurosci.Absts. 11:813 (Nos. 228.9, 228.10),1987]. The intensity of light causing this partial suppression of uptake was the same intensity that caused suppression of K^+-induced release of GABA previously.

GELASMIN, A MAMMALIAN ACETYLCHOLINE RECEPTOR (ACHR) CLUSTERING FACTOR, AFFECTS ACHR SUBUNIT mRNA LEVELS IN EMBRYONIC RAT MYOTUBES: THE EFFECT IS SYNERGISTIC WITH THAT OF CALCITONIN-GENE-RELATED PEPTIDE (CGRP). K.F. Barald. Dept. Anatomy and Cell Biology, University of Michigan Medical School, Ann Arbor, MI 48109.

Gelasmin is a 93kD glycoprotein component of muscle basal lamina (BL) that is found on embryonic rat myotubes prior to innervation. It is not present in motoneurons at any time. After innervation of embryonic myotubes or in adult muscle fibers, gelasmin becomes localized to the synaptic BL. Unlike the Torpedo AChR clustering factor, agrin, gelasmin affects AChR protein levels and localization and AChR α-subunit mRNA levels. Both gelasmin and CGRP increased total receptor protein content significantly: CGRP, as reported previously by Fontaine et al (J. Cell Biol.105,1987), caused a 30% increase in specific ^{125}I-α-bungarotoxin bound; gelasmin a 35-40% increase. While neither CGRP nor gelasmin affected actin mRNA levels, each had a significant effect on AChR α-subunit mRNA levels, measured in Northern blots with a cRNA probe for mouse AChR α-subunit mRNA kindly provided by Dr. Jim Patrick. 15 ug/ml purified Gelasmin induced a 4-5 fold increase in α-AChR mRNA levels; 10^{-7} M CGRP, a 3-4 fold increase (as previously reported by Fontaine et al., 1987) Together, they effected a 6-14 fold increase in AChR α-subunit mRNA levels. The effect of gelasmin and CGRP appears to be synergistic in these preliminary studies. Further studies are underway to determine whether this represents stabilization or induction of the mRNA. Supported by the NSF, NIH, MDA, Phoenix Foundation and Office of the Vicepresident for Research, U. Michigan

A UNIQUE GLYCOSYLATED FORM OF NEURAL CELL ADHESION MOLECULE PRESENT IN FROG AND RAT PRIMARY OLFACTORY NEURONS. B. Key* and R.A. Akeson. Basic Research, Children's Hospital Medical Center, Cincinnati, Ohio 45229

The neural cell adhesion molecule (NCAM) consists of three isoforms of approximate molecular weights 180, 140 and 120kD in the adult vertebrate nervous system. In the present study we have identified and characterized a new subtype of the high molecular weight form of NCAM present only in the olfactory bulb.

Among a group of new monoclonal antibodies (Mabs) generated against both frog and rat olfactory epithelia were three Mabs (Mabs 5FOE, 9OE and 13FOE) all of which strongly labelled the surface of frog primary olfactory neurons. In frog brain sections Mabs 5FOE and 9OE labelled only the olfactory glomeruli in the main and accessory olfactory bulbs whereas 13FOE labelled cells and axons throughout the whole brain. 9OE cross reacted with rat and labelled glomeruli in only the accessory olfactory bulb. A similar distribution of binding was previously described (Key, B. and Giorgi, P.P., Neurosci. Lett. 69: 131, 1986) for the lectin soybean agglutinin (SBA). In immunoblots all three Mabs recognized a single band (approximately 200kD molecular weight) that was immunoprecipitated by a polyclonal anti-NCAM antibody. SBA binding molecules were isolated by affinity chromatography and shown to be a single band at 200kD which in immunoblots reacted with all three Mabs.

In summary, we have identified a unique glycosylated form of NCAM recognized by SBA and Mab9OE which is restricted to only olfactory neurons in frog and rat. The presence of specific cellular or regional NCAM subtypes may represent a mechanism for modulation of cell-cell interactions. Supported by NIH Grants NS23348 and HD21065.

372.3

ANALYSIS OF CD4 RNA AND PROTEIN IN THE DEVELOPING HUMAN NERVOUS SYSTEM. C.A. Kunsch*, H.T. Hartle* and B. Wigdahl. Department of Microbiology, The Pennsylvania State Univ. Col. of Med., Hershey, PA 17033.

The CD4 molecule functions as a cell surface recognition protein in the immune system and is also found in the nervous system of adults, where its function is currently under investigation. Furthermore, CD4 has been identified as the cellular receptor the human immunodeficiency virus type-1 (HIV-1) and its presence in the nervous system may be involved in the susceptibility of selected neural cell populations to HIV-1 infection. We are currently in the process of defining (i) the presence and distribution of CD4 RNA and protein in tissue and primary cell cultures derived from human fetal central and peripheral nervous system and (ii) the role of CD4 in HIV-1 infection of these cell types. We have shown that neural cells derived from human fetal dorsal root ganglia (DRG) are susceptible to HIV-1 infection and that treatment of these cells with monoclonal antibody directed against the T4A epitope (the HIV-1 binding epitope) but not the T4 epitope resulted in approximately a 60% reduction in HIV-1-specific gag antigen expression. However, we have been unable to detect the physical presence on the cell surface (via fluorescence-activated flow cytometric analysis) or the synthesis of (via immunoprecipitation and gel electrophoresis) the CD4 molecule in neural cell populations derived from DRG. RNA blot hybridization analysis of total cellular RNA isolated from primary human fetal DRG and spinal cord utilizing a [^{32}P]-labeled single-stranded antisense RNA probe demonstrated specific hybridization to two unique species of RNA that migrate slower than 28S ribosomal RNA. However, the 3.0-kb transcript commonly found in CD4$^+$ lymphocytes was not detected. The two unique high molecular weight RNA species were not detected in RNA isolated from human fetal heart or when a radiolabeled sense strand was utilized as probe. The cell type specificity, tissue distribution, and structure of these two unique RNA species, as well as their potential to encode a functional CD4 or CD4-like protein are being examined.

ANALYSIS OF PROTEOGLYCANS IN THE DEVELOPING RAT CENTRAL NERVOUS SYSTEM A. D. Lander[1] and W. D. Matthew[2] [1]Dept. of Brain and Cognitive Sciences, Mass. Institute of Technology, Cambridge, MA 02139 and [2]Dept. of Neurobiology, Harvard Medical School, Boston MA 02115

Cell culture and immunochemical studies have led to the identification of cell-surface and extracellular proteins likely to play roles in neural cell adhesion, migration and axon navigation. Of these molecules, surprisingly many--including laminin, fibronectin, thrombospondin, tenascin, N-CAM, acidic and basic fibroblast growth factor, retinal purpurin, and glia-derived protease nexin-1--exhibit specific binding to proteoglycans (PGs). PGs are glycoproteins found on cell surfaces and in extracellular matrices, and appear to be involved in the adhesion, migration and proliferation of many non-neural cells.

To identify functions PGs may have in neural development, we have exposed neuronal cultures to glycosaminoglycans (GAGs), the carbohydrate portion of PGs. Micromolar amounts of heparin, for example, but not chondroitin sulfate, inhibit the neurite outgrowth-promoting activity of laminin. Since GAGs could have non-specific effects, and commercially obtained GAGs may differ from those of PGs in the developing nervous system, a demonstration that a molecule such as laminin interacts functionally with neural PGs requires identifying a neural PG to which it binds, and showing that the molecule's *in vitro* effects can be perturbed by an agent (*e.g.* an antibody) specific for that PG. We are therefore fractionating adult and newborn rat brain, enriching for PGs by a single-column procedure, and analyzing them by SDS-gel electrophoresis after treatment with GAG-degrading enzymes. In adult brain, a large chondroitin sulfate PG (core protein M$_r$ ~400 kd) has been found, as well as minor species. A similar large PG is detected in neonatal brain. A monoclonal antibody (MAb) that recognizes this PG has been obtained, and reacts with sections of adult and neonatal brain. Heparan sulfate PGs have also been identified, including two species associated with neonatal brain membranes. Currently, we are examining binding of identified PGs to laminin, fibronectin, and other molecules, as well as continuing to screen MAbs. Supported by the Whitaker Health Sciences Fund (ADL) and NIH NS02253 (WDM).

MONOCLONAL ANTIBODY IDENTIFIES A PROTEOGLYCAN EXPRESSED BY A SUBCLASS OF GLIAL CELLS. A. Faissner* (SPON: M. Schachner). Dept. of Neurobiology, University of Heidelberg, Im Neuenheimer Feld 364, 6900 Heidelberg, Germany (FRG).

A monoclonal antibody designated 473 was obtained from rats immunized with L2/HNK-1 positive glycoprotein fractions from adult mouse brain. In immunofluorescence double labeling experiments performed on cerebellar cultures of varying ages no overlap with neuronal markers was observed. The antibody stained subsets of immature astrocytes and oligodendrocytes. At earlier stages of culture about half of the 473+ cells did not express any of the conventional markers. Metabolic labeling experiments with subsequent immunoprecipitation performed with glial monolayer cultures in vitro show that the 473 antigen incorporates sulfate, fucose and methionine. It migrates at 10^6 apparent M_r under non-reducing conditions and was recovered from detergent lysates and supernatants of labeled cultures. Material with similar properties could be demonstrated in G26-20 glial tumor cells. Digestion of immunoprecipitates obtained with 473 from metabolically labeled G26-20 cell line supernatants with chondroitinases ABC and AC demonstrates that the 473 antigen is a chondroitinsulfate proteoglycan. The 473 antigen carries the L2/HNK-1 epitope, a carbohydrate common to several adhesion molecules. Functional properties of the 473 proteoglycan are currently being investigated.

372.6

ANALYSIS OF LECTIN BINDING TO DENERVATED AND REGENERATING SKELETAL MUSCLE. G.P. Cole*, S. Iyer*, E.W. Perry* and A.K. Gulati* (SPON: G.S. Doetsch). Section of Neurosurgery and Department of Anatomy, Medical College of Georgia, Augusta, GA 30912.

Ten different fluoroscein-conjugated lectins of various sugar binding affinities were used to compare glycoconjugates in denervated and regenerating rat skeletal muscle. Muscles were denervated by cutting and ligating the sciatic nerve. Muscle regeneration was induced by autotransplanting the extensor digitorum longus (EDL) muscle. Some EDL muscles were reautotransplanted to initiate a second wave of regeneration. Frozen-sections were prepared from all muscles and stained with each lectin. Lectin binding increased with denervation due to the thickening of endomysium. In normal muscle the binding of Glycine max and Bachinia purpurea agglutinins was seen in discrete regions of the endomysium, however, after denervation the distribution became more extensive. Wheat germ agglutinin specifically stained the myogenic zone of the regenerating muscle. Furthermore, in reautotransplanted muscles, Wheat germ agglutinin binding appeared earlier than in muscles transplanted once. These results show that specific changes in glycoconjugates occur during denervation and regeneration.

372.7

MONOCLONAL ANTIBODIES AGAINST NGF-DIFFERENTIATED PC-12 CELL SURFACE ANTIGENS RECOGNIZE CULTURED HIPPOCAMPAL NEURONS. Y. Kuroda, Y. Ohguchi* and K. Kobayashi*. Dept.of Neurochem.,Tokyo Metropol. Inst.for Neurosciences, Fuchu, Tokyo 183, JAPAN.

A library of monoclonal antibodies against cell surface antigens of NGF-differntiated PC-12 cells was obtained. Myeloma was fused with spleen cells of mice injected intact PC-12 cells which were cultured with NGF for 6-8 days. Culture fluid of the resulting hybridoma was screened by ELISA using the intact cells and Millititer filtration system. Many monoclonal antibodies in the library recognized cell surface antigens which expressed on the PC-12 cells in different manner during NGF-treatment.

Hippocampal tissue from 16 days fetal rat were dissociated with trypsin-treatment and cultured for 1-2 weeks. The culture was immunostained with the monoclonal antibodies. Several monoclonal antibodies recognized the cell surface antigens of the cultured neurons which were identified with antibodies against neurofilaments. Some antibodies seemed to recognize extracellular matrix and glial cells. The monoclonal antibody library is an useful tool to study cell surface molecules and their functions not only in PC-12 cells but also in CNS neurons to differentiate.

ECTO-PROTEIN KINASE AT THE SURFACE OF CNS NEURONS. Y.H. Ehrlich, I. Galbraith*, J. Jackman* and E. Kornecki. Dept. of Psychiatry, University of VT and The Ctr. Dev. Neurosci., CUNY/CSI, Staten Island, NY 10301.

To demonstrate secretion of ATP and ecto-protein kinase activity in the CNS, we have utilized embryonic neostriatal neurons differentiated during maintenance for 15-21 days-in-vitro (DIV) in a chemically defined medium. Depolarization by 50mM KCl induced a Ca^{++}-dependent release of ATP, and stimulation by 100μM veratridine induced ATP secretion that was blocked by tetrodotoxin. Incubation of intact, attached neurons with [γ-^{32}P]-ATP (added to the medium) resulted in radiolabeling of surface phosphoproteins within 10-15 min. These proteins were not phosphorylated when intracellular ATP pools were labeled with equivalent amount of inorganic ^{32}Pi. Phosphorylation of surface proteins with M.W.>50Kd was dependent on 1mM Mg^{2+} but not on Ca^{2+}, whereas phosphorylation of surface proteins with M.W. of 39-42 Kd required 1mM Ca^{2+} and was independent of Mg^{2+}, as we reported previously with synaptosomes (J.Neurochem., 50: 263, 1988). Phosphorylation by extracellular AT^{32}P of proteins co-migrating with N-CAMS was high during the period of rapid neurite extension (4-6 DIV) and declined after synaptogenesis and maturation (15-18 DIV); indicating that ecto-protein kinase activity in the CNS is developmentally regulated. Supported by AFOSR grant no. 88-0004.

372.9

BRAIN SPECTRIN(240/235A): A NOVEL ASTROCYTE SPECIFIC SPECTRIN ISOFORM. L.L. Lopresti*, B.M. Riederer, I.S. Zagon, L.A. Casoria* and S.R. Goodman*, The Cell and Molecular Biology Center, The Milton S. Hershey Medical Center, Hershey, PA 17033

We have previously demonstrated the existence of two distinct isoforms of spectrin in mammalian brain. Brain spectrin(240/235) found in neuronal axons and presynaptic terminals, and brain spectrin(240/235E) located in neuronal cell bodies, dendrites, and postsynaptic terminals (Riederer et al. 1986, J. Cell Biol. 102: 2088). In this study we have prepared a panel of monoclonal antibodies which all react exclusively with the 240kD or 235kD subunits of brain spectrin on Western blots of total rat brain protein. Immunohistochemical analysis of rat cerebellum utilizing 32 distinct monoclonal antibodies, yielded 13 antibodies which gave a staining pattern typical of brain spectrin(240/235E), 3 antibodies which detected brain spectrin(240/235), 1 antibody which detected both isoforms, and 15 antibodies which detected a novel isoform in astrocytes. In rat cerebellum this novel isoform was localized in the soma and fibrous processes of astrocytes and in the distal processes of Bergmann glia, but was not present in oligodendrocytes. The immunoprecipitation of rat brain spectrin with the astrocyte specific monoclonals under stringent conditions, yielded 240k and 235kD subunits in a 1:1 (mol/mol) ratio. We refer to this newly discovered mammalian brain spectrin isoform as brain spectrin(240/235A).

372.10

SEX DIFFERENCES IN 67-COPPER UPTAKE BY HYPOTHALAMIC (HT) AND HIPPOCAMPAL (HIP) SLICES. D.E.Hartter, K.R.Bhasker*, G.Cho* and A.Barnea. Depts. OB/GYN & Physiol, Univ. Tx. Southwestern Med. Center, Dallas, TX. 75235, U.S.A.

Cu is an essential trace metal that is highly concentrated in the brain, particularly in axonal terminals and secretory vesicles. A role for Cu in modulating neuronal function is supported by our previous findings that Cu markedly amplifies prostaglandin E_2 stimulation of peptide release from HT tissue and that newly taken-up 67-Cu is released by depolarization. We have recently demonstrated that HT slices take-up 67-Cu by a saturable, ligand-specific process having an apparent Km ($\approx$40 μM) in the operative conc. range of Cu. We addressed the question: Are there sex and/or regional differences in 67-Cu uptake in the brain? Saturation curves were established for 67-Cu uptake by HT and HIP slices obtained from rat brains. MALES: Vmax for 67-Cu was greater ($P<0.001$) in the HIP than in the HT (650 vs 425 pmol/min/mg P) of intact males and castration (14 days) led to an increase ($P<0.001$) in Vmax in both regions (850 vs 525 pmol/min/mg P). FEMALES: Vmax was similar in HIP and HT of pregnant females (650 vs 700 pmol/min/mg P) and it was reduced ($P<0.001$) by ovariectomy (19 days) only in the HT. There was no difference in the apparent Km in these tissues. Thus, there are sex and regional differences in number of Cu-carrier sites in the HT and HIP and gonadal steroids appear to modulate the process of Cu uptake in the brain.

GLUCOCORTICOIDS DECREASE GLUCOSE TRANSPORT IN CULTURED HIPPOCAMPAL NEURONS. Heidi C. Horner* and Robert M. Sapolsky, Biology Department, Stanford University, Stanford, California, U.S.A. 94305

Glucocorticoids (GC's) compromise the ability of hippocampal neurons to survive various neurotoxins both in vivo and in vitro. A general effect of GC's in peripheral tissue is inhibition of glucose transport. We have suggested that the classic, catabolic effects of GC's in peripheral tissue may also occur in the hippocampus and may underlie the GC-enhanced damage. The effect of GC's on glucose transport into cultured hippocampal neurons was examined. Transport of ^{14}C-2-deoxyglucose (2-DG) in cells grown in 48-well cluster dishes is linear for 15 mins ($t_{1/2}$= 6.3 mins) and is D-glucose and cytochalasin B inhibitable. Corticosterone (CORT) and dexamethasone (DEX) treatment resulted in a highly consistent and significant 18% ($p<0.001$) and 20% ($p<0.01$) decrease, respectively, in 2-DG transport. The inhibition is dose- and time-dependent becoming maximal at 1 uM CORT and 100 nM DEX after 24 hrs, and half maximal at 60 nM and 7 nM, respectively. Aldosterone inhibited 2-DG transport only at 1 uM, while testosterone, estradiol and progesterone had no effect on 2-DG transport after 24 hrs at concentrations ranging from 1 nM to 1 uM. CORT had no effect on 2-DG transport into neuronal cultures derived from the cortex, cerebellum, midbrain or hypothalamus. Supported by NIH grant AG-06633.

372.12

CALCIOSOME(S) IN MAMMALIAN BRAIN? P. Volpe*, B.H. Alderson*, C.A. Dettbarn*, P. Palade*, B. Bruno*@, and J. Meldolesi@ (SPON: M.C. Andersen). Dept. of Physiology & Biophysics, UTMB, Galveston, TX 77550 and @S. Raffaele Scientific Inst., Univ. Milano, Milano, Italy.

Recent immunocytochemical and biochemical results have provided direct evidence for the existence of a hitherto unrecognized organelle in nonmuscle cells, homologous to the sarcoplasmic reticulum (SR) of striated muscles, which seems to be the inositol 1,4,5-trisphosphate (IP_3)-sensitive Ca^{2+} store and has been named "calciosome" (Volpe, P., et al., Proc. Natl. Acad. Sci., 85:1091-1095, 1988). In the liver and exocrine pancreas, as well as in two cell lines, HL60 and PC12, proteins related to calsequestrin(s) (CS) and Ca^{2+}-ATPase(s), were shown by immunogold labeling to reside not in the endoplasmic reticulum or other previously identified cytoplasmic organelle, but in a population of vesicles and small vacuoles distributed throughout the cytoplasm. We now have data indicating that subcellular fractionation of canine brain yields a membrane fraction that actively accumulates Ca^{2+}, binds (^{3}H)IP_3, releases Ca^{2+} upon addition of IP_3, and contains a protein immunologically related to CS. Immunocytochemistry of cultured neurons indicates that CS-positive organelles are localized both in the soma and neurites. The calciosome is therefore likely to exist in nerve cells. (Supported by NIH grant GM 40068-01).

LIMBIC SYSTEM II

373.1

THE DISTRIBUTION OF PROJECTIONS FROM THE ANTERIOR THALAMIC NUCLEI TO THE SUBICULAR CORTEX. Th. van Groen* and J.M. Wyss (SPON: J.W. Brown). Dept. of Pharmacology, Univ. of Edinburgh, Edinburgh, Scotland and Dept. of Cell Biol. and Anat., Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Small (<20nl) injections of [^{3}H] amino acids or iontophoretic deposition of Phaseolus vulgaris leucagglutinin (PHA-L) were employed to characterize the distribution and termination of anterior thalamic nuclei projections to subicular cortex. Injections into the anterior dorsal nucleus (AD) labeled terminals in the retrosplenial granular cortex (Rga and Rgb), the postsubiculum (POST), the presubiculum (PRE) and the parasubiculum (PARA) but not the subiculum (SUB). In contrast, injections in the anterior ventral (AV) nucleus labeled terminal fields in Rga and b and all areas of the subicular cortex except PARA. Injections into the lateral dorsal nucleus (LD) labeled terminals in the retrosplenial cortex and all areas of the subicular cortex except SUB. The laminar pattern of terminal labeling was:

	Rgb	Rga	Post	Pre	Para	SUB
AD	I,III,IV	I,II	I,III	(I,III)	IV-VI	-
AV	I,IV	I	I	I,III	-	I,II
LD	-	I	I,III	I,III,IV	IV,V	-

These results demonstrate that AD,AV and LD each have unique interconnections with the limbic cortex, and thus, likely have distinct influences on memory.

373.2

TOPOGRAPHY OF ANTERIOR THALAMIC NUCLEI AFFERENTS FROM THE POSTERIOR LIMBIC CORTEX AND THE CONTRALATERAL ANTEROVENTRAL NUCLEUS. J.M. Wyss, Th. van Groen* and C. Rodenburg* (SPON: S. Lane). Dept. of Cell Biology and Anatomy, Univ. of Alabama, Birmingham, AL. 35294 and Dept. of Pharmacology, Univ. of Edinburg, Scotland.

The afferent projections to the anterodorsal (AD), anteroventral (AV) and laterodorsal (LD) nuclei of the thalamus were studied by placing small iontophoretic deposits of Phaseolus vulgaris leucagglutinin (PHA-L) into the retrosplenial (Rg) and subicular cortices and the anterior thalamic nuclei of the rat. Injections into the postsubiculum labeled an ipsilateral terminal field in AD and ventral LD. This projection was topographically organized with more posterior areas of postsubiculum projecting to more lateral parts of LD and more dorsal regions of AD. In contrast, injections into the adjacent Rg labeled a topographically organized terminal field ipsilaterally in dorolateral LD and bilaterally in AV. PHA-L injections into the presubiculum labeled terminals ipsilaterally in dorsal LD, medial to the Rg projection, and bilaterally in dorsal AV. The projection from the parasubiculum terminated in AD. Injections of PHA-L into the anterior thalamic nuclei demonstrated that AV neurons projected to contralateral AV, but that neither AD nor LD had contralateral thalamic projections. These results emphasize the diversity of projections to the anterior thalamic nuclei, and suggest that each area likely has a different contribution to learning and memory.

373.3

THE CONNECTIONS OF THE CINGULATE CORTEX IN MICE: A DEGENERESCENCE AND HRP STUDY. M. Meunier, J. Villalobos and C. Destrade. (SPON: European Neuroscience Association). Lab. Psychophysiologie, UA CNRS 339, Univ. Bordeaux I, 33405 TALENCE FRANCE.

The afferent and efferent projections of the frontomedial, anterior and posterior parts of the cingulate cortex in BALB/c mice, were studied by analysing silver impregnation of the anterograde degeneration after ibotenic acid lesions in this area and by observing the retrograde axonal transport of WGA-HRP complex. The three cingulate regions have numerous common efferent projections particularly in the other cortical areas, striatum, the ventral thalamus and hypothalamus as well as in the mesencephalon. However, there are some differential connections. In particular, each of the 3 parts of the cingulate cortex shows reciprocal projections with one thalamic nucleus (the frontomedial part with the mediodorsal n., the anterior part with the anteromedial n. and the posterior part with the anteroventral n.). Amygdala appears to be connected with both the frontomedial and the posterior parts, whereas the subicular complex is selectively connected with the posterior cingulate cortex. These results show that the whole cingulate cortex is widely connected with non-limbic structures. In contrast, each part of the cingulate cortex is part of different limbic pathways.

373.4

MORPHOLOGICAL CHARACTERIZATION OF ENTORHINAL NEURONS IN THE RAT: AN INTRACELLULAR HRP STUDY. K. Lingenhöhl* and D.M. Finch (SPON. J. Lieb). Department of Neurology and Brain Research Institute, University of California, Los Angeles, CA 90024.

Intracellular HRP injections were performed in entorhinal neurons. Stained neurons were found in layers III, IV and V. The dendritic trees of two layer III neurons were reconstructed. The primary dendrites of one cell, originating from a triangular soma, started ramifying close to the soma and extended into every layer. The dendrites of the second cell arose from a pyramidal shaped cell body with basal dendrites extending only into layer III. The apical dendrite branched close to the soma and extended with several branches into layer I. The axons of six layer III neurons were reconstructed in part. All of these axons showed a similar course. After crossing the deep layers the axons moved first medially into the angular bundle (AB) before projecting into the subiculum (S). Collaterals were found in the entorhinal cortex, the AB and the S. Most of the axons could be traced into the molecular layer of the S before fading. Only one axon was observed to cross the hippocampal fissure before fading. Three other neurons in or near layer IV showed the same axonal projection pattern. Two layer IV neurons were stained. Most of the dendrites bifurcated in layer IV and V. Only one apical dendrite extended into layer I, without branching out in layer III but with bifurcations in layer II and I. The axons gave off several collaterals in the entorhinal cortex and projected several thin branches ventro-laterally into the AB before fading. Three other neurons in or near layer IV showed the same axonal projection pattern. Two layer V neurons were stained. The apical dendrites showed a similar pattern as in the layer IV neurons, whereas the basal dendrites bifurcated to a lesser extent. Local axonal branches were present, but no major axonal branch was observed leaving the entorhinal cortex.

Supported by NIH Grant NS 16721.

373.5

TEMPORAL POLE PROJECTIONS TO THE MAGNOCELLULAR MEDIAL DORSAL NUCLEUS. E.C. Gower (SPON: J. Kucera). VA Medical Center, Boston, MA 02130.

Efferent projections from rostral temporal lobe cortices to the magnocellular medial dorsal nucleus (MDmc) were studied in the monkey (Macaca mulatta) with intracortical injections of horseradish peroxidase (HRP) and tritiated amino acids (TAA). TAA injections into pyriform allocortex or the transitional neocortical fields of the temporal pole (periallocortex and proisocortex) produced discrete zones of axonal termination in MDmc characterized by bursts of coarse label surrounding neuronal perikarya and their proximal dendrites. Although the same anterograde field was observed when HRP was injected into the transitional cortices, perikarya within the terminal clusters were not retrogradely labeled. Label was not transported to MDmc when injections were made into the superior or middle temporal gyri, and thus restricted to the isocortex. These findings indicate that a non-reciprocal corticofugal pathway to MDmc originates in the phylogenetically older districts of the temporal pole. This pathway constitutes an additional temporal route to MDmc parallelling those contributed by the amygdala and the hippocampal formation. The conduction of limbic sensory information directly from temporal neocortex to the medial thalamus may play a fundamental role in memory. (Supported by VA Medical Research funds.)

373.6

CORTICAL PROJECTIONS TO ORBITOFRONTAL LIMBIC CORTICES IN THE RHESUS MONKEY. H. Barbas. Depts. of Health Sci. and Anatomy, Boston Univ. and Sch. of Med., Boston, MA 02215.

Ipsilateral cortical projections to the least architectonically differentiated basal periallocortical, and to the slightly more differentiated proisocortical prefrontal areas were studied with the use of the retrograde transport of horseradish peroxidase (HRP). These areas, which exhibit an incipient laminar differentiation, received most of their projections from other limbic cortices. While most of the projections originated in nearby orbital and medial limbic prefrontal areas, HRP-labeled neurons were also found in temporal polar, perirhinal, prorhinal, entorhinal, agranular insular, and rostral cingulate limbic cortices, which lie at the origin of differentiation of the sensory and motor cortical systems. The basal limbic areas also received some projections from the more differentiated rostral auditory, visual, and somatosensory isocortices. The orbital periallocortex had fewer links with isocortices than the proisocortex.

The results indicate that orbitofrontal limbic cortices have widespread connections with areas which are found at the onset of differentiation of several sensory cortical systems, suggesting that they may have evolved at the same time.

(Supported by NIH grant NS24760).

373.7

CONVERGENCE OF AFFERENTS FROM MEDIAL PREFRONTAL CORTEX AND MAMILLARY BODY IN MEDIAL PONTINE NUCLEI OF THE RAT. G.V. Allen and D.A. Hopkins. Dept. of Anatomy, Dalhousie University, Halifax, N.S., Canada, B3H 4H7.

The pontine nuclei receive afferent fibers from limbic regions of the cerebral cortex and from the hypothalamus. In order to provide a better understanding of functional links between the limbic system and the cerebellum a light and electron microscopic study of limbic system connections with precerebellar relay nuclei has been undertaken.

Stereotaxic injections of 5% WGA-HRP were made into cortical, hypothalamic and brain stem sites. After three days, rats were perfused with a buffered aldehyde fixative. For light microscopy, frozen sections were incubated for reaction product in tetramethyl benzidine (TMB). For electron microscopy, vibratome sections were incubated in TMB followed by a second incubation in diaminobenzidine (Rye et al., '84). After injections into the medial pontine nuclei, retrograde labeling was present in the medial prefrontal cortex and the mamillary body. After injections into the medial prefrontal cortex or the mamillary body, dense anterograde labeling was found in the medial part of the pontine nuclei. The distributions of labeling from these two sources overlapped extensively in the pontine nuclei. Axon terminals in the medial pontine nuclei which originated from the medial prefrontal cortex and the mamillary body contained small round vesicles and formed asymmetric synapses with small diameter dendrites.

The present results demonstrate that afferents from the prefrontal cortex and the mamillary body with similar morphological characteristics and synaptic organization converge on neurons in the medial pontine nuclei which in turn project to vermal regions of the cerebellum. Thus, impulses from the limbic system may influence the activity of cerebellar regions which are known to be involved in certain autonomic functions.

NEUROPHYSIOLOGICAL MEASURES OF HUMAN LIMBIC SYSTEM CONNECTIONS. C.L. Wilson, M. Isokawa-Akesson, R.C. Frysinger, S.U. Khan, T.L. Babb. Depts. of Neurology and Anatomy and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

Limbic system connections have been analyzed intensively in subprimate species using both anatomical and electrophysiological methods, but since experimental anatomical methods cannot be used in human brain, functional studies must be used to assess connections. Buser and Bancaud (EEG J., 55:1-11, 1983) studied connections between hippocampus (HP) and amygdala (AM) using stimulation of depth electrodes implanted in these structures to monitor epileptic activity in medically intractable patients who were candidates for surgical seizure therapy. They reported mean onset latencies of 18-19 msec between HP and AM.

Studying a group of 31 patients with complex-partial epilepsy, we delivered single-pulse biphasic stimuli 100 μsec/phase in duration to each of five limbic electrodes in turn, while recording evoked field potentials from adjacent electrodes located in AM, anterior HP(aHP), middle HP(mHP), Entorhinal Cortex (EC), Presubiculum, and posterior Parahippocampal Gyrus. Latency and amplitude measures were made of averaged responses to 3-50 stimuli recorded from 4 to 9 sites. During AM stimulation, onset latencies to aHP were shorter (7.1 ms) than the previous study while to mHP they were longer (24.8 ms), suggesting their HP electrodes were targeted at a location between our aHP and mHP sites.

Comparison to other species must be on the basis of conduction velocities (CV), which have not previously been reported in human limbic sites, and therefore 25 CVs were calculated for the connection between each stimulation and recording site. CVs ranged from 0.88 m/s in the AM to EC pathway, to 3.4 m/sec in the perforant path connection from EC to mHP. This was followed closely by a 3.2 m/s CV in the longitudinal association connection from mHP to aHP. Our results are consistent with a trend toward slower rates of conduction higher on the phylogenetic scale, associated with a second trend of decreased fiber diameter and increased number of fibers in primates. NIH grant NS 02808.

373.9

COHERENCE OF EEG BETWEEN NEOCORTEX AND LIMBIC SYSTEMS. C.C. Turbes and G.T. Schneider*. Dept. of Anatomy, Creighton Univ. Sch. of Med., Omaha, NE 68178.

These studies are concerned with the interaction of spontaneous slow wave field potentials (EEG) and evoked potentials between nucleus accumbens, amygdala, septum and frontal, temporal and occipital cortex.

Twenty-four cats are used under nonanesthetic states utilizing telemetry and hardwire recording methods. Analog data is collected on FM tape and processed with a minicomputer. Coherence, partial coherence, phase spectral and cycle time analyses are used on the analog data.

These analyses show the degree of phase locking (coherence) between brain regions. Phase spectra and partial coherence processing show the directionality of neural signal flow between brain areas. Cycle time computations are used to show interaction in the time domain. Comparisons are made with pertinent anatomical data to determine the fit between the frequency and time domain plots and neural network functions. An example of a chemical altered state data is used to show how drugs alter brain region interaction.

373.10

SUBDIVISION AND NEURONAL TYPES IN THE INTERPEDUNCULAR NUCLEUS OF MAN. E.Braak and H.Braak. Dept. Anatomy, J.W. Goethe Univ. D-6000 Frankfurt 70, FRG

In series of sections cut at various thicknesses in the sagittal, frontal and horizontal plane through the human interpeduncular nucleus several subnuclei were delineated on account of lipofuscin pigmentoarchitectonic and cytoarchitectonic criteria. Previous investigations revealed that nerve cell types in the human adult can reliably be characterized by their lipofuscin pigment pattern.

The interpeduncular nucleus extends from the level of the caudal pole of the red nucleus to the level of the frontal pole of the locus coeruleus. It is about 8 mm long, 2 mm broad and 1 mm high. A medial subnucleus extends from the frontal to the caudal pole and contains 2 types of small non-pigmented neurons and 3 types of sparsely pigmented neurons. In the frontal half, additionally a scattered population of richly pigmented neurons occurs. Within the frontal lateral subnucleus small sparsely pigmented and non-pigmented neurons are intermingled with large non-pigmented nerve cells showing distinct Nissl bodies. At the frontal level of the pons, a small lateral cell group can be outlined harbouring small neurons with numerous faintly stained lipofuscin granules. Caudally, this subnucleus is replaced by a group of medium-sized neurons with numerous lipofuscin granules distributed between the elongated Nissl bodies.

STIMULATION OF LATERAL SEPTUM: IS IT ANXIOLYTIC? E. Yadin, E. Thomas, T.N. Holt*, and R.A. Hunt*. Department of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010.

Rats were trained on a water licking conflict procedure in which unpunished and signalled punished periods, each 2 min in duration, were alternated and cycled through twice. The punished period was signalled by tone and every 5th lick was accompanied by a 0.3-0.4 mA footshock. The number of licks was recorded throughout the 8 min session. After a stable baseline was achieved, rats were anesthetized and implanted with bipolar stimulating electrodes in the lateral nucleus of the septum or in the MFB.

After a week's recovery, animals were retested on the conflict test. The next phase consisted of conflict testing sessions during which continuous biphasic square wave stimulation (pulse duration 0.1 msec) was administered. The currents were adjusted individually so as not to produce convulsions and ranged between 75 and 500 μA.

Septal stimulation appeared to mimic the effects of anxiolytic agents. Thus during the first set of sessions at these currents septal stimulation produced increased responding in the punished periods and decreased responding in the unpunished periods whereas MFB stimulation did not. After several replications and raising of current levels in the MFB group, some of these animals displayed increased punished responding as well.

THE ELECTROPHYSIOLOGICAL RESPONSES OF MEDIAL CORTICAL NEURONS (AREAS 4,24,29) TO STIMULATION OF THE BASAL FOREBRAIN OF THE RAT. T.D. White*, A.M. Tan* and D.M. Finch (SPON: M.Nuwer). Brain Research Institute and Reed Neurological Research Center, University of California, Los Angeles, CA 90024.

Numerous anatomical studies have shown that the neocortex is a major target of the basal forebrain. However, the action of basal forebrain afferents on neocortex has not been described. This study presents the first in vivo intracellular characterization of synaptic responses of medial cortex to basal forebrain stimulation. Our sample of responsive neurons included 72 pyramidal cells and two fast-spiking, putatively nonpyramidal cells. The predominant synaptic response of cortical neurons was inhibition (55.4%). Reciprocal connections between recording and stimulating sites was indicated by a high incidence of antidromic action potentials (71.6%). Orthodromic potentials and antidromic spikes were generally observed in ipsilateral layer V neurons. The fast-spiking cells exhibited similar electrophysiological characteristics to previously described inhibitory interneurons, however, one produced an IPSP and both produced antidromic spikes following stimulation (diagonal band of Broca). Supported by NIH grant NS 23074.

INITIAL EXTRACELLULAR ELECTROPHYSIOLOGICAL CHARACTERIZATION OF CHOLINERGIC BASAL FOREBRAIN NEURONS. R. T. Matthews, Dept. of Anat., Texas A&M Univ., College Station, TX 77843.

Previous work has shown that a population of presumed cholinergic (Ch; AChE-positive) neurons of the medial septum/diagonal band (MS/DB) region of guinea pigs can be electrophysiologically distinguished from non-Ch neurons by intracellular recording in vitro (Griffith and Matthews, Neurosci. Lett. 71:169, 1986). Prominent features of Ch neurons include: 1) long duration action potentials (AP), 2) slow firing rate when depolarized by current pulses, 3) presence of an inward Cd^{+2}-sensitive Ca^{+2} conductance resulting in a shoulder on the repolarization phase of the AP and 4) presence of a late Ca^{+2}-dependent K^+ conductance resulting in a long duration post-spike afterhyperpolarization. Extracellular unit recordings from the same slice preparation yield extracellular representations of three of these four intracellular characteristics. Thus a subpopulation of MS/DB neurons (13 of 54) demonstrated: 1) long duration AP's (3.1 ± 0.27 ms versus 1.7 ± 0.13 ms for other neurons), 2) low maximum firing rate when driven by microiontophoresed glutamate (12-17 Hz versus up to 120 Hz for other neurons), 3) a multiphasic AP shape with significant shortening of the AP in a 0 Ca^{+2}/100 μM Cd^{+2} buffer (0.5 ± .07 ms decrease versus 0.1 ± .08 ms decrease for other neurons). It is concluded that at least some Ch neurons of the MS/DB can be distinguished from non-Ch neurons with extracellular recording techniques.

HETEROGENEITY OF BASAL FOREBRAIN CONNECTIONS IN THE RHESUS MONKEY. K.K. Hreib and D.L. Rosene. Dept. of Anatomy, Boston Univ. Sch. of Med., Boston, MA 02118.

Our studies on the basal forebrain (BF) have revealed a complex array of connections that correspond to two major subdivisions: 1) magnocellular neurons comprising the medial septum (MS), vertical diagonal band (VDB), horizontal diagonal band (HDB) and nucleus basalis (NB); 2) parvicellular neurons comprising the lateral septum (LS), intermediate septum (IS), ventral pallidum (VP), ventral striatum (VS) and olfactory tubercle. BF afferents to the magnocellular medial dorsal thalamic nucleus originate mainly from cholinergic neurons in the MS, VDB and NB but also from non-cholinergic neurons in the VP. The major afferents to the NB, HDB, ventral VDB and ventral IS originate from distinct subsets of amygdalar nuclei but those to the MS-VDB, LS and dorsal IS originate from the hippocampal formation. The major afferents to VP originate from the nucleus accumbens, lateral basal (LB) and medial basal amygdala while those of the VS originate from the LB. Cortical afferents to NB and ventral VDB originate almost exclusively from the medial frontal cortex while entorhinal, perirhinal, inferotemporal and insular cortices project to the VS. These distinct patterns of connections suggest an equal diversity of function. (Supported by NS19416 and AG04321.)

CONFLICT BEHAVIOR IN RATS WITH LESIONS OF THE AMYGDALA, MAMMILLARY BODIES, LOCUS COERULEUS, AND DORSAL RAPHE AND THE EFFECTS OF ANXIOLYTIC DRUGS. H. Grishkat* and E. Thomas. Department of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010.

Animals were trained in a conflict test in which they drank for 2 min during unpunished segments which were alternated with 2 min punished segments. The punished periods, signaled by a tone, resulted in mild footshock (0.3-0.6 mA, 1 sec duration) for every fifth lick. The number of licks was recorded for all two minute segments throughout the 8 min session. Animals were trained to a stable baseline of suppression during the punished segments and were then subjected to bilateral electrolytic lesions of the amygdala, mammillary bodies, dorsal raphe, and locus coeruleus. One week after surgery animals were retested in the conflict paradigm for 5 sessions and then administered chlordiazepoxide (10 mg/kg) with two replications.

Approximately half the animals showed some release of suppression during the signaled, punished periods after lesioning. Administration of chlordiazepoxide produced a large release of punished behavior with no effect on unpunished responding. The results argue against these proposed anxiogenic areas as primary sites of action of the benzodiazepines.

ELECTROPHYSIOLOGICAL CHARACTERIZATION OF SINGLE UNIT ACTIVITY IN THE NUCLEUS ACCUMBENS OF THE FREELY MOVING RAT. M.O. West and M. Wolske* (SPON: J. Perhach) Dept. of Psychology, Rutgers University, New Brunswick, NJ 08903.

Previous electrophysiological studies of extracellular activity in the nucleus accumbens have used anesthetized preparations. The purpose of the present study was to examine both single unit activity and field potentials in unanesthetized, freely moving rats. Long-Evans rats (300-350g) were chronically implanted with a detachable, miniature microdrive stereotaxically placed over the nucleus accumbens with reference to bregma (A-P 2.2mm , M-L 1.5mm, D-V 5.8-8mm). The synaptic input to the accumbens from the subiculum could be activated via an electrode implanted either in the ipsilateral fimbria-fornix or subiculum. Units (n = 82) were characterized in terms of waveform, spontaneous activity, synaptically activated response latency, and response to treadmill locomotion. The typical waveform was triphasic, with an initial negativity (200ms duration). Of the synaptically activated units, 58% were spontaneously active (range = 0.2 - 18.5 Hz, $\bar{x}$ = 3.3 Hz). At threshold stimulus intensity, 90% showed a short latency activation (5-11ms). Of these, 24% showed an additional long-latency activation (11ms). The remaining 10% responded only at long latencies, regardless of stimulus intensity. Of the units observed during treadmill locomotion, 91% showed increased firing rates ranging from 1-656% (compared with resting behavior), while 9% showed decreases ranging from 13 to 24%. Since the nucleus accumbens is a major target of ventral tegmental area neurons containing dopamine (a neurotransmitter linked with motor behavior), these studies are significant in that, in addition to eliminating any contaminating influences of anesthesia, they are performed during unrestrained movement such as locomotion, with which the accumbens has been implicated. Beyond this, neural activity patterns that are characterized in these studies can serve as substrates in pharmacological and behavioral studies (Wolske and West, Neurosci. Abstr., this volume). DIURNAL RHYTHM OF β ADRENOCEPTORS IN THE CORTEX AND HYPOTHALAMUS OF C3H/HeN AND C57BL/6 MICE. E. Reuveny* and M. L. Dubocovich (SPON: C. A. Berry). Dept. Pharmacol., Northwestern Univ. Med. School, Chicago, IL 60611.

In this study we measured the diurnal variations in density and affinity of β adrenoceptors in cortical and hypothalamic membranes from C3H/HeN and C57BL/6 mice, using 3-[^{125}I]-Iodocyanopindolol (ICYP). Mice were housed in a 14:10 h L:D cycle and sacrificed at 3 h intervals over a 24 h period. The binding of ICYP to C3H/HeN mouse cortex membranes was of high affinity, reversible and saturable. ICYP (10-400 pM) binding defined with (±) propranolol (1 μM) was to a single site as determined by saturation analysis. In hypothalamic membranes from C3H/HeN mouse sacrificed at 0600 h and 1800 h the Kd (pM) values were 62 ± 10 (n=4) and 67 ± 12 (n=4), and B_{max} (fmol/mg protein) values were 161 ± 11 (n=8) and 121 ± 10 (n=7) ($p<0.05$), respectively. In cortical membranes from C3H/HeN mouse as in hypothalamic membranes, the Kd values did not change over the 24 h period [Kd=35 ± 6 (n=4) and B_{max}=182 ± 6 (n=4) at 1200 h], however the β receptor density was significantly higher during the dark period [B_{max}=226 ± 17 (n=4), $p<0.05$]. In contrast, in mouse hypothalamic membranes from C57BL/6 no diurnal variations in Kd or B_{max} were observed [Kd=59 ± 6 n=4; B_{max}= 119 ± 4 (n=4) at 1800 h]. The diurnal variations in the density of β adrenoceptors observed in the hypothalamus of C3H/HeN but not in C57BL/6 mice may be attributed to existing genetic differences. Supported by DK 38607.

DOES AGE ALTER THE NUMBER OF BETA RECEPTORS IN LYMPHOCYTE MEMBRANES? D.W. Gietzen, T. Goodman*, J.R. Magliozzi, R. Maddock*, and P.G. Weiler*, Depts of Psychiatry & Community Health, School of Medicine, University of Calif., Davis, CA 95616.

Evidence regarding the effects of age on beta receptor binding in lymphocytes has been controversial. In order to address this issue, we used both ^{125}[I]-cyanopindolol (ICYP) and ^{3}[H]-dihydroalprenalol (DHA) as ligands in separate studies carried out over a 2 year period. The ages of subjects ranged from 18-90 years, with a bimodal distribution, having subjects predominantly in young and old groups. Mean ages (± SE; N = number of subjects) were: DHA old gp: 63.8±3.9 (N=35), young gp: 23.4±0.9 (N=21); ICYP old gp: 70.3±1.9 (N=24), young gp: 29.6±2.1 (N=20). Potential subjects were excluded for physical or psychiatric illness. Lysates of lymphocyte membranes were prepared from freshly drawn venous blood according to a modification of the method of Brodde et al. (Life Sci 29:2189, 1981), and used in binding assays with either DHA or ICYP. Scatchard analysis gave estimates of binding maxima (Bmax) and antagonist affinity (Kd). In both studies, increases in Bmax, with no change in Kd, were found in the older groups. Values for Bmax were: DHA old gp: 64.8±3.9, young gp: 48.6±4.0; ICYP old gp: 81.4±11.7, young gp: 47.2±5.6. The increases in Bmax were highly significant (for DHA, F:1,35 = 8.79, $p<0.01$; for ICYP, F: 1,41 = 19.06, $p<0.001$). Thus, in these preparations, the binding of beta antagonists to lysates of lymphocytes was increased with age. Supported by N.I.Aging Grant # K07AG0023003 and McNeil Pharmaceutical, Inc.

THE ONTOGENY OF α_1- AND β_1-ADRENERGIC RECEPTORS IN MOUSE FOREBRAIN: A QUANTITATIVE AUTORADIOGRAPHIC STUDY. C.D. Searles*, H.S. Singer and J.T. Coyle. Depts. of Neurol., Neurosci. and Ped., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Norepinephrine appears to have an important role in the development of the mammalian brain. The transmitter activates at least 4 receptor classes in mammalian brain, designated β_1, β_2, α_1 and α_2, but neuronal functions are most closely related to α_1 and β_1 receptors. This study is a quantitative autoradiographic analysis comparing the appearance and distribution of α_1 and β_1 receptors in mouse forebrain using the radioiodinated ligands HEAT ([^{125}I]hydroxyiodophenylethylaminomethyl tetralone) and ICYP ([^{125}I]iodocyanopindolol) to determine the possible differential expression of these two receptors.

Specific binding of HEAT first appears in mouse forebrain on E16, two days later than ICYP binding. Late in gestation (between E16 and E18), α_1 receptors are restricted to the basal forebrain, in contrast to β_1 receptors, which are present in striatum, cortical plate, and basal forebrain. Early in the postnatal period (P6), moderate densities of HEAT binding sites are present in the striatum, neocortex (diffuse in anterior-medial regions but limited to inner regions more laterally), and thalamus (ventral nuclei). By P15, the adult distributional pattern of α_1 receptors has developed, and on P20 the highest densities of receptor binding have been attained: about 40 fmol/mg tissue are present in frontal and anterior cingulate cortex, layer VI of lateral cortex, basal forebrain and nuclei of the dorsal thalamus. Specific binding is low in the striatum and hippocampal formation. For β_1 receptors, the adult pattern of receptor sites is present at P10, with highest concentrations of receptors found in the cortex, striatum and hippocampus.

This study demonstrates differences in the development, distribution and density of α_1 and β_1 receptors in mouse forebrain. These findings suggest different roles for these two receptors in mediation of adrenergic functions in the developing brain.

COMPARISION OF ^{3}H-DIHYDROALPRENOLOL AND ^{3}H-CGP12177 FOR MEASURING CNS ß-ADRENERGIC RECEPTORS. M. Riva and Ian Creese. Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102.

^{3}H-Dihydroalprenolol (^{3}H-DHA) is one of the most frequently used radioligands for measuring CNS ß adrenergic receptors . Usually the non-specific binding for ^{3}H-DHA is measured using a very high concentration (10-20μM) of a ß adrenergic receptor antagonist, such as propranolol or alprenolol. However these compounds, at this high concentration, have been demonstrated to have a serotonergic component to their binding. In our studies the competition curve of (-)alprenolol for ^{3}H-DHA binding is better fitted to a two site model than a one site model. The Ki of alprenolol for the first subpopulation of sites labeled by ^{3}H-DHA is 1-2 nM while the Ki for the second portion is 0.5-1μM. The lower affinity site for alprenolol is in accordance with its affinity for ^{3}H-5HT binding sites measured by other investigators. These results imply that, even at low concentrations, ^{3}H-DHA must also label a serotonin receptor. We are attempting to determine which serotonin receptor subtype is involved. Neither 8-OHDPAT ($5HT_{1A}$) nor mesulergine ($5HT_{1C}$) are able to displace ^{3}H-DHA binding at low concentrations, while RU24969, a specific $5HT_{1B}$ ligand displaces 15% of ^{3}H-DHA binding with a Ki = 0.5-1 nM that is in accordance with its affinity for the $5HT_{1B}$ receptors. Experiments are in progress in order to determine if the increase of ^{3}H-DHA binding following serotonergic depletion or lesion of 5HT neurons is due to a change in $5HT_{1B}$ receptors as opposed to an increase in ß receptors. We have been using another radioligand, ^{3}H-CGP12177,to measure ß receptors. This radioligand has some advantages over ^{3}H-DHA. Being hydrophilic, it has a very low non-specific binding and competition curves of alprenolol for ^{3}H-CGP12177 are monophasic indicating that it labels only ß receptors. This could be helpful in discriminating the modifications occurring in ß receptors following treatment with antidepressant drugs.

Cytoplasmic Loop of β-Adrenergic Receptors: Synaptic and Intracellular Localizations in the Neocortex, Striatum and Brainstem of Rat Brains Using a Monoclonal Antibody. C. Aoki[1], B.A. Zemcik*[2], C.D. Strader[2] & V.M. Pickel[1]. [1]Lab. of Neurobiology, Cornell Univ. Med. Coll., New York, N.Y. 10021 and [2]Dept. of Biochem. & Mol. Biol., Merck Sharp & Dohme Research Lab., Rahway, New Jersey, 07065.

A monoclonal antibody, βAR(226-239)3-1, against amino acids #226 - 239 of hamster lung β-adrenergic receptor (βAR) (β_2-subtype) has been biochemically characterized to be monospecific to βAR of smooth muscle DDT-1 cells and hamster lung membrane (Zemcik & Strader, Biochem. J., in press, 1988). Further, by analogy with other G protein-linked proteins, its antigenic site is predicted to reside within a cytoplasmic loop between the fifth and sixth transmembrane helices of the protein. We used the ABC method (Hsu et al., J. Histochem. Cytochem. 29, 577, 1981) to ultrastructurally localize the antigenic sites for this antibody within the following areas: the neocortex which exhibits high densities of both noradrergic fibers and βAR; striatum, which exhibits a low density of fibers but a high density of βAR; and brainstem areas which contain high densities of noradrenergic fibers, cell bodies and βAR. In all areas examined, the cellular and subcellular distribution of immunoreactivity was similar. Labeling occurred in discrete cytoplasmic patches within neuronal perikarya and proximal dendrites, particularly in association with rough endoplasmic reticulum, dense-core vesicles and cytoplasmic surfaces of plasmalemma. At select axodendritic junctions, labeling also was detected at presynaptic membrane specializations, but were more numerous along thick and thin postsynaptic densities. The results provide information relevant to the synthesis of βAR and support previous pharmacological evidences for the existence of presynaptic βA-autoreceptors and noradrenergic modulation of excitatory and inhibitory synaptic transmission in these areas. (Supported by grants NIH NS07782 to CA; NIMH MH40342 & MH00078, NIH HL18974 and NSF BNS8023914 to VMP).

BETA-ADRENOCEPTOR DENSITY IN HARDERIAN GLANDS OF HAMSTERS SHOWS PRONOUNCED SEXUAL DIFFERENCES. B.Pangerl *, A.Pangerl *, D.J.Jones +, R.J.Reiter. Dept. Cell. Struct. Biol. & Anesthesiology +, Univ. TX Health Sci. Ctr., 7703 Floyd Curl Drive, San Antonio, TX 78284-7762

Harderian glands, large tubulo alveolar glands in the orbital cavity, are sympathetically innervated by the superior cervical ganglion and present in mammals having nictitating membranes. The beta-adrenoceptor density (Bmax) and the dissociation constant (Kd) of Harderian glands in adult male and female Syrian hamsters were estimated using a Scatchard saturation assay with 7 concentrations (30 pM-1200 pM) of the radioligand (-)[125I] Iodopindolol (I-PIN). Specific binding was saturable and varied between 60-85 % of total binding. Tissues were taken at 15:00 h from hamsters in LD 14:10 (lights on 07:00 h) and immediately frozen on dry ice. Bmax (fmol/mg protein ± SEM) was 16X higher in females vs. males (292 ± 45 vs. 18 ± 3, $p<0.001$) and the Kd (nM ± SEM) was 4X higher in females vs. males (1.08 ± 0.18 vs. 0.26 ± 0.05, $p<0.005$). This finding is the first report of beta adrenoceptors in Harderian glands and adds to the data on hydroxyindole-O-methyltransferase, melatonin and porphyrin contents which also demonstrate higher levels in females.

MPP+ INHIBITS LIGAND BINDING AT DOPAMINE, α_2-ADRENERGIC AND 5-HT_2 BINDING SITES IN HUMAN BRAIN. A.C. Andorn and J. Pickett*. F.D.R. V.A. Hospital, Montrose, N.Y. 10548 and Department of Psychiatry, Case Western Reserve University, Cleveland, Ohio.

MPP^+, an oxidative product of MPTP, is a selective dopaminergic neurotoxin. MPP^+ interactions with the dopamine reuptake system have been well documented. The effect of MPP^+ on dopamine, α_2-adrenergic and serotonin binding sites in striatum and cortex had not been previously reported. Using standard radioligand filtration binding assays, performing dose-response studies of a minimum of 22 points each, replicated, and using LIGAND to resolve the data, we observed that MPP^+ inhibited ligand binding at [^{3}H]spiroperidol ([^{3}HSP]) binding sites in postmortem human cortex (5-HT_2), putamen (dopamine$_2$) and at cortical [^{3}H]UK14,304 (α_2-adrenergic) binding sites. Shown below are the K_A for MPP^+ (the K_i are given in parentheses) at each of the radioligand affinity states detected.

	K_A (+/- SEM) (M^{-1})	
Binding Site	High Affinity	Low Affinity
[^{3}H]SP Cortex	$1.8\pm0.5 \times 10^5$ (5.4×10^{-6}M)	$6.6\pm1.3 \times 10^5$ (1.5×10^{-6}M)
[^{3}H]SP Putamen	$6.4\pm5.9 \times 10^5$ (1.6×10^{-6}M)	$9.3\pm20 \times 10^3$ (1.1×10^{-3}M)
[^{3}H]UK14,304	$2.9\pm1.6 \times 10^6$ (3.4×10^{-7}M)	$4.8\pm1.2 \times 10^4$ (2.1×10^{-5}M)

These findings suggest that MPP^+ has potentially complex interactions with neurotransmitter systems.

374.8

ASPARTAME TREATMENT DOES NOT AFFECT BRAIN AMINES AND RELATED RECEPTOR KINETICS IN RATS. M.A. Reilly*, E.A. Debler, A. Fleischer* and A. Lajtha. Ctr. for Neurochem., N.S. Kline Inst. Ward's Island, NY, NY 10035.

The use of the dipeptide sweetener aspartame (APM, L-aspartyl-L-phenylalanine methyl ester) represents an additional dietary source of phenylalanine (Phe), although plasma levels of this amino acid are not usually elevated for a long period of time after APM consumption. Since Phe and its metabolite tyrosine (Tyr) may influence some CNS neurotransmitter systems, it was of interest to investigate the effects of subchronic APM consumption on brain aminergic activity. Male Sprague-Dawley rats were given 50 or 500 mg/kg APM per day in drinking water for 30 days. Cerebral cortex and striatum were excised for determination of amine levels and for study of binding kinetics at several receptors: adrenergic α_1 (prazosin) and α_2 (clonidine), dopaminergic D_1 (SCH 23390) and D_2 (spiperone), and serotonergic $5HT_2$ (ketanserin). K_d and B_{max} values were estimated from 6 parallel determinations (2 animals pooled per determination), each consisting of 6 ligand concentrations. We found no significant changes in binding parameters for any of the receptors studied. In addition, no significant differences were found in brain dopamine, serotonin, and norepinephrine levels in our present experimental design. Our findings of no change in binding affinity and density lead to the conclusion that, in rats, APM treatment is unlikely to affect catecholaminergic or serotonergic activity.

374.9

MEASUREMENT OF EXTRACELLULAR cAMP IN BRAIN BY MICRODIALYSIS: A METHOD TO STUDY BRAIN RECEPTOR FUNCTION IN VIVO. E.A. Stone and M. Egawa*, NYU Med. Ctr., NY, NY 10016

We have shown previously that cAMP in the extracellular fluid of the brain can be detected using an implanted microdialysis probe (Trans. Am. Soc. Neurochem. 19:159, 1988; Faseb J. 2:A1800, 1988). In the present studies we have further developed this technique into a method for studying the function of noradrenergic and other cAMP-linked receptors in the intact brain. Urethane-anesthetized rats were implanted in the frontal cortex with microdialysis probes which were perfused with various agents for various periods. cAMP in the perfusate (dialysate) was assayed by RIA (sens. 2 fmol). In agreement with previous studies in brain slices, norepinephrine (NE), isoproterenol (ISO) and adenosine (10^{-6}-10^{-3} M) were found to induce dose-dependent increases in in vivo cAMP levels. The response to NE was blocked 80% by the beta antagonist, timolol. Infusion of the alpha receptor agonist, 6-fluoronorepinephrine, led to a potentiation of the responses to ISO and adenosine. Prolonged infusion of ISO caused a progressive desensitization of the cAMP response and the latter effect was partially reduced by prior treatment with corticosterone. The results are in accordance with previous in vitro studies and indicate that the microdialysis-cAMP method can be used to study the function of noradrenergic and other receptors in the brain in vivo. (Supported by MH22768 and MH08616).

PROGESTERONE MODULATION OF α AND β ADRENERGIC RECEPTOR INTERACTIONS IN HYPOTHALAMIC SLICES. N. Petitti and A.M. Etgen. Depts. of Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY, 10461.

Norepinephrine (NE)-stimulated cyclic AMP (cAMP) accumulation in hypothalamic and preoptic area slices was monitored to examine the effects of progesterone (P) on brain adrenergic receptor coupling to adenylate cyclase. P treatment decreased NE-induced slice cAMP accumulation. This effect was dependent on prior estrogen exposure and was independent of increases in phosphodiesterase activity or decreases in adenylate cyclase activity. In all slices cAMP levels were elevated by isoproterenol, a β receptor agonist, but not by α_1 (phenylephrine) or α_2 (clonidine) agonists. However, in slices from estrogen plus P-treated rats, clonidine potentiated the effect of isoproterenol on cAMP formation whereas phenylephrine did not. In contrast, phenylephrine but not clonidine enhanced isoproterenol-induced cAMP accumulation in slices from rats receiving only estrogen. In P-exposed slices, NE-stimulated cAMP accumulation was completely antagonized only by a combination of both β (propranolol) and α_2 (yohimbine) antagonists. The data suggest that P treatment of estrogen-primed rats (1) depresses NE-stimulated cAMP accumulation in hypothalamic and preoptic area slices, (2) decreases or eliminates α_1 receptor facilitation of cAMP synthesis, and (3) promotes an α_2 receptor augmentation of β receptor stimulation of adenylate cyclase.

ADRENERGIC MODULATION OF THE K^+ CONTRACTURES IN TONIC MUSCLE FIBERS OF THE FROG. M. Huerta, J. Muñiz* & X. Trujillo*+. Centro Universitario de Investigaciones Biomédicas, Universidad de Colima. Apdo. Postal 199, 28000 Colima, Col., México.

Tension was isometrically recorded from tonic bundles of cruralis muscle of Rana pipiens. Normal solution was (mM): NaCl 117.5, KCl 2.5, $CaCl_2$ 1.8. pH was adjusted to 7.4 with Imidazole chloride. Experiments were done at room temperature (20-22°C). Epinephrine and Isoproterenol were added from stock solutions. The solutions contained d-tubocurarine (50 uM). In Ca^{++}-free solution $CaCl_2$ was replaced by $NiCl_2$ (0.5 mM). The bundles generated tension while soaked in high K^+ solution and relaxed when they were returned to the normal solution. When tonic bundle was incubated for 30 minutes in Epinephrine (20-40 uM) it enhanced K^+ contractures by approximately 50% (n=4). Similar results were obtained with isoproterenol (1 uM) (n=5). After 10 minutes in Ca^{++}-free solution the peak tension was greatly reduced and sustained component was abolished, but when Epinephrine (20 uM) was added in Ca^{++}-free solution only the peak tension was enhanced by approximately 600% (n=6). These actions were reversible. These results demonstrated the existence of adrenergic receptors in tonic muscle related to the regulation of developed tension.

ADRENERGIC RECEPTOR FUNCTION IN DEPRESSION. E. S. Werstiuk and M. Steiner. Department of Neurosciences and Psychiatry, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Functional alterations in adrenergic receptors have been implicated in depression, and treatment with antidepressants is proposed to lead to modulation of receptor sensitivity. The present study was undertaken to assess the effect of ECT on leukocyte and platelet adrenergic receptor functions in depressed patients. Subjects were 12 acutely depressed patients treated with ECT. 12 healthy subjects served as controls. We measured adrenergic receptor binding parameters (B max and Kd) in intact platelets (3H-Yohimbine) and in intact leukocytes (^{125}I-Cyanopindolol), and receptor function, β-receptor stimulated cAMP levels in leukocytes, α_2-receptor-mediated inhibition in platelets, pre-treatment and 14 days after the last ECT. Pre-ECT receptor binding parameters were not significantly different from those of controls, and treatment had no significant effect. Receptor mediated cAMP levels increased in both platelets, and leukocytes, following ECT, suggesting an enhanced functional response. Whether these changes are specific to ECT, or result from alterations in circulating catecholamines will require further clarification.

Supported by the Ontario Mental Health Foundation.

EFFECTS OF CHRONIC TREATMENT WITH SELECTIVE AGONISTS ON THE SUBTYPES OF DOPAMINE RECEPTORS. **Swaminathan Subramaniam, Irwin Lucki and Paul McGonigle. Dept. of Pharmacology, Univ. of Pennsylvania, Phila. PA 19008.**

The effects of chronic administration of selective agonists on D-1 and D-2 receptor density, affinity and function were measured in rats. Animals received 21 daily injections (i.p.) of the D-1 selective agonist SKF-38393, the D-2 selective agonist quinpirole, SKF-38393 plus quinpirole or vehicle. Serial 20 μm sections that included the caudate putamen (CPu) and nucleus accumbens (NAc) or the substantia nigra (SN) were cut and alternately labeled with ^{3}H-SCH-23390 and ^{3}H-spiroperidol. Treatment with quinpirole or quinpirole plus SKF-38393 decreased the density of D-2 receptors in the CPu (15%), NAc (15%) and SN (43%), whereas SKF-38393 had no effect on these sites. In contrast, treatment with SKF-38393 increased the density of D-1 receptors in the CPu (26%), NAc (22%) and SN (29%). Treatment with quinpirole alone had no effect on D-1 receptors, however, quinpirole attenuated the effect of SKF-38393 on these sites in the CPu and NAc. To ascertain the effects of chronic agonist treatment on functions mediated by each receptor subtype, quinpirole-induced depression of rectal temperature and SKF-38393-induced oral dyskinesias were measured before and after chronic administration of agonists. Treatment with quinpirole or quinpirole plus SKF-38393 resulted in a desensitization of the D-2-mediated depression of rectal temperature which was consistent with results of the biochemical measurements. None of the treatments produced desensitization of the D-1-mediated oral dyskinesias which is also consistent with the biochemical results. (Supported by USPHS grant GM 34781)

375.2

COMPARISON OF BEHAVIORAL AND BIOCHEMICAL CONSEQUENCES OF TWO DISTINCT MODELS OF CENTRAL DOPAMINERGIC DENERVATION SUPERSENSITIVITY B. E. Mileson and R. B. Mailman, Univ. of North Carolina Curriculum in Toxicology and Biological Sciences Research Center, Chapel Hill, NC 27599.

Behavioral and biochemical endpoints of two different models of dopaminergic denervation supersensitivity were compared in order to examine possible mechanisms of supersensitivity. Denervation of central dopamine neurons resulting in severe dopamine depletion was effected in rats by intracisternal (IC) administration of 6-hydroxydopamine (6-OHDA) (200 μg) or bilateral infusion of 6-OHDA into the substantia nigra (8 μg /side). Low-dose agonist challenge of recovered rats lesioned in the nigra elicited a number of behaviors not seen in sham lesioned control rats, including self-biting, intense grooming and ardent gnawing of the cage floor. IC-lesioned rats responded to agonist challenge by explosive locomotor activity and rearing. Receptor binding studies performed on striatal membranes of both lesioned and control rats revealed no change in the maximum number of binding sites (B_{max}) or the dissociation constant (K_d) of either D_1 or D_2 receptors for either lesioned group compared to control. Biochemical function of D_1 receptors was evaluated by measurement of dopamine-sensitive adenylate cyclase in striatal membrane preparations. Differences in dopamine stimulated adenylate cyclase activity due to lesion were slight, indicating additional mechanisms are involved in mediating behavioral supersensitivity. Supported by PHS Grants ES01104 and MH40537.

TEMPORAL CHANGES IN STRIATAL D_1 DOPAMINE RECEPTOR DISTRIBUTION AFTER DOPAMINE DENERVATION. T. DeLorenzo* & M.A. Ariano. University of Vermont College of Medicine Burlington, VT 05405.

A comparison of the morphochemical distribution of striatal D_1 dopamine binding sites, 3 days to 20 weeks following unilateral infusion of 6-OHDA into the substantia nigra, has been performed. Autoradiographic localization of the selective D_1 antagonist ligands ^{3}H-SCH 23390 or ^{125}I-SCH 23982 was assessed in relation to cyclic AMP immunochemically characterized striatal neurons (Br. Res. 443:204,1988). The extent of dopamine depletion in the striatum was determined biochemically or morphologically. All control striatae, contralateral to the 6-OHDA infusion, showed a specific clustered association of D_1 binding with cyclic AMP reactive neurons. In contrast, this morphochemical relationship was lost by 7 days post lesion on the denervated side, and remained uncoupled up to 4 weeks. At 5 weeks, reassociation of D_1 binding sites with cyclic AMP containing neurons occurred in the medial margin of the denervated striatum. This event became more pronounced with time (up to 20 weeks). Biochemical analyses of D_1 binding demonstrated gradual decrements in specific binding up to 4 weeks post-lesion, with a slight recovery after 5 weeks, in good agreement with the anatomical data. Our findings suggest a temporal alteration in D_1 receptor coupling to cyclic AMP reactive neurons following long term denervation of rat striatum.

375.4

CCK ANTAGONIST LORGLUMIDE BLOCKS ACUTE AND CHRONIC HALOPERIDOL-INDUCED EFFECTS ON DA NEURONS L.H. JIANG* AND R.Y. WANG. (SPON: Irwin Fand) Dept. of Psychiat. & Behav. Sci., SUNY at Stony Brook, Stony Brook, NY 11794-8790

The present study examined the ability of lorglumide (LORG) to block acute and chronic HAL-induced effects on midbrain DA cells. LORG is a more potent and selective CCK antagonist than proglumide (PROG) in pancreas. Male Sprague-Dawley rats were treated with HAL for 3 weeks. Standard extracellular single unit recording techniques were used to determine the number of spontaneously active DA cells in anatomically defined A9 and A10 regions. Similar to the results obtained with PROG, i.v. LORG reversed the CHAL-induced reduction of DA cells/track in both A9 and A10. Moreover, microinjection of LORG (4.8 ng in 1 μl), but not naloxone, directly into the medial nucleus accumbens (mNAc), an area containing a high density of CCK/DA nerve terminals and receptors, dose-dependently reversed CHAL-induced effect. LORG injected into the lateral NAc or the caudate-putamen was without effect. In addition, i.v or microinjection of LORG into the mNAc also reversed acute HAL-induced firing rate increase of both A10 and A9 DA cells. These results strongly suggest that CCK receptors in the mNAc form an important link for maintaining HAL-induced effect on midbrain DA neurons and CCK is involved in the therapeutic action of antipsychotic drugs. (Supported by USPHS Grants MH-41440, MH-41696 and MH-00378 to R.Y.W.).

ENHANCED RESPONSES OF NUCLEUS ACCUMBENS (NAc) NEURONS TO DOPAMINE (DA) D_1 AND D_2 RECEPTOR AGONISTS FOLLOWING 6 MONTHS TREATMENT WITH ANTIPSYCHOTIC DRUGS (APDs). Xiu-Ti Hu and Rex Y. Wang, Dept. of Psychiatry & Behav. Sci., SUNY at Stony Brook, Stony Brook, NY 11794-8790.

The present study using double blind design examined the effect of chronic APD treatment on the response of NAc cells to selective D_1 agonist (+)SKF-38393 and D_2 agonist quinpirole (LY). Male Sprague-Dawley rats were treated with either haloperidol (HAL, 1 mg/ kg/day), clozapine (CLOZ, 25 mg/kg/day) or water via their drinking bottles for 6 mo. The techniques of single-unit recording and microiontophoresis were used. At low ejecting currents (1-5 nA), both SKF and LY facilitated the excitatory effects of glutamate, whereas at higher ejecting currents (>10 nA) they inhibited the NAc activity. The inhibitory response of NAc cells to SKF and LY was significantly increased in both HAL and CLOZ-treated rats (with or without drug withdrawal period) compared to controls. Dose-response curves for both SKF and LY were shifted to the left in APD-treated groups. Moreover, a synergistic action of SKF and LY was observed for most cells tested in APD-treated rats but not in control rats. There was no significant difference in the effects produced by chronic HAL and chronic CLOZ on NAc cells, suggesting that the NAc may be importent in mediating the therapeutic action of APDs. (Supported by USPHS Grants MH-41440, MH-41696 and MH-00378 to R.Y.W.)

375.6

THE SENSITIVITY OF RAT CAUDATE-PUTAMEN (CPu) NEURONS TO D_1 AND D_2 RECEPTOR AGONISTS ARE NOT CHANGED BY LONG TERM TREATMENT WITH ANTIPSYCHOTIC DRUGS (APDs). R.Y. Wang, L.H. Jiang* and R.J. Kasser. Dept. of Psychiat. and Behav. Sci., SUNY at Stony Brook, Stony Brook, NY 11794.

It is thought that tardive dyskinesia (TD) might be the result of enhanced dopamine (DA) receptor sensitivity following long-term APD treatment. The present study was designed to test this hypothesis. Male Sprague-Dawley rats were treated with either haloperidol (HAL, 1 mg/kg/day), clozapine (CLOZ, 25 mg/kg/day) or water via their drinking bottles for 6-10 months. Using a double-blind design, we found that there was no significant difference in the sensitivity of CPu neurons to iontophoresed SKF-38393 (a D_1 receptor agonist) or quinpirole (a D_2 receptor agonist) in control, HAL and CLOZ groups, although many of these APD-treated rats showed spontaneous oral movements. These results are consistent with the observations that DA-agonists induced changes in striatal cAMP and inositol phosphate were not different in control and APD-treated groups. They contrast markedly with the results from studies showing that compared to controls, there was a significant increase of D_2 receptor binding sites in the CPu following chronic APD treatment. In conclusion, our results do not support the view that TD is the result of DA receptor supersensitivity. (Supported by USPHS Grants MH-41440, MH-41696, MH-00378 to R.Y.W. and MH-43893 to R.J.K.)

375.7

EFFECTS OF CHRONIC ANTIPSYCHOTIC DRUG (APD) TREATMENT ON STRIATAL cAMP CONTENT IN RESPONSE TO D_1 AND D_2 RECEPTOR AGONISTS. C.R. Ashby, Jr., J.E. Rubinstein*, R.J. Hitzemann and R.Y. Wang. Dept. of Psychiat. and Behav. Sci., SUNY at Stony Brook, Stony Brook, NY 11794-8790

The present study compared the effect of chronic APD treatment on striatal cAMP content in response to dopamine (DA) D_1 and D_2 receptor agonists (+)SKF-38393 (SKF) and quinpirole (LY). In addition, the effects of forskolin and LY plus SKF were examined. Male Sprague-Dawley rats were treated with haloperidol (HAL, 1 mg/kg/day), clozapine (CLOZ, 25 mg/kg/day) or water via their drinking bottles for 12 months. The neostriatal slices were incubated in oxygenated buffer with SKF (10^{-6}-10^{-4} M), LY (10^{-7}-10^{-5} M), forskolin (10^{-5} M) or LY+SKF (10^{-6} and 10^{-5} M) and cAMP content was measured using a RIA method. SKF increased and LY decreased cAMP content. There were no differences among groups in cAMP content in response to SKF, LY or forskolin. These results show that 12 mo. APD treatment failed to alter D_1 or D_2 receptor sensitivity. Additionally, the forskolin results indicate that the activity of adenylate cyclase was unchanged. However, in HAL treated rats, LY+SKF significantly increased striatal cAMP content compared to the water group, suggesting that the interaction between DA receptor subtypes may be differentially affected by chronic APD treatment. (Supported by USPHS Grants MH-41440 and MH-00378 to R.Y.W. and VA Res. Admin. to R.J.H.).

375.8

EFFECTS OF CHRONIC ANTIPSYCHOTIC ADMINISTRATION ON THE FORMATION OF INOSITOL PHOSPHATES IN RAT STRIATUM. J.E. Rubinstein*, R.J. Hitzemann, C.R. Ashby, Jr. and R.Y. Wang (SPON: J.G. May, III). Dept. Psychiatry SUNY: Stony Brook, NY 11794

Previous reports have suggested that muscarinic agents stimulate and D2 dopamine agonists inhibit the hydrolysis of polyphosphoinositides in rat striatum. We sought to replicate these findings and investigate whether long-term treatment with haloperidol (HDL) or the "atypical" antipsychotic clozapine (CLZ) modified these effects.

Male Sprague-Dawley rats were treated for 12 months with HDL, 1 mg/kg/day, or CLZ 25 mg/kg/day. After a 60 min preincubation in Krebs-Ringer-Bicarbonate buffer (KRB), striatal slices were labeled for 2 hr with 0.7 μm [^{3}H]-inositol in a final volume of 1 ml/100 mg tissue. 50 μl of labeled slices were added to KRB containing 10 mM Li^+ and test drugs (final volume = 0.5 ml). After 30 min, the incubation was terminated by the addition of 1.5 ml $CHCl_3$/MeOH/HCl (1:2:.01). All incubations were carried out at 37°C under an atmosphere of 95% O_2/5% CO_2. Inositol phosphates were separated by ion exchange chromatography.

Carbachol (0.5 mM) increased the accumulation of IP by 240% in both treatment groups as well as age-matched controls. IP2 and IP3 were increased 28-44% and 8-30%, respectively. Quinpirole, a selective D2 agonist, had no effect on IP or IP2 levels at concentrations of 0.1-10 μm. Paradoxically, IP3 was increased - minimally in controls, 15% in the CLZ group - however, this effect was not dose-dependent and did not reach statistical significance. This result conflicts with the report by Pizzi et al. (Soc. Neurosci. Abs., Vol. 13, #23.13, 1987) and may represent an effect of aging. The results are discussed in relation to parallel presentations of studies of DA receptor density, neuronal firing rate and adenylate cyclase activity in these chronically treated rats.

375.9

CYCLO(LEU-GLY) (CLG) PREVENTS NIGROSTRIATAL DOPAMINE (DA) SUPERSENSITIVITY (SS) IN MICE. JZ Fields[1], JM Lee*[2], JH Gordon[1] & RF Ritzmann[2], Res Svce Hines[1] & Brentwood[2] VA Hospitals, Hines IL 60141 & Olive View/UCLA Med Ctr, Los Angeles CA 91342

Pro-leu-gly-NH_2 (MIF-1), the C-terminal fragment of oxytocin, and its structural analog, CLG have been shown to alter, after in vivo administration, both DA mediated behaviors and D2 DA receptor binding. In our own studies, CLG coadministration to mice prevented the DA SS in the mesolimbic DA tract (apomorphine (APO) induced locomotion) induced by chronic haloperidol (HAL). In this study we evaluated the effects of CLG on nigrostriatal DA SS. Vehicle (I) or chronic HAL (II)(1.0 mg/kg, ip X 21 days) were given with or without various doses of CLG (sc): [a] 0 mg/kg/day, [b] 1 mg/kg every third day (30 min prior to HAL), [c] 1 mg/kg every day, or [d] 8 mg/kg every third day. Average CLG doses (mg/kg/day) were thus [a] 0, [b] 0.33, [c] 1.0, [d] 2.67. Coadministration of CLG with HAL attenuated the development of the HAL induced SS only at dose [c]: (climbing scores induced by APO (1.0 mg/kg ip) went from +192% (IIa) down to +117% (IIc) of values in control mice [Ia]). The dose response curve for CLG is thus bell-shaped (highest doses not effective) and is similar to many other curves for MIF-1 & CLG effects. The ability to prevent a dopaminergic hypersensitivity induced by neuroleptics suggests a potential therapeutic use in the prevention of tardive dyskinesia. (Supported in part by the Tourette Syndrome Assn & VA grants to JZF and RFR)

375.10

CYCLO(LEUCYL-GLYCYL)(CLG) REVERSES THE PERMANENT DOPAMINERGIC SUPERSENSITIVITY INDUCED BY OVARIECTOMY. JH Gordon[1], JZ Fields[1], R Sami[1]*, JM Lee[1]*, & RF Ritzmann[2], Research Services, Hines & Brentwood VA Hospitals, Hines IL 60141 & Olive View/UCLA Med Ctr, Los Angeles CA 91342.

Several neuropsychiatric disorders (e.g. Tourettes, tardive dyskinesia, schizophrenia) are thought to involve a permanent dopamine (DA) receptor (DAr) supersensitivity (SS). Although many animal models of DAr SS have been studied, the only models in which the SS is permanent are induced by lesions and are obviously not appropriate for evaluating compensatory changes in the presynaptic DA neurons induced by post-synaptic DAr up-regulation. The ovariectomized (OVX) rat circumvents this problem as the the upregulated D2 DAr & the behavioral SS to DA agonists that develop (3 mos post-OVX) appear to be permanent while the DA neurons remain intact. CLG is a DA neuromodulator which prevents the development of a DAr SS in several animal models. However, it has never been shown whether CLG can reverse an already established behavioral SS to DA agonists. We now document such a reversal in the OVX model. OVX rats showed significantly more stereotypic sniffing after apomorphine (APO: 0.45 mg/kg, ip) & more locomotor activity (APO: 0.15 mg/kg). CLG (1X/day for 4 days, 8 mg/kg, sc) reversed these SS responses. We conclude [1] that the OVX rat is useful for modelling the permanent or irreversible aspect of DA SS; [2] CLG may be useful in the treatment of DA related diseases. (Supported by the Tourette Syndrome Assn & VA grants to JZF and RFR)

375.11

ATTENUATION OF SCH-23390-INDUCED ONTOGENIC IMPAIRMENT OF RAT STRIATAL DOPAMINE D-1 RECEPTORS BY L-PROLYL-L-LEUCYL-GLYCINAMIDE (PLG). R.M. Kostrzewa and M.I. Saleh*. Quillen-Dishner College of Medicine, East Tennessee State Univ., Johnson City, TN 37614.

While the effects of receptor antagonists on the development of striatal dopamine D-2 receptors have been studied by several groups, ontogenic actions of D-1 receptor antagonists have not been determined. Rats were treated from the day of birth and once each day for 32 successive days with the selective D-1 antagonist, SCH-23390 (0.30 mg/kg/d i.p.). Using the D-1 binding assay of Schulz et al. (J. Neurochem. 45: 1601, 1985), it was found that chronic SCH-23390 treatment during postnatal ontogeny resulted in a 70-80% reduction in binding of [^{3}H]SCH-23390 to striatal membranes in vitro at 5, 8 and 12 weeks from birth. These changes were associated with a 78% reduction in B_{max} and unchanged K_D, as assessed at 5 weeks. When 12 wk old rats with reduced numbers of striatal D-1 receptors were challenged by 17 d treatment with SCH-23390 (0.30 mg/kg/d i.p.), the D-1 receptors up-regulated 3-fold, up to 75% of control levels. When PLG (1.0 mg/kg/d i.p.) was co-administered with SCH-23390 during development, the ontogenic impairment of striatal D-1 receptors was totally attenuated. These findings demonstrate that the postnatal period is critical in the development of striatal D-1 receptors, and that PLG protects against the adverse ontogenic effects of SCH-23390.

375.12

ATTENUATION OF SPIROPERIDOL-INDUCED ONTOGENIC IMPAIRMENT OF RAT STRIATAL DOPAMINE D-2 RECEPTORS BY L-PROLYL-L-LEUCYL-GLYCINAMIDE (PLG). M.I. Saleh* and R.M. Kostrzewa (SPON: E.A. Daigneault). Quillen-Dishner College of Medicine, East Tennessee State Univ., Johnson City, TN 37614.

Postnatal treatment of rats for 3 weeks with haloperidol results in a persistent increase in the number of striatal dopamine D-2 receptors (Rosengarten and Friedhoff, Science 203: 1133, 1979). Because striatal D-2 receptor development occurs through at least the first 4 weeks from birth, it was of interest to determine the effect of prolonged treatment with a D-2 antagonist, spiroperidol (SP, 1.0 mg/kg/d i.p. 32d from birth), on development of D-2 receptors. Postnatal SP treatment reduced [^{3}H]SP binding to striatal homogenates by 50 to 75% at 5, 8 and 12 weeks from birth. The B_{max} for [^{3}H]SP binding was reduced by 74% at 5 weeks, while the K_D was unchanged. Co-administration of PLG (1.0 mg/kg/d i.p. x 32d) resulted in an attenuation of the D-2 ontogenic impairment produced by SP. These findings indicate that the postnatal period is a sensitive and critical one in regard to striatal D-2 receptor development and that PLG is able to attenuate SP-induced ontogenic impairment of D-2 receptors.

375.13

STRIATAL D-1 DOPAMINE RECEPTOR DENSITY FLUCTUATES DURING THE RAT ESTROUS CYCLE. D. Lévesque*, S. Gagnon* and T. Di Paolo, Department of Molecular Endocrinology, Laval University Medical Center, Quebec, G1V 4G2 and School of Pharmacy, Laval University, Quebec, G1K 7P4, CANADA.

Studies on dopamine (DA) content and turnover across the estrous cycle of rodent illustrate the importance of gonadal steroids in striatal DA regulation. In this study, we have investigated the binding characteristics of striatal D-1 DA antagonist binding sites in intact female, ovariectomized (OVX) animals and during the 4-day estrous cycle. Our results show that the affinity of the striatal D-1 receptor as labelled with [^{3}H]SCH23390 remains constant in female rats during the estrous cycle and OVX animals. By contrast the density of the striatal D-1 DA antagonist binding sites vary during the estrous cycle or after castration. Ovariectomy decreases striatal D-1 density by 16.8% ($p < 0.01$) compared to intact female rats. The density of striatal D-1 DA receptor was higher on the day of diestrus I (DI) and diestrus II (DII) ($p < 0.01$ vs OVX) and fluctuates throughout the estrous cycle with a maximum on the day of DII ($p < 0.05$ vs proestrus PM). The modulation under physiological conditions of striatal D-1 DA receptors as reported here is not correlated in a simple fashion with the variation of a single hormone and may involve several hormones acting synergistically or in opposite way as well as the delayed action of hormones may be observed. Interestingly, ovarian hormones seem to exert a stimulatory role on D-1 DA receptors density while we observe the opposite on the D-2 DA agonist affinity sites. Supported by the MRC.

CATECHOLAMINES IV

376.1

EFFECTS OF THE CATECHOLAMINERGIC NEUROTOXIN, DSP-4, ON ADRENAL CHROMAFFIN CELLS. P. Boksa, Douglas Hosp. Res. Ctr., Depts. Psychiatry and Pharmacology, McGill Univ., Montreal, Quebec, Canada H4H 1R3

N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine (DSP-4) is an inhibitor of noradrenaline (NA) uptake and a neurotoxin known to deplete NA levels with little effect on dopamine (DA), serotonin or adrenaline (A) in the CNS. In the adrenal medulla, A, NA and probably DA are synthesized in separate chromaffin cells together with various neuropeptides; thus a neurotoxin targeting a specific sub-population of chromaffin cells would be a useful pharmacologic tool. The present study tested effects of DSP-4 on catecholamine uptake, release and content in cultured bovine adrenal chromaffin cells. DSP-4 selectively inhibited the acute uptake of [^{3}H]NA with little effect on [^{3}H]A or [^{3}H]DA uptake. In cultures pre-loaded with [^{3}H]catecholamines, DSP-4 stimulated release of [^{3}H]NA, and to a small extent also [^{3}H]A and [^{3}H]DA. However the drug did not stimulate the release of endogenous A, NA or DA. A high concentration of DSP-4 inhibited the carbachol-stimulated release of A, NA and DA. A 1 h exposure to DSP-4 decreased A, NA and DA levels with no gross morphologic changes in the cells. Reductions in A and NA levels were equal in magnitude, while DA was depleted to a somewhat greater extent under some conditions. Longer exposure to DSP-4 resulted in morphological changes in the cells suggesting that the drug is also toxic to chromaffin cells in culture. Supported by MRC of Canada.

376.2

D2 DOPAMINE RECEPTOR-MEDIATED INHIBITION OF CATECHOLAMINE SECRETION, ^{45}Ca UPTAKE AND CALCIUM CURRENTS IN BOVINE CHROMAFFIN CELLS. L. Bigornia*, C. Allen and A.S. Schneider Dept. Pharm. Tox., Albany Med. Coll., Albany, NY 12208.

D_2 dopamine receptors have been identified on chromaffin cell membranes and dopaminergic agonists have been shown to inhibit catecholamine release and ^{45}Ca uptake. In the present study, we examined the subtype of dopamine receptor involved in mediating dopaminergic inhibitory effects. The D_1 receptor agonist SKF 38393 did not inhibit basal or nicotine-evoked catecholamine secretion. The D_2 receptor agonist apomorphine inhibited nicotine- and KCl (60 mM)-evoked catecholamine secretion and this was reversed by D_2 receptor antagonists but not by the D_1 receptor antagonist SCH 23390. Similar effects were observed in parallel experiments examining KCl-evoked ^{45}Ca uptake. These observations suggest that dopaminergic inhibition of catecholamine secretion is mediated predominantly by a specific D_2 receptor subtype. To further examine the mechanism by which dopaminergic receptors modulate Ca^{2+} uptake, we used whole cell patch clamp electrophysiological techniques to directly monitor voltage-gated calcium channels in cultured chromaffin cells. We found that apomorphine reversibly reduced voltage-activated calcium currents and this effect was blocked by the D_2 receptor antagonist haloperidol, thus suggesting that voltage-gated calcium channels undergo inhibitory modulation by D_2 dopamine receptors in bovine adrenal chromaffin cell cultures.

376.3

PRESENCE OF DOPAMINE AUTORECEPTORS IN PC12 CELLS. N.D. Courtney*, A.C. Howlett and T.C. Westfall. Department of Pharmacology, St. Louis University School of Medicine, St. Louis, MO 63104.

Evidence exists for the presence of dopamine (DA) autoreceptors on adrenal chromaffin cells. DA agonists inhibited nicotine evoked catecholamine release from adrenal chromaffin cells and this inhibitory effect was reversed by DA antagonists (Artalego et al., J. Physiol. (Lond.) 362: 359, 1985). Since PC12 cells are derived from transformed chromaffin cells, these cells may also express DA autoreceptors and would make an ideal system to study the intracellular signals that are coupled to such receptors. PC12 cells were grown in DME with 10% heat-inactivated fetal calf serum and 5% heat-inactivated horse serum. Between 1-3 x 10^6 cells were plated on 35 mm wells 16 hr prior to the release experiments. Cells were incubated at 37°C with or without the drugs with Gey's balance salt solution for 2 min. Released DA was measured in the buffer and the cellular DA was measured after the lysis of cells with 10% perchloric acid. HPLC-EC was used for the detection of DA. K^+ (56 mM) was shown to produce marked increase in DA release over basal. This K^+-induced enhancement of DA release was attenuated by apomorphine (1 µM). Furthermore, haloperidol (10 µM) reversed the apomorphine-induced attenuation of K^+ stimulated DA release. Haloperidol (10 µM) had no effect on basal DA release. These results suggest the presence of DA autoreceptors on PC12 cells. (Supported by DA03690 and DA02668.)

BRADYKININ STIMULATES THE RELEASE OF CATECHOLAMINE FROM RAT PHEOCHROMOCYTOMA PC-12 CELLS. H. Houchi, J.S. Masserano* and N. Weiner. Dept. of Pharm., Univ. of Colo. Health Sci. Ctr. 4200 E. Ninth Ave. Denver CO 80262.

Bradykinin is a putative central nervous system neurotransmitter. In a number of cell systems, bradykinin has been shown to increase the accumulation of inositol trisphosphate (IPs). We have evaluated the effect of bradykinin on the release of endogenous dopamine from PC-12 cells. Bradykinin released dopamine in a concentration dependent manner with maximal release (15% of total stores) occurring at 10 µM. The release of dopamine by bradykinin occurred in two phases. The first phase occurred rapidly with 8% of total stores of dopamine released within 15 sec; the second phase was slower, with an additional 7% release occurring between 2 and 10 min. Ten seconds after bradykinin treatment intracellular Ca^{++} measured by Fura-2 was increased 600%. One minute after bradykinin treatment $^{45}Ca^{++}$ uptake was increased 100%. Ten minutes after bradykinin treatment, the formation of [^{3}H]-inositol phosphates were increased 360%. These data indicate that bradykinin regulates the release of dopamine from PC-12 cells, possibly by increasing IPs formation and by activating calcium/calmodulin-dependent protein kinase and protein kinase C. Supported by USPHS grants NS07927 and NS09199.

CATECHOLAMINE (CA) SECRETION MEDIATED BY A OUABAIN RECEPTOR IN THE BOVINE CHROMAFFIN CELL. C. Gonzalez-Garcia*, V. Cena*1 and H.R. Keiser* (SPON: I. De Andres). Hypertension-Endocrine Br., Nat. Heart, Lung, and Blood Institute, and [1]Lab. of Cell Biology and Genetics, Nat. Inst. of Diabetes, Digestive and Kidney Diseases, Bethesda, MD 20892.

We studied the secretion of CA from isolated bovine adrenal chromaffin cells in culture evoked by different cardiac glycosides, its correlation with blockade of Na^+, K^+-ATPase activity and the presence of the cardiac glycoside receptor as indicated by the presence of ^{3}H-ouabain binding sites. Cardiac glycosides release CA (up to l0% of total content) in a dose-dependent manner with an order of potency strophanthidin > ouabain > acetyldigitoxin > digitoxin. The ED_{50}'s varied from l μM for strophanthidin to l0 μM for digitoxin. ^{3}H-ouabain was specifically bound to a single population of high affinity binding sites located on the plasma membrane of chromaffin cells, with a K_d (l3.6 nM) similar to that found in other neural tissues, and a B_{max} of 3.l5 pmol/mg protein.^{3}H-ouabain was specifically displaced from this binding site by cardiac glycosides with an order of potency ouabain > acetyldigitoxin > digitoxin. The IC_{50}'s for displacement range between l0 nM for ouabain and 75 nM for digitoxin. These results indicate a discrepancy between the doses of cardiac glycosides required to occupy the receptor (likely Na^+,K^+-ATPase) and the doses that evoke CA secretion from chromaffin cells.

376.6

ESTROGEN PRIMING INCREASES STRIATAL DOPAMINE RESPONSIVENESS TO 60 mM KCl IN MALE RATS. B.L. Firestein* and J.B. Becker (SPON: S. Gilman). Psychology Dept. & Neuroscience Program, The University of Michigan, Ann Arbor, MI

Previous experiments have shown that there are sex differences in the effects of gonadal steroid hormones on behavioral and neurochemical indices of striatal dopamine (DA) activity. Development of these sex differences appears to be dependent on the presence of the ovaries around the time of puberty (Becker & Ramirez, Neuroendocrinology, 32:168-173, 1981). The experiments to be reported examine the role of estrogen during the peripubertal period of male rats on subsequent striatal DA responsiveness to estrogen.

Male rats 36 days old were castrated and treated with either estradiol benzoate (5 μg) or vehicle for a total of 12 days. After the last treatment, animals were killed by decapitation and striatal tissue was dissected, sliced and placed into superfusion chambers as described previously (Becker et al., J. Neurosci. Meth., 11:19, 1984). After baseline samples were collected, estradiol was infused in pulses [10 min. estradiol (E, 90 pg/ml); 20 min without E] for 3 pulses (90 min). Striata from half of the animals in each group received infusions of vehicle in pulses that paralelled the E pulses. Following the E pulses 60 mM KCl was infused for 2.5 min. Endogenous DA in the effluent was measured by HPLC-EC.

In striatal tissue from males pretreated with estrogen, pulsatile E in the superfusion medium potentiated the subsequent responsiveness to KCl depolarization, relative to the responses of control groups ($p<0.01$). The pulsatile infusion of E in the superfusion medium had no effect on the basal efflux of DA for either group. We conclude that estrogen pretreatment predisposes striatal DA neurons in prepubertal males to be responsive to subsequent estogen exposure. (BNS 84-11763).

PEPTIDE AND AUTORECEPTOR MODULATION OF DOPAMINE RELEASE FROM EXPLANTED MESOACCUMBENS (SOMA-TO-TERMINAL) TISSUE. M.D. Davis* and C.D. Kilts* (SPON: R.M. Quock). Dept. Biology, Univ. Wisconsin, P.O.B. 413, Milwaukee, WI 53201, and Dept. Psychiatry, Duke Univ., Durham, NC 27710.

Midbrain dopamine neurons exhibit several interesting characteristics including somatodendritic and terminal release/synthesis-regulating autoreceptors, and neurotransmitter release from somatodendritic as well as terminal regions. Here we report on certain dimensions of these properties in mesoaccumbens dopamine (DA) neurons utilizing the new technique of "core" explantation which isolates an elongated projection from cell bodies to their terminals.

Male Sprague-Dawley rats (14-21 days old), were decapitated, their brains removed and chilled in buffer. A sharpened cannula (0.6mm i.d.) was driven through the tissue block along a specified pathway, collecting ventral tegmental area (VTA) dopamine cell bodies, medial forebrain bundle (MFB) axons and nucleus accumbens terminals. The explant core was removed from the cannula and perifused in vitro. Media was collected at both ends of the explant for separate analysis of released DA via HPLC-EC.

Following VTA administration of neurotensin (0.06-6 uM), TRH (0.5-5 uM) and substance P (0.5-5 uM), a sustained increase (150-300%) in terminal DA release was observed, lasting for up to 30 minutes. Sulpiride (50 nM) augmented neurotensin-induced DA release, while the DA D2 antagonist, LY171555 (0.1 uM), attenuated it. Stimulation of the MFB evoked an autoreceptor-mediated decline in DA stores.

A POTENT DOPAMINE-RELEASING PROTEIN (DARP) IS PRESENT IN HIGH CONCENTRATIONS IN THE ADRENAL GLAND. G.D. CHANG AND V.D. RAMIREZ, DEPARTMENT OF PHYSIOLOGY AND BIOPHYSICS, UNIVERSITY OF ILLINOIS AT CHAMPAIGN-URBANA, URBANA, IL 61801.

A Hartree's procedure was adopted to preferentially extract the DARP from rat adrenal gland. The 80 % ethanol precipitate was then dissolved and dialyzed against a modified Kreb's Ringer Phosphate buffer (KRP) and used for the in vitro superfusion experiments. This adrenal dialysate elicited dose-dependent rapid and robust increases in endogenous dopamine (DA) release from the rat corpus striatum (CS) accompanied by similar changes in DOPAC release. In addition, the adrenal dialysate also induced small but significant increases in epinephrine output from the superfused adrenal medulla. Further characterization of the adrenal dialysate with Sephadex G-75 column chromatography suggested an apparent Mr 54,000 for the DARP. A similar DARP was purified from bovine adrenal gland to apparent homogeneity under alkaline and SDS PAGE analysis. SDS PAGE of the purified protein showed a single protein band of Mr 55,000. The bovine DARP induced significant increases in endogenous DA release from the rat CS at concentrations around 10^{-7}M.

GENETIC DIFFERENCES IN INHIBITION OF SYNAPTOSOMAL ^{3}H-MONOAMINE UPTAKE BY COCAINE, AMPHETAMINE AND TROPACOCAINE. J.A. Ruth, T.Z. Bosy* and C. C. Duncan. School of Pharmacy, University of Colorado, Boulder, CO 80309-0297.

We have shown that the BALB, C3H, C57 and DBA inbred strains of mice differ in behavioral sensitivity to cocaine (COC) as well as in sensitivity to COC inhibition of synaptosomal uptake of ^{3}H-NE, ^{3}H-DA and ^{3}H-5HT. To assess the generality of these differences for other inhibitors of monoamine uptake, the inhibition of accumulation of ^{3}H-NE, ^{3}H-DA and ^{3}H-5HT by d-amphetamine (AMPH) and tropacocaine (TROP) was examined in synaptosomes from each strain of mouse. For inhibition of ^{3}H-DA uptake, the relative order of potency observed was AMPH > COC > TROP. C57 was most sensitive to AMPH (IC_{50} = 10^{-8} M), and DBA least sensitive (IC_{50} = 10^{-7} M). AMPH was 5-10 fold more potent than COC, and 100 fold more potent than TROP. For inhibition of ^{3}H-5HT uptake, the order of potency observed was COC > AMPH = TROP. DBA was most sensitive to COC (IC_{50} = 8 x 10^{-8} M), and C57 least sensitive (IC50 = 10^{-6} M). COC potency ranged from 100 fold (DBA) to 10 fold (C57) greater than AMPH. For inhibition of NE uptake, AMPH and COC were equipotent in BALB and C57 (IC_{50} = 10^{-7} M), but COC was 10 fold less potent than AMPH in DBA and C3H. The drugs did not significantly differ in maximal lipid solubility in partition experiments. The data suggest genetic differences in the topology of respective monoamine carriers, and suggest that differences in behavioral response to stimulant drugs may involve complex monoamine interactions.

376.10

ROLE OF CORTICOSTRIATAL NERVE PROJECTIONS IN THE REGULATION OF BINDING SITES FOR DOPAMINE UPTAKE BLOCKERS IN RAT CAUDATE NUCLEUS. M. Grilli*, E. Sanna* and I. Hanbauer. HE Branch, NHLBI, N.I.H., Bethesda, MD 20892.

Ablation of the frontal and medial cortex leads to destruction of corticostriatal projections that are presumably glutamatergic/aspartergic in nature. These terminals were reported to impinge directly on dopaminergic terminals in caudate nucleus where they were shown to stimulate ^{3}H-dopamine release. We have studied the effect of cortical ablation on ^{3}H-dopamine uptake and on the regulation of Na^+-dependent specific binding of various radiolabelled dopamine uptake blockers. The ^{3}H-dopamine uptake in slices of caudate nuclei ipsilateral to the lesioned cortex was more sensitive to the inhibition by cocaine (K_i=2.6 x 10^{-7}M) or mazindol (K_i=7.5 x 10^{-7}M) than the contralateral side (K_i=1.3 x 10^{-6}M) three weeks after cortical ablation. In addition, the number of Na^+-dependent ^{3}H-cocaine binding sites in striatal membranes was increased (contralateral: 3.6 pmol/mg protein; ipsilateral: 8.0 pmol/mg protein). In contrast, the binding properties of ^{3}H-phencyclidine, ^{3}H-MK 801, and ^{3}H-GBR 12935, substances that also block dopamine uptake, remained unchanged. The number of ^{3}H-mazindol binding sites was increased by 20% in striatal membranes from the decorticated hemisphere. The present results show that in absence of corticofugal nerve endings the dopamine transport system in caudate nuclei is up-regulated through an allosteric mechanism. It is inferred that corticofugal nerve endings may release an endogenous modulator that inhibits dopamine uptake.

IN VIVO AUTORADIOGRAPHY OF [^{18}F]-GBR 13119 BINDING IN RAT BRAIN. M.R. Kilbourn*, B.J. Ciliax, M.S. Haka*, and J.B. Penney, Depts. of Internal Medicine and Neurology, University of Michigan, Ann Arbor, MI 48104.

We have examined [^{18}F]-GBR 13119's ability to bind to the dopamine uptake site in vivo in adult male Sprague-Dawley rats. Quantitative autoradiography was performed on coronal sections (20 μm) taken through neostriatum, the A9/A10 region, and cerebellum of rats injected with 0.5 - 1.5 mCi [^{18}F]-GBR 13119.

[^{18}F]-GBR 13119 binding was high in striatum, nucleus accumbens, and olfactory tubercle, moderate in ventral tegmental area and substantia nigra pars compacta, and low in cerebral cortex and cerebellum. [^{18}F]-GBR 13119 binding in ipsilateral striatum of unilateral 6-hydroxydopamine lesioned rats was reduced to background levels. Predosing with "cold" GBR 13119 (10 mg/kg) blocked binding throughout the brain, but predosing with fluoxetine (20 mg/kg) or nisoxetine (5 mg/kg), specific serotonergic and noradrenergic uptake inhibitors, respectively, did not block [^{18}F]-GBR 13119 binding. Using PET and [^{18}F]-GBR 13119, we have successfully imaged the striatum of a monkey with a striatum/cerebellum ratio of 1.8. [^{18}F]-GBR 13119 should be a useful presynaptic marker for dopamine neurons and could be used to PET scan patients with Parkinson's Disease.

SOLUBILIZATION OF THE DOPAMINE TRANSPORTER. M.J. Kuhar, J. Sharkey* and D.E. Grigoriadis. (SPON: S.Bird). NIDA Addiction Research Center, Baltimore MD 21224

^{3}H-GBR12935 is recognized as a potent and highly selective ligand for the dopamine transporter, the site related to the reinforcing properties of cocaine. In the present study, ^{3}H-GBR12935 was used to label the solubilized dopamine transporter in digitonin treated striatal membranes. Homogenates of rat striata (50mg/ml) were solubilized in 1% digitonin for 30 min, centrifuged for 1 hr at 100,000g, the supernatant filtered and 0.3ml aliquots used in binding assays. ^{3}H-GBR12935 exhibited reversible, saturable, high affinity binding characteristics to solubilized membranes with an observed K_D of 4nM; a value similar to the 1nM K_D observed in striatal membranes. In competition studies, ^{3}H-GBR12935 binding to solubilized and to membrane homogenate preparations was inhibited in a similar fashion by the dopamine uptake blockers GBR12909, mazindol, nomifensine and benztropine but not by the 5HT and norepinephrine uptake blocker doxepin. Furthermore, following 6-hydroxydopamine lesions of the nigrostriatal pathway parallel reductions in ^{3}H-GBR12935 binding were observed in both homogenized and solubilized membrane preparations. These data indicate that the dopamine transporter can be solubilized and labeled with ^{3}H-GBR12935, providing a useful tool towards the molecular characterization and purification of the dopamine transporter.

376.13

SOLUBILIZATION OF THE DOPAMINE TRANSPORTER: F.R. Sallee*, R.L. Stiller*, H.B. Niznik, N.H. Bzowej, P. Seeman and J.M. Perel*. **Clinical Pharmacol. Prog. WPIC, Univ. of Pittsburgh, Pittsburgh, PA 15213 and Depts. of Medicine and Pharmacol. Univ. of Toronto, Toronto, Ont. M5S 1A8.**

The dopamine transporter, as indexed by [^{3}H]GBR-12935 binding, was solubilized from canine striatal membranes with the detergent digitonin. The protein retained the same pharmacological characteristics as membrane-bound uptake sites. The binding of [^{3}H]GBR-12935 to solubilized preparations was specific, saturable and reversible with a dissociation constant of ~3 nM and a site density of 3.4 pmol/mg protein. [^{3}H]GBR-12935 also bound to solubilized sites in a sodium-independent manner with a K_D of ~6 nM and a 60% decrease in site density. Dopamine uptake inhibitors and substrates inhibited [^{3}H]GBR-12935 binding in a stereoselective and concentration dependent manner with an appropriate rank order of potency for the dopamine transporter. K_D values for these compounds in solubilized preparations were virtually identical with those obtained on [^{3}H]GBR-12935 binding in the native state and correlated with IC_{50} values on [^{3}H]dopamine uptake. The dopamine transporter appears to be a transmembrane glycoprotein by virtue of its absorption and specific elution from WGA-lectin column. Solubilization of this protein with full retention of binding activity now allows for the purification and biochemical characterization of this important membrane protein.

CATECHOLAMINES: ELECTROPHYSIOLOGY II

377.1

ELECTROPHYSIOLOGICAL EFFECTS OF COCAINE IN THE RAT MEDIAL PREFRONTAL CORTEX. D.J. Henry and F.J. White. Dept. of Psychiat., Wayne St. Univ. Sch. Med. & Neuropsychopharm. Lab., Lafayette Clinic, Detroit, MI 48207.

Rats will readily self-administer cocaine directly into the medial prefrontal cortex (mPFC), indicating that this site may be important in mediating the rewarding effects of this popular drug of abuse. Surprisingly, little is known regarding the electrophysiological effects of cocaine in this area. In the present studies, extracellular single-cell recording and microiontophoretic techniques were employed to characterize the effects of cocaine in the dopaminergic terminal area within the mPFC (layers V & VI). Our studies indicate that both cocaine (0.01 M) and dopamine (0.1 M) exhibit a partial inhibitory effect (40-50% inhibition at 16-32 nanoampere current) on both spontaneously active and glutamate-stimulated mPFC cells recorded from male chloral hydrate-anesthetized rats. Procaine (0.01 M), administered in a similar fashion, exerted no such inhibitory effect. The inhibitory effects of cocaine and dopamine were blocked by co-iontophoresis of the D2 dopamine antagonist sulpiride (0.05 M, 16nA). At higher ejection currents, (>32 nA) local anesthetic-like effects (rate inhibition accompanied by spike amplitude reduction) were observed with both cocaine and procaine. Intravenous administration of cocaine also partially inhibited the firing of mPFC neurons. Present studies are investigating the mechanisms underlying the inhibitory effects of cocaine within the mPFC.

SINGLE UNIT ACTIVITY IN THE NUCLEUS ACCUMBENS OF THE FREELY MOVING RAT DURING ORAL SELF-ADMINISTRATION OF COCAINE. M. Wolske* and M.Q. West (SPON: C. Boast) Dept. of Psychology, Rutgers University, New Brunswick, NJ 08903.

The nucleus accumbens has been implicated as a critical neural substrate mediating psychomotor stimulant reinforcement. Previous electrophysiological studies of this region have been limited to anesthetized animals, in which results can be adversely affected by the anesthetic, and in which no behavioral assessment can be made regarding the reinforcing properties of drugs such as cocaine. These problems were eliminated in the present study, in which the schedule-induction technique was used to produce cocaine polydipsia (Tang, M. and Falk J., Pharmacol. Biochem. & Behav. 28:517, 1987). Male Long-Evans rats, aged 90-120 days, were prepared for chronic recording via a detachable, miniature microdrive positioned above the nucleus accumbens (A-P 2.2mm, M-L 1.5mm, D-V 5.8-8mm). Animals were food-deprived to 80% ad lib weight and conditioned to bar-press for food on a FI 60 schedule, in which a tone (1 kHz, 60 dB) served as a discriminative stimulus. Single unit recordings from the nucleus accumbens (verified on line via synaptic activation of the ipsilateral subicular input, and histologically after sacrifice) were analyzed in terms of peri-event histograms constructed around behavioral events such as tone onset, bar pressing and licking. Preliminary results suggest that, in contrast to anesthetized preparations, cocaine produced a general increase in the spontaneous activity of accumbens neurons. In particular, cocaine produced greater elevations in firing rate during movement (such as orienting and bar-pressing), similar to our previous study of caudate-putamen neurons (Shimizu et al, Neurosci. Abstr. 13:979, 1987). This enhancement was selective in that, prior to drug consumption, these same movements were not accompanied by elevations in firing rate. Since the likely mechanism of cocaine's action is to block reuptake of dopamine, a selective effect of cocaine during movement is consistent with a large literature correlating increased dopamine release with movement. REDUCED DURATION OF NEURONAL RESPONSE TO DOPAMINE IN THE ANTERIOR CINGULATE CORTEX AFTER UPTAKE BLOCKADE. Mario Beauregard and André Ferron. Centre de recherche en sciences neurologiques (Département de physiologie), Université de Montréal, Montréal, Canada.

To investigate the effect of dopamine (DA) uptake blockade on neuronal responsiveness to this catecholamine, we compared the duration of the response to DA before and after the administration of GBR 12909 (DA uptake blocker, 500 ug/kg, i.v.). The duration of inhibition induced by iontophoretic applications of DA (40 nA x 40 s) was assessed by the RT90 method, i.e. by measuring the time (in s) between the end of DA application and the return to a neuronal firing rate equal to at least 90% of the pre-injection frequency. In control rats, the duration of DA responses were significantly enhanced by GBR 12909 in the prefrontal cortex (87 s vs 459 s), in the striatum (100 s vs 460 s) as well as in the nucleus accumbens (52 s vs 209 s), but markedly reduced in the anterior cingulate cortex (ACg) (576 s vs 155 s). Furthermore, DA depletions and/or deafferentations, using either -MPT or 6-OHDA, produced a decrease in the duration of the responses to DA (61 and 54 s, respectively) in the ACg, comparable to that observed after GBR administration. A possible explanation for the present results is that in the ACg, under normal circumstances, the released DA is transported back into the presynaptic terminals and in this way induces a further DA release, thus favouring a longer duration of DA effects. Such a positive feedback mechanism could play a key role in the regulation of the activity of ACg neurons by modulating the homeostatic control of DA release. This control mechanism of DA release may be a particular feature of the mesocortical dopaminergic fibers projecting to the ACg and thus be involved in higher integration cortical functions.

377.4

EFFECTS OF AMPHETAMINE ON SINGLE UNIT ACTIVITY IN THE OLFACTORY TUBERCLE. **Charles H.K. West and Richard P. Michael. Department of Psychiatry, Emory University School of Medicine, and Georgia Mental Health Institute, 1256 Briarcliff Road, Atlanta, GA 30306.**

A principal action of d-amphetamine (AMPH), believed to be critical for its behavioral effects, is enhancement of transmission in the midbrain dopaminergic systems. Electrophysiological studies focusing on the effects of AMPH on the spontaneous activity of neurons in dopamine terminal regions have revealed that effects depend on site. Both increases and decreases in activity were induced by AMPH in striatal neurons, but effects were predominantly inhibitory in nucleus accumbens neurons. Here, we report on the effects of AMPH on neurons in the olfactory tubercle, a somewhat neglected area although it receives heavy dopaminergic innervation. Single units were recorded in adult male rats anesthetized with chloral hydrate (400 mg/kg, ip). After records had stabilized, spontaneous activity was measured before and at 5 min intervals after injection of AMPH (0.25 mg/kg, iv). Of the 14 units tested with AMPH to date, activity was increased in 11 (78%), decreased in one and not changed in two. The increase in activity (mean = 57%) was maximal 15–20 min after injection and returned to control levels by 45 min. Preliminary tests with haloperidol blocked the effects of AMPH on unit activity, suggesting that dopamine is involved in these actions of AMPH. Differences between structures in regard to the neuronal response to AMPH (e.g., olfactory tubercle and nucleus accumbens) may help us understand the different behavioral effects of this drug.

377.5

ENHANCED SENSITIVITY OF SUBSTANTIA NIGRA DOPAMINE (DA) CELL AUTORECEPTORS FOLLOWING PARTIAL DA DEPLETIONS IN RATS. Michele L. Pucak and Anthony A. Grace. Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA, 15260.

Studies have shown that 2 weeks after lesions causing greater than 85% depletion of striatal DA, there is development of striatal DA receptor supersensitivity. However, it has not yet been established whether the DA cell body autoreceptor also undergoes changes in sensitivity. The present study investigated this problem using single-unit recording techniques from identified substantia nigra DA cells in 6-hydroxydopamine lesioned and control rats. The relative sensitivity of lesioned and control rats was estimated by their response to systemic administration of apomorphine (APO). APO was given intravenously to rats in each group in dose-response fashion. Preliminary results suggest a slight but not significant trend toward subsensitivity soon after the lesion (six to ten days). However, six to eight weeks post-lesion, our preliminary results suggest a supersensitivity of DA cell autoreceptors, with 50% inhibition in DA cell firing rate occurring with 3.2 ug/kg APO in the lesioned rats, as compared to 8 ug/kg in control rats. We are currently examining this phenomenon after striatonigral lesions to test for any postsynaptic contribution to the changes seen after striatal lesions. (Supported by NS19608).

377.6

EFFECT OF ACUTE AND CHRONIC TREATMENT WITH SCH 23390 ON THE SPONTANEOUS ACTIVITY OF MIDBRAIN DOPAMINE NEURONS. E. Esposito* and B.S. Bunney (Spons: David J. Barker). Dept. of Psychiat., Yale Univ. Sch. Med., New Haven, CT.

In the albino rat, chronic treatment with typical antipsychotic drugs (APD) induces a marked decrease in the number of spontaneously active A9 and A10 dopamine (DA) neurons due to the development of depolarization block (DB). It has been shown that SCH 23390, a selective blocker of D-1 DA receptors, has a biochemical and behavioral profile consistent with potential antipsychotic activity. In the present study, we investigated the effect of acute and chronic administration of SCH 23390 on the spontaneous activity of DA neurons, both in the A9 and A10 areas, in order to elucidate the role of chronic blockade of D-1 DA receptors on the induction of the DB produced by APD. Two groups of rats were given an acute subcutaneous (s.c.) injection of SCH 23390 (0.5 and 1.0 mg/kg). In four separate chronic experiments, SCH 23390 was administered repeatedly for 21 days either s.c. (0.5 and 1 mg/kg) or orally (5 and 10 mg/kg). Active A9 and A10 DA neurons were counted by passing an electrode through a stereotaxically defined block of tissue that could be reproducibly located from animal to animal. No changes in the number of spontaneously active DA neurons were found either after acute or chronic treatment with SCH 23390. D-1 receptor blockade, therefore, would not appear to be involved in the induction of DB by typical APD.

377.7

D1/D2 DOPAMINE RECEPTOR INTERACTIONS IN THE NUCLEUS ACCUMBENS: THE ROLE OF cAMP IN ELECTROPHYSIOLOGICAL RESPONSES. P.A. Johansen and F.J. White. Dept. of Psychiat., Wayne St. Univ. Sch. Med. and Neuropsychopharmacol. Lab., Lafayette Clinic, Detroit, MI 48207.

We have previously reported that a sufficient level of D1 dopamine (DA) receptor stimulation is necessary for (enables) functional expression of postsynaptic D2 DA receptor stimulation. To explore further the nature of this enabling phenomenon, we used iontophoretic techniques to determine whether the D1 receptor responsible for enabling is coupled to adenylate cyclase (AC). Extracellular, single-unit recordings were obtained from the nucleus accumbens (NAc) of chloral hydrate anesthetized male rats. Dose-response curves for three D1 DA agonists exerting varying efficacies (≈24-70% efficacy as compared to DA) at stimulating cAMP formation were compared (SKF 75670, SKF 38393, SKF 81297). Preliminary results with these compounds indicate no differences in their ability to inhibit the firing of NAc neurons, suggesting that activation of AC may not be involved in the inhibitory effects of D1 agonists on NAc neurons, or that only a small activation (≤24%) is required to produce such effects. In additional studies, iontophoretic application of dibutryl-cAMP or 8-bromo-cAMP failed to potentiate (enable) quinpirole-induced inhibition of NAc neurons in DA-depleted rats. The present results suggest the possibility that the mechanism by which D1 receptor stimulation enables D2 mediated inhibition of NAc activity may not involve activation of AC.

377.8

WHOLE-CELL RECORDINGS FROM NEURONS ACUTELY ISOLATED FROM THE RAT SUBSTANTIA NIGRA ZONA COMPACTA N. L. Silva, C.M. Pechura, J. ffrench-Mullen, and J.L. Barker. Laboratory of Neurophysiology, NINCDS, NIH, Bethesda, MD 20892.

Neurons were acutely isolated from the substantia nigra zona compacta of 1-3 week old rats by enzymatic and mechanical dissociation according to the methods of Kay and Wong (J. Neurosci. Methods 16:227-238, 1986). This procedure yielded numerous ovoid and fusiform shaped cell bodies with 2-5 truncated processes. Their electrophysiological properties were investigated immediately following dissociation using whole-cell patch recordings at room temperature. Typically these neurons exhibited spontaneous single or burst firing with spike heights of 60-70 mV. Current clamp recordings revealed that these neurons maintain resting membrane potentials between -50-60 mV and input resistances of 400-600 MΩ. Following the application of TTX spiking was eliminated and evidence of an inward rectifier was observed. Interestingly, this conductance has not been observed in embryonic cultured dopamine neurons. A variety of inward and outward currents were examined under voltage clamp. Two sustained outward currents could be distinguished by their sensitivity to TEA or Co and Cd. A transient outward current which was inactivated at depolarized potentials, deinactivated at hyperpolarizing potentials and sensitive to 4-AP was also present. Two TTX insensitive inward currents which were sensitive to Cd could be distinguished as one was inactivated at more depolarized potentials (-40 mV) and was slowly inactivating over time. In some cells, CCK was observed to enhance an inward current. This peptide is known to modulate the dopamine autoreceptor *in vivo* and in tissue slice experiments.

Nigro-striatal neurons were also labelled *in vivo* by the retrograde transport of rhodamine microspheres. Investigation of cells isolated from these animals is currently in progress.

377.9

IDENTIFIED MESOACCUMBENS DOPAMINE NEURONS *IN VITRO*. S. Rayport, J. Monaco* and S. Sawasdikosol*. Depts. of Psychiatry and Anat. & Cell Biol., Ctr. for Neurobiol. & Behav., Columbia Univ. and NYS Psychiatric Inst., New York, NY 10032.

Dysfunction of mesolimbic dopamine neurons may underlie the schizophrenic psychosis. We have used retrograde labelling to identify these cells in midbrain cell cultures. The nucleus accumbens of neonatal rat pups was injected with rhodamine-coated latex microspheres (Katz *et al.*, 1984), the ventral tegmental area was isolated after 3 days, dissociated (Kay and Wong, 1986), the cells cultured, and studied after 1 week.

Microsphere-labelled cells *in vitro* had the morphology of dopamine cells; they were large, multipolar, and had eccentric nuclei (*cf.* Berger *et al.*, 1982). Tyrosine hydroxylase and catecholamine staining revealed that at least 85% of labelled cells were dopaminergic (*cf.* Swanson, 1982). Intrasomatic Lucifer Yellow injection showed that the cells had grown extensive processes, with varicosities likely to be presynaptic sites; often a single neighboring cell also fluoresced, suggestive of gap junctional connections. Microsphere-labelled cells showed a number of the properties characteristic of midbrain dopamine neurons: *(i)* broad action potentials, measuring 1.6 ± 0.2 msec, from peak to 1/e, *(ii)* hyperpolarizing afterpotentials, *(iii)* anomalous rectification, *(iv)* low-threshold depolarizations often triggering spike generation, and *(v)* responsiveness to exogenous dopamine. Adding physiological criteria, *living* dopamine neurons can be unequivocally identified. Studying synapses formed by these neurons should contribute to understanding of the function of central dopamine systems.

377.10

THE EFFECTS OF DOPAMINE ON CENTRAL AMYGDALA NEURONS, IN VITRO INTRACELLULAR RECORDING. M.C. Schiess, E. Asprodini* and P. Shinnick-Gallagher. Dept. Pharmacology, Univ. Texas Medical Branch, Galveston, TX 77550.

The central nucleus of the amygdala receives a vast amount of monoaminergic input and has one of the highest concentrations of dopamine (DA) in forebrain structures. Using 500 micron coronal slices from adult male rats and intracellular recording techniques, we characterized the effects of superfusing one micromolar DA and apomorphine (Apo) on the central amygdala neurons. DA hyperpolarized the membrane potential, decreased resistance and increased conductance in 41% of the cells tested (N=34) and 50% tested with Apo. The voltage-current (V-I) relationship between control and DA had an intercept at -110 mv suggesting hyperpolarization was mediated by an increase in potassium conductance. In another 40% of the neurons DA superfusion produced hyperpolarization (10/34) or no change (4/34) in resting membrane potential, increased conductance and decreased resistance (Apo 25%). The V-I relationship between control and DA did not intercept but rather displayed a parallel shift. In a small percentage of neurons (12%) DA depolarized the membrane and decreased conductance. According to their active properties there are two types of neurons in the central amygdala (N=100). The majority of neurons do not accommodate, approximately 15% accommodate despite stimulation with large cathodal pulses. Both neuronal types have prominent after-hyperpolarizations that are reduced by DA.

377.11

RESPONSE OF MEDIAL ZONA INCERTA NEURONS TO VENTROMEDIAL HYPOTHALAMUS (VMH) STIMULATION AND APPLICATION OF DOPAMINE: AN *IN VITRO* STUDY. M.J. Eaton and R.L. Moss Dept. of Physiol., Univ. Texas Southwestern Med. Ctr., Dallas, TX 75235

The zona incerta (ZI), located in the subthalamic region of the diencephalon, contains dopaminergic neurons which are believed to have autoreceptors. The ZI has been implicated in such diverse functions as drinking behavior, gonadotropin secretion and sexual behavior. Anatomical studies have shown afferent input into the medial ZI from the VMH, another brain region which plays a role in these functions. The present study was designed to investigate the relationship between the effect of afferent input from the VMH and the micropressure application of dopamine on the electrical activity of neurons in the medial ZI.

Transverse sections through the ZI were obtained from Sprague-Dawley female rats and maintained in a slice chamber with continuous perfusion of warmed, oxygenated artificial cerebrospinal fluid. Extracellular single cell recordings were made from 347 neurons located in the medial ZI. The effect of micropressure application of 0.1M dopamine HCL on the neuronal activity, as well as the orthodromic response to VMH stimulation, was determined for each neuron.

			Dopamine Response		
			None	+	-
Orthodromic (OD)	None	(n=264)	66%	3%	31%
Response type	OD+	(n=73)	44%	5%	51%
(# of neurons)	OD-	(n=10)	60%	10%	30%

These data indicate a large, predominantly excitatory (OD+), input from the VMH to the medial ZI. Many of the cells in this region are dopaminergic and are believed to be capable of autoregulation. The results show a large proportion of the cells which are orthodromically excited by stimulation are also inhibited by dopamine, suggesting that VMH neurons project to and synapse on dopaminergic neurons in the medial ZI. DOPAMINE AND HALOPERIDOL MODIFY LOW THRESHOLD CALCIUM SPIKE AND TRANSIENT CALCIUM CURRENT IN GUINEA PIG THALAMIC NEURONS *IN VITRO*. E. Geijo-Barrientos and R. Llinás (SPON: S. Simon) Dept Physiol. & Biophy. N.Y.U. Med. Ctr. NY, 10016

Recent neuropharmacological work has implicated thalamic dopaminergic receptors in the genesis of certain psychiatric conditions (Oke & Adams, Schiz. Bul.13:589,1987). We have investigated the effects of dopamine and Haloperidol, a dopamine antagonist, on the electroresponsive properties of Guinea Pig thalamic neurons *in vitro*. In particular,calcium-dependent spikes and voltage-dependent calcium currents were investigated in thalamic slices using current clamp and single electrode voltage clamp techniques. In this preparation DA, at concentrations of 200μM, increased the peak amplitude of the transient calcium current by 20-40%. Two other types of experiments have shed light regarding the mechanism of this effect. (1) Haloperidol, which is known to be a blocker of D2 dopamine receptors, decreased the peak amplitude of this current by 44 ± 7% at concentrations of 5-10μM. (2). Forskolin (which increases intracellular cAMP levels) also decreased the peak amplitude of this current by 42.5 ± 3.45% at concentrations of 10μM. These experiments show that the effect of the DA is not mediated via D1 receptors, which, by being coupled to adenyl-cyclase, should increase the intracellular levels of cAMP. The action of these drugs on the low threshold calcium conductance suggests that a class of psychotic events may be related to altered intrinsic electroresponsiveness in thalamic and other central neurons. Supported by NIH grant NS13742 and a Fellowship to E. G-B from the Generalidad Valenciana.

EFFECTS OF APAMIN ON THE MEMBRANE PROPERTIES OF PUTATIVE DOPAMINE-CONTAINING NEURONS IN VITRO. P.D. Shepard, and B.S. Bunney. Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06510.

Recent studies utilizing brain slice preparations have reported differences between the electrophysiological characteristics of putative dopamine (pDA)-containing neurons in vitro and those previously associated with identified cells in vivo, including a tendency for cells in the former group to exhibit an extremely regular discharge pattern. Recently, we reported that administration of apamin, a polypeptide neurotoxin, induced sustained irregular single spike and bursting activity identical to that observed to occur spontaneously in vivo (Shepard and Bunney, Soc. Neurosci., 13:909, 1987). In the present study, intracellular recording techniques were employed to characterize apamin-induced alterations in the membrane properties of pDA neurons in vitro. Bath application of apamin (1 μM) selectively blocked a prolonged post-spike afterhyperpolarization (AHP) which could be attributed to activation of a calcium-dependent potassium conductance (gK(Ca)). The toxin had no effect on spike repolarization but enhanced a shorter duration AHP which had been partially 'masked' by the apamin-sensitive component. Blockade of the slow component of the AHP was accompanied by an increase in repetitive firing during current injection and a reduction in the magnitude of the post-activational AHP. These results suggest that apamin-induced alterations in the spontaneous discharge pattern of pDA-containing neurons in vitro are attributable to inhibition of gK(Ca). ASSOCIATION OF TWO PERTUSSIS TOXIN SENSITIVE G-PROTEINS WITH THE D_2-DOPAMINE RECEPTOR FROM BOVINE STRIATUM. Z. Elazar*, G. Siegel*, C. David*, H. Kanety* and S. Fuchs (SPON: A.S. Gordon). Dept. of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel.

In studying the signal transduction mechanism of the D_2 dopamine receptor it was demonstrated that the solubilized receptor exhibits high and low affinity states for dopaminergic agonists. Guanine nucleotides and pertussis toxin can convert the solubilized receptor from a high affinity state to a low one. A D_2 receptor preparation from bovine striatum, partially purified by affinity chromatography on a haloperidol adsorbent, exhibited agonist stimulated GTPase activity. [^{32}P]-ADP-ribosylation by pertussis toxin of this receptor preparation resulted in the specific labeling of two protein bands corresponding to molecular weights of 39 and 41 kDa, in SDS-PAGE. Association of these G-proteins with the receptor was specifically inhibited by $Gpp(NH)_p$. Proteolytic fragmentation, immunoprecipitation and immunoblot analysis of these G-proteins, indicated that the 41 and 39 kDa protein bands are analogous to brain Gi and Go respectively. These experiments demonstrate that two distinct pertussis toxin sensitive G-proteins are functionally associated with bovine striatum D_2-dopamine receptor.

STIMULATION OF RAT STRIATAL GTPase BY ERGOLINES IN VITRO. J.D.Turner*, P.Marten*, K.-P.Gerbling* and H. Schneider* (SPON: L. Turski).
Research Laboratories of Schering AG (Berlin/Bergkamen), Neuropsychopharmacology, Müllerstraße 170-178, 1000 Berlin 65, F.R.G.
Many ergolines, with pharmacologically defined DA agonistic or antagonistic properties behave atypically in ligand binding assays. Accordingly, functional assays are required to characterise the dopaminergic properties of these substances in vitro. An assay recently proposed as specific for D2 agonism is the DA-stimulated GTPase detec table in striatal membranes (Onali, P. and Olianas, M.C., Biochem. Pharmacol. 36, 2839, 1987). In the present study, we have investigated the effects of some ergolines with differing pharmacological activity in this assay. In rat striatal membrane preparations, DA stimulated a "high affinity" GTPase dose dependently. This stimulation could be blocked by 100 nM haloperidol, but was unaffected by 100 nM Sch23390. Lisuride and pergolide (full D_2 agonists) stimulated GTPase activity in a haloperidol-sensitive manner. Terguride (a partial D_2 agonist) and proterguride (also reportedly a full D_2 agonist) both elicited bell-shaped response curves. Whether these results reflect different modes of interaction with DA receptors or interaction with different receptors (e.g. adrenergic, serotonergic) is currently being investigated.

378.4

DOPAMINE (DA) AGONIST PROFILE AT SYNTHESIS MODULATING DA AUTORECEPTORS (AR) IN STRIATAL SLICES, D. Clark*[1], E.A. Novak*, B.N. Mathews*, R.S. Salah, and M.P. Galloway (SPON: D.M. Kuhn) [1]Univ. Reading, Reading, UK, Wayne State Univ. Sch. Med. & Lafayette Clinic, Detroit, MI 48207

Utilizing striatal brain slices, we have developed an *in vitro* model to study synthesis modulating DA ARs. For eg., Salah et al. (this meeting) used this preparation to demonstrate that stimulation of DA ARs directly modulates the phosphorylation of tyrosine hydroxylase. Using several DA agonists from distinct chemical classes, we found that potencies (EC_{50}'s) obtained *in vitro* generally parallel those obtained in other AR models. Indeed, compounds such as (-)-3PPP and TDHL, previously defined as partial AR agonists, exhibit typical agonist character under basal conditions whereas their partial agonist character becomes evident after increasing extracellular DA. Notable, however, are differences among agonists in their intrinsic activity, i.e., the maximum inhibition of basal synthesis. Catechol containing compounds such as APO, DA, di-OH-aminotetralins, and SKF-38393 produce >90% inhibition whereas ergolines such as quinpirole decrease basal rates by 50% maximum. Although direct inhibition of TH by catechols may contribute to the net effect, the mono-OH aminotetralins (±)-7- and 5-OH-DPAT also exhibit 80-90% inhibition. This characteristic, combined with well-defined stereochemistry of the OH-DPATs, makes these AR agonists useful to define the *in vitro* AR model. Support: USPHS DA-4120, MH-41227, Mich. Dept. Mental Health.

NIGROSTRIATAL DOPAMINE AUTORECEPTORS INHIBIT TRANSMITTER SYNTHESIS BY DECREASING THE PHOSPHORYLATION OF TYROSINE HYDROXYLASE. R.S. Salah, D.M. Kuhn and M.P. Galloway. Depts. Pharmacology and Psychiatry, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

The *in situ* activity and phosphorylation of tyrosine hydroxylase (TH) was studied in rat striatal slices. TH activity was monitored by measuring the accumulation of dihydroxyphenylalanine (DOPA) in the presence of a decarboxylase inhibitor. TH phosphorylation was ascertained by SDS-PAGE and autoradiography after immunoprecipitation of TH with rabbit anti-TH serum. Incubation of slices in the presence of K^+ (55 mM), forskolin (10 uM), dibutyryl-cAMP (1 mM), or 8-bromo cGMP (100 uM) results in an increase in the activity and phosphorylation of TH. The dopamine (DA) autoreceptor agonist pergolide (3-10 uM) inhibits both basal and K^+-stimulated phosphorylation of TH. This change is accompanied by parallel changes in TH activity. The effect of pergolide is blocked by the selective D_2 antagonist eticlopride. In slices prepared from rats pretreated with intrastriatal injections of pertussis toxin, the inhibitory effect of pergolide was greatly diminished. These results are consistent with the hypotheses that 1) nerve terminal DA autoreceptors in the rat striatum are negatively coupled to adenylate cyclase, and 2) inhibitory effects of DA autoreceptor agonists on TH activity are due to a decrease in cAMP-mediated phosphorylation. Supported by MH 09673 (RSS), DA 04120 (MPG), and the State of Michigan.

378.6

STIMULATION OF DOPAMINE (DA) AUTORECEPTORS BY EMD 49,980. K. Harada[1]*, H. Yokoo[1]*, K. Tsuda[1]*, M. Goldstein[1] and E. Meller[2]. N.Y. Univ. Med. Ctr., New York, NY 10016, Neurochem. Res. Labs[1] and Millhauser Labs[2].

We have previously reported that EMD 23,448 has a selective DA action on presynaptic and supersensitive postsynaptic DA receptors (Goldstein et al., J. Neural Transm. 70:193, 1987). As a continuation of our studies we have examined the effects of EMD 49,980, a 5-hydroxy derivative of EMD 23,448, on DA autoreceptors regulating synthesis and release of DA. EMD 49,980 dose-dependently (0.01-0.5 mg/kg, i.p.) inhibited γ-butyrolactone-enhanced striatal dopa synthesis. Following partial inactivation of DA receptors with N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (2 mg/kg) the IC_{50} for EMD 49,980 was shifted to the right, suggesting the presence of a receptor reserve at the DA autoreceptors. The electrically stimulated release of ^{3}H-DA from striatal slices was inhibited by EMD 49,980 at concentrations of 0.01-1uM. However, in the presence of the DA uptake inhibitor nomifensine (10 uM), EMD 49,980 did not inhibit the electrically stimulated release of ^{3}H-DA. The increased concentration of DA in the synapse in presence of nomifensine may diminish the DA agonist activity of EMD 49,980. The results of this study show that EMD 49,980 is a partial DA agonist whose potency is dependent on the synaptic concentration of DA. Supported by NIH grants NS-06801-21 and NS 23618.

COMPARISON OF RECEPTOR RESERVE AT DOPAMINE (DA) AUTORECEPTORS IN RAT STRIATUM, NUCLEUS ACCUMBENS AND OLFACTORY TUBERCLE. K. Bohmaker,* T. Puza,* M. Goldstein and E. Meller (SPON: J.C. Miller). Dept. of Psychiatry, NYU Medical Center, New York, NY 10016.

D2 DA autoreceptors in rat striatum which mediate local negative feedback inhibition of neurotransmitter synthesis show a large receptor reserve for N-propylnorapomorphine (NPA) (Meller et al., Mol. Pharmacol. 31:592-598, 1987), whereas postsynaptic striatal D2 receptors do not (Meller et al., this meeting). It was therefore of interest to determine whether DA autoreceptors in other brain regions (e.g. mesolimbic areas) also possess spare receptors for the full agonist NPA. Dose-response curves were obtained for NPA reversal of γ-butyrolactone (GBL)-induced L-DOPA accumulation in control and EEDQ (6 mg/kg)-treated rats. In control rats, the ED_{50}'s for NPA were 1.24, 0.44 and 0.34 ug/kg in striatum (STR), nucleus accumbens (NAS) and olfactory tubercle (OT), respectively. In EEDQ-treated rats the corresponding values were 3.36, 1.44 and 3.65 ug/kg. After EEDQ treatment, NPA maximally reversed the GBL-induced increase in L-DOPA levels by 57, 79 and 100% in STR, NAS and OT, respectively. Analysis of the results indicated that the DA autoreceptors in all three areas display non-linear receptor occupancy vs. response relationships for NPA; mesolimbic autoreceptors appear to have an even larger receptor reserve than striatal autoreceptors. Supported in part by PHS grants NS 23618, MH 02717 and MH 35976.

SCH 39166 HCl: A SPECIFIC D_1 RECEPTOR ANTAGONIST WITH ANTI-PSYCHOTIC POTENTIAL. L.C. Iorio, V. Ruperto*, M. Grzelak*, V. Coffin*, R.E. Chipkin and A. Barnett, Schering Corp., Dept. Pharmacology, 60 Orange Street, Bloomfield, NJ 07003, USA

This report is on a new D_1 antagonist, SCH 39166 (-)-trans-6,7,7a,8,9,13b-hexahydro-3-chloro-2-hydroxy-N-methyl-5H-benzo[d]-naphtho-[2,1b]-azepine-HCl (SCH). In vitro, SCH potently blocked D_1 receptors (Ki=2nM) and DA-stimulated adenylate cyclase activity (Ki=9nM). SCH was 250 fold less potent at D_2 receptors (Ki=512nM) and 75 fold less potent at 5HT2 receptors (Ki=151nM). In vivo, SCH inhibited conditioned avoidance responding in both rats (MED=10 po) and squirrel monkeys (MED=5 po) with a long duration of action; this is indicative of potential anti-psychotic activity. These in vivo effects are probably not due to D2 receptor blockade since SCH did not cause hyperprolactinemia in rats and did not block apomorphine-induced emesis in dogs. SCH increased dopamine turnover but only to levels 50-70% greater than baseline; in contrast, haloperidol increased levels by >300%. In summary, SCH is a specific D_1 antagonist both in vitro and in vivo with potent, long-lasting anti-CAR effects and is a potential novel anti-psychotic.

378.9

CHARACTERIZATION OF THE BINDING OF SCH 39166 TO D-1 RECEPTORS IN VIVO. R.D.McQuade, R.A.Harney* & R.E.Chipkin. Schering Corp., Bloomfield NJ 07003.

SCH39166 ([-]trans-6,7,7a,8,9,13b-hexahydro-3-chloro-2-hydroxy-N-methyl-5H-benzo[d]naphtho-{2,1b}azepine), a new D-1 selective antagonist, has been analyzed for binding to D-1 receptors, in vivo. Rats receive a single s.c. injection of ^{125}I-SCH38840 (SCH23982) in the presence of increasing doses of SCH39166; after 1 h, the striata and cerebellum are removed and counted. SCH39166 inhibits striatal specific binding of ^{125}I-SCH38840, with an IC_{50} of 11.4 ± 3.9 nmoles. This value is nearly 4 x higher than that observed for SCH23390 (3 nmoles) and correlates well with the relative affinities of the molecules in vitro. However, SCH23390 inhibits greater than 90% of the striatal binding of ^{125}I-SCH38840, whereas 1 umole of SCH39166 displaces only 75% of the bound ligand. The remaining binding is not affected by higher doses of SCH39166 or by 3 nmoles of SCH23390, but 10 umoles of ketanserin, a 5HT-2 antagonist, significantly decreases the residual binding of ^{125}I-SCH38840. Thus, SCH39166, unlike SCH 23390, does not interact with 5HT-2 receptors in vivo. This study shows that SCH39166 selectively labels striatal D-1 receptors in vivo.

378.10

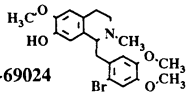
THE SELECTIVE D1 ANTAGONIST, SCH 23390 (SCH) DOES NOT INDUCE EXTRAPYRAMIDAL SIDE EFFECTS (EPS) IN CEBUS MONKEYS. VL Coffin*, MB Latranyi* and RE Chipkin, Schering Corp., 60 Orange St., Bloomfield, NJ 07003.

The following study evaluated the EPS liability of a D_1 antagonist SCH vs the predominantly D_2 selective antagonist, haloperidol (HAL). Cebus monkeys were given either vehicle (N=6), SCH (10 mg/kg po, N=9) or HAL (0.3 mg/kg po N=9) once a week. A Primate Observational Scale was developed and used to measure changes from normal behavior as well as occurrence of EPS. Both drug treatments produced significant increases in sedation scores which were equivalent in magnitude. Through 25 weeks of dosing, monkeys receiving SCH did not show any EPS. In contrast, by week 3, the HAL monkeys were significantly different from the VEH and SCH groups for EPS, and by week 13 all HAL monkeys showed severe EPS. In agreement with prior work, these animals are defined as 'primed' monkeys and also show EPS for the highly selective D2 antagonist, sulpiride (30 po), and for the classic neuroleptic, chlorpromazine (3.2 po). No EPS was seen when SCH (10 po) or the atypical neuroleptic, clozapine (20 po), were given to these recently 'primed' monkeys. These data confirm previous observations of D_2-induced EPS in cebus monkeys, and further demonstrate D_1 antagonists like SCH are unlikely to produce these side-effects.

378.11

A-69024 A NON-BENZAZEPINE D-1 SELECTIVE ANTAGONIST. D. J. Kerkman*, M. Ackerman*, L. D. Artman*, K. Asin, L. Bednarz*, M. C. Johnson*, R. G. MacKenzie, W. Montana, H. Stampfli* and J. W. Kebabian. Neuroscience Research Division, Pharmaceutical Discovery, Dept. 47U, Abbott Laboratories, IL 60046.

We report that A-69024 is an antagonist of the D-1, but not the D-2, dopamine receptor. Radioligand binding studies using rat striatum shows A-69024 (HBr) to have an apparent affinity toward the D-1 receptor of 12.9 *n*M (identified using [^{125}I]-SCH 23390), and an apparent affinity toward the D-2 receptor > 10 μM (identified using [^{125}I]-*N-p*-aminophenethylspiperone). In functional assays, A-69024 (HBr) is an antagonist of the D-1 receptor in fish retina (K_i = 48.3 *n*M) and the D-2 receptor in rat intermediate lobe (K_i = 728 *n*M); A-69024 (HCl) is an antagonist of rat striatum D-1 receptor (K_i = 12.3 *n*M). A-69024 (HBr), at a dose of 5 mg/kg *sc*, blocks amphetamine-induced locomotor activity and stereotypy, and SKF 38393- (but not LY 171555-) induced rotation in 6-OHDA lesioned animals; however, at this dose the compound does not increase serum prolactin levels or potentiate DOPA accumulation in rats pretreated with the DOPA decarboxylase inhibitor NSD 1015. Thus, A-69024 can discriminate between the D-1 and D-2 dopamine receptors and, therefore, may be a useful research tool complementing observations made with other D-1 agonists and antagonists.

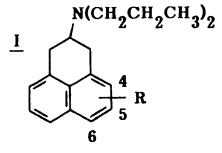


A-69024

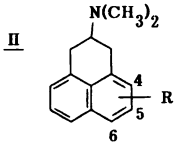
378.12

DOPAMINE AGONIST AND ANTAGONIST ACTIVITIES OF A SERIES OF SUBSTITUTED DIHYDROPHENALENES. A.H.Tang, S.R.Franklin, R.A.Code*, W.H.Darlington*, and J.Szmuszkovicz*. CNS Research, The Upjohn Company, Kalamazoo, MI 49001.

U-66444B (Ic) was reported to have presynaptic dopamine agonist activities (VonVoigtlander et al., 1987). Some closely related analogs are found to be either potent dopamine agonists or antagonists. The following compounds are emetic in dogs: Ia, Ic, Id, IIc, and IId. IIa and IIb are not emetic, but block apomorphine (Apo)-induced emesis. In rats trained to avoid shock in a shuttle box, Ia, Ic, Id, and IIc facilitate avoidance and increase movements between trials. IIa and IIb block avoidance and antagonize Apo-induced stereotypy. Neither compound produces catalepsy. In rhesus monkeys trained to discriminate 0.1 mg/kg of Apo from saline, both compounds block the discriminative stimulus effect of Apo. The dopamine agonist/antagonist activities in this series, therefore, depend critically on the position of the hydroxy group and the amino substitutions.



R = H, Ia, IIa
R = 5-OH, Ic, IIc



R = 4-OH, Ib, IIb
R = 6-OH, Id, IId

378.13

NO-112, NO-756 - NEW DOPAMINE D1 SELECTIVE ANTAGONISTS

Peter H. Andersen†, F.C. Grønvald°*, R. Hohlweg°*, L.B. Hansen°*, E. Guddal°* and C. Braestrup†*.
†Department of Pharmacology, and °Medical Chemistry Lab. II, NOVO Industri A/S, Pharmaceuticals R&D, DK-2880 Bagsvaerd, Denmark.

NO-112 and NO-756 are new benzazepine derivatives. In vitro, NO-112 and NO-756 exhibit a K_i for the D1 receptor of 0.2 nM and inhibit dopamine-stimulated adenylate cyclase with a K_i of 2.5 nM. Corresponding values for SCH 23390 were 0.2 and 40 nM, respectively. NO-112 and NO-756 have also high affinity for the 5-HT_2 receptor (K_i-values of 18 and 4 nM, respectively). The iodina-ted analog of NO-756, i.e. NO-673, had similar affinity for both D1 and 5-HT_2 receptors (K_i=3.6 and 7.2 nM, respectively). In accordance, ^{125}I-NO-673 labelled in vitro and in vivo both D1 and 5-HT_2 receptors.

In conclusion, NO-112 and NO-756 are members of a new series of benzazepines with high affinity for the D1 receptor, but as compared to SCH 23390 with relatively higher affinity for the 5-HT_2 receptor and dopamine-stimulated adenylate cyclase. The latter characteristics equivalate to some extent those of clozapine i.e. NO-112 and NO-756 may have atypical neuroleptic characteristics like clozapine.

378.14

NO-112 AND NO-756, NEW POTENT BENZAZEPINE D-1 ANTAGONISTS: PHARMACOLOGICAL CHARACTERIZATION

E.B.Nielsen, L.B. Hansen*, F.C. Gronvald*, R. Hohlweg*, E. Guddal*, P.H. Andersen, NOVO Industri A/S, Pharmaceuticals R&D, DK-2880 Bagsvaerd, Denmark.

NO-112 and NO-756 ((+)-8-chloro-7-hydroxy-3-methyl-5(7-benzofuranyl)-2,3,4,5,tetrahydro-1H-3-benzazepin and (+)-8-chloro-7-hydroxy-3-methyl-5(7-dihydrobenzofuranyl)-2,3,4,5, tetrahydro-1H-3-benzazepin) are new selective D-1 receptor antagonists (see Andersen, P.H. et al., this meeting). The drugs inhibited amphetamine-induced discriminative effects in very low doses (0.02 mg/kg) and also blocked methyl-phenidate or amphetamine-induced stereotyped behavior, conditioned avoidance responding and D-1 receptor mediated rotational behavior in the same low doses. These effects were obtained at lower D-1 receptor occupancy in vivo when compared with the occupation of D-2 receptors required for obtaining the same effects. When coupled with a large body of data implicating a potential role for D-1 receptors in controlling psychosis, the profile of NO-112 and NO-756 suggests that they may exert anti-psychotic action in the clinic.

378.15

ELECTROPHYSIOLOGICAL AND METABOLIC EFFECTS OF (+)-AJ 76, A SELECTIVE ANTAGONIST OF DOPAMINE AUTORECEPTORS. W.E.Hoffmann, J.T.Lum, and M.F.Piercey, The Upjohn Company, Kalamazoo, MI 49001.

Svensson et al. report that (+)-AJ 76 and (+)-UH 232 are selective antagonists of dopamine (DA) autoreceptors (Naunyn Schmeideberg 334:234, 1986). We describe here 1) the antagonism of DA autoreceptor stimulation in substantia nigra pars compacta (SNPC), and 2) the use of 2-deoxyglucose (2-DG) autoradiography to map the neuroanatomical distribution of (+)-AJ 76 effects. DA neurons of chloral hydrate anesthetized rats were depressed by stimulation of autoreceptors with 100 ug/kg apomorphine (APO). (+)-AJ 76 and (+)-UH 232 reversed APO effects with ED50's of 480±233 and 103±53 ug/kg, respectively. The greater potency for (+)-UH 232 as an autoreceptor antagonist contrasts with its weaker stimulant effects (Svensson et al., ibid) suggesting that, compared to (+)-AJ 76, it is a less specific antagonist for autoreceptors. Pretreatment with either antagonist elevated APO's ED50. (+)-AJ 76 did not alter firing rates of 5-HT neurons in dorsal raphe. Using standard 2-DG protocol (Sokoloff et al., J. Neurochem. 28:897, 1977), 15 mg/kg i.v. (+)-AJ 76 injected 5 min prior to 2-DG increased glucose metabolism in SNPC, VTA, globus pallidus, and n. accumbens, sites also stimulated by dopamine agonists. Locus coeruleus metabolism was also increased. Like dopamine postsynaptic antagonist antipsychotics, (+)-AJ 76 stimulated the lateral habenula. It is concluded that (+)-AJ 76 is a selective DA autoreceptor antagonist.

RESPIRATORY REGULATION III

379.1

DEVELOPMENT OF A THICK MEDULLARY SLICE PREPARATION FOR THE STUDY OF RESPIRATORY RHYTHM GENERATION. H. McLean and J. Remmers, Departments of Medicine and Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

The location of neurons critical to the generation and maintenance of respiratory rhythm is unknown. We have developed a preparation from the brainstem of the neonatal rat (1-3 days old) in which diffusion distances are considerably reduced but respiratory activity and chemosensitivity are maintained. The preparation consists of a thick slice of brainstem extending 1 mm rostral and 1 mm caudal to the obex. Respiratory activity is recorded from the rostral hypoglossal nerve roots. The preparation is maintained at 32°C, superfused with mock CSF equilibrated with 95% O_2 and 5% CO_2 and is viable for approximately 4 hours. The thick slice preparation demonstrates more rapid and pronounced frequency responses to alterations in superfusate PCO_2 than the "intact" in vitro brainstem-spinal cord preparation, suggesting better diffusive accessibility of CO_2 to the central chemoreceptor. Preliminary experiments indicate that ventral regions of the medulla contain neural elements adequate for rhythm generation and chemosensitivity. In addition, when the rostral aspect of the medulla is removed, the frequency of respiratory rhythm is decreased suggesting that this area contains a frequency promoting region. This preparation presents a potentially useful model for investigation of the neural substrate for respiratory rhythm generation.

Supported by grants MRC #MA-9719 and CFSID.

379.2

LOCALIZATION OF A MEDULLARY AREA SENSITIVE TO CHANGES IN CO_2 IN IN VITRO BRAINSTEM-SPINAL CORD PREPARATION OF NEWBORN RATS. F. Issa* and J. Remmers. Dept of Medicine, Univ of Calgary, Calgary, Alberta, Canada T2N 4N1.

The exact location of the central chemoreceptor has not yet been determined. The in vitro brainstem-spinal cord preparation of 1-3 day old rats was used to identify areas within the medulla sensitive to changes in CO_2. The preparation was superfused with a mock CSF solution equilibrated with 5% CO_2-95% O_2 and kept at 28±1°C. A specially constructed compound glass micropipette with a tip diameter of 12-15 μm was used. The micropipette was filled with a mock CSF solution which was equilibrated with 100% CO_2. It was advanced in 50 μm steps into the ventral surface of the medulla using a stepping microdrive. At each depth, pressure ejection of 2-10 nl of CO_2-enriched mock CSF solution was performed while the inspiratory activity of C2-C4 ventral rootlets was continuously monitored. Slowing of breathing from a control of 10-15 to 1-5 bursts/min was observed with ejections made at depths of 0-200 μm in the area bound by hypoglossal nerve rootlets. An immediate and profound increase in breathing rate and amplitude of integrated C2-C4 neural activity occurred with injections in an area 0.50-0.75 mm lateral to midline, 0.5-0.8 mm rostral to the obex and at a depth of 0.25-0.35 mm from the ventral surface of the medulla. We conclude that neuronal elements in the medulla rostral to the obex, sense a change in PCO_2 and augment breathing.

INTERACTIONS BETWEEN THE A-CURRENT AND CALCIUM CURRENT IN BULBOSPINAL NEURONS IN THE VENTRAL PART OF THE NUCLEUS TRACTUS SOLITARIUS. M.S. Dekin, T.H. Morgan School of Biological Sciences, Univ. of Kentucky, Lexington, KY 40506

The Dorsal Respiratory Group in guinea pigs is located within the ventral part of the nucleus tractus solitarius (ventral NTS). Two classes of bulbospinal neurons, termed types I and II, have been identified within the ventral NTS. Both classes of cells express A-current (I_{KA}) and calcium current (I_C). During depolarization, interactions between I_C and I_{KA} will affect repetitive firing activity. In type I neurons, this interaction is manifest as a low frequency burst of spike activity while in type II neurons a long delay is seen between the onset of depolarization and the beginning spike activity. Using brainstem slices from adult guinea pigs and the single electrode voltage clamp technique, the contribution of I_C and I_{KA} to these repetitive firing patterns was studied. In type I neurons I_{KA} was activated at membrane potentials below spike threshold. In type II neurons I_{KA} was activated at membrane potentials which straddled spike threshold. I_C in type I neurons was activated at membrane potentials just below spike threshold while in type II neurons I_C was only observed at membrane potentials more positive than threshold. These data show that I_{KA} and I_C in type I neurons will compete for control of the membrane potential at spike threshold. In type II neurons I_{KA} would be activated at threshold without I_C, allowing it to dominate the membrane potential. (Supported by NIH Grant HL-39929).

***IN VITRO* INTRACELLULAR RECORDINGS IN RAT NUCLEUS TRACTUS SOLITARII AND NUCLEUS AMBIGUUS DURING HYPERCAPNIA.** **J.B. Dean, W.L. Lawing* and D.E. Millhorn. Dept. of Physiology and Curriculum in Neurobiology, UNC, Chapel Hill, NC 27599.**

In vitro intracellular recordings from cells in two respiratory-related areas, nucleus tractus solitarii(NTS) and nucleus ambiguus (NA), were made before and during exposure to hypercapnia(7, 10 and 15%CO_2). Intact & "dorsal" coronal slices prepared from rat were maintained in a humidified interface chamber(5%CO_2, 35-37°C). Most cells in NTS were unaffected or slightly hyperpolarized by CO_2. However, some NTS cells were depolarized and increased their activity during CO_2 in both regular and high Mg^{2+}/low Ca^{2+} synaptic blockade media. In some cases concomitant increases in input resistance were noted during CO_2-induced depolarization. This suggests the depolarization is due to a decreased K^+ conductance. Cells in NA were either hyperpolarized or unaffected by CO_2. Our findings show that a subpopulation of NTS cells are depolarized by CO_2/H^+. Although we cannot guarantee the specific function of these cells, we believe they may be involved in respiratory CO_2/H^+ chemoreception. CHARACTERISTICS OF POST-INHIBITORY REBOUND IN NEURONS WITHIN THE NUCLEUS AMBIGUUS OF ADULT GUINEA PIGS. S.M. Johnson* and P.A. Getting, Department of Physiology and Biophysics, University of Iowa, Iowa 52242

We are interested in the intrinsic properties of neurons that participate in the formation of the respiratory motor pattern in mammals. The Nucleus Ambiguus (NA) contains a concentration of heterogenous respiratory-related neurons including bulbospinal neurons, propriobulbar neurons, and vagal and glossopharyngeal motor neurons. The intrinsic properties of NA neurons were assessed by recording intracellularly (N= 150 cells) from transverse brainstem slices (350-400 microns thick, 0.5-1.5 mm rostral to the obex) of adult guinea pigs.

Following a 200-500 msec hyperpolarizing prepulse, post-inhibitory rebound (PIR) was expressed as a transient depolarization that could give rise to a spike or burst of spikes. PIR was observed in > 50% of the neurons. In the presence of TTX (0.5 ug/ml), PIR had a magnitude of 7-12 mv, a time to peak of 15-35 msec, and a duration of 150-200 msec. The magnitude of PIR depended on both the prepulse voltage and the test voltage (i.e. voltage to which the cell was released). The magnitude of PIR increased linearly as the prepulse voltage was made more negative (approx. 0.25 mv PIR/mv of hyperpolarization). At a constant prepulse voltage, the magnitude of PIR increased as the test voltage was made more positive (approx. 0.45 mv PIR/mv depolarization) until a maximum was reached at -55 to -60 mv.

The expression of PIR was enhanced by thyrotropin-releasing hormone (TRH, 100 nM). Under voltage clamp, however, the current underlying PIR was not affected by TRH. TRH modulation, therefore, must be mediated indirectly by depolarizing the cells or by decreasing the membrane conductance.

SEROTONIN IMMUNOREACTIVE BOUTONS MAKE CLOSE CONTACTS WITH FELINE PHRENIC MOTONEURONS. J.Lipski*, P.M.Pilowsky*, M.D.Voss* and D.de Castro*. (SPON: R.Milne) Department of Physiology, University of Auckland, New Zealand.

There is a large body of evidence indicating that serotonergic mechanisms are involved in the central control of respiration. It has been suggested that this involvement only occurs indirectly, through an action by serotonin-containing neurons onto medullary respiratory neurons. In the present study we have investigated the possibility of a direct input by serotonergic neurons onto phrenic motorneurons.

Cats were anaesthetized with nembutal, and prepared for intracellular recording from antidromically identified phrenic motorneurons. Neurons were filled with Horseradish Peroxidase (10%, 2-10nA, 5-15min). After intravascular fixation and sectioning, filled neurons were detected with the diaminobenzidine-nickel reaction. The sections were then stained to reveal serotonin-like immunoreactivity using the Avidin-Biotin technique and the diaminobenzidine-imidazole reaction,. Phrenic motorneurons were well stained with the procedure used, and showed a dendritic arborization that extended for two to three millimetres rostrocaudally. Numerous serotonin immunoreactive boutons were found to make close contacts with identified phrenic motorneurons. These contacts were generally found on dendrites, and only occasionally on cell bodies. The results support the idea that serotonergic neurons may act directly on phrenic motorneurons.

SEROTONIN IMMUNOREACTIVE TERMINALS ARE INVOLVED IN SYNAPTIC CIRCUITS WITH PHRENIC MOTONEURONS. J.R. Holtman Jr. and B.E. Maley, Dept. of Pharmacology and Dept. of Anatomy and Neurobiology, Univ. KY Med. Ctr., Lexington, KY 40536

A number of neurotransmitters, including serotonin, are presumed to play a role in the control of the output of phrenic motoneurons to the diaphragm. In the present study we report the anatomical localization of serotonin synaptic terminals on phrenic motoneurons in the cat using the double labelling technique of retrograde transport of HRP and EM immunocytochemistry. At the ultrastructural level both phrenic motoneurons and serotonin terminals were easily identifable. Serotonin immunoreactivity appeared as a diffuse reaction product throughout the cytoplasm of the synaptic terminal, while phrenic motoneurons retrogradely labelled with HRP contained distinctive spicules in the cytoplasm of the neuronal cell body and its dendrites. The serotonin immunoreactive terminals contained a mixture of small, clear vesicles and occasional larger, dense core vesicles. The terminals were in synaptic contact with both the cell body and dendrites of phrenic motoneurons. These anatomical findings are indicative of a direct serotonergic innervation of the phrenic motor nucleus

GABA IMMUNOREACTIVE TERMINALS CONTACT PHRENIC MOTONEURONS. D.A. Vascik*, B.E. Maley, and J.R. Holtman Jr., Dept. of Anatomy and Neurobiology and Dept. of Pharmacology, Univ. of Kentucky Med. Ctr., Lexington, KY 40536.

GABA is a major inhibitory neurotransmitter which has a widespread distribution in the central nervous system. In the present report we describe its distribution in the phrenic motor nucleus of the cat both at the light and electron microscopic levels. Using a combination of immunocytochemistry and retrograde transport of HRP we were able to demonstrate that GABA immunoreactive terminals contact phrenic motor neurons that innervate the diaphragm.

GABA immunoreactivity is localized within puncta and small neurons throughout the the phrenic motor nucleus at the light microscopic level. At the ultrastructural level GABA immunoreactivity was located as diffuse reaction product within terminals containing small, clear vesicles that were in synpatic contact with neurons and all parts of their dendritic tree. GABA immunolabelled terminals contacted both HRP retrogradely labelled neurons and unlabelled neurons.

The presence of GABA immunoreactive terminals that contact phrenic motoneurons provides morphological evidence that GABA is involved in synaptic circuits that control the movement of the diaphragm. Supported by NIH grant NS23861 (B.E.M.) and NIH grants HL36050 and HL37146 (J.R.H.)

MICROINJECTION OF A GABA ANTAGONIST INTO THE POSTERIOR HYPOTHALAMUS BLOCKS THE RESPIRATORY RESPONSE TO BARORECEPTOR STIMULATION. G.H. Dillon*, C.A. Doyle* and T.G. Waldrop*.(SPON: M. Holzwarth). Dept. of Physiology, Univ. of Illinois, Urbana, IL 61801.

Prior work has shown that microinjections of a GABA antagonist into the posterior hypothalamus attenuate baroreflex bradycardia. The purpose of the present study was to determine if a similar mechanism modulates the respiratory response to baroreceptor stimulation (baro. stim.) in anesthetized rats. Respiratory responses to baro. stim. (elicited by increases in arterial pressure induced by phenylephrine injections) were determined before and after unilateral microinjections (50-100 nl) into the posterior hypothalamus (PH). Breathing frequency (f) and respiratory drive (Demg) were derived from diaphragmatic EMG recordings. During control conditions, baro. stim. elicited a decrease in f (-9 breaths/min) and a 7% fall in Demg. Microinjections of a GABA antagonist (picrotoxin, 5 ng/nl) into the PH produced increases in respiratory activity and blocked both the fall in f and Demg produced by baro. stim. These effects were reversed by PH microinjections of a GABA agonist (muscimol, 5 ng/nl). Microinjections of a GABA synthesis inhibitor (3-mercaptopropionic acid) also blocked the frequency response to baro. stim. We conclude that a GABAergic mechanism in the PH modulates the respiratory responses to baroreceptor stimulation. (Supported by NIH HL38726).

379.10

BENZODIAZEPINES POTENTIATE POSTSYNAPTIC INHIBITIONS IN BULBAR RESPIRATORY NEURONS OF CATS. R. Takeda and A. Haji*, Dept. of Pharmacol., Fac. of Med., Toyama Med. & Pharmaceut. Univ., Toyama 930-01, Japan.

We have studied the effect of benzodiazepines on the inhibitory postsynaptic potentials (IPSPs) and on the hyperpolarizing response to iontophoresed γ-aminobutyric acid (GABA) in bulbar respiratory neurons obtained from decerebrate, paralyzed cats. Diazepam (0.05-0.1 mg/kg i.v.) hyperpolarized the membrane in all inspiratory and postinspiratory neurons penetrated in the ventral respiratory group. Waves of IPSPs occurring during "inactive" phase of the respiratory cycle substantially increased and the input resistances decreased at that phase of each neuron. The effect during "active" phase include hyperpolarization associated with reduction of the input resistance, a decrease in the firing rate and shortening of the burst duration. Diazepam had no effect on the excitatory postsynaptic potentials induced either by the vagal or the spinal cord stimulation, whereas it increased the stimulus-induced IPSPs. Iontophoresis of flurazepam enhanced hyperpolarization induced by iontophoresed GABA. These results document that benzodiazepines potentiate specifically the phasic and tonic postsynaptic inhibitions in bulbar respiratory neurons, at least part of which are mediated by GABA.

SYSTEMIC ADMINISTRATION OF THE N-METHYL-D-ASPARTATE ACID (NMDA) RECEPTOR ANTAGONIST, MK-801 PRODUCES PRONOUNCED CHANGES IN CARDIORESPIRATORY FUNCTION. T.P.Abrahams*, R.A. Gillis*, P.Hamosh*, and A.M.Taveira da Silva*. (SPONS: Y. Tizabi). Departments of Pharmacology, Physiology and Medicine, Georgetown University Medical School, Washington D.C. 20007.

Because of the potential role of CNS excitatory amino acids in the control of cardiorespiratory function, we evaluated the effects of MK-801 on several indices of cardiorespiratory activity in chloralose-anesthetized cats. I.V. doses of 0.03, 0.1, 0.3 and 1mg/kg produced decreases in respiratory minute volume (VE) of 45±19, 145±25, 285±55 and 325±98 ml/min, respectively. The decrease in VE was due to both decreases in tidal volume (VT) and respiratory rate (f). The decrease in f was due to prolongation of inspiratory duration (Ti) as MK-801 (0.03, 0.1, 0.3 and 1mg/kg) increased Ti by 0.5±0.1, 0.8±0.1, 1.8±0.3 and 1.6±0.4 seconds respectively. The higher doses of MK-801 caused apneustic breathing and apnea. Biphasic changes in arterial pressure (BP) occurred that were dose-related. An initial increase (within 1 min) followed by a later decrease in BP (after 5 min of drug administration) were observed. No significant changes in heart rate were noted. These results indicate that NMDA receptor blockade with MK-801 causes respiratory depression and significant changes in BP (supported by MH42322).

ANTAGONISM OF THE RESPIRATORY EFFECTS OF SOMAN BY CLONIDINE AT THE LEVEL OF THE VENTRAL-LATERAL MEDULLA IN THE CAT. D.P. Walton*, R.A. Gillis*, P. Hamosh* and K.L. Dretchen (SPON: A. Raines). Depts. Pharmacol. & Physiol., Georgetown Univ. Med. Ctr., Washington, DC 20007.

It has been reported that systemic administration of clonidine will protect rodents against the toxic effects of soman (GD) (Buccofusco, 1986). Since GD exerts respiratory effects at the intermediate area on the ventral surface of the medulla (VSM) (Gillis et al., 1987), we determined whether GD-induced respiratory changes could be counteracted by prior treatment with clonidine applied at the VSM. GD (0.04 ug/side) applied bilaterally to the VSM of the chloralose-anesthetized cat decreased respiratory rate (f) by 9 + 2 breaths/min (from 15 + 1 breaths/min) and increased tidal volume (V_T) by 53 + 15 ml (from 32 + 2 ml); respiratory minute volume remained unchanged. Clonidine (1 ug/side) applied to the VSM 5 min prior to GD counteracted both the GD-induced decrease in f and the increase in V_T. GD (0.4 ug/side) produced apnea in 5 of 9 animals tested due to a decrease in f. Animals pretreated with clonidine did not exhibit apnea (0/4) when GD (0.4 ug/side) was applied. These data suggest that the protective effect of clonidine against GD toxicity may occur because of an interaction of the 2 drugs at the VSM. (Supported by the US Army Med. & Development Command, Contract #DAMD17-86-6034).

ROSTRAL VENTROLATERAL MEDULLA M_1 MUSCARINIC RECEPTOR INVOLVEMENT IN CENTRAL VENTILATORY CHEMOSENSITIVITY. E. NATTIE*, J. WOOD*, A. MEGA*, AND W. GORITSKI*. Department of Physiology, Dartmouth Medical School, Hanover, NH 03756. (SPON. F. McCann).

Muscarinic antagonists atropine (4.4 mM), the M_1 receptor antagonist pirenzepine (10 mM), and the M_2 antagonist AF-DX 116 (10 mM) were applied by cotton pledgets to the rostral ventrolateral medulla ventilatory chemosensitive area in separate anesthetized, paralyzed, vagotomized, glomectomized, and servo-ventilated cats with integrated phrenic nerve activity used as respiratory center output. Atropine or pirenzepine significantly decreased the CO_2 response slope 48.3% +/- 6.2 and 40.7% +/- 6.0 respectively and significantly decreased the maximum response value 26.3% +/- 8.1 and 19.2% +/- 3.2 respectively without significant effects on blood pressure. AF-DX 116 had no significant effect on phrenic output or blood pressure. Atropine or pirenzepine had no significant effect on the phrenic response to carotid sinus nerve stimulation. These results suggest the involvement of muscarinic cholinergic receptors of the M_1 subtype in the central CO_2 chemoreceptor process accessible to surface application of agents at the rostral ventrolateral medulla. (Supported by NIH HL 28066. Pirenzepine and AF-DX 116 supplied generously by Boehringer Ingelheim, Inc.)

CARDIORESPIRATORY RESPONSES FOLLOWING MICROINJECTIONS OF NECA INTO THE NTS OF DECEREBRATE RATS. M. El-Ridi*, C. Janusz*, M. Parizon*, E. Schoener* and R. Barraco. Department of Physiology, Wayne State University School of Medicine, Detroit, MI 48201.

Numerous studies have shown that adenosine and its analogs modulate neurotransmitter function in the brain. The Nucleus Tractus Solitarius (NTS) is a major relay nucleus for afferent input from cardiopulmonary receptors. Recent studies in our laboratory have shown that microinjections of adenosine and related drugs into the NTS produce potent cardiorespiratory responses and these responses exhibit a topographical pattern that depends upon which subnucleus is affected. The aim of the present study was to examine adenosinergic modulation of NTS function in decerebrate rats. A limited occipital craniotomy was conducted to expose the brainstem in the region of the obex for microinjections (25-50 nl) into the NTS. In some animals, a mid-collicular decerebration was made and the decerebration was confirmed via a stimulating electrode in the paraventricular nucleus of the hypothalamus. The results show that microinjections of adenosinergic drugs into the ventrolateral subnucleus of intact rats markedly depresses respiratory frequency and elicits pressor and depressor responses whereas only respiratory depression is seen in the decerebrate animal. CORRELATION BETWEEN MUSCLE-FIBER TYPE AND GLYCOGEN CONTENT IN DIAPHRAGM. T.E. Dick, G.S. Supinski* and A.L. Freshler*, Depts. of Med. and of Physiol. and Biophys., Case Western Reserve Univ., Cleveland, OH, 44106.

We identified the fiber types recruited during resting ventilation in awake and anesthetized cats by correlating fiber type with glycogen content. Muscle fibers (>150/sample) were typed histochemically (myosin ATPase and NADH stains) and their glycogen content was assessed qualitatively as rich, partially depleted or poor (periodic acid-Schiff (PAS) stain). Glycogen content of a whole sample was determined quantitatively with anthrone reagent. For all animals (n=10), (Mean±SD) 40±5% of the muscle fibers were characterized as Type I (S), 19±4% as fatigue-resistant (FR) and 41±7% fatiguable (FF) Type II muscle fibers. In diaphragmatic samples (n=4) taken immediately after inducing anesthesia, no Type II and 18±13% Type I muscle fibers were glycogen poor; 60±15% S, 16±19% FR, and 10±9% FF muscle fibers were partially depleted. Glycogen was repleted by hyperventilating animals and infusing glucose (24% increase in whole muscle glycogen content after 8h, $P<0.05$). Then animals were spontaneously breathing at normocapnic levels for 1.5 h. Glycogen poor fibers were evident in both Type I and II fibers. Qualitatively, 78±18% S, 32±33% FR, and 28±20% FF fibers were depleted at least partially of glycogen. In conclusion, nearly all Type I and some Type II fibers are recruited in resting breathing. NMDA RECEPTOR MEDIATES THE INITIAL SYNAPTIC RESPONSE IN SPINAL MOTONEURONS OF RAT EMBRYOS. L. Ziskind-Conhaim. Dept. Physiol., Univ. of Wisconsin, Madison, WI 53706.

Formation of sensory motoneuron contacts was studied in isolated spinal cord of rat embryos at 15-21 days of gestation using intracellular recording and HRP labeling (Ziskind-Conhaim, L., Dev. Biol., 128:1988). At Days 15-16, when most afferents terminated at the intermediate gray matter, dorsal root stimulation generated polysynaptic potentials. By Day 17, mono- and polysynaptic potentials were recorded in 60% of motoneurons, and HRP labeled afferents made synaptic contacts with motoneurons.

In the vertebrate central nervous system, at least 2 receptor subtypes (NMDA and kainate/quisqualate receptors) mediate the excitatory response to L-glutamate. At the onset of sensory innervation, the amplitide of polysynaptic potentials increased with depolarizing currents injected intracellularly and with removal of extracellular Mg^{2+}, a voltage-dependent blocker of the NMDA receptor. The prolonged potentiation induced by the removal of Mg^{2+} was blocked by 2-APV, a specific NMDA antagonist. These manipulations did not change the amplitude of the monosynaptic responses. These results suggest that NMDA receptor mediates the initial polysynaptic responses in the motoneurons of rat embryos. Conductance changes indicate that during embryonic development motoneuron sensitivity to NMDA and kainate was higher than to L-glutamate. Supported by NIH grant NS 23808 and by Spinal Cord Research Foundation grant NBR-489-5.

380.2

ROLE OF EXCITATORY AMINO ACIDS (EAAS) IN TRANSMISSION OF RESPIRATORY DRIVE TO PHRENIC MOTONEURONS I: KAINATE AND QUISQUALATE RECEPTORS. G. Liu, J.C. Smith, & J.L. Feldman, Systems Neurobiology Laboratory, Department of Kinesiology, UCLA, Los Angeles, CA 90024-1568.

We previously demonstrated that excitatory amino acids are likely to play an important role in bulbospinal transmission of respiratory drive (*Fed. Proc. 45*:519, 1986). We report the effects of drugs affecting kainate and quisqualate receptor subtypes on phrenic motoneuronal resting membrane potential, respiratory drive potential and membrane conductance in the *in vitro* neonatal rat brainstem-spinal cord preparation (*J. Neurosci. Meth.21*:321, 1987).

To test the effects of blocking EAA receptors on transmission of respiratory drive, 2 mM Kynurenic acid (KYN), an antagonist acting on all three subtypes of EAA receptors, was applied to the solution bathing the spinal cord only. KYN reversibly abolished action potentials and significantly reduced (~75%) the amplitude of respiratory driving potential. Conductance measurements, using short current pulses, indicated that KYN specifically decreased transmitter mediated channel opening. Given the limited involvement of NMDA receptors in this phenomena (Feldman et al, this volume), these results suggested that non-NMDA receptors plays an important role in neurotransmission of respiratory drive. Thus, we tested the effects of a potent non-NMDA receptor antagonist, 6-cyano-7-nitroquinozaline-2,3-dione (CNQX). Bath application of 20 µM CNQX depressed respiratory drive potential and decreased receptor-mediated conductance changes, resulting in abolition of inspiratory-driven action potentials. Following wash out, phrenic motoneuronal discharge completely recovered. These results suggest that non-NMDA receptors are important in the synaptic transmission of bulbospinal respiratory drive to phrenic motoneurons. This work was supported by NIH Grant NS 24742. J.C.S. is a Parker B. Francis Foundation Fellow.

380.3

ROLE OF EXCITATORY AMINO ACIDS IN TRANSMISSION OF RESPIRATORY DRIVE TO PHRENIC MOTONEURONS II: N-METHYL-D-ASPARTIC ACID (NMDA) AND 2-AMINO-4-PHOSPHONOBUTYRIC ACID-SENSITIVE (AP4) RECEPTORS. J.L. Feldman, G. Liu, & J.C. Smith, Systems Neurobiology Laboratory, Department of Kinesiology, UCLA, Los Angeles, CA 90024-1568.

Excitatory amino acids are likely to play a important role in bulbospinal transmission of respiratory drive (*Fed. Proc. 45*:519, 1986). Mechanisms of actions of drugs affecting NMDA and AP4 sensitive receptors were studied by intracellular recordings from phrenic motoneurons in the *in vitro* neonatal rat brainstem-spinal cord.

Addition of 200 µM 2-amino-5-phosphonovaleric acid (AP5), a specific NMDA antagonist, to the bathing medium surrounding the spinal cord, produced a modest decrease in respiratory drive potential. Increasing AP5 concentrations (< 1 mM) did not abolish phrenic motoneuron firing. Given the relatively high concentrations of AP5, the effects may be due to non-NMDA receptors. AP4 at low concentrations blocked action potentials and depressed driving potentials. Addition of 50-100 µM DL-AP4 to the spinal cord bathing medium completely blocked phrenic motoneuron activity within 1-2 min. The respiratory drive potential decreased gradually, with 90% reduction within ~10 min. Membrane conductance changes during this period suggest that DL-AP4 blocked neurotransmitter-evoked channel opening. Following replacement with control bathing solutions, respiratory driving potential and phrenic motoneuron discharge recovered gradually. Non-specific effect on membrane properties were tested by comparing neuronal rheobase before-during- after drug application; in all cases, rheobase was unaffected. The present results further demonstrate that although excitatory amino acids may transmit descending respiratory drive, NMDA receptors have only a limited involvement. AP-4 sensitive receptors, which may be pre- or post-synaptic, can powerfully affect the transmission of respiratory drive. Supported by NIH Grant NS 24742. J.C.S. is a Parker B. Francis Foundation Fellow.

THE NMDA RECEPTOR: CENTRAL ROLE IN MEDIATING PAIN INHIBITION IN RAT PERIAQUEDUCTAL GRAY. Y. F. Jacquet. Behavioral Neuropharmacology Lab., Nathan Kline Institute, Orangeburg, NY 10962.

The role of the periaqueductal gray (PAG) in the mediation of opiate analgesia is well established (Jacquet & Lajtha, Science, 1974). An injection of morphine in the PAG resulted in a naloxone-reversible analgesia, indicating an opiate receptor mediated action. The present study investigated what role, if any, the excitatory amino acids (EAA) may also play in pain inhibition at this CNS site. An injection of the EAA analogue, N-methyl-D-aspartate (NMDA)(10 nmol) in the rat PAG resulted in potent analgesia in 2 analgesia tests (Tail Flick & Noxious Pinch). A prior injection of the NMDA antagonist, (-)-2-amino-7-phosphonoheptanoate (D-AP7)(3 nmol) antagonized this action, indicating a receptor-mediated action. D-AP7 also completely blocked morphine analgesia. NMDA (10 nmol) given with morphine (25 nmol) potentiated morphine analgesia, while the opiate antagonist, naloxone (5 nmol), only partially reversed this analgesic action. These results are consistent with the view that opiate-mediated analgesia in the PAG may be due to a disinhibitory action on an excitatory descending pain inhibitory pathway (Basbaum & Fields, Ann Rev Neurosci., 1984). The present findings delineate for the first time a functional role for the NMDA receptor in the control of pain in the mammalian central nervous system.

380.5

ALTERATION OF EXTRACELLULAR GLUTAMATE AND GLUTAMINE LEVELS IN THE THALAMIC VENTROPOSTERIOR MEDIAL NUCLEUS (VPM) DURING VIBRISSAL STIMULATION AND FOLLOWING ABLATION OF THE SOMATOSENSORY CORTEX. D.T. Ross, Department of Clinical Neurosciences, Brown University and Department of Neurosurgery, Rhode Island Hospital, Providence, RI 02902.

An excitatory amino acid has been implicated as the neurotransmitter at lemniscal synapses in the thalamic ventrobasal complex on the basis of immunohistochemical, physiological, and pharmacological studies. In order to measure the release of excitatory amino acids during physiological stimulation *in vivo* microdialysis was performed on urethane (1.5 g/ Kg) anesthetized rats.

A microdialysis probe with a 2 mm long tip was stereotactically implanted in the VPM at a 45° angle along the long axis of the nucleus. Diaylsate samples were collected by infusing Ringer's solution through the probes at a rate of 2 µl /min for 30 minutes. Baseline samples were taken during normal spontaneous activity in a still room before and after stimulation. Continuous stimulation of the vibrissae for 30 minutes was accomplished by directing the air flow from a small fan onto the rat's face. After several episodes of stimulation, the SI cortex was ablated by subpial aspiration and dialysate samples were collected at 30 minuute intervals. Dialysate samples were diluted 1:1 with phosphate buffer, filtered, and 100 µl of the sample loaded onto a Beckman 7300 amino acid analyser. The chromatograms produced were examined for alterations in extracellular levels of glutamate, aspartate and glutamine.

Vibrissal stimulation produced a 13.3% increase in the measured level of glutamate in the VPM and a 43.0% increase in the level of glutamine. Baseline levels of aspartate in the VPM were very low and vibrissal stimulation did not produce a detectable increase. The extracellular concentration of glutamate and glutamine collected during ablation of the somatosensory cortex and for the subsequent 29 minutes were significantly lower than baseline levels, 65.3% and 59.7%, respectively. These results reflect the profound decrease in spontaneous activity recorded in the VPM immediately after cortical ablation. Studies in progress are examining alterations in extracellular amino acids in the VPM during cortical stimulation and at longer times following cortical ablation.

380.6

ROLE OF EXCITATORY AMINO ACIDS AND ADENOSINE IN CEREBELLAR CLIMBING FIBERS TRANSMISSION. K.Q.Do*, F.Vollenweider* and M.Cuénod (SPON: M. Schlumpf). Brain Research Institute, Univ. of Zürich, Zürich, Switzerland.

K^+-induced, Ca^{2+}-dependent in vitro release of endogenous aspartate (Asp), glutamate (Glu) and homocysteate (HCA) has been investigated in control and climbing fibers (cf) deprived rat cerebella. Degeneration of the inferior olive was induced by 3-acetylpyridine (3-AP). HCA release was abolished after 3-AP treatment. In hemisphere but not in vermis of 3-AP treated rats, the depolarisation induced release of Asp was decreased by 49% (from 43 to 27 pmole·mg protein^{-1}·min^{-1}) without changes in resting efflux. The decrease of 14% in K^+-induced release of Glu was mostly due to an increase in Glu resting efflux (from 26 to 43 pmole·mg protein^{-1}· min^{-1}). Moreover a Ca^{2+}-dependent K^+-induced release of adenosine (Ado) was observed: Ado efflux was increased from 8.2 (resting conditions) to 21.9 and 29.1 pmole·mg protein^{-1}· min^{-1} (during and after stimulation). In 3-AP treated rats, both the resting (-32%) and stimulated (-62%) efflux were decreased. Furthermore 50 nM of 1,3-dipropyl-8-cyclopentyl-xanthine, a selective antagonist of Ado at A1 sites increased both the basal and stimulated efflux of Glu in cerebellar slices. It is suggested that cf are using HCA and Asp as transmitters. Combined with work of others on Ado, our data are consistent with the hypothesis that cf activity induces release of Ado, which in turn depresses presynaptically the release of the parallel fiber transmitter, presumably Glu.

FAST EPSP'S EVOKED IN THE GOLDFISH MAUTHNER CELL BY SENSORY AFFERENTS ARE DUE TO NMDA RECEPTOR ACTIVATION. L. R. Wolszon* and D. S. Faber (SPON: J. Whitney). Dept. of Physiology, S.U.N.Y. at Buffalo, Buffalo, NY, 14214.

Saccular afferents terminate as mixed (electrotonic and chemical) synapses on the Mauthner Cell lateral dendrite. EPSP's produced by their impulses have time constants of decay in the range of 1-2 ms. To determine whether the transmitter at these synapses is an excitatory amino acid, we pressure-injected the glutamate antagonists γ-D-glutamyl glycine (γ-DGG) and 2-amino-4-phosphono valerate (APV) onto the lateral dendrite while recording, from that dendrite, EPSP's evoked by stimulation of the saccular nerve. The effects of these compounds on EPSP's arising from both single- and paired-pulse stimulation were examined. Neither drug altered resting membrane potential or antidromic spike height. γ-DGG completely abolished both the unconditioned and the facilitated EPSP's, whereas APV reduced each by at least 80-90%, indicating that the receptors at these synapses are predominantly of the NMDA subtype. For both compounds, the second, facilitated, EPSP was more sensitive to the antagonist than was the first.

We conclude that this fast EPSP is primarily due to the activation of NMDA receptors and that the paired-pulse facilitation of this EPSP seen with stimulation of a population of afferents may involve a postsynaptic mechanism, in addition to the presynaptic one described previously for single fibers (Lin, J.W and Faber, D.S (1988), J. Neurosci., 8 (4): 1313-1325). (Supported by NIH #NS 21848 and 15335)

A–DELTA AND C AFFERENT FIBER–EVOKED SYNAPTIC RESPONSES OF RAT SUBSTANTIA GELATINOSA NEURONS IN VITRO. M. Yoshimura* and T.M. Jessell*. Center for Neurobiology & Howard Hughes Medical Institute, Columbia University, New York, NY 10032.

Primary afferent fiber–evoked synaptic responses of substantia gelatinosa (s.g.) neurons have been analyzed by intracellular recording in a transverse slice preparation of adult rat spinal cord that retains an attached dorsal root.

Neurons in s.g. exhibited A–delta and/or C fiber mediated monosynaptic fast epsps in response to dorsal root stimulation. C and A–delta fiber–mediated epsps had similar time courses and amplitudes. To study C fiber input selectively we have used low concentrations (0.05 µM) of TTX that preferentially block the activation of A–delta fibers without substantially affecting C fiber evoked epsps. Higher concentrations of TTX (0.5 µM) blocked C fiber responses.

Both A–delta and C fiber evoked epsps were increased in amplitude with membrane hyperpolarization and decreased with membrane depolarization and reversed in polarity at membrane potentials between −10 and 0 mV. In the presence of TTX (0.5 µM), L-glutamate (0.5 – 5 mM) produced a membrane depolarization in 40–50% of s.g. neurons. The l–glutamate–induced depolarization reversed in polarity at the same membrane potential as that of afferent–evoked epsps. The amino acid antagonist kynurenate (1 mM) depressed the amplitude of A–delta and C fiber mediated epsps and l–glutamate response in some but not all s.g. neurons.

These results indicate that some but perhaps not all A–delta and C afferent fibers release amino acids as fast excitatory transmitters at afferent synapses with s.g. neurons.

380.9

SYNAPTIC PATHWAYS IN RAT PIRIFORM CORTEX. D.O. Carpenter and N.H. Hori*. School of Public Health, NYS Dept. of Health, Albany, NY 12237

We have characterized several synaptic pathways onto pyramidal neurons which can be selectively activated in rat piriform cortex slices. The pathway activated by stimulation of the lateral olfactory tract (LOT) is blocked by amino-phosphonobutyric (APB) and kynurenic acids, but not other excitatory amino acid antagonists. This pathway shows paired pulse (PPP) and long term potentiation (LTP), and afferents terminate on distal apical dendrites. Stimulation deep in the slice, which activates association fibers, elicits two distinct excitatory responses on pyramidal neurons. Both components are blocked by kynurenic acid but not APB or other amino acid antagonists. Neither component shows LTP, and only the faster shows PPP. Both components reverse deeper in the slice than the LOT inputs, the slower in the proximal apical dendrites while the faster appears to terminate on basal dendrites. GABAergic inhibition can be elicited by deep low threshold stimulation, and terminates near the cell bodies. Acetylcholine receptors are located exclusively on basal dendrites, and close voltage dependent M channels.

INITIATION OF SWALLOWING BY LARYNGEAL AFFERENTS: EXCITATORY AMINO ACIDS AS TRANSMITTER CANDIDATES. A. Jean*, N. Cherkaoui*, N. Schaffar*, J.P. Kessler* and D. Catalin*. (SPON: European Neuroscience Association) Lab. de Neurobiologie fonctionnelle. CNRS UA 205. Faculté St Jérôme. 13397 Marseille Cedex 13. France.

Swallowing is a motor activity generated by a central pattern generator including leading neurons located in the nucleus tractus solitarius (NTS). The sequential motor pattern characteristic of swallowing, linked with the inhibition of respiration, is routinely elicited in anesthetized rats by stimulation of laryngeal vagal afferents. The same motor pattern was also selectively generated by glutamate or excitatory amino acids (EAA) agonists (quisqualate, N-methyl-D-aspartate) applied into the swallowing region of the NTS (pressure injections: 5 nl, 0.05-0.5 nmol). Injections of a depolarizing agent (K^+, 0.06-2 M) were without effect. Moreover swallowing initiated by stimulation of laryngeal afferents was blocked by microinjections, into the active sites, of EAA antagonists (glutamate diethylester, γ-glutamylamino-methyl sulfonate, 2-amino-5-phosphonovalerate; 0.5-5 nmol). These results suggest that EAA might be transmitters involved in the initiation of swallowing by laryngeal afferents. Retrograde labeling of nodose cell bodies after injection of D-^{3}H-aspartate (100 µCi) in the swallowing region of the NTS supports the hypothesis that certain vagal afferent fibers use EAA as transmitters.

EVALUATION OF THE PHENCYCLIDINE-LIKE DISCRIMINATIVE STIMULUS EFFECTS OF THE PROPOSED NMDA ANTAGONIST NPC 12626. R.L. Balster*, J. Willetts and J.W. Ferkany (SPON: D.R. Compton). Dept. of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298 and NOVA Pharmaceuticals, Baltimore, MD.

The effects of the proposed competitive N-methyl-D-aspartate (NMDA) antagonist NPC 12626 were compared to those of 3-((+/-)-2-carboxy-piperazin-4-yl)propyl-1-phosphonic acid (CPP) and pentobarbital (PB) in rats trained to discriminate 1.25 mg/kg i.p. phencyclidine (PCP) from saline. Both CPP (3-30 mg/kg i.p.) and NPC 12626 (10-100 mg/kg i.p.) dose-dependently reduced response rates but failed to completely substitute for PCP. Similar effects were observed with PB. For all three drugs, PCP-lever responding was usually associated with response rate decreases, and response rate decreases often occurred without evidence of generalization. These results suggest that there is not a complete overlap in the discriminative stimulus effects of PCP and NPC 12626, CPP and PB. Furthermore, behavioral effects other than PCP-like effects are produced by these drugs, and the effects of the competitive NMDA antagonists are no more PCP-like than are the effects of PB.

(Partially supported by NIDA Grant DA-01442)

380.12

PENTOBARBITAL-LIKE DISCRIMINATIVE STIMULUS EFFECTS OF COMPETITIVE AND NON-COMPETITIVE NMDA ANTAGONISTS. J. Willetts and R.L. Balster*. Dept. of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298.

Various competitive N-methyl-D-aspartate (NMDA) antagonists share certain behavioral effects with the non competitive NMDA antagonist phencyclidine (PCP), however, the selectivity of these drugs to produce only PCP-like effects has not been well-studied. We investigated whether the competitive NMDA antagonist 3-((+/-)-2-carboxy-piperazin-4-yl)propyl-1-phosphonic acid (CPP) also has effects similar to pentobarbital (PB).

The discriminative stimulus effects of CPP and the non-competitive NMDA antagonists MK-801 and PCP were assessed in 8 rats trained to discriminate 5 mg/kg i.p. PB from saline. We found that CPP completely generalized from PB at doses that did not affect response rates. However, neither PCP nor MK-801 completely substituted for PB; and, when present, PB-lever responding was accompanied by reduced response rates.

These results, along with our previous finding that CPP does not reliably substitute for PCP in PCP-trained rats, indicate that the behavioral effects of CPP may be more similar to PB than to PCP. (Supported by NIDA Grant DA-01442.)

6,7-Dinitroquinoxaline-2,3-dione (DNQX) and γ-aminomethylsulphonate (GAMS) selectively inhibit the hypermotility response produced by activation of quisqualic acid (QA) receptors in the nucleus accumbens (NA). R.C. Boldry*, P.E. Shreve*, N.J. Uretsky. (SPON: M.C. Gerald), The Ohio State University College of Pharmacy, 500 W. 12th Avenue, Columbus, Ohio 43210.

DNQX has been introduced as a selective competitive antagonist of non-NMDA receptors. The purpose of this study was to evaluate the ability of this compound to inhibit the hypermotility responses to excitatory amino acids (EAA) injected directly into the NA and to compare its effects with those of GAMS. Different doses of DNQX or GAMS were coinjected into the NA of rats with either kainic acid (KA), N-methyl-D-aspartic acid (NMDA), or α-amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA). Control rats received the EAAs alone. Low doses of DNQX or GAMS were found to selectively inhibit the response to AMPA, a QA receptor agonist, but to have no significant effect on the responses to NMDA and KA. Higher doses of DNQX or GAMS inhibited the responses to all three EAAs. Binding studies show that DNQX is a potent inhibitor of ^{3}H-AMPA binding while GAMS is ineffective except at higher concentrations. These studies show that both GAMS and DNQX can selectively inhibit the behavioral response to the intraaccumbens injection of AMPA. However, while direct antagonism of the QA receptor can account for the inhibitory effect of DNQX, the selective inhibitory effect of GAMS appears to be due to some other mechanism. Supported by NS 22582.

Kainic acid (KA), α-amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA), and N-methyl-D-aspartic acid (NMDA) stimulate locomotor activity (LMA) after injection into the substantia innominata/lateral preoptic area (SI/LPO). P. E. Shreve* and N. J. Uretsky, The Ohio State University College of Pharmacy, 500 W. 12th Ave., Columbus, OH 43210.

The SI/LPO is a region of the ventral pallidum which appears to be a critical neural substrate for LMA initiated in the nucleus accumbens (NA) through a GABAergic projection from the NA. Recent evidence suggests that the SI/LPO also receives glutamatergic innervation. The purpose of these experiments was to determine the effects of excitatory amino acids (EAA) on LMA after direct injection into the SI/LPO. Various doses of KA, AMPA, and NMDA were injected into the SI/LPO and LMA was recorded. KA (15-60 ng), AMPA (0.1-1 μg), and NMDA (1-2.5 μg) produced dose dependent increases in LMA which was similar to that observed in the NA. γ-aminomethylsulphonate (GAMS) has been shown to be a selective quisqualic acid (QA) receptor antagonist in the NA. In the present study, GAMS (1 μg) produced a selective inhibition (82%) of AMPA (0.5 μg) while having no significant effect on KA (30 ng) or NMDA (2.5 μg). These results suggest that QA receptors mediate the LMA produced by AMPA and that activation of EAA receptors in the SI/LPO by glutamate may play a role in modulating goal-oriented behavior initiated in the NA. Supported by NS 22582.

CHANGES IN SPONTANEOUS LOCOMOTOR ACTIVITY AS A RESULT OF ADMINISTRATION OF KYNURENIC ACID IN THE RAT. Z. Dennison, K.-P. Ossenkopp and D.P. Cain. Dept. Psychology, Univ. of Western Ontario, London, Ontario, CANADA N6A 5C2.

Since excitatory amino acid antagonists have been shown to have anticonvulsant actions, it is important to examine the side effects produced by these compounds. Kynurenic acid has been shown to retard the rate of kindling and to act as an anticonvulsant in kindled animals. We examined the effects of intraventricular administration of kynurenic acid on locomotor behavior in rats. A Digiscan Activity Monitor was used to quantify a variety of behavioral measures. Male hooded rats were implanted with bilateral ventricular cannulae and amygdala electrodes. Four groups of animals (HI,MED,LOW,SAL) received 65, 39, 6.5 and 0 μg of kynurenic acid dissolved in saline, respectively. The drug was administered every other day, followed 40 minutes later by electrical stimulation in a standard kindling procedure. Movement data were collected on the first drug day and every third drug day thereafter. A repeated measures MANOVA was performed on horizontal activity and vertical (rearing) activity. The results indicated that HI and MED were significantly different from SAL on both measures ($p<.001$) but LOW was no different from SAL. Further analyses revealed different activity patterns within test sessions for various doses of kynurenic acid.

EFFECTS OF NMDA, L-GLUTAMIC ACID AND L-ASPARTIC ACID ON AUDITORY AND TACTILE STARTLE HABITUATION IN MICE. D. Helton*, J. Tizzano, J. Buelke-Sam, R.N. Tamura*, and P.D. Williams*. Toxicology Division, Lilly Research Laboratories, Greenfield, IN 46140.

The excitatory amino acids, N-methyl-D-aspartate (NMDA), l-glutamic acid (GLU) and l-aspartic acid (ASP) have been shown in our laboratory to exhibit proconvulsive activity in the mouse electoconvulsive seizure model. The present study was designed to evaluate the actions of these three compounds, at both proconvulsive (high) and non-proconvulsive (low) doses, on the startle reflex elicited by either auditory or tactile stimuli. Groups of 10 male CD-1 mice were randomly assigned to one of six drug conditions: 3.125 or 6.25 mg/kg NMDA, 500 or 1000 mg/kg GLU, 500 or 1000 mg/kg ASP. A total of 20 mice received saline injections. Intraperitoneal injections were administered in random order 15 min prior to startle testing in SDI chambers. Each 50-trial session was made up of alternating 5-trial blocks of auditory (120 dBA noise) and tactile (20 psi air puff) stimuli presented at 8-sec intervals. The low dose of NMDA did not alter auditory startle amplitudes compared to controls, but increased tactile startle during the first trial block; the high dose of NMDA decreased both auditory and tactile startle throughout the test session. The low dose of GLU resulted in a slight decrease in auditory startle during the first 3 trial blocks, but did not alter tactile startle responding; the high dose of GLU had no effect on startle elicited via either modality. Both doses of ASP produced comparable and consistent decreases (ca 40%) in auditory and tactile startle across trial blocks. These data indicate that non-proconvulsive doses of NMDA, GLU and ASP differentially altered startle responding. At proconvulsive doses NMDA and ASP, but not GLU, decreased both auditory and tactile startle amplitudes.

EFFECTS OF MK-801 ON MEMORY RETENTION IN THE RAT. D.F. Wozniak, J.W. Olney and L. Kettinger III*. Dept. of Psychiatry, Washington University Sch. of Med., St. Louis, MO. 63110.

Several experiments were conducted to study the effects of MK-801 on learning and memory processes in the rat. In one experiment, rats were trained on a task involving the reversal of a position habit. The protocol consisted of weekly, 3-day training periods. On day 1, rats (n = 38) were trained to go to one side of a T-maze to receive a food reward until they made 9 out of 10 consecutive responses to the reinforced side. On day 2, half of the rats were injected IP with saline and half with MK-801 (0.1 mg/kg), a potent antagonist of the N methyl-D-aspartate receptor-ionophore complex. Fifteen minutes later they were trained to go to the side of the T-maze opposite from the one in which they were reinforced on the previous day. Again, rats were required to make 9 out of 10 consecutive responses to the reinforced side. On day 3, they were given a 1-trial test to see if they would respond correctly, i.e., go to the side reinforced on day 2. The same experiment was repeated once a week for 3 consecutive weeks without crossing over experimental and control groups. The number of saline control rats which responded correctly on the 1-trial test was significantly greater than levels expected by chance for each of the three weekly experiments whereas MK-801 rats consistently failed to perform above chance levels. Performance deficits on day 3 could not be attributed to motor impairment or inebriation since these are acute types of drug effects which would not be expected to endure for 24 hrs; moreover, trials to criterion and choice latencies were not different between the 2 groups on day 2 when experimental rats learned the reversal under the acute influence of drug. The effects of MK-801 do not generalize to all aspects of memory since the drug did not impair working memory tested in a radial arm maze or in a reinforced spatial alternation task. Our experiments suggest that rats are capable of learning while under the acute influence of MK-801 (0.1 mg/kg) but may have difficulty recalling what was learned when tested 24 hrs later. MK-801 PREVENTS COGNITIVE AND BEHAVIORAL DEFICITS PRODUCED BY N-MDA RECEPTOR OVERSTIMULATION IN THE RAT HIPPOCAMPUS. B.C. Rogers*, and H.A. Tilson. LMIN, Nat. Inst. Environ. Health Sciences, Research Triangle Park, NC 27709.

We report that functional and histological damage mediated by the intrahippocampal bilateral injections of N-methyl-D-aspartate (N-MDA) into the hippocampus can be attenuated by the administration of MK-801 (i.p.) 1 hr prior to treatment. First, MK-801 (10.0 mg/kg) was administered prior to increasing doses of N-MDA (5,10, and 20 ug/site). Next, two doses of MK-801 (1.0 and 0.1 mg/kg) were administered prior to one dose of N-MDA (10 ug/site). In both experiments, motor activity was measured 1, 2, and 3 wk after surgery. Also, animals receiving 10 ug/site N-MDA were trained for acquisition of a Morris water maze task 4 wk post-surgery. 10 mg/kg MK-801 completely blocked increases in motor activity produced by 10 and 20 ug/site N-MDA while both 1.0 and 0.1 mg/kg MK-801 abolished 10 ug/site N-MDA-induced hyperactivity. In addition, 10.0 and 1.0 mg/kg MK-801 completely attenuated water maze acquisition deficits produced by N-MDA. Finally, histological examination revealed 10.0 mg/kg MK-801 provided complete protection from damage produced by 5 and 10 ug/site N-MDA while 1.0 and 0.1 mg/kg site MK-801 also prevented cell loss to a lesser extent. These results suggest that MK-801 may be effective in attenuating memory loss associated with the overstimulation of N-MDA receptors. (B.C.R. supported by ES01726.

RESPIRATORY APNEUSIS FOLLOWING N-METHYL-D-ASPARTATE (NMDA) RECEPTOR BLOCKADE. A.S. Foutz*, G. Fortin*, J. Champagnat* and M. Denavit-Saubié, Biologie Fonctionnelle du Neurone, L.P.N. C.N.R.S. 91190 Gif-sur-Yvette (France).

We investigated in-vivo and in-vitro the functional role of NMDA receptors in the brainstem and the possible neuronal networks involved. Systemic administration of NMDA antagonists (MK-801 and phencyclidine 0.03-1 mg/kg ; ketamine 2.5-10 mg/kg ; AP7 120 mg/kg to decerebrated, vagotomized and paralyzed cats increased the duration of central inspiratory activity (Ti) recorded from the phrenic nerve without increasing the duration of expiration. Suppression of pulmonary vagal afferent input was required for obtaining such apneusis. Cats given MK-801 with intact vagus nerves were ventilated (100% O_2) with a pump driven by the discharge of the phrenic nerve. The omission of lung inflation increased Ti from 1-2 sec to up to 2 min. These results were confirmed in chronic cats given MK-801 before and after vagotomy.

Therefore : 1) NMDA-type glutamate receptors are involved in respiratory rhythmogenesis (inspiratory off-switch) ; 2) these receptors are activated by aminoacidergic neurons located within the brainstem. We have looked in-vitro for the possible neuronal basis of these in-vivo results. Coronal brainstem slices perfused with a magnesium-free medium provided evidence for a local network in the dorsal respiratory area involving dicarboxylic aminoacid release and NMDA receptor activation.

DEPOLARIZING SYNAPTIC EVENTS INFLUENCING CAT LUMBAR MOTONEURONS DURING RAPID EYE MOVEMENT EPISODES OF ACTIVE SLEEP ARE BLOCKED BY KYNURENIC ACID. P.J. Soja, F. Lopez*, F.R. Morales, and M.H. Chase *Depts. of Physiology and Anatomy, and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.*

The membrane potential activity of lumbar motoneurons during rapid eye movement (REM) periods of active sleep (AS) is characterized by glycinergic inhibitory processes, as evidenced by brief periods of strychnine-sensitive hyperpolarization (*Sleep Res. 14:* 4, 1985), as well as by complex patterns of paroxysmal depolarizing shifts that lead to full-size or partial amplitude action potentials (*Science, 221:* 1195-1198, 1983; *Neuroscience Lett., 34:* 177-182, 1982). The neurotransmitter(s) responsible for the state-dependent excitatory processes is not known. Accordingly, we examined the effects of excitatory amino acid antagonists on the phasic depolarizing events that occur during REM periods of AS in the chronic cat.

Juxtacellular microiontophoretic applications of the non-selective excitatory amino acid antagonist, kynurenic acid (KYN, 0.15M, pH8.0, -100 to -300nA), were performed during wakefulness (W), quiet sleep (QS) and the transition into and throughout AS. Intracellularly recorded compound mono- and polysynaptic EPSPs, evoked by low-intensity sciatic nerve stimulation during W and QS, were markedly suppressed or abolished by KYN; short latency IPSPs were not blocked, indicating that the drug was adequately released and specific for excitatory neurotransmission. During REM periods of AS, KYN suppressed the naturally occurring phasic depolarizing membrane shifts and action potentials. Membrane potential activity during REM periods following KYN was characterized only by marked recurrent hyperpolarizations. Microiontophoresis of the selective N-methyl-D-aspartate (NMDA) antagonist, 2-amino-5-phosphonovaleric acid (APV, 0.2M, pH8.0, -100 to -300nA), suppressed polysynaptic EPSPs evoked by sciatic nerve stimulation and motoneuronal depolarizations induced by juxtacellularly applied NMDA, but failed to block the naturally occurring phasic depolarizing membrane shifts during the REM periods of AS.

On the basis of the documented selectivity of KYN and APV in antagonizing the postsynaptic actions of NMDA versus non-NMDA-like excitatory amino acids, the present results suggest that the postsynaptic excitatory drives that impinge on lumbar motoneurons during the REM periods of AS are mediated primarily by a non-NMDA-like neurotransmitter. Supported by grants NS2346 and MH43362.

EXCITATORY AMINO ACIDS VIII

381.1

CGP 37849 / CGP 39551: POTENT AND SELECTIVE COMPETITIVE NMDA RECEPTOR ANTAGONISTS WITH ORAL ACTIVITY. G.E. Fagg, H-R. Olpe*, H. Bittiger*, M. Schmutz*, C. Angst*, D. Brundish*, H. Allgeier*, R. Heckendorn* & J.G. Dingwall*, Friedrich Miescher Institute, Central Research Labs., & Research & Development Dept., Pharmaceuticals Division, CIBA-GEIGY Ltd., 4002 Basel, Switzerland.

As part of a rational approach to the development of novel NMDA (N-methyl-D-aspartate) receptor antagonists, we investigated a series of unsaturated analogues of the known blocker, AP5. Compounds were selected on the basis of their activity at NMDA-sensitive L-^{3}H-glutamate binding sites in rat brain synaptic membranes and as antagonists of experimentally-induced seizures in mice. CGP 37849 (D,L-(E)-2-amino-4-methyl-5-phosphono-3-pentenoic acid) inhibited L-^{3}H-glutamate and ^{3}H-CPP binding with Ki values of 220 and 35 nM, respectively (comparative values for DL-AP5 were 1.5 and 0.5 μM), and was weak or inactive in assays for 17 other receptor types (including quisqualate and kainate). Sub-micromolar concentrations blocked NMDA-, but not quisqualate- or kainate-evoked increases in pyramidal cell firing in the rat hippocampal slice *in vitro*. It is thus the most potent and selective competitive NMDA receptor antagonist described to date. In rodents, CGP 37849 and its ethyl ester CGP 39551 (which was weaker in assays *in vitro*) potently antagonized electroshock-induced seizures following oral administration (ED_{50} values 4-21 mg/kg)(for details of their anticonvulsant profiles, see M. Schmutz et al., this meeting).

CGP 37849 and CGP 39551 thus are new drugs with which to examine the roles of NMDA receptor-mediated events in brain function, and are potential candidates for the treatment of disorders such as epilepsy and ischaemic neurodegeneration.

381.2

MODULATION OF A10 DOPAMINE BY EXCITATORY AMINO ACIDS. P.W. Kalivas and P. Duffy*. Dept. of VCAPP, Wash. St. Univ., Pullman, WA 99164

Do excitatory amino acids activate dopamine (DA) neurons in the A10 region? Glutamic acid, aspartic acid, kainic acid or N-methyl-D-aspartate (NMDA) were injected into the A10 region of rats, changes in motor activity and DA metabolism measured. Glutamate and kainate produced a dose-related increase in horizontal photocell counts with a minimum effective dose (MED) of 100 and 1 nmoles, resp. The dose response curves for NMDA and aspartate were biphasic. An increase in activity was seen at high doses of NMDA and aspartate (1 and 100 nmoles), while a decrease occurred after lower doses (0.01 and 10 nmoles). When a behavioral stimulant dose of kainate and glutamate was injected into the A10 region, a significant increase in DA metabolism was produced in both the A10 region and nucleus accumbens, and when a behavioral depressant dose of NMDA was given, an increase in DA metabolism was seen only in the A10 region. In spite of the behavioral depressant effect of low doses of NMDA, it significantly potentiated the motor stimulant effect of kainate to an MED of 0.1 nmoles. Also, a behavioral depressant dose of NMDA potentiated the behavioral stimulant effect of DAGO, a mu opioid agonist. These data show that kainate receptor stimulation activates the DA neurons to increase both somatodendritic and terminal field DA neurotransmission. In contrast, activation of the NMDA receptor appears to enhance only somatodendritic DA neurotransmission.

LOSS OF [^{3}H]GLUTAMATE BINDING AFTER ORBITAL ENUCLEATION
J. McCulloch & D.T. Chalmers*, (SPON. G. Fink), Wellcome Surgical Institute, University of Glasgow, Glasgow G61 1QH.

Glutamate plays a major role within the rat visual system. Using a fully quantitative autoradiographic technique, we have examined the alterations in [^{3}H]-glutamate binding sites which accompany functional disturbances after lesioning of this sensory pathway.

Black-hooded Long Evans rats were unilaterally enucleated under 2% halothane anaesthesia and twenty-four hours later, cerebral glucose use was measured using the (^{14}C)-2-deoxyglucose technique. (^{14}C)-2-deoxyglucose-6-phosphate was eluted from those sections required for receptor autoradiography and these were incubated for 45 min. at 4°C with 200nM [^{3}H]-glutamate, non-specific binding being determined in the presence of 1mM unlabelled glutamate.

Orbital enucleation produced a significant reduction in glucose use in the visually deprived superior colliculus, lateral geniculate nucleus and visual cortex. These functional disturbances were accompanied by a significant reduction in [^{3}H]-glutamate binding in both superficial and deep layers of visual cortex.

This rapid response to altered neuronal activity suggests an important functional role for this site in cortical excitatory neurotransmission. This response will be discussed in relation to specific receptor subtypes and binding conditions.

KAINIC ACID INDUCES HEAT SHOCK PROTEIN IN SPECIFIC BRAIN REGIONS.
Kathleen R. Zahs*+, Manuel F. Gonzalez, Kinya Hisanaga*, Stephen M. Sagar, and Frank R. Sharp+, (SPON: S.F. Akana). Depts. of Physiology+ and Neurology, UCSF, and VA Medical Center, SF, CA 94121 USA.

Following transient ischemia or hyperthermia, specific proteins have been found to be induced in mammalian brains. The present experiments demonstrate that administration of an excitatory neurotoxin also induces such heat shock proteins, suggesting that these proteins may serve as a marker for injured neurons.

Three rats received subcutaneous injections of kainic acid (10 mg/kg) and were killed 3 days later. Heat shock protein was detected using a mouse monoclonal antibody directed against a 72-kD heat shock protein. Immunostaining was observed in hippocampal layers CA1, CA2, CA3, and the parafascicular nucleus of the thalamus. In addition, Golgi-like staining was seen in layers II / III, V, and lower layer VI of piriform and perirhinal cortex. Cerebellar Purkinje cells were lightly stained. Injections of kainate at a dose that fails to cause neuronal death (3 rats, 6 mg/kg) resulted in no detectable staining of these regions.

Local injections of kainate into hippocampus (0.4 microgram in 0.3 microliter) resulted in staining of ipsilateral hippocampal regions CA1, CA2, and CA3 and of the amygdala bilaterally.

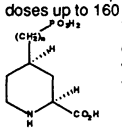
EFFECTS OF A SERIES OF 4-(PHOSPHONOALKYL)PIPERIDINE-2-CARBOXYLIC ACIDS IN PIGEONS AND MICE. SELECTIVE ANTAGONISTS OF NEUROTRANSMISSION AT NMDA PREFERRING EXCITATORY AMINO ACID RECEPTORS.
P.L. ORNSTEIN*, J.D. LEANDER* AND J.W. CHAMBERS* (SPON: D. GOLDSTEIN). Lilly Research Labs, Lilly Corporate Center, Indianapolis, IN 46285.

We recently prepared a series of 4-phosphonoalkylpiperidine-2-carboxylic acids (**I**, n = 1; **II**, n = 2; **III**, n = 3; **IV**, n = 4) as antagonists of neurotransmission at N-methyl-D-aspartate (NMDA) preferring receptors. In order to delineate the extent of antagonist activity, we examined these compounds in a variety of assays: production of phencyclidine (PCP)-like catalepsy and antagonism of NMDA-induced suppression of responding in pigeons; protection from maximal electroshock (MES)-induced convulsions in mice; protection from NMDA- and 3-mercaptopropionic acid (3-MPA)-induced lethality in mice; impairment on the horizontal screen (mice).

Compounds **I** and **III** produced PCP-like catalepsy (both 2.5 mg/kg, i.m., slow onset and long duration of action) and antagonized NMDA-induced suppression of responding (both 0.16-0.32 mg/kg, i.m.) in pigeons, while **II** and **IV** were inactive (>40 mg/kg). In mice, **I** and **III** protected against MES-induced convulsions (10 and 40 mg/kg, i.p., respectively), 3-MPA-induced lethality (both 80 mg/kg, i.p.), and NMDA-induced lethality (10 and 40 mg/kg, i.p., respectively). At doses that afford protection in the above assays, the mice were impaired on the horizontal screen. Compounds **II** and **IV** (at doses up to 160 mg/kg, i.p.) were inactive in mice.



The pattern of activity observed for this series parallels that observed for the acyclic series of ω-phosphono-α-amino acids, where AP5 and AP7 possessed NMDA antagonist activity while AP6 and AP8 were inactive. Reduction of conformational mobility by incorporation of the piperidine ring led to enhanced potency relative to the acyclic analogues.

ALTERATIONS IN RAT BRAIN METABOLIC ACTIVITY BY VARIOUS NON-COMPETITIVE NMDA ANTAGONISTS.
H.D. Everist, J. Monn*, K. Rice* and A. Pert (SPON: L. Hsu). BPB, NIMH, and LC, NIDDK.

The purpose of this study was to compare the effects of three non-competitive NMDA antagonists on the metabolic activity of rat brain. Rats were injected systemically with either phencyclidine (PCP), (+) SKF 10,047 (-) SKF 10,047, MK-801 or saline. Thirty minutes later, all animals were injected with [^{14}C]-2-deoxyglucose (2-DG). Standard procedures of visualizing 2-DG were employed.

Significant increases in metabolic activity were found in the anterior and posterior cingulate cortex, anteroventral, ventromedial and posterior thalamic nuclei, dorsal and ventral hippocampus, and substantia nigra (ZR) following MK-801. PCP also enhanced metabolic activity in the anterior and posterior cingulate and the substantia nigra (ZR), as well as the caudate nucleus. Unlike MK-801, however, PCP decreased metabolic activity in the thalamic nuclei. In general, both enantiomers of SKF 10,047 reduced the metabolic activity of a variety of structures, including the hippocampus, the majority of thalamic nuclei and the substantia nigra. It is clear that these non-competitive NMDA antagonists have vastly different consequences on brain metabolic activity.

CENTRALLY ADMINISTERED QUISQUALIC ACID INCREASES SENSITIVITY TO DIETHYLBARBITURIC ACID IN LS AND SS MICE
C. C. Duncan and J. A. Ruth. University of Colorado School of Pharmacy, Box 297, Boulder, CO, 80309.

A gas-chromatographic assay for the determination of brain diethylbarbituric acid (DB) concentrations has been developed and used to study the role of glutamate neurotransmission in the modulation of the CNS depressant effects of this water soluble barbiturate in long-sleep (LS) and short-sleep (SS) mice. LS and SS mice are lines genetically selected for differential response to acute doses of ethanol as measured by duration of loss of righting response. We have previously demonstrated a differential involvement of NMDA-type glutamate receptors in this response. The current study was designed to extend the ethanol findings using other central depressants.

Mice were injected IP with 15 mg/kg DB. DB brain concentrations were determined at loss of righting response. LS and SS differed significantly in central sensitivity to DB (77.0±7.5 μg/g brain in LS and 120.0±4.0 μg/g brain in SS). Time course studies showed that these diffences were not due to differences in DB clearance rates. These data provide direct evidence for the differential sensitivity of LS and SS mice to the depressant effects of DB. The role of glutamate modulation of DB effects was studied by ICV administration of the NMDA antagonist, D-2-amino-5-phosphonovaleric acid (5-APV). 5-APV had no effect on brain sensitivity to DB in either mouse line. Quisqualic acid (QQA), the non-NMDA receptor agonist, caused a significant increase in central sensitivity to DB as reflected by a 45% decrease in brain DB concentration which induced loss of righting. These data support a role of glutamate neurotransmission in the modulation of the central-depressant effects of water soluble barbiturates.

NMDA RECEPTORS ARE INVOLVED IN THE ACUTE RESPONSE TO ETHANOL IN LS AND SS MICE.
W. R. Wilson and J. A. Ruth, University of Colorado School of Pharmacy, Box 297, Boulder, CO, 80309.

LS and SS are lines of mice that have been genetically selected for their differential response to acute ethanol as measured by duration of loss of righting response. We have shown that the NMDA antagonist 2-amino-5-phosphonovalerate (APV) given by ventricular injection increased CNS sensitivity to ethanol 55% in LS and 45% in SS mice. NMDA had a small effect in LS mice but was without effect in SS mice. The current study was designed to further investigate the role of NMDA receptors in the response to ethanol. Halothane anesthetized mice were injected *icv* with 5μl of drug dissolved in physiological saline. Ten minutes later ethanol was administered *ig* (LS 7g/kg, SS 12g/kg). At loss of righting response blood samples and the brain were analyzed for ethanol content (BEC). Quinolinic acid (QA), an NMDA agonist, significantly and differentially decreased sensitivity of both LS and SS mice to ethanol as shown by increases of 40% (414mg%±15) and 30% (604mg%±22) respectively in BEC at loss of righting response. APV coinjected with QA blocked the effects of QA in a dose related fashion. $MgCl_2$ an antagonist of the NMDA receptor channel increased sensitivity to ethanol in both lines, as shown by a 15% (LS 254±18) and 20% (SS 392±27) decrease in BEC at loss of righting response. When QA was coinjected with $MgCl_2$ the effect of QA was decreased to saline control levels (LS 295mg% ±16; SS 401mg%±37). This study supports the hypothesis that NMDA receptors are involved in the acute response to ethanol in LS and SS mice and may be part of the biochemical profile that is involved in the differential response to ethanol in LS and SS mice.

THYROTROPIN RELEASING HORMONE ENHANCES EXCITATORY SYNAPTIC TRANSMISSION IN VOLTAGE CLAMPED FROG MOTONEURONES. G. Lacey* and A. Nistri. Department of Pharmacology, St. Bartholomew's Hospital Medical College, University of London, London EC1M 6BQ, Great Britain.

Thyrotropin releasing hormone (TRH) facilitates motoneuronal reflex discharges in the spinal cord. Here we have examined the effect of TRH on the excitatory postsynaptic currents (EPSCs) of motoneurones.

Longitudinal slices of frog (Rana temporaria) spinal cord were superfused with Ringer solution containing 1 mM Mg^{2+} at 7°C. Single microelectrodes filled with 3M KCl and connected to an Axoclamp 2A were used to voltage clamp motoneurones (switching frequency 1.5 - 2.0 kHz).

Results were obtained from 12 motoneurones (resting potential 79 ± 1 mV). Polysynaptic current amplitudes were measured over a range of holding potentials (-80 to -30 mV) both before and after the addition of TRH (50 μM). No sustained inward or outward current was produced by TRH, but in some cases there was an increase in the frequency of spontaneous synaptic currents. In 8 of the cells tested, TRH caused a significant ($P < 0.02$) increase in the amplitude of the EPSCs over the entire range of holding potentials used. The reversal potential of the EPSC was estimated, by extrapolation of the I/V curve, to be approximately + 5 mV and was unchanged by TRH. The I/V curves were non-linear, particularly over the range -60 to -80 mV, suggesting a voltage dependence of the channels involved in the production of the EPSC, reminiscent of those channels activated by exogenous glutamate in these neurones.

Our previous work has shown that the membrane conductance of motoneurones and their sensitivity to exogenous glutamate are unchanged by TRH. Together, these results provide evidence for a presynaptic site of action of TRH. This work is supported by the Wellcome Trust.

SEX STEROIDS PRODUCE DIFFERENTIAL ELECTROPHYSIOLOGICAL EFFECTS ON EXCITATORY AMINO ACID AND GABA RECEPTOR SUBTYPES IN THE CEREBELLUM. Sheryl S. Smith, Dept. of Anatomy, Hahnemann U., Philadelphia, PA 19102-1192.

Ongoing studies in this laboratory have demonstrated that systemically administered sex steroids 17β estradiol (E_2) and progesterone (P) alter cerebellar Purkinje (Pnj) cell responses to the amino acids GABA and glutamate (Glu) in the adult female rat. In the present study, in an attempt to delineate the specific receptor subtypes responsible for the observed steroid effects, Pnj cell responses to iontophoretically applied (20s every 50s at 5-50 nA) Glu agonists quisqualate (Quis), kainate and NMDA, as well as to specfic NMDA antagonists such as APV, were tested before and after i.v. application of E_2 (100 ng/kg) or P (50 μg). In addition to a direct excitation, continuous application of NMDA can also produce marked increases (up to 400%) in Quis excitation (22/30 cells). Differential effects of P on $GABA_A$ vs. $GABA_B$ receptors were also examined using baclofen and bicuculline.

The Glu-enhancing actions of E2 appear to have two components: a fast effect (5-10 min) exerted at the Quis receptor and a later component involving NMDA receptor activation: E2 augmented Quis excitation by 100% (35/39 cells), an effect which could only be blocked by APV 20 min post-steroid. Although E2 effects on direct NMDA actions were inconsistent, this steroid produced a 40% increase in NMDA enhancement of Quis excitation. No effects on kainate excitation were noted. In contrast, P depressed excitatory responses of Pnj cells to both Quis (33/36 cells) and kainate (10/11 cells) by 30-70%. Surprisingly, P also potentiated the modulatory effects of NMDA on Quis responses. This latter action may moderate P effects on Glu physiology, as concurrent application of APV increased the magnitude of P suppression of Quis excitation by 10-20%, and prevented recovery to control levels of Quis excitation normally seen by 30 min post-P. P effects on the GABA receptor were found to be predominantly mediated at the $GABA_A$ subtype, as i.) No effects of P on Baclofen inhibition were observed and ii.) A dose of bicuculline resulting in a 40% reduction in GABA inhibition prevented P modulation of GABA responses. Furthermore, P modulation of Quis action was determined to be independent of the $GABA_A$ receptor, as bicuculline application did not prevent P suppression of Quis excitation. *(Supported by NS25809.)*

THE ROLE OF NMDA RECEPTOR MEDIATED CURRENTS IN THE MANIFESTATION OF LTP IN CORTICAL NEURONES. A. Artola and W. Singer. Max Planck Institute for Brain Research, D-6000 Frankfurt/M 71, F.R.G.

In pyramidal cells of rat visual cortex slices, reduction of GABAergic inhibition increases NMDA receptor mediated currents and facilitates long term potentiation (LTP) after tetanic stimulation (TET) of the white matter (Artola A. and Singer W., Nature 330:649). To test the hypothesis that NMDA currents are crucial for the induction and manifestation of LTP we bath applied bicuculline (BIC) at various concentrations (0.1 to 0.5 μM). The BIC effect was quantified by comparing the amplitude of a delayed PSP component (l-PSP), which contains an NMDA mediated potential to that of the early, non-NMDA dependent, PSP component (e-PSP, 8-11 ms poststimulus). At 0.1 to 0.2 μM, BIC neither modified the l/e-PSP ratio (33.6 ± 4.7%,S.D., n=8; control 35.5 ± 9.1%, n=11) nor did it facilitate LTP. At higher concentrations BIC increased the ratio and TET induced LTP. With small ratio increases (l/e = 58.9 ± 11.6%, n=8) only the l-PSP underwent LTP, with large ratio changes (91.3 ± 38.1%, n=11), both e- and l-PSP showed LTP, which amounted to 144.6 ± 22.0% and 127.0 ± 16.1% of control, respectively. APV reversed LTP only of the l-PSP. These results confirm that NMDA conductances are necessary for the induction of LTP and are antagonized by GABA. They indicate further that LTP increases first the NMDA dependent EPSP and, if strong enough, also the non-NMDA EPSP.

381.12

EFFECTS OF NEW KAINATE RECEPTOR ANTAGONISTS ON MUDPUPPY RETINAL NEURONS. E.A. COLEMAN* and R.F. MILLER. DEPT of OPHTHALMOLOGY, WASHINGTON UNIVERSITY, ST. LOUIS, MO 63110. (spon. A.I. Cohen)

We have analyzed the action of 6 new putative kainate (KA) receptor antagonists using whole cell recording techniques in the intact mudpuppy retina. These antagonists were bath applied and in some cases, tested against the excitatory amino acid receptor (EAAR) agonists. The quioxaline derivatives DNQX and CNQX (Honore, et al., 1987, Soc. Neurosci. Abstr. p.383) significantly reduced, if not completely abolished, the light evoked response of 80% of the horizontal and ganglion cells tested at a concentration of 25 μM. Antagonists such as kynurenate required concentrations as high as 3-5 mM to achieve similar effects. A related drug, 6,7-Dichloro-3-hydroxy-2-quinoxalinecarboxylic acid was also effective in reducing synaptic responses but at higher concentrations (100 μM). However, 3-Hydroxy-2-quinoxalinecarboxylic acid, at 100 μM, had virtually no effect on ganglion cell photic responses. Another group of EAAR antagonists were also tested: MLV-6976 and MLV-5860 (Masaki & Shinozaki, 1986, Br. J. Pharmac. 89, 219-228). These compounds also reduced the light evoked response of retinal ganglion cells but at a concentration of 1 mM.

CNQX and DNQX were also tested against exogenously applied EAAR agonists: kainate, N-methyl-D-aspartate (NMDA), and quisqualate (QQ). Both compounds, at 25 μM, blocked the depolarizing effects of KA (50 μM) and QQ (15 μM). CNQX blocked the depolarizing effects of NMDA (300-500 μM) in 40% of the cells tested. In the remaining cases, CNQX reduced the NMDA response to < 50% of the control level. DNQX, which was slightly more effective in reducing the synaptic responses, always blocked the depolarizing effects of NMDA. Though not the most selective of the EAAR antagonists we have tested, CNQX and DNQX are by far the most potent.

BARIUM REVEALS NMDA RECEPTOR-MEDIATED SYNAPTIC TRANSMISSION IN TURTLE HIPPOCAMPUS. Linda J. Larson-Prior and N.Traverse Slater, Dept. of Physiology, Northwestern University Medical School, 303 E. Chicago Avenue, Chicago, IL 60611 U.S.A.

NMDA receptor antagonists reduce convulsant-induced epileptiform discharges in turtle hippocampus (ventromedial cortex), but in the absence of convulsant drugs afferent stimulation of VMC pyramidal neurons evokes a biphasic IPSP which masks underlying excitatory transmission [1]. Direct evidence for NMDA receptor-mediated transmission in this structure has been demonstrated by the bath application of 500 μM $BaCl_2$ or penetration of cells with cesium-filled electrodes, both of which block the late K^+-mediated IPSP and reveal a late, slow EPSP (Fig. 1). This EPSP was reversibly blocked by the NMDA receptor antagonists DL-AP5 (50-100 μM) and ketamine (250 μM).

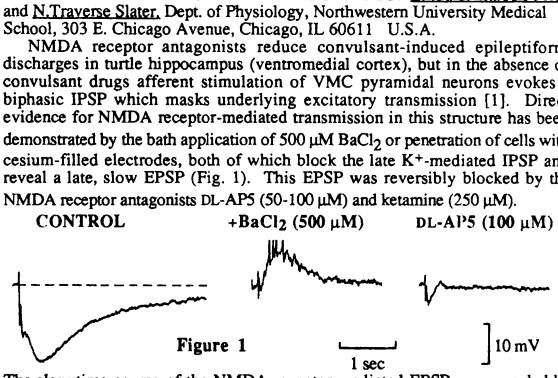

Figure 1

The slow time-course of the NMDA receptor-mediated EPSP was revealed by subtraction of responses before and after the addition of DL-AP5 or ketamine. I-V plots of this potential did *not* display the expected voltage-dependent rectification in the presence of external magnesium. Voltage-clamp of neurons in barium or impaled with cesium-filled electrodes revealed a slow inward current which was reversibly blocked by DL-AP5. These results demonstrate the existence of NMDA receptor-mediated excitatory transmission in turtle hippocampus that likely contributes to the maintenance of convulsant-induced epileptiform discharges.

POTENTIATION BY HALOPERIDOL OF THE ANTAGONISM BY MK-801 OF THE EXCITATORY EFFECT OF DICARBOXYLIC AMINO ACIDS: AN ELECTROPHYSIOLOGICAL STUDY IN THE RAT DORSAL HIPPOCAMPUS. F. P. Monnet*, G. Debonnel and C. de Montigny (SPON: L. Vachon). Institut P. Pinel and McGill University, Montréal, Québec, Canada.

Behavioral and electrophysiological studies have shown that MK-801, an agonist of the PCP_1 receptor, blocks specifically the excitatory and proconvulsive actions of N-methyl-D-aspartate (NMDA).

Male Sprague-Dawley rats were anesthetized with urethane (1.25 g/kg, i.p.). Five-barrelled glass micropipettes were used for extracellular recording and microiontophoresis. The central barrel was used for unitary recording and the side barrels filled with the following solutions: kainate (1 mM in NaCl 400 mM, pH: 8), quisqualate (1.5 mM in 400 mM NaCl, pH: 8), NMDA (50 mM in 400 mM NaCl, pH: 8), and MK-801 (50 mM in 200 mM NaCl, pH: 4).

In both CA_1 and CA_3 regions of the dorsal hippocampus, the suppressant effect of MK-801 on NMDA-induced activation of pyramidal neurons was more than six times greater than its effect on kainate- and quisqualate-induced activations. Haloperidol (2 mg/kg, i.v.) markedly potentiated the suppressant effect of MK-801 on the three excitatory amino acid-induced activations.

These results confirm the selective antagonism of NMDA by MK-801 and suggest an allosteric interaction between the PCP_1 and σ-haloperidol subtypes of receptors.

381.15

STUDIES ON THE EFFECTS OF EXCITATORY AMINO ACID ANTAGONISTS IN THE MEDIAN RAPHE NUCLEUS OF THE RAT. D. Wirtshafter, J. Krebs* & R. Trifunovic*. Dept. Psych., Univ Ill. at Chicago, Chicago, IL 60680.

In previous studies we have shown that injections of a number of excitatory amino acid (EAA) antagonists into the median raphe nucleus (MR), but not adjacent structures, result in marked increases in locomotor activity and food and water intake. In the current experiments, we attempted to clarify the receptor subtypes responsible for these effects.

Locomotor activity was measured after injections of a number of relatively selective competitive NMDA antagonists into the MR, and the threshold doses for the production of hyperactivity were correlated with the affinity of these compounds for the NMDA receptor. The following compounds were examined, in order of behavioral potency: CPP > DL-AP5 = DL-AP7 = Asp-AMP > Glu-AMP > AP6. In contrast AP4, AP8, and L-AP5, which have very low affinity for the NMDA receptor, were without behavioral effect. In contrast, intra-MR injections of the noncompetitive NMDA antagonists PCP and MK-801 were without effect on activity. One explanation of this finding is that NMDA receptors in the MR may not be coupled to PCP receptors. Feeding and drinking in sated rats could also be elicited by injections of the specific NMDA antagonists CPP and AP5, with the former compound being considerably more potent.

Hyperactivity, and feeding, could also be elicited by intra-MR injections of the kainate/quisqualate antagonists pBB-PZDA and GAMS at doses far lower than those expected from their affinity for the NMDA receptor. These results suggest that both NMDA and kainate/quisqualate receptors may play a role in MR function.

381.16

COMPARATIVE ACTIONS OF EXCITATORY AMINO ACIDS ON STRIATAL DOPAMINE AND ENKEPHALIN RELEASE. B.B. Ruzicka*, D.W. Clow* and K. Jhamandas. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, K7L 3N6.

In the present study, the effect of L-glutamate (L-Glu), N-methyl-D-aspartate (NMDA), kainate (KA) and quisqualate (Quis) on the release of endogenous dopamine (DA) and methionine-enkephalin (ME) from slices of the rat caudate-putamen were investigated. L-Glu, NMDA, KA and Quis, in the absence of Mg^{2+}, produced a dose-related, Ca^{2+}-dependent increase in DA release. DA release induced by L-Glu and NMDA was Mg^{2+}-sensitive and antagonized by D-2-amino-7-phosphonoheptanoate (D-APH) (0.5 mM). In contrast to their excitatory actions on DA release, L-Glu, NMDA, KA and Quis, in the absence of Mg^{2+}, had little effect on ME release. L-Glu (10 mM) also failed to influence the 25 mM K^+-evoked release of ME. However, in the absence of Mg^{2+}, the 25 mM K^+-evoked ME release was significantly greater than that observed in the presence of Mg^{2+}. D-APH (0.5 mM) had no effect on the 25 mM K^+-induced ME release in the absence of Mg^{2+}. These results show that activation of excitatory amino acid receptors causes an increase in the release of DA, but no apparent increase in the release of ME.

EFFECTS OF QUINOLINIC ACID ON AMINO ACID RELEASE IN THE RAT STRIATUM IN VIVO. B.A. Donzanti and B.K. Yamamoto, Dept. Pharmacol., Northeastern Ohio Univ. Col. of Med., Rootstown, OH 44272

Quinolinic acid (QA) has been hypothetically linked to a variety of neurodegenerative disorders. Removal of the cortico-striatal glutamatergic input prevents QA-induced neurotoxicity. Thus, it is possible that the neurotoxicity occurs via the presynaptic release of other endogenous excitatory amino acids. However, in contrast to kainic acid (KA), in vitro striatal studies have repeatedly failed to substantiate such a mechanism. Using intracranial microdialysis in conjunction with HPLC with electrochemical detection, we have studied the in vivo release of amino acids from the rat striatum. Urethane anesthesized rats were implanted with 3 mm dialysis probes into the medial caudate. A modified Ringer's medium was perfused through the system at a rate of 2.5 ul/min. Twenty min perfusate samples were collected and analyzed for amino acid content by O-pthalaldehyde derivatization. Following a 2 hr baseline stabilization, QA (12 mM) or KA (12 mM) was perfused through the probe for 20 min. QA perfusion increased ASP (252 + 44%) and GLU (226 + 7%) release. In addition, there was also a marked increase in TAU (333 + 62%). Other amino acids did not consistently change. Similarly, but more dramatically, KA induced ASP (421 + 25%), GLU (319 + 54%) and TAU (6714 + 253%) release. In conclusion, these data suggest that QA-induced striatal release of excitatory amino acids (i.e., GLU and ASP) may be responsible for its neurotoxic properties. We are currently repeating these studies in the unanesthesized, behaving rat.

N-METHYL-D-ASPARTATE RECEPTORS MAY MODULATE DENDRITIC DOPAMINE RELEASE IN RAT SUBSTANTIA NIGRA. G. Bustos, R. Araneda* and J. Abarca*. Lab. of Biochem. Pharmacol., Catholic University of Chile, Santiago, Chile.

A superfusion system was used to study the effects of excitatory amino acids (EAA) on release of [^{3}H]dopamine (DA) previously taken up by rat substantia nigra (SN) slices. The EAA tested (50 to 250 μM), with the exception of quisqualate and kainate, markedly evoked [^{3}H]DA release when Mg^{2+} ions were omitted from the superfusion medium. The EAA receptor agonists exhibited the following relative potency in stimulating [^{3}H]DA release: L-GLU > NMDA = NM(D,L)A > D-GLU >> quisqualate = kainate. Further experiments showed that the NMDA-mediated release of [^{3}H]DA was totally supressed by D-2-amino-5-phosphonovalerate (100-200 μM), or by the omission of Ca^{2+}, or by the addition of TTX (0.1 μM) to the superfusion medium. In addition, strychnine (10 μM) significantly decreased NMDA-evoked as well as glycine-evoked release of [^{3}H]DA from nigral slices. It is suggested that activation of NMDA-subtype receptors in SN may trigger a Ca^{2+}-dependent release of DA from dendrites of nigro-striatal DA-containing neurons. A transynaptic mechanism partially involving glycine-containing interneurons may account for some of the events mediating NMDA-receptor activation and DA release in SN.

EVIDENCE AGAINST THE CO-TRANSMITTER ROLE OF GLUTAMATE IN CORTICAL CHOLINERGIC TERMINALS. J.C.Szerb and A.Fine Dept.of Physiol.Biophys. Dalhousie Univ.Halifax, N.S.B3H 4H7,Canada.

Recently Docherty et al.(Nature,330:64,1987) described the isolation of cortical cholinergic and GABA-ergic terminals by means of ChAT or GAD antisera and magnetic microspheres. These terminals contained and released large amounts of glutamate, which suggested that glutamate (GLUT) may have a major role as a co-transmitter in cholinergic and GABA-ergic terminals. To see whether the GLUT content of rat cortex can be influenced by lesions of the cholinergic terminals, as predicted by the co-transmitter role of glutamate, we compared cholinesterase (ChE) activity and GLUT content of the frontal and parietal cortex of the two hemispheres following unilateral injection of ibotenic acid into the n.basalis. While the ChE activity ipsilateral to the lesion was massively depressed 7 days after the lesion, no change in the GLUT content (102% compared to the intact side) was found. Furthermore, a 67% depression by 10 μM oxotremorine of the rate of [^{3}H]ACh release induced by 25 mM K^+ was not accompanied by any change in endogenous GLUT release. Since it is well established that the release of all co-transmitters is regulated by the same autoreceptors (Bartfai et al. Ann.Rev.Pharmacol.28:285, 1988), the lack of co-regulation of the release of ACh and GLUT by muscarinic autoreceptors also suggest that the co-transmitter role of GLUT with ACh must be minor. The occurrence of large amounts of GLUT in isolated cholinergic terminals is likely to be due to contamination with glutamate-ergic synaptosomes. (Supported by the MRC of Canada.)

MK-801 BEHAVIORAL ACTION AND BLOCKADE OF D_1-DOPAMINE-RECEPTOR PRIMING IN NEONATAL-6-OHDA-LESIONED RATS. **H.E. Criswell, R.A. Mueller and G.R. Breese Univ of North Carolina Sch. of Medicine. Chapel Hill NC 27599**

MK-801 antagonizes NMDA receptor function, enhances locomotor activity in rats, and antagonizes long-term-potentiation. In this work, neonatal- but not adult-6-OHDA lesioned rats were supersensitive to the behavioral activating effects of MK-801. The increased activity induced by MK-801 in neonatal-6-OHDA-lesioned rats was blocked by prior administration of alpha methyltyrosine (40 or 100 mg/kg) indicating that endogenous dopamine is needed for behavioral activation. Even though MK-801 increased activity through a dopaminergic mechanism, unlike other indirect acting agents and a D_1-DA agonist, this drug was unable to prime D_1-DA receptors upon repeated administration. Because the priming of D_1-DA receptors may reflect a long term neural message, the effect of MK-801 on this phenomenon was assessed. The increase in behavioral effects observed in neonatal-6-OHDA-lesioned rats following repeated administration of a D_1-dopamine agonist (priming) was blocked by the concomitant administration of MK-801 at a dose (0.17mg/Kg) which produces behavioral activation by itself or by a higher dose (1 mg/kg) which produced sedation. These results suggest that NMDA receptors influence DA function and can influence priming--a permanent neural message.

IgG FROM PATIENTS WITH LAMBERT-EATON SYNDROME INHIBITS CALCIUM-ACTIVATED POTASSIUM CURRENTS. Yong I. Kim. Depts. of Neurology and Biomedical Engineering, Univ. of Virginia Sch. of Med., Charlottesville, VA 22908.

Recent evidence indicates that the antigenic target of Lambert-Eaton syndrome (LES) IgG is a voltage-dependent calcium channel (Kim and Neher, Science 239:405, 1988). The aim of present study is to determine whether LES IgG also modifies Ca^{2+}-dependent potassium channel currents ($I_{K(Ca)}$). Bovine adrenal chromaffin cells (mean C$_m$=8.03 pF) were incubated for 24 hours with IgG (4 mg/ml) from an LES patient with small-cell carcinoma of the lung and healthy control subjects. In mouse passive transfer studies, this patient's IgG was found to block evoked ACh release by 75%. Using patch clamp technique, whole-cell K^+ currents (I_K) were recorded from the cells held at -80 mV, and depolarized to -40 to +120 mV (exposed to 2 mM Ca^{2+} buffer); peak $I_{K(Ca)}$ occurring at +15 to +35 mV was analyzed by the method of Marty and Neher (J. Physiol. 367:117, 1985). In 22 LES IgG-treated cells, $I_{K(Ca)}$ was 178 pA/pF, declining by 51% from the control (361 pA/pF, n=22 cells) and 55% from the normal untreated (398 pA/pF, n=17). By comparison, I_K elicited at +80 mV fell by 20 and 11%, respectively, relative to the control and normal. These results provide evidence for a significant inhibition of Ca^{2+}-activated K^+ channel currents in this disorder. Clinical implication of this finding is yet to be demonstrated (Supported by NIH grant NS18607 and an MDA research grant).

ELECTROPHYSIOLOGICAL ACTIONS OF THE K^+ CHANNEL ACTIVATORS, BRL 34915 AND PINACIDIL IN GUINEA PIG CARDIAC MUSCLE. J. R. McCullough and M. L. Conder*. Dept. of Pharmacology, Squibb Inst. for Med. Res. Princeton, NJ 08543-4000.

Activation of K^+ channels of vascular smooth cells with resultant hyperpolarization of the resting potential (RP) is thought to underlie the mechanism of action of the novel antihypertensives, BRL 34915 (BRL) and pinacidil (PIN). The actions of BRL and PIN in cardiac cells are not well understood. To this end, we used standard intracellular microelectrode and whole-cell patch-clamping techniques to study the electrophysiological actions of these agents in papillary muscles and isolated ventricular myocytes of the guinea pig. Both BRL (10^{-5}-10^{-4} M) and PIN (10^{-5} - $5x10^{-4}$ M) caused marked shortening of action potential duration (APD) measured at 50 and 90% repolarization; APD was shortened by up to 80% of control with higher concentrations. RP hyperpolarized several mV in the presence of BRL and PIN, with little effects on other parameters. The inhibition of APD by both compounds was completely and rapidly reversed in a dose dependent manner by addition of 10^{-7}-10^{-5} M glyburide, a sulfonylurea known to inhibit ATP-regulated K^+ channels. In isolated myocytes, BRL ($5x10^{-6}$ M) significantly hyperpolarized RP (in 1-10 mM K^+) and increased the slope of the relationship between RP and K^+ from -41 to -55 mV, suggesting an increase in K^+ permeability. Whole cell voltage clamp experiments failed to find an increase in the inwardly rectifying K^+ current responsible for RP with $5x10^{-6}$ M BRL. Higher concentrations of BRL ($5x10^{-5}$-10^{-4} M) increased the outward current positive to -50 mV in some cells, suggesting that this current may be responsible for the APD shortening observed in the multicellular preparations. These results suggest that different mechanisms or channels may underlie the hyperpolarizing and the APD shortening actions of BRL and PIN and that the latter may be mediated through the ATP-regulated K^+ channel.

STIMULATORY EFFECTS OF 4-AMINOPYRIDINE AND pH ON CALCIUM-ACTIVATED K CHANNELS IN GH_3 CELLS. D.J. Fickbohm* and G.S. Oxford (SPON: A.E. Stuart). The Neurobiology Program, Univ. of North Carolina, Chapel Hill, NC 27599.

4-aminopyridine (4AP) is often used to block voltage-dependent K(V) channels and to distinguish them from Ca^{++}-activated K(Ca) channels which are gnerally insensitive to 4AP. However, it has been reported (Herman & Gorman, J. Gen. Physiol. 78:63, 1981; Rogawski et al., Soc. Neurosci. Abs. 11:790, 1985) that 4AP can increase both macroscopic and single K(Ca) channel currents. The present study confirms and extends these findings in GH_3 cells. Cells were examined using whole cell and single channel patch recording techniques. Macroscopic K(Ca) currents were measured at +60mV following a 1 sec prepulse to 0mV to both promote Ca^{++} entry and inactivate competing K(V) currents. 4AP (2-5mM) increased such currents by 300%, whereas little or no change was observed in the absence of extracellular Ca^{++}. Raising the pH_o to 8.5 elicited a similar, yet smaller, increase in K(Ca) which was dependent on external Ca^{++}. In cell-attached recordings, bath applied 4AP (2-10mM) greatly increased single K(Ca) channel activity under standard conditions, but not in the absence of bath Ca^{++}. Preliminary experiments have revealed that : (1) whole cell (L-type) Ca currents are not enhanced by 4AP, (2) single Ca channel activity in cell-attached patches is not changed by 4AP, and (3) 4AP does not obviously alter the Ca^{++} sensitivity of K(Ca) channels in excised inside-out patches. Supported by NIH NS18788.

RYANODINE MODIFIES THE ION-SELECTIVE AND ION-TRANSPORT PROPERTIES OF LOCUST MUSCLE POTASSIUM CHANNELS. E. Gorczynska*, P.L. Huddie* and P.N.R. Usherwood*, Department of Zoology, University of Nottingham, Nottingham NG7 2RD.
(SPON. L.D. Partridge).

Giga-ohm seal patch clamping of adult locust muscle revealed 3 types of K^+ channel, which differed with respect to the voltage dependence and kinetics of channel gating and relative open channel conductances (100pS, 20pS, 10pS). A pNa/pK ratio of 0.067 was estimated (using the Goldman, Hodgkin, Katz equation) for the two largest channels. At concentrations of $\geq 10^{-9}$M ryanodine (a plant alkaloid) increased pNa/pK to a value approaching unity. The ion selective and ion transport properties of these potassium channels have been investigated further in the absence or presence of ryanodine using excised inside-out patches of muscle membrane with a variety of cations, viz. Li, Na, K, Rb, Cs. The relative permeabilities of these ions in the presence and absence of ryanodine will be described. The signficance of these data in terms of the molecular properties of the potassium channels and their transport of cations will be discussed.

PHARMACOLOGICAL CHARACTERIZATION OF SINGLE-CHANNEL K+ CURRENTS IN *DROSOPHILA* MUSCLE. M. Gorczyca, and C.-F. Wu. Dept. of Biology, Univ. of Iowa, Iowa City, Iowa 52242

In *Drosophila* muscle, at least four macroscopic potassium currents can be distinguished by differences in their kinetic and pharmacological properties and by their sensitivity to a number of mutations. Studies of single channel events underlying these currents have only recently been initiated in muscle membrane vesicles and cultured myotubes. We now report single channel currents observed in body wall muscles *in situ* in wild-type larvae.

Using the inside-out patch clamp configuration, we have observed several distinct potassium channel types. The most prominent one was calcium-dependent, becoming activated in the concentration range of 10^{-7} to 10^{-6} M. The channel displayed a very high open probability at 10^{-7} M and greater, had a conductance of 70-80pS (in symmetrical 130K+), and was not sensitive to 50mM TEA, 1mM 4A-P, and 0.1mM quinidine. It was blocked by barium at concentrations greater than 0.1mM. A second channel type with a 12pS (130K+ pipette/2K+ bath) conductance, was partially blocked by 10mM TEA, 0.1mM quinidine, and 0.1mM barium but not by 1mM 4A-P. A third channel type shared the pharmacological profile of the 12pS channel but its conductance was twice as large. Barium caused a slow block in these three channel types whereas TEA and quinidine led to a fast block. A fourth channel type was highly sensitive to TEA, being almost completely blocked at 1mM. We are currently attempting to correlate these single channel conductances to the previously described macroscopic currents.

382.6

OPEN CHANNEL NOISE IN CALCIUM-ACTIVATED POTASSIUM CHANNELS. M.I. Glavinović, Dept. Anaesthesia Research, Physiology and Biomedical Engineering Unit, McGill University, Montréal, Québec, Canada.

The current through an open ion channel is carried by discrete ions and is thus expected to show fluctuations due to a 'shot noise' (Schottky, Ann. Phys. 57, 541-567, 1918), and as recent studies in ACh receptor channels (Sigworth, Biophys. J. 47, 709-720, 1985) have shown due to fluctuations in the conformation of channel protein also.

In this study the single channel currents were recorded from a calcium activated potassium 'maxi' channels in excised inside-out patches of mouse spinal cord neurons and bovine chromaffin cells at room temperature (20-22° C). The variance of the open-channel current exceeds that of the background; shot noise cannot account for the difference. The low-frequency component of the power spectrum (corrected for the background noise and transfer function of recording system) of the open channel noise could be well fitted with a single Lorentzian. It appears to arise from fluctuations in channel conductance of $\sim$ 3% on a time scale of < 0.2 msec arising presumably from conformational fluctuations in the channel protein. The characteristic relaxation time of the low frequency component showed only a marginal voltage dependence, but its variance was altered when current amplitudes changed with changing membrane potential. Fluctuations in the conformation of channel protein appear to be characteristic of each type of ion channel. Supported by MRC (Canada).

J-CURRENT: A RAPIDLY RECTIFYING CALCIUM-DEPENDENT OUTWARD CURRENT MECHANISM Daniel K. Hartline, Donald V. Gassie*, Beverly A. Tomiyasu*, and Bradley R. Jones. Békésy Lab, Univ. of Hawaii, Honolulu, HI 96822

A transient, calcium-dependent outward current (I_J) has been described in somata of neurons of the stomatogastric ganglion in crustaceans (Graubard and Hartline Soc. Neurosci. Abstr. 10:1073; Hartline et al. ibid 11:1023). Study of tail currents shows that:

1. I_J activates between -25 and 0 mV.
2. I_J tails reverse near -60 mV in normal saline (13 mM K^+).
3. Tail reversal is dependent on $[K^+]_o$ but less so (30 mV/decade) than would be expected of a simple K^+ mechanism.
4. Plots of $\exp(E_J F/RT)$ vs $[K^+]_o$ are linear, but do not go through the origin.
5. I_J tail reversal level is not obviously affected by changes in external Na^+, Cl^-, or pH.
6. Current jumps during step-back protocols are consistent with an instantaneously or rapidly developing rectification. Conductance near 0 can be 10-fold greater than near -50 mV.

Supported by NIH grant NS15314 (DKH) and a grant from the Ida Russell Cades fund (BRJ).

382.8

A SLOW, AMINOPYRIDINE-SENSITIVE, TRANSIENT K^+ CURRENT IN FROG AUTONOMIC GANGLION NEURONES. J.A. Zidichouski*, P.A. Smith & A.A. Selyanko*, SPON: R.J. Walker, Dept. Pharmacol., Univ. Alberta, Edmonton, Canada & Bogomoletz Inst. Physiol., Kiev, U.S.S.R.

The whole-cell patch clamp technique was used to study K^+ currents in neurones dissociated from Rana pipiens autonomic ganglia. Membrane repolarization to -60 to -30mV from hyperpolarizing voltage commands to -60 to -140mV revealed classical, fast, transient, outward tail currents (I_A, A-currents) in paravertebral sympathetic ganglion B-cells but not in cardiac parasympathetic or sympathetic ganglion C-cells. In all three neurone types however, our methodology revealed another, hitherto undescribed, transient, Ca^{2+} independent K^+ current (I_{SA}) which exhibited a similar voltage dependence to I_A yet activated and inactivated with a 100-fold slower time course. I_{SA} slowly developed during the course of whole cell patch clamp experiments and was antagonized by 2mM 4-AP but not by Ba^{2+} (2-4mM), TEA (3mM) or d-tubocurarine (70μM). Muscarine (10μM) rapidly and reversibly induced I_{SA} in both B- and C- sympathetic ganglion cells but inhibited it in parasympathetic cells. Control of I_{SA} by neurotransmitters may therefore be important in the modulation of neuronal repetitive discharge characteristics.

Supported by MRC and AHFMR.

INWARD RECTIFICATION IN MAMMALIAN CNS AXONS. D.L. Eng,* T.R. Gordon, J.D. Kocsis, and S.G. Waxman. Neuroscience Research Lab, VA Medical Center, West Haven, CT, 06516.

Inward rectification has been studied in a variety of neuronal systems. Rat optic nerves were studied in a modified sucrose gap using whole nerve current clamp of the axonal membrane. Hyperpolarizing constant current pulses led to a delayed depolarizing sag corresponding to decreased membrane resistance. This inward rectification was present in TTX, 4-AP, and TEA, indicating that it is not dependent on ion channels sensitive to these agents. CsCl, known to block Na^+ and K^+-dependent inward rectifiers in other systems, blocked the inward rectifying conductance in rat optic nerve. $BaCl_2$, a blocker of K^+-dependent inward rectifiers, reduced the inward rectification in rat optic nerve. The inward rectification was absent in Krebs' solution containing choline substituted for K^+ and Na^+. The reintroduction of Na^+ or K^+ led to partial restoration of the inward rectification, with Na^+ being more potent than K^+. The results indicate that inward inward rectification is present on a CNS axon system, the rat optic nerve, and is due to a mixed Na^+/K^+ conductance.

382.10

PATCH-CLAMP RECORDED CHANNELS IN PLASMA CELLS ISOLATED FROM AN AVIAN LACRIMAL GLAND. B. Walcott, S.F. Fan* E. Roemer*and P. Brink. Department of Anatomical Sciences, State Univ. of New York, Stony Brook, N.Y. 11794.

Avian lacrimal glands contain large populations of plasma cells that secrete the immunoglobulins found in high concentrations in the tear fluid. Those regions of the glands particularly rich in lymphocytes are densely innervated by cholinergic and noradrenergic fibers of the autonomic nervous system and there is extensive substance P-like and vasoactive intestinal polypeptide-like immunoreactivity as well. Physiological experiments have shown that carbachol increases the release of total protein and immunoglobulins from isolated gland fragments. Thus there is the possibility of neural modulation of the secretory immune response. To examine this directly, we have begun to characterize the channels found in isolated plasma cells with the intention of determining the effects of neurotransmitters on them. Glands dissected from chickens were carefully cleaned of adhering fat and then were teased apart in RPMI media. The isolated cells were centrifuged once in RPMI, replated and treated with 0.1 mg/ml collagenase for 20 minutes. Morphologically identified plasma cells were patch-clamped and showed large numbers of voltage dependent K^+ channels that were also Ca^{++} dependent.

382.11

PATCH-CLAMP RECORDINGS FROM DISPERSED TURTLE RPE CELLS, by J. A. Fox and R. H. Steinberg, Departments of Ophthalmology and Physiology, U.C. San Francisco, San Francisco CA 94143.

The electrophysiological properties of isolated turtle (*Pseudemys scripta elegans*) retinal pigment epithelial cells (RPE cells) were investigated using the patch-clamp technique. Cells were dispersed with papain and plated onto glass cover-slips for patch recording with fire-polished pipets (Corning 8161 glass, 2-5 MegOhms) under constant flow of solution bubbled with 95 % O2 - 5 % CO2. The bath contained (mM): 115 NaCl, 25 Na HCO_3, 10 dextrose, 3 KCl, 2 $CaCl_2$, 1 $MgCl_2$, pH 7.3. Pipet solutions containing 135 mM KF or KCl, 15 $KHCO_3$, 0.5 mM $CaCl_2$, 5 mM EGTA, and 5 mM $MgCl_2$ were bubbled and then filtered before use.

The average resting potential of 67 cells was -36 ± 20 mV, with average whole-cell capacitance of 85 ± 24 pF. Virtually all cells had outwardly rectifying I-V relations. Most cells exhibited a voltage dependent outward current activated by depolarization beyond about -30 mV, which inactivated during a 500 ms voltage step. This current exhibited steady-state inactivation, being much reduced or absent when cells were held at -30 mV. It was abolished by 500 μM quinidine and was reduced by 100 μM quinidine, 2 mM Ba, 2 mM TEA and 2 mM 4AP. Reversal potentials for this current, as measured by tail currents in 10 cells, were -70 ± 9 mV in normal (3 mM KCl) ringer's and -36 ± 5 mV in 30 mM KCl ringer's, indicating potassium selectivity. Many cells had slowly activating outward currents upon depolarization beyond about + 40 mV which appeared to reverse near 0 mV in both 3 mM KCl and 30 mM KCl solutions. This current was not greatly affected by the blockers which affected the K+ current. Less frequently we observed activating or inactivating (during a 500 ms voltage step) inward currents at potentials more negative than -70.

382.12

CALCIUM-ACTIVATED POTASSIUM AND CHLORIDE CURRENTS IN RABBIT PARASYMPATHETIC NEURONS. T. Tokimasa, T. Nishimura*, M. Tsurusaki* and T. Akasu*. Dept. of Physiology, Kurume Univ. Sch. of Med., Kurume 830, Japan.

Vesical pelvic ganglion cells of the rabbit urinary bladder were voltage clamped using a single microelectrode in a Krebs solution containing TTX (1 μM). Inward rectification at potentials negative to -80 mV was blocked by 2 mM cesium ions. Calcium-activated potassium current which underlies the spontaneous hyperpolarizing oscillations of the resting membrane and the action potential after-hyperpolarization was selectively blocked by apamin (1-10 nM) and curare (30-300 μM). Superfusing the preparation with a nominally calcium-free solution eliminated not only these calcium-activated hyperpolarizations but also the persistent potassium current which was already activated at the resting potential of about -60 mV. The persistent potassium current was insensitive to apamin and curare but was non-selectively blocked by 20 mM TEA and intracellular injection of Cs ions or EGTA. Under the complete suppression of the calcium-activated potassium current, the inward calcium current evoked by commanding the cells from -60 mV to -10 mV for 50-100 ms was followed by an inward tail current. The inward tail was due to an efflux of chloride ions. Both calcium and chloride currents were blocked in a calcium-free solution.

382.13

WHOLE-CELL VOLTAGE-CLAMP STUDY OF TWO DISTINCT COMPONENTS OF "A CURRENT" IN HIPPOCAMPAL NEURONS. B.E. Alger and D. Doerner, Dept. Physiol, Univ. MD. Sch. Med., Baltimore, MD 21201.

Using whole-cell voltage-clamp techniques we identified two distinct transient outward currents in hippocampal neurons acutely dissociated from adult guinea pig or tissue cultured from fetal rat. In control saline with 10-20 mM TEA, depolarizing steps from relatively hyperpolarized holding potentials elicit a rapidly-activating K current which inactivates fully with a time constant of 60-100 ms. 4-AP (1-10 mM) reduces total transient current, unmasking a component which inactivates much more rapidly, with a time constant of 10-20 ms. The 4-AP-insensitive transient current is completely blocked by 100-200 μM Cd or by low Ca saline. Conversely, addition of Cd to the control saline reduces total transient current and slows the overall time constant of inactivation. In Cd, the residual transient current, corresponding to the A current (I_A), was blocked by bath application of 4-AP. Both transient current components showed similar voltage-dependence.

The contribution of I_A and the Cd-sensitive current to total transient current was variable. I_A was ubiquitous and invariably larger than the Cd-sensitive transient in acutely isolated adult neurons. The faster-inactivating, Ca-dependent transient was larger and more prevalent in cultured neurons from fetal rat hippocampus.

SINGLE ELECTRODE WHOLE CELL VOLTAGE AND CURRENT CLAMP ANALYSIS OF POTASSIUM CHANNELS IN HAIR CELLS ISOLATED FROM THE CRISTA AMPULLARIS OF THE FROG. G.D. Housley[1], C.H. Norris[1,2] and P.S. Guth[1]. Depts. [1]Pharmacology & [2]Otolaryngology, Tulane University, New Orleans, LA 70112.

Hair cells from the crista ampullaris of the frog (*Rana pipiens*) were isolated enzymatically (0.17 mg/ml papain in low Ca^{++} artificial perilymph) and placed in short-term culture (Leibovitz L-15 medium; Sigma). The resting membrane potentials (V_z) were -44.9 ± 1.5 mV (x ± SEM; n=51). Two types of outward current were identified corresponding to the fast transient K^+ current (K_A) and the slower Ca^{++} dependent K^+ current (K_{Ca}) reported by Lewis and Hudspeth (Nature 304:538-541, 1983). Using a conditioning pulse protocol; most inactivation of the K_A current occurred between -60 mV and -10 mV, with 50% inactivation occurring with conditioning pulses close to V_z. The K_A channels inactivate exponentially with a time constant of about 16 ms. Tetraethylammonium (TEA; 10 mM) blocked only the K_{Ca} current. Replacing the K^+ (103 mM) with equimolar Cs^+ in the internal solution abolished the outward current and left only a small inward current. The mean K_A and K_{Ca} conductances (from -20 mV to +20 mV) were (x ± SEM) 15.8 ± 3.96 nS and 21.3 ± 1.60 nS respectively (n=7). Injecting 1 nA of current produced damped oscillations in cell membrane potentials. This resonance, only previously reported in hair cells of putative auditory function (Crawford and Fettiplace, J. Physiol. 312:377-412, 1981; Lewis and Hudspeth, Nature 304:538-541, 1983; Pitchford and Ashmore, Hear. Res. 27:75-83, 1987), is thought to be the result of an interplay between an inward Ca^{++} current and the outward K_{Ca} current. TEA blocked this resonance. Support: N.I.H.-NS 22051; Southern Hear. & Speech Fndn.; N.Z.DRF; MRC(N.Z.).

382.15

COMPARISON OF 4-AMINOPYRIDINE (4-AP) AND TETRAHYDROAMINO-ACRIDINE (THA) ON MEMBRANE PROPERTIES AND IONIC CURRENTS IN GUINEA PIG BASAL FOREBRAIN. J.A. Sim* and W.H. Griffith (Spon: L.L. Keeley). Dept. of Medical Pharmacology and Toxicology, College of Medicine, Texas A & M University, College Station, TX 77843.

The actions of 4-AP and THA were studied in basal forebrain (BF) neurons in vitro using intracellular recording and single electrode voltage-clamp (SEVC) techniques. Both compounds decreased several presumed potassium (K^+) conductances, but over different concentration ranges. In all cell types, 4-AP (100-300 μM) hyperpolarized the membrane potential, increased membrane conductance, prolonged action potential duration and increased spontaneous transmitter release. Opposite membrane effects were elicited in all cell types by THA (100-300 μM). A transient outward current (A-current) was described in all three cell types. Both 4-AP (100 μM) and THA (300 μM) reduced the A-current by approximately 50% with no change in voltage dependence. Blockade was concentration dependent and readily reversible with 4-AP. THA, but not 4-AP, had an additional effect to block time-dependent inward rectification in F-AHP cells. Despite structural similarities between the two compounds, our results demonstrate numerous differences between 4-AP and THA when compared in BF neurons. Supported by NIH Grant NS22456 (WHG) and the U.K. Medical Research Council (JAS).

MUSCLE: FUNCTION AND BIOCHEMISTRY

383.1

THE INFLUENCE OF INTERMITTENT ELECTRICAL STIMULATION ON THE MECHANICAL PROPERTIES OF A PREDOMINANTLY FAST MUSCLE IN ADULT AND SENESCENT FISCHER-344 RATS. T.J. Walters*, H.L. Sweeney and R.P. Farrar(SPON: P. MacRea). Dept. of Kinesiology, Institute for Neurolgoical Sciences Research. Univ. of Texas, Austin, TX 78712.

The influence of elevated neural activity on the mechanical properties of the predominantly fast flexor digitorum longus (FDL) was investigated in adult (7-8 mo.) and aged (27-28 mo.) Fischer-344 rats using intermittent electrical stimulation. The FDL was stimulated via an electrode cuff around the tibial nerve at a frequency of 10 Hz for 8 hr/day for periods ranging from 0-90 days (0, 20, 35, 60, and 90 days). Both age groups displayed an increase in the twitch tension/tetanic tension (P_t/P_o) following 20 days of stimulation, with no significant increase at subsequent time points. The increase in P_t/P_o was a result of both an increase in P_t and a decrease in P_o. There was no significant differences between the two ages at any of the corresponding time points. A significant increase in the time to peak twitch tension occurred by 20 days in aged rats (14.03 msec vs. 17.60 msec) and by 30 days in adult rats (15.34 msec vs. 17.64 msec). No subsequent significant increase in TPT occurred after these points. There was no significant difference between any of the corresponding time points between the two ages. The maximal velocity of unloaded (V_{max}) was determined using the slack test. Although an increase in V_{max} occurred at 90 days in both adult rats (248 mm/sec vs. 211 mm/sec) and aged rats (232 mm/sec vs. 169 mm/sec), it was significant only in the aged rats. The fatigue resistance of the FDL was determined using the Burke fatigue test. A progressive significant increase in fatigue resistance occurred through 30 days of stimulation in both ages, at which point a plateau was reached. These data demonstrate that the mechanical properties of the predominantly fast FDL remain remarkably plastic in response to an extreme elevation of neural activity through very old age in Fischer-344 rats.

383.2

THE INFLUENCE OF INTERMITTENT ELECTRICAL STIMULATION ON THE BIOCHEMICAL PROPERTIES OF A PREDOMINANTLY FAST MUSCLE IN ADULT AND SENESCENT FISCHER-344 RATS. R.P. Farrar, T.J. Walters, and H.L. Sweeney Dept. of Kinesiology, Institute for Neurolgoical Sciences Research. Univ. of Texas, Austin, TX 78712.

The plasticity of muscle has been inferred to decline during senescence. Previously we (Cartee and Farrar, 1987) demonstrated that the gastrocnemius of young and old rats, given the same aerobic stimulus imposed by running for an hour per day, at the same absolute workload responded with the same absolute increase in aerobic capacity. The purpose of this study was to determine whether an imposed neuronal stimulus, to a muscle with predominantly fast motor units would induce similar changes both in aerobic capacity and fiber type in young adult and senescent rats. We imposed an altered stimulus to the plantaris muscles in adult (7-8 mo.) and aged (27-28 mo.) Fischer 344 by stimulating the tibial nerve at a frequency of 10 Hz for 8 hr/day for periods ranging from 0-90 days (0, 20, 35, 60, and 90 days). The mass of the plantaris muscle in both adult and aged rats decreased 20-25% following 20 days of stimulation and did not change significantly after that. The aerobic capacity, as measured by citrate synthase, of the plantaris muscle increased 3-fold by day 20 of stimulation and dropped down to approximately a 2-fold increase by day 35 of stimulation and remained there throughout the remaining periods of stimulation. There was not a shift in fiber type, as determined by gel electrophoresis on native myofibrillar proteins, until 60 days of stimulation. The shift in fiber type occurred in the fast population with an increase in IIa fibers and concomitant decrease in IIb fibers of approximately 20%. The time course of change in either aerobic capacity or fiber type did not vary between adult and aged rats. These data demonstrate that the plantaris muscle, which has predominantly fast motor units, maintains the same degree of plasticity in the senescent rat as that of young adult rat, when a neuronal stimulus, similar to that of a slow muscle, is imposed for up to 90 days.

383.3

EFFECTS OF CYCLICAL PASSIVE STRETCH IN MAINTAINING CAT SOLEUS MECHANICAL PROPERTIES. R.R. Roy, D.J. Pierotti*, K.M. Baldwin* and V.R. Edgerton. Brain Research Institute and Kinesiology Dept., UCLA, LA, CA 90024 and Physiology Dept., UC Irvine, Irvine, CA 92717.

Four adult female cats had the lumbar region of their spinal cord functionally isolated (SI) by transecting the cord at T12-T13 and at L7-S1 and cutting all dorsal roots bilaterally between these two cord segments. The cats were maintained in excellent health for 6 months. One limb in each cat was exercised passively through a range of motion mimicking a step cycle for 30 min/day, 5 days/week. During the week prior to physiological testing, two 24-hour EMG recording sessions were used to verify that the muscles in the lower limb were virtually silent and recordings from a force transducer on the soleus tendon showed that up to 1.0 kg of force was generated during the passive exercise. In 3 of 4 cats, the soleus muscles in both limbs of the SI cats were significantly smaller (wet weights), had faster twitch contraction times and maximum rates of shortening (Vmax), produced less tetanic tension (Po) and were somewhat less fatigue resistant than the soleus from control cats. When comparing the two limbs within an SI cat, the soleus in the passively exercised limb was 10-30% larger, had a Po that was 28-42% higher and, although more variable, a 20-60% lower Vmax than the soleus in the unexercised limb. All other parameters were similar in the two legs. Adaptations in the myosin ATPase activities and isozyme patterns were generally consistent with the changes in Vmax. These data indicate that short periods of cyclical passive stretching that results in a significant amount of force at the muscle tendon may have a beneficial effect in maintaining the mass and the mechanical properties of electrically silent mammalian muscles. Supported by NIH Grant NS16333.

383.4

METABOLIC AND CONTRACTILE PROTEIN EXPRESSION IN SINGLE MUSCLE FIBERS OF THE SNAKE. P. M. Nemeth, H. L. Sweeney, & R. S. Wilkinson. Depts. of Neurology and Cell Biology, Washington Univ. Sch. of Med., St. Louis, MO 63110, and Dept. of Kinesiology, Univ. of Texas, Austin TX 78712.

Single fibers from the thin transversus abdominis muscle of the garter snake were identified by physiological criteria as faster twitch (F), slower twitch (S) or tonic (T) (Wilkinson and Lichtman, J. Neurosci., 1985). Fibers were subjected to either (1) microchemical analyses for glycolytic (lactate dehydrogenase), oxidative (malate dehydrogenase, fumerase, B-hydroxyacyl CoA dehydrogenase) and high energy phosphate (adenylokinase, AK) enzymes or (2) denaturing SDS discontinuous PAGE for myosin heavy chain composition.

F fibers had high glycolytic and AK activities, and contained one myosin heavy chain isoform similar to rat fast (IIB) myosin. S fibers had high glycolytic and oxidative activities, intermediate AK activity, and expressed two myosin isoforms, one similar to rat slow (I) and the other to rat fast. T fibers had high oxidative activity with low levels of AK; they expressed a single myosin isoform similar to rat slow. The three fiber groups distinguished by metabolic criteria match those of the rat hindlimb; the same groups are distinguished by myosin isoform composition. Thus energy generating enzymes and myosin isoforms strictly correspond in this reptilian muscle. Supported by NIH grants DK38375, AR35661, NS24752 and the MDA.

RECOVERY OF FORCE PRODUCTION AND FORCE SENSATION FROM FATIGUE. E. Cafarelli and J. Layton-Wood*. Dept. of Phys. Educ., Fac. of Sci., York Univ., Toronto, Ont., M3J 1P3.

Our purpose was to compare the recovery time course of force producing capacity with the recovery time course of force sensation following fatigue. Ten subjects participated after giving their informed consent. During each experimental session fatigue was induced in the right anterior thigh muscles by holding 50% of maximal voluntary contraction force (MVC). This contraction ended when force fell to 20% MVC. In half the experiments a pressure cuff was inflated around the fatigued leg during recovery. The recovery of force production was assessed with: 1) periodic MVC's and 2) the EMG-force ratio during submaximal contractions. Force sensation measurements at 20-50% MVC were obtained using the matching technique (Cannon, R. and E. Cafarelli, J. Appl. Physiol. 63:2396, 1987). In the non occluded experiments, MVC recovered to 80% of control after 3 min but no further. In comparison, force sensation recovered to control after 1 min. Occlusion caused a 10-fold increase in force sensation after 1 min of recovery and a continuous decrease in MVC and EMG in the fatigued leg. When occlusion was removed there was a gradual increase in force producing capacity and a more rapid decrease in force sensation. These results indicate that force sensation recovers somewhat independently of force production and responds to central feed-forward information during recovery from fatigue.

RECURRENT INHIBITION DURING SUSTAINED SUBMAXIMAL CONTRAC_ TION IN HUMANS. *N. McNabb*, J.S. Frank and H.J. Green*. Dept. of Kinesiology, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1.*

This study examined whether increasing recurrent inhibition to active motoneurons could contribute to the reduction of motor drive during sustained submaximal contraction. Subjects (N=6) performed two different fatigue conditions involving sustained isometric contraction of the plantar flexors: constant torque and constant soleus emg (linear envelop) maintained at 60% MVC. Recurrent inhibition was examined at 3-second intervals throughout the sustained contraction by a H-reflex method developed by Hultborn and Pierrot-Deseilligny (J. Physiol., 297:229, 1979). The method involves comparing the amplitude of a reference H-reflex (Href) with that of a H-reflex preconditioned by recurrent inhibition (H'). H-reflexes were elicited in the soleus muscle by stimulation of the tibial nerve. Fatigue was confirmed by a 20% drop in MVCs performed periodically during the contraction. The test of recurrent inhibition revealed relatively greater reductions in H' than Href for 5 subjects in the constant torque condition and 3 subjects in the constant emg condition. For these subjects, H'-Href values dropped by 10% Mmax within 10s and 20-30% Mmax within 20-50s of voluntary contraction. The greater drop of H' versus Href when voluntary emg is constant or declining indicates increasing recurrent inhibition to the soleus motoneurons during sustained contraction. (Supported by NSERC.)

STERNOCLEIDOMASTOID MUSCLE INHIBITION INDUCED BY TRIGEMINAL REGION STIMULATION. P.A. Browne*, G.T. Clark and M. Nakano*. UCLA Dental Research Institute, Los Angeles, CA 90024 & Children's Hospital and Chapman College, School of Physical Therapy.

Research suggests a high degree of coupling between trigeminally and cervically innervated muscles. This study documented the presence of co-inhibition in the sternocleidomastoid (SCM) and masseter muscle when using mechanical and painful electrical stimuli applied to the oral and perioral region. Electromyographic activity of the masseter and SCM muscles was recorded bilaterally with surface electrodes during the following conditions: maximal clenching and maximal neck flexion or rotation. The inhibitory stimuli involved menton taps, electrical stimulation intraorally to the anterior maxilla gingiva or extraorally to the skin over the mental nerve. The subjects all demonstrated clear masseter and SCM inhibition of similar timing with menton tap. It is very likely that this inhibition represents a response of the SCM to stretch caused by the direct mechanical perturbation from the tap. In contrast, SCM inhibition with electrical stimulation though often elicited, was not a consistent response. It was not elicited in all subjects nor in every trial of subjects in whom it was elicited. The SCM inhibition was similar in timing and character to the masseter inhibition (e.g., it was frequently a double silent period).

THE FORCE-VELOCITY AND FORCE-LENGTH BEHAVIOR OF SINGLE MOTOR UNITS OF THE MEDIAL GASTROCNEMIUS MUSCLE OF THE CAT. C.J. Heckman, J.L.F. Weytjens and G.E. Loeb. Lab. of Neural Control, NIH, NINCDS, Bethesda, MD 20892.

Forces developed by single motor units have been studied in reduced preparations (by stimulation of either motoneuron cell bodies or axons), and in humans (by spike-triggered averaging techniques). Detailed information on the mechanical behavior of motor units is available for isometric conditions only. We set out to study the dependence of motor unit twitch and tetanic forces on both muscle length and rate of change of muscle length.

The medial gastrocnemius muscles of 15 cats anesthetized with pentobarbital were separated from the surrounding muscles and their tendons attached to a servo-controlled muscle stretcher through a custom-built force transducer. Precautions were taken to prevent the tendons from drying out. All other hindlimb muscles were denervated. Laminectomies were performed and single motor units were functionally isolated by splitting either the L7 or S1 ventral roots. With this set-up, motor unit twitch forces and tetani at various frequencies were studied at different muscle lengths and during movements at velocities up to half a muscle length per second in both the lengthening and shortening directions. Stimuli were not applied to the units until the velocity of movement was constant.

Analysis of 16 units (5 type S, 4 type FR and 7 type FF) so far showed that 1) with increasing frequency of stimulation the maximum of the force-length curve shifted towards shorter muscle lengths, 2) the force-velocity curves for both single twitches and tetani were "classically" shaped, i.e., forces decreased with shortening and increased with lengthening, 3) the amplitudes of the isometric twitches (zero velocity), however, were heavily dependent on mechanical history: immediately following (100 ms) 2 mm stretches, they were up to 4 times larger than after 10 s or more, 4) the increase in force with lengthening tended to be greater for type S units than for type FR and type FF units.

For further analysis we are presently investigating analytical techniques for separating the velocity effect from the length effect.

MODULATORY EFFECT OF ZERO SODIUM MEDIUM ON CONTRACTION OF BUCCAL MUSCLE OF APLYSIA. J.L. Ram, G.N. Noirot*, M.A. Anderson*, M.J. Cichowlas*, S. Patel*, & M. Harris*. Dept. of Physiology, Wayne State Univ., Detroit, MI 48201.

Acetyl choline (ACh) depolarizes and causes contractions of Aplysia buccal muscles. Expts. with zero sodium (ONa, tris-substituted) and zero calcium media showed that ACh depolarization was both sodium- and calcium-dependent. ONa hyperpolarized muscles 2-6 mV and reduced ACh depolarzations to 20%-50% of control. ACh depolarization recovered within seven min in normal medium (ASW).

ACh elicited contractions were reduced in ONa. Upon return to ASW, ACh contractions partially recovered within 2 min and were subsequently potentiated. Maximal potentiation after 1, 2, & 10 min in ONa occurred within 4 min of returning to ASW and were 130 ± 10% (n=17), 140 ± 10% (n=19), & 600 ± 130% of control, respectively (all $p<.05$). Time constants for recovery were about 10 min.

ONa (10 min) increased Ca-45 influx from 350 ± 70 (n=7) to 1250 ± 200 (n=7) cpm/mg protein ($p<.05$,t test).

ONa may cause Ca influx via Na-Ca exchange. Additional Ca in sarcoplasm or sarcoplasmic reticulum could enhance responses to Ca entering in response to ACh. Saponin-skinned Aplysia muscle fibers contracted in response to Ca. Raising the "background" level of Ca in perfusion medium increased the contractile response to Ca pulses, thereby modeling this proposed mechanism of modulating contraction. (supported by MDA and NIH grant RR-08167).

THE EFFECT OF EXTRACELLULAR MATRIX COMPONENTS ON THE SHAPE AND PROLIFERATION OF SKELETAL MUSCLE MYOBLASTS. H.R. Stephens*, C. Lebrecque*, S. Woerly and J.P. Tremblay. Lab. Neurobiol.,Hop. Enfant-Jésus, Univ. Laval, Québec, Canada, G1J 1Z4.

The importance of the extracellular matrix in muscle cell growth and differentiation is well established. In the present 'in vitro' study, we investigated the effect of various extracellular components incorporated with a collagen-based substratum on 1)the cell shape and 2)the growth of the G-8 mouse myoblast line. The six substrata tested included films of dried type I collagen (Vitrogen 100) in 1)non-fibrillar or reconstituted fibrillar form either 2)alone or in combination with 3)hyaluronic acid (5 % wt.) and fibronectin (1% wt.), with 4)chondroitin-6-sulfate (10% wt.) as well as 5)gelatin (1%) and 6)non-coated polystyrene flasks. In addition, the myoblasts were suspended in three-dimensional collagen gels. The morphology of the cells was examined by phase and scanning microscopy; cell kinetics were measured by incorporation of bromodeoxyuridine and cell numbers were recorded at 1, 4, 8 and 14 days post-plating. The proliferation rate of the myoblasts on the fibrillar collagen films was markedly reduced in comparison with non-fibrillar films or gelatin-coated or plastic flasks. In general, the myoblasts were homogeneously distributed and well spread on the non-fibrillar films. In contrast, on the reconstituted collagen lattices they exhibited a wide range of shapes according to whether the cells were embedded within the fibrils (extensive branching cellular processes) or strode the matrix (network of bipolar, spindle-shaped myoblasts aligned end-to-end). There were also differences in the branching and spacing pattern of the myoblasts depending on the presence or absence of the glycosoaminoglycans within the collagen-based extracellular matrix. These results are consistent with reports demonstrating that the spatial configuration, as well as the chemical nature of the extracellular matrix, set the course of the cell towards differentiation rather than cell proliferation.

INTERSPECIES COMPARISON OF CARDIAC MUSCLE GANGLIOSIDES. K.C. Leskawa* and C.S. Short* (SPON: L.A. Carr). Dept. Anat. Sci. & Neurobiol., University of Louisville, Louisville, KY 40292.

Ganglioside content of hearts from a number of different species was examined, since studies of glycolipids in non-neuronal, electrically excitable tissues are rare. Atria and surrounding adipose tissue were removed and extracted gangliosides were fractionated into mono-,di-, and oligosialosyl forms on DEAE-Sephadex.

Brains of lower vertebrates contain a higher content of complex, oligosialosyl gangliosides; in contrast such phylogenetic patterns were not apparent for cardiac gangliosides. The highest content of di- and oligosialosyl gangliosides was found in the hearts of sheep, horse and pig; human values were slightly lower. Complex gangliosides were much lower in eel, tuna and turtle hearts and lowest in rodent hearts (mouse, guinea pig, hamster and rat).

While calf heart contained numerous complex structures, adult bovine hearts contained only GM3 (99.3% of total). The simplification of cardiac gangliosides with aging is not a generalization, since young and mature rabbit hearts displayed only slight pattern changes although total ganglioside content was reduced.

The remarkable species differences demonstrated by cardiac gangliosides suggests a role in heart function and/or development. (Amer. Heart Assoc., Kentucky Affil.)

MEASUREMENT AND FOCUSSING OF MAGNETIC STIMULI APPLIED TO NEURONAL STRUCTURES R.G. Bickford, P. Fortescue, A. Rivero* and D. Brittain* Lab of Neurophysiology, University of California at San Diego, 92037

The high frequency magnetic pulses (100 microsecond duration) employed in magnetic stimulation of the nervous system (nerves, spinal roots and cerebral cortex) are of sufficient frequency to give rise to a "skin effect" when applied to a metal surface. We have employed the induced field on the inside of a copper cone to compress and concentrate the magnetic field produced by the coil of a magnetic stimulator (e.g. Cadwell). This allows the production of a highly concentrated field at several centimeters from the coil producing the focussing of the field at its exit.

Tests were carried out using a 1 cm current loop connected to a peak reading voltmeter calibrated in kilogauss (designed by Dr. Fortescue). In one such test the field at 5 cm from the coil read 0.4 Kgauss at 5 cm (at apex). When a 16 gauge copper cone (with a diagonal saw cut to prevent current flow) was put in place centering on the magnet coil, the reading was increased to 1.4 Kgauss indicating a tenfold concentration. The clinical features of the focussed field was investigated in the isolated frog muscle and by application to a subject's cutaneous nerves (ulnar, median and digital). EMGs resulting from the experiments will be shown.

FLUCTUATING THRESHOLDS IN HUMAN MOTOR AXONS

J. Daube. Division of Clinical Neurophysiology, Mayo Clinic, Rochester, MN 55905

Percutaneous, submaximal, electrical stimulation of mixed nerves in 30 healthy human subjects resulted in random fluctuation of the amplitude of the compound muscle action potential (CMAP). These fluctuations varied with skin temperature and sympathetic activation. The distributions of the CMAP amplitudes were approximately Poisson near CMAP threshold, and approximately binomial at higher voltages. Estimations of the size of contributing motor unit potentials from the variance and mean of the CMAP distributions (assuming Poisson distributions) resulted in reproducible estimates of the number of motor units contributing to the CMAP.

This may provide an alternative, indirect method of estimating numbers of motor units when direct methods are not possible, just as Poisson statistics do, in estimating quantal numbers at the end plate potential of the neuromuscular junction.

384.1

DEVELOPMENT OF LIMB TRAJECTORY FORMATION. D. L. Claman and J.H. Abbs. Dept. of Neurology & Waisman Center, University of Wisconsin 53706.

Although previous studies of reaching movements indicate invariances in spatial and temporal trajectory properties that are strongly influenced by visual information, little is known about the development of these properties.

Visually elicited planar arm movements were studied in 5-14 year old children. Movements were recorded by sliding a stylus along the surface of a digitizing table to various LED targets. In one experimental condition the target remained lighted for the duration of the trial and in the other the target extinguished at movement onset.

Analyses revealed that the nonlinear relationship between movement speed and size observed in adults for this task emerges slowly during the first 10 years of life. While movement size and velocity in adults is well fitted by a second order relation (R^2 = 0.5 to 0.94), the youngest children exhibited a much weaker coupling of velocity and extent, increasing to adult levels by age 10 to 14.

While movements executed to lighted targets yield faster movements in adults, movement time was unaffected by this additional information for the youngest children and clearly slowed movement for children in the 11-12 age range. Also, end-point accuracy, that was highly variable under both visual guidance conditions for the youngest children, improved with age; the oldest children showed both the adult pattern and the adult degree of end-point control.

The process of trajectory formation and the use of visual information in movement both appear to develop in a slow and orderly fashion through the ages 10-14, at which point more adult-like patterns are seen. Developing adult abilities to use visual information and to scale movement size and speed may underlie the performance of many motor and perceptual tasks. Supported by NIH grants (NS-13274 & HD-03352).

384.2

CONTRIBUTION OF THE EYE MOVEMENT TO THE GUIDANCE OF THE ARM

V. Delreux*, M. Crommelinck* and A. Roucoux. Lab. of Neurophysiology, Univ. of Louvain Sch. of Med., B-1200 Brussels, Belgium. (SPON: M. Meulders)

The contribution of the eye movement to the guidance of the arm not only depends on a pure visual information, but also on extraretinal factors (Mather, J. and Fisk, J., Quat. J. Exp. Psychol., 37A:315-318, 1985). A study of these factors was conducted on right handed, head fixed human subjects sitting in front of a set of LED's aligned in the horizontal plane, in the left hemifield. They were asked to move a handle, with the right hand, in the direction of one of the LED's, without visual feedback about the arm movement. In one series of experiments, the subjects kept their eyes centered; in another, they oriented their eyes, together with their arm. The target was either continually on (visual condition) or turned off three seconds before the onset of the movement (non-visual condition).

The relation of the arm final position error with eccentricity was different in eye fixed and eye mobile conditions.The characteristics of the arm error distribution were comparable in visual and non-visual conditions. The fact that eye movement, in these conditions, does not globally improve the arm precision though it modifies its characteristics, suggests that the extraretinal factors reflect mechanisms different from a simple substitution of vision.

384.3

THE ROLE OF COMPLIANCE IN CONSTRAINED BALLISTIC ARM TRAJECTORY FORMATION. D.J. Bennet and J.M. Hollerbach. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Previously we have argued that a joint level kinematic planning strategy adequately accounts for human ballistic arm movement data. In particular, we consistently observed curved trajectories when a movement between two targets spanned a joint reversal point. In the present study we pose the following question: how is a movement between such target pairs planned when it is constrained (by a frictionless wall) to be a straight line? We hypothesize that the trajectory is commanded as though the constraining wall were not there, and the natural compliance of the arm is relied upon to follow the constraint surface. This hypothesis predicts that the stiffness component of the compliance should produce an envelope of forces on the wall that resembles the unconstrained hand path. Further, we present an analysis of the time scaling property of dynamics which indicates that the differences betweeen forces on the wall in the forward (upward) and reversed directions of movement can only be due to the viscous (passive and active velocity feedback) component of the compliance. In fact, together with our hypothesis, reasonable assumptions about the arm viscosity allow the prediction that the upward and downward forces on the wall should only be equal at the elbow joint reversal point. All of these predictions are found to agree with the data. In addition, simulations qualitatively produce the experimental force envelopes.

384.4

EFFECTS OF COLD PRESSOR PAIN ON LIMB TRAJECTORY FORMATION. E.W. Howland*, D. Claman, T.A. Zeffiro, M. Backonja* AND C.S. Cleeland*. Pain Research Group and Motor Control Lab, Dept. of Neurology, Univ. of Wisconsin, Madison, Wi. 53792. (SPON: S. Zhang)

Although a growing body of research examines the effects of task performance on pain perception little is known about the effects of pain on motor performance. We studied visually elicited planar arm movements of adult volunteers by recording visually elicited hand movements made by sliding a stylus along the surface of a digitizing tablet to various LED targets. In order to reduce the effects of visual control systems, the experimental room was blacked out and the LED targets were turned off before subjects completed their arm movements.

Preliminary analysis of three subjects, each analyzed as a separate experiment, suggest that painful stimulation of the foot (0^{o} ice water) leads subjects to overshoot the target. Although overestimation of targets is typical of normal adults, pain significantly increased our subject's overshoot compared with their pain free performance. Additionally, the point of peak velocity as a fraction of total movement time decreased under pain challenge.

EFFECTS OF AGONIST MUSCLE LOAD ON MOST-RAPID ISOMETRIC FORCE PULSES. E. Logigian*, M. Wierzbicka*, D. Cros* and B. Shahani. Massachusetts General Hospital and New England Medical Center, Boston, MA.

Contraction time (CT) of most-rapid isometric force pulses in intrinsic hand muscles has been reported to be independent of agonist muscle load (AL) prior to contraction (Freund and Budingen, 1978). We investigated the dependence of CT and EMG parameters on AL in most-rapid contractions of elbow flexor muscles to determine if the CNS motor program subserving most-rapid force pulse generation changes according to AL. With visual feedback of the force signal, elbow flexors were isometrically loaded in 5 normal men, ages 25-38, to 0,20,40,60 or 80% of their maximum voluntary force (MVF). At each AL, 10 most-rapid isometric force pulses were made to the same target: 20% MVF. In 4 out of 5 subjects, mean CT and biceps surface EMG burst duration (BD) were relatively constant only for ALs <60% MVF. At ALs >60% MVF, CT and BD significantly increased. In all subjects, the integrated biceps EMG burst (above the level to maintain the load) increased with AL, whereas triceps EMG burst area was unchanged. To generate most-rapid elbow flexor contractions of given amplitude under lower ALs, the CNS scales agonist EMG activity proportional to the load presumably by modulating motorneuron (MN) firing rate and possibly the number of MNs recruited. At highest loads, duration of MN discharge is scaled to the load, perhaps because the limits of MN firing rate and recruitment mechanisms have been reached.

384.7

CHARACTERISTIC PATTERNS OF RAPID POSITIONING ACCURACY FOLLOWING MAXIMAL ISOMETRIC CONTRACTION. B.R. Etnyre, O. Dry*. Human Performance and Health Sciences Dept. Rice University, Houston, Texas 77251

The purpose of this study was to compare post-contraction positioning accuracy and electromyographic (EMG) patterns of biceps and triceps brachii muscles during rapid elbow flexion and extension movements to a target. Following a learning session 10 subjects performed twenty control trials without augmented feedback. Experimental trials were identical to control trials except the subject preceded each movement with a 3 s isometric contraction of the agonist muscle used for the subsequent movement. Separate analyses of variance revealed significant undershooting in positioning accuracy for both flexion and extension post-contraction movements compared with control conditions. Integrated EMG (IEMG) of the agonist muscle was significantly less in the experimental condition than in the control condition for both tasks, with no difference between antagonist IEMG. Frequency Analysis of the EMG revealed significantly higher peak frequencies in the biceps during the post-contraction flexion movement. It was concluded the undershooting following isometric contraction was dependent on the total motor output of the agonist muscle for extension and an interaction of motor output and de-syncronization for flexion movements.

384.8

REFLEXES AND THE EQUILIBRIUM POINT MODEL FOR MOTOR CONTROL. J. McIntyre* (SPON: C. G. Atkeson). Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

The equilibrium point hypothesis, based on the elastic properties of muscles, is an attractive theory for the control of limb movements, but the role of reflexes in the context of this model is unclear. A hybrid control scheme is proposed which combines the equilibrium point model with reflex feedback. Computer simulation techniques are used to demonstrate the competence of this model.

In the equilibrium point model, the neuronal inputs to the muscles serve to specify an equilibrium position for the limb which smoothly varies along the desired trajectory. No explicit computation of joint torques is performed. To move faster along the same path, it is necessary to do one of two things. The stiffness of the muscles can be increased through co-contraction while the equilibrium point trajectory simply scales with movement duration. This is inefficient, as co-contraction consumes more metabolic energy per unit of time. The second possibility is that the equilibrium point trajectory is modified so that it is no longer equivalent to the desired trajectory. Instead, it may lead the actual desired position, even to the point of overshooting the desired endpoint. Computing this overshoot is essentially equivalent to computing the inverse dynamics for the system, thus losing the advantage of computational simplicity.

The proposed hybrid controller retains the computational simplicity of the equilibrium point model. The CNS needs to specify only the actual desired trajectory for the limb. The trajectory is fed directly to the muscles, as in the equilibrium point control scheme. This *virtual* trajectory is modified, however, by reflex feedback during the execution of the movement. The reflex feedback implements a PD controller which serves to increase the responsiveness of the system. This allows the system to produce faster movements without unnecessary co-contraction and without explicit dynamics calculations. Acknowledgements: Dr. E. Bizzi, Whitaker Health Sciences Fund, NIH Grant NS09343.

A CONNECTIONIST NETWORK THAT COMPUTES LIMB POSITION IN A HEAD-CENTERED COORDINATE FRAME. S.J. Hanson* and C.R. Olson (SPON: R. Cholewiak). Bellcore and Psychology Dept., Princeton NJ 08544.

Humans are able without conscious effort to turn their eyes towards a skin point stimulated in the dark. To carry out this act requires combining information about the skin location of the stimulated point with information about the angles of the joints interposed between it and the head. When many joints, each with several degrees of rotational freedom, are involved, the underlying computations are extremely complex. We have investigated the ability of a massively parallel network to carry out these computations.

The network consists of an input layer (10 units), a hidden layer (variable number of units) and an output layer (3 units). The 10 input units encode the angles of rotation about 10 axes at joints interposed between the fingertip and the head. The three output units encode the vertical and horizontal angles of the eye and its fixation distance. By use of back-propagation, the network was trained to bring the eye to bear on the fingertip given an arbitrary posture of the arm and neck.

Several runs with training sets of different sizes (100, 1000, 10000) and random starting points were carried out. In all cases, performance on the training set became extremely accurate. Performance on a transfer set improved as the training-set size increased. The properties of hidden units were characterized by use of several multivariate approaches including cluster analysis and were analyzed qualitatively by examination of Chernoff-face and barplot ("Hinton diagram") displays. The multijoint receptive fields of units in the network form a basis for predictions regarding the properties of neurons responsible for encoding body position in brain regions including area 5.

TWO PARAMETERS DETERMINE WHICH MUSCLES INITIATE PLANAR, TWO-JOINT ARM MOVEMENTS. G.M. Karst and Z. Hasan, Dept. of Physiology, Univ. of Arizona, Tucson, AZ 85724

In attempting to understand the strategy underlying CNS control of human arm movements, we have characterized movements in terms of which muscles (flexors vs. extensors at each joint) are **initially** activated during horizontal-plane pointing movements involving the shoulder and elbow. Since the observed initial muscle activity at each joint is not related simply to the direction of rotation at that joint alone, we examined the dependence of the observed initial activity on the parameters describing the initial and final limb positions. Although four parameters (e.g. initial and final angle of both joints) are required to specify these positions, we found that only two parameters are sufficient for determining initial muscle activity at each joint. This was demonstrated by a partitioning of flexor- and extensor-initiated movement trials when plotted on a plane whose axes correspond to those two parameters, namely initial elbow angle and target angle with respect to the forearm. This partitioning has proven to be a robust finding across subjects for a variety of initial limb configurations and target directions and does not appear to be affected by changes in movement velocity or by inertial loading (1.8 kg at the hand). These findings are consistent with the possibility that the CNS may use a simple criterion for determining which muscles are activated initially, while other mechanisms, including feedback, may be employed to compensate for complex dynamic effects.

KINEMATICS OF TWO AND THREE LINK SAGITTAL ARM AND ARM WITH POINTER MOVEMENTS. J.R. Flanagan* and D.J. Ostry* (SPON: F. Wilkinson). McGill University, Montreal, Canada.

In an effort to understand the control of multi-joint movements, we examined two and three link human arm and arm with pointer movements between targets located in a sagittal plane. Movement path, rate, and direction as well as the inertial properties of the pointer (mass and principal moment of inertia) were varied.

The curvature of endpoint paths was found to vary with target location. Paths for three link movements were similar across differences in movement rate, direction, and the inertial properties of the pointer. Paths for two link movements were qualitatively similiar to comparable three link movements and were likewise independent of rate and direction. In general, the form of the tangential velocity curve of the endpoint scaled with rate and pointer mass and moment but not with movement direction. In many cases, the curve was positively skewed regardless of direction.

For three link movements, path and trajectory invariance of the endpoint are not sufficient conditions for joint path and trajectory scaling. In some instances, invariance in endpoint space was found in the absence of joint space invariance.

The ways in which redundancy is constrained in three link movements and the dynamics of both two and three link movements will be discussed.

384.12

THE INFLUENCE OF TASK AND ORGANISMIC CONSTRAINTS ON INTRALIMB KINEMATICS IN A DRAWING TASK. R. E. A. van Emmerik *, and K. M. Newell. Department of Kinesiology, University of Illinois at Urbana-Champaign, Urbana, IL 61801

Intra-joint and joint-stylus kinematic couplings were examined as a function of various task and organismic constraints in a circle drawing task. The constraints manipulated included natural limb dominance (left-versus right-handers), the use of the dominant or nondominant limb, writing orientation (horizontal versus vertical), and circle diameter. No differences in the style of limb organization were observed between left- and right-handers (N=6), although there was a higher degree of phase-locking between the joints in the nondominant limb for right-handed subjects in the horizontal orientation. This suggests that without the constraint of writing direction, left- and right-handers adopt similar coordination functions. Correlations between the linkages significantly increased with the scaling of circle diameter, and with changing the drawing orientation from horizontal to vertical. The topological features of the stylus kinematics remained invariant under the constraints imposed, inspite of the systematic changes that occurred in the topological features of the joint motions. It is proposed that invariances and transitions in joint and stylus kinematics are a function of the task constraints that need to be optimized.

384.13

EFFECTS OF REPETITION ON ARM TRAJECTORIES DIRECTED TOWARDS MOVING TARGETS. S.I. Tillery* and J.R. Bloedel (SPON: T. Tarby). Division of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013.

Although many findings have been reported regarding directed limb movements in humans, few studies address the interception of moving targets. This study describes the strategies used to intercept a moving target and assesses modifications of performance occurring with practice. Subjects were instructed to maintain contact with an origin switch until a light signalled they could initiate movement towards a target moving along a 1 m horizontal track. The target velocity, ranging from 60 to 95 cm/sec, was unknown to the subject until the first trial. Three twenty trial sets, each at a different velocity, were performed for right to left and left to right target movements. Movement trajectories and EMG's for biceps, triceps, and brachioradialis were determined, and reaction time and movement duration for each trial were calculated. In general the spatial characteristics of the trajectory were quite subject specific and varied little over successive trials. Trajectories usually consisted of at least three components: an initiation phase marked by a movement towards and then away from the target's path; a high acceleration phase which brought the distal limb up to the speed of the target; and a final phase which was directed towards the target. During each phase the hand moved along a curved trajectory. The primary modification with practice was an increased acceleration during the second component of the movement. The EMG data revealed that the recorded muscles were not involved in the first phase of the movement. The data indicate that the trajectory's envelope is subject specific and that changes in performance associated with practice do not alter the spatial characteristics of the movement. Supported by NIH grant NS21958.

384.14

CONTROL OF SINGLE- AND MULTI-JOINT MUSCLES DURING THE MAINTENANCE OF A POSTURE AT THE HUMAN ELBOW JOINT. T.S. Buchanan, G.P. Rovai*, and W.Z. Rymer. Sensory Motor Performance Program, Rehabilitation Institute of Chicago, Chicago, IL 60611.

We examined the activation of muscles that act in elbow flexion/extension and wrist supination/pronation during various static postures. Intramuscular and surface EMGs for five muscles and force at the wrist in three dimensions (flexion/extension, varus/valgus, and supination/pronation) have been simultaneously recorded while subjects produce proscribed steady-state forces at the wrist. Tests were done with subjects at three different degrees of forearm supination/pronation.

We found that some elbow-joint muscles that do not contribute to supination/pronation torque generation are nonetheless varied significantly during these loads. For example, when the wrist is in a supine position, the triceps acts as if it were a supinator—EMGs increase with increasing supination load, all other load conditions being the same. However, when the wrist is held in a pronated position, the triceps mimics a pronator, increasing its EMG activity with increasing pronation torque. Other muscles were also significantly influenced by supination/pronation position. Biceps and pronator teres varied as might be expected, but variations in brachialis were unforeseen.

Since supination/pronation and flexion/extension are performed at independent orthogonal joints, it is surprising to see some muscles at one joint being modulated with loads at another where they have no obvious mechanical action. This is certainly the case for triceps and brachialis. Such observations point to a complex control strategy that provides neural coupling of muscles at nearby joints even when biomechanical coupling may not exist. Such coupling is perhaps important for counteracting inappropriate torques produced by multi-joint muscles that are necessary for torque production. For example, the triceps may be acting to offset torques produced by the biceps which generates elbow flexion torques as it aids in supination.

PATTERNS OF ACTIVITY IN WRIST EXTENSORS DEPEND ON FOREARM POSITION. D.S. HOFFMAN and P.L. STRICK. VA Med. Ctr. and Depts. of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syracuse, NY 13210.

Monkeys were trained to perform wrist movements in 8 different directions. The task was performed with the forearm in 2 positions: fully pronated or midway between pronated and supinated. We examined the patterns of activity in wrist extensors using pairs of fine wire electrodes. The electrodes also were stimulated to determine each muscle's direction of action.

When the forearm position was changed from pronated to the mid position, the direction of maximal agonist activity in all wrist extensors shifted 20-100 degrees in the radial direction. The shift in forearm position also altered the direction of movement produced by electrical stimulation for some, but not all wrist extensors. For example, when the forearm was pronated, agonist activity in extensor carpi ulnaris (ECU) was largest for ulnar deviation. When the forearm was in the mid position, agonist activity in ECU was largest for wrist extension. This shift occurred even though ulnar deviation was evoked by electrical stimulation of ECU in either forearm position.

These results indicate that the activity of a wrist muscle can be dissociated from: the muscle's direction of action, the direction of joint movement and the direction of movement in space. Supported by funds from the VA Medical Research Service.

RAPID REPROGRAMMING OF MUSCLE ACTIVITY DURING VOLUNTARY MOVEMENT. Jerome N. Sanes, NINCDS, NIH, Bethesda, MD 20892.

When voluntary movements are mechanically disturbed, short-latency muscle responses are triggered. The latencies of these responses are similar to responses evoked during postural maintenance. There is a short-latency, presumably myotatic, and then longer-latency responses that depend on mechanical conditions, instructions and the input stimulus. The present experiment investigated whether these triggered muscle responses were similar to responses observed when subjects performed unobstructed movements that started from the obstruction location.

Subjects performed 30° wrist flexion movements in 200±20 msec by moving a handle attached to a torque motor while the surface EMG was recorded from the wrist flexor and extensor muscles. One series of movements began at 0° and terminated at 30° of flexion. A second series of movements started at 10° of extension, 0° or 10° of flexion. In separate series of 100 trials each, 25% of the movements were stopped for 100 msec after 5°, 15° or 25° of movement. The time to complete the movement and the peak velocity after offset of the stop were measured. Subjects then performed movements that were regulated according to the measured movement times (MT) or peak velocities (PV). The triphasic bursts in the EMG were quantified during voluntary movement and after the stop onset according to conventional techniques.

Triggered muscles responses did not always resemble muscle responses accompanying unimpeded voluntary movements beganning from the angular location of the stop. The first agonist burst (AG1) triggered by a stop encountered 5° and 15° into the movement was smaller than the AG1 during unobstructed movements. The antagonist and the second agonist bursts triggered by the stop were typically similar to the EMG observed during unobstructed movements. There were not major differences in response characteristics when subjects regulated MT or PV.

These results illustrate that muscle responses triggered during active movements do not always resemble the EMG of unobstructed movements. The triggered muscle responses that differ from EMG patterns of unimpeded movements are those with short latency but only if they are triggered early in the movement. These results suggest that there is a temporal limit in which triggered EMG responses can be modified to compensate for perturbations occurring during movement. When this temporal limit is exceeded triggered EMG responses resemble programmed responses suggesting that these later responses do not contribute to compensation.

UNILATERAL, BILATERAL AND INTERLIMB COORDINATION OF REPETITIVE MOVEMENTS. R.A. States, C.C. Bassile*, A. Dettwiler-Danspeckgruber*, J.A. Monroe*, A.M. Gentile. Teachers College, Columbia University; NY,NY 10027.

This study investigated coordination of repetitive movements involving one, two or four limbs. Tasks required tapping movements of the hand or foot in the sagittal plane performed at self-determined preferred and fast rates. As prior work (Kay et al., J. Exp. Psych.: HP&P, 1987, 13:178-192) has shown greater stability for simultaneous (0° phase diff.) over alternating (180° phase diff.) movements in bimanual tasks, these two coordinative modes were used in the present study for bilateral (2 limb) and interlimb (4 limb) tasks. Data collected on 8 seated subjects included movement kinematics (period, amplitude, velocity) and for bilateral and interlimb tasks, measures of phase difference and dispersion. At preferred rates, tapping period and variability (coefficient of variation) were comparable for unilateral and bilateral tasks in the simultaneous mode; whereas, in the alternating mode, periods were longer and less variable. No differences between hands and feet were noted for those tasks. In interlimb tasks, similar differences in tapping period and variability were observed between simultaneous and alternating modes. While tapping period did not differ between limbs; the feet were significantly less variable than the hands under the alternating mode. For both bilateral and interlimb tasks, alternating movements were more strongly coupled (as measured by phase dispersion) than were simultaneous movements, especially for the feet. Thus, the major finding is that in interlimb coordination, alternating movements of the feet are more consistent and more strongly coupled than the hands. This coupling may utilize an endogenous neural synergy associated with locomotion as suggested by A.M. Gentile & R.A. States (Neurosci. Abs., 1987, 2:321.10).

THREE DIMENSIONAL TRAJECTORY ANALYSIS OF A PATIENT WITH CONGENITAL MIRROR MOVEMENTS. H. Poizner and M.Kritchevsky*. The Salk Institute, La Jolla, CA 92138, Department of Neurosciences, UCSD, La Jolla and V.A. Medical Center, San Diego.

Mirror movements are involuntary movements executed by one side of the body in response to voluntary activation of homologous muscles of the other side. Although such movements have been described qualitatively and with surface EMG recordings, the spatial and temporal characteristics of these movements remain relatively unexplored. Selected simple, repetitive and complex limb movements were studied in a 20 year old woman with congenital mirror movements and no other neurological disorder. Movements were digitized in three dimensional space, reconstructed computergraphically, and analyzed numerically and graphically. Mirror movements had smaller amplitudes than did the corresponding voluntary movements and there was, in general, temporal coupling between mirror and voluntary movements. Nonetheless, mirror movements were not always a perfect mirror image of the corresponding voluntary movements and sometimes differed in timing and trajectory shape from the original movement. Substantially greater mirror movements were elicited by distal as opposed to proximal movements and mirror movements were enhanced when loads were applied to the hand executing the voluntary movement. These data will be related to anatomical bases of congenital mirror movements.

384.19

COORDINATION DURING A MULTI-JOINT ARM MOVEMENT IN NORMAL HUMANS AND IN PATIENTS WITH CEREBELLAR DYSFUNCTION. W.J.Becker,E.Kunesch*,H.-J.Freund. Neurologische Klinik, Universität Düsseldorf,FRG.

Coordination was studied during a multi-joint arm movement in 3 controls and in 4 patients with cerebellar degenerative diseases and moderate ataxia.

While subjects threw a ball at a target, EMG activity was recorded from 7 arm muscles(Glonner EMG telemetry system) and position data was recorded from 6 points on the arm (Selspot II system). In this movement, triceps(T) and wrist flexors(WF) act synergistically at different joints to accelerate the hand. 31 single movement trials were analyzed for each group. Even though patients threw much less accurately than controls, the mean time interval (T-PV) from T EMG onset to time of distal forearm peak velocity, an indicator of T function, was similar in controls (181+18) and patients (183+18ms). The time interval by which T EMG onset preceded WF EMG onset(T-WF) was shorter in movements with a shorter T-PV interval,allowing for WF to assist in hand acceleration prior to ball release. This correlation between T-WF and T-PV was present in controls (r=0.80) and patients (r=0.70).

The aspects of coordination assessed in this study may be mediated by CNS structures outside the cerebellum. Alternatively, the normal cerebellum may have sufficient functional reserve to allow it to participate in these coordination mechanisms despite marked atrophy and cell loss.

IMPAIRMENT IN PROGRAMMING OF RESPONSE DIRECTION AND AMPLITUDE IN DEAFFERENTED PATIENTS. C. Ghez, R Bermejo, & J. Gordon. Ctr for Neurobiol & Behav, Columbia Univ and NYS Psych Inst, New York, NY 10032.

We have previously shown that the accuracy of phasic isometric responses is markedly degraded in patients with severe large fiber sensory neuropathy. Inaccuracy derived from impairment in the implementation of the normal pulse height control and an inability to correct initial trajectory errors by compensatory variations in rise time. The present experiments were done to determine if the control of hand trajectories in two-dimensional space is also degraded.

Patients and normal controls were to move a hand-held cursor from one target to another on a digitizing tablet. Cursor and target positions were displayed on the screen of a Macintosh computer and vision of the hand was prevented. Several different tasks were used to assess the accuracy of fast and slow movements with visual guidance (screen cursor visible) and without visual guidance (screen cursor blanked). In addition, visuomotor learning was assessed by examining the time required to adjust the direction of visually guided movements when the tablet was rotated 45°. In deafferented patients, rapid visually guided movements from one target to another could be performed accurately only by fragmentation of the trajectory into smaller segments with lower than normal peak velocities. When vision was prevented, patients showed errors in amplitude and direction that were markedly greater than those of normals. Whereas, in the absence of visual feedback, normals could reproduce a given trajectory several times without substantial changes, in patients, the accuracy of sequential movements was further degraded with each repetition. In contrast, one patient thus far tested did not show any specific impairment in the ability to adapt to rotations of the relationship between the spatial coordinates of the hand and of the screen cursor. We conclude that somatosensory information from the limb is necessary to accurately specify the direction and amplitude of responses aimed to visual targets, but may not be necessary to learn a visuomotor transformation. Accurate programming apparently requires information concerning the initial state and position of the limb. (Supported by NS22715)

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: POSTURE AND MOVEMENT VII

CHANGES IN MOVEMENT KINEMATICS DUE TO CEREBELLAR DYSFUNCTION. S.H.Brown, H.Hefter*, M.Mertens*, J.D.Cooke & H.-J.Freund. Dept. of Neurology, Univ Düsseldorf, FRG & Dept. of Physiology, Univ. Western Ontario, London, Can.

The role of the cerebellum in the generation of goal-directed, single joint movements was studied in 10 patients with mild cerebellar deficits. Step-tracking elbow movements were performed at 4 amplitudes and under 3 instructions.

Peak velocity (PV) and movement duration (MD) increased linearly with amplitude. Mean PV and MD values showed slight differences between cerebellar and control groups. Variability of PV and MD, however, was greater in the cerebellar group, especially during slow movements. Marked differences in the relative durations of acceleration and deceleration (symmetry) of the velocity profile occurred across all movement conditions. In all patients, both continuous and discontinuous velocity profiles showed prolonged decelerations. The degree and variability of movement asymmetry increased as the demand for accuracy increased.

These findings support the view that movement trajectory, particularly the deceleratory phase, is under cerebellar control.

EXPERIMENTAL-THEORETICAL ANALYSIS OF THE INTRINSIC GEOMETRY OF LIMB MOVEMENTS *J.R. Bloedel, S.J. Tillery* and A.J. Pellionisz* (Barrow Neurological Institute, Phoenix, AZ, 85013 and Dept. Physiology and Biophysics, New York Univ. Medical Center, New York, NY, 10016)

Problems in motor control are difficult to address without a quantitative model of the motor plant. To assist experimental investigation of locomotor and volitional forelimb movements in the cat, a preliminary computer model of its skeletomuscular system has been constructed and applied to an analysis of the step cycle. The approach is based on the calculation and experimental establishment of coordinate frames that are intrinsic to the skeletomuscular system. Software to calculate intrinsic coordinates from a graphic representation of joints and skeletal muscle attachments was adopted from models of head movements in cats. (*Pellionisz and Peterson*, in: Control of Head Movements, Oxford U. Press).

Specifically, the pulling directions of ten forelimb muscles were determined by first assessing the origin and insertion of each by dissection and then calculating the direction the limb moves from specific locations in the step cycle when the muscle is shortened. These pulling directions were checked qualitatively by observing the forelimb movement evoked by tetanically stimulating each muscle in isolation. Next these directions were used to establish the axes of an intrinsic coordinate system on which the model was based. The most striking finding was that the spatial features of the trajectories could be predicted based on the intrinsic coordinates and the direction of the intention vectors, revealing the functional geometry underlying the execution of the locomotor cycle. Predicted and observed trajectories were compared to determine the extent to which the metric of the intrinsic coordinate system had to be updated to yield a movement whose trajectory was similar to that found experimentally. This updating required the recalculation of the Eigenvectors and the components of the metric tensor during movements. The application of this approach resulted in the generation of "curved geodesics" or trajectories which approximated the locomotor behavior of the animal. These data provide a rationale for further pursuing the basis for the functional geometry underlying the spatial properties of limb movements. *Supported by NIH grants NS22999 and NS21958.*

IBOTENIC ACID LESIONS OF THE RAT RED NUCLEUS. J. Tomie,* R.L. Ladowsky and I.Q. Whishaw, (SPON: E. Castaneda) University of Lethbridge, Alberta, Canada.

Anatomical and electrophysiological evidence suggests a role of the red nucleus (RN) in limb movement, yet its importance is still not understood. The early work of Lawrence and Kuypers found that sectioning of the rubrospinal tract in monkeys produced transient deficits in the use of the ipsilateral arm, whereas combined sectioning of the pyramidal and rubrospinal tracts produced severe and lasting deficits. The present study examined paw use in rats following ibotenic acid lesions of RN.

Rats were trained to reach for food through bars separated by 9 mm, and their paw preferences were established. The RN contralateral to their preferred paw was then infused with ibotenic acid, and their non-preferred paw was bandaged to prevent its use. After recovery, the number of times the rat successfully reached for food with its preferred paw was compared to pre-operative success rates.

Histology showed complete cell loss in both the parvicellular and magnocellular divisions of RN, with minimal damage to nearby structures. Such lesions seem not to impair reaching. These results support previous notions of partially redundant pyramidal and rubrospinal tract function.

385.4

EFFECTS OF GLOBUS PALLIDUS LESIONS IN RATS ON BALLISTIC FORELIMB FORCE EMISSION. J.V. Harrell and R.C. Hicks*. Dept. of Psychology, Hampden-Sydney Coll., Hampden-Sydney, VA 23943

Rats were trained to press with their forepaws on a force transducer under a fixed-ratio 5 (FR5) schedule of reinforcement for water reinforcers (Harrell & Hayes, Neurosci. Abst., 16:1224, 1985). Four rats received bilateral, electrolytic lesions of the globus pallidus (GP) and two rats were unoperated controls.

Rats were trained on the required task until a stable baseline of 20 days data was collected. Surgeries were then performed and on following day testing under preoperative criteria continued. The initial postoperative testing period lasted 27 days. Thereafter ensued a six week hiatus followed by 57 additional testing days. A total of 100 days elapsed from performance of surgeries to the conclusion of the experiment.

Three of the four GP rats showed relatively permanent effects of the lesions. These effects, shown in strip chart recordings, were characterized by a decrease in ability to perform rapid bursts of responses and by an increase in the time between bursts. There were also noticeable changes in postural adjustment capability. While greater performance deficits were observed in this study than in a previous study of effects of caudate nucleus lesions in rats on the same task, essential ability to perform the forelimb response remained unaffected.

TASK DEPENDENCE OF CROSS CORRELATIONS BETWEEN MONKEY RED NUCLEUS AND FORELIMB MUSCLE EMG.

L.E. Miller, P.L.E. van Kan* and J.C. Houk Dept. Physiol., Northwestern Univ. Med. School, 303 E. Chicago Ave, Chicago, IL 60611.

In a prior study, the cross-correlation function was used to assess functional relations between unit discharge in magnocellular red nucleus (RNm) and different forelimb electromyograms (EMGs) recorded while cat subjects performed a food retrieval task (J. Neurosci. Meth. 21: 201, 1987). The goal was to define the spatial and temporal properties of linkages between RNm and limb muscles. A major problem that arises with conventional correlation methodology is the lack of objective criteria for distinguishing between causal and non-causal linkages. Here we present theoretical simulations and experimental data from monkeys suggesting that one can assess the likelihood that a linkage is causal by introducing variations in the behavioral task.

Stereotyped movements such as reaching to the same point in space are particularly susceptible to non-causal correlations because different muscles are activated in a fixed temporal sequence. Muscle activity becomes behaviorally coupled. Under these conditions, if a central neuron is causally linked with any one muscle, other muscles will also be correlated at a variety of lag or lead times. Simulations we performed using the NEXUS software package (Comput. Biol. Med., 14: 385, 1984) suggest that combining several tasks with significantly different temporal sequences of muscle activation reduces non-causal correlations toward zero, without affecting correlations in causal linkages. Experimental data supporting this conclusion was obtained from monkeys trained to perform several movement tasks, each of which evoked distinctly different EMG patterns. RNm unit discharge was recorded simultaneously with EMG activity from 8-14 forelimb muscles. We assessed the extent of behavioral coupling between muscles with cross-correlations between EMGs. When behavioral coupling was decreased, the number of muscles that remained well correlated with RNm discharge also decreased. Correlations that remain under these conditions may represent causal linkages, whereas those that disappear are likely to be non-causal.

FIELD OBSERVATIONS OF HAND MOVEMENTS AFTER DORSAL COLUMN SECTION. C. M. Leonard, C.J. Vierck, Jr., and B.Y. Cooper. Dept. Neuroscience, Box J244, JHMHC, University of Florida, Gainesville, FL 32610.

The accompanying abstract by Cooper et al. reports that monkeys (Macaca arctoides) with dorsal column lesions are permanently impaired in performing multi-articulated, fractionated finger movements when tested in an experimental paradigm. This permanent deficit contrasts with a temporary decrease in the use of the affected limb for walking, climbing, and grooming others. 3 of 4 monkeys showed grossly normal groom patterns within 3 weeks of surgery, including the ability to precisely appose finger and thumb in the precision grip. The 4th animal demonstrated apposition at 3 months. Frame by frame comparisons of pre- and post-surgery videotapes reveal occasional subtle changes in the spacing between the digits that suggest altered mechanisms of control. There is a long-lasting decrease in the use of the limb for self-scratching, foraging and manual sexual investigation. The decrease in scratching was unexpected. Scratching is a stereotyped behavior performed at a fixed rate of 5/sec and does not require either multi-articulation or individual finger movements. It had not previously been thought to depend on intact dorsal columns. Field observations combined with specialized laboratory tests can provide new insights into dorsal column function. (Supported by NS 13516 and NS 17474.)

385.7

Finger movement disorders following section of the dorsal columns. Cooper, B.Y., Schulmann, D.L., Leonard, C.M., and Vierck, C.J., Jr. Dept. of Neuroscience, Box J-244, JHMHC, University of Florida, Gainesville, Florida, 32610.

The present experiments examined the role of the dorsal column (DC) pathway in fine finger movements. A task was designed to assess the ability of subhuman primates to perform, fractionated (individual), ballistic finger movements that required complex multiarticulations (flexion-extension combinations). A second task was designed which assessed both fine adjustments and smooth pursuit of fingers to a moving tactile cue (air puff).

Following lesions of the DCs, deficits were observed on both tasks. Monkeys with DC lesions had enduring deficits on both fractionated, ballistic, and non-fractionated, pursuit, finger movement tasks. Performance on the spared side was comparable to pre-lesion levels. Deficits were characterized by: 1) loss of individual finger movements; 2) loss of complex, multiarticulated finger movements; 3) increased finger movement force; 4) excessive movement range during initiation and terminal phases of movement; 5) failure to track a moving tactile cue (fine adjustive movements) in either flexion or extension; and 6) poor hand orientation to goal objects. Field observations confirmed that monkeys could walk, climb and perform some precise grooming movements (see Leonard et al., 1988, in this volume).

Importantly, pincer movements remained functional. Others have concluded, on the basis of preserved pincer movements, that DC lesions do not impair finger movements.

385.8

FASTIGIAL, INTERPOSED, AND DENTATE NUCLEI: SOMATOTOPIC ORGANIZATION AND THE MOVEMENTS DIFFERENTIALLY CONTROLLED BY EACH. S.A. Kane, J.W. Mink, and W.T. Thach. Dept. of Anatomy, Washington Univ. Sch. Med., St. Louis, MO. 63110.

Rhesus monkeys performed 4 types of wrist movements with and against torque loads: 1) visually cued ballistic movement (VisStep), 2) somesthetically cued hold-perturbation-hold movement (PertHold), 3) slow, visually guided hold-ramp-hold ramp tracking movement (VisRamp), and 4) self paced, rapid alternating movement (RAM). VisStep was performed under 3 types of torque loads: 1) constant torque, 2) viscous, which diminishes tremor amplitude, and 3) negative-viscous, which enhances tremor amplitude.

Fastigius: neurons were not related to these wrist movements. Focal inactivation with microinjection of muscimol gave no deficit in these movements, but instead severe deficits in standing and walking, with weakness of the antigravity muscles of ipsilateral limbs, and falling to the ground on that side. Different injections produced stance- and gait- specific weakness of the arm or the leg only, with the leg represented anteriorly in the nucleus and the arm more posteriorly, as had been previously shown for interposed and dentate nuclei.

Interpositus: In VisStep, neurons changed activity near onset of movement, but inactivation did not delay movement onset. In PertHold, neurons had short latency response (13 msec) to the perturbation (also motor cortex); inactivation delayed the response in motor cortex and in the behavior. In VisRamp, neurons discharged in relation to tremor that decreased under viscous load and increased under negative-viscous load; inactivation increased physiological tremor. In RAM, neurons were phasically active; inactivation made RAM slow and irregular.

Dentate: In VisStep neurons changed activity early before movement onset; inactivation delayed movement onset. In PertHold, neurons had only long latency (20 msec) response; inactivation did not delay behavioral response. In VisRamp, neurons had no tremor signal even when the tremor was exaggerated by the negative-viscous load; inactivation did not increase the physiological tremor. In RAM, neurons were phasically active; but inactivation did not impair this movement.

These results suggest somatotopically organized, functional zones in the cerebellum: fastigius controls antigravity muscle synergies in standing and walking; interpositus controls stretch and other somatosensory reflexes and helps damp tremor; dentate helps initiate volitional movements. DOPAMINE ANTAGONIST ALTERS THE TRAJECTORY OF THE ELBOW JOINT BUT HAS NO EFFECT ON THE FINAL POSITION GENERATED BY MONKEYS POINTING AT VISUAL TARGETS. R.M. Wylie and A. Martinez-Arizala. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

To better understand the role of the nigro-striatal system in movement, we have studied the effect of a dopamine antagonist, metoclopramide, on an elbow flexion task performed by Rhesus monkeys. Three monkeys were trained to track a visual target by rotating their forearms about the elbow in a horizontal plane. The target moved stepwise and the monkeys were required to point to within five degrees of it. Successful responses were rewarded with a liquid nutrient. Unsuccessful trials earned no reward. We recorded acceleration, velocity and position. Effective doses (0.3 to 0.4 mg/kg i.m.) reduced the peak of acceleration and of velocity, but had no effect on final position. Were the effect on acceleration a simple scalar effect, then position, as the second integral of acceleration, should be reduced by the same scalar value. Because the final position does not change significantly, we conclude that the system compensates for the reduction in acceleration. We see evidence of compensation in the increase in the risetime of acceleration and of velocity as well as an increase in the duration of the period of positive velocity, that period during which the arm moves toward the target. We cannot resolve the issue of whether compensation arises internally or reflects the operation of a feedback control system.

385.10

REACHING TO FAR VS. NEAR CONTRALATERAL EXTRACORPOREAL HEMISPACE BY MONKEYS WITH HEMINEGLECT FROM CORTICAL LESIONS Ruthmary K. Deuel. Department of Pediatrics, Washington Univ. Sch. of Med., St. Louis, MO 63110.

In monkeys with cortical removals leading to neglect of corporeal and extracorporeal space, ipsilateral (IPSI) hand use is often impaired in contralateral (CONTRA) space. To test the latencies of reaching for a salient bit of bait near (15°) or far (70°) from visual fixation, the animal was seated in a primate chair with its head in a viewing box and the hand CONTRA to the lesion (or future lesion) restrained. When the head was voluntarily fixed forward and the IPSI hand was voluntarily resting on the chair waist piece, the view box was opened. If the eyes were fixed forward, a piece of bait appeared in one quadrant. The latency from bait presentation to breaking of a light beam by the reaching hand was measured. Preoperatively, in the 15° reach most IPSI hands were faster in the IPSI hemifield. For 70°, the IPSI hand tended to shorter latencies in the CONTRA field, with cross reaching adopted as an efficient strategy. Postoperatively animals tended to faster latencies than preoperatively in both 15° and 70° IPSI fields, contrasted with increased latencies in the CONTRA fields; however without gradation of severity from 70° to 15° CONTRA fields for the group. Individual choice of motor strategy rather than an obligatory visual neglect of far contralateral space appears to have determined these results.

385.11

COMPUTER MODELING OF HUMAN FORELIMB MUSCLE ACTIVATION IN MULTI-DIMENSIONAL INTRINSIC COORDINATE FRAMES *J. Laczkó** (Central Research Institute for Physics, Budapest, 1525 Hungary), *A.J. Pellionisz*, (Dept. Physiol. New York Univ. Med. Ctr. 10016 USA), *H. Jongen*, and *C.C.A.M. Gielen* (Dept. Med. & Physiol. Physics, State U. Utrecht, 3584 Holland) (SPON: *G. Ostriker)*

Computer modeling of motor control of body-appandages initiated with single-dimensional analysis of (paired) muscles of "limbs with a single joint"; the eye. Skeletomuscular systems with *distributed centers of rotation*, such as the head-neck system of the cat *(Pellionisz and Peterson* 1988; In: Control of Head Movements, Oxford U. Press, eds. Peterson & Richmond), required development of graphics-based software (*Laczkó et al.* 1987 Neurosci.Abst. 13:372), where origin and insertion areas of muscles are "carried" with movements of skeletal elements and the changing multi-dimensional coordinate system, intrinsic to activation of motor units, is (re)computed.

Utility of a multidimensional approach is twofold. First, quantitative interpretation of experimental data on complex appendages calls for suitable comprehensive handling (cf. *Gielen and Zuylen*, Neuroscience: 86,17:527). Second, in order to implement, in *neurocomputing and (neuro)robotics*, a theoretical understanding of how biological organisms coordinate movements, a formal expression of the underlying mathematical principles is necessary, such as coordination in Eigenvector-frames (cf. *Pellionisz*, 1984 J.Theor.Biol. 110:353). Basis of developing a model of human arm is *computerized anatomy*, quantitating the structure of an overcomplete number of skeletal elements, joints, spatial arrangement of up to 22 muscles and, ultimately, the much higher number of heterogeneous motor units and motoneurons. Problems of motor control, such as coordination and trajectory-formation can be addressed in such multidimensional intrinsic coordinate systems (cf. *Pellionisz, Soechting, Gielen, Simpson, Peterson, Georgopoulos*, 1986 Neuroscience Abst.12:1). The present preliminary model (representing 2D movements) of the human forearm is based on anatomical data, and is aimed at interpreting physiological measurements, both sets obtained in the Utrecht laboratory. A video will demonstrate the present level of the suitability of the model to geometrize CNS motor control in general non-orthogonal intrinsic coordinate frames and their underlying characteristic Eigenvector-systems. *Supported by NS-22999*

RESPONSES OF ABDUCENS NUCLEUS NEURONS TO VESTIBULAR STIMULATION IN AWAKE RABBIT. J.S. Stahl and J.I. Simpson. Dept. Physiol. & Biophys., NYU Med. Ctr. NY, NY 10016

Single abducens nucleus neurons were recorded extracellularly in awake rabbits and antidromically identified as motoneurons (MN) or internuclear neurons (INT). Firing rate and eye position were obtained during sinusoidal yaw rotation in light and dark (.05-0.4 Hz, 3 °/sec peak velocity). The majority of MN went into cutoff for a substantial part of the stimulus cycle, suggesting that in the rabbit, recruitment occurs at more abducted eye positions than in cat and monkey. The neural response was analyzed using linear multivariate regression to yield measurements of eye position sensitivity (k) and eye velocity sensitivity (r). For MN at 0.1 Hz in the light, the average values were 16.6 spikes/sec/° and 10.3 spikes/sec/°/sec for k and r, respectively (n=5). For INT the corresponding values were 12.0 and 8.9 (n=8). These k and r values are higher than those of the cat and monkey. For both MN and INT, k increased and r decreased with stimulus frequency. For MN, the ratio r/k (T) decreased from an average of 1.00 sec at .05 Hz to 0.45 sec at 0.2 Hz. For INT, the corresponding decrease was from 1.09 to 0.49 sec. The frequency dependence of T means that the oft-used first-order model relating firing rate and eye kinematics is incomplete even for the slow phase of vestibular nystagmus. Supported by NS-13742.

TROCHLEAR MOTONEURONS DECREASE THEIR FIRING RATE FOR OCULAR CONVERGENCE.
L. E. Mays and P. D. R. Gamlin. Department of Physiological Optics, School of Optometry, University of Alabama at Birmingham, Birmingham, AL 35294.

It has long been known that the relationship between ocular torsion and eye position is altered with convergence. Allen and Carter (Am. J. Optom. 44:343, 1967) have shown that most subjects exhibit a small degree of excyclorotation for convergence eye movements. We have examined the firing patterns of 13 trochlear (superior oblique) motoneurons in two Rhesus monkeys trained to make symmetrical vergence eye movements. The horizontal and vertical positions of both eyes was measured using search coils. Ocular torsion was not monitored. Since the secondary action of the superior oblique is depression, a strong relationship between vertical eye position and firing rate was observed (3.86 spikes/sec per degree). The relationship between firing rate and horizontal conjugate gaze shifts was weak. For convergence, however, a clear decrease in firing rate was seen in all cells tested. This decrease (1.57 spikes/sec per degree of vergence adduction) was 5 times larger than that seen for similar conjugate adduction. This decrease, and consequent relaxation of the superior oblique muscles, appears to be responsible for the excyclorotation seen during convergence. (Supported by NIH Grant EY03463 and P30 EY03039).

RESPONSE PROPERTIES OF NEURONS IN THE PRETECTAL NUCLEUS OF THE OPTIC TRACT OF BEHAVING PRIMATES. M.J.Mustari and A.F.Fuchs. Regional Primate Research Ctr., Univ. of Washington, Seattle, WA 98195.

The pretectal nucleus of the optic tract (NOT) is thought to play a role in the horizontal optokinetic reflex in many lower mammals. To examine its role in primates we have studied the discharge properties of 81 pretectal units that were histologically verified to be in the NOT of the rhesus monkey.

The visual properties of NOT units were tested with large-field random dot stimuli that moved while the monkey fixated a stationary target spot. NOT units were sensitive to both the velocity and direction of the visual stimulus. Their response generally was strongest for stimuli that had an ipsilaterally directed component. Unit firing rate was monotonically related to stimulus velocity over at least part of the range (0-200 deg/sec) tested. In addition to responding to large-field stimuli, 27% of NOT units also discharged during smooth pursuit of a small target spot. If the target spot was extinguished briefly during pursuit, but the monkey continued tracking, the responses of the majority (90%) of such units dropped to their resting rates, indicating that they were responding to the visual slip of the target during imperfect tracking. Finally, weak electrical stimulation at the sites of NOT units elicited optokinetic-like eye movements with time courses similar to those generated by optokinetic drums. We conclude that the NOT could play a role in smooth pursuit or optokinetic eye movements.

MEDIUM— LEAD BURST NEURON ACTIVITY DURING OBLIQUE SACCADES. J. S. Nelson*, R. Hartwich-Young and D. L. Sparks. Neurobiology Research Center and Department of Physiology & Biophysics, University of Alabama at Birmingham. Birmingham, Alabama 35294.

The activity of medium-lead burst (MLB) neurons in the paramedian pontine reticular formation (PPRF) has not been studied extensively during oblique saccades. Nevertheless, recent models of the saccadic system make explicit assumptions about the behavior of these cells during oblique saccades (Grossman & Robinson, 1988; Scudder, 1984; Tweed & Vilis, 1985; van Gisbergen et al., 1985). We have generated a body of empirical data that can be used for the evaluation and development of these models. Four rhesus monkeys were prepared for chronic recording and measurement of eye movements using the scleral search coil technique. The monkeys were trained on a saccade task requiring acquisition of a fixation target and an eccentric target. The targets were an array of LED's on a tangent screen. Insulated tungsten electrodes were placed in the PPRF close to the abducens nucleus. Burst neurons were isolated, and their saccade-related activity was recorded for saccades having a wide range of directions and amplitudes. Although the velocity of the horizontal component of oblique saccades and saccade direction are highly correlated, our results indicate that the relationship between burst frequency and saccade direction is stronger than the relationship between burst frequency and the velocity of the horizontal component. First, burst frequency remains relatively constant for saccades of the same direction that differ in vectorial amplitude and, therefore, display a large range of horizontal amplitudes and velocities. Second, the curvilinear relationship between burst frequency and saccade direction is often asymmetric and different in shape from the relationship between saccade direction and the peak velocity of the horizontal component. These findings indicate that the MLB frequency/velocity relationship is direction specific.(Supported by NIH EY01189 and EY05914).

ACTIVITY AND PONTO-BULBAR CONNECTIONS OF RETICULO-SPINAL NEURONS SUBSERVING VISUALLY TRIGGERED ORIENTING EYE AND HEAD MOVEMENTS. A. Grantyn+, O. Hardy+ and A. Berthoz.
Lab. de Physiologie Neurosensorielle, CNRS, Paris, France.

Descending axons in the caudal pons or rostral medulla were recorded intracellularly in alert, head-fixed cats performing orienting to moving visual stimuli. Spike activity was examined for correlations with eye movements and attempted head movements (EMG of dorsal neck muscles). Neurons related to these motor events and receiving mono- or disynaptic excitation from the contralateral superior colliculus were injected with HRP and their axonal trees reconstructed. The sample includes 11 reticulo-spinal neurons (RSN) projecting in RSTm. The types of their signals form a continuum which can be illustrated by 3 representative groups: 1) Phasic RSN generating short bursts linked to the onset of saccades and/or associated neck muscle activity; 2) RSN eventually showing prolonged bursts, frequency modulated in relation to saccades and early parts of dynamic EMG-components; 3) RSN with modulation of spike rate reflecting the profiles of even the longest EMG-transients and nearly lacking saccade-related components. HRP labeling reveales that RSN of groups 1, 3 contact the reticular core only, by a few (1-5) poorly branched collaterals. Group 2 RSN show multiple (8-15 collaterals) branching in the ponto-bulbar RF, prepositus/vestibular complex, and abducens and facial nuclei. The data indicate a distributed nature of the premotor signal in the tecto-reticular network and disclose some aspects of its intrinsic connectivity.

ROSTRAL OUTPUT NEURONS OF SUPERIOR COLLICULUS ARE ACTIVE DURING ATTENTIVE FIXATION. D.P. Munoz and D. Guitton.
Neurology and Neurosurgery, McGill Univ., Montreal, Canada

The superior colliculus (SC) plays an important role in controlling orienting behaviour. A major projection neuron emanating from the deeper layers of the cat SC, the tecto-reticulo-spinal neuron (TRSN), collateralizes in regions of the brainstem and spinal cord involved in controlling eye and head movements. The rostral SC contains an extensive representation of the central visual field. Here we report the discharge characteristics of TRSNs located in this region. Antidromically identified TRSNs were recorded extracellularly in head-fixed/free cats trained to perform several visuo-motor tasks (Brain Res. 398:185). Results: 1)Rostral TRSNs responded to visual, auditory, and somatosensory stimuli; responses were modulated by behavioural context. 2)Visual receptive fields were large (approximately 20° in diameter) and included a representation of the area centralis. 3)Maximum discharge was attained when the cat attentively fixated a visual stimulus. Discharge was reduced when the animal's attention was directed away from the point of fixation. 4)During orienting gaze shifts, discharge was reduced immediately prior to the onset of movement and increased as the gaze shift terminated on the target. These properties are similar to tonically active omnipause neurons (OPNs) that inhibit premotor neurons involved in saccade generation. We speculate that rostral TRSNs may provide excitation to OPNs, thereby suppressing orientation during attentive fixation.

NEURONAL ACTIVITY IN THE POSTERIOR PARIETAL CORTEX (AREA PG) OF ALERT MONKEY DURING OCULAR FOLLOWING RESPONSES. K. Kawano, Y. Watanabe* and S. Yamane* Bionics Section, Electrotechnical Lab., Tsukuba-shi, Ibaraki 305, JAPAN

Previous studies showed that a group of neurons in the posterior parietal cortex (area PG) of the monkey are activated by movements of the entire visual field. In this study, the experiments conducted were concerned with their relation to the ocular following responses, which is always elicited by movements of the visual field in alert monkeys. A monkey faced a screen onto which a random dot pattern was projected, and its eye movements were recorded with the magnetic search coil technique. Single unit activity was recorded in the posterior part of area PG. 166 neurons were activated by the movements of the visual scene showing directional selectivity. Most of them showed similar dependence on the visual properties of the stimulus to that of ocular following, e.g. preference to high speed (80-160°/s), latency delay due to blurring and oscillation at the high temporal frequency (40Hz). Their latencies were very short. 80% of the neurons were activated less than 50ms after the onset of the stimulus, and about half of them started their increase of firing rate more than 10ms before the eye movement. Furthermore, some of them were activated antidromically from the ipsilateral cerebral peduncle. These results suggest an important role of the neurons in the posterior part of area PG in the initiation and control of ocular following.

THE OCULOMOTOR VELOCITY TO POSITION TRANSFORMATION INVOLVES THE NUCLEUS OF CAJAL. D. Crawford*, W. Cadera* and T. Vilis. Depts. of Physiology and Ophthalmology, University of Western Ontario. London, Canada, N6A 5C1.

The mesencephalic reticular formation of Macaca fascicularis monkeys was systematically explored for evidence of an eye velocity to position signal transformation through single unit recording, microstimulation and microinjection of muscimol. Eye rotations in 3D were recorded. Constant frequency microstimulation in the vicinity of the nucleus of Cajal (INC) produced constant velocity eye rotations which held their positions when stimulation ceased. Rotations were clockwise for stimulations on the right and counterclockwise on the left with variable vertical components. As reported elsewhere (Hepp et al. 1986), unilateral injections of muscimol in the riMLF produced tonic torsional deviations of the eyes. These tonic deviations became leaky with unilateral injections between the riMLF and INC, producing nystagmus with torsional and vertical slow phases exponentially drifting toward primary position. Injections in the INC produced either no tonic deviation and thus only a vertical drift or a variable change in set point with both vertical and torsional drift. Goal directed saccades did not overshoot as expected with a loss of position feedback. The results suggest that the velocity to position tranformation involves the INC and that the position signal is not used to terminate saccades.

386.9

SMOOTH EYE MOVEMENTS ELICITED BY MICROSTIMULATION IN THE FRONTAL EYE FIELDS REGION OF ALERT MACAQUE MONKEYS. M.G. MacAvoy, C.J. Bruce, and J. Gottlieb* Sec. Neuroanatomy, Yale Univ. School of Medicine, New Haven, CT 06510.

Smooth eye movements were studied in conjunction with microstimulation of cortex near the frontal eye fields (FEF) of rhesus monkeys. Eye movements were recorded with a search coil in one eye. Both eye position and eye velocity were digitized for later analysis.

Our primary observation is that smooth eye movements, rather than saccadic, were elicited by microstimulation within a discrete region of periarcuate cortex. Smooth movements were seen using currents as low 10-50μA during both attentive fixation of stationary targets and spontaneous oculomotor behavior. These eye movements usually continued for the duration of stimulation (250-500 msec). Eye velocities up to 25°/sec were obtained, with velocity increasing as a function of current. Each site had a characteristic direction of movement. Vertical, horizontal, and oblique movements were seen. The horizontal component was almost always ipsilateral to the stimulating electrode, in contrast to the contralateral saccades usually obtained from the nearby saccadic FEF.

The region over which smooth eye movements were elicited is near the ventral (inferior) FEF region where small amplitude saccadic eye movements are elicited. It appears to be a separate zone as we seldom observed saccadic and smooth eye movements together at a single site nor interdigitating within a single electrode penetration. Instead, on most penetrations saccades were elicited superficially and then smooth movements were elicited deep in the anterior bank of the arcuate sulcus.

This phenomenon of elicited smooth eye movements suggests that the primate FEF region has specializations for directing gaze using the smooth pursuit, as well as the saccadic, type of eye movement. Properties of neurons at smooth movement sites are now being studied.

ELECTRICALLY EVOKED TURNING: ASYMMETRIC AND SYMMETRIC COLLISION BETWEEN ANTEROMEDIAL CORTEX AND STRIATUM. J.S. Yeomans and K. Buckenham*, Psychology, U. Toronto, Canada.

Stimulation of anteromedial cortex (AMC) resulted in contraversive circling mixed with ipsiversive circling in one rat. Stimulation of striatum resulted in smooth contraversive circling. In the collision test, at low currents collision was only 15%, but at high currents collision was near 40%. In both cases, summation at long C-T intervals was only 20%. Collision occurred, it seems, in the corticostriatal pathway mediating contraversive turning, but not in cortical outputs mediating ipsiversive circling. The collision was asymmetric at both low and high currents. That is, the recovery from collision was rapid (0.6 to 1.0 ms) when the C pulses were delivered to the striatum and the T pulses were delivered to AMC, but the recovery was much slower (0.6 to 4 ms) when the C pulses were delivered to AMC and the T pulses to the striatum. The rapid recovery (0.6 to 1.0 ms) was symmetric 20% collision, attributable to corticostriatal axons. The slow recovery (1 to 4 ms) was asymmetric. The asymmetric recovery is proposed to be due to activation of cortical interneurons, resulting in corticostriatal collisions that are delayed by 2 ms. The asymmetry results from the inability of antidromic action potentials from striatum to cross the synaptic barrier. The refractory period curve in AMC rose at the same long C-T intervals (2-4 ms), perhaps also due to blockade of transsynaptic action potentials.

ON COLLIDING ELECTRICALLY EVOKED AND NATURAL SACCADES. J.Schlag, M.Schlag-Rey and P.Dassonville. UCLA, BRI & Dept. Anatomy, Los Angeles,Ca.90024.

The "colliding saccade paradigm" (microstimulation applied during an ongoing saccade) differentiates brain sites processing (*a*)retinal error vs. (*b*)motor error. If (*a*) is the case, the trajectory of evoked saccades compensates for the initial gaze displacement (Exp. Brain Res. 87:68). This implies that the compensatory evoked saccades are directed toward a goal defined with respect to eye position. The time at which eye position is sampled was studied in monkeys by varying the interval between initial saccade and stimulation onsets, and testing 2 hypotheses: (*1*) the artificially created retinal error is referred to an eye position synchronous with the presumed real target onset (i.e. before the electrical stimulus), in order to compute spatial error and motor error (Robinson, 75); (*2*) the artificial retinal error is referred to the synchronous eye position (e.g. Jurgens et al., 81). Compensation for changes of eye position during afferent as well as efferent delays from the electrical stimulus is predicted by (*1*) but not (*2*). The results support (*1*) in the thalamus and (*2*) in the superior colliculus. These findings have implications for models of saccade generation. CHANGES IN PINNA ORIENTATION ACCOMPANY SHIFTS IN DIRECTION OF GAZE IN MONKEYS. C.J. Bruce, D. Burman, M.G. MacAvoy, and G.S. Russo. Sect. Neuroanatomy, Yale Univ. Sch. Medicine, New Haven CT 06510.

Orientation of the external ears was studied while rhesus monkeys made conjugate eye movements under controlled conditions. Eye movements were recorded with a search coil surgically implanted in one eye; pinnae movements were recorded with additional search coils temporarily mounted on the left and right ears.

Our primary observation was that both pinnae systematically oriented towards the direction of gaze. This effect was best shown by having the monkeys fixate a central LED for 1-2 sec and then saccade to a peripheral (e.g. +- 30°) LED and hold this eccentric gaze for 1-2 sec. Both ears usually moved; however, when gaze was directed to the far left the left ear moved more than the right, whereas when gaze was directed to the far right the right ear moved more than the left. Using the average of several trials, we computed a "gain" index equal to the sum of both pinnae movements (in a left-right coordinate system) divided by the horizontal gaze movement. This gain could be as high as +0.5, although it typically was nearer to +0.25. When the monkeys tracked moving visual targets via smooth pursuit eye movements the ears also moved with the eyes, showing approximately the same "gain" as with saccadic eye movements. Surprisingly, when the task was to attend to sustained peripheral sounds while maintaining fixation of a central LED there was little or no effect of the sound's location on tonic pinnae orientation. Instead, both ears transiently moved foward (left ear to the right and right ear to the left) when the sound began, regardless of its direction.

We conclude that the monkey has a basic tendency to orient its pinnae towards its direction of gaze, that is, to center of the current visual field. These pinnae movements must be considered in investigations of the brain's mechanisms for combining visual and auditory space.

386.13

THE EFFECT OF TARGET POSITION AND TARGET STEP SIZE ON SACCADE LATENCY A.D. Epstein, R.J. Tusa, N.R. Miller* Depts of Ophthalmology and Neurology, Johns Hopkins Hospital, 600 North Wolfe Street Baltimore, Maryland 21205-2182.

Horizontal saccade latency varies with target eccentricity, but it is not clear whether this relationship is based on the craniotopic or retinotopic coordinates of the target. Instead of testing only saccades made from primary gaze, which keeps target eccentricity with respect to eye and head identical, we tested saccades made from both primary and eccentric gaze positions.

We measured saccades by electrooculography in 13 normal subjects. Each was instructed to make prompt, accurate saccades to a 3 fL target light that stepped unpredictably to 1 of 7 positions between R 30° and L 30°. Subjects performed 450-900 saccades in one 60-90 minute session.

We performed multiple linear regression analysis on rightward and leftward saccades combined. Latency covaried significantly with target step size (ß=.58, p<.001) but not with initial and final target position. These results suggest that the effect of target eccentricity on saccade latency may reflect retinotopically mapped central processing. (Supported by Heed Foundation and NIH EY-07047)

PIÉRON'S LAW FOR SACCADES. H. Doma* and P.E. Hallett* (SPON: L. C. Doering), Department of Physiology, University of Toronto, Toronto, Canada. M5S 1A8.

Saccadic latencies were measured to small lit stimuli in darkness for two different tasks— foveating or anti saccades. The stimulus is the target for a foveating saccade, or is the cue for an anti saccade which peripheralizes the retinal image of the cue. Stimulus luminance, wavelength and retinal adaptation were varied. For either task Piéron's law fits pure rod or pure cone data with an exponent of -1.00, not -0.33 as others suggest. (a) For an exponent of -1.00 Piéron's law reduces to an oculomotor version of Bloch's law of temporal integration; latency is the sum of a minimal transit time from the photoreceptors to the eye muscles, plus a variable waiting or "response time" for a threshold number of photons. (b) This number for the rods is comparable to the classical perceptual limit of about 100 photons. The corresponding number for cones is roughly a factor of 5 higher than the cone threshold for perception. The implication is that rod-driven saccades are more perceptual in nature in comparison to the more reflex cone-driven saccades. (c) For foveating saccades latencies for mixed rod and cone inputs are substantially shorter than for the rods or cones alone— this is a synergistic effect. For anti saccades the same stimuli show no synergism. A neurophysiological mechanism can be proposed.

386.15

SACCADIC LOCALIZATION OF ECCENTRIC FORMS. Peiyuan He[1],*, E. Kowler[1] & R. M. Steinman[2]. [1]Rutgers Univ., New Brunswick NJ 08903 & [2]Univ. of Maryland, College Park, MD 20742.

How well can subjects direct saccades to selected locations within simple forms? Saccades were made to 1 of 4 possible locations inside an eccentric triangle 90' from fixation. The target location was indicated by a small point inside a central triangle. The eccentric triangle contained no target marker so that saccades would be programmed based only on the contour. When the eccentric triangle appeared, subjects had to make a single saccade to the designated target location as quickly as possible without sacrificing accuracy. In control trials targets were points at the same eccentricities.

Saccades to triangles were accurate (error=5') and precise (SD=11% of saccade size). The high accuracy and precision were not due to saccades learned in the point (control) trials because the same results were obtained when the triangles were tested first. Saccades directed to the "whole triangle" landed in idiosyncratic places, not the center-of-gravity. Latency was shorter and precision better than saccades to locations within the triangle.

The results do not confirm suggestions of reflexive saccades to the center-of-gravity of a form. Saccades are determined in 2 stages: (1) voluntary selection, in which a part of a form, or the whole form, is attended; and (2) automatic computation of the saccadic command based on attended visual information. (Supported by AFOSR 85-0022)

386.16

MULTI-TARGET VISUAL AND AUDITORY SACCADIC LOCALIZATION BY CATS.
D.D. Kurylo, R.L.P. Vimal*, and P.H. Hartline.
Eye Res. Inst. of Retina Foundation, Boston, MA, 02114.

Cats can direct their eyes to within a few degrees of briefly presented visual or auditory targets. We studied sensory-motor transformations underlying this behavior by investigating unimodal and bimodal interactions of auditory and visual stimuli presented at disparate locations in head fixed cats trained by an autoshaping paradigm. When two stimuli were simultaneously presented at disparate locations, most responses were single saccades either to one of the two targets, or to an intermediate position. Targets could both be visual, both auditory, or one visual and the other auditory. When the strength of one of the two stimuli was increased, the distribution of post saccade positions was shifted towards that stimulus. When the eyes were directed between the two stimuli at the time of onset, two-stimulus presentations produced responses similar to those evoked when the eyes were directed near a single target at onset time: saccadic latencies were long and the probability of eliciting a saccade was decreased. These results suggest that the neural computation of an orienting response integrates location information about multiple simultaneous stimuli, whether one or more modalities are involved. They may also reflect properties of the representation and processing of multi-sensory location information in superior colliculus.

386.17

TIMING AFFECTS MULTI-TARGET AUDITORY AND VISUAL LOCALIZATION BY CATS R.L.P.Vimal*,D.D.Kurylo and P.H.Hartline Eye Res. Inst.of Retina Found., Boston MA, 02114

Animals must be able to orient effectively to nearly simultaneous stimuli of different sensory modalities. We investigated the effects of inter-stimulus delay on saccadic orientation responses of cats trained by an autoshaping paradigm and presented with two disparate targets of auditory, visual, or mixed modality.

Saccadic latency increased, perhaps reflecting need for a complex decision, when two stimuli (same or different modality) were simultaneously presented and a single saccade to an intermediate location resulted. If one stimulus preceded the other by less than about 100 ms, a single saccade to either target or to an intermediate location resulted, indicating that decision (choice of one of the two targets) or summation occurred. At intervals < 100 msec, an initial saccade toward one target was occasionally aborted mid-stream by a saccade to a location intermediate between the two targets. For intervals > 250 msec, two sequential saccades toward the two stimulus locations often resulted, reflecting the order of stimulus presentation.

Multisensory enhancement or depression manifested by neuronal responses in optic tectum (a center for sensory motor integration for orienting behavior) can be strongly influenced by the relative timing of the stimuli. There may be complex spatiotemporal integration of tectal point images; selection of one vs integration of two competing stimuli may result from such neural interactions.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: OCULOMOTOR SYSTEM IV

ORBITAL GEOMETRY OF THE ACCESSORY LATERAL RECTUS MUSCLE IN MACAQUE MONKEYS. R. G. Boothe, M. V. Joosse* and M. W. Quick. Yerkes Primate Research Center, Depts. of Psychology and Ophthalmology, Emory Univ., Atlanta, GA 30322.

Simians have an extraocular muscle, the accessory lateral rectus, that is not present in either great apes or humans. Its functional role in monkey eye movements is usually considered to be minor due to the fact that it is short, weak, and attaches far back on the globe (Fuchs & Luschei, J. Physiol., 1971). However, no quantitative measurements or predictions of its function are available. Recently, Miller and Robins (Vis. Res., 1987) have applied a model of the effects of muscle force on human eye movements ("SQUINT") to monkeys. Input parameters for this model are based on quantitative dissections of positions of origins and insertions, and measurements of lengths and cross-sectional areas of each extraocular muscle. Values of these parameters for the accessory lateral rectus are unknown. In order to fill in this gap and provide a basis for making quantitative predictions about the functional role of this muscle, we have made measurements of these parameters in 10 eyes of 5 monkey cadavers (4 Macaca mulatta and 1 Macaca nemestrina). Mean values (expressed in the same stereotaxic coordinates as used in Miller & Robins, 1987) are: Origin: X = -6.8, Y = -13.0, Z = -4.7. Insertion: X = -0.1, Y = -5.6, Z = 2.54. Length = 12.1 mm, width at insertion = 2.86 mm, cross-sectional area = 3.56 sq mm.

EXTRAOCULAR MUSCLE ROTATION AXES: DETERMINATION IN THE INTACT HUMAN BY MAGNETIC RESONANCE IMAGING. E. S. Viirre*, S.J. Karlik* and T. Vilis. (spon. W.F. Brown) Depts. of Physiology and Diagnostic Imaging, University of Western Ontario. London, Canada. N6A 5C1.

As suggested by Simpson et al.(1986), contemporary data on the rotation axes of the extraocular muscles are necessary for current models of oculomotor control. The advantage of Magnetic Resonance Imaging (MRI) over dissection data is that muscle axes can be determined while the subject fixates a target straight ahead, thus giving normal innervations to each muscle.

MRI scans of both orbits were carried out on 2 adult males with no strabismus. The scanner had a 1.5 Tesla magnet which gave a resolution of approximately 0.5mm. Rotation axes, calculated using the centre of the eye and the centres of muscle cross sections, were rotated so that both medial recti were as near vertical as possible. Average direction cosines of the rotation axes are given (left eye). The reference axes are X (anterior positive), Y (left positive) and Z (superior positive) MR -.037 -.053 -.998 LR -.005 .078 .997 SR .308 -.950 -.050 IR -.339 .913 -.227 IO -.836 -.503 -.217. These results indicate that the medial and lateral recti are collinear but that the superior and inferior depart by 10-25°. This is similar to Volkmann, 1869.

387.3

LISTING'S LAW FOR THE HEAD. Douglas Tweed* and Tutis Vilis (spon. A. J. Hudson) Depts. of Physiology and Ophthalmology, University of Western Ontario. London, Canada. N6A 5C1.

If eye positions are described in terms of their rotational displacement from the normal straight ahead position, using an angular position vector which lies along the axis of the rotation and whose length is the size of the rotation, then all these vectors lie in a single plane -- a result known as Listing's law.

We have used the magnetic field/search coil technique to measure the angular position of the head in 6 normal human subjects. When instructed to look around the room, with shoulders still, 5 of the subjects showed head position vectors restricted to within 5° of a single plane -- a scatter comparable to what we have found for eye positions in humans and monkeys. The sixth subject had one plane when looking above head level and another below head level. When subjects made repetitive eye-head gaze shifts between targets at 70° eccentricity, head positions remained roughly in the plane. Small systematic deviations were attributed to motion at lower cervical joints, because they were reproduced by voluntary forward or backward bending of the neck. The existence of Listing's laws for both head and eyes shows that the law is not a consequence of muscle geometry.

387.4

HUMAN VERTICAL OPTOKINETIC NYSTAGMUS (VOKN): UP-DOWN ASYMMETRY WITH AND WITHOUT CENTRAL RETINAL STIMULATION. C. M. Murasugi* and I. P. Howard* (SPON: J. R. Mendelson). Dept. of Psychology, York University, Toronto, Ontario, Canada.

In cats and monkeys the slow-phase gain of VOKN is higher for upward than for downward stimulus motion. The presence of a consistent VOKN asymmetry in humans is controversial, probably due to use of electrooculography which produces an eyelid artifact. We used the magnetic search coil method to measure the monocular VOKN of 10 head-upright normal subjects. A 64°-high x 61°-wide random-dot display moved at velocities ranging from 10 to 70°/s. For seven subjects slow-phase gains were 40% higher in the upward direction for velocities at and above 30°/s. Three other subjects showed symmetrical VOKN. When a vertical band 6° wide spanned the center of the moving display, two patterns of results emerged. In six subjects, including one who showed a symmetrical full-field response, central occlusion caused a larger drop in downward VOKN than in upward VOKN for stimulus velocities of 50 and 70°/s. The other four subjects showed equally poor (<10°/s) VOKN in both directions. They were re-tested with a narrower occluder (3°) with little increase in evoked eye velocity. Thus, an upward dominance in VOKN is prevalent in humans at higher stimulus velocities, and the slower downward response is relatively more susceptible to the effects of central retinal occlusion. Investigations of response properties of neurons in the cat's accessory optic system have revealed that the visual cortex is a major source of upward direction-selectivity and high-velocity tuning, whereas downward direction-selective cells receive their input directly from the contralateral retina (Grasse, K.L. et al., Exp. Brain Res., 55: 69,1984). Our results suggest that human VOKN may involve similar pathways, and at higher stimulus velocities the cortically mediated upward VOKN is more vigorous and more resistant to occlusion of the central retina than the directly innervated downward VOKN.

387.5

RETINAL SLIP SERVES TO "FINE TUNE" SUPPRESSION OF OKN. M. Lustgarten*, J. Pola, H.J. Wyatt and E. Aksionoff*. Schnurmacher Institute for Vision Research, SUNY College of Optometry, NY, NY 10010.

Subjects looked at a target presented against a sinusoidally moving optokinetic inducing field (1/4 Hz). Target retinal feedback was varied from 0 (target foveally stabilized) to -1 (normal closed loop condition). With 0 feedback there was substantial suppression of OKN; however, moderate amplitude slow eye movements remained, counterphase to the field (0 feedback suppression appears to come from target-field relative motion and attention - Vis Res '84, Soc Neurosci '87). As feedback increased, amplitude and phase of this residual movement decreased, until with -1 feedback there was very little movement. The decrease was particularly rapid for small amounts of feedback presented near the stabilized condition. Linear models cannot account well for this decrease in amplitude and phase. However, a simple model with a non-linearity at its input predicts the results nicely. The non-linearity has a gain which is high near the fovea, but decreases with eccentricity from the fovea.

These findings indicate that suppression of OKN comes largely from target-field relative motion and attention, with retinal slip serving to fine-tune the suppression. The model suggests the existence of a fixation mechanism whose sensitivity is maximum at the fovea.

387.6

HORIZONTAL OPTOKINETIC NYSTAGMUS (OKN) IS NON-CONJUGATE IN THE TURTLE. M. Ariel. Depts. of Behavioral Neuroscience & Psychiatry, Univ. of Pittsburgh, Pgh., PA 15260.

The positions of each eye of the awake turtle, pseudmys scripta elegans, were recorded simultaneously during full-field stimuli. Horizontal OKN was strongly asymmetric and non-conjugate during monocular stimuli, with a strong response by the exposed eye to stimuli moving in the nasal direction. The occluded eye hardly moved as the exposed eye viewed nasal stimuli, but was more yoked during temporal stimuli. These dramatic differences between the eyes was also often observed during binocular viewing of identical random-dot patterns drifting horizontally, so that the slow phase velocity of the eye viewing the nasal stimulus was much greater than that of the other eye. This non-conjugate OKN is clearest to stimuli of about 10 deg/sec. Concurrent with the non-conjugate slow phases was the yoked nature of the timing of fast phase eye movements.

OKN was also analyzed simultaneously for both eyes following monocular intravitreal drug injections. Bicuculline, known to evoke spontaneous temporal-to-nasal nystagmus in mammals with yoked eyes, elicited nystagmus mainly in the injected eye of the turtle. Likewise, monocular injections of APB, known to eliminate OKN in rabbits, exclusively blocks OKN of the injected turtle eye, without affecting the eye movements of the uninjected eye. Therefore, monocular OKN and effects of monocular drugs indicate that oculomotor pathways in the turtle can remain functionally independent for each eye.

COMPARISON OF VESTIBULO-OCULAR REFLEX (VOR) MODIFICATION METHODS IN CATS. W. Freedman, J.R. Carroll*, and J.G. McElligott. Drexel Univ. Dept of Electrical and Computer Engineering, Phila., PA 19104, Pennsylvania College of Optometry, Phila., PA, Temple University School of Medicine, Dept. of Pharmacology, Phila., PA 19140, and Moss Rehabilitation Hospital, Phila., PA.

The vestibulo-ocular reflex (VOR) has been measured and optically modified in several animal species. VOR gain can be increased optokinetically by placing a head fixed animal inside an optokinetic drum and sinusoidly oscillating it in a direction opposite to that of the drum rotation. VOR increase can also be accomplished by having an animal wear a set of magnifying lenses. We describe here a comparison of three methods for producing VOR increases in cats using an (i) optokinetic drum, (ii) a pair of 2.2X telescopic lenses, or (iii) a Fresnel lens goggles that we have recently developed in our lab. After initial calibrations to test the VOR in the dark and the light, 10 VOR modification periods of 15 minutes were each followed by a 1 minute period to test for VOR gain modification in the dark (see McElligott and Freedman, *Exp. Brain Res.* (1988) 69:509-521). Throughout the modification and the test periods, each animal was kept in a highly alerted state. The results of the comparison in 4 cats show that the Fresnel lens system produces a greater and more stable VOR gain increase than the other two systems. After 2.5 hours of modification, the VOR gain increases (n=4) were optokinetic drum- 1.15; 2.2X telescopes- 1.25; Fresnel lens- 1.40. These results show that some animals that had poor or minimal VOR modification, now exhibit more robust VOR gain increases using the Fresnel lens system.

BEHAVIOR OF HUMAN VESTIBULO-OCULAR REFLEX (VOR) IN RESPONSE TO HIGH-ACCELERATION STIMULI. E.F. Maas,* W.P. Huebner,* S.H. Seidman* and R.J. Leigh, Ocular Motility Lab Cleveland V.A. Med. Ctr., University Hospitals and Dept. Biomed. Eng. Case Western Reserve University, Cleveland, OH, 44106.

We measured horizontal head position and gaze in 3 normal male subjects (age range 23-30 yrs) using a magnetic search coil system. Each subject clenched his teeth upon a plastic mouthguard attached to a lucite yoke that encircled his head. At the back of the yoke was a spur that was struck in a non-predictable sequence to generate small magnitude ($\lesssim$3.5 deg) but high acceleration (2000-7000 deg/sec/sec) head rotations. Data were filtered (0-150 Hz) and digitized at 2 KHz. Head velocity and eye-in-orbit velocity were then obtained for 10 trials for each subject.

The latency of the VOR (onset of head rotation to onset of eye-in-orbit rotation was $\leq$ 12 msec, which is shorter than values reported with lower acceleration stimuli in monkey. Peak gaze velocity (group mean) was 30 deg/sec, which was 45% of peak head velocity; oscillopsia occurred during each head perturbation. The mean, predominant frequency of head rotations was 11 Hz. These results are relevant to the performance of the VOR during running, when head rotations of similar amplitude and acceleration may occur.

(Supported by NIH grant EY06717, NASA contract 9-17439 and the Veterans Administration)

Temporal Characteristics of Vestibulo-ocular Reflex Cancellation in Squirrel Monkeys. K. E. Cullen, T. Belton*, L.B. Minor, and R. A. McCrea. Comm. on Neurobiol., Univ. Chicago, Chicago, Ill. 60637.

The temporal characteristics of the central systems used to cancel the vestibulo-ocular reflex (VOR) were studied in squirrel monkeys who were trained to fixate a target that moved with the head. Monkeys were passively rotated on a vestibular turntable in the horizontal plane. Two types of experiments were done: 1) The table was turned at a constant velocity of 20°/sec during VOR cancellation, and was then rapidly accelerated to a new velocity of either 50°/sec or -10°/sec. This unpredicted change in head velocity produced a transient eye velocity in the opposite direction. The transient had a duration of 140-210 msec, after which the eye velocity returned to zero. The gain of the VOR during the transient response was less that one, in respect to the step change in head velocity, after a delay of 10-15 msec. 2) A second series of experiments were designed to determine the frequency response characteristics of the cancellation system. The monkeys were rotated sinusoidally at a low frequency (0.1-0.9 Hz), and once eye velocity was cancelled, the frequency of rotation was increased to 1.0-6.0 Hz. VOR gain was zero for stimulus frequencies below 1.2 Hz during cancellation, but was near 1.0 for stimulus frequencies above 4.0 Hz. Thus, the failure of the cancellation system to completely cancel the VOR during unexpected changes in head velocity probably reflects the fact that the input to the cancellation system is only a low pass filtered copy of the signals that drive the VOR.

387.10

HUMAN SUBJECTS SUPPRESS THE VESTIBULO-OCULAR REFLEX DURING VISUAL PURSUIT. V. Matsuo and B.W. Peterson. Sensory Motor Performance Program, Rehabilitation Institute of Chicago, and Department of Physiology, Northwestern University School of Medicine, Chicago, IL 60611.

We have shown previously that when rotating subjects (Ss) pursue a moving target their maximum smooth eye velocity is less than the sum of their VOR and smooth pursuit responses when measured independently. We now report that this is because Ss suppress the VOR when pursuing moving targets. This occurs when Ss pursue a target while they are initially stationary and then are suddenly rotated (condition 1) , as well as when Ss pursue the target during rotation and are suddenly stopped (condition 2) .

Five normal Ss sat in a servo-controlled rotating chair with the head held in a chair-mounted restraint. Eye movements were recorded using d.c. EOG. Head velocity was monitored using a head-fixed angular rate sensor. The pursuit target was a 0.25° projected laser spot. Vestibular and pursuit stimuli consisted of computer-generated 20 and 40 °/sec constant velocity ramp waveforms.

Our criterion for VOR involvement was the latency from change in head velocity, due to the sudden rotation or stop, to change in eye velocity. For 40°/sec median VOR latency was 38 msec (range 12-59). Eye movement latencies greater than 59 msec were thus regarded as putative evidence that the VOR had been suppressed. Group median latency to eye velocity change for condition 1 was 104 msec (medians for the 5 Ss ranged from 69-208). The median latency resulting from condition 2 was 64 msec (range from 56-76). The Mann-Whitney U-test showed greater eye movement latencies during conditions 1 and 2 than during VOR in darkness ($p<0.01$ for all Ss). In three Ss the latencies for condition 1 were significantly greater than those for condition 2 ($p<0.005$), suggesting that the VOR was at least as effectively suppressed when S was initially stationary as when he was moving. Results were similar at 20°/sec except that there were no differences between conditions 1 and 2.

THE ANATOMICAL SUBSTRATE OF BLINK MOVEMENTS: STRUCTURE AND INNERVATION OF PRIMATE LEVATOR PALPEBRAE SUPERIORIS AND ORBICULARIS OCULI MUSCLES. J.D. Porter, P.J. May, and L.A. Burns*. Dept. of Anatomy, Univ. of Mississippi Med. Ctr., Jackson, MS 39216.

The levator palpebrae superioris (LPS) and orbicularis oculi (ObOc) are antagonistic muscles functioning in blinks. Motoneurons innervating these muscles were identified in Cynomolgous monkeys by retrograde transport of HRP. LPS motoneurons were located bilaterally within the caudal central division of the oculomotor nucleus. The lack of any apparent laterality in motoneuron distribution and the high percentage of neurons labeled from injection of one LPS suggest that individual motoneurons may innervate both LPS muscles. Motoneurons innervating the ObOc muscle were distributed within the dorsolateral subdivision of the ipsilateral facial motor nucleus, with a few neurons in the corresponding locus of the contralateral nucleus.

Unlike the other extraocular muscles, the LPS lacks a layered distribution of fiber types. The LPS contains the same 3 ultrastructural types of singly-innervated muscle fibers (SIF) found in the global layer of other extraocular muscles. Fiber types corresponding to extraocular muscle global red SIF (type 3) and global intermediate SIF predominate (type 4), with only a few global pale SIF fibers (type 5) noted. The histochemical/morphological profiles of these fiber types are such that they do not respect "traditional" fiber classification schemes, but are consistent with a role for LPS in tonic elevation of the lid. The multiply-innervated fiber types, which characterize eye muscles, were absent from the LPS, suggesting that this fiber's functional role relates to rotational movements of the globe and not to maintenance of lid position against gravity. The ObOc exhibited two morphological fiber types that, by contrast, resembled "traditional" skeletal muscle fast-twitch fibers. On the basis of mitochondrial content, ObOc fiber types would be fatigue-prone; an assumption consistent with their rapid onset/offset action in blinks. Morphological differences between LPS and ObOc reflect not only their distinct functional roles in blinking, but also their diverse embryological origins. NEI EY05464 (JDP) and EY07166 (PJM).

CEREBELLAR PARTICIPATION IN ADAPTIVE MODIFICATION OF THE BLINK REFLEX. C. Evinger and K.A. Manning. Dept. Neurobiology. & Behavior, SUNY Stony Brook, Stony Brook, NY 11794.

Blink reflex size as measured by EMG activity exhibits rapid, adaptive modification following restraint of the eyelid. Using lesions and electrophysiological techniques on decerebrate rats, we investigated the role of the cerebellum in adaptive changes of the blink reflex.

After hemicerebellectomy, the eyelid ipsilateral to the lesion did not exhibit adaptive modification with eyelid restraint. The contralateral eyelid, however, continued to adapt. Thus, the cerebellum appears to be necessary for adaptive modification of the blink reflex. Single unit recording in Crus I revealed that corneal stimulation and the resultant blink normally evoke a complex spike and a transient increase in the simple spike activity of Purkinje cells. During adaptation induced by lid restraint, complex spike activity decreased and simple spike firing frequency increased for most Purkinje cells. Although these results imply that the cerebellum is the site of adaptation, mossy fibers whose discharge correlated with corneal stimulation also showed an increased activity during adaptation. Since the mossy fiber input to the cerebellum changes with adaptation, the cerebellum may be providing a signal to initiate blink adaptation, rather than serving as the site of adaptation.

AN INEXPENSIVE ULTRASONIC CONTACT LENS TO MEASURE ACCOMMODATION. K.Kozonasky and R. Remmel, Biomedical Engineering Dept., Boston University, Boston, MA 02215.

Optical methods of measuring accommodation, some costing >$10,000, involve observing how a light is focused on the retina. An ultrasonic probe placed against the eye can measure lens thickness. These methods obstruct or restrict vision, possibly biasing the results. Our method measures lens thickness with two ultrasound crystals mounted on a contact lens, leaving vision unobstructed.

The two lead metaniobate crystals are 0.5 mm thick and 1 mm dia. They will be placed on either side of the pupil. The transmitting crystal is excited by a 50 V step, which causes a 6 MHz oscillation with a decay time constant of 2 us. The receiving crystal detects the direct wave traveling across the cornea, and then the echoes from the front and back lens surfaces. In the finished circuit, the time between echoes will be converted to a voltage proportional to lens thickness, which measurement will be repeated 2800 times/s.

Distances as short as 2.5 mm have been measured with 8% accuracy in oil. Testing is underway using cat eyes.

A silicone-rubber contact lens with a hole over the pupil is being tested. The two crystals can be glued on with silicone rubber glue. A local anesthetic should be applied to the eye. A coil of wire can also be glued to the lens so that eye movements can be measured.

Accommodation should thus be measureable for $300.

DOSE RESPONSE EFFECTS OF COCAINE ON EVOKED ACTIVITY RECORDED FROM DORSAL RAPHE AND PARABRACHIAL AREA. W. McVaugh*, A. Shen* and N. Dafny (SPON: A. Schonbrunn). Dept. Neurobiol. & Anat., The Univ. of Texas Medical School at Houston, 77225.

Cocaine has been reported to have variable effects on CNS components. This study investigated the effects of cocaine on Sensory Evoked Responses (SERs) recorded from Dorsal Raphe (DR) and Locus Ceruleus (LC) in the freely moving rat. In addition, the effects of Naloxone (an opiate antagonist) and Desipramine (a NE uptake blocker) were examined. Sixteen male Sprague-Dawley rats were permanently implanted with 120 μm stainless steel semimicroelectrodes. Four sets of 32 averaged visually evoked responses were recorded before (control), and after 1, 5 and 10 mg/kg cocaine (i.p.) and desipramine (20 mg/kg) or naloxone (1 mg/kg), respectively. The P_2 and P_3 wave components were analyzed. In LC, the P_2 amplitude increased with each increasing dose. P_3 exhibited facilitation at 1 mg/kg, but was inhibited at higher doses. P_2 from DR demonstrated a dose-dependent facilitation, while P_3 was inihibited. Naloxone had no effect in either structure, while treatment with desipramine augmented the response from LC but not DR. In conclusion, it was seen that (1) cocaine affects various CNS sites differently in dose-dependent patterns; (2) cocaine can differentially affect the individual components of the SER; and (3) cocaine's effects do not seem to be mediated via opiate receptors.

388.2

EFFECTS OF SEROTONERGIC LESIONS OF THE NUCLEUS ACCUMBENS ON THE DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE. P. Schauwecher*, C. Bimle*, R. Kaltenbach* and S.I. Dworkin (SPON: R.D. Brown). Depts. of Psychiat. and Pharmac. & Ther., LSU School of Medicine, Shreveport, LA 71130.

Neurotoxin lesions of discrete brain regions have been helpful in determining the involvement of specific neuronal systems in drug abuse. The neurotoxin 5,7-dihydroxytryptamine (5,7-DHT) which destroys neurons containing serotonin, increased amphetamine self-administration when injected intraventricularly. However, a localized lesion of the nucleus accumbens did not alter drug intake (Lyness et al., 12, 937-941). It is difficult to assess the effects of a lesion on the reinforcing efficacy of a drug by the use of a single behavioral procedure thus, the effects of a 5,7-DHT lesion of the nucleus accumbens on cocaine drug discrimination was determined.

Adult male Fischer-344 rats were trained to discriminate cocaine (10 mg/kg, IP) from saline using a standard drug discrimination paradigm. Subjects were then tested using a cumulative dosing procedure. After the cocaine discrimination was acquired, generalization gradients were determined. Rats were then lesioned with the neurotoxin and generalization gradients were redetermined. The neurotoxin lesion resulted in a modest attenuation of the discriminative stimulus properties of cocaine. Supported By USPHS Grant DA-03631.

TOXIC CONSEQUENCES OF COCAINE ARE AUGMENTED BY NONCONTINGENT DRUG ADMINISTRATION. S.M. Dworkin*, C. Volkmer* and S.I. Dworkin. Dept. of Psychiatry, LSU School of Medicine, Shreveport, LA 71130.

The pathological consequences of environmental events can depend on the functional relationships between behavior and the delivery of the event. Studies using both monkeys and rats in yoked procedures have shown that yoked animals are more likely to develop ulcers and other other signs of physiological and neurobiological pathology compared to animals given the opportunity to postpone the stimulus. Additionally, the contingent delivery of intravenous morphine produced greater changes in neurotransmitter turnover compared to noncontingent infusions.

Twelve littermate triads of male Fisher F-344 were prepared with chronic indwelling intravenous catheters and placed in individual operant conditioning chambers. Each set of 3 operant conditioning chambers were housed in single sound-attenuating enclosure. Responses by the rat placed in the center of the enclosure resulted in the delivery of cocaine infusions (1.0 or .67 mg/inf) to both the center rat and his littermate on the right, while saline was infused to the animal on the left. Cocaine resulted in the death of only the rats receiving noncontingent injections within a relatively short time period.

HEMODYNAMIC RESPONSE CHARACTERISTICS TO COCAINE (C) IN RATS. M.M. Knuepfer, D.M. Wehner* and T.L. Sellers*. Dept. Pharmacol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

Our laboratory has reported that C produces small, dose-dependent increases in arterial pressure (AP) and mesenteric vascular resistance (MVR) and little change in hindquarter resistance (HQR) in awake rats. We sought to describe the mechanisms by which the hemodynamic responses were mediated using receptor antagonists. Rats were instrumented with an arterial cannula for AP and heart rate (HR) determination and with miniaturized pulsed Doppler flow probes for estimating changes in HQR and MVR. After recovery, C was administered alone or 10 minutes after pretreatment with selective antagonists. The table contains the results expressed as mean ± SEM (N's = 4-12).

DRUG (mg/kg)	AP	HR	HQR	MVR
Cocaine (5)	14±3	-35±13	-3±8	44±20
Pentolinium (7.5)	12±3	11±10	8±6	17±6
Methylatropine (1)	4±2	-27±5	-20±13	13±4
Prazosin (0.1)	-2±2	-16±8	-13±1	9±6
Propranolol (1)	21±3	-69±7	0±8	53±21

These data suggest that the modest AP and MVR responses are dependent upon α_1-adrenergic receptors, that the HR response is due primarily to removal of central sympathetic tone (α_1-adrenergic mediated) and that β-receptor blockade, often used clinically to treat C toxicity, actually exacerbates AP and HR responses to C. (Supported by HL37224, HL38299 and AHA, MO Affiliate.)

COCAINE KINETICS AND DISTRIBUTION IN VARIOUS BRAIN REGIONS OF RAT. R.P. Sharma*, J.I. Javaid, B. Duslak* and J.M. Davis*. Illinois State Psychiatric Institute and University of Illinois at Chicato, Il 60612

It has been proposed that the effects of psychoactive drugs on specific aspects of mental function may be related to the capacity of the drug to selectively concentrate in specific regions of the brain. In rat brain cocaine effects on striatal and nucleus accumbens dopaminergic systems show quantitative differences. In the present studies we report single-dose kinetics in serum and various brain areas of the rat after 10 mg/kg I.P. injection. At different time points after drug administration (5, 10, 20, 30, 60 and 120 minutes), the animals (N = 6 at each time point) were decapitated and cocaine was quantitated in serum and in various brain regions. There were large inter-individual variability in different rats in various kinetic parameters. The average serum $t_{1/2}$ was 50 minutes. There were no significant differences in the total concentration (ng/g tissue) of cocaine in the eight brain regions studied. Similarly the maximum concentration (C_{max}) in various brain regions was also not statistically different. However, the time to achieve maximum concentration (T_{max}) divided the brain regions into two groups; those with T_{max} under 10 minutes and those with T_{max} over 30 minutes. These differences in time to reach maximum drug concentration may account for differential biochemical effects in various brain areas.

388.6

A RELATIONSHIP BETWEEN WITHDRAWAL AND TOLERANCE TO THE DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE. M.W. Emmett-Oglesby, D. M. Wood, D. A. Mathis*, and H. Lal. Department of Pharmacology, TCOM, Fort Worth, TX 76107.

This experiment tested whether tolerance to cocaine was related to cocaine dependence/withdrawal. Animals trained to detect the discriminative stimulus properties of pentylenetetrazol (PTZ) can be used to assay for the occurrence of withdrawal from a variety of drugs of dependence, including cocaine. In addition to producing a PTZ-like stimulus, termination of high-dose cocaine administration is also associated with tolerance to the discriminative stimulus properties of cocaine, suggesting that the occurrence of a PTZ-like stimulus during withdrawal may be a mechanism that produces the apparent tolerance to cocaine. To test this hypothesis, we trained one group of rats to detect the anxiogenic drug pentylenetetrazol (20 mg/kg), and a second group of rats to detect cocaine (10 mg/kg). Given acutely, 1) PTZ shifted the dose-effect curve for the detection of cocaine approximately 2-fold to the right; 2) diazepam did not antagonize or potentiate the cocaine cue; and 3) diazepam (5 mg/kg) antagonized the PTZ cue. Following these tests, cocaine-trained subjects were given cocaine, 20 mg/kg, every 8-hr for 7 days. Subsequently, the cocaine dose-effect curve was redetermined both alone and in combination with diazepam, 5 mg/kg. Subjects receiving cocaine alone were tolerant, showing approximately a 2-fold shift of the dose-effect curve to the right. In contrast, subjects tested with combinations of cocaine and diazepam showed no shift of the dose-effect curve. These data show that diazepam blocks the expression of tolerance to the discriminative stimulus properties of cocaine. In combination with the other results, the most likely explanation for this finding is that termination of high-dose cocaine generates a PTZ-like stimulus that antagonizes the discriminative stimulus produced by cocaine.

388.7

EFFECTS OF PRENATAL EXPOSURE TO COCAINE OR RELATED DRUGS ON RAT OFFSPRING DEVELOPMENT AND DOPAMINERGIC NEUROTRANSMISSION. M. G. Henderson* and B. A. McMillen (Spon. by J. P. DaVanzo), Dept. Pharmacology, Sch. of Medicine, East Carolina University, Greenville, NC 27858.

Gestating rats received 15 mg/kg b.i.d. cocaine, 1.5 mg/kg amfonelic acid (AFA), 10 mg/kg amitryptiline or saline daily throughout pregnancy: cocaine treated dams gained less weight than controls. Male pups from 3 dams were fostered by 2 surrogate mothers, 10 per litter. Cocaine treatment accounted for 2 of 4 still births and all 4 non-fatal birth defects. There were no differences across groups in average birth weight, or weight at 15 or 30 days of age except for AFA exposed pups. All 4 groups had eye opening at the same age, but the cocaine exposed pups took 8.2 days to gain righting reflex vs 6.5 days for saline groups ($p<0.01$). At 30 days of age spontaneous motor activity before and after lights out was similar across groups. These results confirm a report by Richardson and Verhage (Fed. Proc. 2:A1804, 1988). There was no difference in akinetic response to 0.3 mg/kg s.c. haloperidol and no differences in striatal D2 receptor Bmax or Kd values. Data on brain area monoamine metabolism and later developmental ages will be described. These preliminary results indicate that the non-teratogenic effects of cocaine are small and that hyperactivity seen after prenatal amphetamine exposure does not occur. Whether significant effects may become apparent at later ages is yet to be determined.

388.8

SUBCORTICAL BINDING OF COCAINE IN LIVING BABOON BRAIN USING PET. J. S. Fowler, A. P. Wolf*, S. L. Dewey, R. R. MacGregor*, D. J. Schlyer*, D. Christman*, B. Bendriem*, N. Volkow. Brookhaven National Laboratory, Upton, NY 11973.

The mood elevating and euphoric properties of cocaine coupled with its widespread abuse and highly addictive properties has stimulated the study of the neurochemical basis of its behavioral effects. Recent evidence links the behavioral effects of cocaine to its interaction with the dopamine transporter (Ritz et al,Science 237: 1219, 1987). We recently synthesized [N-^{11}C-methyl]cocaine and measured its regional and temporal distribution in living (anesthetized, ketamine, isofluorane) baboon brain with high resolution PET. Uptake was highest in subcortical structures bilaterally, peaking at 4 minutes and clearing to 30 % of the highest value by 30 min. Ratios of striatum to frontal cortex and cerebellum at peak uptake were 2.0 and 2.4 respectively. Plasma clearance of carbon-11 was rapid and at 30 minutes, more than 50 % of the radioactivity was labeled carbon dioxide. The high initial uptake of [^{11}C]cocaine into the brain parallels the rapid mood elevation produced by the drug. The striking regional binding to the striatum suggests that the neurochemical mediator of behavioral activation may reside in subcortical structures. EVIDENCE FOR A BIPHASIC RESPONSE TO COCAINE IN RATS. L.E. Baker and R.J. Barrett. Dept. of Psychology, Vanderbilt University and Veterans Administration, Nashville, TN 37240.

Using a two choice drug discrimination paradigm, rats (n=72) were trained to discriminate cocaine (1.0 mg/kg) from haloperidol (.025 mg/kg). The training doses were chosen such that when Ss were tested on saline, they responded about 50% on each lever. A dose-response function was established by testing independent groups with three doses of cocaine (1.0, .50, .25 mg/kg) and three doses of haloperidol (.025, .0125, .006 mg/kg) during 5 min extinction sessions.

Ss were then injected with a single dose of cocaine (20 mg/kg) and independent groups were tested either 4, 6, 8, 12, 16, 18 or 24 hours later. Percent responding on the cocaine lever gradually decreased over time, such that by 8 hrs, responding was about equal on both bars and by 16 hrs, responding on the cocaine lever was 38%. Over longer intervals, there was a gradual return to pre-drug baseline.

With a single injection of 40 mg/kg cocaine, a similar biphasic effect was observed. At 24 hrs post cocaine, the Ss made 17% of their responses on the cocaine lever (i.e. 83% on haloperidol lever) before returning to predrug baseline.

These data provide evidence for a post-cocaine withdrawal, during which subjects respond in a manner opposite that produced by the primary drug effect. We believe the two drug-drug discrimination paradigm is an appropriate animal model for the study of physiological substrates which mediate the biphasic effect of cocaine in humans.

EFFECTS OF CHRONIC COCAINE TREATMENT ON THE UPTAKE AND RELEASE OF STRIATAL DOPAMINE. S.-J. Yi* and K.M. Johnson, Dept. of Pharmacology and Toxicology, Univ. of Texas Medical Branch, Galveston, TX 77550.

This laboratory has recently shown that repetitive administration of cocaine enhances its acute behavioral effects, and this behavioral sensitization involves the striatal dopaminergic system. (Soc.Neurosci.Abst.13:1718)

Female Sprague-Dawley rats were injected with either saline or 15 mg/kg cocaine (i.p.) twice a day for 7 days. After 7 days of withdrawal, rats were injected with saline or cocaine and were sacrificed 30 min later. Brains were removed and striatum was dissected to assay ^{3}H-DA uptake, ^{3}H-GBR 12935 binding and synaptosomal ^{3}H-DA release. Cocaine-sensitized rats showed an increased V_{max} of ^{3}H-DA uptake without any change in K_m, and no detectable difference in total specific 3H-GBR binding to striatal membranes or in the IC_{50} of cocaine to displace ^{3}H-GBR binding. Further, neither acute nor chronic cocaine administration caused any effects on compartmentalization of ^{3}H-DA in striatal synaptosomes. However, when 1 μM amphetamine (Amp) was added to the superfusion buffer, Amp-induced release of DA from the vesicular pool was potentiated by acute cocaine treatment. Treatment with chronic cocaine prevented this potentiation, and retarded release from the cytoplasmic, readily releasable pool, suggesting that the processes responsible for mediation of Amp's effect on DA compartmentalization show compensation in response to chronic cocaine.

PHYSIOLOGY OF ABUSE POTENTIAL SUBSTANCES IN CENTRAL NEURONAL CIRCUITS: COCAINE EFFECTS ON SOMATOSENSORY AND CEREBELLAR NEURONAL RESPONSES TO IONTOPHORETICALLY APPLIED GLUTAMATE. C.A. Jimenez-Rivera and B.D. Waterhouse. Dept. of Physiol. and Biophys., Hahnemann Univ., Phila., PA, 19102-1192

Cocaine's psychostimulant and reinforcing properties, are well known. However the basic physiological mechanism(s) through which cocaine produces these effects have not been established. Biochemical studies indicate that cocaine can increase central synaptic levels of monoamines through blockade of reuptake mechanisms. Previous work from our laboratory has suggested a modulatory role for norepinephrine (NE) in the cerebral cortex and cerebellum of mammalian brain. The goal of the present investigation was to determine to what extent cocaine might exert similar modulatory actions in neuronal circuits with well characterized noradrenergic projections. Somatosensory and cerebellar unit activity was recorded from halothane or urethane anesthetized rats. Excitatory responses of individual neurons to microiontophoretic pulses (10 sec.) of glutamate (1-65nA) were examined, before, during and after cocaine iontophoresis. Application of cocaine to somatosensory cortical cells produced a dose dependent range of effects; from marked potentiation of glutamate-induced excitation to suppression of both spontaneous and evoked activity. At lower ejection currents (less than 30nA) cocaine's major effect was to enhance glutamate responses (58%, n=12) by either an absolute potentiation of evoked discharge (25%) or by a relatively greater suppression of spontaneous versus transmitter-induced activity (33%). At higher doses (greater than 30nA), cocaine exerted a net depressant effect on both glutamate evoked and spontaneous firing (71%, n=7). A similar range of dose dependent effects was observed in cerebellum, however no absolute potentiation of evoked discharge was observed. Cocaine's facilitating effects on glutamate responses were fourfold greater and more consistent than those mediated by procaine. Overall, these data indicate that cocaine can mimic previously observed modulatory actions of NE and as such may facilitate synaptic excitatory transmission within the cerebral cortex and cerebellum. Such actions in these and other noradrenergic target circuits of the CNS could provide a physiological basis for cocaine's psychostimulant properties. COCAINE ALTERS SENSORY RESPONSIVENESS AND FUNCTIONAL CONNECTIONS WITHIN NETWORKS OF SIMULTANEOUSLY RECORDED NEURONS IN THE SI CORTEX AND VPL THALAMUS OF BEHAVING RATS. C.-H. Shin, C. Jimenez-Rivera, B.K. Jin*, B.D. Waterhouse, J.K. Chapin Hahnemann Univ., Physiol., Phila. PA. 19102

To define the neural circuit basis for cocaine's effect on cognitive and motor functions of the brain, ensembles of single neurons were recorded simultaneously in the somatosensory cortex (SI) and thalamus (VPL) of freely moving rats. Up to 12 single neurons were recorded simultaneously through 25μm microwires implanted in the forepaw regions of the SI cortex and/or VPL thalamus. Movement dependent changes in sensory transmission were tested by generating post-stimulus time histograms of neuronal responses to forepaw stimulation through implanted electrodes, during treadmill locomotion (10 s ON/ 10 s OFF). Single unit responses were recorded for 10 min. before, and 40 min. after cocaine administration (0.25, 1.0 or 10 mg/kg; i.p.). Procaine (1.0 and 10.0 mg/kg) as well as saline were tested in control experiments. Cocaine at 1.0 mg/kg facilitated neuron responses to forepaw stimulation in VPL thalamus and SI cortex during both rest and movement, and thus, counteracted movement-induced suppression of sensory responsiveness. By contrast, higher doses of cocaine(10.0 mg/kg) suppressed sensory responses at rest and also enhanced the suppression of sensory responses caused by movement. Saline as well as the lowest dose of cocaine (0.25 mg/kg) did not alter the magnitude of sensory responses during rest or running. Procaine primarily exhibited depressant effects on sensory transmission. The simultaneous recording of many-neuron ensembles also allowed study of latency relationships and functional synaptic interactions, through use of spike-triggered histograms. Cocaine was found to alter routing of sensory information within a neuronal ensemble and also abolished the cyclic co-firing of cortical neurons that was normally observed during rest. **In conclusion,** our study initiates a major new avenue of investigation for drugs of abuse in awake animals and, moreover, these results are in good agreement with the dose-related modulatory effects of cocaine on synaptic transmission as observed in anesthetized rats. COMPARING EFFECTS OF KETAMINE, ETHANOL, AND BARBITURATES ON SINGLE SOMATOSENSORY CORTICAL NEURONS IN BEHAVING RATS. I.M. Patel and J.K. Chapin, Hahnemann University, Philadelphia, PA 19102

This study defined the differential effects of ketamine, ethanol, and barbiturates on ensembles of somatosensory (SI) cortical neurons simultaneously recorded in behaving rats. Arrays of 25μ microwires (8) were chronically implanted in the SI cortical forepaw region. Discriminated single units from each wire could be recorded for time periods (several days or weeks) sufficient to allow multiple drug experiments to be carried out on the same group of neurons. Neurons were categorized according to their sensory and behavioral properties, and also their dose responses to central administration of different drugs. Treadmill running (5 sec ON- OFF) was used as a standard means of measuring neuronal discharge during rest and movement behavior. Subanesthetic doses of ketamine (5-50 mg/kg,I.M.) caused clear firing rate increases in 35, and decreases in 24 of the total 66 neurons which were used in multiple drug experiments. While these doses produced locomotor hyperactivity, confusion and disorientation, this hyperactivity could not explain the firing rate increases of the 11 neurons which normally fired more slowly during movement. Also, since ketamine markedly reduced the sensory responsiveness of cortical neurons, increases in activation of sensory receptors during movement could not cause the increases in cortical activity. Ethanol (1.6-2.4 g/kg, 20% in normal saline, I.P.) produced moderate to severe intoxication, and supression of spontaneous discharge and evoked sensory responses of all the recorded SI cortical neurons, many of which were excited by similarly analgesic doses of ketamine. While neuronal discharge rates recovered from ketamine in 1-2 hours, full recovery from ethanol required up to 8-12 hours of a single dose. Pentobarbital at subanesthetic doses (15-25 mg/kg, I.P.) also produced universal decreases in neuronal firing rates, which persisted for more than 12 hours. These doses also blocked ketamine-induced behavioral and neuronal excitation, whereas ethanol did not. The ketamine excitatory effects were also more prone to development of tolerance (clear after 3 daily exposures). No such quick tolerance was observed in the depressive effects of either of the three drugs. *Supported by UPHS grants AA00089 and AA06965, and NSF grant BNS18041 to JKC.*

POSSIBLE GENETIC PREDISPOSITION TO COCAINE TOXICITY. R.B. MILLER,* S. HOWARD AND C.L. BLANK, Dept. of Chemistry, Univ. of Oklahoma, Norman, OK 73019.

The normal human metabolism of cocaine involves ester cleavage by serum and other cholinesterases (Stewart et al., Life Sci., **20**, 1557 (1977)). Thus, the existence of genetically atypical individuals should cause concern with respect to their ability to withstand rapidly repeated doses of cocaine, as is commonly encountered in the abuse of this substance. This is of particular concern for individuals who are reported to be homozygons for the so-called "silent" gene. Such persons exhibit little or no butyrylcholinesterase activity (Doenicke et al., Proc. Eur. Congr. Anaesthesiol., **2**, 187 (1962); Liddell et al., Nature, **193**, 561 (1962).

We, thus, decided to examine the tolerance of mice to repeated doses of cocaine following pretreatment with a relatively selective inhibitor of serum cholinesterase, diisopropylfluoryl phosphate (DFP; Foldes et al., Clin. Pharmacol. Ther., **7**, 620 (1966)). In one such test, controls (n=8) were treated 24 hr. prior to cocaine with isotonic saline while experimentals (n=7) received 6.3 mg/kg DFP, i.p. Both groups were subsequently repeatedly injected with cocaine (15 mg/kg, i.p., every 5 min). The mean (±SEM) number of injections required to cause expiratin was: controls, 8.5±1.8; experimentals, 3.9±1.1 ($P<0.001$).

EVIDENCE OF A GABA/BENZODIAZEPINE MECHANISM MEDIATING THE PENTYLENETETRAZOL-LIKE STIMULUS PRODUCED DURING COCAINE WITHDRAWAL. D.M. Wood, P.R. Laraby and H.Lal, **Department of Pharmacology, Texas College of Osteopathic Medicine, Ft. Worth, TX, 76107**

Chronic cocaine users often experience bouts of anxiety and panic attacks following termination of the drug. This effect has been quantitatively assessed in experimental animals with drug discrimination methodology using an anxiety-producing drug, pentylenetetrazol (PTZ), as a discriminative stimulus (Wood and Lal *Life Sci.* **41:1431**, 1987). In the present experiment, rats were trained to discriminate the stimulus properties of PTZ, 20 mg/kg, using a food-rewarded 2-lever choice task. Responding under an FR10 schedule was reinforced on one lever following PTZ injection and on the other lever following saline injection. Following training, substitution tests were performed, and rats selected the PTZ-appropriate lever after PTZ in a dose-dependent manner, but not after cocaine. Subsequently, testing and training were halted, and cocaine, 20 mg/kg/8-hr, was administered for 7 days. Chronic cocaine injections were then terminated and spontaneous withdrawal was assessed by determining if saline would substitute for PTZ. The rationale for this test was that if withdrawal from cocaine produces a PTZ-like stimulus, then subjects injected with saline would select the PTZ-lever rather than the saline-lever. Cocaine withdrawal progressively substituted for the PTZ stimulus reaching a peak (83% PTZ-lever selection) 5 days post-termination of drug. The benzodiazepine, diazepam (1.25-5 mg/kg), but neither the tricyclic antidepressent, imipramine (5- 20 mg/kg), the serotonin antagonist, buspirone (2.5-10 mg/kg) nor the dopamine receptor agonist, bromocryptine (10-40 mg/kg), were effective in blocking the PTZ-lever selection. These data suggest that there is an anxiety-like component in the cocaine withdrawal stimulus which may be mediated by a GABA-deficit and blocked by benzodiazepines such as diazepam. These data also demonstrate the utility of the drug discrimination methodology for investigating drugs of abuse. (Funded by the **American Osteopathic Association**).

EEG AND SUBJECTIVE RESPONSES TO INTRAVENOUS COCAINE IN HUMAN SUBSTANCE ABUSERS. M. Sano, N. Cascella*, B. Glover*, R. Herning* and E. London. NIDA Addiction Res. Ctr., Baltimore, MD 21224.

Cocaine (C)-induced increases in EEG β power have been noted (Berger, 1937; Herning, et al., 1985), but the time course of EEG changes and their potential relation to subjective effects have not been studied. We initiated a double-blind, placebo (P)-controlled, crossover study of C effects on subjective and EEG responses. Subjects were right-handed polydrug abusers (23-38 yr). Responses to 40 mg C or P i.v. were recorded from 13 scalp electrodes on the dominant hemisphere. EEG spectral power for α (10 Hz) and β (25 Hz) were calculated for 30 min after C or P. Subjective effects were recorded on a 5-point scale, using a 23-item questionnaire (Kumor et al., in press). Frontal and temporal lobes showed the greatest increases in β power; α power increased mostly in the occipital lobe. C effects on frontal and temporal β power and occipital α power occurred immediately. Mean occipital α power was elevated (vs. P) for 15-18 min after C. The frontal lobe β effect lasted up to 21-24 min, but the temporal lobe β effect persisted at 30 min. Self-reports of feeling "drug", "high" and "rush" were greatest at 1 min after C, with reductions by 15 min. Reports of feeling "good" also were greatest at 1 min, but persisted for 30 min. That C effects on temporal β power and feeling "good" persisted over approximately the same time suggests that the two phenomena may be related.

STRUCTURE ACTIVITY RELATIONSHIP OF COCAINE AND RELATED COMPOUNDS IN BINDING TO DOPAMINE TRANSPORTERS. M.C. Ritz*, E.J. Cone*, J. Sharkey* and M.J. Kuhar (SPON: R.K. Dismukes). NIDA Addiction Research Center, Baltimore, MD 21224.

The binding of cocaine to dopamine transporters appears to be a primary site of action related to the reinforcing properties of cocaine. We determined the potencies of a series of cocaine derivatives to inhibit ^{3}H-mazindol binding in order to determine the molecular requirements for their interaction at this site. The affinities of these compounds were substantially diminished by 1) isomerization to d-enantiomers; 2) epimerization of the tropane carbon C-2 substituents; and 3) hydrolysis of the C-2 or C-3 substituents to more polar forms. Moderate reductions in affinity resulted from 1) quaternization of the nitrogen; 2) replacement of C-2 substituent with hydrogen, and 3) methylation of the C-3 aromatic ring. Monocyclic and linear chain derivatives of cocaine incorporating the nitrogen and C-3 aromatic substituent also exhibited only moderate decreases in affinity. Modifications which increased affinity or resulted in little change were 1) replacement of the C-3 substituent with benzene or fluorobenzene or 2) N-demethylation. In summary, binding of cocaine derivatives to the mazindol site on the dopamine transporter appears to require the 1-isomeric form, including the nitrogen and C-3 aromatic substituents.

NEUROBEHAVIORAL EFFECTS OF PRENATAL COCAINE EXPOSURE. S.K. Sobrian, L.E. Burton*, N.L. Robinson*, H. James* and L.M. Turner*. Dept. of Pharmacol. HUCM, Washington, DC 20059.

Neurobehavioral ontogeny was studied in the offspring of pregnant Sprague-Dawley rats injected with 20 mg/kg of cocaine (s.c.) once daily on gestation days 15-21. This dose produced blood levels of 0.6 mg/ml of cocaine in the mothers; levels in the pups were not detectable at birth. Control mothers received injections of 0.9% NaCl (0.1 ml/100G). Birth statistics reflected the lack of maternal toxicity; third week gestational weight gains, and length of gestation were unaffected by maternal cocaine administration, as were little size, birth weights and lengths of pups and the male/female pup ratio. Although cocaine mothers were slower to initiate nest building, other indices of maternal behavior were unaltered. Cocaine exposed pups were significantly smaller than control offspring during the first 1.5 postnatal week; subsequent differences in body weights were not evident during the preweaning period. Although the appearance of physical landmarks was not affected by prenatal cocaine, delayed development of surface righting, cliff avoidance and startle response was noted. In utero cocaine exposure did not alter the offsprings response to postnatal stimulants; both cocaine (10 mg/kg) and amphetamine (1 mg/kg) increased spontaneous motor activity. These results indicate that in the absence of overt teratogenicity, fetal exposure to cocaine can delay neurobehavioral development.

388.19

PRENATAL EXPOSURE TO COCAINE IN RATS: EFFECTS ON LOCOMOTION AND STEREOTYPY. C.A. Moody, M. Giordano, E.M. Zubricki, L. Dreshfield*, R.A. Frank, A.B. Norman and P.R. Sanberg. Lab of Behavioral Neuroscience, Depts. of Psychiatry, Psychology, Neurosurgery and Physiology, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267.

Pregnant Sprague-Dawley rats received s.c. injections of 30 mg/kg cocaine HCl or vehicle from day 12 to day 21 of gestation. Pinna detachment, eye opening, righting reflex, negative geotaxis, pivoting, startle response, body length and weight were recorded. Sixty days after birth the pups were monitored for spontaneous nocturnal activity, and drug-induced stereotypy. The stereotypic response to apomorphine (0,0.25, 1.0 mg/kg i.p.); amphetamine (0, 4.0, 8.0 mg/kg i.p.) and cocaine (0, 30 mg/kg i.p.) all at a volume of 1 ml/kg was visually evaluated using the Creese and Iversen (1973) rating scale.

All pups survived throughout the length of the study. Developmental cues appeared at the same rate in all animals regardless of the group to which they belonged. Both groups responded similarly to the psychomotor stimulants as compared to each group's own control session.

This pilot study suggests that prenatal exposure to a mild dose of cocaine does not have deleterious effects on the appearance of developmental cues in rat pups. In addition there was no apparent increase or decrease of sensitivity in the dopaminergic system as evidenced by the lack of differential response to dopaminergic agonists.

389.1

THE EFFECTS OF AMPHETAMINE ON FOOD INTAKE AND BODY WEIGHT IN RATS ALLOWED 24-HR ACCESS TO FOOD. J.R. Jones* & W.F. Caul. Department of Psychololgy Vanderbilt University, Nashville, TN 37240.

Recent investigations of tolerance to amphetamine's anorectic effect (Caul, et al., Behav. Neurosci., 102:441-450, 1988) have suggested the importance of assessing both within-day and day-to-day body weight changes as well as food intake of rats allowed continuous access to food in order to understand the role of homeostatic adaptive mechanisms. In this experiment, independent groups of rats maintained with a LD 12:12 light cycle were injected for 10 consecutive days with either 0, 1, or 2 mg/kg d-amphetamine sulfate either one hour after the lights came on each day or immediately before the lights were turned off. The results showed that "Daytime" injections produced no effects on daily food consumption, however, the drug-treated rats lost weight over days. "Nighttime" drug injections produced increased daily consumption yet day-to-day body weights were comparable to controls. Further analysis of intake and body weight in terms of two 12-hr periods each day, provides a better understanding of amphetamine's effect on eating, homeostatic adaptive mechanisms, and how these factors interact with the circadian organization of eating.

389.2

THE EFFECT OF DEPRIVATION LEVEL ON THE DEVELOPMENT OF TOLERANCE TO AMPHETAMINE ANOREXIA: BEHAVIOURAL AND NEUROCHEMICAL PERSPECTIVES. A. Streather, A.E. Le*, R.E. Hinson, C.X. Poulos*, and H. Cappell*. University of Western Ontario, London, Ontario; Addiction Research Foundation and University of Toronto, Toronto, Ontario, Canada.

The effect of deprivation level on the development of tolerance to amphetamine anorexia was investigated. The neurochemical consequences of tolerance development were also examined. Seventy-three rats, sensitive to amphetamine (AMP) anorexia, were divided into 6 groups. Three groups were maintained at 85% *ad lib.* weight while 3 groups had free access to food (100% groups). Three training groups, a contingent (CONT), noncontingent (NONCON) and saline (SAL), each comprised a 100% group and an 85% group. The CONT groups received 3 mg/kg AMP ip 20 min before 30 min access to milk on Day 1 and saline ip on Day 2. The NONCON groups received saline ip 20 min before 30 min access to milk on Day 1 and 3 mg/kg AMP ip on Day 2. The SAL groups received saline ip 20 min before 30 min access to milk on Day 1 and saline ip on Day 2. After 20 sessions the 100% groups were reduced to 85% *ad lib.* weight before an AMP anorexia test was given. The CONT 85% group consumed significantly more than any other group while the CONT 100% group showed no tolerance to AMP anorexia. At the time of the AMP anorexia test half of the 85% groups were sacrificed 20 min after injection of 3 mg/kg AMP. Later NE, DA, 5-HT, DOPAC, HVA, & 5-HIAA levels were assayed in several brain areas. Preliminary analysis revealed no central differences between the CONT and NONCON groups. The failure of the 100% CONT group to develop tolerance demonstrates that food deprivation is essential to the development of tolerance to amphetamine anorexia.

389.3

PERIPHERALLY OR CENTRALLY ADMINISTERED D-AMPHETAMINE INCREASES THE INTAKE OF CHOW SWEETENED WITH SUGAR BUT NOT SACCHARIN. Evans, K.R. and Vaccarino, F.J. Dept. of Psychology, University of Toronto, Canada.

We have previously demonstrated that when faced with a choice of different food types, low doses of peripherally or intra-nucleus accumbens (N.Acc.) administered d-amphetamine (AMP) preferentially increases the intake of palatable foods such as sucrose. The present study examined whether this AMP-induced/sucrose-selective increase in food intake was related to sweetness or some post-ingestional effect of sucrose. Rats were presented with powdered chow and chow sweetened to an equal degree with either sucrose or saccharin following treatments with systemically administered AMP (0.25 mg/Kg) or intra-N.Acc. AMP (0.5 ug or 2.0 ug). Baseline food intake did not differ in the sweetened chow conditions. AMP significantly increased intake of chow sweetened with sugar but had no effect on intake of unsweetened chow or chow sweetened with saccharin. Results suggest post-ingestional factors may be important with respect to AMP-induced feeding. Alternatively, AMP may cause animals to be more sensitive to any aversive properties saccharin might have. Further, the nucleus accumbens supports these effects, consistent with the view that this site is critical in the expression of the facilitatory effect of AMP on feeding.

389.4

SERTRALINE, A 5HT UPTAKE INHIBITOR, INHIBITS FEEDING AND BODY WEIGHT GAIN IN RODENTS. J. A. Nielsen and M. N. Krupp*. Pfizer Central Research, Depts. Neuroscience and General Pharmacology, Groton, CT 06340.

An extensive literature implicates brain serotonin in the regulation of energy balance (Blundell, Neuropharmacology 23:1537, 1984). More recently, attention has been focused on the ability of serotonin uptake inhibitors to reduce body weight both in laboratory animals and obese humans. Sertraline is a potent and highly selective inhibitor of serotonin uptake (Koe et al., J. Pharmacol. Exp. Ther. 226:686, 1983) and we have conducted preliminary studies to assess its effect on feeding and body weight in rodents.

Sertraline decreased food intake up to 70% and body weight up to 28% in normal mice without any effect on locomotor behavior. Similar effects were observed in normal rats, genetically obese ob/ob mice and fa/fa rats. These effects developed rapidly after initiation of sertraline treatment and were maintained during 5-7 days of continued drug administration. Nonspecific disruption of behavior does not account for the observed effects on feeding and body weight since the sertraline treated animals appeared healthy and their locomotor behavior was unaffected.

Thus, these results are in accord with a growing body of evidence suggesting that selective serotonin uptake inhibitors may be clinically useful agents for managing some obese patient populations.

WEIGHT LOSS EFFECT OF FLUOXETINE IN NORMAL-WEIGHT AND OVER-WEIGHT BULIMICS. J.M. Jonas,* M.S. Gold, L. Bunte,* A.L.C. Pottash. Fair Oaks Hospital, Summit, NJ 07901.

Fluoxetine is a relatively specific serotonin uptake inhibitor which may produce weight loss. In order to investigate this phenomena, we compared the effect of fluoxetine on weight and eating symptoms in 2 groups of bulimic individuals-a normal weight group (N=11) and a group (N=5) of individuals greater than 10% above ideal body weight. All patients met DSM-III-R criteria for bulimia nervosa, were treated a minimum of 8 weeks, were on no structured meal program, and received a minimum of 40 mg of fluoxetine each day. Response was rated in terms of decreased binging and purging, and weight change. Nine of the 16 subjects attained at least a 75% reduction in symptoms. The overweight group was more likely to show improvement in symptoms, with all 5 attaining at least a 75% reduction in symptoms, while among the normal weight bulimics, 4 of 11 (36%) displayed similar improvement (X^2=8.785; $p<.04$). Fluoxetine appeared to have a modest weight loss effect on the group as a whole, with the mean weight decreasing from 144.5 pounds (SD=38.6) to 141.8 pounds (SD=38.8) ($p<.07$ by paired t-test, two tailed). We expected that there would be a relationship between weight loss and decreased binging and purging, but this was not observed. Weight change was not related to outcome as determined by decreased binging (ANOVA p=.83), nor did it differ between groups (t-test for independent samples two-tailed, $p<.53$). The implications of these findings will be discussed.

389.6

FOREBRAIN STRUCTURES ASSOCIATED WITH DEPRIVATION INDUCED THIRST IN THE PIGEON: A (14C) 2-DEOXYGLUCOSE STUDY. K.P. Heuston. Department of Psychology and Social Relations, Harvard University, Cambridge, MA 02138.

(14C) 2-deoxyglucose (2-DG) was used as a metabolic tracer to identify forebrain structures associated with deprivation induced thirst in the pigeon. Pigeons were either water deprived, or else given free access to water, then injected with 2-DG (160uCi/Kg IV). The animals were sacrified, and their brains were removed, sectioned, and processed for autoradiography.

Autoradiographic images were analyzed, and, as compared to the control group, the water deprived animals showed increased 2-DG uptake in a number of telencephalic and diencephalic structures and areas, including a cluster of cells apposing (both ventrally and dorsally) the pallial commissure (a region which houses the subseptal (subfornical) organ in the pigeon).

Reconstructed autoradiographic images for a series of forebrain sections will also be presented.

389.7

CHRONIC D-FENFLURAMINE PRETREATMENT FAILS TO AFFECT SEROTONIN RELEASE FROM RAT HYPOTHALAMIC SLICES. J.D. Schaechter*, E. Armstrong* and R.J. Wurtman. (SPON: S.J. Schein). Lab. of Neuroendocrine Regulation, M.I.T., Cambridge, MA 02139.

D-fenfluramine produces anorexia in rats and man probably by raising intrasynaptic levels of serotonin (5-HT) in the brain via inhibiting its reuptake and promoting its release. A single low dose of d-fenfluramine reduces food intake (ED_{50}=1.3mg/kg). Repeated administration of a high dose of d-fenfluramine (≥10mg/kg) produces a long-lasting depletion (~50%) of brain 5-HT and its metabolite, 5-HIAA; though lower doses of the d-enantiomer (<5mg/kg) have produced no depletion of brain 5-HT. We have applied a novel in vitro experimental system, utilizing superfused rat hypothalamic slices, to address whether endogenous 5-HT release is altered following chronic d-fenfluramine treatment. Rats were treated for 10 days with d-fenfluramine (1.25; 2.5; 5; or 10 mg/kg/day; i.p.). Hypothalamic slices were prepared on day 16. The amounts of 5-HT (and 5-HIAA) released under basal conditions and during electrical field-stimulation (5Hz, 2ms, 100mA/cm^2, 1400 bipolar pulses) were monitored. Hypothalamic 5-hydroxyindole contents were unchanged in rats treated with 1.25 and 2.5 mg/kg/day of d-fenfluramine. Rats which received 5 and 10 mg/kg/day had lowered hypothalamic 5-HT levels (by 18% and 22%, respectively) and lowered 5-HIAA levels (by 20% and 29%). Chronic d-fenfluramine treatment did not affect basal 5-HT release at any drug dose tested. The evoked release of 5-HT and the efflux of 5-HIAA were unaltered from those slices prepared from rats treated with 1.25-5 mg/kg/day of the drug, and reduced only with the highest dose (by 20% and 37%, respectively). These results suggest that chronic administration of a low anorectic dose of d-fenfluramine (1.25-2.5 mg/kg/day) does not produce long-lasting changes in hypothalamic 5-hydroxyindole content nor alter the amount of 5-HT released spontaneously and with neuronal firing.

389.8

REGIONAL BRAIN SEROTONIN (5-HT) FOLLOWING FREE CHOICE INTAKE. J.L. Colmenares. Centro de Investigaciones Biomédicas, UNEFM., Coro, VENEZUELA.

Male Sprague-Dawley rats were fed for 5 days (Pretreatment) one of the following isocaloric diets: 18% Casein hydrolyzate (Tryptophan-free, TF); 18% Casein (Control, C) or Carbohydrate-fat (Protein-free, PF). Brain of rats TF-pretreated had 5-HT levels decreased to 80-75% of control values in the Cortex, Brain Stem, Hypothalamus and Cerebellum ($p<0.05$). Rats PF-pretreated showed 5-HT increases only in the cerebral cortex (122% of control values, $p<0.08$). Other set of rats were allowed to consume 5 or 45% casein diets presented simultaneously for the next 24 hours after their initial dietary pretreatment. 5-HT levels became equal in the regions analyzed, with the exception of the Hypothalamus of the PF-pretreated group, whose levels of 5-HT and 5-HIAA where increased to 127 and 130% of C values ($p<0.07$). The intake of the 5 and 45% protein diets by pretreated rats was significantly different (ANOVA, $p < 0.05$). During the free choice period the TF-pretreated ate respectively 117 and 207% calories of the C- and PF-pretreated groups. The PF-pretreated consumed respectively 115 and 200% of the protein of the TF- and C-pretreated groups. 5-HT cortical changes may participate in the craving for protein and total caloric intake. Hypothalamic 5-HT levels paradoxically increased only after high protein intake. (Supported by Fundacite No F1.22.01.83).

INTRANIGRAL INJECTION OF NEUROTENSIN SUPPRESSES FEEDING IN FOOD-DEPRIVED RATS. T.G. Anticich*, A.A. Baumeister, A. M. Vaughn*, and M.F. Hawkins. Department of Psychology, Louisiana State University, Baton Rouge, LA 70803.

Intraventricular injection of neurotensin (NT) suppresses feeding in food-deprived rats (Luttinger et al., Eur. J. Pharmacol, 81, 1982, 499). The neuroanatomical loci that mediate this effect have not been well defined. The substantia nigra (SN) is involved in ingestive behavior (Ungerstedt, Acta Physiol. Scand., 1971, Suppl. 367, 95) and contains high levels of NT receptors (Young et al., Brain Res.,206, 1981, 273). The present study was conducted to determine whether NT receptors in the SN may be involved in feeding. Male Sprague Dawley rats were deprived of food for 18 hours prior to receiving a bilateral intranigral injection of NT (2.5, 5.0, or 10.0µg/ 0.5µl saline) or saline (0.5µl). Food consumption was measured at 15 minute intervals for 2 hours after injection. Neurotensin suppressed food intake ($p<.05$) during the first 15 minutes at the high and low doses but not at the intermediate dose. During the second 15 minute interval only the high dose of NT suppressed feeding. No effects on feeding were observed after 30 minutes. Intranigral injection of NT at these doses produced no behavioral stereotypies or other signs of general motor impairment. These results suggest that the SN may mediate the hypophagic effect of NT. (Supported by USPHS grant HD-21560).

FEEDING RESPONSE OF THE SPONTANEOULSY DIABETIC RAT (SDR) TO NOVELTY-INDUCED STRESS AND SCH 23390. Q.Ahmad[1] and Z. Merali[1,2]. [1]Psychology and [2]Pharmacology, Univ. of Ottawa, Ontario, K1N 9A9.

This study assessed the feeding response of insulin treated male SDR and matched controls (n=6 each) to: 1) SCH 23390 (SCH) a D-1 receptor antagonist, and 2) novelty stress (NOV). All animals were entrained on a regimen of 17.5 hrs of food deprivation, followed by treatment, presentation of test meal, and behavioral monitoring (for 30 min). In the SDR, SCH (10, 40 ug/kg) incurred a 62% and 27% increase in meal size respectively, as compared to a 3% and 29% increase in controls. Conversely, SCH (100 ug/kg) reduced the meal size by 72% and 30% in the SDR and controls respectively. NOV increased the meal size of SDR and controls by 42% and 24% respectively. Interestingly, at low doses SCH elicits grooming but blocks it at high doses. A similar inverted U dose-response was seen here, with low doses of SCH stimulating and high doses inhibiting the feeding response. We reported earlier that the SDR displays an increased sensitivity to SKF 38393 and novelty stress-induced grooming. In this case, the dose-response curve of the SDR appears to have shifted to the left, again implicating increased sensitivity of the SDR to D-1 receptor and stress associated responses.

389.11

Differential effect of dopamine D-1 and D-2 receptor antagonists on the microstructure of ingestive behavior. J.D. Davis, J.W. Kebabian & C. Vasilatos*, Dept. of Psychology, Univ. of Illinois, Chicago, IL 60680 & Neuroscience Res. Div. Abbott Laboratories, Abbott Park , IL 60064.

Rats ingest liquid diets by licking a drinking tube in bursts separated by pauses. This study determined the effect of selective dopamine D-1 and D-2 receptor antagonism on the size of bursts (SB) and the length of the interburst interval (IBI). Male albino Sprague Dawley rats were trained to drink a highly palatable test diet (.006M Saccharin + 0.1M maltose) for 30 min a day. Time of tongue contact with the drinking tube was measured to the nearest 10 msec by an electronic drinkometer. SCH23390, a selective dopamine D-1 receptor antagonist at doses of .012 to .015 mg/kg (s.q.) reduced volumetric intake in a dose related manner by increasing the IBI and the number of bursts sufficiently to compensate for a significant increase in SB. Piquindone, a selective dopamine D-2 receptor at doses from .03 to .16 mg/kg reduced volumetric intake in a dose related manner principally by decreasing the size of the burst. IBI and number of bursts were significantly altered (increased and decreased respectively) only at the highest dose. The inactive enantiomers of both compounds were ineffective in altering volume intake or the two parameters. We conclude that antagonism of the dopamine D-1 receptor has a different effect on ingestive behavior than does D-2 receptor antagonism.

RATS SHAM FEEDING CORN OIL ARE LESS SENSITIVE TO DOPAMINE RECEPTOR ANTAGONISTS THAN RATS SHAM FEEDING SUCROSE. G.P. Smith and S.C. Weatherford. Dept. Psychiatry, NY Hosp.-Cornell Med Ctr., White Plains NY 10605.

Central dopaminergic (DA) systems are thought to participate in the reward aspects of sham feeding (SF) sucrose (SUC) and corn oil (CO) in rats. Here we examine the effect of the selective D-1 and D-2 receptor antagonists, SCH 23390 (SCH) and raclopride (RAC), respectively, on the intake of 100% CO and 10% SUC in SF rats. RESULTS Values are mean % inhibition of sham intake ± SEM.

RAC	SUC	CO	SCH	SUC	CO
.050	15±8	--	.0125	11±5	--
.100	40±10*#	-8±9	.025	29±11*#	2±5
.200	80±7*#	40±10*	.050	58±10*#	10±10
.300	92±3*	59±10*	.100	80±6*	51±12*
.400	97±7*	80±7*	.200	92±4*	93±3*

Note: tests were conducted in the a.m. after 18 h food deprivation, N=12, doses are mg/kg,i.p., given 15 min before SUC or CO. *drug vs veh, #CO vs SUC, $p < .01$

CONCLUSION When SF CO, rats are less sensitive to D-1 and D-2 antagonists than when SF SUC. It is not clear whether this difference in sensitivity is due to a greater release of DA during CO SF than during SUC SF, or to the possibility that SF CO may be less dependent on DA systems than the SF of SUC. Neurochemical studies are needed to distinquish between these possibilities. [Supported by MH15455 (GPS).]

SHAM FEEDING RATS PREFER CORN OIL TO SUCROSE, BUT WHEN REAL FEEDING, THE PREFERENCE IS REVERSED.

SC Weatherford, GP Smith and J Gibbs. Dept. of Psychiatry N.Y. Hosp.-Cornell Med. Ctr, White Plains NY 10605.

Rats sham feed (SF) corn oil (CO) and sucrose (SUC) in a concentration-dependent manner, suggesting that the orosensory stimuli of these solutions are positively reinforcing. The purpose of this study was to determine the rank order of preference of 100% CO, 6% SUC and 10% SUC in the absence (SFing; cannula open) and presence (real feeding; cannula closed) of postingestive cues.

Three groups of overnight food-deprived rats were trained to SF 2 solutions in alternate 1-bottle tests. Groups 1,2 and 3 sham fed: 100% CO and 6% SUC; 100% CO and 10% SUC; and 10% SUC and 6% SUC, respectively. Rats then received two 30-min, 2-bottle preference tests. Following the SFing preference tests, rats were given three 30-min, 2-bottle preference tests with the cannula closed.

During SFing the rank order of preference was 100% CO >> 10% SUC >> 6% SUC. In contrast, when the cannula was closed, the same order of preference was observed in the first preference test, but by the third preference test the order had changed to 10% SUC >> 6% SUC >> 100% CO.

Thus,in the absence of postingestive cues the orosensory stimulation of CO is more reinforcing than SUC. When postingestive cues are present, however, CO becomes less reinforcing than SUC, while the preference for 10% SUC over 6% SUC remains unchanged.[Supported by MH15455 (GPS).]

DENSITY OF α_1- AND α_2-NORADRENERGIC RECEPTORS IN THE DISCRETE HYPOTHALAMIC AND EXTRA-HYPOTHALAMIC AREAS OF GENETICALLY OBESE ZUCKER RATS.

J. A. Finkelstein, S. R. Kim*, I. Awad*, S. F. Leibowitz, M. Jhanwar-Uniyal.(SPON: N. Miller). N. E. Ohio Univ., Col. Med. Rootstown Ohio 44272, The Rockefeller Univ. New York, N.Y. 10021.

Administration of norepinephrine (NE) into the paraventricular nucleus (PVN) produces eating via the activation of α_2-noradrenergic receptors. Studies suggest that NE levels differ in certain hypothalamic nuclei (including PVN) of Zucker obese vs. lean rats, and therefore may contribute to the development of obesity. The present study examines the density of α_1-and α_2-noradrenergic receptors in discrete hypothalamic and extra-hypothalamic areas of lean and genetically obese rats.

Female, lean (Fa/-) and obese (fa/fa) Zucker rats were used for this study. Seven hypothalamic nuclei, namely, PVN, medial preoptic nucleus, dorsomedial nucleus, ventromedial nucleus, perifornical lateral hypothalamus, supraoptic nucleus and arcuate nucleus-median eminence and four extra-hypothalamic sites (caudate nucleus, nucleus accumbens, hippocampus and frontal cortex) were micropunched. Standard radioligand binding procedures, using the α_2-noradrenergic agonist, [3H]p-aminoclonidine ([3H]PAC; 2.7 nM) and the α_1-noradrenergic antagonist [3H]prazosin (1.0 nM) were employed. Nonspecific binding was determined in the presence of phentolamine (50 µM). The results demonstrate that genetically obese, as compared to lean, littermates had: a) an increase in [3H]PAC binding in the PVN (152%) and caudate nucleus ($p<0.05$; 317%); and b) an increment in [3H]prazosin binding only in the PVN ($p<0.05$; 250%). These findings suggest a possible role of α-noradrenergic receptors in the development or maintenance of genetic obesity.

OCTOPAMINE INJECTED INTO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS (PVN) ELICITS FEEDING IN SATIATED RATS.

P.J.Fletcher* and I.A.Paterson (Spon: T.B.Wishart), Neuropsychiatric Research Unit, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

The trace amine octopamine (OA), which occurs naturally in mammalian brain, has been reported to possess significant actions on noradrenergic systems. The present experiments were designed to examine the effects of the meta and para isomers of OA on feeding behaviour in satiated rats following injection into the PVN, and to compare them with those elicited by noradrenaline (NA).

m-OA induced a dose-dependent increase in food intake which was maximal at 25 nmoles/0.4 µl injection. *p*-OA did not increase food intake unless the rats were pretreated with the monoamine oxidase inhibitor pargyline. The effect of *m*-OA was blocked by the α2-antagonists yohimbine (12.5 and 25 nmoles) and idazoxan (25 and 50 nmoles), but not by the α1-antagonist corynanthine (25 and 50 nmoles), or the β-antagonist propranolol (50 and 100 nmoles). Feeding elicited by 25 nmoles NA was also reversed by idazoxan (but not by yohimbine), but was not affected by corynanthine or propranolol. Depletion of endogenous NA stores by α-methyl-*p*-tyrosine (200 nmoles injected into the PVN, 4 hours) partially blocked the effect of *m*-OA. Inhibition of the NA reuptake system with desipramine (100 nmoles injected into the PVN) significantly enhanced the effect of 12.5 nmoles *m*-OA, but not of 25 nmoles *m*-OA.

The results show that *m*-OA injected into the PVN elicits feeding. This effect occurs via an action at α2 receptors, and appears to involve, at least partially, the release of endogenous NA.

P.J.F. and I.A.P. are Saskatchewan Health Research Board Fellows.

EFFECTS OF ADRENALECTOMY AND HORMONE REPLACEMENT ON NATURAL FEEDING PATTERNS IN THE RAT.

D.L. Tempel, M. Bauer* & S.F. Leibowitz Rockefeller University New York, N.Y. 10021.

Patterns of food intake and macronutrient selection are known to vary as a function of time of the diurnal cycle. When maintained on pure diets of protein (P), carbohydrate (C) and fat (F), freely-feeding animals display a natural preference for the C diet at dark onset, and for the P and F diets at the end of the night. The enhanced carbohydrate seen at dark onset is believed to be mediated by norepinephrine (NE), particularly in the hypothalamic paraventricular nucleus (PVN), in concert with circulating adrenal hormones, specifically corticosterone (CORT). In support of this hypothesis, we have found that adrenalectomy (ADX) abolishes the natural carbohydrate feeding at dark onset (from 3.3 Kcal in SHAM to 0.3 Kcal in ADX animals $p<0.05$). Direct PVN CORT implant reinstates C feeding at this time (to 4.2 Kcal, $p<0.05$). PVN implant of the mineralocorticoid aldosterone (ALDO) also stimulates feeding of C (4 Kcal), as well as F (5 Kcal), during hr 1 of the dark phase. Similar affects of ALDO were seen in SHAM animals. Deoxycorticosterone (DOC) has no effect and dexamethasone (DEX) is less effective ($p<0.05$) than either CORT or ALDO in enhancing feeding at this time of the cycle. In contrast to its effects on food intake at dark onset, ADX has no effect on natural feeding during hr 12 of the dark cycle. Similarly, CORT, DOC and DEX are ineffective in stimulating food intake at this time. However, PVN ALDO implant enhances F and to a lesser extent, C intake during hr 12 of the dark phase in both ADX and SHAM rats. These experiments will help elucidate the neuroendocrine mechanisms, and possible glucocorticoid receptor type underlying natural feeding processes.

389.17

EFFECTS OF CLONIDINE ON SEPARATE SELF-SELECTION OF MACRO AND MICRONUTRIENTS.

K.S. Byrne*, M.D. Chafetz. Department of Psychology, University of New Orleans, New Orleans, LA 70148

The following experiment studied the effects of Clonidine, (CLON) an alpha adrenergic agonist, on the consumption of macronutrients (fats, proteins and carbohydrates) and vitamins (A,D,E,B complex) and minerals (calcium, sodium chloride, potassium chloride, sodium phosphate) in the adult male rat. The self-selection feeding paradigm was fashioned after Richter et al (1938), who found that various physiological manipulations affected the intakes of both macro- and micronutrients. Although Leibowitz et al (1984) was able to determine the effects of CLON on self-selection of macronutrients, no information is available about CLON's effects on separate selection of macro- and micronutrients. Because Richter et al (1938) showed the importance of separate intakes of macro- and micronutrients, it was important to extend the Leibowitz et al (1984) findings to the effects of CLON.

All nutrients were available simultaneously and were eaten ad lib. Baseline measurements were taken five days prior to IP drug injections of 25 ug/kg of CLON, which was found by Mauron et al (1980) and Leibowitz et al (1984) to be the most effect dose for eliciting consumption of various macronutrients. CLON was injected 1-2 hours after onset of darkness, which was the optimal feeding time noted by Leibowitz et al (1984). Measurement of the nutrients were made on a 1 hour and a 12 hour period after injections. Testing was done under natural lighting conditions. We found a significant increase in carbohydrate consumption, but no effects on the consumption of other nutrients. The increase in carbohydrates is in accordance with Leibowitz et al (1984) findings, but differ from those of Mauron et al (1980) who found enlarged protein intake. Since no attempt was made to test weanling animals, no information on differences in selection as observed by Mauron et al (1980) is available. In conclusion, CLON enhances intake of carbohydrates, but has no influence on intake of other macronutrients or micronutrients when they are offered separately.

389.18

α-NORADRENERGIC EFFECTS ON MACRONUTRIENT SELECTION IN GENETICALLY OBESE AND LEAN MICE.

P.J. Currie* and L.M. Wilson, Dept.Psychol., Univ.Manitoba, Winnipeg, MB, R3T2N2 Canada

Although α_2-NA mechanisms increase food intake, especially carbohydrate(CHO) in rats(Leibowitz et al.,Pharm.Biochem. Behav.,23:541,1985), Callahan et al.(Pharm.Biochem.Behav., 20:591,1984) showed that both the α_2 agonist clonidine(CLON) and the α_2 blocker yohimbine HCl(YOH) decreased total intake (g) in obese(ob) and lean(+/?) mice, with obs showing a biphasic response to CLON and suppressing intakes at lower YOH doses than leans. STUDY 1: Obs and leans adapted to 6-h access to CHO, FAT, and protein(PRO) before receiving saline(VEH) injections ip 30 min before diet access, for 2 days, with intakes recorded at 1,3, and 6h. Then, separate groups(n=14/group) of obs and leans got either .1 or .5mg/kg BW CLON(Sigma) or VEH, 30 min before diet access. CLON decreased total intake(kcal) and Kcal from CHO,FAT, and PRO in ob and lean($p<.005$). But, at 1h, .5-CLON increased the proportion of energy from CHO and PRO and decreased from FAT. STUDY 2: When mice had either VEH, or 3 or 5 mg/kg ip YOH 30 min before either .5-CLON or VEH(n=7/group), both YOH and CLON decreased total intake($p<.001$), although the CHO proportion was greater when 3-or 5-YOH preceded CLON, or 5-YOH preceded VEH, than when either 3-YOH or VEH preceded VEH or CLON, or VEH alone($p<.001$). All drug groups suppressed FAT proportion($p<.05$). Although CLON and YOH alone had similar effects, in some cases joint administration reversed the effect either drug had on its own. There were no Phenotype X Drug interactions. (Supported by NSERC-A7937)

390.1

DOPAMINE AND Ca++-BINDING PROTEIN-CONTAINING NEURONS IN THE DORSAL TIER OF THE SUBSTANTIA NIGRA PARS COMPACTA IN NEONATAL- AND ADULT-6-OHDA LESIONED RATS. **L.M. Grimes, M. Sar.*, W. Stumpf, G.R. Breese, H. Criswell, R.A. Mueller, J.-S. Hong, and H.-K. Jiang*. UNC Sch. Med., Chapel Hill, NC 27599 and NIEHS, NIH, RTP, NC 27709**

Rats with neonatal destruction of dopamine (DA)-containing neurons challenged with DA agonists display different behavioral responses than those seen when lesioning is in mature rats (JPET 231:343, 1984). Recent reports have demonstrated a 28 KDa Ca++-binding protein (CaBP) in dorsal tier mesostriatal DAergic neurons which are developmentally distinct (J. Neurosci. 7:3935, 1987). In the present investigation, immunohistochemistry of tyrosine hydroxylase (TH) or CaBP neurons was performed on rats treated neonatally or as adults with 6-OHDA. TH neurons in A-8 and in the A-9 cell groups of the ventral tier were absent in both adult- and neonatal-6-OHDA-lesioned rats. In contrast, TH and CaBP neurons in the dorsal tier were spared in adult-lesioned rats, but were absent in neonatal-lesioned rats that exhibited self-mutilation (SMB) when challenged with apomorphine. Sparing of DA and CaBP neurons in the dorsal tier was associated with sparing of terminals in the ventral striatum. Future studies will define the relationship between CaBP/TH-containing neurons and behavioral responses to DA agonists after 6-OHDA lesions. [Supported by ES-07125(LMG), HD-03110, NS-21345]

CHARACTERIZATION OF THE MOTOR AND SENSORIMOTOR FUNCTIONS OF BRAIN DOPAMINE J.D. Salamone, M.J. Zigmond, E.M. Stricker. (SPON: Shang Yao). Dept. of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260

Dopamine (DA) antagonists or lesions of brain DA neurons produce acute decreases in motor activity and responsiveness to stimuli. To study the sensorimotor effects of haloperidol (HP), rats were tested for conditioned responses to auditory stimuli presented at varied intervals. In different experiments the intensity or duration of the stimulus was varied, and food-deprived rats were rewarded for responding during the stimulus. HP suppressed responding to high and low intensity stimuli equally. In contrast, the anticholinergic atropine had greater effects on the low intensity stimulus. HP also had a greater effect if the rats were required to respond within 2 rather than 5 sec. In a second series of experiments, food-deprived rats were tested in 30-min feeding sessions. As well as measuring food and water intake, an observer kept real-time event records of feeding, drinking and rearing. HP or 6-OHDA lesions decreased food and water intake, total time feeding, rate of feeding, average duration of periods of feeding, and rearing. Feeding rats before the session decreased food intake largely by suppressing feeding time and the number of feeding periods, with little effect on the rate of feeding, and no suppression of rearing. Taken together, these results indicate that HP and lesions of DA neurons decrease motor activity and responsiveness to stimuli in ways that do not resemble interference with sensory processes or a reduction of all aspects of food motivation.

390.3

PARADOXICAL KINESIA IN RATS WITH LARGE DOPAMINE (DA)-DEPLETING BRAIN LESIONS IS NOT MEDIATED BY DA. K. A. Keefe, J. D. Salamone, M. J. Zigmond, & E. M. Stricker, Department of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Rats become akinetic after large DA-depleting brain lesions, yet swim when placed in water and escape from a floating ice bath. Because such stressors increase DA release in intact animals, we examined the hypothesis that this paradoxical kinesia results from DA release from residual DA neurons. In the present studies, the effects of putative DA release were inhibited by treating brain-damaged rats with haloperidol. Rats were akinetic 2 days after near total 6-hydroxydopamine (6-HDA)-induced lesions of the nigrostriatal pathway. Nevertheless, when they were given haloperidol (1 mg/kg) and placed in 31-cm-deep water for 10 min, rats swam effectively for the entire test, although not as vigorously as controls. Enhanced motor function also was seen for a short period (<120 s) after the swim test. In contrast, the haloperidol completely blocked the behavioral response to amphetamine (5 mg/kg). Other 6-HDA-lesioned rats pretreated with haloperidol escaped from a floating ice bath in a 30-cm-deep tank, as they had done prior to brain damage. These results suggest that paradoxical kinesia is not a consequence of DA release from residual DA fibers.

NEUROPHYSIOLOGICAL STUDIES OF SENSORY GATING IN RAT HIPPOCAMPUS: EFFECTS OF AMPHETAMINE AND HALOPERIDOL H.T. Nagamoto*, P.C. Bickford-Wimer, L.E. Adler, M. Egan*, R. G. Johnson*, R. Freedman and G.M. Rose. Depts. of Pharmacology and Psychiatry, VAMC and USHSC Denver, Colorado 80262.

Central mechanisms of sensory gating were assessed in Sprague-Dawley rats by an evoked potential technique similar to one that we have used to show diminished sensory gating in psychotic human subjects. In previous studies, auditory evoked potentials (AEPs) were recorded from the skull of unanesthetized freely moving rats using a conditioning-testing paradigm. In this paradigm, gating mechanisms were assessed by measuring the suppression of response to a 74 dB click test stimulus following an earlier identical conditioning stimulus at 0.5-second intervals. The rats showed significant suppression of the N50 response to the second auditory stimulus. Amphetamine significantly interfered with this suppression; haloperidol injected afterwards returned suppression toward normal pre-amphetamine values. AEPs were recorded from the CA3 region of the hippocampus of rats anesthetized with Chloral Hydrate. These animals had a N40 response that showed significant conditioning-testing suppression. As with the skull potential in freely moving unanesthetized animals, amphetamine interfered with this suppression and haloperidol returned suppression toward normal values. Supported by VAMRS and USPHS MH-38321.

STEREOSELECTIVE DISRUPTION OF SENSORIMOTOR GATING BY N-ETHYL-3,4-METHYLENEDIOXYAMPHETAMINE (MDEA) IN THE RAT. M.A. Geyer and R.S. Mansbach. Dept. of Psychiatry, UCSD Sch. of Med., La Jolla, CA 92093.

N-ethyl-3,4-methylenedioxyamphetamine (MDEA) is a derivative of methylenedioxymethamphetamine (MDMA), a drug with demonstrated abuse liability. MDEA and MDMA share a destructive action on serotonin neurons and appear to induce some similar behavioral effects. The relative importance of hallucinogen-like and amphetamine-like properties in the behavioral effects of these drugs is not clearly understood. The present study investigated effects of racemic MDEA and its stereoisomers on prepulse inhibition, a model of sensorimotor gating that is sensitive to disruption by amphetamine. Rats were subjected to 120 dB acoustic pulses, some of which were preceded at a 100 msec interval by a weak 80 dB prepulse stimulus. After saline, the prepulse induced an approximate 50% reduction in whole-body startle responses elicited by the pulse. Administration of racemic or (+)MDEA (0.3-10.0 mg/kg) induced a significant loss of prepulse inhibition, as indicated by drug-by-trial interactions and increased startle responses to stimuli preceded by prepulses. Racemic MDMA (0.3-10.0 mg/kg) produced similar effects. In contrast, (-)MDEA (0.3-10.0 mg/kg) did not significantly decrease prepulse inhibition. The implications of this stereoselective blockade of prepulse inhibition by MDEA are discussed.

PRESENTATION OF WATER TO DEPRIVED RATS INCREASES CATECHOLAMINE (CA) METABOLISM IN DISCRETE BRAIN REGIONS. David Jolly* and Lewis Seiden (SPON: Dwight Hand).Dept. Pharm/Phys. Sciences, Univ. of Chicago, Chicago, IL 60637.

Inhibition of aromatic-l-amino acid decarboxylase by NSD-1055, the activity of tyrosine hydroxylase (TH) causes accumulation of DOPA (dihydroxyphenylacetic acid) in rat brain. If CA metabolism is a steady state, TH activity is proportional to release. Thus CA effects of operant testing may be manifest in differential DOPA accumulation. Water deprived rats on a variable-interval (VI) schedule had higher striatal DOPA accumulations than did ad-lib, non-VI rats ($p<.05$). Deprived rats non-contingently presented water (RT) had greater DOPA accumulations than did deprived control rats (sham). Also, RT rats had higher DOPA accumulations than did ad-lib controls (quiet). This pattern of DOPA accumulation was observed in striatum ($p<.05$), nucleus accumbens ($p<.001$; quiet vs RT $p<.01$, quiet vs sham $p<.05$), and in amygdala ($p<.001$); quiet vs RT $p<.01$, quiet vs sham $p<.05$. Sham and RT rats had identical hypothalamic DOPA levels ($p<.05$; quiet vs RT $p<.05$, quiet vs sham $p<.05$). Differential brain DOPA accumulation also occurs without operant testing. Deprived rats periodically presented water had higher DOPA accumulations in striatum than did ad-lib rats. Apparently, increased brain CA metabolism occurs irrespective of operant schedule or response contingency. This research was supported by PHS MH-14274; RSA MH-10562 (L. Seiden), MH-11191.

390.7

DOPAMINE CONCENTRATION INCREASES IN THE CEREBRAL CORTEX AND BRAIN STEM OF THE HIBERNATING LITTLE BROWN BAT (MYOTIS LUCIFUGUS). W.A. Bauman*, H. Sershen*, C.A. DeSalvo* and A. Hashim* (SPON: B. Scharrer). Veterans Administration Medical Center, Bronx, NY and Center for Neurochemistry, Ward's Island, NY.

Hibernation (H) is an adaptive orchestrated physiologic response to harsh environmental conditions. The changes in various bioamines during this behavior may afford insight into the mechanism of H and temperature regulation in general. To determine the effect of H on the concentrations of dopamine (DA) and its metabolite DOPAC in the cerebral cortex (CC) and brain stem (BS), we sacrificed euthermic nonhibernating (NH) bats in October and H bats (core body temp 6-20°C) in April. The brain was carefully dissected into CC and BS and stored at -50°C until extraction and assay of the supernatants using HPLC with electrochemical detection. Results are expressed as mean ± SEM:

State	CC	BS
NH	15±2✱/3.5±0.4▪	0.78±0.06✱/0.43±0.04
H	35±3✱/5.9±0.5▪	1.38±0.13✱/0.49±0.05

All concentrations are expressed in ng/mg protein
✱p<0.001, ▪p<.01

Conclusions: (1) CC DA and DOPAC concentrations markedly increased during H, (2) BS DA increased during H, and (3) the increase in DA concentration in the brain may be a generalized finding during H.

390.8

ENRICHED AND IMPOVERISHED ENVIRONMENTS: EFFECTS ON THE TURNOVER RATES OF MONOAMINE NEUROTRANSMITTERS. M. J. Renner (Department of Psychology, University of Wisconsin, Oshkosh, WI 54901), C. L. Blank, & K. Freeman (Department of Chemistry, University of Oklahoma, Norman, OK 73019).

Previously, we reported data concerning tissue concentrations of monoamine transmitters and their metabolites in rats after enriched and impoverished housing experience (Renner, et al., Soc Neur Abs, 1986, 12, 1136). Those studies are extended here by examining turnover rates of these transmitters. Sprague-Dawley male rats (27 wt-match pair, 70 days) were randomly assigned to either an enriched condition (EC; group housing, 75x75x40 cm cage, several objects, rotated daily) or an impoverished condition (IC; solitary housing, small cage, no cagemates), for 30 days. Ss were injected with 200 mg/kg of the L-aromatic amino acid decarboxlyase inhibitor NSD-1015, held 30 min, and sacrificed by 800 msec of 10kW microwave irradiation to the head at 2.45 GHz (New Japan Radio NJE-2603). Brains were dissected into 11 sections and analyzed via HPLC-EC using a reversed phase column packed with 3 u particles (Lin., et al., J. Lig. Chromatog., 1984, 7(3), 509-538). IC significantly exceeded EC in hippocampal serotonin turnover rate (5-HTP buildup; p=.002). Dopamine turnover (Dopa buildup) was significantly different in only one of two replications (p = .04). In occipital cortex, the region of largest EC-IC anatomical differences, no significant differences were found. These findings are opposite the direction of other brain differences reported for EC-IC comparisons.

ASCORBATE INFUSIONS INTO THE NEOSTRIATUM MODULATE COMPONENTS OF THE BEHAVIORAL RESPONSE TO AMPHETAMINE AND HALOPERIDOL. L. K. White, M. A. Maurer*, E. A. Sidell*, M. E. Kraft*, C. Oh* and G. V. Rebec. Department of Psychology, Indiana University, Bloomington, IN 47405.

The neostriatum contains high levels of ascorbate (AA), a water soluble vitamin (Milbey et al., Neurosci. Lett., 28: 169, 1982). Systemic or intraventricular administration of AA attenuates the behavioral response to amphetamine and potentiates the effects of haloperidol (e.g., White et al., Psychopharm., 94: 284, 1988). Because the neostriatum plays a key role in the behavioral response to these drugs, AA may exert its antiamphetamine effects in this site. To test this hypothesis, we infused AA (2.0 ug/ul) or saline (0.9%) bilaterally into the neostriatum of rats at a rate of 0.4 ul/min and monitored the behavioral response to 1.0 mg/kg d-amphetamine administered alone or preceded by 0.025 mg/kg haloperidol. Infusions of AA into the neostriatum attenuate components of the behavioral response to amphetamine and enhance the antiamphetamine effects of haloperidol. Thus, AA appears to antagonize dopamine transmission in the neostriatum.

Supported by DA 02451 and BNS 87-11240.

LONG-TERM ASCORBATE TREATMENT: DIFFERENTIAL EFFECTS ON THE BEHAVIORAL RESPONSE TO ACUTE AND CHRONIC AMPHETAMINE. G.V. Rebec, A. Basse-Tomusk,& M. Lam, Dept. Psychol, Indiana Univ., Bloomington, IN 47405.

Systemic, intraventricular, or intrastriatal ascorbate (AA) attenuates the behavioral response to amphetamine (AMPH)(White et al., Psychopharmacology 94:284,1988). Since AA is actively taken up and retained in the CNS for prolonged periods of time (Hammarstrom, Acta Physiol. Scand. 70:3, 1966), chronic AA pretreatment could alter the behavioral response to a subsequent AMPH challenge. In addition, repeated AMPH injections deplete striatal AA levels (Kamata et al. Brain Res. 362:331, 1986) suggesting that concurrent AA administration also may alter the behavioral sensitization that accompanies chronic AMPH treatment. To test these hypotheses, rats received 5.0 mg/kg d-AMPH in the morning and 250 mg/kg AA or saline in the evening for 6 days. Separate groups of rats were pretrated for the same period with saline in the morning and saline or AA in the evening. On the 7th day, all animals were challenged with 5.0 mg/kg AMPH and the behavioral response rated by an independent observer.

Although concurrent pretreatment with AA failed to alter AMPH-induced behavioral sensitizaton, chronic AA did affect the acute response to AMPH. Thus, AA-pretreated rats showed significantly less sniffing and more oral behaviors in response to AMPH than controls.

Supported by DA02451 and BNS 87-11240.

CAFFEINE-INDUCED CONDITIONED PLACE PREFERENCE AND AVERSION. N.T. Brockwell, R. Eikelboom, and R.J. Beninger. Dept. Psychology, Queen's University, Kingston, Canada.

Although caffeine may be the most widely used behaviorally active drug, few studies have illustrated its reinforcing properties. The place conditioning paradigm has been used to illustrate the reinforcing effects of many drugs of abuse, such as the dopamine (DA) agonists cocaine and amphetamine. Following several pairings of a drug injection with one side of a dual-chambered box, the undrugged animal displays a preference for the drug-paired side. The present study utilized place conditioning to assess the rewarding properties of caffeine in male Wistar rats. Results indicate that a high dose (30 mg/kg IP or SC) produced a significant place aversion, whereas lower doses (0.3-10.0 mg/kg IP) produced place preferences. Using an identical procedure, (+)-amphetamine (2.0 mg/kg IP) produced a significant place preference. These results suggest that doses of caffeine produce a biphasic effect on place conditioning, and are consistent with in vivo electrochemical evidence (Morgan, Dunn, & Vestal, Neurosci. Abstr. 13:253, 1987) which suggests that low caffeine doses increase and high doses decrease caudate DA release. (Funded by NSERC).

EVIDENCE FOR OPIOID-DOPAMINE LINK IN A NEW ANIMAL MODEL OF MANIA. W.Fratta, P.Fadda*, M.C.Martellotta*, G.L.Gessa* Department of Neurosciences Bernard B. Brodie, University of Cagliari, Italy.

Sleep deprivation (S.D.) often precedes the onset of mania. Sleep deprived rats show a stage of excitement before they fall asleep that has striking similarities with symptoms of mania, such as insomnia, hyperactivity, aggressiveness and hypersexuality. To verify if such a response might represent a valid model of mania, we studied the effect of different drugs on the excitement following 72 hrs S.D. in rats. We found that the duration of the excitement and EEG arousal was markedly shortened by chronic lithium, by haloperidol (0.2 mg/Kg^{-1}) and SCH 23390 (at the dose as low as 3 ug/Kg^{-1}) but was not influenced by (-) sulpiride (25 mg/Kg^{-1}).
Moreover, S.D. induced excitement was suppressed by Naloxone and markedly prolonged by morphine and other opioids. The results suggest that S.D. -induced "manic-like" behaviour is mediated by the activation of an opioid-dopaminergic link leading to D_1 receptor stimulation.

390.13

DOPAMINERGIC RECEPTORS IN THE ANTERIOR HYPOTHALAMUS FACILITATE FELINE AFFECTIVE DEFENSE BEHAVIOR. S. Sweidan*, H. Edinger and A. Siegel. Depts. of Neurosciences and Physiology, UMDNJ, Newark, NJ, 07103.

The medial preoptico-anterior hypothalamus (mPO-AH) has been shown to be the origin of the descending fibers mediating hypothalamically-elicited affective defense behavior (AD) in the cat. Since dopaminergic (DA) fibers supply this region, we investigated the contribution of DA mechanisms in the mPO-AH to DA facilitation of AD.

Electrical stimulation was used to elicit AD from the ventromedial hypothalamus. Cannula-electrodes, implanted in the mPO-AH, were used for microinjection of drugs into mPO-AH sites from which AD could also be elicited. The effects of microinjections were determined by examining the changes in current threshold for eliciting AD. Following preinjection response threshold determinations, apomorphine solutions containing 10, 50, 100, 200 or 500ng were microinjected (0.25uL) into the mPO-AH. Apomorphine injections significantly facilitated this response as response thresholds decreased in a dose-dependent manner. Pretreatment with a DA antagonist haloperidol (500 ng into mPO-AH) blocked the facilitatory effect of apomorphine. Vehicle injections had no significant effect upon AD.

The results suggest that DA-receptor-mediated mechanisms in the mPO-AH are involved, at least in part, in the DA facilitation of affective defense behavior.

COMPARISON OF SOCIAL-ISOLATION AND FRONTAL CORTEX DOPAMINE DEPLETION ON CONDITIONED LOCOMOTOR ACTIVITY. G.H. Jones,* T.W. Robbins and C.A. Marsden.*[1] (SPON: M.E. McCourt) Dept. of Experimental Psychology, University of Cambridge, Cambridge, U.K. CB2 3EB and [1]Dept. of Physiology & Pharmacology, Queen's Medical Centre, Nottingham, U.K. NG7 2UH.

When food deprived rats were given daily exposures to photocell activity cages, those reared in isolation were hyperactive on the first two days of testing, when compared to socially-reared controls. By day 3 there was no difference between the two groups. However, when testing was paired with food presentation, the locomotor hyperactivity in the isolated rats was reinstated. Determination of brain tissue concentration of monoamines (DA, NE, and 5-HT) and their metabolites from similarly reared, isolated (individual cages) and grouped rats (6 per cage), indicated a significant reduction in frontal cortex dopamine activity in isolates. This is in confirmation of earlier studies on the effects of isolation housing (Blanc et al, *Nature* 284 1980). This experiment therefore also examined the effects of frontal cortex dopamine depletion (induced by 6-OHDA) on locomotor activity conditioned to the presentation of food, as a comparison with the isolation-induced reduction in mesocortical DA activity. These results will be discussed in terms of the effects of social-isolation on central dopamine function and behaviour.

390.15

EFFECT OF ORAL ASPARTAME ON RAT EXPLORATORY BEHAVIOR FOLLOWING STRESS. H.H. Wichman*, N.H. Copp*, and J.B. Eck* (SPON: A. Jones). Claremont McKenna College, Claremont, CA 91711

It has been shown that combined tail-shock and immobilization depletes norepinephrine in the rat hypothalamus, and depresses locomotor and exploratory behavior. Oral tyrosine ingestion blocks this behavioral depression. Since oral Aspartame also produces increased blood levels of tyrosine it ought to have an effect similar to tyrosine alone. This study had two purposes: A) To determine whether immobilization stress done without shock produces post-stress behaviorial depression; and B) to determine whether Aspartame ingestion would block post-stress behavioral depression of exploratory behavior. Forty Sprague-Dawley rats were fed a high carbohydrate meal dosed with Aspartame (200 mg/kg). Two hours of immobilization stress followed. Immobilization stress depressed all behavior--validating the more humane (non-electric shock) stress stimulus. In the Aspartame condition the post-stress depression was significantly blocked, thus demonstrating a post-stress behavioral effect of Aspartame ingestion not previously reported.

STRAIN-SPECIFIC CATECHOLAMINE VARIATIONS INDUCED BY STRESSORS: RELATION TO BEHAVIORAL CHANGE. N. Shanks, S. Zalcman*, C.R. Prince*, and H. Anisman. Dept. of Psychology, Carleton University, Ottawa, Ont. Canada K1S 5B6.

Exposure to inescapable shock provoked region-specific alterations of norepinephrine (NE) and dopamine (DA) activity and levels which varied across strains of mice. In the mesolimbic frontal cortex and nucleus accumbens shock induced an increase of DOPAC accumulation and pronounced reductions of DA in some strains, while in others these variations were less pronounced or entirely absent. Likewise, the stressor provoked reductions of NE and increases of MHPG accumulation in hypothalamus, hippocampus and locus coeruleus varied appreciably across strains. Strain-specific disturbances of shuttle escape performance associated with inescapable shock corresponded relatively well with the MHPG accumulation in the locus coeruleus and the DA reductions in the frontal cortex. Likewise, stressor-provoked alterations of self-stimulation from the nucleus accumbens were related to DOPAC accumulation in this region.

390.17

ALTERATIONS IN CENTRAL DOPAMINE PATHWAYS INDUCED BY SELECTIVE BREEDING FOR AGGRESSION AND BY SOCIAL EXPERIENCE. M.H. Lewis, J.L. Gariepy*, S. Southerland*, R.B. Mailman, and R.B. Cairns*. Biol. Sci. Res. Ctr. and Depts. of Psychiatry, Pharmacology, and Psychology, Univ. of North Carolina, Chapel Hill, NC 27514

A selective breeding strategy has resulted in rapid, persistent line differences in mice from a common genetic background. NC900 mice exhibit high levels of species-typical, isolation-induced aggression when evaluated in a social interaction test. Conversely, NC100 mice exhibit little aggression, but high levels of immobility. In both lines, even one exposure to the social interaction test decreases the latency to attack. We hypothesized that central dopamine pathways, altered by selective breeding, mediated, at least in part, this line difference. Mice from both lines, half of which had been exposed to the social interaction test, were sacrificed four days after testing. Concentrations of dopamine and its acidic metabolites, DOPAC and HVA were quantified using microdissected samples from various brain regions. Significant effects for both line and social experience were found but with no interaction. NC100 mice had significantly decreased concentrations of DOPAC and HVA, in both the caudate nucleus and amygdala. Irrespective of line, exposure to the social interaction test resulted in substantial increases in dopamine utilization in the caudate and amygdala. The present results support the hypothesis that central dopamine pathways mediate line differences, and also lead to the hypothesis that social experience results in persistent alterations in dopamine utilization, perhaps analogous to that described for amphetamine sensitization. (Supported by PHS Grants HD14648 and HD03110.)

FETAL TRANSPLANTS AS A TOOL FOR STUDYING FUNCTIONAL HETEROGENEITY OF THE DOPAMINE SYSTEM. J.B. Richards and C.R. Freed, Depts. of Med. and Pharm., Univ. of Colo. Health Sci. Ctr., Denver, CO 80262.

Functional heterogeneity of the dopamine (DA) system has typically been studied using localized 6-hydroxydopamine (6-OHDA) lesions and intracranial injections of DA agonists and antagonists. The transplantation of fetal DA cells provides another technique for studying functional heterogeneity of the DA system. In this study, rats were unilaterally lesioned with 6-OHDA and then tested for amphetamine (AMPH) induced turning with 5 mg/kg methamphetamine. Rats which did not meet a criterion of >5 turns per min were not used. The rats received transplants in the nucleus accumbens (NAS), dorsal striatum (DS), and ventral striatum (VS). The effects of DA transplants on AMPH induced turning, locomotion, and stereotypy were observed. Preliminary data showed that NAS transplants caused an increase in AMPH induced locomotion. Transplants in the DS reversed direction of AMPH induced turning. Transplants in the VS decreased the rate of AMPH induced locomotion and turning and increased the amount of time spent in stationary stereotypy.

390.19

SLEEP DEPRIVATION (SD) AND YOHIMBINE INCREASE THYROTROPIN (TSH) SECRETION IN HUMANS. N.Sucher* and A.Baumgartner*(SPON:ENA). Psychiatrische Klinik, Freie Universität Berlin (West), Germany.

A whole night's sleep deprivation improves mood in depressed patients. Nothing is known about the mechanisms involved. Since thyroid disorders have also often profound effects on mood, we investigated changes in TSH during and after sleep deprivation in depressed patients and healthy males.

In 50 patients with major depression, TSH concentration was 1.4+1.35mU/l at 8 a.m. before and 2.14+ 1.84mU/l after SD. The rise in TSH levels was significantly correlated to response measured as changes in scores of visual analog mood scales.

TSH secretion is believed to be under central noradrenergic control. We, therefore, investigated the effects of oral prazosine, yohimbine, and propanolol (a_1, a_2, and ß adrenoceptor antagonists) on TSH secretion in 6 healthy males during SD. TSH concentration rose during SD. Prazosine and propanolol had no effect. Yohimbine led to a significant further increase in TSH secretion, probably induced by antagonistic action on presynaptic a_2 receptors, thereby leading to enhanced norepinephrine activity. We conclude that at least the observed neuroendocrine effect of SD is mediated by increased noradrenergic activity, probably due to activation of noradrenergic neurons in the locus coeruleus.

390.20

BEHAVIORAL EFFECTS OF ACUTE TRYPTOPHAN DEPLETION IN DEPRESSED AND OBSESSIVE CUMPULSIVE DISORDER (OCD) PATIENTS. P.L. Delgado, D.S. Charney, L.H. Price, W.K. Goodman, G.K. Aghajanian, H. Landis*, G.R. Heninger, Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508

Reduction of dietary tryptophan (TRP) decreases plasma TRP, brain TRP, and brain serotonin (5HT) in laboratory animals. In healthy humans, it produces mild impairment of attentive performance, reports of negative mood, enhancement of the prolactin response to I.V. TRP, and reduction of CSF 5-HIAA. METHOD: 32 patients (13 depressed and 7 OCD, drug free; 12 previously depressed, now remitted on antidepressant) received two tests, each consisting of a 24-hr., 160 mg/day, low-TRP diet followed the next morning by administration of a 16-amino acid drink, in a double-blind, placebo-controlled (acute or sham TRP depletion), crossover fashion. On one test the diet was supplemented with 500 mg L-TRP tid and the drink contained 2.3 gm L-TRP (sham depletion) and on the other test the diet and drink were not supplemented with TRP (acute TRP depletion) Four of the 25 depressed patients (three remitted and 1 drug-free) were tested single-blind with no sham test. Behavioral ratings and plasma (for free and total TRP levels) were obtained prior to starting the diet and prior to and 5 to 7 hrs. after the drink. Normal TRP intake resumed 7 hrs. after the drink in both groups of patients. Patients were again rated at 12:00 PM the day following the drink. RESULTS: Total and free TRP were decreased 90% 5 hrs. after the TRP-free drink (p<.0001). Nine of 13 drug-free depressed patients improved (50% Hamilton Depression Scale (HDRS) decrease), and 4 worsened (22% HDRS increase) the day following acute, but not sham TRP depletion. Eight of 12 remitted depressed patients on antidepressant relapsed (374% HDRS increase; HDRS: 9±4 pre-diet, 29±6 after drink) following acute, but not sham TRP depletion. OCD patients were behaviorally unchanged by acute or sham TRP depletion. Implications: Acute TRP depletion followed by resumption of normal TRP intake leads to rapid improvement of depressive symptoms in most drug-free depressed patients. Relapse of remitted depressed patients suggests that the therapeutic effects of some antidepressant drugs (desipramine, fluvoxamine, and tranylcypromine) may depend on 5HT availability. OCD may be pathophysiologically distinct from depression. Acute TRP depletion is a useful method with which to evaluate 5HT function in humans.

PREOPTIC PERIVENTRICULAR LESIONS DECREASE VASCULAR CAPACITANCE IN THE RAT. S.L. Bealer, Dept. Physiology, Univ. Tennessee, Memphis, TN 38163

Ablation of tissue surrounding the anteroventral portion of the third cerebral ventricle (AV3V) produces decreased plasma volume, decreased vasoconstrictor reserve, and acute changes in hemodynamics characteristic of increased central blood volume in the rat. The present experiments were designed to determine if AV3V ablation results in decreased vascular capacitance, which could account for these cardiovascular responses. Following recovery from either electrolytic ablation of the AV3V region (AV3V-X) or control surgical procedures (CONT), mean circulatory filling pressure (MCFP) was determined in anesthetized animals during circulatory arrest. MCFP was significantly greater in AV3V-X rats (7.8 ± 0.3 mmHg) than in CONT animals (5.2 ± 0.3 mmHg). Furthermore, intravenous infusion of whole blood (50% estimated blood volume over 15 min) resulted in a significantly greater pressor response (16 ± 4 mmHg) and natriuresis (154 ± 25 µEq) in AV3V-X rats than in CONT animals (4 ± 4 mmHg; 60 ± 10 µEq) during the 30 min following infusion. These data are consistent with the hypothesis that AV3V ablation results in decreased vascular capacitance. (Supported by USPHS grants HL-25877, HL-01237, and from the American Heart Association)

HYPOTHALAMIC INJECTIONS OF OUABAIN ELICIT PRESSOR RESPONSES IN ANAESTHETIZED RATS. D.L. Jones. Depts. of Physiol. & Med., Univ.of Western Ontario, LONDON, Ontario, Canada, N6A 5C1.

Cardiac glycosides are known to have a narrow therapeutic index, due in part to their effects on the brain. Injections into the ventricles of the brain elicit activation of the autonomic nervous system. However, the specific regions in the brain responsible for such action are unknown. The purpose of this experiment was to map the rostral diencephalon to determine sites at which injections of a low dose of the cardiac glycoside, ouabain, resulted in altered cardiovascular responses in the anaesthetized rat. Microinjections of 20 ηg of ouabain in 250 ηL were made into various rostral diencephalic sites of urethane (1.2g/kg) anaesthetized rats while monitoring heart rate and blood pressure. Injections into the nucleus medianus, periventricular, paraventricular, dorsalmedial, lateral and posterior hypothalamic nuclei produced increases in pressure of from 5 to 25 mm Hg, while similar injections outside these regions were without effect. These data suggest that part of the toxicity resulting from the cardiac glycoside administration may be due to the direct action of the glycosides on these hypothalamic structures.

391.3

INCREASE IN BLOOD PRESSURE AND RENAL SYMPATHETIC OUTFLOW BY STIMULATION OF THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS IN CONSCIOUS RATS. H. Kannan[1], Y. Hayashida*[2], X. J. Jin*[1] and H. Yamashita[1] Dept. of Physiol.[1], and Dept. of Systems Physiol.[2], Univ. of Occup. Environ. Health, Sch. of Med., Kitakyushu, Japan 807.

The paraventricular nucleus (PVN) of the hypothalamus has been suggested to participate in control of autonomic nerve activity. Our previous studies(J. Auto. Nerv. Syst., 19:229-234, 1987 and 21:83-86, 1987) demonstrated in anesthetized rats that PVN stimulation resulted in depressor responses accompanied with decreases in sympathetic outflow. Because anesthesia may alter sympathetic responses and cardiovascular reflexs, we decided to examine the effects of PVN stimulation on blood pressure and renal sympathetic nerve activity in conscious rats. Electrical stimulation through chronically implanted electrode evoked increases in blood pressure and renal sympathetic nerve activity with a slight decrease in heart rate. These responses were dependent upon the frequency and the intensity of the stimulus. Latency of the excitatory response of the renal sympathetic nerve activity was approximately 70 ms. Microinjection of L-glutamate (0.5M, 200nl) into the PVN also elicited increases in blood pressure and renal sympathetic nerve activity. The result suggests that activation of PVN neurons in conscious rats leads to pressor responses due to increasing sympathetic outflow, which contrast with those obtained previously in anesthetized rats.

391.4

MICROINJECTION (MI) OF NEUROPEPTIDE Y (NPY) INTO THE POSTERIOR HYPOTHALAMIC NUCLEUS (PHN) INCREASES ARTERIAL PRESSURE (AP) AND RENAL SYMPATHETIC NERVE ACTIVITY (RSNA). J.R. Martin, M.M. Knuepfer and T.C. Westfall. Dept. of Pharmacol., St. Louis Univ. Sch. Med., St. Louis, MO 63104.

We have reported that MI of NPY into the PHN of urethane-anesthetized rats results in an increase in AP. The present study was undertaken to characterize the mechanism by which this increase occurs. Urethane-anesthetized rats were prepared for AP measurement and intravenous drug administration. A cannula was placed in the PHN for MI of carbachol (CARB, 5.5 nmol) or NPY (2.4 nmol), and RSNA was recorded by rectifying and integrating multiple unit activity of a renal nerve. MI of CARB or NPY into the PHN increased AP and RSNA (see table). The increase in AP could be blocked by pretreatment with the ganglionic blocker pentolinium (PENT, 7.5 mg/kg, i.v.) but not by a V_1 vasopressin receptor antagonist (V_1 ANT, 10 µg/kg, i.v.).

Peak Changes in AP (mmHg) or RSNA (%)

	AP Experiments (N)			RSNA Experiments		
	CONTROL	+ PENT	+V_1 ANT	AP	N	RSNA
NPY	12 ± 3 (14)	1 ± 1 (6)	21 ± 3 (6)	12 ± 3	7	30 ± 9
CARB	21 ± 1 (15)	4 ± 1 (6)	30 ± 3 (6)	20 ± 4	6	55 ± 16

Saline MI had no effect on AP or RSNA. We conclude that the increase in AP produced by MI is likely due to sympathoexcitation. (Supported by HL26319, HL35202, NS07254, HL38299 and an AHA MO Affiliate fellowship.)

391.5

EFFECTS OF SINOAORTIC NERVE DENERVATION ON THE RELEASE OF ENDOGENOUS NOREPINEPHRINE FROM THE PARAVENTRICULAR HYPOTHALAMIC NUCLEUS OF UNANESTHETIZED FREELY MOVING RATS. J.M. Qualy* and T.C. Westfall (SPON: S. Horenstein). Department of Pharmacology, St. Louis University School of Medicine, St. Louis, MO 63104.

We previously reported enhanced basal and K^+ stimulated release of norepinephrine (NE) from the PVH in 7-10 wk old SHR as compared to age matched WKY and SD rats. This increased release was attenuated in 12 wk old SHR suggesting enhanced noradrenergic neuronal activity during the developing phase of hypertension. In addition, a reciprocal relationship exists with respect to blood pressure and NE release such that an increase/decrease in blood pressure resulted in a decrease/increase of PVH NE release. These results suggested that the noradrenergic pathways of the PVH contribute to the maintenance of arterial blood pressure homeostasis presumably via the baroreceptor reflex. The present study examined the effects of sinoaortic denervation (SAD) on PVH NE release. The reciprocal relationship between blood pressure and NE release was abolished after SAD. The administration of phenylephrine no longer attenuated the release of NE, and the administration of sodium nitroprusside no longer exacerbated PVH NE release. These results demonstrate that an intact baroreflex is necessary for the noradrenergic pathways of the PVH to contribute to the maintenance of arterial blood pressure homeostasis. (Supported by NIH grants HL35202 and HL26319.)

391.6

PRESSOR AND VASOCONSTRICTOR RESPONSES PRODUCED BY L-GLUTAMATE IN THE LATERAL HYPOTHALAMUS OF CONSCIOUS RATS. A.-L. Sirén, R. Press* and G. Feuerstein. Dept. of Neurol., USUHS, Bethesda, MD 20814.

The effects of microinjections (50 nl) of l-glutamate (GLU) into lateral hypothalamus (LH) were studied in conscious male Sprague-Dawley rats (n=7, 340-360g). Mean arterial pressure (MAP), heart rate, blood flow (BF) and vascular resistance (VR) in hindquarter (HQ), renal (R) and mesenteric (M) vessels were monitored. The injection site and spread were confirmed on thionin stained sections (50μ) and by a radioactive tracer. GLU (100 nmol) in LH produced a sustained pressor response (+33±7 mmHg, $p<0.01$). The increase in MAP became apparent in 1-2 min and subsided in 10-15 min. In 4/7 animals the pressor response was accompanied by an initial decrease in heart rate (-52±18 bpm, $p<0.05$), and in all animals by a sustained tachycardia (+81±15 bpm, $p<0.01$). The HQBF first decreased (-22±2%, $p<0.05$) and then increased (+37±9%, $p<0.01$) while HQVR increased (+51±9%, $p<0.01$). The BF decreased in R and M blood vessels by -28±7% ($p<0.01$) and -30±12% ($p<0.05$), due to an increase in RVR (+73±34%, $p<0.05$) and MVR (+68±21%, $p<0.05$). The results demonstrate that in the conscious rat GLU in LH produces pressor and vasoconstrictor responses, not depressor responses as reported in the anesthetized rat. It is suggested that GLU receptors in LH mediate the pressor response evoked by electrical stimulation of the LH area.

391.7

LATERAL HYPOTHALAMIC AREA: ROLE IN CARDIOVASCULAR CONTROL S.E. Spencer, W.B. Sawyer*and A.D. Loewy, Depts. of Neurology and Anatomy & Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110.

We have previously reported that L-glutamate stimulation of the lateral hypothalamic area (LHA) in rats lowers both blood pressure and heart rate (Soc. Neurosci. Abst., 13(1): 282, 1987). Stimulation of the subthalamic nucleus and dorsal zona incerta did not alter blood pressure or heart rate; while ventral zone incerta stimulation generated hypotension and bradycardia. We reported that this LHA influence on blood pressure is mediated by reductions in cardiac output and is not a result of decrease in total peripheral resistance (FASEB J., 2(6): A1728, 1988).

In our initial studies, we observed a rostrocaudal organization within the LHA. This report extends these studies to discern potential differences after stimulating different LHA subdivisions or the perifornical hypothalamic area.

Stimulating the tuberal region of the LHA (LHA_t), which lies lateral to the ventromedial nucleus of the hypothalamus, decreased the heart rate and blood pressure. In contrast, stimulating the posterior part of the LHA (LHA_p), which lies caudal to the LHA_t and lateral to the mamillary nuclei, decreased the heart rate and blood pressure minimally. Stimulation of the perifornical hypothalamic area caused a fall in blood pressure but no change in heart rate.

The use of pharmacological blockers permitted a determination of whether the LHA_t bradycardia was sympathetically or vagally mediated. Timolol eliminated the bradycardic response. Atropine reduced the bradycardic response by 35%.

Our results show that the LHA_t influences both heart rate and blood pressure while the LHA_p influences neither. The adjacent perifornical area affects blood pressure but not heart rate.

391.8

EFFECT OF SYMPATHETIC NERVOUS SYSTEM ON DIURNAL VARIATION OF CARDIOVASCULAR PARAMETERS IN CONSCIOUS MONKEYS. M.I. Talan and B.T. Engel*. Lab. of Behavioral Sciences, Gerontology Research Center, NIA, Baltimore, MD 21224.

Heart rate, stroke volume, and intra-arterial blood pressure were monitored continuously in each of four monkeys, 18 consecutive hours/day for several weeks. Mean heart rate, stroke volume, cardiac output, systolic and diastolic blood pressure, and total peripheral resistance were calculated for each minute, and reduced to hourly means. After baseline data were collected for approximately 20 days, observation was continued for equal periods of times under conditions of α-sympathetic blockade, β-sympathetic blockade, and double sympathetic blockade achieved by intra-arterial infusion of atenolol, prazosin, or a combination of both in concentration sufficient for at least 75% reduction of response to injection of respective agonists. A stable diurnal pattern of hemodynamic function was observed in the control condition: cardiac output fell throughout the night, primarily as a result of a fall in heart rate since stroke volume was relatively unchanged; a small reduction in blood pressure also occurred; however, this fall was buffered by a rise in peripheral resistance which paralleled the fall in cardiac output. Average overnight total peripheral resistance was 49% greater during atenolol infusion and 20% greater during double blockade. The hemodynamic pattern was not eliminated by selective blockade of α- or β-sympathetic receptors, or by double sympathetic blockade; in fact, it was exacerbated by sympathetic blockade indicating that the sympathetic nervous system attenuates these events. The fact that sympathetic blockade did not eliminate this pattern suggests that a diurnal loss in plasma volume may mediate the fall in cardiac output, and that the rise in total peripheral resistance reflects autoregulation of arterial pressure.

391.9

CHANGES IN ARTERIAL BLOOD PRESSURE AND RENAL BLOOD FLOW DURING SERIAL SEIZURES IN THE RAT. R.M. Zweifler*, E.M. Slaven*, J.C. Magee*, and N.R. Kreisman. Dept. of Physiol., Tulane Univ. Sch. Med., New Orleans, La 70112.

In status epilepticus, mean arterial blood pressure (MABP) increases during early seizures but decreases during later seizures (Glaser Adv. in Neurol. 34: 395-398, 1983; Kreisman et al., Adv. in Neurol. 34: 231-239, 1983). Renal blood flow (RBF) was measured during serially induced seizures in anesthetized, paralyzed rats to determine whether the fall in ictal MABP results from loss of tone in the renal vascular bed. During early seizures, ictal MABP increased nearly 50% while (RBF) transiently decreased nearly 100%. With subsequent seizures, the rises in MABP either diminished or remained the same while the decreases in RBF became smaller. RBF became pressure passive when later seizures were accompanied by a decrease in MABP. In contrast, i.v. administration of norepinephrine during interictal periods always produced profound renal vasoconstriction, indicating that the renal vascular bed remained responsive. The importance of these changes in the renal vascular response to serial seizures will be discussed. (Supported by NIH NS-17443)

391.10

CENTRAL CARDIOVASCULAR ACTIONS OF CORTICOTROPIN RELEASING FACTOR IN SINOAORTIC DEAFFERENTED RATS. J.M. Overton* and L.A. Fisher. Dept. of Pharmacology, Coll. Med., University of Arizona Health Sciences Center, Tucson, AZ 85724.

Corticotropin releasing factor (CRF) acts within the central nervous system (CNS) to elevate arterial pressure (AP) and heart rate (HR) simultaneously and markedly inhibit reflex bradycardia in response to increased AP. If these cardiovascular changes are mediated by inhibition of impulse transmission of baroreceptor afferent fibers terminating within the CNS, prior removal of such afferents should preclude the ability of CRF to alter cardiovascular function. To examine this possibility, the CNS cardiovascular actions of CRF were measured in rats after sinoaortic deafferentation (SAD). All experiments utilized conscious, unrestrained male rats previously instrumented with lateral cerebroventricular (icv) cannulae for peptide administration and femoral arterial catheters for direct measurement of AP and HR. Sham (n=6) and SAD (n=11) operations were performed in a one-stage procedure two weeks prior to experiments. SAD abolished phenylephrine-induced reflex bradycardia (for a 20 mm Hg rise in AP, HR fell by 3±1 vs. 41±5 bpm in shams). Resting AP (114±3 vs. 101±2 mm Hg) and HR (403±8 vs. 363±5 bpm) were slightly elevated after SAD vs. sham operation. Maximal elevations of AP and HR after CRF (0.15 nmole, icv) administration were 15±2 mm Hg (15%) and 93±15 bpm (25%) in sham-operated rats vs. 23±4 mm Hg (20%) and 64±7 bpm (16%) in SAD-operated rats. These results suggest that although CRF-induced elevations of HR may be attenuated after SAD, this peptide acts in the CNS to increase AP and HR via a mechanism apart from inhibition of baroreceptor afferent transmission.

391.11

RECOVERY OF BAROREFLEX CONTROL OF HEART RATE AFTER RIGHT UNILATERAL VAGOTOMY IN RABBITS. D.D. Lund, B.J. Pardini, A.R. Subieta, G.A. Davey, and P.G. Schmid. V.A. Medical Center, Cardiovascular Center and Dept. of Internal Med., University of Iowa, Iowa City, IA 52240.

The time-course of recovery of arterial baroreflex control of heart rate after unilateral mid-cervical vagotomy was evaluated by measuring the baroreflex sensitivity in urethane-anesthetized, propranolol-treated rabbits. Baroreflex sensitivity was measured as the slope of the regression line between the R-R interval (msec) and mean arterial pressure (mm Hg) during a 30 sec linear ramp change in arterial pressure. The ramp was generated by a an electronic negative feedback device that controlled the infusion rate of phenylephrine from control pressure to 150 mm Hg. There was a significant reduction ($p<0.05$) in the RR/BP response to phenylephrine after an acute right midcervical vagotomy (acute vagotomy = 0.97±0.14 msec/mm Hg vs. Control = 1.82±0.33 msec/mm Hg). This response was still significantly reduced from control at 1 week following vagotomy (1.21±0.24 msec/mm Hg). At 4 weeks following vagotomy the baroreflex sensitivity had returned to control levels (3.4±1.22 msec/Hg). No changes were found in the response to methyl choline indicating that alterations in the muscarinic cholinergic receptors could not account for recovery of baroreceptor reflex response after vagotomy. These data support the concept that recovery of baroreceptor reflex response may be related to compensatory changes in the intact contralateral vagus nerve and not an alteration of cholinergic muscarinic receptors. Supported by Vet Administration and NIH HL38137.

391.12

RECOVERY OF HEMODYNAMIC FUNCTION IN CONSCIOUS RATS AFTER SYSTEMIC 6-HYDROXYDOPAMINE (6HDA). J.M. Sved, S.P.Corey*, E.M. Stricker and R.R. Vollmer*. Depts. Behavioral Neuroscience and Pharmacology, Univ. Pittsburgh, Pittsburgh, PA 15260

These experiments investigated the recovery of neural control of blood pressure (BP) and heart rate (HR) in rats one week after administration of 6HDA (100 mg/kg, sc). Catheters were placed in the femoral artery and vein at least 24 hr before experiments. BP was reduced in the 6HDA-treated rats (104±4 mmHg vs 88±3 mmHg, $p<0.01$) whereas HR was not affected. In plasma samples obtained while the rats rested quietly, norepinephrine (NE) levels were significantly less in the 6HDA-treated rats (211±32 pg/ml vs 128±15 pg/ml, $p<0.05$) whereas epinephrine levels were similar in both groups. In response to an infusion of sodium nitroprusside (2.5 ug/kg/min, iv), BP decreased to 62±2 mmHg in vehicle-treated rats and to 44±3 mmHg in 6HDA-treated rats; yet a similar tachycardia was produced in both groups. At the conclusion of the experiments, ventricular and atrial NE content in the 6HDA-treated rats was found to be 91% and 86% of control values, respectively. These results in the conscious rat agree with our observations in pithed rats (Fluharty et al., J Pharm Exp Ther, 243:415, 1987), in which BP and NE increments to electrical stimulation were found to be significantly impaired whereas increases in HR were normal. (Supported by HL26212 and NS19608.)

CANINE MYOCARDIAL CELL SURFACE ß-ADRENERGIC RECEPTORS ARE NOT ALTERED DURING PROLONGED MAXIMAL STELLATE GANGLIONIC STIMULATION

W.M.Watson-Wright*, M.Wilkinson, D.E.Johnstone* and J.A.Armour
Dept. of Physiology/Biophysics, Dalhousie Univ., Halifax, N.S.

Electrical stimulation of thoracic sympathetic ganglia results in increased inotropism which rapidly peaks and then becomes diminished within a few minutes, even though stimulation continues. This inhibition could be due to a decreased availability of myocardial ß-adrenergic receptors. A myocardial slice preparation (Haddad et al., Can. J. Physiol. Pharmacol. 67:1928, 1987) was utilized to assess the binding characteristics of the hydrophilic ß-adrenergic antagonist, [^{3}H] CGP-12177, to cell surface receptors in tissues which had been removed from the ventral midwall of the left ventricle (LVV) and the right ventricular conus (RVC) prior to maximal stimulation (15V, 10 Hz, 4 ms) of acutely decentralized stellate ganglia of mongrel dogs (PRE) as well as after 20 minutes of stimulation while stimulation continued (20 MIN). Stimulation increased intramyocardial pressure (IMP) in LVV from 78±7 to 258±23 mm Hg initially but after 20 minutes of continuous stimulation it was 90±16 mm Hg. IMP in RVC followed a similar pattern. Bmax in LVV prior to stimulation was 14.61±0.94 fmol/mg wet wt and was not altered after 20 minutes stimulation (14.09±0.62 fmol/mg wet wt)($p>0.05$). Kd likewise was similar PRE (0.29±0.05 nM) versus 20 MIN (0.28±0.05 nM). In RVC, both Bmax (15.21±1.89 fmol/mg wet wt) and Kd (0.32±0.09 nM) were similar to those in LVV prior to stimulation ($p>0.05$) and neither was altered as a result of stimulation. These results demonstrate that 20 minutes of maximal electrical stimulation of canine stellate ganglia does not result in a loss of ß-adrenergic receptors from the myocardial cell surface, and suggest that an acute increase in sympathetic function does not lead to alteration of myocardial ß-adrenergic receptors.

DEVELOPMENT OF A1 ADENOSINE RECEPTORS AND RESPONSIVENESS OF ADENYLATE CYCLASE TO INHIBITION BY CYCLOPENTYLADENOSINE IN EMBRYONIC CHICK HEART. T.A.Blair* and T.F.Murray. Oregon State Univ., Corvallis, OR 97330

The developing chick heart has been used to study the biochemical events involved in the activation and regulation of various neuroreceptors. In the present study we have used the embryonic chick heart to study the development of A1-adenosine receptors and their interaction with adenylate cyclase during embryogenesis. Temporal correlation of these results with previous physiological studies permits inferences to be made concerning the relationship between the development of sensitivity to adenosine analog-induced negative chronotropic response and the appearance of A1 receptors coupled to adenylate cyclase. At 5- and 7-days in ovo the number of receptors in cardiac membranes, as determined by the binding of [3H]cyclopentyldipropylxanthine, appear to have similar densities. Between day-7 and 9 the density increases 1.5 to 2 fold and remains relatively constant through day-16. Equilibrium saturation analysis demonstrated that the Bmax values were 46.8±1.3fmol/mg protein for 7 days, 74.75±6.5 fmol/mg protein for 9 days and 69.2 ±1.6 fmol/mg protein for 14 days in ovo with no apparent change in receptor affinity. Despite these developmental increases in the densities of adenosine receptors there were no corresponding changes in A1-receptor mediated inhibition of basal adenylate cyclase activity between embryonic days 4 and 16. The maximum inhibition obtained using the A1-selective agonist cyclopentyladenosine ranged from 9.2 ±.4% to 14.2±1.2% with IC50 values of 0.22 ± 0.11 to 2.8±0.92 uM. From these data we conclude that the increase in A1 adenosine receptors as a function of ontogeny may partially explain the increase in physiological response seen during embryogenesis. The sensitivity to A1-receptor mediated inhibition of adenylate cyclase is not temporally correlated with physiological responsiveness and therefore does not appear to be involved in the A1-receptor mediated negative chronotropic response.

AGONIST RADIOLIGAND INTERACTIONS WITH THE SOLUBILIZED PORCINE ATRIAL ADENOSINE RECEPTOR. M. Leid and T.F. Murray, Coll. of Pharmacy, Oregon State Univ., Corvallis, OR 97331.

The agonist radioligand [^{125}I]hydroxyphenylisopropyladenosine ([^{125}I]HPIA) was used to characterize solubilized cardiac adenosine receptors (cAdoR). Porcine atrial membranes were solubilized using a mixed detergent system consisting of 0.4% w/v digitonin and 0.08% w/v cholate. [^{125}I]-HPIA showed saturable binding to an apparently homogenous population of solubilized recognition sites with a Bmax of 25 ± 1 fmol/mg protein and a K_D of (6.9 ± 0.8) x 10^{-10} M. The results of kinetic experiments suggest that [^{125}I]HPIA interacts with solubilized cAdoR in a simple bimolecular reaction. Guanyl nucleotides negatively modulated the binding of [^{125}I]HPIA indicating that solubilized cAdoR maintain the ability to interact with guanyl nucleotide binding protein(s). Competition binding experiments using adenosine receptor agonists and antagonists as inhibitors of [^{125}I]HPIA binding suggest that the pharmacological specificity of solubilized cAdoR has been preserved. In summary, [^{125}I]HPIA bound saturably and reversibly to the solubilized cAdoR via an apparent simple bimolecular reaction. Both the pharmacological specificity of the cAdoR and its ability to interact with guanyl nucleotide binding protein(s) are maintained in this detergent system. RELATIONSHIP OF SYMPATHETIC NERVE FIBERS AND MAST CELLS OF THE RAT DURA MATER. **KELLER, J.T., R.Y.W. DIMLICH, M. ZUCCARELLO*, B.E. TIERNEY*, Depts. of Neurosurg.,Emerg. Med., and Anat./Cell Biol., U. of Cincinnati, and J.N. Gamble Inst. of Med. Res., and The Christ Hospital, Cincinnati, Ohio.**

The neural elements associated with meningeal vasculature are similar to those of the cerebral vessels at the base of the brain. We are studying the relationship of nerve fibers associated with dural vasculature as a model to gain an understanding of the mechanisms which govern cerebral blood flow and cephalgias. Because a prominent perivascular mast cell population is associated with the meninges, consideration is given to the relationship of these cells to the sympathetic nervous system. Previous ultrastructural investigations have demonstrated an association between mast cells and nerve fibers, including those of the sympathetic nervous system, in other tissues. The purpose of this study was to: 1. examine the sympathetic innervation of the rat meninges in normal animals and those in which the superior cervical ganglion (SCG) had been bilaterally extirpated, and, 2. examine the mast cell population in these two groups of animals. Using the glyoxylic acid (GA) technique of de la Torre, whole mount preparations of supratentorial dura mater were examined for the presence of catecholamine fibers and mast cells. Robust plexuses of noradrenergic fibers and perivascular mast cells were associated with the middle meningeal artery and its branches. In five animals, examined seven days following bilateral extirpation of the SCG, noradrenergic nerve fibers were no longer identified and the mast cell population had decreased in number as visualized using the GA fluorescent technique. These preliminary results are suggestive that the sympathetic nervous system may have a modulatory influence on meningeal mast cells. These observations warrant further investigation.

CENTRAL α_2 ADRENERGIC MECHANISMS IN THE RENAL NERVE MEDIATED NATRIURESIS AND DIURESIS PRODUCED BY ACUTE VOLUME EXPANSION. KP Patel* (SPON: SB Waller) Dept. of Physiol. & Pharm., University of South Dakota, Vermillion, SD 57069.

To determine whether central α_2 adrenergic mechanisms are involved in the natriuresis and diuresis produced by acute volume expansion (VE), urine flow ($\dot{v}$) and sodium excretion ($UNa\dot{v}$) from innervated and denervated kidneys were measured before and after VE (1 ml/min for 20 min) in presence or absence of intracerebroventricular yohimbine (8 µg/kg/min) in Inactin® anesthetized Sprague Dawley rats. The innervated to denervated (I/D) ratio for $\dot{v}$ and $UNa\dot{v}$ indicated that VE caused a greater natriuresis and diuresis from the intact compared to the denervated kidney.

		Control	Volume Expansion
No Yohimbine	$\dot{v}$	0.23 ± 0.03	0.61 ± 0.10
	$UNa\dot{v}$	0.21 ± 0.03	0.61 ± 0.09
Yohimbine	$\dot{v}$	0.24 ± 0.04	0.36 ± 0.07*
	$Una\dot{v}$	0.21 ± 0.04	0.34 ± 0.07*

Data represent mean I/D ± SEM, *$p<0.05$, No yohimbine vs. yohimbine (n=7). Central administration of yohimbine blunted the increase in the I/D ratio to VE. These data suggest that central α_2 adrenergic mechanisms may be part of the renal sympatho-inhibition responsible for natriuresis and diuresis produced by acute VE.

392.2

THE INVOLVEMENT OF α_1- AND α_2-ADRENOCEPTORS OF NUCLEUS RETICULARIS GIGANTOCELLULARIS IN THE ANTIHYPERTENSIVE EFFECTS OF GUANABENZ. H.C. Lim* and S.H.H. Chan.(SPON: S.F. LEONG) National Univ. of Singapore, Kent Ridge, Singapore 0511, and National Yang-Ming Medical Coll., Taipei 11221, Taiwan.

Guanabenz, like clonidine, is thought to exert its antihypertensive effects via the central α-adrenoceptors. Since the nucleus reticularis gigantocellularis (NRGC) has been shown to be critically engaged in clonidine- and guanabenz-induced hypotension, we investigated the involvement of α-adrenoceptors in the NRGC in the cardiovascular effects of guanabenz, using pentobarbital anesthetized male Sprague-Dawley rats. Pretreatment with α-adrenoceptor antagonists yohimbine (10 µg), phentolamine (2.5 µg) and phenoxybenzamine (20 µg), which were microinjected into bilateral NRGC, significantly antagonized the cardiovascular suppressive effects normally elicited by an intravenous administration of guanabenz (10 µg/kg). In contrast, pretreatment with prazosin (0.25 µg) did not affect the hypotensive, but inhibited the bradycardiac actions of guanabenz. Pretreatment with either clonidine (0.5 µg) or guanabenz (0.5 µg) significantly potentiated the initial hypertension, and antagonized the vasodepression, normally promoted by the other compound. We conclude that guanabenz may produce antihypertension by activating the α_2-adrenoceptors, and to a lesser extent, the α_1-adrenoceptors, in the NRGC.

392.3

INTRATHECAL CLONIDINE PRODUCES PRESSOR EFFECTS BY PERIPHERAL REDISTRIBUTION AND ACTIVATION OF VASCULAR ALPHA-ADRENOCEPTORS. G.F. Gebhart, R.E. Solomon and R.K. Bhatnagar, Department of Pharmacology, University of Iowa College of Medicine, Iowa City, IA 52242.

Intrathecal (i.t.) clonidine in rats produces, at lesser doses (1.0 - 10.0 µg), depressor and antinociceptive effects mediated by spinal α_2-adrenoceptors and, at a greater dose (32.0 µg), pressor effects mediated by peripheral vascular α_1- and α_2-adrenoceptors (Soc. Neurosci. Abs., 13: 1246). The latter observation was further investigated by measuring radioactivity in the blood, brain and spinal cord of rats after i.t. administration of [^{3}H]clonidine. Concentrations of clonidine (in ng/mg) in spinal cord and brain after i.t. injection of 32.0 µg [^{3}H]clonidine were:

TIME	Lumb. s.c.	Cerv. s.c.	Cerebel.	Front. ctx.	Pons-Medulla
5 min:	120.5±39.5	12.6±7.7	0.16±.04	0.17±.03	0.14±.04
20 min:	6.5±1.1	0.1±.01	0.09±.01	0.12±.01	0.08±.01

Concentrations of clonidine (in ng/ml) in the blood were:

DOSE	1 min	2 min	5 min	20 min
3.2 µg:	2.0±0.1	3.5±0.4	3.6±0.2	1.7±0.1
32.0 µg:	27.8±3.6	38.8±6.9	30.0±6.0	20.9±1.9

Administration of 2.5 µg/kg clonidine i.v. (sufficient to produce the peak blood levels observed after 32.0 µg i.t. clonidine) resulted in a transient pressor response. These results suggest that after i.t. administration of 32.0 µg clonidine, sufficient amounts of the drug are distributed systemically to produce peripherally mediated pressor effects.

MECHANISM OF PRAZOSIN INDUCED SYMPATHO-INHIBITION. M.C. Koss, J.A. Hey and T. Ito*. Dept. Pharmacology, Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

Intravenous administration of the alpha$_1$-adrenoceptor antagonist, prazosin (3-300 µg/kg), produced a depression of electrodermal sympathetic-cholinergic responses (EDRs) evoked by electrical stimulation of the posterior hypothalamus in pentobarbital anesthetized cats. Pretreatment with the alpha$_2$-adrenoceptor antagonists yohimbine (0.5 mg/kg) or idazoxan (0.1 mg/kg) significantly blocked the depressant effects of prazosin but had no effect on evoked EDRs when given alone. Electrodermal responses were readily elicited in animals depleted of CNS monoamines. Monoamine depletion, however, totally abolished prazosin's depression of centrally evoked EDRs. Similar results were obtained when EDRs were evoked by electrical stimulation of the cervical spinal cord in spinalized cats. These results suggest that prazosin produces its CNS sympatho-inhibitory effect by facilitation of inhibition mediated by alpha$_2$-adrenoceptor mechanisms and not directly by blockade of excitatory alpha$_1$-adrenergic receptors in the CNS. These findings also suggest a spinal cord site of action for prazosin. (Supported by the National Science Foundation)

RENAL CORTICAL AND MEDULLARY α_2 ADRENOCEPTORS ARE UPREGULATED BY HIGH NaCl DIET IN SHR-S. W. Sripairojthikoon* and J.M. Wyss. Dept. of Cell Biol. and Anat., Univ. of Alabama, Birmingham, AL 35294.

In NaCl sensitive, spontaneously hypertensive rats (SHR-S), a high NaCl diet elevates arterial pressure by decreasing central sympathoinhibition. This study tests the hypothesis that renal α_2 adrenoceptors in both cortex and medulla are upregulated following dietary NaCl loading; an effect that may exacerbate hypertension in SHR-S. In SHR-S the specific binding of the α_2 adrenergic agonist, [^{3}H] p-aminoclonidine (PAC [1 nM high affinity and 10 nM, low affinity]) is increased significantly 2 and 5 weeks after the initiation of a high (8%; compared to a basal, 1%) NaCl diet. In contrast, during the established phase of NaCl exacerbated hypertension (10 weeks), there are no differences in renal [^{3}H] PAC binding between diet groups. Parallel experiments using an α_2 adrenergic antagonist ([^{3}H] rauwolscine) confirm these results. The high NaCl diet does not affect arterial pressure or renal cortical or medullary α_2 adrenoceptors in normotensive, NaCl resistant Wistar-Kyoto rats (WKY) following 2 weeks on the diet, and the diet does not affect renal α_1 adrenoceptor binding in SHR-S or WKY. These findings indicate that in SHR-S, the NaCl induced upregulation of renal α_2 adrenoceptors may be independent of renal nerve activity, since both heavily innervated (cortical) and sparsely innervated (medullary) renal areas are affected equally.

392.6

TACTILE STARTLE IN SPONTANEOUSLY HYPERTENSIVE (SHR), BORDERLINE HYPERTENSIVE (BHR), AND WISTAR KYOTO (WKY) RATS IS UNAFFECTED BY GANGLIONIC BLOCKADE. C. H. Woodworth and A. K. Johnson. Departments of Psychology and Pharmacology, and the Cardiovascular Center, University of Iowa, Iowa City, IA 52242.

Comparisons between SHR and WKY with respect to startle reactivity have yielded conflicting results. However, strain differences in startle reactivity may not be causally related to blood-pressure differences, since selective inbreeding can result in such traits being linked by chance. In the present study, tactile startle (TS) was assessed on two occasions, 7-9 days apart, in male, 17-week-old SHR, WKY and BHR (the F1 progeny of WKY♀ X SHR♂), with either ganglionic blocking agent or vehicle administered 20 min prior to the second test. Strain effects on TS were evident in the first (SHR>BHR=WKY), but not the second test. SHR showed a significantly greater test-retest decrease in TS than BHR or WKY, particularly at later trials and lower airpuff intensities. Hexamethonium (30 mg/kg, IA) produced a significant and equivalent drop in blood pressure across strains, but had no effect on TS. This suggests that startle reactivity is not sensitive to hypotensive changes produced by blocking sympathetic outflow to the periphery in these inbred strains.

DIETARY TRYPTOPHAN INHIBITS DAHL SALT INDUCED HYPERTENSION. L. Lark*, P. Witt*, K. Becker*, W. Studzinski* and J. A. Weyhenmeyer. Neural and Behavioral Biology Program and College of Medicine, Univ. of Ill., Urbana, IL 61801.

Elevated dietary tryptophan (trp) has been found to block the development of DOCA/salt hypertension in rats (Fregley et al., Clin. Exp. Pharm. Physiol. 13: 767, 1986). We investigated the effect of such treatment on the inbred Dahl salt sensitive (DS/JR) rat, its normotensive controls, the inbred Dahl salt resistant (DR/JR) rat, and the outbred Sprague Dawley (SD) rat.

DS/JR animals placed on a supplemented trp diet (50 gm/kg food) at weaning had significantly lower pressures than those maintained on a diet with normal levels of trp (after 6 wks on a 1% salt diet, 123 ± 9 vs. 158 ± 23 mm Hg; after an additional 10 days on 8% salt, 147 ± 26 vs. 191 ± 28 mm Hg). Other groups showed no trp induced pressure differences at 6 wks or after 10 (SR/JR) or 14 days (SD) of salt loading. Slope coefficients were calculated for each animal and averaged within each group. For the initial 6 wk period the slope coefficient of the control DS/JR group was significantly greater than that of all groups on the high trp diet and when calculated over the entire course of the study was greater than all groups. Hearts of the control DS/JR rats were significantly larger than those of the same strain on the high trp diet. We conclude that elevated dietary trp protects against the development of hypertension and cardiac hypertrophy in DS/JR rats. Supported by NSF and AHA-IL.

CHANGES IN NOREPINEPHRINE (NE) MODULATION OF LATERAL HYPOTHALAMIC NEURONAL RESPONSIVENESS TO PUTATIVE NEUROTRANSMITTERS IN DOCA- HYPERTENSIVE RATS. F.M. Sessler and B.D. Waterhouse. Dept. of Physiol. & Biophys., Hahnemann Univ., Philadelphia, PA, 19102.

The lateral hypothalamus (LH) is involved in the central integration of fluid and electrolyte balance. Several studies have suggested a role for NE in these functions. In previous studies we presented evidence in support of a modulatory role for NE within the LH circuitry, i.e. NE was capable of facilitating responses of LH cells to synaptic inputs and putative transmitters. In the present studies we examined interactions of NE with LH neuronal responses to amino acid transmitters in the DOCA hypertensive rat, and compared the results with those from normal (ND) and high salt diet (HSD) rats. Male rats were uninephrectomized and received a DOCA implant (80mg, Dow Corning). They were given 1% NaCl in their drinking water (4-6 weeks). HSD rats received the same treatment but no DOCA. Extracellularly recorded responses from single LH neurons to iontophoretic pulses (5-55nA; 10-20 sec duration) of GABA or glutamate (GLU) were examined before, during and after NE microiontophoresis (5-50nA) in anesthetized rats. The results indicated a shift of NE modulatory action from potentiating to antagonizing effects such that in ND rats, NE routinely potentiated GABA depressant responses (33 of 46, 72%), whereas in HSD rats the ability of NE to enhance GABA responses was reduced to 31% of the cases tested (9 of 29). Likewise, NE did not augment but rather antagonized GABA inhibition in the majority of cells recorded (14 of 23, 61%) from DOCA hypertensive rats. NE action on GLU-induced excitation was also partially reversed from control (ND), in HSD and DOCA rats. In summary, these findings suggest that chronic HSD and DOCA treatments can alter the modulatory capacities of NE within the LH. Although many as yet undetermined mechanisms are likely to be responsible for such alterations, this plasticity of noradrenergic action may represent a central response to afferent synaptic signals which are coding for changes in salt intake and blood pressure.(Supported by AFOSR-87-0138 and NINCDS 18081 to B.D.W.).

392.9

ANALYSIS OF FACTORS PRODUCING AIR STRESS-INDUCED HYPERTENSION (HTN) IN THE BORDERLINE HYPERTENSIVE RAT (BHR). L.D. Fisher and A.K. Johnson. Departments of Psychology and Pharmacology and the Cardiovascular Center, University of Iowa, Iowa City, Iowa 52442.

The BHR is genetically predisposed to develop severe HTN if subjected to certain environmental stressors. We have reported previously that a stressor of intermittent, random jets of compressed air (AJS) directed to the head of BHR while mildly restrained in plexiglas holders (PGH) was effective in inducing HTN. In the present study we examined which of the component(s) (e.g., air jet, air noise, and/or restricted movement) of AJS in PGH was responsible for HTN. Six groups of BHR with comparable systolic blood pressures (SP; via tail cuff) were subjected to different experimental conditions for 2 hrs per day, 5 days per wk for 10 wks. After 10 wks, SP (mmHg) for the six groups were: (1) 189.8 ± 3.2 (n=10) for BHR receiving AJS directed toward the head while in PGH; (2) 187 ± 2.3 (n=7) for BHR receiving the noise of air but no air jet while in PGH; (3) 176.5 ± 2.5 (n=7) for BHR receiving AJS but while free to move about a cage like their home cage (CLH); (4) 164.7 ± 2.9 (n=7) for BHR placed in PGH without AJS: (5) 161.3 ± 2.4 (n=8) for BHR removed from their home cages and placed in CLH; and (6) 165.1 ± 1.5 (n=10) for BHR that served as maturation controls. The results indicate that in confined BHR air noise alone or in conjunction with tactile stimulation provides the most effective condition of those tested to produce HTN. In addition, it can be seen that air noise itself can be used without restraint to elevate SP in BHR.

392.10

LESIONS OF THE ANTERIOR HYPOTHALAMIC AREA (AHA) IN SPONTANEOUSLY HYPERTENSIVE RATS (SHR-S) DECREASE BAROREFLEX RESPONSE. R.M. Thornton*, R.H. Yang*, S. Oparil and J.M. Wyss, Departments of Medicine and Cell Biology and Anatomy and the Hypertension Research Program, University of Alabama, Birmingham, AL 35294.

Lesions of AHA chronically increase blood pressure in SHR-S but not in normotensive rats. To test whether alterations in baroreflex contribute to the hypertensive effect of AHA lesions, bilateral lesions of the AHA were made in 7 week old SHR-S. Three days after surgery, the lesion group displayed significantly elevated systolic arterial pressure compared to the sham-operated group. At 10 weeks of age (three weeks after the lesions were made) the lesion and control rats were instrumented with femoral, arterial and venous catheters, and 2 days later, the rats were volume loaded with whole blood (15% of each rats blood volume; .364 ml/min). Mean arterial pressures were 179 ± 4 and 163 ± 4 mm Hg ($p<0.01$) for the lesion and control rats, respectively. Neither group displayed a significant blood pressure response to the volume load. In contrast, the lesion SHR-S displayed a significant elevation of heart rate (HR; 31 ± 12 bpm, initial HR 377 ± 9 bpm) following the load, while sham operated SHR-S tended to slightly decrease heart rate following the load (12 ± 6 bpm, initial HR 396 ± 12 bpm). The results suggest that the AHA has an influence on baroreflex in SHR-S.

392.11

THE EFFECT OF ONE-KIDNEY GOLDBLATT HYPERTENSION ON ADRENERGICALLY-INDUCED THERMOGENESIS IN COLD ACCLIMATED RATS. J.R. Wilson[1] and D.M. Fyda[2], [1]Department of Psychology, University of Manitoba, Winnipeg, Manitoba R3T 2N2 and [2]Department of Medical Physiology, University of Calgary, Calgary, Alberta T2N 4N1.

The extension of certain thermogenic responses from cold to non-cold acclimated rats, along with the thermal consequences of renovascular hypertension were examined. Sixty-four male, Sprague Dawley rats were either cold or non-cold acclimated and rendered hypertensive (one-kidney, one-clip) or remained normotensive. Arterial and venous catheters were chronically implanted and the animals' metabolic, thermal and cardiovascular responses were assessed during the independent or simultaneous infusions of an α_1- or β_1-agonist. Overall, the α_1-agonist was non-thermogenic; whereas the β_1-agonist increased metabolism and body temperature. The simultaneous infusion of the α_1- and β_1-agonists potentiated the β_1-thermogenic effect. This overall response profile, although observed in the non-cold acclimated animals, was enhanced in the cold acclimated rats. Conversely, renovascular hypertension suppressed thermogenic reactivity to β_1-stimulation. The results suggest that the α_1-potentiation of β_1-induced thermogenesis is not restricted to the cold acclimated endotherm and that the reduced reactivity of the hypertensive animal may be linked to its purported state of hypothyroidism.

392.12

VASODILATORY EFFECT AND MECHANISMS OF CALCITONIN GENE RELATED PEPTIDE (CGRP) IN RESISTANCE VESSELS FROM NORMOTENSIVE AND GENETICALLY HYPERTENSIVE RATS. S.-P. Han* and T.C. Westfall (SPON: W.G. Wood). St. Louis University School of Medicine, St. Louis, MO 63104.

CGRP is known to exert cardiovascular effects. The current study was designed to investigate the effect and mechanisms of CGRP on resistance vessels from normotensive and hypertensive rats. Isolated mesenteric arterial bed from Sprague-Dawley (SD) or from 14 weeks old Spontaneously Hypertensive rat (SHR) was perfused and superfused. Perfusion pressure was continuously monitored and endogenous NE release was measured by HPLC-EC system. CGRP was given over a 5 min perfusion period. In preparations from SD rats, vasoconstriction induced by periarterial nerve stimulation (PANS) was inhibited by CGRP significantly. Both tonic and phasic contraction induced by exogenous NE ($5x10^{-5}$M) was inhibited by CGRP. 90% tension induced by NE was attenuated by 10^{-7}M CGRP. Endogenous NE release stimulated by PANS was not changed. The vasodilatory effect of CGRP on PANS induced vasoconstriction was significantly attenuated in the vascular beds from SHR compared to that from SD rats. Our results suggest that 1) CGRP is a potent vasodilator in mesenteric arterial vascular bed; 2) the postsynaptic mechanism contributes a major part of CGRP induced vasodilation; 3) the vasodilatory effect of CGRP is impaired in SHR which may help to explain the pathogenesis of hypertension. (Supported by HL26319 and HL35202.)

BRAIN STEM NORADRENERGIC TRANSMISSION IN PYRIDOXINE DEFICIENCY-INDUCED HYPERTENSION. M. Viswanathan*, C.S. Paulose*, Y.L. Siow*, and K. Dakshinamurti. Dept. of Biochemistry, Fac. of Medicine, Univ. of Manitoba, Winnipeg, Manitoba, Canada R3E 0W3.

The synthesis of neurotransmitters dopamine and serotonin involves a pyridoxal phosphate-dependent decarboxylation step. We have demonstrated previously that pyridoxine deficiency in adult rats is associated with increased peripheral sympathetic activity leading to hypertension [Paulose et al. Hypertension 11(4) 1988]. The possibility that pyridoxine deficiency-induced hypertension results from altered noradrenergic transmission in the brain stem was investigated.

Adult male Sprague-Dawley rats (150-160 g) were fed either a pyridoxine-supplemented or pyridoxine deficient diet for eight weeks. The kinetic parameters of $alpha_2$ adrenoceptors in the brain stem was studied using p-[3,5-^{3}H] aminoclonidine ([^{3}H]-PAC). There was significant increase ($p < 0.01$) in the B_{max} of [^{3}H]-PAC binding to the high and low affinity $alpha_2$ adrenergic receptors in the brain stems of pyridoxine-deficient rats compared with that in control rats. The increase in B_{max} was not accompanied by any change in binding affinity. Pyridoxine deficiency also caused significant decrease in the maximal activity of dihydroxyphenylalanine (DOPA) decarboxylase in the brain stem (27% of control). These changes correlated with data on norepinephrine turnover in the brain stem of pyridoxine deficient rats. Our findings suggest that hypertension induced by pyridoxine deficiency may result from reduced alpha adrenergic output in the brain stem. STRESS-INDUCED ELEVATION OF PLASMA CATECHOLAMINES (CA) IN STROKE-PRONE HYPERTENSIVE RATS (SHRSP). PRC Howe*, PF Rogers*, X-F Zhou*+ and BG Livett+ CSIRO Divn of Human Nutrition, Adelaide, SA 5000 and + Biochemistry Dept, Univ of Melbourne, Carlton, VIC 3052, Australia.

Lowering blood pressure (BP) with the vasodilator, hydralazine, causes a greater reflex elevation of plasma CAs, esp. epinephrine (EPI), in SHRSP than in normotensive WKY (Howe et al, J Cardiovasc Pharm 8:1113, 1986). Since adrenal CA contents (unpublished results) and basal levels of plasma CAs are greater in SHRSP than in WKY, it was of interest to see whether plasma CA responses to other forms of stress are enhanced in SHRSP. In this study, effects of hypovolemic and hypoglycemic stresses on BP and plasma CAs were examined in conscious, unrestrained adult rats.

Initial BP readings and blood samples were taken at rest via an indwelling arterial catheter. To induce hypovolemia blood was withdrawn at a constant rate of 2.5ml/min. Mean BP fell after 20 min from 113 to 44 in WKY (n=4) and from 167 to 75 mm Hg in SHRSP (n=5). Plasma EPI rose from 180 to 3600 and from 840 to 5200 pg/ml in WKY and SHRSP resp. The corresponding rise of plasma norepinephrine (NE) was less than twofold. Most of the rise in EPI had occurred in SHRSP by 10 min but was unchanged in WKY at that stage.

Other rats were made hypoglycemic by i.v. administration of insulin and somatostatin. Results appear in the table.

Treatment time:	0 min		15 min		30 min	
(n=5 in each case)	WKY	SHRSP	WKY	SHRSP	WKY	SHRSP
PLASMA NE (pg/ml)	360	670	1190	1650	1540	2830
PLASMA EPI (pg/ml)	110	770	5380	7440	5500	15150
PLASMA GLUCOSE (mM)	5.9	6.7	1.8	1.9	2.8	2.1

BP was not affected by the treatment. The increases of CAs after 30 min were reversed by ganglion blockade.

The results confirm that the resting level of plasma EPI is substantially higher in SHRSP than WKY and that EPI is released preferentially in response to both metabolic as well as circulatory stress. They suggest that adrenal medullary function may be selectively augmented in SHRSP.

CIRCADIAN RHYTHM OF ATRIAL NATRIURETIC PEPTIDE IS ABSENT IN HUMAN AUTONOMIC FAILURE. H.C.Kaufmann*, A.R. Pierotti*, J.L.Roberts, and M.D.Yahr. (SPON: T Elizan) Dept of Neurology and Fishberg Center for Neurobiology, Mt. Sinai Sch. of Med., CUNY, New York NY 10029.

Orthostatic hypotension in autonomic failure is due to defective norepinephrine release and exaggerated renal sodium loss, especially at night during recumbancy. The exact mechanism responsable for this defect is not known. Atrial natriuretic peptide (ANP) is a recently discovered hormone that causes natriuresis and relaxation of smooth muscle. To determine the role of ANP in the renal sodium wasting of patients with autonomic failure, the peptide was measured in patients with AF and in age matched control subjects. All subjects were in sodium balance. Blood samples were collected during a 24hr period at 4 hourly intervals with the patients recumbent.

The mean daily plasma concentration of ANP in patients with autonomic failure was 45±6pg/ml and in controls 57±4pg/ml (mean±sem). Control subjects showed significantly higher levels of ANP during the night than during the day. In contrast, patients with autonomic failure exhibited no significant variation in the concentration of ANP throught the day. ANP, however, responded appropriately to changes in extracellular fluid volume induced by the administration or withdrawl of fludrocortisone in patients with autonomic failure.

Since ANP is not increased in autonomic failure, it is unlikely that abnormalities in its secretion are responsible for the salt wasting and low blood pressure seen in these patients. Whether the blunted circadian rhythm of ANP secretion is primary or secondary to the autonomic failure remains to be elucidated.

NEUROPEPTIDE Y PRODUCTION IN RAT ATRIAL MYOCYTE CULTURE. K.L.Marek and R.E.Mains, Depts. Neurology and Neurosci., Johns Hopkins Univ. School of Medicine, Balt. Md 21205.

We have examined Neuropeptide Y (NPY) production in primary atrial myocyte cultures form neonatal rats. NPY content was measured in cell extracts and in culture medium by gel filtration followed by radioimmunoassay. Exogenous NPY was stable in the culture medium for at least 48 hours. NPY mRNA in cell extracts was quantitated by Northern analysis.

Atrial myocyte dissociated cell cultures were maintained in complete serum free medium for up to 3 weeks. NPY-immunoreactivity was identified in atrial myocytes in cultures using the avidin-biotin/peroxidase complex method. Spent culture medium collected over 48 hours contained 0.9 pmole NPY/atrial equivalent. NPY content was reduced 5-fold when cultures were grown in medium containing 100 nM dexamethasone or 100 μM dBcAMP and increased 2-fold by growth in medium containing 100 nM phorbol myristate acetate (PMA). NPY mRNA by Northern analysis showed similar changes in response to these treatments.

Thus cultured rat atrial myocytes produce and secrete NPY. The production of NPY can be regulated in culture by distinct second messenger systems. Experiments are underway to examine further the regulation of NPY production in atrial myocytes. Support: NS01168, DA-00266, DA-00097.

CHARACTERISTICS OF NERVES, NODAL CELLS AND ANF GRANULES IN HEARTS FROM STZ DIABETIC RATS. A.B. Drakontides and M.G. Dominguez*, Department of Anatomy, New York Medical College, Valhalla, NY 10595.

Cardiac disease is commonly present as a complication in chronic diabetes. The streptozotocin (STZ) induced diabetic rat was used as an experimental model to study ultrastructural features of heart tissue. Analysis of nerve bundles in the vicinity of SA and AV nodes indicated that myelinated nerve fibers had the greatest number of aberrations; unmyelinated fibers were either normal or had disrupted axoplasm, increased numbers of vacuoles and myelin whorls. Compared to normal hearts Type P nodal cells in diabetic hearts appeared to have increased numbers of vacuoles and residual bodies; mitochondria often had disrupted cristae. Atrial cardiocytes were significantly smaller in diabetic (41.45 μm^2 ± 5.07) as compared to control (143.25 μm^2 ± 31.04). This appeared to be related to the degree and duration of the diabetic state. Average numbers of atrial granules per area of cell were similar in diabetic and controls. In control hearts, atrial granules were usually of the same electron density; in diabetics, a greater variation in electron density was noted with residual bodies commonly intermingled among granules, furthermore, granules were more frequently distributed closer to cell surfaces. This morphology may be indicative of functional alterations in synthesis, storage and release of natriuretic peptides (ANF) in the diabetic state.

393.1

CHRONIC EXPOSURE TO RO 15-1788 DECREASES GABA FACILITATION OF [3H]FLUNITRAZEPAM BINDING IN RAT NEOCORTICAL MEMBRANES. M. Urbancic* and T.J. Marczynski. Dept. of Pharmacology, Univ. of Illinois, College of Med., Chicago, IL. 60612.

We have investigated the effect of chronic Ro 15-1788 treatment on GABA facilitation of [^{3}H]Flunitrazepam ([3H]FNTZ) binding in neocortical and hippocampal membranes from Ro 15-1788-treated (4mg/kg/day for 14 days in drinking water) and vehicle-treated, 3 months old Wistar rats. The rats were sacrificed 72 hrs following Ro 15-1788 withdrawal. Binding assays were performed in the absence or presence of GABA (10μM) and NaCl (200 mM). Scatchard analysis showed that GABA increased the affinity and the density of benzodiazepine (BDZ) binding sites:

	CONTROL		Ro 15-1788	
	HIPP.	CORTEX	HIPP.	CORTEX
Kd	21.7% ss	18.3% ss	15.3% ss	13.3% ss
Bmax	7.6% s*	11.1% s*	5.4% s	3.7% s

s=p<.04; s*=p<.01; ss=p<.005; paired t-test.

The GABA enhancement of [3H]FNTZ binding was reduced by 67% (p<.02) in neocortical membranes from Ro 15-1788 treated rats, as compared to the control group. Thus, chronic exposure to a BDZ receptor antagonist, Ro 15-1788, has a prolonged effect on the coupling between the BDZ and GABA components of the receptor complex.

DOWNREGULATION OF $GABA_A$ RECEPTOR FUNCTION AFTER CHRONIC CLONAZEPAM TREATMENT IN PRIMARY NEURON CULTURES. R.B. Roy* and L.G. Miller(SPON: L. Happel). Depts. of Medicine and Pharmacology, LSU Medical Ctr., New Orleans, LA 70112.

Chronic benzodiazepine administration has been reported to decrease binding and function at the $GABA_A$ receptor complex in intact animals. To assess the effects of chronic benzodiazepines in a controlled setting, we administered clonazepam, 0.1, 1, and 10 uM, to chick cerebral neurons in primary culture. $GABA_A$ receptor function was assessed by muscimol-stimulated uptake of $^{36}Cl^-$ as described by Thampy and Barnes(J. Biol. Chem., 259:1753, 1984). All assays were performed after 10 days of culture. Chloride uptake in cells treated with vehicle alone for 10 days was similar to controls. Uptake after clonazepam, 1 uM, for 2 and 4 days was similar to controls, and there was a trend toward increased uptake after 6 days. After 10 days, uptake was markedly decreased at all doses of clonazepam evaluated. Chloride uptake was also unchanged compared to controls after 2 days of clonazepam, 0.1 and 10 uM, but in both cases was substantially decreased at 10 days. These results in cultured neurons corroborate reports of decreased $GABA_A$ receptor function in animals, and indicate that downregulation in cultured cells occurs at physiologically relevant drug concentrations.

393.3

DIFFERENTIAL EFFECTS OF ZINC ON VERTEBRATE NEURONAL $GABA_A$ RECEPTORS. T.G. Smart* and A. Constanti* (SPON: M.J. Neal). MRC Neuropharmac. Res. Gp., Dept of Pharmacology, London University, School of Pharmacy, London U.K.

Zinc is an abundant ion in the mammalian central nervous system where it is concentrated into discrete areas including the hippocampus and the cortex. On cultured rat superior cervical ganglion neurones using patch clamp recording, 10-100μM zinc resulted in a reversible inhibition of GABA-evoked membrane current responses. This inhibition was more potent in neurones derived from foetal rats compared to cultures prepared from post-natal and adult animals. However using intact, adult rat sympathetic ganglia, zinc was virtually ineffective as a GABA antagonist. In contrast, intracellular recording from brain slices of hippocampus and pyriform cortex revealed zinc (100-500μM) as a powerful and reversible enhancing agent of GABA responses. This enhancement had a long latency (~30 mins) and was not due to blockade of GABA uptake since it occurred in the presence of 1mM nipecotic acid. These results suggest that zinc has a differential effect on $GABA_A$ receptors which may be dependent on the type of preparation and possibly also on the stage of neural development.

CONVULSANT INSECTICIDES POTENTIATE THE PROTECTIVE EFFECT OF NaCl AGAINST HEAT INACTIVATION OF ^{3}H-FLUNITRAZEPAM BINDING SITES. R.F. Squires and E. Saederup.* Nathan Kline Inst., Orangeburg, N.Y. 10962.

Earlier, we reported that picrotoxin and several "cage" convulsants potentiated the protective effect of NaCl against heat inactivation (60°C, 30 min.) of ^{3}H-Flunitrazepam binding sites on rat brain membranes. We now report that a series of polychlorinated convulsant insecticides, all of which potently inhibit the binding of ^{35}S-TBPS to rat brain membranes, also potentiate the protective effect of NaCl against heat inactivation of ^{3}H-flunitrazepam binding sites with a rank-order or potencies which is similar (but not identical) to the rank-order of potencies for inhibition of ^{35}S-TBPS binding. The most potent protector was α-endosulfan (ΔB_{max}=26%; EC_{50}=120 nM) followed by endrin (39%, 0.20 μM), heptachlorepoxide (24%, 0.96 μM), dieldrin (25%, 1.3 μM), toxaphene (35%, 1.5 μM) and lindane (25%, 3.1 μM). As inhibitors of ^{35}S-TBPS binding, the rank-order of potencies was as follows: α-endosulfan (IC_{50} = 11 nM), endrin (12 nM), dieldrin (130 nM), heptachlorepoxide (170 nM), toxaphene (185 nM) and lindane (210 nM). These results provide further confirmation of a direct molecular coupling of picrotoxin (TBPS) and benzodiazepine (flunitrazepam) binding sites in the GABA-A receptor complex.

393.5

REGULATION OF THE PICROTOXININ RECEPTOR BY ALKYL SUBSTITUTED γ-BUTYROLACTONES AND γ-THIOBUTYROLACTONES. K.D. Holland*, A.C. McKeon*, S.M. Rothman, D.F. Covey*, and J.A. Ferrendelli Depts. of Pharmacology, Neurology, and Anatomy and Neurobiology, Washington Univ. Medical School, St. Louis, MO 63110.

Alkyl substituted γ-butyrolactones (GBLs) and γ-thiobutyrolactones (TBLs) exhibit convulsant or anticonvulsant activity depending on the location of the alkyl substituents. We examined the effects of a convulsant agent, β-ethyl-β-methyl-TBL (β-EMTBL), and two anticonvulsants, α-ethyl-α-methyl-GBL (α-EMGBL) and α-ethyl-α-methyl-TBL (α-EMTBL) on binding of ^{35}S-t-butylbicyclophosphorothionate (TPBS), a ligand specific for the picrotoxinin receptor, and on GABA-mediated currents in cultured rat hippocampal neurons. Beta-EMTBL, α-EMTBL, and α-EMGBL all competitively inhibited ^{35}S-TBPS binding in a dose dependent manner, with IC_{50}s of 9μM, 365μM, and 2.3 mM respectively. In voltage clamped neurons, the convulsants, β-EMTBL and picrotoxinin, inhibited GABA-mediated currents; the broad spectrum anticonvulsant, α-EMTBL, augmented GABA-mediated currents; and α-EMGBL, an anticonvulsant with a limited spectrum of action, had no effect. However, α-EMGBL blocked both the inhibitory effect of picrotoxinin and the facilitory effect of α-EMTBL. Thus, the present results indicate that all three of the above compounds can regulate chloride conductances probably by acting at the picrotoxinin receptor. It appears that each has a different effect. We propose that β-EMTBL is an agonist; α-EMGBL is an antagonist and α-EMTBL is an inverse agonist.

BIOCHEMICAL CHARACTERIZATION OF INSECT GABA-A RECEPTORS. J.J. Rauh* and E.A. Benner* (SPON: J. Meek). Agric. Prod. Dept., E.I. du Pont de Nemours & Co., Wilmington, DE 19898.

Pharmacological differences between insect and vertebrate GABA-A receptors suggest that multiple subtypes of GABA-A receptors may exist. Our studies on the GABA-dependent chloride channel of housefly thorax have revealed additional differences between insect and vertebrate receptors.

Addition of sulfhydryl reducing agents to membrane preparations from housefly thorax increased binding of 35S-TBPS, but had no effect on rat brain membranes. N-ethylmaleimide treatment eliminated 35S-TBPS binding to housefly membranes (IC50=10 μM) but did not alter binding to rat membranes. These results suggest sulfhydryl groups play a role in determining binding interactions at the insect TBPS site.

Insect and vertebrate receptors also differed in their interactions with steroidal compounds which potentiate chloride channel opening. Although we found these steroids to be potent allosteric displacers of 35S-TBPS from rat membranes (IC50=10 nM-1 μM), they were 100-1000 fold less active on housefly membranes. Since steroid displacement of 35S-TBPS was by an allosteric mechanism, we investigated steroid interactions at the ivermectin binding site but found no displacement of 3H-ivermectin from either rat or housefly membranes. This suggests that steroids interact with a unique binding site on GABA-A receptors. We are currently assessing the effects of these steroids, as well as sulfhydryl reagents, on GABA-A receptors of identified neurons from cockroach.

MOLECULAR HETEROGENEITY OF THE GABA/BENZODIAZEPINE RECEPTOR COMPLEX. D.PARK*, J.Vitorica* and A.L.de Blas. Dept. of Neurobiology and Behavior, SUNY at Stony Brook, NY 11794.

Recently, we have reported the production of monoclonal antibodies (mAbs) to the GABA/benzodiazepine receptor (GABAR/BZDR) complex (Vitorica et.al., J. Neurosci.,8:615-622,1988). The mAb 62-3G1 recognized the 57,000 Mr polypeptide of the GABAR/BZDR complex in immunoblots. Immunohistochemistry using this antibody revealed the colocalization of mAb 62-3G1 immunoreactivity and the [^{3}H] muscimol binding sites (De Blas et.al., J. Neurosci.,8,601-614, 1988). It has been proposed that there are subtypes of benzodiazepine receptors with differential distribution in various brain areas. This notion is supported by differences in ligand binding and photoaffinity labeling in various areas of the brain.

In this communication, we are investigating the molecular basis of the heterogeneity in GABAR/BZDR complex. For this purpose, we have used the immobilized mAb 62-3G1 for the purification of GABAR/BZDR complex by immunoaffinity chromatography from both the bovine cerebral cortex and cerebellum. The GABAR/BZDR complex, either photoaffinity labeled or not with [^{3}H] flunitrazepam, was solubilized from bovine cerebral cortex or cerebellum and applied to the mAb 62-3G1 Affi-gel 10 column. The SDS-PAGE and silver staining of the immunoaffinity purified receptor, revealed polypeptides of 51,000, 55,000 and 57,000 Mr in cortex, but only 51,000 and 57,000 Mr polypeptides were apparent in cerebellum.

393.8

DIFFERENTIAL DISTRIBUTION OF $GABA_A$/BENZODIAZEPINE RECEPTOR SUBUNIT mRNAs IN THE BOVINE CEREBELLUM. R.E. Siegel, Dept. of Pharmacology, Case Western Reserve Univ., Cleveland, OH 44106.

The major inhibitory neurotransmitter in the brain, γ-amino butyric acid (GABA), acts at specific neuronal receptors. In addition to GABA, the receptor possesses a binding site for the benzodiazepines, a class of anxiolytics. This $GABA_A$/benzodiazepine receptor complex is composed of α and β subunits to which the benzodiazepines and GABA bind, respectively. While the receptor is generally believed to have a uniform subunit composition throughout the brain, autoradiographic studies with GABA ligands suggest structural heterogeneity in the cerebellum.

To examine further the expression of the $GABA_A$/benzodiazepine receptor in the bovine cerebellum, we have used in situ hybridization histochemistry. Oligonucleotide probes complementary to the mRNAs encoding the α and β subunits of the bovine receptor (Schofield et al, Nature 328: 221, 1987) were chemically synthesized and labeled with ^{35}S. Following hybridization and autoradiography, a uniform distribution of grains was detected over the granule cell layer with probes for both subunits. Intense labeling was also observed over the Purkinje and molecular cell layers with the α subunit probe. In contrast, no β subunit mRNA was detectable in these regions. As cells in these layers respond to GABA, our findings suggest that additional, as yet unidentified, β subunits exist. (Supported by NIH Grant MH42173 and the Mathers Foundation)

393.9

DIFFERENTIAL EFFECT OF R015,1788 ON [^{3}H]-FLUNITRAZEPAM AND [^{3}H]-β-CARBOLINE BINDING ON RHESUS MONKEY BRAIN SECTIONS. J. B. O'Neill[1], J.M. Crawley[2], and D.P. Friedman[3,4]. [1]Section on Brain Biochemistry and [2] Clinical Neuroscience Branch, and [3]Laboratory of Neuropsychology, National Institute of Mental Health, Bethesda, MD 20892, and [4]Division of Preclinical Research, NIDA, Rockville, MD 20857

Biochemical evidence suggests that benzodiazepine (BDZ) and β-carboline (BC) binding sites are part of a supramolecular complex. In support of this, we presented (O'Neill *et al.*, Soc. Neurosci. Abstr. 10(1):552, 1984) anatomical evidence for the co-localization of [^{3}H]-Flunitrazepam (FLU) and [^{3}H]-BC binding sites at the light microscopic level. To extend this analysis and to determine if these two drugs are binding to the same molecular site, we performed competition studies using bicuculline (BIC), diazepam (DZ), RO15,1788 (RO) in μM amounts to displace nM amounts [^{3}H]-FLU and [^{3}H]-BC on slide mounted rhesus monkey brain sections. Three monkeys were deeply anesthetized by intrahepatic injection of sodium pentothal and the brains quickly removed. 25 μM sections were prepared as described previously (Bachevalier *et al.*, Develop. Brain Res. *25*:302-308, 1985).

Binding characteristics were determined for [^{3}H]-FLU and [^{3}H]-BC and incubations took place at their K_ds. Bic did not alter binding under any of these conditions, suggesting that only ineffective concentrations of endogenous GABA remained in these sections

RO and DZ differentially blocked the binding of [^{3}H]-FLU and [^{3}H]-BC, whereas the binding of [^{3}H]-FLU was amost completely blocked by RO and DZ, [^{3}H]-BC binding was only partially inhibited by these compounds.

These differential effects suggest that [^{3}H]-FLU and [^{3}H]-BC are binding to different sites on the GABA/BDZ complex.

393.10

$GABA_A$ RECEPTOR COMPLEX PHARMACOLOGY IN RAT BRAIN SYNAPTONEUROSOMES. T. M. DeLorey, G. B. Brown. The Neuropsychiatry Research Program and the Dept. of Chem., Univ. of AL at Birmingham, Birmingham, AL 35294.

The physiology of the $GABA_A$ receptor complex is being reevaluated under more pysiological conditions with the intention of relating binding efficacy to funtional activity. Ligand binding studies of the $GABA_A$ receptor site are typically done with freeze/thawed synaptic membranes incubated at 0°C in 50 mM Tris-Citrate buffer. Dissociation constants for GABA agonists determined by this method are in the low nanomolar range. This is puzzling because micromolar concentrations are required to elicit a physiological response in vivo. These micromolar concentrations are also seen in $^{36}Cl^-$ flux studies done in vitro. To try to better understand what is occuring in the living system, binding assay conditions have been modified to better reflect the "native" state of the receptor in the living cell membrane. This new method employs the use of synaptoneurosomes containing both pre and post synaptic vesicular structures that have the ability to maintain a membrane potential . In addition, the buffer used in this new approach is more physiologically relevant. The buffer contains 118 mM NaCl, 4.7 mM KCl, 2.5 mM $CaCl_2$, 1.18 mM $MgSO_4$ and 20 mM HEPES/9 mM Tris base (pH 7.4). The incubation period is 25 min. at a temperature of 22°C. This is contrasted with the standard assay incubation temperature of 0°C for 5 min. Incubation is terminated by dilution with ice cold buffer followed by rapid filtration through Whatman GF/C filter paper using a Brandel Cell Harvester. The tissue on the filter is washed twice with approximately 2.5 ml ice cold buffer. Data are analyzed by equilibrium dose response curves and Scatchard analysis using a best fit model (LIGAND).

The K_D values as determined by the standard binding assay show GABA to have two binding affinities with K_D's of 10 nM and100 nM. For muscimol there is only a single site with an K_D of 5 nM. $^{36}Cl^-$ flux studies have demonstrated EC_{50} values for GABA and muscimol of 10μM and 3μM respectively. These values are compared to the K_D values determined in the new binding assay protocol, which reveal GABA to have a K_D of 6 μM and muscimol to have a value of 400 nM. The antagonist (+)bicuculline and the agonists 3-aminopropane sulfonic acid and imidazolacetic acid have also been tested by this new binding method and correlate well with the physiologically relevant dose. Allosteric interactions among the $GABA_A$ receptor complex ligands in this new system compared to the standard system will be discussed.

393.11

BOVINE $GABA_A$ RECEPTOR SEQUENCE-SPECIFIC POLYCLONAL ANTIBODIES. F.A. Stephenson* and M. J. Duggan* (SPON: D. Bousfield) MRC Molecular Neurobiology Unit, Hills Rd, Cambridge CB2 2QH, England.

The primary structures of bovine $GABA_A$ receptor α1 and β subunits have been deduced from the corresponding complementary DNAs (Schofield et al, Nature, 1987, 328, 221-227). We have synthesised five peptides of length 13-17 amino acids which are contained within the α1 and the β polypeptide sequences. These peptides were glutaraldehyde-conjugated to keyhole limpet haemocyanin and used as antigen in the production of sequence-specific polyclonal antibodies. Antibody production was monitored by an enzyme linked immunosorbent assay (ELISA) with the respective immobilised peptide as antigen, followed by ELISA with purified bovine $GABA_A$ receptor as antigen. In all cases, antibodies against peptides were obtained but to date antibodies to three different sequences of the α1 subunit showed reactivity with the receptor in the ELISA assay. It was shown that the sera raised from each of these three antigens reacted with a 53000 (α) polypeptide in Western blots. Additionally, each serum immunoprecipitated specifically GABA and benzodiazepine binding sites from purified preparations and detergent extracts of cerebral cortical $GABA_A$ receptor. Thus we have identified three immunogenic regions of the $GABA_A$ receptor and antibodies directed at these epitopes recognise the receptor in its native and denatured form.

393.12

ENHANCEMENT OF FLUNITRAZEPAM BINDING BY PENTOBARBITAL: AN AUTORADIOGRAPHIC STUDY. H.A. Baghdoyan and R.A. Hawkins. Department of Anesthesia, The Penn. State University, College of Medicine, Hershey, PA 17033.

Previous studies using brain homogenates have demonstrated that pentobarbital enhances the binding of benzodiazepines (BDZ) in the cortex. The purpose of the present study is to investigate whether pentobarbital-induced enhancement of BDZ binding shows regional specificity throughout the brain. Such specificity might help elucidate how barbiturates induce their hypnotic effects. Thin sections of fresh-frozen rat brain were incubated with 3H-flunitrazepam or 3H-flunitrazepam plus pentobarbital and processed for film autoradiography. Various regions were measured throughout the brain, and all regions showed increased 3H-flunitrazepam binding in the presence of pentobarbital. These increases averaged 18% and ranged from 4% to 59%. The greatest increases observed were in the central gray (59%), the occiptal cortex (27%), the insular cortex and the occulomotor complex (24%). Adjacent sections, with and without pentobarbital, have been digitized. Comparison of these images will yield a point-by-point map of the influence of pentobarbital on flunitrazepam binding throughout the brain.

Supported by the Department of Anesthesia and a Research Initiation Grant, The Penn. State University.

393.13

BOTH γ-AMINOBUTYRIC ACID AND BENZODIAZEPINE LIGANDS PHOTOAFFINITY LABEL BOTH α AND β SUBUNITS OF THE GABA RECEPTOR. M. Bureau* and R.W. Olsen (SPON: D.J. Jenden). Department of Pharmacology, School of Medicine, and Brain Research Institute, University of California, Los Angeles, CA 90024.

The γ-aminobutyric acid(GABA)/benzodiazepine(BZ)receptor protein from bovine, rat, and human brain was purified by affinity column (Stauber et al., Eur.J.Biochem. 167, 125-133, 1987) and photoaffinity labeled with (^{3}H)muscimol and (^{3}H)flunitrazepam(FLU), followed by SDS gel electrophoresis. The BZ ligand (^{3}H)FLU was incorporated primarily into the expected 52 kD α subunit, but also significantly (60% of α in rat) into the 57 kD β subunit. Likewise, the GABA ligand (^{3}H)muscimol was incorporated primarily into the 57 kD β subunit, but also significantly (38% of β in human) into the 52 kD α subunit, suggesting that both major subunit peptides carry binding sites for both classes of ligands. Photolabeling was totally prevented by including excess cold ligand, and other peptides present (trypsin inhibitor) were not labeled. Further, both subunits α and β showed doublets for photolabeling with both ligands in all three species of animal, consistent with receptor subtypes possibly a family of gene products (Bureau & Olsen, FASEB J. 2, A622, 1988, #1892). The pharmacological specificity and brain regional distribution of the two α and β subunits were determined and are consistent with receptor subtypes.

Supported by NIH grants NS 22071 and NS 21908.

393.14

EFFECTS OF COCAINE ON BENZODIAZEPINE RECEPTOR LABELING IN VIVO. N. E. Goeders and M. A. McNulty*. Department of Pharmacology & Therapeutics, Louisiana State University Medical Center, Shreveport, LA 71130.

The chronic administration of cocaine has been reported to differentially affect a variety of neuronal systems including benzodiazepine receptor densities measured in vitro in various regions of the rat brain (Goeders et. al., Soc. Neurosci. Abst., 13:724, 1987). This investigation was therefore designed to determine the effects of cocaine on these receptors using in vivo receptor labeling procedures.

Adult male rats were injected via chronically implanted jugular catheters with 25 uCi [^{3}H]Ro 15-1788 5 min following pretreatment with cocaine (5, 10, 20 or 40 mg/kg, ip) or saline (1 ml/kg). The rats were sacrificed by decapitation 10 min following the intravenous injection, the brains were rapidly removed and dissected into cerebral cortex, hippocampus, striatum, cerebellum, diencephalon and brain stem, and radioactivity was directly determined in each tissue sample using liquid scintillation spectrophotometry. Blank values were determined by pretreating the animals with clonazepam (5 mg/kg, ip) 30 min prior to the intravenous injection. The results of this study will be discussed in relation to those obtained in vitro. [Supported in part by USPHS grant DA04293.]

ISOLATION OF cDNAs CLOSELY RELATED TO GABA-A RECEPTOR POLYPEPTIDES. M. Khrestchatisky[1*], A.J. MacLennan[1*], R.W. Olsen[2,3], M. Bureau[2*] and A.J. Tobin[1,3,4]. Departments of [1]Biology and [2]Pharmacology, [3]Brain Research Institute, and [4]Molecular Biology Institute, University of California, Los Angeles, CA 90024-1606.

Our work addresses the molecular composition and heterogeneity of the GABA-A receptor. We have prepared oligonucleotide probes (derived from the sequences of Schofield et al., Nature 328:221-227, 1987) for GABA-A receptor cDNAs and have used them to isolate candidate cDNAs for GABA-A receptor polypeptides.

We isolated several independent clones that hybridize with alpha subunit sequences. These were part of a cDNA library in lambda-gtll originally derived from bovine cerebral cortex mRNA by Dr. Rachel Neve. They have 70-80% identity with the published bovine alpha cDNA sequence. Under hybridization conditions of medium stringency, these probes detect genomic restriction fragments totaling 12-20 kb in the DNA of cows, rats, and humans.

We are presently extending these studies to the genes encoding other GABA-A receptor polypeptides.

This work was supported by grants to AJT from NINCDS (#NS22256 and NS20356), the Scottish Rite Schizophrenia Research Program and a program project grant to Dr. A.V. Delgado-Escueta (#NS21908). AJM was supported in part by a Canadian MRC Fellowship, and MK by a fellowship from the Fondation de l'Industrie Pharmaceutique pour la Recherche.

PURIFICATION OF A MITOCHONDRIAL BENZODIAZEPINE BINDING SITE PROTEIN. L. Antkiewicz-Michaluk*, A.G. Mukhin*, A. Guidotti, and K.E. Krueger. FGIN, Georgetown Univ. Med. Sch., Washington, D.C. 20007.

The photoaffinity probe [^{3}H]PK 14105 was employed to photolabel peripheral-type benzodiazepine binding sites on adrenal mitochondrial membrane fractions. The membranes were solubilized in 1% digitonin and the detergent-soluble extract was subjected to anion-exchange chromatography and reversed-phase high pressure liquid chromatography. This scheme resulted in the purification of a protein covalently modified by [^{3}H]PK 14105 and possessing an apparent molecular weight of 17 kilodaltons as determined by sodium dodecylsulfate-polyacrylamide gel electrophoresis. Electrophoretic analysis of purified preparations of this protein revealed a single band following radioiodination with Bolton-Hunter reagent and also upon silver-staining of the gel. Amino acid analysis of the purified protein predicted a minimal molecular mass of approximately 16 kilodaltons. Cyanogen bromide digestion produced peptide fragments which were isolated and sequenced indicating that this protein shows no significant homology with other known protein sequences. These results demonstrate that a putative protein component of peripheral-type benzodiazepine recognition sites has been purified to apparent homogeneity and partially characterized.

A MOLECULAR CHARACTERIZATION OF THE γ-AMINOBUTYRIC ACID (GABA) RECEPTOR PROTEIN AND mRNA FROM RAT HIPPOCAMPUS DURING DEVELOPMENT. P. Gallombardo, N. Saito*, R. Duman, and J. Tallman, Abraham Ribicoff Research Facilities, Depts. of Pharm. and Psychiatry, Yale Univ. School of Med., 34 Park St., New Haven, CT 06508. K. Garrett and M. Vitek, Lederle Laboratories, Pearl River, NY.

The GABA receptor is composed of at least two subunits (α and β) and contains the binding sites for GABA, the anxiolytic benzodiazepines (BZ), and the anxiogenic β-carbolines. Studies of benzodiazepine binding have suggested the possible existence of multiple receptor "subtypes" or isoreceptors in the rat hippocampus and other brain regions. Photolabeling studies carried out during development have shown the existence of multiple proteins that can be labeled with BZ ligands. Recently, monoclonal antibodies with relative specificity for subunits of the GABA receptor have been raised and a human cDNA clone for the α subunit has been identified (see K. Garrett et al., this issue). Characterization of these subunit specific monoclonal antibodies and cDNA probes will be presented. The existence of multiple GABA receptor subtypes and mRNA in the rat hippocampus during development has been followed using photolabeling, immunobloting, and northern blotting techniques. The relationship of multiple labeled species and genes coding for them will be presented.

393.18

AN IN-VITRO STUDY OF THE EFFECT OF UNSATURATED FATTY ACIDS ON THE GABA/BENZODIAZEPINE RECEPTOR COMPLEX. M.R. Witt* and M. Nielsen. Psychopharmacological Research Lab., St. Hans Hospital, DK-4000 Roskilde, Denmark.

In our search for endogenous modulators of the GABA/benzodiazepine receptor complex (GBRC), we isolated oleic, arachidonic and docosahexaenoic acids from pig brain. At concentrations of 10^{-7}M to 10^{-4}M, these compounds enhance the specific binding of benzodiazepine receptor agonists to rat membranes in-vitro via an increase in affinity (K_D effect).

The stimulation of the binding of benzodiazepine receptor agonist is additional to the binding enhancement of these compounds induced by GABA. The binding of antagonist ([^{3}H]RO-151788) and inverse agonist ([^{3}H]DMCM) is only slightly stimulated. The number of binding sites labelled by [^{3}H]muscimol is increased 2-3 times (B_{max} effect), while the binding of [^{3}H]SR-95333 is unchanged. Pretreatment of the membranes with $AgNo_3$ or incubation with phospholipase A_2 abolish these effects of the fatty acids on the GBRC.

The binding of [^{35}S]TBPS, a ligand that labels sites closely related to the chloride ionophore, is inhibited by the fatty acids in a chloride-concentration-dependent manner. Whether unsaturated fatty acids have any physiological relevance in the regulation of GBRC is unknown.

393.19

A POSSIBLE ROLE FOR PHOSPHORYLATION IN THE MAINTENANCE OF $GABA_A$ RECEPTOR FUNCTION.

M. Gyenes*, M. Farrant*, and D. H. Farb. (SPON: B. M. Altura) Department of Anatomy and Cell Biology, SUNY Health Science Center, Brooklyn, New York 11203.

When using whole-cell recording methods we have observed a time-dependent decline in the responsiveness of cultured chick spinal cord neurons to the neurotransmitter GABA. In the present study we have investigated the role of ATP in this phenomenon. Cells were voltage-clamped at their resting potential (-55 to -70mV) and responses to pressure applied GABA (15-25s) were obtained at 10 minute intervals. Intracellular Ca^{2+} was buffered with EGTA (11mM). The peak amplitude of the inward current evoked by 3μM GABA (~200pA) was stable for up to 60 minutes. In contrast, the response to 30μM GABA (~2nA) progressively declined to approximately 30% of its initial value after 30 minutes. Similar results were obtained when these two concentrations of GABA were applied in sequence to the same cell. "Run-down" of the response to 30μM GABA was reduced when 5mM Mg-ATP was present in the pipet solution (approximately 70% of initial current remaining after 30 minutes). Inclusion of 5 or 28mM ATP-γ-S, an analog that donates a thiophosphate group resistant to hydrolysis, effectively prevented run-down . The non-hydrolysable analog AMP-PNP was without effect. These results suggest that an ATP-dependent process, possibly phosphorylation, is involved in the functioning of the $GABA_A$ receptor.

PEPTIDES: RECEPTORS IV

394.1

NEUROPEPTIDE Y BINDING TO MEMBRANES FROM BOVINE ADRENAL MEDULLA. T.D. Hexum, C. Cherdchu* and J.D. DEUPREE. Dept. of Pharmacol., Univ. Neb. Med. Ctr., Omaha, NE 68105.

Neuropeptide Y (NPY) can inhibit the nicotinic receptor mediated release of catecholamines from bovine chromaffin cells [Higuchi et al., J. Pharm. Exp. Ther. 244 468 (1988)] suggesting the existence of specific NPY binding sites. Bovine adrenal medulla membranes (P_3 fraction, 0.4 mg/ml) were incubated for 30 min, at 0°, in 0.05 M Tris HCl, pH 7.4, containing 0.005 M $CaCl_2$, 0.005 M $MgCl_2$ and 1 % BSA, in the presence of ^{125}I-NPY. Binding was terminated by rapid centrifugation. Specific binding was determined from the difference between ^{125}I-NPY bound in the presence and absence of 1 x 10^{-7} M unlabeled NPY. Binding was linear over a protein concentration range of 0.1 to 0.8 mg/ml. ^{125}I-NPY was stable for 2 h under these conditions. The binding was saturable and reached equilibrium within 10 min at 0°. Scatchard analysis of specific ^{125}I-NPY binding using the LIGAND computer program indicated a best fit for a two site model with K_D of 2.56 x 10^{-10} and 1.64 x 10^{-7} M and B_{max} of 1.2 x 10^{-11} and 6.0 x 10^{-9} moles/mg protein, respectively. The $t_{1/2}$ for dissociation was 9 min. Displacement curves for NPY-free acid, peptide YY, avian or human pancreatic polypeptide revealed IC_{50}'s greater than 300 x 10^{-9} M for these structurally related compounds. Intact chromaffin cells bind ^{125}I-NPY and have a K_D similar to that found for the high affinity site obtained from P_3 membranes. (Work was supported by American Heart Assoc., Inc.)

394.2

AUTORADIOGRAPHIC DISTRIBUTION OF [^{125}I]PEPTIDE YY BINDING SITES IN RAT BRAIN. J.C. Martel[1], A. Fournier*[2], S. St-Pierre*[2] and R. Quirion[1]. (1) Depts. Psychiat. & Pharmacol. and Douglas Hospital Res. Ctr., McGill University, Montreal, QC and (2) INRS Santé, Pointe-Claire, QC.

Peptide YY (PYY) is a member of the pancreatic polypeptide (PP) family which also includes neuropeptide Y (NPY). Some evidence suggests that there could be different types of PP receptors in the brain (Martel et al., Peptides 9 s1: 15, 1988). Here we report on the distribution of ^{125}I-PYY receptor binding sites in rat brain using an autoradiography technique. Twenty micron thick sections of rat brain were prepared and incubated as described before for ^{125}I-NPY (Martel et al. Peptides 7: 55, 1986) using 25pM ^{125}I-PYY (NEN, 2000 Ci/mmol). Specific binding, defined as the difference in binding occurring in absence and presence of 10^{-6} M cold PYY, accounted for 90 % of binding (septum). Important amounts of ^{125}I-PYY binding sites were found in olfactory bulb, septum, hippocampus, substantia nigra pars compacta and lateralis, some amygdaloid nuclei, cerebellum, area postrema, stria terminalis and fimbria hippocampi. Moderate densities of PYY binding sites were seen in outer layers of the cortex, ventral pallidum, claustrum, striatum, thalamic, hypothalamic and amygdaloid nuclei, ventral tegmental area, central gray, reticular formation and inferior olive. Overall, the autoradiographic distribution of ^{125}I-PYY binding sites resembles that of ^{125}I-Bolton-Hunter NPY binding sites described earlier (Supported by MRCC).

394.3

CHARACTERIZATION OF MULTIPLE NEUROPEPTIDE Y (NPY) RECEPTOR BINDING SITES FROM RAT BRAIN. Mary W. Walker* and Richard J. Miller (SPON: S.P. Grossman) Univ. of Chicago, Chicago, Il 60637

Using mono-iodinated neuropeptide Y (NPY), we observed high, moderate and low affinity receptor populations in rat brain. Only the high and moderate affinity sites were clearly detected in equilibrium studies. The majority of binding was to the moderate affinity population, approximately 50% of which was "lost" in the presence of Gpp(NH)p. In kinetic studies, NPY dissociation was best described by 3 rates. Proportions of intermediate and slow dissociating sites matched proportions of high and moderate affinity sites, respectively, in equilibrium studies. There was also a small proportion of fast dissociating sites. When Gpp(NH)p was added during dissociation, the proportion of fast dissociating sites increased to the same extent that the slow dissociating sites decreased. The proportion of intermediate dissociating sites was unchanged. We propose that rat brain contains a minor population of high affinity binding sites with an intermediate dissociation rate and no sensitivity to Gpp(NH)p. There is also a major population of moderate affinity sites with a slow dissociation rate. A component of these sites can convert to a low affinity state with a fast dissociation rate. Gpp(NH)p enhances conversion by stabilizing the low affinity state, thereby producing a "loss" of moderate affinity binding. Similar patterns have been observed for NPY binding to rat dorsal root ganglion cells, a rich source of NPY receptors. NPY receptors were identified in dorsal root ganglion cells by cross-linking with *Bis*-(sulfosuccinimidyl)suberate after equilibrium binding. We observed a major protein of 39,000 daltons and a minor protein of 55,000 daltons, possibly corresponding to moderate and high affinity binding sites.

394.4

DIFFERENTIAL EFFECTS OF BRADYKININ ANALOGUES ON PHOSPHATIDYLINOSITOL TURNOVER IN JH4 AND N1E-115 CELLS. J.H. Fergus*, R.F. Bruns, and D.T. Dudley*, Parke-Davis Pharmaceutical Research, Ann Arbor, Mi 48105.

Bradykinin (BK) is a nonapeptide that mediates pain, vasodilation and smooth muscle contraction. In both JH4 guinea pig lung carcinoma and N1E-115 mouse neuroblastoma cells labeled to equilibrium with [^{3}H]inositol and stimulated with 100 nM BK there is a rapid and large increase in inositol trisphosphate followed by increases in inositol tetrakis-, bis- and monophosphates. These increases peak at 2 min and return to basal levels by 10 min. No effect of stimulation is seen on inositol pentakis- and hexakisphosphates. For routine studies, [^{3}H]inositol phosphate (IP) accumulation in the presence of Li^+ was monitored. Both JH4 and N1E-115 cells have comparable EC_{50} values for BK (8.2 *vs* 12.8 nM); however, JH4 cells consistently show greater stimulation (10 fold *vs* 5 fold). The selective B_1 subtype receptor agonist (des-Arg^9)-BK is inactive at 100 μM in both cell lines, suggesting the [^{3}H]IP accumulation is mediated by B_2 subtype receptors. However, the rank order of potency of a variety of BK analogues is quite different between the two cell lines. Additionally, (D-Arg^0,Hyp^3,Thi^{5,8},D-Phe^7)-BK (NPC-349), which is known to act as a potent, competitive BK antagonist in several smooth muscle systems, is a competitive BK antagonist in JH4 cells, yet acts as a full agonist in N1E-115 cells. These results identify JH4 cells as a sensitive and useful model for studies of the signal transduction and pharmacology of BK receptors and suggest that significant heterogeneity may exist among B_2 subtype receptors.

394.5

CHARACTERIZATION OF ^{3}H-BRADYKININ BINDING SITES IN GUINEA-PIG CNS AND NASAL TURBINATE. Y.Fujiwara*, C.R.Mantione[1] and H.I.Yamamura. Univ. of Arizona, Coll. of Med., Tucson, AZ 85724. [1]Procter & Gamble Company,Cincinnati, OH 45247.

Bradykinin(BK) acts as a putative neurotransmitter and as a mediator of inflammatory reactions. We have obtained evidence for specific high affinity BK binding sites in guinea-pig whole brain(WB), spinal cord(SC) and nasal turbinate(NT). These tissues of adult male guinea-pigs were homogenized in 25mM TES buffer and centrifuged twice. Membrane preparations were incubated with 0.1nM ^{3}H-BK in 1.0 ml of assay buffer (25mM TES, 1mM 1,10-phenanthroline, 140ug/ml bacitracin, 2uM captopril, 1mM DTT and 0.1% BSA) at 25°C for 100 min. Specific binding was determined in the presence or absence of 1uM unlabeled BK.

Specific bindings in WB, SC and NT were linear between 0.2~2.0% tissue weight and reached equilibrium within 30 min at 25° C in the kinetic experiments. ^{3}H-BK binding (<1.0 nM) was saturable and indicated the presence of a high affinity site in these tissues. In competition experiments, D-Phe^7-BK(a B_2 antagonist) inhibited ^{3}H-BK binding (IC_{50}=60nM) while des-Arg^9(Leu^8)-BK(a B_1 antagonist) had no effect at 1.0 uM. These studies indicate the presence of B_2 BK receptors in the guinea-pig WB, SC and NT.

394.6

BINDING OF THE GROWTH HORMONE RELEASING PEPTIDE SK&F110679 TO SPECIFIC HYPOTHALAMIC AND PITUITARY BINDING SITES. E.E.Codd and R.F.Walker* Smithkline and French Labs., P.O. Box 1539, King of Prussia, PA 19406

SK&F 110679 (His-D-Trp-Ala-Trp-D-Phe-LysNH_2)is an enkephalin-derived hexapeptide which specifically releases growth hormone in a wide variety of species in vivo and in vitro. Previous binding studies, using ligands specific for mu and delta opioid binding sites, demonstrated an inverse relationship between the opioid binding potency and the growth hormone releasing effectiveness of a series of SK&F 110679-related peptides (Codd and Walker, Neuropharm., 1988). In an attempt to better understand its mode of action, we established a binding assay for the peptide using a ligand which had been tritium labeled at the histidine residue. Membrane fragments from both hypothalamic and anterior pituitary tissue were found to contain sites to which ^{3}H-SK&F 110679 reversibly and saturably bound. The binding curves for ^{3}H-SK&F 110679 to both hypothalamus and anterior pituitary membrane fragments were resolved into two binding components with the computer program LIGAND. The K_d's obtained were in the 10^{-9}M and 10^{-8}M range. The relation of these binding sites to the peptide's growth hormone releasing activity was explored by examining the relationship between the binding potency and growth hormone releasing effectiveness of a series of peptides related to SK&F 110679. For both hypothalamic and pituitary sites, a significant correlaton between binding and growth hormone release was obtained. Thus these binding sites appear to be involved in the release of growth hormone by SK&F 110679 related peptides.

394.7

DIFFERENT DISTRIBUTIONS OF EPIDERMAL GROWTH FACTOR-LIKE IMMUNOREACTIVITY (EGF-LI) AND IMMUNO REACTIVE EGF-RECEPTOR (IR-EGF-R) IN RAT SPINAL CORD NEURONS. E.V. Joshy,* V. Askanas, W.K. Engel, USC Neuromuscular Center, Los Angeles, CA 90017.

Distribution patterns of EGF-LI and IR-EGF-R in adult rat (Sprague-Dawley) spinal cord sections were compared using peroxidase-antiperoxidase immunocytochemical localization.

EGF-LI was observed in the cytoplasm of neurons of ventral, intermediate, and dorsal horns without apparent difference of staining intensity. Nuclei of some neurons also showed EGF-LI. The distribution of IR-EGF-R was distinctly different. There was no IR in the small dorsal-horn neurons. In the ventral horn there was intense cytoplasmic staining of the larger neurons (>20 um) and lesser staining of the smaller neurons (<20 um) in lamina 7.

Speculatively, EGF might be a transported-exported trophic peptide interacting with post-synaptic EGF receptors in the spinal cord. As suggested by the differential distribution of EGF and its receptors in this study, EGF synthesized in sensory neurons of the dorsal-horn may interact with EGF receptors on large motor neurons. Thus, failure of endogenous spinal EGF, could affect motor more than sensory neurons, and this might be relevant to diseases of preferential motor neuron degeneration.

394.8

A STUDY OF THE SPECIFIC BINDING IN RAT BRAIN MEMBRANES AT THE GASTRIN RELEASING PEPTIDE RECEPTOR AND THE SECOND MESSENGER SYSTEM ASSOCIATED WITH THIS BOMBESIN-LIKE PEPTIDE RECEPTOR. E.B. Hollingsworth. Dept. of Pharmacology, Wellcome Research Laboratories, 3030 Cornwallis Road, Research Triangle Park, NC 27709.

Gastrin releasing peptide, (GRP) binds specifically to rat brain membranes. The binding is saturable, dependent on the tissue concentration, time of incubation and the pH of the buffer. Saturation curves revealed a high affinity site with a Kd equal to 2.4 nM and a B_{max} equal to 6 pmoles/g wet weight of tissue. A lower affinity site is indicated but is not believed to be relevant. Regional distribution studies revealed that the hippocampus contained the highest concentration of binding sites. Hippocampal membranes contained almost twice as much as the tissue with the next highest concentration. The cerebellum contained the lowest density of sites. The affinity of GRP and bombesin and their analogues for the GRP receptor was determined. GRP (14-27) and [Tyr^4] bombesin had the greatest affinity for the receptor of the peptides tested. GRP (1-16) had no affinity for the receptor indicating that the carboxyl end of the peptide is needed for recognition of the peptide for the receptor. Bombesin was shown to stimulate the breakdown of phosphatidylinositol in rat brain hippocampal minces. The concentration required to produce a half maximal effect was in the namomolar range which corresponds to the affinity of bombesin for the high affinity site on the GRP receptor.

394.9

ANTAGONISM OF CENTRAL BOMBESIN (BN) RECEPTORS BY (Psi^{13,14}, Leu^{14})BN. Z. Merali[1], T.W. Moody[2] and D.H. Coy[3]. [1]Psychology & Pharmacology, Univ. of Ottawa, Ontario, K1N 9A9. [2]Biochemistry, George Washington Univ. Washington D.C. 20037. [3]Dept. of Medicine, Tulane Univ. New Orleans, LA 70112.

This study assessed the ability of (Psi^{13,14}, Leu^{14})BN to serve as a central BN antagonist. The in vitro receptor binding studies on fresh frozen coronal rat brain slices, revealed that (Psi^{13,14} Leu^{14})BN inhibited specific (^{125}I-Tyr^4)BN binding activity with IC_{50} value of 100 nM. In contrast, (Psi^{9,10}, Leu^{14})BN and (Psi^{12,13}, Leu^{14})BN were less potent with IC_{50} values of 1000 and 3000 nM respectively. The in vivo studies were done on rats on a regimen of 17.5 hr of food deprivation, followed by i.c.v administration of (Psi^{13,14}, Leu^{14})BN (0.1-10 ug) and/or BN (0.5 ug), meal presentation, and behavioural monitoring. BN decreased the meal size by about 60% and increased grooming by over 5-fold. (Psi^{13,14}, Leu^{14})BN antagonized both these effects, starting at a dose of 0.5 ug. At the dose of 10 ug, it completely blocked the effect of BN on food intake but only partially blocked its effects on grooming. The antagonist alone failed to alter behavior. Thus this pseudo peptide may serve as a pure BN antagonist in the rat CNS, with slightly better in vivo potency than the earlier compounds.
