SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 15, PART 1

19TH ANNUAL MEETING
PHOENIX, ARIZONA
OCTOBER 29–NOVEMBER 3, 1989

1989 © Society for Neuroscience

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0–916110–31–1
Part 2 ISBN 0–916110–32–X
Both parts ISSN 0190–5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 15, Part 1, p. xxx, 1989.

Thematic List of Sessions xii
Abstracts in Session Order*
Monday, October 30–Thursday, November 2..... 1

*8,138 volunteer abstracts, 17 symposia.

1989 PROGRAM COMMITTEE

David P. Corey, Ph.D., *Chairperson*
Massachusetts General Hospital

Edward G. Jones, M.D., Ph.D.
Incoming Chairperson
University of California College of Medicine

Richard W. Aldrich, Ph.D.
Stanford University Medical School

Theodore W. Berger, Ph.D.
University of Pittsburgh

James E. Blankenship, Ph.D.
Marine Biomedical Institute

Dennis W. Choi, M.D., Ph.D.
Stanford Medical School

Suzanne H. Corkin, Ph.D.
Massachusetts Institute of Technology

William C. deGroat, Ph.D.
University of Pittsburgh Medical School

Robert P. Elde, Ph.D.
University of Minnesota

Eberhard E. Fetz, Ph.D.
University of Washington
School of Medicine

Howard L. Fields, M.D., Ph.D.
University of California Medical School

Eric Frank, Ph.D.
University of Pittsburgh Medical School

Karl Herrup, Ph.D.
Eunice Kennedy Shriver Center

John P. Horn, Ph.D.
University of Pittsburgh Medical School

Robert L. MacDonald, M.D., Ph.D.
University of Michigan

Marek-Marsel Mesulam, M.D.
Beth Israel Hospital

J. Anthony Movshon, Ph.D.
New York University

Louis F. Reichardt, Ph.D.
University of California, San Francisco

Elaine Sanders-Bush, Ph.D.
Vanderbilt University School of Medicine

C. Dominique Toran-Allerand, M.D.
Columbia University College of
Physicians and Surgeons

Wylie W. Vale, Ph.D.
Salk Institute

Stanley J. Watson, Jr., M.D., Ph.D.
University of Michigan School of Medicine

Roy A. Wise, Ph.D.
Concordia University

David H. Hubel, M.D., *ex officio*
Harvard Medical School

Patricia Goldman-Rakic, Ph.D., *ex officio*
Yale University School of Medicine

Larry R. Squire, Ph.D., *ex officio*
University of California, San Diego
Medical School

CHRONOLOGICAL LIST OF SESSIONS

(see page xii for Thematic List of Sessions)

Session Number and Title	Page
SUNDAY	
Public Lecture—8:00 p.m.	
1. Neural Networks for Vision and Memory in Humans. A.R. Damasio	No abstract
MONDAY	
Symposia—8:30 a.m.	
2. The Neurobiology of Neuropeptide Y (NPY). *Chaired by:* W.F. Colmers	1
3. Functional Organization of the Thalamus. *Chaired by:* S.M. Sherman	1
Slide Sessions—8:30 a.m.	
4. Visual system: development and plasticity I	1
5. Human behavioral neurobiology: memory	3
6. Serotonin I	5
7. Neural-immune interactions I	7
8. Transplantation I	9
9. Cell lineage and determination I	11
10. Neuroglia	13
11. Calcium channels I	15
12. Trophic agents I	17
13. Neural plasticity in adult animals I	19
14. The aging process	21
15. Biological rhythms and sleep: neuroregulators	23
16. Transmitters in invertebrates I	25
17. Brain metabolism and blood flow	27
Poster Sessions—8:30 a.m.	
18. Mental illness: affective disease	29
19. Comparative neuroanatomy I	31
20. Motivation and emotion I	33
21. Alcohol, barbiturates, benzodiazepines I	36
22. Degenerative disease: Parkinson's I	39
23. Ischemia: pharmacological protection	42
24. Epilepsy: genetic models	46
25. Control of posture and movement I	48
26. Control of posture and movement II	52
27. Motivation and emotion II	55
28. Alcohol, barbiturates, benzodiazepines II	58
29. Acetylcholine I	62
30. Motor systems I	65
31. Motor systems II	66
32. Motor systems III	68
33. Association cortex and thalamocortical relations I	70
34. Association cortex and thalamocortical relations II	72
35. Potassium channels I	74
36. Ion channels: chloride and miscellaneous	78
37. Learning and memory: physiology I	80
38. Long-term potentiation I	84
39. Endocrine control and development I	87
40. Sprouting and sprouting mechanisms I	89
41. Sprouting and sprouting mechanisms II	91
42. Endocrine control and development II	93
43. Genetic models of nervous disorders I	95
44. Genetic models of nervous disorders II	97
45. Respiratory regulation I	98
46. Differentiation, morphogenesis and development: position and form	101
47. Somatic and visceral afferents I	102
48. Uptake, storage, secretion and metabolism I	106
49. Auditory system: cortex and integration	110
50. Auditory system: avian connections and processing	114
51. Retina I	115
52. Visual cortex I	117
53. Visual psychophysics and behavior I	121
54. Degenerative disease: Parkinson's II	123
55. Specificity of synaptic connections	125
56. Trauma I	128
57. Trauma II	131
58. Hypothalamic-pituitary-adrenal regulation: CRH	134
59. Neurotoxicity: dopamine	137
60. Neurotoxicity I	140
61. Opiates, endorphins and enkephalins: tolerance and dependence	143
62. Opiates, endorphins and enkephalins: physiological effects I	146
63. Pain modulation: CNS pathways	149
64. Pain modulation: opioid mechanisms	153
65. Cytoskeleton, transport and membrane targeting	156
Special Lecture—11:45 a.m.	
66. Proto-Oncogenes and Transcription Factors in the Brain: A Role in Adaptation? T. Curran	No abstract
Symposia—1:00 p.m.	
67. New Opportunities for Study of Mechanisms of Central Nervous System Ischemia. *Chaired by:* J.A. Zivin	161
68. From Early Embryogenesis to Circuits: Cellular and Molecular Strategies Applied to the Analysis of Vertebrate Brain Development. *Chaired by:* D. Goldowitz and P. Levitt	161
Slide Sessions—1:00 p.m.	
69. Visual cortex II	161
70. Synaptogenesis I	163
71. Long-term potentiation II	165
72. Second messengers I	168
73. Catecholamine receptors	170
74. Control of posture and movement III	172
75. Subcortical visual pathways I	174
76. Ion channel modulation and regulation I	176
77. Cerebellum I	179
78. Pain modulation	181

Session Number and Title	Page
79. Postsynaptic mechanisms I	183
80. Peptides: biosynthesis, metabolism and biochemical characterization I	185
81. Peptides: anatomical localization I	187
82. Neuroendocrine regulation I	188
Poster Sessions—1:00 p.m.	
83. Presynaptic mechanisms I	190
84. Pharmacology of synaptic transmission	193
85. Sodium channels I	196
86. Excitatory amino acids: receptors I	198
87. Excitatory amino acids: receptors II	201
88. Retina II	204
89. Auditory system: hair cells	207
90. Auditory system: cochlea	209
91. Peptides: physiological effects I	212
92. Peptides: physiological effects II	216
93. Serotonin receptors I	219
94. Serotonin II	223
95. Interactions between neurotransmitters I	226
96. Regional localization of receptors and neurotransmitters I	229
97. Other biogenic amines and purines: adenosine and histamine	232
98. Epilepsy: human studies	236
99. Oculomotor system I	238
100. Biological rhythms and sleep: sleep	241
101. Human behavioral neurobiology: memory and language	244
102. Behavioral pharmacology: analgesics and NMDA	247
103. Drugs of abuse: biogenic amines	249
104. Drugs of abuse: cocaine I	252
105. Synaptic structure and function I	256
106. Aging I	259
107. Regulation of autonomic functions I	263
108. Transplantation: cortex and brainstem	265
109. Psychotherapeutic drugs: dopamine and neuropeptics	268
110. Stress, hormones and the autonomic nervous system	272
111. Differentiation, morphogenesis and development: forebrain	276
112. Trophic agents II	277
113. Cortex I	280
114. Cortex II	282
115. Basal ganglia and thalamus I	284
116. Basal ganglia and thalamus II	287
117. Auditory, olfactory and other sensory systems	290
118. Biochemical and pharmacological correlates of development I	292
119. Neural-immune interactions: stress	295
120. Neural plasticity in adult animals: motor systems	298
121. Learning and memory: anatomy I	302
122. Staining and tracing techniques	306
123. Somatosensory cortex and thalamocortical relationships I	311
124. Somatosensory cortex and thalamocortical relationships II	313
125. Regeneration: general	315
126. Regeneration: GAP43	318
127. Regeneration: CNS I	319
Special Lecture—4:15 p.m.	
128. Genes that Control Aspects of the Development of a Nematode. H.R. Horvitz	No abstract
Presidential Symposium—8:00 p.m.	
129. Visual Pigments, Color Vision, and Color Blindness. J. Nathans. Mechanisms of Phototransduction in Retinal Rods and Cones. K.-W. Yau. Signal Flow in Visual Transduction. D.A. Baylor	No abstract

TUESDAY

Symposia—8:30 a.m.	
130. Hormones, Neural Circuits and Communication. *Chaired by:* A.P. Arnold	322
131. The Initial Events in Taste: Chemosensory Transduction in the Vertebrate Taste Bud. *Chaired by:* S.D. Roper	322
Slide Sessions—8:30 a.m.	
132. Visual cortex III	323
133. Excitatory amino acids: receptors III	325
134. Differentiation, morphogenesis and development: cellular and molecular studies I	327
135. Alzheimer's disease I	329
136. Process outgrowth, growth cones and guidance mechanisms I	331
137. Regeneration I	333
138. Cardiovascular regulation I	335
139. Potassium channels II	337
140. Epilepsy: basic mechanisms I	339
141. Learning and memory: anatomy II	341
142. mRNA regulation I	343
143. Peptides: receptors I	345
144. Neuroethology I	347
Poster Sessions—8:30 a.m.	
145. Neuroglia: myelin and myelin-forming cells	349
146. Neuroglia: active membrane responses	351
147. Calcium channels II	354
148. Ischemia: excitability and neurotransmission	357
149. Ischemia: mediators of neuronal death	360
150. Transmitters in invertebrates II	364
151. Peptides: biosynthesis, metabolism and biochemical characterization II	368
152. Pain modulation: spinal opioid mechanisms	370
153. Differentiation, morphogenesis and development: neuromuscular development	372
154. Comparative neuroanatomy II	374
155. Hormonal control of behavior I	377
156. Neural-immune interactions II	380
157. Subcortical somatosensory pathways I	383
158. Subcortical somatosensory pathways II	385

Session Number and Title	Page
159. Spinal cord and brainstem I	389
160. Control of posture and movement IV	392
161. Control of posture and movement V	395
162. Long-term potentiation III	398
163. Hippocampus and amygdala I	400
164. Cerebellum II	404
165. Acetylcholine II	407
166. Monoamines and behavior I	410
167. Alcohol, barbiturates, benzodiazepines III	414
168. Serotonin III	417
169. Serotonin receptors II	420
170. Catecholamine receptors: dopaminergic (D2)	423
171. Catecholamine receptors: dopaminergic (D1)	428
172. Catecholamine receptors: dopaminergic	431
173. Catecholamine receptors: adrenergic	432
174. Second messengers II	434
175. Neuronal death: models and mechanisms	436
176. Somatic and visceral afferents II	439
177. Neuronal death: lesion induced	442
178. Differentiation, morphogenesis and development: fiber guidance and synaptogenesis	445
179. Brain metabolism and blood flow I	446
180. Brainstem systems	450
181. Epilepsy: kindling I	453
182. Visual system: development and plasticity II	455
183. Subcortical visual pathways II	458
184. Biological rhythms and sleep: invertebrates	461
185. Learning and memory—pharmacology: NMDA	463
186. Learning and memory—pharmacology: monoamines	465
187. Pain pathways: spinal cord	468
188. Pain pathways: primary afferents	470
189. Presynaptic mechanisms: calcium	472
190. Presynaptic mechanisms: facilitation and depression	475
191. Human behavioral neurobiology: event related potentials	476
History of Neuroscience Lecture—11:45 a.m.	
192. Revolutions and Breakthroughs in Nerve and Muscle. Sir A. Huxley	No abstract
Symposia—1:00 p.m.	
193. Optical Imaging of CNS Development, Organization and Function. *Chaired by:* A. Grinvald	479
194. Recent Advances in the Biology of Affective Disorders. *Chaired by:* C.B. Nemeroff	479
Slide Sessions—1:00 p.m.	
195. Excitatory amino acids: excitotoxicity I	479
196. Human behavioral neurobiology: other I	481
197. Presynaptic mechanisms II	483
198. Serotonin receptors III	485
199. GABA and benzodiazepines I	487
200. Transplantation II	489
201. Biological rhythms and sleep: other I	492
202. Visual system: development and plasticity III	494
203. Cholinergic receptors	496
204. Differentiation, morphogenesis and development: cellular and molecular studies II	498
205. mRNA regulation II	500
206. Vestibular system	502
207. Spinal cord and brainstem II	504
208. Learning and memory: physiology II	505
Poster Sessions—1:00 p.m.	
209. Neuroglia in disease	507
210. Neuroglia: structure and biology	510
211. Vestibular system: VOR and integration	513
212. Vestibular system: receptor organs and vestibular nuclei	517
213. Muscle I	519
214. Muscle II	522
215. Postsynaptic mechanisms II	524
216. Pharmacology of synaptic transmission: amino acids and calcium channels	528
217. Excitatory amino acids: receptors IV	531
218. Excitatory amino acids: receptors V	533
219. Sodium channels II	536
220. Potassium channels III	538
221. Opiates, endorphins and enkephalins: physiological effects II	542
222. Pain modulation: biogenic amines I	545
223. Pain modulation: biogenic amines II	547
224. Alcohol, barbiturates, benzodiazepines IV	550
225. Serotonin IV	553
226. Acetylcholine III	554
227. Monoamines and behavior II	557
228. Peptides: anatomical localization II	561
229. Peptides: receptors II	563
230. Membrane composition and cell surface macromolecules I	567
231. Process outgrowth, growth cones and guidance mechanisms II	569
232. Process outgrowth, growth cones and guidance mechanisms III	573
233. Endocrine control and development III	576
234. Endocrine control and development IV	578
235. Interactions between neurotransmitters II	581
236. Regional localization of receptors and neurotransmitters II	584
237. Differentiation, morphogenesis and development: neurogenesis and control of neuron number	587
238. Differentiation, morphogenesis and development: cell surface components	590
239. Cardiovascular regulation II	592
240. Cardiovascular regulation: hypertension	595
241. Cell lineage and determination II	598
242. Uptake, storage, secretion and metabolism II	600
243. Control of posture and movement VI	604
244. Learning and memory: anatomy III	607
245. Cerebellum III	611
246. Ingestive behaviors I	614
247. Neuroethology II	617
248. Epilepsy: anti-epileptic drugs	621
249. Visual psychophysics and behavior II	623
250. Hypothalamic-pituitary-gonadal regulation I	626
251. Regulation of autonomic functions II	630
252. Behavioral pharmacology: benzodiazepines and stimulants	632

Session Number and Title	Page
253. Drugs of abuse	636
Presidential Special Lecture—4:15 p.m.	
254. The Relation of Speech to Other Specializations. A. Liberman	No abstract
Grass Foundation Lecture—8:00 p.m.	
255. Ionic Channels: Modulation by G Protein Coupled Receptors and Second Messengers. B. Hille	No abstract

WEDNESDAY

Symposia—8:30 a.m.	
256. Progress in Research on D1 Dopamine Receptors. *Chaired by:* R.E. Chipkin	639
257. Computing Motion in Flies, Monkeys and Man: Linking Physiology with Psychophysics and Computational Theory. *Chaired by:* C. Koch	639
Slide Sessions—8:30 a.m.	
258. Learning and memory: anatomy IV	639
259. GABA and benzodiazepine receptors I	641
260. Excitatory amino acids: anatomy and physiology I	643
261. Gene structure and function I	645
262. Alzheimer's disease: amyloid I	647
263. Process outgrowth, growth cones and guidance mechanisms IV	649
264. Calcium channels III	651
265. Genetic models of nervous disorders III	653
266. Ingestive behaviors II	655
267. Second messengers III	657
268. Sensorimotor integration	659
269. Regulation of autonomic functions III	661
270. Opiates, endorphins and enkephalins: physiological effects III	663
271. Transmitters in invertebrates III	665
Poster Sessions—8:30 a.m.	
272. GABA and benzodiazepines II	667
273. Peptides: receptors III	670
274. Serotonin receptors IV	673
275. Nicotinic receptors	675
276. Synaptic structure and function II	680
277. Adrenal medullary regulation	683
278. Developmental disorders: genetic and chemical models	684
279. Neurotoxicity II	686
280. Differentiation, morphogenesis and development: glia	689
281. Control of posture and movement VII	691
282. Spinal cord and brainstem: cord anatomy	694
283. Mental illness: schizophrenia	697
284. Epilepsy: basic mechanisms II	700
285. Opiates, endorphins and enkephalins: anatomy and chemistry I	702
286. Trophic agents III	704
287. Trophic agents IV	708
288. Neuropeptides and behavior	711
289. Neural-immune interactions III	713
290. Hypothalamic-pituitary-adrenal regulation I	715
291. Neural-immune interactions IV	718
292. Neuroendocrine regulation: prolactin	721
293. Biological rhythms and sleep: other II	724
294. Human behavioral neurobiology: other II	728
295. Learning and memory—pharmacology: acetylcholine I	731
296. Learning and memory—pharmacology: acetylcholine II	733
297. Transmitters in invertebrates IV	736
298. Peptides: anatomical localization III	739
299. Auditory system: cochlear nucleus	742
300. Auditory system: brainstem and higher nuclei	745
301. Chemical senses: peripheral olfaction	748
302. Chemical senses: taste and carotid receptors	751
303. Spinal cord	754
304. Hormonal control of behavior II	758
305. Excitatory amino acids: excitotoxicity II	761
306. Excitatory amino acids: excitotoxicity III	764
307. Excitatory amino acids: excitotoxicity IV	768
308. Regional localization of receptors and neurotransmitters III	771
309. Learning and memory: physiology III	773
310. Epilepsy: kindling II	777
311. Neural plasticity in adult animals: monoamines and ACH	780
312. Oculomotor system II	783
313. Cortex III	786
314. Cortex IV	788
315. Subcortical visual pathways III	790
316. Visual system: development and plasticity IV	793
Presidential Special Lecture—11:45 a.m.	
317. Visual Perceptions in People and Machines. V.S. Ramachandran	No abstract
Symposia—1:00 p.m.	
318. Mesopontine Cholinergic Neurons: The Neuronal Substrate of the Ascending Reticular Activating System? *Chaired by:* P.B. Reiner	797
319. Hebbian Synapse: Learning Rules and Mechanisms. *Chaired by:* J. Lisman	797
Slide Sessions—1:00 p.m.	
320. Visual cortex IV	797
321. Hypothalamic-pituitary-adrenal regulation II	799
322. Drugs of abuse: cocaine II	801
323. Ischemia	803
324. Oculomotor system III	806
325. Morphogenesis and differentiation	808
326. Interactions between neurotransmitters III	810
327. Cardiovascular regulation III	812
328. Uptake, storage, secretion and metabolism III	814
329. Somatic and visceral afferents III	816
330. Catecholamines I	818
331. Blood-brain barrier I	820

Session Number and Title	Page
Poster Sessions—1:00 p.m.	
332. Calcium channels IV	822
333. Ligand-gated ion channels: cholinergic	826
334. Ligand-gated ion channels: glutamate	828
335. GABA and benzodiazepine receptors II	830
336. Second messengers: protein phosphorylation	832
337. Peptides: anatomical localization IV	835
338. Peptides: biosynthesis, metabolism and biochemical characterization III	838
339. mRNA regulation III	841
340. Opiates, endorphins and enkephalins: behavioral effects	844
341. Pain modulation: afferent mechanisms	847
342. Psychotherapeutic drugs: antidepressants	850
343. Brain metabolism and blood flow II	854
344. Alzheimer's disease: transmitters and behavior	858
345. Trophic agents V	864
346. Trophic agents VI	867
347. Regeneration: CNS II	870
348. Process outgrowth, growth cones and guidance mechanisms V	873
349. Process outgrowth, growth cones and guidance mechanisms VI	875
350. Regeneration: cell biology	878
351. Regeneration: PNS	881
352. Cell lineage and determination III	884
353. Nutrition and prenatal factors	886
354. Learning and memory: anatomy V	888
355. Membrane composition and cell surface macromolecules II	891
356. Ingestive behaviors III	894
357. Regulation of autonomic functions IV	897
358. Basal ganglia and thalamus III	900
359. Basal ganglia and thalamus IV	904
360. Basal ganglia and thalamus V	907
361. Basal ganglia and thalamus VI	910
362. Basal ganglia and thalamus VII	912
363. Motor systems: reflex function I	914
364. Motor systems: reflex function II	917
365. Spinal cord and brainstem: cord physiology	919
366. Retina III	922
367. Chemical senses: olfactory pathways and processing	926
368. Chemical senses: gustatory pathways	929
369. Degenerative disease: other I	931
370. Degenerative disease: other II	934
371. Degenerative disease: Parkinson's III	937
372. Excitatory amino acids: anatomy and physiology II	940
373. Excitatory amino acids: anatomy and physiology III	943
374. Excitatory amino acids: anatomy and physiology IV	946
375. Neuroendocrine regulation: photoperiod/pineal	949
Presidential Special Lecture—4:15 p.m.	
376. Cognitive Illusions in Judgement and Choice. A. Tversky	No abstract

Session Number and Title	Page
THURSDAY	
Symposia—8:30 a.m.	
377. The Basal Ganglia: Structure and Function. *Chaired by:* M.R. DeLong	952
378. Instructive Effects of Activity in the Developing Visual Pathway. *Chaired by:* M. Constantine-Paton	952
Slide Sessions—8:30 a.m.	
379. Trophic agents VII	953
380. Excitatory amino acids: receptors VI	955
381. Gene structure and function II	957
382. Process outgrowth, growth cones and guidance mechanisms VII	959
383. Neural plasticity in adult animals II	961
384. Ingestive behaviors IV	963
385. Cardiovascular regulation IV	965
386. Retina IV	967
387. Ligand-gated ion channels I	969
388. Peptides: physiological effects III	971
389. Receptor modulation: up and down regulation I	974
Poster Sessions—8:30 a.m.	
390. Neural plasticity in adult animals: limbic system	976
391. Limbic system I	979
392. Opiates, endorphins and enkephalins: anatomy and chemistry II	980
393. mRNA regulation IV	984
394. Peptides: receptors IV	987
395. Potassium channels IV	990
396. Potassium channels: modulation and regulation	992
397. GABA and benzodiazepine receptors III	994
398. GABA and benzodiazepines III	997
399. Catecholamines II	999
400. Second messengers: calcium	1003
401. Second messengers: phosphoinositide turnover	1005
402. Catecholamines: neurotoxicity	1009
403. Catecholamines III	1011
404. Differentiation, morphogenesis and development: transmitters and enzymes	1015
405. Biochemical and pharmacological correlates of development II	1017
406. Differentiation, morphogenesis and development: channels and currents	1020
407. Neurotoxicity: metals and organics	1021
408. Nutrition and prenatal factors: substances of abuse	1023
409. Blood-brain barrier II	1025
410. Process outgrowth, growth cones and guidance mechanisms VIII	1027
411. Epilepsy: basic mechanisms III	1030
412. Neuromuscular disease	1033
413. Process outgrowth, growth cones and guidance mechanisms IX	1036
414. Alzheimer's disease: neuropathology	1038
415. Circuitry and pattern generation: vertebrates	1044
416. Circuitry and pattern generation: invertebrates and models	1046
417. Somatosensory system I	1050

Session Number and Title	Page
418. Somatosensory cortex and thalamocortical relationships III	1051
419. Visual cortex V	1054
420. Biological rhythms and sleep: other III	1058
421. Interhemispheric relations	1060
422. Behavioral pharmacology: dopamine	1063
423. Neuropeptides and behavior: CCK	1067
424. Neuropeptides and behavior: CRF	1068
425. Neuropeptides and behavior: oxytocin and vasopressin	1069
426. Regulation of autonomic functions V	1071
427. Epilepsy: benzodiazepines and inhibitor amino acids	1073
428. Neuroendocrine regulation: neurohypophysial peptides	1075
429. Hypothalamic-pituitary-adrenal regulation III	1079
430. Hypothalamic-pituitary-gonadal regulation II	1082
431. Hypothalamus	1085
432. Drugs of abuse: dopamine mechanisms	1090
433. Transplantation: hippocampus and basal forebrain	1093
434. Drugs of abuse: CNS pathways	1095
435. Hormonal control of behavior III	1099
436. Long-term potentiation IV	1101
437. Learning and memory: anatomy VI	1104
Warner-Lambert Lecture—11:45 a.m.	
438. Mechanisms Underlying the Self-Organization of Visual Cortex Functions. W. Singer	No abstract
Symposia—1:00 p.m.	
439. Neuropeptide Regulation of Reproduction. *Chaired by:* P.E. Micevych	1106
440. Inhibitory Influences on Growth Cones and Cells. *Chaired by:* M.E. Schwab	1106
Slide Sessions—1:00 p.m.	
441. Visual cortex VI	1106
442. Biochemical and pharmacological correlates of development III	1108
443. Alzheimer's disease II	1110
444. Trauma III	1112
445. Auditory system	1114
446. Invertebrate learning and behavior I	1116
447. Circuitry and pattern generation	1118
448. Differentiation, morphogenesis and development: cellular and molecular studies III	1120
449. Mental illness	1122
Poster Sessions—1:00 p.m.	
450. Gene structure and function III	1124
451. mRNA regulation V	1127
452. Ingestive behaviors V	1130
453. Monoamines and behavior III	1133
454. Neuroethology III	1135
455. Invertebrate learning and behavior II	1139
456. Ion channels: cell function	1142
457. Calcium channels: modulation and regulation	1147
458. Ligand-gated ion channels II	1150
459. GABA and benzodiazepine receptors IV	1152
460. Monoamines and behavior IV	1155
461. Excitatory amino acids: receptors VII	1159
462. Excitatory amino acids: receptors VIII	1162
463. Excitatory amino acids: receptors IX	1165
464. Learning and memory—pharmacology: other I	1169
465. Learning and memory—pharmacology: other II	1172
466. Behavioral pharmacology: other	1174
467. Cardiovascular regulation V	1177
468. Cardiovascular regulation VI	1180
469. Drugs of abuse: stimulants	1185
470. Pain pathways: CNS	1188
471. Respiratory regulation II	1191
472. Acetylcholine IV	1194
473. Control of posture and movement VIII	1198
474. Control of posture and movement IX	1199
475. Oculomotor system IV	1202
476. Retina V	1206
477. Visual system: development and plasticity V	1210
478. Epilepsy: excitatory amino acids	1213
479. Receptor modulation: up and down regulation II	1216
480. Blood-brain barrier III	1219
481. Neural plasticity in adult animals: sensory systems	1221
482. Catecholamines IV	1225
483. Catecholamines: anatomy	1229
484. Neurotoxicity: MPTP and excitotoxic	1231
485. Psychotherapeutic drugs	1233
486. Clinical CNS neurophysiology	1237
487. Transplantation: spinal cord	1241
488. Limbic system II	1243
489. Hippocampus and amygdala II	1246
490. Hippocampus and amygdala III	1249
491. Interactions between neurotransmitters IV	1252
Special Lecture—4:15 p.m.	
492. Microtubules and Cell Morphogenesis. M. Kirschner	No abstract

FRIDAY

Symposium—8:30 a.m.	
493. Melatonin: New Light on CNS Mechanisms of Action. *Chaired by:* D.N. Krause & M.L. Dubocovich	1255
Special Lecture—8:30 a.m.	
494. Ion Channel Proteins: Structure from Function. C. Miller	No abstract
Special Lecture—10:00 a.m.	
495. Neuronal Organization in the Cerebral Cortex. A. Peters	No abstract
Special Lecture—11:30 a.m.	
496. Signal Processing and Neural Networks in the Oculomotor System. D.A. Robinson	No abstract
Slide Sessions—8:30 a.m.	
497. Visual psychophysics and behavior III	1255
498. Regeneration II	1257
499. Trophic interactions I	1259

Session Number and Title	Page
500. Process outgrowth, growth cones and guidance mechanisms X	1261
501. Invertebrate learning and behavior III	1263
502. Pain pathways	1265
Poster Sessions—8:30 a.m.	
503. Gene structure and function IV	1267
504. mRNA regulation VI	1271
505. Uptake, storage, secretion and metabolism IV	1274
506. Peptides: biosynthesis, metabolism and biochemical characterization IV	1275
507. Ingestive behaviors VI	1277
508. Monoamines and behavior V	1281
509. Invertebrate learning and behavior IV	1283
510. Invertebrate sensory systems I	1286
511. Invertebrate sensory systems II	1290
512. Neuroethology IV	1292
513. Invertebrate motor function	1296
514. Ion channel modulation and regulation II	1299
515. Muscarinic receptors	1302
516. Postsynaptic mechanisms III	1307
517. Catecholamines V	1310
518. Catecholamines VI	1314
519. Receptor modulation: up and down regulation III	1316
520. Second messengers: adenylate cyclase	1320
521. Differentiation, morphogenesis and development: cytoskeleton	1323
522. Biological rhythms and sleep: other IV	1324
523. Differentiation, morphogenesis and development: molecular correlates	1327
524. Differentiation, morphogenesis and development: tissue culture models	1330
525. Somatosensory system II	1331
526. Developmental disorders: human diseases	1333
527. Visual system: development and plasticity VI	1335
528. Hypothalamic-pituitary-gonadal regulation III	1339
529. Ischemia: energy metabolism and ischemic models	1342
530. Neurotoxicity III	1346
531. Neurotoxicity IV	1349
532. Synaptogenesis: neuromuscular junction	1351
533. Transplantation: striatum I	1353
534. Transplantation: striatum II	1356
535. Trophic interactions II	1359
536. Trophic interactions III	1361
537. Trophic interactions IV	1364
538. Transplantation: retina	1367
539. Transplantation III	1368
540. Neuroendocrine regulation II	1371
541. Alzheimer's disease: amyloid II	1375
542. Aging II	1379
543. Infectious disease	1385
544. Synaptogenesis II	1387
545. Subcortical visual pathways IV	1391
546. Retina VI	1395
547. Visual cortex VII	1397

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only.)

Session Number	Session Title	Type	Day and Time
Theme A: Development and Plasticity			
106.	Aging I	Poster	Mon PM
542.	Aging II	Poster	Fri AM
117.	Auditory, olfactory and other sensory systems	Poster	Mon PM
118.	Biochemical and pharmacological correlates of development I	Poster	Mon PM
405.	Biochemical and pharmacological correlates of development II	Poster	Thu AM
442.	Biochemical and pharmacological correlates of development III	Slide	Thu PM
9.	Cell lineage and determination I	Slide	Mon AM
241.	Cell lineage and determination II	Poster	Tue PM
352.	Cell lineage and determination III	Poster	Wed PM
238.	Differentiation, morphogenesis and development: cell surface components	Poster	Tue PM
134.	Differentiation, morphogenesis and development: cellular and molecular studies I	Slide	Tue AM
204.	Differentiation, morphogenesis and development: cellular and molecular studies II	Slide	Tue PM
448.	Differentiation, morphogenesis and development: cellular and molecular studies III	Slide	Thu PM
406.	Differentiation, morphogenesis and development: channels and currents	Poster	Thu AM
521.	Differentiation, morphogenesis and development: cytoskeleton	Poster	Fri AM
178.	Differentiation, morphogenesis and development: fiber guidance and synaptogenesis	Poster	Tue AM
111.	Differentiation, morphogenesis and development: forebrain	Poster	Mon PM
280.	Differentiation, morphogenesis and development: glia	Poster	Wed AM
523.	Differentiation, morphogenesis and development: molecular correlates	Poster	Fri AM
237.	Differentiation, morphogenesis and development: neurogenesis and control of neuron number	Poster	Tue PM
153.	Differentiation, morphogenesis and development: neuromuscular development	Poster	Tue AM
46.	Differentiation, morphogenesis and development: position and form	Poster	Mon AM
524.	Differentiation, morphogenesis and development: tissue culture models	Poster	Fri AM
404.	Differentiation, morphogenesis and development: transmitters and enzymes	Poster	Thu AM
39.	Endocrine control and development I	Poster	Mon AM
42.	Endocrine control and development II	Poster	Mon AM
233.	Endocrine control and development III	Poster	Tue PM
234.	Endocrine control and development IV	Poster	Tue PM
68.	**From Early Embryogenesis to Circuits: Cellular and Molecular Strategies Applied to the Analysis of Vertebrate Brain Development**	**Symp.**	**Mon PM**
319.	**Hebbian Synapse: Learning Rules and Mechanisms**	**Symp.**	**Wed PM**
440.	**Inhibitory Influences on Growth Cones and Cells**	**Symp.**	**Thu PM**
378.	**Instructive Effects of Activity in the Developing Visual Pathway**	**Symp.**	**Thu AM**
391.	Limbic system I	Poster	Thu AM
38.	Long-term potentiation I	Poster	Mon AM
71.	Long-term potentiation II	Slide	Mon PM
162.	Long-term potentiation III	Poster	Tue AM
436.	Long-term potentiation IV	Poster	Thu AM
325.	Morphogenesis and differentiation	Slide	Wed PM
30.	Motor systems I	Poster	Mon AM
31.	Motor systems II	Poster	Mon AM
32.	Motor systems III	Poster	Mon AM
13.	Neural plasticity in adult animals I	Slide	Mon AM
383.	Neural plasticity in adult animals II	Slide	Thu AM
390.	Neural plasticity in adult animals: limbic system	Poster	Thu AM
311.	Neural plasticity in adult animals: monoamines and ACH	Poster	Wed AM
120.	Neural plasticity in adult animals: motor systems	Poster	Mon PM
481.	Neural plasticity in adult animals: sensory systems	Poster	Thu PM
177.	Neuronal death: lesion induced	Poster	Tue AM
175.	Neuronal death: models and mechanisms	Poster	Tue AM
279.	Neurotoxicity II	Poster	Wed AM
484.	Neurotoxicity: MPTP and excitotoxic	Poster	Thu PM
407.	Neurotoxicity: metals and organics	Poster	Thu AM

Session Number	Session Title	Type	Day and Time
353.	Nutrition and prenatal factors	Poster	Wed PM
408.	Nutrition and prenatal factors: substances of abuse	Poster	Thu AM
136.	Process outgrowth, growth cones and guidance mechanisms I	Slide	Tue AM
231.	Process outgrowth, growth cones and guidance mechanisms II	Poster	Tue PM
232.	Process outgrowth, growth cones and guidance mechanisms III	Poster	Tue PM
263.	Process outgrowth, growth cones and guidance mechanisms IV	Slide	Wed AM
348.	Process outgrowth, growth cones and guidance mechanisms V	Poster	Wed PM
349.	Process outgrowth, growth cones and guidance mechanisms VI	Poster	Wed PM
382.	Process outgrowth, growth cones and guidance mechanisms VII	Slide	Thu AM
410.	Process outgrowth, growth cones and guidance mechanisms VIII	Poster	Thu AM
413.	Process outgrowth, growth cones and guidance mechanisms IX	Poster	Thu AM
500.	Process outgrowth, growth cones and guidance mechanisms X	Slide	Fri AM
137.	Regeneration I	Slide	Tue AM
498.	Regeneration II	Slide	Fri AM
127.	Regeneration: CNS I	Poster	Mon PM
347.	Regeneration: CNS II	Poster	Wed PM
126.	Regeneration: GAP43	Poster	Mon PM
351.	Regeneration: PNS	Poster	Wed PM
350.	Regeneration: cell biology	Poster	Wed PM
125.	Regeneration: general	Poster	Mon PM
417.	Somatosensory system I	Poster	Thu AM
525.	Somatosensory system II	Poster	Fri AM
55.	Specificity of synaptic connections	Poster	Mon AM
40.	Sprouting and sprouting mechanisms I	Poster	Mon AM
41.	Sprouting and sprouting mechanisms II	Poster	Mon AM
70.	Synaptogenesis I	Slide	Mon PM
544.	Synaptogenesis II	Poster	Fri AM
532.	Synaptogenesis: neuromuscular junction	Poster	Fri AM
14.	The aging process	Slide	Mon AM
8.	Transplantation I	Slide	Mon AM
200.	Transplantation II	Slide	Tue PM
539.	Transplantation III	Poster	Fri AM
108.	Transplantation: cortex and brainstem	Poster	Mon PM
433.	Transplantation: hippocampus and basal forebrain	Poster	Thu AM
538.	Transplantation: retina	Poster	Fri AM
487.	Transplantation: spinal cord	Poster	Thu PM
533.	Transplantation: striatum I	Poster	Fri AM
534.	Transplantation: striatum II	Poster	Fri AM
12.	Trophic agents I	Slide	Mon AM
112.	Trophic agents II	Poster	Mon PM
286.	Trophic agents III	Poster	Wed AM
287.	Trophic agents IV	Poster	Wed AM
345.	Trophic agents V	Poster	Wed PM
346.	Trophic agents VI	Poster	Wed PM
379.	Trophic agents VII	Slide	Thu AM
499.	Trophic interactions I	Slide	Fri AM
535.	Trophic interactions II	Poster	Fri AM
536.	Trophic interactions III	Poster	Fri AM
537.	Trophic interactions IV	Poster	Fri AM
4.	Visual system: development and plasticity I	Slide	Mon AM
182.	Visual system: development and plasticity II	Poster	Tue AM
202.	Visual system: development and plasticity III	Slide	Tue PM
316.	Visual system: development and plasticity IV	Poster	Wed AM
477.	Visual system: development and plasticity V	Poster	Thu PM
527.	Visual system: development and plasticity VI	Poster	Fri AM

Session Number	Session Title	Type	Day and Time
Theme B: Cell Biology			
331.	Blood-brain barrier I	Slide	Wed PM
409.	Blood-brain barrier II	Poster	Thu AM
480.	Blood-brain barrier III	Poster	Thu PM
65.	Cytoskeleton, transport and membrane targeting	Poster	Mon AM
261.	Gene structure and function I	Slide	Wed AM
381.	Gene structure and function II	Slide	Thu AM
450.	Gene structure and function III	Poster	Thu PM
503.	Gene structure and function IV	Poster	Fri AM
230.	Membrane composition and cell surface macromolecules I	Poster	Tue PM
355.	Membrane composition and cell surface macromolecules II	Poster	Wed PM
142.	mRNA regulation I	Slide	Tue AM
205.	mRNA regulation II	Slide	Tue PM
339.	mRNA regulation III	Poster	Wed PM
393.	mRNA regulation IV	Poster	Thu AM
451.	mRNA regulation V	Poster	Thu PM
504.	mRNA regulation VI	Poster	Fri AM
10.	Neuroglia	Slide	Mon AM
209.	Neuroglia in disease	Poster	Tue PM
146.	Neuroglia: active membrane responses	Poster	Tue AM
145.	Neuroglia: myelin and myelin-forming cells	Poster	Tue AM
210.	Neuroglia: structure and biology	Poster	Tue PM
122.	Staining and tracing techniques	Poster	Mon PM
Theme C: Excitable Membranes and Synaptic Transmission			
11.	Calcium channels I	Slide	Mon AM
147.	Calcium channels II	Poster	Tue AM
264.	Calcium channels III	Slide	Wed AM
332.	Calcium channels IV	Poster	Wed PM
457.	Calcium channels: modulation and regulation	Poster	Thu PM
76.	Ion channel modulation and regulation I	Slide	Mon PM
514.	Ion channel modulation and regulation II	Poster	Fri AM
456.	Ion channels: cell function	Poster	Thu PM
36.	Ion channels: chloride and miscellaneous	Poster	Mon AM
387.	Ligand-gated ion channels I	Slide	Thu AM
458.	Ligand-gated ion channels II	Poster	Thu PM
333.	Ligand-gated ion channels: cholinergic	Poster	Wed PM
334.	Ligand-gated ion channels: glutamate	Poster	Wed PM
84.	Pharmacology of synaptic transmission	Poster	Mon PM
216.	Pharmacology of synaptic transmission: amino acids and calcium channels	Poster	Tue PM
79.	Postsynaptic mechanisms I	Slide	Mon PM
215.	Postsynaptic mechanisms II	Poster	Tue PM
516.	Postsynaptic mechanisms III	Poster	Fri AM
35.	Potassium channels I	Poster	Mon AM
139.	Potassium channels II	Slide	Tue AM
220.	Potassium channels III	Poster	Tue PM
395.	Potassium channels IV	Poster	Thu AM
396.	Potassium channels: modulation and regulation	Poster	Thu AM
83.	Presynaptic mechanisms I	Poster	Mon PM
197.	Presynaptic mechanisms II	Slide	Tue PM
189.	Presynaptic mechanisms: calcium	Poster	Tue AM
190.	Presynaptic mechanisms: facilitation and depression	Poster	Tue AM
85.	Sodium channels I	Poster	Mon PM
219.	Sodium channels II	Poster	Tue PM
105.	Synaptic structure and function I	Poster	Mon PM
276.	Synaptic structure and function II	Poster	Wed AM

Session Number	Session Title	Type	Day and Time
Theme D: Neurotransmitters, Modulators, and Receptors			
29.	Acetylcholine I	Poster	Mon AM
165.	Acetylcholine II	Poster	Tue AM
226.	Acetylcholine III	Poster	Tue PM
472.	Acetylcholine IV	Poster	Thu PM
102.	Behavioral pharmacology: analgesics and NMDA	Poster	Mon PM
252.	Behavioral pharmacology: benzodiazepines and stimulants	Poster	Tue PM
422.	Behavioral pharmacology: dopamine	Poster	Thu AM
466.	Behavioral pharmacology: other	Poster	Thu PM
73.	Catecholamine receptors	Slide	Mon PM
173.	Catecholamine receptors: adrenergic	Poster	Tue AM
172.	Catecholamine receptors: dopaminergic	Poster	Tue AM
171.	Catecholamine receptors: dopaminergic (D1)	Poster	Tue AM
170.	Catecholamine receptors: dopaminergic (D2)	Poster	Tue AM
330.	Catecholamines I	Slide	Wed PM
399.	Catecholamines II	Poster	Thu AM
403.	Catecholamines III	Poster	Thu AM
482.	Catecholamines IV	Poster	Thu PM
517.	Catecholamines V	Poster	Fri AM
518.	Catecholamines VI	Poster	Fri AM
483.	Catecholamines: anatomy	Poster	Thu PM
402.	Catecholamines: neurotoxicity	Poster	Thu AM
203.	Cholinergic receptors	Slide	Tue PM
260.	Excitatory amino acids: anatomy and physiology I	Slide	Wed AM
372.	Excitatory amino acids: anatomy and physiology II	Poster	Wed PM
373.	Excitatory amino acids: anatomy and physiology III	Poster	Wed PM
374.	Excitatory amino acids: anatomy and physiology IV	Poster	Wed PM
195.	Excitatory amino acids: excitotoxicity I	Slide	Tue PM
305.	Excitatory amino acids: excitotoxicity II	Poster	Wed AM
306.	Excitatory amino acids: excitotoxicity III	Poster	Wed AM
307.	Excitatory amino acids: excitotoxicity IV	Poster	Wed AM
86.	Excitatory amino acids: receptors I	Poster	Mon PM
87.	Excitatory amino acids: receptors II	Poster	Mon PM
133.	Excitatory amino acids: receptors III	Slide	Tue AM
217.	Excitatory amino acids: receptors IV	Poster	Tue PM
218.	Excitatory amino acids: receptors V	Poster	Tue PM
380.	Excitatory amino acids: receptors VI	Slide	Thu AM
461.	Excitatory amino acids: receptors VII	Poster	Thu PM
462.	Excitatory amino acids: receptors VIII	Poster	Thu PM
463.	Excitatory amino acids: receptors IX	Poster	Thu PM
259.	GABA and benzodiazepine receptors I	Slide	Wed AM
335.	GABA and benzodiazepine receptors II	Poster	Wed PM
397.	GABA and benzodiazepine receptors III	Poster	Thu AM
459.	GABA and benzodiazepine receptors IV	Poster	Thu PM
199.	GABA and benzodiazepines I	Slide	Tue PM
272.	GABA and benzodiazepines II	Poster	Wed AM
398.	GABA and benzodiazepines III	Poster	Thu AM
95.	Interactions between neurotransmitters I	Poster	Mon PM
235.	Interactions between neurotransmitters II	Poster	Tue PM
326.	Interactions between neurotransmitters III	Slide	Wed PM
491.	Interactions between neurotransmitters IV	Poster	Thu PM
318.	**Mesopontine Cholinergic Neurons: The Neuronal Substrate of the Ascending Reticular Activating System?**	**Symp.**	**Wed PM**
515.	Muscarinic receptors	Poster	Fri AM
275.	Nicotinic receptors	Poster	Wed AM
285.	Opiates, endorphins and enkephalins: anatomy and chemistry I	Poster	Wed AM
392.	Opiates, endorphins and enkephalins: anatomy and chemistry II	Poster	Thu AM
340.	Opiates, endorphins and enkephalins: behavioral effects	Poster	Wed PM

Session Number	Session Title	Type	Day and Time
62.	Opiates, endorphins and enkephalins: physiological effects I	Poster	Mon AM
221.	Opiates, endorphins and enkephalins: physiological effects II	Poster	Tue PM
270.	Opiates, endorphins and enkephalins: physiological effects III	Slide	Wed AM
61.	Opiates, endorphins and enkephalins: tolerance and dependence	Poster	Mon AM
97.	Other biogenic amines and purines: adenosine and histamine	Poster	Mon PM
81.	Peptides: anatomical localization I	Slide	Mon PM
228.	Peptides: anatomical localization II	Poster	Tue PM
298.	Peptides: anatomical localization III	Poster	Wed AM
337.	Peptides: anatomical localization IV	Poster	Wed PM
80.	Peptides: biosynthesis, metabolism and biochemical characterization I	Slide	Mon PM
151.	Peptides: biosynthesis, metabolism and biochemical characterization II	Poster	Tue AM
338.	Peptides: biosynthesis, metabolism and biochemical characterization III	Poster	Wed PM
506.	Peptides: biosynthesis, metabolism and biochemical characterization IV	Poster	Fri AM
91.	Peptides: physiological effects I	Poster	Mon PM
92.	Peptides: physiological effects II	Poster	Mon PM
388.	Peptides: physiological effects III	Slide	Thu AM
143.	Peptides: receptors I	Slide	Tue AM
229.	Peptides: receptors II	Poster	Tue PM
273.	Peptides: receptors III	Poster	Wed AM
394.	Peptides: receptors IV	Poster	Thu AM
256.	**Progress in Research on D1 Dopamine Receptors**	**Symp.**	**Wed AM**
389.	Receptor modulation: up and down regulation I	Slide	Thu AM
479.	Receptor modulation: up and down regulation II	Poster	Thu PM
519.	Receptor modulation: up and down regulation III	Poster	Fri AM
96.	Regional localization of receptors and neurotransmitters I	Poster	Mon PM
236.	Regional localization of receptors and neurotransmitters II	Poster	Tue PM
308.	Regional localization of receptors and neurotransmitters III	Poster	Wed AM
72.	Second messengers I	Slide	Mon PM
174.	Second messengers II	Poster	Tue AM
267.	Second messengers III	Slide	Wed AM
520.	Second messengers: adenylate cyclase	Poster	Fri AM
400.	Second messengers: calcium	Poster	Thu AM
401.	Second messengers: phosphoinositide turnover	Poster	Thu AM

SYMPOSIUM: THE NEUROBIOLOGY OF NEUROPEPTIDE Y (NPY). W.F. Colmers, Univ. of Alberta (Chairperson); J. M. Allen, Roy. Postgrad. Med. Sch.; S.H.C. Hendry, U.C. Irvine; C. Wahlestedt Fidia-Georgetown Inst. Neurosci.; T.A. Westfall, St. Louis Univ.; R.J. Miller, Univ. Chicago.

NPY, discovered in 1982, is one of the most abundant peptides in the nervous system, and is distributed broadly throughout phylogeny. This symposium will examine the present state of knowledge on NPY, its receptors and their physiological effects. cDNA sequences for rat and human NPY are remarkably well conserved; the deduced amino acid sequences are identical. These data also permit comparisons with sequences encoding other related peptides. NPY exists in several classes of neurons: 1) interneurons (NPY + amines or amino acids) 2) interneurons (NPY + peptide(s)); 3) projection neurons (NPY + classical transmitters). Actions of NPY in a given system may be predictable based on its co-transmitters. NPY receptors have effects by themselves, and mediate interactions with other receptors. In PNS, there are 2 types of NPY receptors: the postjunctional (Y_1) receptor mediates excitation in smooth muscle and (at lower concentrations) modulates excitatory effects of other transmitters, while the prejunctional (Y_2) receptor inhibits release of noradrenaline. NPY is involved in many physiological functions, e.g. cardiovascular control, reproduction, feeding, etc., and may be associated with major depression/anxiety in patients. Microinjection of NPY into posterior hypothalamus (which has interneurons 1) and 2) above), increases blood pressure by sympathetic excitation, but intrathecal injections reduce blood pressure by decreasing sympathetic outflow. In slices of hippocampus (interneurons: NPY + GABA), NPY presynaptically inhibits transmission at some, but not all, excitatory pathways, probably by reducing Ca^{++} influx at nerve terminals. This action does not involve a pertussis toxin (PTX)-sensitive G-protein. In cultured rat sensory neurons, NPY inhibits voltage-dependent Ca^{++}influx, in part possibly by activation of phosphatidyl inositide metabolism, an action which is sensitive to PTX.

3

SYMPOSIUM. FUNCTIONAL ORGANIZATION OF THE THALAMUS. S.M. Sherman, SUNY at Stony Brook (Chairperson); E.G. Jones, U.C. Irvine; D.A. Prince, Stanford Univ.; H.J. Ralston, U.C.S.F.

Advances in our understanding of the thalamus have been dramatic in recent years. We have learned much about its overall organization and connectivity. We also now appreciate its role as a variable gateway in the relay of information to cortex, and we are beginning to understand the cellular mechanisms underlying this role. The symposium will cover certain highlights of these advances. *E.G. Jones* will begin with an overview of thalamic organization and thalamocortical relationships. He will also discuss new findings relating morphological, functional, and neurochemical characteristics of thalamic neurons to differential thalamocortical projections. *D.A. Prince* will discuss properties of the low threshold calcium current (LTCC) which underlies burst generation in thalamocortical relay neurons and factors controlling it, including modulation of LTCC by changes in intracellular second messengers and by anticonvulsant drugs. *H.J. Ralston* will use the ventral posterolateral nucleus as a model to describe details of intrinsic thalamic organization, and *S.M. Sherman* will do likewise for the lateral geniculate nucleus. These latter two talks will emphasize the wealth and complexity of thalamic circuitry available to underlie gating functions in the thalamocortical transmission of sensory information.

VISUAL SYSTEM: DEVELOPMENT AND PLASTICITY I

4.1

TRANSIENT EXPRESSION OF A SUBPLATE-SPECIFIC ANTIGEN IN CAT VISUAL CORTEX. J.R. Naegele, C.J. Barnstable and P. Wahle, Dept of Ophthalmology and Visual Sciences, Yale University School of Medicine, New Haven, CT 06510

Transient neurons of the cerebral cortical subplate are thought to play a central role in establishing mature connections. No specific markers have yet been identified that distinguish subplate from cortical plate neurons. We used a novel immunlogical approach to generate monoclonal antibodies against subplate neurons. One of these antibodies stained cortical subplate neurons selectively. This marker, called **Subplate1**, has been characterized further using immunocytochemical double-labeling with antisera against various neuropeptides and GABA.

On the day of birth (P1) and until P21, Subplate1 stained neurons restricted to the cortical subplate. The strongest immunoreactivity appeared within cell bodies, dendrites, axons and growth cones. Several morphologically distinct types were labeled, including inverted pyramids and multipolar forms. Fainter immunoreactivity was also present throughout the subplate neuropil. The immunoreactive staining of subplate neurons was strongest between P1 and P12, diminished by P21 and was absent by adulthood. Subplate1+ neurons were biochemically heterogeneous; nearly half were Somatostatin+, but only a minority were Neuropeptide Y+ or GABA+. These findings indicate that Subplate1 identifies a developmentally-regulated antigen expressed by early-generated, transient cortical neurons. (Supported by NIH grants EY07119 and EY05206).

4.2

SUBPLATE CELLS IN VISUAL CORTEX FUNCTION IN TRANSIENT SYNAPTIC MICROCIRCUITS. E. Friauf, S. K. McConnell and C. J. Shatz, Dept. Neurobiology, Stanford Univ. Med. Sch., Stanford, CA 94305.

During cat fetal development, the immature white matter below the cortical plate is filled with waiting axons, synapses and a special class of transient neurons, the subplate (SP) cells. We investigated whether SP neurons receive synaptic input and function in neural circuits. Intracellular recordings of SP cells were performed in cortical slices *in vitro*. Responses were elicited by electrical stimulation of the white matter. Subsequently, biocytin was injected iontophoretically to reveal the location and morphology of recorded cells. At all ages tested (E50 - P4), short latency EPSP's (average latency: 4.1 ms, range: 2.5-6.0 ms) and orthodromic spikes could be elicited from SP cells. When depolarized by current pulses, most SP neurons displayed a regular spiking pattern. The majority of biocytin-injected SP neurons resembled inverted pyramids. Their axons branched within the subplate; many also entered the cortical plate and ascended to the marginal zone. At neonatal ages, some axons collateralized within the cortical plate as well. Thus SP cells receive functional inputs from the white matter and send outputs to the cortical plate.

To examine the spatial and temporal sequence of synaptic activation in the developing cortex we used current source density analysis in conjunction with white matter stimulation *in vitro*. At E55, a short latency (monosynaptic) response is present in the SP, most likely mediated by inputs from waiting axons to SP neurons. A longer latency (polysynaptic) response is present at the top of the cortical plate. Since at E55, waiting axons have just begun to invade the cortical plate at its base, the polysynaptic pathway is likely to be mediated by ascending axons of SP neurons. Thus SP neurons may participate in a complex circuit during fetal and neonatal life, a circuit that disappears when waiting axons finally reach their adult targets.

Supported by NIH grants EY02858, EY06028 and a DAAD-fellowship.

4.3

RELATION BETWEEN NEUROCHEMICAL PHENOTYPE AND PROJECTION PATTERNS OF SUBPLATE NEURONS.
A. Antonini *and C.J. Shatz. (SPON: C.J.Shatz) Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305

During fetal and early postnatal development, the earliest generated cells of the mammalian telencephalon reside in a region of the white matter beneath the cortical plate (CP) designated the subplate (SP). Previous studies in cat (Chun, J.J. et al., Nature, 6105: 617, 1987) have shown that, although present only transiently during development, SP cells have features typical of mature CP neurons. They have complex dendritic and axonal arborizations and can be involved in local circuits or long range projections. SP cells are also immunoreactive for putative neurotransmitters such as GABA and for one of several neuropeptides including neuropeptide Y (NPY) and somatostatin (SRIF). Here we have examined whether there is a correlation between the neurotransmitter phenotype of SP cells and the targets of their axonal projections. To do so we used a double-label technique, with colloidal gold WGA-HRP or Diamidino-Yellow as retrograde tracer in combination with immunohistochemical visualization of NPY, SRIF or calbindin (used as a marker of a subtype of GABAergic neurons). SP cells in neonatal cats and ferrets were retrogradely labeled from either the thalamus, CP or hemispheric white matter. SP cells immunoreactive for neuropeptides or calbindin could be double labeled with retrograde tracers injected into the cortex or white matter, but never by thalamic injections. On the other hand, SP cells projecting to the thalamus could be labeled by the retrograde transport of 3H-aspartate. Thus, during development, SP neurons, like CP neurons in the adult, can be divided into local circuit neurons that are peptidergic or GABAergic, and projection neurons some of which are likely to employ excitatory amino acids as their transmitter.

Supported by NIH Grant EY02858

4.4

SUBPLATE NEURONS TRANSIENTLY EXPRESS NGF RECEPTOR IMMUNOREACTIVITY. K.L. Allendoerfer,* D.L. Shelton, E.M. Shooter, and C.J. Shatz. Dept. of Neurobiology, Stanford Univ., Stanford, CA 94305.

NGF and its receptor (NGFR) are now known to be present in diverse embryonic and neonatal CNS tissues including the cerebral cortex. We have used immunolabeling coupled with thymidine autoradiography to determine the identity of the cortical cells expressing the NGFR in cat and ferret brain during development. The antibody used for this study was a polyclonal serum generated to a synthetic peptide corresponding to a conserved sequence of the NGFR. Western blots show that this antibody recognizes specific NGFR and precursor proteins. In both species, NGFR immunoreactivity is associated with the transient, early-generated subplate neuron population, as supported by the following evidence: the immunoreactive cells 1) are located directly beneath the developing cortical plate, 2) have the inverted pyramid shape characteristic of many subplate neurons, and 3) can be labeled by an injection of ^{3}H-thymidine at E28, a time when only subplate neurons are being generated. In cat, strong immunostaining is seen associated with the cell bodies of these neurons as early as E30, two days after their birth, and it remains high for about three weeks. The NGFR immunoreactivity begins to decline around E52 and has disappeared from the region altogether by E60. The cellular localization and timing of expression suggest that the NGFR may play a role in subplate neuron maintenance and its loss may be involved in the subsequent death of subplate neurons.

TRANSMITTER-INDUCED CHANGES IN INTRACELLULAR FREE CALCIUM IN BRAIN SLICES OF DEVELOPING NEOCORTEX. R.M. Yuste* and L.C. Katz (SPON: J. Sparrow). Lab. of Neurobiology, The Rockefeller University, 1230 York Ave. New York, NY 10021.

Calcium flux through the NMDA channel may be a critical signal for establishment of long-term synaptic changes in adult and developing cortices. We have investigated the effects of putative cortical neurotransmitters on the intracellular concentration of free calcium ($[Ca^{+2}]_i$) in slices of developing rat visual and somatosensory cortices at postnatal days 2-10 (P2-10). Slices were loaded with 1-10 μM Fura-2 AM, and the changes in $[Ca^{+2}]_i$ of individual neurons in layer 2/3 were monitored using either a photodiode or a SIT video camera.

Neurons at all ages, even those which had just completed migration, were highly sensitive to glutamate and its analogues. All neurons responded within 30 seconds of application of drugs to the perfusion medium with a dramatic increase in $[Ca^{+2}]_i$ in the cell body and proximal dendrites. Threshold for responses were about 30 μM for glutamate, 10 μM for NMDA and ibotenic acid, and 1 μM for quisqualate. After the agonist was removed, $[Ca^{+2}]_i$ returned to baseline in under 3 minutes. No persistent elevation of $[Ca^{+2}]_i$ in cell bodies was detected. Single electrical shocks of the underlying white matter caused transient increases in $[Ca^{+2}]_i$; trains of shocks prolonged the increase, but $[Ca^{+2}]_i$ still returned to baseline after a few seconds.No elevation in $[Ca^{+2}]_i$ was detected in response to norepinephrine (200 μM), substance P (10 μM), somatostatin (10 μM), phorbol esters (PdAc and PdBu) or caffeine. Furthermore, none of these clearly potentiated the increase in $[Ca^{+2}]_i$ elicited by glutamate or NMDA. However, acetylcholine (50 μM) markedly increased $[Ca^{+2}]_i$; this increase was blocked by atropine. By combining optical techniques with brain slices, it is possible to observe the responses of single cells, as well as modulatory interactions, while preserving much of the intrinsic organization of the cortex. Supported by the L.P. Markey Charitable Trust.

EARLY POSTNATAL DEVELOPMENT OF SYNAPTIC AND POTASSIUM CURRENTS IN THE VISUAL CORTEX OF THE RAT. J.J. LoTurco, M.G. Blanton, and A.R. Kriegstein, Dept. of Neurology and the Neurosciences Program, Stanford Univ. Sch. of Med., Stanford, CA 94305.

Whole-cell voltage-clamp recordings were made in slices of visual cortex from 0 to 20 day old rats. Recorded cells were labeled with either Lucifer Yellow CH or biocytin so that location and morphology could be determined for each neuron.

During the first postnatal week, spontaneous synaptic currents were present in neurons within the cortical plate . These spontaneous currents were infrequent, small, and reversed near the equilibrium potential for monovalent cations (4 mV). Stimulation within the cortical layers evoked small currents that resembled the spontaneous currents. The pyramidal cells labeled on these earliest days had descending axons with horizontal collaterals that may be the presynaptic elements of the observed synaptic currents. Through the second and third weeks the frequency of spontaneous synaptic currents increases as did the size of the evoked currents.

By the second week, spontaneous events appeared that reversed at the chloride equilibrium potential and were blocked by 5 uM bicuculline methiodide (BMI). At the same age that BMI-sensitive spontaneous events appeared stimulation of the white matter evoked currents that reversed between the equilibrium potentials for chloride and monovalent cations. In BMI the evoked current reversed near 4 mV and had a large d-APV-sensitive component.

Voltage-activated potassium currents were recorded at all ages. Both an inactivating and a non-inactivating outward current were present at the earliest ages examined, both reversed near the potassium equilibrium potential, and increased in conductance through the first two postnatal weeks.

NMDA RECEPTOR DEVELOPMENT IN THE VISUAL CORTEX OF CATS L.J. Reynolds and M.F. Bear, Dept. Pharmacology, Univ. Pittsburgh, Pittsburgh PA 15261, and Center for Neural Science, Brown Univ. Providence RI 02912.

Neurons in the visual cortex of the cat display an age dependent plasticity that can be demonstrated by modifying the visual environment of the animal. Between 3 and 12 postnatal weeks surgically closing one eye results in a shift in ocular dominance of neurons in area 17 of the visual cortex. These plastic events probably involve NMDA receptors, as the infusion of an NMDA antagonist into area 17 will prevent the shift in ocular dominance (Kleinschmidt et al. Science, 238:355, 1987). In this study we examined the development of NMDA receptors in visual cortex of developing cats through the critical period for visual plasticity.

NMDA receptor density was monitored using $[^3H]$ MK801 binding. Well washed membranes from area 17 or area 6 from cats of different ages were incubated with 0.6nM $[^3H]$ MK801, 100μM Glu and 30μM Gly for 2hr at 24°C. The binding parameters obtained are shown below (Mean±S.E.M. n=3-4).

	B_{max} (pMol/mg prot)		k_D (nM)	
Age, days	Area 17	Area 6	Area 17	Area 6
7	0.66±0.3		4.93±2.72	
36	1.54±0.17	1.49±0.17	1.11±0.12	1.53±0.14
57	1.49±0.18	1.85±0.38	1.16±0.26	1.60±0.25
84	1.34±0.06	1.59±0.16	0.98±0.06	1.46±0.13
Adult	1.24±0.27	1.41±0.03	1.01±0.15	1.45±0.08

There is clearly an abrupt increase in NMDA receptor density associated with the onset of the critical period. However, NMDA receptor density remains relatively high following the end of the critical period. Thus, although NMDA receptors play a critical role in visual plasticity, their presence does not necessarily predict the capability for plasticity.

BLOCAKDE OF VISUAL CORTICAL NMDA RECEPTORS PREVENTS THE SHRINKAGE OF LATERAL GENICULATE NEURONS FOLLOWING MONOCULAR DEPRIVATION. H. Colman* and M.F. Bear. Center for Neural Science, Brown University, Providence, RI 02912.

Monocular deprivation of kittens during the second postnatal month leads to a shift in visual cortical ocular dominance such that few neurons remain responsive to stimulation of the deprived eye. One correlate of this physiological change is a shrinkage of the neurons in the lateral geniculate nucleus that receive input from the deprived eye. Because the morphological changes in the LGN are most prominent in the binocular segment, it has been proposed that they reflect a process of binocular competition. It has been hypothesized that this competition occurs among the converging geniculocortical axons in layer IV of visual cortex. Recent work has suggested that intracortical infusion of APV, an NMDA receptor antagonist, interferes with the physiological consequences of MD. We set out to examine the possibility that LGN cell size changes were also sensitive to cortical NMDA receptor blockade.

Kittens were implanted bilaterally with minipumps that delivered either 50 mM D,L-APV or sterile Ringer directly into area 17 at a rate of .1 μl per hour. At the same time, one eyelid was sutured closed. After 8 days, HRP was injected into striate cortex 6 mm anterior to the infusion site, where we calculate the extracellular APV concentration to be ~150 μM. 2 days later, the animals were perfused and processed for HRP histochemistry. The cross sectional areas of Nissl-stained LGN neurons were measured within the projection column defined by the retrograde label. In the Ringer treated group, lamina A1 neurons ipsilateral to the deprived eye were 18.2±1.1% smaller that those in lamina A. In contrast, in the APV-treated group, lamina A1 cells were 13.9±2.6% *larger* than those in lamina A. Thus, the effects of MD on LGN cell size clearly differ in the APV and control groups, and this difference is significant at P<.001 (t-test).

These data demonstrate that the site of binocular competition in the control of LGN cell size is the striate cortex and, because NMDA receptors are not presynaptic, that binocular competition requires postsynaptic activity. Further, the data suggest that the relevant component of postsynaptic activity depends specifically upon NMDA receptor activation. (Supported by ONR contract N00014-81-K0136 and NIH grant NS06929)

DEVELOPMENT OF LOCAL CONNECTIONS IN HUMAN VISUAL CORTEX. A.Burkhalter and K.L.Bernardo*, Department of Neurosurgery & McDonnell Center for Studies of Higher Brain Function, Washington University School of Medicine, St. Louis, MO 63110.

The human visual system is immature at birth. In primary visual cortex (V1), for example, the synaptic density doubles during the first year of life, indicating the formation of new connections. Because the visual system is extremely sensitive to deprivation during this period, it is important to determine the sequence in which cortical circuits develop.

We have used the fluorescent dye, dil, to trace axonal projections within V1 of post-mortem, fixed fetal (gestational age (GA) 168 and 203d) and 14d postnatal (P) human brains. At GA 168, injections into the cortical plate (CP) label mostly vertical fibers that enter the intermediate zone. Horizontal projections are confined to layer 1 and the subplate. At GA 203, the projection from layer 2/3 to layer 5 has formed within the CP. In addition, long (>2mm) horizontal fibers run along the layer 3/4 and 4/5 borders and short vertical collaterals are seen at regular intervals. Labeling in layer 1 persists. At P 14, the density of the projections in superficial layers of the CP is increased but their horizontal extent remains unchanged. These results suggest that connections within cortical columns are generated before those between columns which largely develop after birth. (Supported by NIH Grant EY05935).

DEVELOPMENT OF CLUSTERED HORIZONTAL CONNECTIONS IN CAT STRIATE CORTEX: PROGRESSIVE AND REGRESSIVE EVENTS. L. C. Katz and E. M. Callaway Laboratory of Neurobiology, The Rockefeller University, 1230 York Avenue, New York, NY 10021.

In the striate cortex of adult cats, horizontal axons of pyramidal cells from layers 2/3 and 5 specifically interconnect regions of similar orientation selectivity (Gilbert & Wiesel, J. Neurosci., in press). Cortical injections of retrograde neuronal tracers label clusters of cells up to 4mm from the injection site. We have examined the development of this intralaminar circuitry based on the pattern of retrograde label in tangential sections of flattened cortex following small (100-400 μm diam.) injections of flourescent latex microspheres in area 17. Following injections at 4-6 days postnatal (P4-6) the pattern of retrograde label was even, unclustered and extended up to 2mm from the injection site. Injections at day 8 resulted in a more extensive pattern of label (3-4mm radius) with clustering just discernable amongst the most distant cells. These results suggested that after P6 horizontal axon outgrowth was more directed. By P12-15 clustering was much more apparent both within and beyond the region labeled at 4-6 days. The changes observed between P6 and P15 appeared to result from two phenomena: a reduction in the number of cells making inappropriate connections to the injection site, and an increase in the number making appropriate connections. Early (P12-15) crude clusters were gradually refined during the third through sixth weeks: the proportion of labeled cells between clusters (those making inappropriate connections to the injection site) declined sharply, and the characteristic adult pattern of crisp clusters emerged. At all ages the pattern of labeling was similar in supragranular and infragranular layers, despite a clear difference in the developmental ages of the laminae. Thus, regulation of both the timing of axonal outgrowth and elaboration of clustered local connections is independent of the ages of the cells involved. These events may be initiated by other developmental influences common to both populations. Supported by NIH grants EY 07960 and EY 06128 and the L. P. Markey Charitable Trust.

4.11

DEVELOPMENT OF CLUSTERED HORIZONTAL CONNECTIONS IN CAT STRIATE CORTEX: ROLES OF PROCESS ELIMINATION AND CELL DEATH. E. M. Callaway and L. C. Katz. Laboratory of Neurobiology, The Rockefeller University, 1230 York Avenue, New York, NY 10021.

We have found that regressive events are an important component in the development of intralaminar horizontal connections. Reductions in the numbers of cells making inappropriate connections contribute to the appearance of early, crude clustering during the second postnatal week and to its subsequent refinement during the third through sixth weeks (see preceeding abstract). The potential contribution of cell death was assessed by experiments in which fluorescent latex microspheres were injected in area 17. In the first experiment, animals were injected at P6 and killed at P16; in the second, injections were made at P15 and the animals killed at P40. In the P6/P16 experiment, the pattern of labeling was unclustered, and identical to that of P6 animals killed on P7. Similarly, in the P15/P40 experiment, clusters were as unrefined as those characteristically observed in P15 animals. These results demonstrate that specific cell death did not contribute to either establishment or refinement of clusters. We therefore investigated specific elimination of axonal processes as a possible mechanism for cluster refinement. When an injection of red microspheres was made on P14, and an injection of green microspheres was made at precisely the same location on P29, the 2 injections resulted in overlapping clusters of retrogradely labeled cells. The double labeled cells were confined almost exclusively to the regions of densest labeling from the early injection. In one representative tangential section 33% (350 of 1076) of the cells labeled by the early injection were outside of clusters, while only 11% (16 of 146) of cells labeled by both early and late injections were outside clusters. Based on these results, and on observations of intracellularly stained cells, we conclude that cluster refinement entails specific elimination of inappropriately projecting axonal collaterals. Supported by NIH grants EY 07960 and EY 06128 and the L. P. Markey Charitable Trust.

HUMAN BEHAVIORAL NEUROBIOLOGY: MEMORY

5.1

WORD STEM COMPLETION PRIMING ACROSS THE LIFESPAN. H.P. Davis and M.G. Gandy*. Department of Psychology, University of Colorado at Colorado Springs, Colorado Springs, CO 80933.

Subjects in each decade of life from the twenties through the eighties, matched on WAIS-R IQ scores, were administered two verbal recall and recognition tests, three tests of frontal lobe functioning, and a word stem completion test of priming. Subjects from twenty through fifty-nine years of age performed similarly on the recall tests and tests of frontal lobe functioning. Sixty, seventy, and eighty year old subjects demonstrated impaired performance on the tests of recall and frontal lobe functioning. Subjects from all decades of life performed similarly on the recognition tests. Baseline guessing scores on the word stem completion task were similar across all decades of life. Priming scores were significantly higher than baseline scores for subjects in all decades of life ($p<.01$). However, the magnitude of priming was significantly less for subjects in their seventies and eighties than for all other age groups ($p<.01$). The findings reported here are relevant to previous suggestions that elderly subjects and amnesic patients have qualitatively similar memory deficits because both are impaired for explicit information, and yet, implicit memory remains intact in both groups as measured by priming. The present study shows that priming does decline with age when old-old subjects are tested, and these results are consistent with the view that amnesic patients and elderly subjects do not have qualitatively similar memory impairments.

5.2

A DISSOCIATION BETWEEN LEXICAL-SEMANTIC AND PERCEPTUAL-STRUCTURAL PRIMING IN ALZHEIMER'S DISEASE. M.M. Keane, J.D.E. Gabrieli, J.H. Growdon, and S. Corkin. Dept. of Brain and Cognitive Sciences and Clinical Research Center, MIT, Cambridge, MA 02139; Dept. of Psychology, Northwestern University, Evanston, IL 60208; and Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

In previous studies, we reported a dissociation in Alzheimer's disease (AD) between lexical-semantic priming (word completion) and perceptual-structural priming (identification of perceptually degraded pictures or words). In those studies, impaired lexical-semantic priming and intact perceptual-structural priming were demonstrated in different groups of AD patients. In the current study, we evaluated the status of both kinds of priming within a single group of AD patients (with dementia ranging from mild to severe). High and low-frequency words were presented one or three times in a study list prior to each of two priming tasks: a word completion task (in which subjects had to complete a 3-letter stem with the first word that came to mind) and a perceptual identification task (in which subjects had to identify briefly presented, masked words). In both tasks, half of the stimuli corresponded to words in the study list and half did not; the measure of priming was the difference between studied and unstudied stimuli in completion or identification performance. Priming in AD (relative to normal control subjects) was impaired in the word completion task and normal in the perceptual identification task. This within-subject dissociation in AD provides strong evidence for the separability of cognitive and neural mechanisms mediating lexical-semantic and perceptual-structural priming.

5.3

COMPUTATIONAL GOALS OF LEXICAL-SEMANTIC PRIMING: EVIDENCE FROM GLOBAL AMNESIA. J.D.E. Gabrieli, M.M. Keane and S. Corkin. Dept. of Brain and Cognitive Sciences and Clinical Research Center, MIT, Cambridge, MA 02139; and Dept. of Psychology, Northwestern Univ., Evanston, IL 60208.

The amnesic patient H.M. has demonstrated intact lexical-semantic repetition priming on word completion, fragment completion, and category exemplar production tasks despite severely impaired recall and recognition memory. We hypothesized that lexical-semantic priming processes reflect context-free memory of word frequencies that contributes to efficient word retrieval. In two experiments, we examined the influence of homophone presentation upon subsequent homophone spelling in H.M. and normal control subjects. In the first experiment, homophones (e.g., STEAK or STAKE) were presented auditorily in sentence contexts that disambiguated the meaning and spelling of the homophone. In the second experiment, homophones were presented visually, and without sentence context; the visual presentation precluded spelling ambiguity. In both experiments, the measure of priming was the number of homophones, relative to baseline, that subjects spelled in accordance with the prior presentation. H.M.'s level of priming was severely impaired after auditory (context-dependent) presentation, but normal after visual (context-free) presentation. H.M.'s recognition memory for the prior presentation of the homophones was severely impaired in both experiments. The sparing of lexical-semantic priming in global amnesia may reflect the contrasting computational goals of context-free, cortico-cortical learning mechanisms subserving word retrieval and context-dependent, cortico-limbic learning mechanisms subserving recall and recognition.

5.4

DETERIORATION OF H.M.'S MEMORY FOR REMOTE EVENTS. S. Corkin, E.V. Sullivan, J.D.E. Gabrieli, and J. Yucaitis*. Dept. of Brain and Cognitive Sciences and Clinical Research Center, MIT, Cambridge, MA 02139.

We used an updated version of Marslen-Wilson and Teuber's (1975) Famous Faces Test to study the time course of remote memory in the amnesic patient H.M., who was born in 1926, and received an operation for intractable epilepsy in 1953, which resulted in severe anterograde amnesia. The present study explored the effects of aging and passage of time on H.M.'s recognition of public figures from black and white newsphotographs. The photographs included 12 assigned to the 1920s, 17 to the 1930s, 17 to the 1940s, 19 to the 1950s, 20 to the 1960s, and 17 to the 1970s. H.M. was tested on five occasions, twice in 1974 and once in 1977, 1980, and 1988. The results show consistently poor unprompted memory for public figures from the 1970s, 1960s, and 1950s, in contrast to consistently good memory for those from the 1940s. H.M.'s memory for public figures from the 1930s and 1920s has become progressively worse with each successive testing. The time course of H.M.'s remote memory reflects impaired initial acquisition of ongoing events postoperatively in the 1970s, 1960s, and 1950s; robust initial acquisition of ongoing events in the 1940s (because at the corresponding ages of 14 to 23 years he was old enough to be interested in the news, and the wartime news had heightened importance); and patchy initial acquisition of ongoing events during his childhood in the 1930s and 1920s. The results indicate a selective vulnerability of memories from H.M.'s childhood relative to those from his adolescent and young adult years.

5.5

RECOGNITION MEMORY FOR TONES: THE IMPORTANCE OF THE LEFT POSTERIOR-SUPERIOR TEMPORAL REGION. J.M. Tonkonogy, M.D.* (SPON. D. Pollen). Dept. of Psychiatry, Univ. of Mass. Med. School, Worcester, MA 01655.

Patients with different types of aphasia were required to recognize a reference tone of 200 Hz interspersed among tones ranging between 205 Hz and 300 Hz. Interstimulus intervals (ISI) ranged between 2.0 sec. and 15.0 sec. While all aphasic patients were able to discriminate tone differences of 5 Hz, when presented with an ISI of 2.0 sec., only patients with temporal lobe aphasia showed deficits in recognition memory for tones. Patients with Wernicke's aphasia (left posterior-superior temporal lesion) were impaired on short term memory for tones and required at least 15 Hz tone difference for recognition. The transcortical sensory aphasics (left posterior temporal lesion outside the Wernicke's area) presented with less impairment in memory for tone recognition. Patients with Broca's aphasia (left fronto-central lesion) did not show any significant impairment in recognition for memory for tones. These results suggest that the left temporal lobe region is important for tone recognition memory.

5.6

ROLE OF HUMAN TEMPORAL LOBES IN MUSICAL AND VERBAL MEMORY. S. Samson* & R.J. Zatorre. (SPON:O Floody) Montreal Neurological Inst., McGill Univ. Canada H3A 2B4

The relative contribution of learning versus retention abilities in auditory memory was tested in two analogous tasks using unfamiliar tunes and nonsense words. Learning on five successive trials as well as delayed recognition was tested. The performance of patients with anterior right (RT) and left (LT) temporal lobectomy was compared with performance of normal control subjects. RT and LT patients were impaired in learning and delayed recognition of tunes, although they did show learning over successive trials. A similar pattern of results was obtained in the learning and retention of nonsense words. Recognition of tunes by LT subjects improved after 24 hours, but word recognition did not. Conversely, word recognition by RT subjects improved after the delay, but recognition of tunes did not. These findings suggest that the learning of auditory patterns difficult to associate with a semantic content requires the contribution of both temporal lobes. The role of RT and LT lobes in consolidation of such patterns seems to depend upon the musical or verbal nature of the material, respectively.

5.7

ROLE OF THE RIGHT TEMPORAL NEOCORTEX IN AUTOMATIC VISUAL-CUE LEARNING. J. Doyon and B. Milner. Montreal Neurological Institute, McGill University, Montreal, Canada, H3A 2B4.

The role of the right temporal neocortex in the learning of a cue-system during tasks requiring visual discrimination of relavant from irrelevant stimuli was investigated in 74 patients with unilateral temporal- or frontal-lobe lesions, the amnesic patient H.M., and 20 normal control subjects. Subjects were tested on both a letter- and an abstract-design version of Rabbitt's (1967) visual-cue learning task. The material for both versions comprised two packs of cards, each containing a different set of irrelevant letters or designs. The subject's task was to sort a pack of cards into two piles according to which of two targets was present on the card. Depending on the condition in which the subjects were to be tested, they were given either 3 or 6 learning trials with one pack of cards before they were transferred to the other pack that contained the new set of background letters or designs. The results showed that with letters, all groups and H.M. took longer to complete the task when the irrelevant information was changed after three learning trials. With abstract designs, only patients with right-temporal lobe lesions failed to show this interference after three learning trials, but did so after six. Hence, it is argued that the right temporal neocortex plays a role in automatic visual pattern-discrimination learning.

5.8

BRAIN MORPHOLOGY ON MR IMAGES IN KORSAKOFF'S SYNDROME. T.L. Jernigan, K. Schaffer*, N. Butters and L.S. Cermak. VA Medical Center, San Diego, CA 92161

Six patients with Korsakoff's Syndrome have been compared to age-matched groups of normal controls and chronic alcoholic patients using Magnetic Resonance Imaging (MRI). Quantitative image-analytic techniques were used to estimate volumes of ventricular, cortical, and cerebellar CSF, and cortical and subcortical grey matter structures. The results reveal CSF increases, but no significant decreases in grey matter volumes, in non-amnesic alcoholics. In contrast, patients with Korsakoff's syndrome when compared to normal controls showed reduced grey matter volumes in addition to CSF increases, with greatest reductions observed in diencephalic structures. Significant grey matter reductions in Korsakoff's Syndrome relative to alcoholics were observed only in subcortical structures, again most dramatically in the diencephalon. Significantly greater involvement of right than left diencephalic structures was also observed in this sample of amnesic Korsakoff's patients. Statistical evidence is presented supporting a specific role for diencephalic damage in the pathogenesis of Korsakoff's Syndrome.

5.9

MESIAL TEMPORAL LOBE SUBSTRATES OF LEXICAL RETRIEVAL. R.J.Caselli*,J.R.Duffy* and R.J.Ivnik* (SPON: A.J.Windebank). Dept. of Neurology, Mayo Clinic, Rochester, MN 55905.

Two nonepileptic adults with chronic mesial temporal lobe lesions were studied with linguistic, neuropsychological, and neuroimaging techniques to explore the hypothesis that neuroanatomical substrates of memory also subserve object naming (lexical retrieval). A 40 year old (yo) right-handed (RH) businessman with magnetic resonance imaging (MRI) documented post-anoxic bilateral hippocampal infarctions had a dense amnesic syndrome and impaired lexical encoding, but only minimal evidence of impaired lexical retrieval from auditory, visual, and somatosensory modalities. In contrast, a 60 yo RH nurse with MRI documented post-encephalitic left amygdala (and possibly temporal pole) damage had severe impaired lexical retrieval as well as impaired lexical encoding. She could recount episodic memories associated with a target object, but was unable to name the object, or in some instances, to either visually or aurally recognize the target word. Both hippocampal and amygdala lesions may impair lexical encoding, but anterior mesial temporal structures appear to be more important for lexical retrieval than the hippocampus.

6.1

DEMONSTRATION OF TWO MORPHOLOGIC CLASSES OF SEROTONERGIC FIBERS IN HUMAN CORTEX. B.E. Kosofsky and N.W. Kowall. Neurology Service, Mass General Hosp., Boston MA 02114.

We employed a monoclonal antibody against monkey phenylalanine hydroxylase (PH8, courtesy of Dr. R.G.H. Cotton) which has been shown to selectively label serotonergic neurons in postmortem human brain (Haan et al, Brain Res. 426:19). Cortical blocks from patients diagnosed with autism and other neurological diseases were immersion fixed in periodate-lysine-paraformaldehyde within 24 hours of death. Frozen 50μ sections were processed with an indirect immunoperoxidase method. The density and distribution of labeled fibers varied from one cortical area to another. Within each cortical field examined, fibers displayed a spectrum of morphological features. Two classes of fibers could be identified by virtue of the size and shape of their varicosities: fibers with small pleomorphic varicosities and fibers with large, spherical varicosities. In neocortex, the predominant fibers have small, fusiform varicosities; gradual expansions in axon diameter, arising at variable distances along the fiber length. Other fibers are interspersed, characterized by large, round, darkly staining varicosities which form abrupt axonal expansions. We performed control experiments to establish the specificity of PH8 antiserum to selectively label serotonergic fibers in postmortem human cortex. We conclude that there are morphologic features that distinguish two classes of serotonergic fibers in human cortex as in other species (Kosofsky and Molliver, 1987). As in rat, these distinct fiber populations may originate from different raphe nuclei providing parallel raphe cortical projections with different structural and functional patterns of organization.

6.2

EXCITATORY AND INHIBITORY ACTIONS OF SEROTONIN ON NEURONS OF THE RAT MEDIAL PONTINE RETICULAR FORMATION *IN VITRO*. D.R. Stevens, R.W. Greene, and R.W. McCarley, Harvard Med. Sch./VAMC, Brockton, Ma. 02401

The striking changes in activity of neurons of the medial pontine reticular formation (mPRF) during the sleep-wake cycle may be modulated by serotonin (5HT). The direct cellular actions of 5HT in the mPRF are not known. We have examined the action of 5HT on 34 mPRF neurons in slices.

5HT applied either by superfusion (1-30 uM) or pressure ejection (0.1-0.2 mM) depolarized (7.5 ±4 mV, n=19) or hyperpolarized (7.0 ±2 mV, n=11) or had no effect (n=4). Depolarizing responses were associated with a decrease in conductance (22 ±15%, n=11) and an inward current (n=5). Hyperpolarizing responses were accompanied by outward current (n=3) and were associated with a conductance increase (25 ±7%, n=7) or no conductance change (n=3). Both responses persisted in the presence of tetrodotoxin. The reversal potentials of both responses were insensitive to chloride loading and consistent with that expected for potassium ions (-76 to -88 mV, n=3, $[K^+_o]$= 5 mM).

We conclude that 5HT acts postsynaptically to either excite or inhibit neurons of the mPRF by opposing actions on potassium conductance(s).

6.3

ACTIVATION OF THE 5-HT ASCENDING FIBERS INHIBITS THE FIRING OF MEDIAL PREFRONTAL CORTICAL NEURONS. R. Godbout, J. Mantz*, J. Glowinski* and A.M. Thierry*. INSERM U. 114, Chaire de Neuropharmacologie, Collège de France, 75231 Paris Cedex 05, France.

The effects of median (MR) and dorsal (DR) raphé nuclei stimulation on the neuronal activity of medial prefrontal cortex (PFC) were studied in the rat. Stimulation of MR and DR respectively inhibited 52.9% (n=210) and 35.0% (n=60) of spontaneously active PFC neurons. Antidromic responses were induced by MR (n=39) and DR (n=5) stimulations and were followed by inhibitions of firing in most cases. Neurotoxic lesion of the ascending 5-HT pathways by microinjections of 5,7-DHT decreased the proportions of inhibited neurons to 8.8% for the MR (n=238) and to 5.5% for the DR (n=145). The inhibitory effect of MR stimulation was blocked reversibly by acute i.p. administrations of the 5-HT_2 receptors antagonists ketanserin (9/11 neurons) and ritanserin (4/5 neurons) at doses of 2.0 and 4.0 mg/kg respectively.

Excitatory responses could be evoked in most PFC neurons by stimulating the mediodorsal thalamic nucleus (MD) at 5 to 10 Hz. This effect was blocked by stimulation of the MR, 5 to 35 ms prior to MD pulses.

These results show that 5-HT midbrain raphé nuclei inhibit the spontaneous as well as evoked firing activity of PFC output neurons, and that the 5-HT_2 receptors are involved in this effect.

6.4

DIFFERENTIAL RESPONSIVENESS OF THE RAT DORSAL AND MEDIAN RAPHE 5-HT SYSTEMS TO 5-HT$_{1A}$ RECEPTOR AGONISTS AND p-CHLOROAMPHETAMINE (p-CA). P. Blier, A. Serrano* and B. Scatton. Synthélabo Recherche, Bagneux, 92220 France.

Dorsal and median raphe 5-HT neurons give rise to projections that differ in axon morphology and in vulnerability to certain amphetamines. In the present study, we studied the effects of 5-HT_{1A} or 5-$HT_{1A/1B}$ agonists and of p-CA on extracellular levels of indoleamines, using differential pulse voltammetry with carbon fiber electrodes, in cell body and nerve terminal regions of these two subsets of 5-HT neurons in anesthetized male Sprague-Dawley rats. The 5-HT_{1A} agonist 8-OH-DPAT (30 μg/kg, i.v.) produced a 60% decrease in the height of the 300 mV oxidation peak in the dorsal raphe and frontal cortex but was ineffective at this dose in the median raphe and dentate gyrus. At 150 μg/kg i.v., 8-OH-DPAT produced a 60% decrease in the 300 mV peak in the median raphe but only a 20% decrease in the dentate gyrus. The microiontophoretic application of 8-OH-DPAT was 3 times more potent in suppressing the firing rate of dorsal raphe 5-HT neurons than that of median raphe 5-HT neurons. 8-OH-DPAT and buspirone were 10 and 4 times, respectively, more potent in decreasing 5-HT synthesis in the cortex than in the hippocampus. The 5-$HT_{1A/1B}$ agonist RU 24969 (10 mg/kg, i.p.) decreased by 70% the 300 mV peak in both raphe nuclei and by 50% in the cortex and dentate gyrus. p-CA (5 mg/kg, i.p.) increased the 300 mV peak in the cortex but was ineffective in the dentate gyrus. In conclusion, the dorsal raphe-frontal cortex 5-HT system exhibits a greater responsiveness to 5-HT_{1A} agonists than the median raphe-dentate gyrus 5-HT system. The terminal 5-HT_{1B} autoreceptor seems to play a more important role in the control of 5-HT release in the dentate gyrus than in the frontal cortex. Finally, 5-HT terminals in the dentate gyrus appear to be insensitive to the 5-HT releasing effect of p-CA, consistent with the inability of this drug to destroy 5-HT terminals in that region of the brain.

6.5

THE β-ADRENOCEPTOR AGONIST FLEROBUTEROL ENHANCES 5-HT NEUROTRANSMISSION IN THE RAT BRAIN: AN ELECTROPHYSIOLOGICAL STUDY. A. Bouthillier*, P. Blier and C. de Montigny. (SPON: L. Vachon). Dept. of Psychiatry, McGill Univ., Montréal, Canada H3A 1A1.

Flerobuterol is a potent β-adrenoceptor agonist which readily crosses the blood-brain barrier and which has been reported to be an effective antidepressant. Acute administration of flerobuterol (up to 2 mg/kg, i.v.) to male Sprague-Dawley rats did not modify the firing activity of dorsal raphe 5-HT neurons. However, a two-day treatment with flerobuterol (0.5 mg/kg/day delivered s.c. by an Alza minipump) markedly reduced the firing activity of these neurons. That this reduction was attributable to an increased activation of somatodendritic 5-HT autoreceptors was suggested by its complete reversal following the administration of the 5-HT_{1A} antagonist spiperone (1 mg/kg, i.v.). After 7 days of treatment with flerobuterol, there was a partial recovery of the firing activity of 5-HT neurons and a complete one after 14 days of treatment. At this point in time, there was a conspicuous attenuation of the effect of i.v. LSD on the firing activity of 5-HT neurons, indicating a desensitization of somatodendritic 5-HT autoreceptors. The responsiveness of postsynaptic dorsal hippocampus pyramidal neurons to microiontophoretically-applied 5-HT was unaltered following a 14-day flerobuterol treatment. However, there was a large increase in the efficacy of the electrical stimulation of the ascending 5-HT pathway in suppressing the firing activity of these neurons.

It is concluded that long-term treatment with flerobuterol results in a marked enhancement of 5-HT neurotransmission. The mechanisms whereby this β-adrenoceptor produces this effect remains to be determined. The effect of flerobuterol on the 5-HT system might underlie its therapeutic efficacy in major depression.

6.6

POTASSIUM CHANNELS BLOCKERS AND 5-HT1A CONTROL OF SEROTONERGIC NEURONAL ACTIVITY IN THE DORSAL RAPHE NUCLEUS. L. Lanfumey, S. Hajj-Dahmane*, B. Franc* and M. Hamon*, INSERM U288. Faculté de Médecine Pitié-Salpétrière, 75634 Paris cedex 13, France

5-HT1A agonists are known to depress the activity of serotonin (5-HT) neurons in the dorsal raphe nucleus (DRN), by acting on somatodendritic autoreceptors. Stimulation of these receptors triggers an increased K^+ conductance through a channel which has yet to be characterized. Attempts to identify which type of K^+ channel is coupled to 5-HT1A autoreceptors were presently made by examining the effects of various K^+ channels blockers on 5-HT1A-evoked response of DRN neurons in rat brain slices. A single barrel pipette of 15MΩ, filled with NaCl 2M, was used for extracellular recording of 5-HT neurons, and drugs were added to the Krebs medium superfusing the slice. The 5-HT1A agonist ipsapirone induced a concentration-dependent inhibition of 5-HT spontaneous neuronal activity, with a IC50 of 60nM. 4-aminopyridine (4-AP, 1mM), which blocks both the A type and G protein-coupled K^+ channels, prevented the inhibitory effect of ipsapirone in low concentration range, and significantly reduced that due to higher concentrations of the 5-HT1A agonist (IC50=110nM). In contrast apamine (50nM), which blocks certain $K^+(Ca^{2+})$ conductances did not alter ipsapirone-induced inhibition of 5-HT neurons. These results indicate that somatodendritic 5-HT1A autoreceptors are coupled to 4-AP-sensitive K^+ channels, which may belong to those associated with G proteins.

DEPOLARIZING ACTIONS OF SEROTONIN ON NEURONS OF THE GUINEA-PIG ISOLATED INFERIOR MESENTERIC GANGLION. A.G. Meehan* and D.L. Kreulen (SPON: S.S. Hsiao). Department of Pharmacology, College of Medicine, University of Arizona, Tucson, Arizona 85724.

The effects of serotonin on neurons of the guinea-pig isolated inferior mesenteric ganglion (IMG) were examined. Intracellular recordings of membrane potential were made in principal IMG neurons. Serotonin was applied by pressure ejection from micropipettes. Responses to serotonin were dependent upon the concentration of the amine in the pipette. High concentrations (10 mM) evoked responses of 2-5 s duration, low concentrations (100 μM) evoked a slow depolarization in 70% of neurons tested. The slow depolarization was unaffected by: ICS 205,930 (5 μM), MDL 72222 (1 μM), ketanserin (1 μM), MDL 11,939 (5 μM), methiothepin (1 μM), methysergide (1 μM), and cyproheptadine (50 μM). The slow depolarization was associated with a 30% decrease in input resistance. In the presence of low Na^+ the serotonin-evoked slow depolarization was markedly reduced but was unaffected by low Ca^{2+}/ high Mg^{2+}, high K^+ or low K^+ medium. In addition, the slow depolarization was not affected by tetrodotoxin (3 μM) or amiloride (1 mM). Thus serotonin evokes a slow depolarization in a subpopulation of guinea-pig IMG neurons through the activation of an as yet unidentified receptor. Furthermore, the slow depolarization appears to be mediated in part by Na^+-influx. Support: DK36289, HL27781.

6.8

LSD ANTAGONIZES 5-HT_2-MEDIATED DEPOLARIZATIONS IN CORTICAL PYRAMIDAL NEURONS. P.A.Pierce and S.J.Peroutka. Department of Neurology, Stanford University School of Medicine, Stanford CA, 94305.

5-HT has been shown to produce both depolarizing and hyperpolarizing effects on cortical neurons. 5-HT produces an increase in K^+conductance and cell hyperpolarization via the 5-HT_{1A}receptor. Membrane depolarization with decrease in K^+conductance appears to be mediated by the 5-HT_2 receptor. Since lysergic acid diethylamide (d-LSD) interactions with 5-HT_2 receptors have been implicated in hallucinosis, we analyzed the effect of d-LSD on the 5-HT_2-mediated depolarization in rat cortical pyramidal neurons.

Intracellular recordings of rat cortical pyramidal neurons (n=65) were performed to determine the membrane effects of 5-HT, d-LSD and the 5-HT_{1A} agonist 8-OH-DPAT. 5-HT (10^{-4} M) produces an initial depolarization of 4.5$\pm$0.4 mV with a decrease in conductance of 24$\pm$9% (7/9 cells). The depolarization is immediately followed by a hyperpolarization of 3.9$\pm$0.5 mV below the original resting membrane potential, and a 16$\pm$5% increase in membrane conductance (6/9 cells). The 5-HT_{1A} agonist 8-OH-DPAT (10^{-7} - 10^{-6}M) produces only a hyperpolarizing response (5.9$\pm$1.1 mV) and increase in conductance of 14$\pm$3% (12/18 cells). Similarly, d-LSD (10^{-6} M) causes only a hyperpolarization (6.0$\pm$1.1 mV) and increase in conductance of 21$\pm$6% (7/9 cells). Application of 8-OH-DPAT does not affect the 5-HT-induced depolarization (4.2$\pm$0.6 mV; 9/13 cells) but slightly increases the 5-HT hyperpolarizing response (4.8$\pm$0.7 mV; 10/13 cells). In contrast, in 13 of 16 cells d-LSD partially inhibits (6 cells) or completely blocks (7 cells) the 5-HT depolarizing response (avg = 0.7$\pm$0.2 mV), in addition to increasing the 5-HT hyperpolarization (5.2$\pm$0.6 mV; 7/16 cells). These data suggest that while 8-OH-DPAT and d-LSD are both 5-HT_{1A} agonists, d-LSD is a potent antagonist of 5-HT_2 receptors mediating cortical neuronal depolarization.

CENTRAL AND PERIPHERAL EFFECTS OF DOI, A SELECTIVE 5-HT_2 AGONIST, ON CORTICOSTERONE SECRETION. R.H. Alper. Dept. of Pharmacology, Toxicology and Therapeutics, University of Kansas Medical Center, Kansas City, KS 66103.

The serotonin (5-HT) agonist DOI [(±)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane] increases corticosterone secretion. The site of action was determined in conscious, unrestrained male rats implanted with arterial and venous catheters. Blood samples (0.25 ml) were obtained via the arterial catheter. Plasma corticosterone levels were increased as early as 5 minutes after DOI (500 μg/kg, iv), and 6-7 fold at 15 to 60 minutes. Pretreatment with the central 5-HT_2 antagonist LY 53857 (100 μg/kg, iv) blocked the effect of DOI on corticosterone secretion at all times. The peripheral 5-HT_2 antagonist xylamidine (100 μg/kg, iv) attenuated the corticosterone response elicited 15 minutes after DOI but did not alter the 60 minute response. In contrast, dexamethasone pretreatment (350 μg/kg, sc) attenuated the corticosterone response at 15 minutes, but abolished the response 60 minutes after DOI. These data suggest that DOI initially increases corticosterone secretion in part through a direct adrenal mechanism not dependent on ACTH, and at later times via a central, dexamethasone-suppressible mechanism. [Supported by the Kansas Affiliate of the American Heart Association]

THE 5-HT3 ANTAGONIST MDL 73,147 RESEMBLES CLOZAPINE, NOT HALOPERIDOL, IN ITS EFFECT ON DA AUTORECEPTOR SUPERSENSITIVITY IN RAT STRIATUM. M. Dudley, S. Sorensen and A. Ogden. Merrell Dow Research Institute, Cincinnati, OH 45215.

Chronic administration of MDL 73,147 (MDL) (1H-indole-3-carboxylic acid-octahydro-3-oxo-2,6-methano-2H-quinolizin-8-yl ester), like haloperidol (HAL), decreased the spontaneous electrical activity of A9 and A10 cells (Sorensen et al., Eur. J. Pharmacol., in press). This treatment resulted in significantly reduced striatal levels of the DA metabolites DOPAC and HVA 24 hr after the last dose. The effect of HAL can be ascribed to autoreceptor supersensitivity. MDL was tested in two models of striatal autoreceptor function to determine if DA receptor changes occur. HAL (1 mg/kg), MDL (5 mg/kg) and clozapine (CLZ, 10 mg/kg) were given ip daily for 21 days. A challenge dose of HAL (0.1 mg/kg, ip) given on day 22 to the HAL treated rats did not produce the 40% increase in DOPAC and HVA that it did in the saline controls. The challenge after MDL and CLZ gave significant increases in DOPAC (167 and 170%, respectively) and HVA (150 and 153%, respectively) above those produced by the challenge in saline controls. Chronic HAL enhanced the ability of apomorphine (APO) to decrease L-DOPA synthesis by activation of presynaptic receptors in the GBL/NSD treated rat. Chronic MDL and CLZ did not increase sensitivity to APO. The biochemical profile of MDL in these two models resembles CLZ, not HAL. MDL may have antipsychotic effects without the extrapyramidal liability of HAL.

6.11

SUMATRIPTAN (GR 43175): A SELECTIVE 5-HT_{1D} AGONIST WITH NOVEL ANTI-MIGRAINE PROPERTIES? S.J. Peroutka and B.G. McCarthy*. Dept. of Neurology, Stanford University, Stanford, CA 94305.

Ergot compounds are the most common class of agents used in the acute treatment of severe migraine. Dihydroergotamine (DHE), for example, has been shown to acutely relieve a migraine attack in approximately 70% of patients. Recently, a novel pharmacological agent, sumatriptan (formerly called GR 43175), has been reported to be extremely effective in the acute treatment of migraine (Doenicke et al., *Lancet*, 1309, 1988). Unlike DHE, sumatriptan appears to exhibit few side effects. In the current study, an attempt was made to assess if DHE and sumatriptan share a common site of action at the molecular level.

The potency of dihydroergotamine (DHE) was determined at 13 neurotransmitter receptors using radioligand binding techniques. DHE is a potent agent (i.e. K_i < 100 nM) at 5-hydroxytryptamine$_{1A}$ (5-HT_{1A}), 5-HT_{1C}, 5-HT_{1D}, 5-HT_2, dopamine$_2$, alpha$_1$- and alpha$_2$-adrenergic binding sites. DHE displays moderate affinity (K_i = 100 - 1000 nM) for beta-adrenergic and dopamine$_1$ sites and is completely inactive (K_i > 10,000 nM) at 5-HT_3, muscarinic and benzodiazepine receptors. These results were then compared to similar data on sumatriptan. Sumatriptan is essentially inactive at all of the above sites (K_i > 10,000 nM) except for 5-HT_{1D} (K_i = 17 nM) and 5-HT_{1A} (K_i = 100 nM) receptors. Therefore, these data suggest that 5-HT_{1D} and/or 5-HT_{1A} receptors may play an important role in the pathophysiology of migraine.

CHARACTERIZATION OF SEROTONIN RESPONSES IN NEURONS OF GUINEA PIG CELIAC AND INFERIOR MESENTERIC GANGLIA IN PRIMARY CULTURE SR Knoper, SG Matsumoto, AG Meehan, and DL Kreulen. Departments of Internal Medicine, Physiology and Pharmacology, University of Arizona. Neurons from adult celiac or inferior mesenteric ganglia were enzymatically dissociated (papain, collagenase-dispase) and maintained in primary culture for 3-30 days. Voltage responses to serotonin (10 μM) applied by pressure ejection were measured with intracellular microelectrodes (80-120 megohms; 3M KCl). Mean resting E_m was -61 mV. All 7 IMG and twenty-eight of 32 celiac cells measured responded with a 2-25 (mean=10.7) mV depolarization and 1-16 (mean=4) second duration to single ejection pulses. Some had superimposed action potentials. In 12 celiac and 5 IMG cells MDL 72,222 (5μM) antagonized the depolarizations (85% mean reduction). Neither hexamethonium nor atropine antagonized this response. Repetitive ejection pulses evoked a two phase response consisting of an initial fast phase blocked by MDL 72,222 and a later slow phase not blocked by MDL 72,222. Neither methysergide nor methiothepin antagonized slow serotonin responses in those cells tested (n=3). These findings suggest serotonin activated $5HT_3$ and non $5HT_3$ receptor mediated events on the same neuron. Supported by DK36289 and HL27781.

6.13

EXPERIMENTAL MODIFICATION OF SEROTONIN EXPRESSION IN CAUDAL VS. ROSTRAL RHOMBENCEPHALON CULTURES: IMMUNOCYTOCHEMICAL AND BIOCHEMICAL ANALYSIS. N. König, D. Becquet*, MJ. Drian* and F. Héry*. INSERM U 249 and CNRS UPR 41, Montpellier; and INSERM U 297, Marseille, France.

This study aimed at the analysis of genetic vs. epigenetic regulation of serotonin expression in neurons taken from different regions of the embryonic rat rhombencephalon (RE). The caudal basal-plate (BP) part of the RE (including groups B1-B3 or B1-B2 alone) and the rostral BP part (including B4-B9) were dissected from day 14 or 16 rat embryos. The cells were dissociated and plated either alone or in cultures where 25 % of BP cells were mixed with 75 % of caudal or rostral alar-plate (AP) cells. Since the embryonic AP does not contain serotonin expressing cells, the number of immunostained cells in the mixed cultures should be reduced to 25 % due to the dilution. In the rostral RE mixed cultures, the number of immunostained cells was close to the expected value; in the caudal RE mixed cultures however, it was significantly lower. Radio-isotopic assays also showed an overproportional decrease in newly synthesized serotonin, and this effect was stronger in the caudal than in the rostral RE mixed cultures. Pharmacological analysis showed that the B1-B3 as well as the B4-B9 cells were able to negatively autocontrol serotonin synthesis by type 1 5-HT autoreceptors. It is likely that additional mechanisms are implicated in the regulation of serotonin expression in RE subpopulations. GRANTS: INSERM, CNRS, IRME.

BRAIN INTERLEUKIN-1 INDUCED IMMUNOSUPPRESSION: DOSE RESPONSE INHIBITION BY ALPHA-MSH. J.M. Weiss, S.K. Sundar*, M.A. Cierpial and J. Ritchie. Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

In recent studies showing that microquantities of IL-1 in brain suppress peripheral cellular immune responses, we found that alpha melanocyte stimulating hormone (a-MSH) introduced into the ventricular system blocked immunosuppressive effects of both exogenous IL-1 and endogenous IL-1 released in response to lipopolysaccharide infused into the lateral ventricle. The present study demonstrated that a-MSH blocks effects of intraventricular IL-1 in a dose-dependent manner.

Animals were infused intraventricularly with IL-1 (100 pg) together with ascending doses of a-MSH (0,0.1,1.0, or 10.0 ng). In comparison to vehicle-infused controls, IL-1 alone (i.e., 0 a-MSH) depressed natural killer cell (NK) activity; increasing concentrations of a-MSH progressively blocked this effect, with the highest dose (10.0 ng) completely blocking the suppressive effect of IL-1.

IL-1 in brain produces part of its immunosuppressive effects by stimulating the pituitary-adrenal axis and elevating plasma corticosteroids. Measurement of plasma steroids showed that the ability of intraventricular IL-1 to stimulate the pituitary-adrenal axis was also blocked by alpha-MSH in a dose-dependent manner, which may account, in part, for how alpha-MSH blocks the immunosuppressive effects of brain IL-1.

7.2

BRAIN INTERLEUKIN-1 (IL-1) INDUCED IMMUNOSUPPRESSION: MEDIATION BY CRF AND SYMPATHETIC ACTIVATION. S.K. Sundar*, M.A. Cierpial, C.D. Kilts & J.M. Weiss. Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

We recently demonstrated that infusion of picogram quantities (i.e. 3.1 X 10^{-15} moles) of IL-1 into the lateral ventricle of rats results in a rapid decrease in peripheral cellular immune responses. This study investigated whether corticotrophin releasing factor (CRF) in brain and the sympathetic nervous system (SNS) mediates immunosuppression produced by IL-1 in brain.

Rats received either ventricular infusion of affinity purified anti-CRF IgG or i.p. injection of the ganglionic blocker chlorisondamine prior to central IL-1 infusion. Fifteen minutes after IL-1, in vitro immune responses of blood and splenic lymphocytes were analyzed. Immunoneutralization of brain CRF attenuated the immunosuppressive effects of IL-1 completely in blood lymphocytes but only partially in splenic lymphocytes. Conversely, chlorisondamine blockade of the SNS attenuated immunosuppression completely in splenic but not blood lymphocytes. These results indicate that brain IL-1 affects immunological cells via CRF pathways in brain and the SNS, and that these pathways differentially affect different populations of lymphocytes.

7.3

THE EFFECT OF DIFFERENT NUMBERS OF MICE PER CAGE ON IL-1 AND BONE MARROW STEM CELLS. B. S. Rabin and S. B. Salvin. Dept. of Pathology, Univ. Pittsburgh, Pittsburgh, PA 15261.

A number of studies have been conducted in our laboratories for the purpose of examining immunologic changes which occur when different numbers of animals are housed per cage. The studies indicate that an alteration of immune reactivity occurs when certain mouse strains are housed either 1 or 5 per cage. C3H/HeJ male mice and CD-1 mice of either sex, when housed individually, have an enhanced immune response to sheep erythrocytes, produce more IL-2 , and respond more vigorously to mitogenic stimulation. We now report that IL-1 production, macrophage phagocytosis, as well as changes occurring as early as bone marrow precursor cells, have an enhanced activity in individually housed C3H/HeJ male mice. Peritoneal exudate cells were collected and incubated with LPS. The supernatants and cell lysates were tested in a mouse thymocyte stimulation assay. The individually housed mice produced more IL-1 in the supernatant ($P<0.005$) and cell lysate ($P<0.02$). Phagocytic activity was increased 50% and colonies of macrophages developing from bone marrows of individually housed mice were 1.5 times more abundant than from group housed mice. The production of macrophage colony stimulating factor from spleen cells was twice that of individually housed mice. The data suggest that housing can influence multiple factors relating to resistance to infection. Environment appears to be an important modulator of immunity.

7.4

INTERLEUKIN-1 POTENTIATES THE SECRETION OF B-ENDORPHIN INDUCED BY SECRETAGOGUES VIA PROTEIN KINASES IN A MOUSE PITUITARY CELL LINE (AtT-20). M.O.Fagerasen[1], M.S.Rinaudo[2], J.F.Bishop[2], and J.Axelrod[3]. [1]Clinical Neuroscience Branch, NIMH and Peptide Design; [2]Experimental Therapeutic Branch, NINDS; [3]Laboratory of Cell Biology, NIMH.

Interleukin-1 (Il-1) enhances the release of B-endorphin induced by corticotropin releasing factor (CRF), vasoactive intestinal peptide, forskolin, norepinephrine, isoproterenol and phorbol ester in the AtT-20 mouse anterior pituitary cell line. The effect is apparent after 12 hours of pretreatment with Il-1, reaches a maximum at 24 hours and is dose dependent. Desensitization of protein kinase C abolishes the potentiation of the secretory action of phorbol esters by Il-1, but only partly reduces Il-1 enhancement of the secretory effects of CRF and other secretagogues. Treatment of the cells with staurosporin, an inhibitor of protein kinases, resulted in further decreases in the enhancement of CRF-induced B-endorphin release produced by Il-1.

To examine the role of protein phosphorylation in Il-1 receptor mediated events, AtT-20 cells were preloaded with ^{32}P and stimulated with IL1-a. Cytosolic phosphoproteins were identified using two dimensional gel electrophoresis with subsequent autoradiography. Il-1 increased the incorporation of ^{32}P into several proteins in a time-dependent manner.

After a 15 minute treatment of the cells with Il-1, an increase in the phosphorylation of a 19 kDa protein associated with secretory activity was observed. After abolishing protein kinase C activity by pretreating the cells with phorbol ester (10^{-7} M, 24 hours), the effect was still apparent indicating that this phosphorylation event does not occur via the protein kinase C pathway. Il-1 also increases early phosphorylation of a 60 kDa protein. After 1 hour of treatment with Il-1, an increased phosphorylation of the 87 kDa protein, which has been previously characterized as a protein kinase C specific substrate, appeared.

These results indicate that Il-1 potentiates the effects of secretagogues in AtT-20 cells possibly by acting on protein kinases in sequential fashion.

7.5

HYPEREXPRESSION OF INTERLEUKIN 1 mRNA BY PERIPHERAL MACROPHAGES OF CEREBELLAR MUTANT MICE STIMULATED IN VITRO BY LPS. B. Kopmels*, E.E. Wollman*, J.M. Guastavino*, N. Delhaye-Bouchaud*, D. Fradelizi* and J. Mariani. Lab. Immunologie, Institut Gustave Roussy, Villejuif (94) and Institut des Neurosciences, Univ. P. et M. Curie. 75005- Paris (France).

Several mutations in mice produce complex patterns of neuronal degeneration of the cerebellum and of its afferent pathways. In the staggerer (sg/sg) mutant, atrophy of the lymphoïd organs and immunological abnormalities have been recently described (Trenkner and Hoffman, 1986). To search for a possible link between the neurological and the immune disorders in this mutant, we studied the production by peripheral monocytes of interleukin 1 (IL-1), whose roles in both immune and nervous system are well established.

Suspensions of peritoneal and/or spleen monocytes from mutants and their controls were stimulated in vitro by LPS; total RNA was prepared and Northern and dot blots were performed by using murine recombinant IL-1 α and β probes. They revealed an up to tenfold expression of IL-1 α and mRNA in staggerer macrophages. A similar phenomenon was detected using bioassay of IL-1 activity. The hyperexpression was found in 3 week to one year old staggerer and also in heterozygous +/sg. A similar phenomenon existed in cerebellar mutants lurcher, pcd and to a lesser extent in reeler but was absent in weaver and jimpy.

Work is in progress to disclose a possible hyperexpression in brain microglia of these mutants and to unravel the mechanisms involved.

7.6

CORTICOTROPIN-RELEASING FACTOR (CRF) RECEPTORS ARE PRESENT ON MOUSE SPLENIC MACROPHAGES. E.L. Webster, D.E. Tracey*, S.A. Wolfe, Jr., M.A. Jutila* and E.B. De Souza. Neurobiology Laboratory, NIDA/ARC, Baltimore, MD 21224; The Upjohn Co., Kalamazoo, MI; Department of Pathology, Stanford University School of Medicine, VA Medical Center, Stanford, CA.

Previous studies in our laboratory have identified CRF binding sites in mouse spleen with kinetic and pharmacological characteristics comparable to the well-characterized CRF receptors in pituitary and brain. In addition, splenic CRF receptors have been demonstrated to be functionally coupled to a guanine nucleotide protein mediating stimulation of adenylate cyclase activity. In autoradiographic studies, ^{125}I-oCRF binding sites were localized to the red pulp and marginal zones of splenic follicles known to be enriched for macrophages. In the present study, the identity of spleen cells bearing ^{125}I-oCRF binding sites was elucidated. The autoradiographic distribution of ^{125}I-oCRF binding sites in spleen was similar, if not identical, to the histological distribution of phagocytic cells in spleen as indicated by uptake of India ink particles *in vivo*. Furthermore, when splenic cells were fractionated on the basis of density, adherence, and phagocytic activity, ^{125}I-oCRF binding significantly correlated with the percentage of cells phagocytosing latex beads and staining with a monoclonal antibody (MONTS-4) specific for resident splenic macrophages. The presence of CRF binding sites on adherent, phagocytic, light density cells, and the histological localization of CRF binding to areas of the spleen known to be enriched in macrophages strongly suggests that splenic macrophages are targets for direct immunomodulatory actions by CRF.

7.7

A DEFECT IN CORTICOTROPIN RELEASING HORMONE (CRH) BIOSYNTHESIS IS ASSOCIATED WITH SUSCEPTIBILITY TO STREPTOCOCCAL CELL WALL (SCW) ARTHRITIS IN LEWIS (LEW/N) RATS. E.M. Sternberg*, W.S. Young III, A.E. Calogero*, R. Bernardini*, J. Glowa, M. Smith, S. Aksentijevich*, C. Smith*, S. Listwak*, G.P. Chrousos, P.W. Gold* and R.L. Wilder*. (SPON:N.H.Spector) NIMH, NIH, Bethesda, MD, 20892.

A CNS-immune system feedback loop has recently been described in which immune mediators stimulate the hypothalamic-pituitary-adrenal (HPA) axis, and the resultant glucocorticoid release suppresses excessive inflammation. We have found that a defect in this feedback loop is associated with susceptibility to development of SCW arthritis in LEW/N rats, while resistance to SCW arthritis in histocompatible F344/N rats is related to intact HPA axis responses to the same inflammatory mediators (*Proc. Natl. Acad. Sci.*, 86:2374, 1989). We now report that the depressed LEW/N ACTH and corticosterone responses to both inflammatory mediators and behavioral stresses are related to a defect in CRH biosynthesis in the paraventricular nucleus (PVN) of the hypothalamus. In contrast to F344/N rats, there was no increase in LEW/N total hypothalamic CRH content in response to intra-peritoneal (i.p.) SCW or recombinant interleukin-1 alpha (rIL-1). CRH secretion from LEW/N hypothalamic explants increased 10% over baseline in response to rIL-1 compared to 150% from F344/N hypothalami. LEW/N rats also exhibited depressed expression of CRH mRNA in the PVN in response to i.p. SCW, as evidenced by *in situ* hybridization histochemistry. The additional finding of deficient expression in the PVN of the co-regulated enkephalin gene suggests that the primary defect is not in the CRH gene but is in its inappropriate regulation.

CLASS II MHC GENE EXPRESSION IN THE MOUSE BRAIN IS ELEVATED IN THE AUTOIMMUNE MRL/Mp-Lpr/Lpr STRAIN. K.R. McIntyre[1], C. Ayer-LeLievre[2], H. Persson[1](SPON: M. Schalling). [1]Dept. of Medical Chemistry, Lab. Molecular Neurobiology and [2]Dept. of Histology and Neurobiology, Karolinska Institute, Box 60400, S-10401, Stockholm, Sweden.

Class II MHC gene expression in the brain of several normal and autoimmune mouse strains has been quantified by RNA blot analysis using murine I-A and I-E genomic probes. We have detected Ia-A and B mRNA in the brain of every mouse strain examined, albeit at levels 30-50-fold lower than those found in the spleen, with the exception of the autoimmune MRL/l strain, in which Ia transcripts in the brain are elevated to a level comparable to that found in normal mouse spleen. The elevation of Ia mRNA in MRL/l as compared to control C3H mice also extends to other organs, being most pronounced in kidney and brain but not significant for thymus and lung. Evidence against a major role for blood cells as the source for Ia mRNA comes, among other things, from the finding that Ia mRNA in MRL/l as compared to control C3H mice is elevated to a greater extent in the poorly vascularized diencephalom than in the richly vascularized choroid plexus. Further experiments with normal rats demonstrated a large quantitative variation in Ia mRNA in different brain regions, with the highest levels being found in the olfactory bulb, followed by the cerebellum, the superior colliculi, and the pons/medulla. The findings are discussed in relation to an animal model for central nervous system (CNS) involvement in systemic lupus erythenatosus.

INTERLEUKIN-1 ADMINISTRATION PRODUCES A STRESS-LIKE REDUCTION OF EXPLORATORY BEHAVIOR IN MICE. F. Spadaro*, C.W. Berridge and A.J. Dunn (SPON: C.S. Sebastian). Department of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130-3932.

The time for which rats and mice investigate novel stimuli in the multicompartment testing chamber (MCC) is reduced by various stressful treatments. This effect is mimicked by corticotropin-releasing factor (CRF) injected intracerebroventricularly (ICV). Because interleukin-1 has been shown to activate the hypothalamic-pituitary-adrenal (HPA) axis, an effect that is presumed to involve secretion of hypothalamic CRF, we have investigated whether IL-1 has any related behavioral activity.

Human recombinant IL-1α was injected ICV in doses of 100-100,000 Units. Each of these doses produced reductions in the time mice spend in contact with the stimuli in the MCC. At the higher doses, locomotor activity was also reduced, but this effect was not observed at the lower doses. Although IP administration of IL-1 activates the HPA axis, we only observed seemingly nonspecific reductions in all behaviors at doses of 10^5-10^6 Units. Similar responses were observed following IP administration of bacterial endotoxin (lipopolysaccharide), a known stimulator of endogenous IL-1 production. Thus our results suggest that central administration of IL-1 may elicit cerebral CRF secretion that elicits the behavioral response. This hypothesis is consistent with the reported role of CRF in ICV IL-1-induced fever.

RELEASE OF INTERLEUKIN-6 FROM RAT HYPOTHALAMUS. B.L. Spangelo*, I.S. Login*, A.M. Judd*, P.C. Isakson* and R.M. MacLeod. Departments of Medicine, Neurology and Pharmacology and the Center for Cancer Research, University of Virginia Health Sciences Center, Charlottesville, Virginia 22908.

We have reported that the inflammatory cytokine, interleukin-6 (IL-6), stimulates anterior pituitary hormone release *in vitro*. We therefore hypothesized that IL-6 may be released from the hypothalamus, thus functioning as a pituitary hormone releasing factor *in vivo*. Female Sprague-Dawley rats were sacrificed and their brains rapidly removed and placed on an ice-cold surface. Medial basal hypothalami were removed to a depth of 3 mm, halved, weighed and placed in 1 ml RPMI-1640 containing 10% serum (complete medium) in a metabolic shaking water bath (1 half/well) under an atmosphere of 95% O_2/5% CO_2. After a 1-hr preincubation, the tissues were removed and placed in fresh complete medium (vehicle) or complete medium containing lipopolysaccharide (LPS) or IL-1. After 2 and 4 hr, aliquots of incubation medium were removed and assayed for IL-6 activity in the hybridoma 7TD1 growth factor assay.

Hypothalamic tissue released an IL-6 activity in a time-dependent manner (2-4 hr; 5.29-18.5 U/mg). LPS (10-100 ng/ml) significantly increased this release after 2 (2.7-fold) and 4 (3.1-fold) hr of incubation. IL-1 (200 U/ml) significantly reduced the basal release of IL-6 by 44%. Sensori-motor cortex released smaller amounts of IL-6 (2-4 hr; 2.38-12.1 U/mg), but this release was not stimulated by LPS.

These data suggest that IL-6 is released from the hypothalamus and cortex. In the presence of LPS, the release of this cytokine from the hypothalamus is much greater than that from the cortex. Hypothalamic production of IL-6 suggests that it could function as an anterior pituitary releasing factor *in vivo*. [Supported by NCI grants CA-07535 to R.M.M. and CA-38228 to I.S.L., and a new initiative grant from the University of Virginia DERC (AM22125) to P.C.I.]

7.11

DIFFERENTIATION OF TRANSPLANTED FETAL NEURAL CELLS AND IMMUNOLOGICAL RESPONSES IN THE HOST BRAIN. K.Shimizu*, M.Yamada*, Y.Matsui*, S.Moriuchi*, H.Mogami*. Dept.of Neurosurg., Osaka Univ., Sch.of Med., Osaka 553, Japan (SPON: E. Senba)

Attempts of neural transplantation have been done in patients with Parkinson disease, who become inexorably progressive disability regardless of administration of drugs. To examine whether or not some immunological responses are induced in the recipient's brain in which some kinds of neural tissues were transplanted, we established Parkinson models which were made the unilateral 6-OHDA lesions in the nigrostriatal pathway of C57BL/6 (H-2^b) mice. A complete recovery of methamphetamine-induced rotational response was shown about 60 days after transplantation of embryonic DA-rich cells from syngeneic or allogeneic (C3H/HeN, H-2^k) mice. Immunohistochemistry showed that TH-immunoreactive cells were deeply embedded in the ipsilateral striatum, with a dense network of neuronal processes, and that the NSE, NFP(200K), GFAP or MBP-positive cells mingled among these grafted cells. The FACS IV analysis revealed no H-2 (H-$2K^k$ and Ia^k) antigens on the embryonic cells of C3H/HeN mice. However, H-$2K^k$ antigens could be induced on these embryonic cells by mouse IFN-gamma. Now, we investigate H-2 antigens on the grafted cells survived in the host brain.

MOLECULAR CLONING AND CHARACTERIZATION OF NEUROIMMUNE GENES. A. Ericsson*, G. Barbany*, W. Friedman and H. Persson*. (SPON: M.E. Ehrlich). Lab. of Molec. Neurobiol., Dept. of Med. Chem., Karolinska Institute, Stockholm, Sweden.

Recent neuroimmunological research has detected the presence of common sets of signalling substances and receptor systems among the neuroendocrine and the immune systems, thus providing a possible mechanism for communication. In order to explore the neuroimmunological interplay, we have isolated several genes from rodent cDNA libraries that are expressed predominantly within the neuroendocrine and immune systems, using a combination of subtractive hybridization and cDNA cloning. Northern blot analysis and *in situ* hybridization revealed that these genes, encoding high molecular weight mRNAs, are expressed by neurons over the entire CNS as well as in various immune tissues from rodents and man. Other tissues examined showed a low or insignificant expression. One clone, termed NI-1, was analyzed in further detail and in CNS this gene was highly expressed in the pyriform cortex, various nuclei in the limbic sysem and in some hypothalamic nuclei. A tenfold increase in total brain mRNA expression was detected around birth. Mitogen stimulation of mouse spleen cells induced a massive mRNA expression. Also, the gene appears to be under negative control by adrenal steroids as adrenalectomy in rat resulted in a tenfold increase in CNS, thymic and splenic expression. The DNA sequence of this cDNA clone showed no significant homology to any other known genes.

TRANSPLANTATION I

8.1

NONINVASIVE LASER-LESIONING OF MOUSE NEOCORTICAL NEURONS IN VIVO. Madison, R.[1], and Macklis, J.D.[2]. [1] Division of Neurosurgery, Duke University, Durham, N.C. 27710, and [2] Dept. of Neurology, Program in Neuroscience, Harvard Medical School and Children's Hospital, 300 Longwood Ave., Boston, MA. 02115

The ability to selectively label neurons on the basis of their connections for subsequent lesioning would constitute a powerful tool for studying the roles of cell-cell interations in development and adult reorganization. Toward that aim, we have labeled neuronal subpopulations in vivo and subsequently lesioned the targeted neurons via noninvasive exposure to unfocused 650 nm laser illumination. Sixty-seven mice were used for these studies. Approximately 50-70% of the surface energy at 650 nm is transmitted through mouse skull and brain. Forty animals served as controls for laser exposure alone. Through intact skull, mice received fractionated unilateral exposures that totaled 12.5, 25, 50, or 160 Joules/cm^2. Animals were perfused 3 hr. - 7 days later and histologically processed, using a silver degeneration stain to demonstrate damaged neurons. Experimental animals received unilateral injections into motor cortex of latex nanospheres with an incorporated cytolytic chromophore (see Macklis and Madison Abst.). Following 2-3 months animals received laser exposure as described above. Variable numbers of damaged neurons were evident in layers II/III and V of lased cortex within the area of laser exposure. Control animals which received either laser exposure alone, or nanosphere injection alone, did not display equivalent damage. Whitaker Fdn., NS26311, HD00859, Alz. Fdn.

8.2

NONINVASIVE LESIONING OF MOUSE NEUROBLASTOMA CELLS BY DYE-TARGETED LASER PHOTOLYSIS AFTER GRAFTING INTO MOUSE NEOCORTEX IN VIVO. J.D.Macklis[1] and R.Madison*, [1]Dept. of Neurology, Prog. in Neuroscience, Harvard Medical School, Children's Hosp., Boston, MA and *Div. of Neurosurgery, Duke Univ., Durham, NC

We are developing methods by which neurons targeted by retrograde incorporation of photoactive chromophores can be noninvasively lesioned within the rodent CNS without injury to intermixed neurons, glia, axons, or vascular and connective tissue. At long wavelengths between 650 and 800 nm, laser energy can penetrate nervous system tissue several millimeters without absorption by unpigmented tissue. Illumination at these long wavelengths damages cells containing latex nanospheres with incorporated cytolytic chromophores (chlorin e6, e.g.). We studied damage by this process of laser photolysis (PL) to C1300 neuroblastoma (NB) cells grafted into mouse neocortex in vivo.

NB cells were cultured by standard methods, labeled in vitro by brief exposure to latex nanospheres containing rhodamine as a fluorescent label and chlorin e6, and repeatedly washed for 24 hours. Young adult mice were injected with labeled NB cells within deep layers of motor cortex bilaterally, and overlying skull was replaced. After 24 hours, mice were exposed unilaterally through intact skull to pulsed 650 nm wavelength laser energy to total doses of approximately 120 Joules/cm^2. Control mice had either labeled NB injections without laser exposure, unlabeled NB injections with laser exposure, or laser exposure alone. Serial sections of brains were examined histologically after 2, 7, and 14 days. Injected control mice and the unlased experimental hemispheres typically showed large NB tumors at 7 and 14 days with areas of necrosis and hemorrhage. Surrounding tissue was undamaged by these laser energies. Injected hemispheres exposed to laser energy showed absence or reduction of NB tumor volume with degenerating NB cells, lymphocytic and macrophage infiltrate, and normal surrounding cellular architecture. These results suggest that prelabeled neurons could be noninvasively removed following transplantation into rodent CNS. HD00859, NS26311, Alzheimer's Assn, Whitaker Fdn

RETROVIRUS-MEDIATED ONCOGENE TRANSFER INTO FETAL BRAIN TRANSPLANTS - A NOVEL APPROACH TO NEURO-ONCOGENESIS. O.D. Wiestler, P. Kleihues* and A. Aguzzi*. Laboratory of Neuropathology, University of Zürich, CH-8091 Zürich, Switzerland.

Using a neural transplantation model and retrovirus-mediated gene transfer, we have introduced activated oncogenes into the developing rat brain. With mock-infected donor cells, the transplants gave rise to highly differentiated neuroectodermal tissue containing all major CNS cell types. A high percentage of transplants exposed to the *polyoma medium T* oncogene developed endothelial hemangiomas which expressed factor VIII-related antigen. No abnormalities were seen in neurons and glial cells. By *in situ* hybridization, transcripts of the *medium T* oncogene were detectable in hemangiomas and in morphologically normal neuroectodermal cells. Medium T protein was also identified in hemangioma-derived cell lines by immunoprecipitation and *in vitro* kinase assay. In order to assess the cell-specificity of the oncogene, analogous experiments were carried out with retroviral constructs harboring the *v-src*, *c-src-Phe527*, *v-Ha-ras* and *v-myc* oncogenes, respectively. Transplants infected with the *v-src* construct developed astrocytic tumors and mesenchymal neoplasms, but no vascular abnormalities. in these grafts, *v-src* transcripts were detectable in the tumors, but also in non-transformed neuroectodermal and endothelial cells. Coexpression of *v-ras* and *v-myc* cDNAs yielded highly malignant, polyclonal lesions apparently derived from poorly differentiated precursor cells. These observations indicate that activated oncogenes are capable of transforming specific target cells in the developing brain. Experiments to uncover the molecular basis of cell-specific oncogene action and to identify target cell lineages are in progress.

GENE TRANSFER INTO NEURONS OF THE ADULT RAT BRAIN. B.A. Sabel, C. Martin*, C. Waldmann*, A. Freese and A. I. Geller. Inst. Med. Psych. U. Munich Med. Sch. F.R.Germany, Div. HST., MIT, Cambridge MA, and Div. Cell Growth & Regulation, Dana Farber Can. Inst. Boston, MA 02115.

Genes were delivered into neurons of the adult rat brain using a defective Herpes Simplex Virus (HSV-1) vector. This approach could be used to alter normal neuronal physiology to study learning and memory or perform gene therapy on neuronal diseases, such as Parkinson's Disease.

We have previously described a HSV-1 vector, pHSVlac, which stably expresses ß-galactosidase from the E. coli Lac Z gene in cultured neurons from throughout the nervous system (Science 241, 1667, 1988). We now demonstrate stable expression of ß-galactosidase in neurons following stereotaxic injection of purified pHSVlac virus into the adult rat brain. Following injection of pHSVlac virus into the anterior medial secondary visual area, dorsal hippocampus, stratum opticum of the superior colliculus, red nucleus, and substantia nigra, ß-galactosidase immunoreactive (ß-Gal-IR) cells were observed around the injection site and in neurons projecting to it, presumably due to retrograde transport of the virus. Furthermore, some ß-Gal-IR cells also contained neurofilament-IR. Expression of ß-galactosidase was stable; injection of pHSVlac virus into the superior colliculus resulted in expression of ß-galactosidase in layer 5 pyramidal neurons of primary visual cortex for at least 1.5 months. In contrast to wild type HSV-1, pHSVlac virus did not spread throughout the brain; persistent pHSVlac DNA was not reactivated. Therefore, the location of the injection site and amount of virus in the innoculum determines which neurons are infected. Finally, the Lac Z gene in pHSVlac can now be replaced by other coding sequences whose products affect neuronal physiology, such as second messenger enzymes or components of neurotransmitter release.

MYELIN FORMATION IN MYELIN-DEFICIENT RAT SPINAL CORD AFTER TRANSPLANTATION OF NORMAL FETAL SPINAL CORD CULTURES. J.Rosenbluth, M.Hasegawa*, N.Shirasaki*, C.Rosen & Z.Liu*. Depts. Physiol. & Rehab. Med., N.Y.U. School of Med., NY 10016.

Normal E15-18 d. rat CNS glial cells cultured 2 or 7 d. and injected into juvenile mdr spinal cord resulted in equal myelin formation in the host 11-14 d. later. In both cases, more myelin formed than after injection of spinal cord fragments, but the area myelinated was still largely restricted to the injection site. Immunostains showed no galactocerebroside in cells cultured 2 d., but after 7 d., ~10-15% of cells were GC+. At both times, ~25% were GFAP+, but none showed neurofilament staining. Injection of donor tissue that had been frozen and thawed, heated to 60°C, or fixed in formaldehyde resulted in no myelin formation. Nor did injection of fetal mouse spinal cord, adult rat cord or a solvent extract of adult rat cord. Thus, we were unable to induce host oligodendrocytes to form normal myelin by injecting killed or disrupted donor cells or tissue extracts. The results imply that the myelin formed after injection of cultured fetal glia is generated by donor glia rather than by host glia that have incorporated injected cell components. Supported by NIH & NMSS.

MYOBLAST TRANSFER THERAPY AND NUCLEAR TERRITORY IN DYSTROPHIC MICE. P.K. Law, H-J. Li*, T.G. Goodwin*, G. Ajamoughli*, X. Y. Zhang*, and M. Chen*. Depts. of Neurology, and Physiology/Biophysics, Univ. of Tennessee, Memphis, TN. 38163.

A therapy has been developed to treat hereditary muscle degeneration. Injection of histoincompatible normal myoblasts into dystrophic muscles improved the structure and function of the muscles to almost normal. Immunosuppression of the dy^{2J}/dy^{2J} hosts was induced by daily subcutaneous injection of cyclosporin-A at 50mg/kg body weight for 6 months. Eleven out of nineteen mice that received myoblast injections in their leg and intercostal muscles on both sides showed locomotive patterns similar to normal. Life spans of the myoblast-injected dystrophic mice were extended from nine to eighteen months. Using dimeric isozymes of glucosephosphate isomerase as genotype markers for host and donor cells, the demonstration of parental and hybrid isozymes inside the injected muscles substantiated the survival and development of donor myoblasts into normal myofibers, and the fusion of normal myoblasts with dystrophic satellite cells to form genetically mosaic myofibers. Immunocytochemical analyses of host and donor nuclei within mosaic myofibers indicated that normal-appearing fibers contained at least 20% of randomly-distributed normal nuclei. The therapy replenishes lost cells and repairs degenerating cells and is based on muscle developmental processes universal to all mammals. (Supported by USPHS NS-20251,26185)

8.7

TRANSPLANTATION OF RODS TO RODLESS RAT RETINA. P. Gouras, J. Du*, M. Gelanze*, R. Lopez* and H. Kjeldbye*. Columbia Univ. Dept. Ophthal. New York, N.Y. 10032

Photoreceptors are highly specialized neurons which can be easily identified in the retina. They can be dissociated from their contacts with other cells and maintained viable in vitro where they can form synapses with other neurons (MacLeish and Townes-Anderson, Neuron 1:751, 1988). We have dissociated rat rods and mixed them with previously dissociated retinal epithelial cells from normal pigmented rats from a strain congenic to an ocular albinotic mutant for retinal dystrophy. The dystrophic rats lose their photoreceptors at 2-3 months of age. We have transplanted the rods and retinal epithelial cells to the subretinal space of 4-5 month old dystrophic rats. The normal pigmented epithelium both corrects the phagocytic defect in the mutant strain and allows tracking of the rods by light microscopy. Electron microscopy reveals the presence of rods, with outer segment, inner segment and nucleus in close apposition to transplanted pigment retinal epithelial cells for at least 24 hours after transplantation. These are transplanted rods because none are found in retinas of contralateral control eyes.

8.8

NEURAL TRANSPLANTS IN AN EXPERIMENTAL MODEL OF AMYOTROPHIC LATERAL SCLEROSIS F. Nothias*, J.C. Horvat*, M. Pécot-Dechavassine*, J.C. Mira* and M. Peschanski (spon: B. Onténiente) INSERM U 161. Univ. Paris V. Inst. Neurosc. CNRS. Paris France.

Amyotrophic lateral sclerosis is a motoneuronal degenerative disease leading to paralysis and muscle atrophy. Deep intra-spinal injections of excitotoxic substances reproduce some aspects of the disease. The present study was undertaken to determine whether fetal spinal neurons transplanted into the lesion as a cell suspension may reconstruct parts of the disrupted circuitry.

Transplanted neurons developed and differentiated although few motoneurons were immunocytochemically identified. Afferent fibers from the host innervated the transplants: descending monoaminergic fibers grew into the transplants and formed a loose network: cortico- and rubro-spinal fibers were few in number and contacted neurons only in the peripheral areas of the grafts: primary CGRP-immunoreactive C-fiber afferents contacted transplanted neurons mostly in their usual localization in the dorsal horn.

Grafted neurons did not grow axons into the host ventral roots. In contrast, axonal outgrowth was obtained when a piece of sciatic nerve was implanted at one end into the neural graft.

These experimental results are presented as a first step in the search for a palliative therapy against motoneuronal degenerative diseases. Supported by APA grants TC88-01 and AI-88002-1

INTRAPARENCHYMAL GRAFTING OF CEREBELLAR CELL SUSPENSIONS TO THE DEEP CEREBELLAR NUCLEI OF pcd MUTANT MICE: RATIONALE AND HISTOCHEMICAL ORGANIZATION. L.C. Triarhou, W.C. Low and B. Ghetti. Dept. Pathol. (Neuropathol.) and Physiol. & Biophys., Med. Neurobiol. Pgm, Indiana Univ. Sch. of Med., Indianapolis, IN 46223

In transplanting embryonic cerebellar grafts to the cerebellar cortex of 'Purkinje cell degeneration' (pcd) mutant mice to replace missing Purkinje cells (Pc), donor Pc leave the graft and migrate to the molecular layer of the host. However, Pc axons do not reach the deep cerebellar nuclei (DCN) of the host, which would be a key element in providing the necessary inhibitory cortico-nuclear projection associated with cerebellar function in normality. Rather, grafted Pc often leave their axon inside the transplant, while the perikaryon migrates to the host molecular layer. In the present study, aiming at re-establishing a Pc innervation of the DCN, we implanted E12 cerebellar cell suspensions intraparenchymally to the DCN of the hosts. The development of grafted Pc was monitored with 28-kDa calcium-binding protein (CaBP) immunocytochemistry. Donor Pc were found in clusters both deeply in the DCN parenchyma and aligned along cortical folia. A CaBP immunoreactive fiber plexus innervated the host DCN. Physical continuity between Pc in the DCN and in the cortex was seen, indicating the possibility that donor Pc establish their axonal contacts in the DCN and then move to their final cortical locality, thus recapitulating a migratory path normally taken during embryonic development. It appears, therefore, that DCN may be an important site for Pc implantation both from the ontogenetic and pathophysiological standpoint.

8.10

ISOCHRONIC TRANSPLANTATION OF NEONATAL GRAFTS IN THE VISUAL CORTEX OF CATS: RESPONSIVENESS, OCULAR DOMINANCE AND SPECIFICITY OF THE CELLS TO VISUAL STIMULATION. U.Yinon and S. Gelerstein*. Physiol. Lab., Goldschleger Eye. Res. Inst., Tel-Aviv Univ. Fac. Med., Sheba Med. CTR, Tel-Hashomer, 52621, Israel.

Neonatal isochronic cortical transplants were studied physiologically in order to reveal possible functional integration within the host cortex. Extracellular unit recording was made in cortical areas 17 and 18 of 3 homograft cats with transplants between brothers (N=225 cells), 4 cats with reimplanted autografts (N=133), and pseudograft controls with analogous sectioning (3 operated kittens, N=173; 5 adults, N=204). Cellular activity was indicated by typical bursts of action potentials in the transplanted sites and in the host tissue. Visual responsiveness in the transplanted sites was the highest in the adult pseudografts (>60%) and the smallest in the homografts (<20%). Ocular dominance distribution of cells showed the highest performance (similarity to the host tissue) in the kitten autografts and the lowest in the homografts. Orientation nonspecificity was the least in the adult pseudografts (<5%) and the most in the kitten autografts (>35%) while directional specificity showed no consistency in the various cats. It is concluded that cells in the transplanted site of the visual cortex showed partial functional recovery; their exact proportions, however, will be known after determining anatomically the boundaries of the transplant.

8.11

VASOPRESSIN NEURONS IN TRANSPLANTED PARAVENTRICULAR (PVN) AND SUPRACHIASMATIC (SCN) NUCLEI ESTABLISH DISTINCT SETS OF EFFERENT CONNECTIONS WITH THE HOST BRAIN. S.J. Wiegand and D.M. Gash. Dept. of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642.

Vasopressin-immunoreactive (VPir) neurons in transplanted fetal hypothalami exhibit several distinct morphological phenotypes. In particular, two types of parvicellular VPir neuron are often present in significant numbers, one of which develops from the anlage of the SCN and the other from the PVN. Previous work with grafts of whole anterior hypothalamus indicated that these morphologically distinct types of VPir neurons established discrete sets of efferent connections with the host brain. The present study was designed to confirm and extend these observations by separately transplanting microdissected PVN and SCN.

Donor tissue was obtained from normal Long Evans rat fetuses (E15-17), and the SCN or PVN from one donor was transplanted to the periventricular hypothalamus of an adult, VP-deficient Brattleboro host. Developing neocortex served as a tissue control. Host animals were sacrificed 6-12 weeks after transplantation; viable grafts were recovered in all cases. All SCN grafts contained VPir cells that resembled those of the endogenous SCN and which projected to areas of the host periventricular diencephalon that ordinarily are innervated by this nucleus. The subparaventricular zone, thalamic paraventricular nucleus and host SCN were especially likely to be densely innervated by SCN grafts. Conversely, transplanted PVN contained VPir neurons that resembled the parvicellular neurosecretory component of this nucleus. VPir neurons in PVN grafts projected to vasculature in the graft and host brain, and also to a well defined set of neural targets that were largely distinct from those innervated by SCN grafts. The medial and dorsal preoptic area, and the rostral paraventricular nucleus of the host brain were most consistently innervated by PVN grafts. Fewer VPir fibers were found in the periaqueductal gray, lateral hypothalamus and basal forebrain areas (especially the bed nucleus of the stria terminalis).

Supported by NIH grant NS 19900.

8.12

MAJOR HISTOCOMPATIBILITY ANTIGEN EXPRESSION AND CELLULAR RESPONSE IN SPONTANEOUS AND INDUCED XENOGRAFT REJECTION. I. F. Pollack*, R. D. Lund and K. Rao. (SPON: E. M. Nemoto). Department of Neurobiology, Anatomy, and Cell Science, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261

Embryonic mouse retinal transplants placed in the midbrains of neonatal rats generally survive for prolonged periods without immune suppression. Only 10 - 20 % of such grafts undergo "spontaneous" rejection, however, rejection can be induced by skin grafting, host eye removal (producing optic tract degeneration), and disruption of the blood-brain barrier with mannitol. In this study, the pattern and time course of major histocompatibility (MHC) antigen expression and the nature of the cellular response in each of these four rejection models were examined in detail histologically and immunohistochemically.

Embryonic CD-1 mouse retinal grafts (E13-14) were implanted in the dorsal mesencephalon of neonatal Sprague-Dawley rats. One month later, host rats received skin grafts, eye lesions, or intracarotid mannitol infusion. Control animals (for evaluation of spontaneous rejection) received none of these sensitizing stimuli. After appropriate survival times, fixation, and tissue preparation, adjacent sections were stained with cresyl violet, OX-6 (for MHC class II), OX-18 (for MHC class I), OX-42 (for microglia), W3/25 (for reactive microglia), anti-lymphocyte antibody, and GFAP (for astrocytes), and examined by light microscopy.

Spontaneous rejection (8 animals) was accompanied by diffuse expression of class I and II antigens (Ags), and widespread infiltration of inflammatory cells throughout the transplant and in the surrounding brain well rostral and caudal to the graft. Skin graft-induced rejection (16 animals) produced a much more localized expression of MHC Ags and infiltration of inflammatory cells that involved only the transplant itself and a small rim of surrounding host brain associated with a profound degree of graft necrosis. After eye removal (18 animals), prominent class I and II Ag expression was seen at 7 days in the optic terminal area of the superior colliculus, within the projections of the graft to the colliculus, and around the graft itself, well in advance of any lymphocytic infiltration. With longer survival times, widespread MHC Ag expression associated with astrocytosis, microgliosis, and perivascular cuffing by lymphocytes, were found within the graft, the optic terminal region, and the surrounding colliculus. Involvement of distant areas of the brainstem, typical of spontaneous rejection, was not seen. Following mannitol infusion (8 animals), widespread MHC Ag expression and cellular infiltration were seen, closely resembling spontaneous rejection. These results suggest that the pattern of MHC Ag expression and cellular infiltration associated with rejection is critically dependent on the mechanism by which graft rejection is induced.

8.13

AN ANALYSIS OF IMMUNE RESPONSE TO CELLULAR AND ACELLULAR NERVE ALLOGRAFTS AND THEIR USE IN NERVE REPAIR. A.K. Gulati* (Spon: T.A. Harrison). Department of Anatomy, Medical College of Georgia, Augusta, GA. 30912.

The present study was designed to determine the immunogenicity of acellular basal lamina allografts and their potential as bridging material for nerve gap repair. Inbred strains of Fischer and Buffalo rats were used. Acellular grafts were prepared by repeated freezing and thawing of 6 week in situ predegenerated nerve. Non-frozen predegenerted nerves were used as cellular grafts for comparison. Fischer rats served as hosts and received 2 cm long cellular or acellular isografts (genetically identical) and allografts (genetically different). Grafts were morphologically evaluated at 1,2,4 and 12 weeks after transplantation for rejection and their ability to support regeneration. The cellular isografts supported axonal regeneration best. The cellular allografts were invariably rejected. Acellular allografts, in spite of their mild immunogenicity were successful in supporting regeneration, as were the acellular isografts. The rate of host axonal regeneration and recovery of target muscle was reduced in acellular allografts and isografts as compared to cellular isografts. It is concluded that acellular allografts exhibit reduced immunogenicity and are suitable for supporting axonal regeneration and may be used to bridge gaps in injured peripheral nerves.

CELL LINEAGE AND DETERMINATION I

9.1

USE OF DiI TO TRACE THE MIGRATION OF NEURAL CREST-DERIVED CELLS TO THE BOWEL H.D. Pomeranz, T.P. Rothman, and M.D. Gershon. Department of Anatomy and Cell Biology, Columbia University, P & S, New York, NY 10032.

Although the enteric nervous system (ENS) has been shown in avian embryos to be formed by emigrés that migrate to the bowel from the neural crest, the axial levels from which these precursors originate is controversial. Experiments with chick-quail chimeras have suggested that both the vagal and sacral crest contribute precursors to the gut. In contrast, the use of morphological markers to study enteric neuronal development *in situ* and in explants of short segments of bowel has failed to confirm a sacral origin of enteric crest-derived cells. The non-deleterious fluorescent probe, DiI, was therefore employed to trace the migration of crest cells by means that do not involve the construction of chimeras. DiI (2.5% in 100% ethanol) was injected with pressure through a micropipette (tip diameter ≅ 10 µm; 1-2 pulses [100 msec] of N_2 at 8 psi) into the neural crest of chick embryos (10 to 28 somites). The embryos were incubated for 24-96 hrs post-injection. DiI-labeled cells were found in the region of the injection site and also in distant locations. Injections into the vagal crest led to the appearance of DiI-labeled cells in the bowel. Some of these cells were round or polygonal, while others had the appearance of neurons with varicose fluorescent nerve fibers. The fluorescent cells were located in the outer gut mesenchyme. Injections of thoracic or lumbar crest did not label cells in the bowel; however, DiI-labeled cells were found in the sympathetic and dorsal root ganglia, peripheral nerves, adrenal glands, and underneath the epidermis. These observations indicate that microinjections of DiI into the neural crest can be used to identify the specific levels of origin of crest-derived cells in target organs, such as the gut. Experiments involving the injection of DiI into the neural crest caudal to somite 28 are now in progress to test the hypothesis that the sacral crest contributes to the formation of the ENS.

DEVELOPMENTAL POTENTIAL OF TRUNK NEURAL CREST CELLS IN SITU. Marianne Bronner-Fraser and Scott E. Fraser, Devel. Biol. Center, U.C. Irvine, Ca. 92717

Trunk neural crest cells migrate extensively and contribute to diverse cell types including cells of the sensory and autonomic nervous system. To analyze the developmental potential of individual neural crest cell precursors, we have microinjected a vital dye, lysinated rhodamine dextran (LRD), into the dorsal neural tube. Previously, we demonstrated that some trunk neural crest cells give rise to descendants in multiple derivatives (Bronner-Fraser and Fraser, 1988, Nature 335:6186). Here, we examine the phenotypes derived from LRD-labelled cells using neurofilament expression as a marker for neurons. By two days after injection, the LRD-labelled clones contained from 2 to 73 cells, which were distributed bilaterally in the majority of embryos, and extended over 20 to 530 microns in the rostro-caudal dimension. Individual labelled precursors gave rise to both sensory and sympathetic neurons (neurofilament positive), non-neuronal cells (neurofilament negative), and cells with the morphological characteristics of Schwann cells or pigment cells (neurofilament negative). Furthermore, in some cases, a single labelled precursor contributed to both neural crest- and neural tube-derived neurons. This suggests that the neural crest is not a presegregated population, but shares a common lineage with some neural tube cells. Several LRD-labelled clones, including three derived from emigrating neural crest cells, contributed only to neural crest derivatives; many of these clones were multipotent. Our data demonstrate that premigratory and emigrating trunk neural crest cells can give rise to multiple neural crest derivatives, and can contribute to both neuronal and non-neuronal elements within a given structure. (Supported by USPHS HD-25138 and BNS 8608356).

RELATIONSHIP BETWEEN TRANSLOCATING PITUITARY PRECURSOR CELLS AND BRAIN CELLS IN THE EXPRESSION OF POMC mRNA IN EMBRYONIC FROG: W.P. Hayes and Y.P. Loh. Laboratory of Developmental Neurobiology, NICHD, Bethesda, MD 20892.

To determine the sequence of events involved in the activation of the proopiomelanocortin (POMC) gene in brain and pituitary, the cells that first express POMC were identified in Xenopus laevis embryos using *in situ* hybridization. Intronic and exonic 48-mer oligonucleotide probes encoding regions of the Xenopus POMC gene (Martens, G., Eur. J. Biochem. 165: 467, 1987) were used to differentiate primary transcript RNA from mRNA.

POMC gene expression was first seen at developmental day 1.3 (Stage 28) in cells of the embryonic stomodeal-hypophyseal plate. In 1.5 to 2 day old embryos (Stage 29/30 to 33/34), this entire structure, which is homologous to Rathke's pouch of amniotes, was labeled by exonic, but not intronic, probes. In frog, these cells undergo a poorly understood process translocating caudally from the oral ectoderm between the brain and foregut. By day 2.3 (Stage 37/38), they near the notochord, where they are presumed to form the anterior and intermediate lobes of the pituitary. It is now clear from these *in situ* findings that many pituitary precursor cells are already differentiated as they pass in proximity to the developing brain. Labeling in neural tube showed that cells are expressing POMC in the diencephalon by Stage 31. These cells were in the most ventral part of the tube just adjacent to the labeled hypophyseal plate. More labeled cells were seen in the dorsolateral part of the ventral diencephalon at Stages 32 and 33/34. These cells appeared to radiate from the point at which the hypophyseal plate made its closest pass with the embryonic brain.

The possibility that the onset of POMC gene expression in brain is somehow dependent on interactions with these hypophyseal cells is being explored. (W.P.H. is supported by an Associateship from the National Research Council.)

ENVIRONMENTAL CUES INFLUENCE DIFFERENTIATION OF RAT RETINAL GERMINAL NEUROEPITHELIAL CELLS. T.A. Reh, Dept. Medical Physiology, Univ. Calgary, Calgary, Alta, CANADA T2N 4N1.

Previous studies in amphibians and fish have shown that local environmental cues play a role in determining the types of neurons produced by the retinal germinal neuroepithelial cells. We have devised an in vitro strategy to demonstrate that the same processes are involved in regulating neurogenesis in the mammalian retina. By co-culturing E15 rat retinal cells, labelled with H3-thymidine, and retinal cells from various postnatal ages, we can determine whether the postnatal cells can influence the types of neurons that the E15 germinal cells differentiate into. We have found that the E15 germinal cells can be induced to form rods when co-cultured with P1 and P3 cells, but not when cultured alone or with P11 cells. Thus, we conclude that the local environment plays a role in determining the phenotypic expression of germinal neuroepithelial cells during rat retinal development. Determination of total segment number in the leech. Katerina Markopoulou* and G.S. Stent. Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

The ectodermal and mesodermal lineages in the leech derive from five bilateral pairs of blastomeres called teloblasts. Each teloblast divides asymmetrically giving rise to a bandlet composed of several dozen primary blast cells. The five bilaterally paired bandlets form the germinal bands, which later coalesce along the ventral midline to form the germinal plate. Each teloblast produces more blast cells than are needed to form the 32 segments of the mature leech. These supernumerary cells do not become incorporated into the germinal plate and degenerate. Previous work (Shankland, M. Nature, 307: 541-543, 1984) has shown that positional signals are probably necessary for the correct termination of blast cell incorporation into the germinal plate. One hypothesis regarding these signals maintains that a progressive disparity in relative developmental age between the various blast cell lineages serves as an indicator of position along the longitudinal embryonic axis, which determines total segment number. The results of preliminary experiments aimed at disturbing the relative developmental age between the bandlets by causing a delayed production of blast cells in one of the lineages appear to support this hypothesis. The injection of the polypeptide antibiotic mithramycin, a non-specific transcription inhibitor, into a teloblast retards blast cell production, which in turn results in the formation of an abnormal number of segments. A variety of other abnormalities are also observed, depending on the blast cell lineage whose production was delayed, such as transfating of elements normally derived from one lineage (o) into elements normally derived from another lineage (p), and changes in the number and position of identified neurons normally derived from a predominantly neural lineage (n). These findings suggest that determination of segment number may be associated with segment-specific deflection of a general metameric developmental pathway.

9.7

CONTROL OF NEURONAL FATE BY THE HOMEOTIC GENE *MAB-5* IN THE NEMATODE *C. ELEGANS* C. M. Loer and C. K. Kenyon*. Dept. of Biochem. and Biophysics, Univ. of California, San Francisco, CA 94143.

The gene *mab-5* is required to determine posterior-specific cell fates in neuronal, epidermal, and mesodermal cells in the posterior body of the nematode *C. elegans* (Kenyon, 1986, Cell 46: 477). For example, cells V5 and V6 divide postembryonically to produce neuronal sensilla called rays, whereas their anterior homologs, V1-V4, produce epidermal seam cells. Loss of *mab-5* activity causes V5 and V6 cells to divide and differentiate like V1-V4. Mutations in the gene *lin-22* cause the opposite changes in cell fate: V1-V4 produce rays instead of seam cells. Varying the dosage of wild-type *mab-5* and *lin-22* can shift the boundary between anterior and posterior cell fates, suggesting that these genes may mutually inhibit one another. The gene encoding *mab-5* has been cloned and partially sequenced (Costa et al., 1988, Cell 55: 747). The sequence suggests that *mab-5* may act by regulating other genes: it encodes a homeodomain, a putative DNA-binding motif, in which 44 of 60 amino acids are identical to those of the homeodomain of *Antennapedia* from *Drosophila*. *In situ* hybridization with *mab-5* cDNA probes reveals that expression of *mab-5* RNA is restricted to the posterior of larvae (Costa et al., *ibid.*) and embryos. We will test whether the expression of *mab-5* message is altered in *lin-22* mutants. If wild-type *lin-22* gene product acts to restrict *mab-5* to the posterior, then *mab-5* expression is predicted to extend anteriorly in *lin-22* mutant worms. We also plan to examine the expression of *mab-5* protein during development of wild-type and pattern-formation mutant worms. We have generated a *ß-gal/mab-5* fusion protein that will be used to produce antisera to the *mab-5* protein.

GENERATION OF ENTERIC NEURONS FROM AN EPITHELIAL PLACODE DURING INSECT EMBRYOGENESIS P.F. Copenhaver and P.H. Taghert. Department of Anatomy & Neurobiology, Box 8108, Washington University School of Medicine, St. Louis, MO 63110.

We have been examining the program of neurogenesis that gives rise to the Enteric Plexus, a discrete region of the Enteric Nervous System of the moth, Manduca sexta. The Enteric Plexus spans the foregut-midgut boundary and contains approximately 400 neurons (the EP cells) of diverse morphological and biochemical phenotypes, including one class that expresses peptides related to the molluscan peptide FMRF-amide. Previously we have shown that during embryogenesis, these neurons achieve their mature distributions by a stereotyped sequence of migration, and that the delayed expression of peptidergic phenotype is regulated by post-migratory cellular interactions. We have now characterized the neurogenic events that precede the onset of migration, and we have analyzed the mitotic relationships giving rise to this neuronal population. All of the EP cells arise from a common placode in the dorsal lip of the foregut epithelium; this placode first appears at 30% of embryogenesis and subsequently evaginates onto the dorsal foregut surface (between 30-40%) to form a discrete packet of several hundred premigratory cells. During this process, columnar epithelial cells cease to be mitotically active, lose their dye coupling with adjacent cells, and round out of the epithelium. Labels for DNA synthesis activity and intracellularly injected lineage tracers indicate that individual epithelial cells undergo a limited number of symmetric divisions prior to their extrusion onto the foregut surface. However, the vast majority of EP cells appear post-mitotic during their subsequent migration and differentiation. Experiments using an in vitro culture preparation have shown that these events can proceed even when the foregut epithelium has been isolated prior to the onset of placode evagination. We are currently studying the role of cell lineage in the differentiation of these placode-derived neurons. Supported by an NIH postdoctoral fellowship to PFC (F32NS07957) and NIH grant #NS21749.

MULTIPOTENT NEURAL CELL LINES, GENERATED VIA RETROVIRAL-MEDIATED GENE TRANSFER, INTEGRATE IN VIVO FOLLOWING TRANSPLANTATION INTO DEVELOPING MOUSE CEREBELLUM (CB). E.Y.Snyder*, D.L.Deitcher*, C.Walsh, C.L.Cepko*, Dept. of Genetics, Harvard Medical School, Boston, MA 02115.

We previously reported generation of immortalized neural cell lines via retroviral-mediated v-myc transfer into neonatal mouse CB cells (Soc.Neurosci.Abstr.13:700,1987). Infection established families of clonally-related lines with neuronal-glial multipotency, some lines evincing heterogeneity & plasticity of phenotype. We now report that, when transplanted into neonatal mice, these lines become integrated into the developing CB. Cells from a given line were marked by infection in vitro with virus containing the lacZ reporter gene. Concentrated helper-free cell suspensions were transplanted into P1 mice. After 9-22 mos., sections of CB, processed to locate labeled cells, revealed integration of transplanted cells in a cytoarchitectonically appropriate, nontumorigenic manner. In some animals, 5-10x10^3cells spanning 1.7mm were incorporated. Furthermore, lines which were multipotent in vitro retained their multipotential nature in vivo within the same animal. Some cells migrated to the internal granular layer & possessed neuronal morphology; others localized to the molecular layer & possessed glial morphology. These lines may have potential for repair or for gene transport into CNS. Future work will establish the functional integrity of these transplanted cells, the extent of their temporal & anatomic plasticity, & their ability to reconstitute deficits in mutant mice.

NEURONAL LINEAGES IN CHIMERIC FOREBRAIN ARE COMPARTMENTALLY SEGREGATED. G. Fishell, J. Rossant*§, and D. van der Kooy Neurobiology Research Group, Department of Anatomy and §Sinai Hospital Research Institute, Department of Medical Genetics, University of Toronto, Toronto, Ontario, Canada, M5G 1X5.

The mammalian forebrain is comprised of two major structures, the cortex and the striatum. These structures can be further subdivided developmentally and biochemically into compartments. The cortex can be subdivided into deep versus superficial layers and the striatum into patch versus matrix compartments. Interspecific chimeric *Mus musculus/ Mus caroli* mice were used to determine the contribution of lineage to cellular position within these forebrain compartments. Cells from either strain could be unambiguously identified in adults using *in situ* hybridization with a satellite DNA probe specific to the *Mus musculus* strain. Qualitative analysis did not reveal any obvious segregation of the ratio of genotypes among forebrain compartments. In contrast, a statistical analysis revealed evidence of both spatial and compartmental lineage segregation. A significant difference depending on chimeric specimen was observed between areas (regardless of compartment) that were separated by greater than 300 μm in the rostrocaudal plane. Perhaps most remarkably, differences were observed between early born (striatal patch and deep cortex) and late born (striatal matrix and superficial cortex) neurons, but not between cortex and striatum, as a whole. On a smaller scale of analysis, differences in genotype ratios were seen between radially aligned deep and superficial cortical areas, in both the neuronal and glial populations. This evidence supports the existence of early lineage restrictions to time of neurogenesis and thus to forebrain compartment.

EXPRESSION OF A NEURONAL PHENOTYPE BY PANCREATIC ISLET CELLS OF ADULT MOUSE *IN VITRO*. G. Teitelman and M. Moustakos, Neurobiology, Cornell U. Med. Coll., NY, NY 10021

Pancreatic islet cells of embryonic and adult mouse contain the catecholamine biosynthetic enzyme tyrosine hydroxylase (TH) and several other neuronal specific antigens. In this study we sought to determine whether endocrine cells of pancreas can express not only neuronal markers but also a neuronal morphology. Pancreatic islets from adult white outbred (CD-1) mice were dissociated into single cells and maintained *in vitro* in culture media [90% RPMI 1640, 10% fetal calf serum (Gibco), 20mM Hepes buffer, 16.7mM glucose and antibiotics]. Two weeks later cells were fixed and processed for immunocytochemical staining. Many cells were found to contain insulin (β cells), while others remained unstained. Some stained cells were round or elongated while others formed neuritic-like processes, did not fasciculate, were often branched, and extended long distances in the culture dish. Preliminary experiments indicate that these elongations also stained with neurofilament antisera (gift of P. Levitt). To test the role of cellular interactions on process formation, adult mouse pancreatic islets were isolated, maintained *in vitro* without dissociation and immunostained 2 weeks later. Transplanted islets contained all endocrine cell types characteristic of islets *in vivo* but did not extend processes. Other cells had a neuronal morphology. Presumably, these cells are the pancreatic parasympathetic neurons, since they were found outside the islets and did not contain pancreatic hormones. Our studies, therefore, indicate that β cells of adult mouse pancreas can form neurite-like processes and that this ability is inhibited by normal histotypical associations. Since islet cells arise from endoderm, this suggests that cells originating in non-ectodermal cell layers may express neuron-like biochemical and morphological traits. Supported by NIH #HL 18974 and DK 38171.

Stage-Specific Mechanisms Regulate Transmitter Phenotype in Developing Rat Sensory Ganglia. D.M. Katz and M.J. Erb*, Dept. Medicine and Center for Neuroscience, Case Western Reserve Univ., School of Medicine, Cleveland, OH 44106.

A subpopulation of petrosal ganglion (PG) sensory neurons express catecholaminergic properties, including functional tyrosine hydroxylase (TH). Most TH cells are also distinguished by innervation of a single peripheral target, the carotid body (Katz, D.M. and Black, I.B., J. Neurosci., 6:983, 1985). During development, however, two different populations of TH neurons appear in the PG; early cells, in which TH is transiently expressed between embryonic day (E) 11.5 - 15.5, and late cells in which expression begins on E16.5 and is subsequently maintained. To elucidate mechanisms of sensory neuron differentiation, immunocytochemical and tissue culture methods were used to determine whether TH expression is triggered by common mechanisms, including neuron-target interactions, at these two stages of development. In culture, TH expression by the transient population occurs in the absence of peripheral target tissues. In contrast, neuron-target interactions appear important for expression after E16.5. Our data suggest that distinct mechanisms may regulate expression of a single transmitter trait at different stages of sensory ganglion development. Grant PL653 (Am. Heart, OH) and Dysautonomia Fndtn., Inc.

CULTURED HUMAN OLIGODENDROCYTES ARE SUSCEPTIBLE TO LYSIS BY MHC CLASS I-DIRECTED CYTOTOXIC LYMPHOCYTES. T.C.G. Ruijs*, A. Olivier*, M.S. Freedman*, J.P. Antel. Montreal Neurological Institute,McGill University, Montreal, Quebec, Canada H3A 2B4.

Adult human oligodendrocytes (OGC) in culture express major histocompatibility complex (MHC) class I antigens, suggesting a potential susceptibility to cytolysis by MHC class I restricted cytotoxic lymphocytes. This interaction could contribute to the tissue injury seen in multiple sclerosis, where abundance of activated T-lymphocytes of all phenotypes, and damage to OGC and myelin are found in CNS lesions. We have previously established a ^{51}Chromium release assay with OGC-enriched cultures of adult human glial cells, derived from surgically resected tissue. In this study, lymphocytes were allo-activated with peripheral blood-derived mononuclear cells from the glial cell donors. Activated lymphocytes exhibited a mean specific lysis of labelled OGC of 30% (n=4, range 19-42% at a 10:1 effector:target ratio). Lysis by the CD8+ (MHC class I restricted) subset exceeded lysis by CD4+ (MHC class II restricted) cells and could be partially blocked by the anti-MHC class I antibody W6/32. Lymphocytes activated against mononuclear cells bearing MHC class I epitopes discordant with the glial cell donor's MHC class I, showed significantly less cytotoxicity (mean 12%, range 8-15%, $p < .02$).

PROLIFERATION OF MATURE ASTROCYTES IN RESPONSE TO TUMOR NECROSIS FACTOR. K.W.Selmaj*, M.Farooq*, W.T.Norton, C.S.Raine and C.F.Brosnan*.(SPON: DC Miller) Dept. of Path., Albert Einstein Coll. Med. Bronx, NY 10461.

The effect of cytokines on primary cultures of mature bovine astrocytes was determined in chemically-defined medium with or without the addition of serum. The results show that in serum-free medium human tumor necrosis factor (TNF) and, to a lesser degree lymphotoxin (LT) and interleukin-6 (IL-6), are mitogenic for astrocytes. Uptake of [^{3}H]-thymidine could be detected within 36h in vitro. In contrast neither IL-1α nor IL-1β induced astrocyte proliferation in serum free medium. The proliferative effect of TNF and LT was also observed in serum-containing medium and was confirmed by autoradiography and cell counting. Analysis of mRNA for GFAP by Northern blotting demonstrated a complex response that was both dose- and time-dependent. None of the cytokines tested was toxic for astrocytes as measured by ^{51}chromium release. No mitogenic effect for oligodendroglia, purified from the same source, was detected. The results support a role for TNF and LT in the development of reactive gliosis such as that found in diseases like multiple sclerosis (MS). Supported by NS 11920 and NMSS 1089.

DISTINGUISHING CELLS FROM THE MAMMALIAN NERVOUS SYSTEM BY PROTON NMR SPECTROSCOPY. R.Small, D.Gadian*,P.Patel*, N.Van Bruggen* and S.Williams*. Institute of Neurology and Royal College of Surgeons of England, London WC1N 3BG, UK.

Proton NMR spectroscopy provides a sensitive non-invasive method for analysing localised regions of brain. Signals obtained include lactate, N-acetyl-aspartate(NAA), choline-containing compounds(Cho) and creatine+phosphocreatine(Cr). Abnormal ^1H spectra have been reported in patients with CNS disorders involving neuronal degeneration and/or proliferation of non-neuronal cells. To understand the processes underlying such alterations, we have examined the ^1H spectra of purified astrocytes, oligodendrocytes, meningeal cells and types of neurons. After assessing samples purity by immunostaining with specific antibodies, cells were washed in PBS and extracted into 12% perchloric acid. Each cell preparation showed a characteristic ^1H profile, marked either by the presence of unique peaks or by distinct concentration ratios between compounds. Cortical astrocytes, for example, showed a Cho/Cr ratio of 0.49±0.07 and no detectable signal from NAA. This ^1H spectra from astrocytes is remarkably similar to ^1H spectra recently reported from astrocytomas (Gadian et al, Soc. Magn. Reson. 1989) showing elevated Cho/Cr ratios, and no NAA signals. Different neuronal-types could also be distinguished by their NMR profiles. These data suggest that in vivo NMR offers a powerful technique for examing alterations in cellular constituents during CNS diseases.

10.4

MICROGLIAL CELLS IN THE RABBIT RETINA AND THEIR RESPONSES FOLLOWING GANGLION CELL DEGENERATION. Jutta Schnitzer* and Jürgen Scherer. MPI für Hirnforschung, Abt. Neuroanatomie, D-6000 Frankfurt/M. 71, F.R.G.

Microglial cells are thought to be involved in phagocytosis of cellular debris when cell death occurs during ontogenesis. The intension of this study was to see whether and how microglial cells would respond to transection of the optic nerve of adult rabbits, which is known to lead to retrograde degeneration of ganglion cells in the retina.

Microglial cells have been studied by using the enzyme-histochemical method for nucleoside diphosphatase (NDPase). In the normal retina, regularly scattered NDPase-positive microglial cells were found throughout the inner plexiform layer (IPL). Their radially oriented processes gave them a star-shaped appearance, processes of individual cells did not overlap. In the nerve fiber layer (NFL), microglial cell density was highest at and close to the medullary ray region, but low in the peripheral retina. Two days after transecting the optic nerve, the number of NDPase-labeled cells began to increase in the NFL as well as in the IPL. This increase continued with longer survival times. Microglial cell density was considerably higher after four weeks compared to controls. Although their density is higher in the IPL of the degenerating retina, each microglial cell still occupies its own territory, which is smaller compared to controls. It is concluded that microglia are involved in processes accompanying ganglion cell death, their particular role needs further studies.

10.5

INDUCTION OF MYELIN SCHWANN CELL PHENOTYPE IN VIVO AND IN VITRO. R. Mirsky*, K.R. Jessen* and L. Morgan*. (SPON: Brain Res. Assoc.) Dept. Anatomy, Univ. Coll. London

The two mature Schwann cell phenotypes seen in mature peripheral nerves, myelin-free and myelin Schwann cells, arise from a common early Schwann cell. Axonally induced developmental events occur in both pathways. The molecular differences between the two mature Schwann cell types all result, however, from axonally regulated events restricted to the myelination pathway. Thus the myelin-free pathway is constitutive. The development of the myelin Schwann cell requires not only induction of myelin proteins but also down-regulation of proteins e.g. N-CAM, A5E3, 217c(Ran-1) and GFAP, associated with the constitutive myelin-free pathway. Schwann cells in short term cultures which express proteins typical of the constitutive pathway, can be induced to up-regulate the myelin protein P_0 and down-regulate N-CAM, A5E3, 217c and GFAP after treatment with cAMP analogues or cholera toxin for a total of 3 days. In induced cells, P_0 is expressed in all areas of the Schwann cell membrane. Furthermore, cells expressing high levels of P_0 show down-regulation of the proteins GFAP, 217c, N-CAM and A5E3. Thus a series of molecular events related to induction of myelin Schwann cells in vivo can be reproduced in early Schwann cell cultures.

NEUROGLIAL CELL LINEAGE: IN VIVO AND IN VITRO DIFFERENCES. R.P. Skoff, P.E. Knapp and M.S. Ghandour. Dept. of Anatomy and Cell Biology, Wayne State University School of Medicine, Detroit, MI 48201.

Astroglial and oligodendroglial (OL) specific antibodies have been used to trace the lineage and differentiation of macroglia in vivo and in vitro. Our work has shown the following differences between the glial lineages in rodent CNS. Immunocytochemistry was combined with ^3H-thymidine autoradiography or bromodeoxyuridine (BdU) immunostaining to determine the origin of OLs in postnatal development. In vivo, one hour after an injection of ^3H-thymidine, galactocerebroside (GC) and sulfatide positive cells are thymidine labeled. The GC+ and sulfatide+, thymidine labeled cells are moderately immunostained, indicating recent expression of these markers. GC is a specific marker for OLs and our preliminary morphologic studies indicate that sulfatide is also specific for OLS in vivo. These findings indicate that cells expressing OL specific markers divide in vivo. In vitro, after a one hour pulse with the thymidine analogue BdU, sulfatide+, BdU+ cells are present but GC+ cells are postmitotic. The in vitro studies support the conclusion that OLs don't divide during development, however, the in vivo studies indicate that they do. Since newly formed OLs in vivo can arise from GC+ OLs, bipotential progenitor cells are not the only source for OLs in postnatal rodent CNS. Supported by NS 15338.

FURTHER EVIDENCE FOR THE EXISTENCE OF TYPE 2 ASTROCYTES IN VIVO. B.A. Barres, L.L.Y. Chun*, and D.P. Corey, Program in Neuroscience, Harvard Med School; Dept of Neurology, HHMI, Mass Gen Hosp. Boston, MA.

Two types of astrocytes have been described in cultures of rat optic nerve and other white matter; these are morphologically, antigenically, and developmentally distinct (Raff *et al.*, 1983), and also electrophysiologically distinct (Barres *et al.*, 1988; in preparation). In neuron-free cultures, type 1 astrocytes are polygonal and A2B5 negative, while type 2 astrocytes are stellate and A2B5 positive. Two classes of astrocytes are also found in Golgi impregnations and after HRP injections: one with radial processes terminating on blood vessels, the other with longitudinal processes terminating at nodes of Ranvier (Miller, Fulton, and Raff, 1989). They suggested that these longitudinal cells are type 2 astrocytes because they develop only after 2 weeks postnatal and because perinodal astrocyte processes *in vivo* are antigenically similar to type 2 astrocytes *in vitro*.

To determine whether a subclass of astrocytes exists *in vivo* with the electrophysiological properties of the type 2 astrocytes in culture, we recorded from acutely isolated cells in a new preparation called a tissue print. Cells were prepared by gently touching papain-treated optic nerve tissue to nitrocellulose-coated glass coverslips. A thin layer of viable cells--still bearing extensive processes--adhered tightly to the glass. Adherent cells were identified using indirect immunofluorescence. Ionic currents in labelled cells were studied using whole-cell patch recording.

These experiments have revealed the existence of a subclass of astrocytes, arising only after the 2nd week of postnatal life, that express the same complement of ion channels observed in type 2 astrocytes that develop in serum-free culture: Na_N, Ca_T, Ca_L, K_{IR}, K_A, K_{CA}. Consistent with the observations of ffrench-Constant and Raff (1986), these cells are not A2B5 surface positive, nor are any other astrocytes in the tissue prints. These results further confirm the existence of a distinct subclass of astrocytes in white matter.

10.8

GAP JUNCTIONS BETWEEN LEPTOMENINGEAL CELLS: IDENTIFICATION OF CONNEXIN PROTEINS AND mRNAs AND CHARACTERIZATION OF MACROSCOPIC AND SINGLE CHANNEL CURRENTS. D.C. Spray, R. Dermietzel, E.L. Hertzberg*, and J.A. Kessler (SPON: H. Buschke). Depts. Neuroscience & Neurology, Einstein Coll. Med., Bronx, NY 10461

Leptomeningeal (LM) cells form the boundary between the CSF and the extracerebral compartment; they are interconnected by abundant gap junctions, which could function in signal relay and in the regulation of osmotic or ionic balance. We identified immunoreactive gap junction proteins using antibodies specific for the 21 and 27 kDa liver gap junction proteins (connexins 26 and 32), the 43 kDa cardiac gap junction protein (connexin 43) and a 34 kDa antigen localized to junctional regions of brain. Indirect immunofluorescence on cultured LM cells indicated immunoreactive puncta at regions of cell contact as well as intracellularly with antibodies to the 21 and 43 kDa proteins; no binding of the other antibodies was detected. Western blots with anti-43 kDa antibodies demonstrated the presence of crossreacting proteins with mobilities similar to that observed in heart samples. At the EM level, the anti-21 and anti-43 antibodies stain junctional membranes. Freshly dissociated cell pairs from intact tissue or from cultures as old as two weeks were electrically coupled. Junctional conductance (g_j) averaged 8.6 ± 1.1 nS (n= 37) and was reversibly reduced by exposure to 2 mM halothane, 1 mM heptanol or 100% CO_2. Forskolin (10 uM) or 8 Br-cAMP (1 mM) increased, and 1 uM phorbol ester (PDBu) irreversibly decreased g_j. Single channel analysis revealed two classes of unitary events with conductances of about 50 and 80 pS. The 50 pS conductance is comparable to that we have observed from 43 kDa-containing junctions in heart cells; perhaps the 90 pS conductance is due to channels formed with the 21 kDa protein.

MODULATION OF INTRACELLULAR Ca^{++} IN ASTROCYTES: STUDIES USING FURA-2 AND INDO-1. B.A. MacVicar, S. Weiss and M. Delay, Neuroscience Research Group, University of Calgary, Calgary, Alberta T2N 4N1.

Astrocytes have voltage activated Ca^{++} channels that can be modulated by β-adrenergic stimulation. Primary cultures of mouse cortical astrocytes were loaded using the AM form of indo-1 or fura-2. Intracellular Ca^{++} levels were calculated from fluorescence images of stained cells obtained with a SIT camera and digitized for fura-2 studies or from fluorescence intensities measured using photomultiplier tubes for indo-1 studies. Intracellular Ca^{++} varied widely between cells but averaged 144nM. Perfusion of K^+ (55mM) alone decreased Ca^{++} in most cultures (1-2 weeks old), however perfusing Bay K-8644 (1μM) with K^+ increased Ca^{++}. The Bay K-induced increase was blocked by nifedipine (1μM) indicating that the Ca^{++} channels are of the L-type. Cells from cultures that were pretreated with dibutyryl-cAMP (0.5mM) demonstrated a K^+-induced increase without the addition of Bay K. Met-enkephalin (1μM), which has been reported to inhibit cAMP synthesis in astrocytes, induced a small decrease in Ca^{++} and inhibited the K^+-induced increase in Ca^{++}. These experiments support the hypothesis of an important role for cAMP in modulating Ca^{++} channels in astrocytes.

Anomalous stimulation of pH regulation by ethylisopropyl amiloride in cultured mammalian astrocytes. G. Boyarsky, B.R. Ransom*, W-R. Schlue, M. Davis, W.F. Boron. Depts. of Cell. and Mol. Physiol. and Neurology* Yale Univ. Sch. of Med., New Haven, CT 06510.

Intracellular pH (pH_i) regulation in the nominal absence of HCO_3^- was studied in single cultured rat astrocytes using the pH-sensitive fluorescent dye BCECF. In other cell types, application of 50μM ethylisopropyl amiloride (EIPA) in HCO_3^--free solution causes an inhibition of Na-H exchange, resulting in either no pH_i change or an abrupt decline. Application of 50μM EIPA to astrocytes caused a triphasic change in pH_i: (1) a rapid pH_i decrease of ~.1 within 20 sec., (2) an alkalinization of ~.6 within 2-3 min., and (3) a slow return to baseline over ~20 min. Similar results were observed with as little as 50 nM EIPA. Unexpectedly, qualitatively similar triphasic responses occured either following removal of external glucose (10.5 mM) or chloride, or following exposure to 100nM arginine vasopressin, 10 μM epinephrine or 10mM lactate, suggesting that some common cellular mechanism may underly this stereotypic pH_i response to such diverse perturbations. Removal of external Na^+, which causes a profound acidification, blocked the pH_i response to addition of EIPA, suggesting that the EIPA-induced alkalinization is Na^+-dependent. In the presence of EIPA, recovery from an acid load (pulsing with 20mM NH_4^+ for ~3min) was ~2-fold greater during the phase-2 alkalinization, suggesting that EIPA stimulated a Na^+-dependent acid-extrusion mechanism. Pulsing with NH_4^+ in the absence of external Na^+ revealed a Na^+-independent recovery which caused pH_i to recover to ~6.3. The subsequent readdition of Na^+ caused pH_i to recover to near the initial level of ~6.8. In the presence of 50 μM EIPA, the Na-independent recovery was only modestly stimulated, whereas the Na-dependent recovery was as much as 4-fold faster, driving pH_i to ~7.1. These results suggest that, in contrast to the effect of EIPA on other cell types, in astrocytes EIPA anomalously stimulates a Na-dependent acid-extrusion mechanism, perhaps Na-H exchange.

AXONAL MODULATION OF MYELIN PROTEIN mRNA LEVELS IN OPTIC NERVE. G.J.Kidd*, P.Hauer* and B.D.Trapp* (SPON: S.M.Logan) Neurology, Johns Hopkins Univ. Sch. of Med., Baltimore MD, 21205.

Previous studies from this lab have demonstrated that significant expression of myelin protein mRNA by myelinating Schwann cells is dependent on axonal influences (Trapp et al, J.Neurosci., 8:3515, 1988). In this study, we have investigated the effect of axonal transection on myelin protein mRNA levels in the CNS. Optic nerves of 21 day old rats were transected and levels of mRNA encoding proteins of CNS myelin were compared with levels from control nerves at 5,10, 20 and 40 days post transection. Specifically, total RNA was extracted from transected and age matched control optic nerves, slot blotted onto nitrocellulose and hybridized with ^{32}P labeled cDNA probes complementary to mRNA encoding proteolipid protein (PLP) and myelin basic protein (MBP). In transected nerves, PLP and MBP mRNA levels were approximately 90%, 75% and 10% of control values at 5, 20 and 40 days post transection. In situ hybridization studies using ^{35}S labeled cDNA probes detected PLP and MBP mRNA in control and transected nerves at all time points. Compared to control nerves, hybridization signal was significantly decreased in sections of 20 and 40 day transected nerves. The distribution of these mRNAs (PLP- in oligodendrocyte perinuclear regions, MBP- distributed diffusely) was similar in control and transected nerves. In contrast to Schwann cells, therefore, oligodendrocytes continue to express significant levels of myelin protein mRNA following loss of axonal contact.

10.12

STRUCTURE AND EXPRESSION OF PLP mRNA IN THE PNS. M. Sessa*, P.L. Baron*, T. Behrman*, D. Pleasure and J. Kamholz. University of Pennsylvania School of Medicine and Children's Hospital of Philadelphia, Philadelphia, PA 19104

PLP is expressed in Schwann cells (SC), but is not incorporated into PNS myelin. We have characterized two overlapping PNS PLP cDNA clones which contain the entire PLP coding region, and a portion of the 3' untranslated region. The sequence of the PNS PLP mRNA was identical to that previously determined from a rat CNS cDNA except for a 250 bp portion at the far 3' end of the non-coding region. Polymerase chain reaction (PCR), performed on sciatic nerve mRNA and genomic DNA with two sets of synthetic oligonucleotides primers specific for either the CNS or PNS sequence, suggests that alternative splicing within the 3' untranslated region of the PNS PLP mRNA can account for this sequence divergence. In situ hybridization studies, performed on adult rat sciatic nerve and spinal cord sections using PLP cRNA probes, demonstrate PLP transcripts diffusely distributed within the endonerium. This pattern is similar to that found for the extrinsic membrane protein MBP, which is synthesized on free ribosomes. In contrast, PLP mRNA's in spinal cord were found in clusters around oligodendrocyte nuclei. This pattern is similar to that found for the major PNS intrinsic membrane protein PO, which is synthesized on membrane bound ribosomes. These data suggest that PLP message is differentially distributed within myelinating glial cells in the PNS and CNS. Alternative splicing within the 3' untranslated region of the PLP mRNA may, in part, determine the different tissue distributions of the PLP message in Schwann cells and oligodendrocytes.

VOLTAGE-DEPENDENT EFFECTS OF PROSTAGLANDIN D_2 AND HISTAMINE ON CALCIUM CURRENTS IN ADULT RAT SENSORY NEURONES IN CULTURE.

R.J. Docherty* and J.F. Fiekers. *Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN, UK. and Dept. Anatomy and Neurobiol., Univ. of Vermont Coll. of Med., Burlington, VT. 05405.*

Prostaglandin D_2 (PGD_2) and histamine (HIS) are inflammatory mediators which increase excitability of sensory neurones - an effect thought to be mediated via an increase in intracellular cAMP levels[1]. We have studied the effect of HIS and PGD_2 on whole-cell voltage-clamped calcium currents (I_{Ca}) in freshly plated adult rat dorsal root ganglion neurones in culture. In about 50% (n=46) of cells either HIS (0.05-10μM) or PGD_2 (0.01-1μM) increased the size of I_{Ca} recorded at command potentials (V_c) near threshold ($\cong$ -40mV) but decreased I_{Ca} near the peak of the IV curve ($V_c \cong$ 0mV). The threshold for activation of I_{Ca} was shifted to more negative potentials. This effect was rapid in onset, not reversed by washing and mimicked by forskolin (1μM). Pretreatment of cells with pertussis (PTX) or cholera toxin (CTX) did not alter the proportion of cells sensitive to HIS or PGD2.

The results show that these inflammatory mediators modulate I_{Ca} in a potential-dependent manner which may be secondary to an increase in intracellular cAMP. This effect may be important in the regulation of transmitter release during neurogenic inflammation as well as in control of sensory neuronal excitability.

BRADYKININ INHIBITS VOLTAGE-DEPENDENT BARIUM CURRENT IN A CLONAL POPULATION OF DORSAL ROOT GANGLION X NEUROBLASTOMA HYBRID CELLS.

L.M. Boland, A. Allen, and R. Dingledine, Curr. Neurobiology, Dept. Biochemistry, Dept. Pharmacology, University of North Carolina, Chapel Hill, NC, 27599.

Currents through voltage-dependent Ca channels in a rat DRG cell line, F-11, were studied using the whole-cell patch clamp technique. Inward currents were carried by 30 mM Ba. An internal Cs solution containing 100 μM GTP and Ca was buffered to 15 nM. F-11 cells have sustained and transient Ba currents, both of which have multiple components based on sensitivity to Cd, Ni, and omega-conotoxin. Both currents were larger when Ba rather than Ca carried the current. Since the F-11 cell line is heterogeneous, we isolated more homogeneous subclones for use in biochemical and electrophysiological experiments. The F11-B9 subclone does not express the sensory neuron antigens SSEA-3, SSEA-4, nor the antigen recognized by B23D8. Bradykinin (BK, 100 nM) reduced the whole-cell Ba current in 73% of the F11-B9 cells. In most cells, block of the sustained was more prominent (39 ± 4% block) than that of the transient current (12 ± 4% block). The block began within 5 sec. of BK application and was maximal within 10 sec. F11-B9 cells were prelabelled with 3H-arachidonic acid and then stimulated with 100 nM BK. An 8 sec. exposure to BK produced nearly a 3-fold increase in diacylglycerol but only a small increase in arachidonic acid release. Current studies are investigating the possible role of diacylglycerol in regulation of the Ba currents by BK.

11.3

BRADYKININ MODULATION OF CALCIUM CURRENTS AND $[Ca^{2+}]_i$ IN RAT DORSAL ROOT GANGLION NEURONES IN VITRO. David Bleakman*, Stanley A. Thayer and Richard J. Miller. Department of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 6063.

In dorsal rat ganglion (DRG) neurones, the nonapeptide bradykinin (BK) has been implicated as a modulator of nociceptive information. In the present study we have made simultaneous measurements of both calcium currents (I_{Ca}) and intracellular calcium concentrations ($[Ca^{2+}]_i$) from primary cultures of rat DRG neurones using a combined patch clamp/fura-2 microfluorimetry technique. BK (100nM) reduced both the I_{Ca} and the subsequent rise in $[Ca^{2+}]_i$ evoked at 0mV from a holding potential of -80mV in 22 of 32 cells examined (Whole-cell patch clamp with (in mM) 140 Cs, 1 Mg, 10 HEPES, 3.6 ATP and an ATP regenerating system in the pipette and 140 TEA , 2 Ca and 1 Mg bathing the neurones). BK was more effective in inhibiting I_{Ca} than the rise in $[Ca^{2+}]_i$ for longer depolarization steps. In 6 of 32 cells tested, BK (100nM) additionally produced a transient increase in basal $[Ca^{2+}]_i$ (1.7 +/- 0.4 fold, n=6) presumably due to BK-stimulated IP3 release.

In current clamp studies, repetitive action potentials were evoked in DRG cells by short duration injection of current and the concomitant rise in $[Ca^{2+}]_i$ measured (Whole-cell patch clamp with (in mM) 144 K, 1 Mg, 10 HEPES , 3.6 ATP and an ATP regenerating system in the pipette and 140 Na, 2 Ca in the bathing solution). BK (100nM) reduced the rise in $[Ca^{2+}]_i$, its effect being more pronounced for shorter spike trains. The resting membrane potential of the DRG cells ranged between -50 and -70 mV. With the resting membrane potential set to approximately -60mV we also observed that BK (100nM) depolarized 69% of cells tested from a membrane potential of -61.7 +/- 1.1 to 51.1 +/- 2.6 mV (n=13).

Thus the actions of BK on the peripheral processes of DRG neurones in situ would reduce $[Ca^{2+}]_i$ and the Ca^{2+} -activated K+ and Cl- currents which normally serve to limit the excitability of these cells. These effects, together with BK-induced depolarization may be responsible for BK-induced excitation in sensory neurones.

11.4

PHORBOL ESTERS INCREASE UNITARY CALCIUM CHANNEL ACTIVITY IN CULTURED HIPPOCAMPAL NEURONS. Daniel V. Madison, *Department of Molecular and Cellular Physiology, Stanford School of Medicine, Stanford, CA 94305-5426.*

Phorbol esters, activators of protein kinase C, modulate the activity of several ion conductances in hippocampal neurons and cause potentiation of excitatory synaptic transmission in hippocampal slices. We have been investigating mechanisms by which this potentiation might occur. In this study we show that application of phorbol esters causes an increase in the unitary activity of voltage-dependent calcium channels in cultured hippocampal CA3 neurons, recorded with cell-attached patch clamp methods. In preliminary analysis, this increase in activity appears to consist of an increase in both the number of openings and the average length of openings evoked by a depolarization. Phorbol ester appears to affect both the N- and L-types of calcium channel in similar ways. This effect is similar to that recorded in frog sympathetic neurons (Lipscombe et. al.). In these neurons, phorbol ester increases unitary calcium channel activity in cell-attached patches, but decreases I_{Ca} in dialyzed whole-cell recordings. Thus, is interesting that in hippocampal cell, phorbol ester also decreases I_{Ca} in whole-cell recordings (Doerner, et. al). This suggests that dialyzed cells may lack a cytosolic component necessary to express the phorbol ester-induced increase.

11.5

CHANGES IN RAPID GATING KINETICS UNDERLYING NOREPINEPHRINE INHIBITION OF UNITARY N-TYPE Ca CHANNEL ACTIVITY IN SYMPATHETIC NEURONS. R.W. Tsien & D. Lipscombe. Dept. Mol. Cell. Physiol., Stanford CA 94305.

Norepinephrine (NE) inhibits Ca channels and transmitter release in frog sympathetic neurons via interaction with an α_2-like receptor linked to the channel by a G-protein. Our previous recordings of whole cell Ca channel currents indicated that α-stimulation selectively inhibits N-type Ca channels. We now describe the inhibitory effect of NE at the single channel level. Cell-attached patch recordings (110 mM Ba) with 10-100 μM NE in the pipette were compared to drug-free patches. Activity of N-type and L-type Ca channels could be studied separately with appropriate voltage protocols: N-type channels were selectively activated by depolarizing from a holding potential (HP) of -80 mV to -10 mV; setting HP=-40 mV largely inactivated N-type channels, but left L-type channels available for opening with stronger pulses to +20 mV. With 30 μM (n=10) and 100 μM NE (n=5) in the pipette, average N currents fell to 45% and 14% of N current without drug (n=33). In contrast, the average L current in the same patches was not significantly affected by NE. Analysis of patches with few overlapping openings indicated that NE did not alter the unitary flux through N-type channels but markedly changed their gating kinetics. The mean open time decreased from 0.87 ms in control to 0.40 ms in 100 μM NE, while the percentage of blank sweeps increased from 8% to 24%. These changes largely account for the overall inhibition of averaged N current records. In contrast to its effects in the patch pipette, 100 μM NE did not affect the average N current in the patch (n=5) when applied to the bulk of the cell, arguing against involvement of a readily diffusible second messenger. The activity of N-type channels was neither increased by cyclic AMP nor decreased by PKC stimulation. A relatively direct G-protein-mediated coupling to the N-type Ca channel seems likely.

11.6

ANTIBODIES TO THE G-PROTEIN, G_o, ATTENUATE THE INHIBITION OF CALCIUM CURRENTS BY NORADRENALINE IN NG108-15 CELLS. I. McFadzean[1]*, I. Mullaney[2]*, D.A. Brown[1] and G. Milligan[2]*. [1]University College London, London WC1E 6BT and [2]University of Glasgow, Glasgow G12 8QQ, U.K.

Noradrenaline (NA) acting on α_2-adrenoreceptors inhibits the whole-cell calcium current in NG108-15 cells. The response is mediated by a pertussis toxin sensitive GTP-binding (G) protein. To identify this G-protein we have studied the response to NA in cells pre-injected with specific antibodies raised against the C-terminal decapeptides of the α-subunits of the G-proteins G_i (recognising both $G_{i}1$ and $G_{i}2$) and G_o. Control cells were injected with pre-immune rabbit serum. We found that the response to NA in cells pre-injected with the antibodies against G_o was attenuated by over 50%. The response in cells injected with the antibodies raised against G_i was unchanged despite the ability of the same antisera to inhibit the agonist-induced inhibition of adenylate cyclase in NG108-15 cells. We conclude that the NA-induced inhibition of the calcium current in NG108-15 cells is mediated by G_o.

INTRACELLULAR $[Ca^{2+}]$ AND TRANSMITTER RELEASE FROM SYMPATHETIC NEURONS STIMULATED WITH K^+, CAFFEINE OR ISOPROTERENOL. S. Kongsamut, D.D. Friel, D. Lipscombe & R.W. Tsien. C & M Physiol., Yale and M & C Physiol., Stanford.

We asked how closely transmitter release is correlated with changes in $[Ca^{2+}]_i$ in frog sympathetic neurons. Transmitter release was measured from sympathetic ganglia (presumably cell bodies) preloaded with $[^3H]$-norepinephrine. K^+ depolarizations produced Ca entry through Ca channels and transmitter release that was (1) steeply dependent on $[K^+]_o$ over the range 30-80 mM, (2) dependent on $[Ca^{2+}]_o$ (EC50 ~ 0.5 mM), (3) completely inhibited by cadmium (IC50 ~10 μM). Release was dominated by Ca entry through N-type Ca channels: it was not affected by selective block of L-type channels with dihydropyridines, but it was strongly reduced by α-adrenergic agents which selectively inhibit N-type Ca channels. Evidently, some pathways for Ca delivery are more effective than others in producing release. Caffeine-evoked Ca release from internal stores represents another means of Ca delivery. In isolated neurons loaded with fura-2, caffeine (10 mM) produced a large $[Ca^{2+}]_i$ transient (even with 0 Ca), comparable to that produced by voltage-gated Ca entry. However, in contrast to the pronounced release evoked by high K^+, caffeine was unable to produce detectable transmitter release from ganglia. This provides further illustration that rises in bulk $[Ca^{2+}]_i$ do not always produce transmitter release.

Conversely, high concentrations (30-100 μM) of NE or isoproterenol were capable of evoking some transmitter release with little or no change in $[Ca^{2+}]_i$. The isoproterenol-induced release was not abolished by removal of external Ca. This suggests that cells with voltage-gated channels also have mechanisms for transmitter release that do not require Ca entry. Overall, transmitter release is not necessarily correlated with changes in bulk $[Ca^{2+}]_i$.

11.8

EFFECT OF RUTHENIUM RED AND RYANODINE ON THE CAFFEINE INDUCED RISE OF INTRACELLULAR CALCIUM IN VERTEBRATE SYMPATHETIC NEURONS. N.V. Marrion*, S.J. Marsh*#, B.J. Burbach*, D.A. Brown*# and P.R. Adams. (SPON: W. G. Van der Kloot) Howard Hughes Medical Institute, SUNY at Stony Brook, Stony Brook, NY 11794, USA. #Department of Pharmacology, University College London,London,WC1E 6BT,England.

Image analysis of intracellular calcium levels (Ca^{2+}_i) and simultaneous membrane current recording was performed on fura 2-loaded whole-cell voltage-clamped dissociated bullfrog sympathetic neurons. Bath application of caffeine (10 mM) evoked a large outward current which was associated with a rise in Ca^{2+}_i. This increase in Ca^{2+}_i was independent of extracellular calcium and was presumed to arise from intracellular stores. Both the outward current and Ca^{2+}_i increase subsided during caffeine's application although their time-courses differed. The transient outward current declined within 2-10 secs to a net inward current, which was associated with suppression of the voltage- and time-dependent M-current. The rise in Ca^{2+}_i decayed over a longer time than the outward current. Ca^{2+}_i increased to approximately 300 nM from a resting level of 60 nM. This increase declined leaving a Ca^{2+}_i near to 150 nM while the M-current was suppressed. Removal of caffeine produced an initially rapid fall in Ca^{2+}_i which slowed to transiently take Ca^{2+}_i below resting conditions, recovering within 5 minutes.

Inclusion of ruthenium red (30 μM) in the electrode solution increased the amplitude and greatly prolonged the duration of both the calcium transient and the outward current evoked by caffeine. Incubation with ryanodine (1-10 μM) was found to block caffeine's response in both control and ruthenium red-treated neurons, leaving a slowly rising residual increase in Ca^{2+}_i. This inhibition occurred with the second application of caffeine, the first being little affected, implying the presence of caffeine and/or raised Ca^{2+}_i was required for its effect. Ryanodine partially antagonized ruthenium red's effect, reducing the amplitude and prolonged duration of caffeine's response. These results suggest that the release of Ca^{2+}_i initiated by caffeine is inhibited by ryanodine and the sequestration of the raised Ca^{2+}_i is modulated by ruthenium red.

11.9

DYNAMICS OF CA-RELEASE FROM CAFFEINE-SENSITIVE INTRACELLULAR STORES IN AMPHIBIAN SYMPATHETIC NEURONS. A. Hernandez-Cruz*, F. Sala* and P. R. Adams. (SPON: J. Fenstermacher) Howard Hughes Medical Institute, SUNY at Stony Brook, NY 11794.

The dynamics of Ca^{2+} mobilization from internal stores were studied with confocal Ca-imaging and membrane current recording in isolated bullfrog sympathetic neurons. $[Ca^{2+}]_i$ was monitored by directly loading the cell with the membrane-impermeant indicators fluo-3 and rhod-2 (200 μM). Macroscopic Ca-activated K currents, IK(Ca), were simultaneously measured as an independent indicator of changes in submembrane $[Ca^{2+}]_i$. (Vh=-30 mV). Caffeine (10 mM), pressure-ejected from a puffer pipette, produced varied responses depending upon the duration of the pulse. A gradual, transient increase of IK(Ca) (50-200 pA) was produced with short (10-100 ms) applications. These responses were additive and showed no refractory period. Pulse durations about 100 ms or longer evoked, on top of the gradual response, a transient, large all-or-none activation of IK(Ca) (0.8-8 nA). These responses exhibit a refractory period of several minutes, suggesting depletion and subsequent replenishment of an internal store. The development of an inward current, lasting tens of seconds, contributed to the termination of this response (see Marrion et al., this volume). High-speed imaging during large caffeine responses revealed that the Ca signal starts earliest in the region where the caffeine first reaches the cell and then propagates throughout the cell, reaching the opposite site within 600 to 1,200 ms. This pattern is in marked contrast to the symmetrical, radial spread of Ca^{2+} seen following electrical stimulation). Changes in $[Ca^{2+}]_i$ appeared to be most prominent in the nucleus and other unidentified structures, suggesting regional variations in density of release sites. Bath application of Dantrolene Na (100 μM), an agent that bloks Ca-release from sarcoplasmic reticulum, produces a reversible, partial inhibition of caffeine-induced IK(Ca) responses. Procaine (2 mM), which inhibits Ca-induced Ca-release in skeletal muscle, suppresses completely and reversibly the all-or-none component of the caffeine response, leaving the gradual component less affected. These data suggest that the gradual component of the caffeine response may result from a direct effect on localized Ca-release site(s), whereas the all-or-none component may result from a generalized response involving a Ca-induced Ca release process.

11.10

SUSTAINED INCREASES IN CYTOPLASMIC Ca ION CONCENTRATION MEDIATED BY TRANSIENT Ca CHANNELS IN CULTURED EMBRYONIC AMPHIBIAN NEURONS. Michael E. Barish (Spon: W.J. Moody). Department of Physiology and Biophysics, University of California, Irvine, CA 92717.

Three components of Ca current corresponding to T-, N- and L-types are found in neurons that differentiate in cultures of dissociated Xenopus neural plate cells. T-type current is activated at voltages more positive than -45 mV and blocked by Ni. Its activation and steady-state inactivation curves overlap between -40 and -30 mV, and within this region a small sustained component of inward current can be recorded. Additional Ca currents are a more slowly inactivating component (N-type) reduced by met-enkephalin (met-ENK), and a nonrelaxing component (L-type) activated at voltages more positive than -10 mV.

Using the Ca-sensitive fluorescent dye fura-2 and a video-interfaced fluorescence microscope, I have investigated the changes in intracellular Ca ion concentration ($[Ca^{2+}]i$) that occur in these neurons during K^+-induced depolarizations. Images were acquired at 10 sec intervals. Typically, application of 50 mM K^+ (determined to depolarize these neurons to about -15 mV) resulted in an increase in $[Ca^{2+}]i$ that rose rapidly to a peak and then decayed over 10's of seconds. The peak amplitude of $[Ca^{2+}]i$ was reduced when 200 μM Ni or 17.5 μM met-ENK were added along with 50 mM K^+, and the peak was almost completely removed when both of these agents were added together. In contrast, depolarization to about -40 mV (using 20 mM K^+ external solution) elicited a slowly rising but sustained increase in $[Ca^{2+}]i$. This maintained increase in $[Ca^{2+}]i$ was sensitive to Ni but not met-ENK.

These observations suggest that sustained Ca^{2+} influx through the population of transient channels active in the voltage region where activation and inactivation curves overlap may be important in regulating resting levels of cytoplasmic Ca^{2+} at subthreshold voltages.

TWO TYPES OF CALCIUM CHANNELS PROVIDE DIFFERENT TEMPORAL CONTRIBUTIONS TO Ca^{2+} ENTRY IN VERTEBRATE NERVE TERMINALS. Martha C. Nowycky, Dept. Anatomy, Med. Coll. Penn., Philadelphia, PA 19129.

Nerve terminals isolated from the neurohypophysis are 1-10 microns in diameter and can be studied with patch clamp techniques. Two types of Ca^{2+} channels coexist in these terminals (Lemos & Nowycky, Neuron, vol. 2, 1989), a typical, dihydropyridine-sensitive, non-inactivating current (L-type) and a second high-threshold transient current (N-like). Neurohypophysial terminals release the peptides oxytocin and vasopressin most effectively when stimulated with characteristic bursts of action potentials (APs). To test the contribution of the two Ca^{2+} channels to Ca^{2+} entry during such bursts, nerve terminals were voltage clamped and stimulated with various test patterns. Both current types have the same voltage range of activation and contribute to Ca^{2+} influx at the beginning of a burst of APs. After 16-32 simulated APs of 1 msec duration, N-current amplitude diminishes. Once inactivated, N-type channels recover very slowly, requiring about 1 to 2 sec at -90 mV to regain full amplitude (stimulation rate = 0.1 Hz). In contrast, the L-type current amplitude changes little even during 1 sec long depolarizing pulses, implying that its contribution will be constant even during hundreds of APs. Thus, different Ca^{2+} channel types may contribute to the temporal shaping of the Ca^{2+} transient which underlies neurosecretion.

11.12

A NEW APPROACH TO OPEN VOLTAGE SENSITIVE CALCIUM CHANNELS AND EVOKE TRANSMITTER RELEASE. D. Przywara*, T. Wakade*, S. Bhave*, J. Ram and Arun R. Wakade, Dept. of Pharm., Wayne State Univ., Detroit, MI 48202.

Sympathetic neurons (SN) cultured from chick embryos were loaded with ^{3}H-norepinephrine (^{3}H-NE) and washed for 1 h. After SN were bathed in Ca/Mg free medium for 15 min, release of ^{3}H-NE was determined in 2 min period ($1.78 \pm 0.1 \times 10^{-2}$). Switchover to Ca-containing medium caused massive release in next 2-min period ($17.1 \pm 4.4 \times 10^{-2}$); release remained elevated for 30 min. Release was related to Ca concentration and blocked by verapamil. Resting membrane potential (Em) of SN averaged -26 ± 1 mV in 2.5 mM Ca medium. In Ca/Mg free medium Em averaged +4 ± 2 mV and recovered to -26 ± 1 mV during 30 min in Ca medium. Intracellular Ca concentrations were determined in Indo-1-loaded SN by laser cytometry. Ca increased from 83 ± 13 nM in Ca/Mg free medium to 597 ± 72 nM following switchover to 2.5 mM Ca medium. Magnitude of Ca influx was similar in cell body and nerve terminal. Excess K (35 mM) produced less depolarization (Em=-13 ± 3 mV) and smaller increases in Ca and release of ^{3}H-NE in comparison to those seen after changeover of the media. We conclude that in addition to elevated K, electrical stimulation or drug application, the present method offers new approach to open voltage sensitive Ca channels and to stimulate transmitter release in cultured SN.

TROPHIC AGENTS I

12.1

NEUROTROPHIC ACTION OF PHORBOL ESTERS AND EXCESS K IS MEDIATED BY A MESSENGER OTHER THAN PROTEIN KINASE C. Arun R. Wakade*, S.V. Bhave*, R.K. Malhotra* and T. Wakade. Dept. of Pharm., Wayne State Univ., Detroit, MI

Phorbol esters have become the drugs-of-choice in studying intracellular signalling because of their stimulatory effect on protein kinase C (PKC). Phorbol 12, 13-dibutyrate (PDB) supported survival of sympathetic neurons (SN) in culture. Effect was related to concentration of PDB and activation of PKC. Excess KCl (17.5 to 75 mM) supported SN and produced concentration-dependent increase in PKC activity (Wakade, et al., J. Neurochem. 51:975, 1988). In this study, we have investigated effects of H_7 and sphingosine, on survival and PKC activity of SN of chick embryo supported in culture by NGF, PDB and 35 mM K. Incubation of SN for 15 min with H_7 (0.3 to 1 uM) and sphingosine (1 to 100 uM) caused dose-dependent inhibition of 100 nM PDB-induced activation of PKC. 1 uM H_7 or 100 uM sphingosine almost completely prevented the effect of PDB. Survival of SN in culture by 100 nM PDB, 40 ng/ml NGF or 35 mM K was unaffected by simultaneous presence of 1 to 30 uM H_7 for 3 to 7 days, although PKC activity of SN remained completely inhibited. Sphingosine proved to be very toxic and killed SN in a day. 1,2- oleoylacetylglycerol (1 to 100 uM) did not support the survival. These results indicate that phorbol esters and excess K may have targets other than PKC to affect survival of SN.

12.2

IN VITRO BIOLOGICAL EFFECT OF NERVE GROWTH FACTOR INHIBITED BY SYNTHETIC NGF PEPTIDES. F.M. Longo, T.H. Vu* and W.C. Mobley. Depts. of Neurology, Pediatrics and Neuroscience Program, UCSF School of Medicine, San Francisco, CA 94143.

Nerve growth factor (NGF) is a neurotrophic polypeptide which acts via specific receptors. The molecular domain(s) of NGF which triggers biological activity is as yet undefined. One strategy for identifying polypeptide regions which interact with their receptors consists of synthesizing short peptides with sequences corresponding to the potential active site. At relatively high concentrations (uM or mM), peptides containing the active site may block or mimic biological activities of the native polypeptide (Nature 309:30, 1984). We synthesized small peptides corresponding to sequences within three regions of NGF which are hydrophilic and highly conserved: Region A, mouse NGF sequence 64-76; Region B, 199-107 and Region C, 26-40. Peptides were synthesized in the C-terminal amide form by solid-phase methods, purified by reversed phase and cation-exchange HPLC and characterized by analytical HPLC, amino acid analysis and sequencing and FAB-mass spectrometry. We reasoned that inhibition of NGF effects may be more readily achieved than NGF agonist responses. Peptides were assayed for NGF antagonist activity by adding them to low density cultures of chick dorsal root ganglia neurons supported by NGF. Four peptides from Region A and 3 from Region B did not inhibit NGF activity. In contrast, 3 out of 8 peptides from Region C inhibited NGF-induced neurite outgrowth with an IC50 of approximately 1mM. Inhibition was overcome by increasing the concentration of NGF. Peptides did not block the neurotrophic activity of ciliary neuronotrophic factor or phorbol 12-myristate 13-acetate. Inhibitory activity was lost when the sequence of residues was randomized or a sterically nonconservative substitution was made. Inhibitory peptides did not decrease neuronal binding of radiolabelled NGF to DRG cells. These studies define one region of NGF which may be required for neurotrophic activity.

12.3

FUNCTIONAL EXPRESSION OF THE NGF RECEPTOR IN A NON-NEURONAL CELL LINE. B.-Y. Wu,* R.H. Edwards, W.J. Rutter,* Hormone Res. Inst., UCSF Sch. of Med., SF, CA 94143.

Nerve Growth Factor-responsive neurons express two apparent types of NGF receptors. The larger population binds NGF with relatively low affinity (Kd 2 nM), whereas the smaller population binds with high affinity (Kd 20 pM). Expression of the cloned receptor cDNA in a variety of neuronal cell lines has previously conferred high-affinity NGF binding and biological responsiveness. Expression of receptor in the non-neuronal mouse fibroblast L929 cells has conferred only low-affinity binding. Because the mechanism of signalling by the NGF receptor remains unclear (the sequence shows no substantial homology to know signalling elements) and may require the action of another, neuron-specific protein which confers both high-affinity binding and biological responsiveness, we have introduced the human NGF receptor into CHO fibroblasts. We have established three stably transformed CHO cell lines, with varying levels of NGF receptor mRNA. Preliminary characterization of the highest expressing cell line shows high affinity NGF binding and transient induction of c-fos. This suggests that the cellular apparatus involved in transducing the NGF signal is not neuron-specific. The appearance of cell lines with only low-affinity NGF receptors (e.g., L929, Schwann cells) may then be due to down-regulation of high-affinity receptors through simultaneous secretion of NGF by the same cell, or to low numbers of receptors which may make a small high-affinity component difficult to detect.

12.4

DETECTION OF mRNA HOMOLOGOUS TO NERVE GROWTH FACTOR RECEPTOR (NGFR) IN RAT DERMAL FIBROBLASTS. P.A Barker*, F. Miller, J. Haskins, R.J. Riopelle†, A. Acheson, R.A. Murphy, Dept of Anatomy and Cell Biology, University of Alberta, Edmonton, Alberta, Canada. †Division of Neurology, Queens University, Kingston, Ontario, Canada.

cDNA molecules representing both rat and human NGFR have been cloned (Nature.325.593. Cell.47.545). In the rat, NGFR mRNA (3.4 kb) encodes a 42.5 Kd protein that has an apparent molecular weight of 82 Kd on SDS-PAGE. NGFR mRNA has been detected in dorsal root ganglia, sympathetic ganglia, brain and Schwann cells.

In this study, riboprobes prepared from a cDNA encoding nucleotides 400 to 3200 of the rat NGFR have detected a mRNA of approximately 3.0 kb in cultured dermal fibroblasts prepared from neonatal rats. To characterize the protein product, we carried out immunocytochemistry using a monoclonal antibody against rat NGFR (192-IgG). Immunoreactivity was apparent throughout the cytoplasm and was visible only when the cells were permeabilized, suggesting that the immunoreactive protein is not located on the cell surface. Under identical conditions, cell surface staining of NGFR was apparent on Schwann cells. Equilibrium binding studies on intact cells with 125I-NGF revealed specific binding sites on Schwann cells but not on fibroblasts. EDAC-mediated crosslinking of 125I-NGF to cell surface receptors followed by immunoprecipitation with 192-IgG revealed a 95 kd complex in PC12 and Schwann cells. A similar complex was detectable when binding was done on detergent solubilized cell extracts. However, no crosslinked immunoprecipitate has so far been identified in fibroblast extracts.

These data suggest that fibroblasts express a 3.0 kb mRNA homologous to NGFR mRNA. Fibroblasts also express a 192-IgG immunoreactive protein that is distributed throughout the cytoplasm but not localized on the cell surface. Further characterization of this mRNA and this protein are underway.

INTERLEUKIN-1 INJECTED INTO NEOSTRIATUM OF ADULT RAT BRAIN STIMULATES SYNTHESIS OF NERVE GROWTH FACTOR

U. Otten[1], H.P. Lorez[*2], R. Gadient[*1] and C. Boeckh[*3]
[1] Dept. of Pharmacology, Biocenter, University of Basel, CH-4056 Basel; [2] Pharmaceutical Res. Dept., Hoffman-La Roche & Co., Ltd., Basel, Switzerland; [3] Dept. of Pharmacology, University of Freiburg, 7800 Freiburg, FRG.

Interleukin-1(IL-1) has been shown to be a potent inducer of nerve growth factor (NGF) synthesis in peripheral tissues. Since IL-1 and NGF have been found to accumulate at sites of brain injury it was interesting to study whether IL-1 acts as a stimulator of NGF synthesis in rat brain. We found that stereotactic intracerebral injection of recombinant human IL-1ß into the neostriatum of adult rats elicited a transient increase in NGF synthesis in a dose-dependent fashion. Within 24 h IL-1ß (1.2 U) maximally increased NGF and NGF mRNA levels by 4- and 2-fold, respectively, as compared to vehicle-treated controls. 5 days after IL-1 treatment NGF and NGF mRNA returned to control levels. The IL-1 effect is specific, since other brain areas including neocortex, hippocampus and hypothalamus, showed only minor changes. Thus, our results suggest a role of IL-1 as a regulator of NGF synthesis in rat brain. Since IL-1 functions as a growth factor for astrocytes it is possible that activated astrocytes are the cellular sites of IL-1 stimulated NGF-synthesis.

12.6

STRIATAL HOMOGENATES TAKEN FROM RATS CHRONICALLY TREATED WITH HALOPERIDOL STIMULATE CELL GROWTH AND DA UPTAKE IN VENTRAL MESENCEPHALIC CULTURES. L.R. Ptak*, L.C. Kao, D.H. Lin*, T.J. Zhang, H.L. Klawans*, and P.M. Carvey. (SPON: R. Zimmerman). Rush University, Chicago, IL, 60612.

Pharmacologic denervation of striatal tissue induced by haloperidol (HAL), leads to DA receptor site hypersensitivity in a fashion analogous to that observed following denervation of muscle. However, denervation of muscle also leads to an increase in a muscle-derived neuronotrophic factor (NTF) capable of stimulating neuron growth. Using ventral mesencephalic cultures, we examined whether or not chronic pharmacologic denervation of rat striatum similarly leads to an increase in a target-derived NTF.

8 rats were rendered behaviorally hypersensitive to apomorphine challenge by 2 months chronic treatment with HAL (0.75 mg/kg). The striata and cerebella of these, and 8 saline treated animals, were homogenized in Hank's Balanced Salt solution. The supernatants from these samples were diluted to achieve equivalent protein content and 250 ul of each were incubated with E-13 ventral mesencephalic cultures for 6 days. Cultures incubated with HAL treated striatal homogenates exhibited an overt increase in cell number as well as process growth relative to cultures incubated with HAL treated cerebellar or saline treated homogenates. Cultures incubated with HAL treated striatal homogenates also exhibited a statistically significant elevation in DA uptake relative to all other culture conditions suggesting increased DA neuron growth. This data would imply that a target-derived, soluble, NTF exists in the adult striatum and further, that it is inducible by chronic pharmacologic denervation. This raises the possibility that alterations in behavioral responsiveness resulting from chronic DA antagonist treatment is the result of an increase in a DA target-derived NTF in addition to the established alterations in DA receptor sensitivity.

γ-INTERFERON PROMOTES MATURATION OF MAMMALIAN CENTRAL NEURONS IN CULTURE. S. Sherry Raissdana*, Michael E. Barish, Neil B. Mansdorf* and Jennifer Kerlin*. Department of Physiology and Biophysics, University of California, Irvine, CA 92717.

We have examined the effect of the lymphokine γ-interferon (IFN-γ) on the development of embryonic mouse brain cells. Cells isolated from the hippocampal region of embryonic day 15-16 CD-1 mice were cultured on poly-L-lysine-coated coverslips in defined medium. By three different measures of properties characteristic of differentiated neurons, recombinant IFN-γ (rat and mouse) promoted neural development.

I. Increase in the number of cells expressing the 160 kD neurofilament protein epitope recognized by monoclonal antibody NN18. Cells cultured in 1-10 U/ml (murine units) IFN-γ for 1-4 days showed increases of up to 250% over control.

II. Increase in the number of neurites per NN18(+) soma. NN-18(+) cells were photographed individually after 18-24 hr of growth, and the negatives were projected onto a digitizing tablet for analysis. IFN-γ at 10 U/ml increased the mean number of processes per soma from about 2.5 to about 4.0. The mean length of individual processes was not affected.

III. Increase in the number of cells expressing NMDA-type glutamate receptors. Cells were grown in the presence of up to 50 U/ml IFN-γ for 20-48 hr. NMDA receptor expression was quantified using a video-interfaced fluorescence microscope by stimulating fura-2-loaded cells with NMDA and measuring changes in cytoplasmic Ca ion concentration. More than 1000 cells were analyzed for each data point. IFN-γ increased the proportion of cells showing responses to NMDA by up to 50%.

These data indicate that lymphokines can promote the differentiation of embryonic brain cells, and add to evidence suggesting linkage in the development of fetal immune and nervous systems.

PREVENTION OF MOTONEURON DEATH IN VIVO BY A PUTATIVE CNS-DERIVED NEUROTROPHIC FACTOR. R. Oppenheim, U. Dohrmann*, D. Prevette* and Y. Qin-Wei*. Department of Anatomy, Wake Forest University Medical School, Winston-Salem, NC 27103 and Department of Neurochemistry, National Hospital, London, U.K.

Previous studies have shown that partially purified extracts from skeletal muscle promote motoneuron survival both in vitro and in vivo. Spinal cord and brain (CNS) extracts and conditioned media (CM) from CNS tissues also enhance motoneuron survival in vitro and these distinct CNS and muscle-derived factors interact synergistically on motoneuron survival (Dohrmann et al., Dev. Biol., 124: 145, 1987). Neither the muscle nor the CNS-derived activities appear to be mediated by NGF, BDNF or FGF. We have now shown that crude or partially purified extracts from embryonic day (E) 10 and E17 chick brain and spinal cord also prevents normal motoneuron death in vivo. Daily treatment from E6 to E9 resulted in 25-30% more surviving spinal motoneurons on E10. Similar effects on survival were found following in vivo treatment with CM from astrocyte cultures. Studies are in progress to determine whether the muscle- and CNS-derived factors interact synergistically in vivo to promote motoneuron survival. Normal motoneuron survival may require trophic support from both targets and CNS cells. Supported by NIH Grant NS20402.

12.9

TROPHIC SUPPORT OF SOMATOMEDIN C (IGF-I) AND MSA (IGF-II) ON CENTRAL NEURONAL CELLS IN VITRO. D.D. SVRZIC[1], L.F. CONGOTE[2], D. SCHUBERT[3] (SPON: D.M. SIMMONS) 1) MBVL, The Salk Institute, San Diego, CA 92138, 2) Endocrine Laboratory, Royal Victoria Hospital, 687 Avenue des Pins Ouest, Montreal, Quebec, Canada H3A 1A1, 3) SSL, The Salk Institute, San Diego, CA 92138.

Trophic support by bovine serum albumin (BSA) and ovalbumin (OA) of pure cultures of central neurons was observed. Our experimental model was monolayered cultures of cells obtained as dissociates of chick forebrain on embryonic day 8 and seeded in serum-free medium. All cells stained positive with monoclonal antibody to neurofilaments. Regardless of the substratum on which they were grown (untreated tissue culture (TC) plastic, polyornithin (PORN) or PORN-laminin pretreated TC plastic or glass) these cells showed not only an unusual longevity (34 days in culture without any condition medium changes), but also the normal maintenance with appropriate neuronal sprouting in the presence of BSA. When we fractionated BSA by HPLC, the activity copurified with somatomedin C (insulin-like growth factor, L.F. Congote et al, In Vitro Develop. Cell Biol. 45:245, 1986). To confirm this finding, the neurotrophic effect was blocked with a neutralizing monoclonal antibody to IGF-I (gift from Dr. Van Wyk, J.), and two batches of recombinant human IGF-I exerted the same effect as the BSA purified material. This trophic support on these particular cells has not been described before.

12.10

PARTIALLY PURIFIED MEMBRANE-ASSOCIATED FACTOR DIFFERENTIALLY REGULATES TRANSMITTER PHENOTYPIC EXPRESSION. J.-M. Lee, J.E. Adler, and I.B. Black, Division of Developmental Neurology, Cornell University Medical College.

Cell-cell contact appears to play a critical role in the expression of transmitter traits in developing neurons. We have previously shown that cell membrane contact induces the *de novo* appearance of choline acetyltransferase (CAT), the enzyme catalyzing acetylcholine synthesis, in virtually pure cultures of dissociated sympathetic neurons. This CAT-inducing activity has been purified 5000-fold from adult rat spinal cords and appears to be a membrane-associated protein factor.

To further characterize the scope of biological activities of this factor, we have examined its effect on a number of different transmitter traits in sympathetic neurons. After three days *in vitro*, cultures exposed to the factor showed 40-fold higher levels of the neuropeptide substance P than controls. The neuropeptide somatostatin was also dramatically elevated by the factor (270pg/well compared to undetectable levels in controls). In contrast, the factor produced the opposite effect on the neuropeptide leu-enkephalin, decreasing levels to half that found in controls. Finally, the specific activity of tyrosine hydroxylase, the rate limiting enzyme in catecholamine biosynthesis, was reduced to 10% of control activity in factor-treated cultures. These effects occurred in the absence of significant changes in cell number. Thus, it appears that cell contact via membrane-associated factors may exert differential effects on phenotypic expression. 12.11

EPIDERMAL GROWTH FACTOR INDUCES A FOS-LIKE NUCLEAR ANTIGEN IN PRESUMPTIVE MULLER CELLS. S.M. Sagar and F.R. Sharp+, Departments of Neurology and +Physiology, Univ. of California, and VA Med. Ctr., San Francisco, CA 94121.

Epidermal growth factor (EGF) is a mitogen for astrocytes and may be a trophic factor for CNS neurons. To identify retinal cells that respond to EGF, 500 ng EGF was injected intravitreally into the eyes of light adapted adult rabbits; phosphate-buffered saline was injected into the opposite eye as a control. 1-3 hr later, the retinas were processed for Fos immunocytochemistry using a polyclonal antiserum raised to a synthetic peptide representing residues 132-154 of Fos.

Specific Fos immunostaining was seen in EGF-injected retinas in numerous nuclei at the middle of the inner nuclear layer. Because of their size, abundance and position, they are presumably nuclei of Muller cells.

We conclude that (1.) Muller cells respond to EGF in vivo, although the response may not be direct; and (2.) Fos immunocytochemistry may be useful for mapping responses to growth factors in a manner similar to its use in mapping neuronal responses to synaptic input.

12.12

Vasoactive Intestinal Peptide Regulates Mitosis, Neurite Outgrowth and Survival of Cultured Rat Sympathetic Neuroblasts D.W. Pincus, E. DiCicco-Bloom and I.B. Black. Div. Dev. Neurol., Cornell Univ. Med. Coll., New York, N.Y., 10021.

While the acute, msec to msec actions of neurotransmitters are well-recognized, diverse, longer-term effects have been discovered only recently. We now present evidence that a single, putative transmitter, vasoactive intestinal peptide (VIP), exerts multiple, long-term effects simultaneously. VIP stimulates mitosis, promotes neurite outgrowth and enhances survival of sympathetic neuron precursors in culture.

Dissociated embryonic rat sympathetic neuroblasts were cultured in fully defined medium and assayed for mitotic activity, neurite elaboration and long-term cell survival. Cells were identified immunocytochemically by detection of neurofilament and the catecholamine biosynthetic enzyme, tyrosine hydroxylase (TH). VIP treatment more than doubled the proportion of TH-positive cells entering the mitotic cycle, as indicated by autoradiography of ^{3}H-thymidine incorporation into nuclei. In addition to regulating mitosis, VIP markedly increased the number and complexity of neurites. The peptide evoked a 6-fold rise in the number of process-bearing cells 10 hours after plating. VIP also increased the percentage of neuroblasts exhibiting long processes at 24 hours. Finally, VIP influenced neuroblast survival: peptide treatment resulted in a 3-5 fold increase in cells per culture after 4 days. The above effects of VIP on sympathetic precursors are highly specific. Two closely related peptides, secretin and growth hormone releasing factor were devoid of effects on SCG cultures.

In sum, our observations suggest that a single neurotransmitter, VIP, influences a spectrum of processes composing early neuronal ontogeny. Since the peptide appears to be a normal presynaptic transmitter in the sympathetic system, synaptic transmission may exert heretofore unexpected effects. (supported by NIH grant HD 22315)

NEURAL PLASTICITY IN ADULT ANIMALS I

13.1

LONG-TERM RESCUE OF DAMAGED FRONTAL CORTEX NEURONS AND SPARING OF VISUALLY GUIDED BEHAVIOR BY ACUTE ADMINISTRATION OF CORTEX CONDITIONED MEDIUM FRACTION. F. Haun, R. Perry, T.J. Cunningham. Dept. of Anatomy, Medical College of Pennsylvania, Phila.,PA 19129.

This study tested both neurotrophic and behavior effects of a macromolecular fraction of conditioned medium (CM) derived from embryonic cortex cultures, compared to a similarly prepared fraction of unconditioned medium (UM). Osmotic pumps (2wk capacity) containing either CM or UM are implanted in adult Long-Evans rats immediately after making a discrete rostral visual cortex lesion unilaterally. At 3-4 mos post-lesion, UM animals show a 31% loss of 3-H thymidine labeled neurons in layers 2,3, and 5 of the caudal third of medial frontal cortex (area 8), a region containing cells of origin of the fronto-occipital pathway. These animals are also impaired in learning a visual discrimination that requires spatially discontiguous responses, a deficit attributable to a 250% increase in the frequency of incorrect responses to the side contralateral to the lesion, compared to normals. In contrast neuron loss is only 9% and visual learning is normal in animals with comparable lesions that received the CM fraction. These results demonstrate a long-term neurotrophic effect on damaged cortical neurons, coupled with a related behavioral improvement, after an acute dosage of a cortex-derived CM fraction, results suggestive of reorganization in the fronto-occipital pathway in response to the trophic agent. Supported by NINDS Grant NS16487 to TJC.

13.2

LESIONS DISRUPTING CORTICAL CHOLINERGIC INNERVATION PREVENT PLASTICITY OF SOMATOSENSORY MAPS IN CAT SOMATOSENSORY CORTEX. S.L. Juliano, D.E. Eslin*, W. Ma. Dept. of Anatomy, USUHS, Bethesda, MD 20814.

A number of recent studies have demonstrated that the organization of maps in the somatosensory cortex (SSC) undergo dramatic changes after manipulations to peripheral somatic input. The mechanisms that produce such changes are only beginning to be understood. Experiments in sensory systems suggest that acetylcholine (ACh) may play a significant role in mediating the capacity of the CNS to adapt to changes in the environment. Previous experiments in our lab demonstrated that disruption of cortical cholinergic innervation substantially reduced the pattern of stimulus-evoked activity in cat somatosensory cortex during a 2-deoxyglucose (2DG) experiment. In contrast to the reduction of metabolic activity, amputation of a single digit in a cat's forepaw causes dramatic expansion of the metabolic pattern evoked by stimulation to an adjacent digit. This change in metabolic pattern was determined using bilateral stimulation to digit 3 in cats that received a unilateral amputation of digit 2, either 2, 4, or 6 weeks prior to a 2DG experiment. The normal, reconstructed pattern of 2DG label produced by stimulation to digit 3 occurs as a broken strip of activity extending through the SSC. The metabolic label evoked in the hemisphere contralateral to the digit amputation was of greater areal extent than that in the normal hemisphere. The reconstructed pattern tended to fill in regions of low activity, thereby making the normally occurring broken strip of activity continuous. Additional strips of activity also occurred. Further experiments performed unilateral digit 2 amputations and concurrent NBM lesions in the same cat. In this situation, which depleted the SSC of ACh, the expansion of stimulus-evoked metabolic activity by stimulation to digit 3 did not occur. These findings suggest that ACh is an important component in mediating the plasticity of somatotopic maps.

13.3

NEONATAL NUCLEUS BASALIS LESION-INDUCED PERTURBATION OF CORTICAL DENDRITIC MORPHOLOGY IN THE ADULT RAT. D.E. Stearn*, R.F. Mervis, R. Dvorak*, and G.W.Arendash#. (SPON: L. Liss). Div. Neuropathology, The Ohio State Univ. College of Medicine, Columbus, OH. 43210,#Dept. Biol.,Univ. South Florida, Tampa, FL.

Neonatal lesions of the nucleus basalis magnocellularis (nBM) will prevent subsequent cholinergic innervation of the neocortex. Adults show prolonged cholinergic hypofunction and cognitive deficits. Two-day-old Sprague-Dawley rat pups had their nBM bilaterally lesioned using ibotenic acid. When 8 months-old, the rats were killed. The parietal cortex was stained using the rapid Golgi method. Controls were sham-lesioned. Analysis of the basilar tree of layer V pyramidal cells showed that nBM-lesioned subjects had significantly more dendritic material and more branching ($p<0.05$); however, dendritic fields retained substantially normal morphology. Long-term nBM lesions appear to result in dropout of cortical neurons. In neonates it produces a transient abnormal cortical cytoarchitecture. The present findings suggest that in the absence of normal extrinsic cholinergic innervation, both neuronal plasticity and a compensatory dendritic response (to neuronal loss) may be important factors influencing neuronal development.

13.4

NUCLEUS BASALIS LESIONS IN THE AGING RAT: EFFECT ON DENDRITIC BRANCHING IN CORTICAL PYRAMIDAL CELLS. R.F. Mervis, M. Bedo-Wierdl*, R. Dvorak*, & G.W. Arendash#. Div. Neuropathology, The Ohio State University College of Medicine, Columbus, Ohio 43210, and #Dept. Biology, Univ. South Florida, Tampa, Florida 33620.

To help develop an animal model for Alzheimer's disease, the effect of long-term excitotoxic lesions of the nucleus basalis (NB) on neocortical branching of pyramidal cells was evaluated in Golgi-impregnated preparations. Sprague-Dawley rats (21 months-old) were infused unilaterally with ibotenic acid in the NB. The subjects were killed 5 months later. The Sholl method of concentric circles was used to evaluated extent of dendritic branching of the basilar tree of layer III pyramidal cells from the frontal cortex. There were two Control groups: neurons from the contralateral (unlesioned) hemisphere and from sham-lesioned rats. Results showed that there was a significant increase in the amount of dendritic branching in the neurons from the NB-lesioned rats compared to controls. There was also a significant increase in the radius of the dendritic domain in neurons from the lesioned hemisphere. Previously, it had been found that long-term NB lesions resulted in loss of cortical neurons. The present findings suggest that the surviving cortical neurons express compensatory dendritic hypertrophy.

RELATIONSHIP BETWEEN BRAIN CATECHOLAMINES AND BEHAVIOR FOLLOWING EXPERIMENTAL TRAUMATIC BRAIN INJURY. A.W.Deckel, A.Merians, B. Fennelly*, P.Freeswick*, and B.Levin. Depts. of Psychiatry, Physical Therapy and Neurology, UMDNJ—N.J. Medical School and Sch Allied Health, Newark, N.J., 07103; Dept. Neurology, E.Orange V.A. Med. Center, E. Orange, N.J.

Twenty-three adult male Sprague Dawley rats, including control (n=7), moderately lesioned (n=8) and severely lesioned (n=8) were analyzed on a variety of behaviors at 1 and 3 weeks post lesion. These measures included assessment of spontaneous locomotor activity in the horizontal and vertical plane and turning behavior following injection with apomorphine (0.2 mg/kg s.c.). At the completion of the 3 week measures, brains were removed and CNS catecholamine (CA) analysis was done via HPLC biochemistry. Severely lesioned animals turned 10 times more frequently to the left side than controls following apomorphine injection ($p<.017$), but less often to the right side ($p<.002$); moderately lesioned animals turned approximately 5 times more often to the left side than controls, while controls turned 3.2 times more often to the right. Controls showed twice as much vertical activity as did severely and moderately lesioned at 1 week post injury ($p<.05$). No statistically significant biochemical differences were seen between controls and lesioned. Nonetheless, left-hemisphere cortical NE "predicted" horizontal locomotor activity in controls when forward stepwise regression analysis was employed, while right-side brainstem DA "predicted" vertical locomotor activity. In contradistinction to controls, in lesioned animals right-sided anterior NE levels accounted for the majority of the variance in most measures of spontaneous locomotion. These results suggest that left cortical NE has a close association with locomotor activity in controls and that this relationship "shifts" following TBI.

13.6

DIFFERENTIAL EFFECT OF DOPAMINERGIC DEAFFERENTATION ON THE MORPHOLOGY OF STRIATAL TARGET NEURONS IN YOUNG AND OLD MICE. T.H. McNeill, S.A. Brown*, B. J. Davis and L.L.Koek*. Andrus Gerontology Center, Univ. of Southern California, Los Angles, CA 90089 and the Dept. of Neurology, Univ. of Rochester, Rochester, NY 14642.

A recent study from our laboratory has provided morphological evidence for the dendritic regression of striatal target neurons in Parkinson's disease (PD) (Br.Res. 455:148,1988). Since it is known that PD is characterized by a partial dopaminergic (DA) deafferentation of the striatum (ST) we hypothesized that the lack of an appropriate compensatory response of striatal target neurons in the aged brain to DA cell loss may underlie the regression of striatal dendrites found in PD. To test this hypothesis we examined by Golgi impregnation the morphology of medium spiny I (MSI) striatal neurons, a principle target population for DA fibers, following a unilateral lesion of the SN using the DA neurotoxin 6-OH-DA. For our study adult (6 mo.) and old (20 mo.) C57Bl/6N mice were given unilateral injections of 6-OH-DA (4.5ug). Mice were killed at 14 days postinjection and tissue blocks containing the ST were processed according to the Golgi Cox procedure of Van der Loos. DA lesions were confirmed by immunocyto-chemical staining. We found that there was a differential response of individual dendritic segments to DA cell loss and the response was age dependent. Specifically, there was a significant increase in the length and number of distal dendritic segments of MSI neurons in adult (6 mo.) but not old (20 mo.) mice following the 6-OH-DA. These data suggest that MSI neurons of aged mice lack the ability to compensate or modify their dendritic arbor in response to DA cell loss and that the absence of a similar compensatory response in the aged brain of man may contribute to the regression of MSI dendrites found in PD. Supported by AG00300, AG05445.

13.7

AUTOMATED COMPUTER RECOGNITION AND QUANTIFICATION OF NEURONS AND NEURITES IN HUMAN BRAIN. T. El Rashidy and J. Rogers. Institute for Biogerontology Research, Sun City, AZ 85351.

Neuron and neurite losses are one of the more likely bases for cognitive changes associated with aging and dementia. Unfortunately, techniques for quantifying perikaryal and, especially, neurite alterations remain extremely labor intensive. Currently available "computer assisted" methods often amount to little more than using the computer as a glorified adding machine, because the operator must still, in one way or another, help identify the quantified elements (i.e., by pointing or tracing each one or by setting parameters for thresholding). To the extent that these techniques rely on gray scale thresholding, they are also error prone: the gray levels of neurons, neurites, and background overlap too extensively for accurate segmentation based on thresholding alone. We have developed an **automated** approach that incorporates both gray scale information and information about spatial frequencies. In a first step, acquisition and preprocessing, adjacent fields of the entire sample (or restricted areas traced by the operator) are automatically digitized and optimized. In a second phase, two original algorithms are used to segment the fields into their different components: cell bodies, neurites, and field background. A specially constructed lowpass, local neighborhood filter preserves perikarya while eliminating high frequency components such as neurites and background debris. Neurites are then separated from background by a second spatial domain algorithm that, in tandem with a highpass filter, analyzes gray level variance along fixed length bars rotated in 32 directions. Conventional measurement programs are then used to quantify the results. Operator assistance is needed only to monitor performance. Advantages of the method include higher sampling rates, objectivity, and precision than currently available techniques for counting neurons and neurites.

13.8

IN VIVO OBSERVATION OF MOTOR NERVE TERMINAL REMODELLING IN REINNERVATED NEUROMUSCULAR JUNCTIONS OF THE FROG. A.A. Herrera, M.J. Werle, & N. Nagaya, Dept. of Biol. Sci., Univ. of Southern Calif., Los Angeles, CA 90089.

The polyneuronal innervation (PI) that forms at adult neuromuscular junctions during reinnervation is reduced by subsequent synapse elimination (SE). We are using electrophysiology, histology, and repeated in vivo observation to examine this process in the reinnervated sartorius of Rana pipiens. Although SE is extensive, PI remains higher than normal even after 2 years. Histology shows that reinnervated junctions are larger and have abnormally-shaped nerve terminals; they also have more axonal inputs, abandoned synaptic sites, and doubly innervated sites than normal junctions. We have posed two hypotheses to explain the persistence of higher PI and the apparent synaptic remodelling: 1) SE may cease after a certain time, freezing the pattern of innervation into a deceptively plastic state. 2) SE may be ongoing, but is balanced by enhanced synapse formation to maintain higher PI in a dynamic equilibrium. We are observing identified reinnervated junctions in vivo to test these hypotheses. Our goals are to explore the validity of this form of SE as a model for development, test the precision of reinnervation of synaptic sites, better define the sequelae of nerve injury, and characterize a convenient preparation for studying pre- and postsynaptic change during synaptic remodelling. Supported by NIH.

13.9

REGULATION OF CONNECTIVITY IN THE ADULT SPINAL CORD. By G.R.Lewin* and S.B.McMahon*, Dept. Physioogy, St Thomas' Hospital Medical School, London SE1 7EH. (SPON: BRA).

We have previously shown that some properties of unmyelinated muscle primary afferents change when they reinnervate a new target. We have now asked whether the connectivity of these afferents has changed in the spinal cord. In adult rats the nerve to the gastrocnemius muscle (GN) and the cutaneous sural nerve (SN) were self- and cross-anastomosed on left and right, so that they regenerated to either appropriate or inappropriate targets. Ten to 12 weeks later, symmetrical recording tracts were made with a tungsten microelectrode to map L4, L5 and L6 spinal segments in these animals under urethane anaesthesia. The microelectrode was advanced to a depth of 720 μm in 6μm steps at 0.5 Hz whilst repetitively stimulating the GN at C-fibre strength, every 2 seconds.

Comparisons between the control and experimental side were made on the basis of estimates of the number of cells activated at C-fibre latencies and quantitative counts of the number of C-evoked spikes in each track. By both these measures the GN now innervating skin showed an average increase of 200% over control which was seen in all 7 animals studied and was significantly different ($p<0.01$). One explanation for this increased connectivity may be the altered peptide content of muscle afferents innappropriately innervating skin (McMahon and Gibson, Neurosci. Lett. 73, 9-15).

RECOVERY OF MOTOR FUNCTION AND PLASTICITY OF DORSAL ROOTS FOLLOWING SPINAL CORD HEMISECTION IN ADULT CATS. M.E. McBride and M.E. Goldberger. Medical College of Pennsylvania, Philadelphia, PA. 19129.

Hemisection sparing the dorsal columns results in a loss of monopedal postural reflexes and locomotion, followed by partial recovery. To test the hypothesis that recovery is associated with increased dorsal root projections we used quantitative densitometry of immunocytochemically identified subpopulations of dorsal roots. Large fibers were labeled with monoclonal antibody Rat 102 (Martin & Hockfield, 1988 Soc.Neurosci.Abst.14:693) and small fibers with CGRP. Descending serotonergic (5-HT) and noradrenergic (DBH & TH) systems were similarly examined. On the hemisected side Rat 102 immunoreactivity increased 4 fold in the medial dorsal horn and in lateral lamina V and 3 fold in medial lamina VII and the medial ventral horn. CGRP increased in laminae I & II. 5-HT decreased 2 fold in laminae I & II and lamina V, 7 fold in the IML and 3 fold in the medial ventral horn. One interpretation of the increase in immunoreactivity of Rat 102 and CGRP is collateral sprouting of dorsal roots. Reactive reinnervation of spinal neurons deafferented by hemisection is consistent with enhanced reflex activity in chronically hemisected cats.

13.11

MECHANISM OF RECOVERY OF FUNCTION AFTER SPINAL CORD TRAUMA: NEW EVIDENCE J.B. Walker, B.Scroggins* Lab of Bio-electronics, Walker Inst. 881 Alma Real Drive, Pacific Palisades, CA. 90272

Recovery of function after brain or spinal cord injury as a function of administration of certain drugs or hormones, fetal transplants, or exposure to enriched environments or electric fields has been described in animals.

A proportion of human subjects with chronic spinal cord injury recover voluntary motor function, below the lesion (Walker,J. Neurosci. 22 S:1669, 1987).

In order to investigate the mechanism by which recovery occurs, we examined muscles that appeared paralyzed by conventional clinical examination using quantitative electromyography. Quantitative electromyography using the Biocomp 1000 system can detect myoelectric activity at a threshold at .5 microvolts. EMG examination of paralyzed muscles hopefully would differentiate between several logical alternatives that could explain recovery of function. These alternatives are:

(1) regeneration
(2) voluntary movement present but "masked" by spasticity
(3) the nerves to the muscle are intact but not functioning because of some reversible or irreversible metabolic deficiency
(4) voluntary muscle function is present but is too weak to be detected with clinical examination.

Electromyograph examination revealed that over 50% of "paralyzed muscles" showed "minipotentials" with recruitment patterns on voluntary effort. We therefore conclude that even in apparently paralyzed muscles, "minipotentials" are present and may represent a mechanism by which this apparent recovery of function occurs. The present data are inconsistent with the existence of regeneration, masking of voluntary function by spasticity as has been suggested by several authors, and any peripheral neuropathy. The present data are also consistent with autopsy data indicating that even with so called complete lesions, much of the spinal cord is spared.

THE AGING PROCESS

14.1

INCREASED NEUROTROPHIC ACTIVITY IN THE AGING BRAIN. B. A. Yankner and P. Dikkes*. Dept. of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115.

The dynamics of aging in the CNS and the mechanisms by which the brain repairs itself are unknown. We have identified a substratum-associated neurotrophic activity in the murine CNS that increases adhesion, viability and neurite outgrowth in cultured cortical neurons. This activity is enriched in grey matter and present at high levels in the hippocampus, amygdala and associative regions of the cortex. Low levels are present in spinal cord and peripheral nerve. The highest levels of activity are present during fetal development with a subsequent decline postnatally. In the aging brain, there is a significant resurgence of neurotrophic activity througout the CNS but with considerable regional variation. The activity is sensitive to digestion with proteinase K and trypsin but resistant to heparinase. Neurite outgrowth was partially inhibited by NCAM antibody but was unaffected by laminin antibody or antibodies to the amyloid precursor protein. Neuronal cell death in the aging brain may trigger the release of neurotrophic factors resulting in compensatory process outgrowth from remaining viable neurons.

14.2

THE MICRENCEPHALIC RAT: AN ANIMAL MODEL FOR THE STUDY OF ACCELERATED AGING ASSOCIATED WITH DEVELOPMENTAL BRAIN DEFECTS. M.H. Lee, A. Rabe, P. Wang* and J. Currie. New York State Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

The rat with prenatally induced hypoplasia of the cerebrum is an animal model of congenital brain defects and mental retardation. Born with profound morphological and neurochemical changes in the brain, these rats show retarded development and impaired memory and spatial competence. All previous studies have focused on developing and young adult animals. In order to determine how such an altered brain would fare in old age, offspring of Long-Evans rats given 30 mg/kg of methylazoxymethanol acetate (MAM) on E15 were tested at old (24 mo), middle (15 mo) and young (6 mo) ages in the Morris maze, a task sensitive to aging. Although the MAM rats of all ages were impaired on all measures of acquisition and retention, the magnitude of the deficit increased linearly with age, the old MAM rats being significantly poorer than the young ones to learn and remember the position of a hidden escape platform. No such age difference was evident in the control group. Moreover, variability also increased as a direct function of age in the MAM group, suggesting individual differences in the aging process. Changes in neurotransmitter balance may be responsible for the accelerated aging in MAM rats. The results suggest the micrencephalic rat may provide a useful model for the study of aging.

14.3

IN VIVO DOPAMINE AND ACETYLCHOLINE RELEASE IS IMPAIRED IN THE BRAIN OF AGED RATS. EFFECTS OF ACETYL-L-CARNITINE. A. Imperato*, M.T. Ramacci*°, O. Ghirardi*° and L. Angelucci*. (SPON: G. Engel). Inst. of Medical Pharmacology, University "La Sapienza", I-00185 Rome. °Sigma Tau Biological Laboratories, I-00040 Pomezia (Rome).

Several in vitro findings have shown deficiency in the aged rat's brain of the neurotransmitter function at the level of synthesis, metabolism and release. We have studied in the conscious rat of different strains, the changes with aging from 3 up to 27-31 months in dopamine (DA) and acetylcholine (ACh) release from the striatum and hippocampus. While a clear decrease of both DA and ACh release is observed in the rat's aging from 18 (-25%) to 24-31 months (-80%), no significant changes in DA and ACh intraneuronal levels are observed. Moreover, starting from 18 month old rats, the stimulation of striatal DAergic and hippocampal cholinergic terminals by K+ 30 mM, enhances release much less than in the younger rats underlining that the release function is impaired in spite of the presence of normal intraneuronal stores. The effects of acetyl-l-carnitine in young and aged rats, will be described.

14.4

FUNCTIONAL DENDRITIC ELONGATION IN CA1 PYRAMIDAL NEURONS IN SENESCENT F344 RATS. D.A. Turner and D.L. Deupree. Neurosurgery, Univ. Minn. and VAMC, Minneapolis, MN 55417.

Dendritic lengthening during normal aging may compensate for a progressive loss of neurons and afferent synapses. However, impaired behavior (senescence) may result from ineffective compensatory mechanisms. A behavioral measure of hippocampal function *in vivo* was correlated with *in vitro* physiological data on CA1 cells, to identify neuronal alterations specific to senescent animals.

Aged F344 rats (>26 months) were divided into behaviorally normal and impaired groups using a water maze task. Subsequent *in vitro* recordings in CA1 neurons demonstrated no difference in intracellular parameters between young and aged groups, including resting potential, spike height and input resistance. Electrotonic length (L, in λ) was calculated from transient responses in young (n=44 cells) and aged (n=17 cells) rats. Neuronal L values from senescent aged rats ($L=0.60\pm0.15$ λ) showed significant elongation ($p<0.001$) compared to either young ($L=0.42\pm0.09$ λ) or normal aged rats ($L=0.38\pm0.05$ λ).

The specific correlation of increased electrotonic length in CA1 pyramidal neurons *in vitro* with behavioral impairment *in vivo* suggests that dendritic lengthening may be a critical element in abnormal dendritic signal processing in senescence. Supported by grants from the VA Research Service, the MMF, the B.S. Turner Foundation and the Alzheimer's Disease and Related Disorders Association.

14.5

INTRAVENTRICULAR PITUITARY GRAFTS STIMULATE THE IN SITU ACTIVITY OF TYROSINE HYDROXYLASE (TH) IN TUBEROINFUNDIBULAR DOPAMINERGIC (TIDA) NEURONS OF AGED RATS. N. Aquila-Mansilla*, W. Kedzierski*, and J.C. Porter. Dept. OB/Gyn and Physiology, U.T. Southwestern Med. Ctr., Dallas, TX 75235

Aging is associated with a decrease in TIDA neuronal function as judged by content, synthesis, and turnover of dopamine (DA) in median eminence (ME) and by the concentration of DA in hypophysial portal blood. Hyperprolactinemia can stimulate TIDA neurons. We investigated whether such stimulation is peculiar to TIDA neurons or occurs in other dopaminergic neurons. Anterior pituitary (AP) tissue was placed in the lateral ventricles of female rats and maintained there as tissue grafts. Liver tissue served as control. Seven days after implantation, the quantity of TH and its in situ activity, assayed by measuring the rate of accumulation of DOPA, were quantified in the ME, substantia nigra (SN) and corpus striatum (CS). TH mRNA was measured in the SN and hypothalamus. TH was quantified by an immunoblot analysis, using rat TH as a standard. DOPA was measured by HPLC with electrochemical detection. TH mRNA was quantified by an S1 nuclease protection assay using TH sense RNA as the standard. Compared to aged OVX animals with liver implants, the molar activity of TH in the ME of aged OVX rats with AP implants was significantly (P<.001) increased (39±3 vs 59±3 moles DOPA/mole TH/hr). The PRL concentration in the CSF of OVX rats with AP implants was 345± 83 ng/ml compared to 23±9 ng/ml in OVX rats with liver implants. In the CS, the activities of TH in OVX rats with AP grafts and liver grafts were 34±4 and 37±4 moles DOPA/mole TH/hr, respectively. In the SN, the in situ activity of TH was 30±2 moles DOPA/mole TH/hr in animals bearing AP grafts and 29±2 in rats with liver grafts. The quantity of TH mRNA was 34±2 attomoles in the hypothalamus of rats with AP grafts and 38±3 attomoles in animals with liver grafts. In the SN of rats with AP grafts and liver grafts, there were 705±63 and 755±47 attomoles of TH mRNA, respectively. In contrast to OVX rats, aged intact animals bearing AP or liver grafts showed no difference in the activity of TH, mass of TH, and TH mRNA levels. Although the PRL concentration in CSF of AP grafted animals was significantly higher (P<.01) than those with liver implants (729±180 vs 223±62 ng/ml), the latter still exhibited a marked elevation in the PRL concentration in CSF compared to OVX rats with liver grafts. These findings show that 1) the secretory activity of TIDA neurons of aged rats is reduced by ovariectomy, 2) the TIDA neurons of aged OVX animals are stimulated by intraventricular AP grafts, possibly due to PRL, and 3) the effect of AP grafts is specific for TIDA neurons and not for DAergic neurons of the SN. Lastly, the increase in TH activity is not attributable to an increase in the quantity of TH mRNA or TH. (Supported by NIH grants AG-04344 and AG-08173.)

14.6

LOSS OF SEXUAL DIMORPHISM IN RAT ARCUATE NUCLEUS (AN) NEURAL MEMBRANES WITH SENESCENT CONSTANT ESTRUS/DIESTRUS. L-M Garcia Segura*, E. Jones and F. Naftolin. Instituto Cajal*, Madrid, Spain and Department of Obstetrics and Gynecology, Yale University, New Haven, CT.

At all ages thus far studied, compared to males, female rats have more intramembranous protein particles (IMP) in their AN neural membranes. During the estrus cycle and as a result of administration of estradiol the number of IMP in female post-synaptic membranes decreases toward that found in males. Estrogen administration also can cause a loss of positive feedback (tonic reproduction/constant estrus), in which case the changes in IMP become fixed at male levels. Since senescent constant estrus is the natural outcome of aging in the cycling female rat, we proposed that cyclic preovulatory estrogen exposure could induce the senescent constant estrus of aging (J Ster Biochem 30:195, 1988). To test this hypothesis we examined AN membranes from aged females in senescent constant estrus or diestrus, comparing them to young cycling females and equally-aged males. EXPERIMENTAL: Following assessment of reproductive status by vaginal smears, female rats and equally-aged male rats were perfusion-fixed and the AN analyzed by freeze-fracture. Cycling females had higher numbers of IMP in post synaptic membranes than males (1265 ± 21 versus 877 ± 29 IMP/μM^2 [P-face], $p < 0.001$); but membranes from 15 month old females in senescent constant estrus (793 ± 32 IMP/μM^2) and 18 month old females in senescent constant diestrus (847 ± 23 IMP/μM^2) had the same IMP density as males. To control for aging, 15 and 18 month old males were compared with 3 month old males and found to have the same IMP density. CONCLUSIONS: Neuronal membranes from senescent female rats have lost their male/female IMP difference. Since estrogen causes both depletion of membrane IMPs and the development of tonic reproduction, the present results support the idea that senescent constant estrus may be the result of repeated synaptic remodelling driven by periodic estrogen surges during the ovarian cycle. (Supported by NIH-HD13587 and CSIC, Spain.)

14.7

STUDIES OF NEURON LOSS WITH AGE IN THREE DIFFERENT BRAIN REGIONS IN HUMANS. JB Lohr, DV Jeste. San Diego VA Medical Center and Univ of CA, San Diego, 92161.

Age-related neuron loss varies in different brain regions although there have been few studies of neuronal density with aging in different areas of the same brains. We examined the cerebellum, hippocampus, and locus ceruleus (l.c.) from 47 brains from the "normative" series of the Yakovlev Collection, Washington, D.C. We have reported the techniques of morphometric analysis previously (Biol Psychiat 21:865, 1986; Acta Psych Scand 77:689, 1988). Pearson's correlation coefficient of neuron density with age ranged from .03 for dentate nucleus to .91 for l.c. After correcting for age effects, there was a significant correlation (r=.67) of neuron density in the l.c. with Purkinje cell density in the anterior vermis. Also, areas in the hippocampus and cerebellum which had the greatest neuron loss with age were those that may receive greater noradrenergic input from the l.c. These results suggest an association between catecholamine content and age-related neuron loss in different brain regions.

14.8

REDUCED BRAIN GREY MATTER VOLUME IN ELDERLY VOLUNTEERS. K. O. Lim*, R. B. Zipursky*, M. C. Watts*, and A. Pfefferbaum*. (SPON: W. Faustman). Stanford University School of Medicine, Stanford, CA and Veterans Administration Medical Center (116A3), Palo Alto, CA 94304.

Magnetic Resonance (MR) imaging affords the potential for quantitative in vivo assessments of brain grey matter and white matter volumes. In order to study differences in grey and white matter in different disease states, it is critical to understand the changes that take place with normal aging.

Accordingly, 8 young men (mean=24yrs) and 7 elderly men (mean=73yrs) underwent a cardiac gated, spin echo, axial MR scan (effective TR≥2400msec; TE=20 and 80msec). Six 5mm thick sections per subject were analyzed. Quantification of cerebrospinal fluid (CSF) and tissue pixels was accomplished by segmenting each section into CSF, grey matter and white matter compartments (Lim and Pfefferbaum, *J. Comput. Assist. Tomogr.*, in press).

The young and the old subjects did not differ significantly in the total intracranial volume of the sections analyzed. Cortical sulcal volume was significantly greater in the elderly subjects ($P<0.001$) as was lateral ventricular volume ($P<0.01$). The elderly subjects had significantly reduced cortical grey matter volume ($P<0.001$) and subcortical grey matter volume ($P<0.05$) relative to the young subjects. The two groups did not differ significantly in cortical or subcortical white matter volumes.

Using quantitative computerized assessment of MR images, significant reductions in cortical and subcortical grey matter were found in elderly men. These results suggest that the age-related increases in ventricular and sulcal volume seen with current structural imaging techniques are due primarily to decreases in grey matter rather than white matter volume.

HOX 1.3, AMYLOID &-PROTEIN AND AGING. D. Goldgaber, D.E. Schmechel, and W.F. Odenwald* (SPON: F. A. Henn). NINDS, NIH, Bethesda, MD 20892; Duke Univ. Durham, NC 22710.

While analyzing the promoter region of the APP gene that encodes amyloid β-protein found in brains of patients with Alzheimer's disease, we found five potential binding sites similar to the Hox 1.3 consensus sequence CPyPyNATTAT/GPy. Two of these sites located near positions -1500 and -2600 were recognized by the Hox 1.3 protein in a band shift assay. This suggests that the APP gene might be a target gene for Hox 1.3 protein. Both APP gene and Hox 1.3 gene are highly conserved in evolution and are expressed in neurons of adult mammalian brain in a very similar distinct pattern. We used antibody to the Hox 1.3 protein to immunostain sections of adult human temporal cortex and hippocampus. As expected, nuclei of most neurons were darkly stained with the antibody. However, this was true only for young adults. When brain sections of old individuals with or without Alzheimer's disease were stained with this antibody the number of stained neurons dramatically decreased.

The homeo box protein Hox 1.3 is a regulatory factor whose expression is regulated in space and time. The disappearance of Hox 1.3 in neurons of aged individuals might have a significant effect on expression of target genes including the APP gene. Our data suggests that aging might be a final stage of development with the Hox 1.3 gene turned off.

14.10

AMYLOID PRECURSOR PROTEIN (APP) UNDERGOES FAST ANTEROGRADE TRANSPORT. E.H. Koo, S.S. Sisodia*, D.R. Archer*, L.J. Martin*, K. Beyreuther*, A. Weidemann* and D.L. Price. Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

In senile plaques, abnormal nerve terminals (neurites) surround extracellular deposits of β-amyloid protein (BAP). BAP is derived from APP that may originate from the circulation or from brain elements. If BAP is derived from neuronal APP and is deposited at locations remote from where synthesis occurs, then APP must translocate from perikarya to distal terminals in proximity to sites of amyloid deposition. In this study, we determined that APP is rapidly transported in axons. Two ligatures (1 cm apart) were placed on sciatic nerves in adult rats; animals were sacrificed 6-48 hours later. Segments of nerve (5 mm) proximal to, within, and distal to the ligatures were analyzed by SDS-PAGE and immunoblotting. APP accumulated after six hours and increased up to 24 hours in segments proximal to the first ligature. In immunoprecipitation experiments, APP labeled by microinjecting sensory neurons was detected in sciatic nerve segments proximal to the ligation. Finally, immunocytochemistry showed APP immunoreactivity within swollen axons proximal to the ligation. These findings suggest that APP is delivered to nerve terminals where proteolysis of APP may liberate BAP into the neuropil, leading to deposits of amyloid.

14.11

BIOSYNTHESIS AND PROCESSING OF AMYLOID PRECURSOR PROTEIN (APP) *IN VITRO*. S.S. Sisodia*, E.H. Koo, L.J. Martin*, A.J. Unterbeck*, K. Beyreuther*, A. Weidemann* and D.L. Price (SPON: D.L. Price). Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

Amyloid deposits in plaques and cerebral blood vessels are hallmarks of Alzheimer's disease. Principally, amyloid is a 42 amino-acid peptide (BAP), a truncated form of a larger precursor, APP. Three APP transcripts code for APP-695, -751, and -770 isoforms that appear to be glycosylated cell-surface molecules; the two larger polypeptides also contain domains homologous to protease inhibitors. We have begun to examine the biochemical mechanisms by which the APP isoforms mature *in vitro*. Engineered APP genes were introduced into mammalian cell lines, and APP isoforms were analyzed by pulse-chase/immunoprecipitation and endoglycosydase cleavage assays, in conjunction with studies using sugar-precursor labeling and metabolic inhibitors. Using both biochemical and immunocytochemical approaches, we document that APP is transported rapidly to the cell surface; a large N-terminal portion of APP is secreted into the extracellular environment. APP does not appear to be cleaved at the membrane/extracellular interface but at a site near the N-terminal of BAP. Mutagenesis techniques and biochemical analyses of wild-type and modified APP polypeptides are being used to define sites that are necessary and/or sufficient for the initial cleavage of APP.

14.12

LOCALIZATION OF AMYLOID PRECURSOR PROTEIN (APP) IN BRAINS OF YOUNG AND AGED MONKEYS. L.J. Martin*, L.C. Cork*, E.H. Koo*, S.S. Sisodia*, A. Weidemann*, K. Beyreuther*, C. Masters* and D.L. Price. (SPON:A. Pestronk). Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

APP is a membrane-spanning glycoprotein that is processed to generate a 42 amino-acid β-amyloid protein (BAP) deposited extracellularly in senile plaques and blood vessels. In plaques, BAP is associated with enlarged neurites (i.e., abnormal axons/nerve terminals). Little is known of the distribution of APP in primate brain or how patterns change with age. We investigated APP-immunoreactive patterns in fresh-frozen cortices from monkeys (n = 11) ranging from 4-41 years of age. APP immunoreactivity was present in neuronal perikarya, proximal dendrites, and axons. APP and synaptophysin (a presynaptic marker) antibodies stained neurites in a subset of plaques containing BAP. Knob-shaped neurites appeared to be capped by BAP immunoreactivity. The presence of APP in axons is consistent with our findings in rats that APP is transported anterogradely. The accumulation of APP in neurites suggests that local alterations in the processing of APP to BAP contributes to amyloid deposition in plaques of aged nonhuman primates.

BIOLOGICAL RHYTHMS AND SLEEP: NEUROREGULATORS

15.1

NORADRENERGIC AND CHOLINERGIC REGULATION OF CANINE CATAPLEXY, A PATHOLOGICAL MODEL OF REM SLEEP ATONIA

E. Mignot*, S. Nishino*, D. Valtier*, R. Dean*, and C. Guilleminault. Stanford University Sleep Disorders Center, 701 Welch Road, Suite 2226, Palo Alto, CA 94304.

Human narcolepsy is usually considered as a REM sleep disorder and its symptoms as dissociated REM sleep manifestations. Using *in vivo* pharmacology and various neurochemical measurements (radioreceptor binding and LCEC measurements of brain monoamines) in a canine model of the human disorder, we suggest that cataplexy is under the dual control of a noradrenergic system involving the locus coeruleus and the amygdala, and a pontine cholinergic system starting from the pedunculopontine nucleus and projecting in the reticular formation. *In vivo* pharmacology clearly indicates that the noradrenergic system inhibits REM sleep and cataplexy whereas the pontine cholinergic system activates cataplexy (Baker T and Dement WC, In Brain Mechanims of Sleep, pp199-234. D. Mc Ginty et al. Eds, New-York , Raven Press, 1985; E. Mignot et al., J. Clin. Invest. 82: 885-894, 1988). The pontine cholinergic system seems to be the final commun pathway since all the effects of the noradrenergic compounds on cataplexy are dependant upon the integrity of the cholinergic system. We included the amygdala in our model because of our findings of abnormal content of catecholamines, metabolites and receptors reported in this brain region (Faull et al., Sleep 9: 107-110, 1986). The involvement of this structure would also explain the fact that cataplexy is precipitated by emotional stimuli since the role of the amygdala in emotional behavior is well documented. The possibility that a specific defect of one of these systems could be the primary cause of canine narcolepsy, an autosomal recessive disorder of REM sleep, will be discussed.

15.2

THE EFFECT OF GONADAL STEROIDS ON THE DIURNAL RHYTHM OF OXYTOCIN IN THE CEREBROSPINAL FLUID OF RHESUS MONKEYS. J.A. Amico and J.L. Cameron. Depts. of Medicine and Psychiatry, Univ. of Pittsburgh School of Medicine and Oakland VAMC, Pittsburgh, PA 15261.

The magnocellular oxytocin (OT) neurons that project to the posterior pituitary release OT into the periphery. Peripheral OT does not cross the blood brain barrier. Parvicellular OT neurons project to other central nervous system (CNS) areas and may be the source of OT in CSF. In primates, OT has a diurnal rhythm in CSF with peak and nadir concentrations occurring during light and dark hours, respectively. Factors influencing this rhythm have yet to be identified. Estradiol (E_2) stimulates OT transmission in the CNS and may alter the CSF OT rhythm. To determine the effect of E_2 and progesterone (P), ovariectomized rhesus monkeys (n = 7) bearing subarachnoid catheters were S.Q. implanted with two 4-cm silastic capsules containing 17β-E_2 for 6 days and one 4-cm P capsule for the last 3 days of E_2 treatment. Hourly samples of CSF were collected before, during and after gonadal steroid treatment and measured for OT by RIA and HPLC. Mean $\pm$ SEM serum E_2 concentrations before, during, and after implantation were 112 $\pm$ 12, 325 $\pm$ 11, and 99 $\pm$ 6, pg/ml. The daily phase, amplitude, peak, and nadir of the CSF OT rhythm were not altered by E_2 or E_2 + P (ANOVA). HPLC chromatograms of CSF before and during gonadal steroid treatment were identical. OT immunoreactivity eluted as a single peak in the position of synthetic OT. We conclude that the CSF OT rhythm in primates is not estrogen or progesterone dependent.

15.3

ULTRADIAN CYCLICITY: MORPHOLOGICAL SEX-LINKED INFLUENCES. J. Fang* and W. Fishbein. Neurocognition Program, CUNY, City College & Graduate School, N.Y. 10031

At the 1987 SN meeting we reported for the first time, in the mouse, that sex differences exist in the ultradian cyclicity of sleep. The findings were the first to indicate that sleep is sexually dimorphic. At the same time we also reported that the sleep of males could be completely sex-reversed by prenatally stressing them. The findings led us to conclude that sleep-cycle rhythmicity follows the same general rule as the genital system: the basic plan is inherently female. In the absence of male hormones the genetic male develops a female brain and female sleep-cycle rhythms. At the 1988 SN meeting we reported that we had extended our observations to the Sprague-Dawley rat.

A key finding in our research, both in mice and rats, is that the sexual dimorphism of sleep is solely accounted for by a sex-linked difference in the frequency of occurrence of paradoxical sleep (PS) bouts. It appears that the normal biological clock timing mechanism(s) that controls the interval between PS episodes is sexually dimorphic and runs at a different speed in male rodents than in females. As a result the total amount of PS is substantially different between the sexes.

Therefore, the pontine-cholinergically mediated sleep-cycle trigger zone must be regulated by extra-pontine, sex-linked influences.

The Locus Coeruleus and Suprachiasmatic Nuclei are sexually dimorphic structures that depend on the levels of gonadal steroids early after birth to influence their morphological architecture. Both structures are thought to be crucially involved in the regulation of circadian and ultradian timing. The gender differentiation of sleep, therefore, may result from sex-linked morphological differences in these structures.

15.4

SOLUBILIZATION OF MELATONIN RECEPTORS FROM LIZARD BRAIN. S.A. Rivkees, R.W. Conron*, S.M. Reppert. Laboratory of Developmental Chronobiology. Children's Service, Mass. Gen. Hosp., Boston, MA 02114

Melatonin receptors from lizard brain (Anolis carolensis), a highly enriched source of melatonin receptors, were identified with ^{125}I-labeled melatonin (I-MEL) after solubilization with digitonin. Receptors solubilized in the absence of Mg^{2+}, retained the essential characteristics of lower affinity receptors (non-G protein coupled) previously characterized in crude membrane preparations (PNAS 86:3882, 1989). Binding was saturable (Kd=347±89 pM, Bmax 86±15 fmol/mg; n=6), reversible, and inhibited in a characteristic manner by melatonin and closely related analogs. Binding was not affected by GTP-gamma-S (100 uM) suggesting that solubilized receptors were not coupled to G proteins. Based on gel filtration chromatography estimates, the molecular range of non-G protein coupled receptors was 110,000 to 150,000 (n=3). When Mg^{2+} was included during solubilization, subsequent specific I-MEL binding was reduced by GTP-gamma-S by 90% suggesting that receptors solubilized in this manner were coupled to G proteins. Gel filtration chromatography yielded an apparent molecular range of ca. 440,000 for G protein coupled ligand-receptor complexes (n=2). These results suggest that I-MEL binding sites in solubilized lizard brain membranes are melatonin receptors, with Mg^{2+}-dependent G protein coupling.

15.5

A D-2 DOPAMINE RECEPTOR AGONIST RESETS THE PHASE OF A CIRCADIAN CLOCK IN CULTURED EYECUPS FROM *XENOPUS LAEVIS*. G.M. Cahill and J.C. Besharse. Dept. of Anatomy and Cell Biology, Emory University School of Medicine, Atlanta, GA 30322.

Dopamine, acting through D-2 receptors, has been implicated in the regulation of rhythmic retinal processes by light and a circadian clock. In the present study, we have begun to explore the role of dopamine in the ocular pacemaker that controls retinal melatonin synthesis. Rhythmic release of melatonin by individually superfused *Xenopus* eyecups was used as an assay of pacemaker function. The defined culture medium includes 100 μM 5-hydroxytryptophan, which elevates melatonin production sufficiently that circadian rhythms of melatonin release can be measured from individual eyecups for up to 5 cycles in constant darkness. When the D-2 agonist quinpirole (10^{-7} M) was added to the superfusion medium, acute suppression of melatonin production, as well as entrainment and resetting of the rhythm were observed. The rhythms of the paired eyes from an individual could be entrained *in vitro* to 180° antiphase by two alternating 12-hr treatments of each eyecup with quinpirole. The phases produced by quinpirole cycles were maintained for over 2 cycles in constant conditions. Single 6-hr pulses of quinpirole caused phase-dependent phase shifts of the rhythms in test eyecups when compared to paired, untreated eyecups. Pulses in the early subjective night caused phase delays, and pulses in the late subjective night caused phase advances. These effects of quinpirole are similar to the expected effects of light, and suggest a role for dopamine receptors in the generation or entrainment of ocular rhythmicity.

CIRCADIAN ACTIVITY RHYTHMS IN HYPERTENSIVE (SHR) AND NORMOTENSIVE (WKY) RATS: STRAIN DIFFERENCES AND EFFECTS OF CLONIDINE. A.M. Rosenwasser, Dept. of Psychology, Univ. of Maine, Orono ME 04469.

Chronic clonidine treatment shortens the free-running period and reduces the level of circadian activity rhythms in rats. The present study extends these observations to spontaneously hypertensive SHR rats and their normotensive WKY controls. SHR rats display several neurochemical differences from WKYs, and the two strains respond differentially to clonidine in certain pharmacological tests. Circadian wheel-running rhythms were assessed before, during, and after clonidine treatment (5.0 ug/ml in the drinking water for 4 weeks), under constant light. SHR rats showed shorter periods and were hyperactive relative to WKYs during baseline conditions. Clonidine administration shortened free-running periods similarly in the two strains, but reduced activity more dramatically in the SHRs. These results suggest that central noradrenergic systems influence both the periodicity and the level of spontaneous activity, and that clonidine may act at different neural or neuronal loci to alter these two parameters.

NEUROPEPTIDE Y (NPY) PRODUCES CIRCADIAN PHASE CHANGES OF SUPRACHIASMATIC NUCLEUS (SCN) NEURON FIRING RATE RHYTHM IN VITRO. S. Shibata* and R.Y. Moore. Dept. Pharmacol., Kyushu University, Fukuoka, Japan and Depts. Neurology and Neurobiology, SUNY Stony Brook, NY 11794.

The geniculohypothalamic tract (GHT) contains NPY neurons projecting upon the SCN. Stimulation of the GHT (Johnson et al, 1989) or injection of NPY into the SCN (Albers and Ferris, 1984) produces changes in the phase of circadian activity rhythms with a phase response curve (PRC) that differs from that for light but is similar to that for triazolam (Turek and Losee-Olson, 1986), protein synthesis inhibition (Inouye et al, 1989) and social interaction (Mrosovsky, 1988). The present study was carried out to analyze the effects of NPY administration on the phase of the circadian rhythm in firing rate of SCN neurons in in vitro (Shibata et al, 1982) and compare this to potassium depolarization, protein synthesis inhibition (cycloheximide), optic chiasm stimulation and calmodulin inhibition. NPY, produces phase changes with a PRC with phase delays during early subjective day, phase advances in mid- to late subjective day and phase delays during subjective night. This PRC was essentially mimicked by cycloheximide and the calmodulin inhibitors. Potassium depolarization and optic chiasm stimulation produced phase changes with PRC's similar to light. These data suggest that there are two principal pathways, receptors and/or second messenger systems, by which entraiing influences interact with SCN circadian pacemakers. Supported by NIH grant NS-16304.

15.8

EFFECTS OF 5,7DHT LESIONS OF THE HAMSTER SEROTONERGIC SYSTEM ON CIRCADIAN ACTIVITY RHYTHMS. K.M. Michels, L. Smale, R.Y. Moore and L.P. Morin. Neurology and Psychiatry, SUNY Stony Brook, NY 11794.

The role of the serotonergic system in the regulation of hamster circadian rhythms was analyzed using intraventricular injections of the selective neurotoxin, 5,7-dihydroxytryptamine (5,7DHT). 5,7DHT depleted immunoreactive serotonin (5HT) in the forebrain, particularly the suprachiasmatic nuclei and intergeniculate leaflet. 5,7DHT also produced an immediate, sustained advance in running wheel activity onset relative to the 14:10 light-dark cycle of 0.71 ± 0.07 h prior to lights out for 5,7DHT treated animals compared to 0.18 ± 0.04 h after lights out for controls. This advanced phase angle was maintained after an 8 hour phase shift of the cycle. Wheel running offset was also delayed by 5,7DHT, but the period in constant darkness, the rate of reentrainment to an 8 h phase advance, and the daily amount of wheel running activity were not significantly affected. In addition, 5,7DHT did not affect the ability of triazolam to accelerate reentrainment to an 8 h phase advance. These data indicate that ascending serotonin projections of the midbrain raphe participate in the pattern of entrainment of the hamster activity rhythm, however, the mechanism of action remains to be elucidated. Supported by NIH grant NS 16304 to RYM and NIH grant NS 22168 to LPM.

THE INTERGENICULATE LEAFLET: DELINEATION BY RETINAL AFFERENTS AND NEURONAL MARKERS. R.Y. Moore and J.P. Card (Spon: K.L. Olsen) Depts. of Neurology and Neurobiology, SUNY, Stony Brook, NY 11794 and Medical Products Division, E.I. DuPont de Nemours, Wilmington, DL 19898

The intergeniculate leaflet (IGL) of the lateral geniculate complex is intercalated between the dorsal (DLG) and ventral (VLG) geniculate nuclei (Hickey and Spear, 1976). The IGL contains neuropeptide Y (NPY+)-and enkephalin (ENK+)-immunoreactive neurons (Card and Moore, 1982; Mantyh and Kemp, 1983) which project to the suprachiasmatic nucleus (SCN; NPY+) and contralateral IGL (ENK+), respectively (Card and Moore, 1989). The present study was directed to a precise delineation of the IGL using anterograde transport of cholera toxin-HRP and quantitative analysis of NPY+ and ENK+ neurons after retrograde transport of fluorogold (FG) from the SCN and IGL. The IGL is present rostrally as a thin lamina of neurons between the VLG and DLG. Caudally, it is a wedge of cells between the VLG and the medial geniculate and then swings ventrally lying between the medial geniculate and the lateral terminal nucleus of the accessory optic system. After FG injection into the SCN, the IGL contains 750+35 labeled cells of which 559+35 are NPY+. After FG injection into the IGL, the contralateral IGL contains 1259+112 neurons of which 1058+85 are ENK+. Thus, the IGL contains approximately 2000 neurons of which 35% project to the SCN and 65% project to the contralateral IGL. Supported by NIH grant NS16304 and the E.I. DuPont Co.

TRANSMITTERS IN INVERTEBRATES I

16.1

PROCTOLIN IS ASSOCIATED WITH CRAYFISH SWIMMERET COMMAND NEURON ACTIVITY. L.D. Acevedo and B. Mulloney. Zoology Dept., University of California, Davis, California 95616.

Five command neurons excite the crayfish swimmeret system. Their axons were mapped to specific locations in the interganglionic connectives [Wiersma and Ikeda, 1964]. Stimulation of any one of these axons will activate the swimmeret rhythm, the motor pattern that drives normal swimmeret beating. The neuropeptide proctolin will also activate the swimmeret rhythm [Mulloney et al., 1987].

To test the hypothesis that proctolin is the transmitter used in these command pathways, we studied the distribution of proctolin immunoreactivity and the stimulus-dependent release of proctolin. We demonstrated that proctolin-like immunoreactivity occurred in the same regions of the ganglion where command axons project. Affinity-purified antibodies to proctolin reveal 15-20 bilateral pairs of axons in each abdominal ganglion. Approximately half of these axons sent branches into the Lateral Neuropils, the region of each ganglion that contains most of the swimmeret pattern generating circuitry. Many of these axons also lie in longitudinal tracts predicted from the positions of command neurons given by Wiersma and Ikeda.

Small bundles of axons teased from the interganglionic connectives that contained one command neuron also contained immunoreactive axons. Stimulation of axon bundles that contained single command axons sometimes released proctolin into the superfusate. Proctolin released during command neuron activity and measured with a locust leg bioassay was blocked by preabsorption of the releasate to proctolin antibodies. These results are consistent with the hypothesis that proctolin is the transmitter used by these command neurons.

16.2

PROCTOLIN AND OCTOPAMINE PRODUCE DIFFERENT PATTERNS OF MUSCLE TENSION ENHANCEMENT AND CALCIUM CHANNEL ACTIVATION IN CRAYFISH SKELETAL MUSCLES. C.A. Bishop, M.E. Krouse* and J.J. Wine, Dept. of Psychology, Stanford Univ., Stanford, CA 94305.

Proctolin, a pentapeptide cotransmitter released by three identified tonic flexor motoneurons, greatly potentiates depolarization-induced tension, in part by increasing activity of voltage-dependent Ca^{2+} channels (Bishop, *Neuro. Abst.*, 1988). Octopamine, a biogenic amine that plays a neurohumoral role in crustacea, can also potentiate tension by direct action on some muscles (Kravitz, *Sci.* 241: 1775, 1988). We compared the effects of proctolin and octopamine on tension-voltage curves [T(V) curves] generated in individual tonic flexor muscle fibers by intracellularly injected currents. **Results:** 1. Neither modulator affected resting muscle tension or membrane potential. 2. Both enhanced induced tension, but in different ways: proctolin (at a maximal dose of 5×10^{-9} M) shifted the T(V) curve to the left with a variable and sometimes small increase in slope, while octopamine (10^{-7} M) caused only a small shift in threshold but a marked increase in slope. 3. Combined effects of the two modulators were at least additive. 4. The rate of tension relaxation was unaffected by proctolin but was increased 1.9-fold by octopamine.

Attempts to account for these findings with single-channel patch-clamp recordings have revealed a large Ca^{2+} channel (50 pS in 137 mM Ba^{2+}) which has an increased probability of opening when depolarized. The open probability of this channel in inside-out patches was greatly increased by proctolin but not by octopamine. We conclude from these results that proctolin and octopamine enhance crayfish muscle tension via different mechanisms and the actions of these two neuromodulators subserve different physiological roles. (Supported by NIH grant NS20557 and the Muscular Dystrophy Assn.)

MODULATION OF MUSCLE TARGET EXCITABILITY BY A DUAL TRANSMITTER MOTONEURON. I.R. Duce and M. E. Adams (SPON: P. Wilson) Dept. of Entomology, Univ. of California, Riverside, CA 92521

The neuropeptide proctolin is contained in a subset of skeletal motor units in insects and crustaceans, where it functions as a cotransmitter with L-glutamic acid. We have investigated the occurrence and possible functions of proctolin and glutamate in motor neurons innervating the longitudinal ventrolateral muscles 6A and 7A of the larval house fly, *Musca domestica*. Immunohistochemical staining with a glutamate-specific antiserum revealed the following three morphological types of motor axons on the surface of these muscles: Type A axons are short and thin (1-2 μm), make large nerve terminals (5-10 μm) and are found predominantly on the lateral muscle cell (6A) in each segment. Type B axons are long and thick (3-5 μm), contain large (5-10 μm) varicosities and arborize extensively over both muscles 6A and 7A. Type C axons are very thin (<1 μm), have small varicosities (1-2 μm) and, unlike Type A or B axons, extend to the outer edges of each muscle cell. Type A axons only are immunoreactive against both glutamate and proctolin antisera.

Muscles 6A and 7A are electrically inexcitable under normal conditions. However, muscles depolarized by current injection or nerve stimulation support calcium-dependent action potentials (APs) following exposure to nanomolar concentrations of proctolin. Proctolin-induced APs are cobalt-sensitive and persist for several minutes after removal of the peptide from the bath.

The effects of bath-applied proctolin on the EJP can be elicited by selective stimulation of one of the motor neurons innervating the muscles. Repetitive stimulation of a low threshold motor neuron results in EJPs which do not generate APs, but recruitment of this unit together with a higher threshold axon leads to the EJPs which generate APs. We hypothesize that a dual transmitter motor neuron containing both glutamate and proctolin modulates voltage-sensitive calcium channels in these muscles.

FMRFAMIDE-LIKE PEPTIDES MODULATE PHASIC NEUROMUSCULAR SYNAPSES IN CRUSTACEANS. A.J. Mercier, M. Schiebe, H. Bradacs and H.L. Atwood. Dept. of Physiol., Univ. of Troront, Toronto, Ont. M5S 1A8

Two FMRFamide-like peptides (TNRNFLRFamide and SDRNFLRFamide), found in lobster neurohaemal organs, are thought to modulate cardiac and tonic neuromuscular systems (Trimmer et al, J. Comp. Neurol. 266: 16, 1987). Both compounds increased nerve-evoked tension in phasic abdominal extensor muscles of crayfish by 5-fold or more. Threshold concentrations were below 10^{-9} M, and resting tension was unaffected. EPSP's increased by up to 90%, with thresholds for an observable effect between 10^{-9} and 10^{-8} M. Input resistance of muscle fibers increased by about 15%, suggesting that the effect on EPSP's was not solely due to postsynaptic changes. An increase in quantal content was observed with extracellular recording at exposed synaptic terminals. Similar changes in EPSP size also occurred in the homologous muscle of lobsters at 10^{-7} to 10^{-6} M. The effect on tension was mimicked by 10^{-7} M YGGFMRFamide and by 10^{-8} M met-enkephalin, but 10^{-6} M FMRFamide had no effect. These data provide the first evidence for modulation of a phasic neuromuscular system in crustaceans.

Supported by NSERC of Canada.

PHARMACOLOGICAL EVIDENCE THAT GLUTAMATE IS THE EXCITATORY NEUROTRANSMITTER TO AN INTERNEURON IN THE CRAYFISH MEDULLA. C.L. Pfeiffer-Linn and R.M. Glantz, Department of Biology, Rice University, Houston, TX. 77001.

Although glutamate is the most likely excitatory transmitter at arthropod neuromuscular junctions, little is known about its role in the CNS. We have examined the distribution and pharmacological actions of glutamate in the optic lobe of the crayfish, Procambarus clarkii. Distribution of glutamate was examined with an antisera to a glutamate-glutaryl-protein conjugate. Glutaraldehyde fixed tissue was sectioned in cryostat, incubated in primary antibody at 1:500 dilution and visualized with the PAP procedure. Glutamate-like reactivity was observed in the lamina's amacrine cell body layer, in the glia surrounding the lamina, in columnar projections of the first and second chiasm, in three layers of the medulla externa and in four layers of the medulla externa.

Pharmacological actions of glutamate were examined on the principle output cells of the medulla externa; the sustaining fibers (SFs). SFs respond to light with a sustained compound EPSP. Pressure injected glutamate (10^{-6} M), quisqualate (10^{-7} M) and kainate (10^{-7} M) all mimic the synaptic action, producing a depolarization associated with an increase in conductance and a reversal potential similar to that of the synaptic response. All of these actions persist in 20 mM cobalt. NMDA and known glutamate antagonists; DNQX, L-glutamic acid gamma methylester and piperidine, have no effect on this receptor. Glutamate has no effect on two other medullary interneurons; tangential and amacrine cells. These results support the hypothesis that glutamate is the excitatory neurotransmitter to the major output cells of the secondary neuropil. Supported by NSF Grant BNS 87-11141.

16.6

ARE TWO SUB-TYPES OF PRESYNAPTIC CALCIUM CHANNELS INVOLVED IN NEUROTRANSMITTER RELEASE AT THE INSECT NEUROMUSCULAR JUNCTION? V. P. Bindokas* and M. E. Adams, (SPON: R. E. Whalen) Div. Toxicol. & Physiol., Dept. of Entomology, Univ. of California, Riverside, CA 92521.

Venom of *Agelenopsis aperta* spiders contains a family of calcium channel antagonists (ω -agatoxins) which blocks transmitter release at the insect neuromuscular junction. The ω-agatoxins are distinguished as Type I and Type II toxins based on structural and biochemical criteria (Adams *et al.*; Pocock *et al*; this meeting). We present evidence showing that Type I (ω-Aga-IA, IB, IC) and Type II (ω-Aga-IIA, IIB) ω-agatoxins may have separate effects on transmitter release at the larval fly (*Musca domestica*) neuromuscular junction.

ω-Aga-IA, a Type I toxin, irreversibly blocks neuronal calcium channels in insects (Bindokas and Adams, *J. Neurobiol.*, 20, in press). Maximal block caused by ω-Aga-IA is 98% in low Ca (0.75 mM) saline, but is reduced to about 40% upon introduction of high Ca (5 mM) saline. This effect appears not to involve displacement of bound toxin, since the block returns to its original level when low Ca saline is re-introduced. Rather, elevated extracellular Ca may provide sufficient Ca flux through ω-Aga-IA-insensitive channels to permit partial recovery of transmitter release. Maximal block caused by ω-Aga-IA in high Ca saline is not increased upon addition of other Type I toxins, suggesting that Type I-sensitive binding sites are saturated. However, application of a Type II toxin (IIA or IIB) increases the partial block caused by ω-Aga-IA to 90%. Similarly, Type II toxins block only partially in high Ca saline, but 90% block is reached upon subsequent application of a Type I toxin.

We hypothesize that separate subtypes of presynaptic calcium channels mediate neurotransmitter release at the insect neuromuscular junction. These are distinguished by differential Type I and Type II ω-agatoxin sensitivity.

16.7

CHARACTERIZATION OF AN AFFERENT-INDUCED CHANGE IN THE EXCITABILITY OF AN INSECT MOTONEURON. B.A. Trimmer and J.C. Weeks. Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

PPR, one of the motoneurons involved in retracting the prolegs of *Manduca sexta* larvae, receives direct cholinergic input from mechanosensory afferents at the tip of the proleg. Unitary EPSPs evoked by each afferent are mediated by nicotinic acetylcholine receptors (nAChRs). After these nAChRs are blocked with mecamylamine, a short train of stimuli to a group of afferents evokes a slowly developing, long-lasting depolarization of PPR (the post-train depolarization, **PTD**). During PTD, PPR is much more excitable, such that further afferent stimulation or depolarization of PPR by current injection cause prolonged spiking. PTD is accompanied by a decreased spike threshold which is not a result of the depolarization measured at the soma. No consistent changes in input resistance can be recorded. Both PTD and the change in spike threshold seem to be mediated by muscarinic receptors since they are blocked by very low concentrations (0.1μM) of scopolamine-methyl bromide and can be mimicked by iontophoresis or bath application of oxotremorine-M or muscarine. The M1 selective agonist McN-A-343 is without detectable effect at concentrations as high as 3μM. The M1 selective antagonist pirenzepine blocks PTD only at concentrations above 10μM. The M2 selective antagonists vary in their effectiveness. 4DAMP is without effect at 10μM but hexahydrosiladifenidol inhibits PTD at 1μM. Thus, we are not able to classify the receptors according to the vertebrate scheme. This is the first system in which a physiological role for insect muscarinic receptors has been established, and we are presently studying the ionic and intracellular mechanisms involved in their actions. Supported by a research grant from the Whitehall Foundation.

16.8

NEUROPEPTIDE EXPRESSION, MODULATION AND FUNCTION IN THE EMBRYO OF AN INSECT. K.S. Broadie*, C.M. Bate* and N.J. Tublitz. Inst. of Neurosci., U. Oregon, Eugene, OR 97403, & Dept. Zool., U. Cambridge, UK.

Little is known about the differentiation and function of peptidergic neurons during embryogenesis. We have addressed this issue in the embryonic CNS of the moth, Manduca sexta, which in post-embryonic stages contains two Cardioacceleratory Peptides (CAPs) that serve several modulatory functions. Using a highly specific anti-CAP monoclonal antibody, the temporal and spatial distribution of a CAP-like antigen was determined in the embryonic moth CNS. Two groups of CAP immunoreactive neurosecretory cells, medial and lateral, were identified in the abdominal ventral nerve cord during the final 30% of embryogenesis. Of these, the lateral cells exhibited a marked and transient drop in CAP-like immunoreactivity between 75 and 80% of embryonic development. This decline in CAP-like immunoreactivity was independently confirmed by measurements of CAP-like bioactivity in whole embryo extracts. Results from immunoprecipitation and chromatographic studies unequivocally identified the embryonic CAP-like factor as Cardioacceleratory Peptide$_2$ (CAP$_2$).

Since these results suggested that CAP$_2$ may be released at 75% embryonic development, a series of physiological studies were undertaken to identify a possible embryonic role for CAP$_2$. The embryonic gut responded in a dose-dependent manner to exogenous application of CAP$_2$. The gut became extremely sensitive to CAP$_2$ at 70-75% development, and in vivo measurements indicated that the previously quiescent gut produced its initial rhythmic contractures at this period. Developmental studies showed that ingestion of extraembryonic yolk occurs between 75% and 85% of development. Based on these observations, we postulate that CAP$_2$ is released during embryogenesis at 75% development to facilitate digestion of the extraembryonic yolk by stimulating gut activity.

This work is supported by NIH grants #NS-24613 and #NS-01258 and by the Sloan Foundation.

16.9

CHARACTERIZATION OF A NEW PEPTIDE IN THE FMRFAMIDE FAMILY FROM THE CNS OF THE HAWKMOTH, *MANDUCA SEXTA* T.G. Kingan[1], D.B. Teplow*[2], J.G. Hildebrand[1], E. H. Hanneman[1], K.R. Rao[3], A.E. Kammer[4], I. Jardine*[5], D.F. Hunt*[6] [1]ARLDN, U. of AZ, Tucson, AZ 85721; [2]Div. of Biol., Cal. Tech., Pasadena, CA 91125; [3]Dept. of Biol., U. of W. FL, Pensacola, FL 32514; [4]Dept. of Zool., ASU, Tempe, AZ 85287; [5]Finnigan-Mat, 355 River Oaks Pkwy, San Jose, CA 95134; [6]Dept. of Chem., U. of VA, Charlottesville, VA

FMRFamide was first identified as a cardioacceleratory peptide in extracts of molluscan ganglia. Since then, additional members of this peptide family, most of which are N-terminally extended, have been identified in four phyla of animals, yet little is known of their actions as hormones or neurotransmitters outside the molluscs. We have purified and determined the amino acid sequence of a new member of this family from the moth Manduca sexta. The purification was monitored by competitive ELISA and accomplished by gel chromatography and ion-exhange and reverse-phase HPLC. Peptides were purified separately from extracts of brain and corpora cardiaca, then sequenced by automated Edman degradation after deblocking with pyroglutaminase. Ambiguities in the second residue were resolved by mass spectrometry. The peptides purified from the two sources are identical. Synthetic analogues were prepared and shown to increase, by 50-80%, the force of the stimulus-evoked contraction in the major flight muscles, the dorsal longitudinals. Histological studies reveal extensive immuno-reactive (ir-FMRFa) patches on the heart, apparently arising from ncc I+II and ncc V; ir-FMRFa in the 55% acetone supernatant of hemolymph declines 2-3 fold with 20 min of forced flight. Thus, hormonal peptide may function in flight by action on muscle or their motorneurons.

16.10

A HISTAMINE RECEPTOR IN THE INSECT VISUAL SYSTEM IS A LIGAND-GATED CHLORIDE CHANNEL. R.C. Hardie* (SPON: P.D. Evans). Dept. of Zool. Cambridge Univ., Cambridge CB2 3EJ U.K.

Recent evidence strongly suggests that histamine is the neurotransmitter released by a variety of arthropod photoreceptors (Hardie, R.C. J. comp. Physiol. 161:201, 1987). To investigate the postsynaptic histamine receptors, patch-clamp recordings have been made from second-order neurones (LMCs) enzymatically dissociated from the first visual neuropile (lamina) of the blowfly, Calliphora vicina. Histamine-activated chloride channels were detected in the majority of inside- and outside-out patches. Open probability depended very steeply on histamine concentration (Hill coefficient ca. 4; KD = 60 μM histamine). The short mean open time of the channel (ca. 0.5 ms) coincides with estimates of the synaptic time constant. The long term stability of single channel activity in perfused, isolated patches and the negligible latency (<0.5ms) of responses to ionophoretically applied histamine support the conclusion that this novel histamine receptor represents a new ligand-gated ion channel.

16.11

AMINERGIC NEUROTRANSMITTERS REVERSE THE EFFECT OF RESERPINE ON BITING BEHAVIOR BUT NOT SWIMMING ACTIVITY IN THE LEECH *HIRUDO MEDICINALIS*. B.A. O'Gara, H. Chae*, and W.O. Friesen. Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22901.

Reserpine injected into the crop (100 μg/leech) causes depletion of aminergic neurotransmitters and induces behavioral and physiological abnormalities (O'Gara and Friesen, Soc. Neurosci. Abstr. 14:383, 1988; Friesen et al., ibid. 14:384, 1988). Biting behavior, which is dependent on CNS serotonin levels (Lent, Brain Res. Bull. 14:643-655), is eliminated by reserpine. We found that biting can be restored by bathing the intact leech in serotonin, dopamine or octopamine. The degree of restoration is dependent on both the concentration and duration of exposure to each transmitter. With a 20 min exposure to serotonin or dopamine, thresholds are between 1 and 10 μM, while the maximal effects occur at 1 mM for serotonin and 9 mM for dopamine. Both serotonin and dopamine inhibit biting behavior when applied at high concentrations or for a long duration.

Swimming activity is enhanced by serotonin or octopamine (Hashemzadeh and Friesen, Soc. Neurosci. Abstr. 13:1060, 1987). The depletion of amines by reserpine abolishes swimming activity from isolated nerve cords. Unexpectedly, reserpine increases the duration of swimming activity that is induced by transferring an intact leech and its home container water to another container. This effect is not reversed by external exposure to serotonin, octopamine, dopamine, or histamine. However, the aminergic antagonist cyproheptadine eliminates all swimming activity. This suggests that the swimming activity of intact reserpine-treated leeches is dependent on the very low levels of amines still present in the nerve cord. We postulate that isolated nerve cords from reserpine-treated leeches do not swim because the small quantities of amines remaining in the nerve cord diffuse into the surrounding bath. These results suggest that biting behavior requires higher levels of amines in the CNS than swimming activity. Supported by NIH grants NS08263 (B.A.O.) and NS21778 (W.O.F.).

BRAIN METABOLISM AND BLOOD FLOW: BLOOD FLOW

17.1

THE EFFECTS OF ENDOTHELIN (ET-1) ON LOCAL CORTICAL MICROVASCULAR PERFUSION IN THE RAT. R.N. Willette, C. Sauermelch*, M. Ezekiel*, G. Feuerstein and E. Ohlstein*. Dept. of Pharmacology, Smith, Kline and French Laboratories, King of Prussia, PA, 19406.

Laser-Doppler flowmetry was used to study the effects of ET-1, a vasoactive endothelin isopeptide, on local cortical microvascular perfusion (CP) and resistance (CVR) in anesthetized rats. The i.v. administration of ET-1 (10-300 pmole) elicited a reduction in blood pressure (BP) and CVR and an increase in CP. A different response profile was obtained when ET-1 was administered at the origin of the internal carotid artery (i.c.). Low doses of ET-1 (10-100 pmole) by this route caused an increase in CP and a reduction in BP and CVR, whereas high doses (≥300 pmole) reduced CP and increased BP and CVR. Occaisionally, high dose/low flow patterns were associated with ischemic changes in the ECoG. The low dose/high flow and high dose/low flow response profile was not altered by blockade of muscarinic and alpha-adrenergic receptors. A mild metabolic acidosis developed following 300 pmole doses (i.c.), but this could not account for any of the cerebrovascular effects observed. Platelet aggregation also did not appear to play a role in the high dose/low flow response. In fact, ex vivo rat platelet aggregation, stimulated with ADP, was inhibited by ET-1 (300 pmole, i.c.). In conclusion, the cerebrovasculature exhibits differential sensitivity to vasodilator and vasoconstrictor effects of ET-1.

17.2

FOCAL ENCEPHALIC MICROVASCULAR ALTERATIONS FOLLOWING CARDIOPULMONARY BYPASS PUMP. D.M.Moody*,M.A.Bell and V.R.Challa*. Bowman Gray Sch. of Med., Winston-Salem, NC 27103.

In the course of a current study using the alkaline phosphatase endothelial stain (Bell and Scarrow, Microvasc Res 27:189-203) to demonstrate cerebral microvascular changes in hypertension, we have had the opportunity to assess four subjects that had recent surgery requiring support from cardiopulmonary bypass pumps.

Some phenomenon is markedly altering small vessels throughout the brain in a way not seen in other (twenty-nine) subjects. The smallest arterioles and capillary network have numerous symmetrical focal dilatations or "bubbles." At this stage we do not know whether these swellings mark the positions of emboli (fat or silicone?) or represent a response of the endothelium to ischemia, emboli, or toxic injury.

Attempts to produce these swellings experimentally and further histochemical procedures to characterize them are planned. Well-documented clinical evidence of subtly reduced mental capacity after surgery assisted by these pumps suggests that careful assessment of hitherto unsuspected cerebrovascular effects is warranted.

17.3

COGNITION-RELATED ALTERATIONS IN REGIONAL CEREBRAL BLOOD FLOW INVESTIGATED BY SINGLE PHOTON EMISSION TOMOGRAPHY. K.J. Shedlack*, R. Hunter*, D. Wyper*, R. McLuskie*, M.T. Hansen*, G. Fink & G.M. Goodwin*. MRC Brain Metabolism Unit, Edinburgh, UK, Wellcome Neuroscience Group, Inst. of Neurological Sciences, Glasgow, UK; McLean Hosp., Harvard Med. Sch., Belmont, MA 02178, USA.

Regional cerebral blood flow (rCBF) patterns were measured at rest and during a cognitively-activated state in which healthy subjects performed a verbal fluency test. As fluency is impaired following frontal lobe lesions, metabolic activation of frontal cortex was expected during this task.

Healthy volunteers and clinical controls were imaged during rest via i.v. ^{99m}Tc-HMPAO in a single photon emission tomography (SPET) split-dose technique for quantification of rCBF. Subsequently, controls were re-imaged at rest while volunteers were re-imaged during oral generation of words beginning with a particular letter.

Volunteers had significantly increased rCBF ($U = 0$, $p < .05$) in two areas of left frontal cortex during the fluency task. Frontal activation was accompanied by a trend towards decreased left posterior rCBF. Alterations in perfusion were not observed the right hemisphere. These data reveal dynamic changes in cortical metabolic demand within the left frontal lobe in association with the performance of a specific cognitive task that is known to depend upon that cortical region.

HUMAN REGIONAL CEREBRAL BLOOD FLOW ALTERATIONS DURING NALOXONE-PRECIPIATED OPIATE WITHDRAWAL: J. Krystal, T. Kosten, S. Woods, J. Seibyl, C. McDougle, L. Price, G. Zubal, P. Hoffer, H. Kleber, D. Charney. Yale Univ. Sch. of Med., CMHC, 34 Park St., New Haven, CT 06508

Regional cerebral blood flow (rCBF) alterations suggestive of changes in regional brain activity were assessed using Single Photon Emission Computerized Tomography (SPECT). **METHODS:** Patients maintained on methadone (20-30 mg./day) and opiate-naive healthy subjects participated in two SPECT scans separated by 1 day. On scan days patients received either placebo or naloxone 0.8 mg., s.c. under randomized double-blind conditions. After symptoms emerged or within 15 min., withdrawal severity was rated and patients were administered 20 mCi of Tc-99m HM-PAO as an rCBF agent. Patients remained at rest in a light- and sound-attenuated room for an additional 5 min., after which, oral clonidine was administered to suppress withdrawal. Approximately 45 minutes later, patients were imaged using a Strichman neuro-dedicated multicrystal camera. **RESULTS:** In the first 6 opiate-dependent patients, naloxone elicited moderate to severe withdrawal. Most patients showed a decrease in frontal and parietal cortical rCBF and an increase in brainstem (pontine) and cingulate rCBF during opiate withdrawal. **COMMENTS:** Pontine activation and frontal inhibition are consistent with the effects of locus coeruleus stimulation on rCBF in animals. These preliminary data are consistent with neuroendocrine data implicating central noradrenergic systems in the human opiate withdrawal syndrome.

BASAL FOREBRAIN (BF)-ELICITED INCREASES IN CORTICAL CEREBRAL BLOOD FLOW (CBF): SELECTIVE AGE-RELATED IMPAIRMENTS. D. Linville* and S.P. Arneric (SPON: J. Couch), Department of Pharmacology, Southern IL University School of Medicine, Springfield, IL 62702

Electrical stimulation of BF elicited up to 150% increases in cortical CBF via nicotinic receptors (Neurosci. Abstr. 14:488.2 1988), whereas destruction of BF neurons reduced CBF topographically corresponding with loss of cholinergic innervation (Neurosci. Abstr. 13:288.12, 1987). We sought to determine: 1) Is there an age-related impairment of increases in cortical CBF elicited by BF-stimulation? 2) If so, are these impairments regionally selective? Sprague-Dawley rats (3-5 or 24-26 months) were anesthetized (chloralose), paralyzed, artificially ventilated and arterial blood gases controlled. CBF was measured concurrently in parietal cortex by laser-doppler flowmetry (LDF) and the ^{14}C-iodoantipyrine (^{14}C-IAP) technique with tissue dissection. In addition, CBF was quantified bilaterally with ^{14}C-IAP in 12 regions throughout the brain. Unilateral electrical stimulation (100 μA; 50 Hz) of BF elicited ipsilateral increases in CBF (ml/100g/min; % increase above contralateral control) predominantly in frontal (175±22; 106%), parietal (238±63; 162%) and occipital (136±25; 56%) cortices of young rats (N=6). Other regions were relatively unaffected. BF-elicited increases were differentially attenuated in aged rats (N=3):frontal (221±22; 95%), parietal (144±24; 58%) and occipital (106±25, - 8%); resting CBF did not differ between ages (range: 85-115). Frequency and current intensity-response curves measured by LDF indicated that efficacy of the response, but not threshold, was decreased ($p < 0.05$). CONCLUSION: Increases in cortical CBF following electrical activation of neurons originating in or passing through the BF are spared in frontal cortex and markedly impaired in parietal and occipital cortex of aged rats. (Supported by the American Health Assistance Foundation for Alzheimer Disease Research).

17.6

DIMINISHED CBF RESPONSE AND CORTICAL FUNCTION IN DIABETIC VERSUS NON-DIABETIC RATS DURING ACUTE HYPOGLYCEMIA. D.A. Pelligrino,* W.E. Hoffman, A. Sharp,* Dept. of Anesthesiology, Michael Reese Hospital, Chicago, IL

A cerebral microangiopathy (CMA) has been reported in diabetic humans and rats. We investigated the possibility that a CMA in diabetic (D) rats could diminish the compensatory CBF increase normally observed in non-diabetics (ND) in response to hypoglycemia (H) and the possibility that this could affect cerebral cortical function as determined via somatosensory evoked response (SER) analysis. The D rats were used at 6-8 weeks post-streptozotocin (plasma glucose [PG] >25 umol/ml). All rats were studied under conditions of N_2O sedation, paralysis and mechanical ventilation. CBF (microspheres) and SER measurements were made in fasted D rats, prior to and following i.v. insulin, at PG levels of 20, 6.8, and 1.8 umol/ml. Fasted ND rats were studied at 7.7 and 1.7 umol/ml. The D rats showed a >50% attenuation of the CBF response to H in cortical and subcortical tissue when compared to ND rats. This analysis is based on the relative CBF change occuring when going from normoglycemia (N) to H in both groups. SER amplitudes in ND rats during H decreased to 60% of the N level. In D rats, during H, the SER amplitude fell to <15% of the N value and <10% of the value observed prior to insulin. We would conclude that D rats have a diminished cerebrovascular reactivity to H. This can produce a greater limit on cerebral glucose supply during H and a greater impairment of brain function.

17.7

REGIONAL CEREBRAL BLOOD FLOW (rCBF) FOLLOWING BRAIN MISSILE WOUNDING (BMW) IN SURVIVING AND NON-SURVIVING ANESTHETIZED CATS. D. Torbati, A.F. Jacks,* J.F. Davidson,* J.B. Farrell* and M.E. Carey* Dept. of Neurosurg. Louisiana State University Medical Center New Orleans, LA 70112.

Extreme reductions in rCBF may be responsible for acute brain death following BMW. we measured rCBF in 15 structures before and after BMW in 12 pentobarbital anesthetized cats using microspheres technique. 4 cats survived up to termination of the experiments at 90 min post-BMW. 8 non-surviving cats developed permanent apnea between 6 to 42 min post-BMW. Arterial blood pressure (BP), intracranial pressure (ICP), EEG, ECG and respiratory frequency (f) were monitored. In surviving cats 10/15 structures had significant reductions in rCBF 90 min post-BMW. However, residual rCBF were relatively normal (22-54 ml/100g/min). Residual rCBF values found in non-surviving cats a few min before death, were 20-56 ml/100g/min at 5 and 20 min post-BMW. In surviving cats BMW-induced increases in ICP, BP, and decreases in heart rate and f were stabilized within 5-10 min, whereas in non-survivors they were unstable with a continuous reduction in f, indicating brain stem damage. The present data do not support the hypothesis that severe reduction in rCBF is primarily responsible for acute brain death following BMW. However, gradual and significant reductions in rCBF may become a late complicating factor in survivors. Supported by contract No. DAMD17-86-C-6098 LAIR, USMRDC.

VASOMOTOR REACTION OF CEREBRAL INTRAPARENCHYMAL BLOOD VESSELS FOLLOWING A TREATMENT OF VASOACTIVE AGENTS: CORROSION CAST AND BLOOD FLOW STUDY. K.Nakai,H.Imai*, M.Nakai*,H.Yokote*,S.Hayashi*,N.Komai*. Dept. Neurol. Surg.,Wakayama Med.Col.,Wakayama 640 Japan.

Morphlogical changes of the actual luminal surface of the intraparenchymal blood vessels in the brain were examined following a treatment of potent vasoactive agents such as neuropeptide Y(NPY) and endothelin(ET) both of which have strong vasoconstrictive effect on the pial arteries in the brain. NPY($1x10^{-5}$M) or ET($1x10^{-6}$M) was locally injected into the rat parietal cortex(1 ul,over 10 minutes) through the glass capillary. Monitoring the local blood flow over the injection point of those agents using a laser flow meter(Advance),animals were perfused with aldehyde mixture. Luminal surface of blood vessels in the parietal cortex were observed either by the corrosion cast technic under scanning electron microscope or the dark field light microscope method (Nakai et al.Stroke 12:653 1981). In the NPY injected cortex where the blood flow was lowered to 50-60% of control, apparently smaller diameter of the proximal portions of perforating arteries was noted. Whereas the injection site of ET showed incresed blood flow for 20-40 minutes (30-80%), when marked dilation of the blood vessels were observed around the injection site ,especially in the perforating veins.

These results suggested a selective role of cortical perforating arteries and veins in the regulation of the cerebral cortical blood flow.

17.9

CEREBRAL BLOOD FLOW (CBF) HETEROGENEITY: SPATIAL AND TEMPORAL CORRELATION. S.C. Jones, M. Shea*, J.R. Little*, A.J. Furlan*. Cleveland Clinic Foundation, Cleveland, Ohio, 44195-5070, U.S.A.

A new hypothesis of CBF regulation, vascular cycling, is supported by the following observations: 1) spatial (~400 μm) and temporal (~6/min) heterogeneity of CBF; 2) the vascular architecture of penetrating arteries; 3) the columnar neuroarchitecture of the cortex; and 4) evidence of capillary recruitment. This hypothesis, that intermittently opening and closing vascular units control CBF, is tested by combining morphological (vessel position) and physiological (blood flow) evidence.

In 7 pentobarbital anesthetized, Sprague-Dawley rats with normal physiological variables (MABP 120± 7; $PaCO_2$ 35± 0.4; PaO_2 137± 5; and pH 7.41± 0.01), vessel position was determined *in vivo* with the intravenously administered fluorochrome, thioflavine S (TS). The spatial distribution of CBF was measured using the 10 sec indicator fractionation autoradiographic technique with ^{14}C-iodoantipyrine (^{14}C-IAP). Vessel positions were mapped and aligned with a digitized CBF image or enlarged autoradiogram that indicated high and low areas of CBF. Two time dependent protocols were used: one involved the simultaneous administration of ^{14}C-IAP and TS 10 sec before decapitation; in the other, TS was administered 45 seconds before, and the ^{14}C-IAP 10 sec before, decapitation. The ratios of the number of vessels in the high CBF region over the total number of vessels were compared.

In the protocol using sequential administration, vessels were found in the low CBF areas, indicating that they had been perfused before the CBF study epoch and the high/total ratio± SEM was 54%± 4% (n=4). In the simultaneous protocol, the high/total ratio was 68% ± 3% (n=3) (t-test, $p<0.01$). This supports the concept that the high CBF areas correspond to open vascular units and the low CBF areas correspond to closed or turned-off vascular units.

These observations confirm the hypothesis that one aspect of CBF regulation involves the intermittent opening and closing of vascular units. Further questions concern the dysfunction of this proposed cycling process in focal cerebral ischemia, especially in border zone areas that are at cerebral vascular risk.

DISTRIBUTION OF CEREBRAL INFARCTION FOLLOWING MIDDLE CEREBRAL ARTERY OCCLUSION AND FASTIGIAL NUCLEUS STIMULATION IN RAT. M.D. Underwood, S.B. Berger, M. Khayata*, N. Zaiens*, M. Springston* and D.J. Reis, Div. of Neurobiology, Cornell Univ. Med. Coll., New York, NY 10021.

Stimulation of the cerebellar fastigial nucleus (FN) reduces the volume of the cerebral infarct produced by occluding the middle cerebral artery (MCA) in spontaneously hypertensive rats (SHRs) (Neurosci. Abstr. 14:1065, 1988). We sought to determine whether the reduction in infarct volume with MCA occlusion and FN stimulation has a specific topography or is randomly distributed. SHRs were anesthetized and the MCA occluded. The FN was stimulated electrically for 1 hour (1 sec on/1 sec off, 50 Hz, 50 μA) following MCA occlusion. 24h later the brains were removed, infarcts reconstructed and the volume computed. In controls (n=6) MCA occlusion resulted in infarction extending from the frontal and parietal sensory-motor cortex rostrally, lateral occipital cortex (OCx) caudally, piriform/insular cortex ventrally and was medially bounded by the lateral half of the caudate-putamen, lateral hippocampus and corpus callosum. The volume of the infarct was 203 ± 11 mm^3, greater than sham-operated controls (1 ± 0.7 mm^3; $p<0.05$; n=4). Electrical stimulation of FN (n=7), but not lateral cerebellar nuclei (n=6), resulted in a 38% reduction in infarct volume to 126 ± 10 mm^3 ($p<0.05$). The area of preservation consistently rimmed the rostral, dorsal and caudal borders of the infarct observed following MCA alone and included frontal, parietal and OCx. We conclude: 1) FN stimulation reduces infarct volume following MCA occlusion and 2) the preserved areas correspond to border zones between different vascular territories. The topography of rescued cerebral cortex following MCA occlusion and FN stimulation suggests that the salvage is mediated by increased local cerebral blood flow to areas with a collateral vascular supply.

RAT BRAIN ATP RECOVERS AFTER PROLONGED CBF ARREST
J.C. de la Torre, J.K. Saunders,* T. Fortin,* K. Butler,* J. MacTavish,* Div. of Neurosurgery, Univ. Ottawa and National Research Center, Ottawa.

We examined the loss and reappearance of ATP/PCr, in rats subjected to cerebral blood flow (CBF) arrest. Rats were anesthetized, intubated, mechanically ventilated and prepared for bilateral subclavian-carotid artery occlusion (Soc. Neurosci. Abs. 14:1211,88). Both subclavian arteries were tied off and loose snares were placed on each common carotid artery (CCA). A surface coil was fixed to the skull and rats were placed in a Bruker Biospec 4.7 T/30 magnet. Both CCA were then occluded for 5,8,15,25,30 and 70 minutes. P-31 spectra showed energy phosphates and ß-ATP peaks disappeared 8-10 minutes after global CBF arrest. The ATP metabolite Pi rose abnormally as it chemically shifted. Following release of both CCA to reperfuse brain, ß-ATP peak returned to normal levels after a delay of 25 min in rats subjected to 5-8 minutes of CBF arrest. Data from rats subjected to 15-70 minutes of CBF arrest indicated that ß-ATP returned after CCA perfusion but delay took several hours. Spectral findings were supported by EEG and CBF analysis. Results suggest that rat brain neurons can idle metabolically during prolonged absence of cerebral blood flow.

GLUTATHIONE MEDIATES THE HYDROPHILIC DEGRADATION OF (99mTc) d,l-HEXAMETHYL-PROPYLENEAMINE OXIME (HM-PAO) IN CULTURED BRAIN CELLS.
S.Huck and E.Suess*, Department of Neuropharmacology and Clinic of Neurology, University of Vienna. A-1090 Vienna, Austria.

Following i.v.-injection, (99mTc)d,l-hexamethyl-propyleneamine oxime (HM-PAO) is rapidly taken up by the human brain, with negligible redistribution after 3-5 min. Although cerebral blood flow is the predominant factor determining the accumulation of radioactivity, additional mechanisms regulate the conversion of HM-PAO into hydrophilic, non-diffusible derivatives.

We have studied this phenomenon using cell cultures 4-6 days *in vitro* from dissociated postnatal rat cerebellum. The basic techniques for the determination of uptake kinetics have been presented previously. Briefly, the uptake was determined after a 5 min incubation period with 2.85pM HM-PAO (Ceretec, Amersham) at room temperature. After several washes with PBS cultures were lysed in distilled water. The released radioactivity was counted in a γ-counter.

In this study we analyzed the chemical composition of the radioactivity accumulated in the cultures by HPLC. After filtering through a 10,000mW cutoff filter unit the lysate was injected into a Hamilton PRP1/5µ 4x150mm column. The filtrate yielded a single peak of free (99m)TcO_4 in the HPLC. However, a substantial amount of radioactivity was bound to cellular fragments or high molecular weight compounds of the retentate and thus not accessible to HPLC-analysis.

The uptake of radioactivity was reduced in dose-dependent manner when cultures were pre-treated with ≤5µM $HgCl_2$ or ≤10mM diethyl maleate (DEM). DEM selectively depletes tissue glutathione by a glutathione transferase-mediated reaction, whereas $HgCl_2$ nonspecifically blocks thiol residues. We have measured 3H-2-deoxyglucose (2-DG)-uptake as an indicator of metabolic requirements of the cultures. The 2-DG-uptake was severely impaired by $HgCl_2$ but unaffected after treating the cultures with DEM.

These observations strongly support the hypothesis of a glutathione-dependent reaction crucial for the conversion of HM-PAO into non-diffusible derivatives trapped within the cells, making HM-PAO a feasible agent for SPECT-supported diagnosis.

MENTAL ILLNESS: AFFECTIVE DISEASE

PLASMA HOMOVANILLIC ACID IN GERIATRIC MAJOR DEPRESSION.
RC Young, GS Alexopoulos*, T Finver*. New York Hospital-Cornell Medical Center, Westchester Division, White Plains, NY 10605

Changes in central dopaminergic turnover have been implicated in both major depression and in normal aging. Differences in plasma homovanillic acid (HVA) between elderly depressed patients and controls were hypothesized.

Inpatients with major depressive episode (DSM III-R) (n=32) and controls without psychiatric disorder (n=11) were studied. All were aged >60 yrs; the average age of the patients was 74.2 yrs ± 6.7 yrs (S.D.) and that of the controls was 77.0 yrs ± 3.8 yrs. Plasma samples obtained in the morning were assayed by high performance liquid chromatography.

Plasma HVA in the patients before treatment averaged 49.2 pmol/ml ± 26.9 pmol/ml and was lower than in controls (79.8 pmol/ml ± 32.5 pmol/ml; t=3.08; p<.005). A subset of 7 patients was sampled again during treatment; plasma HVA increased in 5.

These preliminary findings are consistent with reports of decreased cerebrospinal fluid HVA in some mixed-age depressed patients.

18.2

TWO BEHAVIORAL PARADIGMS FOR STUDYING CORRELATES OF ANXIETY OR DEPRESSION IN RATS: ACTIVITY IN A LIGHT/DARK COMPARTMENT AND THE STARTLE RESPONSE OF OLFACTORY BULBECTOMIZED RATS.
J.V.Cassella+, J.Alexander*, and W.Call*. Neuroscience Program, Oberlin College, Oberlin OH 44074 and +Neurogen Corporation, Branford CT 06495.

Animal models of psychiatric disorders have been instrumental in developing new treatment strategies and compounds as well as gaining an understanding of the underlying physiological mechanisms of the disorders. Using a light/dark chamber, increased crossings between the lighted and dark side and more time spent on the lighted side correlated with anxiolytic treatment while decreases on these measures correlated with anxiety-provoking manipulation. Results obtained in this apparatus were correlated with the Elevated Plus Maze. In olfactory bulbectomized rats, acoustic startle was significantly greater than controls and this hyperreactivity was reversed by chronic, but not acute, imipramine treatment. The change in startle was compared to passive avoidance deficits in these animals. Therefore, activity in a light/dark chamber in rats and the startle response of bulbectomized rats are useful behavioral models for studying anxiety and depression, respectively.

18.3

INTERACTION BETWEEN MONOAMINE OXIDASE-INHIBITORS (MAO-I) AND FLUOXETINE COMPARED TO NON-SELECTIVE UPTAKE-INHIBITORS.
David Calligaro* and David Helton* (Spon. Ilene Cohen). Toxicol. Div., Eli Lilly & Comp., Greenfield, IN 46140.
Studies were conducted to investigate the interactions between fluoxetine (Flu) and MAO-I in the rat. Rats were pretreated with either tranylcypromine or phenelzine (1 to 60 mg/kg p.o.) 30 min prior to Flu or Imipramine (Imi) (0.1 to 10 mg/kg p.o.) administration. A significant potentiation in the median lethal dose of tranylcypromine required 10 mg/kg for Flu or Imi. The potentiation to the interaction was not increased after multiple 5 day dosing of either Flu or Imi (10 mg/kg). While serotonergic behavior was present at lower doses, a general malaise masked this behavior at higher doses. Although the behaviors were unique for each drug combination, all combinations produced a rise in body temperature which correlated with onset of behavioral symptoms. The non-selective 5-HT antagonist cyproheptadine prevented fatal interaction, whereas more selective serotonergic and noradrenergic receptor antagonists did not (e.g. mianserin, ketanserin, piperazine, propranolol, pindolol, phenoxybenzamine). The protective effects correlated with preventing the rise in body temperature. Furthermore, diazepam alleviated the behavioral symptoms, but did not prevent mortality. In conclusion, the non-selective uptake inhibitor Imi produced an interaction with MAO-I at comparable doses to Flu. Also, both interactions result in hyperpyrexia which cyproheptadine was able to reverse.

18.4

PLASMA GABA AND MOOD DISORDERS.
F.Petty and G.L.Kramer*. Dept. of Psychiatry. Univ.Tex.Southwest Med.Cent.Dallas, 4500 S. Lancaster Rd.,Dallas, TX 75216.

During the last 10 years evidence has accumulated to suggest a role for GABA in mood disorders. Briefly, low levels of GABA in CSF have been reported by several investigators and increased density of GABA-benzodiazepine receptor binding sites was found in cortex of depressed suicide victims. Drugs which facilitate GABA transmission such as progabide and valproic acid are useful therapeutic agents for mood disorders. We have previously reported plasma levels of GABA to be low in patients with primary unipolar depression. We have also reported that plasma GABA levels in control subjects are not influenced by diet, exercise, menstrual cycle, or gender. We now report the results of a larger study using high performance liquid chromatography with post-column fluorescence detection. Levels of GABA were significantly low in patients with mood disorders compared to control. Levels of plasma GABA were equally low in bipolar patients whether depressed or manic and in secondary depressives as well as in primary depressives. Plasma GABA levels did not correlate with severity of depression nor did they change with treatment up to 12 months. Taken together, these findings suggest that plasma GABA may represent a stable trait-like marker of mood disorder.

INCREASED PLASMA α_1-ACID GLYCOPROTEIN IN DEPRESSION: BIOLOGIC, CLINICAL AND DEMOGRAPHIC CORRELATIONS. D.L. Knight, L.R. Meyerson, D. Benjamin*, K.R.R. Krishnan*, D.G. Blazer* and C.B. Nemeroff. Depts. of Psychiat. & Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710 and Med. Res. Div., Amer. Cyanamid Co., Mahwah, NJ 07430.

Several investigators have reported a decrease in the number of [^{3}H]-imipramine binding sites in platelets of drug-free depressed patients. The plasma concentrations of α_1-acid glycoprotein (AGP), a putative endogenous inhibitor of the platelet receptor site labeled by [^{3}H]-imipramine, is significantly elevated in depressed patients (n=51) as compared to age- and sex-matched controls (n=36). There was a significant positive correlation between plasma AGP concentration and the maximal post-dexamethasone plasma cortisol concentration. There was a positive correlation between AGP concentrations and two measures of depression severity- the Montgomery-Asberg Rating Scale for Depression and the Center for Epidemiological Studies-Depression Scale. Within the depressed population there was a slight decrease in AGP concentration with increasing age. The relationship between AGP concentrations in plasma and the density of platelet [^{3}H]-imipramine binding sites will also be discussed. These data provide evidence of alterations of an endogenous inhibitor of the [^{3}H]-imipramine binding site/serotonin transporter in depressed patients. (Supported by NIMH MH-40159).

18.6

OLFACTORY BULBECTOMY ALTERS PLASMA α-1 ACID GLYCOPROTEIN LEVELS IN RATS. F.J. Arnold and L.R. Meyerson. American Cyanamid Co., Med. Res. Div., Ramapo College, Mahwah, NJ 07430.

In a previous collaborative effort we have shown that α-1 acid glycoprotein (AGP), an endogenous modulator for the tricyclic binding-serotonin transport complex, is increased 29% in plasma of depressed patients compared to controls (Neurosci. Abs. 14:372,1988). To extend this research to animals, a radial immunodiffusion assay to measure plasma AGP levels in rat tissues was developed. Turpentine induced AGP in rats was purified from plasma to homogeneity by chromatographic techniques. Antisera to purified rat AGP was produced in New Zealand white rabbits. Immunodiffusion plates containing the rabbit antisera in a 1% agarose gel solution were prepared. The AGP concentration in ZML:(SD) rats is approximately 6 times lower compared to normal human values of 617 ± 27 μg/ml. In five week olfactory bulbectomized ZML:(SD) rats, an animal model of depression, a 36% increase in plasma AGP levels was observed compared to sham operated animals (140 ± 8 and 104 ± 4 μg/ml, respectively). Evidence mounts from animal and human studies suggesting that increased plasma AGP may be a biological marker in depression.

18.7

CAUDATE NUCLEUS METABOLISM RELATIVE TO PREFRONTAL CORTEX SPECIFICALLY DISTINGUISHES BIPOLAR FROM UNIPOLAR DEPRESSION. J.M.Schwartz*,L.R.Baxter*, M.Phelps,J.Mazziotta,B.Guze* (SPON:D.X.Freedman) UCLA Sch. of Med., Los Angeles, CA 90024.

Prior work by us using PET demonstrated unipolar depressed (UD) patients show a decreased metabolic rate (MR) in head of caudate nuc. (Cd) relative to ipsilateral hemisphere (Hem),compared with bipolar depressed (BD)patients, and the MR of Cd relative to prefrontal cortex (PFC) mainly accounts for these differences (Schwartz, et. al. JAMA,258:1368, 1987). We extended this work in 10 UD and 10 BD, matched for age, sex,handedness and severity, and 12 matched normal controls (NC).

Cd/hem ratios were decreased in UD compared to BD and NC (Left ANOVA:F=7.85;df=2,29;P=.002; Rt: F=7.92;df=2,29;P=.002). Anatomical analysis calculating Cd MR relative to mid. and inf. frontal gyr.(MFG, IFG), orbital gyri (OG), ant. cingulate gyr (ACG), parahippocampal gyr (PHG),and thalamus (T) demonstrated that only Cd/PFC (PFC=MFG,IFG,OG) ratios sig.($p<.05$) distinguish BD and UD, with UD lower in all cases. Cd MR relative to ACG, PHG, and T did not show sig. differences between UD and BD. Cd/PHG values for UD and BD were identical, and were decreased ($p<.05$) from NC.

These data may indicate relevance of Cd-PFC relations to differing pathophysiology in UD and BD.

18.8

SLEEP DEPRIVATION CHANGES ARDEN RATIOS IN DEPRESSED PATIENTS. K. N. Sokolski*, C. Reist* and E. M. DeMet. Dept. Psychiatry, Long Beach VA Med. Center, Long Beach, CA 90822

One night of sleep deprivation produces significant, but temporary, mood improvements in about two out of three depressed patients. While the mechanism of this improvement is unknown, some evidence suggests a possible dopaminergic role in this action. The Arden ratio (eye potential in bright light divided by eye potential with dark adaptation) is a putative non-invasive measure which may reflect dopaminergic sensitivity. A previous study has shown decreased Arden ratios in depressed patients. The present study examined Arden ratios of depressed patients prior to and following a night of sleep deprivation. Patients were divided into two groups on the basis of symptom severity. A high group had Hamilton depression scores of $\geq$25; and a low group had scores of $\leq$10. Baseline Arden ratios of the high group were significantly lower than either the low group or normal controls. Sleep deprivation significantly improved depressive symptoms and increased Arden ratios of the high group. An inverse relation between clinical response and Arden ratios was also evident in low group responders. In contrast, no change in the Arden ratio was found in non-responders. The results support a possible dopaminergic role in the mechanism of sleep deprivation and underscore the possible usefulness of Arden ratios as a diagnostic marker of depressive illness.

18.9

DEPRESSION LEVELS AMONG HIGH SCHOOL STUDENTS J. W. Jones,* L. C. Parsons, and L. J. Crosby* (spon: L. L. Rankin). College of Nursing, Univ. of Arizona, Tucson, AZ 85721

Suicide is one of the second leading causes of death among young people between the ages of 15 and 24 years. Thus, identification of depression should be very important to teachers, school administrators and families. The purpose of this study was to assess depression levels in a randomized stratified sample of middle class high school students. The sample was composed of 249 high school students between the ages of 14 and 18 years. The depression level of the sample was assessed using the Beck Depression Inventory (BDI). Demographic variables, factors which caused disturbed feelings and self identified priorities were also measured. Frequency counts and descriptive statistics were used to analyze the data. Findings: BDI scores for the total sample revealed that 191 (76.7%) of the subjects were within the range of "no depression", 22 (8.8%) subjects were within the "middle" range of depression and 17 (6.9%) were within the "high" range of depression. Nineteen subjects were eliminated since they did not answer all of the BDI questions. Black subjects were significantly more depressed than white subjects. Orientals were also more depressed than white but the difference was not significant at the $p = .05$ level. Also girls were more depressed than boys but not at significant levels. "Family life" was identified as the factor which caused the most disturbed feelings (40.2%) while "friends" were identified as the highest priority in the total sample. When the sample was split according to depression levels, and as depression levels increased, "family life" was more frequently identified as a disturbing factor. Peer acceptance was not selected by a single subject within the severely depressed group indicating, perhaps, a withdrawal pattern which should be noted by teachers and families. School assumed greater importance as the subject became more depressed as did boyfriend/girlfriend relationships. In summary, of this sample of 249 high school students, 15.65% were moderately to severely depressed. These findings suggested that numerous students could have profited from emotional support and/or counseling.

TRAIT AND STATE CEREBRAL BLOOD FLOW ABNORMALITIES IN DEPRESSION. WC Drevets, ME Raichle, PT Fox, SH Preskorn, TO Videen Washington Univer.St. Louis MO 63110

The neuroanatomical correlates of depression were investigated with PET measurements of regional cerebral blood flow (rCBF). Two unmedicated study groups were selected: 1) (n=7) with unipolar major depression - melancholic subtype in the depressed phase (UPD) and, 2) (n=8) with a history of the same diagnosis, in the euthymic phase (UPE) Appropriate controls were selected for each study group (n=13 and n=14, respectively). PET studies were performed using intraveneously administered $H_2{}^{15}O$, a 40 second emission scan, and the eyes closed rest state. For omnibus testing, primary tomographic images were converted to anatomically standardized 3-dimensional images. rCBF Differences were identified using intra-group image averaging and inter-group subtraction; these were subjected to post hoc statistical analysis. No global CBF differences were found between groups. The UPD subjects demonstrated increased rCBF in the inferior frontal gyrus pars orbitalis (f_3-orb) bilaterally, (left>right) and in the left frontal polar cortex, (LFPC) and decreased rCBF in the left caudate in the UPD group. The UPE subjects demonstrated the same rCBF increase in LFPC and decrease in the left caudate, but the rCBF in f_3-orb did not differ from controls. In addition, the UPE group demonstrated increased rCBF in the left anterior cingulate gyrus(LACG). Our results suggest that persons susceptible to unipolar depression have a trait abnormality manifested by decreased rCBF in the left striatum,and increased rCBF in LFPC and LACG. In the depressed state, they additionally demonstrate increased rCBF in f_3-orb. This suggests that the frontal cortico-striato-pallidal loop may be involved in the pathophysiology of unipolar depression.

ASCENDING THALAMIC PROJECTIONS IN THE SILVER LAMPREY, ICHTHYOMYZON UNICUSPIS. Helmut Wicht* and R. Glenn Northcutt, SIO Neurobiology Unit, Univ. Calif. San Diego, La Jolla, CA, 92093

Attempts to identify telencephalic homologues in lampreys have a long tradition in neurobiology but experimental studies are limited to secondary olfactory projections (Northcutt and Puzdrowski, Brain Behav. Evol. 32: 96-107). This study suggested that the lateral pallium (lp) dominates the cerebral hemispheres and that the dorsal (dp) and medial pallium (mp) occupy an uneverted portion of the telencephalon. This hypothesis can be tested in part by the examination of the ascending projections of the dorsal thalamus (dth). Injections of the flourescent tracer DiI into the dth of the fixed brains of 4 lampreys revealed extensive terminals in the ipsilateral mp and a few fibers and terminals in the contralateral mp. Numerous varicose fibers were seen in the neuropil lateral to the ipsilateral striatum (st) and among the cells of the septum. A number of fine varicose fibers were labelled throughout the ipsilateral lp and dp. A few retrogradely labelled cells occurred in the ipsilateral lp, dp, and st, whereas many labelled cells were present in the ipsilateral mp. Injections in the mp and lp confirm that the dth projects to these telencephalic areas. The reciprocal connection between the mp and dth supports the hypothesis that there is a medial pallial homologue in lampreys but the sparse thalamic projection to other pallial areas as well as the absence of a distinct terminal field adjacent to the st require further attention.

CENTRAL REPRESENTATION OF THE VII, IX AND X CRANIAL NERVES IN GNATHONEMUS PETERSII. G. Lazar*, T. Szabo, S. Libouban*, M. Ravaille-Veron* (SPON: C. Oyster). Dept. of Sensory Neurophysiology, CNRS, F-91198 Gif/Yvette, Cedex and (G.L.) Anat. Inst., Medical School, Pécs, Hungary.

The three cranial nerves were investigated by axonal transport of HRP and Cobaltous-Lysine in order to determine their origins and their projections into the CNS. Retrograde labelling shows that the motoneurons of the IX and X nerves form a continuous column located ventrally to the sensory vagal lobe; the columns of both sides fuse in a single nucleus at the level of the apex of the IVth ventricle. The VII motor nucleus forms a separate nucleus located more ventrolaterally in the reticular formation between the glossopharyngeal and trigeminal motor nuclei. The sensory lobe, into which the three nerves project, forms a continuous volume located below the floor of the IVth ventricle. The X sensory fibers originating from five branches (4 from the gills and one from the oesophagus) terminate in the caudal two thirds of the sensory lobe. The IX sensory fibers arise from the first gill nerve and project to the anterior pole of the sensory lobe,whereas those of the VII nerve run with the trigeminal root and end cranial to the glossopharyngeal terminal area.

19.3

NEURAL SYSTEMS FOR CLASPER CONTROL IN STINGRAYS. L.S.Demski, L.Qin* and H.J.Wynder*. School of Biological Sci. Univ. of Kentucky, Lexington, KY 40506.

The innervation of the clasper has been studied in several rays with emphasis on Urolophus halleri. Several large myelinated nerves (ca. 10 at diameters approx. .7mm; #56-65 counting from the vagus) innervate the clasper muscles and skin. Although the same number of nerves are present (from vagus to level of posterior pelvic fin) in females they appear to be smaller in cross sectional area. In males, low level electrical stimulation (<150μA) of the nerves evokes clasper movements including: rotation, elevation, medial and lateral extension and opening. Stimuli as low as 20uA were effective in triggering opening from nerves 61-63. The responses are abolished by xylocaine. Stimulation of the spinal cord in the area of the roots of the latter nerves also evoked the movements (<100μA with best freq. 3-10 Hz). Cobalt filling of nerves 62 & 63 confirmed that motor neurons and sensory components of the nerves are at the levels indicated by stimulation.

LOCATION OF SEROTONIN-LIKE IMMUNOREACTIVE NEURONS IN TWO BATOID ELASMOBRANCH FISHES: MYLIOBATIS CALIFORNICUS AND PLATYRHINOIDIS TRISERIATA. S.L. Stuesse, W.L.R. Cruce, and R.G. Northcutt. Neurobiology Dept., Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272 and Dept. of Neuroscience, University of California at San Diego, La Jolla, CA 92093

The reticular formation is a phylogenetically old and conservative portion of the brain. Variations in reticular nuclei, when they occur, may be used to test hypotheses of relationships among vertebrates. We are studying elasmobranchs as a group of fish which diverged from other vertebrates about 350-400 million years ago. There is considerable brain variation among batoid elasmobranchs: the thornback guitarfish, Platyrhinoidis triseriata has a relatively smaller cerebellum and telencephalon than the bat ray, Myliobatis californicus. Brain sections were incubated with antisera made in rabbit against serotonin. The avidin-biotin or PAP method was used to visualize cells. In both fish, a presumptive raphe pallidus, obscurus, magnus, and centralis superior could be identified. In Myliobatis, however, raphe pallidus was much smaller than in Platyrhinoidis. Myliobatis had much heavier labeling in the posterior thalamus and the nucleus interpeduncularis. These 5-HT+ cells extended into the ventral tegmental area ventral and lateral to the red nucleus. In both fish, there were numerous 5-HT+ fusiform cells paralleling the ventral surface of the metencephalon and mylencephalon. These were located in several reticular nuclei but were especially prominent in reticularis magnocellularis and reticularis paragigantocellularis lateralis. The homologue of raphe pontis, if present, is very small and no raphe dorsalis was identified. Supported in part by N.I.H. grants NS25895, NS24669, and NS24869.

IMMUNOCYTOCHEMICAL AND HISTOCHEMICAL EVIDENCE FOR TWO NEUROTRANSMITTER SYSTEMS IN THE ELASMOBRANCH NERVUS TERMINALIS GANGLION. J. White* (SPON: M. Meredith). Dept. of Biological Sciences, Florida State University, Tallahassee, FL 32306-3050.

Previous electrophysiological data from this laboratory suggest that acetylcholine and norepinephrine suppress the activity of elasmobranch nervus terminalis (NT) ganglion cells. We are conducting anatomical experiments to further investigate the neurotransmitters and neuronal circuitry of the elasmobranch NT ganglion. Bonnethead sharks (*Sphyrna tiburo*) were perfused with 1% paraformaldehyde in phosphate buffer for 30-45 min. This light fixation was necessary for successful acetylcholinesterase (AChE) histochemical staining. Cryostat sections were first processed for double-label peptide immunocytochemistry (ICC) using 1:500 dilutions of rabbit anti-LPLRFamide (gift of Dr. G. Dockray) and guinea pig anti-LHRH (gift of Dr. L. Jennes) antisera, followed by a secondary antiserum mixture of goat anti-rabbit (Texas Red) and goat anti-guinea pig (FITC). Sections were then processed for AChE histochemistry (Karnovsky & Roots, 1964). Separate populations of LPLRFamide-immunoreactive (ir) and LHRH-ir ganglion cells were seen. Although both ganglion cell types were AChE-positive, the LPLRFamide-ir cells stained more darkly for AChE. In some experiments with long ICC incubation times, the LHRH-ir cells did not stain for AChE. Staining with anti-tyrosine hydroxylase (TH) antiserum (Eugene Tech) revealed fibers and terminal-like puncta in the NT ganglion but no cell bodies, suggesting a catecholaminergic innervation. Experiments are underway to determine which of the cell types in the ganglion are contacted by TH-ir terminals. The anatomical data presented here therefore support the electrophysiological data, suggesting that two neurotransmitter systems are present in the NT ganglion.

SECONDARY OLFACTORY PROJECTIONS IN THE ATLANTIC STINGRAY. R.L. Puzdrowski and R.B. Leonard. Marine Biomed. Inst., Univ. of Tex. Med. Branch, Galveston, TX 77550.

In the classic descriptions of the forebrain, the secondary olfactory tracts were said to distribute fibers to most regions of the telencephalon. In batoids, more recent studies utilizing degeneration techniques have revealed the secondary olfactory projections to be restricted to the lateral pallium. To test these more recent observations horseradish peroxidase was injected unilaterally into the olfactory bulbs of five adult Atlantic stingray, Dasyatis sabina. After survival times of 5 to 15 days, the brains were removed, sectioned at 40μm in either the transverse or horizontal plane, and processed according to Mesulam's ('78) TMB protocol. The distribution of the olfactory tract fibers is entirely ipsilateral to the injected bulb, the majority terminating in the rostral portion of the lateral pallium. Distinct medial and lateral olfactory tracts could not be distinguished. However, a small number of fibers were observed exiting the dorsomedial portion of the olfactory tract and coursing caudomedially into area SP4 of the subpallium (Smeets et al., '83). These results suggest the secondary olfactory projections in rays may be less restricted than studies utilizing degeneration methods have indicated. Supported by NS11255-14 and NS07185-07.

THE DEVELOPMENT OF PURKINJE CELLS AND THEIR EXTRACEREBELLAR PROJECTION TO THE ACOUSTICO-LATERALIS AREA IN THE WEAKLY ELECTRIC TELEOST *EIGENMANNIA* (GYMNOTIFORMES), REVEALED BY THE MONOCLONAL ANTIBODY ZEBRIN II. (SPON: P. Jackson) M. Lannoo[1]*, H. Vischer[2]*, L. Maler[3], G. Brochu[1], R. Hawkes*[1], 1)Lab. Neurobiology, Laval Univ., Quebec, P.Q. Canada G1K 7P4, 2) Scripps, La Jolla, CA 92093; 3) Univ. Ottawa, Ont. K1H 8M5.

The teleost cerebellum consists of three parts, the corpus (CCB), valvula (VA), and eminentia granularis (EG). The monoclonal antibody zebrin II recognizes a single polypeptide antigen of apparent molecular weight 36kD, and selectively reacts with Purkinje cells in CCb, lateral VA, and EG anterior in many teleost species. We use zebrin II to identify Purkinje cells and their neurites within these cerebellar divisions in the developing brain of *Eigenmannia*. We also describe the development of the descending projections of EGa and ventral CCb Purkinje cells to the mechanosensory medial nucleus and the dorsal octavolateral nucleus within the brainstem. Purkinje cells in the dorsolateral portion (probably EGa) of the rostral hindbrain first become immunoreactive at day six; about four cells are stained. Cells in the dorsal CCb first stain at day eight. Axons of the extracerebellar projection appear at day 10 from a cell population that includes CCb and EGa cells. Axons are visible caudally in the acousticolateralis area of the brainstem at day 12. Lateral VA cells do not immunoreact until day 29. These data suggest the presence of separate Purkinje cell growth modes for the three cerebellar divisions. The development of zebrin II expression in this teleost does not follow the pattern of antigenicity in the developing rat cerebellum. Unlike rats, in *Eigenmannia* only cells that are zebrin II$^+$ in adults react during development.

DIFFERENT ELECTROSENSORY PATHWAYS TO THE TELENCEPHALON IN SILURIFORM TELEOSTS, MORMYRID TELEOSTS AND CARTILAGINOUS FISHES. Georg F. Striedter, Dept. of Neurosciences, University of California, San Diego; La Jolla, CA 92093.

Electroreception has evolved independently in cartilaginous fishes, mormyrid teleosts, and siluriform teleosts. The central nervous pathways for electroreception are similar up to the midbrain in all three taxa. An electrosensory pathway to the telencephalon is known for cartilaginous fishes, but not for any of the teleost taxa. This study anatomically describes a telencephalic electrosensory pathway in two siluriform species (a catfish, Ictalurus punctatus, and a gymnotoid, Apteronotus leptorhynchus). This pathway involves two diencephalic nuclei, versus one in cartilaginous fishes, and is not found in the mormyrid teleost examined (Gnathonemus petersii). This suggests that, while there may be stringent constraints on how to construct an electrosensory system up to the midbrain, there are at least three different ways of doing so at forebrain levels.

In siluriform teleosts the lateral preglomerular nucleus was injected in fixed brains (4% paraformaldehyde) with the carbocyanine dye DiI. After 6-45 days the brains were cut on a vibratome and counterstained with m-phenylenediamine (see Quinn and Weber, '88, Soc. Neurosci. Abstr.). Retrogradely labeled were cell groups in the diencephalon which receive an input from the electrosensory midbrain. Anterogradely labeled were two areas (Dm and Dd+Dld) in the telencephalon (see also International Congress for Neuroethology, '89, abstract in press). In mormyrids DiI was injected into the portion of the lateral preglomerular nucleus which projects to the telencephalon (Wullimann and Northcutt, Soc. Neurosci. Abstr., '87). There were no cells retrogradely labeled in the diencephalic nuclei which receive an input from the electrosensory midbrain in mormyrids.

This work was supported by an NIH training grant fellowship (GM08107) to G.F.S. and an NIH research grant NS24669 to R.G. Northcutt.

IMMUNOHISTOCHEMICAL ASPECTS OF NUCLEUS OLFACTORETINALIS (TERMINAL NERVE) IN MORMYRID AND GYMNOTID FISH.

T.SZABO, J.P.DENIZOT*, S.BLAHSER*, M.RAVAILLE-VERON*, D.ROUILLY*. Dept. Neurophysiol. Sens., Lab. Physiol. Nerv., CNRS, F-91198 Gif/Yvette Cedex.-Anatomie und Zytobiol. Univ. Giessen GFR.

The nucleus olfactoretinalis (nor) was identified with immunohistochemical methods in the mormyrid *Gnathonemus petersii* and in several gymnotid species, *Hypopomus* sp., *Gymnotus carapo*, *Ramphychthys rostratus*, *Apteronotus leptorhynchus*, *Eigenmannia* sp. and *Sternopygus* sp. Application of anti-substance P (sP), anti-FMRF and anti-LH antisera showed that, among the seven species, *Hypopomus* and *Sternopygus* have a defined nor whereas in the others, individual neurons scattered along the olfactory nerve and the ventro-medial telencephalic surface, constitued the nor. In all species the nor somata as well as their processes were FMRF immunoreactive(IR). The nor in *Hypopomus* was LH-IR but neither in *Sternopygus* or in *Eigenmannia*. The nor was not sP-IR in any of the species. However, besides, the FMRF-IR elements, a particular sP-IR structure was found in the olfactory nerve and bulbe of *Eigenmannia*, which extends from the olfactory epithelium to the dorsomedial pole of the olfactory bulbe.

SEGMENTAL TEMPLATE FOR RETICULOSPINAL ORGANIZATION. R.K.K. Lee and R.C. Eaton. Neuroscience Group, Univ. of Colorado, Boulder, CO 80309-0334.

The organization of the reticulospinal (RS) system has been conserved over the course of vertebrate evolution. Furthermore, Kimmel et al. '82 and Metcalfe et al. '86 (J. Comp. Neurol. 205:112 and 251:146) have demonstrated that the larval zebrafish contains at least 27 different types of RS neurons organized within 9 serially repeated segments. We have asked whether discrete types of larval RS neurons are retained and distinguishable in the mature brain. Our study, based on retrograde transport of HRP from the spinal cord in adult zebrafish and goldfish, shows 7 segments. In addition, at least 8 of the larval cell types have been found: RoR1, RoL1, RoV, RoM, MiD2cm, MiM1 and CaD (as well as two other midbrain types). We suggest that the preservation of this organization demonstrates a template which may underlie the organization of the adult RS system across a wide range of vertebrates. [Supported by NIH grant NS22621].

19.11

NON-PERCOMORPH TELEOSTS POSSESS A HOMOLOGUE OF NUCLEUS GLOMERULOSUS. M. F. Wullimann and R. G. Northcutt. UCSD, Dept. of Neurosciences A-001, La Jolla, CA 92093.

In derived percomorph teleosts a complex nucleus glomerulosus (NG) receives input from two visually related pretectal nuclei (nucleus corticalis, NC; nucleus intermedius, PSi) and projects to the hypothalamic inferior lobes (LI); PSi receives afferents from the retinofugal nucleus parvocellularis (PSp). More primitive teleosts lack NG but have a more simply organized posterior prectectal nucleus (PO). The carbocyanine dye DiI was applied to specific sites in paraformaldehyde fixed brains of the non-percomorph teleost Osteoglossum bicirrhosum in order to study the connections of PO. After 10-15 days of incubation at 40°C the brains were sectioned with a vibrotome at 50µm. Injections into PO (4 cases) showed that it receives ipsilateral input from NC and projects heavily to the ispilateral LI. After injections into LI (2 cases) neurons in PO were labeled. Injections into PSp (2 cases) revealed a bilateral terminal field in the rostral portion of PO. These results suggest that the rostral portion of PO is homologous to PSi and the caudal portion of PO is homologous to NG of percomorph teleosts. Supported by the Swiss National Science Foundation and NIH grants NS24869 and NS24669.

19.12

PHYLOGENY OF SOME PRETECTAL VISUAL NUCLEI IN TELEOSTS. Ann B. Butler, Mario Wullimann and R. Glenn Northcutt. I.T.N.I., 4433 N. 33rd St., Arlington, Va. 22207; Georg-August-Univ., Zentrum Anat., Kreuzbergring 36, D-3400 Göttingen; Scripps Inst. Oceanog. and Dept. Neurosci., A-001, Univ. Ca. San Diego, La Jolla, Ca. 92093.

In many derived euteleosts 3 prominent pretectal nuclei are present: pretectalis superficialis pars intermedius (PSi), glomerulosus (NG) and corticalis (NC). Their phylogeny has been uncertain. Recent work in Osteoglossum (O.) on a large nucleus--posterior pretectal (PO), to which NC projects--suggests that PO is homologous to both PSi and NG (Wullimann and Northcutt, '89). A cladistic analysis of cytoarchitecture in various teleosts was done. The large PO in O. has a rostral neuropil with cells. We conclude that an L-shaped PO with distal portions connected by neuropil in elopids, clupeids and primitive euteleosts is homologous to the PO in O. and to PSi plus NG, and that a PO nucleus with subdivisions is the plesiomorphic condition for teleosts. Whether the relatively enlarged PO in O. is plesiomorphic or apomorphic cannot presently be resolved. The separate nuclei PSi and NG are apomorphic. Further, in primitive euteleosts NC cells lie within the ventral quadrant of the central tectal zone; the NC cell plate may thus be a specialized, migrated sub-population of tectal neurons.

NUCLEI WHOSE FIBERS CO-LOCALIZE WITH THE SUBSTRATE FOR MEDIAL FOREBRAIN BUNDLE (MFB) SELF-STIMULATION. C.R. Gallistel, P.W. Glimcher and R.R. Miselis. Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Our earlier work has identified two MFB self-stimulation sites in rats connected by continuous reward-relevant fibers (*Soc Nsci Abstr. 18:443.7*). In this study nuclei which contribute fibers to both of these sites were identified as candidate nuclei of origin for the MFB self-stimulation system. True Blue, a retrogradely transported tracer taken up by fibers of passage, was injected into either the medial lateral hypothalamus or the dorsal anterior ventral tegmental area (VTA). Only nuclei labeled by injections into both sites could give rise to the continuous reward relevant axons which connect these sites. The vertical limb of the diagonal band, the bed nucleus of stria terminalis, the lateral preoptic area, the paraventricular nucleus of the hypothalamus, the dorsomedial hypothalamic area, the arcuate/VTA region, the parabrachial nuclei and the dorsal and median raphe, ipsilateral to the site of injection, all contribute fibers to both of these self-stimulation sites. We conclude that one of these nuclei may contain the cells of origin for the directly stimulated substrate for self-stimulation

20.2

DORSOMEDIAL HYPOTHALAMIC NEURONS GIVE RISE TO MOST OR ALL OF THE SUBSTRATE FOR MEDIAL FOREBRAIN BUNDLE (MFB) SELF-STIMULATION. P.W. Glimcher and C.R. Gallistel. Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Work presented in the preceding abstract identified 8 areas likely to give rise to the substrate for MFB self-stimulation. Other investigators have lesioned five of these nuclei without attenuating the rewarding efficacy of MFB self-stimulation. The effect of lesions of the three remaining nuclei on self-stimulation were examined. We report here that electrolytic or ibotenic acid lesions of the dorsomedial hypothalamic area (DMHA) of the rat permanently attenuates the rewarding efficacy of dorsal anterior VTA stimulating electrodes by up to 90%. Electrolytic lesions of the paraventricular nucleus or the posterior arcuate/anterior ventral VTA border have no effect on the rewarding efficacy of stimulation. We conclude that a substantial fraction of the substrate for MFB self-stimulation has its origin in the cell bodies of the DMHA.

Supported by BNS86-19759 and MH17168

20.3

AFFERENTS AND EFFERENTS OF THE DORSOMEDIAL HYPOTHALAMIC AREA (DMHA) IDENTIFIED USING CT-HRP, AN EXAMINATION WITH REGARD TO SUBSTRATES FOR SELF-STIMULATION. R.R. Miselis and P.W. Glimcher. Institute for Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104.

Rats received 20nl injections of cholera toxin conjugated horseradish peroxidase into the DMHA. Afferents were identified in the medial prefrontal cortex, lateral septum, bed nucleus of stria terminalis, medial preoptic area, hypothalamic paraventricular nucleus, amygdala, subiculum, parabrachial nuclei, central gray and periventricular thalamus. Efferents include the lateral septum, bed nucleus of stria terminalis, lateral habenula, amygdala and central gray. These findings confirm and extend earlier work (Ter Horst & Luiten, *Brain Res Bull.* 16: 231-248).

Two principal descending pathways terminate in the central gray. The more ventral of these pathways precisely overlaps the lowest threshold self-stimulation sites of the midbrain. The anatomical circuit(s) in which the DMHA participates are colocalized with many, if not most, of the behaviorally identified sites for self-stimulation. These data support the conclusion that some of these anatomically identified circuits subserve self-stimulation reward processing. Historical data reevaluated in light of this hypothesis further support this conclusion.

MAPPING THE SUBSTRATE FOR BRAIN STIMULATION REWARD IN THE RAT BY MEANS OF CURRENT-NUMBER TRADE-OFF FUNCTIONS. M.L. Forgie and P. Shizgal. CSBN, Dept. of Psychology, Concordia University, Montreal, Quebec H3G 1M8.

In previous studies, the spatial distribution of reward-related neurons has been estimated from across-site changes in the current or number threshold for intracranial self-stimulation (ICSS). We combined these two methods by deriving, at each stimulation site, the trade-off between the current and number of pulses required to sustain a constant level of performance. Thus, we could assess the dependence of depth profiles derived from current or number thresholds on the arbitrary choice of the second parameter.

Using moveable electrodes aimed at the ventral tegmental area, we found some sets of current-number trade-off functions that were roughly parallel in log-log space. Hence, the shape of depth profiles obtained by sectioning these functions was independent of the axis or location of the plane of section. In contrast, trade-off functions for other subjects were non-parallel and sometimes intersecting. Depth profiles derived from these functions depended both on the axis of the plane of section and on its location.

These results suggest that trade-off functions should be substituted for single-parameter threshold estimates in order to map the sensitivity of ICSS sites in a manner that is less dependent on arbitrarily-chosen stimulation parameters.

20.5

REFRACTORY PERIODS OF SINGLE NEURONS INCREASE WITH PULSE DURATION: IMPLICATIONS FOR INTERPRETING PSYCHOPHYSICALLY-DERIVED ESTIMATES. K.L. Conover*, D.C. Schindler*, P.-P. Rompré and P. Shizgal. CSBN, Dept. of Psychology, Concordia University, Montreal, Quebec H3G 1M8.

The slope of behaviorally-derived curves describing the time course of recovery from refractoriness in neurons mediating intracranial self-stimulation (ICSS) decreases with the pulse duration. Bielajew et al. (Behav. Brain Res., 1987, 24, 233) attributed this to recruitment of small fibers by the longer duration pulses. Alternatively, accommodation during long-duration pulses and/or a delay in post-firing repolarization might delay recovery in a fixed population of fibers.

Extracellular recordings of action potentials were obtained in rats from forebrain neurons antidromically driven by stimulation of the MFB. In all 21 neurons tested at currents 1.2 times threshold, refractory period (RP) estimates increased (mean = 66%) as the duration of the pulses was lengthened from 0.1 to 2.0 msec. Ten of these cells were also tested at twice-threshold currents. The RP estimates again increased with the pulse duration, but the magnitude of this increase was smaller (mean = 56%).

Given that the RP of each neuron increased with pulse duration, the decrease in slope of psychophysically-derived RP curves as a function of increasing pulse duration cannot be unambiguously attributed to the recruitment of an additional population of neurons.

20.6

THE EFFECTS OF SEROTONERGIC ANTAGONISTS ON REWARD INDUCED BY DORSAL RAPHE ELECTRICAL STIMULATION. P. BAUCO* and P.P. Rompré (SPON: J.Y. Montplaisir). Psychology Dept., Concordia University, Montreal, Quebec, H3G 1M8.

The present experiment was aimed at investigating the contribution of the serotonergic neurotransmission to the rewarding effect of dorsal raphe electrical stimulation. Changes in the function relating the rate of responses to the stimulation frequency and in the asymptotic rate of responses were measured after systemic administrations of mianserin (0.1, 1 and 10 mg/kg), pirenperone (0.032, 0.1 and 0.32 mg/kg), ketanserin (1, 3.2, 10, 16.4, 24.3 and 36 mg/kg) and ICS 205930 (0.1, 1 and 10 mg/kg). Both the 5-HT3 (ICS-205930) and the mixed 5-HT1/5-HT2 (mianserin) antagonists produced no change in the rate-frequency function and in the asymptotic rate of responding. However pirenperone and ketanserin, the more selective 5-HT2 antagonists, shifted the rate-frequency function by 0.2 log units and decreased the asymptotic responses by less than 20%. The 0.15 log units shift produced by 16.4 mg/kg of ketanserin was not significantly reduced by a pretreatment with 5 mg/kg of the 5-HT2 agonist, DOI; at this dose, DOI alone had the same effect as ketanserin and shifted the function towards higher stimulation frequencies. These results suggest that serotonin, through the 5-HT2 but not the 5-HT1 and 5-HT3 receptors, can modulate the rewarding effect of dorsal raphe stimulation.

20.7

SINGLE UNIT ACTIVITY IN THE NUCLEUS ACCUMBENS OF THE FREELY MOVING RAT DURING MEDIAL FOREBRAIN BUNDLE SELF-STIMULATION. M. Wolske, P-P. Rompre, R.A. Wise, and M.O. West Dept. of Psychology, Rutgers Univ., New Brunswick, NJ 08903 and Dept. of Psychology, Concordia Univ., Montreal, Quebec, Canada.

Previous studies have suggested an involvement of the mesocorticolimbic dopamine system in the reinforcing effects of medial forebrain bundle (MFB) self-stimulation. The present study used extracellular single unit recordings in the nucleus accumbens of the awake, freely moving rat to determine the effects of MFB stimulation on accumbens neurons. Male Long-Evans rats (300g) were permanently implanted with microwires (25 micron diam.) in the nucleus accumbens and ipsilateral stimulating electrodes in the MFB and the fimbria. Verification that recorded units were accumbens neurons was achieved by stimulating the fimbria to evoke unit discharges at monosynaptic latencies (4-11 msec). Rats were trained to lever-press using a train (200-400 msec duration) of MFB pulses (0.1-0.5 mA, 0.1-1.0 msec) as the reinforcer. Intermittent schedules of reinforcement were used, enabling a comparison of reinforced to non-reinforced responses. Interpulse intervals (20-30 msec) were chosen to allow analysis of unit activity evoked by each pulse in the train. Preliminary results (N=73 units) suggest that firing rates decreased (x = -12%) during the MFB train, compared with a period of comparable duration immediately preceding the train. Conversely, in the same time frame following non-reinforced lever presses, firing rates increased (x = 29%). This difference could not be accounted for by factors such as changes in motor behavior, sensory cues, or behavioral state, but rather was apparently due to mono- or polysynaptic neural activity evoked by the MFB train. This study demonstrates the potential usefulness of this technique in elucidating neural activity patterns underlying MFB self-stimulation. Supported by BNS-8708523, DA 04551 and RR 07058-21.

NUCLEUS ACCUMBENS INJECTIONS OF MU AND DELTA BUT NOT KAPPA OPIOIDS FACILITATE HYPOTHALAMIC BRAIN STIMULATION REWARD. T. E. G. West* and R. A. Wise (SPON: Z. Amit). Dept. Psychol., Concordia U., Montreal, Canada, H3G 1M8

Nucleus accumbens injections of morphine (2.5 and 10 ug), the mu agonist DAGO (0.8 and 3.2 ug), and the delta agonist DPDPE (0.8 and 3.2 ug) potentiated the rewarding effects of lateral hypothalamic stimulation, shifting the rate-frequency function to the left with no change in asymptote. Injections in medial and lateral portions of the nucleus seemed equally effective; injections in the rostral portion of the nucleus were less effective and acted with longer latencies than mid-level and caudal injections. The kappa agonist U-50,488H (0.05, 0.2, 0.8, and 3.2 ug) had no effect; it shifted the rate-frequency function neither to the right nor to the left and it had no effect on asymptote. The effects of morphine, DAGO, and DPDPE were blocked by naltrexone (1 and 2.5 mg/kg). These data suggest that mu and delta receptors mediate the reward-facilitating effects of nucleus accumbens opioids; they suggest no role for nucleus accumbens kappa receptors.

EFFECT OF FOOD DEPRIVATION ON SELF-STIMULATION RATE-FREQUENCY FUNCTIONS. S.A. Frutiger. Univ. Wisconsin-River Falls, River Falls WI 54022.

Although food deprivation has been reported to facilitate lateral hypothalamic (LH) self-stimulation on CRF schedules (Blundell & Herberg, 1968) it has been reported to have no effect on rate-frequency functions (Giovono & Wise, 1986). Since significant facilitation of self-stimulation is noted only at current intensities close to threshold (Blundell & Herberg, 1968), it is possible that the effect of food deprivation is intensity dependent. If so, the relatively high current levels which would be necessary to support self-stimulation at 28-33 Hz may have obscured any facilitation by food deprivation in the Giovono & Wise (1986) study. The present study was designed to test this hypothesis.

Male rats were implanted bilaterally with LH electrodes, tested for stimulation-induced eating, drinking, and/or gnawing, and trained to self-stimulate for a 0.5 sec current train. Rate-intensity functions were established at 100 Hz and used to derive the current which supported 50% or 75% maximal response rate. Baseline rate-frequency functions were established at these current values and the effects of 24 or 48 hr food deprivation on rate-frequency functions evaluated. Food deprivation produced no significant change in either the frequency threshold or asymptotic response rate at either current level tested.

ATROPINE FAILS TO REVERSE THE EFFECTS OF PIMOZIDE ON BRAIN STIMULATION REWARD RATE-FREQUENCY FUNCTIONS. S.M. Boye, P.P. Rompré and R.A. Wise. Psychology Dept., Concordia University, Montreal, Quebec H3G 1M8.

Previous reports showed that anticholinergic drugs reverse neuroleptic-induced attenuation of rate of responding for electrical brain stimulation. It is not clear, however, whether the anticholinergic drugs reversed neuroleptic-induced reward attenuation or neuroleptic-induced decrease in asymptotic rate of responding. In this experiment, we studied the effects of atropine on brain stimulation reward threshold and on asymptotic rate of responding as measured with the curve-shift method, in pimozide-naive and pimozide treated animals. Rats were trained to press a lever to obtain intracranial electrical stimulation and were tested first with tartaric acid followed by saline. They were then divided into different groups. Animals in groups 1, 2 and 3 were treated with tartaric acid or pimozide (0.35 mg/kg) followed by atropine sulphate (0.8, 1.6 and 3.2 mg/kg, respectively) and animals in groups 4, 5 and 6 were treated with tartaric acid or pimozide followed by atropine methylnitrate (0.42, 0.84 and 1.68 mg/kg, respectively). Atropine sulphate failed to reverse the attenuation of reward and the decrease in asymptotic rate of responding produced by pimozide. On the contrary, it shifted the curve further to the right without changing the asymptotic rate of responding. Atropine methylnitrate produced a similar shift to the right but further decreased the asymptotic rate of responding.

20.11

POTENTIATION OF BRAIN STIMULATION REWARD BY MICROINJECTION OF NEUROTENSIN IN THE VENTRAL MESENCEPHALON: A COMPARISON WITH THE EFFECTS OF MORPHINE. P.P. Rompré[1], P. Bauco* and A. Gratton[2] Psychology Dept[1], Concordia University, Montreal, Quebec H3G 1M8. Douglas Hosp. Res. Ctr.[2], McGill University, Verdun, Quebec H3H 1R3.

Brain stimulation reward was found to be sensitive to pharmacological treatments that modify central dopamine neurotransmission. Morphine infusions in the ventral mesencephalon, for instance, increase dopamine impulse flow, potentiate brain stimulation reward and reverse the effects of dopamine receptor blockade. In this experiment, we studied the effects on brain stimulation reward, of ventral mesencephalic microinjection of neurotensin, a peptide suspected to regulate the activity of the mesocorticolimbic dopamine system. We compared the effects of neurotensin to the effects of morphine injected at the same sites. Changes in the function relating the rate of responses to the stimulation frequency were measured after central injections of 1) neurotensin (vehicle, 2.5, 5.0, 10 and 20 ug/0.5 ul) and 2) morphine (5.0 ug/0.5 ul). At 5 to 20 ug, neurotensin, like morphine, potentiated the rewarding effect of the stimulation and shifted the curve (by 0.03 to 0.1 log unit) towards lower stimulation frequency. In two cases, neurotensin attenuated brain stimulation reward (0.1 log unit shift) while morphine, injected at the same sites, produced strong facilitations (0.12 and 0.25 log unit shift).

20.12

Effects of dopamine antagonists injected into the ventral tegmental area on lateral hypothalamic self-stimulation. S. Nakajima, Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4J1.

In earlier studies, either SCH 23390 (D1 specific antagonist) or raclopride (D2 specific antagonist), injected IP, reduced operant responding for stimulation of the medial forebrain bundle. When injected into the nucleus accumbens (NAc), SCH 23390 attenuated the reinforcing effect of brain stimulation but raclopride did not. Now these antagonists were injected into the ventral tegmental area (VT), and their effects on lateral hypothalamic (LH) self-stimulation examined.

Rats were implanted with a bipolar electrode into LH and a cannula into VT. Injection of SCH 23390 into VT ipsilateral to the electrode reduced responding with a dose range of 1-3µg. Contralateral injection had either no effect or a delayed effect. Raclopride had no effect up to 5µg; 10µg reduced responding regardless of the side of injection.

These results are similar to the results of injection into NAc. D1 receptors in both NAc and VT seem to be involved in the mechanism of reinforcement, but the participation of D2 receptors in these areas was not confirmed.

(Supported by NSERC of Canada. The antagonists were supplied by Schering Corp. and Astra Alab AB.)

REDUCTION OF HYPOTHALAMIC STIMULATION REWARD BY MEDIAL FOREBRAIN BUNDLE LESIONS: AN AUTOTITRATION ANALYSIS. A. M. McDonald* and D. B. Neill. Dept. of Psychology, Emory University, Atlanta, GA 30322.

Responding for hypothalamic stimulation is reduced by lesions within the medial forebrain bundle (MFB), but it is difficult to separate reward from performance changes. We examined the effect of MFB lesions using the less rate-dependent autotitration ICSS. In our procedure, the stimulation current is reduced 3 uA every 5th lever press. The rat is free to reset the current to the maximum by responding on a separate reset lever. We found that electrolytic lesions anterior and posterior and ipsilateral to the stimulation electrode resulted in decreased response rate and resetting at higher intensities than previously, i.e., decreased reward. Lesions contralateral to the electrode were ineffective. Lesions placed in the posterior midbrain, posterior to the dopaminergic cell fields, also decreased reward. Our results support the idea of decreased reward following these lesions and the ability of autotitration ICSS to detect this reward change. The results also suggest that the reward pathway may continue posteriorly in midbrain past the dopaminergic cell bodies.

20.14

THE EFFECTS OF LATERAL HYPOTHALAMIC SELF-STIMULATION ON SOME IMMUNE MEASUREMENTS. **J. D. Butler and D. B. Neill. Dept. of Psychology, Emory University, Atlanta, Ga. 30322**

Intracranial self-stimulation (ICSS) of the lateral hypothalamus (LH), while highly rewarding, appears to be a stressor in rats. Blood levels of corticosteroids, ACTH, and beta-endorphin have been reported to increase. We report here immunological effects consistent with this hypothesis. Male Lewis rats were implanted with an electrode into the LH and trained to self-stimulate. In experiment 1 the rats were allowed to self-stimulate for 35 days and then sacrificed. On day 19, experimental and operated home-cage control rats were injected with sheep red blood cells (SRBCs) I.P. The ICSS rats had significantly smaller thymuses and SRBC antibody titer. In experiment 2 SRBCs were injected into experimental, unoperated, and operated home-cage control rats on the day ICSS testing began. These rats were sacrificed after 7 days of ICSS. These ICSS rats had significantly smaller thymuses but the SRBC titer was not different from controls.

20.15

SEX STEROID HORMONE ADMINISTRATION DOES NOT INFLUENCE AUTOTITRATION SELF-STIMULATION OF THE PARS-COMPACTA SUBSTANTIA NIGRA OR THE MEDIAL FOREBRAIN BUNDLE IN THE FEMALE RAT. P.R. Hartley and D.B. Neill. Department of Psychology, Emory University, Atlanta, GA 30322.

Steiner et al., (Psychoneuroendocrinology, 6:81, 1981) reported that intracranial self-stimulation (ICSS) in female rats varied with the estrous cycle for electrodes in substantia nigra pars compacta (PC-SN) but not the lateral hypothalamus (LH).

To determine if the above changes were a function of altered motoric or hedonic functioning we studied the effects of exogenous administration of estradiol benzoate (E_2) and progesterone (P) on a rate-independent measure of self-stimulation known as autotitration. In autotitration, the rat presses a bar for electrical brain stimulation on one lever. Every fifth response results in a decrease in the current by 3uA. On the other side of a Plexiglas partition in the chamber there is a lever that, when pressed, resets the current to a predetermined intensity.

Ovariectomized female rats were implanted with electrodes in either the LH or the PC-SN. The first simulated cycle using E_2 and P to produce a state of behavioral estrus produced no differences in mean reset intensity (MRI), or total number of responses (TR) as compared to baseline in either LH or PC-SN implanted rats. The second replacement cycle revealed no differences in any of the response measures in rats with electrode implants in the LH but a trend towards a decrease in MRI was observed in rats with electrodes in the PC-SN.

EFFECTS OF PERFORMANCE AND REWARD MANIPULATIONS ON CURRENT-INTENSITY THRESHOLDS AND OTHER MEASURES DERIVED FROM A DISCRETE-TRIAL SELF-STIMULATION PROCEDURE IN RATS. A. Markou, S.J. Hanley*, A.K. Chehade* and G.F. Koob. Research Institute of Scripps Clinic and UCSD Dept. of Psychology, La Jolla, CA 92037.

Intracranial self-stimulation (ICSS) thresholds are presumed to provide a measure of reward and are used in the study of the anatomical and neurochemical substrates of reward. The purpose of the present experiments was to validate the four measures derived from a discrete-trial current-intsnsity ICSS procedure (modified from Kornetsky and Esposito, Fed Proc, 38, 2473-2476, 1979). The effects of adding weight on the manipulandum (performance manipulation) and changing train duration (reward manipulation) on thresholds, extra responses, time-out responses and reaction time were investigated. It was found that the weight manipulation affected reaction time and both extra and time-out responses, ($p < .05$), with very little effect on thresholds. In contrast, the train duration manipulation primarily influenced thresholds ($p < .05$). Two other experiments examined the effects of acute cocaine injections (reward manipulation) and a muscle relaxant (performance manipulation) on the same measures. These validation studies will allow the detection and discrimination of reward and performance effects of future manipulations (e.g., drugs, lesions).

PERTUSSIS TOXIN BLOCKS MORPHINE SELF-ADMINISTRATION IN THE CA3 REGION OF THE HIPPOCAMPUS. D. W. Self and L. Stein. Dept. of Pharmacology, College of Medicine, Univ. of California, Irvine, CA 92717.

Rats rapidly learn to self-administer the selective μ-opioid agonist morphine directly in the CA3 region of the hippocampus. The reinforcing action of morphine suggests that μ receptors in this region may be involved in opioid reward. The μ-opioid receptor belongs to a family of receptors that can initiate cellular responses via activation of the pertussis toxin-sensitive G_i protein. Pertussis toxin irreversibly blocks the effects of these receptors by catalyzing the ADP ribosylation of the α subunit of G_i. In this study, naive rats were injected with two 500 nl microinjections of pertussis toxin (0.1 or 1.0 μg/injection) or the Ringer's vehicle, through cannula aimed at the CA3 region of dorsal hippocampus 2 days prior to self-administration testing. Untreated rats or rats pretreated with vehicle self-administered morphine (10 pmoles/100 nl injection) through the cannula at rates significantly higher than controls self-administering saline. Rats pretreated with 1 μg of pertussis toxin failed to groom, exhibited seizures, and in half the cases died 6 or 7 days later. In contrast, rats pretreated with 0.1 μg of pertussis toxin exhibited no obvious behavioral deficits or sickness, but they failed to self-administer morphine. These results suggest that pertussis toxin may block acquisition of morphine self-administration behavior by preventing μ-opioid receptor activation of G_i. If so, the reinforcing properties of opioid drugs may depend on the activation of G_i in target neurons possessing the μ-opioid receptors.

20.18

HIPPOCAMPAL SELF-ADMINISTRATION OF MORPHINE AND COCAINE . E. Grauer*, D.L. Lutz* and L. Stein. Dept. of Pharmacology, Coll. of Medicine, Univ. of California, Irvine CA. 92717.

Although the hippocampus has been principally associated with learning and memory functions, this region contains both opioid and dopaminergic neurotransmitters implicated in motivation and reward. Previous work has shown that dynorphin and dopamine are self-administered into the CA3 field of dorsal hippocampus, suggesting that the hippocampus might be an important action site for drugs of abuse. Rats were trained to self-administer morphine or cocaine through a permanently implanted cannula aimed at the CA3 field of the hippocampus. Both drugs were tested at doses of 1, 10 or 100 pmole/100 nl injection using the EMIT self-administration system. Morphine and cocaine supported significant self-administration behavior but only at the 10 pmole/100 nl dose. Rates associated with the higher and lower doses of each drug did not differ from saline control rate. Since the effective 10 pmole/100 nl doses found here is an order of magnitude lower than doses of morphine and cocaine reported effective for other self-administration sites, the hippocampus may be a particularly important site of action for opiate and psychostimulant drugs of abuse.

20.19

MU RECEPTORS MAY MEDIATE HIPPOCAMPAL ENDOGENOUS OPIOID REINFORCEMENT. K.E. Stevens and L. Stein. Department of Pharmacology, University of California, Irvine, CA 92717

Previously, we showed that animals would work to self-administer dynorphin A directly into the CA3 region of hippocampus. Furthermore, mediation of dynorphin A reinforcement via an opiate receptor was demonstrated by a dose-related attenuation of self-administration rates by naloxone co-administered with the opiate. In the current studies, we show that this reinforcement is largely mediated by the mu opiate receptor.

Rats were unilaterally implanted with a chronic indwelling guide-cannula aimed at the hippocampal CA3 region. Self-administration testing using the EMIT self-administration system was conducted every third day for a total of three tests. Rats were allowed access to a 1 pmol/100 nl dynorphin A solution that also contained a "selective" opioid receptor antagonist. Selective kappa receptor blockade was provided by nor-binaltorphimine (5 pmol/100 nl), delta blockade by ICI 174,864 (125 pmol/100 nl) and mu blockade by beta-funaltrexamine (415 pmol/100 nl). The dose of each of antagonist was selected on the basis of its relative binding affinity as compared to naloxone, and was calculated to produce, at the preferred receptor, the same blockade as that produced by 500 pmol/100 nl naloxone. Neither kappa nor delta receptor blockade significantly reduced dynorphin A self-administration rates. However, mu receptor antagonism produced a complete blockade of dynorphin self-administration; in fact rates in the beta-funaltrexamine group were below vehicle control and almost identical to those of a non-injected control group. Taken in conjunction with other work in this laboratory showing that the mu-selective agonist morphine produces high rates of hippocampal self-administration, these results strongly suggest that mu receptors in the hippocampal CA3 region play an important role in opioid reinforcement.

20.20

GUSTATORY IMPAIRMENT CONSECUTIVE TO THE LESION OF THE LATERAL HYPOTHALAMIC NEURONS BY IBOTENIC ACID.
Velley,L. and Touzani*,K., Lab. Psychophysiologie, CNRS URA 339, Univ. Bordeaux I, Av. Facultés 33405 TALENCE FRANCE.

Our previous studies showed that neurons of the lateral hypothalamus modulate both self-stimulation in the parabrachial area and taste preference or aversion. The present study further analyzes this gustatory impairment. Four groups of rats were used: bilaterally,simultaneously or successively lesioned, vehicle injected and intact controls. The effect of these different treatments on body weight, fluid intake and preference-aversion ratio for 6 concentrations of saccharin was compared. No significant difference was observed either between the 2 lesioned or the 2 non-lesioned groups. Lesioned rats displayed neophobia for saccharin, an increase in appetitive and aversive thresholds and a similar decrease in body weight and daily fluid intake. The comparison of the effect of morphine and naloxone on saccharin preference of the same groups of rats showed an altered reactivity of lesioned rats to opiate agonists and antagonists. Animals were then tested for conditioned taste aversion (CTA) with threshold values of saccharin solution as conditioning stimulus. No difference was observed in CTA learning between lesioned and non lesioned groups with a saccharin concentration apparently neutral for lesioned and appetitive for non lesioned rats, suggesting that the gustatory impairment observed in the choice task is not related to a sensory deficit.

COMBINED EFFECTS OF ETHANOL AND NICOTINE ON INTRACRANIAL SELF-STIMULATION AND LOCOMOTOR ACTIVITY IN RATS. G.J. Schaefer and R.P. Michael, Department of Psychiatry, Emory University, School of Medicine, Georgia Mental Health Institute, 1256 Briarcliff Rd., Atlanta, GA 30306.

Two groups of rats were implanted with electrodes in the lateral hypothalamus, and trained to lever-press for intracranial self-stimulation (ICSS) on either a fixed interval 15-second (FI:15 sec) (N = 10), or a fixed ratio 15 (FR:15) (N = 11) schedule of reinforcement. Animals were then tested with graded doses of ethanol (0.1-1.0 g/kg), nicotine (0.01-0.3 mg/kg) and combinations of ethanol and nicotine. By itself, ethanol decreased response rates at 1.0 g/kg in the FI:15 sec paradigm, while nicotine alone increased rates at 0.1-0.3 mg/kg. These doses of nicotine, when combined with 0.1 and 0.3 g/kg alcohol, also increased response rates. In the FR:15, alcohol decreased rates at 0.56 & 1.0 g/kg, while nicotine increased rates at 0.03-0.17 mg/kg. No combination of ethanol and nicotine increased response rates in the FR schedule. A third, non-implanted group (N = 10) was tested in a locomotor activity procedure; ethanol (0.1-1.0 g/kg) did not alter activity, but nicotine increased it at 0.1-0.3 mg/kg. When combined, 0.17 mg/kg nicotine increased activity at all ethanol doses. These preliminary results demonstrated that under certain conditions, combinations of ethanol and nicotine can produce behavioral stimulation.

21.2

ALCOHOL PRODUCES RATE-DEPENDENT FACILITATION OF BRAIN STIMULATION REWARD. M.J.Lewis, J.R.Andrade and S.Reynolds* Dept. of Psychology, Howard Univ.,Washington, DC 20059.

Intraperitoneal injection of ethanol (E) has been found to produce mixed effects on brain stimulation reward (BSR) response rate. No effect or reduction in response rate have frequently been found. Increases have also been found, although less frequently. In the present experiment, analysis of E effects on BSR lever-press response rate in animals with differing baseline response rates indicates that facilitation or depression appears to be rate dependent

Randomly bred albino rats (Charles River) were surgically implanted with stainless steel electrodes in the lateral hypothalamic area. All were shaped to lever-press for electrical stimulation (100 Hz biphasic rectangular wave, 1.0 msec duration, 0.2 sec train; continuous reinforcement) during a 15 min operant session. Animals were injected with saline and then twice with E (0.25 g/kg,ip). Injections were administered 5 to 10 min prior to the operant sessin.

E increased responding in all animals with low to moderate response rates (20 to 50 responses/min) over saline injections. In those with higher response rates (50 responses/min), E generally decreased responding. Animals with very low response rates (20 responses/min) also a general reduction in response rate was found.

These data show that E's effects on lever-press responding are rate-dependent and may account in part for the conflicting data concerning E's effects in this task.

21.3

TASTE REACTIVITY IN ALCOHOL PREFERRING (P) AND NON-PREFERRING (NP) RATS. P.J. Bice* and S.W. Kiefer Department of Psychology, Kansas State University, Manhattan, Kansas 66506.

The taste reactivity test was used to examine the orofacial responses of naive alcohol preferring (P) and alcohol non-preferring (NP) rats to the taste of alcohol. In the initial exposure, rats were tested for reactivity to five concentrations of alcohol (5%, 10%, 20%, 30%, and 40% v/v) and a sucrose and a quinine solution. A two bottle consumption test then was given for a three week period to allow the animals access to 10% alcohol. A second reactivity test was used to examine the taste responses of experienced P and NP rats to the same solutions that were used in the initial reactivity test. The results indicated no significant differences between the P and NP rats during the initial reactivity measures. Taste reactivity following alcohol access indicated that P rats showed more ingestive responses and fewer aversive responses to all alcohol concentrations relative to the NP rats. There were no significant differences between rats in their response to sucrose and quinine. These results suggest that P and NP rats taste response to alcohol differs only after experience with alcohol.

CYCLOOXYGENASE INHIBITORS ANTAGONIZE ETHANOLS' DEPRESSANT EFFECTS: POTENCY CORRELATIONS WITH SCHEDULE CONTROLLED BEHAVIOR. (SPON. N. Khazan), G.I. Elmer* and F.R. George*. NIDA Addiction Research Center, Balt., MD, 21224 and Dept. of Pharmacology and Toxicology, Univ. of MD, 21201.

Ethanol-induced increases in the production of cyclooxygenase (CO) metabolites are proposed to be important in ethanols' mechanism of action. If CO metabolites are important there must be a significant correlation between in vitro anti-enzyme activity and in vivo therapeutic potency. The potency correlation for the ability of PGSIs to antagonize the rate depressant effects of 1.5 g/kg ethanol was investigated in C57Bl/6J mice using operant fixed ratio responding for water. Ethanol decreased responding to 20% of saline baseline levels. Indomethacin, flufenamate, ibuprofen and aspirin antagonized up to 50% of the rate depressant effects of ethanol in a dose dependent manner. The potency of these PGSI's to antagonize ethanols' effects were significantly correlated with their in vitro IC_{50} and in vivo ED_{50} anti-inflammatory values. Pharmacological correlations between enzyme inhibition and antagonism of ethanols' effects may add support to the hypothesis that CO metabolites are important in mediating ethanols' CNS effects.

200 mg/kg Ethanol Enhances Appetitive Pavlovian Conditioning of Motor Activity. James D. Valentine* and Linda L. Hernandez. VA Medical Center and University of South Carolina, Columbia, South Carolina 29201.

A low dose of ethanol, 200 mg/kg, enhances aversively motivated Pavlovian conditioning (Psychopharmac. (1989) 97:476-480). We now report that this dose also enhances appetitively motivated Pavlovian conditioning.

Male Sprague-Dawley rats were reduced to 90% of free-feeding body weight and given 2 daily sessions of pellet-feeder training before being returned to ad lib food. This was followed by 4 days of habituation to a 20 sec tone (Sonalert) that later served as the conditional stimulus (CS). Separate groups then received either 200 mg/kg ethanol or saline, i.p., 15 min before each of 6 Pavlovian conditioning sessions; CS termination was immediately followed by the delivery of 5 food-pellets, the unconditioned stimulus. One week after the completion of conditioning, both groups received 3 days of extinction, followed 5 weeks later by 3 additional days of extinction; no injections preceded the extinction sessions. All sessions were 30 min long, and included 5 trials with a 5 min intertrial interval. Motor activity was measured during all sessions using an ergometric activity monitor (Colbourn).

The conditioned response (CR) was a large increase in motor activity. The ethanol group acquired the CR far more rapidly than did controls, and the duration of their CR may have been increased, as well. During extinction, the CR of the ethanol group showed greater recovery at the beginning of each session, and almost complete recovery during the 5 week period between the 3rd and 4th extinction sessions.

These results show that 200 mg/kg of ethanol enhances appetitive, as well as aversive, Pavlovian conditioning in rats, and that the appetitive model may be more sensitive to these effects.

ETHANOL, DIAZEPAM AND GEPIRONE EFFECTS ON REACTIONS TO DISTANT PREDATORS AND PREDATORY LOCI. R.J. Blanchard, D. C. Blanchard, B.B. Young, and R.J. Rodgers[1]
Békésy Laboratory of Neurobiology, University of Hawaii, 96822 and [1]University of Bradford, United Kingdom.

Ethanol, the serotonin 1A agonist gepirone, and diazepam were compared in a battery of tests designed to measure reactions to the sight and odor of an inescapable distant predator, and to the place where the predator was seen. Three sequential defensive reactions occur to these stimuli: Initial movement arrest (MA); followed by active risk assessment (RA) behaviors; with concommittant inhibition of non-defensive behaviors (INB) (Blanchard & Blanchard, Comp. Psychol., 1989). Measures of these patterns, plus proxemics, the S's spatial location with reference to the predatory stimulus, will be presented.

Diazepam (0, 2 and 4 mg/kg) selectively altered RA in a rate-dependent fashion, with minimal effects on INB. Ethanol (0, 0.6, 1.2 g/kg) influenced MA, RA, and INB evenly, producing moderate reductions in each of these defensive behaviors. Gepirone (0, 5, 10 mg/kg) reduced RA at the higher dose but also reduced most active behaviors.

Each anxiolytic thus reduced some defense measures, but each produced a unique profile of changes in the anxiety-related defense pattern.

DRUG DISCRIMINATION LEARNING WITH RHESUS MONKEYS: AN ASSESSMENT WITHIN THE CONDITIONED TASTE AVERSION DESIGN R. Jeffreys, A. Riley and J. Glowa, Psychopharmacology Laboratory, The American University, Washington, DC 20016 and Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD 20892.

Drug discrimination learning within a conditioned taste aversion paradigm has been reported recently in rats. Under these conditions, rats drink less saccharin-flavored water paired with 1.8 mEq LiCl when the access to this solution is preceded by a drug injection than the same solution that is not paired with LiCl and preceded by distilled water injections. In order to begin to assess the possibility that similar effects could be obtained in primates, two rhesus monkeys were trained under a FR 30 schedule of sucrose pellet delivery and injected with low doses (0.03-0.1 mg/kg) of alprazolam, 60 min prior to sessions which were immediately followed by the adminitration of 1.8 mEq LiCl. On the intervening days, subjects were injected with saline in a similar manner (both 60 min before and immediately after the session). Although these doses of alprazolam originally had no overall effect on FR responding (complete dose-effect determinations from 0.03-3.0 mg/kg were obtained previously using banana pellets), with repeated conditioning trials responding decreased relative to both baseline and saline control. Although overall baseline rates decreased, comparisons between the rates on the day before conditioning trials and the day of the trial revealed a marked decrease in one of the monkeys and smaller effects in the other. These findings are consistent with the notion that drug discrimination can be rapidly acquired in the primate using a conditioned taste aversion design.

21.8

LOW LEVEL HYPERBARIC EXPOSURE DOES NOT AFFECT PICROTOXIN INDUCED SEIZURE LATENCIES IN C57 MICE. P.J. Syapin, L.S. Kobayashi,* B.L. Jones,* D.A. Finn* and R.L. Alkana, Alcohol and Brain Research Lab., Schls. of Pharmacy and Medicine, U. of Southern California, Los Angeles, CA 90033

Exposure to 12 atmospheres absolute (ATA) helium-oxygen (HEOX) gas mixtures antagonizes the acute and chronic behavioral effects of ethanol in animals. To assess the contribution of a pressure-induced increase in general CNS excitabiity in mediating the antagonism, we tested the effects of 12 ATA HEOX on picrotoxin-induced seizure latencies. Male, drug naive C57BL/6J mice were injected with a low dose of picrotoxin (2 mg/kg s.c.), placed 3/chamber and immediately exposed to 1 ATA air, 1 ATA HEOX or 12 ATA HEOX. The subjects were recorded on video tape and scored later for time to onset of drug action (Straub-like tail) and time to first convulsion. Exposure to 12 ATA HEOX did not significantly alter latencies compared to the 1 ATA HEOX controls. In contrast, 1 HEOX significantly altered the onset of picrotoxin's effects, but the effect was not consistent. These results with picrotoxin suggest that 12 ATA HEOX does not antagonize ethanol via increasing CNS excitability. Further studies are in progress to determine the generality of these preliminary results to other convulsant drugs. (Supported by NIAAA research grant AA03972).

ACTION OF ICV EGTA OR VERAPAMIL ON SOME CENTRAL ACUTE ETHANOL EFFECTS IN RATS. X. Paez* and R.D. Myers, Department of Pharmacology, School of Medicine, East Carolina University, Greenville, NC 27858

Ethanol (ETOH)-induced hypothermia can be prevented by EGTA in the third ventricle and attenuated by verapamil in the lateral ventricle of rats. In order to determine the possible involvement of Ca^{++} imbalance in other acute ETOH effects (sleep, loss of righting reflex and motor incoordination), 25 adult rats were prepared for icv EGTA (12.5, 25, 50 ug/15 ul) or verapamil (25, 50 ug/10 ul) injections in the right ventricle. The drugs were given simultaneously with ETOH 4 g/kg ip (to prevent effects) or when the maximum hypothermic ETOH effect was reached (to reverse effects). The colonic temperature was monitored continuously from 1 hour prior to 5-7 hours after injections; sleep, righting reflex and motor coordination were recorded periodically. In a dose-dependent manner, EGTA prevented and reversed the ETOH hypothermia and accelerated the recovery of the other monitored effects. Verapamil was less effective than EGTA on ETOH-induced hypothermia, but accelerated the recovery of righting reflex and motor coordination. These dose-dependent results with a Ca^{++} chelator and a Ca^{++} channel blocker indicated that both the ETOH hypothermia and acute behavioral effects could be prevented or reversed. An imbalance in Ca^{++} may be in part responsible for acute effects of ETOH, but further investigation is necessary.

ETHANOL DIFFERENTIALLY AFFECTS ORIENTING AND RIGHTING REFLEXES IN WEANLING, BUT NOT PREWEANLING OR ADULT, RATS. J.A. Saiers*[1], D.J. Knapp[2], L.A. Pohorecky*[2] and B.A. Campbell[1]. [1]Dept. Psychology, Princeton Univ., Princeton, NJ 08544-1010; [2]Center for Alcohol Studies, Rutgers Univ., New Brunswick, NJ 08855-0969.

The effects of ethanol on orienting and righting reflexes in preweanling (16-17 day-old), weanling (30-35 day-old), and adult (60-70 day-old) rats were assessed in this research. Both cardiac and behavioral measures were used to index the occurrence of the orienting reflex: in response to an auditory stimulus, rats exhibit a bradycardic (40-50 BPM) heart rate (HR) orienting response accompanied by a quick, lateral head jerk. In preweanling, weanling, and adults rats, ethanol (injected i.p. at dosages of 0, .5, 1, 2, or 3 g/kg) blocked these two components of the orienting reflex to a pulsating auditory stimulus in a dose-dependent manner, with prevention of both behavioral and HR responses occurring at a dosage of 3 g/kg of the drug. The righting reflex was also prevented in a dose-dependent manner in preweanling and adult rats 15 min after ethanol administration. In these animals, magnitude of righting and orienting reflex disruption was similar at any given dosage of ethanol. In weanling rats, in contrast, ethanol failed to affect the righting reflex at any dosage. Measures of locomotor activity taken during the 20 min following ethanol injection revealed that ethanol produced behavioral activation in weanling animals but sedation in preweanling and adult animals. Implications of this dissociation between ethanol's effects on the righting reflex and behavioral activation versus its effects on the orienting reflex in weanling animals will be discussed.

EFFECT OF ETHANOL AND GABA ANTAGONISTS IN MICE WITH DIFFERENT SENSITIVITY TO ETHANOL. S. Liljequist. Dept. of Psychiatry and Psychology, Karolinska Institute, S-10401 Stockholm, Sweden.

Various behaviors and the effect of ethanol and GABA antagonists were studied in NMRI, CBA, and C57 mice. Inbred C57 mice habituated rapidly in a locomotor activity test situation, whereas inbred CBA mice showed no habituation. There was no difference between the mouse strains in a passive avoidance learning test. CBA mice were most sensitive to the convulsive effects of picrotoxin, whereas C57 mice were most resistant. No difference between the mice to the convulsive effects of the specific GABA receptor antagonist bicuculline was noted. CBA mice were significantly more sensitive to the muscle relaxant and hypnotic effects produced by acute ethanol administration as compared to NMRI and C57 mice. The ethanol-produced hypothermia was similar in all mice tested. When the mice were given daily injections of ethanol during five consecutive days, C57 developed tolerance to the hypnotic effects of ethanol, whereas no tolerance to ethanol was observed in CBA mice. All animals developed tolerance to the ethanol-produced hypothermia. These results suggest that genetic differences in the regulation of the GABA receptor-coupled chloride channel may be of importance for the observed differences in ethanol sensitivity and in the rate of development of ethanol tolerance.

RO 15-4513 AND ETOH EFFECTS ON OPERANT BEHAVIOR OF MALE AND FEMALE C57 MICE. K. Bao*, H.C. Becker and L.D. Middaugh. (SPON: W. Boggan) Dept Psychiat Behav Science, Med. Univ. So. Car., Charleston, SC 29425.

Previous reports suggest that the behavioral effects of Ro 15-4513 and ETOH may be influenced by gender. The present study investigated the effects of Ro (1,2 or 4 mg/Kg), ETOH (.25 to 3.0 g/Kg), and combinations of the two on lever-responding of male and female C57BL/6 mice maintained on an FR20 schedule of food reinforcement. ETOH disrupted lever responding; however, the only sex difference was a slightly more prolonged disruption for female mice. Ro also produced a transient disruption of lever-responding at all doses examined with no evidence of a sex difference in response to the drug. The disruptive effect of ETOH on lever-responding was not altered by Ro injections given just prior to testing. The results confirm previous work indicating that Ro disrupts behavior under the control of reinforcing stimuli but does not alter the effects of ETOH on this behavior. Since both sexes responded similarly to the two drugs, gender is not accountable for the reported differences in the effects of Ro on ETOH discrimination using operant paradigms. (Supported by NIAAA Grant #AA06611 and MUSC Grant #22620-GR29.)

21.13

ETOH DISCRIMINATION BY C57 MICE IS NOT ALTERED BY Ro 15-4513. L.D. Middaugh, K. Bao,* S.J. Sergent* and H.C. Becker. Dept Psychiat Behav Sci, Med. Univ. So. Car., Charleston, SC 29425.

Of the two reported studies, one indicated that Ro 15-4513 (Ro), the partial benzodiazepine agonist, given to male mice after ETOH injections attenuated its discriminability. When Ro was given to female rats prior to ETOH injection, no attenuation of ETOH discrimination was observed. In the present study we used an operant drug discrimination paradigm and 6 female C57BL/6 mice to determine if the order of injecting Ro relative to ETOH might account for the above difference. After first assessing ETOH discrimination at doses of .5, .75, & 1.0 g/Kg, we determined the effects of Ro (.37, .75, & 1.5 mg/Kg) on responding and ETOH discrimination when it was given 5 min before ETOH or vehicle and 10 min prior to testing. Finally, we assessed the effects of Ro (.15 or .37 mg/Kg) when it was injected 10 min after ETOH and 10 min prior to testing. Although Ro disrupted the lever-response, hence was biologically active, it did not interact with the disruptive effects of ETOH on this measure nor did it attenuate the discriminability of ETOH when given either before or after ETOH injection. (Supported by Grant #AA06611).

21.14

THE BENZODIAZEPINE INVERSE AGONIST RO15-4513 ANTAGONIZES THE ANXIOLYTIC ACTION OF ETHANOL IN A NONSHOCK CONFLICT TASK. H.C. Becker. VA Medical Center and Department of Psychiatry, Medical University of South Carolina, Charleston, SC 29403.

The purpose of this study was to examine the effects of RO15-4513 on the anxiolytic action of ethanol (EtOH) in a consummatory (nonshock) conflict test referred to as negative contrast. The negative contrast task involves quantification of how animals respond to an abrupt, unexpected reduction in reward (sucrose solution). The depressed behavior engendered by reward reduction is antagonized by anxiolytics such as EtOH and benzodiazepine (BDZ) agonists. The BDZ inverse agonist RO15-4513 (0.1875-3.0 mg/kg) dose-dependently antagonized the anxiolytic effect of EtOH (0.75 g/kg) without influencing general consumption ($p<.01$). At the highest dose (3 mg/kg) RO15-4513 alone produced an anxiogenic effect (further response suppression). However, at lower doses this intrinsic activity of RO15-4513 was not apparent. Thus, these data suggest that in the negative contrast task RO15-4513 can antagonize the anxiolytic action of EtOH at doses that do not produce the intrinsic inverse agonist effects of the drug.

PATERNAL ALCOHOL EXPOSURE AFFECTS OFFSPRING ACQUISITION OF WORKING MEMORY TASK IN RADIAL ARM MAZE IN RATS. D.F. Wozniak, T.J. Cicero, L.C. Kettinger III*, E.R. Meyer*. Dept. of Psychiatry, Washington University School of Medicine, St. Louis, MO 63110.

Male rats were given ad libitum access to an alcohol liquid diet containing 35% ethanol-derived calories (ALC) or were pair-fed an isocaloric control diet (PF) for 39 days. The concentration of alcohol in the diet was gradually increased to permit adaptation, then stabilized and then gradually tapered to prevent an alcohol withdrawal syndrome which could confound the results. Following treatment, all males were mated with nontreated females. A behavioral teratologic approach was used to study the offspring throughout development and into adulthood. The offspring sired by the ALC males did not differ from the offspring of PF males on several parameters including: litter size; body weight measured on postnatal days (PNDs) 0 or 1, 4, 7, 14, 21, 30, 60, 90, 120; when various developmental landmarks (incisor eruption, eye opening, testes descent, vaginal opening) appeared; tests of sensorimotor development (negative geotaxis and ascent on an inclined wire screen); or on 1-hr activity tests conducted on PNDs 21 and 60. As adults (beginning on PND 75), the male offspring were trained on the working memory protocol in the radial arm maze and the ALC offspring (n=15) required significantly more days to reach an acquisition criterion (8/9 correct arm choices for 4 consecutive days) than the PF offspring (n=15). After acquisition, rats were tested on a protocol which included a 15 min delay between the first four correct (reinforced) arm choices and subsequent choices and the two groups did not differ according to a post-delay performance criterion (4 consecutive days of 4/4 correct on post-delay choices). The results suggest that high levels of paternal alcohol consumption may lead to relatively selective learning deficits in their male adult offspring. PERSISTENCE OF ACUTE TOLERANCE TO ETHANOL IN THE P LINE OF RATS DOES NOT REQUIRE PERFORMANCE WHILE INTOXICATED. G.J. Gatto*, J.M. Murphy, W.J. McBride, L. Lumeng* and T.-K. Li* Indiana Univ. Sch. Med. & VAMC; Psychology Dept., Purdue Univ. Sch. Science, Indianapolis, IN 46223

Selectively bred, alcohol-preferring P rats develop acute ethanol (E) tolerance faster than nonpreferring NP rats, and P rats maintain E tolerance longer (Pharmacol Biochem Behav 28:105, 1987). This study tested whether performance while intoxicated contributes to the persistence of tolerance. P rats were trained to jump 50 cm to a descending platform to avoid shock. Three groups were injected ip on day 0 as follows: Group E/J (n=8) was given 2.5g E/kg body wt and was tested on the jump task until recovery to criterion (37.5 cm); group S/J (n=21) received saline and testing yoked to an E/J rat; group E/NJ (n=19) received E but no testing. Seven days later, all rats received 2.5g E/kg and were tested to criterion. Recovery times for the E/J (141±11 min) and E/NJ (145±6 min) rats were shorter ($p<0.05$) than the S/J group (169±7 min). Blood E levels at recovery for the E/J group were higher on day 7 than day 0 (259±3 vs 245±4 mg%; $p<0.05$). Blood E levels for the E/NJ group were higher than the S/J group on day 7 and higher than the E/J group on day 0 ($p<0.05$). The findings show that the persistence of tolerance manifested by the P rats does not require performance while intoxicated. (AA-03243, AA-07462 & AA-07611)

EFFECTS OF *IN UTERO* ADMINISTRATION OF ALCOHOL ON SLEEP TIME IN ADULT RATS. E. Reyes, J. Wolfe*, M. E. Marquez*, E. Duran* and S.H. Switzer*. Univ. New Mexico Sch. of Med., Albuquerque, NM 87131.

It has been shown that the *in-utero* administration of alcohol effects tolerance to ethanol in adult rats. This study was designed to demonstrate that prenatal exposure to ethanol also effects sleep times. On day one of gestation female Sprague-Dawley rats received one of five types of food. These types included: lab chow, liquid Bioserv diet containing 6.7% ETOH, 4% ETOH, 2% ETOH, and 0% ETOH. Four percent, 2%, and 0% mothers were pair-fed against 6.7% mothers. At day 45, pups were injected with 3.4 g/kg of a 50% ethanol solution ip. Sleep time was recorded from the loss of righting reflex to the time at which it was regained. Long sleep (LS) was defined as the mean sleep time of control animals plus two standard deviations. The mean sleep time of control animals minus two standard deviations was considered short sleep (SS). Fifty percent of the rats whose mothers were treated with 6.7% ETOH were classified as LS. The animals whose mothers were pair-fed 4%, 2%, and 0% ETOH demonstrated 20, 36, and 11% LS characteristics respectively . Of pups born to mothers fed lab chow, 3.2% were SS and 19% were LS. In addition, the rate of elimination of a 3.0 g/kg dose of alcohol was determined. Blood alcohol levels were determined by the method previously described by Lundquist (Meth. Biochem. Anal.1:217, 1959). The rates of elimination for control and 6.7% ETOH treated animals were 52.57 and 50.66mg%/hr, respectively. It appears that the significant differences in sleep time between the animal groups cannot be attributed to differences in the rates of ETOH elimination.

TEMPERATURE DEPENDENCE OF ETHANOL SENSITIVITY IN HOT AND COLD SELECTED LINES OF MICE. D.A. Finn*, B.L. Jones*, L.S. Kobayashi*, J.C. Crabbe and R.L. Alkana. Alcohol and Brain Research Laboratory, School of Pharmacy, Univ. of Southern California, Los Angeles, CA 90033.

The purpose of the present study was to determine whether manipulation of body temperature during intoxication would affect ethanol sensitivity in mice that were selectively bred for their sensitivity (COLD) and resistance (HOT) to ethanol-induced hypothermia. Replicate lines of HOT and COLD mice were injected with 4.0 g/kg ethanol (20% w/v) and exposed to 22 or 34°C. Exposure to 34°C offset ethanol-induced hypothermia and increased ethanol sensitivity, measured by loss of the righting reflex (LORR) duration and ethanol concentration at return of the righting reflex (RORR) in HOT1, HOT2 and COLD1 animals. The 34°C exposed COLD2 animals became hyperthermic following ethanol injection and died. Overall, the results are consistent with previous work in C57, BALB, DBA, A/He and SS mice. In contrast, 129 and LS mice became less sensitive to ethanol as intoxicated body temperature was increased in previous studies. Taken together, these results indicate that body temperature during intoxication influences sensitivity to ethanol-induced LORR and that there are genetically determined differences in the direction of the response. (Supported by USPHS research grant AA05234, AA03972 and AA05828, NIAAA).

ALCOHOL AND SLEEP DEPRIVATION EFFECTS ON REACTION TIME PERFORMANCE AND EVENT-RELATED POTENTIALS. R.Sinha*, L.T. Smith* and H.L.Williams* (SPON:J.Holloway). Alcohol Research Center, Univ. Of Okla. Health Scs. Ctr., Oklahoma City, OK 73104.

The effects of low and moderate doses of alcohol (.07 mg/kg; .10mg/kg) and 30 hrs. of sleep deprivation were investigated using a reaction time task with a checker-board reversal for the stimulus. There were 18 subjects each in placebo, low and moderate dose groups. Reaction times showed additive treatment effects at the low dose. Sleep deprivation appeared to ameliorate the effects of the moderate dose of alcohol. Forward and backward averaging of the concurrent event-related potentials (ERPS) associated with the reaction process resolved components of the waveform that may have been related to stimulus processing and response execution functions. The forward averaged ERP recorded from Oz, Pz and Cz locations showed significant increases in P2 and P3 component latencies as a function of alcohol dose, and similar increases with sleep deprivation. The P1 and N1' components of the backward averaged motor potential showed similar results. These findings suggest that alcohol, at moderate doses, and sleep deprivation may have independent effects on the reaction process.

IN VIVO CHANGES IN STRIATAL BINDING OF DOPAMINE UPTAKE INHIBITOR [^{18}F]GBR 13119 AND MUSCARINIC RECEPTOR LIGAND [^{11}C]-2α-TROPANYL BENZILATE IN MPTP LESIONED C57BL/6 MICE: DUAL TRACER INJECTION STUDIES. G.K. Mulholland,* M.R. Kilbourn,* P.S. Sherman* and T.L. Pisani*. Division of Nuclear Medicine, Univ. of Michigan, Ann Arbor, MI 48109. (Spons: G. W. Dauth).

This study examined whether previously reported in vitro decreases in striatal dopamine reuptake and muscarinic acetylcholinergic receptor levels in the MPTP lesioned C57BL/6 mouse Parkinsons model could be shown in vivo using positron-labeled ligands [^{18}F]GBR 13119 (GBR, DA uptake inhibitor) and [^{11}C]tropanyl benzilate (TRB: mChR antagonist) using dual tracer injection. Male 16 wk old mice were lesioned (Ricaurte, Brain Res. 403, 43, 1987) and studied 2 and 6 wk later. Mice were co-injected with TRB and GBR and sacrificed at 60 min. Brain regions were excised and counted twice for quantification of ^{11}C ($t_{1/2}$ = 20 min) and ^{18}F ($t_{1/2}$ = 110 min) in samples. GBR striatum/cerebellum (str/cer) ratios were reduced by 45% (p=.0 03) at 2 wk post MPTP and remained decreased (40%) at 6 wk post MPTP, as compared to controls (str/cer = 3.2). In contrast, str/cer ratios for TRB in the 2 wk post MPTP mice did not differ from controls (str/cer = 14). However in 6 wk post MPTP mice there was a 35% drop (p = .007) in str/cer ratio for TRB. Thus, in vivo tracer techniques can be used to demonstrate changes in both DA uptake sites and mChR sites after MPTP treatment; the time course of loss of these binding sites, however, appear different. These results suggest that both ligands for DA uptake sites and mChR should be examined for utility in PET studies of Parkinson's disease.

22.2

DOPAMINE (DA) METABOLITES IN THE FRONTAL CORTEX AND STRIATUM OF NORMAL AND MPTP-TREATED RHESUS MONKEYS MEASURED BY BRAIN DIALYSIS. H. Miyake*, D.J. Doudet, T.G. Aigner & R.M. Cohen*. SCBI/LCM & Lab Neuropsychology NIMH, Bethesda, MD, 20892.

MPTP is known as a neurotoxin that selectively destroys the DA nigro-striatal pathway while sparing the mesocortical system. DA metabolites were evaluated in the dorso-lateral prefrontal cortex, caudate nucleus and putamen of 4 MPTP-treated (2-5 mg/kg, i.v., 3 years before the present study) and 4 age matched normal rhesus. The treated animals acutely showed rigidity and akinesia but spontaneously recovered and were evaluated as neurologically normal at the time of the study by investigators unaware of their previous treatment. The 3 microdialysis probes were stereotaxically implanted in the 3 areas, in the anesthetized animals. Data collection lasted 2 hrs. The DA metabolites levels were reduced in the prefrontal cortex, caudate and putamen in the MPTP-treated monkeys compared to controls by respectively, 60, 75 and 40%

These data suggest that 1) deficits in striatal DA may precede the appearance of clinical symptoms and 2) MPTP may affect mesocortical as well as nigro-striatal neurons.

22.3

^{3}H-MPP$^+$ BINDING SITES: RELEVANCE FOR MPTP NEUROTOXICITY. M.Del Zompo, S.Ruiu*, F.Bernardi*, A.Bocchetta*, M.P.Piccardi*, G.U.Corsini*^, Dept.Neurosciences, Univ.of Cagliari,Via Porcell 4,09124 Cagliari, and ^Inst. Pharmacology,Univ.of Pisa,Via Roma 55, 56100 Pisa, Italy.

The present study was designed to clarify the biological significance of ^{3}H-MPP$^+$ binding sites and their relevance for MPTP neurotoxicity. We used 6-OH-DA-lesioned rats and MPTP-lesioned mice in attempts to localize the ^{3}H-MPP$^+$ binding site. Unilateral 6-OH-DA lesions of the nigrostriatal DA neurons reduced by 30% the B_{max} of the ^{3}H-MPP$^+$ binding in the homogenate of lesioned caudate. The localization of specific ^{3}H-MPP$^+$ site and its modifications in the nucleus caudate will be evaluated by quantitative autoradiography. Inhibition experiments showed that debrisoquin displaces ^{3}H-MPP$^+$ from its sites (IC_{50}: 0.015 μM). Since MPP$^+$ is thought to be the actual toxic metabolite of MPTP, we have investigated whether debrisoquin might be in itself a nigrostriatal toxin. Striatal DA levels were unchanged in mice injected bilaterally intracerebroventri cularly with amounts of debrisoquin up to 50 μg, compared with saline injected animals. A single dose of MPTP (30 mg/kg, i.p.) significantly decreased DA levels to 40-55% of control values. Debrisoquin (up to 100 μM) had no effect on MAO-B activity or MPP$^+$ uptake, whereas it inhibited MAO-A with an IC_{50} of 2,5 μM. We will investigate whether debrisoquin might interact with MPTP toxicity.

22.4

MPTP-INDUCED HEMIPARKINSONIAN MONKEYS EXHIBIT ABNORMALLY HIGH METABOLIC ACTIVITY RATES WHEN EXPERIENCING PASSIVE MANIPULATION. H.H. Holcomb, G.E. Alexander, M.R. DeLong and H.L. Loats, Johns Hopkins Medical Institutes, Dept. of Neurology; U. MD Psych. Res. Ctr.; Baltimore, MD; and Loats Associates, Westminster, MD.

MPTP-induced hemiparkinsonism produces unilateral rigidity, bradykinesia, tremor and visual neglect. Electrophysiological studies have documented marked changes in the internal and external pallidum following MPTP treatment, especially when the subject is manipulated. Using a modification of the double-label quantitative 2-deoxyglucose method we have studied one normal and one MPTP treated primate in resting and passively manipulated conditions, right forearm, to assess the impact of movement on neural metabolic activity patterns. Trained to accept passive, repetitive flexion-extension of the forearm, elbow fixed, one hemiparkinsonian monkey was first given [14C]-2DG, 100 microCuries/kg, immediately following the onset of passive manipulation, 20 minutes. 45 minutes after the first injection, 8 milliCi/kg of [3H]-2DG was given prior to a 45 minute rest phase. Quantitative autoradiographic image subtraction and correction for isotope contamination of the second condition by the first tracer permitted accurate assessment of the movement phase metabolism. In the MPTP primate, during rest the striatum exhibited increased metabolism, external pallidum increased, internal pallidum normal, subthalamus reduced, ventrolateral thalamus normal, and motor cortex normal. During passive manipulation all regions exhibited only modest elevations in the striatum and cortex during passive manipulation. This increase in neural metabolic activity is consistent with the large elevations in electrical activity associated with hemiparkinsonism.

22.5

POTENTIATION OF THE ANTIPARKINSONIAN EFFECT OF BROMOCRIPTINE BY D_1 DOPAMINE AGONISTS IN MPTP MONKEYS. B. Gomez Mancilla*, P.J. Bédard, C. Rouillard, C. Gagnon* and T. Di Paolo. Lab. of Neurobiology, Hôp. Enfant-Jésus and Dept. of Molecular Endocrinology, Laval University, Medical Center, Québec, Canada.

We have previously reported that SKF 38393, a dopamine D_1 agonist had little effect by itself against the MPTP-induced parkinsonian syndrome in monkeys (Falardeau et al. Eur. J. Pharmacol. 150, 59, 1988) thus confirming earlier reports by Nomoto et al. Neurosci. Lett. 57, 37, 1985. Preliminary results of the combination of bromocriptine and SKF 38393 disclosed little additive effect (Rouillard et al. Soc. Neurosci. Abstr., 18, 389, 1988). We now report that after full analysis of the data SKF 38393 5 mg/kg given orally seems to increase the locomotor effect of bromocriptine 5 mg/kg orally. The new putative D_1 agonist CY 208243 also potentiates the action of smaller doses of bromocriptine (0.16 mg/kg) orally in a dose-dependent manner. There was no difference in [^{3}H] Spiperone binding or [^{3}H]-SCH 23390 in the striatum of animals treated with bromocriptine alone or bromocriptine plus SKF 38393. Similar determinations are currently being performed on the brains of animals treated with bromocriptine alone or in combination with CY 208243 and will be reported. Supported by MRC of Canada and the Parkinson Foundation of Canada.

22.6

ALTERATIONS IN OPIATE RECEPTOR BINDING IN MPTP-INDUCED HEMIPARKINSONIAN MONKEYS. L.J. Porrino[1], J.J. Viola[2,3], F.E. Pontieri[3], A.M. Crane[3], K.S. Bankiewicz[1], I.J. Kopin[1]. [1]NINDS, [2]HHMI, [3]NIMH, Bethesda, MD 20892.

The neurotoxin, MPTP, when infused directly into one internal carotid artery of primates, causes selective destruction of the dopaminergic neurons of the substantia nigra pars compacta ipsilateral to the infusion, resulting in a hemiparkinsonian (HP) syndrome (Bankiewicz et al., 1986). Such lesions of the nigrostriatal system cause alterations in the properties of striatal dopaminergic receptors (Joyce et al., 1985). In this study, because of the close link between dopamine and opiate systems, we investigated possible accompanying alterations in the distribution of opiate receptors in the striatum of HP monkeys. In vitro binding with [^{3}H]naloxone (conditions appropriate for the μ receptor subtype) was determined autoradiographically in four HP and two normal monkeys. In normal monkey and on the non-lesioned side of HP monkeys, striatal [^{3}H]naloxone binding was generally arranged in faint patches which were most evident in caudate and anterior putamen. Striatal patches corresponded to acetylcholinesterase-poor zones, assessed in adjacent sections. In regions outside the patches (matrix) the density of opiate binding sites was highest in the nucleus accumbens, and ventral caudate and putamen. Density was also higher rostrally than caudally. In the MPTP-lesioned hemisphere, although the regional distribution of opiate binding remained similar, the differentiation of patch from matrix was more apparent. The density of binding in the patches was increased by 25-50%, whereas a more moderate increase (+13-22%) was observed in the matrix. These data are a further demonstration of dopamine/opiate interactions in striatum, and suggest opiate receptor upregulation in response to dopaminergic denervation by MPTP in the primate.

CONTINUED GM1 GANGLIOSIDE ADMINISTRATION IS REQUIRED TO MAINTAIN BIOCHEMICAL AND BEHAVIORAL RECOVERY IN MICE EXPOSED TO MPTP. **F.B. Weihmuller*, M. Hadjiconstantinou, J.P. Bruno, and N.H. Neff. College of Medicine, Depts. of Pharmacology, Psychiatry, and Dept. of Psychology, The Ohio State University, Columbus, OH 43210-1222.**

Administration of a low dose of haloperidol, one that has no sensorimotor effects in intact mice, produces akinesia, catalepsy, and somatosensory neglect in MPTP-treated mice. Recently, we demonstrated that chronic daily injections of GM1 ganglioside return striatal DA and DOPAC content to near-normal levels and eliminate neuroleptic-induced sensorimotor impairments in MPTP-treated mice (Weihmuller et al., Neurosci. Lett. 92:207, 1988). To determine the extent of GM1-induced recovery, we examined striatal DA and DOPAC content, receptor density, and haloperidol-induced sensorimotor effects at time points up to 30 days after terminating an initial 23 days of GM1 treatments. Discontinuing GM1 therapy reinstated the neurochemical and behavioral profile of mice given MPTP alone. Striatal DA and DOPAC content fell to 50% of control values, striatal D2 receptor density increased, and neuroleptic-induced sensorimotor deficits returned. These results suggest that continued GM1 administration is required to maintain the biochemical and behavioral recovery seen in MPTP-treated mice.

NEUROPATHOLOGY OF MPTP-TREATED SQUIRREL MONKEYS. LONG TERM STUDIES. L.S.Forno, J.W.Langston, L.E. DeLanney and I.Irwin, VA Medical Center, Palo Alto,CA 94304 and Institute for Medical Research, San Jose, CA 95128.

Experimental MPTP-induced parkinsonism in non-human primates has shown great similarities to human Parkinson's disease. Previous studies have dealt mainly with animals living less than a year after treatment. We have examined the brain in 10 squirrel monkeys with 1 to 4 years survival after treatment. The animals were young or middle-aged except for one old monkey. Five of the monkeys received only a brief series (5 days or less) of i.p. injections. Three were given injections over several months. We found considerable nerve cell loss and glial scarring in the substantia nigra in all except one monkey. In contrast to monkeys with acute lesions, the pathology was most pronounced in the ventral and lateral cell groups. There were only questionable changes in the locus coeruleus. No inclusion bodies and no convincing abnormality were seen in other parts of the CNS. The distribution of lesions in MPTP-treated monkeys with long survival closely resembles that seen in Parkinson's disease, but the disease process appears to be relatively inactive.

22.9

CALCIUM CHANNEL AGENTS DIFFERENTIALLY ALTER MPTP INDUCED CHANGES IN MOUSE BRAIN SLICE DOPAMINE. J.A. Wilson, J.S. Boyle*, & Y.-S. Lau. Creighton University School of Medicine, Omaha, NE 68178

A Parkinson's disease like syndrome can be produced by administration of the neurotoxin MPTP. The mechanism by which MPTP exerts its toxic effect is unknown, and while studies are underway to elucidate this mechanism, the structural similarity between MPTP's toxic dihydropyridinium (DHP) metabolite MPDP* and the DHP calcium channel blockers provided an impetus for us to investigate the ability of these drugs to alter dopamine levels.

Mouse brain slices were used to examine the effect of calcium channel agonists and antagonists on MPTP's ability to alter dopamine levels in the slices. Each slice contained the nigro-striatal dopamine system and was maintained in artificial CSF for at least 1 hour before treatments were started. Slices were first pre-treated with the agent acting on the calcium channel and then MPTP was added to the experimental slices. We found that the non-DHP calcium channel blocker diltiazem caused an increase in basal levels of dopamine. The DHP calcium channel blocker nifedipine did not have an effect on basal levels or an effect on MPTP's ability to deplete dopamine whereas the DHP calcium channel agonist BAY-K-8644 decreased the MPTP induced reduction in dopamine concentrations. In light of the earlier physiological finding that low calcium - high magnesium CSF prevented MPTP's ability to decrease the amplitude of synaptic transmission, further studies are now planned to better define the interaction between MPTP and synaptic transmission.

MPTP OR METHAMPHETAMINE INDUCES GLIOSIS AND AXONAL NEUROPIL CHANGES IN THE CAUDATE NUCLEUS. W. G. McAuliffe*, C. Desiderio* and A. Hess (SPON:S. Rosner). Dept. of Anatomy, UMDNJ, R. W. Johnson Med. Sch., Piscataway, NJ 08854.

MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) and methamphetamine, both able to produce a parkinsonian syndrome, cause similar pathological changes in the caudate nucleus of mice. Two s.c. injections of 50mg/kg MPTP, one per day, or three i.p. injections of 10mg/kg methamphetamine at two hour intervals were given. Three to six days after the last injection, brains were immunostained for tyrosine hydroxylase (TH) and glial fibrillary acidic protein. After either drug, the TH content of the caudate nucleus is obviously reduced. In the neuropil, normally occurring densely packed punctate terminals can no longer be detected, but now appearing are long, branching, varicose pre-terminal (sprouting?) fibers. Normally sparse glial cells are not only dramatically increased in number, but are grossly hypertrophied compared with unaffected glia. Gliosis ensues during or soon after degeneration of dopaminergic synaptic terminals. The structural alterations in the axonal neuropil and gliosis are acute pathological manifestations of the dopamine depletion induced by these toxic drugs. Studies are under way to ascertain how long these degenerative effects can still be detected and if there is recovery in the caudate nucleus.

ASTROGLIAL INVOLVEMENT IN MPTP NEUROTOXICITY:ANATOMICAL ASSESSMENT. M. Takada, K.J. Campbell, M.S. Nishihama* and T. Hattori. Dept. of Anatomy, Univ. of Toronto, Toronto, Ontario M5S 1A8, Canada.

The oxidative conversion of MPTP to MPP^+, the major active metabolite, is mediated by the action of monoamine oxidase B, which is localized in astroglia. Various combinations of intranigral injections of MPTP (50 μg) and astroglia-specific toxin, L-alpha-aminoadipic acid (L-alpha-AA, 20-100 μg), were employed to examine the effects of selective astroglial ablation on MPTP-induced nigrostriatal cell death. Varying cell loss was assessed by the aid of fluorescent retrograde tracing. Treatment with MPTP alone caused tremendous nigrostriatal cell loss, while intranigral co-injections of MPTP and L-alpha-AA produced protection against MPTP neurotoxicity in a dose-dependent fashion. Similar protection was seen in the case of gliotoxin pretreatment just prior to or 1 day before MPTP administration. Intraventricular injections of ^{3}H-MPTP (50 μCi, 82.3 Ci/mmol) resulted in perikaryal labeling in various motor-related regions below the midbrain, out of which only the substantia nigra pars compacta and dorsal raphe were accompanied by extremely heavy radiolabeling to astroglia. The present findings thus provide anatomical evidence for the significance of astroglial involvement in the onset of MPTP neurotoxicity. Supported by the MRC of Canada.

MPTP EFECTS IN THE MOUSE BRAIN AND VITAMIN E. Ifeoma N. Odunze*, Lori K. Klaidman* and James D. Adams, Jr. School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

MPTP is known to affect the midbrain levels of the antioxidant, glutathione. Therefore, the relation between another antioxidant, vitamin E, and MPTP toxicity was investigated.

Vitamin E in extracts from various brain regions was assayed by HPLC with fluorescence detection. Catecholamine levels in the substantia nigra and striatum were analyzed by HPLC with electrochemical detection.

MPTP (4 doses at 2 h intervals, 25 mg/kg, ip) was found to alter levels of vitamin E in all brain regions examined. These alterations occurred within 2 days of MPTP administration and may have been reversible.

Vitamin E deficient mice were produced by raising mice on a vitamin E deficient diet for 16 weeks at which time brain levels are about 25% of control vitamin E levels. MPTP was more lethal to vitamin E deficient mice than to control mice, which made using lower MPTP doses necessary (4 X 15 mg/kg). Catecholamine levels in the substantia nigra were depleted to lower levels by MPTP in vitamin E deficient mice than in control mice. This depletion was significantly different for DOPAC and the ratio DOPAC/dopamine. Catecholamines in the striatum were not more depleted in vitamin E deficient mice than in control mice.

Vitamin E may play a role in protection against MPTP toxicity, especially in the substantia nigra. More research is needed to see if vitamin E is important in Parkinson's disease.

22.13

EFFECT OF CHRONIC DOPAMINERGIC TREATMENT ON D-1 AND D-2 RECEPTORS IN PARKINSONIAN MPTP-TREATED MONKEYS. C. Gagnon[1]*, C. Rouillard[1], P.J. Bédard[2] and T. Di Paolo[1] (SPON: S. Radouco-Thomas). [1]School of Pharmacy, Laval Univ. and Dept. of Molecular Endocrinology, CHUL, Québec G1V 4G2 and [2]Dept. of Anatomy, Fac. Med., Laval University, Québec G1K 7P4, Canada

We have compared the effect of chronic treatment (at least 4 weeks) of MPTP monkeys (Macaca Fascicularis) with different DA agonists (Sinemet, D-1 and D-2 agonist; bromocriptine, D-2 agonist or SKF 38393, D-1 agonist). D-1 and D-2 receptors were quantified by autoradiography of [^{3}H]SCH 23390 and [^{3}H]spiperone binding in the striatum of these animals. All MPTP monkeys had a decrease of DA of more than 95%, vs control as measured by HPLC. MPTP increased specific binding of D-1 and D-2 receptors vs intact control by 66% and 55%, respectively Chronic treatment with Sinemet, bromocriptine or SKF 38393 caused respectively, a decrease of 26% ($p<0.01$), 128% ($p<0.01$) and 52% ($p<0.01$) of D-2 receptors and a decrease of 46% ($p<0.01$), 55% ($p<0.01$) and 10% (n.s.) of D-1 receptors, vs MPTP. No dyskinesia was seen in monkeys on bromocriptine or SKF as opposed to the Sinemet-treated animals. The DA receptor changes observed could be implicated in the loss of efficacy and side effects following these different treatments. Supported by the Parkinson Foundation of Canada and the MRC.

CHRONIC EXPOSURE TO MPTP CAUSES COGNITIVE DISTURBANCES WITHOUT PARKINSONIAN MOTOR DEFICITS IN PRIMATES. C.J. Kovelowski,II* and J.S. Schneider (SPON: E.L. Mancall) Dept. of Neurology, Hahnemann Univ., Philadelphia, PA. 19102.

The present study investigates the cognitive status of monkeys chronically exposed to low doses of MPTP. Four Nemistrina monkeys were trained to perform delayed response (DR), delayed alternation (DA), and visual discrimination (VD) tasks. After training, monkeys were given intravenous MPTP injections 3 times/wk. in doses of 0.010 - 0.175 mg/kg over periods ranging from 3 - 11 mos. Total cumulative MPTP doses ranged from 17.68 to 56.07 mg. No animal developed a parkinsonian motor disorder. In contrast, all animals developed great difficulty in performing DR (especially at longer delay intervals) and DA, while VD performance remained intact. Some attentional problems were also noted. The dopamine D-2 agonist Quinpirole enhanced DA performance at low doses, while the D-1 agonist SKF-38393 had no positive effect on behavior. Clonidine, an alpha-2 agonist, enhanced DR performance, especially on trials with long delays. Neurochemical analysis revealed both cortical and subcortical catecholamine deficits. Immunocytochemical findings will be discussed. These results show that specific cognitive disturbances can be produced in monkeys exposed chronically to small amounts of MPTP without an accompanying motor disorder, despite extensive damage to the dopamine system. We propose this as a new model for "early" parkinsonism. (Supported by the Alzheimer's Disease and Related Disorders Association, Inc).

23.1

PRETREATMENT WITH A MIXED CYCLOOXYGENASE-LIPOXYGENASE INHIBITOR IMPROVES BEHAVIORAL AND HISTOLOGICAL OUTCOME FOLLOWING SPINAL CORD ISCHEMIA-REPERFUSION. S.H. Graham*, P.D. Demediuk and A.I. Faden (SPON: M. Lemke). Dept. of Neurology, U.C.S.F. and Center for Neural Injury, V.A. Med. Center, San Francisco, CA 94121.

Prostaglandins, hydroxy-eicosatetraenoic acids and leukotrienes, the cyclooxygenase and lipoxygenase products of arachidonic acid metabolism, have potent pathophysiologic effects and have been shown to accumulate in tissues after ischemic injury. In the present study, spinal cord ischemia was induced in the rabbit by temporary occlusion of the abdominal aorta via a femoral balloon-tipped catheter. BW-755C (10mg/kg iv), a mixed cyclooxygenase and lipoxygenase inhibitor, or saline was given 10 minutes prior to induction of 16 minutes of ischemia. BW-755C treated animals (n=12) had better motor performance scores ($P<.05$) and a greater number of surviving anterior horn cells ($P<.05$) at 48 hours after ischemia than saline controls (n=14). There was no detectable thromboxane B2 (TxB2) in BW-755C treated animals 4 hours after ischemia compared to 32.6±14.0 p.g. TxB2 /mg. protein in control spinal cord ($P<.05$). These data support the hypothesis that cyclooxygenase and lipoxygenase products mediate secondary injury in spinal cord ischemia-reperfusion and suggest that cyclooxygenase-lipoxgenase inhibition may be a potential therapy for spinal cord ischemia.

23.2

THE RELATIONSHIP BETWEEN FREE FATTY ACIDS PRODUCTION, GLUTAMATE RELEASE AND HISTOPATHOLOGICAL OUTCOME AFTER TRANSIENT ISCHEMIA. R. Busto, M.Y.-T. Globus, W.D. Dietrich, I. Valdes*, M. Santiso*, and M.D. Ginsberg. Cerebral Vascular Disease Research Center, University of Miami, School of Medicine, Miami, FL, 33101.

Moderate reduction in intra-ischemic brain temperature inhibits glutamate release and confers a marked protective effect on histopathological outcome. We evaluated the relationship between these findings and ischemia-induced free fatty acids accumulation. Rats whose intra-ischemic brain temperature was maintained at 36°C or 30°C were subjected to 20 min of 4-vessel occlusion plus hypotension. Cortical and striatal free fatty acids were measured at the end of ischemia by gas chromatography. In the 36°C animal group, all cortical free fatty acids were significantly elevated, with a preferential rise in arachidonic and stearic acid levels. A similar increase was observed in striatal levels of the palmitic, stearic and arachidonic acids, while oleic acid remained unchanged. In the 30°C, a similar increase was observed in cortical free fatty acids, while even a greater increase in arachidonic and stearic acid accumulation was found in the striatum. These results suggest that reduction in intra-ischemic brain temperature does not attenuate free fatty acid accumulation. Taken together with our previous findings we conclude that 1. ischemia-induced release of glutamate is not associated with free fatty acids production; 2. free fatty acids accumulation is not a indicator of irreversible ischemic brain injury.

23.3

ADENOSINE AND ITS ROLE IN ISCHEMIA/HYPOXIA. J.C. Fowler, Life Sciences Division, Los Alamos National Lab., Los Alamos, NM 87545

Adenosine is an inhibitory neuromodulator that has been hypothesized to influence neuronal excitability during periods of cerebral metabolic stress such as hypoxia or ischemia. The effect of adenosine antagonists on hypoxia- and in vitro ischemia-induced depression of neuronal activity was investigated in the isolated rat hippocampal slice

The Schaffer collateral pathway was stimulated (1/30 sec, suprathreshold stimulation) while the population spike and small fiber volley were recorded in CA1 pyramidal cell region in the submerged hippocampal slice (400 μm). Slices were superfused with normoxic physiological medium (33-34°C, 2 ml/min) equilibrated with 95% O_2/ 5% CO_2. Hypoxia was initiated by superfusing with medium equilibrated with 95% N_2/ 5% CO_2. Under hypoxic conditions, the population spike was completely blocked within 10 minutes. The addition of the adenosine antagonist theophylline (100 μM) resulted in a population spike 30% of control after 15 minutes in hypoxic medium while 8-phenyltheophylline (8-PT) exerted a dose-dependent protection from hypoxia with 10 μM essentially preventing depression at 15 minutes.

In vitro ischemia (superfusion with hypoxic medium lacking glucose) resulted in an initial depression of the population spike followed by a transient return of the response and finally a depression of both the population spike and the fiber volley. In the presence of 8-PT (10 μM) the transient return of synaptic transmission did not occur prior to a complete depression of the population spike and the fiber volley. These results suggest that the initial depression of synaptic activity in CA1 during hypoxia or in vitro ischemia is due to the release of the inhibitory modulator adenosine.

ADENOSINE AGONISTS INDUCE HYPERGYLCEMIA; IMPLICATIONS FOR ADENOSINERGIC STROKE THERAPEUTIC STRATEGIES. T.M.Loftus* and P.J. Marangos. Gensia Pharmaceuticals, San Diego, CA 92121

Adenosine agonists induce a dramatic hyperglycemia approaching four fold higher than normoglycemic levels. Recently we have shown that the adenosine agonist, N6 cyclohexyladenosine (CHA) is neuroprotective in cerebral ischemia. Blood glucose levels have also been found to affect the outcome of ischemic insult. Hypoglycemia has been shown to be beneficial, (LeMay, D.R. et al., Stroke, 1988; 19:1411-1419) while hyperglycemia has been demonstrably detrimental (Duverges, D. and Mackenzie, E.T., J. Cerebral Blood Flow and Metabolism, 1988; 8:449-461).

Agonists were administered intraperitaneally to mice and rats, and glucose levels were analyzed in plasma by the hexokinase/glucose 6-phosphate dehydrogenase method. Direct addition of agonists to the assay mixture had no effect on the accuracy of determination of solutions of known concentration. Elevations in glucose levels were observed in response to CHA, 5'N-ethylcarboxamidoadenosine (NECA), and the D and L isomers of N6-phenylisopropyladenosine (PIA). These elevations were evident by fifteen minutes and persisted beyond four hours post injection at doses not greater than 1 mg/kg. It was possible to reverse the effect by the coadministration of the peripheral adenosine antagonist 8(p-sulfophenyl) theophylline which blocks the peripheral effects of the agonists while perserving the central effects. These findings suggest that previous results with adenosine agonists in stroke, although impressive, may have been partially masked due to the coincident hyperglycemia. Furthermore, blocking of this hyperglycemia with a peripheral adenosine receptor antagonist might substantially improve the therapeutic efficacy of adenosine agonists in various animal models of cerebral ischemia .

23.5

THE ADENOSINE ANTAGONIST 8-CYCLOPENTYLTHEOPHYLLINE REDUCES THE HYPOXIC DEPRESSION OF SYNAPTIC RESPONSES IN SLICES OF RAT HIPPOCAMPUS. V.K. Gribkoff, L.A. Bauman, and C.P. VanderMaelen. CNS Biology, Bristol-Myers Co., 5 Research Parkway, Wallingford, CT 06492.

The actions of adenosine on hippocampal neurons provide evidence for a purinergic neuroregulatory function in this structure, and suggest a potential therapeutic role in conditions such as neuronal ischemia. In the present experiments we have examined the possibility that the depression of hippocampal synaptic responses during hypoxia may result from an endogenous action of adenosine.

Slices from young rats were bathed in either normal medium, 100nM 8-cyclopentyltheophylline (8-CPT, an A_1 receptor antagonist), 250nM 8-CPT, or 1.0µM 8-CPT. Infusion of 250nM or 1.0µM 8-CPT, but not 100nM 8-CPT produced a small but consistent increase in synaptic responses in CA_1. In normal medium, 15' hypoxic episodes produced rapid and severe depression of all synaptic responses. In 250nM and 1.0µM, but not 100nM 8-CPT, the depression was decreased in amplitude and delayed in onset. Recovery of the responses occured in all conditions. Similar experiments were performed on aged rat slices (Fisher 344, 25-27mo.), using 1.0µM 8-CPT vs. normal medium only. The adenosine antagonist again delayed hypoxia-induced synaptic depression, and reduced its magnitude.

These results suggest that adenosine may protect hippocampal neurons during periods of hypoxia by reducing transmission.

23.6

THE ADENOSINE ANALOGS 2-CHLOROADENOSINE (2CA) AND 5'-(N-ETHYL)CARBOXAMIDOADENOSINE (NECA) PROTECT AGAINST DYNORPHIN A (DYN)-INDUCED RAT SPINAL CORD INJURY. J.B. Long, D.D. Rigamonti, and A. Martinez-Arizala, Dept. of Med. Neurosci., Walter Reed Army Inst. of Res., Washington, D.C. 20307.

Lumbar subarachnoid injection of DYN causes decreased blood flow, ischemic neuronal degeneration and persistent hindlimb (HL) paralysis in rats. Excitatory amino acids have been implicated as mediators of DYN-induced rat spinal cord injury due to protective effects of selective noncompetitive NMDA receptor antagonists. Adenosine analogs, in addition to having potent vasodilatory effects, have also been shown to inhibit presynaptic release of the putative excitotoxin glutamate and to protect against ischemia-induced neuronal cell loss. Therefore, we examined potential protective effects of 2-CA and NECA on the blood flow reductions, ischemia, and HL motor deficits caused by L4-L5 spinal subarachnoid injections of 20 nmoles of DYN. Immediate preinjection of 2CA and NECA (62-250 nmoles, i.t.) failed to block the initial HL paralysis induced by DYN; however both compounds caused significant dose-dependent improvements in motor scores by 24 hr postinjection. In contrast, the spinal cord blood flow reductions (measured by radiolabeled microspheres) and ischemia (reflected by three-fold elevations in CSF lactic acid concentrations 20 minutes after injection of 20 nmoles of DYN) were both unchanged by these compounds. Thus, through mechanisms independent of their vascular effects, these adenosine analogs protect against DYN-induced spinal cord injury.

23.7

THE COMBINATION OF DEXTROMETHORPHAN AND PHENYTOIN HAS POTENT ANTI-ISCHEMIC PROPERTIES. C. Yang*, P.H. Schwartz, H. Hattori*, D.G. Fujikawa, A.M. Morin and C.G. Wasterlain. Epilepsy Res. Lab., V.A. Med. Ctr., Sepulveda, CA. 91343 and Dept. of Neurology, UCLA Sch. of Med., Los Angeles, CA 90024.

Dextromethorphan (DM) and phenytoin (PHT) potentiate each others binding, and both have some neuroprotective properties, yet the anti-ischemic effects of their combination have never been studied. We treated 4 groups of 10 Wistar rats aged 7 days by bilateral carotid ligation under methoxyflurane anesthesia, followed by exposure to an 8% O_2 atmosphere for 1 hour. Three days later the brains were perfused-fixed and sectioned. The surface of infarcted neocortex was measured on a computerized image analysis system and the severity of neuronal necrosis was graded (0-5+ scale). Rats were pre-injected with saline (group 1), DM 20mg/kg (group 2), PHT 50 mg/kg (group 3) or DM & PHT (group 4). The mean surface of neocortical infarct was 9.6 mm^2 ± 3.9 (gr. 1), 6.7 ± 3.9 (gr. 2), 3.5 ± 3.5 (gr. 3), and 0 (gr. 4). Necrosis was graded 2.8 ± 0.6 (gr. 1), 2.2 ± 0.4 (gr. 2), 0.5 ± 0.3 (gr. 3, $p<.01$) and 0 (gr. 4, $p<.01$). These data suggest that the combination of dextromethorphan & phenytoin has powerful anti-ischemic properties in newborn rat neocortex.

23.8

EFFECT OF THE NMDA ANTAGONIST DEXTRORPHAN ON NEUROLOGICAL FUNCTION 24 HOURS AFTER FOCAL CEREBRAL ISCHEMIA. D. Kunis, G. Steinberg, R. DeLaPaz*, and A. Poljak*

The non-competitive NMDA antagonist dextrorphan (DX) has been shown to protect against focal cerebral ischemia when ischemic neuronal damage or ischemic edema is measured at 5 1/2 hours post-ischemia (Steinberg, Stroke, 1989, in press). We tested the ability of DX to protect against clinical stroke, as well as infarct and edema at 24 hours after cerebral ischemia in a rabbit model. Anesthetized rabbits underwent occlusion of the left internal carotid and anterior cerebral arteries with induced hypotension for one hour, followed by 23 hours of reperfusion. One hour prior to occlusion they were loaded with either i.v. DX (15 mg/kg) followed by 15 mg/kg/hr for the next 5 hours or an equivalent volume of normal saline. Anesthesia was terminated with the start of reperfusion. Animals were scored for neurological deficits at 24 hours post-ischemia (scale 0-13), sacrificed and their brains analyzed.

Compared with the controls, DX treated rabbits had a better clinical grade (1.4 vs. 3.8, p=.2), less infarct (13.1% vs. 27.1%, p=.08) and reduction in ischemic edema (14.7% vs. 26.5%, p=.24), but none of these differences reached statistical significance. One DX animal died at 22 hours and one control died at 5 hours post-ischemia. DX treated rabbits were slower to recover from anesthesia than the controls. Despite the lack of statistical significance between groups, our results suggest a trend towards DX protection against neurological deficit and cerebral injury after focal ischemia. Failure to attain significance may be due to 1) adverse systemic effects of DX; 2) discontinuation of DX infusion after 5 hours; 3) severity of the ischemic insult; or 4) large variance within groups.

23.9

DEXTROMETHORPHAN FAILS TO IMPROVE OUTCOME FOLLOWING SPINAL ISCHEMIA IN THE RABBIT. A. Martinez-Arizala, D. D. Rigamonti, J.B. Long, E.E. Echevarria*, J.M. Kraimer*, and J. W. Holaday. Dept. of Med. Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307

Excitatory amino acid transmission, specifically at the NMDA receptor, has been implicated in the pathophysiology of ischemic CNS injury. Recent evidence suggests that the D-opioid dextromethorphan (DM), which can block the NMDA receptor ion channel, is neuroprotective in in-vitro and in-vivo models of CNS ischemia. In the present study, we examined the effects of DM in a model of spinal ischemia in the rabbit. Anesthesized male N-Z rabbits were implanted with a ligature around the infrarenal aorta. The following day, the conscious animals were subjected to 25 min of spinal ischemia, and five minutes after reperfusion they were randomly treated with either DM (n=11; 5 mg/kg i.v. - bolus and infusion), DM (n=10; 10 mg/kg i.v. - bolus and infusion) or saline (n=10). Hindlimb motor function was graded on a 0-5 scale. By six hours post-reperfusion, all groups exhibited similar recovery of motor function. However, this initial recovery was progressively lost such that, at 48 hours, the neurological scores were not different among the groups. In addition, mortality was higher in the DM 10 mg/kg group (6/10 died), when compared to the DM 5 mg/kg group (2/11) or the saline group (3/10). These results indicate that when administered after completion of the ischemic insult in the doses used for these experiments, DM failed to protect against the secondary deterioration of function associated with this model of spinal ischemia.

23.10

ADMINISTRATION OF GLYCINE ANTAGONISTS, HA-966 AND 7-CHLOROKYNURENIC ACID REDUCE ISCHEMIC BRAIN DAMAGE IN GERBILS. J.B. Patel, L.E. Ross*, B. Duncan*, M. Asif*, A.I. Salama and M. Valerio*. Dept. of Pharmacology, ICI Pharmaceuticals Group, ICI Americas Inc., Wilmington, DE 19897.

HA-966 (HA) and 7-chlorokynurenic (7-cl) acid have been shown to inhibit N-methyl-D-aspartate (NMDA) responses via selective antagonism of the modulatory glycine site on the NMDA receptor/ion channel complex. Several NMDA antagonists (e.g., AP-7, CPP, MK-801) have been reported to reduce ischemic brain damage in experimental models. Here we examined the effects of HA and 7-cl on cerebral ischemia induced by bilateral carotid occlusion (10 min) in female gerbils with reference to neuropathological and behavioral (motor activity) changes. Motor activity was assessed 24 hrs and 4 days post ischemia; brains were removed 4 days post ischemia. Drugs were administered intraperitoneally 45 min prior to and immediately post occlusion. As expected, MK-801 (2.0 mg/kg) exhibited greater than 70% protection of damage in hippocampal area. Likewise, HA (10.0 mg/kg) and 7-cl (20.0 mg/kg) produced approximately 60% protection. The ischemia-induced increase in motor activity was also attenuated by these agents, suggesting a restoration of function. These results suggest that a glycine antagonist may be useful in protecting against ischemia-induced damage.

23.11

MK-801, A NONCOMPETITIVE NMDA RECEPTOR ANTAGONIST, DOES NOT PROTECT AGAINST NEURONAL DAMAGE IN THE RAT BRAIN FOLLOWING CEREBRAL ISCHEMIA. B. Nellgård*, J. Gustafson*, A. Hansen*, M. Lauritzen, T.Wieloch* (SPON: M. Lauritzen), Laboratory for Experimental Brain Research, Research Dept. 4, Lund University Hospital, S-221 85 Lund, Sweden. Dept. of Physiol, Panum Institute, University of Copenhagen, Denmark.

Glutamate has been proposed to induce neuronal damage in the hippocampal CA1 region following transient periods of cerebral ischemia, and in some ischemia models competitive and noncompetitive NMDA receptor antagonist have proven cerebro-protective. Ten to 15 min of transient cerebral ischemia induced by bilateral common carotid occlusion combined with hypotension (2-VO), leads to neuronal damage in the hippocampus, neocortex and striatum. Using this model, the effects of MK-801 a noncompetitive NMDA receptor antagonist on ischemic damage was studied. Since MK-801 inhibited spreading depression in the range 0.1-10 mg/kg i.v., a dose of MK-801 was chosen in this range and given either postischemia (post) or before ischemia (pre). In the study 120 animals were used, in the following experimental groups (n=6):

10 min 2-VO isch: 0.1mg/kg i.v. post; 0.1mg/kg i.v.+0.4mg/kg diazepam post; 0.3mg/kg i.p. pre; 1mg/kg i.p. pre; 1mg/kg i.p.+0.4 mg/kg diazepam pre; 3mg/kg i.p. pre; 3mg/kg i.p. pre+1mg/kg/h i.v. for 6h post.

15 min 2-VO isch: 5 mg/kg i.p. pre; 5mg/kg i.p. post; 10 mg/kg i.p. pre.

Cardiac arrest isch: 0.3mg/kg pre; 0.6mg/kg post. Control: 8 groups.

In no experiment was there any significant difference in the extent of neuronal necrosis between a treated group and the appropriate control group.

Conclusion: Glutamate antagonists are not effective in ischemia where complete energy failure has ensured, and where no postischemic complications are evident (hypotension, neuronal hyperactivity). In focal ischemia, and hypoglycemia where some energy production prevail the antagonists may be cerebro-protective.

Supported by United States PHS (NS 25302) and Swedish MRC (14X-08644).

23.12

POSTISCHEMIC TREATMENT WITH OLIGO-PROSTAGLANDIN B_1 (DI- AND TRI- CALCIPHOR) IN GERBILS. D.v. Lubitz, A.E. Kalenak, T.M. Devlin, (Spon. M.C. Kennedy) Dept. of Biol. Chem., Hahnemann University, School of Med., Phila., PA 19102

Injection of the trimer of 16,16'-dimethylPGB$_1$ (Tricalciphor) at 10 mg/kg improves survival of brain ischemia in gerbils. Different concentrations of Tricalciphor and Dicalciphor (dimer) administered 5 min plus 24 hrs postischemia were compared. Brain ischemia was induced in 225 gerbils by bilateral carotid occlusion for 20 min. Body temp., MABP, BPM and blood 02 were monitored during ischemia. Treated animals were injected i.p. with either drug at 2,5,10 or 15 mg/kg at 5 min and 24 hrs postischemia. Controls received the vehicle. Survival was monitored for 14 days.

For both Dicalciphor and Tricalciphor, the 10 mg/kg injections were most effective (68% and 65% survivors respectively vs. 38% for controls, $p > 0.03$). Other concentrations were beneficial up to 4 days post-ischemia; thereafter, the statistical reliability of survival declined. The chemically simpler and better defined Dicalciphor is as effective as Tricalciphor and we believe that Dicalciphor is more advantageous in postischemic interventions. (Supp. by ONR).

23.13

GM1 GANGLIOSIDE REDUCES Ca++ LOADING & BEHAVIORAL DYSFUNCTION IN FOCAL CORTICAL ISCHEMIA. C.G. Wakade, V.A. Bharucha*, A. Tagliavia*, S.P.Mahadik and S.E. Karpiak. Div Neurosci NYS Psychiat Inst, Depts Psychiat, Biochem & Mol Biophys, P&S, Columbia U, NY, NY 10032.

We are studying the protective effects of GM1 ganglioside on biochemical & behavioral dysfunctions/losses associated with focal cortical ischemia. Na+, K+ & Ca++ levels have been studied in primary & peri-infarct cortical areas after ischemia insult. Also, rats were monitored for activity levels, and, behavior on pole grasping/balancing and inclined plane tasks. Rats received GM1 injections immediately after the MCAo+CCAo procedure and daily for the experiment's duration. After 3 days the saline treated rats had Ca++ levels of 250±40 mmoles/gr in the primary infarct area. In GM1 rats (30mg/kg/day i.m.) these Ca++ levels were reduced by 50%. In sham controls Ca++ levels = 10mmoles/gr.

One day after ischemia GM1 & saline treated rats became hyperactive, and had significantly reduced performance scores on the pole and plane tasks. However 2-3 days after ischemia, GM1 treated rats showed significantly reduced levels of hyperactivity and markedly improved performance on the pole & plane tasks as compared to saline controls.Three days after ischemia the activity levels of GM1 rats were almost identical to those of sham controls. GM1 rats continued to show significantly improved performance on the pole and plane tasks as compared to saline treated animals. [NINCDS NS-2525856].

EFFECTS OF ANESTHETIC AGENTS AND ARTERIAL PCO2 IN FOCAL CEREBRAL ISCHEMIA. J.L. Browning, M.L. Heizer* and D.S. Baskin*. Dept. of Neurosurgery, Baylor College of Medicine, Houston, TX 77030.

We studied the effects of halothane (Hal), α-chloralose (α-C) and arterial pCO2 on infarct size and CSF β-endorphin (β-E) levels in a model of focal cerebral ischemia. Cats were anesthetized with either 1.15% Hal or 3% α-C. A cannula was inserted into the cisterna magna for withdrawal of CSF. Arterial pCO2 was maintained at 28-35 mm Hg (LO) or 55-65 mm Hg (HI). Unilateral focal cerebral ischemia was induced by transorbital occlusion of the middle cerebral, anterior cerebral and internal carotid arteries. Samples of CSF were withdrawn prior to ischemia and at 2,4 and 6 hours afterwards. At six hours post-occlusion the animal was sacrificed. The brain was removed, sliced and stained with 2,3,5 triphenyltetrazolium chloride. Increased pCO2 caused a significant increase in infarct size irrespective of type of anesthetic. Hal anesthesia resulted in ipsilateral hemisphere infarct sizes of 32±7% (LO) and 45±7% (HI) while α-C yielded infarct sizes of 31±8% (LO) and 48±3% (HI). Thus, arterial pCO2 should be controlled in order to produce consistent infarct size. The effects of anesthetic, infarct size and time post occlusion on β-E levels will be presented. These results suggest that anesthetic technique may have a significant effect in focal cerebral ischemia.

COMBINED TREATMENT WITH DOPAMINE AND NMDA RECEPTOR ANTAGONISTS PROTECTS AGAINST ISCHEMIC DAMAGE. M.Y.-T. Globus, W.D. Dietrich, R. Busto, I. Valdes*, and M.D. Ginsberg. Cerebral Vascular Disease Research Center, University of Miami, School of Medicine, Miami, FL, 33101.

The release of both dopamine and glutamate is involved in ischemic neuronal death. In this study we evaluated whether combined antagonist therapy aimed at both the NMDA and the dopamine sites would attenuate postischemic damage. Rats were pre-treated with MK-801 (5 mg/kg), SCH-23390 (2.5 mg/kg), sulpiride (10 mg/kg), MK-801 + SCH-23390 or MK-801 + sulpiride. They were subjected to 10 min of bilateral carotid occlusion plus systemic hypotension. Three days later, normal neurons were counted in the medial, middle and lateral sub-regions of the CA1 hippocampus. Dopamine antagonists alone failed to confer protection, and MK-801 produced a moderate effect in lateral sub-region. No additive protection was demonstrated with the combined treatment of MK-801 and D-2 antagonist (sulpiride). However, the combined treatment with MK-801 and D-1 antagonist (SCH-23390) was markedly protective in all CA1 regions. The numbers (mean ± SE) of preserved neurons in the medial, middle and lateral areas were 84 ± 23 (normal = 131 ± 5), 124 ± 15 (normal = 126 ± 6) and 137 ± 8 (normal = 137 ± 7), respectively. This results support the hypothesis that both dopamine (through D-1 receptors) and glutamate (through NMDA receptors) are detrimental in ischemia, and combined pharmacotherapy may have potential in the clinical management of cerebrovascular disorders.

23.16

RS-8359, A REVERSIBLE AND SELECTIVE INHIBITOR OF MAO-A, AMELIORATES ISCHEMIA-INDUCED BRAIN DAMAGES. N. Iwata*, K. Kobayashi*, M. Kozuka*, K. Kato*, T. Tonohiro*, K. Yoshimi* and Y. Kubo* (SPON: T. Kaneko) Biol. Res. Labs., Sankyo Co., Tokyo 140, Japan.

Since monoamines are reduced in the ischemic brain, effects of RS-8359((±)-4-(4-cyanoanilino)-7-hydroxycyclopenta(3,2-e)pyrimidine), a new selective and reversible inhibitor of MAO-A (Ki= 2.9×10^{-7}M) and an inhibitor of c-AMP phosphodiesterase (PDE) whose IC50 value was the same as that of theophylline, were studied upon ischemia-induced brain damages. Brain ischemia was made by occlusion of 4-vessels (rat) or bilateral common carotid arteries (gerbil) for a short term. In these animals, RS-8359 ameliorated passive avoidance tasks impaired by the ischemia at doses which elevated monoamine levels in the brain (10-30 mg/kg, PO), accompanied with mitigation of delayed neuronal death in the hippocampus. RS-8359 also improved erythrocyte deformability like some other inhibitors of c-AMP PDE, and improved hypoperfusion of the local cerebral blood flow (LCBF) after the ischemia. Thus RS-8359 ameliorated ischemia-induced some brain damages probably due to restoration of monoamines in the brain and increase of the LCBF.

23.17

PROTECTION AGAINST ISCHEMIC DAMAGE IN THE RAT BRAIN BY AN ALPHA-2-ANTAGONIST GIVEN POSTISCHEMIA. T. Wieloch*, I. Gustafson*, E. Westerberg* (SPON: J. Storm-Mathisen), Laboratory for Experimental Brain Research, Research Dept. 4, Lund University Hospital, S-221 85 Lund, Sweden

Ten minutes of transient cerebral ischemia induced by bilateral common carotid occlusion combined with hypotension, induces 85 % neuronal necrosis in the CA1 region of the hippocampus and 7 % damage in the cortex, as determined by histological examination one week following the insult. Lesions of the nc. locus coeruleus increase ischemic neuronal damage in the hippocampus.

Idazoxan is an alpha-2-adrenoceptor antagonist that enhances the activity of the LC neurons and increases the release of noradrenaline (NA). When given i.v. as a bolus of 0.1mg/kg immediately after a transient 10 min ischemia period and then continuously for 6 h as an infusion 10ug/kg/min, idazoxan decreased the damage in the hippocampus to 22 %. No significant protective effect was seen when idazoxan was given as a bolus dose 0.1 mg/kg immediately following ischemia. When given 30 min after the insult and for an additional 24 h the protective effects was less marked and the damage decreased from 82 % to 54 %. Idazoxan did not displace [^{3}H]glutamate or [^{3}H]MK-801 from 6um brain slices, and is thus not a glutamate antagonist.

Conclusions:

1. Idazoxan may be protective by enhancing the release of NA thereby stimulating the inhibitory effect of NA at postsynaptic sites.

2. Dispite the delayed neuronal damage observed by light microscopy 48h after the ischemic insult, cellular processes occuring during first hours postischemia are crucial for induction of the necrotic processes.

3. Alpha-2-adrenoceptor antagonists may be a new class of cerebro-protective drugs that are approved for clinical use.

Supported by USPHS (RO1-25302).

SYNAPTOSOMAL UPTAKE AND METABOLISM OF TRYPTOPHAN IN CEREBRAL ISCHEMIA. C. Chang*, K. Kumami* and M. Spatz Lab. of Neuropathology and Neuroanatomical Sciences, NINDS, NIH, Bethesda, MD 20892

The postischemic persistent disturbance of 5-HT in the brain is associated with an increased content of free tryptophan. To further evaluate the mechanism responsible for these observations we investigated the effect of ischemia on synaptosomal uptake of tryptophan and its conversion to 5-HT and 5-HIAA.

Cerebral ischemia was induced in gerbils by bilateral carotid artery occlusion for 15 min with and without 1 hr release. Tryptophan, 5-HT and 5-HIAA content were simultaneously measured (HPLC) in cerebrocortical synaptosomes prior to and after tryptophan addition 5μM/mg protein) according to Wolf and Kahn method (J. Neurochem. 46: 61, 1986).

Ischemia alone had no effect on the intrasynaptosomal uptake of tryptophan and its conversion to 5-HT and 5-HIAA. The 5-HT and 5-HIAA remained significantly decreased (33%) as compared to controls (100%). In postischemia, intrasynaptosomal uptake and the increase in the content of 5-HT and 5-HIAA were significantly lower (50%) than in controls. However, the percentage of indolamines formed from the exogenous added tryptophan was the same in both groups. These findings indicate that the attenuated intrasynaptosomal content of 5-HT is not due to inability of tryptophan to be converted to 5-HT.

FLUMAZENIL PREVENTS MIDAZOLAM INDUCED PROTECTION AGAINST ANOXIC DAMAGE IN THE RAT HIPPOCAMPAL SLICE. A.E. Abramowicz*, I.S. Kass, G. Chambers*, and J.E. Cottrell*, Department of Anesthesiology, SUNY Health Science Ctr., @ Brooklyn, Brooklyn, NY 11203.

We are examining the mechanism of benzodiazepine protection of neurons against anoxic damage.

The evoked population spike in the CA1 region of the rat hippocampal slice recovers little from 5 min. of anoxia (10 ± 6% of preanoxic amplitude). When midazolam 100 uM is present, the response in CA1 recovers to 63 ± 13% (p <.001). Flumazenil 10 mg/L, a competitive benzodiazepine receptor antagonist, has no protective effect on the evoked response (5 ± 5%). When added with midazolam, flumazenil abolishes the protection observed with midazolam alone; these slices recover only 5 ± 3% of the predrug, preanoxic amplitude.

Ca^{45} influx during 5 min. of anoxia was measured in normoxic and anoxic slices with and without midazolam 100 uM. The CA1 Ca^{45} uptake increases during anoxia from 5.82 ± .11 to 6.56 ± .18 nM/mg dry tissue weight (p <.001) when no drug is present. Midazolam prevents the increase in CA1 Ca^{45} uptake during 5 min. of anoxia: 4.9 ± .13 (p <.001 versus normoxic and anoxic slices).

Our results suggest that the protective effect of midazolam on CA1 pyramidal cells in vitro is benzodiazepine receptor mediated and that the electrophysiologic recovery observed correlates with reduced Ca^{45} influx during anoxia.

NICARDIPINE DOES NOT PROTECT NORMOTHERMIC GERBILS AGAINST ISCHEMIC INJURY IN HIPPOCAMPUS. V.A.Harris*, F.A.Welsh, E.S.Flamm. Div. of Neurosurg., Univ. of Penna., Phila., PA 19104.

Administration of nicardipine, an antagonist of voltage-sensitive calcium channels of the "L" type, has been reported to reduce ischemic injury in CA_1 hippocampus of the gerbil (Br. J. Pharmacol., 93:877, 1988). However, even minor degrees of hypothermia induced by drug treatment may contribute significantly to the protective effect. Therefore, we regulated brain temperature at 37°C during 5 min ischemia (bilateral carotid occlusion) and for 2 hr reperfusion in nicardipine- (1 mg/kg, i.p.) and saline-pretreated gerbils. Following recovery for 1 week, the brains were quick-frozen, and alternate thin slices were stained for histologic scoring of CA_1 injury or freeze-dried for microassay of ATP in the CA_1 zone. Both groups of gerbils exhibited maximal histologic change in CA_1 hippocampus. Further, the reduction of ATP content in the CA_1 zone was the same in nicardipine- and saline-pretreated animals. Thus, pretreatment with nicardipine did not reduce ischemic injury in normothermic animals.

INHIBITION OF NMDA RECEPTOR ACTIVATION IN HIPPOCAMPAL SLICES FACILITATES THE RECOVERY OF PROTEIN SYNTHESIS FROM DAMAGE CAUSED BY ANOXIA. A. J. Carter and R. E. Müller (SPON: C.Wehrhahn) Dept. of Pharmacology, Boehringer Ingelheim KG, Ingelheim, West Germany.

We have investigated the relationship between anoxic damage and NMDA receptor activation. Anoxic damage was assessed by measuring protein synthesis (PS) in rat hippocampal slices ([^{14}C]-lysine incorporation for 30 min in normal medium). PS was reduced after anoxia. The extent of anoxic damage and the ability to recover from it was related to the duration of anoxia. Activation of the NMDA receptor by removing Mg^{2+} potentiated anoxic damage. Removal of Mg^{2+} in the absence of anoxia also caused inhibition of PS; this effect was enhanced by adding NMDA. Although the NMDA antagonists, MK-801, PCP and N-allylnormetazocine, did not prevent the inhibition of PS measured immediately after anoxia, they did facilitate the later recovery of PS. Furthermore, they prevented the damaging effects of removing Mg^{2+} and adding NMDA in the absence of anoxia. These results indicate that activation of the NMDA receptor results in a reduction in PS, and that inhibition of NMDA receptor activation facilitates the recovery of PS after anoxic damage.

COMBINED TREATMENT WITH MK-801 AND CNQX PREVENTS ISCHEMIC NEURONAL DEGENERATION IN THE *IN VIVO* RAT RETINA. J. L. Mosinger and J. W. Olney, Washington University School of Medicine, St. Louis, MO.

Anoxia and ischemia are common causes of irreversible neuronal damage in the CNS. We have previously described a non-invasive method of producing vascular occlusion and ischemic neuronal degeneration in the adult rat retina (Expt. Neurol., in press). This method utilizes the ability of rose bengal dye to initiate clot formation in blood vessels when stimulated by intense light. We consider this a promising model for testing the ability of various drugs to block acute ischemic neuronal degeneration in the *in vivo* adult mammalian CNS.

A reproducible pattern of neuronal degeneration was induced in the rat retina using 5 min exposure to an intense light following i.v. injection of rose bengal (40 mg/kg). The typical reaction, after 1 hr, included conspicuous dendritic swelling in both the outer and inner plexiform layers and similar swelling of numerous neurons in the inner nuclear and ganglion cell layers, with early pyknotic changes in the nuclei of these cells. The acute neurodegenerative reaction was judged identical in pattern, cytopathological appearance and time course to the excitotoxic reaction typically seen in the retina following exposure to exogenous glutamate or related excitatory amino acids (EAA).

MK-801 is a powerful antagonist of the N-methyl-D-aspartate (NMDA) subtype of EAA receptor, and CNQX preferentially blocks other (non-NMDA) EAA receptors. Both MK-801 (up to 800 nmol) and CNQX (up to 100 nmol) resulted in inconsistent protection when injected intravitreally prior to induction of ischemia. However, when the two drugs were combined (320 nmol MK-801 and 80 nmol CNQX), little or no swelling or other ischemic changes occurred in either the plexiform or nuclear layers. These results are consistent with the hypothesis that ischemic neuronal degeneration in the adult rat retina is mediated by endogenous glutamate or related excitotoxins acting at both NMDA and non-NMDA receptors, and that neurons possessing multiple EAA receptor subtypes may not be protected from ischemic degeneration by an antagonist that acts at only one EAA receptor subclass. Since EAA receptor heterogeneity probably characterizes many neurons throughout the adult CNS, the relevance of our findings may extend to the rest of the CNS. PROTECTION AGAINST CEREBRAL ISCHEMIA BY THE NMDA ANTAGONIST DEXTRORPHAN IS DOSE DEPENDENT AND CORRELATED WITH PLASMA AND BRAIN LEVELS. G.K. Steinberg, J. Saleh, D. Kunis and R. DeLaPaz*, Div. of Neurosurgery, Stanford Med. Center, Stanford, CA 94305

Dextrorphan (DX), a non-competitive NMDA antagonist attenuates hypoxic neuronal injury in culture and reduces cerebral damage after focal cerebral ischemia. We tested the efficacy of post-ischemic treatment with different doses of DX. Thirty-three anesthetized rabbits underwent occlusion of the left internal carotid and anterior cerebral arteries for one hour, followed by 4 1/2 hours of reperfusion. One hour after the onset of ischemia they were treated i.v. with an infusion of varying DX doses or normal saline. Plasma DX levels were measured. After sacrifice the brains were analyzed for ischemic edema and ischemic neuronal damage (IND). A separate group of unanesthetized rabbits received similar i.v. doses of DX, measuring plasma and brain DX levels at sacrifice.

Compared with controls, the DX 15 mg/kg/hr group had significantly less neocortical IND (5.3% vs. 33.2%, p=.01) and a reduction in cortical edema (9.1% vs. 41.2%, p=.02). The DX 10 mg/kg/hr rabbits showed partial protection and DX 5 mg/kg/hr had no benefit. The protective effect of DX was correlated with plasma DX levels (r=-0.50, p<.02 for IND; r=-0.66, p<.001 for ischemic edema). Rabbits with levels >2,000 ng/ml had <12% cortical IND and <34% edema. Rabbits with levels >3,000 ng/ml showed <7% cortical IND and <11% edema. Plasma levels of approximately 2,500 ng/ml correlated with loss of the righting reflex and with brain DX levels of approximately 7,000 ng/g. These results suggest that systemic treatment with DX after the onset of focal ischemia can significantly protect against cerebral damage if adequate plasma levels of DX are achieved. The brain levels necessary to attain in vivo protection are similar to the concentrations that prevent hypoxic or NMDA-induced injury in neuronal culture.

24.1

INCREASED GABA OR DECREASED GLUTAMATE (GLU) LEVELS IN INFERIOR COLLICULUS (IC) BLOCK AUDIOGENIC SEIZURE (AGS) SUSCEPTIBILITY IN GENETICALLY EPILEPSY-PRONE RATS (GEPRs).
C.L. Faingold, S.P. Arneric, M.E. Randall* and C.A. Copley* (SPON: B.V. Manyam). Southern Illinois Univ., Dept. Pharmacol, Springfield, IL 62794.
Reduced effectiveness of GABA and increased release of excitant amino acids (EAAs) in the IC are suggested to be important in initiation of AGS in the GEPR (Faingold, C.L. **Gen. Pharmacol.** 19:331, 1988). Microinjection of GABA agonists or EAA antagonists into the IC of the GEPR blocks AGS. Microinjection of NMDA or bicuculline into the IC of normal rats induces AGS susceptibility (Millan, M.H. et al., **Exp. Neurol.** 91:634, 1986). Exogenously-applied GABA and GABA-mediated acoustically evoked inhibitory responses are less effective in IC neurons of the GEPR (Faingold, C.L. et al., **Exp. Neurol.** 93:145, 1986). This study examined the effects of microinjection into the IC of gabaculine (GBC), which blocks GABA degradation or L-canaline (CAN), which blocks GLU synthesis, on AGS severity and amino acid levels in the GEPR IC. AGS were evoked using a bell at 122 dB SPL. AGS severity was reduced after bilateral microinjections (0.5-1 μl) of GBC (0.01- 100 μg/side) or CAN (6-50 μg) into IC. The 2 h required for onset of AGS blockade was longer than that needed with EAA antagonists or muscimol (15 min). The duration of AGS blockade was also greater, and AGS susceptibility returned by 24-48 h. Endogenous amino acids levels in IC were compared with contralateral IC micropunches (1.6 mm) taken 90 min after unilateral GBC or CAN microinjection, using HPLC methods. After microinjection of GBC (10 μg) GABA levels rose significantly ($p < .05$) to 202% of control levels [47.4±5.8 (SEM) nmol-/mg protein]. After microinjection of CAN (50 μg) GLU levels decreased below control levels (177.6±21.6), but this change was not significant, probably because of the large metabolic pool of GLU. Slices (0.5 mm thick) were taken from IC, and release of GLU was examined in the presence of 10^{-4} M CAN. Potassium-evoked release of endogenous GLU fell significantly ($p < .05$) to 43% of control (538±36 pmol/mg protein/5 min). **CONCLUSION:** These findings further support an important role of reduced effectiveness of GABA and increased EAA transmission in the IC in the initiation of AGS in GEPRs. (Support: NIH NS 21281, NS 13849)

24.2

INFUSIONS OF GABA AGONISTS OR 2-APH INTO AMYGDALA (AMY) OR MEDIAL GENICULATE (MGB) REVERSIBLY REDUCE SEIZURE DURATION AND CLONUS AFTER REPEATED AUDIOGENIC SEIZURES (AGS) IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR-9).
D.K. Narituku, L.B. Meçozzi,* M.E. Randall,* C.L. Faingold.
Southern Illinois University Sch Med, Springfield, IL, USA.
GEPR-9s display AGS with tonic seizures and hindlimb extension (HLE). After repeated AGS, seizure duration increases with appearance of cortical polyspike and spike-wave activity. Prolongation of seizures occurs after HLE during clonic phase, which is absent before repeated AGS (Naritoku, DK, et al, **Soc. Neurosci. Abs.**, 14:252, 1988). Bilateral microinfusions of muscimol (MUS) (.03 μg), baclofen (BAC) (.001 μg) or 2-amino-7-phosphonoheptanoate (2-APH) (.90 μg) were performed in AMY or MGB after repeated AGS. There was a >50% reduction of mean clonus duration with 2-APH infusions into MGB and nearly total reduction after BAC or MUS. In addition, spike-wave activity was markedly reduced in duration or totally absent. The cortical epileptiform abnormalities did not persist after the end of seizure behavior. With AMY infusions there was an approximate 50% reduction in the mean duration of clonus ($p \leq .01$) following BAC or 2-APH infusions, with almost complete suppression after MUS infusion. The duration of cortical spike activity was reduced by about 50% ($p \leq .01$) with MUS, BAC or 2-APH infusions. Unlike MGB infusions, polyspike (without spike-wave) activity persisted after the end of behavioral seizure following AMY infusions. After AMY or MGB infusions, the seizures resembled those seen before repeated AGS. There were no changes in HLE duration with infusions at either site. Clonus and epileptiform EEG activity returned to the preinfusion patterns by 24 hours after microinfusions. **CONCLUSION:** The data suggest that AMY and MGB are involved in the progressive seizure severity increase in GEPR-9s during repeated AGS, and may participate in the neuronal network subserving the clonic phase following HLE. MGB appears to be crucial for seizure severity increases produced by repeated AGS, whereas the AMY may be critical for behavioral but not EEG severity increases. The differential effects of infusions into AMY and MGB on the cortical epileptiform activity suggest that discrete seizure components involved in increases in seizure severity may be identified. (Support NIH NS 21281, SIU-CRC)

AUDITORY BRAINSTEM RESPONSES (ABRs) AND EFFECTS OF MICRO-INJECTION INTO INFERIOR COLLICULUS (IC) OF AN EXCITANT AMINO ACID (EAA) ANTAGONIST OR GABA AGONIST ON AUDIOGENIC SEIZURES (AGS) IN THYROID DEFICIENT (THX) OR GENETICALLY EPILEPSY-PRONE RATS (GEPRs).
D.L. Patrick* and C.L. Faingold. (SPON: H. R. KONRAD) Dept. Pharmacol. So. IL. Univ. Sch. Med., Springfield, IL 62794.
Neonatally THX rats exhibit cochlear damage and are susceptible to AGS (Van Middlesworth,L. and Norris, C.H. **Endocrinology** 106: 1686, 1980). GEPRs also display AGS and cochlear damage and are THX during development (Penny, J.E., et al., **Life Sci.** 39:887, 1986; Mills, S.A. and Savage, D.D., **Epilepsy Res.** 2:102, 1988). EAAs in IC are critically involved in AGS initiation in GEPRs (Millan M.H. et al., **Exp. Neurol.** 91:634, 1986; Faingold, C.L. **Gen. Pharmacol.** 19:331, 1988). This study examined ABRs and effects of microinjection into IC of a competitive EAA (NMDA) antagonist, 2-amino-7-phosphonoheptanoate (2-APH), or a GABA agonist, muscimol, in GEPRs and THX rats. AGS severity was tested using a bell (122 dB SPL, for 60 sec or until AGS onset). ABRs were examined under ketamine [1024 clicks (0.1 msec) at 8/sec, vertex and mastoid electrodes (nuchal ground)]. The dosage of propylthiouracil (PTU) (0.0075% day 0-19) that produced 100% AGS (with clonus) resulted in a mean ABR threshold of 81 ± 5.5 dB. Higher doses of PTU increased ABR thresholds to a greater extent but decreased AGS severity. Bilateral infusion of 2-APH (in 0.5 μl) into IC completely blocked AGS in THX rats at 25 nmol. The dose required to suppress AGS in GEPRs was 1 nmol (Faingold C.L. et al., **Exp. Neurol. 99:678, 1988**). Microinjection of muscimol (0.12 μg) did not block AGS in THX rats, but 1/4 of this dose produced a significant reduction of AGS severity in GEPRs (Browning, R.A. et al., **Epilepsy Res.** 3: 1989 in press). **CONCLUSIONS:** These data suggest that only a restricted range of ABR threshold elevations results in maximal AGS in THX rats, which is similar to observations in GEPRs (Faingold C.L. et al., **Epilepsia** 28:583, 1987). Since, the sensitivity for blockade of AGS in IC is considerably less in THX rats, cochlear damage may be more important in AGS of THX rats as compared to GEPRs wherein IC may be more critical in AGS control. (Support: NIH NS 13849, 21281)

24.4

DEVELOPMENTAL HEARING IMPAIRMENT AND AUDIOGENIC SEIZURE (AGS) SUSCEPTIBILITY IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR).
C.E. Reigel, M.E. Randall* and C.L. Faingold. Dept. of Basic Sci., Univ. of Ill. Col. of Med. at Peoria, Peoria, IL 61656 and Dept. of Pharmacology, Southern Ill. Univ. Sch. of Med., Springfield, IL 62794.
Studies in mice have suggested that AGS susceptibility may be related to a hearing deficit at a critical developmental period. Recently, Faingold et al. (Epilepsia 28:583, 1987) reported that adult AGS susceptible GEPRs possess elevated auditory brainstem response (ABR) thresholds. However, hearing impairment in adult GEPRs could have developed long after the appearance of AGS susceptibility and thus could be unrelated to AGS susceptibility. The present study examined whether hearing deficits co-exist developmentally with AGS susceptibility in immature GEPRs. ABR thresholds were determined in both moderate seizure (GEPR-3) and severe seizure (GEPR-9) pups at 14, 21 and 30 days of age. Day 14 just precedes the initial appearance of AGS susceptibility in the GEPR. GEPRs first exhibit 100 percent incidence of AGS at 21 days and near adult patterns of AGS at 30 days of age. Animals were anesthetized with pentobarbital and electrodes were placed subdermally at vertex and mastoid (nuchal ground). Clicks (0.1 ms duration, 1024 presentations) were presented at 8/sec. ABR thresholds were elevated in both GEPR-3s and GEPR-9s over controls at 14 days of age (prior to AGS susceptibility). At 21 and 30 days of age, ABR thresholds remained elevated in GEPR-3s and GEPR-9s, however, ABR thresholds were more elevated in GEPR-3s than in GEPR-9s, consistent with the findings of Faingold et al. (1987) in adult GEPRs. GEPR-9 progeny that were not susceptible to AGS exhibited normal ABR thresholds at 21 and 30 days of age. Collectively, these results support the hypothesis that a developmental hearing deficit contributes to AGS susceptibility in the GEPR. (Supported by NIH grant NS 13849.)

24.5

DECREASE IN LOCUS COERULEUS 3H-IDAZOXAN BINDING SITES IN GENETICALLY EPILEPSY-PRONE RAT.
S Razani-Boroujerdi, DY Tso-Olivas*, TJ Hoffman*, GK Weiss*, and DD Savage. Depts. Pharmacology and Physiology, Univ. New Mexico Sch. Med., Albuquerque, NM, 87131.
Widespread deficits in a variety of neurochemical markers for the noradrenergic (NE) system have been reported in Genetically Epilepsy-Prone (GEPR) rats. These NE system deficits may be a consequence of neonatal hypothyroidism (NH). NH, which is profoundly detrimental to the development of monoamine neurotransmitter systems, has been reported in both GEPR-3 and GEPR-9 rats. We have observed that propylthiouracil (PTU)-induced NH causes a significant reduction in 3H-Idazoxan (RX) binding to $\alpha 2$ adrenergic receptors in the locus coereleus (LC). Given the effect of NH on LC 3H-RX binding, we investigated the possibility that LC 3H-RX binding would be decreased in GEPR-3 and GEPR-9 rats.

Coronal sections of brainstem containing the LC were collected from 31-day-old non-epileptic Sprague-Dawley control, GEPR-3 and GEPR-9 rats. The sections were incubated with 20 nM 3H-RX in the absence and presence of 10 μM phentolamine and specific 3H-RX binding determined by quantitative autoradiography. LC specific 3H-RX binding was decreased significantly in both GEPR-3 and GEPR-9 rats compared to controls. Saturation of binding studies indicated that the total number of binding sites was decreased by 23% and 17% in GEPR-3 and GEPR-9 rats respectively. No changes in the affinity constant were observed. The decrease in total number of LC 3H-RX binding sites in GEPR rats was not as great as that observed in PTU-treated rats. This difference may be due in part to the fact that GEPR rats experience a degree of hypothyroidism intermediate to that produced by PTU treatment. Given evidence that LC $\alpha 2$ receptors are located on NE cell soma and nerve terminals, these results would suggest a possible decrease in the number of LC neurons and/or nerve terminal density in GEPR rats. Alternatively, this alteration could decrease presynaptic $\alpha 2$-mediated inhibition of NE release, a mechanism that might compensate for other presynaptic NE deficits. (Supported by NS23262 and RR08139).

24.6

EFFECTS OF EXCITANT AMINO ACID (EAA) ANTAGONISTS ON AUDIOGENIC SEIZURES (AGS) DURING ETHANOL WITHDRAWAL (ETX) AND IN GENETICALLY EPILEPSY-PRONE RATS (GEPRs).
A. Riaz and C.L. Faingold. Dept. Pharmacol. Southern Illinois Univ. Sch. Med. Springfield, IL 62794
Alterations in EAA action are observed following chronic administration of ethanol (Yool, A.J.and Groul, D.L., **Brain Res.** 420:205, 1987). Enhanced EAA neurotransmission in the inferior colliculus (IC) has been suggested to play a crucial role in the initiation of AGS (Faingold, C.L. **Gen. Pharmacol.** 19:331, 1988). Microinjection of NMDA into the IC in normal rats induces AGS susceptibility, and infusion of the competitive NMDA antagonist, 2-amino-7-phosphonoheptanoate (2-APH), into the IC or pontine and mesencephalic reticular formation (RF) blocks AGS in the GEPR (Millan, M.H. et al., **Exp. Neurol.** 91:634, 1986; Faingold, C.L. et al., **Exp. Neurol.** 99:678, 1988). In the present study guide cannulae were implanted bilaterally over the IC or RF (gigantocellular nucleus) stereotaxically. Drugs were infused (0.25 μl/min) for 2 min, and AGS testing involved presentation of a bell (122 dB SPL) for 60 sec or until onset of AGS. Effects of a quinoxalinedione non-NMDA antagonist (CNQX) into the IC were compared with those of 2-APH on AGS in GEPRs. CNQX (20 nMol/side) completely blocked AGS in GEPRs at 15 min post-infusion (with recovery by 24 h), while 10 nMol was ineffective. In the ETX study Sprague-Dawley rats were implanted with guide cannulae over the IC or RF. Ethanol was given intragastrically (9-15 g/kg/day) in divided doses given every 8 h. At the end of day 4, ethanol was withdrawn. Animals exhibiting AGS at 10 h received infusions of vehicle (phosphate buffer or dimethylsulfoxide) into the IC. No effects on AGS incidence or severity was observed with vehicle infusions. This was followed by infusion of 2-APH. The incidence of all behavioral components of AGS were significantly reduced with 2-APH (1 nMol) in IC and in RF (15 nMol). These findings support a role of enhanced EAA neurotransmission in the IC and RF in determining the susceptibility to AGS during ETX and in the GEPR. NMDA antagonists exerted more potent anticonvulsant effects in both AGS models. (Support NIH NS 13849, NS 21281)

INFERIOR COLLICULUS (IC) NEURONAL RESPONSES DURING AUDIOGENIC SEIZURE (AGS) ONSET IN BEHAVING GENETICALLY EPILEPSY PRONE RATS (GEPRs). C.A. Boersma Anderson* and C.L. Faingold. Dept. Pharmacol., So. IL. Univ. School Medicine Springfield, IL 62794
The IC is critically involved in AGS initiation in GEPRs (Browning, R.A., **Life Sci.** 39:856, 1986; Faingold, C.L. **Metab. Brain Dis.** 2:81, 1987). Preictally, IC neurons in the GEPR display abnormal response patterns to acoustic stimuli with evidence of reduced acoustically-evoked inhibition (Faingold et al., **Exp. Neurol.** 93:145, 1986; Faingold, C.L. and Boersma Anderson, C.A. **Soc. Neurosci. Abs.** 14:253, 1988). The convulsions during AGS in the GEPR begin with wild running and progress to tonic hindlimb extension followed by post-ictal depression. The changes in IC neuronal firing that occur during the abrupt and violent transition to the behavioral seizure have not previously been able to be examined. In the present study microwire electrodes were chronically implanted into the IC under ketamine anesthesia, and unit activity was examined at least one week later in freely moving GEPRs during AGS onset in the absence of drugs. Responses were quantified using poststimulus time and interspike interval (ISI) histograms. The AGS-inducing stimulus consisted of 12 kHz tone bursts (60-100 msec duration, 75-105 dB SPL) presented at 2/sec. Use of the chronic microwire technique allowed recording of units during the behavioral seizure in freely moving GEPRs. Just prior to the onset of AGS, the number of neuronal responses evoked by the stimulus increased. However, at the transition to AGS, **evoked** neuronal responses fell abruptly in 61% of units (N=18) to a mean discharge rate of 1/3 of the rate observed immediately prior to AGS onset. At this time, **non**-acoustically-evoked neuronal firing (in 83.3%, of units, N=18) was greatly increased (mean, 30-fold) and large (mean, 16-fold) increases in ISIs at $\leq$ 5 msec, associated with burst firing, occurred in 89% of units. The response to the stimulus returned after AGS in all units that were held throughout the entire seizure. **CONCLUSIONS:** These data indicate that once AGS begins the firing pattern of IC units changes to reflect seizure discharge, and the time-locked response to the acoustic stimulus that evoked the seizure is temporarily lost. (Support NIH NS 13849; NS 21281)

24.8

EFFECTS OF CARBAMAZEPINE AND ANTIEPILEPSERINE ON DIALYZABLE NOREPINEPHRINE AND SEROTONIN FROM HIPPOCAMPUS OF GENETICALLY EPILEPSY-PRONE RATS. **Q-S. Yan*, P.K. Mishra, R. Burger*, P.C. Jobe and J.W. Dailey. Department of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria, Illinois 61656.**

Substantial evidence suggests that previously documented widespread deficits in norepinephrine and serotonin are integral neurochemical components of the seizure predisposition characteristic of Genetically Epilepsy-Prone Rats [GEPRs](Epil Res 3: 3, 1989). Both carbamazepine and antiepilepserine are effective anticonvulsants in GEPRs. It was of interest to determine if these drugs produce part of their anticonvulsant effects through actions on norepinephrine or serotonin. Guide cannulae for dialysis probes were stereotaxically implanted over right hippocampi of moderate seizure GEPRs (GEPR-3) and after recovery from surgery the dialysis probes were inserted. Dialysis sites were confirmed by histology. The animal was placed into a plexiglass chamber and allowed to move freely. Artificial CSF was perfused at 1 ul/min and was collected in microvials containing L-cysteine and HCl to stabilize the dialysates. Norepinephrine and serotonin were analyzed by HPLC with electrochemical detection. Either carbamazepine (45 mg/kg) or antiepilepserine (100 mg/kg) [about an ED_{90} dose of each] was given i.p after establishing basal release and dialysis was continued for 5 more hrs. Significant increases in serotonin, but not norepinephrine, were seen at the approximate time to peak anticonvulsant effect for each drug. This result is consistent with a role for serotonergic neurons in the anticonvulsant effects of both carbamazepine and antiepilepserine in GEPRs. (Supported in part by a grant from Tsumura Juntendo Fdn.)

ASPARTAME FAILS TO FACILITATE BICUCULLINE-INDUCED SEIZURES IN DBA/2 MICE. **A.F. Bettendorf*, J.W. Dailey, S.M. Lasley and P.C. Jobe.**Dept of Basic Sci, Univ of IL Col of Med, Peoria, IL 61656.

It has been proposed that aspartame facilitates seizures in man and animals because its major metabolite (phenylalanine) interferes with brain transport of neurotransmitter precursors and synthesis of monoamine transmitters (norepinephrine, dopamine and/or serotonin). This facilitation is purportedly more likely in subjects predisposed to seizures although we have been unable to detect seizure facilitation in a variety of rodent seizure models including the Genetically Epilepsy-Prone Rat. In the present study, we used DBA/2N Hsd mice because they are genetically predisposed to seizures. The convulsant dose of bicuculline in 50% of the animals (CD_{50}) was determined by giving six doses of the drug i.p. to groups of 20 mice. The CD_{50} was 3.49 mg/kg (confidence interval, 3.14-3.89). Following CD_{50} calculation, aspartame (0, 10, 30, 300 and 1000 mg/kg) or vehicle (0.5% methylcellulose & 0.1% polysorbate-80) was given by gavage to groups (25 each) of 27 day old mice. Four hours later each mouse received 3.5 mg/kg of bicuculline i.p. and was observed for 30 minutes. Incidence of convulsions with loss of righting reflex was recorded. The 10 mg/kg aspartame dose was associated with a statistically significant increase in convulsion incidence. On replication, with 58 mice per group, this increased incidence could not be confirmed. Therefore, no doses of aspartame were associated with an incidence of convulsions different from control. Thus, a wide range of acute oral doses of aspartame did not alter the severity of bicuculline-induced seizures in seizure prone subjects. (Supported by a grant from the NutraSweet Co.)

24.10

AUDIOGENIC SEIZURES IN DBA/2 MICE ARE NOT FACILITATED BY ASPARTAME. **P.C. Jobe, A.F. Bettendorf*, S.M. Lasley and J.W. Dailey.** (SPON: J.D. Lane) Dept of Basic Sciences, Univ of IL Col of Med, Peoria, Illinois 61656.

It has been suggested that aspartame might facilitate seizures because of hypothesized effects of its major metabolite (phenylalanine) on brain transport of amino acids and synthesis of biogenic amine neurotransmitters (e.g.,norepinephrine, dopamine & serotonin). The alleged facilitation is presumed to be more likely in subjects predisposed to seizure disorders. We have previously been unable to detect seizure facilitation in a variety of rodent seizure models. In a further attempt to uncover seizure facilitation, we used DBA/2N Hsd mice because they are genetically predisposed to audiogenic seizures. In these experiments, groups of 27 day old DBA/2 mice were given aspartame (doses from 5 to 2000 mg/kg) or vehicle (0.5% methylcellulose & 0.1% polysorbate-80) by gavage and then subjected to a seizure-provoking audiogenic stimulus (bells at approximately 105 dB for 30 seconds). Convulsion intensity was evaluated on a 5 point scale (0 = no response, 5 = tonus). Approximately 76% (277/366) of the mice had a score greater than 0. In three separate experiments audiogenic seizures were evaluated at 0.5, 2 or 4 hrs after aspartame or vehicle gavage. No dose of aspartame was associated with a significant alteration in convulsion intensity at any of the time points. Thus, a wide range of acute oral aspartame doses did not alter the severity of audiogenic convulsions in DBA/2 mice. (Supported by a grant from the NutraSweet Co.).

GRAFTING OF FETAL LOCUS COERULEUS (LC) TISSUE INTO THE HIPPOCAMPUS (HP) OF GENETICALLY EPILEPSY-PRONE RATS. **R.W. Clough, R.A. Browning, M.L. Lanker, P.C. Jobe, Depts. of Anatomy and Physiology, Southern Illinois Univ. Sch. of Med., Carbondale, IL 62901 and Dept. of Basic Science, Univ. of Illinois-Peoria, Peoria, IL 61656.**

Previous studies have demonstrated that the central norepinephrine (NE) system inhibits seizure behavior in genetically epilepsy-prone rats (GEPRs). Additionally, several brain regions of the GEPR brain including the HP have reduced content and uptake of NE. Furthermore, administration of NE agonists reduces the severity of seizures in GEPRs (Jobe et al., Life Sci. 39:1986). We have attempted to replace NE in the GEPR HP by transplanting tissue from the dorsal pons including the LC of 16 day PC fetal rat donors. Tissues were lowered stereotaxically into the HP using coordinates AP=-4.3 mm,V=3mm and L=3mm. At 1, 4, and 12 weeks post-surgery, rats were tested for audiogenic-induced seizures and were subsequently sacrificed for neurohistology. Seizure response scores were not altered by transplantation of LC or cortical tissue in this experiment. In each of 3 post-surgery tests, the seizure response scores of each rat was 9. Histological studies demonstrated that transplants were present in or immediately subjacent to the HP. Transplanted tissues showed no signs of encapsulation and numerous neuron profiles were present within the grafts. In each case, tissue appeared to be integrated with the HP of the host. In partial support of the present findings, Stevens et al., (Epilepsia 79:1988) have shown that adrenal medula implants into the lateral ventricle also do not alter seizure behavior in GEPR-9s. The present study suggests that the presence of NE within the HP, as delivered by transplanted locus coeruleus does not alter the expression of seizure behavior in the GEPR. Other brain areas are currently under investigation. Supported by HD23209 and the Deafness Research Foundation.

THE EPILEPTIC MUTANT *TOTTERING* SHOWS A VOLTAGE-DEPENDENT PROLONGATION OF DEPOLARIZING SHIFTS IN BURSTING CA3 PYRAMIDAL NEURONS *IN VITRO*.

S. A. Helekar and J. L. Noebels* (SPON: E. M. Barnes), Division of Neuroscience and Section of Neurophysiology, Department of Neurology, Baylor College of Medicine, Houston, Texas 77030.

The mutant mouse *tottering* (*tg/tg*) is a single locus mutation showing a gene-linked noradrenergic hyperinnervation by LC axons, and spontaneous 6 Hz electrocorticographic spike and wave seizures. In isolated mutant hippocampal slices, high extracellular $[K^+]$ (10 mM) induced field bursts in the CA3 region are significantly longer in duration than in control (+/+) slices. To study the cellular mechanisms involved in this prolonged network response, intracellular recording was carried out in CA3 pyramidal neurons under current clamp in *tg/tg* and +/+ mouse hippocampal slices. No obvious qualitative abnormality in spontaneous synaptic and spiking activity was noted under non-epileptic conditions (3 - 5 mM $[K^+]_o$). In contrast, at high $[K^+]_o$ (10 mM) using KCl filled microelectrodes, a 60 % prolongation in the mean duration of paroxysmal depolarizing shifts (PDS) was observed at membrane potentials of -40 - -50 mV in the mutant (393.43 $\pm$ 49.80 msec, n=6) as compared to the control (245.77 $\pm$ 24.17 msec, n=5, $p < 0.05$) but not at -70 - -80 mV. The voltage-dependent prolongation was also observed with K-acetate filled microelectrodes, suggesting that an artificial shift in the chloride equilibrium potential is unlikely to be a factor. In the latter recordings, 6 out of 8 mutant cells showed no post-PDS afterhyperpolarization (AHP) at -40 - -60 mV, as compared to only 1 of 6 control cells. In conclusion, a distinct abnormality in excitability is present in *tg/tg* CA3 pyramidal neurons under epileptogenic conditions. This voltage-dependent prolongation of the PDS may be produced by enhanced release of norepinephrine in the mutant. *(Supported by NIH 11595 and Basil O'Connor grant (JLN)).*

ABNORMAL DISTRIBUTION OF HIPPOCAMPAL MOSSY FIBERS IN THE EPILEPTIC (EL) MOUSE. J.E. Miyashiro* and C.R. Houser, Dept. of Anatomy and Brain Research Institute, UCLA, and VA Medical Center, Los Angeles, California 90024.

The El mouse is a genetic model of epilepsy with apparent involvement of the hippocampus. Timm's staining and dynorphin immunohistochemistry have been used to determine if there are morphological alterations of the mossy fiber path. In control, C57BL/6 mice, mossy fibers end at the junction of CA3 and CA2, but, in adult El mice that had experienced many seizures, mossy fiber staining extended beyond this border. In coronal sections of the rostral hippocampus, a narrow band of staining was present in the suprapyramidal zone of the putative CA2 and CA1 fields. At the most rostral levels, the aberrant staining was continuous with that of CA3; at slightly more caudal levels, the staining became discontinuous but persisted in the medial part of CA1. After 300-400μm, a normal pattern of Timm's staining was present. No intra- or supragranular staining has been observed. Studies are in progress to determine if the aberrant staining is unique to the El mouse or is also present in the ddY (mother) strain. Supported by NS 21908 and VA Medical Research Funds.

THE C57BL10 sps/sps MOUSE; A MODEL OF ABSENCE SEIZURES. J.G. Ortiz, A.E. Negrón*, J.E. Rosado* M.T. García*, C.S. Maldonado*, A.P. Thomas*, J. A. Moreira* and H. Heimer*; Department of Pharmacology, University of Puerto Rico Medical School, San Juan, Puerto Rico 00936

In contrast to other types of epilepsy, there are relative few models of absence seizures. C57BL10 sps/sps mouse mutants have similar behavioral and electroencephalographic characteristics to those observed in generalized absence seizures in humans. (Maxson et. al., 1983)

These animals have reduced glutamate decarboxylase activity (GAD) in cortex, midbrain and hippocampus. ^{3}H-flunitrazepam (^{3}H-Flu) binding is reduced in these areas, as well as, in the cerebellum and brainstem. In the hippocampus of sps/sps mice, the uptake and release of ^{3}H-GABA are significantly reduced when compared to that of the parent strain, SPS/SPS or to their heterozygote littermates.

These results suggest the presence of GABAergic deficits in this animal model, although how these deficits are mediate the absence seizure-like behavior remains to be clarified. STARGAZER: A NEUROLOGICAL MUTANT WITH A COMPLEX PATTERN OF INHERITED SPIKE-WAVE SEIZURES. X. Qiao*, J.L. Noebels, R.T. Bronson[1], M.T. Davisson[1], (Spon: D. Shine) Developmental Neurogenetics Laboratory, Section of Neurophysiology, Dept. of Neurology and Institute of Molecular Genetics, Baylor College of Medicine, Houston, TX 77030, and [1]The Jackson Laboratory, Bar Harbor, ME, 04609.

A new spontaneous recessive mutation, *stargazer* (stg), arising in the A/J inbred mouse strain (now on C3B6Fe F1) has been mapped to chromosome 15 between the Bld and bt loci. The neurological phenotype in the adult homozygous mutant includes mild ataxia and periodic spells of sustained neck retroflexion. Initial histopathological survey reveals no cerebellar or inner ear lesions. The electrocorticographic phenotype features frequent and prolonged (10-30 secs) episodes of 6 Hz generalized spike and spike-wave discharges (500-1000 μv) accompanied by behavioral arrest. While these seizures are virtually identical to, but more frequent than those found in the *tottering* (tg, chr. 8) mutant, a second pattern distinguishes *stargazer* from other known seizure mutants. At either the initial or terminal stage of some seizures, the spike discharge frequency accelerates to 9-11 Hz. During this period, the mouse reinitiates motor activity, resulting in a mixed electroclinical seizure type. HPLC-EC assays of eight mutant brain regions (n=11) compared with age-matched +/+ mice showed no gene-linked elevation in NE or MHPG levels as found in the tg mutant. These data illustrate a frequency-specific correlation of generalized synchronous spike discharges with ictal motor behavior, and underline the genetic and neurochemical heterogeneity of inherited diseases expressing absence seizure phenotypes.

MEGALENCEPHALY IN THE EPILEPTIC CHICKEN IS REGION-SPECIFIC AND IS ASSOCIATED WITH DECREASED NEURONAL DENSITY. D.George*, T.McConnell*, D.G.Munoz, R.D.Crawford*, (SPON:J. S.Richardson). Dept.of Pathology,University of Saskatchewan Saskatoon,Saskatchewan,S7N 0W0

The epileptic chicken is a genetic model of generalized epilepsy (Crawford RD,1983). The epileptic trait is inherited as an autosomal recessive (epi gene) in association with megalencephaly; heterozygous carriers are normal. The objective of this study is to determine the basis of the megalencephaly, and potentially of the epilepsy, which are both the result of a single abnormal gene. Bouins perfused brains of 5 epileptic and 5 carrier adult hens were compared by standard morphometric methods. We found that: 1) megalencephaly is not uniform: there is significant enlargement of some regions (telencephalon ($p<0.01$), hippocampus ($p<0.02$), archistriatum ($p<0.01$) and cerebellar cortex ($p<0.02$)),but not of others (optic tectum and nucleus rotundus); 2) in the enlarged regions that we have studied, neuron density is significantly decreased (hippocampus ($p<0.01$) and archistriatum ($p<0.05$)); 3) glial cell density in the hippocampus and archistriatum is not significantly different. These findings show regional variation in megalencephaly in the epileptic chicken; and they suggest that increased neuron size contributes to the megalencephaly, and may underlie the epilepsy.

CONTROL OF POSTURE AND MOVEMENT I

25.1

TIMING AND MAGNITUDE OF EMG ACTIVITY AT THE SHOULDER AND ELBOW FOR INITIATION OF PLANAR ARM MOVEMENTS. G.M. Karst and Z. Hasan. Dept. of Physiology, University of Arizona, Tucson, AZ 85724.

We have previously demonstrated that during the initiation of planar, reaching movements involving the shoulder and elbow joints, the sign (i.e. flexor or extensor) of the initial muscle activity at each joint is related to the target direction with respect to the forearm (ψ). Further analysis of the initial EMG activity at the shoulder and elbow has revealed that: 1) for most values of ψ, EMG activity at the shoulder precedes that at the elbow; 2) the latency between shoulder and elbow EMG onset varies systematically with ψ; and 3) this latency is positively correlated with the ratio of initial EMG magnitudes at the two joints (shoulder/elbow).

These findings suggest that the temporal aspects of the motor command may be stereotyped at the pre-motoneuronal level, while the systematic variation in EMG latency may result from an inverse relationship between the excitatory drive to a motoneuron pool and the time required to reach motoneuronal threshold.

25.2

EFFECT OF CONTEXT ON GOAL-DIRECTED ARM MOVEMENTS. J. Nativ* and J.H. Abbs (SPON: T. Allard). Speech and Motor Control Laboratories, Waisman Center, Univ. Wisconsin, Madison, WI 53706.

While many studies of human arm movements have highlighted invariant movement parameters, it appears that the context in which tasks are performed influences these relations substantially (Marteniuk et al. 1987). This study attempted to investigate systematically the role of context in simple goal-directed reaching movements by manipulating the inherent meaning, content, and surface characteristics of the object to be moved.

Four subjects performed a self-initiated rapid movement which included reaching, grasping and transporting a test object to a target position. Movement of the forearm and hand were recorded using the WATSMART 3-d system. Inherent task meaning was manipulated using both a cup and an equal sized cylinder as test objects. The content (empty versus full) and surface characteristics (natural versus slippery) of the test object also were manipulated.

The inherent object meaning (cup versus cylinder) and content influenced the time to contact and the proportion of that time associated with movement deceleration. For example, when reaching for the cup, movement time was longer than that for the cylinder ($F=16.73$ $df=1,3$ $p<.05$). Further, the addition of liquid slowed down the reaching and transport movements with the cup but not with the cylinder. Object surface characteristics influenced the transport time depending on object content; whereas a slippery surface slowed down the transport of an empty cup, it actually shortened the transport time of the full cup.

These data indicate that searches for invariant movement parameters may be premature until a richer variety of functional motor tasks are carefully investigated. (Supported in part by NIH Grants NS-16373, NS-13274 and HD-03352)

25.3

PLANNING AND CONTROL OF PREHENSION: GRASPING SCREWDRIVERS. C.L. MacKenzie, B. Sivak, and T. Iberall. Dept. of Kinesiology, University of Waterloo, Canada and Dept. of Computer Science, University of Southern California, Los Angeles.

Prehension studies examined how transport of the hand and finger posturing (grasp) depend on object characteristics and the intent of the individual (Jeannerod, 1981; Marteniuk et al.,1987). An important question in grasp planning for hand held tools such as a screwdriver is how object and task properties affect movement kinematics. Subjects were instructed to make several turns on a screw with 1 of 4 different sized screwdrivers. The screwdriver handle was available from a holder (spatially accessible) or resting on the table surface (obstacle avoidance). Videotape and 3D kinematic analyses of the initial grasp phase showed that as screwdriver size changed, so did the transport component, the posture for grasping the screwdriver (type of opposition) and how the fingers grouped together (virtual fingers). Distinctive finger posturing and wrist transport depended on whether or not grasping the handle required obstacle avoidance. Precision aspects of screwdriver weight and size modified these results. This reflects the functional coordination of grasp and transport components in prehension. (NSERC)

25.4

THE EFFECTS OF OBJECT WEIGHT ON THE KINEMATICS OF PREHENSION. P.L. Weir*, S.L. Cargoe*, R.G. Marteniuk and C.L. MacKenzie. (SPON: E. Roy). Department of Kinesiology, University of Waterloo Waterloo, Ontario, Canada, N2L 3G1.

Several intrinsic object properties affect the planning and control of transport, grasp, or both components of prehension, including: object fragility (Marteniuk et al., 1987), object size (Marteniuk et al., 1989) and object shape (Jeannerod, 1981). This study examined object weight. Subjects grasped visibly similar metal dowels (20,55,150,410 grams) in both a blocked (weights known) and random (weights unknown) order.

Three dimensional kinematic analyses of infrared emitting diodes placed on the thumb and index finger (grasp component), and the wrist (transport component) revealed that: peak aperature, peak velocity and peak deceleration occurred earlier for heavier weights; and peak aperture occurred earlier when weights were unknown than for known weights. These changes in both grasp and transport components indicate a functional linkage in achieving the goal.

25.5

PRECISION EFFECTS AND GRASP TYPES. B. Sivak and C.L. MacKenzie. Department of Kinesiology, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1.

Preliminary kinematic analyses revealed differences in transport and grasp components of prehension depending on the type of grasp: time spent after peak deceleration was relatively shorter and maximum aperture was larger for a collective than for an independent finger grasp. This study examined the effect when when precision is equated between the two grasp types. Subjects grasped dowels 2.5, 4.0 and 7.0 cm in diameter and 11.5 cm in height using a collective grasp that required no precision (CNP), a collective grasp that required precision (CP) and an independent grasp (I). For the transport component, there were no differences. For the grasp component, maximum aperture for the 2.5 cm dowel was wider both for CNP and CP compared to I. The results suggest (1) when precision is equated, the transport component does not depend on the type of grasp used (2) organization of the grasp component may reflect inherent differences in the motor system for collective versus independent grasps (small sized objects only).

25.6

THE COUPLING OF ARM AND FINGER MOVEMENTS DURING PREHENSION: PERTURBATION OF OBJECT LOCATION. Y. Paulignan*, C.L. MacKenzie, R.G. Marteniuk, and M. Jeannerod*. Laboratoire de Neuropsychologie Experimentale, INSERM U94, Bron, France and Dept. of Kinesiology, University of Waterloo, Canada.

To investigate the relation between two components of prehension, we used a visual perturbation paradigm to change the location of an object at movement onset. If transport and grasp components are independent, then changing object location should affect only transport, not grasp. Kinematic analyses of markers placed on the wrist (transport), index finger and thumb tips (grasp aperture) indicated rapid modifications for both transport and grasp components. Speed changes on the trajectory path indicated an interruption about 100 ms after the object changed location; the spatial path and aperture were modified accordingly. Subjects were unaware of these adjustments at the time they were effected. Moreover, different location changes resulted in differential relative contributions of the thumb, finger and wrist, demonstrating motor equivalence. This covariation of transport and grasp components suggest a functional synergy between the proximal and distal segments, to meet the task requirements. (Supported by INSERM, NSERC, and MRC)

25.7

IS THERE A PREFERRED COORDINATE SYSTEM FOR REPRESENTATION OF HAND ORIENTATION IN 3-DIMENSIONAL SPACE? W.G. Darling, L. Gilchrist* and T. Edholm*, Dept. of Exercise Science, University of Iowa, Iowa City, IA, 52242.

Traditionally, perception of location of the limbs in space has been attributed to information regarding joint angles provided by joint, cutaneous and muscle receptors. Recent studies have provided strong evidence that the preferred coordinate system for perception of upper limb orientation in space is in terms of angles of the limb segments relative to the line of gravity and in the horizontal plane (extrinsic coordinate system), rather than relative to the proximal body part (joint angles - intrinsic coordinate system). We have examined this same issue in terms of perception of hand orientation.

Subjects performed a perceptual matching paradigm in which the left hand and forearm were placed in position by the experimenter and the right forearm was also placed by the experimenter. With the eyes closed, the subject then matched a criterion hand or wrist angle (joint angles - flexion, abduction, pronation; hand angles - pitch, yaw, roll) by moving only the right hand. Segment positions in 3-dimensional space were recorded using a two camera WATSMART system with 3 infrared LEDs placed to represent the plane of the palm, forearm and arm (to measure pronation angles only). An overall preference for an extrinsic or intrinsic coordinate system for perception of hand position in 3-dimensional space was not observed.

25.8

ROLE OF THE RETINAL AND EXTRARETINAL FACTORS IN THE DIRECTIONAL CODING OF REACHING. V.Delreux*, S.Vanden Abeele*, M.Crommelinck* and A.Roucoux. Lab. de Neurophysiologie, Louvain Univ. Sch. of Med., B-1200 Brussels, Belgium.

The relative contribution of the retinal signal, documenting the position of the objects in visual space, and of the extraretinal factors, related to the eye and head position, to the elaboration of an internal representation of a body-centered space and to the generation of oriented goal-directed movements remains unclear. The aim of this study was to determine the respective role of the retinal and extraretinal signals in the localization of the objects in space.

Human subjects sat, facing a hemispheric screen, and were asked to move a handle in the direction of LED's presented at several positions along the horizontal meridian. The head and trunk were not allowed to move. The subjects had no visual feedback about the arm displacement. In one series of experiments, the eyes were oriented in the primary position before the movement started; in another, the eyes were deviated (15 deg) from this position, so that a given LED would yield two different retinal errors. In each of the two series, the subjects were either asked to orient their eyes towards the peripheral LED's or to keep them in the initial position. The final arm position was found to be a function of the LED's localization on the screen, when the eyes were allowed to move, and a function of the retinal error, in the immobile eyes condition.

These observations suggest that, when the eyes are not moving, a retinal frame of reference is used, whereas when the eyes can foveate the target, a head or body frame of reference is used. Foveating the target thus changes the spatial frame of reference used to generate the reaching arm movement.

25.9

EYE, HEAD AND HAND COORDINATION WHILE POINTING TO PERTURBED VISUAL TARGETS EITHER AS FAST OR AS ACCURATELY AS POSSIBLE. H. Carnahan, and R.G. Marteniuk. Dept. of Kinesiology, Univ. of Waterloo, Ontario, Canada, N2L 3G1.

The reorganization of eye, head and limb movements to perturbed target lights was studied. Subjects were required to touch with their right index finger, targets consisting of recessed 3mm lights located on a table top 15, 30 and 45 degrees to the left of the subject's midline either as fast or as accurately as possible. Twenty percent of the time, upon finger movement initiation to the 30 degree target, the target light was extinguished and either the 15 degree or 45 degree light was then illuminated. The response of the eyes to this perturbation was measured by EOG and the WATSMART 3-D system was used to monitor the movements of the head and hand. Results showed that not only did the experimental conditions affect the order of initiation of these body parts, but the body parts also responded to the target perturbations very differently. These differences were concerned with whether movement amendments were made and and if so, the latency of these amendments. These results are discussed in terms of the control of multimovement systems which are characterized by flexible and rapid reorganization of their constituent parts.

IS THERE A LEFT-HAND ADVANTAGE FOR AIMING MOVEMENTS MADE WITHOUT VISUAL FEEDBACK? D. P. Carey and M. A. Goodale, University of Western Ontario, London, Canada, N6A 5C2.

A much-cited study by Guiard et al. (*Neuropsychologia, 21(1), 1983*) claimed that when visual feedback was not available in an aiming task, right-handed subjects showed smaller constant errors with their left than with their right hand. The claim that this advantage was due to a right-hemisphere superiority for processing spatial relationships was further supported by a left hemispatial advantage in performance (as measured by constant error). The present study re-examined this claim by studying the aiming movements made by 17 right-handed males with their left and right hands in hand-visible and hand-invisible conditions. The subjects were required to reach out and place their index finger on a single target (0.25^{0} LED) or on the midpoint between two such targets, the location of which varied randomly from trial to trial. The position of the moving finger was monitored via a WATSMART system. In contrast to the results of Guiard et al., but consistent with a number of other studies (*e.g. Fisk and Goodale, Exp. Brain Res., 60, 1985*), subjects made larger constant and larger variable errors using their left hand rather than their right. Moreover, the magnitude of these differences increased rather than decreased when visual feedback about limb position was not available. Some evidence for a left hemispatial advantage was found, however, since constant errors were larger for targets on the right side of space. These findings suggest that the right hand/left hemisphere system may be better able to utilize non-visual as well as visual sources of feedback for producing accurate aiming movements. *Supported by MRCC grant #MA-7269 to M.A.G.*

LEFT/RIGHT HAND DIFFERENCES AND THE ROLE OF VISION IN HUMAN PREHENSION. L. S. Jakobson* and M. A. Goodale (SPON: R. Steenhuis), Dept. of Psychology, U. of Western Ontario, London, Canada, N6A 5C2.

Jeannerod (*J. Mot. Behav., 16, 1984*) has suggested that the relative timing of the two components of human prehension, the reach and the grasp, is achieved through a feedback-independent central motor program. This proposal was tested in the present experiment. Right-handed subjects were asked to pick up objects located at various distances in front of them. For half the session, vision of the hand and target was not available after movement onset. The performance of the left and right hands under each of these conditions was also compared. The kinematics were obtained via a WATSMART system.

Maximum grip aperture was achieved well before contact with the object and was scaled for object size in both viewing conditions. The absence of visual feedback, however, reduced the precision of the grasp; not only did the hand open wider when vision was not available, but the size of that opening showed much more variability from trial to trial. Contrary to Jeannerod's prediction, the relative timing of the reach and grasp components was also affected. When vision was not available, the relative timing of the grasp with respect to the reach was much more variable and maximum aperture occurred earlier. The two hands also differed. The right hand opened 2 cm less than the left, on average, and was less variable in its maximum aperture. This effect did not interact with feedback condition. The greater precision of the right hand, which enjoys privileged access to the left hemisphere, supports the idea that praxis systems within this hemisphere may be specialized for the control of prehension. *Supported by MRCC grant MA-7269 to M.A.G. and an MRCC Studentship to L.S.J.*

25.12

THE EFFECTS OF OBJECT SIZE AND DISTANCE ON VISUALLY GUIDED PREHENSION. M. A. Goodale and L. S. Jakobson*, Dept. of Psychology, U. of Western Ontario, London, Canada, N6A 5C2.

The act of prehension involves not only spatially accurate placement of the arm (the reach), but also appropriate posturing of the hand (the grasp). The present experiment examined the relationship between these two components of human prehension. Right-handed subjects were asked to pick up a small block that varied in size and distance from the subject. The reaching and grasping movements were reconstructed with a 3D-optoelectronic recording system (WATSMART). The manipulations of object size and distance had predictable effects on the kinematics of the reach and the grasp. Thus, reaches to distant objects reached a higher peak velocity than reaches to near objects, and maximum grip aperture was scaled for object size. In addition, maximum grip aperture was delayed in reaches to more distant targets of any size. Since these reaches were also of longer duration, the result was that maximum grip aperture was consistently achieved approximately two-thirds of the way through each reach, regardless of movement amplitude. This finding lends strong support to Jeannerod's contention (*J. Mot. Behav., 16, 1984*) that there is a temporal coupling of the reach and grasp components of prehension. However, the fact that reaches to larger objects (which reached a higher peak velocity) were of longer duration than reaches to smaller objects shows that factors normally thought to influence primarily grip formation can also influence aspects of the reach itself. This would suggest that the reach and grasp components are more than simply temporally coupled and that their normal integration is affected by visually-based estimates of object size and distance. *Supported by MRCC grant MA-7269 to M.A.G. and an MRCC Studentship to L.S.J.*

25.13

DIFFERENCES IN PROGRAMMING OF AMPLITUDE AND DIRECTION IN A TWO DIMENSIONAL FORCE AIMING TASK. R. Bermejo*, S. Pullman and C. Ghez. Ctr. for Neurobiol & Behav, Columbia Univ and NYS Psych Inst, New York, NY, 10032.

We have previously shown that when subjects aim impulses of elbow force to unpredictable flexion and extension targets, direction and amplitude are specified in parallel. Prior to target presentation, subjects prepare a default amplitude at the center of the expected range and select a default direction arbitrarily between the two possibilities. We now examine whether, when direction can vary in a continuous range and alternative directions are close together, subjects prepare a single default direction in the center of the range.

Subjects produced single uncorrected impulses of isometric wrist force in synchrony with a predictable tone and aimed to one of four visual targets appearing at unpredictable times prior to the tone. In each block of trials. The array of targets required flexion combined with either ulnar or radial deviation of the wrist. Target forces had one of two amplitudes. In different blocks of trials, the angle subtended by possible targets was 90° or 22°.

At short S-R intervals (<100ms), subjects' default responses were directed towards one or the other pair of possible targets regardless of their angular separation, never in the center of the range. In contrast, default amplitudes were at the center of the expected range of target amplitudes. As S-R interval increased, the proportion of wrong direction responses decreased progressively while the amplitudes of both right and wrong direction responses gradually converged on the targets. The preparation of response direction thus derives from a selection made among discrete alternatives while amplitude derives from a single average default value. Specification of direction expresses itself as a progressive change in the probability of a correct choice while amplitude specification is reflected in the gradual adjustment of response metrics. 25.14

INDEPENDENCE OF DIRECTION AND AMPLITUDE ERRORS IN PLANAR ARM MOVEMENTS. J. Gordon and C. Ghez. Ctr for Neurobiol & Behav, Columbia Univ and NYS Psych Inst, New York, NY 10032.

This study examined the programming and accuracy of limb trajectories in two–dimensional arm and wrist movements. Subjects moved a hand–held cursor on a digitizing tablet in arm movements, or pointed a pen cursor taped to their index finger in wrist movements, to targets at different distances and in different directions. Targets and cursor were displayed on a computer screen. The subjects' limb was covered, and the screen cursor was blanked after an auditory signal to move. Final cursor position was displayed as knowledge of results. Subjects were instructed to make single uncorrected movements to the target either at a comfortable speed or as fast as possible.

Movements in a given direction had similar trajectories in which bell–shaped velocity profiles were scaled in amplitude and time. However, the relative symmetry of the profiles as well as the scaling factors differed for different directions of movement. The spatial distributions of end points were elliptical in shape for both arm and wrist movements. The long axes of the ellipses were oriented in the direction of movement such that amplitude errors were 2 to 3 times greater than direction errors. The eccentricity and size of the dispersion ellipses varied systematically with movement amplitude and direction whereas the velocity instruction had little effect. Eccentricity decreased with increasing movement amplitude; directional error was independent of movement amplitude, while relative amplitude error decreased. The relationship between eccentricity and movement direction was more complex. Differences in error distributions and trajectory profiles with different directions reflected variations in the contribution of different joints to the movement and resultant differences in the inertial load at the hand. The independence of direction and amplitude errors implies that separate processes contribute to the programming of direction and amplitude of two–dimensional movements. (Supported by NS 22713)

25.15

PATTERNS OF MUSCLE ACTIVITY IN ISOMETRIC ARM POSTURES. M. Flanders and J.F. Soechting. Department of Physiology, University of Minnesota, Minneapolis, MN 55455.

The goal of this study is to understand how the nervous system produces the complex patterns of muscle activity that move the human arm through three-dimensional space. We have begun by measuring the activity of several shoulder and elbow muscles during the production of static forces at the wrist.

Human subjects stood with their right arms in one of several isometric postures. We used a pulley system to require each subject to produce force at the wrist in various directions in three-dimensional space. We measured the electromyographic (EMG) activity of the latissimus dorsi, posterior, medial and anterior deltoid, pectoralis, biceps, brachioradialis, and the long and medial heads of the triceps. We analyzed the EMG data to determine the force direction for which each muscle was maximally active, and the breadth of the range of directions around this "best" direction. We defined coactivity as activity in the direction opposite to the best direction, and determined the extent and breadth of coactivity.

Directions and ranges of activity and coactivity will be compared between different isometric postures and between static and dynamic modes of force production.

25.16

Neuromuscular control of a reversal maneuver during post-contraction movements. B.R. Etnyre. Human Performance and Health Sciences Dept. Rice University, Houston, Texas 77251

A previous study of post-contraction movement accuracy reported undershooting of a target was primarily dependent upon reduced motor output of the agonist muscle with no change in antagonist EMG activity or in the fundamental frequencies of either muscle. The effect may be caused by proprioceptive biasing or by a perceptual distortion. A reversal movement may reset the muscle spindle, which could restore proprioceptive biasing to normal. The purpose of the present study was to compare post-contraction positioning accuracy with EMG quantity and frequency characteristics between biceps and triceps brachii muscles during elbow extension with reversal movements to a target. Following a learning session 20 blindfolded subjects performed 20 control trials in which each attempted to rapidly move past the target (elbow extension) and then return to the target position (elbow flexion). Experimental trials were identical to control trials except the subject preceded each movement with a 3 second isometric contraction of the triceps brachii muscle. Significant undershooting occurred in the post-contraction condition, $t(19) = 4.10$, $p < .001$. Integrated EMG (IEMG) of the triceps muscle was significantly less in the experimental condition than the control condition, $t(19) = 2.1$, $p < .05$, while no difference was observed in biceps IEMG between conditions. Frequency spectrum analysis revealed nearly identical mean peak frequencies between conditions in both muscles. It was concluded the undershooting following isometric contraction was dependent on the motor output of the triceps brachii muscle for reversal of an elbow extension movement with only slight changes in motor frequencies.

RECONSTRUCTION OF SHIFTING JOINT COMPLIANT CHARACTERISTICS DURING SLOW MOVEMENTS. M.L.Latash and G.L.Gottlieb. Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612

The equilibrium-point (EP) hypothesis of motor control is based on a notion of joint compliant characteristics (CCs) which are controlled by a central motor planning system. CCs have until now been recorded only in "static" experiments in which a subject was asked to activate his muscles against a torque bias and "not to intervene voluntarily" with unexpected external torque changes. Recording CCs during voluntary changes in motor command has never been described.

In our experiments, the subjects (N = 7) first learned a simple relatively slow elbow flexion movement (movement time 600-1000 ms) against a torque bias and were asked to reproduce the learned command irrespective of possible external torque changes. Slow torque changes (loadings or unloadings over 800 ms) took place in half of the trials starting 100 ms after the tone signal to initiate the movement. The individual trials were later aligned according to the moment of visible deflection of the acceleration trace corresponding to the beginning of the voluntary movement (t_0). Angle and torque values were measured at different times Δt after t_0. Data for each Δt were plotted in the torque-angle plane and linear regression equations were computed (coefficients of linear correlation over 0.9 for more than 50% of the sets). The regression equations let one assess changes in the CC threshold and slope during a movement and provide for a "virtual trajectory" which was somewhat ahead of the "actual trajectory" (based on averaged unperturbed trials). Similar analysis was used for the static CCs recorded using the classical paradigm.

The method used allows measurement of shifts in CCs during movements. It may also be used for analysis of fast movements if one takes into account inertial torques. Our preliminary data provide direct support for using notions of the EP-hypothesis such as shifts of CCs for movement analysis.

The study was supported by NIH grants AR 33189 and NS 15630.

MEMORY-SCANNING OF MOVEMENT DIRECTIONS: EFFECT OF SET SIZE ON CONTEXT-RECALL. A. Georgopoulos, J.T. Lurito*, and T. Georgakopoulos*. Bard Labs., Dept. of Neuroscience, The Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

Fourteen human subjects performed in a modified Sternberg memory-scanning task. First, they made a series of 2-6 movements in different directions from a central point towards peripheral lights on a planar working surface ("list trials"). Then, after a beep, one of the previous stimuli in the list was presented again ("test trial"). Subjects were instructed to move in the direction of the stimulus which was presented next in sequence in the list. The reaction time (RT) in the test trials was a strong linear function of the number of movements (k) in the list: RT (ms) = 159 + 195k (values are means of 14 subjects; the median Y-intercept and slope were 199 ms and 170 ms/item recalled, respectively). The mean r^2 (N = 14) was 0.932 (median = 0.978). In contrast, the RT did not vary with the serial position of the test movement in the list trials. These results indicate that successful performance in this task involves a recall of the list sequence that is more time consuming the higher the number of movements in the list.

25.19

ISOMETRIC FORCES EXERTED BY HUMAN SUBJECTS WITH AND WITHOUT VISUAL FEEDBACK OF POINT OF ORIGIN. R.A. Drake, J.T. Massey, and A.P. Georgopoulos. Bard Labs., Dept. of Neuroscience, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Twenty human subjects grasped an isometric handle and exerted an X-Y force which moved a cursor in a visual display. Subjects were instructed to exert forces on the handle such that the cursor moved toward a target in a reaction time task. The instruction for the direction of the vector of the upcoming force was defined visually by the location of the cursor and the location of the target on the display. In Experiment 1 the cursor remained visible after target onset, but did not move in response to the force exerted. This resulted in performance similar to the condition in which the cursor did move. In Experiment 2 the cursor disappeared simultaneously with the target onset. This resulted in significantly slower mean reaction times (513 vs. 417 ms) and less information transmitted (2.84 vs. 3.10 bits) than when the cursor remained visible. These results suggest that the generation of force in a particular direction depends on the availability of the visually defined instruction vector during the reaction time.

BILATERAL MOTOR CONTROL DEFICITS IN FRONTAL HEMINEGLECT IN MONKEYS. R.K. Deuel. Washington University School of Medicine, St. Louis, MO 63110

Hemineglect symptoms are generally attributed to abnormal processing in the damaged hemisphere. To test timing and force deployment of hand movements, monkeys were taught to grip handles without exerting force until a lateralized cue light signalled one hand to pull. Before a unilateral periarcuate lesion the pulling hand, whether L or R, exerted up to 6K while the gripping hand exerted <200 gms.. Postop, in monkeys with hemineglect the distribution and timing of forces changed, with the hand contralateral to lesion (Contra hand) pulling 40% less than preop, and the hand ipsilateral (Ipsi hand) pulling 7% more. When Contra hand was cued to pull, the ipsi hand pulled too, and vice-versa. Latency from lateralized cue to reward was also increased for both contra and ipsi hands. This data shows that the motor control of both hands is altered by a unilateral lesion, and that whether or not the undamaged hemisphere has assumed control of both hands, its ability to adequately suppress exertion of force by the hand it usually controls is severely compromised. Thus, processing in the undamaged hemisphere is abnormal in hemineglect. Supported by NIH NS16790.

26.2

AIR-STEPPING IN NEONATAL VERVET MONKEYS. J.A. Vilensky*, P. Wilson-Callmyer* and E. Gankiewicz*. (SPON: M.L. Dyken). Dept. of Anatomy, Indiana Univ. Sch. of Med., Fort Wayne, IN 46805

Limb movements during air-stepping were filmed and analyzed for three neonatal vervet monkeys over a three week period. The analysis showed the movements to have similar temporal organization both across animals and across time. For example, both hind and forelimb cycle durations tended to equal about 500 ms with the hind limb return strokes being much longer than power strokes. Forelimb return strokes were, however, shorter than the hind limb return strokes. In addition, there were clear indications of both intra- and interlimb coordination. Specifically, all the joints of a limb tended to flex and extend simultaneously, and contralateral and ipsilateral limb pairs had an average phase relationship of approximately 50% of cycle duration. Despite a qualitative similarity in limb movements between air-stepping in the neonates and overground locomotion in older animals, there were notable differences both in temporal relationships and joint displacement patterns. For example, hind limb power strokes showed no correlation with cycle duration and all of the hind limb joints exhibited a flexion bias. Finally, there appeared to be similarities between air-stepping in these monkeys and newborn stepping in humans. Most notably, both tend to disappear after a limited period.

26.3

MEDIAN NERVE RECORDING DURING GRASPING. T.E. Milner, C. Dugas, N. Picard* and A.M. Smith, Centre de recherche en sciences neurologiques, University of Montreal, Montreal, Québec, H3C 3J7.

A recording nerve cuff was implanted around the median nerve of a monkey for the purpose of detecting compound neural activity related to grasping. Distal to the level of the cuff the nerve innervated several thenar and lumbrical muscles; sensory innervation included the volar surfaces and nail beds of the first three digits, part of the fourth digit and the skin of the medial palm.

The neural signal was filtered using a high-pass filter with a sharp cutoff at 1500 Hz to remove EMG. By comparing the power spectrum of a signal generated by brushing the skin when the muscles were relaxed with one generated when the monkey was actively gripping and lifting an object, we determined that the filter eliminated almost all of the EMG leaving only a neural signal.

The monkey was trained to grasp, lift and hold an object whose weight and surface texture could be changed. There was an initial dynamic response consisting of a burst of activity which began as the digits contacted the surface of the object. The intensity of this burst rose sharply, reaching a peak well before peak grip force. Activity then declined in an exponential fashion to a steady level which was achieved much later than the onset of steady grip force during holding. This static response was greater for larger forces and rougher textures. When the grasp was relaxed neural activity dropped rapidly to its baseline level. As the object dropped from the hand there was a small symmetrical burst of activity probably caused by the object brushing the skin.

In some blocks of trials a pulse perturbation was applied during holding. It produced a sharp increase in activity coincident with the perturbation. This response preceded the increase in grip force associated with resistance to the perturbation. The amplitude and duration of this neural burst were similar to that observed during the initial lifting of the object. (This work was supported by the MRC and NSERC of Canada and le Fonds FCAR du Québec.)

A BIOMECHANICAL MODEL OF THE MONKEY'S ARM. M.Dornay*, T.Consi*, J.McIntyre*, F.A.Mussa-Ivaldi* and E.Bizzi. Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Several investigations of motor behavior have emphasized the role of muscle spring-like properties in the control of posture. Single-joint experiments have demonstrated that posture of the limb is determined by the equilibrium between length-tension curves of opposing muscles. This finding has been extended to the behavior of the multi-joint arm. It has been shown that if the hand is displaced by some external perturbation, the muscle elastic properties generate a restoring force which depends upon the amplitude as well as on the direction of the perturbation.

In this investigation we analyze the role of specific biomechanical factors in the postural behavior of the multi-joint arm. We have developed a computer model of the arm of the rhesus monkey. The model simulates the postural behavior of the arm in the horizontal plane. Each muscle is represented as an elastic element whose rest-length and stiffness is regulated by a control input. The ranges of stiffness and rest-length values have been estimated on the basis of in-vivo physiological data for the triceps muscle, combined with cross-sectional and length data measured on the corresponding muscles of rhesus monkeys. Other anatomical data concerning the origin and insertion and moment arm of the muscles were obtained by dissection and radiographic techniques. A total of seventeen muscles including shoulder, elbow and two-joint flexors and extensors have been included in the model. Simulation programs that have been developed in LISP on a Symbolics 3600 series computer, were used to determine the effect of a given input pattern on a) the equilibrium posture of the arm b) the restoring force following a displacement of the hand and c) the stiffness of the arm. Inputs to individual muscles in the model were derived by a backdriving technique (Mussa-Ivaldi, McIntyre, Bizzi, 1988). Given a desired posture and/or force output at the end-point of the arm, this approach makes it possible to derive the inputs to all the muscles consistent with a minimum potential energy constraint. Supp. by NIH NS09343, 1-F05-TWO4042-01; ONR N00014-88-K-0372.

INDIVIDUATED FINGER MOVEMENTS OF RHESUS MONKEYS: TO WHAT DEGREE IS MOVEMENT OF EACH DIGIT INDEPENDENT OF THE OTHERS? M.H.Schieber. Dept. of Neurol. & Neurosurg., Washington University Sch. of Med., St. Louis, MO, 63110.

In their natural behavior, monkeys use a variety of individuated finger movements, such as precision pinch. Observation suggests that monkeys, like humans, move their thumb and index finger more independently than digits 3 through 5. In the present study, the degree to which flexion and extension of each digit is independent of the other digits has been quantitated.

Monkeys were trained to perform individuated flexion and extension movements of each digit of the right hand or of the wrist (Soc. Neurosci. Abstr. 14:821). In each successful trial, the instructed digit had the greatest excursion. But the other digits also moved to some extent. To quantitate the motion of the other digits, linear regression was performed using the motion of the instructed digit as the independent variable and the motion of another digit as the dependent variable. The slope of the best fit line then is a measure of the dependence of the other digit's movement on the instructed digit, approaching 0 if they are independent, 1 if highly dependent. An **Individuation Index** then was calculated for each instructed movement by averaging the slopes for all the other digits and subtracting the average from 1. If all other digits moved with the instructed digit, this Individuation Index approaches 0; if the other digits were stationary while the instructed digit moved, the Index approaches 1.

Results support the hypothesis that the thumb is the digit moved most independently (Indexes range from .83 to .97), the index finger next (.64 to .92), and digits 3 through 5 the least independent (.50 to .78). Flexion movements generally were more individuated than extensions. Wrist movements were highly independent of the digits (.87 to .96), and vice versa.

This analysis provides i) a normal baseline for studies of the effects of cortical inactivation on individuated finger movements, and ii) a behavioral reference for comparison with muscle and neuron activity.

INCOORDINATION IN ATTEMPTED REACHING AND PINCHING AFTER INACTIVATION OF CEREBELLAR DENTATE NUCLEUS S.A. Kane, H.P. Goodkin*, J.G. Keating*, and W.T. Thach. Dept. of Anatomy, Washington Univ. Sch. Med., St. Louis, MO 63110.

Rhesus monkeys were filmed or video taped while standing, sitting, walking, reaching and grasping, and using thumb and forefinger to pick food bits from deep, narrow food wells. These activities, along with trained wrist movements, were studied before and after injections of muscimol to produce temporary inactivation and kainic acid to produce a permanent lesion of the dentate nucleus.

Bits of food were normally removed from the well by the coordinated action of the thumb and forefinger. After inactivation, the monkey retained the ability to make individuated movements of the one finger, such as raking and stabbing during the food well task, but no longer coordinated the movements of thumb and forefinger in precision pinching. In reaching for a food bit, the normal pinch was replaced by 1) clawing: simultaneous flexion of all fingers about the food bit, 2) false pinch: holding the food bit between the extensor surface of the flexed thumb and the forefinger, or 3) spider hand: grasping with fingers abducted and independently flexed without effective coordination. Inactivation deficits were not confined to the fingers. During reaching, the shoulder and elbow overextended, sending the hand as much as 3 cm past the target (overshoot). After the permanent lesion, these deficits remained until sacrifice (7 weeks). Dentate inactivation had no effect on standing, sitting, or walking; no tremor was observed; and trained wrist movements were only slightly delayed. Injections aimed at the interpositus and fastigius had no effect on finger grasping during precision pinch and produced no overshoot during reaching.

In contrast to the relative normalcy of single joint movements (20–50 msec delay in initiation) following dentate inactivation, these results demonstrate an inability to make effective volitional movements involving more than one joint. These results suggest that the dentate mediates a type of control concerned primarily with multiple rather than single joints. (NIH grants NS12777 and NS15070; the McDonnell Center).

CHARACTERIZATION OF RESPIRATORY AND LARYNGEAL MUSCLE ACTIVITY ASSOCIATED WITH VOCALIZATION IN M NEMESTRINA. R.A. West, C.R. Larson, Dept. of Communication Sciences and Disorders and Neurobiology and Physiology, Northwestern University. Evanston, IL 60208.

In an attempt to determine the neuromuscular control of vocalization, electromyographic (EMG) activity of laryngeal and respiratory muscles was chronically recorded from five monkeys trained to vocalize for a fruit juice reward. Measured parameters included mean EMG, duration of EMG bursts, and latency from EMG onset to vocal onset for coos and barks.

Of the respiratory muscles recorded, intercostal (IC), rectus abdominus (RA) and external oblique (EO) had latencies that were relatively constant across individuals and call types. The diaphragm (D) generally had an earlier onset time for barks than coos and had reduced activity near vocal onset. This reduction was less frequently observed for longer duration calls. Other parameters of activity were somewhat variable across monkeys and call types.

Of the laryngeal muscles recorded, the posterior cricoarytenoid (PCA) was similar to the D in onset time and reduced activity near vocal onset. Thyroarytenoid (TA) and cricothyroid (CT) were extremely variable on all parameters across monkeys and call types, but were consistent for a monkey giving a specific call.

Overall, vocalizations across monkeys and call types were quite variable in duration and loudness. Latencies of respiratory muscles to vocal onset were much more consistent than those of laryngeal muscles. These data suggest that respiratory muscles may determine vocal onset time, whereas laryngeal muscles contribute to other measures of vocalization.

26.8

THE MOTOR EFFECTS OF UNILATERALLY STIMULATING THE CAUDATE NUCLEUS SIMULTANEOUSLY WITH THE CONTRALATERAL SUBSTANTIA NIGRA IN THE RAT: S.I. Lentz * and D. Asdourian, Department of Psychology, Wayne State University, Detroit, MI 48202

Unilateral electrical stimulation of the head of the caudate nucleus (Cd) elicits activity in the contralateral muscles of the neck and shoulder (15 twin pulse/sec, duration 0.5 msec, interpulse interval 1.0 msec, current 0.2- 0.6 ma, anesthetic sodium pentobarbital 60 mg/kg). If the Cd is stimulated with subthreshold current, the addition of threshold stimulation of the contralateral substantia nigra (SN) at roughly the same parameters as listed above, augments the effects of the subthreshold Cd stimulation so that Cd-elicited activity is seen in the trapezius muscle. In contrast, activity driven in the rectus capitis muscle with suprathreshold stimulation of Cd is almost always completely inhibited by threshold nigral stimulation. This nigrally elicited augmentation and inhibition is unaffected following large kainic acid lesions of the stimulated SN, leading to the conclusion that these results are due to stimulation of the caudally directed fibers of passage that run through that area rather than to outputs of nigral cells.

26.9

NMDA AND GABA: OPPOSITE EFFECTS ON ROTATION BEHAVIOR AFTER INJECTION IN UNILATERAL SUBSTANTIA NIGRA. Y.F.Jacquet. Nathan Kline Institute, Orangeburg, NY 10962.

Separate groups (n = 4-6) of drug-naive rats (previously implanted with 30-gauge cannula) were injected (using a 35-gauge needle) in the unilateral substantia nigra with the following drugs: N-methyl-D-aspartate (NMDA)(10 nmol/0.5 uL); muscimol (a GABA agonist)(0.85 nmol/0.5 uL); the NMDA competitive antagonist, (-)-2-amino-7-phosphonoheptanoate (D-AP7)(2.6 nmol/0.5 uL or 5.2 nmol/1 uL); or D-AP7 (5.2 nmol) + Bicuculline Methiodide (BM)(a potent GABA antagonist)(0.5 or 1 nmol) combined in a total volume of 0.5 uL.

NMDA resulted in ipsiversive rotation (5/6 rats). Muscimol resulted in contraversive rotation (4/4 rats), consistent with previous findings by other workers. The NMDA antagonist, D-AP7, however, not only blocked the ipsiversive rotation, but resulted in a dose-dependent contraversive rotation (5/5 rats). When the NMDA antagonist, D-AP7 was combined with the GABA antagonist, BM, ipsiversive rotation resulted (3/4 rats).

These results suggest that both excitatory (NMDAergic) and inhibitory (GABAergic) influences exert a tonic neuromodulation of the nigrostriatal output affecting posture and rotation behavior. When an imbalance occurs in the two (e.g., blockade of NMDA by D-AP7), the influence of the unopposed neurotransmitter (in this case, GABA) becomes evident in the direction of rotation behavior.

26.10

SCALING OF CHEWING FREQUENCY AND BODY WEIGHT IN MAMMALS. R.E. Druzinsky*.(SPON: C.H. Anderson). Depts. of Anatomy and Oral Anatomy, Univ. of Illinois at Chicago, Chicago, IL 60680.

T.A. McMahon (J. appl. Physiol., 186:1112, 1975) argued that single joint and multiple joint mechanical systems have "natural frequencies" of oscillation. Using his "elastic similarity" model of scaling, McMahon predicted that stride frequencies are proportional to (BODY WT)$^{-1/8}$. He compared animals running at the trot-gallop transition and found that: STRIDE FREQ $\propto$ (BODY WT)$^{-0.14}$ similar to the value of -1/8 he predicted.

In the present study, frequency of chewing cycles for 17 species of mammals was regressed against body weight. A significant correlation was found:
CHEW FREQ = 2.589 (BODY WT)$^{-0.101}$ with chewing frequency in cycles/minute and body weight in kilograms. This result is reasonably close to the predicted -1/8 exponent, and it is also similar to the exponent of -0.13 found for the relationship of STRIDE FREQ to BODY WT at the preferred rate of trotting (Heglund, N.C., and Taylor, C.R., J. exp. Biol., 138:301, 1988).

LOCOMOTOR HYPERACTIVITY IN CASTRATED MALE RATS WITH TESTOSTERONE IMPLANTS: BIOLOGICAL CORRELATES IN SUBCORTICAL STRUCTURES S.E.Starkstein, T.H.Moran,E.Nelson*, J.B.Bowersox*, R.G.Robinson Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205

We have reported that right but not left frontocortical suction lesions in the presence of testosterone produce locomotor hyperactivity as well as bilateral increments in dopamine (DA) turnover in the nucleus accumbens (NAS) in male rats. Whether this increase in turnover was a cause or a result of the hyperactivity is the subject of this study. Thirty-two prepuberally castrated male rats were divided into 4 groups and were given sham or testosterone-filled implants of different sizes (10, 20, and 30mm). Activity was monitored in running-wheel cages for 30 days. Rats with larger implants showed significantly more hyperactivity (% from baseline: sham 87%, 10mm: 118%, 20mm: 139%, 30mm: 179%). Plasma testosterone levels were significantly higher in rats with larger implants (sham: 1.6 ug/ml, 10mm: 7.8 ug/ml, 20mm: 10.4 ug/ml, 30mm: 13.8 ug/ml). Despite this hyperactivity, no significant elevations in either NAS or caudate DOPAC/DA ratios were evident in the testosterone-treated rats. This study showed that increments in NAS DA turnover are not necessary for the production of locomotor hyperactivity and suggests that the increments in NAS DA turnover after a right frontocortical suction lesion are not a result of the hyperactivity and may play a causative role in this behavioral response.

MONOAMINE METABOLISM IN THE BRAIN AND SPINAL CORD OF RATS DURING SWIMMING EXERCISE. T.Yamamoto*, A.Yamatodani*# and H.Wada*# (Spon: T.Watanabe) Faculty of Liberal Arts, Tezukayama University, Nara 631, and #Department of Pharmacology II , Faculty of Medicine, Osaka University, Osaka 530, Japan.

We studied the effects of swimming exercise on monoamine metabolism in several regions of the brain of female S.D. rats after long-term swimming training (120 min a day, 6 days a week for 10 weeks). On the final day, trained and untrained rats (used as controls to examine the effect of non-specific stress) were sacrificed 30, 60, and 120 min after the start of swimming session. Norepinephrine (NE), dopamine (DA), serotonin (5-HT) and their metabolites, and histamine (HA) in the brain tissue were determined by HPLCs. In the untrained rats, forced swimming caused a significant decrease of NE in the hypothalamus and cortex at 30 min, but no significant changes in the contents of DA, 5-HT and their metabolites and HA in any of the regions. In contrast, trained rats showed increases of 5-HT, 5-HIAA, DA and HA in the cortex at 120 min and of 5-HT in the striatum at 30 min, and decreases of DOPAC and HVA in the striatum at 30 and 60 min. The contents of NE, MHPG, DA, DOPAC, 5-HT and 5-HIAA in the thoracic spinal cord of trained rats were also significantly increased at 30, 60 and 120 min. These results suggest that not only the dopaminergic system, but also the noradrenergic, serotonergic and histaminergic systems participate in control of swimming exercise.

ANIMAL MOTILITY: SIGNAL SEGMENTATION AND CHARACTERIZATION. C.M. Arnaldo,* J.F. Czachura,* K.W. Brewer,* and L.P. Gonzalez. (SPON: J.T. Braggio) Department of Psychiatry and Behavioral Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190-3000.

Our laboratory is investigating the use of an automated method to assess changes in motor behavior in small laboratory animals. This method involves the use of a radio-frequency capacitance field transducer that provides an output signal that varies with movements within the field of the transducer. Analysis of motor behavior requires segmentation of the motility signal into portions which contain information related to individual behaviors and characterization of the segment such that individual behaviors can be distinguished from one another. Results are reported comparing several segmentation techniques (arbitrary, fixed-length segments; segments of fixed cycle length; and, segments delimited by autoregression of the motility signal) and two methods of segment characterization (Fourier Analysis and Period Analysis). These methods permitted significant discrimination of motility signals recorded during several types of motor behavior, including spontaneous grooming behaviors and drug-induced stereotyped movements, and provide a useful technique for quantifying fine motor behaviors.

YOHIMBINE-INDUCED CATALEPSY/AKINESIA: FORM AND PARTIAL REVERSAL BY HALOPERIDOL. R.M. Chesire. Psych. Dept., Univ. Hawaii, Honolulu, HI 96822.

Yohimbine HCl (YO), a potent MAOI (1), can prevent a form of catalepsy (CA; vertical rod apparatus) produced by haloperidol (HA; 2). In rats, 5 mg/kg systemic HA can produce a temporary form of catalepsy/akinesia (CA/AK) during which the defense of stable equilibrium is dramatically exaggerated (3). Preserved responses include postural support, tonic grasp, righting from a supine to a prone position, and defense against passive displacement by rigid bracing reactions (3). This report describes a form of YO-induced CA/AK, and a partial instatement of limb rigidity and tonic grasp by haloperidol.

11 male Long-Evans hooded rats were pretested for the defensive reactions mentioned above. They were then treated i.p. with 10 mg/kg YO HCl (retested at 20-30 min.) followed by 5 mg/kg HA (retested at 30-40 min.). YO abolished all normal equilibrium responses and produced AK (to be described). HA did not reinstate support, righting, or effective bracing, but limb rigidity was quite evident, and tonic grasp was reinstated.

YO produces a distinctive form of CA/AK which can be partially reversed by HA. The results suggest that the MAOI YO cannot prevent some HA-induced symptoms.

FROG ORIENTING BEHAVIOR: THE DESCENDING DISTANCE SIGNAL. P. Grobstein and V. Staradub*. Dept. Biol., Bryn Mawr Col., Bryn Mawr, PA 19010.

Visually triggered orienting in Rana pipiens depends on at least two differently organized descending tectofugal pathways, each carrying a distinct component of a signal related to stimulus location in a head or body centered coordinate frame. Information about the horizontal eccentricity (HE) of a stimulus apparently descends unilaterally while information about stimulus distance descends bilaterally. To determine whether the two pathways are also anatomically distinct, and to learn more about the character and location of the distance pathway, we have been studying the behavior of frogs following bilateral lesions at the midbrain/medulla junction.

Following large dorsal lesions, responses to prey items continued to vary appropriately with both the horizontal angle and the distance of stimuli. Descending pathways related to stimulus distance, as earlier shown for those related to HE, must be located in the more ventral white tracts. Following large ventral lesions, frogs responded to stimuli with a small forward movement which varied neither with the HE nor with the distance of the stimulus. This is consistent with a ventral trajectory for the distance as well as the HE pathways. It further suggests that information about the existence of a stimulus can reach the spinal cord in the absence of pathways which carry signals specifying its location.

Smaller bilateral ventral lesions yielded responses which varied more or less normally with HE but not with stimulus distance. The behavior of each of three frogs studied to date indicates that they were, for all stimulus distances, mislocating the stimuli to greater distances. The findings are consistent with the hypothesis of a ventrally located path carrying distance information which is anatomically distinct from the paths carrying HE information. The observations also suggest that distance is coded in terms of total activity in the distance pathway, with reduced total activity corresponding to greater rather than to lesser distance. THE ROLE OF THE CEREBELLUM AND BRAINSTEM IN ADAPTABILITY OF FROG WIPING MOTOR PROGRAMS M. Nitabach., S. F. Giszter*. Dept. Brain and Cognitive Sciences, M. I. T., Cambridge MA 02139.

Previous work has shown that the spinal frog can execute succesful wiping motions to the back and to the other limbs. This wiping can be adjusted on the basis of cutaneous information in spinal frogs but the spinal frog incorporates kinaesthetic information in a relatively coarse grained or discrete fashion. Specifically, spinal hindlimb-hindlimb wiping is restricted to a small area of workspace lying along the rostro-caudal body axis. If the leg is perturbed far from this area the spinal frog misses the target stimulus. Spinal frogs do not modify the wiping strategy in unsuccessful or blocked wipes.

To examine the level of the nervous system at which (1) kinaesthetic sensory motor transformations occur and (2) levels from which information is incorporated into the wiping motor program we have examined the kinematics of wiping frogs with only cerebellum, brainstem and spinal cord.

In the preparation with cerebellum we observe (i) that flexible wiping patterns occur using a larger area of workspace (ii) that the frog can incorporate kinaesthetic information to modify the hindlimb-hindlimb wiping behavior (iii) that the frog has an ability to recognize the location of mechanical restraints and to push against them with the other limbs in a persistent and probably motor equivalent fashion. These types of adjustments are not seen in the spinal cord alone.

These results suggest a layered control of wiping in which the spinal wiping circuits (which are able to use cutaneous information adaptively) are able to operate more flexibly using kinaesthetic sensory motor information mediated via the cerebellum and brainstem.

ELECTROMYOGRAPHIC AND KINEMATIC ANALYSIS OF WIPE AND FLEXION REFLEXES OF THE SPINAL FROG. J.L. Schotland and W.Z. Rymer. Neuroscience Program and Dept. of Physiology, Northwestern University Medical School, Chicago, IL 60611.

The wipe reflex of the spinal frog is a complex, target-directed, rhythmical movement. The animal uses the toes of the hindlimb to remove an irritating stimulus located at any point on its body. This paper extends our previous report analyzing the premovement EMGs of wipe and flexion withdrawal (FWD) reflexes (Schotland and Rymer, 1988) to include an analysis of EMGs during these movements while simultaneously recording joint angles.

Frogs were spinalized and bipolar stainless steel wire EMG electrodes implanted in seven hindlimb muscles. Infrared emitters were attached to six positions on the animals midline and monitored hindlimb. EMG signals were collected on computer, as was an analog signal representing stimulus application and onset of WATSMART strobing (this was to accommodate a variable delay in onset of WATSMART strobing when externally triggered by the computer). Wipes were elicited with 1N HCl and flexion withdrawal with a pinch applied via forceps. A randomly ordered stimulus sequence was delivered and 5 (flexion) or 10 (wipe) second trials were collected.

FWD consists of flexion of all three joints - hip, knee, and ankle. During the forelimb wipe (FW) there is rapid extension of the knee while the ankle is at peak flexion and the hip is nearing peak flexion. The hindlimb wipe (HW) is characterized by alternating flexion and extension of knee and ankle joints superimposed on hip extension. In contrast to the rapid extension and slow flexion observed in FW, both phases are rapid in HW.

Ankle flexors and extensors are coactivated during ankle extension for both forms of the wipe, and precede extension during FWD. All other muscles are coactivated during the flexion phase of FWD. Two-joint muscles generally exert their extensor action at all joints during HW, while hip flexor activity of one- and two-joint muscles acting at the hip predominate during FW. These results suggest that different central circuits coordinate the three movements.

MEASUREMENT OF FROG SEMITENDINOSUS MUSCLE FORCE AND TENDON LOAD-DEFORMATION AND LOAD-STRAIN PROPERTIES. Richard L. Lieber and Margot E. Leonard*. Division of Orthopaedic Surgery, University of California and V.A. Medical Center, San Diego, California 92161

INTRODUCTION AND METHODS: We previously modelled the relationship between sarcomere length and hip and knee joint angle during frog hopping assuming zero tendon compliance (Mai and Lieber, J. Biomech., in press). We found that, during the hopping motion, the ST first shortened and then lengthened . In order to determine the influence of tendon compliance on this finding, we measured the load-deformation and load-strain properties of the distal midportion of the frog semitendinosus (ST) using a dual-mode motor and video dimensional analyzer. Tendon load and strain were then related to the maximum tetanic tension of the isolated ST.

RESULTS AND DISCUSSION: Maximum tetanic tension of the ST averaged 0.3 ± 0.05 N for all samples (mean ± SD). Tendon strain at maximum tension corresponded to about 2%. These data suggest that during an isometric contraction at optimal sarcomere length, the ST muscle fiber would shorten from about 2.2 μm to 2.0 μm with the tendon slack at 2.2 μm. In this case, muscle force would not change. However, at shorter or longer sarcomere lengths muscle force would be altered due to external tendon compliance and altered filament overlap.

SPEED-RELATED CHANGES IN KINEMATIC OUTPUT AND MOTOR PATTERNS OF THE AVIAN HIND LIMB. S. M. Gatesy* (SPON: R. C. Holland). Museum of Comparative Zoology, Harvard Univ., Cambridge, MA 02138.

Walking birds, particularly chicks, have been used extensively as models for investigating the neural control of locomotion. To sample the avian locomotor repertoire more completely, the hind limb of adult helmeted guineafowl (*Numida meleagris*) was studied during walking and running at speeds from 0.2-3.0 m/sec. Simultaneous cineradiography and electromyography were employed to correlate the activity of 16 hip and knee muscles with skeletal movements.

Results show that guineafowl, unlike human bipeds, display a remarkably smooth transition from walking to running. As speed increases, step length is augmented by hip and knee extension late in the stance phase. Several muscles inactive during slow walking are recruited with speed, while others exhibit alteration of motor pattern. The overall pattern of muscle firing at high speeds resembles the reported pattern of motor output for walking in deafferented chicks (Bekoff et al., *J. Neurosci.*, 7:2320, 1987), where flexors and extensors have relatively equivalent burst durations. These results imply that comparisons between locomotor patterns should not be done exclusively with walking, where the central pattern generator (CPG) is being driven at a very low frequency. Study of motor output at different speeds may give clues to the interplay between sensory modulation and the locomotor CPG.

FIXED PATTERNS OF ACTIVITY OF MOTONEURONS AND INTERNEURONS IN LOAD COMPENSATORY REACTIONS OF LOCUSTS. S.N. Zill, S. F. Frazier* and S.E. Fish. Dept. Anat., Marshall Univ. Sch. Med., Huntington, WV 25704

Many animals generate compensatory contractions of limb muscles when the substrate upon which they are standing is displaced. We have reported that such reactions occur in tibial muscles of the locust hindleg when animals stand in a cage that is repeatedly swayed. We here report that fixed patterns of activity also occur in homologous flexor muscles of the middle legs and that motoneurons burst during the phase of movement (mean=.45 std .06) when animals are being pushed away from the surface upon which they stand. Thus, locusts use a number of limb muscles in load compensation to pull themselves toward the substrate. Using these data, we have developed a preparation permitting study of similar reactions during intracellular recordings. Animals are mounted on a beam and grasp a screen, to which forces equal to the animal's weight and additional displacements are applied. Locusts stably generate forces (up to 30 grams) greatly in excess of their weight to resist these displacements and show bursting in flexor muscles during the same phases of movement. A number of local circuit spiking interneurons also fire during this phase in these reactions. This preparation will be useful in determining which parameters are controlled in load compensation. Support by NIH grant NS 22682 and the Whitehall foundation.

MOTIVATION AND EMOTION II

27.1

EFFECTS OF HALOPERIDOL AND AMPHETAMINE ON ATTENTION-RELATED TASK PERFORMANCE IN THE RAT. M. La Cerra, R. Javid*, D. Weiner*, and A. Ettenberg. University of California, Santa Barbara, CA 93106.

Pharmacological antagonism of dopamine transmission produces reductions in operant response rates that are only partially accounted for by induced motor deficits. In the present study, the effect of DA antagonism with haloperidol on attention-related task performance was investigated in an analogue of Leonard's 5-choice serial reaction time task. At a dose that did not affect general locomotor activity, haloperidol (.075 mg/kg, i.p.) selectively diminished the number of correct responses animals emitted in the attention-related task session. In contrast, treatment with the dopamine agonist, d-amphetamine (1 mg/kg) produced both an increase in general locomotor activity and a selective increase in the number of inter-trial interval responses emitted in the attention-related task session. These findings are consistent with the view that pharmacologic manipulations of dopamine transmission alter attentional-reward processes subtending operant performance.

27.2

PROGRESSIVE WITHIN-SESSION DECREMENTS IN RESPONSE DURATION OBSERVED IN RATS RESPONDING FOR FOOD REINFORCEMENT UNDER NEUROLEPTIC CHALLENGE. A.Ettenberg, K.Gonzales* and S.C.Fowler Depts Psychology, Univ. California, Santa Barbara, CA 93106 and Univ. Mississippi, University, MS 38677.

Male albino rats were trained to reach through a small rectangular opening in their operant chamber and press an 18mm dia disk for a reward of either sucrose solution or sweetened condensed milk. The disk was attached to a sensitive isometric force transducer the output of which was monitored by computer to provide detailed information on the magnitude of force emitted during each response (sampled every 0.0025 s), the duration of each response and the number of responses over time. IP injections of both haloperidol (.04, .08, .16 mg/kg) and cis-flupenthixol (.15, .3 mg/kg) produced within-session decrements in response rates and increases in "peak" force similar to those observed when reinforcement was removed. However, only the drug manipulations resulted in reliable increases in response durations. Closer analysis revealed that while "rise times" (from response initiation to maximum or "peak" force) were relatively unaffected by neuroleptic treatment, "fall times" (from "peak" force to paw removal from the disk) greatly increased as the test session progressed. These data demonstrate a motoric deficit (i.e. progressive inability to terminate operant responses) that can account for the "extinction-like" response patterns observed in animals responding during neuroleptic challenge.

27.3

Differential Effects of Haloperidol, Pentobarbital, and Dantrolene on Operant Response Initiation but Not Spontaneous Locomotion.

E. O'S. Hammond, M. L. Torok*, and A. Ettenberg.
Department of Psychology, University of California
Santa Barbara, CA 93106

Intraperitoneal injections of haloperidol (HAL; 0.00, 0.075, 0.15, 0.30 mg/kg), pentobarbital (PEN; 0.00, 4.5, 9, 12 mg/kg), and dantrolene (DAN; 0.00, 5, 7.5, 10 mg/kg) produced similar profiles of within-session decreases in spontaneous locomotion. In contrast, the same drugs produced three distinctly different patterns of response initiation over 10 trials in an operant lever-press task. HAL-treated animals' initiation latencies increased over trials whereas PEN produced latencies that tended to decrease over trials. DAN latencies were elevated throughout the session. Thus, application of food reinforcement in an operant setting revealed differences among drugs that in a spontaneous locomotor setting produce strikingly similar motor impairments. These results suggest that the drugs may in some fashion differentially affect the experience of reward.

27.4

OPPOSITE EFFECTS OF INTRA-ACCUMBENS AND INTRA-PREFRONTAL CORTEX APPLICATIONS OF CIS-FLUPENTHIXOL ON CONDITIONED PLACE PREFERENCES INDUCED BY REWARDING VTA STIMULATION. C.L. Duvauchelle*, M.Levitin* and A. Ettenberg. (Spon. C.W. Scouten). Dept Psychology, Univ California, Santa Barbara, CA 93106

Animals develop preferences for distinct environments in which they experienced sessions of rewarding brain stimulation. These conditioned place preferences (CPPs) are attenuated by systemic injection of the dopamine (DA) antagonist, haloperidol (Ettenberg & Duvauchelle, Behav Neurosci 102:687, 1988). In the present study, CPPs were produced for the side of a two-compartment apparatus in which the rats experienced four 5min exposures to experimenter-administered rewarding VTA stimulation. Pretreatment with bilateral applications of 0, 1, 5 or 10 ug/rat/side of the DA antagonist, cis-flupenthixol into the nucleus accumbens produced a dose-dependent attenuation in the size of the resulting preferences. This result is, therefore, consistent with previous reports that intra-accumbens injections of neuroleptic drugs can reduce the rewarding properties of intracranial stimulation. Conversely, similar applications of cis-flupenthixol into the medial prefrontal cortex resulted in dose-dependent increases in the size of the VTA induced preferences. These data suggest that DA sensitive elements in the prefrontal cortex may provide a modulatory influence on the functional output of DA cells within the nucleus accumbens.

27.5

THE EFFECT OF PIMOZIDE ON WATER-REINFORCED RUNNING AND UNCONDITIONED DRINKING. J.C. Horvitz and A. Ettenberg. Dept. of Psych., Univ. of Calif., Santa Barbara, CA 93106.

Thirsty male albino rats were trained to traverse a straight-arm runway for 100 licks of water reward. The duration of each lick, and interval between licks were recorded. Single daily trials were administered until animals traversed the runway in less than 20 seconds. After animals had acquired the running behavior, they received single daily nonrewarded trials until running speeds had slowed substantially. In the midst of this extinction phase, animals recieved another water-rewarded trial either drug-free or under the influence of dopamine receptor-blocking agent pimozide (PIM) (0.5 or 1.0 mg/kg). Running speeds were recorded 24 hours later, during a drug-free test trial. Animals nondrugged during the water-reinforced trial showed a reinstatement of operant running the following day. PIM (1.0 mg/kg) blocked this response-reinstating effect of water reward. In addition both PIM and non-reward conditions produced a decrease in the duration of individual licks.

27.6

THE KINETICS OF THE MOTIVATIONAL PROPERTY OF SACCHARIN: MEASUREMENT OF REWARDING AND REINFORCING EFFECTS. T.L. Stefurak*, D. van der Kooy (SPON: N. Mrosovsky), Neurobiological Research Group, Dept. of Anatomy, University of Toronto, Toronto, Canada M5S 1A8

We asked if a single motivational property of saccharin can explain its actions in different paradigms.Saccharin preferences measured in the two bottle tests comparing consumption of water against various saccharin concentrations (0.025 to 3.2%) revealed decreasing preferences (rewarding effects) with increasing concentrations. However, the reinforcing effects of saccharin, as measured by the conditioned place preferences produced by consumption of these same concentrations of saccharin, revealed increasing conditioned place preferences with increasing concentration. In fact, any combination of saccharin concentration and volume consumption that resulted in a pairing intake of more than 20 mg of saccharin produced conditioned place preferences. We suggest that high concentrations of saccharin have aversive taste properties that limit their volume consumption, but that the absolute amount of saccharin consumed in mg is still reinforcing. The ability of consumption tests to measure the rewarding effects of low concentrations of saccharin, those measured as non-reinforcing by the conditioned place test, may be accounted for by a greater sensitivity of taste versus place stimuli to assess the motivational properties of saccharin. We suggest that there is only a single positive motivational property of saccharin.

27.7

LACK OF TOLERANCE TO THE INCENTIVE MOTIVATIONAL PROPERTIES OF OPIATES: APPARENT TOLERANCE IS OVERSHADOWING. A.Bechara and D. van der Kooy, Neurobiology Research Group, Dept. of Anatomy, Univ. of Toronto, Toronto,Ont.,Canada,M5S 1A8.

There has been a long controversy as to whether physically dependent subjects become tolerant to the incentive motivational effects of opiates. This question can now be addressed more explicitly because the incentive and the withdrawal motivational properties of opiates can be measured separately in a modified place conditioning paradigm, and because lesions of the tegmental pedunculopontine nucleus(TPP) abolish specifically the incentive motivational effects of opiates. To measure the incentive motivational properties of opiates, rats were placed in a distinctive environment immediately after being injected with a dose of morphine. The incentive effects of morphine were assessed by the conditioned preference rats showed for this morphine associated environment over an unfamiliar neutral one. Apparent tolerance was revealed when naive, but not physically dependent (60 mg/kg/day for a minimum of 14 days prior to conditioning), rats conditioned with 2 mg/kg doses of morphine (i.p.) expressed morphine conditioned place preferences. Higher doses of morphine (20 mg/kg) were effective in producing incentive effects in both the naive and physically dependent rats.TPP lesions blocked the incentive motivational effects of morphine in the naive, but not in the dependent, groups. Most interestingly, when physically dependent animals were administered withdrawal alleviating doses of morphine (20 mg/kg) one hour prior to conditioning with morphine(2 mg/kg), they now showed morphine place preferences equal to those seen in naive rats at 2 mg/kg. Most importantly, these incentive effects of morphine in both naive and dependent groups were abolished by TPP lesions. Thus, the alleviation of withdrawal allowed the unmasking of the unaltered neural mechanisms underlying the incentive motivational effects of opiates. We suggest that the apparent tolerance to the incentive effects of opiates results from overshadowing of these incentive effects by withdrawal mechanisms associated with opiate dependence.

27.8

DIFFERENTIAL DISCRIMINATIVE CONTROL BY MORPHINE AS A DANGER VERSUS SAFETY SIGNAL. G.M. Martin*, A. Pridgar* and D. van der Kooy (Spon: R. Adamec). Dept. of Psychology Memorial University, Newfoundland, A1B 3X9, Dept.of Anatomy, University of Toronto, Toronto M5S 1A8

The conditional control exerted by a morphine induced drug state over consumption was examined. Half the rats received injections of 5mg/kg of morphine, as a danger signal, followed by a saccharin solution, which was followed by the injection of lithium chloride on training days (Morph-Sac-LiCl). Saline injections were substituted for morphine on safe days (Saline-Sac-Saline) in this group. The remaining rats had the roles of the first morphine and first saline injections interchanged so that morphine served as a safety signal.

The control over consumption exerted by morphine, as a danger signal, transferred to novel and familiar foods. Morphine, as a danger signal, was even learned with a delay of one minute between its offset (reversed by naloxone) and the presentation of saccharin. When morphine served as a safety signal, learning did not occur with delays after its offset, nor did transfer occur even when learning had occurred without any delays. It appears that when morphine is a safety signal rats learn that a single configuration of stimuli (morphine/saccharin) predict a motivational event. In contrast, when morphine is a danger signal rats learn that morphine is a conditional cue that is independent of the specific configuration of stimuli used.

27.9

BIPHASIC ALTERATION OF 3-MT LEVELS IN MOUSE NUCLEUS ACCUMBENS DURING STRESS S. Puglisi-Allegra and S. Cabib* Istituto di Psicobiologia e Psicofarmacologia (C.N.R.), Roma I-00198, Italy

Stressful stimulations are known to alter dopamine (DA) metabolism in various brain areas. We have recently presented results suggesting that 30-120 minutes of immobilization stress reduce DA release in the nucleus accumbens (NAS) and, less markedly, in the caudatus putamen of the mouse (Cabib et al. Brain Res., 441:153, 1988).

We now report that immobilization as well as unavoidable footshock induce biphasic alterations of 3-methoxytyramine (3-MT) levels in the NAS of mice. An initial dramatic increase of this metabolism was, in fact, evident within the first 10 minutes of exposure to both type of stressors; followed by a decrease at 30-60 min. An increase of the acid metabolites (DOPAC and HVA) was evident at all times during stressful stimulation.

These results suggest that stressful experiences induce a biphasic alteration of DA transmission in the NAS characterized by an initial increase of DA release, possibly related to an arousal state, followed by by a decrease possibly related to coping failure.

27.10

PREOPTIC STIMULATION SUPPRESSES AND NON-PREOPTIC STIMULATION ENHANCES MATERNAL BEHAVIORS IN POSTPARTURIENT RATS. M.A. Steuer* and M.B. Kristal (SPON: M.A. Bozarth) Dept. of Psychology, SUNY at Buffalo, Buffalo, N.Y. 14260.

In an effort to determine how the preoptic area (POA) modulates the expression of maternal behaviors, the POA of postparturient rats was stimulated using either electrical or glutaminergic stimulation.

During electrical stimulation (100 cps, 0.2 msec separated by 0.1 msec, 2-20 μA) in and around the POA, retrieval was unaffected, but crouching, pup-licking, and nestbuilding were suppressed due to the emergence of arousal-induced autogrooming/locomotor activity which was incompatible with the expression of maternal responsiveness. In contrast, during electrical stimulation outside of the POA (neocortex, caudate, or even of the tail of the rat) retrieval and nestbuilding were not affected, but crouching and pup-licking were enhanced.

Infusion of glutamate (0.25 μL, 0.5 M) into the POA resulted in a strong suppression of all aspects of maternal behavior due to the activation of a thermosensitive motivational system which resulted in the emergence of incompatible responses (sprawling, autogrooming). Infusions into a control site (cortex) did not interfere with any aspect of maternal behavior.

Supported by NSF grant BNS86-01818 awarded to MBK.

27.11

SPECIFIC BUT NOT GENERAL DAMAGE TO HIPPOCAMPAL SUBFIELDS DISRUPTS GROOMING IN RATS. R. L. Cannon*, D. J. Paul*, R. H. Baisden, and M. L. Woodruff. Dept. of Anatomy, Col. of Med., East Tenn. St. Univ., Johnson City, TN 37614.

The purposes of the present investigation were (1) to examine the effects of exposure to TMT on an unlearned, species-typical behavior and (2) to determine whether destruction of specific hippocampal subfields are responsible for behavioral deficits. Adult male Long-Evans rats were exposed to either TMT, kainic acid (KA), which destroys subfield CA3, or colchicine (COL), which destroys the dentate granule cells. Four months later grooming was observed under two conditions. First, rats were viewed in a large open field 15 min per day for 3 days. Next the rats were sprayed with a 16% sucrose solution to elicit excessive grooming and then observed in a transparent Plexiglas cage 15 min per day for 3 days. Normal rats were observed under the same conditions. The sequence of behavior and the efficacy of movement were examined. The TMT-exposed rats did not differ from the normal rats, but both KA- and COL-injected rats showed significant variations from the normal grooming pattern. These results indicate that the damage to the hippocampus induced by TMT does not inevitably correlate with all of the behavioral changes produced by restricted subfield damage. (Supported by NIH grant ES 04070-03 to MLW).

INFLUENCES OF SCHEDULE-INDUCED POLYDIPSIA ON BODY TEMPERATURE IN RATS. G. Mittleman, H. Verdoux, M. Le Moal and R. Dantzer. INSERM U-259, Domaine de Carriere, Rue Camille Saint Saens, Bordeaux, 33077, France.

Schedule-induced polydipsia (SIP) is an example of the larger category of adjunctive behaviors that occur in situations where a strongly motivated appetitive or consummatory behavior is interrupted or prevented. It has been suggested that SIP as well as other adjunctive behaviors arise from the excitement accompanying the delivery of a food reward. Thus, hungry animals exposed to intermittent presentations of small amounts of food show increased arousal as measured by either endocrine or behavioral indices (Brett, L.P. and Levine, S., JCPP, 93:946, 1979; Kileen,P., Hanson, S.J. and Osbourne, S.R., Psychol. Rev., 85:571, 1978) as well as other physiological changes consistent with increased metabolism. In this experiment, body temperature (Tb) and activity of rats food deprived to 85% of their baseline weight was continuously monitored during tests for schedule-induced drinking or forced wheel running. It was found that rats which showed polydipsia (SIP-pos) had a smaller increase in Tb than rats that did not drink (SIP-neg). This difference was related to baseline Tb and food motivation but was independent of water consumption. Forced wheel running induced an increase in Tb in SIP-pos rats similar to that observed during SIP testing, but little or no change in SIP-neg animals, in spite of large differences in activity levels. These results agree with previous demonstrations suggesting that SIP-pos and -neg rats differ in terms of energy metabolism.

DIFFERENTIAL EFFECTS OF PERIPEDUNCULAR AREA LESIONS ON MATERNAL AGGRESSION IN LACTATING RATS. E. M. Factor, A. D. Mayer* and J. S. Rosenblatt* Inst. Anim. Beh., Rutgers Univ., Newark NJ 07102.

Electrolytic lesions of the lateral midbrain which include the peripeduncular area (PPN) eliminate maternal aggression and the milk-ejection reflex in lactating rats when such lesions are made one week postpartum (Hansen,S. and Ferreira,A., Behav.Neurosci. 100:64, 1986). These data support the hypothesis that postpartum aggression in rodents is maintained by suckling stimulation, and suggest the PPN as a locus which integrates somatosensory (e.g. suckling) and motivational impulses. This study examined the behavioral effects of PPN lesions made at specific points in gestation or lactation. Primiparous rats received bilateral PPN lesions (RF current 10 mA/6 sec/side) at one of four reproductive stages: on gestation day 18, or lactation days 2 (24 hours postpartum), 5, or 8. Sham lesions were made without current. Another group received axon-sparing lesions with the cytotoxin N-methyl-d,l-aspartic acid (NMA, 0.4 ug/side) or saline vehicle. Data were recorded for nursing, nestbuilding, pup retrieving, aggression, hoarding and daily litter weight gain. Dramatic reductions in maternal aggression and litter weight gain and longer retrieving latencies developed in rats that received PPN lesions on lactation day 8. Other behaviors were not changed. RF lesions made prepartum or during early lactation did not affect litter weight gain or any of the observed behaviors. The functional significance of PPN neurons may increase with the duration of maternal experience in primiparous lactating rats.

ELECTROLYTIC LESIONS OF THE HABENULA OR DORSAL HIPPOCAMPUS REDUCE ANXIETY-ASSOCIATED BEHAVIORS IN RATS. B.L.Kendis* and J.V.Cassella+ (SPON: C.M.Sinton). Neuroscience Program, Oberlin College, Oberlin,OH 44074 and +Neurogen Corporation, Branford,CT 06405.

Anatomical evidence suggests that the habenula is an important relay between limbic forebrain and midbrain areas. The role of the habenula, as well as the dorsal hippocampus, in anxiety in two behavioral models was assessed. Male albino rats were tested initially in a shuttle-type box in which one side was lighted and the other side was dark (the LDC) and were then tested on an Elevated Plus-Maze (EPM). Testing was conducted at least 1 day before and seven days after surgery : sham, medial and lateral habenula and/or dorsal hippocampus.

Lesions in either the habenula or dorsal hippocampus increased specific activities in the LDC and EPM indicative of anxiety reduction without increasing independently-assessed general locomotor activity. Combined habenula and hippocampal lesions did not produce additive behavioral effects. The data suggest that these structures are independent components of a neural circuitry involved in the expression of anxiety.

27.15

THE INFLUENCE OF EARLY HANDLING AND PRIOR PLAY EXPERIENCE ON OPEN FIELD & ELEVATED-PLUS MAZE EXPLORATION, AND ON BRAIN & ADRENAL WEIGHTS IN JUVENILE RATS. L. Crepeau & J. Panksepp, Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403

Juvenile rats that received early handling (EH) during the first two weeks of life and that were subsequently tested in an open field holeboard exhibited reliably higher levels of grid crossings ($p < .05$) and rearings ($p < .01$), compared to unhandled controls. Rats that were provided with 15 min of daily prior play experience (PPE) for five days beginning at 22 days of age exhibited marginally higher levels of investigatory nose pokes when tested in the holeboard ($p < .07$).

When tested on an elevated-plus maze (Pellow, et al., *J. Neurosci. Meth., 14*, 149-167, 1985), PPE group rats explored onto and spent more time on the open arms of the apparatus, compared to play-naive controls ($p's < .01$). PPE group animals also explored marginally less onto the closed arms ($p < .10$), and spent less time on the closed arms than controls ($p < .01$). Additionally, EH group rats that received PPE exhibited reliably higher levels of closed arm entries, compared to play-naive EH rats ($p < .01$). PPE had no effect on closed arm entries among unhandled controls. This manipulation did not affect open arm exploration.

Brain/body weight ratios were reliably higher in female rats, compared to males ($p < .01$). Additionally, EH reliably increased the brain/body ratios among the males ($p < .01$), but not among the females.

Adrenal/body weight ratios were also reliably higher in female rats, compared to males ($p < .01$). Additionally, EH reliably increased the brain/body ratios in both males and females ($p's < .05$).

27.16

TEMPORAL SPECIFICITY OF FEAR CONDITIONING: EFFECTS OF DIFFERENT CS-US INTERVALS ON THE FEAR-POTENTIATED STARTLE EFFECT. M. Davis, L.S. Schlesinger* and C.A. Sorenson. Dept. of Psychiatry, Yale University School of Medicine, 34 Park St., New Haven, Conn. 06508

Separate groups of rats were given 30 pairings of a light (CS) and a 500-msec shock (US) at CS-US intervals of either 0, 25, 50, 100, 200, 800, 3,200, 12,800 or 51,200 msec. Other groups had lights and shocks inconsistently paired. 2-4 days later the startle reflex was elicited with a noise burst alone or 25-51,200 msec after light onset. Following CS-US pairing over a wide range of intervals (25-51,200 msec), startle was potentiated in testing, sometimes as rapidly as 50 msec after light onset. Magnitude of potentiation and resistance to extinction were generally greater with longer CS-US intervals. In several groups potentiation was maximal at a test interval that matched the CS-US interval used in training. This temporal specificity sharpened with increasing numbers of training trials but even occurred with a single training trial when a 51,200-msec CS-US interval was employed. The data indicate that even during "simple fear conditioning" animals rapidly learn a temporal CS-US relationship, which has important implications for understanding the neural mechanisms of fear conditioning.

27.17

ACTH EFFECTS ON ISOLATION-INDUCED DISTRESS CALLING IN CHICKS. L. Normansell and J. Panksepp. Dept. of Psychology, Muskingum College, New Concord, OH 43762, and Bowling Green State University, Bowling Green, OH 43403.

Previous work has implicated corticotropin releasing factor (CRF) in the brain control of separation distress (Panksepp, Clynes, & Crepeau, Soc Neurosci Abstr 13: 1320, 1987). As well, the pituitary hormone a-MSH has been shown to affect the number of vocalizations emitted by isolated chicks, producing a transient increase followed by a prolonged decrease (Abbott & Panksepp, Soc Neurosci Abstr 14: 287, 1988). In this series of experiments, the effects of adrenocorticotropic hormone (ACTH 1-24 and ACTH 4-10) on isolation- induced distress vocalizations (DVs) was assessed. Initially, a dose response determination was conducted on both peptides. ACTH 1-24 at doses of .5nM and above increased DVs relative to control when the animals were tested in a mirrored environment which generally serves to suppress calling. This effect, however, was short-lived. When tested 1 and 20 hours after injection, the treated animals did not differ from controls. ACTH 4-10 had no effect on vocalization when the animals were tested immediately after injection, but produced an increase in calling when the animals were tested an hour later. In addition to vocalization changes, ACTH 1-24 induced yawning, head shaking, and wing flapping. ACTH-treated chicks also preened themselves more than controls, and had longer latencies to close their eyes when they were held in the cupped hands of the experimenter. Taken together the results suggest that ACTH induces a central state of arousal in chicks that resembles fear/anxiety.

27.18

BEHAVIOURAL IMPAIRMENTS IN DEMANDING LEARNING PARADIGMS FOLLOWING HABENULAR LESIONS.
E.W. Thornton*, Dept. of Psychology, Liverpool Univ. Liverpool, England. (SPON: A.J. Goudie)
Habenular lesioned and control rats were tested for acquisition of either active avoidance or simple discrimination response under more, or less, demanding conditions. In the former, rats had to jump to a platform at heights of either 4 or 17 cm to avoid or escape from shock presented 20 sec after a warning CS. Intensity of shock and inter-trial-intervals (ITI) were also altered to increase the level of demand. Discrimination learning was carried out in conventional Y-maze. More demanding discrimination was carried out in a water tank in which the rat was required to swim to a platform on the non-preferred side of a bimodal spatial location with the correct choice confounded by random presentation of a salient, but irrelevant, visual cue (see Lee, K.K. & Maier, S.F. J. Exp.Psychol, 1988, 14, 302).

Results showed no lesion induced deficit in avoidance learning with non-demanding contingencies but impaired avoidance responding with short ITIs and higher shock intensity and more demanding response without effect on escape latencies. There was no impairment of simple discrimination learning but lesioned rats were impaired in the more difficult swim test. The deficits are indirect evidence consistent with the habenula regulating dopaminergic function.

27.19

BETA-ENDORPHIN WITHDRAWAL EFFECTS IN PREMENSTRUAL SYNDROME.
R.H. Loiselle, A.J. Giannini, D.J. Folts, B.S. Sullivan. Northeast Ohio Medical College, P. O. Box 2169, Youngstown, Ohio 44504.

Sixty women with premenstrual syndrome (PMS) were studied. All were between ages 21 and 34. β-endorphin levels were measured on the first, fifth, tenth, fifteenth, twentieth, and twenty-fifth day of each of two menstrual cycles. Responses were measured with the Brief Psychiatric Rating Scale (BPRS).

Twenty-two women had a significant decline in PMS from the fifteenth to twenty-fifth day ($p < .02$). When the BPRS scores of women with β-endorphin decline were compared to those without decline, there were found to be significant increases in anxiety ($p < .01$), depression ($p < .01$), and discomfort ($p < .01$). Concentration was decreased ($p < .05$). Also, women with β-endorphin decline had significantly increased caloric consumption ($p < .02$).

β-endorphin decline may be physiologically similar to morphine withdrawal. Symptoms in the PMS-β-endorphin group are similar to those of morphine withdrawal. A specific β-endorphin withdrawal syndrome may be a distinct subset of PMS.

MICRODRINKING PATTERNS OF RATS DURING ACQUISITION AND MAINTENANCE OF FREE CHOICE ETHANOL. E.M. Sellers, H.L. Kaplan*, M.O. Lawrin* and B. Brands*, Psychopharmacology Program, Addiction Research Foundation and Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada M5S 1A1.

Regulation of rats' free choice ethanol (E) and water (W) drinking was studied on a minute-by-minute basis, using pressure transducers mounted in the bases of custom-built drinking tubes, continuously monitored by a laboratory computer during the 12-hour dark period. Male Wistar rats (n = 21) were given a free choice of E 2% or W until day 4 (D4) and then divided into 3 groups: n = 4 continued at E 2%, n = 7 were raised by 1% every 2 days to E 4% by D7, and n = 10 were similarly raised to E 6% by D11. All groups continued until D21. On D21, combining the groups, time to consume 50% of each fluid's daily volume (VT50) differed (E = 387 min, W = 204 min, $p = 0.0008$), as did the number of discrete drinks (NDK) (E = 60, W = 18, $p = 0.0001$) and the mean drink size (MDS) (E = 0.75 ml, W = 0.52 ml, $p = 0.04$), though the difference in the volume-weighted median drink size (VWD50) was smaller (E = 1.4 ml, W = 1.2 ml, $p = 0.44$). Considering days D5 and D21, E tube volume (D5 = 25 ml, D21 = 43 ml, $p < 0.0001$), E preference ratio (D5=61%, D21 = 76%, $p = 0.004$), E MDS (D5 = 0.66 ml, D21 = 0.83 ml, $p = 0.03$), and E NDK (D5 = 43; D21 = 60, $p < 0.0001$) all increased; W NDK, W MDS, W VT50, E VT50, and E VWD50 were unchanged; W VWD50 increased only in the E 2% group. Other group differences on these statistics were not statistically significant. E drinks are typically later in the session, more numerous, and somewhat larger than W drinks. If drink number, size, and time of occurrence are under different neuroregulatory control, they should show different susceptibility to drugs.

28.2

SUPPRESSION OF ALCOHOL AND FOOD INTAKE BY LY264453, A NEW INHIBITOR OF SEROTONIN (5HT) AND NOREPINEPHRINE (NE) UPTAKE. J.M. Murphy, W.J. McBride, L. Lumeng*, T.-K. Li* and D.T. Wong. Indiana Univ. Sch. Med. and VAMC; Purdue Univ. Sch. Science, Indianapolis, IN 46223; and Lilly Research Labs, Eli Lilly and Co., Indianapolis, IN 46285

Selective 5HT or NE uptake inhibitors decrease food and alcohol ingestion in rats (Pharmacol Biochem Behav 30: 1045, 1988). This study tested a new agent, LY264453, an inhibitor of both 5HT and NE uptake. Male HAD (high alcohol drinking) rats received ad lib food and water, but ethanol (10%, v/v) access was limited to 4 h/day. Rats were injected ip 10 min before the 4 h ethanol access with either the 5HT uptake inhibitor fluoxetine, the NE uptake inhibitor nisoxetine, LY264453 or saline. Food, water and ethanol intakes were recorded hourly over the 4 h period. LY264453 caused the most potent reduction of ethanol drinking (ED_{50}=3.3 mg/kg), followed by nisoxetine (ED_{50}=6 mg/kg) and fluoxetine (ED_{50}=13 mg/kg). Nisoxetine was 3 times more effective in reducing food (ED_{50}=2 mg/kg) than alcohol intake, while LY264453 was about equally effective in decreasing food (ED_{50}=3 mg/kg) and alcohol intake. Previously, we showed that fluoxetine decreased alcohol drinking more than food intake. Water intake was unaltered by most doses of all three drugs. Both the NE and 5HT transmitter systems may regulate alcohol and food intake of HAD rats, but NE may be less important in control of alcohol intake than 5HT systems. (AA-03243 & AA-07611)

28.3

THE 5-HT REUPTAKE INHIBITOR FLUOXETINE BUT NOT THE 5-HT3 ANTAGONIST ZACOPRIDE DECREASES ETHANOL CONSUMPTION DURING RESTRICTED ACCESS IN RATS. D.J. Knapp* and L.A. Pohorecky* (SPON: C. Vander Wende). Center of Alcohol Studies, Rutgers University, Piscataway, NJ 08855-0969.

One of the most consistent findings in clinical and experimental research on ethanol (ET) consumption is inhibition of drinking by serotonin reuptake inhibition. Serotonergic manipulations are currently an active area of research on ET intake. Male Sprague-Dawley rats (490-640 g) with a 50% free choice preference for 6% v/v ET received fluoxetine (FL) (5 mg/kg) and zacopride (1 and 10 mg/kg) sequentially at 4-5 day intervals, 15 or 45 minutes respectively before scheduled access to ET. FL (which is anxiolytic in rats and has no effect on motor function at this dose), increased latency to drinking and decreased number of bouts of drinking in a one hour restricted access period which began at the onset of the dark cycle. ET consumption was reduced by 52%. Drinking under these conditions followed a two-peaked pattern with a large peak during the first 8 minutes and an attenuated peak during the last 20 minutes. 100% of consumption by FL-treated rats occurred during the second 30 minutes of the hour while 77% of consumption by the saline-treated rats occurred during the first 8 minutes. Lick rate, licks/bout, and time/bout were not altered by FL. Similarly anxiolytic and non-motor impairing doses of zacopride did not significantly affect these measures.

28.4

MICROINJECTION OF THE SEROTONIN AGONIST TFMPP INTO THE NUCLEUS ACCUMBENS INCREASES ETHANOL DRINKING IN P RATS. A.D. Levy, J.M. Murphy, W.J. McBride, L. Lumeng*, & T.-K. Li* Indiana Univ Sch Med & VA, Indianapolis IN 46223

It has been proposed that serotonin (5-HT) systems in brain have an important role in mediating ethanol consumption. We are particularly interested in the role of 5-HT in the nucleus accumbens; studies from this lab on P and NP rats (selectively bred for high and low ethanol preference, respectively), have found lower levels of 5-HT in the accumbens of the P compared to the NP line (PBB (1987) 26:389). In preliminary studies, it was determined that intra-accumbens 5-HT injections decreased ethanol intake in P rats. The effect of intra-accumbens injections of TFMPP (5-HT 1b agonist) on ethanol drinking in P rats was therefore examined.

P female rats (N=9) were allowed access to 10% ethanol for 4 hr/day (food and water were available ad lib). Immediately prior to ethanol access, animals were microinjected with TFMPP (0.5-5 ug) or vehicle. Fluid intake was then monitored over the 4 hr testing period. Low (0.5 and 1 ug) doses of TFMPP substantially increased ethanol drinking (by approximately 60% over the first 30 min), while at higher doses this increase was lessened. The data suggest that the presynaptic 5-HT 1b autoreceptor in the nucleus accumbens is important in the mediation of ethanol intake. (AA03245, AA07472, AA07611)

28.5

EFFECTS OF CENTRALLY INJECTED l-AROMATIC AMINO ACID DECARBOXYLASE INHIBITORS ON ALCOHOL CONSUMPTION BY RATS. B.A. McMillen, F.J. Minano* and R.D. Myers, Dept. of Pharmacol. Sch. of Med., East Carolina Univ., Greenville, NC 27858

The central substrates for induction of alcohol (ETOH) consumption and reversal of this phenomena are unclear. Rats were allowed free choice between water or a concentration of ETOH solution such that the ETOH solution comprised 50% of fluid intake: the bottles were rotated each morning and the amount and proportion of ETOH consumed recorded. Inhibitors of l-AAAD were chosen as a means of manipulating central monoaminergic function. One group's ETOH consumption was increased by i.c.v. 50 ng tetrahydropapaveroline (THP), then the rats received 4 days of i.c.v. artificial CSF, followed by 3 days of benserazide (50 or 100 ug) with or without additional THP and then a 4 day postdrug period was recorded as well. Both doses of benserazide reduced ETOH consumption, which remained suppressed during the postdrug period. Another group had their ETOH intake increased by 15 mg/kg s.c. cyanamide for 4 days. Infusions of 5-1000 ng NSD-1015 (3-hydroxybenzylhydrazine) inhibited ETOH consumption, but there was no dose-response effect as seen with benserazide. Analyses of striata from NSD-1015 treated rats did not show accumulation of l-DOPA, which indicates that inhibition of l-AAAD may not be occuring at these low doses of drugs. The exact mechanism for these effects are unclear. (Supported by USPHS grants DA-04895 and AA-04200)

28.6

OPIOIDS' ENHANCEMENT OF INTAKE OF ETHANOL IS RELATED TO THEIR INDUCEMENT OF PLACE PREFERENCES (REWARD) BUT NOT OF THEIR NOCICEPTION (ANALGESIA). L.D. Reid, K.D Wild*, E.J.Bilsky* and C.L. Hubbell*. Dept. of Psychol., Rensselaer Polytechnic Institute, Troy, NY 12180.

Small doses of morphine, methadone, and fentanyl enhance rats' intake of alcoholic beverages. They also produce analgesia and can be used to establish a preference for the place of the drug-experience. Data will be summarized here, however, showing that some opioids that are agonists with respect to place preference and intake of ethanol are antagonists with respect to analgesia. One of these is WIN 44,441-3 (WIN), an agent that blocks ethylketocyclazocine's analgesia as well as that of other opioids.

Rats were given daily opportunities to take a sweetened alcoholic beverage and, across days, increased intake until they took considerable amounts a day. Then, prior to some sessions, rats were given one of 5 doses of WIN or placebo. Doses of 0.3, 1.0 and 10.0 mg/kg reliably incremented intake, i.e., WIN acted like morphine and not like naloxone. The most effective dose of WIN, 1.0 mg/kg, was also given to other rats in a standard conditioned place preference procedure. WIN produced a place-preference similar to morphine's, but unlike that of naloxone's.

The ability of opioids to enhance intake of ethanol is not due solely to their ability to be analgesic since certain opioids not having that ability increase intakes. When rats are tolerant to morphine's analgesia, morphine increments intake of ethanol. Taken together, the data support the idea that excessive alcohol-intake could be related to opioidergic processes of reward.

28.7

OPIOID EFFECTS ON ALCOHOL CONSUMPTION BY RATS ARE CENTRALLY MEDIATED. M.A. Linseman and S. Harding*. Addiction Research Foundation, Toronto, Canada, M5S 2S1.

Systemic administration of low doses of opioid agonists have been shown to increase subsequent alcohol consumption by rats, and of opioid antagonists to decrease it, but the mechanism(s) and locus(i) of these effects are still unknown. In an initial study, the effects of morphine and naltrexone were compared to those of analogous drugs (loperamide and methylnaltrexone, respectively) that do not cross the blood brain barrier. Drugs were administered i.p. to free-feeding rats 30 min. prior to their one-hour daily drinking sessions. Morphine (1, 3 and 10 mg/kg) increased alcohol consumption but loperamide (0.3, 1 and 3 mg/kg) did not; naltrexone (1, 3 and 10 mg/kg) decreased alcohol consumption but methylnaltrexone (3, 10 and 30 mg/kg) did not; and naltrexone (3 mg/kg) blocked the increased alcohol consumption seen following morphine (3 mg/kg) administration but methylnaltrexone (10 mg/kg) did not. In addition, chronic methylnaltrexone treatment also increased alcohol consumption dose-dependently perhaps through an upregulation of the endogenous opioid system. In a second experiment, intracerebroventricular administration of 10 micrograms of morphine 30 min. prior to access to alcohol, also increased alcohol consumption in a manner similar to that seen following systemic morphine. We conclude that opioid effects on alcohol consumption are mediated within the central nervous system.

28.8

SUBFORNICAL ORGAN LESIONS BLOCK THE ANGIOTENSION II-INDUCED SUPPRESSION OF ALCOHOL INTAKE. L.A. Grupp, E. Perlanski* and R.B. Stewart*. Dept. of Pharmacology, Univ. of Toronto, Toronto, Ont., Canada M5S 1A8.

The subfornical organ (SFO) is known to mediate a number of effects of blood borne angiotensin II (ANG II) including the increase in both water intake and blood pressure as well as the release of vasopressin. Recently, systemically administered ANG II has also been shown to reduce voluntary alcohol intake in rats. In order to assess the role of the SFO in the regulation of alcohol intake, two groups of rats were anesthetized with pentobarbital, lesioned or sham lesioned in the area of the SFO and following a one week recovery period offered a choice between alcohol and water on a daily basis for 6 weeks. While the SFO lesion and sham groups did not differ in the amount of alcohol per se that each consumed, SFO lesions did significantly attenuate the ability of ANG II to suppress alcohol intake. This attenuation was not due to a lesion-induced alteration in the pharmacokinetics of alcohol and was seen only in those lesioned animals which also displayed a verified functional deficit, i.e., a failure of ANG II to increase water intake. These findings suggest that the SFO plays a role in the suppressive effect of systemically administered ANG II on alcohol intake but does not otherwise influence alcohol consumption. STRAIN DIFFERENCES IN VOLUNTARY ETHANOL INTAKE USING THE "SAMSON"-SUCROSE FADING PROCEDURE. D.V. Gauvin*, K.M. Moore*, and F.A. Holloway. (SPON: J. Wood) Department of Psychiatry and Behavioral Sciences, University of Oklahoma Health Sciences Ctr., Oklahoma City, OK 73190-3000.

Two groups of rats were exposed to half-hour sessions of home-cage voluntary ethanol access using a modified Samson-sucrose fading procedure. Long-Evans (LE) and Wistar (WI) rats (n=9 per group) were provided a range of ethanol concentrations (5 to 40% w/v). Tail blood ethanol levels (BAL) were determined by gas chromatography at each concentration after stable volumetric intakes were achieved. With respect to the 10, 30, and 40% concentrations, the group average ethanol intake was a direct relationship to concentration; however, peak BALs demonstrated an inverse relationship to concentration. 20% w/v ethanol resulted in the greatest volumetric intake and peak BALs in both groups. A 20% w/v ethanol maintenance concentration produced consistently greater intake in the WI group compared to LE (WI = 2.67 g/kg; LE = .96 g/kg). Water substitution tests resulted in extremely low intakes in both groups (WI = .77 $\pm$ .13 ml; LE = .33 $\pm$ .11 ml). Intraperitoneal ethanol preloading produced a biphasic voluntary intake with low doses increasing intake. Both naltrexone and naloxone produced dose-dependent decreases in voluntary intake in both groups. However, haloperidol pretreatments increased ethanol intake. These data suggest a reciprocal modulation of a simple behavioral operant for ethanol self-administration between opiate suppression and dopaminergic facilitation of voluntary intake.

28.10

ALPHA-TOCOPHEROL MAY ALTER RATE BUT NOT MAGNITUDE OF ETHANOL TOLERANCE. J.R. Criado, D.V. Gauvin*, D. Brackett*, M.F. Wilson*, and F.A. Holloway. University of Oklahoma Health Sciences Center and Veterans Administration Medical Center, Oklahoma City, OK 73190-3000.

Tolerance development to ethanol's motor-disrupting effects was assessed in Sprague-Dawley rats using a computerized activity chamber before and after chronic treatment. After baseline activity measures were assessed, an initial ethanol dose-effect function was generated. Two groups of rats (n=8 per group) received ethanol (2 g/kg, i.g., q 6 hours) for 18 days. One group received dl-alpha-tocopherol chronically from five days prior to the first ethanol dose; the other group received vegetable oil. After one week of chronic ethanol exposure, half of each group was tested after a 3 g/kg ethanol dose. All animals were tested on Days 19 and 20 of ethanol exposure with 2 and 3 g/kg. Equivalent tolerance developed in both groups to both ambulatory and non-ambulatory activity. Post-chronic blood alcohol levels did not differ between groups. However, the tocopherol-treated group exhibited greater activity measures after one week of chronic exposure, and displayed parallel shifts in the ambulatory activity dose-effect curve. The vegetable oil control group activity measures increased at only the 3 g/kg dose after chronic exposure. These data suggest that the rate of tolerance development to ethanol's disruptive effects was altered by tocopherol treatment, but after equivalent chronic exposure, the magnitude of tolerance was similar in both groups.

28.11

THE PHARMACOLOGY OF ALCOHOL SELF-ADMINISTRATION IN WISTAR AND ALCOHOL PREFERRING RATS. G.F.Koob, M.Mitchiner*, F.E. Bloom, and F. Weiss (SPON:T. Melnechuk). Research Institute of Scripps Clinic. La Jolla, CA. 92037.

The role of opioid, dopaminergic and serotonergic systems in ethanol reward was investigated in Alcohol-Preferring (P) and genetically heterogenous Wistar rats. The animals were trained to respond for ethanol (10% v/v) vs. water under a two-lever, free- choice contingency in the absence of food or water deprivation. Rats of both strains developed stable response rates and consumed ethanol at quantities sufficient to produce pharmacologically relevant blood alcohol concentrations ranging from 25-230 mg% (P-Rats) and 27-75% (unselected Wistars). Free-choice responding for water and ethanol was differentially altered by systemic injections of naloxone, bromocriptine and methysergide. Naloxone (0.125, 0.25 and 0.5 mg/kg) pretreatment resulted in a dose-dependent suppression of both ethanol and water intake, but did not alter ethanol preference when expressed as the ratio of ethanol to total fluid intake. In contrast, bromocriptine (1.0, 2.0 and 4.0 mg/kg) produced a significant, dose-dependent shift in preference from ethanol toward water by inhibiting responding for ethanol while enhancing water consumption. No changes in ethanol preference and water or ethanol intake were observed with methysergide (2.5, 5.0, 10.0 mg/kg) in either strain of rats. While all drug treatments produced similar behavioral changes in P- and Wistar rats, these effects were smaller and not consistently dose-dependent in the genetically unselected line of rats. The results suggest a specific involvement of dopaminergic mechanisms in the reinforcing properties of ethanol, but question the behavioral specificity of opioid systems in these ethanol actions. ETHANOL-INDUCED CONDITIONED PLACE PREFERENCE IN MICE SELECTIVELY BRED FOR INSENSITIVITY TO ETHANOL HYPOTHERMIA. C.L. Cunningham and D.R. Niehus*. Dept. of Medical Psychology, Oregon Health Sci. Univ., Portland, OR 97201.

Recent studies of EtOH-induced conditioned taste aversion and oral self-administration of EtOH in rats have suggested that EtOH's hedonic properties may be related to its thermal consequences. The present study provided a further test of this relation using a genetic animal model in the conditioned place preference paradigm. Male mice selectively bred for their sensitivity (COLD line) or insensitivity (HOT line) to EtOH hypothermia were used (Crabbe, J.C., et al. Alcohol Drug Res., 7:163, 1987). In a counterbalanced, differential conditioning procedure, mice from both lines received four pairings of a distinctive floor stimulus with injection of EtOH (2.25 g/kg). A different floor stimulus was paired with saline. EtOH increased general activity in both lines, but to a significantly greater extent in HOT mice. During the final choice test, HOT mice showed a significant difference in preference for the EtOH-paired vs saline-paired floor, whereas COLD mice showed no difference. This outcome supports the notion that EtOH's hedonic properties may be influenced by its thermal effect. Further, it suggests that the genes governing EtOH's effect on the thermoregulatory system may overlap with those determining EtOH's reward value.

ALCOHOL PREFERRING AND NON-PREFERRING RATS SHOW DIFFERENTIAL SENSITIVITY TO ETHANOL ADMINISTRATION IN A CONFLICT TEST. [1]H.A.Baldwin* [1]G.F.Koob [2]M.A.Schuckit* [3]L.Lumeng* and [3]T.-K.Li*. [1]Research Institute of Scripps Clinic, La Jolla, CA 92037. [2]V.A. Medical Center, La Jolla, CA 92161. [3]Indiana University School of Medicine, Indianapolis, IN 46223 (SPON: E.L.F.Battenberg).

The effect of acute ethanol administration in a modified Geller Seifter conflict test was investigated in Alcohol Preferring (P), Alcohol Non-Preferring (NP) and genetically heterogeneous Wistar rats. Rats were trained to lever-press for food reward where an unpunished RI-30s schedule rotated with an FR-1 incremental shock conflict schedule. Once a stable baseline rate of responding was achieved each rat received 5 doses of ethanol (0,0.25,0.5,0.75 & 1 g/kg i.p.), in a latin square design, with at least 3 drug-free days between each dose. Rats were tested in the conflict test 15 min after each dose of ethanol. ANOVA showed that ethanol significantly ($p<0.05$) and dose dependently increased the rate of punished responding and decreased the rate of unpunished responding in the control Wistar rats. NP rats displayed increased sensitivity to the effects of ethanol on punished and unpunished responding compared with controls. High doses of ethanol reduced punished responding in the NP rats presumably because of increased sedation. P rats showed a reduced sensitivity to ethanol in the punished component whilst ethanol did not significantly reduce unpunished responding compared with baseline scores. Thus, NP rats were more sensitive, and P rats were less sensitive, to the effects of ethanol in this test when compared with control Wistar rats. This work was supported by a grant from NIAAA (AA 06420).

EFFECTS OF STRESS ON ETHANOL INTAKE IN RATS THAT DIFFER GENETICALLY IN ETHANOL PREFERENCE. J.C. Froehlich,* M. Zweifel,* L. Lumeng* and T.-K. Li* SPON: (J. Nurnberger, Jr.) Department of Medicine, Indiana University School of Medicine and VAMC, Indianapolis, Indiana 46223

It has been postulated that stress increases ethanol intake and contributes to chronic ethanol drinking. The present study examined the effect of an intermittent schedule of unpredictable/uncontrollable restraint stress on ethanol intake in rats genetically selected for high (P line) or low (NP line) ethanol drinking. Fifteen male rats from each line were given nine weeks of free-choice between water and a 10% (v/v) ethanol solution with food freely available. Half of the rats from each line were stressed on days 16-25 and the remainder received no stress or handling. Stress consisted of immobilization in a nylon restraint sleeve for 30-120 min per day. Ethanol and water intakes were monitored on days prior to, during, and following stress. Rats of the P line consumed 92-106 mls of 10% ethanol/kg BW per day prior to stress. In contrast, rats of the NP line consumed less than 10 mls of 10% ethanol/kg BW per day prior to stress. In the P line immobilization stress significantly reduced ethanol intake during the first 5 days of stress application and significantly increased ethanol intake only on days 1-5 and 11-20 following stress termination. In contrast, no change in ethanol intake was seen in the NP line during stress application, but ethanol intake was significantly increased on days 16-60 following stress termination. Post-stress increases in ethanol intake were quite small in the P line (12.2%) compared with the NP line (52.1%). The data indicate that stress elevates ethanol intake only when chronic intake is low prior to stress application. (AA03243; AA07611 and AA08312)

28.15

DIFFERENCES IN PERFORMANCE ON ANXIETY TESTS IN RATS GENETICALLY SELECTED FOR ETHANOL PREFERENCE R.B. Stewart*, J.M. Murphy, L. Lumeng* and T.-K. Li* (SPON: S. Morzorati). Indiana Univ. Sch. Med. & VAMC; Purdue Univ. Sch. Science, Indianapolis, IN 46223

Anxiety-reduction is often cited as a motivation for alcohol use and abuse. The relationship between anxiety and ethanol intake was examined in rats selectively bred for high (P line) and low (NP line) ethanol preference. Two methods were used to measure anxiety in each line: 1) time spent exploring the open arms of an elevated plus-maze and 2) suppression of operant responding in an approach-avoidance conflict procedure. P rats spent significantly less time in the open arms of the plus-maze than NP rats during a 5-min test (P:27.9 $\pm$ 8.8 sec. NP:75.2 $\pm$ 9.6 sec.; $p<.01$), suggesting that P rats exhibit greater anxiety than NP rats. Separate groups of P and NP rats were trained to bar-press for food on a VI 60" reinforcement schedule during 60-min daily sessions. For two 3-min periods within each session, bar-presses were reinforced with food and punished with electric footshock at intensities of 0.125, 0.2 or 0.35 mA. The P rats showed greater response-suppression than the NP rats at each shock intensity ($p<.05$), indicating that the P rats are more sensitive to shock and/or more emotionally reactive. These rat lines represent a useful model for further examination of the relationship between anxiety and ethanol intake. (Supported by AA-03243 & AA-07611)

BLOOD-BRAIN BARRIER DYSFUNCTION MAY PERSIST FOLLOWING PROLONGED ABSTINENCE IN A RAT MODEL FOR CHRONIC ETHANOL CONSUMPTION EFFECTS. M. A. King, B. E. Hunter, and D. W. Walker, VA Medical Ctr. and Department of Neuroscience, University of Florida, Gainesville, FL 32610.

Adult male Long-Evans rats were treated for 210 days (30 weeks) with a nutrition-yoked liquid diet administration paradigm containing either ethanol or isocalorically substituted sucrose as previously described. Following the liquid diet treatment rats were maintained on lab pellet/water diets for approximately 300 days. Under pentobarbital anesthesia, horseradish peroxidase (HRP) was injected into the femoral vein and allowed to circulate for 20 min prior to cardiac perfusion with buffered mixed aldehyde fixatives. Vibratome sections were reacted with the Hanker-Yates method. The number and area of HRP leaks were quantified in coded tissue. Preliminary results indicate that alcohol-treated rats had 28% more HRP leaks than sucrose control rats, which accounted for a 37% increase in the total leak area in the alcohol group. The average number and area per tissue section were also increased in the alcohol group, suggesting that the increase in total number was not due to brain volume differences. These data suggest that long-term ethanol consumption may result in a dysfunction of the blood-brain barrier that persists long after ethanol intake ceases.

BASAL GANGLIA AND THALAMOCORTICAL CIRCUIT INVOLVEMENT IN CRAVING AND LOSS OF CONTROL IN ALCOHOL DEPENDENCE. J. G. Modell.* J.M. Mountz (SPON: D. Kuhl). University of Michigan Departments of Psychiatry and Nuclear Medicine; Ann Arbor, MI 48109-0116

We recently proposed a model of neurophysiologic dysfunction in basal ganglia/limbic striatal and thalamocortical circuits as a pathogenetic mechanism of obsessive-compulsive disorder (OCD) (Modell JG, Mountz JM, et. al., J Neuropsychiatry, 1:27-36, 1989). OC symptoms were proposed to result from the development of a positive feedback loop in the reciprocally excitatory frontothalamic neuronal circuit which is inadequately integrated or inhibited by the limbic portions of the caudate nucleus (CN), n. accumbens (NA), and ventromedial pallidum (VP). This neuronal circuitry was collectively referred to as the fronto-striato-pallido-thalamo-frontal loop (FSPTFL). In OCD, the affected individual must struggle with the control of impulses or driven behaviors known to be maladaptive or potentially destructive, a struggle that bears resemblance to that which the alcoholic must endure between "craving" and "loss of control."

To determine whether FSPTFL function may play a role in the behavioral components of alcohol abuse and dependence, we reviewed the literature spanning the neurophysiologic mechanisms operative in alcohol intoxication and dependence; and the neuronal circuitry, neurotransmission, and pathologic processes of the FSPTFL. This review disclosed a wide body of evidence that acute intoxication suppresses the neuronal output of the NA and CN to the VP – probably by dopaminergic and serotonergic mechanisms – and that the effects of this inhibition within the FSPTFL may lead to loss of control and compulsive drinking behavior. The alcoholic patient may also have a defect in normal inhibitory mechanisms within the FSPTFL which may underlie the phenomenon of craving, and also make these individuals particularly vulnerable to the disruptive effects of alcohol on this circuitry. This model provides a novel and specific hypothesis for craving and loss of control in alcoholism which lends itself well to testing by neuropharmacologic and functional imaging techniques.

28.18

ORAL SELF-ADMINISTRATION OF ETHANOL VERSUS EXPERIMENTALLY ADMINISTERED ETHANOL FACILITATES REWARDING ELECTRICAL BRAIN STIMULATION. M. Moolten, G.T. Bain* and C. Kornetsky. Boston University School of Medicine, Boston, MA 02118.

We found ethanol will increase the sensitivity of animals to rewarding brain stimulation. Increased sensitivity was found only after oral self-administration but not when ethanol was given intraperitoneally (ip). Because the stress of ip or gavage administration of ethanol might preclude such an increase in sensitivity, we compared the effects of self-administered ethanol to those in yoked animals receiving ethanol noncontingently through a surgically implanted gastric cannula. Electrodes were stereotaxically implanted in the medial forebrain bundle of male F-344 rats and thresholds for brain-stimulation reward were determined using a rate free measure. Animals were water deprived, and then allowed to either drink or were infused with a sucrose or ethanol-sucrose solution prior to testing. After approximately 24 ethanol-sucrose experimental days over a 2 month period, significant threshold lowering effects were observed in the group of animals self-administering ethanol. Animals receiving ethanol noncontingently failed to show this threshold lowering effect. These findings suggest that learning and/or other non-pharmacologic factors play a role in the threshold lowering effects of ethanol on brain-stimulation reward.

REBOUND PENTYLENETETRAZOLE-SUBSTITUTION BY RATS AFTER A SINGLE LARGE-DOSE OF MIDAZOLAM. D.A. Mathis* and M.W. Emmett-Oglesby. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, Texas, 76107-2690.

For rats trained to discriminate between the anxiogenic compound, pentylenetetrazole (PTZ), and saline, withdrawal from chronic diazepam treatment substitutes for the PTZ stimulus (Emmett-Oglesby *et al., J. Pharmacol. Exp. Ther.*, 244:892, 1988). In addition, for rats trained to discriminate between chlordiazepoxide (CDP) and PTZ, then injected with a large dose of CDP, detection of a PTZ-like stimulus occurs 12 and 18 h after CDP administration (Michaelis *et al., Psychopharmacology* 96:15, 1988). In the present study, the time-course of PTZ substitution and return to baseline after a single administration of midazolam (MDZ; 4 mg/kg) was assessed. Rats were trained to discriminate between MDZ (0.5 mg/kg), PTZ (16 mg/kg) and saline on a three-lever operant task under an FR10 schedule of food reinforcement. Substitution was tested at 1, 3, 6, 12, 18 and 24 h post MDZ injection. At 1 h post injection, rats primarily selected the MDZ lever; by 12 h post, rats primarily selected the PTZ lever. Saline-lever selection was obtained 24 h post MDZ administration. Changes in lever selection were orderly across time. Thus, after a single large-dose administration of MDZ, rats initially detected the MDZ stimulus, then they detected the PTZ cue. These data support the hypothesis that rebound withdrawal after MDZ administration produces a stimulus that is similar to the stimulus produced by the anxiogenic drug PTZ, and that a discrimination between a benzodiazepine, PTZ and saline is useful for assessing onset and recovery from benzodiazepine withdrawal.

29.1

DIFFERENTIAL EFFECTS OF DENERVATION ON ACETYLCHOLINESTERASE ACTIVITY IN FROG PARASYMPATHETIC AND SYMPATHETIC GANGLIA.

L.C. Streichert[1,2] and P.B. Sargent[2]. [1]Neurosciences Program, Stanford University School of Medicine, Stanford, CA 94305, and [2]Division of Biomedical Sciences, University of California, Riverside, CA 92521.

Innervation is known to regulate a number of molecules important in synaptic transmission. The influence of the presynaptic nerve on the enzyme acetylcholinesterase (AChE) was determined by comparing AChE activity in normal and denervated autonomic ganglia in the frog *Rana pipiens*. The effects of denervation upon AChE activity were distinct in the parasympathetic cardiac ganglion and the sympathetic lumbar ganglia. Upon denervation, specific activity was found to *increase* significantly in the cardiac ganglion while it *decreased* significantly in the lumbar ganglia. The contribution of cytoplasmic activity to total activity was determined by incubating the ganglia in echothiophate, a poorly lipid-soluble AChE inhibitor. In the cardiac ganglion, denervation resulted in a proportional increase in both cytoplasmic and extracellular AChE activity; in the lumbar ganglia, the majority of AChE activity lost was attributed to extracellular AChE. Therefore, presynaptic innervation appears to differentially regulate AChE activity in parasympathetic and sympathetic ganglia within a single species. These results suggest that denervation produces selective effects on AChE in cholinergic and adrenergic neurons. (Supported by NIH NS24207).

ELECTRIC STIMULATION OF THE LUMBAR COLONIC NERVE RELEASES ACETYLCHOLINE IN THE GUINEA PIG INFERIOR MESENTERIC GANGLION.

H. P. Parkman*, C. L. Williams, W. H. Stapelfeldt, V. A. Lennon and J. H. Szurszewski. Departments of Physiology and Biophysics, Neurology and Immunology, Mayo Medical School, Rochester, MN 55905.

Cholinergic mechanosensory neurons in the colon project to sympathetic ganglia. The aim of this study was to determine in vitro if acetylcholine (ACh) is released in the guinea pig inferior mesenteric ganglion (IMG) during lumbar colonic nerve (LCN) stimulation. Isolated ganglia with attached LCNs were loaded with ^{3}H-choline (750 nM, 80 Ci/mmole) followed by washing with 50 μM eserine and 10 μM hemicholinium-3. The amount of ^{3}H-ACh and ^{3}H-choline released during 5 minute periods was determined by radio-thin layer chromatography. Stimulation of the LCN increased the fractional release of ^{3}H-ACh from 0.08 ± 0.03 to 0.75 ± 0.15% ($p < 0.025$). Stimulation of the LCN during the loading period increased the amount of ^{3}H-ACh present in the IMG by 35% ($p < 0.05$), and resulted in a similar amount of ^{3}H-ACh released during three successive LCN stimulation periods. When the LCN was not stimulated during the loading period, there was a significant ($p < 0.05$) decline in the amount of ^{3}H-ACh released. These results provide direct evidence for the hypothesis that the LCN contains cholinergic afferent nerves that project to the guinea pig inferior mesenteric ganglion. (DK 17632, DK 07198, CA 37343)

29.3

A MAJOR, MUSCARINIC COMPONENT IN TRANSMISSION IN THE SUPERIOR CERVICAL GANGLION OF THE RAT.

C. Zhang* and J.W. Commissiong. (SPON: G. Melvill Jones). Dept. of Physiol., McGill Univ., 3655 Drummond St., Montreal, Quebec, Canada H3G 1Y6.

Male Sprague Dawley rats (300-325 g) were anesthetized with urethane (1.5 g/kg i.p.). The left, cervical, sympathetic trunk was cleared, and stimulated with a concentric, bipolar, stimulating electrode (SNEX-100, Korf, N.Y.), using a Grass S48 stimulator. The postganglionic, compound action potential (CAP) was recorded with hook, bipolar Ag/AgCl electrodes from the ventral, postganglionic, nerve trunk. Atropine (2.5 - 20 µmol/kg i.v.), caused a dose- and time-dependent suppression of transmission in the SCG. The CAP, measured at 10 sec after the injection of atropine, was decreased by 28%-97%. The second of the main four components of the CAP, was most resistant to the inhibitory effect of atropine, which varied from 5-10 min. The inhibitory effect of atropine was similar to that of hexamethonium (C6), at equimolar doses. Neither atropine, nor C6 affected conduction in fibres of passage in the SCG. The results suggest that a muscarinic mechanism may be equally as important as the traditional, nicotinic receptor-mediated mechanism, in the initiation of action potentials in the post-ganglionic neurons of the SCG.

29.4

EXCITATORY AMINO ACIDS STIMULATE ACETYLCHOLINE SECRETION BY LA-N-2 NEUROBLASTOMA CELLS.

U.I. Richardson* and R.J. Wurtman (SPON: B.E. Slack). Laboratory of Neuroendocrine Regulation, Massachusetts Inst. of Technology, Cambridge, MA 02139.

LA-N-2 are clonal human neuroblastoma cells which have retained cholinergic function during more than 10 years in continuous cell culture. Acetylcholine synthesis and secretion in these cells is regulated by the concentration of choline in the culture medium and can be stimulated up to 3-fold by depolarizing concentrations of extracellular K^+ and by veratridine (Richardson,U.I. et al., Brain Research, 476:323, 1989). We now report that neurotransmitter secretion in LA-N-2 cells is also stimulated by the excitatory amino acids L-glutamic acid (L-Glu) and N-methyl-D-aspartic acid (NMDA) but not by kainic acid. Half-maximal stimulation occurs at 3 mM L-Glu and 0.75 mM NMDA, respectively. The effect of NMDA is potentiated by glycine and by concurrent depolarization with elevated extracellular K^+. NMDA stimulation is inhibited by Mg^{+2} and by the NMDA antagonists 5-APV and MK801. Incubation of monolayer cultures with ^{3}H-L-Glu results in a time-, temperature- and Na^+-dependent association of ligand with the cells. A fraction (25%) of the cell-associated radioligand is displaceable by increasing concentrations of NMDA. This may represent specific membrane binding sites for NMDA which transmit the biological effects of the amino acid.

Supported by NIMH grant MH28783.

29.5

CLONING THE CHOLINE ACETYLTRANSFERASE STRUCTURAL GENE FROM THE NEMATODE C. elegans.

A. Alfonso-Pizarro*, K. Grundahl* and J. B. Rand. Dept. of Zoology, Univ. of Wisconsin, Madison, WI 53706; and Oklahoma Medical Research Foundation, Oklahoma City, OK 73104.

In C. elegans, cha-1 is the structural gene for choline acetyltransferase (ChAT). Severe cha-1 mutants have greatly reduced (>95%) ChAT activity; they are also uncoordinated, slow-growing, and resistant to inhibitors of acetylcholinesterase. Extremely severe mutations lead to complete developmental arrest. cha-1 is a complex gene which includes the previously identified unc-17 locus.

We have now cloned part of the cha-1 gene using the method of transposon tagging with the mobile element Tc1. We have taken advantage of the drug-resistance phenotype and examined more than 400 independent spontaneous resistance mutations isolated from strains with high rates of spontaneous Tc1 transposition. Ten mutations in the cha-1 complex were identified, and at least four of them were shown to be associated with Tc1 insertions. Using the DNA flanking one transposon insertion site, we have cloned a 4.9 kb genomic BamH1 fragment. This fragment represents part of the cha-1 complex because six independent cha-1 mutations and one unc-17 mutation are associated with alterations in this fragment, and three of these seven mutations have been shown genetically to map to the center of the cha-1 complex.

29.6

DROSOPHILA MELANOGASTER CHOLINE ACETYLTRANSFERASE USES GTG CODON AS AN INITIATION CODON.

V. Andrisani*, H. Sugihara* and P. Salvaterra. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

We have previously reported that cRNA produced from Drosophila melanogaster choline acetyltransferase (ChAT) cDNA can be translated into active enzyme following injection into Xenopus oocytes or by rabbit reticulocyte lysates. We have also demonstrated the possibility of ChAT using a non AUG initiation codon by constructing frame shift deletion mutants. We have now constructed two different point mutations to more precisely identify the initiation codon of Drosophila ChAT. A GTG codon at position 33 of the clone is apparently used as the initiation codon. Conversion of this GTG to a GCG codon resulted in a drastic decrease of active enzyme translation. In contrast, when the same codon was changed to ATG (the normal initiation codon), increased efficiency of translation was observed. The ATG mutant produces a major protein with a size of 75 kD and is indistinguishable from the wild-type in vitro translation product or in vivo ChAT. In contrast, a smaller protein is produced by translating the GCG mutant RNA. Our results may indicate an important role for translation regulation of ChAT RNA.

29.7

EVIDENCE FOR PRECURSOR PROCESSING OF CHOLINE ACETYLTRANSFERASE IN *DROSOPHILA MELANOGASTER*.

D.J.Selski*, J.A.Olschowka, J.R.Slemmon*. Dept. of Neurobiology and Anatomy, University of Rochester, School of Medicine, Rochester, NY 14642.

Choline acetyltransferase (ChAT) is generally acknowledged to have a molecular weight of *ca.* 67 kD in *Drosophila melanogaster* (Slemmon,J.R., *et. al., J.Biol.Chem.* 257:3847-52, 1982), as well as in mammals. However, a partial cDNA for *Drosophila* ChAT indicated an open reading frame that would produce a much larger protein, i.e. 50-100 extra amino acids on the amino terminus (Itoh, N., *et.al. PNAS* 83:4081-5, 1986).

We have synthesized a 26-amino acid peptide specific for this amino-terminal presequence, and produced polyclonal antibodies against the peptide, as well as other polyclonal antibodies against a fusion-free plasmid-expressed ChAT from the cDNA indicated above. Western blot analysis of *Drosophila* protein using these antibodies indicated specificity to a *ca.* 75 kD protein for the antisera against the presequence, whereas antisera against the entire ChAT sequence recognized the 67 kD,54kD, and75 kD proteins.

Immunocytochemistry of *Drosophila* brains with these antibodies localized staining specific for the larger form of the protein to neuronal cell bodies, whereas staining against the expressed ChAT molecule was localized to neuronal cell bodies and neuropil regions, which consists of axonal and synaptic processes.

Our data presents evidence that *Drosophila* ChAT is translated as a 75kD (or possibly larger) protein containing an amino terminal sequence that is subsequently cleaved to yield the smaller 67kD protein. We propose that this amino terminal sequence may be involved in the translocation of ChAT from the cell body, where it is synthesized, to presynaptic terminals, where it is utilized.

29.8

ISOLATION OF A GENOMIC CLONE OF HUMAN CHOLINE ACETYLTRANSFERASE.

L. B. Hersh, C. F. Kong*, S. Dyer*, W. Strauss, M. Lorenzi*, and D. Hilt. Dept. of Biochemistry, UT Southwestern Medical Center, Dallas, Tx 75235, Dept. of Pharmacology, Un. of Miami, Miami, Fl. 33101, and Dept. of Neurology, Un. Maryland School of Medicine, Baltimore, Md. 21201.

Oligonucleotides directed toward different regions of the choline acetyltransferase (ChAT) protein were synthesized on the basis of the porcine cDNA and human peptide sequences. These oligonucleotides were used to screen a Charon 28 human genomic library from which a putative human ChAT gene was isolated. On the basis of hybridization profiles it was estimated that this clone contains exons which account for approximately one third of the coding region. A BamH I fragment derived from this clone was sequenced and found to contain a 60 base sequence which showed 88% identity to porcine ChAT. Amongst the 12% non-identical nucleotides was a change from the AUG start codon of the porcine enzyme to an ACG in the human sequence. This indicates that the N-terminal sequence of the porcine and human enzymes differ.

29.9

ChAT mRNA EXPRESSION IN THE MAMMALIAN CNS.

L. Cavicchioli*, T.P. Flanigan*+, G. Dickson*+, F.S. Walsh+ and A. Leon. Fidia Research Laboratories, 35031 Abano Terme, Italy, +Institute of Neurology, The National Hospital, WC1N 3BG London, United Kingdom.

In order to study the regulation of ChAT gene expression in rat CNS, a nucleotide probe of 270 bp, derived from the porcine ChAT mRNA sequence (Berrard S. et al., PNAS, 84:9280, 1987) has been synthesized. Total RNA from cholinergic regions (septum, striatum and spinal cord) and also from other tissues (skeletal and cardiac muscles) or cell lines (glioma C6 or PC12 cells) was used as template to generate, by reverse transcriptase (RT) reaction, copies of ChAT and P1B15 mRNAs. The RT products were then amplified by means of a polymerase chain reaction, for up to 30 cycles. Results obtained show 1) occurrence of ChAT mRNA in discrete CNS areas also possessing ChAT enzymatic activity; 2) presence of ChAT mRNA, although in a very low level, in PC12 cells, but not in glioma C6 cells nor in cardiac or skeletal muscular tissues. In addition, 3) comparison of the relative amount of ChAT mRNA vs p1B15 mRNA in the various CNS areas indicate that ChAT gene transcript is expressed in extremely low abundance, with septum and spinal cord possessing relatively higher levels with respect to striatum. In view of the above results, we are currently evaluating, in different experimental conditions, ChAT gene expression in both developing and adult CNS, in particular forebrain cholinergic neurons.

29.10

TRANSCRIPTION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS IN YEAST.

T.R. Podleski[1,3], K. Jansen*[2], H. Aoshima*[2], J-C Chen*[2], M. Sweet*[2], O. Hamill[1], J. Lindstrom[3] and G. P. Hess[2], [1]Neurobiology and Behavior, [2]Biochemistry Molecular and Cell Biology, Cornell University, Ithaca, NY 14853, [3]Salk Institute, San Diego, CA 92138

Recently, expression of the four subunits of the nicotinic acetylcholine receptor (AchR) from Torpedo has been obtained in yeast (Jansen et al., J. Biol Chem., in press). We initiated the present work with the alpha 4 and beta 2 subunits which were first isolated in c-DNA libraries from PC-12 cells and rat brain and shown to be subunits for a neuronal AchR (Boulter et al., Proc. Natl. Acad. Sci. 84:7763, 1987). Because of the high GC content of the beta 2 5' untranslated leader sequence, and the preference for A rich leader sequences in yeast, we removed the native leader sequence by partial digestion with the endonuclease BssHII, followed by treatment with Mung Bean nuclease. Two constructs for alpha 4 DNA were used. One was the native rat form, and the second was one in which the native leader and signal sequence was removed and replaced with the Torpedo alpha 1 leader and signal sequence. Subsequently alpha 4 and beta 2 DNA were inserted into a yeast expression vector and used to transform yeast. m-RNA purified from transformed yeast was injected into frog oocytes, and functional AchRs were detected using the newly developed photolysible analog of carbamylcholine and laser flash photolysis (Milburn, et al. Biochem. 28:49, 1989). Functional AchRs were present which resulted in the depolarization of the oocyte membrane. We have established, therefore, that yeast cells are capable of synthesizing m-RNA which can direct the synthesis and assembly of functional rat neuronal AchRs in frog oocytes.

TRP was a Visiting Scientist in J. Patrick's laboratory, Salk Institute.

29.11

FURTHER CHARACTERIZATION OF A SUBSTANCE FROM TORPEDO ELECTROPLAQUE WHICH MODULATES NICOTINIC ACETYLCHOLINE RECEPTOR ACTIVITY.

B.A. Coleman, G.A.Weiland, and R.E. Oswald. Dept. of Pharmacology, Cornell Univ., Ithaca, NY 14853.

A substance isolated from *Torpedo* electroplaque which interacts with the nicotinic acetylcholine receptor (nAChR) has properties similar to tachykinins, but may be distinct from this class of peptides. Homogenization of *Torpedo* electroplaque in 6 M guanidine HCl and 0.1% trifluoroacetic acid followed by concentration on Waters' SepPak C-18 columns yielded a reconstituted fraction capable of inhibiting αbungarotoxin (αBgt) and carbamylcholine-stimulated PCP binding, increasing the rate of nAChR desensitization, and inhibiting agonist-stimulated ion flux through the ion channel. Under similar conditions, Substance P has shown the same effects. Consistent with the inhibitory activity being due to an acid-stable proteinaceous component, inhibition of αBgt binding is not affected by prolonged exposure of the extract to low pH but is reduced by prior incubation with proteinase K. As detected by TLC, a protein component of the extract is dialyzable through 6,000-8,000 MW dialysis tubing. Inhbition of PCP binding is also removed by dialysis. Further chromatography on a Beckman Ultrasphere ODS C-18 column using HPLC shows several peaks eluting between 30-40% acetonitrile. One of these peaks has been found to retain activity which inhibits αBgt binding, though at reduced levels. This peak can be detected at 214 nm but not at 280 nm, similar to many tachykinins which lack tyrosine residues. Incubation of the *Torpedo* extract with commercially prepared anti-Substance P antibodies removed the inhibitory activity. However, antibodies known to bind to a variety of tachykinins have not shown reactivity with the *Torpedo* extract. The reason for this discrepancy is unknown at present. Further purification and investigation of the exact nature of this substance is currently underway.

29.12

PROBING THE BINDING SITE FOR OPEN-CHANNEL BLOCKERS IN THE MUSCLE NICOTINIC ACETYLCHOLINE RECEPTOR.

P. Charnet*, C. Labarca*, R.J. Leonard, L. Czyzyk*, N. Davidson, H.A. Lester. (SPON: J.Pine). Div. of Biology 156-29, CALTECH, PASADENA, CA, 91125.

We are using site-directed mutagenesis and oocyte expression to probe the binding site for open-channel blockers at muscle nicotinic acetylcholine receptors. We employ QX-222, the model quaternary ammonium analog of lidocaine. Single channel and macroscopic relaxation recording give information about the residence time in the channel and the binding affinity of the blocker. Our previous studies on position 6' of the second transmembrane segment (M2) of each subunit showed that replacement of serine by alanine (α 248, δ 262) decreases, while the replacement of phenylalanine by serine (β 259) increases the residence time of the blocker. These observations suggest that the hydroxyl groups of the M2 helices line the pore of the channel, and that this site interacts with the positively charged end of the blocker. We now report that the same type of mutation at position 10' produces the opposite effect : replacing serine (α 252) or threonine (β 263) by alanine increases the residence time, while replacing alanine (γ 261) by serine decreases it. These data, taken together, suggest that binding of QX-222 depends on two differents types of interaction: the charged moiety of the molecule binds to the polar OH groups of position 6' whereas its nonpolar moiety binds to position 10', and would prefer a non polar environment. The distance (5.2 A) between the centers of the two moieties (common to most local anesthetics) matches well the distance (5.2 A) between positions 6' and 10' of the M2 segment. Supported by NS-11756.

SOLUTION STRUCTURE OF NEURONAL BUNGAROTOXIN DETERMINED BY TWO-DIMENSIONAL ^{1}H-NMR SPECTROSCOPY. R.E. Oswald[§†*], M. Bamberger[§†], M.J. Sutcliffe[†], R.H. Loring[α*], R.E. Zigmond[*α], C.M. Dobson[†]. [§]Dept. Pharmacology, NYSCVM, Cornell Univ., Ithaca, NY 14853 USA; [†]Inorganic Chemistry Laboratory, Univ. Oxford, Oxford OX1 3QR UK; [α]Dept. Pharmacology, Northeastern Univ. Boston MA 02115 USA; [*]Center for Neurosciences, Case Western Reserve, Cleveland OH 44106 USA.

Neuronal bungarotoxin (nBgt) is a minor protein component of the venom of *Bungarus multicinctus* which binds specifically and with high affinity to neuronal nicotinic acetylcholine receptors (nAChRs) in the peripheral nervous system. In contrast, the major neurotoxic component of α-bungarotoxin (αBgt) binds quasi-irreversibly to skeletal muscle nAChRs but with low affinity (or not at all) to peripheral nervous system nAChRs. These two toxins exhibit considerable sequence homology (~50%); but the sequence differs at several potentially important positions. We hope to determine the 3-D solution structure of nBgt and compare it with the known solution and crystal structures of αBgt and the structures of homologous neurotoxins specific for skeletal muscle nAChRs in an attempt to explain the unique specificity of nBgt. This should illuminate the diversity of nAChR subtypes. Assignment of ^{1}H NMR resonances for 60 of the 66 residues of nBgt have been obtained by sequence specific methods which enabled assignment of over 70% of the crosspeaks observed in the NOESY spectrum, defining distances between specific atoms in the protein. This provided ~550 distance constraints for use in structure determination. Coupling constants (NH-αH) and (αH-βH) were determined from COSY and E.COSY spectra which have in turn provided dihedral angle constraints. Hydrogen exchange work suggested the probable position of hydrogen bonds. The dihedral constraints from the COSY spectra and the known disulfide bonding pattern are being used to calculate the 3-D structure of the protein. Preliminary evidence suggests (1) that the C-terminal portion of the protein probably exhibits more structure than αBgt; and (2) that the triple stranded antiparallel β sheet in long and short neurotoxins may be considerably distorted in nBgt. Efforts are underway to refine the structure and to assign the remainder of the NOESY spectrum in an effort to provide additional distance constraints. Although additional resolution will be required, differences in the 3-D structures of nBgt and αBgt seem to exist and may be related to the differences in specificity of the toxins.

BINDING OF [^{3}H]MECAMYLAMINE TO THE NICOTINIC RECEPTOR COMPLEX IN THE RAT BRAIN: MODULATION BY ATP. E.D. London and M.D. Majewska, Neuropharmacology Lab., Addiction Res. Ctr., NIDA, Baltimore, MD 21224.

Mecamylamine (MEC), an allosteric antagonist of the ACh nicotinic receptor (nAChR), is believed to interact with the cationic channel associated with this receptor. We examined the interaction of MEC with the nAChRs in the rat brain. MEC, at μM concentrations, decreased the Bmax of [^{3}H]methylcarbamylcholine (MCC) (a ligand for nAChR) binding. [^{3}H]MEC interacted with at least two populations of sites: the higher affinity site (Kd = 48 nM, Bmax = 184 fmol/mg protein) and the low affinity site with Kd > 5 μM. Allosteric nAChR antagonists (tetracaine, PCP and its analogs, and chlorpromazine), inhibited [^{3}H]MEC (50 nM) binding, at low μM concentrations. Incubation with *l*-nicotine (Nic) for 30 min (equilibrium) did not alter [^{3}H]MEC binding, but brief exposure to Nic (1-2 min) markedly potentiated binding; the effect of Nic decayed with time. Our data suggest that the high affinity [^{3}H]MEC binding site may be localized in the cationic channel of the nAChRs, and brief activation of nAChRs may facilitate [^{3}H]MEC binding by opening the channels. ATP, which interacts with nAChRs (Takayama, H., et al., Soc. Neurosci. Abstr. 1989), also increased specific [^{3}H]MEC binding, suggesting that ATP modulates nAChRs in the brain, possibly by opening the ion channels.

ATP: AN ALLOSTERIC MODULATOR OF THE NICOTINIC RECEPTOR IN BRAIN. H. Takayama, M.D. Majewska and E.D. London. Neuropharmacology Lab., Addiction Res. Ctr., NIDA, Baltimore, MD, 21224.

ATP is co-released with ACh from Torpedo electric organs and the mammalian neuromuscular junction. We, therefore, assessed whether ATP interacts with nicotinic acetylcholine receptors (nAChRs) in the brain. ATP had a biphasic effect on [^{3}H]methylcarbamylcholine (MCC) binding to nicotinic receptors in the rat brain, increasing the binding affinity at concentrations < 1 mM and decreasing it at > 1 mM. To determine if actions of ATP at nAChRs corresponded to changes in the nAChR-gated cationic channel, we examined ATP effects on the binding of [^{3}H]chlorpromazine (CPZ), presumably to a site in the nAChR-associated channel (Changeux, J.-P., et al, TIPS 8:459, 1987). ATP, but not ACh or nicotine, enhanced [^{3}H]CPZ binding to brain membranes at equilibrium (30 min incubation). Inhibition of [^{3}H]CPZ binding to dopamine receptors by apomorphine did not abolish the effect of ATP, but even enhanced it, suggesting that the effect is not related to dopamine receptors. The interaction of ATP with MCC and CPZ binding sites suggest that ATP may be an agonistic type modulator of nAChR function. It is possible that ATP opens the cationic channels associated with nAChRs, thus facilitating [^{3}H]CPZ binding.

INTERACTIONS OF SUBSTANCE P WITH NICOTINIC ACETYLCHOLINE RECEPTOR-ENRICHED MEMBRANES OF *TORPEDO* ELECTROPLAQUE. C. Min*, J. Owens*, B. Howard*, and G.A. Weiland. Dept. of Pharmacology, NYSCVM, Cornell University, Ithaca, NY 14853.

The neuropeptide substance P (SP) noncompetitively inhibits activation of nicotinic receptors of both the neuronal and muscle subtypes. Inhibition does not appear to reflect an interaction with the high affinity local anesthetic binding site (*Molec. Pharmacol.* 32:625).

The effect of substance P on carbamylcholine (CC) binding was determined by measuring the inhibition of the initial rate of [^{125}I]αbungarotoxin (αBgt) binding. In the presence of 140 mM NaCl, SP did not inhibit αBgt binding at the concentrations used. SP increased the rate and extent of the CC-induced increase in apparent agonist affinity. In the absence of CC, SP did not induce an increase in CC affinity, indicating that the peptide does not stabilize the desensitized state in the absence of agonist. The kinetics of recovery after exposure to CC plus SP were complex and more rapid than after exposure to CC alone. Although it has been shown that SP induces an increase in apparent agonist affinity, the mechanism involves more than allosteric stabilization of the desensitized state.

The interaction of substance P with the nicotinic receptor was studied directly by measuring the binding of [^{3}H]SP to *Torpedo* membranes. In the absence of agonist [^{3}H]SP bound with low affinity (K_d > 40 μM); however, in the presence of CC the affinity was significantly increased (K_d ≈ 5 μM). CC had no effect on the number of [^{3}H]SP binding sites and there was one SP binding site per αBgt site. The CC-induced increase in [^{3}H]SP affinity was blocked by αBgt and d-tubocurarine but not by atropine. The EC_{50} of CC for increasing SP binding was ~1 mM, which implicates the involvement of the recently described low affinity agonist inhibitory site. Displacement of [^{3}H]SP binding by related peptides was consistent with their inhibition of receptor activation. Specific [^{3}H]SP binding dissociated exponentially with a $t_{1/2}$ of ~3 min. These results demonstrate [^{3}H]SP binding to a specific site on the nicotinic receptor which may mediate SP inhibition of receptor activation.

CHARACTERIZATION OF MUSCARINIC RECEPTOR SUBTYPE-SPECIFIC ANTIBODIES. A.I. Levey*, W.F. Simonds, A.M. Spiegel, and M.R. Brann. NIH, Bethesda, MD, 20892 and JHMI, Baltimore, MD, 21205.

Five muscarinic receptor subtypes have been genetically defined (Bonner et al, Neuron, 1, 403), with complex pharmacological differences that do not reliably distinguish between them. In order to develop antibody probes that specifically recognize each of the receptor protein subtypes, we have prepared site-directed antibodies raised in rabbits against oligopeptide sequences specific for each receptor. Antisera were tested for their ability to bind the peptides and 3H-PrBC mustard-labelled receptors solubilized from either cell lines transfected with each of the receptors cDNAs (Buckley et al, Mol Pharmacol 35, 469) or brain or atrial membranes. An immunoprecipitation assay was developed to screen for antibody reactivity in which the amount of label was directly counted in extensively washed precipitates, and in which normal rabbit sera was used for controls. Antisera to the N- and C-terminal regions of the m1, m2, m3, and m4 receptor proteins each specifically bound the peptides derived from the appropriate receptor, but not the opposite terminal region of the same receptor or peptides of the other receptors. Antisera against the C-terminal peptides for the m2, m3, and m4 receptors each precipitated up to 40% of the radiolabeled receptor protein with no significant cross-reactivity to the other receptor subtypes. Preliminary immunoblotting experiments showed that affinity purified antisera to the m3 receptor labelled a band that co-migrated with the 3H-PrBC mustard-labelled receptor subunit identified by autoradiography.

[^{3}H]QUINUCLIDINYL BENZILATE (QNB) HAS DIFFERENT AFFINITIES FOR EACH OF TWO BINDING SITES IN HUMAN BRAIN:THE DENSITY OF THE LOWER AFFINITY SITE (M_1) DECREASES WITH AGE. A.C.Andorn, J.A.Vittorio* and E.S.Miller*. F.D.R. Vet. Adm. Hosp. and Depts. of Psychiat. and Pharmacol. N.Y. Med. Coll., Valhalla, NY 10548.

[^{3}H]QNB labels M_1 and M_2 receptor types but it had been thought that the affinity of [^{3}H]QNB was the same at each receptor. We examined [^{3}H]QNB binding in human brain. The results of saturation studies in prefrontal cortex (PFC) showed that [^{3}H]QNB labeled two affinity states with K_A of 1.4 ± 0.5 x $10^{11}M^{-1}$ and 1.70± 0.6 x $10^{10}M^{-1}$ for K_D of 7 and 59 pM (N=3). The densities of these affinity states were 8.6 ± 3.8 and 26 ± 3.4 pM respectively. In aged PFC the K_D were unchanged but the densities were 14 ± 1.1 and 15 ± 2.3 pM (N=3). The difference in the density of the highest affinity state was not significant, but the decline in the density of the lowest affinity state with aging was significant at $p < 0.01$.

Saturation studies in cerebellum showed only one binding site for [^{3}H]QNB and the K_D of that site was the same as the highest affinity state in PFC. Further, pirenzapine had nearly the same affinity for the cerebellar site (K_i of 80 nM) as it had for the highest affinity state in PFC (K_i of 21 nM). Therefore, the lowest affinity state in PFC most likely represents M_1 binding while the higher affinity state represents M_2.

30.1

HORMONAL REGULATION OF AXON TERMINAL REORGANIZATION DURING METAMORPHOSIS IN THE MOTH *MANDUCA SEXTA*. J.W.Truman. Dept. of Zoology, Univ. of Washington, Seattle, WA 98195.

Loss and regrowth of axon arbors during metamorphosis have been followed for the motoneuron, MN-12. Its larval muscle target (deo1) consists of 5 oblique fibers and begins to degenerate by d 2 after pupation. The lateral 4 fibers degenerate completely, but remains of the medial fiber persist to provide support for the growth of the adult muscle (de5). This remnant reorients on the segment by d 8, and regrows into the adult muscle starting about d 12-14. The adult emerges on d 20.

MN-12's distal axon undergoes a stereotyped series of changes: d 2, loss of larval endplates; d 3, retraction of axon from lateral fibers, maintains rostral and caudal attachments on medial remnant; d 4, localized sprouting at the two sites; d 8, sprouts grow longitudinally along remnant; d 10-12, establishment of higher order axon branches; d 14, establishment of nascent adult endplates.

Axon sprouting is triggered by steroids, the ecdysteroids, in the absence of juvenile hormone (JH). Depending on the time of application, JH blocks outgrowth itself, or just the longitudinal expansion while allowing the production of endplates.

30.2

SPONTANEOUS INNERVATION OF THE SUPERIOR OBLIQUE MUSCLE BY MOTONEURONS OF THE OCULOMOTOR (N III) NERVE AFTER TROCHLEAR (N IV) SURGERY. R. Sonntag* and B. Fritzsch. Univ. Bielefeld, Fac. Biol., 4800 Bielefeld, FRG.

In *Xenopus laevis*, the first trochlear motoneuron axons reach their sole target, the superior oblique muscle (SOM), on the contralateral side at stage 35. Proliferation of motoneurons than continues in a caudal to rostral manner until stage 47 (Sonntag, R. and Fritzsch, B., Progr. Zool. 37:in press, 1989) have tested the possibility that the earliest, most caudal motoneurons behave like pioneer neurons by cutting the trochlear nerve in the velum medullare anterior of embryonic (st.34-36) and larval (st.40-48) *Xenopus*. The pattern of reinnervation of the SOM was studied in 36 larvae, using anterograde and retrograde tracing techniques. Embryonic surgery reduces the total number of trochlear motoneurons, whereas ipsilateral motoneurons are increased in number. In contrast, cutting of the trochlear nerve after onset of ocular movement (st.42), leads to a reduced reinnervation of the SOM by trochlear motoneurons. In addition, the SOM is innervated by oculomotor motoneurons. After surgery in later stages (st.48) the trochlear nerve may not reinnervate the SOM. Instead the SOM is then innervated either by superior rectus or, more frequently, by inferior oblique motoneurons. In cases with successful reinnervation by the trochlear motoneurons, the most caudal, oldest motoneurons always reach the SOM. These data are compatible with the idea that the first trochlear motoneurons are pioneer neurons. That oculomotor motoneurons of adjacent ocular muscles can spontaneously innervate the denervated SOM argues also for a crucial role for pattern formation played by the early innervation. Supported by the DFG (SFB 223).

PATTERNS OF MUSCLE REINNERVATION BY REDUCED NUMBERS OF MOTONEURONES. V. Rafuse*, T. Gordon, S. Erdebil* and T. Martin*. (Spon: J. Jhamandas) Div. of Neuroscience, Univ. of Alberta, Edmonton, Canada T6G 2S2.

To test the possibility that regenerating motor axons follow the branch points of the distal nerve stump to supply muscle fibres in different fascicles, we studied the distribution of muscle fibres in identified motor units in the cat medial gastrocnemius muscle after reinnervation by restricted numbers of regenerating motoneurons. The MG nerve was crushed or cut and sutured either to the nerve stump or to the denervated muscle simultaneously with L7 or S1 root ligation. Four to 12 months later, muscle force was recorded bilaterally, 2-50 single motor units were characterized and a single unit depleted of glycogen for later histological recognition. When the number of motoneurones was close to normal, unit and non-unit fibres showed a normal mosaic distribution. However, as the numbers fell, the distribution became progressively more restricted. Fewer than 10%, muscle fibre units were localized in tight clumps, muscle force was dramatically reduced and extensive fibre degeneration was present. These findings suggest that 1) regenerating motor axons follow the branch points of the distal nerve stump to restore the mosaic pattern and that 2) terminal branching predominants only when the number of regenerating axons is drastically reduced. (Supported by MDAC and AHFMR).

30.4

REDISTRIBUTION OF MUSCLE UNITS IN THE REINNERVATED TIBIALIS ANTERIOR OF THE RAT. J. Totosy de Zepetnek*, S. Erdebil* and T. Gordon. Div. of Neurosci., U. of Alberta, Edmonton, Canada T6G 2S2.

To determine whether regenerating nerve fibres show preference for their former muscle compartments, the distribution of oxidative and glycolytic fibres was examined in reinnervated muscles, 4-10 months after common peroneal nerve section and resuture. Slow oxidative fibres are normally scattered within the deep compartment only, but were found in all regions of reinnervated muscles. Nevertheless, the incidence of slow fibres in the most lateral aspect and superficial regions was low with the fibres being distributed most commonly in small clumps in the deeper zones of the muscle. Identified glycogen depleted single unit fibres rarely occupied an entire clump and were distributed in as many as 3 different ones. These findings suggest that regenerating motor nerves may favor branch points in the distal nerve stump which lead them towards their former compartments. However, the marked clumping of fibres in single units indicates that the nerve branching at the level of the denervated muscle fibres is likely to be substantially different from normal. (Supported by MDAC and AHFMR)

NEUROMUSCULAR COMPARTMENTS: CENTRAL AND PERIPHERAL RESPONSE TO NERVE CRUSH. O.I. Weeks, C. Shum*, A.M. Colls*, and D. Bello*. Dept. of Biological Sciences. Florida International Univ. Miami, Florida 33199.

Our long range goal is to determine whether there is selectivity and/or specificity in the reestablishment of neuromuscular compartments following injury. The study model is the mouse (C576J) lateral gastrocnemius, a compartmentalized muscle and its motor nucleus.

The proximalmost end of the lateral gastrocnemius-soleus nerve was unilaterally crushed with #5 forceps. The contralateral, unoperated side, served as the control. Additionally, unoperated siblings of experimental animals also served as controls. The long term (5-13 months) responses as well as 21-30 day responses following nerve crush in 21 day old animals were analysed. In the present study tracing (HRP, Fluoro-gold), histo- (staining for SDH, myosin ATPase, glycogen), immunohistochemical (parvalbumin) methods were used to compare neuromuscular compartment boundaries, fiber type and motoneuron spatial, numerical and size distribution.

While there is not 100% specificity in reinnervation, neuromuscular compartments are selectively reestablished in that the overall integrity of compartments is maintained. NIH MBRS Suppt.

30.6

AGE-RELATED DENERVATION ATROPHY IN FIBER TYPES OF THE RAT NASOLABIALIS MUSCLE. K.K. White and D.W. Vaughan*. Anatomy Dept., Boston Univ. Sch. of Med., Boston, MA 02118.

Temporal patterns of denervation atrophy in red, white, and intermediate fibers of the nasolabialis muscle were compared in young adult (3-mo) and middle-aged (15-mo) male Sprague Dawley rats. Nasolabialis is responsible for the whisking movement of vibrissae. The facial nerve was crushed and at designated post crush days (dpc), frozen sections of the muscle were reacted for cytochrome oxidase activity to delineate the three fiber types. Cross-sectional fiber areas were traced and measured to determine the extent of atrophy.

The mean areas for all three fiber types are greater in the older animals than in the younger. Patterns of atrophy, therefore, are expressed both as absolute area difference and percent difference relative to control. In both age groups: 1) At 10, 16, 21, and 28 dpc the white and intermediate fibers atrophy to a greater extent than the red fibers. 2) By 28 dpc the red fibers have recovered the closest to normal fiber area.

The nasolabialis muscle is reinnervated by 14 dpc in the 3-mo and by 20 dpc in the 15-mo animals. In each age group, for each fiber type, a significant increase in fiber area occurs during the 7 days after the nasolabialis muscle is reinnervated.

Supported by grants #AG06154 and #AG00115 from NIH.

30.7

THE EFFECT OF ELECTRICAL STIMULATION ON NERVE ATROPHY AFTER AXOTOMY Gillespie, M.J. & Gordon T. Div. of Neuroscience, Heritage Medical Research Bldg., Univ. of Alberta, Edmonton, Can. T6G 2S2

To determine whether chronic electrical stimulation of axotomized nerves could retard or prevent atrophy, either the common peroneal (CP) or tibial nerve was axotomized in both legs in adult rabbits, and the nerve in one limb was stimulated at 10 or 100 Hz for 8 hours per day for up to 227 days. Cross-sections of stimulated and unstimulated nerves were compared.

An early reduction in the proportion of large fibres was greater in unstimulated than stimulated axotomized nerves. However, at longer times, an overall shift to smaller fibres was greater in the stimulated nerves than in the unstimulated nerves. By 227 days no large fibres remained in the stimulated nerves. Myelin thickness correlated directly to fibre diameter, (coefficient of 0.22 to 0.26), and was unaffected by stimulation.

Chronic electrical stimulation may initially protect axotomized nerves from atrophy, but is detrimental at longer periods. Fibres in the stimulated nerves became smaller than in the unstimulated nerves. (Supported by MRC of Canada).

30.8

SMALL CONDUCTANCE ACETYLCHOLINE RECEPTOR (ACHR) CHANNELS AT SNAKE (THAMNOPHIS SP.) TONIC MUSCLE FIBER ENDPLATES ARE IDENTICAL TO EXTRAJUNCTIONAL CHANNELS ON DENERVATED TWITCH FIBERS. R.L. Ruff, Neurology Dept. & Ctr. for Neurosci., Dept. Vet. Affairs Med. Ctr., & CWRU, Cleveland, OH 44106.

Tonic fiber endplates of the inferior costocutaneous muscle of the garter snake have 33pS and 51pS ACHR channels. The 51pS channel is electrically identical to the twitch fiber endplate ACHR. Segments of snake muscle were denervated by cutting serveral consecutive nerve roots. Twitch fibers were identified by their appearance with Nomarski optics. Endplate regions could be identified by degenerated nerve terminals. The extrajunctional membrane of denervated twitch fibers had ACHR channels that were similar in conductance and kinetic properties to the 33pS channel found at tonic endplates. Thus, adult tonic endplates appear to contain both twitch adult-type and fetal-type (extrajunctional) ACHR. Perhaps the development of tonic muscle fibers is altered in comparison to twitch fibers so that the adult tonic fibers support polyneuronal and multiterminal innervation and continue to express fetal-type ACHR.

METABOLIC AND SIZE PROPERTIES OF SOLEUS MUSCLE FIBERS OF ADULT SPINALIZED CATS . B. Jiang *, R. R. Roy, D. J. Pierotti*, and V. R. Edgerton. (SPON: D.S. Maxwell) Brain Research Institute and Kinesiology Dept., UCLA, LA, CA, 90024.

This study was designed to determine the effects of reduced neuromuscular activity on the metabolic and size properties of single muscle fibers in the cat soleus. Adult cats were spinalized (Sp) at T12-T13 and maintained in a healthy condition for 6 months. Some of the cats were trained to weight-support (Sp-WS) for 30 min per day beginning one month post-transection. Cross-sectional area (CSA), succinate dehydrogenase (SDH), glycerophosphate dehydrogenase (GPD), and myosin ATPase activities were determined in a population of single fibers identified in serial frozen cross-sections. Each fiber was categorized as either light or dark based on its staining density for qualitative myosin ATPase, (pH=8.75). The Sp (44%) and Sp-WS (31%) groups had significantly higher percentages of dark fibers than control (<1%). Overall mean fiber CSA were significantly smaller (~25%) than control in both Sp groups. In the Sp-WS, but not the Sp cats, the dark fibers were larger than the light fibers ($p<0.05$). There were no significant differences among the three groups in any of the mean enzyme activities. However, there was a tendency for the Sp cats to have elevated GPD and ATPase activities and this appeared to be directly related to the percentage of fibers staining darkly for myosin ATPase. These data indicate that 6 months after spinalization some of the fibers of the slow soleus atrophy and develop myosin staining patterns and glycolytic capacities that are normally exhibited in fast muscles. Periods of daily weight-support appear to ameliorate some of these adaptations. Further, the observation that SDH activities are maintained at control values in spinalized adult cats, as well as in spinalized kittens (unpublished observations), suggest that, at least in the soleus, skeletal muscle fibers can maintain their oxidative potential even though there is a marked reduction in neuromuscular activity for 6 months. SUPPORTED BY NIH GRANT NS 16333.

30.10

SPATIAL DISTRIBUTION OF DARK ATPase FIBERS IN THE ADULT CAT SOLEUS MUSCLE SIX MONTHS AFTER SPINAL TRANSECTION. A. Garfinkel*, R.R. Roy, D.O. Walter*, G. Penaflor*, B. Jiang*, A. Fuchs* and V.R. Edgerton. (SPON: J.L. Feldman) Department of Kinesiology and Brain Research Institute, UCLA, Los Angeles CA, 90024

In the adult cat soleus muscle, nearly 100% of the fibers stain light for myosin ATPase (alkaline preincubation). Six months after spinal transection at a low thoracic level, a substantial proportion of these convert to dark. In this study, the spatial arrangements of these dark fibers were determined in 9 cats. We found that: (1) the dark fibers tended to be found disproportionately at fascicle boundaries, i.e., in 8 out of 9 animals, there was a statistically significant association (using a chi-squared analysis) between the properties of being adjacent to a fascicle boundary and being a dark fiber; (2) based on Monte Carlo simulations of random distributions, dark and light fibers are distributed spatially in a non-random manner with regard to each other, i.e., in 5 out of 8 animals there were significantly fewer dark/dark adjacencies and/or significantly more dark/light adjacencies than would be expected at random, and (3) there was also a significant tendency for dark fibers to be spread evenly across the region analyzed. These non-random spatial patterns imply that myogenic spatial factors influence the ATPase conversion of these fibers.

Supported by NIH Grant NS16333.

MOTOR SYSTEMS II

31.1

MECHANICAL PROPERTIES OF SELF-REINNERVATED CAT TIBIALIS ANTERIOR MOTOR UNITS. R.R. Roy, G.A. Unguez*, D.J. Pierotti*, S. Bodine-Fowler and V.R. Edgerton. Brain Research Institute and Kinesiology Department, UCLA, Los Angeles, CA 90024.

The reestablishment of neuromuscular connectivity was evaluated 6 months after cutting and reattaching the nerve branches innervating the anterior compartment of the cat tibialis anterior (TA) muscle. One motor unit (MU) in each limb of 7 adult female cats was functionally isolated via ventral root teasing, physiologically tested and glycogen depleted (Unguez et al. *Soc. Neurosci. Abstr.* ,15:, 1989). Based on the criteria established by Burke et al. (*J. Physiol.* ,234:723, 1973), 2 MUs were classified as slow (S), 1 as fast fatigue-intermediate (FI) and 12 as fast fatigue-resistant (FR). The absence of fast-fatigable (FF) units was somewhat surprising considering that the TA in normal cats has over 30% FF units (Dum and Kennedy, *J. Neurophysiol.*, 43:1615, 1980). Contraction and half-relaxation times, frequency-tension responses and fatigue indices were within the range of normal values for each unit type (*Ibid*; Bodine et al., *J. Neurophysiol.*,57:1730, 1987). The maximum tetanic tension was within the range of normal values (1.0-5.7g) in both S units tested (2.7 and 5.4g). In contrast, the maximum tetanic tensions of the FI (103g) and 7 of the FR (19.2-71.9g, mean = 29g) units were outside the range reported for normal FI (4.6-26.9g) and FR (1.5-18.3g) units, respectively. Further, all FR units had maximum tension values that were larger than the mean control value (6.7g). These data suggest that during the process of reestablishing neuromuscular connectivity, the target area (total fiber number and/or cross-sectional area) innervated by a motoneuron increases, while the variables regulating twitch speed and fatigability are unaffected. Further, it appears that the fast units in the TA were more capable of expanding their target area than the slow units after self-reinnervation. SUPPORTED BY NIH GRANT NS16333.

31.2

SPATIAL DISTRIBUTION OF MOTOR UNIT FIBERS IN THE SELF-REINNERVATED TIBIALIS ANTERIOR MUSCLE OF ADULT CATS. G.A. Unguez*, S. Bodine-Fowler, R.R. Roy, D.J. Pierotti*, and V.R. Edgerton. Dept. Kinesiology and BRI, UCLA, Los Angeles, CA. 90024

The spatial distribution of muscle fibers belonging to 6 motor units (MU) was studied in the cat tibialis anterior (TA) muscle 6 months after self-reinnervation (Roy et al., *Soc. Neurosci. Abstr.* 15: 1989). MU fibers were depleted of their glycogen through repetitive stimulation of an isolated ventral root filament. Subsequently, several cross-sections were cut from each tissue block along the length of each muscle and stained for glycogen using a periodic acid-Schiff reaction. For each unit, the location of each MU fiber was digitized in that cross-section which appeared to have the most depleted fibers. The spatial distribution patterns existing between MU fibers were analyzed by calculating the distribution of interfiber distances between all fibers within a unit. These distributions were compared to interfiber distance distributions generated using Monte Carlo simulation techniques. In 5 fast-twitch MUs there was a greater incidence of short and long interfiber distances suggesting the existence of multiple groups of fibers within the MU territory. Moreover, within the individual fiber groups there tended to be an excess of short distances suggesting that MU fibers were more clustered than dispersed. This clustering, however, did not appear to be due to a large increase in the number of adjacencies between MU fibers. For example, in 3 of the 5 fast units 52-63% of the fibers occurred alone which is similar to that observed in normal TA units. In the other 2 units, however, only 21 and 29% occurred alone. These units tended to have larger group sizes. However, entire fascicles were never observed to be depleted. In contrast, the spatial arrangement of fibers belonging to the slow unit was similar to the distributions observed in normal slow units. In general, the innervation patterns of the fast reinnervated units differed from those observed in normal fast TA units showing a greater tendency for clustering. SUPPORTED BY NIH GRANT NS 16333.

MOTOR UNITS OF THE CAT TIBIALIS ANTERIOR 6 MONTHS AFTER SPINAL ISOLATION. D.J. Pierotti*, R.R. Roy, J.A. Hodgson*, S. Bodine-Fowler, and V.R. Edgerton, Brain Research Institute and Kinesiology Dept., UCLA, LA, CA, 90024.

To study the effects of electrical inactivity on the motor units (MU) of the adult cat tibialis anterior (TA) muscle, the lumbar spinal cord was functionally isolated (SI) in 10 cats by transecting the cord at levels T12-T13 and L7-S1 and cutting all dorsal roots bilaterally between these two cord segments. Two 24-hour EMG recording sessions were used to verify that muscles in the lower limb were virtually silent. The cats were maintained in excellent health for 6 months. One MU from the TA of each hindlimb was functionally isolated using ventral root isolation techniques. Each unit was characterized physiologically as either fast fatigable (FF, n=2), fast fatigue resistant (FR, n=3) or slow (S, n=1) based on the classification scheme of Burke et al. (*J Physiol.* 234: 723, 1973), and repetitively stimulated to deplete the muscle unit of glycogen. Spatial distribution, as measured by interfiber distances of the MU fibers, within SI units was found to be similar to that reported for normal TA units. Mean muscle weights were 12% lower than control. Maximum tensions (Po) of the FR and FF units were lower than normal, while the S unit remained within the normal range. All other isometric contractile properties were within normal ranges for each of the unit types. The mean fiber cross sectional areas (CSA) of the fibers within the fast units were 25-50% smaller than normal, while the mean fiber CSA of the fibers within the S unit was normal. Thus, it appears that the decreased Po of the fast units was primarily related to the reduction in fiber size. Correction of Po based on the percentage of fiber atrophy suggests that the relationship between Po and innervation ratio is similar to that observed for normal TA units (Bodine et al., *J. Neurophysiol.*, 57: 1730 1987). These data demonstrate that the normal range of speed related and fatigue properties persists in a mixed muscle after 6 months of virtual silence. CHANGES IN SYNAPTIC INPUTS AND CELLULAR PROPERTIES OF AN IDENTIFIED INTERNEURON DURING INSECT METAMORPHOSIS. B.Waldrop and R.B.Levine, ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721

Metamorphosis is accompanied by striking changes in the organization of the nervous system in the hawkmoth *Manduca sexta*. For example, tactile stimulation of mechanosensory neurons innervating the abdominal body wall of the larva causes a general bending reflex. In the pupa, the same sensory neurons, motor neurons, and muscles mediate the gin trap reflex, during which the motor neurons discharge at a higher rate and in a different pattern than seen in the larva. We have been studying interneurons interposed between sensory and motor elements, attempting to determine how the different motor patterns are generated.

One intersegmental interneuron, designated IN 703, is retained during the larval-pupal transition and maintains the same basic dendritic structure, but its response to sensory inputs changes rather dramatically. In the larva, a train of electrical shocks to the sensory axons produces a brief depolarization and only 1 or 2 spikes in IN 703. In the pupa, IN 703 responds to the same stimulus with a prolonged depolarization and a strong burst of action potentials. We have found that the relative spike threshold is lower in pupal IN 703, which may account for some of the difference in responsiveness. Also, there is a class of synaptic input to IN 703, apparently from other interneurons, which is expressed in the pupa but not in the larva. Low frequency stimulation of sensory axons produces a short latency EPSP in IN 703 that is similar in larvae and pupae, but in the pupa there is also a delayed, asynchronous depolarization. The increase in the sensory response of IN 703 may partially explain the larger pupal motor response.

EVIDENCE FOR DENDRITIC COMPETITION IN THE DEVELOPMENT OF MOTONEURON MORPHOLOGY IN THE RAT SPINAL CORD. E.M. Kurz, L.A. Goldstein, and D.R. Sengelaub. Program in Neural Science, Dept. of Psychology, Indiana University, Bloomington, IN 47405.

The spinal nucleus of the bulbocavernosus (SNB), located in the lumbar spinal cord of rats, contains motoneurons that innervate axial musculature involved in penile reflexes. The dendritic arbor of SNB motoneurons is bilaterally distributed, and overlaps extensively with the arbor of the contralateral nucleus, suggesting that the two halves of the SNB share common afferents. During development, SNB dendrites grow exuberantly to almost twice their adult length and then retract. To determine if the availability of afferents might play a role in regulating the retraction of SNB dendrites, we eliminated motoneurons from one side of the SNB early in development in an attempt to decrease potential dendritic competition.

On the day of birth, the right lateral bulbocavernosus muscle (BC), a major target of SNB motoneurons, was extracted from male rat pups (n=6). This removal results in the loss of BC-projecting motoneurons in the ipsilateral SNB. At seven weeks of age, when SNB dendritic morphology is normally mature, rats received injections of cholera toxin-HRP (.2%; 0.5 µl) into the remaining (left) BC. A group of intact males received similar injections (n=5). After processing with TMB, the length and spatial distribution of all HRP-labeled SNB dendrites were measured.

Following unilateral muscle extirpation, dendritic length of the remaining SNB motoneurons was 52% longer than that of normal males at this age (6493 µm *vs.* 4272 µm; $p < .025$). Despite this increased dendritic length, the spatial distribution of the arbor was unchanged from that of normal animals. These results suggest that an interaction between dendrites from the two halves of the SNB and their afferents may be involved in their retraction during normal development. MUSCARINIC CHOLINERGIC RECEPTOR-BINDING SITES DURING MOTOR RECOVERY AFTER SPINAL CORD HEMISECTION IN RATS. A. P. Thomas*, J. W. Little, R. M. Harris and J. Leik*. Department of Biological Structure, University of Washington School of Medicine, Seattle, Washington 98195.

Hemisection of the thoracic spinal cord (T6) in the rat produces an initial paralysis of the hind limb ipsilateral to the lesion, followed by an early and then a late phase of motor recovery. The early recovery could be mediated by denervation supersensitivity (DS, increases in post-synaptic receptor-binding sites). To test this hypothesis, changes in muscarinic cholinergic receptor (MChR) -binding sites were examined in the ventral horn and intermediate gray matter of the lumbar spinal cord of T6 hemisected adult rats, using in vitro quantitative autoradiography with ^{3}H quinuclidinyl benzilate (QNB). Pre- and post-hemisection, the motor behaviors of the rats were evaluated, and the animals were sacrificed at 5 days postlesion. Cryostat sections (10 µm) were incubated in ^{3}H QNB with or without unlabeled atropine, and then exposed to ^{3}H-sensitive film (LKB) for 28 days. The autoradiographic images thus generated were quantified on a Drexel-DUMAS image-analysis system, with reference to co-exposed ^{3}H-brain mash standards. Specific binding for ^{3}H-QNB was determined in various areas of the cord. The lumbar cord ipsilateral to the lesion shows a significant increase in the densities of ligand-binding sites, compared to the contralateral side. The paralyzed hind limb shows partial motor recovery within 5 days postlesion. These findings may indicate the occurrence of up-regulation of receptor-binding sites resulting in DS in the lumbar cord after partial denervation by T6 hemisection. This DS may allow spared reflex or contralateral, descending pathways to mediate early motor recovery.

A MONOCLONAL ANTIBODY DISTINGUISHES SOMATIC MOTOR NEURONS FROM OTHER NEURONAL POPULATIONS IN THE RAT NERVOUS SYSTEM. H.Urakami* and A.Y.Chiu. Div. of Neurosciences, City of Hope, Duarte, CA 91010

In order to obtain markers selective for motor neurons, an *in vitro* immunization was carried out using a homogenate of embryonic rat ventral hemicords. We report a monoclonal antibody, MO-1, that is strongly immunoreactive for all somatic motor neuronal populations examined in the adult rat brain and spinal cord. MO-1 does not bind to other cholinergic neurons, such as those in the basal forebrain, nor to non-somatic motor neurons including preganglionic neurons within the spinal cord and post-ganglionic neurons in the ciliary ganglion and superior cervical ganglion. In fresh frozen cryostat sections of spinal cord, antibody binding appears to be concentrated within the cell body and proximal regions of axons. Preliminary studies show that immunoreactivity is detectable in the spinal cord by the end of the first week after birth. MO-1 may thus mark mature motor neurons in the final stages of synapse consolidation. (Supported by NIH grant #PO1 NS18858-08)

MORPHOLOGY OF PHRENIC MOTONEURONS IN NEONATAL RAT AS REVEALED BY RETROGRADE LABELING WITH HRP. A. D. LINDSAY* & J. L. FELDMAN (SPON: H. H. Ellenberger), Systems Neurobiology Laboratory, Dept. of Kinesiology, UCLA, L.A., CA, 90024-1568

Application of horseradish peroxidase (HRP) to cut muscle nerves in neonatal and fetal rats can result in Golgi-like staining of motoneuron cell bodies and dendrites in the spinal cord (Smith & Hollyday, J. Comp. Neurol. 220:16-28, 1983). We used this technique to reveal the morphology of phrenic motoneurons in rats ranging in age from 0 to 6 days (6.4 to 15.0 gms). The animals were anesthetized with chloral hydrate (35mg/100g, I.P.), and artificially ventilated. The phrenic nerve was isolated and cut as it traverses the brachial plexus. HRP crystals were placed on the cut nerve, allowed to dissolve for 15 min and then the wound was closed. The animal remained anesthetized for the duration of the incubation period (6-11 hours), at the end of which the animal was perfused with 4% paraformaldehyde. The tissue was cut into 30µm sections and processed with diaminobenzidine. Darkly labeled cell bodies and dendrites were seen in clusters in the ventral most portion of the ventral horn at intermediate laterality in segments C3 to C5. In animals as young as neonatal day 0, intensely labeled, tightly bundled and complexly branching dendrites were present, extending longitudinally as far as 300µm and projecting as far as the medial and lateral borders of the ipsilateral hemi-cord. Dendrites also projected dorsolaterally as far as the level of the central canal and up to 270µm across the midline into the contralateral ventral horn. Many dendrites were clearly studded with spines and appendages. In short, phrenic motoneurons in the neonatal rat have many of the characteristics of those studied in the adult rat (Goshgarian & Rafols, J. Comp. Neurol. 201:441-56, 1981). This is in marked contrast to the morphology of lumbar motoneurons, which do not attain the adult dendritic morphology until neonatal day 10-15 (Bellinger and Anderson, Dev. Brain Res. 35:55-67, 1987). This work was supported by NIH Grants NS24742 and NS08530.

ULTRASTRUCTURAL IDENTIFICATION OF TRANSIENT CEREBROCEREBELLAR TERMINALS IN NEONATAL CATS. D.L. Tolbert & D.S. ZAHM. Dept. of Anat. & Neurobiol., St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

There are transient projections from the cerebral cortex to the cerebellar cortex and deep nuclei in neonatal cats. EM autoradiographic demonstration of orthogradely transported [^{3}H]-amino acids was carried out to determine if these transient axons form synaptic contacts with neurons in the cerebellar nuclei. Analysis of EM autoradiographs revealed numerous labeled cerebrocerebellar axons in the cerebellar white matter. These axons were frequently myelinated. Some labeled axonal profiles were vacuolated and appeared to be degenerating. Others contained large vesicles and had filiopodia and these were identified as growth cones. Labeled axon terminals containing predominantely clear, round vesicles were also observed in autoradiographs of sections through the cerebellar nuclei. Some labeled terminals contacted dendrites at asymmetric synaptic specializations. Other labeled terminals, which were not apparently associated with membrane specializations, were also present. These data represent morphological evidence that transient cerebrocerebellar axons form synaptic contact with cerebellar neurons. Preliminary electrophysiological data suggest that these synapses are functional. Supported by NIH grants NS-20227 and NS-23805.

THE ROLE OF CEREBELLAR CORTICAL POSTSYNAPTIC ACTIVITY ON THE DEVELOPMENT OF SPINOCEREBELLAR TOPOGRAPHY. T. Pittman* and D.L. Tolbert. (SPONSOR: H. Cantor) Depts. of Anat. & Neurobiol., and Surgery (Neurosurg.), St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

The development of topographic maps may be dependent upon conjoint pre- and postsynaptic activity. In adult rats spinocerebellar (Sp-CB) projections terminate in 5 sharply demarcated, sagittally-oriented stripes in the anterior lobe. Initally these projections terminate diffusely, but assume an adult pattern of termination by 7PND. Elvax implants containing muscimol, an GABA agonist, were made onto the surface of the cerebellum of 2PND rats. Sp-CB projections were mapped using orthograde intraaxonal labeling techniques. Compared to controls, the chronic application of muscimol altered the development of Sp-CB projections in two ways. First, Sp-CB axons did not form sharply delineated stripes in the anterior lobe. Distinct columns of labeled Sp-CB terminals were present in the internal granule cell layer, but considerable intercolumnar label was still present at 8-9PND. Second, Sp-CB projections were not restricted to the internal granule cell layer; rather, Sp-CB axons also projected aberrantly to the molecular and external granule (germinal) cell layers. These findings indicate that the initial development of Sp-CB topography is not dependent upon postsynaptic activity, but that the elimination of exuberant interstripe projections and the targeting of some Sp-CB axons is dependent upon cortical neuronal activity. Supported by NIH grant NS20227.

DEVELOPMENT OF KITTEN PRECRUCIATE NEOCORTICAL NEURONS IN BRAIN SLICES: RESPONSE TO ACETYLCHOLINE. K. Uchida*, N.A. Buchwald and M.S. Levine (SPON: D. Birt). MRRC, UCLA, Los Angeles, California, 90024.

The present study assessed the ability of acetylcholine (ACh) to alter electrophysiological parameters of developing precruciate cortical (Cx) neurons. Sixteen kittens (2-90 days of age) were anesthetized with ketamine, sacrificed and coronal brain slices (400-500 μm) were obtained. Effects of ACh were assessed by adding a series of ascending concentrations (10, 20, 30 and 50 μM ACh and 10 μM eserine) to the bath. To date we have recorded intracellularly from 104 neurons, 28 of which were tested with Ach. Animals were divided into 2 age groups (2-19 and 20-90 days). There were no differences in average resting membrane potential (RMP) and average action potential (AP) amplitude between the two groups (-61.4±8.0 (S.D.) and -54.1±6.9 mV for RMP and 71.8±17.2 and 66.7±12.6 mV for AP for younger and older kittens, respectively). Average input resistance was also not different (37.4±15.4 MΩ and 32.8±18.9 MΩ for younger and older kittens, respectively). However, there was a tendency for neurons in kittens under 1 week of age to have higher input resistances. Ach increased excitability and/or input resistance of 75% (21/28) of the Cx cells. The proportion of cells that showed an increase in excitability and/or input resistance was greater in older (84%, 16/19 cells) than in younger kittens (56%, 5/9 cells). Excitability was measured by assessing changes in action potential frequency during depolarizing current pulses (500 msec duration, 0.1-2.0 nA intensity). Increases in input resistance were greater in cells from older kittens (42.9±34.9% (n=7) versus 27±9.8% (n=4)). This study demonstrates that developing Cx neurons are capable of responding to Ach. The magnitude and the type of response appear to mature over the first postnatal month. Supported by USPHS Grant HD 5958.

32.2

MOTOR DEVELOPMENT OF KITTENS WITH SPINAL CORD LESIONS AND TRANSPLANTS. D.R.Howland*, Y.Itoh, A. Tessler, M.E.Goldberger. Department of Anatomy, The Medical College of Pennsylvania, Philadelphia, PA 19129.

Large spinal cord lesions were made in newborn kittens and homotypic embryonic transplants were placed in the lesion. Motor development and adult motor patterns were observed. Unlike normal kittens, newborn operates demonstrated bipedal locomotion on a treadmill within 24 hours. This bipedal locomotion is atypical in time of onset and pattern in comparison to normal development. Long-latency, hypometric proprioceptive placing without weight support can be elicited inconsistently within 24 hours. This placing pattern also differs from that of normal kittens. A transient loss of bipedal locomotion and placing is then seen which lasts from days to weeks. Re-emergence of these behaviors appears to coincide closely with each other and loosely with the acquisition of quadrupedal treadmill and overground locomotion. In adulthood, differences and similarities are observed between bipedal and quadrupedal treadmill and overground locomotion. Thus, motor patterns may not develop as continuous additions and refinements of behavior after neonatal spinal cord injury. This suggests that previously observed motor behavior may be suppressed and emerge again later in development.

32.3

THE EFFECT OF GM1 AND BRIDGING WITH FETAL SPINAL CORD ON RECOVERY OF HINDLIMB MOTOR FUNCTION IN THE SPINALIZED RAT. J.W. Commissiong and G. Toffano. Dept. of Physiol., McGill Univ., Montreal, Canada H3G 1Y6 and Fidia Res. Lab. 35031 Abano Terme, Italy.

Rats recover hindlimb motor coordination spontaneously if they are spinalized at postnatal day (PN) 7, but not at PN14 (Commissiong & Toffano, 1989). Five groups of animals were studied to determine whether bridging the spinal cavity with embryonic day (E) 17 spinal cord tissue, and/or treatment with GM1 ganglioside could promote recovery in animals spinalized at PN14. Ten weeks after surgery, the rats were scored (N=19) for four-limb coordination on a scale of 0 (worst) to 10 (best). The results are shown below.

GROUP	MEAN ± SD
UOC	9.26±1.48
PN14,B$^-$,S	3.18±2.91
PN14,B+,S	2.77±2.01
PN14,B+,G	5.00±1.97
PN 7,B$^-$,S	6.13±2.31

An ANOVA test, followed by a multi-comparison test showed that the PN14,B$^-$,S vs PN14,B+,S; and PN 14,B+,G vs PN7,B$^-$,S groups were statistically identical. UOC: unoperated control; B+: with bridging; B$^-$: no bridging; G: treated with GM1; S: treated with saline. Therefore, bridging plus treatment with GM1 caused a significant recovery in hindlimb motor coordination.

GROWTH, ELIMINATION AND MYELINATION OF CORTICOSPINAL AXONS IN THE POSTNATAL RAT. M.T.S. Cox, D.L. O'Donoghue and D.R. Humphrey. Laboratory of Neurophysiology, Emory University., Atlanta, GA 30322.

Studies have shown that corticospinal axons innervate the cord by the 2nd wk. We now extend these observations by describing the patterns of axon growth, elimination and myelination in the tract from the 1st to the 8th postnatal wks. Rats were perfused at 1, 2, 3, 4, 6, or 8 wks of age. The 5th cervical spinal cord segment was removed and processed for electron microscopy. Using 17 micrographs from each of 4 tracts per age, measurements were made of: (a) the numbers of axons within the areas sampled, and from this an estimate of the total number in the tract; (b) axon diameter; and (c) the percent myelinated. The results support the following conclusions: (1) During wks 1-2, almost all axons are unmyelinated, with a modal diameter of 0.2 um. The modal diameter of unmyelinated axons did not change between wks 1 and 8. (2) During wks 2-3, myelinated axons, 0.65 um in modal diameter, appear. Thus, radial growth of an axon occurs during its myelination. From wks 3-8, the percentage of myelinated axons increases from 19 to 53. (3) From wks 3-4, the number of axons decreases from 115,000 per tract to approximately 80,000. The appearance of myelinated axons in wk 3 may account for the development of functional excitability in the motor cortex-to-muscle system described previously (Cox and Humphrey, Neurosci. Abstr., 12:1119)(Supported by NIH Grant NS 20146).

32.5

POSTNATAL CHANGES IN THE NUMBER, DENSITY AND DISTRIBUTION OF CORTICOSPINAL NEURONS IN THE RAT. D.R. Humphrey and D.L. O'Donoghue. Laboratory of Neurophysiology, Emory University, Atlanta, Georgia, 30322.

During the first two postnatal weeks, corticospinal (CS) neurons are distributed as a continuous 'continent' of cells over the fronto-parietal cortex. In adults, CS cells form 3 discrete islands. Changes in distribution may result from 3 factors: 1. the death of CS cells in 'gap' regions; 2. unequal decreases in CS cell density with cortical growth; and/or 3. the elimination of spinally projecting axons from cells, particularly those located in 'gap' regions. These three factors were studied using a retrogradely transported dye (Fast Blue). To assess factor '1', dye soaked gelfoam was placed into the CS tract at C5 on postnatal day (PND) 6 (N=24). Groups of animals were then sacrificed on PND 10, 15, 20 or 30 and counts of labeled cells were obtained. The number and distribution of labeled cells did not change with age, indicating that cell death plays no role in the postnatal changes. These observations also ruled out factor '2.' Factor '3' was assessed by placing dye into the CS tract at different ages (PND 2,6,10,15,22 or 29; N=33), and quantifying the number and distributions of cells after a survival of one week. These experiments showed that: (a) the number of CS cells declines by PND 17 to 1/2 that seen on PND 7; and (b) axon elimination occurs in all areas, although regional differences can account for the formation of the adult pattern. (Supported by NIH Grant NS20146)

32.6

THE DEVELOPMENT OF CORTICOSPINAL PROJECTIONS IN NEONATAL CATS. T.D. Swink* and D.L. Tolbert (SPON: A. Harolan) Depts. of Anat. & Neurobiol. and Surg.(Neurosurg.), St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

The development of corticospinal (CS) projections was studied in neonatal kittens following unilateral injections of WGA-HRP into the sensorimotor cortex. At 4PND labeled axons were in the lateral corticospinal tracts (LCST) bilaterally through all spinal cord levels. Rostrally, axons entered lamina V-VII bilaterally and spread dorsally to lamina I-III, and ventrally to VII and IX. Label in the ipsilateral LCST was less dense in lumbar segments than in cervical levels, and labeled axons projected only in lamina III-VI. At 7PND lamina V-VIII were filled with diffuse HRP reaction product indicating labeled terminals. Compared to younger animals, labeling in the ipsilateral LCST and spinal gray was markedly reduced in animals 7PND and older. Although the ipsilateral LCST is present in animals as old as 10PND, it does not appear to contribute any input to the gray matter. The lumbar segments of older animals (16PND) showed a pattern of HRP labeling similar to that seen in younger animals (7PND) with extensive labeling of individual axons and diffuse labeling of terminal endings. These data indicate that CS projections appear first to extend to all levels of the spinal cord and then proceed to innervate the gray matter in a rostrocaudal sequence. MATURATION OF CENTRAL CONDUCTION TIME IN CORTICOSPINAL TRACTS PREDICTS DEVELOPMENT OF FASTEST VOLUNTARY MOVEMENTS IN CHILDREN

V. Hömberg*,1, K. Müller*,2 (SPON: ENA). 1:Neurological Therapy Center and 2:Department of Pediatrics, Heinrich Heine University of Duesseldorf, West Germany

Magnetic stimulation of motor cortex provides a non-invasive way to look at the maturation of fastest efferent corticospinal projections to upper and lower extremity muscles. This for the first time allows a direct comparison between the maturational profiles of fastest efferent corticospinal path ways with the maturation of voluntary motor activities in children.

In 70 children between the age of 2 and 10 years fastest stylus tapping movements (TAP), fastest aimed movements using a stylus to touch onto 20 consecutive targets separated by 1 cm (AIM) and fastest peg board transportation rates needed to transport pegs (0.2 mm diameter, 25 mm length) into 25 target positions consecutively (PEG) were measured. The maturational profiles of these motor activities were compared with central conduction times to thenar muscles obtained by magnetoelectrical stimulation (Cadwell MES 10 stimulator). The coil was positioned either over the vertex or over the mid cervical roots. The latency difference between cortical and cervical stimulation served as an estimate of central conduction time (CCT).

A comparison between the age-related slopes of the motor variables and the CCTs demonstrated a marked similarity in the maturational profiles of all motor activities with the maturation of CCTs. This was reflected in very similar exponents after approximations by power functions.

It can be concluded that maturation of fast hand movements is primarily determined by the structure bound maturation of the fastest corticospinal efferents and not by effects of motor learning.

32.8

EFFECTS OF KETAMINE, HALOTHANE, AND PENTOBARBITAL ON LOCOMOTOR RECOVERY AND CELL LOSS FOLLOWING SENSORIMOTOR CORTEX INJURY. M.P. Weisend & D.M. Feeney, Depts. of Psychol. and Physiol., UNM, Albuquerque, N.M. 87131.

This study examined some histopathological sequalae (15-20 days post injury) remote from the area of primary necrosis and beam walking (BW) recovery rate following sensorimotor cortex contusion (SMCx) under four conditions: 1) pentobarbital (PENT-45mg/kg, i.p.); 2) halothane (HALO 2% at 1.5 l/min @ 15 min); 3) PENT with ketamine pretreatment (KET/PENT 60mg/kg ketamine hydrocloride i.m., followed after 10 min by 21mg/kg PENT, i.p.); 4) HALO/KET (contusion under HALO then 5 min post surgery 150mg/kg KET i.p.). Anesthetic conditions had no effect on the rate of BW recovery. SMCx contusion or ablation produced a marked loss of ipsilateral thalamic ventral basal complex and ventralis lateralis neurons accompanied by gliosis. The extent of thalamic reaction was highly correlated with BW recovery but unaffected by treatment. Under PENT contusion produced an extensive ipsilateral loss of hippocampal CA3 pyramidal cells with little effect on CA1 or granule cells. The CA3 cell loss was lessened when contused under HALO and for KET/PENT was severe only in CA3a whereas HALO/KET greatly reduced this cell loss. Hippocampal cell loss was uncorrelated with BW recovery and not observed after SMCx ablation. Supported by DHHS RO1-NS20220-03 AND US Army Contract DAMD17-86-C-6144.

The Role of Experience on Amphetamine-Facilitated Recovery of Beam-Walking in the Rat. L.B. Goldstein and J.N. Davis. V.A. & Duke Medical Centers, Durham, N.C. 27705

Treatment with amphetamine increases the rate of recovery of beam-walking in rats after a unilateral suction-ablation lesion of the sensory-motor cortex. The amphetamine effect is not found if the rats are physically restrained following drug administration (Feeney et al., Science 217, 1982). However, the impact of practice on the beam following drug administration has not been directly tested. Therefore, we carried out an experiment in which four groups of rats were compared: 1. Amphetamine/Practice (n=19), 2. Amphetamine/No Practice (n=20), 3. Saline/Practice (n=18), 4. Saline/No Practice (n=20). Amphetamine was given as a single dose 24 hours after lesioning. Practice was six trials on the beam at one hour intervals beginning one hour after drug/saline administration. "No Practice" rats were handled and allowed to walk in their home cages. Final ratings were performed by a blinded observer 24 hours following drug administration. Group 1 rats had greater improvements in beam-walking scores when compared to rats in the other three groups (Kruskal-Wallis H=15.592, DF=3, p<.01; Fisher LSD, p<.05). Amphetamine treatment alone (Group 2) or practice alone (Group 3) did not enhance recovery (Fisher LSD, P>.05). There were no differences in lesion sizes among the four groups (ANOVA, p=.73). Thus, practice on the beam is required for amphetamine-facilitated recovery of beam-walking.

32.10

RECOVERY OF FORELIMB-PLACING BEHAVIOR IN RATS WHICH RECEIVED UNILATERAL CORTICAL DAMAGE AS NEONATES IS MEDIATED BY THE REMAINING HEMISPHERE T.M Barth and B. B. Stanfield. Lab. Neurophysiol. and Lab. Clin. Sci, NIMH, Poolesville, MD 20837.

Unilateral lesions in the sensorimotor cortex (SMC) of adult rats produce placing deficits with the forelimb contralateral to the damage. However, this deficit is temporary and following complete recovery, a second lesion in the remaining SMC produces deficits only with the forelimb contralateral to the second lesion. This suggests that recovery from unilateral SMC lesions in adult rats does not involve the contralateral homotopic cortex. In contrast, in rats lesioned as neonates (who also recover), there is anatomical evidence consistent with a role for the contralateral hemisphere in the recovery. For example, in adult animals which had been unilaterally lesioned as neonates there is an increase in an ipsilateral corticospinal projection which is not seen following adult lesions. This, as well as other aberrant projections, provides a potential substrate for the mediation of the behavioral recovery. The present study was designed to evaluate the contribution of the contralateral hemisphere in recovery of tactile forelimb-placing behavior following unilateral neonatal SMC lesions.

On the day of birth, rats received a unilateral SMC lesion and were tested for impairments of tactile forelimb-placing on days 30 and 42. There was no evidence of placing deficits with either forelimb. On day 42, some of these rats received a second lesion in the remaining SMC. In contrast to the results with adult rats, the second lesion produced tactile placing deficits with both forelimbs. This suggests that following unilateral SMC lesions in neonates, the contralateral hemisphere mediates the recovery of forelimb-placing. Finally, three days after the second SMC lesion, the rats were perfused and the brains and spinal cords were processed for the presence of degenerating fibers with the Fink-Heimer stain. Analysis revealed axon degeneration in the cord both ipsilateral and contralateral to the second lesion. We conclude that this aberrant ipsilateral corticospinal projection is a potential substrate for recovery of forelimb-placing which follows neonatal SMC lesions.

EXTRAUTERINE MOTOR DEVELOPMENT OF "FETAL RAT" DELIVERED BY C-SECTION. C. Robert Almli and Martina Dyer.* (SPON: J. DUBINSKY). Depts. of Anat. & Neurobiol., Psychol., Pgms. in Neural Science, Occup. Therapy, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Studies of early motor development have revealed "cyclic, spontaneous movement" patterns during embryonic, fetal and neonatal periods for a wide variety of species. This investigation extends the study of early movement to "fetal rats" delivered prematurely to the extra-uterine environment. "Fetal rat pups" were studied at 20 and 21 days gestational age, and compared to fullterm, vaginally delivered rats. The 3 age groups were videotaped in an incubator at 2-3, 5-6 and 24 hours "postnatal". Tapes were analyzed (computer) for movements of mouth, head, limbs and trunk, complex movements (face brush, supine-prone, ambulation), and cycles. Although delivered prematurely, "rat fetuses" at 20 or 21 days gestation displayed movement of all body segments including complex movements, and cyclic, spontaneous movements. However, the groups differed quantitatively on a number of measures, e.g., total number of movements. Overall the results indicate "rat fetuses" are capable of displaying a wide variety of movements in the extra-uterine environment. The major differences between groups were quantitative. (Conducted under NIH Guide for the Care and Use of Laboratory Animals.

ASSOCIATION CORTEX AND THALAMOCORTICAL RELATIONS I

COMPARATIVE ANALYSES OF THE CHOLINERGIC AND SEROTONERGIC INNERVATIONS OF MONKEY (*MACACA FASCICULARIS*) PREFRONTAL CORTEX. D.A. Lewis and S. Slovenec*. Depts. of Psychiatry and Behav. Neurosci., University of Pittsburgh, Pittsburgh, PA 15213.

Immunohistochemical methods were used to visualize fibers immunoreactive (IR) for choline acetyltransferase (ChAT), a marker of the cholinergic system, or serotonin (5HT) in cynomolgus monkey prefrontal cortex. The majority of ChAT-IR fibers were extremely fine and studded with small varicosities. Smooth fibers with a larger diameter were also present, especially in the white matter. The density of ChAT-IR fibers was relatively uniform across cytoarchitectonic regions, although some differences were observed. Layers I-II had the greatest density of labeled fibers, layer VI the lowest, and layers III-V had a range of intermediate densities of ChAT-IR fibers. Compared to ChAT-IR axons, 5HT-IR fibers were morphologically more heterogeneous. However, 5HT-IR fibers had a more homogeneous distribution on both a regional and laminar basis than did ChAT-IR fibers. The patterns of distribution of these afferent systems are distinctly different from those of dopaminergic and noradrenergic axons, suggesting that these four neural systems differ substantially in their regulation of prefrontal cortical function.

33.2

ORGANIZATION OF CHOLECYSTOKININ (CCK)-IMMUNOREACTIVE (IR) STRUCTURES IN MONKEY PREFRONTAL CORTEX. K.M. Oeth and D.A. Lewis. Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15213

CCK-IR structures were analyzed in prefrontal cortical regions of monkeys (*Macaca fascicularis* and *Macaca mulatta*) using antibodies which selectively recognize either the terminal octapeptide (CCK8) or larger forms (CCK58, 39, and 33) of CCK. Large forms of CCK are confined to discrete portions of the soma whereas CCK8-IR is present in fibers as well as in the soma. Common neuronal morphologies include a vertically oval cell with a primary ascending and descending dendrite from which an axon vertically descends, and a multipolar cell with a descending axon. Total CCK8-IR cell density does not differ among cortical regions and is highest in layers II-superficial III. Within a region, CCK8-IR cells have a discontinuous distribution; in serial tangential sections through layers II-superficial III, bands of cells alternate with cell-poor regions. Prominent CCK8-IR terminal fields exist in layers II, IV, and especially VI, while radially oriented fibers traverse the sparsely innervated layers III and V. These radial fibers have a distribution which parallels the location of apical dendrites of pyramidal cells and may descend from the CCK8-IR neurons of layer II-III. Both labeled fibers and neurons are present in high density in layer II, whereas in layers IV and VI, the densities of CCK8-IR fibers far exceed that of labeled neurons. CCK-containing neurons are present in the mediodorsal thalamic nucleus and substantia nigra-ventral tegmental area; axons from these structures terminate in layers IV and VI, respectively, and may account for the CCK8-IR terminal fields in these layers. These data indicate that CCK may influence prefrontal cortical function via multiple neuronal circuits. Supported in part by the Scottish Rite Schizophrenia Research Foundation, N.M.J.,U.S.A.

33.3

DISTRIBUTION OF TYROSINE HYDROXYLASE (TH)-IMMUNOREACTIVE (IR) STRUCTURES IN HUMAN PREFRONTAL CORTEX. L.V. Le* and D.A. Lewis (SPON: J. Puig-Antich) Depts.of Psychiatry and Behav. Neurosci., University of Pittsburgh, Pittsburgh, PA 15213.

The distribution of TH-IR structures was characterized immunohistochemically in post-mortem human prefrontal cortex. The density of TH-IR fibers was heterogeneous across cortical regions. Fiber density was greatest in the cingulate gyrus. The superior frontal gyrus, especially the medial portion, also had a high density of labeled fibers. Fiber density decreased substantially across the middle and inferior frontal gyri. The orbital gyri had intermediate densities of TH-IR fibers. Regional differences were also present in the laminar distribution of fibers, although fiber density was consistently greatest in layers I-II. In addition, a subpopulation of nonpyramidal neurons was labeled with several different anti-TH antibodies, including 2 monoclonals. Labeled neurons were present in every layer with the highest density in layer VI. The density of TH-IR neurons also differed substantially (up to 3-fold) across prefrontal regions. In general, the regional distribution of TH-IR neurons paralleled that of TH-IR fibers. These findings demonstrate that the innervation of human prefrontal cortex by TH-IR fibers is quite similar to that of monkey (Br Res 449:225, 1988). They also suggest that intrinsic neurons may contribute to the catecholaminergic innervation of human prefrontal cortex. Supported in part by MH00519 and the Scottish Rite Schizophrenia Research Program, N.M.J.,USA.

33.4

CORTICOCORTICAL AND OTHER TELENCEPHALIC CONNECTIONS OF THE ORBITAL AND MEDIAL PREFRONTAL CORTEX IN THE MONKEY. S. T. Carmichael* and J. L. Price (Spon. H. Burton), Dept. of Anatomy and Neurobiology, Washington Univ. Sch. of Med. St. Louis, MO 63110.

The ventral and orbital prefrontal cortex (PFC) of the primate participate in many connections with other brain regions. We examined the connections of these areas in 10 Macaca fascicularis monkeys with the use of the retrograde tracers fast blue and diamidino yellow. Analysis of intrinsic prefrontal corticocortical connections revealed two regions with extensive internal connections but with few interconnections linking them: a medial region (Med) consisting of areas 32, 24 a,b, and part of area 10 and an orbital region (Orb) including the agranular insula (Ia), and areas 13, 13a, and caudal parts of 12, 11 and 14. Cells giving rise to projections in these systems formed radial columns or patches and complex, interlocking strips across cortical areas.

Input to these systems is segregated in other telencephalic areas. Temporal cortical cells projecting to Orb are located primarily in the ventral temporal pole and in the extreme rostral portion of the Superior Temporal Sulcus, while cells projecting to Med were fewer in number and located in the dorsal temporal pole and the rostral Superior Temporal Gyrus. Cells in the entorhinal cortex projecting to Med lie lateral and caudal to those projecting to Orb. Within the amygdala cells projecting to Med were primarily caudal and lateral to Orb-projecting cells in the basal nucleus; cells of the accessory basal nucleus projected to both regions. Finally, cells in the claustrum projecting to both PFC regions lie in the rostral ventral claustrum, but Med-projecting cells are clustered lateral and dorsal relative to Orb-projecting claustral cells.

EFFECT OF SPATIAL AND COLOR CUES ON DELAY-RELATED NEURONAL RESPONSES IN PREFRONTAL CORTEX. F.A.W. Wilson & P.S. Goldman-Rakic, Yale Medical School, New Haven, CT

Neurons (n =180) were recorded in area 9 and superior area 46 during the performance of two tasks requiring spatially directed responses: a spatial delayed response (SDR) task in which the monkey moved a joystick left or right after a 1s delay following presentation of a left or right cue; in a color-cued delayed response task (CDR), the left/right responses were indicated by one of two different colored cues presented in the center of the monitor. SDR and CDR trials were presented quasi-randomly within each session and eye postion was monitored. Of the 151 neurons tested on at least 8 trials of each stimulus, a total of 39 neurons responded differentially during the delay period in one or both tasks. The majority of neurons appeared to reflect the nature of the cue rather than the response because they showed an increase in firing rate in the SDR task (n = 20); or in the CDR task (n = 12) but not both. A smaller fraction (n = 7) responded on both tasks, always for the same response direction whether signalled by the color or location of the cue. One neuron that responded differentially during the delay of the SDR task was driven by thalamic stimulation (lat. = 3.8 ms; conduction vel. = 6.6 m/sec) with following of 200 Hz pulse trains, indicating that neurons which participate in memory are connected with the thalamus. None of the 180 neurons recorded responded to the sight of foods, novel and familiar stimuli, or faces. In line with Fuster et al. (Brain Research 474; 1988), these data provide evidence that some prefrontal neurons code direction of the impending response and can do so either for spatial or color information while others represent separate spatial and non-spatial memory channels.

33.6

EVIDENCE FOR A SELECTIVE PROJECTION FROM THE HIPPOCAMPAL FORMATION TO THE PRELIMBIC AREA OF THE PREFRONTAL CORTEX IN THE RAT. T.M. Jay, J. Glowinski*, A.M. Thierry*. INSERM U114, Collège de France, 75231 Paris Cedex 05, France.

Connections from the hippocampal formation to the prefrontal cortex (PFC) were studied using both retrograde and anterograde tracers injected iontophoretically. The retrograde tracer Fluoro-Gold was placed into different subdivisions of the PFC. Only the injections located in the prelimbic area revealed the presence of labelled hippocampal cells in the ipsilateral CA1 temporal field and caudal subiculum. Injections of the anterograde tracer Phaseolus Vulgaris Leucoagglutinin (PHA-L) into CA1 revealed a projection to the PFC which was restricted to the prelimbic area, mainly in the deep layers. PHA-L injections into the caudal subiculum also resulted in labelling in the prelimbic area diffusely distributed over all the layers. All these fibers are branched and highly varicosed. These results demonstrate that the projection from the hippocampal formation to the PFC in the rat is unilateral and restricted to the prelimbic area. On the basis of these anatomical data, the functional interaction between these two structures is currently studied (S. Laroche et al., this meeting).

Prefrontal Projections to the Medial Nuclei of the Dorsal Thalamus in the Rabbit. R.H. Thompson* and S.L. Buchanan. VA Medical Center and University of South Carolina, Columbia, SC 29201.

Rabbits were injected with horseradish peroxidase (HRP) to investigate the efferent projections from the prefrontal cortex (PFC) to the medial nuclei of the dorsal thalamus. Injections limited to the mediodorsal nucleus resulted in labeling of both the agranular midline and insular regions of the PFC. Injections restricted to the ventromedial nucleus labeled the dorsolateral PFC above the forceps minor and a medial region in the granular insular cortex. An injection contained within the intralaminar nuclei, including both the centromedial and paracentral nuclei, labeled cells in both the more dorsal aspect of the agranular precentral PFC, and the dorsolateral PFC. Injections limited to the ventroposterior nucleus resulted in labeling of the dorsolateral portions of PFC with some overlap of the area labeled by VM injections. All labeled cells were observed in the deeper cortical layers (either V or VI), regardless of the architectonic region injected. Injections of WGA-HRP in the PFC confirmed that the observed retrograde labeling was not due to damage to thalamic fibers of passage. Thus, it was shown that there is a differential topographical projection to the various nuclei of the dorsal thalamus from the PFC in the rabbit.

THE CLASSIFICATION AND ORIGIN OF AXON TERMINALS IN THE MEDIODORSAL THALAMIC NUCLEUS (MD) OF THE RAT. M. Kuroda* and J. L. Price, Dept. Anat. & Neurobiol., Washington Univ. Sch. Med., St. Louis, MO 63110.

Electron microscopy and the tracer WGA-HRP have been used to investigate the types and origin of pre-synaptic terminals in MD. At least four types of terminals have been identified on the basis of size, synaptic vesicle morphology and synaptic membrane specialization: 1) small axon terminals (<1 μm in diameter) with round vesicles, which make asymmetric synaptic contacts with small dendrites; 2) large axon terminals (>3 μm) with round vesicles, which make asymmetric contacts with large dendrites; 3) small to medium axon terminals (<2 μm) with pleomorphic vesicles, which make symmetric contacts with soma; 4) large axon terminals (>3 μm) with pleomorphic vesicles, which form symmetric contacts with large dendrites.

In order to label the terminals by anterograde transport, 50-100 nl of 1% WGA-HRP was injected into areas known to project to MD. Ultrastructural examination of the material prepared to date indicates that the first type of axon terminal arises from prefrontal cortical areas such as the prelimbic and lateral orbital cortex. The second type of terminal arises from ventral forebrain structures such as the basal amygdaloid nucleus. However, the ventral pallidum gives rise to the fourth type of axon terminal. On morphological grounds, therefore, the ventral pallidal projection may be inhibitory, while other ventral forebrain afferents may be excitatory. It is presumed that the third type of terminals arises either from interneurons or from the thalamic reticular nucleus.

33.9

THREE-DIMENSIONAL ANALYSIS OF THALAMOCORTICAL PROJECTIONS AND VENTRAL FOREBRAIN AFFERENTS OF THE MEDIODORSAL NUCLEUS OF THE THALAMUS IN THE RAT. J. P. Ray and J. L. Price, Dept. of Anatomy and Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Recent studies have documented direct projections from the amygdaloid nuclei and the piriform (olfactory) cortex to the prefrontal and agranular insular cortices, and to the thalamic nucleus associated with these cortical areas, the medial and central subdivisions of the mediodorsal nucleus (MD_m and MD_c). Hence, there are both direct and transthalamic pathways between the ventral forebrain and prefrontal cortex. We have studied the organization of this system by injecting anterograde tracers into ventral forebrain structures and, in the same rats, retrograde tracers into connected frontal cortical areas, in order to directly compare cells labeled in MD with afferents from the ventral forebrain. 3-D reconstructions of sections through MD have been used to correlate the distibution of cells projecting to amygdaloceptive cortical areas (prelimbic, dorsal agranular insular and dorsolateral orbital cortices (DLO)) or to olfactory-related areas (ventral agranular insula (AI_v) or lateral orbital cortex) with the distribution of afferents in MD from the amygdala or piriform cortex, respectively. **Results indicate that the degree of overlap of thalamocortical cells in MD and ventral forebrain afferents varies, depending upon the cortical area.** For example, cells in MD_c projecting to AI_v are in the same part of MD_c that receives afferents from the piriform cortex, but cells in MD projecting to DLO are distant from basal amygdaloid afferents in MD_m, even though DLO receives direct basal amygdalocortical fibers.

CHANDELIER CLASS INTERNEURONS CONTAINING CORTICOTROPIN RELEASING FACTOR IN PRIMATE PREFRONTAL CORTEX. J.S. Lund and D.A. Lewis. Dept. of Psychiatry and Center for Neuroscience, University of Pittsburgh, PA 15261.

In prefrontal, parietal and temporal granular association areas of squirrel monkey cortex corticotropin releasing factor (CRF) immunoreactivity is present in small, vertically oriented, rod-like structures (Lewis et al., '89). These structures are uniquely located in layers 4-base 3. Golgi impregnations of macaque show layer 4 in prefrontal areas 46 and 9 to have a population of 'chandelier' interneurons whose axon cartridges strongly resemble the CRF positive 'rods.' Chandelier neurons have been shown (Somogyi, '77) to be GABAergic and have axon cartridges encasing pyramidal neuron axon initial segments. In prefrontal cortex we find the cartridges to surround the axon initial segments of pyramidal neurons within layer 4 and at the base of layer 3. Chandelier neurons in other locations do not appear to be CRF immunoreactive, suggesting that this neuron class has subgroups with different cotransmitters. These CRF interneurons lie in a strategic position for controlling the influence of inputs to layer 4 within prefrontal cortex. Supported in part by EY05282, MH00519, MH43784.

34.2

LOCALIZATION OF SOMATOSTATIN (SS) IMMUNOREACTIVITY (IR) IN HUMAN AND MONKEY NEOCORTEX: ARE THERE SPECIES DIFFERENCES? T.L. Hayes and D.A. Lewis, Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15216.

SS28- and $SS28_{1-12}$-IR were analyzed immunohistochemically in the anterior cingulate, inferior temporal and primary visual regions of perfused monkey, unperfused monkey of varying post-mortem (PM) intervals (.5, 1, 2, 4, 8 and 12 hrs) and PM human brains. The regional and laminar distributions of $SS28_{1-12}$-IR fibers were similar across species. For example, in both species anterior cingulate cortex had the greatest density of labeled fibers, and primary visual cortex had the least. However, perfused monkey and .5 hr PM monkey had the greatest overall fiber density, as well as prominent radial fibers in layers III-V that were not labeled after longer PM intervals or in humans. Furthermore, although SS28-IR was clearly evident in perfused monkey, it was not detected in human or PM monkey. In contrast, both perfused and PM monkeys showed a similar density of $SS28_{1-12}$-IR neurons in cortex and white matter, whereas the percentage of $SS28_{1-12}$-containing cells located in the white matter was 3-5 times greater in human than in monkey. Labeled neurons in the white matter were also larger in human than in perfused or PM monkey. These findings indicate that (1) the decrease in $SS28_{1-12}$-IR in humans compared to monkeys is probably an effect of the PM interval; (2) the lack of SS28-IR in humans may be due to the lability of SS28, and does not reflect a species difference; and (3) differences in the number of $SS28_{1-12}$-IR cells and their size do indicate a species difference between humans and monkeys.

34.3

MONOAMINERGIC AND PEPTIDERGIC INNERVATION OF MONKEY TEMPORAL POLE. M.L. Voytko, C.A. Kitt and D.L. Price. Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

The distributions of dopaminergic, serotoninergic, and peptidergic nerve fibers are not well documented in temporal polar cortex. Immunocytochemistry was used to demonstrate regional and laminar innervation patterns of immunoreactive fibers for tyrosine hydroxylase (TH), serotonin (5HT), substance P (SP), and neuropeptide Y (NPY) in the temporal poles of three rhesus monkeys. TH fibers formed a dense continuous band in the deep portion of layer I and throughout layer II. 5HT-positive fibers were also concentrated within layer I. NPY-immunoreactive fibers were conspicuous in layers I-III. Distinct bands of SP-positive fibers were observed in layer I, layers II-III, and layer V of temporal pole.

These findings indicate that temporal polar cortex receives a rich supply of dopaminergic, serotoninergic, and peptidergic afferents, with the highest density of innervation in supragranular layers I and II. These laminae are also primary targets of cholinergic innervation from the nucleus basalis of Meynert [Voytko et al., *Soc. Neurosci. Abstr.* 14:631, 1988]. These results suggest that inputs from diverse neurotransmitter/peptidergic sources have converging influences upon neurons in temporal polar cortex.

34.4

A SUBSET OF PRIMATE CORTICOCORTICAL NEURONS ARE NEUROFILAMENT PROTEIN (NFP) IMMUNOREACTIVE (ir): A COMBINED RETROGRADE IMMUNOHISTOCHEMICAL STUDY. M.J. Campbell, P.R. Hof, K. Cox*, T.A. Kimber*, W.G. Young and J.H. Morrison, Research Institute of Scripps Clinic, La Jolla, CA

In previous primate neocortical studies we observed that SMI-32-ir pyramidal neurons exhibited a regionally heterogeneous distribution and hypothesized that this resulted from shifts in the representation of SMI-32-ir neurons furnishing long corticocortical projections (JCN(1989) 282:191-205). SMI-32 is a Sternberger-Meyer monoclonal antibody that recognizes a non-phosphorylated epitope on NFP. We have initiated combined retrograde tracer and immunohistochemical studies in the *Macaca fascicularis* to test this hypothesis. Fast blue was injected into the cortical region rostral to the arcuate sulcus and ventral to the principal sulcus (PS) and we determined the number of fast blue retrogradely labeled neurons (FB) and double labeled neurons (DL) (those containing fast blue and SMI-32-ir) in 6-10, 1 mm cortical traverses from each source cortical region. Results are presented as a ratio of DL over FB for layers III and V-VI for several regions. Ipsilateral PS (III, 22±3/114±21, 18%; V-VI, 27±5/98±15, 27%); Contralateral PS (III, 23±1/88±5, 26%; V-VI, 10±1/32±2, 31%). Ipsilateral anterior cingulate (III, 0/1, 0%; V-VI, 10±1/20±1, 50%). Contralateral anterior cingulate (III, 0/1, 0%; V-VI, 7±1/14±2, 50%). Intraparietal sulcus (III, 17±2/29±3, 58%; V-VI, 12±1/20±2, 60%). Superior temporal sulcus (III, 11±1/13±2, 85%; V-VI, 9±1/11±1, 82%). These data illustrate: 1) The potential to define distinct subsets of corticocortically projecting neurons based on differences in their molecular constituents. 2) The degree to which specific corticocortical projections of an area vary in their proportional representation of neuronal subsets so defined.

34.5

CORTICOTHALAMIC CONNECTIONS OF THE SUPERIOR TEMPORAL SULCUS IN RHESUS MONKEYS. E.H. Yeterian and D.N. Pandya. Dept. of Psychology, Colby College, Waterville, ME 04901, ENRM Veterans Hospital, Bedford, MA 01730, and Boston Univ. Sch. of Medicine.

The cortex of the superior temporal sulcus (STS) contains both unimodal and multimodal association areas. These areas have distinctive patterns of thalamic afferents (Yeterian and Pandya, 1989). In the present study, the corticothalamic connections of the STS were examined in 20 monkeys using the autoradiographic technique. The results show that the rostral portion of the upper bank projects to the medial and caudal region of the medial pulvinar nucleus (PM), to the medial part of the medial dorsal nucleus (MD), and to the suprageniculate nucleus. The mid-portion of the upper bank projects to central and ventral PM and to the oral pulvinar nucleus (PO), to central MD, and to the magnocellular division of the medial geniculate nucleus (GM). The caudal portion of the upper bank projects to ventral and lateral PM and to PO, to central and lateral MD, and to the parvocellular portion of GM. Regions of the upper bank also have projections to intralaminar nuclei: paracentral, central lateral, central lateral superior, and limitans. In contrast to the upper bank, the lower bank projects to the inferior and lateral pulvinar nuclei, as well as to PM.

Thus the upper bank of STS, which contains multimodal area TPO, has widespread projections throughout the rostral-caudal extent of the thalamus, whereas the lower bank, which contains unimodal visual areas, projects mainly to the pulvinar. Supported by ENRM Veterans Hospital, Bedford, MA, NIH Grant 16481, and Colby College Social Science Grants 01 2202 and 01 2216.

34.6

THALAMOCORTICAL CONNECTIONS OF CORTICAL AREAS PROJECTING TO MULTIMODAL AREAS OF SUPERIOR TEMPORAL SULCUS IN THE MONKEY. C.L. Barnes and D.N. Pandya, Bedford Veterans Hospital, Bedford, MA 01730 and Depts. of Anatomy and Neurology, Boston Univ. Sch. of Med., Boston, MA 02118.

Anatomical (Jones and Powell, 1970; Seltzer and Pandya, 1978) and physiological (Desimone et al., 1984; Bayliss et al., 1987) studies have identified a multimodal region along the upper bank of the superior temporal sulcus (STS). This area has been designated as area TPO. This multimodal area TPO is preferentially related to distal parasensory association areas: area Opt in the inferior parietal lobule, area Ts1 and Ts2 in the superior temporal gyrus, and area TF in the parahippocampal gyrus (Barnes and Pandya, 1986). These areas are themselves in part multimodal in nature. Area TPO has been shown to receive its main thalamic projections from the central part of the medial pulvinar (PM) (Yeterian and Pandya, 1989). The aim of the present study was to see if these distant parasensory association areas have similar thalamic afferents as area TPO. Three Fluorescent Retrograde Tracers (FRT) were injected in parasensory association areas Opt, Ts1-Ts2 and TF in a single hemisphere of three monkeys. The results show that area Opt receives projections from lateral PM, areas Ts1-Ts2 from ventral and medial PM and area TF from dorsal PM. The location of the retrogradely labeled cells surrounds the central sector of PM that projects to area TPO. Thus it seems that medial pulvinar projects to area TPO and to related parasensory association areas. The thalamic projections, however, are differentially organized, with area TPO being related to the central region of PM whereas the parasensory association areas Opt, Ts1-Ts2, and TF are related to peripheral regions of PM. (Supported in part by Veterans Administration, ENRM VA Hospital, Bedford, MA, NIH Grant #16841 and Scottish Rite Schizophrenia Program, NMJ, USA.).

34.7

PROJECTIONS TO THE BASIS PONTIS FROM SUPERIOR TEMPORAL SULCUS (STS) IN THE RHESUS MONKEY. J.D. Schmahmann and D.N. Pandya. Departments of Neurology and Anatomy, Boston University School of Medicine, Boston, MA 02118, and ENRM Veterans Hospital, Bedford, MA 01730.

The projections to the pons from the parietal lobe are derived not only from sensory and parasensory association areas (Nyby and Jansen '51, Brodal '78, May and Anderson '86), but also from the multimodal caudal parietal cortex (Schmahmann and Pandya '89). In the present study the aim was to determine whether there are pontine projections from area TPO in the upper bank of the superior temporal sulcus (STS) which has been shown to be multimodal (Jones and Powell '70; Seltzer and Pandya '78; Desimone et al '84; Bayliss et al '87). The pontine projections were studied after the injection of tritiated amino acids in rostral to caudal regions in the upper bank of the STS in six rhesus monkeys, and in the lower bank in another five animals. Pontine projections were observed from the cases with injections in the upper bank, but not from those with lower bank injections. The projections from the upper bank are observed predominantly in the lateral, extreme dorsolateral, dorsolateral and peripeduncular nuclei.

The presence of projections to the pons from the multimodal area TPO in the upper bank of the STS contrasted with the absence of projections from the unimodal lower bank would seem to indicate that the cerebellum has access to higher order information via the corticopontocerebellar pathway. This would support our hypothesis that apart from its role in motor control, the cerebellum may be involved in the modulation of cognitive function. (Supported in part by the Veterans Administration, ENRM VA Hospital, Bedford MA, and NIH grant #16841).

34.8

PHYLOGENETIC CHANGES IN DENSITY OF GABA-A RECEPTORS IN SENSORY AND ASSOCIATION NUCLEI OF THALAMUS. R. B. Masterton, B. N. Baker* and K. K. Glendenning. Dept. Psychology, Florida State Univ., Tallahassee, FL 32306.

Conventional procedures for the quantitative labeling of high-affinity GABA-A receptors with tritiated muscimol in 3 sensory nuclei (DGL, GM, VB) and two association nuclei (LP, MD) in the dorsal thalamus were compared among 8 species of vertebrates. The species themselves were specifically selected on the basis of the time since their last common ancestor with Anthropoids -- allowing inferences regarding the sequence of changes that probably took place over the reptilian - pre-Eutherian - Eutherian - prosimian Primate segment of the Anthropoid lineage.

The results show that the average density of GABA-A receptors in the dorsal thalamus probably increased with the origin of mammals and after remaining nearly constant through the appearance and early radiations of marsupial and placental mammals, increased once again with the origin of Primates. Both the sensory nuclei and association nuclei considered collectively show this same 2-step increase. Among the individual nuclei, however, the medial geniculate nucleus shows a different pattern. MG appears to have had a single-step increase (at the origin of mammals) and remained nearly constant at least through the origin of true Primates.

34.9

CONTRALATERAL CORTICAL PROJECTIONS OF THE SUPERIOR TEMPORAL SULCUS IN THE RHESUS MONKEY. Benjamin Seltzer and Timothy Murphy*. Dept. of Psychiatr. & Neurol., Tulane Univ. Schl. of Med., V.A. Med. Ctr., New Orleans, LA 70112.

The superior temporal sulcus (STS) of the rhesus monkey contains unimodal and multimodal zones (Seltzer and Pandya, '78). Their contralateral cortical projections have not previously been explored.

Five monkeys received discrete injections of radio-labelled amino acids in each of four rostral-to-caudal divisions of multimodal area TPO in the upper bank of the STS, and in area IPa, in the depth. Following processing for autoradiography, each sulcal area was found to project to a restricted portion of the homotopical zone in the opposite STS. Each area also projects to immediately rostral and caudal zones within the contralateral STS as well as to certain post-Rolandic areas (insula, cingulate gyrus, parahippocampal gyrus, caudal superior temporal gyrus, and posterior parietal lobe). Thus the contralateral connections of areas TPO and IPa resemble their ipsilateral projections to the STS and post-Rolandic cortex (Seltzer and Pandya, '84;'87). Most contralateral projections terminate in and around layer IV, but those to caudal heterotopical areas in the STS terminate over layer I. Rostral regions of the STS send contralateral fibers by way of the anterior commissure; more caudal regions through the body of the corpus callosum.

THE DEVELOPMENT OF CORTICAL FOLDING IN RHESUS AND HUMAN BRAINS. E. Armstrong, M. Curtis*. Yakovlev Collection, A.F.I.P., Washington DC. 20306 and Dept. Anatomy, U.S.U.H.S., Bethesda, MD.

Differences in the degree of cortical folding between adult human and rhesus brains are a function of brain weight. The rhesus attains adult levels of gyrification before its brain weighs 50 g. At this weight the human brain is lissencephalic. To analyze the roles of maturation and brain weight, the gyrification indices (GI) of fetal and perinatal rhesus and human brains were compared. The GI's are the ratios of the total to the superficially exposed cortical contours and were measured in brains from the Yakovlev Collection.

The GI's are low until the 17th gestational week in rhesus monkeys and the 20th in humans. Following this both species exponentially increase their GI's. The exponential increase in cortical buckling has a longer duration in human than in rhesus brains. When the GI values were plotted from the frontal to occipital poles, the middle and caudal portions of the adult human brain resembled those portions of fetal monkeys. This pattern is expected if delayed maturation (neoteny) produced the enlarged human brain. On the other hand, the human brain has a high prefrontal GI which is never observed in the rhesus cortex. This suggests that the developmental strategy here follows separate maturational events.

CORTICAL AFFERENTS TO CAUDAL AREA 24C (THE CINGULATE MOTOR AREA) AND ROSTRAL AREA 23C. R.J. Morecraft*, G.W. Van Hoesen and J.A. Maynard* (SPON: W.W. Kaelber). Depts. of Anatomy and Neurology, Univ. of Iowa, Iowa City, IA 52242

Epicortical and intracortical stimulation studies have shown that motor responses can be elicited from the anterior cingulate area. Cytoarchitectural studies have suggested that the anterior cingulate cortex is the evolutionary precursor of M2 and may be a primordial motor area. These efforts have prompted recent neuroanatomical investigations to focus on the cingulate gyrus for additional motor representations. For example, connectional studies in the monkey have demonstrated that select portions of areas 24c and 23c project topographically to M1, M2 and the spinal cord. Thus, a study was initiated to examine the cortical input to areas 24c and 23c. Four rhesus monkeys were injected with the retrograde tracer diamidino yellow, fast blue or both into areas 24c and 23c and their cortical afferents were identified. Several cortical areas were found to project to both 24c and 23c. Both areas received afferents from: frontal areas 10, 11, 12, 14, 46, 9, 8B, 6DR, 6DC, M2 and M1; parietal areas 7 (PG), PGm, PGop and S2; limbic areas 29, 30, 31 and 35; and occipital areas OA. Powerful intracingulate and insular afferents were observed. Areas 13, 25, 6VB, 38 and 28 projected only to area 24c, while areas 1, 2, 5 (PE), and POa projected to area 23c. These afferents originated from layers III and V, and were most extensive on the medial and dorsal lateral convexity of the hemisphere. Labeling within frontal and parietal cytoarchitectural subdivisions was widespread, while labeling within the temporal and limbic subdivisions was well represented but more focal in its overall distribution. If additional motor representations are present in the cingulate cortex, the diversity of cortical input is impressive and appears to exceed that of M1 and M2. Our connectional data suggest that the anterior cingulate is the pivotal link between limbic and motor cortices, and may play an important role in complex motor functions subserved by the cerebral cortex such as emotional expression, attentional direction and motor memory. (Support: NS 14944 and PO 19632.)

CORTICAL INPUTS TO VISUAL (area 7a) AND TACTUAL (areas 7b & 5) SUBDIVISIONS OF POSTERIOR PARIETAL CORTEX IN RHESUS MONKEYS. J. Chmielowska, T.P. Pons and R.C. Saunders Lab Neuropsych. NIMH Bethesda, MD 20892.

Posterior parietal cortex (PPC) has traditionally been thought of as "association" cortex, where information from different sensory modalities is integrated. To determine the anatomical basis for such integration we injected fluorescent tracers, fast blue (FB), diamidino yellow (DY), and latex microspheres (LM) into electrophysiologically defined portions of visually and tactually responsive regions of PPC. A total of 16 injections were made into 8 hemispheres of 4 animals with a callosal commisurotomy. Cells projecting to 7a were found in the frontal eye field, in the depths of the superior temporal sulcus, and at the border region between visual areas PO and 18. Labeled cells were also observed in area 23 of cingulate cortex and areas TF\TH of the parahippocampal gyrus. Tactile sensory areas projecting to 7b included areas 1 & 2, SII, area 5, and the insula. Other cortical inputs to 7b included primary (area 4) and non-primary (areas 6 and 9) motor regions. In one case with an injection site located between areas 7a & 7b we observed connections characteristic of both areas. Finally, following injections of tracers into a tactually responsive region of area 5, labeled cells were seen in areas 1 & 2, 7b, and cingulate area 23. Our findings support recent electrophysiological studies which suggest that much of the PPC is modality specific.

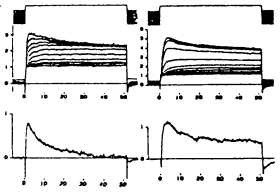
34.13

SOME THALAMOCORTICAL CONNECTIONS OF AREAS 5, 7a AND 7b OF POSTERIOR PARIETAL CORTEX IN RHESUS MONKEYS. J. Duda, T.P. Pons, and R.C. Saunders. Lab Neuropsych. NIMH, Bethesda, MD 20892.

We compared the pattern of thalamic connections between visually and tactually responsive regions of the posterior parietal cortex (PPC) by injecting fluorescent tracers and tritiated amino acids into 5 monkeys (see prior abstract). Our results indicate that the major thalamic input to a tactually responsive region of area 5 is from the lateral posterior nucleus (LP). By contrast, another somatically responsive region of the PPC, area 7b, receives its primary input from the anterior pulvinar (Pa) and the rostral portion of the medial pulvinar (Pm) with a less dense input from the ventroposterior inferior nucleus (VPI). Major thalamic inputs to visual area 7a include Pm and caudal Pa, with less dense input from the suprageniculate and limitans nuclei. We did not observe label in LP following injections of 7a. These results indicate that at least two separate regions of PPC that are responsive to tactile stimulation receive inputs from different thalamic nuclei. Finally, since the border between Pa and Pm is not well defined cytoarchitectonically, our findings suggest that the rostral portion of Pm as clasically defined might better be redefined as the caudal portion of Pa. In this view, area 7b would receive its major thalamic input from Pa and none from Pm, while 7a would receive its major input from Pm, the suprageniculate and limitans nuclei, and none from Pa.

34.14

PATTERN OF CORTICAL LABELING FOLLOWING TRACER INJECTIONS INTO THE PULVINAR COMPLEX OF RHESUS MONKEYS. T.R.S. Johnston, T.P. Pons and R.C. Saunders. (SPON: R. Michaelis) Laboratory Neuropsychology, NIMH, Bethesda, MD 20892.



The pulvinar complex (PC) in rhesus monkeys can be divided into 4 classically recognized nuclei, the inferior (Pi), lateral (Pl), medial (Pm) and anterior or oral (Pa). While there has been a modest effort to study connections of visually responsive portions of the PC (Pi & Pl), there has been virtually no effort to study connections of more rostral portions (Pa & Pm). We have begun such a study by placing injections of different fluorescent tracers (see prior abstract) or tritiated amino acids into Pa and Pm of monkeys. Following injections of tracers into Pa dense cortical label was observed in several somatosensory related areas including SII, the insula, areas 2, 5, and 7b. Other densely labeled regions included the depths of the superior temporal sulcus (STS), rostral pole of the temporal lobe, the frontal eye field, cingulate cortex and TF\TH of the parahippocampal gyrus. Injections of tracers into Pm resulted in heavy labeling of visual areas 7a, the frontal eye field, and area 18. Dense label was also seen in areas TF\TH of the parahippocampal gyrus, cingulate cortex and the fundus and upper bank of the STS. These findings suggest that different nuclei of the PC have a distinct pattern of connections with modality specific cortical regions, as well as overlapping connections with multimodal cortical areas.

POTASSIUM CHANNELS I

35.1

POTASSIUM CURRENTS CHANGE IN CULTURE AND WITH DEVELOPMENT IN CHICK DORSAL ROOT GANGLION (DRG) NEURONS. C.D.Westbrook* and J.L.Kenyon* (SPON: C.ORT) Dept. of Physiol., Univ. of Nevada School of Med. Reno, NV 89577

We used the whole cell voltage-clamp to study K currents in DRG neurons isolated from 10, 14, and 18 day embryonic chickens. Pipettes contained K aspartate, ATP, creatine phosphate, and EGTA. The bath solution contained NaCl, TEA, and TTX but no added Ca. K currents during depolarizations from the resting potential showed little inactivation over 50 to 100 ms but did inactivate over 2 s. The top left panel of the figure shows currents (nA) from a 10 day neuron elicited after 2 s steps in the range -100 to 0mV. As conditioning voltage was made less negative the early current during the test pulse was reduced before the late current. The bottom left panel shows the difference between currents elicited from -80 and -100 mV. In cells from older embryos (right panels, 18 day) and in cultured 10 day cells, both the early and late currents were inactivated at the most negative conditioning voltages. These data suggest that the kinds of channels or the gating of K channels change with time in DRG neurons.

35.2

NON-INACTIVATING K^+ CHANNELS ON GROWTH CONES, NEURITES, AND SOMATA OF LEECH RETZIUS CELLS IN CULTURE. S.R. Young, R.R. Stewart, Y. Liu , K.J. Muller and W.N. Ross. Dept. of Physiol., New York Med. Col., Valhalla, NY 10595; Dept. of Pharmac., Biocenter, Univ. of Basel, Basel, Switzerland CH-4056; Dept. of Physiol. & Biophys., Univ. Miami, Miami, FL 33101.

In order to examine the role of membrane ion channels in development and synapse formation, we have begun to apply standard techniques to record single channel activity in isolated leech neurons in culture (Hamill et al., Pfluegers Arch. 391:85, 1981; Bookman and Dagan, J. Physiol. 390:76P, 1987; Dietzel et al., J. Physiol. 372:191, 1986). At least four channel types were seen under steady-state voltage conditions with 125 to 140 mM KCl in the pipette. Two small channels of 10-15 and 20-30 pS were present in nearly all cell-attached patches. An intermediate channel with an inward conductance of about 30 pS and an outward conductance of 60 pS was also common in cell-attached patches. A larger channel of about 60 pS inward and 100 pS outward conductance was less common until the patches were excised, when it became dominant. The large channel was not permeable to Cl^- in inside-out patches. It was selective for K^+ over Na^+, and was only partially blocked by 50 mM internal TEA. Neither voltage changes nor 5 μM Ca^{++} internal markedly activated the large channel. All four channel types were seen on actively extending growth cones; none appear to be excluded from any other part of the cell.

Supported in part by the NIH and the Whitaker Foundation.

35.3

K-CHANNELS IN DISSOCIATED MUSCLE CELLS OF S. MANSONI (PLATYHELMINTHES). K. Blair, M. Lewis*, J. Bennett*, T. Day*, and R. Pax. Michigan State University, E. Lansing, MI 48824.

Muscle cells were isolated from adult S. mansoni by enzymatic and mechanical disruption of whole worms. Spindle-shaped muscle cells exclude trypan blue and contract when touched or exposed to high $[K^+]$. Cell-free (inside out) patches of sarcolemma contain multiple, non-inactivating K^+ conductances. Slope conductances of 20, 100, and 270 pS were observed in symmetrical KCl (130 mM)(0.4 mM Ca^{2+}). The 100 pS conductance is selective for K^+ over Na^+, as indicated by a shift in E_{rev} from 0 mV to -50 mV when bath (cytosolic side) K^+ was exchanged for Na^+. The probable open time (p_o) is sensitive to voltage (p_o=0.05 at -60 mV pipette potential, p_o= 0.98 for $\geq$0 mV). TEA (4 mM) in the bath reduced conductance at negative, but not positive, pipette potentials. Ba^{2+} (5 mM), and apamin applied to the cytosolic side reduced p_o. EGTA (EGTA:Ca^{2+}, 11:1) added to the cytosolic side decreased p_o from 0.95 to 0.05. The role of K^+ and other ion conductances in the primitive in muscle of S. mansoni is under study.

35.4

A LARGE-CONDUCTANCE ION CHANNEL IN THE TEGUMENT OF S. MANSONI (PLATYHELMINTHES). T. Day*, K. Blair, J. Bennett*, M. Lewis*, and R. Pax. Michigan State University, East Lansing, MI 48824.

The tegument of the parasite S. mansoni is a unique syncytial epithelium essential for nutrient transport, ion regulation and evasion of the host's immune system. Cell-free (inside-out) patches have been used to examine ionic conductances in the outer membrane of this tegument. A large-conductance ion channel (>230pS) was observed with 130mM KCl in the pipet and culture medium (125mM NaCl, 5mM KCl, 0.4mM Ca^{++}) in the bath. Channel activity was observed only when pipet potentials were more negative than -10mV. At those potentials, channel activity could be initiated or increased by +70mV pulses. An extrapolation of the I vs. V relationship predicted an E_{rev} of 0mV. E_{rev} and slope-conductance did not change when the culture medium in the bath was replaced with 130mM NaCl, 130mM N-methyl-glucamine chloride, or 130mM Na-gluconate.

35.5

SINGLE-CHANNEL RECORDING OF A POTASSIUM CURRENT ACTIVATED BY INTRACELLULAR SODIUM IN SENSORY NEURONS

C. Haimann*, and C.R. Bader, Département de Physiologie, Centre Médical Universitaire, 1211 Geneva 4 Switzerland.

Whole-cell recording in avian ganglionic neurons suggested the existence of a potassium current activated by intracellular sodium (Bader et al. Nature, 317:540-542). Here we describe the single-channel activity induced by sodium applied to the intracellular face of inside-out patches excised from quail trigeminal neurons. In the presence of sodium, channels of high conductance were seen (170 pS, with K_{in}=50 mM and K_{out}=150 mM), which showed no rectification between -75 and +50 mV. With physiological concentrations of potassium the conductance was 50 pS. Ion substitution experiments indicated that potassium ions were the major charge carriers of this current. Channel activity could be evoked in the presence of 12 mM sodium. Openings occurred in bursts and the burst frequency increased with Na concentration. Calcium, lithium and choline did not induce K_{Na} single-channel activity.

In neurons, whole-cell recording suggested that K_{Na} could be activated by a single action potential. Since this current can be activated already at low sodium concentrations, it is possible that K_{Na} could also contribute to the resting potential of neurons.

35.6

Voltage-Dependence of Fast and Slowly Inactivating A-Channels on Mammalian Sensory Neurons in Tissue Culture. *Sarah McFarlane*and Ellis Cooper. Dept. of Physiol. McGill Univ. Montreal, P.Q. H3G 1Y6*

We have recently found that A-channels on cultured neonatal rat nodose neurons inactivate in 3 different modes: a rapid mode where the channel opens once and then closes to an inactivated state, an intermediate mode where the channel opens and closes 3-4 times before inactivating, and a slow mode where the channel opens and closes several hundred times. Single channels gating in these 3 modes give rise to ensemble averages with time constants of 10-30 msec, 100-300 msec and 1-3 sec respectively. We find that the proportion of A-channels inactivating in any one mode varies from neuron to neuron, with the majority expressing channels of more than one type. While the single channel conductance for channels inactivating in the 3 modes is the same, the channels differ in their voltage-dependence. The I-V relationships for activation and the h_∞ curves for inactivation of the different A current components were fit by a Boltzmann distribution. Activation curves for the rapidly inactivating component had a $V_{1/2}$=-25mV and k=12, and $V_{1/2}$=-73mV and k=-6 for steady-state inactivation. The voltage-dependence of the slower inactivating components, however, was shifted approximately 25mV more positive and had values of $V_{1/2}$=-1mV and k=14 for activation, and $V_{1/2}$=-44mV and k=-14 for inactivation. Our results are consistent with the idea that nodose neurons express different subtypes of the same basic A channel. (Funded by MRC & FRSQ)

35.7

A STUDY OF ANOMALOUS (INWARD) RECTIFICATION IN FROG MYELINATED AXON. A.L. Padjen and M.O.Poulter. Dept. of Pharmacology and Therapeutics McGill University. Montreal, Canada, H3G 1Y6.

Anomalous or inward rectification (AR) was studied in intact large frog myelinated axons by single microelectrode current clamp. In response to a negative current step, which hyperpolarized the membrane 15-40 mV below resting membrane potential, all fibres showed a characteristic attenuation of the voltage response or a "sag" after an initial peak voltage deflection (400 to 600 ms after the start of the pulse; cf. Padjen & Hashiguchi, 1983, Can J Physiol Pharm 61, 626). In addition, an afterdepolarizing potential (ADP; 1-5 mV in amplitude; 2-10 s in duration) was evident following a current pulse in which inward rectification had been activated. The "sag" and ADP was abolished by external application of cesium ions (3 mM) but not by barium ions (2 - 10 mM). Reducing the potassium concentration in the perfusate increased the slope resistance calculated from the peak voltage response and at steady state; replacing sodium ions with choline in the perfusate increased the steady state resistance and decreased or abolished the ADP, suggesting that the AR is a mixed potassium and sodium conductance.

The experimental results were incorporated in a computational model of myelinated axon membrane based on Hodgkin-Huxley expressions. The model required that the AR activates near -100 mV, with both a short and a long time constant (4-7 and 450-600 ms, respectively) and a reversal potential near -55 mV.

Supported by the MRC of Canada.

35.8

THE SLOW-ACTIVATING SLOW-INACTIVATING POTASSIUM CURRENT IN MELANOTROPHS OF THE RAT PITUITARY. S.J. Kehl, Department of Physiology, University of British Columbia, Vancouver, Canada, V6T 1W5

Whole cell recordings were made from cells in which I_{Na} and I_{Ca} were blocked with TTX (1 micromolar) and Cd (300 micromolar). Under these conditions the outward current consisted of two components: a fast-activating fast-inactivating I_K ($I_K(f)$) (Kehl, S.J., J. Physiol., 411: 457, 1989) and a slow-activating slow-inactivating I_K ($I_K(s)$). The activation threshold for $I_K(s)$ was normally between -10 to 0 mV and it showed voltage-dependent sigmoidal activation kinetics in cells where its onset was not obscured by $I_K(f)$. The current-voltage relationship for $I_K(s)$ was monotonic with a maximal slope conductance of 26±6 nS (n=8). The reversal potential estimated from tail currents was near -75 mV in cells where the calculated value for E_K was near -90 mV; in symmetrical K concentrations the reversal potential was near 0 mV. $I_K(s)$ showed little or no inactivation during depolarizing commands lasting for up to 200 ms and it was reversibly blocked by quinidine sulphate (50 micromolar), TEA (20 mM) and Ba (10 mM).

Supported by a grant from the BCHCRF.

35.9

TWO A-CURRENTS IN HYPOTHALAMIC HISTAMINE NEURONS Peter B. Reiner, Robert W. Greene and Helmut L. Haas*. Kinsmen Laboratory of Neurological Research, Univ. of British Columbia, Vancouver, BC, Canada; Dept. Psychiatry, Harvard Medical School & VA Medical Center, Brockton, MA; Dept. Physiol., Univ. of Mainz, FRG.

Histamine neurons of the rat tuberomammillary nucleus exhibit remarkably long-lasting transient outward rectification. The present study was undertaken to characterize this phenomenon using the single-electrode voltage clamp technique applied to an *in vitro* slice preparation of the rat hypothalamus. The transient outward current was inactive at the resting potential, and removal of inactivation was both time- and voltage-dependent. The decay of the current was best fitted by two exponentials with time constants of 107±41 and 559±134 ms. 1 mM 4-AP blocked only the rapidly decaying component. 10 mM TEA reduced the slow component slightly, and blocked the non-inactivating outward current(s) seen with depolarizing steps from -50 mV. Removal of calcium from the medium reduced the amplitude of the slow component slightly, and addition of nimodipine further depressed the slow current. The reversal potential of the fast component was -110 mV in 2.5 mM external K^+, while the slow component reversed at -92 mV. Activation of the slow component occurred some 5-10 mV positive to that of the fast component, while removal of inactivation of the slowly decaying current was shifted 5-10 mV negative. It is concluded that histamine neurons possess two transient outward currents which can be distinguished on the basis of their inactivation kinetics, 4-AP sensitivity, calcium dependence, reversal potentials, and voltage-dependence of inactivation.

35.10

MULTIPLE COMPONENTS OF VOLTAGE-DEPENDENT POTASSIUM CURRENT IN RAT ANTERIOR PITUITARY CELLS. J. Herrington* and C. Lingle. Dept. of Anesthesiology, Wash. Univ. Sch. of Med., St. Louis, MO 63110.

Voltage-dependent potassium (K^+) current was studied using whole-cell clamp techniques on enriched populations of lactotrophs isolated from lactating rats. Pipette and bath salines were chosen to exclude inward currents and Ca^{+2}-dependent K^+ and Cl^- currents.

Total Ca^{+2}-independent K^+ current could be clearly separated into three components based on pharmacological sensitivities and the differential effects of conditioning pulse level and duration on potassium tail currents. The 3 currents are: 1) a lower threshold, rapidly inactivating current completely blocked by 5 mM 4-aminopyridine (4-AP) but insensitive to TEA (30 mM); 2) a slowly inactivating current sensitive to TEA and 4-AP; and 3) a sustained current sensitive to TEA but not to 4-AP. The rapidly inactivating current activates above about -40 mV, is half-inactivated at -97.9 mV (+ /- 8.6; n= 5), and inactivates with τ = 20-30 msec at -30 mV. Deactivation is fast with τ = 1-2 msec at -50 mV. Holding at -40 mV completely inactivates the current and removes the fast component of tail current. Another inactivating current is activated above about -20 mV and inactivates over hundreds of msec at + 60 mV. Deactivation of this current is also distinct from the lower threshold current with τ = 6-8 msec at -50 mV. The 3rd component of current is also activated above about -20 mV and inactivates over seconds. Deactivation is also very slow with τ = 30-40 msec at -50 mV.

All three currents were also found in prolactin-secreting cells identified by the reverse hemolytic plaque assay. The differential expression of these currents among lactotrophs may contribute to the variation in responses evoked by secretagogue application to single cells. Supported by NIH-DK-37109.

ANOMOLOUS COUPLING BETWEEN I_A AND I_J IN LOBSTER STOMATOGASTRIC NEURONS. B.R. Jones and D.K. Hartline. Békésy Laboratory of Neurobiology, University of Hawaii, Honolulu, HI 96822.

Many stomatogastric somata exhibit two outward currents (Graubard, K. and Hartline, D.K., Soc. Neurosci. Abstr. 10:1073, 1984): one is transient, voltage-activated, and 4AP-sensitive (I_A); the other is transient, Ca^{++}-dependent, and Cd^{++}- and TEA-sensitive (I_J). Last year (Hartline, D.K., et al., Soc. Neurosci. Abstr. 14:946, 1988) we reported that I_J tail currents show strong outward rectification, with a reversal potential dependence on $[K^+]_o$ that is only about half that expected for a pure K^+ current. We now report that:

1) I_A tail currents in these cells also show strong outward rectification, with a reversal potential dependence on $[K^+]_o$ that is less than 58 mV per decade.

2) I_A magnitude at a given voltage (measured by curve subtraction) is dependent on I_J. When I_J is reduced with Cd^{++} or TEA the apparent magnitude of I_A increases. The increase in I_A is directly proportional to the reduction in I_J magnitude. The constant of proportionality varies from cell to cell (range = 0.2 to 0.7).

3) Magnitudes of both I_A and I_J are reduced by replacing 90% of the external NaCl with mannose.

These properties seem consistent with a model which includes a shared, local, rectifying series resistance for A and J channels, and a shared external space having a higher $[K^+]$ than the bathing medium.

35.12

CELL-SPECIFIC TEMPERATURE ACCLIMATION OF I_A CURRENTS IN IDENTIFIED NEURONS IN APLYSIA CALIFORNICA. A.J. Grant and S.N. Treistman. The Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

I_A is important in regulating action potential production, and exhibits temperature-sensitive kinetics and amplitude. We examined the effects of whole animal temperature acclimation on the subsequent temperature sensitivity of I_A in identified Aplysia californica neurons. Sibling cohorts of Aplysia were reared following metamorphosis at two different temperatures (10 and 20 °C). When animals were approximately two months old, I_A was measured from two sets of identified cells; B_1 or B_2 in the buccal ganglion and L_2, L_3, L_4, or L_6 (left upper quadrant cells) in the abdominal ganglion. In buccal cells, I_A amplitude at any given temperature was significantly greater in animals reared at the colder temperatures, compared with those raised in warmer conditions, conforming with classical acclimation. Cell size was also larger in the cold-reared animals, and when current was normalized to cell size, the resulting computed current density was the same in the two groups of buccal cells. Kinetics of I_A were not affected by rearing temperature in the buccal cells. In the LUQC, neither I_A amplitude nor cell size was dependent on rearing temperature. Thus, acclimation of I_A is cell-specific and occurs by changes in cell size rather than alteration of individual channel properties.

35.13

CHARACTERIZATION OF POTASSIUM CHANNELS OF *HERMISSENDA* PHOTORECEPTORS. R. Etcheberrigaray*, P.L. Huddie and D.L. Alkon. LMCN-NINDS, NIH, Bldg 9, Rm 1w125, Bethesda, MD 20892.

Reduction of potassium conductances of the type B photoreceptors of the nudibranch mollusc *Hermissenda crassicornis* contributes to the expression of the behavioral modification induced by associative conditioning. The K^+ currents of the soma membrane that are modified by conditioning include a Ba^{2+}-sensitive Ca^{2+}-dependent K^+ current (I_c), and a fast transient K^+ current (I_A). We have recorded several classes of steady state single K^+ channels in membrane patches from protease treated *Hermissenda* photoreceptors *in vitro*. One or more types of channel was usually seen in each patch; a ubiquitous small channel (γ < 10 pS), a medium conductance Ba^{2+}-sensitive channel (γ = 44 ± 2.9 pS; n = 6), and a large conductance channel (γ = 79 ± 5.8 pS; n = 11); a very large conductance channel was seen infrequently ($\gamma \approx$ 300 pS; n = 3). The 79 pS channel had mean open time 6.6 ± 33 ms, mean closed time = 56 ± 241 ms (means ± std. deviations); 2 open and 2 closed states were apparent from the open and closed time histograms. When $[Ca^{2+}]_i$ = 10 mM the Ba^{2+}-sensitive channel had an open probability (p_o) of 0.35; mean open time of outward currents was 8.6 ± 35 ms, and mean closed time was 15.5 ± 64.5 ms . Probability density functions derived from > 3300 events, reveal 2 open and 2 closed states; for the open state τ_1 = 1.8 ms, and τ_2 = 16.5 ms; for the closed state τ_1 = 6.5 ms, and τ_2 = 835 ms. With 4mM Ba^{2+} the mean open time was 4.9 ± 21 ms, and mean closed time was 27 ± 125 ms: Ba^{2+} appears to block the open state since τ_1 = 0.1 ms and τ_2 = 5.6 ms; for the closed state τ_1 = 8.9 ms, and τ_2 = 1335 ms. Ba^{2+} reduced p_o to 15% and reduced event frequency from 16 s^{-1} to 12 s^{-1}; this implies Ba^{2+} also inhibits the closed state of I_c. These single channel properties can now be assessed as a function of conditioning.

35.14

FAST, TRANSIENT K^+ CURRENT IN NEUROHYPOPHYSIAL NERVE TERMINALS. J.R. Lemos and P.J. Thorn*. Worcester Found. Expt. Biol., Shrewsbury, MA 01545.

Nerve terminals of the rat posterior pituitary were acutely dissociated and studied under whole-cell patch clamp. In physiological solutions depolarizing steps from a holding potential (H.P.) of -80 mV elicited a fast inward followed by a fast, transient outward current. The outward current reached a peak and then decayed to a steady but non-zero level. The decay was best fit by two exponentials with time constants 21.1 ±2.85 and 143.02 ±36 ms. At the above H.P. the threshold of activation of the outward current was -60 mV. The time to peak of this current decreased and the amplitude increased with increasing depolarized potential steps. The transient outward current showed steady-state inactivation at more depolarized H.P. (1/2 maximal at -50 mV). The time course of recovery from inactivation was complex, full recovery taking more than 16 s. The outward current was blocked by the substitution of K^+ with Cs^+ and its reversal potential was consistent with a potassium current. 4-AP (1-6 mM) blocked the transient K^+ current but charybdotoxin (4 μg/ml) had no effect. Low $[Ca^{++}]_o$ had no effect on the outward current, nor did the calcium channel blocker Cd^{++}. The neurohypophysial terminal transient outward K^+ current thus appears to be I_A and is different from the outward currents found in the corresponding cell bodies. (Supported by grant NS22542)

CALCIUM SENSITIVITY OF TWO LARGE CONDUCTANCE POTASSIUM CHANNELS IN CEREBELLAR PURKINJE NEURONS. D.L. Gruol and T. Jacquin*, Res. Inst. Scripps Clinic, La Jolla, CA 92037.

Cerebellar Purkinje neurons (PNs) in culture express two large conductance voltage-sensitive K+ channel types (Gruol et al, Soc. Neurosci. Abst. 14, 1988). Mean single channel conductances are 90 and 70 pS under physiological conditions and 220 and 134 under symmetrical K+ conditions. Both channel types are activated by depolarizations from a holding potential of -60 mV. The 70 pS channel type is active at depolarizations of 20 to 80 mV; the 90 pS channel is active at stronger depolarizations. Both channel types show similar sensitivity to K+ channel blockers. In the present series of experiments, the activity of these channel types was compared in cell-attached (CA; n=69), outside-out (O/O; n=59) and inside-out (I/O; n=25) patches. The 90 pS channel type was observed in 67% of the CA, 44 % of the O/O and 84% of the I/O patches. In contrast, the 70 pS channel type was observed in 58% of the O/O patches but only 19% of the CA and 19% of the I/O patches. In O/O patches, the frequency of detecting each channel type varied with the internal level of free Ca++. The 70 pS channel type was observed in 38% of the patches with 50 nM internal Ca++ (n=21) compared to 87% of the patches with 500 nM internal Ca++ (n=15). The 90 pS channel type was observed in 67% of the patches with 50 nM internal Ca++ compared to 27% of the patches with 500 nM internal Ca++. In I/O patches, the activity of the 90 pS channel dramatically increased as internal Ca++ was raised from 10 to 200 nM. These data indicate that the activity of both channel types is influenced by the level of intracellular Ca++. Supported by NS 21777 and the French Ministry.

PROPERTIES OF UNITARY POTASSIUM CHANNELS IN CULTURED ADULT HUMAN OLIGODENDROCYTES. J. G. McLarnon and S. U. Kim. Dept. of Pharmacology & Therapeutics and Div. of Neurology, Dept. of Medicine, The University of British Columbia, Vancouver, B.C. V6T 1W5, Canada.

In this study the properties of a potassium inward rectifier channel have been studied in cultured oligodendrocytes obtained at autopsy from adult human brain. With the cell-attached patch clamp configuration and a K^+ concentration of 140 mM in the pipette, inward K^+ currents were recorded with amplitudes increasing with patch hyperpolarization. Over the voltage range studied, the current-voltage relation was linear and the conductance of the channel was 21 pS. The mean channel open time showed an exponential dependence on potential with a hyperpolarization of 20 mV associated with an e-fold decrease in the mean open time. The probability of channel opening showed a sigmoid dependence on patch potential and was decreased with hyperpolarization. The voltage-dependent properties of the channel gating would be consistent with a role for the inward rectifier channel in the human oligodendrocytes as part of a regulatory mechanism in the maintenance of K^+ concentrations in the intercellular cleft. The channels, which passed inward but not outward current, were open for relatively long times at the normal cell resting potentials (mean open times of about 75 ms at the resting level) and the mean open times were increased with depolarization. In particular, the latter property could be important during periods of high neuronal activity to limit the accumulation of extracellular K^+.

35.17

EVIDENCE THAT A BARIUM-SENSITIVE POTASSIUM CURRENT CONTRIBUTES TO THE RESTING POTENTIAL AND SPIKE REPOLARIZATION IN RAT HIPPOCAMPAL NEURONS.

J.F. Storm and M. Helliesen*. Institute of Neurophysiology, Karl Johans gate 47, N-0162 Oslo 1, Norway.

Little is known about the ion channels generating the resting potential in vertebrate central neurons. Here we report evidence that a Ba-sensitive Ca-independent K current ($I_{K,rest}$) mediates at least 50-75 % of the resting conductance in CA1 neurones, and also contributes to the repolarization of the action potential. $I_{K,rest}$ seems to be distinct from seven K currents already postulated in the hippocampus (I_M, I_A, I_K, I_D, I_C, I_{AHP}, and the muscarine-sensitive "leak" K current), as well as the mixed Q-current.

CA1 pyramidal cells (n=14) in rat hippocampal slices were impaled with KCl-filled micro-electrodes, at 28-32°C. The input resistance (R_{inp}) was measured by injecting current pulses (200-400 ms duration), and action potentials were elicited by brief depolarizing pulses (2-10ms). Barium (0.2 - 1 mM) produced depolarization, increased R_{inp}, and spike-broadening, even when I_{Ca}, I_C, I_{AHP}, I_M, I_D, and/or I_Q had been eliminated prior to Ba, by adding 0.2-0.6 mM Cd, 100 µM carbachol, 40 µM 4-amino-pyridine and/or 3mM Cs to the bath. In the presence of Cd and carbachol, Ba induced spontaneous repetitive bursting. Current/voltage (I/V) plots indicated that $I_{K,rest}$ is active at least from -110 to -40 mV, and reverses near -95 mV in Cl-loaded cells. Thus, the activation range of $I_{K,rest}$ differs from those of I_M (> -60 mV), I_K (> -40 mV), I_A (> -60 mV), I_D (> -70 mV) and I_Q (< -80 mV); I_K, I_D and I_Q are also less sensitive to Ba (Halliwell & Adams 1982, Brain Res. 250, 71-92; Storm 1988, Nature 336, 379-381).

(Supported by the Norwegian Research Council and Nycomed. The effects of $I_{K,rest}$ were first noticed by JFS in P.R.Adams' laboratory, at SUNY, Stony Brook in April 1987. Thanks to P.Andersen, Oslo, for lab. space and support).

THE EFFECTS OF CESIUM ON THE SYNAPTIC AND INTRINSIC PROPERTIES OF NEOCORTICAL NEURONES MAINTAINED "IN VITRO".

G.G.C.Hwa & M.Avoli. MNI, McGill Univ., Montreal, Que., Canada.

We have observed that Cs^+ potentiates epileptiform discharges in rat neocortical slices (Avoli & Hwa, this meeting). Here, we recorded intracellularly from neurons in layers I-III to examine the mechanisms responsible for this increase in excitability. Bath application of Cs^+ (2-3mM) usually depolarized the cell by 5-15 mV, and disclosed spontaneous EPSP-IPSP. I-V plots indicated that Cs^+ increased the input resistance measured by injecting hyperpolarizing pulses. However, a sag which resembled the anomalous rectifier was still discernible (13/15 cells). This suggests that in these superficial cells, there is a component of rectification activated by membrane hyperpolarization that is insensitive to Cs^+. Other effects of Cs^+ include a prolongation of the action potential duration evoked by brief pulses of intracellular current, and a reduction of the IPSPs elicited by white matter stimulation. While the Cs^+ effects on the intrinsic and synaptic conductances may account for an increase in excitability, the significance of these changes in relation to epileptogenesis remains to be determined.

AXONAL CONDUCTION AND EXTRACELLULAR POTASSIUM ACTIVITY IN SPINAL CORD OF THE MYELIN-DEFICIENT MUTANT RAT.

W.Young, J.Rosenbluth, J.C.Wojak, K.Sakatani. Depts. Neurosurgery, Physiology & Rehab. Medicine, NYU Medical Center, New York, NY 10016.

The myelin-deficient (md) mutant rat has a gross deficincy of central myelin. We recorded somatosensory evoked potentials (SEPs), extracellular K^+ ion activity ($[K^+]_e$), and K^+ clearance rates in the spinal cords of 14 md rats and 16 normal siblings (ns). Under pentobarbital anesthesia (25 mg/kg i.p.) and hypothermia (32-34°C), both groups had delayed cortical SEP latencies: 67±20 msec in md rats vs. 48±15 msec in ns rats ($p<0.05$). Resting $[K^+]_e$ levels were 2.6±0.8 mM and 2.6±0.5 in the md and ns groups. K^+ clearance rates were similar in both groups. Sciatic nerve stimulation (2-20 Hz, 2-6 second trains) produced 1-3 mM transient $[K^+]_e$ rises in the md spinal cords and no or very small rises in the normal cords. The $[K^+]_e$ rises were largest in dorsal horn at 200-500 µm depth. In md rats, injections of 1 mM 4-aminopyridine (4-AP) solution into the spinal cord completely suppressed the $[K^+]_e$ responses and increased spinal and cortical SEP amplitudes for 2-3 hours. In ns rats, 4-AP injections blocked spinal conduction for 20-30 minutes but thereafter enhanced cortical SEP amplitudes for 2-3 hours. We conclude that sciatic nerve stimulation produce larger spinal cord $[K^+]_e$ responses in md rats than in ns rats, that the $[K^+]_e$ rises result from greater K^+ release rather than impaired K^+ clearance, and that the K^+ ions come from 4-AP blockable sources.

SODIUM DEPENDENT ACTION POTENTIALS ELICIT A POTASSIUM DEPENDENT AFTERHYPERPOLARIZATION IN FROG MYELINATED AXON.

M.O. Poulter and A.L. Padjen. Dept. of Pharmacology and Therapeutics, McGill University. Montreal, Canada, H3G 1Y6.

Blockade of voltage dependent potassium conductances in myelinated axons results in an increase in excitability, observed as trains of action potentials lasting a maximum of 100 ms in response to depolarizing constant current steps. We have observed that these pulses are followed by a 50-100 ms long afterhyperpolarizing potential (AHP). We are reporting some of its properties.

Intracellular recordings were made from the large myelinated axons impaled at the entry zone of dorsal roots in isolated hemisected frog spinal cord continuously superfused with Ringer solution (at 14°C). Microelectrodes contained either 4-aminopyridine (4-AP, 5-10 mM) or 4-AP and tetraethylammonium (TEA, 5-25 mM).

The AHP was absent when stimulation was below the threshold for the generation of one spike. The magnitude of the AHP increased proportionally with the number of spikes, up to a maximum of some 4 mV. No AHP was observed after blockade of action potential generation with 250 nM tetrodotoxin. The AHP was unaffected by reducing extracellular calcium and adding 10 mM magnesium or 2 mM manganese to the perfusing solution. The AHP reversal was around -95 mV at resting membrane potential. Increasing the external potassium concentration from 2 to 10 mM shifted the reversal potential 10-15mV in positive direction. Similar AHP was observed in experiments on isolated dorsal roots.

These results are consistent with the presence of a sodium-activated potassium conductance in frog myelinated axons, insensitive to intracellular 4-AP and/or TEA, which may be important for the regulation of repetitive activity in myelinated axon. Supported by the MRC of Canada.

ELECTROGENIC PUMP ACTIVITY IN RAT OPTIC NERVE.

T.R. Gordon, J.D. Kocsis, S.G. Waxman, Dept. of Neurology, Yale Med. Sch. and VA Med. Ctr., West Haven, CT. 06516.

Electrogenic (Na^+/K^+) pump activity can hyperpolarize sites of demyelination; therefore its block may improve conduction (Bostock and Grafe J Physiol 365:239-257, 1985). We investigated electrogenic pump activity in rat optic nerve. An afterhyperpolarization (AHP) up to 4.8 mV, >30 sec., was elicited by repetitive whole nerve stimulation in a sucrose gap chamber. The K^+ channel blocker tetraethylammonium (TEA) and the Ca^{2+} channel blocker $CoCl_2$ did not alter the AHP amplitude, but the K^+ channel blocker 4-aminopyridine alone and in combination with TEA increased AHP amplitude. Passage of hyperpolarizing and depolarizing constant current during stimulation did not alter the AHP amplitude, indicating that activation of K^+ channels is not responsible for the AHP. The AHP varied directly with temperature and was blocked by strophanthidin and by Li^+ substituted for Na^+. The response to a submaximal stimulus during the AHP was smaller than that at rest, an effect reversed by strophanthidin, which blocks Na^+/K^+ ATPase. The results indicate that the post-tetanic AHP in rat CNS myelinated axons is due to electrogenic pump activity that can increase threshold, mediated by Na^+/K^+ ATPase; this might lead to conduction block in demyelinated fibers with decreased safety factor and may be reversed by cardiac glycosides. Supported by NMSS, NIH, VA.

POTASSIUM CHANNEL FAMILY IN THE JELLYFISH, AGLANTHA.

R.W. Meech*, S.A. Arkett, G.O. Mackie*, & N.J. Maitland*. Departments of Pathology & Physiology, University of Bristol, UK. and Department of Biology, University of Victoria, Canada.

Jellyfish are the simplest animals to have evolved a nervous system and Aglantha is particularly interesting as it has an escape mechanism which is absent in other jellyfish. Both slow and fast ("escape") swimming arise from contractions in a single sheet of muscle innervated by a single set of motor axons. Differences in the force of contraction arise from differences in the electrical events generated postsynaptically by two different propagating impulses. Slow swimming depends on a low amplitude Ca++ spike; fast swimming depends on an overshooting Na+ dependent action potential (Mackie & Meech, 1985).

The Ca++ spike is prevented from reaching the threshold of the Na+ spike by a rapidly activating outward current. Patch clamp analysis of the K+ selective channels that form the basis of this current shows them to be steeply voltage dependent. Four classes of K+ channel have been identified. Each channel has different kinetics but they have the same conductance (43pS in 250mM KCl) and may be considered to be members of the same family (Mackie & Meech 1989). We have identified several fragments of Aglantha gDNA that hybridize with Shaker (ShA1, kindly supplied by Drs. Y&L Jan, Univ. of California).

36.1

CULTURED POSTNATAL RAT HIPPOCAMPAL NEURONS HAVE A Ca^{2+} INDEPENDENT AND VOLTAGE DEPENDENT Cl CURRENT. J. Yang, G.D. Clark, L.L. Thio, D.B. Clifford, and C.F. Zorumski, Dept. of Psychiatry, Washington Univ. Sch. Med., St. Louis MO 63110

Adult rat hippocampal pyramidal neurons in slices possess a time and voltage dependent Cl conductance largely localized on the dendrite (Madison, D.V., et al., Nature, 321:695, 1986). Using the whole cell mode of the patch clamp technique, we have found a similar conductance in postnatal rat hippocampal neurons cultured for 3 hours to 7 days. When E_{Cl} is 0mV, voltage steps to potentials more negative than -50mV from holding potentials more positive than -10mV evoke slow inward relaxations. Current activation is slow requiring 3-7s to reach a peak amplitude. At voltages more negative than -100mV, the relaxation sometimes declines in amplitude after reaching its peak. A tail current having a duration of several seconds occurs at the end of the voltage step. Although the current is inhibited by 400μM Cd^{2+}, the current is observed in cells simultaneously bathed with a solution containing no added Ca^{2+} and intracellularly dialyzed with a strong Ca^{2+} buffer. This result indicates that the conductance is not Ca^{2+} dependent. The properties of this Cl conductance suggest that it is located on the somas of cultured postnatal rat hippocampal neurons and may contribute to the resting membrane potential of these neurons.

36.2

ETHYLENEDIAMINETETRAACETIC ACID (EDTA) STIMULATES A Ca^{2+}-DEPENDENT, PICROTOXIN-INSENSITIVE Cl^- UPTAKE IN RAT BRAIN VESICLES J. Mathew* & G.D. Frye (SPON: B.Rohde) Dept. Med. Pharmacol., Texas A&M Col. of Med., College Station, TX 77483

During studies of Ca^{2+}, ethanol and sialic acid modulation of $GABA_A$-mediated Cl^- uptake, the cation chelator EDTA showed marked stimulation of Cl^- uptake into brain vesicles. The present report characterizes EDTA-stimulated Cl^- uptake and compares it with that induced by muscimol. Incubation of EDTA (0.5-2.5mM) with vesicles and $^{36}Cl^-$ for 10s induced dose-related increases in net Cl^-uptake with a maximum uptake of 33.9±0.6 nmoles/mg protein above basal levels. Maximal net Cl^- influx stimulated by EDTA was similar to that stimulated by a maximal concentration of muscimol (25uM); the effects of EDTA and muscimol were additive. Neither picrotoxin (100uM) nor strychnine (100uM) altered uptake induced by EDTA but picrotoxin completely blocked that induced by muscimol. Removal of Ca^{2+} completely blocked EDTA-stimulated Cl^- uptake but not that induced by muscimol. Readdition of Ca^{2+} (0.01-10mM) caused a graded reinstatement of EDTA (1mM) induced Cl^- uptake which was maximal at Ca^{2+} (1mM) and then decreased with higher Ca^{2+} (2.5-10mM). Cd^{2+} and La^{3+}, but not Ni^{2+}, Co^{2+} or Mn^{2+} blocked EDTA-stimulated Cl^- uptake. Of the more Ca^{2+} selective chelators, EGTA (0.5-2.5mM) and BAPTA (0.5-10mM), only EGTA induced Ca^{2+}-dependent Cl^-uptake. These results suggest that EDTA stimulates a Ca^{2+}-dependent, picrotoxin-insensitive influx of Cl^- that may not depend on external chelation of Ca^{2+}. (Supported by AA06322 & AA00101)

36.3

EFFECTS OF K^+ ON ANION AND CATION TRANSPORT IN ASTROCYTES AND NEURONS. S.Y. Chow*, Y.C. Yen-Chow*, H.S.White* and D.M. Woodbury Depts of Physiology and Pharmacology, Univ. of Utah, Salt Lake City, UT 84108.

Effects of K^+ concentration in medium ($[K^+]_o$) on the intracellular concentration of Cl^-, I^- ($[Cl^-]_i$ and $[I^-]_i$, derived from $^{36}Cl^-$ and $^{125}I^-$ studies), HCO_3^- (derived from measurements with ^{14}C-DMO), Na^+ and K^+ were studied in primary cultures of mouse astrocytes and neurons. In astrocytes, as $[K^+]_o$ was increased ($[Na^+]_o$ was decreased to maintain the same osmotic pressure), $[Cl^-]_i$, $[I^-]_i$, $[HCO_3^-]_i$ and $[K^+]_i$ all increased, but $[Na^+]_i$ decreased. Changes in $[Cl^-]_i$, $[I^-]_i$ and $[HCO_3^-]_i$ paralleled those with $[K^+]_i$ and were inversely related to $[Na^+]_i$. Changes of $[Cl^-]_i$, $[Na^+]_i$ and $[K^+]_i$ were much greater than those of $[I^-]_i$ and $[HCO_3^-]_i$. The changes in intracellular concentration of ions were more prominent in $[K^+]_o$ between 1.2 and 4.2 mM and between 60 and 122 mM. In neurons, altering $[K^+]_o$ produced biphasic changes in $[Cl^-]_i$ and $[I^-]_i$ and triphasic changes in $[Na^+]_i$. In lower $[K^+]_o$ (1.2 - 5.4 mM), $[Cl^-]_i$ and $[I^-]_i$ decreased as the $[K^+]_o$ increased whereas in higher $[K^+]_o$ (5.4 - 122 mM), $[Cl^-]_i$ and $[I^-]_i$ were directly proportional to the $[K^+]_o$. In addition, in lower $[K^+]_o$ (1.2 - 10 mM) changes in $[Cl^-]_i$ and $[I^-]_i$ paralleled those with $[Na^+]_i$, whereas in higher $[K^+]_o$ (10 - 122 mM) changes in these two anions paralleled those with $[K^+]_i$. Changes in $[HCO_3^-]_i$ paralleled those with $[K^+]_i$ at all $[K^+]_o$. These studies demonstrate that anion and cation transport in astrocytes and neurons are different. (NIH Grant #5R01 NS 21834).

36.4

BRADYKININ AUGMENTS CHLORIDE CURRENT IN T-LYMPHOCYTES VIA A RISE IN INTRACELLULAR CALCIUM. M.A. Schumann*, D.B. Maldonado* and P. Gardner. Dept. of Medicine, Stanford Univ. Sch. of Medicine, Stanford, CA 94305.

Bradykinin (BK), a potent vasoactive and pain impulse-involved peptide, has been known to be involved in inflammation and cellular immune response. Contrary to its well defined action on some neurons, its action on T-lymphocytes is unknown. We have used a tight seal-whole cell recording to investigate the mechanism by which BK affects a chloride current in Jurkat lymphocytes. Perfusion of the bathing solution with BK induced, with an onset of 0.5 to 1 minute, a dose- and time-dependent increase in current peak amplitude. The peak response, with an increase of 43.5%±7.5 (n=7), was attained in 6 minutes by $2x10^{-5}$M. In addition, the time constant of the current decay was prolonged 1.5 to 12 times. The effect of BK was mimicked by bath application of $1x10^{-7}$M Ca^{2+} ionophore (A23187). Diisothiocyanostilbene-2,2'-disulfonic acid (DIDS, $5x10^{-5}$M), a blocker of anion transport included in the pipette solution, blocked the action of BK and of A23187. Current enhancement by BK was dependent on Ca^{2+} since bathing the cells in a solution containing 5 to $25x10^{-6}$M bis-(o-aminophenoxy)-ethane-N,N,N',N' tetra-acetic acid, acetoxymethyl ester (BAPTA, AM, a Ca^{2+} chelator), resulted in complete elimination of the response to $4x10^{-5}$M BK or to $1x10^{-6}$M A23187. Furthermore, BK (0.01 to $1x10^{-4}$M) increased intracellular $[Ca^{2+}]$ up to two-fold as measured by the mean violet:blue fluorescence ratio of Indo-1-loaded Jurkat cells. The data are consistent with the mediation of intracellular Ca^{2+} in augmenting the chloride current in T-lymphocytes by BK.

36.5

REGULATION OF A RECTIFYING CL^- CHANNEL FROM JURKAT LYMPHOCYTES BY TEMPERATURE AND 8Br-cAMP. S. S. Garber and R.W. Aldrich, Dept. of Neurobiology, Stanford Univ., Stanford, CA 94305-5401

We have studied a rectifying Cl^- channel found in human Jurkat T-lymphocytes. This Cl^- channel can be activated by excising a patch of membrane using the inside-out (i/o) patch-clamp configuration and holding at depolarized voltages for prolonged periods of time (1-6 min at +80 mV, 20°C). The single channel current at +80 mV is 4.5±0.3 pA. The single channel amplitude is complicated by the presence of subconductance states. The ratio of current at +80 mV to -80 mV 4.3±0.7. This rectifying I/V relationship was used as a marker for Cl^- channel activity. 20% of attempts made at 20°C resulted in Cl^- channel activity. Patches usually showed only a single active channel. In contrast, 50% of i/o-excised patches showed multiple Cl^- channel activity when the temperature was increased to 30°C. There was no marked change in the single channel conductance or in appearance of substates at 30°C. Once active, the probability of being open (P_o) is voltage-independent but mean open and closed times are voltage-dependent such that P_o is constant. These observations suggest that the # of channels available to be activated depends on temperature. Channels observed in the cell-attached, or i/o configuration in cells treated with 100 µM 8Br-cAMP (20°C) exhibit shorter mean open and closed times. The gating kinetics observed in 8Br-cAMP-treated cells are distinct from excised, voltage-activated Cl^- channels suggesting 8Br-cAMP may regulate the gating of the channel or the recruitment of a different channel type. Supported by NS23294, National Cystic Fibrosis Foundation RDP and NCF fellowship to SSG.

ELECTROPHYSIOLOGICAL BEHAVIOR OF PLASMA CELLS FROM CHICKEN LACRIMAL GLANDS. P.R.Brink, E.J.Roemer*, S.Fan* and B. Walcott. Dept. of Anat. Sci., SUNY, Stony Brook, NY 11794.

Whole cell, detached and attached patch clamp modes were used to investigate the membrane channels of plasma cells isolated from chicken Harderian glands. Whole cell recordings show no inward current, but there is a large, slowly inactivating outward current, carried primarily by K ions, which is increased by perfusion with uM carbachol. In whole cell mode, with 100 mM Ba^{++} and 10 mM TEA, there is a small "inward current", which is reduced by verapamil, indicating the presence of Ca^{++} channels. In current clamp mode, the cell resting potential hyperpolarizes within 60s of exposure to 1 uM carbachol. Single channel records obtained from inside-out patches have revealed a dominant maxi-K channel with a 230 pS unitary conductance. Application of voltage steps to multichannel inside-in patches reveals activity which decays with the same time course as whole cell currents. The maxi-K channels appear to be largely responsible for the whole cell currents. Alteration of Ca^{++} concentration from 1-100 nM dramatically influences open time probability. These data suggest that carbachol increases cytoplasmic calcium, enhancing the activity of maxi-K channels, resulting in hyperpolarization of plasma cell membrane. Modulation of membrane potential may be an important aspect in the regulation of plasma cell function.

EPITHELIAL mRNA-INDUCED ION CHANNEL EXPRESSION IN *XENOPUS* OOCYTES. D.H. Feldman, R.S. Schackmann*, M.S. Urnes*, and D. Carroll*. Dept. of Biochemistry, Univ. of Utah Med. Sch., Salt Lake City, UT 84132.

Secretory epithelia of the airway and elsewhere express various ion channels, including a cAMP-kinase regulated Cl^- channel whose function is disrupted in cystic fibrosis (CF). This defect affects either the Cl^- channel itself, or a regulatory component necessary for its function. We are using the *Xenopus* oocyte expression system to aid in the identification and isolation of the "CF gene" and genes for other constituents of epithelial transport. Ionic currents induced by injection of mRNA from canine or human epithelia are monitored by voltage clamp.

Oocytes injected with canine tracheal mRNA have 2-3 fold elevated steady Cl^- current, indicated by Cl^- replacement, compared to controls injected with water or liver mRNA. It is not yet established whether this represents expression of the Cl^- channel affected by CF. A slow-onset (4-5 min. to reach steady-state), voltage-dependent (-50 to >50 mV) K^+ current also appears in oocytes injected with either canine or human tracheal mRNA. The current resembles that observed in oocytes injected with mRNA transcribed from a rat kidney cDNA (Takumi *et al.* 1988, *Science 242*:1042); thus, we tested by means of a hybrid-arrest procedure whether the tracheal mRNA-induced K^+ current is due to a gene product related to the rat kidney cDNA. An anti-sense 45-base oligonucleotide constructed from the sequence of the rat cDNA, when mixed with tracheal mRNA prior to injection, prevented the appearance of the slow K^+ current. In contrast, the oligonucleotide did not affect the expression of TTX-sensitive Na^+, and A-type and delayed rectifier K^+ currents directed by rat brain mRNA.

Thus, it appears that canine and human tracheal epithelia express a transcript that is closely related to one cloned from rat kidney, and is unrelated to common brain ion channel genes. It is not yet known whether this transcript codes for a K^+ channel, or for a regulatory protein that alters the expression of an endogenous oocyte channel.

36.8

WHOLE CELL PATCH CLAMP STUDIES OF CULTURED EPITHELIAL CELLS. C. Pappas*, A. Oyler* and B. Koeppen* (SPON: E.M. Ostapoff). Depts. Med. and Physiol., Univ. Conn. Hlth. Ctr., Farmington, CT 06032.

The medullary collecting duct (OMCD) of the kidney secretes H^+ by an electrogenic ATPase. We have attempted to develop a model system for the electrophysiological study of this transporter. As a first step, we report the baseline electrical properties of these cells.

OMCD cells were isolated from the rabbit kidney, and grown in primary culture on collagen-coated coverslips. The input resistance of the cells averaged 686 ± 134 MΩ immediately after patch rupture, and 872 ± 181 MΩ after 20-30 min. of recording. The membrane voltage (Vm), as measured under current clamp conditions, was -36 ± 4 mV. The IV plot was nonlinear, with a chord conductance at Vm -40 to -80 mV of 1.94 ± 0.36 nS, and at Vm = +40 to +80 mV of 2.47 ± 0.41 nS. Removal of Cl^- from the bathing medium reduced outward current, and decreased the chord conductance at Vm = +40 to +80 mV from 3.68 ± 0.65 to 2.10 ± 0.41 nS. The chord conductance at Vm = -40 to -80 mV was reduced, but not significantly (1.95 ± 0.47 vs 1.74 ± 0.39 nS). Barium (1mM) did not have an effect when added to the bath. However, 10 mM barium reduced outward current, and decreased the chord conductance at Vm = +40 to +80 mV from 4.38 ± 1.37 to 3.01 ± 1.20 nS. The chord conductance at Vm = -40 to -80 was also reduced from 2.72 ± 1.14 to 1.45 ± 0.42 nS.

Conclusion: Cultured medullary collecting duct cells contain both Cl^- and barium-sensitive conductances. The electrical properties of the cultured OMCD cells are similar to those reported for the native cells measured with voltage-recording microelectrodes (Am. J. Physiol. 248: F500, 1985).

36.9

EFFECTS OF DEUTERIUM OXIDE ON THE GAP JUNCTION CHANNEL ACTIVITY OF EARTHWORM GIANT NERVE FIBER SEPTUM L. Barr[1], S.F. Fan*[2], and P.R. Brink[2]. [1]Dept. Physiol. Biophys., Univ. Illinois, Urbana, IL 61801, [2]Dept. Anat. Sci., HSC, SUNY at Stony Brook, NY 11794

With the double voltage clamp technique it had been shown that the reduction of junctional conductance of the earthworm giant nerve fiber septum with the exchange of H_2O with D_2O has two phases (Verselis, V. and Brink, P.R., Biophys. J., 50:1003, 1986). The reduction occurs within three minutes can be explained by the solvent isotope effects. The further reduction, which reaches steady state about 15-20 minutes after exchange, could only be explained by a primary solvent effect. The reduction of conductance could be the results of a decrease of the unitary conductance of individual channel or of a decrease of the open probability of the channel openings or both. With tight seal patch clamp technique we showed that after prolonged D_2O treatment, both the unitary conductance and the open probability of individual channels decrease. CONNEXIN 32, A MAJOR GAP JUNCTION PROTEIN OF LIVER AND NEURONS, FORMS VOLTAGE DEPENDENT INTERCELLULAR CHANNELS IN CELLS STABLY TRANSFECTED WITH ITS cDNA. A.P. Moreno*, B. Eghbali*, J.A. Kessler and D.C. Spray (SPON: J.A. Umbach). Department of Neuroscience, A. Einstein Coll. Med., Bronx, NY 10461

Coexpression of two or more gap junction proteins in a single cell type is common and has complicated the study of physiological properties of connexin 32 (Cx32), a major gap junction protein in rat liver and between neurons. We have stably introduced cDNA encoding Cx32 into a communication incompetent cell line (see Abstract by Eghbali et al), enabling direct study of channel properties. In control cells, junctional conductance (g_j, measured under dual voltage clamp) was generally undetectable (48/52 pairs in one series; 16/22 in another; in the 10 coupled pairs, g_j was 60-300 pS). More than 70% of the transfected pairs displayed g_j > 1 nS (in one series of 23 cell pairs, all were coupled with mean g_j 5.19±5.7 nS). g_j was reduced by heptanol and halothane, agents that gate g_j in tissues expressing Cx32. Unitary conductances of channel events in untransfected and transfected cells were compared; in control cells where g_j was detectable (2 cases, > 100 events in each), sizes averaged about 20-30 pS, and may represent a novel connexin. In transfected cells (7 pairs, some of which showed hundreds of analyzable events), a larger channel type was present, with a unitary conductance of about 120 pS; the small channel seen in control cells was also usually present. The open time of the channel corresponding to transfection with Cx32 was markedly voltage dependent. Since this gap junction protein is also expressed between neurons and between oligodendrocytes, we hypothesize that voltage dependent junctional conductance may play a role in electrotonic coupling in the nervous system.

36.11

GAP JUNCTIONS DO NOT AFFECT GROWTH RATE: STUDIES ON COMMUNICATION-INCOMPETENT CELLS STABLY TRANSFECTED WITH cDNA ENCODING CONNEXIN 32, A MAJOR GAP JUNCTION PROTEIN OF LIVER AND NEURONS. B. Eghbali*, J.A. Kessler, and D.C. Spray. Dept. of Neuroscience, A. Einstein College of Medicine, Bronx, NY 10461

A role for gap junctions in normal tissue growth and differentiation has long been postulated. As a direct test for a role of gap junctions in growth control, we have compared the growth rates of a noncommunicating, highly metastatic cell line (SKHep1) with those of clones in which we have introduced the cDNA encoding the major liver gap junction protein, connexin 32. SKHep1 cells are normally not coupled with respect to the dye Lucifer Yellow, do not express mRNAs detectable by low stringency hybridization with cDNA encoding connexin 32, and do not express junctional proteins as detected immunocytochemically. Following stable transfection and selection, first with selectable marker and then using intracellular injection of Lucifer Yellow to choose clones with high degree of dye spread, connexin 32 mRNA and punctate connexin-32 immunoreactive membrane contacts became abundant, and cells became strongly coupled with regard to dye and electrical current (macroscopic and unitary junctional conductances of about 10 nS and 120-150 pS were recorded in cell pairs). Growth rates during the rapid proliferation of the cells (1-5 days after plating at low density) were not altered after transfection; maximum cell density achieved in confluent dishes (7-10 days in culture) was slightly lower in transfectants than in controls. These observations suggest that the reduction in functional gap junctions often associated with tumorigenesis is not responsible for the increased growth rate of tumor cells.

A GENERAL METHOD FOR FUSING RECONSTITUTED PROTEOLIPOSOMES WITH PLANAR MEMBRANES. D. J. Woodbury*, A. G. Goldberg* and C. Miller* (SPON: T. Egan). Graduate Department of Biochemistry; Brandeis University; Waltham, MA 02254.

We are attempting to purify and characterize the voltage-dependent Cl^- channel from the electric organ of *Torpedo Californica*. Passive flux measurements on liposomes reconstituted with detergent-solubilized protein indicate the presence of a Cl^- channel. However, ardent attempts to fuse these liposomes with planar membranes have been unsuccessful.

We now report a novel method for fusion of liposomes. The liposome membrane is doped with nystatin-ergosterol channels that promote fusion and cause a transient increase or spike in bilayer conductance. This spike is due to active nystatin-ergosterol channels that close within seconds as ergosterol is diluted into the lipid bilayer. Spikes signal that individual fusion events have occurred without permanently altering bilayer conductance. Presumably, nystatin and ergosterol facilitate fusion by forming channels throughout the vesicle population (Woodbury and Hall, *Biophys. J.*, 54:1053-1063, 1988; Cohen et al., *J. Gen. Physiol.*, 93:201-210, 1989).

Using this method, we have observed the voltage-dependent Cl^- channel following fusion of liposomes as indicated by conductance spikes. Preliminary results indicate that only a subset of the vesicles contain the Cl^- channel, in agreement with flux measurements. This research was carried out during the tenure of a Postdoctoral Fellowship from Muscular Dystrophy Association, and was additionally supported by NIH grant #AR-19826.

EFFECT OF IBOTENATE AND QUISQUALATE LESIONS OF THE nBM ON WATER MAZE PERFORMANCE. D.J. Connor, L.J. Thal, Dept. Neurosciences, UCSD, La Jolla, CA 92093; Neurology Ser., VAMC, San Diego, CA 92161

Injection of ibotenic acid (IBO) and quisqualic acid (Quis) into the nucleus basalis magnocellularis (nBM) of rats resulted in depletion of cortical choline acetyltransferase (ChAT) in F-344 rats of 45.5% and 58.9% respectively. Acquisition of the Morris water maze task was determined using a dark maze with digital tracking. Acquisition over a 10-day period (2 trials/day) was significantly different between groups (ANOVA with repeated measures, $p < .01$), and post-hoc analysis showed both lesioned groups were significantly different from sham-operated controls (NK, $p = .01$). The acquisition deficit was greater for the IBO group than the Quis group. No change in performance was seen after a 10-day retention interval for any of the groups ($p > .05$). Spatial probe analysis indicated a significant difference on annulus swimming (ANOVA, $p < .01$) with post-hoc testing revealing a significant difference between all three groups (NK, $p = .05$). The 72-hour retention of a passive avoidance task (600 sec/max) was not significantly different between groups (ANOVA, $p > .05$). Biochemical analysis of cortical tissue from the three groups revealed no differences in catecholamines or indolamines but a significant decrease in the IBO group was seen with amino acid analysis. The greater impairment seen in the IBO group may be due to the lesioning of noncholinergic cell populations in addition to the known cholinergic lesion.

37.2

ENHANCEMENT OF BOTH EXCITATION AND INHIBITION IN THE SAME POPULATION OF HIPPOCAMPAL NEURONS BY AN α_2 ANTAGONIST. S.J.Sara & O.Bergis*, LPN2, CNRS, Gif/Yvette, France.

The α_2 adrenoceptor antagonist idazoxan (IDA) facilitates cognitive performance in the rat (Sara & Devauges, Behav. Neural Biol., 1989). The effective dose (2 mg/kg) increases firing rate of cells in the locus coeruleus (LC) and release of noradrenaline (NE) in forebrain. The effect of IDA on excitability of neurons of the dentate gyrus (DG) in awake and freely moving rats is examined here. 8 rats were implanted with stimulating electrodes in the perforant pathway and recording electrodes in the DG. The awake freely-moving rat was stimulated (single pulse, 0.1 ms duration at variable intensity, 100-800 μamp). Amplitude of the population spike and slope of the EPSP were measured as a function of intensity of stimulation. In 7/8 rats, IDA induced a large (±100%) increase spike in amplitude, with no effect of the EPSP. Paired pulses at 300 μamp were administered with interpulse intervals (IPI) varying from 15-80 ms. An IPI of less than 30 ms produced a reduction in the response to the 2nd pulse. IDA significantly increased this inhibition for the maximal IPIs. Thus, NE can not only increase the excitatory population response in the DG but can increase the efficacy of inhibitory circuits in the same population of neurons at the same time. Such a dual action could serve to hone and sharpen information input to the hippocampus and thus contribute to the cognitive enhancing effects of LC stimulation and IDA seen in behavioral experiments.

INVESTIGATIONS INTO THE ROLE OF SEPTAL α-NORADRENERGIC AND NMDA RECEPTORS IN THE INDUCTION AND MAINTENANCE OF SEPTO-HIPPOCAMPAL CHOLINERGIC ACTIVATION INDUCED BY SPATIAL MEMORY TESTING IN THE MOUSE.

DURKIN, T., MARIGHETTO, A., LEBRUN, C., TOUMANE, A. and JAFFARD, R., Laboratoire Psychophysiologie, CNRS URA 339, Université de Bordeaux I, 33405 TALENCE FRANCE.

Previous studies showed that spatial memory testing of mice in an 8-arm radial maze, induced long-term activation (measured by sodium-dependent high affinity choline uptake) of the cholinergic septo-hippocampal pathway and whose duration progressively decreased during repeated daily testing (TOUMANE et al., Behav. Neural Biol., 1989, in press). We have tested the hypotheses that 1) the initial cholinergic activation may be mediated by phasic excitatory noradrenergic septal afferents via α receptors and 2) the duration of the activation may be controlled by a feedback system mediated by glutamatergic hippocampal pyramidal neurones via septal NMDA receptors. Intraseptal injection of phenoxybenzamine (500 ng/0.2 μl bilateral) 20 min before working memory testing blocks the cholinergic activation induced by testing (while having no effect on quiet control mice) and produces a selective interference-related working memory deficit. Intraseptal injection of +MK801 (500ng/0.2μl bilateral) 30 sec after an acquisition session of a reference memory test suppressed the maintenance of the cholinergic activation and produced a deficit in retention in a subsequent session 24 hours later.

INTERACTION OF GABAERGIC AND CHOLINERGIC DRUGS ON MEMORY AND UNIT CELL HIPPOCAMPAL FUNCTION. D.J. CRITCHETT*, R.M. MANGANO, B. BEER AND D.E. CLODY*. Medical Research Division, American Cyanamid Co., Pearl River, NY 10965.

The present studies tested for the potential interaction of effects of cholinergic and GABAergic systems on passive avoidance behavior and single cell hippocampal function. When given to rats prior to the training trial, both scopolamine (SCOP) and diazepam (DZP) produced dose related amnestic-like effects on the performance of passive avoidance behavior. Ro15-1788(Ro15), a specific benzodiazepine receptor antagonist, completely reversed the amnestic effects of DZP, but was without effects on the passive avoidance deficits induced by SCOP. However, the cholinomimetic oxotremorine was able to antagonize the passive avoidance deficits of both SCOP and DZP. The basal and acetylcholine (ACh) induced changes in the electrical activity of hippocampal pyramidal cells was recorded from rats *in vivo*. After intravenous (iv) administration of DZP (1 mg/kg), ACh responding (microiontophoretic ejection of ACh at 50nA) and basal firing rate were reduced to < 50 % of control. This DZP induced reduction of basal rate and ACh stimulated firing was reversed by iv injection of 1 mg/kg of Ro15. In fact both basal and ACh rate were increased 25% over control levels following the combined Ro15 and DZP treatment. Ro15 or vehicle alone produced no change in basal rate nor ACh induced acceleration of firing rate. The behavioral and electrophysiological data together suggest that the amnestic effects of SCOP and DZP may be mediated by a common cholinergic pathway, and these effects may be related to hippocampal function.

MODULATION OF MEDIAL SEPTAL AREA OUTPUT ALTERS WORKING MEMORY. B.S. Givens and D.S. Olton, Department of Psychology, The Johns Hopkins University Baltimore, MD 21218

The role of the septohippocampal pathway in working memory was investigated by examining the behavioral and electrophysiological effects of compounds microinfused into the medial septal area. Saline, tetracaine, muscimol or carbachol was microinfused into the medial septal area. Behavior and hippocampal EEG were assessed 0.5 and 1.5 hr after infusion. Behavior was measured by performance in a continouous spatial alternation task conducted in a T maze. Choice accuracy was the number of correct choices in 20 trials; performance time was the amount of time required to complete 20 trials. Hippocampal EEG was measured by FFT analysis (1-20 Hz). Saline had no effect on choice accuracy, performance time or hippocampal EEG. Both muscimol (20 ng) and tetracaine (10 μg) decreased choice accuracy, and the amount and the power of the 7-8 hertz theta frequency range. All measures of behavioral performance and hippocampal physiology were normal 1.5 hr after infusion. Carbachol (0.5 μg) did not affect choice accuracy but decreased performance time. These data support a role for the septohippocampal projection in working memory.

EFFECTS OF AGING ON ^{3}H-NIMODIPINE BINDING IN RAT BRAIN. P.W. Landfield, D.G. Fleenor*, J.C. Eldridge*, and B.S. McEwen. Dept. Physiol. & Pharmacol., Bowman Gray School of Medicine, Wake Forest Univ, Winston-Salem, NC 27103, and Rockefeller Univ., New York, N.Y. 10021.

Several recent studies indicate that aging is associated with an increase in voltage-dependent Ca influx into hippocampal neurons (cf., Landfield, Pitler, Science, 1984; Soc. Neurosci. 1987; Pitler, Landfield, under review; Campbell, et al, this meeting). In order to determine whether this effect may be associated with an increase in the concentration of calcium channels, studies were conducted on binding of a dihydropyridine (DHP) calcium channel antagonist, nimodipine, to hippocampal and other forebrain structures. DHP ligands bind with high affinity to L-like calcium channels and much is known about DHP pharmacology and binding patterns (cf. reviews in Scriabine, Structure and Physiology of the Slow Inward Calcium Channel, Liss, 1987; Janis, Silver, and Triggle, Adv. Drug Res., 1987).

Using ^{3}H-Nimodpine as the tracer, and 100-fold excess unlabeled nimodipine to define specific binding, we prepared membrane fractions from paired hippocampi and paired remaining forebrain for Scatchard plot analyses, in individual young adult (3-5 mo. old) and aged (24-27 mo. old) specific-pathogen-free Fischer rats.

Results showed a significant aging-related decrease in the B_{max} for ^{3}H-nimodipine binding in both hippocampus (134 vs. 69 fmol/mg, $p < .05$) and forebrain (129 vs. 72 fmol/mg, $p < .05$). However, the K_d exhibited no age differences in either region. These data were unexpected in light of the increased Ca currents that have been found in aging rat hippocampal neurons (Campbell, et. al., this meeting). Thus, they may reflect some form of Ca-mediated down-regulation of Ca channels, or they may reflect the fact that DHPs bind to Ca channels most effectively in the inactivated state, and, with aging, some channels may resist inactivation even during membrane preparation. Alternatively, since the data are expressed per mg of protein, they may reflect the loss of neurons and replacement by glia containing fewer channels. Further studies will be needed to understand the relations of DHP binding to Ca currents in aged brain, but the present data indicate that a complex interaction may be present (supported in part by AG 04542 and Miles, Inc.).

SPATIAL MEMORY RELATED NEURON ACTIVITY IN MONKEY HIPPOCAMPUS. T.Ono, K.Nakamura*, R.Tamura* and M.Fukuda. Dept. Physiol., Fac. Med., Toyama Med.& Pharmaceu. Univ., Sugitani, Toyama 930-01, JAPAN

Single neuron activity in the monkey hippocampus was recorded during bar press to manipulate a mobile device. Monkey sat in a half-mirrored cabin that could move linearly and rotate. The monkey could change light, sound and temperature in the cabin by change of position (internal environment). The laboratory light was switched on or off (external environment). One of five cue tones predicted a trial. After a short delay the monkey could see food or an object. By pressing the appropriate levers, it could move some distance to get the food or a drop of juice.

Of 104 neurons analyzed, 72 responded in some tasks. Of these, 24 were place recognition related. Their activity increased maximally when the monkey moved to a restricted position related to the external and internal environment. Movement with the laboratory light off, or the internal environment fixed, suppressed the neuronal activity increase about 50%. Tewenty one direction selective neurons responded maximally when the experimenter or the monkey moved to a specific position. Responses to cabin rotation were allocentric, egocentric or reduced. The result suggest hippocampal involvement in spatial memory defined by each coordinate of self location, and external and internal environment.

TONE-EVOKED POTENTIALS INDICATE DIFFERENTIAL PROCESSING OF SENSORY INFORMATION IN THE HIPPOCAMPUS AND NEOCORTEX OF THE RAT. R.E. Hampson, H.H. Willis, III, C.R. Breese*, and S.A. Deadwyler. Dept. of Physiology & Pharmacology, Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC, 27103.

Auditory evoked potentials (AEPs) from the hippocampus exhibit characteristics of sensory information processing which differ from cortical AEPs recorded in a two-tone discrimination task (Hampson, Breese & Deadwyler, *Soc. Neurosci. Abstr.*, **14**:1015, 1988). Two main components were present in the cortical AEP with peak latencies that differed from those in the hippocampus: a negativity at a mean latency of 40 ms (N_{40}) and a positivity at 140 ms mean latency (P_{140}).

During a two-tone discrimination task, the cortical N_{40} was present on rewarded and unrewarded trials. In contrast, the cortical P_{140} was evoked by the tone only on rewarded trials. P_{140} amplitude in the rat was altered by the sequence of prior tones in a manner similar to previous observations of sequence-dependent changes in the human P_{300}.

Implementation of a single-tone signal detection task (Heyser, Breese, Hampson & Deadwyler, *Soc. Neurosci. Abstr.*, **14**:1030), revealed that N_{40} was present in the cortical potential on all trials in which the tone stimulus was detected, but also on trials when tones were not detected. In contrast, the P_{140} component was present only on trials when the tone was detected behaviorally. Hippocampal AEPs in this task showed only a late (70 ms) component of the AEP (previously described as N_2) associated with detected tones.

These two studies suggest that information regarding the current tone and preceding sequence of tones appears to be available in the hippocampus prior to the occurrence of the task-sensitive cortical components in the two-tone discrimination task. However, in the tone detection task, the same information appears to be present in the neocortex first, and hippocampus later. This suggests that separate neural processes may be used to transmit sensory information between neocortex and hippocampus as a function of the behavioral requirements of the task.

RECEPTIVE FIELD PLASTICITY DURING CARDIAC CONDITIONING IN THE DORSAL MEDIAL GENICULATE NUCLEUS OF THE GUINEA PIG. Jean-Marc Edeline* and Norman M. Weinberger, Cntr. Neurobiol. Learn. Memory and Dept. Psychobiol., Univ. Calif., Irvine, Ca. 92717.

Associatively-induced, frequency-specific receptive field plasticity has been found in auditory cortical fields (Br. Res., 1986, 372, 357). We report here data on receptive field plasticity in the dorsal medial geniculate nucleus.

Single unit (n=4) and cluster (n=8) discharges were recorded in 10 adult guinea pigs before, during and after Pavlovian training (CS = tone, 6.0 sec.; UCS = 250 ms footshock at CS offset). Cardiac decelerative conditioned responses developed in all subjects during pairing but not during a prior sensitization period. Frequency receptive fields (FRF) were determined immediately before and following training by repeatedly presenting a range of tones (50 ms) at different intensities (40-80 db). All acoustic stimuli were delivered with controlled intensity to the contralateral ear. FRF plasticity was observed both in single or cluster recordings in 7 cases, of which 5 were specific to the frequency used as the conditioned stimulus.

These findings, the first demonstration of receptive field plasticity in the auditory thalamus, indicate that such plasticity is not restricted to the auditory cortex and suggest that interactions between subdivisions of the medial geniculate nucleus and the auditory cortex be studied to understand modifications of information processing during learning.

Supported by Lavosier fellowship (JME) and ONR (NMW).

EYE BLINK CONDITIONING IN THE FREELY MOVING MIDDLE-AGED RAT. C. Weiss, T.J. Shors, L.B. Tran, and R.F. Thompson. Dept. of Psych., U. Southern Cal., L.A., Ca. 90089-1061.

Both rabbits and humans exhibit the same basic properties of eyeblink conditioning in a closely similar manner, including severe association deficits as a result of aging. Because of the lack of age verifiable rabbits, we have implemented this paradigm in the freely moving Fischer-344 male rat.

We implanted chronic wires to record activity from the external eyelid muscle and to evoke an unconditioned blink (Skelton,1989). In addition, we have implanted some rats with a 19 gauge cannula to permit the use of an airpuff unconditioned stimulus (US).

Animals maintained electrical contact via a tether and miniature swivel. Shock intensity (100 msec, 60 Hz, AC) was adjusted to elicit a blink (<0.5mA). After habituation/threshold testing the rats were trained by pairing a tone (350 msec, 2.8 kHz, 85 dB) with the shock or airpuff US. Ten blocks of 10 trials/day (1 CS alone, 8 paired, 1 US alone) were given with an average intertrial interval of 30 sec. After training, hippocampal slices were prepared for long-term potentiation (LTP).

Our results to date suggest that middle aged (1 yr old, 400-500 gm) rats exhibit LTP (recording from CA1), and that eyeshock is not inducing stress related impairments.

37.11

INTRACELLULAR RECORDING FROM CORTICAL NEURONS OF CONSCIOUS RATS. M.P. Kristensen* and C.D. Woody (SPON:B. Swartz). UCLA Med. Ctr., Los Angeles, CA 90024.

In order to study subcellular mechanisms underlying changes in mammalian behavior and their modulation by pharmacological agents, the availability of intracellular recording methods allowing direct measurement of membrane properties of central neurons in the absence of trauma and anesthesia is useful. Intracellular recording in conscious animals has previously been done in cats (Woody and Black-Cleworth, J. Neurophysiol. 1973; Woody and Gruen, Brain Res. 1987) and primates (Matsumura, Brain Res. 1979; Aou et al Brain Res. 1988). The purpose of the present study was to design a preparation enabling intracellular recording from conscious rats in a manner consistent with current guidelines and comfort of the animal. Adapting previous methods used for studying primates (Jasper et al, EEG clin. Neurophysiol. 1960; Evarts, J. Neurophysiol. 1968), a fitting was attached to the skull to prevent cranial movement. It allowed recording more than 2 months after implantation. During fixation of the head-fitting (with the body free to move within in a plastic cylinder), stable intracellular recordings of cortical neuronal activity were obtained for more than 15 minutes. Using rectangular currents (60 ms duration), input resistances of 10-15 Mohm and spontaneous as well as evoked spike amplitudes of 70 mV were seen. It is the objective using this method to study cellular and subcellular changes during operant conditioning of licking behavior.

37.12

THE LEARNING-SPECIFIC REDUCTION IN CA1 NEURON AHP IS VOLTAGE-DEPENDENT. M. deJonge*, J. Black, R.A. Deyo* and J.F. Disterhoft, Dept. of Cell Biology and Anatomy, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Classical eye-blink conditioning in rabbits leads to a learning-specific decrease in amplitude of the slow afterhyperpolarization (AHP) in hippocampal CA1 cells. In the present study the effect of resting membrane potential (RMP) on the conditioning-reduced AHP was measured while current clamping the resting membrane potential (RMP) to different levels.

Subjects were young adult albino rabbits: Naive (N=10), Trace conditioned (N=8) or Pseudo conditioned (N=9). Following behavioral training, and with the experimenter blind to training condition, hippocampal slices were prepared and microelectrodes filled with 2M KCH_3SO_4 were used to record CA1 cells which exhibited stable membrane potentials, action potential amplitudes larger than 70 mV and accommodation to a depolarizing pulse. Slow AHP's were measured following bursts of 4 action potentials elicited by a 100 msec intracellular current pulse. A significant learning-specific reduction in AHP amplitude was observed but only when the RMP was clamped at -70 to -80 mV. For example, the AHP amplitudes (mV) were 4.15 ± 0.50 (N=20 cells), 4.58 ± 0.39 (N=23) and 4.43 ± 0.34 (N=19) for Naive, Pseudo and Trace cells, respectively, when the RMP was held between -60 to -65 mV; and 2.66 ± 0.29 (N=15), 2.81 ± 0.26 (N=15) and 1.87 ± 0.21 (N=16) ($p<.05$), when RMP was between -70 to -75 mV.

These results suggest that the current(s) affected by conditioning was (were) inactivated at RMPs more positive than -70 mV. Recently, Numann et al. (*J.Physiol.*1987,*393*:331-353) described two $K_{(Ca)}$ currents in isolated CA1 cells. $K_{2(Ca)}$ was completely inactivated at holding potentials of -55 mV, had a low threshold, and developed and inactivated slowly. This current may be altered during conditioning.

37.13

HIPPOCAMPAL ACTIVITY AND LATENT INHIBITION IN THE RABBIT. A. G. ROMANO. Med. Coll. of PA at EPPI, Philadelphia, PA 19129.

CA1 hippocampal activity was monitored in 2 groups of rabbits during the latent inhibition (LI) paradigm. Animals experienced either 0 or 300 preexposures of a tone CS followed by classical conditioning of the nictitating membrane response.

The 300 CS preexposures produced a decline in CS-evoked hippocampal activity ($p < .0005$) which was predictive of the subsequent rate of learning. Preexposed animals learned significantly slower than nonpreexposed animals ($p < .01$). Moreover, preexposed animals maintained baseline levels of CA1 activity throughout acquisition whereas nonpreexposed animals showed reliable increases in CS-evoked activity ($p < .05$).

The results suggest that CA1 activity may reflect two different aspects of the LI paradigm. During preexposures, activity may be reflecting the decline in the attentional value of the CS. However, during acquisition, the persistent depression in CA1 activity may be indicative of a potent memory component underlying the LI effect.

37.14

HIPPOCAMPAL RESPONSES TO TONE DURING JAW MOVEMENT DISCRIMINATION IN RABBITS. L.J.Dreshfield*, M.P.Galupo* and S.D. Berry. Dept. of Psychology, Miami Univ.,Oxford,OH 45056.

To assess the generality of conditioned hippocampal responses observed during nictitating membrane conditioning bilateral recordings were made from CA1 during go/no go jaw movement discrimination training and reversal in 5 New Zealand White rabbits. Electrodes were implanted under general anesthesia (Ketamine, 50 mg/kg; Rompun 10 mg/kg IM) In the task, one tone (CS+) signalled water 500 msec later; another tone (CS-) signalled no water. 1 KHz and 8 KHz tones were counterbalanced as CS+ and CS-. Non-parametric analysis indicated significant neural responses to the tones in all subjects. Surprisingly, individual subjects displayed a tone preference (e.g., 1 KHz or 8 KHz, regardless of whether it was the CS+ or CS-). Conditioned responses occurred to that tone only, and the effect of discrimination reversal was to reduce, but not eliminate, this response to the preferred tone even after behavioral reversal. Animals given unpaired control tones do not display hippocampal neural responses. These results suggest that hippocampal neurons may be involved in coding the behavioral significance of either the CS+ or CS- during successful behavioral responding to the CS+ only.

37.15

POSSIBLE ROLE OF KINDLING-INDUCED NEURONAL ALTERATIONS IN DISCRIMINATION-REVERSAL TRAINING OF THE RABBIT NICTITATING MEMBRANE (NM) RESPONSE. C.R. Sears* and G.B. Robinson (SPON: F.V. Szeligo). Univ. of New Brunswick, Fredericton, N.B. Canada, E3B 6E4.

We recently demonstrated that kindled rabbits acquired a discriminative response significantly faster than controls but were significantly impaired in reversal learning (Robinson et al., Behav. Brain Res., 31, 1988). Kindling of the perforant path results in significant LTP of the perforant path-granule cell (PP-GC) population spike and a long-lasting increase in the magnitude of paired-pulse inhibition. The possible contribution of these neural alterations to the effect kindled seizures have on discrimination-reversal learning of the rabbit NM response was investigated in the present experiment.

The results showed that kindling resulted in significant LTP, but it's duration was less than the maximum period allowed for reversal learning (28 days). In contrast, the increased magnitude of paired-pulse inhibition persisted throughout both discrimination and reversal training, with little recovery toward control levels. These results raise the possibility that altering the nonlinear transformational characteristics of PP-GC synapses, and thus transmission through the hippocampal formation, disrupts learning tasks dependent on an intact, neurophysiologically normal hippocampus. Supported by MRC.

37.16

LATERALITY OF THE CLASSICALLY CONDITIONED NICTITATING MEMBRANE RESPONSE IN THE RABBIT. S.L. Stewart*, V. Bracha* and J.R. Bloedel (SPON: A.S. Schwartz). Division of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013.

Although the classically conditioned nictitating membrane response (NMR) is considered to be largely confined to the eye exposed to the unconditioned stimulus (US), differences in degree of NMR laterality in individual animals have been reported in earlier studies. Because the extent of NMR bilaterality is important to issues pertaining to the neural substrates required for conditioning, experiments were performed to examine this question.

Awake rabbits were conditioned in a standard delay paradigm: 100 ms right corneal airpuff (US); 450 ms, 1 kHz, 85 dB tone (conditioned stimulus); interstimulus interval - 350 ms; intertrial interval - 17-23 sec; 100 paired trials/day. Movements of the nictitating membrane were recorded in both eyes. Most subjects demonstrated few or no responses in the nonstimulated eye during the first day of conditioning, but the incidence of responses in this eye gradually increased in subsequent training days. By the fifth day of training conditioned responses occurred in 85% of the trials in the stimulated eye and in 40% of trials in the unstimulated eye. In the unstimulated eye the increased number of conditioned responses was accompanied by an increase in the incidence of unconditioned responses, which reached 35% on day five.

The observed increase of both conditioned and unconditioned responses in the nonstimulated eye over the course of conditioning indicates that the bilateral responding in this paradigm is complex and may not relate only to changes in pathways exclusively mediating the conditioned response. (NIH Grant NS21958)

COGNITIVE DISRUPTION FOLLOWING AMYGDALA KINDLING: EFFECTS OF HISTORY, STIMULATION PARAMETERS, AND FOOTSHOCK. D.B. Peele, M.E. Gilbert, C.M. Mack*, S.K. Acheson*, and S.D. Allison*. NSI Environmental Sciences, RTP, NC 27709.

The effects of amygdala kindled seizures on two tests of cognitive function were examined using long-delay flavor-aversion (FA) and passive avoidance (PA) conditioning paradigms in rats. The purpose of the study was to compare the cognitive effects of unilateral and bilateral kindled seizures with those due to a kindling history. FA conditioning was unaffected by a history of either unilateral or bilateral kindling. However, seizures induced during the period separating saccharin (CS) and lithium (US) disrupted FA conditioning in a delay-independent manner. These effects could not be mimicked by administering trains of potentially interfering footshock during the CS-US interval (0.5 mAmp, 0.5sec every 6 seconds for either 30 or 90 sec). In contrast to the seizure-dependent disruption of FA conditioning, PA conditioning was disrupted by a history of bilateral but not unilateral kindling. This disruption was not dependent on seizures induced during training. The data from the FA experiments suggest that kindled seizure activity produces deficits that are more a function of a failure of associative learning than of an accelerated memory loss, since the deficits lacked a temporal dependency. The findings support previous research showing an important role of the amygdala in maintaining aversive conditioning, yet suggest that the cognitive impact of kindling and kindled seizure induction may depend critically on the task.

UNIT-ACTIVITY IN THE AMYGDALOID BASOLATERAL NUCLEUS DURING ACQUISITION AND OVERTRAINING OF DISCRIMINATIVE AVOIDANCE BEHAVIOR IN RABBITS. S. Maren*, A. Cox, and M. Gabriel. Department of Psychology, University of Illinois, Champaign, IL, 61820.

Multiple-unit and integrated-unit activity were recorded in the amygdaloid basolateral (BL) nucleus during differential conditioning of avoidance (wheel-running) behavior in rabbits. The conditioned stimuli (CS+ and CS-) were pure tones of different auditory frequency, and the unconditioned stimulus (US) was a constant-current footshock delivered through the grid floor of the wheel. Both the multiple-unit and the integrated-unit activity manifested significant (onset latency = 60-90 ms) discriminative neuronal discharges (i.e., greater discharges to the CS+ than to the CS-) during acquisition and overtraining of the conditioned avoidance behavior. Significant discriminative activity developed during the first session of conditioning, increased in magnitude as training continued, and reached maximal magnitude as the rabbits reached the asymptote of behavioral discrimination. Also, a significant increase in overall (non-discriminative) discharge magnitude occurred in the first conditioning session relative to the preceding pretraining session in which the CSs and US were presented non-contingently. These overall and discriminative neuronal discharges were substantially attenuated during overtraining (i.e., training beyond the first attainment of behavioral asymptote). Rapidly developing neuronal plasticity also occurs in structures (anterior cingulate cortex; mediodorsal thalamic nucleus) directly interconnected with the BL nucleus. In contrast, plasticity in the posterior cingulate cortex and anteroventral thalamic nucleus develops more slowly and is more persistent. Thus, neurons of the BL nucleus are the first to exhibit plasticity among neurons comprising a system that generally exhibits rapid changes. The rapid changes are in agreement with other data indicating that BL amygdaloid neurons and the system in which they participate subserve the earliest stages of learning (supported by NIH grant 26736 and AFOSR grant 89-0046 to MG).

Neuronal Activity in the Rabbit's Medial Prefrontal Cortex (PFCm) is Influenced by Aversive and Appetitive Pavlovian Contingencies. C.M. Gibbs, K.L. Watson* & A.W. Gibbs*, VA Med. Center & Univ. of South Carolina, Columbia, SC 29201.

Numerous findings have indicated that the PFCm participates in the development of aversively conditioned bradycardia in rabbits (e.g. Buchanan SL, Powell DA: JCPP 96:755; Gibbs CM, Powell DA: Brain Res 442:86; Gibbs CM: Soc Neurosci Abstr 14:862). The present studies were undertaken to evaluate single-unit activity in the PFCm during either differential aversive Pavlovian conditioning (one tone (CS+) paired with eye-shock, another (CS-) presented alone) or differential appetitive conditioning (CS+ paired with an intraoral pulse of water, CS- presented alone).

Our results to date indicate that: (1) Most (63/96; 66%) PFCm cells show quantitatively distinct activity patterns to the tone CSs during aversive training, with 97% of these showing greater responsivity to the CS+; further, the tone-evoked activity of the majority of these cells is significantly correlated with concomitant changes in heart rate (HR). (2) Similarly, most (33/48; 69%) PFCm cells show discriminative activity to appetitive CSs; however, in contrast to the aversive data above, a larger percentage of these cells (30% vs. 3%) show greater responsivity to the CS- ($\chi^2 = 14.57$, $p < .001$), and the relationship(s) between unit activity and concomitant HR changes has yet to be uncovered. Thus, the PFCm may be differentially involved in aversive and appetitive Pavlovian conditioning processes.

Multiple Unit Activity in the Mediodorsal Nucleus of the Thalamus Evoked by Pavlovian Conditioning. D.A. Powell and K. Watson*. Neuroscience Laboratory, VA Medical Center and University of South Carolina, Columbia, SC 29201.

Chronic multiple unit recording electrodes were implanted in the mediodorsal nucleus of the thalamus (MD) in rabbits. Two weeks later the animals were exposed to orienting, Pavlovian conditioning and extinction, in which tones served as conditioned stimuli (CSs) and paraorbital electric shock was the unconditioned stimulus (US). Tone-evoked multiple unit activity (MUA) from MD and heart rate (HR) changes were recorded. The initial HR response to the tone, as well as the conditioned HR response, consisted of decelerations from pre-tone baseline. A training-induced short latency increase in MUA was also observed, which began during the first 100 msec interval following tone onset and reached its peak amplitude during the third 100 msec interval. Although this response occurred during initial tone presentations, when the CS was not yet reinforced with the US, it habituated greatly over ten unreinforced habituation trials. Presentation of the CS paired with the US augmented this response two-to-three fold, and it remained at this level until the end of paired CS/US training. The presentation of the CS without the US during extinction again resulted in a quick decline of MUA to pretraining levels.

LONG-LASTING ENHANCEMENT OF ANTERIOR THALAMIC (AT) SYNAPTIC RESPONSIVENESS BY STIMULATION OF A BRAINSTEM CHOLINERGIC (Ch) GROUP. D. Paré, M. Steriade, M. Deschênes and S. Datta. Lab. Neurophysiol., Sch. of Med., Univ. Laval, Québec, Canada.

To study how the Ch laterodorsal tegmental (LDT) nucleus influences AT neurons, a series of intra- and extracellular recordings were performed in urethane-anesthetized, reserpine-treated cats. LDT stimulation evoked a short-latency (5 msec), short-duration (≈20 msec) depolarization and enhnaced the responsiveness of AT cells to cingular and mammillary body (MB) stimuli. This effect varied as a function of the number of trials. The gradual increase in responsiveness was paralleled by a progressive increase in input resistance. In some neurons, LDT trains also increased the probability of fast prepotentials being triggered by sub-threshold orthodromic volleys. In order to distinguish the cumulative effects of repeated LDT trains from the possibly slow time-course of LDT influences, we studied the effects of a unique 1-sec LDT train (at 30 Hz) on the synaptic responsiveness of AT cells. Such LDT trains induced a 3 fold increase in synaptic responsiveness, reaching its peak 40-50 sec after the LDT train and lasting up to 4 min. Iontophoretic application of scopolamine abolished these effects, thus indicating that the long-lasting AT potentiation is a muscarinic effect.

LATERALIZED BEHAVIORAL AND NEURONAL RESPONSES OF THE CINGULATE CORTEX DURING DISCRIMINATION CONDITIONING IN THE CAT. M. Penttonen*, T. Korhonen* and K. Hugdahl* (spon: P. Helén). Univ. of Jyväskylä, Finland and Univ. of Bergen, Norway.

The purpose of this experiment was to study the effects of symmetrical conditioned stimuli (CS) and asymmetrical unconditioned stimuli (US) on the lateralization of conditioned responses. The tone CS was delivered through earphones attached in front of both ears, and the US was the electrical stimulation of either the left or right lateral hypothalamus. The cats learned discrimination by showing greater head turning response amplitudes to the CS+ than to the CS-. In almost every cat the conditioned response was a head turn to the left. This response was accompanied with a negative evoked response (128-328 ms from the CS onset) to both CS- and CS+. The evoked response was greater in the right than in the left cingulate cortex. The magnitude of the difference was greater for the CS+ than the CS- with the advantage always in the right cingulate cortex. No differences were found in the behavior or the neural activity due to left versus right stimulation. Regardless of the hemisphere which received the US, the UR and CR headmovements were to the left, and contralateral to the hemisphere exhibiting the greater neural response. The greater activity of the right cingulate cortex might reflect some basic differences between hemispheres in this paradigm.

37.23

AUDITORY TRANSFER EFFECTS ON RECOVERY OF FUNCTION AFTER VISUAL SYSTEM LESIONS IN RATS. E.R. Delay. Dept. of Psychology, Regis College, Denver, CO 80221.

Previous studies (Delay, 1988) found that postoperative auditory discrimination (cross-modality transfer) training enhanced behavioral recovery of a brightness discrimination after occipital cortex (OC) ablations in rats. This study extended that research to examine the effects of cross-modality transfer on recovery of a brightness discrimination after lesions of the pretectal area (PA) and superior colliculus (SC). Each lesion occurred either separately or simultaneously with ablations of the OC. All rats were trained with a brightness cue to avoid shock. Twenty-four hours later surgery was performed under sodium pentobarbital anesthesia. Six days later, six rats in each surgery and control condition received either: 1) 20 trials with the original visual avoidance task, 2) 20 trials of avoidance training but with auditory intensity cues, or 3) no training. The next day, all rats were retrained on the original visual task. SC lesions produced a small behavioral deficit which was reduced by visual and auditory training. Rats with lesions of the SC plus OC showed large relearning deficits which were unaffected by auditory training. Recovery of deficits from PA, OC, and PA plus OC lesions was enhanced by auditory training. Auditory transfer training appears to aid recovery of a visual discrimination but only if either the SC or the OC are intact.

POSTSYNAPTIC LONG-TERM-ENHANCEMENT (LTE) BY DOPAMINE IS MEDIATED BY Ca^{2+} AND CALMODULIN. B.Libet and S.Mochida*, Dept.Physiology, Univ.California, San Francisco, CA. 94143.

LTE (lasting>3hr) of the muscarinic slow depolarization, or the equivalent slow (s-)EPSP, is induced either by a brief exposure to dopamine (DA) (Libet&Tosaka, P.N.A.S. 67: 667, 1970) or by preganglionic neural input which releases DA intraganglionically (Libet&Mochida, Brain Res. 473:271, 1988), in rabbit superior cervical ganglia. DA induction is effected through D_1 receptors and a rise in cyclic AMP.

We now tested the effects of reduced extracellular Ca^{2+}_o and of a specific calmodulin antagonist (calmidazolium) on DA induction of LTE, as seen in postsynaptic responses of ganglia to methacholine (MCh), in a perfusion sucrose-gap chamber. Lowering Ca^{2+}_o to either 1.0 or 0.2 mM completely abolished DA-induction of LTE, with no significant effects on the MCh depolarizing response per se. The Ca^{2+}_o action does not depend on a voltage-sensitive influx of Ca^{2+}. Calmidazolium (5μM) blocked LTE if present before treatment with DA, but did not when added after DA. Although hippocampal long-term-potentiation (LTP) exhibits similar sensitivities to Ca^{2+}_o and calmidazolium (Reymann et al., Brain Res. 461:388, 1988), LTE and LTP are quite different processes, on other grounds.

These results suggest that DA-induction of the enduring change in muscarinic responses may involve a cyclic AMP-dependent protein kinase that is activated by Ca-activated calmodulin. (Supported by U.S.P.H.S.grant NS-00884.)

IS LONG-TERM POTENTIATION (LTP) IN SYMPATHETIC GANGLIA INDUCED BY AN ENDOGENOUS MODULATOR? R. Wu*, F.G. Shon*,and D.A.McAfee. Dept. Pharmacology, University of California, Irvine, CA 92717.

Previous studies (Briggs, et al.,J. Physiol.,359:503,1985) have demonstrated that a few seconds of repetitive stimulation of the preganglionic nerve enhances ganglionic synaptic transmission for hours. Our previous observations are consistent with the hypothesis that in addition to ACh, preganglionic tetany induces secretion of a non-cholinergic, non-adrenergic modulator. Accordingly, this modulator, acting through a cyclase-coupled presynaptic receptor, produces a prolonged facilitation of the stimulus-evoked release of ACh, resulting in enhanced synaptic transmission. We now test the idea that this modulator, possibly a peptide, is susceptible to depletion by sustained preganglionic activity (Bachoo, et al.,Brain Res.400:377,1987).

Rat superior cervical ganglia were isolated, maintained in vitro as described above. Suction electrodes were used to deliver preganglionic stimuli and record postganglionic discharge. The timing of the stimuli and acquisition of the responses was controlled and quantified by computer using custom software developed in our laboratory.

Brief tetanic preganglionic stimulation (20hz/20sec) reproducibly enhanced responses to single test stimuli (1/min) about two fold. This potentiation decays exponentially (over 2 hours) to less than 20%. However, prolonged preganglionic stimulation (40hz/2hrs) inhibited these responses to brief periods of tetany. Quantitative analysis revealed that the prolonged stimulation did not inhibit generation of post-tetanic potentiation (PTP), but greatly reduced the magnitude and time course of LTP even when generated more than two hours later. The effects of prolonged stimulation were blocked if carried out in a low Ca-high Mg media which blocks release of neurotransmitters. These observations are consistent with the idea that an as yet unidentified modulator is released in a Ca-dependent manner during preganglionic activity from a pool which is readily depleted and not replenished. (This work was supported by PHS grant NS-22470.)

38.3

INVOLVEMENT OF PROTEIN KINASES IN TWO PHASES OF LONG-TERM POTENTIATION IN RAT HIPPOCAMPAL SLICES. G.L.Collingridge*, K.G.Reymann*, and S.N.Davies*. (SPON: Brain Research Association) Department of Pharmacology, University of Bristol, Bristol BS8 1TD, U.K.

We have reported that long term-potentiation (LTP) in the Schaffer collateral-commissural pathway is associated with a delayed increase in sensitivity of CA1 neurones to ionophoretically administered α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid (AMPA). We suggested that this represents a slowly developing postsynaptic phase of LTP and that the initial phase may be presynaptic. We have now studied the effects of the protein kinase C inhibitor K-252b on these two phase of LTP.

In control slices tetanic stimulation usually resulted in non-decremental LTP (>180 min) and a slowly developing increase in sensitivity to AMPA. Perfusion of K-252b (50 nM, 40-90 min) starting immediately after the tetanus resulted in only an early phase of LTP (lasting 45-90 min) and no change in sensitivity to AMPA. A similar decremental LTP was seen if K-252b was applied from 15-120 min before to 40 min following the tetanus. However, if K-252b was applied for 30-60 min starting 1-3 h after the tetanus it had no effect on either the potentiated synaptic or AMPA-induced responses.

These results suggest that there is a transient K-252b sensitive process activated following the tetanus that leads to a postsynaptic change associated with LTP.

38.4

IS PROTEIN KINASE C INVOLVED IN THE MAINTENANCE OF LONG TERM POTENTIATION ? A. Arai*, J. Larson*, M. Kessler, M. Oliver* and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

Recent studies using protein kinase C (PKC) inhibitors and activators have suggested a prominent role for PKC in long term potentiation (LTP). In particular, the inhibitor H-7, which acts directly on the catalytic subunit of the kinase, has been reported to reverse LTP for the duration of its infusion, even if applied 1 hour after the establishment of LTP. We have further examined the effects of H-7 and other PKC inhibitors on the physiology and the maintenance of LTP in field CA1 of the hippocampal slice. H-7 (75-450 μM) was perfused 10-20 min after establishing LTP in one of two input pathways. Low concentrations of H-7 (75 or 150 μM) had no influence on the slope of either control or potentiated EPSP's. Above 150 μM single stimulation pulses evoked repetitive neuronal discharge, and seizures were observed at concentrations above 300 μM. An incision between CA1 and CA3 could supress the seizures and the delayed part of the spiking activity and was, therefore, routinely applied. Intracellular analysis suggested that spiking resulted from a blockade of inhibitory synaptic potentials; this could at least partially be due to an interaction with GABA receptors, since H-7 at 400 μM was found to inhibit [3H]muscimol binding by more than 50%.

At concentrations of 300 and 450 μM, H-7 reduced both control and potentiated responses but did not show a preferential effect on the latter. These results do not support the hypothesis that sustained activation of PKC is required for the maintenance of LTP. (Supported by AFOSR 86-0099 and NS 21860)

38.5

REGULATION OF CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II IN CEREBELLAR GRANULE CELLS. K. Fukunaga*, D.P. Rich*, and T.R. Soderling. (SPON: T. Inagami), Dept. of Mol. Physiol., Vanderbilt Med. Sch., Nashville, TN 37232-0615.

CaM-kinase II is highly enriched at synapses where it may regulate Ca^{2+}-dependent functions including long-term potentiation. In vitro studies have identified a unique consequence of autophos. of Thr-286/287 to produce a Ca^{2+}-independent form of the kinase. We have investigated generation of this Ca^{2+}-indep. form of CaM-kinase II in 8-10 day cultured rat cerebellar granule cells. Under basal conditions about 4-5% of total CaM kinase II activity (assayed with Ca^{2+}/CaM) was the Ca^{2+}-indep. form (assayed with EGTA). Depolarization with 56 mM K^+ produced a rapid increase to 10% Ca^{2+}-indep. activity within 15-30 sec followed by a decline to 5-6% at 10 min. Ionomycin produced 10% Ca^{2+}-indep. activity which remained elevated. Inclusion of 5 μM okadaic acid, a protein phosphatase inhibitor, in the incubation medium potentiated the increases in Ca^{2+}-indep. activity. Removal of Ca^{2+} from the Krebs-Ringer medium reduced Ca^{2+}-indep. activity to 1-2% and eliminated the elevations in response to high K^+. Phosphopeptide mapping of the ^{32}P-labeled 58-60 kDa subunit of the CaM-kinase II revealed a correlation between generation of Ca^{2+}-indep. activity and ^{32}P-incorporation into peptide CB1 which contains Thr-286/287. These results indicate that formation of the Ca^{2+}-indep. CaM-kinase II is regulated in cerebellar granule cells by Ca^{2+} influx and by endogenous protein phosphatase activity and correlates with phosphorylation of Thr-286/287.

38.6

DIRECT EVIDENCE THAT ACTIVATORS OF PROTEIN KINASE C INCREASE THE PHOSPHORYLATION OF SYNAPSIN I AND PROTEIN III IN RAT HIPPOCAMPAL SLICES. E. Barnes* and M.D.Browning. Department of Pharmacology, University of Colorado H.S.C., Denver, CO 80262.

Previous studies have shown that activators of protein kinase C (PKC) produce LTP-like potentiation of synaptic transmission in the hippocampus. We have recently shown in chromaffin cells that phorbol dibutyrate (PdBu, a PKC activator) increased the phosphorylation of protein III (two synaptic vesicle-associated phosphoproteins protein IIIa M_r 74,000 and protein IIIb, M_r 55,000 that are collectively referred to as protein III) in chromaffin cells. Protein III is a very poor substrate for PKC but an excellent substrate for cAMP-dependent and Ca^{2+}/calmodulin dependent protein kinases. Thus we felt that activators of PKC like PdBu might leading to activation of a kinase cascade in chromaffin cells. In this report we test the hypothesis that similar effects on protein III and synapsin I (a protein very homologous with protein III) might be obtained in hippocampal slices.

Hippocampal slices were incubated for 90 min in $^{32}PO_4$ in PO_4-free buffer followed by ten minute incubation in various treatments. After 10 min the slices were sonicated in 1% SDS and synapsin I and protein III were immunoprecipitated and run on SDS-PAGE. PdBu produced dose-dependent increases in the phosphorylation of synapsin I and protein III with half-maximal effects at 100 nM. Maximal increases at 1.0 μM PdBu were 82%, 55%, and 56% for synapsin I, protein IIIa and protein IIIb respectively. We also performed phospho-site analysis of synapsin I using limited proteolysis. These studies indicated that PdBu increased the phosphorylation of multiple sites on synapsin I. These sites have previously been shown to be phosphorylated by both cAMP and Ca^{2+}/calmodulin dependent protein kinases. Previous studies have provided direct evidence that synapsin I regulates neurotransmitter release at the squid giant synapse. Accordingly, we hypothesize that the phosphorylation of synapsin I and the related protein, protein III may play an important role in mediating the increased transmitter release elicited by activators of PKC. (Supported by PHS grants DK40483 and NS26377 to M.D.B.)

38.7

DIRECT EVIDENCE THAT NOREPINEPHRINE INCREASES THE PHOSPHORYLATION OF SYNAPSIN I AND PROTEIN III IN DENTATE SLICES OF YOUNG BUT NOT AGED F344 RATS. K. Parfitt*, B.J. Hoffer, M.D. Browning. Dept. Pharmacology, U. Colorado HSC, Denver, CO 80262.

Previous investigations have shown deficiencies in noradrenergic neurotransmission in the hippocampus of aged rats. Mobley and Greengard (PNAS 82,945, 1985) have shown that norepinephrine (NE) stimulates the phosphorylation of synapsin I in rat frontal cortex. The purpose of this study was to determine whether NE was capable of enhancing phosphorylation of synapsin I and protein III, two homologous phosphoproteins thought to be involved in transmitter release, in the dentate of young (3 mos) F344 rats and aged (26 mos) F344 rats. We focussed on the dentate because of reports that NE produces LTP in this region of the hippocampus. LTP, thought to be an electrophysiological correlate of memory, in part involves an augmentation of transmitter release. Dentate slices were incubated for 90 min in $^{32}PO_4$ in PO_4-free buffer followed by 10 min incubation in various treatments. The slices were then sonicated in 1% SDS, and synapsin I and protein III were immunoprecipitated and run on SDS-PAGE. Viability of slices was assessed by electrophysiological criteria, including evoked responses as well as LTP. NE (10 uM) and isoproterenol (ISO, 250 nM) produced an increase in the phosphorylation of synapsin I and protein III in dentate slices of young rats but failed to alter the phosphorylation of these proteins in aged rats. Phospho-site analysis of synapsin I, performed using limited proteolysis, suggested that NE and ISO increased the phosphorylation of sites modified by cAMP-and Ca^{2+}/calmodulin-dependent protein kinases. Neither of these sites exhibited NE- or ISO-enhanced phosphorylation in the aged rats. This β-adrenergic agonist-stimulated phosphorylation of synapsin I and protein III is hypothesized to play a role in the potentiation produced by NE in the dentate. Thus, the failure of the aged rats to show such phosphorylation may underlie, in part, the failure of aged rats to exhibit LTP. (Supported by PHS grants GM07635 to K.P., AG04418 to B.H. and NS26377 & DK40483 to M.D.B.)

38.8

ISOPROTERENOL AND BACLOFEN SYNERGISTICALLY PRODUCE A LONG-LASTING POTENTIATION OF EVOKED RESPONSES IN RAT DENTATE GYRUS. J. M. Sarvey and E. C. Burgard. Dept. of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Bath application of ß-adrenergic agonists in the rat hippocamal slice preparation produces a long-lasting potentiation of evoked responses recorded in the dentate gyrus. The $GABA_B$ receptor agonist baclofen has been shown to augment the intracellular second messenger response to ß-adrenergic agonists in the hippocampus. Here we demonstrate that baclofen can also potentiate the electrophysiological effects of isoproterenol in the rat dentate gyrus.

Hippocampal slices were maintained in an interface recording chamber. Stimulation of the medial perforant path evoked a population spike (PS) recorded extracellularly in the granule cell layer of the dentate gyrus. A 20 min bath application of isoproterenol produced a dose-dependent potentiation of the evoked population spike amplitude which persisted throughout a 30min wash. ISO-induced potentiation, measured at 30 min wash was reliably induced at a concentration of 1µM (mean 191% of control, n=5). A concentration of 0.1 µM ISO had no effect on the PS (mean 96% of control, n=6). A 15 min bath application of (-) baclofen produced a dose-dependent enhancement of PS amplitude. This effect was maximal at a concentration of 5µM and was associated with a decrease in paired-pulse inhibition (interpulse intervals of 20-30ms). At a concentration of 0.1µM, baclofen did not significantly affect PS amplitude (mean 106%, n=8). However, administration of baclofen (0.1µM) together with ISO (0.1µM) produced a significant long-lasting potentiation of the PS amplitude measured at 30 min wash (mean 163%, n=6). These results demonstrate that ISO and baclofen, when administered together in doses below threshold for measurable effects, can produce a synergistic long-lasting potentiation of evoked responses in rat dentate gyrus. (Supported by NIH grant NS23865)

38.9

INDUCTION OF LONG-TERM POTENTIATION IN RAT CA1 REGION IS NOT ALTERED BY CHOLINERGIC STIMULATION. R.D. Blitzer, O. Gil*, and E.M. Landau. Dept. of Psychiatry, Bronx VA Medical Center, Bronx, NY 10468

The activation of NMDA receptors is essential to LTP in certain components of the rat hippocampal circuitry, including the Schaffer collateral - CA1 pathway. The CA1 region also receives a cholinergic innervation, and the effects of cholinergic stimulation on LTP in CA1 may give insight into the cholinergic role in memory. We have investigated the effect of carbachol (CCh) on the LTP induced in the CA1 region in rat slices. Extracellular recording and stimulating electrodes were placed in stratum radiatum. Tetanus consisted of two 100 Hz trains. CCh was present for 10-20 min before tetanus, and removed immediately after tetanus. The stimulus intensity used for tetanus was adjusted in CCh to control for EPSP depression, and returned to baseline after tetanus.

1 µM CCh depressed the EPSP by 34% before tetanus. Field potentials recorded during tetanizing trains were similar in CCh and control slices. Following tetanus, when time was allowed for CCh washout, LTP (measured either as % change EPSP amplitude or slope) was found to be unaffected by CCh administration. 30 min post-tetanus, EPSP amplitude was increased in control and CCh-treated slices to 147±11 and 146±7% of baseline, respectively; EPSP slope was increased to 162±17 and 180±14%.

5 µM CCh depressed the EPSP further (by 47%), but also failed to affect LTP. Similar results were obtained in the presence and absence of picrotoxin. The data show that a cholinergic agonist fails to reduce LTP in CA1, in contrast to the depression of LTP observed in CA3 (Williams & Johnston Science, 242: 84, 1988). Supported by NIH Grant 5-P50-AG05138-02.

INFLUENCE OF CHOLINERGIC NEUROTRANSMISSION ON HIPPOCAMPAL SYNAPTIC PLASTICITY. D. A. Engstrom and G. M. Rose. Department of Pharmacology, UCHSC & Medical Research, VAMC, Denver CO 80262

The purpose of this study is to determine what effect increasing synaptic levels of endogenously released acetylcholine has on primed burst potentiation. Primed burst potentiation, (PB), is a model of hippocampal synaptic plasticity, in which a patterned stimulation paradigm is used to evoke long term changes in synaptic efficacy.

Male Sprague-Dawley rats (275-350 g) are anesthetized with either urethane (1.5 g/kg, i.p.), secobarbital (50 mg/kg, i.p.) or pentobarbital (60 mg/kg, i.p.). Animals given barbiturates are maintained with a supplemental infusion to maintain adequate anesthesia. The animals are then prepared for acute in-vivo recordings. A glass multi-barrel recording electrode is lowered into the CA1 region of the hippocampus, and a teflon insulated wire stimulating electrode is lowered into the contralateral hippocampal commissure. Recordings and measurements are made of cell firing rates and attributes of the evoked field potentials, namely the population spike and slope of the e.p.s.p. Physostigmine, an inhibitor of acetylcholinesterase, is administered either i.p., i.c.v., or by local application through a barrel of the recording electrode.

Results to date suggest that within a narrow dose window, physostigmine can lower the threshold for eliciting PB or increase its magnitude, while doses outside this window can have opposite effects. The data suggest a complex, "inverted-U" type dose response similar to dose response relationships found for the drug in behavioral pharmacological paradigms. Differences in the quality and efficacy of the different routes of administration of physostigmine will be discussed.

38.11

LONG TERM POTENTIATION IN THE HIPPOCAMPUS INDUCED BY THE MAST CELL DEGRANULATING PEPTIDE : RELEASE OF AMINOACIDS AND PROTEINS.

M.P. ROISIN*, C. CHARRIAUT-MARLANGUE*, L. ANIKSZTEIN* and Y. BEN ARI. (SPON. by I. Hunter). INSERM U29, 123 Bld de Port-Royal, 75014 Paris.

The Mast Cell Degranulating peptide (MCD) is a bee venom peptide which produces seizures and convulsions in the rat following intracerebroventricular application. MCD, which blocks a specific K^+ channel produces in the CA_1 hippocampal region a long lasting enhancement of synaptic transmission similar to the long term potentiation (LTP) produced by a high frequency train of electrical stimulation. Using a push pull device, we have analyzed in vivo, in the CA_1 region of the hippocampus, the release of endogenous excitatory amino acids and proteins induced by MCD in relation to long term potentiation.

Application of MCD (20 µM for 10 min) produced a long lasting potentiation of the field E.P.S.P (4 hours). This potentiation was associated only with a short transient increase (10 min) in the release of glutamate (5 fold) and aspartate (6 fold), and with a delayed (1-2 hours) enhanced release of pre-existing (64, 54, 48, 45 kDa) proteins and the appearance of newly secreted proteins (33, 19, 16 kDa). These experiments confirm our earlier observations that LTP produced by a train of high frequency stimulation is not due to a sustained enhanced release of glutamate and aspartate. Our results cannot be readily reconciled with a presynaptic type of mechanism and suggest that postsynaptic mechanisms may play a crucial role in LTP.

BLOCKADE OF MAINTENANCE OF LONG-TERM POTENTIATION BY DENTATE, BUT NOT ENTORHINAL, INHIBITION OF PROTEIN SYNTHESIS. W.C.Abraham and S. Otani*. Dept.of Psychology and the Neurosci. Res. Center, Univ. of Otago, Dunedin, New Zealand.

We investigated whether the new protein synthesis, previously shown to be important for perforant path LTP maintenance, occurs in the dentate gyrus or the entorhinal cortex. Anisomycin, but not boiled anisomycin or the saline vehicle, injected into the dentate gyrus of urethane-anesthetized rats led to nearly complete decay of LTP within 3 hours. Intra-entorhinal anisomycin had no effect on LTP maintenance even over 6 hours. Intra-dentate injection of actinomycin-D (a mRNA synthesis inhibitor) also did not affect LTP maintenance over 6 hours. These results suggest that the proteins necessary for LTP maintenance over 6 hours are synthesized in the dentate gyrus from already existing mRNA, without involving protein synthesis in the cell bodies of the afferent fibers.

TETANIZATION-INDUCED LONG-LASTING DEPRESSION OF HIPPOCAMPAL CELL EXCITABILITY IS MEDIATED BY VOLTAGE-DEPENDENT CALCIUM CHANNELS. J. Wickens* and W.C.Abraham. SPON: (J.G.Anson). Depts. of Psychology and Anatomy and the Neurosci.Res. Centre, Univ. of Otago, Dunedin, New Zealand.

The induction of long-lasting depression of the orthodromic population spike in area CA1 was investigated using extracellular recordings in hippocampal slices from which area CA3 had been removed. Antidromic tetanization (6 trains of 50 pulses; 200, 50, or 15 Hz) induced transient reductions in the stratum radiatum evoked population spike and field EPSP that lasted 5-10 min. When the slices were bathed with 20 uM picrotoxin, the depression of the spike, but not of the EPSP, persisted for at least 30 min. Orthodromic tetanization (200 Hz) of the stratum oriens gave greater long-lasting depression than antidromic stimulation. An antibody to L-type calcium channels and nimodipine (20 uM) both prevented the induction of the long-lasting spike depression. These data suggest that a lasting, generalized depression of pyramidal cell excitability, mediated by voltage-dependent calcium channels, can result from large depolarizations.

38.14

BRAIN DNA SYNTHESIS DURING LONG-TERM POTENTIATION OF THE PERFORANT PATH-GRANULE CELL SYNAPSE.

A. Giuditta*, A. Neugebauer*², F. Morelli*², U.A. Gironi Carnevale*, A.G. Sadile³, G. Buzsaki⁴. (SPON: A. Cerbone). Dept. Gen. Environm. Physiol., Univ. Naples; ²Int. Inst. Genet. Biophys., Naples; ³Inst.Hum.Physiol.& Med.Biophys., Univ. Naples, Italy; ⁴Inst. Physiol., Univ. Pècs, Hungary.

Long-term potentiation (LTP) of perforant path-granule cell synapse was adopted as plasticity model to investigate its effect on DNA synthesis in hippocampal and cortical areas of rat brain. Three groups of adult Long-Evans rats were given 50μCi of ³H-thymidine intraventricularly under urethane and received a train of high (HFS: 400Hz) or low frequency (LFS: 0.1Hz) in the perforant bundles, or were not stimulated (CON). Field EPSP and population spike were monitored from dentate gyrus before and 5, 10, 15, 60 min afterwards. DNA synthesis was measured post-hoc by the incorporation of the radioactive precursor into DNA in hippocampal and cortical areas of either side. Discriminant function analyses separated the groups along 2 main axes, explaining 83% (LTP) and 17% (DNA synthesis) of between-group variance. Correlative analyses showed that LFS covaried positively and HFS negatively with field EPSP in the stimulated dentate area, and with population spike in dentate area and frontal cortex of both sides, and in CA3 and CA1 of the stimulated side. The results suggest a modulatory role of LTP on DNA synthesis in hippocampal and functionally related cortical areas.

38.15

INCREASED POSTSYNAPTIC RELEASE AND PRESYNAPTIC ACTIONS OF ARACHIDONIC ACID SUGGEST A RETROGRADE MESSENGER ROLE IN LONG-TERM POTENTIATION.

M.A. Lynch*, M.P. Clements*, K.L. Voss* and T.V.P. Bliss*. (SPON: ENA). National Institute for Medical Research, Mill Hill, London NW7, U.K.

The aims of the present ex vivo study were two-fold: to identify the source of the increased release of arachidonic acid (AA) into push-pull perfusates which is associated with LTP in the dentate gyrus (Lynch, M.A. et al., Neuroscience, 30, No 3, 1989), and to examine the presynaptic actions of AA and its lipoxygenase metabolites. Synaptosomes, and fractions enriched in glia and in postsynaptic densities (PSDs) were prepared from potentiated and control dentate gyrus. A significant increase in liberation of free AA was found in PSDs from potentiated tissue (LTP: 0.87 ±0.20;, control: 0.39±0.10 μmol AA/mg protein, n=6, $p<0.05$); no significant changes were found in membrane-associated fractions from synaptosomes or glia. The increased release of AA is therefore probably postsynaptic in origin. Enzymatic studies suggest that the increase is initiated by enhanced phospholipase A_2 activity and sustained by increased phospholipase C activity. Presynaptically, AA and its 12-lipoxygenase metabolites 12-HETE and 12-HPETE stimulated glutamate release and phosphoinositide turnover in synaptosomes.

38.16

INFLUENCE OF GROWTH FACTORS ON SYNAPTIC PLASTICITY: DIFFERENTIAL EFFECTS OF EGF AND FGF ON LTP IN THE HIPPOCAMPAL SLICE. *H. Terlau* and W. Seifert*
Max-Planck-Institut für biophys. Chem. Department of Neurobiology, Göttingen (F.R.G)

Rat hippocampal slices were perfused either with epidermal growth factor (EGF) at a concentration of 10^{-8}M or fibroblast growth factor (FGF) at a concentration of 10^{-9}M. During extra- and intracellular recordings in the pyramidal cell body layer of the CA_1-region no influence of EGF on the evoked potentials was seen if single or paired pulse stimulation was used. However the presence of EGF in the bath medium lead to an increase in the magnitude of potentiation after tetanic stimulation. This increase was maximal directly after tetanisation but still present 30 min after the tetanus was given (Terlau and Seifert, Brain Research, in press).

Also in the presence of FGF no changes in the population spike amplitude and field EPSP during low frequency stimulation were seen. However there was a little increase in the magnitude of potentiation, which becomes bigger with the time after tetanisation. The increase in the field EPSP slope 2 min after the tetanus was: Control: 155.3±8.2%, FGF: 162.0±8.6%; mean±S.E.M.; not significant. After 30 min the increase was: Control: 128.1±4.3%, FGF: 144.0±5.3%; n=20; $P<0.01$.

These observations show that growth factors with neurotrophic potential like EGF and FGF can modulate synaptic plasticity, but there are clear differences in this modulatory action.

38.17

EFFECTS OF INTERLEUKIN-2 ON LONG-TERM POTENTIATION IN RAT HIPPOCAMPUS.

V. Tancredi, C. Zona, F. Farrelly*, A. Santoni*, F. Eusebi*. Dipt. Med. Sper. Sci. Biochem. Univ. Roma "Tor Vergata" - Dipt. Med. Sper. Univ. L'Aquila, Italy.

The T lymphocyte response to mitogen or antigen results in the secretion of the polipeptide growth factor interleukin (IL-2). Since in the cancer therapy IL-2 subministration causes some neurological side effects, such as memory inpairment, experiments were performed to investigate whether IL-2 may affect the long-term potentiation (LTP) of synaptic transmission that is widely regarded as a candidate substrate for aspects of memory in the CNS. We give here evidence that IL-2 at threshold dose of 1000 U/ml strongly inhibits in a dose-dependent manner, LTP in rat hippocampus. This is possibly related to a post-synaptic IL-2 action since IL-2 did not influence voltage-dependent Na+, K+, and Ca2+ currents in patch-clamped neocortical cultured neurones of the rat, while reduced mean open time of single acetylcholine channels in mouse cultured myotubes. This work is supported by a grant from Fidia.

CHANGES IN THE INPUT/OUTPUT (I/O) PROFILE WHICH ACCOMPANY HIPPOCAMPAL LONG-TERM POTENTIATION (LTP). A. AU* AND L.S. LEUNG (SPON: W.T. BLUME). DEPTS. PHYSIOLOGY AND CLIN. NEUROL. SCI., UNIV. WESTERN ONTARIO, LONDON, CANADA, N6A 5A5.

Population spikes were recorded in the CA1 cell layer following test pulses of varying intensities delivered to the stratum radiatum in the slice preparation. I/O profiles were recorded for 30 minutes prior to and 60 minutes after LTP induced by a patterned burst stimuli. Responses were normalized by the maximal population spike amplitude before LTP.

Low-amplitude baseline responses showed post-tetanic potentiation (PTP at 10 sec) and to a lesser degree LTP (>10 min) while high-amplitude responses showed no PTP although they demonstrated LTP.

	Baseline	10 sec	10 min	30 min	60 min
Percent	0	30 ± 8#	8 ± 3#	7 ± 4	1 ±.1
of	11 ± 1	72 ± 9#	54 ± 8#	38 ±11#	26 ±11
Maximal	45 ± 2	87 ± 6#	78 ± 4#	69 ± 6#	64 ±9#
Baseline	84 ± 1	104± 6#	108± 5#	106± 7#	102±4#
Response	100 ±.5	106± 5	110± 3#	109± 5	112±3#

(# $p<.05$)

The magnitude and time course of both PTP and LTP appear to depend upon the size of the population spike. Supported by MRC and NSERC.

HORMONAL INFLUENCES ON INSECT MOTONEURONS DEVELOPING IN CELL CULTURE. L.Griffin* and R.B. Levine. Arizona Research Labs. Division of Neurobiology, University of Arizona, Tucson, AZ 85721.

In the hawkmoth, Manduca sexta, many larval motoneurons (MNs) persist through metamorphosis to innervate new muscles in the adult. During this process identified thoracic and abdominal MNs undergo substantial changes in their dendritic branching patterns that are known to be under hormonal control. To facilitate the analysis of hormonal influences on MN morphological and biophysical properties, we have developed techniques for following the postembryonic development of identified motoneurons in primary cell culture. The culture conditions were adapted from those devised by Dr. Jon Hayashi (Neuro. Abs.,1989). Neurons were grown in a modified L-15 medium, on glass cover slips that had been coated with laminin and con-A. Thoracic leg MNs were labeled as a population by injecting di-I into several leg muscles early in the fifth larval instar. At various times thereafter the thoracic ganglia were desheathed and dissociated enzymatically. Although the cultures contained many neuronal types, leg MNs were identified after plating by the presence of di-I in their somata, and have been followed for up to four weeks in vitro. Intracellular soma recordings revealed that the MNs had normal resting potentials and were able to generate action potentials upon depolarization. In vivo, thoracic leg MNs undergo dendritic regression at pupation, followed by the growth of new dendrites during the first two weeks of adult development. MN somata isolated from early pupal (P0-P2) ganglia assumed a unipolar, or occasionally bipolar morphology during the first two weeks in culture. In the absence of the steroid 20-hydroxyecdysone (20-HE), the MNs grew one or two long, broad processes. Process outgrowth, especially the extent of fine branching, was enhanced by the addition of 20-HE to the medium in levels similar to those experienced in vivo (1 μg/ml).

AN ECDYSTERONE-REGULATED GENETIC LOCUS IS REQUIRED FOR CNS METAMORPHOSIS IN *DROSOPHILA*. L.L. Restifo and K. White*, Department of Biology, Brandeis University, Waltham, MA 02254.

The *Broad Complex* (*BR-C*) is an ecdysterone-regulated locus which is essential for metamorphosis in *Drosophila*. It consists of at least two distinct functional domains required for development of the adult epidermis (Kiss *et al.*, *Genetics* **188**:247, 1988). We have previously demonstrated that *BR-C* transcripts are expressed in the larval and adult CNS, and that some *BR-C* mutants exhibit abnormalities of CNS reorganization during metamorphosis (Restifo and White, *Soc. Neurosci. Abstr.* **14**:733, 1988). We have now extended this analysis to include mutants representing the several functions encoded at this complex locus. The CNS phenotypes observed in *BR-C* mutants include abnormalities of i) formation of the cervical connective between the brain/subesophageal ganglion and the thoracic ganglion; ii) movement of the subesophageal ganglion into the developing head capsule; iii) rotation of the optic lobes; and iv) expansion of the synaptic neuropil of the dorsal brain. Some *BR-C* mutations are also associated with decrease or absence of the dorsal-ventral muscle class of indirect flight muscles. These morphological abnormalities will be discussed with respect to the genetic organization of the locus. In addition, a molecular analysis of *BR-C* transcription in the CNS will be presented. (Funded by NIH grant NS01259 to LLR.)

REDUCED FERTILITY IN MALE GENETICALLY OBESE ZUCKER RATS IS NOT ASSOCIATED WITH DECREASED NUMBER OF MOTONEURONS IN THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS. J. A. Finkelstein, L. Jasenak*, W. Lee* and P. C. Doherty. Dept. of Anatomy, Northeastern Ohio Univ. Col. Med., Rootstown, OH 44272.

Genetically obese Zucker rats are known to have impaired reproductive function. This impairment has been studied in obese and lean male Zucker rats by comparing 1) ability to impregnate female rats, 2) sexual organ weights and 3) number of motoneurons in the sexually dimorphic spinal nucleus of the bulbocavernosus (SNB). Nineteen obese (fa/fa) and 9 age-matched lean (Fa/-) male rats were each placed with two lean female rats. Sperm was seen in vaginal smears from all females, regardless of whether or not pregnancy occurred. Females were removed when pregnant or at the end of forty days. While all lean males induced pregnancy, only nine of the nineteen obese males were able to sire litters. Testes weights did not differ between obese and lean rats, but weights of both the seminal vesicles and the bulbocavernosus muscle complex were lower in the group of obese rats as a whole. On these measures, however, obese males whose mating resulted in successful pregnancy did not differ from those who were not successful. Number of motoneurons in the SNB (uncorrected counts) was not associated with increased fertility. These data indicate that no single morphological parameter correlates with the ability of an obese male rat to induce pregnancy. ANDROGEN METABOLITES MASCULINIZE MOTONEURON NUMBER IN A SEXUALLY DIMORPHIC RAT SPINAL NUCLEUS. L.A. Goldstein and D.R. Sengelaub. Program in Neural Science, Dept. of Psychology, Indiana University, Bloomington, IN 47405.

The development of masculine motoneuron number in the sexually dimorphic spinal nucleus of the bulbocavernosus (SNB) in rats is determined by an androgen-regulated cell loss. Females treated with testosterone propionate perinatally have a masculine SNB, but treatment with the metabolite dihydrotestosterone is ineffective. To determine if masculinization of the SNB involves the conversion of testosterone into both dihydrotestosterone and estrogen, we compared motoneuron numbers in females treated with estrogen alone or in combination with dihydrotestosterone.

Timed-pregnant female rats were injected with estradiol benzoate (EB, 100 μg) or EB and dihydrotestosterone propionate (DHTP, 2 mg) on embryonic days (E) 16-22. Pups were cross-fostered and injected on the day of birth [postnatal day (P) 1], P3 and P5. At E18, E20, E22, P4 and P10 counts of SNB motoneurons were made in hormone-treated females and compared with counts from normal animals.

At E18, counts of SNB motoneurons were low in all groups and increased through E22. At E22, SNB motoneuron numbers in both EB and EB+DHTP females were similar to that of normal females, but significantly lower than that of normal males. Between E22 and P10, cell numbers declined in all groups. This decline was greatest in EB and normal females (52-67%) who did not differ at P10 (79 *vs.* 72 motoneurons). Motoneuron loss in normal males was much less (31%), resulting in significantly more SNB motoneurons at P10 (215). Cell loss after E22 in EB+DHTP females was only 14%; by P10 the number of SNB motoneurons was not different from that of normal males (199). These data suggest that both metabolites can act synergistically to masculinize SNB development. (Supported by NIH NS24877)

TESTOSTERONE MASCULINIZES THE DEVELOPMENT OF THE SUBSTANCE P INNERVATION OF THE MEDIAL NUCLEUS OF THE AMYGDALA AND BED NUCLEUS OF THE STRIA TERMINALIS. C.W. Malsbury & S.A. Brown*. Dept. Psychology and Division of Basic Medical Sciences, Memorial U. of Newfoundland, St. John's, NF, Canada, A1B 3X9.

Our laboratory has previously described marked sex differences in the substance P (SP) innervation of the most posterior divisions of both the medial nuc. of the amygdala (MePD) and medial bed nuc. (BSTMP) in the adult rat brain. We have now examined the effects of early postnatal testosterone exposure. Four groups (n=4/group) were compared. Males were either sham-operated (SM) or gonadectomized (GM) on day 1, while females were injected sc with either vehicle (SF) or 500 ug testosterone propionate (TF) on days 2 and 5. All animals were killed at day 26. Alternate sections were either stained with cresyl violet or for SP using the PAP method. The areas of dense SP fiber staining and of relevant cell groups (cresyl) were measured. Marked sex differences were seen in the MePD and BSTMP before puberty (day 26). Neonatal testosterone injections masculinized SP staining in females, while castration of newborn males prevented the development of the masculine pattern of staining, eg. means of the total areas (mm^2) of SP staining in MePD were: SM, 4.90 > TF, 4.22 > GM, 3.04 = SF, 2.95.

39.6

ONTOGENY OF ENKEPHALIN IMMUNOREACTIVITY IN THE SEXUALLY DIMORPHIC MEDIAL PREOPTIC NUCLEUS. R.P. Hammer, Jr., D. Yoshishige* and S.A. Tobet (SPON: H.L. Gillary). Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. Med., Honolulu, HI 96822 and Dept. Biochem. and Developmental Neurobiol., E.K. Shriver Ctr., Waltham, MA 02254.

In the adult rat medial preoptic nucleus (MPN), sex differences in the density and distribution of enkephalin-immunoreactive (ENK-IR) fibers have been reported (Simerly, et al., *J. Comp. Neurol.*, 276: 442). In the present study we examined the ontogeny of ENK-IR fibers during the early postnatal period to determine when, in relation to the formation of cytoarchitectonic sexual dimorphisms, opioid peptide immunoreactivity becomes sexually dimorphic in the MPN.

Rats of different postnatal ages through P12 were perfused with neutral buffered 4% paraformaldehyde, brains were postfixed in 5% acrolein and sectioned by Vibratome prior to processing with leu-enkephalin antibody (Immunonuclear Corp.) using the ABC technique with 3, 3'-diaminobenzidine as substrate. The most striking ontogenetic change in ENK-IR expression was the rapid increase in MPN fiber density, which achieved the adult pattern of higher density in lateral MPN than medial MPN earlier in the male. In contrast, lateral septum ENK-IR fiber density transforms from dense and unpatterned at P4 to the characteristic pericellular adult pattern in both sexes by P12. At the earliest ages, ENK-IR fiber density in the lateral preoptic area is greater than in MPN, but this changes with age in both sexes. Sexual dimorphism of MPN morphology develops in the first postnatal week (Hammer and Jacobson, *Int. J. Devel. Neurosci.*, 2: 77), before a sex difference in MPN ENK-IR is present.

We conclude that sex differences in MPN cytoarchitectonics precede sexual differentiation of MPN ENK-IR. Therefore, factors within the MPN may influence the ontogeny of MPN enkephalinergic fiber distribution, rather than the converse. CORPUS CALLOSUM: OVARIAN HORMONES AND FEMINIZATION IN THE RAT.
R. H. Fitch*, P. E. Cowell*, L. M. Schrott* and V. H. Denenberg. (SPON: E. Thoman). Biobehavioral Sciences Graduate Program , U-154, Univ. of CT, Storrs, CT 06269-4154

The rat's corpus callosum (CC) is sexually dimorphic with the male's being larger (Berrebi et al., Br. Res., 1988, 438:216-224). This sex difference appears to depend in part on the neonatal presence of testosterone in the male, and estrogen in the female (Fitch et al., ms. in preparation). To further investigate the possibility that neonatal hormones act in the development of the female's CC, rats were ovariectomized (Ovx) on postnatal days 8, 12, and 16. Female littermates received 1 mg of testosterone propionate (TP) on corresponding days, while others received sham surgery. Male littermates were also retained for comparison. All animals were handled daily from birth until weaning. Animals were sacrificed at 110 days and a mid-sagittal section of the callosum was obtained. For controls, the male CC was larger. The time of Ovx (Day 8, 12 or 16) was not significant, and thus Ovx data were pooled across days. Ovx acted to enlarge the CC of females compared to controls. Ovx female values were equal to or greater than male values for most CC measures. Brain weight was significantly larger for Ovx females, although still significantly less than for control males. TP had no effect on any CC variable when administered on Days 8, 12 or 16.

We conclude that ovarian hormones - presumably estrogen - act to feminize the callosa of females, and that the removal of estrogen from females results in defeminization. Furthermore, the fact that ovariectomy was effective as late as Day 16 while TP treatment on Day 8 or later had no effect suggests that masculinization and feminization of this structure may constitute separate processes with distinct critical periods.

39.8

CORPUS CALLOSUM: INTERACTIVE EFFECTS OF INFANTILE HANDLING AND TESTOSTERONE IN THE FEMALE RAT. V. H. Denenberg, R. H. Fitch*, P. E. Cowell*, L. M. Schrott* and N. S. Waters*. Biobehavioral Sciences Graduate Program, U-154, Univ. CT., Storrs, CT 06269-4154.

In the rat the male's corpus callosum (CC) is larger than the female's. Further, neonatal handling enhances this sex difference (Berrebi et al., Br. Res., 1988, 438:216-224). More recently, 1 mg testosterone propionate (TP) given on Day 4 of life increased the female's CC to the size of the male. These animals had been handled in infancy to maximize the base-line sex difference (Fitch et al., ms. in preparation). In the current set of experiments the effects of handling (H) vs nonhandling (NH) were studied. In Experiment 1 the Fitch et al. study was replicated using NH animals. Within a litter two males were castrated on Day 1 and two received sham surgery; two females received 1 mg TP on Day 4 and two received an oil injection. At 110 days a mid-sagittal section of the CC was obtained. In controls the CC was larger in males. Neither castration nor TP treatment had any effect on any CC parameter. Experiment 2 included both H and NH rats. Surgery and hormone regimens were the same as in Experiment 1. H pups were placed for 3 min into cans containing shavings on Days 1-20. NH pups were undisturbed until weaned at 21 days. A mid-sagittal section of the CC was obtained at 110 days. Within the H treatment, control males and TP females had a larger CC than control females while castration of males had no effect. In the NH group, the CCs of control males were marginally larger than those of females; neither TP treatment to females nor castration of males affected CC size.

In a series of three experiments TP on Day 4 was effective in masculinizing the CC of handled , but not nonhandled, female rats when measured in adulthood. This probably involves an interaction of adrenal and gonadal hormones.

39.9

REGIONAL SPECIFICITY OF SEX DIFFERENCES IN THE RAT NEOCORTEX. Silvia N. M. Reid & Janice M. Juraska. Dept. of Psych. and Neural & Behavioral Biology Program, Univ. of Ill., Champaign, IL 61820.

The cerebral cortex has both a regional and laminar organization. While several studies have indicated that the male rat cortex is thicker than that of the female, it is not known whether every cortical region or layer is dimorphic.

Coronal frozen sections (30-50 microns) were obtained from brains of paraformaldehyde perfused 90 day old Long-Evans hooded rats (10 littermate pairs; socially housed) and stained with methylene blue-Azure II. Differences in the cortical thickness (male>female) were found in all four major regions (16 of 25 measures). Sex differences in layer thickness (male>female) showed regional specificity. Sex differences were found in layers 2-3 (6.9%) and 5 (9.1%) of the primary motor area, in layer 6 (8.9%) of the forelimb part of the sensory-motor area, and in layers 2-3 (8.0%) and 6 (6.6%) of the binocular portion of the primary visual area. No sex difference was found in the monocular area of the primary visual cortex, and no sex-related left-right asymmetry was detected in any measurement. We will be examining whether there are sex differences at the cellular level that underlie these laminar dimorphisms.

39.10

THE DISTRIBUTION OF THE CALLOSAL PROJECTION NEURONS IN THE VISUAL CORTEX OF MALE AND FEMALE RATS. P. Seymoure*, J. R. Kopcik, S. K. Schneider*, J. H. Y. Kim, and J. M. Juraska. Dept. of Psychology and Neural and Behavioral Biology Program, University of Illinois, Champaign, IL 61820.

In our previous research female Long-Evans rats had more axons than male rats in the splenium of the corpus callosum (Juraska & Kopcik, Br.Res., 450, 1, 1988). In the present study we hoped to determine if the sex differences in axon number might be reflected in different patterns of callosal projection neurons. Following extensive injections of horseradish peroxidase (HRP) in the posterior cortex of rats at 60 days of age, we examined the tangential pattern of labeled projection neurons in the visual cortex. The area 17/18a border was computer reconstructed from serial-sections of five male and female pairs matched for equivalent HRP labeling. While variability in projection neurons at this border was found between animals, qualitative comparisons failed to reveal any differences between the sexes. Quantitative measures of length and width did not demonstrate any significant differences. Although no sex differences were found in the distribution of the projection neurons at the area 17/18a border, this study does not preclude the possibility of differences in the density of projection neurons.

ESTROGEN BIOSYNTHESIS IN THE DEVELOPING RAT BRAIN: REGIONAL AND TEMPORAL ASPECTS Neil J. MacLusky and C.D. Toran-Allerand Div. Reprod. Science, University of Toronto Medical School, Ontario, Canada, and Center for Reproductive Sciences, College of Physicians and Surgeons, Columbia University, New York, NY.10032

Previous studies in mice (MacLusky *et al* Soc. Neurosci 1986 p.1217) and rhesus monkeys (Clark *et al*, Endo 123:932, 1988) have suggested that the cerebral cortex is a target for developmental effects of locally-synthesized estrogens. The present studies were performed to re-evaluate the regional distribution and ontogeny of aromatase in the brain of the rat, which has been reported to lack cortical aromatase activity. METHODS: **[I]** Explant cultures from the brains of newborn rats were incubated for 72h with [1,2,6,7-^{3}H] androstenedione (A). Tritium-labelled [^{3}H] A metabolites were separated by TLC. **[II]** Aromatase activity was measured by tritium release from [1β-^{3}H] A (Roselli & Resko, Endo. 114:192, 1984) in tissues from rats killed at intervals over the first 25 days of postnatal life. RESULTS: **[I]** Estrogen formation was detectable in cultures from the preoptic area (POA), septum (SEPT), hippocampus (HIPP), mid-brain central grey (MB) and anterior cingulate cortex (ACCTX) but not in posterior cingulate cortex, olfactory bulb or cerebellum. Activity in the ACCTX was much lower than in the other aromatase positive structures (<1/10 that in HIPP; <1/50 that in POA). **[II]** At birth, aromatase activity was detectable in all brain regions studied (POA, mediobasal hypothalamus, amygdala, HIPP, MB and ACCTX). Activity/mg protein declined rapidly during postnatal development, except for HIPP, where it remained stable until postnatal day 10, then declined. These results demonstrate that aromatase activity is widely distributed in the neonatal rat brain, including regions of the cerebral cortex. However, the relatively low concentrations of cortical aromatase in the rat, as compared to previous findings in other species, suggest that there may be significant species differences in the role played by local estrogen biosynthesis in cerebral cortical development (Supported by NIH grant HD08364).

39.12

EFFECT OF SEX, INTRAUTERINE POSITION, AND ANDROGEN MANIPULATION ON THE DEVELOPMENT OF BRAIN AROMATASE ACTIVITY IN FETAL FERRETS. R. W. Krohmer and M. J. Baum. Boston University, Department of Biology, 2 Cummington St., Boston, MA 02215.

Experiments were conducted to explore the possible relationship between testicular androgen secretion and the development of brain aromatase activity in fetal ferrets. Aromatase activity in the preoptic + medial basal hypothalamus and temporal lobe was similar in fetuses of both sexes between embryonic days 26 and 36 even though whole body androgen content was invariably higher in males than females. Whole body androgen content was significantly higher in females located caudally (downstream) from two or more as opposed to 0 or 1 males in the same uterine horn; nevertheless their brain aromatase activity was similar. Finally, maternal treatment with either the androgen receptor antagonist Flutamide or 5α-dihydrotestosterone propionate beginning on gestational day 24 did not affect brain aromatase activity in fetal offspring of either sex, delivered on embryonic day 34. Previous studies suggest that the biosynthesis of estrogen in the fetal ferret brain is normally greater in males than females. The present results suggest that this sex difference results primarily from increased androgenic substrate being available to non-saturated aromatizing enzymes and not from an androgen-dependent activation of aromatase. AROMATASE ACTIVITY (AA) IN THE HYPOTHALAMIC/PREOPTIC AREA OF NEONATAL MALE AND FEMALE RATS: TESTOSTERONE (T) AND ETHANOL (EtOH) EXPOSURE. P.K. Rudeen and S. Paredez*. Dept of Anatomy, University of Missouri School of Medicine, Columbia, MO 65212

Neuronal AA is critical to masculinization of the rodent central nervous system. The effects of EtOH and T on AA in neonatal male and female rats were determined by the measurement of stereospecific [^{3}H]-water formation from [^{3}H]-1ß-androstenedione. Neonatal male rats exposed to EtOH showed only a modest increase in AA ($p<0.05$), but were not affected by the presence of T either acutely (24h) or chronically (6 days). AA was lower on postnatal day one in female rats (235 fmol/mg prot/h) compared to AA observed in male rats (387 fmol/mg prot/h). EtOH exposure had no observable effect on the basal level of AA in female rats (235 vs 220 fmol/mg prot/h). Furthermore, acute exposure to T failed to induce AA in the neonatal female rats (235 vs 245 fmol/mg prot/hr). The data indicate that AA is greater in male than in female neonatal rats, but that neither sex significantly responds to either T or EtOH (Supported by grants AA05893 and AA00107).

39.14

TRANSIENT ELEVATION OF ESTROGEN RECEPTORS IN THE NEONATAL RAT HIPPOCAMPUS. J.A. O'Keefe* & R.J. Handa*(SPON: A.J. Castro) Dept. of Anatomy, Loyola Univ., Maywood IL 60153

The presence of sex differences in hippocampal morphology and function suggests that this brain region may be sensitive to the organizational actions of gonadal steroids. Therefore, we examined the postnatal development of estrogen receptors (ER) in the rat hippocampus. ER was measured by the in vitro cytosolic binding of ^{3}H-estradiol. Radioinert R2858 was used to determine nonspecific binding. Hippocampal ER concentrations increased from birth through postnatal day (PND) 4 when levels peaked (10.05 ± 1.2 fmol/mg protein); these were maintained through PND-7 (9.45 ± 1.4) and declined thereafter to low levels characteristic of the adult (2.05 ± .35). This ontogenic profile is similar to that found in other cortical regions but is distinct from that observed in the hypothalamus, where ER levels remain high in the adult. Saturation analysis of PND-7 hippocampal cytosols demonstrated a single, high affinity binding site (Kd: $0.46 \pm 0.13 \times 10^{-9}$ M). ^{3}H-E binding was specific in that it was displaced by R2858, DES and E but not by non-estrogenic steroids. Significantly greater ER levels were found in hippocampal nuclear extracts from DES-treated PND-7 animals compared to controls (73.40 ± 15.62 vs. 3.14 ± 2.16 fmol/mg DNA; $p < .01$). The presence of elevated hippocampal ER levels during the perinatal critical period and evidence of functional transformation to the DNA binding state after DES treatment suggests that the hippocampus is a potential substrate for estrogen-mediated organizational events.

SPROUTING AND SPROUTING MECHANISMS I

40.1

CLIMBING FIBRE COLLATERAL SPROUTING AND FORMATION OF NEW SYNAPSES IN THE CEREBELLUM OF THE ADULT RAT. F. Rossi[1]*, L. Wiklund[2]*, J.J.L. van der Want[3]* and P. Strata[1]. [1]Dept. of Human Anat. and Physiol., Univ. of Turin, I-10125 Turin, Italy; [2]Lab. Physiol. Nerv., C.N.R.S., F-91190 Gif-sur-Yvette, France; [3]The Netherlands Ophth. Res. Inst., NL-1100 AC Amsterdam, The Netherlands.

The present study was aimed at demonstrating that climbing fibres (CF), survived to a subtotal lesion of the inferior olive (IO), are able to emit collateral sprouts and reinnervate Purkinje cells (PC). IO was lesioned by means of 3-acetylpyridine (62-70 mg/kg i.p.) in adult Wistar rats (b.w. 120-250 g). The animals were killed 3 days to 6 months after the lesion. Surviving CF were visualized by means of the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L). At 7 days after the lesion short sprouts, emitted by CF terminal arbours, end in small terminal plexuses made of branchlets and varicosities. From 1 month on, thick branches, up to some hundreds µm long, give rise to several new terminal plexuses, surrounding PC dendrites. At longer survival times, single CF form clusters of new terminal plexuses, extended for several hundreds µm in both the longitudinal and the sagittal plane of the folium. The ultrastructural study showed new synapses formed by labeled CF on spines projecting from major PC dendrites. These results show that CF are capable of remarkable plastic changes leading to the reinnervation of PC.

40.2

A MOLECULAR MECHANISM FOR THE "TRACING CIRCUIT" MODEL FOR HUMAN MEMORY: ACTIVITY-DEPENDENT RELEASE OF ATP, SUBSTRATE OF ECTO-PROTEIN KINASE, CAN STABILIZE THE IN-CIRCUIT SYNAPSES BY SPROUTING. Y. Kuroda, Dept.of Neurochem., Tokyo Metropolitan Institute for Neurosciences, Fuchu-shi, Tokyo 183, Japan.

A "tracing circuit" model has been proposed for the human memory process (Kuroda,Y.:Neurochem. Intern. 14, 309, 1989). In the model, a "tracing circuit" of neurons corresponding to human memory is established by a mechanism in which impulses originating from sensory organ(s) make closed circuits, then repeatedly trace the connecting circuit or pathways. At every synapse in the "tracing circuit", LTP should occur. With a slower time course, dynamic changes of synaptic contacts follow: activity-dependent elimination of ex-circuit synapses and resulting sprouting of in-circuit axonal terminals, preserving the circuit pattern for the order of years. To explore molecular mechanism of sprouting, we have developed an experimental system by which we can quantitatively observe in vitro synapse formation of cerebral cortical neurons by multi-site Ca^{2+} fluorometry(Muramoto, K.et al.:Proc.Japan Acad.,64B, 319, 1988). Rat cerebral cortical neurons make glutamatergic synapses on each other after 7 days in culture. During the culture, continuous application of a protein kinase inhibitor(K-252b), which does not permeate the cell membrane, appeared to block the synapse formation in a dose-dependent manner. This result suggests that a specific phosphorylation of surface proteins on synaptic membrane by an ecto-protein kinase is involved in formation and/or stabilization of immature synapses, and can be triggered by a supply of substrate ATP released from tetanically stimulated axon terminals in the "tracing circuits", but not from terminals out of the circuit.

40.3

IPSILATERAL INTERPOSITORUBRAL PROJECTION IN THE RAT AND ITS MEANING TO PLASTICITY. W.-J. Song*, Y. Nagisa* and F. Murakami, Dept. of Biophysical Eng., Fac. of Eng. Sci., Osaka University, Toyonaka 560, JAPAN

Lesion-induced aberrant projections observed in the CNS may be interpreted as proliferations of already present sparse projections. In the interpositorubral (IN-RN) system, hemicerebellectomy induces ipsilateral IN-RN projection only in neonatal animals. Following the interpretation, this age-at-lesion effect would mean disappearance of a sparse aberrant ipsilateral IN-RN projection which exists in neonatal animals. However, evidence suggesting the existence of the projection in adult rats has been provided by a degeneration study (Castro, 1978). Since degeneration methods are not suitable for demonstrating sparse projections, we attempted to verify the projection in adult rats with the PHA-L method. Injection of PHA-L into the nucleus interpositus resulted in labeling of terminals in ipsilateral red nucleus, indicating the existence of ipsilateral IN-RN projection. The present study suggests factors other than disappearance of neonatal aberrant projections are involved in age-at-lesion effect on post-lesion plasticity.

40.4

INCREASED DENSITY AND ALTERED MORPHOLOGY OF HISTAMINE-CONTAINING NERVE FIBERS IN KAINIC ACID-INDUCED BRAIN LESIONS. P. Panula, M.S. Airaksinen, L. Kivipelto and A. Willman*.

To elucidate the role of histamine in the CNS, small injections of kainic acid (KA) were made in different parts of the rat brain selected on the basis of their histamine-immunoreactive (HA-ir) innervation pattern. In some cases, similar injection of saline was made on the contralateral side. After two or six weeks, the rats were perfused with 4% carbodiimide and processed for histamine-immunocytochemistry.

A clear increase in the density of HA-ir nerve fibers was observed in the cerebral cortex, neostriatum, amygdala and ventral pallidum (= all KA injection sites) in comparison to the control side. The lesion-induced fibers formed dense networks and contained numerous varicosities of various size. The increase was obvious after two weeks, and a further increase in the number of fibers was evident after six weeks. The results suggest that KA lesions are associated with accumulation of histamine in pre-existing fibers in the lesions, or that sprouting of histaminergic fibers occurs even in those areas of the brain where these fibers are not numerous in normal brain. HA-ir nerve fibers are also found in the brain during fetal development (Auvinen and Panula, J. Comp. Neurol. 276:289,1988). Histaminergic mechanisms may, therefore, be involved in the development of the brain. It is possible that these mechanisms are activated during regenerative processes.

40.5

MORPHOLOGY OF INDIVIDUAL VISUAL CALLOSAL AXONS IN NORMAL AND EYELESS HAMSTERS AS DEMONSTRATED BY ANTEROGRADE TRACING WITH PHASEOLUS VULGARIS LEUCO-AGGLUTININ. S.E. Fish, R.D. Mooney, C. Bennett-Clarke and R.W. Rhoades. Depts. of Anatomy, Medical College of Ohio, Toledo, OH 43699 and Marshall University School of Medicine, Huntington, WV 25704.

Phaseolus vulgaris leuco-agglutininwas used to label visual callosal axons in normal, bilaterally enucleated, and congenitally anophthalmic hamsters. Callosal axons in the area 17-18a border region of normal hamsters left the white matter and followed a trajectory that was usually orthogonal to the cortical surface. They gave off short branches and had swellings indicative of boutons en passant in layers V and VI. A smaller number of fibers did collateralize extensively in these laminae. Most callosal axons extended through lamina IV with little or no branching, but they did give off en passant swellings in this layer. Callosal fibers collateralized fairly extensively and gave off both en passant and terminal swellings in layers II and III. In layer I, callosal axons paralleled the pial surface, branched only occasionally, and gave off both en passant and terminal boutons. Some callosal fibers extended into lamina VI and lowermost layer V of medial area 17. They left the white matter near the 17-18a border, angled medially, branched very rarely, and had swellings indicative of boutons en passant. In both binocularly enucleated and congenitally anophthalmic hamsters, callosal fibers were visible in the supragranular layers of medial area 17. There was no qualitative difference between the morphological characteristics of these axons and callosal fibers in normal hamsters. It thus appears that expanded visual callosal projection in experimentally manipulated and anophthalmic hamsters is the result of axons with normal morphological characteristics occupying cortical regions that they do not in normal animals.

40.6

INDUCTION OF CHOLINERGIC FUNCTION IN RAT SYMPATHETIC NEURONS CO-CULTURED WITH HIPPOCAMPAL CELLS. MD Johnson* and DD Potter Dept. Neurobiology, Harvard Medical School, Boston, MA 02115

Perivascular sympathetic axons from the superior cervical ganglion sprout into the parenchyma of the rat hippocampal formation after fimbria lesions; this sprouting may result from loss of the cholinergic input to the hippocampal formation from the basal forebrain (review: Crutcher, 1987, Brain Res. Rev. 12). Given evidence that denervated cardiac cells in culture produce a "conditioned medium factor" that can induce cholinergic status in initially noradrenergic postnatal sympathetic neurons in culture (e.g. Patterson, 1978, Ann. Rev. Neurosci. 1), it was of interest to see if cholinergically-denervated cells of the hippocampal formation induce not only sprouting but also cholinergic function in sympathetic neurons. Induction of cholinergic function can be tested in culture. Cells from the hippocampal formation and superior cervical ganglion, dissociated from Long Evans rats 0-6 days old, were co-microcultured for 6-44 days in medium containing NGF. In 37 co-microcultures there were neurons whose appearance and electrical behavior were characteristic of cultured sympathetic neurons; approximately 70% (60/86) of these exerted an excitatory synaptic effect on themselves or another neuron that appeared sympathetic. In all 44 trials in which the ganglionic blocker hexamethonium was used ($\leq 10^{-3}$M), the excitatory effect was strongly reduced or eliminated. It will be of interest to determine which cells are responsible for this induction of cholinergic function in the sympathetic neurons. Supported by NSO2253.

40.7

ROLE OF CYCLIC AMP IN INSULIN AND INSULIN-LIKE GROWTH FACTOR I DIRECTED NEURITE OUTGROWTH IN SH-SY5Y CELLS. C. Wang*, B. Wible*, K. Angelides* and D.N. Ishii (SPON: J. Masken) Physiology Dept., Colorado State Univ., Ft. Collins, CO 80523; Physiology and Molecular Biophysics Dept., Baylor College of Medicine, Houston, TX 77030.

We previously showed that insulin and insulin-like growth factors (IGFs) selectively increase the relative abundance of 68 kD and 170 kD neurofilament (NF) mRNAs which precedes neurite formation in cultured human neuroblastoma SH-SY5Y cells. Others have shown that cAMP can increase neurite growth. In the present study, the possibility that cAMP might regulate neurite growth through effects on NF gene expression was examined on Northern blots. Dibutyryl cAMP increased both 68 and 170 kD NF mRNA, but not histone 3.3 mRNA. Together with insulin, dibutyryl cAMP was additive, and theophylline and caffeine were either additive or synergistic. Dibutyryl cAMP and theophylline seemed additive with IGF-I. These studies suggest cAMP may mediate the capacity of insulin and IGFs to increase 68 and 170 kD NF mRNAs. (Supported by NIH grant RO1 NS24327).

40.8

INSULIN-LIKE GROWTH FACTORS INDUCE NERVE SPROUTING IN ADULT MOUSE MUSCLE. Caroni, P. and Grandes, P.* Brain Research Institute, University of Zurich, August-Forel-Str. 1, CH-8029 Zurich/Switzerland

Partial denervation or paralysis of mammalian skeletal muscle results in massive sprouting from intact neighboring motoneurons, a reaction which might initiate reinnervation. Such intramuscular sprouting has been shown to be due to a diffusible activity released by the inactive muscle fibers. IGF-2 has been shown to promote sprouting of sensory neurons in vitro. In addition, IGF-2 mRNA in muscle correlates with neurite growth phases. A possible direct involvement of IGFs in motoneuron sprouting was therefore investigated. The following finding are interpreted as being consistent with a direct physiological role of IGFs in intramuscular sprouting: 1.) rapid and massive stimulation of neurite growth in vitro from purified motoneurons by IGFs; half-maximal effect by 0.2 nM IGF-2; 2.) direct high-affinity and specific binding of IGFs by the fine processes of motoneurons in vitro (identified by retrograde labeling); 3.) induction of intramuscular sprouting in intact adult mouse gluteus muscle by non-lesioning subcutaneous injections of low doses of IGFs. Additional reactions in IGF-injected adult muscle included: 1.) enhanced GAP 43 levels in intramuscular nerves; 2.) stimulation of peanut agglutinin binding sites; 3.) no changes in N-CAM nor J1 immunoreactivity; 4.) moderate capillary growth.

RECOVERY OF HIPPOCAMPAL SEROTONIN CONTENT AFTER MEDIAN RAPHE LESION. G.L. Marshall* and J.H. Haring. (SPON: J. Arends). Dept. of Anatomy & Neurobiology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Six wks after lesions of the median raphe (MRN), an apparent proliferation of serotonergic (5HT) axons is seen in the area dentata using immunocytochemistry. The purpose of this study was to measure changes in hippocampal 5HT levels by HPLC and 5HT terminal density by high affinity uptake to see if axon proliferation was actually induced by MRN lesion or if 5HT synthesis was merely increased without sprouting.

Adult male rats (250-300g) received a MRN injection of 5,7DHT (3µg in 250nl artificial CSF) and were studied 2 and 6 wks later. Rats injected with vehicle served as controls. Each hippocampus was cut into 300µm slices perpendicular to the septotemporal axis for the biochemical analyses. Two wks after MRN lesion, depletions of hippocampal 5HT ranging from 80-92% were observed. Histological assessment of lesion sites showed that the residual 5HT represented not only dorsal raphe projections but also spared MRN neurons. The projections of these spared neurons to the hippocampus was confirmed in similar lesion cases by retrograde tracing. Six wks after lesion, 5HT levels of 66-82% of normal values have been observed. Uptakes indicate that terminal density changes generally parallel changes in hippocampal 5HT content. These observations suggest that axon sprouting contributes to the recovery of 5HT innervation in the hippocampus after MRN lesion. Support: NS25752.

41.1

TEMPORALLY REGULATED CHANGES IN ALPHA$_1$-TUBULIN AND APOLIPOPROTEIN E mRNA's IN THE DENTATE GYRUS FOLLOWING ENTORHINAL CORTEX LESION. M. A. Hess, J. Poirier,* P. C. May, and C. E. Finch. Andrus Gerontology Center, Dept. Biological Sciences, USC, Los Angeles, CA 90089. We sought to identify differentially expressed mRNA's underlying the morphological changes that occur after deafferentation of the hippocampus by entorhinal cortex lesioning. Male Fischer 344 Rats underwent bilateral, electrolytic lesions of the entorhinal cortex. At 14 days post lesion the hippocampi were removed and poly A + RNA was isolated. A cDNA library was subsequently constructed and screened for clones of differentially expressed mRNA's. We have now identified 2 such clones by sequence analysis; alpha$_1$-tubulin, a microtubule subunit protein and apolipoprotein E, a protein involved in cholesterol transport. Northern blots of hippocampal RNA isolated 2, 6, 14, and 30 days post lesion showed a differential time course of induction between the two mRNA's. Alpha$_1$-tubulin mRNA prevalence was maximal at 2 and 6 days, returning to control levels by 30 days. Apolipoprotein E mRNA was highest at 6 days and returned to control levels by 30 days. Preliminary In situ hybridization studies localized alpha$_1$-tubulin mRNA to CA1, CA3, and CA4 neurons with intense labelling of hilar neurons adjacent to the granule layer. Increased apolipoprotein E mRNA was detected predominantly in astrocytes of the outer molecular layer of the dentate gyrus at 6 days post lesion. These results suggest differential temporal regulation of neuronal and astrocyte specific mRNA's and a possible role for astrocytes in membrane remodelling and subsequent synaptogenesis. Supported by the John D. and Catherine T. 41.2

AGE-RELATED CHANGES IN NEURONAL PLASTICITY AND FUNCTIONAL RECOVERY FOLLOWING PARTIAL DENERVATION OF A TARGET G.A.Kuchel*[1,2] and R.E.Zigmond[1] (SPON:M.S.Albert) Dept. Biol. Chem. & Mol. Pharm.[1], Division on Aging[2], Harvard Medical School, Boston, MA 02115

The activity of the rat pineal gland enzyme N-acetyltransferase (NAT), exhibits a dramatic circadian rhythm. Increased NAT activity at night is dependent on stimulation of the gland by its sympathetic innervation which reaches the gland via the two internal carotid nerves (ICN). Specific neuronal ^{3}H-norepinephrine (NE) uptake was measured in homogenates of this tissue and utilized as an index of its innervation. Studies were conducted on 3,9,15 and 24 month old male F344 rats. Surgical lesion of the right ICN resulted in an approximately 50% reduction in ^{3}H-NE uptake compared to controls in all age groups when examined 15 days after surgery. Ten days after surgery, ^{3}H-NE uptake was similar to control values in both 3 and 9 month old animals. At the same time point, ^{3}H-NE uptake remained at 49% and 45% of the sham values in 15 and 24 month old aged animals respectively. We have previously shown that unilateral denervation results in impaired NAT function the first night, followed by a rapid recovery by the second night after surgery. While 3 month old animals exhibited full nighttime NAT activity 10 days after unilateral denervation (114% of control), 24 month old lesioned animals showed somewhat lower NAT activity (78% of control).

These data demonstrate a dramatic failure of collateral sprouting following partial denervation in aged animals. Further studies are required to determine the functional consequences of this age-related deficit for the recovery of function after partial denervation. (NS17512, MH00162, the MacArthur Foundation Program on Successful Aging and a fellowship from the Brookdale Foundation[2])

41.3

COLCHICINE-INDUCED CHOLINERGIC DENERVATION OF THE HIPPOCAMPUS ELICITS SYMPATHETIC INGROWTH. S.R. Ginn, G.W. Lanford and G.M. Peterson. Department of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858-4354.

It has been demonstrated that sympathetic neurons from the peripheral nervous system will invade the hippocampus following destruction of its septal inputs. It is thought that this is due to the loss of cholinergic innervation since the medial septum-diagonal band complex (MSDB) provides the major source of cholinergic fibers projecting to the hippocampus. However, non-cholinergic (e.g., GABAergic) neurons also arise in the MSDB and project to the hippocampus. Thus, the role of cholinergic denervation in sympatho-hippocampal sprouting cannot be directly tested by non-specific lesion techniques. Colchicine, a plant alkaloid that blocks tubulin transport, has previously been demonstrated to be specifically toxic to cholinergic neurons in the medial septum. We have injected colchicine into the lateral ventricles of female Sprague-Dawley rats (10 μg in 2.5 μl 0.9% saline). Following a survival period of one, two, or three weeks the rats were killed by transcardiac aldehyde perfusion, and four sets of 40 μm thick adjacent sections were cut through the MSDB and the hippocampus. Septal sections were stained with thionin, acetylcholinesterase (AChE), choline acetyltransferase (ChAT) and nerve growth factor receptor (using the monoclonal antibody 192-IgG). Hippocampal sections were similarly stained except that dopamine-β-hydroxlase (DβH) replaced ChAT. Colchicine toxicity was demonstrated by a decrease in the number of ChAT and 192 IgG-immunoreactive (-ir) neurons in the MS, and a decrease in AChE-positive fibers in the hippocampus. Coarse, branched DβH-ir fibers were observed in CA3 and the dentate gyrus. Morphologically similar fibers were immunoreactive for 192-IgG, suggesting that the DβH-ir fibers were of peripheral origin. These results support the hypothesis that the invasion of the hippocampal formation by sympathetic fibers results from cholinergic denervation. *(Supported by ADRDA IIRG-88-059)*

NGF-INDUCED ELIMINATION OF UNINJURED AXONAL PROJECTIONS IN THE MATURE RAT: EVIDENCE FOR TROPHOMORPHISM B.N. Saffran and K.A. Crutcher. Dept. of Neurosurgery, Univ. of Cincinnati, Cincinnati, Ohio 45267

The occurrence of transient axonal projections within the developing mammalian nervous system has been documented in some detail, but evidence for the continued remodeling of mature, uninjured axonal projections has been less well established. One example of axonal remodeling within the mature brain is the growth of sympathetic axons into the septal-denervated rat hippocampal formation. In a previous study (Saffran et al., 1989), we found that intraventricular infusion of NGF failed to elicit sympathetic sprouting into the hippocampal formation but increased the sympathetic innervation of the internal carotid artery. Furthermore, intraventricular infusions of NGF given at various times after sympathetic axons have been induced to grow into the brain by a medial septal lesion reduced the amount of sprouting and delayed its onset. Cessation of NGF infusion permitted subsequent sprouting, indicating that the hippocampal tissue retained its receptivity to sympathetic axonal growth and that sympathetic axons could still respond to the sprouting signal. To test the possibility that NGF directly inhibits sympathetic axon growth in the brain, animals received a unilateral superior cervical ganglion transplant and a medial septal lesion followed by NGF infusion. In these animals, NGF did not inhibit sympathetic ingrowth from the transplant. In fact, in addition to the growth into the denervated HF, sympathetic fibers were observed in the fimbria, corpus callosum and tissue surrounding the lateral ventricle. On the contralateral side there was no evidence of sympathetic sprouting within the hippocampal tissue in spite of extensive septal denervation. These results suggest that the loss of sprouted fibers within the hippocampal formation is not a result of direct inhibition by NGF but likely occurs secondary to the proliferation of vascular sympathetic fibers. If this intrepretation is correct, NGF, in the absence of injury, can elicit remodeling of axonal projections in the mature nervous system. (Supported by NIH grant # NS 17131)

41.5

NGF-INDUCED SPROUTING OF MATURE, UNINJURED NEURONS. L. G. Isaacson, B.N. Saffran, and K.A. Crutcher. Department of Neurosurgery, University of Cincinnati, Cincinnati, OH 45267.

Nerve growth factor (NGF) mediates trophic interactions between sympathetic neurons and their peripheral targets (Levi-Montalcini and Angeletti 1968;Thoenen and Barde 1980) and exerts local effects on growing neurites in vitro (Campenot 1977;1981;1982) and developing axons in vivo (Menesini-Chen et al. 1978). NGF has also been reported to increase the sympathetic innervation of targets in mature animals (Bjerre et al. 1975), but it is not known whether this represents an increase in the number of axons or in the norepinephrine content of individual fibers. Following the intraventricular infusion of NGF, we observed an increase in sympathetic fluorescence associated with the internal carotid artery (Saffran et al. 1989). In the present study, we investigated this response at the ultrastructural level in order to determine whether the NGF-induced increase in perivascular catecholamine histofluorescence represents an increase in the number of axons. Intraventricular infusion of NGF or vehicle (cytochrome C) was accomplished by the use of an osmotic minipump (Alzet #2002) as described by Williams et al. (1987). Infusions took place over a two-week period delivering solution at a rate of 0.5 ul/h. Segments of the intradural portion of the internal carotid were processed using routine electron microscopic techniques. The total number of axons located in the tunica adventitia of the internal carotid artery at three rostral-caudal levels was tallied. Axonal counts revealed a statistically significant (ANOVA, $p < .0001$) 3-fold increase in the number of fibers in the NGF-infused animals. The increase in perivascular axons in NGF-infused animals demonstrates that NGF infusion can elicit growth from mature uninjured axons. These results also suggest that NGF normally may play a role in the regulation of the autonomic innervation of cerebral blood vessels in the mature animal and that infusion of NGF into humans, as has been suggested for Alzheimer's disease, may elicit similar changes in autonomic vascular innervation. (Supported by NIH grant NS 17131.)

41.6

COMPENSATORY SPROUTING OF MAGNOCELLULAR NEUROSECRETORY AXONS FOLLOWING PARTIAL DENERVATION OF RAT NEURAL LOBE. J.A. Watt* and C.M. Paden. Dept. of Biology, Montana State University, Bozeman, MT 59717.

Sprouting of vasopressinergic axons has previously been demonstrated following transection of the pituitary stalk or lesion of the paraventricular nucleus in adrenalectomized animals. In a continuing investigation of the plasticity of the magnocellular neurosecretory system we have partially denervated the neural lobe (NL) using unilateral knife cuts of the hypothalamo-neurohypophysial tract. Animals were sacrificed at 5, 10, 32 and 90 days post-surgery and the NL prepared for ultrastructural analysis. A total of 15 low magnification electron micrographs were collected randomly throughout the NL for each animal (n=3 per group). Mean axon density and axon number were estimated for each group. A significant reduction in axon number was observed in the 5 and 10 day post-surgical groups (60.11% and 57.9% of control values) with a partial recovery in axon number observed in the 32 and 90 day groups (72.4% and 78.8% of control values). These data, in conjunction with results of immunohistochemical and morphometric analysis in similarly prepared subjects (Soc. Neurosci. Abst. 47.6, 1988) indicate that intact magnocellular axons arising from the contralateral hypothalamus undergo a sprouting reaction in the partially denervated rat NL. Supported by NIH grant NS23642 and RCDA NS01318 to CMP.

ANATOMICAL CHANGES IN CENTRAL TERMINALS OF INTACT VIBRISSAE AFTER NEONATAL NERVE SECTION. P.M.E. Waite and P.J. de Permentier. Sch Anat, Univ. New South Wales, Sydney 2033 Australia

Section of the infraorbital nerve (ION) in neonatal rats is followed by functional reorganization throughout the trigeminal nuclear complex (nuclei principalis, oralis, interpolaris and caudalis: NP, NO, NI and NC). Cells deafferented by the nerve section develop new receptive fields on the nose, cheek and on uninjured whiskers over the eye and in front of the ear. The present study examines the mechanism by which these changes occur by labelling the terminals of the 'ear' whisker. This whisker is innervated by the zygomaticofacial nerve, a branch of maxillary trigeminal uninjured by ION section. The infraorbital nerves were sectioned unilaterally within 12 hours of birth and regeneration prevented by repeated weekly sectioning. At 6-12 weeks of age, the 'ear' whiskers were injected bilaterally with horseradish peroxidase (0.9µl of 30% HRP in 2% DMSO over 1 hr). After 24-30 hrs survival, the animals were perfused and the brain stem sectioned and reacted for HRP by the TMB method. Serial sections throughout the whole trigeminal nuclear complex were examined. All patches of labelled terminals were drawn on both the normal and lesioned sides and the areas compared.

On the normal sides, terminal labelling for the 'ear whisker was found in discrete oval patches localized ventrolaterally in NP and NO and laterally in NI. In NC and C_1 cervical cord the labelling occurred centrally in the magnocellular region. On the lesioned side, the patches in NP, NO and NI were less localized and extended medially into the nucleus. For these nuclei, labelled terminal areas were approximately doubled after lesioning and this increase was highly significant in all animals ($p < 0.001$). In contrast, NC and C_1 showed no significant change with lesioning.

These results suggest that for NP, NO and NI, the functional changes associated with ION section may be related to anatomical alterations, such as sprouting, in the central terminals of adjacent uninjured nerves.

EFFECTS OF FETAL INFRAORBITAL NERVE DAMAGE UPON THE PROJECTIONS OF INDIVIDUAL TRIGEMINAL PRIMARY AFFERENT NEURONS. N.L. Chiaia, G.J. Macdonald, W.R. Bauer and R.W. Rhoades. Depts. of Anatomy, Medical College of Ohio, Toledo, OH 43699 and Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Transection of the infraorbital nerve (ION) in newborn rats produces marked alterations in the peripheral projections of trigeminal (V) ganglion cells, but only subtle alterations in the central arbors of large caliber axons whose parent cells survive the lesion (Renehan, W.E. et al., in submission). It may be that the central axons of these damaged fibers have passed the stage in development during which reorganization of peripheral connectivity can alter central projections. We have tested this possibility by transecting the ION on embryonic day 16 and assessing the peripheral and central projections of surviving ganglion cells when the animals reached at least 6 wks of age. Retrograde tracing and extracellular single unit recording from the V spinal tract revealed numerous abnormalities in the peripheral connectivity of surviving ganglion cells. Retrograde tracing demonstrated that the somatotopic representation of the rows of vibrissa follicles in the V ganglion was disrupted and single fiber recording showed that 50.7% of 73 axons that projected into the regenerate ION did not have peripheral receptive fields. Furthermore, 16.7% of 60 fibers with non-ION receptive fields were also activated by stimulation of this nerve. The central arbors of HRP injected fibers that projected into the regenerate ION were reconstructed in V subnucleus interpolaris and caudalis (SpC) and they were generally much larger than those in normal rats. The central arbors of several ION fibers showed qualitatively abnormal structure-function relationships. Two of these fibers are of particular interest. These rapidly conducting, large caliber axons were activated only by vibrissa deflection, but had their major terminations in layers I and II of SpC.

NEUROMUSCULAR JUNCTION FINE STRUCTURE FOLLOWING TENOTOMY. B.R. Pachter and N.I. Spielholz*. Dept. of Rehab. Med., New York Univ. Med. Ctr., New York, NY 10016.

Experimental tendon transection is often studied as a model of muscle disuse. The present study was designed to assess qualitatively and quantitatively the fine structure of the neuromuscular junctions in rat soleus muscle after tenotomy. Female Wistar rats (250-300g) had their Achilles tendon cut about 5-7mm proximal to their insertion into the calcaneus and the cut ends left free. After two weeks, the soleus muscles were removed whole and prepared for EM examination. The innervation zone was located and ultrathin sections were taken. Morphologically, the tenotomized soleus muscle fibers appeared atrophic and the mitochondria and fibrillar size reduced. The majority of the endplates contained two or more axonal terminals separated by Schwann cell cytoplasm within the same synaptic cleft. The junctional folds appeared highly irregular shaped and attenuated; some folds exhibited signs of degeneration. Quantitatively, the mean nerve terminal area and mean postsynaptic area of junctional folds and clefts per nerve terminal was significantly reduced as compared to those of controls. It would appear that Achilles tenotomy results in an altered muscle morphology as well as degenerative and regenerative changes at the endplate.

PLASTICITY OF SPINAL SYSTEMS AFTER UNILATERAL LUMBOSACRAL RHIZOTOMY IN NEONATAL RATS. S. D. Wang, M. E. Goldberger and M. Murray. Dept of Anat., The Med. Coll. of Pa., Phila., PA 19129.

Previous studies of spinal systems in adult rat have shown anatomical plasticity of substance P and serotonergic systems in response to complete unilateral lumbosacral rhizotomy. In the present study, we used the same paradigm to examine the plasticity of these systems in neonatal rat. Dorsal roots were cut and/or ganglia were removed from L1 to S2 in 5 day old rats. The animals survived up to 126 days postoperatively. Substance P (SP) and serotonin (5HT) immunocytochemical staining were compared on the control and deafferented sides at the L4 level. An image analysis system was used to quantify SP and 5HT immunocytochemical reaction product in the dorsal horn. After deafferentation, SP decreased to 65% of normal on the experimental side in laminae I and II by 10 days. The density of SP staining recovered to between 97% and 92% of normal values after 30 and 60 days postoperatively. Recovery of SP in the dorsal horn is thus more complete after neonatal deafferentation than adult deafferentation where recovery is only between 51% and 74%. After rhizotomy, the area fraction occupied by 5HT immunoreaction product increased more than two times normal on the experimental side in laminae I and II. Dorsal rhizotomy in neonatal rats produces 17% shrinkage of the dorsal horn by 10 days postoperative. Therefore shrinkage contributes to but does not account for the increase in density of 5HT staining. The increase in 5HT staining and the extent of shrinkage are similar in adult and neonatal deafferented rats. Thus there is evidence for more plasticity of SP in rat dorsal horn in response to neonatal deafferentation than in adult. Supported by NIH grants NS16629, NS16556 and NS24707.

DISSOCIATION OF TERMINAL SPROUTING AND ENHANCED TRANSMITTER RELEASE INDUCED BY CHRONIC DISUSE AT RAT NEUROMUSCULAR JUNCTIONS. T.Tsujimoto*, M.Umemiya* and M.Kuno* (SPON: Y. Kayama). Dept. of Physiol., Kyoto Univ. Sch. of Med., Kyoto 606, Japan.

An increase in transmitter release observed at neuromuscular junctions in chronically paralyzed muscle has been postulated to result from the formation of sprouts. We examined this assumption in the rat extensor digitorum longus muscle following chronic block of the sciatic nerve by locally applied tetrodotoxin. Transmitter release was measured by the quantal analysis, and motor nerve terminals were stained with nitro blue tetrazolium. Terminal sprouts or terminal enlargement were not expressed until 3 days after nerve block, whereas transmitter release was significantly enhanced already 24 hr after nerve block. When nerve block had been maintained for 6 days, approximately 50% of the terminals examined showed sprouting. Under this condition, terminal size was measured at junctions identified by injections of carboxy-fluorescein during electrophysiological studies. Terminal size was significantly larger in the terminals with sprouts than in those without sprouts. However, the amount of transmitter release was uniformly enhanced at all junctions, being independent of the presence or absence of sprouts. It is concluded that the formation of terminal sprouts and enhancement of transmitter release induced by prolonged elimination of nerve-muscle activity are not causally related.

SPROUTING OF CORTICOSPINAL FIBERS INTO DENERVATED CONTRALATERAL SPINAL CORD REVEALS SPECIFICITY OF NEW AXON ARBORS. R.Z. Kuang*, and K. Kalil. (SPON: A.W. Clark). Dept of Anatomy and Neuroscience Training Program. University of Wisconsin, Madison, WI 53706.

Corticospinal projections in the hamster are completely crossed at all ages and project topographically from sensorimotor cortex to all segments of the spinal cord. We recently showed an anatomical segregation of sensory cortical axons to the dorsal horn and motor cortical axons to the ventral horn, and wished to determine whether corticospinal axons sprouting into territory denervated by a contralateral lesion of the corticospinal pathway would maintain this topographic and functional specificity.

Unilateral lesions of the medullary pyramidal tract were made in hamsters ranging from 5 days to adult, and 12-15 days later the intact corticospinal pathway was labeled by iontophoretic injections of PHA-L (Phaseolus vulgaris leucoagglutinin) into sensorimotor cortex opposite the lesion. This method reveals details of the entire corticospinal axon arbor. Sprouting from the uninjured corticospinal pathway into the denervated spinal cord was robust after a 5-day lesion and almost equalled the density of the normal projection. Sprouting after a 12-day lesion was somewhat less dense, after a lesion at 19 days was relatively sparse, and after lesions in animals older than 19 days ceased to occur. At all ages, corticospinal axons sprouted into the topographically correct segments of the cord. Moreover, the arbors from sprouting axons maintained their functionally appropriate territories in the dorsal or ventral horn, depending on their origin from sensory or motor cortex. These results suggest that sprouting of corticospinal axons is maximal after early lesions, but can persist beyond the time period for corticospinal axon outgrowth. Moreover, since sprouting corticospinal axons maintain their topographic and functional specificity even when innervating the incorrect side of the spinal cord at a time later than normal, the signals within the target regions that determine this specificity must persist until relatively late in development. (Supported by NIH Grant NS14428 to K. Kalil.)

SYNTHESIS OF NA,K-ATPASE IN THE RETINA OF THE BB SPONTANEOUSLY DIABETIC RAT. S.C. Specht. Dept. Pharmacol., Inst. Neurobiology, Univ. P.R. San Juan, Puerto Rico 00936

Synthesis of Na,K-ATPase was determined in retinae of diabetic and diabetes-resistant BB/Wor rats labeled with a two-hour intravitreal pulse of 35S-methionine. Retinal Na,K-ATPase was isolated, separated by SDS-PAGE and the protein bands containing the alpha and alpha(+) subunit isoforms were dissolved and analyzed by liquid scintillation counting. Retinal incorporation was 11-16% higher than control in rats that had been diabetic for 4 weeks, although the difference was not significant. Degradation of the two bands, measured at 16, 24 and 48 hours, was significantly slower in diabetic retinae. In rats that had been diabetic for 16-18 weeks, retinal incorporation was significantly higher: labeling of the alpha(+) band was increased from 1460 to 2460 cpm/retina, alpha from 890 to 2000. In other systems, inhibition of Na pump activity stimulates its synthesis. Hence, these data are compatible with observations of decreased Na pump activity in diabetic rats. (NIH grants NS-07464 and S06RR08224).

42.2

MATURATION OF OLFACTORY RECEPTOR NEURONS IN DEVELOPING HYPO- AND HYPERTHYROID RATS. M.A. Paternostro and E. Meisami. Dept. of Physiology and Biophysics, Univ. Illinois Urbana, IL 61801.

The total number of olfactory receptor neurons (ORN) increases markedly (10x) during the rat's suckling period (Meisami, Dev. Brain Res. 46: 9-19, '89). This proliferation is reduced by 35% in hypothyroid rats as is the increase in olfactory epithelium (OE) surface area. The thickness of OE and packing density of ORNs remains unaltered, however (Paternostro & Meisami, Int. J. Dev. Neurosci. 7, '89). To examine the role of thyroid hormones on maturation of ORNs, we determined the surface density of ORN dendritic knobs, in thin (lum) sections, obtained from nasal septum of 25-day male hypothyroid rats [treated from birth with PTU (0.1% w/v in drinking water)] and hyperthyroid pups [thyroxin (3 ug/g bw, daily sc)]. The dendritic knobs are characteristic of mature ORNs (1 knob/mature ORN). The surface density of the knobs increases significantly during the postnatal period, reaching a value of about 45,000/sq mm of OE surface in normal 25-day pups. Hypothyroid pups show about 25% ($p<0.05$) reduction in this parameter, indicating a delay or retardation in maturation of ORNs. This deficit grows larger in 50-day hypothyroid animals, because increases in knob density continue in normal animals but not in the hyperthyroid ones. The results of knob counts in hyperthyroid pups will also be reported.

42.3

ONTOGENY OF GNRH NEURONS IN THE FETAL RHESUS MACAQUE. O.K. Ronnekleiv and J.A. Resko*. Dept. of Physiology, Oregon Health Sciences University, Portland and Oregon Regional Primate Research Center, Beaverton, OR.

We studied the ontogeny of GnRH neurons in the fetal rhesus macaque from days 36 to 135 of gestation. The nasal region, pituitary and the brain were dissected, fixed in 4% paraformaldehyde, sectioned on a cryostat (10μm) and mounted on slides. Immunohistochemistry and in situ hybridization were performed as described previously (Ronnekleiv et al., Mol Endocrin. 3:363, 1989). At 36 days, clusters of GnRH cells were found in the nasal region only. GnRH fibers extended into the brain and large bundles projected laterally towards the basal hypothalamus (BH). By day 38 GnRH cells were also localized in the olfactory region of the brain. With increasing fetal age a gradual caudal extension of GnRH cells occurred. These cells were first observed in the BH at 47 days. Cells containing prolactin and LH were detected in the pituitary at 47 and 50 days, respectively. Low levels of proGnRH mRNA were present in the nasal septum, the nervus terminalis and the brain by day 50 of gestation, which significantly increased by day 135. These data suggest that GnRH neurons in the primate brain originate in the nose. Furthermore, GNRH neurons exhibit low levels of synthetic activity at the early fetal stages but higher synthetic activity close to term. (Supported by PHS HD16793 and HD16022)

NEONATAL MSG ADVANCES, BUT GLUTAMATE ANTAGONISTS DELAY THE ONSET OF PUBERTY IN THE FEMALE RAT. M. Wilkinson and M.C. MacDonald*. Obst. and Gynecol. and Physiol. Biophysics, Dalhousie University, Halifax Nova Scotia, Canada B3H 4H7

We have suggested (Endocr. 113 596) that a gradual decrement in opioid feedback, coupled with the emergence of an excitatory drive, may be part of the mechanism which regulates the timing of puberty. Based on this premise, the effect of glutamate antagonists was investigated as well as the influence of neonatal monosodium glutamate (MSG) which is known to destroy POMC neurons in the arcuate nucleus.

The glutamate antagonist MK-801 (0.1 mg/kg) was injected daily from day 27 until vaginal opening (VO) was observed. MK-801 significantly delayed VO (31.6±0.3 days vs 33.5±0.6) and elevated body weight at VO ($p<0.05$). The effect of MK-801 was completely prevented by co-injection of the agonist NMDA (15 mg/kg)

In a second series of experiments we examined whether neonatal MSG treatment might advance puberty through removal of arcuate ß-endorphin neurons. Four injections of MSG (4 mg/gm; days 2,4,6 and 8) slightly advanced the time of VO (33.6±0.6 vs 34.4±0.5 $p<0.05$) and lowered body weight ($p<0.005$). However, when MSG dose was reduced (days 2 and 4; 4mg/gm) VO was significantly precocious (30.1±0.2 vs 34.8± 0.4 days) and in keeping with a smaller body weight. (80.1±1.1 gms vs 114.6±2.1). All rats ovulated at VO.

These data provide evidence for glutamate as an excitatory neurotransmitter at puberty. The neonatal MSG lesions, however, possibly remove an opiatergic, inhibitory ,pathway.

CHRONIC TREATMENT WITH OPIATES ONLY PARTIALLY ATTENUATES ONSET OF PUBERTY IN FEMALE RATS. M.C. MacDonald* and M. Wilkinson. (SPON: R.E.Brown). Depts. Obst. Gynol. and Physiol. Biophysics, Dalhousie University, Halifax, Canada B3H 4H7

We have suggested that the hypothalamic opioid system becomes gradually less able to suppress LH in peripubertal rats (Endocr. 113 596). However, little is known concerning the influence of exogenous opioid agonists, e.g. morphine, on puberty in female rats. We have now investigated the effects of opiate treatment which avoids daily injections. Firstly, morphine (MOR) or fentanyl citrate (FEN) was administered orally, via the drinking water. Secondly, rats were treated with FEN released from s.c. osmotic minipumps.

Beginning at age 22 days the rats were habituated to MOR by slowly increasing the concentration in the drinking water (over 2 days) to give final concentrations of 100, 400 and 800 mg/L at day 24. Controls received sucrose and water. Vaginal opening (VO) was significantly delayed at both the higher doses; CON: 33.6 days; 400 and 800 mg/L groups: 38.2 and 38.5 days. The treated rats were 15% heavier than controls ($p<0.01$) on the day of VO and produced a normal set of corpora lutea. Experiments with FEN gave similar results (concentrations: 9.6, 19.2 and 30 mg/L) with delay times of 33.7, 35.0 and 36 days (CON: 32.1). We next treated immature rats with FEN released from osmotic minipumps (implanted day 24; pump concentration: 4.5 mg/ml). VO was significantly delayed (32.4 vs 35.9 days $p<0.005$).

Our results show that the hypothalamic opioid system can be desensitized to allow VO to occur even in the face of continous agonist treatment. Supported by the Canadian MRC.

42.6

ONTOGENY OF MINERALOCORTICOID (TYPE 1) RECEPTORS IN BRAIN AND PITUITARY. P. Rosenfeld*, W. Sutanto*, S. Levine and E. R. de Kloet. Rudolf Magnus Institute for Pharmacology, University of Utrecht, Utrecht, The Netherlands.

The ontogeny of high affinity (^{3}H)corticosterone uptake and retention in brain and pituitary of 24-hour adrenalectomized rats was examined using autoradiography of in vivo labelled brain sections. Our data indicate: (1) There is specific uptake of radiolabelled steroid in both brain and pituitary already at 2 days of age, following administration of a tracer (2 µCi/gbw) dose of (^{3}H)corticosterone. This uptake is maximum around 4 to 8 days of age and decreases towards adult values around postnatal day 16. (2) High affinity uptake, at least in the brain, probably represents mostly binding to the mineralocorticoid receptor (MR) and not to the glucocorticoid receptor (GR), as it was not displaced by an excess dose of a GR antagonist, RU 38486, and its location in the hippocampus resembled that of MRs in the adult animal. The tracer amounts of (^{3}H)corticosterone circulating after injection in the rat pups resulted in steroid levels comparable to basal levels of non-adrenalectomized animals during the SHRP. Thus, MRs may be the receptors mainly responsible for mediating physiological effects of glucocorticoids in the hippocampus during early ontogeny.

42.7

REDUCTIONS IN BRAIN OPIATE RECEPTORS IN PRENATALLY-STRESSED MALE AND FEMALE RATS. C.H. Kinsley, T.R. Insel[1], P.E. Mann and R.S. Bridges. Harvard Medical School, Laboratory of Human Reproduction and Reproductive Biology, Boston, MA 02115 and [1]N.I.M.H., Laboratory of Clinical Science, Poolesville, MD 20837

Prenatal stress affects the display of numerous opioid-regulated behaviors and physiological responses in adulthood, e.g., maternal and sexual behavior and morphine-induced analgesia and prolactin release. The present work examines alterations in central opiate receptors which may underlie some of the effects observed in prenatally-stressed (P-S) animals. Forty-two day old offspring from females stressed on days 15-22 of pregnancy and their non-stressed Controls had their brains removed. Membrane homogenates from striatum, but not several other brain regions, exhibited decreased binding of the mu-opioid ligand ^{3}DAGO in P-S animals compared to Controls. Saturation studies suggest that this difference is due to significantly fewer mu-opiate receptors in the striatum of P-S offspring. Employing in vitro receptor autoradiography, the decreased binding in striatum was found mostly in the rostral striatum, extending into the nucleus accumbens, with conservation of the normal anatomical distribution of receptor-rich patches. These data indicate that the aberrant perinatal endocrine environment associated with the prenatal stress procedure may contribute to an alteration in brain-opiate dynamics.

42.8

POSTNATAL CHANGES IN ACTH RESPONSE TO ACUTE PHYSOSTIGMINE ADMINISTRATION IN THE RAT. J. T. McCracken* and R. E. Poland*, (SPON: W.O. Shekim). Dept. of Psychiat., Harbor-UCLA Med. Ctr., Torrance, CA 90509.

In order to explore possible changes in cholinergic regulation of the hypothalamo-pituitary-adrenal axis associated with pubertal development, the release of ACTH in response to an acute injection of the cholinergic agonist, physostigmine (PHYSO), was measured in four age groups of male rats (12, 28, 45 and 90 days old). Within each age group PHYSO 0.25 mg/kg or saline was injected IP followed 20 min later by rapid decapitation and collection of trunk blood for analysis. Each group also contained a non-treated group for comparison. ACTH was analyzed by double antibody radioimmunoassay. Mean ACTH concentrations for the 12, 28, 45 and 90 day old animals were 376, 555, 316, and 1189 ng/ml respectively. An analysis of variance revealed significant differences between age groups ($F_{3,26}$=4.54; P< 0.012). Post-hoc comparisons revealed significantly less ACTH release in the 12, 28, and 45 day old animals after PHYSO when compared to the adult 90 day old animals. While preliminary, these data suggest that HPA axis sensitivity to cholinergic agonists undergoes significant modification during or following pubertal development in the male rat.

42.9

EFFECT OF STRESS DURING DEVELOPMENT ON SPATIAL LEARNING IN RATS. P.J. Gutierrez* and J.S. Meyer (SPON:N.Carlson). Dept of Psychology, Univ. of Massachusetts, Amherst, MA 01003.

We previously reported that histamine stress in developing rats inhibits hippocampal cell proliferation, possibly by stimulating corticosterone secretion (Gutierrez and Meyer, Soc. Neurosci. Abstr. 14:281, 1988). In the present research, the possible behavioral effects of such treatment were investigated. Rats were either untreated or injected daily with histamine from days 7 to 19 postnatal, then tested for spatial learning in the Morris water maze. Separate groups were tested early in development (days 20 to 26) and in adulthood (days 90 to 96). Testing was carried out for 6 days (4 trials/day), the first 5 days representing task acquisition and the 6th day a reversal test in which the hidden platform was moved to the opposite quadrant of the tank. Although no group differences were found in acquisition performance, effects of stress were noted on the reversal day. During reversal testing, all control animals (both young and adult) showed a high latency on trial 1, followed by 3 trials with significantly lower latencies. In contrast, stressed animals tested early in life did not initially perseverate in the original platform location but instead showed low latencies across all reversal trials. Finally, among the stressed subjects tested in adulthood, males but not females displayed relatively high latencies across all reversal trials, suggesting a deficit in adjusting to the new escape location. (Supported by NSF BNS-8704702 and BRSG RR07048 from NIH)

42.10

PROOPIOMELANOCORTIN POST-TRANSLATIONAL EVENTS DURING THE STRESS NONRESPONSIVE PERIOD. D.M. Vazquez* and H. Akil. Mental Health Research Institute and Department of Pediatrics, University of Michigan, Ann Arbor, MI 48109-0720.

The POMC producing cells of the anterior (AL) and intermediate lobe (IL) of the pituitary are derived from a common primordium. However, these cells exhibit distinct tissue specific post-translational processing. The AL response to biosynthetic and secretory demands differs depending on the type of challenge. Acute stress activates translational or post-translational events such that the precursor is processed to the final products twice as rapidly. With repeated stress the cell resorts to pre-translational events reflected by an increase of POMC mRNA (Endocrinol. 119:1793). Unlike the adult, the developing POMC cell products are similar in both lobes and a tissue specific pattern is not achieved until day 21. POMC mRNA levels increase (Endocrinol. 124:60), but the capacity of the developing animal to respond to stress is blunted during the first two weeks of life. A pulse paradigm was used to assess cellular dynamics on rats age 3,7,14 and 21 days. AL cell suspensions were prepared by the Mulder and Smelik method and ^{3}HLeu was used for incorporation. Cell extracts obtained were purified by immunoprecipitation using a midportion β-endorphin antibody and the different POMC derived molecular forms were separated on a SDS-PAGE. Day 14 AL cells appeared to process the POMC precursor at a faster rate when compared to adult (31K:β-LPH ratio 1:0.86 vs. 1:0.06). It is conceivable that the developing corticotroph relies on efficient translational events to maintain basal levels of the circulating peptides. Unlike the adult corticotroph, the capacity to increase the rate of translation may be limited when confronted with a greater demand, thus contributing to the Stress Nonresponsive Period. This work is supported by NIMH MH09720.

HYPOTHALAMIC NEURONS IN NON-CONTACTING THREE-DIMENSIONAL CULTURE RELEASE VASOPRESSIN AND OXYTOCIN. P.A. Doris, M.S. Walker * & P.W. Coates. Dept. Cell Biol. & Anat., TTU HSC Sch. Med., Lubbock, TX 79430.

Contact with neurons and glia may provide signals that regulate release of neuropeptides from hypothalamic neurons. It is not known whether these neurons are inherently capable of this important function in the absence of cell contacts because connections normally form *in vivo* and under standard culture conditions. However, hypothalamic neurons from late gestation fetal rats grow and differentiate rapidly as single cells without cell contacts when cultured at low cell density in a three-dimensional matrix (3D gel) (Coates and Walker, Biol.Rep.38:186, 1988) and express immunohistochemically detectable vasopressin (VP) (Dudley et al., SN Abs.14:417, 1988). In order to determine whether hypothalamic neurons are intrinsically capable of release, radioimmunoassays were used to quantitatively assess VP and oxytocin (OXY) in this system. Cells and medium were harvested after two days, as were blank controls (gels with no cells and medium from gels with no cells). Quadruplicate dishes were pooled for sample analysis with data expressed in pg (mean ± SEM) per sample. Repeated experiments gave consistent results. Statistical evaluation was performed using Student's t test. VP content of a typical sample of hypothalamic neurons in non-contacting 3D culture was 1.37 ± 0.24, more than 5 times that present in blank gels lacking cells (0.25 ± 0.25). VP content of medium from cells grown in 3D gels was 3.5 ± 0.29, twice that of control medium (1.75 ± 0.75). OXY was undetectable in blank gels, but was 0.13 ± 0.1 in gels with cells. OXY content of medium from cells in 3D gels was twice that for medium from blank gels (1.26 ± 0.32 and 0.65 ± 0.65, respectively). Results demonstrate that it is feasible to assay quantitatively for VP and OXY despite low numbers of neurons in this system. The data suggest that single hypothalamic neurons can release neuropeptides independent of synaptic or other cell contact mediated mechanisms. (Supported by NS20802, HD22806 and HL36217)

42.12

CHANGES IN THERMAL RESPONSIVENESS OF RAPHE NEURONES DURING PROESTRUS LIKE PHASES. P.Hinckel,H.B.H.Dick* and C.Hiemke*. Physiologisches Institut, Universität Giessen, Aulweg 129, D-6300 Giessen 1, F.R.G. and Institut für Physiologische Chemie, Universität Essen, Hufelandstrasse 55, D-4300 Essen 1, F.R.G.

In female mammals the preovulatory phase is characterized by surges of luteinizing hormone (LH) and a shift in the basal body temperature. The stimulation of gonadotropin release is triggered primarily by estradiol via the central nervous system. The elevation of body temperature seems to be due to increased production of progesterone in the ovary. The present study examines the effects of s.c. progesterone application on thermoresponsive neurones in the nucleus raphe magnus (NRM) during proestrus like phases in ovariectomized rats.

Spike rate maxima of warm-responsive neurones decreased and peak activity of cold-responsive neurones increased 20 - 50 minutes after progesterone injection, whereas no significant change in spike rate was seen after sham or control injection. After pretreatment with estradiol the progesterone induced inhibitory effect on warm-responsive units and the excitatory effect on cold-responsive units was amplified. Serum concentrations of LH and the two steroids were measured by using specific radioimmunoassays.

It is concluded that the hormonal control of basal body temperature change is mediated by complex effects of the steroids on thermal neurones in the lower brain-stem.

42.13

DEVELOPMENTAL APPEARANCE OF ALTERED HYPOTHALAMIC DOPAMINE AND TYROSINE HYDROXYLASE LEVELS IN AMES DWARF MICE. D. L. Hurley*, S. W. Carlson*, and C. J. Phelps (SPON: J. Hansen). Dept. Neurobiology & Anatomy, Univ. Rochester Med. Ctr., Rochester, NY 14642.

The hypopituitary Ames dwarf (df/df) mouse presents a model system of hypothalamic dysfunction in the absence of normal target hormone secretion. Dwarf mice lack growth hormone and prolactin (PRL); normal growth ceases beyond 10 days of age. Because of hypothalamic arcuate nucleus (catecholaminergic area A12) dopamine (DA) involvement in PRL regulation, adult dwarf mice have been assessed with regard to the A12 regions of the hypothalamus. Median eminence DA levels (Morgan et al., Endocrinol. 109: 2069, 1981), and histofluorescence are decreased, concomitant with a decrease in visible cell bodies in the A12 region (Phelps et al., Cell Tiss. Res. 240: 19, 1985). In order to determine whether this adult condition is primary or regressive, brains of dwarfs and normal (Df/?) littermates at 7, 14, 21 and 90 days of age were prepared for catecholamine histofluorescence (formaldehyde/ glutaraldehyde perfusion fixation). At 7 days, strongly fluorescent perikarya appeared in A12, and rich fiber innervation of the median eminence was observable in normal mice (DF/?); slight reduction in the fluorescence of both areas was noted in df/df littermates. This difference continued to increase through development; continued decline in fluorescence intensity was seen in 3 month old dwarf animals relative to normals, and maximal differences were observed in dwarfs greater than 1 yr old. Immunocytochemical staining for tyrosine hydroxylase (TH), the rate-limiting enzyme in the DA pathway, was performed on alternate hypothalamic sections to compare levels of TH during development. Numbers and staining intensity of TH-positive cell bodies were reduced in dwarf A12 regions, and TH-reactive fibers were less pronounced in the median eminence of the dwarfs, each with a pattern of gradual decline through the first months after birth. In situ hybridization to TH mRNA is being performed to quantify the decrease in dwarfs during these developmental stages. The long-term decline of DA neurons in the Ames dwarf mouse is indicative of a primary effect of the mutation on PRL gene expression with secondary alterations in the hypothalamus. Supported by NIH grant NS25987 (CJP)

42.14

THYROID HORMONE EFFECTS ON MICROTUBULAR COMPOSITION IN DEVELOPING CEREBRAL CORTEX. [1]S.A. Stein, [2]G.S. Bloom*, [1,2]G.A. Mihailoff, [3]P.M. Adams and [4]D.R. Shanklin*. Depts. of [1]Neurology, [2]Cell Biol. and [3]Psychiatry, UT Southwestern Med. Ctr., Dallas, TX 75235; and [4]Depts. of Path. and Ob.-Gyn, Univ. of Tenn.-Memphis, Memphis, TN 38163.

Hypothyroidism may lead to reduced microtubule numbers (Faivre et al, Dev. Br. Res., 8: 21-30, 1983), which may contribute to the observed abnormal and delayed axonal and dendritic process development in Layers II-V cerebral cortex (CC) as early as 15 days post conception (d pc) to 10 days after birth (d ab). To illuminate the potential mechanisms behind these abnormalities we have used the hyt/hyt mouse (Stein et al. Neuroendo., 49: 509-519, 1989), which has primary inherited congenital hypothyroidism starting at 15 d pc, their euthyroid hyt/+ littermates and the progenitor strain BALB/cBY mouse, to look at the abundance and localization of isotype-specific mRNA's and polypeptides of tubulin, the principal microtubule protein. In BALB/cBY mice, the Mß5 tubulin isotype mRNA is abundant in CC starting at 15 d pc, falls at 8 d ab and is localized to Layers II-V. In comparing hyt/hyt to hyt/+ littermate CC, the Mß5 mRNA is depressed 3-5-fold on the day of birth (Stein et al., in Iodine in the Brain, Adv. Exp. Med. Biol., pp. 59-78, 1989) and remains depressed until 7 d ab. However, total ß-tubulin mRNA and protein are unchanged. These results are being evaluated in terms of *in situ* hybridization and immunofluorescence. The timing and duration of the decrease in Mß5 mRNA abundance may influence the composition of functionally important neuronal microtubules at a critical time in CC development and contribute to some of the previously reported neuroanatomical abnormalities (Escobar et al., in Congenital Hypothyroidism, pp. 85-127, 1983) in specific CC regions to which Mß5 is localized.

COMPARISONS OF THE NUCLEAR UPTAKE OF TESTOSTERONE AND ITS METABOLITES IN THE BRAINS OF MALE AND FEMALE MACAQUE FETUSES. R.P. Michael and R.W. Bonsall*, Department of Psychiatry, Emory University School of Medicine, Atlanta, Georgia 30322 and the Georgia Mental Health Institute, Atlanta, Georgia 30306.

To investigate the mechanism by which testosterone (T) might influence the development of the primate brain during fetal life, we compared the uptake of T in cell nuclei from the brains of 7 intact female and 5 intact male fetuses (*Macaca fascicularis and M. mulatta*) at 121-124 days gestation 60 min after the injection of ^{3}H-T (250 μCi i.v. or 500 μCi s.c.). Purified nuclear pellets prepared from 8 brain regions were analyzed by HPLC to measure levels of ^{3}H-T and its metabolites. In both males and females, concentrations of radioactivity extracted from cell nuclei were significantly higher in the hypothalamus-preoptic area than in other brain regions ($P<0.001$). ^{3}H-estradiol represented 65.0 ± 5.7% of this radioactivity, and nuclear concentrations of this aromatized metabolite were 73% lower in males than in females ($P<0.001$). ^{3}H-T represented 68.9 ± 8.8% of the radioactivity in cell nuclei from pituitary gland, and concentrations were 48% lower in males than in females ($P<0.001$). Levels of ^{3}H-T in plasma and in tissue supernatants in males and females did not differ significantly, but males had significantly higher levels of endogenous T in plasma (599.8 ± 208.2 ng/100 ml) than did females (37.7 ± 28.5 ng/100 ml)($P<0.01$). Thus, the differences between males and females in steroid uptake by cell nuclei could not be explained by differences in the bioavailability of ^{3}H-T, but may have been due to the prior occupation of receptors by endogenous steroids in the male fetus. This supports the view that T produced by the male testis may act on the fetal brain, and suggests that aromatization might be involved in some of its actions.

IMMUNOCYTOCHEMICAL LOCALIZATION OF INTRACELLULAR ANDROGEN RECEPTORS IN SPINAL MOTOR NEURONS R. C. Yu, P. Vuong*, C. Chang*, S. Liao*, and B. G. W. Arnason. The Brain Research and Ben May Institutes, Univ. of Chicago, Chicago, Il 60637.

Somatic motor neurons(MN) are one of the major sites for androgen(A) action within the central nervous system. The effects of A on responsive cells are mediated by an intracellular receptor(R) which in turn interacts with the genome to activate specific genes. We have examined, immunohistochemically, the distribution of AR in rat spinal cord and ventral prostate (VP). Monoclonal and polyclonal antibodies specific for AR were generated by using a fusion protein containing a segment of human AR corresponding to amino acid positions 331 to 527 from the N-terminal. The sensitivity of the immunoperoxidase stains(IS) of AR on the tissue sections was greatly affected by the fixative and the duration of fixation. Tissues fixed in 4% paraformaldehyde for 2 hours displayed IS in both nucleus and cytoplasm of spinal cord MN. Some neuronal processes including the axon hillock were also stained. Only nuclear IS was observed in VP epithelia. Prolonged(>4 hrs) fixation with aldehyde-based fixative reduced IS intensity. IS was also diminished following alcohol-based fixation (OmniFix) or fresh frozen unfixed tissue. Acetone fixation obliterated IS in VP cells and reduced nuclear IS in MN while the intensity of IS in the perikaryon remained unchanged. Our results demonstrate that the distributions of nuclear and cytoplasmic intracelluar AR are different in spinal cord MN and VP.

GENETIC MODELS OF NERVOUS DISORDERS I

43.1

HPRT DEFICIENT MICE ARE BEHAVIORALLY SUPERSENSITIVE TO AMPHETAMINE. H.A. Jinnah, F.H. Gage, and T. Friedmann*. Depts. of Neurosciences and Pediatrics, UCSD, La Jolla, CA 92093.

Congenital HPRT deficiency in humans results in a severe neurological disorder know as Lesch-Nyhan syndrome. Behavioral abnormalities in this disorder are thought to result from dysfunction of dopamine systems in the basal ganglia. Recently however, mice with a large HPRT gene deletion resulting in complete HPRT deficiency were reported to exhibit normal behavior. In the present study, we tested the sensitivity of these mice to amphetamine, a drug which stimulates dopamine release and which can produce Lesch-Nyhan like self-injurious behavior in normal rodents. Mice (n=20) were scored for stereotypic behavior using a stereotypy scale. No difference between the scores of HPRT+ and HPRT- animals was observed after sc injection of saline, 2, or 4 mg/kg amphetamine. However, after a dose of 8 mg/kg amphetamine, HPRT- animals engaged in stereotypic gnawing, sniffing, and licking much more frequently than HPRT+ animals, resulting in significantly higher scores for HPRT- animals ($p<.05$). Additional mice (n=32) were tested for locomotor activity in photocell chambers. In five hour test periods, no consistent differences between HPRT+ and HPRT- animals were observed after injection of saline, 2, or 4 mg/kg amphetamine. However, after a dose of 8 mg/kg, the activity profiles of HPRT+ and HPRT- animals were strikingly different. HPRT+ animals displayed a single peak of activity which subsided after 2 hours. HPRT- animals exhibited biphasic activity profiles, indicative of the intervening phase of stereotypy observed in the previous study. This difference was also statistically significant (ANOVA for repeated measures, $p<.01$). These results document the existence of an abnormal behavioral phenotype in HPRT deficient mice, and provide further support for a relationship between HPRT and dopamine systems in the brain. We are currently testing the sensitivity of these mice to other pharmacologic agents.

TRANSGENIC MICE EXPRESSING THE HUMAN SOD-1 GENE IN PRIMARY CELL CULTURE OF NEURONS: EFFECT OF OXIDATIVE STRESS. P.H. Chan, S. Chen,* L. Chu,* E. Carlson,* C.J. Epstein*Depts. of Neurology & Pediatrics, University of California, San Francisco, CA 94143

Oxygen radicals have been implicated in cerebral ischemia and reperfusion injury. Supplementation of liposome-entrapped CuZn-superoxide dismutase (SOD) ameliorates cerebral ischemic infarction. Recently transgenic mice carrying the human CuZn-SOD (h-SOD-1) gene have been developed as animal models for the study of the effects of the increased SOD-1 activity in Down syndrome (Epstein *et al.*, PNAS 84:8044, 1987). The availability of these animals has allowed us to examine the effects of oxidative stress on neurons. Primary cultures of cerebellar neurons (14 days *in vitro*) were developed from 7-day-old transgenic mice and from the normal diploid littermates. The total SOD activity in the transgenic neurons was 2.3-fold higher than in normal diploid cells. In addition to the mouse SOD activity, the h-SOD-1 activity was identified when the transgenic neurons were subjected to native gel electrophoresis followed by staining with nitroblue tetrazolium. Since increased h-SOD-1 activity will affect the oxidative states and may provide protection for neurons from oxidative stress, we studied the levels of glutathione (GSH) and the effects of H_2O_2 on transgenic cells. The levels of GSH were 10.9 ± 1.1 and 10.8 ± 0.9 nmoles GSH/mg protein for normal diploid and transgenic neurons, respectively. Exposing neurons to H_2O_2 at various concentrations (0, 10, 50, 100 mM) at 1 hour caused dose-dependent cell injury as measured by the release of lactate dehydrogenase (LDH) into the incubation medium by the cells. However, LDH releases were significantly lower at 10 mM (4.7 vs. 11.3 U/L/h) and at 50 mM (7.1 vs. 16.2) for transgenic neurons. LDH release was similar for both normal and transgenic neurons at 100 mM (34.4 vs. 32.4). These data suggest that transgenic neurons are more resistant to low levels of H_2O_2 toxicity, and this resistance may be due to adaptation of the neurons to the H_2O_2 produced constantly by increased h-SOD-1 activity. Supported by NS-14543, NS-25372, and HD-17001.

DIFFERENTIAL MURINE SENSITIVITY TO SCOPOLAMINE IN TWO DISSOCIATED TASKS. M. Buckley and M.A. Pelleymounter. Abbott Laboratories, Abbott Park, IL 60064

Cell loss in the basal forebrain cholinergic system and memory deficits are well-documented characteristics of Alzheimer's Disease (AD). There is also evidence for a genetic component in AD. It is unclear, however, whether the cholinergic degeneration found in AD has genetic basis. We have examined a possible genetic basis for cholinergic involvement in AD-like memory impairments by observing the effects of a cholinergic antagonist on spatial memory in DBA mice. Several groups have shown that this strain has a severe spatial learning impairment. Male DBA, C57 and CD1 mice were injected with saline or scopolamine (1 mg/kg;ip) 20 min prior to training in the plus maze version of the Morris water maze. Latencies to reach a hidden, stationary escape platform were measured, along with the number of trials to reach a spatial bias criterion. DBA mice required significantly more trials to criterion and had longer overall latencies than C57 or CD1 mice. Further, DBA mice were more disrupted by scopolamine than either of the other two strains. These animals were also tested for retention of a step-through, passive avoidance response after pretraining injections of scopolamine or saline. Again, DBA mice were the most sensitive to the disruptive effects of scopolamine, suggesting that a hyper-responsive cholinergic system might be part of the genetic component for the memory impairments in these mice. We are currently assessing the effects of scopolamine (1 mg/kg) on hippocampal and cortical high affinity choline uptake in the three strains of mice.

INCREASED SENSITIVITY TO CHOLINERGIC AGONISTS: A GENETIC TRAIT M.Steiner, T.Sota*, and B.G.Orpen. St. Joseph's Hospital Research Institute, and Dept. of Psychiatry and Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada.

Wistar-Albino-Glaxo (WAG) rats are supersensitive to the temperature-depressing effects of the muscarinic agonist, oxotremorine. We have cross-bred the WAG with the pigmented Dark Agouti (DA) rat to provide a pigmented, cholinergically-supersensitive rat model for the cholinergic supersensitivity demonstrated in depression. We report here on our preliminary studies of the cholinergic supersensitivity observed in the F1 offspring of WAGxDA crosses.

Cholinergic supersensitivity, as indicated by the drop in core body temperature 30 minutes after giving oxotremorine (.25 mg/kg, i.p.) in the presence of peripheral receptor blockade by methyl atropine, was studied in male and female WAGxDA and DA rats.

Body temperature dropped significantly more in WAGxDA than in DA rats (Males: 2.25 C.$\pm$ 0.41 vs. 1.84 $\pm$ 0.56, df=46, p<0.01; Females: 2.85 $\pm$ 0.49 vs. 2.03 $\pm$ 0.48, df=27, p<0.01). Also, female WAGxDA rats showed a greater temperature drop than males (2.85 $\pm$ 0.49 vs. 2.25 $\pm$ 0.41, df=53, p<0.01). Thus, the cholinergic supersensitivity appears to be a dominant, but complex, genetic trait in these animals. Preliminary results from studies of muscarinic receptor binding in "live" punches from brain slices suggest that the difference in drop in body temperature is due to increased numbers of muscarinic receptors in the hypothalamus of the WAGxDA rats.

PHYSIOLOGICAL ANALYSIS OF THE BRAIN OF THE MUTANT HAN-WISTAR RAT: XENOPUS OOCYTE ASSAY OF GLUTAMATE RECEPTORS. R.W. Cohen, R.S. Fisher, A.T. Campagnoni and C.D. Hull. MRRC, UCLA, Los Angeles, CA 90024.

A mutant strain of Han-Wistar rats carries an autosomal recessive gene that produces spastic paresis which is characterized by hyperexcitability, tremor and rigidity in the hindlimbs (Neurosci. Lett. 2:45-49). Immunohistochemical analysis of the brains of these animals revealed three major sites of degeneration: (1) in purkinje cells of the cerebellar cortex, (2) in myelinated fiber tracts to and from the cerebellum, and (3) in ascending fiber tracts to the thalamus. We utilized the Xenopus oocytes assay which involves the expression of foreign mRNA injected into oocytes to search for a possible source of this brain dysfunction. Brains of affected rats and unaffected littermate controls were bisected at the mesencephalon into rostral and caudal halves (the caudal half contained the cerebellum). Each brain half was homogenized and its mRNAs were isolated. Samples of these mRNAs were injected into Xenopus oocytes. These oocytes were voltage clamped at -60mV and exposed to 1mM glutamate which produces a strong inward current. Unaffected (31.6$\pm$7.2nA) and affected (31.0$\pm$8.5nA) rostral halves showed similar responses to glutamate; the caudal halves had statistically different responses: Unaffected=41.7$\pm$6.0; affected=95.8$\pm$7.1 ($\bar{x}\pm$S.E.). These results suggest that the Han-Wistar dysfunction involves either a large increase in glutamate receptors or a change in receptor sensitivity of the caudal brain. Presently, we are attempting to determine which type of glutamate receptor is contributing to this phenomenon.

MORPHOMETRIC ANALYSIS OF NEOCORTEX IN THREE MALES WITH THE FRAGILE X SYNDROME.
V.J. Hinton*, W.T. Brown* and R.D. Rudelli*. (SPON: J. Currie). NY State Institute for Basic Research in Developmental Disabilities, 1050 Forest Hill Rd, Staten Island, NY 10314.

Fragile X syndrome [fra (X)] is the second most prevalent chromosomal developmental disorder which clinically presents as a form of mental retardation (MR) and is associated with a position q27 marker on the X chromosome. Postmortem investigation of three males with karyotype confirmed fra (X) included cortical intra-layer neuronal cell counts. Layers II-VI were identified by neuronal characteristics in cingulate and temporal association areas, (Brodmann's 23 and 38). For each layer, cresyl violet stained neurons were counted in ten visual fields (an area of 20μm X 15μm magnified to 1400X on a video screen), and the mean computed. A 3-way ANOVA (condition by area by layer) performed on the transformed counts showed no significant differences, [$F(1,4)=.61$, $p>.05$], between fra (X) and control neocortex. Thus, fra (X) associated MR may not be related to either neuronal developmental deficits or postnatal neuron loss.

43.7

DELIVERY OF UV-INACTIVATED RADIOLABELED HERPES VIRUS ACROSS THE BLOOD-BRAIN BARRIER AFTER OSMOTIC BLOOD-BRAIN BARRIER DISRUPTION. E.A. Neuwelt*, R. Dix*, & M.A. Pagel*. (SPON: Fred O. Risinger). Departments. of Neurosurgery and Biochemistry, Oregon Health Sciences University, Portland, Oregon and University of Miami, Miami, Florida.

The present studies were undertaken to evaluate the possibility of delivering a viral particle across the blood-brain barrier (BBB). Osmotic BBB modification with intracarotid (IC) mannitol (25%) was immediately followed by bolus IC administration of UV-inactivated 35S-labeled Herpes virus (2.0×10^6 cpm). After 60 min, intravascular virus was cleared by saline perfusion and the animals were then sacrificed. A marked increase (fourfold, $p \leq .02$) in protein-precipitable radioactivity was observed when compared with controls without barrier modification. Administration of virus intravenously (IV) immediately after BBB modification displayed no difference in delivery compared with IC saline-infused (non-BBB modified) controls suggesting the importance of a first-pass phenomenon. There were no significant differences in serum concentrations among IC or IV groups. These preliminary studies would suggest the possibility of delivering viral particles across the BBB with the osmotic technique which may permit delivery of genetic material in replication-defective viral vectors for gene therapy in our feline model of Gm2-gangliosidosis. PATHOLOGIC CHANGES IN SKELETAL MUSCLE IN AN INHERITED CANINE HYPOKALEMIC PERIODIC PARALYSIS. G.A. Hegreberg. Dept. Vet. Pathol., WSU, Pullman, WA. 99164-7040

An autosomal recessive neuromuscular disorder in the dog resembles human hypokalemic periodic paralysis and is clinically accompanied by skeletal muscle weakness which is especially expressed as intolerance to exercise, cold and excitement stresses. Muscle atrophy is generalized and slowly progressive. Studies were performed to characterize the skeletal muscle morphologic changes. Biopsies were surgically removed from the biceps femoris of 5 affected and 5 nonaffected adult dogs. Frozen and 4F-1G fixed specimens were examined. A consistent and pronounced change in the skeletal muscle from affected dogs was the variation in fiber diameter size with increased atrophy and hypertrophy factors. There was a marked apparent decrease in the number of type II fibers. Some sarcoplasmic masses were present and consisted of peripherally located myofibril-poor sarcoplasm. Some nuclei were internally placed and in rows. Perinuclear vacuoles were associated with the centrally located nuclei and some perinuclear regions contained coarse PAS positive granules. Large vacuoles, present in the sarcoplasm of muscle fibers from older affected dogs, contained a floccular material which was PAS positive and diastase susceptible. Supported in part by NIH 00515 and Washington State University.

EYE-OPENING IN MUTANT ALBINO VS. PIGMENTED RAT LITTERMATES, CONGENIC HYBRIDS OF F344 AND WLE INBRED STRAINS. I.S.Westenberg.Psychol.Dep't.,Glendale Com.Col.,Glendale,AZ 85302.

Precocious eye-opening in albinos has been seen in albino-vs.-pigmented comparisons of rats in which a difference at the albino (c) gene locus was confounded with other genetic differences. This problem is solved by comparing congenic rats that differ only at the c locus, e.g., albino (c/c) vs. pigmented (c/+) F_1 hybrids of the Fischer (F344) inbred and Westenberg-Long-Evans (WLE) segregating inbred strains. I bred c/c F344 females with c/+ WLE males to get 12 litters of F3WLF1 hybrid rats. All littermate F3WLF1 pups were c/c or c/+ but otherwise almost identical genetically, matched for maternal and paternal effects, prenatal and post-natal environment, etc. In each litter, checked daily, 3 outcomes were possible; the first-detected eye-opening could have been in c/c, c/+, or c/c & c/+ (tie). There was 1 tie; in all other litters (11/11) the first-detected eye-opening was in a c/+ pup. Often the eyes of all c/+ in a litter opened before eye-opening in any c/c. Statistical analysis conservatively included only litters where the number of c/c was $\geq$ the number of c/+; in each of 8 such litters the first-detected eye-opening was in c/+. This statistically significant finding ($p < 0.01$, sign test) reinforces warnings about the use of albinos as "normal" subjects and supports the albino mutation's value as a research tool to be used with proper genetic controls.

44.2

A NEW LINE OF CONVULSION-PRONE MICE. R.E. Wimer and C.C. Wimer*. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010

Mice that exhibit convulsions were an unanticipated result of a breeding experiment designed to produce recombinant inbred strains differing in the number of pyramidal cells in hippocampal regio superior (CA1). Animals were selectively bred for convulsion-proneness, and simultaneously inbred, resulting in a new strain in which nearly all of the mice have convulsions during weekly cage changing, from the age of 10-12 weeks. Severity ranges from immobility, rapid breathing, body tremor, and exopthalmia to vocalization, back arching, falling over, occasionally followed by tonic extension of the limbs frequently terminating in death. Otherwise the strain appears to be behaviorally and neurologically normal, with an average life span and normal reproductive behavior. Preliminary tests suggest that products (probably chemo-olfactory) of other mice may be effective in eliciting the convulsions. Abnormalities in cell lamination in the hippocampus have been observed, although hippocampal involvement remains to be demonstrated.

INCREASED NUMBER OF SOMATOSTATIN-IMMUNOREACTIVE NEURONS IN PRIMARY CULTURES OF TRISOMY-16 MOUSE CORTEX. G. Capone, P. Corsi, M. Caserta, M.L. Oster-Granite, R. Reeves* and J.T. Coyle. Depts. of Neuroscience, Psychiatry and Physiology, The Johns Hopkins School of Medicine, Baltimore, Maryland 21205.

Since the gene encoding pre pro-somatostatin (ppSS) is located on mouse chromosome 16 (MMU 16), we have examined the effects of trisomy (Ts) of MMU 16 on SS immunoreactivity (IR) and ppSS mRNA expression by *in situ* hybridization in primary cultures of papain dissociated neocortex from 15 day gestational Ts16 and euploid littermates. Cultures were grown for 1-3 weeks on polylysine coated 35 mm plastic plates in MMEM containing 10% heat inactivated horse serum. Neurons were identified by neuron specific enolase IR. Immunocytochemical analysis indicated an increase in the relative density of SS-IR neurons, ranging from 1-3-fold above euploids in Ts16 cultures at 1 and 2 weeks *in vitro* although differences become attenuated at 3 weeks. SS-IR was more intense in Ts16 neurons but was expressed in the same cell types. No difference in the relative density of glutamate decarboxylase or neuropeptide Y IR neurons was observed. *In situ* hybridization for ppSS mRNA and SS-IR on the same cultures revealed the same density of positive neurons. Thus, under the culture conditions used, the presence of an extra copy of ppSS gene in Ts16 appears to result in SS expression in an increased number of cortical neurons.

44.4

ACCLERATED DEVELOPMENT OF SODIUM CHANNELS IN CULTURED ASTROCYTES FROM THE TRISOMY 16 MOUSE. P.J. Yarowsky[1], T.A. Bunting*[3], S. Baharloo*[1], M.L. Oster-Granite[3] and B.K. Krueger[2]. Depts. of Pharmacology & Experimental Therapeutics[1] and Physiology[2], Univ. of Maryland Sch. of Med., Baltimore, MD 21201, Developmental Genetics Lab[3], Johns Hopkins Univ. Sch. Med., Baltimore, Md. 21205.

Previous studies revealed that cultured neonatal rat cerebral astrocytes have two types of Na channels; channels with low STX-affinity were present throughout four weeks in culture and high STX-affinity Na channels appeared in the second week (Yarowsky and Krueger, J. Neurosci. 9:1055, 1989). This spontaneous change in STX-affinity coincided with changes in astrocyte morphology from polygonal immature cells with few processes to mature stellate cells with numerous processes. In primary cultures of cortical astrocytes from trisomy 16 mice we observed predominantly $GFAP^+$ stellate astrocytes (75%) as early as 8 days in culture. At the same time in culture, astrocytes from normal siblings were mostly polygonal (85%). Also, at 8 days in culture, trisomic cells showed a two-fold increase in high STX-affinity Na channels over normal astrocytes. This increased and premature expression of Na channels persisted throughout three weeks in culture. (NSF BNS 8711829 and NIH NS16285, HD19920, HD19932)

EFFECT OF MPTP ON STRIATAL DOPAMINE LEVELS IN THE WEAVER MUTANT MOUSE. E.H. Stotz*, J.R. Simon, B. Ghetti and J.A. Richter (SPON: A.N. Siakotos). Indiana Univ. Sch. of Med., Indpls., IN 46202.

Compared to normal (+/+) mice, weaver mutant mice (wv/wv) have a substantial decrease in the number of dopaminergic neurons in the nigrostriatal pathway; heterozygous (wv/+) mice do not undergo such a cell loss (Triarhou et al., 1988). In one effort to compare the neurochemical characteristics of the surviving nigrostriatal dopamine (DA) neurons in wv/wv with those in the wv/+ and +/+ mice, we have tested if the effects of the neurotoxin MPTP on striatal DA levels are the same in the three genotypes.

A total of four injections of 6 mg/kg of MPTP-HCl or saline were given (s.c. every 2 hr) to all three genotypes. The mice were decapitated one week later, and the striata were assayed for DA levels by HPLC-EC. In the saline-treated groups, the DA levels in +/+ and wv/+ were the same whereas the levels in wv/wv were much decreased. MPTP treatment decreased the striatal DA levels in both +/+ and wv/+ mice but seemed not to affect the striatal DA levels of the wv/wv mice.

MPTP action requires the uptake of its metabolite MPP^+ into DA neurons. A depressed DA uptake system in the remaining nigrostriatal DA neurons in these adult wv/wv mice could explain the lesser MPTP effect. Currently we are testing this idea by measuring several DA markers in the three genotypes. (Supported by NS 14426).

44.6

STRIATAL AND MESENCEPHALIC SUBSTANCE P CONTENT IN THE WEAVER MUTANT MOUSE AND THE EFFECT OF MPTP. J.R. Simon, J.A. Richter, B. Ghetti and M.R. Vasko. Indiana University School of Medicine, Indianapolis, IN 46202.

The weaver mutation induces a decrease in the number of dopaminergic neurons in the nigrostriatal pathway of the weaver (wv/wv) relative to homozygous (+/+) and heterozygous mice (wv/+). One consequence of this cell loss is a substantial decrease in dopamine (DA) content in the striatum (STR) of the wv/wv. In view of the evidence suggesting interactions between DA- and substance P (SP)-containing neurons, we determined the striatal and mesencephalic(MES) SP content in wv/wv, wv/+ and +/+ mice. We also investigated the effect of the DA neurotoxin, MPTP, on SP content in STR and MES of the three genotypes.

A total of four injections of 6 mg/kg MPTP-HCl or saline were given (s.c. q 2h) to adult mice of the three genotypes. Mice were sacrificed one week later and the STR and MES assayed for SP by RIA. In the saline-treated groups, SP content was greater in the MES than in the STR with no apparent differences in content among the three genotypes. Following MPTP treatment, SP content tended to decrease in the STR and MES of +/+ and wv/+ mice, but did not appear to be affected in either region of the wv/wv. Thus, there appear to be differences in the manner in which SP-containing neurons respond to acute (MPTP) and chronic (wv/wv) depletion of DA. (Supported by NS 21697 and NS 14426)

44.7

MONOAMINERGIC ALTERATIONS AND MATERNAL EFFECTS IN ATAXIC HOTFOOT MICE. L.J. Draski* and G.A. Gerhardt[1] (SPON: J.M. Masserano). Depts. of Pharmacology and Psychiatry[1], Univ. of Colorado Health Sciences Center, Denver, CO 80262.

The single gene mouse mutation, hotfoot, is characterized by a progressive ataxia and body tremor which first can be observed after approximately the second postnatal week. In an attempt to investigate neurochemical correlates of the pathogenesis of the ataxia, tissue levels of monoaminergic neurotransmitters and their metabolites were determined in cerebellum and striatum of 30 homozygous recessive male mice (ho/ho) and 30 phenotypically normal (+/-) littermates by HPLC-EC methods. In addition, animals were identified as being raised by either a phenotypically normal or hotfoot mother. Normal males born to hotfoot dams and hotfoot males, regardless of maternal genotype, exhibited significantly greater amounts of norepinephrine (NE), as well as lower MHPG/NE and 5-HIAA/serotonin (5-HT) ratios, in cerebellum, relative to phenotypically normal males raised by normal dams. However, in striatum, significantly greater levels of 5-HT were observed only in hotfoot males with no significant effects of maternal genotype noted. These results suggest that monoamine neurotransmitter systems are involved in the expression of the hotfoot ataxia, as well as illustrate the susceptability of the normally developing central nervous system to the effects of early environment. Supported by USPHS AG06434, AG00441.

QUANTITATIVE ANALYSIS OF VARIATION OF FUR PATTERN AS A MARKER FOR NEUROCHEMICAL ABNORMALITY IN FEMALE BRINDLED MICE. P.M. Martin, M. Irino*, Q.D. Walker*, Kinuko Suzuki, M. Lewis and R.B. Mailman. Toxicol. Curric., BSRC, and Dept. of Pathology, Univ. of North Carolina, Chapel Hill, NC 27599.

We have developed a method of quantifying the fur pattern of mice with varied coat color (e.g., chimeric mice), and have used it to study mice heterozygous for the brindled gene. Brindled (MO^{br}) is an X–linked neurological mutation in mouse, arising spontaneously in the C57BL inbred strain. The hemizygous males (MO^{br}/y) have low copper concentrations in brain, an almost total lack of fur pigmentation, and neuronal degeneration of the cerebrum. Thirty day old female mice heterozygous for the brindled gene have similar characteristics, including large patches of lightly colored fur, the extent of which appears to be in proportion to the number of abnormal Purkinje cells in the cerebellum. Eleven female mice (5–11 mo of age) were tested in locomotor chambers, then photographed from a standardized height and position. An imaging system measured absorbance, yielding a mean density (± S.D.) for each mouse. After euthanasia, concentrations of dopamine, norepinephrine, serotonin, and their metabolites in various microdissected brain regions were measured by HPLC–EC. NE from the hypothalamus, but not other brain regions, was higher in the more lightly colored females ($r=-0.516$). Since copper is a cofactor for dopamine–β–hydroxylase, the extent of lightly colored fur may serve as a marker for neurochemical abnormalities due to abnormal copper distribution in the brain. This method of quantifying fur patterns may also be useful in measuring the extent of introduction of new genetic material into chimeric mice. (Supported by Grants ES70126, NS24453 and ES01104).

BRAIN CATECHOLAMINE CONCENTRATIONS IN THE BRINDLED MOTTLED MOUSE RESEMBLE THOSE SEEN AFTER INHIBITION OF DOPAMINE–β–HYDROXYLASE. Q.D. Walker*, M.H. Lewis, K. Suzuki, P.M. Martin, S.W. May, and R.B. Mailman. Univ.of North Carolina, Chapel Hill NC 27599 & Georgia Institute of Technology, Atlanta, GA.

The brindled mottled mouse has an X–linked mutation resulting in abnormal copper homeostasis, compromised function of copper–dependent enzymes, and neurodegeneration. The neuropathology in this murine model of the human neurodegenerative disease, Menkes' kinky hair syndrome, is prominent in a few neural loci, the fronto–parietal cerebral cortex and thalamic nuclei. As the susceptible nuclei are terminal fields for norepinephrine (NE), their degeneration may be associated with a decrease in dopamine–β–hydroxylase (DBH) activity and subsequently, NE depletion. To test this hypothesis, catecholamine concentrations in selected brain regions of both brindled mottled mice and mice treated with the DBH inhibitor, disulfiram, were compared. Administration of disulfiram (200 mg/kg) to normal mice produced > 70% depletions of NE in all cerebral regions assayed. Concomitantly, dopamine concentrations increased at least 2–3 fold in all but the dopamine–rich midbrain. NE concentrations in all brain regions of brindled mottled mice were lower than the detection limits of the assay. Dopamine levels in the mutants were higher than those of control mice but similar to the concentrations in disulfiram–treated mice. These data with disulfiram were compared with those using novel inhibitors of DBH. Together, this work provides evidence for the hypothesis that a profound lack of noradrenergic innervation during a critical period of development may interfere with synapse formation and lead to neuronal degeneration (ES01104, HL28167, NS24453 & ES07126).

RESPIRATORY REGULATION I

45.1

TOPOGRAPHIC ORGANIZATION OF RETICULOSPINAL PROJECTIONS TO RESPIRATORY MOTONEURON POOLS IN THE RAT. S. Manaker, T.L. Bigler*, A.R. Morrison and A.I. Pack*. Depts. of Medicine and Animal Biology, University of Pennsylvania, Philadelphia, PA 19104

During rapid eye movement sleep (REMS), the somatic musculature is inhibited by descending pathways from the reticular formation. However, during REMS the activity of the respiratory musculature continues. This different behavior in REMS may reflect differential organization of projections from pontomedullary inhibitory areas to the different motoneuron pools. We therefore examined in rats the origin of reticulospinal projections to three motoneuron pools: the lumbar spinal cord, the cervical spinal cord, and the hypoglossal nucleus as representing somatic, respiratory and upper airway motoneuron pools, respectively.

Ten nl of Fast Blue (3% solution) were injected into one of the motoneuron pools, and the animal allowed to survive up to five weeks. Rats with extension of tracer out of the ventral cord or hypoglossal nucleus were excluded from analysis. Every third tissue section (32 μm) through the medulla and pons was examined under epifluorescence, and retrogradely labeled fluorescent neurons plotted on camera lucida drawings.

Greatest numbers of fluorescent neurons were observed after hypoglossal injections, and fewest after lumbar injections. Reticular formation neurons were topographically organized: neurons projecting to the hypoglossal nucleus were most dorsal, neurons projecting to cervical spinal cord were intermediate, and neurons projecting to lumbar spinal cord were most ventral. Relatively little overlap among these three groups of neurons was observed. These data indicate a distinct topography to the organization of reticulospinal projections that may mediate motor inhibition in REMS. (Supported by SCOR grant HL-42236)

45.2

EFFERENT PROJECTIONS FROM NEURONS IN THE NUCLEUS TRACTUS SOLITARIUS WHICH MAY PLAY A ROLE IN THE BREUER-HERING REFLEX. A. C. Bonham, D. R. McCrimmon, & S. K. Coles*, Northwestern Univ. Med. School, Chicago, IL 60611.

We previously identified an area in the nucleus tractus solitarius (NTS) just medial to the tractus and centered about 300μm caudal to the obex in which: 1) chemical excitation mimicked the Breuer-Hering (BH) reflex (produced apnea), 2) interruption of synaptic transmission impaired the BH reflex and, 3) slowly adapting pulmonary stretch receptor interneurons (pump cells) were recorded. (Soc. Neurosci 114:189.2, '88). To identify potential efferent projections from the cells in this region, we injected *Phaseolus vulgaris* leucoagglutinin (PHA-L). The site was physiologically identified by injecting the excitatory amino acid DL-homocysteic acid (DLH) through one barrel of a double barrel pipette. Once the center of the region was identified in which DLH (3nl of 5 or 20mM) produced an apnea (cessation of diaphragm EMG), PHA-L was injected through the adjacent barrel. From the injection site a band of axons swept caudally (up to 700μm) and medially (up to midline) within the NTS. In separate preliminary experiments, DLH injections in this area produced apnea; in contrast to the rostral region, the apnea elicited from this caudal area was accompanied by increases or decreases in arterial pressure. Following PHA-L injections, which were larger but still restricted to the medial NTS, labelled axons and varicosities were located in the rostral NTS, para ambigual region, locus coeruleus, and Kölliker-Fuse.

These data suggest that some neurons with a presumptive role in the BH reflex synapse caudally within the NTS. Supported by R01 HL 40336 and HL 07717.

HISTOLOGICAL STUDIES ON BRAINSTEM RESPIRATORY CHEMOSENSITIVE AREA IN RATS. Y. Pan*, F. Bada *, D.G. Bernard*, J.A. Holloway, C.O. Trouth. Dept. of Physiol. & Biophysics, Coll. of Med., Howard Univ. Washington, D.C. 20059.

The caudal respiratory chemosensitive area on the ventral medullary surface (VMS) of choralose-urethane anesthetized rats was explored electrophysiologically for neurons which increased their firing rate in response to increased inspired CO2 (PICO2) but not to other modalities of sensation. Recording sites of CO2 sensitivity were found between and lateral to the hypoglossal rootlets at the exit from the brainstem. The recordings sites were marked electrolytically and controlled histologically. Light and electronmicroscopic examination showed neuronal elements with a rich array of synapses scattered among astrocytic processes within the marginal glia, similar to those described in the cat. Neurons rich in synapses were also found within the marginal glia along blood vessels as they pierce the VMS making intimate contact with vascular walls. These latter are reminiscent of neurovascular elements and may be involved in 1)neurosecretion, 2)chemoreception, or 3) vasomotor function. (Supported by the NIH Grant-MBRS 2-S06-RR-08016 AND PH 55-T 32 GM-07800.)

45.5

ONTOGENY OF OPIOID RECEPTORS IN THE RAT BRAINSTEM. Y.Xia * and G.G. Haddad (SPON: J. Stitt). Dept. of Pediatrics (Div. Respir. Medicine),Yale Univ., New Haven, CT 06510.

Opioids have been shown to play a role in modulating cardiorespiratory function during hypoxia. Differences in hypoxic responsiveness between young and adult can be attributed in part to differences in the maturation of the opioid system. Little is known, however, about the ontogeny of opioid receptors in the brainstem. In this work, we use autoradiographic techniques to study opioid receptor distribution in the pons and medulla of rats at ages of 1, 5, 10, 21 and 120 days. Ten μM sections from 4 standard planes were incubated for 45 min. at 25°C with 4 nM of either 3H-DAGO for labelling mu-receptors or 3H-DADLE with cold DAGO for labelling delta-receptors. Results show that the density of delta-receptors is much less than that of mu-receptors in most regions. High concentration of mu-receptors is found in nuclei such as Nucleus Tractus Solitarius (NTS), Dorsal Vagal Nucleus (DMNX), Nucleus Ambiguus, Parabrachial and Kölliker-Fuse Nuclei. Fewer receptors are present in the Hypoglossal and Raphe nuclei. Although different concentrations of mu-receptors are found in various areas at birth, mu-receptors increase with age in all regions, especially in NTS and DMNX. We conclude that: 1) brainstem regions containing the highest mu-receptors are cardiorespiratory-related; 2) marked differences in mu-receptor density exist in the respiratory-related areas and 3) the developmental time schedule of mu-receptors varies among brainstem nuclei.

RESPIRATORY PATTERNING FOLLOWING ACUTE COCAINE ADMINISTRATION. R.R. Terreberry, R.M. Harper, R.K. Harper*, R.C. Frysinger and C.A. Richard. Dept. of Anatomy & Cell Biology and Brain Research Institute, UCLA, Los Angeles, CA 90024.

We examined patterning of diaphragmatic activity in intact, freely moving cats following intravenous or intraventricular administration of 3 dose levels of cocaine (5, 7.5, and 10 mg/kg intravenously; .625, 1.25, and 2.5 μg intraventricularly). EEG, EMG, EOG, diaphragmatic EMG, hippocampal slow wave, and core temperature recordings were continuously gathered during sleep and waking states following which cocaine was administered intravenously or intraventricularly. Low dose cocaine administration was followed by tachypnea; high dose cocaine was followed by convulsive seizures in which respiratory patterning continued independently of the phasic motor activity associated with seizures. Extreme elevation of core temperature associated with high levels of cocaine induced panting with greatly enhanced genioglossal and facial motor upper airway muscle activity. Both intravenous and intraventricular administration resulted in tachypnea. Cocaine greatly altered respiratory patterning, with pronounced reduction of respiratory period and recruitment of upper airway muscles; some of these patterning changes may be secondary to cocaine-induced hyperthermia. Supported by DA04913.

45.7

ROLE OF ENDOGENOUS OPIATES AT BRAINSTEM RESPIRATORY CHEMOSENSITIVE AREAS. D.G. Bernard*, F. Bada*, Y. Pan*, P. Archer*, C.O. Trouth. Dept. of Physiol. & Biophysics, Coll. of Med., Howard University, Washington, D.C. 20059.

Sensing elements on the ventrolateral medullary surface (VMS) are involved in the central chemical regulation of breathing. In spontaneously breathing cats anesthetized with chloralose-urethane, the ventilatory responses to morphine (MOR), Beta-endorphin (END) and naloxone (NAL) applied topically to the caudal chemosensitive area were investigated. MOR and END depressed minute ventilation $\dot{V}E$, whereas NAL increased $\dot{V}E$. Increased $\dot{V}E$ induced by increased inspired CO2 or topically applied acetylcholine was augmented by NAL. These findings suggest a modulatory role for endogenous opiates at VMS chemosensitive sites. Immunocytochemical studies by light microscopy revealed positive reaction product in cell bodies and axons of superficial neurons using peroxidase-antiperoxidase technique. Electron microscopy identified reaction products in mitochondria and secretory granules. No reaction products were found in control sections without antibody. 45.8

MODULATION BY μ OPIOID ANTAGONISM OF RESPIRATORY PATTERN IN RELATION TO SLEEP/WAKE STATE IN BEHAVING PIGLETS. S.C. Scott, J.G. Inman and I.R. Moss*. Depts. Pediatrics, Physiology/Biophysics, UT Southwestern, Dallas, TX 75235

Young (8-13 days; y) and older (28-34 days; o) piglets were instrumented aseptically for chronic recording of sleep/wake states (biparietal electroencephalogram, horizontal and vertical electrooculogram, nuchal electromyogram (EMG)), posterior cricoarytenoid and diaphragmatic EMG (EMG_{pca}, EMG_{di}), arterial pressure and heart rate, and measurement of arterial pH and gas tensions. Following recovery from surgery, 1-2 ∿1.5 h daily sessions of control recordings were conducted with the piglet in a sling. Then, on each of three successive days, recording sessions were divided into control and post μ antagonism (CTP, a somatostatin analog, 10-40 mg/kg i.v.). In quiet sleep, that state which best reflects the uninfluenced respiratory oscillator, respiratory frequency increased following CTP, inspiratory time decreased in the o and y, peak amplitude of EMG_{di} increased in the y and the rate of rise of EMG_{di} increased in both but to a greater extent in y. The effect of CTP on EMG_{pca} was inconsistent. Similar results were seen during transitional sleep and wakefulness but not during active sleep. We conclude that μ opioid antagonism enhances basic diaphragmatic respiratory drive in neonatal piglets, young more so than older. (HL36939)

45.9

A GLUTAMATERGIC SYSTEM IN THE VENTROLATERAL MEDULLA IS REQUIRED FOR RESPIRATION. T.P. Abrahams, P.J. Hornby, D.P. Walton, A. Taviera DaSilva* and R.A. Gillis*. Depts. of Pharmacology and Medicine, Georgetown University, Washington, D.C. 20007.

Recently, we have described a site in the ventrolateral medulla of cats where blockade of tonic GABAergic tone by microinjection of bicuculline produced dose-dependent decreases in mean arterial pressure (MAP; Neurosci. Abstr. 12:536, 1986). This area is approximately 2.5mm rostral to obex, 4mm lateral to the midline and 1mm below the ventral surface. The purpose of the present study was to determine whether blockade of tonic glutamatergic tone at this site by microinjection of kynurenic acid would alter cardiorespiratory activity. Kynurenic acid (50nl of 250mM solution) was microinjected bilaterally into this region in chloralose-anesthetized cats (N=6), while monitoring MAP, heart rate (HR), tidal volume (V_t) and respiratory rate (f). Kynurenic acid produced a decrease in V_t (-18.5±2.6ml, $P<0.05$) and an increase in f (+17±5 breathes/min, $P<0.05$). These changes progressed to apnea in each animal tested. No significant changes in MAP and HR were observed. Unilateral microinjection of kynurenic acid was ineffective in producing pronounced respiratory depression and apnea. The inactive analogue of kynurenic acid, xanthurenic acid, microinjected bilaterally into this site did not result in significant alterations of cardiorespiratory activity. These data suggest that a glutamatergic system in the ventrolateral medulla is required for breathing to occur in chloralose-anesthetized cats. Supported by USPHS grant MH 42322.

45.10

MICROINJECTION OF AN EXCITATORY AMINO ACID ANTAGONIST INTO THE VENTROLATERAL MEDULLA INCREASES RESPIRATORY ACTIVITY AND POTENTIATES THE RESPONSE TO HYPOXIA. G.H. Dillon*, D.E. Welsh* and T.G. Waldrop (SPON: G.Iwamoto). Dept. of Physiology, Univ. of Illinois, Urbana, Il. 61801.

Several studies suggest that an excitatory amino acid (EAA) mechanism in the ventrolateral medulla (VLM) may be involved in modulation of cardiorespiratory reflexes. The purpose of this study was to determine if an EAA mechanism in the VLM modulates the respiratory response to hypoxia or hypercapnia in anesthetized rats. Respiratory responses (diaphragmatic EMG activity) to hypoxia and hypercapnia were determined before and after bilateral microinjections of the EAA antagonist kynurenic acid (KYN) into the VLM. Bilateral microinjections of KYN into the VLM produced significant increases in respiratory activity. Hypoxia elicited a significantly larger increase in respiratory activity after KYN injection. The response to hypercapnia tended to be larger also, but was not significantly different from control levels. Accentuated responses returned to pre-injection levels after a 45-60 min. recovery. Furthermore, xanthurenic acid, an inactive analog of KYN, had no significant effects on resting levels or on the reflex responses. We conclude that an excitatory amino acid mechanism in the VLM exerts a tonic effect on respiration and modulates the respiratory response to hypoxia. (NIH HL 38726 and AHA)

45.11

BETHANECHOL MICROINJECTED INTO THE MEDIAL PONTINE RETICULAR FORMATION (mPRF) CAUSES STATE-DEPENDENT CHANGES IN RESPIRATION.
H.A. Baghdoyan, R. Lydic, and K.A. Gilbert.* Medicine and Anesthesia, Pennsylvania State University, College of Medicine, Hershey,Pa 17033.

Microinjection of cholinergic agonists into the mPRF of intact, unanesthetized cats produces a state which is similar to naturally occurring rapid eye movement (REM) sleep. Following our recent demonstration that the mixed cholinergic agonist carbachol causes state-dependent changes in respiration (Neurosci. Letts. 102:[In Press], 1989) the present study is examining the hypothesis that these respiratory effects are muscarinically mediated. To date we have performed 12 microinjection trials in 2 cats using the muscarinic cholinergic agonist bethanechol (4.3ug/0.25 ul). Respiratory frequency (f), tidal volume in ml (VT), and minute ventilation in ml/min (Vdot) were analyzed for 30 one min bins during waking (W) and for 30 one min bins during the REM sleep like state evoked by bethanechol (D-BETH). The means (±s.d.) during W were: f=30.7(±5.7), VT =22.4(±4), and Vdot=675(±105). During D-BETH the means(±s.d.) were: f=19.8(±3.2), VT=27.1(±6.5), and Vdot=527.4(±105). In D-BETH the respiratory measures were significantly different from respiration during W, and mPRF injections of atropine sulfate (15ug/0.25ul) blocked D-BETH. These findings demonstrate that muscarinic cholinergic mechanisms in the mPRF can cause state-dependent changes in respiration.

45.12

THE CHOLINOCEPTIVE MEDIAL PONTINE RETICULAR FORMATION (mPRF) MEDIATES STATE-DEPENDENT CHANGES IN THE VENTILATORY RESPONSE TO HYPERCAPNIA (HCVR) AND HYPOXIA (HVR). R. Lydic, H.A. Baghdoyan, and R. Wertz. Medicine and Anesthesia, Pennsylvania State University, College of Medicine, Hershey,Pa 17033.

In most mammals, including humans, the ability to generate a compensatory ventilatory response to hypoxic or hypercapnic stimuli is highly dependent on states of consciousness. The central mechanisms underlying this state-dependence is unknown. Since the mPRF is known to play a role in sleep cycle control, this study is testing the hypothesis that the cholinoceptive mPRF can also cause state-dependent alterations in the HVR and HCVR. Using 2 cats, we have performed 24 HCVR and 24 HVR drives during W and during the REM sleep-like state (D-BETH) evoked by mPRF injections of the muscarinic cholinergic agonist bethanechol (4.3ug/0.25ul). Regression analyses of min ventilation (y) and end-tidal CO_2 (x) described the HCVR in W as Y=52.2(x)-897 and during D-BETH as Y=33.4(x)-452. HVR regressions describing y as a function of x (O_2 saturation) were Y=-35.4(x)+4118 during W and Y=-27.3(x)+3551 during D-BETH. For both the HCVR drives (n=302 x,y pairs) and the HVR drives (n=375 x,y pairs) the slopes of the ventilatory response were significantly less during D-BETH than during W. Thus, muscarinic cholinergic mechanisms in the mPRF can cause state-dependent alterations in the ventilatory responses to hypoxia and to hypercapnia.

45.13

EFFECTS OF INTRAVENOUS BICUCULLINE AND STRYCHNINE ON TRANSIENT INSPIRATORY INHIBITORY RESPONSES IN THE CAT. D.F. Speck, D. Karius* and L. Ling*. Dept. of Physiology, Univ. of Kentucky Med. Ctr., Lexington, KY 40536-0084.

Single shock stimulation of the superior laryngeal nerve (SLN), the intercostal nerves (ICN), the phrenic nerve (PN) or within the dorsal respiratory group (DRG) has been shown to produce a transient, short-latency attenuation of inspiratory motor activity. This study determined if i.v. injection of either strychnine or bicuculline could affect these transient inhibitory responses. Experiments were conducted in decerebrate cats initially anesthetized with 50 mg/kg pentothal (i.p.). A microelectrode was positioned within the right DRG and the right PN, SLN and left ICN were mounted on bipolar electrodes for stimulation. After recording individual control responses of left PN activity to threshold stimulation of the three nerves and the DRG, bicuculline (1 mg/kg) or strychnine (50 ug/kg) was injected. Five minutes after injection the responses to stimulation were again recorded. With strychnine administration, the procedure was reiterated until the cumulative dose elicited marked convulsions. Systemic bicuculline had no effect on transient inspiratory inhibitory responses. However strychnine prolonged the onset latency of all four inhibitory responses examined. Since the duration of inhibition was not shortened, the onset prolongation is unlikely to result solely from increased motoneuronal excitability. (Supported by P01 HL40369).

45.14

HYPOTHALAMIC GABAERGIC MODULATION OF THE RESPIRATORY RESPONSE TO HYPERCAPNIA. C.A. Peano* and T. G. Waldrop. Dept. of Physiology, Univ. of Illinois, Urbana, IL 61801.

Previous reports from this laboratory have shown that a GABAergic mechanism in the posterior hypothalamus (PH) regulates cardiorespiratory activity. The purpose of the present study was to determine if a similar mechanism modulates the respiratory responses to hypercapnia and hypoxia in the anesthetized rat. Cardiovascular and respiratory responses to hypercapnia (5% CO_2) and to hypoxia (10% O_2) were recorded before and after microinjection of an inhibitor of GABA synthesis (3-mercaptopropionic acid, 3-MP) into the PH. Respiratory output was derived from diaphragmatic EMG activity. Microinjection of 3-MP evoked increases in arterial pressure, heart rate and respiratory frequency which occurred after a latency of $\sim$ 20 minutes. Moreover, the fall in heart rate as well as the increase in respiratory activity evoked by hypercapnia were accentuated after microinjection of 3-MP. In contrast, the arterial pressure response to hypercapnia and the responses to hypoxia were not altered by the microinjections. These results indicate that a GABAergic mechanism exerts a tonic inhibitory action upon posterior hypothalamic neurons. Lifting this inhibition provides a specific excitatory effect upon resting cardiorespiratory activity and responses to hypercapnia. (Supported by NIH HL 38726 and the AHA).

46.1

A POSITION-SPECIFIC ANTIGEN IN THE EARLY QUAIL EMBRYO
J.H. Sabry and P.H. Patterson. Division of Biology, 216-76, California Institute of Technology, Pasadena, CA 91125.

Transplantation studies in avian embryos have suggested the existence of positional cues that can inform donor neural tube and neural crest of their location along the rostrocaudal axis. This rostrocaudal, positional information has been postulated to exist on cells or in the extracellular matrix. We report here on the generation of monoclonal antibodies to position-specific antigens using the cyclophosphamide immunosuppression technique. One antibody, atipo-1[< Jap *atama* = head + *shipo* = tail] recognizes an antigen located on the surface of ectodermal cells, in the subectodermal space, and around the neural tube and notochord. Antibody binding is present only in the most caudal region of stage 13 quail embryos, just before neural crest migration. However, in the cranial region when crest migration occurs(stage 7), atipo-1 does not bind. This caudal-specific distribution of the atipo-1 binding differs strikingly from that of known molecules thought to be involved in embryonic morphogenesis. Thus, the atipo-1 antigen is a candidate for providing position-specific information in the early quail embryo.

46.2

SPECIFIC POSITIONAL CUES USED BY AFFERENT PROJECTIONS ARE PRESENT IN ECTOPIC NEUROPILS IN THE LEECH.
M.B. Passani*, A. Peinado, C.A. Baptista* and E.R. Macagno. (SPON: D. Gorlick) Dept. of Biological Sciences, Columbia University, New York, N.Y. 10027.

Afferent projections segregate into four distinct bilateral longitudinal tracts in the neuropils of most segmental ganglia in the leech *Hirudo medicinalis*, as revealed by staining with the monoclonal antibody Lan 3-2 which is specific for afferent axons in *H. medicinalis*. We found that an additional tract exists in the neuropils of the fifth and sixth body ganglia (SG5 and SG6, also known as sex ganglia). These fibers appear to originate in the reproductive tissues, since they are anterogradely labelled by rhodamine isothyiocianate (RITC) applied to the gonopores. Also, animals which had the sexual organs removed at early embryonic stages did not have the additional tract. To assess (a) whether segment-specific differences exist in the pattern of cues available to incoming fibers and (b) the degree of specificity with which the incoming fibers recognize appropriate pathways, we transplanted the primordia of the male reproductive tissue to body segments that normally do not receive afferents from the male organ (SG7-SG15). Transplants were carried out in 9-10 day old animals. Transverse sections of the SG adjacent to the ectopic male reproductive tissue in animals 30-60 days old were stained with the mAb Lan 3-2. In 6 cases out of 22, the afferent fibers appeared to be sorted out in five fascicles, as seen in SG5 and SG6. In contrast, when homotopic patches of skin were transplanted, the afferent fibers organized themselves in four bundles as in non sex ganglia. We propose that the ganglionic neuropils in all segments express the positional cues required by afferent axons to select a particular tract, regardless of whether such cues are normally required in any particular location.

46.3

RHOMBOMERE DEVELOPMENT IN THE CHICKEN EMBRYO.
P.G. Layer, R. Alber* and S. Kaulich*. Max-Planck-Institut für Entwicklungsbiologie, D-7400 Tübingen, FRG.

In order to correlate patterns of neuronal proliferation, migration and differentiation during the development of rhombomeres (called R1 - R7 according to their rostrocaudal position) in the chick hindbrain between stages HH 9 - HH 22, we have combined cholinesterase- (AChE, BChE), peanut lectin- (PNA) and immunohistochemistry (BrdU-, HNK-1-, G4-antibodies). From the onset of rhombomere formation at HH 9-10, four preotic (R2-R5) and one postotic (R6/7) rhombomeres are discernible. Pairs of R4+R5 and R2+R3 corresponding to the acusticofacial and the trigeminal complexes respectively, differentiate almost concomitantly with a delay in R5 and R3. A segregation of R1 from the 2nd rhombomere is indicated after HH 13/14 by a weak PNA-border. Then the postotic rhombomere (Glossopharyngeal-Vagus-Complex) is further subdivided into R6 and R7; R6 is delayed. We failed to locate the caudal limit of an 8th rhombomere. We conclude, that in addition to a segmental pair rule (see Lumsden, A. & Keynes,R., Nature 337, 424-428, 1989), superimposed mechanisms at both ends of the hindbrain (R1, R7/8) and at the otic placode have to be postulated.

46.4

CUES USED BY MUSCLES FOR THEIR POSITIONING IN CAENORHABDITIS ELEGANS.
C. Li[1,2] and M. Chalfie[2]. [1]Dept. of Biology, Boston Univ., Boston, MA; [2]Dept. of Biol. Sci., Columbia Univ., New York, NY.

The positioning of the vulval muscles in the egg-laying system of the nematode Caenorhabditis elegans appears to be dependent on cues from the somatic gonad and vulva. Both the position of the vulval muscles and their orientation around the vulva can be visualized with an anti-myosin antibody (kindly provided by Dave Miller).

Ablation of the somatic gonad precursors (Z1 and Z4) in wild-type animals, resulting in the loss of the somatic gonad and vulva, leads to the appearance of vulval-like muscles that are randomly distributed and oriented along the length of the animal. When only the vulva is absent, as in the Vulvaless mutants *n300*, *lin-2*, and *lin-10*, vulval-like muscles develop in their correct positions, but the muscles are randomly oriented. Thus, the muscles can be positioned with cues from the somatic gonad alone, but they are oriented incorrectly.

The presence of extra vulval cells in the Multivulva mutant *lin-15* has little or no effect on either the position or orientation of the vulval muscles. In *lin-15* animals in which Z1 and Z4 are ablated, however, vulval-like muscles in their correct orientation are visible at the vulva and extra vulval cells. No vulval-like muscles are detected elsewhere. These results suggest that the vulval cells also provide cues for positioning and orienting the vulval muscles.

The VC and HSN neurons innervate the vulval muscles. In lin-*15* mutants in which Z1 and Z4 are ablated, vulval-like muscles appear in positions independent of VC and HSN processes. The neurons, therefore, do not appear to provide cues to the muscles for positioning.

46.5

MAINTENANCE OF STRIATAL COMPARTMENTS IN THE REELER MOUSE SUGGESTS PATTERN FORMATION INDEPENDENT OF RADIAL GLIAL GUIDANCE.
J.G. Johnston, L.A. Krushel and D. van der Kooy, Neurobiology Research Group, Department of Anatomy, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

Radial glial fibers appear to be critical in the guidance of young postmitotic neurons to their final destinations in the cortex. However, it is not clear whether radial glial cells play a similar role in the development of the other major structure of the telencephalon, the striatum. The striatum is a compartmentalized structure which can be subdivided into the patches and surrounding matrix, on the bases of distributions of neurotransmitters, receptors and connections. Several studies have suggested that similar developmental mechanisms (commitment to birthdate, adhesion) underly pattern formation in the striatum and cortex. To test if radial glial cells are necessary for the compartmentalization of the striatum, we have studied the development of the patch compartment in the mutant reeler mouse(*rel+/rel+*). The reeler's deficit appears to be expressed primarily in radial glial cells. Migrating neurons, which normally detach from radial glial fibers, fail to do so, resulting in the reversal of cortical lamina. We have shown that opiate receptor patches in the reeler appear normal in number, size and distribution in comparison to unaffected littermates (*rel-/rel-*; *rel+/rel-*). These results suggest that in the absence of a glial guidance mechanism, that is critical to cortical lamina organization, other developmental mechanisms (such as selective adhesion of early born patch cells or the afferent connections of patch cells) are sufficient to constrain the formation of striatal compartments.

46.6

THE LEECH HOMEOBOX GENE LOX2 IS EXPRESSED EMBRYONICALLY IN POSTERIOR SEGMENTAL GANGLIA OF *HIRUDO MEDICINALIS*.
J. W. Wysocka-Diller* and E. R. Macagno. Dep. of Biological Sciences, Columbia University New York, NY 10027, USA

Homeobox genes, first characterized in *Drosophila*, have been shown to be expressed in the developing nervous systems of many species. We have isolated several homeobox genes of the leech *Hirudo medicinalis* on the basis of sequence homology to fly *Antp*-type homeobox genes and determined that at least two of them are expressed in the developing leech CNS in temporally and spatialy restricted domains. *In situ* hybridization studies of wholemounted, 5-14 day embryos with probes generated from one of these, Lox2, first show detectable expression of this gene in 7 day embryos, in the ganglionic primordia of body segments 7 to 12. By the 8th day of development, the signal has extended posteriorly to the 15th body ganglion and become detectable on two small bilateral clusters of cells near the posterior margin of the 6th body ganglion. By the 11th day, all posterior ganglia, including the fused tail ganglion, show expression of Lox2. At later stages there is a decrease in the level of the signal seen over the ganglia in segments posterior to the 14th. These observations indicate that the Lox2 domain of expression has an invariable anterior boundary and a dynamic posterior boundary during the developmental stages examined. Moreover, expression appears to precede neuronal differentiation. Since homologues of many if not most of the neurons in segmental ganglia that show expression of Lox2 are also present in ganglia which do not, our observations suggest that neurons with the same function may have position-dependent levels of expression of Lox2. Thus, it would seem that Lox2 by itself cannot specify cell type, but it might have such a function in conjunction with other genes that are expressed in a spatially distinct manner.

46.7

EXPRESSION OF COMPARTMENTATION ANTIGENS IN RAT CEREBELLAR TRANSPLANTS

N. Leclerc*(1), J. Rafrafi*(1), M.Wassef*(2), C. Sotelo (2), M. Thomasset (3), A. C. Granholm (4), and R. Hawkes*(5) (SPON: M. Colonnier). (1) Lab. Neurobiology, Laval U., Quebec G1K 7P4, Canada. (2) Lab. de Neuromorphologie, (3) INSERM U-106, 75651, Paris Cedex 13, France. (4) Dept Cell Biology, U. Linköping, S-581 85, Linköping, Sweden (5) Dept. Anatomy, U. of Calgary, Calgary, Alberta T2N 4N1, Canada.

Zebrin I (the mabQ113 antigen) is expressed in rat by a subset of Purkinje cells that form 14 parasagittal bands that correspond to divisions in the olivocerebellar projection. The OCP compartments are present prior to the expression of the mature zebrin I phenotype, suggesting that afferent input may regulate the zebrin I phenotype of the target. Lesion studies revealed no role for afferent inputs in the regulation of zebrin I expression postnatally, but a prenatal role remained open. To explore this possibility, cerebellar anlagen were dissected from rat embryos (E14) and transplanted ectopically into adult hosts, either into the anterior chamber of the eye or into cavities prepared in the neocortex. Grafts were allowed to mature and then immunostained. Zebrin I was expressed by grafted Purkinje cells *in cortico* and *in oculo*. Double-labelling experiments using anti-zebrin and the anti-calbidin confirm that both the zebrin I^+ and the zebrin I^- phenotypes are present. It therefore seems probable that afferent input does not determine the PC zebrin I phenotype.

46.8

COMPARATIVE MORPHOLOGY OF +/+ PURKINJE CELL DENDRITES IN STAGGERER, LURCHER AND WILD TYPE CHIMERIC MICE.

J. M. Soha and K. Herrup. E. K. Shriver Center, Waltham, MA 02254.

Previous studies from this lab described aberrant and frequently atrophic dendritic morphologies among the wild type Purkinje cells (PCs) remaining in the cerebella of lurcher↔wild type chimeric mice after the loss of all lurcher PCs. A working hypothesis to account for these morphological irregularities and the enhanced survival of granule cells in these mice is that wild type PCs are deafferented, and consequently provide additional trophic support to granule cells during the postnatal episode of cell death. The hypothesis predicts normal morphology for wild type PCs in staggerer↔wild type chimeras.

To test this prediction by comparison of a statistically significant number of PCs, a subjective scoring scheme was employed. Golgi processed PCs were assessed in relation to a series of 10 morphological criteria (e.g. size, complexity, orientation). PCs were visually assigned scores of 1 (aberrant) to 5 (ideal) for each property. As reported previously, wild type PCs in lurcher chimeras differed significantly from PCs in the wild type chimera for several of the scored properties, consistent with their atrophic, deafferented appearance. In contrast, wild type PCs in a staggerer chimera scored similarly to PCs in the normal chimera, while differing significantly from lurcher chimera PCs for this set of properties. PCs in staggerer and wild type chimeras differed significantly for a second set of properties, apparently due to a more erratic orientation in staggerer chimeras. Golgi impregnated PCs displaying the staggerer phenotype were also identified in the staggerer chimera. Supported by NIH grants NS20591 and HD07251.

46.9

CEREBELLAR PHENOTYPE OF TWO ALLELES OF THE REELER MUTATION ON SIMILAR BACKGROUNDS.

A.M. Goffinet, Univ. Louvain Med. Sch., Brussels, Belgium.

Reeler mutant mice exist as two alleles (Ed and Orl) on different backgrounds (C57 and BALB/c). Orl *reeler* mice on BALB/c are less affected and survive better than Ed mutants on C57 background. Their cerebellum has better developed folia (such as a well-defined fissura secunda) and a thicker molecular layer. To assess whether these differences are allelic or due to background, congenic strains have been produced by successive backcross, allowing the comparison of the two alleles on similar backgrounds.

The phenotype of mutant animals was progressively modified during backcrosses, in parallel to changing background. From F10, mice on similar backgrounds are indistinguishable. That is, Ed and Orl *reeler* mice survive well (approx. 50%) on BALB/c, but not on C57 background. The cerebellar phenotype also changes with modification of the background: in C57 *reeler* mice (both Ed and Orl), the cerebellum is almost smooth and the molecular layer thin, while the BALB/c *reeler* cerebellum has a well-defined fissura secunda and a thicker molecular layer.

These observations show that phenotypic differences between the Ed and Orl *reeler* mutants are due to differences in genetic background.

46.10

PATTERNS OF CEREBELLAR FOLIATION IN RECOMBINANT INBRED MICE.

D. Wahlsten and M. Andison*, Dept. of Psychology, Univ. of Waterloo, Waterloo, Ontario, CANADA N2L 3G1.

Foliation of the cerebellum was quantified by measuring depth of fissures at the mid-sagittal plane for the inbred strains BALB/cByJ(B), C57BL/6ByJ(C), and their recombinant inbred strains (D, E, G, H, I, J, K). Six extra fissures were seen in various mice: intracentral(1), intraculmen A and B(2A, 2B), intradeclive(3), intrauvular A and B (4A, 4B). In a sample of 186 mice, the strains with a larger cerebellum showed more fissures and proportionately greater depth of the extra fissures ($r = 0.63$), but size alone could not entirely account for the qualitatively different patterns of fissures for different strains. Strain B had frequent 3 and deep 4B; C had shallow 4B and few others; D usually had no extra fissures; E showed no 1 but always had 4B; G had deep 1; H had deep 2A; I resembled B; J had deep 2B; and K had deep 4A. Because only two of the nine strains resembled each other in foliation pattern (B and I) and each of the other seven was unique, the genetic difference between B and C must involve several loci. Within a strain there were noteworthy qualitative differences among individual mice.

Supported in part by grant 4878 from the Natural Sciences and Engineering Research Council of Canada.

SOMATIC AND VISCERAL AFFERENTS I

47.1

TOPOGRAPHY OF IDENTIFIED CAT DRG AFFERENTS.

R.D. Rose. Biological Sciences, Duquesne University, Pgh PA 15282 and Neurobiology & Behavior, SUNY Stony Brook NY 11794

Topographical organization (TO) within the cat DRG was studied using orthograde tracers, somal reconstruction, intracellular recording, and physiological identification of peripheral receptors supplied. Some statistically significant TO was found. For example, in S1, somata supplying sural nerve are widely distributed, yet concentrated in the rostral pole. Further, there is clustered organization of somata supplying at least some muscle nerves. Finally, anecdotal observations of likelihood to next record intracellularly from a physiologically similar cell were examined statistically. In summary, while there exists some degree of topographical organization within the DRG, it is substantially less apparent and demonstrable than elsewhere. My interpretation is that extant topography is likely the consequence of system development. Particularly, large afferent populations supplying single peripheral targets are likely derived from similarly located neural crest cells; and, further, since proliferation continues after migration is complete (Honig 1982 JP) and afferents supplying similar receptors have similar somal membrane properties (Rose 1986 diss.), post-migratory clones of afferents might supply similar peripheral receptors within a given peripheral target.

47.2

SELECTIVE DECREASE OF SMALL SENSORY NEURONS LABELED WITH HRP AFTER LASER IRRADIATION OF THE RAT TIBIAL NERVE.

U. Wesselmann, S.-F. Lin* and W. Z. Rymer, Dept. of Physiology & Biomedical Engineering, Northwestern University Medical School, Chicago, IL 60611.

Recent electrophysiological evidence indicates that Q-switched Nd:YAG laser irradiation might have selective effects on neural impulse propagation in small slow conducting sensory nerve fibers as compared to large diameter afferents (Wesselmann et al., Soc. Neurosci. Abstr. 14:698, 1988). In an attempt to clarify the ultimate fate of sensory neurons after laser application to their peripheral axons, we have used HRP to retrogradely label dorsal root ganglion (DRG) cells. Q-switched Nd:YAG laser light was applied to the tibial nerve at pulse energies of 70 or 80 mJ/pulse for 5 min in seven experimental rats. Seven days later HRP was applied to the left (laser-treated) and right (untreated) tibial nerve 5 mm proximal to the site of laser application, as previously described for injured axons (Wesselmann et al., Neurosci. 13:1299, 1984). In control animals (n=3) the numbers of labeled DRG cells were not significantly different between sides (left: 3699±897, right: 3683±892)*. In contrast, after previous laser irradiation, labeling was always less on the laser-treated side as compared to the untreated side (left: 2183±513, right: 3937±225)*. The mean decrease (-47%±12 of contralateral labeling)* was significantly different from the differences in labeling between sides in the control group ($P<0.03$). Analysis of the dimensions of labeled cells suggested, that the reduction of labeled cells on the laser-treated side was mainly due to a deficit in small sensory neurons. The reduced labeling of small sensory cells after laser irradiation might be due to 1) impaired uptake, 2) altered axonal transport, or 3) increased rate of HRP breakdown. Since the conduction velocity of afferent fibers in rats is related to the size of their somata (Harper et al., J. Physiol., 359:31, 1985), our histological data imply that laser light selectively affects slow conducting fibers. This is in agreement with our previous electrophysiological observation. The functional characteristics of these slow conducting sensory fibers impaired by laser irradiation remain to be examined electrophysiologically. 47.3

ANALYSIS OF MU, DELTA, AND KAPPA OPIOID BINDING SITES IN RAT SPINAL CORD IN AN EXPERIMENTAL MODEL OF PERIPHERAL NEUROPATHY. C.W. Stevens, K. C. Kajander, G. J. Bennett and V. S. Seybold Department of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455 and NAB, NIDR, NIH, Bethesda, MD 20892.

An experimental model for peripheral neuropathy induced by loose ligation of the sciatic nerve has been developed in rats (Bennett and Xie, *Pain 33*, 1988). These rats exhibit hyperalgesia in response to chemical and thermal stimuli, and other behaviors consistent with neuropathy in the affected hindlimb. Thus, this model in rats may be useful to investigate neuropathic pain disorders in humans. The present study examined changes in mu, delta, and kappa opioid receptor binding in discrete areas of the rat spinal cord associated with primary afferent neurons putatively involved in this peripheral neuropathy.

Spinal segment L4 was obtained from control rats (N=4) and 2, 5 and 10 days after nerve ligation (N=8 rats/group). Autoradiographic studies of opioid binding sites were performed on spinal cord sections using tritiated sufentanil (0.3 nM), DPDPE (5 nM), and U-69593 (3 nM) to label mu, delta, and kappa sites, respectively. Data were analysed by computerized densitometry. Specific binding was defined as total binding minus the non-specific binding obtained in the presence of cold ligands. A significant *decrease* in the density of mu sites occurred in lamina X on the ligated side compared to the nonligated side at 10 days postsurgery. Delta sites *increased* in laminae I-II on the ligated side on day 2, however significantly *decreased* in laminae I-II on day 10. Changes in kappa opioid binding were difficult to assess due to overall low binding. These differences may represent alterations of opioid receptors in conjunction with changes previously shown for endogenous opioid peptides in this model. Supported by USPHS grants DA05309 and NS17702.

47.4

ANALYSIS OF ^{125}I-SUBSTANCE P BINDING SITES IN RAT SPINAL CORD IN AN EXPERIMENTAL MODEL OF PERIPHERAL NEUROPATHY L. M. Aanonsen, K. C. Kajander, G. J. Bennett and V. S. Seybold
Department of Cell Biology & Neuroanatomy, University of Minnesota, Minneapolis, MN 55455; NAB, NIDR, NIH, Bethesda, MD 20892

An experimental model for a peripheral neuropathy induced by tying loose ligatures around the sciatic nerve has been characterized in rats (Bennett and Xie,1988). These rats exhibit hyperalgesia in response to chemical and thermal stimuli. Thus, this peripheral neuropathy in rats may represent a model of neuropathic pain disorders in humans. In addition to behavioral changes, immunohistochemical studies showed a significant depletion of substance P (SP) in laminae I/II and V on the nerve ligated side of the spinal cord of rats, 20 days after ligation (Bennett et al., 1988). The present study examined changes in SP receptor binding in laminae I/II, V and X, regions of termination of primary afferent neurons putatively involved in this peripheral neuropathy.

Spinal segment L4 was obtained from rats 2, 5 and 10 days after nerve ligation (n=8 rats/group) and from control rats (n=4). Autoradiographic studies were performed on spinal cord sections using 50nM ^{125}I-SP. Nonspecific binding was<5% in laminae I/II and X. Significant *increases* in grain densities were observed on the side ipsilateral to the ligation compared to the nonligated side at 5 and 10 days postsurgery. In a related study, ^{125}I-SP grain densities in laminae I/II were also increased eight days after dorsal rhizotomy in rats. The increase in ^{125}I-SP grain densities after dorsal rhizotomy may be indicative of an upregulation of SP receptors due to the absence of SP release from primary afferent terminals. Thus, the increase in ^{125}I-SP grain densities in laminae I/II in this model of peripheral neuropathy may also be indicative of an upregulation of SP receptors. An upregulation of SP receptors is consistent with the decrease in SP immunoreactivity in laminae I/II previously reported in this model. Supported by USPHS grants DA05309 and NS17702.

47.5

ANALYSIS OF ^{125}I-CGRP BINDING SITES IN RAT SPINAL CORD IN AN EXPERIMENTAL MODEL OF PERIPHERAL NEUROPATHY. M.G. Garry, K.C. Kajander, G.J. Bennett, and V.S. Seybold. Dept. of Cell Biol. and Neuroanatomy, Graduate Program in Neuroscience, Univ. of Minnesota, Minneapolis, MN 55455; NAB, NIDR, NIH, Bethesda, MD 20892.

In an experimental model of peripheral neuropathy, calcitonin gene-related peptide immunoreactivity (CGRP-IR) is significantly depleted in the nerve-damaged side of the dorsal horn of the spinal cord (Bennett et al., 89). Following injury, decreases were observed at 10 and 20 days by RIA, and in laminae I-V at 20 days by immunohistochemical techniques (Bennett et al., '89). The goal of our study was to examine ^{125}I-CGRP binding sites in the dorsal horn of this model to determine whether CGRP binding sites were modified in conjunction with changes in CGRP-IR. In each animal (male rats), loosely constrictive ligatures were placed around the left sciatic nerve. The right hindlimb underwent sham surgery. Control animals received left hindlimb sham surgery only (n=4). L4 spinal cord was examined at 2, 5, and 10 days following ligation (n=8/group). Autoradiography was performed using 0.1nM ^{125}I-CGRP; nonspecific binding (NSB) was determined on adjacent sections by the addition of 100nM unlabeled CGRP with the labeled ligand. The densities of autoradiographic grains over laminae I/II, V, and X were examined using a computerized densitometry system. Specific binding (SB) was determined by subtracting the NSB value from the total binding value within each region of interest in each spinal cord. No changes in SB were observed in laminae I/II, V, or X at any time point examined. These data suggest that changes in CGRP binding sites do not occur in parallel with changes in CGRP-IR as determined by RIA. Changes in binding sites at a later time point (20 day post-ligation), however, remain to be addressed. This work was supported by USPHS grants NS 17702 and T32 DA 07234.

47.6

U-TURN AFFERENT FIBERS IN THE RAT VENTRAL ROOT. K.J. Kim, E.J. Baik-Han* and J.M. Chung. Marine Biomed. Inst. and Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77550.

Neurophysiological evidence for the existence of looping afferent fibers was obtained in the rat ventral root.

Experiments were conducted on 26 adult Sprague-Dawley rats anesthetized with an intraperitoneal injection of sodium pentobarbital. A laminectomy was performed at the lumbosacral level and ventral roots (L4-L6) were cut close to the spinal cord. The distal stump of the cut ventral root was placed on an electrode assembly which consisted of pairs of proximal and distal bipoloar recording electrodes. Action potentials from spontaneously active units were recorded simultaneously from these two pairs of electrodes.

In 6 ventral roots, single unit activity appeared as pairs of spikes with opposite polarity in both the distal and proximal recording electrodes. The timinig and polarity of the spikes can only be logically explained by supposing that they are simultaneous recordings from two pairs of electrodes of two action potentials traveling opposite directions in a single fiber. This explanation was reinforced by recording the activity after sectioning various parts of the ventral root.

These data suggest that there are spontaneously active ventral root fibers that enter the root and then loop back out toward the dorsal root ganglion. (Supported by NIH NS 21266, NS 11255 and RCDA NS 00995)

47.7

SPROUTING VENTRAL ROOT AFFERENT FIBERS PRODUCE SPONTANEOUS ACTIVITY. E.J. Baik-Han*, K.J. Kim and J.M. Chung. Marine Biomed. Inst. and Depts. Anat. & Neurosci. and Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77550.

Regenerating afferent nerve fibers following injury may generate spontaneous activity. We examined the possibility of producing spontaneous activity from the sprouting ventral root afferent fibers, using a paradigm which is known to make ventral root afferents sprout; neonatal peripheral nerve injury.

Experiments were done on 24 anesthetized adult Sprague-Dawley rats which were subjected to a sciatic nerve section at the neonatal stage. Ventral roots (L4-L6) were cut close to the spinal cord and the distal stump was placed on two pairs of proximal and distal recording electrodes. Action potentials from spontaneously active units were recorded simultaneously from these two pairs of electrodes to detect the direction of their propagation.

The activity which propagates proximally is commonly seen and likely originates from the periphery. However, there were other activities which propagate in the distal direction. We interpreted this activity is generated from a site in the ventral root proximal to the recording electrodes. Since the root has been cut near the cord, it is likely that the impulse generating site is the sprouting ending of afferent fibers in the ventral root. This possibility was reinforced by results obtained when the root was sectioned at different levels. (Supported by NIH NS21266, NS11255 and RCDA NS00995)

47.8

EXPRESSION OF GABA-IMMUNOREACTIVITY BY SUBPOPULATIONS OF SENSORY NEURONS IN THE CHICK DORSAL ROOT GANGLIA. G. ROY* and E. PHILIPPE* (Spon: M. Filion), Dept. of Anatomy, Laval University and Center of Neurobiology, 2075 Vitré, Quebec - Canada.

In order to determine the central and peripheral projections of sensory neurons in the chick dorsal root ganglia (DRG), characterization of phenotypes expressed by these neurons was defined by a combination of immunocytochemical and ultrastructural criteria.

Immunocytochemistry was performed with polyclonal antibodies raised against gamma-aminobutyric acid (GABA) according to the peroxydase anti peroxydase procedure (PAP).

Among the whole population of sensory neurons located in the lumbosacral DRG, a few large A and occasionally small B neuronal cell bodies exhibited a GABA-immunoreactivity in their cytoplasm. These immunostained cell bodies could be related to the A2 and B2 subpopulations of chick sensory neurons according to the ultrastructural classification of Philippe and Droz (Neuroscience, 26, 215-224, 1988).

Since defined subclasses of DRG neurons innervate defined tissues, it is assumed that the phenotypic expression reflects in part influences exerted by the central and peripheral target tissues. (Supported by grant of C.R.M.).

47.9

HISTOCHEMICAL AND IMMUNOHISTOCHEMICAL ANALYSIS OF THE RELATIONSHIPS BETWEEN CYTOCHROME OXIDASE (CO), CARBONIC ANHYDRASE (CA), PARVALBUMIN (PV), CALBINDIN D28K (CaBP), CALCITONIN GENE-RELATED PEPTIDE (CGRP) AND FLUORIDE-RESISTANT ACID PHOSPHATASE (FRAP) IN RAT DORSAL ROOT GANGLIA (DRG). P.A. Carr[1], T. Yamamoto[1], K.G. Baimbridge[2] and J.I. Nagy[1] [1]Dept. of Physiol., Univ. of Manitoba, Winnipeg, Man., Canada R3E 0W3 and [2]Dept. of Physiol., Univ. of British Columbia, Vancouver, B.C., Canada V6T 1W5

Quantitative histochemistry for CO activity in neurons of rat lumbar DRG showed a full range of CO staining densities in each size class with many more large type A cells intensely stained than small type B cells. Immunohistochemistry for CO gave similar staining patterns. Histochemically, all neurons with dense CO staining were CA positive. The majority (85%) of cells containing dense CO were also immunoreactive (IR) for PV and CaBP. Dense CO product was found in 90% of PV- and CaBP-IR cells. Staining for CA was displayed by 87% of PV-IR and 76% of CaBP-IR cells. Among all lumbar DRG cells 22% were CaBP-IR while 14% were PV-IR. Greater than 99% of PV-IR cells also contained CaBP. Less than 1% of PV-IR cells and 9% of CaBP-IR cells were immunopositive for CGRP. Thirty percent of all CGRP-IR cells (about 44% of type B CGRP-IR cells) displayed FRAP staining while 50% of FRAP-positive cells were CGRP-IR. These observations suggest that a subpopulation of primary afferent neurons contains high levels of CO, CA, PV and CaBP and that CGRP coexists with FRAP.

47.10

CHOLECYSTOKININ MESSENGER RNA IS PRESENT IN GUINEA PIG BUT NOT RAT DORSAL ROOT GANGLIA (DRG). K.B. Seroogy, N.K. Mohapatra*, M. Rethélyi, D.S. McGehee, P.K. Lund* and E.R. Perl. Dept. of Physiology, University of North Carolina, Chapel Hill, NC 27599 and Second Department of Anatomy, Semmelweis University Medical School, Budapest, Hungary.

The controversy about the immunochemical detection of the neuropeptide cholecystokinin (CCK) in rat primary sensory neurons led us to examine the expression of CCK messenger RNA (mRNA) in rat and guinea pig DRG using *in situ* hybridization and Northern blot techniques. Two different synthetic oligodeoxyribonucleotides (oligomers) complementary to different regions of rat CCK mRNA were 5' end-labeled with ^{32}P and used as probes on fresh tissue sections. After overnight hybridization and washing, the sections were processed for emulsion autoradiography. In guinea pig, CCK mRNA was detected in small and medium sized neurons comprising 10-15% of the total DRG cell population. In contrast, in neurons of rat DRG, CCK mRNA was not detectable. Northern blot analyses revealed a single CCK mRNA species of expected size (0.8kb) in guinea pig DRG but not in rat DRG. A 0.8kb CCK mRNA was detected in spinal cord and cortex of both rat and guinea pig. These results suggest that CCK is normally not synthesized in DRG of rat and that there are species differences in CCK gene expression in mammalian sensory ganglia. (Supported by grants NS 23804 and NS 08525 from NINCDS)

47.11

LOCALIZATION OF SUBSTANCE P AND SOMATOSTATIN MESSENGER RNAs IN DORSAL ROOT GANGLIA (DRG) OF SIX MAMMALIAN SPECIES. N.K. Mohapatra*, K.B. Seroogy and P.K. Lund*. (SPON: S.P. Schneider). Dept. of Physiology, University of North Carolina, Chapel Hill, NC 27599.

The cellular localization of messenger RNAs (mRNAs) encoding the neuropeptides substance P and somatostatin (SOM) was examined in DRG of mouse, rat, hamster, guinea pig, rabbit and cat using *in situ* hybridization. Synthetic oligodeoxyribonucleotides labeled at the 5' end with ^{32}P were used as probes. Sequences were complementary to regions of substance P and SOM mRNAs that are best conserved across mammalian species. Probe specificity was verified based on hybridization with rat and guinea pig substance P and SOM mRNAs on Northern blots. *In situ* hybridizations were performed overnight on fresh tissue sections followed by autoradiographic processing. In each of the six species analysed, substance P mRNA was detected primarily in small neurons comprising 10-20% of the total DRG cell population. These finding indicate a similar pattern of substance P mRNA expression across DRG of different mammalian species. SOM mRNA was detected in similar numbers of DRG neurons in mouse, rat, hamster and rabbit. In cat and guinea pig, SOM mRNA was found in distinctly fewer numbers of DRG perikarya. These findings suggest that, in contrast to substance P, SOM mRNA expression in DRG neurons is more variable and species-specific. (Supported by grants NS 23804 and NS 08525)

47.12

IDENTIFICATION OF DYNORPHIN-CONTAINING SACRAL DORSAL ROOT GANGLION CELLS IN THE CAT USING *IN SITU* HYBRIDIZATION. S. Erdman*, J. Keast and W.C. de Groat. (SPON: B. Boston). Depts. of Pharmacology and Behav. Neuroscience, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA, 15261.

Previous immunohistochemical (IHC) studies have provided evidence that some afferent projections to the sacral spinal cord of the cat contain dynorphin (DYN), however, dynorphin cell bodies in the dorsal root ganglia (DRG) could not be identified using IHC methods. In the present studies in situ hybridization techniques were used in an attempt to identify mRNA coding for prodynorphin in these DRG's. Additional sections were processed for localization of somatostatin (SOM) mRNA, a substance which is known to be present in some primary afferent neurons. Cryostat sections (14-28 µm) of snap-frozen ganglia were fixed in paraformaldehyde solution, washed and incubated with hybridization buffer containing ^{35}S-labelled synthetic oligonucleotide probes for SOM or proDYN mRNA (Dupont NEN). After washing off unbound probe on the following day, sections were processed for emulsion autoradiography, developed 9-30 days later and counterstained. Neurons with SOM or proDYN mRNA were identified in all sections, the former being more common. This suggests that there are primary afferent neurons that synthesize DYN, but store it in amounts too small to be detected by immunohistochemical methods. (J. Keast is supported by an NH & MRC C.J. Martin Fellowship).

47.13

IDENTIFICATION OF NEUROPEPTIDES IN UTERINE AFFERENT NEURONS IN LUMBOSACRAL DORSAL ROOT GANGLIA OF THE CAT. M. Kawatani and W.C. de Groat. Dept. Physiol., Showa Univ., Tokyo, and Depts. Pharmacol. and Behav. Neurosci., Univ. Pittsburgh, Pittsburgh, PA 15261.

Vasoactive intestinal polypeptide (VIP), leucine enkephalin (LENK), substance P (SP), calcitonin gene-related peptide (CGRP) and cholecystokinin (CCK) have been identified in lumbosacral dorsal root ganglia (DRG). We showed previously that VIP is present in a high percentage of pelvic nerve (PLN) (42%) and hypogastric nerve (HGN) (45%) afferent neurons (AN) but in a lower percentage of pudendal nerve (PUDN) afferents (10%). Approximately equal proportions of these afferents contained LENK (30%) and SP (24%). In the present experiments, afferent pathways from the uterine cervix which are contained in PLN, HGN and PUDN were studied with axonal tracing and immunocytochemical techniques to examine their content of neuropeptides. The uterine cervix afferent neurons (UCAN) were small to medium size (<40 µm) and were located primarily (>90%) in the S1-S3 DRG. Most significantly, 60-82% of these neurons contained VIP. CGRP was present in 35-53% of the cells. SP, CCK and LENK were present in 20-32% of UCAN which is similar to their distribution in PLN afferents. Somatostatin was present in the DRG but not in UCAN. In summary, several types of neuropeptides are present in the UCAN. VIP and CGRP are most prominent and may play a role in afferent transmission from this region of the reproductive tract.

47.14

HORMONAL VARIATION IN SENSITIVITY OF AFFERENT FIBERS SUPPLYING REPRODUCTIVE ORGANS IN THE FEMALE RAT. A. Robbins[1,2], Y. Sato[1], and K.J. Berkley[1,3]. Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan[1]; Rockefeller University, NY, NY 10021[2]; Florida State Univ., Tallahassee, FL 32306[3].

The hypogastric and pelvic nerves contain sensory fibers that innervate the uterus and vagina. Recording simultaneously from both nerves, this study examined the responses of these afferent fibers to mechanical stimulation (distension of the uterus and vagina) across days of the estrous cycle. As determined by response thresholds, hypogastric nerve fibers were most sensitive to uterine distension on the day of estrus, and least sensitive on diestrus. Pelvic nerve fibers were most sensitive to vaginal distension on the day of proestrus and least sensitive on diestrus. These hormonal variations in sensitivity indicate that both uterine and vaginal afferent fibers are more responsive to distension during the days of the cycle associated with ovulation and mating.

Supported by grants from the Japanese government and grant RO1 NS11892 from NIH.

47.15

COEXISTENCE OF PUTATIVE NEUROTRANSMITTERS IN VISCERAL AFFERENT NEURONS OF THE NODOSE AND PETROSAL GANGLIA. A.J. Niederer* and C.J. Helke. Dept. of Pharmacol., Uniformed Services Univ., Bethesda, MD 20814.

Visceral afferent neurons of the nodose (NG) and petrosal (PG) ganglia are immunoreactive (ir) for many neurotransmitters [e.g. substance P (SP), neurokinin A (NKA; substance K), calcitonin gene-related peptide (CGRP), and dopamine (tyrosine hydroxylase-ir; TH)]. Coexistence of SP-ir with CGRP-, NKA- or TH-ir was studied in individual neurons of the rat using fluorescence immunocytochemistry. SP- and CGRP-ir were found to be similarly distributed in scattered cells concentrated mostly in the rostral pole of the NG and in numerous neurons throughout the PG. SP-ir completely coexisted with CGRP-ir. However, there was at least twice the number of CGRP-ir neurons as SP-ir neurons. SP- and NKA-ir were present in equal numbers of cells and were consistently colocalized. In contrast, SP- and TH-ir had different distributions in both the NG and the PG. SP-ir was located in the more rostal regions of both the NG and the PG whereas TH-ir was detected throughout the entire NG and only in the most caudal region of the PG. There was no colocalization of SP- and TH-ir.

The differential localization and coexistence of peptides in visceral sensory neurons in the NG and PG provide evidence for a "chemotopic" organization of these ganglia. (NIH NS20991)

CONDUCTION VELOCITY AND SEGMENTAL DISTRIBUTION OF BLADDER AND RECTAL AFFERENT FIBERS IN THE FEMALE RAT. P.L. Vera and I. Nadelhaft. VA Med. Ctr. and Depts. of Pharmacology and Neurosurgery and Center for Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA.

The conduction velocity of individual afferent fibers innervating the bladder or the rectum was examined electrophysiologically by recording from post-ganglionic bladder nerves or rectal nerves arising out of the major pelvic ganglion, while stimulating the distal cut end of the ipsilateral L6 and S1 dorsal roots. The bladder nerves responded to distension of the bladder whereas the rectal nerves responded to distension of the colon. The distributions of conduction velocities were similar for bladder (0.5-21 m/s; n=243) and rectal (0.5-23.5 m/s; n=135) afferents. 64% of the bladder afferents and 58% of the rectal afferents had conduction velocities < 2 m/s and were considered to be unmyelinated. The segmental distributions, however, were quite different. 84% of the bladder afferents traveled in the L6 dorsal root and 16% in the S1 dorsal root, compared to only 4% in L6 and 96% in S1 for the rectal afferents.

AFFERENT FIBERS IN THE HYPOGASTRIC NERVE OF THE FEMALE RAT: CONDUCTION VELOCITY AND SEGMENTAL DISTRIBUTION. I. Nadelhaft and P.L. Vera. VA Med. Ctr. and Depts. of Pharmacology and Neurosurgery and Center for Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA.

Rat hypogastric nerve afferents innervate the pelvic viscera; their cell bodies are located in T13-L3 dorsal root ganglia [Nadelhaft and McKenna, JCN 256:308 (1987)]. We have measured the conduction velocities of individual fibers by stimulating dorsal root fascicles and recording from the hypogastric nerve. The nerve responded to pinching of visceral structures; e.g., cervix, ureters, bladder. Fibers were activated mainly from the L1 and L2 dorsal roots bilaterally but more units were activated from the ipsilateral roots. Of a total of 167 units, 52% were from L1, 47% were from L2 and 1% were from T13. 64% were ipsilateral and 36% were contralateral. Conduction velocities ranged from 0.15 to 4.5 meters/sec and 87% of the units were below 1.5 meters/sec suggesting that the overwhelming majority of these afferents are unmyelinated.

47.18

SPINAL CORD ACTIVITY IN ANESTHETIZED FEMALE DURING VAGINAL-CERVIX STIMULATION. M. Martínez-Gómez, R. Chirino-Vargas*, C. Beyer*, B.R. Komisaruk and P. Pacheco. Univ. Aut. de Tlaxcala, Méx.; CIRA, CINVESTAV-Tlax. Méx.; IAB, Rutgers Univ., Newark, N.J., USA; and IIB-UNAM. Méx., D.F.

In our previous studies vaginal cervix stimulation (CS) by a blunt glass probe produces analgesic effects, reflex contractions of psoas major-iliacus muscles and the blockage of the ilio-pubococcygeus reflex contractions evoked by genital stimulation. Two pathways could account for these effects, one producing indirect excitatory effects upon motoneurons and other provoking inhibitory effects. For the analysis of those probable pathways, the first step was to determine the spinal dorsal (DR) and ventral (VR) roots involved during CS. After exposition of segments S_1 to L_6 in female anesthetized rats (Urethane), the left VRs were sectioned and recorded. The proximal segment of the dorsal roots sectioned near the spinal cord, was recorded. On DRs from segments S_1 to L_3 CS evoked afferent activity without adaptation, 1"off"3responses and no afterdischarges. The quantity of this response was related to the spinal segment and stimulus intensity. CS produced afterdischarges on the sectioned dorsal root. The VRs from segments S_1 to L_4 were reflexively activated during CS. Afterdischarges and syncronous activity characterized the VR response. Thus CS, through "on" receptors, evokes on several spinal cord segments dorsal horn interneuronal activity which outlasted stimulation provoking motoneuronal afterdischarge. Primary afferent depolarization and/or postsynaptic inhibition by CS still need to be determined.

RELATIONSHIPS OF THE PELVIC NERVE BRANCHES WITH THE COPULATORY PHENOMENAE. J. Manzo-Denes*, R.A. Lucio*, M. Martínez-Gómez, B.R. Komisaruk and P. Pacheco. Univ. Veracruzana, Méx.; CIRA Univ. Aut. Tlaxcala, Méx.; IAB Rutgers Univ., Newark, N.J., USA; and IIB-UNAM, Méx.,D.F.

The differential participation on mating behavior of the viscero-cutaneous (VB) and somato-motor (MB) pelvic nerve branches was studied. Copulatory parameters, seminal plugs, pelvic movements and muscular reflexes were analyzed in sexually experienced male rats before and after surgery from trials compound of two ejeculatory series. Bilateral transection of VB in both series increased the latency of mount (ML), intromission (IL) and ejaculation (EL) as well as the number of mounts (NM), while decreasing the number of intromission (NI). MB transection increased IL, EL and NM. The copulatory efficiency (NI/NI + NM) was significantly reduced in the VB transectioned rats. Weight of the seminal plugs was reduced after the surgeries, but more with VB transection. Also acelerometric mount recordings had less duration after nerve sectioning. In urethane anesthetized animals EMG from the ilio-pubococcygeus muscles, innervated by MB, was evoked by perineal, scrotal, preputial and groin skin pressure. Also vesical and urethral pressure produced reflex contractions. It has been assumed that pelvic nerve transection does not affect copulatory behavior, however, VB sectioning alters seminal plug and copulatory parameters which could reflect delayed erection, and MB sectioning alters the seminal plug and the quality of copulatory movement.

COMPARISON OF SPINAL AND BRAIN STEM PROJECTIONS OF RAT MEDIAN, ULNAR, SCIATIC AND SAPHENOUS NERVES USING EITHER INJECTIONS OF WGA-HRP OR BHRP. C.C. LaMotte, S.E. Kapadia, C.M. Kocol*., Sect. of Neurosurgery, Yale Univ. of Med., New Haven, CT. 06510.

With light and electron microscopy we verified that wheat germ agglutinin HRP (WGA-HRP labelled only unmyelinated (C) and small diameter myelinated (Aδ) afferents, and that B subunit cholera toxin HRP (BHRP) labelled all sizes of myelinated afferents, but not unmyelinated afferents. For example, in the sciatic, WGA-HRP labelled lamina I and the substantia gelatinosa, but light label also was found in the N. of Clarke,and moderate label in the N.gracilis. Using BHRP, dense label was present in laminae I, III-V, the ventral horn, N. of Clarke, and N.gracilis; no label was found in lamina II. A similar segregation occurred for the other nerves; saphenous projections were minor except to the dorsal horn. Extent and location of labelled areas are summarized for the dorsal horn (DH) and for motoneuron pools (MN):

Median	DH	C3-T2	max at C6-7, entire width; C3-6 & C8-T2, medial
	MN	C3-C8	dorsolaterally at C3-8; ventrolaterally at C6-7
Ulnar	DH	C3-T2	max at C6, from medial border to root entry
	MN	C6-C8	max dorsolaterally at C6-8; ventrolaterally at C7
Sciatic	DH	L1-S2	max at L4-5 entire width
	MN	L3 -L6	dorso & ventrolaterally at L3-6; medial at L5-6
Saph.	DH	L2-L4	max at L3-4; centromedial. (Note: No MN in saph.)

The N. of Clarke received both median and ulnar afferemts from C8 to T8 with a maximum at C8-T4. Sciatic projections to N. of Clarke were from T7 to L1, and saphenous from T12 to L1, but minor. In the dorsal column nuclei, separate but overlapping territories could be differentiated between the median and ulnar, and the sciatic and saphenous. (NS10174 & NS13335)

DOPAMINE TRANSPORTER mRNA and cDNA: *XENOPUS* OOCYTE EXPRESSION. S. Shimada, B.F. O'Hara*, T. Nishimori*, J.M. DiGiorgianni* and G.R. Uhl. NIDA, Addiction Research Center, Baltimore, MD 21224 and Depts. of Neurol. & Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The *Xenopus* oocyte can express biological transporting activity after injection of mRNAs encoding several carrier molecules. We have used mRNA from NGF-pretreated PC12 cells and rat midbrain as well as transcripts from a rat midbrain cDNA library to confer pharmacologically-specific dopamine uptake activity on previously-nonexpressing Xenopus oocytes.

mRNA-injected oocytes incubated with 3H-dopamine contain 3H-dopamine and metabolites, while oocytes coincubated with cocaine or uninjected oocytes contain only radiolabeled metabolites. 3H-dopamine uptake into mRNA-injected oocytes is time, sodium, and temperature dependent, as also reported by Blakely *et al.* It is blocked by cocaine or mazindol, but not by other agents including haloperidol. It is not found after injection of mRNA from other brain regions.

A size-selected rat midbrain library was constructed in the plasmid vector, pCDM8, that contains T7 promoter sequences facilitating *in vitro* transcription of mRNA corresponding to the cDNAs (see O'Hara *et al.*, this meeting). mRNA transcribed from this library yields cocaine-blockable 3H-dopamine uptake into injected oocytes. These findings suggest that cDNA(s) encoding the dopamine uptake site are present in the library, and provide a means to moniter their purification.

48.2

XENOPUS LAEVIS OOCYTE EXPRESSION OF THE RAT AND HUMAN DOPAMINE TRANSPORTERS. M.J. Bannon, C.-H. Xue*, L.J. Dragovic* and G. Kapatos. Cent. for Cell Biology, Sinai Hospital of Detroit, the Cellular and Clinical Neurobiology Program, Wayne State University and the Wayne County Medical Examiner's Office, Detroit, MI 48235.

The actions of dopamine (DA) are terminated by DA reuptake through a specific Na+/DA cotransporter. Psychostimulants such as cocaine and amphetamine enhance synaptic DA by interfering with this transporter. Thus it is important to understand the cellular/molecular biology of the DA transporter. As an alternative to purification of this low abundance membrane protein, poly A mRNA isolated from human or rat substantia nigra was injected into isolated oocytes and several days later 3H-DA accumulation was monitored as an index of DA transporter expression. After a 60 min incubation, 3H-DA accumulation in oocytes injected with nigral mRNA was several times that seen in uninjected oocytes. 3H-DA uptake into injected oocytes was completely prevented by coincubation with 1uM unlabelled DA or by removal of Na+. The DA reuptake inhibitors cocaine (3uM) and GBR 12909 (100nM) also completely blocked specific 3H-DA accumulation. Injection of poly A mRNA isolated from human globus pallidus (an area devoid of DA cells) did not result in 3H-DA accumulation above the levels in uninjected oocytes. Further pharmacological and kinetic analyses of the expressed DA transporters are currently underway.

48.3

EFFECT OF A PHYSIOLOGICAL DOSE OF 17β-ESTRADIOL OR PROGESTERONE ON OVARIECTOMIZED RAT STRIATAL DOPAMINE UPTAKE SITES. M. Morissette* and T. Di Paolo. Dept. of Molecular Endocrinology, Laval University Medical Centre, Québec G1V 4G2 and School of Pharmacy, Laval University, Québec G1K 7P4, Canada

Striatal dopamine (DA) uptake sites labelled with [^{3}H] GBR-12935 binding were investigated in ovariectomized (OVX) rats acutely treated with 17β-estradiol (17β-E_2) or progesterone (P). One injection of P (110 µg/0.2 ml, sc) to OVX rats increases these steroid plasma levels from 15 to 120 min (peak of 11.8±1.5 ng/ml plasma, $p<0.01$ vs control) while plasma prolactin (PRL) levels remained unchanged. [^{3}H]GBR-12935 binding density and affinity remained unchanged (0.43± 0.02 nM; 4177±276 fmol/mg protein) up to 120 min after the P injection. By contrast, one injection of 17β-E_2 (100 ng/0.2 ml, sc) to OVX rats increases plasma levels of this steroid after 15 min (78.8±18.7 pg/ml plasma, $p<0.01$ vs control) while plasma PRL levels remained unchanged. The 17β-E_2 injection leaves striatal [^{3}H]GBR-12935 binding affinity unchanged (0.49±0.03 nM) while the maximum density increases at 15 and 30 min after injection (+24% after 15 min, $p<0.01$ vs control; +18% after 30 min, $p<0.05$ vs control; 3541±222 fmol/mg protein for control). Thus, acutely, 17β-E_2, but not P, modulates striatal DA uptake sites in OVX rats. The effect of 17β-E_2 appears in coincidence with the peak of this steroid plasma concentration. This increase is rapid and is probably non-genomic and suggests a causal-effect relationship although the primary site of action of 17β-E_2 is yet to be determined. Supported by the MRC of Canada.

CHARACTERIZATION OF NOREPINEPHRINE AND GABA UPTAKE MECHANISMS IN THE PC12, SH-SY5Y AND TE671 CLONAL CELL LINES. Ann Marie Anderssohn[1,2,*], Allan L. Bieber[1,*] and Ronald J. Lukas[1,2] (SPON. R.F. Spetzler). Dept. Chem., Arizona St. Univ., Tempe AZ 85287[1] and Div. Neurobiol., Barrow Neurological Institute, Phoenix AZ 85013[2].

Specific uptake of tritium-labeled norepinephrine (NE) or tritium-labeled gamma-aminobutyric acid (GABA) was examined in the PC12 rat pheochromocytoma, the SH-SY5Y human neuroblastoma, and the TE671 human medulloblastoma clonal cell lines. Reserpine-sensitive uptake of NE was observed to reach maximal values within a 10 minute period of exposure to radiolabeled transmitter for both PC12 and SH-SY5Y cells, but did not occur in TE671 cells. Total NE uptake (i.e., reserpine-sensitive and -insensitive) was linear over a 2 hour time course for SH-SY5Y cells, but was nonlinear for PC12 cells, reaching a maximal value after 30 minutes of NE exposure. Nipecotic acid (NpA)-sensitive GABA uptake was observed in all three cell lines. This specific uptake was linear over a 30 minute time course in SH-SY5Y cells (IC_{50} for NpA of 10 uM at 20°C), but reached maximal values within 10 and 30 minutes, respectively, of GABA exposure to PC12 cells (IC_{50} for NpA of 100 uM at 37°C) and TE671 cells (IC_{50} of 300 uM at 20°C). These results demonstrate the usefulness of neuron-like clonal lines for studies toward a characterization of mechanisms of neurotransmitter uptake and release and co-localization.

CONFORMATIONAL AND BIOCHEMICAL ANALYSIS OF DRUG BINDING TO THE VESICULAR AMINE TRANSPORTER

Patrick M. Kelley[S] and Edwin R. Hortelano*', [S]Dept. of Biol. Sci. and 'Dept. of Chem., Wayne State Univ., Detroit MI 48202

Biogenic amines (catechol- and indoleamines) are transported into secretory vesicles, such as the chromaffin vesicles of the adrenal medulla, by a specific transporter. Since the flexible amine molecules can exist in numerous conformers, it is not surprising that the amine binding site of the transporter differs from the amine binding sites of various biogenic amine receptors. To elucidate the transporters binding site, the rigid inhibitors, reserpine and tetrabenazine, were studied using molecular mechanics. Of particular interest is the orientation of the 5-nitrogen lone pair in reserpine and tetrabenazine. Our calculations indicate that only one significant isomer of each compound exists. We propose these isomers fits in the amine binding site of the biogenic amine transporter. This proposal is supported by the following: (a) modification of the 5-nitrogen in reserpine, by oxidation to an iminium ion or by alkylation to a quaternary ammonium, causes a total loss in physiologic activity; (b) similar molecules (such as isoreserpine) have little or no activity; and (c) our data on the inhibition of biogenic amine uptake correlates well with the minimized geometry of this nitrogen. Funded by NIH grants GM 33849 and GM 30500.

IN VIVO CHARACTERIZATION OF DOPAMINE UPTAKE INHIBITORS BY BRAIN MICRODIALYSIS. G.G. Nomikos, G. Damsma, D. Wenkstern*, H.C. Fibiger. Division of Neurological Sciences, Univ. British Columbia, Vancouver, Canada.

This study employed *in vivo* microdialysis to profile the effects of dopamine (DA) uptake inhibitors on extracellular concentrations of DA in the striatum of awake, freely moving rats. d-Amphetamine, nomifensine, methylphenidate, cocaine, benztropine, bupropion and GBR 12909 were administered via the perfusion fluid in increasing concentrations, from 1 to 1000 µM. All drugs increased extracellular DA in a dose dependent manner. Although no absolute discrimination between uptake and releasing properties of the drugs could be derived from the present study, the data suggested uptake-inhibition effects for cocaine, GBR 12909, nomifensine, benztropine, methylphenidate and bupropion, and release plus uptake-inhibition for amphetamine. At the highest concentration nomifensine, benztropine, methylphenidate and bupropion also appeared to have DA-releasing effects. The rank order of potency, as determined by the relative extracellular DA increase induced by 10 µM of the drugs after correction for *in vitro* recoveries of the drugs applied, was: GBR 12909>benztropine>amphetamine>methylphenidate>nomifensine>cocaine>bupropion. Addition of tetrodotoxin (0.3 µM) to the perfusion fluid showed that the effects of all drugs, except amphetamine, were prevented suggesting that only action of amphetamine was not dependent on action potentials. The *in vivo* characterization of changes in extracellular dopamine following local administration of DA uptake inhibitors further documents the effects of these drugs on DA transmission.

48.7

DOPAMINE TRANSPORTERS/COCAINE RECEPTORS SELECTIVELY LABELED BY A NOVEL PHOTOAFFINITY PROBE: [^{125}I]DEEP. A.A. Wilson*, D.E. Grigoriadis, R. Lew and M.J. Kuhar. (SPON: A. Goldberg). Neuroscience Branch, Addiction Research Center, and the Johns Hopkins Medical Institutions, Baltimore, MD 21224.

The dopamine transporter has been studied directly in binding experiments using a variety of radiolabeled ligands. The cocaine binding site on the transporter has been related to drug self-adminstration in monkeys suggesting that it is a cocaine receptor related to drug dependence. Several photosensitive compounds related to GBR 12909, a selective inhibitor of dopamine transport, were designed. One of these compounds, [^{125}I]-[2-(diphenylmethoxy)ethyl]-4-[2-(4-acido-3-iodo-phenyl)ethyl] piperazine ([^{125}I]DEEP) had a high affinity for the transporter and was covalently attached to its binding protein component following exposure to UV light. In rat striatal homogenates, ^{125}I-DEEP bound to a protein with an apparent molecular weight of 58,000 Da. The pharmacological properties and regional distribution of the binding was that which would be expected for binding to the dopamine transporter. The ^{125}I-DEEP binding protein appears to exists in a glycosylated form since wheat germ-agglutinin lectin adsorbed the DEEP labeled protein. Thus, as a photoaffinity ligand, ^{125}I-DEEP will be a useful tool in the characterization and purification of the dopamine transporter.

48.8

DOPAMINE TRANSPORTER IN RAT CAUDATE-PUTAMEN IS GLYCOSYLATED. R. Lew*, D.E. Grigoriadis, A.A. Wilson*, and M.J. Kuhar. Neuroscience Branch, NIDA Addiction Research Center, Baltimore, MD 21224 and Johns Hopkins Medical Institutions, Baltimore, MD 21205.

Recently, we have demonstrated in rat caudate-putamen that the photoaffinity probe [^{125}I]1-[2-(diphenylmethoxy) ethyl]-4-[2-azido-3-iodophenyl)-ethyl]piperazine ([^{125}I]DEEP) binds to a 58 kDa protein with the pharmacological properties of the dopamine transporter (D.E. Grigoriadis et al. 1989, J. Neurochem., in press). Using [^{125}I]DEEP, the present study further investigates the biochemical nature of the dopamine transporter. Membrane preparations of rat caudate were prepared and photolabelled with [^{125}I]DEEP. In lectin affinity chromatography studies, photolabelled membranes were solubilized and loaded onto WGA-sepharose columns. In enzyme studies, photolabelled membranes were treated with neuraminidase (2 U/ml) in 100 mM sodium acetate (pH 5.0) containing 100 µM PMSF for 60 min at 37°C and electrophoresed on SDS-PAGE. In WGA affinity chromatography studies, labelled proteins bound to WGA Sepharose and could be specifically eluted with 200 mM ß-N-acetyl-glucosamine. SDS-PAGE studies revealed a shift of the labelled protein by 7 kDa following neuraminidase treatment. In conclusion, the present data suggest that the dopamine transporter is a glycoprotein containing terminal sialic acid residues.

48.9

EVIDENCE FOR A NUCLEOPHILIC AMINO ACID RESIDUE AT THE STIMULANT BINDING SITE OF THE DOPAMINE TRANSPORTER. M.M. Schweri* (SPON: A.Black). Div. of Basic Medical Sciences, Mercer Univ. Sch. of Med., Macon, GA 31201-1554.

N-ethylmaleimide (NEM) was used to covalently modify stimulant binding sites contained in the P_2 fraction of striatal tissue from Sprague-Dawley rats. This compound reacts rapidly with sulfhydryl groups, but can alkylate amino groups under certain conditions. NEM was used in these studies to investigate the presence of nucleophilic amino acid residues at the site on the nigrostriatal nerve terminal where psychomotor stimulants bind to block dopamine uptake. Stimulant binding was studied using the [^{3}H]methylphenidate ([^{3}H]MP) radioreceptor assay [Schweri et al, J. Neurochem., 48:102, 1987]. Reaction with 0.1 mM rapidly inactivated the site ($t_{½}$ = 7min.). The IC_{50} was 0.33 mM under the conditions of the study. Inactivation of binding was irreversible, remaining constant after the tissue was washed three times. Reaction with 0.5 mM NEM reduced the B_{max} by 61% (5.0 vs 12.7 pmols/mg protein for controls), while slightly increasing the affinity of the remaining sites for [^{3}H]MP (K_D = 62 vs 82 nM for controls). Pretreatment of the tissue with saturating concentrations of unlabeled MP (5 µM) completely protected [^{3}H]MP binding from inactivation by NEM. These results suggest that the stimulant binding site on the dopamine transport complex contains one or more nucleophilic amino acid residues which react readily with NEM.

48.10

PERIPHERAL AND CEREBRAL METABOLISM OF 6-[^{18}F]-FLUORODOPA IN MONKEYS. W.P. Melega, J.M. Hoffman*, J.S. Schneider, C.H.K. Nissenson*, M.M. Perlmutter*, M.E. Phelps, and J.R. Barrio*. UCLA School of Medicine, Los Angeles, CA 90024.

The peripheral and cerebral metabolism of 6-[^{18}F]-fluorodopa (FDOPA) was analyzed to determine its metabolic pathways and thus validate its use as a biochemical probe of presynaptic dopaminergic function with positron emission tomography (PET). Macaca nemestrina monkeys (n=5) were pretreated with a peripheral aromatic amino acid decarboxylase inhibitor (carbidopa, 5 mg/kg, i.v.) 60 min before injection of FDOPA (5-8 mCi, i.v.). Arterial plasma samples were obtained at 5, 10, 30, 60, and 120 min and analyzed by HPLC (C-18 reverse phase column, 80% 0.1 M Na_2HP0_4, 2.6 mM OSA, 0.1 mM EDTA; 20% MeOH, pH 3.5). As FDOPA plasma levels decreased (30 min:42%, 60 min:28%, 120 min: 10%), the major peripheral metabolite remained 6-[^{18}F]fluoro-3-0-methyl-L-DOPA (3-OMFD), (30 min:45%, 60 min:62%, 120 min:70% of total radioactivity) indicative of the rapid in vivo methylation of FDOPA by peripheral catechol-0-methyl transferase in primates. The cerebral metabolism (n=3) at 60 min was determined for the putamen, caudate, cortex and cerebellum. The total radioactivity ratio for the putamen/cerebellum was 1.9. The major metabolites in the putamen were 3-OMFD (36%) and 6-[^{18}F]fluorodopamine (FDA) (35%), 3,4,-dihydroxy 6-[^{18}F]fluorophenyl acetic acid (FDOPAC) (8%), and 6-[^{18}F]fluorohomovanillic acid (FHVA) (12%); for the caudate, 3-OMFD (39%) and FDA (32%), FDOPAC (10%) and FHVA (14%). Cerebellum radioactivity was restricted to 3-OMFD (80%) and FDOPA (20%), while in the cortex 3-OMFD (84%) and FHVA (5%) were detected. The peripheral origin of 3-OMFD was indicated by its distribution (counts/g) ratios: putamen/cerebellum, 0.8; caudate/cerebellum, 0.8; and cortex/cerebellum, 0.9; the (plasma/mL)/(cerebellum counts/g) ratio was 0.8. These biochemical data when correlated with tomographic data in primates indicate that a quantitative relationship between peripheral FDOPA metabolism and cerebral FDA metabolism can be established.

48.11

EFFECT OF REPEATED AMPHETAMINE (AMPH) OR L-DOPA INFUSIONS UPON DOPAMINE (DA) RELEASE FROM SUPERFUSED CORPUS STRIATAL (CS) TISSUE FRAGMENTS. W. Lin, J. McDermott*, D. Dluzen & V. Ramirez. Department of Physiology and Biophysics and Medicine-Carle Foundation Hospital, University of Illinois Urbana, Illinois 61801.

In an attempt to understand some mechanisms by which L-DOPA alters nigrostriatal dopaminergic function we compared DA release rates of superfused CS fragments in response to either repeated AMPH (10 uM) or L-DOPA (5 uM) infusions. Male rat CS were superfused using a modified KRP medium with samples collected at 10 min intervals and assayed for DA using HPLC-EC. During intervals 3,7 and 11, KRP medium containing AMPH (N=5) or L-DOPA (N=4) was directly infused into superfusion chambers. Both AMPH and L-DOPA evoked increases in DA release following this initial infusion. Assigning this first response a value of 100% we calculated the changes in response to the second and third infusions. In response to the second and third AMPH infusions, DA release decreased to 82.6±16.9 and 41.1±15.9%, respectively, while subsequent responses to L-DOPA appeared to be potentiated with DA release following the second and third L-DOPA infusions increasing to 175.5±43.4 and 266±65.1%, respectively. These results indicate that repeated AMPH infusions apparently result in a depletion of a releaseable pool of DA, while L-DOPA stimulated DA release appears to potentiate processes involved in the synthesis and/or release of DA from CS tissue fragments following repeated L-DOPA stimulation.

FURTHER CHARACTERIZATION OF THE NOREPINEPHRINE-RELEASING PROPERTIES OF 9-AMINO-1,2,3,4-TETRAHYDROACRIDINE (TACRINE, THA): COMPARISON WITH VARIOUS RELEASING AGENTS. C.P. Smith, W. Petko* and F.P. Huger Dept. of Biological Research, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ, 08876-1258.

There are an increasing number of reports which demonstrate that tacrine (THA) has direct effects on membrane ion channels in addition to inhibiting cholinesterases. Although the therapeutic relevance is controversial, direct ion channel effects may cause activation of other neurotransmitter systems in the brain. We have previously shown that THA increases spontaneous NE release from cortical slices in a calcium-independent manner, increases electrically-stimulated NE release and increases the turnover of phosphatidylinositol (PI) in pre-labeled cortical slices. In this report, we describe additional experiments to compare the necessary conditions for release by THA and other classes of releasing agents and also to examine the relationship between effects on PI turnover and release.

The effects of THA on spontaneous NE release differed from those of tyramine, veratridine, 4-AP and ouabain based on Ca^{2+}-dependency and sensitivity to tetrodotoxin, nomifensine and reserpine.

THA-induced PI turnover was blocked by neomycin and a Ca^{2+}-free buffer but the THA effect on spontaneous NE release was unaffected by these conditions. Furthermore, a Na^+-free medium and amiloride prevented the THA stimulation of PI turnover, but did not block the enhancement of spontaneous release, suggesting that there is not a cause-effect relationship between PI turnover and spontaneous release of NE.

48.13

MECHANISM OF TETRAHYDROBIOPTERIN (BH_4) UPTAKE INTO RAT BRAIN SYNAPTOSOMES: EFFECTS ON SEROTONIN METABOLISM. P.Z. Anastasiadis*, W.A. Wolf*, D.M. Kuhn, and R.A. Levine. Lab. of Molecular Neurobiology, Lafayette Clinic and Cellular and Clinical Neuroscience Pgm., Dept. Psychiatry, Wayne State Univ., Detroit, MI.

BH_4 is the naturally occurring cofactor for phenylalanine, tyrosine and tryptophan hydroxylases, the latter two enzymes being rate-limiting for catecholamines and serotonin synthesis. Deficiencies in $BH_{4\ synthesis}$ occur in newborns (atypical PKU) and may be involved in Parkinson's and Alzheimer's disease and familial dystonia. Enhancing dopamine and/or serotonin synthesis in brain using BH_4 therapy has been only partially successful; this may be due to not enough exogenous BH_4 entering brain or an inability of BH_4 to enhance hydroxylation. Our studies examined the mechanism and extent of BH_4 uptake into rat brain synaptosomes and its effects on 5-TH metabolism. Synaptosomes were incubated with BH_4 (.2 - 2000 uM) with and without 5 uM tryptophan; 5-HT and metabolites were measured by HPLC after 30 min and BH_4 uptake was measured by HPLC-ED at various times up to 60 min. BH_4 entrance into synaptosomes was higher at 37°C than at 0oC and linear at high concentrations, with an apparent rapid accumulation at lower levels. Omission of glucose had no effect on the uptake process at low BH_4 levels after 10 min. Regarding 5-HT metabolism, exogenous BH_4 had no effect on total synaptosomal indole content, whereas 5 uM tryptophan increased total indoleamines 3-fold; this effect was not enhanced by 200 uM BH_4. Further studies are testing whether BH_4 is actively taken up and whether BH4 can stimulate indoleamine synthesis in brain slices.

IN VIVO MEASUREMENT OF LONG-TERM EFFECTS OF MDMA ON 5-HT UPTAKE SITES AND 5-HT_2 RECEPTORS. U. Scheffel*, J.R. Lever* and G.A. Ricaurte. Departments of Radiology, Environmental Health and Neurology, The Johns Hopkins Medical Institutions, Baltimore, MD. 21205. (Sponsor: Z. Annau).

With a view towards developing a positron emitting ligand for documenting subclinical MDMA-induced 5-HT neural damage in the living human brain, the present study investigated the feasibility of detecting MDMA neurotoxicity through either in vivo measurement of ^{3}H-paroxetine binding to 5-HT uptake sites, or ^{125}I-N-methyl-iodo-LSD (^{125}I-MIL) binding to 5-HT_2 receptors.

One week after treatment with MDMA (8 x 20 mg/kg, s.c.), rats were injected intravenously with either ^{3}H-paroxetine or ^{125}I-MIL. Specific binding of these ligands was then quantified in various brain regions. In all CNS areas examined, MDMA produced a significant decrease in the specific binding of ^{3}H-paroxetine binding, suggesting loss of 5-HT uptake sites. The same MDMA treatment produced no long-term effects on 5-HT_2 receptors as measured by the in vivo binding of ^{125}I-MIL. There were no changes in ^{125}I-MIL binding at either one or two weeks after MDMA treatment.

These results indicate that in vivo binding of ^{3}H-paroxetine can be used to detect MDMA-induced 5-HT neuronal damage in living animals, and suggest that a PET ligand for the presynaptic element of 5-HT neurons would be useful for detecting MDMA neurotoxicity in the living human brain. Such a ligand should also be of value for further investigating the role of 5-HT in the human brain during both health and disease.

REAPPEARANCE OF MAO TYPE A AND TYPE B IN THE RAT STRIATUM AFTER IRREVERSIBLE INHIBITION. G.S. Carter and A.J. Azzaro. Departments of Neurology, Pharmacology/Toxicology and Psychiatry, West Virginia University Health Science Center, Morgantown, WV 26506.

The reappearance of monoamine oxidase (MAO) subtypes A and B was examined in the striatum of adult, male Sprague-Dawley rats after complete irreversible inhibition of MAO activity with the nonselective MAO inhibitor nialamide. A dose of 125mg/kg body weight of nialamide given intraperitoneally produced greater than 90% inhibition of MAO activity. Using the specific substrates serotonin (5-HT) and phenylethylamine (PEA) at their Km concentrations, the return of MAO activity was assessed. The activities of the MAO subtypes were compared with their activities in uninhibited animals of the same approximate weight and age. The deamination of PEA (MAO B activity) showed a rapid return to the uninhibitied value with a calculated half-life of 10.4 days. The deamination of 5-HT(MAO A activity) showed a slower return to uninhibited levels with a calculated half-life of 17.5 days.

Most MAO B in the rat striatum is located in astrocytes. Only a small fraction is found in serotoninergic neurons. A significant fraction of MAO A, however, is found in nigrostriatal dopaminergic neurons. As axoplasmic transport is required to replace a significant portion of MAO A, its reappearance is delayed compared to MAO B. Our findings support the concept that the primary neuronal form of MAO is type A.

NEUROTENSIN AND DOPAMINE RELEASE IN THE RAT PREFRONTAL CORTEX: IN VIVO PHARMACOLOGICAL AND PHYSIOLOGICAL STUDIES. A.J. Bean, M.J. During, R.H. Roth, Department of Pharmacology and Psychiatry, Yale Univ. School of Medicine, New Haven, CT 06510.

Dopamine (DA) and neurotensin (NT) are colocalized in a subset of mesencephalic neurons. Some of the mixed DA/NT neurons project to the prefrontal cortex (PFC), a brain region which does not contain intrinsic DA or NT cells. Stimulation of the axons of mesocortical neurons may be expected to result in the release of both DA and NT. However, studies on the stimulation-evoked release of colocalized molecules in the peripheral nervous system (PNS) by Lundberg, Bartfai and coworkers have suggested that there may be frequency and/or pattern dependent differential release. Additional studies in the PNS have suggested that autoreceptors may control the release of more than one colocalized molecule. We have studied the effects of electical stimulation and autoreceptor stimulation of mesocortical axons on PFC DA and NT release using microdialysis coupled to HPLC-EC and RIA methods. DA and NT were measured within the same dialysis sample and their release was found to be calcium dependent. Stimulation of mesocortical axons produced frequency dependent release of both DA and NT. Burst stimulation increased both DA and NT release more than tonic stimulation for the same number of spikes. DA autoreceptor stimulation decreased DA release and increased NT release. These data suggest that mixed DA/NT mesocortical neurons can release both DA and NT and that differential release can occur.

METAPHIT ANTAGONIZES THE EFFECT OF PCP AND NOMIFENSINE, NOT AMPHETAMINE, ON ENDOGENOUS DOPAMINE RELEASE IN RAT STRIATAL SLICES. S.T. Buxton*, G.A. Gerhardt, N.R. Zahniser, A.E. Jacobson*, R.A. Lessor* and L.P. Dwoskin (SPON: N. Bhat). Univ. Kentucy Col. Pharmacy, Lexington, KY 40536, Dept. Pharmacol., Univ. Co. Hlth. Sci. Ctr., Denver, CO 80262, and NIADDK, Bethesda, MD 20892.

Metaphit is a phencyclidine (PCP) analog which acylates PCP binding sites in vitro (Rafferty et al, 1985). The ability of Metaphit to antagonize the effect of 10 uM PCP, nomifensine (NOMI) or amphetamine (AMPH) on electrically (1 Hz, 60 pulses) evoked release of endogenous dopamine (DA) and dihydroxyphenylacetic acid (DOPAC) from superfused striatal slices was examined. Prior incubation (30 min) with Metaphit resulted in a dose-dependent decrease (EC50 10 uM) in the stimulation-evoked overflow of DOPAC. Metaphit (10 uM) antagonized both the increase in DOPAC and DA induced by PCP exposure. Metaphit antagonized the increase in DA, and further decreased DOPAC as a result of NOMI exposure. Metaphit did not alter the increase in DA and decrease in DOPAC induced by AMPH exposure. The results suggest that Metaphit interacts with a PCP receptor closely associated with the DA uptake site. Metaphit selectively antagonizes DA release induced by PCP, and not that induced by AMPH. Therefore, the results do not support the suggestion that DA release induced by PCP and AMPH is via a similar mechanism. Supported by USPHS NS09199, AG06434 and Univ. KY Med. Ctr. Research Fund.

EFFECT OF AN ACUTE COMBINED INJECTION OF HALOPERIDOL AND ESTRADIOL ON RAT BRAIN DOPAMINE METABOLISM. T. Di Paolo, M.A. Gagné* & M. Daigle* (SPON: A. Dupont), School of Pharmacy, Laval University, Qc G1K 7P4, and Dept of Mol. Endocrinol., Laval Univ. Med. Centre, Qc G1V 4G2 Canada.

We have shown that estradiol (E_2) and progesterone (P) at physiological doses, acutely increase dopamine (DA) and its metabolite levels in the rat brain. It has also been recently reported that the effect of haloperidol on rat brain DA metabolism fluctuates during the estrous cycle (Neuropharmacol. 27:73 (1988)). This report investigates the acute combined E_2 and haloperidol effect on brain DA metabolism of ovariectomized rats. DA and its metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) were measured by HPLC with electrochemical detection in the frontal cortex and striatum. An intraperitoneal injection of haloperidol (0.1 mg/kg) increased DA turnover as measured by the ratio DOPAC/DA and HVA/DA in the striatum and frontal cortex 30-180 min after the injection ($p < 0.05$). An E_2 injection (100 ng/0.2 cc) 15 or 30 min before sacrifice of the haloperidol injected rats potentiated the DA turnover increase caused by the neuroleptic in the frontal cortex from 30 to 180 min ($p < 0.05$); striatal changes were smaller and more variable. Our results suggest that physiological levels of E_2 can potentiate the DA turnover increase induced by haloperidol and could explain the variations of DA turnover induced by this neuroleptic during the estrous cycle. Supported by the MRC.

Separation of vesamicol-binding and NE-containing compartments in fractionated PC12 cells. D. Blumberg and E.S. Schweitzer. Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

We examined whether sorting of integral membrane proteins occurs within the regulated secretory pathway by following the binding of vesamicol (AH5183, a putative ligand for the ACh transporter) to fractionated PC12 cell membranes, and comparing this with [^{3}H]norepinephrine (NE) (as a marker for organelles possessing the catecholamine transporter) as well as two other vesicle-specific integral membrane proteins, synaptophysin (P38) and SV2.

We first characterized binding properties of [^{3}H]vesamicol in PC12 cells. PC12 cells exhibit saturable binding for vesamicol, binding 130.8 $\pm$2.91 pmol/mg protein, with a K_d of 1.91 $\pm$0.37 μM, association rate constant of 1.65 x 10^6 $min^{-1}M^{-1}$, and dissociation rate constant of 0.056 $\pm$0.004 min^{-1}.

PC12 cell homogenates were fractionated on linear Ficoll gradients. Results showed a peak of vesamicol binding at ~10% Ficoll, which was distinct from [^{3}H]NE, which peaked at ~22% Ficoll. These data suggest that ACh and NE are packaged into separate subcellular compartments. The majority of synaptophysin immunoreactivity co-migrated with [^{3}H]vesamicol binding, whereas SV2 immunoreactivity appeared to co-migrate with both [^{3}H]NE-containing and [^{3}H]vesamicol-binding structures.

MEASUREMENT OF SUBSECOND COMPONENTS OF ENDOGENOUS DOPAMINE RELEASE AND REUPTAKE RATES IN RAT STRIATAL TISSUE. J.S. McElvain and J.O. Schenk. Dept. of Chemistry and Program in Biochemistry, Washington State University, Pullman, WA 99164-4630.

We have developed a semi-micro electroanalytical technique (500 uL volume) for making rapid measurements of endogenous dopamine (DA) release from and reuptake into homogenates of striatal tissue using a rotating disk electrode (RDE). This method makes it possible to monitor both endogenous DA release and uptake rates on msec time scales in the same tissue preparation. Using glassy carbon rotating disk electrodes, the detection limit is ca. 5-10 nM DA in physiological buffer. The magnitudes and rates of striatal DA release were shown to be K^+, Ca^{2+}, and temperature dependent. At 37°C the K^+ depolarization release rate of DA from rat striatal tissue was found to be 300 pmoles/gm wet wt/second. DA uptake rates were also shown to be temperature dependent and inhibited by the uptake blocker cocaine. At 37°C the uptake rate of DA was found to be 49.3 pmoles/gm wet wt/sec. These rates are ca. 10 x greater than previously reported. This RDE technique can also be used to determine the effects that certain drugs of abuse and autoreceptor feedback control mechanisms have on endogenous DA uptake and release rates. (Supported in part by the Washington Alcohol and Drug Abuse Program (Initiation 171) and MH42759 (J.S.))

INTERACTION OF [^{3}H]-DIHYDROTETRABENAZINE BINDING ACTIVITY FROM BOVINE STRIATUM WITH IMMOBILIZED LECTINS. Michael S. Vincent* and Joseph A. Near. Medical Sciences Program, Indiana University School of Medicine, Myers Hall, Bloomington, IN 47405.

Synaptic vesicles and other secretory granules accumulate catecholamines and serotonin by means of an uptake system that is coupled to a proton-translocating ATPase by a transmembrane proton electrochemical gradient. Two classes of catecholamine depleting agents, represented by reserpine and dihydrotetrabenazine (TBZOH), interact with the transporter but exhibit different binding properties. We have recently been engaged in the solubilization and characterization of tritiated TBZOH binding activity from bovine *corpus striatum*. A crude synaptosomal fraction (Azarian, *et al.*, J. Neurochem. 50:824, 1988) was prepared, and TBZOH binding activity solubilized with sodium cholate (1% w/v) as described by Scherman and Henry (Biochem 22:2805, 1983). While the synaptosomal fraction contains two classes of binding sites for TBZOH, only the higher affinity class of sites was observed in pellet or supernatant after cholate treatment. Because the lower affinity sites are not found in purified synaptic vesicles, but are present in liver membranes, they are probably unrelated to catecholamine storage. More than 50% of the cholate soluble binding activity was retained by wheat germ lectin sepharose and concanavalin A sepharose after incubation for 60min at 4°C. The interactions could be blocked by inclusion of 200mM N-acetyl-glucosamine or alpha-methyl-mannoside respectively, but not by glucosamine or cellobiose.

These findings suggest that a TBZOH binding subunit of the transporter, or a membrane component closely associated with this subunit, is glycosylated.

THE ROLE OF THE HIGH AFFINITY 5-HYDROXYTRYPTAMINE CARRIER IN THE RELEASE OF 5-HYDROXYTRYPTAMINE IN THE ABSENCE OF EXTRACELLULAR CALCIUM. S.M. Evans*, K.J. Collard * and L.S. Wilkinson* (SPON: E.M. Meyer). Department of Physiology, University of Wales in Cardiff, Cathays Park, Cardiff, Wales.

The dependence on extracellular calcium of 5-hydroxytryptamine (5-HT) release from rat brain synaptosomes was examined under various conditions using a rapid superfusion system. Release was evoked from synaptosomes preloaded with tritiated 5-HT in the presence or absence of an inhabitor of monoamine oxidase (MAO) by perfusion with medium containing 50 mM potassium. The release was found to be only partially dependent on calcium, and the requirement for calcium decreased significantly when an inhibitor of MAO was present. However, the release occurring in the absence of calcium when MAO was inhibited was abolished by specific 5-HT uptake inhibitors, suggesting that this release may involve the 5-HT carrier. The release evoked by p-chloroamphetamine (p-CA), a drug whose releasing action is thought to involve the 5-HT carrier, was significantly increased when MAO was inhibited although the dependence on extracellular calcium was not significantly altered. P-CA was found to inhibit the uptake of tritiated 5-HT into synaptosomes, suggesting that p-CA may be a substrate for the 5-HT carrier. These data support the suggestion that 5-HT can be released by reversal of the carrier when tissue is depolarised or treated with p-CA, and that the magnitude of release via this route can be increased by inhibition of MAO, presumably due to the increased levels of 5-HT available to the carrier intraterminally.

THE EFFECT OF THALLIUM ON THE RELEASE OF ENDOGENOUS MONOAMINES FROM RAT BRAIN. M.G. Kolta and S.F. Ali (SPON: N. Uretsky). Division of Reproductive & Developmental Toxicology, NCTR, Jefferson, AR 72079.

Thallium (TL), a rodenticide and pesticide, has been shown to be neurotoxic to humans and animals. Recent results from our laboratory showed that acute or sub-acute doses of TL to rats produced alterations in CNS monoaminergic systems. The present study examined the effect of TL on the release of dopamine (DA), serotonin (5-HT) and their metabolites from the caudate nucleus (CN). Adult male CD rats were sacrificed and CN were dissected. CN slices were incubated with either 0, 10, 100 uM of TL or 10 uM of amphetamine (A) as a positive control. A induced a significant increase in DA levels in the medium, tissue slices and total content (medium + tissue slices) when compared to untreated control slices. TL at 10 or 100 uM also caused an increase in total dopamine content. While total DA content was equally enhanced in TL and A-treated slices, DA released into the medium from slices exposed to TL was significantly reduced and that retained in the slices was significantly higher when compared to A or control. No significant effect of TL was observed on DOPAC levels in the medium, tissue slices or total content as compared to A, nor on HVA as compared to control. These in vitro data suggest that TL-induced neurotoxicity may be due to its blocking effect on DA release.

Botulinum Neurotoxin Light Chain Inhibits 3H-Norepinephrine Release from Permeabilized PC-12 Cells. Rich Lomneth*, T. F. J. Martin*, and B. R. DasGupta* (SPON: J. Adler) Dept. of Food Microbiology and Toxicology, and Dept. of Zoology, Univ. of Wisconsin, Madison, Wisconsin 53706.

The botulinum neurotoxins (NT) are a class of neurotoxins which are among the most potent known. The well established action of NT is the inhibition of acetylcholine release from neurons. The NTs are comprised of a heavy chain (~100 kD) which is involved in the binding of the NT to the cell, and a light chain (~50 kD) which is believed to cause the intracellular lesion. To understand the NT structure-function relationships, we studied the effects of NT serotype B on the pheochromocytoma cell line PC-12. The 150 kD NT has no effect on the K^+-stimulated 3H-norepinephrine release from intact cells. However, after mechanically permeabilizing the cells so that the Ca^{+2}-stimulated secretory pathway remains functional (Martin, T. F. J., Methods Enzymol., 168;451, 1989), the 150 kD NT inhibits almost all of the Ca^{+2}-dependent 3H-norepinephrine release. The isolated light chain is at least as effective as the 150 kD NT while the isolated heavy chain has no effect. Therefore, we have developed a model system to study NT structure-function relationships and the intracellular mechanism of action (funded by NS24545 and DK40428).

49.1

LOCALIZATION OF CAT-301 IMMUNOREACTIVITY ON NEURONS IN THE GERBIL BRAINSTEM AUDITORY NUCLEI. I.R. Schwartz*# and S. Hockfield# Sections of Otolaryngology* and Neuroanatomy# Yale Univ. Sch. of Med., New Haven, CT 06510.

Cat-301, a monoclonal antibody generated against adult cat CNS, recognizes a proteoglycan on the extrasynaptic surface of a subset of mammalian CNS neurons. In the visual system of primates and cats Cat-301 appears to recognize a functionally distinct subset of neurons, those involved in processing the motion, or low contrast, component of a visual stimulus.

The distribution and identity of Cat-301 immunoreactive auditory neurons was determined in serial sections of adult gerbil brains. A characteristic, selective pattern of labeling marked distinct classes of auditory neurons. The labeled neurons were among the larger cell types present in each nucleus. Staining covered the soma and major dendritic trunks and varied in intensity depending on the specific neuronal class. Cells labeled include: giant or radiate neurons of the deep dorsal cochlear nucleus; octopus, multipolar and large elongate neurons of the posterior ventral cochlear nucleus; spherical and multipolar neurons of the anterior ventral cochlear nucleus; most neurons of the medial superior olive and of the medial, lateral and ventral nuclei of the trapezoid body; principal neurons of the lateral superior olive, primarily in the lateral limb; large oval neurons of the ventral nucleus of the lateral lemniscus; large oval and multipolar neurons of the dorsal nucleus of the lateral lemniscus; and very large multipolar neurons of the lateral (external) nucleus of the inferior colliculus. The results appear consistent with the hypothesis that Cat-301 labels a subset of auditory neurons responding to some dynamic property of sound.

Supported by NS14503 and EY06511.

INTRINSIC CONNECTIONS OF CAT PRIMARY AUDITORY CORTEX SHOWN WITH THE ANTEROGRADELY TRANSPORTED LECTIN PHASEOLUS VULGARIS LEUCOAGGLUTININ (PHA-L). M.N. Wallace, L.M. Kitzes and E.G. Jones. Dept. of Anatomy and Neurobiology, Univ. of California, Irvine, California 92717.

Iontophoretic injections of PHA-L were made bilaterally into the primary auditory cortex (AI). Four days later the animals were reanesthetised and the best frequency of cells at the injection site and in the surrounding cortex was determined by recording single and multiple unit responses to contralateral stimulation. Electrode tracks were marked by electrolytic lesions, the brain was perfused with 4% paraformaldehyde and the cortex was flattened and sectioned tangential to the pial surface at 40μm on a sliding microtome. One series of sections was stained immunohistochemically for PHA-L and the second with the monoclonal antibody, CAT-301. CAT-301 staining, as well as staining for acetylcholinesterase and cytochrome oxidase, were useful for defining the location of AI as they all showed elevated levels within layer IV. Patches of anterogradely labeled fibers occurred in the surrounding auditory fields. In addition, between three and eight patches of terminals occurred within AI. Despite being arranged in a variety of patterns around the injection site, these patches usually occurred in parts of AI that had a similar best frequency to the injection site.

Supported by NIH Grant NS25674.

AUDITORY KONIOCORTEX IN THE RAT: ANTEROGRADE TRANSPORT OF PHA-L TO NEOCORTEX FROM THE VENTRAL DIVISION OF THE MEDIAL GENICULATE BODY. *L.M. Romanski and J.E. LeDoux*, Div. Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021

The primary auditory receptive region of cortex, the auditory koniocortex, can be defined anatomically as the cortical projection field of the ventral division of the medial geniculate body (MGV). While the cortical projections of MGV have been examined in a number of mammalian species, these remain poorly characterized in the rat. To identify auditory koniocortex in this species, PHA-L was iontophoretically injected into MGV in male Sprague-Dawley rats. Labeled fibers entered temporal neocortex from the external capsule and extended towards the pial surface. Anterograde transport was heavily concentrated in the middle laminae (III and IV). With small injections, labeling appeared to occur in discrete, column-like ramifications. The labeled areas overlapped parts of Krieg's areas 39, 40 and 41 and Zilles' area TE3. PHA-L was also injected into auditory koniocortex. Anterograde transport was present in MGV, in a region ventral to auditory koniocortex and dorsal to perirhinal cortex that may represent a secondary auditory field, and in the posteromedial striatum. These findings thus anatomically define the primary auditory projection area in the neocortex of the rat and will facilitate behavioral studies of the function of rat auditory cortex. Supported by MH 38774.

GABA IMMUNOREACTIVE NEURONS AND PUNCTA IN LAYERS IV AND V OF CAT PRIMARY AUDITORY CORTEX (AI).
B.A. Peterson and J.A. Winer. Department of Molecular and Cell Biology, University of California, Berkeley, California 94720-2097.

The organization of layer IV in primary auditory cortex is significantly different than that of layer V. Layer IV is the main thalamic recipient zone, and it has a variety of non-pyramidal cells, many with axons intrinsic to AI. In contrast, layer V receives little thalamic input, and contains pyramidal and non-pyramidal cells, many of which project in the commissural and corticofugal systems. It would be interesting to compare the patterns of GABAergic cells and puncta in these layers since each has different functional roles. Tissue from adult cats was sectioned, then immunostained with either GAD (1:2000) or GABA (1:5000) and the avidin-biotin immunoperoxidase technique (S.M. Hsu et al., *J. Histochem. Cytochem.* 29:1349-1353 [1981]).

A substantial fraction of the population of AI neurons is GABAergic; however, there are significant laminar differences in their arrangement. The main results within layer IV are that (i) members of several classes of neurons are GABAergic; (ii) many GABAergic neurons have relatively small non-pyramidal perikarya that, in Golgi studies, were common in the upper half of layer IV (J.A. Winer, *J. Comp. Neurol.* 224:535-567 [1984]); (iii) at least one class of larger neuron is also GABAergic; (iv) small and medium-sized GABAergic terminals dominate the neuropil; and (v) immunonegative cells are often ringed by puncta, less so in layer V. The findings for layer V are that (i) members of each class of non-pyramidal neuron are GABAergic; (ii) certain inverted pyramidal cells are also GABAergic, including some accumulating [^{3}H]GABA; and (iii) immunopositive axon terminals are coarser and sparser than those in layer IV.

The high density of GABAergic terminals in layer IV is consistent with results in the primary visual cortex, while the layer V GABAergic inverted pyramidal neurons represent either a unique class of pyramidal neuron or may be more properly construed as non-pyramidal.

AUDITORY CORTEX NEURONS SENSITIVE TO CORRELATES OF AUDITORY MOTION IN THREE-DIMENSIONAL SPACE. E. Stumpf*, J.A. Manley-Toronchuk* and M.S. Cynader. (SPON: R.M. Douglas) Depts. of Psychology and Ophthalmology, University of British Columbia, Vancouver, B.C., V6T 1Y7, Canada.

Amplitude modulation at the receiver's ears is a characteristic of moving sound sources. When a sound source moves from side to side, stimulus intensity decreases in one ear and increases in the other. When a sound source moves toward or away from the organism, the two ears receive correlated increases or decreases in sound level.

We recorded from single units in the auditory cortex (AI) of anesthetized cats while presenting amplitude modulated pure tones via a sealed system. The stimuli consisted of AM ramps presented to the two ears and simulated movement in four canonical directions: toward vs. away, and toward ipsilateral vs. toward contralateral hemifield. Most cells encountered responded selectively to these correlates of moving sound, generally showing preferred directions emphasizing motion toward, away, or into the contralateral hemifield. In addition, all movement sensitive units responded selectively to the rate of rise of the AM ramps, a feature analogous to stimulus velocity. These findings suggest a role for auditory cortex units in three-dimensional localization of moving sound.

CORTICAL NEURONS SENSITIVE TO AUDITORY MOTION: UNDERLYING MECHANISMS. J.A. Manley-Toronchuk*, E. Stumpf* and M.S. Cynader. Depts. of Psychology and Ophthalmology, University of British Columbia, Vancouver, B.C., V6T 1Y7, Canada.

The traditional response properties of auditory cortical neurons, such as monotonicity vs. non-monotonicity, phasic vs. tonic, on vs. off, and E/E vs. E/I have usually been studied in isolation from one another. However, these response properties can be shown to interact synergistically, providing an underlying mechanism for selectivity to auditory motion. This poster will provide specific examples of the types of interaction found in cortical area AI in the cat. Several general rules for mechanisms underlying auditory motion selectivity have emerged from our studies. For example: 1) Neurons preferring a simple increase in sound intensity respond to the binaural correlates of sounds moving toward the head. Neurons reponding to stimulus offset prefer movement away. 2) E/E cells respond best to simulated movement toward the head, while E/I cells respond, best on average, to movement toward the contralateral hemifield. 3)Non-monotonic cells tend to show a preference for lower rates of sound source movement than do monotonic cells.

The rules described above are only first approximations, however, and the interactions among these response properties can be subtle and intricate. Illustrative examples will be presented.

49.7

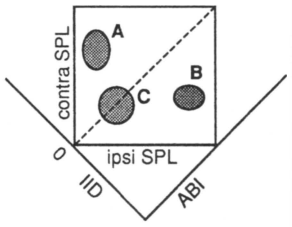
LEVEL-DEPENDENCE OF FREQUENCY AND LATENCY TOPOGRAPHY IN CAT PRIMARY AUDITORY CORTEX. C.E. Schreiner Coleman Laboratory, University of California, San Francisco, CA 94143-0526.

With near threshold stimuli, a strict cochleotopic organization can be demonstrated for mammalian primary auditory cortex (AI). This study defined the topographic representation of a pure tone in AI as a function of stimulus level. Frequency-response areas (FRAs) were measured for multiple-unit responses in AI of barbiturate-anesthetized cats. From these FRAs, a measure of cortical activity strength (spike count) in response to a pure tone of fixed frequency (8 kHz) was extracted for each recording site, and normalized to the maximum activity observed at that location. A cortical area was mapped corresponding to CFs spanning approximately 1.5 octaves. For stimulus levels of 10 to 40 dB SPL, the spatial distribution of the tone response evoked a band of increasing activity. This band was oriented in the dorso-ventral dimension of the iso-frequency domain, as determined with near threshold stimuli. By contrast, for stimulus levels above 40 dB SPL, no clear frequency-specific pattern of activity strength was observed. Instead, three distinct bands of activity were obtained that were oriented along the rostro-caudal extent of AI, i.e. orthogonal to the iso-frequency domain. The dorsal and ventral bands were associated with a high level of activity, whereas the central band showed only a relatively small amount of excitatory activity. On the other hand, a level-dependent spatial distribution of minimum latencies exhibited a clear frequency-specific pattern up to the highest levels tested (70 dB SPL), foremost in the center of AI. It is concluded that at low levels, spectral information is represented by a rate distribution. At high stimulus levels, spectral specificity in AI is preserved in the spatial pattern of response timing. Supported by NIH NS-10414, HRI, and the Coleman Fund.

49.8

CONNECTIONS OF AUDITORY CORTEX IN OWL MONKEYS. A.E. Morel, L.A. Krubitzer and J.H. Kaas. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

Cortical and thalamic connections of AI and surrounding cortex were investigated in owl monkeys (Aotus trivirgatus) with injections of WGA-HRP and fluorescent dyes (FB and NY). Fields AI and R were identified by patterns of tonotopic organization in microelectrode mapping experiments and were related to areas of dense myelination and cytochrome oxidase reactivity in brain sections cut parallel to the surface of flattened cortex.



Injections in AI demonstrated major connections with field R, the cortex adjoining AI caudally and medially, and the principal division of the medial geniculate body (MGB). Injections including cortex immediately lateral to AI and R labeled AI, R and cortex medial, lateral and rostral to AI and R. Three of these injections also labeled the frontal cortex. Thalamic connections to cortex lateral to AI and R were largely with the medial and dorsal divisions of the MGB, the suprageniculate nucleus and the medial pulvinar.

These results support previous conclusions that auditory cortex in owl monkeys includes both a core (AI and R) and a surrounding fringe of cortical fields. The fringe is distinguished from the core by having more widespread thalamic and cortical connections, including, for some part of the fringe, connections with the frontal cortex. (NS-16446).

TWIN (TWO-WAY INTENSITY NETWORK) NEURONS IN THE CAT PRIMARY AUDITORY CORTEX. M. N. Semple and L. M. Kitzes. Dept. of Anatomy and Neurobiology, Univ. of California Irvine, Irvine, CA 92717.

We have previously described a response type in gerbil inferior colliculus (IC) and cat primary auditory cortex (AI) for which the optimal tonal stimulus is a two-way intensity network (TWIN), constituting a particular sound pressure level (SPL) at one ear and a particular SPL at the other (Semple and Kitzes, *Soc. for Neurosci.*, 1987, 13: 1467). TWINs in IC are always contra-excited with a mixed ipsi influence of low-level facilitation and higher-level suppression. Within the ipsi by contra SPL matrix, the excitatory focus always favors the contra ear (A). Here we report more extensively on TWIN tuning of single neurons in cat AI.

TWINs are abundant in AI. Some are similar to those in IC (A), whereas others have an ipsi excitatory focus (B). Predominantly-binaural neurons respond best when the SPL is similar at both ears (C). These are functionally like other TWINs, except that the optimal SPL at each ear is similar.

Excitatory foci for different TWINs span the SPL matrix and their best frequency distribution is broad. Thus, TWINs would be selectively activated according to the spectral content of a sound and the amplitudes of the component frequencies at each ear.

CROSSCORRELATION AND SYNAPTIC STRENGTH IN A BIDIRECTIONAL ASSOCIATIVE MEMORY (BAM) MODEL. I.Espinosa, R.Lara* and F.Heredia*. Cybernetics Lab., Mexico National Univ., Mexico, D.F. 04510.

We are trying to interpret data from cat's auditory cortex AI (Espinosa I. and Gerstein G., Soc. Neurosci. Abstr. 11:249,1985) within the context of models which perform collective computation using two layers of neurons.

We simulated BAMs (Kosko,B., Byte, Sept. 1987,p.137) using a simulator which takes into account neurophysiological findings (MacGregor,R. Neural and Brain Modeling, A.P. 1987). Several sets of associations were stored in a 35x20 neurons BAM and activity of selected neuron pairs was analyzed with crosscorrelation.

These BAMs show a dominant state which results in a poor recovery of information. From one set to another synaptic strength changes massively. However, crosscorrelation barely detects those changes because of neurons' firing synchronicity.

It is not known if functional changes in AI assemblies are function of synaptic strength. In any case, crosscorrelation detects them (Espinosa I. and Gerstein G., Brain Research 450:39,1988). These experiments and simulations indicate that in the brain collective computation circuits with more layers, sparser connectivity and less synchronization are more likely.

THE INFLUENCE OF AUDITORY CORTEX ON THE ACOUSTICALLY EVOKED RESPONSES OF NEURONS IN THE INFERIOR COLLICULUS AND CEREBELLUM OF ECHOLOCATING BATS. D.X. Sun*, X.D. Sun* and P.H.-S. Jen. Department of Biology, East China Normal University, Shanghai PRC and Division of Biological Sciences, University of Missouri, Columbia, Missouri USA.

The influences of the auditory cortex on the responses of inferior collicular (IC) and cerebellar (CBL) neurons to sound stimulation in echolocating bats were studied by electrical stimulation of the auditory cortex. Among 471 IC neurons isolated, about 26% of them were affected by cortical stimulation. Responses of 103 (22%) IC neurons were inhibited and 17 (3.6%) were facilitated. The degree of inhibition is dependent upon the amplitude of both auditory and electrical stimuli. For a given acoustic stimulus, inhibition increased with increasing amplitude of electrical stimulus. Conversely, for a given electrical stimulus, inhibition decreased with increasing amplitude of acoustic stimulus. The point of cortical stimulation is crucial in influencing the responses of IC neurons. Among 186 CBL auditory neurons examined, responses of 139 (74.7%) neurons were facilitated upon electrical stimulation of the contralateral auditory cortex. Inhibitory effect was not observed. For a given electrical stimulus, the degree of facilitation varied not only among individual neurons but also among different sound amplitudes within each neuron. The facilitatory pathways to different parts of the cerebellum were studied by examining the difference in the facilitatory effect on each part of the cerebellum before and after a topical application of a local anesthetic, procaine, onto the point of electrical stimulation in the auditory cortex. The results showed that the facilitatory pathways to vermal and hemispheric neurons differ from the pathway to paraflocculer neurons. The modulation of responses of IC and CBL neurons by the auditory cortex is believed to be a part of a neural mechanism to sharpen the acoustic processing in the IC and to enhance the role of the CBL in acoustic orientation. (Supported by NIH grant)

SPECTRAL PROCESSING OF FM PULSES IN THE AUDITORY CORTEX OF AN FM BAT. S.L. Shannon* and D. Wong, Anatomy Dept, Indiana U. Sch. Med., Indpls., IN.

The echolocating bat, *Myotis lucifugus*, must extract multiple acoustic cues for target feature analysis (e.g., size, shape and texture) from the spectral content of its emitted FM signals. This species emits ultrasonic FM pulses that sweep downward approximately one octave within 4 msec. Virtually all neurons in *Myotis* auditory cortex are sensitive to specific FM sweeps. The FM signal which elicited maximal neuronal response was presented in discrete quadrants to an awake bat to determine which sweep segment presented alone was sufficent to evoke neural response, and how other sweep segments affected the response magnitude. Most FM units respond weakly when only the third quadrant of the sweep is presented and exhibit little or no response when the first half of the sweep is presented alone. However, presentation of the second or last quadrant along with the third quadrant greatly facilitates the response with little change in response latency. Resolving how different components of an FM signal shape the neuronal response may elucidate how spectral cues convey target information for an FM bat (Supported by NIH grant R01 NS27182).

EFFECT OF CALLOSAL STIMULATION ON SINGLE UNIT RESPONSES IN PRIMARY AUDITORY CORTEX OF THE FERRET. D.W. Doherty and L.M. Kitzes. Dept. of Anatomy and Neurobiology, University of California Irvine, Irvine, CA 92717.

The functional properties of the extensive callosal pathways between auditory cortices were examined. Single unit activity was recorded in primary auditory cortex (A1) of ferrets anesthetized with Nembutal. The callosal system was stimulated electrically via a pair of rostrocaudally oriented, monopolar electrodes placed in the middle layers of contralateral A1. Single electric shocks of 100 to 200 μs duration and between 100 and 600 μa in magnitude were delivered in a systematic temporal relationship to monaural or binaural tonal stimuli delivered through sealed and acoustically calibrated ear assemblies.

Callosal activity, triggered by a shock to contralateral A1, can facilitate or suppress acoustically evoked responses of EE, EO, EI, and PB units.. Callosal stimulation can evoke a burst of activity in EE units. In PB units, callosal stimulation can also evoke a burst of activity that may be accompanied by a suppression of acoustically evoked discharges. In units that exhibit suppression, the suppression of acoustically evoked responses varies parametrically with shock amplitude. Differential effects upon single unit responses to acoustic stimuli were observed, e.g., no effect upon contralaterally evoked responses with marked suppression of ipsilaterally evoked responses. These data indicate that callosal activity influences units of several response types in A1. Additionally, this influence can have complex facilitatory or suppressive effects on acoustically evoked responses.

CONTRIBUTION OF THE CORPUS CALLOSUM (CC) TO AUDITORY LOCALIZATION IN THE CAT. P. Poirier*, L. Richer*, F. Lepore, M. Ptito, and J.-P. Guillemot. Univ. de Montréal and Univ. de Québec, Montréal, QC, H3C 3J7.

Anatomical and electrophysiological studies with cats suggest that the primary auditory cortex (AI) is involved in sound localization and in the treatment of interaural time (ITD) and intensity differences (IID). Behavioral studies have shown that CC is not involved in these functions. Electrophysiological and tracing studies of AI, however, suggest its implication in the fusion of auditory hemispace and its contribution to the temporal aspects of auditory localization. We report here evidence that CC fibres do contribute to sound localization. We recorded CC fibres and tested spatial tuning by varying ITDs. Cats were anesthetized and paralyzed. Pure tones (PT) and broad-band noise (BBN) bursts were delivered independently to each ear through a sealed-speaker system. Fibres exhibited binaural properties which were similar in most respects to those found in AI. ITD-sensitivity functions showed three different types of patterns: some showed a selectivity to a precise ITD; some responded maximally to a range of delays; others did not respond to ITDs. Fibres were narrowly tuned to PTs. They responded preferentially BBNs. Some fibers adapted rapidly while others slowly. Some were bimodal (auditory-somatosensory, auditory-visual). Testing auditory space representation in free-field stimulation, which we are presently carrying out, should reveal whether spatial sensitivity to static position is independent of its dynamic position.*(supported by FCAR and CRSNG).*

SPEECH PROCESSING IN PRIMATE PRIMARY AUDITORY CORTEX (A1). M. Steinschneider*, J. Arezzo and H. G. Vaughan, Jr. Albert Einstein College of Medicine, Bronx, NY 10461

Concurrent laminar recordings of current source density (CSD) and multiple unit activity (MUA) were performed in A1 of an awake monkey to /da/, /ba/ and /ta/, their formants and to tones.

Differential MUA patterns that reflected the spectral characteristics of formant frequencies and consonant place of articulation occurred at sites excited by tones within the syllables' spectral range and were determined by the sites' tonotopic specificity. In contrast, tonotopic specificity was not required to encode the temporal characteristics of fundamental frequency and voice onset time.

MUA evoked by the syllables was often a nonlinear sum of the isolated formant responses. Interactions among the formants modulated the activity to the syllables and sharpened response differences that reflected place of articulation.

CSD and MUA depict complementary aspects of laminar processing, namely synaptic events and axonal firing patterns. Laminar profiles of the CSD and MUA revealed specific response transformations between the thalamocortical input and the cortical cells. Encoding of formant transitions and steady-state vowels appeared to occur differentially within auditory cortex.

EFFECT OF UNILATERAL AUDITORY CORTEX ABLATION ON THE ABILITY OF MACAQUES TO PERCEIVE DICHOTICALLY PRESENTED VOCALIZATIONS H. E. Heffner and S. E. Mooney*. Lab. of Comparative Hearing, Dept. of Psychology., Univ. of Toledo, Toledo, OH 43606.

Sounds presented to one ear are processed mainly by the contralateral hemisphere. Which hemisphere processes sounds that are presented to both ears but lateralized (using time and intensity differences) to one ear?

Four Japanese macaques (Macaca fuscata) were tested on their ability to discriminate two types of their "coo" vocalizations following unilateral auditory cortex ablation. The coos were presented via headphones 1) to one ear at a time (monaural condition) or 2) to both ears with a binaural time delay and/or an intensity difference sufficient to produce a lateralized signal (binaural condition).

Unilateral ablation resulted in a deficit in the monaural condition for sounds presented to the ear contralateral to the lesion. However, no deficit was observed in the binaural condition even when the sound should have been lateralized to the contralateral ear.

These results demonstrate that information regarding sound arriving at one ear is sent primarily to the contralateral hemisphere. Information regarding sound arriving at both ears is sent to both hemispheres even when it is lateralized to one ear. (Supported by NIH grant NS 12992)

MINIATURE ELECTRODE ARRAYS REVEAL TONOTOPIC AUDITORY EVOKED POTENTIALS IN PIG CORTEX. D. L. Woods, T. C. Chimento#, R. J. Andrews*, R. Kirby*, Clinical Electrophysiology Laboratory, Depts of Neurology/Neurosurgery, U.C. Davis, VA Medical Center, Martinez, CA, 94553, and #Coleman Laboratory, UCSF, San Francisco, CA.

Although auditory evoked potentials (AEPs) provided important historical insights into the localization and organization of auditory cortex, contemporary studies rely almost exclusively on single and multi-unit neuronal recording. A miniature electrode array was constructed (21 electrodes in 1.6 cm^2) to determine whether the topography of AEPs would reveal a tonotopic organization of auditory cortical areas of domestic swine.

Domestic swine were sedated, intubated and maintained under inhalation anesthesia (isoflurane 1.5-2.5%). After craniectomy, the array was placed epidurally over the temporal lobe. To evaluate tonotopic organization, tonebursts (0.25-8.0 kHz, 10 ms duration, 2 ms rise/fall times) were presented binaurally at interstimulus intervals of 1.0 sec. Peak amplitudes of the P25 component, presumed to arise in primary auditory cortex, shifted systematically with frequency. A tonotopic map was generated in about 10 minutes: low frequencies were represented rostromedially and high frequencies caudolaterally. Mini-array recording of AEPs can rapidly characterize functional cortical topography (Supported by the VA Research Service and the NINCDS).

CORTICAL AUDITORY EVOKED RESPONSE IN THE ALBINO RAT: EFFECTS OF INTERAURAL TIME DELAY. S.L. SALLY*, J.B. KELLY AND G.L. KAVANAGH* (SPON: E. Peterson). Laboratory of Sensory Neuroscience, Carleton University, Ottawa, Canada, K1S 5B6.

The effects of interaural time delays (ITD's) on cortical evoked potentials have been investigated in the cat. However, similar studies have not been reported for the rat. In the present study cortical evoked potentials were used to determine the range over which manipulation of ITD's produces variation in response amplitude. Recordings were made on the surface of auditory cortex. Clicks were delivered to each ear independently through sealed loudspeakers inserted into the external meatus. ITD's from -600 usec (left stimulus leading right) to +600 usec (right leading left) were examined. The function for the left hemisphere response was relatively flat from -600 usec to -250 usec and then rose sharply to reach a maximum amplitude at about +250 usec. At this point the function reached a plateau. The function for the right hemisphere began to decline at about -250 usec and reached a minimum amplitude at about +250 usec. Beyond these values the function was relatively flat. As in the cat, the highest amplitude response appeared in the hemisphere contralateral to the ear which was first stimulated. However, in the rat variation in response amplitude occurred over a smaller range of interaural time differences than the cat.

HOMOLOGY BETWEEN HUMAN AND CAT AUDITORY BRAINSTEM POTENTIALS (ABR). M. Zaaroor*, A. Starr. Neurology, U. Calif. Irvine, CA 92717. In humans and animals a sequence of short latency (<10msec) components to clicks can be recorded from scalp electrodes. In human the vertex positive components are labelled serially with Roman numerals. In cat, the vertex components are labelled by their polarity and latency in msec. We have studied the generator sites for the cat ABR using intracranial recordings from round window, VIII nerve, cochlear nucleus and superior olive while comparing their latency with the latency of the scalp ABR. These results were then related to intracranial recordings in man reported by Moller to define the homologies between the ABR components in the two species as follows:

ABR COMPONENTS (IN MSEC) (VERTEX NON-CEPHALIC REFERENCE) TO 60 dB nHL CLICKS.

Wave	Human	Cat	Generator Site
I	1.5	1.0	ipsi VIII N, distal
II	2.8	1.4	ipsi VIII N, proximal
III	3.7	2.0	ipsi cochlear nucleus
IV	4.9	3.0	contra superior olive
V	5.6	4.0	both superior olive
VI	7.1	5.0	?

COMPARISON OF THE BRAINSTEM AUDITORY EVOKED RESPONSES (BAER) IN TAURINE-SUPPLEMENTED AND TAURINE-DEFICIENT CATS. M-H. Vallecalle*, G. Heaney, E. Sersen, J.A. Sturman*.

Cats fed taurine-deficient diets develop pronounced reductions in retinal functions, such as electroretinogram responses and visual acuity, and degeneration of the retina and tapetum lucidum. Despite the reports of many-fold reductions of taurine concentrations throughout the central nervous system in taurine-deficient cats there have been no reports of other functional or behavioral deficits. Brain-stem auditory evoked response (BAER) has proved to be a useful instrument for electrophysiological measure of brainstem dysfunction and sensorineural hearing loss. We have recorded the BAER in adult cats fed a taurine-deficient or taurine-supplemented diet for an extended period (> 2 years). The BAER were elicited by rarefaction clicks at different intensities. The responses of the cats were measured as functions of peak latency, peak amplitude and threshold. Our preliminary results are as follows: The BAER of all cats contain five peaks (I to V). A detailed analysis of peak IV, chosen because of its similarities to peak V in humans, shows no difference in threshold between taurine-deficient and taurine-supplemented cats. Analysis of all five peaks suggests that taurine-deficient cats show shorter latencies than taurine-supplemented cats. These results suggest that the reduction of the inhibitory action of taurine may lead to faster conduction of nervous impulses.

THE AUDITORY 40 HZ-BAND EVOKED RESPONSE LASTS 150 MS AND INCREASES IN SIZE AT SLOW RATES. S. Makeig* and R. Galambos Naval Health Research Center, San Diego, CA.

The auditory middle latency response (MLR) extracted from the EEG when tones or clicks are delivered at a rate near 10/s resembles two or more cycles of a 40 Hz sinusoid. Our experiments demonstrate that brief auditory stimuli actually evoke a burst of waves near 40 Hz in frequency lasting at least 150 msec. Moreover, at very slow presentation rates (<< 1/1s), the amplitude of this 40 Hz-band response increases to up to ten times its size at faster rates (> 1/s). The accompanying figure superimposes the vertex 40 Hz-band click responses (means of three subjects) for four presentation rates (1/10s-3/s).

In the Figure response amplitudes have been normalized. Below these 40 Hz-band responses, the mean wide-band 1/10s response is plotted to illustrate the presence of the 40 Hz-band oscillations in the larger and slower evoked response activity. We conclude that a major consequence of each acoustic stimulus is to evoke a rhythmic response consisting of several near-40 Hz oscillations, and that both the conventional 10/s MLR and the 40/s steady-state response (SSR) represent partial superimpositions of this 40 Hz-band evoked rhythmicity.

49.22

FORTY HERZ (40Hz) AND SENSORY MOTOR RHYTHMS (SMR) AS EEG STATE VARIABLES AND RELATED EVOKED POTENTIALS. C. C. Turbes and G. T. Schneider*. Creighton University, Department of Anatomy, Omaha, NE 68178.

There is evidence that certain brain rhythms may signal the occurrence of different brain states. Support for this hypothesis may be provided by evidence that processing of information is changed during different brain states.

The prestimulus period proceeding the auditory evoked potential (AEP) is converted to a power spectral estimate. These power spectra are used to sort for the AEP when certain power values for the (36-42Hz) and the (11-16Hz) are reached in the prestimulus period of the sensory motor cortex, nucleus accumbens and amygdala.

Attempts are made to measure the performance of the 40Hz and SMR estimators. These studies are made in the cerebral cortical and subcortical regions in cats. In these studies D and L isomers of amphetamine are used to induce a chemical brain state changes. The AEP are selected in the amphetamine altered states based on the prestimulus auto spectra.

49.23

DIFFERENCES BETWEEN HUMAN AND AUTOMATIC WORD RECOGNITION. Henry J. deHaan. U.S.Army Research Institute. Alexandria, VA. 22333.

In order to determine some of the ways in which automatic word recognition differs from human word recognition, humans spoke a list of minimally-different words into a microphone connected to a word recognizer. The overall accuracy was lower for automatic word recognition than for human word recognition. Confusion matrices were prepared and a phonetic analysis was undertaken to determine errors associated with particular phonemes and classes of phonemes. Further analyses were performed on some of the more important distinctive features of speech, such as voicing and place and manner of articulation and some tentative conclusions were drawn about particular features and phonetic classes. The differences between human and automatic word recognition indicate that at the present time there is neither a cognitive model nor brain model adequate to account for human speech perception and language processing.

DISTORTIONS IN AUDITORY GENERALIZATION OF SUPPRESSION FROM SALICYLATE INDUCED TINNITUS IN RATS. J.F. Brennan and P.J. Jastreboff. Dept. of Psychology, Univ. of Massachusetts at Boston, MA 02125.

Tonal generalization was examined in water deprived rats exposed to continuous low level, wide band noise. 3 days of lick training were followed by acclimation to 5 presentations of the to-be-conditioned stimulus (CS), consisting of 1 min offset of the noise. 2 subsequent sessions introduced Pavlovian conditioned suppression of licking through 5 CSi each terminating with a 0.5 s mild footshock. In 5 extinction sessions, CSi were accompanied by a tonal frequency: 7-, 8-, 9-, 10-, or 11-kHz. 8 rats began daily salicylate injections, 350 mg/kg, 2 hrs prior to the first Pavlovian session, while a second group started injections before the first extinction session. The remaining 8 rats served as saline injected controls. Systematic gradients revealed greater suppression at higher frequencies in the group starting injections before training, while just the opposite occurred in the group starting salicylate after training. These data are explained by the presence of subjective auditory perception from salicylate injections which interferes with the generalization at higher frequency tones. (Supported by DRF, 1988).

50.1

MEASUREMENT OF ACOUSTICAL CROSS-TALK THROUGH THE BARN OWL'S EAR CANAL. T. Haresign and A. Moiseff. Department of Physiology and Neurobiology, University of Connecticut, Storrs, CT 06269.

The Barn Owl's interaural canal transmits low frequency sound between the ears. Computer modeling predicted that a small frequency difference between the ears should produce monaural intensity modulations dependent on the instantaneous phase relationship of the sound between the ears and the length of the interaural canal.

Single unit recordings in the monaural nucleus magnocellularis confirmed that the interaural canal acts as a low pass filter, effectively isolating the ears at frequencies above 4 khz. In cases where acoustical cross- talk was present tonal stimuli differing by 3 Hz. were delivered to the two ears. Intensity sensitive units showed variations in their firing rate reflecting beat frequencies that arise at the ear. Analysis of the response revealed the canal attenuation at the test frequency in addition to the effective acoustical delay through the conductive pathway. These results were used to refine the mathematical model.

50.2

SENSITIVITY OF BARN OWL AUDITORY NEURONS TO CONSTANTLY VARYING INTERAURAL TIME DIFFERENCES. A. Moiseff and T. Haresign. Dept. of Physiology and Neurobiology, Univ. of Conn., Storrs, CT 06269.

We have adapted the binaural beat technique of Kuwada *et al* (*Science* 206:586, 1979) to determine the ITD sensitivity of owl auditory neurons.

Tonal stimuli differing by 3 Hz were delivered to each ear. At frequencies where the owl's ears are acoustically isolated such a stimulus subjected binaural cells to a continuous, smoothly varying interaural phase difference but a constant interaural intensity difference. Each action potential was treated as a vector on a unit circle at an angle equivalent to the instantaneous interaural phase difference. From these data mean vector angle was calculated, converted to an equivalent ITD (and termed dynamic ITD), and then compared to the statically obtained ITDs. Static and dynamic ITD measurements were correlated significantly ($r^2 = 0.96$).

The simplicity and rapidity of the dynamic technique allowed us to extend our understanding of ITD sensitivity in the owl with respect to the effects of frequency and interaural intensity differences.

Supported by NIH Grant NS21480 to AM.

50.3

BINAURAL CUES FOR DIRECTIONAL HEARING IN ACOUSTICALLY NON-SPECIALIZED BIRDS. O.N. Larsen, R. Tweedale* and M.B. Calford. V.T.H.R.C., Dept. of Physiol., Univ. of Queensland, 4067 Australia.

We wanted to determine the cues for directional hearing available to birds with symmetrical ears and a functional interaural canal.

Bilateral recording of cochlear microphonics on urethane anaesthetized birds (boobook owls, noisy miners, chicks and quail) was used to measure variations in interaural time differences (ITD) and intensity differences (IID) as a tonal free-field stimulus was moved to different positions in the bird's frontal field.

ITDs varied smoothly with stimulus azimuth for all frequencies and elevations tested and were close to those expected from the pathlength round the head at high frequencies, but up to two times larger at low frequencies. For any frequency and azimuth the largest ITDs were produced in the horizontal plane, successively decreasing with increasing elevations (roughly proportional to cos(elevation angle)). IIDs increased smoothly with azimuth from 0^0 (frontal) to at least $+/-40^0$ for the frequencies and elevations tested. Beyond this range more complex variations occurred. IIDs generally decreased with elevation. Thus binaural cues in "normal" birds are mainly for azimuth localization.

50.4

DEVELOPMENT OF THE DELAY LINES IN NUCLEUS LAMINARIS IN THE BARN OWL. C. E. Carr and R. E. Boudreau*. Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642.

In the barn owl, sensitivity to interaural time differences arises in the brainstem nucleus laminaris (NL). Maps of interaural phase difference are formed in the dorso-ventral dimension of NL by interdigitating axons from the isp- and contralateral magnocellular cochlear nuclei (NM). The normal development of these axonal delay lines has been studied during the first month of life when the distance between the ears almost doubles in size, subjecting the bird to constantly changing interaural time differences.

The first NM afferents find their targets in NL a few days before hatching. In the first week posthatch, NM axons continue to arborize and form synapses on NL neurons. Around hatching, large numbers of oligodendrocytes line the borders of NL, and a wave of myelination of the NM axons in NL begins towards the end of the first week posthatch. Myelination is significant for development of delay lines, as the amount of delay mapped in NL depends on their conduction velocity. The dorso-ventral dimensions of NL are also important, as the depth traversed by the NM axons in NL determines the interaural phase difference mapped. Depth of NL increases from about 200μm at hatching to about 600μm at 1 month posthatch. The increase in size is mainly due to continuing myelination of delay lines, although fiber diameter also increases from 1.5 μm at hatching to 2 μm at 1 month posthatch. At this time the circuit in NL is almost adult in appearance. The major anatomical difference between the 1 month old and the adult is the depth of NL. In the second month posthatch, the axonal delay lines grow to an average diameter of 3μm, and NL reaches its adult depth of about 700μm.

TRANSITION FROM SINGLE TO MULTIPLE FREQUENCY CHANNELS IN THE PROCESSING OF BINAURAL DISPARITY CUES IN THE OWL'S MIDBRAIN. I. Fujita[1,2] and M. Konishi[1]. [1]Div. of Biology, Caltech, Pasadena, CA 91125 and [2]Frontier Research Program, RIKEN, Wako 351-01, Japan.

Interaural level (ILD) and time (ITD) differences are the primary cues for the barn owl to localize the vertical and horizontal positions of sound, respectively. Distinct anatomical pathways in the brainstem process ILD and ITD separately and reach the external nucleus of the inferior colliculus (ICX). We analysed neuronal selectivity to ILD and ITD in the ICX and its input nucleus, the lateral shell of the central nucleus of the inferior colliculus (ICL).

ICL neurons responded to monoaural stimulation of one or both ears. ILD functions were either bell-shaped or monotonic. ICL neurons could be divided into two groups according to their noise ITD curves: one with multiple peaks of identical height (type I, "phase ambiguous") and the other with a main peak and smaller secondary peaks (type II). All neurons with monotonic ILD function belonged to type I. The peak width of bell-shaped ILD functions was narrower in type II than in type I. In type II cells, the peak was sharper with noise stimuli than with tone bursts. As reported earlier, ICX neurons were broadly tuned to frequency and responded maximally to noise at a unique ITD. They responded exclusively to binaural stimuli with a range of ILD. Monoaural stimulation evoked no response or inhibited the cells. ILD curves of ICX neurons were thus sharply peaked.

These results suggest that ILD information is first combined with ITD information in type I ICL cells and then multiple frequency inputs begin to converge in type II ICL cells and eliminate phase ambiguity. The results also suggest that convergence of different frequency channels contributes to neuronal selectivity to ILD and explain the behavioral observation that in the vertical direction, barn owls locate noise sounds much better than tones. (Supported by the Uehara Memorial Foundation and NIH).

50.6

MODEL OF THE COMPUTATION OF AUDITORY STIMULUS DIRECTION AND TUNING TO INTERAURAL LEVEL DIFFERENCE IN THE INFERIOR COLLICULUS OF THE BARN OWL. J.C. Pearson, C.D. Spence*. SRI-David Sarnoff Research Center, CN5300, Princeton, NJ 08543.

The direction of auditory stimuli are represented in a map-like form in the external nucleus of the inferior colliculus (ICx) of the barn owl. The spatial receptive field of each neuron derives from its sensitivity to a particular combination of interaural time delay (ITD) and interaural level difference (ILD). The ICx map is produced by merging the map of ITD in the IC with the map of ILD in nucleus ventralis lemnisci lateralis pars posterior (VLVp). Our two-step model of this process (an early version was presented in *Advances in Neural Information Processing Systems, I*) predicts that the lateral shell of the IC contains a three-dimensional map of cells tuned to ITD, ILD and frequency. The tuning (bell-shaped response curve) of these neurons to ITD and frequency is inherited from their inputs, whereas the tuning to ILD must be derived as the cells in the VLVp are only sensitive to ILD (sigmoidal response curve). ILD is represented by bands of activated cells oriented along the dorsal-ventral axis in the VLVp. Our model produces ILD tuning by effectively computing the spatial derivative of these bands through asymmetric lateral inhibition in the projection to the lateral shell. (Supported by the AFOSR)

50.7

SINGLE UNIT RESPONSES TO MULTIPLE SOUND SOURCES IN THE INFERIOR COLLICULUS OF THE OWL. J.A.MAZER* (SPON: J.ALLMAN). Division of Biology 216-76, Caltech, Pasadena, CA 91125.

Neurons in the external nucleus (ICx) of the inferior colliculus (IC) are tuned to interaural time differences (ITD); tonal stimuli presented at varying ITD's generate maximal responses at a neuron's characteristic delay (CD) and its phase equivalents. A plot of ITD versus response, an ITD curve, shows a characteristic pattern of peaks and troughs in ICx. By mixing two synthetic sounds, each with different delays and different spectral characteristics, I have been able to examine the effects of multiple sound sources on ITD-channels in ICx.

A conventional ITD curve was generated for ICx neurons using a single sound source; a second ITD curve was generated for the same neuron in the presence of a second sound source with a constant ITD at or near the neuron's CD. The presence of this second source appeared to cause a general suppression of activity when compared to the single source responses. This suppression occurred even though the absolute combined intensity of the multiple source stimuli may have been equal to or greater than the intensity the single source stimuli. This suppression was not uniform across ITD-space. The second source appeared to maximally suppress sidepeaks near the CD, while not dramatically affecting the troughs immediately adjacent to the CD. Finally, preliminary observations have shown shifts in peak positions on ITD curves generated in the presence of a second source source.

Previous experiments using a free-field paradigm have shown the existence of auditory center-on surround-off receptive fields in ICx (Knudsen and Konishi,*Science*, 202:778-780, 1978). The cross ITD-channel interactions seen with multiple dichotic sources may correlate with the center-surround fields seen in free-field recordings.

50.8

RESOLUTION OF AUDITORY LOCALIZATION AMBIGUITIES BY SPACE-SPECIFIC NEURONS IN THE OWL'S OPTIC TECTUM. M. S. Brainard*, S. D. Esterly and E. I. Knudsen. Dept. Neurobiology, Stanford Univ., Stanford, CA 94305.

Frequency-specific interaural differences in timing (ITD) and intensity (IID) provide important cues for sound localization. However, for a single frequency, ITD and IID cues are ambiguous in that sounds from many different locations give rise to identical cue values. To localize a sound source, the auditory system must resolve these ambiguities. Space-specific neurons in the optic tectum of the barn owl exhibit restricted receptive fields when stimulated with broadband sounds. Thus, they somehow resolve the ambiguities that are inherent to individual cue values. We studied the response properties of these neurons to determine how this was accomplished.

We used probe tube microphones placed in the ear canals to measure the values of IID and ITD produced by sounds at 178 frontal locations. We then recorded neuronal responses to free-field stimuli, and compared the spatial pattern of responses with the spatial distributions of cue values. Tectal neurons responded to tonal stimuli from regions of space outside the broadband receptive field. These regions of ambiguity occurred only where the values of both ITD and IID cues closely matched their values within the broadband field. Thus, within a narrow frequency band, tectal neurons resolve some of the ambiguity inherent to either ITD or IID alone by requiring the conjunction of specific ITD and IID values. The remaining ambiguities were reduced by the addition of a second tone to the stimulus. At a location from which one tone was excitatory, the addition of a second tone suppressed the response to the first if either the ITD or the IID of the second differed substantially from its value at the center of the broadband field. Thus, by combining information both within and across frequency, localization ambiguities are resolved and neuronal responses become space-specific.

FREQUENCY-DEPENDENT TUNING FOR INTERAURAL DIFFERENCE CUES IN SPACE-SPECIFIC NEURONS IN THE OWL'S OPTIC TECTUM. S.D. Esterly and E.I. Knudsen. Dept. Neurobiol., Stanford Univ., Stanford,CA 94305

The binaural cues for sound localization, interaural intensity differences (IID) and interaural time differences (ITD), are frequency-dependent. Space-specific neurons in the optic tectum of the barn owl are sensitive both to IID and to ITD, and they respond to free-field broadband sounds only when the source is within a restricted receptive field. To determine whether the tuning of space-specific units to IID and ITD is frequency-dependent, we tested these units with computer-generated narrowband and broadband dichotic stimuli. Units tuned to locations where IID increases monotonically as a function of frequency were found to be tuned to progressively larger IID values as the frequency of a dichotic stimulus was increased. Conversely, non-monotonic tuning to IID was observed for units tuned to locations where IID values vary non-monotonically with frequency. Thus, the pattern of a unit's tuning to IID, as a function of stimulus frequency, agrees well with the frequency-dependent pattern of IID values produced by a free-field sound located in the unit's receptive field. The frequency-dependence of ITD is small at most free-field locations, and most units showed little frequency-dependence in their ITD tuning. Some units, however, did show substantial shifts in ITD tuning with frequency, and these units were tuned to locations where ITD is strongly frequency-dependent. Broadband dichotic stimuli containing identical cue values at all frequencies drove most space-specific units well. However, some units could not be driven by such stimuli. In these cases we found that broadband dichotic stimuli containing appropriate frequency-dependent cue values were effective in driving the units.

These results indicate that the auditory system interprets interaural difference cues in a frequency-specific manner when deriving the location of a sound source.

PHOTORECEPTOR RESCUE IN THE RCS RAT WITHOUT PIGMENT EPITHELIAL TRANSPLANTATION. M.S. Silverman* and S.E. Hughes* (SPON: D.H. Eldredge). Central Institute for the Deaf and Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Transplantation of normal retinal pigment epithelium (RPE) to the subretinal space has been reported to rescue photoreceptors in the RCS rat (Li and Turner, Exp Eye Res, 47:911, 1988; Lopez et al, IOVS, 30:586, 1989). Moreover, the rescue effect was surprisingly large considering the relatively small number of RPE cells transplanted. The reason for this widespread rescue of photoreceptors is not known, nor is the mechanism for outer segment phagocytosis in photoreceptors not apposed to the transplanted RPE cells. This suggests that the rescue effect may not be solely mediated by the transplanted cells. We therefore wished to test whether the transplantation surgery itself might contribute to the rescue of RCS photoreceptors.

Control surgery was performed on 26- to 28-day-old RCS rats. At this age, the RCS rat is just beginning to show degenerative changes and still has almost a full complement of photoreceptors. For these control experiments, we performed the surgery described by Li and Turner for the transplantation of RPE but instead of injecting RPE, we injected saline. We sacrificed the RCS control operates two months following surgery. In the area of the surgery (superior retinal quadrant) the outer nuclear layer (ONL) was up to 8-10 photoreceptor cells thick, while at the extreme inferior margin of the retina the ONL was almost eliminated. The degree of rescue of photoreceptors that we obtained with saline injections (6 cases) was comparable to that obtained with the transplantation of intact RPE by our transcorneal procedure (Silverman and Hughes, IOVS, Suppl 28:288, 1987) or by the dissociated RPE cell injection techniques of Li and Turner or Lopez et al. It therefore appears that the rescue of photoreceptors in this animal does not require transplantation of normal RPE cells, but only the surgical manipulation for such transplantation.

PHOTOPIC AND SCOTOPIC ERG MODIFICATIONS AS WELL AS NEUROCHEMICAL CHANGES IN STREPTOZOTOCIN-INDUCED DIABETES IN THE RAT. P. Olivier, A. Drumheller and F.B. Jolicoeur. Depts of Ophthalmology and Psychiatry, Univ. of Sherbrooke, Fac. of Med. Sherbrooke, Qc, Canada. J1H 5N4.

Concommitant ERG modifications and retinal neurochemical changes in light and dark adapted rats rendered hyperglycemic (above 300 mg/dl) by the I.V. administration of 65 mg/kg streptozotocin (STZ). ERG parameters were both scotopic and photopic B-wave amplitudes and implicit times generated by various intensities of stimulation. Retinal concentrations of dopamine (DA), its main metabolites DOPAC and HVA, as well as 5-HT, 5-HIAA, and NE were measured using HPLC-ECD. ERG recordings and neurochemical determinations were performed in control and treated animals prior to and at 1,4 and 8 weeks following STZ treatment. To verify the specificity of possible neurochemical alterations in the retina, the same neurochemical measurements in striatum were performed at 8 weeks after injections of STZ. Results indicate that B-wave amplitudes, but not implicit times were differentially affected by these two conditions of light adaptation: amplitudes were significantly enhanced but markedly decreased under photopic and scotopic conditions respectively. Retinal levels of NE, 5-HT and 5-HIAA were not altered. However, significant increases in the ratios of each metabolite DOPAC and HVA to DA retinal concentrations were found. These increases became more pronounced with time. Striatal levels of all amines and metabolites were not affected. Together, these results indicate that STZ induced diabetes in rats produces light adaptation dependent changes in B-wave amplitudes. Using ratios as indices of DA utilization, our result suggest that experimental diabetes produces a specific enhancement of retinal DA turnover which could underlie the observed electrophysiological modifications.

THE LEAD-INDUCED SELECTIVE ROD DEGENERATION: ROLE OF LIPID PEROXIDATION, VITAMIN E, ZINC AND CALCIUM. D.A. Fox, R.D. Weigand* and R.E. Anderson*. College of Optometry, University of Houston, Houston, TX 77204 and Cullen Eye Institute, Baylor College of Medicine, Houston, TX 77030.

The mechanism by which developmental Pb exposure produces a selective rod degeneration[1] is unknown. Direct evidence for involvement of lipid peroxidation, or a vitamin E or Zn deficiency in photoreceptor degeneration has come from several laboratories. Alternatively, the influx and accumulation of [Ca] in the rod could result from the elevated retinal cGMP[1] and lead to rod cell death. To examine the role of each these factors, we determined the composition of the major fatty acids (22:6 and 20:4) of rod outer segments (ROS), production of lipid hydroperoxides (lipid conjugated diene content) of ROS, Vitamin E content of ROS, and the neural retina [Zn] and [Ca] at end of Pb exposure and in adult hooded rats exposed to Pb (0.2% PbAc to dam) on postnatal days 0-21. There were no indications of lipid peroxidation or of a change in vitamin E. In contrast, retinal [Zn] was decreased 9-14% and [Ca] was increased 18-31%. The decrease in [Zn] and increase in [Ca] correlate with our findings of a decreased rhodopsin content[2] and impaired retinal mitochondrial energy metabolism[3], respectively, in Pb-exposed rats. These divalent cation alterations may mediate the selective rod degeneration. Supported by ES 03183 and EY 04149. 1. EER 46: 597-611 and 613-625, 1988; 2. EER 48: 237-249, 1989; 3. RETINAL MÜLLER CELLS IN PIGEONS EXPRESS GLIAL FIBRILLARY ACIDIC PROTEIN FOLLOWING CENTRAL LESIONS THAT DISRUPT NEURAL REGULATION OF CHOROIDAL BLOOD FLOW. B.A. Vana*, M.E.C. Fitzgerald and A. Reiner. Dept. of Anat. & Neurobiol., UT-Memphis, Memphis, TN.

Retinal Müller cells have been shown to express glial fibrillary acidic protein (GFAP) following various types of retinal pathologies but not in normal healthy retina. We have found that choroidal blood flow in birds is regulated by medial Edinger-Westphal (mEW) (Reiner & Fitzgerald, 1989), and EW lesions that interrupt such regulation result in pathological modifications of photoreceptors of the ipsilateral eye (Fitzgerald & Reiner, 1989). To further explore the apparently deleterious effects of mEW lesions on the health of the eye, we have examined the expression of GFAP in Müller cells, using anti-GFAP, following unilateral electrolytic mEW lesions.

One week postlesion, the GFAP label of Müller cells was confined to the nerve fiber layer while at 3 weeks postlesion, labeling spanned from the nerve fiber layer through the inner plexiform layer. In all eyes ipsilateral to mEW lesions, Müller cells and their processes throughout the retina expressed GFAP. No GFAP expression by Müller cells was observed in control eyes.

These results indicate that EW lesions that disrupt regulation of choroidal blood flow lead to the expression of GFAP by Müller cells, a phenomenon typically seen with retinal injury or disease. Thus, disruption of the role of EW in control of choroidal blood flow adversely affects the health of the retina. The expression of GFAP by Müller cells may play a role in the adaptation of the retina to this stressed state. Supported by EY-05298.

FOVEAL GLARE EFFECT ON RHESUS SPATIAL VISION FOR TRANSIENT AND PROLONGED VIEWING. D.O. Robbins, H.Zwick* and R.C. Long*. Ohio Wesleyan University, Delaware, OH 43015 and Letterman Army Institute of Research, San Francisco, CA 94129.

The transient and more persistent deficits in spatial acuity and contrast sensitivity were examined in nonhuman primates following exposure to small spot foveal laser irradiations. Retinal exposure durations varied from being relatively brief to prolonged for both on- and off-axis exposures. In these experiments, levels as low as 1000 times below the Maximum Permissible Exposure (MPE) were utilized for spot sizes of less than 50 microns on the retina.

In previous studies single 15 nsec pulses both below and above the MPE produced prolonged deficits suggesting involvement of nonpigmental factors. In comparison, the current study employed extended duration, low-energy exposures that produced deficits suggestive of a combination of retinal edema and photochemical/neural saturation of retinal receptor mechanisms. Both acuity and contrast sensitivity were immediately affected by the onset of exposure and resulted in periods of significantly depressed visual functioning. Full recovery typically occurred upon termination of relatively low level exposures but this trend is not expected as energy levels increase. These results may be compared to visual problems associated with extended source viewing of lasers in a variety of present day laser applications.

LOCALIZATION OF RETINAL HEAT SHOCK (STRESS) PROTEIN AND mRNA INDUCED BY HYPERTHERMIA. M. Tytell[1], M.F. Barbe[2], D.J. Gower[3], and I.R. Brown[4], [1]Anatomy, Bowman Gray Sch. Med., Wake Forest U., Winston-Salem, NC; [2]Anatomy, Med. College Penn., Philadelphia, PA; [3]Neurosurgery, Univ. Oklahoma Health Sci. Ctr., Oklahoma City, OK; [4]Zoology, Univ. Toronto, Scarborough Campus, Toronto, Ontario, Canada.

A 4-5° C rise in body temperature for 15 min makes the retina of the albino rat resistant to light damage, while stimulating the accumulation of the 70,000 Dalton heat shock (stress) protein (HSP70; Barbe et al., Science 241:1817, 1988). The relationship between that resistance and HSP70 was examined further in retinal sections from control and hyperthermia-treated rats by in situ hybridization for the HSP70 mRNA and immunohistochemical detection of the protein itself. Autoradiographic localization of the HSP70 mRNA with a labeled riboprobe showed that it was increased primarily in the photoreceptor nuclear layer, especially between 4 and 18 hrs after hyperthermia. An anti-HSP70 monoclonal antibody (W.J. Welch, Univ. Calif., San Francisco) showed that the protein also was increased at those times, particularly in the layers including the cytoplasm of the photoreceptors; however, the retinal ganglion cells (RGCs) and inner plexiform layer (IPL) contained elevated HSP70 as well. These results support the possibility that the induction and accumulation of HSP70 in the photorecetors is responsible for their resistance to light damage after hyperthermia. Furthermore, the increase in HSP70 in the RGCs and IPL without a similar rise in the mRNA suggests that some of the photoreceptor HSP70 may be transferred to those layers. Supported by grants from the NEI (EY07616; MT) and MRC (Canada; IRB).

CYTOSKELETAL ALTERATIONS OF THE BASAL SURFACE OF THE RETINAL PIGMENT EPITHELIUM OF PEARL MUTANT MICE. M. A. Williams*, Dept. Biol. Sci., Purdue Univ. and D. Drenckhahn*, Dept. Cell Biol., Univ. of Marburg, F.R.G. (Spon: G. Das)

Lack of infoldings over 20% of the basal surface of the retinal pigment epithelium (RPE) of pearl mice could affect transport of macromolecules and ions. Electron microscopic immunolocalization and morphometric analyses were used to analyze the distribution of components of the cytoskeleton associated with the basal surface of the RPE. Substantial amounts of bound antibodies to actin, α-actinin and vinculin were localized over the basal infoldings of pearl and wild-type RPE. Surfaces of the pearl RPE which lack infoldings exhibited virtually no bound antibodies. The normalized density of coated vesicles (CVs) over the basal surface was four times greater for pearl compared to wild-type due to the high density of CVs over the flattened surface of the pearl RPE. Cytosolic pH (pHi) < 6.8 has been shown to prevent CV disassembly and endocytosis. If localized acidic pHi contributes to the high density of CVs of the pearl RPE, alkalinization should reduce the density. The RPE of pearl mice, perfused with PBS containing 20 mM NH_4Cl, showed a 55% reduction of CV density at the flattened surface compared to controls perfused with PBS. Therefore, CVs may be "stabilized" at the flattened surface due to localized pHi reduction, consequently excluding actin filaments from associating with the surface.

ULTRASTRUCTURAL LOCALIZATION OF BLOOD-RETINAL BARRIER (BRB) BREAKDOWN IN EXPERIMENTAL MODELS OF DIABETES. S.A. Vinores, R. McGehee*, A. Lee*, C. Gadegbeku* and P.A. Campochiaro*. Dept. Ophthalmol., Univ. of Virginia Sch.Med., Charlottesville, VA 22908

Breakdown of the BRB is associated with macular edema, the major cause of visual morbidity in diabetics. Immunohistochemical localization of extravascular albumin demonstrated that disruption of the inner BRB, composed of the retinal capillary endothelium (RCE), predominates in human diabetic retinopathy, but outer BRB disruption (RPE) also occurs (Am J Path 134:231, 1989). To explore the nature of the BRB disruption, we performed electron immunocytochemical staining for albumin in the retinas of diabetic and galactosemic rats. In these models, inner BRB breakdown also predominates with occasional disruption of the outer BRB. In the inner retina, albumin was demonstrated on the abluminal side of the RCE in intercellular spaces, and within pericytes, astrocytes, and some neural cells. In the outer retina, albumin was detected in the subretinal space and within photoreceptors. Albumin did not appear to cross RCE or RPE cell junctions, but was demonstrated (although infrequently) in RCE and RPE cytoplasm of diabetic, galactosemic, and aged rats. These findings suggest that specific sites of BRB compromise are infrequent, but once albumin has penetrated the RCE or RPE, it freely fills intercellular spaces and permeates the membranes of cells not directly involved in maintenance of the BRB.

51.9

CHOROIDAL VASOACTIVE INTESTINAL PEPTIDE IMMUNOREACTIVITY IS INCREASED IN DYSTROPHIC RATS. M.E.C. Fitzgerald, R.B. Caldwell, and A. Reiner, Dept. of Anatomy and Neurobiol. UT-Memphis, TN 38163 and Dept. of Anatomy, Medical College of GA., Augusta, GA 30912.

In the dystrophic Royal College of Surgeons (RCS) rat, vascularization of the retinal pigment epithelium (RPE) is associated with retinal neovascularization (Weber *et al.*, '89) and increased retinal vascular density (Caldwell *et al.*, '89), suggesting that RPE alterations stimulate retinal vascular proliferation. Since RPE alterations could also affect choriocapillaris and choroidal vessels, we have now studied these vessels in RCS and control rats during the period that retinal vascular changes are observed (7 mos and later).

Light microscope morphometry of numerous 1.25 mm^2 areas showed no significant differences in number or size of choriocapillaris or coroidal vessels (choriocapillaris: RCS=14.6 vessels, 15 μm^2, control=12.2 vessels, 16 μm^2; choroid: RCS=8.0 vessels, 35 μm^2; control=6.0 vessels, 46 μm^2, p>.2, t-test). Electron microscopic study showed similar vascular morphology in both groups, but indicated that vascular innervation was increased in RCS rats. Nerve fibers with varicosities containing densely packed round vesicles and a few large dense core vesicles were more abundant in the RCS choroid. Such fibers were less common in control rats. We next studied the distribution of choroidal neurotransmitters using immunofluorescent techniques. In both groups antibodies for substance P (SP), dopamine-ß-hydoxylase (DBH) and vasoactive intestinal peptide (VIP) labeled thin fibers with varicosities. Immunoreactive fibers were located on the vessel walls and in the extracellular matrix between vessels. VIP positive fibers were more abundant in RCS rats than the controls in the same area where electron microscopy showed increased fibers and varicosities. Numbers of fibers immunoreactive for SP and DBH were similar in both groups.

Because released VIP is likely to dilate choroidal vessels, this change may allow for increased blood flow in the absence of vascular density changes. This could reflect a long term adaptation to RPE alterations in the RCS retina. Supported by NIH-EY-04618 (RBC), Juvenile Diabetes Foundation (RBC) and NIH-EY-05298 (AR).

VARIABILITY IN THE PATTERN ELECTRORETINOGRAM DUE TO EYE SQUINTING. J. Mishra, E. Reszel* and T.C. Prager*. Dept. Of Ophthal., Univ. of Texas Med. Sch., Houston, TX 77030.

Reliability of pattern electroretinogram (PERG) technique depends upon identification and careful study and control of the variables affecting the PERG amplitude. In this study we focused on the effect of eye squinting on PERG.

A total of 14 normal control subjects, between 18-56 yrs, with 20/20 visual acuity, were tested. The pattern ERG was recorded monocularly with a DTL thread electrode. The visual stimuli was 30' black and white checks with 98% contrast reversing at 8.3 hz, stimulating the central $16^0 x 19^0$ retina with 200 presentations. The waveforms were replicated and combined into a single evoked potential. Subjects were instructed to 1) keep both eyes open during recording 2) to squint the contralateral occluded eye.

Results show that squinting produced variability in the PERG waveforms with a significant reduction in the amplitude (normal amp=3.13uv, 0.64 SD squinting amp=1.80uv, 1.03 SD). Changes in the shape and latency of the PERG waveform were also noted. Analysis of Variance demonstrated a significant value for amplitude change (P=.0004) but not latency (P=.0925). Since squinting masks the inner retinal layers response it is important to instruct the patients to keep both eyes open to minimize the effect of eye muscle tremor on the PERG.

CHEMICAL SENSITIVITIES OF THE SCOTOPIC THRESHOLD RESPONSE OF THE CAT ERG. F. Naarendorp and P. A. Sieving. Kellogg Eye Center, University of Michigan, Ann Arbor, MI 48105

Previous work from several laboratories has demonstrated a proximal retinal origin for the Scotopic Threshold Response (STR) of the Electroretinogram (ERG) of cat (Frishman and Steinberg, J. Neurophys., 1989; Sieving, et al. J. Neurophys., 1986) and monkey (Wakabayashi et al. Invest. Ophthal., 1988). In this communication we present our most recent studies done in cat on the chemical sensitivity of the STR to neuropharmacological agents that are known to have active sites on third order neurons. Specifically, we evaluated effects of Glycine, Gaba, Dopamine, Acetylcholine, Serotonin and their antagonists given by intravitreal injection. Our results with Gaba and Glycine showed selective, but reversible suppression of the STR; other neurotransmitter analogues showed considerably less selective influence on the STR. As reported last year, Strychnine enhanced the STR and completely blocked Glycine-induced effects. Gaba-effects on the STR, however, were only partially blocked by Gaba-a receptor antagonists. We now report that Bicuculline, when combined with a dopamine antagonist, blocks Gaba-effects on the STR and PII, suggesting that bicuculline induces dopamine release in the cat retina. Dopamine in very low concentrations has noticeable suppressive effects on STR and PII. Preliminary results suggest that at scotopic levels of illumination, dopamine may modulate the potency of selected neuroactive substances in the inner retina of the cat. NEI R01-06094

Q-WAVESHAPE ANALYSIS OF SINGLE TRIAL FLASH EVOKED HUMAN RETINAL POTENTIALS. D.S. Weiss* and S. Reinis. (SPON: J.P. Landolt). Department of Psychology, University of Waterloo, Waterloo, ONT., Canada.

Sets of forty single trial events were recorded from human volunteers at the School of Optometry of the University of Waterloo. The retinal potentials were recorded using a nylon fiber electrode. Twenty potentials were recorded with the subjects reclining in a supine position; twenty potentials were recorded with the subjects tilted 40 degs head downward. In the latter condition, changes in intra-occular blood perfusion pressure are known to alter the waveform morphology of *averaged* retinal potentials. The purpose of this study was to determine whether or not such alterations would be evident in single trial potentials as well.

The data were evaluated using a method of pattern recognition called Q-Waveshape Analysis, a system for cross-validating complete linkage Euclidean distance cluster analysis with rotated factor analysis of waveforms. The matrix of *factor loadings* in association with the *cluster dendrogram* provides the separation of single trial events into clusters. The *factor scores* may be plotted as a function of time to provide a standardized representation of idealized or *cluster specific* waveforms. Taken together, these procedures may confirm the cluster solution, establish limits on the number of acceptable clusters, help visualize important waveform characteristics which separate the clusters, and provide a measure of variability for the solution.

In all cases, Q-Waveshape Analysis divided the single trial data into two meta-clusters which corresponded exactly to the two categories of body orientation. Each analysis was replicated with analogous results. It is suggested that Q-Waveshape Analysis may be an accurate and efficient method of evaluating patterns of variation and change in large sets of single trial data without the concomitant loss of waveform information associated with ensemble averaging and other univariate approachs to biological signal analysis. Furthermore this method of analysis may be helpful in assisting the researcher or clinician divide seemingly homogenous data into more uniform subgroups prior to ensemble averaging, thus insuring a consistent preservation of relevent biological signal.

52.1

COMPARISON OF VISUALLY EVOKED POTENTIALS GENERATED WITH LIGHT FLASH AND OPTIC NERVE SHOCK IN RAT. I. Siegel and D.F. Sisson. School of Life and Health Sciences, University of Delaware, Newark, DE 19716 and J.H. Lucas. U.S. Army Engineering Lab., Aberdeen, MD 21005.

VEPs from OC1, generated by light flash (fVEPs) of optic nerve shock (sVEPs), were compared in acute chloral hydrate anesthetized rats. Shapes of both VEP types were similar when corrected for latency differences. The first components of both fVEPs and sVEPs were positive potentials (P_1) with 27 and 4 msec latencies, respectively; the second were negative (N_1) with 33 and 12 msec latencies; the third were positive (P_2) with 55 and 28 msec latencies. Later components of the fVEPs did not coincide with sVEP components.

Current source density analysis was used to compare the early components of fVEPs and sVEPs. Current sinks with latencies coinciding with P_1 were distributed in layer IV and superficial layer V; their sources were found in layer I, superficial layer II and layer VI. Sinks with latencies coinciding with N_1 appeared in layer II/III and along the layer V-VI border; sources were in layer IV. Sink with latencies coinciding with P_2 were located in layers I and VI; sources were found in layers II and V. This distribution of sinks and sources indicates that the initial components of fVEPs and sVEPs are generated by the same cortical circuitry.

52.2

HUMAN AND RAT VISUAL EVOKED POTENTIALS IN RESPONSE TO STIMULUS CONTRAST. W.K.Boyes and H.K. Hudnell. Neurotoxicology Div. USEPA, RTP, NC 27711.

The extent to which visual evoked potentials (VEPs) recorded from humans and rats reflect similar visual processes is unknown. Previously, we compared steady state pattern on/off VEPs in the two species by varying stimulus spatial and temporal frequency (Boyes and Hudnell, SFN abstract 1988). The spectral amplitude at the stimulus rate (1F) was bandpass in spatial frequency (SF) profile, whereas that at twice the stimulus rate (2F) was low pass for both species.

The current studies examined the response to contrast. VEPs were recorded from rats and humans using vertical sinusoidal gratings at several SFs (0.05-0.8 cpd(rat); 0.5-16.0 cpd(man)). Stimuli were temporally modulated at 3 Hz. The range of contrast values was adjusted for each SF.

The data were similar for both species in that: (1) the 2F response reached higher amplitude than 1F; (2) at low contrast, the 1F and 2F responses predominated at high and low SFs, respectively; and (3) neither species showed response amplitude saturation for either 1F or 2F as contrast increased. These results suggest that, although the spatial resolution limit is lower in rats than humans, qualitatively similar processes operate in both species.

52.3

HUMAN AND RAT VISUAL EVOKED POTENTIALS IN RESPONSE TO DIAZEPAM. H.K. Hudnell and W.K.Boyes. Neurotoxicology Div. USEPA, RTP, NC 27711.

The extent to which visual evoked potentials (VEPs) recorded from humans and rats reflect similar visual processes is unknown. One avenue of comparison is to examine the response to drug treatments.
VEPs were recorded before and after diazepam treatment from both rats and humans. Stimuli were 30% contrast, vertical, sinusoidal gratings at several spatial frequencies (SFs) (0.05-0.8 cpd(rat); 0.5-8.0 cpd(man)). Gratings were temporally modulated in an on/off fashion at 5 Hz. Dosage was 0-0.5 mg/kg for rats and 0 or 10 mg for humans.
The data for both species showed a response depression of spectral amplitude at twice the stimulus rate (2F). The rat 1F response was generally unaffected, whereas the human 1F was slightly depressed. In addition, the human study, which used a battery of VEP tests, found effects of diazepam on transient flash and pattern VEPs. Similar flash VEP changes have been reported previously for rats (Dyer, SFN Abstract, 1987). These results suggest that diazepam, thought to potentiate GABA mediated inhibition in sensory cortex, similarly affected the two species' visual function.

52.4

INTERACTIONS OF AMBIENT LIGHT AND FLASH INTENSITY ON N_{160} PEAK AMPLITUDE OF FLASH-EVOKED POTENTIALS (FEPs). D.W. Herr*[1], V.T. Griffin*[2], and R.S. Dyer. Neurotoxicol. Div., US E.P.A., and [2]NSI, RTP, NC 27711.

The N_{160} peak of FEPs may reflect a sensitization and/or habituation process (Dyer, R.S., Physiol. & Behav., 45:355-362, 1989). The influence of the "contrast" between ambient lighting and flash intensity in modulating the N_{160} peak was examined. Long-Evans hooded rats were implanted with epidural electrodes over the visual cortex and allowed to recover. Overhead lighting (0, 115, 250 lux) and flash intensity (409, 81, 24, 5 lux-sec) were between-groups factors. On each of 13 consecutive test days 64 flashes/day (0.3 Hz) were presented. The N_{160} peak amplitude (from baseline) increased over several days, reaching a plateau by day 13. Overhead lighting and flash intensity interacted in influencing N_{160} development. Low flash intensities produced larger N_{160} amplitudes when rats were tested in the dark than in a lighted chamber. Conversely, bright flash intensities promoted larger N_{160} amplitudes in lighted chambers than in the dark. Data suggest that optimizing "contrast" between ambient lighting and flash intensity will maximize development and amplitude of the N_{160} peak, and that processes in addition to sensitization may be involved. DOES BILATERAL CORTICAL REPRESENTATION OF TEMPORAL VISUAL FIELDS EXIST IN MAN? C Iadecola, M M Conte and J D Victor. Dept of Neurology Cornell Univ Med Coll, New York NY 10021. Ganglion cells of the temporal retina project to the ipsilateral area 17 while those of the nasal retina project to the contralateral area 17. However, in primates there are cells in the nasal half of the fovea which project to the ipsilateral area 17 (Leventhal et al., Science 240:66, 1988). If this double representation is physiologically significant, macular viewing of homonymous hemifields (HFs) would produce unequal patterns of cortical activation a portion of area 17 ipsilateral to the stimulus would be activated through the ispsilateral, but not the contralateral, eye. We studied visual evoked responses (VERs) elicited by HF stimulation in man to determine whether such differences between homonymous HFs could be detected. Stimuli (4 min checks, 40% contrast, 8.4Hz reversal) were delivered monocularly in 30 sec episodes to each HF. VERs were recorded from 9 electrodes placed at 2.5 cm intervals along a horizontal line centered at OZ. Scalp topography of VERs was characterized by the spatial weights corresponding to the first principal component extracted from the 8 bipolar pairs. In 3 of 4 subjects there was a statistically significant ($p<0.02$) eye dependence of the VER topography elicited from homonymous HFs. Such eye dependence is consistent with models of retino-calcarine projections. We conclude that the bilateral cortical representation of temporal visual fields found in primates is likely to be present also in man. Thus, postchiasmatic lesions may cause an incongruous loss of macular vision resulting in varying degrees of macular sparing.

52.6

A Low Dose Barbiturate Effect on the Cat Visual Evoked Response. A.W. Kirby and A.T. Townsend*. USAARL, P.O. Box 577, Ft. Rucker, AL 36362.

We previously have reported a preferential loss to low spatial frequency stimulation in the cat visual evoked response (VER) following cholinesterase inhibition, while others report uniform reduction under similar conditions. The only apparent difference was that others added supplemental surital (thiamylal sodium, 1.0 mg/kg/hr) to the maintenance anesthesia. We report here results which show that the nature of VER reduction changes, based upon the presence of barbiturate, even at this low dose.

Anesthesia was induced in 4 adult cats with i.v. surital, and they then were prepared for VER recording. Each cat received a continuous infusion of surital (1 mg/kg/hr), and was maintained on nitrous oxide. Following capture of baseline VERs, physostigmine was given (0.4 mg/kg). The VERs showed a uniform reduction. Surital then was removed from the infusion mixture and the animal allowed to recover for 3 hours. The physostigmine dose then was repeated and the VER showed a preferential loss of low spatial frequencies. We believe this demonstrates the effect of even small amounts of barbiturate on central neural processing.

RECEPTIVE FIELDS OF NEURONS AT THE CONFLUENCE OF AREAS 17, 18 AND 20 IN THE CAT. Bertram Payne and Donald Siwek*. Department of Anatomy, Boston University Medical School, Boston, MA 02118.

In the course of electrophysiological studies on the boundary between areas 17 and 18 on the posterolateral gyrus of the cat we recorded the activity of neurons with very unusual receptive field properties. The most notable feature of the receptive fields was their extraordinary large size which could range in size from 40 or more degrees per side to half or even most of the visual field of the contralateral eye. At least part of each receptive field could be activated by both eyes, and small (2°) or large, flashing or moving rectangles of light were potent stimuli, and the neurons exhibited spatial summation but not internal inhibition when the stimuli were increased in size within the receptive field. In addition, some neurons had receptive fields with distinct "hot spots". Subsequent anatomical and histological identification of the recording sites revealed that the neurons studied were located at the ventral end of the posterolateral gyrus where it blends with the posterior suprasylvian gyrus. In this region portions of areas 17, 18, 20a and 20b lie adjacent to each other in a rather complex arrangement with each area bounded at least partially by at least two of the other areas. In reconstructing the region in more detail it became clear to us that the neurons we had studied lay in a common transition zone separating all four of these areas. While the morphological basis for these large receptive fields is not known, we propose that the large receptive fields may result from disturbances in the individual areal mapping functions as the individual representations merge in this region. (Supported by EY06080 and EY06404)

A SINGLE CONTINUOUS VISUAL AREA EXTENDS ALONG THE ANTERIOR ECTOSYLVIAN SULCUS (AES) IN CAT. Gy. Benedek*, Y. Katoh*, G. Sáry*, G. Kovács*, and M. Norita. Dept. Physiol., Albert Szent-Györgyi Med. Univ., Szeged, Hungary and Dept. Anat., Fujita-Gakuen Med. Univ, Toyoake, Japan.

Two distinct visual areas with similar physiological characteristics have been described recently: the anterior ectosylvian visual area (AEV) and the insular visual area.

Extracellular microelectrode recording was performed along the AES in pentobarbital anesthetized cats. We were successful in finding visually sensitive cells along the whole extent of the sulcus when we approached the area from an oblique angle, which eliminated the technical limitations encountered in the earlier experiments. Two main types of visually responsive cells were recorded: "tonic" cells discharging steadily while a light stimulus was moving in the fairly large and uniform receptive fields of the cells, and "phasic" ones that respond to a moving light stimulus only with a short burst of discharge. The two types of cells exhibited showed different velocity and length sensitivity. The cells had a rather homogeneous distribution pattern, although a predominance of "phasic" cells could be seen in the caudal one-third of the sulcus and in the deep sulcal regions. Cells with a sensitivity to squares increasing or decreasing in size were often found.

We conclude that there is only one visual area that plays a role in movement-detection in this part of the feline brain.

52.9

VISUAL PROCESSING IN AWAKE MACAQUES UNDER ACTIVE AND PASSIVE CONDITIONS. C.E.Schroeder, S.J.Givre, C.E.Tenke, J.C.Arezzo and H.G. Vaughan Jr. Neurosci. and Neurol. Depts., Albert Einstein Coll. Med., Bronx, NY.

Profiles of visual evoked potentials (VEP), current source density (CSD) and multiunit activity (MUA), elicited by bar gratings subtending 4^{o} radial to a fixation point were obtained from V1 and V2 using multicontact electrodes. Pattern responses were recorded during a "passive" fixation task, and during an "active" task requiring a match between a feature of the bar grating and a cue in the fixation stimulus. Initial activation in V1 occurs in thalamorecipient laminae, followed by responses in supra- and infragranular laminae. Initial activation of V2 is reflected in two groups of responses in the middle laminae, and lags the earliest activity in V1 by only a few ms. Activity in both V1 and V2 extends well beyond 200 ms poststimulus. The most prominent active/passive effect in V1 is increased amplitude and duration of activity in supragranular laminae. Enhancement of the later response in upper 4C was noted occasionally. Similar enhancement was noted in V2, but any gradient of effect is not yet clear. Preliminary results from LGN do not show active/passive effects in the time frame of the initial retinal volley; such effects in LGN occur at longer latencies than those in V1. The time frame of activity across LGN, V1 and V2 is essentially concurrent. Motivational/attentional variables may affect visual processing at its ear-liest cortical stage.

52.10

REACTIVATION RESPONSES IN STRIATE AND EXTRASTRIATE VISUAL CORTEX DURING A PERIPHERAL ATTENTION TASK. B.C. Motter* (SPON: S. Mitchell) V.A. Med. Ctr. & Depts. Physiology & Neurosurgery, SUNY-HSC @ Syracuse, Syracuse, NY 13210.

A reactivation of neural activity occurs to a stimulus already present within the visual receptive field of V1 & V4 neurons when the stimulus becomes a potential target for a saccadic eye movement (Fischer & Boch, Brain Res. 345(1985)111-123; Boch, Exp. Brain Res. 64(1986)610-614). A similar reactivation response, reported here for those same areas and for areas V2 & V3, occurs in a paradigm requiring maintained fixation of a central target and peripheral attention to a cued spatial location. Reactivation activity was observed to a small, non-optimal cue used to direct attention to one of several locations in the visual field at which the macaque monkey was required to make a bar orientation discrimination. The cue was present in the receptive field for 500-1200 msec before it became 'selected' by the disappearance of several other false cues. The onset latencies of the reactivation response were found to be nearly the same in each cortical area, about 150 msec or 2-3 times the response latency to cue onset. The dissociation of the reactivation response from saccades and from the explicit release of visual fixation suggests it reflects a more general attentional phenomena.

FACTORS AFFECTING PURSUIT RECOVERY FOLLOWING LESIONS VISUAL AREA MT. Dwayne S. G. Yamasaki and Robert H. Wurtz. Lab. of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Punctate chemical lesions in the middle temporal area (MT) of the monkey produce deficits in pursuit eye movements that recover within about a week. We further investigated the effects on the rate of recovery of: 1) type of lesion, 2) visual motion experience after the lesion, and 3) size of the lesion.

Monkeys (*Macaca mulatta*) were trained to pursue a spot of light moving at 16^{o}/sec in a step-ramp paradigm. Small chemical lesions were produced by injecting 2-6 µl of ibotenic acid (IBO, 4 hemispheres) or AMPA (2 hemispheres), and one large AMPA lesion (51.8 µl) was made in the superior temporal sulcus to remove all of MT and much of MST. An electrolytic lesion (500 µA/15 min, 5 sites) was also made in one monkey.

1. Pursuit recovery was only slightly longer for AMPA (3-11 days) than for the IBO (2-5 days) lesions. Recovery still occurred after the electrolytic lesion (9 days), suggesting that the recovery seen after previous chemical lesions is not due to an artifact of the chemical lesion method. 2. To study the effect of visual experience on recovery, we made a lesion (2 µl, IBO) in MT and placed the monkey in a light-tight room illuminated by a 4 Hz strobe light. When compared to the recovery time of previous IBO lesions, this recovery took longer: 10 days for eye speed, and 21 days for eye position error. This effect indicates that experience is a factor that facilitates the recovery process. 3. Recovery was dramatically delayed following a large lesion. At post lesion day 175, the monkey was not yet fully recovered. This suggests that previous recoveries were facilitated by active processes occurring in areas removed by the large lesion. Furthermore, immediately after the lesion eye speed was not reduced to zero (0.1 ± 0.3 to 4.4 ± 0.8^{o}/sec), suggesting that other areas normally contribute only a small amount of information on target velocity to the pursuit system.

52.12

EFFECT OF THE PERIPHERAL VISUAL FIELD ON DISPARITY SENSITIVE CELLS IN CORTICAL VISUAL AREA MST. J. P. Roy and R. H. Wurtz. Lab. of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

We have previously shown that neurons in the medial superior temporal area (MST) of extrastriate visual cortex are sensitive to visual motion at different disparities in the central region of their visual receptive fields. In the present experiments we determined the effect of disparity and other factors in peripheral regions of the visual field on the response of these cells to stimuli falling in the central visual field. While monkeys (Macaca mulatta) fixated on a spot on a tangent screen and the position of both eyes was measured, a random dot pattern moved within the central 80 degrees of the visual field. This pattern was presented at different disparities by using a red-green color anaglyph viewed by the monkey through a red or green filter over each eye. We identified the central region of the receptive field and moved the pattern in this region in the preferred direction, speed, and disparity (corresponding usually to near or far) for the particular MST cell under study. We then added outside of this central region a second random dot pattern moving in the same or the opposite direction as the center, with different speeds, and at different disparities (near, far, or zero). The effect of these variables in the peripheral regions influenced the response of different neurons to varying degrees, but the factors identified as more effective were: 1) Motion in the peripheral area in the direction opposite to the preferred direction of the central area increased the discharge rate of the cells. 2) With such antiphase motion, motion of the periphery at a depth that was the same or nearer than that of the center was the most frequently effective. 3) Motion of the periphery at a speed higher than that in the central region was usually more effective than motion at the same speed in the center and periphery. These characteristics are all appropriate for cells that contribute to the differentiation of figure from ground.

52.13

RADIAL AND AXIAL DIRECTIONALITY IN CORTICAL VISUAL AREA MST. C. J. Duffy and R. H. Wurtz. Lab. of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

A subset of neurons in monkey medial superior temporal area (MST) selectively respond to the radial motion of expanding or contracting patterns (Saito, et al., *J. Neurosci.*, 1986). We have studied the receptive fields of these neurons in the awake monkey (Macaca mulatta) to understand the mechanisms of their response selectivity and their possible role in conveying information on optic flow fields. The visual receptive fields studied were 50 to 100 degrees wide, and centered up to 50 degrees from the fixation point. They were mainly contralateral but extended as far as 50 degrees into the ipsilateral visual field. Responses to wide field motion were more robust than responses to spot motion. We have confirmed that many of these neurons have radial selectivity for inward or outward motion covering the receptive field. We also found that when the stimulus was limited to a 10 or 30 degree square in different areas within the receptive field, the radial selectivity was frequently maintained. Therefore neither a change in the position of the center of radial motion nor changes in the local directions and speeds of motion eliminate the radial selectivity. Radially selective neurons also frequently showed preference for motion along a single axis during full field stimulation. When small parts of the fields were stimulated, different axial directions frequently were preferred in different parts of the receptive field. There was a tendency for this to vary in systematic ways throughout the visual field. For example, inward axial motion tended to be preferred in fields that preferred inward radial motion; outward axial motion in fields that preferred outward radial motion. We conclude that radial and axial selectivity are nearly coextensive but their relative strength varies across the receptive field. This may reflect the overlap of superimposed fields of selectivity or one of these properties may be more fundamental, creating others by the interactions of parts of the field.

52.14

ATTENTIONAL INFLUENCES ON NEURONS IN PARIETAL CORTEX OF THE MACAQUE. Caroline Kertzman and David Lee Robinson. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda MD 20892.

Clinical and physiological studies have linked parietal cortex with attentional functions. We studied the activity of neurons in this area while a monkey performed a variety of attentional tasks. In one paradigm the monkey fixated a spot of light and contacted a bar when target lights appeared. Reaction times for responding to the onset of visual targets were modified by antecedent visual cues. Faster reaction times occurred when the cue correctly predicted the subsequent target location. The cue is hypothesized to control the direction of attention. We found that parietal cells responded differently to the identical target depending on cue validity. The intensity of the modulation varied as a function of how close in time the target followed the cue. For some cells we found enhanced responses in a saccade task: neurons responded better to a light when it was the target for an eye movement than when the same light was presented during continuous fixation. Cells modulated in the cuing paradigm were not always enhanced in the saccade task. These data show that neurons in parietal cortex are influenced by attentional processes. Since damage to this region of cortex dramatically alters performance in the cuing paradigm, these neurons probably participate in attentional shifts.

52.15

COLOR SELECTIVITY OF NEURONS IN THE INFEROTEMPORAL CORTEX OF THE MONKEY. H. Komatsu, S. Kaji*, S. Yamane*, K. Kawano and T. Ideura*. Neuroscience Section, Electrotechnical Lab., Tsukuba, Ibaraki, 305, Japan.

In an attempt to study the role of the inferotemporal cortex (IT) on color recognition, we recorded single unit activities from IT of an awake macaque monkey and examined their color selectivity. Spots or rectangles with various hue, saturation and luminance were used as visual stimuli. The monkey fixated a stationary spot to detect its dimming. Visual stimuli were presented on a monitor display while the fixation spot was blinked off for a short period of time. In the anterior part of IT, we found a cluster of cells with high selectivity to the color of the stimulus. These cells were activated by stimuli with certain range of hue and saturation. In some cells, such a range was constant regardless of the luminance of the stimuli, but in others, the preferred range shifted with the change of the luminance of the stimuli. Preferred hue varied from cell to cell. A small number of cells in this area were activated by non-colored stimuli (white, gray and black) but responded little to colored stimuli. Activities of cells in this area were only weakly influenced by the size or shape of the stimuli. The receptive fields of these neurons always included the fovea, and most of them extended 10 degree or more from the fovea in any direction. We concluded that these cells are mainly involved in the processing of the color information.

52.16

RESPONSES OF INFERIOR TEMPORAL NEURONS IN A SHORT-TERM MEMORY TASK. Lin Li* and Robert Desimone, (SPON: J. Bachevalier) Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

Previous studies have found that inferior temporal (IT) neurons show maintained, stimulus-specific activity during the delay interval in delayed matching-to-sample tasks (Fuster and Jervey, '82, Miyashita and Chang, '88), suggesting that the maintained activity "holds" the representation of the sample, thereby mediating short-term or recency memory. To test this possibility, we recorded from 104 neurons in the ventral aspect of middle and anterior IT cortex in 1 rhesus monkey. A sample stimulus (not trial-unique) was followed by a series of up to 5 different test stimuli, presented successively, and the monkey was required to respond when one of the test stimuli matched the sample. All stimuli were separated by 500 msec delay intervals, and fixation was required throughout the trial. Although many cells showed maintained, stimulus-specific activity in the delay interval immediately following the sample, the activity during subsequent test stimuli and delays did not appear to vary with respect to the sample stimulus. That is, the activity averaged across all test stimuli and delays was invariant across different samples. Furthermore, we did not find consistent differences in response to matching versus non-matching test stimuli. The major task-related activity found was that over 90% of the cells responded best to a given stimulus when it was a sample than when it was a matching or non-matching test stimulus, which we interpret as enhancement due to increased attention to the sample. Our results support an attentional, rather than mnemonic, explanation for task-related IT responses in recency memory tasks (also see Baylis and Rolls, '87), at least for the portion of IT cortex we studied.

52.17

THE RESPONSES OF NEURONS IN THE INFERIOR TEMPORAL CORTEX OF THE MACAQUE TO PATTERNS DEFINED BY TEXTURE ELEMENTS. P.M.Mueller*, B.O.Moore, P.Alvarez-Royo, H.Pashler* and G.C.Baylis Depts. of Neuroscience and Psychology, University of California, San Diego, La Jolla, CA 92093.

Human subjects are readily able to perceive objects when their boundaries are defined by different types of texture elements. It is clear that neurons in the visual system must be able to represent objects as equivalent whether defined by gray-scale, color or texture.

We have recorded the activity of single neurons in the inferior temporal cortex and superior temporal sulcus in two awake behaving macaque monkeys as they viewed patterns defined by gray-scale and the same patterns defined only by equiluminant texture fields. The patterns chosen were 2D Walsh functions, since this set allows inferences to be made about the degree of selectivity between patterns. These were presented on fixation for 1.0 sec. It was found that most neurons responded selectively to patterns defined either by gray-scale or texture elements. In many cases the response was the same to a pattern and its contrast-reversed pair. However, in many cases, there was poor correlation between the response to a pattern defined by gray-scale and the response to the same pattern defined by texture elements. These results suggest either that the patterns were not perceived as equivalent by the monkey or that equivalence has not been achieved by the time information reaches the inferior temporal cortex. We are currently investigating these two possibilities.

52.18

TRANSLATION INVARIANCE IN THE RESPONSES OF NEURONS IN THE INFERIOR TEMPORAL VISUAL CORTEX OF THE MACAQUE. P.Azzopardi* and E.T.Rolls. Dept. of Exptl. Psychology, University of Oxford, England.

To investigate whether neurons in the inferior temporal visual cortex and cortex in the anterior part of the superior temporal sulcus operate with translation invariance when these cortical regions are operating normally in the awake behaving primate, their responses were measured during a visual fixation (blink) task in which stimuli could be placed in different parts of the receptive field. Neurons with responses selective for faces (Rolls 1984 Hum. Neurobiol.3: 209-222) were investigated. It was found that in many cases the neurons responded (with a greater than half-maximal response) even when the monkey fixated 2-5 degrees beyond the edge of a face which subtended 3-20 degrees at the retina. Moreover, the stimulus selectivity between faces was maintained this far eccentric within the receptive field. These results held even across the visual midline. It is concluded that some neurons in the temporal lobe visual areas do have considerable translation invariance so that this is a computation which must be performed in the visual system, and that their selectivity is maintained in different parts of their receptive fields.

52.19

FACE-RESPONSIVE COMPONENTS IN THE TEMPORAL LOBE VISUAL EVOKED POTENTIALS (EPs) OF JAVA MONKEYS. O.-J. Grüsser and L. Fuhry*. Dept. of Physiol. Freie Universität Berlin, Arnimallee 22, 1000 Berlin 33 (West) Germany.

EPs were recorded with nine epidural electrodes implanted above the right hemisphere of a Java monkey trained to distinguish monkey or human faces (F-stimuli) from complex non-face stimuli (NF-stimuli, b/w slides 5.1° diameter). Eye movements were monitored (EOG). Either F-stimuli or NF-stimuli were rewarded. EP averaging began 200 ms before stimulus change and lasted 1 s. Stimuli were presented within a randomized time slot of 2.9-4.1 s. In one set 53 F- and 59 NF-stimuli were applied three times. Fig. 1 illustrates the responses to monkey F- and NF-stimuli (electrodes -9/4 and 1/30 mm ant./lat.). A face-responsive component began about 110 ms after stimulus change, having a positive peak at about 150 ms. This component did not change when NF-stimuli were rewarded, and also appeared with human F-stimuli (fig. 2). The distribution of the face-responsive component recorded over the temporal lobe showed marginal regional differences for monkey and human F-stimuli. (DFG-grant Gr 161).

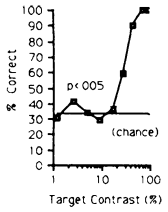
COMPONENTS OF VISUAL EVOKED POTENTIALS RESPONSIVE TO SILHOUETTES OF PERSONS OR HANDS. Margitta Seeck*, Elke Heusser* and O.-J. Grüsser. (SPON: EBBS). Dept. of Physiol., Freie Universität Berlin, Arnimallee 22, 1000 Berlin 33, Germany.

Visual evoked potentials (EP) were recorded when silhouettes of persons (P-stimuli) in various positions (neutral standing, boxing, greeting, depressed body posture) were presented. As controls "non-persons" (flowers, tools, abstract figures) were applied in random sequence (EEG-recordings from T3, T5, T4, T6, CZ and OZ, reference electrode linked mastoids, 9 male and 9 female subjects). Category-specific differences between EPs evoked by P- and non-P-stimuli were small, but most pronounced in the temporo-occipital electrodes, i.e. the "bipolar" recordings (T4-T6, T3-T5). Differences between EPs evoked by the various P-stimuli were absent.

In a second study (5 males, 3 females) we investigated the EPs of silhouettes of hands, face profiles and abstract figures. Again the greatest category-specific differences were found in CZ, T5, T6, starting about 200 ms after the stimulus change. In CZ the "hand-responsive" EP-component consists of a broader, more positive amplitude, whereas in the temporo-occipital electrodes it differs from non-hand stimulus EPs in having a "W"-form.

(DFG grants Gr 161, S 520).

53.1



SPARING OF FUNCTIONS IN CORTICAL BLINDNESS. S. AGLIOTI*, M. CORBETTA*, M. BENASSI* (Spon. European Neuroscience Association), Institute of human physiology, University of Verona, I-37134.

Evidence of visual information processing into separated pathways has been obtained in a 33 years old brain damaged patient, with a complex cortical blindness-like syndrome consequent to an electrocution accident that provoked heart failure and a two-week lasting coma. Electrophysiological measurements (EEG and Evoked potentials) and imaging techniques (CT scan, NMR and SPECT) documented a diffuse cortical damage more pronounced in the posterior areas. The intelligence of the patient is preserved to a large extent. Despite poor visual acuity and very bad form perception, color vision results highly preserved and the use of color-related cues improves acuity discrimination tasks. Furthemore, perception both of real and apparent movement is mildly impaired for light displacement across visual hemifields along the horizontal meridian but is preserved if the light is moved along the vertical meridian. Finally, preliminary data indicate an improvement of form recognition when the stimulus is moved across the visual field. Our patient's visual behavior is in agreement with the idea of modularly organized, but strictly cooperant, visual pathways.

53.2

NON-CONSCIOUS 'VISION' IN NORMAL HUMANS: EVIDENCE FOR TECTAL MEDIATION. R. Lahav* and H.A. Buchtel. Departments of Psychiatry and Psychology, University of Michigan and Psychology Service, VA Medical Center, Ann Arbor, MI 48109-2399.

We found that under scotopic conditions, shape-discrimination of sub-threshold visual targets accompanied by a higher-contrast stimulus displays a non-monotonic function. This is manifested as a significantly better-than-chance discrimination ability in a narrow band of target figure-to-background contrasts (around 1%-5%), which is lower than, and not adjacent to, the traditional range of shape-discrimination contrast values. Discrimination was found to be dependent on the presence of a second stimulus of about 70% contrast, and appeared in 10 out of 12 human subjects tested.

Several findings implicate the retino-tecto-cortical pathway as responsible for the effect: discrimination was accompanied by the subjects' absence of (reported) visual experience; acuity was found to be low (about 3°); discrimination was found to quickly habituate upon repeated presentation of the same target; and it was found to dishabituate upon changes in target-contrast. The latter two effects have been seen in the superior colliculus of the monkey. In addition, a subject whose striate cortex was unilaterally removed showed a similar discrimination capacity in her blind field.

Despite some similarities, the effect seems to be different from previously reported phenomena, such as 'blindsight' (which is monotonic: Pöppel, Held & Frost, Nature, 1973), or the pedestal effect, which, among other things, occurs at much lower contrasts, and does not show habituation (e.g. Barlow et al., J. Opt. Soc. Am., 1987).

53.3

MODELLING OF VISUAL RECOGNITION STRATEGIES IN THE TWO CEREBRAL HEMISPHERES. M.B.Pavlovskaya*, I.A.Vol* and V.M.Bondarko* Pavlov Institute of Physiology, Academy of Sci. of the USSR, Leningrad, 199034, USSR.

In terms of computer simulation model we have analyzed whether there is a difference in visual recognition strategies in the left and the right hemispheres. The stimuli (four meaningless line drawings) were randomly presented in the left or the right visual hemifield (LVF,RVF) for 10-100 ms. Object confusion matrices for different exposure durations were obtained for the LVF and the RVF separately. The statistical model of visual processing based on the spatial-frequency approach (Fourier transforms) was used to generate predicted confusions among stimulus pairs. The probability of confusion of two objects was suggested to be determined both by the similarity of image spectra and the probability of a priory preference for the given stimulus. Good fits of theoretical to experimental similarity matrices were obtained only for the RVF (Pearson's correlation coefficient reached 0.93), whereas in the LVF this value didn't exceed 0.34. Then the suggested recognition strategy is realized in the RVF only.

53.4

REACTIVITY OF NEUROMAGNETIC ALPHA FREQUENCY ACTIVITY IN HUMAN SUBJECTS. C. Gallen*, S. Hampson*, W. Young, F. Bloom, Div. of Preclinical Neuroscience, Research Institute of Scripps Clinic, La Jolla, CA 92037.

Reactivity (event-related desynchronization) of intrinsic cortical rhythmical activity has been proposed as a potentially sensitive measure of cortical function. Determination of the optimal conditions for generation of stimulus-related reactivity is necessary before such a measure can be applied to the magnetoencephalographic study of human cortical function.

The time course and extent of reactivity of the human alpha rhythm was studied in three subjects using a 14-channel Neuromagnetometer. Serial recordings during 20 epochs of cycling lights-off/lights-on stimulus conditions were made from 100+ sites distributed across the cranium. The total alpha power in the five one-second periods preceding and following the onset of visual stimulus was measured and used to calculate an index of alpha reactivity. Occipital alpha power was markedly increased in darkness compared to the light stimulated condition (5-20-fold) while frontal and temporal regions showed much less alteration (0-2-fold). The field patterns for magnetic alpha power and reactivity were tightly and reproducibly localized in the posterior superior cranial region suggesting an occiptial lobe source. Reduction of alpha power with light stimulus occured rapidly (less than 1 sec), persisted for 1-3 seconds, then rebounded even with continuing light. Reactivity varied markedly from epoch to epoch and was maximal when the stimulus occured in the middle of an alpha spindle. These findings indicate that recordings of magnetic alpha reactivity offer a vehicle for the study of the neuronal generator sources underlying the cortical response to visual field stimulation.

SUPPRESSION OF CHROMATIC AND ACHROMATIC LETTER PERCEPTION BY MAGNETIC COIL STIMULATION OF HUMAN VISUAL CORTEX. P.J. Maccabee*, V.E. Amassian, R.Q. Cracco, V. Zemon*, A. Rudell* and L. Eberle*, (SPON: J.B. Ranck, Jr.), Depts. Physiol. and Neurol., SUNY, Hlth. Sci. Ctr. Bklyn. and Lab. of Biophys., Rockefeller Univ., N.Y.

Studies of primate cellular physiology and human perception reveal separate pathways for chromatic and achromatic stimuli. We now extend the perceptual studies by using a magnetic coil (MC) over visual cortex to suppress recognition of briefly presented alphabetic letters (J. Physiol., 1988, 398, 40P). Subjects with normal color vision were briefly presented stimuli consisting of: 1) against a grey background, randomly presented letters at positive contrast; 2) against a red background, isoluminant green letters. Following letter presentation, the MC was energized at various randomized latencies. In the youngest subject, 45-60 msec intervals resulted in progressive loss of perception; at 60-100 msec, perception was absent and at 100-140 msec perception recovered to normal. Curves in older subjects had similar shapes but with longer onset latancies. In all subjects, isoluminant stimuli revealed sharper curves which were significantly prolonged by e.g. 20-40 msec. Isoluminant (chromatic contrast) stimuli are apparently processed by the parvocellular - blob pathway whereas achromatic (luminance contrast) stimuli are processed by magnocellular and remaining parvocellular pathways. The increased latency differences may reflect different dynamics in these subsystems.

53.6

VISUAL PERCEPTION UNMASKED BY MAGNETIC COIL STIMULATION OF HUMAN CEREBRAL CORTEX. V.E. Amassian, P.J. Maccabee*, R.Q. Cracco, A. Rudell* and L. Eberle*. Depts. of Physiology and Neurology, SUNY Health Sci. Ctr. at Brooklyn, New York 11203.

We used a Cadwell magnetic coil (MC) over visual cortex (VC) to suppress perception of 3 random letters, briefly presented 80-100 ms before the MC pulse (J. Physiol. (1988) 398, 40P). However, single words could not be suppressed with the MC over Wernicke's area, supramarginal and angular gyri. To reduce the possibility of VC 'refreshing' subsequent processing areas, a 2nd random word was presented 50-83 ms after the 1st; an MC pulse given 90-150 ms after the 1st word significantly reduced its retrieval. Next, a paradigm was sought yielding a positive response with the MC. Two word or 3 letter arrays or arbitrary linear patterns, with the second stimulus (S_2) 4X brighter than S_1 masked the response to S_1 at intervals of, e.g. 100 ms, the masking then occurring after VC. The response to S_1 was reliably retrieved (unmasked) when the MC pulse was delivered to VC 80-100 ms after S_2. An MC pulse delivered to tempero-parieto-occipital cortex 100-150 ms after S_2, also unmasked letter responses to S_1, but less than with VC stimulation. Beyond visual cortex, suppression is weaker possibly because multiple pathways conveying the information must be affected.

53.7

RESONANT CORTICAL EEG PATTERNS EVOKED IN RHESUS MONKEYS BY A CHOICE TASK. D. Krieger, R. Coppola, R. J. Sclabassi, R. K. Nakamura. NIMH, Bethesda, MD 20892 and Lab. Comp. Neurophys., U. Pitt., Pittsburgh, PA 15213.

This work was directed to the question: Are behaviorally relevant resonant EEG patterns present in the cortex of the rhesus monkey during performance of a GO/NOGO visual discrimination task? The results support an affirmative answer to the experimental question. EEG recordings were obtained simultanously from 16 bipolar placements distributed across the cortical convexity of chronically implanted rhesus monkeys. A machine algorithm was used to identify resonant activity electrode by electrode and trial by trial. Resonances were then analyzed to identify temporal and spatial relationships to task relevant parameters. Strong temporal relationships were found between resonance latency and both stimulus latency and reaction time. The pattern of intensity across the cortex at the resonant frequency was a consistently good classifier for which of four stimuli was presented (up to 77% accuracy; chance = 25%), stimulus orientation, i.e. slanted left vs right (up to 90% accuracy; chance = 50%), stimulus type, i.e. diagonal vs diamond (up to 67% accuracy; chance = 50%), and trial type, i.e. GO vs NOGO (up to 84% accuracy; chance = 50%).

DEVELOPMENT OF VISUAL TEXTURE SEGMENTATION IN KITTENS. F. Wilkinson & R. Ohayon* Department of Psychology, McGill University, Montreal, Canada, H3A 1B1.

In this study, we have used preferential looking and two-alternative forced choice discrimination on the jumping stand to investigate the development of texture segmentation in very young kittens. Beginning at 3 weeks of age, detection thresholds for texture arrays were assessed by preferential looking. In this paradigm, textures were paired with homogeneous grey fields of matched mean luminance. Kittens as young as three weeks showed clear preferences for textures over homogeneous fields provided the texture elements were above a critical size. Pairs of such textures (e.g., with vertically and horizontally oriented elements) were then presented to the kittens on the jumping stand in a texture segmentation task (Wilkinson, **Behav. Brain Res.**, 1986, 19, 71-82). Twelve kittens have been tested in this sequential paradigm on textures with oriented elements. In spite of clear evidence of detection of the textures before 6 weeks of age, no animal was successful on the texture segmentation task before 80-120 days of age. The generality of this effect is currently being examined using other texture patterns. The results will be discussed in relation to the development of striate and extrastriate visual mechanisms.

VERNIER ACUITY IN STEREOBLIND CATS.

B. Timney, L.A. Symons* and K. Keil* . Dept. Psychology, Univ. Western Ontario, London, Canada, N6A 5C2.

The similarities between vernier acuity and stereoacuity have led to the suggestion that they may share a common mechanism. However, the evidence in support of such a suggestion is mixed. One way to compare two abilities is to eliminate one and look for an equivalent deficit in the other. We measured vernier acuity in stereoblind kittens (induced by monocular deprivation between 40 and 50 d) and compared it with that of control animals. Vernier and stereoacuity were measured in these animals using a jumping stand procedure. In control animals vernier thresholds were typically less than 5 min arc and binocular depth thresholds less than 10 min arc. The MD animals showed little difference between monocular and binocular depth thresholds, indicating a loss of stereopsis. These animals found the vernier task very difficult to learn and final thresholds were much worse than those of the controls, ranging from 30 to 50 min arc. The deficit was not attributable to a reduction in resolution acuity. We conclude that the mechanisms for vernier and stereoacuity must at some level share a common pathway.

APB ALTERS VISUAL CONTRAST SENSITIVITY IN GOLDFISH. J. Bilotta*, P. DeMarco* and M. Powers. Dept. of Psych., Vanderbilt University, Nashville TN 37240.

APB (DL-2-amino-4-phosphonobutyric acid) is believed to suppress activity in the ON-pathway of the visual system (Slaughter, M.M. & Miller, R.F. Science, 211:182, 1981). However, we have shown that APB reduces the sensitivity of ON and OFF responses from the retina (Powers M.K. et al, IOVS sup., 29:104, 1988). We now report the behavioral consequences of this sensitivity reduction. Contrast sensitivity functions (CSFs) were measured from goldfish before and after intraocular injections of APB. Fish were classically conditioned to suppress respiration to a sinusoidal grating drifting at 1 Hz. CSFs were derived from an experimenter-based two alternative forced choice procedure (Bilotta, J. & Powers, M. IOVS sup., 30:505, 1989). Baseline CSFs were first obtained; in subsequent sessions injections of APB (100 µM or 1000 µM) or fish Ringer's were made prior to testing. Results showed that (1) CSFs obtained from fish injected with Ringer's were identical to baseline CSFs. (2) APB-treated fish had CSFs shifted to lower spatial frequencies and had lower contrast sensitivity. (3) 1000 µM APB decreased contrast sensitivity more than 100 µM APB. We conclude that APB not only reduces the absolute sensitivity of the goldfish retina, but that it also reduces spatial contrast sensitivity and resolution.

THE ROLE OF CORTICAL DIRECTIONAL SELECTIVITY IN PERCEPTION OF COHERENT MOTION. Daniel Harvitt*, Joanne Albano*, and Tatiana Pasternak, (SPON: R. Sekuler). *Dept of Neurobiology and Anatomy and Center for Visual Science, Univ. of Rochester, Rochester, NY 14627.*

We examined the perception of coherent motion in cats with severely reduced cortical directional selectivity. Such animals, are unable to discriminate the direction of moving gratings at low contrasts (eg. Pasternak, et al, 1985). We used high contrast dynamic random-dot displays (Williams and Sekuler, 1984), in which the direction of motion for each dot could be chosen at random from a specified distribution. When the bandwidth of the distribution is broad (360 deg), the display consists only of local random motion of individual dots and no coherent motion is reported. However, when the bandwidth is limited, the dots appear to flow coherently in a single direction. We measured the bandwidth needed to reliably discriminate between opposite directions of motion and manipulated the strength of motion signal by varying the proportion of dots in the display with bandwidth of 360 deg (noise). When no noise was present in the display, cats with reduced directionality were able to discriminate direction as well as the normal cats (threshold bandwidth: 270-300 deg). As the strength of motion signal was reduced, a narrower bandwidth was required to perform the discrimination. With a very narrow bandwidth (1 deg) normal cats were able to discriminate direction when only 10% of the dots contributed to the motion signal. However, cats with a reduced number of motion detectors required a much greater signal strength (25-30%) to perform the same task. Thus, in the absence of noise, even an abnormally small number of directionally selective cells can perform spatial pooling of local directional signals and support normal perception of coherent motion. However, a full complement of directional detectors is needed when the motion signal is weak (low contrast) or is masked by noise. (Supported by EY06175 and EY01319)

RECOVERY IN HEMIPARKINSONIAN RATS FOLLOWING INTRASTRIATAL IMPLANTATION OF ACTIVATED LEUKOCYTES. R.J. Weber*, S.E. Ewing*, A. Zauner*, and R.J. Punkett*. (Spons. D.M. Jacobowitz). Laboratory of Medicinal Chemistry, NIDDK, and Surgical Neurology Branch, NINCDS, NIH, Bethesda, MD 20892.

A hemiparkinsonian syndrome resembling idiopathic Parkinson's disease in humans was induced in Sprague-Dawley rats that had undergone prior superior cervical ganglionectomies, using a modification of a recently reported technique for selectively lesioning the pars compacta of the substantia nigra by unilateral stereotactic injections of 6-hydroxydopamine. Phytohemagglutinin-stimulated rat peritoneal cells, predominantly T-cells and macrophages, were stereotactically implanted in the lesioned caudate-putamen, and behavioral recovery assessed by measuring rotation induced by D-amphetamine, a dopamine releasing agent. Animals receiving implants of activated leukocytes (n=13), showed a 47% decrease in amphetamine-induced turning 8 weeks after implantation (p=0.05), which was not seen in control (n=10) or sham-operated (n=7) animals. The recovery in leukocyte-implanted animals was correlated with an increases in striatal dopamine content and the presence of increased tyrosine hydoxylase reactivity on the lesioned side. We conclude that implantation of leukocytes promotes recovery in hemiparkinsonian rats, possibly through restoration of striatal dopaminergic activity.

CRYOPRESERVED HUMAN FETAL NEURAL TISSUE REMAINS VIABLE 4 MONTHS AFTER TRANSPLANTATION INTO HUMAN CAUDATE NUCLEUS. D.E.Redmond, Jr., D. Spencer, F. Naftolin, C. Leranth, R.J. Robbins, T.L. Vollmer, R.H. Roth, B.S. Bunney, J.H. Kim, Depts. Psychiat., Neurosurg., Ob.Gyn., Neurol., Med., Pharmacol., & Neuropath. (Yale Neural Transplant Program),Yale Univ. Sch. Med., New Haven, CT 06510.

Cryopreserved human fetal mesencephalic tissue survived transplantation into monkeys in a previous study (*Science*, 242:768,1988), but viability of neural tissue grafted into the brain of a human subject has not been demonstrated.

We retrieved mesencephalic tissue from an 11 week aborted human fetus, using the method previously reported, and transplanted it into two areas of one caudate nucleus in a 69 year old patient who was deteriorating from end-stage parkinsonism. The study was approved by the Yale Human Investigation Committee. During the first 8 weeks, the patient received cyclosporin (blood levels 100-150 ng/ml). After 4 months the patient died from complications of parkinsonism. Examination of the brain revealed no complications from the implantation of tissue, and a diagnosis of Parkinson's disease was confirmed by usual pathological findings, but without Lewy bodies. Both grafts found in the caudate nucleus appeared to have been viable at the time of death. They contained erythrocyte-packed capillaries and pyramidal-shaped neurons with synapses, reactive glia, and some macrophages, based on light and electron microscopy. No inflammatory process indicating tissue rejection was apparent. Tyrosine hydroxylase (TH) immunohistochemistry did not label cells in the grafts, but labelled a few in surrounding caudate tissue.

These data demonstrate that cryopreserved human fetal mesencephalic neural tissue survives four months after transplantation into the mature human caudate nucleus. The absence of TH-labelling of identified neurons in the grafts is unexplained and unexpected since similar tissue which was cultured or grafted into monkeys contained TH-positive neurons (*Science, ibid.*).*(Supported by private funds).*

HUMAN PARKINSON'S DISEASE TREATED BY FETAL DOPAMINE CELL TRANSPLANT. CR Freed, RE Breeze*, NL Rosenberg*, JN Barrett, D Eidelberg* and DA Rottenberg, U. Colorado Sch. of Med., Denver, CO, U. Miami Sch. of Med., Miami, FL, and Memorial Hosp., NY, NY.

We have implanted fetal dopamine cells from a 7 week human embryo into caudate and putamen of a 52 year old man with a 20 year history of Parkinson's disease, Hoehn and Yahr stage 4. Fetal tissue was obtained from elective abortion with informed consent obtained after the procedure. Maternal blood was negative for HIV and hepatitis B. Five months prior to transplant the patient began evaluations by a neurologist and by a home based computer system for daily measurement of walking and hand movements. Preop fluorodopa PET scan showed severe bilateral dopamine depletion. Tissue was implanted stereotaxically in caudate and putamen on the right side via 10 needle tracks. Fetal tissue and the patient were ABO matched and the patient was not immunosuppressed. Data 26 weeks after surgery show a 50% increase in walking speed on a full day basis. There was a 30% increase in left finger speed and a smaller increase in right finger speed. Left sided performance became equal to right sided. Peak dose dyskinesias were seen on the left. Reaction time was not affected. Drug doses have been reduced. These data indicate that transplants of human fetal dopamine cells may be of benefit in patients with Parkinson's disease.

54.4

HISTOLOGICAL ANALYSIS OF THE BRAIN AND THE ADRENAL GLAND OF A PARKINSONIAN PATIENT TREATED BY UNILATERAL TRANSPLANT OF ADRENAL MEDULLA. E.C.HIRSCH, C. DUYCKAERTS*, F. AGID*, J.-J. HAUW*, Y. AGID*. INSERM U289 and Laboratoire R. Escourolle, Hôpital de la Salpêtrière, 75013 Paris, France.

An autologous unilateral adrenal medullary transplant to the caudate nucleus was performed on a 54 yrs old patient with idiopathic Parkinson's disease (PD) as described by Madrazo. After surgery no clinical benefit was observed and he died 120 days later, suffering from meningitis. Autopsy findings showed an important astrocytic gliosis and an inflammatory infiltrate surrounding the graft. No cell bodies containing catecholaminergic markers (tyrosine hydroxylase TH, dopamine-beta-hydroxylase, chromogranin A and mRNA coding for TH) were detected in the graft, in contrast such cells were numerous in the non grafted adrenal medulla. A few TH-positive DBH-negative fibers were visualized in the graft. In the host striatum, a hyperdensity of TH-positive sprouting fibers was observed in periphery of the graft. However, no TH-positive fibers were evidenced throughout the remaining part of the grafted striatum nor in the non-grafted striatum. The fiber density of other striatal fiber systems (methionine-enkephalin, neuropeptide Y or choline acetyl-transferase) was similar in both striata. The data suggest that in PD the adrenal transplants may have a selective stimulating effect on the host.

ADRENAL AUTOTRANSPLANT IN HEMIPARKINSON MONKEYS. B. Brooks[1], D.C.German[2], and C. McGregor*[1]. [1]Univ. of TX Hlth Sci. Ctr. (Physiol.), San Antonio, TX. [2]UT SW Med. Ctr. (Psychiat.), Dallas TX.

A monkey was trained to bar-press rapidly with either hand as a measure of motor function. After press rates were stabilized, MPTP (.5 mg/kg) was injected via one internal carotid artery. Bradykinesia, rigidity, and severely reduced bar pressing occurred contralateral to injection; the ipsilateral limb remained normal. SINEMET (oral L-dopa/carbidopa) transiently restored the disabled limb. The deficits persisted for 7½ weeks until an adrenal medulla-to-caudate transplant was performed on the injected side. Within 76 hours, a stepwise improvement in bar pressing occurred, which gradually increased over 4½ months to about 90% recovery. SINEMET had no effect on pressing in the recovering limb.

Sections of perfused brain received either tyrosine hydroxylase (TH) antibody or Nissle stains. TH immunoreactivity throughout the rostral-caudal extent of the caudate and putamen nuclei on the treated side was markedly depleted, compared to the contralateral hemisphere, which showed intense staining typical of normal animals. An ipsilateral reduction in midbrain DA containing cells affected areas A8, A9, and A10. Evidence of a viable graft was found in the walls of the lateral ventricle; a gradient of enhanced TH-IR extended from the ventricular surface of the caudate inward. Sponsored by NIH Grant #EY5R01NS22187-03 and DAPS.

SPECT IMAGING OF DOPAMINE D_2 RECEPTORS IN MPTP-TREATED MONKEYS FOLLOWING BRAIN TRANSPLANTATION. R.H. Roth, P.B. Hoffer, D.E. Redmond, Jr., J.D. Elsworth, J.R. Taylor, J.R. Sladek Jr.†, T.J. Collier†, H.F. Kung††*, A. Alavi††*, and R.B. Innis. Yale Univ. Sch. Med., New Haven, CT 06510; †Dept. Neurobiol. and Anat., Univ. Rochester Sch. Med. & Dentistry, Rochester, N.Y. 14642 and ††Section of Nuclear Med., Univ. Penn., Philadelphia, Pa.

Pilot studies in non-human primates indicate the feasibility of using brain imaging with Single Photon Emission Computed Tomography (SPECT) as a noninvasive technique to assess D_2 receptor localization *in vivo* (see abstract by Innis et al). In this study we examine the feasibility of monitoring possible dopamine receptor changes associated with transplanted neural tissue in parkinsonian primates. Two MPTP-treated vervet monkeys received either fetal substantia nigra or cerebellum transplanted unilaterally into striatum. They were examined with SPECT brain imaging 21 months after grafting. Animals were injected with 4-5 mCi ^{123}I-labelled IBZM (iodobenzamide, a specific dopamine D_2 receptor probe). They were scanned for 2 hr. in a Strichman 810X Brain Imager with repeated 2 min scans through the striata. Small lateralized differences in radiolabel uptake were seen in the nigral-transplanted monkey. The uptake of radiolabel was markedly different in the two monkeys: at 120 min post injection, striatal to extrastriatal ratio of label was 1.8 in nigral-transplanted animal but only 1.3 in the cerebellar-transplanted animal. Animals were sacrificed immediately after the scan. Direct measures of ^{123}I in tissue punches removed from brain slices were consistent with the SPECT results. These results, added to morphological and chemical analyses, suggest that SPECT neuroreceptor imaging may be useful in assessing PD and monitoring its treatment with brain transplantation.

54.7

MRI OF FETAL NEURAL TISSUE TRANSPLANTS IN MONKEYS: STRIATAL GRAFTS SHOW NO ENHANCEMENT AFTER Gd-DPTA.

E.L.Kier*, D.E.Redmond, Jr., J.R.Sladek, Jr.†, J.R.Taylor, J.D.Elsworth, T.J.Collier†, and R.H.Roth (SPON: P.D.Shepherd). Dept. Diagnostic Radiology*, Psychiat. & Pharmacol., Yale Univ. Sch. of Med., New Haven, CT. 06510 and †Dept. of Neurobiology and Anatomy, Univ. of Roch. Sch. of Med., Rochester, N.Y. 14642.

Magnetic resonance (MR) imaging may allow *in vivo* assessments of the accuracy of tissue placement, surgical complications, breaches in the blood-brain-barrier, and the development of neural tissue grafted into the brain. Six St. Kitts green monkeys *(Cercopithecus aethiops sabaeus)* were imaged approximately 21 months after unilateral grafts of fetal neural tissue from fetal substantia nigra or two types of controls.

Several sequences of spin echo and gradient echo images were performed in a 1.5 Tesla *GE Signa* MR Scanner in sagittal, axial, and coronal projections. Pre- and post-gadolinium-DPTA scans were obtained. Several imaging parameters were used to establish the best resolution. Coronal sections were made at sacrifice and correlations were made between the MR coronal images and the actual locations and conditions of the grafts using histological techniques. MR scans in the coronal projection were found to be the most informative. Both tracts and graft areas with hemosiderin deposits were visualized. Gadolinium enhanced a prominent vascularity in the lateral ventricle of one monkey, but no enhancement was seen in any graft located in the striatum.

The high quality resolution and anatomic detail provided by a 1.5 Tesla magnet may make MR scanning useful for the evaluation of neural grafts and also provide an anatomic foundation for localizing receptor images derived from Single Photon Emitting and Positron Emitting tomographic techniques *in vivo*. The lack of gadolinium enhancement in identified grafts within the striatum suggests the absence of a significant break in the blood-brain-barrier at 21 months after transplantation.

BIOCHEMICAL STUDIES ON THE REVERSAL OF MPTP-INDUCED PARKINSONISM IN PRIMATES FOLLOWING TRANSPLANTATION OF FETAL SUBSTANTIA NIGRA TO STRIATUM

J.D.Elsworth, J.R.Taylor, D.E.Redmond,Jr., †T.J. Collier, †J.R. Sladek,Jr. and R.H.Roth. Depts. Pharmacol. & Psychiat., Yale Univ. Sch. Med., New Haven, CT 06510; †Dept. Neurobiol. & Anat., Univ. Rochester Sch. Med., NY 14642.

Previous studies have shown that transplantation of fetal substantia nigra to the caudate nucleus of MPTP-treated monkeys reverses the toxin-induced parkinsonism. This study (and abstract by Roth et al.) provides biochemical data that address the mechanism of recovery.

MPTP-treated vervet monkeys received fetal substantia nigra grafted bilaterally or unilaterally to caudate nucleus or putamen; other MPTP-treated subjects received non-dopaminergic fetal tissue transplanted similarly or underwent "sham" surgery. CSF homovanillic acid (HVA) concentrations were measured over time and parkinsonian behavior was regularly rated. After 18 months brains were examined by a method that allowed dopamine (DA) and HVA measurements and tyrosine hydroxylase immunohistochemistry to be performed in the same slice of tissue.

In order to distinguish DA production by transplanted cells from that generated by remaining host DA neurons, DA concentrations and HVA/DA ratios in striatum were related to cannula placements and tyrosine hydroxylase staining.

These data provide information on survival and function of transplanted cells and on the mechanism of behavioral recovery from MPTP-induced Parkinsonism.

Supported by USPHS NS 24032, Axion Research Foundation and the St. Kitts Biomedical Research Foundation. DER is supported by Research Scientist Award MH-00643.

EFFECTS OF DOPAMINERGIC GRAFTS IN THE STRIATUM AND SUBSTANTIA NIGRA ON TURNING BEHAVIOUR IN 6-HYDROXYDOPAMINE-LESIONED RATS.

George S. Robertson[1], Harold A. Robertson[1] and Alan Fine[2] Dept. of Pharmacology[1], Dept. of Physiology and Biophysics[2], Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7.

L-Dopa administration elevates dopamine (DA) levels in the substantia nigra (SN) and striatum (ST) reduced by prior 6-OHDA-lesions of the SN. L-Dopa-induced circling in these lesioned animals may result from increased nigral DA levels (Robertson and Robertson, Neurosci. Lett. 89, 204-208). The reduction in turning to dopaminergic agonists which occurs after fetal dopaminergic grafts to the 6-OHDA-denervated ST might therefore be further augmented by a dopaminergic graft to the ipsilateral SN. To test this possibility, fetal nigral grafts were placed in the SN, ST and SN+ST ipsilateral to 6-OHDA-lesion of the SN. A fourth group of ungrafted 6-OHDA-lesioned rats served as additional controls. Circling produced by the selective D1- and D2-receptor agonists SKF 38393 and LY 171555, respectively, was evaluated 1, 2 and 3 months after transplant surgery. Animals with a graft to the SN only did not show a consistent reduction in rotation. Animals grafted to the ST or the SN+ST showed a greater reduction in D1- than D2-receptor-mediated rotation. However, a combined SN+ST graft did not produce a greater reduction in turning behaviour than a ST graft. Supported by Parkinson Foundation and MRC of Canada

54.10

COMPARISON OF SUBCUTANEOUS AND INTRAVENTRICULAR ADMINISTRATION OF DOPAMINE AGONISTS IN ANIMAL MODELS OF PARKINSON'S DISEASE,

W.C. Koller, T. Basham*, Dept of Neurology, Univ of Kansas Medical Center, Kansas City, KS 66103

Chronic levodopa therapy in Parkinson's disease (PD) is limited by response fluctuations and loss of efficacy. Parenteral forms of administration may offer certain advantages. We have therefore compared the effects of apomorphine and PHNO, a D-2 dopamine agonist, administered subcutaneously (s.c.) versus intracerebroventricularly (i.c.v.; cannulae in the left lateral ventricle) in normal rats and in rats with unilateral 6-OH dopamine lesions of the substantia nigra. Apomorphine (0.1, 0.25, 0.50, and 0.75 mg/kg) and PHNO (1.0, 5.0, 50.0 and 100 ug/kg) produced dose-dependent stereotypic behavior (SB) both with s.c. and i.c.v. injections. Comparison of the two routes revealed a more immediate effect with i.c.v. and a more intense behavioral response in some animals (i.e. gnawing and licking), however, there was no statistical difference ($p < 0.05$) in the percent of animals with SB and in the duration of SB. Several animals had seizures following i.c.v. injection. Apomorphine (0.1 to 0.50 mg/kg) but not PHNO (1 to 50 ug/kg) produced dose-dependent turning behavior measured for ten minutes following injection in 6-OH dopamine lesioned animals. There was no difference in turning behavior between the two routes of administration. It is concluded dopamine agonists can be given by the s.c. and i.c.v. routes and i.c.v. confers no major advantage over s.c. administration.

54.11

L-DOPA PRODUCES HIGHER LEVELS OF EXTRACELLULAR DOPAMINE IN DOPAMINE DEPLETED VS. INTACT STRIATA.

A.E.Bonatz*, H.J. Morris*, M.J. Zigmond, and E.D. Abercrombie (SPON: O.M.Reinmuth) *Dept. of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.*

The effect of L-DOPA administration upon dopamine (DA) in extracellular fluid was examined both in the intact striatum and in the DA-depleted striatum of rat using in vivo microdialysis. The basal amount of DA in 20µl of dialysate (corrected for recovery of the probe) in DA-depleted animals was significantly less than in controls when striatal tissue DA was reduced by more than 86%. Peripheral dopa decarboxylase (DDC) inhibition (RO4-4602, 50 mg/kg i.p.) followed by L-DOPA treatment (100 mg/kg i.p.) elevated extracellular DA in controls from 37 ± 5 pg to 84 ± 13 pg (n=7). In animals with bilateral striatal DA depletions (mean tissue DA depletion 82%; n=6), L-DOPA increased extracellular DA from 17 ± 9 pg to 244 ± 53 pg. In unilaterally DA-depleted animals (mean tissue DA depletion 98%; n=6). The increase in extracellular DA after L-DOPA was greater on the lesion side (from 7 ± 4 pg to 245 ± 67 pg) than on the intact side (from 28 ± 11 pg to 61 ± 8 pg). Unilaterally lesioned animals showed contralateral circling behavior after L-DOPA suggesting that DA formed from L-DOPA functionally stimulates postsynaptic receptors. It is proposed that the greater absolute effect of L-DOPA on extracellular DA concentration in the DA-depleted striatum is due to: (1) a substantial reduction in high affinity DA reuptake as a consequence of DA nerve cell degeneration and (2) DDC activity in non-dopaminergic striatal elements. Thus, the failure of Parkinsonism patient to continue to respond to L-DOPA treatment may be due in part to the overstimulation of DA receptors leading to desensitization. (Supported by Grant NS19608 and the National Alliance for Research on Schizophrenia and Depression.)

54.12

DOPA-INDUCED INHIBITION OF STRIATAL ACH RELEASE: INCREASED EFFECTIVENESS AFTER 6-HYDROXY-DOPAMINE.

D. Jackson, and M. J. Zigmond, *Dept. of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, Pa. 15260*

Although the motor activity of normal rats is relatively unaffected by large doses of DOPA, increased locomotion is observed after administration of DOPA to rats lesioned with 6-hydroxydopamine (6-HDA). In the present study, we looked at the effects of DOPA on the release of striatal dopamine (DA) and acetylcholine (ACh), a transmitter normally inhibited by DA. Striatal slices (350 um) were prepared from control and lesioned rats (250 ug 6-HDA,ivt), preincubated with [^{3}H]choline (.07 uM), and superfused (100 ul/min) with Krebs bicarbonate buffer containing hemicholinium (10 uM). Slices then were exposed to two periods of electrical field stimulation. Tritium, an index of ACh efflux, and endogenous DA were measured. DOPA (10 uM), added after S_1, elevated the basal efflux and overflow of DA from intact and lesioned slices, although these effects were greatly reduced by the lesion. Nonetheless, 6-HDA pretreatment greatly enhanced the inhibitory influence of DOPA on ACh overflow. Thus, while DOPA had no detectable effect on ACh overflow from intact slices (-4±4%), it caused a considerable inhibition of ACh overflow from lesioned slices (-37±4%). A comparable potentiation of the inhibitory influence of DOPA could be produced by the addition of nomifensine (1 uM) to intact slices. Collectively, these data suggest that the ability of DOPA to restore striatal function results from an DOPA-induced increase in DA release coupled with the relative lack of high affinity DA uptake sites. (Supported in part by USPHS grants NS-19608 and MH-00058 and the American Psychological Association)

54.13

PRESYNAPTIC AND POSTSYNAPTIC INDICIES OF STRIATAL DOPAMINERGIC FUNCTION IN THE 10 DAY RAT PUP. R.A. Wallace and M.J. Zigmond, *Department of Behavioral Neuroscience and the Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 152-60.*

The striatum of 10-day old rat pups contains 40% less dopamine (DA) than that of the adult, yet neurological function appears relatively mature. To examine the capacity of endogenous DA to control striatal function, tissue slices (350 um) were preincubated with ^{3}H-choline and exposed to electrical field stimulation (10 Hz, 9 sec). Tritium, a measure of acetylcholine (ACh), and endogenous DA overflow then were determined. Sulpiride (1 uM) increased ACh overflow approximately 2-fold from slices prepared both from adult and neonatal rats. No evidence of postsynaptic supersensitivity was observed in neonatal slices, and DA overflow was significantly less than from adult slices. However, in the presence of nomifensine (10 uM), DA overflow from neonatal slices increased 12-fold to a level comparable (3.14 ± 0.51 ng/mg protein) to that seen from adult slices examined under the same conditions (2.46 ± 0.10 ng/mg protein). These results suggest that the amount of DA released from individual DA terminals in neonates may be much greater than from adults but that it is rapidly inactivated by reuptake. (Supported in part by NS-19608, MH-18273, and MH-00058.)

54.14

L-DOPA FACILITATES GABA RELEASE ACTIVATING D-1 DOPAMINE RECEPTORS IN THE BASAL GANGLIA OF THE RAT BRAIN. J. Aceves* and B. Florán* (SPON: J. Alanís). Dept. of Physiology. CINVESTAV-IPN. 07000 México, D.F.

L-Dopa increases GABA levels in the CSF of parkinsonian patients (Manyam, B., Arch. Neurol. 39: 391, 1982). This could be due to L-dopa-induced facilitation of GABA release. Here we have tested this possibility. The experiments were done on slices of substantia nigra pars reticulata, entopeduncular nucleus, globus pallidus and caudate-putamen of 6-OHDA lesioned rats. The lesion was produced by applying 6-OHDA into nigra compacta. [3-H]GABA release was induced by high (15 mM) K^+. L-Dopa markedly increased GABA release in all these nuclei (EC-50 = 2 µM). The increase was competitively antagonized by the selective D-1 DA antagonist SCH-23390. The effect was stereo-specific, since D-Dopa also stimulated the release but at higher concentrations (EC-50 ≃ 300 µM). The effect was not due to L-Dopa acting as DA precursor because the experiments were done having Dopa-decarboxylase inhibited by NSD (500 µM). Dopamine also stimulated GABA release in all of the nuclei; the stimulation was blocked by SCH 23390. These results suggest that in the parkinsonian patient L-Dopa could activate striatal output acting as both DA precursor and D1 DA agonist facilitating GABA neurotransmission at the output relay nuclei of the striatum.

PARKINSONIAN TREMOR AND PETIT MAL EPILEPSY: COMMON MECHANISMS. G. Buzsaki, A. Smith*, A. L. Roskies*, L. J.Fisher and F. H. Gage. Dept. of Neurosciences, UCSD, La Jolla, CA 92093

Neocortical activity, face muscle EMG and body tremor were recorded in young (3-10 mo) and aged (22-30 mo) Fischer 344 and Sprague-Dawley rats. During immobility high voltage spindles (HVS) appeared in the neocortex, the rhythmicity of which was phase-locked to the vibrissal and body tremor. The HVS had spike and wave components (< 5 mV) in F344 rats but only wave components in SD rats. The incidence of both HVS and tremor was 5-8 times higher in aged rats than in young adults. Peripheral administration of ethosuximide, valproic acid, scopolamine and apomorphine reduced the incidence of HVS and tremor. Chlorpromazine, acepromazine and haloperidol increased both parameters when injected peripherally or into the head of the caudate nucleus (CP; 1-10 nM) but not when administered into the thalamus. 6-OH lesion of the nigrostriatal dopamine system similarly inreased the incidence of HVS and tremor. Neuorons in the neocortex, thalamus, and CP, fired in a phase-locked manner with the HVS, and single pulse stimulation of the CP triggerred HVS during immobility. We suggest the thalamopetal GABAergic inputs (pars reticulata of substantia nigra, entopeduncular nucleus, pallidum) are burst- and oscillation-promoting systems, whose output is controlled by the striatum. Experimental or disease-related decrease of the striatal dopamine levels increase the efficacy of the GABAergic burst-promoting systems resulting in rhythmic network oscillation of thalamocortical neurons during rest.

SPECIFICITY OF SYNAPTIC CONNECTIONS

OLIVOCEREBELLAR FIBER MATURATION IN NORMAL AND LURCHER MUTANT MICE: DEFECTIVE DEVELOPMENT IN LURCHER. J. A. Heckroth, D. Goldowitz, and L. M. Eisenman. Department of Anatomy, Jefferson Medical College, Philadelphia, PA 19107

Olivocerebellar fiber maturation was examined in normal and lurcher mutant mice between postnatal day 5 (P5) and P15, using the anterograde transport of WGA-HRP from the inferior olive. Immunocytochemistry for the Purkinje cell specific peptide PEP-19 (antiserum provided by J.I.Morgan) was used to demonstrate Purkinje cell development in the same material. In mutant and normal animals a regional developmental variation is observed, such that, when compared at a given age, cortex lining the vermal fissures appears developmentally advanced to cortex in the cerebellar hemispheres. In the primary fissure of the normal animals the first recognizable Purkinje cell dendrites appear on P6, and the olivocerebellar fibers first enter the climbing stage of their development on P9. In lurcher animals Purkinje cell development proceeds on this schedule, although their somata and dendrites are abnormal in appearance. In contrast to normal, lurcher olivocerebellar fibers are never observed to enter the molecular layer, and instead maintain dense perisomatic nests around Purkinje cells, even at P13-15. Examination of WGA-HRP labeling in P14 lurchers by transmission electron microscopy indicates that the olivocerebellar fibers form synapses on Purkinje cell somatic spines, and that the basket cell axons fail to form their typical perisomal nests around Purkinje cells. In addition, parallel fibers are observed to have synapses on dendritic spines of the Purkinje cell primary dendrites. We interpret these results as indicating a specific recognition defect between olivocerebellar fibers and Purkinje cell dendrites. An analysis of this defect in lurcher may reveal how the developmental transformation of olivocerebellar fibers, from "perisomatic nests", to the "climbing" phase is achieved in the normal animal. Supported by NINCDS grant #NS22093.

DENDRITES OF PURKINJE CELLS IN REELER MUTANT CEREBELLUM INVADE THE MOLECULAR LAYER OF THE DORSAL COCHLEAR NUCLEUS. A. S. Berrebi and E. Mugnaini. Laboratory of Neuromorphology, U-154, Univ. of Connecticut, Storrs, CT. 06269-4154.

The murine mutation reeler affects neuronal migration and orientation. In the cerebellum, the defect results in grossly underdeveloped folia, disruption of lamination, substantial loss of Purkinje cells and secondarily, of granule cells. Lamination is also altered in the adjacent dorsal cochlear nucleus (DCoN), and the granule cells of the cochlear nuclei are reduced in number. We have examined the cerebellum and DCoN of reeler mice using Purkinje cell specific immunocytochemical markers. One of these, L7 (gift of Dr. J. I. Morgan, Roche Research Center), reveals all surviving Purkinje neurons, including those clustered in the deep region of the cerebellum. Some large clusters of Purkinje cells are adjacent to the DCoN, and their spine-laden dendrites enter and ramify within the DCoN molecular layer. In this layer, cerebellar-like parallel fibers, the axons of cochlear granule cells, presumably provide synaptic input not only to DCoN neurons, but also to the ectopic Purkinje cell dendrites. This finding suggests that growth of Purkinje cell dendrites can be chemotropically directed by vicinal axons. Moreover, such ectopic cells may be inappropriately activated via connections normally involved in acoustic processing.

55.3

SPATIAL COOPERATIVITY BETWEEN NEARBY IMMATURE PURKINJE CELLS MEDIATED BY THEIR INHIBITORY RECURRENT COLLATERALS.

C. BERNARD*, H.AXELRAD* and B.GIRAUD* (SPON: J.P. CHANGEUX) Lab. de Physiol. CHU Pitié -Paris 13e & Dept.Phys.Théor. CEN Saclay - FRANCE

In the 7 days potsnatal rat the cerebellar cortex is composed of immature Purkinje cells (PC), forming a monoplanar layer, coupled to each other by recurrent collaterals of their Gabaergic inhibitory axons. It is devoid of interneurons and PCs receive only few excitatory inputs. It is thus an interesting model to study how inhibitory coupling modifies ongoing activity and the spatiotemporal extent of cooperativity in a simple neuronal network. Extracellular recordings of pairs of PCs were made with methyl blue filled micropipettes (in 3M Nacl) in the cerebellar vermis of 6-8 days pups under control conditions and after blocking all inhibitory actions by superfusion of a Gaba antagonist. Relative positions of electrode tips was deduced from 3D morphologic reconstruction of the recorded folium. Treatment of data was done off-line and included classical methods as well as a method to calculate the informational entropy (Axelrad & al: 1st INNS Conf., 4:59,1987). Analysis of 8 pairs of PCs studied in both the coupled and uncoupled mode clearly indicate that: 1)recurrent collaterals exert a powerful inhibitory action leading to a 30% reduced rate of activity ; 2) in this case the shape of the interspike interval histogram (usually of Poisson or Gaussian types) is broader with greater values; 3) as judged from crosscorrelograms the cell seem to have symetrical connections if they are separated by less than 80µm, asymetrical ones from 80 to 300µm and none if they are further apart; 4)a minute fall in entropy takes place in the control mode (i.e the network has more informational capabilities). These results indicate that due to the action of the PC's inhibitory recurrent collaterals a spatially oriented cooperativity takes place between cells in the immature cerebellar network.

GRAFTED MESENCEPHALIC DOPAMINERGIC NEURONS, BUT NOT OTHER EMBRYONIC DA CELLS, DEVELOP IN ACETALDEHYDE/MPTP LESIONED, BUT NOT IN NORMAL, MOUSE ADULT STRIATA.

A. Zuddas", G.U. Corsini^, I.J. Kopin" and U. di Porzio.^^. "Clinical Neurosci. Branch, ^^Lab. Neurophysiology, NINDS, NIH Bethesda, USA; ^ Inst. Pharmacol, Univ. Pisa, ^^ Internl. Inst. Genetics Biophysics, CNR, Naples, Italy.

We have shown that acetaldehyde/MPTP treated mice represent a good model to study in rodents the development of grafted embryonic DA neurons. Lesioned C57BL mice, grafted with dissociated mouse ventral E13 mesencephalic cells, develop an amphetamine induced turning behavior which well correlates to the number of TH^+ neurons that survive two to four months after the implant. On average, the number of TH^+ neurons corresponded to 0.1-0.2% of the implanted cells. They develop a rich network of fibers selectively and extensively innervating the lesioned host striatum. In implanted untreated controls, substantially fewer TH^+ neurons were found, a few localized in areas of the striatal parenchyma destroyed during the injection; most located in the corpus callosum or cortex and their fibers did not enter the normally innervated striatum. When hypothalamic E17 cells were used for the graft, implanted lesioned mice showed little or no rotation after amphetamine. In these animal the number of TH^+ neurons was much lower than that found when mesencephalic cells were implanted, and their network of fibers was very poor. Taken together, these data indicate that striatal cells deprived of the normal DA innervation, but not the normally innervated striata, can very effectively sustain the survival and development of DA neurons from the embryonic mesencephalon, but not that of other DA cells. It is postulated that trophic and/or tropic factor(s), specific for mesencephalic DA neurons, are produced by striatal cells when nigral DA cells are lost. It is also possible that such putative factors may be equally produced by the normal striatum but are not available for exogenous DA neurons when the endogenous DA fibers are intact.

AGE DEPENDENT CHANGES IN DISTRIBUTION OF SUBSTANCE P-LIKE IMMUNOREACTIVITY IN COHO SALMON.

T. Östholm* and S. O. E. Ebbesson (SPON: D. Cohen) Institute of Marine Science, University of Alaska, P. O. Box 730, Seward, Alaska 99664, USA

In an effort to understand the neural plasticity during smolt transformation (ST) in salmon, a number of neurotransmitters and neuromodulators are examined systematically. We report here our findings on substance P (SP). Brains and retinas of presmolt (n=6), postsmolt (n=3) and adult (n=1) coho salmon were fixed by perfusion with 4% paraformaldehyde and 0.25% picric acid dissolved in 0.1M Sorensens phosphate buffer (pH 7.2) and post fixed in the same fixative overnight. After several rinses in Tyrode buffer to which successively 25% sucrose was added, serial cryostat sections were prepared (33 µm). The tissue sections were incubated with anti-substance P (SP) (immunonuclear) diluted 1:1600-1:2000 overnight and the immunoreactive sites were visualized by standard PAP techniques. Method specificity was checked by using SP that had been preabsorbed with synthetic substance P (100 µg/ml antisera) or with omission of the primary antibody. Controls abolished all immunoreactivity.

The distribution of SPLI fibers and cells is similar to those reported in adult goldfish (Sharma, S.C. *et al., J. Comp. Neurol.*:279:104; 1989) with some exceptions. The dorsomedial area (DM) of the salmon telencephalon e.g., contains a large number of SPLI fibers, the DM increasing in size significantly with ST. The SPLI fibers in the tectum and habenula are also numerous, changing their distribution with aging. The quantity and distribution of SPLI change dramatically throughout life suggesting that SP systems are important in neural plasticity in salmon.

Supported by grants from NIH and Alaska Sea Grant College Program.

55.6

THE ELIMINATION OF LOCUS COERULEUS AXONS DURING DEVELOPMENT CAN BE PREVENTED BY EARLY TRANSECTION OF THE NORMALLY MAINTAINED COLLATERALS.

B. B. Stanfield. Lab. Clin. Sci., NIMH, Poolesville, MD 20837.

In adult rats, coeruleospinal (c⇒s) neurons are found only at mid-rostrocaudal levels of the nucleus, where they are essentially confined to its ventral, wedge-shaped half. However, during early postnatal development, c⇒s neurons are found throughout the nucleus. This developmental restriction of the distribution of c⇒s neurons is due to axonal elimination rather than to cell death, since neurons retrogradely labeled through their spinal axons perinatally are still present in the dorsal portion of the locus coeruleus at survival times beyond the age at which these cells lose their spinal projection (Chen & Stanfield, *Brain Res.* 410[1987]154). In the present study unilateral transections of the dorsal adrenergic bundle were made in newborn rats (n=12). Over one month later diamidino yellow was injected into the cortex of four of these rats and fast blue was injected into the upper spinal cord of all twelve. Similar injections were made in age-matched control rats (n=15).

In control animals which received the cortical diamidino yellow injection, many labeled cells are seen in the locus coeruleus. But none is found in the locus coeruleus of lesioned rats, though some are seen in other regions known to project to the cortex, including the midline raphé. The distribution of fast blue labeled c⇒s neurons is consistently more widespread in the lesioned animals than in controls. While still concentrated ventrally, many c⇒s cells are present in the dorsal half of the nucleus; some are even at its dorsalmost tip. In addition, c⇒s cells are found within the posterior pole of the nucleus. These results indicate that the absence of the normally maintained collateral of a locus coeruleus neuron is sufficient to prevent the elimination of a c⇒s collateral which would otherwise be lost, and also imply that during normal postnatal development, the presence of the maintained collateral may somehow contribute to the elimination of the transient c⇒s collateral.

55.7

THE FORMATION OF SPECIFIC MONOSYNAPTIC SENSORIMOTOR CONNECTIONS IN CHICK EMBRYOS IS NOT DEPENDENT ON PATTERNED NEURONAL ACTIVITY OR MOTONEURONAL CELL DEATH.

B. Mendelson and E. Frank. Dept. of Neurobiology, Anatomy and Cell Science, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

In vertebrate animals the sensorimotor connections involved in the stretch reflex exhibit a stereotypical pattern. Muscle spindle afferents monosynaptically excite motoneurons that innervate the same and synergistic muscles while they polysynaptically inhibit motoneurons that project to antagonistic muscles. The importance of patterned neuronal activity and motoneuronal cell death in the formation of these connections was studied by injecting d-tubocurarine (dtc) into eggs during the period when sensorimotor connections are made (St 28-40). Dtc blocked limb movements, thereby interrupting stretch evoked activity in spindle afferents. Short latency, fatigue-resistant synaptic potentials were recorded intracellularly from identified brachial and lumbosacral motoneurons upon stimulation of identified populations of spindle afferents. In both normal and curare-treated animals large excitatory potentials were evoked in homonymous motoneurons (those that innervate the same muscle) and were often observed in synergistic motoneurons as well. In contrast, these potentials were uncommon in antagonistic motoneurons. We saw no difference in the pattern of sensorimotor connections in normal versus curare-treated embryos. These observations suggest that neither normal patterns of neuronal activity nor motoneuronal cell death play a large role in the development of specific connections between sensory and motor neurons.

55.8

NETWORK ACTIVITY, AFFERENT ACTIVITY AND THE ROLE OF NMDA CHANNELS IN SYNAPTIC PLASTICITY IN VITRO.

R.D. Fields, C. Yu* and P.G. Nelson. Lab. of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Three factors which may be involved in the mechanism of activity-dependent synaptic plasticity: (1) electrical activity of afferents converging on a postsynaptic neuron, (2) activity in the neuronal network impinging on the postsynaptic neuron, and (3) NMDA channels, were studied in a multicompartment tissue culture chamber containing neurons dissociated from the mouse spinal cord (Nelson et al., Science, 1989). A three-way analysis of variance showed that synapses from stimulated afferents developed significantly stronger EPSPs than unstimulated convergent afferents ($p < 0.03$). Suppression of the network activity also significantly increased the amplitude of EPSPs from both active and inactive convergent afferents ($p < 0.01$), but the effect of blocking the NMDA channel depended on network activity ($p < 0.0001$; interaction term). If network activity was not suppressed, the NMDA channel antagonist APV (100 µM) inhibited the competition between active and inactive convergent afferents; but when network activity was suppressed with medium containing 3 mM Ca^{++}/3 mM Mg^{++}/5 nM TTX, the activity-dependent competition between convergent afferents was not inhibited by the NMDA channel antagonist. These changes in amplitude of synaptic potentials were paralleled by similar changes in the number of synaptic connections. As the medium used to decrease network activity contained elevated calcium, the influence of high calcium under normal network activity needs to be examined (Nelson, P.G. et al., these proceedings).

55.9

NMDA RECEPTOR AND CALCIUM INVOLVEMENT IN SYNAPSE ELIMINATION. P.G. Nelson, C.Yu*, R.D. Fields and D. Brenneman. Lab. of Dev Neurobiology, NICHD, NIH, Bethesda, MA 20892.

In medium containing 1.8 mM calcium and 100 μM amino-phosphonovaleric acid (APV), a specific blocker of the N-methyl-d-aspartate (NMDA) receptor, the activity-dependent plasticity occurring in APV-free medium in a spinal cord (SC)-dorsal root ganglion culture system (Fields, R.D., et al., these proceedings) is blocked. In media containing elevated calcium (3 mM) plus 100 μM APV, plasticity does occur despite the NMDA receptor blockade. The number of unstimulated afferents synaptically connected to each VH neuron was significantly reduced in medium containing 3 mM calcium + APV compared to unstimulated afferents in medium containing APV but normal (1.8 mM) calcium. The stimulated afferents connected to SC neurons in the two conditions were not significantly different. Thus, the elimination of connections from unstimulated afferents occurred in high calcium medium and was not dependent on NMDA receptor activation. Previous experiments (Brenneman, D., et al., J. Cell Biol., 104:1603, 1987) have shown that neural activity is accompanied by release of VIP which stimulates release of neurotrophic material from glia cells. We propose a dual effect of neural activity (1) a synapse (and perhaps neuronal) elimination process dependent on calcium ingress into neurons through NMDA and non-NMDA channels; (2) a synapse and neuronal stabilizing effect mediated by neurotrophic material released from glia in response to specific stimulation by neurally released glial secretogogues such as VIP. These processes and their appropriate spatial and temporal organization could subserve activity-dependent neural circuit formation in the developing brain.

MUSCLES DENERVATED AT BIRTH ARE REINNERVATED BY A NEW POPULATION OF MOTONEURONS. S. Presley*, and L. Ziskind-Conhaim. Dept. of Physiology and Center for Neuroscience, University of Wisconsin, Madison WI 53706

We have examined whether denervated muscles of newborn rats are reinnervated by the original or by a new motoneuron population. Fluoro-Gold (FG), a long-lasting fluorescent dye, was injected into one intercostal muscle (T_8) to retrogradely label its motoneurons. Two days later intercostal nerves T_7-T_9 were cut. Intercostal muscle T_8 was reinnervated within two to three weeks. Three to four weeks after axotomy tetramethylrhodamine isothiocyanate (TRITC) was injected into T_8 to label the population of motoneurons that reinnervated it. The Table summarizes the percentage of labeled motoneurons stained with FG, TRITC or double-labeled with FG and TRITC.

	2-3 days after birth		2-3 weeks after birth	
	axotomy	no axotomy	axotomy	no axotomy
FG	14*	38	36	29
TRITC	83	58	51	36
FG-TRITC	3	4	13	35
	(n=7)	(n=3)	(n=5)	(n=3)

*FG was absent in sections of 3 spinal cords.

Our results suggest that, in newborn rats, axotomy results in motoneuron death and muscle reinnervation by a new population of motoneurons. Supported by Research Career Development Award and NIH grant NS 23808.

DEVELOPMENT OF A NEURON-SPECIFIC TYPE III INTERMEDIATE FILAMENT PROTEIN AT THE RAT NEUROMUSCULAR JUNCTION. A.W. English, J.G. Wood, and G. Schwartz*. Dept. Anatomy & Cell Biology, Emory Univ., Atlanta, GA 30322

A type III intermediate filament protein has been described in adult motoneurons (57k IF, peripherin, clone 63) (e.g.Parysek and Goldman, J. Neurosci. 8:555, 1988). To examine its role in the development and stabilization of neuromuscular synapses, we examined its developmental appearance and localization in rat hindlimb muscles. In adults, 57k IF immunoreactivity (IR) was found in pre-terminal axons and throughout neuromuscular synaptic terminals. In embryos as young as E17, 57k IF was expressed in axons, but was not seen in terminals until P8. During early postnatal life, synaptic terminals associated with more than one 57k IF IR pre-terminal axon were seen uncommonly. Labelling of multiple synaptic terminals was found at these ages on muscle cells stained either for neurofilament proteins or for the microtubule asscociated protein Tau, but not with anti-57k IF. This selective presence of 57k IF at some synaptic sites but not others may be related to their ultimate survival of the process of synapse elimination. Supported by NS 20545.

JUVENILE ANDROGEN TREATMENT PERMANENTLY PREVENTS SYNAPSE ELIMINATION IN THE LEVATOR ANI MUSCLE . J.L. Lubischer, C.L. Jordan and A.P. Arnold, UCLA Dept. of Psychology, Los Angeles, CA 90024-1563.

In rats, the levator ani (LA) is one of the target muscles of motoneurons of the spinal nucleus of the bulbocavernosus (SNB). SNB cell size and number and the presence of the LA in adults are sexually dimorphic and can be masculinized by neonatal androgen treatment.

The pattern of innervation of the LA is also sensitive to the effects of androgen. Synapse elimination normally occurs between two and four weeks after birth. However, multiple innervation is maintained in the LA in juvenile castrates given daily androgen injections from postnatal day 7 (P7). This effect persists in the young adult rat (P63 and P90), even after androgen treatment has ended (at P34). The current study was undertaken to determine if this androgen-induced maintenance of multiple innervation is a permanent effect or if synapse elimination eventually occurs during adulthood in these animals.

Male rat pups (N = 5 per group) were castrated on P7 and given four weeks of daily subcutaneous injections of testosterone propionate (TP; 100 μg / 50 g body weight) or the oil vehicle. At 13 months of age, the LA was stained with tetranitroblue tetrazolium to visualize motor nerve terminals. Muscles were analyzed without knowledge of the hormone treatment received, and the percentage of fibers multiply innervated was determined for each muscle. Animals who received TP as juveniles showed elevated levels of multiple innervation in the LA (63%) compared to oil-treated animals (23%), despite the absence of androgens for one year. The effect of androgen on synapse elimination in the LA thus appears to be permanent.

EXPRESSION AND LOCALIZATION OF DIFFERENT GAP JUNCTION PROTEINS IN RETINA AND OTHER REGIONS OF THE CNS. EA Finch* and DL Paul* (Spon: SM Shankland) Prog. in Neuroscience and Dept. of Anatomy and Cellular Biology, Harvard Medical School.

The expression of different gap junction proteins in the CNS was studied using antibodies and cDNA's specific for either rat connexin32 (Cx32) or rat connexin43 (Cx43). The retina was examined by immunofluorescence because its distribution of gap junctions is well characterized. Staining patterns consistent with known gap junction size and distribution were observed in horizontal cells using anti-Cx32 antibodies in mouse, rabbit and monkey retina. Rabbit retinal ganglion cells and cells in monkey inner nuclear layer were also labelled with anti-Cx32 antibodies. Cx43 immunoreactivity was detected in mouse outer plexiform layer and outer nuclear layer, mouse pigment epithelium and the stria medullaris of rabbit retina. Anti-Cx43 antibodies also strongly labelled cell borders in mouse optic nerve. Cultured astrocytes, studied using Northern blot analysis and immunocytochemistry, exhibited high levels of Cx43 expression. Cx32 was not detected. The levels of Cx43 and Cx32 mRNA in different brain regions were assayed by Northern blot analysis. Highest levels of Cx32 mRNA were detected in spinal cord and brainstem, moderate levels in midbrain, caudate and thalamus, and lower levels in cortex, hippocampus, hypothalamus, and cerebellum. Cx43 mRNA was present at relatively uniform levels in all brain regions examined except cortex. These results suggest that Cx32, a junction protein associated with epithelial cell types, may be expressed in some neurons. Cx43, which is expressed in many mesenchymal cell types, is clearly expressed in some glia, although we do not exclude neuronal expression.

SUPPRESSION OF NEURONAL ACTIVITY DOES NOT AFFECT SPECIFICITY, STABILITY OR COUPLING RESISTANCE OF NEW ELECTRICAL SYNAPSES. R.C. Berdan and A.G.M. Bulloch. Department of Medical Physiology, University of Calgary, Calgary, Alberta, Canada T6G 2E9

Our aim was to determine whether Na+-dependent regenerative activity plays a role in synaptogenesis of electrical synapses between identified neurons following axotomy. Buccal neurons 4 and 5 from the mollusc, Helisoma trivolvis, were induced to extend neurites and form new electrical synapses within cultured buccal ganglia by axotomy. Electrical coupling occurs between heterologous and homologous neurons within five days after axotomy (J. Neurophysiol. 48:569, 1982). We compared the incidence of coupling and coupling resistance between neurons B4-B5 and the contralateral pair of neurons B5 after axotomy in the presence and absence of tetrodotoxin (TTX). TTX (2 X 10-5M) effectively and reversibly blocked activity of buccal neurons B19, 5 and 4. Neurite outgrowth was unaffected by its presence, as determined by filling neurons with Lucifer Yellow. No differences in the incidence of electrical coupling or the coupling resistance were detected in the presence of TTX within 5 days after axotomy. We conclude that Na+-dependent neural activity does not play a role in the formation, maintenance or specificity of new electrical synapses formed following axotomy. Supported by AHFMR and MRC of Canada.

DEVELOPMENT OF SYNAPTIC CONNECTIONS IN A FILIFORM HAIR INTERNEURON SYSTEM IN LOCUSTS. H.J. Pflüger. Institute of Neurobiology, Free Univ. Berlin, D-1000 Berlin 33, FRG

An identified locust interneuron (A4I1) extends from the brain to the first unfused (fourth) abdominal ganglion (A4). The cell body is in A4 and the main input zone in the prothoracic ganglion (PRO). Its receptive field includes filiform hairs on the prosternum, similar hairs on the pronotum and a few hairs of windsensitive head hair field 1, all projecting to the PRO. Hairs on the ipsilateral prosternum, pronotum and head connect monosynaptically with the ipsilateral interneuron. Those of the ventral prosternum connect with the contralateral interneuron. Epsps in A4I1 generated by receptor spikes differ enormously in size. A few connections are powerful enough to generate spikes within A4I1. It appears that the most powerful connections are made by hairs already present in a first instar. In following instars these hairs increase in length and become those most sensitive to air displacements. Developmental age may determine the number of synapses made with A4I1. Supporting this conclusion, smaller filiform hairs, which appear later in postembryonic development, have much weaker connections.

55.16

PATTERNS OF SYNAPTIC INTERACTIONS WITHIN A PERIPHERAL NERVE IN *DROSOPHILA*: IN WILDTYPE STRAINS AND IN *PASSOVER*. M.D. Egger, R.S. Nowakowski, B. Peng* and R.J. Wyman†. Dept. of Anatomy, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854; †Dept. of Biology, Yale University, New Haven, CT 06511.

The jump-flight escape response in the fruitfly, *Drosophila melanogaster*, is mediated in part by a peripherally synapsing interneuron (PSI) that synapses with axons which innervate the dorsal longitudinal flight muscles (DLM) (King & Wyman, (1980) *J. Neurocytol.* 9, 753-770). In a search for possible neuroanatomical defects in *Passover* (*Pas/Pas*), a mutant in which the jump-flight escape response is defective, we examined electron microscopically, at intervals of 0.7 μm, the patterns of synapses formed between the PSI and the DLM motoneuron axons in *Passover*, and in two strains of wildtype flies, Canton-S and Oregon-R. Because of the stereotypy of the anatomy of the posterior dorsal mesothoracic nerve (PDMN) in which the peripheral process of the PSI runs, each of the five DLM motoneuron axons can be recognized individually. The PSI processes and the DLM axons within the PDMNs displayed no obvious ultrastructural abnormalities in *Passover*. Synapses were located in the PDMN from near the thoracic ganglion to about 30 - 50 μm distal to it. The total numbers of synaptic contacts within the PDMN were similar for wildtype (mean: 46.0 for n = 8 nerves) and *Passover* (mean: 50.3 for n = 6 nerves). The cumulative distributions of synaptic contacts in both wildtype and *Passover* are fit closely by a function of the form $f(x) = A(1 - e^{-Bx})$, where x = the distance from the thoracic ganglion, and A & B are constants. With respect to the individual axons, the distributions of synaptic contacts between the PSI and the DLM motoneuron axons (percent total contacts on each axon) were as follows:

Axon:	#1	#2	#3	#4	#5
Wildtype:	4.4	21.5	16.9	25.3	32.1
Passover:	0.0	18.2	35.4	17.6	28.8

The *Passover* pattern differed significantly from that of the wildtype (χ^2 = 84.6, $p < 0.001$), with most of the difference accounted for by the contacts with axon #3.

55.17

CELL CONTACT REDUCES NON-SYNAPTIC CHANNEL ACTIVATION BY TRANSMITTER (5-HT) DURING SYNAPSE FORMATION. P. Drapeau, McGill Univ. Ctr. Res. Neurosci. & Montreal Gen. Hosp., 1650 Cedar Ave., Montreal, Quebec, Canada H3G 1A4.

When serotonergic Retzius neurons of the leech contact pressure sensitive (P) neurons in culture, they selectively reduce a cationic response to 5-HT and reform the inhibitory, Cl-dependent synapse seen in vivo. Single cationic channel recordings (cell-attached patches) were performed in order to determine whether the number or activity of the channels is reduced by cell contact.

The largest i observed at V_{rest} (~-50 mV) had a γ = 60 +/- 2 pS (n=11), V_{rev} = +62 +/- 1 mV (i.e. E_{rev}~+12 mV), P_{open}= 10^{-4}-10^{-3} and τ_{open} ~1 ms. This cationic channel was observed in 52% (26/50) of the patches recorded from single P cells. In the presence of 10 μM 5-HT, 69% (18/26) of these channels showed a 2-10 fold increase in the number (but not the duration) of openings. No other channels were activated by 5-HT at V_{rest} (near E_{Cl}).

Recordings from P cells paired with Retzius cells showed a similar incidence (56% - 24/43 patches) of this channel. However, only 21% (5/24) of these channels were activated >2 fold by 5-HT. These results suggest that activation (and not the number) of cationic channels is reduced upon cell contact. The early clearing of the non-synaptic (excitatory) response to 5-HT appears to be a prelude to (inhibitory) synapse formation.

Supported by the MRC, FRSQ, and FCAR of Canada.

TIME COURSE OF LOCAL CEREBRAL GLUCOSE UTILIZATION (LCGU) ALTERATIONS AFTER MOTOR CORTEX ABLATION IN THE RAT. R.L.Sutton, D.A.Hovda, and H.T.Chugani. Brain Res. Lab., Rutgers Univ., Newark, NJ 07102 and UCLA School of Med., Los Angeles, CA 90024.

The quantitative 2-[14C]deoxyglucose autoradiographic method of Sokoloff et al. (1977) was used to compare LCGU in normal rats to that of rats sacrificed at 1, 3, 9 or 15 d. after right (R) sensorimotor cortex (SMC) ablation. Injury reduced LCGU in R and left (L) cortex (parietal, prefrontal, temporal, occipital), with largest decreases at d. 3 (L: -4.3 to -12.1%; R: -15.1 to -18.6%). LCGU in L SMC decreased on d. 1 & 3 (-3.1 to -2.9%) but increased 13.9% by d. 15. Greatest subcortical reductions in LCGU occurred at d. 1 or 3 in the n. accumbens, caudate, medial dorsal, anterior, & ventrobasal thalamic n. (L: -3.8 to -11.8%; R: -9 to -17.6%), with smaller reductions in the red n., nigra, locus coeruleus, cerebellar n. & globus pallidus (L:-1.3 to -7.3%; R: -2.6 to -8.1%). Reduced LCGU in cerebellar cortex (Crus I) at d. 1 & 3 was greater ipsilateral to injury (L: -7.7 to -10.1%; R: -8.3 to -10.6%). Gradual recovery towards normal LCGU values is evident by d. 9 to 15 in all regions, with some showing hypermetabolism. Data on LCGU alterations at 6, 12, 20 & 30 d. postinjury will also be presented. Support: USPHS Grant HD-07032.

AN IN VITRO MODEL OF RAPID ACCELERATION CNS INJURY (RAI) J.H. Lucas and A. Wolf*, Dept. of Biological Sciences and Center for Network Neuroscience, The University of North Texas, P.O. Box 5218, Denton TX 76203

We have developed an in vitro model of RAI which utilizes a ballistic pendulum impact apparatus. Impacts are delivered to flasks containing monolayer cultures of mouse embryo brain or spinal cord tissue. Impacts can be either tangential or normal to the plane of growth. The magnitude of an impact is expressed as Impulse (J) which equals the maximum momentum transferred to m_2. Thus, $J = m_2 [2gh]^{1/2}$. By measuring the impact duration (T), we can obtain force ($F = J/T$) and acceleration ($A = F/m_2$, also monitored by a g-meter). Initial studies have examined the effects of multiple tangential RAI on nerve cell survival. Six small neuronal circuits (5-10 cells each) were selected in separate regions of each flask. Flasks were given 5 or 10 tangential impacts (J_{cum} = 17.5 or 35 N·s). Time between impacts was approx. 3 s. The culture medium was removed just before RAI and replaced immediately after the last impact. Viability was determined by erythrosine B at 15 min, 2 h, 24 h, and 48 h after RAI. Mean cell death after 5 impacts was 37%, 41%, 40% and 34%. Mean cell death after 10 impacts was 40%, 44%, 43% and 51%. In the control group (medium removal, no RAI) mean cell death was 4%, 7%, 7% and 8%. Each mean represents 3-5 separate observations (flasks). Preliminary data indicate that tangential RAI are more damaging than normal RAI of the same J_{cum}. Cell death starts at cumulative tangential accelerations above 350g.

Planned studies will compare the effect on survival of: 1) multiple and single RAI of the same J_{cum} and 2) multiple RAI of the same J_{cum} but different intervals between impacts. We will also examine subcellular reactions to normal and tangential RAI including: 1) damage due to organelle shifts, 2) changes in DNA, RNA and protein synthesis, and 3) stress responses. Supported by the Hillcrest Fndtn. of Dallas, TX.

56.3

FOCAL STIMULATION OF STRESS PROTEIN SYNTHESIS DJ Gower, RS Glasser Section on Neurosurgery and Department of Anatomy, University of Oklahoma, Oklahoma City, OK 73103

Stress protein (SP, heat shock protein) synthesis is a primary cellular response to trauma. Barbe et al (1988) demonstrated in vivo protection of the retina from light damage was possible if the SP synthesis was initiated, by elevation of core body temperature, 18 hours prior to light exposure. This project develops a model with SP synthesis in a single retina without stressing the entire animal.

Anesthetized rats were administered 2ul intraocular injection of a 1mM solution of ten test substances known to induce the SP response in culture. The opposite (control) eye was injected with carrier vehicle only. Eighteen hours after injection the retinas were harvested and evaluated using 2-D gel electrophoresis and western blots probed with antibodies against SP-70 (H11, H7, N27 kind gift of Dr. William Welch). Silver nitrate, cadmium and arsenite are effective stimulants of retinal SP synthesis.

These data suggest that SP synthesis can be stimulated in a small subset of cells in vivo and this model will be useful to study the role of SP's in the protection of CNS from injury.

56.4

ANATOMICAL BASIS OF SENSORY MOTOR DYSFUNCTION FOLLOWING TRAUMATIC BRAIN INJURY. A.S.Merians, A.W.Deckel University of Medicine and Dentistry of New Jersey, Newark, N.J. 07107.

Defining morphological changes occurring post TBI in relationship to changes in behavior provides an understanding of the anatomical basis of sensory motor dysfunction. Previous work demonstrated that this impact model manifests persistent behavioral deficits resembling the hemiplegia, balance and tactile deficits evident clinically. Lesioned animals demonstrated dysfunction in vertical locomotor activity, sensation, and balance and increased ipsilateral rotation at 1, 3 and 6 weeks. There were consistent changes in peripheral physiology and metabolic brain activity.

Image analysis was used to quantify the morphological effects of TBI on 23 rats (10 control and 13 lesion). Analysis indicates a decrease in the depth of the neocortex and the area of the striatum, and an increase in the area of the ventricles ipsilateral to the lesion. Stepwise regression analysis using these neuroanatomical measures to "predict" behavioral outcome measures indicates that the left anterior striatum and neocortex are strongly associated with the regulation of horizontal movement in the controls, while in animals with left TBI this relationship shifts. The ipsilateral or contralateral neocortex and the contralateral striatum become dominantly associated with locomotor activity.

ALTERATION OF CUTANEOUS SENSATION FOLLOWING BURN INJURY. R.S. Ward,* J.R. Saffle* and R.P. Tuckett. Dept. Physiol., Univ. Utah School of Medicine, Salt Lake City, UT 84108.

Though alterations in cutaneous sensation following severe burn injury have been frequently reported, there have been few quantitative psychophysical studies of such changes. Sensory testing was performed on burn patients (N=60) ranging in age from 18-65 years (mean [M] = 34) with burn size ranging from 1-60% of total body surface area (M = 27%). All patients had undergone skin grafting. Fifty-eight patients (97%) exhibited significantly diminished or absent responses to sharp/dull, hot/cold and light-touch over their grafted areas. Deep pressure sensation remained intact (N = 60). In all but one case the difference between measures in normal skin and skin in donor areas or in areas of healed (ungrafted) partial thickness burns was not significant. Grafted areas in which some dermis remained intact (i.e., tangentially excised, deep partial thickness burns) showed significantly greater recovery than full thickness or deeply excised areas of injury. In addition, patients described alterations in sensation including chronic pruritus (25%) and pain (25%). There was no significant correlation between sensory loss, age, burn size or type of burn. In conclusion, alterations in sensory profile following thermal injury can be highly significant both in terms of sensory deficit and ongoing sensations of pruritus and pain. Supported by USPH grant NS15102.

56.6

A PHOTOCHEMICALLY-INDUCED SPINAL CORD INJURY MODEL. V.R. Holets, A. Salvatierra, R. Prado, M.B. Bunge, R.P. Bunge and B.D. Watson[1]. Depts. of Neurological Surgery and [1]Neurology, Univ. of Miami, Miami, FL 33136.

The goal of the present study was the development of a spinal cord injury model with characteristics similar to the human lesion. Using a modification of the photochemical method of spinal cord injury in non-laminectomized rats (Prado et al, J Neurosurg 67:745, 1987), a model has been developed in which there is a central cyst, lesion of the entire central grey at the epicenter, and demyelination of some white matter tracts.

Young adult rats received a photochemically-induced spinal cord lesion using a focused argon dye laser beam and the photosensitizer Rose Bengal. Two to four weeks later, the animals received an injection of lysolecithin into the cyst at the epicenter of the lesion (T7). Immediately after surgery the animals had flaccid paralysis of the hindlimbs, but recovered some movement of the hindlimbs after 3-5 days. Histological examination using one micron thick plastic sections showed demyelination of the some white matter tracts in the ventral and ventrolateral funiculi. Future studies will demonstrate the physiological and functional consequences of this lesion. The potential use of this model for transplantation of cells into the repository provided by the cyst will also be examined. Funded by The Miami Project and The Daniel Heumann Fund for Spinal Cord Research.

Delayed loss of function, and long term recovery after spinal cord compression in the rat. J.A. Gruner, K. Sakatani, H. Iizuka*. Dept. of Neurosurgery, NYU Medical Ctr., 550 First Ave., New York, NY 10016.

Following spinal cord injury (SCI) a period of delayed or "secondary" cell damage or death is presumed to occur, which constitutes the primary rationale for efforts to develop clinical SCI treatments. Still, there is little evidence to support this assumption, and no model of the phenomenon. Here we report on the course of recovery of somatosensory evoked potentials (SEP) and auditory evoked "startle" responses (ASR) after spinal compression in the rat.

Rats were anesthetized with sodium pentobarbital. Using sterile surgical procedures, the skull was exposed and 3 metal screws implanted for recording SEP. Metal staples were placed over the vastus laterals (VL) and tibialis anterior (TA) muscles of the hindlimb for recording ASR. A laminectomy was performed to expose the cord at T8 with the dura left intact. A 40 gram vascular clip was used to compress the sides of the cord for 5-20 sec. SEP were recorded before and after laminectomy, and 10 min after compression. At 24 and 48 hrs and 1, 2, 4, and 8 wks after injury, SEP and ASR were recorded. ASR were evoked in the awake animal by a 10 ms tone, after which SEP were evoked by sciatic stimulation under light ketamine anesthesia.

The predominant response pattern following compression was a partial to complete loss of SEP at 10'. Several animals showed strong SEP at 10' and complete loss at 24 hours; all animals showed some deficit at 24 hours. SEP and ASR amplitudes recovered in parallel between 48 hours and 8 weeks, reaching maximum after 4 weeks. ASR and SEP during this period appeared correlated with motor function. Thus animals which could support and move their limbs at 24 hours showed ASR and SEP, while completely paralyzed animals did not. As animals progressively became able to move their hindlimbs, then achieve full standing posture, and finally locomote (generally by 4 weeks), ASR and SEP also progressively improved. In conclusion, a) rat spinal cord compression may represent a useful model of delayed SCI, and b) ASR appear to provide a reliable motor function test for awake rats.

56.8

DYNAMICS OF EXTRACELLULAR LACTATE, PYRUVATE, ASCORBATE, AND PURINES FOLLOWING BRAIN CONTUSION IN THE RAT. L.Hillered (1,2), P.Nilsson*(2), U.Ungerstedt*(3), and U.Pontén*(2).
Depts. of Clinical Chemistry(1) and Neurosurgery(2), University Hospital, S-751 85 Uppsala, and Dept. of Pharmacology(3), Karolinska Institute, Stockholm, Sweden.

The aim of this study was to measure changes in extracellular energy metabolite levels following a compression contusion trauma. A craniotomy (6x9 mm) was made over the right parietal cortex in artificially ventilated rats. A microdialysis probe (CMA/10, Carnegie Medicin, Stockholm) was inserted stereotaxically into the cortex at the medial edge of the craniotomy. The probe was perfused with Ringer solution (2 ul/min) using a CMA/100 microinjection pump (Carnegie Medicin) and samples were collected in 10 min fractions for 2 hours after implantation. At that time the probe was removed and the contusion device put in position. After the trauma, the probe was reinserted into the same position within 45 s, using the stereotaxic instrument. Microdialysis samples were collected for another 2 hours following this procedure, and analyzed by HPLC. The trauma induced a dramatic increase in the dialysate concentration of lactate, ascorbate, adenosine, inosine, and hypoxanthine while pyruvate increased slightly. The changes virtually normalized within 2 hours. In control animals (subjected to removal and reinsertion of the probe without the trauma) no concentration changes occurred.

56.9

XANTHINE OXIDASE IN EXPERIMENTAL SPINAL CORD INJURY (ESCI) C.Y. Hsu, J. Xu*, J.S. Beckman*, P.L. Perot Jr.* and E.L. Hogan (SPON: N.L. Banik) Depts. of Neurology and Neurosurgery, Medical University of South Carolina, 171 Ashley Avenue, Charleston, SC 29425, USA; and Dept. of Anesthesiology, University of Alabama, Birmingham, AL 35233, USA.

Conversion of xanthine dehydrogenase (XDH) to xanthine oxidase (XD) may produce oxygen free radicals which are mediators of inflammation, and have been implicated in the pathogenesis of brain edema. Proteolytic formation of XO may be mediated by calpains which are activated in ESCI. We studied XDH and XO activity in ESCI using a sensitive fluorometric assay. Trauma caused an increase in both XDH and XO activity (Sham: XDH, 27±2 μunits mg protein, XO, 10±1 [N=11]; Trauma XDH, 51±7, XO, 21±3 [N=9]). Allopurinol (AL) treatment (100mg/kg, IP x 1 hr prior to and 6 hr after trauma) resulted in no detectable XDH or XO activity in traumatized spinal cord. AL treatment did not affect post-traumatic edema formation (H_2O content, control 76.54±0.30 %; AL 76.67±0.32, N=10) or polymorphonuclear cell (PMN) infiltration (myeloperoxidase activity, control 1.29±0.17 units/g wet weight, AL 1.14±0.15, N=15). The results suggest that if oxygen free radicals contribute to post-traumatic edema and PMN infiltration in ESCI, XO is not likely to be the main source of free radicals.

56.10

LACK OF EFFICACY OF A 21 - AMINOSTEROID IN THE RAT VENTRAL SCI MODEL E.Wilcoxson*, E.C.Benzel, T.Woods*, M.Fowler*, J.Lancon*, L.Kesterson*, T.Hadden*

A ventral rat SCI model was used to test the efficacy of a 21-aminosteroid, U74500A. 39 animals were studied in 2 groups: (1) treatment group (1 mg/kg at 45 min and 0.5 mg/kg U74500A I.P. at 2 1/2 hrs following lesioning), and (2) control group. Subsequent to pre and postinjury neurologic assessment, histologic evaluation at the level of injury and 1 cm above the injury was also performed. No difference between treatment and control groups was noted with respect to neurologic outcome or histologic changes. The lack of efficacy of U74500A is in contrast to previously published data. Perhaps the use of a different 21-aminosteroid, the use of the same agent at a higher or lower dose or its administration at a different time following lesioning may offer superior results. The model utilized may also yield results which are at variance with other techniques. It should be kept in mind, however, that the model used here closely mimics the human SCI pathophysiological situation and that it may be a more appropriate model for the assessment of potentially useful therapeutic regimens.

56.11

OPIOID VS. NON-OPIOID MECHANISMS OF DYNORPHIN A-INDUCED PARALYSIS: INVOLVEMENT OF κ-OPIATE AND N-METHYL-D-ASPARTATE (NMDA) RECEPTORS. R. Bakshi* and A.I. Faden.(SPON: B.Lester) Center for Neural Injury, University of California, San Francisco, CA 94121.

Endogenous dynorphin A (Dyn A)-related peptides may contribute to the pathogenesis of spinal cord injury. Intrathecal administration of such peptides causes paralysis; these include Dyn A(1-17) and Dyn A(1-13), which bind to opiate receptors, as well as Dyn A(2-17) and Dyn A(2-13), which are inactive at opiate receptors. It has been suggested that either opiate receptor antagonists or N-methyl-D-aspartate (NMDA) antagonists may modify effects of intrathecal (i.t.) Dyn A. In the present studies, the κ–active opiate receptor antagonist nalmefene, the κ-selective antagonist nor-Binaltorphimine (nor-BNI), the competitive NMDA antagonist CPP, and non-competitive NMDA antagonist dextrorphan were tested for their ability to modify rat hindlimb paralysis produced by Dyn A(1-17) and Dyn A(2-17). Intrathecal pretreatment with each of the drugs significantly limited the acute motor dysfunction ($p<.005$) and mortality ($p<.05$) associated with Dyn A(1-17). Effects of nor-BNI and CPP were dose related ($p<.01$). However, while CPP and dextrorphan also significantly attenuated the paralytic effects produced by Dyn A(2-17) ($p<.005$), nor-BNI and nalmefene did not. From these data we suggest that Dyn A-induced paralysis includes an opioid component involving κ-opiate receptors and a non-opioid component involving NMDA receptors.

56.12

SEPARATE ROLES FOR SODIUM AND CALCIUM IN NEURONAL INJURY. **D. G. Emery, J. H. Lucas and G. W. Gross. Zoology Dept., Iowa State University, Ames IA 50011, and Biology Dept., University of North Texas, Denton, TX 76203.**

After laser dendrotomy, neurons from dissociated mouse spinal cord cultures were examined by TEM. After injury in medium with normal Na and Ca, mitochondria (MIT) were dilated, many vacuoles formed in the cytoplasm, and the cytoskeleton (CS) was disrupted. Vacuoles appeared in the somata before vacuolization in the dendrite had spread to the perikaryon, indicating a two-phased pathology. If all extracellular ions were replaced with sucrose, dendrotomy had little effect on ultrastructure. After injury in low-Ca, MIT did not dilate but became electron dense, and many vacuoles formed in dendrites and somata. In low-Na few vacuoles formed in somata after injury. The sodium ionophore, monensin, caused dilation of the Golgi in uninjured neurons. Dilation of the Golgi also occured with monensin if isothionate replaced the extracellular Cl.

Therefore, we hypothesize the following roles for ions in physical injury: rows of vacuoles in injured dendrites (dilated smooth endoplasmic reticulum) are due to Na and Ca influx through the lesion. Dilation of Golgi is due to general influx of Na, perhaps due to neuronal depolarization after injury. MIT dilation and CS disruption are due to influx of Ca through the lesion. There is no clear role for anions (chloride) in physical trauma.

56.13

ALTERATION IN EXTRACELLULAR AMINO ACIDS AFTER TRAUMATIC SPINAL CORD INJURY S. Scott Panter, Sabrina W. Yum*, Paul Demediuk, and Alan I. Faden., Department of Neurology (127), University of California San Francisco and Veterans Administration Medical Center, San Francisco, CA 94121.

Tissue damage following spinal cord trauma is diminished by the posttraumatic administration of N-methyl-D-aspartate antagonists, suggesting that excitatory amino acids (EAA's) play a significant role in the secondary injury response. Using microdialysis, we have studied the concentrations of extracellular amino acids in rabbit spinal cord after the administration of impact trauma. Nine different excitatory, inhibitory, and non-transmitter amino acids were evaluated; the extracellular concentration of each was elevated following trauma. Of note were the prolonged elevations of glutamate, aspartate and glycine. Following moderate (40 gm-cm) trauma, the concentrations of glutamate, aspartate, and glycine increased 357, 261, and 330%, respectively. Peak levels were detected 10 minutes posttrauma but returned to control values by 20 minutes. Following severe (150 gm-cm) trauma, a more significant elevation of glutamate, aspartate and glycine was observed, attaining increases of 410, 542, and 454%, respectively. Peak levels were measured at 20 minutes posttrauma, and a significant elevation was maintained for 50-60 minutes. Peak concentrations of glutamate, aspartate, and glycine were elevated beyond levels that might arise from the leakage of plasma free amino acids into the injury area. These results are consistent with the hypothesis that EAA's may contribute to delayed tissue injury after CNS trauma.

56.14

EFFECTS OF ANTAGONISTS OF EXCITATORY AMINO ACIDS ON FUNCTIONAL DEFICITS AFTER CONTUSIVE SPINAL CORD INJURY. M. Reynolds*, C. McCauley*, B. Sullivan* and J. Wrathall (SPON: H. Bernstein-Goral). Dept. of Anat. & Cell Biol., Georgetown Univ., Washington, D.C. 20007.

Recent studies indicate a potential role of excitatory amino acids (EAA) in traumatic injury of the brain and spinal cord. To investigate this hypothesis we examined the effects of EAA antagonists present at the time of injury on functional deficits resulting from a standardized contusive spinal cord injury. Rats were anesthetized with chloral hydrate, cannulated for intravenous drug infusion and a laminectomy performed at the T8 vertebral level. They were randomly assigned to groups (n = 12) receiving the EAA antagonists MK-801 (1 mg/kg), dextromethorphan (10 mg/kg), kynurenate (KYN, 300 mg/kg), or controls receiving an equal volume of saline. One half of the total dose was given 5 min prior to, and the remainder 15 min after a moderate contusive injury. Functional deficits were assessed at 1, 7, 14, 21 and 28 days after contusion using a battery of behavioral tests. All groups showed maximal deficit at 1 day with recovery of some function over time. However, the KYN group showed greater and especially more rapid recovery of several hindlimb reflexes as well as weight-bearing and use of the hindlimbs in locomotion. There was a significantly better combined behavioral score (CBS) by day 14. The results suggest that EAA-mediated processes may be involved in some aspects of the functional deficits resulting from contusive injury.

56.15

NMDA-RECEPTORS MEDIATE ACTIVATION OF THE c-fos PROTO-ONCOGENE IN A MODEL OF BRAIN INJURY. D.G. Herrera and H.A. Robertson. Department of Pharmacology, Faculty of Medicine, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7

The proto-oncogene c-fos is rapid and transiently induced in central nervous system by a variety of stimuli. Brain injury, disruption of pia-arachnoid in a limited area, is one of the situations that leads to a dramatical increase in c-fos immunoreactivity. This increase is limited to the lesioned hemisphere Injection of atropine (25 mg/kg i.p.), naltrexone (5 mg/kg i.p.), nifedipine (5 mg/kg i.p.), and W7 (20 mg/kg i.p.), prior to the injury, did not affect the activation of c-fos as assesed by immunohistochemistry in adult Sprague-Dawley rats perfused two hours after the lesion. The non-competitive NMDA antagonists ketamine (100 mg/kg i.p.) and MK-801 (3 mg/kg i.p.) markedly reduced c-fos activation. PCP (10 mg/kg i.p.) produced a slight reduction in damage-induced c-fos activation. This study suggests that c-fos activation in this particular model is N-methyl-D-aspartate receptor-mediated and supports the idea that the c-fos proto-oncogene might play a role in plasticity and/or neurotoxicity.

HYPOTHERMIA PROTECTS SPINAL CORD NEURONS AFTER INJURY
G. Wang*, J. H. Lucas, and G. W. Gross, (SPON: J.B.Kirkpatrick) Center for Network Neuroscience, University of North Texas, P.O. Box 5218, Denton, TX 76203

There have been many investigations of the protective effects of low temperature following spinal cord injury (SCI). Despite strong interest, the therapeutic efficacy of hypothermia is still controversial. The cascade of responses to SCI in the intact animal makes it difficult to determine the specific action of a given intervention. In the present study we used an in vitro model of injury to evaluate the direct effects of low temperature on neuron survival after dendrite amputation.

A laser microbeam was used to transect primary dendrites from mouse spinal cord neurons growing in monolayer cultures. In each experiment, 10 neurons were operated and 10 others served as unoperated controls. Lesion distance was 100 μm from the soma of each operated cell. Experiments were performed as pairs with one culture at a reduced temperature and one at 37°C. After 2 h at the selected temperatures (T), erythrosine B was used to determine cell viability.

Studies to date have shown that the probability of nerve cell survival 2 h after lesioning is a function of 1/T. At 27°C survival was 70% ± 9 (SD) compared to 60% ± 9 survival at 37°C. At 17°C survival was 86% ± 13 compared to 68% ± 8 at 37°C. At 7°C survival was 100% compared to 56% ± 6 survival at 37°C. There were 5 matched pair experiments in each study. Unoperated control survival was 100% in all studies.

Below 17°C both lesioned and control neurons tended to swell, and, upon rewarming to 37°C, some cells died. One day after lesioning, viability of nerve cells maintained initially at 17°C for 2 h and then restored to 37°C was 64% ± 11; viability of operated normothermic neurons was 50% ± 12 (N=5 pairs of experiments). These data suggest that low temperature not only slows cell deterioration, but may actually increase the numbers of neurons which survive a physical trauma. Experiments are in progress to determine whether longer intervals at 17°C will cause a further increase in cell survival. We will also examine how soon after injury hypothermia must be applied in order to be effective.

EXOGENOUS AND ENDOGENOUS OPIATES AFTER SEVERE HEAD INJURY R.S. Zimmerman,*[1] R.L. Hayes[1], D.L. Morris,*[2], and W.L. Dewey[2] Divisions of Neurosurgery[1] and Neuropharmacology[2] Medical College of Virginia, Richmond, VA 23298

It has been suggested that release or production of endogenous opiates after brain trauma worsens the prognosis for neurological recovery. Thus, the present study was undertaken to examine if an association existed between acute levels of endogenous opiates in ventricular CSF (vCSF) and functional outcome. All severely head injured patients at the Medical College of Virginia were entered into a uniform treatment protocol which included the placement of a ventricular catheter. Samples of vCSF were obtained <24 hrs after injury in 15 patients. Immunoreactive beta endorphin (ir-βE) was then quantified with radioimmuno assay. Ir-βE had *no* significant correlation with either 6 month or 1 year outcome based on the Glascow Outcome Score, even when stratified by age, sex, or initial degree of injury. However, levels of ir-βE *were* significantly lower if the patients had received exogenous opiates for sedation (85.9 pg/ml vs. 47.4 pg/ml with morphine sulfate, $p<0.05$). These results suggest that 1) there is no correlation between acute vCSF ir-βE levels and long-term outcome after severe head injury, and 2) systemic administration of exogenous opiates (morphine) reduces the level of ir-βE in vCSF.

HISTOCHEMICAL AND BEHAVIORAL CHANGES FOLLOWING EXPERIMENTAL BRAIN INJURY IN RAT. D. Becker, B. Shook, L. Gorman, and Y. Katayama. BRI, Depts. Neurosurgery and Anatomy & Cell Biology, UCLA Med. School, Los Angeles, CA 90024.

Cytochrome oxidase (CYO) histochemistry and an operantly conditioned bar press (bp) were used to study the effects of fluid percussion (animal model of concussion). The effects were compared to normals and sham operates.

Fluid percussed rats exhibited a selective absence of oxidative metabolism in the medial septum and hippocampal cell layers. Sham operates showed a mild decrease in CYO activity in the same regions. These effects cannot be attributed to a contusion, since in all animals the intervening striatum showed no deficit in metabolic activity.

Relative to pre-operative bp rates (mean = 13.39 bp/min), post-injury rates covaried with the extent of CYO activity; percussed mean = 2.07 and sham mean = 5.94 bp/min.

This is the first report of a localized functional deficit which correlates with a concussive behavioral disorder.

57.2

MEASUREMENT OF DEPRESSION LEVELS IN MINOR HEAD INJURED ADOLESCENTS USING EEG SLEEP AND PSYCHOMETRIC TESTS. L. C. Parsons, and T. Britt*, Sleep Lab., College of Nursing, Univ. of Ariz., Tucson, AZ 85721.

One purpose of this study was to correlate the relationship between electroencephalographic (EEG) sleep variables indicative of depression with psychometric measurements of depression in persons following Minor Head Injury (MHI) within 72 hours, 6 weeks, and 12 days of injury. Sleep variables which identified depression were latency to the first rapid eye movement (REM) period, expanded time in the first REM period, decreased deep (delta) sleep, early morning awakening, and increased sleep stage cycling. The psychometric instruments used to measure depression were the Beck Depression Inventory (BDI) and the Center for Epidemiologic Studies-Depression (CES-D). The sample consisted of 20 subjects, 10 adolescent MHI patients and 10 gender and age matched control subjects. The variables of gender and age were treated as covariates during statistical analysis. Randomization was achieved by matching MHI patients with control subjects. ANOVA was used to determine significant changes within groups. Independent t-tests were used to assess between group differences. Findings indicate that depression levels when measured using the BDI and CES-D were significantly higher ($p < .05$) in the MHI group when compared to the control subjects at the measured time intervals. Alterations within the sleep patterns of the MHI patients indicative of depression were also identified. Interpretation of these data raise two questions, 1) were the MHI patients depressed before the injury and if so could this have contributed in some way to their accident, or 2) could the MHI have contributed to the depression levels? Identified depression indicators within the sleep patterns appeared to support the hypothesis of a preexisting depression. Factors indicative of depression in both the EEG sleep pattern and psychometric tests may provide a profile related to the time course of depression following MHI.

REPAIR OF DAMAGED SQUID GIANT AXON. P.E. Gallant, K. Hammar* and T.S. Reese. Laboratory of Neurobiology, NINDS, NIH, & Marine Biological Laboratory, Woods Hole, MA 02543

Repair of mechanically injured squid giant axons was studied with four microscopic techniques, dark-field and DIC microscopy of living axons and light and electron microscopy of fixed axons, at various intervals after injury. After transection constriction of the axon began within mins near its severed ends and progressed for approximately 1 hr. A condensed plate of axoplasm formed at the neck of this constriction 50-100 μm from the cut end. This condensed axoplasm marked the densest part of the white area formed at the cut ends of living axons and it shrank radially as the axon progressively constricted. The axolemma and cytoskeletal elements closest to the transection were severely disrupted but became progressively more normal until they finally appeared completely normal at 500-600 μm from the transection; they remained normal for up to 10 hrs after transection. In living axons punctured with a micropipette a small plate of disrupted axoplasm developed and soon surrounded the puncture site. The disruption of axoplasm, axoplasmic whitening and constriction were inhibited when the extracellular calcium, magnesium and chloride were replaced with sodium aspartate. What powers axonal constriction is unclear, but an ion-dependent contraction of the axoplasm might be responsible since the axoplasm in the constricted area occupied progressively less space without folding, while the axolemma, Schwann cells, and connective tissue became highly folded around the shrunken axoplasm.

TASKS TRADITIONALLY USED TO ASSESS CALLOSAL FUNCTION REVEAL PERFORMANCE DEFICITS ASSOCIATED WITH MILD CLOSED HEAD INJURY. B.D.Fantie† and B.Kolb, Psychology Dept, University of Lethbridge, Lethbridge, Alberta, Canada T1K 3M4.

Neuropathological studies have consistently indicated that there is disproportionately severe damage to the corpus callosum in cases of closed head injury (CHI) and that this can occur in cases when the trauma seems relatively minor. Our aim was to determine if we could assess hemispheric disconnection or callosal dysfunction in the processing of various stimuli presented preferentially to one hemisphere or the other. Visual stimuli (words, alphabetic trigrams, and numerals) were tachistoscopically presented (150 ms) to the right or left of a fixation point and the subjects were required to identify verbally what they had just seen. A haptic information transfer test required subjects to match small patterns of pinheads using only their sense of touch. On the visual task, the CHI group (n=18, mean age=24 years, mean WAIS-R IQ=114) made more errors identifying words, $F(1,43)=4.50$, $p=.040$, and alphabetic trigrams, $F(1,43)=4.60$, $p=.038$. Males did more poorly than females overall ($F(1,23)=7.66$, $p=.011$) and were more affected by injury. The CHI group also made more errors on the haptic transfer task, $F(1,99)=14.22$, $p<0.001$. Therefore, we have evidence that CHI causes deficits in the performance of tasks traditionally used to assess callosal functioning. Although likely the consequence of some degree of callosal dysfunction, the pattern of results is not compatible with a simple hemispheric disconnection explanation. HEAT SHOCK PROTEIN EXPRESSION IN RAT BRAIN AFTER EXPERIMENTAL BRAIN INJURY. T. McIntosh, H. Soares, M. Gonzalez and F. Sharp, Dept. of Surgery, Univ. of Conn. Health Ctr., Farmington, CT 06032 and Dept. Neurology, Univ. California San Francisco, CA 94121.

Heat shock proteins (HSPs) of 70-80 kDa molecular weight are synthesized in the mammalian brain in response to a variety of stressors including hyperthermic shock, ischemia and various pharmacological agents. Recently, Gonzalez et al (1989) suggested that the 72 kDa HSP (HSP72) may be used as a marker of cellular injury in the mammalian brain. Little is known concerning the response of HSPs to traumatic brain injury. We examined whether HSP72 expression was correlated with the severity of injury following experimental fluid-percussion (FP) traumatic brain injury. Male Sprague-Dawley rats (350-400 g, n=12) were anesthetized with sodium pentobarbital (50 mg/kg i.p.) and subjected to mild (1.9-2.0 atm), moderate (2.3-2.4 atm) or severe (2.7-2.9 atm) parasaggital FP brain injury centered over the left parietal cortex. All rats were sacrificed at 48 h postinjury, 50-100um coronal sections were cut and reacted immunohistochemically using a monoclonal antibody to HSP72 and the avidin-biotin-peroxidase (ABC) method. Moderate FP brain injury but not mild or severe injury induced dark, specific HSP72 immunostaining in the injury site (left parietal cortex), left hippocampus and right (contralateral) hippocampus. This pattern of immunostaining coincided with previous histological data on neuronal damage produced by FP brain injury. Although it is unclear whether cells exhibiting HSP72 immunoreactivity survive or die, these results suggest that HSP72 immunocytochemistry may be used to identify injured cells in neural tissue after traumatic brain injury.

ALTERATIONS IN BRAIN NEUROPEPTIDE Y AFTER EXPERIMENTAL BRAIN INJURY. V. Head*, H. Soares, D. Ferriero and T. McIntosh (SPON: S. Wentzel). Dept. Surgery, Univ. of Conn. Health Ctr., Farmington, CT 06032 and Dept. Neurology, Univ. of California, San Francisco, 94143.

Immunocytochemical studies have demonstrated that cerebral blood vessels are supplied by perivascular nerve fibers containing Neuropeptide Y (NYP)-like immunoreactivity. NPY has also been implicated in cerebral vasospasm. Although vasospasm may be involved in the pathophysiological sequelae of traumatic brain injury, nothing is known of the response of central NPY to brain trauma. Male Sprague-Dawley rats (n=40) were anesthetized with pentobarbital (50 mg/kg i.p.) and subjected to fluid-percussion (FP) brain injury centered over the left parietal cortex. Animals were sacrificed prior to injury (baseline) and at 1 min, 15 min, 1 h and 24 h following brain injury. Regional brain homogenates were analyzed for NPY concentration using radioimmunoassay. A second group of animals (n=4) were sacrificed at 15 min postinjury, brains sectioned and subjected to NPY immunocytochemistry. No significant changes in NPY were observed in the contralateral (uninjured) cortex, brainstem or hypothalamus. NPY concentrations increased significantly at the injury site within the first minute postinjury ($p < 0.05$), reached a peak at 15 min ($p < 0.05$) and remained significantly elevated up to 1 h postinjury ($p < 0.05$). At 15 min, NPY immunoreactive neurons were present at the injury site and around the areas of hemorrhage. By 24 h postinjury, NPY concentrations had returned to baseline values. These data demonstrate that NPY concentrations are elevated acutely in the injury site after brain injury and suggest that NPY may be involved in the pathophysiology of posttraumatic cerebral vasospasm or ischemia.

RESERPINE PRETREATMENT BLOCKS AMPHETAMINE FACILITATED LOCOMOTOR RECOVERY FOLLOWING SENSORIMOTOR CORTEX ABLATION. K.A. Krobert, S.A. Queen*, & D.M. Feeney. Depts. of Phys. and Psych., UNM, Albuquerque, NM. 87131.

Unilateral injury to sensorimotor cortex (SMCX) produces a transient contralateral hemiplegia observed on a beam walking (BW) task. A single administration of amphetamine (AMPH) given 24 hrs after SMCX injury, combined with BW experience, produces an enduring facilitation of BW recovery. Prior work implicated norepinephrine in this promotion of functional recovery (Crit. Rev. Neurobiol., 3(2):135-197.). To further assess differential roles of catecholamines, this study examined the effect of reserpine given prior to AMPH. Reserpine enhances AMPH evoked striatal dopamine (DA) release and behavioral stereotypies (TIPS, Oct, 1983., p.429-432). If the AMPH facilitation of recovery from hemiplegia involves striatal DA, reserpine pretreatment should enhance this effect. Rats received a right SMCX ablation or sham surgery and at 20 hrs post surgery received a BW test, showing normal BW in sham controls and hemiplegia in SMCX rats. Reserpine (5 mg/kg;i.p.) abolished BW performance. At 4 hrs post-reserpine (24 hrs post-surgery), AMPH (2 mg/kg;i.p.) or saline was administered. During the first hr after AMPH, both SMCX and sham animals displayed a marked increase in activity and motor stereotypies. For 2 hrs after AMPH BW performance returned to normal in sham controls. However, for reserpinized SMCX rats given AMPH, BW performance only returned to pre-reserpine baseline disability levels. These results indicate reserpine blocks the enduring AMPH facilitation of BW recovery after SMCX lesion but not AMPH evoked "striatal DA" activity and stereotypies. Supported by DHHS RO1 NS20220-03.

d-AMPHETAMINE ATTENUATES LEARNING AND MOTOR DEFICITS FOLLOWING CORTICAL INJURY IN RATS. G.L. Dunbar, G.A. Smith*, S.K. Look*, and R.J. Whalen*. Department of Psychology, Central Michigan University, Mt. Pleasant, MI 48859.

In this experiment, we examined whether daily treatments of d-amphetamine counteract lesion-induced learning and motor deficits when rats were not under amphetamine "intoxication" (i.e., when injections were given 22 hrs prior to testing). Rats were given unilateral aspiration lesions of the frontal cortex or sham surgery, followed by IP injections of saline or d-amphetamine. Injections started immediately (seconds) after surgery and were given at 24 hr intervals for 15 days. Postoperative testing on a balance beam and a linear maze began the day after surgery and continued daily for 15 days. d-Amphetamine-treated rats with lesions (AL) showed less impairment on a balance beam task than saline-treated rats with lesions (SL). However, d-amphetamine treatments caused initial disruptions on this task for the sham-operated rats, compared to saline-treated sham-operated rats (SC). Maze acquisition was facilitated by d-amphetamine treatments for both rats with lesions and those with sham operations, compared to their respective saline-treated counterparts. In addition, AL rats made significantly fewer errors than SL rats, and performed at the same level as SC rats. These results indicate that (1) d-amphetamine treatments can attenuate lesion-induced learning and motor deficits, and (2) these effects can occur when specific training is dissociated from acute amphetamine "intoxication."

EFFECTS OF ALCOHOL INTOXICATION ON RECOVERY OF SENSORY CONDUCTION AFTER SPINAL CORD TRAUMA. **S. Katz, H.F. Martin, Dept. of Physiology and W.O. Boggan, Dept. of Psychiatry. Medical University of South Carolina, Charleston, South Carolina, 29425.**

The objective of this study is to clarify the role of alcohol on spinal cord transmission following trauma to the spinal cord. The results of this study should enable us to develop a model to better predict prognosis of spinal cord injured patients who were intoxicated at the time of injury.

Previous experimental studies found that acute intoxication may potentiate the outcome of spinal cord injury resulting in increased spinal cord necrosis and impaired functional recovery. There is however, a paucity of information relating blood to tissue alcohol concentration at the time of trauma and to the degree of recovery from injury. The initial studies in this investigation measured the blood and tissue ethanol concentration produced at various times after a 15 min. infusion of 5, 10, or 15% solution of ethanol in saline. The 15% solution produces a blood concentration of 173.8 mg%, and spinal cord and brain concentration of 7.81 and 9.42±1.51 mg/gm tissue, respectively. The effect of alcohol intoxication on the recovery of sensory conduction was studied by obtaining somatosensory evoked potentials (SEP's), before and after impact trauma to rat spinal cord. Recovery of SEP's are compared between ethanol treated rats and control animals given a caloric equivalent sucrose solution.

CHANGES IN PHOSPHOLIPID PHOSPHORUS CORRELATE WITH INCREASED BRAIN PHOSPHOLIPASE C ACTIVITIES FOLLOWING TRAUMATIC BRAIN INJURY IN THE RAT. B. Vishwanath*, G. Clifton*, R. Franson*, B. Lyeth, R. Hamm, L. Jenkins and R. Hayes. Department of Biochemistry & Molecular Biophysics and Division of Neurosurgery, Medical College of Virginia, Richmond, Va 23298.

Previous studies of traumatic brain injury (TBI) have demonstrated disturbances in arachidonic acid metabolism in both the cat and rodent (J Neurochemistry 37:892, 1981; J Neurotrauma 5:331, 1988) and changes in total phospholipase C (PLC) activity in the cat (J Neurosurgery 56:695, 1982). However, the activity of specific brain PLCs following rodent or cat fluid percussion injury have not been measured. In the present study, both acid and neutral pH sensitive PLC activities were evaluated 5 minutes following moderate fluid percussion injury (2.2 ATM) and compared to sham animals. Phospholipid phosphorus alterations in whole brain homogenate were correlated with in vitro measurements of phospholipase C activity in homogenate and supernatant fractions using [N-methyl-^{14}C] sphingomyelin (SM) and ^{3}H-phosphatidylinositol (PI) as substrates. Five min post-injury, total phospholipid phosphorus (umols/mg) was decreased 9.1±1.2% (mean ± SEM). At the same time metal-ion independent PLCs, most active at pH 4.5-5.0, hydrolyzing SM and PI, were increased 25±8.3% and 35±6.8%, respectively. Mg^{2+}-dependent PLC mediated hydrolysis of SM at neutral pH was increased 106±21%. These results demonstrate that loss of phospholipid phosphorus immediately following TBI in the rat is associated with activation of both acid and neutral active PLCs.

MOVEMENT RELATED CORTICAL POTENTIALS (MRCP) IN POST ACUTE TRAUMATIC BRAIN INJURED (TBI) SUBJECTS. A. Nativ,* R. Rosas-Ramos* and R. Balliet* (SPON: P. Bach-y-Rita). Neuromuscular Retraining Clinic, Dept. of Rehab. Med., Univ. of Wisconsin, Madison, Wisconsin, 53705.

Slow cortical potentials, putatively associated with the planning and initiation of simple goal directed forearm and finger movements, were recorded in post-acute, hemiplegic, TBI and in normal control subjects to operationally define motor related brain dysfunction. Subjects activated a mechanical trigger with either flexion of the index finger, or by flexion or extention of the elbow. Two seconds of movement related EEG activity were recorded from frontal and parietal electrodes placed on the scalp according to the 10/20 system and averaged on line by a Nicolet Pathfinder 1 computer.

Post-acute TBI subjects showed reduced MRCPs compared to the control group for hemiplegic arm movements, and also, to a lesser degree, for movements of their relatively 'non-affected' arm. TBI subjects also demonstrated unusual waveforms (e.g., opposite deflections in homologous recordings) and uncharacteristic cross-cortical MRCP correlations associated with specific electrode configurations, as well as with specific movement conditions. These preliminary data suggest that, aside from its general sensitivity to motor related brain dysfunction in clinical populations (e.g., Shibasaki et al., 1987; Barrett et al., 1987), the study of MRCPs may also offer a non-invasive diagnostic tool to investigate specific cerebral disorders associated with motor dysfunction.

57.12

DURA EXERTS LONGITUDINAL TENSION ON SPINAL CORD, B.R. Fink, Anesthesiology, Univ. of Washington, Seattle, WA 98195.

The tendency of spinal dura mater to retract upon incision was investigated. Direction of connective tissue fibers was evaluated in an orthogonal morphometric survey on human posterior L3-4 dura from three autopsies; in x5000 micrographs the dural collagen fiber bundles pursued wavy, irregular courses whereas the elastic fibers took rectilinear orthogonal paths, either longitudinal or transverse in approximately equal quantity. In Papio, Macaca, and sheep laminectomized 1-2 h after death longitudinal or circumferential incision of dura led to spontaneous separation of cut edges by up to one third of the cord diameter, depending on the length of the cut. Partial transverse dural incision followed by complete transverse section of cord produced a wedge-shaped gap which lengthened as the dural incision was extended circumferentially and suddenly became cylindrical and surged to 3% of the cord length when the last shred of the dural circumference was divided. Successive transections at T9, L3, and T3 were each followed by a similar train of events, indicating that in the non-humans, including fetal lambs, probably the entire length of the cord was under longitudinal tensile stress originating in the dura. The human functional significance of dural elasticity is unclear and raises important questions regarding repair of cord injury.

EVALUATION OF THE EFFICACY VERSUS SAFETY OF SPINAL CORD STIMULATION FOR THE GENERATION OF MOTOR EVOKED RESPONSES. S. Sabato*, C.A. Agresta* and S.K. Salzman. Alfred I. duPont Institute, Research Dept., Wilmington, Delaware 19899.

Direct and indirect spinal cord stimulation paradigms were evaluated for their ability to produce viable motor evoked potentials (MEPs) versus their effect on spinal function. Male Sprague-Dawley rats (N=50) were anesthetized with pentobarbital (60 mg/kg, i.p.) and positioned in a spinal stereotaxic unit. A laminectomy was performed at T6, and bipolar silver ball stimulation electrodes were positioned 0.5-1.0 mm above the intact dura and covered with saline. In other animals, stimulation was obtained from screw electrodes threaded into the intact spinous process. Varying intensities of both constant voltage and constant current stimulation were employed. MEPs were recorded as compound muscle action potentials (cMAPs) using bipolar platinum needles inserted into the quadriceps muscle. Spinal cord function was evaluated using three methods: somatosensory-evoked potential (SEP) morphology during the experiment, post-operative neurologic testing, and post-mortem spinal serotonin content and metabolism.

Stimulation intensities sufficient to produce a reproducible N-P or N-P-N complex (latency of 7, 8 and 10 msec, respectively) in the recorded cMAP consistently resulted in neurologic deficits, SEP abnormalities and depletion of spinal serotonin when stimulation was applied directly to the cord. In contrast, with intraspinous stimulation, lower intensities were required to obtain reproducible cMAPs and spinal function was always preserved. Implications for intraoperative spinal cord monitoring of motor function are discussed.

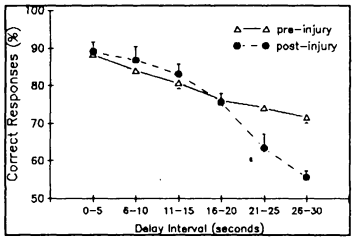
VISUAL REHABILITATION TRAINING IN BRAIN-DAMAGED PATIENTS. H.J. Markowitsch^{+} and K. Pommerenke^{+} (SPON: ENA), Fac. of Psychology, Univ. Bochum, D-4630 Bochum, Fed. Rep. Germany

In patients with damage of the occipital lobe and some surrounding brain tissue it was investigated whether it is possible to use computer programs as screening tests to diagnose visual field defects. Second, visual exploration was trained using an electronic reading and exploration training apparatus (ELEX). With ELEX it was hoped to increase the visual field or search field - measured by standard perimetric conditions - even a considerable time after brain damage. Thirdly, ELEX was used to improve reading performance with respect to speed, number of errors, comprehension.



While a number of quite specific relations were found between various variables in individual patients, the overall results indicated that specific training may improve reading abilities even after a considerable post traumatic period, and that a computer monitored perimetry is an effective screening device. On the other hand, a training dependent expansion of the visual field could not be established unequivocally.

EFFECTS OF EXPERIMENTAL TRAUMATIC BRAIN INJURY ON SHORT-TERM MEMORY. C.H. Napper*, D.S. Prough*, D.S. DeWitt* (SPON: J. Turner) Dept. of Anesthesia, Bowman Gray Sch. of Med., Winston-Salem, NC 27103

Impairment of short-term memory is the most common cognitive disorder reported by patients following traumatic brain injury (TBI). Short-term memory deficits assessed using the 8-arm radial maze occur in rats following TBI (Lyeth, et al, Soc Neurosci Abstr 13:1253, 1987). Our study examines the effects of fluid percussion injury (FPI) on memory using a delayed matching-to-sample (DMTS) task (Dunnett, SB: Psychopharm 87:357-363, 1985) in rats.

Male Sprague-Dawley rats (n=5) were water restricted to 85% of their free-feeding weight and trained to a stable performance level on the DMTS task prior to moderate FPI (2.3 atm.). After injury, animals were assessed daily for short-term memory deficits.

Pre-injury, rats achieved 88.4±0.5% correct responses at shortest delays (0-5 sec.) and 71.7±2.5% correct responses at longest delays (26-30 sec). These values are comparable to values previously reported in rats (see Dunnett). After injury, memory performance at shortest delays remained at pre-injury levels (89.7±1.2%). At longest delays, performance dropped to 55.7±1.7%. These data indicate that TBI produces deficits in short-term memory which persist for several days. (Supported, in part, by NS 19355)

ATTENUATION OF SYNAPTIC TRANSMISSION IN HIPPOCAMPAL SLICES FOLLOWING WHOLE ANIMAL EXPOSURE TO IONIZING RADIATION. G.E. Hollinden and T.C. Pellmar. Physiology Dept., AFRRI, Bethesda, MD 20814

Ionizing radiation directly alters neuronal excitability in vitro (Tolliver & Pellmar 1987, Rad. Res. 112, 555). However, in vivo many other factors (e.g. blood flow, neuromodulators) are likely to influence CNS function. To examine the contribution of these factors to neuronal deficits, we irradiated male guinea pigs in vivo (20 and 50 Gy, 20 Gy/min, 60-Co radiation) and prepared slices of hippocampus from animals euthanized 30 min, 1 day, 3 days or 5 days post-radiation. Hippocampal slices were incubated 1-2 hrs, transferred to a submersion chamber and perfused with aCSF (30°C). A stimulating electrode was placed in s. radiatum. Recording microelectrodes were placed in s. radiatum to record the afferent volley and population postsynaptic potential and in s. pyramidale to record the population spike. Following a 30 min equilibration period, an input-output curve was produced by varying stimulus intensity from 0 to 0.5 mA.

Both 20 and 50 Gy γ-radiation decreased synaptic transmission and spike generation at 3 days post-radiation. The combination of longer survival and in vivo exposure revealed deficits at 20 Gy, a previously ineffective dose.

57.17

IONIZING RADIATION ALTERS ELECTROPHYSIOLOGY OF HIPPOCAMPUS IN VITRO. T.C. Pellmar, D.A. Schauer*, and G.H. Zeman*. Physiology and MRA Dept., AFRRI, Bethesda, MD 20814-5145

A new x-ray source has made it possible to directly examine radiation damage to isolated neuronal tissue. With the x-ray machine inside a lead Faraday cage, electrophysiological properties can be recorded before, during and immediately after exposure.

Hippocampal slices were prepared from euthanized guinea pigs and placed in a submersion chamber perfused with aCSF (1-2 ml/min; 30°C). The afferent volley and population synaptic response (pPSP) were recorded in s. radiatum of CA1. The population spike was recorded in s. pyramidale of CA1. Afferents to CA1 in the s. radiatum were stimulated (0.2 Hz) to monitor slice excitability. By varying stimulus intensity (0.0 to 0.5 mA, 300 μs), input-output (I/O) curves were obtained before, 5, 30, and at some doses, 60 min. after radiation exposure (17 keV x-rays; 1.5 Gy/min, 5 to 65 Gy). I/O curves in control slices were obtained at similar time points.

Following exposure to doses as low as 40 Gy the pPSP was enhanced, reaching a steady level soon after exposure. The ability of the pPSP to generate a spike was reduced and damage progressed after termination of the radiation. No unusual activity was observed during the exposure. These results demonstrate that an isolated neuronal network can show complex changes in electrophysiological properties following moderate doses of ionizing radiation.

57.18

EXTRACELLULAR ELECTRIC FIELD EFFECTS IN A MODEL OF MAMMALIAN MYELINATED MOTOR NERVE EXCITABILITY. J.D. Sweeney[1,3], K. Deng[2*], E. Warman[3] and J.T. Mortimer[3]. (1) Dept. Chem., Bio., and Materials Engin., Arizona State Univ., Tempe, AZ 85287; (2) Dept. Elec. Engin. and Applied Physics, and (3) The Applied Neural Control Lab., Dept. Biomed. Engin., Case Western Reserve Univ., Cleveland, OH 44106.

Neural Prostheses elicit changes in the excitability of the nervous system through the introduction of electric fields. By solving for the extracellular electric field created by a neural prosthesis, and by modelling the excitability changes elicited by the field, we can potentially improve the design of neural prosthetic electrode systems and predict their performance. Towards this goal, our present objective has been to determine the effects of changes in extracellular electrode type and position (e.g. monopolar or linear; aligned or offset with respect to nodes) and extracellular medium conductivities (e.g. isotropic, anisotropic) using an improved version of a previously developed computer model of mammalian myelinated motor nerve [see Soc. Neurosci. Abstr. 12:1306, 1986]. In this compartmental cable model (implemented in FORTRAN, and run on an IBM AT with INMOS transputer) the nodal and internodal parameters are based on known or estimated mammalian peripheral nerve values [from e.g. J. Physiol., 292:149, 1979; J. Physiol., 298:171, 1980]. For a given motor axon diameter, electrode type and configuration, and extracellular medium representation, strength-duration curves have been generated (and fit to Lapicque's and Weiss's equations) for rectangular current stimuli with pulse widths of 10 to 500 usec. In general, representation of the extracellular space as a highly anisotropic medium increased both spatial selectivity and selectivity relative to axon size (although, for very small monopolar electrode-node separations axon size selectivity was minimal). In all instances, increased electrode-node separation or offsetting an electrode over the internodal region resulted in larger chronaxies.

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: CRH

58.1

THE EFFECTS OF CRH IMMUNONEUTRALIZATION ON ULTRADIAN RHYTHMS OF PLASMA ACTH IN THE RAT. M. Carnes, S.J. Lent*, S. Erisman*, J. Saydoff, C. Mueller*. VA Medical Center and University of Wisconsin, Madison, WI 53705.

Time series of plasma ACTH concentrations reveal circadian and ultradian rhythms. The diurnal surge of ACTH has been shown to require endogenous CRH. To determine whether ultradian fluctuations in plasma ACTH also require CRH, 6 rats were immunoneutralized with 0.5 ml i.v. of an antiserum raised against rCRH (anti-CRH) and 6 rats were given 0.5 ml normal rabbit serum as a control (NRS). All rats had jugular and femoral venous cannulae inserted at least 48 hr prior to blood sampling. Blood was withdrawn by peristaltic pump at 35 ul/min from the jugular cannula with simultaneous infusion of warmed, extracted rat plasma into the femoral cannula. Two-minute samples were collected for 4 hr. Plasma was assayed for irACTH. Resultant time series were analyzed by PULSAR (P) and Cluster Analysis (C). Comparison of pulse parameters identified in anti-CRH and NRS groups revealed a significant decrease in amplitude (P,C), and area (C) in anti-CRH rats but no significant difference in frequency (P,C), interpeak interval (P,C), or peak width (P,C). These results suggest that some ultradian rhythms of ACTH secretion occur independently of CRH stimulation and support in vitro findings of an endogenous rhythm of ACTH release by the corticotroph.

58.2

SHORT-LOOP FEEDBACK EFFECTS OF ADRENOCORTROPHIC HORMONE ON CORTICOTROPIN-RELEASING FACTOR AND VASOPRESSIN-IMMUNOREACTIVITY IN THE PARAVENTRICULAR NUCLEUS. P.E. Sawchenko, The Salk Institute, La Jolla, CA 92037.

The observation that hypophysectomy (HYPOX) results in a more pronounced enhancement of corticotropin-releasing factor-(CRF) and arginine vasopressin- (AVP) immunoreactivity (IR) in the parvocellular division of the paraventricular nucleus (PVH) than does adrenalectomy (ADX) suggests a role for adrenocorticotrophic hormone (ACTH) in modifying peptide dynamics in this system. To test this notion, ACTH or vehicle was administered systemically via osmotic minipump for seven days to rats submitted to both HYPOX and ADX surgeries. Lower replacement doses (0.5 ug/day) of ACTH reduced the number of detectable AVP-IR cells in the parvocellular PVH to 53% of that seen in vehicle-treated HYPOX/ADX controls; the number of CRF-IR cells was not significantly affected. Higher doses of ACTH (2.0 ug/day) resulted in counts of AVP- and CRF-IR neurons that were 32% and 70%, respectively, of control values. Qualitatively, staining patterns for the two peptides in the external lamina of the median eminence generally followed the cell count data. The results suggest that ACTH can in fact serve as an inhibitor of corticotropin-releasing peptide expression in the PVH, and that AVP-IR appears to be preferentially targeted. The sites and mechanisms by which short-loop feedback effects may be exerted remain to be specified.

58.3

BED NUCLEUS OF STRIA TERMINALIS PROJECTIONS TO HYPOTHALAMIC PARAVENTRICULAR CRF, OXYTOCIN AND VASOPRESSIN CELLS IN THE RAT. D.J. Magnuson and T.S. Gray, Department of Anatomy, Loyola University Stritch School of Medicine, Maywood, IL. 60153

The present study was designed to determine whether the bed nucleus of stria terminalis (BST) projects to oxytocin, vasopressin and/or corticotropin - releasing factor (CRF) cells in the hypothalamic paraventricular nucleus (PVN). Phaseolus vulgaris leucoagluttinin (PHA-L) fibers and terminals were visualized with horseradish peroxidase-brown diaminobenzidine and then processed with standard immunocytochemistry for oxytocin, vasopressin and CRF cells with a glucose oxidase-nitro-blue tetrazolium reaction product. The densest projections to the paraventricular nucleus are from ventral portions of BST. Ventral BST projects to all parts of the PVN, with labeling densest in medial and lateral parvocellular nuclei and slightly less dense in anterior parvocellular nucleus. Lighter labeling was present in posterior magnocellular paraventricular nucleus and the least amount of labeling was in anterior magnocellular paraventricular nuleus. Ventral BST projections to the paraventricular nucleus are much heavier in contrast to central nucleus of amygdala projections to the same nuclei (Gray et al, Neuroendocrinology, in press, 1989). Brown PHA-L labeled fibers and terminals were found in close proximity to all three types of cell bodies throughout the PVN. Vasopressin and CRF cells were more likely to have BST PHA-L terminals in close proximity than were the oxytocin cells due to heavier projections to the caudal magnocellular and parvocellular areas of the PVN. The parvocellular regions of the PVN known to have projections to the autonomic spinal cord received heavy projections from ventral BST. The BST receives afferents from a variety of limbic areas including hippocampus, septum, amygdala, and insular and prefrontal cortex. Via BST projections to the PVN including oxytocin, vasopressin and CRF cells the limbic system can strongly modulate autonomic and hypothalamo-hypophyseal function. INVOLVEMENT OF CALCIUM IN RELEASE OF CORTICOTROPIN-RELEASING FACTOR (CRF) BY THE BOVINE MEDIAN EMINENCE. T.H. Welsh,* M.R. Sutton,* P.L. Chen,* P.G. Harms* and N.H. McArthur. Depts. of Animal Science and Veterinary Anatomy, Texas A&M University, College Station, TX 77843.

The involvement of calcium in the release of CRF by the bovine median eminence (ME) was studied in vitro. Individual ME halves from steers were perifused for 300 min with Krebs-Ringer bicarbonate medium (500-µl chambers; 5.5 mM glucose; 95% O_2:5% CO_2; 37°C; 1 ml/10 min fractions for CRF radioimmunoassay). ME halves were challenged for 30-min periods at 90 and 200 min of perifusion with depolarizing agents [50 µM veratridine (V) or 60 mM potassium (K^+)] in the presence or absence of calcium-free medium containing 1.25 mM EGTA. Depolarization with veratridine (a sodium channel activator; n=7) at 90 min of perifusion increased CRF release (from 130 ± 48 pg/ml pre-V to 378 ± 73 pg/ml at 30 min post-V). At 200 min of perifusion, veratridine treatment (n=3) also increased CRF release (from 14.6 pg/ml pre-V to 156 pg/ml at 30 min post-V). However, over a similar time period EGTA treatment (n=3) blocked V-induced CRF release (44.5 pg/ml pre-V vs 43.2 pg/ml at 30 min post-V). EGTA treatment also inhibited K^+-induced CRF release at 90 and 200 min of perifusion. The inhibitory effect of EGTA on veratridine- and potassium- induced CRF release supports the concept that release of this neurohormone by the bovine median eminence is calcium-dependent.

CHRONIC BEHAVIORAL STRESS INCREASES CRF IMMUNOREACTIVITY AND CRF/VP CO-LOCALIZATION. J.A.Barrett*, A.J.Silverman, A. Hou-Yu and D.D.Kelly, Depts. of Psychiatry and Anatomy & Cell Biol., Columbia Univ., & NYS Psychiatric Inst, NY,NY 10032.

We previously found that chronic stress increased the size, staining intensity and detectable number of CRF cells in the paraventricular nucleus. To evaluate whether stress-sensitive CRF cells might also contain vasopressin (VP), a synergist of CRF in the release of ACTH, we employed a double label protocol with antibodies against CRF and the glycopeptide portion of VP neurophysin (courtesy of A. Robinson). Five sets of male Fischer 344 rats were housed in groups of four. One from each group was removed and exposed to 240 hrs of stress (alternating 30-min sessions of white noise and of conditioned emotional response training), another to 72 hrs of stress, and a third served as a no-stress control. In the hypothalamus of intact control subjects, few cells were CRF positive, and only a very small percentage of these contained VP. Exposure to stress increased both the number of CRF and CRF/VP cells; the more prolonged the stress, the more numerous the cells. Because a pilot study suggested that isolation housing might also alter stress-sensitive CRF cells, the remaining subject from each group was isolated for 4 weeks. Relative to the group-housed controls, isolation stress markedly enhanced both the number of detectable CRF cells and the proportion of these containing VP. These results illustrate the sensitivity of CRF cells to the behavioral history of the individual, in particular, the prior exposure to stress. NS 23858

HIPPOCAMPAL-HYPOTHALAMIC CIRCUITS MEDIATING TONIC INHIBITION OF THE HYPOTHALAMO-PITUITARY-ADRENOCORTICAL (HPA) AXIS. I.P. Herman, E.A. Young, A. Savina* and S.I. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

Removal of the hippocampus results in up-regulation of the ACTH secretagogues corticotropin-releasing hormone (CRH) and vasopressin (VP) mRNA in the parvocellular paraventricular nucleus (PVN) and in increased release of corticosterone and β-endorphin into plasma (Herman et al., J. Neurosci., in press). These data are consistent with the hypothesis that hippocampus exerts a tonic inhibitory influence on the HPA axis. In an effort to define presumably multi-synaptic hippocampal-hypothalamic circuitry mediating this inhibition, electrolytic lesions were made to the fimbria-fornix or medial corticohypothalamic tract (MCHT) of Sprague-Dawley rats. Expression of CRF mRNA in the PVN was analyzed by semi-quantitative *in situ* hybridization histochemistry, and ACTH in plasma was determined by RIA. Fimbria-fornix lesions, which disrupt the majority of hippocampal outflow to subcortical structures connecting with PVN, results in a two-fold increase in CRF mRNA in PVN and a significant rise in plasma ACTH. MCHT lesions, which specifically interrupt connections between the ventral subiculum and hypothalamus, had no effect on either CRF mRNA or plasma ACTH. Results indicate that inhibitory pathways between hippocampus and hypothalamus are carried in the fimbria-fornix system exclusive of the MCHT. Primary structures receiving afferents from the fornix and projections to the PVN or proximity include the lateral septum and bed nucleus of the stria terminalis; studies are presently being conducted to determine the role of these nuclei in HPA regulation. Supported by MH422251, NS08267.

EFFECT OF LOCUS COERULEUS LESIONS ON mRNA EXPRESSION AND CSF LEVELS OF CORTICOTROPIN RELEASING HORMONE IN RAT. Evagelia Mamalaki*, Linda S. Brady, Sam Listwak*, and Miles Herkenham (SPON: M. A. Smith) Unit on Functional Neuroanatomy, Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD 20892.

Although norepinephrine stimulates *in vitro* release of corticotropin releasing hormone (CRH), previous studies have provided conflicting results regarding its effects on the CRH system *in vivo*. Levels of CRH in the cerebrospinal fluid (CSF) and CRH mRNA in the hypothalamic paraventricular nucleus (PVN) were assessed in male Sprague-Dawley rats with electrolytic destruction of the locus coeruleus (LC) or no lesion CSF (100-250µl) was drawn from the cisterna magna 4 days before and again 10 days after the operation and assayed for CRH by radioimmunoassay. Cryostat-cut sections through the PVN and LC were hybridized with ^{35}S-labeled oligonucleotide probes for CRH mRNA and tyrosine hydroxylase mRNA, respectively, and exposed to film for quantitative autoradiography. CRH levels in CSF were unaffected by the lesion (p>.05). CRH mRNA in the PVN was increased by unilateral and bilateral lesion of the LC (p<.03):

Condition	CSF CRH levels (pg/ml)	CRH mRNA (µCi/g tissue)
Control (N=4)	24.2 ± 6.1	3.2 ± 0.2
Bilateral LC lesion (N=4)	31.4 ± 5.6	3.9 ± 0.7
Unilateral LC lesion (N=4)	31.0 ± 9.8	3.5 ± 0.3

The data suggest that the LC has a minor influence on hypothalamic CRH production but not on CSF levels of CRH in non-stress conditions. Further studies should be done to investigate the relationship of the central noradrenergic and CRH systems during stress.

58.8

NPY-INDUCED RELEASE OF HYPOTHALAMIC CRF IS POTENTIATED BY REDUCTION OF NORADRENERGIC/ ADRENERGIC NEUROTRANSMISSION. D.A.Haas and S.R.George. Depts.of Medicine and Pharmacology, Univ. of Toronto, Toronto, ONT, M5S 1A8, Canada

We have reported that neuropeptide Y (NPY) administration increases hypothalamic corticotropin-releasing factor (CRF) concentration and release (Life Sci. 47:2725, 1987), and that there exists a tonic alpha-1 adrenergic inhibition of CRF release (Can. J. Physiol. Pharmacol., 66:754, 1988). Since adrenergic neurons appear to regulate CRF, and are closely associated with NPY neurons anatomically, their role in the NPY-induced changes of CRF was investigated.

All studies conformed with the guidelines for experimental procedures and involved adult male rats. Noradrenaline and adrenaline were selectively depleted by i.c. 6-OHDA prior to administration of NPY. This resulted in decreased median eminence CRF ($p < .025$) and increased plasma adrenocorticotropin (ACTH) (26-fold compared to 6-OHDA treatment alone, $p < .0005$). NPY induced a 2-fold increase in ACTH without 6-OHDA treatment ($p < .05$). Administration of the alpha-2 agonist clonidine resulted in a significant decrease in median eminence CRF ($p < .005$) and a 24-fold increase in plasma ACTH ($p < .005$). All of these results are consistent with the release of hypothalamic CRF. Concurrent administration of clonidine with the alpha-2 antagonist yohimbine prevented the clonidine-induced changes in plasma ACTH and hypothalamic CRF, consistent with mediation of effect through alpha-2 receptors. These data imply that NPY stimulation of CRF release is inhibited by normal adrenergic tone. Depletion of these neurotransmitters allowed NPY to profoundly stimulate CRF release, a result common to alpha-2 stimulation.

58.9

EFFECT OF NEUROPEPTIDE Y (NPY) ON HYPOTHALAMIC-PITUITARY-ADRENAL FUNCTION IN THE RAT. T.C. Kamilaris*, A.E. Calogero*, E.O. Johnson*, S.J. Listwak*, M.T. Gomez,* P.W. Gold and G.P. Chrousos (SPON: G. Guroff). CNB/NIMH & DEB/NICHD, Bethesda, MD, 20892.

Neuropeptide Y (NPY), a 36 amino acid peptide, co-exists and is co-secreted with catecholamines at the terminals of catecholaminergic neurons. These include the ascending noradrenergic bundle neurons, originating from the central arousal/sympathetic system in the brainstem and terminating at the paraventricular nucleus of the hypothalamus, and the catecholaminergic cells of the adrenal medulla. Recent data indicate that catecholamines are excitatory to the corticotropin releasing hormone (CRH)-secreting neurons of the hypothalamus and to ACTH secretion by the rat pituitary corticotrophs. The purpose of this study was to evaluate the possible effects of NPY on the function of the hypothalamic-pituitary-adrenal (HPA) axis. Intravenous administration of NPY to chronically cannulated, freely moving male rats resulted in dose-dependent elevation of plasma ACTH and corticosterone concentrations. Previous sectioning of the pituitary stalk, and pretreatment with rCRH antisera or with dexamethasone significantly decreased or eliminated the plasma ACTH response to NPY, suggesting that NPY exerts direct effects on the hypothalamus stimulating secretion of CRH. Interestingly, however, in all of the above three situations there was an unexpectedly adequate plasma corticosterone response to NPY, consistent with direct effects of this peptide on the adrenal cortex. We hypothesize that NPY represents another link between the arousal/sympathetic system and the HPA axis on the levels of both the hypothalamus and the adrenal cortex.

58.10

POLYCLONAL ANTIBODIES AGAINST RECOMBINANT HUMAN PRE-PROCORTICOTROPIN RELEASING HORMONE (h-PRE-PROCRH). M.G. Castro*, R. Dils*, P. Saphier*, E. Linton*, D. Savva* and P.J. Lowry*.(SPON: Brain Research Assn., U.K.) Department of Biochemistry and Physiology, School of Animal and Microbial Sciences, University of Reading, Reading RG6 2AJ, United Kingdom.

Corticotropin releasing hormone (CRH) is cleaved from a larger precursor by the action of endopeptidases at pairs of basic amino acids. In this study we have expressed h-pre-proCRH fused to β-galactosidase in E. coli (TG2) and used the recombinant protein as a ready made hapten-carrier molecule for raising antibodies against h-pre-proCRH. A human pre-proCRH genomic clone (kindly provided by S. Numa) was digested with HinfI, the 584 base pair restriction fragment was blunt ended, ligated to BamHI linkers and cloned into the BamHI cloning site of the pUR292 expression vector. The recombinant plasmid was transformed into competent TG2 cells. The identity of the chimeric β-galactosidase-pre-proCRH was confirmed by western blotting using a rabbit anti h-proCRH fragment (a.a. 125-151) antibody, DomI, and a two site immunoradiometric assay using a radio-labelled sheep anti h-CRH (a.a. 36-41) antibody and the DomI antibody. The chimeric protein was purified by SDS-PAGE followed by electroelution and was injected into rabbits. The presence of specific antibodies was determined by binding studies using 125I-h-CRH (a.a. 1-41) and 125I-h-pro-CRH fragment (a.a. 125-151), and by western blotting using E. coli (JM83) expressing h-pre-proCRH as an unfused protein. The antibodies raised using this approach recognise the full length precursor as well as h-CRH-(1-41), hence, they should provide useful tools for studying post-translational processing as well as tissue distribution and different circulating forms of the CRH precursor.

ALTERED RATIO OF VASOPRESSIN (VP) TO CRF IN HYPOPHYSIOTROPHIC CRF NEURONS FOLLOWING ADRENALECTOMY. L.T. Bertini* and J.Z. Kiss*. Dpt. of Morphology, Univ. of Geneva, Sch. of Med., Geneva, Switzerland. (SPON: J.-J. Dreifuss)

Paraventricular CRF neurons represent the final common hypothalamic pathway that regulates pituitary ACTH secretion. CRF neurons seem to regulate ACTH secretion by releasing a neuromediator mixture including CRF and VP. Physiological evidence that: 1) VP potentiates the action of CRF on ACTH secretion, and 2) this potentiation is resistent to the inhibitory effect of dexamethasone, suggest that the ratio of VP to CRF is important in regulating ACTH release. Quantitative electron microscopic study was conducted to estimate VP and CRF immunoreactive sites over neurosecretory vesicles of CRF neurons in control and adrenalectomized rats. Immunoreactive sites were visualized on consecutive thin sections by the postembedding protein A-gold technique. Adrenalectomy significantly increases VP immunoreactive sites over neurosecretory vesicles while CRF immunostaining remains unchanged. In addition, the size of CRF/VP containing neurosecretory vesicle increased about 25% after ADX. These results suggest, that the quantitative proportion of VP to CRF is variable, and can be modified by endocrine manipulation such as adrenalectomy.

58.12

ANGIOTENSIN RECEPTORS IN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS REGULATE CRF RELEASE. E. Castrén and J.M. Saavedra. Dept. of Anatomy, University of Helsinki, 00170 Helsinki, Finland, and LCS, NIMH, Bethesda, MD 20892.

We have studied the role of hypothalamic angiotensin (Ang) receptors in the regulation of pituitary hormone release by measuring Ang receptor densities in the hypothalamic nuclei of hypophysectomized, adrenalectomized or repeatedly stressed rats.

Ang receptors in the parvocellular paraventricular nucleus (pPVN) were significantly decreased after both hypophysectomy and adrenalectomy. Replacement therapy with either gluco- or mineralocorticoid after adrenalectomy restored the receptor densities. After repeated stress, Ang receptors in the pPVN were significantly increased. Magnocellular PVN had a low number of Ang receptors, and these were regulated similarly to those in pPVN. Lack of vasopressin in Brattleboro rats did not influence Ang receptors in the PVN. Ang receptors were not found in the supraoptic nucleus.

These results suggest that Ang receptors in the pPVN regulate CRF release and might have a physiological role in the adaptation to stress.

58.13

CHRONIC ADMINISTRATION OF CORTICOTROPIN-RELEASING HORMONE (CRH) ATTENUATES PLASMA ACTH RESPONSE TO ETHER STRESS. Y. Tizabi and G. Aguilera* Dept. of Pharmacology, College of Medicine, Howard Univ., Washington, D.C. 20059 and Endocrinology and Reproduction Research Branch, NICHD, NIH, Bethesda, MD 20892.

The responses of the hypothalamic pituitary-adrenal axis during chronic stress are characterized by normal or slightly elevated plasma ACTH, increased hypothalamic CRH secretion, decreased pituitary CRH receptors and hypersensitivity of the ACTH and glucocorticoid responses to a superimposed stress. To determine the role of CRH in the pituitary hyperresponsiveness to a novel stress, pituitary CRH receptors and plasma ACTH responses were measured in rats receiving a minipump infusion of CRH, 3 μg/hr for 50 hr. Rats were killed by decapitation with or without prior exposure to ether vapors for 5 min. Blood was collected for ACTH RIA. Pituitary CRH receptor concentration, measured by binding of ^{125}I-Tyr oCRH was reduced by 45% in CRH infused rats, with no change in receptor affinity. Ether exposure had no effect on pituitary CRH receptors. Adrenal weight was significantly increased in CRH infused rats ($p<0.001$ n=21). Plasma ACTH levels were markedly increased after ether exposure in both groups ($p<0.001$). However, in contrast with the responses during chronic stress, the increases in ACTH were 40% lower in CRH infused rats ($p<0.05$, n=10). The data indicate that CRH alone does not account for the enhanced ACTH response to a novel stimulus superimposed on chronic stress and emphasize the multifactorial nature of the regulation of the corticotroph function.

58.14

CHRONIC ETHANOL TREATMENT LEADS TO REDUCED MEDIAN EMINENCE CRH AND PITUITARY POMC mRNA IN THE PRESENCE OF NORMAL PLASMA ACTH AND CORTICOSTERONE LEVELS. A. Thiagarajan, M. Grino*, M. Palkovits*, E. Mezey* and R. Eskay*. Laboratory of Clinical Studies, NIAAA and Laboratory of Cell Biology, NIMH, National Institutes of Health, Bethesda, MD 20892.

In order to explore the effects of ethanol on the hypothalamic-pituitary-adrenal axis from the acute-activation phase through the less-responsive, chronic-exposure period, male rats received a standard liquid diet containing ethanol via a gastric cannula to continuously maintain blood ethanol levels between 150-300 mg% for 0.5, 1, 3 or 7 days. Asynchrony between plasma ACTH and corticosterone (Cs) was observed with elevated Cs on 0.5, 1 and 3 days only of ethanol treatment. Plasma ACTH levels did not differ from controls at any time interval. Median eminence levels of CRH were reduced on days 3 and 7 without a change in hypothalamic CRH mRNA levels. Median eminence AVP and hypothalamic AVP mRNA remain unchanged throughout. Anterior and intermediate lobe POMC mRNA levels were reduced by 75 and 50%, respectively, only on day 7 of sacrifice. The lack of change in plasma ACTH levels during continuous ethanol exposure in spite of significant reductions in pituitary POMC mRNA and median eminence CRF suggests the involvement of other compensatory stress-axis regulators.

58.15

CORTICOTROPIN RELEASING FACTOR DECREASES SLOW WAVE (SW) SLEEP WHILE IT INCREASES RAPID EYE MOVEMENT (REM) SLEEP IN REM DEPRIVED RATS. F.Marrosu*, M.Giagheddu*, G.Mereu* and W.Fratta*. (SPON: S.L.Pocotte).Inst. of Neurology and Dpt. of Pharmacology, University of Cagliari, ITALY.

The intracerebro-ventricular injection of CRF causes behavioral modification known as "stress-like behavior" characterized by prolonged period of arousal, and complex hormonal manifestations (release of ACTH and endorphins etc.). We report here a novel action of CRF on the sleep patterns of REM deprived rats. The rats were REM deprived by keeping them for 72 hrs in a platform surrounded by water, then injected with 1 mg of rCRF. The animals showed an important delay in the first sleep onset, a strong decrease of SW while a prolonged REM sleep which lasted about 50% of the total sleep recorded in the first 100 min. Since CRF increases the firing rate of noradrenergic (NA) cells we might hypothesize that this action prolongs the "on-phase" in the NA cells (responsible for the long-lasting arousal) and that, soon after, the necessity of a prolonged restoration (or up-regulation) in NA system causes an increase in REM which is considered crucial in order to up regulate NA receptors.

58.16

CORTICOTROPIN SECRETAGOGUES HAVE DIFFERENT ELECTROPHYSIOLOGICAL ACTIONS IN AtT-20 PITUITARY CELLS. S. J. Kom, J. A. Connor and R. Horn. Neurosciences Dept., Roche Institute of Molecular Biology, Nutley, NJ 07110.

Stimulation of corticotropin (ACTH) secretion by corticotropin releasing factor (CRF) and β-adrenergic agonists is accompanied by a rise in intracellular [Ca^{++}] and cAMP. We are using the perforated patch recording method and fluorescent Ca^{++} indicators to examine the mechanisms by which these secretagogues act. With the calculated Cl^- equilibrium potential (E_{Cl}) set between -53 mV and -22 mV, AtT-20 cells had a resting potential of approximately -50 to -60 mV and spontaneously fired Ca^{++} action potentials (APs). CRF (30 nM) decreased the duration of, or abolished APs, and decreased the amplitude of Ca^{++}-dependent Cl^- currents (I_{Cl}). In contrast, isoproterenol (ISO; 1 μM) prolonged APs and prolonged I_{Cl} (E_{Cl}= -22 mV). Resting $[Ca^{++}]_i$ in AtT-20s, measured with fura-2, was 46.9 ± 23.8 nM (n=24). CRF (20-50 nM) and ISO (10 μM) stimulated a rise in $[Ca^{++}]_i$ to 446.9 ± 154.1 nM (n=9) and 285 ± 51.9 nM (n=8) respectively, but with different latencies. The CRF-induced [Ca^{++}] rise was delayed by ~25 sec (measured with 5 sec resolution) following the start of CRF application, and reversed very slowly. The ISO-induced [Ca^{++}] rise had a more rapid onset (~8-9 sec), and reversed rapidly after ISO application was terminated. These data suggest that CRF and isoproterenol may elevate intracellular Ca^{++} and stimulate secretion *via* different mechanisms.

NEUROTOXICITY: DOPAMINE

59.1

TOXIC EFFECTS OF POTENTIAL ENVIRONMENTAL TOXINS RELATED TO MPP+ ON RAT DOPAMINERGIC NEURONS IN CULTURE. F. Hefti, P.P. Michel, B.K. Dandapani*, B. Knusel*, J. Sanchez-Ramos*, and S. Efange.. Andrus Gerontology Center, U.S.C., Los Angeles, CA 90089.

Exposure of cultures of dissociated embryonic rat mesencephalic cells to 0.1-30uM MPP+ results in selective degeneration of dopaminergic neurons. At 10uM MPP+ reduced TH activity by 89%, the number of TH-positive cells by 85%, and [3H]dopamine uptake by 96%, whereas protein content, GABA uptake and the number of neurons visible in phase contrast microscopy remained unchanged. MPP+ also failed to affect cholinergic neurons in septal cultures.

A total of 48 compounds with structural similarity to MPP+ were tested for their ability to produce a selective dopaminergic degeneration. Only MPP+ and its close derivatives, 2'-methyl MPP+, p-amino-MPP+, 1-methyl-4-cyclohexyl-, 1-methyl-4-(4'-acetamido)phenyl- (MACPP+), and 1-ethyl-4-phenyl pyridium exhibited selective dopaminergic toxicity. After MPP+, MACPP+ was the most potent selective toxin. It is concluded that the structural requirements for a selective dopaminergic neurotoxin are rather strict and that our studies so far failed to support the environmental hypothesis of Parkinson's disease.

59.2

SELECTIVE DECREASE IN EXTRACELLULAR DOPAC CONCENTRATIONS IN RAT STRIATUM FOLLOWING *IN VIVO* DIALYSIS WITH LOW CONCENTRATIONS OF MPP^+

E.J. Caliguri* and J.N. Johannessen.
Laboratory of Clinical Science, Building 10/3D-40, NIMH, Bethesda, MD 20892

Doses of MPTP which do not result in nigral cell death or striatal dopamine loss in the dog do cause a long term but reversible loss of the dopamine metabolite DOPAC without affecting total MAO activity. Since MPP^+, the toxic metabolite of MPTP, is retained in monkey and dog dopamine terminals for long periods of time and since MPP^+ has been shown to be an effective inhibitor of MAO-A, low concentrations of MPP^+ may cause selective inhibition of the small pool of MAO-A within dopaminergic terminals. While the rat does not retain MPP^+ for long periods of time and is thus an inappropriate model for studying the effects of systemically administered MPTP, using *in vivo* dialysis the concentration of extracellular MPP^+ can be regionally maintained for extended periods while the effects on amine metabolism are simultaneously determined.

Dialysis probes (concentric, 3mm) were inserted into the striatum of chloral hydrate anesthetized rats (3-4/group) and operated at 1.5μL/min using an artificial CSF. Following a 3 hr baseline period, effects of the following compounds were tested: MPP^+ at 1 or 10 μM, GBR-12909 at 1 μM, or a combination of MPP^+ and GBR-12909 at 1 μM each. Twenty minute fractions were collected onto dry ice and analyzed for DA, DOPAC, HVA, 5-HT and 5-HIAA by HPLC-EC.

Unlike millimolar concentrations of MPP^+, micromolar concentrations administered through the probe did not produce a detectable increase in extracellular DA concentrations. There were observed decreases in extracellular DOPAC concentrations of 50% and 80% in response to 1 hr of dialysis with 1 and 10 μM MPP^+ respectively. These changes were selective, since concentrations of HVA and 5-HIAA were uneffected. The addition of 1 μM GBR-12909, a selective dopamine uptake blocker, prevented the DOPAC decrease induced by 1 μM MPP^+, indicating that uptake of MPP^+ into dopaminergic terminals mediates this response. GBR alone had no effect on DOPAC efflux. These results suggest that low micromolar concentrations of MPP^+ can be taken up and concentrated within dopamine terminals to produce a selective inhibition of presynaptic MAO-A without affecting surrounding neuronal (e.g. serotonergic) or glial metabolism.

59.3

COMPARISON OF THE EFFECTS OF INTRACEREBRALLY ADMINISTERED MPP^+ IN THE MOUSE, RAT AND MONKEY: MICRODIALYSIS OF DOPAMINE AND METABOLITES.

Hans Rollema, Guillermo M.Alexander, John R.Grothusen*, F.Fátima Matos*, Neal Castagnoli Jr.*
Division of Toxicology, School of Pharmacy and Department of Anatomy, School of Medicine, University of California, San Francisco, CA 94143.
Department of Neurology, Jefferson Medical College, Thomas Jefferson University, Philadelphia, PA 19107.

Intracerebral microdialysis in three awake species allowed the measurement of the basal output of dopamine (DA), dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA) and 5-hydroxyindoleacetic acid (5-HIAA) from rat and mouse striatum and monkey caudate in vivo. The DOPAC/HVA ratios in dialysates from mouse and rat striatum were about 1 and 2 respectively, but only 0.06 in monkey caudate dialysates. The estimated extracellular levels of the metabolites correlated well with reported tissue levels; extracellular DA levels were 3 orders of magnitude lower than tissue concentrations. The effects of intracerebrally administered MPP^+ were essentially similar in the three species. In all cases an immediate, massive release of DA was accompanied by a pronounced, persistent decrease in the output of the metabolites. Basal DA release was no longer detectable 5-12 hours after MPP^+ administration and a second MPP^+ perfusion failed to induce another increase in the release of DA. Also systemically administered MPTP had comparable acute effects on the output of DA and metabolites from rat striatum and monkey caudate.

EVALUATION OF THE NEUROTOXICITY OF MPP^+ ANALOGS BY INTRACEREBRAL MICRODIALYSIS. N. A. Naiman,* H. Rollema*# and N. Castagnoli, Jr.* (SPON: R. Young). Dept. of Chemistry, Virginia Tech , Blacksburg, VA 24061 and # Dept. of Medicinal Chemistry, State University Groningen, The Netherlands

The neurotoxicity of the Parkinsonian inducing agent MPTP is mediated by its MAO-B generated 1-methyl-4-phenyl-pyridinium metabolite MPP^+ which appears to be formed extraneuronally and then concentrated within striatal dopaminergic terminals. Cell death ultimately results from the the MPP^+ mediated inhibition of mitochondrial respiration and the concomitant depletion of ATP. With the aid of an intracerebral microdialysis assay we have examined the neurotoxic potential of a variety of N- and pyridine ring-substituted MPP^+ analogs. Unlike the strict structural requirements observed for compounds which display MAO substrate properties, a variety of pyridinium species appear to be neurotoxic as measured by their ability to deplete striatal dopamine irreversibly following intracerebral perfusion. Additionally, some non-toxic analogs may potentiate the dopamine depleting effects of MPP^+. Since few tetrahydropyridine derivatives are likely to be MAO substrates, these results point to the importance of identifying alternative pathways that may lead to the formation of potentially neurotoxic pyridinium and presumably related (isoquinolinium, β-carbolinium) metabolites.

59.5

TETRAPHENYLBORON POTENTIATES THE INHIBITORY EFFECTS OF MPP^+ ON MITOCHONDRIAL RESPIRATION. S. Ofori*, R.E. Heikkila, J. Hwang* and W.J. Nicklas. Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

The inhibition of mitochondrial respiration by MPP^+ has been proposed to be an important mechanism in MPTP-induced neurotoxicity. We have confirmed recent findings that tetraphenylboron anion (TPB) potentiates both the accumulation of MPP^+ by mitochondrial preparations and the inhibition of Complex I respiration. However, present data suggest that the potentiation by TPB of the inhibitory effects of MPP^+ on mitochondrial respiration is only partly due to the facilitation by TPB of MPP^+ accumulation. For example, when mitochondria were incubated with MPP^+ at levels which produce a 50% inhibition (IC_{50}) of Complex I respiration (200 μM MPP^+ alone or 3 μM MPP^+ plus 10 μM TPB), the accumulation of MPP^+ was 8.46 nmoles/mg protein and 0.14 nmoles/mg protein respectively. When mitochondrial preparations were incubated with 3 μM MPP^+ without TPB, 0.06 nmoles of MPP^+/mg protein were accumulated. A second potential mechanism to explain some of the effects of TPB might be that it enhances the accumulation of the pyridiniums in the membrane close to the inhibitory site on NADH dehydrogenase of Complex I.

CARDIAC INOTROPIC EFFECTS AS A MODEL TO STUDY THE MECHANISM OF MPTP'S TOXICITY. D.T. Shearer,* J.S. Wilson, and R.G. Carpentier* (SPON: D.E. Matsumoto). Dept. Anat., Dept. Phys., Howard Univ., Wash., D.C. 20059.

Because of structural similarites to Ca++ channel agonists (dihydropyridines), it has been suggested that MPTP or its oxidative metabolite, MPP+, may induce Ca++ loading of neurons resulting in their death. In support of this hypothesis, we found that MPTP's effects on neostriatal brain slices were blocked by superfusing with high Mg++, low Ca++ (Neuro Sci Abst 86 12:1309). We have also found that MPTP caused high amplitude swelling of mitochondria similar to that produced by kainic acid and seizure induced Ca++ loading of neurons. To analyze the mechanism of action of MPP+, we studied its effects on the contraction of rat heart atrial muscle, in vitro. MPP+ caused dose-dependent increases in peak tension developed and velocity of development of tension. The positive inotropic effect at 10 uM was completely blocked by propranolol and in the reserpinized rat; and therefore, can be explained by the indirect activation of beta-adrenergic receptors and not by the direct activation of dihydropyridine receptors. MPTP also caused a dose-dependent positive inotropic effect which was smaller than that of MPP+. Depletion of norepinephrine by reserpine blocked MPTP's positive inotropic effect and uncovered a negative inotropic effect. Muscle contraction did not recover to control values following washout. Instead, contraction continued to deterioriate progressively. In pilot experiments, MPTP's negative inotropic effect was blocked by both MAO inhibitors and SOD/catalase. These preliminary data suggest that the oxidation of MPTP may produce radicals responsible for the negative intropic effect. Supported by NIH-MBRS 2S06RR 08016 to JSW.

THE UPTAKE AND SUBCELLULAR LOCALIZATION OF MPTP IN CULTURED CEREBELLAR ASTROCYTES. A. Marini*, J.P. Schwartz, R. Lipsky*+ and I.J. Kopin (SPON: J. Stevens) Clinical Neuroscience Branch, NINDS, NIH Bethesda, MD 20892 and +American Red Cross, Rockville, MD 20894.

MPTP is a potent neurotoxin that destroys nigrostriatal dopaminergic neurons. The conversion of MPTP to MPP+ is thought to occur in astrocytes, the principle site of MAO B. Cerebellar astrocytes rapidly take up MPTP (2.5 nM) with equilibrium reached within 15 min: no conversion to MPP+ was detected at this time but by one hour MPP+ was being formed and released into the medium. Temperature had no effect on uptake, indicating that it occurs by passive diffusion. Uptake of MPTP was linear over a wide concentration range (up to 1 mM) for 15 min. Radiotracer studies showed that MPTP is concentrated about 30-fold. Since lysosomotropic agents like chloroquine, ammonium chloride and monensin (a Na+/H+ antiporter) abolished MPTP accumulation, lysosomes are a possible MPTP storage site. High micromolar concentrations of MPTP (up to 100 uM) had no effect on cell number or GFAP as analyzed by immunoassay.

EFFECTS OF NICOTINE AND HYDRAZINE ON MPTP-INDUCED NEUROTOXICITY. L.A. Carr. Department of Pharmacology, University of Louisville, Louisville, KY 40292.

We have previously reported that chronic exposure to cigarette smoke significantly attenuates the decrease in striatal dopamine and metabolite levels caused by MPTP, 10 mg/kg, in the C57Bl/6 mouse and that this effect is probably not due to decreased oxidation of MPTP to MPP^+ in cerebral tissues. The purpose of this study was to determine whether various individual components of cigarette smoke were responsible for this protective effect. Mice were chronically infused with nicotine (3.3 mg/kg/day) or hydrazine (10 mg/kg/day) for 14 days via osmotic minipumps. On day 7, mice were treated with MPTP, 10 mg/kg subcutaneously. The striata were assayed for content of dopamine, dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA). Treatment with nicotine alone significantly increased striatal HVA levels. In mice treated with MPTP, nicotine increased levels of DOPAC and HVA. Treatment with hydrazine significantly increased DOPAC and HVA levels when administered alone and in combination with MPTP. These results suggest that both nicotine and hydrazine may contribute to the attenuation of MPTP toxicity caused by smoke exposure. There is some indication that these components may exert direct effects on nigrostriatal neurons unaffected by MPTP to increase turnover and/or release of dopamine and thus compensate for the loss of function caused by MPTP.

59.9

EFFECTS OF GBR 12909, A SPECIFIC DOPAMINE UPTAKE BLOCKER, ON MPTP'S TOXICITY IN DOG. J.S. Wilson. Dept. Anatomy, Howard Univ., Washington, D.C. 20059.

The selective toxicity of MPTP is thought to be mediated by its oxidative metabolite MPP+. Although MPP+ is toxic to most cells, it has high affinity for dopamine uptake sites and thus is thought to be concentrated to toxic levels in catecholaminergic neurons. The selective toxicity of MPTP can be explained by the fact that the nigrostriatal system has the highest dopamine uptake levels in the brain. In support of this hypothesis, it has been shown that inhibitors of dopamine uptake block MPTP's toxicity in mice; however, the data in monkey are equivocal. Therefore, we decided to test this hypothesis in dog. Two dogs received injections (2.5 mg/kg i.v.; 2.5 mg/kg i.p.) of GBR 12909 (Res. Biochem.) 30 minutes before MPTP (3.0 mg/kg; i.v.) and were sacrificed one month later. GBR completely blocked the acute effects of MPTP such as dilation of eyes; however, within 24 hrs, dogs began to show chronic hypokinesia. After sacrifice, histological examination of the brains revealed an exasperation of damaged which in many respects was equivalent to dogs receiving twice (6.0 mg/kg) the dose of MPTP, only. Thus there was an absence of TH-immunostaining in not only the caudate N. and putamen but also in the N. accumbens. In addition, cell loss was conspicuous in areas A8, A9 and A10. Although GBR is thought to have a half life of approximately 16 hrs in dog, it may not be inhibiting dopamine uptake for a long enough period to block the concentration by nigral cells of MPP+ still remaining in the brain. To resolve this issue, GBR will have to be administered for a prolonged period to determine if inhibition of dopamine uptake blocks or exasperates MPTP's toxicity in dog. Supported by NIH-MBRS 2S06RR-08016 to JSW.

EFFECTS OF MPTP ON PROENKEPHALIN mRNA AND MET-ENKEPHALIN CONTENT IN THE MOUSE STRIATUM. C.Cosi, H.Shinoda, J.D.Harvey-White*, A.Zuddas and J.P.Schwartz
Clinical Neuroscience Branch, NINDS, NIH, Bethesda, MD 20892

MPTP causes a selective destruction of the nigrostriatal dopaminergic cells in mice. It is known that dopamine (DA) exerts a tonic inhibition on striatal enkephalinergic turnover. We thus investigated the effect of a sub-lesioning dose of MPTP (30 mg/kg, i.p., free base) on brain proenkephalin (PE) mRNA gene expression and Met-enkephalin (ME) peptide level in C57/Bl mice, in vivo. DA, PE mRNA and ME contents were measured in the striata of the same animal. One week after the drug treatment DA content was depleted to 40% and PE mRNA decreased to 65% of control whereas ME increased to 140% of control. PE mRNA did not change in the olfactory tubercle or in the prefrontal cortex of the same animals.

These data suggest that a partial depletion of DA differentially affects PE mRNA gene expression and ME levels in the striatum and that this effect is region-specific.

59.11

ULTRASTRUCTURAL CHANGES INDUCED BY 1-METHYL-4-PHENYLPYRIDINE (MPP+) IN NIGRAL AND STRIATAL COMPONENTS OF AN *IN VITRO* MODEL OF THE CANINE NIGROSTRIATAL SYSTEM. B. Christie-Pope and W.O. Whetsell, Jr. Neuropathology, Vanderbilt Sch. of Med., Nashville, TN 37232-2561.

Incubation of organotypic cultures of canine substantia nigra (SN) with micromolar concentrations of MPP^+ results in a generalized destruction of neuronal and glial cells within 72 hours (Christie-Pope et al, Exp. Neurol., 104:235-240, 1989). The present study was designed to examine whether candate nucleus (CA) in co-culture with substantia nigra (SN) would also exhibit degenerative changes in response to MPP^+. Portions of CA and SN were cultured in an SN-CA-SN configuration with a separate CA explant placed in the same culture but 2-4 mm away. Ultrastructural examination of SN components of such co-cultures after 72 hours of exposure to 0.1 µM MPP^+ showed severe degeneration of glia and neurons; severe degeneration was also observed in both the separated CA and the CA in SN-CA-SN. In cultures of CA alone (without SN present), no ultrastructural changes were observed after incubation in 0.1 µM MPP^+ for 72 hours. The medium of SN-CA cultures developed greater acidity by 24 hours of MPP^+ exposure than the medium of cultures of CA alone. Results suggest that acidosis, possibly resulting from MPP^+ toxicity in SN neurons of SN-CA-SN cultures may induce or contribute to a non-specific degeneration in CA co-cultured with SN. [Supported by a grant from the United Parkinson Foundation and a Pharmaceutical Manufacturers Foundation Fellowship Award (BCP)].

MPP+ INHIBITS MITOCHONDRIAL ENERGY PRODUCTION AND DEPLETES ATP IN SYNAPTOSOMES. K.P. Scotcher*, D.A. Di Monte*, I. Irwin*, L.E. DeLanney and J.W. Langston. Institute for Medical Research and California Parkinson's Foundation, San Jose, CA 95128.

The neurotoxic effects of MPTP are thought to be mediated via its conversion to the fully oxidized metabolite, MPP+. Neuronal damage by MPP+ may result from its ability to block NADH-linked substrate oxidation in mitochondria. We investigated the effects of MPP+ on the energy metabolism of neuronal terminals using 95% pure mouse forebrain synaptosomes (non-synaptosomal mitochondria were separated by centrifugation through discontinuous Ficoll gradient). Addition of MPP+ to synaptosomes caused a dose-dependent depletion of ATP; about 40% less ATP was detected after incubation for 60 min with 100 µM MPP+. Thus, MPP+ was effective at concentrations in the same range as those reached in the brain after administration of MPTP. In order to identify the site of inhibition of ATP production, we compared the toxic effects of MPP+ to those of known inhibitors of mitochondrial electron transport (rotenone and antimycin A) and glycolytic production of ATP (iodoacetate). As expected in view of the glucose-dependent metabolism of our synaptosomal preparations, iodoacetate was the most effective of the three compounds tested in depleting ATP. ATP depletion caused by antimycin A, which completely blocks mitochondrial electron flow, was more pronounced than that produced by rotenone, an inhibitor of mitochondrial NADH oxidation. The extent of ATP depletion induced by rotenone was the same as that induced by MPP+; MPP+ and rotenone together had no additive effect. Synaptosomal preparations are a useful model for studying the effects of neurotoxicants on neuronal terminals. Inhibition of mitochondrial NADH-linked substrate oxidation by MPP+ may be critically involved in the neurotoxic action of its parent compound MPTP.

59.13

REGIONAL EFFECTS OF 6-HYDROXYDOPAMINE(6OHDA) AND NEUROLEPTIC ON FREE RADICAL SCAVENGING SYSTEM IN RAT BRAIN. A.S.Perumal*,T.B.Cooper*,S.Fahn andJ.L Cadet. (SPON:S.P.Bagchi). Dept. of Psychiatry and Neurology, Columbia Uni. and NYSPI, NY, NY 10032

It has been hypothesised that free radicals may play an important role in the pathogenesis of neurodegenerative diseases. The free radical scavenging system such as superoxide dismutase(SOD), catalase(CAT), glutathione peroxidase(GSH-Px), glutathione reductase (GR) and total glutathione (GSH) were analysed in caudate-putamen(CP), brain stem(BS), hippocambus(HIP) and frontal cortex(FC) of control and rats treated with either intracerebroventricular infusion of 6OHDA or Prolixin(IP for a month. Injection of 6OHDA resulted in significant decreases in the activity of SOD in CP (20%) and BS(30%) but not in HIP. CAT was reduced only in BS(25%). There were no changes in GSH-Px in any of the brain regions studied. GSH levels dropped in CP(23%) and BS(38%) without affecting HIP. In Prolixin treated animals, there were significant decreases in SOD(12%), CAT(34%) and GR (17%) in HIP. CAT activity was increased (62%) in FC. Prolixin treatment did not show any significant effect on other regions. These changes may be secondary to the production of free radicals due to the drug treatment in rat brain.

59.14

ENZYMES OF OXY-RADICAL METABOLISM AFTER HALOPERIDOL TREATMENT OF RAT. J. Murthy*, H. Laev, S. Karpiak, S. Mahadik, Div Neurosci NYS Psychiat Inst, Depts Psychiat, and Biochem & Mol Biophys, P&S, Columbia U, NY, NY 10032.

Molecular mechanism(s) underlying the deleterious effects associated with potent neuroleptic treatment are poorly understood. Haloperidol is a potent neuroleptic commonly used for the treatment of psychiatric disorders. Acute haloperidol treatment increases the oxidative metabolism of catecholamines resulting in the production of oxy-radicals and other toxic intermediates. If these are not eliminated by specific enzymes (superoxide dismutase, SOD; glutathione peroxidase, GSHPOD; catalase, CAT) neuropathological changes can occur in target tissues. These enzyme levels were measured in different rat brain regions after haloperidol treatment. Six rats (male, Sprague-Dawley) were injected with haloperidol (5mg/kg/day, i.m.) or saline. Enzymes were analyzed at 1,7,14,21,28,42 days of treatment. All three enzyme levels differed significantly among the brain regions. When comparing control and haloperidol treated rats, enzyme levels were unaltered in hippocampus, thalamus & striatum. While there was no change in GSHPOD levels in cortex, the levels of SOD and CAT were 30% higher in the haloperidol treated rats. This variable marginal response against oxy-radical toxicity following haloperidol treatment probably reflects the variable deleterious effects and the vulnerability of CNS to toxicity.

59.15

TRIETHYL LEAD SELECTIVELY ENHANCES THE MOTOR STIMULANT EFFECTS OF DOPAMINE AGONISTS. L.A. Taylor and T.J. Walsh, Rutgers University, Department of Psychology, New Brunswick, NJ 08903.

Triethyl lead (TEL) is a neurotoxic organometal that has been shown to produce functional supersensitivty of dopamine (DA) receptors which manifests itself as an enhanced behavioral response to both indirect (amphetamine) and direct acting (apomorphine) DA agonists. Neurochemical evidence also supports an enhanced sensitivitity of DA-stimulated adenylate cyclase activity following exposure to TEL (Walsh et al. Brain Res 363, 1986; DeHaven-Hudkins et al. Neurotoxicol. Teratol. 10, 1988.)

The present experiment examined whether TEL-treated rats were differentially sensitive to other drugs that enhance motor behavior via non-DA mechanisms of action. Male Sprague-Dawley rats were injected with 7.88 mg/kg TEL chloride or vehicle. Seven days later, the motor stimulant effects of the indirect acting DA-agonist, d-amphetamine sulfate (2mg/kg), the serotonin agonist, 5-methoxy-N,N-dimethyltryptamine (5-MeDMT) (0, 2.5, & 5.0 mg/kg), and the adenosine antagonist/phosphodiesterase inhibitor, caffeine (0, 6.25, 16.5, & 40 mg/kg) were examined. Our results demonstrated that TEL significantly enhanced amphetamine (2mg/kg) induced locomotor activity but it did not enhance the motor stimulant effects of caffeine, or the profile or degree of the motor symptoms associated with the 'serotonin syndrome' induced by 5-MeDMT.

These results support the hypothesis that TEL produces its behavioral supersensitivity through brain DA systems, and not through other neurotransmitter or modulatory systems involved in the regulation of motor activity.

AUTORADIOGRAPHIC ANALYSIS OF DOPAMINE (DA) AND GABA/BENZODIAZEPINE RECEPTORS FOLLOWING CHRONIC NEUROLEPTIC TREATMENT IN RATS. R.E.See and G.D. Ellison. Dept. of Psychology, UCLA, Los Angeles, CA 90024.

Repeated administration of neuroleptics has previously been found to alter dopamine and GABA receptor binding in extrapyramidal brain regions. In the present study, female, Sprague-Dawley rats were administered the typical neuroleptic haloperidol, one of the two atypical neuroleptics clozapine or raclopride, or no drug for 8 months and then withdrawn from treatment for 21 days. Coronal brain sections at various AP levels were sectioned and prepared for autoradiography using the following ligands: [^{3}H]spiperone and [^{3}H]raclopride for DA D-2 receptor binding, [^{3}H]SCH23390 for DA D-1 receptors, [^{3}H]muscimol for GABA receptors, and [^{3}H]RO15-1788 for benzodiazepine receptors. Haloperidol, but not the two atypical neuroleptics, increased D-2 receptor binding in striatal regions and GABA receptor binding in the substantia nigra reticulata. No significant differences were found between groups for [^{3}H]SCH23390 or [^{3}H]RO15-1788 in any regions examined. These results support previous findings of altered DA/GABA function following prolonged HAL, but not atypical neuroleptic treatment. Implications for neuroleptic-induced dyskinesias will be discussed.

59.17

FORMATION OF 6-HYDROXYDOPAMINE (6-OHDA) AND 5,6-DIHYDROXYTRYPTAMINE (5,6-DHT) ARE FOUND AFTER A LARGE SINGLE DOSE OF METHAMPHETAMINE (MA) IN GUINEA PIGS. Lewis S. Seiden and Georgetta Vosmer* Dept. Pharm/Phys. Sciences, Univ. of Chicago, Chicago, IL 60637.

Male Hartley guinea pigs (650 grams) were injected with MA (100 mg/kg, s.c.) or saline and killed 15, 30, or 60 mins after injection. 6-OHDA was detected in the caudate of 2/7 (.003 ng/mg tissue) at 30 min and 3/7 (.005 ng/mg tissue) at 60 min. Lower levels of 5,6-DHT were detected in hippocampi in 2/4 (.001 ng/mg tissue) at 15 min, 3/7 (.001 ng/mg tissue) at 30 min and 6/7 (.0025 ng/mg tissue) at 60 min. DA levels in the caudate were 75% of control and 5-HT levels in the hippocampus were 46% of control 1 hr after injection. These results are consistent with results found in rats showing formation of either 6-OHDA or 5,6-DHT in approximately one half the rats after any given experiment. Reasons for the variability in findings will be discussed. This is consistent with the notion that neurotoxicity of MA is related to formation of neurotoxins from the transmitters DA and 5-HT. This research supported by NIDA #00250 Project VI, RSA MH-10562 (L. Seiden).

MODIFICATION OF METHAMPHETAMINE-INDUCED NEUROTOXICITY IN MICE. C. Konradi*, L. Manzino, P.K. Sonsalla and R.E. Heikkila. Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

The present study was an attempt to determine the effects of pretreatment with various drugs on methamphetamine induced neurotoxicity to neostriatal dopaminergic neurons. On four consecutive days, male Swiss-Webster mice received vehicle or increasing doses of either methamphetamine, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) or cocaine, three times a day at 3 hour intervals. On day five, the animals were challenged with three injections of methamphetamine, 16mg/kg per injection at three hour intervals. Five days later the mice were killed and the neostriatal content of dopamine was determined. In mice pretreated with methamphetamine prior to the methamphetamine challenge, there was a significantly smaller reduction of dopamine content than in mice pretreated with vehicle. In MPTP or cocaine pretreated mice there was no such tolerance to the dopaminergic neurotoxicity of methamphetamine. In fact, of the four experimental groups, the cocaine pretreated animals had the largest decrease in dopamine content after the methamphetamine challenge. Possible explanations for these interactions will be presented.

59.19

TETRAHYDROPYRIDINE ANALOG OF HALOPERIDOL CAUSES PROFOUND DEPLETION OF STRIATAL DOPAMINE. N. Castagnoli*, B. Subramanyam*, and G.A. Ricaurte (SPON: M. Bleecker). Department of Chemistry, Virginia Polytechnic Inst., Blacksburg, VA. 24061 and Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD. 21224.

The haloperidol derived compound 4-(4-chlorophenyl)-1-[4-(4-fluorophenyl)]-4-oxobutyl-1,2,3,6-tetrahydropyridine (PCOTP) bears close structural resemblance to 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), a parkinsonogenic compound with known dopaminergic neurotoxic activity. One of the major side-effects of haloperidol therapy is an extrapyramidal syndrome with prominent parkinsonian features. This study examined the dopaminergic neurotoxic potential of PCOTP, and compared it to that of MPTP.

Male C57 black mice weighing 25-30 grams were injected with equivalent doses of PCOTP and MPTP (20 mg/kg/hour X 4; i.p.). Each drug was tested in a group of 6 animals. Control animals received an equivalent volume of saline. Four days later, all animals were sacrificed and striatal dopamine content was determined. PCOTP-treated mice showed a large (70-80%) depletion of striatal dopamine. The dopamine-depleting effects of PCOTP were comparable to those of MPTP.

These results demonstrate that the haloperidol analog PCOTP produces a severe depletion of striatal dopamine in mice. The duration and basis of the dopamine depletion are currently under investigation. The relevance of these findings to haloperidol-induced parkinsonism in humans remains to be determined.

59.20

AMPLIFICATION OF THE ACTION OF 6-HYDROXYDOPAMINE BY ETHANOL F.F. Ahmad*, D.L. Cowan*' and A.Y. Sun (SPON: Vincent V. St. Omer). Sinclair Comparative Medicine Research Farm and Departments of Biochemistry and Physics*, University of Missouri, Columbia, MO 65203

6-hydroxydopamine (6-OHDA) has been used extensively to induce brain lesion in dopaminergic neurons for the study of dopamine (DA) deficient state such as Parkinsonism. Production of free radicals by 6-OHDA has been suggested as the cytotoxic mechanism for neuronal degeneration. However, direct evidence for free radical formation is lacking. By using electron spin resonance (ESR) and spin trapping technique (Ahmad, Cowan and Sun, Life Sci. 43:1169-1176, 1988), we demonstrated the direct participation of 6-OHDA in the free radical reaction. In the presence of ethanol, the free radicals formed were converted to the longer lived hydroxyethyl free radicals (·OHEt) which may cause more damage than the short lived species. The formation of ·OHEt increased in proportion with increasing ethanol concentration (0-.05%). The results suggest that ethanol ingestion may amplify the action of neurotoxin, such as 6-OHDA in causing the brain lesion and Parkinsonism. (Supported in part by Grant AA02054 from DHHS.)

NEUROTOXICITY I

TAURINE DEFICIENCY EXACERBATES CYSTINE NEUROTOXICITY IN CAT RETINA: A MORPHOLOGICAL STUDY. H. Imaki and John Sturman*, N.Y.S. Inst. for Basic Res. in Devel. Disabil., Staten Island, New York 10314.

Dietary taurine deprivation in cats causes severe visual dysfunction associated with photoreceptor degeneration. To examine if such effects of taurine deficiency may be offset by excess dietary precursor, we fed mature cats a synthetic diet containing 5% cystine and either 0 or 0.05% taurine. All the cats fed cystine without taurine exhibited clear neurological symptoms and died or were killed when they appeared terminal, while some cats fed taurine in addition to cystine showed no adverse effects for up to a year, the rest dying after showing minimal symptoms. The most common and conspicuous changes noted in these retinas were reductions in the number of cells in INL and GCL, and swelling of many cells and their processes in INL and IPL. Many of such cells exhibited irregularly shaped nuclei containing dense clumps of chromatin, and greatly distended mitochondria and vacuolar profiles in unusually pale cytoplasm, most frequently among amacrine cells of cats fed cystine and no taurine, but also among some horizontal, bipolar and ganglion cells of most cats fed cystine. Muller cells appeared normal as did astrocytes, microglial and endothelial cells. Photoreceptor cells remained relatively intact, but subtle ultrastructural changes, such as dilated disc membranes in outer segments and swollen mitochondria in inner segments, were more prevalent in the retinas of cats fed taurine-free than -supplemented diet with cystine. These results suggest that taurine plays a protective role not only in photoreceptor cells but in other retinal neurons against the neurotoxic effects of cystine.

60.2

FACILITATION AND INHIBITION OF NEURONAL EXCITABILITY BY LEAD IN THE ISOLATED TURTLE CORTEX. D. M. Wilkison. Dept. Pharmacology and Toxicology, Med. Col. Wisconsin, Milwaukee, WI 53226

The actions of lead on central nervous system synaptic function were investigated by studying the effects of bath-applied lead acetate (Pb-Ac) on the dynamic firing response to pairs of stimuli in the isolated cortex. Turtles (Pseudemys scripta) were cooled in ice water prior to decapitation. The anterior dorsal (visual) cortex was removed to a tissue chamber. Tissue was perfused with a balance buffer at room temperature. Extracellular recordings were made by standard glass-microelectrode techniques. Cells identified by application of glutamate and GABA were activated by electrical stimulation of afferent, thalamocortical, or intracortical fibers. Paired-stimulations (10-200 msec) delivered at 0.3 Hz produced potentiation of the evoked discharges. This potentiation was inhibited by Pb-Ac (1-30uM). In contrast, single shock stimulation was facilitated by Pb-Ac over the same exposure range. Interactions between Pb+2 and Ca+2 and GABA function are under investigation. The data are somewhat consistent with data from synaptosomes (TAP 84:400-411, 1986) in which Pb increased spontaneous release and decreased evoked release. Studies are supported by NIEHS, ES04184.

60.3

THE EFFECTS OF CADMIUM CHLORIDE ON SPONTANEOUS LOCOMOTOR ACTIVITY. M.A. Blackshear, K. Phillips*, R.A. Sawrie* and E.J. Olson*. Dept. of Biological Sciences, Tennessee State University, Nashville, TN and Dept. of Pharmacology, Meharry Medical College, Nashville, TN 37208.

This study investigates the acute and chronic effects of cadmium chloride ($CdCl_2$) administration on spontaneous locomotor activity (SLA) and examines the possible involvement of brain dopamine receptors. Male mice (Swiss ICR, 20-26g) received either a single injection of 2 mg/kg $CdCl_2$ or 14 daily injections of 0.14 mg/kg $CdCl_2$. Control animals received 0.01 ml/mg physiological saline. Locomotor activity was measured for 20 minutes post $CdCl_2$ or saline injections in the acute studies. To determine the effects of chronic $CdCl_2$ administration, locomotor activity was monitored on days 1, 3, 7 and 14 for 20 minutes post Cd treatment and compared to that of saline controls.

Acute administration of $CdCl_2$ caused a marked decrease in SLA, 46.3 ± 2.5 and 9.5 ± 0.7, respectively, for control and Cd treated mice. With chronic Cd treatment, SLA was decreased on day 1 (40 ± 3.9 vs 59 ± 2.9 for controls) and on day 3 (30.4 ± 3.9 vs 49.4 ± 3.0 for controls). [^{3}H]-spiroperidol binding to striatal membranes was increased after acute Cd treatment (1.80 ± 0.17 fmol/mg protein vs 1.06 ± 0.5 fmol/mg protein for controls), but was unaltered after chronic treatment. Although Cd was not detected in the brain, it was present in the liver (0.144 ± 0.5 mg/100 dry wt.) of acutely treated mice. Cd was not detected in the brains or livers of control animals.

These findings indicate that both acute and chronic administration of $CdCl_2$ decrease SLA, and suggest that central dopamine receptors are probably not involved in this behavior.

EFFECTS OF IN VITRO LEAD EXPOSURE ON VOLTAGE-SENSITIVE CALCIUM CHANNELS DIFFER AMONG NEURONAL TYPES IN LYMNAEA STAGNALIS. T. Audesirk and G. Audesirk. Biology Dept., U. Colorado-Denver, 1200 Larimer Street, Denver, CO 80204.

The effects of acute in vitro lead exposure on barium currents through voltage-sensitive calcium channels were studied under voltage clamp. Three physiologically distinct cell types were used: the pedal giant neuron (RPeD1) and two subsets of the B cell cluster (B_{pos} and B_{neg}). Free Pb^{2+} concentrations were buffered by using a Leibovitz-L15-based saline, and were measured with a Pb^{2+}-selective electrode. In B_{pos} neurons, 5 nM free Pb^{2+} irreversibly inhibits current flow through calcium channels by 38 ± 10%. In B_{neg} neurons, 5 nM free Pb^{2+} slightly inhibits inward currents (12 ± 6%) and may shift their voltage dependence to more depolarized voltages. The inhibition and voltage shift are irreversible. In RPeD1 neurons, Pb^{2+} inhibits inward current by 18 ± 19% (5 nM free Pb^{2+}) to 31 ± 23% (30 nM free Pb^{2+}). The effects of Pb^{2+} are fully reversible. These data indicate that (1) voltage-sensitive calcium channels in Lymnaea neurons are inhibited by nanomolar concentrations of free Pb^{2+}; (2) different neuronal types in Lymnaea possess different types of calcium channels; and (3) the effects of in vitro lead exposure differ qualitatively among channel types.

ULTRASTRUCTURAL FINDINGS IN FROGS WITH CIS-PLATIN INDUCED NEUROTOXICITY. Karen S. Blisard PhD MD and Deborah A. Harrington. Research Service (151), Veterans' Administration Medical Center, and Department of Pathology, University of New Mexico Medical School, Albuquerque, NM 87108.

Cis-diamminedichloroplatinum II (cis-platin) is a cancer chemotherapeutic agent whose usefulness is often limited by side effects, including peripheral sensory neuropathy or central nervous system (CNS) toxicity with seizures. We have developed a model system for CNS toxicity using the frog. The animals had tonic-clonic seizures 3 to 5 weeks after a single dose of 10 mg/kg cis-platin. The principle pathology was found in the spinal cord, where there was vacuolization in the anterior gray horns. Ultrastructurally, the vacuoles consisted of swelling of astrocytic processes in the neuropil and around neurons. Generalized edema with swelling of perivascular astrocyte foot processes was not seen. There was increased nuclear irregularity in motor neurons from treated animals. Cup-shaped or ring-shaped mitochondria occasionally were seen in processes and mitochondrial pleomorphism could be observed in motor neurons. Further study of this model may help elucidate the mechanisms of cis-platin's neurotoxicity in humans.

60.6

MANGANESE TOXICITY: FREE AMINO ACIDS AND TRACE ELEMENTS IN THE MOUSE BRAIN E. Bonilla, A. Arrieta*, J.O. Dávila* and I. Quiroz*. Instituto de Investigaciones Clínicas, Universidad del Zulia and INBIOMED-FUNDACITE, Aptdo. 376, Maracaibo-Venezuela.

We studied the effect of manganese administration on the levels of 20 free amino acids and 4 trace elements in the striatum and olfactory bulb.

Male albino mice weighing 20-25 g were injected intraperitoneally with manganese chloride (5mg Mn/Kg b.w.) in 0.9% NaCl solution. Both control and Mn-treated mice received one daily injection five days per week. After nine weeks, 11 animals of each group were sacrificed by decapitation and the brain extracted immediately. The analysis of the amino acids was performed by HPLC. Brain manganese, copper, zinc and iron concentrations were determined by flameless atomic absorption spectrophotometry.

The growth rate and water intake of the Mn-intoxicated mice were normal. The means ± S.E. of the manganese content (ug/g dry weight) at the ninth week were: a) striatum: 4.05 ± 0.34 in controls and 11.44 ± 0.61 in Mn-loaded mice; b) olfactory bulb: 5.22 ± 1.16 and 13.78 ± 2.62. The iron concentrations were as follows: a) striatum: 46.79 ± 1.85 in controls and 70.39 ± 4.30 in Mn-treated mice; b) olfactory bulb: 56.18 ± 9.55 and 91.02 ± 8.65 . The striatal and olfactory bulb copper and zinc levels did not change with the manganese administration.

No alterations were observed in the levels of free amino acids in the striatum of Mn-treated mice. However, in the olfactory bulb the contents of alanine, alpha-amino-n-butyrate, arginine, asparagine, aspartate, citrulline, GABA, glutamine, glutamate, glycine, isoleucine, leucine, methionine, phenylalanine, serine, threonine, tyrosine, and valine were significantly diminished. The changes produced in the olfactory bulb must be thoroughly evaluated to determine its importance on the pathophysiology of manganese poisoning.

60.7

***IN VIVO* EFFECTS OF DIFLUROMETHYLORNITHINE ON INDUCED BRAIN ODC-mRNA & ACTIVITY.** N. Zawia*, C. Huntington* and S. Bondy* (SPON: C. GORENSTEIN). Dept. of Pharm., Dept. of C.&E. Med. & the S.O.H.C., U. of California, Irvine, CA 92717.

Ornithine decarboxylase (ODC) is the rate limiting enzyme in the polyamine pathway, which is known to be involved in the adaptive mechanisms of the CNS. We previously found that the induction of enzyme activity in the neocortex in response to electroconvulsive shock (ECS) was accompanied by an increase in ODC-mRNA which persists longer than the transient change in activity, while the elevation of enzyme activity in the hippocampus was transcription-independent. This prompted us to study the effect of difluromethylornithine (DFMO), a specific ODC inhibitor, on the regional regulation of ODC activity and mRNA. DFMO was administered to rats in 2 doses (5 hr. interval) of 500 mg/Kg I.P.. ECS was applied 15 min. after the second injection and the animals were sacrificed 5 hrs. later and their brain regions were dissected. ODC-mRNA was studied by Northern blot analysis using a mouse cDNA as a probe. Enzyme activity was determined by counting evolved $^{14}CO_2$ from ^{14}C-ornithine. Our results show that the basal ODC activities in the neocortex and the cerebellum are resistant to *in vivo* DFMO inhibition, while the hippocampal ODC activity which is higher than other regions is very susceptible to DFMO blockade. Upon ECS treatment, the hippocampus exhibits greater susceptibility to *in vivo* DFMO than other brain regions. The ODC-mRNA in all cases was not significantly altered by DFMO applications. The susceptibility of hippocampal ODC implies that here the enzyme may have a distinctively longer half-life than that in other regions.

A RODENT MODEL OF METHANOL-INDUCED VISUAL TOXICITY. J.T. Eells. Dept. of Pharmacology and Toxicology; Medical College of Wisconsin, Milwaukee, WI 53226.

Methanol is an important environmental neurotoxin with selective actions on the primate visual system. Methanol poisoning in primates is characterized by metabolic acidosis and ocular toxicity accompanied by the accumulation of formate in body fluids and tissues. Rodents do not exhibit these signs of toxicity and do not accumuate formate following methanol administration. The objective of this investigation is to establish a rodent model in which to study the pathogenesis of methanol-induced ocular toxicity. To accomplish this objective, we studied the development of formic acidemia and visual dysfunction following methanol administration in rats made folate-deficient by treatment with N_2O. Rats were exposed to N_2O/O_2 (50/50) for 4 hr prior to the administration of methanol (4 g/kg) and throughout the course of the experiment. Accumulation of blood formate (peak values 13.5 ± 1.0 mM) was observed in these animals. Visual dysfunction was assessed by measurements of the electroretinogram (ERG) and the flash-evoked cortical potential (FEP). A reduction in the amplitude of the ERG (b wave; 56 ± 12 % of control) and the FEP (P20-N30 component; 50 ± 9 % of control) occurred coincident with the accumulation of blood formate indicative of a temporal relationship between methanol-induced metabolic and visual disturbances. The highest concentrations of formate were measured in the vitreous humor and retina suggesting that the target organ toxicity of methanol may result from the differential distribution of this toxic metabolite.

ETHANOL-INDUCED AXONAL TRANSPORT CHANGES IN SENSORY NERVES DETECTED BY COMPUTER-ENHANCED VIDEO MICROSCOPY. J.A. McLane[1], M.B. Atkinson[*2] and A.C. Breuer[2]. [1]Neuroscience Research, VA Hospital, Hines, IL 60141, [1]Dept. [2]of Biochem., Loyola University, Maywood, IL 60153, and [2]Dept. of Neurology, Cleveland Clinic Fndt., Cleveland, OH 44195.

We hypothesize that ethanol-induced alterations in axonal transport lead to the peripheral neuropathy often observed in chronic alcoholism. In rats, we have shown that chronic ethanol exposure through a liquid diet leads to reduced accumulation of anterogradely transported proteins at a nerve ligation (Alcohol 4:385, 1987), but no change in transport rate (Trans Am Soc Neurochem 20:234, 1989). Also, the amount of material delivered to the dorsal root ganglia by retrograde transport was reduced (Abstr Soc Neurosci 13:124, 1987). We have used computer-enhanced video-microscopy to obtain preliminary transport rate data in sural nerves from chronic (5 month) ethanol-fed rats. This data confirms that the rate of fast anterograde axonal transport was unchanged (ethanol = control = 1.50±0.06 um/sec). However, this treatment produced a significant increase in the rate of organelle transport in the retrograde direction (ethanol = 1.78±0.02 um/sec, control = 1.60±0.03 um/sec, $p<0.001$). These results suggest that a compensatory mechanism in the retrograde transport system attempts to offset the reduced delivery of materials to the cell body from the sensory nerve ending by increasing the transport rate.

60.10

AXONAL AND TERMINAL DEGENERATION IN THE CNS OF THE FERRET FOLLOWING EXPOSURE TO BIS (1-METHYLETHYL) PHOSPHOROFLUORIDATE (DFP). D. Tanaka, Jr., S.J. Bursian*, and E. Lehning*. Depts. of Anatomy and Animal Science, Michigan State Univ., East Lansing, MI 48824.

Although it has been well established in mammals that exposure to the organophosphorus delayed neurotoxin DFP results in delayed degeneration in spinal tracts and peripheral nerves, it is not clear to what extent other areas of the CNS may be affected. Ferrets were injected subcutaneously with 4mg DFP/kg body weight and killed 7, 14, 21, and 28 days after exposure. Brains and spinal cords were processed using a modified Fink-Heimer method. At 7 days, minimal degeneration was noted only in the nucleus gracilis. From 14 to 28 days, increasing amounts of degeneration were noted in the fasciculus and nucleus gracilis, medial and dorsal accessory olivary nuclei, inferior vestibular nucleus, lateral reticular formation, dorsal and ventral spinocerebellar tracts, and cerebellar folia I-IV. Degenerating fibers were also noted in laminae VI-VII of the lumbar spinal cord. Hindlimb ataxia and paralysis were also noted at 21 and 28 days post-DFP. These results suggest that exposure to DFP primarily results in degeneration of selected ascending tracts associated with exteroceptive and proprioceptive pathways.

PROTECTIVE ENZYMES ARE NOT INVOLVED IN NGF-INDUCED RESISTANCE OF PC12 CELLS TO OXIDATIVE INJURY. Margaretann Halleck* and Frederick Kauffman. Lab. for Cellular and Biochemical Toxicology, Rutgers University, Piscataway, NJ 08854

NGF enhances the resistance of PC12 cells to H_2O_2 toxicity as indexed by trypan blue uptake (Perez-Polo, *et. al.*, Clin. Neuropharm, **9**, 98, 1986) or maintenance of high energy phosphate (O'Brien & Kauffman, Pharmacologist, **30**, A47, 1988). Accordingly, we examined enzymes involved in detoxification of reactive O_2 species in PC12 cells after 2, 5 and 14 days of treatment with NGF. Enzymes studied were catalase, glutathione reductase (GR), glutathione peroxidase (GPO) and superoxide dismutase (SOD). H_2O_2 (250 µM) caused rapid and profound (>80%) decreases in ATP and P-creatine at 15 min in both groups of cells; however, recovery occurred only in NGF-treated cells. Although this pattern of NGF-induced protection was seen at each day studied, enzyme activities were the same in both groups (Table).

Enzyme	*Control*	*5 day NGF-Treated*
Catalase (µmole/min/mg protein)	1.4 ± 0.1	1.4 ± 0.1
GPO (nmole/min/mg protein)	30.8 ± 1.0	31.6 ± 0.8
GR (nmole/min/mg protein)	34.0 ± 2.4	33.3 ± 1.2
SOD (units/mg protein)	69.7	64.8

Rates of removal of H_2O_2 by intact cells were the same in control and NGF-treated PC12. Thus, protection conferred by NGF is not due to enhanced degradation of H_2O_2. Experiments employing flow cytometry and ion sensitive dyes to monitor intermediates involved in cell injury and protection are being applied to elucidate the novel mechanism of resistance to oxidative injury in NGF-treated PC12 cells. CHICK EMBRYO EXPOSURE TO CARBAMATES ALTERS NEUROCHEMICAL PARAMETERS AND BEHAVIOR. M. Farage-Elawar* and W. D. Blaker (SPON:B.S. Jortner). VA/MD Regional College of Veterinary Medicine, Department of Biomedical Sciences, Blacksburg, VA 24061.

Recent evidence has shown that exposure to pesticides can lead to long-term neurophysiological and functional deficits. We have demonstrated that behavior and locomotion in chicks exposed to some organophosphates and carbamates could be persistently altered without concomitant central or peripheral esterase inhibition. Furthermore, histopathology on the ataxic chickens showed no lesions in either the central or peripheral system. In this study, we examined the hypothesis that locomotion alterations seen in chicks exposed to carbaryl and aldicarb are accompanied with perturbations in particular central neurotransmitter systems. Carbaryl and aldicarb were injected in ovo on day 15 of incubation at 6, 16 and 65 mg/kg and at 0.2, 0.4 and 3.5 mg/kg respectively. Neurotransmitter levels (assayed by HPLC-ED) and locomotion were measured at various times (1-50d) after dosing. At the lower doses of both carbaryl and aldicarb a trend towards prolonged decreases in cerebral dopamine and HVA was seen. The high dose of carbaryl significantly reduced dopamine and the high dose of both compounds significantly decreased HVA and 5-HIAA. Persistent behavioral alterations were observed only at the higher doses of both carbaryl and aldicarb.

60.13

GENE PROBE FOR PO MESSAGE USED TO INDEX ACRYLAMIDE TOXIC NEUROPATHY IN RATS. B.Veronesi[1]*, K.Jones [1]* S.Gupta, J. Pringle* and C.Mezei (SPON: D.L.Brown) United States Environmental Protection Agency,[1] HERL, RTP, NC, 27711, and Dalhousie University, Department of Biochemistry, Halifax, Nova Scotia, B3H 4H7, Canada

Cumulative exposure to acrylamide produces axonal damage to the distal lengths of both central (CNS) and peripheral (PNS) nerve fibers and subsequent hind-limb paralysis. Gene probes for the major PNS myelin glycoprotein PO (PO-mRNA) were used to monitor this toxic neuropathy in Sprague Dawley rats prior to, concurrent with and subsequent to ultrastructural pathology. Rats were dosed every other day with acrylamide (50 mg/kg, IP) and sacrificed intermittently throughout a 4 wk exposure. Slot Blot and Northern gel analysis of the sciatic nerve was used to determine the quantity and quality of PO-mRNA. PO-mRNA was depressed 12% after 3X exposures in the distal sciatic nerve in the absence of discernable ultrastructural neuropathy. Levels of PO-mRNA continued to decline 20% and 40% after 6X and 12X treatment. PO-mRNA from rats exposed 12X and allowed to recover hind-limb function for 30-40d, was depressed by 28%. These results suggest that gene probes are highly sensitive to neurotoxic damage, that they can be used to monitor the progression of pathology and may be used to index toxic neuropathy at low levels and early time-points when PNS fiber damage is reversible.

60.14

THE EFFECTS OF ARACHIDONIC ACID METABOLISM INHIBITORS ON METHYL IODIDE-INDUCED NEUROTOXICITY IN VITRO. C.J. Davenport and K.T. Morgan*. CIIT, RTP, NC 27709.

The monohalogenated methanes - methyl chloride (MeCl), methyl bromide (MeBr) and methyl iodide (MeI) - are established neurotoxins. Whereas, following inhalation exposure of rodents to monohalomethanes most organs show degenerative rather than inflammatory changes, the dual lipoxygenase-cyclooxygenase antagonist 3-amino-1-[m-(trifluoromethyl)phenyl]-2-pyrazoline (BW755C) inhibited MeCl and MeBr toxicity in vivo and MeI neurotoxicity in vitro (EC50 100µM). The present experiments, using mature dissociated murine (CD-1 strain) neocortical cultures, assessed the effects of 1 hr pretreatment with the lipoxygenase inhibitor nordihydroguaiaretic acid (NDGA) or the cyclooxygenase inhibitors salicylic acid, lysine acetyl salicylate and indomethacin on MeI (10mM, 5min) neurotoxicity. Cytotoxicity was attenuated in a concentration-dependent fashion by 1-10µM NDGA (EC50 3µM), with almost complete protection at 10 µM NDGA. Lysine acetyl salicylate (27mM), salicylic acid (10mM) and indomethacin (100µM) failed to inhibit cytotoxicity. In addition to correlating well with existing in vivo and in vitro data on the inhibition of monohalomethane toxicity by BW755C, and the lack of protection by indomethacin, these results indicate that prostaglandins do not play an essential role in MeI-induced neurotoxicity.

AIDS VIRUS ENVELOPE PROTEIN GP120 KILLS RODENT RETINAL GANGLION CELLS IN VITRO. Peter K. Kaiser, Jeffrey T. Offermann*, Rafael Campo, Jorge Arroyo, Edward Lamperti, and Stuart A. Lipton. Department of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115.

The envelope protein gp120 of HIV-1 kills rat hippocampal neurons in culture (Brenneman et al., *Nature* 335:639, 1988). Here we report that another mammalian central neuron, the rat retinal ganglion cell, is also susceptible to gp120 and that this lethal effect can be prevented by anti-gp120 sera. Postnatal ganglion cells were identified with fluorescent markers, dissociated from the retina and cultured as previously described (Leifer, Lipton et al., *Science* 224:303, 1984). As little as 0.1 pM-1.0 nM purified gp120 from two native isolates as well as an extremely pure recombinant preparation of gp120 killed retinal ganglion cells in vitro in a dose-dependent manner. Neurotoxicity could be abated by specific anti-gp120 sera but not by control preimmune sera, suggesting that the lethal effects of the purified preparations of the envelope protein were due to gp120 and not to a contaminant. Taken together with the previously reported neurotoxic effects of gp120 on hippocampal cells, these findings in retinal ganglion cells may account at least in part for the dementia and blindness that develop in some patients with AIDS.

60.16

CALCIUM CHANNEL ANTAGONISTS PARTIALLY PREVENT NEURONAL CELL KILLING BY HIV-1 COAT PROTEIN GP120 IN VITRO. Rafael Campo, Jeffrey T. Offermann,* Jorge G. Arroyo, Peter K. Kaiser, Huei-sheng V. Chen and Stuart A. Lipton. Depts. of Neurology and Biological Chemistry & Molecular Pharmacology, Children's Hospital & Harvard Medical School, Boston, MA 02115.

Picomolar concentrations of the viral envelope protein gp120 increase a prolonged component of Ca current and kill rat retinal ganglion cell and hippocampal neurons in culture (S.A. Lipton et al.; P.K. Kaiser et al., these abstracts). An increase in $[Ca^{2+}]_i$ is associated with and apparently responsible for several forms of neurotoxicity, including that mediated by excitatory amino acids binding at the NMDA receptor. Thus, the increase in Ca current engendered by gp120 could conceivably be related to its toxic action. Since the dihydropyridine antagonists nifedipine and nimodipine were found to offset the increase in Ca current produced by gp120 (Lipton et al., these abstracts), these agents were used in an attempt to block the neurotoxicity of gp120 on rat retinal ganglion cells in vitro. The addition of 1-10 μM nifedipine or nimodipine partially prevented the death of 1 week postnatal retinal ganglion cells cultured in the presence of gp120 (20 of 22 experimental trials, $P < 0.001$). However, the higher concentrations of nifedipine and nimodipine were toxic by themselves, although to a far lesser extent than gp120.

OPIATES, ENDORPHINS AND ENKEPHALINS: TOLERANCE AND DEPENDENCE

61.1

EFFECTS OF OPIATE WITHDRAWAL ON RAT LOCUS COERULEUS NEURONS: BEHAVIORAL, BIOCHEMICAL, AND PHYSIOLOGICAL CORRELATES. D.B. Beitner, K. Rasmussen, J.H. Krystal, G.K. Aghajanian, and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

We have compared the onset and duration of the behavioral manifestations of opiate withdrawal to the *in vivo* activity of locus coeruleus (LC) neurons and to increases in the levels of G-proteins, adenylate cyclase, and cAMP-dependent protein kinase that occur in the LC during chronic morphine treatment.

Rats were given morphine by daily implantation of subcutaneous morphine pellets (75 mg) for 5 days. On the sixth day, morphine withdrawal was induced by administration of naltrexone (100 mg/kg, s.c.), with additional doses given 6 and 24 hours later.

We found a striking parallel between the time courses of the behavioral symptoms and the increased activity of LC neurons during withdrawal. Both were most pronounced within 30 min, recovered rapidly (>50%) within 6 hr, but did not recover completely until after 72 hr of withdrawal. Adenylate cyclase and cAMP-dependent protein kinase activities in isolated LC membranes, both elevated in tolerant animals, recovered to control levels in 6 hr, in parallel with the rapid phase of withdrawal. Levels of Gi/Go, also elevated in tolerant animals, returned to normal by 24 hr. Taken together, these data suggest that increased neuronal activity in the LC is associated with the behavioral morphine withdrawal syndrome and that increased levels of G-proteins and an up-regulated cAMP system may contribute to the withdrawal activation of these neurons.

61.2

MORPHINE REGULATION OF C-FOS EXPRESSION IN THE LOCUS COERULEUS AND OTHER REGIONS OF RAT BRAIN. M.D. Hayward, R.S. Duman, E.J. Nestler (SPON: S. Stine). Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

The proto-oncogene c-fos has been shown to be induced rapidly in neurons in response to seizures and increased neuronal activity. In this study, we investigated morphine regulation of c-fos induction in the locus coeruleus (LC), since firing rates of LC neurons are known to increase 4-fold during opiate withdrawal (Beitner et al, this volume).

In morphine tolerant rats, levels of Fos immunoreactivity increased several-fold 2 hr after the initiation of opiate withdrawal by naltrexone. Levels of Fos immunoreactivity returned to normal after 6 hours of withdrawal even though LC neuronal activity remains elevated 2-fold at that time. Induction of c-fos was also seen at the mRNA level, analyzed by northern blot and in situ hybridization, after 1 hr of withdrawal. In contrast, c-fos is not induced in the LC in response to naltrexone administration to control animals, in response to acute morphine, or in non-withdrawing, morphine tolerant animals. We also found similar regulation of c-fos induction in frontal cortex and amygdala, but not in a number of other brain regions, including pons cross-sections (from which LC had been excised), hippocampus, dorsal raphe, and paragigantocellularis.

Region-specific regulation of c-fos during morphine withdrawal indicates that c-fos can be used as a marker to map neuronal pathways and neuronal cell types activated in response to acute and chronic opiate administration and during opiate withdrawal, as well as in response to other psychotropic drug treatments.

61.3

OPIOID-INDUCED REWARD AND AVERSION: INVOLVEMENT OF THE MESOLIMBIC DOPAMINE SYSTEM. T.Shippenberg* R.Spanagel*, R.Bals-Kubik*, C.Stein and A.Herz* Dept. Neuropharmacology, Max-Planck Institute for Psychiatry, D-8033 Martinsried, FRG.

Opioids produce rewarding or aversive effects depending on the receptor types with which they interact. The neurochemical substrates mediating such motivational (MOT) effects of opioids is unknown. This issue was addressed using place preference conditioning and in-vivo microdialysis. μ-(DAGO, morphine) or δ-(DPDPE) agonists functioned as reinforcers, producing marked place preferences in rats. In contrast, the k-agonists U69593 and E2078; a dynorphin analog produced aversions. Mapping studies revealed the mesolimbic dopamine (DA) system as a critical site for these effects. Injections of μ-agonists into the ventral tegmentum (VT) were reinforcing whereas injections of κ-agonists into either the VT or n. accumbens (NAC) were aversive. Both MOT effects were abolished after 6-OHDA lesions of the NAC or NAC D-1 but not D-2 receptor blockade. Microdialysis studies showed that μ- and δ-agonists increased NAC DA release whereas k-agonists decreased DA release. These results demonstrate a role of the mesolimbic DA system in opioid reward and aversion and suggest that both result from an alteration in the tonic activation of D-1 receptors in the NAC.

61.4

NOREPINEPHRINE TURNOVER IN CORTICAL BRAIN AREAS OF MICE WITHDRAWN FROM REPEATED MORPHINE TREATMENT AND IN RESPONSE TO A MORPHINE CHALLENGE. M. Attila*, E. Etemadzadeh* and L. Ahtee. Div. of Pharmacology and Toxicology, Dept. of Pharmacy, Univ. of Helsinki, SF-00170 Finland.

In contrast to its effects in rats acute morphine administration accelerates the cortical norepinephrine (NE) turnover in mice (Attila, L.M.J. et al., Pharmacol. Toxicol., 61:26, 1987). The α-methyl-p-tyrosine (αMT)-induced NE depletion is enhanced in morphine-withdrawn rats and a morphine challenge during withdrawal counteracts such an enhancement in cortical hemispheres (Attila, L.M.J. & Ahtee, L., Naunyn-Schmiedeberg's Arch. Pharmacol., 327:193, 1984). To study the effects of morphine withdrawal and morphine challenge in mice we gave male NMRI mice 3 daily morphine injections (100-200 mg/kg, s.c.) for 5 days followed by a morphine challenge (10 or 30 mg/kg) after various withdrawal periods. Withdrawal did not alter the rate of αMT-induced NE depletion in the brain area consisting mainly of cerebral cortex. In control mice morphine challenge clearly enhanced the αMT-induced NE depletion as well as increased the MHPG levels but a clear tolerance to these effects was found in morphine-withdrawn mice. Thus, in contrast to rats cortical NE turnover is not accelerated in mice spontaneously withdrawn from morphine. Furthermore, during withdrawal mice are tolerant to the NE turnover accelerating effect of morphine challenge.

61.5

SPINAL MET-ENKEPHALIN CONTENT INCREASES FOLLOWING PRECIPITATED WITHDRAWAL IN THE MORPHINE-DEPENDENT RAT. R. Cridland*, M. Sutak* and K. Jhamandas (SPON: J. Milligan), Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, K7L 3N6.

The present study examined changes in spinal met-enkephalin (ME) levels following a naloxone precipitated withdrawal in morphine tolerant/dependent rats. Morphine (5 µg/µl/hr) or saline was given by continuous intrathecal infusion for 6 days via osmotic minipumps (ALZET). Development of tolerance was assessed by monitoring daily reaction time in the tail flick and paw pressure tests. Acute intrathecal injection of naloxone (5 µg) on day 6 precipitated classical withdrawal symptoms in morphine tolerant rats. On day 7, cords were removed, rapidly frozen and analyzed for ME content by radioimmunoassay. In saline-treated rats, ME levels were 2.6 ± 0.4 and 1.4 ± 0.2 ng/mg protein (mean ± S.E.M.; n=4) in the sacral and lumbar regions, respectively. In morphine-treated rats (n=5), ME levels increased to 3.4 ± 0.5 and 3.5 ± 0.9 ng/mg, respectively. These results suggest that spinal morphine withdrawal is associated with augmented levels of met-enkephalin.

61.6

SUFENTANYL AND MORPHINE DEPENDENCE: BEHAVIOR AND FUNCTIONAL ANATOMY DURING WITHDRAWAL. **R.E. Adams and G.F. Wooten, Department of Neurology, Univ. of Virginia, Charlottesville, VA. 22908**

Regional cerebral glucose utilization (RCGU) and behavior during precipitated withdrawal were studied in rats made dependent on morphine, or the selective mu agonist, sufentanyl. Sufentanyl citrate was infused into the right jugular vein in graduated doses over 7 days (2 µg/.5 µL/hr - 16 µg/.5 µL/hr) using Alzet model 2002 osmotic minipumps. Subcutaneous morphine base pellets were implanted for a total of 5 days (1 pellet/45 g for 3 days followed by 1 pellet/70 g for 2 days). After completion of the dependence protocols rats were given an IV bolus of naloxone, 5 mg/kg followed by ^{14}C-2-deoxy-D-glucose, 10 µCi/100 g. Withdrawal behaviors were observed for the next 50 min after which time rats were killed and brains prepared for autoradiography. RCGU in both withdrawing groups was increased compared to controls in the following structures: medial and lateral preoptic areas, lateral septum, central nucleus of the amygdala, periventricular nucleus, lateral hypothalamus, lateral habenula, and interpeduncular nucleus. Withdrawal behaviors, including autonomic signs of withdrawal, withdrawal jumping, and weight loss were comparable between the two groups.

The similarity of the RCGU pattern and behaviors during withdrawal in rats dependent on sufentanyl, a selective mu agonist and morphine, an opiate agonist of arguable selectivity, indicates that dependence and withdrawal are phenomena mediated by the mu opiate receptors.

61.7

OPIOID MODULATING OCTAPEPTIDE PRECIPITATES MORPHINE ABSTINENCE SYNDROME IN RAT. D.H. Malin, D.E. Fowler*, J.R. Lake*, J. Sims*, S. Brown*, M.V. Hammond* and J. Miller*. Univ. of Houston - Clear Lake, Houston, TX 77058.

Yang et al. (PNAS 82:7757, 1985) have isolated an endogenous octapeptide ("opioid-modulating" or "morphine modulating" or "FMRF-like peptide") with strong anti-opiate actions. At these meetings last year, our laboratory reported that infusion of 15 µg of this octapeptide i.c.v. induced a quasi-abstinence syndrome in opiate-naive rats. In the present study, i.c.v. infusion of 2 µg octapeptide induced a vigorous abstinence syndrome in morphine-dependent but not in non-dependent rats.

Twelve rats were infused with morphine via Alzet osmotic minipump (0.3 mg/kg/hr s.c. for 7 days), while 12 rats were infused with saline vehicle alone. Half of each group was then injected in the 3rd ventricle with octapeptide (2 µg in 20 µl saline with 0.003 ug/µl bestatin), while the other half was injected with saline and bestatin alone. Each rat was observed under blind conditions for standard abstinence signs over 20 mins. with the following results:

	OVERALL ABSTINENCE SIGNS M ± SEM	
	OCTAPEPTIDE ICV	VEHICLE ICV
MORPHINE INFUSED	49.3 ± 7.0 **	5.3 ± 1.9
SALINE INFUSED	7.5 ± 2.4	3.8 ± 0.9

** $p<.01$ vs all other groups (Dunnett's Test)

ANOVA revealed significant, $p<.01$, morphine effect, octapeptide effect and interaction effect.

61.8

RIA OF FMRF-NH_2-LIKE OCTAPEPTIDE: INCREASED IMMUNOREACTIVITY IN CSF OF MORPHINE-DEPENDENT RATS. J.R. Lake*, D.E. Fowler*, T. Dougherty*, J. Leyva*, J.B. Sloan*, D.H. Malin and H-Y. T. Yang (SPON: R.E. Marc). Univ. of Houston - Clear Lake, Houston, TX 77058 and Lab. of Biochemical Genetics, NIMH, Washington, D.C. 20032.

The FMRF-like octapeptide (F-8-F-NH_2) discovered by Yang et al. (PNAS 82:7757, 1985) appears to have some anti-opiate properties such as precipitating opiate abstinence syndrome (Malin et al., this vol.). Therefore, it was of interest to determine whether CSF levels of F-8-F-NH_2 are increased in morphine-dependent rats. Thirteen rats were rendered morphine-dependent by 7 days continuous s.c. infusion of 1.5 mg/kg/hr morphine sulfate via 2ML1 Alzet osmotic minipump. Thirteen rats were infused with saline alone. Bestatin(.06µg) was injected into the cisterna magna of each rat and approximately 180µl CSF was withdrawn. HCL was added to a final concentration of 0.1N and the CSF was heated (100°C,10 min.). Following centrifugation (20,800 g, 20 min.), 50µl aliquots of supernatant were taken for F-8-F-NH_2 analysis as previously described (Majane et al., Peptides 9:1137, 1988)except that a 1ml reaction mixture was used. CSF from morphine dependent rats had F-8-F-NH_2 LIR of 0.082 ± 0.029 pmol/ml (M±SEM), while saline-infused rats had 0.025 ± 0.016 pmol/ml, a significant difference, $p<.05$. In another experiment, acute exposure to morphine failed to affect F-8-F-NH_2 LIR. F-8-F-NH_2 LIR appears to reflect actual F-8-F-NH_2, since it co-chromatographs with F-8-F-NH_2 in reverse-phase HPLC of pooled CSF.

61.9

OPIOID MEDIATION OF COCAINE-INDUCED HYPERACTIVITY AND REINFORCEMENT. A.A. Houdi, M.T. Bardo and G.R. Van Loon. Departments of Medicine and Psychology, University of Kentucky and VAMC, Lexington, KY 40536.

The mechanisms by which cocaine produces hyperactivity and reinforcement remain poorly understood. Since reinforcement is also a property of other drugs of abuse including opiates, we examined the possible mediation of these cocaine-induced behaviors by endogenous opioid peptides. Adult Male Sprague-Dawley rats (275-375gm) were pretreated with either naloxone HCl(0.5mg/kg s.c.) or saline, followed immediately by an injection of cocaine (20 mg/kg i.p.) or saline, and locomotor activity was then assessed. For the conditioned place preference study, rats were pretreated with naloxone HCl or saline and conditioned with cocaine (5 mg/kg i.p.) paired with white compartment or saline paired with black compartment. Our results confirmed previous reports that cocaine increases locomotor activity and conditioned place preference in rats. We have also demonstrated that opioid receptor blockade, using a mu-selective dose of naloxone, antagonizes completely the locomotor-activating effect of cocaine and attenuates the strength of the place preference conditioning produced by cocaine. These data support the thesis that endogenous opioids are involved in mediation of cocaine-induced behavior.

61.10

BILATERAL LESIONS OF THE MEDULLA OBLONGATA ALTER MU-OPIOID MODULATION OF AUTONOMIC OUTFLOW. M. Palkovits*, L. Marson, F. Bobbitt*, A. Houdi and G.R. Van Loon. (SPON: D.Frazier). Dept. Medicine, U. Kentucky and VAMC, Lexington, KY 40536 and Dept. Anatomy, Semmelweis Univ., Budapest.

The role of medulla oblongata and more rostral areas of brain in mu-opioid receptor modulation of autonomic outflow was examined by studying the effects of icv DAGO on plasma catecholamines (CA), blood pressure (BP) and heart rate (HR) in conscious rats with bilateral medullary lesions. Knife cuts were made at the rostral extent of the medulla (RM), the caudal extent of the motor facial nucleus (MM), or at the caudal extent of the medulla (CM), 0.7-2.5mm lateral to the midline. Three days later, rats received DAGO, 5nmoles. Cuts at the MM and CM levels blocked the DAGO-induced increases in BP and plasma CA, but did not affect the DAGO-induced bradycardia. Cuts at the RM level blunted the sustained aspect of the DAGO-induced increase in BP and produced a delayed potentiated fall in HR, without significantly altering the plasma CA responses to DAGO. The data are consistent with mu-opioid activation of rostral medullary bulbospinal pathways to augment sympathetic outflow and of vagal nuclei to activate parasympathetic outflow. Higher centers appear to play a modulatory role.

61.11

NICOTINE-INDUCED RELEASE OF ENDOGENOUS OPIOIDS IN BRAIN. K. Davenport*, A. Houdi and G.R. Van Loon (SPON: J.Dougherty). Dept. of Medicine, Univ. of Kentucky and VA Med. Center, Lexington, KY 40536.

In this study, we tested the hypothesis that nicotine-induced release of endogenous opioids in brain mediates some of the effects of nicotine. Specifically, we hypothesized that nicotine-induced release of endogenous opioids would protect against the antagonistic effects of subsequently administered β-funaltrexamine (BFNA) on morphine-induced antinociception. Morphine antinociception was studied in adult male rats using a tail-flick method in which trials of repeated exposure to radiant heat were carried out every 3 min after sc injection of morphine. Animals received icv injections of either BFNA or saline vehicle 24 hrs before testing for morphine antinociception. Animals also received either nicotine 0.1 mg/kg sc or saline vehicle -40 and -10 min before icv injections. BFNA antagonized greatly the antinociceptive effect of morphine. Nicotine pretreatment partially protected against this antagonistic effect of BFNA. These data suggest that nicotine enhanced the release of endogenous opioids which protected opioid receptors from subsequent alkylation by BFNA. Thus, some effects of nicotine are mediated by neuronal release of endogenous opioids.

61.12

NICOTINE-INDUCED INCREASES IN ENKEPHALIN RELEASE IN DISCRETE BRAIN NUCLEI. G.R. Van Loon, A.A. Houdi, L. Marson and M. Palkovits*, Department of Medicine, University of Kentucky and VA Medical Center, Lexington, KY 40536 and Department of Anatomy, Semmelweis University, Budapest.

Some effects of nicotine may be mediated by endogenous opioids, and more specifically by proenkephalin A-related peptides. Thus, it would be of interest to assess nicotine-induced changes in activity of brain enkephalin neurons by demonstrating changes in brain enkephalin levels. However, acute administration of nicotine may alter enkephalin release without affecting brain enkephalin levels. Tyr-Gly-Gly (YGG) concentrations in brain provide an index of enkephalin release *in vivo*. Thus, we examined the thesis that nicotine alters brain neuronal enkephalin release by measuring YGG levels in specific brain nuclei punched 30 minutes after acute administration of nicotine 0.3 mg/kg s.c. in adult male rats. Acute nicotine increased YGG in several brain nuclei including nucleus accumbens, dorsal raphe, pontine reticular formation, locus ceruleus, sensory trigeminal nucleus and caudal ventrolateral medulla. This single exposure to nicotine did not alter YGG in caudate nucleus, hypothalamic paraventricular nucleus, median eminence, central amygdala, rostral ventrolateral medulla and dorsal horn of spinal cord. These brain areas in which we found nicotine-induced increases in YGG are known to be involved in mediation of analgesia, autonomic function and reinforcement. Thus, effects of nicotine on these parameters may be mediated by nicotine-induced release of enkephalins at these brain sites.

61.13

EVIDENCE FOR AGONIST AND ANTAGONIST ACTIVITY OF (+)-NICOTINE AT BRAIN SITES REGULATING AUTONOMIC OUTFLOW. L. Dong*, A. Houdi and G.R. Van Loon (SPON: R.Miller). Depts. Medicine and Pharmacol., Univ. of Kentucky and VAMC, Lexington, KY 40536.

We hypothesized that (+)-nicotine might act as a nicotinic receptor antagonist. We examined the responses of plasma catecholamines (CA), blood pressure (BP) and heart rate (HR) to icv (-)-nicotine after initial icv exposure of equimolar (-)-nicotine or (+)-nicotine or saline vehicle. (+)-Nicotine was less potent than (-)-nicotine in decreasing HR and increasing BP, but equipotent in increasing plasma CA. On the other hand, (+)-nicotine was more effective than (-)-nicotine in inhibiting HR and BP responses to subsequent (-)-nicotine, but less effective in inhibiting plasma CA responses. The data are consistent with the thesis that (+)-nicotine acts as partial agonist at nicotinic receptors on neurons regulating parasympathetic outflow and on neurons regulating outflow to sympathetic nerves, but as a full agonist on neurons regulating outflow to adrenal medulla. Using the site classification of Martin et al., the data are also consistent with the thesis that Sites 2 or 4 are the agonist site and Site 3 the antagonist site, and the brain areas regulating different aspects of autonomic outflow have differential populations of these sites.

61.14

EFFECT OF CHRONIC ETHANOL TREATMENT ON THE BIOSYNTHESIS AND POST-TRANSLATIONAL PROCESSING OF PRO-OPIOMELANOCORTIN BY THE RAT HYPOTHALAMUS. C. Gianoulakis, Douglas Hospital Research Centre and Department of Psychiatry, McGill University, Montreal, Quebec.

Previous studies have shown that chronic ethanol treatment (using a liquid diet containing 6.5% ethanol V/V), increases the biosynthesis of β-endorphin like peptides (β-EPLPs) by the anterior and neurointermediate lobe of the pituitary gland. To study the effect of chronic ethanol treatment on the biosynthesis of hypothalamic β-EPLPs animals were fed with a liquid diet for 15 days. As controls were used rats pair-fed to the ethanol group with an isocaloric sucrose diet or rats fed ad libitum with regular laboratory chow diet (basic control group). Immediately following sacrifice of the animals the hypothalamus was dissected and incubated in the presence of radioactive amino acid (^{3}H-phenylalanine or ^{35}S-methionine). The biosynthesized pro-opiomelanocortin, β-lipotropin and β-endorphin were purified by immunoprecipitation with an antiserum to β-endorphin and analyzed by polyacrylamide disc gel electrophoresis with sodium dodecyl sulfate. Results indicated that ethanol induces an increase in the rate of incorporation of radioactive amino acids into pro-opiomelanocortin β-lipotropin and β-endorphin. Thus chronic ethanol treatment alters the activity of the hypothalamic β-endorphin system. Supported by the MRCC grant MA-6923

DIFFERENTIAL RESPONSES IN PITUITARY AND HYPOTHALAMIC DYNORPHIN GENE EXPRESSION AFTER ESTROGEN AND ANTIESTROGEN IN THE RAT. S.Spampinato, T.Bachetti*, M.Canossa* and S.Ferri*. Inst.Pharmacol., Univ. of Bologna, 40126 Bologna, Italy.

In this study we have evaluated the pituitary and hypothalamic content of ir-dyn A and B (by RIA) and prodyn mRNA (by an extremely sensitive solution hybridization assay using a 400 bp RNA probe) in the adult female rat, with the aim to ascertain if estradiol benzoate (EB) and the antiestrogen tamoxifen (TAM) influence gene expression of these peptides or act at posttranslational level only. EB (administered for 14 days by sc implants) significantly reduced ir-dyn A and B as well as prodyn mRNA in the anterior pituitary (0.85±0.15 vs 1.47±0.20 pg/ug total RNA, $p<0.01$); TAM (50 ug/rat/day, sc), concomitantly administered, prevented these effects and injected alone for 14 days induced a marked increase of ir-dyn A and B and mRNA (2.94±0.46 vs 1.47±0.20 pg/ug total RNA, $p<0.01$). As regards the neurointermediate lobe, ir-dyn A and B were not changed in rats exposed to EB whereas TAM greatly reduced both peptides. However, no significant changes in mRNA were observed in the supraotic and paraventricular nuclei of the hypothalamus from which posterior pituitary dyn originates.

61.16

IDENTIFICATION OF OPIOID PEPTIDES ASSOCIATED WITH CELL PROLIFERATION IN THE DEVELOPING BRAIN. K.L. Cook*, P.J. McLaughlin and I.S. Zagon (SPON: T. Pritchard). Dept. Anatomy, Penn. State Univ. Coll. Med., Hershey, PA 17033.

Endogenous opioid systems are known to modulate the growth of developing brain; cell proliferative events are a target of opioid action. To ascertain which opioid peptide(s) is(are) related to growth, a series of studies using the cerebellar cortex (lobule VIII) of 6-day old rats subjected to opioid peptides and monitored with ^{3}H-thymidine and autoradiography were conducted. Previous findings indicated that [Met^{5}]-enkephalin (ME) is a potent opioid involved with growth. In the first experiments, the effects of ME were measured 1-24 hr following injection. Rats receiving ME (100 μg/kg) had significant reductions in labeling index (LI) from 2-24 hr (mean decrease = 15%) relative to controls. Dosages of ME ranging from 0.1 to 1000 μg/kg were tested and the LI determined 4 hr after drug exposure. ME dosages of 0.1-50 μg/kg did not alter the LI, but 100 to 1000 μg/kg markedly reduced the LI (mean decrease = 17%) relative to controls. Using these parameters to establish an appropriate paradigm, testing of a wide variety of opioid compounds revealed that ME was the most potent inhibitor of cell replication in developing cerebellum.

61.17

ENHANCED GROWTH OF CELLS IN CULTURE BY NALTREXONE, AN OPIOID ANTAGONIST. P.J. McLaughlin and J.S. Zagon. Dept. Anatomy, Penn. State Univ. College of Medicine, Hershey, PA 17033.

Endogenous opioids and opioid receptors regulate the growth of murine neuroblastoma (-NB), as well as other neural and non-neural cells of human and animal origin; opioid peptides exert an inhibitory influence on cell replication. Paradigms using opioid antagonists to perturb interaction of opioids and receptors *in vivo* have demonstrated that complete blockade of this equilibrium enhances tumorigenic events. To further explore the role of endogenous opioid systems *in vitro*, S20Y NB cells were seeded and, 24 hr later, various concentrations (10^{-5} to 10^{-13}M) of naltrexone (-NTX) or sterile water (-CO) were added to the media; media and drugs were changed daily. Cells were counted by trypan blue exclusion 48 hr later. Cultures exposed to 10^{-6} to 10^{-8}M NTX had 38-43% more cells than CO levels. The mitotic and labeling indexes of NB cells grown in 10^{-6}M NTX for 48 hr was increased 13% and 60%, respectively, over CO values. NTX (10^{-6}M) also increased the growth of mouse N115 NB, human SK-N-MC NB, and human fibrosarcoma HT-1080 by 33-53% from CO values. These results indicate that human and animal cells in culture are tonically regulated by endogenous opioid systems.

61.18

CHARACTERIZATION OF LUNG ORNITHINE DECARBOXYLASE (ODC) RESPONSIVITY TO INSULIN AND ITS MODULATION BY CNS BETA-ENDORPHIN (BE) IN RAT PUPS N.L. Greer, S.M. Schanberg*, and J.V. Bartolome. Dept. of Pharmacology, Duke Univ. Med.Ctr., Durham, N.C. 27710

Opposite regulatory roles for insulin and opioids, particularly BE, on lung development have been reported. The importance of ODC (a key developmental enzyme) in lung maturation has also been documented. This study examined whether the opposite effects of insulin and BE on lung development could be explained by opposite actions on lung ODC activity. Both 2- and 6-day-old rat lungs were analyzed representing two distinct stages in lung maturation.

Central (but not peripheral) BE markedly reduced ODC activity while insulin increased activity in both ages. BE pretreatment altered ODC responsivity to insulin in an age-dependent manner. Changes in Vmax rather than Km accounted for these changes in ODC activity. Dialyzing or mixing supernatants from treatment groups indicated a minor role for an endogenous activator of ODC activity. Actinomycin pretreatment completely prevented the increased ODC activity evoked by insulin. While de novo ODC synthesis by trophic agents appears to be mediated through cAMP in some tissues, neither diBut-cAMP, 8-BR-cAMP, PGE-1, nor cGMP increased basal lung ODC activity. These findings indicate that changes in lung ODC activity induced by insulin or BE might explain, at least in part, the opposite effects of these endogenous compounds on lung development. (Sup. by NIH Grants RO1-NS25738 and RO1-MH13688)

61.19

NICOTINE ALTERS OPIOID PEPTIDE LEVELS IN STRIATUM AND HYPOTHALAMUS OF MOUSE BRAIN K.P. Gudehithlu*, J.P. Hubble*, M. Hadjiconstantinou and G.A. Tejwani. Dept. of Pharmacology, Col. of Med., Ohio State Univ. Columbus, OH 43210

In vitro studies have shown that nicotine(N) stimulates dopamine(DA) release from striatal(STR) slices. DA has been shown to alter the level of opioid peptides(OP). The purpose of this study was to investigate whether cholinergic and/or DA receptors are involved in the effect of N on OP. Nicotine(1mg/kg, s.c.,n=27) was injected with or without mecamylamine(M)(1mg/kg, i.p.,n=7) or haloperidol(H)(1mg/kg, i.p.,n=8) and animals were sacrificed after 60 min. Nicotine elevated striatal DA(30%) and DOPAC(58%) content and M prevented this effect. Nicotine decreased β-endorphin(β-E) level in hypothalamus(HYP,31%) and STR(44%). Met-enkephalin (ME) level increased in HYP(81%) while decreased in STR(58%). Mecamylamine prevented the effect of N on β-E only in STR while, H prevented the effect in HYP and STR. Mecamylamine and H both prevented the effect of N on ME in HYP and STR. The changes observed in opioid system with nicotine treatment may be due to the binding of nicotine to cholinergic receptors and its effect on dopamine content. (Supported in part by State of Ohio, Dept. Aging)

OPIATES, ENDORPHINS AND ENKEPHALINS: PHYSIOLOGICAL EFFECTS I

62.1

OPIOIDS INHIBIT GABA-MEDIATED SYNAPTIC POTENTIALS IN NUCLEUS RAPHE MAGNUS IN VITRO. Z.Z. Pan* and J.T. Williams. Vollum Institute, OHSU, Portland, OR 97201

Neurons in raphe magnus were recorded intracellularly in slice preparations. Focal electrical stimulation was used to evoke synaptic potentials (SP) which consisted of two components, excitatory amino acid (EAA) and $GABA_A$. Combination of excitatory amino acid and $GABA_A$ antagonists completely blocked the SP. The action of opioids was studied on the membrane properties and synaptic potentials. Opioids had no effect on the membrane properties of most raphe magnus neurons, but both [Met^5]-enkephalin (ME) and DAGO depressed the amplitude of the GABA mediated synaptic potential. This action was dependent on the concentration applied and the maximum depression was to 47% of control. The EC_{50} for DAGO was 74 nM in control and 5 μM in the presence of naloxone (100 nM) giving an estimated naloxone K_d of 1.5 nM. ME (30 μM) had no effect on the EAA-SP. The depolarization induced by GABA applied exogenously was not changed by ME or DAGO suggesting that the action of opioids on the GABA-SP was presynaptic. The GABA-SP was not changed by the δ-opioid agonist, D-Pen,D-Pen-enkephalin (300 nM). These results suggest that opioids increase the activity of raphe magnus neurons by inhibition of GABA-mediated inhibitory input through μ-opioid receptors. This action may be one mechanism by which opioids modulate descending inhibition from raphe magnus in the endogenous pain-modulating system. Supported by USDHHS DA 04523.

62.2

NEURONAL ACTIVITY OF DORSAL PERIAQUEDUCTAL GRAY NEURONS OF FEMALE RATS: RESPONSIVENESS TO GABA AND ENKEPHALIN. Sonoko Ogawa, L.-M. Kow and D.W. Pfaff. The Rockefeller University, New York, NY 10021.

To test responsiveness to GABA as well as enkephalin, we recorded extracellular single-unit activity of dorsal periaqueductal gray (dPAG) neurons in tissue slices prepared from either estrogen-treated or nontreated ovariectomized female rats. GABA inhibited 86% (109/126) of dPAG neurons; and both GABA-A (THIP) and GABA-B (baclofen) agonists were effective. Some inhibited neurons were sensitized to repeated GABA (28%), THIP or baclofen applications. Bicuculline methiodide (GABA-A antagonist) excited 60% (55/92) of dPAG neurons suggesting that many dPAG neurons are tonically inhibited by intrinsic GABA through GABA-A receptors. 21 out of 55 excited neurons fired in bursts after bicuculline application. Inhibition was the predominant response to met-enkephalin. Out of 98 tested dPAG neurons, 37 showed inhibition, 8 showed excitation and 4 showed biphasic response. Most dPAG neurons fired regularly (78%) and the mean resting firing rate was 5.8±0.5 spikes/sec. Electrophysiological properties, either resting activity or responsiveness to GABA and enkephalin, were not influenced by in vivo estrogen treatment. A small percentage of units were excited by enkephalin and inhibited by GABA or excited by bicuculline as might be related to lordosis (Mobbs et al., 1988).

62.3

DELTA-SELECTIVE OPIOID AGONISTS PRODUCE SUSTAINED INCREASES IN MOSSY FIBER-CA3 RESPONSES: OPIOID PEPTIDE-INDUCED LONG-LASTING POTENTIATION ?

B.E. Derrick & J.L. Martinez Jr., Dept. of Psychology, University of California, Berkeley 94720

Previously, we reported that naloxone blocks induction, but not maintenance, of mossy fiber LTP (Soc. Neurosci. Abstr., 13:767, 1988). Since NMDA produces only a short-term potentiation at other hippocampal synapses, we investigated whether selective opioid agonists produce similar transient effects.

The delta-selective agonist D-Pen^2-[L-Pen^5]-enkephalin (DPDPE, 10 nmols) initially produced increases in CA3 responses evoked by both mossy fiber (MF) and commissural (COMM) afferents when measured < 30 min following application. After 1.5 hr, COMM-evoked responses had return to baseline, but MF-evoked increases were greater than the increase measured < 30 min. DPDPE in quantities (1 nmol) that did not produce initial excitatory effects in either MF- or COMM-evoked responses still produced increases in only MF-evoked responses when measured at 1.5 hr. These effects were not observed with mu- or kappa agonists at equivalent concentrations. Thus, a delta agonist appears to produce an LTP-like potentiation of MF responses similar to that observed following tetanization.

62.4

OPIOID MODULATION OF THE IN VIVO RELEASE OF CCK-8 FROM THE DORSAL HORN OF THE RAT .

R.E.Rodriguez and M.P.Sacristán. Dept of Biochemistry Univ. of Salamanca 37007 Salamanca, Spain. (SPON: M. Lafarga)

CCK-8 immunoreactivity is observed in the superficial layers of the dorsal horn of the rat. Most of the CCK-8 containing fibers as seen by immunohistochemistry, represent primary sensory neurons, suggesting that this peptide may be involved in pain control and transmission.

We show that CCK-8 like immunoreactivity, as determined by RIA, is released from the spinal cord of the rat in vivo (1) following potassium stimulation (2) by direct activation of high threshold peripheral afferents. The addition of potassium to the media resulted in a 160% increase in the levels of CCK-8 above resting levels. Peripheral stimulation resulted in a 283% increase. This release was completely abo abolished by analgesic doses of the mu selective agoniat Dagol, and partially affected by the delta selective agonist DPDPE in a naloxone (0.1mg/Kg and 1mg/Kg respectively) reversible fashion. Perfusion with the Kappa agonist U69593 did not affect the in vivo release of CCK-8. These results suggest a mu/delta opioid modulation of the in vivo release of CCK-8

62.5

CHOLERA TOXIN (CTX) BLOCKS OPIOID-INDUCED PROLONGATION OF THE ACTION POTENTIAL DURATION (APD) OF MOUSE DORSAL ROOT GANGLION (DRG) NEURONS IN CULTURE WHEREAS PERTUSSIS TOXIN (PTX) BLOCKS OPIOID-INDUCED SHORTENING.

K.-F. Shen* and S.M. Crain (SPON: D.P. Purpura). Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

APD shortening elicited by 1-10μM DADLE is mediated by opioid receptors coupled to PTX-sensitive inhibitory Gi/Go proteins (Shen & Crain, Br.Res.'89), whereas APD prolongation by 1-10nM DADLE is mediated by excitatory opioid receptor subtypes whose effects are blocked by injection of an inhibitor of cyclic AMP-dependent protein kinase (Chen et al, Br.Res.'88). The A fraction of CTX, which ADP-ribosylates Gs and attenuates ligand-activation of associated receptors, was used to determine if excitatory opioid receptors on DRG neurons are coupled via Gs to the adenylate cyclase (AC)/cAMP system. After treatment of DRG-cord explants with CTX-A (0.1-1ng/ml; >15min) or with whole toxin (at even lower concentrations), APD prolongation elicited by 1-10nM μ, δ, or k opioids was blocked (28/31 DRG cells tested), whereas APD shortening by opioids was unaffected. Higher levels of CTX (0.1-1μg/ml) also blocked opioid excitatory effects when tested after initial APD prolongation elicited by CTX alone. Our results indicate that excitatory opioid receptors on DRG neurons are coupled via Gs to the AC/cAMP system (resembling β-NA receptors) in contrast to inhibitory opioid receptor linkage to Gi/Go (resembling α_2-NA receptors). (Supported by NIDA grants DA-02031 & DA-05203 to SMC.)

62.6

DYNORPHIN PROLONGS THE ACTION POTENTIAL DURATION (APD) OF MOUSE DORSAL ROOT GANGLION (DRG) NEURONS BY DECREASING A K^+ CONDUCTANCE WHEREAS THE SPECIFIC KAPPA OPIOID, U-50,488H DOES SO BY INCREASING A Ca^{2+} CONDUCTANCE.

S.M. Crain and K.-F. Shen. Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

High (μM) concentrations of kappa opioids shorten the APD of DRG neurons by decreasing a voltage-sensitive Ca^{2+} conductance (Werz & Macdonald, JPET'85). In addition to these inhibitory effects, low (nM) levels of dynorphin and U-50,488H prolonged the APD in >80% of DRG neurons in DRG-spinal cord explants (tested in 5mM Ba^{2+}/BSS). However, when opioid responsivity tests were carried out in the presence of multiple K^+ channel blockers (Ba^{2+},Cs^+,TEA), 1nM dynorphin prolonged the APD in only 10% of the neurons (n=21), whereas 1nM U-50,488H still elicited APD prolongation in 60% of the cells (n=37). During K^+ channel blockade, 1nM dynorphin shortened the APD in 33% of the DRG cells (vs 7% in control media), presumably by unmasking inhibitory kappa receptors that attenuate Ca^{2+} channel activity. These data suggest that dynorphin prolongs the APD of DRG neurons by activating a kappa receptor subtype that decreases a voltage-sensitive K^+ conductance(see Fan, Shen & Crain, this vol.), whereas U-50,488H prolongs the APD by activating another kappa receptor subtype that increases a voltage-sensitive Ca^{2+} conductance. Thus U-50,488H-induced APD prolongation appears to be mediated by an excitatory subtype of kappa opioid receptors that produces the opposite effect on Ca^{2+} channels as occurs during APD shortening mediated by inhibitory kappa receptors. (Supported by NIDA grants DA-02031 & DA-05203 to SMC.)

62.7

DYNORPHIN-INDUCED SUPPRESSION OF THE ACTIVITY OF A SPECIFIC SUBTYPE OF VOLTAGE-SENSITIVE K^+ CHANNELS IN MOUSE DORSAL-ROOT GANGLION (DRG) NEURONS MAY UNDERLIE PROLONGATION OF THE ACTION POTENTIAL DURATION(APD).

S.F.Fan[1], K.-F.Shen[2] and S.M.Crain[2] (SPON:S.Yazulla). Dept.of Anat. Sci.[1],HSC,SUNY at Stony Brook,NY 11794 and Dept.of Neuroscience[2],Albert Einstein Coll. of Med.,Bronx,NY 10461.

Tight-seal whole-cell voltage-clamp recordings were made on DRG neurons in dissociated cell cultures. Outward K^+ current during depolarizing pulses was markedly decreased by 1nM dynorphin (in 5mM Ba^{2+}/BSS). These data confirm our current-clamp results suggesting that APD prolongation elicited by 1nM dynorphin in >80% of DRG neurons in DRG-cord explants is mediated by a kappa receptor subtype that decreases a voltage-sensitive K^+ conductance (Crain & Shen, this vol.). Cell-attached patch-clamp recordings from dissociated DRG neurons revealed two subtypes of voltage-sensitive K^+ channels with different conductances and activities. Bath application of 1nM dynorphin decreased the probability of opening of K^+ channels with smaller(~40pS) conductance, whereas it increased opening of K^+ channels with larger (~100pS) conductance. Attenuation of ~40pS K^+ channel activity was so prominent, that it might account for the observed opioid suppression of the whole-cell K^+ conductance and resulting APD prolongation. In contrast, the enhanced openings of ~100pS K^+ channels may account, in part , for the 1nM dynorphin-induced APD shortening in some DRG cells. Since dynorphin added to the bath solution altered the activities of both types of K^+ channels in the patch sealed off by the pipette tip, our results provide direct evidence that some modes of excitatory and inhibitory modulation of the APD of DRG neurons are mediated by diffusible second messengers (regulated by G proteins: Shen & Crain, this vol.).(Support: NIDA grants DA-02031 & DA-05203 to SMC and HL-31299 to P.R. Brink, SUNY.)

62.8

OPIOID REGULATION OF ADENYLATE CYCLASE AND PRO-ENKEPHALIN mRNA IN NEONATAL RAT PRIMARY NEURONAL CULTURES.

D.R. Marckel and S.R. Childers. Dept. of Pharmacology, Univ. of Florida Coll. Med., Gainesville, FL 32610.

Opioids regulate adenylate cyclase activity in mammalian brain and several cell lines. Proenkephalin mRNA levels are in part regulated by cAMP levels through protein kinase A. Neonatal rat primary neuronal cultures were chosen to study the relationship between opioid regulation of adenylate cyclase and proenkephalin mRNA levels, both acutely and chronically.

Primary neuronal cultures were made from 1 day old rats in which the forebrain was removed, cleaned of pia, triturated, treated with trypsin and DNAse I, and plated. After 2 days, cultures were treated with cytosine arabinoside for 3 days to decrease the glial population and obtain cultures of 80-85% neurons. After 10 days of culture, cAMP levels were measured in cells incubated for 5 min at 37° with isobutylmethylxanthine (IBMX) and various agents. Both isoproterenol and forskolin stimulated cAMP levels in intact cells 5-10 fold. D-Ala enkephalinamide decreased stimulated cAMP levels by 20-30%. These effects were also observed when adenylate cyclase activity was measured in membrane preparations by an HPLC method.

Proenkephalin mRNA levels in primary neuronal cultures, measured by Northern blot analysis, were significantly increased by 18 hour treatment with isoproterenol or forskolin . This effect was diminished by including opioid compounds with the stimulatory agent. These results suggest that opioid agonists may regulate the level of endogenous enkephalin, possibly through the inhibition of adenylate cyclase

Supported by PHS grant DA-04534 from the National Institute on Drug Abuse.

62.9

CHOLINERGIC TONE IS REQUIRED FOR OPIOID ENHANCEMENT BUT NOT OPIOID INHIBITION OF STIMULATED ENKEPHALIN RELEASE. H.Xu*and A.R. Gintzler, Department of Biochemistry, SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203.

This laboratory has previously demonstrated that opioids can enhance and inhibit the evoked release of methionine enkephalin from the myenteric plexus. Low doses (nanomolar) enhance release whereas higher concentrations (10-100 nM) inhibit release. Following pretreatment with forskolin, the opioid inhibition of stimulated met-enkephalin release is no longer observed. Instead, a previously inhibitory concentration of opioid now produces an enhancement of release. Excitatory responses to low concentrations of opioids are not affected by an identical pretreatment with forskolin. The muscarinic receptor antagonist atropine selectively blocks opioid-mediated enhancement of evoked enkephalin release but has no effect on the opioid inhibition of release. Furthermore, in the presence of atropine, forskolin still completely attenuates opioid inhibition but the opioid enhancement of release is no longer unmasked. These results indicate the divergence of the biochemical pathway that mediates opioid enhancement or inhibition of stimulated enkephalin release. It is suggested that the intracellular concentration of a muscarinic receptor coupled second messenger(s) might be crucial for the manifestation of opioid enhancement of stimulated met-enkephalin release.

62.10

ELECTRICALLY-INDUCED RELEASE OF PRO-ENKEPHALIN-DERIVED PEPTIDES FROM THE GUINEA-PIG MYENTERIC PLEXUS PREPARATION. A.D.Corbett*, M.G.C.Gillan* and H.W.Kosterlitz. U.R.A.D., University of Aberdeen, Aberdeen AB9 1AS, Scotland.

Two preparations were set up in organ baths and perifused with Krebs solution containing cycloheximide, tetraethylammonium and peptidase inhibitors. One preparation was a non-stimulated control while the other was stimulated at 2 Hz, 50mA for 15 min. The tissue contents of opioid peptides and the amounts released into the Krebs solution were determined by bioassay after HPLC fractionation. Stimulation caused 45% decrease in tissue contents of [Met^5]enkephalin and [Leu^5]enkephalin. The amounts of [Met^5]enkephalin and [Leu^5]enkephalin in the perifusing Krebs solution were 58 and 10 pmol/g, being 40-50% of this decrease in tissue contents. In contrast, the tissue contents of [Met^5]enkephalyl-Arg-Gly-Leu and [Met^5]enkephalyl-Arg-Phe were decreased by 20-30%, the amounts in the perifusing Krebs solution being only 25% of this decrease in tissue contents. Thus, pro-enkephalin-derived opioid peptides are released differentially by electrical stimulation of the guinea-pig myenteric plexus. (Supported by NIDA grant DA00662).

62.11

THE ENKEPHALINASE INHIBITOR SCH 32615 INCREASES DOPAMINE (DA) TURNOVER IN THE NUCLEUS ACCUMBENS (NACC) OF THE RAT BRAIN. G. Biggio, O. Giorgi, E. Ongini, M. Trampus*. Dept. of Exp. Biology, Univ. of Cagliari and Res. Labs., Schering-Plough, Milan, Italy (SPON: W. Fratta)

Previous studies have shown that the enkephalinase (ENKase) inhibitor acetorphan stimulates locomotion in rats and mice. This effect depends on the integrity of the mesolimbic DAergic system, since it is prevented by the infusion of 6OH-DA into the NACC (J.P.E.T., 243: 1062, 1987). Therefore, we considered of interest to investigate the effects of the novel ENKase inhibitor SCH 32615 (J.P.E.T., 245: 829, 1988) on the activity of dopaminergic neurons as reflected by the alterations in the content of the major DA metabolite dihydroxyphenyl acetic acid (DOPAC). SCH 32615 (10-30-100 mg/kg, s.c., 60 min before sacrifice) elicited a dose-dependent increase in the concentration of DOPAC in the NACC without affecting the DA content. The maximal increase in DOPAC content was 48% above the control value at the dose of 100 mg/kg. No changes in DA turnover were detected in the s. nigra, striatum and prefrontal cortex. The acceleration of DA metabolism in the NACC induced by SCH 32615 (50 mg/kg, s.c.) was maximal by 60 min and DOPAC content returned to basal values by 2 h after drug injection. Our results support the view that endogenous enkephalins may modulate the activity of mesolimbic DAergic neurons.

ALTERATIONS IN METABOLIC ACTIVITY OF RAT BRAIN STRUCTURES FOLLOWING INJECTIONS OF MORPHINE INTO THE SUBSTANTIA NIGRA H.D. Everist and A. Pert (SPON: D. Lozovsky). BPB, NIMH, Bethesda MD 20892 and OEP, ADAMHA, Rockville MD

Microinjections of opiate agonists into the substantia nigra produce profound behavioral effects. We have employed 2-DG metabolic mapping procedures to assess the functional activity in rat brain following bilateral intranigral injections of morphine (10 nmoles) or saline (1 µl). Immediately following intranigral injections, all rats were injected with 150 µCi/kg of ^{14}C-2DG (i.p.). Forty-five minutes later the animals were sacrificed, their brains removed and prepared for autoradiographic analysis. Intranigral injections of morphine had little effect on metabolic activity in the striatum or n. accumbens. Structures receiving nigrothalamic input, such as the mediodorsal, laterodorsal and parafascicular nuclei of the thalamus had decreased activity. Modest increases in metabolic activity were seen in the superior colliculus which also receives afferents from the substantia nigra. Increases in metabolic activity were also found in structures that receive nigrotegmental input such as the pedunculopontine tegmental nucleus, central gray matter, as well as other pontine reticular nuclei. It appears that the behavioral effects seen following nigral injections of morphine are determined through nigrotegmental or nigrotectal pathways and not through nigrostriatal activation.

OPIATES INHIBIT RELEASE OF IMMUNOREACTIVE BRADYKININ (iBK) FROM INFLAMED TISSUE, AS EVALUATED BY PERIPHERAL MICRODIALYSIS PROBES. Laureen Wells*, Anna Solodkin* and Kenneth Hargreaves*, (Spon: R. Traub), Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

We have reported that systemic opiates suppress edema and plasma extravasation during carrageenan (carra)-induced inflammation (Pain Res. Clin. Mngmt., 3:55;1988, Elsevier). This study determined if systemic opiates inhibit iBK release. A 2 cm cellulose dialysis probe (Travenol 15-11) was inserted s.c. into the plantar hindpaws of anesthetized rats (n=8-17/group) who were then injected with 8 mg carra. iBK in the diasylate was measured by RIA. Rats were given either i.p. levorphanol (L; 1.5 mg/kg), dextrorphan (D; 1.5 mg/kg), or saline (S) every hour starting 1 hour before anesthesia. Data were analyzed by ANOVA followed by Duncan's test. In vitro studies indicated a 8.9% recovery of iBK at 8 µ l/min flow with the amount of iBK collected linearly related to its external concentration (r=0.96). During an initial study, iBK levels from carra-treated paws (260 ± 45 fm/ml) were significantly greater than levels in saline-injected paws (45.2 ± 9 fm/ml; $p<0.005$). In carra-injected rats treated with L, iBK levels (140± 32 fm/ml) were significantly lower than iBK in rats given either D (212± 67fm/ml; $p<0.05$) or S (239± 52fm/ml; $p<0.05$). L ($p<0.05$), but not D, significantly reduced carra-induced edema by approximately 20% as compared to saline-treated rats. The results indicate that the suppression of carra-induced inflammation by systemic opiates is accompanied by a reduction in the levels of peripheral iBK, one of the chemical mediators involved with plasma extravasation and edema.

62.14

THE ZINC CHELATOR, DITHIZONE, LOWERS HIPPOCAMPAL LEVELS OF OPIOID PEPTIDES. C.L. Mitchell, M.I. Barnes*, J.S. Hong and J.F. McGinty. LMIN, NIEHS/NIH, Research Triangle Park, NC 27709 and Dept. of Anatomy and Cell Biology, School of Medicine, East Carolina University, Greenville, NC 27858.

Zinc is present in particularly high concentrations in the giant boutons of dentate granule cell mossy fibers (Haug, Histochemie 8:355, 1967). One postulate for its function is an involvement in storage of vesicular products (Storm-Mathisen, Prog. Neurobiol. 8:119, 1977). We, therefore, examined the ability of dithizone (D) to alter the levels of hippocampal opioid peptides. D was administered subcutaneously in doses of 25 and 50 mg/kg. Both doses lowered the level of dynorphin A(1-8) (DYN). The 25 mg/kg dose lowered DYN by 13% and the 50 mg/kg dose lowered it by 21%. The higher dose lowered the level of methionine enkephalin (ME) by 31%. The effect on DYN was transitory, with DYN returning to control levels within one hour. The effect on ME was more sustained (>2.5 hrs). These doses of D reduced TIMM staining, thus indicating a reduction in mossy fiber zinc. The data are consistent with the notion that this zinc may play a role in the storage and/or release of these peptides in the mossy fibers.

REPEATED STRESS OF DEFEAT INCREASES LOCOMOTOR RESPONSE TO MORPHINE. M.L. Thompson* and C. A. Paronis* (SPON. L. Shuster), Dept of Pharmacology, Tufts Medical School, Boston, MA 02111.

It has previously been demonstrated that acute stress induces an activation of the mesocorticolimbic dopaminergic system (Herman et al 1982). Furthermore, Antelman & Chiodo (1983) demonstrated that repeated exposure of rats to stress increases the stereotypy response to amphetamine, similar in extent to that observed following repeated injections of amphetamine. Herman et al (1984) extended these results to amphetamine induced locomotor activity as well. Repeated exposure to amphetamine leads to "reverse tolerance" or enhanced locomotor activity, rather than a decrease. "Reverse tolerance" has also been demonstrated following repeated morphine exposure (Shuster, 1975). In this experiment, we report that mice injected with morphine following repeated exposure to a biologically relevant form of stress, social conflict, show "reverse tolerance" to morphine similar in extent to that seen in mice injected repeatedly with morphine. Male B6AF1 mice, 3-4 months old, were either injected with morphine, 5 mg/kg ip every other day for 10 days or subjected to a bout of social conflict (70 bites duration, about 3-4 min.) as intruders in a resident-intruder paradigm. 5 days after the last injection or bout of conflict, mice were housed individually overnight in a standard mouse cage. The next afternoon mice were injected with 5 mg/kg ip morphine and locomotor activity was assessed for 30 min. in an Opto- Varimex (Columbus Instruments) set to record ambulatory activity. The resulting scores were expressed as percent of a control group of mice receiving an injection of saline on test day. A fourth group of mice had no prior experience but was injected with morphine on the test day. Morphine significantly suppressed locomotor activity in this latter group, to a level of 50% of controls. Repeated morphine treated mice showed significant "reverse tolerance", showing activity levels 160% of controls. Mice which were exposed to repeated defeat also showed significantly increased ambulatory scores compared to controls or the group receiving a single injection of morphine. Activity levels in the defeated group were almost identical to those of the repeated morphine mice. Thus in addition to its marked effects on the endogenous opioid system, defeat also appears to mimic the effects of morphine on dopaminergic systems of the brain as well.

62.16

CARDIAC LEVELS OF DYNORPHIN A AND LEU-ENKEPHALIN DURING THE POSTNATAL DEVELOPMENT OF SPONTANEOUSLY HYPERTENSIVE RATS. M. Dumont, L. Sabourin* and S. Lemaire. Department of Pharmacology, University of Ottawa, Ottawa, K1H 8M5, CANADA.

The levels of immunoreactive dynorphin A (ir-Dyn A) and ir-Leu-enkephalin (ir-Leu-Enk) were measured in acid extracts of hearts of male Wistar (WR), Wistar Kyoto (WKY) and spontaneously hypertensive (SHR) rats at different ages (4-16 weeks). Heart contents in ir-Leu-Enk were much higher than those of ir-Dyn A in all strains studied. The hearts of 8 week-old WR, WKY and SHR rats contained comparable levels of ir-Leu-Enk (7.4, 6.4 and 4.8 pmol/g, respectively). On the other hand, the cardiac levels of ir-Dyn A were significantly higher in SHR rats (731 fmol/g) than in WR (84 fmol/g) and WKY (250 fmol/g) rats at 8 weeks of age. Ir-Dyn A and ir-Leu-Enk were also measured during the development of hypertension. In addition to the increased levels of ir-Dyn A in 8 week-old SHR rats, significant changes were also found in the levels of both opioid peptides at 16 weeks. At this age, where hypertension is well established, we observed a 2 fold decrease in the levels of ir-Dyn A and a concomitant 1.8 fold increase in the levels of ir-Leu-Enk in SHR compared to WKY rats. These results suggest that cardiac Dyn A and Leu-Enk may play a role in the development and/or maintenance of hypertension. Supported by the HSFO.

ROLE OF β- ENDORPHIN AND cAMP IN MANIA. A.J. Giannini, R.Q. Quinones, D.M. Martin. Ohio State University, P.O. Box 2169, Youngstown, Ohio 44505.

Forty male subjects had assays of serum β-endorphin and serum cAMP. Twenty subjects were actively manic while 20 were age matched, race-matched controls. Assays were performed by double antibody radioimmunoassay.

Ratios of cAMP (cyclic adenosine monophosphate) β-endorphin were compared. Manics showed a significant lower ($p > .02$) ratio than did the controls. There were no significant differences in manic/control cAMP levels or manic/control β-endorphin levels. The characteristic rise of cAMP and fall in β-endorphin bipolar (manic-depressive) disease may have contributed to the significant differences in the ratios. Since the significance occurred only in the ratio rather than in individual comparison, it is posited that a physiological relationship exists between β -endorphin and cAMP.

62.18

GLUCOSE UTILIZATION DURING ALFENTANIL INDUCED SEIZURES IN RATS. W.A. Kofke, R.A. Hawkins. Pennsylvania State University, Hershey, PA 17033

Seizure activation of subcortical foci has been reported in rats with a variety of narcotics. Our aim was to determine, using ($6\text{-}^{14}C$) glc autoradiography, if a similar phenomenon occurs with alfentanil (A). Methods. Rats were anesthetized with halothane, intubated, paralyzed, ventilated, and catheterized. After surgery all rats were ventilated with N_2O/O_2 for one hour, then they entered 1 of 3 grps: (1) N_2O/O_2, (2) low dose A (150 ug/kg IV then 15 ug/kg/min), (3) high dose A (1000 ug/kg IV then 100 ug/kg/min). After another hr each rat was injected with ($6\text{-}^{14}C$) glc and glc consumption was measured over 5 min by autoradiography (Am J Physiol 245:C428, 1983). Results. High dose alfentanil produced seizure on EEG with thalamic depression and activation of ventral hippocampus and lat. septal N ($p<.001$). Conclusions. Seizures occur with high dose alfentanil with activation apparently arising from the hippocampus and lat. septal N. These data from us and others (Young;Tommasino) suggests existence in rats of a proconvulsant opiatergic system which manifests with hippocampal activation and thalamic depression.

PAIN MODULATION: CNS PATHWAYS

63.1

THE RELATIVE EFFICACY OF MONOPOLAR VS. BIPOLAR ELECTRODES IN STIMULATION PRODUCED ANALGESIA. K.Jones* and B.Thorn. Dept. of Psychology, The Univ. of Al., Tuscaloosa, Al. 35487

This study explored the differences in the analgesic properties elicited between bipolar electrodes delivering a biphasic current and monopolar electrodes delivering a biphasic or monophasic current in the ventral area of the periaqueductal gray (PAG). Analgesia was evaluated by relative increases in tail-flick latencies upon focal brain stimulation (FBS). Ability of naloxone to reverse the stimulation-produced analgesia was also evaluated.

Results indicate that electrode configuration is crucial to whether analgesia is likely to be produced by FBS of the ventral PAG. Also, while naloxone reliably attenuated the analgesia produced by either stimulation parameter with monopolar electrodes, it failed to alter the analgesia elicited by bipolar/biphasic stimulation. A potential confound is that monopolar electrodes were located in the dorsal part of the ventral PAG, whereas bipolar electrodes were located in the ventral aspect. It is possible that the analgesia elicited from the dorsal and ventral areas of the ventral PAG may differ in underlying mechanisms.

63.2

INVOLVEMENT OF PERIAQUEDUCTAL GRAY NMDA RECEPTORS IN STRESS-INDUCED ANALGESIA IN MICE. B.Siegfried* (1) and R.L. Nunes de Souza*(2) (SPON: European Brain and Behaviour Society). (1) Inst. Pharmacol. Univ. Zurich, CH-8006 Zurich, Switzerland. (2) Lab. Psychobiol., FFCLRP, Campus Univ. Sao Paulo, 14049 Ribeirao Preto, Brazil.

Recently, a functional role for PAG NMDA receptors in pain inhibition has been suggested (Jacquet, Eur. J. Pharmacol. 154: 271, 1988). The present study assessed the effect of PAG NMDA receptor blockade on stress-induced analgesia, using the model of social conflict (Siegfried et al., Behav. Neural Biol. 42: 91, 1984). Saline injected, attacked mice exhibited a marked analgesia (tail-flick latency, TFL 1 min postexposure, median and interquartiles; 3.30(2.62-4.87)s) which was prevented by prior injection into the PAG of AP-7 (2.0 nmol; TFL 1.33(1.23-1.43)s, $p<0.005$, Wilcoxon test) or naloxone (6.0 nmol; TFL 1.33(1.23-1.43)s), as well as by i.p. injection of the non-competitive NMDA antagonist MK 801 (33 nmol; TFL 1.55(1.50-1.70)s). The results indicate an involvement of NMDA receptors in endogenous analgesic mechanisms activated by stress, and show that social conflict analgesia can be antagonized by intervention at either opioid or nonopioid receptor sites within the PAG.

63.3

ELECTRICAL BRAINSTEM STIMULATION IN THE C5 - T2 DORSAL ROOT GANGLIONECTOMIZED RAT J. Ovelmen-Levitt, L. Fox*, J. Bazoukis*, J. Aruda* and B.S. Nashold, Jr. Div. of Neurosurgery, Duke U. Med. Ctr., Durham, N.C. 27710

Central pain states in humans have been reported to be relieved in some cases by electrical stimulation in certain brainstem locations. An animal model of central or deafferentation pain has been developed in the rat with C5 - T2 ganglionectomies. The efficacy of intermittent brainstem stimulation is being studied in this model to alter or ameliorate the behavioral manifestations (biting and/or scratching of the deafferented limb). Fifty nine (59) rats with bipolar implants in VPL, Internal Capsule (IC), PAG-PVG, and Lateral Hypothalamus (LH) and/or C5-T2 ganglionectomies have been studied. No rats with implants only (IO) exhibited biting. Animals with implants in VPL, IC, and PAG followed by ganglionectomies, but without stimulation, had mean onset days of biting which were similar to those with ganglionectomies only (GO); while ganglionectomized animals with LH implants started biting significantly earlier than other controls. So far, animals with stimulation in the IC showed a reduced tendency to bite, while those with PAG-PVG stimulation a greater tendency to bite when compared with (GO) controls. The results indicate that intermittent brainstem stimulation in certain regions can alter the progress of a deafferentation syndrome which follows C5-T2 ganglionectomies in rats.

TIME COURSE FOR THE DISSIPATION OF TOLERANCE TO THE ANTINOCICEPTIVE EFFECT OF CONTINUOUS PAG STIMULATION IN RATS. M. M. Morgan and J. C. Liebeskind. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563.

Tolerance to the antinociceptive effect of electrical stimulation of the periaqueductal gray (PAG) has been shown to occur with prolonged stimulation. The objective of this study was to determine the duration of this tolerance. Two groups of male Sprague-Dawley rats were chronically implanted with a bipolar electrode in the PAG. Nociception was assessed using the tail-flick test to noxious heat. Brain stimulation consisted of 50 Hz monophasic pulses (0.4 ms) preceding by 10 s and remaining on throughout the test. The first group was used to assess the stability of stimulation-produced antinociception (SPA) by determining the threshold for SPA twice at an interval of 4 to 8 days. The threshold for SPA was found to be unchanged at 6 of 17 stimulation sites. A slight change (10-20 μA) occurred at 7 other sites. Aversive reactions occurred at the 4 remaining sites. The second group of rats was made tolerant to SPA by administering 6 min of continuous stimulation at the SPA threshold level. Six of 15 sites supported antinociception throughout the stimulation period. Tolerance to SPA occurred at the remaining 9 sites. One day after tolerance was induced, 4 of these 9 sites supported SPA at the stimulation intensity used to induce tolerance. SPA threshold had returned to pre tolerance levels at 8 of 9 sites 1 week after induction of tolerance. These findings demonstrate that SPA threshold is relatively stable across test sessions, and that tolerance to SPA induced with continuous stimulation dissipates with time. (NIH grant NS07628).

63.5

COMPARISON OF DESCENDING INHIBITION OF NOCICEPTIVE HINDPAW- AND TAIL-FLICK REFLEXES FROM STIMULATION OF THE PERIAQUEDUCTAL GRAY MATTER (PAG) IN THE RAT. R. Levine*, M. M. Morgan, J. T. Cannon, and J. C. Liebeskind. Departments of Psychology, UCLA, Los Angeles, CA 90024-1563 and University of Scranton, Scranton, PA 18510.

Electrical stimulation of the PAG is known to inhibit nociception. The goal of this study was to compare the strength of this descending inhibition for the tail and the ipsilateral and contralateral hindpaws. Male Sprague-Dawley rats were anesthetized with pentobarbital, implanted with a bipolar electrode in the right or left caudal PAG, and the thresholds for stimulation-produced inhibition of the tail-flick and paw-flick reflexes to noxious heat were determined. PAG stimulation consisted of 50 Hz monophasic pulses (0.4 ms) for 10 s preceding and throughout the test. The mean current required to inhibit nociception in the hindpaw ipsilateral to the electrode was significantly lower than that needed in the contralateral hindpaw (119 vs 164 μA). Mean baseline paw-flick latencies did not differ from each other, but were significantly shorter than the mean baseline tail-flick latency (3.0 vs 3.4 s). In addition, the threshold for inhibition of the tail-flick reflex (66 μA) was significantly lower than that of the hindpaws. In a follow-up study, the heat source was adjusted so that the baseline paw-flick latencies approximated that of the tail-flick latency (3.8 to 3.6 s). This change resulted in a reduction in the thresholds for inhibition of the paw-flick. The threshold for inhibition of the ipsilateral paw-flick was not significantly different than that of the tail-flick (57 vs 48 μA). However, a difference in threshold between ipsilateral and contralateral paws was still evident (57 vs 97 μA). (NIH grant NS07628).

63.6

NALOXONE-SENSITIVE INHIBITION OF LIMB-WITHDRAWAL REFLEXES PRODUCED BY ELECTRICAL STIMULATION OF THE ARCUATE NUCLEUS IN ANESTHETIZED MICE. J. T. Cannon, R. Yirmiya and J. C. Liebeskind. Departments of Psychology, University of Scranton, Scranton, PA 18510 and University of California, Los Angeles, CA 90024.

Electrical stimulation of the periaqueductal gray (PAG) can inhibit limb-withdrawal reflexes in several strains of mice. A striking characteristic of this inhibition is the marked degree to which it can be reduced by opiate antagonists. Such sensitivity stands in stark contrast to work with rats in which the effects of opiate antagonists either prove elusive to demonstrate or, when observed, are typically only small to moderate in magnitude. As projections from the arcuate n. are a major source of opioids in the PAG, we determined whether electrical stimulation of the arcuate also produces naloxone-sensitive inhibition of limb-withdrawal. Male Swiss Webster mice were anesthetized with Nembutal and maintained at a level of anesthesia sufficient to block spontaneous movements throughout testing. Baseline limb-withdrawal latencies to a noxious heat source were determined for both hind limbs. Brain stimulation consisted of 0.4 msec cathodal pulses delivered at 50 pulses per sec for 10 sec preceding and throughout a withdrawal trial. The lowest stimulation threshold for inhibiting the withdrawal of either limb was determined before and after an injection of either naloxone (5 mg/kg) or an equal volume of saline. Stimulation of the arcuate n. consistently inhibited limb-withdrawal. Paralleling PAG stimulation in the mouse, naloxone elevated stimulation thresholds for this inhibition by over 200%. Supported by NIH grant NSO7628.

63.7

AN EXAMINATION OF THE TIME COURSE OF ANALGESIA PRODUCED BY INJECTION OF LIDOCAINE INTO THE ANTERIOR CINGULUM. A.L. Vaccarino and R. Melzack*, Department of Psychology, McGill University, Montreal, Quebec, Canada, H3A 1B1.

In a previous study (Soc. Neurosci. Abstr. 14:855, 1988) we reported that injection of lidocaine, a local anesthetic, into the anterior cingulum bundle of the rat produced a significant reduction in formalin pain scores but had no effect on foot-flick latencies. The analgesia in the formalin test persisted for the entire 40 minute observation period.

In the present study we examined the time course of the functional block produced by lidocaine. A cannula was stereotaxically implanted into the anterior cingulum on one side in anesthetized rats. Seven to ten days after surgery the rats were injected with 1 ul of 2% lidocaine or saline into the cingulum at various times before and after injecting one hind paw with 50 ul of 2.5% formalin. Rats injected with lidocaine 60 minutes prior to formalin injection showed no analgesia, suggesting that no permanent damage was produced by the lidocaine. Rats injected at other times showed various analgesic profiles relating to time of injection and laterality. These results are discussed. Supported by NSERC grant A7891.

63.8

EFFECTS OF VENTROLATERAL ORBITAL CORTEX STIMULATION ON THE JAW-OPENING REFLEX (JOR) AND SPINAL CORD DORSAL HORN NEURONS. C.Y. Chiang*, N. El-Yassir*, E.M. Moustafa*, J.O. Dostrovsky and B.J. Sessle. (SPON: L. Spero) Dept. of Physiology, and Fac. of Dentistry, Univ. of Toronto, Ontario, Canada.

Anatomical studies have reported that the ventrolateral orbital (VLO) region of prefrontal cortex (PFC) sends a descending projection to the periaqueductal gray (PAG). It is also known that the VLO receives a dense projection from nucleus submedius, a thalamic nucleus which receives direct spinal and trigeminal ascending projections, and which has been implicated in nociception. These findings suggest that the VLO may be involved in descending modulation and thus we have investigated the effects of prefrontal cortex stimulation on the tooth pulp-evoked JOR and on spinal cord dorsal horn neurons. All the experiments were conducted on rats anesthetized with chloralose-urethane. Dorsal horn neurons were activated by percutaneous electrical stimulation and mechanical stimuli. Conditioning stimuli consisted of trains of stimuli (100Hz, 100ms) delivered, 150ms prior to the test stimulus, to the VLO region of PFC; in some mapping experiments, the effects of stimulation at many sites within PFC were examined. Stimulation sites were reconstructed from histological sections. Modulatory effects were assessed by comparing 16 averages of the JOR before and immediately following the conditioning stimulation, and for dorsal horn neurons on the basis of rate-meter and post-stimulus histogram plots. Stimulation at some sites in PFC, including medial VLO, were found to reduce the magnitude of the JOR. However PFC stimulation did not result in marked alterations in the responses of nociceptive or non nociceptive neurons in the spinal dorsal horn. In summary, PFC stimulation depresses the JOR but appears to have little effect on dorsal horn neurons.
Supported by the Canadian MRC.

ELECTRICAL STIMULATION OF SENSORY CORTEX INCREASES THE NOXIOUS THRESHOLD OF SPINOTHALAMIC TRACT CELLS, C. Owens, D. Zhang and W.D. Willis, Marine Biomedical Institute and Department of Anatomy & Neurosciences, University of Texas Medical Branch, Galveston, TX 77550

Stimulation of the cortex caudal to the central sulcus affected responses of spinothalamic tract (STT) cells to natural cutaneous stimulation. In 9 chloralose/pentobarbital anesthetized, Flaxedil paralyzed Macaca fascicularis, unit recordings were made from 14 STT cells. The responses of each cell to four cutaneous stimuli ranging from innocuous to frankly noxious were quantified. The stimuli were repeated during cortical stimulation (1mA, 333Hz, 0.5mS duration) near the location of the maximum evoked potential from sural nerve. The predominant (n=8) effect on the transmission of sensory information by the STT cells was an increase in threshold for noxious stimulation and a reduction in response to innocuous stimulation. Similar results were obtained from microstimulation (100μA) of the cerebral peduncles. Ablation of these modulatory centers might cause decreased thresholds for noxious stimulation and hyperexcitability to innocuous stimuli, as is characteristic of central pain. (Supported by NIH grants NS 11255 and NS 09743 and Bristol-Myers Co.)

63.10

THE RESPONSES OF SPINOTHALAMIC TRACT (STT) NEURONS TO ELECTRICAL STIMULATION OF CORTEX AND CEREBRAL PEDUNCLE (CP). D. Zhang, C.M. Owens and W.D. Willis. Dept. of Anatomy & Neurosciences and Marine Biomedical Institute, Univ. of Texas Medical Branch, Galveston, TX 77550.

The activity of STT neurons can be modulated by electrical stimulation of cortex. The present study employs extracellular and intracellular recording to investigate the spinal mechanism involved in such modulation. Fifteen anesthetized adult monkeys (M. fascicularis) were used. Extracellular recording from 25 STT neurons showed that stimulation of cortex or CP could excite or inhibit STT neurons. The responses to sural nerve Aδ-fiber volleys were preferentially inhibited. Intracellular recording showed that the stimulation of CP or cortex evoked either depolarization or hyperpolarization in 14 STT neurons. The depolarization proved to be an EPSP, since there was an increased membrane conductance and an increased amplitude of the depolarization as the membrane potential was hyperpolarized. The hyperpolarization was, in some neurons, due to an IPSP proved by an increased membrane conductance and a decreased amplitude when the membrane potential was hyperpolarized. However, in some neurons the amplitude of hyperpolarization was increased by hyperpolarizing the membrane potential and the membrane conductance was slightly decreased during hyperpolarization, suggesting a mechanism of disfacilitation. (Supported by grants from NIH (NS 09743, NS 11255) and the Bristol-Myers Co.)

63.11

ORGANIZATION OF CORTICAL INPUTS TO RAT PERIAQUEDUCTAL GREY. M.T. Shipley[1], L.B. Fu[1]*, M. Ennis[2] and M. Behbehani[2]. Dept. Anat.[1] & [2]Dept. Physiol.[2], Univ. Cinti. Coll. Med., Cincinnati, OH 45267.

Previous studies indicate that periaqueductal grey (PAG) receives inputs from medial prefrontal and lateral cortical areas. Our recent findings reveal that innervation of PAG from these areas is much more substantial than previously reported. Here, we have examined the distribution of PAG-projecting cortical neurons, and their terminal labeling patterns in PAG.

Single discrete or large multiple injections of WGA-HRP into several rostrocaudal levels of PAG retrogradely labeled substantial populations of neurons in both medial prefrontal and lateral cortex. Neurons in medial cortex were heavily distributed in orbital, prelimbic, infralimbic and cingulate fields, forming a continuous band of neurons spanning the entire dorsoventral extent of medial cortex. Laterally, labeled neurons were centered primarily adjacent to the rhinal fissure; caudal to the genu of the anterior commisure, labeled cells were also located just dorsal to the fissure. This lateral population of labeled neurons extends the entire rostrocaudal length of the cortical mantle.

Injection of WGA-HRP into subregions of medial or lateral cortex revealed heterogeneous terminal patterns within PAG. However, one common innervation pattern was observed from both inputs: discrete bands of labeling in dorsomedial and lateral/ventrolateral PAG.

These results indicate that PAG receives heavy input from cortical fields associated with visceral function and limbic-sensory integretion. These cortical inputs may overlap within two distinct subregions of PAG. (Supported by PHS Grants NS20643 and NS24698.)

CHOLINERGIC MEDIATION OF ANTINOCICEPTION PRODUCED BY ELECTRICAL STIMULATION OF THE PEDUNCULOPONTINE TEGMENTUM. LF Fitzgerald and HK Proudfit. Dept of Pharmacology, University of Illinois at Chicago, Chicago, IL 60680.

Activation of neurons in the nucleus raphe magnus (NRM) by injection of cholinergic agonists produces antinociception. The current studies defined the origin of the cholinergic projections to the NRM, and determined if stimulation of the origins of those projections could produce antinociception.

Retrograde labeling and immunocytochemistry were used to demonstrate cholinergic neurons. These experiments revealed cholinergic projections from both the pedunculopontine tegmental nucleus (PPT) and the cuneiform nucleus to the NRM.

The area of the PPT in lightly anesthetized rats was electrically stimulated at various depths in the brain stem for 60 seconds and tail flick response latencies were measured. Atropine sulfate (5mg/kg, sc) was given to determine if the stimulation-induced antinociception was mediated by acetylcholine.

Stimulation of the site corresponding to the PPT produced antinociception lasting from 4-150 minutes. This effect was blocked by atropine. Immunocytochemistry revealed cholinergic neurons around the PPT stimulation site. (Supported by USPHS Grant 03980.)

GABA NEUROTRANSMISSION IN ROSTRAL VENTROMEDIAL MEDULLA OF THE LIGHTLY ANESTHETIZED RAT: ROLE IN NOCICEPTIVE MODULATION. M.M. Heinricher and H.J. Kaplan*. Dept. Neurology, Univ. California, San Francisco, CA 94143

Local microinjection of GABA receptor agonists and antagonists into the rostral ventromedial medulla (RVM) was used to examine the contribution of GABA to the nociceptive modulating function of the RVM in the lightly anesthetized rat.

Animals were maintained in a lightly anesthetized state using a continuous infusion of methohexital. The tail flick response (TF) was used as an index of nociceptive responsiveness. Microinjection of the $GABA_A$ receptor antagonist bicuculline methiodide (BMI, 25-200 ng in 0.5 ul, injected over 3 min) produced a dose-related inhibition of the TF (10-s cut-off) that was reversed by the GABA antagonists THIP and muscimol microinjected at the same site. BMI-induced TF inhibition was seen within one minute of completing the injection and lasted from 10 to 30 min. Microinjection of BMI outside of the RVM, in n. reticularis gigantocellularis or n. raphe pallidus, had no effect on TF latency. Microinjection of THIP (12.5-100 ng) or muscimol (1-50 ng) alone produced an immediate and consistent decrease in TF latency. Microinjection of saline did not affect the TF.

These results demonstrate that GABAergic transmission within the RVM plays a key role in the nociceptive modulating functions of the region. The observation that local application of a $GABA_A$ receptor antagonist produces TF suppression would indicate that a class of inhibitory output neurons within RVM receives a GABA-mediated inhibitory input. Moreover, the fact that microinjection of $GABA_A$ receptor agonists results in enhancement of the TF would suggest that an RVM neuron which is susceptible to GABA-mediated inhibition exerts an on-going suppressive effect on spinal nociceptive transmission.

ANTINOCICEPTIVE AND BEHAVIORAL EFFECTS OF STIMULATION IN THE DORSAL RAPHE, LATERAL HABENULA, PRETECTAL AREA, AND VENTRAL TEGMENTAL AREA. C. Preston*, P. Dougherty*, and N. Dafny. (SPON: D. Marshak). Dept. Neurobiol. & Anat., UT Medical School at Houston, TX 77225.

Focal brain stimulation is reported to produce both analgesia (SPA) and aversive effects. This study compared the analgetic and aversive effects of stimulating the dorsal raphe (DR,n=6), lateral habenula (LHb,n=4), pretectal area (PTA,n=8), and ventral tegmental area (VTA,n=4). Male Sprague Dawley rats were implanted with bipolar 120 μm stainless steel electrodes, teflon insulated except at the tips. Tail-flick latencies (TFLs), before (baseline), and during a 10 min period of stimulation with constant current (100-400 μA), 0.2ms, 20 Hz pulses were averaged. The lowest current intensity at which the TFLs exceeded baseline by at least 2 SDs was designated the threshold current for analgesia. The threshold currents for each site were similar. VTA stimulation at threshold produced less elevation of a computed analgesia index. PTA stimulation at threshold produced the longest lasting post-stimulation analgesia. Threshold stimulation induced site specific behavioral patterns. Stimulation of DR and VTA appeared to be more aversive than stimulation of LHb or PTA. Thus, the SPA of VTA may be partially stress induced, while PTA stimulation may be a clinically useful pain therapy.

DESCENDING FACILITATION (AND INHIBITION) FROM THE NUCLEI RETICULARIS GIGANTOCELLULARIS (NRGC) AND GIGANTOCELLULARIS PARS ALPHA (NRGCα) IN THE RAT. M. Zhuo* and G.F. Gebhart (SPON: W. Steele). Dept. Pharmacology, The University of Iowa, Iowa City, Iowa, 52242

It is well documented that the ventral medulla is important to descending modulation of spinal nociceptive transmission. In the present work, descending inhibitory and facilitatory influences on the spinal nociceptive tail-flick (TF) reflex produced by eletrical stimulation and glutamate microinjection in the NRGC/NRGCα were examined and characterized in pentobarbital-anesthetized rats. Inhibition and facilitation of the TF reflex were produced by eletrical stimulation at identical sites in the NRGC/NRGCα; glutamate microinjection only inhibited the TF reflex. The chronaxie of stimulation was 140 μsec; the inhibitory effect of stimulation on the TF reflex did not outlast the period of stimulation. At threshold intensities of stimulation, blood pressure was not significantly affected. Inhibition of the TF reflex was produced throughout the NRGC/NRGCα; thresholds for inhibition were least (10-25 μA) in the ventral NRGC and NRGCα. Facilitation of the TF reflex was produced at many of the same sites, but always at lesser intensities (mean, 10 μA vs 45 μA for inhibition, n=21) and primarily in the NRGCα. These results reveal intensity-dependent, bi-directional modulatory descending influences from the NRGC/NRGCα.

THE SOMATODENDRITIC MORPHOLOGY OF ON- AND OFF-CELLS IN THE RAPHE MAGNUS AND ADJACENT RETIULAR FORMATION. P. Mason and H.L. Fields. Depts of Neurology, University of California, San Francisco, CA, 94143

Neurons in the nucleus raphe magnus (NRM) were recorded intracellularly during the hindlimb flexion withdrawal reflex evoked by noxious pinch or heat in the lightly anesthetized cat and ferret. Cells that either increased (on-cells) or decreased (off-cells) their discharge rate during the nociceptive reflex were labeled with horseradish peroxidase. Labeled cells were reconstructed in semi-coronal sections.

On-cells in the rostral NRM were either large multipolar or small fusiform neurons with their long axes oriented dorsoventrally. Off-cells in NRM and the adjacent ventral reticular formation were typically fusiform with a mediolateral orientation. Large multipolar off-cells were also observed.

The dendritic arbors of both on- and off-cells that had somata within NRM extended up to 1.5mm lateral to the cytoarchitechtonic boundaries of the NRM. These dendrites arborized throughout the ventral magnocellular reticular formation bilaterally. In contrast, the dorsal extent of the dendritic field was typically more restricted; few dendrites reached the dorsal pontomedullary reticular formation. Several on- and off-cells in rostral NRM had dendritic arbors that extended ventrally into the trapezoid body.

The somatodendritic morphology of on- and off-cells in the cat is further evidence for the functional connection between the NRM and the adjacent ventral reticular formation.

INTRATHECAL THEOPHYLLINE ATTENUATES ANTINOCICEPTION EVOKED BY STIMULATION IN THE VENTRAL MEDIAL MEDULLA. S. Aran, and H.K. Proudfit. Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL. 60680.

We examined the capacity of intrathecal (i.t.) theophylline (THEO)* to attenuate the antinociception evoked by electrical stimulation of the ventral medial medulla (VMM).

Animals were implanted with an i.t. catheter and a bipolar stimulating electrode. One week after surgery baseline nociception was determined using the tail flick test. After determination of baseline tail flick latencies (TFL), a stimulus-response curve was generated for electrical stimulation of the VMM. Animals were then given an i.t. injection of THEO (100 μg). TFLs were redetermined 7 min after drug injection and stimulus-response curves were again constructed. VMM stimulation produced significant increases in TFL before THEO injection. However, VMM stimulation failed to increase TFL after THEO injection. These data suggest that antinociception produced by stimulation of VMM neurons is at least, in part, mediated by the release of adenosine in the spinal cord. This work was supported by USPHS Grant DA03980.

EFFECTS OF STIMULATION OF NUCLEUS RAPHE MAGNUS ON RENAL AFFERENT INPUT. M.M. Knuepfer and I.L. Holt*. Dept. of Pharmacol., St. Louis Univ, St. Louis, MO 63104.

Electrical stimulation (ES) of the raphe magnus (NRM) inhibits dorsal horn neurons responding to somatic nociceptive input. Supraspinal modulation of visceral input is less well understood. We reported that the NRM contains tonically active neurons inhibiting some renal afferent input (RAI) to the spinal gray. In this study, we sought to define the extent and nature of projections from the NRM modulating RAI. Chloralose-anesthetized rats were prepared for ES of the renal nerve, ES or chemical stimulation of the NRM, and extracellular recording of single neurons in the lower thoracic spinal gray. In 8 of 10 neurons, ES of the NRM inhibited spontaneous activity and in 6 of 9 neurons RAI was also inhibited. Glutamate (10 nmol/μl) injections into the NRM (0.5-1 μl) elicited either an increase (3), a decrease (5) or no change (5) in spontaneous activity in neurons excited by RAI. Evoked activity was increased (3), decreased (5) or unaffected (5). These neurons were unaffected by equivalent injections of saline. Neurons receiving RAI were also tested with cervical cold block. Opposite changes in spontaneous (8/12) and evoked activity (6/12) were often observed compared to glutamate. Therefore, ES of the NRM activates primarily inhibitory projections whereas selective stimulation of neuronal soma demonstrates a mixed population of facilitatory and inhibitory neurons modulating RAI. These data suggest that projections through the NRM actually mediate much of the descending inhibition observed with ES. (Supported by HL38299).

RADIATION-CONTROLLED FOCAL BRAIN PHARMACOLOGY INCREASES TAIL-FLICK LATENCY.

M.P. Remler, W.H. Marcussen*, and K.A. Sigvardt. Department of Neurology, University of California, Davis.

Radiation-controlled focal brain pharmacology is a method to concentrate a drug in a selected part of the brain by irradiating that area and thereby lowering the BBB in that area and that area only. Then, when a drug that does not cross the normal BBB is administered systemically after the radiation has lowered the BBB in that area, the drug will preferentially penetrate the selected part of the brain. Systemic carbachol, which cannot cross the BBB, has no effect on the tail-flick latency in control rats. 200 days after rats received 20 Gy to the medulla, the BBB is open in that region and systemic carbachol 0.5 mg/kg and 1.0 mg/kg IP caused a 38% increase in tail-flick latency which lasted for two hours, demonstrating that with a radiation-induced focal lesion of the blood-brain barrier in the ventral medulla systemic carbachol can act pharmacologically and the effect monitored as an increase in the latency of the rat heat-induced tail flick. Activation of the rostral ventral medulla using radiation-controlled focal brain pharmacology could provide a method for pain control by drugs that pharmacologically activate the pain modulating system and would be isolated from the pharmacologically identical non-antinociceptive CNS effects of these drugs.

REFRACTORY PERIOD ESTIMATES OF THE SUBSTRATE FOR ANALGESIA DERIVED FROM STIMULATION OF THE ROSTRAL MEDULLA. S. Schenk and R. Peltier*. TAMU, Dept. Psychol., College Station, TX. 77843

Stimulation of the rostral medulla produced an analgesic effect as indicated by an increased latency for the rat to flick it's tail out of heated water. Refractory periods of the directly stimulated substrate for this behavior were estimated using psychophysical techniques. Electrical stimulation consisted of 10 sec trains of single pulses or pairs of pulses. The intrapulse-pair interval was varied from 1.0-10.0 msec and frequency thresholds for analgesia were determined at each interval. The effectiveness of paired pulse stimulation increased steadily between pulse pair intervals of 1.5 and 6.0 msec. These data provide an estimate of the refractory period of the directly stimulated substrate. They were comparable to those obtained when dorsal and ventral PAG sites were tested. Thus, the substrates for the analgesic effects of dorsal and ventral PAG stimulation and stimulation of rostral medullary sites is comprised of similar caliber neurons. The refractory period estimates obtained suggest that these substrates consist of small, unmyelinated neurons with slow conduction speeds.

THE EFFECTS OF MELATONIN MANIPULATIONS ON PAIN THRESHOLD AND AFTERDISCHARGE THRESHOLD FROM THE AMYGDALA IN THE RAT. J.H. Peck, A. LaBanca*, F. Scholl* and L.J. Grota, Dept. of Psychology, Ithaca College, Ithaca, NY 14850.

Past research has shown that pinealectomy lowers afterdischarge threshold from the amygdala and lowers the nighttime rise in pain threshold on the hotplate. We sought to replicate these two findings by directly injecting melatonin (afterdischarge test) and doing superior cervical ganglionectomy (SCGX, pain test).

AFTERDISCHARGE THRESHOLD. Rats were implanted with an intraventricular cannula, bipolar amygdala electrodes and cortical screw electrodes. One week later, they were injected with either melatonin or saline during the light portion of their daily cycle. The amygdala was given an ascending series of constant current shocks every 5 min. and afterdischarge as well as seizure stage was noted on the record. Melatonin marginally raised the afterdischarge threshold but did protect the rats from behavioral seizures ($p<.05$).

PAIN TEST. Rats were either SCGX'd or sham operated and were tested on a hotplate for analgesic responses during the light and dark phases of the daily cycle. The sham rats showed an increase in latency to pawlick on the hotplate at night relative to the day. The SCGX rats had this rhythm greatly attenuated with day and night latencies being about the same. This produced a significant interaction between type of surgery and time of testing ($p<.05$).

PAIN MODULATION: OPIOID MECHANISMS

64.1

BIOAVAILABILITY, PHARMACOKINETICS AND AUTORADIOGRAPHIC DISTRIBUTION STUDIES WITH PD 129290, A NOVEL ANALGESIC KAPPA OPIOID RECEPTOR AGONIST. C.M. Barksdale, W.P. McNally, G.D. Nordblom*, M.J. Coon*, P.D. DeHart* D.S. Wright*, R.J. Guttendorf*, D. Turluck*, L.A. Pachla* and T. Chang*. Pharmacokinetics/Drug Metabolism Dept., Parke-Davis Pharm. Res. Div., 2800 Plymouth Road, Ann Arbor, MI 48105

Kappa opioid receptor agonists offer the possibility of producing effective analgesia via a novel mode of action when compared with existing therapies. PD 129290 (Eur. Pat. Pub. #0207773; 06/30/86) has a high *in vitro* affinity, selectivity and specificity for the k opioid receptor. We now report the *in vivo* bioavailability and pharmacokinetics of PD 129290 in rat plasma using a RIA, and the autoradiographic distribution of ^{3}H-PD 129290 in rats. In male Wistar rats given 1 mg/kg dose, half-life of the drug was 4.6 and 9.1 hours following IV and IM administration, respectively. Absolute IM bioavailability was 10%. Rats given 40 µg/kg of ^{3}H-PD 129290 by IM injection were sacrificed at intervals from 10 min to 24 hr for whole body autoradiography. Concentrations in brain were primarily in gray matter with indication of higher concentration in cortex and areas of hippocampus corresponding to regions in CA3 reported to have high k receptor density. Radioactivity was rapidly cleared from most tissues and by 6 hours postdose preliminary exposures showed residual label in liver and kidney only.

64.2

INHIBITORS OF ENDOPEPTIDASE 24.15 & 24.11: COMPARISON OF ANTINOCICEPTIVE AND OPIOID PROPERTIES IN RATS. B. Kest, M. Orlowski*, C. Molineaux, and R. J. Bodnar. Department of Psychology, Queens Col., CUNY, Flushing, N Y,11367, & Department of Pharmacology, Mt Sinai School of Medicine, New York, N Y, 10029.

Endogenous opioid antinociception is limited by succeptibility to peptidase degradation. While endopeptidase 24.11 degrades pro-enkephalin opioids, endopeptidase 24.15 degrades pro-dynorphin and alpha neo-endorphin opioids. Inhibitors of the former (EPI 24.11) elevate antinociceptive thresholds and potentiate antinociception induced by pro-enkephalin-derived opioids.The present study compared the central antinociceptive properties of EPI 24.11 and two recently developed inhibitors of endopeptidase 24.15 (EPI 24.15) using threshold measures of reactivity to thermal (tail-flick test) and aversive (jump test) stimuli. Intracerebroventricular administration of all three inhibitors produced a dose-dependent (0.05-50 nmol) antinociception on both tests, with more pronounced effects on the supraspinally-mediated jump test.The gradual (5-7 h) appearance of antinociception suggested an effect upon peptidases rather than receptor substrates. The reversal of antinociception by naloxone (1 mg/kg, sc) suggests that EPI 24.15 and EPI 24.11 antinociception is mediated in part through an opioid synapse. The two inhibitors of endopeptidase 24.15 were selective for this enzyme relative to endopeptidase 24.11 and differed in their relative potencies and inherent resistance to degradation themselves. These data indicate the putative involvement of pro-dynorphin-related peptides in supraspinal antinociception, and suggests that the relative inability of these peptides to induce antinociception may be due to their rapid enzymatic degradation.

64.3

SENSORY-MOTOR FUNCTION IN RATS FOLLOWING INTRANIGRAL MORPHINE INJECTION. A.A. Baumeister, M. Nagy*, G. Hebert*, M.F. Hawkins, and M.O. Chatellier*. Department of Psychology, Louisiana State University, Baton Rouge, LA 70803.

Intranigral (IN) injection of morphine suppresses pain-related behavior on the tail flick and hot plate tests (Brain Res., 1987, 411, 183). The following study was conducted to determine whether this effect may be due to nonspecific sensory-motor impairment. Male Sprague Dawley rats received bilateral IN injections of morphine sulfate (10 µg/0.5 µl saline) or saline (0.5 µl). Between 5 and 10 minutes after the injection animals were assessed on the following measures: 1) hot plate and formalin analgesia tests, 2) rotorod and catalepsy tests, 3) righting, placing, pinna, eye blink, and startle reflexes, and 4) wet dog shakes after brief submersion in water. Latency to rear paw lick on the hot plate test was significantly increased, whereas duration on the rotorod and number of wet dog shakes were significantly reduced in animals that received IN morphine. On all other measures, sensory-motor function appeared normal following IN morphine. Thus, simple reflexes, other than the nociceptive tail flick reflex, are unaffected by IN morphine. Impairments are demonstrable on more highly integrated tasks. However, a general sensory-motor defect does not appear to account for the analgesic-like effect of IN morphine on the hot plate test because 8 of 9 animals that received IN morphine licked, bit or sniffed the rear paw on the formalin test.

64.4

MORPHINE IN THE VTA AND VENTRAL STRIATUM PRODUCES ANALGESIA IN THE FORMALIN TEST. M.J. MORGAN and K.B.J. FRANKLIN., Dept. of Psychology, McGill University, P.Q., Canada, H3A 1B1.

Recently we found that systemic administration of the mixed DA antagonist alpha-flupentixol or 6-OHDA lesions of the ventral tegmental/substantia nigra areas abolished morphine analgesia in the formalin test (Morgan and Franklin, in press). This suggests that morphine analgesia in this test may be mediated by limbic DA systems. We examined this possibility by micro-injecting 5 nM morphine sulphate, bilaterally, in a 0.5 ul volume, into the peri-aqueductal gray (PAG), ventral tegmental area (VTA), ventral striatum (VS) and surrounding regions. This dose of morphine produced strong analgesia (>90%) in the VTA and PAG, whereas it produced only moderate analgesia in the VS (>40%) and marginal analgesia (<30%) at sites dorsal to the VTA or VS. These results suggest that mesolimbic DA neurons are involved in morphine analgesia in the formalin test and that morphine acts at receptors pre- and/or post-synaptic to DA neurons innervating the ventral striatum.

64.5

CENTRAL ALLOXAN DIFFERENTIALLY ALTERS OPIOID AND NONOPIOID ANALGESIA IN RATS. E. Lubin and R. J. Bodnar, Dept. of Psychology, Queens Coll., CUNY, Flushing, NY 11367.

While peripheral administration of alloxan destroys pancreatic beta cells and thereby produces diabetes, central administration of far lower doses of alloxan (40 and 200 µg, ICV) selectively reduces opioid-mediated 2-deoxy-D-glucose hyperphagia and analgesia, but not hyperglycemia, presumably by altering either brain glucoreceptors or a glucoprivic control mechanism. We recently found that central alloxan treatment significantly reduces morphine (2.5 and 5 mg/kg, SC) analgesia on two threshold measures of nociceptive reactivity to thermal (tail-flick test) and aversive (jump test) stimuli in rats. To evaluate possible opioid-nonopioid differences, the present study examined whether central alloxan (200 µg, ICV) alters nonopioid analgesia induced by either continuous cold-water swims (CCWS: 2°C for 3.5 min) or the muscarinic receptor agonist, pilocarpine (0.5-5 mg/kg, IP), in rats. CCWS analgesia on the jump test was initially reduced but subsequently potentiated by central alloxan. In contrast, alloxan failed to alter CCWS analgesia on the tail-flick test, nor did it alter CCWS hypothermia or pilocarpine analgesia on either nociceptive measure. The dissociations of opioid and nonopioid analgesia following alloxan occurred in the absence of changes in basal nociception.

64.6

INHIBITION OF MORPHINE (MOR) ANTINOCICEPTION BY CENTRALLY - ADMINISTERED H_2 - ANTAGONISTS. J.W. Nalwalk*, K.R. Gogas* and L.B. Hough (SPON: S. Glick). Dept. Pharmacol. & Toxicol. Albany Medical College, Albany, NY 12208.

To directly test the hypothesis that brain histamine and brain H_2 receptors play a role in opiate antinociception, the effects of several H_2 antagonists of varying structure and H_2 affinity were assessed on nociceptive (radiant heat) thresholds in the presence and absence of MOR (10 mg/kg, 30 min, ip). When given directly into the lateral ventricle of conscious rats, 5 H_2 antagonists exhibited dose - dependent inhibition of MOR antinociception 10 min after administration, with no effects on baseline nociception. As shown below, the potencies of these compounds for inhibition of MOR antinociception were highly correlated with their potencies as H_2 antagonists ($r = 0.98$, $P < 0.005$), supporting the hypothesis that activation of brain H_2 receptors is important for opiate-induced attenuation of nociception. (Supported by DA-03816).

ACTIONS OF MORPHINE (MOR) ON CNS HISTAMINE (HA) DYNAMICS IN MICE. S.P. LICATA,* J.W.NALWALK* & L.B. HOUGH. Dept. Pharm & Tox, Albany Medical College, Albany, NY 12208.

The effects of MOR on the levels of HA and its metabolite tele-methylhistamine (t-MH), and on t-MH synthesis rates were examined in brains and spinal cords of mice. In DBA/2J (DBA), a strain sensitive to MOR anti-nociception, MOR (1-56 mg/kg, s.c.) suppressed t-MH levels, had no effect on HA levels and produced a dose-dependent decrease in whole brain t-MH synthesis rates, measured by the pargyline-induced accumulation of t-MH. In DBA, MOR (10 mg/kg) produced a generalized inhibition (11 to 48%) of t-MH synthesis in 8 brain regions, and *increased* t-MH synthesis in the spinal cord. In contrast, MOR had no effects on HA metabolism in either whole brain or spinal cord in C57/BL6 mice, a strain resistant to morphine antinociception. In Swiss-Webster mice, MOR exerted a slight inhibition of HA metabolism.

These results find no evidence in 3 strains of mice for a MOR-induced increase in brain HA metabolism, in contrast to results in ddY mice (Nishibori et al., J. Neurochem. 45: 719, 1985). In the strains studied presently, MOR inhibits and stimulates HA metabolism in brain and spinal cord, respectively, and the magnitude of these effects in a strain parallels that strain's sensitivity to morphine antinociception. Although further studies are needed to show this, morphine may release HA from the spinal cord as a component of its antinociceptive mechanism. (Supported by DA-03816).

64.8

GENDER AND GONADECTOMY MODULATE NONOPIOID CHOLINERGIC ANALGESIA IN RATS. J.M. Kiefel and R.J. Bodnar, Department of Psychology, Queens College, CUNY, Flushing, NY 11367.

Gender differences appear to modulate opioid-mediated and nonopioid-mediated analgesia induced by exposure to environmental stressors, such that females display a smaller magnitude of both forms of analgesia than males. Adult gonadectomy reduces the magnitude of both forms of analgesia relative to same-sex, sham-operated controls. Our laboratory found gender, and to a lesser degree gonadectomy, differences in analgesia elicited by central and systemic morphine and endogenous opioids with male rats displaying greater responses at significantly lower effective doses than females, and gonadectomy reducing the magnitude of effects. The present study evaluated whether a nonopioid form of analgesia displayed similar gender and gonadectomy differences by examining analgesia induced by the muscarinic receptor agonist pilocarpine (0.25-10.0 mg/kg, IP) using two threshold measures of nociceptive reativity to thermal (tail-flick test) and aversive (jump test) stimuli in rats. Male rats displayed significantly greater pilocarpine analgesia (4-fold shift) on both tests than estrous females across doses. In contrast, gonadectomy produced smaller reductions in pilocarpine analgesia. These data indicate a modulatory influence of gonadal steroids upon both opioid and nonopioid analgesia.

64.9

GENDER AND GONADECTOMY MODULATE CENTRAL ENDOGENOUS OPIOID ANALGESIA IN RATS. K.L. Kepler and R. J. Bodnar, Department of Psychology, Queens College, CUNY, Flushing, NY 11367.

Analgesic responses induced by systemic morphine as well as opioid and nonopioid forms of environmental stressors are sensitive to gender differences such that females display a smaller magnitude of analgesia than males. Adult gonadectomy reduces the magnitude of these forms of analgesia relative to same-sex sham-operated controls. We found profound gender differences in central morphine analgesia with male rats (5 µg, ICV) displaying peak effects at significantly lower effective doses than females (40 µg, ICV). Significant reductions in central morphine analgesia were less pronounced in gonadectomized rats. The present study evaluated gender and gonadectomy effects upon analgesia induced by the specific μ_2 opiate receptor subtype agonist, D-Ala^2, *N*-Me-Phe^4, Gly-ol-enkephalin (DAGO: 0.5-20 µg, ICV) using threshold measures of reactivity to thermal (tail-flick test) and aversive (jump test) stimuli. Male rats displayed significantly greater DAGO analgesia (2-fold shift) than estrous females across doses on both tests. Gonadectomy produced significant, though smaller, reductions in analgesia, especially in gonadectomized males. These data indicate a modulatory influence of gonadal steroids upon endogenous supraspinal opioid analgesia.

64.10

EFFECTS OF MORPHINE ON REFLEXES AND AVOIDANCE RESPONSES IN MONKEYS. D.C.Yeomans, C.J.Vierck, Jr., and B.Y.Cooper, Dept. of Neuroscience and Center for Neurobiological Research, Univ. of Florida, Gainesville, FL

Low doses (0.25-0.75 mg/kg) of systemic morphine attenuate operant responses to C fiber stimulation when given to monkeys, whereas higher doses are required to attenuate responses of monkeys to stimuli which produce predominantly A-delta associated pain in humans. An autonomic reflex (skin temperature response) is affected by doses in the same range as that which affected C fiber responses. To determine the effects of a similar range of morphine dosages on a somatic reflex, the force of shock-evoked nociceptive reflexes was measured in monkeys. In addition, the effect of morphine on components of electromyographic recordings of the reflex evoked by activation of A-beta, A-delta and C fibers respectively was determined. The lowest dose (0.5 mg/kg) facilitated the force of the response and both the A-delta and C fiber evoked components of the EMG, while the highest dose (2.0 mg/kg) attenuated both of these components. The A-beta component was unaffected by morphine in this dosage range.

Following the initial stimulus, which was used to elicit reflexes, animals could avoid further electrocutaneous stimulation by pulling up on a foot lever. The force of these avoidance responses was used to assess the affects of systemic morphine on operant motoric capacity in the absence of nociceptive stimulation. Avoidance response force was unaffected by 0.5 to 2.0 mg/kg of morphine, suggesting that neither the facilitation of reflexes seen in the same animals nor the attenuation of operant responses to nociceptive stimuli are induced by a general alteration in motor function. Supported by USPHS Grant NS07261.

64.11

CONDITIONAL HYPOALGESIA ON THE FORMALIN TEST IS BLOCKED BY NALTREXONE APPLIED TO THE PAG F.J. Helmstetter & J. Landeira - Fernandez*, Psychology Department, Dartmouth College, Hanover, N.H. 03755

The mesencephalic central gray is involved in the endogenous modulation of nociceptive reactivity and the expression of defensive behavior in rats. The present study was designed to determine if the ability of peripherally administered naltrexone (NTX) to reverse the hypoalgesia shown by rats upon presentation of shock-associated conditional stimuli is related to PAG opioids. Rats were given an s.c. injection of 15% formalin into a hind paw followed by microinjection of either 5µg/0.5µl of NTX or an equal volume of the saline vehicle into the ventral PAG before being placed in an observation chamber in which footshock (1 mA/.5 sec) occurred 24 h earlier. Shocked rats tend to suppress stereotyped reactions to the formalin injection. NTX reversed this suppression. Thus while the PAG may not be critical for the suppression of formalin behavior by systemically administered morphine, the conditional hypoalgesia measured with this test may involve opioids within the PAG.

64.12

PAIN-RELATED BEHAVIORS AND NOXIOUS STIMULUS-EVOKED EXPRESSION OF FOS PROTEIN IMMUNOREACTIVITY IN THE SPINAL CORD ARE INHIBITED BY SUPRASPINAL ADMINISTRATION OF THE MU-SELECTIVE OPIOID RECEPTOR AGONIST, DAMGO. K.R. Gogas, R.W. Presley*, J.D. Levine* and A.I. Basbaum, Departments of Anatomy, Physiology, Anesthesiology and Medicine, University of California, San Francisco, CA, 94143.

Noxious stimulation induces neuronal expression of the *Fos* protein product of the c-fos proto-oncogene in the rat spinal cord. We previously reported that systemic morphine produces a dose-related, naloxone-reversible, inhibition of noxious stimulus evoked *Fos* immunoreactivity (FI) in the spinal cord (Presley et al., 1988). To characterize the relationship between FI and pain behaviors and to examine the contribution of descending inhibitory pathways to opioid analgesia, we studied the effect of supraspinal (icv) administration of the selective mu opioid-receptor agonist, DAMGO ([D-Ala^2, NMe-Phe^4, Gly-ol^5] - enkephalin), on pain behaviors and on spinal cord FI evoked by unilateral formalin injection into the hindpaw of rats.

Formalin elicited a quantifiable behavioral syndrome and evoked spinal cord FI in neurons of laminae I and IIo, the nucleus proprius, the neck of the dorsal horn and in laminae VII, VIII and X of the ventromedial gray. The most intense staining was found in laminae I and IIo and in the neck of the dorsal horn. DAMGO (icv) produced a dose-related (0.006-0.60 µg), naloxone-reversible, inhibition of both the behavior and the spinal cord FI. Although the highest dose of DAMGO tested completely suppressed the formalin-evoked behaviors, the FI was never completely eliminated; substantial labelling persisted in laminae I and IIo. The inhibitory effects of icv DAMGO (0.6 µg) on both the pain behavior and FI were prevented by bilateral dorsolateral funiculus lesions, providing strong support for the contention that stimulation of supraspinal opioid receptors produces analgesia by increasing descending inhibition of spinal cord nociceptive neurons. Supported by: NS14627, 21445 & Training grant NS07265.

64.13

MORPHINE AND U50488H SUPPRESS NOXIOUS VISCERAL STIMULATION-EVOKED FOS PROTEIN IMMUNOREACTIVITY IN THE SPINAL CORD AND NUCLEUS OF THE SOLITARY TRACT (NTS) OF THE RAT. R.W. Presley*, D.L. Hammond, K.R. Gogas, J.D. Levine* and A.I. Basbaum, Depts. of Anesthesia, Anatomy, and Medicine, UCSF, CA 94143, and Dept. of Anesthesia and Critical Care, U. of Chicago, Ill. 60632

The *c-fos* proto-oncogene encodes a nuclear phosphoprotein, Fos, that has been proposed as a marker of neuronal activity in the CNS. We have previously shown that Fos immunoreactivity (FI) evoked in spinal cord neurons by somatic noxious stimulation is suppressed by systemic morphine (Presley *et al.*, Neurosci. Abst. 1988). Here we report on the effect of systemic morphine and U50488H, a κ opioid-receptor agonist, on FI evoked in a model of visceral nociception, intraperitoneal injection of acetic acid in awake rats. The pattern of FI was correlated with the behavior produced by the noxious stimulus.

Fifty micron frozen sections of spinal cord and medulla, from rats perfused with 4% paraformaldehyde, were immunostained with an antiserum directed against Fos. In unstimulated rats, FI was limited to very light labelling in lamina III and IV; only a few labelled cells were noted in the NTS. Two hours after injection of acetic acid, intense FI was present bilaterally in the mid and lower thoracic segments in lamina I, lateral lamina V, VIII and X, and in the intermediolateral cell column (IML). The spinal distribution of FI extended into rostral cervical and sacral segments, primarily in lamina I. Very dense labelling was recorded bilaterally in the NTS; the staining was particularly intense in the commissural nucleus and the nucleus medialis of the NTS. Both morphine (1.0, 3.0, and 10.0 mg/kg sc) and U50488H (3.0, 10.0, and 30 mg/kg sc) injected 20 minutes prior to the acetic acid, produced a dose-dependent suppression of FI in all laminae of the cord, and in the NTS. The suppression was most apparent in the deeper laminae of the cord and in the IML, and was naloxone reversible. Importantly, the opioid effects on staining paralled their effects on stretching behavior evoked by the noxious stimulus. We are presently examining the differential contribution of spinal and vagal inputs to the visceral-evoked Fos changes in the NTS. Supported by NS 14627, 21445, and G.D. Searle.

TIME COURSE OF PERIPHERAL NEUROMA-INDUCED EXPRESSION OF FOS PROTEIN IMMUNOREACTIVITY IN THE SPINAL CORD OF RATS AND EFFECTS OF LOCAL ANESTHETICS. S.-I. Chi*, J.D. Levine* and A. I. Basbaum, (SPON: D.M. MacDonald). Depts. Anatomy, Physiology and Medicine, UCSF, San Francisco, CA 94143.

It has been suggested that persistent pain produced by nerve injury results, in part, from the development of hyperactivity of regenerating sprouts in the neuroma. To test this hypothesis and to study the pattern of central changes produced by such nerve injury, we have examined the expression of the c-fos proto-oncogene product, Fos, in the spinal cord of the rat up to one month after unilateral transection and ligation of the sciatic nerve to induce a neuroma. Consistent with the topographic organization of primary afferents, acute nerve injury evoked Fos-immunoreactivity (FI) most densely in neurons of laminae I-VII of the ipsilateral L4/5 segments; labelled neurons, however, were detected at all lumbar levels and in the contralateral cord (with a different laminar distribution). After the initial, acute induction of FI by nerve injury, the staining gradually diminished, however, two days after nerve injury, many labelled cells were again detected in laminae I-VII. By 7 days, the staining had again diminished. At two weeks a third peak of FI appeared, also in laminae I-VII; this pattern persisted for the next two weeks.

To test whether the persistent FI observed after injury was dependent on hyperactivity arising in the neuroma, we maintained a proximal sciatic nerve block in the 2 (n=3) and 14 day (n=4) neuroma rats for a four hour period prior to sacrifice. Local anesthetic reduced the early (2 day) peak of Fos expression in laminae I, II and V-VII. The most profound effect was on cells in laminae V-VII. In contrast, the reduction in FI by sciatic blockade at 14 days was no different from that produced by systemic (sc) injection of the local anesthetic. These data suggest that factors in addition to hyperactivity of the neuroma contribute to the central effects of peripheral nerve injury. (Supported by NS 14627, NS 21445 & NS 21647).

THE ANTINOCICEPTIVE EFFECT OF MORPHINE IS MODULATED BY GABAERGIC NEUROTRANSMISSION. J.H. Rosland* and K. Hole (SPON: B.T. Walther). Dept. of Physiology, University of Bergen, N-5009 Bergen, Norway.

Benzodiazepines and other drugs acting on the GABA-benzodiazepine receptor complex may change the antinociceptive effect of morphine and other opioid drugs. We have shown that diazepam given intraperitoneally to mice antagonizes the antinociceptive effect of subcutaneously injected morphine using the tail flick test. This effect was totally reversed by the benzodiazepine antagonist flumazenil (10 mg/kg), and partially reversed by the $GABA_A$ antagonist bicuculline (4 mg/kg). Bicuculline, although having no effect in itself, potentiated the effect of morphine. Flumazenil had no effect on morphine analgesia. Phenobarbital, which stimulates GABAergic neurotransmission by a direct effect on the Cl^--channels, had a similar effect on morphine analgesia as diazepam. None of these effects could be explained by a change in tail skin temperature.

It was concluded that the antinociceptive effect of morphine is modulated by the GABA-benzodiazepine complex. Stimulation of the GABA-benzodiazepine complex seems to reduce the antinociceptive effect of morphine, while inhibition of the complex may increase the antinociceptive effect of morphine.

EFFECTS OF NALOXONE, TYR-MIF-1, AND MIF-1 ON MORPHINE-INDUCED ANALGESIA IN THE LIZARD. A.S.Wensel*, M.C.Liles*, M.D.Brown*, A.J.Kastin, G.A.Olson, and R.D.Olson. Dept. of Psychology, Univ. New Orleans, VAMC, New Orleans, LA 70148.

To assess the efficacy of members of the Tyr-MIF-1 family of peptides as opiate antagonists, lizards (**Anolis carolinensis**) were injected sc with 0.0, 0.2, or 2.0 mg/kg of naloxone, Tyr-MIF-1, or MIF-1 followed 10 min later by an injection of diluent or 10 mg/kg of morphine. After another 10 min wait, lizards were either handled for 15 sec or induced into tonic immobility (TI), and then tested for analgesia in a tail-flick apparatus. Half of the lizards were tested after reversal of injection order.

Results showed a significant difference among the antagonists, with the faster latencies associated with naloxone. The agonist was reliable, with morphine producing significantly longer latencies. Injection order was also significant, with the reversed order leading to much quicker times. Finally, injection order interacted with TI. No difference existed after handling, but after TI the latencies increased significantly with the original order but decreased when the order was reversed.

In summary, only naloxone functioned as an opiate antagonist in this paradigm.

64.17

DIFFERENTIAL EFFECT OF TRIGEMINAL AND SPINOTHALAMIC TRACT NOXIOUS STIMULI ON THALAMIC INTRALAMINAR NEURONS IN THE CAT. C.E. Poletti, K. Baker* and W.E. Foote. Pain Research Laboratory, Mass. General Hospital, Boston, MA 02114.

225 single neurons were studied in nucleus centralis lateralis (CL) (140 units) and parafascicularis (Pf) (85 units). The median spontaneous firing rate was 5-10 spikes/sec. The spike durations, contours and spatial distributions represented somato-dendritic neuronal recordings. The noxious stimuli applied to the spinothalamic tract (STT) were: limb joint rotation and hyperextension; and firm forceps pinch of body, limbs, and tail. The stimuli applied to the trigeminal system were: firm forceps pinch of facial skin and tongue; hyperextension of the jaw; and cornea brush.

In CL 44% of units (11/25) responded to STT noxious stimuli. In contrast, only 1.5% (3/200, 115 in CL; 85 in Pf) responded to trigeminal noxious stimuli. The 3 trigeminal responsive units showed convergent STT input.

This differential influence of trigeminal and STT mediated nociception on CL and Pf may be partially responsible for the unique features of oro-facial pain syndromes.

64.18

PAIN THRESHOLDS AND MORPHINE EFFICACY MODIFIED IN HABITUATED RATS: BULBOSPINAL SEROTONIN IMPLICATED.

R.J. Milne and G.D. Gamble*, Dept. of Physiol., Univ. of Auckland, Auckland, New Zealand.

Repeated exposure of a rat to a testing environment ('habituation') enhances its sensitivity to noxious thermal stimuli and reduces its responsiveness to a subsequent acute dose of morphine ('behavioural tolerance'). We have interpreted this and other findings in terms of reduction of tonic descending inhibition of nociceptive transmission [Gamble, G.D. & Milne, R.J., Neurosci. Lett., 96:312-317, 1989; Milne, R.J. et al, Brain Research, (in press)]. Do these effects involve serotonin which is known to be involved in stress and arousal? Wistar rats (200-250g) were housed in an animal facility until the commencement of the experiment ('novices') or habituated by extensive handling and sham nociceptive testing for at least 5 days. Both novice and habituated rats were treated with either parachlorophenylalanine (PCPA: 350 mg/kg daily for 3 days) or 5-hydroxytryptaphan (5HTP: 80 mg/kg i.p) to depress or enhance serotonin synthesis respectively, or vehicle and then randomly subjected to a variety of morphine doses (D). Data were fitted to the model: $E(D) = E_0 + ((E_{max} \times D^n)/(ED_{50}^n + D^n))$, where E_{max} is the extrapolated maximal effect of morphine from baseline (E_0). In novice animals, PCPA reduced E_0 and E_{max} on tail flick and leg flexion (49°C) tests. 5HTP increased both parameters. In habituated animals, both drugs had little effect. PCPA had no effect upon E_0 or E_{max} in acute spinal animals. 5,7-DHT [20µg ith with DMI 25mg/kg s.c) or methysergide (30µg) reduced tail flick latencies of novice animals by 37%, to that of habituated animals. Neither drug had any effect on tail flick latencies of habituated animals. Mean cutaneous tail temperatures were unchanged. These results suggest that the bulbospinal contribution to morphine analgesia as established in experimentally naive animals may represent an interaction between the stress of environmental novelty and the action of morphine.

PREVIOUSLY FOOD DEPRIVED RATS EXHIBIT A NALTREXONE REVERSIBLE INCREASE IN BOTH REACTIVITY TO SHOCK AND SHOCK-INDUCED ANALGESIA. P.A. Illich & J.W. Grau. Dept. of Psychology, Texas A&M University, College Station, TX 77843.

Prior work has shown that exposure to uncontrollable shock elicits a strong, hormonally mediated, opioid analgesia (Terman et al., Science, 226:1271, 1984). In addition, it sensitizes subjects to becoming analgesic 24 hrs later upon exposure to mild shock (Grau et al., Science, 203:1409, 1981). Here we assess the impact of another manipulation that elicits a hormonally mediated opioid analgesia, food deprivation (Hamm et al., Physiol. & Beh., 35:879, 1985). After 2 days of baseline testing, deprived subjects had their food removed. At the end of day 3, they received 9 grams of food. Food was returned on day 4. Contrary to other reports, food deprivation per se did not induce a significant analgesia. On day 5, 24 hrs after food was returned,we assessed the impact of mild shock (3, 0.75-sec, 1-mA). Interestingly the subjects who had been previously food deprived vocalized and strained significantly more to the mild shock. Oddly, this heightened reactivity was blocked by naltrexone. After the last shock, pain reactivity was assessed with the tail-flick test. Previously food deprived subjects exhibited a potentiated analgesia. This effect too was attenuated by naltrexone.

64.20

EFFECTS OF FREQUENCY, INTENSITY, AND OPIATE-RECEPTOR ANTAGONISM ON VAGAL AFFERENT-MEDIATED ANTINOCICEPTION.

D.F.B. Bossut, E.A. Whitsel, W. Maixner, Dental Research Ctr., Univ. North Carolina at Chapel Hill.

This experiment further evaluated conditioning parameters of the right thoracic vagus (RTV) which inhibit the jaw-opening reflex (JOR) in cats and the putative role of opioids in mediating these effects. An array of frequencies (1-10 Hz) and intensities (0.1-2.0 mA) were delivered for 90 sec to the central end of the RTV before and during naloxone infusion (1 or 10 mg.hr/kg, iv). JOR inhibition occurred at stimulation above 1 Hz and above 0.1 mA and appeared maximal at 5 Hz x 2 mA. The magnitude of inhibition correlated with the density of stimulation (frequency x intensity) but was independent of cardiovascular responses to vagal stimulation. Post-stimulation inhibition depended on the magnitude of inhibition observed during stimulation. Naloxone treatment failed to alter JOR inhibition at all conditioning parameters examined.

These findings indicate that antinociceptive effects induced by RTV afferent stimulation increase with frequency and intensity, are independent of cardiovascular responses, and are insensitive to opiate-receptor blockade.

CYTOSKELETON, TRANSPORT AND MEMBRANE TARGETING

65.1

A NOVEL DOMAIN FOR INTRACELLULAR TRAFFIC GUIDES GAP-43 TO PARTICULAR MEMBRANE DOMAINS. M.X. Zuber*, S.M. Strittmatter* and M.C. Fishman. Howard Hughes Medical Institute, Developmental Biology Laboratory of the Massachusetts General Hospital, Boston, MA 02114

GAP-43 is a membrane protein enriched in the growth cones of neurons. It is not known what regions of this molecule cause its hydrophobic association with the membrane. We have found that the GAP-43 protein, when expressed in neuronal or in non-neuronal cell lines, binds tightly to the membrane and can be extracted by hydrophobic reagents under conditions similar to that used to extract GAP-43 from growth cone membranes. As determined by site-directed mutagenesis, particular amino acids at the amino terminus have been found to be critical to the membrane binding. Mutants that lack large internal pieces of the molecule or differ at the carboxy terminus from GAP-43 are unaffected in membrane binding. The domain of GAP-43 defined as important for its membrane binding is sufficient when coupled to chloramphenicol acetyl transferase to cause membrane association of this normally cytosolic protein. The distribution of transfected GAP-43 and these chimeric proteins appears to be the same in NGF-treated PC12 cells, including an enrichment of these proteins on the growth cone membrane. This work suggests that the amino terminus of GAP-43 includes a novel type of sorting signal that is responsible for its distribution to particular regions of the nerve, including the growth cone. This distribution is compatible with our previous suggestion that GAP-43 may play a direct role in causing the extension of filopodia (Zuber et al., Science, 1989).

COMPARTMENTATION OF CREATINE KINASE ISOFORMS IN RAT BRAIN. David L. Friedman, Bruce R. Kenwood, Peter R. Puleo, M. Benjamin Perryman, (SPON: Michael D. Schneider). Departments of Medicine, Molecular Cardiology Unit, Baylor College of Medicine, One Baylor Plaza, Room 506C, Houston, Texas 77030.

Multiple creatine kinase (CK) isoforms serve to sustain the available energy supply within cells through the interconversion of ADP and creatine phosphate. In muscle, the enzymes are physically associated with specific cellular ATPases such as the actinomyosin ATPase, sarcoplasmic Ca^{++} ATPase, and plasma membrane Na^+ pump. Brain tissue was previously thought to contain only BB-CK and the mitochondrial isoform. We now provide evidence for the presence of MM-CK isoforms in rat brain, which have electrophoretic and chromatographic properties distinct from muscle MM-CK. Using *in situ* hybridization and immunocytochemistry we have localized CK isoforms to specific cell populations in hippocampus and cerebellum. Our results demonstrate that these CK isoforms are differentially distributed within cells. The BB-CK isoform is primarily associated with the nuclear membrane of most Pyramidal and granule cells of the hippocampus, and some Purkinje cells of the cerebellum. The MM-CK isoform, in contrast, is associated with the dendritic fields of these cells, especially in the locunosum molecular layer of CA1-CA3, and the molecular layer of the cerebellum. In contrast, the mRNA for these CK isoforms is found in the cytoplasm of the somata in cells which express these CK proteins. These results suggest a complex cell specific regulation of CK isoenzyme gene expression and compartmentation in rat brain.

SECRETION OF VGF8a: A NGF-INDUCIBLE GENE. R.Possenti*°, M.Benedetti*, P.Galeffi*, B.Paterson#, A.Levi*. °Dept. Exper. Med. Univ. Tor Vergata, Rome; #NIH, NCI, Bethesda MD; *I. Neurobiology CNR V.le Marx 15, 00156 Rome Italy. We have previousy isolated a cDNA clone induced by NGF in PC12 cell line (Levi et al.1985 Science 229,1393-1395) and the complete sequence of the protein named VGF8a, has been deduced from the cDNA sequence. Two different portions of the proteine, as fusion products with ßGal, have been expressed in E. Coli to generate antisera. By these antisera we show that VGF8a is associated with intracellular vescicles and we also prove that the secretion of this protein is under stimuli of secretagogue-agents. (Possenti et al.EMBO J. in press). Immunoblot with antisera shows two bands in SDS page and preliminary data indicate that the larger molecule is post translationally processed into the smaller one. Moreover sulfatation and phosphorilation of this protein can be evidentiated by immuno-precipitation. We are now investigating which portion of the VGF8a is involved in the regulated secretion by fusing different parts of the protein with \chain of the immunoglobuline (Clone \1S43). In this way we hope to elucidate a possible interference of the VGF8a protein over the constitutive secretory pathway of the \chain.

MEMBRANE-BOUND PHOSPHOLIPASE A2 IN BOVINE ADRENAL MEDULLARY SECRETORY GRANULES IS CALCIUM DEPENDENT. E. Hildebrandt* and J. P. Albanesi* (SPON: L. C. Ellis, Jr.). Dept. of Pharmacology, Univ. of Texas Southwestern Medical Research Center, Dallas, TX 75235.

In chromaffin cells, catecholamine secretion requires Ca and is associated with release of arachidonate (AA), a precursor for eicosanoid biosynthesis which may also act as a membrane fusogen. Release of AA from phospholipids is believed to be controlled by a Ca-dependent phospholipase A2 (PLA2), but the enzyme participating in exocytosis has not been identified. We prepared subcellular fractions of bovine adrenal medulla and assayed PLA2 activity as follows. Fractions were incubated at 37°C with sonicated vesicles of diarachidonylphosphatidylcholine (0.1 mM) containing 1-palmitoyl-2-(^{14}C-arachidonyl)-phosphatidylcholine ($7 \cdot 10^5$dpm/ml) in 0.15 M Tris pH 9.0 for 90 min. The released ^{14}C-AA was extracted, isolated by TLC, and counted. When comparable amounts of protein (0.25 mg/ml) from each fraction were assayed, PLA2 activity was greatest in the secretory granule membrane (GM) fraction. The activity was not removed by washing in 0.25 M KCl, and hence appeared tightly bound. GM PLA2 was stimulated 2.5-3 fold by 2.5 mM Ca, but 7-10 fold stimulation by Ca was achieved in the presence of 1.25 M sucrose or 50% glycerol. The Ca-dependent PLA2 had an alkaline pH optimum, and it was inhibited by addition of NaCl, KCl, or Tris-Cl. The GM PLA2 exhibits properties appropriate for a regulable enzyme involved in exocytosis.

65.5

THYROID HORMONE PROMOTES INTERNALIZATION OF MEMBRANE PROTEINS VIA AN INTERACTION WITH THE ACTIN CYTOSKELETON IN ASTROCYTES. A.P. Farwell*, R.M. Lynch*, W.C. Okulicz*, J.L. Leonard* (SPON: J. Cooke). Mol. Endo. Lab., Depts. Physiol. & Ob/Gyn., UMass. Med. Sch., Worcester, MA 01655

In cultured astrocytes, dibutyryl cAMP (bt2cAMP) induces synthesis of iodothyronine 5'deiodinase, a short-lived integral membrane protein. Enzyme turnover is modulated by a thyroxine (T4)-dependent mechanism that requires an intact actin cytoskeleton. The effects of hormones on the redistribution of this enzyme, labeled with N-bromoacetyl-T4, were examined with an anti-T4 antibody. Immune complexes were visualized by indirect immunocytochemistry and F-actin with FITC phalloidin. In serum-free bt2cAMP-stimulated cells, a distinct punctate pattern was seen at the cell periphery that was absent in unpermeabilized cells, showing an intracellular location. Laser scanning confocal microscopy localized this pattern to the plasma membrane. Cell F-actin content was markedly reduced. After 10-20 min exposure to T4, most of the membrane-associated labeling was internalized, coinciding with repolymerization of the actin cytoskeleton. Inhibition of actin polymerization blocked this rapid, T4-stimulated response. Treatment for 10-20 min with T3 or BSA failed to promote movement or to polymerize actin. These data suggest that T4 regulates polymerization of the actin cytoskeleton and promotes the rapid internalization of specific membrane proteins in cultured astrocytes.

AXONAL TRANSPORT OF UBIQUITIN IN NORMAL AND HEAT SHOCK CONDITIONS. A. Bizzi*, B. Schaetzle*, L. Autilio-Gambetti and P. Gambetti Div. of Neuropathology, Case Western Reserve University, Cleveland OH 44106.

Ubiquitin (Ub), a heat shock protein, is found in cells either free or covalently bound to various proteins. Ub is thought to play a regulatory role by either modifying the function of proteins or targetting them for degradation. Recently, Ub has been found to be associated with abnormal inclusions in several neurodegenerative diseases. In Alzheimer Disease, Ub is associated with the paired helical and straight filaments in neuronal perikarya and distal neuronal processes. Ub is also present in abnormal axons of giant axonal neuropathy and of infantile neuroaxonal dystrophy. We have used the rat visual system to investigate whether free Ub is axonally transported and if there are changes in the amount of transported Ub following heat shock. Heat shock was induced in 5 week-old rats by raising their body temperature to 41°C for 15 min in a heated box. Controls were kept in a box at room temperature for the same length of time. Two hrs later, animals were injected intraocularly with ^{35}S-methionine and sacrificed after 4 hrs, 9 days and 25 days to study the fast and slow components of axonal transport. Labeled proteins from retinas and segments of optic system were analyzed in flurograms of 1D- and 2D-PAGE. Nine days after ^{35}S administration, labeled Ub (8 kDa, pI 6.2) was present in the optic tract, along with labeled polypeptides characteristic of slow component b. Labeled Ub was not detected in either the fast or slow componet a of axonal transport. Following heat shock, the amount of transported labeled Ub, relative to the major SCb components, was not different from that of controls. Supported by NIH Grants NS14509 and AG00795.

CHANGES IN THE RATE OF SLOW TRANSPORT AFTER AXOTOMY AND DURING THE REGENERATION OF ADULT RAT RETINAL GANGLION CELL AXONS. L. McKerracher, M. Vidal-Sanz*, C. Essagian*, A.J. Aguayo. Neurosci. Unit, Montreal Gen. Hosp., and McGill Univ. Montreal, Quebec, H3G 1A4.

To investigate changes associated with injury and regrowth in the adult mammalian CNS we examined the slow transport of cytoskeletal proteins following optic nerve crush, during the regeneration of retinal ganglion cell (RGC) axons, and in controls. Axotomized RGC axons were prelabelled with ^{35}S-methionine by an intraocular injection then crushed 6 days later. To obtain labelled regenerating RGC axons, peripheral nerve (PN) grafts were attached to the ocular stump of transected optic nerves 7 days prior to injection. Five to 60 days after labelling the segments of normal, axotomized or PN-grafted RGC axons were examined by SDS PAGE. The rate of tubulin and neurofilament (NF) transport was decreased following injury compared to the unoperated controls. These changes were first detected 6 days after crush and lasted at least 60 days. In contrast, the rate of tubulin and NF transport was increased 2-fold in regenerating RGC compared to controls. In addition, there was only one slow transport rate rather than the two separate rates observed in unoperated animals. The changes in slow transport during RGC regeneration may reflect growth-associated responses which are not elicited by injury alone.

65.8

DENDRITIC TRANSPORT OF RECENTLY SYNTHESIZED RNA IN HIPPOCAMPAL NEURONS IN VIVO. R. Kleiman, G. A. Banker[1] and O. Steward. Dept. of Neuroscience, Univ. of VA, Charlottesville, VA 22908 [1]Dept. of Anatomy, Albany Medical College, Albany, N.Y., 12208

Recent studies have shown that hippocampal neurons in culture selectively transport newly synthesized RNA into dendrites (Davis et al., 1987, Nature, 330:477-479). The rate of transport is about 250-400 µm/day. The present study evaluates RNA transport in hippocampal neurons in vivo. 17 day old rat pups received stereotaxic, intracranial injections of ^{3}H-uridine (20µCi/pup) to selectively label newly synthesized RNA. Pups were perfused with 10% phosphate buffered formalin at 15 min, 30 min, 1 hour, 3 hours, 6 hours, 12 hours, and 24 hours following the uridine injection. Brains were embedded in paraffin and 10µm sections were cut and prepared for autoradiography. 15 min post-injection, the label was primarily localized to the nucleus; at 30 minutes label began to appear in the cytoplasm. One hour following injection, the label had expanded to cover the cell body, although there was a higher density of label in the nucleus relative to the cytoplasm. Three hours post injection proximal portions of the dendrites became labeled. By six hours dendritic profiles were heavily labeled, and could be seen to extend into the molecular layer for at least 50-100µm. At longer intervals there was considerable redistribution of the label making it difficult to trace individual dendritic profiles. By 12 hours the relative density of label in the nucleus compared to the cell body had decreased, and by 24 hours post-injection there was no difference in the density of labeling in the nucleus and cell body. These results demonstrate that hippocampal neurons in vivo transport newly synthesized RNA into their dendrites. The rate of transport is similar to that described in vitro. Supported by NIH NS23094 to GB and OS. RK received a predoctoral fellowship from NIH HDO7323.

QUANTITATIVE ANALYSIS OF THE VELOCITY OF DENDRITIC TRANSPORT OF RNA BY MATHEMATICAL MODELING. L. Davis, B. Burger, G.A. Banker[1], and O. Steward. Dept. of Neuroscience and the Neuroscience Program, Univ. of VA, Charlottesville, VA 22908. [1]Dept. of Anatomy, Cell Biology and Neurobiology, Albany Medical College, Albany, NY, 12208.

We previously demonstrated that recently synthesized RNA is transported into the dendrites of cultured hippocampal neurons (Davis, *et al.*, (1987) Nature 330; 477-479). We reported that the transport velocity was approximately 0.25mm/day based on measurements of the distance of label in the total population of dendrites and 0.5mm/day in the dendrites with the longest distance of label. Because our measurement of transport velocity would be compromised by the fact that the total population of dendrites included some very short dendrites, we devised a mathematical model to determine transport velocity in populations of dendrites of varying lengths. The length of the dendrites was determined following MAP2 staining. The mean distance of transport in either the total population of dendrites, or the longest dendrites, was modeled where the maximum distance of transport was equal to the length of the dendrite. The modeled time course of transport was compared with the observed time course of transport in sister cultures that were pulse-labelled with 3H-uridine and either immediately fixed or allowed to transport 3H-RNA for 1.5, 3, 6, 9, 12, or 24 hours pdor to fixation and processing for autoradiography. Use of the model suggested that the average transport velocity in the total population of dendrites was 11um/hour (0.26mm/day). However, the modeled transport velocity that best fit the time course of transport in the dendrites with the longest distance of label was 21um/hour (0.5mm/day). These results suggest that the velocity of dendritic transport may be faster in longer dendrites. Supported by NIH NS23094 to GB and OS. LD was the recipient of a predoctoral fellowship from NIH NS07199.

TRANSPORT KINETICS OF SLOW COMPONENT b PROTEINS IN OPTIC NERVE AND TRACT WINDOWS. P. Paggi[1,2], R.J. Lasek[1] and M.J. Katz[2]. Bioarchitectonics Cntr CWRU School of Medicine, Cleve. OH 44106. [2]Dip. Scienze e Tecnologie Biomediche e Biometria, Università de L'Aquila, 67100 L'Aquila, Italy.

The transport kinetics of three slow component b (SCb) proteins (clathrin, a 30 kDa protein, and actin) were studied in axons of mouse retinal ganglion cells. ^{35}S-methionine was injected into the right vitreous body of anesthetized C57Bl mice. At 1-119 days after injection, the mice were killed and 2 mm segments from the right optic nerves (N) and the contiguous left optic tracts (T) were removed; these segments represented "windows" through which we watched the movement of axonally transported proteins. Radiolabeled proteins were separated by 1- and 2-dimensional SDS-PAGE, and individual radiolabeled bands were quantified. The three studied proteins entered and cleared the optic axons between 1 and 119 days post-labeling. Each protein had a broader transport wave in the more distal T window than in the N window. This spreading of the transport waves as the proteins advance along the axon appears to be produced by a playing out of the natural heterogeneity of axonal transport rates within each population of proteins. Although these proteins can all be classified with SCb, their detailed kinetics differed: for instance, the median transit times and the rates of movement differed. The residence times of clathrin and the 30 kDa protein were similar between N and T. This is consistent with the simple hypothesis that the local environment of the optic axon remains unchanged throughout the length of the axon.

ACCELERATED TRANSPORT OF NEUROFILAMENTS IN 2,5-HEXANEDIONE NEUROPATHY IS ACCOMPANIED BY A DECREASE IN PHOSPHORYLATION-DEPENDENT IMMUNOREACTIVITY. D.F. Watson, K.P. Fittro* and J.W. Griffin. Dept. of Neurology, Johns Hopkins Hospital, Baltimore MD 21205.

Previous experiments have shown that high levels of neurofilament (NF) phosphorylation (P), as detected by immunoassay, are correlated with slow rates of NF transport along axons. We have examined the immunoreactivity of NF in rats with accelerated NF transport due to intoxication with 2,5-hexanedione (HD) 0.5% in drinking water for 8 weeks. Segments of L5 dorsal roots, ventral roots, and peripheral sensory axons were dissolved in 8M urea\ 5% 2-mercaptoethanol, and immunoreactivity was determined toward antibodies SMI31 (P-dependent) and SMI32 (P-inhibited) and BM68 (P-independent epitope on the low molecular weight NF subunit) by quantitative enzyme-linked immunosorbent assay.

In HD rats the transport of labeled NF was accelerated. The ratio SMI31/SMI32 was significantly decreased in HD rats at all sites. This result extends prior observations that lower NF P-dependent immunoreactivity is associated with higher NF transport rate.

SLOW AXONAL TRANSPORT OF TUBULIN: A QUANTITATIVE ANALYSIS. A.P. Amaratunga*, J.F. Skee* and R.C. Weisenberg. Biology Department, Temple University, Philadelphia, PA 19122

The slowest phase of Axonal transport, termed slow component a (SCa), transports tubulin in the axon. The transport state of axonal tubulin is an unresolved issue: one view is that the microtubule lattice itself moves; an alternative is that tubulin moves relative to a stationary microtubule lattice. To help resolve this issue we quantitatively analyzed the SCa (labeled) tubulin and the total (labeled and unlabeled) tubulin in the mouse optic nerve. We compared the amounts of soluble and particulate tubulin using microtubule stabilizing (3 Mm $MgCl_2$, 1Mm EGTA, 25% glycerol at 37°c) and destabilizing (5 Mm $CaCl_2$, 1M Nacl at 4°C) media. Preliminary results indicate that more than 60% of the transported tubulin in the axon is present in an insoluble state under conditions that will depolymerize both cold labile and stable microtubules. However, our results indicate that this labeled tubulin fraction represents less than 20% of the total tubulin in the axon. When microtubule stabilizing medium is used, there is only about a 5% increase in the amount of particulate labeled tubulin while the total particulate tubulin increases by more than 50%. These results demonstrate that the labeled SCa tubulin is a minor fraction of the total tubulin in the axon and that a large majority of axonal microtubules are stationary. Using negatively stained electron microscopy, we observed microtubules only in the particulate fraction prepared in microtubule stablilizing medium; no microtubules were visible in the microtubule destabilizing particulate fraction. These results support the hypothesis that SCa involves the movement of an insoluble, non-polymeric form of tubulin along a stationary microtubule lattice (Weisenberg et al. Science (1987) 238:1119, Bamburg et al. Nature (1986) 321:788).

AXONALLY TRANSPORTED PROTEINS AND ORGANELLES DIFFER IN THEIR TIME REQUIRED TO REVERSE DIRECTION AT A LESION. R.E. Snyder, X. Chen* and R.S. Smith. Depts. of Applied Sciences in Medicine, Surgery, and Anatomy and Cell Biology, University of Alberta, Edmonton, Canada T6G 2G3.

Although both proteins and organelles which undergo rapid axonal transport are known to be able to reverse their direction of transport adjacent to the proximal side of a lesion, it has not been established whether they do so as a common unit. The question of whether proteins and organelles reverse their direction independent of one another was studied by measuring the time required for each to reverse direction at a lesion. Transport and reversal of ^{35}S-methionine labelled protein was monitored using a position-sensitive detector of ionizing radiation; organelle transport and reversal was monitored in isolated myelinated axons using computer-enhanced video microscopy. Both studies were performed using amphibian sciatic nerve maintained *in vitro* at room temperature. Under similar conditions, protein was found to require ≥1.50 h to reverse its direction of transport at a lesion, whereas organelles were observed to reverse direction within ≤10 min following their arrival at a lesion. The results of this study demonstrate that proteins and organelles differ in their kinematics of reversal, and suggest that proteins must dissociate from organelles prior to reversal at a lesion. (This work was supported by the Medical Research Council of Canada.)

REVERSAL OF RAPID AXONAL PROTEIN TRANSPORT ADJACENT TO A LESION IS BLOCKED BY LEUPEPTIN, BUT REVERSAL OF ORGANELLE TRANSPORT IS UNAFFECTED. R. S. Smith and R. E. Snyder. Depts. of Surgery, Anatomy and Cell Biology, and Applied Sciences in Medicine, University of Alberta, Canada.

It has been suggested that proteolysis is a necessary event in the reversal of rapid axonal transport adjacent to a lesion. We have tested this idea by investigating in crushed sciatic axons of Xenopus laevis, 1) the effect of leupeptin on the reversal of rapid anterograde protein transport, and 2) the effect of leupeptin and low calcium on the reversal of organelle transport. In the studies of protein transport, the progression of a pulse of protein, metabolically labeled with ^{35}S-methionine, was followed in living sciatic nerves using a position-sensitve detector of ionizing radiation. Control preparations showed that 30 - 50% of anterogradely transported protein became retrogradely transported at the proximal side of a lesion. Treatment of the specimens with 0.1 mM leupeptin abolished all detectable reversal of anterograde protein transport. Organelle transport was detected in isolated myelinated axons using computer-enhanced video microscopy. In preparations bathed in a potassium glutamate based medium with added ATP, 65 % of anterogradely transported organelles and 41 % of retrogradely transported organelles reversed direction adjacent to a crush lesion. Modification of Ca^{2+} over the range 10^{-8} - 10^{-4} M with or without the addition of 1.0 mM leupeptin did not significantly change the proportion of organelles that changed transport direction. This result suggests that proteolysis is required for the reversal of protein transport, but not for the reversal of organelle transport. (Supported by MRC, Canada and by AHFMR)

TIME DEPENDENT ACCUMULATION OF RADIOLABEL IN THE DORSAL ROOT GANGLIA AFTER INTRANEURAL INJECTION OF [^{3}H]myo-INOSITOL INTO THE RAT SCIATIC NERVE. S. Padilla, C.N. Pope[1], and V.Z. Wilson[2]. (SPON: M. Gage) Neurotox. Div. (MD-74B), US E.P.A. and [2]NSI, Res. Tri. Pk, NC 27711.

Although autoradiography has demonstrated local axonal incorporation of [^{3}H]inositol after intraneural injection (Gould,1976,Br.Res.,117,169-174),retrograde axonal transport of phosphatidylinositol has only been demonstrated after injection of lipid precursor into the cell body regions (Armstrong et al,1986,J. Neurosci.5,965-969). We now report that after microinjection (1µl) of myo-[2-^{3}H]-inositol (12.8Ci/mmol;10µCi) into the rat sciatic nerve (45-50mm distal to L_4 and L_5 DRGs) time dependent accumulation of [^{3}H] occurred in the DRGs ipsilateral (ipsiDRGs) to the injection site: at 2 or 8 hours after isotope injection, the ratio of dpm present in the ipsiDRGs to that in the contralateral DRGs was not significantly different from unity, but by 24hrs this ratio rose to 10.0(±2.5, sem); at 46.3hrs=12.3(±3.2) and at 72 hrs=10.4 (±1.4). At 46.3 hrs post injection, only about 43% of the [^{3}H] in the injection site was $CHCl_3$/MeOH soluble, while >90% of the [^{3}H] in the ipsiDRGs was $CHCl_3$/MeOH soluble. The presence of this delayed, primarily lipid, radiolabeling in the ipsiDRGs is probably due to retrograde axonal transport because: (1)if the isotope is injected closer to the DRGs, the label appears sooner in the ipsiDRGs, and (2)nerve ligation prevents the radiolabel accumulation.

THE ESSENTIAL ROLE OF MICROTUBULES IN RESPONSES TO A HYPOTONIC ENVIRONMENT IN TISSUE CULTURED NEURITES. H.Takahashi[1]*, H.Horie[3], Y.Tanaka[2]*, and T.Takenaka[3]. Dept. of Ophthalmol., UOEH[1], Keio Univ.[2] and Dept. of Physiol., Yokohama City Univ.[3], Japan.

Mammalian neuronal cell bodies can adapt to a hypotonic environment with a cell volume regulatory mechanism (Horie, H. et al., Brain Research, 477, 233, 1989). In this study, responses of neurites growing from cultured dorsal root ganglion neurons dissected from 3-month-old mice to a hypotonic environment were analyzed by a Nikon phase contrast microscope equipped with a video-system. When a half osmolal concentration solution was applied to neurites, neurites partially swelled and then shrank to a smaller size than the initial. These partial swellings were strongly enhanced by the application of a hypotonic solution after the 1 hr treatment with 1×10^{-5}M colchicine. However, after the 5 hr treatment with 2×10^{-6}M taxol, the hypotonic solution scarecely induced morphological changes in neurites. These results indicate that swelling might occur in a specific region in neurites where microtubule density is very low when a hypotonic solution is applied.

A PREPARATION OF NEURONAL CELL BODIES FROM RAT SUPERIOR CERVICAL GANGLION PERMITTING STRUCTURAL ANALYSIS AFTER DIRECT RAPID FREEZING. L.L. Hall and T.S. Reese. Lab. of Neurobiology, NINDS, NIH, Bethesda, MD 20892.

Direct freezing yields optimal preservation of native tissue structure and chemistry, permitting subsequent analyses by a variety of structural and analytical techniques. Application of these techniques to neuronal cell bodies has previously been limited to one preparation, the ventral cochlear nucleus, due to the physical requirement for close proximity to the cooled copper freezing surface. A method for desheathing superior cervical ganglia (SCG) from adult rats *in vivo* was developed in order to expose these neuronal cell bodies to optimal rapid freezing; our goal was to use freeze-substitution to analyze the reorganization of microtubules and organelle domains during chromatolysis, which is clearly manifested in axotomized SCG neurons. Ice crystals were imperceptible in the freeze-substituted neuronal cell bodies adjacent to the freezing face of the SCG. When compared with perfusion-fixed ganglia, the hallmarks of effective cryopreservation were present: smooth membrane contours; prominent and completely stained microtubules; an abundance of smaller cytoskeletal elements, evenly distributed throughout the perikarya; and increased electron density of the mitochondrial matrix. Additionally, cisternae of the rough endoplasmic reticulum were grouped more loosely in the perikarya of freeze-substituted neurons and their wider lumens contained a sparse filamentous network. Individual Golgi cisternae typically had narrow lumens. Further experiments suggested that handling does not produce these changes; our images appear to represent the native state of the ER and Golgi membranes. Thus, the SCG preparation described here appears to be suitable for a variety of analytical and structural studies of neuronal cell bodies which depend on direct rapid freezing.

SEPARATION OF NEUROFILAMENT POLYPEPTIDES AND PROTEOLYTIC FRAGMENT BY HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY (HPLC). J.C. Troncoso, J.L. March*, E. Barbosa*, V.W. Vogel*, M. Häner* and U. Aebi*. Neuropathology Lab., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

To assess variations in neurofilament (NF) composition in different neuronal compartments and anatomical regions, we have begun to use HPLC to separate and quantitate NF polypeptides from bovine spinal cord. Following solubilization of NF in 6 M urea, reproducible separation of the three NF subunits (NF-H, NF-M, and NF-L) was achieved using a Mono Q anion exchange column (Pharmacia) eluted with a multistep NaCl gradient (200-500 mM). All three NF subunits reassembled into filaments following removal of urea. There was consistent separation of the 54-kD protein. Sequencing of this protein revealed three regions of complete homology with the reported protein sequence of porcine NF-L (residues 99-105, 400-409, and 438-442). We were not able to reconstitute filaments from the 54-kD polypeptide. Subsequently, we have determined that this polypeptide accumulates distal to a ligature placed around rat sciatic nerve. We think that the 54-kD polypeptide represents a major proteolytic fragment of NF-L. Studies of the axonal transport of this NF proteolytic fragment are in progress.

CHARACTERIZATION OF NEUROFILAMENT ASSOCIATED PROTEIN KINASES AND RESOLUTION OF A FRACTION THAT PREFERENTIALLY PHOSPHORYLATES THE MID SIZE NEUROFILAMENT SUBUNIT. A. Dosemeci*, C. Floyd* and H.C. Pant. Laboratory of Neurochemistry, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD 20892, USA

Protein kinases associated with a neurofilament (NF) preparation from bovine spinal cord were extracted with 0.8M KCl solution and the extract was assayed for its ability to phosphorylate endogenous and exogenous substrates. It was shown that the extract contains regulator independent kinase activity that can phosphorylate high-, middle- and low-molecular weight NF subunits (NF-H, NF-M, NF-L) and casein. In addition, assays utilizing activators, inhibitors, protein and peptide substrates specific for identified kinases revealed a significant level of Ca^{2+}-calmodulin dependent protein kinase activity and some cyclic nucleotide- and Ca^{2+}-phospholipid-dependent kinase activities. Fractionation of the salt extract by gel filtration chromatography (Ultragel AcA44) resolved a kinase activity identified by its ability to phosphorylate purified NF-M. This fraction was shown to be devoid of Ca^{2+}- and cyclic nucleotide-dependent kinases. The kinase activity in the fraction could phosphorylate all three NF-subunits, either in isolated form or in assembled form, as well as following exhaustive dephosphorylation with alkaline phosphatase. When equimolar concentrations of proteins were employed, the level of phosphate incorporation was in the following order: α-casein>NF-M>NF-H≅NF-L. The results suggest that this fraction contains a unique protein kinase which shows a preference for NF-M compared to NF-H and NF-L.

PHOSPHORYLATED NEUROFILAMENT ACCUMULATION IN NEURONAL PERIKARYA AND DENDRITES IN HUMAN BRAIN FOLLOWING STROKE OR OTHER FOCAL LESIONS. J.C. Hedreen, V.E. Koliatsos and D.L. Price. Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

The accumulation of phosphorylated neurofilaments in neuronal perikarya and dendrites has been demonstrated in rats following experimental transection of axons in the central nervous system [Koliatsos et al., *Brain Res.* 482: 205-218, 1989] and in humans in a variety of degenerative diseases. In the present study, we examined autopsy cases of stroke or other focal lesions of human brains (survival from five days to ten weeks) and control cases without neurological disease. Following formalin fixation, tissues were processed for immunocytochemistry of phosphorylated neurofilaments.

Neurons whose axons were thought to pass through the lesion sites often contained perikaryal and dendritic accumulations of phosphorylated neurofilaments. Such neurons were identified in the locus coeruleus, thalamus, and homotopic contralateral cortex following neocortical lesions, and in stratum oriens of hippocampal field CA3 following an anoxic lesion of Sommer's sector. The abnormal accumulation of phosphorylated neurofilaments in cell bodies and dendrites is presumed to be a retrograde response of the neuron to axonal injury and may prove useful for the study of neuronal connections in human brain.

cDNA CLONING OF A NEUROFILAMENT-LIKE GENE FROM THE SQUID. B.G. Szaro, J. Battey*, and H.C. Pant. Lab. Neurochem., NINDS, NIH, Bethesda, MD 20892.

Neurofilament (NF) proteins with conserved biochemical and immunological properties have been identified in all vertebrates and in several invertebrate phyla. Although cloned and sequenced in some vertebrate species, no invertebrate NF sequences have yet been described. Using a cDNA probe to a mouse NF protein at low stringency, we screened a cDNA library made from squid optic lobe. We isolated three distinct clones which hybridized with an abundant 5 kilobase RNA on Northern blots of total RNA from squid optic lobe and from stellate ganglia. Two of the three clones overlapped and contained nucleotides coding for the amino acid sequence: LeuGluLeuGluIleAla-AlaTyrArgLysLeuLeuGluGlyGluGlu. This sequence contains an intermediate filament protein consensus sequence and additional amino acids highly homologous with amino acids from the 2b portion of the rod domain of the mouse NF protein. It is also more homologous with mammalian NF proteins than with other intermediate filament proteins, e.g., vimentin, GFAP or cytokeratins. We are now determining the remaining sequence of this 5 kilobase RNA and its cellular specificity. By highlighting those portions of the NF protein that are conserved between these two animals, which diverged around 600 million years ago, the sequence of this mRNA will help elucidate functionally important domains of NF proteins.

65.22

ENHANCEMENT OF ^{3}H-ACh RELEASE BY THA IN HIPPOCAMPAL SLICES FROM RATS TREATED WITH AF64A P.E. Potter & S. Nitta*. Department of Anesthesiology, Albert Einstein Coll. Med., Montefiore Medical Center, Bronx, NY 10467

The effects of tetrahydroaminoacridine (THA) and physostigmine were studied on the release of ^{3}H-acetylcholine (ACh) evoked by electrical field stimulation (2 Hz, 2 msec, 30 V, for 2 min) from rat hippocampal slices. In slices from control animals, THA, in concentrations ranging from 10^{-8}M-10^{-5}M, significantly decreased ^{3}H-ACh release in a dose dependent manner. Physostigmine, 10^{-6}M, also decreased ACh release. In contrast, in hippocampal slices taken from rats which had received intraventricular injection of 2 nmoles of ethylcholine mustard aziridinium (AF64A), and in which hippocampal choline acetyltransferase activity was decreased by at least 50%, THA caused a marked enhancement of ACh release. In addition, ACh release from these tissues was not decreased by physostigmine. The increase in release by THA was prevented by simultaneous addition of 10^{-5}M d-tubocurarine to block nicotinic receptors, suggesting that it may have been mediated through presynaptic nicotinic receptors.

65.23

PHOSPHORYLATION OF TAU PROTEIN BY GLYCOGEN SYNTHASE KINASE-3. C. W Scott*, A.I. Salama and C.B. Caputo* (SPON: M.E. Goldberg). Dept. of Pharmacology, ICI Pharmaceuticals Group, ICI Americas Inc., Wilmington, DE 19897.

Glycogen synthase kinase-3 (GSK-3) was recently shown to associate with microtubules (MT) and phosphorylate the MT-associated protein MAP-2 (Li et al., J. Cell Biol., 107:840a, 1988). We have found that GSK-3 phosphorylates an additional set of MT-associated proteins, the microheterogeneous group of tau proteins. GSK-3 from rabbit skeletal muscle phosphorylated porcine brain tau to a stoichiometry of 0.6 mol/mol. Pretreating tau with alkaline phosphatase had no effect on its subsequent phosphorylation by GSK-3. Phosphorylation of tau by GSK-3 resulted in a change in the electrophoretic mobility of some, but not all, tau isoforms. The reactivity of tau protein with tau-1, a monoclonal antibody which recognizes a phosphate-dependent site on tau, was unaffected by phosphorylation with GSK-3, suggesting that GSK-3 phosphorylated a site(s) distinct from the tau-1 epitope. Since GSK-3 appears to require a phosphoserine for substrate recognition (Fiol et al., Arch. Biochem. Biophys. 267:797, 1988), experiments are underway to test various kinases for their ability to generate a GSK-3 phosphosubstrate sequence on tau protein, thereby increasing subsequent phosphorylation of tau by GSK-3.

CALPAIN-INDUCED PROTEOLYSIS OF TAU, MAP-2 AND TUBULIN. G.V.W. Johnson, L.I. Binder and R.S. Jope. Dept. Neurology, Cell Biology & Anatomy, Pharmacology and Neuropsychiatry Research Program, University of Alabama, Birmingham, AL 35294.

Tau, MAP-2 and tubulin are cytoskeletal proteins necessary for the maintenance of neuronal integrity and function. In this study we have examined the characteristics of calpain-induced degradation of each protein in vitro. In a microtubule preparation with a substrate to calpain ratio of 100:1, the relative rates of proteolysis of tau, MAP-2 and tubulin were determined using quantitative immunoblot analysis with monoclonal antibodies. Of these 3 proteins, MAP-2 was most rapidly hydrolyzed by calpain, with 50% of the MAP-2 being degraded within 30 sec and almost total degradation occurring within 2 min. Tau was 50% degraded in 90 sec and nearly completely proteolyzed in 10 min. In contrast to these findings, microtubule β-tubulin was found to be a relatively poor substrate for calpain. After 30 min at an increased substrate to calpain ratio of 20:1 less than 10% of the protein was degraded. These microtubule protein degradation rates are now being compared to the degradation rates of purified tau, MAP-2 and tubulin. Supported by NIH Fellowship AG05382.

CHARACTERISTIC RATES OF PROGRAMMED DEATH WITH AGING FOR DIFFERENT AMINERGIC MURINE NEURONAL POPULATIONS. W.G. Tatton, D. Holland*, M. Kwan*, N. Seniuk*, M. Verrier, C.E. Greenwood and F. Biddle* (SPON: J.Stevens). Depts.Physiology, Nutritional Science and Rehab. Medicine Univ. of Toronto,Toronto and Dept. Biochemistry,Univ. of Calgary, Calgary, Canada.

Immunocytochemistry for tyrosine hydroxylase, dopa beta hydroxylase, dopamine, serotonin and neurofilament proteins was carried out for serial brainstem sections and retinal whole mounts in order to identify, count and three dimensionally reconstruct the populations of dopaminergic (Dag) neurons in the substantia nigra compacta (SNc) and the retina (amacrines), noradrenergic (NEg) locus coeruleus (LC) neurons and serotonergic (5HT) raphe obscurus and pallidus (Rpe) neurons. Six to ten nuclei or retina were examined at ages of 8, 14, 20, 26, 35, 44, 60, 75 and 88 weeks from isogenic (approximately 200 sister-brother matings) C57BL/6Jbid mice. Each of the identified monoaminergic populations showed characteristic relationships between total neuronal number and age. All of the realtionships could best be characterized by the linear equations shown in the following table where Neuronal Number (normalized against mean number at 8 weeks) = slope x age in weeks + Y Intercept:

Population	Slope	Y Intercept	R^2
SNc DAg	-0.010	1.076	0.860
LC NEg	-0.009	1.037	0.813
Rpe 5HT	-1.67E-4	1.003	- 0.069
Amacrine DAg	-0.003	1.010	0.841

The neurons were deleted randomly within each nuclei/retina and neurofilament immunoreaction revealed cytoskeletal alterations that paralleled the neuronal loss. Cellular/molecular mechanisms underlying the characteristic relationships for the different neuronal populations will be considered. (Supported by MRC Canada)

INJURY-INDUCED VESICULATION AND MEMBRANE REDISTRIBUTION IN SQUID GIANT AXON. H.M. Fishman*, K.P. Tewari* and P.G. Stein* (SPON: D. Rassin). Dept. of Physiology and Biophysics, Univ. Texas Med. Branch, Galveston, TX 77550.

Injury to a squid (Loligo, Loliguncula or Sepioteuthis) giant axon initiates the following previously unreported processes (easily observed by phase and differential interference contrast microscopy): i) intraaxonal vesiculation extending along the axon several mm from the site of injury, followed by ii) vesicular fusions that result in the formation of large vesicles ("axosomes") and finally iii) axosome migration to and accumulation at the injury site, which eventually seals. Vesiculation does not occur after axonal injury unless divalent cations (Ca^{+2} or Mg^{+2}) are present in the external solution. Recordings of propagated action potentials in regions of profuse vesiculation, subsurface localization of the vesicles and the recognized role of the endoplasmic reticulum (ER) as a Ca^{+2}-regulating organelle that can swell after Ca^{+2} loading together suggest that these vesicles originate from ER. Patch clamp of axosomes (up to 250 μm diam.) that emerged from transected axons prior to sealing showed the presence of ion channels. Vesiculation and membrane redistribution seem to be fundamental processes in the short-term (mins to hrs) neural response to injury preceding repair and regeneration. These processes appear related to "vacuolar degeneration" observed in some mammalian neuropathies. Aided by ONR Contract, NIH grant and AHA-Wyeth-Ayerst Laboratory Grant-In-Aid (PGS).

SYMPOSIUM. NEW OPPORTUNITIES FOR STUDY OF MECHANISMS OF CENTRAL NERVOUS SYSTEM ISCHEMIA. J. ZIVIN, Univ. California, San Diego (Chairperson); T. WIELOCH*, Lund Univ. Hospital; D. CHOI, Stanford Univ.; R. KRAIG, Univ. Chicago; B. RANSOM, Yale Univ.

For many years, most basic investigations of stroke primarily centered on cerebral neuropathology, energy metabolism, and blood flow. Several recent advances in the study of CNS ischemia permit a wider scope of evaluations of the mechanisms of acute cell death and suggest new ways that damage may be limited or delayed. It is probable that major improvements in clinical therapy for stroke will soon be available, but further advances depend on new scientific developments. Our objective is to acquaint neuroscientists with some of these exciting possibilities. J. Zivin will discuss new *in vivo* stroke models for investigation of protein phosphorylation changes during ischemia. T. Wieloch will review receptor mediated processes in selective neuronal death following cerebral ischemia. D. Choi will comment on the use of *in vitro* methods for examination of mechanisms of cell death induced by excitatory neurotransmitters and hypoxia. R. Kraig will talk about the use of new selective microelectrodes for studies of glial pH behavior in ischemic brain injury and edema. B. Ransom will address the pathophysiology of anoxic injury in white matter of the brain by electrophysiological methods.

68

SYMPOSIUM. FROM EARLY EMBRYOGENESIS TO CIRCUITS: CELLULAR AND MOLECULAR STRATEGIES APPLIED TO THE ANALYSIS OF VERTEBRATE BRAIN DEVELOPMENT. D. Goldowitz, Jefferson Med. Coll. & P. Levitt, Med. Coll. Penn. (Chairpersons); C. Kintner*, Salk Inst. Biol. Studies; J. Rossant*, Mt. Sinai Hosp. Res. Inst.; R. McKay, MIT.

Technical advances now make it possible to integrate molecular and embryological strategies in understanding vertebrate CNS development. The goal of this symposium is to bridge these disciplines and present new concepts and approaches to investigate vertebrate neurodevelopment. Using Xenopus embryos, neural plate RNA transcripts have been identified and their activation studied during neural induction. Transgenic Xenopus embryos have been made to alter expression of specfic molecules to assay the role of these molecules during early neurogenesis (C. Kintner). Using experimental interspecies mouse chimeras, the spatial and temporal features of cell allocation in the CNS have been explored yielding novel insights into the construction of the mammalian CNS (D. Goldowitz). The use of insertional mutagenesis in transgenic mice and targeted mutations in embryonal stem cells are presented as means to study how genes are involved in neural development (J. Rossant). The use of immortalized cell lines from rat brain is presented as a means to study and reconstruct complex cellular systems both in vitro and in vivo (R. McKay). Finally, studies will be described that relate molecular specificity of functional systems to the assembly of circuits during mammalian brain development (P. Levitt). Each of the participants will highlight the use of emerging cellular and molecular techniques to investigate a particular stage of vertebrate brain development.

VISUAL CORTEX II

69.1

DISTRIBUTED HIERARCHICAL PROCESSING IN MACAQUE VISUAL CORTEX. D.J. Felleman[1] and D.C. Van Essen[2], Neurobiology and Anatomy, UT Medical School[1], Houston, TX 77225, Div. of Biology, Caltech[2], Pasadena, CA 91125.

In recent years, many new visual areas have been identified in the macaque monkey, and there has been an even more dramatic increase in the number of identified connections. We report here on: (1) a computerized database for storing and representing, in easily accessible fashion, the large amounts of information on cortical connectivity patterns, and (2) the application of these data to the analysis of hierarchical organization of the visual pathway.

Our analysis deals with 26 cortical areas that are predominantly or exclusively visual in function, plus an additional 7 areas that we regard as visual association areas by virtue of their extensive visual inputs. A total of 236 cortico-cortical connections among these areas have been reported, and there are an additional 16 connections whose existance is more questionable. Altogether, these represent 21% of the possible number of pathways if each area were connected with all others. Many pathways have yet to be adequately tested, and we estimate that the actual degree of connectivity is closer to 30-35%. The great majority of pathways involve reciprocal connections between areas, and there are only a few reported exceptions to this rule.

An analysis of the laminar patters of connections has allowed us to extend the cortical hierarchy proposed by Maunsell and Van Essen (*J. Neurosci.*3:2563,'83). However, this has entailed a significant modification of the criteria for identifying feedforward and feedback directions. In the revised scheme, a bilaminar (infragranular and supragranular) distribution of cell bodies after retrograde tracer injection can be associated with feedforward as well as feedback and lateral pathways. Consequently, the anterograde labeling pattern is, in general, more useful for establishing unequivocal hierarchical relationships. The current hierarchy includes 11 cortical levels and extends from V1 to high-level association areas such as the hippocampus and amygdala. Within this hierarchy, there are multiple, intertwined processing streams, which at low levels are related to the compartmental organization of areas V1 and V2 and at a high level are related to the distinction between processing centers in the temporal and parietal lobes. Supported by grant EY-02091.

69.2

FUNCTIONAL ARCHITECTURE OF VISUAL AREA 18 OF MACAQUE MONKEY. *D.Y. Ts'o, C.D. Gilbert, R.D. Frostig, A. Grinvald, T.N. Wiesel.* Laboratory of Neurobiology, The Rockefeller University, NY, NY 10021 and IBM Research Division, Yorktown Heights, NY 10598.

The *in vivo* optical imaging of intrinsic signals has enabled us to directly view the functional architecture and the cytochrome oxidase-rich thick and thin stripes of area 18. We have combined this optical imaging method with single unit electrophysiology in the same experiment. These studies have shown a close correspondence between the functional maps obtained with optical imaging and the receptive field properties of single cells in the imaged regions. For example, regions with poor orientation tuning indicated with optical imaging contained cells that were often unoriented, as seen electrophysiologically. These regions were localized to alternate sets of stripes. We have also found regions of rapid changes in orientation tuning or ocular dominance within a single vertical penetration and between two adjacent penetrations, while other regions contained cells with very uniform orientation tuning or binocular responses.

We have also used this combination of recording techniques to explore the receptive field properties within a single stripe. For example, among disparity-sensitive cells, the clustering of sharply tuned excitatory cells was often found to be spatially separated from the clustering of near and of far cells. Color-selective cells were also clustered within a particular stripe according to color-opponency. Color oriented cells were found in proximity to unoriented color cells of the same color selectivity. One intriguing type of oriented color cell had ON responses to red and green slits that were spatially distinct but adjacent. This type of cell responded best to a stimulus with a red-green border at a particular position and orientation. Taken together, our studies revealed a clustering of receptive field properties and suggests a substructure or a compartmentalization of function within a stripe of area 18.

69.3

ELEMENTS OF FORM PERCEPTION IN MONKEY V2 - A CORRELATION WITH THE CYTOCHROME OXIDASE PATTERN. E. Peterhans* and R. von der Heydt* (SPON: M.R. Dürsteler). Dept. of Neurology, University Hospital, CH-8091 Zürich.

We have studied the receptive fields of single cells in the second visual area (V2) of the alert rhesus monkey. From series of vertical sections we have reconstructed the recording sites with respect to the cytochrome oxidase pattern.

We found orientation selective cells in all parts of the stripe pattern, most frequently in the thick dark (85%) and pale (81%) stripes, less frequently in the thin stripes (63%) which also held the cells unresponsive to our monochromatic stimulation. Neuronal signals related to the perception of contour (real and illusory) were recorded from half of the oriented cells in the pale and thick dark stripes, but not in the thin stripes. Cells involved in the analysis of shape from coherent motion were most frequently found in the thick stripes, as were cells concerned with stereoscopic depth. By contrast, cells with end-stopped receptive fields were more evenly distributed. In conclusion, our results suggest for neurons of V2 in the alert monkey a functional segregation which correlates with the cytochrome oxidase pattern.

MAGNOCELLULAR AND PARVOCELLULAR CONTRIBUTIONS TO AREA MT IN MACAQUE EXTRASTRIATE CORTEX.

T.A. Nealey*, D.D. DePriest*, J.H.R. Maunsell
Dept. Physiology, Univ. of Rochester, Rochester, NY 14642

Visual signals relayed by the parvocellular and magnocellular subdivisions of the lateral geniculate nucleus (LGN) remain largely segregated in striate cortex (V1). However, the degree of separation between these two classes of signals in extrastriate cortex remains an important question. We used reversible inactivation of individual LGN layers to determine directly the relative contributions of these channels to responses in the middle temporal visual area (MT). We tested 75 single or multiunit sites in MT using a small monocular stimulus while inactivating its representation in individual LGN layers with small injections (25 - 200 nl) of lidocaine (2%) or MgCl2 (40 mM).

Magnocellular blockade consistently abolished or greatly reduced responses in MT. Parvocellular blockade generally produced a less robust and more variable effect, even in anterior LGN where there is only one contralaterally-driven parvocellular layer. A few sites in MT showed a clear and repeatable reduction in response with parvocellular blockade, but many others showed no effect at all. Thus it appears that MT receives its primary excitatory drive from the magnocellular LGN layers, but also a contribution from the parvocellular layers.

MOTION ANALYSIS IN THE INFERIOR PARIETAL AREA 7A OF THE RHESUS MONKEY. R.M. Siegel. Lab. Neurobio., Rockefeller Univ., New York, NY 10021.

Human and monkey subjects use similar visual motion cues to obtain two and three-dimensional perceptions (Siegel and Andersen, '88). The present study attempts to analyze the role of area 7a in these phenomena with single unit recordings in the awake behaving monkey performing reaction time tasks.

Simple stimuli were used to map the receptive fields (RFs) of area 7a neurons while the monkey fixated a central point. In one hemisphere 200 of 298 neurons studied were found with directional selectivity to drifting squares or random dot fields, opponent vector fields (Motter and Mountcastle, '81), and/or responses to flashed, rotating, expanding and shrinking squares. These cells were scattered over area 7a.

In order to directly test the involvement of these neurons in the monkey's extraction of two and three-dimensional motion perceptions, the animal was also trained to fixate a central point and then to release a key when an unstructured 10° display became structured. The structured display consisted of 128 dots moving along the motion vectors associated with planar rotations, expansion or compression, and the three-dimensional rotation of a sphere. In the unstructured displays, the motion trajectories were randomly shuffled destroying the percept.

Of the 71 neurons tested under these conditions, 20 clearly varied their rate of firing when the stimulus changed from unstructured to structured motion. The response of the neurons was dependent on the type of structured motion; cells differed in selectivity to the three different structured motions. Of these 20 cells, 13 were restricted to a 2x2mm region within area 7a. There was no obvious correlation between the response to the structured motion and the simpler stimuli. This inability to obtain a RF underlying the structured motion response indicates either extremely non-linear RFs or attentional modulation of RFs.

These results suggest that area 7a is involved in the analysis of structure from motion. This dependency on form is interesting from the clinical perspective of the inferior parietal lobule as a visuo-spatial, not shape, processing region.

VISUAL RESPONSE PROPERTIES AND ATTENTIONAL MODULATION OF NEURONS IN THE VENTRAL INTRAPARIETAL AREA (VIP) IN THE ALERT MONKEY.

C. L. Colby, J.-R. Duhamel and M. E. Goldberg. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

We have investigated the visual responsiveness of neurons in the intraparietal sulcus of the alert monkey. Area VIP has previously been defined on the basis of receiving ascending projections from area MT (Maunsell and Van Essen '83; Ungerleider and Desimone '86). We have now identified a physiologically distinct zone in the depths of the intraparietal sulcus which corresponds to area VIP. This zone includes the fundus and most ventral portions of the lateral and medial banks in the anterior portion of the sulcus. Cells in this area are strongly responsive to visual stimulation and typically exhibit the following characteristics: large receptive fields; direction selectivity; speed selectivity; responsiveness to whole field motion. A striking feature of VIP is the similarity of these response properties to those observed in area MST, a visual area which also receives strong inputs from area MT. Unlike cells in MST, VIP neurons exhibit enhanced responses to stationary visual stimuli when they are the target for a subsequent saccade. The attentional modulation commonly found in other parietal regions thus extends to the depths of intraparietal sulcus.

69.7

PARIETAL VISUAL NEURONS ACHIEVE SPATIAL ACCURACY BY COORDINATE TRANSFORMATION OF THE VISUAL MAP.

M. E. Goldberg, C. L. Colby, and J. R. Duhamel. Lab. Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Posterior parietal cortex neurons discharge before particular saccades even when the retinal position of a target does not predict the direction of eye movement necessary to acquire that target. In order to see if such neurons require a visual stimulus, we studied them using a number of tasks in the monkey: 1) visual fixation with a peripheral visual stimulus; 2) visual saccade task in which the monkey had to make a saccade to the peripheral visual stimulus; 3) visual memory task, in which the stimulus appeared briefly during fixation, and the monkey had later to make a saccade in total darkness to where the target had been; 4) learned saccade task in which visual saccade trials were mixed with trials in which no target ever appeared and the monkey had to make the same saccade; and 5) double step task in which two stimuli, A and B, were flashed within a saccadic reaction time and the monkey had to make saccades from the fixation point to A to B. Saccades to the second stimulus from the first could not be computed from the retinal location of the target, but required knowledge of either the intervening saccade or the spatial location of the target.

A subset of parietal neurons discharged after the first and before the second saccade of the double step task. Of these neurons, the majority discharged in the visual saccade and visual memory tasks but not in the learned saccade task, establishing that for these neurons the visual presence of the target is necessary for discharge. Although some of these neurons have orbital-position dependent gain fields, none discharge to targets acquired by non-preferred saccades. The results suggest that spatial accuracy in parietal visual neurons is maintained through coordinate transformation of a retinal signal by a discharge corollary to the intervening saccade, and not by explicit coding of target position in space.

69.8

CONGRUENT VISUAL AND SOMATOSENSORY RESPONSE PROPERTIES OF NEURONS IN THE VENTRAL INTRAPARIETAL AREA (VIP) IN THE ALERT MONKEY.

J.-R. Duhamel, C. L. Colby and M. E. Goldberg
(SPON: E.J. Fitzgibbon). Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Projections from somatosensory and visual association cortices converge in the intraparietal sulcus (IPS). We have mapped the IPS physiologically and found that single cells in visual area VIP, located in the depths of the sulcus, also have robust somatosensory responses. The receptive fields are most often found on the head, face and forelimbs. These cells respond well to passive somatosensory stimulation (light touch) as well as to stimulation produced by active movement. The somatosensory (S) response properties correspond to the visual (V) response properties in two ways. First, the locations of the S and V receptive fields match: cells with S fields on brow or forehead invariably have upper field V receptive fields, while cells with S fields around the mouth or on the hands have V receptive fields in the lower field. Second, S and V receptive fields exhibit comparable direction selectivities: cells which prefer visual motion away from the fixation point for a stimulus on the screen also prefer somatosensory stimulation moving away from the center of the face with eyes closed. This correspondence between somatosensory and visual response properties suggests that such cells contribute to the elaboration of a supramodal spatial reference system.

EFFECTS OF DEACTIVATION OF LATERAL PULVINAR OR SUPERIOR COLLICULUS ON THE ABILITY TO SELECTIVELY ATTEND TO A VISUAL STIMULUS.

Robert Desimone, Mark Wessinger*, Linda Thomas*, and Walter Schneider*. Lab. Neuropsychology, NIMH, Bethesda, MD, and LRDC, Univ. of Pittsburgh, Pittsburgh, PA.

It has previously been found that extrastriate neuronal responses to ignored receptive field stimuli are suppressed. To identify possible sources of the suppression, we have studied the effects of unilateral deactivation (with the GABA agonist muscimol) of either the posterior lateral pulvinar (LP) or superior colliculus (SC) on the ability of two rhesus monkeys to attend to one extrafoveal stimulus (the target) and ignore another (a distractor), in the absence of eye movements. A brief spatial cue indicated the location of the subsequent target. The monkey's task was to indicate the color of the target (on for 100 msec), and ignore the distractor, which could have the same or different color. With no distractor, deactivation had no effect on correct performance. Reaction times, as well as the reaction time "cost" when the target was invalidly cued, were also normal. By contrast, the presence of a distractor had a devastating effect. When the distractor was located in the field ipsilateral to the affected LP or SC and the target was in the contralateral field, correct performance dropped as much as 50%. Errors were caused by the animal basing its behavior on the distractor rather than the target. When both stimuli were located in the contralateral hemifield, the effects of SC deactivation were larger than LP deactivation. The results support the notion that there is a close correspondence between attentional and oculomotor control structures and suggest that at least some attentional structures are critical for object recognition only when there is more than one stimulus in the visual field.

69.10

NEURONAL CORRELATES OF VISUAL SEARCH IN THE FRONTAL EYE FIELDS OF RHESUS MONKEY.

J.D. Schall
Department of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

Prior studies of presaccadic activity in the frontal eye fields (FEF) have utilized single visual stimuli as targets for saccades. These studies have shown that many of the cells exhibit visual responses either alone or in conjunction with a saccade related discharge. The purpose of this study was to record the activity of visually responsive cells in the FEF of a monkey confronted with multiple stimuli, among which the target had to be discriminated. Two groups of stimuli were used. The first consisted of a red spot among 3-7 green spots, and the second consisted of the letter T among 3-7 L's. The red/green search was achieved with shorter saccade latencies than the letter search. The unit recordings yielded four main results: 1) The activity of most of the visual and visuomovement cells during visual search with multiple stimuli could be predicted from their spatial tuning and temporal discharge characteristics in response to a single stimulus. 2) The response latency of a few visual cells was longer when presented with multiple stimuli. 3) The response duration of other visual cells was prolonged during search. 4) During visual search some visuomovement cells exhibited spatial tuning according to the location of the correct target relative to the receptive/movement field. These results suggest that while the reponses of many FEF neurons appear to be dictated soley by the characteristics of the visual stimulus and the resulting eye movement, some neuronal activity in FEF may be related to the process of saccade target selection during visual search.

ATTENUATION OF RESPONSES OF INFERIOR TEMPORAL NEURONS IN AWAKE MONKEYS BY ADDITION OF A SECOND STIMULUS E.K. Miller, P.M. Gochin, C.G. Gross, G.L. Gerstein. Dept. Psychol., Princeton Univ., Princeton, NJ 08544, Dept. Physiol., Univ. Penn. Sch. Med., Phila., PA 19104

We compared the responses of inferior temporal (IT) cortex neurons to individual and pairs of pattern stimuli. Monkeys were trained to fixate a small (0.5 deg) spot of light while the stimuli were presented extrafoveally. Each stimulus subtended about 1.5 deg and was projected at one of two sites 5 deg contralateral to fixation. On a given trial, stimuli were presented either at one of the sites or simultaneously at both sites.

We found that for eighty-seven percent of responsive IT neurons, addition of a second stimulus decreased the cell's response relative to the response of the more effective of the two stimuli presented alone. While many of the neurons tested responded preferentially to a specific single stimulus, the magnitude of the response attenuation was similar whether the second stimulus was the same as or different from the first stimulus. Furthermore, this effect occurred whether the second stimulus was within or outside the cell's excitatory receptive field. While previous investigations have shown that directed attention can attenuate responses of IT neurons, the effect we have observed is unlikely to be due to attention since our behavioral task only required the animal to maintain fixation of the fixation point.

VISUAL RESPONSE PROPERTIES OF INFERIOR TEMPORAL NEURONS IN ALERT INFANT MACAQUES. H.R. Rodman, J.P. Skelly and C.G. Gross. Dept. of Psychology, Princeton University, Princeton, NJ 08544.

Previously, we found that visual responsiveness is virtually absent in inferior temporal (IT) cortex before about 4 months of age in macaques under immobilization and N_2O anesthesia, although control recordings in striate cortex and area MT showed normal responsiveness and selectivity (Rodman et al., NS Abs., 14: 11). As a further check on the effects of anesthesia, we recorded in alert infant macaques implanted with a search coil and trained to fixate on a spot of light.

Over 70 single IT units were studied in 2 male and 1 female M. fascicularis ranging between 5 weeks and 3 months of age. Stimuli were typically presented for 500 ms at the fixation point and included pictures of faces, boundary curvature descriptors, lines, and other patterns. Objects were also presented by hand.

About three-quarters of all IT units studied in the alert infants were visually responsive, in contrast to our findings in anesthetized infants. Moreover, there was no tendency to find fewer responses at younger ages. IT cells showed stimulus selectivity in the earliest recording sessions, particularly for boundary curvature; a few cells selective for faces or color were also found. As in adults, responses were strongest at the fovea when compared with responses at other locations. Although responses were found in IT in each animal in the alert condition, IT cortex was not responsive when the same animals were studied under N_2O.

These findings show that IT, a critical substrate of visual recognition, has adult-like properties as early as 5 weeks. These properties are masked by anesthesia until about 4 months, indicating that developmental changes in cellular metabolism, extrinsic modulating influences or other factors persist up to or occur at this point.

SYNAPTOGENESIS I

70.1

AN HYPOTHESIS TO EXPLAIN THE TRIGGERING OF NEUROMUSCULAR SYNAPTOGENESIS. E. Rodriguez-Marin* and M.W. Cohen. Dept. of Physiology, McGill University, Montreal, Que. H3G 1Y6.

In cultures of spinal cord neurons and myotomal muscle cells derived from Xenopus embryos the neurite-muscle interactions which lead to co-localization of a synaptic vesicle antigen and acetylcholine receptors (AChRs) can occur along pre-existing, non-growth-cone portions of neurites. Following neurite-muscle contact the portion of neurite proximal, but not distal, to the contact loses its capacity to participate in these interactions.

These findings can be explained by assuming that a neural synaptogenic factor (nSF) is inserted into the surface membrane only at the growth cone and is mobile within the surface membrane. A muscle SF is also mobile within the surface membrane and is assumed to be the AChR. In regions of neurite-muscle contact the nSF and AChR cross-link with each other and become immobilized. With time membrane nSF is depleted proximal to the contact as more of it enters the contact region and becomes immobilized there. Synaptic vesicles accumulate at sites of immobilized nSF and thereby become co-localized with AChRs. Only cholinergic neurons possess the appropriate nSF for cross-linking the AChR. The cross-linking is short-lived and is replaced by indirect linkages when molecules are externalized to form the synaptic basal lamina. (Supported by MRC of Canada.)

REDISTRIBUTION OF AGRIN BINDING SITES DURING ACETYLCHOLINE RECEPTOR CLUSTERING ON CULTURED MYOTUBES. J. R. Fallon, Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545

Agrin derived from Torpedo electric organ induces the clustering of AchR when added to cultured chick myotubes. We have assessed the distribution of Torpedo agrin binding sites on the myotube surface before and during AchR clustering using immunofluorescence microscopy with species-specific antibodies directed against Torpedo agrin. Torpedo agrin is initially distributed over the entire myotube surface in a uniform, finely punctate pattern. Preferential binding to pre-existing, spontaneous AchR clusters is not observed. This distribution is distinct from the more coarsely punctate and/or fibrillar pattern that is seen for chick muscle-derived agrin (Lieth and Fallon, this volume) or for LN, COLL IV, FN, and HSP. After two hours of incubation, increasing levels of Torpedo agrin binding are observed in the vicinity of newly formed AchR microaggregates; by 24 hrs the binding sites are concentrated almost exclusively at AchR clusters. These results indicate that Torpedo agrin binding sites are uniformly distributed on the surface of untreated myotubes, and that these binding sites redistribute during agrin-induced AchR cluster formation.

AGRIN: A SYNAPTIC ORGANIZING MOLECULE CLOSELY RELATED TO NON-SYNAPTIC BASAL LAMINA PROTEINS. Earl W. Godfrey. Dept. of Anatomy & Cellular Biol., Medical College of Wisconsin, Milwaukee, WI 53226.

Agrin is a synapse-organizing protein that is found in motor neurons and is concentrated in the synaptic basal lamina at the neuromuscular junction; agrin is also associated with the basal laminae of many tissues. Agrin purified from extracellular matrix (ECM)-enriched fractions of several Torpedo tissues, including skeletal muscle, heart and intestine, is similar biochemically to agrin from the nervous system and electric organ, and aggregates acetylcholine receptors (AChRs) on cultured skeletal muscle cells regardless of tissue source [Godfrey et al., J. Cell Biol. 106: 1263-1272; 1988].

Here I report that, in the chicken, while agrin-like proteins were associated with most basement membranes, the AChR-aggregating activity of agrin preparations differed depending on the tissue of origin. Agrin enriched by immunoaffinity chromatography from the cytosol of embryonic or adult chicken CNS aggregated AChRs with a dose-response relationship similar to that seen with Torpedo agrin. However, agrin preparations from embryonic skeletal muscle and heart and adult kidney induced a small number of AChR aggregates at low doses, but had little or no biological activity at higher doses. Despite this apparent difference in AChR-aggregating activity, the major agrin-like proteins from the nervous system and other tissues were biochemically and immunochemically similar. Basement membranes of several tissues, as well as spinal cord motor neurons, were stained by antisera against agrin-like proteins from chicken kidney. These antisera also precipitated and inhibited AChR-aggregating activity from chick embryo brain and spinal cord, adult chicken brain and Torpedo electric organ. Thus, agrin-like proteins of non-neural tissues in the chicken are closely related to agrin from the nervous system. The apparent difference in biological activity between these agrin preparations may be due to inhibitory molecules that co-purify with agrin from non-neural tissues.

70.4

AGRIN-LIKE MOLECULES ARE TRANSPORTED IN AN ANTEROGRADE DIRECTION IN MOTOR AXONS C. Magill-Solc & U.J. McMahan. Dept. of Neurobiology, Stanford University, Stanford, CA 94305

Several lines of evidence indicate that molecules in the synaptic basal lamina at the neuromuscular junction that direct the formation and maintenance of acetylcholine receptor (AChR) and acetylcholinesterase (AChE) aggregates on the muscle fibers and that the active basal lamina molecules are similar to agrin, a protein extracted from Torpedo electric organ. We reported previously that agrin-like molecules are concentrated in the cell bodies of motor neurons. This led us to suggest that motor neurons synthesize agrin-like molecules in their cell bodies, transport them anterogradely along their axons, and secrete them at their axon terminal, to become incorporated into the basal lamina at the neuromuscular junction. An alternative possibility is that agrin-like molecules are produced by muscle fibers and are taken up by axon terminals to be transported retrogradely along motor axons to their cell bodies. The experiment described here tests these hypotheses.

We ligated the sciatic nerves of adult frogs and 3 days later examined the distribution of agrin-like molecules on each side of the ligature. Others have shown that proteins synthesized in the cell bodies of neurons and transported anterogradely along their axons accumulate on the cell body side of such a ligature. In normal frog nerves axoplasm does not stain with our anti-agrin antibodies. However, in the ligated nerves the axoplasm of some of the myelinated axons on the cell body side of the ligature stained intensely. Severing the ventral roots that carry the motor axons to the sciatic nerve prior to ligation resulted in the absence of anti-agrin staining in such nerves. Extracts of the portion of ligated nerves on the cell body side of the ligature contained a high concentration of molecules that cause AChR aggregation on cultured myotubes, as does agrin. Such molecules were immunoprecipitated by anti-agrin antibodies and were not detected in normal nerves or in nerves where ventral roots had been severed prior to ligation. Altogether, these findings provide evidence that agrin-like molecules in motor neurons are transported from cell body to axon terminal.

IDENTIFICATION OF AN AGRIN cDNA. M.A. Smith, F. Rupp, P. Snow, J.W. Schilling, B.G. Wallace, R.H. Scheller and U.J. McMahan. Dept. of Anatomy and Neurobiology, California College of Medicine, University of California, Irvine, CA 92717. Dept. of Zoology, University of California, Berkley, CA 94720. Cal. Biotech. Inc. Mountain View, CA 94043. Dept. of Neurobiology and Dept. of Biology, Stanford University, Stanford, CA 94305.

Agrin proteins, isolated from a basal lamina-rich fraction of *Torpedo* electric organ, induce specializations on cultured chick myotubes that contain a high concentration of acetylcholine receptors and other postsynaptic components of the neuromuscular junction. Anti-agrin antibodies recognize four proteins Mr. 150, 135, 95 and 70kD. Two proteins, Mr 150 and 95kD representing agrin, induce the aggregation of postsynaptic components; the 135 and 70kD agrin-like proteins are inactive by this assay. As a step towards understanding the relationships between the different forms of agrin and agrin-like proteins, determining their source and assessing their role at the neuromuscular junction we have isolated an agrin cDNA clone and deduced its amino acid sequence.

A cDNA library was constructed in λgt11, from poly(A)$^+$ RNA isolated from the electric lobe of *Discopyge ommata*, an electric ray closely related to *Torpedo*, and screened with an antiserum raised against a mixture of SDS denatured, affinity purified, agrin and agrin like proteins. One of four clones initially isolated was determined by epitope selection of the antiserum, to encode a fusion protein containing antigenic determinants shared with all four *Torpedo* agrin/agrin-like proteins. This recombinant contains a 4.3kb cDNA insert that predicts an amino acid sequence containing a stretch of 11 out of14 amino acids previously identified by Edman degredation as the N-terminus of the 95/70kD *Torpedo* proteins. Two of the three mismatches represent single base changes. The deduced sequence contains several EGF-like domains and a region of sequence similarity to the active site of pancreatic secretory typsin inhibitor.

Thus a cDNA has been isolated from a *Discopyge ommata* electric lobe library, that codes for a protein that exhibits strong antigenic and structural similarity to *Torpedo* agrin.

70.6

FURTHER CHARACTERIZATION OF AN ACETYLCHOLINE RECEPTOR-INDUCING PROTEIN AND DEVELOPMENT OF AN OLIGONUCLEOTIDE PROBE FOR THIS MOLECULE. D.L. Falls, D.A. Harris, R.M. Dill-Devor*, R.L. Cole*, W.D. Walsh*, and G.D. Fischbach. Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, Missouri, 63110.

The 42kD AChR Inducing Activity (ARIA), a glycoprotein purified from chicken brain, may be a trophic factor released by motoneurons which promotes synthesis and insertion of acetylcholine receptors (AChRs) at nascent neuromuscular synapses. ARIA appears as a broad band on SDS polyacrylamide gels and as a cluster of sharp OD_{210} peaks eluted from a reverse phase HPLC column. We have found that this apparent heterogeneity is due, in large part, to variable glycosylation of the core protein. Each of the peaks eluted from the HPLC column exhibits the same N-terminal amino acid sequence. With recoveries in the 10 pmole range, we unambiguously identified 24 of the first 27 amino acids. A rabbit antiserum raised against a synthetic peptide corresponding to the N-terminal 11 amino acids labeled bands that ranged between Mr 34,000 and 42,000 on western blots of partially purified ARIA. When the same preparation was digested with N-glycanase to remove N-linked carbohydrate side chains, all of these bands migrated at Mr 31,000. Receptor inducing activity eluted from gel slices was localized to the same region of the gel as the protein labeled by the anti-peptide antibody and, after N-glycanase treatment, shifted with the labeled protein. When ARIA was exposed to reducing agents, the activity was completely destroyed. Starting with cDNA prepared from chick brain poly(A)$^+$ RNA, we have used the polymerase chain reaction and degenerate oligonucleotide primers based on the N-terminal sequence to amplify a 34-base nucleic acid sequence corresponding to the 3' base of the 7th amino acid through the 3' base of the 18th amino acid. A cDNA clone identified with the PCR product (see Harris et al., this volume) predicts a protein with four potential N-glycosylation sites and two cysteine residues. We conclude that a disulfide bond is essential for receptor inducing activity, but that N-linked carbohydrates are not. The fact that the receptor-inducing activity shifts along with the protein band following removal of the N-linked carbohydrate provides evidence that the amino acid sequence and cDNA clone are in fact ARIA.

70.7

MOLECULAR CLONING OF AN ACETYLCHOLINE RECEPTOR-INDUCING PROTEIN. D.A. Harris, D.L. Falls, W. Walsh*, and G.D. Fischbach. Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, Missouri 63110.

42-kD ARIA (AChR-inducing activity) is a glycoprotein isolated from chicken brain that stimulates synthesis of acetylcholine receptors (AChRs) by cultured chicken myotubes. This protein may play a role in the accumulation of receptors at the developing neuromuscular junction. Using the polymerase chain reaction we amplified a 34-nucleotide segment from chicken brain poly(A)$^+$ RNA that encodes 11 amino acids of the chemically determined N-terminal sequence of ARIA (see Falls et al., this volume). This 34-nucleotide sequence was then used to isolate several cDNA clones from adult and embryonic chicken brain libraries. Complete nucleotide sequencing of a 2.2 kb embryonic brain cDNA revealed an open reading frame encoding 267 amino acids, including a putative signal peptide. The sequence includes four potential N-glycosylation sites, a proline- and glycine-containing hexapeptide repeat near the N-terminus, and two hydrophobic regions: one at the C-terminus, and one near the middle of the molecule that is long enough to span the plasma membrane. Northern blots demonstrate a prominent 2.9 kb mRNA in brain and spinal cord from adult chickens as well as from embryos as young as E5. We have noted significant similarity between the amino acid sequence encoded by our cDNA and that of the prion proteins PrP 33-35^{Sc} and PrP 33-35^{C}, which are thought to play a critical role in the pathogenesis of certain degenerative neurological diseases. To confirm the identity of our cDNA clone, we are attempting to express AChR-inducing activity by transfection of mammalian cells and by translation in vitro.

70.8

ACh RECEPTOR CLUSTERING IS TRIGGERED BY LOCAL ACCUMULATION OF NON-AChR MOLECULES. J. Stollberg and S.E. Fraser. Dept. Physiology and Biophysics, UC Irvine, Irvine, CA 92717.

We have shown previously that a simple model system - cultured *Xenopus* muscle cells exposed to electric fields - preserves the components and interactions required to initiate specific ACh receptor clustering (Stollberg and Fraser *J. Cell Biol.* 107, 1988). Using digitally-analyzed fluorescence video-microscopy, we found that receptor aggregation is due to lateral migration of receptors, and is mediated by a diffusion-trap mechanism. Other experiments have ruled out the possibility that receptor aggregation is triggered by electromigrational accumulation of AChRs (*Nrsci. Abstr.* #360.5, 1988). The only remaining triggering mechanisms are *i*) the electromigrational accumulation of non-AChR molecules, or *ii*) a voltage-sensitive mechanism (at 8 V/cm there is a depolarization of about 16 mV at the cell pole where clustering occurs).

Several experiments appear to rule out voltage-sensitive mechanisms. First, receptor clustering can be induced by fields which result in a depolarization as low as 1-2 mV; this is a small effect compared to the sensitivity of voltage-gated ion channels. Furthermore neither 10 mM cobalt nor the removal of sodium affect field-induced receptor clustering, indicating that neither calcium nor sodium fluxes are involved in the process. Finally, alternating electric fields can induce bipolar receptor clusters if the period of field reversal is on the order of 40', but not if the period is shorter. Thus the time-constant of the triggering event is on the order of 10's of minutes - consistent with a mechanism in which the critical event is the electromigrational accumulation of components, but not with the much faster response characteristics of voltage-gated ion channels.

These results suggest that voltage-sensitive mechanisms do not trigger the observed AChR clustering in the model system. The only possibility consistent with all the data is that field-induced receptor clustering is triggered by the accumulation of non-AChR molecules.

70.9

S-LAMININ INHIBITS NEURITE EXTENSION PROMOTED BY LAMININ. J. Weis*, D.D. Hunter*, J.P. Merlie[1] and J.R. Sanes. (SPON: J. Ferrendelli) Depts. of Anatomy & Neurobiology, and [1]Pharmacology, Washington University School of Medicine, St. Louis, MO 63110

Motor axons preferentially reinnervate original synaptic sites in denervated skeletal muscle, a selectivity mediated at least in part by the basal lamina of the synaptic cleft. We have recently isolated a protein, s-laminin (SL), that is concentrated in synaptic basal lamina, and is adhesive for chick ciliary motoneurons. Molecular cloning revealed that SL is homologous to laminin (L) a potent promoter of neurite outgrowth (Hunter et al., Nature 338: 229, 1989). The use of recombinant fragments and synthetic peptides has allowed us to map a site in SL to which motoneurons adhere but sensory or tectal neurons (which adhere to L) do not; thus, this site is selectively recognized by motoneurons.

To assess the consequences of neuronal interaction with SL, ciliary neurons were incubated overnight on dishes coated with L, recombinant SL, or L+SL. Neurons extended neurites on L but not on SL. Furthermore, SL reduced adhesion to and neurite outgrowth on L, suggesting that SL may inhibit outgrowth rather than merely failing to support it. This hypothesis was tested by growing neurons on a dish uniformly coated with L, then overlaid with stripes of SL. Neurons adhering to L extended neurites that stopped abruptly at the L/L+SL border. This result suggests that whereas L directs axons to grow, SL directs axons to stop. In vivo, motor axons regenerating along L-rich pathways might stop growing and/or differentiate upon encountering SL at original synaptic sites. (Support: NIH, MDA, M. Kade Foundation, and Monsanto)

70.10

DEVELOPMENT OF SYNAPTIC TRANSMISSION AND TRANSMITTER SENSITIVITYOF SYMPATHETIC NEURONS INNERVATED *IN VITRO* BY APPROPRIATE VS INAPPROPRIATE PRESYNAPTIC INPUT. R. Gardette & L.W. Role, Dept of Anat. & Cell Biol., Ctr for Neurobiol. and Behav., Columbia Univ, P & S, 630 W 168th, NY, NY 10032

We have studied the development of embryonic sympathetic neurons innervated by either dorsal (dSPX) or ventral (vSPX) spinal cord explants which, in the chicken, contain the sympathetic preganglionic neurons or skeletal motoneurons, respectively. We monitored spontaneous synaptic currents and acetylcholine (ACh) induced currents in voltage clamped neurons to determine the development of innervation and transmitter sensitivity from 1 day (D1) to 4 days (D4) after addition of presynaptic input.

Innervation by either input was detected by D1, but the percentage of neurons innervated with vSPX was half that with dSPX, probably due to relatively poor adhesion and neurite extension from the vSPX. In contrast, the development of enhanced ACh sensitivity was similar regardless of the source of cholinergic input. Both dSPX and vSPX induced a steep increase in the ACh sensitivity by D1 and a smaller linear increase between D1 and D4. Non-innervated cells co-cultured with the vSPX showed a similar (though smaller) increase in ACh sensitivity, perhaps due to the influence of a soluble factor as previously suggested (Role, L. PNAS 1988 85:2825). There is little change in transmitter sensitivity of neurons maintained *in vitro* in the absence of presynaptic input or in the presence of non-cholinergic explants. Thus, although the extent of innervation of sympathetic neurons is somewhat dependent on the appropriate presynaptic input, there is apparently little specificity with respect to the source of cholinergic input in the developmental regulation of ACh sensitivity. *Supported by NS22061, Klingenstein and McKnight Foundations (LWR). SELECTIVE REINNERVATION OF MUSCLE BASEMENT MEMBRANES BY THEIR ORIGINAL MOTONEURONS. V. Boss and D.J. Wigston. Departments of Biology and Physiology, Emory University, Atlanta, GA 30322.

The reinnervation of axolotl hindlimb muscles by their original motoneurons suggests the existence of muscle-specific cues that promote selective synaptogenesis during reinnervation. We have investigated whether these cues are associated with muscle fibers or their basement membrane sheaths. Motoneurons were retrogradely labeled by injecting the long-lasting tracer diamidino yellow (DY) into either the left anterior or posterior ilio-tibialis (aILT or pILT). Myofibers in the right a- and pILT muscles were destroyed and their regeneration prevented by γ-irradiation. The left a- and pILT were removed and replaced with the right myofiberless a- and pILT, but in reversed a-p orientation. Motoneurons were able to reinnervate these myofiberless muscles. After reinnervation, we labeled motoneurons projecting to the myofiberless former pILT, now in the position of the original aILT, by intramuscular injection of rhodamine-HRP (R-HRP). We found that a higher percentage of motoneurons contained both labels when equivalent muscles were injected (DY → left pILT, R-HRP → transplanted myofiberless pILT) than when different muscles were injected (DY → left aILT, R-HRP → transplanted myofiberless pILT), despite the novel position of the transplanted muscles and their lack of myofibers. This suggests that the basement membranes of different muscles are distinguished by cues that are recognized by regenerating motoneurons.

COMPETING MOTOR NERVE TERMINALS AND THE ACETYLCHOLINE RECEPTORS UNDERLYING THEM ARE REARRANGED DURING SYNAPSE ELIMINATION. R.J. Balice-Gordon & J.W. Lichtman, Department of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

By repeatedly visualizing both the pre- and postsynaptic elements of the same developing neuromuscular synapses, we have studied the elimination of multiple innervation in living mouse pups. During the first days after birth, some motor nerve terminals are rapidly eliminated at multiply innervated neuromuscular junctions. At the same time, the acetylcholine receptors underlying these nerve terminals become progressively less dense and are also eliminated. To determine whether pre- or postsynaptic elimination occurs first, we have followed motor nerve terminals and acetylcholine receptors continuously over many hours. Several different fluorescent compounds, particularly dicationic voltage-sensitive dyes (e.g., RH 795; Hildesheim and Grinvald, unpublished) were found to vitally stain the membranes of axons and nerve terminals and were used with 4-Di-2-ASP, a vital mitochondrial marker, to determine how competing motor nerve terminals are rearranged during synapse elimination. Using rhodamine- and coumarin-conjugated alpha bungarotoxin, we have begun to differentially label receptors at individual multiply innervated synapses to follow their redistribution during competition. Finally, we have differentially labeled nerve terminals converging at the same synapses using anterograde diffusion of DiI (red; Honig and Hume, 1986) and a second lipophilic dye, Di10ASP (green). In this fashion we have studied the spatial segregation of motor nerve terminals and the temporal sequence of events during synaptic competition.

70.13

PROGRESSIVE LOSS OF SYNAPTIC EFFICACY DURING SYNAPSE ELIMINATION. J. Nabekura and J.W. Lichtman, Department of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

The amplitude of each of the synaptic inputs to multiply innervated muscle fibers was measured in the sternomastoid muscle of neonatal mice by recording intracellularly while stimulating the motor axons with multiple electrodes. At birth, all muscle fibers were innervated by more than one axon (usually 2), whereas at 2 weeks of age, all of the muscle fibers were singly innervated. At birth, the amplitude of each input to a muscle fiber was approximately the same. However, during the next 14 days, the relative amplitudes of the multiple inputs to individual fibers became progressively different. Near the end of the period of multiple innervation, there was roughly a five-fold difference in the amplitudes of the synaptic inputs to each of the few muscle fibers still maintaining multiple innervation. For several reasons, this shift in synaptic strength may be due in part to a decrease in the density of postsynaptic acetylcholine receptors under the terminal being eliminated. First, in some cases, the smaller evoked potentials were smaller than the miniature endplate potentials emanating from the other axon terminal. Furthermore, such unequal innervation occurs at developmental stages when endplates contain areas of high and low density of acetylcholine receptors (Balice-Gordon and Lichtman, Soc. Neurosci. Abs. 14: 894, 1988). Because synapse elimination also involves the structural loss of some presynaptic nerve terminals, we are presently attempting to resolve the relative roles of pre- and postsynaptic elements in the functional loss of synaptic transmission at multiply innervated junctions.

LONG-TERM POTENTIATION II

71.1

LONG-TERM DEPRESSION IN HIPPOCAMPAL PYRAMIDAL NEURONS INDUCED BY LOW-FREQUENCY PRESYNAPTIC ACTIVITY PAIRED WITH POSTSYNAPTIC HYPERPOLARIZATION. P.K. Stanton and T.J. Sejnowski (spon: W. Lytton). Albert Einstein Coll. Med., Bronx, NY 10461 and Salk Institute, La Jolla, CA 92037.

Long-term potentiation (LTP) is a persistent increase in synaptic strength following high-frequency afferent stimulation. Recently, we have shown that low-frequency inputs *in phase* with a high-frequency bursting input exhibit LTP, while *out of phase* inputs exhibit long-term depression (LTD) of synaptic strength. Out of phase inputs arrive while the postsynaptic neuron is hyperpolarized by i.p.s.p's and intrinsic conductances. This suggests that pairing postsynaptic hyperpolarization with low-frequency presynaptic activity should also yield LTD of the activated input.

We recorded intracellularly from CA1 pyramidal neurons in rat hippocampal slices (400 μm thick), stimulating Schaffer collateral or subicular inputs onto apical dendrites. The test input received low-frequency stimuli (5 Hz, 2 sec x 4 trains), and constant current was injected (starting 1-2 min before) to either depolarize (+20 mV) or hyperpolarize (-20 mV) the neuron during stimulation.

Pairing postsynaptic hyperpolarization with low-frequency synaptic stimulation produced LTD specific to the activated pathway, while pairing depolarization yielded homosynaptic LTP. Cells fired action potentials during injection of depolarizing, but not hyperpolarizing, current. Pairing hyperpolarization with stimulation decreased synaptic e.p.s.p.'s of the stimulated pathway -57.6 ± 6.8% (30 min post-stimulation), but only -13.4 ± 8.4% in the control, unstimulated pathway. Thus, hippocampal plasticity follows a two-way Hebbian rule which can either enhance or depress synaptic strength as a function of pre- and postsynaptic covariance.

71.2

INDUCTION OF ASSOCIATIVE LONG-TERM DEPRESSION (LTD) IN HIPPOCAMPAL FIELD CA3 IS NOT MEDIATED BY NMDA RECEPTORS. S. Chattarji, P.K. Stanton[1] and T.J. Sejnowski. Salk Institute, La Jolla, CA 92037 and [1]Albert Einstein Coll. of Med., Bronx, NY 10461.

Brief, high frequency activation of excitatory afferents in the hippocampus produces long-term potentiation (LTP) of synaptic strength. In field CA3, pyramidal cells receive separate inputs via commissural/associational (COM/ASSOC) and mossy fiber (MF) synapses. LTP of COM/ASSOC synapses depends on activation of glutamate receptors of the N-methyl-D-aspartate (NMDA) subtype, but MF synapses do not. CA3 COM/ASSOC synapses exhibit an associative form of LTP when low frequency (LF) stimuli are *positively* correlated in time with a train of high frequency MF bursts (HF). Recently, we have shown that when LF COM/ASSOC stimulation is *negatively* correlated in time with HF stimulation of MF, associative long-term depression (LTD) at COM/ASSOC synapses is induced. Is associative LTD of COM/ASSOC synapses also mediated by NMDA receptors?

Extracellular recordings from rat hippocampal slices (400μm thick) were made in CA3 pyramidal cell somatic and apical dendritic fields. HF stimuli to MF consisted of trains of 10 bursts of 5 pulses each at a frequency of 100 Hz, with an interburst interval of 200 msec. The LF stimuli to COM/ASSOC, a 5 Hz train of single shocks, was given either superimposed on the middle of each burst (in phase), or symmetrically between bursts (out of phase).

In control experiments, the HF stimuli alone induced homosynaptic LTP of either COM/ASSOC or MF synapses, while LF stimuli alone induced no change. In bath applied AP5 (30μM), the HF stimuli alone elicited homosynaptic LTP at MF, but not COM/ASSOC synapses. In AP5, out-of-phase LF COM/ASSOC stimuli given with HF bursts to MF still elicited associative LTD, while associative LTP normally induced by in-phase stimuli was blocked. Thus, induction of associative LTD at CA3 COM/ASSOC synapses does not require NMDA receptor activation.

71.3

DIFFERENTIAL EFFECTS OF NMDA RECEPTOR ANTAGONIST APV ON CALCIUM INDUCED AND TETANIC STIMULATION INDUCED POTENTIATION IN AREA CA1 OF IN VITRO HIPPOCAMPUS. L. Grover & T. Teyler, Neurobiology Dept., N.E. Ohio Univ. Col. Med., Rootstown, OH 44272.

The dependence of calcium induced potentiation on extracellular potassium concentration in area CA1 may reflect involvement of a postsynaptic, voltage-dependent mechanism (Grover & Teyler, Brain Res., in press). Since tetanus induced long-term potentiation is blocked by APV, we asked if calcium induced potentiation is also blocked by APV. Population spike (PS) and population EPSP (PE) were recorded in s. pyramidale and s. radiatum. Potentiation was induced by 10 min exposure to high calcium and potassium, or by high frequency stimulation (200 Hz, 0.5 s, 4X) of s. radiatum fibers. Effects of potentiating treatments were assessed after a 40 min interval. In the absence of APV, tetanic stimulation (n=8) resulted in a 159 ± 13% (mean ± SEM) increase in PS and a 50 ± 13% increase in PE. Calcium induced potentiation (n=6) of PS was 67 ± 21%, and of PE was 19 ± 7%. In the presence of 50 uM D,L-APV, tetanic stimulation (n=5) induced significantly less potentiation: PS was increased by 21 ± 13% ($p<.03$), and PE decreased by 19 ± 5% ($p<.001$). In contrast, potentiation induced by exposure to high calcium (n=7) was not significantly reduced by 50 uM APV: PS increased by 99 ± 20% ($p<.28$), and PE increased by 7 ± 3% ($p<.10$). Calcium induced and tetanus induced potentiation may therefore depend on different mechanisms for induction. (Supported by EPA and ONR.)

71.4

MODULATION OF $[Ca]_i$ BY A CAGED EGTA AFFECTS NEURONAL PLASTICITY IN THE RAT HIPPOCAMPUS. M. Segal* and A. Patchornik* (Spon: U.Z. Littauer) Center for Neuroscience, The Weizmann Institute Rehovot 76100 ISRAEL

The crucial role of intracellular calcium ($[Ca]_i$) in neuronal plasticity has been illustrated extensively in recent years (Lynch et al. Nature 305 719, 1983; Malenka et al. Science 242 81, 1988). We have used a new caged EGTA which is activated by UV irradiation. Experiments were conducted with hippocampal slices maintained in an interface chamber or with dissociated cultured hippocampal neurons voltage clamped with a patch pipette which allows a more precise control of $[Ca]_i$. Tetanic stimulation of stratum radiatum produced long term potentiation (LTP) of EPSP's as seen before. Cells recorded with EGTA (0.1M in 2M K-acetate pH 7.2) containing pipettes failed to express a large afterhyperpolarization (AHP) following a burst of action potentials evoked by a depolarizing current pulse. In addition, these cells failed to express LTP. Cells recorded with caged EGTA containing pipettes expressed normal AHP's and LTP's. However, following UV irradiation the cells ceased to express AHP's. The time course of disappearance of AHP's was used to assess the effect of the activated EGTA on $[Ca]_i$, on EPSP's and LTP. Newly activated EGTA did not affect EPSP size but did prevent generation of LTP. Once an LTP is established, activation of the EGTA could only partially reduce the potentiated EPSP. We are currently studying the critical duration of Post-tetanic elevated $[Ca]_i$ needed to maintain LTP.

71.5

INHIBITION OF POSTSYNAPTIC PROTEIN KINASE BLOCKS INDUCTION BUT NOT EXPRESSION OF LONG-TERM POTENTIATION. R. Malinow, H. Schulman and R. W. Tsien. *Depts. Mol. Cell. Physiol. & Pharmacol., Stanford Univ.*

Long-term potentiation (LTP) of synaptic transmission is a widely studied cellular example of synaptic plasticity. However, the identity, localization and interplay among the biochemical signals underlying LTP remain unclear. It is generally accepted that postsynaptic NMDA activation and calcium entry are events critical in the triggering of LTP. To learn more about the role of the postsynaptic cell in LTP, and the possible involvement of particular protein kinases, we used intracellular microelectrodes to deliver protein kinase inhibitors to postsynaptic cells. We tested four inhibitors: H-7, a general protein kinase blocker; PKC(19-31) and PKC(19-36), peptide fragments of PKC that act as potent and specific inhibitors of PKC activity; and P3, a synthetic calmodulin-binding peptide. We find that delivery of these inhibitors to postsynaptic cells prior to tetanic stimulation blocks LTP. This suggests that postsynaptic kinase activity is required to produce LTP. Previous studies have shown that established LTP can be blocked by bath-applied H-7, which presumably does not discriminate between pre- and postsynaptic protein kinases. To test if persistent *postsynaptic* kinase activity is required to express LTP, we delivered H-7 to postsynaptic cells after the establishment of LTP. We find that once established, LTP appears unresponsive to postsynaptic H-7. Furthermore, postsynaptic H-7 does not reduce the inhibition of potentiated transmission caused by bath-applied H-7. Our results suggest the involvement of postsynaptic PKC in the induction of LTP and a presynaptic protein kinase in the expression of LTP.

71.6

ESSENTIAL ROLE OF POSTSYNAPTIC CALMODULIN AND PROTEIN KINASE ACTIVITY IN LTP D.J. Perkel, R.C. Malenka, J.A. Kauer, P.T. Kelly, M.N. Waxham*, M.D. Mauk & R.A. Nicoll. Depts. Physiol., Pharmacol., & Psychiatry UCSF, San Francisco, CA 94143 & Depts. Neurol. & Neurobiol. & Anat., Univ. Texas Health Sci. Ctr. Houston, TX 77225

The mechanisms by which the influx of calcium ion through NMDA receptors contributes to the generation of LTP in the CA1 region of the rat hippocampus remain unclear. We have investigated, in the slice preparation, the possible role of postsynaptic calmodulin (CaM) and protein kinase activity by intracellular application of compounds known to interfere with such biochemical processes. Tetanic stimulation elicited a slowly decaying potentiation (approx. 30 min.) in pyramidal cells recorded with electrodes filled with calmidazolium (0.5 mM, 1% DMSO; n = 5) or with the peptides (CBP or CBP_{-3}, 190 µM; n = 11, 8) that bind CaM and prevent Ca/CaM-dependent substrate phosphorylation by Ca/CaM-dependent protein kinase type II. In all experiments included, the initial slope of the simultaneously recorded field EPSP remained greater than 120% of control values 60 min. after the tetanus. A control peptide sharing many properties with CBP but not its CaM antagonism did not block LTP (CTP_2, 190 µM; n = 8). Intracellular application of H7 (20 mM, n = 8), a non-specific inhibitor of protein kinase activity, also blocked LTP. We conclude that LTP requires activation of postsynaptic CaM and protein kinase activity.

71.7

ZIF/268 mRNA LEVELS AND INDUCTION OF LTP ARE REGULATED IN PARALLEL BY PERFORANT PATH STIMULATION. P.F. Worley, A.J. Cole, D.W. Saffen* and J.M. Baraban. Dept. of Neuroscience, Johns Hopkins University, Baltimore, MD.

Recent studies have demonstrated that neuronal stimulation elicits rapid increases in c-fos as well as several other transcription factor mRNAs in brain. To study synaptic mechanisms involved in regulating this rapid genomic response in brain, we stimulated neurons of the dentate gyrus via perforant path afferents in vivo and monitored mRNA levels of 4 genes previously shown to be rapidly induced by seizures (Saffen et al., PNAS 1988) using in situ hybridization. High-frequency stimulation of the perforant path (twelve 20 msec 500 hz trains), which induces long-term potentiation, but not low frequency stimulation (0.1 hz), markedly increases zif/268 mRNA levels in ipsilateral granule cell neurons within 15 minutes. mRNA levels of c-fos, c-jun and jun-B are less consistently increased by this stimulus. NMDA antagonists CGS-19755 and MK-801, which block neuronal NMDA responses and LTP, also block high-frequency stimulus induced increases in zif/268 mRNA. Furthermore, tetanic stimulation of CA4 neurons in the contralateral hippocampus prior to the conditioning stimulus, which blocks LTP by a feed-forward inhibitory mechanism, also blocks increases in mRNA levels. These results indicate that like LTP, zif/268 is rapidly induced by synaptic activation of NMDA receptors and may be involved in mediating long-term synaptic plasticity.

71.8

EVIDENCE SUGGESTING THAT AMBIENT GLUTAMATE LEVELS ACTIVATE NMDA RECEPTORS IN HIPPOCAMPAL CA1 NEURONS. S. Hestrin*, P. Sah*, and R.A. Nicoll (SPON: M. Block). Depts. of Physiology and Pharmacology, University of California, San Francisco, CA 94143

The high sensitivity of NMDA receptors to glutamate raises the possibility of activation by ambient levels of extracellular glutamate. To test this possibility experiments were performed in rat hippocampal slices *in vitro*. We found that in CA1 pyramidal neurons under voltage clamp (hp: -35 mV), application of 50 µM dl-APV induced an outward current (250-500 pA). To characterize this current further, tight-seal whole-cell recordings were made from thin hippocampal slices. These recording conditions revealed a standing current noise with the following properties: 1) The variance of the membrane current at -40 mV was much larger than that measured at -80 mV; 2) At -40 mV application of APV reduced the variance to that measured at -80 mV; 3) At -80 mV removal of extracellular magnesium increased the variance, which was APV-sensitive; 4) Power spectra of this membrane noise were Lorentzian and similar to those induced by application of NMDA. These observations suggest that there is a persistent activation of NMDA receptors in hippocampal CA1 neurons.

71.9

MECHANISMS UNDERLYING LTP AT AN EXCITATORY SYNAPSE IN RAT ANTERIOR CINGULATE CORTEX. P. Sah* and R.A. Nicoll. Depts. of Pharmacology and Physiology, University of California, San Francisco, CA 94143.

Although a great deal is now known about LTP in the hippocampus, the existence of similar synaptic plasticity at cortical synapses is not well established. We have studied the monosynaptic synapse between the commissural fibres and layer V pyramidal neurones in rat anterior cingulate cortex. At the resting membrane potential (-90 mV) the EPSP at this synapse was blocked by CNQX indicating that quisqualate/ kainate receptors mediate the EPSP. Depolarization of the postsynaptic cell revealed a slower APV-blockable component. High frequency stimulation of the commissural afferents (100 Hz, 1 sec) resulted in a large potentiation of the initial slope of the EPSP which lasted approximately 60 minutes. A critical stimulus strength was required to elicit potentiation, indicating that LTP at this synapse exhibited cooperativity. The potentiation also was blocked by 50 μM APV indicating that NMDA receptor activation is required for LTP. Loading the cell with the calcium chelator BAPTA also blocked the induction of the LTP. These experiments show that there are many similarities between LTP at this cortical synapse and LTP at excitatory synapses in the CA1 region of the hippocampus. However, one clear difference is the failure to elicit LTP by pairing postsynaptic depolarization with synaptic activation. Possible explanations for this difference will be discussed.

71.10

HORIZONTAL LONG-TERM POTENTIATION OF RESPONSES IN RAT SI CORTEX. S.M. Lee, M.G. Weisskopf*, and F.F. Ebner. Center for Neural Science, Brown University, Providence, RI 02912

Although the role of LTP in neocortex is not as established as in the hippocampus, there is an emerging line of evidence that in neocortex, NMDA receptors strongly influence cells' responsiveness to sensory input. Here we provide direct evidence that a conditioning stimulus (CS) presented in layer VI of a rat neocortical slice results in an APV-sensitive enhancement of responses in layer II/III horizontal to the radial recording site.

Neocortical slices 400 um thick were taken from five adult Long-Evans rats (300-350 g) and placed in an interface chamber superfused with an oxygenated medium containing (in mM) 126.0 NaCl, 3.0 KCl, 1.25 NaH_2PO_4, 2.0 $MgCl_2$, 2.0 $CaCl_2$, 26.0 $NaHCO_3$ and 10.0 dextrose. Field potentials in layer II/III to single shocks (200 us, 100 uA) in layer VI were recorded directly above ("radial") and at various distances away ("off-radial") from a concentric stimulating electrode. This intensity elicited a radial response 75-80% of maximum in layer II/III. The CS was delivered in the presence of low levels of Mg^{2+} (100-500 uM). The degree of potentiation at various sites was measured >1 hr following reinfusion of the normal medium.

The most effective CS for eliciting LTP in the superficial layers was 2 Hz for 45-80 sec. Two types of APV-sensitive long-term enhancements were seen in the superficial layers: i) 50-400% potentiation over baseline responses and ii) induction of novel responses (1000-1500 um "off-radial").

In vivo, this horizontal potentiation may determine the cortical domain of active sensory inputs and could support the reorganization of neocortical sensory maps. (Supported by NIH grant #NS-13031)

71.11

DIFFERENTIAL CONDITIONING AT CELLULAR LEVEL (CAT MOTOR CORTEX) WITHOUT ASSOCIATED POSTSYNAPTIC FIRING ACTIVITY. A. Baranyi, M.B. Szente and C.D. Woody. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA 90024

Mechanisms of long-lasting potentiation (LLP) of excitatory postsynaptic potentials and currents (EPSPs/EPSCs) were studied in intracellular microelectrode and single channel voltage clamp experiments in the motor cortex of conscious cats. Two different EPSPs/EPSCs were elicited in neurons in which the firing activities were blocked by intracellular injection of QX-314. One of the postsynaptic responses was explicitly paired with intracellular current pulses in voltage clamp mode (ISI:0-200 ms, ITI:0.1-0.5 Hz), and the other unpaired response was tested simultaneously in the same target neuron. Input-specific LLP of paired vs. unpaired EPSPs/EPSCs was induced in the absence of firing activity after 20-60 pairings. However, LLP occurred only in neurons where the paired voltage responses regularly attained a membrane potential of -35mV or the command pulses were larger than 30 mV from the holding potential of -65mV. Intracellularly injected aminopyridine, Cs^+ (vs. TEA and apamin), Co^{2+}, Cd^{2+}, EGTA and extracellularly injected dendrotoxin precluded the induction of LLP. The results suggest that input-specific LLP in neocortical neurons requires local postsynaptic depolarizations which provide sufficient Ca^{2+} levels at the postsynaptic zones of paired inputs. (Supported by HD05958.)

71.12

LONG-TERM FACILITATION OF ELECTROTONIC AND CHEMICAL COMPONENTS OF MIXED EXCITATORY SYNAPSES ON THE MAUTHNER CELL. X.-D. Yang* and D.S. Faber. Neurobiology Lab, Dept. Physiology, SUNY Buffalo, Buffalo, NY 14214.

The goldfish Mauthner (M-) cell receives a monosynaptic excitatory input from the VIIIth nerve. Impulses in single fibers produce both electrotonic coupling potentials and glutamatergic EPSPs. The EPSP is transiently facilitated when two or three presynaptic action potentials are evoked at ~500 Hz. We now report that when the nerve is stimulated repeatedly with similar brief trains once every 2 sec for 4 min, both responses exhibit prolonged enhancements.

Intracellular recordings were obtained from the lateral dendrite at the site of synaptic input. The conditioning stimulus was suprathreshold for the M-cell while the test stimulus was subthreshold. Within 10 min after training the coupling potential and EPSP were increased, on average by 23% (range 0-62%, n=6) and 85% (range 31-144%), respectively, while resting membrane potential was unchanged, and antidromic spike height was slightly reduced (5%). Electrotonic and chemical facilitations could be quantitatively dissociated, indicating they were not due to changes in stimulating electrode properties. They persisted throughout the recording period, up to 80 min after training.

Long-term facilitation of the coupling potential might be due to an increased junctional conductance, which would be consistent with the reduction in antidromic spike height. It would be interesting to determine if a common intracellular modification triggers both enhancements. Supported in part by NIH grant #NS 15335.

71.13

N-METHYL-D-ASPARTATE ANTAGONISTS INFUSED INTO THE AMYGDALA BLOCK ACQUISITION OF FEAR-POTENTIATED STARTLE. M.J.D. Miserendino*, K.R. Melia*, C.B. Sananes & M. Davis. (Spon: R.J. Storella). Psychiatry Dept., Yale Univ. Med. Sch., 34 Park St., New Haven, CT. 06508.

The amygdala plays a critical role in a variety of aversive conditioned responses. N-methyl-D-aspartate (NMDA) receptors, which may be involved in synaptic plasticity related to learning and memory, occur densely in the lateral and basolateral amygdaloid nuclei. We therefore examined whether an NMDA receptor-mediated process in the amygdala might underlie aversive conditioning as measured by the fear-potentiated startle paradigm.

Rats were implanted with bilateral cannuli aimed at the basolateral nucleus of the amygdala. Following recovery, animals received two training sessions in which 10 light-footshock (0.6 mA) pairings were presented (ISI=4 min). Immediately prior to each session, rats were infused with the competitive NMDA receptor antagonists DL-2-amino-5-phosphono-valeric acid (AP5; 1.25, 2.5, 5.0, 10.0, or 20.0 μg/0.5 ul), 3-((+-)-2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP; 2.5, 5.0 μg) or vehicle. One week after training, fear-potentiated startle was assessed by comparing the startle response to a brief noise burst presented alone or in the presence of a light.

Both CPP and AP5 blocked fear-potentiated startle in a dose-dependent manner, with a complete blockade at doses of 5.0 μg or higher. AP5 did not produce catalepsy, nor did it alter sensitivity to shock, perception of the light CS (measured with a visual prepulse inhibition paradigm), or baseline startle amplitude. Anatomical specificity of this effect was demonstrated by the fact that bilateral infusion of AP5 (20 ug) into cerebellar nucleus interpositus prior to training had no effect on potentiated startle.

These data suggest that activation of NMDA receptors in the amygdala is necessary for the acquisition of conditioned fear, as measured by fear-potentiated startle.

72.1

SUBSTITUTION OF SERINE FOR CYSTEINE351 PREVENTS PERTUSSIS TOXIN (PTX)-MEDIATED ADP-RIBSOSYLATION OF THE GTP-BINDING PROTEIN G o_α. T.J. Murphy§*, W.F. Simonds¶, T. M. Storman§, A. M. Spiegel¶ and M. R. Brann§. §LMB, NINDS; ¶NIDDK; NIH, Bethesda, MD 20892.

A mutant Go_α gene created by excision of a DNA restricition fragment from a cloned Go_α gene and replacement of the fragment with a cohesive synthetic linker differs from the wildtype gene by three bases and lacks 288 bases of the 3' untranslated region. The mutant gene encodes Go_αser351 which differs from wildtype Go_α by a single amino acid substitution of serine for cysteine at residue 351. The mutant gene was cloned into the mammalian expression vector pCDps and transiently expressed in COS-7 cells. The size of this mutant, as assessed by SDS-PAGE and immunoblots using two anti-peptide antisera specific for Go_α is indistinquishable from an immunoreactive 39 kDa bovine brain membrane protein or wildtype recombinant Go_α also expressed in COS-7 cells. However, [32P]-ADP-ribosylation of membrane proteins using PTX failed to result in labeling of a 39 kDa species in membranes prepared from mutant transfected cells whereas wildtype recombinant Go_α was labeled. Our results demonstrate that the cysteine residue in the carboxyl terminal region of Go_α is required for ADP-ribosylation by PTX. The mutant gene has been stably transfected into A9L cells expressing recombinant m4 muscarinic receptor. We are currently isolating subclones to study second messenger responses to Go_αser351.

ISOLATION OF A DROSOPHILA GENE ENCODING A Go α-LIKE PROTEIN. J. Yoon*, R. D. Shortridge*, B. T. Bloomquist*, S. Schneuwly*, M. H. Perdew*, and W. L. Pak, Dept. Biol. Sci., Purdue Univ., West Lafayette, IN 47907.

We have isolated a D. melanogaster gene encoding a Go α subunit homolog by screening genomic and adult head cDNA libraries using bovine transducin α subunit cDNA as probe at reduced stringency. Sequence analysis of cDNAs showed that this gene encodes two α subunits which differ in 7 amino acids in the N-terminal region and that the deduced amino acid sequences for both proteins are highly homologous to a rat Go α subunit (81% identity). Analysis of genomic DNA revealed that two proteins differ in the 5'-noncoding region and the first coding exon, but share the remaining 6 coding exons, and that the expression of the two proteins seems to be regulated by two different promoters. The gene was mapped to 47A on the second chromosome. Three transcripts were detected: a 3.9 kb transcript found in all stages of development, a 5.4 kb transcript present predominantly in adult heads, and a 3.4 kb transcript present only in adult bodies. In situ hybridizations to adult tissue sections showed that this gene is expressed abundantly in neuronal cell bodies in the brain and thoracic ganglia. This work was supported by grants from NIH (EY00033, EY04767, EY02723).

IMMUNOCYTOCHEMICAL LOCALIZATION OF THE NEURAL-SPECIFIC REGULATORY SUBUNIT OF THE TYPE II cAMP-DEPENDENT PROTEIN KINASE IN RAT BRAINS. N. Ludvig*, C.E. Ribak, S. Glantz* and C.S. Rubin* (spon: R.B. Wuerker). Dept. of Anatomy and Neurobiology, Univ. of Calif., Irvine, CA. 92717 and Dept. of Molecular Pharmacology, Albert Einstein College of Med. Bronx, NY. 10461.

The subcellular localization of the neural-specific regulatory subunit of the type II cAMP-dependent protein kinase (RII-B) was analyzed with electron microscopic immunocytochemical methods in the brains of Sprague-Dawley rats. It was found that: (1) the RII-B immunoreactivity (RII-Bi) was exclusively localized to neurons; glial and endothelial cells did not contain RII-Bi; (2) Some neuronal somata lacked RII-Bi, (3) RII-Bi was concentrated in postsynaptic structures, dendrites and perikarya, and not in axons and axon terminals, (4) RII-Bi was associated with postsynaptic densities opposing both excitatory and inhibitory types of axon terminals.

These data provide morphological support for the electrophysiologically and pharmacologically demonstrated interaction between cAMP-dependent protein kinases and post-synaptic receptors and voltage-gated ion-channels. In fact, the subcellular distribution of RII-B seems to correspond with the subcellular distribution of neurotransmitter-receptors (i.e., $GABA_A$ and mAch) reported by other groups. EXTRACELLULAR 3',5'-CYCLIC NUCLEOTIDE PHOSPHODIESTERASE IN RAT CEREBRAL CORTEX IN DISSOCIATED CELL CULTURE. S. Vasquez* and P.A. Rosenberg (SPON: A. Lorenzo). Dept. of Neurol., Children's Hosp., Harvard Med. Sch., Boston, MA 02115

One possible mode of action of norepinephrine as a neuromodulator in cerebral cortex is via stimulation of cAMP efflux from astrocytes, thereby increasing the concentration of cAMP or metabolites in the extracellular space. One or more of these adenine nucleotides may interact with receptors on neurons. Previous experiments demonstrating cAMP efflux from cerebral cortex in culture suggested that extracellular cAMP was not stable but was degraded, suggesting the existence of an extracellular phosphodiesterase. In order to pursue this observation, the fate of extracellular cAMP was studied. Mixed cultures of neurons and glia were incubated with ^{3}H-cAMP, and media was sampled at selected times. Cyclic AMP, AMP, and adenosine were separated by thin layer chromatography. Extracellular ^{3}H-cAMP progressively decayed from its original concentration, and the decay of cAMP was accompanied by the appearance of material that cochromatographed with adenosine and with AMP. The phosphodiesterase inhibitors isobutylmethylxanthine (IBMX) and RO 20-1724 (an imidazolidinone), at 300 μM, blocked the phosphodiesterase activity, demonstrated by the reduction in the formation of AMP. Supported by the Grass Foundation and NS00993.

EFFECTS OF A SELECTIVE BLOCKER OF A LOW K_M cAMP-PHOSPHODIESTERASE ON RAT NEOCORTEX SLICES.
B. Sutor*, G. Meier*, G. ten Bruggencate
Institute of Physiology, University of Munich, 8000 München 2, F.R.G.

The intracellular action of the second messenger cAMP has to be terminated by an effectively regulated inactiviation mechanism. Cyclic AMP is degraded by cAMP-phosphodiesterases (cAMP-PDE). Thus, the regulation of the activity of these enzymes may be of crucial importance for neuronal excitability. The availability of selective inhibitors for cAMP-PDE isozymes offers the possibility to study the influence of different cAMP-PDEs on the excitability of CNS neurons.

In biochemical experiments, the inhibitory efficacy of the selective blocker of a low K_M, Ca^{2+}/calmodulin-independent PDE denbufylline (DBF) on the total cAMP-PDE activity in a crude homogenate from rat frontal cortex slices was compared to that of the non-selective inhibitor IBMX. At concentrations of 100 μM, DBF reduced the PDE activity by 20-25 %, whereas IBMX decreased the enzyme activity by 65-70 %.

In electrophysiological experiments, intracellular recordings were performed from superficial neurons of rat frontal cortex slices. At concentrations of 30-100 nM, DBF led to a pronounced increase in synaptic and direct evoked excitability. Upon an increase in concentration up to 10 μM, a marked prolongation of IPSPs was observed. These changes occurred without significant changes in membrane potential or input resistance.

These experiments demonstrate that the selective inhibition of a cAMP-PDE isoenzyme leads to marked changes in the excitability of rat neocortical neurons, although this isoenzyme represents only a fraction of the total PDE activity in the frontal cortex.

72.6

REGULATION OF TYPE II (cGMP-ACTIVATABLE) PHOSPHODIESTERASE IN PC12 CELLS. M.E. Whalin*, J.G. Scammell*, W.J. Thompson*, and S.J. Strada. Dept. of Pharmacology, Univ. of South Alabama College of Medicine, Mobile, AL 36688.

Characterization of phosphodiesterase (PDE) activity in cell-free preparations of PC12 cells showed that the major cAMP hydrolytic activity was Type II (cGMP-activatable) PDE. This activity was inhibited by the isoquinoline compounds papaverine and HL-725 (trequinsin). cAMP accumulation induced by adenosine (ADO) in intact cells showed a peak response (5-8 fold)at 5 min and removal of ADO by the addition of adenosine deaminase resulted in the decay of cAMP to basal levels in 3 min. Papaverine or HL-725 potentiated the ADO response, whereas preincubation of PC12 cells with nitroprusside (NP) or atrial natriuretic factor (ANF), agents which increase cGMP, attenuated the ADO induced cAMP accumulation and increased the rate of cAMP decay. An attenuation of the ADO response by NP or ANF was not observed in the presence of papaverine or HL-725. We conclude from these studies that, in PC12 cells, agents that increase intracellular cGMP can regulate cAMP metabolism by the activation of Type II PDE. INHIBITION OF ADENYLATE CYCLASE IN PERMEABLE NCB-20 CELLS IS COUPLED TO THE STIMULATION OF THAT ENZYME. J.H. Gordon and M.M. Rasenick. Dept of Pharmacol, Loyola Univ Med Sch; Res Svce, VA Hosp, Hines, IL 60141 and Dept Physiol and Biophys, Univ IL College Med, Chicago, IL 60680.

The relationships between receptors, G proteins and the catalytic unit of adenylate cyclase (AC) remain intact in cells made permeable by saponin (FEBS Lett. 207:296,1986), this may not be the case in isolated membranes. In saponin treated NCB-20 cells, GTP S elicited a dose-dependent stimulation (stim) of AC. In forskolin activated cells, GTP S provoked a dose-dependent inhibition (inhib) of the AC. At 0.1 uM GTP S produced a minimal stim of AC; the addition of dopamine (DA) produced a dose-dependent stim of AC. At 1.0 uM GTP S produced a modest stim of AC, which was not modifed by the addition of DA. GTP S concentrations >10 uM produced a substantial stim of AC which was inhibited by DA. In contrast, isoproterenol (ISO) produced a dose dependent stim of AC at all concentrations of GTP S. The stim of AC by ISO was also inhibited in a dose-dependent manner by DA. However, ISO produced a dose-dependent inhib of AC when the reaction mixture contained 1.0 uM GTP S and 100 uM DA. The results suggest the existence of a complex series of interactions between the receptors, the various G proteins, and the catalytic unit of AC. Such interactions may involve nucleotide binding and transfer between the various G alpha subunits. TRANSDUCTION MECHANISMS UNDERLYING THE COUPLING BETWEEN ALPHA1 AND 5-HT1a-LIKE RECEPTORS ON CULTURED PACEMAKER SPINAL CORD NEURONS. P.Legendre*, M.Dubar* and J.D.Vincent (SPON:J. Clements).INSERM U.176,33077 Bordeaux cedex, France.

Intracellular recordings were made from cultured mammalian spinal cord pacemaker neurones and the action of noradrenaline (NA)and serotonin (5-HT) were studied. These compounds acted on alphal and 5-HT1a-like receptors to reduced the same K^+ conductance and this effect was mimicked by IBMX, forskolin and 8-bromo-cAMP applications. Such responses were also mimicked by the application of mellitin, an activator of the phopholipase A2, and by the application of arachidonic acid (AA) and Prostaglandin E2 (PGE2). NA, 5-HT and PGE2 induced responses were inhibited by the protein kinase A and G inhibitor H8 while the guanylate cyclase inhibitor methylen blue had no effect. Only the NA induced depolarization was inhibited by the application of AA metabolism inhibitors such as ETYA and indomethacin. Furthermore, ETYA prevented the AA-induced response but did not alter the PGE2 induced depolarization. These results suggest that 5-HT1a-like and alphal receptors on cultured pacemaker spinal cord neurons, are coupled to the same K^+ conductance through different second messenger pathways. NA evoked responses involves PGE2 production which induces adenylate cyclase activity, while 5-HT1a-like receptors appear to be directly coupled to the adenylate cyclase.

72.9

ROLE OF SECOND MESSENGERS IN ACETYLCHOLINE (ACh)-AND VASOACTIVE INTESTINAL POLYPEPTIDE (VIP)-EVOKED SECRETION OF CATECHOLAMINES (CA). T. Wakade, R.K. Malhotra and Arun R. Wakade (Spon. M.A. Marrazzi) Dept. of Pharm., Wayne State Univ., Detroit, MI 48201.

Perfused rat adrenal gland was used to determine relationship between second messengers and CA secretion evoked by ACh, VIP or stimulation of splanchnic nerves. VIP (10 uM) increased cAMP, ^{3}H-inositol trisphosphate ($^3IP_3$) and protein kinase C (PKC) activity. ACh (30 uM) increased ^{45}Ca uptake, ^{3}H-IP_3 and PKC activity. Since ACh activates nicotinic and muscarinic receptors to evoke CA secretion, effects of nicotine and muscarine were investigated. Muscarine (100 uM) increased ^{3}H-IP_3 and PKC activity. Nicotine (17.5 uM) increased only ^{45}Ca uptake. Stimulation of splanchnic nerves (10 Hz for 10 min), which causes release of ACh and VIP, increased ^{45}Ca uptake, cAMP, ^{3}H-IP_3 and PKC activity. None of the procedures affected cGMP content. We conclude that stimulation of adrenal medulla by its neuronal supply results in activation of 4 second messengers that are coupled to 3 types of receptors of chromaffin cells. These messengers interact with each other to modulate Ca concentration and thereby CA secretion.

72.10

REGULATION OF NICOTINE EVOKED DOPAMINE RELEASE FROM PC12 CELLS. N.D. Courtney, A.C. Howlett and T.C. Westfall. Dept. of Pharmacology St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Nicotine (NIC) stimulates dopamine (DA) release from PC12 cells presumably by activating nicotinic acetylcholine receptors. It is also known that the NIC induced depolarization results in the opening of L type voltage sensitive Ca^{2+} channels with the subsequent increase in Ca^{2+} influx. Not much, however, is known about the events between Ca^{2+} influx and the ultimate DA release. The present series of experiments were designed to determine the nature of the intracellular signals following activation of nicotinic receptors and Ca^{2+} influx. For release experiments, cells were incubated in Gey's balanced salt solution with or without drugs for 2 min. Released and cellular DA was measured in the incubation buffer and cell lysate respectively, by HPLC-EC. NIC significantly increased DA release above basal release (BSL 5.11% ± 1.6, 100 µ M NIC 11.7% ± 3.9). In the absence of extracellular Ca^{2+}, the NIC evoked DA release was not seen. Calmidazolium - a calmodulin antagonist, blocked NIC evoked DA release (NIC 12.9% ± 4.9, NIC + CDZ 4.5% ± 1.6). 2',3' Dideoxyadenosine, which blocks adenylate cyclase, completely abolished the NIC evoked DA release (NIC 12.9% ± 4.9, NIC + DDA 5.4% ± 0.3). A cAMP analog and agents which elevate intracellular cAMP also enhanced nicotine evoked dopamine release. These results suggest an important role for cAMP and calmodulin in the DA release. (Supported by DA03690, DA02668 and NS07254).

CHRONIC ANTIDEPRESSANT DRUGS MODIFY cAMP-DEPENDENT PHOSPHORYLATION SYSTEM IN RAT CEREBRAL CORTEX. J. Perez*; D. Tinelli*, E. Bianchi*, N. Brunello and G. Racagni, Center of Neuropharmacology, University of Milan Italy.

We have shown that chronic treatment with desmethylimipramine (DMI), a tricyclic antidepressant drug, induces a specific change in the endogenous phosphorylation of a microtubule associated protein, immunologically recognized as MAP-2. This neuronal phosphoprotein is highly enriched in the dendritic portion of neurons and represents one of the major substrate for the cAMP-dependent PK type II. Since several studies have demonstrated that cAMP-PK can be associated to microtubule fraction suggesting that endogenous substrate proteins and PK have a similar subcellular distribution, we have analysed both the endogenous phosphorylation of MAP-2 in the cerebrocortical crude microtubule fraction and the photoaffinity labelling of cAMP-PK after chronic DMI treatment. An increase in the ^{32}P incorporation was found in the MAP-2 of crude microtubule fraction after DMI treatment without changes in its concentration. Moreover, both in the soluble and in the microtubule fraction, DMI treatment specifically affected the photoaffinity labelling with 8-N_3-^{32}P-cAMP of a protein band of 52 KDa which represents the regulatory subunit of PKII. Chronic administration with other antidepressant drugs such as fluoxetine, a specific serotonin uptake blocker, and (+)oxaprotiline induces a similar pattern of changes in the photoactivated incorporation of cAMP to crude microtubule fraction, thus indicating that this modification may be related to those adaptive changes elicited by prolonged antidepressant treatment at synaptic level.

73.1

ISOLATION OF A PARTIAL RAT BRAIN cDNA CLONE RELATED TO THE β_1 ADRENERGIC RECEPTOR. M.W. Hamblin, K. Ariani, G.L. Tan, J. Eberwine, and R.D. Ciarancllo. Laboratory of Developmental Neurochemistry, Stanford University School of Medicine, Stanford, CA 94305.

We have been using probes based on known sequences of G-protein linked receptors to isolate new members of this gene family. We screened a rat hippocampus pCD cDNA library using a mixture of different ^{32}P end-labeled oligonucleotide probes based on the presumed membrane spanning regions of the human $5HT_{1A}$ receptor (Kobilka et al., Nature 329:75, 1987) A 2.5kb clone, AE5A, strongly hybridized at low stringency to probes from presumed membrane spanning regions VI and VII but only weakly or not at all to probes from other membrane spanning regions. Northern hybridization analysis of rat brain total RNA with AE5A showed labeling of a single message species 3kb in size. Partial sequencing shows greater than 90% sequence identity with the previously identified human β_1 adrenergic receptor sequence (Frielle et al., PNAS 84:7920, 1987) over much of the length of the clone. This clone may thus represent the rat β_1 adrenergic receptor. Sequence in the region of the presumed cytoplasmic loop III, however, is less well conserved. Clone AE5A is truncated near the sequence specifying the presumed membrane spanning region II. Although it is not full length, AE5A may be useful as a probe in the study of regulation of rat β_1 adrenergic receptors.

73.2

EXPRESSION OF A D_2 DOPAMINE RECEPTOR cDNA. O. Civelli, P. Albert*, K. Neve, H.H.M. Van Tol*, D. Grandy, J.A. Salon, C. Machida and J.R. Bunzow*, Vollum Inst., OHSU, Portland, OR 97201.

The dopamine receptor belongs to the family of the G protein-coupled receptors. These receptors are expected to share a significant degree of sequence similarity. We have used the hamster β_2-adrenergic receptor gene as probe under low-stringency hybridization conditions to isolate related genes. We have thus been able to isolate a cDNA which directs the expression of a protein with the characteristics of a rat D_2 dopamine receptor (Bunzow, J. et al., Nature 336:783-787). We have since shown that this receptor is functional. The D_2 dopamine receptor is known to couple to G proteins to inhibit cAMP production and hormone release. We show that the D_2 receptor cDNA when transfected into the rat somatomammotrophic cell, GH_4 C_1, directs the expression of a D_2 receptor which couples to a pertussis toxin-sensitive G protein. We further show that this interaction results in an inhibition of cAMP accumulation, adenylate cyclase and prolactin secretion, thus demonstrating that the cDNA codes for a functional receptor. In addition, site-directed mutagenesis is being used to examine the D_2 receptor sites which are important for ligand-binding, G protein-coupling and receptor desensitization.

CLONING OF A NEW G-PROTEIN-COUPLED RECEPTOR HOMOLOGOUS TO THE ALPHA-2 ADRENERGIC RECEPTOR R.L. WEINSHANK*, H.M. LICHTBLAU* AND P.R. HARTIG Neurogenetic Corporation, 215 College Road, Paramus, NJ 07652

We have used the genomic clone G21, which encodes the serotonin 5-HT_{1A} receptor, to screen a human spleen genomic library. Restriction map analysis of the clonal isolates indicates that most fall within three related families. Two of these families have been identified as previously characterized clones, but the DNA sequence of one clone, designated 5A, is unique. This human genomic clone contains an uninterrupted long open reading frame encoding a protein with seven putative transmembrane segments. All of the expected structural features of a G-protein coupled receptor were present. A comparison of the amino-acid sequence of this putative G-protein coupled receptor with other members of this family showed greatest homology to the human platelet alpha-2 and human kidney alpha-2 adrenergic receptors. Data will be presented describing the pharmacological binding properties of clone 5A transfected into COS cells along with data on the regional distribution in brain of mRNA corresponding to this clone.

73.4

α_2-ADRENERGIC RECEPTOR (A2AR) STIMULATION OF PHOSPHOLIPASE A_2 (PLA2) AND OF ADENYLATE CYCLASE IN TRANSFECTED CHO CELLS ARE MEDIATED BY DIFFERENT MECHANISMS. D.B. Bylund, S.B. Jones*, S.P. Halenda*, C.M. Fraser* and J.C. Venter*. Dept. Pharmacology, Univ. Missouri, Columbia, MO 65212, and NINDS, NIH, Bethesda, MD 20892.

In CHO cells transfected with the A2AR gene (Fraser et al, in press), the effect of epinephrine (EPI) on forskolin-stimulated cAMP production is biphasic. At low concentrations, EPI inhibits cAMP production, whereas at high concentrations, it is stimulatory. EPI also stimulates arachidonic acid mobilization (AAM) presumably via PLA2. We used 3 approaches to test the hypothesis that the potentiation of forskolin-stimulated cAMP production was mediated by PLA2 1. A Ca^{++} ionophore increased AAM, whereas EGTA blocked both basal and EPI-mediated AAM. Neither affected cAMP. 2. Pretreatment with pertussis toxin blocked AAM by EPI (but not by Ca^{++} ionophore), but increased cAMP. 3. Quinacrine blocked the EPI-mediated AAM, but did not alter cAMP. Thus, it appears that in these cells, the A2AR is coupled through G_i to the inhibition of adenylate cyclase and to the stimulation of PLA2, but increases cAMP production by a different mechanism. Supported by NIH GM37664 and HL38406.

IN VIVO STIMULATION OF D1 DOPAMINE RECEPTORS INCREASES THE PHOSPHORYLATION OF PROTEINS IN THE STRIATUM. I. Levari*, M.J. Zigmond and R.M. Lewis. Univ. of Pittsburgh, Pittsburgh, PA 15261.

DARPP-32 is a neuron-specific phosphoprotein phosphatase inhibitor which co-localizes with D1 receptors in the mammalian CNS. Phosphorylation of DARPP-32 increases when slices of rat striatum are perfused with dopamine or 8-bromo-cAMP. We tested whether this occurred *in vivo*, if it was specific for D1 receptors, and whether the phosphorylation of other proteins was affected. Rats were injected with L-dopa, or the D1 specific agonist SKF 38393, and the striatum was dissected out. The ratio of phosphorylated to total protein for each distinct band on SDS/acrylamide gels was determined by back-phosphorylation. The phosphorylation of several proteins was stimulated by L-dopa in a dose-dependent manner. The lowest concentration of SKF 38393 tested so far led to complete phosphorylation of some of the proteins. Other phosphoproteins appeared to be unaffected by L-dopa or SKF 38393. One of the bands migrated at a position consistent with the molecular weight of DARPP-32, but none of the bands have been positively identified at this time. These data are consistent with the hypothesis that dopamine agonists stimulate the adenylate cyclase coupled to D1 receptors. The increase in cAMP leads to an increase in the phosphorylation of specific substrates by a cAMP-dependent protein kinase.

73.6

POSTNATAL DEVELOPMENT OF DOPAMINE D-1 RECEPTORS MAY REQUIRE D-1 RECEPTOR STIMULATION. H.A. Gelbard*, M.H. Teicher, A.L. Gallitano*, J. Zorc*, G. Faedda* and R.J. Baldessarini. Laboratory of Developmental Psychopharmacology & Mailman Research Center, McLean Hospital & Harvard Medical School, Belmont, MA 02178.

In man (Seeman et al., *Synapse*, 1:339-404, 1987) as well as rat (Gelbard et al., *Dev. Brain Res.*, in press), there is a marked increase in the density of dopamine (DA) D-1 receptors in forebrain during early postnatal life. The density of striatal D-1 receptors (assayed by binding of the D-1 antagonist ^3H-SCH-23390) increased, relative to levels at postnatal day 8, by 1.5-fold at d10, 3.9-fold at d15, and peaked to 5.7-fold by d40. Early depletion of forebrain DA with intracisternal 6-OH-DA (given after desipramine to protect noradrenergic neurons) markedly attenuated this age-dependent increase in D-1 receptor density. Rats treated with 6-OH-DA on d3 had a 50% *reduction* of striatal D-1 receptor site density (Bmax) at d21. In contrast, more mature rats DA-depleted at d35 and also sacrificed 18d later, showed no change in D-1 receptor Bmax. These results accord with observations by Kostrzewa and Saleh (*Dev. Brain Res.*, 45:95-101, 1989) of a 78% decrease in the development of striatal D-1 receptor site Bmax after daily postnatal treatment with SCH-23390 to d32. We found, further, that daily administration of the D-1 agonist SKF-38393 (3 mg/kg, i.p., at days 6-18) after 6-OH-DA treatment on postnatal d3 restored striatal D-1 sites to 120% of control Bmax at 21d. Furthermore, similar daily treatment with SKF-38393 in unlesioned neonatal rats increased striatal D-1 Bmax to 140% of control at 21d. These findings suggest a requirement for DA agonism at a critical time (evidently before d35) in the neonatal brain to induce development of D-1 receptors. [Supported by USPHS [NIMH] grants MH-34006, MH-43743, MH-47370, and awards from the Bruce J. Anderson, Charles Dana, and Milton Foundations, Marion Ireland Benton Trust, and an award from the Regione Autonoma della Sardegna.]

DOPAMINE D_2 and D_1 RECEPTOR CHANGES IN MPTP PARKINSONIAN PRIMATES. G.M.Alexander, D.L.Brainard* S.Gordon*, J.Grothusen* and R.J.Schwartzman. Department of Neurology, Jefferson Medical College, Philadelphia, PA 19107.

Twenty one monkeys were used in this study. Ten animals were made parkinsonian with MPTP, eleven were used as controls. The parkinsonian animals demonstrated 90-97% dopamine depletion in the striatum. Three of the MPTP monkeys were treated with PHNO, a dopamine D_2 agonist. The brains were frozen and cut into 20 micron sections. For the D_2 assay total binding was determined using various concentrations of ^{3}H-spiperone in buffer containing 300 nm mianserine. For the D_1 assay, total binding was determined using various concentrations of ^{3}H-SCH-23390. Tissue isotope concentration was determined from the autoradiographs. Ligand binding was evaluated in the caudate and putamen nuclei at the level of the anterior commissure. The untreated parkinsonian monkeys demonstrated an increase in the number of D_2 sites as compared to controls. This increase was greatest at the dorso-lateral putamen. The PHNO treated animals demonstrated a 50% decrease in D_2 sites in both caudate and putamen. There was no change in the number of D_1 binding sites in both the untreated and the PHNO treated monkeys.

73.8

IS DEXMEDETOMIDINE'S ANESTHETIC ACTION DEPENDENT ON ISORECEPTOR SELECTIVITY? J.W.Regan, K.Daniel, and M.Maze (SPON R.Jaffe). Howard Hughes Medical Institute Duke University NC 27710; Dept Anesthesia Stanford University, Stanford CA 94305 and PAVAMC, Palo Alto CA 94304

D-medetomidine (D), an alpha2(a2) adrenergic agonist, produces anesthesia while its L stereoisomer, which also binds with high affinity, is not an anesthetic. We wondered if D's anesthetic properties are due to isoreceptor (either a2C10 or a2C4) selectivity. Binding parameters of the D and L isomers were determined from competition curve analysis using [^{3}H]rauwolscine and membranes prepared from COS 7 cells transiently expressing a2C4 or a2C10. D binds with 7-fold greater agonist affinity to the a2C4(K_i=2nM; Hill coefficient=0.69) compared to a2C10(14nM; 0.92). L binds with similar, albeit weaker affinity to both a2C4 (48 nM; 0.99) and a2C10 (59 nM; 0.92). Isomer function was assessed by their inhibition of forskolin-stimulated cAMP formation in hamster fibroblast cell lines (P120) stably expressing the a2 isoreceptors. Functionally, D is even more effective than epinephrine (epi) at inhibiting forskolin-stimulated cAMP accumulation in a2C4 (110%) while displaying weaker agonist activity at a2C10 (65% of epi). L is either ineffective (<5% of epi in a2C10) or exhibits only partial activity (25% in a2C4). In summary D more selectively binds and activates the a2C4 while L appears to have little isoreceptor selectivity and thus no anesthetic activity. These results are consistent with a mediating role for a2C4 in the anesthetic action of a2 agonists.

SPECT IMAGING OF DOPAMINE D2 RECEPTORS IN NON-HUMAN PRIMATE BRAIN. R.B. Innis, G.R. Heninger, S. Zoghbi, M. Al-Tikriti, S.W. Woods, E. Johnson, D.S. Charney, K. Koster, I.G. Zubal, E.O. Smith, H. F. Kung*, A. Alavi*, P.B. Hoffer. Depts. Psychiatry and Diagnostic Radiology, Yale University School of Medicine, New Haven CT 06510 and *Division of Nuclear Medicine, University of Pennsylvania.

Single Photon Emission Computed Tomography (SPECT) has the potential for non-invasive measuremnent of in vivo biochemical events in human brain. However,many questions exist about the appropriate methods for SPECT data analysis, in part due to attenuation of the gamma radiation emission and the applicability of kinetic versus equilibrium models. Thus, SPECT imaging of animals (non-human primates) with postmortem examination of the brain will be critical to carefully control experimental interventions and to test the accuracy of SPECT imaging in comparison to direct biochemical measuremnts in brain tissue.

We have studied the distribution of radiolabel uptake into brain following i.v. injection of the specific dopamine D2 receptor probe 123I-labeled IBZM (iodobenzamide). Two baboons (10 kg female Papio anubis) were injected with 1.8 and 12 mCi 123I-IBZM and scanned for approximately 2.5 hr in a Strichman 810X Brain Imager. The distribution of label was monitored in mutiple 2-3 min scans throughout the brain with a focus on slices in striatum (caudate, putamen, and globus pallidus). Radiolabel uptake was concentrated in the two striata (with a clear midline separation) within 30 min and was relatively stable for the remaining 120 min. Uptake in extra-striatal tissue washed out within 90 min and maintained that level. At 2 hr. the ratio of striatal to extra striatal label was 2-2.5 to 1.

The pharmacological specificty of radiolabel uptake was tested by injecting one animal with haloperidol (0.02 mg/kg i.v.). The striatal label was rapidly displaced by greater than 65% within 35 min.

These promising studies demonstrate the feasibility of kinetic SPECT imaging with the dopamine D2 receptor probe 123I-labeled IBZM. Further studies, including correlatiuons with MRI scans and direct postmortem measurements, are in progress.

73.10

BEHAVIORAL AND NEUROCHEMICAL EFFECTS OF INTRASTRIATAL 6-HYDROXYDOPAMINE (6OHDA) INJECTIONS DURING DEVELOPMENT IN THE RAT. J. Franks*, B.S. Neal and J.N. Joyce (SPON: D. Schambron). Departments of Pharmacology and Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Central administration of 6OHDA during early postnatal development results in different behavioral responses to dopaminergic drugs than do injections given adult rats. The mechanisms underlying these behavioral differences are currently unknown. Using the method of Gerfen and coworkers (J. Neurosci. 7:3935, 1987), we gave intrastriatal 6OHDA injections to rat pups on postnatal Day 1. Experiments with these rats during adulthood revealed a potentiation of dopamine (DA) D1 agonist-mediated behaviors, including increased abnormal perioral movements after administration of the D1 agonist SKF 38393, and self-biting behavior after SKF 38393 and the nonselective DA agonists L-DOPA and apomorphine. Animals receiving lesions as neonates also exhibited a decreased sensitivity to D1 antagonist (SCH23390)-induced catalepsy. However, there were no differences in the cataleptic responses to the D2 antagonist haloperidol. Quantitative autoradiography on sections of brain tissue from rats given unilateral 6OHDA or bilateral 6OHDA injections showed a significant decrease in dopamine uptake sites (^{3}H-mazindol) and in the number of μ-opiate (^{3}H-naloxone) receptor patches in the caudate-putamen. DA D1 (^{3}H-SCH23390) and D2 (^{3}H-spiroperidol) receptor density appeared unchanged. Further analyses of the behavioral and neurochemical changes in these neonatally 6OHDA- treated rats are underway.

This research was supported by USPHS grants MH 43852 and GM 34781.

ONTOGENY OF THE D-1 AND D-2 SUBTYPES OF DOPAMINE RECEPTOR IN RAT BASAL GANGLIA: A QUANTITATIVE AUTORADIOGRAPHIC STUDY. P.A.Rao, P.B. Molinoff and J.N. Joyce, Departments of Pharmacology and Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

We conducted a quantitative autoradiographic study of the density and distribution of D-1 and D-2 dopamine receptors in rat basal ganglia using the iodinated ligands [125I]-SCH 23982 and [125I]-IBZM, respectively, in an attempt to discern: 1.) whether their pattern of development is dependent or independent of each other; and 2.) what their relationship is to the pattern of development for cellular components of the striatum--viz., presynaptic dopamine terminals as indicated by HPLC analysis for dopamine concentration in homogenates and by [3H]-mazindol binding in sections and presynaptic choline terminals as indicated by [3H]-hemicholinium-3 binding in sections. Results indicate that both dopamine concentration and [3H]-mazindol binding in whole striatum increase linearly with age (r=.95). D-1 receptors were found at earliest ages studied (P1-P5), with a patchy distribution consistent with previous work (Murrin, L.C. et al., Brain Res., 480, 1989); by P10 this binding was homogeneously distributed. This patterning was similar to that of [3H]-mazindol binding at the same ages. Both D-2 receptors and [3H]-hemicholinium-3 binding, first evident in appreciable levels at day P5, developed in a lateral-to-medial gradient. D-1 receptors were found in substantia nigra from age P1 through adulthood, increasing 9-fold in density over this period; Bmax for pars reticulata was consistently greater than that for pars compacta. D-2 receptors were not found at appreciable levels in substantia nigra until age P7; from that time on Bmax for pars compacta was greater than that for pars reticulata. These findings are consistent with the hypothesis that D-1 receptors, being noted primarily in patches at the earliest ages studied, are located on the processes of the medium spiny neuron, which is first seen developing in these patches. Also, the synchrony of D-2 receptors and presynaptic choline uptake sites suggests that a large percentage of D-2 receptors may be associated with neurons in the matrix or on the presynaptic processes of the large cholinergic interneuron.

RESPONSE OF STRIATAL DOPAMINERGIC RECEPTORS TO INTROCEREBROVENTRICULAR 6-HYDROXYDOPAMINE

J. N. Joyce and S.B. Caine*, Departments of Pharmacology and Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA.

Loss of dopamine (DA) terminals following intranigral injections of 6-hydroxdopaminen (6-OHDA) results in up-regulation of the DA D2 receptor subtype, but decreases in the density of D1 receptor density. In contrast, chronic reserpine injection produces an up-regulation of both receptor subtypes. In order to determine if a critical degree of DA loss is required to see independent regulation of the receptor subtypes, different doses of 6-OHDA or vehicle (VEH) were administered introcerebroventricularly (ICV) to rats. Two weeks later the brains were removed and processed for quantitative autoradiography or for HPLC analysis of DA and NE levels. The lowest dose of 6-OHDA (150 ug/ventricle) produced a 56% reduction in DA concentration, higher doses (250 and 300 ug) produced an 85% and 92% reduction in DA levels in the striatum. Similar reductions in the density of [^{3}H]mazindol labeling of DA uptake sites were observed in animals from the same groups, but the loss was heterogeneous. No 6-OHDA treated animals showed an increase in D1 receptor density ([^{3}H]SCH 23390), the lower doses of 6-OHDA produced consistent declines (15%) in D1 receptor density. The ICV injection of 6-OHDA resulted in an increase in the density of DA D2 receptors ([^{3}H]spiroperidol) at the higher doses but a reduction in density at the lowest dose. These data suggest that ICV and intranigral injections of 6-OHDA that remove DA terminals produce a loss of D1 receptors that is not mimiced by removal of DA or D1 receptor blockade

BEHAVIORAL EFFECTS OF DOPAMINE D_1 AND D_2 AGONISTS ALONE AND IN COMBINATION WITH THE NOVEL D_1 ANTAGONIST SCH39166.
J. Bergman, S. Johnson*, B.K. Madras, and R.D. Spealman*. Harvard Medical School; N.E. Reg. Primate Res. Ctr., Southborough, MA 01772.

Cocaine and selected dopamine agonists were studied alone and in combination with the D_1 antagonist SCH39166 in squirrel monkeys responding under a fixed-interval (FI) schedule of stimulus-shock termination. Intermediate doses of cocaine (0.1-1.0 mg/kg, i.m.), the selective D_2 agonist quinpirole (0.03-0.3 mg/kg, i.m.), and the nonselective D_1/D_2 agonist (-)-apomorphine (0.03-0.3 mg/kg, i.m.) increased FI responding, whereas higher doses increased responding less or decreased it. In contrast, the D_1 agonists R-SKF38393 (0.3-3.0 mg/kg, i.m.) and SKF81297 (0.3-3.0 mg/kg, i.m.) only decreased responding in a dose-related manner. Pretreatment with SCH39166 (0.03 mg/kg, i.m.) antagonized the rate-increasing effects of cocaine in a surmountable fashion. SCH39166 also attenuated the rate-increasing effects of quinpirole, but did not shift the dose-effect curve rightward. Unexpectedly the effects of R-SKF38393 generally were unchanged by SCH39166, suggesting that mechanisms other than or in addition to those associated with the actions of dopamine may be involved in the behavioral effects of the dopamine D_1 agonist.

CONTROL OF POSTURE AND MOVEMENT III

74.1

CHRONIC EMG IMPLANTS IN MONKEYS USED TO STUDY THE RELATIONS BETWEEN RED NUCLEUS DISCHARGE AND LIMB MUSCLE ACTIVITY DURING A VARIETY OF TASKS
L.E. Miller, G.D. Harris *, and J.C. Houk Departments of Physiology and Surgery, Northwestern University Medical School, 303 East Chicago Ave., Chicago, IL

The red nucleus (RNm) is thought by many to be a source of motor commands directing movements of the distal limbs. As a means of understanding the nature of these putative control signals, we have been studying the spatial and temporal relationships between firing rate of single RNm units and electromyographic (EMG) signals from a large group of forelimb muscles in the alert monkey. We are now able to make long term recordings from the intrinsic hand muscles, as well as those of the shoulder, arm, and forearm.

Prior to surgery, we fabricate and sterilize an assembly of 16 EMG electrodes leading to a miniature connector mounted in surgical dacron mesh. The dacron lies above the muscle and is sutured to the skin in an incision just off the midline of the animal's back. Skin and subcutaneous tissue (but virtually no muscle) readily grows into the dacron, greatly enhancing wound healing and resistance to infection. This technique, and the use of time series analysis algorithms, has allowed us to make objective comparisons of these relations during a number of different behaviors.

Our results suggest that significant differences may exist in the timing between RNm and EMG during execution of a visually guided tracking task, and reaching and grasping tasks. RNm unit activity led EMG modulation during the visually guided tracking for the great majority of well related unit/EMG pairs. By contrast, during the reaching tasks, approximately as many units followed well related EMG activity as led it. The longer lags observed during tracking could occur if neurons in the descending pathways were further from threshold during the tracking task. Alternatively, task dependent differences in the sequence of activation of well correlated RNm units or muscles could be important. Although unlikely, the timing difference might underlie different roles of the RNm in these two types of tasks. We are currently investigating these and other hypotheses, which we expect to lead to a better understanding of the role of the RNm in many types of limb movements.

74.2

FOUR INDEPENDENT SACCADE GENERATORS CONTROL VERTICAL AND HORIZONTAL COMPONENTS OF ORIENTING HEAD MOVEMENT IN OWLS.
T. Masino and E.I. Knudsen. Dept. Neurobiology, Stanford Univ., Stanford CA. 94305

Barn owls make saccadic head turns in response both to natural stimuli and to electrical stimulation of the optic tectum. In the oculomotor system, the optic tectum issues a place-coded command for an eye saccade to four component generators, each coding for movement in one direction: upward, downward, leftward or rightward. Robinson (Vision Res. 12:1795, 1972) demonstrated the independence of these generators by electrically stimulating in rapid succession two tectal sites eliciting two differently directed eye movements. When a particular component of the first movement was shared with the second movement, the shared component disappeared from the second movement. Since the directions that decremented coincided with pull-directions of the extraocular muscles, it seemed reasonable that the underlying generators conformed to the orthogonal arrangement of the eye muscles.

We sought to determine if distinct component generators also exist in a complex movement system and, therefore, actually represent an intermediate spatial code for motor control. We assayed head turns in the barn owl, which involve multiple articulations and geometrically complex musculature. Electrical microstimulation was applied to different sites in the tectum at various intervals, and head movements were measured with a search coil. Results show an effect similar to that in the oculomotor system. For example, while an up-left movement had no effect on a subsequent up-right movement at long interstimulus intervals (>500 msecs), at short intervals (80-100 msecs), the second movement was purely rightward. Examination of many combinations of movement directions yielded four discrete directions that could be made refractory indicating four independent component generators, one each for upward, downward, leftward, and rightward directions. Component decrement occured even when stimulation sites were in opposite tectal lobes, suggesting that the circuits that were made refractory are post-tectal. Thus, even in the control of a complex motor system, between the place-coded representation of motor space in the optic tectum and the motorneuron code for muscle tension, there exists four component generators coding for orthogonal directions of movement.

74.3

HEAD STABILITY DURING NATURAL POSTURAL AND LOCOMOTOR ACTIVITIES.
J. Goldberg and J. Chimenti*. Clayton Laboratory, Otorhinolaryngology Dept., Baylor College of Medicine, Houston, TX 70030.

Spontaneous head movements about the pitch axis were measured during sitting, standing, walking and other activities in 11 normal subjects. Angular head velocity was recorded by a lightweight sensor carried on a headband, digitized at 50 Hz and Fourier-transformed. Root mean square velocity (RMS) was computed over 0-15 Hz bandwidth. Vision could be eliminated by opaque goggles, and pitch axis neck rotation restricted by a Philadelphia collar.

Head movements recorded during sitting and standing exhibited peak velocities of several °/sec, most of the energy within 5 Hz bandwidth, and Fourier components corresponding to harmonics of the pulse rate well above 5 Hz. Low-frequency components were larger during standing than sitting presumably due to the addition of whole body sway. Walking induced peak head velocities on the order of 50 °/sec with Fourier components over 15 Hz.

Median RMS velocity during sitting and standing while fixating a target 2m away was 0.82 (range: 0.66-1.25) and 1.20 (0.90-1.56) °/sec, respectively. Excluding vision (eyes open) while sitting and having the subjects imagine the target **reduced** RMS significantly both with the neck free and fixed. During standing, excluding vision had little overall effect on RMS with neck free but **increased** it significantly with neck fixed. During walking, median RMS head velocity was 12.9 (range: 10.0-25.2) and 14.5 (11.3-22.1) °/sec with neck free and fixed, respectively.

The head motion observed during sitting and standing is sufficient to cause visual acuity loss when the vestibulo-ocular reflex is impaired or high-magnification optical aids are worn. Oscillopsia and balance loss can result from these conditions during walking. Effects of vision observed during postural activities suggest that it contributes to stabilization of the trunk in space but has a destabilizing effect on the head relative to the trunk.

ORGANIZING PRINCIPLES FOR SINGLE JOINT ISOMETRIC CONTRACTIONS.
G. L. Gottlieb, D. M. Corcos, G. C. Agarwal and B. Flaherty*. Rush-Presbyterian.-St. Luke's Medical Center, Chicago, IL 60612 & University of Illinois at Chicago, IL 60680.

The dual-strategy hypothesis of motor control postulates certain classes of movements that are controlled by regulating the duration of an "excitation pulse" to the motoneuron pool. They are tasks that may be performed over a range of speeds and as such, are "speed insensitive" (SI). Other classes of movements are generated by regulating the intensity of the excitation pulse. They are "speed sensitive" (SS) and must be performed in a specified duration or at a specific speed. This "dual-strategy" hypothesis has emerged from studies of inertially loaded movements about the elbow. Our purpose is to extend these concepts to isometric contractions about the elbow.

Subjects made isometric elbow contractions (both pulses and steps) of different amplitudes and rates. We measured joint torque and electromyograms from two agonist and two antagonist muscles. The SS strategy is employed when task requires the subject to explicitly regulate the rate at which torque is generated. The SI strategy is employed whenever the SS strategy is not required, such as in generating different isometric torque amplitudes.

The SS strategy is implemented by the nervous system by increasing the excitation intensity to both agonist and antagonist motoneuron pools when the rate of rise of torque must be increased. Increases in the initial slope, peak and area of the EMG bursts accompany increases in the rate of torque rise. The SI strategy is implemented by controlling the duration of motoneuron excitation pulses of uniform intensity. The result is that the initial slope of the EMGs and the torque rise uniformly, regardless of the target torque. Pulse duration proportionally increases with torque in the agonist muscle.

The rules defining SS and SI strategies are broadened to include steps of excitation for sustained isometric contractions and a gradually rising patterns of excitation for contractions occurring over several hundreds of ms.

PERCEIVED PROPERTIES OF OBJECTS USING KINESTHETIC SENSE DEPEND ON WORKSPACE LOCATION. B.A. Kay*, N. Hogan*, F.A. Mussa-Ivaldi*, and E. Fassé* (SPON: W. Richards). Depts. of Brain and Cognitive Sciences and Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139.

Mussa-Ivaldi, Hogan, & Bizzi (1985, J. Neuroscience, 5, 2732-2743) found that the functional stiffness of the arm, as measured at the hand, varies systematically with changes in location in a two-dimensional workspace. Do these changes in impedance of the arm have any consequences for (1) the production of movement or (2) the perception of the environment using the kinesthetic sense? We conducted experiments in which subjects performed movements of the shoulder and elbow in the horizontal plane, in the absence of visual cues, in order to make perceptual judgements of two simple object properties, size and compliance. The stimulus objects were mechanically simulated two-dimensional rectangles, created using a two-link robot arm under computer control. In judging the relative lengths of the sides of the rectangles, subjects overestimated lengths directed outward from the body relative to lengths directed parallel to the trunk axis, and this overestimation increased with increasing distance from the shoulder. A linear fit of the data indicates that no differential length judgement should occur at the shoulder itself. In judging stiffness of the sides (preliminary results) of the rectangles, stiffness in the trunk axis direction was overestimated relative to the outward direction.

74.6

THE EQUILIBRIUM POINT MODEL FOR TWO-JOINT ARM MOVEMENT CONTROL. J.R. Flanagan*, A.G. Feldman*, and D.J. Ostry* (SPON: L. Bernier). McGill University, Canada and Institute for Information Transmission Problems, USSR.

The present model is based on a recent version of the equilibrium point hypothesis (Berkinblit et al, BBS, 9:585-638). This hypothesis states that the level of activation of a muscle depends on the difference between its actual length and its threshold length and the rate of length change. Central commands control two parameters (R and C) which determine threshold lengths. These parameters, along with external loads, specify the equilibrium position (R) and the level of co-concentration (C) respectively.

In the two-joint model, these are separate R and C commands associated with single-joint muscles spanning the shoulder and elbow and two-joint muscles spanning both joints. The R commands shift the threshold lengths of flexors and extensors in opposite directions; C commands shift them in the same direction.

A simple geometric model and Newton-Euler equations of motion are used to compute joint accelerations and velocities from which muscle lengths and velocities are derived. In this paper, the kinematics predicted by the model will be compared to experimental data from studies of two-joint human arm movements.

74.7

CONTROL OF HINDLIMB MOVEMENT IN FROGS. D.J. Ostry*, A.G. Feldman*, J.R. Flanagan*, S.V. Adamovich*, A. Karpovich*, and L.E. Sergio* (SPON: L.A. Jones). McGill University, Montreal, Canada and Institute of Information Transmission Problems, Academy of Sciences, Moscow, U.S.S.R.

Hindlimb movements were examined in both intact and spinal frogs. The aim was to map out the intrinsic capabilities of the spinal apparatus and the effects of supraspinal input on spinal organization. In studies of hindlimb withdrawal movements, initial joint angles at the hip, knee and ankle were varied systematically. This enabled us to determine the influence of the position of single joints on the coordination of remaining joints. Characteristics of the movement path in joint space and the form of the joint angular velocity profile were examined in both withdrawal and crossed extension reflexes. Our findings to date indicate that the slope of the path in joint space is dependent on the initial joint configuration. Joint angular velocity functions are generally unimodal but differ from one another in skew in some of the joint configurations we have studied. In swimming movements in the intact frog we have observed that the joints do not begin or end moving at the same time but have similarly shaped velocity functions at the joints. Our data are compared to model data based on the equilibrium point hypothesis.

74.8

MOVEMENT CUES ARE NECESSARY FOR LOAD STABILIZATION AGAINST LOW FRICTION. P.R. Burgess. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108

In order to hold a weight steady it is necessary that muscular force not fluctuate beyond the range of static friction. Subjects with eyes closed pushed on a force transducer mounted on a horizontal track with the right hand. They were asked to support a 50 N weight against 3 N of static friction for 10 sec with the instruction that if the weight moved, the trial would be considered a failure. In some trials, unknown to the subject, the friction was abruptly increased so that no movement could occur. The force did not fluctuate much beyond the range of static friction during the low friction trials because whenever the weight moved 1-2 mm, a force correction occurred even when the subject was not aware of the movement. When the friction was increased so that movement cues were eliminated, the force typically wandered enough that the weight would have traveled many cm during a single low friction trial. Thus, even when maintaining a steady force is critical to success, subjects cannot keep their force sufficiently constant to reliably hold a weight steady for 10 sec in this task unless the range of static friction amounts to about 25% of the weight. However, when movement cues are available, force fluctuations are markedly reduced and the weight rarely moved more than a cm during a 10 sec trial.

74.9

ISOMETRIC FORCES EXERTED BY HUMAN SUBJECTS WITH AND WITHOUT BIAS FORCES. J.T. Massey, R.A. Drake and A.P. Georgopoulos. Bard Labs., Dept. of Neuroscience, The Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

The position of a cursor in a visual display was proportional to the net X-Y force exerted on an isometric handle. Nine human subjects were instructed to exert forces on the handle such that the cursor moved in a stimulus direction in a reaction time task. In the absence of a constant bias force the direction of force exerted by the subject on the handle coincided with the direction of motion of the cursor in the display. In contrast, in the presence of a constant bias force subjects exerted forces of varying direction and magnitude throughout a trial such that the vector sum of the subject's force and the bias force was in the stimulus direction. Good performance in this condition was achieved without significant change in reaction time or information transmitted, compared to the performance without a bias force. These results indicate that human subjects can specify the direction of an intended net force effectively and efficiently even when that requires continuous change of the direction and magnitude of their own forces.

74.10

CONTRIBUTION OF PRIOR EXPECTATION TO CORRECTIVE MOVEMENTS. W.E.McIlroy and J.D.Brooke. Human Biology /Biophysics, Univ. Guelph, Guelph, CANADA. N1G 2W1.

The purpose of this study was to identify a role played by prior expectation during corrective movements. Three loads, 100%, 200% and 300% of a control load (12 Kg), were used to perturb the movement which consisted of isometric leg extension. Subjects received trials of 'predictable' magnitude (10 consecutively for each load) and an 'un-predictable' trial of 30 (10 of each load randomly ordered). They were instructed to return to the starting position as accurately as possible. All subjects restored position accurately, for all loads, when they could predict the magnitude. However during 'unpredictable' loading they made errors. These were easily measured as a change in peak velocity during the corrective extension. Three of four subjects consistently predicted high loads, seen by higher velocities at 100% and 200% as compared to the load-matched 'predictable' trials. The fourth subject appeared to predict low loads. Several factors, which we are currently evaluating, likely determine this level of dependence on prior expectation (including the speed/task, range of loads, the number of decisions required, and the probability of disturbance). Interestingly, from this study, 1) subjects selected this strategy with no imposed constraints on speed (accuracy was stressed) and 2) the correction strategy involving prior expectation could not be detected using 'predictable' loading (funded by NSERC).

74.11

AN ANALYSIS OF LOWER LEG MUSCLE ACTIVITY IN HUMAN POSTURAL CONTROL. V.P. Panzer*, D.J. Conti**, S. Thomas* and M. Hallett,
Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892 and
**Select Engineered Systems, Inc., Hialeah, FL 33016.

Previous investigations of human postural control have described the temporal relationships of muscle response onset to perturbations, attributing primary control of upright stance to muscles surrounding the ankle joint. However, results from our laboratory have demonstrated significant EMG activity at the knee and hip associated with postural adjustments. The purpose of this study was to evaluate EMG activity relative to maximum voluntary contractions (MVC) and temporal relationships among these muscles.

Surface EMG was recorded from Tibialis Anterior (TA), Soleus (SO) and Gastrocnemius (GA), while subjects stood quietly for 30 sec. EMG was sampled at 200 Hz, bandpassed, rectified and low pass filtered to obtain the envelope of the signal. Three evenly spaced 500 msec windows were evaluated for each trial. Temporal relationships were obtained by cross correlating muscle pairs and subsequently sliding each signal in 5 msec steps. The muscle pairs were correlated in this manner for 500 msec in each direction. When muscles are in phase, a high positive correlation is observed, while a high negative correlation would indicate reciprocal activity. Zero or low correlation values suggest independent EMG activity.

TA exhibited low amplitude activity (1-5% MVC), while SO showed sustained activity (10-20% MVC). GA was characterized by bursting (10-20% MVC) and relatively quiet periods (1-6% MVC). GA bursts appear to brake forward sway. Low level tonic activity in SO and TA probably provide support to the ankle. GA and SO were temporally correlated with no lag, although a slightly higher correlation sometimes occured with a 20 msec GA lag. High negative correlations between TA and triceps surae were not observed. The relationship between TA and triceps surae lacked the reciprocal characteristics which the inverted pendulum model of postural sway would predict. Ongoing control of upright stance does not appear to be dominated by the ankle joint muscles as has been previously suggested.

74.12

DISCRIMINATORY ANALYSES OF STABILIZING REACTIONS IN YOUNG, ELDERLY, AND PARKINSONIAN POPULATIONS. J.H.J. Allum, E.A. Keshner, F. Honegger* (SPON: D. McCrimmon). ORL Dept., Basel Univ., Basel, CH, and Dept. of Physiology, Northwestern Univ. Med. School, Chicago, IL 60611.

Postural strategies during rotational perturbations at the ankle tend to be replicable within a population. The temporal organization and magnitude of EMG responses, as well as resultant torques are significant indicators of vestibulospinal dysfunction (Allum et al., 1988). Examining the same parameters in other populations should help identify mechanisms that underlie diminished stability. In this study, we have compared latencies and areas under ankle and neck muscle EMG responses, and torque exerted on the support surface during platform dorsiflexion perturbations with eyes open and closed in 3 populations: young normals (20-40 years), elderly normals (50-80 years), and Parkinsonian patients (50-80 years). A stepwise discriminant analysis clearly distinguished between the 3 groups on the basis of the variables in Table 1.

Table 1: Significant Classifying Variables and F Values

	Eyes Open	F	Eyes Closed	F
Latencies				
	SL tibialis anterior (TA)	18.9	SL TA	15.9
	ML trapezius (TRAP)	5.4	ML TA	11.1
Areas				
	ML TRAP	8.0	ML TRAP	6.7
	ML torque	6.3	LL torque	4.4
	SLb soleus (SOL)	5.0	SLb SOL	3.7
	LL TRAP	3.7		

N.B. SL = short latency; ML = medium latency; LL = long latency.

Bonferroni t-tests revealed that elderly normals had significantly longer latencies of SL TA than both other groups. Longer ML SOL latencies, increased areas under SLb (80-120 ms) responses in TA and SOL, and decreased magnitudes of ML torque as compared to young normals suggest impaired balance in the elderly is produced by delayed vestibulospinal and propriospinal reflex responses that are poorly compensated by enhanced response magnitudes. Balance problems in age matched Parkinsonian patients is a function of both age and disease related variables.

74.13

EVIDENCE FOR A TRANSCORTICAL STRETCH REFLEX FROM THE STUDY OF PATIENTS WITH CONGENITAL MIRROR MOVEMENTS. C. Capaday, R. Fraser*, R. Forget* and Y. Lamarre. Centre de recherche en sciences neurologiques, Ecole de réadaptation et Hôpital Hôtel-Dieu, Université de Montréal, C.P. 6128, Succ. A, Montréal, Canada, H3C 3J7

When a patient with congenital mirror movements is asked to flex the distal phalanx of his left thumb he also involuntarily flexes the right distal thumb phalanx and vice versa. Our hypothesis is that the involuntary mirror movement is due to the same motor cortex command reaching the motoneuron pools on both sides of the body. If the long latency EMG responses to muscle stretch were produced by a transmotorcortical pathway, then stretching a muscle should produce long latency EMG responses in the ipsi and contralateral muscles. We tested this idea in three patients by stretching the flexor pollicis longus (FPL) muscle by 10 degrees of arc at a speed of 200 degrees/s using a servocontrolled DC-motor. The patients were required to maintain a tonic level of activity of about 10-20% of their maximum on the stretched side and between 0-20% with the contralateral FPL. Stretch of the distal phalanx of the thumb produced occasional short latency EMG responses (25 ms) in the ipsilateral FPL and longer latency EMG responses consisting of a small burst at about 40 ms and a second much larger response at 55 ms. In the contralateral side of all three patients, short latency responses were never observed but a long latency response was always present at about 55 msec. It was, however, smaller than on the ipsilateral side. No contralateral response, of any kind, was ever observed in any of ten normal human subjects in the same paradigm. The latency of the 55 ms EMG response is considerably shorter than the fastest voluntary reaction to the same stretch which is about 110 ms. To determine if the motor cortex ouput reached the motor pools on both sides, we used transcranial magnetic stimulation of the motor cortex focus for activating hand muscles. This produced responses on both sides in the two patients tested but not in four normal subjects. These results are consistent with the idea that long latency EMG responses to muscle stretch are, at least in part, mediated by the motor cortex. Supported by MRC of Canada.

PHASE ATTRACTIVE DYNAMICS AND PATTERN SELECTION IN COMPLEX MULTIFREQUENCY BEHAVIORS. J.A.S. Kelso and G.C. deGuzman, Program in Complex Systems and Brain Science, Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431.

Frequency and phase-locking are ubiquitous features of rhythmic behavior in neurobiological dynamical systems and crucial to temporal self-organization in general (Kuramoto, Y. *Chemical Oscillations, Waves and Turbulence* Springer, 1984). Previous empirical and theoretical work has pointed to the significance of *relative phase* as an order parameter (collective variable) characterizing coordinated behaviors. Less well-understood are cases of multifrequency behaviors in which the component frequencies are not 1:1. We report results of bimanual experiments in which humans are requested to sustain one frequency (1.5 Hz or 2.0 Hz) with one hand, while the other is passively driven by an external force at another frequency. Phase attraction to 0 or π (in-phase and anti-phase patterns) is demonstrated to persist especially in lower order frequency ratios (1:2, 1:3), along with short-term transitions from one phase-locking to another within a given frequency ratio. Jumping from less stable to more stable frequency ratios, e.g. 4:3 to 1:1 or 5:2 to 2:1 also occurs. A modified sine circle map with built-in phase attractive dynamics accommodates these results and generates new predictions. Observed patterns arise from the *competition* between the extrinsic driving force and the intrinsic, phase attractive dynamics. The relative strength of extrinsic and intrinsic dynamics determines the width of the Arnold tongues (stable mode-locked regions) and consequently the delay or acceleration of irregular behavior (quasiperiodicity and chaos). Universal features of a system's ability to generate multifrequency behaviors are governed by the differential stability of mode-locked states, as seen through the width of Arnold tongues. Behavioral complexity is inversely proportional to this measure, thereby rationalizing the relative difficulty of performing different patterns as well as their frequency of appearance..

SUBCORTICAL VISUAL PATHWAYS I

75.1

ILLUMINATION OF THE RECEPTIVE FIELD SURROUND CONTROLS THE CONTRAST GAIN OF MACAQUE P RETINAL GANGLION CELLS. *Ehud Kaplan*[1] *and R.M. Shapley*[2], [1]The Rockefeller University and [2]New York University, N.Y.

The retino-cortical pathway of the primate visual system comprises two streams, the Magnocellular (M) and the Parvocellular (P) streams. The contrast gain (response per % contrast) of the M pathway is approximately 8 times higher than that of the P pathway.

We investigated the source of this sensitivity difference in anesthetized and paralyzed macaque monkeys. Retinal ganglion cell activity was recorded in the LGN as synaptic (S) potentials. Sinusoidally modulated (4 Hz) spots and steady annuli were generated on the face of a white CRT. The response measure was the fundamental Fourier component of the average response.

We discovered that steady illumination of the receptive field surround lowered dramatically the gain of all ON-center P ganglion cells, and raised the gain or had no effect on OFF-center P cells. M cells were not significantly affected. The effect on Parvo- and Magnocellular LGN units was similar to the effects observed in their retinal afferents.

The fact that steady (DC) illumination can affect the response to modulated stimuli indicates the presence of a non-linear process, probably shunting inhibition at the level of the inner plexiform layer of the retina.

CONVERGENCE AND INPUT-OUTPUT RELATIONS IN THE CAT DORSAL LATERAL GENICULATE NUCLEUS (LGNd) ASSESSED BY S POTENTIAL RECORDINGS. J.S. Tootle, L.-A. Coleman* and M.J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

Our previous work suggests that in neonatal kittens the convergence of retinal ganglion cells onto single LGNd neurons differs from their adult counterparts. Moreover, many kitten LGNd cells have weaker inhibitory surrounds than in adult cats. (Tootle, J.S. & M.J. Friedlander, J.Neurosci. 9:1325, 1989). Here we address these issues directly in adult cats by simultaneously recording the activity of single A-laminae LGNd neurons and their retinal drive - the latter being recorded as geniculate S potentials. Convergence ratios and input-output relations were derived for spontaneous activity, size-response functions and contrast sensitivity functions. S and action potentials were digitized and frequency histograms of S potential amplitude were constructed. Analysis of the amplitude distribution of the S potentials revealed that from 1 to 3 retinal ganglion cells converge onto individual LGNd X-(n-14) and Y- (n=4) cells. For both X- and Y-cells the input-output ratio (LGNd spikes/S potentials) was highest for small spots (high spatial frequencies) and was reduced for large spots (low spatial frequencies). These data demonstrate an intrageniculate contribution to the receptive field inhibitory surrounds of adult LGNd neurons. Supported by NSF grant BNS-8720069.

BRAINSTEM MODULATION OF GENICULATE CELLS IN CATS D.J. Uhlrich, N. Tamamaki*, P.C. Murphy* & S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794.

The projection from the midbrain parabrachial region (PBR) to the lateral geniculate nucleus (LGN) modulates the gain of retinogeniculate transmission. To examine this more closely in cats, we compared the responses of LGN cells to drifting sinusoidal gratings with and without accompanying electrical stimulation of the PBR. The effects of PBR stimulation on the visually evoked responses of LGN cells were generally much greater than predicted from effects on spontaneous activity alone. PBR stimulation sharply increased the depth of visually modulated responses of most geniculate X and Y cells. The enhancement was greatest at roughly 100ms after PBR stimulation and lasted 200-700ms. Some cells also showed evidence of modest response suppression with complex time-courses. For both X and Y cells, the size of the PBR response enhancement usually varied with the grating's spatial frequency and was coupled with a general increase in contrast sensitivity. Y cells showed the greatest enhancement at low spatial frequencies, while the effects on X cells were more variable. Furthermore, PBR activation made Y cells less transient to the grating stimuli, while no such temporal effects were seen for X cells. Thus not only can PBR activity enhance retinogeniculate transmission, it also seems to affect the spatiotemporal tuning characteristics of the visual information relayed to cortex.

75.4

BRAINSTEM MODULATION OF PERIGENICULATE CELLS IN CATS. P.C. Murphy*, D.J. Uhlrich, N. Tamamaki* & S.M. Sherman. (SPON: H. Petry). Dept. of Neurobiology, SUNY, Stony Brook, NY 11794.

Activation of the afferent pathway from the midbrain parabrachial region (PBR) to the perigeniculate nucleus (PGN) is thought mainly to inhibit PGN cells via muscarinic action. However, some evidence suggests that PGN cells are excited by PBR activation. We studied this further in anesthetized, paralyzed cats by recording the effects in PGN cells of activation of the PBR. We found that spontaneous activity is simply decreased by PBR stimulation. However, for most cells, the visually evoked response was strongly enhanced, with or without a decrease in background activity. In each cell, this PBR-induced enhancement followed a similar time course to the inhibitory effect on spontaneous activity, lasting 0.25-1.25s after stimulating the PBR. The inhibition of spontaneous activity may reflect a direct muscarinic action, and the enhancement of visually evoked responses may reflect an indirect facilitation of PGN cells via a direct enhancement of geniculate relay cell responses (see Uhlrich et al., this volume). In any case, the presence or absence of effective visual stimuli strongly influences the effect of PBR activation on PGN cells. Through the role of the PGN in gating retinogeniculate transmission, the PBR thus disinhibits geniculate relay cells in the absence of visual stimuli but enhances the visually driven inhibition of these cells.

75.5

LAGGED AND NON-LAGGED X-CELLS IN THE CAT LATERAL GENICULATE NUCLEUS RECEIVE RETINAL INPUT THROUGH DIFFERENT GLUTAMATE RECEPTORS. P. Heggelund and E. Hartveit*. Inst. of Neurophysiology, Univ. of Oslo, Oslo, Norway.

The lagged and non-lagged X-cells in LGN are two types of relay cells which have similar spatial receptive field properties but markedly different temporal response properties (1-2). We have compared the effect of the NMDA receptor antagonist CPP on the visual response of the two cell types. The response of single cells in the A-laminae to a stationary light spot was recorded before, during and after iontophoretical application of CPP through a multibarrel glass pipette glued to the recording electrode.

CPP dramatically reduced, or completely abolished the response of all the recorded lagged cells (N=21). The non-lagged cells (N=40) were not or only weakly suppressed by CPP. This selective effect of CPP indicates that lagged and non-lagged cells are excited by retinal afferents through different glutamate receptors; the lagged cells mainly through NMDA receptors and the non-lagged cells mainly through non-NMDA receptors.

75.6

OFF-CENTER CELLS IN THE CAT LATERAL GENICULATE NUCLEUS ARE SENSITIVE TO NMDA RECEPTOR BLOCKADE. Y.H.Kwon, M.Esguerra and M.Sur. Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

The putative neurotransmitter at the retinogeniculate as well as the corticogeniculate synapse in the cat visual system is glutamate (Kemp and Sillito, J. Physiol. 323, 377-391, '82; Baughman and Gilbert, J Neurosci. 1, 4:427-439, '81). We have examined the role of NMDA and non-NMDA receptors in the visual responses of lateral geniculate nucleus (LGN) cells in adult cats.

We used six-barrel glass electrodes for extracellular recording as well as for microiontophoresis of the agonists NMDA and kainate, the NMDA-antagonist DL-2-amino-5-phosphonovaleric acid (APV) and the non-NMDA antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). After we identified each cell as On- or Off-center and as X or Y, we presented a flashing (1Hz) spot of light in the cell's receptive field center and collected post-stimulus time histograms before, during and after application of the drugs. We report on a total of 29 LGN cells from 7 cats. CNQX attenuated visual responses of both On- and Off-center X cells by 33% (n=4) and 38% (n=7) respectively. APV, on the other hand, reduced the responses of Off-center X cells to a much greater extent (52%, n=4) than On-center X cells (7%, n=7). The effect of CNQX on both On and Off-center Y cells was small (<6%, n=8), while the effect of APV may be greater for Off-center Y cells (38%, n=1) than for On-center Y cells (3%, n=6). However, a few On-center Y cells (n=2), as well as Off-center X and Y cells, were excited by NMDA, while On-center X cells were not.

These results demonstrate that glutamate receptors are involved in the transmission of visual information through the cat LGN. Under our recording conditions, X cells are more sensitive to the glutamate receptor antagonists than Y cells. For both X and Y cells however, visual responses of Off-center cells are more sensitive to blockade of NMDA receptors. This suggests that On- and Off pathways are not only segregated physiologically through the LGN but pharmacologically as well.

75.7

NMDA AND NON-NMDA RECEPTORS MEDIATE RETINOGENICULATE TRANSMISSION IN CAT AND FERRET LGN *IN VITRO*. M. Esguerra, Y.H. Kwon and M. Sur. Dept. of Brain and Cognitive Sciences, MIT, Cambridge,MA 02139.

In the cat lateral geniculate nucleus (LGN), *in vivo* iontophoresis of the specific NMDA receptor antagonist APV (dl-2-amino-5-phosphonovalerate) partially blocks visual responses of OFF-center cells, while CNQX (6-cyano-7-nitroquinoxaline-2,3-dione) antagonizes non-NMDA receptor mediated responses of both ON and OFF center cells (Kwon et al., this volume). In order to determine the site of these drug actions, we made single-unit extracellular recordings from slices of cat and ferret LGN while electrically stimulating the retinal or cortical afferents. We studied the effects of APV and CNQX on responses to single shocks and 30Hz trains delivered to the two pathways.

In normal medium, APV (40μM) attenuated the optic tract-evoked response to single shocks and trains by an average of 72% in 6 of 12 cells. In 10 of the 12 cells, CNQX (5μM) reduced the frequency of responses to optic tract stimulation by an average of 71%. CNQX blocked responses similarly in 4 cells driven by optic radiation stimulation, while APV attenuated this response in 2 of the 4. These results are consistent with our results in the cat LGN *in vivo* and indicate that both NMDA and non-NMDA receptors mediate retinogeniculate and corticogeniculate transmission. Further, the APV sensitivity of single-shock responses suggests that at the retino-geniculate postsynaptic site, non-NMDA receptor mediated EPSPs are necessary and sufficient to activate NMDA receptors, which are in turn necessary for suprathreshold depolarization.

In preliminary experiments, we have studied the effects of APV on paired sub-threshold stimulation of cortical and retinal afferents. The results suggest that conjoint retinal and cortical afferent activity can increase the retinogeniculate transfer ratio by depolarizing LGN cells and activating NMDA receptors postsynaptic to retinal terminals.

75.8

ORIENTATION SENSITIVITY OF RELAY CELLS IN THE CAT LATERAL GENICULATE NUCLEUS (LGND) Kirk G. Thompson*, Tiande Shou, Yifeng Zhou*, and Audie G. Leventhal. Dept. of Anat., Univ. of Utah Sch. of Med., Salt Lake City, Utah 84132

We studied the physiological orientation biases of over 800 LGNd relay cells as well as of a matched sample of over 1,000 retinal ganglion cell dendritic fields.

Most retinal ganglion cells were orientation biased and there was a strong tendency for cells to prefer stimuli oriented radially relative to the area centralis. Ganglion cells were not clustered according to preferred orientation.

Most LGNd cells were orientation biased and preferred radial stimuli. However, unlike in the retina, there was a relative over-representation of LGNd cells preferring stimuli oriented tangentially. Cells preferring radial and tangential orientations were clustered separately. The change in preferred orientation with distance was non-random along our penetrations (see Shou and Leventhal, Neurosci. Abs. 1988).

While the orientation tuning of most retinal ganglion cells and LGNd cells studied could be accounted for by an elliptical center/surround receptive field (see Soodak et al., J. Neurophysiol. 58:267, 1987), some could not. These cells were strongly biased and overall did not prefer radial stimuli. Their tuning curves were 'butterfly' shaped suggesting inhibition at the orientation orthogonal to the optimal.

We conclude that the orientation biases of most LGNd cells reflect those of their retinal inputs but that significant transformations are occurring in the LGNd.

75.9

CORTICAL CONTRIBUTION TO THE ORIENTATION SENSITIVITY OF RELAY CELLS IN THE CAT LATERAL GENICULATE NUCLEUS (LGND) Audie G. Leventhal, Yifeng Zhou*, Steven J. Ault, and Kirk G. Thompson*, Anat. Dept., Univ. of Utah Sch. of Med., Salt Lake City, Utah 84132

The orientation sensitivity of LGNd relay cells was studied in cats in which Areas 17, 18, 19, and LS were inactivated.

In decorticate cats most LGNd cells were orientation biased, clustered according to preferred orientation and preferred radial stimuli. Unlike in normal cats, in decorticate cats there was no over-representation of LGNd cells preferring tangential stimuli.

As in normal cats, in decorticate cats the responses of some cells could not be modeled by an elliptical receptive field. These cells were similar to the 'butterfly' cells in the LGNd of the normal cat (Thompson et al., Neurosci. Abs., 1989).

We conclude that most LGNd cells prefer radial stimuli as a result of their retinal inputs. Inputs from visual cortex serve to specify the preferred orientation of a minority of cells, most of which prefer tangential orientations. Since LGNd cells are grouped according to preferred orientation in normal and decorticate cats, it appears that sorting according to preferred orientation is occurring during the development of both the retinogeniculate and corticogeniculate projections. The presence of 'butterfly' cells in both normal and decorticate cats suggests that the orientation sensitivity of some LGNd relay cells are enhanced or determined by intrageniculate mechanisms.

75.10

COOLING STRIATE CORTEX ALTERS THE TEMPORAL ENCODING OF SPATIAL PATTERNS BY GENICULATE NEURONS.

J. W. McClurkin, B. J. Richmond, and L. M. Optican. Laboratory of Sensorimotor Research, National Eye Institute, and Laboratory of Neuropsychology, National Institute of Mental Health Bethesda, Maryland 20892.

Last year, we reported here that parvocellular LGN neurons encode multiple, simultaneous messages about visual stimuli in multiplexed temporal codes. These temporal codes could arise from differential delays of retinal inputs, interactions within the LGN, and/or feedback from other brain areas such as V1. This study assessed the contribution of cortical feedback on the temporal encoding.

Visual stimuli based on a complete, orthogonal 2D set of Walsh patterns were presented on a video monitor. The visual responses of LGN neurons during reversible inactivation of V1 by cooling (when the feedback was presumably blocked), were compared with their responses when V1 was at normal temperature (when the feedback was presumably present).

In the control condition, the shapes of the response waveforms varied with stimulus pattern and had a 60 Hz component that was obviously driven by the raster of the video monitor. Cooling V1 produced both global and specific effects on the temporal structure of responses. First, cooling V1 reduced the magnitude of the 60Hz component of all of the responses. Second, cooling V1 caused marked changes in the shapes and amplitudes of the response waveforms to some stimulus patterns but not to others. Thus V1 feedback both facilitates high frequency responsiveness of LGN neurons and is critical for generating the normal temporal codes related to individual stimuli.

ORIENTATION BIAS OF NEURONS IN THE LATERAL GENICULATE NUCLEUS OF MACAQUE MONKEYS. E.L. Smith III, Y.M. Chino, W.R. Bidder III, A. Langston, and K. Kitagawa. College of Optometry, University of Houston, Houston, Texas 77204-6052.

The purpose of this investigation was to analyze the influence of orientation on the responses of neurons in the lateral geniculate nucleus (LGN) of macaque monkeys (n=10). For the majority of both parvo- and magnocellular neurons, response varied in a systematic fashion with stimulus orientation (mean orientation bias = 0.19, range = 0-0.54; Levick and Thibos, 1982). Typically, the preferred stimulus orientations were either parallel to the line connecting the cell's receptive field and the fovea or were rotated slightly toward horizontal. Spatial frequency response functions measured at a cell's optimal and orthogonal orientations were used to derive the response profile for the receptive field center mechanism using a two-dimensional difference of Gaussians model (Soodak et al., 1987). The orientation response bias appears to primarily reflect an elongation of the receptive field center mechanism.

75.12

THREE-DIMENSIONAL FORM AND SIMPLE, ACCURATE FLAT MAPS OF SINGLE LAYERS IN THE LATERAL GENICULATE NUCLEUS (LGN) OF THE CAT. D.B. Bowling and J.I. Caverhill* Department of Medical Physiology and The Lion's Sight Centre, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Recently, there has been an increase in understanding of how the geniculate in the cat is organized in terms of afferent geometry, single cell responses, cell classification, sublaminar organization and projections to and from the visual cortex. We are interested in modelling these features to suggest how they may contribute to cortical function. As a first step we have considered the three-dimensional structure of single layers in the nucleus (a video image will be presented) and how the retinotopic maps in the layers change through depth as a consequence of three-dimensional form. In this we have needed a way to make accurate flat maps of curved surfaces to model and compare the topographic organization at different depths. We chose to make maps in which the representations of the surfaces are interrupted to form a series of map lunes that can be flattened individually with minimal distortion. Though discontinuous, the resultant maps are close approximations to the ideal of faithfully representing the total areas of the original surfaces, providing constant scales throughout the maps for comparing different regions, and being conformal over small regions. ION CHANNEL MODULATION AND REGULATION I

76.1

PROPERTIES OF THE INWARDLY RECTIFYING CHANNELS MODULATED BY SUBSTANCE P. S. Nakajima, Y. Nakajima, P.R. Stanfield* and K. Yamaguchi. Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN 47907.

Previous studies showed that substance P produces neuronal excitation by inhibiting inwardly rectifying K-channels (1). This modulation is mediated through a G-protein which is resistant to pertussis toxin (2). We have investigated this K-channel modulation in more detail. Primary cultured neurons from the nucleus basalis of Meynert were prepared from rat brains. The whole-cell patch clamp was used. The dose-response curve of this substance P effect suggested that the half-effective concentration is roughly 40nM. Continuous presence of substance P (30 nM - 3μM), applied through exchanging the superfusing solution, produced desensitization.

The substance P-sensitive current was obtained by subtracting the current during the action of substance P from the control current. The time course of the substance P-sensitive current showed that there is no time-dependent inactivation even at large hyperpolarizing potentials. As already reported (1), the substance P-sensitive current had properties very similar to the inward rectification of skeletal muscles or oocytes. Application of Cs^+ (0.1 mM) blocked the substance P-sensitive current. This inhibition is consistent with a model which assumes voltage dependent binding of Cs^+ to a site causing channel blockage. The effective valence of this Cs^+ effect was 1.9, suggesting that Cs^+ blockage occurs at a multi-ion pore. Ba^{2+} also blocked the substance P-sensitive current. The effect, however, was less voltage-dependent. Application of Na-nitroprusside neither affected the action of substance P, nor consistently mimicked the substance P effect, suggesting that cyclic GMP does not play a role in mediating the substance P effect. (Supported by NIH grant AG06093, and a grant from Wellcome Trust.)

RAS ALTERS PROPERTIES OF A VOLTAGE-DEPENDENT K+ CURRENT IN AtT-20 CELLS. R.E. Flamm, N.C. Birnberg*, & L.K. Kaczmarek. Dept. Pharmacology, Yale Univ. Sch. Med., New Haven, CT 06510.

We have found that transfection of an activated cHa-*ras* oncogene into an excitable pituitary cell line, AtT-20, alters its electrical properties. Control AtT-20 cells generate spontaneous, long duration action potentials, whereas *ras* AtT-20 cells are not usually spontaneously active but when depolarized generate narrow action potentials. We have compared K+ currents recorded under whole-cell voltage clamp. Cells were held at -90mV and stepped to depolarized potentials to activate the current. Both control and *ras* AtT-20 cells generate a delayed rectifier-like potassium current. Threshold for current activation is -15mV. The current differs from the classical delayed rectifier current by showing significant inactivation at potentials depolarized from +15mV. The current differs in the two clones in two ways. First, peak current density (step to +40mV) in *ras* cells is double that of control cells, 183$\pm$57 pA/pF (n=10) to 97$\pm$48 pA/pF (n=14) respectively (mean$\pm$SD). Secondly, the rate and amount of inactivation during a 300ms depolarizing pulse is greater in control cells than in *ras* cells. In control cells inactivation occurred with a time constant of 83.7$\pm$46.4ms whereas the time constant for inactivation of *ras* AtT-20 cells was 167.7$\pm$42.9ms. The control cell current is reduced by 44$\pm$10% over the same pulse but *ras* cells showed only a 30$\pm$11% reduction in current. These differences in properties of the K+ current are consistent with the differences we observe in electrical activity. Work is ongoing to determine whether other voltage-dependent currents are differentially expressed in the two clones.

76.3

EFFECTS OF 2-CL-ADENOSINE ON MEMBRANE CURRENTS AND SYNAPTIC TRANSMISSION IN CULTURED RAT HIPPOCAMPAL PYRAMIDAL NEURONS. Kenneth P. Scholz, Wendy K. Scholz and Richard J. Miller. Dept. of Pharm. and Physiol., Univ. of Chicago, Chicago, IL 60637.

Activation of adenosine receptors has been shown to induce presynaptic inhibition in a number of systems, including excitatory synapses onto CA1 hippocampal pyramidal neurons. We have begun to examine the roles of Ca2+ and K+ currents as well as G-proteins in mediating this effect. Rat pyramidal neurons were cultured by the methods of Banker and colleagues (1977) as modified by Scholz et al., (1988). Preliminary experiments indicate that 1 uM 2-Cl-adenosine (2-CA) produces presynaptic inhibition between synaptically coupled pairs of cells. To begin assessing the role of Ca2+ currents (ICa) in the modulation of synaptic transmission by 2-CA, ICa was recorded using whole-cell patch clamp techniques. Addition of 1 uM 2-CA to the bath caused a 24±1.5% reduction in ICa. This effect was completely reversible and was blocked by addition of 200 uM theophylline to the bath. In addition, preincubation of the cells with pertussis toxin (250 ng/ml) for 16 to 42 hours abolished the ability of 2-CA to reduce ICa. GTP-γ-S augmented the effects of 2-CA while GDP-β-S reduced the efficacy of 2-CA. Measurements of [Ca2+]i using fura-2 microfluorimetry have also shown that 2-CA can reduce Ca2+ entry triggered by depolarization in 50 mM K+. These results indicate that activation of adenosine receptors can regulate ICa in these cells by a mechanism dependent upon a G-protein. We have also found that 2-CA activates a K+ current in these cells, as shown by Trussell and Jackson (1987).

76.4

ADP-RIBOSYLATION AND IMMUNOLOGICAL CHARACTERIZATION OF G PROTEINS THAT MEDIATE PRESYNAPTIC INHIBITION. G.G. Holz IV, T.J. Turner and K. Dunlap. Dept. of Physiology, Tufts University School of Medicine, Boston, MA 02111.

Regulation of voltage-dependent calcium channels by G proteins is a likely means by which inhibitory transmitters suppress excitation-secretion coupling in presynaptic nerve endings. We previously reported that in chick DRG neurons, presynaptic inhibition is blocked by prior exposure of cultures to pertussis toxin (PTX). Here we report that in these same cells, PTX catalyzes ADP-ribosylation of G proteins migrating on SDS-PAGE (1-D gel electrophoresis) as a doublet of M_r 40-41 kDa. Isoelectric focusing combined with SDS-PAGE (2-D gel electrophoresis) demonstrates that this doublet is resolvable as four distinct spots with pI of ca. 5-6. Western immunoblot analysis of 1-D gels using antisera directed against synthetic peptides corresponding to amino acid sequences predicted from cDNAs for PTX-sensitive G protein α subunits reveals a *minimum* of two G_i-like proteins (M_r 40 and 41 kDa) and a third G_o-like protein (40 kDa). Subcellular fractionation of chick cerebral cortical homogenates by sucrose density gradient centrifugation indicates that these ribosylatable, immunoreactive G proteins are included in the synaptosomal plasma membrane and synaptic vesicle fractions. We conclude that G_i and G_o may regulate transmitter release not only at the level of calcium entry, but also at subsequent steps in the secretory pathway.

PERTUSSIS TOXIN BLOCKS A FAMILY OF NEUROTRANSMITTER RESPONSES, CONSISTING OF ACTIVATION OF 'S'-LIKE K CURRENT AND SUPPRESSION OF Ca CURRENT, IN *APLYSIA* NEURONS. V. Březina*, S.S. Vogel, G.J. Chin & J.H. Schwartz. Howard Hughes Medical Institute, Columbia University, New York.

Aplysia neurons have been proposed (*J. Physiol. 407*:15; *Soc. Neurosci. Abstr. 14*:754) to possess a family of 'slow' neurotransmitter responses, i.e. a distinct receptor for each of a number of transmitters that simultaneously mediates activation of a slow K current resembling the 'S' current and suppression of the Ca current. We have studied such responses in neurons L2-L6, R2 and LP1 (to ACh and the neuropeptide FMRFamide), and L10 (to ACh, FMRFamide and histamine). G-protein involvement is suggested by the finding that GTP-γ-S mimics both the K- and the Ca-current component of the responses. Another probe of G-protein function, pertussis toxin (PTX), blocks similar transmitter-activated slow K currents in other *Aplysia* neurons (*Nature 325*:259; *Jap. J. Physiol. 37*:551; *PNAS 85*: 7810), and indeed, under current clamp, the histamine-induced hyperpolarization in L10 (*Soc. Neurosci. Abstr. 13*:597). We now show that injection of PTX blocks both the activation of 'S'-like K current and the suppression of Ca current due to each of ACh, FMRFamide and histamine. Characterization and quantitation of G proteins in single isolated L10 and R2 cells using PTX-catalyzed [^{32}P]ADP-ribosylation and Western blotting reveals a single PTX-sensitive band, presumably the G protein mediating the transmitter responses.

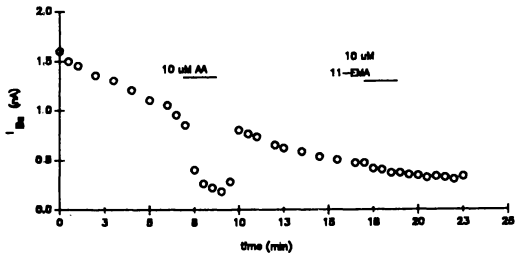
76.6

12-LIPOXYGENASE METABOLITES OF ARACHIDONIC ACID OPEN SINGLE S-K^+ CHANNELS: ROLE FOR AN EXTERNAL MEMBRANE RECEPTOR? N. Buttner, S.A. Siegelbaum and A. Volterra. Ctr for Neurobiology and Behavior, Dept. of Pharmacology, Columbia University. 722 W. 168 St. New York, NY 10032.

FMRFamide increases the S K^+ channel open probability (p_o) through the 12-lipoxygenase metabolite of arachidonic acid (a.a.), 12-HPETE (Piomelli et al., Nature, 1987). This may be due to a direct action on the S channel (or some other membrane protein) since 20 uM 12-HPETE modulates S channel activity in cell-free inside-out (i.o.) patches (Buttner et al., Biophys. J., 1989; see also Belardetti et al., Soc. Neurosci. Abstr., 1988). Since a.a. metabolites are released from cells and can act at external receptors, we have tested the action of 12-HPETE on S channels in cell-free outside-out (o.o.) patches.

Surprisingly, 12-HPETE is more effective in modulating S channel opening in o.o. patches compared to its action in i.o. patches. 20 uM 12-HPETE causes a 14 fold increase in p_o in o.o. patches (n=4), compared to a 2.9 fold increase in p_o in i.o. patches (n=5). In o.o. patches, 12-HPETE is effective at low concentrations, with 500 nM 12-HPETE causing a 4.6 fold increase in p_o (n=6). 500 nM 12-HPETE has little effect in i.o. patches. Neither a.a. nor 12-HETE, a stable metabolite of 12-HPETE, have any significant effect in i.o. or o.o. patches (at 20 uM). These results confirm the ability of 12-HPETE to modulate S channel activity in cell-free conditions (no ATP or GTP) and suggest that the lipoxygenase metabolite receptor may be at the external surface of the membrane.

76.7



IS PROTEIN-PHOSPHATASE ACTIVATION INVOLVED IN FMRFa RESPONSE IN APLYSIA? G.Demontis*, S.-I.Yang*, M.Mumby* and F.Belardetti Department of Pharmacology, UT Southwestern Medical Center at Dallas, Dallas, TX 75235-9041

In Aplysia sensory neurons (SNs) 5-HT closes the S-K^+ channel through cAMP-dependent phosphorylation. FMRFa: 1. increases the opening of this channel through lipoxygenase metabolism of arachidonic acid, and 2. reopens S channels closed by 5-HT or cAMP. We assayed the protein phosphatase activity in the soluble fraction of homogenates from whole Aplysia nervous systems using phosphorylated histone-H1 as a substrate (12 animals). Under basal conditions, we found a prominent phosphatase activity (7.9 pmoles ^{32}P/μg prot/min) which was suppressed (0.3 pmoles ^{32}P/μg prot/min) by 0.2 μM okadaic acid (OA), a protein phosphatase inhibitor. We then studied the action of OA on the FMRFa response. Brief puff application of FMRFa (2μM) elicited a slow hyperpolarization (8.8±3.3 mV, mean±s.e.m., n=4) in current-clamped SNs or a slow outward current (140 pA, Vh=-40 mV, n=1) in a whole-cell voltage-clamped SN. Then OA was applied to the bath for 20 min (3-8 μM) and the response to FMRFa tested again: the FMRFa response was not changed from the control level (117.6±21.3%, n=5). These experiments suggest that the FMRFa basal action on the S channel does not require the activation of an okadaic acid-sensitive protein phosphatase.

76.8

ARACHIDONIC ACID INHIBITS CALCIUM CURRENT IN CHICK SYMPATHETIC NEURONS. W. Bug, L. Role, S.A. Siegelbaum and L. Simmons. Ctr. Neurobiol. and Behavior. 722 W. 168 St. NY, NY 10032

Arachidonic acid (a.a.) metabolites mediate presynaptic inhibition in Aplysia sensory neurons (Piomelli et al., Nature, 1987). To investigate whether the a.a. cascade plays a similar role in vertebrates, we studied the effects of exogenously applied a.a. on inward calcium current (I_{Ca}) in chick sympathetic neurons using whole cell recording. Arachidonic acid (10 uM) inhibited I_{Ca} by 54% +- 27% (mean, +- S.D., n=5). This effect was reversible in three experiments (Fig.). As a control for non-specific effects of fatty acids, eicosa-11-monoenoic acid (10 uM;11-ema) was shown to have no significant effect on I_{Ca} (n=2). The question now is whether a.a. plays a physiological role in these neurons.

76.9

ARACHIDONIC ACID DEPRESSES HIPPOCAMPAL CALCIUM CHANNEL CURRENT UNDER WHOLE-CELL VOLTAGE CLAMP. D.O. Keyser and B.E. Alger. Dept. of Physiology, School of Medicine, Univ. of Maryland at Baltimore, Baltimore, MD, 21201.

Recent evidence suggests that unsaturated fatty acids (FA) including arachidonic acid (AA) act as second messengers to modulate ionic currents and can activate protein kinase C (PKC). This hypothesis predicts that: 1) the biologically active FA should mimic known PKC activators such as phorbol esters, 2) they should be active in the dose range at which the FA activate PKC and 3) inactive FA should have no effect. To begin to test the hypothesis we used acutely isolated guinea pig hippocampal pyramidal cells and studied calcium channel currents carried by barium under whole-cell voltage clamp.

Bath-applied AA (10-100 uM) decreased I_{Ca} in a dose-dependent manner. Maximal reduction of I_{Ca} was 80% at 100 uM AA. There was no change in holding or leak currents or the voltage dependence of I_{Ca}. The latency of the effect decreased with increasing concentrations of AA. Oleic acid, another active unsaturated FA, also depressed I_{Ca}. The effect of AA and oleic acid resembles that of the phorbol ester PDBu, a PKC activator. The trans isomer of oleic acid, elaidic acid, which does not activate PKC, had no effect. Our results demonstrate for the first time that AA and other FA can modulate calcium channel currents in the hippocampus. The data are consistent with the hypothesis that PKC is involved.

ACTIVE VS INACTIVE PHORBOL ESTER EFFECTS ON WHOLE-CELL CALCIUM CURRENT IN HIPPOCAMPAL NEURONS. D. Doerner and B. E. Alger. Univ. MD, Sch. Med., Baltimore, MD 21201.

We have reported that phorbol esters that activate protein kinase C (PKC) suppress whole-cell calcium channel current (I_{Ca}) carried by barium in hippocampal neurons acutely-isolated from guinea pig. At the same concentrations inactive phorbol esters had no effect. We now report that high doses of inactive phorbol dibutyrate, 4-α-PDBu, also depress I_{Ca} and have tested the hypothesis that the two isomers act via the same mechanism.

Both 4-α- and 4-β-PDBu reduce I_{Ca} when applied extracellularly, but 4-α-PDBu was less potent by 2-3 orders of magnitude. When applied intracellularly, 4-β-PDBu was effective at doses as low as 20 nM, whereas 4-α-PDBu was inactive up to 100 μM. Besides depressing maximum I_{Ca} conductance, 4-β-PDBu caused a left shift in the voltage dependence of inactivation of I_{Ca} of about 10 mV. 4-α-PDBu did not affect inactivation and neither agent altered voltage dependence of activation. Finally, I_{Ca} suppression due to 4-β-PDBu (50-500 nM) was antagonized by the PKC inhibitor H-7 (20-50 μM), while H-7 did not affect comparable depressant effects of 4-α-PDBu (20-50 μM). We conclude that active and inactive PDBu isomers differ according to potency, cellular site and biophysical mode of action and susceptibility to PKC inhibitors. Apparently 4-β-PDBu depresses hippocampal I_{Ca} via PKC while 4-α-PDBu acts through another mechanism.

cAMP DEPENDENT MODULATION OF TRANSIENT Ca^{2+} CURRENT IN RAT THALAMIC RELAY NEURONS

J.R. Huguenard, D.A. Coulter and D.A. Prince
Department of Neurology, Stanford University Medical Center
Stanford, California 94305

A low-threshold, Ca-dependent spike underlies burst generation in thalamic relay neurons and has an important function in regulating thalamocortical excitability during changes in behavioral state. The underlying Ca^{2+} conductance is affected by agents which alter resting membrane potential, however little information is available regarding the direct effects of intrinsic modulatory substances on the Ca^{2+} currents. Since phosphorylation by cAMP-dependent protein kinase (A-kinase) is known to mediate a number of modulatory cellular responses, we examined the effects of agents which activate A-kinase on the transient (T-type) Ca^{2+} current which is responsible for bursting in these cells.

Using whole-cell clamp procedures, Ca^{2+} currents were recorded from acutely isolated rat ventrobasal complex neurons (Coulter, Huguenard, & Prince, *J. Physiol.*, 1989). Bath application of a membrane permeable analog of cAMP (db-cAMP, 1mM) reversibly reduced T current by 28-53% and induced smaller decreases in L current. Extracellular cAMP and db-cGMP were ineffective. Forskolin (50μM), a direct stimulator of adenylate cyclase, and isobutylmethylxanthine (0.1-1mM), an inhibitor of phosphodiesterase, produced similar effects, with reduction of 20-50% and 10-50%, respectively. The effects of all of these agents were reversible within 15 minutes.

We conclude that A-kinase dependent reduction of T current occurs in thalamic relay neurons, and that modulators which activate the kinase (e.g. ß-adrenergic agonists) may regulate thalamocortical excitability via this mechanism. Supported by NIH grants NS06477 and NS12151.

A NEW PATCH CLAMP CONFIGURATION FOR STUDYING SINGLE ION CHANNELS: THE NYSTATIN-PERFORATED VESICLE. E.S. Levitan, R.H. Kramer,and L.K. Kaczmarek, Dept. Pharmacol., Yale U. Sch. Med., New Haven, CT 06510 and HHMI, Columbia U. CPS, 722 W. 168th St., NY, NY 10032.

We have developed a new patch clamp configuration for studying outside-out ion channels while they remain exposed to cytoplasmic factors necessary for normal activity and modulation. First, a giga-ohm seal is formed on a pituitary tumor cell (GH3 or GH4) with a patch electrode containing the pore-forming substance nystatin, along with K, Cl, Mg, SO4, Na, and HEPES ions. After nystatin perforates the patch (Rs<50 Mohm), the cell can be voltage-clamped to measure ionic currents (Horn and Marty, 1988). Withdrawing the pipette results in formation of a vesicle which retains water-soluble or mitochondria-specific fluorescent dyes loaded into the cell, suggesting the vesicle contains cytoplasm. The hemisphere of the vesicle in contact with the pipette solution remains perforated and allows the recording of single channel activity in the nystatin-free hemisphere facing the bath. Single channel currents in such vesicles (Rin ~ 10 Gohm) exhibit rapid kinetics and are unattenuated, unlike those in unperforated vesicles. Depolarization activates a 110 pS K channel that is blocked by 50 nM charybdotoxin. These channels open rarely in intact vesicles, but opening increases if the perforated membrane in the pipette ruptures, suggesting that the vesicle maintains low Ca. The peptide hormone TRH, known to induce IP3-stimulated Ca release, increases the macroscopic Ca-activated K current in perforated cells, and activates the K channel in perforated vesicles. Hence these vesicles can be used to study modulation of ion channels because they contain cytoplasmic components necessary for channel survival and regulation.

76.13

MODULATION OF VOLTAGE-GATED CALCIUM CHANNELS STUDIED USING THE PERFORATED PATCH AND PERFORATED VESICLE CONFIGURATIONS R.H. Kramer, E.S. Levitan and L.K. Kaczmarek, Dept. Pharmacol., Yale Univ. Sch. Med., New Haven, CT 06510 and Howard Hughes Med. Inst., Columbia Univ. CPS, 722 W. 168th St., New York, NY 10032

Ca channels are inactivated by intracellular Ca ions. It is difficult to study this phenomenon in small mammalian cells because both whole-cell and excised patch clamp configurations require replacement of the physiological Ca buffering system with exogenous Ca buffers. Hence, we have used the perforated patch configuration to study modulation of Ca channels by agents known to elevate internal Ca in pituitary tumor cells: caffeine and TRH. Dihydropyridine-sensitive Ca or Ba whole-cell currents measured in the perforated patch configuration are reduced 15-60% by 10 mM caffeine, and less dramatically by 1 µM TRH. T-type currents are not affected. 1 µM ryanodine also decreases Ca current, and reduces the effect of caffeine. In outside-out patches, caffeine does not reduce the conductance of single Bay K-treated L channels, and has no obvious effect on gating. We are further investigating the possibility that caffeine inactivates Ca channels indirectly by mobilizing intracellular Ca. We are also using the perforated vesicle configuration to study this phenomenon. Perforated vesicles exhibit a 20 pS L-type channel whose activity persists for more than 15 min in the absence of added EGTA, ATP, or other agents usually necessary for Ca channel survival in cell-free patches. Since the perforated vesicle may be capable of internal Ca release, it presents an ideal preparation for studying the single channel basis of Ca-dependent inactivation of Ca current.

Cerebellar Evoked Potentials from the Rat: Cord and Sciatic Nerve Responses. R.J. Hurlbert, C.H. Tator, G. Niznik, M.G. Fehlings, R.D. Linden. Spinal Cord Research Laboratory, Playfair Neuroscience, University of Toronto, Canada M5T 2S8.

We have studied the value of cerebellar evoked potentials in an attempt to better monitor the integrity of the ventral spinal cord. The spinal response to cerebellar stimulation has been characterized in 13 rats and the sciatic responses in 5. Using alpha-chloralose and urethane anaesthesia a burr hole was placed 2mm inferior to the occipital protuberance and 2mm lateral to midline; a platinum ball stimulating electrode was inserted epidurally over the cerebellum. A laminectomy at T9/10 allowed the introduction of recording microelectrodes into the spinal cord. Where sciatic potentials were measured, both sciatic nerves were exposed and bipolar recording needle electrodes inserted. A Cadwell 8400 Signal Averager was used to record the waveforms.

The responses have been characterized using intensities of 10 - 25 mA at a rate of 8.1 Hz and a pulse width of 50 us. Lesion studies indicated that the cord potentials were carried primarily in the ventral funiculus while the sciatic responses were conducted in the dorsal columns. This technique is potentially of great value in experimental and clinical spinal cord monitoring. Further studies are needed to clarify the anatomical pathways involved.

RESPONSES OF CAT EXTERNAL CUNEATE NEURONS DURING PASSIVE AND ACTIVE MOVEMENTS. K.M. Horn, P.L.E. van Kan*, and A.R. Gibson. Division of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013.

Previous work (Van Kan et al., Soc. Neurosc. Abst., 12(1):578, '86) has identified sensory and motor components in proprioceptive signals of mossy fibers in intermediate cerebellum of awake monkey. The present study is part of a series designed to identify and characterize sensory and motor response components in the sources of mossy fiber inputs. External cuneate (ECN) neurons were recorded in decerebrate, decerebrate-paralyzed, anesthetized, or awake cats. Units recorded in the decerebrate preparations before and after paralysis demonstrated comparable response magnitudes and characteristics. The overall response characteristics in the decerebrate, anesthetized and awake preparations were similar. Units were responsive to movements of single forelimb joints and contained tonic and phasic response components. Some units showed largely tonic firing rates that were proportional to joint angle. Units with largely phasic components showed increased and decreased responses dependent upon the direction and velocity of joint movement. Preliminary comparisons of the neural responses during passive and active movements indicate that active movement participation may be a significant factor in determining response characteristics of some ECN units.

RED NUCLEUS MEDIATED INHIBITION OCCURS WITHIN THE INFERIOR OLIVE. A.R. Gibson and T. M. Hamm, Barrow Neurological Inst., Phoenix, AZ 85013.

Weiss et al. (Soc. Neurosci., '85) reported that stimulation of the cat magnocellular red nucleus (RNm) inhibits responses of the rostral dorsal accessory olive (rDAO) to peripheral stimuli. We investigated the locus of the inhibition by studying responses of hindlimb rDAO cells. These cells receive hindlimb afference from the gracile nucleus and the spinal cord. We sectioned the dorsal half of the spinal cord at midthoracic levels leaving only spinal input via the ventral funiculus. The section also removed RNm influences on lumbar cord. Olivary responses to hindlimb shocks were still inhibited by RNm stimulation indicating that the inhibition occurred in the olive. As a further control, we bypassed the lumbar cord by directly stimulating either the dorsal columns or ventral funiculus. In both cases the olivary responses were inhibited following RNm stimulation. Although it is likely that afferent pathways are modulated at many levels, the specific action of RNm stimulation on rDAO responsiveness may play an important role in preventing olivary responses to active movement. (Supported by USPHS grants NS24042, NS22454)

REGULATION OF SIMPLE SPIKE RESPONSES OF PURKINJE CELLS BY THE CLIMBING FIBER SYSTEM IN CEREBELLAR SAGITTAL ZONES. T.M. Kelly, J.D. McAlduff*, J.R. Bloedel. Div. of Neurobiol., Barrow Neurological Inst., Phoenix, AZ 85013, and Dept. of Physiol., U. of A., Tucson, AZ 85724.

Our previous studies demonstrated that perturbations of a forelimb movement activate climbing fiber inputs to sagittal strips of Purkinje cells and that this input is associated with increased simple spike responses of the same neurons. The present experiments were performed to test the hypothesis that this interaction is used to specify which populations of Purkinje cells will be modulated by a distributed mossy fiber input. Two five-electrode arrays were placed sagittally in zones B-C_3 of lobule V in acutely-prepared decerebrate, ambulating cats. The zones were identified electrophysiologically. Purkinje cells recorded with each array were treated as a population of neurons, and the RTPR algorithm was employed to characterize each population's response to a perturbation of the step cycle. The synchronous activation of climbing fiber inputs was quantified in each zone by calculating the synchrony index: the fraction of Purkinje cells receiving evoked climbing fiber inputs within an 80 msec window. The data indicate that the modulation of simple spike activity was much greater in those sagittal strips receiving synchronously activated climbing fiber inputs. The findings support the dynamic selection hypothesis which argues that the sagittal distribution of activated climbing fiber inputs can specify sagittally-oriented populations of Purkinje cells whose simple spike activity is most highly modulated by mossy fiber inputs responding to the same conditions. (Supported by NIH Grant NS21958)

INTRAOLIVARY INJECTION OF PICROTOXIN CAUSES REORGANIZATION OF COMPLEX SPIKE ACTIVITY. E. J. Lang, M. Chou, I. Sugihara, and R. Llinás. Dept. of Physiol. & Biophys., New York Univ. Med. Ctr., 550 First Ave., New York, NY 10016.

Intravenous injection of picrotoxin, a GABA antagonist, changes the pattern of synchronization of complex spike (CS) activity in cerebellar Purkinje cells (Sasaki & Llinás, Soc. Neurosci. Abst. 11:181, 1985). These results have lent support to the hypothesis that release of GABA within the inferior olive (IO) controls the pattern of electrical coupling of olivary cells (Llinás, R. The Physiologist 17:19-46, 1974).

In order to test this hypothesis in a more rigorous manner picrotoxin was directly injected into the IO of anesthetized rats. A single barreled pipette was carefully lowered through the brain towards the IO while an electrical microstimulation was delivered. Detection of the climbing fiber activation of Purkinje cells on the suface of the Crus IIa of the cerebellum was the criteria for having reached the IO. Following this procedure simultaneous extracellular recordings of up to 22 Purkinje cells in Crus IIa was implemented using the multiple extracellular microelectrode technique. The distance between electrodes was 250 μm and they were organized in a rectangle over the surface of the folium. Pressure injection (1 μl/min) of picrotoxin (2-5 μl of 1 μg/μl) produced a distinct change in the organization of the climbing fiber activity over the cortex. Thus, in the rostro-caudal direction the degree of synchronicity of CS was typically increased by 3 to 4 fold. More significantly however, the degree of synchronicity in the medio-lateral direction as determined by cross-correlation, which is particularly poor under control condition, rose from between 0.03-0.01 to 0.1-0.06. On occasions cross correlations as high as 0.16 were observed after the picrotoxin microinjections. These increases in CS cross-correlation were qualitatively and quantitatively similar to that seen with I.V. injection. In control experiments intraolivary injections of Ringers solution did not produce changes in the pattern of synchronization of CS activity.

These results indicate blockage of intraolivary inhibition is sufficient to reorganize the spatial distribution of CS synchronicity.

REAL TIME VISUALIZATION OF CALCIUM ENTRY INTO GUINEA PIG PURKINJE CELLS *IN VITRO*. M. Sugimori and R. Llinás, Dept. of Physiology & Biophysics, NYU Med. Ctr., NY 10016.

Study of calcium concentration changes in the soma and dendrites of mammalian Purkinje cells during spike activity have been determined with the use of calcium-sensitive dyes such as Arsenazo III (Ross & Werman, J. Physiol 389:319, 1986) and Fura II (Tank et al., Science 242:633, 1988). In the latter study, a distinction was made between the calcium entry which occurs at the onset of plateau potentials in the peripheral dendritic branchlets and that which occurs in the main branches of the dendritic arbor. The suggestion was made that the spontaneous electrical oscillatory activation of Purkinje cells are initiated by inward calcium current at peripheral dendritic level which upon reaching sufficient amplitude evoked full calcium-dependent action potenials in the main dendritic tree. The measurements reported in this study were obtained at a maximum speed of 250 msec. Presently with improved imaging techniques (a photon counting camera and a high speed video receiver capable of recording 400 frames per second) the actual time course and the distribution of calcium entry during single action potentials in Purkinje cells was directly determined. Because the fluorescence measurements using Fura II were made at only one light frequency (340 μm) the measurements indicate only relative calcium concentration changes in the Purkinje cell cytosol. Simultaneous recordings of light absorption by Fura II and of intracellular Purkinje cells voltage clearly indicates that the plateau potentials which proceed the activation of Purkinje cells occur in the spiny branchlets. The full action potentials are then observed in the main dendrites is followed by a synchronous, antidromic invasion into the fine dendritic tree. This oscillation in light absorption occurs at frequencies of 5-10 Hz per second and return to baseline within 50-100 msec in cells in good condition.

Finally, activation of the climbing fiber system demonstrated a rapid activation of both the main dendritic tree as well as the peripheral branches with the main dendritic tree being the first to demonstrate calcium entry. Support: NS13742.

TOPOGRAPHY AND ANALYSIS OF VESTIBULAR-VISUAL CLIMBING FIBER SIGNALS IN THE RABBIT CEREBELLAR NODULUS. N.H. Barmack and H. Shojaku*, R.S. Dow Neurological Sciences Institute, Good Samaritan Hospital and Medical Center, Portland, OR, 97209.

The cerebellar nodulus receives primary and secondary vestibular afferent mossy fiber inputs, a vestibular climbing fiber input and a visual climbing fiber input. We have recorded the responses of single Purkinje cells evoked by vestibular and optokinetic stimulation in lobules 9c,9d and 10 of rabbits anesthetized with chloralose-urethane. About 60% of all nodular Purkinje cells received climbing fiber signals (CFRs) which were modulated by dynamic and/or static vertical vestibular stimulation. CFRs which were evoked by stimulation in the plane of the left posterior-right anterior semicircular canals (Lpc-Rac) were found in Purkinje cells distributed over the medial 1.5 mm of the nodulus. CFRs in these Purkinje cells were also evoked by downward vertical optokinetic stimulation in the posterior field of the left eye. These optokinetic responses were synergistic with rotation of the head in the plane of the Lpc-Rac. CFRs in Purkinje cells located in the ventral layer of the nodulus (.5-1 mm from the midline) and with no vestibular sensitivity, were evoked by posterior-anterior stimulation of the left eye. CFRs evoked by stimulation in the plane of the Lac-Rpc were found 1-2 mm laterally in the nodulus. The topographic distribution of these vestibularly and optokinetically evoked CFRs might reflect a medio-lateral gradient of postural response to these signals.

VISUAL PONTOCEREBELLAR PROJECTIONS IN THE MACAQUE. M. Glickstein, A. Gibson, C. Legg, B. Mercier, J. Stein & J.Voogd. Dept of Anatomy, University College London, London WC1, England.

The pontine nuclei receive visual inputs from cortical and midbrain visual areas of monkeys. The great majority of visual fibers terminate dorsolaterally in the rostral pons. Where do pontine visual cells project on the cerebellar cortex? We first recorded from this region of the pontine nuclei to identify cells responding to visual stimuli. We injected a small amount of wheatgerm agglutinin horseradish peroxidase (WGA HRP) amongst visually driven cells. After two days survival the brains were prepared for HRP histochemistry. We confirmed the visual input by plotting the location of retrogradely filled cells in cortex and midbrain. In addition to projections from areas 19 and 7, this region also receives fibers from area 8 and from the superior colliculus and pretectum. Orthograde projections were distributed bilaterally to caudal cerebellar vermis and hemispheres. The principal target was the contralateral paraflocculus, paramedian lobe and the adjacent ansiform lobe. There were lighter ipsilateral projections to these same targets and a vermian projection which was maximal on the uvula, but which extended rostrally to Lobule VI. Surprisingly, there were few or no efferent fibers from this region of the pontine nuclei to the flocculus of either side.

77.9

ORIENTATION SPECIFICITY OF OPTOKINETICALLY MODULATED NEURONS IN THE GOLDFISH CEREBELLUM. J.F. McGurk and W.M. Graf, The Rockefeller University, New York, NY 10021

Responses of individual neurons in the corpus cerebelli of the goldfish (*Carassius auratus*) during optokinetic stimulation revealed that they are sensitive to visual field rotation. Extracellular recordings were made from 67 neurons in the corpus cerebelli during visual field rotation with a planetarium projector with the axis of rotation located in the horizontal plane (producing vertically directed movement). Neurons were characterized by the orientation of the axis of visual field rotation that produced the greatest modulation in firing rate (the preferred axis). Two response types were found. One population (N = 21) was excited by visual field rotation around the preferred axis in one direction and inhibited by rotation in the opposite direction. Visual field rotation about an axis 90^{o} apart from the preferred axis produced little modulation in firing rate. These neurons were sensitive to both the orientation of the axis of rotation and the direction of movement of the visual field, and were termed **direction-specific.** The second population (N = 17) showed an increase or decrease in firing rate during rotation in either direction around the preferred axis and no modulation in firing rate during visual field rotation about an axis 90^{o} apart from the preferred axis. This population of neurons was called **axis-specific.** In addition, 67% of tested direction-specific neurons and 50% of tested axis-specific neurons were also modulated during visual field rotation about a vertical axis (horizontal visual field motion). This suggests that, for these neurons, the preferred axis is tilted up or down from the horizontal plane.

The preferred axes were widely distributed, and had no tendency to cluster. This is unlike the situation that obtains in the rabbit, where the preferred axes of Purkinje cells in the cerebellar flocculus tend to be close to the sensory axes of the labyrinthine semicircular canals and the axes of rotation of the extraocular muscles.

77.10

FRACTAL GEOMETRY OF PURKINJE NEURONS: RELATIONSHIPS AMONG METRICAL AND NON-METRICAL NEURAL GEOMETRIES. *A.J. Pellionisz* (Dept. of Physiology and Biophysics; New York University Medical Center, New York, NY, 10016).

In one decade since inception of a geometrical approach to brain theory, an alternative was established to the untenable dogma that Euclidean geometry (with a Kronecker delta as the metric tensor) is sufficient to account for structurofunctional features of the CNS. In time, implications of *multidimensional geometrical concepts and formalisms* will be absorbed, intrinsic coordinate systems will be experimentally measured and thus features of neural geometries that are spun over such frames will be established (e.g. spacetime geometry of sensorimotor transformations). *Sensorimotor system neuroscience* may lead this progress since metrical properties of skeletomuscular systems and their governing neural nets can be measured and multidimensional computational properties are to be used in neurocomputing, rehabilitation medicine and (neuro)robotics. Also, representation of distances (and judgements and decisions based on them) in functional spaces with metric tensors that are characteristic to non-Euclidean spaces may become a conceptual and formal basis in *cognitive science* (theory of association of generalized vectors).

Raising sights above Euclidean spaces it is apparent that metrical properties of (quasi)linear, derivable multidimensional manifolds (e.g. those governing gaze) are but the simplest features of neural geometry. It is known that if neural systems revert to a nonlinear non-metrical domain, strange attractors emerge, revealing chaotic geometry. It is postulated here that beneath a chaotic geometry (e.g. of EEG) and the functional "smooth" metrical spaces it may relapse to, a third kind of neural "microstructure" exists: *The growth of cellular (neural) elements reveals a fractal geometry* that is a direct manifestation of the process based on repeated access to the genetic code during growth.

The presentation demonstrates the fractal growth of dendritic trees of Purkinje cells, displaying self-similarity of micro- and macro-features of the arbor, showing that the bifurcation-rule of branching expresses a fractal dimension, and revealing codes responsible for generating normal or pathological arbors. Relation of growth- and functional models of neurons and neural nets is discussed; since fractal, metrical and chaotic neural geometries of the micro-, medium- and macro-domains of the CNS are interdependent (just as relativistic-, Newtonian- and quantum-mechanics apply together to the external world).

77.11

THE CEREBELLUM AS AN ADAPTIVE SMITH-PREDICTOR IN VISUO-MOTOR CONTROL. (SPON: European Neuroscience Assoc.) R.C. Miall*, J.F. Stein* and D.J. Weir*. King's College Research Centre, King's College, Cambridge CB2 1ST, U.K. & Univ. Lab. of Physiology, Oxford OX1 3PT, U.K.

To help us understand the role of the cerebellum in the visual guidance of movements, we have been analysing manual tracking in human subjects, cerebellar patients and rhesus monkeys with temporary cerebellar lesions. We present here a model of visuo-motor tracking based on these experiments. The main features of the model are: i) that tracking is controlled by intermittently sampled negative feedback; ii) that both short- and long-term predictions of target motion are employed; and iii) that an internal representation of the visuo-motor control system helps the system to predict its own performance.

This internal model has two components: The first represents the dynamic behaviour of the visuo-motor system. This allows rapid prediction of the expected outcome of a motor command. The second component models only the time delays in the feedback loop (Smith, 1957), determined by sensory, computational and execution delays. This enables any discrepancies between the predicted and actual movement to be processed as a feedback signal without de-stabilizing the high performance achieved by the dynamic component of the model. Both the dynamic and temporal components of the model must be plastic to adapt to changes in the visuo-motor system or in external visual feedback.

We suggest that the generation and adaption of these two components of the Smith Predictor take place in the cerebellum, lateral regions being responsible for a visuo-motor model, operating in visual coordinates, and medial regions for an executive model, operating in motor coordinates. (Reference: O.J.M. Smith, *Chem. Eng. Prog. 53*, 1957, pp. 217-219)

78.1

THE α_2 AGONIST MEDETOMIDINE POTENTIATES THE ANTINOCICEPTIVE ACTION OF OPIATES. M.H. Ossipov, E. Messineo*, B.-S. Lin, and S. Harris* Anaquest, Division of BOC, 100 Mountain Ave, Murray Hill, NJ 07974, U.S.A.

We examined the antinociceptive interaction between morphine, fentanyl, and meperidine with medetomidine (medet). Male S-D rats received fixed combinations of medet to fentanyl (10:1) or meperidine (1:3) i.t. and i.v., or morphine (10:1) i.t. and (1:10) i.v. Antinociceptive tests were the tail-flick (TF) and hot plate (HP). Response latencies were measured before (Control) and several times after (Post) drug injection. Cut-off (CO) times of 10 (TF, i.v.), 7 (TF, i.t.) or 30 (HP) sec were used. Data were converted to % maximal possible effect (%MPE) by: 100 x [(Post - Control)/(CO - Control)]. The A_{50} (50 %MPE dose) at time of peak effect for each treatment was determined.

A_{50} with/no medet:	fentanyl	morphine	meperidine	medet.
TF i.v. (mg/kg)	.0017/.0031	.183/1.54	.093/1.66	0.034
HP i.v. (mg/kg)	.0027/.0072	.42/4.73	.179/3.23	0.042
TF i.t. (µg)	.158/1.20	.104/1.37	4.75/432	3.06
HP i.t. (µg)	.535/1.59	.351/.72	20.1/none	13.7

Medet consistently increased the potency of each opiate tested. Isobolographic analysis indicated that the interaction between medet and the opiates was synergistic for spinal reflexes when given i.t. and was additive otherwise.

78.2

HIGHLY POTENT INHIBITORY EFFECTS OF 5-HT_3 ANTAGONIST, GR38032F, ON DEFEAT ANALGESIA IN MALE MICE. R.J. Rodgers, J.K. Shepherd* and J.I. Randall*, Department of Psychology, University of Bradford, BD7 1DP, U.K.

Social defeat in male mice is associated with an acute non-opioid form of analgesia. Behavioural and pharmacological studies have strongly suggested that anxiety is a critical factor in the generation of the reaction (Rodgers R.J. and Randall J.I., Psychopharmacology 96: 45, 1988). In this context, recent evidence indicates that selective 5-HT_3 receptor antagonists exert highly potent anxiolytic effects in rodents and primates (Jones B.J. et al., Br. J. Pharmacol. 93: 985, 1988). In the present study, we assessed the effects of one such compound, GR38032F, on basal nociception and defeat analgesia in male DBA/2 mice. GR38032F was studied over the dose range 0.00001-1000 microgm/kg, and administered 45 min before testing. Results show that, while devoid of intrinsic effects on the tail-flick assay, GR38032F potently inhibited the analgetic consequences of social defeat. Total inhibition was evident over the range 1.0-1000 microgm/kg; partial inhibition at 0.0001-0.1 microgms/kg; lower doses were ineffective. These data suggest that 5-HT_3 receptor mechanisms are involved in the mediation of defeat analgesia and further support the putative anxiolytic potential of this compound.

We thank Glaxo Group Research for the gift of GR38032F. This work was supported by a YRHA research grant.

78.3

STIMULATION OF NUCLEUS RAPHE MAGNUS (nRM) REDUCES THE NUMBER OF LUMBAR SPINAL CORD NEURONS DEMONSTRATING *FOS* ONCOPROTEIN-LIKE IMMUNOREACTIVITY FOLLOWING NOXIOUS HEAT STIMULATION OF THE FOOT IN THE RAT. A.R.Light and S.L.Jones. Dept of Physiology, UNC-Chapel Hill, Chapel Hill, NC 27599-7545

The proto-oncogene *c-fos* is expressed by lumbar spinal cord neurons following noxious stimulation of the hindlimb (Hunt, 1987). In the present study we confirmed the presence of *fos*-oncoprotein-like immunolabeling in the nuclei of lumbar spinal grey neurons following noxious heat stimulation of the foot of sodium pentobarbitol-anesthetized rats. The foot of the rat was stimulated with a feedback controlled thermal stimulator. The probe was placed in contact with the plantar surface of the foot, and the probe was heated rapidly to 70°C. Stimulation was terminated when a flexion reflex was evoked. After 10-20 repetitions, the rat was allowed to survive for four hours, following which it was perfused with paraformaldehyde. The lumbar cord was removed, cut transversely with a vibratome into 50µm thick sections and reacted for *fos*-immunoreactivity with an antibody to *fos* proteins (Cambridge). In addition, we demonstrated that stimulation in nRM at an intensity sufficient to inhibit flexion reflexes evoked by noxious heat did not lead to *fos* immunolabeling in the spinal grey. However, nRM stimulation did cause a 50% reduction in the number of neurons demonstrated by *fos*-immunolabeling following noxious heat stimulation of the rat's foot. Supported by PHS grants #DA04420, #DA05341, and #NS16433.

EFFECTS OF OPIOIDS ON PHYSIOLOGICALLY CHARACTERIZED SUPERFICIAL DORSAL HORN NEURONS IN THE CAT. S.L. Jones, M.J. Sedivec and A.R. Light. Department of Physiology, University of North Carolina, Chapel Hill, NC 27599.

The mechanism(s) and site(s) of action of opioids and opioid peptides are not clearly understood. The objectives of the present study were 1) to determine the effects of opioids and opioid peptides applied locally via microiontophoresis on physiologically characterized laminae I and II dorsal horn neurons and 2) to examine the morphological characteristics of dorsal horn neurons influenced by opioids after intracellularly filling them with horseradish peroxidase. Pentobarbital-anesthetized and decerebrate, spinally transected cats were used. In the absence of spontaneous unit activity, the excitatory amino acid, DL-homocysteic acid (DLH), was used to evoke background unit activity. In pentobarbital-anesthetized cats, morphine (MOR) produced mixed effects on DLH-evoked unit activity; to date, 22/45 units were inhibited, 12/45 were excited and 11/45 were unchanged. Similarly, naloxone (NALO) inhibited 24/36 units, excited 4/36 units and produced no change in the DLH-evoked unit activity of 8/36 units. In decerebrate, spinally transected cats both MOR and DAGO (μ agonist) inhibited DLH-evoked activity in the majority of units examined to date(7/9 units); 2/9 units were excited. Whether MOR, DAGO or NALO exert excitatory or inhibitory influences on DLH-evoked unit activity does not appear to depend on the modality or morphological characteristics of the dorsal horn neuron. Supported by DA04420 and DA05341.

DESCENDING INHIBITION ON SPINAL NEURONS WITH INPUT FROM NORMAL AND ACUTELY INFLAMED KNEES IN THE CAT. H.-G. Schaible*, V. Neugebauer*, F. Cervero*, R.F. Schmidt. Physiologisches Institut der Universität, D-8700 Würzburg, F.R.G.

In order to study modifications of the descending inhibition onto the spinal cord during an inflammatory lesion in the periphery we recorded from spinal neurons with inputs from normal and acutely inflamed knee joints in chloralose-anesthetized cats. Descending inhibition was estimated from the effects of reversible cold blocks in the lower thoracic cord on the resting and evoked discharges of the spinal neurons.

The cold blocks led in most neurons with joint input to increases of background activity and enhanced responses to A- and/or C-volleys. Descending inhibition was more pronounced on neurons in the deep dorsal and ventral horn than in the superficial dorsal horn. There was a tendency in the whole sample for increased effects of the blocks on neurons with input from inflamed knees suggesting increased descending inhibition in animals with arthritis.

Continuous observation of individual neurons with joint input during developing arthritis showed directly that not only the responses of these cells to stimulation of the joint were enhanced but that descending inhibition onto most of these neurons increased as well showing up as progressive increases of background activity and/or enhanced responses to stimulation of the knee joint during cold blocks.

We conclude that during acute arthritis descending inhibition on spinal neurons is becoming more pronounced. But increase of descending inhibition is not sufficient to block enhancement of responsiveness of spinal neurons during developing inflammation.

PROPRIOSPINAL ANTINOCICEPTION INDUCED BY HETEROSEGMENTAL NOXIOUS STIMULATION BUT NOT BY SPINAL SUBSTANCE P SUPERFUSION.

M.ZIMMERMANN, J.SANDKÜHLER, Q.G.FU* & B.STELZER*
Univ. Heidelberg, II.Physiologisches Institut, 69 Heidelberg, FRG.

Propriospinal antinociceptive neurones, which inhibit nociceptive neurones some segments apart, can be activated by spinal glutamate application. We now report that noxious cutaneous stimuli may also trigger propriospinal antinociception, while superfusion of related spinal cord segments with substance P, a candidate for an excitatory neurotransmitter in nociceptive afferent nerve terminals, or bicuculline, a $GABA_A$-receptor antagonist, failed to do so.

Single dorsal horn neuronal responses to noxious skin heating were recorded in the lumbar spinal cord of pentobarbital anaesthetized cats after high cervical spinal transection. Mean heat-evoked responses of 6 of 11 neurones tested were reduced to 61.3 ± 21.2 % of control during a conditioning immersion of the ipsilateral front paw in 54°C hot water. Superfusion of the same cervical segments which processed this conditioning stimulus, or superfusion of lower thoracic or sacral spinal segments with substance P (1-100 µM) or bicuculline (0.1-10 mM) failed to likewise trigger propriospinal antinociception.

Thus, propriospinal antinociceptive neurones are apparently not tonically inhibited via $GABA_A$-receptors and spinal substance P does not mimick the effect of conditioning cutaneous noxious stimulation.

ANALGESIA FROM THE PERIAQUEDUCTAL GREY (PAG) IN DEVELOPING RATS IS REVERSED BY INTRATHECAL ADMINISTRATION OF SEROTONERGIC AND NORADRENERGIC ANTAGONISTS. L.A. Tive and G.A. Barr Biopsychology Dept., Hunter College of the City University of New York, New York, N.Y. 10021 and Dept. of Psychiatry, Albert Einstein School of Medicine, Bronx, N.Y.

To compare stimulation produced analgesia (SPA) to opiate induced analgesia (OA) mediated by the PAG, the analgesic effects of glutamate and morphine administration to this area were compared in developing rats. It was found that OA and SPA develop differentially but are present by 14 days of age. A possible explanation for the differences in development is that OA and SPA are supported by distinct bulbospinal monoaminergic systems. The goal of this study was to determine the degree to which the analgesia produced by glutamate and morphine in the PAG could be antagonized by intrathecal administration of the serotonergic antagonist methysergide and the noradrenergic antagonist phentolamine. Fourteen day old rat pups were implanted with cannulae aimed at the PAG and with intrathecal cannulae. Pups received glutamate microinjections (180 mM/0.2 µl) to the dorsal or the ventral PAG or morphine microinjections (6 µg/0.2 µl) to the ventral PAG only. PAG injections were immediately followed by intrathecal injections of either methysergide (0, 15, or 45 µg) or phentolamine (0, 15, or 30 µg) and withdrawal latencies to noxious thermal and mechanical stimuli was measured. Both morphine and glutamate produced robust analgesia that was attenuated by methysergide and phentolamine in a dose dependent manner. Phentolamine attenuated analgesia against the mechanical stimulus to a greater degree for all PAG injections. These results indicate that although there are developmental differences between OA and SPA, the analgesia resulting from morphine and glutamate administration to the PAG are supported by the same bulbospinal monoaminergic systems. Furthermore, the analgesic effects of spinal serotonin and norepinephrine may be selective for specific stimulus types.

STIMULATION OF THORACIC VAGAL AFFERENTS INHIBITS THE JAW-OPENING REFLEX IN CATS. W. Maixner, D.F. Bossut and E.A. Whitsel*. Dental Research Center, U. of North Carolina, Chapel Hill, N.C. 27514.

In the present study, we have examined the relative ability of cervical, thoracic, and subcardiac vagal afferent stimulation to modulate the jaw-opening reflex (JOR) produced by tooth pulp (TP) stimulation.

In anesthetized cats, the right maxillary TP was stimulated at 1X to 5X threshold and the JOR was recorded from the right digastric muscle. Conditioning stimuli (7 pulses: 333 Hz, 1.0 msec, 0-10 mamp) were applied to vagal segments at conditioning-test intervals (CTI's) ranging form 5 to 1000 msec.

In general, cervical and thoracic vagal stimulation inhibited the JOR at CTI's greater than 50 msec with maximum inhibition observed at 200 msec. In contrast, subcardiac vagal stimulation produced a weaker inhibition of the JOR. The relative ability of different vagal segments to inhibit the JOR was: Thoracic > Cervical >> Subcardiac.

These findings suggest thoracic vagal afferents may be the primary source of vagal afferents which modulate the JOR in the cat.

HYPERTENSION-INDUCED ANTINOCICEPTION: CHARACTERIZATION WITH RESPECT TO CENTRIFUGAL PAIN MODULATION., C.L. Thurston, & A. Randich, Dept. of Psychology, Univ. of Iowa, Iowa City, IA 52242

Previous investigators have shown that hypertension is correlated with antinociception. The purpose of the present series of experiments was to examine the antinociception produced by an acute, drug-independent, hypertension. We found that occlusion of the abdominal aorta just proximal to the renal arteries produces a pressor response (135 % control) and bradycardia (90 % control). In addition, occlusion results in antinociception as measured by the tail flick test. This antinociception is blocked by pretreatment with intrathecal phentolamine (30 ug), but not with intrathecal methysergide (30 ug) or naloxone (30 ug). Cold block applied to the spinal cord at the level of the second thoracic vertebra also prevents the tail flick suppression produced by occlusion. We also showed that sinoaortic denervation, but not bilateral vagotomy, blocks the tail flick suppression. Since lumbar spinal cord blood flow may be impaired with aortic occlusion, we are currently expanding the experiments to include forepaw and hindpaw pinch as a measure of nociception. Aortic occlusion decreases the response to pinch in both the forepaw and hindpaw suggesting that our measure of antinociception may not be a consequence of spinal ischemia. This research was supported by NIH grants NS24958, NS22966, and HL07121.

CONTRIBUTION OF SUBDIAPHRAGMATIC VAGAL AFFERENTS TO THE ANTINOCICEPTION PRODUCED BY ELECTRICAL STIMULATION OF THE CERVICAL VAGUS. S. A. Aicher, S. J. Lewis,* and A. Randich. Depts. of Psych. & Pharm., U. Iowa, Iowa City, IA 52242.

Electrical stimulation of either the dorsal or ventral subdiaphragmatic vagus produces antinociception via afferents travelling in either the right or left cervical vagus, respectively. This experiment examined the contribution of subdiaphragmatic vagal afferents to the antinociception produced by electrical stimulation of the cervical vagus. In order to completely remove subdiaphragmatic fibers from the cervical region, a unilateral subdiaphragmatic vagotomy was performed by intraneural microinjection of ricinus comminus (100 ng) into the dorsal branch of the subdiaphragmatic vagus. 72 hrs prior to testing, all animals received an i.p. injection of Fast Blue to allow visualization of intact afferent cell bodies in the nodose ganglion and confirm the vagotomy in ricin-treated rats. The minimum intensity of electrical stimulation of the right cervical vagus necessary to produce inhibition of the nociceptive tail-flick reflex was determined for each rat. There were no differences between sham- and ricin-treated groups (n=10 per group) in the ability to produce antinociception during electrical stimulation of the cervical vagus. These data indicate that although subdiaphragmatic fibers can support antinociception, they do not significantly contribute to the antinociception seen during electrical stimulation of the cervical vagus. This work supported by NIH Grants NS24958 & NS22966.

EFFECTS OF ACTIVATION OF CAROTID SINUS BARORECEPTORS (CSB) ON HUMAN PAIN RATINGS. K.-D. Kniffki, A.V. Apkarian, M.K.C. Mengel* and A. Stiefenhofer*. Physiologisches Institut, Universität Würzburg, D-8700 Würzburg, F.R.G.

In 6 female and 7 male healthy adult volunteers pain was induced by electrical tooth stimulation and by constant pressure on a 2 mm² dorsal area of a finger for 20 s. The pain thresholds (T) were determined and pain sensations were rated (R) on a 50 point category scale. The CSB were stimulated by applying negative pressure (-40 to -100 mmHg) bilaterally to the neck, starting 15 s before the application of the noxious stimulus. In control trials the electrical stimuli resulted in reproducible Ts and the mechanical stimuli evoked continuously increasing Rs. During neck suction trials the mean T as well as the magnitude of the average R were reduced as compared to control. However, clear individual differences were observed. The reductions of T and R were insignificant for 2/10 and for 3/11 subjects, respectively. The mean absolute difference in the Rs between test and control trials increased, and the mean relative difference in the Rs was constant (16%).

The data show that, for at least 20 s, activation of carotid sinus baroreceptors in most subjects results in a reduction of pain perception.

ACETYLCHOLINE (ACh), GLUTAMATE (Glu), GABA, AND ELECTRICAL STIMULATION (ES) IN THE INTERPEDUNCULAR NUCLEUS (IPN) SYSTEMATICALLY MODIFY ON- AND OFF-CELLS OF THE NUCLEUS RAPHE MAGNUS (NRM). V. Budhrani* and I.D. Hentall. Univ. Puerto Rico Med. Sci. Campus, Dept. Physiol., San Juan, 00936

To explore limbic effects on pain-modulating NRM neurons, pentobarbital-anesthetized female Wistar rats received stereotaxic microinjections of 50mM ACh, Glu, or GABA, or ES (20Hz pulse trains) in their IPN. Cutaneous hindlimb ES evoked responses in extracellularly recorded on- and off-cells in the NRM (about 70 cells in all). Brain stimulation and recording sites were corroborated histologically.

From various IPN locations, ES and Glu ($5x10^{-7}$ l) mostly inhibited off-cells and excited on-cells, but GABA ($5x10^{-7}$ l) showed mixed results. ACh (10^{-6} l), at the optimum IPN location, inhibited all off-cells and mainly excited on-cells.

Since nociception is probably reduced by off-cells and augmented by on-cells, these results fit with the reported lessened acquisition of passive learned avoidance following IPN lesions, and implicate the cholinergic habenulo-interpeduncular pathway in the amplification of pain.

SEROTONIN BLOCKS THE M-CURRENT IN HUMAN CORTICAL NEURONS. D.A. McCormick, A. Williamson, and D. Spencer. Sect. Neuroanatomy and Neurosurgery Yale Univ Sch Med, New Haven, CT

Excitability of neurons in the cerebral cortex is under the influence of ascending serotonergic and cholinergic inputs. We investigated here the postsynaptic actions of ACh and 5HT in human neocortical pyramidal neurons maintained with the *in vitro* slice technique. Tissue was a small portion of that normally removed for the treatment of intractable epilepsy.

Local application of 5HT (300 μM) resulted in three responses: 1) hyperpolarization and increase in membrane conductance. Under voltage clamp conditions (SEVC) this response reversed near E_K, and exhibited non-additivity with outward currrents induced by adenosine or the $GABA_B$ agonist baclofen and therefore probably represents an increase in potassium conductance. Local application of 8-OH-DPAT resulted in a small hyperpolarization and blocked further hyperpolarizing responses to 5-HT, indicting that the 5-HT-induced increase in potassium conductance was mediated by $5HT_{1A}$ receptors; 2) slow depolarization and decrease in input conductance. Under SEVC this slow depolarization appeared as a suppression of the M-current, which was also blocked by stimulation of muscarinic receptors. This current was not a Ca^{++} or Na^+ activated potassium current since neither intracellular injection of EGTA (500 mM) or extracellular application of TTX blocked this effect; Finally, 3) reduction in spike frequency adaptation, block of the slow afterhyperpolarization and the current which underlies it, I_{AHP} (histamine, norepinephrine, and acetylcholine also had these effects).

Serotonin, therefore, has multiple actions in human cerebral cortical neurons and these actions are shared with other putative neurotransmitters. Supported by NINCDS & Jacob Javits Center.

BETA-ADRENERGIC RECEPTOR-MEDIATED EFFECTS ON CORTICOTECTAL NEURONS. J.S. Solomon & J.M. Nerbonne. Dept. of Pharmacology, Washington Univ., St. Louis, MO 63110.

The actions of norepinephrine (NE) in the mammalian visual cortex are complex: single unit recordings during adrenoreceptor stimulation have revealed excitatory, inhibitory, biphasic and null responses. Because this variety may reflect the diversity of cell types or adrenergic receptor subtypes (α_1,α_2,β_1,β_2) in visual cortex, we are examining the effects of selective adrenergic agents on isolated corticotectal (CT) neurons from rat primary visual cortex (area 17).

To identify CT cells, fluorescent "bead" injections were made into the superior colliculus of P4-7 Long-Evans rats. Area 17 was dissociated 1-8 days later and whole-cell voltage-clamp recordings were obtained from labeled cells. Bath solution contained (mM): 140 NaCl, 10 HEPES, 5 glucose, 4 KCl, 2.5 $CaCl_2$, 2 $MgCl_2$, 1μM TTX. Pipets contained (mM): 140 KCl, 10 HEPES, 5 EGTA, 5 glucose, 3 Mg*ATP, 0.1 Tris*GTP. In 28/65 CT cells, 1 sec applications of 10μM isoproterenol (ISO), a selective β-agonist, evoked small (10-45pA) outward currents at a HP of -90 mV. The ISO-sensitive currents peaked within 1-2 sec, decayed over 10-30 sec and were attenuated ≥50% in the presence of 50μM propranolol (n=2). Similar currents were evoked in all 28 cells by 1 sec exposures to 500μM dibutyryl-cAMP. Current-voltage relations suggest that these outward current shifts result from a decrease in resting inward current due to cation influx or anion efflux; however, the participation of an electrogenic pump cannot be ruled out. These results suggest that the inhibitory effects of NE in visual cortex may be mediated by β-adrenergic receptors. (Support: NSF #BNS 8809823;NIH #5T32 GM07805)

79.3

MECHANISM OF ADENOSINE INHIBITION AND REDUCTION OF CALCIUM CURRENT. R.W. Greene, U. Gerber, D.R. Stevens & H.L. Haas*. Harvard Med. Sch./ VAMC, Brockton, MA 02401; Johannes Gutenberg-Universitat, Mainz

Endogenous adenosine (AD) tonically inhibits CA1 neurons in vitro. Application of exogenous AD either in the perfusate (50uM) or by pressure injection (1mM) was employed with intracellular recordings under voltage clamp control to examine the mechanism of the inhibition. AD increased a voltage insensitive conductance. The ratio of the AD evoked current (ΔI) to the change in conductance (ΔG) varied with the extracellular potassium ($[K^+]_o$) as predicted for a K^+ permeability change, $[K^+]_o=[K^+]_i\exp(E_m/26)\exp-(\Delta I/26\Delta G)$ where E_m is the holding potential. AD also reduced Ca^{++} currents. This reduction correlated both in time and magnitude with the increase in the AD evoked K^+ conductance (G_K). When the G_K was blocked by the replacement of Ca^{++} with Ba^{++} no reduction in Ca^{++} currents was observed.

We conclude AD inhibition is mediated by an increase in a G_K distinct from the voltage sensitive G_K elicited by carbachol, norepinephrine, opioids and serotonin. The observed reduction in Ca^{++} currents results from a shunt by the AD evoked G_K.

79.4

GLUTAMATE BLOCKS PROTEIN-KINASE C MEDIATED REDUCTION OF $GABA_A$ - CURRENTS IN HIPPOCAMPAL NEURONS.

A.Stelzer* and R.K.S.Wong (SPON: R. Miles). Department of Neurology, Columbia University, New York, N.Y. 10032.

The regulation of $GABA_A$ receptor function by protein phosphorylation was examined using acutely dissociated CA1 hippocampal neurons of adult guinea-pigs. Under whole-cell voltage-clamp recording conditions stimulators of protein kinase C (PKC) - phorbol 12-13 dibutyrate (200-500 nM) and 1-Oleolyl-2-Acetyl-rad-Glycerol (OAG; 200-400 nM) - reduced $GABA_A$-mediated chloride currents (Soc. Neurosci. Abstr. 14, 369.2). Experiments were performed at room temperature. GABA (200 μM) was applied by short pressure pulses (10-80 ms). When glutamate (50 μM) was added to the extracellular solution, the GABA-current suppressing effect of both PKC stimulators, phorbol 12-13 dibutyrate and OAG, was blocked. This action of glutamate was mimicked by glutamate analogues quisqualate and N-methyl-D-aspartate (NMDA) at similar concentrations (50 μM). The NMDA-receptor antagonist APV (50 μM) did not prevent the NMDA-mediated protection of GABA currents against PKC stimulators. It remains to be seen whether the PKC antagonizing action of glutamate and its analogues is specific for the $GABA_A$-current. Supported by grants from Klingenstein Foundation, Epilepsy Foundation of America and N.I.H.

MONOAMINES MODULATE THALAMIC NEURONAL FUNCTION THROUGH INCREASE OF A HYPERPOLARIZATION-ACTIVATED CATION CURRENT

H.-Ch. Pape and D.A. McCormick. Section of Neuroanatomy, Yale University School of Medicine, New Haven, CT 06510. (SPON: M. Schwartz)

Ascending noradrenergic and serotonergic fibers from the brainstem are involved in the control of thalamic neuronal excitability. Here we describe a new mechanism of action of norepinephrine (NE) and serotonin (5HT) in the dorsal lateral and medial geniculate nuclei of cat and guinea pig. Application of NE (0.5mM) to geniculate cells maintained in vitro resulted in a α_1-mediated decrease in K^+ conductance (McCormick & Prince, J.Neurophysiol.,59: 978,1988). Blockade of α-receptors unmasked a NE-induced slow increase in apparent input conductance at potentials negative to -60 mV that was mimicked by the ß-agonist isoproterenol (50μM) and blocked by local application of the ß-antagonist propranolol (100μM). Application of 5HT (0.3mM) elicited a similar conductance increase that was blocked by methysergide (10μM) but not propranolol. Monoaminergic responses persisted in the absence of synaptic transmission, were blocked by Cs^+ (2mM) and were unaffected by Ba^{++} (0.5mM). The block by Cs^+ suggested a enhancement of a hyperpolarization-activated cation current. Indeed, hyperpolarizing voltage pulses from a holding potential of -50mV to beyond -60 mV demonstrated a slowly developing (time constant 0.2 to 1.5 s) inward current, termed I_h. Application of NE or 5HT enhanced I_h with little change in "leak" current. Changing the extracellular concentration of Na^+ or K^+, but not Cl^-, shifted the NE/5HT-induced current in parallel to I_h on the voltage axis by an amount expected for a mixed Na^+/K^+ conductance. The NE and 5-HT induced increase in I_h may be mediated by activation of adenylate cyclase, since local application of 8-bromo-cAMP (500 μM) or forskolin (25 μM), but not 1,9-dideoxy-forskolin (100 μM), resulted in a marked and selective enhancement of I_h.

We conclude that 5HT and NE increase a hyperpolarizing-activated Na^+/K^+ current in thalamic neurons. In this way the ascending noradrenergic and serotonergic systems may inhibit the generation of rhythmic burst activity and promote the accurate transfer of synaptic inputs during increased arousal and attentiveness.

79.6

CALCIUM ACCUMULATION IN ENDOPLASMIC RETICULUM OF PURKINJE CELL DENDRITES. S.B. Andrews*, D.M.D. Landis and T.S. Reese. Lab. Neurobiology, NINDS/NIH, Bethesda, MD 20892 and Dept. Neurology, Case Western Reserve University, Cleveland, OH 44106

We have previously used electron probe microanalysis to show that cisterns of endoplasmic reticulum (ER) in dendritic spines of Purkinje cells accumulate substantial amounts of calcium in response to depolarization of parallel fiber synapses (PNAS 85:1682 (1988)). Based on evidence that the sequestered calcium was derived partly or entirely from the extracellular fluid, we suggested that it entered through ligand- or voltage-gated channels on the spine membrane. Here we examine calcium sequestration in Purkinje dendritic shafts, where cytosolic calcium is regulated by neuron-specific, voltage-gated calcium channels in the dendritic membrane (Tank et al, (1988) Science 24:773; Llinas et al, (1989) PNAS 86:1689). Electron probe microanalysis of cryosections from freshly excised, directly frozen mouse cerebellar cortex reveals that some ER in spine-bearing dendrites accumulates large amounts of calcium (mean concentration 11.2 mmol/kg dry weight) as compared with other dendritic organelles, *e.g.*, mitochondria (1.9 mmol/kg), and with the cytosolic compartment (2.6 mmol/kg). The calcium increase in dendritic ER appears to be at least as large as in spine cisterns (previously reported as 6.7 mmol/kg). While loading of dendritic ER is consistent with calcium entry through voltage-gated channels on dendritic membranes, it leaves open the route of calcium accumulation in spines. Plausible explanations are: 1) voltage-gated calcium channels are also present on the spine membrane; 2) calcium influx is directly coupled to glutamate binding to spine receptors; or 3) spine cisterns backfill by diffusion (some of these are in continuity with the dendritic ER). However calcium enters spines, the spine ER appears to be a component of a larger sequestration system which includes the ER in dendrites.

79.7

INHIBITION ON DENDRITIC SPINES AND THIN DENDRITES MAY BE INEFFECTIVE BECAUSE OF IONIC CONCENTRATION CHANGES. N. Qian and T. J. Sejnowski. Laboratory for Computational Neurobiology, The Salk Institute, P. O. Box 85800, San Diego, CA 92138

The Nernst-Planck equation for electro-diffusion was applied to axons, dendrites and spines. For thick processes (greater than 1 micron) the results of computer simulation agreed accurately with the cable model for passive conduction and for propagating action potentials. For thin processes and spines, however, the cable model may fail during transient events such as synaptic potentials. First, ionic equilibrium potentials assumed to be constant in the cable model can change and alter the driving forces for movement of ions across the membrane. Second, longitudinal diffusion, not considered in the cable model, may dominate over electrical forces when ionic concentration gradients become large. In particular, our model predicts that inhibition is effective only on cell bodies or large processes, but not on small structures such as spines and thin processes (less than 0.1 micron). Large inhibitory input on a spine head may in fact give an excitatory response, because of the shift of the reversal potential caused by large concentration changes. We suggest modifications to the cable model that lead to better agreement with the electro-diffusion model.

79.8

MUSCARINIC EXCITATION IN THE GUINEA PIG INFERIOR MESENTERIC GANGLION. T.L. Anthony* and D.L. Kreulen (SPON: P. Pickens). Department of Pharmacology, University of Arizona, College of Medicine, Tucson, AZ. 85724.

Sensory neurons (mechanoreceptors) located in the wall of the guinea pig large intestine are both cholinergic and noncholinergic. Colonic distension evokes excitatory cholinergic and noncholinergic synaptic potentials in neurons in the inferior mesenteric ganglion, the cholinergic component has been shown to be partly muscarinic in nature. Our goal was to characterize the cholinergic muscarinic responses. Intracellular recordings were made in principal ganglionic neurons through glass micropipettes (tip resistance: 45-110 Mohms). Bethanechol (100 μM), administered by pressure-ejection, elicited a slow depolarization with an average amplitude and duration of 7.2 $\pm$ 0.6 mV, 348 $\pm$ 15.9 seconds (n=6, 3 preparations). In one cell the depolarization was associated with a 27% increase in conductance. Atropine (1 μM) diminished the depolarization in 84% of cells tested without affecting the resting membrane potential. Low Na^+ (9.6 mM) caused an 40% reduction of the depolarization (n=2, 2 preparations). These results demonstrate a muscarinic depolarization which is mediated in part by sodium influx in a subpopulation of neurons in the IMG. Supported by DK36289, HL27781.

MUSCARINIC RESPONSES FROM CELIAC GANGLION NEURONS IN PRIMARY CULTURE. J.S. Coggan*, D.L. Kreulen, S. G. Matsumoto, R. Gruener (SPON: P. Consroe). Department of Pharmacology, University of Arizona, College of Medicine, Tucson, AZ. 85724.

The electrophysiologic responses of celiac ganglion neurons in primary culture to acetylcholine were investigated. Neurons dissociated from adult guinea pigs were incubated in serum-containing medium (modified MEM, CO_2) for 30 days prior to recording. Intracellular recordings of E_m, spike amplitude, after spike hyperpolarization, time constant, and rheobase, were similar to those found in whole ganglion. Superfusion of acetylcholine (10 μM) evoked slow depolarizations with superimposed bursts of action potentials (20-30 per cluster). These depolarizations could be distinguished from one another by their amplitude, duration and burst content and each neuron gave one characteristic response. In 10 neurons the depolarizations ranged from 8-20 mV and were from 4-8 min in duration. Each response was abolished by atropine (1μM), but none was sensitive to hexamethonium (500μM). In 1 cell low Ca^{2+}/high Mg^{2+} had no effect on the depolarization. These results suggest that there are cell subtypes in the celiac cultures each with a characteristic muscarinic response. Support: DK36289, HL27781, NS25644.

SUBSTANCE P INCREASES $[Ca^{2+}]_i$ IN DORSAL HORN NEURONS VIA TWO DISTINCT MECHANISMS. M.D. Womack*, A.B. MacDermott, and T.M. Jessell. Center for Neurobiology and Behavior and Howard Hughes Medical Institute, Columbia University, New York, NY 10032.

Substance P (SP) functions as a transmitter at primary afferent terminals in the dorsal horn of the spinal cord. However the mechanisms by which SP regulates the excitability of dorsal horn neurons (DHN) is not understood. To address this question, we have monitored the effects of SP on the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) of acutely dissociated postnatal rat DHN using the Ca^{2+} indicator fura-2. SP (>/= 1 nM) evoked increases in $[Ca^{2+}]_i$ in 25% of DHN. In about half the SP-sensitive DHN (type E), responses to SP were inhibited by 0.5 mM $LaCl_3$ or in Ca^{2+}-free medium indicating that the increase in $[Ca^{2+}]_i$ is dependent on the entry of extracellular Ca^{2+}. SP responses in type E neurons were also blocked by TTX (0.5 μM) suggesting that SP promotes Ca^{2+} entry via voltage-dependent Ca^{2+} channels. In the remaining SP-sensitive DHN (type R), SP-evoked increases in $[Ca^{2+}]_i$ were detected in the presence of $LaCl_3$ or in Ca^{2+}-free medium indicating that SP promotes Ca^{2+} release from an intracellular store. Caffeine-sensitive Ca^{2+} stores were found in 30% of type R neurons and in 95% of type E neurons. In type R neurons, depletion of caffeine-sensitive stores did not abolish subsequent SP-evoked increases in $[Ca^{2+}]_i$, however the release of $[Ca^{2+}]_i$ by SP abolished subsequent caffeine-induced responses. The SP-sensitive Ca^{2+} stores are therefore at least partially distinct from caffeine-sensitive Ca^{2+} stores. In both type R and type E neurons, responses to SP were mediated by the NK1 class of tachykinin receptors. Thus, the same class of tachykinin receptors regulates $[Ca^{2+}]_i$ by two distinct mechanisms in different populations of DHN.

79.11

PROCTOLIN AND ACETYLCHOLINE ACTIVATE A VOLTAGE-DEPENDENT INWARD CURRENT IN MOTONEURONS OF THE LOBSTER CARDIAC GANGLION. J.E. Freschi and D.R. Livengood. Neurology Dept., Emory Univ. Sch. of Med., Atlanta, GA 30322.

We used the two-electrode voltage clamp technique to study the ionic basis of the slow depolarization caused by the neuropeptide proctolin and by muscarinic cholinergic agonists on motoneurons in the cardiac ganglion of the lobster, Homarus americanus. Both proctolin (10 µm and muscarinic agonists (e.g., methacholine, 1 mM) caused a dose-dependent slow inward current. The agonist-induced current was voltage-dependent: with membrane hyperpolarization the response declined; with membrane depolarization up to 0 mV the response enlarged. With further depolarization the agonist-induced current declined and then reversed at potentials around +20 mV. The response to proctolin and muscarinic agonists depended on $[Na]_o$, and was blocked in Na^+-free solutions. The response also varied with $[K]_o$, but did not show a strong dependence on this ion. Various blockers of Na^+, K^+, and Ca^{++} channels did not appreciably affect the evoked current, nor did changes in E_{Cl}. In summary, the agonist-induced current reversed at positive membrane potentials, strongly depended on $[Na]_o$, and remained inward at membrane potentials negative to E_K. These data indicate tht both proctolin and acetylcholine activate a voltage-dependent inward current that is mainly carried by Na^+.

79.12

SYNAPTIC VARIABILITY OF FOUR-CELL NETWORKS IN THE BUCCAL GANGLIA OF *APLYSIA*. Daniel Gardner. Department of Physiology and Biophysics, Cornell University Medical College, New York NY 10021.

Identified neurons of *Aplysia* ganglia permit recording from several cells in parallel and analyzing differences between similar cells, as well as between the same cells in different individuals. In buccal ganglia, paired presynaptic neurons B4 and B5 each produce inhibitory postsynaptic conductances (PSCs) in several neurons. Synaptic efficacy here depends upon peak conductance (g_{peak}) and decay time constant (τ), each of which is readily determinable and independent of V_m. Previous work in these ganglia analyzed variability at single synapses and in 3-cell networks. I now report data obtained by simultaneous recording from the 4-cell network of B4, B5, and a pair of common postsynaptic cells, with four similar inhibitory synapses whose g_{peak} averaged 0.43 µS and τ = 25 ms. Sequential stimulation of B4 and B5 gives 4 PSCs; pairing by common presynaptic or postsynaptic cell, or cross-pairing, yields 6 comparisons, in which similarities within pairs suggest general presynaptic or postsynaptic determinants of efficacy, while lack of paired similarity implies synaptic independence. I compared both individual PSCs and their means at each synapse.

PSC-TO-PSC COMPARISON: Cross-correlograms of PSC amplitude compare fluctuations between sequences of PSCs paired by pre- or postsynaptic neuron. Correlation of PSCs from the same presynaptic neuron is significantly greater than unpaired, both with ($\rho(0)$ = 0.87 paired, 0.01 unpaired; $P < 0.001$) and without ($\rho(0)$ = 0.56 paired, 0.26 unpaired; $P < 0.05$) deliberate presynaptic modulation.

SYNAPSE-TO-SYNAPSE COMPARISON: Each synapse is summarized by its mean g_{peak} and τ, permitting synapse-to-synapse comparisons. Both g_{peak} and τ of synapses sharing a common postsynaptic neuron are significantly more similar (P = 0.0001) than synapses unpaired by pre- or postsynaptic neuron. Correspondingly, postsynaptically-paired $|\log(g_{peak}/g_{peak})|$ and $|\log(\tau/\langle\tau\rangle)|$ are less than half the unpaired case. In contrast, pairing the same data by common presynaptic neuron reveals no similarity, and log ratios are no smaller than the unpaired case.

I conclude that similarities of synapses on the same postsynaptic neuron are consistent with a postsynaptic site for long-term specificity of synaptic efficacy, while similar fluctuations of PSCs produced by the same presynaptic neuron suggest short-term variability is presynaptically specified.

DO HALOPERIDOL AND SWIM STRESS ACT THROUGH A COMMON MECHANISM IN INTERMEDIATE LOBE POMC REGULATION? E.A. Young, D.M. Bronstein and H. Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

Thirty minutes of swim stress at 30°C is accompanied by release into plasma of NAcβ-endorphin$_{1-31}$ from the intermediate lobe of the rat. Previous work had demonstrated that this release can be antagonized by apomorphine, a dopaminergic agonist. When administered for 30 minutes daily for 14 days, swim leads to an increase in POMC mRNA and an increase NAcβ-endorphin-IR in the intermediate lobe as well as a two-fold increase in plasma levels of NAcβ-endorphin.

To explore dopaminergic regulation, rats were given both apomorphine and haloperidol in conjunction with swim. Daily apomorphine had no effect on intermediate lobe NAcβ-endorphin content or on plasma levels of NAcβ-endorphin. Daily apomorphine concurrent with daily swim stress did not antagonize the swim stress induced increase in NAcβ-endorphin stress. However, apomorphine induced down-regulation of dopaminergic receptors cannot be excluded. Studies with haloperidol indicated that both chronic haloperidol and chronic swim stress lead to a 30% increase in NAcβ-endorphin stores. There were no further increases in the swim stress plus haloperidol group. POMC mRNA levels in the intermediate lobe of these same animals demonstrated a 1.8-fold increase in POMC mRNA levels in the chronic swim and chronic haloperidol groups. The combined haloperidol and swim group demonstrated a 2.8-fold increase in POMC mRNA levels. The mRNA data suggest that these two stressors are acting through independent mechanisms. Studies are currently underway evaluating why this increased mRNA level in the haloperidol swim group does not lead to a greater increase in peptide stores.

80.2

CHRONIC HALOPERIDOL ALTERS REGIONAL B-ENDORPHIN METABOLISM IN THE RAT BRAIN. T. P. Davis and T. J. Gillespie* Dept. of Pharmacology, Univ. of Arizona, Health Sciences Center, Tucson, AZ 85724.

Our laboratory has previously shown that chronically administered haloperidol (HL) can alter the in vitro metabolism of B-endorphin (B-E) and neurotensin (NT) by twice washed, whole rat brain homogenates or purified synaptosomal membranes leading to the accumulation of behaviorally active peptide fragments. The present study examined the effect of chronic haloperidol on the regional metabolism of B-E by using rat brain micro slices from caudate putamen, nucleus accumbens, hypothalamus and hippocampus. Male Sprague-Dawley rats (189-236g) were dosed I.P. for 9 days with HL (3mg/kg/day) or vehicle. Rats were sacrificed and the brain was sliced into 2mm coronal slabs using a rat brain matrix. Caudate putamen and n. accumbens were stereotaxically identified and micropunched (2mm). Hippocampus and hypothalamus were also dissected and 2mm punched. Punches were sliced to a thickness of 250u, using a newly developed tissue slicer and time-course incubated with B-endorphin (43uM) for 0 to 240 minutes. B-endorphin remaining and major peptide fragments produced were isolated and identified by amino acid analysis after HPLC. Major B-E fragments formed were B-E 1-17, 18-31, 2-17, 1-18, and 2-18. B-E half-lives for vehicle treated rats versus HL treated rats were: hypothalamus 603 vs. 485 mins., hippocampus 281 vs. 137 mins., n. accumbens 360 vs. 332 mins., and caudate putamen 367 vs. 462 mins. These data agree with our previous studies of NT in whole brain which showed a shorter half-life for HL treated rats. In contrast, the accumulation of specific behaviorally active fragments was significantly lower in HL treated rats. Since brain slices retain a greater degree of morphology, metabolic properties and intact physiological systems than homogenates, these data suggest that HL can selectively alter the half-life of B-E in specific brain regions of the rat leading to a shift in peptide fragment accumulation. (Supported by NIMH Grant 42600).

80.3

EFFECT OF PEPTIDE STRUCTURE ON PEPTIDE DEGRADATION:DES-ENKEPHALIN-γ-ENDORPHIN (DEγE) METABOLISM BY RAT BRAIN SLICE. Z.W. Li*, K. Brendel* and T. P. Davis (Spon: R. Gruener). Dept. of Pharmacology, Univ. of Arizona, Health Sciences Center, Tucson, AZ 85724.

The enzymatic metabolism of Des-enkephalin-γ-endorphin (DEγE) and its cyclized analogue [cyclo-6α-Glu^{11}]-6-17 was examined by using regionally dissected rat brain slice time-course incubation in vitro. DEγE has been shown to have antipsychotic activity that mimics classic neuroleptic drugs, but does not cause extrapyramidal side effects. However, the rapid in vivo degradation of DEγE limits its clinical use. Therefore, cyclo-DEγE was synthesized by Organon Sci. Dev. Group (Oss, Netherlands) in an attempt to improve resistance to enzymatic degradation. Peptide metabolism was studied by time-course incubations with rat brain regions. The half-life of DEγE was 110.6 min vs 59.3 min for [cyclo-6α-Glu^{11}]-6-17 in caudate-putamen, nucleus accumbens was 183.6 min vs 129.1 min, hypothalamus was 161.7 min vs 209.3 min, and hippocampus 154.9 min vs 118.4 min, respectively. In addition, there were 4 major peptide fragments formed from DEγE metabolism, and 2 from [cyclo-6α-Glu^{11}]-6-17. The data imply a structural effect on peptide degradation. Since both peptides incubated yielded their shortest half-lives in caudate-putamen and the longest half-lives in nucleus accumbens (DEγE) and hypothalamus ([cyclo-6α-Glu^{11}]-6-17), the data also suggest a regional specificity of enzyme population, which has been confirmed in our laboratory by measuring levels of endopeptidase 24.11, 24.15 and aminopeptidase. Slice viability was also examined by measuring ^{3}H-GABA uptake and release. The results showed that ^{3}H-GABA uptake and release was maintained stable for at least 5 hr. The data demonstrate that the brain slice technique is a valid and unique approach for studying peptide structure dependent metabolism, but cyclization of DEγE does not improve enzymatic stability except in the hypothalamus. AN ECTOENZYME FORM OF ENDOPEPTIDASE-24.15 RAPIDLY DEGRADES INTRAVENTRICULARLY (ICV) ADMINISTERED DYNORPHIN A-(1-8). C.J. Molineaux and J. Ayala.* Department of Pharmacology, Mount Sinai School of Medicine, CUNY, New York, NY 10029.

Aminopeptidases, angiotensin converting enzyme, and EP-24.11 ("enkephalinase") contribute to the rapid degradation of ICV injected leu- (LE) and met-enkephalin (ME). The larger LE and ME containing peptides such as the dynorphin (Dyn)-like peptides, and ME-Arg-Gly-Leu are more resistant to the actions of these enzymes, but are excellent substrates of the enzyme endopeptidase-24.15 (EP-24.15), being rapidly converted to LE or ME by purified enzyme in vitro (Chu and Orlowski,Endocrinol. 116: 1418,1985). In the present studies, cannulae were placed in the lateral ventricle of urethane-anesthetized rats, and peptides were administered in the presence or absence of the EP-24.15 inhibitor N-[1-carboxy-3-phenylpropyl]-Ala-Ala-Phe-pAB (cFP-AAF-pAB). The concentration and identity of Dyn-like peptides within the CSF was then monitored by RIA and HPLC in CSF taken from the cisterna at various times. When Dyn A-(1-8) was administered ICV in the presence of cFP-AAF-pAB, the CSF concentration of the ir-Dyn A-(1-8) after 5 min was found to be 40 times higher when compared with administration of Dyn A-(1-8) alone. The inhibitor of EP-24.15 also afforded protection of full length Dyn A and of α-neo-endorphin, but was of a smaller magnitude, corresponding to the affinity (K_m) of the enzyme for each peptide. No EP-24.15 activity was found in rat CSF. Taken together, these data clearly indicate that an ectoenzyme form of EP-24.15 rapidly converts ICV-administered Dyn-like peptides within the extracellular spaces of the brain. This work was supported by NIDA grant DA04218.

ENKEPHALIN PRECURSOR PROCESSING ENZYME ACTIVITY IN BOVINE CHROMAFFIN GRANULES: DIFFERENTIAL PROCESSING IN VITRO. V.Y.H. Hook, D. Hegerle*, and H.-U. Affolter*+.(SPON: N.Lee). Dept. of Biochem., Uniformed Services University, Bethesda,MD.,&Brain Research Institute, Univ. of Zurich.

The processing enzyme(s) responsible for conversion of proenkephalin to intermediates and small active opiate peptides has not been definitively identified. The lack of available enkephalin precursor for use as substrate has hindered progress in this area. Using authentic substrate ^{35}S-(Met)-prepro-enkephalin (PPE), synthesized from the rat PPE cDNA by in vitro transcription with SP6 polymerase (cDNA in Riboprobe vector) followed by cell-free translation of the PPE mRNA, we have identified enkephalin precursor processing activity in purified bovine chromaffin granules. PPE products generated in vitro were similar to known endogenous enkephalin intermediates present in bovine chromaffin granules. The pH optimum was 4.5 and there was no activity at pH 7.0 or above. Different PPE-derived products were formed at pH 4.5-5.0 compared to pH 5.5-6.0. In addition, stimulation of activity by DTT resulted in the formation of different enkephalin products. The differential processing of PPE seen in vitro suggest that pH, reducing conditions, and perhaps other factors may regulate the extent of enkephalin precursor processing, which can vary from tissue to tissue. Inhibition by pepstatin and stimulation by DTT show that aspartyl and thiol-dependent proteolytic activity is responsible for enkephalin precursor processing.

80.6

ENKEPHALIN AND TACHYKININ PRECURSORS ARE CLEAVED BY SPECIFIC PROCESSING ENZYME ACTIVITIES IN BOVINE CHROMAFFIN GRANULES. T.J. Krieger*, H.-U. Affolter*+, and V.Y.H. Hook. Dept. of Biochem., Uniformed Services University of the Health Sciences, Bethesda, MD. and +Brain Research Institute, University of Zurich.

Bovine chromaffin granules contain prohormone processing enzyme activities that cleave ^{35}S-(Met)-preproenkephalin (PPE) and ^{35}S-(Met)-preprotachykinin (PPT) into appropriate products. Purification of these activities present in the soluble component of these granules was initiated. Conconavalin-A Sepharose bound both PPE- and PPT-cleaving activities. Two distinct activities were then separated by size exclusion on Sephacryl S200. The first peak cleaves both PPE and PPT. The second peak cleaves PPT, but not PPE under the conditions employed. The PPE-cleaving activity was further purified on thiopropyl Sepharose at pH 5.0. It was completely inactivated during the purification, but was reactivated by treatment with DTT, suggesting that it is a thiol protease. This PPE-cleaving activity exhibits a pH optimum at 6.0 and is strongly inhibited by leupeptin and chymostatin. In contrast, PPT-cleaving activity exhibits a pH optimum of 5.0 and is inhibited by pepstatin indicating that it is an aspartyl protease. These preliminary studies show that at least two distinct proteases with substrate selectivity are involved in chromaffin granule prohormone processing.

80.7

NOVEL SUBSTRATES AND INHIBITORS FOR PEPTIDYLGLYCINE a-AMIDATING MONOOXYGENASE: IMPLICATIONS FOR THE MECHANISM OF ACTION. A.G. Katopodis and S.W. May, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332.

Peptidylglycine a-amidating monooxygenase (PAM; EC 1.14.17.3) is a copper and ascorbate requiring monooxygenase, responsible for the bio-activation of numerous neuropeptides by catalyzing the cleavage of a C-terminal glycine to produce the active amidated peptide. The mechanism of action of PAM is of great interest, because of the attractiveness of this enzyme as a target for effectors, and because of its similarities to dopamine beta hydroxylase (DBH). We now report that N-benzoyl glycine and several p-substituted derivatives are substrates for purified PAM, producing the corresponding benzamides and stoichiometric amounts of glyoxylic acid in a copper and ascorbate dependent manner. Km for N-benzoyl glycine is 7 mM, and Vmax is about 1/3 of that for the tripeptide trinitrophenyl-D-Tyr-Val-Gly. The oxygen analog 4-methoxy benzoxy acetic acid, however, is not a PAM substrate and is instead a good competitive inhibitor exhibiting a Ki of 0.6 mM. Thus, while 4-methoxy-N-benzoyl glycine is a good PAM substrate, the ester analog cannot be oxidized by this enzyme, suggesting that the amide nitrogen is essential for turnover. S-(4-nitrobenzyl)-2-thioacetic acid is also a PAM substrate producing the corresponding sulfoxide product. In addition a-dideuterio 4-nitro-N-benzoyl glycine exhibits a high deuterium isotope effect on apparent Vmax, which is similar to that reported by others for a tripeptide substrate. Our results therefore suggest, that while alpha C-H bond cleavage contributes substantially to the rate determining step in catalytic turnover, this step is not the initiating step in the mechanism of action of PAM.

80.8

CHARACTERIZATION OF HIGH AFFINITY DIGITONIN-SOLUBILIZED CORTICOTROPIN-RELEASING FACTOR (CRF) RECEPTORS IN RAT CEREBRAL CORTEX. D.E. Grigoriadis, D. Pearsall*, and E.B. De Souza. Neurobiology Lab., NIDA Addiction Research Center, Baltimore, MD 21224.

Corticotropin-releasing factor (CRF) is the primary physiologic regulator of proopiomelanocortin-derived peptides from the pituitary. In addition, CRF has been identified as a neurotransmitter in the central nervous system where it acts to coordinate the endocrine, autonomic and behavioral responses to stress. CRF receptors have been characterized in both brain and pituitary membrane homogenates and found to have identical binding characteristics but different molecular weights. In this study, we have determined the binding characteristics of CRF receptors in rat frontal cerebral cortex membranes solubilized in 1% digitonin. The binding of ^{125}I-Tyr^{0}-oCRF (^{125}I-oCRF) to solubilized membrane proteins was dependent on incubation time, temperature, and protein concentration, was saturable and of high affinity. The solubilized receptors retained their high affinity for ^{125}I-oCRF in the solubilized state exhibiting a dissociation constant (K_D) of 200 pM as determined by direct binding saturation isotherms. Association/dissociation kinetics also revealed high affinity binding of ^{125}I-oCRF with a calculated K_D of 50 pM. Solubilized CRF receptors maintained the rank order of potencies for various related and unrelated CRF peptides characteristic of the membrane CRF receptor: r/h CRF ≥ oCRF ≥ Nle^{21,38} r/hCRF > α-helical(9-41)oCRF > oCRF(7-41) >>> VIP, AVP or substance P antagonist. Interestingly, the absolute potencies (K_i) for the various CRF-related peptides were almost identical to those observed in the membrane preparations suggesting that the CRF receptor retains its high-affinity binding capacity in the digitonin-solubilized state.

DISULFIRAM, A METAL CHELATOR, LOWERS BRAIN CONCENTRATIONS OF CHOLECYSTOKININ OCTAPEPTIDE (CCK-8). G.P. Mueller, A. Singh* and P.A. Deuster*. Depts. of Physiology and Military Medicine, Uniformed Services University of the Health Sciences, Bethesda, Maryland 20814.

Evidence that metals control gene expression and enzyme activities in vitro indicates that these metals probably have essential roles in the synthesis of peptide neurotransmitters in vivo. In this study we sought to determine if concentrations of CCK-8, an abundant neuropeptide in brain, are altered by the administration of disulfiram, a recognized metal chelator. Groups of male rats received daily injections of disulfiram (400 mg/kg, sc) for 1,3,7 or 10 days. Plasma levels of Zn were reduced ($p<0.05$) by 28% and 32% after 3 and 10 days treatment, respectively. Plasma Cu and Mg concentrations were not altered as markedly as Zn. Concentrations of immunoreactive CCK-8 in cerebral cortex, hippocampus and whole brain were significantly reduced ($p<0.05$) by disulfiram with a maximal 44% decrease observed in the hippocampus by 7 days. Gel filtration chromatography revealed that virtually all of the immunoreactivity resembled CCK-8 in molecular size. This suggests that disulfiram preferentially inhibits transcription of the CCK gene and/or translation of CCK mRNA rather than inhibiting the enzymes involved in the posttranslational processing of pro-CCK. This effect of disulfiram may reflect its ability to chelate Zn or other metals involved in the processes of transcription or translation. (Supported by USUHS grant RO 7644 to GPM)

80.10

MICRODIALYSIS OF CCK AND NEUROTENSIN IN THE RAT BRAIN: PRACTICAL CONSIDERATIONS AND PRELIMINARY RESULTS. N.T. Maidment*, D.R. Brumbaugh*, E. Erdelyi*, Y.D. Rudolph*, J.D. Barchas and C.J. Evans. (SPON: K.F.Faull). Pritzker Laboratory, Dept. of Psychiatry, Stanford University School of Medicine, Stanford, CA 94305.

We have previously demonstrated the feasibility of using microdialysis to monitor opioid peptide release in the rat globus pallidus/ventral pallidum (Maidment et al., Soc.Neurosci. Abstr.1988). The present study is directed towards the development of a system for measuring extracellular levels of CCK and neurotensin in the mesocorticolimbic system of the rat. The recovery of radiolabelled forms of these peptides across several types of dialysis membranes was assessed in solution. Polyacrylonitrile membranes (4mm) exhibited recoveries of approx. 8% and 5% for CCK-8 and neurotensin respectively at a flow rate of 2.7μl/min. A novel and highly sensitive radioimmunoassay was developed which enables the serial measurement of sub-fmol quantities of CCK-8 and neurotensin in the same sample. The assay takes place on solid phase with antibody bound via protein G to 96-well plates. This results in negligible non-specific binding such that at the end of the CCK-8 assay the samples can be transferred to a second plate for assay of neurotensin. Preliminary in vivo experiments in the medial nucleus accumbens suggest that basal extracellular concentrations of these peptides are at the limit of detection of the assay and that these levels are elevated by incorporation of high potassium in the perfusion medium.

80.11

POSTTRANSLATIONAL PROCESSING PRODUCTS OF DBI IN HUMAN BRAIN. P. Guarneri*, M.L. Barbaccia[1], E. Costa and A. Guidotti. FGIN, Georgetown Univ., Wash., DC 20007, [1]Dep. Exp. Med., 2nd Univ. Rome Med. School, Italy.

DBI (diazepam binding inhibitor) is an endogenous polypeptide present in rat and human brain. In rat brain the polypeptide (86 residues) is posttranslationally processed into at least two fragments biologically active at different $GABA_A$ receptor subtypes (DBI 17-50 and DBI 32-50). In human brain, tryptic digestion of DBI (104 residues) yields DBI 51-70 (ENP) having high homolgy with rat DBI 32-50 (ODN). We monitored the emergence from reverse phase HPLC of DBI posttranslational processing products in post-mortem human brain extracts with an antibody raised in rabbits against synthetic ENP. Six peaks of ENP-like immunoreactivity were identified; one of them corresponded to ENP itself suggesting that like rat ODN, ENP might naturally exist in human brain and might possess a similar biological activity. PAGE analysis of the other ENP-like immunoreactivities revealed that one of them has a molecular weight of approximately 8kDa and the others appear to have a similar size (3-4kDa). All these ENP-like immunoreactivites were observed in CSF suggesting that they are natural processing products of DBI. Similar to ENP, at least three of these peaks could be obtained by in vitro tryptic digestion of DBI. By using antibodies directed against the synthetic peptides DBI 37-50 and DBI 81-100, we suggest that the 8kDa fragment may include DBI 37-100, while the other 3-4kDa peptides might include DBI 37-80. These inferences are being verified by amino acid sequencing.

80.12

BRADYKININ-EVOKED RELEASE OF CALCITONIN GENE-RELATED PEPTIDE (CGRP) AND SUBSTANCE P (SP) FROM CULTURED VAGAL SENSORY NEURONS: INHIBITION BY INDOMETHACIN. D.B. MacLean and L. Hayes*. Endocrinology Div. Brown Univ. Rhode Island Hospital, Providence, RI 02903.

In this study, the effect of bradykinin (BK) on neuropeptide release from cultured vagal sensory neurons was further characterized. Neonatal rat vagal sensory ganglia were enzymatically dispersed and maintained in L-15, 10% FBS and NGF. Release studies were performed in KRB, 1% FBS and 5mM captopril between 10-20d in culture. Peptides were measured by RIA. 35mM K+ and 1 uM capsaicin evoked SP and CGRP release 6-8 times basal release, i.e. 8-10% of total peptide content during 15-20 min epochs. BK, maximum effect at .01uM, evoked release 2.5-4x basal, similar to phorbol ester (3-5x basal) and forskolin (2-3x). Cobalt, 3.5 mM, blocked K+ and capsaicin-evoked release, whereas the response to BK was not reduced. Pertussis toxin, lug/ml for 16h, had no effect on basal or BK-stimulated CGRP release but increased SP release by 40-50% ($P<.01$). Prior (20 min) and concurrent exposure to indomethacin, 10uM, did not affect basal release but abrogated BK-evoked release of both peptides by 70-80%. In preliminary studies, indomethacin did not block CGRP release (2x basal) by prostaglandin E1. Conclusion: BK evokes submaximal release of CGRP and SP from cultured vagal neurons by pathways independent of extracelluar Ca^{++} flux and may be mediated by prostaglandins.

81.1

LOCALIZATION OF ENDOTHELIN-1 MRNA AND IMMUNOREACTIVITY IN NEURONS OF BRAIN, SPINAL CORD AND DORSAL ROOT GANGLIA IN MAN

A. Giaid*, S. Gibson*, [3]N.B.N. Ibrahim*, [1]S. Legon*, [2]S.R. Bloom*, [4]M. Yanagisawa*, [4]T. Masaki*, [5]I.M. Varndell* and J.M. Polak.

Depts. of Histochemistry, [1]Chemical Pathology and [2]Medicine, RPMS, London, W12 ONN, U.K.; [3]Dept. of Histopathology, Frenchay Hospital, Bristol BS16 1LE, U.K.; [4]Institute of Basic Medicine and Sciences, University of Tsukuba, Tsukuba, Ibaraki 305, Japan; [5]Cambridge Research Biochemicals Limited, Cambridge CB2 5NX, U.K.

Endothelin is a 21 amino acid peptide recently isolated from the supernatant of porcine aortic endothelial cell cultures. The localization of endothelin-1 mRNA and endothelin-like immunoreactivity was investigated in ten cases of neurologically normal human nervous system (4-7 h post-mortem) using in situ hybridization and immunocytochemistry. Following hybridization with a ^{35}S-complementary (c) RNA human endothelin-1 probe, positively labeled neurons were present in the spinal cord, in laminae IV-VI, thoracic intermediolateral cell columns, with considerably denser labeling in laminae IX, where many motoneurons expressed endothelin transcripts. Sensory neurons of both large and small size were labeled after hybridization in the dorsal root ganglia. In the brain, labeled neurons were seen in laminae III-VI of the frontal and parietal cortices, the hypothalamus and in the Purkinje cell layer of the cerebellum. Antisera raised to endothelin revealed a similar distribution of endothelin-immunoreactive neuronal cell bodies, but fewer positively stained cells were seen when compared with the hybridization. In the motoneurons and dorsal root ganglia, endothelin and CGRP mRNAs or their respective immunoreactivities were often colocalized. In addition a subset of dorsal root ganglion cells coexpressed endothelin and ß-preprotachykinin mRNAs or endothelin and substance P immunoreactivities. The data provide evidence for the presence of endothelin-1 in neurons and suggests that this peptide, in addition to its known vascular-related actions, may play a part in neural transmission/modulation.

81.2

ENDOTHELIN: IN SITU HYBRIDIZATION AND BINDING STUDIES IN THE BRAIN AND PERIPHERY. M. W. MacCumber, C. A. Ross and S. H. Snyder. Neuroscience and Ophthalmology, Johns Hopkins Sch. of Med., Baltimore, MD 21205

Endothelin (ET) is a recently discovered potent vasomodulatory peptide which is synthesized by cultured vascular endothelial cells (Yanagisawa, et al. Nature 332:411, 1988). It has binding sites in the rat brain which are densest in the cerebellum (Jones, et al. Neurosci. Lett. 97:276,1989). We have examined ET synthesis by in situ hybridization and binding sites for ^{125}I-porcine ET in membrane homogenates and tissue sections. In situ experiments reveal ET message that is highest in vessels in densely vascularized organs (e.g. the lung, kidney, intestine and eye). Preliminary experiments in the brain suggest lower message levels, highest in the cerebellar granule cells and less in the thalamus and other brain regions.

The measured K_D in binding experiments is approximately 1 nM in cortex, cerebellum and heart homogenates. Binding is markedly enhanced by monovalent and divalent cations at physiologic concentrations and by low pH (optimum near 6.0). In tissue sections, the distribution of binding sites resembles that of mRNA message with the highest levels in densely vascularized tissues.

These studies suggest a vasomodulatory role for ET throughout the body and a possible neuromodulatory role in the brain.

81.3

GALANIN-LIKE IMMUNOREACTIVITY IS LOCALIZED TO THE CORTICOTROPHS OF THE HUMAN PITUITARY. D.W. Hsu*, M. El-Azouzi*, E.T. Hedley-Whyte, P.McL. Black, & L.M. Kaplan. Massachusetts General Hospital, Brigham & Women's Hospital, and Harvard Medical School, Boston, MA 02114.

Galanin is a neuropeptide which regulates the secretion of several pituitary hormones, including prolactin, GH, TSH, and ACTH. We have previously demonstrated that galanin-like immunoreactivity (Gal-IR) and galanin mRNA in the rat anterior pituitary is located primarily in GH- and prolactin-secreting cells. We examined the cellular distribution of Gal-IR in normal postmortem human pituitaries and pituitary tumors. Paraffin sections were subjected to immunoperoxidase staining using antisera directed against porcine galanin which has been shown to bind human galanin-like peptides specifically. In normal pituitaries, Gal-IR was present in scattered cells throughout the gland. Co-localization studies using antisera directed against GH, prolactin, LH, TSH, and ACTH revealed that Gal-IR is present predominantly in corticotrophs. There was no appreciable staining of other identifiable cell types. Gal-IR was also present in hyperplastic and neoplastic corticotrophs of 5/10 patients with Cushing's disease. Neoplastic pituitary cells exhibited less stringent cell-type specificity: Gal-IR was present in 4/7 GH-secreting tumors and 3/11 nonfunctioning pituitary gonadotrophic tumors. In contrast, we did not detect Gal-IR in any of 5 prolactinomas examined. These results demonstrate that the cellular distribution of Gal-IR in the pituitary is species-dependent. Its restriction to corticotrophs suggests that *human* galanin may participate in the regulation of the hypothalamic-pituitary-adrenal axis. The altered cellular distribution in pituitary adenomas suggests that galanin gene expression may also be a useful marker of pituitary cell dedifferentiation.

81.4

DISTRIBUTION OF GALANIN-LIKE IMMUNOREACTIVITY AND ^{125}I-GALANIN BINDING SITES IN THE CAT SPINAL CORD. B.Ulfhake[1*], T.Hökfelt[2], U.Arvidsson[1*], S.Cullheim[1*] and E.Theodorson[3*]. Departments of 1) Anatomy,2) Histology and Neurobiology and 3) Clinical Chemistry, Karolinska Institutet, S-104 01 Stockholm, Sweden.

The distribution of galanin(GAL)-like immunoreactivity (LI) in the lumbo-sacral spinal cord was studied by use of indirect immunofluorescence technique in normal cats and in cats subjected to chronic spinal cord transection (SCT) alone, or in combination with unilateral dorsal root (DR) rhizotomy below the SCT. GAL-LI axons in the ventral horn (VH) were most frequent in the ventral part of lamina IX. Double-labeling showed that GAL-LI coexisted with serotonin-LI in the axons of lamina IX. Following SCT, all GAL-immunoreactive(IR) fibres in lamina IX disappeared. Together, these two findings implicate that the GAL-IR fibres of lamina IX belong to the serotonergic bulbospinal pathway. In the superficial laminae of the dorsal horn (DH) a dense GAL-IR axonal plexus was present, which did not show any serotonin-LI. Furthermore, SCT did not alter the pattern of GAL-LI within this plexus. Here the vast majority of GAL-IR axonal swellings, however, disappeared following dorsal root sectioning. Small-to-medium sized GAL-IR cell bodies were found in laminae II-III, X as well as in the dorsal root ganglia (DRG). In the DRG, GAL-IR cell bodies in many cases also expressed CGRP-LI. The fine structure of the GAL-IR axonal boutons is described as revealed by the peroxidase-antiperoxidase technique.

Radioimmunoassay analysis revealed that the content of GAL-LI was about 3 times higher in the DH than in the VH, while the DRGs showed values between these. The lumbar and, in particular, the sacral spinal cord had a higher content of GAL than the cervical and the thoracic spinal cord segments investigated. A high density of ^{125}I-GAL binding sites was present in the superficial laminae of the DH.

In conclusion, the GAL-IR axons of spinal cord lamina IX is of supraspinal origin, probably exclusively belonging to the serotonergic bulbospinal pathway. GAL-IR axons in the DH is mainly of primary afferent origin, while a minor portion derives from supraspinal and segmental sources. There was a fairly good concordance between location of GAL-IR axons, tissue content of GAL and distribution of ^{125}I-GAL binding sites.

NEUROPEPTIDE Y AND LHRH IN THE RAT HYPOTHALAMUS: ANATOMICAL RELATIONSHIPS. J. Calka and J.K. McDonald, Dept. of Anatomy & Cell Biology, Emory University School of Medicine, Atlanta, GA 30322

Neuropeptide Y (NPY) affects LH and LHRH secretion *in vivo* and *in vitro* (for a review see McDonald, 1988: *CRC Crit. Rev. Neurobiol.* 4:97-135). We have investigated relationships between NPY and LHRH immunoreactive neurons in the rat hypothalamus to explore the anatomical basis for the effects of NPY on LHRH secretion. Ovariectomized rats were provided with Silastic capsules containing estrogen (235 µg/ml) or vehicle (Sabatino et al., 1989: *Endo.* 124:2089-98). Three days later 100 µg of colchicine was injected into the lateral ventricle. Rats were perfused with fixative the next day and their brains sectioned coronally at 40 µm. Serial sections were incubated in NPY or LHRH antisera and processed using conventional immunohistochemical techniques. Sections from other animals were treated sequentially with LHRH and NPY antisera to visualize both peptides in the same section. The results show extensive overlap of NPY and LHRH fibers in the ventral retrochiasmatic area and in the subependymal, internal zone and lateral aspect of the median eminence. NPY fibers were concentrated in close proximity to LHRH perikarya and dendrites in the medial preoptic area and the horizontal limb of the diagonal band. NPY containing fibers may influence LHRH secretion via effects on LHRH fibers and perikarya. Supported by HD-19731, HD-00727, March of Dimes 5-524 and the Fulbright Foundation.

PROJECTIONS OF PEPTIDE-CONTAINING NEURONS INTO THE MEDIAL PREOPTIC AREA OF THE SYRIAN HAMSTER. C. R. Neal, Jr. and S. W. Newman. Department of Anatomy and Cell Biology. University of Michigan Medical School. Ann Arbor, Michigan. 48109

Fibers and terminals containing dynorphin B (rimorphin and leumorphin), adrenocorticotropin (ACTH), beta-endorphin (ßE) and substance P (SP) have been reported in the medial preoptic area (MPOA) of the rat and hamster. The dynorphins, SP and ßE have been shown to affect male sexual behavior in these species, and lesions in the caudal MPOA completely disrupt this behavior. To identify the cells of origin of these fiber systems, we placed Fluoro-gold (iontophoresis) or rhodamine-impregnated latex microspheres (pressure injection) into the caudal MPOA seven days prior to sacrifice. Two days prior to sacrifice, colchicine was injected into the lateral ventricle. The animals were perfused and their brains processed for fluorescence immunohistochemistry. Numerous retrogradely labelled cell bodies were observed in the ipsilateral lateral septum, medial bed nucleus of the stria terminalis (BNSTm), midline thalamic nuclei, several hypothalamic nuclei, the peripeduncular nucleus, medial nucleus of the amygdala (AMe) and amygdalo-hippocampal area. A small, ventral sub-population of ßE- and ACTH-containing neurons in the arcuate nucleus accumulated retrogradely transported tracer. In addition, cells containing both tracer and C-terminus leumorphin immunofluorescent labelling were observed in the preoptic part of the BNSTm and in the ventral part of posterodorsal AMe. However, no SP-immunolabelling was observed in retrogradely labelled cells in BNSTm or AMe. Supported by NIH NS20629 to SWN and NIGMS GM10341-04 to CRNJ.

HISTOCHEMICAL LOCALIZATION OF NEUROKININ B IMMUNOREACTIVITY IN RAT BRAINSTEM. R.E. Harlan, L.R. Lucas* and J.E. Krause. Dept. Anatomy and Neuroscience Training Program, Tulane Univ. Sch. Med., New Orleans, LA 70122 and Dept. Anatomy and Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Two genes encode tachykinins in mammals: preprotachykinin (PPT) A, encoding substance P (SP) and neurokinin A (NKA), and PPT B, encoding neurokinin B (NKB). All three peptides derived from these two genes have identical C-terminal sequences. Thus, immunocytochemical differentiation among the peptides has been difficult. We have utilized an antiserum apparently specific for NKB for immunocytochemical localization of NKB immunoreactive fibers in the brainstem of the female rat. The antiserum, raised in a rabbit against conjugated cys^{10}-NKB, does not cross react with SP or NKA in a competitive binding assay. In the brainstem of animals perfused with Zamboni's fixative, prominent immunostained fibers were seen with antibody dilutions ranging from 1:1000-1:10,000. Immunoreactivity was completely abolished by preabsorption of the antiserum with 10uM NKB, but not with 10uM SP or NKA. Bundles of immunoreactive fibers were found in the spinal trigeminal tract and coursing into and through the nucleus of the spinal trigeminal tract. Extremely dense immunoreactivity was seen in the lateral portions of the interpeduncular nucleus. Scattered immunoreactive fibers were found in many other regions of the brainstem.

PROENKEPHALIN MESSENGER RNA IS EXPRESSED IN RAT PITUICYTES. M.K.-H. Schafer*, R. Day, H. Akil and S.J. Watson. Mental Health Research Inst., University of Michigan, Ann Arbor, MI 48109-0720.

The existence of opioid peptides in the posterior pituitary is well-known. Their synthesis occurs in hypothalamic magnocellular neurons and in smaller neurons projecting to the posterior pituitary. To date there has been no evidence to suggest synthesis of opioid peptides in the neural lobe itself. To determine potential sites for opioid peptide synthesis in the neurointermediate lobe, the presence of proenkephalin (proENK) and prodynorphin (proDYN) mRNA was examined using *in situ* hybridization histochemistry with [^{35}S] labeled cRNA probes on 10 µm frozen pituitary sections of untreated rats. Cells containing proENK mRNA were found exclusively in the posterior pituitary, but not in the intermediate lobe. No proDYN mRNA could be detected in the neural lobe. The size of proENK mRNA was determined by Northern blot analysis of neurointermediate lobe tissue extracts and compared to the proENK mRNA of rat striatum. Both bands showed the same size of ca. 1.5 kb. Further characterization with a cDNA complementary to glial fibrillary acidic protein (GFAP), a marker for astroglial cells, and an antibody raised against GFAP revealed that the proENK mRNA containing cells are pituicytes, a special class of astroglial cells in the neural lobe. Using antibodies specific for proENK fragments we were not able to detect enkephalin-like immunoreactive material in pituicytes, only in nerve terminals. From these studies we conclude that pituicytes in the posterior pituitary of untreated adult rats express proENK mRNA *in situ* and could be a potential source for proENK derived peptides in this tissue. The regulation of proenkephalin mRNA during different physiological stages of pituicytes and its functional significance is currently being investigated. [cDNA clones were provided by S. Sabol (ENK) and J. Douglass (DYN). Supported by DA02265, MH422251, Theophile Raphael Fund; R.D. is a fellow of the Medical Research Council (MRC) of Canada].

82.2

TESTOSTERONE REGULATES POMC mRNA LEVELS IN A REGIONALLY SPECIFIC MANNER IN THE ARCUATE NUCLEUS OF THE ADULT MALE MACAQUE. L.A. Adams*, L. Vician*, D.K. Clifton*, R.A. Steiner. Depts of Ob/Gyn, and PBIO, Univ. of Washington, Seattle, WA 98195.

Endogenous opioid peptides (EOP) are involved in the steroid-mediated negative feedback control of gonadotropin secretion, and steroid hormones have been shown to influence EOP synthesis and activity. In the primate brain, neurons containing POMC (the precursor for the EOP ß-endorphin) are located in the arcuate nucleus; given the diversity of POMC projections and the variety of physiological actions ascribed to POMC products, these neurons are likely to be a functionally heterogeneous population. We tested whether testosterone (T) influences POMC gene expression in a regionally specific manner in the male primate brain. Using *in situ* hybridization we compared POMC mRNA levels in the arcuate nucleus among intact (n=3), castrated (n=4), and castrated, T-treated (n=4) adult male macaques, *Macaca fascicularis*. Frontal sections (20µm) through the arcuate nucleus were processed for *in situ* hybridization with an ^{35}S-labeled ribonucleotide probe, and the autoradiographic signal (grains/cell) was quantified with a computerized image analysis system. Castration resulted in a small (12%), but statistically significant, decrease in grains/cell when the arcuate nucleus as a whole was considered, and T treatment reversed this effect ($p<0.05$). Analyzing the anterior and posterior halves of the nucleus independently, we saw that the castration-induced decrease in grains/cell was greater in the anterior half of the nucleus (32%; $p<0.03$), whereas the decrease in the posterior half was not statistically significant. T treatment reversed the effects of castration in both halves of the nucleus. Thus, castration decreases, and T treatment restores to intact values, cellular POMC mRNA levels in the arcuate nucleus of the male primate, and this effect of T on POMC mRNA levels is most pronounced in the anterior aspect of the nucleus. The augmentation of POMC gene expression by T provides a mechanism for increasing EOP activity, which in turn subserves the steroid-mediated negative feedback control of gonadotropin secretion.

82.3

NEUROPEPTIDE Y MODULATION OF GONADOTROPIN-RELEASING HORMONE INDUCED CALCIUM ELEVATIONS IN SINGLE IDENTIFIED GONADOTROPES. Gary A. Shangold*, Everett Y. Lee* and Richard J. Miller (SPON: P.R. Huttenlocher). Depts. of Pharm./Phys. and Ob./Gyn., Univ. of Chicago, Chicago, IL 60637.

Neuropeptide Y (NPY) has been shown to inhibit gonadotropin-releasing hormone (GnRH)-induced luteinizing hormone (LH) release *in vivo*. In order to determine whether these effects on gonadotropin secretion are achieved by a direct action on gonadotropes, we studied $[Ca^{++}]_i$ signals in single gonadotropes from 60-day old female rats, plated on etched-grid coverslips, identified via a reverse hemolytic plaque assay for LH, and loaded with the Ca^{++}-sensitive fluorescent indicator Fura-2, with a microspectrofluorimeter. Perifusion of cells with GnRH (1 nM) elicited an initial brisk rise in $[Ca^{++}]_i$, which then returned toward basal levels (~100-150 nM), only to rise again to a lower and more sustained secondary plateau phase. The first peak of $[Ca^{++}]_i$ has been previously shown to be independent of extracellular Ca^{++}, and thus appears to reflect mobilization of Ca^{++} from intracellular stores. The secondary plateau could be prevented by either removal of extracellular Ca^{++} or by L-calcium channel blockade with nitrendipine, and is thus felt to represent influx of extracellular Ca^{++} via voltage-sensitive Ca^{++} channels. Perifusion of cells with NPY (100 nM or 1 µM) during the second phase of the GnRH-induced elevation in $[Ca^{++}]_i$ brought about suppression of this secondary plateau in $[Ca^{++}]_i$. However, no apparent effect on the first (intracellularly-generated) part of the GnRH-induced $[Ca^{++}]_i$ signal could be so demonstrated. Furthermore, NPY did not block $[Ca^{++}]_i$ transients evoked by depolarization with 50 mM K^+. Thus, NPY inhibits Ca^{++} influx into gonadotropes through L-type Ca^{++} channels, but an indirect mechanism appears to be involved.

82.4

***IN VIVO* RELEASE OF NEUROPEPTIDE-Y IN THE STALK-MEDIAN EMINENCE OF CASTRATED RHESUS MONKEYS IS PULSATILE.** M.J. Woller*, J.K. McDonald†, E. Terasawa. Wis. Reg. Primate Res. Ctr., Univ. Wisconsin, Madison, WI 53715 & †Dept. Anat. & Cell Biol., Emory Univ., Atlanta, GA 30322.

It has been shown in rodents that neuropeptide-Y (NPY) modulates LH release, and presumably LHRH release. However, whether NPY has any role in control of LHRH release in primates is unknown. As a first step in investigating this, we have examined *in vivo* release of NPY in conscious rhesus monkeys using a previously described push-pull perfusion method . Long-term castrate male (n=3) and female (n=3) monkeys were used. A modified Krebs-Ringer phosphate buffer solution was perfused through the stalk-median eminence (S-ME) at a rate of 20 µl/min and 10 min fractions were collected for 12-15 h. NPY concentration in perfusates was measured in duplicate by RIA. Results: 1) NPY release in the S-ME of both male and female monkeys was pulsatile. 2) NPY pulses detected using strict criteria with the PULSAR algorithm indicated that NPY pulses occur at 40-62 min (48.1 ± 3.5 min) intervals. 3) Basal NPY release (trough value) ranged from 40-160 pg/ml (103.6 ± 20.9 pg/ml), and NPY pulse amplitude (difference between peak and trough) ranged from 50-125 pg/ml (90.2 ± 14.8 pg/ml). These results suggest that NPY release in the S-ME is pulsatile and that the frequency of NPY release is similar to that reported for LHRH release. Whether any correlation between NPY and LHRH release exists remains to be determined. (Supported by NIH Grants HD15433 & HD11355).

BRAIN STEM PROJECTIONS ARE REQUIRED FOR THE TESTOSTERONE (T)-INDUCED AUGMENTATION OF MEDIAN EMINENCE NEUROPEPTIDE Y (NPY). A. Sahu, P.S. Kalra, W.R. Crowley[1] and S.P. Kalra, Dept. OB-Gyn, Univ. Fla. Col. Med., Gainesville, FL and [1]Dept. Pharmacol. Univ. TN Col. Med., Memphis, TN.

Various hypothalamic nuclei are innervated by two populations of NPY producing cells - one resident in the arcuate nucleus (ARC) and the other in the brain stem, the latter also display coexistence with adrenergic transmitters. We observed that two weeks after castration, hypothalamic NPY release in vitro in response to KCl decreased and, of the 6 microdissected sites in the hypothalamus, NPY levels were reduced selectively in the median eminence (ME), ARC and ventromedial hypothalamus (VMH). T replacement in the physiological range to castrated rats, restored the NPY release response as well as levels in these three sites, implying a crucial participation of steroid concentrating cells in the brain stem and hypothalamus. Therefore, brain stem projections to the hypothalamus were severed in the next experiment with a 2 mm wide knife lowered on either side of the sagittal sinus to the depth of the dorsal tegmentum in the mesencephalon. In these neurally transected (NT) gonad-intact rats, NPY levels decreased significantly in the ME and not in the ARC or VMH. When castration was performed simultaneously with NT, NPY levels fell in all three nuclei. Replacement of physiological T prevented the decline in NPY levels in the VMH and ARC regardless of whether rats previously underwent NT or not. In contrast, T replacement in the NT group was ineffective as it failed to prevent the castration-induced decrease in the ME NPY levels. These studies show that T facilitates NPY neurosecretion selectively in three hypothalamic sites, but the site of T action is different. To augment NPY levels in the ME, T may require an intact brain stem-hypothalamic link, whereas in the VMH and ARC, the site of T action may be resident locally in the hypothalamus. (Supported by NIH HD 11362 & HD 08634).

82.6

THYROID HORMONE HAS A PERMISSIVE EFFECT IN THE REGULATION OF GALANIN GENE EXPRESSION IN THE RAT ANTERIOR PITUITARY. S.C. Hooi*, J.I. Koenig, J.B. Martin, L.M. Kaplan (SPON: N.T. Zervas). Gastrointestinal Unit and Dept. of Neurology, Massachusetts General Hospital, Boston, MA 02114.

Galanin is a neuropeptide which regulates the secretion of several pituitary hormones, including GH, prolactin, TSH, and ACTH. We have previously shown that galanin gene expression and peptide concentrations in the rat anterior pituitary (AP) are dramatically stimulated by high circulating estrogen levels. In addition, thyroid hormones are required for the maintenance of normal concentrations of galanin-like immunoreactivity in the AP. We used Northern blot analysis to examine the effects of thyroid hormone depletion and replacement on basal and estrogen-stimulated galanin gene expression in normal male rats. Treatment for 4 weeks with propylthiouracil (PTU; a single i.p. injection of 10 mg/kg followed by addition of 0.05% in drinking water) led to a 6-fold reduction in galanin mRNA levels in the AP. Concurrent administration of thyroxine (50 μg/kg/day s.c.) fully reversed this effect. Thyroxine treatment of normal animals had no effect. Pretreatment with PTU for 5 weeks also decreased galanin gene expression in the AP of animals exposed to high doses of 17β-estradiol benzoate (100 μg/kg/day s.c.) for 2 days. Galanin mRNA levels in the AP of these animals was reduced 3-fold compared with animals treated with estrogen alone. Thyroxine administration during the final 2 weeks of PTU treatment partially reversed (to 56% of control levels) the effect of PTU. These observations suggest that thyroid hormones are necessary for normal pituitary expression of the rat galanin gene and that they exert a permissive effect on the estrogen-induced stimulation of galanin gene expression.

EXPRESSION OF C-FOS IN MAGNOCELLULAR HYPOTHALAMIC NEURONS: SPECIFICITY FOR OXYTOCIN AND VASOPRESSIN. G.E. Hoffman, M. M.Roberts*, J. G. Verbalis, F. Grant*, A.G. Robinson. Dept. Physiology and Div. Endocrinology, Dept. of Medicine, Univ. Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

Upon activation, the hypothalamic magnocellular neurons express c-fos, an oncogene product implicated in gene regulation. In these experiments, we related changes in c-fos immunoreactivity in oxytocin (oxy) and vasopressin (vp) neurons to plasma levels of these hormones after stimulation under several different conditions. Magnocellular neurons expressing c-fos were identified with standard double label immunocytochemistry (ICC) by first staining with a c-fos specific antibody, followed by staining with antibodies generated specifically against the 14 amino acids of the c-terminus of oxytocin or vasopressin neurophysin (NP). The VPNP and OXYNP antibodies showed no crossreactivity with each other either in RIA or with ICC. The results are shown below.

	plasma levels vs. baseline		c-fos staining	
Treatment	oxy	vp	oxy	vp
H2O deprivation, (24 hr.)	2-3x	5-7x	+/-	++
NaCl, 9.0M (4.0cc, i.p.)	>50x	>50x	++++	++++
CCK (100μg/kg, i.p.)	8-10x	1x	++++	-

These results demonstrate a significant relationship between c-fos immunoreactivity and stimulus-induced neurohypophyseal secretion. C-fos staining accurately reflects the relative magnitude of the secretory response as well as the specificity of the peptide secreted. Consequently, c-fos expression can be used to study functional anatomy of the hypothalamus in response to specific physiological and pharmacological stimuli.

82.8

CHOLECYSTOKININ ACTIVATES C-FOS EXPRESSION IN PARAVENTRICULAR OXYTOCIN AND CORTICOTROPIN RELEASING HORMONE NEURONS. J.G. Verbalis, G.E. Hoffman, E.M. Stricker and A.G. Robinson. Depts. of Medicine, Physiology and Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261

Previous studies from our laboratories have shown that in rats cholecystokinin (CCK) causes pituitary secretion of oxytocin (OT), but not vasopressin (AVP), by stimulating hypothalamic magnocellular neurons. However, because OT secretion is also correlated with inhibition of food intake and gastric motility produced by CCK, we have hypothesized that centrally-projecting parvocellular OT neurons may be activated in concert with the pituitary-projecting magnocellular neurons to stimulate these responses. To evaluate which types of neurons in the paraventricular nucleus (PVN) are activated by CCK in rats, we utilized immunohistochemical techniques to identify cells activated to express c-fos antigen 1h after treatment with CCK-8 (100 μg/kg ip). Neurons expressing nuclear c-fos were then further characterized by dual-labelling using specific antisera to OT and AVP neurophysins and corticotropin releasing hormone (CRH, courtesy A. Silverman). C-fos expression was easily detected in magnocellular OT but not AVP neurons, and also in OT neurons located in the lateral parvocellular subdivision of the PVN known to project to the brainstem. Another group of non-OT neurons in the medial parvocellular subdivision known to project to the median eminence was found to contain CRH. These results *demonstrate that CCK stimulates selective groups of neurons in both* the magnocellular and parvocellular subdivisions of the PVN, and suggests a potential mechanism whereby centrally-projecting OT and CRH neurons might act to coordinate the autonomic, behavioral and neuroendocrine effects produced by CCK.

Blockade of Pulsatile LH Secretion in Ovariectomized Rats by an Alpha1-Adrenergic Receptor Antagonist. J. E. Levine, S. Sun*, and L. Conaghan*. Department of Neurobiology & Physiology, Northwestern University, Evanston, IL 60208.

These experiments were conducted to determine if alpha1-adrenergic receptor activation is required for generation of luteinizing hormone (LH) pulses in ovariectomized (OVX) rats. Female rats were fitted with atrial catheters on day 7 following OVX, and blood sampling sessions were begun at 1200h on the next day. Samples were obtained in each animal at 5min intervals for 4-5h. After 2h of sampling, rats received injections of saline vehicle or the alphal-antagonist, prazosin, at 0.5 *mg/kg* or 1.0 *mg/kg, i.p.. Plasma LH levels were* determined by RIA. Secretion of LH in all animals prior to injections was pulsatile with interpulse interval = 25.9+ 3.0min (mean + SE) and pulse amplitude = 2.23+ .26 ng/ml. While control injections were without effect, administration of prazosin at both doses either abolished pulsatile LH secretion for the remainder of sessions or completely blocked LH pulses for a period of 1/2-2h. Virtually no LH pulses of reduced amplitude were observed throughout the onset, duration, or recovery from drug effects. We conclude that the patency of at least one population of noradrenergic synapses is required for the normal operation of the LHRH pulse generator. Noradrenergic transmission via alpha1 receptors may either regulate the frequency of the LHRH pulse generator or function as a component of the pulse generator itself. Supported by NIH HD20677.

LHRH mRNA: NEURONAL DISTRIBUTION AND STEROID HORMONE REGULATION. K.F. Malik, A.-J. Silverman, and J.I. Morrell. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102

We are able to identify cells producing LHRH mRNA in rat brain with in situ hybridization cytochemistry using previously described methodology (Zoeller et al., Endocrinol., 122:2570, 1988) and a 51 base cDNA probe 3'-end labeled with ^{35}S-dATP. The distribution of labeled cells is limited to loci previously demonstrated to contain LHRH immunoreactive neurons. The majority of cells identified to contain LHRH mRNA were found in the medial septum, vertical and horizontal limbs of the diagonal bands of broca, and rostral portions of the preoptic area. In these areas we have counted as many as 96 very robustly labeled cells per 10 micron section. No cells in the MBH have been identified to contain LHRH mRNA.

Preliminary results from these experiments suggest that the number of labeled cells is stable between 7d OVX rats and 7d OVX rats that receive 10 micrograms EB and are sacrificed 40h later. We are also currently performing in situ hybridization studies investigating the regulation of LHRH mRNA over the rat estrous cycle. COLOCALIZATION OF LUTEINIZING HORMONE-RELEASING HORMONE IN NEURONS CONTAINING PROGESTIN RECEPTORS IN GUINEA PIG BRAIN. J.C.King, J.D. Blaustein and G. R. Seiler*. Dept. of Anatomy and Cell Biology, Tufts University Health Sciences Campus, Boston, MA 02111 and Neuroscience and Behavior Program, Univ. Mass., Amherst, MA 01003.

Secretion of hypothalamic LHRH, central to successful reproduction, is regulated by multiple modulators, including gonadal steroids. It has been suggested that neurons which synthesize LHRH in female rats do not concentrate estradiol. We have reexamined this issue using double-label immunocytochemistry to simultaneously localize progestin receptors [PR] and LHRH, within Vibratome acrolein-fixed sections through the preoptic area/ hypothalamus. Ovariectomized adult guinea pigs received estradiol-replacement to maximize antigen detection. A subpopulation of LHRH immunopositive [+] neurons displayed PR+ nuclei. These double labelled neurons were confined to regions that were rich in both LHRH+ and PR+ neurons, specifically in the midline nuclei of the preoptic area. No double labelled neurons were detected in the basal preoptic area overlying the optic chiasm or in the more caudal anterior hypothalamic area. PR+ reaction product is only detected within estrogen receptor+ neurons and is enhanced in the preoptic/hypothalamus by estradiol treatment (Blaustein and Turcott, in press). Thus, the PR+ neurons in this study also represent ER+ neurons. Although the number of LHRH-PR double labelled neurons appears to be small [<10% of the population], these neurons may play a critical role in mobilizing the entire population of LHRH neurons. We hypothesize that the influence of this subpopulation is mediated by interconnections within the microarchitecture of the total population of LHRH neurons. Finally, these data are consistent with the hypothesis that a sub-population of LHRH neurons does contain gonadal steroid receptors. NIH HD19803, NS19327, RCDA NS00970.

CHARACTERIZATION OF A GONADOTROPIN-RELEASING HORMONE (GnRH) CELL LINE OBTAINED FROM A TUMOR IN TRANSGENIC MICE. R.I. Weiner, P.C. Goldsmith, J.J. Windle[1]*, C.A. Padula*, J.L. Roberts[2] and P.L. Mellon[1]*. Reproductive Endocrinology Center, Univ. Calif., San Franicsco, CA 94143, [1]Salk Institute, La Jolla, CA 92037, and [2]Mt. Sinai, Med. Ctr., New York, NY 10029.

Expression of the oncogene SV40 T antigen (TAG) was directed to GnRH neurons of transgenic mice using the GnRH promoter. A tumor in the anterior preoptic area was obtained which expressed GnRH and TAG mRNAs. The tumor was dispersed and cultured. Over a six month period a cell line (GT-1) was established and cloned by limiting dilution. We have characterized the GT-1 cells at the light and electron microscopic level using PAP immunostaining. GT-1 cells produced and released radioimmunoassayable GnRH. Cultures contained flattened cells adhering to the surface of the dish as well as rounded cells layered above. The attached cells have a neuronal appearance and immunostain for GnRH and neuron specific enolase, but not for glial fibrillary acidic protein. GnRH staining was observed within the cytoplasm of the cell bodies as well as in processes. Characteristic protein producing neurons were seen with well-formed secretory organelles. GnRH was localized in dense granules. At sites of contact there was evidence for cell to cell communication. Rounded cells containing mitotic figures were intensely stained for GnRH. These findings demonstrate for the first time the feasibility of producing a neural cell line by expression of TAG under the control of a promoter for a gene normally expressed tissue specifically in terminally differentiated neurons. Supported by NIH grants HD20377 (P.M.), HD08924 (R.W.) and the Keck Foundation (R.W.).

VESICULAR CORELEASE OF ACETYLCHOLINE AND ATP FROM THE ELECTROMOTOR SYSTEM OF "NARCINE BRASILIENSIS". C.D. Unsworth* and R.G. Johnson* (SPON: J. Trojanowski). HHMI and Depts. of Med. and Physiol. Univ. of Pa., Phila., PA. 19104

Despite the acceptance of the exocytotic theory of quantal vesicular acetylcholine (ACh) release, reports concluding that ACh is released directly from the cytosol continue to challenge vesicular release. Two independent studies were undertaken to establish the mechanism of ACh release from the cholinergic electromotor system of "Narcine brasiliensis". Since the ATP is colocalized with ACh in the cholinergic vesicle, the exocytotic theory would predict the corelease of these two components with a stoichiometry identical to that of the vesicle contents. Quantitation of the release of ATP from synaptosomes could be accurately quantitated only if the ATPase inhibitor α,β-methylene ATP was included in the medium. A variety of secretagogues including KCl, veratridine, and ionomycin all induced the corelease of ACh and ATP in a constant molar ratio of 5.6:1, a stochiometry consistent with that of the vesicle content. In parallel to these studies, the compound 2-(4-phenylpiperidino)cyclohexanol (AH5183) was used to specifically inhibit vesicular accumulation of newly synthesized (radiolabelled ACh) without affecting cytosolic levels of newly synthesized Ach in cholinergic nerve terminals. Treatment with AH5183 specifically inhibited the release of newly synthesized ACh without markedly affecting total ACh release. We conclude that ACh released upon stimulation originates exclusively from the vesicular pool.

Amplitude and frequency gradients of unitary EPPs along the frog NMJ. J. P. Tremblay, R. Robitaille and S. Beauregard, Neurobiology Lab., Laval University, Québec, Canada, G1K 7P4.

The frog NMJ was recorded in a low Ca^{++} Ringer simultaneously with two intracellular electrodes placed at its distal ends. The motor nerve was stimulated at 10Hz. The ratio of the intracellular amplitudes of unitary EPPs and MEPPs was used to calculate their site of origin using the Spatial Decay Method. When the junction is divided in 10 equal regions, the evoked release activity was more frequent in the proximal regions than in the distal regions, as previously observed for the spontaneous release activity (Tremblay et al. Neur. Lett. 51, 247, 1984; Robitaille et al. Br. Res. 408, 353, 1987). The mean amplitude of unitary EPPs was also significantly higher in the proximal than in the distal regions (analysis variance) as previously observed for MEPPs (Robitaille and Tremblay, Br Res 408, 353, 1987). In fact the mean amplitude of unitary EPPs in a given region matched exactly the mean amplitude of MEPPs in the same region. This suggests that the same mechanisms are responsible for the nonuniform amplitude distributions. A gradient in the length of postjunctional folds along the frog NMJ could be one of the contributing factors (Tremblay et al., Neurosc., in press).

EFFECTS OF ANTICHOLINESTERASE AGENTS ON QUANTAL CONTENT IN THE RAT. C. Prior*, W.C. Bowman* and I.G. Marshall*. (SPON: Brain Research Association). Dept. Physiology and Pharmacology, University of Strathclyde, Glasgow, U.K.

The effects 1μM neostigmine (NEO), 10μM edrophonium (EDR, submaximal dose) and 3-4μg/ml of the irreversible anti-cholinesterase (anti-AChE) snake toxin, fasciculin 2 (FS2) have been studied on endplate currents (EPCs, 0.1-0.5Hz) and miniature endplate currents (MEPCs) in cut fibers of rat diaphragms at 32°C. All produced similar moderate increases in peak EPC and MEPC amplitudes (maximum increase 27%). EPC quantal content (direct method) was not significantly altered by the agents (NEO, 91 ± 4% control (n=5); EDR, 102 ± 8% (n=3) and FS2, 105 ± 8% (n=3). However, all three agents increased the decay time constant of EPCs (τ_{EPC}) significantly more than they increased τ_{MEPC} (control: τ_{EPC}, 0.53msec; τ_{MEPC}, 0.45msec; 1μM NEO: τ_{EPC}, 5.4msec; τ_{MEPC}, 1.2msec). Doubling $[Ca]_o$ accentuated this effect. All the effects of FS2 persisted even after prolonged wash in control solution. The observed changes in decay time constants can be accounted for by a cooperative interaction of ACh molecules at the receptor level (Magleby, K.L. and Terrar D.A., *J.Physiol.*, 244:467, 1975). The absence of a selective effect on peak EPC amplitude suggests that neither anti-AChEs *per se*, nor the increased [ACh] in the synaptic cleft associated with their use, have any major effect on the peak quantal release of ACh.

83.4

ACTIONS OF L-VESAMICOL ON NEUROMUSCULAR TRANSMISSION IN THE SNAKE. I.G. Marshall*, T. Searl* and C. Prior* (SPON: N.N. Durant). Dept. of Physiology and Pharmacology, University of Strathclyde, Glasgow, Scotland. U.K.

The actions of the active l-isomer of vesamicol, an inhibitor of the vesicular storage of acetylcholine, has been studied on miniature endplate currents (MEPCs) and endplate currents (EPCs) in cut muscle fibers of the garter snake. In controls, 5 min of 10Hz nerve stimulation produced two populations of MEPCs with mean amplitudes of 37% and 97% of the prestimulation MEPC. Preincubation in 2μM vesamicol reduced the small MEPC amplitude to 24% and 5μM completely abolished them. However, vesamicol had no affect on the larger, normal sized MEPC. After 15 min of 10Hz nerve stimulation EPC amplitude was markedly reduced in both controls (to 6%) and 5μM vesamicol (to 2%). Analysis of EPC amplitude variance showed that in control the decrease was due to reductions in both quantal content (to 18%) and quantal size (to 46%) while in vesamicol the decrease was due entirely to a change in quantal content (to 2%) with no change in quantal size (97%). Thus vesamicol selectively inhibits the release of stimulation-induced small-mode quanta both as MEPCs and as components of EPCs. These quanta are possibly derived from a highly active, readily releasable pool. The selective action of vesamicol on this pool is consistent with its effects to inhibit the vesicular storage of acetylcholine.

LONG LASTING ENHANCEMENT OF SPONTANEOUS M.E.P.S.P.S. BY MAST CELL DEGRANULATING PEPTIDE (MCD) IN CA3 HIPPOCAMPAL REGION. E. Cherubini, Y. Ben-Ari and R.S. Neuman (SPON. C. Polosa). INSERM U029, 123 Blvd. de Port Royal, 75014 Paris, France.

MCD, isolated from bee venom, produces LTP in the CA1 region (Cherubini et al., Nature, 1987) and persistent bursts in the CA3 region of the hippocampus (Cherubini et al., Brain Res., 1988). We have now studied the action of MCD on the transient outward current (I_A) and on minature excitatory postsynaptic potentials (m.e.p.s.p.s.) in rat hippocampal slices.

Neurones were recorded with KCl electrodes and voltage clamped in the presence of TTX (1 μM) to block synaptic transmission and bicuculline (30 μM) to block m.i.p.s.p.s. The m.e.p.s.p.s. appeared to fit a Poisson distribution. Bath application of MCD (200-500 nM) for 3-5 min, blocked I_A and increased the amplitude and frequency of m.e.p.s.p.s. Enhancement of the m.e.p.s.p.s. persisted for several hrs (>2) after wash of MCD and outlasted the blockade of I_A. Application of 4-aminopyridine (1-2 mM) blocked I_A but only transiently increased the m.e.p.s.p.s. It is concluded that a transient blockade of I_A is not sufficient to produce the long lasting enhancement of m.e.p.s.p.s. induced by MCD.

RECEPTOR-MEDIATED POLYPHOSPHOINOSITIDE HYDROLYSIS DOES NOT STIMULATE CALCIUM MOBILIZATION IN PRESYNAPTIC NERVE TERMINALS. T.L. Smith and E.C. Hamlin. Veterans Administration Medical Center, Tucson, AZ 85723 and Department of Pharmacology, University of Arizona, Tucson, AZ 85724.

Although polyphosphoinositide (PPI) hydrolysis has been linked to Ca^{2+} mobilization in peripheral tissues and neurotumor cells, the function of PPI hydrolysis in nerve endings is unclear. It was of interest, therefore, to determine both receptor-stimulated PPI hydrolysis as well as intracellular free calcium, $[Ca_i^{2+}]$, in a purified synaptosomal preparation. $[Ca_i^{2+}]$ was determined fluorometrically using the new calcium indicator, Fluo 3/AM. PPI hydrolysis was determined by monitoring $[^3H]$inositol phosphate production in the presence of Li^+. While both 1mM norepinephrine and carbachol stimulated inositol phosphate production, neither was able to elevate $[Ca_i^{2+}]$ above its resting level. Furthermore, KCl - induced Ca^{2+} influx was completely abolished in the presence of either 1mM norepinephrine or carbachol. It is concluded that stimulation of PPI hydrolysis through $alpha_1$ - adrenergic and M_1 muscarinic receptors is not coupled to presynaptic calcium mobilization. Furthermore, activation of presynaptic adrenergic and muscarinic receptors (possibly $alpha_2$ and M_2, respectively) inhibit voltage-dependent Ca^{2+} influx.

PRESYNAPTIC INHIBITION IN THE CRAYFISH OPENER NEUROMUSCULAR JUNCTION INCLUDING EFFECTS OF ETHANOL. J.A. Blundon and G.D. Bittner. Dept. Zoology and Inst. for Neurol. Sci. Res., Univ. TX, Austin, TX 78712.

We have published data which suggest that crayfish (Procambarus clarkii) show behavioral changes in righting time and the escape reflex within 12 - 24 hours of exposure to concentrations of ethanol (EtOH) as low as 75mM (Friedman et al. 1988, JPET 246:125-131). The excitor axon-opener muscle junction in the crayfish walking leg provides synapses whereby we can study changes in synaptic plasticities that may be linked with these behavioral changes due to EtOH exposure. EtOH in concentrations as great as 150 mM had no effect on synaptic facilitation, presynaptic action potentials (APs), or excitatory postsynaptic potentials in the muscle fiber. Other researchers have found synaptic plasticities involving the neurotransmitter γ-aminobutyric acid (GABA) to be especially sensitive to low concentrations of EtOH. The opener inhibitor axon provides presynaptic inhibition via axo-axonal contact with the opener excitor axon and also provides postsynaptic inhibition via synapses on muscle fibers. Both pre- and postsynaptic inhibition are mediated by GABA. Hence, we have begun to study effects of low concentrations (< 100 mM) of EtOH on presynaptic inhibition.

Baxter and Bittner (1981, Brain Res. 223:422-428) reported that presynaptic inhibition decreased excitor axon AP amplitude via an increase in chloride conductance in the nerve terminal which in turn decreased the release of excitatory neurotransmitter. However, our observations using lower frequency stimulus paradigms than used by Baxter and Bittner have shown no decrease in excitor AP amplitude during presynaptic inhibition. We are now studying presynaptic inhibition using a variety of stimulus paradigms including that used by Baxter and Bittner in order to clarify the mechanism of presynaptic inhibition.

PHACLOFEN-INSENSITIVE PRESYNAPTIC INHIBITORY ACTION OF (±) BACLOFEN IN NEONATAL RAT MOTONEURONS. M. Y. Wang* and N. J. Dun (SPON: M. Kiraly). Dept. of Pharmacol. Loyola Univ. Med. Ctr., Maywood, Il 60153

Intracellular recordings were made from antidromically identified motoneurons in transverse spinal cord slices of neonatal (12-16 days) rats. Baclofen (0.5-50 μM) concentration-dependently depressed the excitatory postsynaptic potentials (EPSPs) and inhibitory postsynaptic potentials (IPSPs) evoked by dorsal root entry zone stimulation. While depressing the synaptic potentials, baclofen (<5 μM) caused little or no change of membrane potential and input resistance. At higher concentrations (>5 μM), baclofen caused a hyperpolarization associated with increased membrane conductance. Spontaneously occurring EPSPs and IPSPs were also reversibly eliminated by baclofen. While reducing the EPSPs evoked synaptically, baclofen (5 μM) did no affect significantly the depolarization induced by exogenously applied glutamate. GABA (1 mM) in the presence of uptake inhibitor nipecotic acid (1 mM) reduced the synaptic potentials as well. Pretreating the slices with phaclofen (0.5-1 mM) or bicuculline (50 μM) did not nullify the inhibitory action of baclofen in any of the motoneurons tested. The results suggest that baclofen reduces the excitatory and inhibitory transmission in motoneurons primarily by a presynaptic action that is mediated by a phaclofen-insensitive $GABA_B$ receptor. PREJUNCTIONAL INHIBITION BY D-2 DOPAMINE RECEPTORS: DEPENDENCE ON STIMULATION INTENSITY. D.J. Friedman*, D.N. Krause and S.P. Duckles (Spon: J. Belluzzi). Dept. of Pharmacology, College of Medicine, Univ. of California, Irvine, CA 92717.

Activation of prejunctional D-2 dopamine receptors inhibits norepinephrine release from vascular adrenergic nerves. The selective D-2 dopamine agonist, ±N-0437; the non-selective dopamine agonist, apomorphine; and the negative isomer of N-0437 inhibited contractile responses to transmural nerve stimulation (1 Hz, 100 pulses) in the rat tail artery in vitro with ED_{50} values of 1.6, 30 and 0.4 nM, respectively. Most striking, however, was the profound dependence of the inhibitory effect of all three agonists on the intensity of nerve stimulation. When stimulated at 1 Hz for 100 pulses, ±N-0437 (100 nM) produced an inhibition of 73 ± 7%. However as frequency was increased to 2, 4 and 6 Hz, ±N-0437 produced progressively less inhibition so that no significant inhibition was produced at 6 Hz. In addition, variation in stimulation train length (at a frequency of 3 Hz) produced a similar effect. 100 nM ±N-0437 caused a 96 ± 3% inhibition with stimulation trains of 9 pulses but only 34 ± 11% inhibition with 90 pulse trains. Thus, ±N-0437, its (-) enantiomer and apomorphine produce an inhibition of contractile responses to adrenergic nerve stimulation in the rat tail artery that is dependent on the intensity of nerve stimulation. This phenomenon may be inherent to the mechanism by which the prejunctional D-2 dopamine receptor inhibits norepinephrine release from adrenergic nerves.

GABAERGIC NEURONS CULTURED FROM RAT HIPPOCAMPUS FORM AUTO-INHIBITORY SYNAPSES. M. Benveniste*, N. L. Harrison, D. Bekelman*, and J. L. Barker. Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

Simultaneous pre- and postsynaptic whole cell recordings (145 mM K gluconate intracellularly) have been made on 2 week cultures of E19 rat embryonic hippocampal neurons. Action potentials (AP) evoked in the presynaptic cell produced a short-latency, long-lasting, bicuculline-sensitive hyperpolarizing potential in the presynaptic cell in 30% of recordings where an inhibitory postsynaptic current (IPSC) was also observed. Under voltage clamp, a brief step depolarization of the presynaptic cell to 0 mV produced an unclamped AP that elicited an IPSC in the postsynaptic cell and simultaneously evoked a bicuculline-sensitive inhibitory current in the presynaptic cell. The latter reversed between -65 mV and -85 mV, had peak conductances ranging from 2 to 20 nS and decayed exponentially with a decay time (τ) ≈ 10 to 50 msec at -40 mV. These inhibitory synaptic currents recorded from the presynaptic cell had latencies similar to those recorded from the postsynaptic cell. Hyperpolarizing pulses in current clamp to either the presynaptic or postsynaptic cell elicited no response from the corresponding cell of the pair indicating that the cells were not electrically coupled. Recordings with a 145 mM KCl-filled electrode yielded a reversal potential of ≈ 0 mV for these events and clearly showed that the bicuculline-sensitive potential is distinct from, and follows the repolarization of the presynaptic AP due to K^+ currents. Thus, the bicuculline-sensitive potential appears to be mediated by a $GABA_A$ receptor-activated Cl^- conductance. These bicuculline-sensitive potentials functionally inhibit AP generation in the presynaptic cell for 20 to 150 msec. These observations indicate that GABAergic neurons from rat hippocampus are capable of forming autoinhibitory synapses in dissociated cultures. The morphological basis for this phenomenon has also been studied using HRP-filled pipettes during the recordings.

TWO STRUCTURAL MECHANISMS FOR REGULATING NEUROTRANSMITTER RELEASE. S. E. Huestis*J. P. Walrond* and C. K. Govind. Dept. Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523 and Life Sciences Division, University of Toronto,1265 Military Trail, Scarborough, Ontario, M1C 1A4 Canada.

To investigate the structural mechanisms which may regulate the amount of neurotransmitter released at the synapse, excitatory and inhibitory axon terminals on the lobster (*Homarus americanus*) Distal Accessory Flexor Muscle (DAFM) were examined with light microscopic immunohistochemistry and freeze-fracture electron microscopy. The DAFM consists of 5 muscle fiber bundles innervated by one excitatory and one inhibitory axon. The excitatory axon releases 3-10 times more transmitter from synapses on the most distal bundle than from synapses on the most proximal bundle. Serial thin section studies suggest that muscle fibers in the distal and proximal bundles contain a similar number of excitatory synapses. However, freeze-fracture studies show that the difference in the amount of excitatory transmitter released from synapses in the two bundles correlates with the number of large intramembrane particles clustered at the active zones. The inhibitor releases 3 to 4 times more transmitter from synapses on the distal bundle than from synapses on the proximal bundle. Immunohistochemical staining for the inhibitory transmitter, γ- aminobutyric acid, labels the inhibitory axon terminals and outlines varicosities where most of the synapses are located. These studies show that there are 3 to 4 times more varicosities on muscle fibers in the distal bundle than on fibers in the proximal bundle. Since freeze-fracture and thin section studies suggest that active zones at inhibitory synapses on distal and proximal muscle fibers are similar, the inhibitor appears to regulate the amount of transmitter it releases by regulating the number of synapses formed in the two bundles. In contrast, the excitor appears to regulate the amount of transmitter it releases by regulating active zone structure.

NH_4^+ DECREASES CHOLINERGIC EXCITATION IN CAT SPINAL CORD. W. Raabe. Neurology, VA Med. Ctr. and University of Minnesota, Minneapolis, MN 55417.

NH_4^+ decreases monosynaptic and glutamate mediated excitatory synaptic transmission in cat spinal cord. This effect of NH_4^+ is not due to inhibition of the glutamine cycle by $NH4^+$, but due to a depolarization, which decreases and eventually blocks action potential conduction in presynaptic terminals [low threshold (Ia-) afferents]. This study examines whether NH_4^+ also decreases nicotinic, cholinergic excitatory synaptic transmission from motoneuron axon collaterals to Renshaw cells.

In deeply barbiturate anesthetized cats with spinal section at L_2, an extracellular electrode in the ventral horn recorded the discharge of Renshaw cells in response to stimulation of the L_7 or S_1 ventral roots. Stimulation of a peripheral nerve (PBST, MG or LG) elicited a monosynaptic, glutamatergic motoneuron pool EPSP which was recorded from the L_7 or S_1 ventral roots (VR-EPSP). Ammonium acetate i.v., 6 mmol/kg, abolished the discharge of Renshaw cells when the VR-EPSP decreased to less than 20% of control.

These observations show that NH_4^+ rather unspecifically decreases glutamatergic and cholinergic excitatory synaptic transmission in cat spinal cord. Most likely, NH_4^+ depolarizes and blocks conduction of action potentials in all small diameter, unmyelinated presynaptic terminals. However, effects of NH_4^+ on the presynaptic release of ACh and ACh-receptors on Renshaw cells need to be ruled out.

83.13

A PHYSIOLOGICAL BASIS FOR MAC. S.A. Raymond. Anesthesia Research Laboratories, Brigham & Women's Hospital, Harvard Medical School, Boston, MA 02115.

MAC, originated by Eger et al (Anesthesiology 26:756-763, 1965), is now the most common index of anesthetic potency. MAC is the minimum alveolar concentration (partial pressure at 1 atmosphere) of anesthetic that, at steady state, will ensure immobility during noxious stimulation such as a surgical skin incision. MAC has been shown to be: 1) consistent in serial measures in the same subject; 2) similar (within 20% or so) for many agents across species; 3) essentially unchanged when ½MAC concentrations of 2 different agents are added; and 4) the point where probability of coordinated movement during a noxious event depends most steeply on dose for inhalational agents.

We have measured changes in the threshold of axon membrane for electrical stimulation following conditioning impulses. Anesthetic agents disrupt these activity-dependent changes in threshold in ways that parallel the properties of MAC. In particular, 1) activity-dependent excitability changes were suppressed consistently in serial tests by 3 inhalational agents; 2) pump inhibitors and pulse patterns altered the excitability changes so as to suggest that they depend on common ionic and metabolic mechanisms shared broadly among species; 3) inhalational agents are known to reduce membrane currents in voltage clamp, implying a reduction of net ion transfer across the membrane per impulse during activity, which would be expected to have additive, not synergic or antagonistic interaction on the excitability changes; 4) the dose-response relation for suppression of aftereffects is steepest at concentrations corresponding to MAC for 3 inhalational agents tested. These correlations support the proposition that activity-dependent excitability changes in the membrane, not synaptic processes or impulse conduction itself, are the physiological target of anesthetic action.

83.14

COMPUTER SIMULATION OF ACTION POTENTIAL PROPAGATION IN COMPLEX TERMINAL ARBORIZATIONS. H.-R. Lüscher und J. Shiner*. Dept. of Physiology, University of Berne, CH-3012 Berne, Switzerland.

Nerve fibers reaching their central destination usually branch repeatedly forming complex arborizations before synapsing upon their target neurons. Axon branch points and boutons en passant may be regions of low safety for impulse propagation. Therefore, the propagated action potential may die out before reaching all the synaptic endings. Such a mechanism could explain why some central synapses do not release transmitter after activation of the parent fiber, leading to transmission failure.

In order to study the consequences of conduction failure in axon terminations, impulse propagation in arbitrarily complex arborizations was simulated using SPICE, a general purpose network analysis program (Bunow et al., Biol.Cybern.43:1985). A software package was developed which takes as input a list of the axon segments along with their properties: whether excitable or passive, dimensions, and connections to other segments. In addition, information on how the action potentials are to be initiated at the initial compartment of the branching scheme must be input. From this input list the SPICE code is generated and SPICE called as a subroutine. Output consists of the time course of the membrane potential and various currents in each compartment.

The simulations revealed that the action potential may fail to propagate through boutons en passant and branch points in complex arborizations. Propagation improved at lower temperature. For a regular train of action potentials, impulses may fail either irregularly or at constant ratios. Propagation into only one of two branches was common. Synapses beyond branch points are not depolarized after conduction failures, even on very short collaterals. The serial and parallel organization of branch points in complex arborizations can lead to an unpredictable behavior of the propagated action potential. These results are consistent with the hypothsis that incomplete invasion of the terminal arborizations by the propagated action potentials may be responsible for transmission failure at central synapses. Conduction block at CNS axon bifurcations: a central synaptic switch. X. Gu and K.J. Muller. Dept. of Physiol. & Biophys., U. of Miami School of Med., Miami, FL 33101

Synaptic transmission between neurons can be influenced by neuronal geometry. One mechanism for this is axonal conduction block (CB), whereby impulses in the presynaptic neuron fail to propagate beyond points of low safety factor, such as axon bifurcations. We found that naturally occurring CB in one presynaptic neuron in leech ganglia, the medial pressure (mP) sensory cell, affects transmission to different postsynaptic neurons. The mP cell has three cutaneous axons, converging at a single point within the ganglion. The anterior axon appears to contact the Longitudinal (L) motoneuron and Anterior Pagoda (AP) cell, while the posterior contacts the Annulus Erector (AE) motoneuron. Typically, impulses originating in either of these axons block at the central bifurcation. During anterior CB in the mP cell, transmission to the AE cell stops (70% of cases) or is reduced (30%) while it is maintained to AP and L cells. The reverse occurs for impulses arising in the posterior axon, with transmission continuing only to the AE cell. When a laser microbeam was used to cut either the anterior or posterior axon at the bifurcation, transmission to AP and L or to AE cells was interrupted, confirming the CB results. Thus, CB acts as a switch at central synapses and can be used experimentally to analyze the distribution of effective contacts between neurons. (Supported by NIH Grant NS20607.)

O-GLYCOSYLATION OF SYNAPSIN I T.Lüthi*, M.Bähler* & P.Greengard (SPON: K.Tsou) The Rockefeller University, New York,NY 10021.

Synapsin I is a neuron-specific phosphoprotein which is highly concentrated in the presynaptic nerve-terminal and is associated with the cytoplasmic surface of synaptic vesicles. Electrophysiological studies on the squid giant synapse suggest that phosphorylation of this protein plays a role in neurotransmitter release. Recent reports indicate the existence of a novel form of cytoplasmic protein glycosylation:N-acetylglucosamine (GlcNAc) in O-linkage to serine and threonine residues. We have investigated the possibility of such a protein modification on synapsin I. Our results have shown that the GlcNAc-specific lectin WGA binds a protein doublet in rat brain homogenate which is pH 3 soluble and of the same molecular weight as synapsin I. The WGA reactivity is associated with a subpopulation of synapsin I. Purified synapsin I is labeled with UDP-[3H] galactose upon incubation with bovine milk galactosyl transferase. Both collagenase treatment and cysteine-specific cleavage with NTCB localized the sugar moiety to its head fragment. One of the proposed functions for O-GlcNAc residues involves a "block" for protein phosphorylation. We are currently testing the relationship between phosphorylation and O-glycosylation of synapsin I.

83.17

AMILORIDE INCREASES THE UPTAKE OF ZINC INTO HIPPOCAMPAL SLICES. M.K. SLY, Y. WANG, & I.L. CRAWFORD*. Departments of Neurology and Pharmacology, The University of Texas Southwestern Medical School at Dallas and Epilepsy Center, VA Medical Center, Dallas, Tx 75216.

The molecular mechanisms by which the hippocampus accumulates and regulates endogenous concentrations of zinc are largely unknown. We tested the hypothesis that the uptake of zinc is linked to an antiporter mediating Na+/H+ flux. Amiloride binds to and inhibits the membrane exchanger.

Guinea pig hippocampal slices (400u) were incubated (37 C) in Krebs solution bubbled with O2/CO2 (95/5%). After 30 min in control or experimental media, radiolabelled zinc-65 was added to each teflon chamber. Uptake was terminated 30 to 60 min latter by transfer to cold Krebs (4 C).

Data for each slice (cpm/ug dry weigh) was normalized for media cpm. Amiloride (1.0 mM) significantly increased uptake by 20% (N=44) compared to control slices (N=49). The results raise the possibility that zinc transport into hippocampal tissue is affected by Na+/H+ exchange.

PHARMACOLOGY OF SYNAPTIC TRANSMISSION

84.1

SYNAPTIC "FATIGUE" OF EMBRYONIC AVIAN CILIARY GANGLION IS MEDIATED BY A NOVEL MUSCARINIC RECEPTOR. C.W. Bowers, C.J. Schmidt*, G. Pilar. Dept. Physiology and Neurobiology, Univ. of Connecticut, Storrs, CT 06269.

The avian ciliary ganglion contains two populations of neurons: choroid and ciliary. Although both populations are driven via nicotinic cholinergic transmission in ovo, choroid but not ciliary synaptic transmission fails at stimulation frequencies of 5-10 Hz (embryonic days 12-17). This frequency-dependent block (FDB) is much less pronounced after hatching. We demonstrate that the FDC in embryonic ganglia is prevented by 0.3μM atropine, indicating the involvement of a muscarinic receptor rather than a non-specific/metabolic inability to follow high-frequency stimulation. Furthermore, 10μM oxotremorine-M, a relativly new muscarinic agonist, mimics the FDB by specifically blocking choroid but not ciliary transmission. This effect of oxotremorine-M is blocked by atropine. Two other muscarinic agonists, bethanecol (10μM) and oxotremorine (0.1-10μM), do not block synaptic transmission. This pharmacology is similar to that reported in the CNS for a muscarinic receptor involved in phosphatidyl-inositol turnover (Freedman et al., Trends Pharmacol. Suppl. Feb. 1988: 54). Intracellular studies are in progress to determine whether the muscarinic inhibition is pre- or postsynaptic.

84.2

MUSCARINIC RESPONSES OF BASOLATERAL AND LATERAL AMYGDALOID NEURONS RECORDED *IN VITRO*. M. S. Washburn* and H. C. Moises. Dept. of Physiology and Neuroscience Program, University of Michigan, Ann Arbor, MI 48109.

The amygdala is known to receive a massive cholinergic input from the nucleus basalis of Meynert (NB) in the basal forebrain. To characterize the role of this cholinergic input in regulating amygdaloid neuronal activity we compared the cellular actions produced by exogenous application of cholinergic drugs to neuronal responses elicited by synaptic release of endogenous ACh *in vitro*. Intracellular recordings were obtained from cells in the basolateral and lateral nuclei in horizontal or coronal slice preparations of the rat amygdala to examine cholinergic effects on passive membrane properties and synaptic responses elicited by activation of the external capsule or NB. Drugs were applied by bath application or by pressure ejection from a pipet positioned above the slice.

Superfusion of carbachol (300 nM-10 μM) produced a dose-dependent block of the slow AHP and, when tested in cells depolarized to just below threshold (positive to -63 mV), elicited a voltage-dependent depolarization accompanied by an increase in membrane input resistance and elevations in spontaneous firing. Carbachol also blocked the epsp and the early and late ipsp evoked by stimulation of amygdaloid afferents. Pressure ejection of carbachol (1-10 mM) produced the same profile of effects and, in addition, elicited a membrane hyperpolarization which was associated with a decrease in input resistance and reversed near -75 mV. All of the repsonses to carbachol were blocked by atropine (1 μM). Based on the actions of the M_1 antagonist pirenzipine and the M_2 antagonist gallamine, it appeared that an M_1 receptor mediated the reduction in the AHP and late ipsp as well as the changes in membrane potential, whereas the carbachol-induced attenuation of the epsp and early ipsp was mediated by an M_2 receptor. Upon repetitive NB activation, the epsp/ipsp sequence gave way to a series of epsps followed by an ipsp and a slow epsp associated with an increase in neuronal excitability. These responses to tetanic NB stimulation were potentiated in eserine and blocked by muscarinic antagonists. They also mimicked some of the effects elicited by exogenous application of carbachol.

These results are the first to demonstrate muscarinic actions in areas of the amygdala known to receive cholinergic innervation. These effects appear to involve both direct and indirect mechanisms and to result from the activation of both the M_1 and M_2 classes of receptors.

TRIFLUOPERAZINE CAUSES A SLOW DEPOLARIZATION IN HIPPOCAMPAL SLICES. N. Agopyan and K. Krnjević. Anaesthesia Research Department, McGill University, Montréal, Québec, Canada, H3G 1Y6.

Trifluoperazine (TFP), a neuroleptic and a proconvulsant, is a potent calmodulin antagonist. In previous experiments TFP, like ACh, reduced dendritic field responses reversibly. Hence we studied the effect of TFP on membrane properties and synaptic potentials in hippocampus in vitro.

At a concentration of 50-100 μM TFP consistently depolarized CA1 pyramidal cells by 10-35 mV, one min after the start of its superfusion. Full recovery of membrane potential was seen within thirty min of wash. This effect was accompanied by a reduction in input resistance and a marked depression of slow afterhyperpolarization (both measured at initial resting potential). The depolarization induced by TFP was affected neither by TTX, nor by 4 mM Cs^+, suggesting that it is not mediated by Na^+ current or anomalous rectification. The involvement of Ca^{2+} currents is presently being investigated.

Synaptic potentials were not significantly affected by TFP, suggesting that the reduction seen in dendritic field responses in both in vitro and in situ experiments is due to the depolarization induced by TFP.

BINDING CHARACTERISTICS OF OXYTOCIN RECEPTORS IN THE VENTROMEDIAL HYPOTHALAMIC NUCLEUS OF STEROID TREATED RATS. A.E. Johnson and T.R. Insel, Section on Comparative Studies of Brain and Behavior, Laboratory of Clinical Sciences, NIMH, Poolesville, MD 20837.

Ovarian steroids modulate oxytocin (OT) receptor binding in both brain and uterus. In the hypothalamus, estradiol (E_2) increases [^{3}H]OT binding in portions of the ventromedial hypothalamic nucleus (VMN) that contain the greatest density of E_2 concentrating cells. Recently we have shown that the binding of the selective OT receptor antagonist ^{125}I-d(CH_2)$_5$[Tyr(Me)^2,Thr^4,Tyr-NH_2^{9}]OVT (^{125}I-OVTA; Elands et al., 1987) is similarly regulated by E_2 (Johnson et al., in press). The experiments reported here describe the binding characteristics of ^{125}I-OVTA to sites in the VMN of steroid treated rats with receptor autoradiographic procedures.

Adult female rats were ovariectomized and treated one week later with either E_2 (10μg), E_2 and Progesterone (P, 500μg) or Oil for two days and killed 24h after the last injection. Brains were removed, frozen on dry ice and stored at -60°C. For saturation studies, brain slices (20μm) through the caudal VMN were exposed to a range of ^{125}I-OVTA concentrations (1 to 100pM) with unlabeled OT (5μM) used to define nonspecific binding. Several concentrations of OT and AVP as well as selective OT and AVP ligands were used to characterize ^{125}I-OVTA binding in competition studies. Brain slices and ^{125}I-brain paste standards were apposed to film for 3 days and autoradiograms were analyzed by conventional densitometric methods.

Saturation analysis revealed that ^{125}I-OVTA labeled a single class of high affinity binding sites (K_d=60pM) in the VMN. Competition profiles confirmed that as in hippocampal membranes (Elands et al., 1987), sites labeled by ^{125}I-OVTA are characteristic of OT receptors. Differences in ^{125}I-OVTA binding between steroid treatment conditions were due to changes in the number of ^{125}I-OVTA binding sites rather than binding affinity. ^{125}I-OVTA binding was greatest in E_2 treated animals (70 fmol/mg prot) compared to animals treated with either E_2+P (45 fmol/mg prot) or Oil (15 fmol/mg prot). Data from these experiments confirm previous results on the interaction of ovarian steroids and hypothalamic OT receptors and show that the steroid-dependent increase in OT receptor binding in the VMN is due to an increase in the number of specific OT receptors rather than a change in binding affinity.

RECEPTOR CHARACTERIZATION OF ADRENERGIC EFFECTS IN THE MEDIAL PONTINE RETICULAR FORMATION IN VITRO. U. Gerber, R.W. Greene, H.L. Haas*, and R.W. McCarley. Harvard Medical School/VAMC, Brockton, MA 02401; Johannes Gutenberg-Universitat, Mainz, FRG

Anatomical and physiological evidence indicates that the medial pontine reticular formation (mPRF) receives a noradrenergic projection from the locus coeruleus. Adrenergic binding sites have been demonstrated autoradiographically in the reticular formation and an extracellular microiontophoretic study (Greene and Carpenter, 1985) has shown that norepinephrine (NE) decreases glutamate-evoked neuronal firing in mPRF. The in vitro slice preparation was employed to investigate the mechanism of action and to characterize the receptors mediating adrenergic responses in mPRF. Adrenergic agonists were bath applied (10^{-6}-10^{-5}M) or pressure ejected with a "puffer" micropipette. NE depolarized 18 of 24 cells by 3 to 10 mV and increased PSP frequency; 5 cells were hyperpolarized. Depolarization seen with NE could be mimicked with phenylephrine in 17 of 20 cells and with isoproterenol in 2 of 9 cells. Voltage clamp in 3 of these cells demonstrated an inward current associated with decreased chord conductance. Clonidine hyperpolarized 5 out of 8 cells (>3mV in 2 cells;<3mV in 3 cells). Responses were unchanged by TTX in 4 cells consistent with a direct, non-synaptic action. These results provide functional evidence for the presence of α_1 and α_2 receptors mediating opposing responses in the mPRF.

MODULATION OF NEOCORTICAL NORADRENALINE RELEASE BY ACTIVATORS AND INHIBITORS OF PROTEIN KINASE C. D.J. Dooley, C. Schächtele*, C. Rudolph*, H. Osswald* and G. Satzinger*. Gödecke Research Institute, D-7800 Freiburg, F.R.G.

Protein kinase C (PKC) is hypothesized to have a role in the process of neurotransmitter release. The characterization of this role has, however, been hindered by the nonavailability of potent and selective PKC inhibitors. We tested several PKC inhibitors (PKCI; e.g., staurosporine, UCN-01 (7-hydroxystaurosporine)) and activators (PKCA; e.g., 4ß-phorbol-12,13-dibutyrate (4ß-PDB)) for effects on [^{3}H]-noradrenaline release evoked from superfused rat neocortical slices by electrical stimulation, or on such release enhanced or inhibited by various pharmacological or electrical means. Additionally, we established the in vitro potency and selectivity of the PKCI to inhibit this enzyme relative to three other protein kinases (cAMP, cGMP, MLC). The PKCA markedly increased depolarization-evoked [^{3}H] overflow without substantially altering basal [^{3}H] outflow. The PKCI, exemplified by UCN-01 having a desirable potency and selectivity, generally lacked effects on control [^{3}H] overflow or outflow; only enhanced [^{3}H] overflow, esp. in response to direct PKC activation (e.g., 4ß-PDB), was attenuated by these substances. These results indicate that PKC modulates neocortical noradrenaline release under quasi-physiological conditions. PKCI can conceivably normalize excessive neurotransmitter release induced by a dysregulation of the phosphatidylinositol/PKC system.

CALMODULIN ANTAGONISTS MODULATE SYNAPTIC ACTIVATION OF HIPPOCAMPAL PYRAMIDAL CELLS. M.D. Mauk, P.T. Kelly, R.J. Cormier, and M.N. Waxham. Univ. Texas Medical School, Houston, TX 77225.

Recent studies suggest possible roles for calmodulin (CaM) in synaptic transmission (Llinas et al, **PNAS 82**, 1985) and synaptic plasticity (Perkel et al, **Neurosci Abstr. 15**, 1989). We have observed that bath application of CaM antagonists to hippocampal slices can alter EPSPs elicited in CA1 pyramidal cells. Two of these antagonists (CBP & CBP-3) are peptides based on the CaM binding region of CaM kinase-II and reversibly attenuate EPSPs (100uM, 10 min). The naphthalenesulfonamide CaM antagonists W7 and W5 (0.1-1.0 mM) also reversibly attenuate EPSPs with a potency that parallels their CaM antagonism (W7 > W5). In addition, W5 produces a delayed, robust, and long-lasting (1-3 hrs) facilitation of EPSPs. W7 can produce this effect, although variably and much less potently. We have observed no facilitation with the peptide CaM antagonists. Preliminary experiments suggest that the facilitation of EPSPs produced by W5 is attenuated by the protein kinase antagonist H7.

There are several known CaM-dependent processes which could be mutually antagonistic with respect to synaptic transmission. For example, there are CaM-dependent protein kinases as well as CaM dependent phosphatases. Also CaM can serve to activate some kinases and inhibit the activation of others. In future studies we hope to distinguish among such possibilities.

SYNAPTIC PLASMA MEMBRANE PHOSPHOPROTEIN PHOSPHATASE 2Ao MAY REGULATE AUTOPHOSPHORYLATION OF cAMP AND Ca^{+2}/CAM DEPENDENT KINASES. G.N.Barnes*, J.T.Slevin and T.C.Vanaman* (SPON: M.McQuillen) VAMC & Univ.of KY, Lexington, KY 40536

The hippocampus is enriched in protein kinase and phosphoprotein phosphatase activities which appear to play a central role in controlling hippocampal neuronal excitability. We have partially purified a high molecular weight phosphoprotein phosphatase which appears to redistribute from the cytosol to synaptic plasma membranes (SPM) of rat hippocampus after electroconvulsive shock. Here we report purification of the phosphatase by a combination of ion exchange and gel filtration chromatography. This purified phosphatase from both cytosol and SPM contains 63, 55, and 38 Kd polypeptides. Tentatively identified as phosphoprotein phosphatase 2Ao (pp2Ao), the enzyme catalyses the release of $^{32}P_i$ from the purified catalytic and regulatory subunits of cAMP-dependent protein kinase in vitro, and is able to release $^{32}P_i$ from an endogenously phosphorylated 50 Kd band in SPM tentatively identified as the α-subunit of Ca^{+2}/Cam-dependent kinase II. Pp2Ao is a major phosphatase in hippocampus, whose membrane association is enhanced by K^+-depolarization of hippocampal neurons in vitro (Barnes etal, Soc.Neurosci.Abstr, 1989). These data suggest that pp2Ao may regulate kinases actuated by transmitter-triggered operation of cAMP and Ca^{+2}-activated second messengers. EXTRACELLULAR BARIUM INCREASES THE AMPLITUDE OF SOMATIC POPULATION SPIKE AND DENDRITIC FIELD POTENTIALS IN THE RAT HIPPOCAMPUS *IN VITRO*. J.P. Harris. Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec H3G 1Y6, Canada and Department of Computer and Information Sciences, S.U.N.Y. at Potsdam, Potsdam, N.Y. 13676.

The effect of the potassium channel blocker barium (Ba^{2+}) on synaptic transmission was studied in the hippocampal slice *in vitro*. Somatic population spike and dendritic field potentials were simultaneously recorded from the CA1 region following delivery of constant current stimuli to the stratum radiatum. The input current intensity was systematically varied in 0.1 mA steps from I_0, the lowest level at which some degree of neural response was recognizable, to I_{100}, the level that produced a maximal spike amplitude.

Addition of Ba^{2+} (1 mM) to the perfusing medium resulted in i) production of a large population spike at I_0, ii) an approximately 50% increase in the amplitude of the population spike at I_{100} and other intermediate current intensities, and iii) a corresponding increase in the amplitude of the dendritic field potential. The presynaptic volley of the dendritic field potential was also more pronounced during perfusion with Ba^{2+}. The observed results may be due in part to enhanced transmitter release. (Supported by MRC Canada grant to R. Capek and B. Esplin.)

EFFECTS OF 1,10-o-PHENANTHROLINE ON ELECTROPHYSIOLOGICAL RESPONSES IN HIPPOCAMPAL SLICES. Y. WANG, M.K. Sly, H.J. DOLLER, & I.L. CRAWFORD* (SPON: R.W. Honan). Department of Neurology, The University of Texas Southwestern Medical School at Dallas and Epilepsy Center, VA Medical Center, Dallas, Tx 75216.

The distribution of zinc in the hippocampus is highly localized. Since the chelate or competitve metal affinity and binding properties of many drugs posit zinc as a locus for drug action , we investigated the effect of different chelators on hippocampal physiology. 1,10-o-phenanthroline is a well established chelator used widely in biochemical studies of zinc metalloenzymes. The 1,7 isomer has been shown to be a useful nonchelating control.

Granular cell population spike responses to perforant pathway stimulation were recorded from guinea pig hippocampal slices. Glass recording electrodes of 1.4-1.8 Meg-ohms were used. Responses were measured as area of the population spike. Stimulating voltages ranged from 5 to 70 volts. Inter-stimulation intervals were 20 sec to minimize stimulation interaction.

We found that 5 to 200 uM 1,10-o-phenanthroline inhibited evoke responses. The log-dose response curve indicated the ED50 was around 30 uM. The 1,7 isomer had no effect over this same range. The results provide more suggestive evidence that pertubation of zinc affects neural transmission.

84.12

INHIBITION OF HIPPOCAMPAL AND NEUROMUSCULAR SYNAPTIC TRANSMISSION BY *CAUSUS RHOMBEATUS* VENOM. Nancy L. Peterson and James F. Koerner. Dept of Biochemistry and Neuroscience Grad. Program, Univ. of Minn., Minneapolis, MN 55455.

Eight venoms were screened for their ability to inhibit synaptic transmission in the rat hippocampal slice preparation. Of these venoms, only venom from the snake *Causus rhombeatus* (rhombic night adder) inhibited synaptic transmission. Upon purification by gel filtration, two active venom components were isolated. One component (F-II) was identified as adenosine monophosphate via HPLC elution and enzymatic assays. The identity of the other component (F-I) has not been determined. A molecular weight of 1100-1600 was estimated from Sephadex G-25 elution. Assuming mw=1400, and the total protein concentration of F-I, the IC_{50} in the CA1 pathway would be less than 3 μM if F-I is a peptide. F-I reversibly inhibited both hippocampal CA1 synaptic responses which were recorded extracellularly and frog neuromuscular synaptic responses which were recorded intracellularly. During the intracellular assay, the membrane potential, capacitance and time constant remained unchanged. Furthermore, it was possible to intracellularly stimulate action potentials in the presence of F-I. These data suggest that F-I may be a potent, reversible presynaptic inhibitor.

URETHANE ATTENUATES PHORBOL ESTER-INDUCED INCREASES IN HIPPOCAMPAL CA3 RESPONSES IN VIVO. D.N. Lieberman*, B.E. Derrick, & J.L. Martinez Jr. (SPON: S. Roberts) Dept. of Psych., Univ. of California, Berkeley CA 94720

We previously reported that the mechanisms of induction and maintenance of mossy fiber LTP appear distinct from the NMDA-dependent form of LTP found at commissural-CA3 synapses (Neurosci. Abstr. 13:565, 1988). Urethane anesthesia distinguishes these two forms of LTP since it blocks LTP of mossy fiber-evoked (MF), but not commissurally-evoked (COM), CA3 responses. In this study, phorbol 12,13-diacetate (PDAc) was used to examine the possible roles of protein kinase C (PKC) in these two hippocampal pathways. PDAc pressure-ejected into the CA3 region induced transient increases in both MF- and COM-evoked CA3 responses in both pentobarbital and urethane anesthetized animals. The PDAc-induced increases were significantly greater than in either vehicle or inactive phorbol ester (4-alpha-phorbol 12,13 didecanoate) controls, suggesting these increases were due to PKC activation. While the PDAc-induced excitation under urethane was less overall than that observed under pentobarbital anesthesia, urethane significantly attenuated increases in the MF field EPSP, but not the COM field EPSP or COM population spike. This parallels the earlier results in which urethane blocks LTP of MF but not COM responses.

EFFECT OF REACTIVE OXYGEN SPECIES ON THE SQUID GIANT SYNAPSE. Gilbert, D. L., Yao, J.*, C. A. Colton, and M. Spencer*. Lab. of Biophysics, NINDS, NIH, Bethesda, MD 20892, Dept. of Physiol. Biophys., Georgetown Univ. Med. Sch., Washington, D.C. 20007, and Marine Biological Lab., Woods Hole, MA. 02543.

The effect of H_2O_2 on synaptic transmission in the neuromuscular junction in the synapse of the lobster (Colton, C., Colton, J., and Gilbert, D., J. Free Radical Biol. Med. 2:141-148, 1986) and in the hippocampus slice preparation (Colton, C.A., Fagni, L., and Gilbert, D., Free Radical Biol. Med. 6:, in press) has been reported. We now report on the effect of 0.01 mM, 0.1 mM, and 1 mM H_2O_2 on the perfused squid giant synapse. Excitatory post synaptic potentials were depressed or not changed at 0.01 mM or 0.1 mM. However, a significant depression was seen at the high dose of 1 mM. Addition of Fe^{++} or Cu^{++} ion did not enhance the depression induced by H_2O_2.

Superoxide anion was generated by the enzymatic reaction of xanthine with xanthine oxidase. The reaction mixture was prepared in artifical sea water at a temperature of 22 degrees C, 20 min prior to exposure of the synaptic preparation to allow for the superoxide production. Superoxide conc. was analyzed on separate samples using a cytochrome C reduction assay and was about 0.01 mM. Again, excitatory post synaptic potentials were generally depressed by this reactive oxygen intermediate.

84.15

END-PLATE (EPC) AND MINIATURE END-PLATE CURRENT (MEPC) KINETICS IN VOLTAGE-CLAMPED RAT HEMIDIAPHRAGM FOLLOWING ACUTE EXPOSURE TO THE PARALYTIC AGENT 2,4-DITHIOBIURET (DTB). J.M. Spitsbergen and W.D. Atchison. Dept. Pharmacol./Toxicol., Neurosci. Program, Mich. State Univ., E. Lansing, MI 48824.

Previous microelectrode recording studies have revealed an increased rise and decay time for end-plate potentials (EPPs) and miniature end-plate potentials (MEPPs) following exposure to DTB. To determine if DTB alters kinetics of current flow through the acetylcholine (ACh)-channel at the neuromuscular junction, EPCs and MEPCs were recorded from hemidiaphragms of control rats or 1 hr after treatment of rats with DTB (25 mg/kg, ip) using a two-microelectrode voltage clamp. Only MEPCs with fast rise and decay were used for determination of rise and decay kinetics. Rise and decay times of EPCs appeared to be decreased by DTB. This was even more apparent for MEPCs for which the rise time (10-90%) decreased from 507±41 to 431±28 μsec and the half time of decay decreased from 1.23±0.09 to 0.94±0.03 msec following treatment. Although the rise and decay for normal MEPCs appeared faster in muscles from treated rats, the number of abnormal large slow MEPCs increased from 11 to 20% of recorded MEPCs. Thus, the increase in EPP and MEPP rise and decay times cannot be explained by an increase in the duration of current flowing through the ACh-channel following DTB exposure. One possible explanation for the observed slowing is the increase in the number of abnormal MEPCs following DTB exposure. (Supported by NIH grant NS20683 and a Muscular Dystrophy Association grant.)

84.16

METHYLMERCURY (MeHg) INHIBITS [^{3}H]CHOLINE UPTAKE AND INDUCES [^{3}H]ACETYLCHOLINE (ACh) RELEASE FROM RAT BRAIN SYNAPTOSOMES INDEPENDENTLY OF EXTRACELLULAR CALCIUM CONCENTRATION. P.C. Levesque and W.D. Atchison. Dept. Pharmacol./Toxicol., Mich. State Univ., E. Lansing, MI 48824.

Effects of MeHg on transmitter release from central nerve terminals were tested by labeling ACh in rat brain synaptosomes during a 30-min incubation with 1 μM [^{3}H]choline. [^{3}H]choline accumulation occurred via the high-affinity uptake carrier since uptake was reduced greatly by 20 μM hemicholinium-3 or by Na^+-free medium. MeHg reduced synaptosomal [^{3}H]choline uptake by 20-25% at 10 μM and 35-40% at 100 μM. ACh release was tested by incubating [^{3}H]choline-loaded synaptosomes in the absence or presence of MeHg and Ca^{2+}, filtering and then measuring [^{3}H]ACh in the filtrate by liquid cation exchange chromatography. [^{3}H]ACh release increased by 10-15% when synaptosomes were incubated with 10 μM MeHg for 5 sec and 1 min and by 20-25% when incubated for 3 min. 100 μM MeHg increased [^{3}H]ACh release by 20-25% at 5 sec and 1 min and by 35-40% at 3 min. Excluding Ca^{2+} from the incubation medium moderately attenuated the release of [^{3}H]ACh by 10 μM MeHg and slightly diminished the release induced by 100 μM MeHg. These results indicate that the MeHg-induced increase of spontaneous release of ACh from synaptosomes is only partially dependent upon external Ca^{2+} and corroborate the results of an earlier study (J. Pharm. Exp. Ther. 237: 672, 1986) which utilized a peripheral synapse. (Supported by NIEHS grant ES03299.)

IN VIVO ELECTROCHEMICAL AND ELECTROPHYSIOLOGICAL MEASUREMENTS USING MULTICHANNEL SOLID-STATE RECORDING ELECTRODES. C.G. Van Horne*,1, S. BeMent*,3, B.J. Hoffer1,2 and G.A. Gerhardt1,2 (SPON: R. Freedman). Depts. of Pharmacology1 and Psychiatry2, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262 and Dept of Electrical Engineering and Computer Science3, Univ. of Michigan, Ann Arbor, Michigan 48109.

Solid-state multi-channel recording electrodes have numerous potential advantages over existing "laboratory-fabricated" designs, such as precise spatially-resolved multiple recording sites, reproducible electrophysiological and electrochemical recording characteristics, and increased mechanical strength. In the present study, five-channel silicon-based microprobes were sputter-coated with carbon, coated with Nafion, and used for both in vivo electrochemical and single unit electrophysiological recordings. High-speed electrochemical studies were performed in vivo and showed that these multi-site probes were capable of monitoring the evoked overflow of monoamines in selected brain regions of the rat. In addition, action potentials from Purkinje cells in the rat cerebellum, identified electrophysiologically, were recorded from different sites on the same probe. The change in firing rate in response to systemic administration of PCP was found to decrease in a dose-dependent manner. These results provide preliminary evidence that solid-state multi-site probes can be utilized for in vivo electrochemical and electrophysiological studies in the rat brain. GENETIC ANALYSIS OF THE *SEIZURE* LOCUS IN *DROSOPHILA MELANOGASTER*. P. Deak and L.M. Hall Dept. of Molecular Genetics, Albert Einstein College of Medicine, Bronx, NY 10461. Current Address: Department of Biochemical Pharmacology, SUNY at Buffalo, Buffalo, NY 14260.

Previous genetic, biochemical and electrophysiological studies of two temperature-sensitive paralytic alleles (sei^{ts1} and sei^{ts2}) suggested that the *seizure* locus may be involved in the formation of functional voltage-sensitive sodium channels. In order to understand the molecular nature of the *seizure* gene product and its role in the functioning of sodium channels, we have isolated new alleles in this locus. We report here a genetic and cytological characterization of these mutants as well as complementation analysis with existing deficiencies in this region. Some of these new alleles represent visible deficiences in region 60 of salivary gland chromosomes. They are viable over each other and produce a paralytic phenotype at 38°C. This strongly suggests that the null phenotype (no gene product present) for *seizure* is temperature-induced paralysis. These deficiency alleles can be used as cytogenetic landmarks for cloning the locus. Furthermore, the new alleles interact with other temperature-sensitive mutations affecting membrane excitability providing further evidence that *seizure* shares related function with these genes.

Nested Genes Inside a Putative Drosophila Sodium Channel Gene are Conserved. C. Smith*, A. Butler*, and L. Salkoff. Dept. of Anatomy & Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Two putative sodium channel genes have been cloned in Drosophila (Salkoff et. al., Science 237: 744, 1987; Ramaswami and Tanouye, PNAS, USA 86: 2079, 1989). An interspecies comparison of the first sodium channel gene is underway in D. melanogaster and in D. virilis (melanogaster and virilis diverged 50-80 million years ago). We find that the sequence and genomic organization of the gene is highly conserved between virilis and melanogaster. Significantly, two other small genes, with multiple introns and exons, are encoded in separate 5′ introns of the sodium channel gene. This creates multiple overlapping transcription units. Remarkably, these nested genes are conserved between species, with respect to their sequence, intron/exon configuration, and position. It is possible that these nested genes are conserved inside the sodium channel gene because of a functional relationship to the sodium channel, perhaps involving control of gene expression.

85.3

ALTERNATIVE SPLICING GENERATES DISTINCT SODIUM CHANNEL SUBTYPES IN *DROSOPHILA*. B. Ganetzky and K. Loughney*. Lab. of Genetics, University of Wisconsin, Madison, WI 53562.

By use of P element transposon tagging and chromosome walking, we have cloned the *Drosophila para* locus, mutations of which cause defects in action potential propagation. Overlapping cDNAs representing essentially all of the *para* coding region have now been sequenced. The *para* polypeptide is extremely similar to rat brain sodium channels in overall structure and amino acid sequence. The deduced *para* polypeptide shares 46% identity with rat brain sodium channels; within membrane spanning domains there are 60-70% amino acid identities. Thus, genetic, molecular, and electrophysiological data all indicate that *para* encodes a functionally predominant class of sodium channels. Three independently isolated cDNAs encoding the amino terminal half of the *para* polypeptide were analyzed. Each of these has a unique structure and each encodes a slightly different amino acid sequence as a consequence of alternative splicing. These alternative splice events result in the optional inclusion of three microexons of 21, 8 and 13 amino acids respectively. Two microexons are located within the first cytoplasmic linking region and the other is located within the second cytoplasmic linking region. The first optional microexon includes an additional potential site for cAMP-dependent phosphorylation. Another splicing variation results in a choice between two exons, both encoding a 56 amino acid segment spanning a portion of region IIS4 and all of IIS5. Although these two alternative exons are only 80% identical at the nucleotide sequence level, they encode amino acid sequences that are identical at all but two positions. One of the changes results in the creation of an additional potential site for glycosylation in the extracellular region between IIS5 and IIS6. Our data suggest a minimum of three, and potentially more, structually distinct forms of sodium channel may be expressed from the *para* locus by alternative splicing. Whether any of these different forms are also functionally distinct remains to be determined.

85.4

NAP^{TS} AND *MLE*: MUTATIONS IN ONE GENE AFFECTING SODIUM CHANNEL ACTIVITY AND TRANSCRIPTION CONTROL IN *DROSOPHILA*. M. Kernan*, M.Kuroda*, B. S. Baker* and B. Ganetzky (SPON: M. D. Bownds). Lab. of Genetics, Univ. of Wisconsin, Madison, WI 53706 and Dept. of Biol. Sci., Stanford Univ., CA 94305

We have shown by genetic complementation and mutagenesis that nap^{ts1}, a mutation causing temperature-sensitive block of action potentials by affecting sodium channel activity, is a gain-of-function mutation in the *mle* gene. Loss-of-function mutations in this gene eliminate the male-specific hyperactivation of X chromosome transcription and are male-lethal. nap^{ts1} appears to act via $para^{+}$, an X-linked sodium channel structural gene, but its effect cannot be explained as a simple defect in male X transcription.

We have cloned the *nap/mle* gene by chromosome walking and have rescued both *nap* and *mle* effects with 10 kb of wild type genomic DNA in a germline transformation experiment. Analysis of cDNAs from this region shows at least two different transcripts, with different deduced protein products, produced by alternative splicing. To distinguish the nap^{+}, mle^{+} and nap^{ts} activities at a molecular level, and to investigate the nature of the nap^{ts} effect on sodium channels, we are using a nuclease assay to locate and characterize the different types of point mutation. First results indicate that four independently isolated nap^{ts} mutations show a similar, possibly identical alteration. DNA sequence analysis and transformation with mutant and chimaeric mutant/wild-type DNA will be used to confirm the identity of changes giving rise to the mutations.

85.5

STRUCTURAL AND FUNCTIONAL ANALYSIS OF THE VOLTAGE GATED SODIUM CHANNEL. V. Auld#*, T.Hebert#*, A. Goldin+, D.Krafte@, N.Davidson@, and R.Dunn#. #Dept. Medical Genetics, University of Toronto, Toronto, M5S 1A8. +Dept. Molecular Genetics, U.C. Irvine, CA, 92717. @Church Chemical Labs and Division of Biology, Caltech, Pasadena, CA, 91125.

We have cloned and constructed a full length cDNA that encodes a rat brain Na^+ channel α subunit termed Rat IIA. In vitro transcribed RNA from this clone produces a functional sodium channel. The properties of the Rat IIA channel differ with respect to its current/voltage relationship from the Rat II and III channels. We are interested in correlating predicted structural features with this difference in the channel's activation as well as with general functional characteristics of the channel protein. Our approach has been to produce mutations in the channel cDNA by i) site-directed mutagenesis and by ii) random linker-insertion mutagenesis. Functional analysis of these mutant channels in *Xenopus* oocytes will provide clues as to the components that are responsible for the sodium channel's electrophysiological properties.

85.6

EXPRESSION OF SODIUM CHANNEL II AND IIA GENES IN RAT BRAIN. C.M.I.Ahmed*, H.Lester and N.Davidson. Division of Biology California Institute of Technology, Pasadena, CA 91125

The alpha subunit of voltage-sensitive sodium channels expressed in rat brain has been shown to exist in four different isoforms,which are designated as I,II,IIA and III(Noda,M. et al.,1986 Nature 320,188-192;Auld et al.1988 Neuron 1,449-461). The isoforms II and IIA differ in only 6 of 2005 aminoacids.Comparison of cloned subtype II and IIA alpha subunits,as expressed in Xenopus oocytes, shows that the current-voltage relatioship of IIA is shifted by 20-25 mV in the depolarizing direction(Stuhmer,W.et al. 1987 Eur.Biophys.J. 14, 131-138; Auld,V. et al.,1988). The polymerase chain reaction(PCR) technique permits specific and very sensitive detection of mRNA and genomic DNA sequences. Using PCR with primers that are specific for and distinguishable between II and IIA sequences, we find that both II and IIA subunits occur in brain, in a 10:1 ratio. When the polymerase chain reaction was carried out with genomic DNA, using again primers specific for II or IIA subunits, a difference in the intron/exon arrangement for these two subunits was observed. This indicates either alternative splicing or the presence of two different genes for the two polypeptides,most probably the latter.

CHARACTERIZATION OF A FULL-LENGTH cDNA FOR A SODIUM CHANNEL DIFFERENTIALLY EXPRESSED IN DENERVATED RAT SKELETAL MUSCLE. R.G. Kallen*, Z. Sheng*, L.Q. Chen*, K. Fischbeck and R.L. Barchi. (SPON:A. Rosenquist). University of Pennsylvania School of Medicine, Philadelphia, PA 19104-6059

Pharmacological, electrophysiological, biochemical and immunological data favor the existence of multiple voltage-sensitive sodium channel subtypes in rat skeletal muscle. We now report the complete nucleotide sequencing of a second channel subtype from rat muscle that is preferentially expressed in adult denervated muscle, in fetal muscle, and in rat primary muscle cells in culture. It exhibits a tetra-domain repeat sequence with 6 putative transmembrane alpha-helical subdomains per domain as do all previous sodium channels reported. It differs from skeletal muscle subtype I (SkM-I) as follows: overall length is about 100 amino acids greater, the length of the interdomain I-II is 174 amino acids greater, the putative inter-subdomain 5-6 extracellular loop within Domain I is 28 amino acids shorter and has far fewer prototypical glycosylation sites. The cellular and subcellular localization of the mRNAs encoding individual subtypes have been examined in normal and denervated adult skeletal muscle with in situ hybridization. For the SkM-II probe, grain density increases dramatically with denervation, is concentrated around the subsarcolemmal nuclei, and does not appear fiber type specific. Supported by NIH NS-08075 and NS-18013 and the Muscular Dystrophy Association.

DIFFERENTIAL EXPRESSION OF mRNAs ENCODING TWO SUBTYPES OF VOLTAGE-DEPENDENT SODIUM CHANNEL IN SKELETAL MUSCLE. J. Yang, Z. Sheng, R.G. Kallen, and R.L. Barchi. University of Pennsylvania School of Medicine, Philadelphia PA, 19104.

The cDNAs of two voltage-dependent sodium channel isoforms found in rat skeletal muscle have recently been cloned and sequenced (Trimmer, J. et al. Neuron, in press, 1989; Kallen, R.G. et al., Biophysical J. 55, 319a, 1989). We have studied the differential expression of these channel messages during myogenesis and under various physiological states in adult muscle. [^{32}P]-antisense RNA probes specific for each subtype were prepared from appropriate restriction enzyme cleaved cDNA fragments cloned in the Bluescript expression vector. Total RNA was isolated from relevant muscle samples, separated on formaldehyde-agarose gels and quantitated both by UV absorbance and by hybridization with a -actin probe. Electrophoretic transfers of identical quantities of total RNA were then hybridized with the subtype-specific RNA probes. The two sodium channel subtype messages show reciprocal temporal regulation during development of skeletal muscle in vivo. Type I message is very low at birth but increases as a sigmoid function of age, rising 10-fold between 1 and 35 days post partum. The expression of type II is transient, being most prominent at birth and dropping below detectable levels by 7 days post partum. In primary muscle cells derived from rat embryos, on the other hand, the type II channel message is expressed at a much higher level than the message for the type I channel.

To investigate the influence of neuronal factor(s) on the differential regulation of type I and II mRNA expression, we examined the effect of surgical denervation of hind leg muscles of adult rats on the steady-state level of subtype-specific message. Type I mRNA is prominent in innervated muscle and appears to increase slightly following denervation. Type II message is undetectable in innervated adult muscle but exhibits at least a 10-fold increase in expression following denervation to levels comparable to that of the type I mRNA. This work was supported in part by NIH grants NS-08075 and NS-18013 and by a grant from the Muscular Dystrophy Association.

EXTRACELLULAR REGIONS OF HOMOLOGOUS DOMAINS I AND IV OF THE RAT BRAIN SODIUM CHANNEL α-SUBUNIT CONSTITUTE THE RECEPTOR FOR α-SCORPION TOXINS. W.J. Thomsen*, L. Maechler*, S. Rossie*, and W.A. Catterall. Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195.

Site-directed and monoclonal antibodies that recognize diverse regions of the rat brain Na^+ channel α-subunit have been used to determine the amino acid sequence(s) that comprise the receptor for α-scorpion toxins. To achieve this goal, the influence of these different antibodies on the voltage-dependent binding of an α-scorpion toxin isolated from *Leiurus quinquestriatus* (LqTx) was evaluated. Of five site-directed antibodies (IgG) tested, two which recognize residues 355 - 371 and 382 - 400 located between the S5 and S6 segments of homologous domain I, respectively, and one antibody which recognizes residues 1736 - 1753 located between the S5 and S6 segments of homologous domain IV decreased specific binding of [^{125}I]LqTx to either rat brain synaptosomes or purified rat brain Na^+ channel reconstituted in phospholipid vesicles. This decrease was time- and concentration- dependent and similar half maximally effective concentrations (0.5 μM) and maximal levels of inhibition (40 - 50%) were observed for three antibodies. Fab fragments of all three site-directed antibodies also inhibited binding to similar levels as IgG. Three monoclonal antibodies which all specifically recognize an amino acid sequence located in the extracellular loop between segments S5 and S6 of homologous domain I also reduce toxin binding in a concentration-dependent manner with a maximal inhibition of 80%. These results suggest that proposed extracellular regions of homologous domains I and IV of the rat brain Na^+ channel α-subunit are in close spatial proximity and comprise at least part of the receptor for α-scorpion toxins.

ISOLATION OF NOVEL NA CHANNEL GENES BY PCR GENE AMPLIFICATION. J.H. Caldwell and K.L. Schaller*, Dept. of Cellular and Structural Biology, Univ. of Colorado Health Sciences Center, Denver, CO 80262.

Gene amplification is ideally suited for isolating members of multigene families. Total RNA was isolated and cDNA made from rat brain, skeletal and cardiac muscle. Oligomers (a 29-mer and 30-mer) that are virtually identical for the three published Na channel brain cDNAs were used in the Polymerase Chain Reaction (PCR) to amplify a region that is highly variable between the brain genes. The different sizes of the products were obvious on EtBr-stained polyacrylamide gels. Southern analysis with oligomers to the expected region confirmed that these were from Na channel genes. The amplified products were gel purified and subcloned into M13; they are now being sequenced.

PROBING THE TOPOGRAPHY OF THE MUSCLE VOLTAGE-DEPENDENT SODIUM CHANNEL BY PROTEOLYTIC CLEAVAGE. S. Kraner*, S. Zwerling* and R.L. Barchi, University of Pennsylvania Medical School, Philadelphia PA, 19104.

The alpha subunit (260 kDa) of the rat skeletal muscle sodium channel is sensitive to limited cleavage by endogenous and exogenous proteases. Using antisera against five oligopeptides spaced along the primary structure, cleavage fragments generated by endogenous muscle proteases during membrane isolation were first examined to define the location of protease-sensitive regions of the structure in its native environment. Major components that included the amino terminus were 130 and 90 kDa with lesser contributions from other peptides extending to 12 kDa. Antisera to epitopes within the carboxy terminal half recognized two fragments of 110 and 78 kDa.

The effects of exogenous trypsin, chymotrypsin, and V-8 protease on the intact 260 kDa alpha subunit in isolated membranes and in solubilized channel preparations were then examined using the same antibodies. All three exogenous proteases produced amino terminal fragments identical to those seen with endogenous proteolysis. The 90 kDa fragment was particularly resistant to further cleavage by these enzymes. The C-terminal antibodies identified an initial cleavage fragment of 110 kDa, but a 78 kDa fragment was not seen; rather several different smaller peptides were labeled by the three antisera in this group.

The similarity in cleavage patterns suggests that sites of proteolysis are located in loops easily accessible from the solvent in the tertiary structure. Comparison of the cleavage map to the primary structure indicates that these sites fall within putative cytoplasmic loops linking the homologous repeat domains; the domains themselves appear to be protected from cleavage by their compact transmembrane structure regardless of the protease involved. The region between D-III and D-IV is resistant to the endogenous protease, yielding a 78,000 MW limit fragment, but easily cleaved by exogenous proteases. The overall distribution of regions of protease sensitivity and resistance supports the predictions of current structural models for the channel. This work was supported in part by NIH grants NS-08075 and NS-18013 and by a grant from the Muscular Dystrophy Association.

N-ALKYLAMIDE NEUROTOXINS ACT AT TWO BINDING DOMAINS ON THE VOLTAGE-SENSITIVE SODIUM CHANNEL. J. A. Ottea* and D. M. Soderlund. Dept. of Entomology, NYSAES, Cornell University, Geneva, NY 14456.

Synthetic analogs of naturally-occurring *N*-alkylamide neurotoxins activated sodium flux through mouse brain sodium channels in the presence of scorpion (*Leiurus quinquestriatus*) venom. For some compounds, concentration-dependent activation was monophasic and was correlated with the inhibition of both batrachotoxin-dependent sodium uptake and [^{3}H]batrachotoxinin A-20-α-benzoate (BTX-B) binding. These compounds appear to act as partial agonists at the activator recognition site (Site 2) of the sodium channel. Other analogs exhibited biphasic concentration-response curves; in these cases, only the larger, low affinity response was correlated with inhibition of BTX-B binding, whereas the smaller, high affinity response occurred at concentrations that did not affect BTX-B binding. The latter effect therefore involves an action at another binding domain of the sodium channel. Among the analogs examined, only those with insecticidal activity were found to stimulate sodium uptake. Some nontoxic analogs also partially inhibited BTX-B binding but did not produce a corresponding activation of sodium flux; these compounds may therefore act as weak antagonists at Site 2. Our findings suggest that *N*-alkylamides may act at two distinct binding domains of the voltage-sensitive sodium channel but that the neurotoxic effects of these compounds in insects are correlated with their actions at Site 2. [Supported by NIH grant ES02160]

EXCITATORY AMINO ACIDS: RECEPTORS I

THE MULTIPLE EFFECTS OF MAGNESIUM ON THE GLUTAMATE- AND GLYCINF-STIMULATED ^{3}H-TCP BINDING IN RAT CEREBRAL CORTEX. T. Hori*, T. Yamamoto* and T. Moroji*(SPON: K. Yoshikawa). Dept. of Psychopharmacology, Psychiatric Research Institute of Tokyo, Tokyo 156, JAPAN.

Phencyclidine(PCP) has been well known to elicite psychotic condition in human. An accumlating evidence indicates the existence of a PCP receptor complex, consisting of the PCP binding site, the NMDA receptor, glycine receptor and K^+-channel molecules in the brain.

In this study, we have shown multiple regulatory effects of Mg^{2+} on the ^{3}H-TCP binding sites. The binding of ^{3}H-TCP to the well washed membrane was determined as described by Bonhaus and McNamara (Mol. Pharmacol., 34: 250-255,1988).

Mg^{2+} has a biphasic effect on ^{3}H-TCP binding, e.g.a stimulatory effect at low concentrations (EC_{50}= 5 uM) and an inhibitory effect at high concentrations (IC_{50}= 5 mM). In the presence of glutamate (10 uM) or glycine (10 uM), the EC_{50} value for Mg^{2+} was lowered by one fifths or one half, respectively. On the contrary, the IC_{50} value for Mg^{2+} was reduced by one tenths in the presence of glutamate but not glycine. On the other hand, K^+ inhibited dose-dependently both glutamate- and glycine-stimulated ^{3}H-TCP binding in the same manner. The present findings indicate the presence of multiple sites for Mg^{2+} of the PCP receptor complex associated with both glutamate and glycine (high affinity site) and only with glutamate (low affinity site).

CHRONIC MK-801 TREATMENT ENHANCES NMDA RECOGNITION SITE BINDING IN PERINATAL RATS. J. Uckele*, J.W. McDonald, K. O'Mara*, F.S. Silverstein, & M.V. Johnston. Neuroscience Program, Depts. of Pediatrics & Neurology, University of Michigan, Ann Arbor, MI 48104 & Johns Hopkins University, Baltimore MD 21205.

We previously reported that MK-801, a non-competitive NMDA antagonist, induces a rapid up-regulation of NMDA recognition sites (30-50% increase)when administered (i.p., 1 mg/kg)to postnatal day (PND)7 rats 2 or 24 hrs prior to sacrifice (McDonald et al., Soc. Neurosci. Abst., 1988). This study examines the effect of chronic treatment with MK-801 on binding to the NMDA receptor/channel complex & quisqualate-type glutamate receptors. Beginning on PND 5, rats received 4 i.p. doses of MK-801 (1 mg/kg, n=5) or saline (n=5)at 24 hr intervals. Animals were sacrificed on PND 13, 5 days after the last treatment. MK-801 treatment produced a 38±10% to 66±13% mean increase in NMDA recognition site binding in 3 hippocampal regions, 78±17% & 90±15% increase in cingulate cortex & striatum, & a 265±60% increase in the granule cell layer of the cerebellum compared to saline treatment ($p < 0.001$, ANOVA). Binding to glycine modulatory sites & PCP receptors associated with the NMDA receptor complex were unchanged. Quisqualate receptor binding was increased in all regions by 13±5% to 29±10% by MK-801 compared to saline($p < 0.001$,ANOVA). The data indicate that chronic treatment with the NMDA antagonist MK-801 produces a selective & marked increase in NMDA recognition site binding without altering glycine or PCP receptor/channel binding; MK-801 may alter the relationship between the receptor components of the NMDA receptor complex.

ONTOGENY OF THE RECEPTORS COMPRISING THE NMDA RECEPTOR COMPLEX. J.W. McDonald, M.V. Johnston and A.B. Young, Dept. Neurology, Univ. of Michigan, Ann Arbor, MI 48109.

The ontogeny of 3 binding sites on the NMDA receptor complex was examined in rat hippocampus by quantitative autoradiography. The NMDA recognition site was labeled using [3H]glutamate. [3H]Glycine was used to label the strychnine-insensitive glycine modulatory site and [3H]TCP to label the PCP receptor. Binding to each receptor was examined in adjacent brain sections from postnatal day (PND) 1, 4, 7, 10, 14, 21, 28, 90 rats (n=4/age). Values represent mean±SEM and are expressed as % of adult binding. A different developmental pattern was observed for each receptor component of the NMDA receptor complex. In stratum oriens of area CA1, NMDA receptor binding rose from 20% to 40% from PND 1 to 7, then increased rapidly to maximal densities at PND 14 (145% of adult), stabilized through PND 28 and then decreased to adult levels. Glycine and PCP receptor binding developed more slowly than NMDA receptor binding; densities rose in a linear fashion from PND 1 through PND 21 and maximal densities were at PNDs 21 (110%, PCP) and 28 (150%, glycine). Age of maximal binding and age at which binding began to decrease to adult levels varied between hippocampal areas for each receptor. Data suggest that the relationship between the component binding sites of the NMDA receptor complex changes markedly during development. Supported by USPHS grant NS 19613.

NMDA AND QUISQUALATE/AMPA RECEPTORS: DIFFERENTIAL REGULATION BY PHOSPHOLIPASE C (PLC). G. Massicotte*, M. Kessler, G. Lynch, and M. Baudry. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717, U.S.A.

Activation of membrane-associated phospholipases has been proposed to participate in the regulation of synaptic transmission at glutamatergic synapses. The present study was directed at determining the effects of PLC on the binding properties of different subclasses of glutamate receptors. Treatment of membranes with PLC (from Clostridium perfringens) produced an increased affinity of the quisqualate/AMPA receptor for [^{3}H]-AMPA, while kainate receptor binding was not affected. Both kinetic analysis and equilibrium saturation experiments indicate that PLC treatment produced a decrease in affinity for [^{3}H]-TCP (a ligand for the NMDA receptor associated ionic channel) when the channel was fully activated by high concentration of glutamate and glycine. The binding of [^{3}H]-glutamate and [^{3}H]-glycine was not modified by PLC treatment, but the binding affinity for the NMDA antagonist [^{3}H]-CPP was decreased by about 2 fold. The decrease in [^{3}H]-CPP binding was accompanied by a loss of the stimulation by glycine of [^{3}H]-glutamate binding. These data suggest that modification of glutamate receptors resulting from phospholipase activation might be involved in various forms of synaptic plasticity.

Supported by Grants BNS 81-12156 to M.B. and NS 21860 to M.K. G.M. has a fellowship from the "Fonds FCAR".

TWO MOLECULES OF AGONIST ARE REQUIRED FOR NMDA RECEPTOR ACTIVATION. D.C. Javitt, M.J. Frusciante* and S.R. Zukin. Departments of Psychiatry and Neuroscience, Bronx, NY 10461.

PCP and related psychotomimetic agents induce unique neurobehavioral effects by binding to a site (PCP receptor) located within the ion channel of the *N*-methyl-D-aspartate (NMDA) receptor complex. Access of PCP-like agents to the PCP receptor depends upon the functional state of the NMDA receptor complex. Binding of the PCP receptor ligand [^{3}H]MK-801 was studied in order to determine mechanisms of NMDA receptor functioning.

Kinetics of [^{3}H]MK-801 binding fit best to a biexponential model, suggesting the presence of two discrete components of association. The time course for the fast component of association ($t_{1/2}$=5 min) was similar to the predicted time course for MK-801-induced open channel blockade. Fast association of [^{3}H]MK-801 thus appears to represent association via the open channel of the activated conformation of the NMDA receptor complex. Addition of L-glutamate induced a dose-dependent 40-fold increase in steady-state binding to the fast component of [^{3}H]MK-801 association. The Hill coefficient for stimulation of fast binding, 2.06 ± 0.08, was statistically indistinguishable from 2, suggesting that the cooperative binding of 2 molecules of agonist may be required for NMDA receptor activation. Hill coefficients of 2 have been reported for agonist-induced activation of nACh and $GABA_A$ receptors, both of which are members of the Class I superfamily of neurotransmitter receptor. The existence of functional homology between NMDA and Class I receptors may suggest structural homology as well. (Support: PHS DA03383, Ritter Foundation and David Berg Family Fund (SRZ); MH00631 (DCJ); AECOM Department of Psychiatry, H.M. van Praag, M.D. Ph.D., Chairman.)

TWO CLASSES AND TWO STATES OF NMDA RECEPTORS. D.T. Monaghan[1], H.S. Lin*[1], and C.W. Cotman[2]. Div. Neurosurgery[1] and Dept. Psychobiology[2], University of California, Irvine, CA 92717.

We have previously shown that there are two forms of the NMDA receptor (Monaghan et al., 1988; PNAS 85: 9836-9840). These two subtypes display differing regional distributions and differing relative affinities for agonists and antagonists. Furthermore, glycine increases L-[^{3}H]glutamate binding while decreasing radiolabelled antagonist binding.

In this study we have evaluated the effect of glycine and the glycine antagonist HA-966 upon the distribution of binding sites for L-[^{3}H]glutamate and the NMDA antagonist [^{3}H]CPP. If the anatomically-distinct forms of NMDA sites simply represent different states of the NMDA receptor that are regulated by glycine, then addition of glycine or glycine antagonists should result in identical L-[^{3}H]glutamate and [^{3}H]CPP binding site autoradiograms. (Autoradiographic methods described in PNAS 85: 9836) Glycine stimulates L-[^{3}H]glutamate binding but not [^{3}H]CPP binding; HA-966 stimulates [^{3}H]CPP binding, but not L-[^{3}H]glutamate binding. However, in the presence of 5 μM glycine or 100 μM HA-966, NMDA-displacable L-[^{3}H]glutamate and [^{3}H]CPP binding sites retain their differing regional distributions. Glycine exhibits a greater percent stimulation of L-[^{3}H]glutamate binding in antagonist-preferring regions than in agonist-preferring regions; however, the regional distribution of glycine stimulation of L-[^{3}H]glutamate binding appears to be the average of both the agonist-preferring and the antagonist-preferring distributions. Together these results suggest that there are two distinct NMDA receptor subtypes and that each has two states regulated by glycine.

(+)3-PPP BINDING SITES IN PC12 CELLS. G.A. Paleos, Z.W. Yang, and J.C. Byrd. Developmental Neurobiology Program, University of Pittsburgh School of Medicine, W.P.I.C., Pittsburgh, PA 15213.

Phencyclidine (PCP) binds with high affinity to PCP and sigma receptors. The clonal cell line PC12 is known to express (+)3-PPP binding sites but no PCP receptors (Yang et al., Eur. J. Pharmacol., in press). Neither nerve growth factor nor sodium butyrate treatment affected the expression of either binding site. The binding of (+)3-PPP was linearly dependent upon protein concentration and was protease sensitive. the pH maximum of (+)3-PPP binding was 9.5, at which the K_D of (+)3-PPP was 27 nM. The time required for binding to reach equilibrium was moderately temperature sensitive. This (+)3-PPP binding site differs from the CNS sigma receptor in two respects. First, divalent cations cause a greater decrease in the affinity of (+)3-PPP for its PC12 binding site than for the sigma receptor. Secondly, the stereoselectivity for benzomorphan opiates is reversed, with the (-) isomer being favored (cf. Bowen et al., Neurosci. Abst., 1988); however, classical opiate antagonists are inactive at this site. These data suggest that the (+)3-PPP binding site in PC12 cells is either a sigma receptor subtype, or, alternatively, a binding site unrelated to the CNS sigma receptor.

86.8

(+)3-PPP AND TCP BINDING SITES IN RAT AND BOVINE ADRENAL MEDULLA. F. DePietro*, G.A. Paleos, and J.C. Byrd. Developmental Neurobiology Program, University of Pittsburgh School of Medicine, W.P.I.C., Pittsburgh, PA 15213.

The radioligand (+)[^{3}H]3-PPP is often used to label CNS sigma receptors. We have recently shown (Yang et al., Eur. J. Pharmacol., in press) that the rat pheochromocytoma cell line PC12 contains (+)3-PPP binding sites, but no PCP receptors, which have a similar pharmacological profile to sigma receptors. The (+)3-PPP site in PC12 cells differs from the CNS sigma receptor, however, with regard to the mechanism of binding inhibition by cations as well as its stereoselectivity for benzomorphan opiates. Since PC12 cells resemble primitive neuroblasts, we investigated whether adult rat and bovine chromaffin cells express either PCP or sigma-like receptors. Rat adrenal glands were found to contain both a large number (B_{max} = 900 fmol/mg protein) of high affinity (K_D = 26 nM) (+)3-PPP sites, as well as a significant number (B_{max} = 300 fmol/mg) of high affinity [^{3}H]TCP binding sites. Bovine adrenal medullae showed a higher number (B_{max} = 4380 fmol/mg) of high affinity (K_D = 69 nM) TCP binding sites, as well as a large number (B_{max} = 1250 fmol/mg) of high affinity (K_D = 48 nM) (+)3-PPP binding sites. In both species, there was a 10-fold stereo-selectivity for (+)3-PPP vs. (-)3-PPP. These data suggest that immature chromaffin cells may express only (+)3-PPP sites, while mature cells express both (+)3-PPP and TCP binding sites.
