In order to test the influence of hippocampal-and caudate-lesions on maze-exploration of rats guided by cue- and praxis-strategies, animals were tested in an automated 6-arm radial tunnel maze which provides neither visible nor auditory extramaze cues. In this maze, each arm is divided into a short blind arm and a long main arm. Rats explored the maze on the basis of spontaneous exploration, i.e., neither positive nor negative reward were provided. Following the lesion, rats were allowed to recover for 2 weeks. Acquisition was tested for 7 days, then the maze configuration was reversed to its mirror image from day to day for 5 days and, following 2 sessions using the same configuration as used during the last reversal session, rats were re-tested in the maze for 3 days after a 7-day break. From each session, several behavioral measures were obtained, i.e., number of blind arm entries, number of repetitive arm entries, locomotor activity, incomplete arm entries. From the beginning of the experiment, rats with hippocampal-lesions showed major behavioral changes in entering blind arms more frequently than sham operated animals. In contrast, caudate-lesioned rats showed no behavioral changes during the acquisition session, and only slight impairments during the reversal and re-test sessions.

The results will be discussed in terms of the ability of lesioned rats to use different strategies to explore a complex spatial task.

NEUROBIOLOGICAL ANALYSIS OF COGNITIVE MEMORY: ROLE OF THE HIPPOCAMPUS IN SPATIAL AND CUED DISCRIMINATION. S.Golski-Brennan, D.S. Olton, M. Mishkin, J.L. Olds, D.L. McPhie, and D.L. Alkon. Dept. of Psych., Johns Hopkins University, Baltimore, MD 21218.

The functional role of the hippocampus was examined by testing rats in a spatial and cued discrimination with equivalent conditions, except for the relevant discriminative stimuli. In Exp.1, acquisition (ACQ) was tested following control (CON, n=6) operations and complete hippocampal (HPC, n=6) lesions. HPC lesions in both the spatial and cued discrimination impaired ACQ (p's<0.01). During the 15-18th blocks of 12 trials, the mean choice accuracy (and standard error) was: spatial discrimination, CON=11(0.23), HPC=8(0.77); cued discrimination, CON=11(0.35), HPC=7(0.56). In Exp.2, protein kinase C (PKC) distribution was determined by autoradiography of 3 groups of rats (n=4 each group): tested in the spatial discrimination, tested in the cued discrimination, and untested (cage controls). [3H]PDBu binding in the CA1 region was consistent with the lesion data, as well as with the results of previous investigations suggesting that learning alters PKC localization. [3H]PDBu binding was normalized to each rat's global mean. The normalized value (and the standard error) for the CA1 region for each group was: cage=1.63(0.12); spatial discrimination=1.82(0.10); cued discrimination=1.89(0.09). Together, these data suggest that the hippocampus is involved in acquisition of both the cued and the spatial discriminations.

244.4

DISSOCIATION OF PREFRONTAL, POSTERIOR PARIETAL, AND TEMPORAL CORTICAL REGIONS TO SPATIAL NAVIGATION AND RECOGNITION MEMORY IN THE RAT. B. Kolb, K. Buhrman*, and R. McDonald* Dept of Psychology, University of Lethbridge, Lethbridge, Canada, T1K 3M4.

Rats with lesions of the medial prefrontal (Zilles Cg1, Cg3, Fr2), posterior parietal (Zilles anterior Oc2M; Krieg's 7), temporal (Zilles Te2, Te3), or visual (Zilles Oc1) cortex were trained on several learning tests designed to assess: (1) spatial navigation using distal cues; (2) spatial navigation using a landmark cue; (3) egocentric-directed spatial navigation; (4) visual recognition memory; and (5) visual pattern discrimination. Rats with prefrontal lesions were impaired at spatial navigation in all tests, especially the egocentric test, and were impaired at delayed but not immediate recognition memory. The rats with parietal lesions were mildly impaired at the first two spatial navigation tasks but performed normally on the visual discrimination and visual recognition tasks. The rats with temporal lesions were impaired only on recognition memory, even with 0 sec delay. These results: (1) dissociate the prefrontal, parietal and temporal regions; (2) are parallel to those observed in primates; and, (3) in view of the mild deficits from parietal lesions suggest that this area is poorly developed in the rat relative to the primate and may play a minor role in spatial navigation in rodents.

244.5

THE ROLE OF THE HIPPOCAMPUS AND THE MEDIAL PREFRONTAL CORTEX IN THE TEMPORAL CODING OF SPATIAL LOCATION. A. Chiba* and R.P. Kesner(SPON: S. Stensaas). Department of Psychology, University of Utah, Salt Lake City, Utah 84112.

Research suggests that the hippocampus and the medial prefrontal cortex play important roles in memory for the temporal order of events. As an extension of this research, memory for the temporal order of spatial locations across lags was examined.

Rats with medial prefrontal cortex, hippocampal lesions, or sham operated controls were tested on an eight arm radial maze. During the study phase of each trial, animals were allowed to visit each of eight arms once in an order that was randomly selected for that trial. The test phase required the animals to choose which of two arms occurred first in the running sequence of the study phase. The arms to be selected varied according to lag (0-6), or number of items in the running sequence that occurred between the two test arms.

The control animals performed at chance at a lag of zero, but their performance was above chance for the remaining lags, improving as the lag increased. The hippocampal lesioned animals showed a marked deficit, performing at chance for all lags, whereas the medial prefrontal animals showed a less severe deficit. The results of these data support the notion that both the hippocampus and the medial prefrontal cortex play significant roles in the temporal ordering of spatial locations.

244.6

DOES THE HIPPOCAMPUS PLAY A ROLE IN MEDIATING SPATIAL AND TEMPORAL CONFIGURATIONS? P. Jackson-Smith* and R.P. Kesner. Department of Psychology, University of Utah, Salt Lake City, Utah 84112.

Rudy and Sutherland (1988) have shown that the hippocampus is critical for acquisition and retention of configural associations, but not simple discriminations. A configural association is one in which a subject learns to respond to a compound stimulus as a separate entity that is distinct from the compound's components. In their study, the presentation of the compound stimulus (light and tone) confounded spatial (emanated from different spatial locations) and temporal (presented sequentially) components. The present experiment attempted to avoid this confound by using 3-dimensional cues that were presented singly or as a temporal configuration (one stimulus presentation immediately following the other) for the other half of the rats. A food reward was located beneath the stimulus on S+ trials and latency to move the stimulus on S+ and S- trials was measured. When performance on the compound S+ stimulus was significantly better than performance on both S- stimuli, the rats received control or hippocampal lesions. Contrary to Rudy et al.'s study, there was no postoperative change in performance of the hippocampal lesioned rats on the spatial configuration task, and little change in performance on the temporal configuration task.

244.7

HIPPOCAMPAL FORMATION AND CONFIGURAL LEARNING AND MEMORY. R. J. Sutherland, R. J. McDonald*, J. M. Hoesing* and J. W. Rudy. Dept. of Psychology, Univ. of Lethbridge, Lethbridge, Canada, T1K 3M4 and Univ. of Colorado, Boulder, CO 80309.

We have hypothesized that the hippocampal formation (HPC) is necessary for normal performance in memory tasks if, and only if, animals must learn a configural discrimination (Sutherland & Rudy, Psychobiol., 1989). We now present a series of four experiments designed to test and extend this notion. Experiment 1 examined the retention of a preoperatively acquired configural discrimination by rats with bilateral HPC damage induced by intraHPC microinjections of kainic acid + colchicine. The rats were trained in a negative patterning discrimination 4 or 12 wk before receiving HPC damage or sham lesions. Control rats displayed good retention, but HPC damaged rats neither retained nor relearned the discrimination. Experiment 2 compared acquisition of the negative patterning discrimination by rats with either kainate-induced CA field damage or colchicine-induced dentate gyrus damage. The two types of lesion produce similar, severe impairments in acquisition. Experiment 3 compared acquisition of the negative patterning discrimination and acquisition of a context-based, conditioned defecation response by rats with electrolytic amygdala lesions, or kainate+colchicine HPC lesions, or combined lesions. Only the rats with HPC or HPC + amygdala lesions were impaired in both tasks. Rats with amygdala damage exhibited a specific deficit in responding to auditory cues. Experiment 4 demonstrated that HPC damage disrupted retention of a conditional black/white discrimination based upon time of day.

The results extend the empirical support for the idea that the HPC is essential for memory processes underlying configural associations.

244.8

EFFECTS OF NEUROTOXIC LESIONS OF THE HIPPOCAMPUS ON ACQUISITION OF A MODIFIED T-MAZE. D.L.Whittington*, R.H.Baisden and M.L. Woodruff. Dept. of Anatomy, Quillen-Dishner Coll. of Med., East Tennessee State Univ., Johnson City, TN 37614.

The effects of selective destruction of hippocampal subfields on performance in T-mazes requiring trial independent discrimination in the stem and a trial dependent alternation discrimination in the arms were studied. Rats in Group 1 were untreated. Groups 2 and 3 received either an intradentate injection of colchicine (CO) or an intraammonic injecton of kainic acid (KA). Group 4 rats were gavaged with TMT (6 mg/kg). Two identical split-stem T-mazes were placed in the same room with opposite sides of the stem blocked. All rats were given 160 trials of discrimination training. Each trial had a forced run and a choice run into the reinforced arm of one of the mazes. The treated groups were significantly impaired in both the stem and arm components of the task. Rats given TMT were more impaired in the stem choice component than either the CO- or KA-treated rats. Damage to the hippocampus in rats may cause deficits in spatial memory whether working or reference memory is involved. Although CA3a,b, CA1 and the dentate are relatively spared by TMT, it caused a greater defect than KA or CO. This may be due to entorhinal cortex damage produced by TMT. (Supported by NIH grant ES04070-03 to MLW).

EARLY OLFACTORY LEARNING INCREASES THE NUMBER OF NEURONS WITHIN ENHANCED 2-DG UPTAKE FOCI. C. Woo* and M. Leon. (SPON: D. Aswad) Department of Psychobiology, University of California, Irvine CA 92717

Early odor training given to rat pups induces a behavioral preference and an increased uptake of 14-C 2-deoxyglucose (2-DG) in focal regions of the glomerular layer of their olfactory bulbs. The glomeruli underlying these high uptake foci are larger in conditioned pups than in control pups. To determine whether this increase was in part due to an increased number of neurons, we characterized the distribution of cells within these high uptake foci.

Pups were exposed to either peppermint-scented or clean air with concurrent reinforcing tactile stimulation for 10 min/day on postnatal days 1-18. On day 19 all pups were injected with 2-DG followed by exposure to peppermint odor. Autoradiographs and Nissl-stained sections of olfactory bulbs were aligned and analyzed using a computer-based digital image processor and a light microscope camera lucida.

A 21% increase in total neuronal number was observed in conditioned pups relative to their controls. Since these neurons arborize in nearby glomeruli, increases in cell number could account for the increased area observed within the glomerular layer. The packing density of these cells does not change, but rather, the glomerular layer expands in width to accommodate the increases in cell number. Early olfactory learning in young rats, therefore, induces an increase in neuronal number in responsive regions of their olfactory bulbs.

HIPPOCAMPUS AND OLFACTION: "WORKING MEMORY" AND PAIRED-ASSOCIATE LEARNING. U.Staubli, T.Le & G.Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

From a neurobiological perspective, the olfactory system is well suited to study the properties of hippocampal interactions with memory. It has most direct access to the hippocampus of all modalities, and the hippocampus has been implicated in some forms of olfactory discrimination learning (Staubli et al., 1984, 1986; Eichenbaum et al., 1986). Here we present results from studies in which novel forms of olfactory memory were sampled to provide a more complete characterization of the hippocampal role in memory.

In the first experiment, rats were trained in a radial maze to discriminate between several simultaneously present odors, a subset of which denoted food rewards. Bilateral entorhinal lesions did not affect memory of pre-operatively learned positive and negative odors, a result in agreement with earlier findings (Staubli et al., 1986), but dramatically interfered with "working memory", i.e., the ability to finish a trial by choosing each positive odor only once. In contrast, intact animals rarely re-entered positive odor-arms, even in trials with 6 positive odors and a delay interposed between the 3rd and 4th choice, during which the maze was either rotated by 90 degrees or all odors were relocated to different arms. In the second study, the same animals were trained on a paired-associate learning task to test the hypothesis, derived from anatomical arguments (Lynch, 1986), that the hippocampus plays an essential role in the forming of odor-object associations. Each of 6 positive odors was assigned an object that differed in shape and color. To obtain a reward, the animal had to displace the correct one of two objects located at the distal end of the chosen odor-arm. Intact animals learned to displace the correct object to a given odor (4-6 correct decisions per trial), while animals with entorhinal lesions performed at about chance level even after extensive training.

The results demonstrate that rats are capable of a type of paired associate learning and provide evidence that the hippocampus is essential for the formation of memories that place minimal demands on spatial information.

HIPPOCAMPAL REPRESENTATION IN VISUALLY-GUIDED DISCRIMINATION LEARNING PARALLELS THAT IN ODOR-GUIDED DISCRIMINATION LEARNING. H.Eichenbaum & K.Russo , Dept. Biol. Sci., Wellesley College, Wellesley MA 02181.

Rats with fornix lesions(FX) are impaired in learning a simultaneous odor discrimination. Even after achieving criterion performance levels, they base performance on an abnormal stimulus sampling strategy and representation of cues (Eichenbaum, etal, Beh. Nsci. 103:331,1988). The present study extends these findings to visually-guided discrimination.

Animals were trained in a cross-maze to approach one of three two-dimensional patterns, each located above the end of a maze arm. The spatial relationships among the cues and reward were constant, but the arms associated with the cues and reward, the maze's orientation within the room, and the start arm varied. As in our odor task, FX rats learned the discrimination slowly; even after reaching criterion performance, they demonstrated abnormal stimulus sampling strategies and stimulus representation as revealed by their performance in probe tests. In probe trials where one cue was deleted, FX rats performed poorly upon removal of the rewarded cue, and were less affected by removal of other cues. In probe trials where cues were transposed, performance deteriorated slightly in both normal and FX rats; furthermore, in normal, but not FX rats, response latencies were substantially increased.

Combined, these findings confirm our results in odor-guided discrimination learning: Normal rats sample each cue individually and guide performance by a representation of the relations among cues, while FX rats acquire approach responses guided by the stimulus compound. This interpretation is compatible with O'Keefe and Nadel's cognitive map theory of hippocampal representation, but applies as well to both spatial and non-spatial discrimination learning.

244.12

SERIAL OLFACTORY DISCRIMINATION LEARNING IN RATS - A 'PRIMATE-LIKE' LEARNING CAPACITY? IC Reid*, RGM Morris* (SPON:Brain Research Association) Dept of Pharmacol. University of Edinburgh, EDINBURGH EH8 9JZ, Scotland.

To investigate claims of a "primate-like" learning capacity in rats trained on tasks using olfactory rather than visual or auditory cues, hooded rats were trained in an automated olfactory maze designed to present simultaneous 2-odour discrimination problems. Three groups were trained on: (1) serial novel discriminations, or (2) serial reversals of a single discrimination, or (3) a single discrimination continuously. Each group was then transferred to a novel discrimination problem and their performance compared.

Prior to transfer, group 1 showed progressive improvement across problems, consistent with apparent "learning set" acquisition. Animals in group 3 eventually performed with greater than 95% accuracy on the single discrimination. Group 2 performed inconsistently, only some subjects showing progressive improvement across reversals. All groups, however, transferred to the novel problem with few errors, and no significant difference was found between groups. The results suggest that exposure to a series of discriminations or reversals is not necessary for the rapid learning of novel discriminations. This in turn suggests that although rats show rapid learning of olfactory discrimination problems, this kind of learning may differ substantially from that seen in analogous primate studies.

244.13

DISSOCIATION BETWEEN COMPONENTS OF SPATIAL MEMORY AFTER IBOTENATE LESIONS OF THE HIPPOCAMPUS. R.G.M.Morris*, F.Schenk*, F.Tweedie* and L.E.Jarrard (SPON: H.E.King) Dept.Pharmacol., Univ.Edinburgh, Edinburgh EH8 9JZ, Universite de Lausanne and Washington and Lee University.

Rats with ibotenate (IBO) lesions of the hippocampus show an impairment in learning a radial-maze but performance reaches control levels if the task is first learned preoperatively (Bouffard and Jarrard, 1988). We have followed up these findings using a spatial water-maze.

Rats were given IBO lesions of the hippocampus (HPC) or subiculum (SUB) but classified as HPC1, SUB or HPC + SUB groups on the basis of histology. These and controls (C) were trained (hidden platform, 28 trials) and then given a transfer test. The C group was superior to the IBO groups on all measures. However, in a 2nd transfer test after a further 48 trials, the HPC1 and SUB groups did not differ from C's in their search bias, while HPC + SUB's remained impaired. The HPC1 group was still impaired in annulus crossings. The C rats were then given an HPC lesion or control surgery and 28 retraining trials. In a final transfer test, performance showed the opposite pattern to the earlier one, ie. HPC2 rats were now as accurate as C2 rats in annulus crossings but impaired in search bias.

These findings may be explained if spatial information is viewed as being stored outside the hippocampus, and if rats without a hippocampus have to learn ad hoc strategies for encoding or utilising spatial information.

244.14

ON THE HIPPOCAMPUS AND LEARNED CONDITIONAL RESPONDING: EFFECTS OF ASPIRATION VS. IBOTENATE LESIONS. L.E. Jarrard and T.L. Davidson*, Dept. Psychol., Washington and Lee Univ., and Dept. Psychol., Virginia Military Institute, Lexington, VA 24450.

Rats with either aspiration or ibotenate (IBO) lesions of the hippocampus, together with controls, were trained on concurrent conditional and nonconditional discriminations similar to those used by Ross et al. (Behav. Neurosci 98:211, 1984). In agreement with the earlier findings, rats with aspiration lesions of hippocampus were impaired in learning the conditional but not the nonconditional discrimination. Rats with IBO hippocampal lesions learned both discriminations as well as controls. Data obtained from transfer trials yielded results compatible with the idea that both IBO hippocampal and control rats solved the conditional discrimination using "if-then" rules.

Since rats that had the hippocampus removed with IBO were similar to controls in learning both conditional and nonconditional discriminations, while rats with aspiration lesions were unable to learn the conditional discrimination, it would appear that added damage to extrahippocampal neural elements and/or the vasculature found in rats with aspiration lesions may account for the differences.

Our results indicate that the hippocampus is not necessary for the acquisition of complex Pavlovian conditional discriminations, and thus do not support the view that the structure plays a crucial role in the control of conditional behaviors.

244.15

HIPPOCAMPAL LESIONS DISRUPT ACQUISITION BUT NOT RETENTION OF NAVIGATIONAL BEHAVIOR IN A HIGHLY FAMILIAR ENVIRONMENT. J.L. Kubie, S. Davvani,* R.J. Sutherland and R.U. Muller*. S.U.N.Y. Health Science Center Brooklyn NY and Univ. of Lethbridge, Alberta, CAN

A recent finding by Sutherland *et al* suggests a synthesis of the apparently disparate effects of hippocampal lesions in rats and primates. Among other results, it was shown that rats trained in the water maze to navigate to a specific location and given hippocampal lesions 14 weeks later have a sparing of this navigational ability (*Soc for Neuro*, 1988). The present study is aimed at replicating this observation. It also asks whether rats that exhibit spared function are capable of learning to navigate to a novel location within the familiar apparatus. The navigation procedure employed here is an appetitive task run in a dry, cylindrical enclosure (Kubie *et al*, *Soc for Neuro.*, 1987).

Twelve rats were trained for 30 trials within a two week interval, each to a particular location. Fourteen weeks later rats were subjected either to bilateral injections of colchicine and kainic acid into the hippocampus and dentate gyrus, or sham injections. After recovery, rats were given a 30-trial block of *familiar-location testing* where a rat was rewarded for digging in the the same location as 16 weeks earlier. A block of *novel-location testing* was then initiated, where the rewarded location for each rat was changed.

Rats with hippocampal lesions were able to quickly and accurately find buried food in the familiar-location test block. The same rats were unable to learn to find food buried in a novel location. Sham rats readily learned to find food in both test blocks. These results indicate that rats with hippocampal lesions can perform a navigational task if it is learned well before surgery, but cannot learn to navigate to new locations, even in a highly familiar environment. (supported by NIH grant RO1-NS20686)

244.16

DEVELOPMENTAL DISSOCIATION OF FACILITATION AND DISAMBIGUATION FUNCTIONS OF CONTEXT M. B. Carew and J. W. Rudy, Dept of Psych, Univ of Colorado, Boulder, CO 80309

Contextual stimuli may influence conditioned behavior in at least two ways (e.g. Bouton and Bolles, 1985). They may serve a **facilitating** function (**FF**) by acquiring excitatory strength through association with the US that can summate with the excitatory strength of phasic CSs also associated with that US, or a **disambiguating** function (**DF**) by specifying the meaning of an otherwise ambiguous CS (e.g. a CS that has undergone acquisition and extinction). Using an appetitive Pavlovian conditioning paradigm, we found that the processes mediating these two functions are dissociated during development. Rat pups 17-20 days old or 20-24 days old were trained using a vibratory CS paired with 2% sugar water delivered through a cheek cannula which elicited a conditioned mouthing response. A **FF** was observed in rats 17-20 days old, however no evidence for a **DF** was found until pups were 20-24 days old. Evidence for a **FF** was obtained by demonstrating that US alone presentations in the training context restored conditioned responding to an extinguished CS. Evidence for a **DF** was obtained by demonstrating that a context shift, concurrent with extinction of responding to a phasic CS, preserved responding to the CS when subsequently tested in the training context.

The comparatively late emergence of the **DF** may be related to the development of the hippocampus; the age at which the **DF** emerges corresponds to the age at which another hippocampal-dependent behavior, spatial learning, emerges. We suggest that the **DF** may be hippocampal-dependent because it may require the rat pup to construct a configural representation of contextual stimuli and phasic CSs, which Sutherland and Rudy (1989) have hypothesized requires a functioning hippocampal formation.

244.17

THE TRANSVERSE PATTERNING PROBLEM, CONFIGURAL PROCESSES AND THE HIPPOCAMPUS. M. C. Alvarado and J. W. Rudy. Psychology Department, University of Colorado, Boulder, CO 80309.

The transverse patterning problem (TPP), (Spence, *Psych. Rev.*, 59, 1952), requires that an animal concurrently solve three visual discrimination problems constructed from only three stimulus cards: [B+ vs W-; W+ vs V-; V+ vs B-; where B,W and V represent a black card, a white card and a card with black, vertical stripes]. An interesting property of the TPP is that it requires a non-linear solution. The animal cannot solve the problem simply on the basis of the excitatory strengths of the individual elements (B,W&V). Rather, solution requires the animal to utilize a configural representation of each stimulus pair. Sutherland and Rudy (*Psychobiol.*, in press) have proposed that a functioning hippocampal formation (HF) is essential to the construction of configural representations. If so, animals with damage to the HF should be unable to solve the TPP. We have studied the TPP in a water-escape version of the Lashley jump stand (Rudy and Castro, *Psychobiol.*,15:1, 1987). We report the following: **A)** Long-Evans rats solve the TPP when trained over three successive phases: Phase I: B+ vs W-; Phase II: Concurrent training on two problems, B+ vs W- and W+ vs V- ; Phase III: Concurrent training on three problems, B+ vs W-/ W+ vs V- and V+ vs B-. **B)** Normal animals begin to employ a configural strategy in Phase II, even though an elementistic strategy, in principle, will allow solution of two concurrent discriminations. **C)** Consistent with Sutherland and Rudy's hypothesis, preliminary data suggest that animals with damage to the HF are unable to solve the TPP.

244.18

HIPPOCAMPAL DAMAGE IMPAIRS RETENTION OF A CONFIGURAL CHOICE DISCRIMINATION. J. W. Rudy and R. J. Sutherland. Departments. of Psychology, University of Colorado, Boulder 80309 and University of Lethbridge, Lethbridge, Alberta, Canada T1K-3M4

We have proposed that the hippocampal formation makes a contribution to learning and memory by providing circuitry for the construction of new functional units or configurations that represent the joint occurrence of two or more elementary stimulus events (Psychobiol. in press). In support of our position, we have reported that rats cannot solve or retain a go/no go negative patterning discrimination (Behav. Br. Res. in press). In this problem the animal was reinforced for bar pressing when either a tone or light alone was presented and not rewarded whenever the tone and light were presented in compound (T+, L+ vs TL-). Although this problem requires a functioning configural representation system for its solution, it also requires the animal to withhold responding to the compound stimulus. Consequently, impaired performance may reflect a general inability of the animal to withhold responding rather than an inability to construct a configural representation of the compound. In order to address the response inhibition interpretation, we trained animals to solve a novel stimulus-patterning choice discrimination problem that requires a configural representation system for its solution but does not require the animal to withhold responding to either the compound or its elements. Specifically, animals were trained to bar press (BP) in the presence of either a light or tone alone but to chain pull (CP) when the compound stimulus was presented (T->BP, L->BP vs TL->CP). Subsequent damage to the hippocampus severely impaired performance on this problem, a result that supports the configural process view of hippocampal function.

244.19

ATTENTION TO NONSPATIAL VS. SPATIAL CUES FOLLOWING DORSAL NORADRENERGIC BUNDLE (DNAB) LESIONS. D.A. Warren*, C.A. Castro, L.R. Watkins, M. Fleshner*, W.W. Woodmansee & S.F. Maier. Department of Psychology, University of Colorado, Boulder, CO 80309.

The DNAB, which projects from locus coeruleus to diverse forebrain areas, has been implicated in attention. We used the Morris water maze (Morris, 1981) to test if DNAB lesions would influence attention to spatial and non-spatial cues. Either the neurotoxin 6-hydroxydopamine (6OHDA, 12 ug per site) or equivolume (1 ul) 0.1% ascorbic acid-saline vehicle was injected bilaterally into DNAB or ventral NAB (VNAB) (specificity of neurochemical disruption to be determined by HPLC). Animals were trained 1-2 wk later to swim to a visible platform (nonspatial cue) located in the same quadrant of the circular maze on each trial. A probe trial, in which the platform was removed, was then conducted. Animals given vehicle injections into DNAB or VNAB and those given 6OHDA into VNAB spent more time in the training quadrant than in nontraining quadrants, indicating the learning and use of spatial cues. Rats given 6OHDA into DNAB spent equivalent time in training and nontraining quadrants, indicating failure to use spatial cues. Later tests showed that DNAB lesioned rats were not impaired in learning to swim to a submerged invisible platform. Thus, DNAB lesions do not impair spatial navigation, but produce a bias toward attending to nonspatial cues. Supported by NSF grant BNS-8809527.

APPARATUS CONFIGURATION, CIRCADIAN EFFECTS AND HIPPOCAMPAL ANATOMY IN GENETICALLY DEFINED MICE. D. F. Peeler, Neurosurgery, Univ. Mississippi Med. Ctr., Jackson, MS 39216

It has been reported that the extent of mossy fiber innervation of pyramidal cells and shuttle-box performance are negatively correlated, and that the former is genetically determined. Both shuttle-box performance and circadian effects have been demonstrated to reflect genetic determinants. Seven recombinant inbred strains and their progenitors (C57BL/6ByJ & BALB/cByJ) which have a genetically determined difference in hippocampal mossy fiber distribution, were used to further examine these variables as a function of apparatus constraints. Male mice (Mus musculus) of the 2 progenitor and 7 recombinant strains were tested in 1 of 2 apparatus configurations (different barriers) at 1 of 3 times of day. Six mice were in each group. Strain was a strong and pervasive effect under all conditions, but the third-order interaction was significant. Number of avoidance responses and rate of acquisition changed with strain, time of day and type of barrier. The data support findings of genetic determinants for shuttle-box performance and circadian effects, and indicate that mode of acquistion and coping with environmental constraints are also subject to major genetic influence. Avoidance performance, circadian effects and mode of acquisition do not share genetic determinants with the mossy fiber distribution in the hippocampus, nor are they related in any simple fashion with one another.

244.21

LONG-TERM POTENTIATION ALTERS GLIAL PROCESSES IN THE DENTATE GYRUS. K. R. Isaacs, A.Marks*, A. M. Sirevaag, F.-L. Chang, W. Greenough. Neural & Behav. Biol. Prog., Depts. of Psych. & Cell & Struct. Biol., U. Illinois, Champaign IL 61820.

Ten adult rats received long-term potentiation (LTP) or equivalent low frequency control stimulation 30-70 days after the implantation of electrodes into the dentate hilus (recording) and angular bundle (stim.). 24 hours after the last LTP train the rats were perfused and 10um frozen sections were processed for immunocytochemistry using monoclonal anti-GFAP (ICN). A stereologically unbiased estimate of astrocyte surface density (Sv; Braendgaard and Gundersen, 1986) was calculated from astroycte ramifications in the molecular layer of the upper blade of the dentate gyrus. Tissue was sampled from 100 to 400um distal to the recording electrode to monitor effects due to gliosis and treatment. Gliosis was evident at 100um but not at 400um from the electrode, and at 400um LTP astrocytic Sv was approximately 7% greater than the control group Sv. In further analyses the LTP group had thicker astrocytic processes than the control group. (Supported by NIMH 35321 and ONR N00014-89-J-1556).

RATS IN COMPLEX, SOCIAL AND INDIVIDUAL ENVIRONMENTS EXHIBIT ASTROCYTIC PLASTICITY AFTER 30 AND 60 DAYS OF ENVIRONMENTAL EXPOSURE. A M. Sirevaag, O. Bell, and W.T Greenough. Depts., Psych & Cell & Struct. Biol., & Neur. & Beh. Biol. Prog., Univ. IL, Champaign, IL 61820.

In the upper half of the occipital cortex rats raised in complex environments (EC) have larger neurons with more synapses than rats raised in social (SC) or individual cage (IC) environments. Astrocytes are indicators of cellular metabolic and ionic environments and may also exhibit plasticity. Preliminary examinations of astrocytes labeled with anti-GFAP showed that after 30 days of EC, astrocytes had a greater surface density (Sv) but lower numerical density (Nv) than ICs. Recent examinations of anti-GFAP labeled astrocytes in young adult rats exposed to their environments for 10, 30 or 60 days have shown that the duration of the animal's exposure to its environment determines astrocytic response. After 10 days of environmental exposure EC and IC rats did not differ on Sv, or mean astrocytic size but they had 14% lower Nv than ICs. An estimate of the total number of astrocytes within Area 17 (N) showed no difference between EC and ICs. After 30 days of exposure EC rats had a 16% greater Sv, 40% greater mean astrocytic size and 20% lower Nv than ICs. The estimate of N within Area 17 showed no difference between EC and ICs. After 60 of environmental exposure EC rats had a 10% greater Sv than ICs. There was no difference in mean astrocytic size and Nv between ECs and ICs. However, the estimate of N within Area 17 showed that ECs had 16% more astrocytes than IC rats and that gliogenesis had probably occurred. Thus, astrocytes do not show plasticity after only 10 days of exposure to a complex environment and the initial response of astrocytes after 30 days of exposure appears to be an increase in astrocytic processes. However, after 60 days of exposure astrocytes appear to have proliferated. Supported by MH 35321.

ASTROCYTE HYPERTROPHY IN DENTATE GYRUS OF YOUNG MALE RATS IS MODULATED BY INDIVIDUAL STRESS RATHER THAN COMPLEX EXPERIENCE. J.E. Black, A.M. Sirevaag, A.C. Katz*, & W.T. Greenough. College of Medicine, Depts of Psychology, and Cell & Structural Biology, Neural & Behavioral Biology, Beckman Institute, Univ of Illinois, Champaign, IL 61820.

Glial hypertrophy has been associated with stress-induced damage in the hippocampus and with synaptogenesis in visual cortex of male rats given complex experience. This study examines GFAP immunoreactive astrocytes in a brain region where the synaptogenesis response to complex experience in male rats is minimal and under conditions of minimal environmental stress.

The 21 weanling male rats used in this study (also used in Sirevaag, et al, adjacent) were placed in three conditions for 30 days: a large cage with many toys and other rats to interact with (EC), and standard caging with rats kept in pairs (SC) or individually (IC). Astrocyte surface densities (Sv) in the upper and lower blades of dentate gyrus were estimated by counting the intersections of GFAP processes with a cycloid grid. No group differences were found for adrenal weight or Sv of upper or lower blades. Upper blade Sv and adrenal weight were positively correlated ($r=.54$, $p<.02$).

This study indirectly supports the idea that astrocyte hypertrophy is associated with synaptogenesis, for in this case of the hippocampus the glial effect is absent where the synaptogenesis effect is absent. The role of astrocytes in stress- induced damage is also supported by this study. The lack of group differences in adrenal weight and Sv suggests that the groups experienced similar levels of stress. However, adrenal weight was closely related to upper blade Sv, suggesting that within this paradigm an individual rat's experience of stress may have contributed to hippocampal damage.

IDENTIFICATION OF A, X AND B CORTICAL ZONES AND WHITE MATTER COMPARTMENTS IN THE ANTERIOR VERMIS OF THE CEREBELLUM OF THE MONKEY (*Macacca Fascicularis*). J. Voogd* and D.T. Hess*. (SPON: D. Schreyer) Dept. of Anatomy, Erasmus Univ. Rotterdam, 3000 DR Rotterdam, Netherlands (JV) and Dept. of Neurobiology, Stanford Univ. Sch. Med., Stanford, CA 94305 (DTH).

In the cat, the cortex of the anterior vermis of the cerebellum has been divided on the basis of its afferent climbing fiber (CF) and efferent Purkinje cell (PC) connections into a medial A zone (CF: from caudal medial accessory olive [MAO]; PC: to fastigial and medial vestibular nuclei), an intervening X zone present only in lobules IV-VI (CF: from transition between caudal and rostral MAO; PC: to junction of fastigial and posterior interposed nuclei) and a lateral B zone (CF: from caudal dorsal accessory olive [DAO]; PC: to Deiter's nucleus). In the monkey, acetylcholinesterase (AChE) histochemistry reveals a compartmentalization of the cerebellar white matter (Brain Res., *369*:385, 1986). In *Macacca fascicularis,* injections of WGA-HRP into the vestibular nuclei resulted in retrograde labeling of PCs and their axons in AChE-identified A and B cortical zones and white matter compartments, sparing the X zone and compartment. After injection of ^{3}H-leucine into caudal MAO and DAO, labeled olivocerebellar fibers were confined to the A and B zones and compartments, while the X zone and compartment were labeled by injections of the rostral MAO. These observations allow the identification of A, X and B white matter compartments and cortical zones in the monkey, and demonstrate the precise correspondence between the modular organization of the primate cerebellum as revealed by afferent and efferent connectivity and by AChE histochemistry.

ELECTRON MICROSCOPIC AND IMMUNOCHEMICAL STUDIES CONCERNING THE INTRINSIC SYNAPTIC CIRCUITRY OF THE MONKEY BASILAR PONS. G.A. Mihailoff and B.G. Border. Dept. of Cell Biology and Anatomy, Southwestern Medical School, Dallas TX 75235.

Two important questions regarding the synaptic circuitry of the basilar pontine nuclei (BPN) are: (1) do the axons of pontocerebellar projection neurons give rise to collateral branches within the pontine gray and (2) are BPN interneurons present and if so, how do they participate in the synaptic circuits of the pontine gray? Regarding the interneuron, recent studies in the rat, cat, and baboon have documented the presence of GABA-immunoreactive neurons and axon terminals within the BPN. Additionally in the rat, double-labeling studies have shown that certain BPN afferent projections contain GABA-ergic components thus indicating that some GABA boutons in the BPN must originate from afferent axons while others presumably arise from the population of BPN GABA neurons. Using a rabbit anti-GABA antibody and the post-embedding immunogold method, we report here the presence of GABA boutons within the monkey BPN. Such boutons participate in serial synaptic complexes where they are postsynaptic to a round vesicle-containing bouton and presynaptic to a dendritic element. GABA boutons also form non-glomerular axodendritic synapses. The involvement of GABA boutons in serial synaptic arrangements is consistent with the organization of other brain regions such as the dorsal lateral geniculate and supports the suggestion that such boutons might arise from a GABA interneuron. Concerning projection neuron collaterals, in control BPN neuropil, certain profiles including dendrites and synaptic boutons are readily distinguished in electron micrographs by their content of a dense background matrix. Such profiles do not exhibit GABA labelling and are tentatively identified as a class of BPN projection neurons that gives rise to intrapontine collaterals. Supported by NIH NS-12644.

245.3

DEVELOPMENT OF GLUTAMATE IMMUNOREACTIVITY IN THE RAT BASILAR PONS: LIGHT AND ELECTRON MICROSCOPIC IMMUNOCHEMISTRY B.G. Border and G.A. Mihailoff. Dept. of Cell Biology, Univ. of Texas Southwestern Medical Center, Dallas, TX 75235.

The postnatal development of glutaminergic neural elements was studied in the rat basilar pontine nuclei (BPN) using a hemocyanin-conjugated glutamate (GLU) antiserum. Light microscopic immunoperoxidase techniques were applied to perfusion-fixed neonatal rat brains ranging from a few hours (PN 0) to 30 days (PN 30) of age, while post-embedding immunogold procedures were utilized to visualize the ultrastructural details of glutamate immunoreactive (GLU-IR) structures. Basilar pontine neuronal somata, fibers and axon terminals first exhibited GLU-immunoreactivity at PN 3, and the relative numbers of GLU-IR structures gradually increased with age with an adult-like pattern of immunostaining achieved by PN 18. Electron microscopic observations revealed specific, albeit light, immunogold labeling over neuronal somata of the PN 0 BPN, while GLU-IR vesicle-containing profiles were first observed at PN 3. BY PN 5, neuronal somata, dendrites, and myelinated axons were immunogold labeled. In addition at this stage, immunolabeled presynaptic boutons formed clearly defined asymmetric membrane specializations with both GLU-IR dendrites and neuronal somata. The sequence of events which characterizes the initial appearance and subsequent proliferation of GLU-IR structures within the BPN coincides with the ingrowth and maturation of cortical and cerebellar afferent projections as well as a time when substantial dendritic growth, synaptogenesis and dendritic spine elimination take place in the BPN.

HIGH TIME RESOLUTION CALCIUM IMAGING OF GUINEA PIG PURKINJE CELL OSCILLATIONS IN VITRO. H. Miyakawa, V. Lev-Ram, N. Lasser-Ross and W.N. Ross. Dept. of Physiology, N.Y. Medical College, Valhalla, NY 10595.

The correlation of intracellular calcium changes with somatically recorded electrical activity during spontaneous oscillations was measured simultaneously from many locations in Purkinje cells using a photodiode array and the calcium indicator fura-2. Beginning with the first complex action potential calcium increased simultaneously all over the cell. Immediately following the end of the burst calcium began to decline at all locations, usually levelling off by the end of the 10-15 second interburst interval. However, the time courses of the calcium changes at different cellular locations were very different. In the fine dendrites calcium peaked within one second, remained almost constant during the rest of the burst, and declined rapidly at the end. In the soma calcium increased slowly all during the burst, declined slowly during the silent period, and the peak level was much lower than over the fine dendrites. The time course and the peak level of calcium over the mid-dendritic regions of the cell were intermediate between these extremes. In many cells the burst of complex spikes was preceded by a shortlasting plateau supporting fast sodium spikes. This plateau was eliminated by TTX and there was very little calcium change associated with this event. These results show that at all locations the calcium increase during oscillations is dominated by the contribution due to calcium spikes.

MODIFICATIONS OF PARALLEL FIBER-PURKINJE CELL SPATIAL ACTIVITY IN THE RAT CEREBELLAR CORTEX, IN VIVO.
S.A. Elias, H. Yae*, T.J. Ebner. Depts. Neurosurgery and Physiology, Neuroscience Grad. Prog., Univ. of Minnesota, Mpls., MN 55455.

Electrical stimulation of the molecular layer of the cerebellar cortex activates parallel fibers which in turn excite Purkinje cells. The pattern of activity has been shown to be beam-like in a transverse direction by both electrophysiological recording and imaging with voltage sensitive dyes. Using the latter approach we examined the spatial pattern after neuropharmacological modification. The cerebellar cortex of anesthetized rats was stained with RH795. Optical images were recorded using an epi-fluorescence microscope and a CCD video camera. Following filtering and windowing the averaged (up to 600 times) control and stimulation images were subtracted. When Ca^{2+} free Ringers was perfused across the cerebellar surface (0.5 ml/min), the synaptically generated field potentials disappeared, leaving the pre-synaptic volley. The imaged beam was also reduced in intensity and spread, but recovered partially with normal Ringers, and increased in magnitude with Ringers containing 40 uM picrotoxin. The recorded field potentials followed similarly. These experiments show that optical recording can follow spatial pattern changes in parallel fiber-Purkinje cell excitability. Supported by NIH grants NS-18338 and NS-27210.

ACTIVITY PATTERNS IN THE CEREBELLORUBROSPINAL PATHWAY OF THE *IN VITRO* TURTLE HINDBRAIN REVEALED WITH ACTIVITY-DEPENDENT UPTAKE OF FLUORESCENT DYE.
J.C. Houk, J. Keifer and D. Vyas. Dept. of Physiology, Northwestern University Medical School, Chicago, IL 60611.

The cerebellorubrospinal circuit is believed to include recurrent excitatory connections between the cerebellum, red nucleus and medullary reticular formation. Burst activity in this positive feedback pathway is postulated to be important in the production of central motor programs. Recently we developed an *in vitro* turtle brainstem-cerebellum preparation in order to study bursting (Keifer & Houk, Neurosci. Lett., 97: 123, 1989). Here we describe the use of soluble, small molecular weight fluorescent probes to demonstrate loop activity. These probes, introduced by Lichtman et al. (Nature, 314: 357, 1985), appear to be internalized exclusively by active neurons.

The isolated brainstem-cerebellum was placed in a recording chamber and the cerebellorubrospinal pathway was activated by single pulse stimulation of the contralateral dorsolateral spinal cord. The preparation was bathed in a 0.1% solution of sulforhodamine 101 (Molecular Probes) during stimulation (4 mA, 0.1 ms, 0.5 Hz) for 1 hr. Stimulation was discontinued, the preparation was washed with physiological saline for 40 min, and the tissue was then immersion fixed in 4% paraformaldehyde. Well labeled cell bodies and proximal dendrites were observed in the contralateral red nucleus, ipsilateral lateral cerebellar nucleus, magnocellular reticular formation, nucleus of flm, raphe, perihypoglossal nucleus, and cerebellar Purkinje cells. When the bathing solution containing the dye was changed to low Ca-high Mg, which blocks synaptic activation, no label was seen.

The use of fluorescent probes to identify functionally active regions in the *in vitro* preparation should facilitate our electrophysiological studies of the cerebellorubrospinal pathway of the turtle. Furthermore, we are presently exploring the use of sequential application of different colored dyes to examine topography of this circuit. These preliminary results suggest that positive feedback in the rubro-reticulo-cerebellar loop may contribute to the production of central motor programs.

CORRELATION OF LOCAL CYTOSOLIC FREE CALCIUM DYNAMICS WITH ELECTRICAL ACTVITY OF PURKINJE CELLS IN CEREBELLAR SLICE CULTURES
T. Knöpfel and B.H. Gähwiler. Brain Research Institute, University of Zürich, CH-8029 Zürich (Switzerland)

Monolayered slice cultures grown on glass coverslips offer an unique opportunity to apply optical recording techniques to organotypically organized neuronal networks.

Fura-2 was injected through the recording electrodes into cerebellar Purkinje cells in slice cultures. Optical mapping was achieved using a combination of an 10 x 10 array of photodiodes and a charge coupled device. Electrical activity and intracellular free Ca^{2+} ($[Ca^{2+}]_i$) were simultaneously recorded by means of single electrode current-/voltage-clamp and microfluorometric techniques.

Bursts of action potentials induced by intracellular current injections, evoked synaptic activity as well as spontaneous activity were all paralleled by a transient rise in $[Ca^{2+}]_i$, which was most pronounced in dendritic regions.

These results demonstrate a dendritic segregation of Ca^{2+} conductances in slice cultured Purkinje cells as has been previously demonstrated in acute slice preparations. In more general terms, measurements of local $[Ca^{2+}]_i$ dynamics, in particular in combination with multi-site recordings of membrane potentials using voltage sensitive dyes appear to provide a promising approach for studying dendritic information processing.

245.8

PHARMACOLOGICAL CHARACTERIZATION OF EXCITATORY POSTSYNAPTIC POTENTIALS OF PURKINJE CELLS IN ORGANOTYPIC CO-CULTURES OF CEREBELLUM AND INFERIOR OLIVE.
E. Audinat, T. Knöpfel and B.H. Gähwiler; Brain Research Institute, University of Zürich, CH-8029 Zürich (Switzerland)

Both the climbing fiber and the parallel fiber inputs to cerebellar Purkinje cells (PCs) have been proposed to use an excitatory amino acid (EAA) as neurotransmitter. We have, therefore, used specific EAA receptor antagonists to compare the pharmacology of excitatory postsynaptic potentials (EPSPs) with that of EAA induced responses of PCs. Slices from cerebellum and inferior olive (IO) were obtained from newborn rats and co-cultured for 2-4 weeks. PCs were then current- or voltage-clamped at a potential of -55 to -65 mV. Postsynaptic potentials were evoked by field stimulation applied either within the cerebellar tissue or within the IO. Individual PCs were identified by their morphology, their location within the cultured slices, calbindin immunostaining and by intracellular injection of Lucifer yellow. In the presence of 1 µM TTX, inward currents were induced in PCs by L-Glutamate (500 µM), L-Aspartate (500 µM) and L-Homocysteate (500 uM), but not by NMDA (50 µM to 1 mM). These agonist-currents, the locally evoked EPSPs and the EPSPs evoked by IO-stimulation were all reversibly antagonized by CNQX (10 µM). D-APV (10 µM) had no affect on any of these responses.

These observations demonstrate that in mature PCs which apparently do not respond to NMDA, EPSPs and responses induced by EAA are mediated by non-NMDA EAA receptors.

VARIABILITY IN AND COMPARISONS OF: 1) TACTILE PROJECTIONS TO THE GRANULE CELL LAYERS OF CEREBELLAR CORTEX; AND 2) THE SPATIAL DISTRIBUTION OF ZEBRIN-I LABELED PURKINJE CELLS.
Giri Gundappa-Sulur*, Hadi Shojaeian, Mike Paulin, Leila Posakony*, Richard Hawkes(t) and James M. Bower. Div. Biol. 216-76, Caltech, Pasadena, CA. 91125 (t-Centre Res. Neurobiol., Quebec, CA. G1J 124).

Tactile responses in the granule cell layers of the cerebellar hemispheres of rats and mice are topographically arranged in patches (Shambes et al., Brain Behav. Evol. 15, 94-140, 1978). Further, casual observation suggests that specific patches recur in similar folial positions in different individuals. We have modified a statistical sequence comparison algorithm used in molecular biology, to demonstrate quantitative similarities between maps found in several folia in both rats and mice.

Certain monoclonal antibodies also display consistent patterns of labeling in the cerebellum. We were interested in comparing one of these, Zebrin-I which selectively labels bands of Purkinje cells (Hawkes et al., Brain Res., 333: 359, 1985) to the underlying tactile maps. To do so, we first electrophysiologically determined and anatomically marked tactile patch boundaries. Then, the brain tissue was sectioned and processed immunocytochemically with the positions of stained Purkinje cells eventually being reconstructed using a computer-linked microscope.

Results showed that the pattern of monoclonal staining in the cortex is highly reproducible from animal to animal. Second, superimposition of this anatomical pattern on the tactile maps revealed that some physiological patch boundaries coincided quite precisely with boundaries between regions of labeled and unlabeled Purkinje cells. In other cases, however, several transitions from labeled to unlabeled regions occurred in Purkinje cells overlying single patches. The significance of this result must await a better understanding of the function of the protein labeled by the antibody. (supported by NIH grant NS- 222205).

245.10

FUNCTIONAL PROPERTIES OF DORSAL HORN NEURONS THAT PROJECT TO THE DORSAL ACCESSORY OLIVE.
H.H. Molinari, N. El-Yassir*, and J.O. Dostrovsky. Department of Anatomy, Albany Medical College, Albany, NY 12208 and Department of Physiology, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

The major sources of input from the hindlimb to the rostral dorsal accessory subdivision of the inferior olive (DAO) are dorsal horn lamina V, the ventromedial ventral horn, and the gracile nucleus. This study investigated the physiological properties of neurons in the dorsal horn that project to DAO. Single neurons in cats anesthetized with pentobarbitone were antidromically activated by microstimulation of contralateral DAO.

All of the neurons examined were excited by some form of peripheral stimulation; 87% responded to cutaneous stimuli. About one third could be excited by light cutaneous stimuli, such as air puffs or von Frey hairs less than 0.3 grams. Half required moderate stimuli such as tap or brisk brush. The receptive fields were located on the foot and/or toes; many displayed gradients of sensitivity. Conduction velocities from the dorsal horn to DAO averaged 26.7 m/s.

The population of DAO projection neurons in the dorsal horn was much more sensitive to cutaneous stimulation than that in the gracile nucleus (studied with the same techniques by Molinari and Dostrovsky, 1987). Thus, the cutaneous sensitivity of neurons in DAO (Gellman et al., 1983) may largely reflect the influence of inputs from the dorsal horn.

SOMATOSENSORY MAPPING OF ANTIDROMICALLY IDENTIFIED PURKINJE CELLS IN LOBULES V AND VI IN CAT CEREBELLUM. J.F. Brons, L.T. Robertson, G. Tong*. Dept. Anatomy,SD, Oregon Health Sciences Univ., Portland, OR 97201

The projections of somatosensory fields to lateral cerebellar nucleus in cats were determined for a population of Purkinje cells in the lateral areas of lobules V and VI. Under Nembutal anesthesia, the receptive fields of Purkinje cells were determined by extracellular unit reponses to mechanical stimulation of the body surface. The cells were antidromically activated by bipolar stimulation of the lateral cerebellar nucleus. Of 330 cells, 70% in lob V and 51% in lob VI responded to tactile input; the rest were unresponsive. Cells in both lobules responded primarily to facial or forelimb input with 10% responding to both. 63% of all responsive cells could be antidromically activated. Local areas within the lateral nucleus received input from relatively well circumscribed areas of cerebellar cortex, but were not specific to body area represented. These results indicate that somatosensory input projects to the most lateral areas of deep cerebellar nuclei.

245.12

VAGAL REPRESENTATION BY THE CLIMBING AND MOSSY FIBER SYSTEMS IN THE CEREBELLUM OF THE CAT. G. Tong*, L.T. Robertson, J.F. Brons. Dept. Anatomy, SD, Oregon Health Sciences Univ., Portland, OR 97201

The role of autonomic input to cerebellum and its relation to somatosensory input is not well understood. This study investigates the organization of vagal input in the somatosensory region of lobules V and VI in cat cerebellum. The distribution of convergence of vagal and somatosensory input by the mossy and climbing fiber systems was examined. Using alpha chloralose (100 mg/kg) anesthesia, extracellular activity of single Purkinje cells in the vermal and intermediate zones of the lobules V and VI were recorded with microelectrode. The ipsilateral cervical vagus nerve was stimulated with bipolar electrodes. The somatosensory receptive fields were defined with hand delivered stimuli. About 55% of the 155 isolated Purkinje cells were activated by mossy and/or climbing fibers to low (A-fibers) or high-threshold (C-fibers) vagal stimulation. All of these units also receive convergent input from the body surface, mainly from the face or forelimb.

245.13

RESPONSES OF PURKINJE CELLS IN ANTERIOR AND POSTERIOR CEREBELLAR LOBULES TO HINDLIMB ROTATION. V. Perciavalle*, R. Poppele, L. Shen* Deptartment of Physiology, Univ. of Minnesota, Minneapolis MN 55455

Spinocerebellar pathways from hindlimb areas project separately to the anterior and posterior lobes of the cerebellum. We investigated these projections areas by recording the responses of Purkinje cells to small rotations of the foot about the ankle joint (5^{o}- 8^{o} in extension or flexion). Recordings were made from 120 Purkinje cells in pentobarbital anesthetized cats. Post-stimulus spike densities showed significant changes with respect to background discharge in 64% of the cells recorded both anterior and posterior. The highest percentages of responses were found in anterior lobules II and III and posterior lobules VIIIa and VIIIb. Responses were mostly transient increases in spike density although decreases were also observed, alone or in combination with excitation. Anterior lobe responses had a relatively short latency to peak increase in density (25 - 40 ms) and responses of a given cell to extension and flexion were usually different. Posterior lobe responses were generally larger, had a much longer latency (60 - 85 ms) and the responses to flexion and extension were usually the same. Differences among responses were also noted for cells located either medially or laterally in the paravermal areas in both the anterior and posterior areas.

Supported by NIH grant NS 21143.

CHANGES IN SIMPLE AND COMPLEX SPIKE ACTIVITY IN PURKINJE CELLS INDUCED BY SLIP OF AN OBJECT HELD BETWEEN THE THUMB AND FOREFINGER. Claude Dugas, Nathalie Picard*, & Allan M. Smith Centre de recherche en sciences neurologiques, Univ. de Montréal, Québec, Canada

Two fascicularis monkeys were trained to grasp, lift and hold an object within a narrow position window for 1.0 sec. On certain trial-blocks a predictable perturbation was introduced during the static holding which caused the object to slip between the fingers. The perturbation produced a reflex-like increase in grip force at a latency between 60 and 100 ms. In addition, anticipatory responses, characterized by gradual increases in the grip safety margin (defined as an increase in the grip force/load force ratio) and increases in the rate of grip force application, appeared increasingly within blocks of consistently perturbed trials. Together, these anticipatory and compensatory adjustments to grip force dynamics allowed the animal to reliably overcome the effects of the perturbation.

In the paravermal hand area of the cerebellar anterior lobe, twenty seven Purkinje cells (PCs), identified by their climbing fiber discharge (CF), demonstrated activity changes related to the grasping task. In 19 PCs, simple spike (SS) responses to the perturbation occurred at a latency of 37 (± 7 ms). Of these 19 PCs, 7 demonstrated an additional activation of the CF discharge. Adaptive changes in SS discharge correlated with the anticipatory responses were observed in five PCs only three of which also responded to the perturbation. Fifty of 78 non-identified cerebellar neurons responded to the perturbation and 17 cells demonstrated adaptive anticipatory changes in activity. The short latency reflex-like responses to the perturbations were locked to the stimulus and did not persist in the absence of the perturbation. In contrast, the adaptive anticipatory changes carried on for 5 or 10 trials after the cessation of the perturbation. These adaptive changes in cerebellar activity appear to be related to the alterations in the motor strategy which is continually revised as a function of both the expectancies, and real stimulus conditions encountered by the animal. Supported by the MRC and NSERC of Canada, and le Fonds FCAR du Québec.

DIRECTION TUNING OF FLOCCULAR PURKINJE CELLS IN MONKEY. R.J. Krauzlis* and S.G. Lisberger. Dept. of Physiology, Neurosci. Graduate Prog., Univ. of California, San Francisco, CA 94143

Visual tracking of moving targets requires a change in coordinate systems. All directions of motion are represented in visual areas specialized for processing of visual motion, yet the motor commands must ultimately pull the eyes in the directions of the six pairs of extraocular muscles. Therefore, the omnidirectional representation of visual motion must be converted to a more restricted coordinate system compatible with the oculomotor system. Because the cerebellar flocculus is critical for generating pursuit tracking, we asked if the output of the flocculus reflects this transformation.

We recorded the simple spike activity of 107 Purkinje cells (P-cells) in two flocculi and examined their directional preferences during tracking of moving visual targets. We assessed direction tuning using tracking of sine wave and step-ramp target motion. For sine wave tracking, we computed a tuning curve that described eye velocity sensitivity as a function of tracking direction. For step-ramp tracking, we computed separate tuning curves for the visually driven transient response and the eye velocity driven sustained response. Best directions were determined by fitting a cosine function to the data. P-cells showed broad tuning for both eye velocity and visual responses and their best directions clustered around two primary directions. Horizontal P-cells have an average best direction that is ipsilateral and a few degrees above exactly horizontal. Vertical P-cells have a best direction that is about 10 degrees oblique and contralateral of exactly down. Best directions for the visual response generally coincided with best directions for eye velocity. Our data show that both the visual and oculomotor output of the flocculus is in a coordinate frame consistent with the pulling directions of the extraocular muscles. (Supported by NSF grant BNS8616509)

EYE MOVEMENTS EVOKED FROM HISTOCHEMICALLY DISTINGUISHED COMPARTMENTS OF THE RABBIT FLOCCULUS. I. Van der Steen*, I. I Simpson and I. Tan*. Depts. Physiol. 1 and Neuroanatomy, Erasmus University, Rotterdam, Holland, and Dept. Physiol. & Biophys., NYU Med. Ctr., New York, NY 10016.

Division of the cerebellar white matter into compartments containing axons of distinct sets of climbing fibers and their associated Purkinje cells has been shown with a variety of anatomical methods, but a direct demonstration of the significance of these compartments in relation to behavior has been wanting. One method of revealing the compartments uses acetylcholinesterase histochemistry (Hess and Voogd, 1986). In the rabbit this method reveals five compartments within the floccular white matter (Tan, Voogd and Gerrits, personal communication). The present study investigated the possibility of a correspondence between the individual compartments and the particular classes of eye movements previously found (Van der Steen et al., 1987) with electrical stimulation of the floccular white matter in the alert rabbit. The three largest compartments in the flocculus are serially adjacent from medial to lateral. The dominant response evoked by stimulation of the middle compartment was abduction of the ipsilateral eye, usually accompanied by a smaller adduction of the contralateral eye. The dominant response evoked by stimulation of the two bordering compartments was a rotation of the ipsilateral eye produced by the vertical rectus muscles; in about half of these cases the dominant response of the contralateral eye was a rotation produced largely by the oblique muscles. The association of particular eye rotations with the anatomically distinguished compartments suggests that they may be the structural correlate of a coordinate system whose axes represent a particular subset of all possible eye rotations.

245.17

CAN THE CEREBELLUM BE STIMULATED THROUGH THE SCALP IN MAN? J.C.Rothwell,* Y.Ugawa,* B.L.Day,* P.D.Thompson,* and C.D.Marsden*. MRC Human Movement and Balance Unit, Institute of Neurology, Queen Square, London WC1N 3BG, U.K. (SPON: W. Hening)

In an attempt to stimulate the cerebellum, high voltage electric stimulation (Digitimer D180) was applied through two disc electrodes fixed 5cm lateral on a line joining the inion and the external auditory meatus. The stimulus intensity was set so that no EMG response occurred in either relaxed or active arm muscles. From 1-15ms after, motor cortex excitability was tested by giving a magnetic stimulus (Novametrix Magstim 200) at an intensity sufficient to produce responses in relaxed forearm and hand muscles with the coil centred over the vertex of the head. Trials were randomised so that the subject received stimuli either to the "cerebellum" or to the motor cortex, or both. In 7 subjects, "cerebellar" stimulation reduced the size of cortically-evoked EMG responses when the interstimulus interval was 5-8ms. Maximum inhibition was seen when the "cerebellar" anode was ipsilateral to the tested muscles. If the polarity was reversed, inhibition was reduced. H-reflexes evoked in forearm flexor muscles were not made smaller by the "cerebellar" stimulus. The effect is compatible with a cerebellar influence on contralateral motor cortex, although stimulation of other brainstem structures cannot be ruled out.

245.18

CEREBELLAR DISORDERS; FAST GOAL-DIRECTED FLEXION MOVEMENTS AT ELBOW, WRIST AND FINGER IN MAN B.Wild*[1] H.C.Diener[1] J.Dichgans[1] J.Hore[2] [1]Dept.of Neurology, Tuebingen University,7400 Tuebingen,West Germany;[2]Dept.of Physiology,Univ. of Western Ontario, London N6A 5CI, Canada.

Dysmetria is a prominent symptom in patients with lesions of the cerebellar hemispheres. Under clinical conditions dysmetria is tested in proximal joints only (e.g.finger-finger-test). Little is known about the disturbance of movements in more distal joints. We therefore tested 6 patients with unilateral cerebellar lesions comparing function of the affected and healthy sides, 3 patients with diffuse cerebellar atrophy and 10 normal subjects. Fast goal-directed flexions of varying amplitude (5°,30°,60°) were tested seperately at finger, wrist and elbow. Surface EMGs from agonist and antagonist were registered along with the position signal derived from a potentiometer attached to the manipulandum.

Normal subjects show remarkable similarities between the three joints for reaction times and kinematic parameters such as symmetry of acceleration and deceleration but significant differences for maximal acceleration, velocity, deceleration and accuracy.

Patients showed an increase in reaction time and movement duration. Acceleration, velocity and deceleration significantly differed from normals but could be either in- or decreased even at the same joint in one subject performing movements of various amplitudes. Hypermetria was most prominent for small movements. A constant feature was the increase of deceleration in relation to acceleration. This can be explained by the delayed onset of antagonist activity being thus less counteracted by an already ceasing agonist activity. These changes were found at all three joints despite their greatly varying anatomical features.

INGESTIVE BEHAVIORS I

246.1

INHIBITION OF INDEPENDENT INGESTION IN RAT PUPS BY GLUCOSE BUT NOT SUCROSE. S.E. Swithers* and W.G. Hall. Dept. of Psychology, Duke Univ., Durham, NC 27713

Rat pups, tested independent of the mother and suckling, will actively ingest a diet spread on the floor of test containers. We have previously shown that in pups 6 days of age, intake is controlled solely by pups' level of gastric fill and hydrational status. By 9 days of age, however, nutritive glucose pre-loads will inhibit ingestion by an additional mechanism. Because pups at this age lack sucrase activity, they are unable to digest and absorb sucrose. If the inhibition by glucose in 9-day-old pups is specific to its nutritive or metabolic consequences, then sucrose should be ineffective in suppressing intake of pups at this age. We tested the specificity of nutritive inhibition using gastric pre-loads of sucrose, glucose, glucose plus fructose or water. Pups were deprived for 4 hours, given pre-loads by gavage and ingestive responses were tested 2 hours later. In 9-day-olds, pre-loads of glucose or glucose plus fructose suppressed intake, while sucrose and water loads were ineffective. In 20-day-old rat pups, in which sucrase activity is present, sucrose, glucose, and glucose plus fructose had similar suppressant effects on independent ingestion. These data suggest that the inhibition by glucose seen in 9-day-olds is specific to a nutrient that can be absorbed by the pup, and thus may depend on its metabolic effects. Because this nutritive inhibition emerges so early, it may be fundamental to control of ingestion at all ages.

THE CHOLECYSTOKININ ANTAGONIST L364,718 BLOCKS THE CALMING EFFECTS OF INTRAORAL INFUSIONS OF MILK AND FAT BUT NOT SUGAR IN NEONATAL RATS. D.J. Shide* & E.M. Blass Dept. of Psychology, Johns Hopkins University, Baltimore MD 21218.

Intraoral infusions of milk, fat, and sucrose calm the infant rat, as measured by a reduction in ultrasonic distress vocalizations (DV's). The temporal qualities of milk-elicited calming differ from those for fat or sucrose calming; for milk the effect is delayed, suggesting involvement of a post-oral mechanism. Low doses of CCK also calm the infant rat, implicating this peptide in post-oral calming. Exp. 1 tested the hypothesis that CCK systems are involved in the calming effects of some orally infused substances. Day 10 pups were weighed and marked, and received either an injection of L364,718 (2.0 mg\kg\ml) or its vehicle control. Individually isolated rats received an intraoral infusion of milk, corn oil, 7.5% sucrose, distilled water or no substance, while the number of DV's was recorded for experimental and control groups. Pretreatment with L364,718 blocked the calming effects of milk and corn oil, but not sucrose. Compared to their vehicle controls, L364,718 treated pups vocalized twice (corn oil) or three times (milk) as much. In contrast, there were no differences between L364,718 or vehicle treated pups who received infusions of 7.5% sucrose or distilled water. These results suggest that an endogenous CCK system is involved in calming produced by intraoral infusions of milk and corn oil.

246.3

OVARIECTOMY INCREASES INTAKE OF SUCROSE DURING SHAM FEEDING. B. Tofel-Grehl*, G.P. Smith and D. Greenberg. E.W. Bourne Lab, N.Y. Hospital-Cornell Med. Ctr., White Plains, NY 10605.

The intake of sucrose during a sham feeding test is a monotonic function of concentration in female rats (Nissenbaum & Sclafani, 1987). To determine if the orosensory effect of sucrose is modulated by ovarian hormones, we compared the potency of sucrose (0.1-0.8M) to stimulate sham feeding in pair-fed, 17-h food deprived, ovariectomized and intact rats fitted with chronic gastric fistulas. Ovariectomized rats sham fed significantly more sucrose at all concentrations ($p<.04$, Table).

		SUCROSE CONCENTRATION (M)			
GROUP	n	0.1	0.2	0.4	0.8
OVX	6	23.2*	37.5*	56.2*	60.7*
INTACT	6	13.2	31.2	41.3	47.7

Note. Numbers are mean intake (ml) in 30 min; *$p<.05$.

The results suggest that ovarian hormones decrease the orosensory effect of sucrose during sham feeding after 17h of food deprivation.

246.4

FOOD AVERSION INDUCED BY AREA POSTREMA ABLATION (APX): RELATIONSHIP TO HYPOPHAGIA AND WEIGHT LOSS. Nancy J. Kenney Department of Psychology University of Washington, Seattle, WA 98195

Rats are hypophagic and lose weight immediately following APX. Lesioned rats develop aversions to foods ingested during the first 8 days after the ablation when weight loss and hypophagia are maximal. But, neither hypophagia nor weight loss are necessary aspects of the UCS underlying the food aversion. Intake and weight gain of APX rats recovers to control levels within 2-3 wk after the ablation. But, APX rats develop aversions to foods ingested after recovery. Weight reduction prior to APX eliminates the post-lesion hypophagia but does not preclude development of an aversion to foods ingested after the ablation. When rats are force fed during the first 10 days after APX, they maintain food intakes and body weights similiar to those of intact rats even after the cessation of force feeding. Force-fed APX rats develop aversions to foods ingested after the force feeding has ended. Thus, while the lesion-induced food aversion may play role in the hypophagia and weight loss which result from APX, the UCS underlying this aversion is present and effective in eliciting aversions when no hypophagia or weight loss are evident.

246.5

FOOD AVERSIONS INDUCED BY AREA POSTREMA ABLATION (APX): EFFECT OF DIET FAMILIARITY. M. Kathleen Burkhart* and Nancy J. Kenney (SPON: H.Samson). Dept. of Psychology, Univ. of Washington, Seattle Wa. 98195.

Rats develop aversions to foods ingested after APX. This study shows that pre-lesion familiarity with the post-APX food attenuates weight loss, hypophagia and food aversion induced by the lesion.

APX rats were fed a familiar pelleted chow (PEL), a novel food (AIN), or both AIN and PEL for the first 8 days after ablation. All 3 APX groups ate less and lost more weight than diet-matched sham-lesioned rats (SHAMs) during this time. Weight loss and hypophagia of APX rats fed AIN were greater than those of APX rats fed PEL or both PEL and AIN.

Food aversion was assessed through a series of 24-hr, 2-food choice tests. Rats fed PEL or AIN after APX showed aversions to the post-lesion food but the aversion to AIN was more reliable than that to PEL. APX rats fed both PEL and AIN showed aversion to both foods when they were paired with a totally novel food (MILK). The aversion to AIN was stronger than that to PEL. When offered a choice between AIN and PEL, these APX rats ate less AIN than diet-matched SHAMs but did not differ from SHAMs in PEL intake.

INTRAPERITONEAL ADMINISTRATION OF SEROTONIN (5-HT) INHIBITS SHAM-FEEDING WITHOUT ELICITING THE SATIETY SEQUENCE IN RATS. K. Eberle-Wang, F. C. Sisk*, A. Vaidya* and K. J. Simansky. Dept. Pharmacology, Med. Coll. of Pennsylvania, Philadelphia, PA 19129.

This study analyzed the effects of peripherally administered 5-HT on sham-feeding by rats restricted to 6 h daily access to milk. After injecting vehicle, rats equipped chronically with gastric cannulas sham-fed continuously during the 30-min test period and consumed 53 ± 4 ml of milk. Given in random order, 3 doses of 5-HT (1.6, 4 and 10 umol/kg, i.p.) inhibited sham-feeding by 12, 42 and 80%, respectively. These reductions agreed proportionately with those obtained previously in intact rats. 5-HT did not retard the onset of feeding. Sham-feeding rats consumed large volumes even after 5-HT (e.g., 31 ± 4 ml after 4 umol/kg), thereby arguing against motor debilitation producing the anorexia. Indeed, after 5-HT as after vehicle, rats fed virtually continuously for the 30-min testing period. Thus, 5-HT reduced sham-feeding by decreasing the rate of feeding rather than its duration. We used a time-sampling procedure to characterize the effects of 4 umol/kg 5-HT on the microstructure of feeding. Sham-feeding rats ingested less milk after 5-HT and occasionally groomed, sniffed or explored. However, these rats displayed the complete sequence of satiety **only when the cannulas were closed.** Thus, 5-HT requires more than oral stimuli to produce satiety. Supported by NIMH 41987 to KJS

NEONATAL DIETRY EXPERIENCES INFLUENCE ADULT RESPONSES TO MACRONUTRIENTS. J. Diaz, P. Garvie', G. Watkins* and E. McGarvey. Dept. of Psychology, University of Washington, Seattle, WA 98195.

We have shown that rat pups rendered obese by adjusting the volume or the content of the infused formula given during gastrostomy feedings defend this obesity throughout their lives. In the present study, shorter gastrostomy feeding periods were used and adult behavior examined.

At four days rat pups were: 1) mother reared in litters of eight (MR); 2) gastrostomy fed for eight days (Days 5-12) to match the growth of the MR group (WM); and 3) gastrostomy fed with a formula supplemented with 10% fat (OB). At Day 12, the gastrostomy fed groups were returned dams to form litters of eight. As adults, all the groups were given fat adulterated mash for 10 days, and later were given sucrose adulterated mash. Following these challenges the animals were tested in a radial arm maze. The OB animals ate more fat and sucrose adulterated mash than did the MR controls. The OB animals also took less time to complete the radial arm maze. These data suggest that there may be sensitive or critical periods early in life for adult responses to fat and sucrose, and for the reinforcement value of food.

246.8

THE EFFECT OF VASOPRESSIN ON CARBOHYDRATE AND PROTEIN PREFERENCES IN RATS. C.H.Wideman and H.M.Murphy. John Carroll Univ.,Cleveland,OH 44118.

Brain vasopressin may modulate the activity of serotonin-containing systems in the brain which affect carbohydrate and protein intake. Vasopressin-deficient (DI) and Long-Evans (LE) rats were presented with a sucrose solution, a saccharin solution, tap water, and regular rat chow (relatively high in protein) for a 7 day habituation period followed by a 9 day experimental period in which the animals were food-restricted for 23h each day and given ad-lib access to the fluids. DI rats drank more sucrose than LE rats during the habituation period, but no difference was evident in the experimental period. The sucrose was preferred over saccharin and water by DI and LE rats during both the habituation and experimental conditions. Food intake differed significantly during the latter part of the habituation period where LE rats consumed more food than DI animals. This phenomenon was reversed during the experimental period. DI rats follow eating and drinking patterns that are much different from LE animals. The cyclic pattern of carbohydrate and protein intake in LE rats, which is absent in DI rats, indicates a role for vasopressin in consummatory behavior. This role may involve the neurotransmitter serotonin.

246.9

DIETARY FAT INFLUENCE ON CARBOHYDRATE AND PROTEIN SELECTION MAY BE MEDIATED VIA CENTRAL SEROTONIN SYSTEM. BJ Mullen* and RJ Martin (SPON: T. Reigle) Dept. of Foods & Nutrition, University of Georgia, Athens, GA 30602

We have shown previously that type and level of dietary fat can influence an animal's subsequent selection for carbohydrate (CHO) and protein (Pro). High levels of dietary tallow result in preference for dietary protein while high levels of corn oil result in carbohydrate feeding. Present studies investigate the role of the central serotonin system in mediating this behavior. Male, Sprague-Dawley rats (75-99 g) were divided into 2 groups and fed diets containing either 34% corn oil or 34% tallow for 2 days. These diets were then replaced with 2 diets given simultaneously to test dietary selection: 1) 15% CHO/60% Pro and 2) 65% CHO/10% Pro. During this diet selection period, the corn oil and tallow groups were subdivided into 3 groups which were injected with either: 1) saline, 2) 2 mg/kg BW fenfluramine or 3) 6 mg/kg BW fenfluramine. Injections were given IP 2 hours before onset of the dark cycle. As noted earlier, the rats previously fed tallow exhibited a preference for protein while the corn oil group preferred carbohydrate. The fenfluramine depressed consumption of CHO in both corn oil and tallow groups but had a significantly greater effect in the tallow group. We propose that the central serotonin system may be mediating, in part, the behavioral effect of dietary fat on macronutrient selection.

EFFECTS OF EARLY DIETARY NACL EXPOSURE ON DIETARY OBESITY AND BLOOD PRESSURE IN ADULT RATS. R. J. Contreras. Department of Psychology, University of Alabama, Birmingham, AL 35294.

We investigated the long-term effects of early dietary NaCl exposure on body weight and blood pressure in normotensive Sprague-Dawley rats. Adult female rats were fed a diet containing either 0.12% (low) or 3% (high) NaCl throughout pregnancy and lactation. The offspring were continued on these same NaCl-containing diets until 30 days postpartum. Thereafter, all the offspring were fed Agway 1% NaCl chow. Beginning at 60 days of age, the rats raised on the low and high NaCl diets were subdivided into two groups. One group was continued on the Agway chow and the other group was fed a high fat mash and sweetened milk (HF/M) diet. Body weight and caloric intake were measured weekly as were systolic blood pressure and heart rate using tail plethysmography in awake restrained rats. After 16-wk, mean arterial pressure (MAP) and heart rate (HR) responses to the pressor effects of bolus intravenous infusions of angiotensin II (20, 40, 80, 120 ng/kg of body weight) and atriopeptin II (20, 40, 80 ug/kg) were obtained from the femoral artery in awake rats.

HF/M feeding resulted in significant elevations in body weight and in terminal brown fat pad and white fat pad weights for both the low and high salt rats. There seemed to be a group by sex interaction effect; HF/M feeding led to a greater obesity in low salt females compared to high salt females, but the obesity for the two male groups were similar. The blood pressure data are currently being analyzed.

Supported by NIH Grant HL-38630.

246.11

EFFECT OF PROLONGED PHARMACOLOGICAL STARVATION ON CALORIC INTAKE AND MACRONUTRIENT SELECTION.
J. Duhault*, F. Lacour* and Y. Rolland* (SPON: J.C.R. Randle). Institut de Recherches Servier, Suresnes, France

The present experiments were undertaken to compare the effects of complete food removal with the effects of pharmacological starvation on meal size and macronutrient selection during the refeeding period. dl-Fenfluramine and Fluoxetine were used as pharmacological tools. In self-selection experiments 18 h food-deprived adult fatty Zucker rats were offered three pure macronutrient isocaloric diets (CHO 80 %, PRO 80 %, LIP 80 %) for a 2 h period. Group 1 was maintained on the standard lab chow, group 2 was subjected to a 4 day fast, groups 3 and 4 received daily i.p. administration of dl-Fenfluramine (100 µmol/kg per day for 4 days) or Fluoxetine (100 µmol/kg per day for 4 days), respectively. On the 5th day, rats of different groups were allowed to select their food from the three separate sources of macronutrients. In group 2, the refeeding selection after fasting was characterized by a small decrease (-21 %) in total caloric intake, the percentage of total calories as carbohydrate was increased (16.5 ± 3 % versus 5.9 ± 2 %). dl-Fenfluramine and Fluoxetine had suppressant effects on overall food intake, but 6 out of 10 animals died in the Fluoxetine group before the refeeding selection trial. Total caloric intake was still reduced (-44 %) in the dl-Fenfluramine group and in the 4 surviving Fluoxetine-treated rats (-91 %). When energy stores were low, a switch in preference for carbohydrates occured in untreated food-deprived rats, whereas pharmacological activation of the 5HT system by dl-Fenfluramine or Fluoxetine administration resulted in a return to a relative preference for proteins.

RELATION BETWEEN PREFERENCE FOR "SWEET" STIMULI AND SINGLE FIBER ACTIVITY IN THE HAMSTER CHORDA TYMPANI NERVE.
B.G. Rehnberg*, T.P. Hettinger, and M.E. Frank. UCONN Health Center, Farmington, CT 06032.

Preference data and conditioned aversion studies for the hamster (Mesocricetus auratus) show that a variety of gustatory, olfactory, and trigeminal stimuli are preferred only if they are "sweet" (sucrose-like). Putative sweet stimuli at preferred concentrations (compared to water) were presented to the anterior tongue of the hamster while recording from the chorda tympani nerve. The order of stimulatory effectiveness for integrated responses of the whole nerve was Na 2-mercapto-ethanesulfonate (0.03 M) > p-phenetylurea (0.005 M) = Na 3-nitrobenzenesulfonate (0.003 M) = Ca cyclamate (0.01 M) = sucrose (0.03 M) = Na saccharin (0.001 M) > D-phenylalanine (0.01 M) = glycine (0.1 M). Single fiber recordings indicate that all are good stimuli for sucrose-sensitive (S) fibers with the exception of Ca cyclamate and Na nitrobenzenesulfonate. Ca cyclamate, instead, appears to be a good stimulus for a population of generalist (H) fibers. As expected, the sodium salts are good stimuli for both sodium-sensitive (N) and H fibers. These results suggest that sucrose-sensitive fibers carry information leading ultimately to ingestion of preferred stimuli. However, a role for other populations of fibers in the chorda tympani in initiating preferential drinking cannot currently be ruled out. (Supported by NSF BNS-8519638, NIH NS16993, and NIH NS07299).

246.13

EFFECT OF DIETARY CARBOHYDRATE SOURCES ON FEEDING BEHAVIOR, PLASMA GLUCOSE, INSULIN AND TRYPTOPHAN, AND BRAIN SEROTONINERGIC SYSTEMS IN SELF-SELECTING RATS.
L. Thibault. School of Dietetics and Human Nutrition, Macdonald Coll. of McGill Univ., Montréal, Canada, H9X 1C0.

The present study was undertaken to investigate hypothalamic and extrahypothalamic neural and hormonal mechanisms involved in the control of food intake. Sprague-Dawley rats were offered pairs of 0 and 60% casein diets using either sucrose, fructose or glucose, for an 8h daily period during 16 days. At the end of the last feeding period, arterial and venous blood samples were collected, or animals decapitated and brain dissected out. Fructose fed rats displayed slower growth rate and higher dietary energy chosen as protein (%P-E) than rats fed either sucrose and glucose. Rats fed glucose had a higher %P-E but a lower %CHO-E than those fed sucrose. Fructose feeding induced lower arterial and venous (AV) glucose levels than sucrose and glucose feeding, whereas glucose feeding induced higher AV glucose and tryptophan levels and AV difference of insulin, than sucrose feeding. The brain serotoninergic parameters showed: a fructose-induced 1) decrease in 5-HIAA/5-HT ratio and increased in tryptophan and 5-HT levels in the hypothalamus but these changes were in the opposite direction in extrahypothalamic areas, when results were compared to glucose, and 2) increase in 5-HIAA/5-HT ratio and in tryptophan and 5-HIAA levels in the raphe nuclei, and an increase in 5-HT and 5-HIAA in the brain stem, when compared to sucrose, and; a glucose-induced increase of 5-HIAA/5-HT ratio and decreased tryptophan and 5-HT content in the hypothalamus, when compared to sucrose. These results show that dietary CHO sources affect differently glycemia and insulin secretion as well as brain serotoninergic systems. Supported by NSERC Canada.

246.14

EFFECTS OF DIET AND OVARIAN STEROIDS ON BODY WEIGHT AND ADIPOSITY IN OVARIECTOMIZED (OVX) SYRIAN HAMSTERS.
A.J. Bhatia and G.N. Wade. Univ. of Massachusetts, Dept. of Psychology and Neuroscience and Behavior Program, Amherst, MA 01003.

In OVX Syrian hamsters administration of estradiol alone or with progesterone results in weight loss and reduced carcass lipid. Since it has been suggested that the weight-reducing effects of estradiol are dependent on an elevated level of body weight and estradiol treatment is reported to dictate a low weight level independent of the diet offered in OVX rats, we assessed the weight- and adiposity- reducing actions of estradiol alone and with progesterone in OVX hamsters of differing body weights and adiposity. Animals received subcutaneous Silastic implants of estradiol alone, estradiol and progesterone, or empty blanks. Hamsters given hormone implants lost body weight and lipid. The amount of weight loss depended on body weight at the time of hormone implantation, but not on the amount of dietary fat intake. Groups that had higher body weights had larger absolute losses, but the percentage of weight and carcass lipid lost among the different groups was similar. Hamsters heavier at the time of hormone implantation had higher absolute amounts of terminal carcass lipid than hamsters that were lighter at the time of hormone implantation. Thus, the weight and adiposity-reducing actions of estradiol and progesterone are enhanced in fatter animals, but an absolute low level of body weight or fatness is not dictated by the actions of these steroids.

246.15

THE PATTERN OF FOOD CHOICE FOLLOWING FOOD DEPRIVATION.
M.B. DeStefano*, T.W. Castonguay, S.K. Kramlik*, T.T. Ton*, J.J. Valeri*, and P.U. Dubuc*. Dept of Human Nutrition and Food Systems, U. Maryland, College Park, MD 20742 and Sansum Research Foundation, Santa Barbara, CA 93102.

Adult male Sprague-Dawley rats were given ad libitum access to separate protein (PRO), carbohydrate (CHO) and fat sources for 9 days. The animals were then divided into 3 groups on the basis of body weight. The first group continued to have ad libitum access to macronutrient sources and water. The second group was subjected to a 24 h food deprivation period, after which time access to all three of the food sources was restored. Intakes were measured after 1, 3, 6, 12, and 24 hours of restored access. The third group was treated similarly, except that they had had food access restricted for 48 h. During each of the 5 times that intake was measured after reinstated access, each animal was bled via tail venipuncture, and circulating levels of glucose, insulin and corticosterone were measured. Deprivation led to an increase in dietary fat during the first hour of refeeding. Controls ate 0.1 g fat during the first hour on the test day. 24 h deprived rats ate 1.67 g of fat, and 48 h deprived rats ate 2.37 g of fat during the first hour of refeeding. During this first hour of daylight, controls composed a diet that was 25% CHO, 41% PRO and 33% FAT, yielding only 2.4 kcals. During the first hour of access, 24 h deprived rats selected a diet that was 7.8% CHO, 36% PRO and 56% FAT, and yielded 23.6 kcals. 48h deprived rats selected of a diet during this first hour of access that was 9.7% CHO, 33.7% PRO and 56.5% FAT, and yielded 33.2 kcals. Deprivation played no role in altering 24 h dietary PRO. The % of calories taken from CHO, PRO and FAT by the control group was 19.8%, 42.1% and 38.1% (84.6 kcals). By comparison, on the day food access was reinstated 24 h deprived rats composed a diet made up of 2.9% CHO, 41.4% PRO, and 55.7% FAT (105.3 kcals). Similarly, 48 h deprived rats composed a diet made up of 13.2% CHO, 42.1% PRO, and 44.7% FAT (121.7 kcals). These selection patterns are consistent with the hypothesis that dietary fat intake is partially controlled by circulating corticosterone. (Supported by a grant from the Whitehall Foundation.)

ELECTRICAL STIMULATION OF HYPOTHALAMIC SITES WHICH INDUCE EATING DRIVES MASTICATORY NEURONS IN THE BRAIN STEM.
E. Murzi*, T. Baptista* & L. Hernandez* (SPON: J. Litto). Laboratorio de Fisiologia de la Conducta, Escuela de Medicina, Universidad de Los Andes, Merida, Venezuela

Previous experiments showed that electrical stimulation of the perifornical region of the hypothalamus (PFH), which induces feeding in unanesthetized rats, drives gustatory neurons in the nucleus tractus solitarii, but not in the pontine taste area in anesthetized rats[1]. This suggests that some feeding related centers in the lower brain stem are modulated by hypothalamic feeding centers. In order to further explore this functional relationship we implanted multiple electrodes in the PFH. After recovery from surgery each rat was tested for electrically induced feeding. Some electrodes induced stimulation-bound feeding (SBF) and some did not (NSBF). Then each rat was anesthetized and a glass insulated tungsten microelectrode was lowered in the masticatory nucleus of the trigeminal nerve. Masticatory neurons were identified by excitatory or inhibitory responses when the jaws of the rat were passively opened or closed. Stimulation through SBF electrodes affected the firing rate of masticatory neurons more than stimulation through NSBF electrodes. In order to produce this effect, the frequency and the duration of the stimulus train had to be at least 30 Hz and 5 seconds respectively. We conclude that a functional relationship between the lateral hypothalamic feeding center and the brain stem masticatory center exists. This relationship might underlie the increased energy biting observed in food deprived animals[2]. Additionally, this relationship might be involved in gnawing and aggression biting.

CHARACTERIZATION OF 5-HYDROXYTRYPTAMINE (5-HT) RECEPTOR BINDING IN OBESE MALE ZUCKER RATS. Steven Rothman* and Edmund T. S. Li. Department of Nutritional Sciences, University of Toronto, Toronto, Ontario M5S 1A8, Canada.

5-HT_1 receptors which have high affinity for 5-HT are known to play a role in feeding control. 5-HT_1 receptors are composed of mainly 1A and 1B subtypes. The 1A subtype also has high affinity for the compound 8-OH-DPAT. The present study examined the binding characteristics of 5-HT to cortical membranes of the genetically obese Zucker rat which is hyperphagic. Lean (mostly fa/+) and obese (fa/fa) rats were fed lab chow for 3 to 4 weeks and killed by decapitation. Radioligand binding assays were performed using (^3H)5-HT. Total 5-HT_1, nonspecific (in the presence of unlabelled 5-HT) and 1B binding (in the presence of unlabelled 8-OH-DPAT) were determined by Scatchard analyses. 5-HT_{1A} binding was obtained by subtracting the B_{max} (pmol/g tissue) of 1B from that of the total. At 12 weeks of age, obese rats had 23% less total 5-HT_1 binding than their lean littermates (5.2 vs 6.8, t=2.70, df=22, P<0.025). 5-HT_{1B} binding was not different between genotypes (3.6 vs 3.7). Binding to 5-HT_{1A}, however, was significantly different with the obese having 48% less binding sites than the lean (1.6 vs 3.1, t=3.69, P<0.005). Affinity was not different for any of the subtypes. These preliminary results suggest a potential area of investigation in the etiology and / or maintenance of genetic obesity.

THE EFFECT OF CENTRALLY ADMINISTERED ICS 205-930 ON FOOD INTAKE OF RATS FED AN AMINO ACID IMBALANCED DIET. B.J. Hrupka*, J.L. Beverly*, D.W. Gietzen, V.A. Hammer*, Q.R. Rogers. Dept. Physiol. Sci. and Food Intake Lab, Univ. Calif., Davis, CA, 95616.

These experiments were conducted to study the effect of intercerebroventricular (ICV) injections of the serotonin$_3$ antagonist ICS 205-930 (ICS) on food intake of rats fed ile imbalanced (IMB) diets. Serotonin$_3$ receptors may be involved in rat's anorectic response to amino acid imbalanced diets. Male Sprague-Dawley rats, fitted with chronic unilateral 20 gauge guide cannulae 1 mm above the lateral ventricle, were prefed a low protein basal (BAS) diet. All ICV injections were administered in 7 µl volumes over a 30-60 sec period. To verify cannulae placement, 100 ng Angiotensin II was injected, and drinking responses recorded. In the following experiments, rats received ICV injections of either ICS or saline (SAL), 30 min before onset of the dark cycle. The test diet was presented to rats at the beginning of the dark cycle, and food intake (FI) was recorded 3, 6, 12, or 24 hr after presentation. In experiment one, 26 rats (n=6-7/trt) were given ICV injections of either ICS (10 nmoles) or SAL, and fed either BAS or a severe IMB diet. ICS injected rats ate less than saline injected rats when fed a BAS diet (mean ± SE 24 hr FI=9.5±2.8 g vs 18.8±1.2 g, P<.05). ICS injections did not affect food intake of rats fed the IMB diet (mean±SE 24 hr FI=3.9±0.6 g vs 5.0±1.3 g for ICS and SAL trt respectively, P>.05). Because ICS reduced FI in rats fed the basal diet, a second experiment was conducted to investigate the effect of lower ICS doses. Twenty four rats (n=6/trt) received ICV injections of either 0, 0.01, 0.1, or 1 nmole ICS and fed a mild IMB diet. Food intake was not affected (P>.05) by ICS at any time period (mean ± SE 24 hr FI=5.2±1.3, 7.1±1.6, 5.5±1.8, 5.0±1.9 for 0, 0.01, 0.1, and 1.0 grps respectively). Additional experiments are being conducted to determine if ICS's effect is peripherally or centrally mediated. Supported by NIH AM-07355, DK-13252; USDA CRCR1-2418; CNRU DK35747-04.

LIMITED ROLE OF $5HT_{1C}$ RECEPTORS IN THE ANOREXIA AND LOCOMOTION CHANGES PRODUCED BY 5HT AGONIST ADMINISTRATION TO RODENTS. J. A. Nielsen. Pfizer Central Research, Groton, CT 06340.

An extensive literature implicates serotonin (5HT) in the regulation of food intake. It has been suggested that postsynaptic $5HT_1$ receptors (possibly of the $5HT_{1C}$ type) play an important role in the control of feeding in rats (Dourish *et al.*, *Psychopharmacol.* **97**:54, 1989) and that hypophagia induced by mCPP requires activation of both $5HT_{1C}$ and $5HT_{1B}$ receptors while that caused by RU 24,969 only requires stimulation of $5HT_{1B}$ receptors (Kennett and Curzon, *Psychopharmacol.* **96**:93, 1988). The present study extends these findings by determining the effects of the $5HT_{1C}$ antagonists mianserin and mesulergine on the anorexia and behavioral disruption caused by direct $5HT_1$ receptor agonists (RU 24,969; mCPP and TFMPP) and indirect 5HT agonists (d,l-fenfluramine; d-fenfluramine and fluoxetine) in mice and rats.

Mianserin (3.2 mg/kg, sc) and mesulergine (0.32 mg/kg, sc) antagonized the decreased food intake and hypolocomotion caused by mCPP (1.0-3.2 mg/kg, ip) in rats, but were ineffective at blocking the actions of mCPP in mice. In addition, these antagonists had no effect on the anorexia and behavioral disruption caused by TFMPP (1.0-3.2 mg/kg, ip), d,l-fenfluramine (1.0-3.2 mg/kg, ip), d-fenfluramine (1.0-3.2 mg/kg, ip), fluoxetine (5.6-17.8 mg/kg, ip) and RU 24,969 (1.8-5.6 mg/kg, ip) in rats or mice.

These data suggest that the hypophagia and behavioral disruption caused by direct and indirect 5HT agonists is not solely related to activation of $5HT_{1C}$ receptors in rodents.

NEUROETHOLOGY II

HARMONIC COMBINATION-SENSITIVE NEURONS IN THE ZEBRA FINCH. E.S. Fortune* and D. Margoliash.(SPON: J.D.Cowan) Dept. Org. Bio. and Anat., Univ. Chicago, Chicago, IL 60637.

Zebra finch song is rich in harmonics whereas white-crowned sparrow song is not. In the forebrain song system nucleus HVc of the white-crowned sparrow, auditory neurons are sensitive to temporal features of song. We explored how harmonics are represented in zebra finches by recording from single HVc neurons in urethane anesthetized birds.

In our preliminary sample, we isolated 24 'complex' neurons in 11 birds that responded well to song syllables from the individual's own (autogenous) song but poorly to tone bursts. In all pair-wise comparisons (n=61), such neurons responded better to autogenous than conspecific songs. We tested these neurons with reversed autogenous song, spectrally similar song modified to remove the natural AM, and white noise shaped with identical AM as autogenous song. Typically, these neurons did not respond to the AM-noise, AM-modified, or reverse autogenous song. Although zebra finch syllables are complex, occasionally we could produce effective artificial models of syllables. These demonstrated that complex neurons typically required 1) both 2nd and 3rd but not higher harmonics or the missing fundamental, 2) each harmonic comprising a continuous sound of one or several FM segments specified within a narrow band of starting and ending frequencies and a limited range of durations, and 3) a distinct harmonic amplitude relationship. Some neurons exhibited closed amplitude tuning curves. It appears that combination sensitivity and selectivity for autogenous song are emergent properties of HVc that may obtain widely in songbirds.

CYTOARCHITECTURE AND DIFFERENTIAL PROJECTIONS OF NUCLEUS OVOIDALIS IN THE ZEBRA FINCH, *Poephila guttata*. P. M. Bell, D. Margoliash and P. S. Ulinski. Dept. of Organismal Biology and Anatomy and Comm. on Neurobiology, Univ. of Chicago, Chicago, IL 60637.

Nucleus ovoidalis is a thalamic auditory nucleus that projects to Rose's field L in the telencephalon of birds. In songbirds, it may play a role in processing auditory cues associated with song recognition and production, but its internal circuitry is not understood. Consequently, we have begun analyzing the neuronal organization of ovoidalis. In zebra finch Nissl material, ovoidalis is composed of large (~18 µm) densely stained neurons with elongate, fusiform somata and a lesser number of small (~7 µm) diffusely stained neurons with round or oblong somata. Large injections of HRP into field L result in clouds of retrogradely filled neurons in ovoidalis. Large neurons all contain vesicular reaction product in the centers of such clouds, but are less consistently filled at the clouds' peripheries. Small neurons are apparently never labeled. Additionally, the range of cases indicates some degree of topography in the projection from n. ovoidalis to field L. Large neurons situated medially in the former project to the medial region of the latter, and large neurons in lateral ovoidalis project to the lateral portion of field L. We are currently using focal HRP injections within field L to further investigate the topography of the projection involving the large, fusiform cells within n. ovoidalis. If the small neurons do not project to field L, then they could represent either an interneuronal population or a parallel auditory path to a second target. Supported by grants to D.M. from the NIH (NS25677-01) and the Searle Scholars Program/Chicago Community Trust.

247.3

PLASTIC SONG IN ADULT INDIGO BUNTINGS (*Passerina cyanea*). D. Margoliash and C. A. Staicer*. Dept. of Organismal Biology and Anatomy, Univ. Chicago, Chicago, IL 60637.

Some songbirds such as the indigo bunting retain the ability to modify song into adulthood. In the field, buntings already singing a stereotyped song will alter their songs to closely match a territorial neighboring adult. Using a computer-based system, we have exhaustively examined singing behavior of individuals or pairs of males housed in IAC sound booths. Some birds sang spontaneously; others were primed with testosterone.

Over a period of months, as well as stereotyped song both yearling and older males sang bouts of what we have termed 'adult plastic' song. Characteristics of adult plastic song included standard, well-formed bunting syllables not found in the individual's stereotyped song, variable temporal pattern and bout duration (1-30s), and low amplitude singing. For 7 yearlings and 6 older birds, syllable types were distributed as follows: stereotyped $\bar{n} = 5.2$, range 3-11; plastic $\bar{n} = 12.3$, range 7-18. Adult plastic songs are therefore distinct from the short, invariant stereotyped songs. Cage mates did not exhibit song matching, but may have incorporated new syllables into their plastic songs. We are automating the analysis of this large (10^8 Kb) data base.

Buntings therefore engage in two distinct singing behaviors. These observations suggest that the mechanism for song matching in adult birds involves adult plastic song. Furthermore, buntings are clearly capable of vocal motor patterns that are normally not expressed in the stereotyped song. We are currently exploring how these alternate patterns are expressed in the (motor) song system.

247.4

SELECTIVE IMPAIRMENT OF SONG DEVELOPMENT IN ZEBRA FINCHES FOLLOWING LESIONS OF THE SONG CONTROL NUCLEUS, AREA X. F. Sohrabji, E.J. Nordeen and K.W. Nordeen. Psychology, U. Rochester, Rochester, NY, 14627.

Area X has been assumed to participate in the control of avian song because it connects with other vocal nuclei, and its size is positively correlated with the ability to sing. We report here that Area X specifically contributes to song development and is not needed for production of adult song.

Area X in adult and juvenile male zebra finches was bilaterally lesioned with ibotenic acid. Songs of adult birds were recorded prior to surgery, and both adult and juvenile birds were recorded weekly after surgery. Birds were sacrificed 3-5 weeks after surgery and coronal brain sections through Area X were examined to verify the location and size of the lesion.

Lesioning Area X in adult birds did not affect song quality. However, song development was severely impaired when Area X was lesioned in juvenile males. At all post-operative timepoints, these lesioned juveniles were judged to be in earlier stages of vocal development than age-matched sham lesioned controls. In fact, by 75 days, control males were producing stable adult song, yet lesioned birds were producing subsong, lacking in stereotypy and syllable definition. These results suggest that Area X is not necessary for sustaining the production of juvenile or adult song, but is important for either the acquisition of a song model, or the improvement of song through vocal practice. (Supported by USPHS, NS24862)

247.5

LESIONS IN AREA X AFFECT SONG IN JUVENILE BUT NOT ADULT MALES ZEBRA FINCHES. C. Scharff* and F.Nottebohm SPON: (A. Alvarez-Buylla). The Rockefeller University, New York, NY 10021.

The forebrain nucleus area X is implicated in the circuitry of brain nuclei controlling vocal behavior: it receives a projection from HVC and projects itself to dorsal thalamus which in turn connects to MAN, a nucleus involved in song aquisition in Zebra finches. As yet, no functional role has been ascribed to area X.

We investigated if area X plays a role in song production or development by lesioning the nucleus electrolytically. An angled approach was used so as to avoid MAN. The song of 10 adult males did not change during the two months post-operative survival. In contrast, striking impairments were seen when juveniles that had been lesioned between 28 and 45 days were recorded between 68 and 134 days. These birds did not show normal progression from plastic to crystallized song. Fewer notes (usually 1-3), poor note morphology and control of frequency modulation, unusually long notes (250+ ms) and long inter-note intervals, as well as non-stereotypic combination of notes into motifs were among the most prominent features.

These results suggest that destruction of area X interferes with the normal process of song acquisition and results in significant changes in song structure relative to normal adult song.

247.6

EFFECTS OF HVC LESIONS ON SONG SYLLABLE PRODUCTION IN ZEBRA FINCHES (POEPHILA GUTTATA). J. Cynx. Field Research Center, Rockefeller Univ., Millbrook, NY 12545.

Lesions to brain nucleus HVC cause aberrant song production in zebra finches and other songbirds. In this study, temporal properties of such aberrant song were determined. This in turn suggests how HVC might and might not control song production.

A zebra finch can be induced to stop singing in the midst of song if confronted with a brief flash of light. Song interruptions occur only between song syllables (Cynx, J., J. Comp. Psych., in press), suggesting syllables have unitary coherence, and that song is produced on a syllable-by-syllable basis. This technique was used to determine the temporal coherence of aberrant song structures.

Zebra finches were tested with the above procedure, given bilateral HVC lesions, then tested again. All birds could be induced to stop vocalizing. All interruptions occurred between syllabic structures. This suggests that HVC may not be essential to the maintenance of temporally coherent motor units. More generally, lesions to a part of the song control pathway can be shown to produce well-defined and measurable changes in song production.

247.7

EVIDENCE FOR SUBDIVISIONS WITHIN UVAEFORMIS, AN AVIAN SONG NUCLEUS. H. Williams, G.F. Ball, P.L. Faris*, Rockefeller University, Millbrook, NY 12545, Williams College, Williamstown, MA, 01267, Boston College, Chestnut Hill, MA 02167, Univ. of Minn. Sch. Med., Minneapolis, MN 55455.

Uvaeformis (Uva) is a small thalamic nucleus in the avian song system which projects to two forebrain nuclei (HVc and NIf). Using immuno-histochemical methods to stain for corticotropin releasing factor (CRF), we have identified two subregions of Uva in European starlings (*Sturnus vulgaris*), song sparrows (*Melospiza melodia*), and zebra finches (*Poephila guttata*). A dorsomedial cap of the nucleus contains CRF-reactive perikarya in males and females of all three species. This cap is least prominent in the rostral portion of the nucleus and most extensive at the caudal end of Uva.

Microstimulation in these two subdivisions of Uva while recording from the left and right tracheosyringeal nerves (NXIIts; the pathway is Uva-HVc-RA-nXIIts) of zebra finches indicates that there are differences in the connectivity of the cap and body of Uva. Stimulation of the cap region results in greater activation of the contralateral pathway while stimulation of the main body of Uva elicits larger responses in the ipsilateral NXIIts.

Reciprocal connections between the two portions of Uva may help in coordinating song production in the two hemispheres of song birds, which are acallosal. The localization of CRF to a subregion of Uva suggests that CRF may play a role in the motivation and initiation of singing.

Together, these results suggest a larger role for Uva in song production than has hitherto been hypothesized.

FUNCTIONAL PROPERTIES OF OUTPUTS FROM NUCLEUS ROBUSTUS ARCHISTRIATALIS (RA) IN A SONGBIRD. David S. Vicario, The Rockefeller University, New York, NY 10021

The motor pathway for vocalization in songbirds includes forebrain nuclei HVc and RA, DM of ICO, and the part of the hypoglossal nucleus (nXIIts) that controls the syrinx, the bird's vocal organ. RA of the male zebra finch can be divided into subregions with different projections (Vicario & Simpson 1988). The most dorsal part projects to DM, a midbrain vocalization area. The ventral area contains zones that preferentially project to different parts of nXIIts known to control different syringeal muscles. The present study used electrical stimulation, lesions, and chronic recording to explore the functional contributions subregions of RA make to vocal behavior in the zebra finch.

Microstimulation was applied at sites throughout RA while EMG's were recorded from the largest syringeal muscles, ventralis and dorsalis, and from the abdominal respiratory musculature. Single shocks (≤10 μA) were effective at activating all three recorded muscles with a latency of 20-25 mS, indicating that RA can contribute to respiratory aspects of vocalization (perhaps via its output to DM) as well as to syringeal control. Complete bilateral **lesions** of RA abolish song production. Electrolytic lesions of dorsal RA disrupt both temporal and acoustic features of song. Lesions limited to ventral RA affect syllable morphology, but the characteristic temporal structure of song is largely spared. Microelectrode **recordings** of neural activity in RA of awake zebra finches show bursts of activity that precede song syllables and calls by 30-50 mS (cf. McCasland 1983); a regional analysis is currently in progress. In summary, these data suggest that subregions of RA may participate in the control of temporal and acoustic features of vocalization. 247.9

SEASONAL EFFECTS ON BIRDSONG PRODUCTION AND ACQUISITION: II. TESTOSTERONE INDUCED SINGING BEHAVIOR IN SONG SPARROWS S. Nowicki* and G.F. Ball (SPON: P. Marler). Rockefeller University, Millbrook, NY 12545, Duke University, Durham, NC 27706, Boston College, Chestnut Hill, MA 02167.

Song sparrows (*Melospiza melodia*) show seasonal changes in the production of male-typical singing behavior, with far more song produced in the spring and early summer than in the fall and winter. The expression of song is highly influenced by the sex steroid testosterone (T), acting on sexually dimorphic telencephalic nuclei involved both in its acquisition and production. We examined the extent to which seasonal production differences are due to changes in the ability of T to activate song as opposed to changes in T titres. Song rates in 6 male sparrows were compared in the following 5 conditions: (1) birds responsive to long days (photosensitive), experiencing short days, and with low plasma titres of T; (2) photosensitive, on short days, with high T titres; (3) photosensitive, on long days, with high T titres; (4) insensitive to long days (photorefractory), on long days, with low T titres; and (5) photorefractory, on long days, and with high T titres. Plasma levels of T were monitored by radioimmunoassay; song behavior was evaluated sound spectrographically. T was equally effective in inducing song both while photosensitive and photorefractory. Thus, no seasonal change was found in the sensitivity to hormone action of the neural sites mediating this behavior in song sparrows.

247.10

SEASONAL EFFECTS ON BIRDSONG PRODUCTION AND ACQUISITION I: SONG LEARNING IN STARLINGS G.F. Ball, J Böhner*, M Chaiken*, P Marler, Rockefeller University Field Research Center, Millbrook, NY 12545; Department of Psychology, Boston College, Chestnut Hill, MA 02167,

European starlings *(Sturnus vulgaris),* like many periodically breeding songbird species, show dramatic seasonal changes in their propensity to respond to light that are associated with substantial differences in peripheral endocrine activity and hypothalamic neurochemistry. In this study we asked if this seasonal variation in physiological state had any effect on the propensity of males to acquire new songs. Such differences would presumably reflect seasonal changes in the functioning of at least a subset of the sexually dimorphic telencephalic nuclei that underly song acquisition and production.

Male starlings (N= 12) were collected as nestlings, hand-reared, and housed individually in soundproof chambers where they were tutored with recordings of adult song from 1.5 to 4.5 months of age. Photoperiod was manipulated so that at an age of 11 months, 6 of the subjects were in a photosensitive state, as naturally occurs in late winter and spring (i.e. responsive to stimulatory daylengths) and 6 of the birds were in a photorefractory state, as naturally occurs in summer and fall (i.e. non-responsive to long photoperiods). At that age both groups were exposed to a set of recordings of starling songs for 6 weeks. Analysis of singing behavior revealed that there were no significant differences between the groups in the amount of song material acquired during the learning session. Thus in male starlings the propensity to learn songs in the first breeding season does not depend on a physiological state of photosensitivity.

247.11

EFFECT OF FIELD "L" LESIONS ON AUDITORY DISCRIMINATION IN THE BUDGERIGAR (MELOPSITTACUS UNDULATUS). S. E. Brauth, S. D. Brown, T. Park, K. Okanoya and R. J. Dooling, Dept. Psychology, Univ. of Md., College Park, MD.

Operant conditioning techniques were used to assess auditory discrimination performance in budgerigars both before and after placing lesions within Field "L" (the primary telencephalic auditory area) or within portions of the adjacent neostriatum and hyperstriatum. In addition, response latencies were analyzed using multidimensional scaling (MDS) and cluster analysis procedures in order to reveal the underlying stimulus dimensions salient to the animals making discriminations among acoustic stimuli.

The results indicate that Field "L" lesions do not affect discrimination performance by several measures for either pure tones or calls (contact calls and alarm calls). However MDS and cluster analysis reveal that these lesions alter the perceptual dimensions underlying discrimination among calls. Prior to lesioning, analysis of response latency data using MDS and cluster analysis reveals that contact calls and alarm calls are grouped into separate clusters consistent with prior work showing that stimulus characteristics correlated with call type are salient to the animals. After lesioning Field "L", the structure of the stimulus groupings is altered, indicating that telencephalic auditory stuctures are involved in determining the perceptual basis on which these calls are normally discriminated.

247.12

SEASONAL CHANGES IN AVIAN SONG CONTROL NUCLEI WITHOUT SEASONAL CHANGES IN SONG REPERTOIRES. **E. Brenowitz, D. Kroodsma, B. Nalls, and J. Wingfield, Depts Psych & Zool, Univ. Wash., Seattle, WA 98195 and Dept. Zool, Univ. of Mass., Amherst, MA 01003.**

In canaries neural song control regions (SCRs) are larger in spring than in fall (Nottebohm 1981). This may relate to development of a new song repertoire each spring. An alternative hypothesis is that SCR changes result solely from changes in androgen levels. We tested predictions of this in rufous-sided towhees since their song repertoires are constant between seasons (Ewert 1978).

Towhee males were exposed either to long (n = 10) or short days (n = 10) for 1 month. Blood samples were analyzed for testosterone (T) and estradiol (E). We measured the volumes of 5 song nuclei (HVc, RA, MAN, Area X, and nXII) and of 2 visual nuclei (Rt, Pt) in their brains.

Ratios for Long:Short day groups were: HVc=1.68*, RA=1.54*, X=1.62*, MAN=1.01, nXII=1.19*, Rt=0.96, Pt=1.07*, brain wt.=0.98, testes wt.=50*, T level=14.5, E level=1.76 (* P < .05, t-test). The results indicate that dramatic seasonal changes in SCR size may occur without associated changes in song repertoire.

247.13

THE RELATIVE CONTRIBUTIONS OF THE LEFT AND RIGHT SIDES OF THE INTACT SYRINX TO BIRD SONG. Roderick A. Suthers and Rebecca S. Hartley*, School of Medicine and Department of Biology, Indiana University, Bloomington, IN 47405.

In order to assess the degree of lateral vocal dominance when both sides of the syrinx are able to function normally, we used a pair of heated microbead thermistors to measure the rate of airflow through each side of the intact syrinx of the brown thrasher (Toxostoma rufum, family Mimidae) during song. About 80% of the song syllables studied were produced while air flowed through both sides of the syrinx. In some of these cases the bilateral pattern of airflow was similar, suggesting that both sides were making a similar contribution to the vocal output. In other cases flow was markedly different on the right vs the left side--indicating independent motor control with unequal or varying contributions from each side. About 10% of the syllables were produced only by the left and a similar proportion only by the right side of the syrinx, the contralateral side being closed as indicated by zero airflow despite a positive subsyringeal pressure. In these instances sound must be produced entirely by the side through which air is flowing. Repetition of the same syllable, as occurs in couplets, is accompanied by repetition of the same flow pattern. Although mimic thrushes such as the catbird (Dumetella carolinensis) show a greater song deficit after section of the left compared to the right tracheosyringeal nerve, data on airflow through the intact brown thrasher syrinx suggest a complex bilateral coordination in which both sides are more or less equal partners. (Supported by grant BNS 87-20192 from N.S.F.).

247.14

CHANGED DAYLENGTH CAUSES CHANGES IN DENDRITIC STRUCTURE IN A SONG-RELATED BRAIN REGION IN RED-WINGED BLACKBIRDS. K. M. Hill, D. E. Kroodsma* and T. J. DeVoogd, Depts. of Psych. and Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853

The production of birdsong is controlled by a well-demarcated system of brain nuclei including HVc, RA, nXII, MAN and Area X. Previous work has indicated that seasonal changes in singing behavior are associated with changes in the sizes of song control nuclei (Nottebohm, '81). This suggested that the capacity to modify song seasonally might be associated with adult plasticity in the neural substrate for song. In support of this hypothesis, seasonal changes in HVc and RA volume have also been observed in red-winged blackbirds (Kirn et. al, '89).

To better understand the basis for these seasonal changes in structure, microanatomical differences were quantified in RA. Male red-winged blackbirds were lab-reared and maintained under a normal circadian cycle until their second spring. Half were then sacrificed and half were placed on short days. After 4 weeks, these were also sacrificed and brain tissue from all the birds was stained using a Golgi-Cox procedure. RA volume was reduced by 26% in short-day birds ($p < .01$), replicating our earlier finding. Dendritic structure of four neurons from each animal were quantified using a computer microscope system. The density of dendritic spines was reduced by more than 20% in the short-day birds ($p < .05$). The summed length of dendritic branches was reduced by 22% ($p < .05$). Together, these results indicate a loss of at least 1/3 of the spine synapses on these neurons as a result of the altered environment.

247.15

***NUCLEUS OVOIDALIS* OF THE RING DOVE: NON-CLASSICAL PROJECTIONS AND ELECTROPHYSIOLOGICAL RESPONSES TO NEST COOS** S.E. Durand*, M.-F. Cheng, & J.M. Tepper, Institute of Animal Behavior and Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Studies of avian vocal communication have provided data conducive to an integrated analysis of neuronal function and behavior. Most of these studies have utilized species of vocal learners. However, the Ring Dove, *Streptopelia risoria*, provides an excellent model for analysis of neuronal discrimination of individually variable vocal patterns in a non-vocal learner. Individuals of both sexes discriminate each other on the basis of prior social interaction and it has been physiologically demonstrated that a female dove can acoustically discriminate her own nest coo vocalization from those of other females. In avian species, examination of the neural bases of discrimination of individually specific vocal features has been restricted to the telencephalon. The nucleus *Ovoidalis* (Ov) is a prime candidate for a diencephalic site contributing to vocal discrimination.

Single unit responses were recorded from Ov to multiple presentations of male and female nest coos and pure tones in urethane anesthetized doves of both sexes. Recording sites were marked by iontophoresis of Pontamine Sky Blue and verified in Nissl stained sections. A number of units in both male and female subjects have exhibited discriminatory responses that appear to correlate with the gender of the call presented; i.e., some units fired preferentially to either male or to female nest coos. The degree of response selectivity correlated with a neuron's response to pure tones ranging from 100 Hz to 1 kHz: the more highly selective units either showed no response to pure tones or exhibited a preferred frequency below the fundamental frequency of the nest coo vocalization (~500 Hz).

In conjunction with the electrophysiological studies, *Phaseolus vulgaris* leucoagglutinin was used to map the projections of Ov more precisely than has been possible with techniques used previously. Thus far, injections have been into ventral Ov, with possible spread of the tracer into immediately adjacent regions of the nucleus *Subrotundus*. Labelled fibers have been identified in the ventral hyperstriatum, parolfactory lobe and in the paleostriatum, in addition to the classic projection area, Field L. A descending projection from Ov into the region of the hypothalamus has also been tentatively identified. LIMB MOVEMENTS IN CHICK MOTOR BEHAVIORS: VARIABILITY AND CONSTRAINTS. A. Bekoff and R. M. Johnston, EPO Biology Dept., University of Colorado, Boulder, CO 80309

This study was designed to identify constraints on chick leg motor patterns to determine which features appear to be most tightly controlled. We have done this by examining variability in temporal and spatial features of both kinematic and electromyographic (EMG) records. In addition, we have compared three different locomotor behaviors to determine whether there are consistencies across behaviors.

Data were collected from 0- to 4-day old chicks during walking, swimming or airstepping. For kinematic analysis, chicks were videotaped and the hip, knee and ankle joints digitized. Cycle period, duration and latency of extension and flexion at each joint, minimum and maximum angles, joint excursions and phase of onset of flexion and extension at each joint were calculated from the digitized data. For EMG analysis, electrodes were implanted in hip, knee and ankle muscles. Records were digitized and cycle period, burst duration, latency, interburst interval and phase of burst onset were calculated for each muscle. Coefficients of variation were calculated for all variables.

Our analyses of the kinematic data indicate that temporal features (cycle period, duration, latency) are more variable than spatial features (angle, phase). Furthermore, these results are consistent across all three locomotor behaviors. Preliminary analyses of the EMG data indicate similar findings. These results indicate that aspects of form, or spatial features, are more tightly controlled than temporal aspects of the patterns.

FEMALE PREFERENCE FOR LOWER FREQUENCY MATING CALLS IN THE FROG PHYSALAEMUS PUSTULOSUS: SEXUAL SELECTION THROUGH DIFFERENTIAL SENSORY EXCITATION. **J. H. Fox, M. J. Ryan*, W. Wilczynski, and A. S. Rand*. Depts. of Psychology and Zoology, Univ. of Texas, Austin, TX 78712 and STRI, Panama.**

P. pustulosus has a mating call consisting of a whine, followed by 0-6 "chucks". Approximately 90% of the chuck energy falls within the sensitive range of the inner ear's basilar papilla (BP). Females prefer calls with lower frequency chucks. Our study examines the hypothesis that this preference results simply from greater BP excitation.

Audiograms were determined for 5 animals through multiunit recording in the torus semicircularis. Audiograms were averaged and truncated below 1.5 kHz to yield a filter function expressing average BP tuning (BF= 2.13 ± 0.07 kHz). Normal (mean dom freq=2.55 ± 0.06 kHz) and frequency-shifted FFTs from chucks of 54 males were integrated against the filter function to yield relative sensitivity. As hypothesized, sensitivity was maximized as FFT frequencies were lowered ($t=2.0$, $p<.025$) by 1.8 ± 0.9%.

Audiograms for P. coloradorum (N=7; BF=2.23 ± 0.13), which like most Physalaemus species does not produce a chuck, were compared to those of P. pustulosus. BP tuning does not differ significantly ($t=0.63$, $p>0.5$), suggesting that BP tuning characteristics preceded evolution of the chuck. We propose, therefore that males have evolved chucks so as to exploit pre-existing female sensory characteristics and that these characteristics furthermore select for lower frequency chucks. (Funded by NSF BNS 8606289)

TESTOSTERONE EFFECTS ON MOTOR BEHAVIOR AND DOPAMINE BINDING IN RANA PIPIENS. **W. Wilczynski, J. L. Knoll*, H. B. Anderson*, S. A. Castner*, and R. E. Wilcox. Depts. of Psychology and Pharmacology, Univ. of Texas, Austin, TX 78712.**

Sex steroids increase striatal dopamine D2 receptor binding in mammals, and in so doing influence motor behavior (Becker & Beer, Behav. Brain Res., 19:27-33, 1986). This has important implications for animals manifesting seasonal reproductive behavior coincident with increases in circulating sex steroids. We investigated testosterone's effects in such a seasonal breeder, the leopard frog. Adult males were anesthetized, gonadectomized, and implanted intraperitoneally either with 5 mg of testosterone propionate (T) in silastic capsules or with empty capsules. After 2-4 weeks, motor responsiveness was assessed by measuring the latency to postural recovery from a 10 min cold (3°C) challenge. T implanted frogs recovered much faster: mean latency was 99 sec (SD=11.3) vs. 231 sec (SD=36.8 sec) for the sham implanted frogs. Normal unoperated males recovered with a mean latency of 182 sec. After testing, frogs were anesthetized by cold narcosis and rapidly decapitated. Brains were removed rostral to the midtectum, homogenized, and assayed for D2 binding levels via standard techniques (Wilcox et al., Brain Res., 443:190-198, 1988) using 0.5 nM 3H-spiperone as the radioligand. Preliminary results suggest that T implants increased D2 binding by approximately 30% compared with gonadectomized sham-implanted controls. (We thank A. Hesslin and M. Bordelon for assistance. Supported by NSF grant BNS 8606289.)

CORRELATIONS BETWEEN ADVERTISEMENT CALL CHARACTERISTICS AND LARYNGEAL AND AUDITORY ANATOMY IN THREE POPULATIONS OF CRICKET FROGS (ACRIS CREPITANS). B.E. McClelland, W. Wilczynski and M.J. Ryan. Depts. of Psychology and Zoology, Univ. of Texas, Austin, TX 78712.

Previous studies indicate that the production and reception of species-typical vocalizations may have coevolved in cricket frog (Acris crepitans) populations, resulting in an acoustic match between sender and receiver which may promote local mate preference and speciation events (Sci. 240: 1786-1788). This study explores the relationships between some spectral and temporal advertisement call characteristics of individuals, and the size of the anatomical features responsible for the production and reception of vocalizations in allopatric populations from Sabine (SA), Conroe (CON) and Balmorhea (BA), Texas. Vocalizations from 30 individuals were analyzed, and serial sections of the head region enabled the snout-vent length, head width, tympanic membrane diameter, arytenoid cartilage, vocal cord, laryngeal muscle, middle ear, inner ear and the extra columellar cartilage volumes to be measured. The dominant frequencies of the three populations are significantly different from each other (Student's t-test, $p<.01$) and decrease from east to west (SA=4.03, CON=3.53, BA=2.78 kHz). Dominant frequency is negatively correlated ($p<.05$) with the laryngeal and ear anatomy which suggests that the vocal and auditory systems change in concert across the populations. Within populations, however, the relationships between morphology and dominant frequency are more complex. Although within populations some significant correlations exist between the size of laryngeal and auditory anatomy with both dominant frequency and some temporal characteristics of the final call, we observed no consistant trends. SEXUAL BEHAVIOR AND 2-DEOXYGLUCOSE UPTAKE IN MALE RED-SIDED GARTER SNAKES (THAMNOPHIS SIRTALIS PARIETALIS). **E. E. Allen and D. Crews, Inst. Reproductive Biol., Zoology Dept., Univ. of Texas, Austin, TX 78712.**

The anterior hypothalamus/preoptic area (AH/POA) plays a critical role in the expression of sexual behavior in all male vertebrates studied to date. While lesions of this area disrupt courtship behavior in male garter snakes, neural activity of this region during sexual activity has not been studied. Male garter snakes court females intensely and synchronously for the first month after emergence from hibernation. In this study males recently emerged from hibernation were injected subcutaneously with ^{14}C-labeled 2-deoxyglucose (2DG) and exposed to attractive females. Patterns of 2DG accumulation throughout the brain were examined in 7 males displaying vigorous sexual activity and in 6 males exhibiting no courtship behavior. Accumulation in the AH/POA, nucleus sphericus (NS), septum (SP), and optic tract (OTR) was measured. Shown below are percent increases (+/- S.E.M.) relative to the OTR and the significance levels (T-test) of the differences between courters and non-courters.

	AH/POA	NS	SP
Courters	83.3 (30.1)	74.6 (25.1)	57.6 (19.6)
Non-courters	35.5 (10.7)	55.3 (17.1)	49.8 (35.0)
P	.003	.09	.33

These studies illustrate the utility of the 2DG technique for elucidating the neural mediation of complex, species-typical behaviors in reptiles.

Supported by NIH 41770, Research Scientist Award 00135 to D. Crews, and NICHD training grant HDO7264.

PROSEIZURE-ANTISEIZURE ACTIVITY OF CALCIUM CHANNEL AGONIST ANTAGONISTS. M.A.Moron and T.L. Yaksh. Pharmacol. Dept., Mayo Clinic, Rochester, MN 55905.

The proseizure-antiseizure relationship of calcium channel agonist-antagonists was examined in a conscious rat seizure model in which the EEG was continuously monitored and drugs were administered intracerebroventricularly (icv) This agonist-antagonist relationship is thought to be mediated via interactions at sites that regulate neuronal calcium channels. The dihydropyridine calcium channel antagonist (CCA) analogue, BAY k 8644, has calcium channel agonist activity. This agent produces convulsive-like behavior after icv administration (Shelton et al., Brain Res. 402:399,1987), however EEG evidence that this behavior is seizure activity is lacking. The present studies demonstrate agonist EEG seizure activity and reversal by CCAs via 3 approaches, 1)effects of agonist on behavior/EEG and reversal by CCAs--BAY k 8644 produced convulsive behavior, but not EEG seizure activity; 2)the stereospecific ability to lower pentylenetetrazole (PTZ) seizure threshold-- (+) BAY k 8644 has the greatest agonist activity and ability to reduce PTZ seizure threshold; 3)stereospecific reversal of 2) by CCAs--readily demonstrated. The results of this investigation show that the proseizure-antiseizure activity of calcium channel agonist-antagonists is similar to interactions at sites that requlate calcium channels, suggesting a possible site of seizure regulation.

SIMILARITIES BETWEEN DEXTROMETHORPHAN (DM) AND SIGMA SITES IN GUINEA PIG, RAT AND MOUSE BRAIN. M. Klein*, J. J. Paturzo* and J. M. Musacchio. (SPON: R. U. Margolis). Dept. of Pharmac., N.Y.U. Med. Ctr, New York, NY, 10016.

DM, a non-narcotic antitussive binds to specific high-and low-affinity sites in the guinea pig and the rat brain. In the mouse, DM binds to two sites, differentiated only by competing drugs. In all three species, several sigma ligands bind to the DM high-affinity site. Their rank order of potency, as defined by the respective Ki values, is similar to that for sites labeled with [^{3}H](+)-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine ((+)-3-PPP). The (+)-isomers of benzomorphans display higher affinity than the (-)-isomers in all three species. [^{3}H](+)-3-PPP binds to high- and low-affinity sites in the guinea pig, but to one site only in the rat and the mouse with Kd values of 70 and 20 nM respectively. Moreover, in the guinea pig, DM- and (+)-3-PPP- high-affinity binding are both displaced by several drugs with identical affinities, and are both allosterically modified by the anticonvulsants ropizine and phenytoin (Musacchio, et al, Mol. Pharmac. 35:1, 1989). This suggests that σ ligands bind to a high affinity DM site. Computer-assisted analysis of cross-displacement studies confirm this hypothesis in all three species. This work was supported in part by USPHS grants NS-23926, DA-02013, MH-29591 and MH-17785.

248.3

AUTORADIOGRAPHIC VISUALIZATION OF THE DIFFERENTIAL EFFECTS OF ROPIZINE ON DEXTROMETHORPHAN (DM) BINDING IN THE GUINEA PIG BRAIN: ENHANCEMENT OF BINDING IN SOME STRUCTURES, AND DISPLACEMENT IN OTHERS. P. Canoll* and J. M. Musacchio. Pharmacol. Dept., N.Y.U. Med. Ctr., New York, NY, 10016.

DM, an antitussive with anticonvulsant activity, binds to high and low affinity sites in guinea pig brain. Autoradiographic studies demonstrated that [^{3}H]DM binds to discrete structures throughout the brain with a distribution strikingly similarity to that of sigma ligand (+)-3-(-3-hydroxyphenyl)-n-(1-propyl)piperidine ((+)-3-PPP) (Gundlach et al, J. Neurosci., 6:1757, 1986). Ropizine, an experimental anticonvulsant, allosterically enhances both (+)-3-PPP and DM binding to brain homogenate. This effect is biphasic, with an inhibitory component at higher concentrations (Musacchio et al, Mol. Pharm., 35:1, 1989). Ropizine, 10 μM, specifically enhances the [^{3}H]DM binding to the cranial motor nerve nuclei, Purkinje cell layer, granular cell layer of the dentate gyrus, pyramidal cell layer of the hippocampus, presubiculum, and other structures, but selectively displaces binding from the dorsal raphe nucleus, dorsal tegmental nucleus, substantia nigra, inferior colliculus, and other structures. These findings demonstrate that ropizine can be used to differentiate the DM sites into distinct subsites with different anatomical distributions. This work was supported in part by USPHS grants NS-23926, DA-02013, MH-29591 and MH-17785.

ANTICONVULSANT ACTIONS OF MK-801 ON THE LITHIUM-PILOCARPINE MODEL OF STATUS EPILEPTICUS IN RATS. G.C. Ormandy*, R.S. Jope and O.C. Snead. (Spon: J. Monti), Depts. of Pharmacology and Pediatrics and Neuropsychiatry Research Program, Univ. of Alabama, Birmingham, AL 35294.

MK-801, a non-competitive NMDA receptor antagonist, was tested for anticonvulsant effects in rats using two seizure models, coadministration of lithium and pilocarpine and administration of a high dose of pilocarpine. Three major results are reported. First, pretreatment with MK-801 produced a dose-dependent anticonvulsant action with the lithium-pilocarpine model but not with rats treated with pilocarpine alone suggesting that different biochemical mechanisms control seizures in these 2 models. Second, the anticonvulsant effect of MK-801 in the lithium-pilocarpine model only occurred after initial periods of seizure activity. This demonstrates in vivo that MK-801 binding requires agonist-induced opening of the NMDA receptor channel. Third, administration of MK-801 30 or 60 min after pilocarpine i.e. during status epilepticus, gradually reduced electrical and behavioral seizure activity and greatly enhanced the survival rate. These results indicate that NMDA receptor activation plays an important role in status epilepticus and brain damage in the lithium-pilocarpine model. This was further supported by results showing that non-convulsive doses of NMDA and pilocarpine were synergistic resulting in status epilepticus and subsequent mortality. Supported by USPHS grants MH-38752 and NS-26165.

PRENATAL EXPOSURE TO VALPROIC ACID REDUCES CONVULSIVE BEHAVIOR IN ADULT RATS CHALLENGED WITH PENTYLENETETRAZOL. W.J. Pizzi, L. Morris* and R. Jersey*. Department of Psychology, Northeastern Illinois Univ., Chicago, IL 60625.

The literature on antiepileptic drugs has suggested that prenatal exposure to these agents may alter seizure behavior in adult animals. In this study, we examined the effects of prenatal exposure to valproic acid (VPA) on the seizure profile in adult rats challenged with a 50 mg/kg i.p. dose of pentylenetetrazol (PTZ). Pregnant rats were dosed orally from gestational days 9-18, and allowed to proceed to term. Prenatally-exposed animals were challenged with PTZ as adults (minimal age was postnatal day 90). Convulsive behavior was quantified using a 7-point rating scale, with a score assigned every 30 seconds over a 7-minute test period. All VPA-exposed animals in both the original experiment and a replication showed a protection effect which manifested itself as fewer periods of seizure activity over the test period. The PTZ invariably caused a maximal convulsion in both VPA and control animals; however, the VPA-exposed animals appeared to be more efficient than controls in terminating the convulsive episodes.

248.6

ETHOSUXIMIDE AND VALPROIC ACID INHIBIT ACETYLCHOLINE-INDUCED EXCITATION OF SPINAL CORD NEURONS IN CELL CULTURE. A.W. Wamil*and M.J. McLean. Department of Neurology, Vanderbilt Univ. Med. Ctr., Nashville, TN 37212.

Ethosuximide (ES) and valproic acid (VPA) are useful in the treatment of generalized absence seizures. Using conventional intracellular recording techniques, we observed effects of ES and VPA on responses of spinal cord neurons in monolayer cell culture to acetylcholine (ACh, 10^{-6} to 10^{-4}M) and N-methyl-D-aspartate (NMDA, 10^{-5} to 10^{-3}M). Neurons were superfused with phosphate buffer containing 7-10 mM Mg^{++} to suppress spontaneous activity. Brief applications of ACh or NMDA by pressure ejection from a patch clamp pipette near the impaled neuron produced depolarization and firing of action potentials for up to 30 sec. Co-application of either ES (10^{-4} to 10^{-3}M) or VPA (6-120 uM) reduced or abolished responses to ACh reversibly. Phenytoin (PT, 10 uM) did not affect the responses to ACh. Responses to NMDA were not blocked by ES, VPA or PT. High frequency firing of action potentials elicited by 400 msec depolarizing current pulses applied through the recording electrode was limited to a few spikes at the onset of the current pulse by VPA and PT, but not ES. The ability to block postsynaptic responses to ACh, but not the excitatory amino acid neurotransmitter analog, NMDA, may contribute to the anticonvulsant efficacy of ES and VPA. CARBAMAZEPINE BLOCKS NEITHER EPILEPTOGENESIS NOR LONG-TERM POTENTIATION INDUCED IN RAT HIPPOCAMPAL SLICES. S. Clark, A.C. Bragdon and W.A. Wilson, Depts. of Pharmacology and Medicine (Neurology), Duke Univ. and V.A. Medical Centers, Durham, N. C. 27710.

We have investigated the effect of carbamazepine (CBZ) on two models of neural plasticity: (1) stimulus-induced electrographic seizures (EGSs) and (2) long-term potentiation (LTP).

EGSs are induced by a series of kindling-like stimulus trains delivered every 10 minutes to the Schaffer collateral pathway. The first few trains evoke few afterdischarges. Later trains evoke longer, biphasic activity, culminating in EGSs with a tonic-like phase followed by a clonic-like phase. We have previously reported that CBZ (≥4ug/ml) can either suppress the tonic phase of EGSs or inhibit them entirely. This action of CBZ is consistent with its anticonvulsant potential. In contrast, we now report that similar CBZ concentrations do not appear to prevent the induction of the EGSs. In some slices CBZ did mask the expression of the EGSs during induction, but after the drug was washed off, fully induced ESGs could be evoked. This implies that CBZ does not have antiepileptogenic action.

LTP was induced by a standard protocol. We found that CBZ does not prevent the induction of LTP.

Therefore, CBZ does not appear to inhibit the process of induction in either model of neural plasticity.

ANTICONVULSANT EFFECTIVENESS OF CARBAMAZEPINE IN THE COBALT-EPILEPTIC RAT. Charles R. Craig and Brenda K. Colasanti. Dept. of Pharmacol./Toxicol., WVU Health Sciences Center, Morgantown, WV 26506

Adult female Sprague-Dawley rats rendered epileptic by bilateral cerebral implantation of cobalt wire were simultaneously prepared with permanent cortical and temporalis muscle electrodes for continuous recording of EEG and EMG activities. Carbamazepine (50 or 100 mg/kg) in 10% PEG was administered intraperitoneally twice daily for 4 days commencing 8 days after cobalt placement. Cobalt-epileptic rats either not treated or administered the highest volume of vehicle and normal rats administered the highest dose of carbamazepine served as controls. Results indicated that rats receiving carbamazepine, 100 mg/kg, exhibited a reduced frequency of seizures over the 4 day period of drug administration. Although rats receiving carbamazepine, 50 mg/kg did not show a reduction in seizures over any 24 hr period, a definite reduction in seizure frequency was observed during the six-hour period following drug administration during the first two days of drug administration. (Supported by NIH NINDS Grant # NS 20226).

PHENOBARBITAL REDUCES POST-SYNAPTIC POTENTIALS AND CALCIUM CURRENTS IN RAT NEOCORTICAL NEURONS. I. Spigelman and P. L. Carlen. Playfair Neuroscience Unit, Toronto Western Hospital, Toronto, Ontario, Canada.

The actions of phenobarbital were examined using current- and voltage-clamp recording techniques on neurons in layers II & III of rat (Wistar) neocortex. In current-clamp recordings using electrodes filled with 3 M $KMeSO_4$, evoked exitatory postsynaptic potentials (EPSPs) were observed at resting membrane potentials, whereas depolarizing current injections (DC) were required to observe inhibitory postsynaptic potentials (IPSPs). Phenobarbital perfusion, at a clinically relevant concentration (100 μM), reversibly reduced the size of EPSPs (n=6) and IPSPs (n=4), measured at 35°C.

In single electrode voltage-clamp mode, calcium currents were recorded with 3 M CsCl-filled electrodes in the presence of Na^+- and K^+-channel blockers. Phenobarbital application (100 μM) consistently and reversibly reduced the amplitude of the calcium currents measured at 30°C (n=8). In addition, phenobarbital application in these neurons increased an outward current evoked by the largest depolarizing voltage commands.

These findings indicate that the reduction of calcium currents by phenobarbital may be an important component of its anticonvulsant activity in the mammalian central nervous system.

CGS 18416A: A SOLUBLE,POTENT AND NOVEL ANTICONVULSANT. P.Bernard*, R.Bowman*, M.Williams, J.Lehmann, J.Liebman and R.Robson*. Res. Dept., Pharm. Div., CIBA-GEIGY Corp., Summit, NJ 07901.

A structurally novel imidazolyl alkyl benzisoxazole, CGS 18416A, was found to have potent anticonvulsant activity. This compound prevented maximal electroshock-induced seizures in rats (ED50,8.3 mg/kg po and 2.4 mg/kg i.v.) and in mice (ED50, 17.3 mg/kg po), indicating potential efficacy against grand mal seizures. Its antagonism (ED50 = 9.8 mg/kg p.o.) of clonic seizures induced by PTZ (24 mg/kg i.v.) suggests that concurrent efficacy against absence seizures may also be present. No impairment of motor function was evident at oral doses as high as 200 mg/kg in rats or 100 mg/kg in mice, indicating relatively low neurological involvement at projected anticonvulsant doses. CGS 18416A did not bind to brain benzodiazepine receptors, indicating that this is not its mechanism of action. Aconitine-induced inhibition of [3H]L-glutamate uptake was blocked by CGS 18416A, a property shared by phenytoin and indicative of interaction with sodium channels. In marked contrast to available anticonvulsant drugs, CGS 18416A is highly water-soluble, an advantage in preparing parenteral formulations for emergency intervention in status epilepticus. The high oral efficacy, low neurological involvement, possible efficacy against absence as well as grand mal seizures and high water solubility may confer significant therapeutic advantages on CGS 18416A.

248.11

KINETIC ANALYSIS OF THE ANTIEPILEPTIFORM EFFECTS OF L-BACLOFEN DURING K⁺-INDUCED INTERICTAL DISCHARGES IN RAT HIPPOCAMPUS. F.J. Lebeda, T.H. Ton' & P.A. Rutecki. Sect. Neurophysiol., Dept. Neurol., Baylor Col. Med., Houston, TX 77030.

L-baclofen was equipotent (IC_{50} *ca.* 150 nM) in abolishing spontaneously occurring interictal discharges in the CA3 subfield that were induced *in vitro* by bethanechol, picrotoxin or soman. This effect was independent of the initial discharge frequency (f_0). In contrast, baclofen was less potent (IC_{50} values up to 1979 nM) in abolishing the discharges induced by high $[K^+]_o$. We tested the hypothesis that baclofen's potency was dependent on both $[K^+]_o$ and the f_o of these K^+-induced events. Using data from slices exposed to 7.5-10 mM K^+ and discharging at an f_o between 0.3-0.6 Hz, the [baclofen]*vs.*%(f_o) curves (plotted at a given $[K^+]_o$) were shifted in parallel to the right as $[K^+]_o$ increased. Similarly, in 10 mM K^+, the [baclofen]*vs.*%(f_o) plots were shifted in parallel to the right as f_o increased from 0.6 to 1.2 Hz. Results from Schild and Dixon analyses suggested that the changes in baclofen's potency were consistent with a coupled reaction scheme - an *apparent* non-competitive reaction between baclofen and K^+, and an *apparent* competitive reaction between baclofen and an endogenous factor that promoted discharge generation.

248.12

ATTENUATION OF EPILEPTOGENESIS BY NONSTERIODAL ANTIINFLAMMATORY DRUGS IN RAT. M.C. Wallenstein Dept. Physiology, New York Univ., NY NY 10010

Subconvulsive doses (25 mg/kg) of pentylenetetrazol (PTZ) were administered at 4 day intervals for 20 sessions to induce kindling in conscious, free-moving rats with chronically implanted electrodes. In initial sessions, PTZ produced periods of motor arrest concurrent with bursts of spike-wave activity. Over subsequent sessions, this increased to clonic convulsions concurrent with spike activity.

Pretreatment with paracetamol (150 mg/kg) or mefenamic acid (20 mg/kg), over 20 sessions, reduced both amount of myoclonus and appearance of convulsions. The initial effects, i.e. motor arrest and spike-wave activity, were not affected by either of these pretreatments. Ibuprofen (30 mg/kg) had no significant effect on any level of the induced excitation.

The results suggest a differential activity for nonsteriodal antiinflammatory drugs in attenuating progression to convulsions. Possible explanations include tissue specificity and drug-specific actions not related to cyclooxygenase inhibition.

248.13

INFLUENCE OF NORADRENERGIC MECHANISMS ON THE ANTICONVULSANT EFFECTS OF FELBAMATE AND PHENYTOIN. R. Gordon*, W. Diamantis* and R.D. Sofia* (SPON: J.L. Perhach) Wallace Laboratories, Div. of Carter-Wallace, Inc., Cranbury, NJ 08512.

A growing body of evidence suggests that catecholamines, especially norepinephrine (NE), exert an inhibitory influence on seizure development. The purpose of this study was to determine the influence of noradrenergic mechanisms on the anticonvulsant activities of felbamate (F) and phenytoin (PH) against maximal electroshock seizures (MES) in mice. Phenoxybenzamine (30 mg/kg i.p.) and prazosin (0.15 mg/kg i.p.) significantly reduced the anticonvulsant effects of orally administered F and PH, whereas yohimbine (10 mg/kg i.p.) did not appear to influence the protective effects of F and PH. The tyrosine hydroxylase inhibitor, α-methyl-p-tyrosine (250 and 100 mg/kg i.p.) antagonized the effects of F and PH against MES. Desipramine (15 mg/kg i.p.) significantly increased the anticonvulsant activity of F but not of PH.

These results indicate that the antagonism of α_1-adrenergic receptors reduces the anticonvulsant effects of F and PH against MES, whereas blocking α_1-adrenoceptors suggests an opposite effect. Inhibiting NE synthesis also appears to reduce the anticonvulsant effects of F and PH. Finally, increasing NE availability enhances the anticonvulsant activity of F but not of PH.

248.14

ANTICONVULSIVE PROPERTIES OF TETRONIC ACID DERIVATIVES IN RAT HIPPOCAMPAL AREA CA1 AND CA3 IN VITRO.
G. Köhr* and U. Heinemann* (SPON: European Neuroscience Association) Institute for Neurophysiology, University of Cologne, Robert-Koch-Straße 39, D-5000 Köln 41, FRG

In the hippocampal slice preparation the two tetronic acid derivatives AO33 and AO78 blocked epileptiform activity which was induced by picrotoxin (PTX) or by perfusion with Mg^{2+}-free and Ca^{2+}-free medium, respectively. The slow negative field potentials and $[Ca^{2+}]_o$-decreases in PTX and in low Mg^{2+} during repetitive stimulation of either the Schaffer collateral/commissural fibers or the alveus were reduced in a dose-dependent manner. The drugs were applied in concentrations between 10 and 100 µM.

Intracellular studies showed that the resting membrane potential of CA1 cells didn't change by more than 3 mV (n=18), the input resistance was slightly decreased, but the slope conductance was reversibly reduced by AO33, especially when the membrane potential was deplarized by current injection. The threshold to evoke action potentials in CA1/CA3- and bursts in CA3-neurons seemed to be little increased. The amplitude and duration of the action potentials were unchanged. Afterhyperpolarizations which followed depolarizing current pulses were diminished by AO33. In all experiments AO33 increased the accomodation of pyramidal cell discharges. Because of missing effects on the low- and high-threshold Ca^{2+} currents, we suggest that AO33 and AO78 act as K^+ channel agonists.

EFFECTS OF ANTICONVULSANTS ON PENTYLENETETRAZOL INDUCED NEURONAL ACTIVITY OF GIANT AFRICAN SNAIL *ACHATINA FULICA* FERUSSAC. M.C.Tsai, M.L.Chen* Pharmacological Institute, College of Medicine, National Taiwan University, Taipei, Taiwan, R.O.C.

Effects of phenobarbital, succinimide and valproic acid on pentylenetetrazol (PTZ) induced neuronal activity were studied electrophysiologically on the central neuron of giant African snail *Achatina fulica* Ferussac. The neuron tested was located in the upper part of right parietal ganglion. The neuron showed a tendency of spontaneous firing of action potential. The frequency of action potential was increased if glutamic acid was added.After PTZ perfusion, the neuron produced a phasic depolarization followed by a sustained depolarization with a characteristic bursting firing pattern of action potential. The response strongly resembled the PTZ induced changes in the mammalian cerebral cortical neuron. The bursting firing pattern induced by PTZ was not affected by *d*-tubocurarine, tetrodotoxin or atropine. However, the frequency of the burst firing of neuronal action potential was decreased after phenobarbital or succinimide (2,5-pyrrolidinedione) or valproic acid administration. PTZ was a useful laboratory tool for screening anticonvulsants. Our results suggest that the decreasing of the frequency of bursting firing action potential may be associated with anticonvulsant activity.

STUDIES OF POTENTIAL ANTICONVULSANTS IN SOMAN POISONING. T.-M. Shih, T. Koviak* and B. Capacio*. U. S. Army Med. Res. Inst. Chem. Def., Aberdeen Proving Ground, Md 21010.

The acute toxic effects of the organophosphorus cholinesterase inhibitor soman include tremors, convulsions and death. The purpose of this study was to evaluate various classes of compounds for their efficacy in preventing soman-induced convulsions. They include benzodiazepines (diazepam, midazolam, clonazepam, loprazolam, alprazolam), the NMDA blocker MK-801, barbiturates (phenobarbital, pentobarbital), calcium channel blockers (flunarizine, nifedipine), anticholinergics (aprophen, atropine sulfate and methyl nitrate, azaprophen, benactyzine, benztropine, biperiden, scopolamine hydrobromide and methyl nitrate, trihexyphenidyl) and others (phenytoin, cabamazepine, valproate, caramiphen, Organon 6370 and Norwich F-721). Male rats were injected with the oxime HI-6 (125 mg/kg, ip), to increase survival time, along with various doses of these compounds (im) with or without atropine sulfate (ATS; 16 mg/kg, im) 30 minutes prior to a soman challenge dose (1.6 LD50; 180 ug/kg, sc) that produced 100% convulsions. Without ATS, only tertiary anticholinergics, MK-801 and caramiphen were effective anticonvulsants. In the presence of ATS, benzodiazepines became effective; e.g., the anticonvulsant ED50s for diazepam and midazolam were 136 and 192 ug/kg respectively. These findings indicate that certain classes of compounds are potent anticonvulsants in soman poisoning either alone or in the the presence of ATS.

VISUAL PSYCHOPHYSICS AND BEHAVIOR II

249.1

SELECTIVE ATTENTION MODULATES VISUAL PROCESSING OF FORM, COLOR AND VELOCITY: I. PSYCHOPHYSICAL OBSERVATIONS. F.M.Miezin*, M.Corbetta*,G.M.Shulman*,&S.E.Petersen. (SPON: T.O.Videen). Dept. Neurology & Neurol.Surg., McDonnell Center for Higher Brain Function, and Mallinckrodt Inst. of Radiology. Wash. Univ. Sch. of Med., St. Louis, MO. 63110.

Psychophysical data were collected during a match-to-sample task in which subjects (n=11) fixated on a small stationary spot in the center of an array of coherently moving rectangles. The rectangles all had the same shape and color and were randomly distributed against a dark background. Three of the stimulus attributes were varied during the experiment: shape, velocity & color. The moving array was displayed for 400 ms. followed by a blank black screen for 200 ms. The array reappeared for a second 400 ms. interval with 1, 2, 3 or none of the stimulus attributes changed. During the 1.5 sec. intertrial interval, the subject indicated whether the two presentations were the same or different. Stimuli were presented in blocks during which the subject was instructed to either attend to one of the attributes and report changes in it, or to attend to all three attributes and report changes in any of them. The subject's sensitivity, d', was determined for each attention condition. In each subject, before formal testing started the slight supra-threshold discriminative changes to be used for each dimension were assessed such that the subject's average performance was about 1.6 d' units (80% correct responses, 20% false alarms).

Subjects were significantly more sensitive to stimulus changes when they attended to only one attribute compared to when they simultaneously attended to all attributes (mean d' change = .9, $p < .001$). Sensitivity to velocity change was reduced when shape simultaneously changed (d' change = .6, $p < .056$) but not for color changes. Color discrimination however was not affected by variations in shape or velocity. These data suggest that selective attention modulates the visual processing of the simple visual attributes of form, color and velocity and that there is crosstalk or interference between the processing of at least 2 of the attributes.

249.2

SELECTIVE ATTENTION MODULATES VISUAL PROCESSING OF FORM, COLOR, AND VELOCITY: II. VISUAL AREAS. M.Corbetta*, F.M.Miezin*, S.M.Dobmeyer*, and S.E.Petersen. (SPON: M.I.Posner) Dept. Neurology and Neurol.Surgery, McDonnell Center for Higher Brain Function, and Mallinckrodt Inst. of Radiology. Washington University School of Medicine, St.Louis, MO 63110.

PET subtraction images of blood flow (BF) change were utilized to study normal subjects performing a match-to-sample task in which they had to attend and discriminate along one visual dimension (i.e. hue) while ignoring variations along other dimensions (i.e. shape or velocity)(Abstr. I). Two conditions were used as subtraction scans: passive presentation of test stimuli, and a divided-attention task where subjects were instructed to detect any occurring change.

Across all active conditions, BF increased in areas 17 and 18 in comparison to the passive stimulation. Area 17 (but not area 18) activation disappeared when the divided-attention scan is subtracted away, arguing for a nonspecific, arousal effect. Several extrastriate areas were modulated by attention and some of them were found only in one condition. Regions of enhanced activity along the superior temporal sulcus and area 39 were active only when attending changes in velocity. Such regions overlapped location of previously described areas related to motion detection and smooth-pursuit visual tracking. Bilaterally, the lingual and the fusiform gyri (ventro-medial area 19 and 37) and area 21 in the temporal lobe were enhanced for shape discrimination, but not for velocity discrimination. Area 21 activation was stronger on the right side, and was also present when using stationary flashing bars. Some lingual gyrus foci were also found for color-discrimination and a left lateral region in area 19 was observed only during color discrimination. There was no overlap between color- and velocity- enhanced regions.

These findings support early selective modulation in extrastriate areas during visual processing in humans.

249.3

SELECTIVE ATTENTION MODULATES VISUAL PROCESSING OF FORM, COLOR AND VELOCITY: III. AREAS RELATED TO HIGHER-ORDER SELECTIVE PROCESSES. S.E.Petersen, M.Corbetta*, F.M.Miezin*, and S.M. Dobmeyer*. Dept. Neur. and Neur. Surg., McDonnell Center for Higher Brain Function, and Mallinckrodt Inst. of Rad.. Wash. Univ. Med. Sch., St. Louis, MO.

As shown in the preceding abstracts, subjects in a divided-attention match-to-sample task are less capable of seeing a change in color, shape, or velocity than when they are attending to changes in one of these attributes. These selective changes in processing are reflected in enhanced activation of specific extrastriate areas in PET blood flow change images, e.g., different extrastriate areas are activated when attending to color change than when attending to velocity change. This enhanced activation is an effect of top-down, or higher-order, selective processes.

Two questions relating to the higher-order processes are: 1) Are there areas that are directing the early selective enhancement in the extrastriate visual areas? Candidates for such areas would be active in all three selective conditions when compared to the divided-attention condition. Several areas meet these criteria: right posterior thalamus/colliculus, right anterior thalamus/caudate nucleus, and left putamen/globus pallidus. In all cases, the activations are localized near the boundaries of two structures making a clear anatomical assignment ambiguous.

2) Are there areas that are part of a late-selection system active when an early-selective strategy along single stimulus dimensions is not useful? Such areas would be active only in the divided-attention condition, not in any of the selective-attention conditions. An anterior cingulate region fulfills these criteria, and has been active in other studies from this laboratory that demand late-selection strategies, such as verb-generation and semantic-monitoring tasks. This region appears to be a node in a general late-selection system crossing both lexical and visual tasks.

The results from this and the preceding abstracts outline brain regions that take part in both early and late selective attention processes.

TRANSPARENCY AND COHERENCE IN HUMAN MOTION PERCEPTION. G.R. Stoner*, T.D. Albright and V.S. Ramachandran* (SPON: F.H.C. Crick). Salk Institute and University of California at San Diego, La Jolla, CA 92093.

A central problem faced by motion detectors is that of integrating local motion signals. A number of criteria (e.g. relative spatial frequency, contrast, depth, speed, direction) may be used to determine whether multiple signals arise from the same moving object and should thus be combined. We have now explored the role of perceptual transparency in the integration of motion signals using the "coherence" paradigm. Subjects were required to judge whether two superimposed drifting gratings cohere, appearing as a uniformly moving plaid. We predicted that if one grating were perceived as transparent, motion signals would not be combined and we would observe a decline in coherence. We manipulated transparency by varying the relative intensities of two gratings with respect to their intersections. The "rules" of transparency dictate that optimal conditions will be achieved when the relative intensities of these different figural regions are set appropriately. Stimuli were presented at center of gaze through an 11° aperture. Grating orientation differed by 135° and both were drifted at 3°/s. Probability of coherence was greatly reduced when one grating appeared transparent. Thus the motion system has tacit knowledge of the rules of transparency, which it uses to decide whether motion signals arise from the same object. This insures that movement of transparent objects (or shadows) will not be confused with movement of objects over which they move.

249.5

OCCLUSION AND TRANSPARENCY IN MOTION PERCEPTION. V. S. Ramachandran* and D. Rogers-Ramachandran* (SPON: P. S. Churchland). Psychology Department, University of California, San Diego, La Jolla, CA 92093.

A large square-wave grating oriented 45° was moved obliquely (at right angles to its orientation) and viewed simultaneously through two narrow rectangular apertures, a vertical one and a horizontal one, cut out of an opaque circular window. Instead of seeing two independent "barber poles" (as in Wallach's experiment) subjects usually saw two holes through which they perceived a single rigidly moving grating.

Next, we cut out a single horizontal window from a transparent occluder that was superimposed on the grating. Instead of seeing horizontal motion within the window subjects always saw oblique motion. On the other hand, if the luminance contrast of different portions of the grating was adjusted so as to destroy transparency, horizontal motion was seen.

Lastly, two moving gratings of different orientations were superimposed so that they appeared to cohere and move in a single direction ("pattern motion"; Adelson & Movshon) instead of moving independently ("component motion"). We used two square wave gratings and found that if the luminance of the intersections between the two gratings was chosen appropriately the grating looked transparent and moved independently whereas if the luminance was inappropriate "pattern motion" was seen (Stoner, Albright & Ramachandran, in press).

We conclude that the solution to the aperture problem is powerfully constrained by occlusion and transparency.

249.6

MIXING DIMENSIONS IN CORTICAL VISUAL MOTION PROCESSING

Sima Shechter* and Shaul Hochstein
(SPON: H. Parnas)
Neurobiology Dept., Life Sciences Institute
Hebrew University, Jerusalem, ISRAEL.

Apparent motion is perceived when two slightly different picture frames are viewed in succession. The correspondence problem of relating the various elements in the two frames to each other is solved by the visual system with the aid of information deriving from numerous visual dimensions. Using a competitive paradigm we find that the dimensions available to the long range apparent motion system include element proximity, shape, size, luminous flux (but not luminance), and contrast polarity. Thus, information seems to be integrated in the motion processing visual areas from the form and contrast pathways, the ON and OFF pathways, and from center-surround antagonistic units. These findings restrict the classes of models of cortical parallel and hierarchical visual processing.

249.7

MOTION FIELD DETECTORS AND MOTION SEARCH-LIGHT

Jun Zhang and Siye Wu*. Neurobiology Group, University of California, Berkeley, CA 94720 and Department of Mathematics, MIT , Cambridge, MA 02139

We propose a theory of human motion perception. In this scheme, two stages of processing are involved: 1) a motion detection stage whereby motion detectors locally compute the temporal derivative of the spatial gradient of the image brightness function. 2) a motion integration stage whereby individual motion detector's responses are summed up over an area, determined by a hypothetical "motion search-light", to yield the perceived "velocity".

The local motion signal (a 2-D vector) computed by the detector is: 1) complete in that any physically extractable velocity information is preserved; 2) unique in that they are contravariant and hence independent of the particular choice of basis detector pair; 3) invariant under the addition of a background brightness pattern.

The motion search-light, reminiscent of the work by Treisman & Gelade (1980) and Crick (1984), determines the area of integration on the local motion signals. It is proved that 1) during this integration, the nearby responses cancel out so that the effective contribution is from the boundary; 2) the perceived velocity thus obtained is the correct one, so long as the search-light encompasses the entire object undergoing 2-D translational motion.

249.8

"TEMPORAL CAPTURE" AND THE ROLE OF TRANSIENCY IN VELOCITY DISCRIMINATION. S. Treue, R. J. Snowden* & R. A. Andersen. Dept. of Brain & Cog. Sci., M.I.T., Cambridge, MA 02139

Recent models of velocity perception use information about transiency in a moving stimulus. They postulate that increasing activity in a "transient" channel relative to a "sustained" channel increases perceived velocity.

This study investigated the influence of transiency on velocity perception. The stimuli consisted of dynamic random dot patterns moving at a constant velocity. Each point lasted for a preset number of frames (its lifetime) before it was randomly replotted. Decreasing the point lifetime therefore increases the transiency of the display by increasing the number of points turning on and off at any given time. Subjects were presented with two patterns (duration 400 ms) appearing left and right of a central fixation spot and were asked to indicate the faster pattern. Typically one pattern ("reference") was compared against other patterns ("comparators") moving at different speeds centered around the reference speed. These comparators were of the same dot density but in most cases the transiency was different from the reference.

The amount of transiency was varied in two ways: **I)** by changing the point lifetime and **II)** by introducing **stationary** points of very short lifetime.

The two major results were: **I)** Using lifetimes of 100 ms and longer subjects tended to perceive the patterns with **shorter** lifetimes as moving **faster**. For lifetimes lower than about 100 ms the effect reversed. At these short point lifetimes it became difficult to perceive the motion of the pattern at all. **II)** The patterns also appeared **faster** if the **moving** points of both patterns were of the same lifetime but one pattern contained a few **stationary** points of very short lifetime.

In summary our results offer support for the models mentioned above although these models cannot account for the reversal of the effect when using very short lifetimes. Interestingly the high temporal frequency of the stationary flashed dots appears to be captured by the moving dots and used in the velocity estimate, thus increasing the perceived velocity. We therefore term this effect "temporal capture".

249.9

NEURAL DYNAMICS OF VISUAL MOTION PERCEPTION: GROUP AND ELEMENT APPARENT MOTION. S. Grossberg and M. Rudd*. Center for Adaptive Systems, Boston Univ., Boston, MA 02215.

This work further develops a neural network model of motion segmentation by visual cortex that was outlined in Grossberg (1987). We illustrate model properties by simulating data concerning group and element apparent motion (Breitmeyer & Ritter, 1986; Petersik & Pantle, 1979; Ternus, 1938), including the tendency for group motion to occur at longer ISIs and under conditions of short visual persistence. These phenomena challenge recent vision models because the switch between group and element motion is determined by changing temporal but not spatial display properties. The model clarifies the dependence of short-range and long-range motion on spatial scale. Its design specifies how oriented (x cell) and unoriented (y cell) detectors cooperate and compete in successive processing stages to generate motion signals that are independent of direction-of-contrast. Ternus (1938) displays and Burt & Sperling (1981) displays generate appropriate motion signals in the circuit. The model clarifies motion after-effects and how preprocessing of motion signals is joined to long-range cooperative mechanisms to control phenomena such as induced motion and motion capture. The total model system is a motion Boundary Contour System (BCS) that is computed in parallel with the BCS of Grossberg & Mingolla (1985).

249.10

A PHYSIOLOGICAL MODEL OF BINOCULAR RIVALRY. T. J. Mueller. Dept. of Biology, *Harvey Mudd College*, Claremont CA 91711.

I present a modified reciprocal inhibition model for the temporal dynamics of binocular rivalry. The model is based on neurophysiological mechanisms and is derived from human psychophysical data. The reciprocal inhibition oscillator has long been proposed as a mechanism for binocular rivalry, but its detractors have correctly pointed out that simple reciprocal inhibition does not account for some aspects of the temporal behavior of binocular rivalry. These include the effects of contrast change on alternation rate and on the magnitudes of changes in duration of the suppressed and dominant phases.

Matsouka (1984) described a simple reciprocal inhibition oscillator with a set of four coupled differential equations having a neurophysiological interpretation. I modify those equations and their simulation to reflect three new parameters: 1) presynaptic inhibition of the reciprocal inhibition by the input, 2) the motor delays that occur when a human observer tracks rivalry and 3) a minimum threshold for each neuron's state variable. The result is a very defendable fit to psychophysically obtained data on the temporal behavior of binocular rivalry.

Finally, the model is incorporated into a larger model to suggest how rivalry can occur in a network that usually exhibits binocular fusion.

249.11

PERIPHERAL FIELD STIMULATION AFFECTS FLICKER, BUT NOT COLOR, SENSITIVITY. Z. He* and M.S. Loop. Physiological Optics, Sch. of Opt., Univ. Alabama at B'ham., Birmingham, AL 35294.

Magnocellular neurons have better temporal resolution while parvocellular neurons have better wavelength selectivity which has suggested to some that color-opponent parvocellular neurons carry the information for color vision while broadband magnocellular neurons carry the information for high frequency flicker discrimination. We have examined the effect of peripheral field stimulation upon our thresholds for color and flicker perception. Spectral increments, flickering at 25Hz, were added to a steady white background and thresholds determined for detection of stimulus color and flicker. Surrounding, but not overlapping, the background and stimulus was a peripheral field which appeared steady (70Hz) or flickering (10Hz). Surround flicker did not affect color thresholds. Surround flicker reduced flicker sensitivity when viewing was binocular or monocular but not when the flickering surround was viewed by the left eye and the background plus stimulus was viewed by the right eye. Thus neurons which carry the information for color perception are unaffected by peripheral field stimulation while neurons which carry the information for the perception of rapid flicker are affected. The effect is likely retinal in origin. Interestingly, in macaque lateral geniculate nucleus magnocellular neurons, but not parvocellular neurons, show a strong peripheral (McIlwain) effect.

249.12

TEMPORAL VISUAL FILTERS IN THE HUMAN PERIPHERAL FIELD R.J. Snowden* and R.F. Hess* (SPONS: M. Husain) Kenneth Craik Laboratories, University of Cambridge, U.K.

It has long been suggested that the periphery is somehow specialized for moving stimuli, however, more recent theories claim that it is merely a coarser version of the foveal field. In this study we present evidence that the transient aspects of a stimulus are emphasized relative to the sustained aspects as one moves to the peripheral field. We used a novel masking technique to examine changes in temporal filtering properties with respect to eccentricity. **Probe stimuli** (Gabors in space, sinusoidal in time) were presented 4 dB above threshold. Superimposed **masking stimuli** (narrow band noise in space, sinusoidal in time) were then increased in contrast until the probe was no longer visible. Stimulus size was not scaled with eccentricity.

The number of temporal filter types isolated by this technique varied with eccentricity. Three (one low-pass & two band-pass with peaks of 8 & 16 Hz) were found foveally, two (low-pass & band-pass peak 8 Hz) at 10°, and only one (band-pass peak 8 Hz) above 30° eccentricity. Variations in spatial frequency did not reveal a low-pass channel above 30° eccentricity. This trend was also reflected in the modulation transfer function which was low-pass foveally and band-pass peripherally. This suggests that the sensitivity of the low-pass channel falls more rapidly with eccentricity than that of the band-pass (8 Hz peak) channel.

These results imply that the peripheral field is not merely a 'coarser' version of the fovea but has qualitative differences that emphasize transient information. The finding of a single channel at threshold for peripherally viewed stimuli can be used to explain why rapidly flickering stimuli viewed peripherally can be matched by foveal flicker of around 8 Hz, and why moving stimuli often appear slower when viewed peripherally.

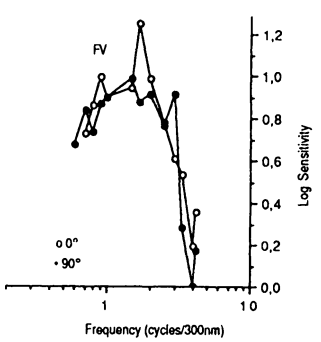
SPATIAL FREQUENCY DISCRIMINATION FOR INPHASE AND COUNTER-PHASE RED-GREEN STIMULI: EFFECT OF APPARENT MOTION. R.L.P. Vimal* and R.Pandey* (spon: P.H.Hartline) Eye Research Institute Boston, MA



Based on the spatial (size of the stimuli) and/or spatial frequency (SF) (number of cycles/deg) criteria, the SF discrimination (SFD) thresholds to counter-phase stimuli were reported to be lower than the inphase stimuli at lower SF, but at higher SF the reverse was true[1] suggesting a possible interaction between form and color. We investigated whether this conclusion held when the criterion was apparent motion. For this purpose, high contrast spatially localized stimuli (sixth derivatives of spatial Gaussian function: $2^o \times 0.5^o$ on 6.4^o equiluminant inphase surround) were presented to two color normal observers at about 29 cd/m^2 using the Adage 3006 system. The relative luminances of red and green stimuli were determined by the minimum flicker isoluminant criterion. The method of constant stimuli with blocked two interval (each of 500 msec) forced choice procedure was used. The zero interstimulus interval (500 msec in previous study[1]) produced an apparent motion of contraction if second interval has high SF and apparent expansion if it has lower SF. The observer initiated a trial and reported the interval with lower SF using the contraction/ expansion criterion. The percent discrimination thresholds to inphase stimuli were found to be lower than that to counter-phase stimuli for all SFs. The results are consistent with the segregation of color and motion.[2] The *parvo-interblob* system may be sensitive to both achromatic and chromatic contrasts.[2] The achromatic channel might include both the *magno* system[2] as well as an achromatic component of the *parvo-interblob* systems. The stronger contribution of motion to inphase SFD may be due to the achromatic channel. The weaker contribution of motion to counter-phase SFD may be due to chromatic contrast component of *parvo-interblob* system. 1. Vimal R.L.P., Invest.Ophthalmol.Vis.Sci. (Suppl.) 29:448,1988. 2. RESPONSE OF HUMAN COLOR VISION TO SINUSOIDAL SPECTRAL DISTRIBUTIONS. V.Bonnardel* and F.Varela, Institute of Neuroscience, CNRS-U.Paris VI, Paris, France

We have constructed a device producing illuminants whose intensity varies sinusoidally over the visible spectrum to obtain the first measurements of the Modulation Sensitivity Function for human color vision. Frequency (13 values between 0.6 to 4.25 cycles/300 nm), contrast (through rotation of a polaroid to 0.25 deg precision), and phase (three phases, with 0 deg corresponding to maximum transmittance at 400 nm) were all under experimenter's control.

The threshold sensitivity when the baseline white became just detectably coloured were obtained. Each frequency and phase were also mapped in Munsell coordinates. The figure shows a typical result for one subject and two phases. These results can be compared with Fourier transforms of chromatic channels previously proposed.

TWO ROD MECHANISMS IN DARK-ADAPTED VISION. P.E.Hallett*, C.S.Barnes* and M.I.Hofmann* (SPON:H.Kwan). Dept. of Physiology, University of Toronto, Toronto, ONT. M5S 1A8.

Experiments with continuous lighting have recognized three major regimes— scotopic, mesopic and photopic. In the present experiments, briefly flashed sine-wave gratings are presented to the dark-adapted peripheral retina. This procedure divides the scotopic regime into low and high luminance sections between which there is a fairly abrupt transition (at roughly -2.5 log scot td sec at 20° retinal eccentricity). Cone contributions are excluded by appropriate tests. Contrast sensitivity curves in the high rod regime are best fitted by Gaussian or Difference-of-Gaussian functions with a constant centre size ($\sigma_{centre} \cong 1.5°$). Simple Gaussians with a variable centre size ($\sigma \cong 1.5$ to $3°$) provide the best fit in the low rod regime, size increasing with decreasing flash energy. A comparison of brief flash results with long duration or flickering gratings suggests that vision in the low rod regime does not depend on stimulus duration, but may be impaired for brief flashes in the high rod regime.

249.16

LOSS OF SHORT-WAVE CONE SENSITIVITY AND POSSIBLE ACCELERATED AGING ASSOCIATED WITH CHRONIC EXPOSURE TO ULTRAVIOLET RADIATION J.S. Werner, V.G. Steele* and D.S. Pfoff*
Department of Psychology, University of Colorado, Boulder, CO 80309

The crystalline lens of the human eye absorbs most of the incident ultraviolet radiation (UVR), but when the lens is removed, this radiation can reach the photoreceptors. The consequences of UVR-exposure on cone receptor sensitivity were determined from psychophysical measurements in eight patients who had undergone bilateral cataract extraction and implantation of intraocular lenses. The lens implanted in one eye contained chromophores that absorb incident UVR, while the lens implanted in the other eye transmitted UVR. Two-color increment thresholds were measured to determine the spectral sensitivities of isolated cone mechanisms. Five years of differential exposure to ambient UVR was associated with a selective loss in sensitivity of the short-wave cone photoreceptors, although visual acuity and sensitivities of middle- and long-wave sensitive cones were not significantly different for the two eyes. These losses in short-wave cone sensitivity associated with UVR may be similar to losses in sensitivity that occur in normal aging. Using our sample of 76 normal subjects (ages 10-84 years) as a baseline, the results of this study show that five years of additional exposure to ambient UVR produces a loss in sensitivity that is equivalent to over 30 years of normal aging.

249.17

MECHANISMS UNDERLYING THE SPECTRAL TUNING OF X-CHROMOSOME LINKED HUMAN CONE PIGMENTS. J. Neitz*, M. Neitz* and G. H. Jacobs. Neuroscience Research Institute, University of California, Santa Barbara, CA 93106.

Nathans et al. (Science, 232:203, 1986) proposed that red-green color vision deficiencies arise from homologous recombination of the X-chromosome linked visual pigments genes that occur in individuals with normal color vision. They suggest that the fusion genes resulting from recombination encode pigments with the same spectrum as one or the other of the original normal pigments in dichromats and also encode pigments with spectra intermediate between the two original normal pigments in anomalous trichromats. The amino acid differences responsible for the spectral positioning of different pigments have not been identified. In the present experiments, an X-chromosome linked visual pigment gene was isolated from a red-green color blind male (a protanope) and its nucleotide sequence determined. The spectral properties of the pigment specified by this gene were determined by analyzing a corneally recorded gross potential, the electroretinogram. The spectrum of this photopigment (λ_{max} = 530 nm) is not different from that of a normal middle wavelength sensitive (MWS) pigment even though about half of the DNA coding sequences appear to be derived from a normal long wavelength sensitive (LWS) pigment gene. These results indicate which regions of the photopigment apoproteins govern the spectral tuning of the X-chromosome linked photopigments. A region in exon 4 appears to be responsible for the small spectral shift characteristic of the difference between X-linked pigments in anomalous trichromats, while a region in exon 5 is responsible for the larger spectral shift between MWS and LWS pigments.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION I

250.1

BINDING CHARACTERIZATION OF PROGESTERONE BOVINE SERUM ALBUMIN CONJUGATES (P-BSA) TO RAT BRAIN TISSUES. F.C.KE AND V.D.RAMIREZ. Department of Physiology and Biophysics, University of Illinois, Urbana, IL 61801

The membrane mechanism of progesterone (P) action on nerve cell remain unclear. Previously, we demonstrated specific binding of P-BSA to rat brain tissues. To examine the possibility that P-BSA interact with ion channel proteins, the binding of P-BSA to cerebellum and brain stem P_2 fractions was characterized by changing ionic condition of the incubation medium.

Depolarization of brain tissue by changing the Na^+/K^+ ratio increased the binding capacity but decreased the binding affinity. At either normal or depolarized conditions, the binding was diminished in presence of 2 mM EDTA. The presence of specific divalent cations (Mg^{++},Ca^{++},Sr^{++},Ba^{++}, Mn^{++}, but not Fe^{++},Co^{++},Ni^{++},Cu^{++},Zn^{++}) was essential for the binding of P-BSA. The binding was also regulated by guanine nucleotides (GTP and GDP).

The results indicate that the binding of P-BSA to rat brain tissue is sensitive to depolarization and requires specific divalent cations. This support the hypothesis that the membrane mechanism of P may be mediate by modulation of ion channel proteins on nerve cell membrane.

250.2

COLOCALIZATION OF PROGESTIN RECEPTOR- AND β-ENDORPHIN- OR ENKEPHALIN-IMMUNOREACTIVITY (IR) IN GUINEA PIG BRAIN. D.H. Olster and J.D. Blaustein. Psychology Department, Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Many behavioral and physiological effects of steroid hormones have been hypothesized to be mediated by opiate peptides. We used double-label immunocytochemistry (ICC) to ascertain whether progestin receptor (PR) and β-endorphin (βEP) or enkephalin (ENK) were colocalized in the same neurons. Ovariectomized guinea pigs were treated with estradiol to induce high levels of PR-IR. Colchicine was injected intraventricularly 48 h prior to perfusion to improve visualization of βEP-IR and ENK-IR. Brain sections were processed for PR-, followed by βEP- or ENK-IR. The ENK antiserum (Incstar) was preferential for leucine-ENK, but cross reacted with methionine-ENK slightly. ENK-IR and PR-IR were both found in the preoptic area, dorsomedial (DMA) and ventrolateral areas of the hypothalamus and arcuate nucleus (ARC). However, it was only in the ARC that evidence of some colocalization was found. Many βEP-IR neurons were found in the ARC, with fewer in the DMA and ventromedial nucleus (VMN). Furthermore, substantial numbers of βEP-IR cells in the VMN (58%), DMA (69%) and ARC (30%) also contained PR-IR. These data provide neuroanatomical evidence that hypothalamic actions of progesterone may be mediated by opiate peptides. (Supported by NIH HD 23483, RCDA NS 00970 and NS 19327)

250.3

DOWN-REGULATION OF HYPOTHALAMIC PROGESTIN RECEPTOR-IMMUNOREACTIVITY (PR-IR) BY PROGESTERONE IN FEMALE GUINEA PIGS. J.D. Blaustein, Neuroscience & Behavior Program & Psychology Dept., Univ. Mass., Amherst, MA 01003

Progesterone injection in estradiol-primed ovariectomized guinea pigs results in down-regulation of hypothalamic progestin receptors (PRs) determined by in vitro binding assays. In order to determine if there are neuroanatomical areas in which progesterone preferentially down-regulates PRs, ovariectomized guinea pigs were injected with minimal behaviorally-effective doses of estradiol benzoate (10 µg 2 d before perfusion) and oil or progesterone (500 µg 4 h before perfusion), and PR-IR cells were observed immunocytochemically. Estradiol dramatically increased cell nuclear, and to a lesser extent cytoplasmic, immunostaining in defined regions of the preoptic area and hypothalamus. Subsequent progesterone injection resulted in significant decreases in PR-IR in all regions by 24 h after injection. The ventrolateral hypothalamus (VLH) was particularly sensitive showing a substantial decrease in PR-IR by 12 h after injection. This decrease is not due to occupation of receptor by hormone; while progesterone injection caused a nearly total absence of cytoplasmic immunostaining within 4 h, it did not decrease the intensity of cell nuclear staining.

The data extend earlier results of in vitro binding experiments. They point to the VLH as a site at which PRs may be particularly sensitive to down-regulation by progesterone. (Support: NIH NS 19327 and RCDA NS 00970)

ESTROGEN RECEPTOR-IMMUNOREACTIVITY IN THE FOREBRAIN OF THE FEMALE GUINEA PIG: DISTRIBUTION AND EFFECT OF STEROID HORMONE TREATMENT. L.L. DonCarlos, E. Monroy, K. Malik, and J.I. Morrell. Inst Animal Behav, Rutgers Univ, Newark, NJ 07102.

We have mapped the distribution of cells that contain estrogen receptors (ER) in the brain of the adult female guinea pig. Cellular ER content was detected using monoclonal antibody H222 (gift from Abbott Lab.) and the Vectastain-Elite method with nickel-intensified DAB. Deletion, titration and adsorption controls established the specificity of the staining. Dense collections of ER-immunoreactive (ER-IR) cells were found in medial preoptic, medial hypothalamic, and limbic nuclei (amygdala, bed n. stria terminalis, lat. septum). Numerous ER-IR cells were scattered throughout the remainder of the preoptic area, hypothalamus and limbic system, and also in the midbrain (central gray). Elsewhere, ER-IR cells were rare or absent. Treatment of ovx animals with Estrogen (E) or E plus progesterone decreased ER staining compared with oil. Our map of ER-IR cells in the guinea pig forebrain markedly extends previous maps based on E-binding. The presence of ER in many forebrain cell groups is a provocative reminder that E may modify, and thus coordinate, diverse behavioral and physiological processes. Supported by HD22983 and NS07997.

DIURNAL PATTERNS OF PROOPIOMELANOCORTIN (POMC) GENE EXPRESSION IN THE ARCUATE NUCLEUS OF PROESTROUS, OVARIECTOMIZED AND OVARIECTOMIZED, STEROID-TREATED RATS. P.M. Wise, K. Scarbrough, N.G. Weiland, G.H. Larson*. Dept. Physiology, U. Maryland, Baltimore, MD 21201

Opiate peptides are thought to modulate the pattern of LH release in female rats. Using *in situ* hybridization, we examined whether diurnal changes in POMC gene expression occur in proestrous, ovariectomized (OVX), or OVX steroid-treated rats and whether differences in the diurnal rhythm or average level of expression in these animal models may explain their different patterns of LH secretion. Four groups of young rats were used in this study: proestrus, OVX for 9 days, OVX for 7 days followed by 2 days of estradiol treatment (OVX-E_2), and OVX-E_2 plus progesterone treatment on day 9 at 1000h (OVX-E_2P). Rats (n=6-7/treatment/time) were killed at 2300, 0300, 1000, 1300, 1500, 1800 or 2300h. Brain sections (20um) were fixed in paraformaldehyde and hybridized at 45°C with a ^{35}S-labeled riboprobe prepared according to the methods of Chowen-Breed et al (Endocrinol 124:1697, 1989). After RNase treatment and stringent wash, slides were dipped in emulsion, exposed and developed. Experimental conditions were optimized for probe concentration and time of exposure to emulsion. POMC mRNA per cell was quantitated using a computerized image analysis system. On proestrus, POMC mRNA expression exhibits a diurnal rhythm: levels rise during the morning, plateau between 1000-1500h and decrease by 2300h. Assuming that there is a delay between a decrease in transcription rate and a measurable decrease in mRNA pool size, the observed decrease in POMC mRNA on proestrous evening may reflect decreased opiate tone that is hypothesized to occur at the time of the onset of the LH surge. OVX decreases the level of POMC mRNA per cell and no difference in the level of mRNA was observed between 1000 and 2300h in this group. The data demonstrate that steroidal milieu plays a role in the level and diurnal pattern of POMC expression in the arcuate nucleus and suggest that changes in these parameters may modulate the cyclic release of LH.

250.6

SEXUAL DIFFERENTIATION OF THE BRAIN IN MALE RATS IS ALTERED BY PRENATAL ACTH OR NICOTINE TREATMENT A.C.Segarra, M.Frankfurt, V.N.Luine and F.L.Strand. The Rockefeller Univ., New York, New York 10021.

Decreased sexual behavior was observed in male rats treated prenatally with nicotine or ACTH (Segarra & Strand, Brain Res.480:151,1989). We decided to investigate if this decrease was correlated with changes in catecholamines (CA) and/or serotonin(5HT) levels in the preoptic area (POA) of the brain. The POA was dissected from 6 day and 80 day old male rats treated prenatally with ACTH (0.1mg/day) or nicotine (1,0.5 mg/kg/day); CA and 5HT levels were measured by HPLC. ACTH-treated pups showed no difference in CA or 5HT levels whereas adults exhibited higher levels of 5HT in the POA. Prenatal nicotine treatment (1 mg/kg/day) decreased 5HT levels in the pups; adult POA levels were the same as controls. These studies provide further evidence of the remarkable plasticity of the brain during the process of sexual differentiation. Supported by the Council for Tobacco Research.

ESTROGEN INDUCED ALTERATION OF ADP-RIBOSYLATED PROTEIN EXPRESSION IN ANTERIOR PITUITARY BUT NOT IN STRIATUM OR UTERUS. B. Borgundvaag and S.R. George. Departments of Medicine and Pharmacology, University of Toronto, Toronto, Ontario, M5S 1A8 Canada.

Estrogen (E2) treatment reliably results in hyperplastic growth of anterior pituitary (AP) lactotrophs. We have previously shown attenuation of adenylate cyclase activity in AP after E2 treatment, with blunted responses to stimulation by VIP and inhibition by bromocriptine. The effect of E2 on the postreceptor mediators of function, guanine nucleotide binding proteins were studied.

Ovariectomized female rats were treated with E2 for 21 days. The studies were in accordance with the established guidelines for animal research. The guanine nucleotide binding proteins were studied using bacterial toxins to catalyse ADP-ribosylation. Cholera toxin mediated ADP-ribosylation (ADP-R) of several proteins, as determined by SDS-PAGE. The estrogen-treated pituitaries had an identical ADP-R Gs band (45K) as the untreated ovariectomized controls. There was a marked alteration in labelled protein expression in the 20-25K range. No effect of estrogen treatment on CT catalysed ADP-R in striatum or uterus were evident. Pertussis toxin mediated ADP-R in the same tissue was not affected by estrogen treatment. The potential significance of the novel 25K substrate for CT catalysed ADP-R in AP with respect to signal transduction, growth induction or oncocytic transformation remains to be clarified.

ESTROGEN RECEPTOR IMMUNOREACTIVITY IN HUMAN HYPOTHALAMUS. **E.G. Stopa, S. H. Hauser*, J.C. King, J.D. Blaustein, G. L. Greene*, and S. Reichlin. Depts. of Endocrinology, and Anat. and Cell Biology, Tufts U. Sch. of Med., Boston, MA, Ben May Institute, Univ. of Chicago, Chicago, IL, Neurosci. and Behavior Program, Univ. of MA, Amherst, MA, and Dept. of Pathology, SUNY Health Sci. Ctr, Syracuse, NY.**

The distribution of estrophilin-like immunoreactivity (ELI) in the human hypothalamus and adjacent regions was studied using a monoclonal antibody (D-75) raised against estrophilin derived from MCF-7 human breast cancer cells.

Hypothalami (n=5) were fixed by immersion in either 4% paraformaldehyde or Zamboni's fixative. The immunocytochemical reaction was performed on unmounted sections (30 - 60 um) using a modification of the PAP technique, after incubation in primary antiserum (11.5 ug/ml) for 72 hours.

Reaction product was found in restricted populations of neurons and astrocytes. ELI-positive neurons were medium-sized, multipolar, and diffusely distributed within the basal forebrain and preoptic area, infundibular region, central hypothalamus, basal ganglia, and amygdala. Immunoreactive astrocytes were noted within specific brain regions, including the lamina terminalis and subependymal layer. These data suggest that estrogens may influence the cellular functions of both neurons and supporting elements within the human brain. **(NIA: 1K11AG00295, DK16684)**

TEMPORAL EFFECTS OF E_2 AND P ON ARCUATE POMC MRNA LEVELS. S.L. Petersen. Dept. of Anatomy, Univ. of Missouri Sch. of Med., Columbia, MO 65212.

Opioid peptides have been implicated as mediators of both negative and positive feedback effects of estrogen (E_2) on LH release. Because opiate neurons in the arcuate nucleus contain E_2 receptors, this study examined changes in arcuate POMC mRNA in ovariectomized controls, in animals demonstrating both negative and positive feedback effects of E_2, and in those with progesterone-augmented LH surges. Representative 12 μm sections through the entire arcuate nucleus were hybridized *in situ* with a ^{35}S-labelled 48-base synthetic oligomer specific for POMC mRNA. E_2 decreased POMC mRNA levels at 0800 h (when E_2 exerts a negative feedback effect on LH release), but increased POMC mRNA significantly by 1200 h (just before the LH surge begins). At 1600 and 2000 h, POMC mRNA levels were similar to those seen at 0800 h. Progesterone increased POMC gene expression slightly, but not significantly, over that of animals treated with E_2 alone at 1200 and 1600 h. POMC mRNA levels were highest in OVX females at 0800 h, decreased by 1200 h and remained low at 1600 and 2000 h. These findings are consistent with the hypothesis that the negative feedback effect of E_2 may be opiate-independent. In addition, these results demonstrate that opiate gene expression appears to increase just prior to the onset of the LH surge. This increase may be necessary for the surge release of LH.

IN VITRO INHIBITION OF MUSCARINIC BINDING BY STEROID HORMONES. G.P. Dohanich, D.A. Cada* and B.E.F. Wee. Dept. of Psychology and Neuroscience Program, Tulane University, New Orleans, LA 70118.

The presence of micromolar concentrations of various steroid hormones inhibited binding of the muscarinic ligand [^{3}H]quinuclidinyl benzilate (QNB) in brain homogenates from ovariectomized rats. The order of potency was progesterone > corticosterone >> testosterone = androstenedione. Pregnenolone and dihydrotestosterone failed to inhibit binding. Progesterone inhibited [^{3}H]QNB binding in homogenates obtained from hypothalamus, brain stem, cortex, and forebrain. Under equilibrium conditions, progesterone inhibited [^{3}H]QNB binding at a K_I of approximately 5 uM. Scatchard analyses revealed that progesterone and corticosterone increased the apparent K_D of [^{3}H]QNB by 200-300% while reducing B_{MAX} by less than 15%, indicating a competitive inhibition of the steroids with [^{3}H]QNB for muscarinic binding sites. Although these steroids appear to be interacting with muscarinic binding sites throughout the brain, our procedures do not rule out the possibility that a direct ligand-steroid interaction could account for the observed inhibition. Data confirm and extend the original work of Klangkalya and Chan (Neuroendocrinology 47:294, 1988) that progesterone inhibits [^{3}H]QNB binding in vitro in rat brain homogenates.

ESTRADIOL-CONCENTRATING FOREBRAIN AND MIDBRAIN NEURONS PROJECT DIRECTLY TO MEDULLA. K.P. Corodimas and J.I. Morrell. Inst Animal Behav, Rutgers Univ, Newark, NJ, 07102.

Estradiol (E2)-concentrating neurons afferent to medulla were investigated by combining a retrograde neuroanatomical tracing method with steroid hormone autoradiography. Injections of the fluorescent tracer Fluoro-Gold (FG) were made into the medulla of seven ovx/adx female rats. Seven days later, 3H-E2 (0.8ug/250g BW; SA=95.4 Ci/mMol) was given ip (Fahrbach et al, JCN, 247, '86, for protocol).

We examined the distribution of three neuron populations: medulla afferents, E2-concentrating neurons, and E2-concentrating neurons afferent to medulla. The largest proportion of E2-receptive neurons that projected to medulla were found in the paraventricular nucleus of the hypothalamus (PVN). Of the E2-concentrating neurons in PVN 69% projected to medulla. In central nucleus of the amygdala, 38%, and in lateral bed nucleus stria terminalis 13% of the E2-concentrating neurons were medulla-bound. The central gray was the only midbrain area which contained E2-target neurons that coursed to medulla (42%). Our findings suggest that E2-sensitive neurons may influence parasympathetic tone via direct projections.

THE DISTRIBUTION OF NEURONS HAVING ESTROGEN RECEPTOR-IMMUNOREACTIVITY AND SUBSTANCE P INNERVATION OVERLAPS IN THE MIDBRAIN CENTRAL GRAY OF GUINEA PIGS. J.C. Turcotte* and J.D. Blaustein. (SPON:J. Desmond) Neuroscience and Behavior Program and Psychology Dept., University of Mass., Amherst, MA 01003

The midbrain central gray has been shown to play a role in hormonally induced female sexual behavior. Injections of Substance P (SP) into the central gray, an area known to contain estrogen receptors as well as SP fibers and terminals, facilitate lordosis in rats. In guinea pigs we found SP-immunoreactivity (SP-IR) and estrogen receptor-immunoreactivity (ER-IR) in the same areas of the central gray. ER-IR cell nuclei were distributed at all levels of the central gray, increasing in numbers along the rostrocaudal axis. Most ER-IR nuclei were found slightly ventrolateral to the cerebral aqueduct where SP-IR appears most dense. By using a multiple bridging technique to enhance ER-IR immunostaining, we have been able to visualize ER-IR in the cytoplasm of cell processes as well as in cell nuclei. This enabled us to observe SP-immunoreactive punctate structures, suggestive of terminal boutons, in close association with a small number of ER-IR cell processes and more frequently, with ER-IR cell bodies. This overlap of SP-IR innervation with ER-IR neurons suggests a neuroanatomical substrate for the facilitating effects of SP on lordosis.

NORADRENERGIC INNERVATION OF HYPOTHALAMIC ESTROGEN RECEPTOR-IMMUNOREACTIVE CELL BODIES AND PROCESSES IN FEMALE GUINEA PIGS. M.J. Tetel and J.D. Blaustein. Neuroscience and Behavior Program and Psychology Department, University of Massachusetts, Amherst, MA 01003

Catecholamines regulate a variety of estradiol-influenced events in the hypothalamus of rats and guinea pigs. An immunocytochemical technique was used to study noradrenergic (NA) afferent input to estrogen receptor-immunoreactive (ER-IR) cells in the hypothalamus and preoptic area of ovariectomized guinea pigs. Brain sections were first immunostained for ER-IR by an immunoperoxidase technique using diaminobenzidine (DAB) as the chromagen, which stains ER-IR cell processes up to 250 um in length. Next, nickel-enhanced DAB was used for dopamine-B-hydroxylase-IR (DBH-IR). DBH-IR punctate structures were observed in close association with ER-IR cell bodies and processes throughout the hypothalamus. Furthermore, some ER-IR neurons in the dorsomedial hypothalamus appeared to have their surfaces completely enveloped by DBH-IR punctate structures, suggestive of terminal boutons. This NA interaction with ER-IR cells could provide a possible mechanism by which environmental stimuli could elicit neuronal changes in distinct subpopulations of estradiol-sensitive neurons.

INVOLVEMENT OF THE CALCIUM MESSENGER SYSTEM IN THE STIMULATION OF LUTEINIZING HORMONE SECRETION BY NEUROPEPTIDE Y IN RATS. W.R. Crowley, G.V. Shah*, D. Kennedy*, M.E. Dockter*, and S.P. Kalra. Depts. of Pharmacology and Microbiology & Immunology, University of Tennessee, Memphis College of Medicine, Memphis, TN 38163 and Dept. of OB/GYN, University of Florida College of Medicine, Gainesville, FL 32610.

The stimulatory effect of neuropeptide Y (NPY) on luteinizing hormone (LH) secretion in female rats occurs via increased release of LH-releasing hormone (LHRH) from the median eminence and enhanced response of anterior pituitary cells to LHRH. Further studies investigated the involvement of the Ca^{++} messenger system in these effects. The stimulatory effect of NPY on *in vitro* LHRH release persisted in Ca^{++} free/EGTA-chelated medium, but was prevented by TMB-8, an agent that inhibits the mobilization of intracellular Ca^{++}. The facilitatory effect of NPY on LHRH-induced LH release from cultured anterior pituitary cells was mimicked by Bay K 8644, a dihydropyridine agonist at voltage-sensitive Ca^{++} channels, and the effects of either Bay 8644 or by NPY were blocked by the dihydropyridine Ca^{++} channel antagonist, nitrendipine. Dispersed pituitary cells were loaded with the Ca^{++} probe INDO-1 AM and scanned in a Flow Cytometer, at the rate of 1000 cells/sec, by a UV argon ion laser. LHRH alone increased intracellular Ca^{++} levels in a population of pituitary cells. After pretreatment with NPY, an increased number of cells responded to LHRH with increases in Ca^{++}. These results suggest that 1) the central action of NPY to stimulate LHRH release may occur via mobilization of intracellular Ca^{++}, and 2) the facilitatory effect of NPY on LHRH-induced LH release from the pituitary occurs through increased influx of extracellular Ca^{++}.

250.15

ENDOGENOUS INHIBIN SUPPRESSES BASAL FSH SECRETION WHILE E_2 SUPPRESSES PULSATILE FSH SECRETION IN THE FEMALE RAT. M.D. Culler* (SPON: E. Field), Repro. Neuroend. Sec., Lab. Mol. and Integrative Neurosci., NIEHS, NIH, Res. Tri. Pk, NC 27709.

In order to investigate the role of ovarian factors in regulating FSH secretion, cannulated female rats were either ovariectomized (OVX), with or without E_2 replacement, or sham-operated (SHAM) and injected with either anti-inhibin serum (AS) or normal sheep serum (NS) on the afternoon of diestrus II. Eighteen h later, blood samples were collected every 10 min for 4 h from the unanesthetized rats. The OVX, OVX-E_2 and SHAM-AS treatments all induced similar, significant increases in overall mean FSH and mean FSH trough levels as compared with the SHAM-NS controls. The parameters of pulsatile FSH secretion (pulse amplitude and frequency) were not altered by SHAM-AS or OVX-E_2 as compared with SHAM-NS rats. OVX, however, induced a significant increase in FSH pulse amplitude without affecting pulse frequency. Pituitary sensitivity to exogenous LHRH, in terms of FSH secretion, was the same in all groups. These results suggest that endogenous inhibin suppresses basal FSH secretion while E_2 suppresses pulsatile FSH secretion through a mechanism independent of pituitary sensitivity to LHRH.

OVARIAN STEROIDS INCREASE VERATRIDINE-INDUCED RELEASE OF AMINO ACID TRANSMITTERS IN PREOPTIC AREA SYNAPTOSOMES. A. Fleischmann*, M.H. Makman and A.M. Etgen. Albert Einstein College of Medicine, Bronx, NY 10461.

To evaluate the role of ovarian steroid hormones in the control of GABA and glutamate (GLU) neurotransmission, the release of GABA and GLU and the de novo synthesis of GABA from glutamic acid were studied in hypothalamic (HYP) and preoptic area (POA) synaptosomes from ovariectomized (OVX) and OVX, steroid-treated rats. Female Sprague-Dawley rats were injected with oil or 2 μg of estradiol benzoate (EB) 48 and 24 hr before sacrifice and with progesterone (P, 500 μg) or oil 4 hr before sacrifice. Synaptosomes isolated from the HYP and the POA were incubated with ^{3}H-glutamic acid for 30 min, then washed and reincubated in order to examine KCl- and veratridine-induced release of ^{3}H-GABA and GLU. Conversion of ^{3}H-glutamic acid to GABA in both HYP and POA synaptosomes was 7-9% in all groups. Neither basal nor KCl-induced release of GABA or GLU varied as a function of hormonal condition. In contrast, veratridine-induced release of GABA and GLU from POA synaptosomes of EB+P-treated animals was approximately twofold higher than that in OVX controls or OVX rats treated with EB or P alone. Steroid treatment had no significant effect on veratridine-induced release of GABA or GLU in HYP synaptosomes. Thus different mechanisms may underlie KCl- and veratridine-induced amino acid release, and these mechanisms may be affected differentially by steroid hormones.

250.17

MOST FOREBRAIN NEURONS PROJECTING TO THE ESTROGEN RECEPTOR-RICH VENTROLATERAL HYPOTHALAMUS DO NOT CONTAIN ESTROGEN RECEPTOR-IMMUNOREACTIVITY IN FEMALE GUINEA PIGS. Y.Delville and J.D.Blaustein. Neuroscience and Behavior Program and Psychology Department, University of Massachusetts, Amherst, MA 01003.

We have found that the stimulation of the rostral ventrolateral area (VLA) of the hypothalamus by estradiol is critical for the expression of sexual receptivity facilitated by progesterone. We looked at the forebrain afferent neurons to this area using a fluorogold retrograde tracing technique. Most noticeably, retrogradely-labelled neurons were found in areas known to contain many estrogen receptor-immunoreactive (ER-IR) neurons and also known to be involved in the control of female sexual behavior, such as the preoptic area (POA). We predicted that these retrogradely-labelled neurons in the POA would also contain estrogen receptors. Surprisingly, few if any retrogradely-labelled neurons also contained ER-IR. However, in many cases, retrogradely-labelled neurons were found adjacent to cells immunoreactive for estrogen receptors. Therefore neuronal connections between the POA and the VLA do not appear to be directly estrogen-responsive. (Supported by NS 19327 and RCDA NS 00970 from the NIH)

PERIPUBERTAL CHANGES IN ESTROGEN BINDING IN DISCRETE REGIONS OF THE FEMALE RAT HYPOTHALAMUS AND PREOPTIC AREA. T.J. Brown[1], F. Naftolin*[1], W. Jacobson*[2], and N.J. MacLusky[2] Dept. OB/GYN, Yale University School of Medicine[1], New Haven, CT 06510, and Division of Reproductive Science, Toronto General Hospital[2], Toronto, Ontario, M5G 2C4.

The events surrounding the onset of reproductive cyclicity in the female rat include a profound change in the sensitivity of the neural substrate to the feedback effects of estradiol on LH secretion. To test the hypothesis that this alteration in sensitivity could be associated with a change in intracellular receptors for estrogen, changes in mediobasal hypothalamus/preoptic area (MBH/POA) receptor content were assessed in 25-37d old female rats by *in vitro* binding assays and by quantitative analysis of *in vivo* neural uptake of 11β-methoxy-16α-[^{125}I]estradiol. Cytosol progestin receptors in the MBH and pituitary gland increased dramatically from d25 to d35. Occupation of nuclear estrogen receptors in the pituitary and MBH/POA of 34d old rats were increased 2-3 fold above that measured in 23 and 30d old rats. Nuclear estrogen receptor binding capacity in the arcuate nucleus increased by 48% from d25 to d32, and by 64% from d25 to d38. Similar but smaller changes in estrogen binding capacity were found in the ventromedial nucleus and medial POA. These results indicate that during the peripubertal period an increase in estrogen binding capacity occurs in specific regions of the rat brain known to play a vital role in the control of reproductive function. Supported by NIH grant HD13587.

BEHAVIORALLY-CORRELATED SINGLE UNIT DISCHARGE RECORDED FROM ENSEMBLES OF NEURONS IN THE PREFRONTAL CORTEX VARY ACROSS THE ESTROUS CYCLE. Sheryl S. Smith and Christina Bergqvist*, Dept. of Anatomy, Hahnemann Univ., Broad and Vine, Phila., PA 19102-1192.

Ongoing studies from this laboratory have shown that 17 β estradiol (E_2) augments excitatory responses of cerebellar Purkinje cells to the iontophoretically applied excitatory amino acids glutamate, quisqualate and NMDA. Using a behavioral paradigm, we have also shown that E_2 administration as well as estrous-associated hormonal changes increase cerebellar discharge during treadmill locomotion to a greater extent than during stationary periods, an effect compatible with the hypothesis that E_2 enhances evoked neuronal excitation, whether elicited pharmacologically or behaviorally.

In the present study, another CNS site was tested for possible locomotor-correlated discharge relative to spontaneous across the days of the estrous cycle. Neurons from the rat dorsomedial prefrontal cortex (PFC), an area shown to contain classic receptors for E_2 and which may be implicated in some of the psychoactive effects of this steroid, were recorded using chronically implanted arrays of 5-7 microwires (0.001" dia).Implanted animals were trained to locomote on a computer- controlled treadmill device (alternately on-off, at 10 s intervals) for a period of 1-2 hs daily during neuronal recording. PFC activity was found to be correlated either with locomotion (tread on) or non-movement (tread off) on almost an equal basis, when recorded from rats on diestrus 1 or 2 (D) during the light segment of the light:dark cycle. The tread off- correlated discharge was markedly augmented by three-fold on estrus (E) relative to values obtained on D, with little alteration in tread on correlated activity. In many cases, cells exhibiting tread on-correlated maximal activity were transformed to tread- off-correlated cells. Furthermore, increasing treadmill speed (from 4 to 11 cm/s) produced greater alterations in neuronal- correlated discharge when tested on D compared to E. When tested during the dark part of the cycle, tread-off correlated discharge was higher on E when compared with similar values during the light. Thus, the present results suggest that hormonal as well as light-dark fluctuations produce alterations in the response of PFC neurons to pre-movement conditions. *Supported by NS 25809 to SSS.*

POSTMENOPAUSAL HYPERTROPHY OF NEURONS EXPRESSING THE ESTROGEN RECEPTOR GENE IN THE HUMAN HYPOTHALAMUS. N.E. Rance*, N.T. McMullen§, D.L. Price and W.S. Young III†. Neuropathology Lab., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205; §Dept. Physiology, Univ. MD Sch. Med., Baltimore, MD 21201; †Lab. Cell Biology, NIMH, Bethesda, MD 20892.

This study examines whether the loss of ovarian steroid secretion in postmenopausal (POSTM) women is associated with morphological alterations in the infundibular nucleus. Hypothalami from premenopausal (PREM) (n=3) and POSTM (n=3) women were serially sectioned and Nissl stained. Soma areas of >3500 infundibular neurons were digitized using a computer microscope. The mean cross-sectional area of neurons in POSTM women ($\bar{X}$ = 190 μm²) was 30% greater than that of PREM women ($\bar{X}$ = 147 μm²). To determine whether hypertrophied neurons were potential targets for estrogens, frozen sections from PREM (n=3) and POSTM (n=2) hypothalami were hybridized with a cDNA probe to estrogen receptor (ER) mRNA. Quantitative image analysis revealed that hypertrophied neurons in POSTM females contained ER mRNA. Finally, analysis of the infundibular nucleus from an ovariectomized 38-year old woman also revealed hypertrophied neurons containing ER mRNA. We propose that hypertrophy of infundibular neurons in POSTM women is not a function of chronological age *per se* but is secondary to loss of the inhibitory feedback of ovarian estrogen.

251.1

A MEDULLARY SITE MEDIATING INHIBITION OF SPINAL SEXUAL REFLEXES. L. Marson and K. E. McKenna Dept. of Physiology, Northwestern Medical School, Chicago IL 60611.

We have previously described a sexual response, the coitus reflex, elicited in anesthetized male and female rats. This reflex in under tonic descending inhibition. the goal of the present study was to identify the supraspinal site(s) mediating this inhibition.

Male rats were anesthetized with urethane and mounted in a stereotaxic frame. A urethral catheter was inserted for eliciting the coitus reflex, which was monitored by EMG recordings of the bulbospongiosus muscle. As previously reported, the coitus reflex cannot be elicited in this preparation in intact rats. Brainstem and spinal transection experiments identified the rostral medulla as the level of the neuraxis mediating the inhibition. Bilateral electrolytic lesions (1 mA, 15-60 sec) were made to identify the inhibitory site. Small (< 1 mm diameter) bilateral lesions of a site just rostral to the inferior olives and lateral to the pyramidal tract in the paragigantocellular recticular cell group were sufficient to release the coitus reflex. Bilateral injections of kainic acid (0.1M, 50-250nl) also released the inhibition of the coitus reflex, indicating that cell bodies in this region, and not axons of passage, mediate the inhibition. Injections of fluorogold (1 µl, 4%) into the lumbosacral cord retrogradely labelled numerous neurons in this area. These findings suggest that a population of bulbospinal neurons in the ventromedial rostral medulla mediate inhibition of spinal sexual reflexes.

251.2

EXTERNAL URETHRAL SPHINCTER EFFERENTS AND AFFERENTS IN THE SPINAL CORD OF THE MALE CAT. B. Mallory, M.N. Kruse, J.R. Roppolo and W.C. de Groat. Dept. of Pharmacol., Univ. of Pittsburgh, Pittsburgh, PA 15261.

Micturition involves the coordination of somatic and autonomic neuronal activity to the lower urinary tract (LUT). The main somatic innervation to the LUT is the afferent (AFF) and efferent (EFF) innervation of the external urethral sphincter (EUS). This study examined in the male cats the AFF and EFF projections of the EUS to the lumbosacral spinal cord using HRP tracing techniques. Under halothane anesthesia the EUS was exposed and injected bilaterally with either 1% WGA-HRP or 20% HRP. Three days later the animal was perfused with fixative and spinal cord removed. Labeled EFF neurons were seen at the base of the ventral horn in the S_1 and S_2 segments in an area known as Onuf's nucleus (ON). The majority of neurons were in the S_1 segment and at the most ventral part of ON (mean area 391 μm^2). HRP in the primary AFF pathway labeled neurons in the S_1 to Cx_1 dorsal root ganglia (DRG) with the majority of neurons in the S_2 DRG (mean area 849 μm^2). AFF fiber labeling could be seen along the lateral edge of the dorsal horn (DH) extending into lamina V and projecting toward the dorsal commissure (DC). AFF fiber labeling could also be seen at the medial edge of the DH projecting into lamina IV & V and into the DC. The close proximity of the EUS AFF and EFF with those of the sacral parasympathetic nucleus suggests the possible coordination of these systems during micturition.

251.3

THE EFFECTS OF MK-801 ON THE MICTURITION REFLEX IN THE CAT. J.R. Roppolo and W.C. de Groat. Dept. of Pharmacology, University of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

A variety of evidence strongly suggests that several amino acid including L-glutamate and L-aspartate are important neurotransmitters at excitatory receptors in the vertebrate central nervous system. The present study was undertaken to determine if MK-801, a potent excitatory amino acid antagonist at NMDA receptors could modify the micturition reflex of the cat.

Cats anesthetized with α-chloralose 60 mg/kg were used in this study. Bladder pressure was recorded isovolumetrically via a urethral catheter connected to a pressure transducer.

Doses of MK-801 from 0.001 to 3 mg/kg given I.V. were examined in this study. Small doses 0.001 to 0.03 mg/kg had little or no effect on the amplitude or frequency of rhythmic bladder contractions. Doses of 0.1 to 0.3 mg/kg reduced the frequency and/or amplitude 10 to 30%. Doses of 1 to 3 mg/kg abolished all rhythmic bladder activity. Infusion of additional saline into the bladder could produce partial recovery of bladder activity. Complete recovery, however, was not seen.

This data suggests that excitatory amino acid neurotransmitter mechanisms maybe involved in the micturition reflex pathway.

251.4

BLADDER REFLEXES IN THE NEONATAL RAT. M.N. Kruse and W.C. de Groat. Depts. Pharmacology and Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Micturition in the adult rat is mediated via a supraspinal bladder-to-bladder reflex. The neonatal rat has a spinal perineal-to-bladder reflex that initiates micturition when the mother licks the perineal area. We report here on the development of the bladder-to-bladder reflex in the first few postnatal days. Urethane anesthetized, decerebrate and spinalized pups at 2-31 days of age were used. A needle was placed in the dome of the bladder through which bladder pressure was monitored and saline was infused. Awake pups of all age groups showed a perineal-to-bladder reflex. Urethane anesthesia depressed the micturition reflexes as many pups anesthetized with urethane did not exhibit a bladder-to-bladder or perineal-to-bladder reflex. Most pups of all age groups exhibited small amplitude, short duration bladder contractions following bladder distension which were probably intrinsic to the bladder smooth muscle as they occurred following ganglionic blockade with trimethaphan (25 mg/kg IM). Cystometrograms induced bladder-to-bladder micturition reflexes in decerebrate pups on day 6 and older, but not in spinal pups of the same age. A few 2-day-old decerebrate pups (3 of 13) showed the supraspinal bladder-to-bladder reflex. We conclude that rats develop a supraspinal bladder-to-bladder micturition reflex within the first few days after birth. During this period the perineal-to-bladder reflex is necessary to promote emptying of the bladder. If neonatal pups have a spinal bladder-to-bladder reflex, it is indistinguishable from the peripherally generated contractions.

CHOLECYSTOKININ HAS EXCITATORY EFFECTS ON TRANSMISSION IN VESICAL GANGLIA AND ON BLADDER CONTRACTILITY IN CATS. J.R. Keast, M. Kawatani and W.C. de Groat. Departments of Pharmacology and Behavioral Neuroscience, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261.

Cholecystokinin (CCK) is found in subpopulations of preganglionic autonomic neurons and primary afferent neurons. We have investigated the effects of exogenous CCK on transmission in vesical ganglia and bladder contractility in anesthetized cats in vivo. CCK 1-8 (sulphated form; 2-20 µg) was administered in 0.1-0.2 ml saline into the inferior mesenteric artery and caused a rapid, transient increase in firing on postganglionic nerves on the bladder surface (latency 2-5 s, duration 20-60 s). These effects were similar or greater in magnitude than those evoked by acetylcholine or methacholine (10-25 µg) and were abolished by hexamethonium (C_6, 1-2 mg). CCK in similar doses enhanced transmission in vesical ganglia, increasing the amplitude of pelvic nerve-evoked compound action potentials by 50-100% for up to 2-3 min. The excitatory effects of CCK were also seen on bladder activity. CCK (10 µg) caused a transient bladder contraction, which was reduced 60-80% by C_6 (1-2 mg) and the remaining effects were usually blocked by atropine (150-200 µg).

These results suggest that CCK causes the release of acetylcholine from nerve terminals in vesical ganglia and bladder smooth muscle, thereby enhancing transmission and contractility, respectively. CCK may play an important role in regulation of bladder function by facilitating excitatory pathways.

IMPROVED MICTURITION WITH DIRECT CURRENT STIMULATION OF THE SPINAL CORD IN THE SPINAL CAT. Khan, T., Dauzvardis, M., Walter, J., and Robinson, C.J., Rehab. R&D Center, Hines VA Hospital, Hines, IL 60141.

Changes in micturition behavior were noted as side effects in experiments that studied the effects of spinal cord stimulation on functional enhancement in six chronically spinalized female cats. A complete contusion injury was performed at the T9 level under anesthesia. These animals received daily post-operative care in accord with AAALC guidelines. Platinum disc electrodes were inserted 2 cm above and below the level of the lesion and connected to an 15 µA implantable DC source.

Three control animals were lesioned but did not receive stimulation. Two remained continent of urine during our 10-week study and required four or five Crede procedures (suprapubic pressure) for voiding. The third control animals was not distinguishable from experimental subjects.

Three stimulated animals were all incontinent by the third week and their bladders could be easily emptied with Crede applied once or twice.

High urethral resistance following spinal injury makes it difficult to empty the bladder. Improved voiding with spinal cord stimulation indicates inhibition of the urethral sphincter. This inhibitory effect may occur through activation of spinal inhibitory pathways or spinal cord regeneration.

Supported by funds from Veterans Administration, Rehabilitation R&D Service, Rehab. R&D Grant #B423R.

251.7

EFFECTS OF SUPRASACRAL SPINAL CORD STIMULATION ON BLADDER AND EXTERNAL URETHRAL SPHINCTER ACTIVITY IN THE DECEREBRATE CAT. B. Fedirchuk and S.J. Shefchyk. Depts. Med. and Physiol., Univ. of Manitoba, Winnipeg, Canada R3E 0W3.

The effects of electrical stimulation of the suprasacral spinal cord on urinary bladder pressure and external urethral sphincter (EUS) activity were examined in precollicular, postmammillary decerebrated male cats paralysed with Flaxedil. Electroneurographic recordings were made from the EUS and anal sphincter branches of the right pudendal nerve as well as from flexor and extensor hindlimb muscle nerves. Bladder pressure was monitored using a catheter inserted suprapubically into the bladder. Electrical stimulation (100-200 μA; 50 or 100 Hz; 0.2 ms) of the pontine micturition centre (PMC) elicited coordinated voiding characterized by synergistic bladder and EUS activity. Monopolar tungsten electrodes (70-110 kΩ) were placed within the superficial dorsolateral funiculus (DLF) at the T10 and T9 spinal segments. Stimulation (50-200 μA;100 Hz;0.2 ms square pulses) at these sites produced coordinated bladder pressure increase and decreased EUS activity during voiding. Subsequent transection of the dorsal columns rostral to the stimulating electrodes did not alter the response, nor did sacral dorsal root transections. Additional DLF lesions caused an apparent increase in tonic EUS activity and bladder pressure increases were no longer produced by stimulation of the spinal cord caudal to the DLF lesion, although the tonic EUS activity was inhibited by the stimulation. Voiding evoked from the PMC or the spinal cord rostral to the DLF lesion was not altered; distension-evoked reflex micturition was abolished. The results suggest that stimulation of the DLF at the thoracic spinal cord activates an ascending portion of a spino-bulbo-spinal loop which facilitates micturition. The apparent increase of activity of the EUS efferents following DLF lesion and the inhibition of EUS activity during DLF stimulation is consistent with reports by others which describe a descending pathway within the DLF which provides an inhibitory influence on a variety of spinal cord neurons. This pathway appears to be separate from the one responsible for the inhibition of the EUS activity during electrically evoked micturition. This research was supported by the Medical Research Council (MRC) of Canada. BF is supported by the Manitoba Health Research Council. SJS is an MRC Scholar.

COMPARISON OF SACRAL AND PUDENDAL NERVE STIMULATION FOR BLADDER INHIBITION IN THE SPINAL CAT

James S. Walter, Rebecca H. Sidarous*, John S. Wheeler*, Charles J. Robinson, Paul J. Zaszczurynski*, Robert D. Wurster, Rehab. R&D Center, Hines V.A. Hosp., Hines, IL 60141, and Dept. of Urology and Physiol., Loyola Medical Center, Maywood, IL 60153.

In order to develop neuroprosthetics for inhibiting the hyperreflexic bladder, electrical stimulation of pudendal and sacral nerves was compared in male unanesthetized cats (complete T1). For sacral stimulation, a quadripolar electrode (Pisces Quad, Medtronic), was inserted into the sacral canal on the midline. For pudendal nerve stimulation, wire electrodes (LifeTech) were inserted percutaneously adjacent to the bulbous urethra. Spontaneous bladder contractions were recorded before, during and after 10 min inhibitory procedures in animals 4 to 10 wk post-lesion.

Our first animal did not show inhibition. However, in our next two animals, bladder contractions of 40 to 60 mmHg were partially or entirely prevented; larger contractions were not inhibited. With sacral stimulation, effects of pulse duration and electrode location were inconclusive. Currents above threshold for pelvic floor stimulation were effective, from 1 to 2 ma, and 3.5 pps was better than 10 or 35 pps. Anesthesia of the pelvic floor prevented inhibition.

With pudendal stimulation, 1 to 4 ma, and 3.5 pps were most effective. Pudendal stimulation may be more selective for bladder inhibition than sacral stimulation. Supported by funds from Hines Veterans Administration Hospital, Rehabilitation R&D Center, and Rehab. R&D Grant B441 RA.

PHARMACOLOGICAL STUDIES OF VARIOUS AGENTS ON K^+ EVOKED RELEASE OF ^{3}H-NOREPINEPHRINE (T-NE) FROM RAT CORPORA CAVERNOSA. L. L. Truex and M. M. Foreman. Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN 46285.

The sympathetic innervation of the corpora cavernosal (CC) smooth muscle is known to be important for control of penile erection. The focus of our studies is to establish a procedure to study the effects of pharmacologic agents on K^+ evoked T-NE release from CC tissue in vitro. CC tissue was removed from adult male Sprague Dawley rats. Transverse sections (0.5 mm) of CC tissue were made and preincubated for 30 minutes at 37° in buffer containing 119 mM NaCl, 4.6 mM KCl, 1.2 mM $KH_2PO_4 \cdot H_2O$, 25 mM $NaHCO_3$, 10 μM pargyline and 1 μM T-NE. Following the incubation period, tissue sections were superfused in a 0.2 ml chamber (3 per chamber) at a flow rate of 0.4 ml/min. Release of T-NE was induced by adjusting the K^+ concentration to 50 mM for 5 min. A double stimulus protocol was used and comparisons between treatments were made via the S2/S1 ratio. Release of T-NE was K^+ and Ca^{++} dependent and could be increased in the presence of 1 μM tomoxetine, a NE reuptake inhibitor. Release of T-NE was attenuated by both α_1 and α_2 agonists (methoxamine and clonidine) and increased by α antagonists (phentolamine, yohimbine, prazosin and phenoxybenzamine). Carbachol inhibited the release of T-NE. This procedure appears to be a useful model for studying pharmacological control of CC-NE release in vitro.

NEUROPEPTIDE Y INNERVATION OF PENILE ERECTILE TISSUE. Y. Carrillo*, E. Fernandez*, W. G. Dail and G. D. Walton*, Dept. of Anatomy, Univ. New Mexico Sch. of Med., Albuquerque, NM 87131.

Owing to the important role proposed for neuropeptide Y (NPY) in the regulation of blood vessels, the present study was designed to investigate the distribution of NPY immunoreactive fibers to the vascular tissue in the rat penis. In the corpora cavernosa penis (CCP), a dense plexus of NPY-IR fibers was present in relation to arteries, intrinsic cavernosal muscle, and veins, including the deep dorsal vein. The density and distribution of NPY-IR fibers was similar to that for noradrenergic nerves to this tissue. In the corpus spongiosum (CS), NPY-IR fibers were present on the scant cavernosal muscle in this tissue and at the base of the acini of the many periurethral glands. Noradrenergic fibers, stained by the glyoxylic acid method, were present over smooth muscle of the corpus spongiosum but were absent in the glandular acini. Immunohistochemistry of neurons, located by injection of fluorogold into the CCP or the CS, indicates that the majority of neurons in the sympathetic chain were NPY+ while less than 10% of the CCP and CS neurons in the pelvic plexus were NPY-IR. In summary, (1) NPY may be important in the regulation of blood flow in the penis, functioning on the venous as well as the arterial side, (2) the sympathetic chain is the most likely source of the NPY-IR fibers in the CCP and the CS, and (3) NPY may play a role in the secretory or absorptive functions of the periurethral glands.

251.11

THE EFFECT OF CHRONIC DECENTRALIZATION ON THE SYNAPTIC INPUT TO PENILE NEURONS. **N. M. Minorsky, G. D. Walton*, and W. G. Dail. Dept. of Anatomy, Univ. of New Mexico Sch. of Med. Albuquerque, NM 87131**

Synaptic connections within autonomic ganglia may become rearranged subsequent to deafferentation. To study this phenomenon further, the synaptic input to penile neurons in the major pelvic ganglion was examined following partial or total decentralization. Penile neurons were identified by injecting the retrograde dye, fluorogold into the corpora cavernosa penis. The synaptic plexus of nerve fibers surrounding penile neurons was immunolabeled with antibodies to met-enkephalin (m-Enk). The percentage of cells surrounded by a m-Enk plexus was averaged for each experimental group. Image analysis was used to obtain a measure of the degree of innervation around each penile neuron. Comparisons of synaptic profiles were made between animals which had received an acute or chronic nerve lesion of either pelvic or combined pelvic and hypogastric nerves. There was a marked increase in the number of neurons which receive innervation in chronically decentralized animals compared to the acute lesion paradigms. Also, the degree of m-Enk innervation increased for a small percentage of chronically decentralized neurons. Surprisingly, the reinnervation of penile neurons which were totally decentralized was comparable to that found for partial decentralization. Dependent upon the lesion paradigm, reinnervation in the pelvic plexus may involve the spared hypogastric nerve, intrinsic neurons or possibly contralateral preganglionic fibers.

251.12

SENSORY AND MOTOR BRANCHES OF PUDENDAL NERVE OF MALE RATS: ROLES IN COPULATION AND REFLEXIVE PENILE ERECTION. B.D. Sachs, Y.C. Liu*, D.B. McQuade*, J.X. Wang*, and G.M. Holmes. Univ. of Connecticut, Storrs, CT 06269-1020.

Male rats were tested for copulation and reflexive erections 5-7 days after bilateral section of the motor pudendal nerve (MPNx; n=10), which innervates the striated penile muscles, the sensory pudendal nerve (SPNx; n=7), which carries genital afference, or sham surgery (n=7). MPNx surgery was confirmed by EMG recording from the bulbocavernosus muscle; SPNx was verified by absence of response to probing the glans with forceps. Among SPNx males, 5/7 displayed intromissions. Only 5/10 MPNx males showed intromission patterns ($p<.05$), and a mean of 52% of these apparent intromissions missed the vagina. Of rats with SPNx or MPNx, only 1 male (SPNx) achieved ejaculation, and only he displayed reflexive erections, in contrast with 6/7 sham operated rats. Because reflexive vascular erections survive excision of the striated penile muscles, the absence of reflexive erection after MPNx was a surprise. This effect implies that the MPN carries some sensory or autonomic motor fibers essential for penile erection.

251.13

MOTOR CONTROL OF PENILE ERECTION: FUNCTIONAL HETEROGENEITY OF THE RAT BULBOCAVERNOSUS MUSCLE. G. M. Holmes, W. D. Chapple, and B. D. Sachs. Univ. of Connecticut, Storrs, CT 06269-1020, USA.

Erection of the glans penis results from vascular mechanisms augmented by constriction of the penile bulb by the bulbocavernosus (BC) muscle. We asked whether the recognized anatomical division of this muscle into a lateral (latBC) and a medial (medBC) portion was reflected by functional differences in their activity during erection. During copulation, the latBC had the characteristic EMG activity we have described previously (Soc. Neurosci. Abst. 14:41.5, 1988). Conversely, activity in the medBC, although synchronous in onset with that of the latBC, displayed uniform firing during the burst which did not vary significantly across changes in copulatory behavior and erection intensity. During reflexive erections, the medBC was periodically silent during latBC activity. The structure and dissociated EMG activity of the medBC and latBC suggest (a) that the BC muscle operates as a two-part pump in enhancing glans erection, and (b) that the two parts of the muscle may be regulated by separate motoneuron pools.

251.14

ULTRASTRUCTURAL CHANGES IN THE UTEROVAGINAL GANGLION OF THE PELVIC NERVE OF HENS DURING MOLT. S. L. Freedman and R. M. Kriebel. Depts. of Anatomy & Neurobiology, Univ. of Vermont, Burlington, VT 05405 and Philadelphia College of Osteopathic Medicine, Philadelphia, PA 19131.

The hen's ovary and reproductive tract undergo marked atrophy during molt. Extensive hormonal changes accompany the cessation of egg production, feather loss, and renewal. This study examined the fine structural modifications in the uterovaginal ganglion of the pelvic nerve in 3 hens concomitant with molt and reproductive inactivity. Prominent aggregations of ribosomes were present, but were not associated with cisternal membranes typical of RER. A marked alteration was the presence of crystalloid, ribbon-like inclusions often associated with dilated cisternal profiles. These structures may represent modified endoplasmic reticulum in storage form until the resumption of reproductive activity. Within synaptic profiles, which appeared to be degenerating, there was a noticeable decrease in the number of large granular vesicles. There was hypertrophy of the capillary endothelium. Plasma cells were present throughout the stroma, however, the absence of phagocytic activity suggests that tissue degeneration was not occurring. The question remains, if the neurons were quiescent or degenerating to be replaced when egg production was reestablished.

251.15

LATERAL HYPOTHALAMIC DAMAGE INDUCED BY KAINIC ACID OR ELECTROLYTIC CURRENT: EFFECTS ON GASTRIC EROSION FORMATION. B. Roland and C.V. Grijalva. BRI, Dept. of Psychology, UCLA, Los Angeles, CA 90024

Electrolytic lateral hypothalamic (LH) lesions in rats induce gastric mucosal erosions as well as other autonomic dysfunctions. In the present study, the effects of LH lesions were compared to infusions of Kainic Acid (KA) into the LH area on gastric mucosal injury. Rats were anesthetized with sodium pentobarbital and then given either bilateral LH lesions, N= 8 (1.2 ma anodal DC current/10 sec) or infused bilaterally with KA, N=9 (1.0µg/0.5µl/12 min) into the LH. Stomach were analyzed for gastric mucosal injury 24 hr postoperatively. Although gastric erosions were associated with both procedures, the incidence was significantly greater following electrolytic lesions (39.3mm^2 vs 5.0 mm^2; $p<0.05$). Furthermore, lesioned rats displayed more pronounced feeding deficits and overt autonomic dsyfunctions (salivation, lacrimation, diarrhea). Although these findings suggest that selective damage to LH neurons contribute to gastric lesion formation, the autonomic disruptions may be more closely linked to damage to axonal fibers of passage.

251.16

LATERAL HYPOTHALAMIC LESIONS ARE ASSOCIATED WITH STIMULATION OF GASTRIC CONTRACTILITY. C.V. Grijalva, T. Garrick*, and K. Jacobs*. VA Med.Ctr., CURE, BRI, Depts. of Psychology and Psychiatry, UCLA, Los Angeles, CA 90024

Changes in gastric contractility following lateral hypothalamic (LH) lesions were measured in urethane anesthetized rats. LH lesions were induced with anodal DC current (1.2ma/10sec) passed through stainless steel electrodes. Gastric contractility was recorded continously for 4 hr with acutely implanted strain gauge force transducers and analyzed by computer for cumulative force index. Rats with LH lesions consistently displayed stimulated gastric contractions in comparison to sham-operated controls (313.±96 vs 172±20 force units; $p<0.05$), and also had significantly more gastric mucosal erosions (5.7±2.4 vs 2.7±0.9 mm^2; $p<0.05$). Vagotomy, a procedure which blocks mucosal injury, also blocked LH lesion-induced gastric contractions as compared to sham vagotomy (25.6±2.1 vs 189.0±99 force units; $p<0.05$). These findings indicate that LH lesions are associated with stimulation of vagally mediated high amplitude gastric contractions which may be pathogenetically linked to erosion formation.

BEHAVIORAL PHARMACOLOGY: BENZODIAZEPINES AND STIMULANTS

252.1

A BEHAVIORAL TEST FOR ANXIETY IN RATS. J. C. Stout* and J. M. Weiss. (SPON: M. G. Caron). Depts. of Psychology and Psychiatry, Duke University, Durham, NC 27706.

A behavioral test for anxious behavior in rats has been developed by modifying Britton's open field test for anxiety (Britton & Britton, Pharmacol., Biochem, & Behav.:15:577, 1981). Sprague-Dawley rats are given access to water for 1 hour/day for 3 days. Rats are then tested in a novel, brightly-lit Plexiglas box (36 X 36 cm) containing a water spout at its center. Observations recorded for 10 min. include: latency to drink, seconds of drinking, number of drinking bouts, and approaches to the spout. Also recorded are grooming, rearing, inactivity, urination, and defecation.

Diazepam (.375-1.5 mg/kg) injected s.c. 30 min. before testing significantly increased measures of drinking, and decreased measures of inactivity, urination and defecation. This was not due to an effect of diazepam on thirst since the drug did not affect time spent drinking in the home cage. Behavior changes similar to those produced by diazepam resulted when rats were repeatedly exposed to the test condition, a procedure also designed to reduce anxious behaviors.

These experiments indicate that this test is useful for assessing anxious behavior in rats, and may thus be useful for studies of neurophysiological correlates of anxiety.

252.2

A COMPARISON OF ANXIOLYTIC AND NON-ANXIOLYTIC AGENTS IN THE SHOCK-PROBE/BURYING TEST. D. Treit. University of Alberta CANADA T6G 2E9.

The effects of IP pentobarbital (10.0-20.0 mg/kg), midazolam (1.0-2.0 mg/kg), chlorpromazine (2.5-5.0 mg/kg), and pentylenetetrazol (10.0-20.0 mg/kg) were compared in the shock-probe/burying test. Consistent with results found previously for chlordiazepoxide and buspirone, the anxiolytic agents midazolam and pentobarbital decreased rats' burying behavior toward a continuously electrified (2 mA) shock-probe, and increased the number of probe-shocks rats received. These concurrent, bidirectional, anxiolytic drug effects occurred at doses that did not affect rats' general activity. Although the non-anxiolytic agents pentylenetetrazol and chlorpromazine also suppressed burying behavior, neither of these drugs induced an increase in probe-shocks; in fact, pentylenetetrazol, which is believed to be anxiogenic, tended to reduce probe-shocks compared to vehicle controls. In addition, chlorpromazine, a standard neuroleptic, produced a significant suppression of general activity at 5 mg/kg. Thus, concurrent increases in probe-shocks and decreases in probe-burying seem to be characteristic effects of known anxiolytic agents, which distinguish them from non-anxiolytic agents.

252.3

MODULATION OF THE SEDATIVE EFFECTS OF DIAZEPAM BY THE VARIOUS BENZODIAZEPINE$_{BZ}$ RECEPTOR TYPES IN RATS. M.Massotti, C.De Luca* and L.Mele*. Lab. Farmacologia, Istituto Superiore di Sanità. 00161 - Roma, Italy.

In rats, diazepam (0.1-10 mg/kg iv) produces two distinct electrocorticographic(EEG) patterns: 1) synchronization and spindle bursts associated with behavioral sedation: 2) 20-30 Hz waves associated with signs of slight behavioral excitation (gnawing, eating,twitches of ears and vibrissae).

These effects are counteracted by administration of the selective antagonist of central benzodiazepine (BZ) receptor types Ro 15-1788 (0.01-1 mg/kg iv). A desynchronized record appears, associated with a state of arousal, lasting 10-20 min. In contrast, no significant effect is observed after the selective antagonist of peripheral BZ receptor type, PK 11195 (5 mg/kg iv).

In animals receiving diazepam (10 mg/kg) plus Ro 15-1788 (1 mg/kg), the subsequent administration of PK 11195, 1 min after Ro 15-1788, reduces the antagonizing effect of the imidazobenzodiazepine. A synchronized pattern rich in spindles is present in the EEG, associated with behavioral sedation.

These data suggest that peripheral BZ receptor type located in CNS can modulate the sedative effects of diazepam.

252.4

THE EFFECTS OF DIAZEPAM ON THE BEHAVIORAL TOPOGRAPHY OF RATS IN AN ELEVATED RUNWAY. S.L.M. Widgiz and C.H.M. Beck. Department of Psychology, University of Alberta, Edmonton, AB, Canada T6G 2E9.

The elevated plus-maze test has proven to be a suitable procedure for providing a behavioral correlate in rats for the clinical efficacy of the anxiolytic effects of drugs. Normal animals spend 80 to 90% of their time in the two maze arms with enclosing walls (walled arms) and only 10 to 20% of their time in the arms without walls (open arms). The generally accepted explanation of the effect is that the animals are fearful of the cliff-like edges of the open arms (Pellow, S. et al., J. Neurosci. Meth., 14:149, 1985). This hypothesis is supported by the demonstration that anxiolytic drugs increase the amount of time spent in the open arms (ibid.). An alternative interpretation is that normal animals have a thigmotaxic tendency to stay close to walls, whereas tranquilized animals do not (Treit, D. & Fundytus, M., Pharmacol. Biochem. Behav., 31:959, 1989). We tested this hypothesis in an elevated runway with no enclosing walls, but instead with a wall on the centre line of one end of the runway (walled end). The other end of the runway had no walls (open end). Rats treated with saline spent 80 to 90% of a 5-min session in the walled end. Animals receiving 2.0 mg/kg of diazepam, ip., 30-min before the test, doubled the time spent in the open end by the saline animals, a replication of the effect in the elevated plus-maze. The results favour the thigmotaxic hypothesis since the two ends of the runway differed in the length of wall but not in the length of elevated edge.

252.5

THE EFFECTS OF RO15-4513 ON ETHANOL DRUG DISCRIMINATION LEARNING. M. Kautz, J. Logan*, A. Romero*, M. Schwartz*, and A. Riley.
Psychopharmacology Laboratory, The American University, Washington, D.C. 20016.

The imidazole, RO15-4513, a benzodiazepine inverse agonist with high affinity for central benzodiazepine receptor binding, has been shown to block several behavioral effects of ethanol, including its reinforcing, anxiolytic and intoxicating properties. The present study further examined the interaction of RO15-4513 and ethanol by assessing the ability of RO15-4513 to antagonize the stimulus properties of ethanol within the conditioned taste aversion paradigm. Specifically, every fourth day rats were given ethanol (1 g/kg) prior to receiving a pairing of saccharin with LiCl. On intervening days, they were given distilled water prior to nonpoisoned access to saccharin. Following acquisition of the discrimination, RO15-4513 (3.0 and 5.0 mg/kg) was given alone and in combination with various probe doses of ethanol. RO15-4513 had no effect on the ethanol discrimination. The basis for the differences between these findings and others reporting antagonism remains unknown, although recent reports noting that antagonism may require an interaction of the intrinsic effects of RO15-4513 and ethanol suggest that antagonism is not a necessary outcome of the drug combination.

252.6

DISCRIMINATIVE STIMULUS PROPERTIES OF THE ANXIOLYTIC BETA-CARBOLINE ZK 112119. J.S. Andrews* and D.N. Stephens* (SPON: M. Reddington) Dept. Neuropsychopharmacology, Schering AG, POB 650311, D-1000 Berlin 65, FRG

The beta-carboline ZK 112119 has been identified as a partial agonist at the benzodiazepine (BZ) receptor. ZK 112119 has anticonvulsant and anticonflict properties in rats and is currently in Phase II trials as an anxiolytic. ZK 112119 substitutes for chlordiazepoxide (CDP) in rats trained to discriminate CDP from vehicle. However, as ZK 112119 also antagonises several BZ effects it may be that the interoceptive stimuli differ. The interoceptive effects of ZK 112119 and CDP were compared using a drug-discrimination procedure. Rats were trained to discriminate CDP (5mg/kg) or ZK 112119 (0.5 mg/kg) from vehicle in a standard 2-lever procedure. Following training, generalisation and antagonism testing was carried out using both BZ and non-BZ receptor ligands. Generalisation to the CDP cue by full, eg diazepam, or partial agonists eg ZK 95962 and CGS 9896 was similar to previous reports. However, these substances did not substitute for ZK 112119, although as with CDP the discriminative stimulus could be blocked by BZ antagonists such as RO 15-1788. These results suggest that the stimulus properties of beta-carboline partial agonists, though BZ receptor mediated, differ from those of full receptor agonists.

252.7

DISCRIMINATIVE STIMULUS EFFECTS OF ANXIOLYTICS IN THE HIPPOCAMPUS. S. Gleeson* & J.E. Barrett (SPON: H.C. Holloway). Dept. of Psychiat., Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Drug discrimination studies can provide information about the mechanisms of drug action. For example, both benzodiazepine (BZ) and serotonin (5-HT) compounds are anxiolytic, but generalization between these two drug classes does not occur. Because the limbic system has been implicated in the effects of anxiolytics and is rich in both GABA/BZ and 5-HT receptors, we employed either intramuscular (i.m.) injections or direct injections into the hippocampus in a drug discrimination procedure. Pigeons' pecks on one of two keys were reinforced on a fixed-ratio 30 schedule following (i.m.) injections of buspirone (right key) or saline (left key). In substitution tests, both buspirone and 8-hydroxy-2-(di-*n*-propylamino)tetralin (8-OH-DPAT) resulted in generalization regardless of the route of administration, whereas hippocampal injections of midazolam produced primarily saline-key responding in all pigeons. Furthermore, i.m. injections of the putative 5-HT antagonist NAN-190 (1-(2-methoxyphenyl)-1-[4-(2-phthalimido)butyl] piperazine) attenuated the effects of hippocampal 8-OH-DPAT. The results suggest that receptors in the hippocampus are involved in mediating the discriminative stimulus and perhaps anti-conflict effects of 5-HT drugs, but not the effects of the benzodiazepines. Supported by DA-02873.

252.8

DISCRIMINATIVE STIMULUS CHARACTERISTICS OF A HIGH AND A LOW DOSE OF DIAZEPAM IN RATS. S.R.Franklin and A.H.Tang. CNS Research, The Upjohn Company, Kalamazoo, MI 49001

Two groups of rats were trained to discriminate either 1 mg/kg (LOW) or 10 mg/kg (HIGH) of diazepam (DZ) from IP injections of vehicle. The experimental paradigm was a 2-lever, FR-10 schedule for food reinforcement. For both dose groups, response rate at the training doses was equal to or greater than that in vehicle sessions.

Alprazolam, adinazolam, and pentobarbital completely generalized to both doses of DZ. Only pentobarbital reduced response rate at the dose of complete generalization. The benzodiazepine partial agonist, ZK 91296, generalized to DZ in the LOW group, but not in the HIGH group. Flumazenil (F) produced no drug-appropriate lever choice, and blocked the DZ cue effects from DZ or ZK 91296. Response rate was unchanged at the dose of cue-antagonism. The drug lever choice from pentobarbital in either group was not reversed by F, although F reversed the rate-reducing effect of pentobarbital. It is concluded that the DZ cue-effects in both HIGH and LOW groups are mediated by benzodiazepine receptors. It is not associated with sedation, as measured by reduction in response rate. There is a significant difference in the intensity of the drug cues, since the partial agonist generalized in the LOW dose, but not in the HIGH dose group.

252.9

EFFECTS OF NEONATAL TREATMENT WITH NORELEAGNINE ON ADULT MOTOR ACTIVITY AND CONVULSIONS INDUCED BY ELECTROSHOCK. P. McGuire, J. Tizzano, and D. Helton*. Pharmacol. and Toxicol., Ind. Univ. Med. Cen., Indianapolis, IN 46223, and Toxicol. Div., Lilly Res. Labs., Eli Lilly & Co., Greenfield, IN 46140.

Previously, it has been shown that neonatal treatment with noreleagnine (NOR) can result in increased juvenile activity in rats. This study examined potential persistent effects of such treatment on adult activity and electroshock-induced convulsions following NOR challenge. Twelve litters of CD rats were treated with NOR on postnatal days 13-20 (1 pup/sex/litter was dosed ip with 0, 2, 4 or 8 mg/kg/day NOR). There was no neonatal treatment related difference in adult baseline activity. When challenged with these doses as adults, dose-related decreases in activity were seen. Rats treated neonatally with 0 or 8 mg/kg were then challenged with 16 and 32 mg/kg NOR. Both doses decreased activity in a manner unrelated to neonatal treatment. Neonatal treatment did not alter the proportion of adult rats which showed tonic seizures produced by corneal electroshock. There also was no indication of a proconvulsant effect of NOR challenge with 32 mg/kg to adult rats treated neonatally with either 0 or 8 mg/kg. Neonatal treatment with NOR did not result in persistent changes in baseline motor activity, seizure susceptibility, or responsiveness in either end point after NOR challenge.

252.10

NEONATAL COCAINE TREATMENT DECREASED ACOUSTIC STARTLE RESPONSE LATENCY IN THE ADULT RAT. H. E. Hughes, L. A. Freed, L. A. Scribani*, T. H. Milhorat and D. L. Dow-Edwards. Laboratory of Cerebral Metabolism, Department of Neurosurgery, SUNY Health Science Center, Brooklyn, N.Y., 11203.

Our lab has demonstrated brain metabolic effects and changes in locomotor activity in adult female rats treated with cocaine during the first 20 days of postnatal life. The present study investigated the acoustic startle response (ASR) in adult rats treated with cocaine during this same period. Female littermates received 50 mg/kg/day cocaine HCl sc or vehicle during either 1-10 or 11-20 days of age. At age 90-100 days, animals from each group were tested on two consecutive days in an SR-Lab Startle Response System. Response amplitude was measured in voltage as the difference between the force of the animal at rest and at the height of the ballistic type movement that characterizes ASR. The latency to reach this maximum amplitude was also recorded. The results show that the latency to reach maximum ASR on the first trial was diminished on Day 2 of testing in the 11-20 day cocaine treated rats. There was no effect on response magnitude. These results are consistent with other studies that have dissociated ASR latency and magnitude (Horlington, M., *Physiol & Behav.*, 3: 839-844, 1968). Previous investigations using lesioning and stimulation have shown brain structures mediating ASR to include the v. cochlear nucleus, nuclei of the lateral lemniscus and v. nucleus reticularis pontis caudalis (Davis, M. et al., *J. Neurosci.*, 2: 791-805, 1982) We will report rates of brain glucose metabolism in ASR related structures of cocaine treated rats using the deoxyglucose method of Sokoloff. Supported by ADAMHA grant #DA04118.

252.11

BEHAVIORAL TOXICITY OF ORALLY ADMINISTERED COCAINE IS GREATER IN MALE, COMPARED WITH FEMALE S.-D. RATS. S.B.Sparber and M. Kubak* (SPON: G. Wilcox). Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

Prior to injection of pregnant rats with cocaine HCl, p.o., to determine the effects of this drug, if any, upon mature offspring exposed *in utero*, we compared the effects of 3 daily doses of 15 mg/kg or 45 mg/kg, spaced 3 hr & 40 min apart, upon food reinforced fixed ratio 15 operant behavior of rats maintained at 90% of their free-feeding weights (females: 274-324 gm; males: 459-599 gm, ca. 165 days old). Rats were given water (2 ml/kg) or cocaine 55 min after their 1st 15 min behavior session of the day and the effects of cocaine were measured 30 min and 2 hr & 30 min after treatment. Acute and subacute behavioral toxicity, including carryover effects from previous days' treatment, could thus be determined during subsequent daily sessions. Results indicated that the low dose of cocaine (15mg/kg x3/day) produced minimal behavioral suppression acutely or subacutely, 30min or 2 hr & 30 min after dosing of either sex (N=3/group). The high dose (45mg/kg x3/day) caused significant suppression of behavior 30 min, but not 2 hr & 30 min after the 1st dose, but only in the males. Carryover effects were evident in males given the high dose; behavior was suppressed prior to and after treatment. Females given the high dose started to show suppressed behavior 30 min after the 2nd daily dose after several days of treatment. We conclude that oral treatment of pregnant rats with such doses distributed over 8-10 hr should enable us to maintain exposure of the dam (and fetuses) without resorting to multiple i.p. or s.c. injections of pregnant rats, which lead to problems caused by local vasoconstriction, intrauterine injection and limited exposure to this short-acting drug of abuse. Supported in part by USPHS grant DA04979.

252.12

POST-CONDITIONING DRUG EFFECTS ON CONDITIONED PLACE PREFERENCE INDUCED BY THE COADMINISTRATION OF MAGNESIUM AND COCAINE. S.I. Lawley and K.M. Kantak. Lab. of Behav. Neurosci., Dept. of Psychol., Boston University, Boston, MA 02215.

It was hypothesized that $MgCl_2$ and cocaine would have interactive rewarding stimulus effects in a conditioned place preference (CPP) paradigm, using a submaximal dose of cocaine, based upon data which show a robust conditioning effect of 5 mg/kg cocaine and a moderate conditioning effect of 15 mg/kg $MgCl_2$. The interaction of 15 mg/kg $MgCl_2$ with 0.612 mg/kg cocaine was found to produce stronger conditioning effects than other submaximal dose combinations. In animals where this dose combination switched side preference, the acute administration of amphetamine (1.0 mg/kg) potentiated CPP relative to saline, haloperidol, or pentobarbital. Previously reported results show that this dose of amphetamine potentiates cocaine-induced CPP (using 5.0 mg/kg) and $MgCl_2$-induced CPP (using 15 mg/kg). In the present set of experiments, pentobarbital (10 mg/kg) attenuated cocaine + $MgCl_2$ CPP. It was previously shown that pentobarbital attenuates cocaine-induced CPP, whereas it maintains $MgCl_2$ induced CPP. Haloperidol (0.25 mg/kg) attenuated cocaine + $MgCl_2$ CPP as it does when each drug is used alone as the conditioning agent. It appears that the coadministration of MgCl2 with a submaximal dose of cocaine enhances the potency of cocaine and produces a profile of post-conditioning drug effects more similar to cocaine than MgCl2.

252.13

LONG TERM PREEXPOSURE TO MAGNESIUM INHIBITS THE REWARDING EFFECTS OF SELF ADMINISTERED COCAINE. K.M. Kantak, J.F. Bourg* and S.I. Lawley. Lab. of Behav. Neurosci., Dept. of Psychol., Boston University, Boston, MA 02215.

Previous research has shown that $MgCl_2$ robustly substitutes for self administered cocaine in rats in a dose dependent manner such that a steady intake pattern of $MgCl_2$ is maintained in the absence of cocaine. In contrast, in drug naive rats, $MgCl_2$ fails to be self administered which indicates that $MgCl_2$ has low abuse potential. These data are consistent with data obtained in a conditioned place preference procedure, and with a number of studies showing that $MgCl_2$ has stimulant - like behavioral effects. Additional research has shown that the disruptive effects of chronic cocaine on D1 receptor binding and on aggressive behavior could be prevented by concurrent administration of $MgCl_2$. Thus, besides serving as a non-addictive substitute for cocaine, $MgCl_2$ appears to have prophylactic effects against cocaine. This notion was further studied in the present experiments in drug naive rats who contingently responded for I.V. $MgCl_2$ for 4 weeks prior to access to I.V. cocaine. Normally, rats acquire a response for cocaine on the first day or two of access to cocaine. Preexposure to hypertonic saline results in a typical cocaine access pattern as well. In contrast, preexposure to $MgCl_2$ prevents the acquisition of a response for cocaine, even after two weeks of exposure to cocaine. The animals show a typical extinction curve of responding which indicates that cocaine is not rewarding under these conditions.

252.14

COCAINE AND OTHER LOCAL ANESTHETICS AS DOPAMINE AGONISTS. P.B. Silverman. Dept. of Psychiatry, U. Texas Health Science Ctr., Houston, TX 77030

Cocaine and some local anesthetics are self-administered and have similar stimulus properties. But unlike cocaine, other locals have little if any documented dopamine (DA) agonist activity. In order to determine if local anesthetics have previously undetected psychomotor stimulant-like effects, we tested locals in a unilaterally lesioned rodent preparation sensitive to both direct and indirect dopamine agonists. Under pentobarbital anesthesia, rats were lesioned in one substantia nigra by 6-hydroxydopamine infusion. They were subsequently tested for rotational behavior after apomorphine, cocaine and one or more of the locals.

Cocaine (10 mg/kg; 29 μmol/kg) induced ipsilateral rotation in the lesioned rats indicating indirect DA agonist activity. Chloroprocaine, etidocaine, lidocaine, mepivacaine, procaine and tetracaine induced no significant rotation. Dimethocaine at 50 and 100 μmol/kg, induced ipsilateral rotation at rates comparable to cocaine. Ritz et al. (Science 237:219, 1987) have reported a common DA uptake binding site for cocaine, related compounds and local anesthetics. Significantly, the local with highest affinity for the site is dimethocaine.

INTERACTIVE EFFECT OF COCAINE AND CAFFEINE AS ASSESSED BY CONDITIONED PLACE PREFERENCE. J. B. Bedingfield* and F.A. Holloway. (SPON: A.M. Revzin) University of Oklahoma Health Sci. Ctr., Oklahoma City, OK 73190-3000.

The conditioned place preference (CPP) paradigm is a behavioral assay where previously neutral environmental stimuli are classically conditioned to interoceptive drug-induced stimuli. CPP is an animal analogue to the "rewarding" effects of drugs in man. Eight groups of male Sprague-Dawley rats (n=9/group) were trained in the CPP paradigm using saline, cocaine (COC; 1.0, 3.2, or 5.6 mg/kg), or caffeine (CAF; .32 or 1.0 mg/kg) as conditioning stimuli. Saline failed to produce a significant level of CPP, but both COC and CAF produced dose-dependent increases in the amount of time subjects spent in the drug-paired environment. CPP was robust and statistically significant. When a marginally effective dose of COC (1 mg/kg) was combined with a marginally effective dose of CAF (1.0 mg/kg), a strong CPP resulted. When a non-effective dose of CAF (.32 mg/kg) was combined with a non-effective dose of COC (.32 mg/kg), a robust CPP again resulted. These results suggest that at certain doses, caffeine acts in a multiplicative fashion with cocaine. Motivational effects of these combinations may contribute to an abuse liability greater than each drug separately.

CROSS-GENERALIZATION BETWEEN COCAINE AND "LEGAL" STIMULANTS. F.A. Holloway, D.V. Gauvin*, and K.M. Moore*. Department of Psychiatry and Behavioral Sciences, University of Oklahoma Health Sciences Ctr., Oklahoma City, OK 73190-3000.

To examine the abuse liability of "legal" over-the-counter stimulants, 4 groups of male Sprague-Dawley rats were trained in a two-choice drug discrimination task. Phenylpropanolamine (PPA; 17.8 mg/kg) or Ephedrine (EPH; 10 mg/kg), or Caffeine (CAF; 42 mg/kg), or a combination of these three stimulants (CEP; 15 mg/kg CAF, 3 mg/kg EPH, and 6 mg/kg PPA) and saline served as stimuli in separate groups (n=12/group). PPA and EPH groups displayed symmetrical cross-generalization between PPA and EPH. Each element of the CEP compound training stimulus produced at least partial generalization to that stimulus. Tests with cocaine resulted in complete generalization to the PPA, EPH, and CEP training stimuli. Cocaine produced only partial generalization to the CAF training stimulus. We have previously reported that a CEP compound test stimulus generalized to a cocaine training stimulus (Life Sciences, 44, 67-73). Such symmetrical cross-genereralization between cocaine and CEP suggest an abuse liability of these "legal" over-the-counter stimulants that is greater than would be predicted from existing self-administration data.

d-AMPETAMINE, MDMA, AND PCP EFFECTS ON AGGRESSIVE AND CONDITIONED BEHAVIOR: 5-HT AND DOPAMINE ANTAGONISTS. M. Haney*, K.A. Miczek (SPON: H.B. Barry III). Dept. Psychology, Tufts Univ., Medford, MA 02155.

Dopamine and 5-HT receptors maybe significant in several behavioral effects of amphetamine, MDMA and PCP. We developed an experimental preparation that permitted the concurrent assessment of behavioral performance under the control of a multiple schedule of reinforcement as well as aggressive behavior by a resident toward an intruder. First, the rate-increasing effects of amphetamine and, to a lesser extent, of MDMA and PCP were confirmed. Second, an aggression test was incorporated into the conditioning session. After ca. 22 min in the conditioned performance task, the mice confronted an intruder in their home cage for ca. 5 min, and then completed the remainder of the conditioning session. Aggressive behavior disrupted conditioned performance only transiently, and eventually enhanced responding in the second half of the conditioning session. Amphetamine, but not MDMA or PCP, increased aggressive behavior in a subset of individual subjects. The dose-effect curves for the suppression of aggressive behavior by amphetamine, MDMA and PCP paralleled those for FR and FI performance. SCH23390 blocked the enhancing but not the suppressive effects of amphetamine on FI performance and aggressive behavior. When mice were pretreated with 5-HT_2 receptor antagonists, MDMA and amphetamine decreased aggressive behavior and operant performance at lower doses than before. These observations indicate experience with aggressive behavior shares some rate-increasing effects with amphetamine. The D_1 antagonist effects suggest a role of this receptor subtype in the activation of aggressive and conditioned behavior by amphetamine.

252.18

NON-NEUROTOXIC RIGID ANALOGS OF 3,4-METHYLENEDIOXY-AMPHETAMINE (MDA). D. E. Nichols, W. K. Brewster* M. P. Johnson* R. Oberlender* and R. M. Riggs* Depts. of Pharmacol. and Toxicol., and Med. Chem. and Pharmacog., School of Pharmacy, Purdue Univ., W. Lafayette IN 47907.

MDMA and its α-ethyl analog (MBDB) have novel behavioral characteristics inconsistent with their classification as either hallucinogens or stimulants (Nichols et al., J. Med. Chem. 29:2009, 1986). Both MDMA and MBDB are selective neurotoxins for serotonin terminals (Johnson et al., Pharmacol. Biochem. Behav., in press).

Several methylenedioxy-substituted aminoindans and aminotetralins were examined in the rat drug-discrimination paradigm for MDMA or LSD like effects and were screened for serotonin neurotoxicity. Both 5,6-methylenedioxy-2-aminoindan (5,6-MDAI) and 6,7-methylenedioxy-2-aminotetralin (6,7-MDAT) but not 4,5-MDAI or 5,6-MDAT substituted for MDMA in drug-discrimination experiments. The ED_{50} values and 95% confidence limits were 0.64 (0.46-0.89), 0.59 (0.34-1.00), and 1.29 (0.75-2.21) mg/kg for MDMA, 5,6-MDAI and 6,7-MDAT, respectively. None of the compounds substituted for LSD. One week after a 40 mg/kg s.c. injection of 5,6-MDAI and 6,7-MDAT there was no change in any rat brain monoamine or metabolite level examined. There was also no change in B_{max} values for [^{3}H]-paroxetine binding, a measure of the number of serotonin uptake sites. In contrast, 40 mg/kg s.c. of MDMA significantly decreased 5-HT and 5-HIAA levels and decreased the B_{max} for [^{3}H]-paroxetine binding.

252.19

EFFECTS OF CAFFEINE ON FLASH EVOKED POTENTIALS OF HOODED RATS. B.E. Hetzler and A.C. Bauer*. Department of Psychology, Lawrence Univ., Appleton, WI 54912.

Caffeine is a widely consumed behavioral stimulant. However, its effects on evoked potentials have not been well characterized. In the present study, flash evoked potentials (FEPs) were recorded from the visual cortex of hooded rats 30 min following i.p. injections of distilled water, and of 25 and 100 mg/kg caffeine on separate days. Rats were tested at a standard (22°C) ambient temperature. The 25 mg/kg dose did not significantly alter the amplitude or latency of any FEP component. Amplitudes of components P2 and N3 were significantly reduced by the 100 mg/kg dose, and a reduction in the amplitude of component P3 approached significance. In contrast, the latencies of only the early components were significantly altered by the 100 mg/kg dose. Components P1, N1, and P2 were increased in latency by 1.42, 1.58, and 2.66 msec, respectively.

The increased latencies may be at least partially explained by caffeine-induced hypothermia. In a separate experiment, a 100 mg/kg dose produced hypothermia of about 0.5°C. The amplitude data suggest that manipulation of the brain adenosine system results in selective alterations of FEP components, since caffeine is an adenosine receptor antagonist. However, only the high dose of caffeine resulted in significant changes, so it is also possible that non-adenosinergic mechanisms are involved. UNILATERAL INTRASTRIATAL CAFFEINE PRODUCES A CONTRALATERAL BIAS IN THE TURNING BEHAVIOR OF RATS R J Beninger and S.A. Josselyn*. Dept. Psychol., Queen's University, Kingston, K7L 3N6, Canada

Caffeine stimulates locomotor activity but its site of action in the brain has not been established. Thus, the present study was undertaken to assess the possible effects of unilateral intrastriatal microinjections of caffeine on turning behavior in rats. 17 rats were implanted with chronic cannulae placed in the dorsoanterior striatum. They received 7 20-min tests, each separated by 72 h, in circular arenas (30 cm diam). The first and last sessions were preceded by no injection, the second and sixth by saline (1.0 µl) injections and the remaining three by caffeine (1.0, 10 or 20 µg in 1.0 µl), the order of doses being counterbalanced across rats. The total number of complete turns in each direction was recorded for each session. Results revealed no significant turning bias in rats receiving no injection or saline either before or after caffeine sessions. The low dose of caffeine produced no effect but the two higher doses produced a contralateral turning bias. Furthermore, the highest dose produced an increase in the total number of turns These results suggest that caffeine may produce its stimulant effects at least in part by an action in the striatum. SIMULTANEOUS ASSOCIATIONS OF TASTES WITH NICOTINE. F.W. Flynn, D. Dracos and C. Ksir. Dept. of Psychology and Neuroscience Program, Univ. of Wyoming, Laramie, WY 82071.

Depending on the contingencies and doses, nicotine is reinforcing or an aversive stimulus to animals. Flynn, Webster and Ksir (1989) reported that, over days, rats develop a significant preference for a 1 µg/ml nicotine solution. In the current experiment, a simultaneous association procedure was used in an attempt to further demonstrate nicotine's reinforcing property in rats. On alternate days rats were given 1-bottle access to either a compound of a neutral taste (CS+) mixed with nicotine or a different taste stimulus presented alone (CS-) for 1 h/day. Rats having access to the compound solution with 1 µg/ml nicotine ingested 17.5 ± 0.7 µg of nicotine during each exposure and rats having access to the 5 µg/ml concentration ingested 61 ± 7 µg nicotine during each 1 h CS+ exposure, $p < .01$. Two-bottle preference tests between the CS+ and CS- were conducted every 14 days for 56 days. For each of the 4 tests, the preference ratios for tastes associated with 1 µg/ml nicotine (51 ± 3%) were greater than the preference ratios for tastes presented as a compound with 5 µg/ml nicotine (21 ± 3%), $p < .01$. In the present procedure, 1 µg/ml nicotine was found to have neither reinforcing nor aversive consequences whereas intake of 5 µg/ml nicotine was shown to have aversive consequences.

253.2

TOLERANCE TO ANXIETY-LIKE EFFECT OF NICOTINE (NIC) IN RATS. C. M. Harris and H. Lal, Depts. of Pharmacology, NYCOM, Old Westbury, NY 11568, and TCOM, Fort Worth, TX 76107.

NIC produces a stimulus similar to that of the anxiogenic drug pentylenetetrazol (PTZ) (Harris et al., Psychopharmacol., In Press). Eight rats trained to discriminate PTZ, 20 mg/kg, from saline in a 2-lever choice task were tested for tolerance to this effect during chronic NIC treatment. NIC base was infused at 0.477 ul/hr via Alzet osmotic pump. Rats first detected a PTZ-like direct effect of NIC (50% selected PTZ lever), then exhibited signs of toxicity, then recovered normal overt behavior and ceased to detect the PTZ-like effect of NIC. Convulsions abated by day 4; failure to eat and to complete the food-reinforced lever-choice task abated by day 6; selection of the PTZ-lever declined to 12.5% by day 10. After pump removal on day 12, a PTZ-like withdrawal effect emerged within 24 hours, as in a previous study (Harris et al., Psychopharmacol. 90:85-89, 1986). Within three days rats regained sensitivity to the PTZ-like effect of NIC (stimuli produced by withdrawal and by high doses of NIC were additive) but remained tolerant to the disruptive effect of NIC in the lever-choice task. Supported by AOA 82-11-045 and NIH-BRSG RR05879.

253.3

EFFECTS OF THE ACUTE AND CHRONIC ADMINISTRATION OF MK-801 ON BEHAVIOR AND BODY TEMPERATURE IN THE RAT. R.N. Pechnick, M. Hiramatsu*, R. George*, A.K. Cho and E. Di Stefano*. Department of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024-1735

Phencyclidine (PCP) binds to PCP and sigma receptors, but the differential roles of these two receptors in mediating the effects of PCP is not currently known. MK-801[(+)-5-methyl-10,11-dihydro-5H-dibenzo[a,d]-cyclohepten-5,10-imine maleate] has been found to have a high degree of selectivity for PCP over sigma receptors. The present study characterized the effects of the acute and chronic administration of MK-801 on behavior and body temperature in the rat. Like PCP, the acute administration of MK-801 produced ataxia, locomotion, sniffing and head weaving. MK-801 produced hyperthermia, in contrast to the hypothermia observed after the acute administration of PCP. There was tolerance to MK-801-induced ataxia after 6 days of daily administration; however, the hyperthermic response was enhanced. PCP produced less ataxia in chronically MK-801-treated rats, indicating the development of cross-tolerance. However, PCP, at a dose that did not affect body temperature in chronically saline-treated rats, caused hyperthermia in chronically MK-801-treated subjects, indicating the development of cross-sensitization to the effects on body temperature. The differences in response were not due to changes in biodisposition as the plasma levels of PCP were not significantly different. These results suggest that both MK-801 and PCP may produce ataxia by interacting with PCP receptors; however, PCP-induced hypothermia must be caused by interactions with receptors other than the PCP receptor. (Supported NIDA grants DA-02411, DA-04113 and DA-05448).

253.4

EFFECTS OF ACUTE ADMINISTRATION OF (+)-PENTAZOCINE ON BODY TEMPERATURE IN THE RAT. M. Bejanian[1], R.N. Pechnick[1], R. George[1], A. Thurkauf[2*], A.E. Jacobson[2*] and K.C. Rice[2]. Department of Pharmacology[1] and the Brain Research Institute, U.C.L.A. School of Medicine, Los Angeles, CA 90024-1735, and Lab. of Neuroscience[2], NIDDK, Bethesda, MD 20892.

(+)-Pentazocine has a greater selectivity for sigma versus phencyclidine receptors. The current study investigated the effect of acute administration of (+)-pentazocine on the body temperature of the rat. Baseline rectal temperatures of adult male Sprague-Dawley derived rats were recorded and the rats were injected subcutaneously with saline or (+)-pentazocine (20, 40 or 80 mg/kg). Rectal temperatures were recorded at 30 minute intervals for 180 minutes post-injection. Administration of 80 mg/kg (+)-pentazocine resulted in significant hypothermia when compared to saline-injected rats and rats injected with 20 and 40 mg/kg (+)-pentazocine. The hypothermic effect of 80 mg/kg (+)-pentazocine was evident for 120 minutes post-injection and was followed by a hyperthermic response. (+)-Pentazocine at doses of 20 and 40 mg/kg did not cause hypothermia, but showed a hyperthermic response in the rats at 120 minutes post-injection. In conclusion, (+)-pentazocine has a biphasic effect on body temperature such that at the dose of 80 mg/kg it causes an initial hypothermic response followed by hyperthermia. At the lower doses, only the hyperthermic response is evident. These results along with evidence from the studies of other selective ligands suggest that there may be different mechanisms underlying the hypothermic and hyperthermic effects of (+)-pentazocine. (Supported by NIDA grants DA-04113 and DA-05448).

253.5

PHENCYCLIDINE (PCP) EXPOSURE IN HUMAN ADDICTS DOES NOT ALTER REGIONAL SIGMA (σ) BINDING. A.D. Weissman, M.F. Casanova* and E.B. De Souza. Neurobiology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224; Clinical Brain Disorders Branch, NIMH, Washington, DC 20032.

PCP is an abused drug which is capable of precipating psychotic episodes in man. Some of the psychotomimetic properties of PCP are thought to be mediated by interactions with σ binding sites. Alterations in the σ site have also been associated with schizophrenia (Weissman et al., Soc. Neurosci. Abstr. 14, 104, 1988). The present study sought to examine whether chornic exposure to PCP in human addicts would alter σ binding in postmortem brain tissues. Saturation studies of [^{3}H]haloperidol binding in the presence of 50 nM spiperone were performed in the brains of addicts who had died by suicide and had high postmortem blood levels of PCP. Age and postmortem interval matched individuals who had committed suicide, but had no history or postmortem evidence of abusing drugs, served as controls. In our previous studies, both suicide and normal individuals showed similar σ binding. The present study showed that the affinity (K_D) and number of binding sites (B_{max}) was not different in the brain of PCP addicts in occipital, frontal and anterior cingulate cortex as well as in hippocampus and cerebellum. Potential changes in brain PCP binding sites are currently being examined in these tissues. The results suggest that the brain σ binding site remains unchanged in humans despite repeated challenges with a potent psychotomimetic drug.

253.6

THE SIGMA ANTAGONIST (±)BMY14802 DOES NOT REVERSE (+)N-ALLYLNORMETAZOCINE-INDUCED BEHAVIORAL CHANGES IN MEMBERS OF A NONHUMAN PRIMATE SOCIAL COLONY. **D.J. McGinness*, R.F. Schlemmer, Jr., N.L. Katz, J.M. Davis. Univ. of Illinois at Chicago & Illinois State Psychiatric Inst., Chicago, IL 60612.**

(+)N-Allylnormetazocine (NANM) is a drug that is commonly used as a sigma agonist in psychopharmacological studies. (+)NANM induces several significant behavioral changes in selected members of Stumptail macaque social colonies (McGinness et al., Neurosci. Abst. 14:525, 1988). The present study sought to determine if the preferential sigma antagonist and antipsychotic candidate (±)BMY14802 could reverse the behavioral changes induced in monkeys by (+)NANM. The subjects were 4 adult Stumptail macaques who formed a stable social colony. Following observation of baseline behavior, each monkey received treatment with (+)NANM (1 mg/kg, i.m.), then 3 escalating doses of (±)BMY14802 (3-10 mg/kg, i.m.) alone & in combination with (+)NANM. Only 2 monkeys received drug treatment/day & at least 72 hr separated each drug treatment. Two 1 hr observation sessions were conducted each day by a "blind" observer who rated behavior in the entire colony. The first observation session began 2 hr after administration of BMY14802. The second session began 30 min after the first concluded & was preceded by an injection of (+)NANM or saline 15 min before the next observation. In agreement with our previous study, (+)NANM decreased initiated social grooming, self grooming, checking (visual scanning) & locomotion, and increased resting with eyes open. None of the BMY14802 doses significantly antagonized the (+)NANM-induced behavioral changes. The results suggest that the behavioral changes induced by (+)NANM cannot only be attributed to mediation by sigma binding sites. One plausible explanation would be that behavioral effects of (+)NANM may be mediated by PCP receptors.

253.7

BOTH MORPHINE AND COCAINE INCREASE GLUCOSE METABOLISM IN THE OLFACTORY TUBERCLE IN FREELY-MOVING RATS.
D. Huston-Lyons, L.J. Porrino#, G.T. Bain*, and C. Kornetsky, Boston University School of Medicine, Boston, MA, #NINCDS, Bethesda, MD.

Although cocaine (COC) and morphine (MS) have markedly different spectra of actions on most behaviors, they are abused by humans, self-administered by animals, and facilitate brain-stimulation reward. However, previous experiments have reported that COC (ip) had little or no effect (London et al., 1986) and MS (sc) decreased or had no effect (Ito et al., 1983) on rates of local cerebral glucose utilization (LCGU) in structures of the meso-corticolimbic dopamine system, a system directly involved in motivation and drive. In order to compare the effects of COC and MS in the same laboratory and under the same conditions, the 2-[14-C]deoxyglucose method was used to determine rates of LCGU following the administration of COC 10 mg/kg (ip) or MS 4 mg/kg (sc) to freely-moving rats. COC increased LCGU in the olfactory tubercle (OT), medial prefrontal cortex, and substantia nigra reticulata. MS, however, caused a significant LCGU increase only in the OT, with either a decrease or no effect in other structures. Because of the significant role of the OT in the motivational system of the rat, these results support an hypothesis that drug-induced euphoria caused by COC or MS is mediated, at least in part, by activation of similar forebrain areas. (Supported in part by NIDA grant DA02326 and Research Scientist Award DA00099 to CK).

253.8

QUALITATIVE DIFFERENCES IN HEROIN AND COCAINE SELF-ADMINISTRATION BEHAVIOUR. D.C.S. Roberts and S.A.L. Bennett*, Department of Psychology, Carleton University, Ottawa, Ont., K1S-5B6.

Differences between heroin and cocaine motivated behaviour were investigated using progressive ratio (PR) schedules of reinforcement. On one schedule, the first response of the daily test session resulted in an IV injection. Thereafter, the response requirements increased through an escalating series (2,4,6,9,12,...). Breaking-points were defined as the last ratio completed prior to one hour of non-reward. On this schedule, animals self-administered cocaine in a regular fashion then stopped abruptly at relatively high "breaking-points". By contrast, rats responding for IV heroin self-administered in an irregular pattern, often pausing for long periods only to resume later. In general the breaking-points were substantially higher for cocaine (0.6mg/inj) than for heroin (25 ug/inj). On a different PR schedule, the requirements regulating reception of the session's first injection were adjusted. Higher breaking-points were obtained under heroin reinforcement than under cocaine. Animals often failed to respond for cocaine reinforcement without "priming," whereas rats would respond 60-80 times for their first injection of heroin without "priming". These data demonstrate that the intense motivation to receive heroin is diminished after the first few injections. The motivation to receive cocaine is cocaine-induced. (Supported by the M.R.C)

253.9

TOLERANCE TO MORPHINE-LIKE STIMULUS EFFECTS OF AGONIST AND AGONIST-ANTAGONIST MU OPIOIDS IN RATS. A.M. Young, G. Kapitsopoulos*, and E.S. Steigerwald*. Department of Psychology, Wayne State University, Detroit, MI 48202.

Experiments evaluated the ability of repeated treatment with morphine (MS) to confer tolerance to the MS-like discriminative stimulus effects of methadone (MET), nalbuphine (NBP), and buprenorphine (BUP). Male Sprague-Dawley rats were trained to discriminate saline and 3.2 mg/kg MS under FR15 schedules of food delivery. After establishment of stimulus control, cumulative doses of MET (0.1-3.2 mg/kg), BUP (0.00032-0.32 mg/kg), and NBP (0.032-5.6 mg/kg) were tested for generalization in separate groups of rats (N = 5 or 6). Then, training was halted and a dose of 10 mg/kg MS was administered b.i.d. for 14 to 17 days. Each drug was tested for generalization on the 7th and 14th day of MS treatment and at selected times after treatment ended. One or two weeks of MS treatment increased by 2- to 3-fold the doses of MET or BUP required for generalization. In contrast, repeated MS treatment produced an insurmountable increase in the dose of NBP required for generalization, so that doses of 32 to 56 mg/kg evoked only 40% MS-appropriate responding and suppressed response rates slightly. After MS treatment ended, the doses of MET or NBP required for generalization returned to initial values within 1 week; those of BUP, within 2 weeks. Such differential tolerance suggests that NBP has lower efficacy as a MS-like stimulus than do MET and BUP. (DA-03796.)

253.10

ACUTE DEPENDENCE AND WITHDRAWAL IN NEONATAL CHICKENS. M.E. Bronson* and S.B. Sparber. Dept. of Pharmacology, University of Minnesota, Minneapolis, MN 55455.

The importance of studying consequences of opioid exposure during development includes the need to study effects of withdrawal from opioids, which may be more detrimental than exposure to the opioid itself. Accordingly, we have previously used the chick embryo to study this phenomenon during earlier development and now report acute opioid dependence and withdrawal in neonates of this species. To characterize the signs of withdrawal, various doses of naloxone (Nx) were administered 1 hour after 8 mg methadone (M)/kg. Isobutylmethylxanthine (IBMX) was also given without prior opioid exposure to study quasi-opioid withdrawal. All drugs were given i.p. In chicks pretreated with M, mild to moderate withdrawal, after 0.8 mg Nx/kg, was manifest as distress vocalization and head shaking. More severe withdrawal (8-32 mg Nx/kg or 20 mg IBMX/kg) caused tremor, wing extension, splayed feet and , at the highest dose of Nx, loss of righting reflex and apparent convulsions. Some of these signs were observed in saline pretreated 1 day-old chicks injected with 48-64 mg Nx/kg, suggesting greater sensitivity to nonspecific actions of very high doses of Nx, or sensitization due to high titers of endorphins which may be caused by the hatching process, since most of these signs were not observed in older (ie., 3 day-old) chicks injected with 64 mg Nx/kg. These data demonstrate the utility of using the chick neonate to study further the consequences of dependence and/or withdrawal alone (IBMX) during early development in the absence of maternal influences. Supported by USPHS grant DA01880 and T32 DA 07097.

MORPHINE PHYSICAL DEPENDENCE DURING HYPOTHERMIA IN THE GROUND SQUIRREL (CITELLUS LATERALIS). M.L. Jourdan*, A.L. Beckman, and L.C.H. Wang*. Dept. of Zool., Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E9 and Dept. of Psychol., California State Univ., Long Beach, CA 90840.

To test the possibility that hibernation induced blockade of morphine dependence (Beckman et al., Science 212:1527, 1981) may be due to the low body temperature (Tb) associated with deep hibernation, we examined the development of morphine dependence during deep hypothermia.

Morphine (M; 55 μg/hr), naloxone (Nx; 5 μg/hr) or artificial cerebrospinal fluid (aCSF; 1 μl/hr) were infused continuously via a chronic cannula in the lateral cerebral ventricle during 48 hr of induced hypothermia (Tb: 7°C). M-infused, aCSF-infused, and sham animals (no infusion) injected with Nx (1 mg/kg, s.c.) upon rewarming to normal Tb showed typical abstinence signs. Infusion of Nx during hypothermia significantly decreased the total amount of Nx-precipitated abstinence behavior below that of the other three groups.

The results suggest that the hibernation-block of morphine dependence is not due to low Tb alone. Further, the abstinence behavior of aCSF-infused and sham animals suggests that deep hypothermia is a stress that substantially increases the activity of brain opioid peptide systems.

INTERACTIONS BETWEEN SUCROSE FEEDING AND MORPHINE DEPENDENCE AND WITHDRAWAL. D.S. Roane*, G. Scheonbaum* and R.J. Martin (SPON: C. Phelix). Dept. of Foods and Nutrition, Univ. of Ga., Athens, Ga. 30602.

This study examines the effect of dietary sucrose on the development of tolerance to morphine analgesia and on the severity of subsequent naloxone-precipitated withdrawal.

In the first experiment, 15 male albino rats fed a 20% sucrose supplement ad libitum were given injections of morphine sulfate, (20 mg/kg) every 12 hours for one week. Tail flick latencies were measured every a.m. Tolerance to morphine analgesia developed similarly in sucrose-fed and control rats. Withdrawal was precipitated with naloxone HCl (2 mg/kg). Subsequent 18 h. weight loss - an index of withdrawal severity - was similar between sucrose-fed and control rats. During the development of tolerance sucrose consumption followed a bi-phasic pattern, first decreasing and subsequently increasing. Sucrose-fed animals were hyperphagic during withdrawal, consuming most of their dietary energy from sucrose.

In the second experiment 30 animals were assigned to the sucrose group and were treated as before. Immeditately prior to precipitated withdrawal sucrose access was denied to half this group. The severity of withdrawal, in terms of 18 h. weight-loss, was greater in the sucrose-denied group as compared to both the sucrose-maintained or control animals. The abrupt change in diet exacerbated a deleterious effect of precipitated morphine withdrawal.

ROLE OF SPINAL AND MEDULLARY α-ADRENERGIC RECEPTORS IN THE ANTI-MORPHINE WITHDRAWAL ACTION OF CLONIDINE. J.J. Buccafusco (SPON: F. Carl). Dept. Pharmacology and Toxicology, Medical College of Georgia and Veterans Administration Medical Center, Augusta, GA 30912.

Clonidine and related drugs have proved to be particulary useful in treating the autonomic symptoms narcotic withdrawal in addicts. The site of action of clonidine has been ascribed to the pontine locus coeruleus, however, recent studies in this and other laboratories have suggested that the spinal cord mediates many of the symptoms morphine withdrawal in the rat. We have also demonstrated that the magnitude of the increase in post-withdrawal mean arterial pressure (PWMAP) provides a direct index of the degree and intensity of the withdrawal response. Rats were made dependent upon morphine following a schedule of increasing dosage of morphine infused over a 5 day period through a permanent arterial catheter. They were also prepared either with chronic intrathecal (IT) or intracisternal (IC) catheters. Withdrawal was precipitated with 5mg/kg of naloxone injected through the i.a. line or by 60μg though the IT line. Naloxone produced a 30-45mmHg increase in PWMAP which lasted for 30-45min. Rats also exhibited several behavioral signis of withdrawal, including body shakes and escapes. Pretreatment with clonidine (0.5-10μg) IT produced a dose-dependent inhibition of the PWMAP elicited by i.a. naloxone. Clonidine administered IC did not affect precipitated withdrawal. When withdrawal was precipitated by IT naloxone, clonidine pretreatment did not alter the PWMAP. These results are consistent with a spinal site for the antiwithdrawal effect of clonidine, if the withdrawal response originates from higher centers. Sup: Vet. Admin.

STRAIN-SPECIFIC FACILITATION OF BRAIN STIMULATION REWARD BY Δ⁹-TETRAHYDROCANNABINOL IN LABORATORY RATS IS MIRRORED BY STRAIN-SPECIFIC FACILITATION OF PRESYNAPTIC DOPAMINE EFFLUX IN NUCLEUS ACCUMBENS. E.L. Gardner, J. Chen*, W. Paredes*, J. Li*, and D. Smith* (SPON: L. Goodman). Departments of Neuroscience and Psychiatry, Albert Einstein College of Medicine, New York, NY 10461.

We previously showed that Δ⁹-tetrahydrocannabinol (THC), the psychoactive constituent of marijuana, acutely facilitates brain-stimulation reward in the rat (Gardner et al. Psychopharmacology 96:142, 1988), and that this facilitation is rat strain-specific (Gardner et al. Collegium Internationale Neuro-Psychopharmacologicum 1988), implicating genetic variation in vulnerability to the brain reward facilitating effects (and thus, presumably, to euphorigenic effects and abuse potential) of marijuana. Due to the postulated role of CNS dopamine (DA) systems in mediating and/ or modulating the rewarding properties of drugs of abuse (Spyraki et al. Psychopharmacology 79:278 1983), we have now carried out in vivo microdialysis studies to see if the strain-specific brain-reward enhancing effects of THC are mirrored by strain-specific effects of THC on basal presynaptic DA efflux in the nucleus accumbens (Acc), a crucial anatomic convergence of brain-reward-relevant DA circuity. Lewis strain rats, which show robust brain-reward enhancement by THC, showed robust enhancement of basal DA efflux in Acc at 0.5 and 1.0 mg/kg THC. Sprague-Dawley rats, which do not show brain-reward enhancement by THC, show virtually no effect of THC on Acc basal DA within this dose range.

A PERTUSSIS TOXIN-SENSITIVE G PROTEIN IS INVOLVED IN THE MODULATION OF CYCLIC AMP BY CANNABINOID DRUGS IN THE RAT BRAIN. M. Bidaut-Russell* and A.C. Howlett. Dept of Pharmacology, St Louis Univ. Sch. of Med, St Louis, MO 63104.

The hypothesis that canabinoid drugs alter certain neuronal functions by affecting the adenylate cyclase/cyclic AMP system has been tested in the rat corpus striatum. Desacetyl-levonantradol (DALN) (10 μM), a synthetic cannabinoid analgetic (Pfizer), significantly decreased cyclic AMP accumulation in Forskolin-, VIP- or Dopaminergic D1 agonist (SKF 38393)-stimulated striatal slices by 30% to 50%. Neither spiperone nor naloxone reversed the inhibitory effects of DALN on cyclic AMP levels. This suggests that cannabinoid activity in the striatum is not taking place at the opioid or D2 dopaminergic receptors levels, but rather via a specific cannabinoid receptor. Unilateral injection of pertussis toxin (2 μg) in the striatum, hours before sacrifice of the rat, reduced the inhibitory effect of DALN by 70% compared with slices from the contralateral side. This suggests the involvement of a pertussis toxin-sensitive G protein in the mechanism of action of cannabinoid drugs in the brain.

Δ-9 TETRAHYDROCANNABINOL (Δ-9 THC) FACILITATION OF LATERAL HYPOTHALAMIC STIMULATION-INDUCED FEEDING. W. Trojniar* and R. A. Wise. Ctr. Stud. Behav. Neurobiol., Dept. Psychol., Concordia U., Montreal, Canada.

Δ-9 THC--the psychoactive agent in marijuana--has recently been shown to produce naloxone-reversible facilitation of self-stimulation (ICSS). Opiates facilitate both ICSS and feeding. We studied whether Δ-9 THC shares the feeding-facilitating effect of opiates. Six male Lewis rats which ate reliably in response to lateral hypothalamic stimulation were tested after i.p. injections of Δ-9 THC (0.4 mg/kg) alone or after naloxone ((1.0 and 2.0 mg/kg). Δ-9 THC reduced (by 20.5±4.3%) the stimulation frequency required to induce eating at a fixed latency. It also reduced the stimulation frequency necessary to induce maximal (asymptotic) performance. The effects of Δ-9 THC were blocked completely by 2.0 mg/kg and partially by 1.0 mg/kg of naloxone. These data suggest the involvement of endogenous opioid mechanisms in the appetite-enhancing effects of Δ-9 THC.

EFFECT OF PERINATAL DELTA-9-TETRAHYDROCANNABINOL (THC) ON RAT BRAIN MU OPIOID RECEPTORS. J.E. Margulies and R.P. Hammer, Jr. Dept. Anatomy & Reprod. Biol., Univ. Hawaii, Honolulu, HI 96822.

Delta-9-tetrahydrocannabinol (THC) has been shown to modulate mu opioid receptors *in vitro* in a noncompetitive manner (Vaysse et al., *J. Pharm. Exp. Ther.*, 241: 534, 1987). To evaluate the effect of THC on developing opioid receptors *in vivo*, we examined the binding properties of [^{3}H]DAGO to mu-opioid receptors following perinatal treatment with THC. Either 1.0 or 10.0 mg/kg of THC, or 5% propylene glycol and 0.5% Tween 80 vehicle was administered daily to gravid dams from gestation day 12 through postnatal day 9 (P9). Pups were sacrificed by decapitation on P10, 24 hours after the last THC treatment. Brains were removed, frozen and stored at -70°C during tissue collection. Saturation experiments using [^{3}H]DAGO were performed on cryosections taken through the caudatoputamen.

Scatchard analyses indicate that THC produced an increase in receptor affinity (K_D), but had no effect on receptor density (Bmax). The K_D of [^{3}H]DAGO binding in brain sections following vehicle treatment compared favorably to the K_D previously obtained for untreated adult sections (1.27 nM). Following perinatal THC treatment, K_D is reduced to 0.41 and 0.47 nM for 1.0 and 10.0 mg/kg THC-treated sections, respectively, compared to 1.29 nM for vehicle treatment. In addition, autoradiographic studies of similarly treated tissue sections suggest that THC has a selective effect on regional brain opioid receptor binding.

These results suggest that maternal THC administration has dramatic effects on the development of fetal brain opioid receptors, and they are consistent with the concept that the interaction of THC with opioid receptors is noncompetitive. (Supported by USPHS Awards DAO4081, NS01161 and RRO3061.)

ACUTE NEUROENDOCRINE RESPONSE TO DELTA-9-TETRAHYDROCANNABINOL (THC): THE INFLUENCE OF CHRONIC THC PRETREATMENT. L.L. Murphy*, R.W. Steger* and A. Bartke* (SPON: D. Smith). Department of Physiology, Southern Illinois University School of Medicine, Carbondale, IL 62901.

The influence of chronic THC pretreatment on the neuroendocrine response to acute THC administration was investigated. Adult male rats were treated for 7, 14 or 28 days with sesame oil vehicle or a low dose (0.5 mg/kg b.w., p.o.) of THC. Approximately 24 h after the last dose of chronic pretreatment, animals were given an acute dose of either vehicle or THC (0.5 mg/kg b.w., p.o.) and sacrificed 60 min later. Plasma LH levels in chronic vehicle controls were significantly reduced after acute THC administration ($p<0.05$). Chronic THC pretreatment did not alter the ability of acute THC to suppress LH levels. Acute THC treatment in vehicle pretreated animals significantly reduced norepinephrine turnover ($p<0.01$) within the median eminence (ME) but did not affect ME dopamine (DA) activity. Chronic THC pretreatment for 7 or 14 days prevented the reduction in NE activity by acute THC treatment. After 28 days of chronic treatment, however, NE and DA activities in the ME were significantly reduced by acute THC ($p<0.01$). Therefore, chronic THC pretreatment does influence the response of the ME catecholamine systems to acute THC but does not interfere with the ability of acute THC to inhibit LH secretion. This suggests that other neuromodulators, besides NE and DA, may be involved in the ability of THC to alter LH secretion. (Supported by DA 03875)

SYMPOSIUM. PROGRESS IN RESEARCH ON D1 DOPAMINE RECEPTORS. R.E. Chipkin, Schering-Plough Corp. (Chairperson); Marc Caron, Duke University; James Wamsley, (Western Inst. Neuropsychiatry); Francis White, Lafayette Clinic; and William Woolverton, Univ. of Chicago.

Dopamine receptors have been subtyped into two categories: D1 and D2. Although drugs affecting the D2 receptor have been known for decades, it has only been recently that specific agents for the D1 receptor have been available. These compounds have been of enormous value in elucidating the actions of D1 receptors. The purpose of this symposium is to discuss the progress in research in this area. Following opening remarks by the chairperson, Dr. Caron will present his work on the isolation and purification of the D1 receptor. These biochemical studies will orient the audience to the physiochemical nature of the receptor. Having this information as a background, Dr. Wamsley will discuss the localization of D1 receptors in the brain. These data are important since some of the functions of the D1 receptor can be linked with its heterogeneous distribution in the brain. To complement these in vitro studies, Dr. White will talk about his work on the electrophysiological effects of D1 agonists and antagonists. This work gives insight into the function of D1 receptors in vivo. Since the identification and function of the D1 receptor is based on the availability of selective ligands, Dr. Chipkin will discuss pharmacological work on new D1 receptor drugs. Finally, Dr. Woolverton will present his recent research on the behavioral actions associated with the D1 receptor. It is anticipated that this symposium will present a balanced, interdisciplinary view of the status of research on D1 receptors.

SYMPOSIUM. COMPUTING MOTION IN FLIES, MONKEYS AND MAN: LINKING PHYSIOLOGY WITH PSYCHOPHYSICS AND COMPUTATIONAL THEORY. C. Koch, Caltech (Chairperson); W. Reichardt*, Max-Planck Institute for Biological Cybernetics, Tübingen; T. Albright, Salk Institute; K. Nakayama, Smith-Kettlewell Institute; R. Andersen, MIT.

This symposium will highlight a number of convergent advances in understanding how optical flow fields and 3-D structure from motion is processed in the visual system of both invertebrates and vertebrates. W. Reichardt will discuss the correlation model of motion detection, first postulated in 1956 on the basis of behavioral experiments on insects and now thought to underlie human perception, and his recent extension of this model that can cope with the aperture problem. How 2-D motion and motion contrast information is processed in the middle temporal area (MT) in the primate's visual system is next discussed by T. Albright. C. Koch will give an account of a neural network model, based on the physiology of the magnocellular neuronal pathway from the retina to MT, which computes optical flow fields and mimics a number of psychophysical results. K. Nakayama will illustrate several motion phenomena and illusions and demonstrate how their study can serve to illuminate the physiological and computational constraints that underlie the computation of optical flow. Finally, R. Andersen will discuss his psychophysical (in man and monkey), electrophysiological (in area MT), and modeling work studying how 3-D surfaces can be inferred at both the single cell and the system level from optical flow fields.

LEARNING AND MEMORY: ANATOMY IV

258.1

INTRA-CEREBELLAR LIDOCAINE: DISSOCIATION OF LEARNING FROM PERFORMANCE. J.P. Welsh and J.A. Harvey. Univ. Iowa, Iowa City, IA 52242 & Med. Col. of Pa/EPPI, Phil., PA 19129.

This study examined whether rabbits could acquire CRs when performance was impaired by infusions of lidocaine (LID) into the n. interpositus (INT). There were 3 phases to the study. In Phase 1, rabbits were trained to make nictitating membrane CRs to a light CS that was paired with an air puff UCS. In Phase 2, rabbits received infusions of LID into INT during a conditioning session in which a tone CS was paired with the UCS. Interpolated light-CS trials were used to monitor the degree to which performance of CRs was being impaired by LID infusion. In Phase 3, two days later, animals received tone-CS alone trials to determine whether learning had occurred in phase 2 but was not observed due to a performance deficit resulting from inactivation of INT by LID. Infusion of LID into INT during Phase 2 eliminated CRs to the light CS and blocked any evidence of CR acquisition to the tone CS. However, in Phase 3, when no LID was infused and performance was not impaired, these animals demonstrated CR retention that was not different from that of controls that had received LID in adjacent sites and whose performance had not been impaired. Unpaired controls demonstrated less than 8% responding in Phase 3. These results confirm our previous suggestions that INT is essential for performance but not for acquisition or retention of learned responses. Supported by NIMH Grant MH16841.

258.2

EFFECT OF INFERIOR OLIVE LESIONS AND OLIVOCEREBELLAR TRACTOTOMY ON A CONDITIONED LIMB FLEXION RESPONSE IN THE CAT. T.J. Voneida, D. Jefford-Christie* & R. Bogdanski*, Dept. of Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Cats trained to perform a right forelimb flexion to a tone conditioned stimulus underwent olivocerebellar tractotomy or left olivary lesions (radio frequency; quinolinic acid).

The most severe CR losses resulted from rostromedial lesions, as reported by McCormick et al, '85; Yeo et al, '86, in the rabbit nictitating membrane response (NMR). Furthermore, we observed a gradual postoperative decline in CR levels from high scores to zero or near zero level scores, similar to that observed during extinction, as reported also by McCormick et al ('85). Coincidental with CR decline was an increase in CR latency and decrease in amplitude, as noted also by Welsh & Harvey ('89) following anterior interpositus cerebellar lesions in NMR conditioned rabbits.

Prolonged postoperative training of our subjects resulted in recovery of limb flexion CR's, with concomitant decrease of response latency and increase of response amplitude. (Supported by NINCDS Grant NS26053).

258.3

PSYCHOPHYSICAL LAWS OF ELICITATION OF THE RABBIT'S NICTITATING MEMBRANE RESPONSE (NMR) TO ELECTRICAL STIMULATION OF BRAINSTEM AND CEREBELLAR NUCLEI. A. J. Nowak, B. Marshall-Goodell, E. S. Miller, and I. Gormezano, Dept. of Psychology, Univ. of Iowa, Iowa City, IA 52242.

Previous studies have reported NMR conditioning with electrical brain stimulation (EBS) of the spinal trigeminal nucleus (TRIG) and inferior olive (IO) as an UCS, whereas EBS of the interpositus (IP) and red (RN) nuclei have not. Since these studies have generally employed subject-defined EBS parameters, the behavioral laws relating EBS parameters at these sites to UCR elicitation and CR acquisition have yet to be determined. Accordingly, the present study sought to determine for the above sites, the psychophysical laws relating NM extension to EBS amplitude, frequency, pulse width, and train duration. The frequency of NMRs elicited by EBS of RN, TRIG, and IP was found to be a monotonic increasing function of the parameters of EBS with the highest values (250 uA, 500 Hz, 0.8 ms, 60 ms) producing levels of UCRs at RN (85%), TRIG (61%), and IP (40%) significantly above baseline. In contrast, stimulation of IO failed to yield any significant effects across parameters of EBS. The observed UCR frequencies suggest that EBS of IP, TRIG, or RN could serve as an increasingly effective UCS for NMR conditioning, whereas even at the highest levels of stimulation, IO may be an ineffective site. Ongoing research from our laboratory is directed at determining the validity of these expectations.

CLASSICAL CONDITIONING IN RABBITS WITH INTRACEREBELLAR ELECTRICAL STIMULATION AS THE US. P. G. Shinkman, R. A. Swain*, and R. F. Thompson. Dept. Psychology, Univ. Southern California, Los Angeles, CA 90089.

The purpose of this experiment was to replicate and extend observations reported by Brogden and Gantt about 50 years ago, in which classical conditioning was accomplished in dogs using a visual or auditory CS and electrical stimulation of the cerebellum as the US. Stainless steel electrodes for localized microstimulation were implanted in white matter underlying lobule HVI of cerebellar cortex in New Zealand White rabbits. Upon recovery animals were tested for unconditioned responses elicited by intracerebellar stimulation (ICS) and then given conditioning trials consisting of paired presentation of tone and ICS. Of 9 implanted animals, 8 showed reliable elicited behaviors to the ICS, including eyeblink, head turn or extension, or lip movement. Every animal showing such unconditioned responses developed clear, unequivocal conditioned responses to the tone during 2-8 daily sessions of 108 trials. For 7 animals training was extended to include extinction (tone alone) followed by reacquisition; each of these animals showed rapid extinction (1-2 sessions) and reacquisition (1-2 sessions) of the conditioned response.

Supported by NSF (BNS-8718300), ONR (N00014-88-K-0112), and a McKnight Foundation grant, all to RFT; and by USPHS (HD-03110) to the University of North Carolina.

258.5

EFFECTS OF DEEP CEREBELLAR LESIONS ON CLASSICAL CONDITIONING IN RABBITS USING INTRACEREBELLAR STIMULATION (ICS) AS THE US. R. A. Swain*, P. G. Shinkman, and R. F. Thompson. Dept. Psychology, Univ. Southern California, Los Angeles, CA 90089.

Paired presentations of tone and electrical stimulation of cerebellar white matter produce robust classical conditioning (Brogden & Gantt, 1937; Shinkman, Swain, & Thompson, 1989). The present experiment was designed as a first step in specifying the locus of synaptic plasticity underlying this phenomenon. New Zealand White rabbits were implanted with bipolar microstimulation electrodes in the white matter of HVI and with a lesioning electrode or cannula in the nucleus interpositus (IP). Following recovery, classical conditioning was established in paired tone-ICS trials. IP lesions were then made electrolytically or by kainic acid injection. These lesions produced deficits in responding. In particular, small electrolytic IP lesions selectively abolished conditioned eyeblink responses either permanently or temporarily. Unconditioned responses also disappeared, either immediately following the lesion or after a few days. These results provide additional support for the role of the IP as a critical site of plasticity underlying many classically conditioned behaviors.

Supported by NSF (BNS-8718300), ONR (N00014-88-K-0112), and a McKnight Foundation grant, all to RFT; and by USPHS (HD-03110) to the University of North Carolina.

258.6

THE EFFECTS OF COMBINED LESIONS OF CEREBELLAR CORTICAL AREAS ON ACQUISITION OF THE RABBIT CONDITIONED NICTITATING MEMBRANE RESPONSE. C. G. Logan, D. G. Lavond, and R. F. Thompson. Dept. of Psychology, University of Southern California, Los Angeles, CA 90089-1061

In order to test the hypothesis that multiple cerebellar cortical sites participate in a parallel fashion in classical conditioning of the rabbit nictitating membrane response, lesions of various cerebellar cortical areas were performed in combination, and the lesioned animals were then trained.

New Zealand white rabbits received either bilateral lesions of the flocculus and paraflocculus, bilateral lesions of the flocculus and paraflocculus and unilateral lesions of neocerebellar cortex, or bilateral lesions of flocculus and paraflocculus along with bilateral lesions of the hemispheric areas. The flocculus/paraflocculus group was trained to criterion on the left eye and then switched to right eye training. All rabbits in this group learned the conditioned response on both eyes, indicating that the flocculus and paraflocculus are not essential for classical conditioning of the eyeblink response.

All animals in the other 2 groups were given 10 days of tone-airpuff pairings on one eye, then the airpuff was switched for 10 days of training on the opposite eye. To date, animals in this group which did not have damage to the deep nuclei acquired the conditioned response, with the exception of one animal which did not learn on the eye ipsilateral to the hemispheric lesion. In all cases, damage to the deep nuclei was assessed by an observer blind to the animal's behavior.

Supported by the McKnight Foundation, ONR grant N00014-88-K-0112, and NSF grant BNS-8718300 to RFT.

258.7

INCREASED BRANCHING OF SPINY DENDRITES OF RABBIT CEREBELLAR PURKINJE NEURONS FOLLOWING ASSOCIATIVE EYEBLINK CONDITIONING B.J. Anderson, S.Lee, J.Thompson, J.Steinmetz, C.Logan, B. Knowlton, R.F.Thompson & W.T.Greenough Depts Psych & Cell & Struct Biol, & Neur &Behav Biol Prog, Univ IL, Champaign, 61820, and Dept Psych, Univ So Calif, Los Angeles, CA

Prior findings implicate cerebellum as essential for conditioned eyeblink responses in rabbits. When dorsolateral pontine n. (DLPN) stimulation serves as CS, cerebellar cortex lesions abolish CRs. Previous findings indicate increased Purkinje cell spiny branchlet dendrite, site of parallel fiber termination, after complex experience in rodents and monkeys. Acrobatic training also increases molecular layer synapse number in rats. We trained rabbits unilaterally, using DLPN stimulation as CS and corneal airpuff as US. Golgi-stained Purkinje neurons in lobule HVI were analyzed for the branching pattern of spiny branchlets. Altered pattern was indicated by greater numbers of 5th order branches and of 4th order bifurcating branches ($p<.05$). Mean total dendritic length for spiny branchlets was 5% greater in the conditioned hemisphere (ns). These results, taken with previous findings, suggest the formation of new parallel fiber to Purkinje cell connections as a consequence of conditioning.

STRUCTURAL PLASTICITY IN CEREBELLAR CORTEX: LEARNING EFFECTS ON AFFERENT AND INTRINSIC FIBER SYSTEMS. W.T. Greenough, B.J. Anderson, K.R. Isaacs, J.E. Black, & A.A. Alcantara Depts Psych., Cell & Struct Biol, Neur & Behav Biol Prog, Beckman Inst. Univ Illinois, Champaign, 61820.

Quantitative Golgi studies indicate that weanling or old animals housed in complex environments have more spiny branchlet material per Purkinje neuron. Spiny branchlets receive parallel fiber (pf) input. One cannot directly assess other Purkinje afferents in light microscopy. Using electron microscopy, we found that visuomotor training increases cerebellar cortex thickness without significantly affecting synapse density, such that there are more synapses per Purkinje neuron (Black, et al SN Abs 13:1596; Anderson et al SN Abs 14:1239). We studied apex of paramedian lobule in 38 adult rats run for 30 days in 4 groups: an acrobatic condition (AC) given extensive motor-learning with relatively little exercise, two exercise conditions (FX, VX) that allowed little learning but given 10x the amount of AC exercise, and an isolated control group (IC). The AC group had about 30% more synapses than the others, all of which were roughly equivalent. As pf synapses are by far most numerous in the molecular layer (Eccles, Brain Res., 127:327), their numbers must have increased. Whether changes also occur in climbing and inhibitory fibers is now under study and will be discussed in the context of extant and plausible neural models of cerebellar cortical learning. NIMH-43830

LESIONS OF DEEP CEREBELLAR NUCLEI SELECTIVELY ABOLISH CONDITIONED BUT NOT "SPONTANEOUS" EYE BLINKS IN RATS. R. W. Skelton. Dept. of Psychology, Univ. of Victoria, B.C., Canada, V8W 2Y2.

The present study examined the topography of eyelid responses in rats given paired and unpaired presentations of tones and periorbital shocks, and evaluated the effects of deep cerebellar lesions on responses under both conditions.

In the paired condition, eyelid responses to tones contained two distinct components. The "CR" component consisted of multiple bursts of EMG with variable amplitude and frequency. It was clearly distinguishable on 40-60% of trials and resembled the well-known conditioned eyelid response (CRs) of rabbits. The "spontaneous blink" component consisted of a single burst of EMG that was invariably large and brief. It was present on 10-20% of trials and resembled eye blinks emitted by the rats "spontaneously" before conditioning, during the intertrial interval, and shortly after the unconditioned response to the eye shock. In the unpaired condition, "spontaneous blink" responses occurred on 10-20% of tone trials, but "CR" responses were rare.

After bilateral lesions of the deep cerebellar nuclei eyelid responses under paired and unpaired conditions were equivalent and were almost entirely "spontaneous blink" responses.

Supported by grant #URF0034961 from NSERC of Canada.

LESIONS OF THE CEREBELLAR VERMIS SEVERELY IMPAIR ACQUISITION OF PAVLOVIAN CONDITIONED BRADYCARDIC RESPONSES IN THE RABBIT. W. F. Supple, L. Archer* and B.S. Kapp. Department of Psychology, Univ. Vermont, Burlington, VT 05405.

Recent lesion data in the rat (Supple & Leaton 1986) and electrophysiological data in the rabbit (Supple & Kapp, 1988) has indicated an important contribution of the midline cerebellar cortex to the acquisition of fear-conditioned heart-rate(HR) responses. This experiment examined the effects of restricted vermis lesions on the acquisition of classically conditioned bradycardia in rabbit.

Electrolytic or aspiration lesions of the anterior vermis blocked the development of conditioned bradycardic responses to a pure tone CS paired with a 2.0 mA eyelid shock UCS. Importantl the lesions did not affect baseline HR, the unconditioned HR orienting response or HR responses to the UCS, thus indicating that these lesions selectively disrupted conditioned but not unconditioned HR responses.

These data implicate the anterior lobules of the vermis as being importantly involved in this rapidly acquired CR in the rabbit; a species in which the lateral cerebellum has been shown to be essential for acquisition of the classically conditioned eyeblink CR.

258.11

THE CEREBELLUM AND LONG-TERM HABITUATION OF ACOUSTIC STARTLE IN RATS: LESIONS OF FASTIGIAL (MEDIAL) AND DENTATE (LATERAL) NUCLEI. R. N. Leaton and W. F. Supple, Jr. Department of Psychology, Dartmouth College, Hanover, NH 03755.

In a series of experiments we have shown that the vermis of the cerebellum is essential for long-term habituation (LTH) of the acoustic startle response in rats. Lesions of the vermis of the cerebellum prevent long-term habituation but leave short-term habituation unaffected (Leaton & Supple, Science, 1986). The effects are at least partially response specific (Supple & Leaton, SNS, 1986) and are anatomically specific within the cerebellum: vermal lesions blocked LTH while lesions of the cerebellar hemispheres were without effect on LTH (Leaton & Supple, SNS, 1986).

The present experiment was an effort to expand the anatomical substrate of the LTH circuitry. We compared rats with lesions of the fastigial nuclei (a projection target for the cerebellar vermis) with rats with lesions of the dentate nuclei (a projection target for the cerebellar hemispheres). Startle response was measured to 118-dB, 100-msec white noise bursts on a 60-sec interstimulus interval (ISI) in 8 daily 6-trial sessions. Retention of LTH was assessed 6 days later. Then responsiveness to a systematic variation of ISI was tested over intervals of 5,10,30,60, and 120 sec. Three groups of rats were tested following (1) bilateral electrolytic lesions of the fastigial nuclei (n=12), (2) bilateral electrolytic lesions of the dentate nuclei (n=11), and (3) sham surgery (n=9).

Fastigial lesions blocked LTH suggesting that these projection nuclei are part of the LTH pathway from the cerebellar vermis. Dentate lesions were without affect on LTH but in the ISI series appeared to reduce sensitization relative to controls. These data are consistent with and extend our previous findings that the medial cerebellum is part of an essential circuitry for LTH of the acoustic startle response in rats.

GABA AND BENZODIAZEPINE RECEPTORS I

259.1

STRUCTURAL BASIS OF TYPE I AND TYPE II $GABA_A$/BENZODIAZEPINE RECEPTORS. D.P. Pritchett, H. Lüddens* and P.H. Seeburg*. ZMBH, University of Heidelberg, INF 282, 6900 Heidelberg, F.R.G.

$GABA_A$ receptors expressed upon transfection of mammalian cells with cDNA expression vectors and assembled from one of three different α subunit variants (α_1 or α_2 or α_3) in combination with a β_1 and a γ_2 subunit displayed the pharmacological properties of the previously described type I and type II subtypes of the $GABA_A$/benzodiazepine receptor. Each of the three expressed receptors contained high-affinity binding sites for benzodiazepines. However, the triazolopyridazine CL 218872 showed a 10-fold higher affinity for receptor containing an α_1 rather than an α_2 or α_3 subunit. A similar selectivity for α_1 subunit containing receptors was seen using the benzodiazepine 2-oxo-quazepam and the β-carboline β-CCM. Four other benzodiazepines (clonazepam diazepam Ro 15-1788) or β-carbolines (DMCM) with no type I or type II selectivity displayed indistinguishable binding characteristics for the three recombinantly expressed receptors. The affinity of all compounds tested, except 2-oxo-quazepam, was indistinguishable from their affinity for brain membranes. The selectivity of CL 218872 and 2-oxo-quazepam compounds was reduced at 37°C, as observed with BZ I receptors from cerebellar membranes. No such temperature-induced decrease in affinity for benzodiazepines was observed for receptors carrying α_2 or α_3 subunits, again consistent with results using brain membranes. These results strongly suggest that α subunit heterogeneity constitutes the structural basis for type I and type II receptors.

259.2

4'-CHLORODIAZEPAM DECREASES FUNCTION OF Cl^- CHANNELS COUPLED TO NATIVE AND TRANSIENTLY EXPRESSED $GABA_A$ RECEPTOR SUBUNITS IN A MANNER INSENSITIVE TO FLUMAZENIL. G.Puia, M.R.Santi, S.Vicini*, D.B.Pritchett[1]*, P.Seeburg[1]*, & E.Costa*. F.G.I.N. Georgetown Univ.,Wash.,D.C.20007. [1]ZMBH, Univ. Heidelberg, FRG.

4'-chlorodiazepam (RO 5-4864), the peripheral benzodiazepine receptor agonist, also acts as a negative modulator of central $GABA_A$ receptors. We employed whole-cell recordings of GABA-induced Cl^- currents in rat cortical neurons in primary culture. RO 5-4864 decreased these currents with a potency 10 fold lower than that of DMCM. Flumazenil antagonized DMCM but was without effect on 4'-chlorodiazepam reduction of Cl^- currents. Utilizing the transient expression of the different subunits constituting the $GABA_A$ receptor in a mammalian cell line(1), it has been shown that transfection of a third subunit (γ), along with the previously identified α and β subunits, is necessary to observe the benzodiazepine increase of GABA-activated Cl^- currents (2). The transiently expressed combination α_1 and β_1 subunits produced Cl^- channels downregulated by picrotoxin but not affected by benzodiazepine receptor ligands (1). We did not observe any decrease of Cl^- currents induced by GABA in these transfected cells either by RO 5-4864 or by DMCM. Conversely, when the GABA receptor Cl^- channels were reconstituted together with the γ_2, subunits both compounds were effective with similar potency and efficacy, as on the native receptors. Our results indicate that there is no similarity between the picrotoxin and the 4'-chlorodiazepam sites of action, as previously thought. 1) D.Pritchett et al. Science 242:1306 (1988). 2) D.Pritchett et al. Nature 338:582 (1989).

259.3

THE TRIAKONTATETRANEUROPEPTIDE (TTN) A BRAIN PROCESSING PRODUCT OF DIAZEPAM BINDING INHIBITOR (DBI): A PUTATIVE ALLOSTERIC MODULATOR OF $GABA_{A3}$ RECEPTOR. E. Slobodyansky, H. Alho, P. Bovolin, A. Guidotti and E. Costa. FGIN Georgetown Univ., Washington, D.C.

Several lines of investigation suggest that 4'Cl diazepam (Ro-5 4864) binds to neuronal membranes and functions as a $GABA_{A3}$ receptor modulator. ^{3}H-4'Cl diazepam binds to synaptosomes (K_D 53 nM) and mitochondria (K_D 7nM) of brain. In synaptosomes ^{3}H-4'Cl diazepam can be displaced with picrotoxinin, but not protoporphyrin and in mitochondria with protoporphyrin IX but not picrotoxinin. mRNA levels (monitored by Northern blot analyses) for the peripheral BZ receptor are much lower in the brain than in kidney, implying that 4'Cl diazepam binds in brain to some other receptor in addition to the mitochondrial one. The functional role of TTN in brain is supported by following data 1) Immunocytochemical investigations done with antibodies directed against TTN reveal its coexistence with GABA in cortical, reticulothalamic and cerebellar neurons. 2) Its proconflict effect is blocked by PK-11195 (antagonist of 4'Cl diazepam), but not by flumazenil. 3) TTN displaces 4'Cl diazepam from synaptosomes with K_i 5uM, but does not displace flumazenil. Similarly to 4'Cl diazepam TTN potentiates the effect of picrotoxinin on ^{3}H-flunitrazepam binding to brain homogenate. The effect of TTN on 4'Cl diazepam binding in cultured cells expressing $GABA_A$ receptors with different subunit composition is currently being studied.

259.4

DIFFERENCES IN THE PHARMACOLOGICAL PROFILES OF BENZODIAZEPINE RECOGNITION SITE LIGANDS REFLECT INTERACTIONS WITH HETEROGENEOUS POPULATION OF $GABA_A$ RECEPTORS. J.L. Schlichting, M. Massotti, M.D. Antonacci* and A. Guidotti, FGIN, Georgetown University, Washington, D.C. 20007.

Heterogeneity of $GABA_A$ receptor is supported by binding and molecular studies (Memo et al., Neurosci. Abst. 1989). $GABA_{A1}$ is abundant in cerebellum, cortex, olfactory bulb but absent in spinal cord; $GABA_{A2}$ is most abundant in spinal cord, but also present in striatum, hippocampus and thalamus; $GABA_{A3}$ is abundant in olfactory bulb. In rats, the pharmacological profiles of acutely adminstered diazepam (DZP), alprazolam (AZP), clonazepam (CZP), or zolpidem (ZPD) suggest an action at selective populations of $GABA_A$ receptor subtypes. CZP and ZPD elicit anticonvulsant, anticonflict, and sedative effects but have weak myorelaxant action suggesting that $GABA_{A1}$ receptors are responsible for sedative and anticonvulsant activity, $GABA_{A2}$ receptors for myorelaxant action, whereas the pharmacology of $GABA_{A3}$ receptors is less well understood. When DZP or CZP are administered to rats for 14 days, tolerance to the effects of DZP results but not to the effects of CZP. The induction of tolerance to effects of DZP can be correlated with changes in the dynamic state of endogenous DBI (diazepam binding inhibitor) in specific brain regions. On-going studies on tolerance characteristic of AZP and ZPD suggest that AZP, like DZP, can elicit changes in the dynamic state of DBI.

259.5

EXPRESSION OF A cDNA ENCODING A PROTEIN COMPRISING PERIPHERAL-TYPE BENZODIAZEPINE RECOGNITION SITES.
A.G. Mukhin*, M.R. Santi*, D.R. Grayson*, and K.E. Krueger. (SPON: W. Norman). Fidia-Georgetown Institute for the Neurosciences, Georgetown University Medical School, Washington, D.C. 20007.

PKBS (PK binding site) is a protein of approximately 17 kDa which was identified earlier as being intimately associated with peripheral-type benzodiazepine recognition sites (PBR). A full-length rat cDNA probe for PKBS was inserted into an eucaryotic expression vector, pSV-globin, placing it under transcriptional control of the β-globin promoter and SV40 enhancer. The transformed human embryonic kidney cell line, 293, was transfected with this construct and transient expression of PBR was studied. Cells transfected with the pSV-PKBS vector exhibited about a 1 pmol/mg of protein increase in specific binding for [^{3}H]PK11195 and for [^{3}H]4-chlorodiazepam when compared to cells subjected to a mock transfection or transfected with the original pSV-globin vector. The dissociation constants of the PBR expressed was 5-8 nM and of higher affinity than the human form of PBR endogenous to 293 cells (K_D = 19-55 nM). The rank order of potency at inhibiting [^{3}H]4-chlorodiazepam binding to the expressed PBR was PK11195 > 4-chlorodiazepam > diazepam > clonazepam. These studies demonstrate that expression of PKBS is required and apparently sufficient for the manifestation of PBR.

259.6

BENZODIAZEPINE SENSITIVITY AND STRUCTURE OF GABA- A RECEPTOR SUBTYPES.
M. Memo, M. Massotti, A. Guidotti, D.R. Grayson* and E. Costa. FGIN, Georgetown Univ., Washington, D.C. 20007.

Recent transient expression of various cDNAs coding for GABA-A receptor subunits suggests that the structural composition of the reconstituted receptor determines its senistivity to various benzodiazepines (BZs). The experiments were performed with poly A+ mRNA and neuronal membranes prepared from cerebellum and spinal cord. The Bmax for tritiated diazepam, clonazepam, zolpidem, flumazenil and CCM (a beta carboline) binding is approximately the same in cerebellum. Spinal cord membranes fail to bind clonazepam, zolpidem and CCM, but bind tritiated diazepam and flumazenil with Kd similar to the cerebellum and a Bmax which was 5 fold lower. The steady state mRNA content of the alpha-1-subunit of GABA-A receptor was measured by northern blot analysis of RNA isloated from either tissue. The alpha-1- subunit cDNA clone gave two strong hybridization signals in cerebellum but neither poly A+ species was detected in multiple RNA preparations from spinal cord. These results indicate that the binding profile of Bz to GABA-A receptor populations present in spinal cord might be correlated with the different subunit composition of GABA-A receptors.

259.7

RESOLUTION AND IDENTIFICATION OF THE PUTATIVE SUBUNITS OF THE PERIPHERAL BENZODIAZEPINE RECEPTOR (pBr) OF RAT KIDNEY MITOCHONDRIA.
M.W.McEnery, A.M.Snowman, and S.H.Snyder Dept. Neuroscience, Johns Hopkins Sch. of Med.,Baltimore, MD 21205.

Benzodiazepines have been shown to bind with nanomolar affinity to two distinct classes of sites. The central site has been shown to be components of the GABA-A receptor associated with Cl^- channels. The peripheral site (pBr) is pharmacologically distinct from the central site and is found in kidney and adrenals. The pBr has been localized to the mitochondrial fraction of these tissues, specifically to those complexes associated with the outer membrane. We have previously reported a procedure for the purification of the pBr from rat kidney mitochondria. The intact complex is composed of two proteins with apparent molecular weights of 30-35kDa and 18kDa. This preparation has been characterized with regard to its ability to bind those drugs which are diagnostic for the pBr (the benzodiazepine Ro 5-4864 and the isoquinoline carboxamides PK11195 and PK14105) in either a reversible or covalent manner. In all respects, the soluble and purified pBr is identical to the native, membrane-bound receptor. We have recently resolved the 30-35kDa protein from the 18kDa protein and herein report our attempts to examine the binding characteristics of the components. The function of the pBr will be discussed as well as our conclusions as to the identity of the 30-35kDa component.

GABA RECEPTOR HETEROGENEITY: NEW INSIGHTS FROM RECEPTOR RADIOAUTOGRAPHY AND IN SITU HYBRIDIZATION HISTOCHEMISTRY.
J.G. Richards, J.M. Séquier*, P.Malherbe* T. Giller* and H. Möhler*. Pharma Research CNS, F. Hoffmann-La Roche AG., CH-4002 Basel, Switzerland.

Allosteric sites on the $GABA_A$ receptor complex, a pentameric (?) heterooligomer in pre-, post- as well as extra-synaptic neuronal membranes in the CNS, are targets for a variety of psychoactive drugs including benzodiazepines and barbiturates. Recent evidence from receptor mapping and cloning studies suggest a structural and possibly functional heterogeneity of the receptor in rat CNS. The distribution of rat α_1 and β_1 mRNA in rat brain has been described (Séquier, J.M. et al., Proc. Natl. Acad. Sci. USA, 85: 7815, 1988).

Recently, a variety of receptor subunits and subtypes thereof have been cloned (5 α's, 1 β, 1 γ); their regional expression in the CNS, mapped by in situ hybridization histochemistry (using ^{35}S- or ^{3}H-labelled cRNA and synthetic oligonucleotide probes), differed profoundly. α_1 was the most ubiquitously and highly expressed subtype but was not detected in A9 DA neurones, for example. $\alpha_{2,3,5}$ and β_1 were restricted to the olfactory bulb, caudate putamen (α_2), hippocampal formation and cerebellum. α_4 and γ_2 (highly homologous to human γ_2) were much more widely expressed but again differed from the α_1 pattern of distribution, e.g. absence of signal in pallidum, most thalamic regions and substantia nigra (except α_4 which was present in the zona compacta). None of the clones to date have been detected in spinal cord. Moreover, the interaction of GABA with a variety of benzodiazepine receptor ligands (GABA-shift), determined for 13 rat brain regions by quantitative receptor radioautography and image analysis, revealed markedly different profiles.

The functional implications of these findings will be discussed.

259.9

ISOLATION OF MULTIPLE PHARMACOLOGICALLY DISTINCT GABA AND BENZODIAZEPINE BINDING SUBUNITS OF THE GABA-A RECEPTOR.
M. BUREAU* and R.W. OLSEN (SPON: D.J. Jenden). Department of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024.

At least two different α subunits (photoaffinity labeled by [^{3}H]flunitrazepam [FLU]) and two different β subunits (photolabeled by [^{3}H]muscimol) were detected on SDS gels of GABA-A/benzodiazepine (BZ) receptor from rat cortex purified by BZ affinity column. The two bands labeled by each ligand showed differential sensitivity to inhibition by nonradioactive analogs. [^{3}H]Muscimol photolabeled two bands at 56 kDa (β_{56}) and 58 kDa (β_{58}) to equal extent, despite a greater amount of β_{56} than β_{58}, indicating a higher affinity for β_{58}. β_{58} also showed a higher affinity for nonradioactive THIP, (IC_{50} = 0.2 μM versus 3 μM for β_{56}), GABA, bicuculline, SR-95531, and taurine. [^{3}H]FLU photolabeled two bands at 51 kDa (α_{51}) and 53 kDa (α_{53}) with a higher affinity of α_{51} for FLU, and the BZ1-specific ligands CL 218872 (IC_{50} = 50 nM versus >1 μM for α_{53}), quazepam, and beta-carbolines. Barbiturates showed differential modulation of GABA and BZ binding to the two bands. Thus, multiple subunit subtypes on SDS gels show different binding affinities for drugs in the native oligomeric state. These can be correlated with brain regional variation in ligand binding, and appear to represent different gene products.

260.1

GLUTAMATERGIC REGULATION OF GABAERGIC NEURONAL ACTIVITY
R. Bernasconi*, P. Martin*, A.F. Steulet*, T. Leonhardt*, M. Schmutz*, P. Baumann*, H. Bittiger* and M. Williams. (SPON: S. Bischoff). Pharmaceuticals Div. CIBA-GEIGY Ltd. CH-4002 Basel.

The nature of the GLU receptors which mediate the excitatory synaptic modulation of GABAergic neurons in the striatum is still unknown. Therefore, we examined the effects of competitive NMDA antagonists (CPP, CGS 19 755, CGP 37 849, CGP 39 551) on GABA turnover in comparison with those of non-competitive antagonists (PCP, MK-801, dextromethorphan). The rate of GABA accumulation after irreversible inhibition of GABA-T by gabaculine, an index of GABA turnover, was measured in 4 brain structures of the mouse. Anticonvulsant doses of all competitive NMDA inhibitors did not alter steady-state levels of GABA, but dose-dependently decreased its turnover rate. MK-801, PCP and dextromethorphan had no effect on GABA turnover. In the absence of any direct effect of the competitive NMDA antagonists on GABA-A, GABA-B, chloride channel, central benzodiazepine binding sites and on GABA uptake (at conc. > 100 uM) in vitro and on GABA levels in vivo, these results confirm that GABAergic pathways are subject to regulation by GLUergic transmission. This effect seems to be mediated, at least in part, via NMDA receptors located on GABA neurons. Furthermore, NMDA receptors which modulate GABA synthesis are not blocked by PCP-like channel ligands.

260.2

PROTEIN KINASE C TRANSLOCATION IN PRIMARY CULTURES OF NEURONS: REGULATION BY EXCITATORY AND INHIBITORY NEUROTRANSMITTERS.
F.M. Vaccarino AND J.F. Tallman, ABRAHAM RIBICOFF RES. FACILITIES, DEPT. PSYCHIATRY, YALE UNIV. SCHOOL OF MEDICINE, NEW HAVEN, CT 06508.

In primary cultures of cerebellar granule cells, Protein Kinase C (PKC) translocates from the soluble to the membrane compartment (with subsequent activation) after stimulation of intact neurons with agonists, such as glutamate, NMDA and kainate, which promote the influx of calcium through receptors-gated transmembrane channels (Vaccarino et al, Proc.Natl.Acad.Sci, 84:8707,1987). No significant PKC translocation was elicited after treatment of cell monolayers with agonists primarily affecting PI turnover, such as carbachol, quisqualate or noradrenaline. In primary cultures of cortico-striatal neurons, PKC translocation, assessed by the binding of radiolabelled β phorbol-12,13-dibutyrate (PDBu) to intact cell monolayers, was stimulated by the excitatory amino acid glutamate in the absence of Mg with the same efficacy and potency as in cerebellar granule cells and this stimulation was blocked by the specific NMDA allosteric antagonist MK-801. Differently than in cerebellar granule cells, PKC translocation could also be stimulated by ligands for the quisqualate-type excitatory amino acid receptor and by the muscarinic cholinergic agonist carbachol, which cause an increase in PI turnover in these cultures. Moreover, bicuculline, which antagonizes $GABA_A$ receptor-activated chloride channels, greatly enhanced the efficacy and the potency of glutamate (in Mg-free medium) in inducing PKC translocation. Bicuculline's potentiation was blocked by MK-801 as well as by tetrodotoxin, suggesting that it involved a depolarization-induced enhancement of NMDA receptor action. These data support a tonic antagonism of glutamate-mediated PKC translocation by GABA, which may explain the blockade of bicuculline-induced seizure activity by NMDA receptor antagonists.

260.3

EFFECTS OF EXCITATORY AMINO ACID (EAA) ANTAGONISTS ON SYNAPTIC CURRENT IN PHRENIC MOTONEURONS.
G. Liu and J. L. Feldman, Systems Neurobiology Lab., Dept. of Kinesiology, UCLA, Los Angeles, CA 90024-1586.

In spite of the presumed importance of EAA receptors in synaptic transmission, little is known about their role in mediation of synaptic drive during ***natural behaviors***. Our previous results suggest the involvement of EAAs in the bulbospinal transmission of inspiratory drive to phrenic motoneurons (e.g., Soc. Neurosci. Abs. 14:938, 1988). The present study used single electrode voltage-clamp techniques to explore the effects of different EAA receptor antagonists on the endogenous rhythmic respiratory synaptic drive current to phrenic motoneurons *in vitro*. When the membrane potential of a phrenic motoneuron was clamped at end-expiratory potentials (-65 to -75 mV), the peak amplitude of synaptic current during inspiration (duration 200-500 msec) was ~1 nA. After bath application of 10 μM 6-cyano-7-nitroquinozaline-2,3-dione (CNQX), a non-NMDA antagonist, the amplitude and duration of the inspiratory drive current was reduced. This concentration of CNQX did not produce any change in resting membrane potential, action potential characteristics, input resistance, cell excitability, or membrane frequency/current relationship. These results suggest that CNQX specifically blocked inspiratory-modulated synaptic transmission without changing intrinsic (passive or active) membrane properties. Bath application of 100 μM 2-amino-5-phosphonovaleric acid (AP5) induced only a small reduction of synaptic drive current, and did not affect membrane properties. Combined with our previous work, these data indicate the involvement of EAA receptors, especially of the non-NMDA type, in synaptic transmission of bulbospinal inspiratory drive to phrenic motoneuron. Supported by NIH Grant NS 24742.

WHEAT GERM AGGLUTININ INHIBITS QUISQUALATE DESENSITIZATION IN CULTURED POSTNATAL RAT HIPPOCAMPAL NEURONS.
L.L. Thio, D.B. Clifford, & C.F. Zorumski, Depts. of Psychiatry & Neurology, Washington U. Sch. Med., St. Louis, MO 63110

Quisqualate evokes a rapidly desensitizing inward current in postnatal rat hippocampal neurons. We have studied this current using the whole cell mode of the patch clamp technique. We found that the amplitude of the desensitizing current produced by 100μM quisqualate is irreversibly increased by 240% after applying 25μg/ml of the lectin wheat germ agglutinin (WGA) for 30s. WGA potentiates the desensitizing current in a dose dependent manner with an ED_{50} of 3μg/ml, and decreases the rate of desensitization markedly. The lectin does not appear to unmask a new set of quisqualate receptor-channel complexes since the ED_{50} for the quisqualate current in WGA treated neurons is comparable to that for the desensitizing current in naive neurons. In addition, the current-voltage relationship for the current in WGA treated neurons is linear with a reversal potential of 0mV as it is untreated neurons. WGA also augments the rapidly desensitizing current evoked by α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid and glutamate, but it has no effect on N-methyl-D-aspartate, kainate, and γ-aminobutyric acid (GABA) currents. In particular, it has no effect on NMDA and GABA desensitization. Thus, WGA may be useful in determining both the physiological role and molecular mechanism of quisqualate desensitization.

QUISQUALATE ACTIVATES A DELAYED AP5-SENSITIVE INCREASE IN $[K^+]_o$ AND DECREASE IN $[Ca^{2+}]_o$ IN THE GRANULAR LAYER OF THE TURTLE CEREBELLUM.
M.E. Rice and C. Nicholson, Dept. Physiol. & Biophys., New York University Medical Center, New York, NY 10016.

Iontophoresis of excitatory amino acid agonists changes $[K^+]_o$ and $[Ca^{2+}]_o$ in the granular layer (GrL) of the isolated turtle cerebellum (Rice & Nicholson, Soc. Neurosci. Abstr. 13:764, 1987). Quisqualate, in contrast to glutamate, aspartate, NMDA and kainate, had little effect on $[K^+]_o$ and $[Ca^{2+}]_o$ during iontophoresis, but increased $[K^+]_o$ and decreased $[Ca^{2+}]_o$ 4-40 s after application ended. We have investigated this secondary response using ion-selective microelectrodes for K^+ and Ca^{2+} located 50-60 mm from the double-barreled iontophoresis pipette.

Quisqualate-activated secondary ion shifts in the GrL were enhanced in zero Mg^{2+} and low Ca^{2+} solutions and inhibited by 10 mM Mg^{2+} or 20 μM AP5. Iontophoresis of quisqualate in the molecular layer (MoL) produced ion changes only during iontophoresis but secondary $[K^+]_o$ and extracellular potential changes were recorded in the MoL following quisqualate iontophoresis in the GrL; the latter MoL events were simultaneous with those in the GrL. Co-iontophoresis of NMDA or kainate (at currents insufficient to elicit ion changes) with quisqualate in the GrL produced only direct ion changes, with no secondary response. Co-iontophoresis of GABA with quisqualate enhanced the secondary effect slightly.

The lack of a primary effect and the characteristics of the secondary response to quisqualate application suggest that quisqualate receptors are located on inhibitory interneurons in the GrL. The secondary response may represent the relief of tonic inhibition of granule cells by inhibitory receptor desensitization. We cannot exclude, however, a modulatory action of quisqualate at kainate or NMDA receptors. Funded by USPHS Grants NS-13742 and NS-07745.

260.6

LIPOXYGENASE MEDIATES THE FORMATION OF CYCLIC GMP INDUCED BY EXCITATORY AMINO ACIDS IN CEREBELLAR GRANULE CELLS.
B. Wroblewska*, J.T. Wroblewski, P.W. Ramwell* and E. Costa. (SPON: A. Berkovich). Dept. of Physiology and Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, D.C. 20007.

In primary cultures of cerebellar granule cells, the activation of N-methyl-D-aspartate and kainate-sensitive excitatory amino acid (EAA) receptors leads to increased entry of extracellular Ca^{2+} and to Ca^{2+}-dependent transient accumulation of cGMP. Our results indicate that the EAA-induced accumulation of cGPM in granule cells depends on the activity of phospholipase A_2, since the enzyme inhibitors quinacrine, p-bromophenacyl bromide or 7,7-dimethyleicosadienoic acid reduced cGMP formation induced by glutamate, aspartate or kainate, but failed to affect the stimulation of guanylate cyclase by sodium nitroprusside. Further experiments on the role of arachidonic acid metabolites in receptorial signal transduction showed that indomethacin, a cyclooxygenase inhibitor, and BW755C, a monoxygenase inhibitor, failed to affect the EAA-induced cGMP accumulation. In contrast, nordihydroguaiaretic acid, an inhibitor of lipoxygenases, abolished the EAA receptor-mediated cGMP accumulation. These resuls indicate that increased accumulation of cGMP, induced by EAA receptors, is mediated by the consecutive action of phospholipase A_2 and one of the lipoxygenases. The transient character of the cGMP response may suggest the regulatory involvement of short-lived lipoxygenase products - hydroperoxyeicosatetraenoic acids.

260.7

DISTRIBUTION OF QUINOLINIC ACID PHOSPHORIBOSYLTRANSFERASE IN THE HUMAN HIPPOCAMPAL FORMATION. F. Du, [1]W.O. Whetsell, Jr., E. Okuno, C. Köhler and R. Schwarcz. Maryland Psych. Research Center, Baltimore, MD 21228 and [1]Dept. Pathology, Vanderbilt Univ., Nashville, TN 37232.

For better understanding of the metabolism of the endogenous excitotoxin quinolinic acid, the distribution of its catabolic enzyme, quinolinic acid phosphoribosyltransferase (QPRT), was studied in the human hippocampal formation with immunohistochemical techniques. In 7 normal human brains obtained at autopsy, QPRT-immunoreactivity (QPRT-i) was found in glial cells and neurons. Glial cells exhibiting QPRT-i were observed in all hippocampal subfields. The polymorphic layer of the dentate gyrus contained the highest density of QPRT-i glial cells. Numerous QPRT-i glial cells also occurred along both sides of the fused hippocampal fissure and in the alveus of Ammon's horn, whereas only a few were observed in the granule cell layer and the stratum pyramidale. Neurons containing QPRT-i were found mainly in the subiculum and in strata oriens and pyramidale of CA1. In addition, moderate numbers of QPRT-i glial cells and neurons were observed in layers II-IV of parahippocampal cortex. The preferential localization of QPRT-i in selected glial cells and neurons suggests that these cellular elements might play specific roles in the regulation of extracellular concentrations of quinolinic acid in the regions examined. Supported by USPHS grants NS 16102 and NS 20509.

260.8

ELECTROPHYSIOLOGICAL EVIDENCE FOR AN EXCITATORY AMINO ACID PATHWAY FROM MEDIAL PREFRONTAL CORTEX TO LATERAL DORSAL TEGMENTAL NUCLEUS AND ROSTRAL LOCUS COERULEUS. D. Highfield and S.J. Grant, Dept. Psychology and Program in Neuroscience, Univ. Delaware, Newark, DE. 19716

We previously reported that electrical stimulation of the Medial Prefrontal Cortex (MPFC) in the rat reliably activated single units in the Lateral Dorsal Tegmental nucleus (LDT), rostral Locus Coeruleus (rLC), and adjacent brainstem areas. The present experiments test the hypothesis that this activation is mediated by an Excitatory Amino Acid (EAA) receptor.

Extracellular single unit recordings from cells driven orthodromically from the MPFC were obtained from chloral hydrate anesthetized rats. All recording sites were histologically verified. In 12/12 units tested, Kynurenic acid (0.1-0.4 µmoles, icv.) produced a dose dependent blockade of the orthodromic response with complete suppression at the highest dose. The NMDA antagonist AP7 (0.04-0.16 µmoles, icv.) did not block the orthodromic response (4/4). Vehicle injections had no effect (2/2).

The results thus far support the hypothesis of an EAA pathway from the MPFC to the LDT-rLC region, but suggest that the receptor is probably not of the NMDA subtype. Work is in progress to determine whether the receptor is the Kainate or Quisqualate subtype.

Supported by a Biomedical Research Support Grant to SJG.

DISTRIBUTION OF GLUTAMATE-LIKE IMMUNOREACTIVITY IN RAT BRAIN. L. Thai*, J.S. Hong, S. Merchenthaler*, W.E. Stumpf, and M. Sar*. Neurobiology program, Department of Cell Biology and Anatomy, University of North Carolina, Chapel Hill, NC 27599; and Laboratories of Molecular and Integrative Neuroscience, National Institute of Environmental Health Sciences, P.O. Box 12233, RTP, NC 27709.

The distribution of Glutamate-like immunoreactivity in forebrain and mid-brain was studied by Avidin-Biotin peroxidase technique using anti-serum to Glutamate (Hepler et al, J. Histochem. Cytochem 36;13-22 1988.) Male rats were perfused with 4% paraformaldehyde solution and 50µm vibratome brain sections were immunostained. Immunostaining with anti-serum to Glutamate (1:7000) was observed in several areas of the brain with varying intensities. No immunostaining was detected with immunoserum pre-absorbed with Glutamate. In the forebrain, specific immunostaining of perikarya was found in the cortex, amygdala, hippocampus, thalamus, preoptic-septal region, anterior hypothalamic areas, and central hypothalamus. In the mid-brain, perikarya staining was detected in the central gray, substantia nigra, and interpeduncular nucleus. The results show a wide distribution of Glutamate containing cells and suggest an excitatory role of these neurons in brain functions (supported in part by NIH grant NS17479.)

COLOCALIZATION OF ASPARTATE- AND GLUTAMATE-LIKE IMMUNOREACTIVITY IN RAT VESTIBULAR NUCLEI. C.S. Toomim and P. Petrusz*. Dept. of Cell Biology & Anatomy, University of North Carolina, Chapel Hill, NC 27599-7090.

Neuronal perikarya in the four main vestibular nuclei (spinal, medial, lateral, superior) stain with antisera specific for aspartate (anti-Asp) and glutamate (anti-Glu) (Toomim et al., Soc. Neurosci. Abst. 12:419, 1986 & 13:1562, 1987). The present experiments were undertaken to determine if staining with the two antisera was colocalized in the same cells. Consecutive 4 um paraffin sections were stained with either anti-Asp or anti-Glu, counterstained with toluidine blue and compared for position and appearance of stained cells. All distinguishable neurons within the vestibular nuclei stained strongly with anti-Asp and less strongly with anti-Glu. Also, strong staining was present in the fibers of the ascending medial longitudinal fasciculus, the path projecting from the vestibular nuclei to the oculomotor nucleus. These data are consistent with the presence of high concentrations of both Asp and Glu in the neurons of the vestibular nuclei. Alternatively, the results may be explained by the presence in these neurons of a single unknown antigen recognized by both antisera.

PROLINE AS AN EXCITATORY AMINO ACID IN THE HIPPOCAMPAL FORMATION: UPTAKE AUTORADIOGRAPHY AND RECEPTOR PHARMACOLOGY. J.V. Nadler, D. Martin, S.D. Bray* and D.A. Evenson*. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Proline is an excitatory and excitotoxic amino acid in the rat hippocampal formation. We have used slice preparations to determine the sites of proline uptake and the mechanism of proline-induced neuronal excitation.

An autoradiographic method was developed to localize Na^+-dependent L-[^{3}H]proline uptake sites. The laminar pattern of uptake sites closely resembled that of D-[^{3}H]aspartate uptake sites. Lesion studies indicated that the perforant path and Schaffer collateral-commissural projections take up proline. The laminar pattern of uptake was largely obliterated by co-incubation with non-radioactive L-proline, but not by co-incubation with L-glutamate or threo-3-hydroxyaspartate. These results suggest that excitatory pathways in the hippocampal formation express transport carriers for proline as well as for glutamate/aspartate.

Pharmacological studies performed on a grease-gap preparation of area CA1 indicated that L-proline depolarizes CA1 pyramidal cells at concentrations of 0.5 mM or higher. D-Proline was inactive. Depolarizing responses to L-proline were largely blocked by D-AP5, Mg^{2+} and Zn^{2+}, but were insensitive to concentrations of Mn^{2+} that abolished synaptic transmission. CNQX was a relatively weak antagonist. TTX reduced L-proline-evoked depolarizations (30-40%) much more than NMDA-evoked depolarizations (10-15%). These results suggest that L-proline depolarizes CA1 pyramidal cells largely by activating postsynaptic NMDA receptors, but may also directly or indirectly activate postsynaptic TTX-sensitive Na^+ channels. (Supported by NIH grant NS 16064.)

HOMOCYSTEIC ACID AS TRANSMITTER CANDIDATE IN RAT CEREBELLAR CLIMBING FIBERS. M. Cuénod, E. Audinat*, K.Q. Do, P. Grandes*, T. Knöpfel, P. Streit, F. Vollenweider* and B.H. Gähwiler. Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland

Homocysteic acid (HCA), known as a strong excitant, has recently been proposed as transmitter candidate, with mixed agonist properties and a preference for NMDA receptors (Do et al., 1986, J. Neurochem. 46:779, J. Neurosci. 6:2226). Upon depolarization of cerebellar slices by 50 mM K^+, the Ca^{++}-dependent HCA efflux was increased by 48% in hemispheres and by 125% in vermis. Ten days after 3-acetyl-pyridine injections, which leads to degeneration of olivo-cerebellar climbing fibers (cf), the stimulated HCA release was abolished, indicating its cf origin.

Highly specific polyclonal antibodies were obtained with glutaraldehyde-linked HCA-albumin conjugates. Immunohistochemistry was performed on semithin sections of perfusion-fixed rat cerebellar tissue. HCA-like immunoreactivity was conspicuous in terminal-like dots and beaded fibrous profiles mostly in close association with Purkinje cell (PC) perikarya and dendrites. Moreover, the immunoreactivity was totally abolished in cf deprived cerebella. These observations suggest that HCA is localised in cf.

In organotypic rat cerebellar slice cultures, PC were voltage-clamped at a potential of -55 to -65 mV. L-HCA (500 uM), NMDA (50 uM to 1 mM), and the non-NMDA receptor antagonist CNQX (10 uM) were superfused in presence of 1 uM TTX. Inward currents were induced by HCA in PC, as well as by aspartate and glutamate, whereas NMDA had no direct effect on PC. The agonist currents were fully antagonized by CNQX. Thus, in mature PC where no-classical NMDA receptor has been reported, HCA activates a non-NMDA receptor.

Taken together, these results support the proposal that HCA is a transmitter in rat cerebellar cf, acting on non-NMDA receptors of PC.

261.1

SYNERGISTIC ACTIVATION OF PROENKEPHALIN GENE EXPRESSION BY CAMP, PHORBOL ESTERS, AND DEPOLARIZATION. S.E. Hyman, M.J.Comb, T.V. Nguyen. Molecular Neurobiology Lab, Massachusetts General Hospital East, 149, 13th St. Charlestown, MA 02129

The integration of multiple intracellular signals is an important mechanism regulating neuronal responses. Here we present evidence that multiple second messenger pathways interact to regulate proenkephalin gene expression. cAMP acts synergistically with phorbol esters, calcium entry, and membrane depolarization to produce high levels of transcription from the human proenkephalin enhancer-promoter. The magnitude of this synergy suggests that pairing of signal transduction pathways is an important mechanism regulating gene expression. Although cAMP is required as one of the partners for maximal stimulation of proenkephalin transcription, the observed synergy is not simply a result of increased activation of the cAMP pathway: the level of gene expression produced by paired inputs is significantly greater than the maximum achievable by cAMP alone. Moreover, prolonged exposure to cAMP agonists results in desensitization of the transcriptional response to cAMP, but even when the cAMP pathway is desensitized, phorbol esters remain active. Surprisingly the synergistic responses to cAMP, phorbol esters, calcium entry, and membrane depolarization all map within the proenkephalin enhancer, suggesting that this short region of DNA confers responsiveness to multiple second messengers.

261.2

MULTIPLE RNA CAP SITES ARE INVOLVED IN THE TISSUE-SPECIFIC EXPRESSION OF THE RAT PREPROENKEPHALIN GENE. G. Weisinger*, J.D. DeCristofaro & E.F. La Gamma (SPON: L. Fochtmann) Depts of Peds and Neurobio, SUNY, Stony Brook, NY

Cholinergic agonists can elevate rat adrenal preproenkephalin (preproenk) steady state mRNA by >100 fold and 3 fold in the brain striatum (see DeCristofaro et. al. Neurosci. Abstr., 1989). One molecular process that could result in these tissue-specific observations, at the transcriptional level, is the regulation of RNA initiation at the gene's cap site(s). To address this, we treated groups of rats with: nicotine (5mg/kg sc ql2h), oxotremorine (1mg/kg sc ql2h), both agents, saline vehicle, or no drug for 4d. Twelve hours after the last injection total RNA was extracted and hybridized to a 133 bp end labelled PvuII-SacI preproenk fragment overlapping the putative RNA cap site(s). S1 nuclease analysis (40ug RNA) revealed multiple cap sites from brain striatum derived from unmanipulated animals and 5-10 fold increased initiation (preserving a similar start site ratio) from all the treated groups striatal RNA. In contrast, 40ug of unmanipulated rat adrenal RNA showed essentially no preproenk initiation but large increases in RNA initiation in the cholinergic agonist treated groups. Changes in the pattern of adrenal preproenk cap site usage observed in these experiments will be verified by primer extension analysis. These studies demonstrate that preproenk RNA expression involves multiple RNA initiation sites, tissue-specificity, and is induced by cholinergic agonists. Supported by NSF #BNS8719872.

261.3

PREPROENKEPHALIN DNA BINDING PROTEINS ARE TISSUE-SPECIFIC. E.F. La Gamma, G. Weisinger* and J.D. DeCristofaro. Depts of Peds & Neurobio, SUNY at Stony Brook, NY 11794-8111.

Transcript initiation and levels of rat preproenkephalin mRNA differ by as much as 10- to 100-fold between the adrenal medulla and brain striatum in baseline and induced states, respectively (DeCristofaro & Weisinger, Neurosci '89). This indicates tissue-specific expression exists in this species. Regulation appears to reside at the level of membrane-linked signal-transduction or at "cis"-acting elements/DNA binding proteins. To address this, we are exploiting gel shift assays to initially characterize nuclear proteins from adrenal medulla, brain striatum, liver, AtT-20 cells, HeLa cells, and other lines. These tissues show unique as well as shared patterns of protein binding to fragments of the rat preproenkephalin gene from -360 to -249, from -248 to -89, and from -88 to +51 (relative to the putative Cap site). Strongest banding is localized to the region -360 to -88; is competed away by unlabeled homologous DNA; but not by non-specific DNA (dA/dT). Competition studies using fragments of the double stranded DNA tumor virus SV40 (38-fold excess) indicate that two striatal-specific bands can be competed away by the promoter region containing the 21 bp repeats but not by the 72 bp enhancer. This suggests an SP1-like DNA binding protein may exist in native rat tissues. Whether differences in banding represent site-specific binding or function is being evaluated by footprinting and transfection studies. Supported by NSF grant #BNS8719872.

STRUCTURAL LINKAGE OF RAT VASOPRESSIN AND OXYTOCIN GENES. T.G. Sherman and S.J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

The rat vasopressin/neurophysin-I and oxytocin/neurophysin-II precursors are encoded by a pair of genes whose close homology strongly suggested that these genes arose via a duplication event from an ancestral gene during evolution. As part of ongoing studies into the neuroendocrine regulation of vasopressin and oxytocin mRNA expression, vasopressin and oxytocin genes were isolated from a rat lambda gt10 library. Closer examination of the 3' non-transcribed regions of two lambda inserts, one from a vasopressin positive and one from an oxytocin positive, revealed a short segment of DNA that cross-hybridized between the two clones. The possibility existed, therefore, that the vasopressin and oxytocin genes existed side-by-side in the rat genome, analogous to what had been shown in a human small cell lung cancer cell line, H378. To investigate this further in rat, a cosmid library was prepared in pWE15 using MboI-partially digested liver DNA with an average insert size of 40-45 Kbases. Screening of duplicate lifts of 100,000 recombinants with either vasopressin gene exon C or oxytocin gene exon C resulted in 4 positives, three of which were double positives. The fourth was positive for only vasopressin. Southern mapping of these double positives revealed that the EcoRI, PstI, and NcoI positive vasopressin or oxytocin hybridizing fragments were identical in size to those on the previously isolated individual lambda clones. The 3' localization of the shared fragments in the lambda clones suggests that the vasopressin and oxytocin genes reside on opposite DNA strands, with their 3' ends facing each other at a distance of 10-15 Kbases. This orientation has been closely associated with recent gene duplication events. Studies are continuing in the mapping of the inter-genic domain, as well as elucidating the apparent divergence of duplicated tissue-specific and transcriptional regulatory regions.

RAT CORTICOTROPIN RELEASING HORMONE GENE: ANALYSIS OF TRANSCRIPTIONAL CONTROL ELEMENTS. A.F. Seasholtz* and R.C. Thompson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

The rat corticotropin releasing hormone (CRH) gene has been isolated and characterized (Thompson, R.C., Seasholtz, A.F., and Herbert, E., Mol. Endo., 1:363, 1987). The CRH gene is expressed in many regions of the brain as well as several peripheral tissues including rat testis which expresses a significantly larger CRH transcript. CRH mRNA structural analyses have mapped the brain transcription initiation sites and suggest that the testicular CRH mRNA represents an alternatively spliced mRNA arising from a more distant 5' promoter element. In addition to the CRH mRNA structural analyses, transcriptional control elements in the 5' flanking sequence of the rat CRH gene are being identified and localized using cultured cells that have been transfected with a chimeric gene (CRHCAT) containing the rat CRH 5' flanking DNA linked to the bacterial chloramphenicol acetyltransferase gene. A cAMP responsive element has been localized to the region between 238 and 180 bp 5' to the major brain CRH mRNA cap site (Seasholtz, A.F., Thompson, R.C., and Douglass, J.O., Mol. Endo., 2:1311, 1988). The endogenous rat CRH gene has been shown to be negatively regulated by glucocorticoids in the hypothalamus, and we have been able to demonstrate regulation of rat CRHCAT expression by glucocorticoids in several transfected cell lines. The exact location of the glucocorticoid responsive element is being determined using in vivo competition studies and deletion analysis in both transiently and stably transfected cell lines.

261.6

CLONING AND CHARACTERIZATION OF cDNAS AND GENES ENCODING RAT AND HUMAN NEUROMEDIN B, A MAMMALIAN BOMBESIN-LIKE PEPTIDE. I.M. Krane*, W.W. Chin* and E.R. Spindel (SPON: P.C.K. Leung). Div. of Genetics, Dept. of Medicine, Brigham & Women's Hospital; Harvard Med. School; Boston, MA 02115 and Div. Neurosci., Oregon Regional Primate Research Ctr.; Beaverton, OR 97006.

The diverse biological effects of amphibian bombesin and its mammalian homolog, gastrin-releasing peptide (GRP), are well documented. Less is known about the amphibian bombesin-like peptide ranatensin and its homolog, neuromedin B (NMB). NMB has been isolated from porcine spinal cord as a decapeptide (NMB-10) and as a 32 amino-acid peptide (NMB-32). GRP and NMB have a similar but distinct distribution throughout the brain and GI tract. Our laboratory has reported previously the isolation of the human NMB cDNA and we now report the isolation and characterization cDNAs encoding rat NMB as well as the genes encoding both the human and rat forms. Using a full-length human NMB cRNA probe, human genomic clones containing the three exons of the NMB gene were isolated from a genomic library. The intron/exon organization of the human NMB gene is similar to that previously reported for the human GRP gene in that there are two introns, one of which interrupts a codon coding for a Gly residue in the bioactive portion of the peptide. In order to characterize tissue specific NMB gene expression more fully, the human NMB cDNA was used to isolate both the rat NMB gene and its corresponding cDNA. Sequence analysis of hybridizing cDNA clones revealed a 670 bp cDNA encoding an 83 amino-acid preprohormone. In the precursor, a signal peptide is followed by NMB-32 and a short C-terminal extension peptide. The amino-acid conservation among the rat, porcine and human NMB-32 peptides is quite remarkable; the only differences occur in the amino-extended form of the peptide where the rat and human differ by three amino acids and the rat and porcine sequences differ by only two. RNA blot analysis shows hybridizing RNAs of approximately 900 bases, with highest mRNA concentrations found in the pituitary.

NEUROENDOCRINE EXPRESSION OF A SOMATOSTATIN-SV40 T ANTIGEN FUSION GENE IN TRANSGENIC MICE. R. Ventimiglia, V. Fairchild*, R. H. Goodman*, and M. J. Low*. Division of Molecular Medicine, New England Medical Center, Tufts U. School of Med., Boston, MA 02111

Somatostatin is a peptide hormone produced in neurons in discrete regions throughout the central nervous system as well as in non-neural tissues including the endocrine pancreas and gut. To identify the elements within the somatostatin gene that direct tissue-specific expression, we have examined the expression of a somatostatin fusion gene in transgenic mice. Fertilized mouse eggs were injected with a 4.0 kilobase fragment of the rat somatostatin gene fused to a 2.6 kb fragment containing a mutant (non-transforming) SV40 T antigen. Five mice carrying the integrated hybrid gene were identified by dot blot analysis. T antigen (TAg) expression was detected immunohistochemically in four of the five lines of mice. A consistent pattern of expression was observed in each of the four lines. TAg immunoreactivity was restricted to cell nuclei, and was detected in layers II-VI of the cerebral cortex, the stratum oriens, pyramidal cells, and hilus of the dentate gyrus of the hippocampus, and in the caudate nucleus, reticular nucleus of the thalamus, and zona incerta. In the retina, TAg immunoreactivity was detected in presumptive amacrine cells in both the inner nuclear layer and ganglion cell layer. TAg immunoreactivity was also detected in peripheral cells of the pancreatic islets, characteristic of somatostatinergic D cells. We conclude that elements within 4.0 kb of the 5' flanking region of somatostatin are sufficient to direct both neural and endocrine expression of the gene.

IDENTIFICATION OF GENETIC ELEMENTS IMPORTANT FOR CELL-SPECIFIC EXPRESSION OF THE HUMAN VIP GENE. J. S. Fink Lab. of Molecular Neurobiology, Dept. of Neurology, Massacusetts General Hospital, Boston, MA 02129.

The cell-specific expression of many genes has been determined to result from the action of one or more genetic elements that act in *cis* to control transcription. To begin to understand the molecular mechanisms which control the cell-specific and developmental regulation of neural genes, genetic elements in the human VIP gene that are important for directing its neural-specific expression were identified. VIP is a 28 amino acid peptide that is present in neurons of the central and peripheral nervous systems, sparsely in cells of the adrenal medulla and ectopically in some tumors of neural crest origin. Fusion genes containing portions of the 5'-flanking region of the VIP gene linked to a reporter gene chloramphenicol acetyltransferase (CAT) were transfected into several VIP-producing or VIP-lacking cells lines. CAT activity in the cell lysates assayed 48-72 hours after transfection provided an index of transcriptional activity under the control of portions of the 5'-flanking sequences. Both positively and negatively-acting genetic sequences that direct cell-specific expression of the VIP gene were identified. VIP-CAT fusion genes containing 94 bp of 5'-flanking sequence and 146 bp of exon 1 (VIP94CAT) were 7 to100-fold more active in the VIP-expressing human neuroblastoma cell lines SH-SY5Y and NB-Fl than in cells that do not synthesize VIP (PC12, HeLa, C6 glioma, COS-7). A 31 bp fragment within this postively-acting region was capable of transferring cell-specific expression to a heterologous viral promotor. In cells that do not synthesize VIP the activity of VIP94CAT was much less than a fusion gene containing 2000 bp of 5'-flanking sequence. In the VIP-expressing neuroblastoma cell lines, the activity of VIP-CAT fusion genes containing 94 or 2000 bp of 5'-flanking sequence were comparable. These studies demonstrate that (1) a positively-acting cell-specific genetic element is contained within 94 bases of the 5'-flanking region of the human VIP gene, and (2) a negatively-acting genetic element(s) or "silencer" acts to repress VIP gene transcription in non-neuronal cell types.

261.9

ESTROGEN REGULATION OF RAT GALANIN TRANSCRIPTION IS MEDIATED BY SEQUENCES IN THE 5'-FLANKING REGION OF THE GALANIN GENE. L.M. Kaplan, D. Abraczinskas*, M. Davidson*, W.W. Chin*. Gastrointestinal Unit, Massachusetts General Hospital and Division of Genetics, Brigham & Women's Hospital, Boston, MA 02114.

Galanin is a neuroenteric peptide which regulates the secretion of several pituitary and pancreatic hormones. We have previously shown that galanin gene expression in the rat anterior pituitary (AP) varies over a several thousand-fold range depending on the levels of circulating estrogens (PNAS **85**:7408, 1988). We investigated the mechanisms by which estrogen regulates galanin gene expression. Nuclear run-on studies were performed using rat pituitaries isolated after treatment *in vivo* with 17β-estradiol benzoate (100 μg/kg s.c.) or carrier. These studies revealed that estrogen increases AP galanin gene transcription up to 70-fold with a maximal effect 6 hr after treatment. In order to examine transcriptional regulation further, we isolated and characterized the gene encoding rat galanin. This gene contains 6 exons and extends approximately 6 kb. Plasmids containing the native galanin promoter and up to 1.8 kb of 5'-flanking sequence inserted upstream of the firefly luciferase gene were transfected into AP-derived GH_3 cells that were subsequently incubated for 48 hr in medium ± 17β-estradiol (10^{-9} M). Expression of the chimeric plasmids was determined by luciferase activity in GH_3 cell extracts. Estrogen stimulated the expression of plasmids containing the full 1.8 kb fragment approximately 30-fold. Mutants deleted in various portions of the galanin 5'-flanking region abolished the response to estrogen in this system. We have used these mutants to identify sequences which confer the observed estrogen-induced stimulation of galanin gene transcription.

261.10

MOLECULAR CLONING OF THE TRYPTOPHAN HYDROXYLASE (TPH) GENE IN *DROSOPHILA*. W. Neckameyer* and K. White * (spon: T. Tully). Dept. of Biology, Brandeis University, Waltham MA 02254

A full-length cDNA encoding rabbit TPH (Grenett *et al*, PNAS **84**:5530, 1987) was used to isolate *Drosophila* cDNA clones on the basis of hybridization at reduced stringency. Sequence analysis of an essentially full-length *Drosophila* cDNA showed considerable homology to rabbit TPH at both the DNA and deduced protein levels, but greater homology to rat phenylalanine hydroxylase (PAH). However, Southern analysis of *Drosophila* genomic DNA with rabbit TPH and and several of the *Drosophila* cDNA isolates indicated a single gene that was recognized by all probes used. The *Drosophila* cDNA clone hybridized to a single site on larval polytene chromosomes at region 66A. Northern analysis showed a single transcript of 1.75 kb which was enriched in adult heads, but which was also present in adult bodies and 0-6 hour embryos. This data raises the possibility that *Drosophila* has only two hydroxylase-family genes: tyrosine hydroxylase (TH, Neckameyer and Quine, Neuron **2**:1167, 1989) and a gene encoding both TPH and PAH functions.

261.11

MAPPING OF A FUNCTIONAL GLUCOCORTICOID RESPONSE ELEMENT IN THE RAT PHENYLETHANOLAMINE N-METHYLTRANSFERASE PROMOTER. M.E. Ross, M.J. Evinger, T.H. Joh, D.J. Reis, and H.M. Goodman Depts of Mol. Biol., Mass. Gen. Hosp., Boston, MA 02114 and Neurol. and Neurosci., Cornell Univ. Med. Coll., New York, NY 10021. The catecholaminergic phenylethanolamine N-methyltransferase (PNMT) gene was cloned in rat and a consensus sequence for a glucocorticoid response element (GRE) was found at -513 bp, 5' to the transcriptional start site (Ross et. al., Soc. Neurosci. 1988, 14:1250). In order to define the function of this element, fusion genes containing the PNMT promoter and a chloramphenicol acetyltransferase (CAT) reporter were constructed. However, they did not express in any of 7 continuous cell lines transfected, none of which endogenously produce PNMT. A system for transfecting bovine adrenal chromaffin cells in primary culture was therefore devised. Using these chromaffin cells, both basal and regulated CAT expression of the PNMT fusion constructs was detected. In the presence of dexamethasone (dex) (20 μM) pPNMT3000 and pPNMT900, containing the putative GRE and 3000 bp or 863 bp of PNMT promoter sequence, respectively, displayed a 4 to 10 fold induction in CAT activity. Both pPNMT300 and pPNMT100, which lack the GRE and contain 273 bp or 99 bp of PNMT promoter sequence, respectively, were unaffected by dex. Addition of the PNMT region spanning -490 bp to -863 bp conferred full dex responsiveness to a thymidine kinase promoter. Deletion of the putative GRE by oligonucleotide directed mutagenesis abolished the response to dex. These data identify the sequence at -513 bp in the rat PNMT gene as a functional GRE.

GAD SEQUENCES MAP TO TWO MOUSE CHROMOSOMES. M. H. Brilliant[1], G. Szabo[2*], Z. Katarova[2*], C. A. Kozak[3*], T. M. Glaser[4*], R. J. Greenspan[5] and D. Housman[4*]. [1]Fox Chase Cancer Center, Philadelphia, PA; [2]Hungarian Academy of Sciences, Hungary; [3]NIH, Bethesda, MD, [4]MIT, Cambridge, MA; [5]Roche Institute, Nutley, NJ.

The chromosomal locations of mouse DNA sequences homologous to a feline cDNA clone encoding glutamic acid decarboxylase (GAD; Kaufman et al., Science 232:1138, 1986) were determined. Although cats and humans are thought to have only one gene for GAD (Erlander et al., Soc. Neurosci. Abstr. 13:857, 1987), GAD cDNA sequences hybridize to two distinct loci in the mouse, on Chromosomes (Chrs) 2 and 10. The mapping of sequences homologous to GAD cDNA utilized Southern hybridization analysis of DNA from mouse-hamster hybrid cells, an inter-specific backcross and recombinant inbred strains. Mouse genomic sequences homologous to GAD cDNA were isolated and used to determine that GAD is encoded by a locus on mouse Chr 2 (Gad-1) and that an apparent pseudogene locus is on Chr 10 (Gad-1ps). The Gad-1 locus maps near several neurological mutations and is part of a homology of synteny between mouse Chr 2 and the long arm of human chr 2.

QUANTITATIVE AND QUALITATIVE CHARACTERIZATION OF MULTIPLE APP RNA FORMS IN NORMAL AND ALZHEIMER'S BRAINS BY S_1 PROTECTION ANALYSIS. J. Steven Jacobsen*, Robert J. Donnelly*, Arthur J. Blume, Bernard Beer and Michael P. Vitek. Molecular Neurobiology, CNS Research, Lederle Laboratories, American Cyanamid Company, Pearl River, NY 10965.

Three Amyloid Peptide Precursor RNAs (*i.e.*, APP 695, 751 & 770) have been identified in Alzheimer's diesease (AD) and normal brain. To determine if the amount of one or more of these APP RNAs changes in AD, we used an anti-sense [^{32}P]-riboprobe derived from the protease inhibitor region of APP 770 (*i.e.* the *Dde*1-*Xho*1 fragment) in an S_1 nuclease protection assay [Donnelly, R.J. *et al. in* Alzheimer's Disease and Related Disorders, Alan R. Liss, Inc., NY, 1989]. All brain regions examined and some peripheral tissues contain 695, 751 and 770 APP RNAs. The rank order in frontal cortex of normal and AD brains is 695>751>770. In temporal cortex from AD brains, there are individuals with the frontal rank order and others which rank 751>695>770. Data from additional brain regions (*e.g.*, parietal and occipital cortex) are complex. Using microtubulin-associated protein (MAP2) and cyclophilin internal controls, our data imply a change in the absolute amounts of APP RNA forms between normal and AD brains. S_1 analyses also reveal protected probe fragments which are not predicted by the known APP cDNA sequences indicating the existence of additional as yet uncharacterized APP RNAs. In addition, S_1 analysis has been used to determine the effects of several hormones on the quality and quantity of APP gene expression.

262.2

SYNAPTIC LOCALIZATION OF THE A4 PROTEIN PRECURSOR OF THE AMYLOID OF ALZHEIMER'S DISEASE. J. Beer*, A. Weidemann*, P. Fischer*, D. Bunke*, C. Masters* and K. Beyreuther* (SPON: S. Scheff). Center for Molecular Biology of the University of Heidelberg, 6900 Heidelberg, FRG.

Alzheimer's disease is a progressive neurodegenerative disorder which is characterized by the deposition of amyloid A4 protein in the central nervous system. The A4 protein is part of a precursor protein (PreA4). Three different mRNAs arise from the PAD-gene (Precursor of Amyloid in Alzheimer's disease and Down's Syndrome) by alternative splicing and encode primary translation products of 695, 751 and 770 amino acids.

We have raised polyclonal and monoclonal antibodies against the brain specific $PreA4_{695}$ and the synthetic cytoplasmic domain common to all three primary translation products. Using standard immunolabelling techniques we demonstrated the neuronal and synaptic localization of PreA4 proteins in cryosections of snap frozen tissues from rat brain. This immunolocalization supports the hypothesis of a role for PreA4 proteins in cell-cell interactions. Furthermore these proteins may contribute to synaptic function and may be degraded to amyloid at synaptic sites. These results forward the hypothesis of the neuronal origin of A4 amyloid deposition.

262.3

BETA AMYLOID PROTEIN PRECURSOR (BAPP) DEPOSITION AND CYTOSKELETAL DISRUPTION MAY BOTH BE PREREQUISITES FOR ALZHEIMER'S DISEASE (AD) AC McKee, LI Binder, KS Kosik and NW Kowall Depts Neurol & Neuropathol, Harvard Med Sch, Boston MA 02114; Dept Cell Biol Anat, UAB, Birmingham AL 35294.

We found isolated deposits of BAPP (antiserum courtesy of DJ Selkoe) in temporal isocortex of aged adults and of a Down's child. Staining with MAP2, MAP 1b and tau was normal. MAP 1b stains dentate granule cells and forms a trilaminar pattern in the molecular layer. Pyramids in CA3>CA2>CA4 were intensely MAP 1b ir, while CA1, pre-, and subiculum were not. Pro- & para-subicular pyramids were strongly ir as were entorhinal star cells and layer III-VI neurons. In AD, BAPP forms variably sized globular deposits in the dentate molecular layer, CA fields and subiculum.Superficial pro- and para-subiculum contain clouds of punctate BAPP. Entorhinal layers III-VI, subpial and layers II-VI temporal isocortex are positive.MAP 1b staining in AD shows enhanced ir of CA1 pyramids and loss of the laminar pattern in dentate molecular layer.Tau abnormalities do not parallel BAPP deposition. Tau dystrophic neurites are numerous where BAPP deposition is absent, BAPP deposits outnumber tau neurites of senile plaques, and the confluent areas of punctate BAPP staining are not tau ir.These findings show that, in AD, BAPP deposition and tau ir are not co-extensive, and that BAPP deposition may precede tau neurites and neurofibrillary tangles and MAP2 proliferative abnormalities.Furthermore, MAP 1b, which is under strong developmental regulation, is reexpressed in CA1 pyramids in AD suggesting that neuritic proliferation is associated with the re-emergence of fetal characteristics.BAPP deposition and cytoskeletal disruption may both be necessary for the development of AD.

SPATIAL RELATIONSHIP OF AMYLOID PLAQUES AND CAPILLARIES IN ALZHEIMER DISEASE. M. Kawai*, S.I. Harik, R.N. Kalaria and G. Perry. Inst. Pathology and Dept. Neurol., Case Western Reserve Univ., Cleveland, OH 44106.

The theory that amyloid plaques (AP) of Alzheimer disease (AD) are formed by abnormal leakage from brain capillaries finds much of its support in reports that AP contain capillaries. Since these studies did not perform statistical analysis, we quantitatively analyzed the spatial relationship between capillaries and APs in AD. Vibratome sections (60μm) of AD hippocampus were immunostained with a MAb to β-protein (gift of G. Glenner) (APAPP) and counterstained with a rabbit serum to collagen IV (PAP). Classification of the APs showed that while 60% of AP are associated with capillaries only 8% are penetrated by a vessel, remainder being adjacent. To test whether (1) the interior of the AP or (2) the borderzone (10μm rim outside the AP) has statistically higher density of capillaries than (3) the rest of the cortical gray matter, similarly double-stained 6μ sections from 3 cases of AD were photographed and the capillary densities in the 3 areas calculated by using a BioQuant. The capillary densities of (1), (2) and (3) in one of the 3 cases were 36.5/mm^2, 250.0/mm^2 and 127.6/mm^2 respectively. x^2-test demonstrated that (1) and (3), (2) and (3) are significantly different at p=0.01. The combined area of (1) and (2) had a density of 137.9/mm^2, not significantly different from the rest of the gray matter (3). Essentially identical results were obtained for the other 2 cases. It is concluded that the frequently observed association of AP to capillaries can be statistically explained by chance contact as well as by exclusion of capillaries from the plaque interior. ARYLESTERASE AND PARAOXONASE LEVELS IN SUSPECTED ALZHEIMER PATIENTS AND AGE-MATCHED CONTROLS. D.E. Moss, D. Wong*, A. Enriquez*, S.F. Sands, and R.H. Whitworth*. Alzheimer's Disease Research Project, Univ. Tex. El Paso, El Paso, TX 79968-0553.

Reduced levels of serum arylesterase (ARYL) and paraoxonase (PXN), proteases implicated in degrading amyloid A, are found in reactive systemic amyloidosis [Maury et al., J. Lab. Clin. Med. 104:761, 1984]. Beta amyloid in Alzheimer's disease may also come from extracellular sources [e.g., Glenner and Wong, Biochem. Biophys. Res. Commun. 122:1131, 1984]. Serum ARYL and PXN were studied in 10 patients suspected of SDAT and 10 age-matched controls. There was no difference between SDAT and normals in ARYL. Surprisingly, however, PXN was significantly higher in SDAT; almost double control values. In brain bank tissue, 6 samples from autopsy-confirmed Alzheimer cases or 6 normals showed no difference in ARYL. However, the one available case of Creutzfeld-Jakob disease had ARYL levels about twice all other brains. There was insufficient PXN activity in brain for reliable measurement. Increased expression of serum PXN in patients with neurological disorders may mark an enzyme response related to amyloid metabolism. Further research will be required to extend this limited study and determine if this change is unique to Alzheimer's disease.

Supported in part by NIMH (RR08012) and MBRS Program.

PROTEOLYTIC PROCESSING OF β-PROTEIN PRECURSOR-RELATED SYNTHETIC PEPTIDES. C.R. Abraham and H. Potter. Dept. Neurobiology, Harvard Med. Sch., Boston, MA 02115.

We have shown that the serine protease inhibitor α_1-antichymotrypsin (ACT) is found in the amyloid deposits of the β-protein type in Alzheimer's disease (AD), Down's syndrome, normal aging of humans and monkeys and hereditary cerebral hemorrhage with amyloidosis of Dutch origin. It is believed today that an aberrant proteolytic processing of the β-protein precursor or inadequate clearing of the β-protein is the cause of the β-protein accumulation. The identification of brain-specific proteases involved in this process is therefore crucial. Since ACT is known to inhibit serine proteases such as chymotrypsin and cathepsin G, we tested whether these proteases can cleave synthetic peptides made around the extracellular N-terminal cleavage site of the β-protein. Using thin-layer chromatography (TLC) and HPLC, we showed that these two proteases are able to cleave between methionine and aspartic acid, aspartic acid being the N-terminus. Chymotrypsin and cathepsin G, though, are not found in the brain. In order to detect brain serine proteases that are able to cleave at the met-asp bond, we added a histidine at the N-terminus of the peptide and iodinated it so we could follow the cleavage products after incubation with brain extracts. Cathepsin G cleaved the labeled peptide, as did the soluble fractions of brain homogenates from both control and AD brain, as seen on TLC. Specific cross-linking of the iodinated peptide to brain fractions and separation on SDS gels revealed bands of approximately 20-35 kD, which are in the process of being characterized. Labeling of brain homogenates with ^{3}H-DFP also reveals bands of similar molecular weights, suggesting that these proteins may be serine proteases.

ALZHEIMER AMYLOID PRECURSOR PROCESSING: RAMIFICATIONS TOWARD DISEASE ETIOLOGY. B.D. Greenberg, D.E. Lowery*, P.A. Gonzalez-DeWhitt* and R.A. Altman*. Molecular Biology Research, The Upjohn Company, Kalamazoo, MI 49001.

The role of amyloid precursor processing in the etiology of Alzheimer's Disease is still unclear. We and our collaborators, as well as several other groups have shown that protein sequences within the amyloid precursor, but outside the plaque core protein domain are associated with amyloid deposits in Alzheimer brain. These observations, however, do not distinguish two likely scenarios. The amyloidogenic β-protein might be created by *in situ* processing of the precursor, or full length precursor may adventitiously associate with preexisting amyloid deposits following release by degenerating neurites. This is an important question since the two pathways significantly differ, impacting potential therapies based on etiological models of the disease. We are proceeding with our efforts to resolve such questions, employing recombinant DNA technology toward generating precursor protein and related antisera. These approaches and the application of these reagents will be the topic of this presentation.

PCR AMPLIFICATION OF REVERSE TRANSCRIBED RNA REVEALS A FOURTH ALTERNATIVELY SPLICED βAPP mRNA. T. E. Golde, S. Estus, L. H. Younkin, and S. G. Younkin. Institute of Pathology, Division of Neuropathology, and Department of Pharmacology, Case Western Reserve University School of Medicine, Cleveland, OH 44106

The ß amyloid protein precursor (βAPP) gene has been shown to produce at least three mRNAs (βAPP_{695}, βAPP_{751}, and βAPP_{770}) through alternative splicing of two adjacent exons that encode 56 and 19 amino acid inserts. We have used polymerase chain reaction (PCR) amplification of reverse transcribed mRNA to unambiguously detect the various βAPP mRNAs and to quantitate their relative levels. Using oligonucleotide primers that flank the site of alternative splicing, we specifically amplify 87, 255, and 312 bp fragments derived respectively from the βAPP_{695}, βAPP_{751}, and βAPP_{770} mRNAs. In RNA isolated from U87-MG, a human glioblastoma cell line, and from a variety of human brain regions, an additional band at 144 bp is also specifically amplified. Sequencing of this band reveals that it is derived from a previously undocumented βAPP_{714} mRNA containing only the insert that encodes the 19 amino acid domain. As expected, relative quantitation of the various βAPP mRNAs reveals expression of βAPP_{695} > βAPP_{751} >> βAPP_{714} and βAPP_{770} in all regions of the brain examined, whereas levels of βAPP_{751} and βAPP_{770} > βAPP_{695} in the liver. Significantly, we also observed high levels of expression of all forms of the message in white matter RNA. This indicates that non-neuronal cells in the brain produce appreciable amounts of βAPP mRNA. To assess expression of the βAPP gene in Alzheimer's disease, we are currently using the polymerase chain reaction to analyze RNA from a variety of brain regions in a number of Alzheimer's disease cases and in well matched controls.

262.10

PHYSIOLOGICAL FUNCTION OF AMYLOID β-PROTEIN PRECURSOR M. Sundsmo*, J.-M. Roch, T. Oltersdorf*, D. Schenk*, and T. Saitoh. University of California, San Diego, Dept. of Neurosciences, M-024, La Jolla, CA 92093, U.S.A. and Athena Neurosciences, Inc., 800 F Gateway Blvd., South San Francisco, CA 94080, U.S.A.

Amyloid β-protein precursor (ABPP) has a nearly ubiquitous tissue expression and is conserved through varying species from Drosophila to man, suggesting a potential major role in cell biology. This work elucidates a possible function for ABPP. A fragment of amyloid β-protein precursor cDNA was conjugated in the antisense orientation to an eukaryotic promoter and transfected into fibroblasts. The fibroblasts harboring this construct (pNCA, neuritic core antisense) produced 75% less ABPP mRNA (by Northern blot analysis) and 60% less ABPP (by Western blot analysis using an antibody directed against a synthetic peptide from the N-terminal region of ABPP). These transfected cells grew poorly in the presence of 10% serum as compared to nontransfected control cells . Normal growth was restored when medium conditioned by parent cells (final concentration of 30%) or partially purified ABPP (final concentration of 10 ng/ml) was provided. The capacity of the conditioned medium (CM) to restore cell growth was entirely abolished by passage through an anti-ABPP affinity column; the activity was recovered in the bound fraction. These results are consistent with the hypothesis that ABPP is released from cells into the medium and has an autocrine function, suggesting its basic role in growth regulation.

INDUCTION OF THE AMYLOID PRECURSOR PROTEIN GENE PROMOTER IN CULTURED CELLS. R. J. Donnelly*, A. J. Friedhoff, B. B. Beer#, A. J. Blume#, and M. P. Vitek#. Millhauser Laboratories, Department of Psychiatry, NYUMC, 550 First Avenue, NY, NY 10016 and #Molecular Neurobiology, CNS Research Dept., Lederle Laboratories, Pearl River, NY.

Using sequences from the APP 770 cDNA (Donnelly et al., Neurobiol. Aging 9(1988)333), we have isolated the promoter region of the single copy gene for Amyloid Precursor Protein (APP). DNA sequencing has identified several elements homologous to either constitutive or inducible genes. We have constructed a reporter gene system in which fragments of the promoter were fused to the human growth hormone (hGH) gene. We have found that cells transfected with different promoter fragment constructs produce varied levels of hGH suggesting that constitutive elements within the promoter are functional. Inducibility of the promoter fragments containing different groups of elements was tested by treating the transfected cells with human recombinant interleukin-1 (IL-1). This treatment resulted in a two fold stimulation of hGH production. Promoter constructs containing nucleotides -485 to +101 responded to the induction but constructs containing nucleotides -305 to +101 did not. Therefore the IL-1 responsive sequences map between nucleotides -485 and -305, a region which may also be responsive to other trophic factors. We have now produced stably transfected cells containing promoter fragment constructs to enable characterization of the nature of IL-1 induction and the effect of other trophic factors on this promoter.

262.12

MITOGENIC ACTIVITY OF MEDIUM CONDITIONED BY TRANSFECTED CELLS EXPRESSING A NEUROTOXIC FRAGMENT OF THE ALZHEIMER AMYLOID PRECURSOR. S. Fidel*, L.R. Dawes, R.L. Neve. (SPON: K. Walton) The Children's Hospital, Boston, MA 02115

Neuritic plaques in Alzheimer disease often contain core deposits containing beta-amyloid (a peptide derived from the C-terminus of the amyloid precursor protein [APP]) in association with dystrophic neurites and proliferating glial cells. Recent work has shown that peptides derived from the C-terminal region of APP have effects on neuronal outgrowth and survival.

Conditioned medium (CM) from transfected NIH 3T3 cells expressing the C-terminal 105 amino acids (AB1) of APP has previously been shown to be toxic to differentiated PC12 cells, as well as to cultured hippocampal neurons. We are now examining the mechanism of the neurotoxic activity of this AB1 CM. One possibility is that the AB1 CM is mitogenic, which could have deleterious effects on nonproliferating terminally differentiated neurons. Significant mitogenic activity, as measured by DNA synthesis in quiescent BALB/c 3T3 cells, was present in AB1 CM compared with control CM from nontransfected cells. Genetic and biochemical studies are currently underway to further characterize the mitogenic activity of the AB1 CM. We thank Paul Fanning for technical assistance, and Dan Raben for helpful discussions.

THE PROTEASE INHIBITOR CONTAINING FORM OF β-AMYLOID PRECURSOR PROTEIN PROMOTES NEURITE OUTGROWTH L.D.Altstiel[1,2], N.K. Robakis[1], (SPON: P. Knott) [1]Department of Psychiatary and Fishberg Neurobiology Center, Mount Sinai School of Medicine, New York, N.Y. 10029. [2]Department of Psychiatry, Bronx VA Medical Center, Bronx, NY.

The major component of the neuritic plaque and cerebrovascular amyloid of Alzheimer disease is a 4.2 KDa protein termed β-protein or A_4 peptide. The sequence of β-protein is part of at least three distinct precursors βAPP_{695}, βAPP_{770}, βAPP_{751}. βAPP_{770} and βAPP_{751} contain a 57 amino acid insert with high sequence homology to the Kunitz-type serine protease inhibitors (KPI) which is not present in βAPP_{695}. Synthetic peptides with amino acid sequence derived from the sequence predicted by βAPP cDNA were used as antigens to prepare antisera against specific regions of βAPP. Immunofluoresence and immunohistochemical microscopy indicated that the KPI containing βAPP is located on the cell bodies, axons, and growth cones of cultured neuronal cells (PC12 and Sy5y cells). Antisera specific to the KPI insert inhibited nerve growth factor (NGF) induced neurite outgrowth in both PC12 and Sy5y cells while antisera specific to βAPP regions common to all three precursors had no effect on neurite outgrowth. NGF-treated PC12 cells shed large amounts of the KPI containing βAPP into the culture medium. In addition, NGF treated PC12 cell culture medium contained high levels of protease inhibitory activity. Antibodies specific to the KPI-insert present in βAPP blocked the protease inhibitory activity present in the conditioned medium. These results indicate that 1) KPI-containing βAPP promotes neurite outgrowth and 2) that this effect may be mediated via the protease inhibitory activity of the KPI.

PROCESS OUTGROWTH, GROWTH CONES AND GUIDANCE MECHANISMS IV

263.1

MOLECULAR CLONING OF UNC-116, A GENE INVOLVED IN AXONAL GUIDANCE IN C. ELEGANS. Jorge R. Mancillas and Danielle Thierry-Mieg, Dep. of Anatomy and Cell Biology, UCLA and CNRS, Paris, France.

Unc-116 is a mutant of C. elegans which was isolated during a screen for mutants with abnormalities in backward locomotion. Unc-116 displays anatomical defects which include mispositioning of a number of longitudinal nerve processes normally occupying a lateral position.

We cloned unc-116 by a combination of transposon tagging and use of the C. elegans physical map: 1) a polymorphic 1.67 kb Hind III fragment was identified by probing genomic Southern blots with a set of overlapping cosmid clones in the mab-5/unc-86 contig of the physical map; 2) probing with TC5 (one of the C. elegans transposons), revealed a band that consistently segregates with the unc-116 phenotype.

A 2.8 kb transcript that hybridizes to the Hind III fragment and to the cosmid clones was identified by Northern blot analysis of wild type mRNA. In unc-116 mRNA, this band appears as a 6.4 kb transcript, suggesting that the TC5 sequence is transcribed in the mutant. We have isolated 3 cDNAs and placed them and the transcript in a detailed restriction map of the region, allowing us to select a complete set of genomic fragments (putative coding region) for sequence analysis. Injection of clones from that region into unc-116 oocytes rescues the mutant phenotype. We are now sequencing the 3 cDNAs and genomic fragments as a first step in the molecular characterization of unc-116.

263.2

PATHFINDING OF SENSORY NEURONS IS DISRUPTED IN THE MOTH HOMEOTIC MUTATION *OCTOPOD*. R. Booker* (SPON: C. Miles). Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In the moth *Manduca sexta* the projections of larval mechanosensory (MS) neurons form a somatotopic map within the CNS. The rules governing the formation of this map are believed to be both segment and tissue specific. Thoracic and abdominal MS neurons show distinct projection patterns. In addition, MS neurons located on the thoracic legs arborize in a specialized region of the ganglia known as the leg neuropile. The moth homeotic mutatant *Octopod* was used to test these rules. This mutation results in the appearance of ectopic thoracic legs on the first abdominal segment (A1). Cobalt backfills were used to examine the projections MS neurons from the affected segment into the CNS. In mutant animals, only MS neurons on the ventral surface of A1 were transformed. Based on their projection patterns, the segmental identity of 80% and 20% of MS neurons in the anterior and posterior half of the ventral surface of A1, respectively were transformed; their projection pattern was thoracic like. The segmental identity of the remaining ventral A1 MS neurons appeared to be abdominal. In addition, all of the MS neurons located on the ectopic leg appeared to be determined as leg tissue, independent of their segmental identity. All ectopic leg MS neurons had anamolous branching in the lateral margin of A1 neuropile. Those MS neurons on the anterior half of the ectopic leg whose segmental identity was wild-type (i.e. abdominal), sent a branch anteriorly which arborized along the midline of the 3rd thoracic ganglion. In addition to their normal midline projection these abdominal like anterior MS neurons on the ectopic legs of A1 had an anamolous branch which aborized in the region of the T3 leg neuropile. Thus, while their segmental identity was abdominal they remained leg MS neurons. These results suggest that the determination of *Manduca's* MS neurons occurs in at least two independent steps involving both positional and tissue specific information.

263.3

SELECTIVE AGGREGATION OF DISSOCIATED AFFERENT GRASSHOPPER NEURONS. Maureen L. Condic. Neurobiology Group, University of California, Berkeley, CA 94720.

The growth cones of embryonic grasshopper neurons orient towards and selectively contact the somata of other neurons as they migrate *in vivo*. Recent work has shown that this selective affinity is due, at least in part, to adhesive interactions between neurons. We have previously reported that many of the neuronal interactions observed *in vivo* are replicated by dissociated neurons *in vitro*. In particular, dissociated neurons adhere to other neuronal cells when rotated in suspension culture. Neuronal and non-neuronal aggregation were further quantified by determining the time course and selectivity of cell aggregation. Limbs and antennae were dissected from embryos at 40-43% of embryonic development, incubated in 0.4% elastase for 1.5 hrs, rinsed in calcium-magnesium free saline for 1.5 hrs, then triturated until a single cell suspension of 1-5 x 10^6 cells/ml (in 100-200 ul) was obtained. Neurons were labeled during the cell dissociation by including 0.8 mg/ml rabbit anti-horseradish peroxidase (HRP) serum antibodies during the elastase digestion and 0.08 mg/ml FITC-conjugated goat anti-rabbit IgG during the Ca-Mg free rinse. Aliquots were taken at 20 minute intervals, and the number of single cells remaining in suspension was determined by cell counts. The number of single cells rapidly declined to approximately 20% of the initial value within the first 80 minutes of rotation. The rate of this decline during the first 20 minutes was higher when calcium was included in the aggregation media. Aggregates were optically sectioned using confocal microscopy to determine the distribution of neuronal cells. After 80 minutes of rotation, 22% of the neurons were found in large, purely neuronal aggregates of 15-75 cells. This selective aggregation represents over a ten fold purification relative to the initial density of neurons in the single cell suspension. These results indicate that afferent embryonic neurons strongly and selectively adhere to other neurons. This adhesion is relatively resistant to the dissociation conditions, including elastase digestion, low calcium concentration and the presence of high concentrations of antibodies directed against neuronal cell surface components.

263.4

DEVELOPMENTAL EXPRESSION OF A GLIAL ANTIGEN IN GRASSHOPPER EMBRYOS E. M. Carpenter and M. J. Bastiani, Dept. of Biology, University of Utah, Salt Lake City, UT 84112

During development, glial cells may provide pathway cues or favorable substrates for axonal growth. Identification and characterization of glial cells associated with developing axonal pathways may reveal information dictating how initial nerve pathways are established. We have examined an antigen, recognized by the 7F7 monoclonal antibody, which is expressed on subsets of glial cells during embryonic development in the grasshopper embryo. Antigen expression in the CNS begins at 27% of development. Labeling appears in three regions, one associated with the developing anterior commissure and two associated with the longitudinal connectives. Observations on wholemount embryos using Nomarski optics show that the antigen is expressed on cell processes. Labeling is also apparent on live wholemount embryos, indicating that epitope is expressed on a surface molecule. As embryonic development proceeds, antigen expression diminishes and finally disappears from the CNS by 55% of development. However, the antigen is present in sections through adult ganglia suggesting that a second wave of expression must occur at a later stage of development. In adult ganglia, the 7F7 antibody labels small cell bodies in a ring around the neuropil, corresponding to the neuropilar glia of Hoyle (JCN 246: 85-103, 1986). These observations suggest that the 7F7 antibody recognizes an antigen present on a subset of early glial cells which are positioned appropriately to play a role in the formation of nerve pathways. Immunoprecipitation using the 7F7 antibody reveals that the antibody recognizes a single molecule having a molecular weight of 60kD. Supported by the NIH and the McKnight Foundation.

263.5

SEGREGATION OF PRESYNAPTIC INPUTS ON AN IDENTIFIED TARGET NEURON IN VITRO VISUALIZED OVER TIME. M. J. Bank and S. Schacher. Ctr. for Neurobiol. & Behav., Columbia CPS & NYS Psych. Inst., New York, NY 10032.

Sensory cells of Aplysia form synaptic connections with the motor cell L7 in culture, and appear to segregate their processes to different areas on the target (Glanzman et al., Soc. Neurosci. Abstr. 14:840, 1988). To investigate how this mature pattern is generated, two sensory cells were cocultured with L7 to maximize the neuritic interactions between each other and L7. The pattern of growth of each sensory cell was visualized by video fluorescense microscopy at two times (on day 2 and day 4 or 5 after plating) following injection of each cell with a different fluorescent dye (n=8 cultures). The strength of the synapses increased from 12.0 ± 1.8 mV on day 2 to 17.5 ± 2.8 mV on day 4-5. Segregation of the sensory cell processes on L7 in mature cultures is established in two ways. In some cases (n=3), areas of neurite overlap observed on day 2 appear to be occupied by only one sensory cell on day 4-5. In other cases (n=2), sensory cells neurites are segregated on day 2, and this segregation persists on day 4-5. In contrast, segregation of neurites is absent even in mature cultures if the sensory cell bodies are in direct contact with one another (n=3); conditions which facilitate the formation of electrical coupling between the sensory cells. The importance of interactions between the presynaptic cells and their target cell L7 in establishing this segregated patttern of neuritic outgrowth is currently being investigated.

263.6

NICOTINE INDUCES RETRACTION OF NEURITES IN CULTURED RAT RETINAL GANGLION CELLS. T.P.O. Cheng* and Stuart A. Lipton (SPON: A. Ganser). Dept. of Neurology, Children's Hospital & Harvard Medical School, Boston, MA 02115.

Previous evidence indicated that nicotinic antagonists enhanced neurite outgrowth by rat retinal ganglion cells (Lipton et al., *Science* 239:1293, 1988). We have now used real-time, computer-enhanced video microscopy to show that application of nicotine to identified retinal ganglion cells induces neurite retraction. Rat retinal ganglion cells were labeled, dissociated, and plated in MEM containing 10% fetal calf serum and 5% rat serum at 37° C, or frozen in DMSO for later use. To protect cultures against photodamage during video imaging, mineral oil and antioxidants were used. Identified retinal ganglion cells were microperfused with different concentrations of nicotine (10-100 μM) in the presence or absence of antagonists. Neurites retracted consistently with 40 μM nicotine in solutions containing 1.25 and 2.5 mM Ca, but they did not retract in 0.2 mM Ca, suggesting that Ca is involved in their retraction. Also, application of solutions containing 5.8 or 50 mM K did not produce retraction, indicating that membrane depolarization is not the cause of neurite retraction. Typically, retraction began 30 sec after nicotine exposure, was complete within 2-5 min, and could be blocked by 10 μM *d*-tubocurarine, mecamylamine or hexamethonium. Most (80%) of the retinal ganglion cells reacted in this fashion to nicotine. In addition, the degree of labeling of the growing neurite tips with rhodamine-phalloidin, an indicator of assembled F actin, was greatly diminished in the presence of ≥50 μM nicotine. Collectively, these findings suggest that binding to nicotinic cholinergic receptors leads to an influx of Ca and disassembly of actin fibers, resulting in neurite retraction.

263.7

GROWTH OF RAT SYMPATHETIC NERVE FIBERS LOCALLY DEPRIVED OF CALCIUM IN VITRO. R. B. Campenot. Dept. of Anatomy and Cell Biology, Faculty of Medicine, Univ. of Alberta, Edmonton, Alta., Canada T6G 2H7.

Experiments were conducted employing three-compartmented cultures of newborn rat sympathetic neurons to determine the effects of extracellular calcium deprivation on neurite growth. Nerve growth factor (NGF) was supplied in left, center, and right compartments, and neurons plated in center compartments extended neurites on a collagen substratum, across silicone grease barriers, into left and right side compartments.

When the center compartments were calcium-deprived (0 added calcium, 0.5 mM EGTA), neurite elongation ceased in left and right side compartments after 3 days, and the neurites subsequently degenerated. In cultures in which center compartments and left side compartments were supplied with normal calcium (1 mM), but right side compartments were given no added calcium and 0.5-5 mM EGTA, neurites readily grew into and elongated 4 mm within the right side compartments. The calcium-deprived neurites were very dense although they elongated at about 70% of the rate of neurites in calcium-supplied, left compartments.

Thus, the entry of extracellular calcium into the neuron locally at or near the growth cone does not appear to be required for sustained neurite growth in this experimental system. Neither does calcium-dependent adhesion to the collagen substratum appear to be required. Since previous work (Campenot, R. B., *Proc. Natl. Acad. Sci. USA*, 74:4516, 1977) has shown that NGF must be supplied in side compartments for rat sympathetic neurites to grow into them, the growth of neurites into NGF-containing, calcium-deprived compartments shows that the local requirement of NGF for neurite growth is not mediated by the entry of extracellular calcium.

263.8

NON-UNIFORM DISTRIBUTION OF FREE CALCIUM WITHIN A NEURONAL GROWTH CONE. V. Rehder*, P.B. Guthrie, P. Dou, S.B. Kater. Program in Neuronal Growth and Development and Dept. Anatomy & Neurobiology, Colorado State University, Ft. Collins, CO 80523

We have recently used fura-2 to demonstrate that cell bodies of different neurons of the snail *Helisoma* and of the rat hippocampus have distinct intracellular free calcium concentrations ($[Ca]_i$) (Guthrie et al. 1988, Soc. Neurosci. Abstr. 14:582; Kater et al. 1988, Soc. Neurosci. Abstr. 14:582). Upon perturbation by a variety of stimuli, these cells regulate their calcium concentrations back to their previous values; i.e. they display a high degree of calcium homeostasis.

We demonstrate here that there is a dramatic heterogeneity in the calcium distribution in the motile growth cones of *Helisoma*. The $[Ca]_i$ in the lamellipodial veil appears quite low. (This region is quite thin and therefore potentially subject to error). The $[Ca]_i$ in the leading edge of the organelle containing region is markedly higher and sharply decreases towards the growth cone/neurite junction.

Exposing growth cones to cobalt or low extracellular calcium concentrations leads to a transient decrease in $[Ca]_i$ but the original calcium distribution is rapidly restored, demonstrating calcium homeostasis of the neuronal growth cone as well.

We have begun studying the formation of the gradient during the generation of a new growth cone. New growth cones are generated by experimentally severing neurites. An immediate influx into the neurite's cut end, leading to a homogeneous local calcium rise, is detected. As the growth cone develops, the calcium concentration becomes non-uniform, establishing the characteristic gradient. This new calcium map is essentially indistinguishable from the maps displayed by control growth cones.

Our work is now directed towards understanding the generation and functional role of this non-uniform calcium distribution in growth cones.

263.9

SUBCELLULAR DISTRIBUTION OF MAP1.2 AND ß-TUBULIN DURING NGF-TRIGGERED NEURITE OUTGROWTH. J.M. Aletta, D.J. Asai* and L.A. Greene Columbia U. NY, NY 10032; Purdue U. W.Lafayette, IN 47907.

The phosphorylation of several cytoskeletal proteins in PC12 cells is enhanced concomitantly with NGF-triggered neurite outgrowth. Among these are the microtubule-associated protein1.2 (MAP1.2) and ß-tubulin (ßT). The functions of these molecules are not understood, but their distributions in different subcellular compartments impose certain constraints on their possible actions. We have therefore studied their localizations in PC12 cells, by western blotting and 32P-metabolic labeling, before and after NGF-exposure. Separation of neurites from cell bodies (Meth.Enzymol. 147 207) enabled us to measure the enrichment in neurites of the phospho-forms of these proteins relative to total radiolabeled phosphoprotein; MAP1.2=5-fold (n=3), ßT=2.1-fold (n=4). >90% of 32P-labeled MAP1.2 is removed from non-treated or NGF-treated cells with 0.1% Triton in a microtubule-stabilizing buffer. Although similar results were obtained from isolated cell bodies, only ~33% of 32P-labeled MAP1.2 was removed by the same treatment of neurites. In contrast, phospho-ßT is detectable only in long-term NGF-treated cells and is most abundant in an extract containing Ca-, cold-sensitive microtubules. Immunoblotting with a polyclonal MAP1.2 Ab or a mAb to ßT indicates that the proteins partition differently than their radiolabeled forms. Based upon blotting with mAb 7-1.1, which recognizes a phosphoepitope of MAP1.2, ~30% of the total antigen in whole cells is Triton-extractable. Further experiments should explain whether these data reflect different rates of phosphate turnover or protein exchange between compartments. We conclude that phospho-MAP1.2 exists in a dynamic equilibrium among different subcellular loci and that the associations of phospho-MAP1.2 and -ßT with the cytoskeleton are relatively enhanced in neurites.

GROWTH FACTOR-REGULATED CHANGES IN METALLOPROTEASE RELEASE FROM PC12 CELLS. J.C.Noszek* R.B. Nelson, and R. Siman. (SPON: B. Wolfson). Neuroscience Group, The DuPont Company, Wilmington, DE. 19880-0400.

Protease release by neurons has been hypothesized to serve as a mechanism for tissue penetration by developing neurites, and as a means by which neurites alter the extracellular matrix to allow for growth. Using substrate-containing polyacrylamide gels, we studied how the release of proteases by PC12 cells was altered by addition of growth factors already having defined effects on neurite outgrowth. PC12 cells released three metalloproteases, designated MP-92, MP-70, and MP-50, the former two of which we have previously described in rat brain. Dibutyryl cAMP or bFGF, which produce transient formation of short neurites, each caused a selective increase in MP-70 activity. Conversely, NGF, an inducer of stable neurite outgrowth, selectively reduced activities of MP-92 and MP-70. Combining NGF with dibutyryl cAMP or bFGF, which causes synergistic induction of neurite outgrowth, also decreased MP-92 and MP-70 and caused a massive increase in MP-50. The decreases in MP-92 and MP-70 only occurred after several days in growth factor, whereas the increase in MP-50 was essentially immediate. NGF, which includes a putative serine protease as part of its structure, did not directly alter the metalloprotease profile. Phorbol esters and EGF elicited no neurite outgrowth and had no effect on metalloprotease release. These results suggest that specific shifts in extracellular metalloprotease activities may be an important factor underlying the extent and stability of neurite outgrowth in PC12 cells.

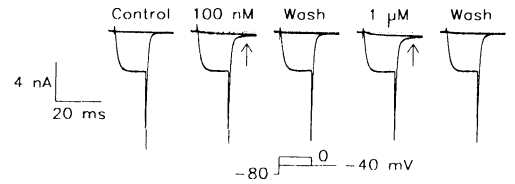
263.11

THY-1 DIMERIZATION, THY-1-DERIVED PEPTIDES, AND NEURITE OUTGROWTH. N.K. Mahanthappa and P.H. Patterson, Div. of Biol., 216-76, Caltech, Pasadena, CA 91125.

We previously demonstrated that anti-Thy-1 antibodies can enhance neurite outgrowth from rat sympathetic neurons, adrenal chromaffin cells, and PC12 cells, and that Thy-1-deficient mutant PC12s spontaneously sprout neurites. Thus we have suggested that Thy-1 can stabilize neuronal membranes and inhibit sprouting, and that this inhibition is reduced by mutation or antibody binding. Affinity purification of Thy-1 has now revealed a 50 kD protein that co-purifies with the 25 kD Thy-1 protein. By 2-D peptide mapping it appears that the larger protein is a Thy-1 dimer, yet it is resitant to boiling in SDS and disulfide reduction. Superimposition of the Thy-1 sequence onto the IgV tertiary structure (a presumed homolog) enabled us to select candidate sequences that could be involved in homophillic binding and dimerization. Synthetic peptides corresponding to these sequences are being tested for effects on neurite outgrowth *in vitro*, and at least one of these peptides promotes outgrowth from sympathetic neurons. This peptide could disinhibit sprouting by perturbing either homophillic Thy-1 binding and dimerization, or the binding of Thy-1 to other surface or matrix ligands.

263.12

CHARACTERIZATION OF AN ENDOGENOUS RECEPTOR FOR THY-1 AND ITS ROLE IN NEURITE OUTGROWTH. E. B. Dreyer, N. K. Mahanthappa, P. H. Patterson, R.L. Neve, C. J. Barnstable, L. A. Levin,* & Stuart A. Lipton. Dept.of Neuro., Harvard Med. Sch., Boston, MA; Yale Med. Sch., New Haven, CT; Cal. Inst. Tech, Pasadena, CA.



Specific Thy-1 monoclonal antibodies have been shown to promote the outgrowth of postnatal rodent retinal ganglion cells in culture [Leifer et al., *Science* 224:303, 1984; Lipton et al., *Soc. Neurosci. Abstr.*, 1988]. Using two anti-idiotypic antibodies as probes, we have therefore sought to identify a natural analog for this antibody effect -- a Thy-1 receptor. A Thy-1 receptor has now been tentatively identified on rodent astrocytes. Competitive binding to astrocytes between purified Thy-1 and the anti-idiotypes has been demonstrated. In Western blots and isoelectric focusing gels of whole brain and astrocyte preparations, a Thy-1 receptor binding site has been identified. By employing these anti-idiotypes as probes of a brain cDNA library in λ-gt11, tentative identification has been made of a clone for this receptor. The anti-idiotypes have been shown to affect the outgrowth of retinal ganglion cell neurites over astrocyte monolayers. These data strongly suggest that a receptor for the neuronal glycoprotein Thy-1 exists on the surface of astrocytes and that this receptor plays a role in modulating neurite outgrowth.

CALCIUM CHANNELS III

264.1

BAY K 8644 IS HIGHLY POTENT, BUT HAS SMALL MAXIMAL EFFECTS, ON CALCIUM CURRENTS OF ISOLATED FROG SYMPATHETIC NEURONS. Stephen W. Jones and Leila S. Jacobs*. Dept. Physiology & Biophysics, Case Western Reserve University, Cleveland, OH 44106.

Dihydropyridine calcium channel agonists and antagonists are relatively inactive against calcium currents of neurons, and most studies have used high (1 - 10 μM) concentrations in order to obtain clear effects. We also find that the agonist Bay K 8644 has little effect on the peak calcium current, in contrast to its actions on muscle. However, currents at negative membrane potentials can be greatly increased, and tail currents measured at -40 mV 5-6 ms after repolarization from -10 or 0 mV were enhanced several fold by Bay K 8644 with half maximal effect at ~50 nM. This suggests that Bay K 8644 acts on neuronal L currents as it does on calcium currents of muscle, but that the major calcium current of these cells is a dihydropyridine-resistant N current.

264.2

Ca^{++}DEPENDANT INACTIVATION OF N-TYPE Ca^{++}CURRENTS IN THE MELANOTROPH **.P.J.Williams, B.A.MacVicar, & Q.J.Pittman. Neuroscience Research Group, U of Calgary , Calgary , Canada.** Ca^{++} currents were analyzed by S.E.V.C in melanotrophs in intact pituitary maintained in vitro. Following pharmacological blockade of Na^{+} & K^{+} currents 3 protocols were tested . 1) with cells held at -90mV a small inactivating current was evoked by 200msec pulses to test potentials above -40mV. A larger, more slowly inactivating current was activated above -10mV and was maximal around 0mV. When the cell was held at -30mV a pulse to 0mV elicited 2 seconds after the shift to -30mV contained an initial transient component followed by a more sustained current. The transient current in subsequent test pulses declined until , after 12 sec, only a sustained , non-inactivating current remained. This suggests that an inactivating portion of the current was abolished when the cell was held at -30mV. 2) In a second protocol test pulses from -90mV to 0mV were elicited 150msec after a pre-pulse of 200msec to potentials between -70mV and +70mV. The peak current was reduced significantly following a pre-pulse to +10mV and the reduced current was non-inactivating. The maximal inhibition of Ca^{++} currents (70%) occurred at a pre-pulse potential between +10 and +30mV. As the pre-pulse potential was increased above +30mV the inhibition of peak current was reduced until, with a pre-pulse to +70mV , only a 20% reduction was seen. The prepulse potentials that maximally inhibited peak current are in the same range as those which evoke maximal Ca^{++} current which suggests that Ca^{++} entry rather than voltage alone may be responsible for the inactivation of peak Ca^{++} current. 3) The magnitude of the transient current evoked by a pulse from -90mV to 0mV was the same in 2mM Ca^{++} (47.5±17 pA , mean±S.D. ,n=3) and in 2mM Ca^{++} plus 2mM Ba^{++} (52.5±13 pA , n=4) but was greatly increased in 4mM Ca^{++} (125±22 pA , n=4). Although transient current did not increase on addition of Ba^{++} sustained current was increased from 116±15 pA in 2mm Ca^{++} to 160±20pA in 2mM Ca^{++} plus 2mM Ba^{++}. The size of the transient current is therefore dependant on the concentration of Ca^{++} in the medium and Ba^{++} does not substitute for Ca^{++} in this regard. We conclude this N-type current is Ca^{++} rather than voltage inactivated.

264.3

CALCIUM-DEPENDENT INACTIVATION OF A PERSISTENT CALCIUM CURRENT OF RAT HIPPOCAMPAL NEURONES. A. Nistri[1] and E. Cherubini. INSERM U29, 123 Bd Port-Royal, 75014 Paris, France and [1]Pharmacology Dept., St. Bartholomew's Hospital Med. Coll., London EC1M 6BQ., England.

Hippocampal neurones possess a persistent Ca^{2+} current presumably due to voltage-dependent opening of L-type Ca^{2+} channels. The present experiments were initiated to examine the mechanisms responsible for the inactivation of this current and used single electrode voltage clamp of CA1 neurones of the rat hippocampal slice at room temperature. K^{+} currents were depressed by Cs^{+} and TEA while fast Na^{+} currents were blocked by TTX. At -40 mV holding potential 1 s long depolarizing pulses elicited an inward Ca^{2+} current (threshold about -25 mV) comprising an early transient and a sustained component which usually reversed between 0 and +30 mV. Depolarizing pulses applied at frequencies higher than 0.03-0.05 Hz attenuated the slow current. Double pulse inactivation protocols showed 55% (maximal) inactivation of the persistent current at +10 mV with half-maximal reduction at -10 mV. While in control conditions no inward tails were found, such tails were seen with intracellular BAPTA or extracellular Ca^{2+} replacement by Ba^{2+} which also increased the slow current size. With intracellular BAPTA the inactivation of inward tail currents was only 30% at +10 mV. Intracellular free Ca^{2+} seems thus to contribute to the macroscopic process of inactivation of a persistent Ca^{2+} current.

264.4

Facilitation of Calcium Channel Current in Bovine Chromaffin Cells is Due to The Recruitment of a Different Class of Calcium Channels. A.P. Fox*, M. Dahmer, R.L. Perlman, C.R. Artalejo* (SPON: P. Hoffman), Dept. of Pharmacol. and Physiol. Sci., Univ. of Chicago, 947 E. 58th St. Chicago, IL 60637

Facilitation of calcium currents by a prior depolarization pulse has been previously described in chromaffin cells (Fenwick et al., J. Physiol. 331,1982; Hoshi et al., Proc. Natl. Acad. Sci. 81,1984). Our data suggest that the facilitation seen in chromaffin cells represents the recruitment of a new class of Ca channels rather than a novel property of a single type of Ca channel. Whole-cell patch clamp recordings showed that facilitation currents were sensitive to dihydropyridine antagonists while control currents were not. Inactivation of the control Ca^{2+} currents showed no voltage-dependent inactivation, while the facilitation Ca^{2+} currents did. Tail currents measured at -30 mV were different before and after the induction of facilitation. Recordings in 90 mM extracellular Ba^{2+} showed that control and facilitation Ca^{2+} currents could activate at different potentials; the threshold of activation for facilitation was approximately 20 mV more depolarized than control. Single-channel recordings showed three different types of unitary events 14 pS, 18 pS and 27 pS. We believe that the large-conductance 27 pS channel mediates facilitation. As the Ca^{2+} influx through voltage-dependent calcium channels regulates the secretory response in these cells, it will be very interesting to uncover the various roles that the different Ca^{2+} channels play in the physiology of release.

264.5

Is Facilitation of Calcium Channel Current in Bovine Chromaffin Cells Due to Long-lived Openings of a 27 pS Ca^{2+} Channel? C.R. Artalejo*, M.K. Dahmer, R.L. Perlman, A.P. Fox* (SPON: A. Heller), Dept. of Pharmacol. and Physiol. Sci., Univ. of Chicago, Chicago, IL. 60637

Experiments were performed to explore the process of Ca^{2+} channel facilitation at the single-channel level (Hoshi & Smith, J. Neurosci. 7, 571, (1987)). Three different types of unitary currents (14, 18 and 27 pS) were found to exist. Neither the 14 pS channel nor the 18 pS channel were sensitive to dihydropyridines (DHP). The 27 pS channel, in some respects similar to L-type Ca^{2+} channels previously described, was sensitive to both DHP agonists and antagonists, consistent with our whole-cell facilitation results. Under control conditions, the 27 pS channels were relatively silent. The addition of the DHP agonist BAY K 8644 increased the activity dramatically by promoting very long-lived openings (mode 2), usually uncovering the presence of multiple channels under the pipette. Under drug free conditions, long-lasting openings, similar to those seen in the presence of Bay K 8644, could be elicited by protocols shown to induce facilitation (rapid trains of depolarizations or by changing the cells to a depolarized HP). Fig. 1 shows single-channel currents recorded while holding the patch potential at -10 mV; the first trace was recorded at time=0 sec, the second trace was obtained at time=25 sec, while the last trace was acquired at time=75 sec. At first there was little activity of the 27 pS channel; 15 seconds after changing to HP=-10 mV, long-lasting openings were observed. After another 50 seconds, the activity subsided. This behavior correlated very well with whole-cell facilitation. Alternate long-lived open states of Ca^{2+} channels may play an important role in governing Ca^{2+}-influx into cells.

264.6

ω-AGATOXINS: A FAMILY OF NEURONAL CA^{++} CHANNEL ANTAGONISTS FROM FUNNEL WEB SPIDER (*AGELENOPSIS APERTA*) VENOM. M. E. Adams[1], V. P. Bindokas*[1], A.C. Dolphin*[3], J. S. Imperial*[2], B.M. Olivera[2], R.H. Scott*[3], and V. J. Venema*[1]. [1]Div. Toxicol. & Physiol., Dept. of Entomology, Univ. of California, Riverside, CA 92521, [2]Dept. Biology, Univ. of Utah, Salt Lake City, UT 84112 and [3]Dept. of Pharmacology, St. Georges Hospital Medical School, London, SW17 0RE, UK.

Five polypeptide antagonists (ω-agatoxins) of insect neuromuscular transmission were purified from *Agelenopsis aperta* spider venom. Physiological and biochemical data indicate that the ω-agatoxins comprise a family of presynaptic voltage-sensitive Ca^{++} channel antagonists. Although all ω-agatoxins block insect neurotransmission, biochemical criteria distinguish them as two subclasses. Type I toxins (ω-Aga-IA, IB IC) are 7-8 kDa, have closely related N-terminal amino acid sequences, and exhibit high tryptophan-like UV absorbance. Type II toxins (ω-Aga-IIA and IIB) are 10-11 kDa, show minor sequence homology to Type I toxins, and exhibit low tryptophan-like absorbance. Type II, but not type I toxins inhibit specific binding of ^{125}I-labeled ω-conotoxin GVIA to chick synaptosomal membranes. In accordance with this binding data, both Type II toxins and ω-conotoxin block ^{45}Ca flux in chick synaptosomes, while Type I toxins are either inactive (IA, IB) or less potent (IC) under identical conditions (see Pocock, J.M. *et al*, this meeting).

Type I and II ω-agatoxins may define distinct Ca^{++} channel subtypes in both insects and vertebrates. ω-Aga-IA (10 nM) blocks high threshold Ba^{++} and Ca^{++} currents in rat dorsal root ganglion neurons. It also blocks transmission in insect and frog skeletal muscle (Bindokas and Adams, *J. Neurobiol.* in press). Our binding data suggest that these actions involve a unique binding site unrelated to that defined by ω-conotoxin. However, Type II toxin inhibition of ω-conotoxin binding suggests that they may block Ca^{++} channels in a similar manner. Thus, the ω-agatoxins provide two novel sub-classes of polypeptide calcium channel antagonists active in diverse animal phyla.

264.7

EFFECTS OF ω-AGATOXINS ON VOLTAGE-DEPENDENT CA^{++} FLUX IN CHICK BRAIN SYNAPTOSOMES. J. M. Pocock*, V. J. Venema* and M. E. Adams (SPON: R. Farley) Division of Toxicology and Physiology, Department of Entomology, University of California, Riverside, CA 92521.

ω-agatoxins purified from *Agelenopsis aperta* spider venom are presynaptic calcium channel antagonists which block insect neuromuscular transmission (Adams et al.; Bindokas and Adams, this meeting). These toxins also appear to interact with vertebrate calcium channels. For example, Type II (ω-Aga-IIA, IIB), but not Type I (ω-Aga-IA, IB) ω-agatoxins inhibit the specific binding of ^{125}I-labeled ω-conotoxin GVIA, a known neuronal calcium channel antagonist, to chick brain synaptosomal membranes. We compared the effects of ω-agatoxins with those of ω-CgTx on voltage-activated Ca^{++} flux in intact synaptosomes.

Synaptosomes prepared from whole brains of 2-day old chicks were pre-incubated for 5-25 minutes in toxin followed by a 5 sec depolarization in 100 mM K^+ saline. Type II ω-agatoxins and ω-conotoxin directly inhibit voltage-dependent Ca^{++} influx into synaptosomes at 10-100 nM concentrations within 15 minutes. ω-Aga-IA and IB do not block Ca^{++} influx at concentrations up to 500 nM. ω-Aga-IC blocks Ca^{++} influx, but is less potent than the Type II toxins.

We conclude that the Type II ω-agatoxins constitute a subclass of calcium channel antagonists interacting with the ω-conotoxin binding site to block Ca^{++} flux through neuronal calcium channels.

FURTHER STUDIES ON THE P TYPE CALCIUM CHANNEL IN LIPID BILAYERS AND ON THE NATURE OF FTX CALCIUM CHANNEL BLOCKER. B. Cherksey,* J.W. Lin, M. Sugimori and R. Llinás (SPON: D. Hillman) Dept. Physiol. & Biophysics., New York Univ. Med. Ctr., New York, NY 10016.

Funnel web spider venom contains a potent and selective neuronal calcium channel blocker, FTX, which was purified from the crude venom of A. aperta by deproteination followed by size-exclusion and ion-exchange chromatography. The final product exhibited a single, sharp absorption band at 220 nm. The purified FTX was subjected to structural analysis using NMR and FT-IR spectroscopy and mass spectrometry. The results obtained show that this toxin is not a peptide nor does is resemble the known polyamine channel blockers but rather possesses a unique and unexpected aliphatic structure. A purified FTX-Sepharose affinity gel was used to isolate protein from guinea pig cerebellar homogenate which was then studied functionally in the lipid bilayer (Cherksey, et al. Neurosci Abstract, 1988). The reconstituted protein exhibited voltage-dependent single channel activity with the divalent ion selectivity Br>Sr>Ca. In 80 mM solutions, the conductance for Ba++ was 10-12 pS, for Sr++ 8-10 pS, and for Ca++ 6-8 pS. The conductance was pH sensitive with no channel openings present at pH 6.8 and below. In the absence of divalent cations, a monovalent ion conductance could be determined. The permeabilities, determined from the reversal potentials, were: Na>K>Cs>TEA. The channel was not blocked by either dihydropyridines or conotoxin thus ruling out its identity as an L-type channel. Macroscopic currents derived from ensemble averages of channel activity during pulses indicated that the channel does not inactivate as would be expected for either a T- or N-type channels. However, the voltage dependence, lack of inactivation and specific block by FTX suggest its identification as a P-type channel (Llinas, et. al., 1989, PNAS, 68: 1689).NINCDS13742, NEI08002 and FIDIA Research Foundation.

A FUNNEL-WEB SPIDER TOXIN (FTX) FRACTION BLOCKS CALCIUM CURRENTS INDUCED BY RAT BRAIN mRNA IN XENOPUS OOCYTES. J.W. Lin, B. Rudy, B. Cherksey, M. Sugimori and R. Llinás. Dept. Physiol. & Biophys., New York Univ. Med. Ctr., NY 10016.

A fraction of funnel-web spider toxin has been shown to block Ca conductances in Purkinje cells and the squid giant synapse (Llinás et al., 1989, PNAS, 89: 1689). To further characterize this toxin, we examine its effect on the Ca currents (I_{Ca}) expressed by rat brain mRNA in Xenopus oocytes. Similar to the P channel reported for Purkinje cells and the squid giant synapse, this I_{Ca} differs from conventional Ca channel types in that it is not blocked by organic Ca channel blockers (dihydropyridine) or conotoxin (Leonard et al., 1987, J. Neurosci, 7:875). The fact that this current is the only Ca channel type expressed by the whole brain mRNA suggests its abundance in CNS. After mRNA injection, a Ca activated Cl current ($I_{Cl(Ca)}$) can be activated upon depolarization. The tail of this Cl current has a threshold of -40mV and peaks between 0 to +10mV when $[Ca]_o$ is 1.8 mM. FTX blocks this current irreversibly while the amplitudes of Na and K currents are unmodified. The blockade affects Ca channel directly since $I_{Cl(Ca)}$ can still be activated by intracellular Ca injection in the presence of FTX. Furthermore, a small intrinsic $I_{Cl(Ca)}$ of uninjected oocytes is not affected by the toxin. In 40 mM Ba, 1 mM TTX and Cl free solution, FTX eliminates an inward current, presumably carried by Ba. This FTX sensitive I_{Ba} has similar properties as that reported by Leonard et al. (1987), namely it does not inactivate over a duration of 400 msec, has a threshold of -20mV and reaches the maximal amplitude at +20mV. The diffference in the voltage sensitivities between I_{Ba} and the $I_{Cl(Ca)}$ is probably due to the increased extracellular divalent cation concentration, since a similar shift to the right is observed for $I_{Cl(Ca)}$ when $[Ca]_o$ is raised to 15 mM. In addition, Cd blocks the same I_{Ba} as does FTX.

264.10

A FAMILY OF PUTATIVE VOLTAGE-DEPENDENT CALCIUM CHANNELS FROM RAT BRAIN. T.P. Snutch[1], J.P. Leonard[2], M.M. Gilbert*[1], H.A. Lester[3] and N. Davidson[3]. [1]Biotechnology Laboratory, U. of British Columbia, Vancouver, Canada V6T 1W5, [2]Dept. of Biology, U. of Illinois at Chicago, Chicago IL 60680 and [3]Dept. of Biology, California Institute of Technology, Pasadena CA 91125.

Calcium entry through voltage-dependent calcium channels (VDCCs) contributes both to the membrane potential of neurons and also to increase the intracellular concentration of this important second-messenger. Electrophysiological and pharmacological analyses have identified a number of distinct types of VDCC in mammalian neurons. In an attempt to determine the molecular relationships between the various described VDCCs we are utilizing a molecular genetic approach to isolate rat brain cDNAs which may encode neuronal VDCCs.

Northern blot analysis of 26 isolated cDNAs shows that they can be grouped into four distinct classes. Class A cDNAs hybridize with approx. equal intensity to messages of 8.0 and 8.7 kilobases (kb). Class B cDNAs hybridize to a major message 9.5 kb in size. Class C cDNAs hybridize to two messages of approx. 8.8 and 12 kb, while Class D cDNAs hybridize mainly to a 9.3 kb mRNA. DNA sequencing shows that the four classes of cDNA are related to the brain Na channel and rabbit skeletal muscle dihydropyridine (DHP) receptor/Ca channel. Antisense experiments in Xenopus oocytes injected with rat brain mRNA indicate that these cDNAs are not voltage-dependent Na channels. The class C cDNAs show a very high degree of amino acid similarity to the muscle DHP receptor/Ca channel (>90%); this suggests that this group may represent the brain DHP receptor. (Supported by MRC of Canada and NIH grants GM-10991 and GM-29836).

LOW THRESHOLD, TRANSIENT CALCIUM CURRENT IS PRESENT IN YOUNG, BUT NOT ADULT, ISOLATED RAT HIPPOCAMPAL PYRAMIDAL CELLS. Scott M. Thompson and Robert K. S. Wong, Dept. of Neurology, Columbia University, NY, NY 10032

Several types of Ca++ currents may be distinguished on the basis of their threshold, rate of inactivation, and pharmacology. Ca++ currents in acutely isolated adult guinea-pig CA1 cells are predominantly high-threshold and sustained (Kay and Wong, 1987). We examined the development of Ca++ currents in pyramidal cells obtained from rats between 4 days and 5 weeks after birth. Ca++ currents were recorded with whole-cell voltage-clamp using 10 mM Ba++. Na+ and K+ currents were blocked with pharmacological antagonists and substitution of impermeant ions. In cells of all ages, depolarizing steps from -50 mV activated inward currents at a mean threshold of -33 mV. The current was non-inactivating near threshold, and slowly inactivating at more positive potentials. In cells > 4 weeks of age, the threshold was little affected by hyperpolarizing prepulses. In contrast, in all cells < 2 weeks of age, hyperpolarizing prepulses (3 sec, > -85 mV) revealed a component of Ca++ current with a lower threshold (mean = -58 mV) and rapid decay rate (time constant = 38 msec at -40 mV). The low threshold, transient current in young cells was selectively reduced by ethosuximide (350 uM) and amiloride (200 uM), as are Ca++ currents with similar kinetics in other cell types. No significant differences in Ca++ currents were observed between CA1 and CA3 cells at any age. These results suggest that low threshold, rapidly inactivating Ca++ channels are expressed in the soma and proximal dendrites of young pyramidal cells and are lost or redistributed to distal dendrites during development. Supported by NIH grants F32 NS08306 (SMT) and NS24682 (RKSW).

THREE-DIMENSIONAL RECONSTRUCTION OF VOLTAGE-DEPENDENT CALCIUM CHANNEL DISTRIBUTION IN HIPPOCAMPAL SLICES BY CONFOCAL MICROSCOPY. KJ. Angelides', B.D. Mensh*', and O.T. Jones*. (SPON: H. Epstein). 'Division of Neuroscience and Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.

Influx of calcium through voltage-dependent calcium channels (VDCCs) may be critical in the induction of long-term potentiation (LTP) at the mossy fiber synapse in the hippocampus (Gray, R. & Johnston, D. *Nature* 327:620, 1987). To examine the distribution of VDCCs on CA1/3 neurons in the hippocampus we have utilized biologically active fluorescent analogs of ω-conotoxin. Previous studies on cultured CA1 hippocampal neurons show that VDCCs are segregated in clusters at synapses and on dendrites. The goal of the present work was to extend our studies in primary culture to hippocampal slices using confocal microscopy in order to reveal the three-dimensional organization of VDCCs on CA1/3 neurons with the aim of exploring VDCC dynamics during LTP.

Adult rat hippocampal slices (300 μm) were incubated at 25°C in solutions of artificial CSF containing fluorescent ω-conotoxin. In some experiments the sections were incubated with DiI, a voltage-dependent dye, to outline cells. Images at low magnification showed staining in the pyramidal cell body layer. At high magnification, single neurons were selected to include cell bodies and basal and apical dendritic arbors, and a through-focus series was performed at ~1.0 μm sectional resolution. Non-uniform staining of cell bodies in CA1 and CA3 regions, as well as strings of clustered staining particularly visible in the region of apical dendrites was observed. Further optical sectioning on processes revealed hotspots which appeared as thin, short branches projecting from the thicker processes. While synapses have not been identified, these areas of punctate staining are candidate dendritic spines. Reconstruction of VDCC distribution in three-dimensions will be presented. Supported by NS24606, NS01218 and MSTP.

GENETIC MODELS OF NERVOUS DISORDERS III

265.1

THE deg-1 GENE OF *CAENORHABDITIS ELEGANS* MAY ENCODE A CELL MEMBRANE RECEPTOR E. J. Wolinsky and M. Chalfie, Dept. Biol. Sci., Columbia University, New York, NY 10027

The u38 mutation of the deg-1 gene induces late-onset vacuolar degeneration of the PVC interneurons. This phenotype is dominant and temperature sensitive. Our goal is to determine the normal function of the wild type deg-1 gene, and how the u38 mutant gene product causes selective neurodegeneration.

We have cloned both wild type and mutant deg-1 DNA. Our physical map of the gene is defined by four DNA rearrangements which inactivate the dominant u38 mutation (2 deletions, 2 transposon insertions), spanning about 25 Kb. Germ line transformation experiments using a fragment of u38 DNA have resulted in transformed lines expressing the degeneration phenotype.

We have sequenced wild type deg-1 cDNA clones to deduce a partial amino acid sequence of 293 residues. The most striking features of the predicted deg-1 protein are a 27 amino acid hydrophobic sequence, two possible glycosylation sites, and a cystine rich region. The possible glycosylation sites and cystine residues are probably located extracellularly. The cystine rich sequence can be aligned with the EGF-like repeats of thrombomodulin, a cell surface receptor of the same class as the EGF receptor. We hypothesize that deg-1 encodes an integral membrane protein which may function as a receptor.

265.2

STUDIES OF CNS LUPUS IN TRANSGENIC AUTOIMMUNE MRL-lpr MICE EXPRESSING A SINGLE T CELL RECEPTOR. J.D. Mountz*, J.M. Mountz. Univ of Alabama, Birmingham, Alabama 35294, and Univ of Michigan Medical Center, Ann Arbor, Michigan 48109.

Lupus cerebritis has been postulated to be due to antineuronal tissue autoreactive T cells. In support of this, autoreactive T cell clones from patients with lupus cerebritis have been isolated. The MRL-lpr/lpr mouse develops many symptoms of Systemic Lupus Erythematosus (SLE), including arthritis, glomerulonephritis, arteritis, Sjögren's Syndrome, and infiltrates the (CNS) with T cells. To further clarify the role of CNS cell infiltrates in the development of CNS lupus, a "non-lupus" C57 BL/6 transgenic mouse expressing a single T cell receptor (α-A heterodimer) against the male HY antigen in association with class Ib restrictive element was backcrossed to MRL-lpr/lpr C57 BL/6-lpr/lpr mice to produce transgenic mice homozygous for the lpr gene. These mice demonstrated a decrease in T cell mediated autoimmunity as opposed to the MRL-lpr/lpr strain.

CNS lupus cerebritis and cerebral blood flow (CBF) alterations in these mice strains were studied utilizing CBF radionuclide tracer and autoradiographic techniques. MRL-lpr/lpr mice were found to have an increase in CBF. In contradistinction, neither the MRL- +/+ or the MRL-lpr/lpr with the transgenic T cell receptor showed abnormal CBF. In addition, these mice showed decreased T cell activity in comparison to the autoimmune strain of mice. The presence of T cell dependent CNS lupus suggest anti-T cell antibodies and perhaps T cell immunization may be of therapeutic value. These results suggest improved methods of diagnosis and therapeutic monitoring of CNS lupus in humans may be possible using single photon emission computed tomography (SPECT) imaging of ^{99m}Tc-Hexamethylpropyleneamine oxime.

IN SITU LOCALIZATION OF ANTI-SENSE MYELIN BASIC PROTEIN TRANSCRIPTS IN MYELIN DEFICIENT MICE Robert T. Fremeau,Jr.[1] and Brian Popko*[2], 1. Glaxo Research Laboratories, Research Triangle Park, NC, 27709 and Department of Neurobiology, Duke University; 2. Biological Sciences Research Center CB#7250, U. of North Carolina, Chapel Hill, NC 27599

Mice homozygous for the myelin deficient (mld) mutation have an unusual phenotype in which the gene encoding the myelin basic protein (MBP) is expressed at low levels and on an abnormal developmental schedule. Mld mice are characterized by severe central nervous system (CNS) hypomyelination, hindquarter tremors, tonic seizures, and premature death. The mld mutation is the result of a DNA rearrangement within the myelin basic protein gene. The mld MBP locus consists of two tandem MBP genes with the upstream gene containing an inversion of its 3' region (Popko, B. et al. Neuron 1:221,1988). In this study we have used RNA probes from the inverted region of the upstream mld MBP gene to identify anti-sense MBP transcripts in the CNS of mld animals by in situ hybridization. These RNA molecules apparently initiate off the upstream mld MBP promoter and elongate through the inverted region of the upstream gene.

HUMAN DYSTONIA GENE FOUND ON CHROMOSOME 9q32-q34 X.O. Breakefield, L. Ozelius*, P. L. Kramer*, C.B. Moskowitz*, D.J. Kwiatkowski*, M.F. Brin*, S.B. Bressman*, D.E. Schuback*, D. DeLeon*, Y.-P.P. Hsu*, C. Craft, G. Hu*, J. Haines*, R.E. Burke, T. Nygaard*, J. Raese, J.F. Gusella*, S. Fahn* E.K. Shriver Ctr, Waltham, MA, 02254 Neurology & Hematology Depts., Mass. General Hosp., Neuroscience Program & Genetics Dept., Harvard Med. Sch. Boston, MA; Dept. Neurology, Columbia CPS, New York, NY; VA Med. Ctr, Dallas, TX.

Torsion dystonia is a movement disorder characterized by sustained muscle contractions and/or abnormal posture. The etiology of this disease is unknown, but symptoms are thought to arise from abnormalities in the basal ganglia. About one-third of cases are familial with most being inherited in an autosomal dominant manner with reduced penetrance. Genetic linkage analysis using DNA polymorphisms has been used to locate the gene for torsion dystonia to the q32-q34 region of chromosome 9 in a large, non-Jewish kindred with early onset. Multi-point linkage analysis using six DNA marker probes in this region gives a lod score of >+4 in this family. Two-point linkage analysis is being used to evaluate the role in this disease of two candidate genes encoding gelsolin and dopamine beta-hydroxylase, which lie in this region. Studies are also underway to evaluate whether other ethnically and/or clinically distinct forms of hereditary dystonia are caused by gene(s) in this same chromosomal region.

NGF EFFECTS ON PC12 CELLS TRANSFECTED WITH THE B-AMYLOID GENE R.E. Majocha, S.B. Zain, W.G. Chou, B. Tate-Ostroff, M. Ventosa-Michelman and C.A. Marotta Mass. Gen. Hosp., Harvard Med. Sch., Boston, MA; U. Rochester Sch. Med.; McLean Hosp., Belmont, MA.

PC12 cells were permanently transfected with DNA of the A4 to C terminal region of the amyloid precursor protein (APP; Marotta et al., PNAS 86, 33, 1989). Transfectants that received in frame DNA (IF) as well as out of frame DNA (OF) and untransfected cells (UF) were grown on polylysine-treated plates for two days at 10,000 cells/well. Morphological and immunological differences were apparent between UF and IF cells (Tate-Ostroff et al., these abstracts). Cells treated with NGF at 100ng/ml for 48 hrs exhibited increased neurites/cell and neurite length in both UF and OF cells but not IF cells. In addition, IF cells did not cease dividing. After two weeks in NGF at concentrations up to 200ng/ml, IF cells showed no apparent morphological response. Efforts are under way to determine if these effects are due solely to overaccumulation of the A4 region. Supported by AG02126, CA 11198, CA 36432, AHAF and the Sandoz Found.

MORPHOLOGICAL AND IMMUNOLOGICAL STUDIES OF PC12 CELLS TRANSFECTED WITH THE B-AMYLOID REGION OF THE AMYLOID PRECURSOR PROTEIN B. Tate-Ostroff, E.C. Walcott, P. Paskevich, S. Zain, W.G. Chou, C. Labonne, R.E. Majocha and C.A. Marotta McLean Hosp, Belmont, MA; Mass Gen Hosp, Harvard Med Sch, Boston, MA; U. Rochester Sch Med, Rochester, NY

PC12 cells were permanently transfected with cDNA of the A4 to C terminal region of the amyloid precursor protein (APP; Marotta et al., PNAS 86,33:1989). Cells transfected with in-frame (IF) and out-of-frame vectors were examined by light and electron microscopy (EM) and compared to untransfected cells. IF cells were morphologically different from controls. IF cells immunoprocessed with antibodies to B-amyloid (A4) and C terminal regions of the APP were darkly stained compared to controls. At the EM level, the A4 staining of IF cells was heaviest in the membrane. These studies indicate that over production of the B-amyloid to C terminal region of the APP can affect the morphology of cells. In addition, insertion of A4 into the membrane requires only the A4 to C terminal region of the APP. Supported by AG02126, AHAF, the Sandoz Found. CA 11198, CA 36432.

ULTRASTRUCTURAL PATHOLOGY OF MIDBRAIN DOPAMINE NEURONS IN THE WEAVER MUTANT MOUSE AND PROGRESSION OF NEURON LOSS WITH AGING. B. Ghetti and L.C. Triarhou. Dept. of Pathology & Med. Neurobiology Pgm, Indiana Univ. Sch. of Med., Indianapolis, IN 46202

Homozygous weaver mutant mice (wv/wv) on the B6CBA-A^{w-J}/A hybrid strain may live up to 24-30 months. In these mice, loss of midbrain dopamine (DA) neurons is part of the neuropathologic phenotype at P20 and P90. The specific aims of this study were (1) to analyze the fine structure of degenerating neurons in substantia nigra (SN) and ventral tegmental area (VTA) and (2) to investigate whether loss of DA neurons progresses with old age. Electron microscopic examination of 4 wv/wv and 4 +/+ mice at P20-P45 showed osmiophilic cytoplasm, disrupted organelles and a pyknotic nucleus in neurons of the SN and VTA of wv/wv; cell debris was surrounded by astrocytic processes. Immunocytochemical study of wv/wv at P355-P756 (n=7) and +/+ (n=4) at P538-P894 with tyrosine hydroxylase (TH) antibodies revealed the presence of some surviving TH cells in the SN of wv/wv at P355, most of which are lost by P756. Furthermore, we re-examined 3 wv/wv and 3 +/+ mice at P90 from previously studied material to compare cell losses at maturity and in old age. In rostral VTA, loss of TH neurons appears to be severer on P756 than on P90. A quantitative analysis of midbrain DA neurons will establish whether the progression of losses beyond 90 days of age in wv/wv is part of the wv phenotype or represents an age-related phenomenon superimposed on the wv gene-induced condition.

MONOAMINE UPTAKE KINETICS IN BRAIN REGIONS FROM GENETICALLY RELATED WISTAR-KYOTO RATS WITH SPONTANEOUS HYPERTENSION AND/OR HYPERACTIVITY. E.D. Hendley and W.G. Ohlsson*. Dept. Physiology & Biophysics, Univ. of Vermont, Burlington, VT 05405.

Four inbred strains derived from the Wistar-Kyoto (WKY) rat were used to study the neurochemical correlates of genetic hypertension and behavioral hyperactivity. Spontaneously hypertensive rats (SHR strain) when compared with WKY controls are known to exhibit both hypertension and hyperactivity. Two additional, new, inbred Wistar-Kyoto strains, WK-HT and WK-HA, were developed in this laboratory from an original SHR X WKY cross in order to separate the two traits using recombinant inbreeding procedures. WK-HTs are hypertensive and not hyperactive, and conversely, WK-HAs are normotensive but hyperactive in behavior. Together, these four related strains allowed us to search for neurochemical correlates of both of these genetic traits. Previous studies in this laboratory revealed few significant correlations with altered levels of monoamines and metabolites in brain regions from the four strains. However, when functional changes in monoaminergic transmission were studied, using high affinity uptake of norepinephrine, dopamine and serotonin, significant correlations were observed in selected brain regions. Supported by NSF grant R11-860679.

THE SPONTANEOUSLY HYPERTENSIVE RAT (SHR) AS AN ANIMAL MODEL OF ATTENTION-DEFICIT HYPERACTIVITY DISORDER: IMPROVED TIME DISCRIMINATION AND NO "PARADOXICAL EFFECT". T. Sagvolden* and B. Wultz* (SPON: J.A. Bevan). Inst. of Neurophysiology, Univ. of Oslo, N-0162 Oslo 1, Norway.

SHR may be used as an animal model of attention-deficit hyperactivity disorder (ADHD), a disorder frequently treated with psychomotor stimulating drugs. Several studies have addressed the hyperactivity of SHR, but none has investigated attention processes in these animals. The present study investigated attention processes of SHR and Wistar-Kyoto control rats. SHR were hyperactive. In particular, SHR had elevated rates of responses with short inter-response times. At the same time, SHR timed their responses more effectively than WKY. It is concluded that the behavior of SHR may have two components: One consists of responses with short inter-response times and is primarily expressing the hyperactivity of these animals. The other consists of the timing of the response according to the schedule of reinforcement and is reflecting attention. Methylphenidate did not change the animals' timing of their responses. Neither were there any "paradoxical" effects. Response rates started to decrease following high doses in SHR, but in WKY already following medium doses, indicating that both groups are affected similarly by the drug, but SHR are less sensitive to the drug.

266.1

FAILURE TO DETECT INCREASES IN BRAIN DOPAMINE TURNOVER IN CORN OIL AND SUCROSE SHAM FEEDING RATS. S.C. Weatherford, J. Gibbs and G.P. Smith Dept. Neurobiology and Obesity Research, Hoffmann-La Roche, Nutley, NJ 07110 and Dept. Psychiatry, New York Hospital-Cornell Medical Center, White Plains, NY 10605.

Sham feeding (SF) rats prefer corn oil (CO) >> 10% sucrose (suc) >> 6% suc. The preferences are evidence for the rank order of reward value of these solutions. The relative potency of dopamine (DA) antagonists for decreasing sham intake is 6% suc >> 10% suc >> CO. To test that the relative antagonist potencies are due to differential release of DA, dependent on the reward value of the sham-fed solution, DA turnover was measured using HPLC-electrochemical detection in forebrain-DA terminal fields microdissected from rats that had sham fed CO, 6% and 10% suc immediately before decapitation. The results did not support our hypothesis: no increase in DA turnover was observed after SF of any solution.

266.2

DIFFERENTIAL D1/D2 ANTAGONISM OF SUCROSE SHAM FEEDING. L.H. Schneider, C.A. Watson*, J.D. Davis, J. Gibbs & G.P. Smith. E.W. Bourne Lab, NY Hosp-Cornell Med Ctr, White Plains, NY 10605 & U. Illinois, Chicago, IL 60680

Selective antagonists for D1 (SCH 23390) and D2 (RAC; raclopride) receptors inhibit sucrose sham feeding (Schneider et al, 1986, 1987, 1988). To determine if equivalent reductions in the volume sham fed in 30 min after ID_{50} doses (ip) of the D1 and D2 antagonists are achieved through the same effects on the pattern of licking, the microstructure of licking was analyzed in 8 male, 4.75h food-deprived rats sham feeding 40% sucrose. The only significant differential effect on the microstructure of D1 vs D2 blockade ($p<.005$) was that SCH 23390 shortened the interval from the first to the last lick [min, mean $\pm$SE; Veh=25.7 $\pm$ 1.0, SCH=17.6 $\pm$ 2.4, $p< .02$)], but RAC did not [Veh=25.5 $\pm$ 0.9, RAC=26.0 $\pm$ 1.4]. Neither SCH 23390 nor RAC changed licking rate [6.0 $\pm$ 0.1/sec] or efficiency [163.1 $\pm$ 9.7 licks/ml], providing further support for our hypothesis that antagonists of D1 or D2 receptors reduce sham intake by attenuating the rewarding potency of sucrose without impairing the motor mechanisms of licking. The differential effect on lick duration suggests that under these conditions, antagonism of dopamine at D1 but not D2 receptors decreased the positive reinforcing effect of sham fed sucrose below the threshold necessary to sustain licking.

MAPPING THE NEURAL CIRCUITRY OF A FEEDING RESPONSE: REGIONAL BRAIN CHANGES IN ^{14}C-2DG UPTAKE INDUCED BY INTRAHYPOTHALAMIC NOREPINEPHRINE INJECTIONS. J.N. Nobrega and D.V. Coscina, Clarke Institute of Psychiatry, Toronto, Ont., M5T 1R8, Canada.

Norepinephrine (NE) injections into the paraventricular hypothalamus (PVN) are well known to induce feeding in satiated rats. There is, however, a paucity of information on the neural pathways involved in this response. The PVN has extensive afferent and efferent connections and is involved in neuroendocrine and autonomic functions, which may be related to its role in feeding. Thus one area of interest in defining the functional anatomy of PVN feeding responses relates to the extent to which such feeding circuits may overlap autonomic/endocrine pathways. In this study the quantitative ^{14}C-2-deoxyglucose (^{14}C-2DG) technique was used to investigate regional brain changes induced by PVN NE injections. Male Wistar rats, bearing unilateral PVN cannulae and previously screened for NE feeding, were given 125 μCi/ kg ^{14}C-2DG i.v. immediately following a PVN injection of either 40 nmol NE or vehicle, then killed 45 min later. ^{14}C-2DG uptake was examined in 97 brain structures using computerized densitometry. PVN NE injections resulted in small but statistically significant changes in a discrete number of areas. Forebrain areas included the somatosensory parietal cortex (+15%), the CA3 hippocampal field (-8%), and the reticular thalamic nucleus (+14%). Midbrain areas included the anterior pretectal (+8%) and central gray areas (-11%). At the hindbrain level the lateral reticular nucleus showed the most pronounced changes in the brain (-24%), followed by the nucleus of the solitary tract (-16%) and the laterodorsal tegmental nucleus (+16%). No changes were seen in the median eminence or in other hypothalamic areas. This pattern of results is compatible with recent proposals for the anatomy of a PVN-hindbrain feeding pathway. In addition, however, it suggests that some forebrain structures may also be involved in this response.

5-HT$_{1A}$ AND 5-HT$_{1B}$ RECEPTOR BINDING SITES IN DISCRETE HYPOTHALAMIC NUCLEI: RELATION TO FEEDING. S.F.Leibowitz and M.Jhanwar-Unival. The Rockefeller Univ, New York, N. Y. 10021

In this study, we examined biochemically, in albino rats, hypothalamic serotonin (5-HT) receptors that may control feeding behavior. Eight hypothalamic nuclei (paraventricular (PVN), ventromedial (VMH), suprachiasmatic (SCN), dorsomedial (DMN), supraoptic (SON), arcuate-median eminence (ARC-ME), perifornical lateral (PLH) and preoptic (POM)) were micropunched and assayed. Using the radioligand binding technique, we estimated the binding of the 5-HT$_{1A}$ receptor antagonist [^{3}H]8-OH-DPAT (2 nM) to 5-HT$_{1A}$ receptor sites (in presence or absence of 10 µM 5-HT). For the 5-HT$_{1B}$ receptors, [^{3}H]5-HT (2 nM) was incubated with or without 10 µM 5-HT and in presence of 8-OH-DPAT (100 nM) and mesulergine (100 nM).

The results revealed a considerably higher concentration of 5-HT$_{1B}$ (average = 150 fmol/mg P) than 5-HT$_{1A}$ (20-40 fmol/mg P) binding sites throughout the hypothalamic nuclei. The 5-HT$_{1B}$ sites were densest in the VMH and PVN (>200 fmol/mg P), moderate in the SCN, SON and POM, and lowest in the DMN, PLH and ARC-ME (<100 fmol/mg P). This agrees with cannula-mapping results, showing 5-HT's inhibitory effect on feeding (a 5-HT$_{1B}$ response) to be strongest in VMH, PVN and SCN, and weaker or absent in POM, DMN, and PLH. The 5-HT$_{1A}$ binding sites were found to be uniformly low throughout the hypothalamic nuclei. Moreover, in 48-hr food deprived rats, 5-HT$_{1B}$, but not 5-HT$_{1A}$, binding sites were significantly increased in the medial, but not lateral, hypothalamus.

PERIPHERALLY ADMINISTERED 5-CARBOXAMIDOTRYPTAMINE (5-CT) INHIBITS FEEDING IN RATS. K. J. Simansky and K. Eberle-Wang. Dept. Pharmacology, Med. Coll. of Pennsylvania, Philadelphia, PA 19129.

Peripheral administration of serotonin (5-HT) reduces feeding in rats. Pharmacological evidence suggests that 5-HT$_2$ receptors mediate this anorexia. We assessed the actions of the selective 5-HT$_1$ agonist, 5-CT, in male albino rats maintained with 6 h access to a milk diet during the light period. 5-CT (.015-.24 umol/kg, i.p.) produced a dose-related decrease of milk consumption during the 30-min test period (controls, 15.9 $\pm$ 1.3 ml). 5-CT (estimated ID_{50} = .04 umol/kg) was 100-fold more potent than 5-HT. Pretreatment with 5 umol/kg of the ergots methysergide or LY53857 but not with ketanserin or xylamidine antagonized the anorectic effect of 5-CT (.03 umol/kg). This dose of xylamidine maximally inhibited 5-HT-induced anorexia. In rats with gastric cannulas, .03 umol/kg 5-CT reduced "real" feeding with closed cannulas but not sham-feeding with open cannulas. Although 5-CT decreased real feeding, .03 umol/kg of this indole did not act as an unconditional stimulus for a conditioned taste aversion using a two-bottle test. This dose of 5-CT also failed to reduce locomotion, rearing or investigation of novel objects in an open field. Based upon these data, we are pursuing the hypothesis that 5-CT potently and selectively inhibits feeding by stimulating a peripheral, xylamidine-insensitive, 5-HT receptor. Supported by NIMH Grant 41987.

266.6

PARTITIONING OF LABELED AMINO ACIDS INJECTED INTO THE PREPYRIFORM CORTEX OF RATS FED AMINO ACID IMBALANCED DIETS. J.L.Beverly*, B.J.Hrupka*, D.W.Gietzen, P.M.B.Leung and Q.R.Rogers, Dept. Physiol. Sci. and Food Intake Lab, Univ. Calif., Davis, CA, 95616.

Injection of the dietary limiting amino acid (DLAA) into the anterior prepyriform cortex (PPC) ameliorates the depression in intake of amino acid imbalanced diets (IMB). This response, specific for the DLAA, becomes apparent approx. 6 hr after injection possibly involving protein synthesis. Incorporation of injected amino acids into protein in the PPC was evaluated in rats fed a low protein basal diet and fitted with chronic bilateral 24 gauge cannulae 3 mm above the PPC. Immediately prior to the onset of the dark cycle, and the feeding of thr IMB, rats received bilateral injections, 0.5 µl/5 min via 32 gauge injection needles, into the PPC of aCSF containing [^{3}H]-leu (100 pmole/5µCi/µl) +/- [^{14}C]-thr (4 nmole/µCi/µl). Rats were sacrificed at 15, 30, 60, 90, 120, 180 and 360 min post-injection and the PPC dissected from consecutive 0.5 mm brain slices. After homogenization in 1 ml Krebs-Ringer buffer, 0.1 ml 10% TCA was added and the homogenates separated into supernatant and protein fractions by centrifugation. Supernatants were decanted and 1 ml of 0.3 M KOH added to each protein pellet. [^{3}H] and [^{14}C] were analyzed in 0.5 ml aliquots of supernatant and protein. Incorporation of [^{3}H] and [^{14}C] into the protein fraction plateaued 60-90 min post-injection. 50% of injected [^{3}H] and 30% of [^{14}C] were recovered in the protein fraction within 1.25 mm of the injection site. Supernatants contained 8% and 3% of labels, respectively. In rats receiving DLAA [^{3}H] in protein was $\geq$150% of the level measured in rats not receiving the DLAA ($p=.02$). [^{3}H] and [^{14}C] in the hypothalamus and cingulate cortex were at or near background. The results of this study suggest that following injection of the dietary limiting amino acid into the brains of animals fed IMB there is an increase in protein synthesis in the immediate area of injection. Supported by NIH AM-07355, DK-13252; USDA CRCR1-2418; CNRU DK35747-04.

BLOOD GLUCOSE DYNAMICS, MEAL INITIATION AND METABOLIC RESPONSES IN FREE-FEEDING RATS HABITUATED TO A POLYCOSE DIET OPTION. L.A.Campfield, D.W.Driscoll* and F.J. Smith Department of Neurobiology and Obesity Res. Hoffmann-La Roche Inc., Nutley, NJ 07110

The goal of this study was to determine if transient declines in blood glucose (TDBG) precede meals of highly preferred polycose diet option in the presence of chow and to define the metabolic responses to these meals. Rats with cardiac cannulas were habituated to a CHO option (CO) of 32% polycose gel or powder in addition to chow. Meal pattern and blood glucose were continuously monitored at the light/dark transition in free-feeding rats. TDBG, within the limits previously reported, were observed prior to each polycose meal recorded in the late light and early dark (n=13). Each meal initiated after a normal latency was either CO or CO plus chow and the rise in blood glucose was larger than that observed following a chow meal. The metabolic response to oral polycose and glucose (1 ml of 50% solution) were compared; blood glucose responses were similar, while the plasma insulin response was increased following polycose. These studies suggest that TDBG reliably predict meal initiation in rats habituated to a preferred diet option and that differential metabolic responses occur following these meals. The experiments provide additional support for the role of blood glucose dynamics in the control of feeding.

TRANSPORT OF INSULIN FROM PLASMA TO CSF IS NOT ALTERED BY CAFETERIA DIET OBESITY IN THE RAT. D.F. Lattemann*, P. Israel*, M. Schwartz*, P. Green, A. Sipols, F. Mukaida*, D. Porte, Jr.*, and S.C. Woods. University of Washington, 98195, and VA Medical Center, 98108, Seattle WA.

We have hypothesized that steady-state plasma insulin (I) provides an adiposity signal at the CNS. I transport from plasma to CSF is impaired in obese Zucker rats. In this study we tested whether I transport is altered in cafeteria diet obesity. Osborne-Mendel rats were fed either chow (C;n=20) or chow and snacks (S;n=20) to achieve a 23% weight difference (359±7 vs 292±6 gm;Lee Index=.319±.002 vs .302±.002). Rats were infused SQ 24 hr with I, or with vehicle with an overnight fast. Basal plasma I was elevated in S vs C rats (113±10 vs 45±7 uU/ml;n=5 each) but CSF I was 10% of plasma I in both (10.0 vs 4.6±1.5 uU/ml). Plasma I (395±117 vs 369±58 uU/ml) and CSF I (5.7±1.2 vs 7.8±2.9 uU/ml) were comparable for C (n=7) vs S (n=10) rats with I infusion. Thus at both basal and elevated plasma I there is no defect of I transport into CSF in the S rats. This suggests that rats with mild non-genetic obesity receive an appropriate I adiposity signal at the CNS.

CIRCADIAN CHANGES IN I.V. NUTRIENT SATIETY. E.K. Walls*, A.E. Willing* and H.S. Koopmans, Dept.Med.Physiol., Univ. of Calgary, Calgary, Alberta, Canada T2N 4N1.

Most previous studies have delivered i.v. nutrients over 24 hours to study their effect on daily food intake. In this study, nutrients were delivered to dark fed rats during different portions of the 12:12 hr light/dark cycle to determine whether feeding-generated gut signals act in conjunction with i.v. nutrients to suppress food intake. During 4 day test periods, 6 rats were infused with 35.5 - 37.0 kcal of a solution containing 25% glucose and 4.25% amino acids (Travasol). Saline baseline intakes were 63 - 75 kcal/day. During 8 and 12 hr infusions in the dark phase, food intakes were reduced by 40.5 ± 1.1 and 30.7 ± 1.8 kcal/day (or 110 and 87% of infused calories) respectively ($p < .01$). These rats gained 1.1 ± 0.2 and 1.1 ± 0.3 g/day. Following 8 or 12 hr infusions in the light phase, food intakes were reduced significantly less than in the dark, 21.3 ± 1.1 and 19.6 ± 0.7 kcal/day (or 57 and 55% of infused calories, $p < .01$) and greater weight gains were observed 3.0 ± 0.3 and 2.1 ± 0.3 g/day ($p < .01$). With 24 hour infusions, as in previous studies, food intake was reduced by 24.5 ± 2.1 kcal/day (or 68% of infused calories, $p < .01$) and rats gained 2.4 ± 0.3 g/day. This study shows that gut signals generated by concurrent feeding act with i.v. glucose and amino acids to produce a more compensatory reduction of voluntary intake. In the light phase when gut signals are absent and fat is being burned, i.v. nutrients produce a much smaller reduction in subsequent food intake.

266.10

SUPPRESSION OF FEEDING BY INTRAINTESTINAL MALTOSE IS MEDIATED BY PHLORIZIN-SENSITIVE MECHANISM. R.C. Ritter and E. Simon*. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Intraintestinal infusion of maltose suppresses food intake. This effect is mediated by vagal sensory neurons that are destroyed by the neurotoxin capsaicin. To further examine the mechanism by which maltose suppresses food intake, we made intraintestinal infusions of monosaccharides or maltose in sham feeding rats. We also made coinfusions of these substances with phlorizin, a blocker of sodium-coupled intestinal glucose transport. Glucose, which is absorbed by a sodium-coupled carrier, suppressed food intake in a dose dependent manner. 3-o-methylglucose, a glucose analogue that is absorbed but does not move by the sodium-coupled glucose carrier, did not suppress sham ingestion. Suppression of ingestion by either glucose or maltose was attenuated by phlorizin. Our data suggest that suppression of food intake by maltose is mediated by glucose liberated from maltose digestion. Furthermore, the data indicate that for suppression of feeding to occur, glucose must interact with the sodium-coupled carrier or a similar receptor site. (Supported by NIH RO1 NS20561).

266.11

HEPATIC PORTAL INFUSION OF GLUCAGON ANTIBODY INCREASES SPONTANEOUS MEAL SIZE IN RATS. J. Le Sauter and N. Geary, Psychology Department, Columbia University, NY, NY 10027.

Pancreatic glucagon (PG) administration reduces the size of test meals elicited by food deprivation, by presentation of palatable food, and, as we recently reported (Le Sauter et al., Proc. EPA 60: 51, 1989), spontaneous meals in free feeding rats. All these data suggest exogenous PG may signal postprandial satiety. Endogenous PG has also been implicated in satiety because intraperitoneal injection of PG antibodies increases the size of post-deprivation meals (Langhans et al., Science 218: 894, 1982). We now report that endogenous PG also appears necessary for the normal control of spontaneous meals. Nine rats with chronic intraportal cannulas were infused twice each with either rabbit PG antibodies (Radioassay Sys., Carson, CA) or non-immunized serum according to separate crossover tests. A dose sufficient to neutralize 3 ng PG in vitro was remotely infused at .034 ml/min during the first 2 min of the first spontaneous meal in the last quarter of the dark phase. Antibody infusion increased meal size in 16 of 18 tests. The mean increase was 57%, from 2.8 ± 0.3 to 3.8 ± 0.4 g, $t(8)= 2.36$, $p<.05$. Meal duration increased 71%, from 11.2 ± 1.3 to 16.2 ± 2.6 min, but this was not statistically reliable. These data suggest pancreatic glucagon operates physiologically to control spontaneous meals.

266.12

PREFERENCES BETWEEN CONCURRENTLY PRESENTED FLAVORS REINFORCED BY DELAYED NUTRITIONAL DIFFERENCES. B.J. Baker* and D.A. Booth, School of Psychology, University of Birmingham, B15 2TT, U.K.

The site and nature of a nutritional signal to the brain can be characterised by the effects on ingestive behavior of administering particular nutrients selectively to parts of the gut, liver or brain. Flavor preference reinforcement effects (conditioned choices) are more specific than (food-intake suppression) satiety effects. Rats were conditioned by differences between two concurrently presented high- and low-carbohydrate-containing diets and protein-containing and non-nutritive diets so that they preferred the flavor of the richer or nutritive diet. Such learning occurred with a 10-minute delay between the presentation of both dietary stimuli and the intubation of the nutrient mixture proportional to the flavor intakes. Thus, rats are able to perceive the difference between the nutritional aftereffects of two distinctive diets presented concurrently and to learn to respond differentially to associated flavors.

Therefore, reinforcement that has been suggested to arise from gastric chemoreception may be attributable to delayed postgastric effects.

EFFECTS OF MAITOTOXIN (MTX) ON cGMP GENERATION IN PC12 CELLS. Fabian Gusovsky, Andrew Schulick*, Takeshi Yasumoto* and John W. Daly, LBC, NIDDK, NIH Bethesda, MD 20892

The marine toxin MTX is a calcium channel activator and it stimulates phosphoinositide breakdown in most cells. In PC12 cells MTX has no effect alone on cAMP or cGMP formation, but as was the case for phorbol esters that activate protein kinase C, MTX potentiates forskolin-stimulated cAMP accumulation, probably through formation of diacylglycerol. Atrial natriuretic factor (ANF) induces a dose dependent formation of cGMP in PC12 cells through the stimulation of a particulate membrane bound guanylate cyclase. ANF-mediated cGMP formation is not affected by varying $[Ca^{2+}]_o$. MTX inhibits ANF-induced cGMP formation. The inhibitory effect is calcium-dependent and is eliminated in the absence of $[Ca^{2+}]_o$. But the inhibition by MTX is not reduced by the calcium channel blocker nifedipine. The calcium ionophore ionomycin does not affect ANF-mediated cGMP formation. Phorbol-12-myristate-13-acetate (PMA), but not 4α-phorbol, also inhibit ANF-mediated cGMP accumulation. Sodium nitroprusside (NPS) induces large increases in cGMP through the stimulation of a soluble guanylate cyclase in PC12 cells. Neither MTX nor PMA inhibit NPS-induced cGMP accumulation. The results indicate that in PC12 cells, protein kinase C (PKC) activation leads to inhibition of ANF-mediated cGMP accumulation. Such PKC activation can be attained either directly with PMA, which binds to and activates PKC, or with MTX, through calcium-dependent phosphoinositide breakdown and subsequent diacylglycerol formation. Since NPS-mediated stimulation was not affected with MTX or PMA, it is possible that the particulate, but not the soluble guanylate cyclase, is phosphorylated by PKC resulting in an inhibition of activity.

267.2

TETRAHYDROPAPAVEROLINE INHIBITS IN VITRO BRAIN PROTEIN KINASE C ACTIVITY. R.Del Vesco*, S.Govoni*~, F.Battaini~, C.Lopez* and M.Trabucchi*~ (SPON. V.Olgiati).Ins. Pharmacol. Sci. Univ. of Milan; ~Pharmacobiol. Dept. Univ of Bari;~Chair of Toxicol., 2nd Univ. of Rome , Italy.

It has been demostrated that isoquinolinsulfonamides, in particular H-7, inhibit in vitro brain PKC activity interacting, in a competitive manner, with the ATP site on the catalytic domain of the enzyme. Moreover H-7 doesn't modify 3H-Phorbol dibutyrate (3H-PDBu) binding further suggesting that this compound interacts specifically with the catalytic domain of the enzyme. We have investigated the in vitro effect of tetrahydropapaveroline (THP), which has a chemical structure related to H-7, on 3H-PDBu binding and on partially purified PKC activity from rat brain. THP doesn't modify 3H-PDBu binding up to a concentration of 300 μM. On the other hand THP inhibits in vitro, in a concentration dependent manner, from 10 to 300 μM, the enzyme activity both in the soluble and the particulate fraction. The IC50 is 50 μM, a value similar to that of H-7 (basal activity: 1.5±0.11 nmoles 32P incorporated/min./mg protein).

The present data demostrate that THP, a tetrahydroisoquinoline derivative, inhibits PKC activity with the same potency and, probably, the same mechanism of H-7. Moreover THP has been isolated from mammalian brain and urine of human subjects suggesting the possibility that endogenously formed THP could act as a PKC regulator.

267.3

DUAL MECHANISMS OF INHIBITION BY DOPAMINE OF BASAL AND TRH STIMULATED INOSITOL PHOSPHATE PRODUCTION IN ANTERIOR PITUITARY CELLS. A. Enjalbert, G. Guillon*, B. Mouillac*, V. Audinot*, R. Rasolonjanahary*, C. Kordon and J. Bockaert*. U. 159 INSERM (Paris) and CCIPE (Montpellier), France.

In primary culture of anterior pituitary cells dopamine inhibited basal and thyrotropin releasing hormone inositol monophosphate, inositol diphosphate and inositol triphosphate production. This inhibition by dopamine was a biphasic phenomenon. One of the component of the inhibition was very rapid and already present after 10 seconds. The other was slower, starting after 1 min, and was mimicked by nimodipine, a dihydropyridine calcium channel antagonist. The effects of dopamine and nimodipine were not additive on both basal and TRH stimulated inositol phosphates production. Furthermore, the dopamine inhibition in the presence of TRH was much higher (51 %) than the inhibition induced by nimodipine (20 %).

In conclusion dopamine appears to inhibit inositol phosphates production by two distinct mechanisms. The slow inhibition is likely due to an inhibition of voltage dependent calcium channel. This is further substantiated by the fact that ionomycine (10 μM) was able to reverse this slow component. In contrast the rapid inhibition induced by dopamine was not reversed by ionomycine. This fast component of the dopamine inhibition could represent a direct coupling, though a pertussis toxin sensitive G protein of D2 dopamine receptors with phospholipase C.

267.4

REGULATION OF INOSITOL 1,4,5-TRISPHOSPHATE (IP_3)-INDUCED Ca^{2+} RELEASE FROM CANINE CEREBELLUM MEMBRANE PREPARATIONS. P. Volpe, B.H. Alderson-Lang* and M. Tzinas*. Department of Physiology and Biophysics, UTMB, Galveston, TX 77550.

Intracellular Ca^{2+} stores capable of accumulating and releasing Ca^{2+} have been shown in CNS neurons. The Ca^{2+} store sensitive to IP_3 seems to be particularly enriched in membrane preparations obtained from the cerebellum. Regulation of IP_3-induced Ca^{2+} release is not well understood yet. To this end, we have studied the effects of cAMP, cAMP-dependent protein kinase (PKA) and $[Mg^{2+}]$ on IP_3-induced Ca^{2+} release from canine cerebellum membrane preparations actively preloaded with Ca^{2+}. The catalytic subunit of PKA increases the extent of IP_3-induced Ca^{2+} release, shifts the dose-dependence curve for IP_3-induced Ca^{2+} release to the right, and does not affect Ca^{2+} uptake rate. cAMP appears to have no effect on both Ca^{2+} uptake and Ca^{2+} release. Reduction of free $[Mg^{2+}]$ causes no change of Ca^{2+} uptake rate, provided that [MgATP] is kept well above K_m for Ca^{2+} transport. Furthermore, low $[Mg^{2+}]$ increases the extent of IP_3-induced Ca^{2+} release, and shifts the dose-dependence curve for IP_3-induced Ca^{2+} release to the left. These results suggest that: a) PKA-dependent phosphorylation and high $[Mg^{2+}]$ may decrease the affinity of the receptor for IP_3; b) no appreciable, endogenous membrane-bound PKA is detected; c) dephosphorylation and high $[Mg^{2+}]$ favor the transition to a closed state of the IP_3-sensitive Ca^{2+} channel. Supported by NIH grant GM40068.

EFFECTS OF SINGLE AND REPEATED DOSES OF LITHIUM ON BRAIN REGIONAL INOSITOL, INOSITOL-1-PHOSPHATE AND CALCIUM CONCENTRATIONS. K.M. Savolainen and M.-R. Hirvonen*. National Public Health Institute, Department of Environmental Hygiene and Toxicology, P.O.Box 95, SF-70701 Kuopio, Finland.

The effects of an i.p. single (10 mEq/kg) dose of LiCl during 24 h, and of repeated doses (2 mEq/kg daily) at one and two weeks on brain regional inositol, inositol-1-phosphate (InsIP), intermediates of brain phosphoinositide (PI) cycle, and calcium (Ca^{2+}) concentrations were studied in male Han/Wistar rats. Inositol and InsIP were measured by GLC, and confirmed with a mass selective detector. Ca^{2+} and Li^+ were measured by atomic absorption sepectrophotometer. There was a slight gradual, but significant increase in cerebral InsIP after a single dose of LiCl during 24 h, and a much more pronounced decrease in brain inositol. Brain Ca^{2+} and Li^+ increased during the same time period. During repeated dosing of LiCl there was an increase in brain InsIP levels at one week which were decreased at two weeks; brain nositol and Ca^{2+} were unchanged, but there was a constant decrease in brain Li^+. These results suggest that a high singl. dose of LiCl disturbs brain PI cycle, not only by inhibiting InsIP monophosphatase but other enzymes of the cycle as well. Elevated brain Ca^{2+} levels support this interpretation. Accumulation of Li^+ in the brain may also partly explain these results. During repeated administration of LiCl, InsIP levels increased at one week but decreased again at two weeks indicating an adaptation of PI metabolism to the effects of LiCl. Alternatively, decreased brain Li^+ may contribute to his effect.

PHOSPHOINOSITIDE (PI) SECOND MESSENGER MARKERS IN RAT CEREBELLAR PURKINJE CELLS. C.A Ross, A. Verma, T. Milner, M.W. MacCumber, S. Suppatapone, J. Meldolesi, and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins University, School of Medicine, 725 N. Wolfe Street, Baltimore, MD 21205.

Cerebellar Purkinje cells are enriched in elements of the PI cycle, such as protein kinase C, G_o protein, and IP_3 receptors (Worley et al. Ann. Neurol. 21:217-229, 1987). By EM immunocytochemistry, we find Purkinje cell IP_3 receptors in smooth and rough endoplasmic reticulum (ER) and the nuclear membrane, sites where IP_3 could influence synaptic transmission, protein synthesis, and nuclear events. IP_3 releaseable $^{45}Ca^{++}$ uptake into ER in brain sections is highly concentrated in Purkinje cells. In situ hybridization studies show that mRNA for an intracellular calcium pump is also most highly concentrated in Purkinje cells. Another mRNA wich is most enriched in Purkinje cells is that of one particular isozyme of phospholipase C (Bennett et al. Nature 334:268, 1988). The high concentration of PI elements in Purkinje cells is explained by the finding that the synapse from parallel fibers to Purkinje cells, quantitatively the most prominent in the brain, involves a specific glutamate receptor which activates the PI cycle (Blackstone et al. PNAS, in press). These studies suggest that cerebellar Purkinje cells are an excellent model system for studying brain PI system function.

267.7

AUTORADIOGRAPHIC VISUALIZATION OF INOSITOL-1,4,5-TRIPHOSPHATE (IP_3) SENSITIVE CALCIUM POOLS IN RAT BRAIN. A. Verma, C.A. Ross, S. Supattapone, D. Verma* and S.H. Snyder. Johns Hopkins Univ. Sch. of Med., Dept. of Neurosci., Baltimore, MD 21205 and *Univ. of MD Med. Sch., Baltimore, MD 21201.

Fresh frozen 10 μm rat brain sections demonstrated ATP-Mg^{2+} dependent uptake of $^{45}Ca^{++}$ which was markedly enhanced by oxalate. This uptake involved a non-mitochondrial pool, being insensitive to ruthenium red or azide, but inhibited by vanadate and abolished by A23187. Autoradiographic distribution of accumulated $^{45}Ca^{++}$ oxalate precipitate overlapped the distribution of IP_3 binding sites in serial brain sections. Highest levels of both $^{45}Ca^{++}$ uptake and IP_3 binding were in cerebellar Purkinje cells.

Accumulation of $^{45}Ca^{++}$ oxalate precipitate was diminished 30-40% by 10μM IP_3, an effect blocked by heparin. A similar effect was seen with I(2,4,5)P_3 but not I(1,3,4)P_3 or other inositol phosphates. The effect of IP_3 on $^{45}Ca^{++}$ accumulation was limited to brain regions with IP_3 binding. Thus, CNS IP_3 binding sites appear to represent functional receptors which modulate a non-mitochondrial, oxalate permeable calcium pool.

267.8

FUNCTIONAL RECONSTITUTION OF PURIFIED INOSITOL 1,4,5-TRISPHOSPHATE RECEPTOR FROM RAT CEREBELLUM. C.D. Ferris, R.L. Huganir, S. Supattapone and S.H. Snyder. Dept. of Neuroscience, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 20205.

IP_3 receptor was purified as described (Supattapone, S., et al., JBC 263:1530-1534, 1988). Purified receptor protein was mixed with sonicated, solubilized liposomes. After detergent removal reconstituted vesicles were used for both [^{3}H]IP_3 binding and [$^{45}Ca^{++}$] flux assays. The affinity and inositol phosphate specificity of binding in the vesicles is nearly identical to that of the native membranes and the purified receptor. [^{3}H]IP_3 binding in the vesicles has a K_d of approximately 80 nM at pH 7.4, is largely insensitive to other inositol phosphates, and is completely inhibited by heparin (100ug/ml). [$^{45}Ca^{++}$] flux was assayed by mixing reconstituted vesicles with [$^{45}Ca^{++}$] in the presence or absence of Ins (1,4,5) P_3 or other inositol phosphates followed by cation exchange chromatography. In the presence of 10 uM IP_3 maximum [$^{45}Ca^{++}$] flux occurs within 10 sec. Dose response analysis for Ins (1,4,5) P_3 shows an EC_{50} of 100 nM. All other inositol phosphates are inactive at micromolar doses. Thus, a single protein receptor contains both the IP_3 binding site and the calcium release mechanism.

267.9

ANGIOTENSIN II MOBILIZES CYTOSOLIC CALCIUM IN NG108-15 CELLS. E.A. Tallant*, M.C. Khosla and C.M. Ferrario. Research Institute, Cleveland Clinic Foundation, Cleveland, OH 44195.

Angiotensin II (Ang II) participates in the central regulation of cardiovascular function and has been identified, along with its receptor, in regions of the CNS which participate in cardiovascular regulation. To define the signal transduction mechanisms of Ang II in neuronal cells, we have used a transformed cell line of neural origin, the neuroblastoma x glioma hybrid NG108-15, which contains a specific, high affinity binding site for Ang II. Incubation of intact NG108-15 cells with ^{125}I-Ang II revealed a single population of binding sites with a K_D of 1.09±0.06 nM and a Bmax of 7.35±0.94 fmol/mg protein. Ang peptides competed with Ang II for binding, with an order of potency of Ang II>Ang-(2-8)>Ang I>Ang-(1-7)>Ang-(2-7)>>Ang-(1-6). Incubation of NG108-15 cells with 1 mM dibutyryl cAMP for 6 days, which produces morphological differentiation of the cells, resulted in a 50-fold increase in the number of Ang II binding sites (362.7±98 fmol/mg protein) and a smaller decrease in their affinity (5.38±1.6 nM), suggesting that a cAMP-dependent mechanism may be involved in neuronal Ang II receptor regulation. Nanomolar concentrations of Ang II elevated the level of cytosolic Ca^{2+}, measured in NG108-15 cells loaded with the fluorescent Ca^{2+} indicator dye Fura 2, and the response was specifically blocked by the Ang II antagonist Sar^1Ileu^8-Ang II or Sar^1Thr^8-Ang II. Because Ca^{2+} mobilization in response to Ang II was not blocked by chelation of extracellular Ca^{2+} with EGTA or by verapamil, the peptide mobilizes Ca^{2+} from intracellular stores. The data suggest that Ang II in neuronal cells is coupled to hydrolysis of inositol lipids and the subsequent mobilization of cytosolic Ca^{2+}. (Supported in part by HL-6835 and the Storer Foundation).

G-PROTEIN CROSSTALK IN RECEPTOR COUPLING TO PHOSPHOLIPASE C. E.M. Landau, T.M. Moriarty, S.C. Sealfon*, D.J. Carty*, G. Omri*, J.L. Roberts and R. Iyengar* Depts. of Psychiatry, Pharmacology and Fishberg Research Center, Mount Sinai School of Medicine, New York, N.Y. and Dept. of Psychiatry, Bronx V.A. Medical Center, Bronx, N.Y.

Heterotrimeric G-proteins can be categorized into molecularly divergent groups by their differential sensitivity to pertussis toxin (PTX). Receptors specifically use either PTX sensitive or insensitive G-proteins to activate effectors. To determine if this specificity is absolute we tested the possibility that receptors which utilizes PTX insensitive pathways in native tissues might use PTX sensitive G-proteins in a foreign environment. *Xenopus* oocytes injected with rat liver RNA expressed liver V_1-type vasopressin receptors which are known to couple to a PTX insensitive G-protein in liver. Oocytes injected with rat brain RNA expressed brain CCK-A receptors which are also thought to use a PTX insensitive G-protein. We studied coupling to phospholipase C by monitoring a receptor-evoked IP_3 dependent Cl^- current. The coupling of the liver V_1 receptor in the oocyte was inhibited by PTX, whereas the brain CCK-A receptor coupling was not sensitive to PTX. Both responses were regulated by purified G-protein βγ subunits. The results indicate that the V_1 receptor can utilize two different G-proteins as signal transducers whereas the brain CCK-A receptor maintains specificity for a PTX insensitive pathway, and further suggest the hitherto unrecognized possibility of the existence of closely related G-proteins that are differentiated only by their PTX sensitivity.

ENDOTHELIN AND SARAFOTOXIN STIMULATE PI TURNOVER IN CLONAL HSDM1C1 CELLS. N.A.Sharif* and R.L.Whiting (SPON:R.P.Rosenkranz), Inst. of Pharmacology, Syntex Research, Palo Alto, CA 94303 (USA).

The peptides, endothelin (ET) and sarafotoxin (ST), are 21-amino acid-containing peptides that share 67% structural homology but which have been isolated from porcine cells and snake venom respectively. We have studied the mechanism of action of these peptides in clonal murine fibrosarcoma cells (HSDM1C1) using phosphoinositide (PI) hydrolysis as an index of receptor activation.

In [^{3}H]inositol-labelled HSDM1C1 cells, ET and ST produced a dose-related (0.1 nM - 10 μM) accumulation of [^{3}H]inositol phosphates. Human/porcine ET (HP-ET) and ST were more potent than rat ET (R-ET) at stimulating PI turnover in these cells. The ED_{50} values were (nM; $\bar{X}$ ± SEM; n = 3-6) : HP-ET = 87.4 ± 16.8; ST = 61.4 ± 5.3 and R-ET = 224 ± 22. However, all three peptides were full agonists and yielded a 4.5-5.6-fold increase in PI turnover at 10 μM. Although the actions of these peptides were reduced in Ca^{2+}-free-EGTA-containing buffer, the addition of the Ca^{2+}-channel blockers, nifedipine and w-conotoxin (0.1nM-1μM), failed to alter ET-induced PI hydrolysis. In contrast, numerous other neuroactive agents failed to induce PI hydrolysis in this cell-line.

In conclusion, these data suggest that the clonal cell-line, HSDM1C1, contains specific receptors for ET and ST which are linked to a PI turnover mechanism.

267.12

ENDOTHELIN-INDUCED PHOSPHOINOSITIDE TURNOVER IN CEREBELLAR GRANULE CELLS. W.-W. Lin[*1,2], C.Y. Lee[2] and D.-M. Chuang[1] (Spon: V. Gilad). [1] Lab. of Preclinical Pharmacol., National Institute of Mental Health, Washington, DC 20032 and [2] Dept. of Pharmacol. College of Medicine, National Taiwan Univ. Taipei, Taiwan, ROC.

The effect of endothelin (ET) on phosphoinositide (PI) hydrolysis was studied in primary culture of cerebellar granule cells. ET induced approximately 10-fold increase in ^{3}H-inositol monophosphate accumulation. The EC_{50} and saturation concentrations of ET were 1.3 and 10 nM, respectively. The PI response elicited by ET was dependent on the presence of extracellular calcium but was only slightly affected by 1 mM of Co^{++} or Mn^{++} and 10 μM of nimodipine or nisoldipine. Sodium depletion resulted in a marked increase in basal PI turnover and a corresponding decrease in the fold-stimulation elicited by ET; however, the net increase of PI turnover was not attenuated. ET-induced PI breakdown was partially inhibited by a phorbol ester and was unaffected by pertussis toxin. The ET-induced PI turnover appeared to be additive to that induced by carbachol, histamine, NE and serotonin. Prestimulation of cells with ET for 30 sec or longer resulted in virtually complete loss of the ability of ET to stimulate PI hydrolysis, without affecting subsequent responsiveness induced by carbachol, histamine, NE, serotonin and maitotoxin. However, the response induced by sarafotoxin was desensitized by ET prestimulation.

RESPONSES FROM PRIMARY SOMATOSENSORY CORTEX IN M. MULATTA DURING ACTIVE DISCRIMINATION OF TEXTURED SURFACES. R. Sinclair & H. Burton. Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Two trained monkeys (M. Mulatta) stroked their fingertips over pairs of horizontal gratings (Sinclair & Burton, Somato Res 5,1989, 283) with constant ridge (250um) and varying groove (500-2900um) width (roughness), and identified the smoother (smaller groove), while recordings were made from somatosensory cortex. All findings are preliminary. From ~140 single units in SI areas 1 & 3b, 3 response types were found: 1. Response proportional to surface roughness; vigorous response to roughest and none to smoothest surface. Instantaneous firing rates appear linearly related to roughness. This graded response is similar to that of peripheral receptors. 2. Graded response, but smaller response difference to same roughness range as #1. 3. Response not correlated with roughness. All 3 response types were seen in areas 1 & 3b. No significant differences found between 1 & 3b in cells with rapidly adapting (RA) responses to punctate stimuli. Slowly adapting (SA) cells in 3b showed similar response patterns. Some SA responses correlated both with applied force and roughness. A few 3b cells (SA) showed inverse responses to roughness (greater activity on smoother surfaces). Contrast effects were noted where response rate was greater if smoother surface was stroked first. No difference was found in SI responses preceding correct or incorrect discrimination. Discrimination of horizontal gratings differing by groove width could be served by activity proportional to groove size in a large population of SI cells. Supported by NIH NS09809.

PARALLEL PROCESSING OF MOVING BAR PATTERNS IN PRIMATE S-I CORTEX. S. Warren, H.A. Hamalainen, C.I. Palmer and E.P. Gardner. Dept. of Physiology and Biophysics, NYU School of Medicine, NY, NY 10016.

Horizontal bar patterns swept across the tactile array of an OPTACON stimulator have been used to map receptive fields of cutaneous afferents and SI cortical neurons. Cortical single unit recordings in alert macaques reveal a remarkable central transformation of peripheral sensory information, involving (a) amplification, prolongation and merger of sensory signals; (b) temporal frequency filtering; and (c) frequency dependent receptive field plasticity. Cortical responses are stronger, longer in duration and less tightly phase locked to OPTACON pulses than receptor activity. Four types of spike trains are observed. ***Pulse neurons*** resemble sensory afferents discharging highly synchronized, short duration bursts of spikes which are tightly time-locked to OPTACON pulses; they are found in area 3b and anterior area 1, and respond at shortest latencies (15-18 ms). ***Burst neurons*** also show tight response coupling to stimulus pulses, but display longer lasting discharges; spikes evoked by successive stimuli merge, forming a continuous discharge at high pulse frequencies. Burst neurons have similar cytoarchitectural distributions in SI, but show longer latency peak responses (18-25 ms). Firing patterns of ***modulated neurons*** are more loosely coupled to OPTACON pulses, while those of ***non-modulated neurons*** are completely uncoupled from the pulse train, showing only a generalized rise in excitability. The pulsatile characteristic of the stimulus is smoothed into a signal of continuous motion by modulated and non-modulated neurons. They form 60% of the activated cortical population, and are generally located posteriorly. Burst neurons show the greatest increase in spikes/pulse, and non-modulated neurons the least.

Unlike peripheral afferents whose firing rates mimic stimulus frequency, *average firing rates* of cortical neurons are relatively *uniform* at all frequencies. Temporal frequency of stimulation appears to be coded primarily by the spike trains of pulse and burst neurons. Frequency coding is degraded by the other classes; at high frequencies they fire continuous discharges in which individual pulse responses are merged. Non-modulated neurons require closely spaced temporal inputs, as they fire at higher rates to 100 Hz than to 25 Hz stimuli. We suggest that differences in conduction velocities of individual afferents spread out central inputs, allowing separate pulse responses of receptors to be merged into a continous cortical discharge. This temporal amplification may provide the neural basis for the sensation of apparent motion across the skin. *(Supported by USPHS Research Grant NS11862.)*

DIFFERENCES IN SENSORIMOTOR INTEGRATION IN CORTICAL AREAS 3b AND 1. OF THE MONKEY. R. J. Nelson and V. D. Douglas* . Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, 875 Monroe Avenue, Memphis, TN 38163.

Areas 3b and 1 of monkey somatosensory cortex receive similar afferent input and are topographically mirror-images of each other. However, their functional differences in sensorimotor integration are not completely understood. To determine the differences in the activity of area 3b and 1 neurons during sensory triggered motor behaviors, Rhesus monkeys were taught to make identical wrist flexion and extension movements in response to either vibration delivered to the palm by the apparatus' control handle or visual cues consisting of changes in the display lamps that also signaled the current wrist position. These cues were presented randomly in blocks of ten trials. Animals were required to make the same movements in response to either sensory stimulus. From single-unit activity records of 35/44 and 90/115 area 3b and 1 neurons the onset times and magnitudes of activity changes related to the onset of sensory cues and premovement activity were measured. In general, the onsets and magnitudes of non-stimulus related premovement activity were significantly different for vibratory as compared to visually cued trials for area 1 but not for area 3b neurons ($p<0.01$ and $p<0.05$; t-test). Premovement activity differences of area 1 neurons were related to vibratory stimulus frequency, receptive field type and the direction of movement. Area 3b premovement activity differences were not. For 40 area 1 cue related-neurons, increases in vibratory responsiveness were correlated with proportional decreases in the magnitude of premovement activity when movements were made against a load and in the direction of the stimulated body hand. Seventeen area 3b neurons did not show this trend.

These findings and previously reported differences in sensory and premovement related activity suggest that while areas 3b and 1 are similar in many respects, neurons in these areas respond differently to peripheral and centrally generated modulatory inputs. This study met NIH animal utilization guidelines.

DISTINCTIVE PATTERNS OF PROJECTIONS TO STRIATUM FROM PHYSIOLOGICALLY-MAPPED SOMATOSENSORY REPRESENTATIONS IN PRIMATE CORTEX. A. W. Flaherty*, A. M. Graybiel, M. Sur, P. Garraghty (SPON: M. Nastuk). Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

To help understand the way the striatum represents bodily sensation, we have investigated how electrophysiologically-defined areas 3a, 3b, and 1 of the primate primary somatosensory cortex (SI) project to the striatum. With multiunit recording, we mapped hand or mouth receptive fields (RFs) in 8 squirrel monkeys, and injected small volumes of distinguishable anterograde tracers (HRP-WGA and 35S-methionine) into mapped regions. **(1) Pattern of SI projections to the striatum.** Projections appeared as a constant pattern of patches and bands of label, exclusively in the extrastriosomal matrix of the putamen. Some abutted striosomes identified by enkephalin-like immunostaining. **(2) Different representations in the same functional areas.** When we injected two different parts of the hand representation within a single cortical area (e.g. the thumb and fifth fingers in area 3b), we saw partially overlapping and interdigitating projection patterns. In contrast, corticostriatal projections from the hand and mouth representations within a single cortical area projected to distinctly different, non-overlapping areas of the putamen. **(3) Matched representations in different functional areas.** We injected homologous representations of a single body part within different functional areas--e.g. representations of the index finger in areas 1 (primarily cutaneous RFs) and 3a (primarily deep, muscle spindle RFs). Such injections produced overlapping zones of projection in the putamen, but in the rostral putamen the regions of densest labeling did not always overlap. These anatomical findings suggest that there is a functional mosaic of somatosensory fields in the primate striatum. Supported by Javits Award 2 R01 255290101 and The Seaver Institute.

RETROGRADE LABELING OF STRIATONIGRAL AND STRIATOPALLIDAL NEURONS IN THE RHESUS MONKEY. L.D. Selemon, and P.S. Goldman-Rakic, Sect. of Neuroanat., Yale Univ. Sch. Med., New Haven, CT 06510.

The topography of striatonigral and striatopallidal neurons and their relative apportionment in the caudate and putamen was examined in five rhesus monkeys. In Cases 1-3, following simultaneous retrograde transport of the fluorescent dyes, diamidino yellow (DY) and fast blue (FB), from the rostral globus pallidus (GP) and rostral substantia nigra (SN), respectively, labeled neurons were densely distributed within corresponding topographic zones of the precommissural neostriatum. Both striatofugal populations were observed in the caudate, as well as in the putamen. Despite intermingling of striatonigral and striatopallidal cells in two of the cases, very few double-labeled neurons were observed. In Case 4, in which DY was injected into the caudal GP, striatopallidal neurons were found in the posterior putamen and dorsolateral caudate. Although labeling was largely dense and homogeneous in the fluorescent cases, clusters of DY and FB-labeled neurons were observed. More prominent clustering was observed in the posterior putamen in Case 5 following an injection of WGA-HRP into the caudolateral SN.

Retrograde labeling in the present study indicated that striatofugal neurons are not segregated on a gross morphological level but may be organized as a mosaic of GP- and SN- projecting clusters. The observation that each population is widely distributed in both the caudate and putamen, suggests that strict parallelism is not maintained in the cortical-basal ganglia loop. (MH38546, MH00298, AG05310).

268.6

TRANSNEURONAL TRANSPORT OF HSV1 FROM THE PRIMARY MOTOR CORTEX OF PRIMATES. M.C. ZEMANICK,* P.L. STRICK and R.D.DIX*. VA Med. Ctr. and Depts. of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syracuse NY, 13210 and Depts. of Ophthal. and of Microbiol. and Immunol., School of Medicine, Univ. of Miami, Miami, FL, 33101.

We injected Herpes Simplex Virus Type 1 (HSV1, strain H129, titre: 10^{12} PFU/ml) at 4-12 sites (0.05ul/site) in the 'arm' area of the primary motor cortex in 2 monkeys (Cebus apella). After a 3 or 4 day survival time, immunohistochemical procedures were used to demonstrate virus transport. We observed intense labeling of neurons in regions which receive input from the injection site (e.g., portions of the putamen, thalamic reticular nucleus, red nucleus, and pontine nuclei). Brain regions which project to the injection site (e.g., portions of the nucleus basalis) or are reciprocally connected with the injection site (e.g., portions of the ventrolateral and intralaminar thalamus, and frontal and parietal cortex) also contained intensely labeled neurons. In addition, we observed several striking instances of anterograde transneuronal transport to 'third-order' neurons. For example, clusters of labeled granule cells were located at multiple sites in the cerebellar cortex, and labeled neurons were seen in the external segment of the globus pallidus. Our results suggest that anterograde transneuronal transport of HSV1 can be used to examine connections between primate cerebral cortex and the cerebellum and basal ganglia. Support: VA Res. Serv. and USPHS 24328, 8705, 2957.

INTRACELLULAR STAINING WITH BIOCYTIN REVEALS THE COMPLETE TELENCEPHALIC ARBORIZATIONS OF RAT PYRAMIDAL TRACT NEURONS. R. L. Cowan and C. J. Wilson, Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis TN 38163.

Incomplete labeling of distant axonal processes limits the usefulness of intracellular staining techniques. The most desirable marker would completely label distant axon collaterals after intrasomatic injection. Horikawa and Armstrong have recently introduced biocytin, whose characteristics suggest it might be a less toxic and more mobile intracellular label than HRP. We tested this possibility by injecting antidromically identified pyramidal tract neurons with biocytin *in vivo*. After incubation in avidin-biotin-HRP solution and reaction with diaminobenzidine, all the injected neurons were recovered, and no degenerating neurons were seen with survival times up to 4 hours. Intracortical collaterals of these neurons could be traced from their origin to fine distant terminal branches. The main axons of the neurons could be traced through the internal capsule and were darkly labeled at least as far as the cerebral peduncle at the level of the pons. Many neurons had intrastriatal collaterals arising in the internal capsule and dividing into smaller varicose branches. These could be traced to their terminal arborizations in widely separated regions of the neostriatum. Some neurons with intrastriatal collaterals also had small diameter varicose collaterals in the basal forebrain. These collaterals were also stained completely, including their finest terminal arborizations.

Biocytin injection is a substantial improvement over previous intracellular staining techniques, causing less damage to the injected neurons, and more effectively staining distant axonal arborizations.

ELECTROPHYSIOLOGICAL PROPERTIES OF IDENTIFIED CORTICOSPINAL TRACT NEURONS STUDIED IN VITRO. Guo-Fang Tseng, David A. Prince, Dept. of Neurology and Neurological Sciences, Stanford Univ. School of Medicine, Stanford, CA 94305.

Intracellular recordings were obtained from 37 double labelled neurons in rat motor cortical slices. Cells had been retrogradely filled in vivo with Rhodamine beads (spinal cord injections), and intracellularly labelled in vitro with biocytin. Three types of neurons were distinguished based on patterns of spike discharge elicited by intracellular current pulses. 1) Regular spiking cells (RS; N = 19) fired at a relatively constant frequency after a brief period of spike adaptation. Distinct fast (f) and medium (m) AHPs followed each spike but slow (s) AHPs were not readily evoked. Subpial stimulation evoked EPSPs and early and/or late IPSPs in these neurons. 2) Adapting neurons (n = 10) showed significant spike frequency accommodation and generated no clear f AHP. Subthreshold current pulses evoked an early graded active depolarization in these neurons. Orthodromic stimuli elicited EPSPs and large amplitude, early and late IPSPs more readily than in RS cells. 3) A third class of neurons (n = 8) generated prominent depolarizing spike afterpotentials which often evoked spike doublets or triplets during current injection. Preliminary examination showed no gross differences in the general morphology of these three types of pyramidal cells. Thus, even a seemingly uniform population of corticospinal tract neurons possesses subsets that have strikingly different intrinsic properties, as well as differences in the character of their synaptic inputs. We speculate that this physiological diversity may underlie different functional properties in vivo. Supported by NIH grants NS06477 and NS12151 from the NINDS.

INTRINSIC OSCILLATORY PROPERTIES OF LAYER 5 NEOCORTICAL NEURONS. L.R. Silva, Y. Chagnac-Amitai and B.W. Connors. Section of Neurobiology, Box G, Brown University, Providence, RI 02912.

We have observed that a majority of pyramidal neurons in layer 5b have the intrinsic tendency to fire rhythmically at about 5 to 15 Hz. Neurons were recorded intracellularly from slices of rat SmI neocortex maintained *in vitro*. Periods of oscillatory firing lasting as long as 20 sec were elicited by brief stimuli (EPSPs or positive or negative current pulses of a few msec) when the membrane potential was held a few mV negative to spike threshold. Oscillations were comprised of either repetitive bursts (each burst = 2 to 5 spikes firing at 150-300 Hz) or single spikes. Repetitively bursting neurons had minimal rates of 4-9 Hz, while single-spike neurons had minimal rates of 6-15 Hz. When stimulated with long (~1 sec) depolarizing pulses at resting potential, neurons displayed all-or-none responses at threshold; i.e. either they did not spike at all, or they generated long, rhythmic trains. As current was increased, mean oscillatory bursting frequency rose from about 5 to a maximum of 15 Hz; oscillatory single-spiking increased from about 9 to >35 Hz. During strong, sustained stimuli, oscillatory bursting cells often shifted abruptly from bursting to single-spiking, with an accompanying 2-fold increase in frequency. The firing rates of oscillatory neurons did not adapt. Oscillatory firing was unaffected by doses of kynurenic acid that blocked EPSPs; thus, oscillations probably arise from intrinsic membrane properties rather than local synaptic circuitry. Injections of biocytin revealed that oscillatory neurons were large pyramidal cells of layer 5b. Intrinsically oscillating neurons of layer 5b may contribute to the generation of certain neocortical EEG rhythms and seizures.

INTRINSIC 40 HZ OSCILLATORY PROPERTIES OF LAYER IV NEURONS IN GUINEA PIG CEREBRAL CORTEX *IN VITRO* R. Llinas and A.A. Grace,* (SPON: S. Ferris) Dept. of Physiology and Biophysics, N.Y.U. School of Medicine, New York, NY 10016 and Depts. Behav. Neurosci & Psychiat., Univ. Pittsburgh, Pittsburgh, PA 15260.

Oscillations at 40 Hz have been recorded in mammalian EEG during high vigilance states (Bouyer et al., Neurosci. 22:863, 1987). Single unit and field potentials recorded from cat visual cortex show that visual stimuli elicit 40 Hz oscillations in these cells (Gray et al., Nature, 338:34, 1989). The origin of this 40Hz rhythm is presently unknown. *In vitro* intracellular recordings were obtained from brain slices of guinea pig frontal cortex, following standard techniques. Smooth or sparsely spinous multipolar neurons (SMNs) of layer 4 (identified after HRP or Lucifer yellow filling) demonstrated sustained subthreshold oscillatory activity at 38-45 Hz spontaneously or upon direct depolarization. In some cells the oscillatory event was all-or-none and was superimposed on a plateau potential which could outlast the depolarizing current pulse. Depolarization sufficient to bring the cell to the firing level elicited well-defined spike activity at the frequency of the oscillations. Similar results were observed in 20 SMNs. The ionic conductances underlying the oscillations were a voltage-dependent sodium conductance which could be blocked by bath application of TTX (1-2 $_{\mu}$M) and a delayed rectifier. Thus, in sharp contrast to other CNS neurons, cortical SMNs require only sodium and potassium conductance increases to generate their oscillations. These results suggest that the well-defined 40 Hz rhythm in the cerebral cortex is driven by the intrinsic properties of neurons located in the same cerebral cortical layer that receives the specific thalamo-cortical afferents. The results imply that the thalamic input to the cortex serves as a trigger for the inherent rhythmic activation of specific cortical columns.

SPONTANEOUS AND EVOKED CORTICAL ACTIVITY IN THE ISOLATED ADULT GUINEA PIG BRAIN MAINTAINED *IN VITRO* Marco de Curtis* and Rodolfo R. Llinas (SPON: R. Llinás) Dept. Physiology and Biophysics, New York University Medical Center, 550 First Ave, New York, N.Y. 10016.

Cortical activity has been recorded extracellularly from the *in vitro* isolated, arterially perfused brain of guinea pig. The preparation combines the advantages of the *in vitro* slice preparations with the preservation of intact neuronal circuits. Substantial improvements in the methodology has been developed, which have allowed studies on the isolated brainstem cerebellar (Llinas and Muhlathaler 1988, J.Physiol. 404, 215-240) and whole brain preparations (Llinas, Muhlethaler and Walton 1989 J. Physiol. in press).

Field potentials evoked by electrical stimulation of the ipsilateral optic tract were recorded in the primary cortical visual areas both from the surface and at different cortical dephts. Evoked activity from the lateral geniculate nucleus and from the superior colliculus were recorded and correlated with the simultaneously recorded cortical potentials. Most of the recordings were obtained at 23-26^{0} C. The waveform observed in these structures together with the pattern of temporal invasion of the optic tract-driven activity closely resemble the results reported in the mammalian brain in vivo. In preliminary experiments the perfusion fluid temperature was slowly raised to 36^{0} C, at which temperature spontaneous electrocortical activity could be recorded. Spindle sequences with a duration of 2-4 sec and an inner rate of 4-6 Hz were observed by adding barbiturates to the perfusate.

These results confirm the viability of the *in vitro* whole brain preparation maintained under complete isolation and offer a new tool for the study of the mammalian brain rhythmicity.

269.1

INJECTION OF NPY INTO THE RAT HYPOTHALAMIC PVN SUPPRESSES GASTRIC ACID SECRETION THROUGH POSSIBLE AUTONOMIC NERVOUS INTERACTIONS IN THE STOMACH. G.A. Humphreys*, J.S. Davison and W.L. Veale. Dept. of Medical Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

We have shown previously that injection of Neuropeptide Y (NPY) into the hypothalamic paraventricular nucleus (PVN) of anesthetized rats inhibits basal and pentagastrin stimulated gastric acid output. This antisecretory effect of NPY was abolished by truncal vagotomy, coeliac ganglionectomy, atropine, phenoxybenzamine, yohimbine, and by bethanecol stimulation. The effect was present with electrical stimulation of the distal cut ends of the cervical vagus nerves and under α_1 receptor blockade using prazosin. These results indicate that the antisecretory action of NPY in the PVN is dependent on the integrity of the subdiaphragmatic sympathetic and parasympathetic nerves and on the function of α_2 adrenergic and peripheral muscarinic acetylcholine receptors. The effect was absent during exogenous administration of muscarinic cholinergic agonist which indicates that the inhibitory effect of central NPY may be acting through inhibition of peripheral acetylcholine release. Together, these results indicate that the antisecretory effect of NPY in the PVN may be mediated by sympathetic nerves which may suppress gastric acid output by inhibiting vagal release of acetylcholine via activation of α_2 receptors.

VAGAL INHIBITORY EFFECTS ON THE RAT STOMACH: INVOLVEMENT OF DOPAMINERGIC NEURONES. E.K.Tayo*, P.Trye* and R.G.Williams* (SPON: Brain Research Association). Dept. of Phys. & Pharmacol., Univ. Southampton, Southampton SO9 3TU, U.K.

Dopaminergic vagal abdominal efferents have been described and dopamine has been shown to have inhibitory effects on gut motility. However, a physiological role for dopamine in the control of the gut in the rat has not been established.

Male Wistar rats (fasted overnight but allowed free access to water) were anaesthetised with urethane (125mg/100gm body weight I.P.). A balloon catheter was inserted into the stomach for measurement of intragastric pressure, the jugular vein was catheterised for administration of drugs, the carotid artery for recording arterial blood pressure and the peripheral cut end of left cervical vagus was placed over silver stimulating electrodes. Supramaximal stimulation (20 volt. 20Hz) produced an increase in intragastric pressure which was followed by a decrease below the baseline. Both responses were inhibited by hexamethonium (hex., 10-20mg/kg). In the presence of hex. carbachol (0.0125mg/kg) produced a sustained increase in intragastric pressure which was inhibited by vagal stimulation. This effect was partially but not completely antagonised by domperidone (5-10mg/kg). The results support a role for dopamine as an inhibitory transmitter in the rat stomach and support morphological evidence for the existence of dopaminergic vagal abdominal efferents.

RAPHE OBSCURUS STIMULATION INCREASES GASTRIC PRESSURE AND MOTILITY IN THE RAT. P.J. Hornby, D.H. Kuhn* and R.A. Gillis*. Dept. of Pharmacology, Georgetown University, Washington, D.C. 20007.

Recently, we have demonstrated that chemical stimulation of the caudal medullary raphe nuclei in the cat results in increases in gastric motility, acid and pepsin secretion. These effects of raphe stimulation on gastric function are vagally-mediated, and are likely due to activation of neurons in the raphe subnuclei which project to the dorsal motor nucleus of the vagus (DMV) where vagal neurons controlling gut function are located. The present study was designed to evaluate the role of specific medullary raphe subnuclei, the raphe obscurus (Ro) and raphe pallidus (Rp) in control of gastric motility and pressure in rodents, a species where extensive projections from the raphe subnuclei to the dorsal vagal complex are known to exist. This was accomplished by microinjection of 20nl L-glutamate (0.5M) into the Ro and Rp in urethane-chloralose anesthetized rats while monitoring pyloric motility (g.tens.), stomach pressure (ccH_20) and blood pressure (mmHg). Stimulation of Ro (N=9), from the level 0.5-1.5mm rostral to obex, resulted in significant increases in pyloric motility (2.6±0.7 peak g.tens. $P<0.05$) and stomach pressure (0.8±0.3 cmH_20, $P<0.05$). However, stimulation of Rp (N=5) did not result in statistically significant increases in pyloric motility (O.8±0.4 peak g.tens.) or stomach pressure (0.1±0.1 cmH_20). Blood pressure increases (5-25mmHg,N=9) and decreases (10-15 mmHg, N=5) were not specific to one or other subnucleus. These data suggest that activation of neurons in an anatomically defined region of the medullary raphe, i.e. Ro but not Rp, results in excitation of gastric smooth muscle. Supported by NIH grant AM29975.

RAPHE OBSCURUS STIMULATION PRODUCES INCREASES IN GASTRIC SECRETION AND MOTILITY. R.L. White*, C.D. Rossiter*, P.J. Hornby, D.K. Kasbekar*, J.W. Harmon*,W.P. Norman, R.A. Gillis* (SPON: K.L. Dretchen). Depts. Pharm., Surgery, Physiol., Georgetown Univ. Med. Sch., Washington, D.C. 20007

Previous data from our laboratory indicate that the raphe obscurus provides major afferent innervation to the portion of the dorsal motor nucleus of the vagus (DMV) that innervates the stomach. The purpose of the present study was to elucidate the role of the raphe in control of gastric function. The studies were performed in chloralose anesthetized cats while monitoring gastric pH, pyloric motility, and pepsin production. After sealing the pylorus and attaching a pyloric strain gauge a gastrotomy was created through which two catheters were inserted into the stomach. The stomach was continuously irrigated with saline and the pH constantly monitored. Acid output was determined by titration to pH 7.0. Chemical excitation of neurons in the raphe increased gastric motility(MMI +3.1±1.3, $p<0.05$) and acid secretion [baseline was 6±2 microequivalents (μeq)/15 min increasing to 11±4 μeq/15 min (n=8), 34±12 μeq/15 min($p<0.05$), and 39±19 μeq/15 min ($p<0.05$) during the first, second and third 15 minute periods after microinjection, respectively]. Pepsin output increased from a baseline of 287±67 pepsin units (p.u.) to 507±126 p.u. 15 min. post injection (n=4), 541±118 p.u. 30 min. after injection ($p<0.05$), 608±92 p.u. 45 min. after injection ($p<0.05$), and 700±156 p.u. 60 minutes post injection ($p<0.05$). Atropine methylbromide (0.5 mg/kg I.V.) abolished the increases in gastric acid and motility. These data indicate that activation of raphe neurons results in cholinergically mediated increases in gastric function. These are the first findings to our knowledge that implicate raphe nuclei in gastric function.

GASTRIC VAGAL AND GREATER SPLANCHNIC INPUT TO THE TEGMENTAL NUCLEI IN THE CAT. C.S. Yuan* and W.D. Barber. Dept. of Anatomy, Coll. of Med., Univ. of Arizona, Tucson, AZ 85724.

Our previous studies demonstrated gastric vagal and greater splanchnic (GS) evoked unitary responses in nucleus tractus solitarius (NTS). Immunohistochemical studies localized neuropeptides common to both NTS and the dorsal and ventral tegmental nuclei (TN) suggesting a neuronal link between the caudal brainstem and pons. In the present study unitary responses were recorded in the dorsal and ventral TN in anesthetized cats in response to electrical stimulation of proximal gastric vagal and/or left GS fibers. The mean latency of 181 gastric vagally-evoked orthodromic responses, bilaterally distributed in the TN, was 352.2 msec, while the latency of the splanchnic-evoked response was 63.2 msec. Convergence of input from gastric vagal and GS fibers upon single cells was observed in 151 units (83 percent). Stimulation of the GS fibers resulted in a short latency excitation followed by an inhibition of the gastric vagally-evoked response. Projections from NTS and the parabrachial nucleus upon cells in the TN were also identified electrophysiologically by direct microstimulation of the two former structures. The significant number of gastric vagal and splanchnic evoked unitary responses recorded in the dorsal and ventral TN suggested that they may serve an important role in the neuronal link for processing visceral information between NTS and forebrain structures. (Supported by USPHS Grants DK 35434 and DK 36289)

MESENTERIC NERVES MEDIATE PLASMA VASOPRESSIN (AVP) RESPONSE TO SPLANCHNIC OSMORECEPTOR STIMULATION IN CONSCIOUS RATS. S.C. Kwon* and A.J. Baertschi. Dept. of Physiology, Univ. of Virginia, Charlottesville, VA 22908

Hypertonic (598 mOsm/kg) or isotonic (290 mOsm/kg) saline solution was infused over 4 min via stomach tube at a rate of 0.57 ml/min in conscious rats with indwelling arterial catheters. The average baseline of plasma AVP was 4.7 ± 0.4 pg/ml. Plasma AVP in time controls (isotonic gastric infusion) was unchanged. Mean changes of plasma AVP over 30 mins following gastric infusions of hypertonic saline solutions were 5.9 ± 0.8 pg/ml ($p < 0.01$) in intact rats. The response was significantly ($p < 0.001$) attenuated by 59.4 % in rats with lesion of side branches of splanchnic nerves innervating the mesentery of the upper small intestine and the portal vein area, but not affected by subdiaphragmatic vagotomy. Right splanchnic nerve lesion decreased the plasma AVP response by 32.2 % between 11 and 21 min ($p < 0.025$). Left splanchnic nerve lesion also caused a decrease in the plasma AVP response by 35.5 % between 11 and 16 min ($p < 0.05$). Plasma osmolality over 30 mins in each group was not significantly different from baseline, indicating that central osmoreceptors could not have been involved. The results show that 1) splanchnic receptors are located in the mesentery of the upper small intestine and possibly the portal vein area ; and 2) splanchnic osmoreceptors project to the spinal cord via right and left major splanchnic nerves (supported by NSF BNS-8819877).

269.7

THE RELATIVE CONTRIBUTION OF ALPHA- AND BETA-ADRENOCEPTORS TO THE METABOLIC RESPONSE OBSERVED DURING A PROSTAGLANDIN E_1 HYPERTHERMIA IN THE RAT. D.M.Fyda, K.E.Cooper, and W.L. Veale, Department of Medical Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

Although the thermal effects of pyrogens have been extensively examined, few studies have assessed the effector systems responsible. Thus, these experiments investigated the contribution of nonshivering thermogenesis (NST) and its effector system to a prostaglandin E_1 (PGE_1) hyperthermia. Thirty-two male rats had guide cannulae directed to a lateral cerebral ventricle (LCV) and were fitted with indwelling carotid and jugular catheters and radio-transmitters for the remote monitoring of core temperature (Tc). During the LCV injection of PGE_1 (30 ng/µl), Tc rose by 0.9°C, metabolic rate more than doubled and brown adipose tissue temperature (Tbat) increased by 1.1°C. When the rats were pretreated with the β-blocker propranolol (1 mg/kg), PGE_1 evoked only a 0.2°C increase in Tc and both metabolic and Tbat responses were reduced by 80%. Following the α_1-antagonist prazosin (50 µg/kg), PGE_1 elevated Tc by 0.4°C, metabolic increase was reduced by 26%, whereas the rise in Tbat was unaffected. The results suggest that brown adipose tissue-mediated NST is, at least in part, responsible for a PGE_1 hyperthermia and that 80% of the response is due to β- and 20% to α_1-adrenoceptors. Although the relative contribution of shivering, NST and vasoconstriction is unclear, it appears that about 25% of the hyperthermia may result from an α-mediated vasoconstriction.

269.8

DENDRITIC MORPHOLOGY OF FUNCTIONALLY IDENTIFIED NEURONS IN THE DORSAL MOTOR NUCLEUS OF THE VAGUS. E.A. Fox and T.L. Powley, Lab. of Regulatory Psychobiology, Purdue U., W. Lafayette, IN 47907.

The dorsal motor nucleus of the vagus (dmnX) is composed of five primary, topographically separate, longitudinal columns of neurons; each is associated with a different subdiaphragmatic vagal branch (ie. one of the two celiac, two gastric, or unpaired hepatic branches), and each mediates a different but overlapping set of functions. To investigate the relation of morphology to function of dmnX neurons, randomly selected cells (n=250/column) from each functionally identified dmnX column were injected with Lucifer yellow (Neurosci. Abstr. 14(1988) 315) in 100µm coronal, sagittal or horizontal brain slices.

The location, extent and complexity of branching of dendritic fields was different for celiac vs. gastric vs. hepatic cells. Within all columns mid-rostrocaudal neurons differed from rostral and caudal ones in terms of dendritic field extent and complexity of branching, soma profile area, percentage of neurons with extra-dmnX dendrites, and dendritic orientation (dendrites ramified most extensively in the horizontal plane, with those of the most rostral and caudal cells oriented longitudinally and those of middle ones oriented radially). Additionally, classification of neurons demonstrated that all cell types were found in each column, but in different proportions.

The different location and extent of dendritic fields associated with each column provide the basis for differential interaction with inputs and local circuits. Thus, the differential distribution of cell types within and across columns may provide the basis for the different but overlapping subsets of functions mediated by each column (NIH grant DK 27627).

269.9

THE FIBER COMPOSITION OF THE RAT ABDOMINAL VAGUS. J.C. Prechtl and T.L. Powley. Laboratory of Regulatory Psychobiology, Purdue University, W. Lafayette, IN, 47907.

The subdiaphragmatic vagal trunks and all of the primary abdominal branches of six rats were analyzed with complete cross-sectional electron microscopic (EM) montages (X10,000). All fibers were counted, and more than 10% of them were morphometrically evaluated with an image analyzer. Nerve whole mounts were used to analyze the branching patterns and intraneural organization.

The mean diameters (perimeter-derived) of unmyelinated axons in each of the branches were similar (0.75-0.83 µm). But the shapes of the size distributions as summarized by their coefficients of skewness, revealed significant differences between the bilateral gastric branches and the two celiac branches; the hepatic branch size distribution differed from all others. Most of the myelinated fibers (85%) in the vagal branches were less than 2.6 µm in diameter, and had myelin sheath widths between 0.1 and 0.5 µm. The gastric branches, however, consistently contained a few larger myelinated fibers with sheath widths as great as 0.85 µm. Whole mounts also revealed fiber bundles within the vagal branches which were not of supradiaphragmatic origin; these adventitial bundles could be traced along the perineurium between the adjacent vagal branches. The sum of the fibers in the combined branches (26,930) was 21% more than the number of fibers counted in the parent trunks (22,272); this excess probably reflects the adventitial fiber content.

The results demonstrate a cytological diversity between and within the individual vagal branches. The fiber counts, when considered with observations on the number of efferents and adventitial fibers in the nerve, indicate that the abdominal vagi contain considerably fewer nodosal afferents and more autonomic efferents than have been traditionally inferred. (DK27627)

INNERVATION OF URINARY BLADDER IN BB DIABETIC RATS: FUNCTIONAL AND STRUCTURAL ALTERATIONS ARE PREVENTED BY GANGLIOSIDES ADMINISTRATION. M. Paro*, M.G. Fiori, M. Prosdocimi*, and A.A.F. Sima*(1) (SPON: V. Magri). FIDIA Research Laboratories, Abano Terme 35031, Italy and (1) Faculty of Medicine, University of Manitoba, Winnipeg, Canada R3EOW3.

A previous study in the spontaneously diabetic BB-rat has demonstrated functional and structural autonomic polyneuropathy affecting bladder function (Paro et al., Diabetes, in press). BB-Wistar rats (7-11 mo) underwent cystometrographic (CMG) analysis and morphological evaluation of pelvic and hypogastric nerves after gangliosides (GA) administration. BB rats, in comparison with their respective controls, had significantly greater bladder capacity and weight, symptoms of polyuria and polydipsia. In particular the rate of bladder contractions (RC) (index of vesico-vesical excitatory reflex) was significantly decreased in diabetic animals (48% normal). These functional findings were correlated with morphometric changes in the autonomic nerves (hypogastric and pelvic) constituting the neural reflex arc. Treatment with GA (10 mg/kg i.p. die) for 1 month was able to restore RC (91% normal) and the morphometric changes due to diabetic autonomic neuropathy in BB-rats.

269.11

METABOLIC ALTERATIONS IN BRAINS FROM RATS WITH STREPTOZOTOCIN-INDUCED DIABETES MELLITUS. T.L. Krukoff and K.P. Patel*. Dept. of Anatomy & Cell Biology, Univ. of Alberta, Edmonton, Canada, T6G 2H7, and Dept. of Physiol. & Pharmacol., Univ. of S. Dakota, Vermillion, USA, 57069.

Effects of streptozotocin (STZ)-induced diabetes mellitus on metabolic activity of discrete regions of the brain were studied with hexokinase (HK) histochemistry. Two weeks after 1 injection of STZ (65 mg/kg i.p.), blood glucose and osmolarity levels were elevated; blood sodium was depressed. These changes were reversed in diabetic rats treated with insulin (2 U/day, s.c.). In the brain after 2 weeks, significant increases in HK were seen in the magnocellular paraventricular n. (mPVH, 12.1%), medial division of the n. tractus solitarius (mNTS, 15.5%), and commissural division of the NTS (cNTS, 10.9%). (An increase just below significance was seen in the supraoptic n. (SON, 11.5%)). In insulin-treated rats, increases in HK activity were reversed in cNTS (and SON) and only partly reversed in mPVH and mNTS. No changes in HK activity were found in subfornical organ, medial preoptic area, parvocellular PVH, locus coeruleus, or dorsal motor n. of the vagus of diabetic rats. These results demonstrate that the brain is not exempt from changes associated with diabetes. Metabolic alterations in mPVH and NTS of diabetic rats are likely related to changes in vasopressin production and blood volume, respectively.

Supported by the MRC of Canada and the NIH.

269.12

CARDIOVASCULAR RESPONSES TO ADMINISTRATION OF BICUCULLINE INTO THE PARAVENTRICULAR NUCLEUS (PVN) OF CONSCIOUS RATS. D. S. Martin*, T. Segura* and J. R. Haywood. Department of Pharmacology, The University of Texas Health Science Center, San Antonio, Texas 78284-7764.

This study was undertaken to determine whether GABA exerts a tonic sympathoinhibitory action at the PVN of the hypothalamus. Rats were instrumented with guide cannulae directed at the PVN and with femoral venous and arterial catheters. Artificial CSF (aCSF) or bicuculline methiodide (BMI; 2 mM) was infused bilaterally (100 nl) to achieve a steady state response. Blood samples (1 ml) were taken during the baseline period and during the response to BMI for the measurement of plasma catecholamines. The BMI infusion was repeated after treatment with either a β_1 adrenergic antagonist, metoprolol tartrate (2 mg/kg/i.v.), or a ganglion blocking agent, chlorisondamine chloride (12.5 mg/kg/s.c.).

Infusion of BMI into the PVN caused blood pressure (BP) to increase by 20 ± 2 mm Hg from a resting level of 118 mm Hg, while heart rate (HR) rose by 108 ± 10 b.p.m. from a control level of 372 b.p.m.. Plasma norepinephrine (NE) and epinephrine (EPI) increased by 623 ± 100 and 1212 ± 250 pg/ml, respectively. aCSF did not alter BP (-1 ± 1 mm Hg), HR (-1 ± 6 b.p.m.) or plasma NE (11 ± 21 pg/ml) and EPI (-89 ± 53 pg/ml). After β_1 adrenergic blockade, the BP response to BMI was unchanged (27 ± 7 mm Hg), but the tachycardia was reduced significantly (17 ± 8 b.p.m.). Ganglionic blockade abolished both the BP (-1 ± 2 mm Hg) and HR (14 ± 23 b.p.m.) responses. These results suggest that an endogenous GABA system exerts a tonic depressor effect at the level of the PVN. Blockade of this GABA-ergic tone results in activation of the sympathoadrenal axis. (Supported by HL36080 and HL32977. DSM supported by a Fellowship from MRC Canada.)

OPIATE-INDUCED MUSCLE RIGIDITY IS MEDIATED BY MU, AND NOT DELTA OR KAPPA RECEPTORS, IN THE RAT. M. B. Weinger and J. B. Bronson*, Dept. of Anesthesiology, Univ. Calif. San Diego and V.A.M.C., San Diego, CA. 92161.

Opiate-induced muscle rigidity is a significant clinical problem. We examined the role of receptor subtypes in opiate rigidity by comparing the effects of selective mu (D-Ala^2,N-Me-Phe^4-Gly^5-ol-enkephalin [DAGO]), delta (D-Ala^2,D-Leu^5-enkephalin [DADL]), and kappa agonists [U50488h] on alfentanil-induced rigidity in spontaneously ventilating rats. Forty-five anesthetized male Wistar rats received a 10 µl "blinded" intracerebroventricular (ICV) injection of either saline, DAGO (2.5, 5.0, or 10.0µg), or DADL (17.75 or 35.5µg). U50488h (2.5, 5.0, or 10.0 mg/kg) was administered intraperitoneally to an additional 37 animals. Muscle rigidity was assessed using electromyographic (EMG) activity from the left gastrocnemius muscle. After a 15 min baseline, all rats were injected with either alfentanil (ALF, 0.5mg/kg s.c.) or saline, and data were then collected for 60 min. Data from the 3 experiments were analyzed individually and for each group the mean (±SEM) of the area under the EMG voltage-versus-time curve (AUC) was calculated. The addition of ICV DAGO increased the magnitude of ALF rigidity in a dose-dependent fashion ($P<0.05$ by ANOVA). In contrast, pretreatment with U50488h or DADL had no significant effect. Neither DADL (37.5µg) or U50488h (5mg/kg) in the absence of ALF produced significant rigidity (AUC 44% and 53% of ALF controls, respectively; $P<0.05$). This data supports the hypothesis that mu but not delta or kappa receptors play the major role in mediating opiate rigidity. Since mu receptors are critical for analgesia, opiates with high mu affinity will be more likely to produce rigidity. Thus, development of more potent mu agonists may not further the quest for opiate anesthetics with fewer clinical side-effects.

USE OF COMPUTER SIMULATION TO PREDICT THE MAGNITUDE AND DURATION OF ANALGESIA PRODUCED BY EXOGENOUS OPIOIDS. M. J. C. Holland. Baruch College CUNY, New York, NY 10010 and New York Univ. Med. Ctr., New York, NY 10016.

A computer program for the simulation of binding of exogenous opioid agonist (EOA) to specific opioid binding sites in brain has been constructed. Program assumes that plasma EOA concentration (following i.v. administration) can be expressed as the sum of three exponential terms, EOA molecules pass the blood brain barrier in both directions by passive diffusion, and EOA molecules in brain extracellular fluid bind reversibly to specific opioid binding sites on exterior face of cell membranes. For each simulated experiment user supplies: (1) initial plasma EOA concentration, (2) total concentration of opioid binding sites in brain region of interest, (3) pharmacokinetic constants, and (4) EOA-receptor interaction rate constants. Program calculates the concentration of EOA in brain extracellular fluid and amount bound to specific opioid binding sites as functions of time following injection. Levels of analgesia predicted by two models of drug action: Occupation Theory (as modified by Stephenson, R.P. 1956. Br. J. Pharmacol. 11:379.) and Rate Theory (Paton, W.D.M. 1961. Proc. R. Soc. B. 54:21.) are compared. Simulated experiments have been performed for three EOAs (morphine, etorphine and buprenorphine) for which good pharmacokinetic and receptor binding data are available.

HIGH AFFINITY SIGMA RECEPTORS COUPLED TO GTP BINDING-PROTEIN(S). Y. ITZHAK* (SPON: D. Wilson). Dept. of Biochemistry & Mol. Biology, REPSCEND Labs., University of Miami School of Medicine, Miami, FL 33101.

Sigma receptors have been postulated to be involved in the psychotomimetic effects of certain opiate-benzomorphans (pentazocine, cyclazocine and (+)SKF 10047). This receptor is selectively labeled with (+)-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine[(+)-3-PPP]. The effect of the stable GTP analog, GppNHp, on the binding kinetics of (+)[^{3}H]-3-PPP and on the affinities of sigma receptor agonists and postulated antagonists was examined. The association rate of (+)-3-PPP (1nM; 25°C) binding in rat brain membranes is inhibited by~6 fold in the presence of GppNHp (0.1mM). The dissociation kinetics (25°C) of (+)[^{3}H]-3-PPP in control brain preparations display biexponential decay, suggesting the occurrence of multiple steps in the formation of the ligand receptor complex. However, inclusion of GppNHp during the association eliminates the slow-dissociation binding component. Hill coefficients for cyclazocine, pentazocine and (+)SKF 10047 but not haloperidol and chlorpromazine, for competing for (+)-3-PPP binding are less than 1 (0.5-0.6). In the presence of GppNHp the affinity of the agonist, but not the "antagonist", is reduced and Hill values are close to 1. These results suggest that the sigma receptor exists in a high affinity state that is coupled to GTP-sensitive binding protein(s).

PERTUSSIS TOXIN DIFFERENTIALLY AFFECTS MORPHINE ANALGESIA AND SUPERSENSITIVITY. V. Sierra*, S.C.J. Lee*, K. Lutfy* and B.C. Yoburn. Coll. of Pharmacy, St. John's Univ., Queens, NY 11439.

Pertussis toxin (PT) interferes with inhibition of adenylate cyclase (AC) by ADP-ribosylation of the guanine nucleotide regulatory protein (G_i). Opioid agonists will inhibit AC via G_i; and correspondingly, PT will reduce morphine analgesia. This study examines if morphine analgesia and opioid antagonist-induced supersensitivity are mediated by a common PT-sensitive mechanism. Mice were injected intracerebroventricularly and intrathecally (ICV+IT) with saline or 0.5ug PT. Morphine analgesia (4mg/kg,sc) was blocked at 6 days but not at 1 day following PT. These results indicate that morphine analgesia is sensitive to PT treatment in a time-dependent manner. To determine if PT altered opioid antagonist-induced supersensitivity, mice were injected ICV+IT with saline or PT, and 24hr later implanted sc with a placebo or 15mg naltrexone (NTX) pellet. Pellets were removed in 8 days, and 1 day later, mice were injected with morphine (1-15mg/kg,sc). PT inhibited the analgesic effects of morphine, while NTX treatment increased the analgesic potency of morphine in both control and PT-treated groups. These results suggest that morphine antinociception is mediated through the G_i protein but that some other mechanism is involved in opioid antagonist-induced supersensitivity. (supported by NIDA DA 04185).

270.5

THE EFFECT OF CHRONIC MORPHINE ON SPINAL OPIOID ANALGESIA AND CONVULSIONS. B.C. Yoburn, K. Lutfy*, V. Sierra*, J. Candido*, and F. Tortella!. (SPON: J. WURPEL). Coll. of Pharmacy, St. John's Univ., Queens, NY 11439; !Walter Reed Army Inst. of Research, Wash., DC 20307-5100.

Opioid receptors in the spinal cord have been shown to mediate the analgesic effects of opioid agonists. In the course of examining tolerance to spinal opioids, we found that supra-analgesic doses of spinal morphine produced prominent hindlimb convulsions in the mouse. These studies examined the opioid nature of these effects. Administration of morphine into the spinal intrathecal (IT) space produced dose-dependent analgesia (tailflick) in the mouse (ED_{50}=0.6µg/mouse). At higher doses IT morphine induced seizures of the hindlimbs (ED_{50}=8.7 µg/mouse). Mice treated chronically with morphine (75mg pellet, sc) for 72hr and tested with the pellet in place were tolerant to the analgesic effects of IT morphine (ED_{50}=4.8µg/mouse), but not to the proconvulsant action (ED_{50}=6.3µg/mouse). Chronic morphine treatment produced physical dependence as determined by naloxone-precipitated withdrawal jumping. Spinal morphine analgesia was dose-dependently attenuated by naloxone (5 & 10mg/kg, sc), whereas IT morphine-induced seizures were not. These results indicate that spinal opioid receptors mediate analgesia, but not seizures following IT morphine treatment in the mouse. (supported by NIDA DA 04185)

F-8-F-Amide AND A-18-F-AMIDE, MAMMALIAN FaRPs, ACT LIKE OPIOID AGONISTS, NOT ANTAGONISTS IN MOUSE COLON. R.B. Raffa and H.I. Jacoby.* Dept. of Biol. Res., Janssen Res. Fndtn., Spring House, PA 19477.

Morphine and the two endogenous mammalian FMRFamide (Phe-Met-Arg-Phe-NH_2)-related peptides known as morphine-modulating neuropeptides, F-8-Famide (Phe-Leu-Phe-Gln-Pro-Gln-Arg-Phe-NH_2) and A-18-Famide (Ala-Gly-Glu-Gly-Leu-Ser-Ser-Pro-Phe-Trp-Ser-Leu-Ala-Ala-Pro-Gln-Arg-Phe-NH_2), were administered intracerebroventricularly (i.c.v.) to mice and the effect of each on colonic bead expulsion time was measured. Each of the three compounds delayed expulsion of a 3 mm glass bead placed in the distal colon. A-18-Famide was more potent than F-8-Famide [ED_{50} = 2.3 µg (1.2 nmole) and 13.9 µg (13.0 nmole), respectively]. A-18-Famide: (i) did not block morphine-induced delay of bead expulsion time, and (ii) was blocked by simultaneous administration (i.c.v.) of 1.0 µg of the competitive opiate antagonist naloxone. These data demonstrate apparent opioid modulatory or agonist-like, rather than antagonist-like, properties of A-18-Famide and F-8-Famide.

270.7

ROLE OF METABOLISM AND RECEPTOR-SUBTYPE INVOLVEMENT IN β-ENDORPHIN (β-END) ANESTHESIA. J.L. Lewis & F.S. LaBella, Lovelace Inhal. Tox. Res. Inst., Albq.,NM and Dept. of Pharmacol., U of Manitoba, Wpg., Man. Canada.

We have reported that ICV infusions of β-END in rats result in naloxone reversible general anesthesia which is mediated within or periventricularly to the inferior third (I3V) or fourth (4V) ventricles. Mean latency to onset of anesthesia from both areas is nearly one hour. We now assess the role of metabolism of β-END in the delayed onset and the type(s) of opioid receptor(s) that mediate the response. Presumed inhibition of β-END degradation by PMSF did not modify latency to onset nor duration of anesthesia. ICV administration of β-END fragments 1-27, 1-17, and 30-31 did not produce anesthesia. Neither the δ ligand DPDPE nor the μ ligand DAGO alone produced anesthesia, but the less specific ligand metkephamid produced anesthesia in 50% of the animals tested with a latency to onset of only 25 min. DAGO + DPDPE, each at one-half the dose used individually, effected anesthesia in all animals tested at either ventricular region. Compared to β-END, latency to onset with the combined peptides was significantly shortened (by nearly 50%), but duration was not affected. These results indicate that (a) metabolic fragments of β-END do not mediate the anesthetic response, (b) the entire β-END molecule is required for anesthesia, (c) both μ and δ receptors must be activated in concert, and (d) the latency to onset reflects recruitment of a yet unidentified physiological system. ABNORMAL ACTIVITY OF BRAINSTEM NOCICEPTIVE MODULATORY NEURONS IN OPIATE TOLERANCE.
J.B. Bederson*, H.L. Fields and N.M. Barbaro. Depts. of Neurosurgery, Neurology, and Physiology, University of California, San Francisco, CA, 94143

There is evidence that spinal nociceptive reflexes are modulated by reciprocally active inhibitory ("off-cell") and facilitatory ("on-cell") medullary neurons. Opiate analgesia is associated with off-cell activation and on-cell suppression. Tolerance to opiate analgesia could be due in part to increased on-cell activity (and thus increased nociception for a given concentration of opioid).

In rats lightly anesthetized with methohexital, recordings of on-on, off-off, or on-off cell pairs were made. Activity relationships in opiate-naive rats were compared to those in rats with morphine pellets implanted five days earlier.

In opiate-naive rats, the activity of on-on, or off-off pairs was positively correlated (mean Kendall rank correlations, r, =.68 and .60, respectively, $p < .05$, Wilcoxon signed rank test). On-off cell pairs demonstrated strict reciprocity and an inverse activity relationship ($r = -.53$, $p < .05$). In opiate-tolerant rats, although the positive correlation between like pairs was retained, on- and off-cells consistently showed simultaneous activity, i.e. loss of the usual reciprocal discharge pattern, with absence of the normal inverse activity correlation ($r = -.07$, p=ns). On-cells were active despite the continued presence of a morphine pellet.

Thus, opiate tolerance may be explained in part by an increased tendency of the on-cell to fire while opiate-induced off-cell activity continues. It is the increased on-cell firing that leads to decreased antinociception at a maintained concentration of opiate.

270.9

ANXIOGENIC EFFECTS OF TWO SELECTIVE SIGMA LIGANDS IN THE RAT. N.L. Lai*[1], W.D. Bowen[2], R.R.Matsumoto, A. Thurkauf[3], K.C. Rice[3], and J.M. Walker[1], (SPON: R.M. Church) [1]Department of Psychology and [2]Division of Biology and Medicine, Brown University, Providence RI, 02912 and Laboratory of Neuroscience, Section on Drug Design and Synthesis, NIDDK, Bethesda, MD 20892.

1,3 di-o-tolylguanidine (DTG) and (+)-pentazocine appear to be selective ligands for the sigma receptor. Previous work suggested that sigma ligands affect movement and posture, but the effects of sigma ligands on more complex behavior remain obscure. A role in emotional behavior is suggested by the presence of sigma receptors in limbic areas and reports of anxiety in humans following injections of (+)-pentazocine. To test whether sigma ligands have effects on fear in rats we used a modified version of the Vogel test, a conflict test that predicts anxiolytic potency in humans. Thirsty rats licked a tube for water and were administered a mild electric shock after every 21st lick. As in previous work, chlordiazepoxide reduced the lick suppression produced by this regimen, while a beta-carboline caused a greater suppression. The sigma ligands, DTG and (+)-pentazocine had effects similar to the anxiogenic drug in that they too significantly suppressed licking under both shocked and unshocked conditions. These findings suggest that sigma ligands have fear-inducing effects.

270.10

(+)-OPIATE INHIBITION OF OXOTREMORINE ANALGESIA. J. Michael Walker[1], Saundra L. Patrick[1], Andrew Thurkauf[3], Kenner C. Rice[3] and Wayne D. Bowen[2]. [1]Department of Psychology and [2]Division of Biology and Medicine, Brown University, Providence RI, 02912 and Laboratory of Neuroscience, Section on Drug Design and Synthesis, NIDDK, Bethesda, MD 20892, USA.

Previous work showed that (+)- but not (-)-pentazocine reverses acetylcholine-induced analgesia in mice. Considering the inhibition of carbachol-stimulated phosphoinositol turnover by sigma ligands, it seemed plausible that this effect was mediated by sigma receptors. However, our data suggest that this effect of (+)-pentazocine is not mediated by sigma receptors. (+)-Pentazocine antagonized the analgesic effects of oxotremorine with 50% reversal occurring around 10mg/kg sc. However, this effect was not produced by other sigma ligands including 1,3 di-o-tolylguanidine (DTG), (+)-SKF 10,047, or dextrallorphan. Furthermore, a steep parallel dose curve of nearly equal potency was produced by (+)-nordihydrocodeinone, a compound with negligible (K_i>10,000 nM) affinity for sigma receptors. Yet, (-)-nordihydrocodeinone failed to produce the effect. Several other sigma-inactive (-)-opiates also lacked activity. These findings suggest that some (+)-opiates can produce effects outside the Sigma or PCP system.

EFFECTS OF SELECTIVE OPIOID AGONISTS ON HIPPOCAMPAL CA3 RESPONSES EVOKED IN OPIOIDERGIC AND NON-OPIOIDERGIC AFFERENTS J. L. Martinez Jr. & B. E. Derrick, Dept. of Psychology, University of California, Berkeley, 94720

Induction of LTP of mossy fiber-CA3 responses is blocked by naloxone and may involve opioid mechanisms at presynaptic sites (Soc. Neurosci. Abstr., 13:767, 1988; Neuron, 1:96, 1988). We therefore compared the effects of selective opioid agonists on CA3 responses evoked in two projections to the CA3 region in vivo: the putatively opioidergic mossy fibers (MF), and the non-opioidergic commissural projection (COMM).

DAGO, a mu-selective agonist (1-100 nmols), produced large transient increases in both MF- and COMM-evoked CA3 responses. Dynorphin A (1-13) amide (10 nmols), a kappa-selective agonist, produced a transient depression of only the MF-evoked CA3 response. The delta-selective agonist D-Pen^2-[D-Pen^5]-enkephalin (DPDPE, 1-10 nmols) produced increases in both the MF- and COMM- evoked field EPSP. The increases in MF-evoked field EPSP were significantly greater than COMM-evoked field EPSPs. The effects observed with DAGO are consistent with an attenuation of GABAergic inhibition. The different effects produced by kappa- and delta-selective agonists on MF and COMM responses suggests that these peptides are not acting exclusively through disinhibition, but through other mechanisms, perhaps at presynaptic sites.

NALOXONE INCREASES DELTA ACTIVITY IN THE EEG OF OPIOID NAIVE RATS DURING PERIODS OF HEIGHTENED AROUSAL. K.Grasing* and H.Szeto* (SPON: D.Hinman), Department of Pharmacology, Cornell University Medical College, New York, NY 10021.

Exogenous opioids such as morphine cause a dose dependent increase in high voltage, slow wave EEG activity with stuporous behavior which is followed by a period of increased motor activity with an alert EEG pattern. In previous studies, naloxone has shown no effect on the EEG of opioid-naive animals. Rats were prepared with chronic jugular catheters and electrocortical electrodes, and EEG was analyzed on line by fast fourier transformation. A single 1 mg/kg intravenous infusion of naloxone given at night, when rats are normally active, is followed by an increase in delta power over the 1 to 3 Hz range, a decline in beta 2 power over the 15 to 30 Hz range, and diminished motor activity. These effects did not occur when naloxone was administered during daytime, inactive periods. Dose response analysis revealed that a maximal response was achieved with .3 mg/kg of naloxone.

Endogenous opioid activity is elevated during periods of heightened arousal, and this may explain why naloxone EEG effects are only apparent at night when rats are more active. Activity of endogenous opioids may be associated with different effects on arousal than pharmacologic doses of exogenous opioids.

271.1

STRUCTURE DETERMINATION AND CELLULAR LOCALIZATION OF A NOVEL MYOMODULIN RELATED OCTOPEPTIDE IN *APLYSIA*. E.S.Vilim, E.C.Cropper, A. Alevizos, R.Tenenbaum, I.Kupfermann and K.R.Weiss. Cntr. Neurobiol.& Behav., P & S. Columbia Univ., and NYS Psych. Inst., NYC, NY 10032.

The ARC muscle has provided a model for the study of the behavioral role of neuromodulation and cotransmission. Our previous studies have demonstrated that contractions of this muscle are potentiated by several neuropeptides that are present in the cholinergic motoneurons B15 and B16 . When applied exogenously these peptides interact to modify the properties of muscle contractions. To gain insight into the physiological role of modulation we have undertaken to define the complement of modulatory peptides in the ARC., and have been purifying and sequencing the peptides (e.g. myomodulin and buccalin) that are present in the ARC. motoneurons. We have now purified a new bioactive peptide, and localized it to B16. The structure of the peptide is; Gly-Ser-Tyr-Arg-Met-Met-Arg-Leu-amide. This peptide (MMb) shares a significant homology with another peptide, myomodulin (MM) which is also present in B16. Radiolabeling experiments suggest that B16 synthesizes approximately ten times more MM than the related MMb. Similar synthesis patterns were obtained in cell L10, which also synthesizes both peptides. The homology of peptide structures and the similarity of the rate of their synthesis in L10 and B16, suggests that these peptides may be encoded by the same gene and that MM may be represented by a higher number of copies than MMb. While both peptides potentiate contractions at low concentrations (threshold below $5x10^{-9}$M), their actions diverge at higher concentrations. MM powerfully depresses contractions at concentrations higher than 10^{-7}M, while MMb acts as a depressant only at concentrations higher than 10^{-5}M. The possible physiological significance off these differences is being investigated.

271.2

THE BUCCALIN NEUROPEPTIDE FAMILY IN *APLYSIA*: PURIFICATION OF BUCCALIN C AND SEQUENCE OF ADDITIONAL PEPTIDES PREDICTED BY A cDNA CLONE.
M.W. Miller*, E.C. Cropper, K. Eisinger*, F. Vilim, R. Tenenbaum*, S. Beushausen*, J. Brosius, I. Kupfermann, and K.R. Weiss . (SPON: D. I. Schuster) Center for Neurobiol. and Behav., Columbia Univ., Coll. P & S, and NYS Psychiat. Inst., New York, NY 10032; and Fishberg Ctr. for Neurobiol., Mount Sinai Med. Ctr., New York, NY 10029.

The neuropeptide buccalin, originally purified and sequenced from the accessory radula closer (ARC) muscle of *Aplysia*, has been shown to be present in the two cholinergic motor neurons (B15 & B16) innervating this muscle, where it has been proposed to act as a modulatory cotransmitter (Cropper et al.,1988). The identification of a related peptide, buccalin B (parabuccalin of Weiss et al., 1988), with similar actions, i.e. depression of ARC contractions (and EJPs) produced by motor neuron stimulation, suggested that these peptides may be members of a larger peptide family. Utilizing the methods originally developed for the purification of buccalin A and buccalin B, i.e. HPLC fractionation of an ARC extract and bioassay of fractions for modulatory actions on ARC contractions produced by motor neuron stimulation, we have purified and sequenced a third related peptide, buccalin C, with the following sequence: Gly-Phe-Asp-His-Tyr-Gly-Phe-Thr-Gly-Gly-Ile-amide. A 20-base oligonucleotide derived from this sequence was used to isolate a clone from an *Aplysia* buccal ganglion cDNA library (provided by R. Scheller). The partial cDNA sequence that has been obtained predicts an amino acid sequence which could comprise part of a propeptide containing at least nine distinct, but related neuropeptides. Successive peptides are separated by two or three basic amino acids, possible proteolytic cleavage sites. A glycine residue, which could serve as a donor for amidation, is present on the carboxy terminus of each peptide. Sequences encoding the identified peptides buccalin B and buccalin C are present on this clone.

271.3

RELEASE OF PEPTIDE COTRANSMITTERS UNDER PHYSIOLOGICAL CONDITIONS. E.C. Cropper,[1] D. Price,[2] R. Tenenbaum,[1] I. Kupfermann,[1] and K.R. Weiss.[1] Ctr. Neurobiol. & Behav., Columbia Univ. P&S, & NYS Psych. Inst. NY,NY 10032[1]; C V Whitney Lab., St. Augustine, FL 32086[2].

The cholinergic motor neuron B15, which innervates the ARC muscle of *Aplysia*, contains the neuropeptides, SCP_A and SCP_B. When exogenously applied these peptides increase muscle cAMP levels, and modulate parameters of muscle contraction; they increase contraction size and relaxation rate.

To determine whether B15 releases the SCPs under physiological conditions, electrodes were implanted in ARC muscles of intact animals, and *in vivo* firing patterns of neuron B15 were determined by recording synaptic currents from ARCs of feeding animals. During ingestion of strips of food B15 fired in bursts for about 3.5 sec (duty cycle 50%) at about 7.5-10 Hz. This firing pattern was simulated on one side of buccal ganglion-buccal mass preparations and comparisons were made for control and stimulated levels of SCP_A and SCP_B. Stimulation produced a decrease in SCP levels, indicating that peptide release occurred. In a second group of animals the relaxation rates of contractions produced by physiological patterns of stimulation of B15 were compared to those of contractions produced by a nonphysiological pattern of stimulation with long interburst intervals. Relaxation rates under physiological conditions progressively increased; those under nonphysiological conditions remained unchanged.

These results indicate that the SCPs are released when neuron B15 fires at physiological frequencies, and suggest that the SCPs are released in sufficient quantities to act physiologically as cotransmitters.

271.4

SORTING OF THE BAG CELL PEPTIDES AND EGG-LAYING HORMONE: LOCALIZATION OF THE SORTING EVENT. W.S. Sossin and R.H. Scheller. Department of Biological Sciences, Stanford University, Stanford, CA 94035-5020.

We have recently demonstrated, using immunohistochemical techniques, that two regions of the egg-laying hormone (ELH) prohormone are localized to different classes of dense core vesicles (DCVs) (Fisher et al., Cell, 54: 813-822, 1988). By taking advantage of the asymmetric distribution of amino acids in the two regions of the prohormone, and the technique of electron microscopic autoradiography, we have independently demonstrated that the different regions of the prohormone are sorted into distinct DCVs. Furthermore, we have identified the time course and locale of the sorting event. Sorting occurs soon after the cleavage of the prohormone in immature vesicles. The sorting compartment is part of the Trans-Golgi network as defined by staining with acid-phosphatase. A model for the mechanism of sorting based on these findings will be presented.

271.5

DIFFERENTIAL PEPTIDE SECRETION FROM THE BAG CELLS OF *APLYSIA*. G. Whitney* and S. Arch. Biological Laboratories, Reed College, Portland, OR 97202

We have employed a combination of electrophoretic and HPLC procedures to investigate the secretory output of the bag cells. Our principal interest has been to use K^+-evoked depolarization to evaluate previous indications that bag-cell derived peptides are not secreted in fixed stoichiometries. When bag cell organs (BCO) are isolated from the abdominal ganglion, incubated in ^{3}H-leu for 18hr, and exposed to high-K^+ medium, 8 peaks of radiolabeled material are reliably resolved by HPLC. To evaluate secretion stoichiometry, we have concentrated on the 3 most abundantly labeled of these (p4, p10, and p12). Under conditions of 2 sets of 3 successive 15min superfusions with high-K^+ medium separated by 60min of normal saline incubation, the radiolabel content ratio between p4 and p10 remains effectively constant. However, the ratio between p12 and either p4 or p10 changes systematically in a manner indicating increasing relative amounts of p12 secretion with increasing depolarization exposure. The IEF- and SDS-PAGE profiles obtained from p10 and p12 are consistent with their identification as the peptides AP and ELH respectively. Moreover, neither of these species is detected in secretion medium collected from cells labeled with ^{3}H-phe. Analyses of p4 indicate that it is labeled with ^{3}H-phe, has an acidic pI and a molecular weight of *ca.* 20kD. Although speculative at present, the labeling and physical characteristics of p4 are consistent with those expected of the N-terminal intermediate derived from the initial cleavage of the proELH molecule at positions 181-184. Extraction of neurites and terminals separated from cell bodies demonstrates the presence and secretory depletion of p4 along with AP and ELH. The secretory pattern indicates that p4 and AP are cosecreted while ELH secretion is kinetically distinct.

NEUTRAL METALLOENDOPEPTIDASE (NEP)-LIKE ENZYME CLEAVES ALPHA-BCP IN CNS OF *APLYSIA*. G.A. Phares*¶, B.S. Rothman¶, A. Arvand*¶, M. Talebian*¶, D.B. Borson*#, J.A. Nadel*#, J. Calaycay*§, J.E. Shively*§, M.P. Nusbaum¶, S.T. Lockhart*¶, L.D. England¶*, and K.A. Briggs-Crawford¶*. ¶ Dept. of Biology, San Francisco State University, San Francisco, CA 94132; # Cardiovascular Res. Inst., U.C.S.F., San Francisco, CA 94143; § Beckman Research Institute, City of Hope Med. Ctr., Duarte, CA 91010.

We are studying inactivation of the peptide neurotransmitter alpha-bag cell peptide (α-BCP[1-9], single letter code: **APRLRFYSL**) in the CNS of *Aplysia*. We mimic release of α-BCP without the concomitant release of the other bag cell peptides by arterially perfusing synthetic α-BCP into an isolated abdominal, pedal-pleural or cerebral ganglion. The perfusate is analyzed by reverse phase-HPLC. When perfused at 1-50 μM, 5% to 15% of α-BCP[1-9] is recovered as α-BCP[6-9], and somewhat lower amounts recovered as α-BCP[1-5], and [7-9]. These products were identified by amino acid composition, sequence, and FAB-mass spectroscopic analyses. (α-BCP[6-9] was incorrectly identified as α-BCP[1-8] in a previous abstract (Rothman et al., *Neurosci. Abstr.* 13: 39, 1987)). Thiorphan, phosphoramidon or carboxymethyl-Phe-Leu (10 μM each) each significantly inhibit generation of these products, whereas captopril (10 μM) is ineffective. The same set of products, plus α-BCP[1-6], is generated by incubating α-BCP with recombinant human NEP. Our results suggest that α-BCP[1-9] is cleaved in the CNS of *Aplysia* by an enzyme resembling NEP (E.C. 3.4.24.11). NEP exists in mammalian brain, where it cleaves enkephalin and possibly other neuropeptides at bonds N-terminal to hydrophobic residues. In *Aplysia* the NEP-like enzyme is likely to inactivate α-BCP and other peptides after their release by the bag cells. *Supported by NIH grants RO1-NS-24046 (BSR) & K04-NS-01177 (BSR).*

AMINOPEPTIDASES IN BLOOD AUGMENT DEGRADATION OF ALPHA-BAG CELL PEPTIDE IN *APLYSIA*. C. R. Squire*¶, B. S. Rothman¶, J. Calaycay*§, J. E. Shively*§, and E. H. MacNeale*¶. (SPON: J.S. Williston¶). ¶ Dept. of Biology, San Francisco State University, San Francisco, CA 94132; § Beckman Research Institute, City of Hope Med. Ctr., Duarte, CA 91010.

We are investigating the role that enzymes in blood play in the inactivation of the neurotransmitter alpha-bag cell peptide (α-BCP[1-9], single letter code: APRLRFYSL) by incubating synthetic α-BCP (1 and 10 μM) in plasma. Enzyme activity is halted by TCA-precipitation and samples are analyzed by reverse phase HPLC. α-BCP[1-9] is slowly degraded in blood ($T_{1/2}$=36 min), whereas α-BCP[3-9], a neuroactive product of a membrane-bound ganglionic peptidase (Rothman et al., *Neurosci. Abstr.* 13: 39, 1987), is degraded rapidly ($T_{1/2}$=3 min). Bestatin (65 μM) considerably extends the life of α-BCP[3-9] ($T_{1/2}$=32 min). α-BCP[3-9] yields four cleavage products in blood: α-BCP[4-9], [5-9], [6-9], and [7-9]. These were identified by amino acid composition, sequence, and FAB-mass spectroscopic analyses. When each cleavage product alone is incubated in blood, [4-9] yields [5-9], [6-9] and [7-9]; [5-9] yields [6-9] and [7-9]; [6-9] yields [7-9]. Each of these cleavages is blocked by bestatin. These findings are consistent with the hypotheses that: 1) α-BCP[3-9] is sequentially cleaved in blood by one or more aminopeptidases, and 2) α-BCP[1-9] resists aminopeptidase cleavage due to the Pro residue at position #2. Because blood perfuses *Aplysia* ganglia *in vivo*, and there is no functional blood-brain barrier, the aminopeptidases in blood most likely act in concert with membrane-bound ganglionic peptidases to degrade α-BCP[1-9] into inactive fragments, thereby limiting the range of its actions. This experimental system may be a useful model of the actions of peptidases in the cerebrospinal fluid of vertebrates.

271.8

RELEASE OF PEPTIDE COTRANSMITTERS (SCPs) FROM A CHOLINERGIC MOTOR NEURON IN *APLYSIA*. P.E. Lloyd and M. D. Whim* Dept. Pharm. Physiol. Sci. & Comm. on Neurobiol. Univ. Chicago, Chicago, IL 60637.

Cholinergic motor neuron B15 innervates buccal muscle I5 (also termed ARC) and contains and synthesizes the SCPs (A & B)(Cropper et al.,PNAS 84:3486, '87). SCPs synthesized in the buccal ganglia are transported to terminals in I5 (Lloyd, J.Neurosci.8: 3507,'88). However buccal nerves contain only ~1% of the SCPs found in muscle so, over periods <4 h , release cannot be replaced by axonal transport and should produce depletion of SCPs from muscle. SCP levels were found to be identical for bilateral muscles from the same animal when measured with the sensitive accurate snail heart bioassay. Thus, release can be measured by comparing SCP levels of I5 muscles after B15 stimulation with those of contralateral control muscles. Stimulation of B16, a cholinergic I5 motor neuron which does not contain the SCPs, at 50 Hz for 1s every 9s, or sustained hyperpolarization of B15, for 1 h produced no depletion (stim/control ratio =1.04±0.04 & 1.05±0.03 SEM, N=4 for each) . The first experiments used stimulation of B15 at an overall rate of 5 Hz for 1 h with varied spike grouping. Tonic stimulation at 5 Hz, or 25 Hz for 2s every 8s produced no sigificant depletion (1.04±0.04 & 0.99±0.07, N=4 for each) while 50 Hz for 1s every 9s produced a depletion of 27±3% (N=4). This corresponds to release of ~10 fmol SCPs/min in 10 mg muscles. Increasing the burst duration (25 Hz for 4s every 6s for 1 h) also depleted SCP levels by 26±6% (N=4). Thus significant release of SCPs from B15 occurs only during highly facilitated release conditions such as high frequency firing or lower frequency firing for longer durations. Some physiological consequences of this release are addressed in the accompanying abstract (Whim & Lloyd,'89). Supported by NS 23569.

271.9

RELEASE OF PEPTIDE COTRANSMITTERS (SCPs) FROM AN IDENTIFIED MOTOR NEURON ELEVATES cAMP IN ITS TARGET MUSCLE IN *APLYSIA*. M.D. Whim* and P.E. Lloyd. (SPON: J. Goldberg). Dept. Pharm. Physiol. Sci. & Comm. on Neurobiol. Univ. Chicago, Chicago, IL 60637.

Cholinergic motor neuron B15 synthesizes the SCPs and innervates muscle I5. SCPs potently elevate cAMP in the I5 muscle (Lloyd et al., PNAS 81: 2934, '84). We tested the ability of B15 stimulation to increase cAMP in an I5 muscle compared to the unstimulated contralateral muscle. After 10 min stimulations, muscles were frozen and cAMP levels determined. Stimulation of B15 at 50 Hz for 2s at 3s intervals produced very large increases of cAMP (stim/control ratio = 330.8±63.0; SEM, N=4). Using the same paradigm, stimulation of a second cholinergic motor neuron (B16) which innervates I5 but does not contain the SCPs resulted in very little elevation (1.44 ±0.66; N=4). Several B15 stimulation paradigms at an overall rate of 5 Hz were tested. Tonic 5 Hz or 25 Hz for 2s every 8s produced very little elevation (respectively, 1.39±0.47; 1.44±0.46; N=4), however 50 Hz for 1s every 9s resulted in a 5.34 ±2.11 (N=4) increase in cAMP. Qualitatively, these results parallel very closely the direct measurements of SCP release using an unrelated procedure (see accompanying abstract). Frequency, length of stimulation and interburst intervals were systematically varied. B15-induced elevation of cAMP levels was very sensitive to these parameters. For example, stimulation of B15 for 4s at 3s intervals now produced an increase in cAMP at a much reduced frequency (15Hz; 16.48±5.0; N=4). We conclude that the elevation of muscle cAMP levels are produced by the release of the SCPs from B15 terminals in the muscle. Supported by NS 23569.

MOLECULAR STUDIES ON LUQ-SPECIFIC NEUROPEPTIDE GENES AND ON NEUROPEPTIDE DEGRADATION IN APLYSIA CALIFORNICA.
L. DesGroseillers*, L. Wickham* and X. Yang* (SPON; A. Ferron) Department of Biochemistry, University of Montreal, Montreal, Canada H3C 3J7

My laboratory is interested in the characterization of molecules involved in neural cell communication. We used molecular genetic approaches to isolate these molecules and study their regulation and functions. LUQ cells seem to play important roles in the control of the kidney. In order to study neurotransmitters involved in kidney functions, we used differential screening to isolate LUQ-specific neuropeptide genes. The LUQ-1 cDNA clone is 3.7kb long. Dot blot and in situ hybridization experiments have revealed that the gene is expressed in only 1 of the 5 LUQ cells. Southern blot experiments also show that the gene is present in 1 copy per haploid genome.

To understand the homeostasis of the peptidergic nervous system, we also want to study the mode of peptide degradation. To do this we have cloned a neutral endopeptidase-like enzyme (NEP-like) whose function is believed to terminate the action of some neuropeptides. This clone shows 82% homology with the mammalian NEP sequences around the active site. Characterization of this enzyme in the simple Aplysia nervous system will help to understand the fine tuning of neural cell communication.

271.11

INSULIN RELATED SUBSTANCES IN THE CENTRAL NERVOUS SYSTEM OF PULMONATES AND *APLYSIA CALIFORNICA*. J. van Minnen and A.B. Smit. (SPON: European Neuroscience Association) Dept. of Biology, Vrije Universiteit, Amsterdam, The Netherlands

In the snail *Lymnaea stagnalis* the presence of an insulin-related substance was demonstrated by means of molecular biological techniques. Using *in situ* hybridization it was shown that transcription of this molluscan insulin-related peptide (MIP) occurs in 2 clusters of giant neuroendocrine cells that are located in each cerebral ganglion. There exists endocrinological evidence that these neurons are involved in the regulation of processes related to body growth, such as growth of the soft body parts and shell, glycogen metabolism and ornithine decarboxylase activity. Screening of the cDNA of the CNS and *L. stagnalis* genomic library revealed the presence of at least five closely related MIP genes, all encoding prohormones that share the characteristics of vertebrate proinsulin, *i.e.* they are composed of an B- and A-chain and a connecting C-peptide and have amino acids that are essential for the tertiary structure of proinsulin (*viz.* cysteins) at identical positions as vertebrate insulins. Remarkably, the C-peptide of the various MIPs showed a high degree of homology at the amino acid level, which may suggest an important function for this peptide (in vertebrates no function is known for the C-peptide). By means of immunocytochemistry, using antibodies that were raised against the C-peptide of MIP, the CNS of other pulmonates and the opisthobranch *A. californica* were investigated. In basommatophoran snails immunoreactive neurons were found at identical locations as in *L. stagnalis*; in the stylommatophorans *Helix aspersa* and *Limax maximus* in each cerebral ganglion one cluster of immunoreactive neurons was found. Previous experiments have shown that those neurons in *H. aspersa* produce a growth hormone. In *A. californica* all central ganglia contained immunoreactive neurons. The highest number was observed in the abdominal ganglion (approximately 50 with diameters varying from 30-150 μm). In each pedal ganglion a cluster of about 40 neurons (diam. 20-40 μm) was found.

271.12

DOPAMINE-DEPENDENT MODULATION OF IONIC CONDUCTANCES AND PROTEIN PHOSPHORYLATIONS IN HELIX ASPERSA NEURONS.
S. Tiwari¶ Y-K. Kim*and M.L. Woodruff. Depart. of Chem. and Biochem., Southern Ill. Univ., Carbondale, Ill 62901.

Dopamine (DA) causes an inhibition of neurons in the circumesophageal ganglion of the land snail Helix aspersa. The neurons hyperpolarize and their spontaneous action potentials cease with DA. In addition, the shape of evoked action potentials is modified--action potential height and duration are decreased. Voltage-clamp experiments reveal that Ca^{2+} conductance, Ca^{2+}-dependent K^+ conductance and a transient K^+ conductance are decreased by DA. The Ca^{2+} current may be mediated by two different channel types, a transient and a sustained Ca^{2+} channel current. Both are inhibited by DA.

Forskolin, a potent activator of adenylate cyclase, effects the physiology, but does not mimic the DA effect. Oleoyl acetyl glycerol (OAG), an activator of protein kinase C, partially blocks the DA-dependent decrease in Ca^{2+} current. The possible role of protein phosphorylation in mediating the effects of DA is being examined by in vivo ^{32}P labeling experiments. Intact ganglia and F-lobe cells in primary cell culture both show DA-dependent phosphorylations and dephosphorylations; however the pattern of labeling is different in the two cases. Cells in primary cell culture eliminate glial cells and this could be partially responsible for the different patterns. We are presently trying to relate specific phosphorylations and dephosphorylations to decreases in ionic conductances.

272.1

NO-949: ANXIOLYTIC GABA-UPTAKE INHIBITOR. Erik B. Nielsen. CNS Pharmacology Lab., NOVO Industri A/S, CNS Division, DK-2880 Bagsvaerd, Denmark.

NO-949 (N-((4-phenyl-4-N-methyl pyrrol-2-yl)buten-3-yl)guvacine hydrochloride) is a potent, selective GABA-uptake inhibitor (IC_{50} for synaptosomal GABA-uptake ~185 nM) which was characterized in various anxiolytic models. NO-949 was active in a modified Vogel conflict test in rats (MED 1 mg/kg i.p.) and in a conditioned emotional response (CER) test with a MED of 0.3 mg/kg i.p. Further, NO-949 was also active in a "light-dark" test in mice with a MED of 1 mg/kg (i.p.). Finally, since GABA-uptake inhibitors fail to substitute for diazepam in drug discrimination situations, it indicates that anxiolytic effects of GABA-uptake inhibition may be obtained in the absence of benzodiazepine-like subjective effects.

272.2

BIOCHEMICAL CHARACTERIZATION OF CI-966: A CENTRALLY ACTIVE GABA UPTAKE INHIBITOR. L.J. Brahce,* R.D. Schwarz, D.K. Boyd, L.L. Coughenour,* T.A. Pugsley, and C.R. Clark (SPON: L. Copeland). Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI.

Recent studies have shown that enhancing synaptic GABA-ergic activity in rodents results in a variety of anti-convulsant behaviors. 1-[2-[bis(trifluoromethyl)-phenyl]methoxy]ethyl]-1,2,5,6-tetrahydro-3-pyridine-carboxylic acid, HCl (9CI-966) is a novel GABA uptake inhibitor which has anticonvulsant properties. CI-966 was found to selectively block [^{3}H]-GABA uptake into rat hippocampal slices (IC_{50}=0.32uM) while having no effects on $^+$DA, NE, 5-HT, or D-aspartate uptake. Inhibition of Na^+ flux was observed at 10uM. There was no detectable affinity for most receptors examined, however, some binding was observed at DA_2 and sigma receptors as well as site 2 of voltage-sensitive Na^+ channels. CI-966 did not affect the rate of DA and 5-HT synthesis in rat brain, but did appear to slightly increase (+28%) the rate of NE synthesis in cortex (but not brain stem) following the IP administration of 30mg/kg. These results, together with those of Taylor, et al. (this meeting), suggest that the mechanism by which CI-966 blocks convulsant activity is inhibition of GABA uptake. In initial clinical trials, CI-966 produced adverse effects.

272.3

ANTICONVULSANT AND BEHAVIORAL EFFECTS OF CI-966 AND PD 126141, POTENT GABA-UPTAKE INHIBITORS, IN ANIMALS. C.P. Taylor and M.G. Vartanian*. Parke-Davis Pharmaceut. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

CI-966 selectively inhibits GABA uptake in vitro (IC_{50} = 322 nM) and is an anticonvulsant in rodents, but was associated with adverse events in initial clinical trials.

CI-966 potently blocks clonic threshold seizures from pentylenetetrazole (PTZ, ED_{50} = 0.4 mg/kg PO mice) but prevents maximal electroshock extensor seizures only at much higher doses (ED_{50} ≈ 60 mg/kg PO mice). CI-966 (ED_{50} = 2.6 mg/kg PO) raises afterdischarge threshold in rat hippocampus, a model for partial seizures. PD 126141 (GABA uptake IC_{50} = 200 nM) blocks PTZ seizures in mice and causes ataxia with potency similar to CI-966 while its enantiomer is inactive for either effect at 100 mg/kg PO.

CI-966 reduces spontaneous locomotor activity (30 mg/kg PO mice) and causes ataxia (64 mg/kg PO mice, 27 mg/kg PO rats, approx. 5 mg/kg PO dogs, approx. 3 mg/kg IM rhesus monkeys). At ataxic doses, reactions to sensory stimuli are reduced with tremors or myoclonus of extremities; patellar reflexes are enhanced with splayed hindlimbs. Behavioral changes reverse within 4-10 hr. CI-966 has only slight cardiovascular effects.

PD 126141 blocks GABA uptake in vitro and is active in vivo with much greater potency than its enantiomer. We conclude that both anticonvulsant and behavioral actions are mediated by stereospecific blockade of GABA uptake.

272.4

ELECTROPHYSIOLOGICAL ACTIONS OF A POTENT GABA-UPTAKE INHIBITOR. D.M. Rock, C.P. Taylor, U. Ebert* and K. Krnjevic. Parke-Davis Pharmaceutical Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105 and Physiol. and Anaesth. Res. Depts., McGill Univ., Montreal.

CI-966 is a GABA uptake inhibitor (IC_{50} = 322 nM) that has anticonvulsant activity in animals but was associated with adverse events in initial clinical trials. We tested potential mechanisms of CI-966 in vivo and in vitro using electrophysiological techniques.

In urethane-anesthetized rats, CI-966 (1-10 mg/kg IP) tended to reduce the amplitude of population spikes, and increased inhibition of paired orthodromic (commissural stimulus) population spikes in hippocampal area CA1. Recurrent inhibition (alvear stimulus) was also increased. CI-966 (10 mg/kg IP) extended the duration of orthodromically-induced inhibition by as much as 30-fold and also enhanced and prolonged the depressant action of iontophoretically-applied GABA on population spikes.

In cultured mouse spinal cord neurons, CI-966 (10 μM) did not change intracellular responses to iontophoretically-applied GABA or glutamate. However, CI-966 blocked sustained rapid firing (IC_{50} ≈ 10 μM), presumably by acting on voltage-sensitive sodium channels.

These results with CI-966 are consistent with a functional decrease in the uptake of GABA in vivo, and an additional effect on neuronal sodium channels at relatively high concentrations.

272.5

ACTIONS OF A GABA-UPTAKE INHIBITOR, CI-966, AND MUSCIMOL ON NEUROTRANSMITTER OVERFLOW IN THE RAT STRIATUM USING IN VIVO MICRODIALYSIS. L.W. Cooke, L. Ball*, C.P. Taylor, and M.D. Davis* (SPON: M.J. Callahan) Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

CI-966 is a selective GABA reuptake inhibitor (IC50 = 320nM) as established in a number of biochemical and pharmacological tests that also exhibits anticonvulsant properties in rodents. We report here changes in amino-acid and catecholamine overflow from the rat striatum after systemic administration of CI-966 and muscimol.

Adult male Sprague-Dawley rats were anesthetized with urethane, mounted in a stereotaxic frame and implanted with a Carnegie Medicin microdialysis probe (4mm) into the left striatum. Artificial CSF was infused through the probe (2ul/min) and samples were collected at 20 min intervals for analysis by HPLC with electrochemical detection. After a suitable baseline was established drugs were injected IP.

In preliminary studies, CI-966 (5,10,25 mg/kg) caused a dose-dependent increase in dopamine overflow of up to 105% with little change in DOPAC or HVA. At 10 mg/kg, GABA and glycine levels were also elevated in the dialysates by 123% and 168% respectively. The GABAa agonist, muscimol (4mg/kg), increased dopamine overflow by 98%. These results demonstrate that CI-966 is a modulator of GABA neurotransmission in vivo and that this action may also influence brain dopamine neuronal function. In initial clinical trials with CI-966, adverse side-effects were observed.

272.6

EFFECTS OF THE GABA UPTAKE INHIBITOR, CI-966, ON THE FIRING ACTIVITY OF MIDBRAIN DOPAMINE NEURONS. K.A. Serpa, C.L. Christoffersen and L.T. Meltzer. Department of Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

There is a complex interaction between dopamine (DA) and GABA. Depending on the intensity, electrical stimulation of the mainly GABAergic striatal-nigral pathway can either excite or inhibit DA neurons in the substantia nigra (SN) (Grace and Bunney, Brain Res. 333:271,1985). Additionally, systemic administration of the GABA-A agonist, muscimol, paradoxically increases the activity of DA neurons (Grace and Bunney, Eur. J. Pharmacol. 59: 211, 1979). We have begun to evaluate the effects of CI-966, a potent GABA uptake inhibitor in vitro (IC-50 = 322 nM), on the firing activity of SN DA neurons extracellularly recorded in chloral hydrate anesthetized male S-D rats.

CI-966, 10 & 20 mg/kg IP, increased, decreased or did not change DA neuron firing. In contrast, muscimol, 5 mg/kg IP, consistently increased firing activity. The different effects due to GABA uptake blockade and direct GABA-A agonist action may be due to low tonic GABA release in the anesthetized rat. Studies are now examining the effect of CI-966 on the response of DA neurons to stimulation of the striatal-nigral pathway.

Adverse effects occurred during the initial clinical trial of CI-966.

272.7

EFFECT OF GABA-BENZODIAZEPINE RECEPTOR LIGANDS ON SEIZURE THRESHOLD IN DIAZEPAM-SENSITIVE AND -RESISTANT MICE. E.J. Gallaher* and S.E. Gionet* (SPON: JK Belknap). VA Medical Center and Depts. of Pharmacology and Medical Psychology, Oregon Health Sci. Univ. Portland, OR 97201.

Diazepam (DZ)-sensitive (DS) and DZ-resistant (DR) mouse lines were developed by selective breeding based on rotarod impairment (Gallaher et al., Psychopharmacol., 93:25, 1987). DS and DR mice do not differ in pentylenetetrazol (PTZ) seizure threshold or DZ protection against PTZ, suggesting different mechanisms for rotarod and seizure activity. Here we study other GABA-BZ receptor ligands.

Bicuculline (competitive GABA antagonist), DMCM (BZ inverse agonist), and picrotoxin (chloride channel blocker) were infused into the tail vein until seizures were observed; DS and DR lines did not exhibit differences in seizure threshold. Since they do not produce seizures themselves, the partial inverse agonists FG-7142 (0-550 mg/kg) and beta-CCE (0-300 mg/kg) were injected ip, followed by PTZ infusion. Dose-dependent decreases in PTZ threshold indicated pro-convulsant activity; again no line differences were observed. Ro 15-1788, a BZ receptor antagonist, was injected ip (0-100 mg/kg) followed by PTZ infusion; this drug did not affect the PTZ threshold in DS or DR mice.

These data further suggest that the mechanism underlying seizure activity differs from that involved in the rotarod behavior used for selective breeding. (Supported in part by VA Research Service and PHS RO1 NS23927.)

272.8

PRENATAL EXPOSURE TO DIAZEPAM ACCENTUATES AGE-RELATED DIFFERENCES IN SEIZURE SENSITIVITY TO BICUCULLINE.
Daniel Bitran, Rajesh Miranda, Renee Primus, and Carol K. Kellogg.
University of Rochester, Department of Psychology, Rochester, NY 14627

Prenatal diazepam (DZ) exposure has been shown to alter neurochemical and functional indices of early interaction at the GABA/BDZ receptor complex long after the drug has disappeared from the brain and periphery (see Kellogg, *Prog Brain Res* 73: 207, 1988). Since GABAergic mechanisms have been implicated in convulsive disorders, we examined seizure susceptibility in juvenile (21 day old) and adult (75 day old) male offspring of female rats treated with DZ (1 or 2.5 mg/kg, SC) over gestational days 13 to 20.

Seizure was induced by IV administration of bicuculline (BIC, 50 μg/ml) at an average rate of 200 μl or 2 ml per minute, in juvenile and adult males, respectively. EEG recordings were used to discern the appearance of epileptogenic activity, continuous high-amplitude rapid spiking, and post-ictal depression. Animals were anesthetized, paralyzed, and ventilated during seizure induction.

Onset of seizure activity was found to vary as a function of age and prenatal drug exposure. Control animals were less sensitive to the convulsive effects of BIC at 21 days of age, relative to 75 day-old control animals. Prenatal treatment with DZ enhanced this age-related difference in seizure threshold: Juvenile drug-exposed animals showed a 30-40 percent increase in the convulsant dose of BIC (333 ± 10 μg/kg), relative to age-matched controls (250 ± 9 μg/kg); in adult males seizure threshold was lower in DZ- exposed males (130 ± 10 μg/kg) relative to age-matched controls (200 ± 4 μg/kg). Thus, prenatal treatment with DZ decreased seizure susceptibility to BIC in juvenile males but increased the sensitivity to BIC-induced seizure in adult animals. In contrast, neither age nor prenatal drug treatment affected the duration of high intensity rapid spiking activity and post-ictal depression. In order to facilitate interpretation of these functional changes, studies examining GABA/BDZ receptor-mediated chloride influx and receptor binding in prenatally DZ-exposed offspring are underway. Supported by grant MH31850.

272.9

GLUTAMATERIC PROCESSES INVOLVED IN KINDLING INDUCED BY THE BENZODIAZEPINE RECEPTOR INVERSE AGONIST; FG 7142.
D.N. Stephens*, L. Turski, J.D. Turner* and H.H. Schneider*. (SPON: W. Kehr) Dept. Neuropsychopharmacology, Schering AG, P.O.B. 65 03 11, 1000 Berlin 65, FRG

FG 7142, a beta-carboline partial inverse agonist at central benzodiazepine receptors induces kindling in rats and mice on repeated administration. Kindling depends on FG 7142's action at benzodiazepine receptor, but no changes in the biochemical pharmacology of the benzodiazepine/GABA receptor complex have been found which could explain the increased sensitivity. Now we report that in mice both the expression of FG 7142 (40 mg/kg, i.p.) kindled seizures and the development of kindling were antagonised by 2-aminophosphonoheptanoic acid (2-APH; 0.025 μmol, i.c.v.) and MK 801 (0.5 mg/kg, i.p.), respectively competitive and non-competitive antagonists at glutamate receptors of the NMDA subtype. The quisqualate antagonist, CNQX (0.025 μmol i.c.v.) and kainate antagonist, AMPA (0.025 μmol i.c.v.) did not antagonise the expression of FG 7142 kindled seizures. Preliminary autoradiographic studies suggest an increase in ^{3}H-glutamate binding in hippocampus and cortex of FG 7142 kindled rats (15 mg/kg, i.p.). These results suggest that FG 7142-induced kindling, in common with electrical kindling, may be associated with changes in glutamatergic activity.

272.10

IN VITRO AND IN VIVO ACTIONS OF 3α-OH-5α-REDUCED PREGNANE STEROIDS. D. Belelli*, M. Bolger* and K.W. Gee, Univ. of So. Calif, School of Pharmacy, Los Angeles, CA 90033

Progesterone (P) and some of its metabolites modulate the $GABA_A$/Benzodiazepine receptor linked Cl^- ionophore (GBRC) by specific interactions with a putative steroid recognition site. The most potent P metabolite, 5α-pregnan-3α-ol-20-one (3α-OH-DHP), has been reported to inhibit completely the binding of [^{35}S]t-butylbicyclophosphorothionate ([^{35}S]TBPS) to a site on or near the Cl^- ionophore whereas 5α-pregnan-3α,20α-diol (5α-pregnanediol) was found to have limited efficacy as an inhibitor. This allosteric modulation of [^{35}S]TBPS binding led us to evaluate the possibility that the action of the two pregnanes are mediated through a common site associated with the chloride ionophore. In this study 3α-OH-DHP and 5α-pregnanediol behave like full and partial agonist respectively, in the modulation of GABA-stimulated ^{36}Cl uptake. Moreover, the high potency of 3α-OH-DHP in both binding and functional assays is reflected in in vivo studies. 3α-OH-DHP has potent anticonvulsant actions in standardized anticonvulsant screens with maximum potency against (+)bicuculline (ED_{50} = 4.1 mg/kg, i.p.) induced seizures and no activity against maximum electroshock and strychnine induced convulsions. These studies suggest that therapeutically useful anticonvulsant steroids can be identified. (Supported by NIH Grant NS 24645)

272.11

DIFFERENTIAL BEHAVIORAL EFFECTS OF RO 15-4513 AND FG 7142 IN CHRONIC ETHANOL-TREATED RATS. A. K. Mehta* and M. K. Ticku. Dept. of Pharmacology, Univ. of Texas Hlth. Sci. Ctr., San Antonio, TX 78284-7764.

Pentylenetetrazol (PTZ)-induced convulsions were studied in control, chronic ethanol-maintained, and ethanol-withdrawal rats. Ethanol-maintained rats required higher doses of PTZ to produce convulsions, compared to control and ethanol-withdrawal rats. Ro 15-4513 (2 mg/kg, i.p.) and FG 7142 (20 mg/kg, i.p.) produced proconvulsant effect in control and ethanol-withdrawal rats as they potentiated the effect of subconvulsive dose of PTZ. A higher dose of Ro 15-4513 (4 mg/kg, i.p.), but not FG 7142 (up to 80 mg/kg, i.p.) also produced proconvulsant effect in ethanol-maintained rats. Furthermore, Ro 15-4513 (5, 10 mg/kg, i.p.), but not FG 7142 (up to 80 mg/kg, i.p.) produced clonic-tonic seizures of short duration in ethanol-withdrawal rats. These effects of Ro 15-4513 and FG-7142 were reversed by diazepam, as well as by Ro 15-1788, thereby, indicating the involvement of central benzodiazepine (BZ) receptors in the action of Ro 15-4513 and FG 7142. These observations suggest that chronic ethanol treatment selectively alters the receptor sensitivity to Ro 15-4513, a partially negative ligand for BZ sites.

272.12

PARALLELES BETWEEN THE BEHAVIORAL EFFECTS OF DMCM & CONDITIONAL FEAR. M. S. Fanselow, F. J. Helmstetter, & D. J. Calcagnetti* Dept. of Psychology, UCLA, LA, CA 90024 & Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

The benzodiazepine inverse agonist methyl 6,7-dimethoxy-4-ethyl-ß-carboline-3-carboxylate (DMCM) has been reported to act as an anxiogenic. Therefore, we examined its behavioral effects to determine if it would produce behaviors similar to those produced by Pavlovian conditional fear stimuli. In situations associated with electric shock rats exhibit a species typical freezing response, increased defecation, and analgesia. DMCM produced similar responses in nonshocked rats. That is, it produced freezing (in a small chamber and an open field), increased defecation, and analgesia (formalin and hot plate tests). DMCM also enhanced freezing to a shock associated context. Opioid antagonists reverse conditional fear-induced analgesia but naltrexone produced only a weak attenuation of DMCM analgesia. Conditional fear stimuli potentiate the acoustic startle reflex. However, DMCM attenuated acoustic startle. Thus there are some similarities between conditional fear-induced behavior and the behavioral effects of DMCM but there are also some important differences. While benzodiazepine antagonists (Ro 15-1788 & ZK 93-426) reversed DMCM's effects, they had no effect on fear conditioning itself. It seems unlikely that an endogenous inverse agonist is a critical mediator of fear.

272.13

ANXIOLYTIC EFECT RESULTING FROM CHRONIC EXPOSURE TO FLUMAZENIL (Ro 15-1788). M. Urbancic* and T.J. Marczynski. Dept. of Pharmacology, Univ. of Illinois, College of Med., Chicago, IL. 60612.

The Vogel drinking-punishment test was used in order to evaluate the response to conflict situation in adult rats chronically treated with the benzodiazepine (BDZ) antagonist, flumazenil (4mg/kg/day for 3 weeks in drinking water). Tests were repeated on day 3, 6 and 10 following drug withdrawal, each time in 44 hr water- deprived rats. One min. of unpunished drinking was followed by 5 min. of punished drinking (0.35 mA shock after each 20 licks). In the first session, there was no difference in unpunished drinking between control and flumazenil-treated rats. However, in control animals shock experience caused a precipitous decrease in unpunished drinking during next two trials, while the shock experience did not affect the unpunished drinking in the flumazenil-exposed rats. In addition, the rate of punished drinking was significantly higher in the flumazenil-exposed rats on day 3 and 6 after drug withdrawal, as compared to controls. Nociceptive treshold, measured by the tail-flick test and tail-shock vocalization test, was not altered during the same time period. Hence, our data show a strong anxiolytic effect resulting from chronic exposure to a "neutral" BDZ antagonist, flumazenil, the nature of which warrants further investigation. Supported by USAF grant 87-0364.

INTRASEPTAL ADMINISTRATION OF GABA & BENZODIAZEPINE AGONISTS & ANTAGONISTS: ALTERATIONS IN HIPPOCAMPAL CHOLINE UPTAKE AND COGNITIVE BEHAVIOR. R.W. Stackman, D.F. Emerich, L.A. Taylor and T.J.Walsh. Rutgers University, Department of Psychology, New Brunswick, NJ 08903.

The present studies examined the neurochemical and behavioral effects of pharmacologically manipulating the GABA or benzodiazepine (BDZ) receptor in the septum. A second study examined the effects of intraseptal chlordiaxepoxide (CDP) upon working memory processes.

Sprague-Dawley rats implanted with intraseptal cannulae were injected with either vehicle, or an agonist: muscimol (0.75, 3.0nM), baclofen (3.0, 6.0nM), CDP (1.5, 3.0nM), or an antagonist: bicuculline (0.5, 1.0nM), RO15-1788 (5.0, 10.0nM), or ß-CCM (1.0, 2.0nM), of the GABA or BDZ receptor. One hour later, rats were sacrificed and hippocampal high affinity choline uptake (HAChU) evaluated. Dose-related decreases in HAChU were produced by each of the agonists: muscimol (15-30%), baclofen (15-26%), CDP (30-49%). Dose-related increases in HAChU were produced by only the high dose of RO15-1788 (30%) and ß-CCM (31%).

In a second experiment, Sprague-Dawley rats were trained to perform a working memory version of the eight arm radial maze (RAM) task in which a one-hour delay was imposed between the fourth and fifth arm choices. Following acquisition of the task, animals were implanted with intraseptal guide cannulae, allowed one week to recover, and returned to the RAM for further testing. Intraseptal injection of 10 µg, but not 5 µg CDP or vehicle, immediately after the pre-delay RAM session, significantly impaired performance on the working memory task, as did muscimol or baclofen in a previous report (Chrobak et al., in press). These studies provide additional evidence that GABA/BDZ mechanisms in the medial septum modulate (1) cholinergic neurons (2) their afferents to the hippocampus and (3) the behavioral processes served by these neurons. Supported by BRSG Grant 07058 to TJW.

EFFECTS OF Ro 5-4864 AND CHLORDANE ON LIMBIC EVOKED POTENTIALS IN THE FREELY BEHAVING FEMALE RAT. K.-S. DAI*, Z. A. HASAN* and D. E. Woolley. Dept. of Animal Physiol., Univ. of Calif., Davis, CA 95616.

The atypical benzodiazepine Ro 5-4864 (15 mg/kg i.p. in DMSO) and the insecticide cis-chlordane (25 mg/kg p.o. in oil) produced similar effects on limbic evoked potentials, though the effects of Ro 5-4864 appeared earlier and the effects of chlordane were more marked and lasted longer. The doses used produced minimal seizure activity of the myoclonic type. Both produced the following signs of enhanced limbic excitability: 1. an increase in appearance and amplitude of afterpotentials in the response produced in the prepyriform cortex (PPC) by stimulation of the lateral olfactory tract; 2. a nearly 2-fold increase in amplitude of the PPC-evoked response recorded in the dentate gyrus (DG); 3. paired pulse potentiation of the PPC-evoked DG response; and 4. a several-fold increase in the population spike interrupting the slow wave recorded in the DG in response to stimulation of the dorsal perforant path (DPP). Chlordane produced a transient decrease in recurrent inhibition during paired pulse stimulation of the DPP, in keeping with its reported effect at the PTX/TBPS site on the GABA-activated chloride channel, whereas we have not yet observed this effect with Ro 5-4864.

BENZODIAZEPINE RECEPTOR-MEDIATED CONTROL OF BICUCULLINE-INDUCED CHANGES IN CEREBRAL ENERGY METABOLISM. R. Miranda, D. Bitran, T. Ceckler,* and C.K. Kellogg. Dept. of Psychology, Univ. of Rochester, Rochester, NY 14627.

Changes in rat brain cellular energy metabolism following IV injection of the GABA antagonist bicuculline (BIC) were studied using 31P-NMR spectroscopy. Rats were anesthetized, cannulated, paralyzed and ventillated. Spectra were averaged over 10 min. bins using a GE 2.0 Tesla CSI system. Bic (125-1000 µg/kg) induced dose-related alterations in inorganic phosphate, cellular pH and in EEG activity. A nonconvulsive dose of BIC (170 µg/kg) induced changes in energy metabolism not accompanied by EEG patterns characteristic of a seizure, indicating that changes in brain cellular metabolism may precede full seizure expression. Diazepam (DZ, 1.0 mg/kg) given alone had no effect on metabolism, but it prevented the metabolic changes induced by 170 µg/kg BIC. Concurrent administration of the benzodiazepine (BDZ) antagonist Ro 15-1788 (10 mg/kg) attenuated this effect of DZ. The results indicate that changes in cellular energy metabolism may precede seizures rather than be merely a consequence of seizure and that the BDZ receptor may mediate influences on energy metabolism during states of neuronal activation but not during basal states. Supported by Grant MH31850.

PK 11195 AND Ro 15-1788 ALTER THE TOXICITY OF Ro 5-4864 AND LINDANE. H. L. Drummer and D. E. Woolley. Dept. of Animal Physiol., Univ. of Calif., Davis, CA 95616.

We have shown that the effects in vivo of Ro 5-4864, lindane, and picrotoxin are similar and include hypothermia, convulsions, reduced food intake and long-term enhancement of the limbic evoked potential elicited in the dentate gyrus of the hippocampal formation by single and paired-pulse stimulation of the prepyriform cortex in the rat. PK 11195 and Ro 15-1788, putative antagonists for peripheral and central benzodiazepine sites, respectively, have been reported to antagonize some of the in-vivo effects of Ro 5-4864. Further, PK 11195 is reported to antagonize some of the effects of the type II pyrethroids which, like lindane, are convulsant insecticides. Surprisingly, in the current study, a dose of PK 11195 (30 mg/kg), which by itself had no effect, exacerbated the hypothermic and anorexic effects of Ro 5-4864 (10 mg/kg) and exacerbated the hypothermic but not the anorexic effects of lindane (10 mg/kg). A dose of Ro 15-1788 (20 mg/kg), which alone had no effect, unexpectedly exacerbated the hypothermic effects of lindane (10 mg/kg) but did not alter the anorexic effects. All drugs were administered i.p. in DMSO (0.5 ml/kg) to adult female rats. The complex interactions in vivo of these drugs suggest that caution should be used with the clinical use in humans of PK 11195, Ro 15-1788 and lindane.

273.1

ANATOMICAL LOCALIZATION OF GUANINE NUCLEOTIDE-SENSITIVE AND GUANINE NUCLEOTIDE-INSENSITIVE VIP RECEPTORS IN RAT BRAIN.
J.M. Hill, D. Lambie* and A. Harris* NSB NIMH, Bethesda, MD 20892 and Peptide Design, 12321 Middlebrook Rd, Germantown, MD 20874.

A heterogeneity of VIP receptors in mammalian tissues has been demonstrated by pharmacological studies, electrophoretic patterns of labeled VIP crosslinked to cell membranes and in studies of adenylate cyclase activity. In intestine, two binding sites can be differentiated by their sensitivity to GTP regulation and the stimulation of adenylate cyclase.[1] In the present study the GTP inhibition of VIP receptor binding at the GTP sensitive site was used to differentiate GTP-sensitive from GTP-insensitive VIP receptors in rat brain.

In vitro autoradiography with ^{125}I-VIP was performed on rat brain slices with and without GTP. The presence of GTP (10^{-5}M) abolished ^{125}I-VIP binding at several VIP binding sites including those in the caudate putamen, many cortical regions, locus coeruleus, and central grey. ^{125}I-VIP binding was reduced to varying degrees in many regions including the hippocampus, cerebellum, and entorhinal cortex. In a third set of brain areas, including the olfactory bulb, thalamus, pituitary, superior olive, and superior colliculus superficial grey, ^{125}I-VIP binding appeared to be unaffected by the addition of GTP.

These results suggest that VIP binding sites not linked to G protein/adenylate cyclase are distributed unevenly throughout the brain and that in some regions, e.g., the olfactory bulb and thalamus, they represent the primary subtype of receptor.

273.2

INFLUENCE OF HISTONES ON AN ANATOMICALLY DI STINCT SUBSET OF VIP RECEPTORS IN RAT BRAIN SUGGEST AN INTERACTION BETWEEEN VIP AND HISTONE. J. B. O'Neill, A. Harris,* P.Laing,* and J.M. Hill. NSB, NIMH Bethesda Md 20892 and Peptide Design 12321 Middlebrook Rd. Germantown, Md 20874

Affinity labeling of VIP receptors by crosslinking ^{125}I-VIP to Sub T1 cells (human T cells) and brain membranes produces a band at ~16 kD, the molecular weight range of histones, which is displaceable with VIP and peptide T. Nuclear VIP receptors have been reported (Omary *et al* Science, 238:1578, 1987) A histone-like protein has been found on activated T cell surfaces (Stricker *et al*, IV International AIDS Conference, 1988). This study examines the possibility that VIP might bind to histones or homologous proteins.

^{125}I-VIP was bound to Sub T1 cells and rat brain membranes, displaced with cold VIP and peptide T, crosslinked with DSS and subjected to SDS-PAGE. SDS-PAGEs were blotted and probed with anti-histone H2b. The H2b immunoreactive band occurred at ~16kD and in Sub T1 cells this band was reduced with VIP and peptide T. *In vitro* autoradiography was performed on rat brain sections using ^{125}I-VIP pretreated with histone or myelin basic protein. Pretreatment of ^{125}I-VIP with histone changed the binding pattern of VIP by reducing binding in the thalamus, olfactory bulb, and other VIP binding sites which are insensitive to GTP but did not reduce binding in the GTP-sensitive sites (Hill *et al.* Neuroscience Abstacts 1989.

This data is consistent with the hypothesis that VIP interacts with a histone.

273.3

VASOACTIVE INTESTINAL PEPTIDE RECEPTORS IN DISPERSED ACINI FROM RAT SUBMANDIBULAR GLAND MEDIATE CYCLIC AMP PRODUCTION AND MUCIN RELEASE. J.T. Turner and J.M. Camden, Department of Pharmacology, University of Missouri-Columbia School of Medicine, Columbia, MO 65212.

Vasoactive intestinal peptide (VIP) has been identified as an important regulator of submandibular salivary gland function, consistent with its co-localization with acetylcholine in parasympathetic neurons innervating this gland. Enzymatically dispersed acini from rat submandibular gland are a useful system in which to study gland regulation at the cellular level. In this study, we examined three aspects of VIP interactions with acini: inhibition of binding of ^{125}I-VIP, stimulation of cyclic AMP production and enhancement of mucin release. VIP and peptide histidineisoleucineamide (PHI) inhibited ^{125}I-VIP binding to intact acini with IC_{50} values of 16 ± 3 nM and 46 ± 17 nM, respectively. This rank order of potency agrees with that observed previously in assays using rat submandibular gland membranes and is similar to values obtained in assays measuring increases in cyclic AMP production in which the ED_{50} values for VIP and PHI were 3.1 ± 1.8 nM and 29 ± 13 nM, respectively. Although VIP stimulation of cyclic AMP production was only about 10% of that seen in response to isoproterenol, mucin release levels induced by the two agents were more similar. The ED_{50} for VIP-stimulated mucin release was 0.12 ± 0.05 nM, thus suggesting a "spareness" in the VIP receptor-coupled signal transduction pathway at a point between cyclic AMP production and mucin release. Supported by NIH Grant DE07389.

273.4

LOCALIZATION OF ^{3}H-ARGININE-VASOPRESSIN BINDING SITES IN THE CNS OF THE GOLDEN HAMSTER. P. Szot, C. F. Ferris and D. M. Dorsa. GRECC, Seattle VAMC, WA 98108 and Dept. of Physiology, Univ of MA Medical Ctr, Worcester, MA 01605.

Microinjection of arginine^{8}-vasopressin (AVP) into specific brain regions of the golden hamster elicits dramatic changes in behavior. This study was undertaken to localize AVP binding sites in the CNS of the golden hamster. Autoradiography with ^{3}H-AVP at a concentration of 2.5 nM was performed on coronal sections from 3 animals as previously described (J Neurosci 4:1764, 1984). Non-specific binding was defined in the presence of 1μm unlabeled AVP. ^{3}H-AVP binding sites were concentrated in the dorsal, ventral and lateral septum, bed nucleus of the stria terminals (BNST), central amygdala and hippocampus in the golden hamster. This pattern of labeling is very similar to that observed in the adult rat. In contrast, the anterior cingulate cortex and the endopiriform nucleus were also intensely labeled by ^{3}H-AVP in the hamster CNS. ^{3}H-AVP binding was further characterized using septum-BNST membranes. Saturation analysis performed in 3 groups of 12 animals resulted in a B_{max} of 12.4 ± 0.82 fmol/mg protein and a K_D of 2.5 ± 0.36nM. These values are similar to those obtained from crude septal membranes prepared from adult rat. Comparisons of the pharmacologic specificity of hamster and rat brain ^{3}H-AVP binding sites are in progress.

273.5

GUANINE NUCLEOTIDES AND PERTUSSIS TOXIN ALTER AGONIST BINDING TO RAT SEPTAL V_1-VASOPRESSIN RECEPTORS. M. W. Swank* and D. M. Dorsa. GRECC, VA Med. Ctr., and Depts. of Physiol. and Psychol. Univ. of WA, Seattle, WA 98108.

To determine whether the septal V_1-vasopressin (VP) receptor is coupled to phospholipase C by a GTP-binding protein, we investigated the effects of GTP analogues and pertussis toxin (PTX) on binding of ^{3}H-VP to synaptosomal membranes prepared from rat septum. Nucleotides were present in the reaction mix at a concentration of 1μM. Saturation isotherms revealed that none of the nucleotides significantly altered the B_{max}. All GTP analogs increased the Kd significantly, but ATP had no effect, indicating the specificity of the effect. Nonhydrolyzable analogs Gpp(NH)p ($p<0.01$) and GTPγS ($p<0.001$) had the greatest effect on receptor affinity.

	CONTROL	GTP	GDP	GPPNHP	ATP	GTPγS
B_{max} (fm/mg)	12.28	9.78	12.88	11.06	10.03	12.78
Kd(nM)	0.81	1.29	1.29	1.70	0.75	3.41

Synaptosomal membranes were incubated with 10μg PTX per mg membrane protein and binding of 2nM ^{3}H-VP was measured. PTX reduced specific binding by over 50% ($p<0.05$) suggesting that the septal VP receptor is associated with a G_o/G_i-type G protein.

273.6

THE RAT BRAIN CONTAINS EXCLUSIVELY VASOPRESSIN BINDING SITES OF THE V_1 SUBTYPE. E.M. v.d. Beek*, F.W. van Leeuwen*, J.J. van Heerikhuize* and Y.P. Wan**. (SPON: ENA) *Neth. Inst. for Brain Res., Amsterdam, The Netherlands, **Dupont-NEN, Boston, MA.

In the rat brain vasopressin (VP) binding sites have been revealed using radiolabeled VP and VP antagonists. Many studies pointed to the existence of V_1 type binding sites. In addition, central effects of the V_2 agonist dDAVP and effects of VP on cyclic AMP accumulation were shown. The present study examined directly the presence of V_2 binding sites in the rat brain, pituitary, kidney and liver. For that purpose the localizations of the tritiated V_2 antagonist desGly$(NH_2)_5$[D-Ile^2,Ile^4]VP and the V_1 antagonist d$(CH_2)_5$Tyr(Me)VP were compared (Van Leeuwen et al., Neurosci. Lett., 80: 121, 1987). The V_2 antagonist used is the most selective V_2 antagonist known to date (Manning et al., J. Med. Chem., 30: 2245, 1987). Whereas in the brain the V_1 antagonist appeared to bind to many areas, there was a total lack of V_2 antagonist binding. In the pituitary neither compound showed any labeling. In the kidney, cortical regions were labeled by the V_1 antagonist. The V_2 antagonist showed a dense labeling of the medulla; the cortical part was less intensely labeled. In the liver only V_1 binding was present. The present results support electrophysiological and pharmacological data indicating the exclusive existence of V_1 binding sites in the rat brain. Therefore central effects thought to be mediated via V_2 binding sites most probably reflect indirect effects.

273.7

"VASOTOCIN" RECEPTORS ARE INTRINSIC TO THE SONG CONTROL SYSTEM IN THE CANARY BRAIN. T.A.M. Voorhuis*, J.P.M. Elands*, E.R. de Kloet and D. de Wied* (SPON: Tj.B. van Wimersma Greidanus). Rudolf Magnus Institute, University of Utrecht, Vondellaan 6, 3521 GD Utrecht, The Netherlands. Vasotocin (VT) immunoreactive fibers were visualized in extra-hypothalamic areas in the brain of the canary. A strong VT innervation was observed in regions thought to be involved in mediation of limbic and autonomic function (septum), in sensory function (optic tectum), and in vocal control (nucleus robustus archistriatalis (RA)). The VT immunostaining in septum and dorsal diencephalon is increased following testosterone administration. In vitro autoradiography revealed a discrete neuroanatomical pattern of binding sites labelled with 3H-vasopressin. A low density was observed in the RA region, which increased however two fold after testosterone treatment. Using an ^{125}I-oxytocin antagonist (OTA) a high density of binding sites (Kd:0.05nM) was found exclusively in the RA region. VT has to these sites a high affinity (Ki:0.43nM), while mesotocin (Ki:7.95nM), oxytocin (Ki:2.91nM) and vasopressin (Ki:5.13nM) have a lower affinity. Accordingly the RA seems to contain two classes of binding sites, one of which is testosterone sensitive.

273.8

EFFECT OF ENDOTHELIN ON Ca^{2+} INFLUX, INTRACELLULAR FREE Ca^{2+} LEVELS AND LIGAND BINDING TO N AND L TYPE Ca^{2+} CHANNELS IN RAT BRAIN. Paul M. Lundy*, Robert Frew* and Murray G. Hamilton* (SPON: A.L. Miller). Defence Research Establishment Suffield, Ralston, Alberta, Canada, T0J 2N0.

Endothelin is a potent agonist on various peripheral smooth muscle preparations. It appears to cause vasoconstriction via stimulation of Ca^{2+} influx by activation of specific endothelin receptors and also by promotion of Ca^{2+} influx through the peripheral L type voltage sensitive Ca^{2+} channel (VSCC). The possibility that endothelin has similar effects on Ca^{2+} movements in central neurons was investigated as a result of the discovery of specific endothelin receptors in mammalian brain (Jones et al., Neurosci. Lett. 97:276, 1989). In the present study, endothelin by itself failed to induce Ca^{2+} influx nor did it potentiate Ca^{2+} influx in partially depolarized (15 mM K^+) synaptosomes. Endothelin failed to alter intracellular free Ca^{2+} concentrations nor did it induce acetylcholine release from brain slices. Endothelin also did not displace specifically bound ^{3}H nitrendipine or ^{125}I-conotoxin from L or N type VSCC's in synaptic membranes respectively. The results suggest that endothelin does not alter Ca^{2+} influx either by a direct effect on its own receptors or through L or N VSCC's in neural tissue.

273.9

GALANIN RECEPTORS IN BASAL NUCLEUS OF MEYNERT IN THE POSTMORTEM HUMAN BRAIN - CHANGES IN ALZHEIMER'S DISEASE. Ch.Köhler[1] and V.Chan-Palay[2]. [1]Astra Research Centre AB, Dept. of Neuropharmacology, S-Södertalje and [2]Neurology Clinic, University Hospital, CH-Zürich.

Recent studies in the postmortem human brain have shown that the nucleus basalis of Meynert (nbM) is densely innervated by galanin (GAL)-immunoreactive fibers arising from local GAL interneurons as well as possibly from cells situated outside this region. In brains from patients with senile dementia of the Alzheimer type (SDAT) taken from the Zürich dementia study a hyperinnervation by the GAL-fibers is observed. We have now studied the distribution of ^{125}I-GAL binding sites in the nbM of postmortem human brains using quantitative autoradiographic techniques with subtraction. The nbM is rich in specific binding sites for ^{125}I-GAL. The binding sites are distributed in distinct patches of high density on a background of low densities. Correlation with sections stained for AchE showed that the high density of ^{125}I-GAL binding sites did not correlate with areas of highest AchE staining suggesting that ^{125}I-GAL binding sites are not necessarily always in register with cholinergic cells giving rise to cortical projections. There is considerable interindividual variation in the findings from each patient. Comparisons between normal and SDAT cases showed no significant reductions in ^{125}I-GAL binding in the nbM in SDAT, despite the drastic loss of cholinergic neurons.

273.10

CHARACTERIZATION OF GP120 BINDING IN CEM CELLS AND HIPPOCAMPUS. M.R. Kozlowski, E. Hall, A. Watson. Department of Screening and Biochemical Research, Bristol-Myers Company, Wallingford, CT 06492-7660 and Oncogen, Seattle, WA 98121.

Entry of HIV into cells involves, in most cases, the binding of the viral protein, gp120, to the CD4 cell surface antigen. Since HIV infection is frequently associated with neurological abnormalities, neurons may also contain CD4-like binding sites. This report first examines gp120 binding to a CD4 antigen-bearing cell line, CEM, and then searches for similar binding sites in a brain region, the hippocampus.

Binding of radio-iodinated virion gp120 to intact CEM cells or hippocampal homogenates from the cow or the rat was measured at 37C in either PBS with BSA and glucose (PBG); PBG with bacitracin, aprotinin, and leupeptin; or HEPES (50mM) with the same protease inhibitors. Specific binding, defined as that inhibited by the CD4a antibodies OKT4a or G17-2, amounted to 85% of total.

The binding of gp120 to CEM cells was unusual. Thus, only 50% of the binding dissociated even after 4h. Furthermore, Scatchard plots of the saturation data were non-linear, with prominent convexities. We were unable to demonstrate specific gp120 binding to either rat or cow hippocampus. These data suggest that gp120 binding to CEM cells is not a simple competitive process.

273.11

CHARACTERIZATION OF [1-SARCOSINE, 8-THREONINE] AII IN RAT BRAIN. V.I. Cook and J.W. Harding. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

The specific AII antagonist [1-Sarcosine, 8-Threonine] AII (Sarthran) is known to significantly lower pressor activity in both hypertensive and normotensive rats when given i.c.v. Sarthran also exhibits less inherent agonist activity than [1-Sarcosine, 8-Isoleucine] AII and [1-Sarcosine, 8-Alanine] AII. Preliminary reports implicate Sarthran as a valuable compound in hypertensive research, with possible clinical applications.

Radioligand binding assays were carried out utilizing the HTSA portion from the brains of male Sprague-Dawley rats. Using ^{125}I-Sarthran, receptor binding assays included association and dissociation kinetics, saturation isotherms, and a series of competition curves with several angiotensin associated ligands. Using HPLC, metabolism data was also gathered, comparing Sarthran, AII, and AIII. Equilibrium dissociation constants were determined by both kinetic (K_D = .15 nM) and equilibrium (K_D = .3 nM) methods. Analysis of data from saturation isotherms indicated a Bmax of approximately 30 fmol/mg protein competition curves indicated the following rank order of affinity for the various angiotensin analogs: Sar^1-AII = Sar^1,Ile-AII > Sar^1, Thr^8-AII > AIII ≥ AII > AI > AII(3-8) > AII(4-8) >> AII(1-7). ^{125}I-Sar^1, Thr^8-AII was shown to be very stable in the binding as revealed by HPLC analysis.

273.12

MOLECULAR CLONING OF THE HUMAN BRAIN β-DENDROTOXIN ACCEPTOR. J.D. Hirsch, L. Malkowitz*, B. Beer, A.J. Blume and M.R. Ziai*. Molecular Neurobiology Group, Dept. CNS Research, Medical Research Division, American Cyanamid Co., Pearl River, NY 10965.

The snake venom-derived toxin, β–dendrotoxin (β-DTX), blocks the voltage-dependent slow or delayed-rectifier-type K^+ channel (Kdr), and is used to study its function. The Kdr is responsible for repolarization of neurons following action potentials and represents an intriguing target for drug discovery. We attempted to clone the β-DTX acceptor as a first step toward cloning the entire Kdr. With a fetal human brain-derived cDNA library in bacteriophage λgt11 as the starting point, we screened this library using β-DTX as the probe. After FPLC purification from crude snake venom, the β-DTX was biotinylated. This permitted us to detect positive (i.e. toxin-binding) plaques following incubation with avidin conjugated to alkaline phosphatase. Out of one million plaques screened, ten putative clones were identified. A detailed characterization of these clones may elucidate the molecular profile of K^+ channels.

273.13

ISOLATION AND PARTIAL CHARACTERIZATION OF AN ELH-BINDING PROTEIN FROM THE OVOTESTIS OF APLYSIA CALIFORNICA. J.V.A. Choate, T.E. Kruger* and J.E. Blankenship. Marine Biomed. Inst., Univ. Tex. Med. Br., Galveston, TX 77550.

Egg-laying in Aplysia californica has served as a model for studying the control of a behavior by a peptidergic neuroendocrine system. The neuroendocrine bag cells in this animal release a family of peptides, including the amidated 36-amino acid egg-laying hormone (ELH). ELH diffuses into the hemolymph and interstitial spaces to reach its target tissues, which include the ovotestis and certain identified neurons in the abdominal and buccal ganglia. While ELH has been well characterized, very little is known about its receptor. In an attempt to isolate and characterize the ELH receptor, we have covalently linked synthetic ELH to a solid matrix (Reacti-Gel 6X, Pierce Chemical Co.) and used this to form a ligand-affinity column. Ovotestes were homogenized using a Potter-Elvehjm glass-teflon homogenizer and then solubilized by sonication. The solubilized membranes were loaded onto the affinity column and eluted with 0.1M glycine (pH 2). The column eluate was analyzed by SDS-PAGE and by IEF. We have purified a 50 kDa protein which can be reduced with β-mercaptoethanol to subunits of 25 kDa. The intact protein has a pI of 4.9, while the subunits, which appear to be highly similar, have a pI of 4.3-4.4. Supported by NINCDS NS 23169 (JEB), 07185 (TEK), 11255, and NSF BBS8711368.

273.14

EXPRESSION OF THE NEUROTENSIN RECEPTOR IN *XENOPUS* OOCYTES WITH RNA TRANSCRIBED FROM λ AND pCDM8 LIBRARIES. B.F. O'Hara*, J.M. DiGiorgianni*, S. Shimada, L. Kushner, C.E. Spivak, J. Lerma, R.S. Zukin, M.V.L. Bennett, and G.R. Uhl. NIDA/ARC, Baltimore, MD, 21224, Depts. of Neurology & Neuroscience, Johns Hopkins University Sch. of Med., Baltimore, MD, 21205, and Dept. of Neuroscience, Albert Einstein Col. of Med., Bronx, NY, 10461.

Following injection of brain mRNA, *Xenopus* oocytes express several neurotransmitter receptors. In this study, mRNA from rat cerebral cortex or ventral midbrain was injected into the oocyte cytoplasm. Application of neurotensin produced an inward current with a concomitant increase in membrane conductance, while control eggs gave no response.

cDNA libraries derived from these mRNAs were constucted in λ-ZAP and in the eukaryotic expression vector pCDM8. Both vectors contain a T7 promoter for *in vitro* transcription. However, pCDM8 also contains a CMV promoter and an SV40 origin for eukaryotic replication, and can be used in conjunction with ligand-autoradiographic receptor screening (Rattray, *et al.* this meeting). In addition, receptor binding properties conferred by pooled or individual clones can be readily tested in appropriate cell lines. Further, with its strong eukaryotic promoter, injection into the oocyte nucleus may allow direct expression of cDNAs. Plasmid libraries also offer greater ease for virtually all manipulations and can be size fractionated even after construction.

In vitro transcripts from both pCDM8 and λ libraries produced positive signals in oocytes following neurotensin application. Under voltage-clamp conditions (-60mV) responses were up to 26nA in size, and displayed the same characteristics seen after injection of brain mRNA. Fractionation of these libraries should allow isolation of cDNAs coding for a functional neurotensin receptor.

IDENTIFICATION OF SIZE CLASSES OF mRNA ENCODING KAINATE AND NEUROTENSIN RECEPTORS. S.G. Fan*, L. Kushner*, J. Lerma*, B.F. O'Hara*, G.R. Uhl, M.V.L. Bennett and R.S. Zukin. (SPON: S. Salinas) Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461, and NIDA/ARC, Baltimore, MD 21224.

Binding, electrophysiological, and pharmacological studies have defined receptors responsive to the neuropeptide neurotensin and the excitatory amino acid analog kainic acid. However, little is known about the molecular properties of these receptors or of the mRNAs encoding them.

In *Xenopus* oocytes injected with rat brain mRNA neurotensin evoked delayed oscillatory inward currents, ascribable to coupling of activated receptors to the inositol triphosphate system, followed by opening of Ca^{2+}-dependent chloride channels. Kainate evoked smoothly rising, non-desensitizing inward currents. Fractionation of rat brain poly(A$^+$)RNA over a 5-25% linear sucrose gradient produced mRNA samples of 0.3-9.5 kb. Individual fractions were injected into *Xenopus* oocytes. After 6 days, responses to application of γ-aminobutyric acid (GABA), serotonin, neurotensin and kainate were assessed by voltage clamp analysis. mRNA encoding serotonin-1c and $GABA_A$ receptors were in the size range of 5-7 and 3-7 kb, respectively, as expected from reported data. mRNA encoding the kainate receptor was found in fractions of 6.0-8.5 kb and was enriched approximately 10-fold. mRNA encoding the neurotensin receptor (3.1-4.8 kb) was enriched several-fold in one fraction. These partially purified mRNAs provide enriched source material for the cloning of kainate and neurotensin receptors. [Supported by NIH grants NS20752 and NS07512, and Fogarty Fellowship TW 04040].

AUTORADIOGRAPHIC DISTRIBUTION OF CALCITONIN GENE-RELATED PEPTIDE (CGRP) BINDING SITES IN THE MONKEY SPINAL CORD. K. YASHPAL*, T. DENNIS and R. QUIRION (Spon R. MALMO). Douglas Hospital Res. Ctr. and Dept of Psychiatry, Verdun, Quebec, Canada H4H 1R3.

Immunohistochemical studies show the presence of CGRP in dorsal root ganglion cells as well as in axons of the dorsal root. Nerve terminals containing CGRP are localized predominantly in laminae I, II and V. Physiological studies provide evidence for its actions at the spinal level. Therefore, to provide further information on the possible involvement of CGRP in spinal transmission, the present study examines the distribution of [^{125}I]-hCGRP binding sites in the monkey spinal cord. Male green monkeys (cercopithecus aethiops) were sacrificed by an overdose of nembutal. Spinal cords were removed, sectioned, snap frozen and stored at -80^{0}C. Each segment was cut in 20 micron sections and thaw mounted on gelatin coated slides. The autoradiographic procedure, as described by Sexton *et al* (Neurosci 19, 1235 1986), was followed. Binding of 0.1nM [^{125}I]-hCGRP was observed throughout the length of the spinal cord and was relatively constant. However, high densities were seen in layers I and II and in the inner borders of layers III to V, around lamina X and in the lateral horn region. Moderate densities were present in the ventral horn, thus showing differences in distribution as compared to the rat spinal cord where high densities of these sites were localized in the medial borders of the dorsal horn and around the central canal only.

HUMAN CALCITONIN GENE-RELATED PEPTIDE (hCGRP) ANALOGUES DIFFERENTIATE RECEPTOR SUB-TYPES. T. Dennis[1], A. Fournier[2], S. St Pierre*[2] and R. Quirion[1]. [1]Douglas Hospital Res. Ctr., Dept of Psychiatry, McGill University, Verdun, QC, H4H 1R3. [2]INRS-Santé, Pointe Claire, QC, Canada.

The use of a variety of hCGRP analogues and fragments to study the structural requirements of the CGRP receptor showed that the radioligand binding characteristics in brain and spleen membrane preparations are similar. Furthermore, the *in vitro* biological activities of these compounds revealed differential agonist and antagonist potencies in a number of preparations suggesting the existence of CGRP receptor subtypes. Binding of the ligand to the CGRP receptor is independent of the N-terminal 2,7 disulfide bridge as indicated by the nM affinity of the analogues [Cys(ACM)^{2,7}]-hCGRP and cyclo^{2,7}[Asp^2,Lys^7]-hCGRP and the C-terminal fragments $hCGRP_{8-37}$ and $hCGRP_{12-37}$. Indeed, 6 to 8 amino acid residue cyclo^{2,7}-N-terminal fragments showed a total lack of affinity. The linear analogue [Cys(ACM)^{2,7}]-hCGRP retained high potency in the inhibition of the twitch response of the rat vas deferens but displayed no agonistic activity in the right and left guinea pig atrial preparations. Moreover, competitive antagonistic properties were displayed by $hCGRP_{8-37}$ and $hCGRP_{12-37}$ in atrial but much less so in vas deferens preparations. We propose that the receptor present in atria, which is highly sensitive to the antagonistic properties of C-terminal fragments be classed as the $CGRP_1$ subtype while $CGRP_2$ refers to the [Cys(ACM)^{2,7}]-hCGRP-sensitive sub-type resistant to the antagonist properties of $hCGRP_{8-37}$ and $hCGRP_{12-37}$.

CLONING, mRNA DISTRIBUTION, FUNCTIONAL EXPRESSION OF THE RAT SEROTONIN 1A RECEPTOR GENE. P. Albert*, Q.Y. Zhou*, H. Van Tol*, J. Bunzow*, O. Civelli. (SPON: E. Lewis)
Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

We have screened a rat genomic library under low stringency hybridization conditions with the hamster β_2-adrenergic receptor gene to isolate new members of the G protein-coupled receptor gene family. We show that one of this gene codes for a functional 5-HT_{1a} receptor on the basis of five criteria: (1) it possesses an intronless open reading frame encoding a protein with seven putative transmembrane domains and 89% amino acid identity with the human 5-HT_{1a} receptor; (2) its corresponding mRNA's are present in rat brain as three RNA species with the distribution expected for the 5-HT_{1a} receptor; (3) when transfected into fibroblast cells it expresses a ligand binding site with the pharmacology of the 5-HT_{1a} subtype; (4) it encodes a binding site which interacts with G protein; (5) it encodes a functional receptor which mediates agonist-induced inhibition of basl and stimulated cAMP accumulation in transfected GH4 C1 pituitary cells.

274.2

CLONING OF MOUSE GENOMIC 5-HT_2 RECEPTOR

Nancy Lan[1]*, Wu Yang[1]*, Kevin Chen[1]*, Kai Wang[2]*, and Jean C. Shih[1]. [1]School of Pharmacy, University of Southern California, Los Angeles, CA 90033 and [2]Biology Division, Caltech, Pasadena, CA 91125

Based on ligand binding specificities, 5-hydroxytryptamine (5-HT) receptors have been classified into at least six subtypes: 5-HT_{1A}, 1B, 1C, 1D, 2 and 3. The cDNAs encoding human 5-HT_{1A}, rat 5-HT_{1C} and 5-HT_2 receptors have been cloned. The latter two receptors share 78% of sequence similarity in their transmembrane domains. However, Northern and Southern blot analyses show that the 5-HT_2 receptors from human and rat have high sequence homology, whereas the 5-HT_{1C} receptor appears to have low sequence similarity between these two species.

The restriction patterns of Southern blotting of mouse genomic DNA using the 5-HT_2 receptor cDNA as a probe suggest that the 5-HT_2 gene contains intron(s) and probably occurs as a single copy in the mouse genome.

Using the 5-HT_2 receptor cDNA probe, a Balb/c mouse genomic library constructed in the pWE 15A cosmid vector was screened. Two positive clones were obtained with insert sizes of approximately 35Kb. Comparing the restriction patterns of cloned DNAs to that of the genomic DNA indicates that partial genomic 5-HT_2 clone was obtained. The structural organization and DNA sequences of these genomic clones will be discussed. (Supported by MH39085, MH00796, MH37020 and Welin professorship)

274.3

EXPRESSION OF FUNCTIONAL ADULT HUMAN SEROTINERGIC RECEPTORS IN XENOPUS OOCYTES.

Chad,J.E., Foreman,R.C.*, Nightingale,K.* & Wheeler,S.*
Dept. of Physiology, University of Southampton, Hants, SO9 3TU, UK.

Problems inherent in obtaining tisssue complicate analyses of human neurotransmitter receptor function.These problems can be circumvented by the use of *in ovo* expression of mRNA extracted from adult human brain tissue at post-mortem.

RNA was extracted from frontal cortex of adult human brain. Poly(A)$^+$mRNA was purified by oligo(dT) chromatography and the integrity of extracted RNA was examined by formaldehyde agarose gel electrophoresis. *In vitro* translation yielded ^{35}S-methionine labelled proteins up to a molecular weight of 200KD as determined by PAGE.

Samples of mRNA (50nl of 1mg/ml in H_2O) were injected into Xenopus oocytes which had been denuded of their outer layer of follicular cells by collagenase treatment and mechanical stripping. Two electrode voltage-clamp measurements (holding potential -80 mV) of oocyte responses to bath applied 5HT revealed a dose dependent inward current. Control oocytes (uninjected or sham injected with H_2O) were unresponsive to 5HT, suggesting that 5HT receptors in mRNA injected oocytes were exogenous. Repeated application of equal doses of 5HT produced an apparent desensitisation of response in some oocytes. The ramping of the command voltage (-100mV to 0mV /1s, constant dV/dT) during the stable phase of the drug response showed an increased conductance in response to 5HT with a reversal potential of approximately -20mV. These results suggest that the *in ovo* expression of human brain mRNA is a viable approach to the investigation of human neurotransmitter receptor systems.

Decreased density of platelet [^{3}H] imipramine, but not [^{3}H] paroxetine binding sites in major depression. B.E.Suranyi-Cadotte, L. Iny, P. Desjardins, R. Yassa and S. Welner.
Douglas Hospital Research Centre and Dept. of Psychiatry, McGill University, Montreal, Quebec, H4H 1R3.

A reduction in the number of binding sites for imipramine on platelets has been proposed to serve as an index of altered 5-HT uptake and a potential biochemical correlate of depression. Recent findings, however, suggest that ^{3}H imipramine binding sites are not consistently associated with 5-HT uptake, whereas [^{3}H] paroxetine, a selective 5-HT uptake inhibitor labels the 5-HT transporter. To further characterize the relationship between [^{3}H] imipramine and [^{3}H] paroxetine binding we investigated these binding sites in parallel on platelets of 11 depressed patients (RDC-major depression) and 10 age-matched healthy volunteers, who were drug-free prior to [^{3}H] imipramine (Briley et al, Science 209;303;1980) and [^{3}H] paroxetine (Mellerup et al, Eur. J. Pharmacol,96;303;1983) binding assays. Consistent with previous findings, the density (Bmax) but not the affinity (Kd) of [^{3}H] imipramine binding sites was significantly lower in depressed patients than in controls. In contrast [^{3}H] paroxetine binding variables did not differ between the two groups. There were no correlations between the two binding site variables. These results provide further evidence that [^{3}H] imipramine and [^{3}H] paroxetine bind to distinct sites and that reduced platelet [^{3}H] imipramine binding may serve as an index of depression.

RESPONSIVENESS OF SEROTONIN-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS IS INCREASED IN PLATELETS FROM UNMEDICATED DEPRESSED PATIENTS. M.Mikuni, I.Kusumi*, A.Kagaya*, H.Yamamoto*, Y.Kuroda*, T.Nishikawa* and K.Takahashi*.
Div. of Mental Disorder Res., Natl. Institute of Neurosci. NCNP, Kodaira, Tokyo, 187, Japan.

Studies of 5HT receptor function should provide important information about the role which receptor modulation or dysfunction may play in alterations of serotonergic function in affective disorders. The presence of 5HT-2 receptors on the human platelets as a readily accessable peripheral model for the certain function of 5HT neurons, may permit direct study of function of 5HT-2 receptors in living persons. Recently, it has been suggested that 5HT-stimulated phosphoinositide(PI) hydrolysis in rat cerebral cortex, rat aorta and human platelets is mediated by the 5HT-2 receptors. In this preliminary study, we have assessed 5HT-stimulated PI hydrolysis in platelets from a normal control group and depressed subjects. In a group of unmedicated patients with major depression matched for age with normal control group, we found a significant increase in 5HT(100uM)-induced accumulation of inositol-monophosphate, one metabolic product of PI hydrolysis (150$\pm$7% of basal for depressed patients, 132$\pm$3% for controls). This result may reinforce the hypothesis that serotonergic receptor abnormality play a role in affective disorder.

274.6

ANTI-IMIPRAMINE ANTIBODIES RECOGNIZE POTENT ENDOGENOUS SUBSTANCES WHICH INHIBIT SEROTONIN UPTAKE AND IMIPRAMINE BINDING. S.W. Tang, A. Strijewski*, S. Cheung*, D.M. Helmeste and J. Chudzik*. Psychopharmacology Unit, Clarke Institute of Psychiatry, Toronto, Ontario, Canada M5T 1R8.

Anti-Imipramine antibodies raised in rabbits were tested against a variety of antidepressant compounds, uptake inhibitors, antihistamines, neuroleptics and other psychotropic drugs and hormones. Compounds which show high affinity for the antibodies all possess a similar partial structure. Serotonin uptake inhibitors were generally not recognized. Brain, plasma and urinary extracts further purified by multiple chromatographic procedures all contained substances which showed high affinity for the antibody preparation. Some, but not all of these substances also demonstrated potent action when tested for inhibition of serotonin reuptake and ^{3}H-Imipramine binding. The data suggest the possible existence of endogenous compounds which modulate serotonin reuptake. Such compounds may show partial molecular structure similar to that identified by the antibodies.

274.7

LECTIN CHROMATOGRAPHY FOR PURIFICATION AND CHARACTERIZATION OF SOLUBILIZED PLATELET ^{3}H-IMIPRAMINE BINDING SITES. D.M. Helmeste, J. Chudzik* and S.W. Tang (SPON: P. Brawley) Clarke Institute of Psychiatry, Toronto, Ontario, Canada, M5T 1R8.

The glycoprotein nature of cell surface receptors offers purification strategies based on the affinity of lectins for different carbohydrate moieties. Accordingly, a variety of lectins have been tested for their ability to bind and retain the platelet serotonin transport complex, as labelled with the antidepressant ^{3}H-Imipramine. Human platelets were solubilized with CHAPS and passed through lectin-sepharose columns of differing sugar specificities. ^{3}H-Imipramine or RO-11-2465 binding was used to monitor receptor specifically eluted with sugar (0.5 M). Of the lectins tested, wheat germ (Triticum vulgaris), Lens Culinaris and Ulex Europaeus I appear to be useful for affinity purification of solubilized ^{3}H-IMI binding sites. Peanut (Arachis hypogaea) and Dolichus biflorus Agglutinins had no affinity for this receptor, whereas Concanavalin A showed strong non-specific adsorption of the applied protein. None of these lectins interfered with the binding of ^{3}H-Imipramine. The results suggest that the carbohydrate moieties are extrinsic to the ligand-binding domain and may be useful for purification of solubilized ^{3}H-Imipramine binding sites.

274.8

NEW EVIDENCE FOR MULTIPLE ANTIDEPRESSANT BINDING DOMAINS IN SEROTONIN TRANSPORTER. J. Chudzik*, D.M. Helmeste and S.W. Tang. Psychopharmacology Unit, Clarke Institute of Psychiatry, Toronto, Canada M5T 1R8.

The interaction of imipramine and paroxetine with the serotonin transport protein provides a useful model for the study of mechanisms of actions of antidepressant drugs. Previous data imply both a single and a two-site binding model for ^{3}H-imipramine and ^{3}H-paroxetine. We have systematically investigated the effects of temperature, various protein and lipid modifying agents, as well as proteolytic, lipolytic and glycolytic enzymatic digestions, on the binding parameters of these two ligands in intact and solubilized platelet membrane preparations. The results clearly suggest that the binding of ^{3}H-paroxetine and ^{3}H-imipramine to the membrane preparations could be differentially manipulated. The presence of multiple binding domains for antidepressant compounds in the serotonin transport protein is proposed. (Supported by Ontario Mental Health Foundation Grant OMHF #1019-88-90).

COMMON EFFECTS OF 5HT REUPTAKE INHIBITORS AND 8-OHDPAT: REVERSAL OF 5HT-1B EFFECTS ON 5HT RELEASE AND SYNTHESIS. M.P. Galloway, E.A.Novak*, B.N.Mathews*, Lafayette Clinic, CCN, Psychiatry, Wayne State Univ Sch Med Detroit MI

We have previously reported that 5HT synthesis in cortical brain slices is inhibited by 5HT-1B, but not 5HT-1A agonists, suggesting that synthesis modulating 5HT autoreceptors are present on 5HT nerve terminals. Although 5HT-1A agonists have no effect on 5HT synthesis in vitro, compounds such as 8-OHDPAT actually block the inhibition produced by 5HT-1B agonists suggesting a possible interaction between 1A and 1B receptor subtypes. We have extended these studies to examine the relationship among 5HT-1 agonists, 5HT release and synthesis (5HTP accumulation after NSD-1015) in cortical slices. TFMPP, a 5HT-1B agonist, induces a 3-5 fold Ca^{++} independent increase in both basal and K^+ stimulated 5HT release. As with 5HT synthesis, the 5HT releasing effect of TFMPP is blocked by 8-OHDPAT, which is without effect by itself. Removal of tryptophan from the media does not block the effect of TFMPP on 5HT synthesis or release, nor does it alter the antagonism afforded by 8-OHDPAT on release. Fenfluramine, a 5HT releaser, promotes 5HT release and inhibits 5HT synthesis, both effects reversed by 8-OHDPAT. 5HT reuptake inhibitors sertraline, imipramine and fluoxetine also blocked the effects of TFMPP on both 5HT release and synthesis. These studies provide functional evidence for an interaction of 5HT-1A and 1B ligands with the 5HT reuptake or transporter site. Support: MH-41227 DA-04120 State of Michigan, DMH.

SEROTONIN (5HT) UPTAKE AND [^{125}I]-CYANOPINDOLOL ([^{125}I]-CYP) BINDING TO $5HT_{1B}$ RECEPTORS IN SPINAL CORD SYNAPTOSOMAL SUBFRACTIONS. I. Matsumoto*, M.R. Combs*, D.J. Jones. Dept. of Anesthesiology, UTHSC, San Antonio, TX 78284-7838

Based on anatomical studies, the percentage of 5HT terminals compared to the overall population of neuronal terminals in spinal cord is small. In order to utilize a cellular fraction enriched in 5HT terminals, the present studies compared presynaptic 5HT uptake and $5HT_{1B}$ receptor binding in subfractions of spinal cord synaptosomes isolated via Percoll gradients of 23, 15, 10 and 3% (Robinson and Lovenberg, Neurochem Int 9:1986).

Electron microscopic analysis indicated enrichment of synaptosomes in the 10-15% interphase (Fraction 3) and 15-23% interphase (Fraction 4). The uptake of [^{3}H]-5HT (fmols/mg protein) in Fraction 3 was 19.25 $\pm$ 1.63, in Fraction 4, 37.50 $\pm$ 1.78 and 6.48 + 0.22 in the crude synaptosomal preparation (P_2). The receptor site labelled by [^{125}I]-CYP in the presence of isoproterenol has been proposed as the autoreceptor which regulates 5HT release (Engel et al, NS Arch Pharmacol 332:1986). Using crude synaptosomal preparations, specific binding of [^{125}I]-CYP in spinal cord averaged around 30%. A comparison of saturation isotherms in crude vs purified subfractions of synaptosomes demonstrated 50-60% specific binding in Fraction 3 with 30-40% specific binding in Fraction 4. Bmax's (fmol/mg protein) in Fractions 3 and 4 and the crude synaptosomal preparation were 113 $\pm$ 7, 79 $\pm$ 11 and 34 + 6, respectively. The Kd's were similar (0.16 $\pm$ 0.22 nM). Displacement of [^{125}I]-CYP binding by 5HT and RU 24969 was monophasic in both the crude preparation and Fraction 3. However, displacement occurred over a range of concentrations from 10^{-8} - 10^{-4} in the crude preparation vs 10^{-8} - 10^{-6} in the purified synaptosomal preparation. Ki's for displacement were the same. It is concluded that purified subfractions can provide a more suitable tissue preparation for studying the neurochemistry of spinal cord 5HT terminals. 274.11

DECREASED ^{125}I-AMIK BINDING TO 5HT2 SITES IN RAT BRAIN FOLLOWING CHRONIC ADINAZOLAM TREATMENT.

F.Lafaille, S. Welner, P. Desjardins*, R.Quirion, B. Suranyi-Cadotte. Douglas Hospital Research Center, Verdun, Canada H4H 1R3

Prolonged antidepressant treatment down-regulates $5HT_2$ binding sites, an effect possibly related to the therapeutic efficacy of these agents in depression. We postulated that adinazolam, a triazolobenzodiazepine with both anxiolytic and antidepressant efficacy may exert part of its action via $5HT_2$ binding sites. We have tested this hypothesis by chronic administration to rats of either adinazolam (4 mg/kg), desipramine (DMI), a classical antidepressant (10 mg/kg) and diazepam , an anxiolytic benzodiazepine (5 mg/kg). Animals were injected i.p. with drugs or vehicle for 21 days. Binding parameters (Kd and Bmax) of 7-amino-8-[^{125}I]-ketanserin ([^{125}I]-AMIK) using homogenates of frontal cortex 24 hours after the last injection were determined according to a modified method of. W. Wouters et al., (Biochem. Pharmacol. 35: 3199-3202). Chronic DMI treatment elicited a significant, 25% reduction in the density (Bmax) of [^{125}I]-AMIK binding sites without altering Kd values. Adinazolam, like DMI produced a 27% reduction in Bmax values, whereas diazepam an anxiolytic agent devoid of antidepressant activity produced an increase by 21% in the number of [^{125}I]-AMIK binding sites following chronic treatment. These results confirm previous reports that chronic antidepressant treatment can decrease the density of $5HT_2$ binding sites and suggest that this mechanism may also be operative in the antidepressant activity of adinazolam.

274.12

MODULATION OF 5-HT1A BINDING SITE AFFINITY BY MAO INHIBITION. R. Mongeau, S. Welner, R. Quirion, C. de Montigny, Y. Chaput and B.E. Suranyi-Cadotte. Douglas Hospital Research Center and Dept. Psychiatry, McGill Univ., Montreal, Canada H4H 1R3.

The purpose of the study was to investigate the effect of MAO inhibition on [3H]-8-OH-DPAT binding which specifically label 5-HT1A receptors. [3H]-8-OH-DPAT binding was performed as previously described by Peroutka et al. (J. Neurochem., 47, 1986). Specific binding was defined using 10 uM 5-HT and represented 80-90 % of the total binding. Radioligand concentrations ranging from 0.3-10 nM identified a single population of sites, however,a tendency toward a second site was observed. When the range was expanded to 100 nM ,this tendency was confirmed with a ten-fold difference between the affinity of the two sites; this represented statistically a better fit than the one site model. Biphasic scatchards have already been reported in cerebral cortex (Hall et al.,J. Neurochem.,44,1985); we now report similar results in hippocampus and striatum.

Monophasic curves with loss of the high affinity component were observed following chronic (21 day) and acute MAO A inhibition by clorgyline (1 mg/kg),as well as by the addition of this compound to the preincubation membrane preparation. A blockade of the high affinity component by endogenous 5-HT cannot, however,explain this effect,since inhibition of [3H]-8-OH-DPAT by nM concentations of 5-HT did not affect the curvilinearity of the scatchards. The mechanism and the clinical relevance of this modulation is under further investigation.

274.13

EFFECT OF CHRONIC ANTIDEPRESSANT TREATMENTS ON SEROTONIN$_{1A}$ (5HT$_{1A}$) RECEPTOR DENSITY AND RESPONSIVENESS. J. Hensler & A. Frazer, Dept. Psychiatry, Univ. of Pennsylvania & VA Med. Ctr., Philadelphia, Pennsylvania 19104.

Chronic treatment of rats with monoamine oxidase inhibitors (MAOIs) or 5HT uptake inhibitors produces subsensitivity of responses elicited by somatodendritic autoreceptors in the dorsal raphe nucleus and a diminished serotonin behavioral syndrome or hypothermia in response to 5HT$_{1A}$ receptor agonists. In agreement with this, we have found that DPAT (1mg/kg, sc) produced a decrease in body temperature of 1.3±0.6°C (n=7) in rats injected chronically with saline but only 0.5±0.4°C in rats treated for 21 days with the MAOI tranylcypromine (5mg/kg, qd; ip, n=7). Chronic treatment of rats with either trazodone or DMI did not alter the hypothermic response to DPAT. Experiments were done to determine whether subsensitive responsiveness is mediated by changes in the binding of ^{3}H-DPAT to 5HT$_{1A}$ receptors as measured by quantitative autoradiography. Chronic administration (14-21 days) of 5HT uptake inhibitors (citalopram or sertraline) or MAOIs (phenelzine or clorgyline) did not alter the binding of ^{3}H-DPAT (1nM) to 5HT$_{1A}$ receptors in the dorsal or median raphe nuclei or regions of the frontal cortex, hippocampus or hypothalamus. From these data, it may be inferred that decreased sensitivity of 5HT$_{1A}$-mediated responses may not result from decreased density of 5HT$_{1A}$ receptors but probably occurs through some other mechanism. **(Supported by Vet. Admin. & USPH grants MH14654 & GM34781.)**

AGE-RELATED ALTERATIONS IN 5-HT$_1$-LIKE AND ADENOSINE A$_1$ RECEPTOR SYSTEMS IN THE CNS OF FISCHER 344 RATS.

C. D. Mahle[1], D. P. Healy[1] and S. Maayani[1,2]. Depts. Pharmacology[1] and Anesthesiology[2], Mt. Sinai Sch. of Med., CUNY, New York, NY 10029.

Different membrane components of signal transduction may be affected by age. To test whether receptors, their coupling to G-proteins or their effectors are altered by age, membrane receptor systems (receptor/G-protein/effector) in Fischer 344 rat CNS were examined by three assays: functional (inhibition of forskolin-stimulated adenylyl cyclase, FSAC; "response"), occupancy (quantitative receptor autoradiography) and modulation of occupancy by guanyl nucleotides. Three Gi-linked membrane receptors, the adenosine A$_1$ (AD A$_1$), the 5-HT1$_A$, and the 5-HT$_1$-like, ("non-5-HT1$_A$"), were studied in 3 and 23 month-old animals, using their respective agonists, (R)-phenylisopropyladenosine (PIA), 8-hydroxy-2-(di-n-propylamino)-tetralin (DPAT) and 5-HT. Similar to reported observations in Sprague-Dawley rats, the receptor systems are differentially distributed across the Fischer rat CNS. In membrane preparations, the response to 5-HT (5-HT$_1$-like receptor) and PIA were region dependent, and the former showed age-related, region dependent decreases. Occupancy of AD A$_1$ and 5-HT$_{1A}$ receptors and their attenuation by 5'-guanylimidodiphosphate (Gpp(NH)p) (100 uM) and NaCl (1 mM) appeared to be receptor, region, and age dependent. These two receptor systems may serve as a model to study age-related alterations in receptor systems that may play a role in the pathophysiology of CNS aging. (Supported by USPH GM 34852 and HL 42585).

DEVELOPMENTAL CHANGES IN THE 5-HT$_3$ RECEPTOR OF NG108-15 CELLS. M.X. Shao, J.L. Yakel, and M.B. Jackson. Department of Biology, UCLA, Los Angeles CA 90024-1606.

NG108-15 cells, a rat glioma-mouse neuroblastoma somatic cell hybrid, undergo morphological differentiation when PGE$_1$ and theophylline are added to the culture medium. This cell line is also a useful system for the study of the 5-HT$_3$ receptor, which is found in both central and peripheral mammalian nervous systems. We have used whole-cell patch-clamp techniques to compare the responses mediated by the 5-HT$_3$ receptor in differentiated and undifferentiated NG108-15 cells, and have found that a number of changes in receptor function accompany morphological differentiation. These changes include a reduction in the rate of desensitization, an increase in the voltage dependence of desensitization, and an increase in the mean response amplitude. There may also be changes in the curvature of the current-voltage curve and in the susceptibility of the receptor to modulation of desensitization. The desensitization of the 5-HT$_3$ receptor in primary cultured neurons is also voltage dependent. Thus, the increased voltage dependence of desensitization is consistent with the morphological change in that it represents the acquisition of a neuronal characteristic. The changes we observed in the 5-HT$_3$ receptor indicate that it has different functional forms which are expressed in a manner that corresponds with different stages of development. This may also reflect the existence of different subtypes of the 5-HT$_3$ receptor.

NICOTINIC RECEPTORS

275.1

CRYSTALS OBTAINED FROM PREPARATIONS OF NICOTINIC ACETYLCHOLINE RECEPTOR FROM TORPEDO ELECTRIC TISSUE. Hucho, F.*, and Hertling-Jaweed, S.* (SPON. W.Huttner). Institut für Biochemie, Freie Universität Berlin, Thielallee 63, looo Berlin 33.

Crystals were obtained from preparations of nicotinic acetylcholine receptors in detergent solutions. The receptors were prepared by a novel procedure avoiding affinity columns. This procedure allows large scale purification of receptor protein in mg quantities within two days. The conditions are chosen to preserve the receptor's activity and to obtain a homogeneous population of undenatured receptor molecules. Crystals appeared reproducibly and abundantly within three days. They had the shape of rods of about 25 /um length with a hexagonal cross-section of about 8 /um. They are too small yet for X-ray diffraction. Their abundance but not their phenotype is affected by the crystallization conditions, especially by the type of detergent used for solubilization.

275.2

CHARACTERIZATION OF THE NICOTINIC ACETYLCHOLINE RECEPTOR OF *MANDUCA SEXTA*. M.L. Perez and D.J. Prescott*, Biology Dept., Bryn Mawr College, Bryn Mawr, PA 19010.

The CNS of *Manduca sexta* is responsive to bath applied cholinergic ligands but is less sensitive to nicotine than is *Periplaneta americana* CNS (C. Morris, J. Exp. Zool. 229: 361-374, 1984). We are characterizing the receptor in *Manduca* cerebral ganglia to determine if it is a variant type as has been suggested (C. Morris, Ibid.). The Triton X-100 solubilized receptor forms complexes with monoiodinated α-bungarotoxin. The DEAE filter disk assay is used to follow complex formation (Schmidt, J. and Raftery, M.A., Anal. Biochem. 52: 349-354, 1973). Nicotinic ligands such as methyllycaconitine, dihydro β erythroidine, curare and nicotine are effective competitors of α-toxin binding. Also, strychnine and bicuculline are effective competing ligands illustrating binding correlates to the molecular homology seen within the ligand-gated channel superfamily. The competition binding curves for dihydro β erythroidine, methyllycaconitine and especially nicotine exhibit unusually shallow slopes over a concentration range of several orders of magnitude. The shallow slopes may indicate a heterogeneity of affinities within the two ligand binding areas of the receptor and explain the insensitivity to nicotine.

The preliminary results of structural studies show a monomer which has a sedimentation coefficient which corresponds to a M_r of 300,000. The curare eluate of the toxin-affinity column shows four polypeptides on non-denaturing gel electrophoresis and two major polypeptides on denaturing gel electrophoresis. These results indicate the receptor is composed of hetero-oligomers.

BIOCHEMICAL CHARACTERIZATION OF A NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR FROM DROSOPHILA. P.Wu*, X.Mai*, J.Wu*, X.Chang*, L.C.Yang*, H.Meones*, S.Bobin* and T.Schmidt-Glenewinkel*. Department of Biological Sciences, Institute for Biomolecular Structure and Function, Hunter College of CUNY, New York, NY 10021

The central nervous system of Drosophila contains an α-bungarotoxin binding site with the properties expected of a nicotinic acetylcholine receptor. The receptor was purified 5500-fold by affinity chromatography. Sodium dodecyl sulfate polyacrylamide gel electrophoresis revealed four subunits with apparent molecular weights of 42000, 57000, 65000, and 79000. Polypeptides of identical size were also identified by in situ photoaffinity labeling of the membrane fraction. The receptor has a $s_{20,w}$ of about 9.5 and a Stoke's radius of 7.4nm. The frictional coefficient was calculated to be 1.7 indicating a highly asymmetrical protein complex. From sedimentation analysis in H_2O and D_2O a molecular weight of 270000 was determined. The individual polypeptides were blotted on a nitrocellulose membrane, digested with trypsin and subjected to internal amino acid sequence analysis. Screening of cDNA library from heads of Drosophila with mixed oligonucleotide probes derived from the amino acid sequence allowed identification of several cDNA clones.

ACETYLCHOLINE RECEPTOR TRANSCRIPTS ARE COMPARTMENTALIZED IN NUCLEI OF MYOTUBES. S.Bursztajn[1], S.Berman[2], and W.Gilbert[3]. [1]Baylor College of Medicine, Houston, Tx. 77030; [2]University of Chicago, Chicago, Il. 60637; [3]Harvard University, Cambridge, Ma. 02138

We have previously demonstrated that not all nuclei of the multinucleated skeletal myotube are equally active in expressing the acetylcholine receptor (AChR) α subunit message. In order to further understand AChR transcript processing within individual nuclei we have used in situ hybridization, while simultaneously staining nuclei with bisbenzamide to localize the position of intron and exon RNA sequences in intact cells with respect to the nuclei. We employed probes for chicken AChR exon #2 and intron #1 (Fontaine, B and Changeux, J. Cell Biol. 108: 1025-1037, 1989). For comparison we used actin intron and exon sequences as well as a sequence for U1 small nuclear RNA. We made ^{35}S labelled single stranded probes and hybridized these in situ to cultured chick embryonic muscle cells.

The cells hybridized with the AChR α subunit intron probe showed a striking perinuclear localization characterized by grains confined to the periphery of the nuclei, frequently forming a ring. Both the actin and AChR exon showed a uniform cytoplasmic distribution whereas the actin intron and U1 probes showed a homogeneous grain distribution within nuclei. Quantitative analysis showed variations in the level of activity among nuclei of cells hybridized with the AChR intron and actin intron but no significant differences were observed when cells were hybridized with U1 probes. Our data indicates that the AChR α subunit intron is compartmentalized in the myotube nuclei.

TE671 CELLS EXPRESS AN ABUNDANCE OF UNASSEMBLED α SUBUNITS OF THE HUMAN MUSCLE ACETYLCHOLINE RECEPTOR WHICH HAVE PROPERTIES OF AN ASSEMBLY INTERMEDIATE. William G. Conroy* and Jon Lindstrom. The Salk Institute, La Jolla, CA 92037

The muscle-type nicotinic acetylcholine receptor (AChR) is composed of four homologous subunits which assemble into an $\alpha_2\beta\gamma\delta$ pentamer which forms an ACh-gated ion channel. The α subunit, before assembly, goes through a maturation process in which it acquires the conformation for binding α-bungarotoxin (α-Bgt) and antibodies to the main immunogenic region (MIR). Whether the maturation process involves covalent modification and/or conformational changes of the α subunit is unknown.

We have found that TE671 cells express an abundance of unassembled α subunits of the human AChR which have properties of an assembly intermediate. Sucrose gradient density sedimentation analysis of Triton X-100 extracts of TE671 cells indicates the presence of a 5S species which binds α-Bgt and MIR-specific monoclonal antibodies (mAbs). The conformation of this α subunit was compared and contrasted to the α subunits of native TE671 AChRs by analyzing the binding of α-Bgt, mAbs, and the small ligands d-tubocurarine and carbamylcholine. The unassembled α subunit has lower affinity for α-Bgt (Kd = 0.6 nM) than the native AChR (Kd = 0.1 nM) and has negligible affinity for d-tubocurarine or carbamylcholine ($K_i > 10^{-2}$ M). These binding properties are similar to the assembly intermediate identified in BC3H-1 cells and rat myotubes. Thus, the TE671 cell line may be a useful model for studying the conformational changes which take place during the maturation of the α subunit of AChRs.

275.6

A SYNTHETIC PEPTIDE (RESIDUES 172-227) OF THE α-SUBUNIT OF THE NICOTINIC ACETYLCHOLINE RECEPTOR (AChR) CONTAINS BINDING SITES FOR COMPETITIVE ANTAGONISTS AND NONCOMPETITIVE INHIBITORS (NCIs). D. L. Donnelly-Roberts*, M. Gastka* and T. L. Lentz. Dept. of Cell Biology, Yale University School of Medicine, New Haven, CT 06510.

A 56 residue peptide (172-227) (α56mer) from the α-subunit of the AChR was synthesized because it contains a region (172-204) previously shown to bind α-bungarotoxin (α-Btx) and it contains the first 18 residues of the first transmembrane spanning region (M1). α-Btx bound to the α56mer in a solid phase assay. Binding was markedly enhanced by .02% sodium dodecyl sulfate (SDS) and was competed by d-tubocurarine. Equilibrium saturation binding experiments in the presence of SDS revealed an apparent K_D of 3.5 nM for α-Btx. The NCI, [^{3}H]phencyclidine (PCP) was photolabeled to the α56mer. PCP binding was saturable and inhibited by unlabeled PCP, chlorpromazine and tetracaine. Saturation binding experiments revealed two saturable sites, high and low affinity, for [^{3}H]PCP. The binding of [^{3}H]PCP to the receptor peptide was also enhanced by .02% SDS. These studies demonstrate that this 56 residue region contains sites for both the antagonist, α-Btx, and an NCI, [^{3}H]PCP, supporting the suggestion (Dipaola et al., 1986 Neurosci. Abstr. 12:961) that these sites are tightly coupled and part of one functional domain. Supported by NIH NS21896 and the Osserman/McClure Fellowship of the Myasthenia Gravis Foundation.

NICOTINIC ACETYLCHOLINE RECEPTORS AND N-GLYCOSYLATION REQUIREMENTS. V.M. Gehle*, R. Miledi, and K. Sumikawa. Lab. of Cellular and Molecular Neurobiology, Dept. of Psychobiology, Univ. of Calif., Irvine, CA 92717.

The role of N-glycosylation in the function, assembly, and membrane insertion of nicotinic acetylcholine receptors (nAChR) was studied using the Xenopus oocyte as an expression system. Initially, oocytes were injected with normal subunit mRNAs and incubated with tunicamycin. These oocytes showed reduced responses to acetylcholine (ACh). Biochemical data indicates this may have been at least partially due to inefficient insertion of the receptors into the plasma membrane, but was not attributable to a lack of assembly of the subunits.

To further study this problem, we also expressed mutant nAChRs by injection of various combinations of mutant (lacking N-glycosylation consensus sequences) and normal subunit mRNAs into oocytes. Data from cells injected with normal β, γ, δ, and mutant α subunit mRNAs indicate that mutant α subunits can assemble with normal β, γ, and δ subunits, but the resultant receptors are not inserted into the plasma membrane. Oocytes injected with normal α, β, γ, and mutant δ subunit mRNAs show responses to ACh which are smaller than those of control oocytes. Since assembly occurs with the mutant δ subunits, the reduced response may also be due to inefficient insertion. These results support the conclusions derived from the earlier experiments with tunicamycin. (Supported by NIMH Training Grant MH14599, NIH grants NS25928 and NS 23284, and the Muscular Dystrophy Association)

THE HYDROPHOBIC PHOTOREAGENT 3-(TRIFLUOROMETHYL)-3-(m-[^{125}I]IODOPHENYL)DIAZIRINE ([^{125}I]TID) AFFINITY LABELS A UNIQUE SITE ON THE TORPEDO NICOTINIC ACETYLCHOLINE RECEPTOR (AChR). B.H. White* and J.B. Cohen. Dept. of Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Studies of [^{125}I]TID photolabeling of AChR in Torpedo postsynaptic membranes indicate that this compound specifically labels the AChR at a site (or sites) distinct from, but probably coupled to, the agonist and noncompetitive antagonist binding sites (White, B.H. and Cohen J.B., Biochemistry, 27:8741, 1988). To further characterize the binding of [^{125}I]TID we have studied the effects of nonradioactive TID on [^{125}I]TID photolabeling of the AChR and on the binding of tritiated cholinergic agonists and noncompetitive antagonists to Torpedo membranes. We find that nonradioactive TID inhibits [^{125}I]TID photolabeling with an IC_{50} of 10 μM and that specific photoincorporation saturates at 0.6 moles of TID per mole of AChR. Since [^{125}I]TID specifically labels all AChR subunits, this suggests a single TID site per AChR lying in close proximity to all subunits, probably within the central pore. We further find that TID causes a (maximal) five-fold increase in the K_D of [^{3}H]histrionicotoxin providing direct evidence for allosteric coupling of the noncompetitive antagonist and TID binding sites. A smaller inhibitory effect of TID is noted on the binding of agonists. We conclude that the AChR contains a central hydrophobic binding site for [^{125}I]TID that is distinct from, but linked to, the agonist and noncompetitive antagonist binding sites.

IDENTIFICATION OF NICOTINIC RECEPTORS ON CULTURED CORTICAL NEURONS USING ANTI-IDIOTYPIC ANTIBODIES. P.M. Lippiello, K.G. Fernandes*. Research and Development Dept., R.J. Reynolds Tobacco Co., Winston-Salem, NC 27102 and J.J. Langone*, R.J. Bjercke*. Baylor College of Medicine, Houston, TX 77030.

Based on the binding of L-[3H] nicotine to cell membrane preparations,we previously reported the presence of putative high-affinity nicotinic receptors on cultured neurons derived from fetal rat brain. (Lippiello and Fernandes, J. Pharmacol. Exp. Ther. 246:409, 1988). In the present studies we have identified these sites on intact cells by indirect immunofluorescence, using two anti-idiotypic monoclonal antibodies (422F11, 422G11) that represent the internal image of nicotine. Primary monolayer cultures of cortical neurons were fixed with 4% paraformaldehyde, followed either by incubation with L-[3H] nicotine (to assess receptor binding properties) or by successive incubations with anti-idiotypic antibodies and rhodamine-conjugated anti-mouse IgG (to determine the locations of cell-surface receptors). The affinity, kinetic binding properties and pharmacological specificity of cell-associated receptors were the same as those previously determined for cell membrane preparations and adult brain tissue. Approximately 10-20 % of the cells exhibited specific staining with both anti-idiotypes. Neurons with bipolar and pyramidal morphology exhibited the most intense fluorescence, primarily at the distal portion of cellular processes. No staining of glial cells was observed. The specificity of both anti-idiotypes was indicated by their ability to completely block the binding of L-[3H] nicotine to the receptors. Binding was not blocked by the myeloma protein MOPC. The snake toxins, alpha- and kappa-bungarotoxin, did not block the binding of either anti-idiotype to cells. The results suggest that anti-idiotypic antibodies to nicotine may provide appropriate structural, and possibly functional probes that are specific for high-affinity nicotinic receptors in mammalian brain.

CO-LOCALIZATION OF PHOSPHOTYROSINE WITH THE NICOTINIC ACETYLCHOLINE RECEPTOR AT THE RAT NEUROMUSCULAR JUNCTION Z.Qu* and R.L.Huganir. HHMI, Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

The nicotinic acetylcholine receptor (nAChR) is a ligand gated ion channel which has served as an excellent model system for the study of the structure, function and regulation of neurotransmitter receptors and ion channels. The nAChR is phosphorylated by cAMP-dependent protein kinase, protein kinase C and by a protein tyrosine kinase on a total of seven different phosphorylation sites. We have previously demonstrated that the nAChR isolated from Torpedo californica electroplax is highly phosphorylated on tyrosine residues. In contrast, the nAChR isolated from rat primary muscle cell cultures has a very low level of tyrosine phosphorylation. To examine whether tyrosine phosphorylation of the nAChR in muscle requires some signal from the nerve that is not present in the primary muscle cell cultures, we have used immunocytochemical techniques with affinity purified antibodies against phosphotyrosine to examine tyrosine phosphorylation in intact skeletal muscle. Immunofluorescent labelling of frozen sections of rat diaphragm with anti-phosphotyrosine antibodies shows specific intense labelling of the neuromuscular junction which directly co-localizes with the nAChR at the postsynaptic membrane. These results suggest that the nAChR is highly phosphorylated on tyrosine residues at the neuromuscular junction. The effect of denervation and development on tyrosine phosphorylation is currently being investigated.

275.11

SITE-SPECIFIC MUTAGENESIS OF THE PHOSPHORYLATION SITES OF THE NICOTINIC ACETYLCHOLINE RECEPTOR. P.Hoffman*, K.L.Choi*, P.Kienker*, G.Yellen and R.L.Huganir. HHMI, Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

The nicotinic acetylcholine receptor (nAChR) is a ligand gated ion channel which has served as an excellent model system for the study of the structure, function and regulation of neurotransmitter receptors and ion channels. The nAChR is phosphorylated by cAMP-dependent kinase, protein kinase C and a protein tyrosine kinase on seven different phosphorylation sites. The phosphorylation of the nAChR by all three of these protein kinases has been reported to modulate the rapid phase of receptor desensitization. We have now removed the known phosphorylation sites by site specific mutagenesis and have expressed these mutants (0phos receptor) in Xenopus oocytes. Wild type nAChR expressed in Xenopus oocytes is phosphorylated on the gamma and delta subunits. Peptide maps of the phosphorylated gamma and delta subunits are consistent with these subunits being phosphorylated at the known cAMP-dependent protein kinase sites. Expression of the 0phos receptor subunits in Xenopus oocytes produces a functional receptor, which is not phosphorylated, with single channel properties similar to the wild type channel. The 0phos receptor still displays slow desensitization in response to prolonged exposure to acetylcholine. These results suggest that although phosphorylation of the nicotinic receptor may regulate the rate of desensitization, it is not an absolute requirement for desensitization.

MEMBERS OF THE NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR FAMILY DISPLAY DISTINCT PHARMACOLOGICAL AND TOXICOLOGICAL PROPERTIES. C. W. Luetje* and J. W. Patrick. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

A family of genes has been identified which encode subunits of nicotinic acetylcholine receptors (nAChR) expressed in the brain. The alpha2, alpha3 and alpha4 subunits can each form functional nAChR when expressed in *Xenopus* oocytes in combination with the beta2 subunit (Boulter et al., 1987, P.N.A.S. 84: 7763; Wada et al., 1988, Science 240: 330). We find that these neuronal nAChR each possess distinct pharmacological and toxicological properties. Neuronal subunit combinations, as well as subunits encoding the muscle nAChR, were expressed in *Xenopus* oocytes and studied under two electrode voltage clamp. The nicotinic antagonist dihydrobetaerythroidine (DHBE) more effectively blocks the alpha4-beta2 receptor than the alpha2-beta2 receptor (16 fold difference in IC50), the alpha3-beta2 receptor (27 fold difference) and the muscle nAChR (at least a 200 fold difference). Neosurugatoxin is 100 fold more effective in blocking neuronal nAChR responses than muscle nAChR responses. Neuronal bungarotoxin blocks the alpha3-beta2 receptor 100 fold more effectively than the alpha4-beta2 receptor, while the alpha2-beta2 is insensitive to this toxin. These results demonstrate that homologous but distinct members of the neuronal nAChR alpha subunit gene family encode subunits with distinct functional properties.

EXPRESSION OF NEURAL NICOTINIC RECEPTOR SUBUNIT GENES IN GOLDFISH RETINA AND TECTUM. K.A. Cauley*, B.W. Agranoff and D. Goldman. Mental Health Research Institute and the Dept. of Biological Chemistry, University of Michigan, Ann Arbor, MI 48109.

Nicotinic Acetylcholine receptors (nAchRs) are expressed in the vertebrate retina. The numbers of different types of receptors, their cellular distribution, and their function within the retina, is not known. We have begun addressing these issues by characterizing cDNA clones encoding neural nAchR subunits isolated from a goldfish retinal cDNA library. One of these clones, referred to as goldfish non-alpha 2 (GFnα-2), was found to encode a putative structural subunit of the nAchR. The GFnα-2 gene is expressed predominantly by the ganglion cells of the retina (Cauley et. al., J. Cell Biol. 108:637, 1989). Here we report the identification of a second novel nAchR structural subunit sequence, GFnα-3, and a partial sequence of a ligand binding subunit, GFα-3, believed to be the goldfish homologue of the rat α-3 clone (Boulter et. al., Nature 319:368, 1986). In situ hybridization reveals that, like GFnα-2, the GFnα-3 and GFα-3 genes are expressed by the ganglion cells. However, GFnα-3 is expressed at a significantly higher level by cells of the inner-nuclear layer. In the tectum, which recieves synaptic input from the retinal ganglion cells, we find low expression of the GFα-3 and GFnα-2 genes. GFnα-3 is expressed throughout the tectum with highest levels of expression in the deepest layers. These data indicate that multiple types of neural nAchRs are expressed in retina and tectum.

275.14

IN SITU HYBRIDIZATION IDENTIFIES MEMBERS OF THE NICOTINIC RECEPTOR GENE FAMILY EXPRESSED IN DEVELOPING AND ADULT RAT RETINA F. Hoover* and D. Goldman (SPON: S. Easter). Department of Biological Chemistry and Mental Health Research Institute, University of Michigan, Ann Arbor MI, 48109.

Expression of neural nicotinic acetylcholine receptor (nAChR) subunit genes in the rat retina has been determined using c-RNA *in situ* hybridization techniques. Three members of the nAChR family have been investigated; two ligand binding subunit genes, α-3 and α-4 (Boutler *et al.*, Nature, 319:368, 1986 and Goldman *et al.*, Cell, 48:965, 1987) and a structural subunit gene, β-2 (Deneris *et al.*, Neuron, 1:45, 1988).

In the adult rat retina, these genes are expressed heterogeneously in the ganglion cell layer (GCL) and inner nuclear layer (INL). In the GCL, which consists of both ganglion and amacrine cells, approximately half of the cells contain detectable levels of α-3 RNA, while the majority of the cells contain α-4 and β-2 RNA. In the INL, which consists of predominantly amacrine cells, high levels of α-4 and β-2 RNA but low levels of α-3 RNA are found. *In situ* hybridization was used to investigate when nAChR genes are expressed during retinal development. At the earliest experimental time point studied (embryonic day 18), α-3, α-4 and β-2 genes are expressed by neuroblasts and post-mitotic cells, with the highest level of RNA found in cells closer to the inner wall of the retina. Many of these cells are likely to represent ganglion or amacrine cells. At postnatal day 1 (PN1), when a distinct GCL has been formed, α-3, α-4 and β-2 RNA levels are highest in this layer. From PN4-PN12, when ganglion cell death is occurring, nAChR gene expression gradually becomes adult-like.

These data indicate that multiple nicotinic receptor systems are used in the mammalian retina.

275.15

THE DEVELOPMENT OF ACH RESPONSES ON CHICK CILIARY GANGLION NEURONS IS NOT DEPENDENT ON THE TARGET.
K.L. Engisch* and G.D. Fischbach. Dept. of Anat. and Neurobiol., Wash. Univ. Sch. Med., St. Louis, MO 63110.

ACh responses on chick ciliary ganglion (CG) neurons increase in two discrete steps during development. A 2-fold increase in ACh responses occurs between embryonic day 8 (E8) and E9; a 3-fold increase between E14 and E18. Both occur after the establishment of 100% ganglionic transmission.

We investigated whether the development of ACh responses on embryonic CG neurons is dependent upon interaction with their target by removing the primordial eye on E2. Cells were dissociated from "eye-less" ganglia and studied 3-6 hours after plating. Neurons were clamped to -50 mV in the whole-cell configuration of the patch-clamp technique and ACh (250 μM) was applied by pressure-ejection. Peak ACh-induced currents in neurons that develop without target structures are reduced by 1.5-fold as early as E7, prior to the period of cell death. Responses of target-deprived neurons increase 2.7-fold between E7 and E10, and 3.5-fold between E12 and E18. The 1.2-1.5-fold reduction throughout development following target removal is not specific to ACh responses: GABA currents, voltage-activated G_{K+} and cell size are all reduced by a similar proportion in target-deprived neurons.

There is no profound effect of target removal on the ACh responses of embryonic neurons. This is in contrast to the 8-fold reduction in ACh sensitivity following axotomy of adult chick ciliary ganglion neurons.

275.16

TOXINS OF *CONUS* MARINE SNAILS BIND THE NICOTINIC ACETYLCHOLINE RECEPTOR AT SITES NOT IDENTICAL TO THOSE OF TRADITIONAL ANTAGONISTS.
R. A. Myers* (SPON: B. Olivera) Dept. of Biology, University of Utah, Salt Lake City, UT 84112.

The fish-hunting cone snails use venom to subdue their more agile prey. Paralysis is achieved with "conotoxins" against a multitude of neuronal and muscle receptors, including both voltage-activated Ca^{++} and Na^{+} channels, and the nicotinic acetylcholine receptor (nAChR) (Olivera et al. (1985) *Science* 230, 1338-1343). The α-conotoxins are a class of small (13-19 amino acids), basic, and homologous peptide antagonists of the nAChR which are lethal upon intraperitoneal injection in mice. α-Conotoxins compete for all α-bungarotoxin (BTX) and d-tubocurarine binding sites of the nAChR. However, there is evidence that the α-conotoxin's binding sites are not identical with those of other cholinergic antagonists. For example, α-conotoxin does not compete with BTX for binding to the 32 amino acid BTX-binding fragment of the α subunit (Wilson et al., (1985) *Proc. Natl. Acad. Sci. USA* 82, 8790-8794). Furthermore, crosslinking of α-conotoxin to the nAChR with bifunctional reagents of decreasing (12-, 8-, and 4-atom) tether lengths labels the β and γ subunits with increasing selectively. Photoaffinity labeling tags these subunits exclusively. The α subunit, putative site of cholinergic ligand binding, is not significantly labeled. Photolabeled segments have been preliminarily localized to segments β138-213 and γ121-183. These results suggest that the α-conotoxin binding site is distinct from those of other cholinergic ligands, and that with their smaller size, α-conotoxins are potentially sensitive probes of nAChR fine structure.

275.17

INTERACTIONS OF ANATOXIN-a ANALOGUES WITH NEURONAL ACETYLCHOLINE RECEPTORS.
S Wonnacott[1], S Jackman[1]*, VB Cockcroft[1]* RS Aronstam[2], H Rapoport[3]*, KL Swanson[4] & EX Albuquerque[4], [1]Dept Biochem, Univ Bath, BATH, BA27AY, U.K; [2]Dept Pharm Toxicol, Med Coll GA, Augusta, GA 30912; [3]Dept Chem, Univ CA, Berkeley CA 94720; [4]Dept Pharm Exp Ther, Univ MD Sch Med, Baltimore, MD 21201.

(+)Anatoxin-a (AnTx), a potent, stereospecific nicotinic agonist, has a semi-rigid structure that makes it attractive for structure-activity studies. Synthetic analogues of AnTx have been compared in ligand binding assays for cholinergic receptors in rat brain. The rank order of potency was the same at both [^{3}H]nicotine and [^{125}I]αBgTx binding sites: **AnTx > dihydro-AnTx = AnTx-methylester > AnTx-dimethylamide = dimethyl-AnTx = AnTx-al = AnTx-ol = AnTx-ol-O-methyloxime = αhydroxy-AnTx > nor-AnTx-ol = N-methyl-AnTx acid methyl ester.** All compounds were two orders of magnitude more potent at [^{3}H]nicotine sites than at [^{125}I]αBgTx sites. Interestingly, the potency at brain αBgTx sites correlated with binding to muscle nAChR.

With respect to functional groups involved in agonist recognition (the secondary amine and the conjugated carbonyl), N-methylation coupled with removal of >C=O results in total loss of binding, shown by (S)- and (R)N-methyl-AnTx-ol, whereas either change alone does not eliminate binding. These studies are being used to define acetylcholine binding sites in the CNS.

Supported by MRC Grant G8722675N and NATO Award 0243/87.

THYMOPOIETIN COMPETES WITH α-BUNGAROTOXIN FOR ITS BINDING SITE IN BRAIN SECTIONS: AN AUTORADIOGRAPHIC STUDY.
R. Afar*, P.B.S. Clarke*, T. Audhya*, G. Goldstein* and M. Quik. Dept. Pharmacol., McGill U., Montreal, Canada & Immunobiol. Res. Inst., Annandale, NJ.

Studies in neuronal tissues now suggest that the α-bungarotoxin (α-BGT) receptor is distinct from the neuronal nicotinic acetylcholine receptor, at least in some species. Recent studies in our laboratory have shown that thymopoietin (Tpo), a thymic peptide, can block α-BGT binding to rat brain membranes, possibly implicating a role for this polypeptide at this receptor. As an extension of this work, the interaction of Tpo with the α-BGT receptor was investigated in unfixed 20 μm thick rat brain sections. A dose-dependent inhibition of ^{125}I-α-BGT binding was observed with Tpo (IC_{50}=6 nM); this was similar to results obtained with non-radioactive α-BGT. The inhibitory effect of Tpo was not mimicked by splenin, a peptide differing in only 1 amino acid in its active site from Tpo. In contrast to its effects at the α-BGT receptor, Tpo ($\leq$1 μM) did not affect high affinity ^{3}H-nicotine binding to brain sections. Autoradiographic analysis of a number of brain areas provided no evidence for regional variation in the inhibitory effect of Tpo on ^{125}I-α-BGT binding. Thus Tpo can interact with the α-BGT binding protein in brain.

275.19

AGMATINE ACTS AS AN ANTAGONIST OF NICOTINIC RECEPTORS.
R.H. Loring and Y. Xie* Dept. of Pharmacology, Northeastern University, Boston, MA 02115

^{3}H-Agmatine is a cation at a physiological pH and has been used by others in ion flux methods to demonstrate nicotinic receptor function in neurons (e.g. Yoshikami, D. Science, 212:929, 1981). However, at high concentrations, we find that agmatine blocks nicotinic receptor function in both the chick retina and the rat superior cervical ganglion. In intact chick retina, 1 mM agmatine decreases depolarizations measured from the optic nerve that are induced by the nicotinic agonist, dimethylphenylpiperazinium (DMPP, 100 μM) by approximately 70%. In contrast, 5 mM agmatine has little or no effect on depolarizations in the retina induced by the glutamate analogs kainic acid or quisqualate (100 μM each), suggesting that agmatine selectively affects the nicotinic receptor. DMPP dose-response curves are reduced in a manner consistent with a non-competitive effect of agmatine. Furthermore, agmatine at 1 mM does not prevent binding of ^{125}I-neuronal bungarotoxin, a snake venom neurotoxin that competitively binds to functional nicotinic receptors in chick retinal homogenates (Loring et al., J. Neurosci., in press).

Agmatine influx has been used to demonstrate activation of nicotinic receptors in the rat superior cervical ganglion (SCG) at concentrations of 1-3 μM ^{3}H-agmatine (Quik, M., Brain Res., 325:79, 1985). However, 10 mM agmatine substantially blocks both DMPP-induced depolarizations of the rat SCG (80%) and synaptic transmission through the ganglia. These data raise the possibility that although agmatine is a cation that will traverse the channel of neuronal nicotinic receptors, agmatine also acts as a weak blocker of the open channel in a manner similar to hexamethonium or high concentrations of acetylcholine (e.g. Sine, S.M. and Steinbach, J.H., Biophys. J., 46:277, 1984). Supported by NIH grant NS22472.

A SERUM FACTOR MODULATES AGONIST ACTIVITY AT FUNCTIONAL NICOTINIC ACETYLCHOLINE RECEPTORS EXPRESSED BY THE PC12, SH-SY5Y AND TE671 CLONAL LINES.
Linda Lucero* and Ronald J. Lukas (SPON. T.J. Tarby). Division of Neurobiology, Barrow Neurological Institute, Phoenix AZ 85013.

Studies were initiated toward the identification of neuroactive substances that might act as cofactors in the regulation of nicotinic acetylcholine receptor (nAChR) function, which was assessed in clonal cell lines using a 86-Rb efflux assay. In the presence of as little as 1% horse serum, dose-response profiles for suberyldicholine (SbdCh) are shifted to higher concentrations by about 1, 2, and 3 log units, respectively, for activation of nAChR expressed by the human neuroblastoma lines SH-SY5Y and IMR-32 and the TE671 human medulloblastoma. Conversely, SbdCh (at concentrations as high as 10 mM) does not activate nAChR function on the PC12 rat pheochromocytoma cell line except in the presence of 1% horse serum. No effects of fetal calf serum are observed on SbdCh functional activity, nor are there observed effects of horse serum on activity of other nicotinic agents including a bis-choline compound (succinyldicholine) structurally related to SbdCh. The horse serum factor appears to have a molecular mass greater than 8 kDa and is selectively depleted upon passage over the anion exchanger, DEAE-Sepharose. Yet to be demonstrated is whether the horse serum factor acts on SbdCh or nAChR and whether it or SbdCh recognizes distinct ligand binding subsites on nAChR isotypes.

IN VITRO AND IN VIVO CORTICOSTERONE MODULATES NICOTINIC CHOLINERGIC RECEPTOR BINDING. J.R. Pauly, E.A. Ullman*, M.J. Marks* and A.C. Collins. Institute For Behavioral Genetics, Univ. of Colorado, Boulder, CO 80309.

Previous studies from our laboratory have shown that corticosterone (CCS) modulates nicotine sensitivity in the mouse. Adrenalectomy increases the sensitivity of animals to nicotine while chronic administration of CCS induces nicotine sub-sensitivity. These experiments were performed to determine if CCS has direct actions on nicotinic cholinergic receptor binding. For in vivo experiments, animals were adrenalectomized and supplemented with various concentrations of CCS in pelleted form. Following one week of chronic CCS therapy, nicotinic sites labeled by alpha-[^{125}I]-bungarotoxin (BTX) were decreased by 30-50%, depending on brain region; however, the binding of [^{3}H]-nicotine was unaltered. In vitro experiments were also performed to test for CCS-induced changes in the kinetics of NIC and BTX binding. Inclusion of CCS in binding assays (100 uM - 1mM) caused partial inhibition of single concentration binding (10-40%) for both ligands and also induced a concentration-dependent shift to the right of the K_I for nicotine inhibition of BTX binding. These data suggest that acute or chronic administration of CCS has profound effects on the binding of nicotinic cholinergic ligands to their receptors. Supported by DA-05131, DA-00116 and a grant from R.J. Reynolds Tobacco Company.

NICOTINE-EVOKED CALCIUM CHANGES IN SINGLE FETAL RAT CORTICAL NEURONS MEASURED WITH THE FLUORESCENT PROBE FURA-2. E.N. Fluhler*, P.M. Lippiello, K.G. Fernandes, R. J. Reynolds Tobacco Co., Winston-Salem, NC 27102 (SPON: J. Robinson)

The presence of nicotinic acetylcholine receptors (nAChRs) in the mammalian CNS is now widely accepted. Others have shown nicotine-evoked release of neurotransmitters from various CNS synaptosome preparations, indicating that these receptors may be of functional importance (1,2). We are using fluorescence microscopic and image analysis techniques to investigate the functional properties of putative nAChRs which we previously identified on cultured fetal rat cortical neurons (3). Administration of nicotine (100-1000 nM) to cultures loaded with the fluorescent calcium probe fura-2 resulted in a transient increase in intracellular calcium in approximately 5-15% of the neurons measured. The magnitude of the response was enhanced under partially depolarizing conditions, in some cases causing the cells to "fire" with a concomitantly large change in intracellular calcium. The ability of classical nicotinic antagonists to attenuate changes in calcium was consistent with the involvement of nicotine receptor activation in the response. Our results suggest that nicotine receptor-mediated events can lead to an increase in intracellular calcium, which has been proposed to play a role in neurotransmitter release.

LONG TERM NICOTINE TREATMENT IN RATS WITH BILATERAL NUCLEUS BASALIS LESIONS. N. N. Sjak-Shie*, J. Burks*, W. J. Millard and E. M. Meyer. Dept. of Pharmacology, Univ. of Florida, College of Medicine, Gainesville, FL 32610.

Bilateral nucleus basalis magnocellularis (nbm) lesions were shown previously to elevate cortical neuropeptide Y (NPY) levels and cause cell loss of cerebral cortical neurons by 10 months post-lesioning. In the present study, we examined the potential role of nicotinic transmission in these transsynaptic effects. We also investigated whether the increase in NPY levels may be due to increased transcription of the NPY gene. Male Sprague Dawley rats received bilateral nbm-infusions of 5 ug ibotenic acid. Starting 6 months post-lesioning, groups of sham-operated or lesioned rats received daily injections of saline or nicotine (0.2 mg/kg) until their sacrifice 2 months later. By 6 months post-lesioning, partial recovery of passive avoidance behavior was observed, and nicotine had no additional ameliorative effect. Behavioral recovery was complete by 8 months post-lesioning. High affinity [3H]acetylcholine-binding to nicotine receptors increased only 20% at 8 months post-lesioning, down from a 40% increase at 5 months. Nicotine-treatment in the lesioned animals increased receptor levels by an additional 30% by 8 months, suggesting that nicotine may partially block the loss of cells possessing nicotinic receptors. Brain sections from these animals are being analyzed for Nissl-staining cell bodies to corroborate this hypothesis. Our preliminary results indicate that 2 months post-lesioning, mRNA encoding pre-proNPY was reduced 24% using a NPY cDNA probe (from Dr. Janet Allen), while total NPY levels were unaffected. Levels of pre-proNPY mRNA are currently being measured from the animals in the aforementioned chronic nicotine study.

TOLERANCE TO NICOTINE IN CEREBELLAR CORTEX NEURONS. R. de la Garza. Univ. of Colo., Health Sci. Ctr., Dept. of Pharmacol. C236, 4200 E. 9th St., Denver, CO 80262 and Denver VAMC.

Recent studies from our laboratory have shown the heterogenous electrophysiological actions of nicotine in the rat cerebellum (de la Garza et al., J. Pharmacol. Exp. Ther., 240: 689, 1987). More recent studies have shown the pharmacological specificity of these actions of nicotine on cerebellar neurons (de la Garza et al., Psychopharmacology, in press). However, an important characteristic of the actions of nicotine in the peripheral nervous system is the rapid desensitization to its agonist actions and the present study attempted to determine the development of tolerance to the excitatory actions of nicotine applied from glass micropipettes.

Local application of nicotine produces excitations of cerebellar cortex interneurons. This study found that the mode of local application determines the extent of desensitization or acute tolerance. Repeated pressure- ejection of nicotine leads to a reduction in the response to nicotine if applications are spaced by less than 30 sec. Repeated iontophoretic applications of nicotine lead to reductions in the response to nicotine even if applications are spaced 90 sec apart.

Acute tolerance to nicotine may occur in cells of the cerebellar cortex if the mode of drug application maximizes the exposure of the tissue to nicotine and local concentrations of nicotine are higher after iontophoresis than after pressure-ejection. These findings are further evidence of the pharmacological nature of these cerebellar responses. (USPHS grant DA 07043 and VAMC).

INTRACELLULAR RECORDING OF NICOTINIC RESPONSES IN LATERAL SPIRIFORM NEURONS OF THE CHICK. E.M. Sorenson and V.A. Chiappinelli. Dept. of Pharmacology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

The lateral spiriform nucleus (SPL) in the chicken mesencephalon is innervated by cholinergic fibers as demonstrated by choline acetyltransferase immunohistochemistry (Sorenson, E.M., et al., J. Comp. Neurol. 281:641, 1989). Autoradiography reveals a high density of ^{3}H-nicotine sites in the SPL, but little or no ^{125}I-alpha-bungarotoxin (ABgT) or ^{125}I-kappa-bungarotoxin sites (in preparation). The SPL is also recognized by monoclonal antibody mAb35 (Swanson, L.W., et al., J. Neurosci. 7:3334, 1987). The immuno-purified mAb35 binding site has a high affinity for ^{3}H-nicotine but does not bind ABgT. These results suggest that nicotinic transmission occurs in the SPL and that the functional receptor has a high affinity for nicotine. We now report that SPL neurons in chick brain slices respond to nicotine and carbachol in the presence of 1 μM atropine. Intracellular recording from SPL neurons display a depolarization and a decrease in input resistance following exposure to nicotinic agonists. Evoked action potentials are often seen during the depolarization. The nicotinic responses are reversibly blocked by 60 μM tubocurarine and 100 μM dihydro-β-erythroidine. ABgT (1 μM) does not antagonize these responses. We conclude that the high affinity ^{3}H-nicotine binding sites found in SPL neurons are functional receptors. (Supported by NS17574 to V.A.C.).

IRREVERSIBLE ORGANOPHOSPHATE EFFECTS ON NICOTINIC ACETYLCHOLINE RECEPTORS/ION CHANNEL COMPLEX. D.E. Menking*, R.G. Thompson and J.J. Valdes. Biotechnology Div., Chem. Res. Devel. & Engr. Ctr., Aberdeen Proving Ground, MD 21010-5423.

Organophosphate (OP) toxicity is primarily due to its inhibition of acetylcholinesterase. In sublethal doses, OPs induce symptoms which cannot be solely attributed to cholinesterase inhibition, with preliminary data indicating a direct interaction of OPs with postsynaptic nicotinic acetylcholine receptors (nAChR). Membrane fragments from Torpedo electric organ were used to determine OP interactions with the nAChR-coupled Na+ channel using 3H-phencyclidine (3H-PCP) as a probe. Highly toxic OPs (O-ethyl S-(diisopropylaminoethyl) methylphosphonothiolate, ethyl-N,N-dimethylphosphoramidocyanidate, isopropyl methylphosphonofluoridate and pinacolyl methylphosphonofluoridate) were found to potentiate binding of 3H-PCP to the nonactivated acetylcholine ion channel and to inhibit carbachol-activated 3H-PCP binding. To determine the irreversibility of the OP effects, membrane preparations were preincubated with OPs and washed several times with Tris-HCl buffer before assessing binding with 3H-PCP. Results show that OPs irreversibly potentiate 3H-PCP binding. These results are consistent with the hypothesis that OPs bind to, and irreversibly phosphorylate, an allosteric site on the ion channel associated with the nAChR.

276.1

ANTIBODIES AGAINST RAT LIVER CONNEXIN32 RECOGNIZE SUBSURFACE CISTERNS IN MOTONEURONS: IMMUNOHISTOCHEMICAL EVIDENCE FOR SIMILARITIES BETWEEN GAP JUNCTIONAL AND SUBSURFACE CISTERNAL PROTEINS. T. Yamamoto[1], E.L. Hertzberg[2] and J.I. Nagy[1] [1]Dept. of Physiol.,[2]Univ. of Manitoba, Winnipeg, Man., Canada R3E 0W3 and [2]Dept. of Neurosci., Albert Einstein College of Medicine, Bronx, N.Y., U.S.A. 10461

A polyclonal antibody against the 27kD rat liver gap junctional protein (connexin32) and a monoclonal antibody against a synthetic peptide corresponding to the carboxy-terminus of this protein gave discrete immunohistochemical labelling patterns in rat liver and in spinal cord and brain stem motoneurons. In sections of liver, staining with both antibodies was localized to puncta by double immunofluorescence and to gap junctions in this tissue by immuno-EM. In the facial motor nucleus, the polyclonal antibody labelled widely distributed fine puncta, the Golgi apparatus within somas of some motoneurons and large puncta on these somas and their initial dendrites. By immuno-EM the punctate labelling was localized to glial gap junctions and axon terminals in apposition to motoneurons at sites of subsurface cisterns. These subsurface cisterns were labelled by the monoclonal antibody. These results suggest that there may be some homology between gap junction proteins and the protein constituents of subsurface cisterns.

276.2

IMMUNOHISTOCHEMICAL LOCALIZATION OF THE 27KD AND 43KD GAP JUNCTION PROTEINS IN THE RAT CENTRAL NERVOUS SYSTEM. J.I. Nagy[1], T. Yamamoto[1], P.A. Carr[1] and E.L. Hertzberg[2] [1]Dept. of Physiol.,[2]Univ. of Manitoba, Winnipeg, Man., Canada R3E 0W3 and [2]Dept. of Neurosci., Albert Einstein College of Medicine, Bronx, N.Y., U.S.A. 10461

Intercellular communication in peripheral tissues is mediated by gap junctions composed of various junctional proteins referred to as connexin21, 32 and 43. Polyclonal antibodies against connexin32 as well as monoclonal and polyclonal antibodies against oligopeptides corresponding to different regions of each protein were used to determine immunohistochemically the localization of gap junctions, junctional proteins and what may be polypeptides related structurally or functionally to junctional proteins in the rat CNS. Antibodies against presumed cytoplasmic domains of connexin43 gave dense, heterogeneously distributed punctate staining throughout the CNS which in some structures was associated with glial gap junctions as seen by immuno-EM. Polyclonal anti-connexin32 gave immunoreactive neuronal and glial gap junctions as well as immunoreactive synaptic vesicles and dendritic and axonal cytoplasmic membranes. Antibodies against presumed extracellularly located regions of connexin32 and 43 gave intracellular immunoreactivity in neurons. These results indicate a differential and heterogeneous distribution of various connexin and possibly connexin-like proteins in the rat CNS.

SPECTROSCOPIC CHARACTERIZATION OF THE INTRINSIC FLUORESCENCE OF SYNAPSIN I. F. Benfenati, P. Neyroz°, M. Bähler+, F. Masotti*, L.F. Agnati* and P. Greengard+ Institue of Human Physiology, University of Modena, Italy, °Institute of Biological Chemistry, University of Parma, Italy and +Laboratory of Molecular and Cellular Neuroscience, The Rockefeller University.

Synapsin I is a major neuron-specific phosphoprotein which binds to synaptic vesicles and F-actin in a phosphorylation-dependent fashion. The existence of conformational transitions of synapsin I in response to microenvironmental changes were investigated by analyzing the steady-state and time-resolved intrinsic fluorescence of the protein. The steady state emission spectrum of native synapsin I was centered at 330 nm and underwent a clear-cut red shift upon denaturation, as expected for tryptophan residues mostly segregated from the external aqueous environment. The intrinsic fluorescence of synapsin I was resolved in its time-dependent components and their distribution as a function of wavelength was defined. Three major decay components with lifetimes of about 0.2, 3, and 7 nsec were resolved. Possible changes in synapsin I conformation upon site-specific phosphorylation were investigated by comparing the decay associated spectra obtained from the dephospho-form and the various in vitro phosphorylated forms. Upon phosphorylation of the tail sites, the spectra associated with the medium and long lifetimes were shifted to the red region of the spectrum, whereas the spectrum associated with the shortest lifetime was shifted to the blue region, in the absence of significant changes of the lifetimes. Similar changes were observed for the fully phosphorylated form of synapsin I. Supported by a NATO grant (0039/89) for collaborative research.

RETINAL RIBBON SYNAPSES LACK SYNAPSIN IMMUNOREACTIVITY J.W. Mandell*[1], E. Townes-Anderson[1], R. Cameron[2], P. Greengard[3], and P. De Camilli[2]. Cornell U. Med. Coll.[1], New York, 10021, Yale Univ. Sch. Med.[2], New Haven, 06510 and Rockefeller U.[3], New York, 10021

The vertebrate retina contains two ultrastructurally distinct types of vesicle-containing synapses. Conventional synapses are made predominantly by amacrine cells in the inner plexiform layer (IPL), while ribbon synapses are made by bipolar cells in the IPL and by photoreceptors in the outer plexiform layer (OPL). We have investigated, using immunocytochemical techniques, whether ribbon and conventional synapses differ in their content of three characterized synaptic vesicle proteins. Immunofluorescence labeling of adult rat retinas with antisera to P38 (synaptophysin) or with a monoclonal antibody to the synaptic vesicle protein SV2 revealed identical labeling patterns: intense labeling of large terminals, presumably rod cell spherules, in the OPL and bright labeling throughout the IPL. At the vitreal border of the IPL, large bulbous structures, possibly bipolar cell terminals, were intensely labeled. In contrast, antisera to synapsin I labeled the OPL extremely weakly. Labeling in the IPL was very bright though the bulbous structures were not labeled. To positively identify the cell types possessing the synapsin-negative, P38/SV2-positive terminals, enzymatically isolated retinal neurons were examined. The synaptic endings of intact rod photoreceptors and bipolar cells contained immunoreactive P38 and SV2 but not synapsin . In addition, protein A-gold labeling of ultrathin frozen sections demonstrated the localization of P38 to synaptic vesicles of photoreceptors terminals. Synapsin has been proposed to mediate the clustering and exocytosis of synaptic vesicles at the active zone. Its absence from rod and bipolar cells suggests that the mechanism of transmitter release is different in conventional and ribbon synapses . Supported by: NIH grant EY06135 (ETA), Life & Health Ins. 276.5

LOCALIZATION OF SYNAPSIN I IN ADULT RAT BRAIN. L.J. DeGennaro, P.J.Apostolides*, D.Pulaski-Salo*, and J.E. Hamos. Dept. of Neurology, Univ. of Mass. Med. Ctr., Worcester, MA 01655.

To gain insight into the relationship between the neuronal phosphoprotein Synapsin I and synaptic function, we used anti-Synapsin I antibody to map the distribution of the protein in the brains of 6 adult rats. Synapsin I immunoreactivity was restricted to the neuropil and essentially no staining was seen in fiber tracts. There was marked regional heterogeneity in staining with a generally increasing caudorostral gradient along the neuraxis. Immunoreactivity was highest in the pyriform and cingulate cortices, the CA1 and CA3 fields of the hippocampus, the septal nuclei, ventral pallidum, globus pallidus, substantia nigra, and the median eminence of the hypothalamus. More modest staining was found in layers I, II, III, and V of cortex, the acellular glomerular and external plexiform layers of the olfactory bulb, the molecular layers of the cerebellum and dentate gyrus, the caudate-putamen, thalamus, amygdala, central gray, and spinal cord. Specific staining differences were also noted within various nuclei of the thalamus and amygdala. This heterogeneous staining pattern raises the question of whether the distribution of Synapsin I solely reflects variation in synaptic size and/or density, or whether it represents a variation of the protein's concentration within individual synapses that may be dependent on synaptic function and/or activity.

276.6

SYNAPSIN I EXPRESSION DURING POSTNATAL DEVELOPMENT OF THE RAT HIPPOCAMPUS. P.J. Apostolides*, D. Pulaski-Salo*, L.J. DeGennaro, and J.E. Hamos. Dept. of Neurology, Univ. of Mass. Medical Center, Worcester, MA 01655.

Synapsin I is a neuronal phosphoprotein whose phosphorylation has been implicated in the regulation of neurotransmitter release. To gain insight into the molecular mechanisms of synaptogenesis in the rat hippocampus, we employed immunocytochemical techniques using antibodies directed against purified Synapsin I to study the expression of this protein during a range of postnatal time points. Synapsin I immunoreactivity was present in the newborn rat (P0) despite the paucity of mature synapses within the hippocampus at this time and was present in both fiber bundles as well as select synapses. During early postnatal days, immunoreactivity revealed diffuse staining within the molecular layer of the dentate gyrus and a distinctively increasing mediolateral gradient of immunostaining within the mossy fiber terminals of the dentate granule cells. By the second postnatal month, Synapsin I immunoreactivity assumed its adult-like characteristics and was limited to the neuropil. Our results suggest that the temporal and spatial expression of Synapsin I within the developing rat hippocampus reflects the process of synaptogenesis. These findings are consistent with previous studies of Synapsin I expression in other developing regions of the rat brain, and provides further support for its developmental regulation.

276.7

DISTINCT PLATELET-ACTIVATING FACTOR (PAF) BINDING SITES IN SYNAPTIC MEMBRANES AND MICROSOMES FROM RAT CEREBRAL CORTEX. NG Bazan[1], VL Marcheselli[1]*, P Braquet[2]*, and JM Cluzel[1]*. LSU Eye Center, New Orleans, LA[1], Institut Henri Beaufour, Le Plessis Robinson, Paris, France[2].

PAF binding sites were studied in enriched subcellular fractions from rat brain cortex. The Kd in synaptic membranes is 1.2 nM and the Bmax is 0.99 pmole/mg protein. The high-affinity binding site in microsomes has a Kd of 22.5 pM and a Bmax of 82.5 fmole/mg protein; the low-affinity binding site Kd is 25.0 nM and the Bmax is 60.0 pmole/mg protein. The order of potency of antagonists on synaptic binding sites is BN-50726 (IC_{50}=1.33·10^{-7}M), BN-50727 (IC_{50}=1.46·10^{-7}M), and BN-52021 (IC_{50}=1.64·10^{-7}M). Even if BN-50727 has identical potency in both membrane preparations, the other BN compounds are more potent in the synaptic membranes than in microsomes. BN-52021 appears to be a non-competitive inhibitor for both membrane preparations. A comparison of other PAF antagonists shows that CV-3988 is the most potent in microsomes, with an IC_{50} of 1.57·10^{-9}M. In synaptic membranes it has an IC_{50} of 2.54·10^{-7}M. Because of its different subcellular location and its different kinetics and response to antagonists three binding sites of PAF appear to be present in cerebral cortex. Supported by NS 23003.

276.8

DISTRIBUTION OF VESICLE ASSOCIATED MEMBRANE PROTEIN mRNA IN RAT CENTRAL NERVOUS SYSTEM. T.S. Gray, L.A. Elferink, W.S. Trimble, R.H. Scheller and M.C. Wilson. Loyola Univ., Maywood, IL 60153, Stanford Univ., Stanford, CA 94305, Res. Inst. Scripps Clinic, La Jolla, CA 92037.

Recently, cDNA clones of mRNAs encoding two synaptic terminal vesicle associated proteins (VAMP) of rat brain have been isolated that are 84% and 75% homologous to a VAMP-1 protein isolated in Torpedo ray (Elferink et al., J.B.C., 1989). The rat VAMP-1 & -2 predicted protein sequences consist of 118 and 116 amino acids and are encoded by distinct genes. Here we report the distribution of VAMP-1 & -2 mRNA within rat brain via in situ hybridization of ^{35}S RNA probes directed against the distinct 3' untranslated sequence of mRNA. In spinal cord VAMP-1 mRNA levels were highest in ventral horn cells while VAMP-2 was higher in dorsal horn. In brainstem VAMP-1 mRNA was localized to the lateral reticular formation, the 12th, 7th, 5th, 4th and 3rd cranial nerve motor nuclei. VAMP-2 mRNA levels were highest in inferior olivary, the vagal motor, dorsal raphe', parabrachial and parabigeminal nuclei. mRNA levels for both VAMPs was high within the pontine gray. In forebrain VAMP-1 mRNA was localized to the thalamic reticular, entopeduncular and the lateral mammillary nuclei. VAMP-2 hybridization was generally higher within the forebrain and was localized within the hypothalamus, amygdala and cortex. High levels of mRNA to both VAMPs was observed within the anterior thalamic nucleus. The present findings indicate some functional correlations for the differential VAMP mRNA expression; e.g., VAMP-1 is associated with somatomotor neurons while VAMP-2 is expressed in autonomic motor neurons. Supported by NS20041 (TSG) and NS23038 (MCW).

A SUBPOPULATION OF SYNAPTIC VESICLES FROM RAT BRAIN CONTAINS TUBULIN. E. Floor, Dept of Anatomy, Univ. of Wisconsin Medical School, Madison, WI 53706.

Many studies have reported tubulin in partially purified synaptic vesicles from brain. At the final step in preparation of >90% pure synaptic vesicles from rat brain, tubulin co-purifies with synaptophysin, a synaptic vesicle protein. Thus isolated brain synaptic vesicles do appear to contain tubulin. About 30% of total protein in >90% pure synaptic vesicle preparations can be immunoprecipitated by polyacrylamide beads (Immunobeads, BioRad) coated with KMX-1, a monoclonal antibody to β-tubulin (Birkett et al. (1985) *FEBS Lett.* **187**, 211-218). In contrast, ~90% of total protein is immunoprecipitated specifically by monoclonal antibodies to synaptic vesicle proteins SV2, synaptophysin, or p65 (Floor and Feist (1988) *J. Neurochem.* **52**, In press). Antibody KMX-1 immunoprecipitates all of the tubulin in these experiments as shown by Western immunoblot analysis with polyclonal tubulin antibody of proteins remaining in the supernatant after immunoprecipitation. Tubulin, then, is present on a subpopulation of rat brain synaptic vesicles. One of the major proteins in these synaptic vesicles observed by SDS-PAGE with Coomassie staining, protein R2, can be identified as tubulin by Western immunoblotting. Protein R2 is a tightly-bound, extrinsic membrane protein. It remains bound at high or low ionic strength but dissociates in 50mM NaOH. The strong association of vesicular tubulin with synaptic vesicles suggests that its presence there is not artifactual. Because tubulin is an abundant protein in brain, its presence on a subpopulation of synaptic vesicles also argues that tubulin does not bind nonspecifically to these organelles. The function of tubulin in synaptic vesicles is not known, although a role in mediating interactions with the cytoskeleton seems likely. (Supported by NIH Grant NS 24890.)

DOES MUTAGENESIS OF ASP-135 IN CA^{2+}/CALMODULIN-DEPENDENT PROTEIN KINASE II (CK-II) ALTER SUBSTRATE BINDING? S. A. Westgate*, P.T. Kelly and M.N. Waxham. Depts. of Neurology, and Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77225.

Through comparison of conserved sequences in protein kinase catalytic domains it was determined that serine/threonine specific kinases share a conserved stretch of amino acids not found in tyrosine specific kinases (Hanks, S.K. et al., Science, 241:42, 1988). This consenses sequence Asp-Leu-Lys-Pro-Glu-Asn (DLKPEN) is located at residues 135-140 in the amino terminal half of the 50 kDa subunit of CK-II and was proposed to be involved in protein substrate binding. Using site directed mutagenesis we have substituted Asn for Asp-135 in the DLKPEN region of the 50 kDa subunit and expressed the protein in bacteria. The expression in bacteria of the 50 kDa subunit of CK-II using the expression vector PK233-2 was previously reported by this lab. The Asn-135 substituted enzyme was purified and compared with non-mutated bacterially expressed CK-II using phosphorylation assays as an indicator of activity. The Asn-135 substituted enzyme showed no autophosphorylation or phosphorylation of any substrates in the presence or absence of calcium and calmodulin, whereas the original Asp-135 enzyme phosphorylated itself and synapsin only with calcium and calmodulin present. In order to determine whether the absence of phosphorylation could be due to alterations in ATP binding, photoaffinity labeling experiments were done using alpha-^{32}P-8-azido ATP. After labeling, both the Asp-135 and Asn-135 enzymes were analyzed by SDS-PAGE and the autoradiographs showed the 50 kDa proteins to be labeled suggesting both were able to bind the azido-ATP analogue. These results suggest that the Asn-135 mutant binds ATP but is unable to undergo the phosphoryl transfer reaction presumably due to an alteration in its ability to bind protein substrates.

A MONOCLONAL ANTIBODY SPECIFIC FOR TAP-1. M. Iwata*, A. Davis* and S.S. Carlson. Dept. of Physiology and Biophysics, University of Washington, Seattle, WA 98195.

TAP-1 is a large (10^6 dalton) chondroitin sulfate proteoglycan (CSPG), hypothesized to act as a glue at the elasmobranch electric organ synapse (Carlson and Wight, 1987, *JCB*, 105:3075-3086). This proteoglycan was originally identified because it shares a carbohydrate epitope (SV4) with a smaller synaptic vesicle proteoglycan (Carlson, et al., 1986, *JCB*, 103,509-520).

We have produced a monoclonal antibody which is specific for TAP-1 and does not react with the synaptic vesicle proteoglycan. The antigenic site (T1) identified by this monoclonal antibody is destroyed by protease digestion. That is, when TAP-1 is subjected to overnight digestion with pronase, it can no longer inhibit the immunoprecipitation of ^{125}I-TAP-1 with the anti-T1 mAb. This is in contrast to the SV4 epitope which is pronase resistant in this test. Thus, the anti-T1 mAb may be directed against the polypeptide core of the TAP-1 CSPG.

By immunocytochemistry at the light level, the T1 antigenic site has a broad tissue distribution in electrically excitable tissue of the elasmobranch electric fish. It is present on both the innervated and non-innervated face of the electrocyte, and on the surface of muscle cells. It is present in the electromotor nucleus which innervates the electric organ, other regions of the fish brain, and spinal cord. We also find the antigen present in the mammalian amphibian retina.

The SV4 antigenic site behaves like a glycosaminoglycan. It can be released from TAP-1 by alkaline borohydride cleavage. When chromatographed on Sepharose 6B, the released antigenicity elutes as a broad peak with an apparent molecular weight range of 23,000-76,000. The SV4 antigenicity requires approximately 0.5 M NaCl at pH 4.9 to be eluted from DEAE nitocellulose. It is resistant to all glycosaminoglycan lyases except keratinase by which it is partially digested.

VAT-1: AN ABUNDANT MEMBRANE PROTEIN FROM TORPEDO CHOLINERGIC SYNAPTIC VESICLES. M. Linial*, K. Miller* and R.H. Scheller. Department of Biological Sciences, Stanford University, Stanford, CA 94035-5020.

Expression screening of a lambda gt-11 library constructed from electromotor nucleus of Torpedo was used to isolate cDNA clones encoding a synaptic vesicle membrane protein, VAT-1. The RNA is specifically expressed in the electric lobe and to a much lower extent in the brain. The predicted protein has a molecular weight of 41,572 daltons and contains several hydrophobic regions. The best homology found is to calcium translocase of rabbit muscle and several other ATPases. An antibody raised against a fusion protein recognizes an abundant 42 kD protein which copurifies with synaptic vesicles. The integrity of VAT-1 to vesicles was confirmed by direct amino-acid sequencing and by tryptic digestion of vesicles. Hydrodynamic studies suggest VAT-1 is part of a high-molecular weight complex of the vesicle.

NEURONAL EXCITABILITY IN LONG-SLEEP AND SHORT-SLEEP MICE: II. POTASSIUM-STIMULATED CALCIUM-DEPENDENT RELEASE OF GABA FROM FRONTAL CORTEX SYNAPTOSOMES. B. C. Jones*, C. C. Duncan and V. G. Erwin. Alcohol Research Center, University of Colorado, Boulder, CO 80309.

Long-sleep (LS) and short-sleep (SS) mice, are known for their differential initial sensitivity to the hypnotic effect of ethanol (EtOH); the LS line being the more sensitive both in sleep time and in blood ethanol content upon awakening from a hypnotic dose of EtOH. We recently completed an experiment in which we examined calcium-dependent, potassium-stimulated release of GABA from synaptosomes prepared from the frontal cortex of LS and SS brains. Enriched synaptosomal fractions were prepared from frontal cortex tissue and incubated in Krebs-Ringers-HEPES (KRH) buffer containing ^{3}H-GABA. Using a superfusion technique, (Tapia, R. and Sitges, M., *Brain Res.*, 250:291, 1982) synaptosomal samples (0.3-0.5 mg protein), samples were washed in KRH buffer containing 4.7mM potassium and 2.5mM calcium. Following the wash, KRH containing 4.7, 9.4, 18.8, 37.6 or 47mM potassium was added to the superfusion chamber and 0.5 ml samples were collected for liquid scintillation counting of released GABA. Findings included calcium dependency and differential thresholds for GABA release in LS and SS synaptosomes. While there was no difference between LS and SS in GABA release at 37 or 47 mM potassium, 9.4 and 18.8 mM potassium produced greater GABA release (percent of baseline) in LS, compared to SS synaptosomes. EtOH (22 and 88 mM) added to all release buffers produced a dose related tendency for reduction in GABA release with no differential sensitivity seen between the two lines of mice. Supported by USPHS Grants no. AA03527, AA00079 and AA07330.

Na^+-Ca^{2+} EXCHANGE ACTIVITY IN SYNAPTIC PLASMA MEMBRANES FROM POSTMORTEM HUMAN BRAIN. **G. Hoel*, and M.L. Michaelis. Dept. Pharmacology/Toxicology and Center for Biomedical Research, University of Kansas, Lawrence, KS 66046**

Procedures have been developed for the preparation of resealed plasma membrane vesicles from postmortem human brain. The vesicles were enriched in synaptic junctions and exhibited the capacity to transport Ca^{2+} in the presence of a Na^+ gradient. The kinetic characteristics of the Na^+-Ca^{2+} exchange process were determined in synaptic plasma membrane vesicles isolated from human brain hippocampus and cortex. The K_{act} for Ca^{2+} was calculated with computer assisted curve fitting to be 33.7 uM for the hippocampal tissue and 17.6 uM for the cortical tissue. The maximal rate of Ca^{2+} uptake (V_{max}) was determined to be 3.6 nmol/mg protein/15 sec and 3.34 nmol/mg protein/15 sec for hippocampal and cortical tissue respectively. Dependence of Ca^{2+} transport on the magnitude of the Na^+ gradient was found to be fairly complex as might be expected from the stoichiometry reported in other tissues. The effect of varying the pH of the incubation medium was examined and an optimum observed at pH ~9. The results of these studies demonstrate that Na^+-dependent Ca^{2+} transport activity can be preserved in membranes isolated from postmortem human brain. Such preparations could potentially be used to determine the influence of various pathological conditions on this transport system. **[Supported by grants AA 04732 from NIAAA, DAAL-03-88-K0017 from ARO, and AG 04762 from NIA].**

SYNAPTIC VESICLES AND CALCIUM HOMEOSTASIS AT THE SYNAPSE. M.Mata and D.J.Fink. University of Michigan and VA Medical Center, Ann Arbor, MI, 48105

Using the oxalate-pyroantimonate technique to demonstrate the ultrastructural localization of calcium *in vivo*, we have previously found that calcium appears to be sequestered in synaptic vesicles of the neuromuscular junction (Histochem. 87:339, 1987). Similar localizations of calcium in synaptic vesicles have been reported by others in CNS synapses (J.Anat. 129:869, 1979).

We have now used EM enzyme cytochemistry (modified from Ando, Acta Histochem.Cytochem. 14:705, 1981) to localize the calcium pump (Ca-ATPase) at synapses in the central nervous system and the neuromuscular junction. Vibratome sections from rat cerebral cortex, spinal cord, and muscle were incubated in medium containing 3 mM ATP, 10 mM $CaCl_2$, 4 mM lead citrate and 8 mM levamisole, rinsed with cacodylate buffer, post-fixed with osmium, and embedded in Epon-Araldite. Ca-ATPase activity, visualized as the electron dense lead phosphate deposits, was demonstrated in the plasma membrane and was prominent intracellularly along all synaptic vesicle membranes.

We propose that calcium entry accompanying depolarization at the synapse may be buffered in part by pumping of calcium into synaptic vesicles by Ca-ATPase. This calcium pool would then be released from the presynaptic terminal when vesicle release is triggered by depolarization. Such a mechanism may constitute a very efficient method for dealing with calcium entry that accompanies stimulation at the synapse.

Supported by grants from the JDF, the NINDS, and the VA.

EFFECT OF CHRONIC ETHANOL ADMINISTRATION ON THE INTERMEDIATE STEPS OF (Na,K)-ATPase ACTIVITY. P.M. Wixom and A.Y. Sun. Sinclair Research Farm and Dept. of Biochem. Univ. of Missouri, Columbia, MO 65203

(Na,K)-ATPase activity depends greatly on the structural integrity of the membrane. Previous studies have indicated that ethanol, which partitions into membranes freely, hinders the conformational changes of the (Na,K)-ATPase in the reaction sequence. Using (γ-^{32}P)ATP and autoradiography, we have been able to separate the steps involved in the conformational changes of the enzyme by manipulating the Na^+ and K^+ in the assay medium. Previous studies have found that in vitro ethanol did not block the phosphorylation process, but did inhibit the protein dephosphorylation step.

In this study, synaptic plasma membranes were isolated from cerebral hemispheres of C57/Bl mice who had been on a liquid diet containing 5% ethanol for 5 weeks. In the ethanol tolerant membranes, the phosphorylated intermediate was increased, possibly reflecting an increase in the amount of enzyme. This provides a structural basis for the increase in specific enzyme activity of (Na,K)-ATPase after chronic ethanol administration observed in our laboratory as well as others. Also in ethanol tolerant membranes the dephosphorylation process in the presence of K^+ was increased, reflecting a faster turnover rate. Since (Na,K)-ATPase is responsible for the regulation of membrane repolarization by the transport of the Na^+ and K^+ across plasma membranes, the increase in enzyme activity after chronic ethanol ingestion may be related to the adaptational process leading to ethanol tolerance. (Supported in part by NIAAA grant # AA02054.)

PREFERENTIAL RELEASE OF EPINEPHRINE FOLLOWING MUSCARINIC STIMULATION OF BOVINE ADRENAL MEDULLA CELLS: EFFECT OF LITHIUM. R.H. Lenox, A. Hussein* and O. Zinder*, Neurosc. Res. Unit, Dept. of Psychiatry, UVM Med. Coll., Burlington, VT; Dept. of Clin. Biochem., Rambam Med. Ctr., Haifa, ISR.

Acetylcholine (ACH) stimulation of adrenal medullary chromaffin cells results in the release of both epinephrine (EPI) and norepinephrine (NEPI). Nicotinic (NIC) stimulation produces a depolarization dependent influx of calcium, triggering release; while muscarinic (MUSC) receptors are coupled to phosphoinositide metabolism and intracellular mobilization of calcium. We have been examining the pattern of catecholamine (CAT) release following MUSC vs NIC activation and the effects of lithium on this process.

Medullary chromaffin cells were isolated from fresh bovine adrenal glands and stabilized in incubation medium. Basal secretion was 75% EPI reflecting the CAT content of the cells. Following stimulation with either ACH or NIC, the pattern of CAT released was 62% EPI and 38% NEPI; a significant shift to NEPI release. Mecamylamine partially blocked ACH mediated release and significantly increased the EPI/ NEPI ratio. Release of CAT following MUSC activation was diminished relative to ACH with an EPI/NEPI ratio similar to basal conditions; and was blocked by atropine. Pre-exposure of cells to lithium markedly reduced MUSC mediated release of CAT and decreased the EPI/NEPI ratio. The MUSC receptor appears to mediate preferential release of EPI which predominates during basal secretion. Lithium appears to preferentially block MUSC mediated release.

277.2

MODULATION OF CATECHOLAMINE SECRETION FROM ADRENAL CHROMAFFIN CELLS BY ADENOSINE AND ADENINE NUCLEOTIDES. M. Diversè-Pierluissi, W.N. Kopell, K.T. Kim and E.W. Westhead. Program in Molecular and Cellular Biology, University of Massachusetts, Amherst, MA 01003.

We have previously reported that adenosine and adenine nucleotides can inhibit or enhance nicotinic or K^+ triggered release of catecholamine from chromaffin cells (Chern et al, J. Neurochem,1987,1988). Enhancement by ATP is instantaneous but inhibition develops over about 3 min.. Cholera toxin prevents the former effect, pertussis the latter. ATP elevates IP_3 causing release of Ca^{2+} from internal stores but this effect appears unrelated to enhancement or inhibition since neither effect is mimicked by UTP which also causes IP_3 production and Ca^{2+} release. ADP-ribosylation of membrane proteins by cholera and pertussis toxins identifies at least two proteins whose labeling is altered by the presence of ATP or ADP during toxin treatment. Studies with antibodies to specific G-proteins are in progress to identify the nucleotide-sensitive proteins. Phenylisopropyl-adenosine (PIA) can inhibit secretion by >90%,an effect apparently not related to its effect on cAMP. Preincubation of chromaffin cells with ^{32}P phosphate, followed by stimulation, shows that many proteins are phosphorylated or dephosphorylated in response to stimulation. A subset of these shows marked sensitivity to preincubation with PIA under conditions in which PIA inhibits secretion.

277.3

ARACHIDONIC ACID METABOLITES AS MEDIATORS OF THE LONG TERM EFFECTS OF ANGIOTENSIN ON CHROMAFFIN CELL SECRETION. A.M. Poisner*, M.K. Stachowiak, H.K. Jiang*, P. Hudson* and J.S. Hong (SPON: E.J. Walaszek). Dept. of Pharmacology, University of Kansas Medical Center, Kansas City, KS 66103 and NIEHS, Research Triangle Park, NC 27709.

We recently reported that 24 hr treatment of chromaffin cells with Sar-1-angiotensin II (ANG) (0.2-20 nM) causes the secretion of catecholamines (CAT) and met-enkephalin (MET), while simultaneously increasing the levels of mRNA for tyrosine hydroxylase, PNMT and proenkephalin (FASEB J. 2:A1799, 1988). We now report that some of the effects of ANG appear to be mediated by arachidonic acid (AA) and/or its metabolites. AA and PGE2 caused a marked increase in CAT and MET secretion. The effects of ANG and AA were greatly reduced by 1-10 uM indomethacin, whereas the stimulant effect of veratridine was unaffected. Similar results have been found when examining mRNA induction. The results suggest that some of the long term effects of ANG on chromaffin cell function are mediated by cyclooxygenase metabolites. Other experiments implicate protein kinase C and lipoxygenase products. Interaction between AA metabolites and protein kiase C seems likely.

MUSCARINIC BINDING AND EFFECT ON CATECHOLAMINE RELEASE IN OVINE ADRENAL MEDULLA. C.Y. Cheung. Dept. Repro. Med., Univ. Calif., San Diego, CA 92093

Catecholamine(CA) release from the adrenal medulla(AM) is mediated through nicotinic receptors. In species such as the rat, muscarinic agonists can also stimulate CA release. The present study investigated the presence and function of muscarinic receptors in the AM of fetal and adult sheep. Muscarinic binding was determined by incubating aliquots of purified AM membrane fraction with [^{3}H]QNB at 5 to 1000 pM in the presence or absence of 2.5 uM atropine (to define nonspecific binding). Specific binding of [^{3}H]QNB to adult ovine AM membrane was saturable and of high affinity, where K_D=20±2pM and Bmax=90.6±3.9fmol/mg. Scatchard analysis revealed a second binding site with K_D=19±8nM and Bmax= 3.3±1.6pmol/mg. In AM of fetuses at 130 days gestation (term=147 days), [^{3}H]QNB binding was observed with K_D and Bmax of 24±4pM and 91.2±11.9fmol/mg, resp. for the first, and 23±11nM and 2.1±0.8pmol/mg, resp. for the second site. These values were not different from those in the adult. Muscarine at 5 to 50 uM had no effect on CA release from AM cells in vitro. Thus, muscarinic binding sites can be identified in the AM of the adult and fetal sheep. However, it appears that these receptors may not be playing a role in regulating CA release.

277.5

CHARACTERIZATION OF GLUCOCORTICOID RECEPTORS IN CULTURES OF BOVINE ADRENAL MEDULLARY CELLS K. Betito, M.J. Meaney, D.H. Aitken*, J. Diorio* and P. Boksa Douglas Hosp. Res. Ctr., Depts. of Pharmacol. & Psychiatry, McGill Univ., Verdun, Quebec, H4H 1R3

The adrenal cortex and medulla are closely interrelated, such that levels of catecholamines (CAs) and other neurohormones secreted by the chromaffin cells of the adrenal medulla are influenced by the glucocorticoids (GCs) from the adrenal cortex. In the present study, we have measured GC receptors in cultured bovine adrenal medullary cells isolated using a Percoll gradient. We observed specific binding of [^{3}H]-dexamethasone (DEX) (Kd=3.5±0.7 nM; Bmax=40.2±4.0 fmol/mg protein) and of the pure GC receptor agonist, [^{3}H]-RU 28362 (Kd=1.5±0.2 nM; Bmax=33.3±3.4 fmole/mg protein). The GC receptor is a typical type II GC receptor, as observed by competition studies, and has relative binding affinities of RU 28362 > cortisol > aldosterone. In the presence of cortisol, translocation of the GC-receptor complex from a soluble to a chromatin-bound compartment was dose-dependent, and the soluble receptor levels were replenished within 30 minutes following removal of steroid. Nuclear uptake of GCs was observed by measuring the amount of [^{3}H]-DEX in the nuclear fraction. Incubation of these cultured cells with 100 nM cortisol produced increased PNMT activity. Treatment with insulin or reserpine produced no change in GC receptor Bmax, while treatment with 8-bromo-cAMP, an analogue of cAMP, decreased soluble GC receptors. In chromaffin and non-chromaffin cell cultures further purified by differential plating, preliminary data indicate that GC receptor numbers did not correlate with CA content. This suggests the presence of GC receptors in both chromaffin and non-chromaffin cells. Supported by FRSQ & MRC of Canada.

ADRENAL CHROMAFFIN CELLS EXPRESS IMIDAZOLE RECEPTORS WHICH BIND CLONIDINE AND AN ENDOGENOUS CLONIDINE-DISPLACING SUBSTANCE. P. Ernsberger, M.J. Evinger, M.P. Meeley, G. Feinland* & D.J. Reis. Div. Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021.

In the medulla oblongata, clonidine binds not only to α_2-adrenergic receptors but also to non-adrenergic sites specific for imidazoles (Ernsberger et al. *Eur J Pharmacol* 134:1 '87). Since clonidine induces mRNA for PNMT in bovine adrenal chromaffin cells (BACC) by a non-adrenergic mechanism (Evinger et al. *this meeting*) we sought to determine whether BACC express imidazole receptors which bind clonidine. BACC were isolated, homogenized, and fractionated into P1, P2, and P3 by differential centrifugation. Membranes (P2) were incubated (40 min, 25°C) with the clonidine analog ^{3}H-*p*-aminoclonidine (^{3}H-PAC) prior to vacuum filtration. Nonspecific binding was defined by piperoxan or phentolamine (0.1 mM). Specific, saturable, high-affinity ^{3}H-PAC sites were abundant in BACC P2 membranes (B_{max}=-345±111 fmol/mg protein; K_d=0.66±0.24 nM). Most of the ^{3}H-PAC sites in BACC were present in P2 (72±12%); lesser amounts were recoved in P1 (19±3%) and P3 (9±2%). Adrenergic agents with imidazole rings, e.g. phentolamine, piperoxan, PAC and idazoxan, completely and potently inhibited ^{3}H-PAC binding (K_i<300 nM), whereas non-imidazoles such as epinephrine, phenylephrine and SKF-86466 were inactive (K_i>1 mM). Imidazoles lacking adrenergic potency exhibited high affinity for ^{3}H-PAC sites on BACC (cimetidine: K_i=3.3±0.9 µM; IAA: K_i=5.2±1.3 µM). Brain extracts containing clonidine-displacing substance (CDS), the putative natural ligand at imidazole receptors, potently inhibited ^{3}H-PAC binding (K_i=0.21±0.04 Units). We conclude that clonidine binds to imidazole but not to α_2-adrenergic receptors in BACC. Imidazole receptors may mediate the actions of clonidine on BACC, and CDS may be the endogenous ligand.

277.7

EFFECT OF MPTP ON THE MORPHOLOGY OF THE PRIMATE ADRENAL MEDULLA. S.W. Carmichael, L.E. DeLanney, D.A. DiMonte*, L.S. Forno, I. Irwin*, and J.W. Langston, Dept. Anatomy, Mayo Clinic/Foundation, Rochester, MN 55905 and California Parkinson's Foundation, San Jose, CA 95128.

1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) was administered systemically to 15 squirrel monkeys. The doses varied from 1-3 s.c. injections of 2.5 mg/kg. Animals were sacrificed 1 to 41 days after the last injection. Two monkeys served as naive controls. Following sacrifice, the adrenal glands were removed and the adrenal medulla was prepared for transmission electron microscopy. There was little cytological evidence of toxic stress in chromaffin cells from animals treated 24 hours earlier. By three days post-injection, some necrotic and some functioning chromaffin cells were evident. The majority of cells from animals treated 5 to 10 days previously were necrotic, indicating the effects of stress. Evidence of stress was also seen in chromaffin cells from two animals who received repeated doses of MPTP. Some chromaffin cells from one animal sacrificed after 41 days were necrotic and others were depleted, indicating that the toxic effects of MPTP on the adrenal medulla can be long-lasting. The present study demonstrates that systemically-administered MPTP has a toxic effect on the adrenal medulla. This effect is manifested a few days after administration, but can be long lasting.

277.8

DETECTION OF TRANSMITTER SPECIFIC CNS NEURONS REGULATING THE ADRENAL GLAND WITH THE RETROGRADE TRANSNEURONAL VIRAL LABELING METHOD. A.D. Loewy, A.M. Strack, W.B. Sawyer, K.B. Platt*, and Dept. of Anatomy & Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110, and *Dept. of Veterinary Microbiology, College of Veterinary Medicine, Iowa State Univ. Ames, IA.

The retrograde transneuronal viral cell body labeling technique was used to detect the CNS cell groups that innervate the sympathoadrenal preganglionic neurons. A suspension of pseudorabies virus (PRV) was injected into the adrenal gland of rats with a glass micropipette. After two days, the rats received intracerebroventricular injections of colchicine (100 μg/10 μl saline). Two days later, the rats were perfused with 4% paraformaldehyde. Viral infections were detected using a pig antibody against PRV. Neurotransmitter enzymes and neuropeptides were detected using antibodies simultaneously with PRV antibodies.

Five key areas of the brain were labeled: parvocellular paraventricular hypothalamic nucleus, A5 noradrenergic cell group, rostral ventrolateral medulla, ventromedial medulla, and the caudal raphe nucleus. Putative neurotransmitters are found to co-localize with PRV infected cells. In the brain stem: substance P, serotonin, neuropeptide Y and PNMT immunoreactive cells co-localize with PRV; also smaller numbers of somatostatin and enkephalin cells co-localize. In the A5 cell group, most of the PRV infected cells co-localize with tyrosine hydroxylase and some co-localize with somatostatin. In the parvocellular paraventricular hypothalamic nucleus, several transmitters co-localize with a small percent of the PRV infected cells, including substance P, tyrosine hydroxylase, enkephalin, oxytocin, neurotensin, somatostatin and vasopressin. These data indicate that the sympathoadrenal preganglionic neurons are innervated by a wide spectrum of chemically coded CNS neurons.

CENTRAL AND PERIPHERAL REGULATION OF SYMPATHOADRENAL ACTIVITY DURING EXERCISE. AJW Scheurink* and AB Steffens* (SPON: O Hathaway). Dept of Psychology, Univ of Washington, Seattle WA, 98195 USA, and Dept of Animal Physiology, Univ of Groningen, 9750 AA Haren, The Netherlands.

The role of the sympathetic nervous system in the regulation of energy substrate release was investigated in exercising rats. Exercise consisted of strenous swimming against a counter current for 15 min. Before, during, and after exercise blood samples were taken through permanent heart cannulas for determination of plasma glucose, FFA, insulin, E, NE, and corticosterone concentrations.

Infusion of adrenoceptor antagonists into distinctive areas of the hypothalamus (VMH, LHA, or PVN) interfered with the normal hormonal and metabolic responses to exercise. Glucose, FFA, corticosterone, and catecholamine levels changed independently of each other after hypothalamic adrenoceptor blockade and exercise. Experiments dealing with intravenous administration of selective adrenoceptor agonists and antagonists in intact and adrenodemedullated exercising rats demonstrated that the two branches of the sympathoadrenal system are functionally and metabolically dissociated. The experiments also showed that presynaptic adrenergic regulatory mechanisms at the peripheral sympathetic nerve endings influence the activation of the sympathetic nervous system during exercise.

The results suggest that the organization of an organ specific activation of sympathetic output during exercise may take place at different levels of the CNS. The hypothalamus can be considered as the major of these levels. Further, the activity of the sympathetic nervous system may be affected at the level of extrahypothalamic areas in the limbic system, in various nuclei of the brain stem, in the intermediolateral column of the spinal cord, in the sympathetic ganglia and the adrenal medulla, and at the level of the peripheral nerve endings of the sympathetic nervous system. (Supported by the Netherlands Organization of Scientific Research).

DEVELOPMENTAL DISORDERS: GENETIC AND CHEMICAL MODELS

ENHANCED PRODUCTION OF SUPEROXIDE BY MICROGLIA FROM TRISOMY 16 MICE. Carol A. Colton, Jibin Yao*, Daniel Gilbert and Mary Lou Oster-Granite. Department of Physiology and Biophysics, Georgetown University Medical School, Developmental Genetics Laboratory, Johns Hopkins University School of Medicine and the Lab of Biophysics, NINDS, NIH.

Disruption of normal oxygen radical metabolism in the CNS may contribute to the neuropathological changes associated with Down Syndrome (trisomy 21) and its mouse counterpart, the trisomy 16 (Ts16) mouse. Our lab has shown that one potent source of oxy-radicals is the CNS-specific macrophage, the microglial cell. We prepared primary glial cultures from the cerebral cortices of Ts16 and normal littermate mice taken at day 15 of gestation. Microglia were isolated from confluent cultures after 14 days in vitro and assayed for superoxide anion production using a cytochrome C reduction assay. Stimulation by either opsonized zymosan (OPZ) or phorbol myristate acetate (PMA), produced significantly higher levels (2.8 to 20 fold) of superoxide per mg protein in Ts16 microglial cultures. Resting, i.e., unstimulated secretion, was not significantly different from littermate controls. Astyrocyte enriched cultures, stimulated by OPZ, exhibited low levels of superoxide production which ranged from 1.4 to 2 fold higher than astrocytes from normal littermate cultures. Rat microglial enriched cultures were exposed for 24 hours to medium from the Ts16 glial cultures. Superoxide production in the Ts 16-media treated rat microglia was significantly higher compared to those treated with littermate conditioned media. Supported in part by HD 19920.

OLIGOSACCHARIDE ACCUMULATION IN BRAIN AND SPINAL CORD IN CAPRINE β-MANNOSIDOSIS. P.J. Boyer, M.Z. Jones, E.J.S. Rathke*, N.K. Truscott* and K.L. Lovell. Dept. Pathol., Mich. State Univ., East Lansing, MI 48824.

Goats affected with β-mannosidosis have deficient activity of the lysosomal enzyme β-mannosidase along with tissue accumulation of a trisaccharide (TS, Manβ1-4GlcNAcβ1-4GlcNAc), a disaccharide (DS, Manβ1-4GlcNAc), and small quantities of complex oligosaccharides. A caudal-to-rostral pattern of increasingly severe central nervous system myelin deficiency is a major pathological feature of caprine β-mannosidosis. In this study, TS and DS content in cerebral hemisphere (CH) gray matter and white matter and in spinal cord from three affected and two control neonatal goats was measured to determine the extent of association between oligosaccharide storage and myelin deficiency. In affected goats, content of TS and DS (expressed as ug hexose per mg protein) was 40% higher in spinal cord (moderate myelin deficiency) than in CH white matter (severe myelin deficiency) or gray matter. The ratio of TS:DS content was about 6:1 in all three regions. Thus, in affected animals, greater accumulation of TS and DS is not associated with more severe myelin deficiency. The similarity of TS and DS content in gray and white matter was an unanticipated result, considering the higher concentration of lysosomal storage vacuoles in gray matter cells. Supported by NS 20254 (KLL) and NS 16886 (MZJ).

SPATIAL LEARNING DEFICITS IN TWO YEAR OLD MICE HETEROZYGOUS FOR THE *TWITCHER* (C57Bl/6j/*twi*) MUTATION. Ch. E. Olmstead UCLA Sch. of Med., Mental Retardation Res. Center Group at Lanterman Developmental Center, Pomona, CA 91769.

The *twitcher* mouse is an enzymatically authentic model for recessively transmitted globoid cell (Krabbe) leukodystrophy. We have previously described subtle neurological (Behav. Brain Res. 25(1987) 143-153) and learning (Soc. Neurosci. Abstr. 13, 1987) differences between developing heterozygotes (*twi/+*) and their normal (*+/+*) littermates. Aging *twi/+* show decreased nerve conduction velocities compared to *+/+* (Soc. Neurosci. Abstr. 14, 1988), suggesting that this mutant is also a model for heterozygote risk during lifespan development.

We report here for the first time a longitudinal investigation of spatial learning in the Morris water maze in 32 mice of both sexes (*twi/+*, N = 19; *+/+*, N = 13) studied during the first month of life and after two years of age. Genotype was determined by assay of galactosylceramidase from short segments of tail in the first week of life. As we originally reported there were substantial differences between *twi/+* and *+/+* as juveniles and these differences, as measured by both water and radial maze indices, disappeared in early adulthood. Those behavioral deficits were again seen with increasing frequency in aged animals where *twi/+* showed significantly longer latencies in finding the platform, swam slower and showed more error trials. The features most associated with adolescence, floating, escape, etc, were seen on a significantly higher number of trials in the *twi/+* than in the *+/+*.

METHYLMERCURY-INDUCED MOVEMENT AND POSTURAL DISORDERS IN THE DEVELOPING RAT: INHIBITED DEVELOPMENT OF INTRACORTICAL CAPILLARY NETWORKS. J.R. O'Kusky. Dept. of Pathology, Division of Medical Microbiology, University of British Columbia, Vancouver, B.C., Canada V5Z 1M9.

The neurotoxicity of methylmercuric chloride (MeHg), administered to neonatal rats (5 mg/kg/day) beginning on postnatal day 5, produces movement and postural disorders during the fourth postnatal week. Stereological analyses of the length density of intracortical capillaries (L_V, total capillary length per unit volume) were performed in individual laminae of the visual cortex (area 17) at the onset of neurological impairment and at three subclinical stages of toxicity. When MeHg-treated rats were compared to weight-matched controls, the L_V of capillaries was significantly less in lamina IV and in the adjacent regions of laminae III and V at the onset of neurological impairment (30-40%) and at two subclinical stages of toxicity (20-35%). The laminar distribution of this decrease in the L_V of capillaries correlates with the distribution of degenerating stellate neurons in laminae III, IV and V of the visual cortex (O'Kusky, J., Exp. Neurol., 89:32, 1985). Since the inhibited development of intracortical capillaries precedes the onset of neuronal pathology in this animal model, it would appear that the degeneration of neurons in the visual cortex is secondary to these vascular abnormalities. ADULT HYPERACTIVITY RESULTING FROM POSTNATAL ADMINISTRATION OF DELTA, BUT NOT MU OR KAPPA, OPIOID AGONIST. J. W. Spain, Dept. Biomedical Sciences, Univ. Illinois College Medicine, Rockford, IL 61107.

Chronic perinatal morphine or methadone treatments have been reported to induce hyperactivity in young adult rats. However, the opioid site responsible for this persistent developmental effect has not been identified. Rat pups were treated (s.c.) daily from postnatal days 1 to 16 with either DAGO (0.5 mg/kg), DPDPE (1 mg/kg), U-69593 (1 mg/kg), or vehicle (0.1 ml/15 g). On the last day of treatment, there was a tendency for mean body weight of all treatment groups to be lower control but only U-69593 treated rats were significantly lower. When rats were between 40 and 55 days old, hourly activity of a single rat was measured over a 24 hr period using a commercial optical activity monitor. Rats treated with the delta agonist, DPDPE, were significantly hyperactive ($p>.05$; one-way ANOVA with Tukey post-hoc test) with a 37% increase over controls during the dark phase of the circadian cycle (6 pm-6 am). Non-significant increases of 19% and 9% were seen in rats treated with DAGO and U-69593, respectively. Activity during the light phase was similar for all groups. When the data was further compared for each sex, only in the DAGO treatment group were sex differences detected (6% vs. 33% increase for males vs. females, respectively). Our results implicate the delta opioid site in hyperactivity resulting from perinatal opioid exposure.

278.6

THE EFFECT OF PERINATAL HYPOXIA-ISCHEMIA IN A UNILATERAL RODENT MODEL ON STRIATAL TYROSINE HYDROXYLASE(TH)-POSITIVE FIBER INNERVATION. J Kent,* A Karanas,* RE Burke.(SPON: Y STERN). Dept. Neurology, Columbia Univ., NYC, NY, 10032.
Little is known of the effect of perinatal asphyxial injury on the neurochemical anatomy of the brain. The striatum often shows the predominant pathology in dyskinetic cerebral palsy. Johnston (1983) had previously shown in a unilateral rodent model that striatal dopaminergic biochemical indices are relatively preserved. We studied whether there is morphologic evidence for sparing of these systems. Rat pups underwent left carotid ligation and exposure to 8% oxygen at 7 days of age, and were sacrificed at 3-4 weeks. Cryostat cut sections were stained for TH (ETI). Because striatal TH-positive fibers were too numerous to count, we used optical density as an ordinal measure, at the population level, of degree of TH-positive fiber innervation, to compare striata on the same section. This approach had been validated in 6-OHDA lesioned animals in relation to rotational behavior. We found that pups with mild striatal asphyxial injury (no volume loss) showed no change in extent of TH-innervation. Pups with moderate injury (decreased striatal volume) (N=7) showed an increased density of staining on the asphyxiated side (Wilcoxon $p<.001$, for N=83 sections in 4 striatal planes). Thus, there is clear morphologic evidence of sparing of striatal dopaminergic systems, with an increase in their innervation density, in the asphyxia-injured striatum. NINDS #KO7NS00746, DMRF, PDF.

DENDRITIC EFFECTS OF EXPERIMENTAL INFANTILE HYDROCEPHALUS AND VP SHUNTS. J.P.McAllister, M.H.Park*, S.D.Katz* and R.M.Kriebel. Depts. of Anatomy, Temple U. Sch. of Med. & PCOM, Philadelphia, PA 19140.

Since dendritic damage may underlie the neurological deficits which persist following surgical treatment of infantile hydrocephalus, we have examined a feline model suitable for placement of ventriculoperitoneal (VP) shunts. Hydrocephalus was induced in neonatal kittens by intracisternal injection of kaolin. Hydrocephalic animals were sacrificed 15-25 days later and compared to age-matched controls. VP shunting was performed 10-18 days post-kaolin on those animals that were confirmed to be hydrocephalic. Tissue from cortical areas 22 and 17 was processed for Golgi-impregnation and 370 pyramidal cell dendrites were analyzed light microscopically. Apical and basal dendrites from hydrocephalic brains consistently displayed decreased numbers of spines and thinner shafts. Some dendrites were nearly devoid of spines and numerous constrictions gave the shafts a beaded appearance. In contrast, shaft thickness and spine density of dendrites from shunted brains increased steadily over the 30 day post-shunt period to reach levels similar to controls. However, more dendrites from area 17, which was most affected initially, retained their retarded appearance. These results suggest that most, but not all, of the dendritic alterations caused by hydrocephalus can be corrected with VP shunts.

NEURAL TUBE DEFECTS INDUCED BY AMNIOTIC INJECTION OF CON A IN MOUSE EMBRYOS. S. Nakahara*, J. Fiacco*, D.G. McLone, M.G. Hvizd*, R.G. Higbee, and P.A. Knepper. Division of Neurosurgery, Children's Memorial Medical Center, Northwestern University, Chicago, IL 60614.

Carbohydrates may serve as determinants of differentiating cells in cell-to-cell interaction and maturation. To test the possibility that an exogenous lectin (Concanavalia ensiformis, Con A) may bind to mannose/glucose containing glycoconjugates of neuroepithelium during the process of neurulation and induce neural tube defects (NTD), a novel method of administration of Con A was tested in mice embryos. The amniotic cavity of individual embryos of time-bred C57BL/6J mice was injected with 100 ng of Con A (in a volume of 2 µl) on gestation day 8.2, 8.4 (prior to anterior neuropore closure, which normally closes at gestation day 8.5), and 9.0, 9.2 (prior to posterior neuropore closure, which normally closes at gestation day 9.5). Control embryos received 2 µl of saline, a sham injection, or no treatment. Con A administered prior to anterior neuropore closure resulted in exencephaly without spinal NTD, whereas Con A administered on gestation day 9.0 resulted in thoracic and/or lumbar NTD without exencephaly. Thus, these results indicate that the effects of an exogenous lectin were dependent on the time of its administration, and Con A administration resulted in target-specific NTD.

FITC-CON A BINDING IN NEURAL TUBE DEFECTS INDUCED BY HYPOTHERMIA DURING NEURULATION IN CHICK EMBRYOS.
S. Robinson*, D.G. McLone, R.C. Dauser*, R.G. Higbee, W. Goossens*, and P.A. Knepper. Division of Neurosurgery, Children's Memorial Medical Center, Chicago, IL 60614.

Neurulation involves cell-to-cell recognition and adhesion mediated in part by cell surface and extracellular glycoconjugates (GC). The timing of the expression and post-translational modification of GC may be influenced by environmental factors such as temperature. To test this hypothesis, chick embryos were incubated at 38°C for 30 hr (start of neurulation) and then at 35°C for 18 hr (during neurulation). Stage 11 embryos were examined by SEM and by serial sections of FITC-Con A-incubated 1-µm araldite sections using low-intensity light video microscopy. The majority of embryos subjected to hypothermia had a large (400-600 µm) zone, i.e., neural tube defect (NTD), characterized by closely apposed neural folds that did not adhere or fuse, whereas the control embryos had a small (50 µm) zone of neural fold apposition prior to closure. In abnormal embryos, the dorsal basal lamina of the neural fold was FITC-Con A positive within a few microns of the zone of closure, whereas in control embryos, it was FITC-Con A positive 50 µm rostral to the zone of closure. These results are consistent with the hypothesis that NTD may relate to an alteration in the intrinsic developmental timetable of the neuroepithelium and the expression of GC.

ALTERED PATTERN OF SHOCK-MOTIVATED ESCAPE IN RATS WITH PRENATALLY INDUCED MICRENCEPHALY.
H.K. Chang*, B.K. Chung*, S.K. Park* and M.H. Lee (SPON: A. Rabe). Yeungnam University, Korea; NY State Institute for Basic Research in Developmental Disabilities, Staten Islandy, NY 10314.

The rat with methylazoxymethanol (MAM) induced forebrain hypoplasia is a model of congenital brain defects. With its forebrain reduced by 60% and neurotransmitter imbalance, it displays, in addition to maze learning deficits, behavior indicative of emotional/motivational changes. It is hyperactive, shows enhanced performance in a shuttle box, and altered responsivity to different motivational conditions. In order to further explore its altered emotionality, we examined the effect of inescapable shocks on escape behavior. Male Sprague-Dawley rats (3 mo) received either 80 inescapable shocks (1.0 mA for 6s) or simple confinement in a chamber, followed in 24h by 30 shock-escape trials during which escape was allowed 6s after the onset of shock. In the no-preshock condition, the MAM rats displayed a significantly longer escape latency than the controls. Following inescapable shocks, however, no group difference was revealed; thus, compared to the no-preshock condition, the inescapable shock significantly increased the latency of the control rats, while it had no effect on the MAM rats. It indicates the MAM rats' performance is severely curtailed by a moderate level of stress, possibly reflecting an imbalance in relative concentrations of monoamines and acetylcholine.

278.11

MASKING OF ATTENTIONAL DYSFUNCTION BY NUTRIENT RESTRICTION.
M. Bunsey,* B.J. Strupp, J. Stasior,* D.A. Levitsky* and S. Ginsberg.* Dept. of Psychology and Div. of Nutritional Sci., Cornell Univ., Ithaca, NY 14853.

The present study was designed to test the hypothesis that attentional dysfunction (AD) may be obscured when nutrient restriction is used to motivate learning; prenatal ethanol (PE) exposure was used to induce AD. On days 5-20 of gestation, dams were maintained on a liquid diet containing 0 or 35% ethanol-derived calories. At 42 days of age, the female offspring (n=260) were tested. Half of the subjects were given a simple discrimination task (the Non-Distraction Task), while the other half was tested on a Distraction Task with both predictive and non-predictive cues present. For both tasks, half of the rats were fed ad libitum and half were maintained on a food restriction (FR) schedule. The pattern of results indicated increased distractability in the PE rats. While FR, as predicted, reduced distractability, its effect on learning rate was comparable for the PE and control groups. However, evidence for the hypothesized masking of AD by FR was obtained in further analyses of the types of errors committed by the animals. One particular type of error -- failing to pick the same object after a correct choice on the previous trial -- was evident in the PE rats only in the ad libitum feeding condition; it was masked by FR.

POLYLYSINE-DTPA-Gd ENHANCED MR IMAGES OF C6 GLIOMA AT 1.5 AND 9.4 TESLA.
S. Kornguth, M. Anderson, P. Turski, H.I. Robins, J. Cohen, J. Sorenson, A. Rappe, J. Markley. University of Wisconsin, Madison WI 53705.

A novel agent, polylysine-DTPA-Gd (PL-DTPA-Gd), was employed to define the margin between C6 glioblastoma and normal brain by magnetic resonance imaging (MRI) at field strengths of 1.5 and of 9.4 Tesla. Sixteen Wistar Furth rats (300 gms) were injected with $2X10^6$ C6 cells and four rats were injected with control vehicle. Seven days later the rats were injected intra-aortically with 0.5 ml of PL-DTPA-Gd (either 100, 10, 1 or 0 ug PL) and on the tenth day they were imaged by MRI. The PL (DP88) was modified with 1 Gd per 15 lysine residues. Images obtained at 1.5 Tesla were 3 mm slices while those obtained at 9.4 Tesla were 125 or 500 um slices. Without the PL-DTPA-Gd contrast agent, the tumors were barely detectable at either field strength. The tumors in animals that received PL-DTPA-Gd (1 ug or greater) were readily identified at 1.5 and 9.4 Tesla. The central tumor region had a reduced signal intensity (SI) with a high SI at the margin between tumor and normal brain. The size, location and histology of the tumors were examined in frozen brain sections that were stained with thionine. The high SI margin of the tumor was heavily vascularized and the 9.4 T instrument permitted detailed images of the margin structure. This study is the first to demonstrate the utility of the PL-DTPA-Gd imaging agent for definition of intracranial tumors and the utility of the 9.4 Tesla instrument as a microscopic analyzer of brain and gliomas.

NEUROTOXICITY II

279.1

NEUROTOXIC EFFECTS OF 3,4-METHYLENEDIOXYAMPHETAMINE (MDA) ON DOPAMINE (DA) AND SEROTONIN (5-HT) NEURONS IN REAGGREGATE TISSUE CULTURE.
L. A. Won, P. J. Kontur, P. C. Hoffmann and A. Heller. Dept. of Pharm. and Phys. Sciences, Univ. of Chicago, Chicago, IL 60637.

Methylenedioxyamphetamine is a synthetic amphetamine analog with abuse potential. MDA is toxic to 5-HT-containing, but not DA-containing, neurons in adult animals (Ricaurte et al., Science, 1985). (+)-MDA possesses amphetamine-like properties, while (-)-MDA has properties resembling hallucinogens. Neurotoxicity of these isomers was examined in three-dimensional reaggregate tissue cultures formed from dissociated cells of fetal mesencephalic tegmentum and corpus striatum. Reaggregates were exposed to (+)-MDA or (-)-MDA in concentrations ranging from 10^{-7}M to 10^{-4}M between 15 and 22 days in culture. Reaggregates were then analyzed for endogenous DA and 5-HT levels using HPLC, and DA and 5-HT cells were examined. DA and 5-HT cells were visualized using tyrosine hydroxylase (TH)- and 5-HT-immunocytochemistry, respectively. 10^{-4}M and 10^{-5}M (+)-MDA and (-)-MDA significantly decreased endogenous DA levels, with the (+) isomer being more potent. Both isomers of MDA at 10^{-4}M were equally effective in reducing endogenous 5-HT levels. At 10^{-4}M (+)-MDA and (-)-MDA, both DA and 5-HT cells showed evidence of damage including vacuolization and fragmentation. These results indicate that (+)-MDA and (-)-MDA affect both DA and 5-HT neurons in reaggregate cultures. In contrast to studies in adult animals, MDA decreased DA levels and at high concentrations produced evidence of cellular damage in the reaggregates suggesting that developing DA neurons may be more susceptible to this agent.

PRENATAL EXPOSURE TO METHYLENEDIOXYMETHAMPHETAMINE (MDMA)IN THE RAT: BEHAVIORAL AND NEUROCHEMICAL EFFECTS.
S.F. Ali, V.E.V. St. Omer*, H. Duhart*, R.R. Holson, F.M. Scalzo and W. Slikker, Jr*. Div. of Reprod. and Dev. Tox., NCTR, Jefferson, AR and Dept. of Vet. Biomed. Sci., College of Vet. Med., Univ. of Missouri, Columbia, MO.

The developmental toxicity of MDMA was assessed by measuring behavioral and neurochemical endpoints in offsprings after prenatal MDMA treatment. Pregnant CD rats were gavaged with 0, 2.5 or 10 mg/kg/day MDMA during gestation on alternate days 6-18. Pregnancy weight gain, gestational length, litter size, birth weight, physical appearance at birth, progeny growth and several behaviors were not altered by prenatal treatment. Olfactory discrimination on PND 9-11 and Figure 8 maze activity on PND 22-23 were enhanced in both male and female MDMA-treated progeny while negative geotaxis at PND 7-10 was delayed. Whole brain serotonergic uptake sites on PND 9 and 21 and 5-HT and 5-HIAA concentrations on PND 27 in frontal cortex (FC), hippocampus (HC) and caudate nucleus (CN) were not altered by treatment. Maternal 5-HT concentrations on PND-27, however, were significantly decreased in FC, HC and CN at 10 mg/kg. These data suggest that prenatal exposure to MDMA produces selective behavioral alterations without affecting 5-HT neurochemistry in the developing rat brain. Persistent neurochemical alterations, however, were observed in maternal brain.

279.3

COMPARED EFFECTS OF CHRONIC INFUSION OF GABA INTO THE NUCLEUS BASALIS AND FRONTAL CORTEX IN RATS.

M. Majchrzak* (1), S. Brailowsky (2) and B.E. Will (1).
(1) DNBC - Centre de Neurochimie du CNRS - 67084 Strasbourg, France. (2) Inst. Fisiol.Celular - UNAM - Mexico 04510 D.F., Mexico.

GABAergic neurons exert an inhibitory control on the cholinergic neurons of the nucleus basalis magnocellularis (NBM) which project onto the fronto-parietal cortex. Behavioral and morphological effects of a chronic infusion (by osmotic minipumps) of GABA into the NBM were compared to those of similar infusions into the frontal cortex. Rats were infused with GABA (at either 10, 50 or 100 µg/µl/h) in one hemisphere and simultaneously with saline in the contralateral hemisphere for 4 days ; the catheters were then exchanged and infusion pursued for 4 more days. Both cortical and NBM GABA treatments induced an ipsilateral turning bias (followed by a rebound effect after treatment with high doses) . Only cortical GABA infusion at the highest dosage induced a locomotor deficit in beam walking, which recovered after treatment. The highest doses of GABA, whether infused in the cortex or the NBM, induced a dose-dependent lesion (with extensive gliosis in NBM) only on the side first infused with GABA. These data corroborate previous results which also showed preventive effects of chronic intracerebral saline treatment. They may be of interest for interpreting some aspects of neurodegenerative diseases such as Alzheimer's disease.

279.4

CHANGED SETTING OF NORADRENALINE NEUROTRANSMISSION IN ADULT RAT BRAIN DUE TO NEONATAL AGONIST AND ANTAGONIST TREATMENT

G.J. Boer, M.G.P. Feenstra, E. Ernste (SPON:ENA). Neth.Inst for Brain Research, Amsterdam, The Netherlands.

Noradrenaline(NA) is functionally active early in brain development. Interference with NA neurotransmission during maturation therefore brings about advanced or delayed signals. Unlike reversible effects seen in adults such pharmacological interferences in neonates may reveal life-span changes in the NA system.

Male rat pups were injected twice daily with the α-agonist clonidine(0.1mg/kg), α-antagonist yohimbine(2.5mg/kg) or the β-antagonist propranolol(15mg/lg) either between birth and day 10 or between day 10 and 20. Brain monoamines and metabolites were determined in nine areas by means of HPLC/ED 2h after the last injection (direct effects) and at 2 or 3 months of age (long-term consequences).

Direct effects confirmed the functional activity of the NA system. Neonatal clonidine decreased, whereas propranolol and yohimbine increased MHPG. Early clonidine or yohimbine treatments gave no longlasting effects on NA or MHPG values. However, for clonidine αMpT-induced NA depletion was significantly retarded in some areas. Day 1-10, but not 11-20 propranolol injections revealed higher MHPG/NA ratios in the adult brain. The latter strongly indicate that antagonistic interference of the NA system during maturation can alter regional NA brain activity in adult stages.

279.5

PRENATAL HALOPERIDOL (H) EXPOSURE REDUCES OFFSPRING BRAIN WEIGHT.

R.R. Holson, S.F. Ali, F.M. Scalzo and R.L. Williams*. Division of Reproductive and Developmental Toxicology, National Center for Toxicological Research, Jefferson, AR 72079-9502.

The effect of prenatal H exposure on offspring brain weight was assessed in Sprague-Dawley derived rats. In two independent experiments, pregnant dams were given daily sc injections of vehicle, 2.5 or 5.0 mg/kg H, over gestational days (GD) 6 through 20. In both experiments, GD 20 maternal weight was reduced by 13% in the high-dose H group. Offspring body weight was reduced in experiment 1 (around 10%) but not experiment 2. In both experiments, whole brain weight at postnatal day (PND) 30 was significantly depressed (5 to 10%) in both male and female high-dose offspring. This reduced brain weight was seen at birth and on PNDs 15, 30, and 60. Dry weight of PND 30 H brains was also significantly reduced by a similar percentage. Gross dissection of PND 30 brains revealed that weight loss was restricted to certain brain regions. Caudate and brainstem were most affected. Weights of thalamus, hypothalamus and posterior cortical remnants were not reduced by prenatal H. It is concluded that dopamine may play a trophic role in early brain development, since prenatal receptor blockade seems to reduce brain weight even when body weight is not altered.

279.6

IN VIVO ELECTROCHEMICAL AND ELECTROPHYSIOLOGICAL STUDIES OF THE CAUDATE NUCLEUS OF NEONATAL 6-OHDA-LESIONED RATS.

J. Luthman[1,*], M.N. Friedemann[2,*], P. Bickford-Wimer[2,3], G. Rose[2,3], L. Olson[1], B.J. Hoffer[2] and G.A. Gerhardt[2]. Dept. of Histology[1], Karolinska Inst., Stockholm, Sweden and Depts. of Pharmacology and Psychiatry[2], Univ. of Colo., Denver, CO 80262 and VAMC[3], Denver, CO 80220.

Neonatal destruction of dopamine (DA)-containing neurons via intracerebroventricular or intracisternal (i.c.) treatment with 6-hydroxydopamine (6-OHDA) has been shown to produce rats that exhibit hyperactivity. The permanent decrease in DA levels is also associated with an increase in serotonin (5-HT). However, the neuronal mechanisms underlying the hyperactive behavior remain unclear. In the present study, high-speed electrochemical measurements of potassium-evoked monoamine overflow and extracellular single-unit electrophysiological recording methods were used to characterize the caudate nucleus of rats that had received neonatal i.c. injections of 6-OHDA (75 micrograms). Potassium-evoked electrochemical signals were diminished in amplitude as compared to control caudate nucleus, and the electrochemical responses were characteristic of extracellular 5-HT overflow rather than DA. Local applications of 5-HT, DA or phencyclidine into the caudate nucleus elicited excitations of caudate cells rather than the normal inhibitory effects seen in control animals. These data suggest that the function of remaining monoamine striatal circuits is dramatically changed as a consequence of the neonatal 6-OHDA exposure. Supported by USPHS grants AG06434, NS09199 and the VA.

279.7

INHIBITION OF RETROGRADE AXONAL TRANSPORT BY 3,4-DIMETHYL-2,5-HEXANEDIONE.

M.I. Sabri and P.S. Spencer. Oregon Health Sciences University, Portland, OR.

Previous studies from this laboratory have shown that single injections of high doses of 2,5-hexanedione (2,5-HD) produce reversible decreases in the rate of retrograde axonal transport (RT). We have examined the question whether 3,4-dimethyl-2,5-hexanedione (DMHD; a gift from Dr. L. Sayre), is capable of inhibiting RT. Rats were dosed daily with DMHD (0.25 mmol/kg I.P.) for nineteen days. DMHD-treated rats lost considerable body weight and developed severe hind limb weakness. Twenty-four hours after the last injection, gastrocnemius muscles of control and DMHD-treated rats were injected unilaterally with ^{125}I-labeled tetanus toxin. At 3 and 5 hours after tetanus-toxin injection, five rats, from each group, were sacrificed, ipsilateral and contralateral sciatic nerves, including tibial branches innervating the gastrocnemius muscle, were removed, cut into 3-mm segments and radioactivity in each segment determined with a gamma counter. The leading edge of retrogradely-transported ^{125}I was determined by plotting percent total radioactivity in each nerve segment against the distance transported. The apparent rate of RT in the control group was 6.8 ± 0.4 mm per hour. Animals treated with DMHD showed a reduced rate of RT (3.7 ± 0.9 mm per hour). These data show that multiple injections of DMHD inhibit RT velocity by approximately 45%. Dose-dependent inhibition of RT with DMHD is currently under study. Supported by NS 19611.

279.8

SUBTLE BEHAVIOURAL CHANGES PRODUCED IN RATS BY IN UTERO EXPOSURE TO DIAZEPAM

R. Cagiano*, M.A. De Salvia*, G. Renna*, M. Tattoli* and V. Cuomo* (SPON: G. Racagni). Institute of Pharmacology, Faculty of Medicine and Surgery, University of Bari, Italy.

The purpose of this experiment was to evaluate in rats whether the prenatal treatment with diazepam (0.1 or 1.0 mg/kg) could affect the ultrasonic vocalization which seems to be a sensitive indicator of emotional and motivational changes (Cagiano, R. et al., Life Sci., 38:1417, 1986 and Cagiano R. et al., Eur. J. Pharm.,157:45, 1988). In particular, the following parameters were evaluated: a) ultrasonic vocalization elicited by the removal of the rat pups from their nest; b) ultrasonic vocalization of male rats during sexual behaviour.

Primiparous pregnant Sprague Dawley dams were administered a single daily s.c. injection of diazepam or vehicle, over gestation days 14-20. The results show that the administration of diazepam during gestation produced in rat pups removed from their nest marked changes in the lenght of ultrasonic calls. Finally, adult male rats (120 days of age) prenatally exposed to diazepam showed a notable impairment in copulatory activity as well as a significant decrease in the duration of ultrasonic 22 kHz post-ejaculatory calls emitted during sexual behaviour.

These results further confirm that prenatal treatment with diazepam produces short and long-term behavioural changes at dose levels below those associated with overt signs of neurotoxicity.

279.9

NUCLEUS BASALIS LESIONING IN NEONATE RATS: A SELECTIVE CORTICAL CHOLINERGIC HYPOFUNCTION AND BEHAVIORAL IMPAIRMENT DURING ADULTHOOD. G.J. Sengstock[1]*, K.B. Johnson[1]*, E.M. Meyer[2], A.J. Dunn[3] and G.W. Arendash[1]. (SPON: C. Edwards) Dept. of Biology, U. of South Florida, Tampa, FL 33620[1], Dept. of Pharm., U. of Florida, Gainesville, FL 32610[2] and Dept. of Pharm., Louisiana State U., Baton Rouge, LA 70803[3].

Ibotenic acid was infused bilaterally into the nucleus basalis magnocellularis (nBM) of 2 day-old neonate rats to eliminate immature cholinergic neurons within the nBM before they develop functional termination points in the neocortex. Behavioral testing was initiated 2 months post-lesion and all animals were sacrificed at 8 or 12 months of age. Histological analysis of the subcortex from these lesioned animals revealed a gliosis essentially restricted to the globus pallidus (containing the nBM). Neurochemically, cortical choline acetyltransferase (CAT) activity was reduced significantly by 25% at 8 months and by 18% at 12 months after lesioning. Cortical concentrations of biogenic amines and their metabolites were unaffected, indicating the selectivity of these lesions. Behaviorally, lesioned animals had a marked deficit in passive avoidance retention and 2-way active avoidance acquisition. They also demonstrated significant deficits in two spatial tasks: Lashley III maze and 17-arm Radial maze. These data indicate that neonate nBM lesions may provide a useful animal model for elucidating changes in the plasticity of the developing brain as a result of cortical cholinergic anervation.

279.10

6-HYDROXYDOPAMINE TOXICITY IN MESENCEPHALIC CULTURES IS POTENTIATED BY THIOLS. H. Kalir* and C. Mytilineou. Dept. of Neurology, Mt. Sinai Sch. of Med. New York, N.Y. 10029.

Mesencephalic neuronal cultures from 14 day old rat embryos were treated with 6-hydroxydopamine (6OHDA; 0.1mM), 6OHDA + N-acetylcysteine (NAC; 1mM) or 6OHDA + cysteamine (CAM; 1mM) for 1 hour. Toxicity was assessed by measurement of [^{3}H]dopamine uptake 24 hours later. A reduction in uptake was noted in all 3 cases, but adding NAC or CAM to 6OHDA resulted in a potentiation of the toxic effect (1.75 and 2.94 fold increase in toxicity respectively, compared to 6OHDA alone). The potentiating effect of NAC was not due to protection from 6OHDA auto-oxidation in the medium, since HPLC measurements showed no change in the extra- or intracellular levels of 6OHDA when NAC was added. Extracellular auto-oxidation of NAC or CAM, which could result in formation of reactive oxygen species, was not a factor in the potentiation of 6OHDA neurotoxicity, since addition of catalase and superoxide dismutase to the medium had no protective effect. The mechanism of potentiation of 6OHDA toxicity by thiols is currently being investigated. Supported by NIH grants NS-11631 and NS-23107.

279.11

COMPARISON OF THE EFFECTS OF INTRADENTATE VERSUS INTRAVENTRICULAR INJECTIONS OF COLCHICINE: NEUROBIOLOGICAL AND BEHAVIORAL CORRELATES. D.F. Emerich, R.W. Stackman and T.J. Walsh. Rutgers University, Department of Psychology, New Brunswick, NJ 08903.

Intradentate injection of colchicine (COL) produces an extensive loss of dentate granule cells, a 25% loss of cholinergic neurons within the medial septum and persistent memory impairments (Emerich and Walsh, Physiol. Behav., 45, 93-101, 1989). In the following studies we compared the behavioral and neurobiological effects induced by COL injected into either the hippocampus (HPC) or lateral ventricles (ICV)

Sprague-Dawley rats were trained on a standard radial arm maze (RAM) task. Following training, COL was injected bilaterally into the HPC or ICV (3.5 or 7.0 ug/.5 ul/site). Animals receiving intradentate injections of COL, regardless of dose, were markedly impaired on the RAM task and showed no evidence of recovery. Depending on the dose, ICV COL produced either a transient impairment which recovered within 15 trials (3.5 ug) or a long lasting impairment (7.0 ug).

Quantitative histological analysis (9 weeks following COL) revealed that intradentate COL produced a significant decrease in the thickness of both blades of the dentate gyrus and a 15-18% loss of cholinergic neurons within the medial septum. ICV COL had no effects on hippocampal morphology but did produce a 40% loss of septal cholinergic neurons (7.0 ug).

An analysis of the time course of cholinotoxicity (7.0 ug) revealed that both intradentate and ICV COL produced significant decreases in hippocampal ChAT activity and HAChU at 1 and 3 but not 9 weeks following surgery. No alterations were observed in either ChAT or HAChU in the striatum, frontal cortex or olfactory bulbs.

These data suggest that, in these model systems, COL exerts a pronounced and selective effect on the septohippocampal cholinergic system which is not dependent upon the loss of granule cells but appears to result from a direct cholinotoxic effect.

NEUROTOXICITY OF INTRAVENTRICULARLY INJECTED RIBOSOME INACTIVATING PROTEINS. R.G. Wiley and K. Leone*, VAMC, Nashville, TN 37212.

Immunotoxins consisting of monoclonal antibodies coupled to ribosome inactivating proteins (RIPs) are potentially useful for making experimental lesions and in the treatment of CNS cancer. We sought to compare the neurotoxicity of 3 free RIPs that might be used to construct such toxins to 3 toxic lectins. Test agents were pressure injected into the left lateral ventricle of anesthetized, adult, male Sprague-Dawley rats using stereotactic technique. Animals were observed and weighed daily for up to 2 weeks. The toxic lectin, volkensin, was most potent with a minimal lethal dose (MLD) <2.7 ng/rat. The MLD for ricin was <50 ng/rat and for viscumin <100 ng/rat. By comparison, the RIPs that had no specific binding activity were much less potent. The MLD for ricin A chain was >6.5 ug/rat and >4.2 ug/rat for deglycosylated ricin A chain. The MLD for saporin was <50 ug/rat. Only 1 of 42 rats died in <42 hrs. The neurologic deficits seen at doses near the MLD often suggested cerebellar dysfunction, but at higher doses inanition appeared rapidly followed by death. The results will form a basis for comparison with specific immunotoxins. (This work supported by Veterans Administration.)

EFFECTS OF CHRONIC DELTA-9-THC ON HIPPOCAMPAL ULTRASTRUCTURE AND ADRENAL HYPERTROPHY. L.B. Cadwallader*, S.L. Vinsant* and P.W. Landfield (SPON: M. Levitt). Dept. Physiol. & Pharmacol., Bowman Gray Sch. Med., Wake Forest Univ. Winston-Salem, NC 27103

In a previous study (Landfield, et al, Brain Res, 1988) we found that long-term treatment with 8 mg/kg delta-9-tetrahydrocannabinol (THC) induced aging-like neuronal loss and glial reactivity in the hippocampus of young rats. In addition, the chronic THC treatment increased adrenal-pituitary hormonal release during restraint stress. The similarity between THC and glucocorticoid molecular structures led to the hypothesis that THC may mimic the hippocampal aging-like neurotoxic effect of corticosteroids. Alternatively, THC might interfere with negative feedback, causing increased release of endogenous corticosteroids.

In the previous study, however, no clear effects on synaptic density were seen, possibly due to sprouting or remodeling. It was also unclear whether adrenal steroids were elevated continually in THC-treated rats. In the present study, we attempted to increase the effect with a higher dose of THC (10 mg/kg, s.c., 5 x weekly) given for 9 months to young, male rats. Hippocampal structure was quantified in 50 electron micrographs and 5 semithin sections from each of 11 vehicle controls and 14 THC rat brains that met all criteria for good fixation. Stereological methods were used, and all micrographs were coded and scored blind.

The results replicated our previous work on the loss of CA1 neurons and increased astrocyte reactivity. However, only a borderline effect on one category of synapses was seen. Nevertheless, ultrastructural effects were found in the neuronal somata, such that cell volume occupied by the Golgi apparatus was increased. Endoplasmic reticulum also exhibited an increase. These data seem consistent with greater genomic activation, perhaps due to increased steroid-like stimulation.

Adrenal gland weights were significantly elevated in THC-treated animals, indicating that THC interactions with corticosteriod systems are persistent and, therefore, viable mechanisms for the neurotoxic effects of THC (supported by DA 03637, ADAMHA).

EFFECTS OF IMINODIPROPRIONITRILE ON AUDITORY FUNCTION IN THE RAT. K.M.Crofton, R.Janssen, L.D.Williams* and R.C.Hamrick*. Neurotoxicology Division, US EPA, RTP, NC 27711 and NSI Technology Services, RTP, NC 27709.

3,3-Iminodiproprionitrile (IDPN) is a neurotoxicant that induces a hyperkinetic syndrome in rats consisting of spontaneous head movements, abnormal circling, backwards locomotion, and sensory disruption. The present study was designed to compare IDPN-induced auditory dysfunction using behavioral and electrophysiological techniques. Adult male Long Evans hooded rats (n=9-12/group) were exposed to saline, 100, 150, or 200 mg/kg IDPN for 3 consecutive days. Auditory thresholds were determined for 5 and 40 kHz tones using acoustic reflex modification of the auditory startle response (ARM). Motor function was assessed using figure-eight maze activity and hindlimb gripstrength. Behavioral endpoints were measured 24hrs, 1, 3, and 9 weeks post-dosing. Brainstem auditory evoked response (BAER) thresholds were determined for 5 and 40 kHz filtered clicks at 11 weeks post-dosing. ARM thresholds for 5 kHz tones were elevated 25-35 dB in the high dosage group starting 3 weeks post-dosing, and 40 kHz thresholds were increased 50-55 dB within 48 hrs in the 200 mg/kg group and 15-25 dB in the 150 mg/kg group. BAER thresholds for 5 and 40 kHz clicks were elevated 50-55 dB in the 200 mg/kg group only. Motor function tests indicated a 400% increase in locomotor activity in the 200 mg/kg group that persisted for up to 9 weeks, whereas gripstrength was unaltered at any dosage. These data demonstrate dosage- and time-dependent alterations in auditory and motor function following IDPN exposure.

DEVELOPMENT OF MAJOR HISTOCOMPATIBILITY COMPLEX ANTIGEN EXPRESSION IN RATS FOLLOWING EYE REMOVAL AT VARIOUS POSTNATAL AGES K. T. Yee*, A. M. Smetanka*, R. D. Lund, K. Rao. Department of Neurobiology, Anatomy and Cell Science, Univ. of Pittsburgh, School of Medicine, Pittsburgh, PA 15261

Cells in the mature nervous system, unlike other tissues in the body, do not normally express major histocompatibility complex (MHC) antigens. However, expression is seen in certain disease states such as multiple sclerosis and Alzheimer's disease. We have found that MHC antigen expression can be induced in mature animals after eye removal--class I MHC antigens are expressed in degenerating optic terminal regions while class II MHC antigens are expressed mainly in degenerating pathways. A retinal graft implanted into the brain of a mature animal is subject to a higher rate of spontaneous rejection than one implanted into the brain of an early postnatal animal. This study examines the relationship between MHC antigen expression, myelination and transplant rejection.

The time course of MHC antigen expression was studied in Sprague-Dawley rats after unilateral eye removal on postnatal day (PND) 0, 5, 7.5, 10, 12.5, 15, 17.5. Normal and eye lesioned animals were perfused, fixed, and sections were stained with OX-6 for class II MHC, OX-18 (class I MHC), OX-42 (microglia), W3/25 (reactive microglia), and GFA (astrocytes). As in adults, normal postnatal rats do not express class II MHC antigens. In contrast, however, large areas of the normal postnatal rat brain contain cells which express class I antigen. After eye removal on PND 0, an increase in class I expression is seen in the superficial layers of the superior colliculus and optic tract by PND 5. In contrast, the first evidence of class II expression is seen in the optic tract after eye removal on PND 12, and in the superior colliculus after enucleation on PND 15; this is at the time when the optic pathway becomes myelinated.

These results support the hypothesis that class II expression is associated with myelin degeneration. The absence of lesion induced class II expression may explain why eye removal in early postnatal animals does not cause rejection of xenografts placed in neonatal brains, while eye removal at later times does result in graft rejection.

280.2

DEGENERATING UNMYELINATED AXONS INDUCE CLASS I BUT NOT CLASS II MHC ANTIGEN EXPRESSION. A. M. Smetanka*, K.T. Yee*, R.D. Lund, and K. Rao. Department of Neurobiology, Anatomy, and Cell Science, Univ. of Pittsburgh, School of Medicine, Pittsburgh, PA 15261

Major histocompatibility (MHC) antigen (Ag) induced expression in the adult rat following eye lesion is known to follow two distinct patterns of expression in the superior colliculus of the brain (Rao et al. Brain Res., in press). Class I Ags are present in degenerating tracts and terminal regions, while class II Ags are predominantly associated with degenerating fiber tracts. To test the hypothesis that class II Ag expression is uniquely associated with degenerating myelinated pathways, we have examined expression patterns after lesions of an unmyelinated pathway. Small lesions confined to the molecular layer of the cerebellum were made, using a 26 gauge needle, in adult Sprague-Dawley rats. Animals were perfused with zinc-aldehyde after 1-9 days survival. Alternate sections were then stained with OX-6 (for class II Ags), OX-18 (for class I Ags), OX-42 (for microglia), and GFAP (for astrocytes).

Class I and II Ag staining was always found around the lesion and positively stained large cells with few processes, presumed to be invasive macrophages. These presumptive macrophages were seen extending variable distances into the brain from the lesion site. Class I Ag staining appeared in cells in the molecular layer, being heaviest 2-3 days after the lesion. The cells had the morphology of microglia. No class II Ag staining was seen in these cells throughout the survival period studied. When lesions extended into the granule cell layer, class II Ag expression on these microglia-like cells was still not seen in the molecular layer; however, large numbers of these labelled cells were present in the white matter, extending into the deep nuclei of the cerebellum.

These findings support the hypothesis that there is a special relationship between degenerating unmyelinated axons and the induction of class II Ag expression.

SCHWANN CELL PROLIFERATION IS UNDER NEGATIVE AUTOCRINE CONTROL

D. Muir*, C. Gennrich*, S. Varon, M. Manthorpe. (SPON: C. Wiley) Dept. of Biology, U.C.S.D., La Jolla, CA. 92093.

Unlike most other cell types, purified populations of rat sciatic nerve Schwann cells (SCs) divide very slowly (10-20 day cycle) under standard serum-containing culture conditions. However SCs are capable of robust proliferation if provided with mitogens such as cholera toxin or neurons in coculture. Here we have examined whether such cultured SCs release substance(s) that inhibit their proliferation in the absence or presence of added mitogens. SC proliferation was monitored in subconfluent microcultures by direct cell counting and [3H]thymidine incorporation. When serial dilutions of medium conditioned by confluent SC cultures were added to mitogen stimulated microcultures, a concentration-dependent and reversible inhibition of cell proliferation was observed. The inhibition of proliferation by SC conditioned medium occurred when test SCs were under the influence of mitogens believed to have different mechanisms of action, suggesting that negative regulation involves a common process in the proliferative pathway. A similar inhibitory activity was found in medium conditioned by rat RN22 Schwannoma cells, but not in media conditioned by rat astroglial or mouse 3T3 fibroblastic cells. The above results indicate that SC proliferation is under negative autocrine control.

BASAL LAMINA DEPOSITION ON SCHWANN CELLS CULTURED WITH FIBROBLASTS IN THE ABSENCE OF NEURONS. M.B. Bunge and P.M. Wood*. Dept. Anat. & Neurobiol., Washington U, St. Louis, MO.

In well differentiated neuron-Schwann cell (SC) cultures, the abaxonal surface of SCs is covered with basal lamina (BL). Additional culture studies suggest that substantial axonal contact (as during the process of SC ensheathment of an axon) is critical for SCs to fully assemble this BL (Clark and Bunge, '89). We as well as other investigators have repeatedly observed that, although SCs grown without neurons in differentiation supporting medium deposit BL constituents, typical BL is not seen (e.g., Baron-Van Evercooren et al., '86). When neurons and SCs are co-cultured but kept separate, the same result is obtained, even though mRNA for a BL component, laminin, is increased in SCs (Dean et al., '89). In this study cultures consisting of SCs and fibroblasts (Fbs) were studied electron microscopically; to our surprise, we observed that a BL-like structure enclosed singly situated SCs or encircled the external border of clustered SCs. These neuron-free cultures had been prepared as follows. Purified SCs were obtained from cultures of embryonic rat dorsal root ganglia first treated with fluorodeoxyuridine to eliminate Fbs and then maintained in defined medium to allow proliferation of BL-free SCs. The ganglia were excised and the remaining SCs were resuspended and plated ; 1 to 3 d later Fbs obtained from outgrowth regions of periosteum explants were added. Assembled cultures were grown in medium containing serum and embryo extract for 6-8 wk. The BL (lamina densa) was as thick or thicker than that observed in neuron-SC cultures; the lamina lucida was sometimes obscured. This is the first observation of substantial BL assembly on SCs (initially devoid of BL) cultured without neurons. Because SCs (without neurons) given exogenous BL components (Matrigel; PMW, unpublished) do not assemble BL to as great a degree, we suggest that the Fbs are not simply providing additional BL components for assembly of the SC. (NIH NS09923).

A NEW GLIAL CELL SPECIFIC IMMUNOPROBE SHOWS PARTIAL TISSUE SITE SPECIFICITY. L. Zhang* AND N. G. F. Cooper. Dept. of Anatomy and Neurobiology, Univ. of Tenn., Memphis, TN 38163

The regional distribution of glia in the developing cerebral cortex, hippocampus, basal ganglia and cerebellum of the rat was studied with the immunoprobe, GLIAS, a glial cell specific antiserum. The serum was prepared by immunizing Balb/c mice with a subcellular fraction of cultured glial cells isolated from fetal rat striatum. Aldehyde perfused brains of anesthetized rats were used to obtain vibratome sections. Glia cells were recognized with a light microscope by the presence of dark brown horseradish peroxidase product after immunocytochemical staining. Radial glia were strongly stained at prenatal stages and were substituted by the less extensive and more astro-like immature glia at early postnatal stages in all areas. In cerebellar cortex, strongly stained radial glial processes of Bergmann cells were evident in early postnatal and adult animals. Mature astrocytes were predominantly present in the basal ganglia, cerebellar white matter, hippocampus, and corpus callosum in the adult brains. GLIAS labeled fewer glia cells than did anti-GFAP in the CNS of adult animals which suggests that a distinctive subpopulation of glia exists in the CNS of mature animals. Thus GLIAS may provide a sensitive method for the study of the organization and the histogenic role of glia during development. Finally, when glial antigens derived from fetal rat striatum were used to immunize mice, the resultant antibodies recognized a subpopulation of glia present in adult rat striatum, cerebellum, hippocampus and corpus callosum, but not cerebrum, thalamus, and brainstem. Supported by NIH:NEI EY02708 (NGFC) and a Neuroscience Center of Excellence predoctoral fellowship (LZ).

NEUROPEPTIDE GENE EXPRESSION IN CULTURED ATROCYTES: BRAIN REGION AND GENE SPECIFICITY.
J.P.Schwartz, H.Shinoda, A.M.Marini* and C.Cosi
Clinical Neuroscience Branch, NINDS, NIH, Bethesda, MD 20892

Astrocytes exhibit many neuronal characteristics, such as neurotransmitter receptors, ion channels and neurotransmitter uptake systems. We now present evidence that cultured astrocytes express certain neuropeptide genes, with a specificity shown for both the gene expressed and the brain region from which the cells were prepared. Somatostatin (SS) mRNA and peptide are present only in cerebellar astrocytes whereas proenkephalin (PE) mRNA and enkephalin peptides are present in astrocytes of cortex, cerebellum and striatum. Cholecystokinin is not expressed in any of the cells. Exposure of either cortical or striatal astrocytes to forskolin, which elevates cyclic AMP, increasesd both PE mRNA and enkephalins. The content of neuropeptide mRNA decreases with age of the donor animal: cells prepared from E20 and postnatal day 3 rat cerebellum contain the highest levels of SS and PE mRNA, the levels are reduced by PND8 and undetectable in adult. We propose that peptides synthesized in astrocytes may play a role in CNS development.

EPHEMERAL PATTERN OF CELL PROLIFERATION IN THE DEVELOPING OPOSSUM SUPERIOR COLLICULUS. L.A. Cavalcante*, P. C. Barradas* and A.M. Vieira* (SPON: C. Timo-Iaria), Instituto de Biofísica Carlos Chagas Filho, UFRJ, Rio de Janeiro, RJ, 21944, Brasil.

The appearance of GFAP$^+$ astrocytes in the opossum superior colliculus (SC) follows an outside/in gradient (Barradas et al., Glia, in press, 1989). To verify whether this gradient of glial differentiation is linked to patterns of non-neuronal cell proliferation, we have mapped the distribution of cells able to take up tritiated thymidine (3H-T) in pouch youngs of ages from 18-58 days. In selected stages, sections were also reacted for non-specific esterase or nucleoside diphosphatase. 3H-T$^+$ cell nuclei were few and dispersed in most stages but were numerous and arranged in 3 tiers in 30 day SC. No evidence was found for the involvement of macrophage/microglial precursors in this pattern of proliferation. The results show no link between the patterns of cell proliferation and sequence of GFAP expression. In addition they suggest that either macroglial percursors in the collicular parenchima reenter the mitotic cycle or that there is short-term immigration of macroglial precursors in the SC. PRIMARY ENCEPHALOCELE CULTURES CAN YIELD PURE POPULATIONS OF NORMAL HUMAN ASTROCYTES.
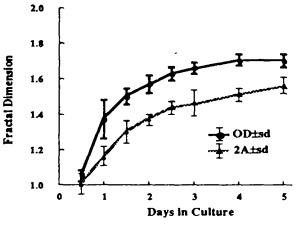
R.L. Alterman*, J.T. Goodrich, R.M. Morrison and J.R. Moskal. Department of Neurological Surgery, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY 10461



In order to develop a reliable source of human astrocytes for *in vitro* studies, we established a primary explant culture of a human encephalocele. A sample of encephalocele-derived white matter was minced and the pieces placed in a 25 cm^2 T-flask containing RPMI-1640 supplemented with 10% fetal bovine serum and antibiotics. A confluent monolayer of cells was obtained after two weeks at which time the cells were passaged by mild trypsinization (0.025%). Two cell-types with morphologies corresponding to fibrous and protoplasmic astrocytes were identified. All of the cells expressed glial fibrillary acid protein as determined by indirect immunofluorescence but none expressed somatostatin, galactocerebroside or neuron-specific enolase. Cytogenetic analysis revealed a normal 46XY karyotype. Cell growth was anchorage dependent. By passage 13 the cells exhibited phase III degeneration. The cells demonstrated a mitogenic response to epidermal growth factor (10ng/ml) and to basic fibroblast growth factor (10ng/ml). These results demonstrate that tissues derived from human encephaloceles can be used to generate pure populations of normal astrocytes.

FRACTAL ANALYSIS OF THE MORPHOLOGY OF DIFFERENTIATING GLIA. G.D. Lange[3], T.N. Behar*[1], T.G. Smith, Jr.[1], W.B. Marks[2] and W.H. Sheriff, Jr.*[3]. [1]LNP, [2]LNLC, [3]SIC, NINDS, National Institutes of Health, Bethesda, MD, 20892, USA.

Bi-potential progenitor cells (O-2A) derived from 7 day old rat optic nerve were used to generate synchronized, differentiating cultures of oligodendrocytes (OD) or type 2 astrocytes (2A). Populations enriched for each phenotype were produced by modifying the growth medium. Cultured cells were fixed at 12 hour intervals and identified immunocytochemically (GC$^+$ for OD; A2B5$^+$-GFA$^+$ for 2A). Video images of representative cells from each time were digitized and the borders were extracted. Fractal dimensions (FD) were calculated with a border dilation method.

FD correlated well with perceived morphological complexity. FD monotonically increased in both populations. It increased most rapidly and reached a plateau in OD. The plateau was not the result of a cessation of growth but its onset does coincide with the end of the period when a maturing OD can still be transformed to a 2A.

We believe that FD could replace biochemical markers as an indicator of the stage of differentiation of cultured cells and therefore provide a continuous "timeline" along which to study functional development.

280.11

UNIQUE MORPHOLOGY OF OLFACTORY BULB RADIAL GLIA: ROLE IN GLOMERULAR DEVELOPMENT? M.S. Bailey, M.R. Poston*, M.T. Shipley. Dept. of Anatomy and Cell Biology, Univ. of Cincinnati, Cincinnati, Ohio 45267.

Radial glia are considered an immature type of astrocyte which functions as a scaffold for the migration of neurons during development. In the rat olfactory bulb (OB), neurons migrate in an inside-outside manner similar to that in cerebral cortex; migration continues into postnatal development. We have examined the development of astrocytes in the postnatal rat immunohistochemically, using a polyclonal anti-GFAP antibody. Our observations suggest that radial glia in the OB may function in the formation of glomeruli, the multineuronal substrate of first order olfactory synaptic integration.

At the day of birth (P1) abundant radial glia course from deep layers of the bulb to the superficial glomerular layer (GL). Upon reaching the GL, many of these glia branch profusely, forming a plexus of glial processes. This plexus is in contrast to the continuous parallel course of cortical radial glia to the pial surface. In addition, mature stellate astrocytes can be found in GL at P1. In the GL at P5, P9, and P18, there is a decrease in the number of radial glia and an increase in the number of mature astrocytes prior to the increased numbers of mature astrocytes in the deeper layers of the OB. The adult pattern of astrocyte distribution is present by P36.

The differentiation of radial glia in embryonic development is suggested by the abundance of specialized branched radial glia and the presence of mature astrocytes in the GL of the OB at P1. Glial processes may interact with elongating mitral cell dendrites and/or primary olfactory neuron axons to form the glomeruli. Embryonic studies are now in progress. (Supported by NS23348.)

CATALASE-CONTAINING PEROXISOMES IN CULTURED GLIAL CELLS OF RAT AND CHICK. M. Beard, M. Saito and V. Sapirstein (SPON:G.Stone). The Nathan Kline Institute for Neuropsychiatric Research, Orangeburg NY 10962.

Peroxisomes, previously identified by others in neonatal and adult rat brain and adult chick spinal cord by their content of catalase, are implicated in the formation of myelin by virtue of their content of enzymes catalyzing the early steps in plasmalogen synthesis and their numerical increase in glia at the onset of myelination in cerebellum.

In order to investigate the more global relationships between brain and peroxisome function, primary glial cultures were established from perinatal rat and pre-hatching chick brains. Peroxisomal presence was monitored microscopically using the 3,3'-diaminobenzidine technique demonstrating catalase, the peroxisomal "marker" enzyme. We established that catalase-reactive peroxisomes are expressed in glial cells in culture. Peroxisomes were most prominent in oligodendrocytes grown in the presence of astrocytes; astrocytes from these cultures had few peroxisomes. Peroxisomes became more easily found in astrocytes when cultures contained fetal calf serum. Thus, it appears that culture conditions affect peroxisome expression, and that neural peroxisomes are responsive to environmental cues as are peroxisomes in non-neural systems.

CELLULAR INTERACTIONS BETWEEN BRAIN ENDOTHELIAL AND NEURONAL CELLS IN VITRO. J.H.Tao-Cheng, L.Chang*, O.Okuda* & M.W.Brightman.Lab Neurobiol.,NINDS,NIH,Bethesda,MD 20892

Bovine brain endothelial cells (BE) were co-cultured with primary cultures of cerebral tissues from 17-20 day fetal rats (1°brain cultures), or with PC12 cells, which were primed with nerve growth factor or infected with the K-Ras virus to express neuronal features, to see whether the different milieu of the co-cultures has any effect on the differentiation of the various cell types.

BE greatly enhanced the survival and growth of neurons from the 1° brain cultures. There were many more (>10x) neurons in the co-cultures with BE than in the solo 1° brain cultures. These neurons were positive for MAP2 and neuron specific enolase. Their neurites had many microtubules and some synaptic vesicles and occasionally formed mature synapses. BE also enhanced PC12 cells' neurites to bear more small, clear vesicles in the co-cultures than in the solo PC12 cultures. In return, BE were induced by the 1° brain cultures and PC12 cells to have (1) greatly distended rough endoplasmic reticulum (0.5 μm in lumen diameter) filled with fuzzy material, (2) abundant and tightly packed actin-like filaments and (3) an excessive extracellular matrix up to 1.5 μm in thickness. These BE cellular responses appeared to be induced by the neuronal elements in the co-cultures because enriched astroglial cultures without neurons did not induce such responses from BE. Thus, BE and neuronal cells reciprocally influence each other's differentiation and growth in vitro.

MODULATION OF THE H-REFLEX DURING STATIONARY CYCLING IN NORMAL HUMANS AND PATIENTS WITH SPINAL SPASTICITY G.I. BOORMAN *, W. J. BECKER, R.G. LEE. Dept. of Clinical Neurosciences, University of Calgary, Calgary, Canada.

It has been shown that the H-reflex is modulated during the step cycle in normal humans during walking (Capaday, C. and Stein, R., J. Neurosci. 6:1308, 1986). To further investigate modulation of spinal stretch reflexes during patterned voluntary activity we recorded H-reflexes while subjects were pedalling a stationary bicycle.

Normal subjects and patients with spasticity due to incomplete spinal cord injury were studied. Using a modified exercise bicycle, electrical stimuli were delivered to the posterior tibial nerve at defined points in the pedal cycle. EMG was recorded from gastroc-soleus and tibialis anterior muscles using surface electrodes. The M-wave amplitude was used to ensure that stimulus strength was constant at each pedal position. Background EMG was measured during a 30 ms interval prior to nerve stimulation.

In normal subjects the H-reflex varied in magnitude during the pedal cycle. The H-reflex was increased during the downstroke as compared to the upstroke. Patients with spasticity also showed H-reflex magnitude changes during the pedal cycle. The patterned changes in H-reflex amplitude were greater than could be accounted for by variations in prestimulus background EMG.Normal subjects are able to modulate spinal stretch reflexes. Some modulation also occurs in patients with spasticity.

281.2

LIMB TRAJECTORY DISORDERS IN HEREDITARY CEREBELLAR ATAXIA. Thomas Zeffiro. Human Motor Control Section, Medical Neurology Branch, NINDS, National Institutes of Health, Bethesda, MD 20892.

Damage to the cerebellum in man commonly results in an incoordination of goal-directed limb movement referred to as cerebellar ataxia. This study examines the kinematics of ataxia under varying conditions of visual guidance.

Hand trajectories were recorded during visually-elicited planar movements in 8 patients with hereditary cerebellar ataxia and 20 age-matched, healthy controls. Each subject, while sitting in total darkness, tracked a visual stimulus on the surface of a 20" x 20" digitizing tablet. In order to explore the effects of vision on trajectory properties, the appearance of the target was manipulated as follows: In one condition the target vanished as the movement began (T_{off}); and in the other the target remained visible throughout the trial (T_{on}).

Trajectories generated by patients with clinically mild ataxia exhibited primarily spatial abnormalities. Although errors in the initial direction of movement were seen in both visual guidance conditions, dysmetria, as measured by errors in final position, was greater in the T_{off} condition. Accuracy improved with visual guidance due to directional changes occurring during the decelerative phase of the movement. In contrast to the observed spatial abnormalities, temporal trajectory properties, including the scaling of peak velocity with movement size, were normal.

These results are consistent with the notion that specification of movement direction is impaired in cerebellar dysfunction, resulting in errors in final position. Visual information may be used to correct the trajectory as the hand nears the target.

281.3

POSTURAL INSTABILITY IN HUNTINGTON'S DISEASE (HD) J-R. Tian*, S.J. Herdman, D.S. Zee, The Johns Hopkins University, Baltimore, Maryland, 21205.

We measured A-P sway using moving platform posturography in 20 patients with HD and 20 age-matched normal controls. We determined the relative contributions of sensory cues to postural stability by eliminating proprioception and/or vision. Because of chorea, results were normalized to sway under normal vision and proprioception. With a criterion of abnormality of > 2 SD from the mean, 10 of 20 patients could not use vestibular cues alone to maintain postural stability. Thus, they relied more upon vision and proprioception to maintain balance.

In response to translations of the support surface, patients showed normal response strength but increased latencies (by 30-50 ms). In response to rotations patients had greater response amplitude than controls though, with repetition, response amplitude decreased normally.

HD patients have a consistent pattern of abnormality on posturography that may be clinically useful. Since labyrinthine function is thought to be normal in HD, our patients may have had difficulty in central processing of vestibular information.

281.4

SHORT LATENCY POSTURAL RESPONSES TO HEAD/NECK PERTURBATIONS. C.Shupert,F.B.Horak,V.Dietz* and G.Horstmann*.R.S.Dow Neuro. Sci.Inst.,Good Samaritan Hosp.,Portland,OR,97209&Dept.Clin. Neurol./Neurophysiol.,Univ.Freiburg,D-78 Freiburg,FRG.

To explore the relative contribution of sensory information from the head and neck and from the feet and legs to automatic postural responses during stance, we compared responses to A/P perturbations induced at the head (using a backpack-mounted apparatus) or at the feet (using a hydraulically-driven platform). Ten healthy adults and two patients with profound bilateral vestibular loss were tested with eyes closed. Head perturbations caused large, early head accelerations, but negligible center of mass movements, while platform perturbations produced small early head head accelerations and large center of mass movements. Both types of perturbations resulted in activation of the same ankle, knee, and hip muscles, but with different timing relationships. Ankle muscle response latencies were shorter for head perturbations (70 ms vs. 97 ms), but muscle burst amplitudes were 3 times larger for platform perturbations. Responses to head perturbations were nearly absent in the patient who lost vestibular function as an adult, but similar to normals in the patient who lost function as an infant. These results suggest that the contribution of different senses to coordinated postural responses depends on the nature of the body's displacement.

281.5

RESPONSE CHARACTERISTICS OF SPASTIC MUSCULATURE TO PASSIVE CYCLING MOTION. J.J. Fuller*, R.M. Herman, R.A. Yapp*, A.H. Seif-Naraghi*, S.C. D'Luzansky* (SPON: M.J. Perlow). Samaritan Rehabilitation Institute, Phoenix, AZ 85006.

Traditionally, the magnitude and sensitivity of stretch reflexes in patients with spinal spasticity have been measured during and following passive movement of a single joint. A motor-driven stationary bicycle has been developed that produces a passive, rhythmic, cyclical movement of the lower limbs. Electromyographic (EMG) activity, kinetics and kinematics related to velocity sensitivity, interlimb relationships, and phase modulation of spinal reflexes in patients with spinal lessions were recorded. The following observations were made during passive cycling: a) cycling rates beyond a threshold velocity produced intralimb dependent, sustained, rhythmic muscle activity of both flexor and extensor muscles which increased in magnitude with cycling velocity, b) spasms, often induced during the first cycle and during continuous cycling at higher rates, could "reset" or enhance rhythmic motor activity, c) phase modulation of electocutaneously induced flexor reflexes was not observed, and d) changes in hip angle may alter spinal reflex sensitivity. These results support the notion of velocity sensitive stretch reflexes and describe other features of spinal reflex behavior among patients with spinal spasticity.

281.6

TIME COURSE OF CHANGES IN TRICEPS SURAE ACTIVATION DURING GAIT IN SPASTIC CEREBRAL PALSY AFTER WEARING AN ORTHOSIS. F. Dumas, F. Malouin and C.L. Richards. Neurobiology Lab. and Dept. of Physiotherapy, Fac. Medicine, Laval University, Quebec, Canada, G1K 7P4.

We studied the time course of changes in muscle activations of a child with spastic hemiparesis (31 months old at first evaluation) after wearing an ankle foot orthosis (AFO) that maintained the ankle in about 5° of dorsiflexion. Following baseline measures of the gait movements (electrogoniometer) and electromyographic activity of the triceps surae (TS) and tibialis anterior (TA) muscles, the child wore the orthosis (4 hrs/day, 5 days/wk) during daily activities. Post-tests were made monthly during a 6 month consecutive AFO-wearing period, then after the AFO was removed for 1.5 months, and again after a second 2.5 month AFO-wearing period. Changes in TS activation began to emerge after 3 months of AFO-wearing. At the end of the 10 month evaluation period, the spastic TS activation profile was remodelled and showed a prominent late stance burst which resembled that found in 3 year old normal children but an abnormal early stance phase peak persisted. This early peak activation was accentuated by a higher cadence in the early months but became less sensitive to cadence with time of AFO-wearing. In contrast, only minor changes were observed in the TA. One can question whether the emergence of a near-normal TS activation pattern is due primarily to the effects of AFO-wearing (prolonged TS stretching) which helps to unmask a basic activation pattern, to the gradual maturation of the activation pattern or to their interaction. This work was supported by a grant from the Fondation du Conseil des Clubs de Service, Québec.

281.7

MUSCLE PATTERNS DURING WALKING AND PEDALLING IN SUBJECTS WITH HEMIPLEGIA. C.A. Giuliani. Division of Physical Therapy, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7135.

The purpose of this study was to compare the EMG patterns during walking and pedalling in a group of subjects with hemiplegia.

Ten subjects with hemiplegia secondary to stroke walked and pedalled on a stationary bicycle at two speeds. EMG was recorded from the vastus lateralis (VL), biceps femoris (BF), tibialis anterior (TA), and triceps surae (LG/SO). Myopotentials were sampled off-line, full-wave rectified, and analyzed with computer software (ANAPAC). The onset latency of BF, TA, and LG/SO was referenced to the onset of the VL and expressed as a percent of cycle time.

During pedalling and walking, the TA and LG/SO were reciprocally active, and the SO, BF, and VL were active as extensor synergists. During both activities, TA onset latency occurred between 46 and 85% and the LG/SO and BF were within 10% of the cycle. There was less cocontraction between flexor and extensor muscles, and more consistent muscle patterns with fewer abnormal cycles during pedalling than during walking. Average I-EMG values for the LG and BF decreased during pedalling while the VL value increased significantly ($p < .05$).

These results suggest that the temporal pattern of muscle activity of walking and pedalling are similar. A more consistent pattern with fewer periods of cocontraction during pedalling than walking provide a rationale for using pedalling as a method of exercise for improving muscle patterns in patients with movement dysfunction.

FORCE CONTROL IN SCHIZOPHRENICS WITH DYSKINESIA. P. B. Vrtunski, L. D. Alphs* and H. Y. Meltzer. VA Med. Center and CWRU Sch. of Med., Cleveland OH 44141.

Recent studies of force control of neurologically impaired (Mai et al, Brain, 111:973, 1988) and schizophrenic patients (Biol Psychiat, 25:529, 1989), suggest the usefulness of this paradigm for evaluating movement dysfunction in patients with tardive dyskinesia (TD). 33 subjects participated in this study, 12 with mild to moderate TD, and 21 nondyskinetic controls. Force control (FC) was measured by means of five force transducers fitted into a bite-piece (for oro-mandibular FC), both armrests of the test chair (for index finger FC) and two footrests (for pedal FC), respectively. The task consisted of matching the target force with a generated force. A score was developed from the mean error of matching performance. Results indicate significant impairment of the FC function in TD subjects: with high target forces, impairment was greater with the dominant hand than with the nondominant, whereas with low target forces, impairment was greater in the nondominant hand. Pedal FC (with higher target forces) showed a greater impairment than index finger FC. Oro-mandibular FC was the least valuable for discriminating the two groups of patients. Our results on force and laterality differentiation of patients with TD suggest a more complex mechanism for dyskinetic impairment than has previously been believed.

RELATIONSHIP BETWEEN RIGIDITY AND BRADYKINESIA DURING WEARING-OFF IN PARKINSON'S DISEASE. M.P. Caligiuri. Motor Function Laboratory, VA Medical Center, San Diego, CA 92161

The traditional view that rigidity underlies bradykinesia in Parkinson's disease (PD) contrasts with evidence showing that many rigid PD patients are not bradykinetic. In the present study, quantitative measures of rigidity (muscle stiffness) and bradykinesia (movement velocity) were used to test the hypothesis that rigidity and bradykinesia do not follow the same pattern of deterioration during the wearing-off phase of the medication cycle.Idiopathic PD patients were studied for four hours immediately following their morning dose of Sinemet. Upper extremity rigidity and bradykinesia were evaluated hourly. Preliminary findings indicated that the wearing-off patterns of rigidity and bradykinesia were independent of one another. An increase in stiffness associated with end-of-dose deterioration was not phasically related to slowing of movement. These results support the hypothesis that muscular rigidity may not underlie the slowness of movement and underscore the value of serial quantitative measures in revealing differential effects of Sinemet on parkinsonism. DELAYED VISUOMOTOR CONTROL: OSCILLATIONS IN NORMAL AND PARKINSON'S PATIENTS. A. Beuter, C. Labrie, Milton*, J. L. Glass* Univ. of Québec at Montréal, C.P. 8888, Succ A H3C 3P8 and McGill Univ., Montréal.

Patients with Parkinson's disease (PD) have deficits in planning and executing voluntary movements. We compared the effect of delayed visual feedback on a simple motor task for 12 subjects: 4 Stage II PD, 4 age-matched and 4 young adults. This task required the subject to maintain a constant finger position relative to a stationary baseline displayed on an oscilloscope. The finger positions (not directly seen by the subject) were recorded for 60 sec. using a LVDT and digitized at 150 Hz. In the absence of delayed visual feedback, power spectral analysis revealed a baseline oscillation in finger position with a peak at 5.5-7 Hz for 4/4 PD patients and 9-11 Hz for 4/8 normal subjects. With the addition of delayed visual feedback, a complex higher-amplitude, low-frequency oscillation was superimposed on the baseline oscillation. The average peak-to-peak time interval (INT) of this low frequency oscillation increased linearly as the visual delay was increased from 600-1400 msec. No significant difference was found in the change INT as a function of added delay between PD and normal subjects. These observations indicate that adjustments to alterations in the information guiding movement are preserved in Parkinson's disease.

MOTOR CONTROL IN SPINAL MUSCULAR ATROPHY. A. Beric, J. Bojakowski*[1], M.R. Dimitrijevic, I. Hausmanowa-Petrusewicz*[1] and A. Michalik*[1], Baylor College of Medicine, Houston, TX 77030, and [1]Warsaw Academy of Medicine, Poland.

We compared voluntary and automatic motor activity in humans with intact neuromuscular systems and in persons with degenerative disorders of the common final path. We studied a group of 18 subjects with spinal muscular atrophy (SMA) in comparison to an group of 10 healthy subjects. Surface EMG electrodes were placed over paraspinal, abdominal, tensor fasciae latae, quadriceps, adductors, hamstrings, tibialis anterior and triceps surae muscles. Ink jet recordings were carried out during quiet standing, forward and backward leaning, standing on one leg, and various maneuvers while sitting or lying supine. When responses of SMA and healthy subjects were compared, the patterns of activity induced by skillful voluntary efforts were not obviously different between the two groups. In a comparison of postural activity during standing, the SMA subjects demonstrated a noticeable increase in EMG amplitude as well as a spread of activity to muscles not active in the healthy subjects. There was more coactivation of antagonistic pairs, which was not restricted to the muscles with most clinically evident weakness. There was a more pronounced loss of selectivity and loss of local response in the more severely disabled individuals. This decrement in performance is similar to that observed in intact subjects at the limits of endurance.

CHANGES IN MUSCLE ACTIVATION DURING THE MAINTENANCE OF A POSTURE AT THE HUMAN ELBOW JOINT. T.S. Buchanan, J.P.A. Dewald, G.P. Rovai*, and W.Z. Rymer. Sensory Motor Performance Program, Rehabilitation Institute of Chicago, Chicago, IL 60611.

We examined the activation of muscles that act in shoulder and elbow flexion/extension and wrist supination/pronation during various static postures. Intramuscular and surface EMGs for up to ten muscles and force at the wrist in 3 dimensions (flexion/extension, varus/valgus, and supination/pronation) were recorded while subjects produced steady-state forces at the wrist. Subjects held one of 3 forearm pro-supination angles and two shoulder flexion/extension angles. Data was recorded from the normal side of spastic hemiparetic subjects (see abstract by Dewald et al.).

It was observed that some elbow-joint muscles that undergo no change in length with shoulder angle changes (ie. do not cross the shoulder joint) are nonetheless varied significantly with postures at different shoulder horizontal abduction angles. For example, when the shoulder was held in 25° horizontal abduction, the brachialis EMGs increased compared to those collected when the shoulder was at 0° (extension). Inverse relationships were observed in the pronator teres which, similarly, is far removed from the shoulder.

It is surprising to see muscles being modulated with changes in the joint angle of a secondary joint at which they have no obvious mechanical action. Changes in joint angles induce changes in lengths for muscles which cross the joint. Such is the case in this situation for shoulder muscles and two-joint muscles such as the biceps brachii which shortens with increased abduction. With muscle shortening, length/tension relations would predict that biceps tension would drop, barring changes in activation. The increased activation of the brachialis could be a result of compensation for force/EMG changes in such two-joint muscles or for other changes in the roles of these muscles associated with their actions at the secondary joint.

These observations point to a complex control strategy that alters a muscle's activation level with the load conditions at joints where the muscle may have no mechanical action. Such coupling is perhaps important for compensating for torques produced by multi-joint muscles that are necessary for torque production. This underscores the importance of taking into account the load state at nearby joints when building models of muscle coordination.

281.13

CONTROL OF MUSCLE ACTIVATION DURING THE MAINTENANCE OF ARM POSTURES IN THE SPASTIC HEMIPARETIC SUBJECT. J.P.A. Dewald, T.S. Buchanan, G.P. Rovai*, and W.Z. Rymer. Sensory Motor Performance Program, Rehabilitation Institute of Chicago, Chicago, IL 60611.

In an effort to study the effects of different perturbations on muscle coactivation patterns in hemiparetic stroke we compared electromyographic activation levels in both upper extremities of such subjects for different positions. EMG activities in up to ten muscles that act in shoulder and elbow flexion/extension and wrist supination/pronation were recorded with surface and intramuscular electrodes during very controlled static postures. Forces were applied at the wrist and were measured in three dimensions (flexion/extension, varus/valgus, and supination/pronation) while the arm position was fixed at 90° elbow flexion, neutral pro-supination position, and one of two different shoulder horizontal abduction angles angles (0° and 25°).

The EMGs were examined as a function of the direction of the force at the wrist in the plane orthogonal to the forearm. For most muscles, the EMGs revealed a broadening of muscle activation as a function of torque direction in the spastic limb compared to the normal limb. This is a result of an increase in co-contraction of muscle activity. However in moderate to severely involved subjects this increase in range of activation was observed to change significantly at different shoulder horizontal abduction angles. As the shoulder horizontal abduction angle increased, EMGs became more focused (ie. had a narrower range) in the spastic limb. Compared to 0°, at 25° shoulder horizontal abduction spatial EMG characteristics of elbow muscles appeared more 'normal'. The fact that the 25° horizontal abduction angle places the arm in a position which is close to the typical hemiplegic arm posture is an interesting observation. It appears that in this arm posture the moderate to severely affected subjects are able to produce more normal muscle coactivation combinations during the static tasks of our experimental paradigm.

The loss of corticospinal descending fibers in the spastic hemiparetic subject due to cortical or subcortical lesions thus favors not only a particular arm position through the intact vestibulo- and reticulospinal systems, but also appears to affect muscle coactivational behavior in the involved upper extremity.

This work is supported by NIH grant NS-19331.

281.14

Effect of Head Orientation on Human Postural Stability Following Unilateral Vestibular Ablation (UVA). C.R.Fox and G.D.Paige. Washington Univ, St Louis, MO 63110.

Vestibular input to postural control is important but remains poorly understood. Appropriate postural responses to vestibular input during sway requires that orientation of the head on the body is known. Postural stability might deteriorate when vestibular input and information about head on body are not properly coupled. Perhaps this condition arises in subjects with vestibulopathy. Postural sway was assessed in 9 normals, and in 9 vestibulopathic patients before and 1 wk, 1 mo and 4 mo after UVA. Postural stability with eyes closed was quantified as scaled pk-pk sway during 20 s trials in which the support surface was modulated proportionally with sway. Subjects were tested with the head upright and facing forward, 45 deg R and 45 deg L. In normals, sway was uninfluenced by head orientation. Sway was greater in patients than in normals both before and after UVA. Further, UVA subjects showed head orientation-dependent asymmetries. Before UVA, 22% of subjects showed abnormally large R-L asymmetry, but split as to whether sway was less with the normal (contra) or abnormal (ipsi) ear facing forward. 1 wk after UVA, 60% showed asymmetry, with 2/3 of them displaying better stability with the contra ear forward. The proportion of subjects with asymmetry declined to 44% after 1 mo, and the contra-ipsi difference was eliminated by 4 mo. It is concluded that head orientation, in conjunction with vestibular input, is important in postural control.

EMG ANALYSIS OF CO-CONTRACTION IN ACUTE HEMIPARESIS: EMG-INITIATED ELECTRICAL STIMULATION VS CONVENTIONAL THERAPY. S.S.Fitts,M.C.Hammond* and G.H.Kraft*. Department of Rehabilitation Medicine, University of Washington, Seattle, WA 98195.

Electromyographic (EMG) analysis of isolated agonist recruitment and co-contraction was used to assess poststroke motor recovery in patients treated with EMG-initiated electrical stimulation (EMG-Stim) and/or conventional therapy (CONV). Patients were recruited within four (X=2.9) wks of their first unilateral, non-hemorrhagic cerebrovascular accident (CVA). Five received EMG-Stim, plus conventional therapy; five received only conventional therapy. Intramuscular EMG was recorded simultaneously from flexor carpi radialis (FCR) and extensor carpi radialis longus (ECR) during isometric wrist flexion and extension at an average of 8.4 wks post-CVA. The number of events exceeding 250 recorded from agonist muscles did not differ between the two groups. However, fewer antagonist FCR events were recorded from EMG-Stim than from CONV patients during wrist extension (X's=28.4 vs 61.5; $p<.10$); and more antagonist ECR events were recorded from EMG-Stim than from CONV patients during wrist flexion (X's=130.9 vs 11.6; $p<.025$). Compared to CONV, EMG-Stim patients had lower co-contraction ratios (antagonist events divided by the total of agonist plus antagonist events) during extension (X's=.06 vs .14; $p<.10$) and higher co-contraction ratios during flexion (X's=.18 vs .06; $p<.05$). The difference between groups was maintained at least 3 months for wrist extension (X's=.06 vs.13; $p<.10$); but not for flexion (X's=.034 vs .037). We conclude that EMG-Stim patients achieved a more functional balance of opposing flexor and extensor muscles, although post-CVA recovery of isolated agonist recruitment was not affected.

EFFECTS OF SOMATOSENSORY THRESHOLD TRAINING ON MANUAL MOTOR PERFORMANCE IN NORMALS AND PATIENTS WITH HEMIPARESIS. M. Pause*, E. Kern*, M. Haller*, V. Hömberg* (SPON: K.H. Mauritz). Dept of Rehabilitation, Univ. of Cologne and Dept. of Neurology, Univ. of Düsseldorf, FRG.

Data of motor performance in non-paretic patients with isolated marked sensory deficits suggested that afferent feedback is crucial for the precision of fine motor acts (Rothwell et al., Brain 105, 515-542,1982). This leads to the hypothesis that systematic (re-)training of somatosensory functions might induce an improvement of fine motor functions as well. In our study therefore we investigated the relative impact of somatosensory training on manual motor performance in normals and hemiparetic patients.

The non-dominant hand of 10 healthy subjects was examined with a standardized battery of 14 different motor tests comprising automated-proximal-visually guided (APV) movements and non-automated- distal-somatosensory guided (NADS) movements. Under occlusion of vision these normals were trained by verbal feedback over ten days for tactile discrimination of threshold stimulus pairs in 10 different paradigms (*Proprioceptive:* position sense, load estimation, distance estimation, form discrimination; *cutaneous* discrimination of vibration, roughness, dynamic and successive two-point stimuli, movement direction and pressure) at their non-dominant hand, whereby active movements were minimized. After the training the motor test battery was repeated. The same protocol was used in the affected hand of 8 patients suffering from focal cerebral lesions causing mild unilateral motor disturbances with or without additional somatosensory deficits.

Motor performance either for APV- or NADS- movements of *normal subjects* was not altered by the somatosensory training despite a mean improvement of somatosensory discrimination thresholds of 31%. In the *patients* the mean initial sensory discrimination thresholds were elevated by 77% compared to normals. After training this value was reduced to 48%. The mean of the initial motor test of the patients was 41.8% of the average value of the normal subjects. After sensory training the APV-movement-score showed an amelioration by 10.3%, the NADS-movement-score by 21.5%. From these preliminary investigations it can be concluded that somatosensory threshold training is beneficial for reeducation of non-automated fine manual movements in patients with upper motor neuron lesions.

EFFECT OF HYPOXIA ON REACHING IN NORMALS AND IN PATIENTS ON LONG-TERM OXYGEN. M.C.Verrier,K.R.Chapman*,W.G.Tatton,A.S.Rebuck* and C.Diep*. Restorative Motor Control Lab. Departments of Rehab. Medicine, Medicine and Physiology, Univ. of Toronto, Toronto, CANADA. M5T 1W5.

Hypoxia has been shown to have complex effects on lever press accuracy and response time in highly trained primates(Nicholson,A.N. and Wright,C.M.,Exp. Neurol. 47:535- 543,1975). In an ABAB design, reaction time (RT), movement time (MT), 3-D kinematics and oxygen saturation (SaO_2) were used to determine if hypoxia alters routine reaching in a simple RT task in young normals (n=10) and chronic obstructive pulmonary disease patients (COPDs) on chronic O_2(n=8). Individual $\bar{x}$ RTs (35 trials) in 4 of 15 and $\bar{x}$ MTs in 6 of 13 cases decreased significantly ($p < 0.05$) in COPDs when O_2 was removed, with a change in $\bar{x}$ SaO_2 from 93 to 88%. Mild hypoxia improved reaching performance in the COPD group by a $\bar{x}$ of 63 msec ($\bar{x}$RT=25msec;$\bar{x}$MT= 38msec). The results in normals were more complex. Mean SaO_2 levels were decreased from 97 to 80% using a rebreathe technique in 6 subjects. Four subjects were unable to tolerate hypoxia. In contrast to COPDs individual $\bar{x}$ RTs in normals were marginally but significantly increased in 4 of 11 and decreased in 1 of 11 cases while $\bar{x}$ MTs decreased in 5 of 11 and increased in 1 of 11 cases. However, the $\bar{x}$ group increase was only 8msec (RT) and 2msec (MT) demonstrating marked variability. These results in normals could be accounted for by the difference in individual ability to tolerate marked hypoxia which causes temporary alterations in both processing (RT) and execution (MT) functions of neural structures essential for reaching. In contrast, mild hypoxia in COPDs improves performance which could indicate their adaptive ability to tolerate mild hypoxia. Supported by NIH.

SPINAL CORD AND BRAINSTEM: CORD ANATOMY

282.1

THE ORIGINS OF DESCENDING PATHWAYS TO THE SPINAL CORD IN THE BRAZILIAN OPOSSUM, MONODELPHIS DOMESTICA. M-C Holst, R. Ho and G.F. Martin. Department of Anatomy, The Ohio State University, Columbus, OH 43210.

The North American opossum, Didelphis virginiana, is a good model for developmental studies of descending spinal pathways because of its immaturity at birth and protracted postnatal development. The smaller, gray short-tailed Brazilian opossum, Monodelphis domestica, can be bred more easily however, and offers other advantages as a laboratory animal. Since little is known about the organization of descending pathways in adult Monodelphis, we have begun studies to determine their cells of origin. Cervical, lumbar and sacral cord injections of WGA-HRP or True Blue (TB) labeled supraspinal areas comparable to those labeled by similar injections in Didelphis, plus some additional ones. For example, cervical injections labeled neurons in the amygdala and basal forebrain. As in Didelphis, the neocortex was labeled only after cervical injections and the distribution of labeled neurons in the red nucleus indicates that rubrospinal somatotopy is not as distinct as in placental mammals. The origin of monoaminergic projections to the cervical cord was studied using the retrograde transport of TB combined with immunofluorescence for serotonin or tyrosine hydroxylase. The results are similar to those obtained in Didelphis, but differences were noted. This is the first comprehensive report on descending pathways to the spinal cord in a marsupial other than Didelphis. Supported by the Bremer Foundation and NS25075.

282.2

ORIGIN OF THE CERVICAL PROJECTIONS TO THE LUMBOSACRAL ENLARGEMENT (LS) OF THE SPINAL CORD IN THE OPOSSUM, MONODELPHIS DOMESTICA, T. Cabana and J.P. Parent*, Département de Sciences biologiques, Université de Montréal, C.P. 6128, Succ. "A", Montréal, Canada H3C 3J7.

The origin of the cervical projections to LS was investigated with the retrograde tracing of WGA-HRP and TMB technique in adult opossums as a basis for interpreting developmental studies on interlimb coordination. Injections of 1-5µl of 1.5-2%WGA-HRP were placed in LS, involving, in some animals, some or all areas of the gray matter. The 8 cervical & 1st thoracic levels were examined. Labeled cells were found in all the segments studied but in relatively greater number in the lower cervical and first thoracic segments. Lamina VII, then lamina VIII, contained the greatest number of labeled neurons. Labeling was also present in laminae VI and V, especially their lateral portion, and ventrally and ventrolaterally to the central canal. In all these areas, the labeled cell bodies were often large (mean diameter of 30 to 50µm). A few small sized, labeled neurons were observed in the lateral part of lamina I. No attempts were made at establishing the laterality of the projections by performing hemisections rostral to the injections, but the little spread of the injectate to the contralateral side in some cases indicated that the labeling is bilateral, except in lamina I where it is ipsilateral. These data generally conform with those known of other mammals.

282.3

DIFFERENCES IN SEXUALLY DIMORPHIC SPINAL MOTOR NUCLEI AS REVEALED BY TRANSNEURONAL TRANSPORT OF WGA. K.R. Peshori, J.T. Erichsen and W.F. Collins, III, Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

We have previously demonstrated retrograde transneuronal transport of wheat germ agglutinin [WGA] between motoneurons [MNs] in the dorsal medial nuclei [DMN or SNB] of the rat spinal cord (Rose et al., 1987). The present study was undertaken to examine the distribution of transneuronally labeled MNs and interneurons [INs] following injection of WGA into different penile muscles. In adult male rats (Sprague-Dawley), WGA (1%, 0.5 ul) was injected into either the left lateral bulbospongiosus [LBS] or ischiocavernosus [IC] muscles. Prior to injection of WGA, the left and right pudendal sensory nerves, the contralateral pudendal motor nerve, and the nerves to either (1) the ipsilateral IC and urethral sphincter muscles (LBS injections) or (2) the bulbospongiosus and anal sphincter muscles (IC injections) were cut. Following 1 to 7 days survival, rats were sacrificed and the spinal cords processed immunohistochemically for visualization of WGA. With LBS injection, direct retrograde labeling of ipsilateral DMN MNs (1-7 days) and bilateral transneuronal labeling of DMN MNs (2-7 days) and INs (3-7 days) were observed. Transneuronal labeling increased with longer survival times. Labeled INs were located bilaterally in segments L_5 and L_6 lateral to the DMN and extended dorsally to the dorsal grey commissure. In contrast, IC injection resulted in direct retrograde labeling of the medial portion of the ipsilateral dorsal lateral nucleus [DLN] (1-7 days) with little or no transneuronal labeling of other MNs or INs (1-7 days). These results suggest differences between the DMN and the DLN with respect to (i) afferentation, (ii) MN interactions, and/or (iii) baseline activity. Supported by EY04587 and a grant from the Center for Biotechnology SUNY Stony Brook (JTE), NS24206 (WFC) and NS14899 & NS16996 to L.M. Mendell.

282.4

ALTERED LEVELS OF CALCITONIN GENE-RELATED PEPTIDE (CGRP)-LIKE IMMUNOREACTIVITY OF CAT AND RAT MOTONEURONS AFTER DIFFERENT TYPE OF LESIONS. U. Arvidsson[1*], S. Cullheim[1*], B. Ulfhake[1*], H Johnson[1*], F. Piehl[1*], T. Hökfelt[2], M. Risling[1*] and L. Terenius[3]. (Spon. T. Carlstedt). Departments of [1]Anatomy and [2]Histology and Neurobiology, Karolinska Institutet, Stockholm (Sweden) and [3]Department of Pharmacology, Uppsala University, Uppsala (Sweden).

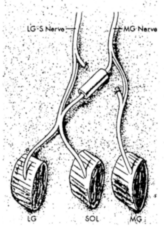
The indirect immunofluorescence technique has been used to study CGRP-like immunoreactivity (LI) in motoneuron cell bodies in the lower lumbar segments after sciatic nerve transection (cat and rat) and in chronic thoracic spinal cord transection (SCT) alone (cat) or in combination with unilateral rhizotomy of all dorsal roots below the SCT (cat).

In the lower lumbar motor nucleus of normal cats and rats almost all large neurons (of alpha motoneuron size) express CGRP-LI. However, dorsally located neurons in the nucleus, innervating distal muscles groups, are less intensely labeled than ventrally located neurons innervating proximal muscles groups. Seven days after sciatic nerve transection in the cat, the CGRP-LI in motoneurons with a location corresponding to the sources of the sciatic nerve was significantly stronger on the axotomized side. In rats, the effects of sciatic nerve transection was studied at various post-operative intervals (1-21 days). These experiments revealed a stronger CGRP-LI expression in motoneurons on the operated side after 2-5 days, while no clear side difference could be detected after 11 or 21 days.

After SCT in the cat (44 days post-operatively) there was a decrease in CGRP-immunoreactive labeling of the neurons in the motor nucleus compared to normal. When SCT was combined with unilateral rhizotomy, the CGRP-LI in the motor nucleus displayed an apparantly normal pattern on both sides. Thus, removal of the primary afferent input on one side of the cord seems to diminish the effects of spinal cord transection on both sides.

The present results indicate that surgical interventions such as axotomy or manipulation of afferent inputs to motoneurons induce changes in the level of CGRP-LI in motoneurons.

282.5



DISTRIBUTION OF CATECHOLAMINERGIC AND MU-OPIOID RECEPTORS IN THE CAT SPINAL CORD. C.D. Barnes, S.J. Fung, R.C. Speth, L. Churchill, and H. Zhuo*. (SPON: J. Chan) Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520

In the cat, it has been reported that the locus coeruleus complex, including the Kölliker Fuse nucleus, supplies the vast majority of catecholaminergic fibers to the spinal cord. Additionally, it has been shown that a significant percentage of these descending catecholaminergic neurons contain met-enkephalin. The present study was done to determine if there is a differential distribution of α_1, α_2 and β adrenergic and mu-opioid receptors, the presumed targets of these fibers, in the spinal cord. 60-65 pM of ^{125}I-HEAT ± 1 μM prazosin, 7nM of ^{3}H-idazoxan ± 10 μM phentolamine, 60-65 pM of ^{125}I-(-) cyanopindolol ± 1 μM l-propranolol and 0.2 nM [^{125}I] Tyr-D-Ala-Gly$_5$-me Phe-Gly(ol) ± 5 μM naloxone, were used to autoradiographically label these receptors, respectively.

In the ventral horn all four receptor types are present in Rexed's lamina IX, but mu-opioid and β are also present in lamina VIII. There is a concentration of α_2 receptors near the nucleus intermedio-medialis, and both β and mu-opioid receptors appear in area VI near Clark's column. Both α_1 and α_2 receptors appear in the nucleus intermedio-lateralis, and all four receptors were represented in differing degrees in the dorsal horn areas I, II and III. A dorsal rizotomy eliminated the mu-opioid receptors of the dorsal horn but not those of the ventral horn. A relatively heavy concentration of β receptors was also found in fibers of both the dorsal column and the dorsal lateral funiculus (Supported by grant NS 24388).

282.6

LONG-TERM DIRECT INNERVATION OF SOLEUS MUSCLE BY MEDIAL GASTROCNEMIUS NERVE IN THE CAT. JB Munson & RC Foehring. U of FL Med Ctr, Gainesville, & U of TN Med Ctr, Memphis.

The proximal portion of ~1/3 of the MG nerve was coapted with soleus nerve distally; ~2/3 of MG nerve remained innervating the MG muscle. 18 mo later, MN and/or muscle-unit properties were determined for MG MNs innervating MG, soleus or no muscle. Properties and percents of motor units in the MG muscle were normal: thus a normal population of MG motor axons had been directed to soleus. 74% of cross-innervated soleus (Xsol) units were type-S (by contractile measures), despite cross-connection by ~75% fast MNs. 35% of MG MNs cross-connected to soleus nerve failed to innervate muscle (cf ~10% when MG nerve was coapted with MG or LG-S nerve): MG MNs innervating soleus muscle thus may be disadvantaged. Electrical properties of axotomized MG and soleus MNs, and of Xsol MG MNs, differed from normals; Xsol MN properties approached those of axotomized MG MNs. It appears that fast MG MNs which innervated large (strong) soleus muscle units failed to convert those muscle fibers to fast types, and were thereby prevented from recovering their normal electrical properties. Conversion and recovery did occur for fast MG MNs which innervated small (weak) soleus muscle units, and for cross-reinnervated slow MG MNs. Supported by NS-15913.

282.7

CHARACTERIZATION OF GABA-LIKE IMMUNOREACTIVE MOTONEURONS IN THE VENTRAL HORN OF THE CHICK SPINAL CORD. **E. PHILIPPE* and C. DELAGRAVE*** (SPON: L. Larochelle), Dept. of Anatomy, Laval University and Center of Neurobiology, 2075 Vitré, Quebec - CANADA.

In order to determine the role of peripheral and central tissues on the phenotypes expressed by chick lumbo-sacral spinal neurons, characterization of motoneurons was performed according to a combination of anatomical, immunocytochemical and ultrastructural criteria.

Motoneurons were characterized by the means of retrograde transport of fluorescent latex spheres from the Sartorius and the Femoro-tibialis muscles of one hindlimb.

Immunocytochemistry was performed with polyclonal antibodies raised against gamma aminobutyric acid (GABA) according to the peroxydase anti-peroxydase procedure (PAP).

Among the whole population of neurons located in the lumbo-sacral spinal cord, a few large neuronal cell bodies were both retrogradely labeled with the fluorescent latex spheres and immunostained with anti-serum raised against GABA. These immunostained motoneurons, mainly located in the lamina 7 and 9, according to the laminar distribution of the chick spinal cord (Martin, 1979) were large, ovoid and mainly characterized by a well developed rough endoplasmic reticulum and numerous straight Golgi apparatus.

These preliminary results raised the questions of the role of amino acid in the motor innervation of skeletal muscles in the chick.(Supported by grants of C.R.M. and F.R.S.Q.)

282.8

ORGANIZATION OF MOTOR NUCLEI SUPPLYING INTERVERTEBRAL MUSCLES OF THE CAT REVEALED BY MULTIPLE LABELLING. D.C. Gordon* and F.J.R. Richmond, Dept. of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

In previous electromyographic studies we have shown that deep neck muscles have highly modulated patterns of recruitment during head movement. Spinalis dorsi, semispinalis cervicis and rectus capitis posterior (RC) are primarily active during elevation of the head whereas obliquus capitis caudalis (OC) is more strongly recruited during head turns. In this study we have used a multiple labelling method to examine the topographical organization of motoneurons supplying different intervertebral muscles. Intervertebral muscle nerves were isolated, cut and exposed separately to one of three different retrograde tracers, Fluorogold, Fast Blue and horseradish peroxidase. This method permitted us to compare directly the location of different motoneuron groupings in a single cat. Motoneurons supplying dorsal intervertebral muscles were arranged in overlapping cell columns from rostral C1 to mid C5. The segmental location of motor nuclei corresponded to the rostrocaudal location of the muscles along the vertebral column. Cells serving the extensor RC interdigitated with those supplying the turning muscle OC. Results suggested that the topographical organization of the cell groupings may not be a major factor influencing the specialized recruitment of deep neck muscles. Supported by the MRC of Canada.

LUMBAR INPUT TO RAT SACROCAUDAL SPINAL CORD. M.L. Sparkes*, C.R. Murray* and L.A. Ritz. Depts. of Neurosurgery and Neuroscience, Univ. of Florida, Gainesville, Fl. 32610.

The sacrocaudal spinal cord, that portion of the neuraxis which innervates the tail, has been the subject of anatomical, physiological and behavioral analyses in our laboratory. The present study investigates propriospinal input to rat sacrocaudal spinal cord. Rats were injected at spinal level S3 with 0.5-1.0 ul of 2% fluoro-gold. After 3-10 days the rats were sacrificed and the lumbar, sacral and caudal segments processed. Injection sites involved, bilaterally, portions of dorsal horn, medial intermediate zone and ventral horn, but not the ventral white matter. To date, data have been analyzed for the L4-S1 segments. Most labelled neurons were localized to the intermediate zone, adjacent to the central canal and to the medial portion of the ventral horn. Cells were also found at the base of the dorsal horn. About 10-20 neurons were labelled per 50 micrometer section. The present data support the idea that there are propriospinal connections between lumbar and sacrocaudal spinal cord, which could contribute to coordination of hindlimb-tail interactions. Research supported by NS23683.

MORPHOLOGY AND SEGMENTAL DISTRIBUTION OF INHIBITORY INTERNEURONS IN WHOLE-MOUNTS OF GOLDFISH SPINAL CORD. J.R. Fetcho. Dept. of Physiology, SUNY at Buffalo, NY 14214.

The morphological variability and segmental distribution of spinal inhibitory interneurons were studied with a newly developed whole-mount technique. Crossed inhibitory interneurons in the spinal network for escapes were physiologically identified based on an electrotonic input from the Mauthner cell and then filled by intracellular pressure injection of HRP. All of the filled cells were morphologically similar to one another and to the small number crossing interneurons studied previously in serial sections. The cell body gave rise to a single axonal process that crossed the cord and then bifurcated into a relatively short, thin rostral branch and a thicker, longer caudal one. Branches arose from these processes and terminated near M-axon collaterals. The axons of interneurons extended longitudinally over a distance of from one to two body segments. However, the location of cells with respect to segmental boundaries (as defined by ventral roots) was variable; axons always straddled segments even when the axons were only one segment long. These observations indicate that the interneurons form a morphologically homogeneous class that distribute inhibition to motoneurons (and other interneurons) in a local, but not strictly segmental manner. Supported by NS 26539.

RETROGRADE LABELING OF SPINAL NEURONS FOLLOWING INJECTIONS OF FLUORESCENT MICROSPHERES AND HRP INTO DIFFERENT REGIONS OF THE CAT'S LUMBAR CORD. J.E. Hoover* and R.G. Durkovic. (SPON: S. Nord). Dept. of Physiol., SUNY-Health Science Center, Syracuse, NY 13210.

In order to retrogradely label interneurons projecting to motor nuclei, fluorescent latex microspheres were pressure injected into motoneuron pools of anesthetized cats. Single small injections of red and green beads (+HRP in one) were made at the L-7 level (one fluorochrome on each side) into either deep peroneal or PBST motoneuron pools. The micropipette tip was positioned by recording the antidromic field potential elicited by stimulation of the motor nerves. Animals remained anesthetized 60 hr before sacrifice.

Retrogradely labeled neurons were observed on both sides of the spinal cord from L-1 to S-2. Most cells labeled ipsilateral to the injection site were located in laminae VI and VII. However, labeled neurons were also found in laminae V, VIII, IX and X. Cells labeled contralateral to the injection site were restricted to laminae VII, VIII, and X, the majority being located in VIII. A few double labeled cells (red and green) were observed in lamina X. Even though diffusion of HRP occurred far outside the area of bead injection, HRP labeled cells were located in qualitatively the same spinal cord regions as those labeled with fluorescent microspheres. Supported by NSF grant BNS 8808495.

VARIATION IN ULTRASTRUCTURAL CHARACTERISTICS OF BOUTONS OF INDIVIDUAL MG Ia FIBERS CONTACTING MOTONEURONS.

J.P. Pierce, H.R. Koerber and L.M. Mendell. Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794

Individual Ia fibers project to large numbers of α-motoneurons (MNs) from dif ferent subgroups (innervating FF, FR and S motor units), and the physiological properties of each connection correlates with the type of MN contacted. While single fiber EPSPs in high rheobase MNs (associated with FF motor units) display facilitation in response to high frequency stimulation, single fiber EPSPs in low rheobase MNs (associated with S motor units) display depression (Collins et. al., J. Neurophysiol., 52, 1984). Studies in vertebrate cortex (Bower and Haberly, PNAS, 83 1986) and at the lobster NMJ (Meiss and Govind, J. Neurobiol., 11, 1980) have shown that these types of response characteristics are associated with presynaptic ultrastructural differences. If a similar correlation exists at the Ia-MN synapse, then there should be as much variation in the given feature among the boutons of a single fiber as within the whole population. In the present study medial gastrocnemius Ia afferents were identified physiologically in barbiturate anesthetized cats, injected with HRP, and processed for light and electron microscopic analysis. Light level reconstructions were made to define the location of individual boutons and neighboring boutons were serially thin sectioned. MN contacts were identified by the size of the postsynaptic profiles. Ultrastructural features measured included cross sectional area, shape, vesicle density (VD), fractional mitochondrial area (FMA), fractional apposed perimeter (FAP) and active zone length (AZL). Within the boutons of an individual fiber, VD and shape were the most variable features (VD varied up to 3-fold). FMA and FAP were relatively constant. All characteristics were consistent through virtually all of the sections for a given bouton. These findings suggest a possible correlation between ultrastructure and physiological properties in this system. Sup. by NSO8239 (JPP), NS23725 (HRK) and NS16996 (LMM).

282.13

MORPHOMETRIC ANALYSIS OF DEVELOPING CAT PHRENIC MOTONEURONS LABELED BY INTRACELLULAR INJECTION OF HRP. He,F.*, J.S.Jodkowski*, R.D.Guthrie* and W.E.Cameron (SPON: J.Fernstrom), Depts. Neurobiology and Pediatrics, Univ. of Pittsburgh and Magee-Womens Hospital, Pittsburgh, PA 15213

A detailed description of the morphologic changes of phrenic motoneurons during postnatal development is prerequisite to our interpretation of the intrinsic electrical properties of these cells measured in physiological experiments. Phrenic motoneurons were impaled, identified by antidromic activation of thoracic phrenic nerve and filled with HRP. Spinal cord sections were reacted with DAB and neurons reconstructed at X100. Data derived for motoneurons of 1 and 2 month old kittens are compared to earlier data from the adult (Cameron et al, JCN 231:91,1985).

	1 month	2 month	Adult
Comb. stem dendrite diam. (um)	32.6	55.4	58.3
# terminal branches/dendrite	3.5	5.8	7.0
Length to dendrite termination (um)	569	754	1236
Total surf area of cell (um^2)	72,712	162,629	351,073
Somal/dendritic surf area (%)	5.4	3.7	2.6

The diameter of primary was positively correlated with combined dendritic length, dendritic surface area and volume for the motoneurons at one month. This relationship was not as strong in the 2 month old and adult animals; the diameter of the primary was only a fair predictor while the diameter of the second order dendrite provided a much stronger correlation. Supported by grants from the NIH (HD 22703) and American Lung Association.

282.14

ROLE OF INTRINSIC PROPERTIES IN DETERMINING SPONTANEOUS ACTIVITY OF CAT PHRENIC MOTONEURONS DURING POSTNATAL DEVELOPMENT. Cameron,W.E.,Jodkowski,J.S.*,He F.* and Guthrie,R.D.* Depts. of Neurobiology and Pediatrics, Univ. of Pittsburgh and Magee-Womens Hospital, Pittsburgh, PA 15213

The activity patterns and intrinsic membrane properties of phrenic motoneurons (PMs) were studied at 4 different postnatal ages (2,4,8,12 weeks). The cells were impaled then identified by antidromic activation of the thoracic phrenic nerve. All cells analyzed had membrane potentials less than -60mV and positive overshoots. There were no differences in the mean amplitude of the action potential/overshoot or the membrane potential among the age groups studied. PMs were classified as early (E) or late (L) recruited relative to the onset of phrenic nerve activity or quiescent (Q). Significant differences ($p<.05$) were found between the axonal conduction velocities of E and L cells in all groups except 2 wks and between L and Q for 8 and 12 wks. Mean discharge frequency was found to decrease with age from 31.6Hz (4wks) to 25.4Hz (8wks) to 16.5Hz (12wks) without any significant change in the duration of the afterhyperpolarization (AHP; 62.2, 59.9, 66.2ms, respectively). Differences were found between the mean duration of the AHP of E and L cells at all ages except 2wks while no differences were found for this same parameter between L and Q cells at any age. In all experiments in which 4 or more cells were fully characterized, the E cells could be segregated from L cells based on input resistance and rheobase current and the active cells (E and L) could be separated from Q cells based on axonal conduction velocity. The strongest predictor of recruitment order in the developing phrenic nucleus was input resistance. Supported by NIH grants HD22703 and HL34875.

282.15

A Probabilistic Description of Motoneuron Dendrites. W. B. Marks and R. E. Burke, Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892

We used morphological data from 43 dendrites belonging to four type-identified cat motoneurons (one type S, two FR, and one FF; Cullheim et al., *J. Comp. Neurol.* 255:68, 1987) in order to determine whether relatively simple probabilistic rules can be used to describe features of dendritic morphology. When branches ended in branch points (**parent branches; PAR**), the mean branch length was a monotonically decreasing function of the initial branch diameter, $\mathbf{d_0}$. In contrast, mean branch length of **terminating branches (TRM)** was a monotonically increasing function of $\mathbf{d_0}$. The probabilities of branching or terminating ($\mathbf{P_{br}}$ and $\mathbf{P_{trm}}$) were determined from these means for relatively short segments (Δlength = 25 μm). Surprisingly, $\mathbf{P_{br}}$ and $\mathbf{P_{trm}}$ were not correlated with order of branching or distance from the soma, except as these relate to local segment diameter, $\mathbf{d_i}$. The length distributions of **PAR** ($\mathbf{d_0}$ between 0.75 and 13.5 μm) and **TRM** ($\mathbf{d_0}$ between 0.25 and 2.75 μm) depended not only on $\mathbf{P_{br}}$ and $\mathbf{P_{trm}}$ but also on the rate of branch diameter taper ($\mathbf{R_{tpr}}$) during probabilistic growth. The best fits to date between the modeled and observed branch length distributions for all $\mathbf{d_0}$ have been obtained when $\mathbf{R_{tpr}}$ monotonically decreases with $\mathbf{d_i}$. In mature cat alpha-motoneurons, the lengths of dendritic branches can be described as relatively simple probabilistic functions of local dendritic diameter.

282.16

QUANTITATIVE MORPHOLOGY OF GAMMA MOTONEURONS IN THE CAT SPINAL CORD. A. K. Moschovakis, W. B. Marks and R. E. Burke. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

We have examined the quantitative morphology of the dendritic trees of three triceps surae gamma-motoneurons after intracellular injection with horseradish peroxidase. In keeping with earlier studies, these cells had fewer and thinner dendrites, much less branching, and a greater proportion of unbranched dendrites, in comparison with alpha-motoneurons. However, the distances of dendritic terminations from the soma were comparable. Because of the more restricted branching, gamma-motoneuron dendrites occupied their perisomatic dendritic territory much more sparsely than alpha-motoneurons and the occupied territories were more restricted in three-dimensional space than found for alpha-motoneurons, particularly in the rostro-caudal direction. The distributions of individual dendritic branch lengths as a function of initial diameter showed the same basic pattern found in alpha-motoneuron dendrites (Marks and Burke, this meeting), suggesting that gamma-motoneuron dendrites can be described according to probabilistic rules that are fundamentally similar to those that apply to alpha-motoneurons.

282.17

MORPHOLOGY OF PRIMATE TRICEPS SURAE (TS) MOTONEURONS AND THEIR PRIMARY AFFERENT CONNECTIONS: INITIAL STUDIES. C.L. Lee, J.S. Carp, and J.R. Wolpaw, Wadsworth Laboratories, New York State Dept Health, Albany, NY, 12201.

Detailed morphologic data are not available for primate spinal motoneurons and their Ia-afferent connections. In preparation for seeking the anatomic basis of the spinal cord memory traces produced by operant conditioning of the H-reflex (J Neurophysiol 61:563-572, 1989; Wolpaw et al, this vol), we are labelling TS motoneurons and primary afferents in Macaca nemestrina with HRP.

Animals are deeply anesthetized throughout study. HRP is injected into identified TS motoneurons. HRP crystals are crushed onto appropriate dorsal rootlets 12-18 h before animals are sacrificed by overdose and perfused. Motoneurons are reconstructed by camera lucida.

Soma diameters of injected motoneurons range from 40 um to 61 um. Motoneurons have 7-13 primary dendrites. Dendritic trees are ellipsoid in shape. The largest extends at least 2100 um rostrocaudally, 680 um dorso-ventrally, and 400 um mediolaterally. Putative Ia synaptic boutons on these motoneurons range from 1.6 x 1.8 um to 3.0 x 7.2 um, and are located on somata as well as on proximal and distal dendrites.

Morphologic data from naive animals will be compared to data from conditioned animals to assess the spinal cord changes caused by H-reflex conditioning.

(Supported by NIH NS22189 & Paralyzed Veterans of America)

282.18

PHYSIOLOGIC PROPERTIES OF PRIMATE LUMBAR MOTONEURONS: INITIAL STUDIES. J.S. Carp, C.L. Lee, and J.R. Wolpaw. Wadsworth Laboratories, NYS Dept Health, Albany, NY 12201.

Operant conditioning causes side-to-side asymmetry in the H-reflex, the electrical analog of the monosynaptic spinal stretch reflex (J Neurophysiol 57:443-459, 1987). Conditioning changes the spinal cord itself, since reflex asymmetry is still present in the anesthetized animal after transection removes supraspinal influence (J Neurophysiol 61:563-572, 1989; Wolpaw et al, this vol). The most likely sites of change are the elements of the H-reflex pathway--the Ia afferent and the motoneuron.

In preparation for studying the spinal cord alterations produced by H-reflex conditioning, we are recording intracellularly from triceps surae (TS) motoneurons of anesthetized naive (i.e., unconditioned) Macaca nemestrina. In 48 TS motoneurons from the first five animals, axonal conduction velocities were comparable to human values and slower than those of the cat. Mean values and ranges for input resistance, resting potential, action potential amplitude and threshold, rheobase, afterhyperpolarization amplitude and duration, and composite EPSP amplitude were comparable to those previously described for cat and baboon.

Data from naive and conditioned animals will be compared to elucidate the sites and mechanisms of the spinal cord changes produced by H-reflex conditioning.

(Supported by NIH NS22189 & Paralyzed Veterans of America)

282.19

COMPUTER GENERATION OF ISOPOTENTIAL CONTOUR MAPS. G.R. Detillieux[1]*, L.M. Jordan[2], and D.J. Kriellaars[2]*. [1]INFO WEST Inc., Box 130, St. Boniface, Winnipeg, Canada, R2H 3B4; and [2]Dept. Physiol., Univ. Manitoba, Winnipeg, Canada, R3E 0W3.

The various steps and algorithms involved in generating isopotential contour maps on a computer are presented. This covers the data collection techniques, and the major components to the contour mapping program: 1) a two-dimensional spline interpolation algorithm used to calculate a smooth surface over a matrix of measurements of limited resolution, 2) the contour scanning and contour following algorithms which locate and trace out the contour lines on the calculated surface, and 3) the coordinate transformations used to position the generated map over a traced diagram.

Contour maps have various uses in science, such as isopotential mapping of voltage fields, isobar mapping of pressure fields, isotherm mapping of temperature, radiography, etc. A contour map can also be sued for mapping source-sink distributions. Any two-dimensional matrix of measurements can be viewed as a contour map. Examples of isopotential, source-sink and isobar contour maps are presented.

MENTAL ILLNESS: SCHIZOPHRENIA

283.1

LAMINA SPECIFIC CLONIDINE BINDING IN HUMAN CORTEX Grant N. Ko, M.D.; ; V. Haroutunian Ph.D.; T.B. Horvath M.D.; S. Lim, M.D.; E Scala; K.L. Davis, .MD. Dep. of Psychiatry Mt. Sinai School of Medicine/Bronx VAMC, New York, NY

Norepinephrine (NE) dysfunction has been implicated in the pathophysiology of schizophrenia. For instance, elevated CSF NE as well as increased NE in limbic brain regions post mortem have been reported. The purpose of the present study was to compare α_2 adrenergic receptors in the frontal cortex of postmortem brains from patients with schizophrenia and control subjects. Unfixed frontal cortex material from Brodmann's Area 9 was obtained, cut and mounted on brass microtome chucks. Coronal cryostat sections of 10μ thickness were thaw mounted on subbed microscope slides and allowed to air dry at room temperature before being stored. (^{3}H) para-aminoclonidine (PAC) was used to label α_2 adrenergic binding sites in the mounted tissue sections, prior to exposing tritium sensitive film for 6-8 weeks. Cresyl Violet was used to stain cells in alternate serial sections. At 1.0 nM PAC, lamina I binding=610 nC/g. wet weight of tissue; lamina III=930 nC/g.; lamina VI=390nC/g. (ANOVA $F=13, p=0.0001$). Schizophrenic binding and controls did not differ, suggesting that these cortical receptors are not involved in the pathogenesis of schizophrenia.

This work was supported by the Veteran Administration.

283.2

THE COMPARATIVE BEHAVIORAL EFFECTS OF THE D1 AGONIST SKF38393 AND THE D2 AGONIST QUINPIROLE IN SELECTED MEMBERS OF PRIMATE SOCIAL COLONIES. **R.F. Schlemmer, Jr., D.J. McGinness* & J.M. Davis. University of Illinois at Chicago and Illinois State Psychiatric Institute, Chicago, IL 60612.**

This study sought to evaluate the role of D1 & D2 subtypes of dopamine (DA) receptors in DA agonist-induced behavior in monkeys using acute doses of the D1 agonist SKF38393 (SKF) & the D2 agonist quinpirole (QUIN). Two stable adult Stumptail macaque social colonies each composed of 1 male & 4 females who were continually housed in a large group cage served as subjects. Following determination of baseline behavior, each of the 10 monkeys received 5 acute doses of SKF (0.3-10 mg/kg) & QUIN (1-10 mg/kg) i.m. in random order. Only 1 monkey received drug treatment/day & at least 6 days elapsed between each drug treatment. A 1 hr observation session was conducted daily by a "blind" observer beginning 15 min after drug or saline administration. QUIN induced behavioral changes which were qualitatively similar to those induced by amphetamine & apomorphine including increased scratching, submissive gestures, checking, stereotypy & distancing from other monkeys, & decreased initiated social grooming, self grooming, locomotion & feeding. SKF failed to induce similar dramatic changes, but decreased social & self grooming, locomotion, & increased huddling. These results suggest that the behavioral changes induced in primates by dopamine agonists such as apomorphine & amphetamine are predominantly mediated by D2 receptors which is in agreement with similar studies in most other species. Importantly, behaviors modelling human psychotic behavior such as increases in scratching, submissiveness & social withdrawal appear to by mediated by D2 receptors since SKF did not significantly affect these behaviors. (Supported by the Campus Research Board, University of Illinois at Chicago.)

283.3

NEUROLEPTICS HAVE TWO MODAL EFFECT ON SKIN CONDUCTANCE RESPONDING IN SCHIZOPHRENIC PATIENTS. S.Alfisi*, M.Mintz and M.Sigal* (SPON: H.Frenk). Psychobiol. Unit, Tel-Aviv Univ. Ramat-Aviv, 69967 and Pardesia Mental Health Hosp., Israel.

To test whether neuroleptic treatment affects the skin conductance response (SCR) to loud tones, chronic schizophrenic patients with and without drug-induced abnormal involuntary movements were tested before and after drug withdrawal. Patients demonstrated a high rate of SCR on both sessions. The daily neuroleptic dose correlated negatively with SCR, suggesting that the immediate effect of neuroleptics is to inhibit the autonomic nervous system (ANS) reactivity. Only patients with tardive dyskinesia (TD) showed habituation of SCR while on treatment and facilitation of reactivity after short drugs withdrawal, indicating that TD pathophysiology is associated with development of brain susceptibility to the attenuating effect of neuroleptics.

These findings confirm that alterations of ANS reactivity, considered by some as a potential markers of schizophrenia, might in fact reflect an iatrogenic side effect due to both acute and chronic effects of neuroleptic treatment.

AMPHETAMINE PSYCHOSIS AS A MODEL OF SCHIZOPHRENIA IN THE RAT: NEUROTRANSMITTER RELEASE FROM BRAIN SLICES. Pirjo Kontro, S.M. Lillrank*, T. Seppälä* and S.S. Oja. Tampere Brain Research Center, Department of Biomedical Sciences, University of Tampere and National Public Health Institute, Helsinki, Finland.

In addition to dysfunction of dopaminergic neurons also hypoactivity of glutamatergic tracts has been proposed as a primary cause for schizophrenia. As an animal model for schizophrenia, adult rats were exposed to amphetamine sulphate for 7 days using implanted osmotic minipumps (Alzet) (24 mg/kg/day). The rats exhibited loss of appetite and hyperkinesia. The potassium-stimulated (50 mM) and resting release of preloaded labeled dopamine, GABA and D-aspartate (a nonmetabolized analogue of glutamate) was characterized in superfused striatal and frontal cortical slices. The levels of amphetamine in the brain and blood serum were analyzed by gas chromatography. The potassium-stimulated release of dopamine from striatal and cortical slices was attenuated in the amphetamine-treated rats. The release of D-aspartate was slightly increased in the striatum. Potassium-evoked GABA release was potentiated in the frontal cortex more than in the striatum. When brain slices were exposed to amphetamine in vitro the resting and potassium-stimulated release of dopamine was considerably enhanced but not the release of D-aspartate. Nor did amphetamine stimulate the release of D-aspartate in the treated rats.

283.5

THE PRESENCE OF γ-ENDORPHIN IN EBSTEIN BARR VIRUS (EBV)-TRANSFORMED LYMPHOCYTES DERIVED FROM HEALTHY DONORS AND SCHIZOPHRENIC PATIENTS. M. Diamant*, C.J. Heijnen*, V.M. Wiegant*, D. de Wied* (SPON: M.F. Von Meyenfeldt). Rudolf Magnus Institute, Medical Faculty, State-univ. of Utrecht, 3521 GD Utrecht, The Netherlands.

Processing of the pro-opiomelanocortin (POMC)-derived peptide β-endorphin (βE) leads to the generation of γ-endorphin (γE) and its non-opioid fragments des-TYR^1-γE (DTγE) and des-ENK-γE. These γ-type endorphins have been demonstrated to possess neuroleptic-like activity in behavioural tests in rats. The observed beneficial effects of DTγE-treatment in schizophrenics and the deviant concentrations of γE found in post mortem hypothalamic tissue obtained from schizophrenic patients point towards a possible role for γE in the pathogenesis of schizophrenia. Recent demonstration of POMC-peptide production by cells of the immune system has provided a tool for studying endorphin production and metabolism in lymphocytes derived from schizophrenic patients versus controls. Peripheral blood lymphocytes were immortalized by in vitro transformation with EBV and cultured to yield up to 1400.10^6 cells. βE- and γE-immunoreactivity was demonstrated in EBV-cell homogenates (350 - 450pg and 3 - 6pg/10^7 cells respectively). Currently, γE-isolation from EBV-cell homogenates by specific affinity chromatography is performed. Immunoreactivity versus bioactivity of the POMC-peptides will be discussed.

NEW ANTIBODIES TO STUDY SCHIZOPHRENIA

W.G. Honer*, C.A. Kaufmann, J.E.Kleinman, M.F. Casanova*, P.Davies* (SPON: C.S. Raine), Dept. of Pathology, Albert Einstein College of Medicine, Bronx, NY 10461

With an approach similar to that used to develop the antibody Alz-50 for the investigation of Alzheimer's disease (Science 1986; 232:648) we have developed new antibodies for the study of schizophrenia. Five limbic regions of schizophrenia brain were used for immunization. Twelve antibodies were selected from 7601 hybrids screened. Enzyme-linked immunoadsorbent assay comparison of homogenates from four cases of schizophrenia and four controls revealed differences in reactivity from two- to eightfold. Three antibodies were more reactive with specific regions in the schizophrenia brains, four were more reactive with regions in the control brains, the relative differences in reactivity for the final five antibodies depended on the region tested. Preliminary studies using antibody EP10 were of particular interest. Immunocytochemistry revealed staining essentially confined to gray matter. In the cerebellum, the molecular layer was stained diffusely, the Purkinje cell layer was essentially devoid of reactivity, and the granule cell layer exhibited focal areas of staining. Other antibodies appear to be reactive with neuronal cell processes, white matter elements and astrocytes.

FIBROBLASTS: NEUROPATHOLOGICAL MODEL FOR SCHIZOPHRENIA. H. Laev, R. Reddy*, S. Mukherjee* and S. Mahadik. NYS Psychiatric Inst., and Dept. of Psychiatry, College of P. & S. Columbia Univ., New York.

Fibroblast cultures are useful as cellular models for studying some of the molecular mechanisms underlying the pathophysiology of CNS diseases, and for determining the genetic linkage of certain inheritable diseases. In schizophrenia, neuropathological changes have been detected in CNS. These neuropathologies may be associated with one or more genetic abnormalities.

Fibroblast cultures have been established from skin biopsies of 10 schizophrenic patients and 12 age-matched normal subjects. Fibroblast cultures from these patients showed differences on the following growth parameters. Initial growth: fibroblasts from schizophrenic patients took considerably longer to establish that those from controls. Established cultures were obtained from most normals at <1 month as compared to 2-4 months for schizophrenic patients. Rate of growth: the doubling time for fibroblasts from schizophrenics was markedly longer than that of normals. Morphological differences: fibroblasts from normals showed typical uniform, long, spindle-like appearance and unidirectional orientation; fibroblasts from schizophrenics exhibited random sizes (shorter and flatter) and orientation. These differences probably reflect 1) common cellular pathophysiological changes associated with the disease process, or 2) result from the treatment of the disease.

283.8

DECREASED ANTICONVULSANT RESPONSE TO ELECTROCONVULSIVE SEIZURES IN SCHIZOPHRENIC AND SCHIZOAFFECTIVE PATIENTS: A PHYSIOLOGICAL FEATURE THAT CORRELATES WITH SCHIZOPHRENIFORM SYMPTOMS. A.L. Politoff* and H.S. Lee. LIJMC, New Hyde Park, NY 11042.

Normal experimental animals and depressive illness patients are known to respond to electroconvulsive treatment (ECT) with an anticonvulsant response, which consists of shortened seizure duration (SD) and raised seizure threshold (electrical energy required for eliciting a seizure). The anticonvulsant responses of 11 schizophrenics, 7 schizoaffective disorder patients and 38 depressed illness patients were analyzed retrospectively. At the onset of ECT, SD and stimulus energy were similar in all diagnostic groups; with time, there was simultaneous decrease in SD and increase in stimulus energy in depressed illness patients, independently of medication. In contrast, SD and stimulus energy remained unchanged troughout ECT duration in schizophrenic and schizoaffective disorder patients, with or without medication. Thus, the central nervous system of schizophrenic and schizoaffective disorder patients seems to be deficient in the adaptive mechanism(s) necessary for developing an anticonvulsant response.

GLIAL PROTEINS IN SCHIZOPHRENIA. C.N. Karson, W.S.T. Griffin, M. Cassanova* & J.E. Kleinman, Depts. of Psychiatry/Behavioral Sci. Pediatrics & Anatomy, UAMS & J. L. McClellan VAMC, Little Rock AR., 72205 & Lab. of Clinical Brain Studies, NIMH, Wash. D.C., 20857.

We are examining gliosis in schizophrenia in postmortem brain tissue from regions of cortex, cerebellum, rostral brain stem and diencephalon using Western blot to determine relative levels of glial proteins (glial fibrillary acidic protein (GFAP) and interleukin-1 (IL-1)). Initial negative results from frontal lobe (below) suggest this approach is practical and may ultimately answer whether gliosis (neurodegeneration) occurs in this disorder.

THE MORPHOMETRY OF THE CORPUS CALLOSUM IN SCHIZOPHRENIA. M.F. Casanova*, M. Zito*, E.F. Torrey*, T. Goldberg*, L. Bigelow*, R. Sanders*, D.R. Weinberger and J.E. Kleinman. (SPON: P. Oliver) CBDB, NIMH Neurosciences Center at St. Elizabeths, Washington, D.C. 20032.

It has been suggested that faulty interhemispheric communication underlies some of the symptoms observed in schizophrenic (SC) patients. Since the corpus callosum (CC) is the major conduit for corticocortical fibers, this structure has been the focus of several morphometric studies in SC patients. Unfortunately, it has been difficult to replicate many of the reported findings and the role of the CC in SC still remains controversial. In an attempt to improve the reliability of morphometric measurements of the CC we used a computer image analysis system to quantitatively examine the shape, area, thickness and length of the CC in MRI scans in 12 pairs of monozygotic twins discordant for SC. The study failed to replicate previous findings, but partially supported the notion of disease related shape differences in the middle segment of the CC. In a follow up study the mean curvature of the middle segment of the CC in the same MRI scans was measured to define the basis of this structural distortion. The results indicated that the CC of SC patients have an increased upward convexity. In order to determine whether the structural distortion was the result of a primary histological lesion involving the CC, axonal counts in postmortem tissue were performed in the CC of 11 SC and 13 age matched controls. Independent t-tests (SC vs controls) were non-significant at the 0.01 level for the anterior, middle and posterior sites. Since hydrocephalus is associated with an upward bowing of the CC, it seems possible that the conformational disturbance observed in our SC patients is secondary to ventriculomegaly and not the result of an intrinsic CC lesion.

AN ANIMAL MODEL OF SCHIZOPHRENIA: EFFECTS OF HIPPOCAMPAL CELLULAR DAMAGE. K.S. Seybold*, J.L. Stotler*, P.W. Parsons*, and R.L. Port. Depts of Psychology, Grove City College, Grove City, PA 16127, and Slippery Rock University, Slippery Rock, PA, 16057.

Recent evidence suggests that neuropathy within the hippocampal formation may provide an anatomical substrate for schizophrenia (Conrad & Scheibel, Schizo. Bull. 13, 1987). In the present experiment, slight pyramidal cell loss was induced in rats via intraventricular injection (1 ul) of kainic acid (0.5 and 1.5 nM). Animals were tested in shuttlebox avoidance for sixty trials over two days. The results showed a facilitation of acquisition in damaged animals that is consistent with reports of accelerated simple conditioning in schizophrenics and dissimilar to the deleterious effects which often accompany disruption of hippocampal activity. Performance of the low-dosage group was most similar to the control group early in training and resembled the high-dosage group later in training. These effects are suggestive of an interaction between the compromised hippocampus and the induction of long-term potentiation over training.

283.12

100ms AUDITORY RESPONSES IN PATIENTS WITH SCHIZOPHRENIA AND NORMAL CONTROLS USING MAGNETOENCEPHALOGRAPHY. A.Reeve, D.F.Rose, S.Sato, D.R.Weinberger. NIMH and NINDS, 9000 Rockville Pike, Bethesda, MD. 20892.

Anatomical studies have shown decreased temporal lobe volume and loss of cortical cells of temporal lobe in patients with chronic schizophrenia. We studied a physiologic measure of temporal lobe function in chronic schizophrenics on neuroleptic medication and controls. Three patients (2 male, 1 female, ages 30-40) and four controls (2 male, 2 female, ages 24-50) were administered tone bursts (1000Hz, 20ms plateau, 2ms rise/fall, 65dB SL, 0.25/s, 100 epochs, from Nicolet CA-1000) to each ear unilaterally. All subjects were alert; state of arousal was monitored with EEG. The 100ms magnetic field response (N100m) was recorded contralateral to the stimulated ear with a 7-channel magnetometer in a shielded room (Biomagnetic Technologies,inc.). Simultaneous EEG (10-20 system to balanced non-cephalic reference) recording of N100 permitted verification of the presence of N100m and its reproducibility over time. Locations of equivalent current dipoles varied without a consistent pattern between or within groups. Using MRI, the N100m localized to the temporal lobe in right and left hemispheres in all subjects.

These results suggest that previous reports of interhemispheric differences in dipole locations may reflect differences in anatomical substrate, rather than in processing of auditory information in either hemisphere.

SCHIZOPHRENIA: LINKAGE ANALYSIS WITH CHROMOSOME 5 MARKERS. K.L. Newell[1]*, E.I. Ginns[2]*, J. Schreiber[2]*, R. Long[2]*, J.R. Kelsoe[2], T. Manschreck[3]*, C.N. Pato[2]*, D. Pickar[2]*, S.M. Paul[2]*. [1]Howard Hughes Medical Institute-NIH; [2]Clinical Neuroscience Branch, National Institute of Mental Health, Bethesda, MD 20892; [3]Massachusetts General Hospital, Boston, MA.

Schizophrenia is a psychiatric disorder affecting approximately 1% of the human population. Family and adoption studies of this disorder have suggested that both environmental and genetic factors may be involved in its etiology. The initial report of a partial trisomy of the 5q11.2-13.3 region in association with schizophrenia in an Asian family (Bassett, A.S. et al., Lancet 1:799-801, 1988) prompted further study using DNA probes at this site resulting in the discovery of linkage between a disease locus and this region in seven Icelandic and British families (Sherrington, R. et al., Nature 336:165-67, 1988). We have utilized three chromosome 5 probes from the region 5q11-13 (D5S76, D5S39 and D5S78) to analyze genomic DNA for co-segregation of schizophrenia and these marker loci in a large North American pedigree exhibiting a high incidence of chronic psychosis and affective disorder. Preliminary results do not support linkage between schizophrenia and the 5q11-13 probes used in this investigation. These data further suggest the presence of genetic heterogeneity in schizophrenia.

283.14

PREFRONTAL CORTICAL BLOOD FLOW IN MONOZYGOTIC TWINS CONCORDANT AND DISCORDANT FOR SCHIZOPHRENIA. K.F. Berman, E. Fuller Torrey*, D.G. Daniel* and D.R. Weinberger. CBDB, NIMH Neurosciences Center at St. Elizabeths, Washington, D.C. 20032.

Several converging lines of evidence suggest abnormal prefrontal cortical function in schizophrenia (SCH). However, nothing is known about the etiology of such a deficit in this illness. To explore one of the proposed major etiologies, that of genetic determination, we used the Xe133 inhalation technique to measure regional cortical blood flow (rCBF) in 10 pairs of monozygotic twins discordant for SCH as well as in 8 pairs of monozygotic twins concordant for SCH. Each subject completed 3 rCBF measurements during 3 different cognitive conditions: first during the resting state and then during 2 tasks: an automated version of the Wisconsin Card Sort (WCS), which is specifically linked to prefrontal cortex; and a simple numbers matching task which controlled for non-prefrontal aspects of the procedure. Within each discordant twin pair the twin with SCH had lower relative prefrontal flow during the WCS (for well twins mean(±SEM) = 111±2, for ill twins mean = 104±2, matched pairs T = 5.6, p = .0004). The mean relative prefrontal flow during the WCS for the twins concordant for SCH (105±2) did not differ from that of the SCH discordant twins. Within 6 of the 8 concordant pairs, the twin who had more lifetime neuroleptic treatment had the higher relative prefrontal flow, suggesting that neuroleptic treatment cannot explain prefrontal dysfunction in SCH. These data reconfirm a pathophysiological defect in prefrontal function in patients in SCH, even when compared to genetically identical individuals without schizophrenia. While these results do not lend strong support for genetic control of "hypofrontality," they suggest that neuroleptic treatment does not account for prefrontal dysfunction in SCH.

284.1

REDUCTION OF PARVALBUMIN-IMMUNOREACTIVITY IN THE SUBCORTICALLY DENERVATED HIPPOCAMPUS. L.S. CHEN, T.F. FREUD, G. BUZSAKI, K.D. BAIMBRIDGE AND F.H. GAGE. Dept. of Neuroscience, UC San Diego, CA92093.

Removal of subcortical and commissural inputs to hippocampus (HP) by fimbria-fornix (FF) lesions permanently produces large amplitude EEG spikes and decreases threshold to stimulus-induced seizure (Neuroscience 28:527-538,1989). In this study, we examined parvalbumin (PV, a calcium binding protein specific to GABA neurons) immunoreactivity to test the hypothesis that hyperexcitability of the subcortically denervated HP results from a decrease in GABA-mediated inhibition.

Two months after FF lesions, female Sprague-Dawley rats (n=7) were perfused and coronal sections were taken from dorsal HP for PV immunohistochemistry. Age-matched, non-lesioned rats (n=7) were served as control. The cell density (number of cells/area) of PV-immunoreactive cell (PV-IR) was the parameter used for comparison.

In normal rats, a gradient of the cell density of PV-IR was observed in the dorsal HP. The cell density in the anterior 1/3 was significantly greater than that of the posterior 2/3 in the stratum granulosum (DG), hilus (H) and CA3c regions by 75%, 75% and 50% respectively ($P<0.01$). In rats with FF lesions, a reduction in the cell density was demonstrated in the DG (20%, $P<0.05$), H (40%, $P<0.01$) and CA3c (50%, $P<0.01$) in the anterior region. While in the posterior region, the reduction was found only in the H (30%, $P<0.05$).

We propose that a decrease of calcium buffering capacity of interneurons consequent to the reduction of PV expression may be causally related to the hyperexcitability of the denervated hippocampus.

THE SUBCORTICALLY DEAFFERENTED HIPPOCAMPUS: EPILEPTIC PATTERNS AND PLASTIC PROPERTIES. Z. Horvath*, S. Berger*, M. Hsu*, F. H. Gage and G. Buzsaki. (SPON: R. Livingston) Dept. of Neurosciences, UCSD, La Jolla, CA 92093

Spontaneous and evoked electrical activity was studied in the subcortically denervated (fimbria-fornix; FF) hippocampus in rats. Within one week after FF surgery short-duration, large amplidude (up to 12 mV) interictals spikes (IIS) emerged and persisted for up to 10 mo. Simultaneous microelectrode recordings along the longitudinal axis of the hippocampus revealed that IIS invaded the entire hippocampus simultaneously (<5 ms) or slowly (<0.5 m/s) by recruiting new sets of neurons successively. IIS occurred independently in the two hemispheres, but occasionally IIS could spread to the contralateral hippocampus via the retro-hippocampal commissural system. IIS occurred more frequently during immobility and slow wave sleep than during movement. Very large IIS were frequently followed by startle reactions, indicating that limbic activity could invade motor structures. In contrast to intact rats large amplitude, multiple population spikes were recorded in the dentate gyrus and CA1 region in response to stimulation of the perforant path (PP). IIS-triggered evoked responses were several times greater than responses elicited between the IIS. High frequency stimulation of PP increased the incidence of IIS for several hours and the morphology of the IIS became similar to the stimulus-evoked responses. These finding indicate that a) the deafferented hippocampus is hyperexcitable, b) the excitability of the hippocampal network is increased substantially during the IIS and c) tetanic stimulation of PP produces long-term changes of the spontaneous excitability of the hippocampal circuitry.

LOCAL CIRCUIT INTERACTIONS IN THE CA1 REGION OF HYPER-EXCITABLE KAINATE-LESIONED RAT HIPPOCAMPUS. S. Nakajima*, J.E. Franck and P.A. Schwartzkroin. Dept. of Neurological Surgery, Univ. of Washington, Seattle, WA 98195.

Intraventricular (icv) injection of kainic acid (KA), with loss of hippocampal CA3 pyramidal cells (PCs), produces a model of temporal lobe epilepsy. Hyperexcitability in remaining CA1 PCs is associated with a loss of IPSPs and possible recurrent excitation. Despite the functional loss of inhibition, the purported inhibitory interneurons remain viable. The present study evaluates local circuit interactions in this hyperexcitable CA1 in order to determine the cause of IPSP failure and identify excitatory collateralization.

Paired intracellular recordings were obtained *in vitro* from physiologically identified interneurons and PCs 2-4 weeks following bilateral icv KA (0.6 μg/1 μl saline/side). Recorded slices had an abnormal population burst response to stimulation of stratum radiatum. No synaptic interactions were detected in simultaneous recordings from 33 pairs of PCs. Five of six PC/basket cell pairs (interneurons at the pyramidale/oriens border) and two PC/OA interneuron pairs (interneurons at the oriens/alveus border) also showed no interactions. In one pair, PC discharge evoked EPSPs in a basket cell; the PC was unaffected by interneuron discharge.

These data are consistent with reports that there are few, if any, excitatory synaptic connections among CA1 PCs. The development of such connections does not appear to underlie KA-induced CA1 hyperexcitability. In normal hippocampus, previous data indicate that 30% of CA1 PCs show inhibitory PSPs to basket cell activation. Our failure to detect any such connections in KA-lesioned hyperexcitable tissue suggests a functional disconnection at the interneuron to PC synapse.

THE SEIZURE-ASSOCIATED LOSS OF INHIBITION IN THE RAT HIPPOCAMPUS; INHIBITORY CELLS SURVIVE AND ARE FUNCTIONAL IN VIVO. R.S. Sloviter, Neurol. Res. Ctr., Helen Hayes Hosp., W. Haverstraw, NY 10993

We hypothesized that the seizure-associated loss of inhibition in the hippocampus was not due to inhibitory cell loss or dysfunction but, rather, to the loss of cells that excite basket cells (Sloviter, R.S., Science, 235:73-76, 1987). This "dormant basket cell" hypothesis implies that inhibition might be restored if the basket cells could be activated. Weeks after perforant path stimulation (PPS) that produced dentate and CA3 damage, CA1 pyramidal cells responded abnormally to ipsilateral PPS (0.1-3Hz) with large amplitude multiple spikes. Twin pulse inhibition (40ms) was decreased in CA1 despite no apparent CA1 damage. Contralateral PPS restored CA1 pyramidal cell inhibition immediately and completely (n=20). We suggest that inhibition in CA1 is decreased as a result of CA3 damage that decreases feedforward activation of ipsilateral CA1 basket cells. Contralateral stimulation activates the same basket cells via the commissural projection from CA3 to CA1. Thus, the hypothesis that the loss of inhibition **in vivo** is due to the loss of excitatory input to surviving basket cells, rather than to basket cell loss or malfunction, is confirmed.

DO CHANGES IN SYNAPTIC EXCITATION OR INHIBITION UNDERLIE GENERATION OF LONG-LASTING, BURSTING-INDUCED LATE EPSPs IN PIRIFORM CORTEX? W.H. Hoffman and L.B. Haberly (SPON: J. Hind) Neurosci. Training Prog. and Dept. of Anatomy, Univ. of Wisconsin, Madison WI 53706.

Stimulation of afferent or association fibers in piriform cortex slices in Mg free bathing medium evokes burst responses which lead, upon return to normal Mg concentrations, to the appearance of long-latency, all-or-none EPSPs that persist for the duration of experiments (Hoffman & Haberly, J. Neurosci. 9:206). Evidence has also been presented that these late EPSPs are initiated in layer III of piriform cortex and propagate synaptically to pyramidal cells in layer II (Hoffman & Haberly, Soc. Neurosci. Abs. 14:278). The present experiments were designed to test the hypothesis that late EPSPs in deep cells result from reverberating positive feedback following a disruption in the balance between excitatory and inhibitory processes as postulated for the hippocampus (Traub et al, J. Neurophysiol. 58:739). Possible sources of such a disruption include potentiation of EPSPs mediated by intrinsic association fibers or decreases in the early Cl mediated or late K mediated IPSPs.

Measurements of rise times of monosynaptic EPSPs evoked by stimulation of association fibers revealed an enhancement in only 1 of 6 layer III cells following induction of late EPSPs, but this increase disappeared within 50 min despite the continued presence of late EPSPs. Blockage of the K mediated IPSP by phaclofen (a specific $GABA_B$ receptor antagonist) failed to induce late EPSPs (n=6), suggesting that any reduction in the late IPSP plays a minor role. To determine if reduction in Cl IPSPs underlies late all-or-none EPSP generation, bicuculline was applied over a range of concentrations (1.25-10 μM) (n=9). Substantial reduction in Cl IPSP amplitudes did not directly lead to the appearance of late EPSPs. Late EPSPs only appeared after onset of bursting evoked by the accentuated early EPSP. Moreover, comparison of Cl mediated IPSPs before and after induction of late EPSP by 0 Mg revealed an average increase in amplitude of 16% in layer II cells (n=5) and 32% in layer III cells (n=4). These results suggest that changes in known synaptic processes are not responsible for the generation of late EPSPs. It is postulated that enhancement of slowly developing synaptic or endogenous currents underlies development of the observed late EPSPs. Such slow excitatory activity could occur while the Cl IPSP is refractory following activation by the early EPSP and lead to all-or-none EPSPs via positive feedback. Supported by grant NS 19865 to LBH.

MULTIPLE POPULATION SPIKES IN THE DENTATE GYRUS TO HILAR STIMULATION AFTER BLOCKADE OF $GABA_A$ RECEPTORS. J. CRONIN[1] and F. E. DUDEK[2]. [1]Psychology Dept., Tulane Univ., New Orleans, LA 70118 [2]Mental Retardation Research Center, UCLA Med. Sch., Los Angeles, CA 90024.

The hippocampal mossy fibers of the kainate-treated rat sprout collaterals that project to the granule cell dendrites. Hilar stimulation, which normally evokes a single population spike, could trigger multiple spikes in slices from kainate-treated rats; this suggested that the collaterals had formed a functional pathway (Tauck & Nadler, J. Neurosci. 5:1016, 1985). To evaluate hilar stimulation as a test for new recurrent excitatory circuits, we examined this response in the normal dentate gyrus and under conditions of increased excitability.

After bath application of picrotoxin (50-100 μM, 5 of 5 slices) or bicuculline (100 μM, 5 of 9 slices), hilar stimulation evoked 2 to 8 population spikes. Intracellular recordings revealed stimulus-evoked EPSPs. Raising extracellular $[K^+]$ from 3 mM to 8 mM, or use of Mg-free medium, caused 2 to 4 additional spikes per stimulus. In one slice that did not respond to bicuculline, raising extracellular $[K^+]$ led to multiple spikes from hilar stimulation.

We conclude that hilar stimulation can evoke EPSPs and multiple population spikes from granule cells. Since the response recorded in the normal dentate gyrus from hilar stimulation can have an orthodromic component, multiple population spikes do not necessarily indicate the formation of a new recurrent excitatory pathway.

THE EFFECTS OF OSMOLALITY ON SYNCHRONOUS BURSTING IN THE ABSENCE OF CHEMICAL SYNAPTIC TRANSMISSION IN HIPPOCAMPAL SLICES. J.G. Tasker and F.E. Dudek, Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

Numerous studies using low-[Ca^{2+}] solutions have indicated that non-synaptic mechanisms can synchronize electrical activity in the hippocampus. We examined the effects of altered extracellular osmolality on CA1 population responses after blocking chemical synaptic transmission in slices of rat hippocampus. Synaptic responses to single and repetitive electrical stimuli were completely blocked in solutions in which Ca^{2+} was replaced with EGTA (1-2 mM) and kynurenate (3 mM). Bursts of population spikes and/or negative shifts were induced in CA1 when [K^+] was raised to 5 mM. When negative shifts occurred without population spikes, reduction of the extracellular osmolality by adding water (5-20%) or lowering NaCl (10-20 mM) caused bursts of population spikes. When bursts occurred in solutions of normal or lowered osmolality, addition of mannitol or sucrose (+5-40 mOsm/kg), which are membrane impermeant, dramatically reduced the bursts. Addition of glycerol (+5-40 mOsm/kg), which is membrane permeant, had little or no effect. The effects of mannitol and sucrose could be reversed by diluting the medium (i.e., decreasing osmolality). All effects of changing osmolality were at least partially reversible. Thus cellular swelling in dilute media, and the resultant reduction of the extracellular space, enhance neuronal synchrony, even in the absence of chemical synaptic transmission. Similarly, cell shrinkage from increased extracellular osmolality reduces synchrony. These data strongly support the hypothesis that electrical field effects and/or changes in extracellular [K^+] play an important role in the synchronization of hippocampal neurons. Supported by AFOSR 87-0361.

FUNCTIONAL RE-ORGANIZATION OF THE PERIRHINAL-PYRIFORM BURST RESPONSE BY PROLONGED EXPOSURE TO O-Mg++:SUPPORT FOR AN INVITRO MODEL OF KINDLING. J.R.Plant* & D.C. McIntyre. Dept. of Psychology, Carleton Univ., Ottawa, Canada K1S 5B6.

It has been previously demonstrated that the Perirhinal (PRc) & Pyriform (Pc) cortices are capable of O-Mg++ induced discharges INVITRO, & exhibit a functional relation ship determined by the history of the donor rat. In slices from unstimulated controls, onset & development of O-Mg++ induced discharges originated exclusively from the PRc & led those in the Pc. In contrast, discharges in slices from amygdala kindled rats originated in the Pc & led those in the PRc, suggesting a kindling-induced re-organization of the relationship between the PRc & Pc, & a long-term increase in Pc excitability. In the present study we investigated the effects of prolonged exposure of control slices to O-Mg++ perfusate. Under Mg++ perfusate only 6% of all discharges originated in the Pc. In contrast, after aprox. 4 hours under O-Mg++ perfusate, 82% of all discharges originated in the Pc & led those in the PRc. When returned to Mg++ perfusate for a minimum of 1 hr, 100% of all discharges now originated in the Pc. Results of the study demonstrate that prolonged exposure of control slices to O-Mg++ perfusate results in an increase of discharges originating in the Pc & a re-organization of the relationship between the PRc & Pc which is identical to that seen in slices taken from electrically kindled rats.

MAGNESIUM REMOVAL INDUCES HYPERACTIVITY AND NEURONAL DEGENERATION IN VITRO. K. Rose*, C. W. Christine and D.W. Choi (SPON: E.S. Tecoma). Dept. of Neurology, Stanford Univ. Med. Sch., Stanford CA 94305.

Removal of extracellular Mg^{++} has been shown to induce epileptiform activity in hippocampal slices, and was recently observed by R.J. Miller and colleagues to trigger NMDA receptor-mediated neuronal degeneration in hippocampal cell cultures (personal communication). We report here that removal of extracellular Mg^{++} for 24-72 hr produced extensive neuronal degeneration in murine cortical cell cultures. The glial layer was not damaged. This selective neuronal injury could be substantially attenuated by addition of either an NMDA antagonist (e.g., 50uM dextrorphan) or 3uM tetrodotoxin, to the bathing medium. Whole cell voltage clamp recording revealed that neurons perfused with Mg^{++}-free extracellular medium fired at substantially higher rates than when perfused with the same medium containing 1 mM Mg^{++}. Dextrorphan was also effective in quelling this neuronal hyperactivity induced by Mg^{++} removal.

These observations support the idea that Mg^{++} removal is sufficient to trigger NMDA receptor-mediated neuronal degeneration in vitro, most likely by simultaneously increasing neuronal activity and reducing blockade of the NMDA channel. Mg^{++} removal may be a useful method of modeling epileptic brain injury in vitro.

HIGH [Ca++]o AND LOW [K+]o SUPPRESS INTERICTAL SPIKES AND PROMOTE ELECTROGRAPHIC SEIZURES IN SLICES OF RAT HIPPOCAMPUS-ENTORHINAL CORTEX IN LOW Mg++ MEDIUM. H. Kojima*, A.C. Bragdon and W.A. Wilson. Depts. of Medicine (Neurology) and Pharmacology, Duke University and VA Medical Centers, Durham, NC 27710.

In vitro models exhibiting electrographic seizures (ES) provide an opportunity to study physiological factors regulating epileptiform activity. Brain slices of hippocampus and entorhinal cortex (HC/EC) exhibit ES when first exposed to "0-Mg" (no added Mg) medium. These ES are eventually suppressed by discharges resembling interictal spikes (IIS). We hypothesized that, in this model, lowering K+ and raising Ca++ in the medium would promote ES by suppressing IIS.

Extracellular recordings were made in area CA3 of HC/EC slices from adult male Sprague-Dawley rats. Standard medium had 3.3 mM K+, 1.8 mM Ca++ and 1.2 mM Mg++. In 0-Mg medium, slices exhibited ES with a rapid-firing (2-12 Hz) "tonic" phase of simple population bursts, followed by a slower-firing (0.2-2 Hz) "clonic" phase of complex bursts. In all slices, ES gave way to IIS after 30-120 min in 0-Mg medium. 20 slices were then studied at a fixed Ca++ of 2, 2.5, 3, 3.5 or 4 mM in progressively lower K+. By 1.5 mM K+, ES had reappeared in all slices; all ES had only a tonic phase; ES duration correlated with Ca++ (confirmed in 11 more slices). In 1.5 mM K+, IIS were suppressed completely in 3-4 mM Ca++ but, unexpectedly, occurred along with ES in 2-3 mM Ca++.

Lowering K+ promoted ES and, with high Ca++, suppressed IIS in the 0-Mg seizure model. However, ES and IIS were not completely mutually exclusive. One possible explanation for this semi-independence may be: IIS originate in HC whereas the ES arise in EC; HC and EC are influenced separately by Ca++ and K+; and the end result reflects a balance between effects on the two areas.

These results contrast sharply with results in two other in vitro seizure models in which seizures were induced by low Ca++ and/or high K+, and suggest the roles played by Ca++ and K+ in epilepsy are more complex than previously thought.

284.11

MODEL OF HIGH POTASSIUM INDUCED SYNCHRONIZED BURSTS IN THE RAT HIPPOCAMPAL SLICE: POSSIBLE ROLE OF SPONTANEOUS EPSPs IN INITIATION. Roger D. Traub, Nancy L. Chamberlin and Raymond Dingledine. IBM Watson Res. Ctr., Yorktown Heights, NY 10598 & Dept. of Pharmacology, Univ. of N. Carolina, Chapel Hill, NC 27514.

High extracellular K^+ (7 to 10 mM) induces repeating synchronized epileptiform bursts in the CA3 region of rat hippocampal slices [Rutecki et al., *J. Neurophysiol.* **54** (1985) 1363]. High K bursting differs from picrotoxin (PTX)-induced synchrony: (i) pyramidal cells in high K do not generate intrinsic bursts; (ii) high K does not block Cl^- IPSP conductance, but rather moves E_{IPSP} toward resting potential. A model of PTX synchrony has been proposed [Traub, Miles and Wong. *J. Neurophysiol.* **58** (1987) 739] in which bursting spreads via excitatory collaterals between disinhibited, intrinsically bursting pyramidal cells; the model requires (and it has been shown) that bursting be able to spread from one cell to connected cells. We report here that, with modifications dictated by experiments, a similar model can account for high K bursting. We used 9,900 cells, none intrinsically bursting; E_{IPSP} was set at resting potential. Each pyramidal cell receives spontaneous EPSPs with mean interval 150 ms or more, as observed in high K. Firing in one cell does *not* elicit firing in a connected cell. Synchrony develops when synaptic noise generates, in concert with intrinsic cellular depolarization, a threshold number of firing cells. Spread of firing then occurs along excitatory collaterals; spread is cooperative rather than the chain reaction of the PTX model. Our model agrees with these data: (i) a subthreshold excitatory buildup occurs in many cells just prior to a synchronized event; (ii) the interburst interval is regulated largely by a K-dependent AHP; (iii) blockade of IPSPs leads to more intense, less frequent bursts; (iv) total block of EPSPs abolishes synchronized bursts. That the same network accounts for two different types of synchronized bursting supports the basic model.

284.12

PHARMACOLOGICAL STUDY OF THE CESIUM-EVOKED SPONTANEOUS DISCHARGES IN DISINHIBITED RAT NEOCORTEX MAINTAINED "IN VITRO". M.Avoli & G.G.C.Hwa. MNI, McGill Univ., Montreal, Que., Canada.

Several K^+ channel blockers are used as convulsants in experimental studies. Here, we report that in rat neocortical slices perfused with 50 µM bicuculline methiodide (BMI), application of Cs^+ (2-3mM) increased the stimulus-induced burst duration (>500%), and concurrently triggered spontaneous discharges (0.06-0.21 Hz) that were not observed in BMI alone. Morphologically, there was no discernible difference between the evoked and the spontaneous discharges (1-4s). Manipulation of the membrane potentials indicated that both types of activities were network in origin. While the NMDA antagonist CPP reversibly reduced the rate of occurence of the spontaneous discharges by 13±8.9% (n=12), the change was not significant (T-test, $p>0.1$). Furthermore, preliminary data indicate that the non-NMDA antagonist CNQX appeared to depress or abolish the spontaneous activties. Thus, the epileptiform discharges described in the present experiments may represent a seizure model that is mediated primarily by non-NMDA receptors.

284.13

SEIZURE SUSCEPTIBILITY IN HIPPOCAMPAL SLICES: RELATION TO REGIONAL VARIATION IN EXTRACELLULAR SPACE. S.F. Traynelis, C.J. McBain* and R. Dingledine. Department of Pharmacology, University of North Carolina, Chapel Hill, NC 27599.

Electrographic seizures arise spontaneously in the CA1 region but not in CA3 or dentate gyrus of rat hippocampal slices perfused with elevated [K]o. Such seizures are readily blocked by hyperosmotic media, suggesting a role for K-induced restrictions of extracellular space in seizure initiation. To determine if variations in extracellular volume fraction (Vo) might account for the different susceptibility of these hippocampal subregions, we measured the diffusion profile of impermeant ions with the Nicholson-Phillips method to estimate Vo. In each region of the hippocampal slice the diffusion profile of iontophoretically introduced tetramethylammonium (TMA) measured with an ion-sensitive electrode was consistent with the laws of macroscopic diffusion. TMA had minimal effect on population spikes at the concentrations attained (2mM). Vo measured in 11 slices was 12% in CA1 stratum pyramidale (SP), 19% in CA3 SP and 18% in the granule cell layer. Vo was higher in stratum radiatum than in SP in both CA1 and CA3. The tortuosity, or mean increase in path length of a diffusing particle, was the same in all three regions (range 1.67-1.89). These data are consistent with the proposal that regional differences in extracellular volume could contribute to the different behavior of CA3 and CA1 neurones during electrographic seizures.

284.14

SPONTANEOUS SPIKE AND WAVE DISCHARGES IN RATS: ONTOGENY AND EFFECTS OF THE EXPOSURE TO DIFFERENT ENVIRONMENTS. M.Buonamici*,R.Maj*,M.A.Cervini*,P.Cassutti*and A.C.Rossi R&D.,Farmitalia Carlo Erba-Erbamont Group, C.N.S. Line, 20014 Nerviano, Italy.

The so called Spontaneous Spike and Wave Discharges (SSWDs) have been described as genetically determined in Wistar rats, but we have observed that they occur with much higher frequency also in Long Evans (LE) rats. To assess the relevance of genetic versus environmental factors in the genesis of SSWDs we exposed LE rats to "normal" or highly "enriched" environmental conditions from day 43 to day 180 after birth. Fifty-five rats in "normal" laboratory conditions were singly housed in standard cages, whereas the fifty-five rats in "enriched" environment underwent twice daily various standardized manipulation (for a total of 25 different "games"). EEG from chronically implanted electrodes were recorded for 1h, each session and then analyzed by computer for measurement of the number of bursts and percentage of time occupied by SSWDs (100%=60 min). No differences were observed between the two groups in both variables under observation. This suggests that different environments do not modulate SSWDs and assigns a more determinant role to genetic factors in the genesis of SSWDs. As expected at the end of the experiment the rats kept in "enriched" conditions performed better in a simple learning test (repeated hot-plate).

METAPHIT. AN ISOTHIOCYANATE ANALOG OF PCP, INDUCES AUDIOGENIC SEIZURES IN MICE. E.A. Debler[1], M.N. Lipovac*[2], A. Lajtha[1], B.V. Zlokovic*[2], A.E. Jacobson*[3], K.C. Rice[3], and M.E.A. Reith[1]. [1]Ctr. Neurochem., NKI, Ward's Is., NY, NY 10035; [2]Inst. Med. Physiol., Belgrade U., Belgrade, Yugoslavia; [3]NIDDKD, NIH, Bethesda, MD 20892.

Phencyclidine (PCP), a psychotomimetic drug that produces a psychosis resembling schizophrenia, has both convulsant and anticonvulsant activity (Hayes and Balster, Eur. J. Pharm., 117:121, 1985). Many PCP related effects have been shown to be mediated by the PCP recognition site that modulates the action of excitatory amino acids at the N-methyl-D-aspartate (NMDA) receptor. In in vitro binding studies, metaphit (MET) has been found to irreversibly bind to the PCP receptor (Rafferty et al., FEBS Lett., 181:318, 1985). In the present study we demonstrate that MET (administered either retro-orbitally [r.o.] or i.v., 20 mg/kg) induces audiogenic seizures in BALB/cBy mice. The most severe clonic/tonic seizures occur 18 to 24 h after MET administration. After 48 h the incidence of the seizure episodes begin to diminish. These audiogenic seizures can be prevented by the administration of either PCP (i.p., 7 mg/kg) or MK-801 (i.p., 0.5 mg/kg) 24 h after MET and 30 min prior to audio stimulation. PCP itself (r.o., 1, 5, 10 mg/kg) failed to elicit sound dependent seizures 24 h after administration. These MET-induced seizures may be due to a modulation of the PCP recognition site by MET which results in an enhanced probability that the PCP/NMDA ion channels are open.

OPIATES, ENDORPHINS AND ENKEPHALINS: ANATOMY AND CHEMISTRY I

285.1

CHANGES IN HYPOTHALAMIC MET-ENKEPHALIN IMMUNOREACTIVITY IN THE LACTATING RAT. M.D. Fitzsimmons and G.E. Hoffman. Dept of Physiology, Univ. of Pittsburgh, Pgh PA 15261

Opiate agonists increase serum prolactin levels. A leading hypothesis for the mechanism of action postulates that these agonists decrease the tonic inhibitory tone of hypothalamic dopamine neurons in the arcuate region, the A12 cell group. Our double labeling immunocytochemical studies have demonstrated a significant innervation of A12 neurons (more than 60% of the perikarya counted) by dynorphin axons. Modest but statistically significant increases in contact frequency occur during diestrus and proestrus. Nevertheless, differences in prolactin levels during pregnancy and lactation are not reflected by changes in dynorphin interactions with dopamine perikarya.

In the course of these experiments, two significant changes in hypothalamic Met-enkephalin (mEnk) immunoreactivity emerged. Lactating rats showed a striking increase in the amount of mEnk immunoreactivity in the median eminence relative to the other groups examined. In addition, mEnk staining frequently colocalized with A12 neurons (as indicated by tyrosine hydroxylase immunoreactivity). The appearance of mEnk immunoreactivity in A12 perikarya without colchicine pretreatment suggests significantly increased mEnk synthesis in these dopaminergic neurons.

These results are consistent with the existence of two kinds of influence of opioid peptides on prolactin regulation: dynorphin innervation of dopamine neurons may account for changes in prolactin release during the estrus cycle and mEnk released from the median eminence may stimulate prolactin release during lactation. The mechanism of mEnk stimulation of prolactin during lactation remains unclear. Leading hypotheses include: 1) direct stimulation of lactotrophs by opioid peptides; 2) opioid peptide interference with dopaminergic inhibition of prolactin at the level of the pituitary; 3) paracrine effects of mEnk at the median eminence on other trophic influences over anterior pituitary function.

DIFFERENTIAL EXPRESSION OF PREPROENKEPHALIN AND PREPRODYNORPHIN mRNAs IN THE RAT BRAIN. Yasuhiro Morita, Takashi Hironaka*, Jian-Hua Zhang*, Masaya Tohyama*, and Shiro Nakagawa*. Dept. of Anatomy, Kagoshima Univ. Med. Sch., Kagoshima, and Osaka Univ. Med. Sch., Osaka, Japan

Proenkephalin and prodynorphin are opioid precursor proteins which yield various forms of opioid peptides following posttranslational proteolitic processing. Proenkephalin- and prodynorphin-derived peptides were localized immunologically in a variety of brain tissues, but there were substantial discrepancies about localization of cell bodies. In the present study, neurons containing preproenkephalin(PPE)- or preprodynorphin(PPD)-mRNA were examined in the rat brain by in situ hybridization.

A large number of neurons containing PPE-mRNAs were distributed in various regions of the rat brain, while neurons with PPD-mRNA were primarily localized in the forebrain tissues. Neuronal population containing PPE- or PPD-mRNA were clearly separated in the rat brain tissues: e.g., different layers in the parietal cortex, discrete cell populations in the hyppocampal formation, and caudate-putamen, paraventricular, ventromedial hypothalamic, and solitary nuclei.

285.3

IMMUNOCYTOCHEMICAL LOCALIZATION OF β-ENDORPHIN CONTAINING NEURONS IN THE OVINE HYPOTHALAMUS. R.L. Goodman and C.S. Whisnant*. Physiology Department, West Virginia University, Morgantown, WV 26506

Endogenous opioids, including β-endorphin (END), have been implicated in the control of gonadotropin secretion in breeding season ewes, but little is known about the anatomy of these neural systems in this species. In this study, we identified END-containing neurons in the ovine hypothalamus using immunocytochemistry. Breeding season ewes (n=4) were anesthetized and their heads perfused with saline followed by Zamboni's fixative. A block of tissue containing the preoptic area (POA) and medial basal hypothalamus (MBH) was dissected, embedded, and 70 μm coronal sections cut with a vibrotome. Free floating sections (490 μm apart) were stained using the avidin-biotin-HRP procedure with a primary antiserum against END. Preincubation of antiserum with END (2 μg/ml) abolished all staining. Nerve fibers stained for END were observed in the median eminence and scattered throughout the medial hypothalamus and POA. END-containing cell bodies were localized in the MBH, but were not limited to the arcuate (ARC) nucleus. Just posterior to the optic chiasm, perikerya were in the periventricular area at the bottom of the third ventricle (3V). More caudally, cell bodies were concentrated in the ARC, but were also observed laterally and ventrally (in the ME). A high concentration of perikerya were visible in the posterior MBH around the ventrolateral border of the mammillary recess of 3V.

285.4

SIGMA RECEPTOR BLOCKADE BY BMY 14802 INVERSELY AFFECTS ENKEPHALINERGIC AND TACHYKININ NEURONS IN THE BRAIN OF THE RAT. J. A. Angulo, J. L. Cadet°, and B. S. McEwen °Columbia University, Dept. of Neurology, N.Y. and The Rockefeller University, Lab. of Neuroendocrinology, N.Y.

Typical neuroleptics inversely affect striatal proenkephalin and protachykinin mRNA biosynthesis in rat brain. These effects are attributed to the anti-dopaminergic activity of neuroleptic drugs. In the present study we determined proenkephalin and protachykinin mRNA levels in the rostral, medial, and caudal aspects of the caudate nucleus of the rat by in situ hybridization histochemistry in controls and in animals treated for 14 days with the potential neuroleptic drug BMY 14802 (15 mg/kg, i.p.). Proenkephalin mRNA levels were increased relative to control values by 207, 188, and 194% and protachykinin mRNA levels decreased to 83, 72, and 90% in the rostral, medial, and caudal aspects of the caudate-putamen, respectively. Similar effects of proenkephalin and protachykinin mRNA levels were observed in the nucleus accumbens. Unlike commonly used neuroleptic drugs, BMY 14802 lacks anti-dopaminergic activity but displays potent antagonistic activity at the haloperidol-sensitive sigma receptor site. The data suggest that sigma receptor activity, directly or indirectly, affects proenkephalin and protachykinin mRNA expression in striatal and nucleus accumbens neurons.

285.5

OPIOID RECEPTOR DISTRIBUTION IN RAT BRAIN USING IMMUNOHISTOCHEMISTRY. C.J.C.Boersma*,C.Gramsch**, A.Herz**,and F.W.Van Leeuwen* (SPON: ENA). Neth. Inst.for Brain Res.,Amsterdam,The Netherlands*; Max Planck Inst. für Psych.,Martinsried,F.R.G.**.

We are currently studying the distribution of opioid receptors by means of a monoclonal antibody (anti-Id-14). This antibody was raised using the anti-idiotype procedure (Gramsch et al., J. Biol.Chem., 263:5853). For immunohistochemistry, rats were perfused with 4% formaldehyde and post-fixed for 2 hrs, followed by an ABC staining method. We demonstrated opioid receptor immunoreactivity distributed in the following structures: paraventricular and supraoptic nuclei, stria terminalis, claustrum, central amygdala, caudate putamen, suprachiasmatic and paraventricular thalamic nuclei, lateral habenula, arcuate nucleus and median eminence. This distribution of opioid receptor immunoreactivity is similar to that previously described, utilizing autoradiography (Mansour et al.,J.Neurosci., 7:2445). The present results are in agreement with data indicating that anti-Id-14 primarily recognizes the μ and δ opioid receptors, whereas it has a low affinity for the κ subtype (A.Hassan, personal communication).

285.6

MONOCLONAL ANTIBODIES REVEAL ENKEPHALIN PRECURSOR FORMS IN CEREBELLAR ASTROCYTES AND NEURONS B.A. Spruce*, R. Curtis*, G.P. Wilkin*, and D.M. Glover*. (SPON:J.Brockes). Biochemistry Dept., Imperial College,London,SW7 2AZ,U.K.

We have generated 15 monoclonal antibodies to human proenkephalin-b-galactosidase fusion proteins synthesised in *E. coli* which recognise the unprocessed enkephalin precursor in stable transformants of PC12 cells. Several antibodies stain Golgi cells, deep cerebellar nuclei, and a subpopulation of Purkinje cells in the young adult rat cerebellum. In addition, 6 antibodies, which recognise different domains of preproenkephalin, stain a subpopulationof both grey and white matter astrocytes. One monoclonal which is predominantly directed to high molecular weight cleavage products rather than the intact precursor, stains neurons only and not astrocytes. This suggests a predominance of unprocessed proenkephalin in the astrocytes. Immunostaining using a metenkephalin antibody reveals staining of the outermost pial layer only. In situ hybridisation experiments, using an antisense RNA probe, combined with a glial fibrillary acidic protein immunostain, support the findings. Our results are consistent with a previous report of low levels of enkephalin peptides in the cerebellum,despite levels of mRNA comparable to those in the striatum, a region rich in enkephalin peptides. They indicate that processing of proenkephalinin the cerebellum is markedly less than in other regions of brain. Our results are also consistent with previous findings of proenkephalin mRNA in cultured astrocytes,and of unprocessed proenkephalinin the C6 rat glioma cell line, which could indicate a contribution of astrocytes to the neuroendocrine network.

285.7

AUTORADIOGRAPHY OF ^{3}H-ETHYLKETOCYCLAZOCINE BINDING SITES: SODIUM EFFECT. **D.D. Conrad and G.F. Wooten. Dept. of Neurology, University of Virginia School of Medicine, Charlottesville, VA. 22908.**

We have examined the effect of sodium (Na) on the distribution of ^{3}H-ethylketocyclazocine (EKC) binding sites in rat brain with respect to putative areas of high density kappa receptors, specifically the paraventricular thalamic nucleus and periventricular hypothalamic nucleus (J. Neurosci. 7(8): 2445-2464, 1987). Twenty micron thick frozen sections were incubated with ^{3}H-EKC at concentrations three times the K_d to define total binding in either Tris base 50 mM or K_2HPO_4 30 mM with NaCl 100 mM buffer. ^{3}H-EKC binding in the presence of 10 μM ketocyclazocine defined non-specific binding. The sections were then processed for autoradiography. Ten anatomic areas were analyzed by quantitative autoradiography using the DUMAS Image Analysis System. There was no significant difference in binding between the two buffer systems in striatal patches, nucleus accumbens, striatal matrix, medial amygdala, presubiculum, medial geniculate, superior colliculus or cortical amygdala. There was however, a 100% increase in binding in the paraventricular thalamic nucleus and a 174% increase in the periventricular hypothalamic nucleus (p<.01 and .05, respectively) in brain slices incubated in Na buffer when compared to incubation in Tris buffer. These results suggest that Na selectively enhances ^{3}H-EKC binding in areas of the brain previously demonstrated to be rich in putative kappa receptors.

285.8

(+) and (-)-Cyclofoxy: Application to the Quantitation of Opiate Receptors In Vivo. A. H. Newman,[1] N. L. Ostrowski,[2] R. Cohen,[2] M. A. Channing,[3] K. C. Rice.[4] [1]Walter Reed Army Institute of Research, Washington D. C. 20307-5100, [2] NIMH, [3]Clinical Center, NIH, [4]NIDDK, NIH, Bethesda, MD. 20892

(-)Cyclofoxy, a 6β-fluoro-derivative of the opiate antagonist naltrexone, was prepared as a model opiate ligand potentially suitable for positron emission tomography (PET). In vivo and in vitro autoradiography using (-)[^{3}H]cyclofoxy demonstrated that this ligand labeled a population of opiate receptors in the brain that was identical to those labeled by [^{3}H]naloxone. (-)[^{18}F]cyclofoxy has now enabled the visualization of opiate receptors in humans, using PET. However, an important issue in the successful application of this ligand to study the human opiate receptor-endorphin system is the necessary capability of quantitating occupied opiate receptors. Such quantitation is essential in detecting small but significant differences in the receptor density and/or endogenous ligand concentration between clinically normal and abnormal human subjects. Opiates with the naturally occuring (-) stereochemistry demonstrate a 10,000-fold stereoselectivity in binding to classical opiate receptors suggesting that (+)[^{18}F]cyclofoxy could serve as an ideal control for only opiate receptors occupied by (-)[^{18}F]cyclofoxy by enabling accurate quantitation of nonspecific binding. Synthesis of these ligands and in vivo autoradiography using (+) and (-)[^{3}H]cyclofoxy will be described.

285.9

ELECTRON MICROSCOPIC LOCALIZATION OF KAPPA OPIOID RECEPTORS IN GUINEA-PIG NEOSTRIATUM. C. Jomary*, J.E. Gairin*, J. Cros* and A. Beaudet (SPON:G. Karpati). Mont.Neurol.Inst., 3801 University Montreal, H3A 2B4, Canada and *LPTF, 205 Rte de Narbonne, 31077 Toulouse Cedex, France.

The distribution of kappa opioid receptors was examined by light and electron microscopic radioautography in sections of guinea-pig neostriatum labelled with the selective mono-iodinated probe, [125-I-Tyr^{1},D-Pro^{10}]dynorphin (1-11) (125-I-DPDYN). Pilots studies indicated that prefixation of the brain with 0.5% glutaraldehyde modified neither the affinity nor the capacity of 125-I-DPDYN binding to striatal sections. 125-I-DPDYN binding was also found to be pseudo-irreversible, allowing for post-fixation, defatting and liquid emulsion processing of the tissue without redistribution of the radioligand. In the light microscope, 125-I-DPDYN-labelled sites were distributed uniformly in the ventrolateral aspect of the neostriatum, but showed patches of high binding in the dorsomedial tier. At high magnification, the label was mostly confined to the neuropil, sparing both neuronal perikarya and myelinated fibbers bundles. In the electron microscope, the labelled binding sites were almost exclusively associated with the plasma membranes of neuronal and/or glial elements. Most of the label was detected over axo-dendritic interfaces, many of which exhibited a synaptic specialization in the plane of section. These results indicate that in the guinea-pig neostriatum, kappa opioid receptors are mainly membrane-bound, and often associated with axo-dendritic synapses.

285.10

(+) AND (-)-CYCLOFOXY: RADIOLABELED OPIATE ENANTIOMERS ALLOW VISUALIZATION OF SPECIFIC AND NON-SPECIFIC LIGAND BINDING IN VIVO. N.L. Ostrowski, A. Hauck-Newman, K.C. Rice and R.M. Cohen. Section on Clinical Brain Imaging, Lab. of Cerebral Metabolism, NIMH and Lab. of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892

(-)Cyclofoxy (CF; Burke, et al., 1985) has high affinity for opiate receptors in vivo, no pharmacological activity in tracer doses and no metabolites are detectable in brain. We investigated whether the inactive enantiomer of CF, [^{3}H](+)CF (Hauck-Newman, et al., 1989; this meeting) could be used as an in vivo measure of non-specific brain accumulation. Comparisons of tritiated (+) and (-)-CF using brain to cerebellar ratios, brain to plasma ratios, brain and arterial microdialysates and autoradiographic data strongly indicate that the distribution of [^{3}H](+)CF is unrelated to, and independent of, the distribution of opiate receptors. This is the first demonstration that an enantiomeric pair of ligands can be used to differentiate specific from non-specific labeling of receptors in vivo.

285.11

DISTRIBUTION OF MU, DELTA, AND KAPPA OPIOID RECEPTOR SUBTYPES IN THE RAT SPINAL CORD. M.A. Romagnano, E.K. Richfield, L.S. Brady, and R.W. Hamill. Neurology Dept. Monroe Community Hospital/Univ. of Rochester School of Medicine and Dentistry, Rochester, N.Y. 14603 and Unit on Functional Neuroanatomy, NIMH, Bethesda, MD. 20892

The distribution of the mu (μ), delta (δ), and kappa (κ) opioid receptor subtypes were examined throughout spinal cord levels C8-S2-4 in the rat. Fresh frozen horizontal serial sections were incubated with [^{3}H]D-ala^{2}-N-methyl-phe^{4},gly^{5}-ol-enkephalin (DAGO) or [^{3}H]D-ala^{2}-D-leu^{5}-enkephalin (DADLE) to label μ and δ receptors, respectively. In order to study κ receptors, sections were incubated with [^{3}H]bremazocine in the presence of unlabeled DAGO and DADLE. Adjacent slides were coincubated with excess unlabeled competitors to determine nonspecific binding. Following incubation, slides were apposed to LKB Ultrofilm-^{3}H or coated with Kodak NTB-2 emulsion and allowed to expose for 1-2 months.

In the thoracic cord, specific dense μ and κ binding was found in laminae I and II. Moderate κ binding was present throughout the dorsal horn and in laminae VII while moderate-dense κ binding was found in laminae X in the dorsal commissural nucleus. In the sacral cord, dense μ and κ binding was observed in laminae I and II. Moderate κ binding was present throughout the rest of dorsal horn. In the dorsal commissural nucleus at sacral levels moderate μ and κ binding was found. These data establishing the presence of different opioid receptor subtypes in several spinal cord laminae support the involvement of opioid peptides in sensory and autonomic regulation.

TROPHIC AGENTS III

NERVE AND GLIAL CELL LINES SECRETE MITOGENS FOR GLIAL PROGENITOR CELLS. J.M.Levine and F.Stincone*,Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook,NY,11794

The development of O2A progenitor cells, the precursors of some astrocytes and oligodendrocytes, is regulated by environmental factors. For example,platlet-derived growth factor(PDGF) is a mitogen for glial progenitor cells and ciliary neurotrophic factor(CNTF) can initiate astrocyte differentiation. To characterize potential novel factors that might effect the development and differentiation of glial progenitor cells, we assayed the trophic effects of serum-free medium that had been conditioned by several neuronal and glial cell lines.

Post-natal rat optic nerve cells were grown in conditioned medium(CM) for 3 days, pulse labeled with 3H-thymidine and immunofluorescently stained with antibodies that identify progenitor cells, astrocytes and oligodendrocytes.The CMs were also tested for the stimulation of DNA synthesis in NIH/3T3 cells which respond to PDGF and CHO cells which lack a PDGF receptor.

Medium conditioned by 3 neuronal cell lines(B103,B50 and B35) stimulated DNA synthesis in progenitor cells,3T3 cells and CHO cells. Medium conditioned by PC12 cells and N2A neuroblastoma cells did not stimulate progenitor cells to divide however, the number of oligodendrocytes that developed in the cultures was reduced when compared to control cultures grown in defined medium.PC12 CM stimulated the division of CHO and 3T3 cells and N2A CM increased cell division only in CHO cells. Among the glial cell lines tested,C6,B92 and B82 cells secreted a mitogen for progenitor cells. The effects of these media on 3T3 and CHO cells was variable; B82 CM stimulated both CHO and 3T3 cells,C6 CM stimulated only CHO cells and B92 CM stimulated 3T3 cells but not CHO cells. In no cases were oligodendrocytes stimulated to divide.

These data demonstrate that neuronal and glial cell lines are valuable sources of trophic activities. The CMs that stimulate O2A progenitor cell division may contain a PDGF-like molecule.

286.2

LONG TERM SURVIVAL OF PRIMARY CULTURE OF ADRENAL CELLS FROM ADULT RATS: IMMUNOHISTOCHEMICAL CHARACTERIZATION. K.Shimoda , M. Poltorak and H.-Y.T. Yang. NIMH, Neuroscience Center at St. Elizabeths, Washington D.C. 20032.

Previously we have developed a primary culture of medullary cells from adrenals of adult rats. These cells can survive for a very long term of culture, (5 months or longer). To determine whether chromaffin cells survive, the cells were cultured for two months and characterized immunohistochemically with various antisera after being stimulated with or without NGF. Without NGF, few outgrowth of neurite was observed but tyrosine hydroxylase and NPY were detected in cell bodies. With NGF, extensive NPY positive neurites were observed. The results clearly indicate the survival of chromaffin cells which are responsive to NGF. NGF also enhanced Thy-1 suface expression molecules and glyoxylic acid induced fluorescence on the cells and neurites further indicating the responsiveness of the cells to trophic agent. The reason(s) for the long term survival of the chromaffin cell cultured in this study is still unclear. Interestingly, we observed that the 2 month old cultured cells can extend neurites spontaneously if culture media were not changed for a week. The result seems to suggest that trophic material may be produced and accumulated in the culture medium of the adrenal medullary cells.

286.3

USE OF EMBRYONIC BRAIN SLICES TO ASSAY POTENTIAL NEUROTROPHIC FACTORS

Kathy V. Callison and Jill M. Roberts-Lewis. Cephalon, Inc., West Chester, PA 19380.

Because of the need to establish a high-throughput assay with maximum sensitivity to potential neurotrophic factors, we have developed a method which examines the induction of ornithine decarboxylase in embryonic brain tissue slices.

Pooled brains from E16 rat fetuses were minced thoroughly with a razor blade in Earle's Balanced Salt Solution and brought to a final concentration of approximately 100 mg wet weight/ml. Fifty ul aliqouts of this mince were added to 400 ul of Earles in each well of a 24-well tissue culture plate. The covered 24-well plate(s) were placed into a tissue culture incubator (37^{o}C, 10 % CO_2). Following a one hour equilibration period, asparagine dissolved in 50 ul Earle's was added to the wells (9 mM final) and allowed to incubate for another 5 hours. The tissue suspension was then removed from each well and briefly centrifuged. The pellets were assayed for ornithine decarboxylase activity using a radiometric ornithine decarboxylase microassay. Asparagine elicited a 10-fold induction of ornithine decarboxylase in fetal brain tissue under these incubation conditions.

The novel use of a tissue culture incubator to maintain brain slices for a prolonged period of time may have broad applicability for a number of neurochemical assays using brain slices, such as neurotransmitter uptake and release, or genome activation studies.

286.4

PREPARATION OF HIGH YIELD HIGHLY PURIFIED NEURONAL CULTURES FROM RAT CNS.

M.E. Blake, J.F. McKelvy and J. Chen, (SPON: D.E. Frail) Neuroscience Research Division, Pharmaceutical Discovery, Abbott Laboratories, Abbott Park, IL 60064

Highly pure primary cultures of CNS neurons, obtainable reproducibly and in high yield, represent an important tool for studying many aspects of neuronal function *in vitro*. We have developed a useful new approach which gives rise to such cultures. For example, rat embryonic cerebral cortices (E15) were dissociated by passage through fired pasteur pipets, followed by Percoll gradient centrifugation. Live cells were plated onto poly-D-lysine treated cover glasses, 35 mm dishes, and multi-well plates in alphidicolin containing media. Approximately, $3x10^8$ cells could be obtained from 30 cortices. After three days in culture, process outgrowth had proceeded to a point where extensive arborization and dense interconnecting networks of processes could be seen, with a remarkable uniformity of distribution of cell bodies. Immunocytochemical staining with neuronal specific neurofilament and GFAP antibodies revealed that the culture was at least 98% neuronal cells. These cultures are being used to explore growth factor actions; e.g. FGF and PDGF were found to enhance neurite outgrowth as well as neuronal maintenance.

286.5

A RE-DESIGNED INTRAVENTRICULAR INFUSION DEVICE PREVENTS PUMP TOXIN INDUCED BRAIN LESIONS.

H.L. Vahlsing*, T. Hagg, M. Manthorpe, A. Dekker*, M. Manley*, S. Varon. [SPON : M.E. Baker] Dept. Biology, M-001, UCSD, La Jolla, CA 92093.

We had previously introduced improvements in a device for continuous infusion of NGF or other substances into the lateral ventricle of adult rats which addressed, among others, the problem of infusion-related lesions in the tissue around the cannula tip. The severity of the lesion could be limited by decreasing the infusion rate suggesting either a mechanical or a toxic origin. To evaluate the latter possibility, sterile phosphate buffered saline (PBS) was introduced into the different components of the cannula device and incubated sterilely in vitro for 2-14 days at 37°C. This "conditioned" PBS was added in sequential two-fold dilutions to cultures of chick neurons, rat astroglial cells, and mouse fibroblasts and the cultures examined 24 hr later for cell survival. Toxic activity was found only in fluid taken from the Alzet 2002 mini-osmotic pump, its half-maximal activity seen between 100 and 500 fold dilution.

In a re-designed infusion device the cannula was connected to the pump by a coil of siliconized vinyl tubing. Pump-derived toxins are prevented from reaching the brain by an air or mineral oil spacer which separates the infusate in the coil from the fluid in the pump. With the new device infusion-related brain lesions were no longer seen even after infusions lasting a full month or delivered directly into the brain parenchyma. Additional advantages are i) the effects of the infused agent are not complicated by the presence of toxins, ii) the volume of infusate in the coil can be varied according to the infusion duration, an important point for treatments with scarce or expensive agents, iii) coil and spacer material can be adapted to fit properties of different agents, iv) different agents can be administered sequentially by alternating infusate and spacers in the coil, v) the volume of actually infused fluid can be calculated from its advancement in the coil. Supported by grants BNS-88-08285 (NSF) and NS-16349, NS-25011 (NINCDS).

286.6

NERVE GROWTH FACTOR RECEPTOR IN NEURAL TUMORS.

Alonzo H. Ross[1], David L. Baker[2*], Balaka Chattopadhyay[1*], Jie Chen[1*], David Pleasure[2], Usha Reddy[2], Amit Roy[1*], and Gita Venkatakrishnan[1*]. [1]Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545; [2]Childrens Hospital of Philadephia, PA 19104.

A 75,000-dalton glycoprotein (gp75) has been identified as nerve growth factor receptor (NGF-R). Using flow cytometry, Western blotting, and Northern blotting, we have surveyed a series a human neural tumor cell lines for gp75 expression. All 5 neuroepithelioma cell lines tested expressed gp75 but only 9 of 17 neuroblastoma cell lines tested expressed gp75. One of 4 medulloblastoma cell lines tested expressed gp75. NGF-induced neurite extension was observed for 3 neuroblastoma cell lines all of which lack amplified N-myc oncogene.

Two neuroblastoma cell lines apparently lacking gp75 expression were infected with a defective retrovirus encoding gp75, and one was found to express high-affinity NGF-R and to up-regulate fos expression in response to NGF. The other infected neuroblastoma cell line expressed only low-affinity NGF-R and lacked a fos response.

286.7

SYNTHESIS OF A NERVE GROWTH FACTOR-LIKE MOLECULE BY GRANULOMAS.

G. W. Varilek*, J. V. Weinstock* AND N. J. Pantazis, Departments of Anatomy and Internal Medicine, Univ. Of Iowa Medical College, Iowa City, IA 52242.

NGF is critical in the maintenance and development of specific neuronal cell types, but it is unclear whether NGF functions outside of the nervous system. The possibility that NGF is involved in the immune system was examined in this study. Our goal was to determine whether granulomas isolated from mice infected with the parasite, Schistosoma mansoni, synthesize NGF. These granulomas are t-cell mediated inflammatory lesions composed primarily of macrophages, eosinophils, lymphocytes and fibroblasts. METHODS: Granulomas were isolated aseptically from 10-wk infected mice. NGF bioactivity was assayed by neurite outgrowth from pheochromocytoma (PC12) cells. Granulomas were either co-cultured with PC12 cells or conditioned medium (CM) was collected from granuloma cultures and this CM was tested on PC12 cells. NGF concentrations were also determined by radioimmunoassay (RIA). RESULTS: In co-culture experiments, granulomas induced neurite outgrowth from PC12. In addition, granuloma CM stimulated neurite outgrowth. The RIA detected immunoreactive NGF in granuloma homogenates. The displacement curve generated by the granuloma "NGF" paralleled the standard curve derived with NGF purified from mouse submandibular gland. CONCLUSIONS: Biological and immunological assays determined that granulomas, isolated from mice infected with Schistosoma mansoni, synthesize an NGF-like molecule. The cell type responsible for the synthesis of NGF as well as the role of NGF in the immune system are under investigation. Supported by NFIC, NIH: AM34986, AM38327, GM28644.

286.8

TEMPORAL CHANGES IN NGF RECEPTOR LABELING IN PRIMARY CULTURES OF RHESUS AND RAT ADRENAL CHROMAFFIN CELLS.

M. A. Herman*[†] and P. Claude*. Wisconsin Regional Primate Research Center, [†]Dept. of Physiology and *Neuroscience Training Program, UW-Madison 53715.

Nerve growth factor (NGF) promotes the outgrowth of neurites from adrenal chromaffin cells, but little is known about NGF receptor (NGFR) deployment during this response. We examined changes in immunostaining for NGFR in chromaffin cells cultured for four weeks in the presence or absence of NGF, with or without dexamethasone (dex), which inhibits neuritic outgrowth from these cells (Unsicker et al. 1978). As previously described, differentially plated adrenal chromaffin cells from rhesus monkeys of various ages (Lillien and Claude, 1985a), or from 8 day old rats (Lillien and Claude, 1985b), were grown on collagen-coated glass coverslips in 25 ng/ml 7S NGF, 15 μM dex, NGF plus dex, or control medium. 1, 2, 3 or 4 weeks after plating, cultures were immunostained with monoclonal antibodies directed against NGFR (NGFR5 for rhesus or 192 for rat) and scored for percent of cells with neurites and percent of labeled cells with and without neurites. **Results.** The percentage of rhesus cells labeled for NGFR increased with time in culture in all conditions. However, cells were not uniformly labeled; not all neurite-bearing cells were labeled, and some cells without neurites were labeled. Different intensities of labeling occurred in all conditions, with dex-treated cells staining the most intensely at all time points. The intensity of labeling dramatically decreased with time in NGF alone. A slight decrease in intensity was seen in NGF plus dex and in control medium, while there was no change in dex alone. These results suggest that culturing *per se* may cause chromaffin cells to upregulate NGFR, that NGF may downregulate its own receptors, and that dex may antagonize this NGF-dependent downregulation of NGFR. Preliminary experiments using cells from young rats yielded similar results. (We thank C.A. Schulz for technical help and M. Bothwell for monoclonal antibodies. Supported by NSF BNS-8616958 to P.C. and NIH RR00167 to the WRPRC.)

286.9

EFFECTS OF NERVE GROWTH FACTOR AND ITS ANTISERUM ON SYMPATHETIC GANGLION CELLS IN YOUNG ADULT AND AGED MICE. K.G. Ruit[1], P.A. Osborne*[2], R.E. Schmidt[3], E.M.Johnson, Jr.[2], and W.D. Snider[1]. Depts. Of Neurology[1], Pharmacology[2], and Pathology[3], Washington Univ. Sch. Med., St. Louis, MO 63110.

The extent to which neurons in mature animals depend on neurotrophic molecules remains controversial. We have therefore investigated the effects of prolonged systemic injections of NGF and its antiserum on the survival and morphology of sympathetic ganglion cells in young adult and aged mice.

Treatment with guinea pig anti-mouse NGF led to substantial cell death in the superior cervical ganglion, as well as to retraction of dendritic arborizations. Neuronal counts showed that 32% of neurons had died after 1 month of treatment. Intracellular staining revealed that cross-sectional somatic area was reduced by 54% and that the total length of dendritic processes was reduced by 33%. After 3 months of treatment up to 60% of neurons had died. When a similar protocol was employed in aged animals (22 months old), cell loss in the superior cervical ganglion was 31% after one month of treatment.

To determine whether NGF stimulates dendritic growth in maturity, adult animals were treated systemically with 5-10 mg/kg of NGF for 2-4 weeks. Despite the fact that tyrosine hydroxylase activity increased in treated ganglia, this protocol resulted in little change in sympathetic ganglion cell morphology. Preliminary data suggest that total dendritic length was increased by only 14%.

Our results in anti-sera treated animals show that even in maturity sympathetic ganglion cells remain dependent on NGF for survival and maintenance of dendritic arborizations. Interestingly, administration of NGF to adult animals, even in very large doses, appears to have only a modest effect on ganglion cell morphology.

STRIVING FOR AN ANIMAL MODEL OF ALZHEIMER'S DISEASE: GENETIC CONSTRUCTION AND EXPRESSION OF A FAMILY OF TOXINS TARGETED TO NGF RECEPTORS. P.A. Schimke*, L Penchuk*, T. Jerome*, J.R. Muprhy* and G. Heinrich. Biomolecular Med., Boston University Medical Center, Boston, MA 02118

In Alzheimer's disease, a severe cholinergic deficit involving neurons that bear NGF receptors occurs. Induction of a corresponding deficit in animals would advance the understanding of the mechanisms of Alzheimer's disease, but specific cholinergic toxins are not available. To develop such toxins, we took advantage of previous work, in which fusion toxins were produced by replacing the sequence encoding the binding domain of diphtheria toxin (DT) or Pseudomonas exotoxin A (PEA) with sequences encoding alpha-MSH (PNAS 83:8258, 1986) and IL-2 (Protein Eng. 1:493,1987, PNAS 84:4538, 1987), which were specifically cytotoxic for cells bearing the targeted receptors. DT-NGF constructs, containing or lacking signal sequence, have NGF sequences extended from the 3' end of DT, therefore, the fusion junction occurs at the N-terminus of NGF. In NGF-PEA constructs, the preproNGF sequence is extended from the 5' end of PEA, with the fusion junction at the C-terminus of NGF. These fusion toxins are suitable for bacterial and mammalian cell expression. For mammalian expression, DT-resistant COS cells were selected in 5 uM DT, and transfected with fusion toxin expression vectors to study the resultant products and their effect on PC12 cells. Supported by ACS grant PF2973(PAS), ADRDA grant PRG88-055 (GH).

NERVE GROWTH FACTOR (NGF) AND ITS RECEPTOR IN ALZHEIMER'S AND PARKINSON'S DISEASE. N. J. Pantazis, S. Ning*, D. R. Brady and E. J. Mufson. Anatomy, Univ. of Iowa Medical College, Iowa City, IA 52242 and Institute for Biogerontology Research, Sun City, AZ. 85372

NGF is required for maintenance and development of sympathetic and sensory neurons of the peripheral nervous system and cholinergic (Ch) neurons present in the basal forebrain of the central nervous system. These Ch neurons express NGF receptor (NGFR), provide the major cholinergic innervation to neocortex and hippocampus, and degenerate in Alzheimer's disease (AD) and in Parkinson's disease with dementia (PKD). Since NGF is involved in maintaining Ch neurons, our hypothesis was that concentrations of either NGF and/or NGFR are reduced in AD and PKD, resulting in loss of basal forebrain Ch/NGFR neurons.

Brain samples were obtained postmortem (2.5 - 5 hr delay) and frozen in liquid nitrogen. Samples of basal forebrain (BF; nucleus basalis), hippocampus (HP) and motor cortex (MC) were homogenized and NGF concentrations were determined by radioimmunoassay. NGFR was determined by NGF immunoprecipitation. When AD or PKD samples were compared to unafflicted controls, there were no differences in NGF or NGFR concentrations in the brain areas studied. The lack of a difference in NGF suggests that the source of NGF is not altered in these disease processes. Since many NGFR neurons in the basal forebrain degenerate in AD and PKD, it is surprising that NGFR expression is not altered. Possibly, surviving NGFR neurons increase their expression of NGFR. Although the role of NGF in AD and PKD remains to be elucidated, loss of NGFR neurons in these diseases does not appear to be directly linked to reduced NGF or NGFR concentrations. (Support: American Health Assistance Foundation)

RE-EXPRESSION OF NERVE GROWTH FACTOR RECEPTOR IN ADULT BRAINSTEM MOTOR NEURONS AFTER AXONAL INJURY. S.J. Wood* and M.V. Sofroniew. (SPON: G. Ugolini) Department of Anatomy, University of Cambridge, U.K.

Nerve growth factor (NGF) is a trophic factor essential for the development and maintenance of sympathetic and some sensory neurons. NGF is thought not to be a neurotrophic factor for motor neurons, since experiments similar to those used on sympathetic and sensory neurons show no effects. Nevertheless, motor neurons transiently express NGF receptors (NGFr) and retrogradely transport 125-I labelled NGF during development (from E15 to P6) (Yan et al. *Neuron* 1:335). We report here, that some motor neurons re-express NGFr following axonal injury in the form of crush or transection.

The hypoglossal (Hg) and vagus (Vg) nerves were exposed unilaterally in the neck of young adult rats, and were either crushed, or transected and ligated. After varying survival times, animals were perfused and the brainstems immunohistochemically stained for NGFr using monoclonal antibody MC-192.

In contrast to neonatal animals (P1-P3), normal adult rats showed no staining of Hg or Vg motor neurons for NGFr. 7 days after a crush injury, many, but not all, Hg or Vg neurons stained positively for NGFr. Staining had declined by 14d after nerve crush in the Hg, and by 28d in the Vg. After axotomy and ligation, similar numbers of neurons were positively stained for NGFr in the Vg, but far fewer in the Hg; these were found at later survival times (>14d) and were observed in some neurons up to 100d after injury. While the function of NGFr in motor neurons remains obscure, re-expression of these receptors after axonal injury suggests they may be involved in similar events during development and the reaction of these neurons to injury.

ULTRASTRUCTURAL EVIDENCE FOR NERVE GROWTH FACTOR-MEDIATED ENHANCED SURVIVAL OF DEVELOPING CENTRAL CHOLINERGIC NEURONS IN REAGGREGATE CELL CULTURE. B.H. Wainer[a], S.D. Price[a*], S.G. Nelson[a*] and W.C. Mobley[b]. The University of Chicago[a], Chicago, IL, 60637 and The University of California[b], San Francisco, 94143.

Nerve Growth Factor (NGF) exerts trophic effects on cholinergic neurons of the basal forebrain. We previously reported that while NGF increases the number of developing cholinergic neurons in reaggregate cultures of the fetal septal region (Hsiang et al. Neuroscience 29: 209-223, 1989), the results of ultrastuctural analysis suggested that this effect was more likely to result from increased expression of the histochemical cholinergic marker, acetylcholinesterase (AChE), than from enhanced cholinergic cell survival (Wainer et al. Soc Neurosci Abs.14: 36. 1988). In the present experiments the effects of NGF treatment were examined in reaggregate co-cultures of embryonic day 15 septal cells and cerebellar cells, which normally do not support cholinergic cell survival. The analysis consisted of ultrastuctural quantitation of healthy versus degenerating AChE-positive cells in septal-cerebellar (S-Cb), and septal cerebellar + 20ng/ml NGF (S-Cb +NGF) co-aggregates following both 15 and 21 days of culture. Preliminary results of the analysis obtained thus far are as follows: In three S-Cb culture flasks at 15 days, ultrastructural analysis yielded a mean ± SE of 156 ±46 healthy; 35 ± 7 dying or 79 ± 7% intact cells. In three S-Cb culture flasks at 21 days, results yield 160 ± 55 healthy, 48 ± 4 dying or 73 ± 6% intact AchE-positive cells. In S-Cb + NGF cultures, three flasks at 15 days yielded 236 ± 52 healthy, 16 ± 5 dying or 95 ± 1% intact cholinergic cells. At 21 days, analysis of three flasks yielded 215 ± 73 healthy, 12 ± 2 dying or 94 ± 2% intact. These preliminary results suggest that when developing septal cholinergic neurons are cultured at lower effective density with cells that normally do not support their survival (ie. nontarget cerebellar cells) then the presence of NGF can enhance their survival. Supported by NS-25787.

CULTURED RAT HIPPOCAMPAL ASTROCYTES SECRETE NERVE GROWTH FACTOR IN VITRO, BUT DO NOT SUPPORT AXOTOMIZED CHOLINERGIC NEURONS IN VIVO. K. Yoshida, A.M. Fagan, and F.H. Gage. Dept. of Neurosciences, University of California-San Diego, La Jolla, CA 92093.

Two-site enzyme immunoassay was used to determine the secretion of Nerve Growth Factor (NGF) from cultured cells. Astrocyte rich cultures (GFAP-positive cells >90%) were obtained after 2 passages from neonatal rat hippocampal formations. Pure fibroblast cultures isolated from primary brain cell cultures were also examined. Cells were grown on poly-L-lysine coated 24-well culture plates with DME containing 10% fetal calf serum. After reaching confluence, the cells were incubated with 1 ml/well culture media as described above for 24 hrs, and NGF content in the culture media was measured. The results clearly show that hippo-campal astrocytes secrete NGF at the rate of 40-70 pg/24 hr/well (~ 4 x 10^5 cells per well). On the contrary, NGF levels in brain derived fibroblast conditioned medium were lower than the detection limit (10 pg/ml). The cultured hippo-campal astrocytes (1 x 10^5 cells/animal) were grafted into rat brains with unilateral fimbria fornix lesions, but astrocytes did not protect the medial septum cholinergic neurons from retrograde degeneration. We are presently investigating mechanisms for regulation of NGF secretion in primary astrocytes.

INTRACEREBROVENTRICULAR NGF INFUSIONS PREVENT RETROGRADE CHOLINERGIC NEURON DEGENERATION IN THE PRIMATE. M.H. Tuszynski, D.G. Amaral, H.-S. U, K. Yoshida, F.H. Gage. Depts. of Neurosciences and Neurosurgery, University of California-San Diego, La Jolla, California, 92037, and Salk Institute for Biological Studies, La Jolla, CA. 92037.

Cholinergic neurons of the adult rat basal forebrain undergo retrograde degeneration when deprived of target-derived nerve growth factor (NGF). Primate basal forebrain cholinergic neurons possess NGF receptors and may therefore also require NGF. To test this hypothesis, Macaca fascicularis monkeys underwent unilateral lesions of the fornix. Control animals received 4 week infusions of artificial CSF while experimental animals received mouse 2.5S ß-NGF, 180 ug/ml. All animals had complete unilateral interruption of the fornix as judged by extensive depletion of acteylcholinesterase and cholineacetyltranferase (ChAT) staining in the hippocampal formation ipsilateral to the lesion. Control animals had an average 50% loss of ChAT-immunoreactive (IR) neurons in the medial septal nucleus ipsilateral to the fornix lesion. Animals that received NGF had only a 24% ChAT-IR cell loss compared to the unlesioned contralateral side, and fewer of the remaining neurons were atrophic. NGF receptor-IR staining demonstrated similar changes. Thus, NGF treatment sustains some basal forebrain neurons that may otherwise undergo retrograde cell death. This may have implications for the treatment of neurodegenerative disorders characterized in part by cholinergic cell dysfunction, such as Alzheimer's disease.

STRESS DOWN REGULATES RAT BRAIN NGF RECEPTORS G. Taglialatela*, P.J. Foreman, M.T. Ramacci*, L. Angelucci* & J.R. Perez-Polo. SPON:(R. Stach) HBC&G Dept., Univ. of Texas Medical Branch, Galveston, TX, 77550.

The highest concentrations of nerve growth factor receptors (NGFR) in rodent brain are in basal forebrain area (BFA), hippocampus (H) and cortex (Cx,) all related to limbic function that regulates the stress response. To determine the effect of stress on NGF binding, we exposed rats to one hour of cold stress for five days. There was a 50% reduction in NGF binding in BFA, H, Cx but no significant change in cerebellum (Cb).

Decrements in NGF binding in aged rodent CNS can be ameliorated by acetyl-l-carnitine (ALC) (Angelucci et al, 1988). In ALC-treated rats, the stress induced reduction of NGF binding was abolished in H and Cx, but not in BFA. In unstressed ALC-treated rats there was a decline in NGF binding in H, but not in BFA, Cx or Cb. We are currently studying NGFR mRNA expression following stress exposure and ALC-treatment. Supported in part by NINDS, CNR & Sigma-Tau Co.

NERVE GROWTH FACTOR STIMULATES BASAL FOREBRAIN CHOLINERGIC NEURONAL DIFFERENTIATION IN TRISOMY 16 MICE. P. Corsi*, J.E. Sweeney and J.T. Coyle (SPON: M. Saltarelli) Depts. of Neuroscience and Psychiatry, The Johns Hopkins School of Medicine, Balto. MD 21205.

Since Down Syndrome (DS) results in Alzheimer's Disease (AD) pathology by the third decade, we have examined the differentiation of the basal forebrain cholinergic neurons (BFCN from mice with trisomy (Ts) of chromosome 16 (MMU16), a murine genetic model for DS. Basal forebrain dissected from 15 day gestational fetuses (Ts16 and euploid littermates) was disaggregated with papain and grown in MMEM containing 10% heat inactivated horse serum on polylysine coated multiwell plastic plates. Choline acetyltransferase (ChAT) immunoreactivity was visualized with antiserum, and its activity was measured enzymatically. After 10 days in culture, euploid BFCN exhibited extensive neurite extension whereas Ts16 BFCN had scanty perikaryal cytoplasm and sparse, short neurites. Exposure to β-nerve growth factor (NGF; 100 ng/ml) for 10 days resulted in a marked stimulation of neurite elaboration in the Ts16 BFCN but not in controls. Although, in the absence of NGF, ChAT was significantly lower in Ts16 cultures as compared to controls, NGF stimulated a greater increase of ChAT activity in Ts16 cultures. Preliminary results suggest that the increased NGF dependency of Ts16 BFCN persists in cells grown in completely defined medium. These findings indicate that BFCN from Ts16 may be more dependent upon NGF than those from littermate controls and suggest a mechanism of BFCN vulnerability in DS.

EXPRESSION OF NERVE GROWTH FACTOR RECEPTOR MESSENGER RNA IS DEVELOPMENTALLY REGULATED AND INCREASED AFTER AXOTOMY IN RAT SPINAL CORD MOTONEURONS. L. Olson[1], P. Ernfors*[2], A. Henschen*[1], M. Bygdeman*[3], C. Wetmore[1], M. Eriksdotter-Nilsson*[1], T. Ebendal*[4], H. Persson*[2]. Depts. of [1]Histology & Neurobiology and [2]Molecular Neurobiology, Karolinska Institute, S-104 01 Stockholm; [3]Dept. of Obst. & Gyn., Karolinska Hospital, S-104 01 Stockholm; [2]Biomedicum, Uppsala Univ., S-751 23 Uppsala, Sweden.

High levels of nerve growth factor receptor (NGF-R) mRNA in rat spinal cord motoneurons have been detected during the period of naturally occurring cell death (E13-14) with in situ hybridization and RNA-blot analysis. This expression is sustained, but reduced, during the time of synapse formation, and appears to be greatly reduced in the adult spinal cord. Comparably high hybridization of NGF-R mRNA was also found in human fetal anterior horn cells. Unilateral crush lesion of the adult rat sciatic nerve resulted in an 8-fold increase in NGF-R mRNA in spinal cord motoneurons 3 days after lesion compared to the non-lesioned side. Induction of NGF-R mRNA in spinal motoneurons was even more pronounced 7 and 14 days after the lesion, reaching levels 12 times higher on the lesioned side. However, 6 weeks after unilateral lesion, when the motor function of the leg was largely restored, the level of NGF-R mRNA decreased to a level similar to the unlesioned side. Studies in progress, including the administration of NGF or NGF-producing cell lines to the lesioned sciatic nerve, will further characterize the regulation of the NGF-R mRNA as well as the expression of NGF-R protein. We suggest that the NGF-R mediates a trophic or axonal guidance function for developing and regenerating spinal cord motoneurons.

286.19

SOMATOFUGAL AXONAL ATROPHY IN INTACT ADULT SENSORY NEURONS FOLLOWING INJECTION OF NERVE GROWTH FACTOR (NGF) ANTISERUM. S.F. Matheson*[1], B.G. Gold[1] and W.C. Mobley[2] (SPON: J. Falk). [1]Rutgers Univ. College of Pharmacy, Piscataway, NJ 08854 and [2]Dept. of Neurology, Univ. of California, San Francisco, CA 94143.

Induction of the neuronal perikaryal response to axonal injury appears to involve loss of a retrogradely transported trophic factor, perhaps originating in target tissue. Somatofugal axonal atrophy is a readily quantifiable component of the axon reaction. Recent studies have demonstrated that application of NGF to a proximal nerve stump reduces the degree of axonal atrophy in some sensory fibers in the dorsal root ganglia (DRG). In the present study, we asked whether NGF functions to regulate axonal caliber in intact adult neurons. Four week old rats were injected daily with antiserum to ß-NGF (0.5 ul/g body wt, for 11 days) in the footpad; age-matched controls were injected without antisera. Numbers of small and large neuronal perikarya in the L5 DRG demonstrating eccentric nuclei increased 2- and 3.6-fold, respectively, in rats given NGF antiserum. At this level, axonal calibers of sensory fibers were smaller and fibers less circular in shape compared to controls; motor fibers in the proximal L5 ventral root were unchanged. The results suggest that, in some sensory neurons, NGF regulates axonal caliber and that its loss initiates some features of the axon reaction. (Supported by NS 26265).

Fimbria-fornix transections influence NGF-receptor gene expression in the rat basal forebrain. J.E. Springer[1], M.E. Lewis[2], E. Robbins[2], S. Meyer[2],and F. Baldino, Jr.[2]. [1]Dept. of Neurology, Hahnemann Institute of Neuroscience, Philadelphia, PA 19102-1192, and [2]Cephalon Inc., 145 Brandywine Parkway, West Chester, PA 19380.

Several lines of evidence support the involvement of nerve growth factor (NGF) as a trophic substrate for basal forebrain cholinergic neurons in the central nervous system. However, the physiological events associated with the trophic effects of NGF are not well understood. It is known that the trophic actions of NGF are initiated by and require a receptor-coupling event. We have studied the effects of NGF removal on NGF receptor (NGFR) mRNA expression in a well defined cholinergic system, the rat septo-hippocampal pathway. Rats received a unilateral fimbria fornix transection (FXT) and were sacrificed 4 hr, 24 hr, 4 days, or 21 days following surgery. This process results in the loss and/or dysfunction of the majority of cholinergic neurons in the ipsilateral medial septal and vertical limb of the diagonal band (MS/VDB), and is presumably due to the loss of target-derived NGF. A NGFR cDNA (a gift from E. Shooter) was used to generate ^{35}S-labeled RNA probes for in situ hybridization histochemistry. Cells in the MS/VDB expressing NGFR mRNA were localized in a pattern similar to immunocytochemical studies using choline acetyltransferase and NGFR antibodies. In the ipsilateral MS/VDB, there was an apparent decrease in NGFR mRNA expression without cell loss at 4 hr following FXT. At all other times analyzed, the number of cells expressing the NGFR mRNA was significantly decreased. In addition, the level of NGFR mRNA expressed in the remaining cells in the ipsilateral MS/VDB was much less than the intact cells in the contralateral side. This observation could be due to a number of factors including; 1) remaining cells may have intact collaterals that transport NGF through a pathway not damaged by the transection, 2) remaining cells are able to acquire an alternate source of NGF, and 3) cells in the ipsilateral MS/VDB are not lost, but rather are functioning at some lower homeostatic level. Supported by the ADRDA and BRSG 1-S07RR07241-01.

287.1

DIRECT AND INDIRECT TROPHIC ACTIONS OF bFGF, EGF, TGF-a AND INSULIN ON RAT SEPTAL AND MESENCEPHALIC NEURONS IN CULTURE; LACK OF EFFECT OF GLIA DERIVED NEXIN. B. Knusel, P.P. Michel, C. Bakhit and F. Hefti (SPON: R. Clark), Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90089 and Genentech, Inc., South San Francisco, CA 94080.

This study is aimed at characterizing effects of various trophic factors in cultures of embryonic rat septum and mesencephalon. bFGF and insulin increased the activity of choline acetyltransferase (ChAT) in septal, and the uptake of dopamine (DA) in mesencephalic cultures. EGF and TGF-a failed to act on ChAT but stimulated DA uptake. Preventing cell proliferation by arabinoside-C (ara-C) did not affect the bFGF mediated ChAT increase in septal cultures, but abolished the stimulatory action of bFGF, EGF or TGF-a on DA uptake in mesencephalic cultures. The action of insulin in septal and mesencephalic cultures was only slightly reduced by ara-C. Glia derived nexin (GDN) failed to affect the appearance of our cultures and did not enhance biochemical activities in septal or mesencephalic cultures, and, therefore, is not a likely candidate to affect the development of cholinergic and dopaminergic neurons in the brain.

287.2

INSULIN-LIKE GROWTH FACTOR-I ENHANCES TYROSINE HYDROXYLASE ACTIVITY IN CULTURED BOVINE CHROMAFFIN CELLS. M. K. Dahmer and R. L. Perlman. Departments of Pharmacological Physiological Sciences and Pediatrics, The University of Chicago, Chicago, IL 60637.

We have previously reported that bovine chromaffin cells have receptors for insulin-like growth factor-I (IGF-I) and that IGF-I enhances secretagogue-stimulated Ca^{2+} uptake and catecholamine secretion in these cells. In this study we examined the effect of IGF-I on tyrosine hydroxylase activity in chromaffin cells. We cultured cells for 3 days in serum-free medium in the absence or presence of 10 nM IGF-I and then assayed tyrosine hydroxylase activity by measuring dopa synthesis in cells incubated in medium containing 0.1 mM tyrosine and 0.15 mM brocresine, a dopa decarboxylase inhibitor. Dopa synthesis was stimulated by incubating the cells in medium containing elevated K^+ (55 mM). High K^+-stimulated dopa synthesis was 30-150% higher in IGF-I treated cells than in untreated cells. This effect of IGF-I was time dependent, requiring at least 3 days to become maximal. High K^+-stimulated tyrosine hydroxylase activity was dependent on extracellular Ca^{2+} in both untreated and IGF-I treated cells. The enhanced high K^+-stimulated tyrosine hydroxylase activity in IGF-I treated cells may be explained, at least in part, by increased Ca^{2+} influx into the cells. (Supported by NIH grants HD-04583,HD-09402 and HL-29025 and NSF grant BNS-8820342.)

287.3

INSULIN-LIKE GROWTH FACTOR-I STIMULATES TYROSINE PHOSPHORYLATION IN BOVINE CHROMAFFIN CELLS. A.L. Cahill and R.L. Perlman Depts. of Pediatrics and Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637

Previous studies in our laboratory have shown that insulin-like growth factor-I (IGF-I) receptors are present on bovine chromaffin cells and that these receptors possess tyrosyl kinase activity against exogenous substrates (Dahmer, Li & Perlman, J. Neurochem. in press, 1989). In the present study we have used antiphosphotyrosine antibodies on Western blots to identify chromaffin cell proteins whose phosphotyrosine content is increased by acute treatment of the cells with IGF-I. Unstimulated chromaffin cells had three major phosphotyrosine containing proteins with approximate Mr's of 122, 71, and 35 kD. When chromaffin cells were treated with IGF-I the phosphotyrosine content of the 122 kD protein was increased and three additional phosphotyrosine containing proteins became apparent: a doublet of 183 and 167 kD, and a band at 96 kD. The 96 kD protein may be the ß-subunit of the IGF-I receptor which is known to be autophosphorylated on tyrosine residues. The effects of IGF-I were maximal at 10 nM and were rapid. Maximal effects of 10 nM IGF-I occurred within 1-2 min, but were detectable after as long as 60 min. (Supported by NIH grants HD04583 and HL29025.)

287.4

REGULATION OF TYROSINE PHOSPHORYLATION BY INSULIN AND IGF-I IN CULTURED FETAL NEURONS. K.A. Kenner* and K.A. Heidenreich Dept.of Medicine, UCSD, La Jolla, CA 92093

Tyrosine kinases are abundant in brain and thought to play a role in neuronal function, but little is known about their identity or regulation. In this study we examined the effects of various growth factors on tyrosine phosphorylation in cultured fetal chick neurons. Phosphotyrosine proteins were detected by immunoblot analysis using antisera against phosphotyrosine. Under basal conditions 3 separate antisera detected 5 major phosphoproteins (174 kDa, 139 kDa,115 kDa, 103 kDa, and 44 kDa) and 9 minor phosphoproteins (150 kDa, 128 kDa, 92 kDa, 87 kDa, 58 kDa, 51 kDa, 39 kDa, 37 kDa, and 35 kDa). Detection of the proteins was prevented by coincubation of the blots with antisera plus 2mM phosphotyrosine, but not by coincubation with 2mM phosphoserine or 2mM phosphothreonine. Insulin or IGF-I increased the phosphorylation of an 87 kDa membrane protein (tentatively identified as the beta-subunits of insulin and IGF-I receptors, respectively). Both peptides enhanced the phosphorylation of pp 87 within 30 sec and achieved maximal levels within 1 min of exposure. Phosphorylation was retained for 30 min (the maximum duration of exposure performed). Comparison of the dose-response curves for insulin and IGF-I suggest that each peptide stimulates autophosphorylation of its own receptor beta-subunit. The maximal response obtained with IGF-I was about 10x higher than that obtained with insulin (6 fold), consistent with the larger number of IGF-I receptors in these cells. EGF and NGF had no effect on neuronal tyrosine phosphorylation. These results demonstrate that both insulin and IGF-I receptors are active tyrosine kinases in fetal neurons and raise the possibility that the growth promoting effects of these peptides may depend on an activated receptor kinase.

COMPARATIVE EFFECTS OF CERTAIN NEURONAL LESIONS ON GROWTH FACTOR AND INTERLEUKIN-2 RECEPTORS IN RAT BRAIN. J.-G. Chabot, D.M. Araujo, P.A. Lapchak, L. Gewis and R. Quirion. Douglas Hospital Research Centre, Dept. of Psychiatry, McGill University, Montreal, Quebec, Canada.

Receptors for epidermal growth factor (EGF), insulin-like growth factor-I (IGF-I) and interleukin-2 (IL-2) have recently been demonstrated in the mammalian central nervous system (CNS). The fact that the expression of certain growth factors and lymphokines is increased after brain injury prompted us to examine the effect of various CNS lesions on EGF, IGF-I and IL-2 binding sites. Adult male albino rats were subjected to unilateral stereotaxic chemical lesions of either the striatum (kainic acid), hippocampus (kainic acid), and subtantia nigra (SN) (6-OHDA) or a mechanical lesion of the fimbria-fornix. 7 to 21 days after the surgery, brains were processed for *in vitro* receptor autoradiography as previously described. Under our incubation conditions, no significant modification in the density of [^{125}I]EGF binding sites was observed in any lesioned brain. An increase in the levels of [^{125}I]IGF-I binding was observed in the striatum and hippocampus after kainic acid lesion while no modification was observed in these areas after SN lesion and fimbriaectomy. The density of [^{125}I]IL-2 binding was also increased following a chemical lesion of the hippocampus. These results indicate that the expression of EGF, IGF-I and IL-2 binding sites are differentially modulated following the lesion of a given neuronal pathway. (Supported by MRCC and FRSQ, Canada).

EPIDERMAL GROWTH FACTOR IS NEUROTROPHIC IN RAT EMBRYO MESENCEPHALIC PRIMARY CULTURE. D. Casper, M. Blum and C. Mytilineou Fishberg Research Center in Neurobiology and Department of Neurology, Mount Sinai Medical Center, New York, NY 10029.

Epidermal growth factor (EGF), originally described to exert its effects on epithelial- and mesenchymal-derived tissue, has also been implicated as a neurotrophic factor. The presence of EGF-like immunoreactivity and EGF receptor in the basal ganglia have led us to examine the potential role of this factor on neurons of the midbrain, which receive afferent input from and project to these EGF-containing areas. Primary cultures of rat embryonic mesencephalon from several ages of gestation were established in a chemically defined medium. Cell survival, neuronal morphology and glial cell proliferation were monitored in the presence and absence of EGF by measuring cell number, DNA content, and using immunocytochemistry with neuronal- and glial-specific antibodies. EGF receptors were detected by ^{125}I-EGF binding. Neurotransmitter-specific high affinity uptake systems were measured by inhibitable uptake of radiolabelled dopamine (DA), GABA and serotonin (5-HT). Preliminary results indicate that EGF treatment (at 10ng/ml medium) has effects on both neuronal and glial populations, dependent on expression of the EGF receptors in the cultures. Over the course of the experiment (15 days), there was a 3-4 fold increase in the protein content of the EGF treated and control cultures respectively, suggestive of either cell division or morphological differentiation. GFAP and neurofilament immunocytochemistry demonstrated increases in the number of glia and neurons, indicating that EGF is a mitogen. DA uptake increased up to 10-fold in EGF-treated cultrues, whereas 5-HT uptake increased only 1.5 fold and changes in GABA uptake were only detected in younger embryos under certain conditions. Tyrosine hydroxylase immunohistochemistry indicated that the increase in DA uptake is due to quantitative and qualitative changes in dopaminergic neurons, i.e. increases in cell number and process outgrowth. These neurons however, comprise a small percent of neuronal elements in EGF-treated cultures, suggesting that the mitogenic properties of EGF are exerted either on a population of neuronal precursors not yet expressing markers of neurochemical diffferentiation, or on additional neurotransmitter-synthesizing systems.

INTACT SMOOTH MUSCLE PREPARATIONS SECRETE TROPHIC FACTORS THAT SUPPORT DISSOCIATED CILIARY NEURONS IN VITRO. L.A.F. Wentzek, C.W. Bowers, E.D. Oliva*, G. Pilar. Dept. Physiol. & Neurobiol., Univ. of Connecticut, Storrs, CT 06269.

The chick ciliary ganglion is divided into two neuron populations, one (choroid neurons) innervating smooth muscle and one (ciliary neurons) innervating striated muscle. Previous studies have established that during development the survival of both types of neurons depends on their target tissues. Although dissociated striated muscles secrete a factor that supports both neuron populations, and extracts of smooth muscle targets contain a factor (CNTF) that supports both neuron populations, attempts to demonstrate that such a factor is secreted from dissociated smooth muscle have failed (Creedon & Tuttle, J. Neurosci. 8: 3100 (1988)).

We demonstrate that when the normally uninnervated avian amnion (a smooth muscle-epithelial preparation) is cultured intact in a defined medium (N2), it secretes a factor that supports greater than 50% of the dissociated ciliary neurons for at least 5 days in defined N2 medium. When the normal target for choroid neurons (the choroid coat of the eye) is cultured intact, it too secretes a trophic factor for ciliary ganglion neurons. Studies are in progress to determine the maximum survival attainable with these secreted factors, their molecular identity, and the reasons for the apparent discrepancies between the trophic effects of intact and dissociated smooth muscle tissues.

BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF): CDNA CLONING AND SEQUENCING J. Leibrock (SPON: Y.-A. Barde). Dept. of Neurochemistry Max-Planck-Inst. 8033-Martinsried FRG

BDNF is a protein that has been purified from pig brain using its ability to support the survival of embryonic neurons in culture. It has been defined as a very rare (purification factor: several million-fold), basic (pI= 10.0) and small (MW=12,300 d) protein. Microsequencing of BDNF (F. Lottspeich, Martinsried) allowed the synthesis of oligonucleotides that were used to isolate cDNA clones. Sequencing of these clones revealed that BDNF is synthesized as a large precursor, pre-pro-BDNF, a protein that consists of 252 amino acids. Mature BDNF corresponds to the last 119 amino acids. The most striking result of the sequence analysis of BDNF is its distinct relatedness to the protein nerve growth factor (NGF). Southern blot analysis reveals that there is only one gene coding for BDNF. A mouse NGF probe used on the same blot reveals that the pig NGF gene is located on DNA fragments of different sizes. Thus, it appears that BNDF and NGF, 2 proteins allowing the survival of (for the most part) different embryonic neurons, are structurally related and coded by different genes.

NEURONAL SURVIVAL IS PROMOTED BY THE OPENING OF VOLTAGE-GATED SODIUM CHANNELS. F. Collins, J. D. Lile*, and D. J. Smith*, Synergen, Inc., 1885 33rd St., Boulder, Colorado 80301.

The survival of chick embryo ciliary, sympathetic, and sensory ganglia neurons by elevated extracellular potassium requires neuronal depolarization and the opening of L-type voltage-gated calcium channels (Soc. Neurosci. Abs. (1988) 14:368 and Collins and Lile (1989) Brain Res., in press). One would anticipate that other depolarizing agents would also promote neuronal survival by the same means. We have found that veratridine and batrachotoxin, which depolarize neurons by opening voltage-gated sodium channels, also promote survival of ciliary, sympathetic, and sensory ganglia neurons in vitro to approximately the same extent as elevated potassium or the protein neurotrophic factors NGF, bFGF, and CNTF. Neuronal survival promoted by veratridine or batrachotoxin is inhibited by tetrodotoxin, suggesting that these agents act by opening voltage-gated sodium channels. Elevated potassium, which depolarizes by another mechanism, is insensitive to inhibition by tetrodotoxin. Potassium-mediated neuronal survival depends on the opening of neuronal voltage-gated calcium channels: survival is strongly potentiated by voltage-gated calcium channel agonists, such as Bay K 8644, and strongly inhibited by calcium channel antagonists, such as nitrendipine, verapamil, and diltiazem. In striking contrast, these agents have little or no effect on neuronal survival promoted by veratridine or batrachotoxin. These results suggest that although the three depolarizing agents potassium, veratridine, and batrachotoxin all promote extensive neuronal survival, veratridine and batrachotoxin-mediated survival, unlike potassium-mediated survival, does not depend on the opening of voltage-gated calcium channels.

OLIGODENDROGLIAL SURVIVAL FACTOR FROM PRIMARY HEART CULTURE. A.L. Gard, G.E. Gonye* and S.E. Pfeiffer. Dept. of Microbiology, University of Connecticut School of Medicine, Farmington, CT 06032.

We have observed that ≥ 75% of OL progenitors bearing the O4 surface antigen die within 2-3 days when cultured in modified N2 medium (mN2) following their immunoselection from dissociated postnatal rat telencephalon (Gard, A.L. and Pfeiffer, S.E., *Development*, 106: in press). Working under the hypothesis that specific growth factors present in the developing brain are absent from this culture system, conditioned media from primary cultures of rat neural cell types (Type I astrocytes, cerebellar interneurons, meninges, brain macrophages), newborn skin, heart tissue and 3T3 cells were assayed for activity promoting survival and process regeneration of freshly isolated O4+ progenitors. Target cells were seeded at low density (1.5×10^4 cells cm^{-2}) as microcultures on a polyornithine substratum in mN2 containing 0.25% (v/v) heat-inactivated fetal calf serum and 5-50% (v/v) conditioned mN2 medium (CM). Dose-dependent survival was observed only in CM from dissociated newborn heart (HCM), which promoted up to 80% survival of seeded cells at 3 days in culture; the cells remained non-proliferative and 90% were O4+ by immunofluorescence. A substantially weaker effect (10-20% survival) occurred with 3T3 cell and brain macrophage CM. By 16 hr in culture HCM markedly stimulated process outgrowth from progenitor perikarya. HCM pre-treated with heat (100°C, 10 min) or trypsin did not facilitate process outgrowth or subsequent survival. To test for the specificty of HCM, neuron-enriched cultures were prepared from dissociated 7-8 day-old postnatal rat cerebella in mN2 ± 33%(v/v) HCM. Although >95% of the seeded cells died within 7 days in both treatment groups, a minor population of OL produced myelin-like membrane and was selectively spared in the HCM-treated cultures.

CHOLINERGIC DEVELOPMENT OF SPINAL MOTOR NEURONS BUT NOT SPINAL AUTONOMIC NEURONS IS REGULATED BY A FACTOR (MANS) ISOLATED FROM SPINAL CORD MEMBRANES. D. Lombard-Golly*, V. Wong and J.A. Kessler (SPON: K.Spiegel). Dept. of Neurology, Albert Einstein College of Medicine, Bronx, New York 10461.

Neurotransmitter expression is influenced by neuronal interactions with the cellular environment and particularly by contact between cells. We have been examining the effects of cell-cell contact on the development of 2 major populations of cholinergic neurons isolated from ventral (motor neuron enriched) and mediodorsal (autonomic neuron enriched) spinal cord (s.c.). In cultures of ventral s.c., levels of choline acetyltransferase (CAT), were stimulated by increased plating density. At all densities tested, CAT activity decreased during the first week *in vitro* and then increased over the subsequent three weeks. Our laboratory has partially purified a factor (MANS) from s.c. membranes which reproduces the effects of cell-cell contact on sympathetic neurons in culture (Wong and Kessler, 1987). Treatment of ventral s.c. cultures with MANS prevented the decrease in CAT activity normally observed during the first week. Further, MANS treatment resulted in elevation in CAT activity which persisted during the entire 4 week culture period. MANS treatment did not increase the number of cholinergic neurons visualized by CAT immunocytochemistry, suggesting that the factor increased CAT activity per neuron rather than increasing neuronal survival. CAT activity was regulated differently in the mediodorsal s.c. cultures. First, increased plating density did not elevate CAT activity. Second, MANS treatment resulted in only a small initial elevation in CAT activity which did not persist beyond the second week. Our observations suggest that different mechanisms regulate the development of cholinergic motor neurons and autonomic neurons in the s.c.. In motor neurons, cholinergic development is stimulated by cell-cell contact, and this stimulatory effect may be mediated by MANS.

SOMATOSTATIN EXPRESSION IN CULTURED CILIARY GANGLION NEURONS IS REGULATED BY TARGET DERIVED MACROMOLECULES. **J.N.Coulombe and R.Nishi, Dept. of Cell Biology and Anatomy, Oregon Health Sciences University, Portland, Oregon. 97201**

The avian ciliary ganglion contains two distinct populations of neurons: ciliary neurons which innervate the striated muscle of the iris and ciliary body; and choroid neurons which innervate vascular smooth muscle in the choroid layer of the eye. Although both types of neurons utilize acetylcholine as a neurotransmitter, only the choroid neurons employ the neuropeptide somatostatin as a co-transmitter. We previously found that induction and maintenance of somatostatin in cultured ciliary ganglion neurons (CGNs) depended upon the prescence of cells from the choroid layer. Moreover, somatostatin expression in these neurons was regulated independently of cholinergic differentiation. Here we report that the somatostatin stimulating activity (SSA) present in choroid cell cultures is also found when the choroid cells are lysed with water. This result indicates that SSA does not depend upon the neuron interacting with live target cells and suggests that SSA may be a membrane or matrix attached molecule(s). On the other hand, SSA is also released into the culture medium by choroid cells and can be concentrated by a filter which retains molecules greater than 10kD. In cultures of E8 CGNs, concentrated choroid cell conditioned medium can induce somatostatin expression in more than 75% of the neurons. Further biochemical characterization of SSA is in progress.

CONDITIONED MEDIUM FROM ACTIVATED SPLENOCYTES STIMULATES SUBSTANCE P (SP) IN SUPERIOR CERVICAL GANGLIA. G. M. Jonakait and S. Schotland*, Dept. of Biological Sciences, Rutgers University, Newark, N.J. 07102

Conditioned medium from con-A-stimulated rat splenocytes (Rat T-cell Polyclone, Collaborative Research; PC) causes a dramatic, dose-dependent increase in levels of SP in cultures of rat neonatal superior cervical ganglia (SCG). The effect is somewhat specific for SP since the activity of tyrosine hydroxylase, the rate-limiting enzyme in catecholamine biosynthesis, is unaffected. Antibodies to nerve growth factor (anti-NGF; from Dr. Michael Coughlin, McMaster University) do not alter the increase, suggesting 1) that PC can substitute for NGF and 2) that NGF is not involved in mediating the action of PC.

In order to begin to identify active molecule(s), we grew SCG cultures in rat interleukin-2 (IL-2) partially purified from PC. The purification involved ammonium sulfate fractionation and DEAE column chromatography (Collab. Res.). Concentrations equivalent to 5 U/ml of IL-2 mimicked a 5% solution of PC. Higher doses stimulated SP further. However, concentrations up to 20 U/ml of human recombinant IL-2 failed to mimic the effects of 5% PC. While IL-1a increased SP, even 20 U/ml did not mimic the effect of PC. Moreover, the inclusion of anti-NGF eliminated a significant proportion of the increase, suggesting an NGF requirement for IL-1a different from that seen with PC. Purified goat antibodies against IL-1a (a gift from Hoffmann-La Roche) actually increased the efficacy of PC slightly. Further characterizations are in progress.

287.14

ELUCIDATION OF THE PRIMARY STRUCTURE OF CILIARY NEUROTROPHIC FACTOR (CNTF). M. Sendtner*(Spon: H. Thoenen), Dept. of Neurochemistry, Max-Planck-Institute, D-8033 Planegg-Martinsried, FRG.

CNTF was originally characterized as a target-derived neurotrophic factor supporting the survival of chick ciliary ganglionic neurons in vitro. However, it showed a broad spectrum of additional activities including the survival of chick sensory and sympathetic neurons, the shifting of rat optic nerve O-2A progenitor cells towards type 2 astrocytes and inducing cholinergic properties in sympathetic neurons. In view of these diverse activities of CNTF it was mandatory to elucidate its structure in order to approach the physiological and possibly pathophysiological functions of CNTF. The initial steps of CNTF purification were performed according to Manthorpe et al. (Brain Res. 357, 282 (1986)) followed by further HPLC purification suitable for microsequencing after BrCN and tryptic cleavage. Antibodies raised against corresponding synthetic peptides precipitated both purified CNTF and CNTF-activity of crude tissue extracts. In Western blots of rat sciatic nerve and type I astrocytes a single band at the position of purified CNTF was stained. Nucleotide sequence information obtained from cDNA and genomic clones confirmed determined peptide sequences.

FIBROBLAST GROWTH FACTOR ENHANCES (^{3}H)NOREPINEPHRINE RELEASE AND EXPRESSION OF GAP-43 mRNA IN PC12 CELLS A. A. Lettes, B. Costello*, and J. A. Freeman, Dept. of Cell Biology, Vanderbilt University, Nashville, TN 37232.

In the presence of nerve growth factor (NGF), rat PC12 pheochromocytoma cells undergo differentiation which includes neurite extension and enhanced release of catecholamines by cholinergic agonists. Fibroblast growth factor (FGF) has been proposed to mimic the actions of NGF in PC12 cells. We compared the actions of NGF and FGF on (^{3}H)norepinephrine (NE) release, neurite extension, and induction of GAP-43 mRNA. GAP-43, a growth associated protein, has been proposed to be essential for axonal outgrowth during neuronal development and regeneration.

PC12 cells treated with either NGF or FGF (bovine pituitary) for 3 days released 2-3 fold greater amount of (^{3}H)NE compared to controls when stimulated with 0.5 mM carbachol. These cells were grown in 70% well conditioned medium which maximizes the efficacy of FGF. We failed to demonstrate an effect of FGF on neurite growth even after treatment for 7 days. The induction of GAP-43 message by FGF closely resembled that by NGF.

Our results suggest that (1) FGF can promote functional differentiation even under conditions which do not promote axonal growth, and (2) GAP-43 expression is not related to the extent of neurite growth but rather to the pharmacological differentiation of PC12 cells.

DEVELOPMENT OF TRANSFORMING GROWTH FACTOR ALPHA IMMUNOREACTIVITY IN RAT BRAIN. S.E. Loughlin, J.A. Noriega*, G. Lee* F.M. Leslie, C.M. Annis and J.H. Fallon, Depts. of Anatomy and Neurobiology and Pharmacology, University of California, Irvine CA 92717.

Transforming growth factor alpha (TGFa) is present in the adult rodent brain. Immunocytochemical techniques determined whether the appearance of this growth factor is correlated with developmental events in rat brain. Three antisera were used which were raised against defined sequences of the precursor, including TGFa 137-151,137-159, and 153-159. In adult brain, all three antisera produced similar patterns of staining in a subpopulation of glial fibrillary acidic protein (GFAP)-like immunoreactive (LI) astrocytes. In developing brain, TGFa-LI was also present in a subpopulation of glia. While many GFAP-LI profiles were present at postnatal day (PND) 0, TGFa-LI glia were restricted to dorsal medial septum. By PND 4, corpus callosum, deep cortex and hippocampus were stained. TGFA-LI was observed in cerebellum by PND 10. Even by PND 36, some regions did not exhibit the same number of TGFA-LI profiles as the adult brain, especially in cortex and striatum. The presence of large numbers of TGFa-LI glia in developing fiber tracts is consistent with a role in the development and maintenance of axonal connections. Since it is a neural mitogen, it is surprising that, at all ages studied, no TGFa-LI was observed in ventricular germinal zones. However, the presence of TGFa-LI in hippocampal and cerebellar germinal zones is consistent with a role in postmigrational mitogenesis. Studies on prenatal brains are currently in progress. Supported by NS 15321 and NS 19319.

287.17

THE DISTRIBUTION OF BASIC FIBROBLAST GROWTH FACTOR mRNA IN THE ADULT RAT BRAIN. A.M.Gonzalez*, N.Emoto*, P.Walicke+, S. Shimasaki* and A. Baird* Molecular and Cellular Growth Biology, The Whittier Institute, La Jolla, CA 92037. +Department of Neuroscience, University of California, San Diego, La Jolla, CA 92037.

The distribution of basic fibroblast growth factor (FGF) mRNA in the adult rat brain was studied by *in situ* hybridization, Northern blot analysis and immunohistochemistry. A single hybridizing mRNA of 6Kb length was clearly detected in the total RNA prepared from hypothalamus, cortex, hippocampus and pons. In contrast, a similar band was barely detectable in pituitary and cerebellum. A series of studies using cells in culture established that *in vitro*, the mRNA is expressed in astrocytes rather than neurons. However, *in situ* hybridization of the rat brain using an anti-sense cRNA probe for rat basic FGF identified a distinct population of neurons in the field CA1 and CA2 of hippocampus, indusium griseum, fasciola cinerea and medial (cingulate) cortex. Thus, there exist discrete loci of basic FGF synthesis in the adult rat brain. These results were supported by the immunolocalization of basic FGF using specific polyclonal antibodies. Basic FGF was localized in perikaria, axons and dendrites of several populations of cells in the hippocampus as well as in cells in the cortex and hypothalamus.

The results establish a wide distribution of basic FGF in the rat brain and suggest that basic FGF may play a particularly important role in the hippocampus.

287.18

IMMUNOLOGICAL LOCALIZATION AND CHARACTERIZATION OF BASIC FGF IN THE ADRENAL GLAND. C.Grothe*, R. Westermann*, and K. Unsicker (SPON: H. Reitböck). Dept. of Anatomy and Cell Biology, Univ. of Marburg, F.R.G:

FGF is a small heparin-binding multifunctional protein. Biological functions include angiogenesis and mitogenicity for many mesoterm-derived cells. In addition, a neurotrophic role of bFGF for several types of neuron has recently been established. Basic FGF has been purified from bovine adrenal gland. Using an antiserum against the full length bFGF we studied its precise distribution, cellular and subcellular localization as well as biochemical characterization in the bovine adrenal gland. Basic FGF-like immunoreactivity was found in the steroidogenic cells of the cortical zona glomerulosa and in the medullary chromaffin cells. Immunoelectron-microscopy revealed a vesicular localization of bFGF in chromaffin cells. Immunochemical analysis using bFGF-enriched fractions (ammoniumsulfate precipitation, anti-bFGF affinity chromatography) revealed the presence of the typical 16-18 KD bFGF band in adrenal extracts of cortex, medulla, and chromaffin cell vesicle content. In addition, immunoreactive material of higher molecular weight (24, 30-33, 46 KD) could be identified. In conclusion, bFGF is distributed in a cell type-specific pattern in the adrenal gland. The location of bFGF in chromaffin vesicles suggests release by exocytosis.

BASIC FGF AMELIORATES MORPHOLOGICAL AND CHEMICAL DEFICITS IN THE MPTP-MODEL OF PARKINSON'S DISEASE. D. Otto* and K. Unsicker. Dept. of Anatomy and Cell Biology, Univ. of Marburg, F.R.G.

Curative effects of adrenal chromaffin grafts to the Parkinson brain have been suspected to be due to the release of trophic material rather than dopamine. Our group has recently shown that bFGF which can act as a potent neurotrophic factor in vitro and in vivo, is contained in chromaffin cells. Consequently, we have investigated whether bFGF (4 µg), unilaterally administered in gel foam to the striatum of MPTP-treated C57-BL/6 mice, may promote morphological and chemical recovery. Treatment with MPTP (3 x 30 mg/kg on 3 consecutive days) caused an 80 % reduction of dopamine (DA) and virtually complete disappearance of TH-immunoreactive fibers after two weeks in both striata of mice carrying a cytochrome C implant in the right striatum. Replacing cyto C by bFGF led to the reappearance of TH-fibers on the ipsilateral side and diminished the reduction of DA to 55 % on the ipsilateral and 68 % on the contralateral side. Determinations of TH-activity and TH-immunoblotting suggested that bFGF nearly fully reversed the 50 % loss of TH-activity on either side, but restored TH-protein more on the ipsi- than on the contralateral side. Our results suggest that bFGF can mimic the beneficial effects of chromaffin cell grafts to the Parkinsonian brain.

287.20

BASIC FIBROBLAST GROWTH FACTOR PROMOTES THE OUTGROWTH OF FETAL DOPAMINERGIC CELLS TRANSPLANTED TO THE DENERVATED CAUDATE-PUTAMEN OF THE ADULT RAT. H.W.M. Steinbusch, R.J. Vermeulen*, and J.A.D.M. Tonnaer. Dept. Pharmacology, Free University, Amsterdam, The Netherlands.

Basic fibroblast growth factor (bFGF) has been identified as trophic factor for fetal CNS cells. It has shown in vitro a positive effect on the survival of fetal astrocytes and in vivo a preserving effect on damaged adult septal cells. The working mechanism of bFGF is possibly related to a heparin receptor. In our study we have transplanted fetal (E 15) dopaminergic cells to the rat caudate-putamen, which was 6-OHDA denervated 14 days prior to the implantation. The cell suspension was mixed either with bFGF, bFGF and heparin or vehicle. After a survival of 6 weeks the animals were processed for dopamine immunocyto-chemistry. In all three groups of rats dopaminergic transplants survived. bFGF alone has only a very limited positive effect on the outgrowth and number of surviving fetal dopaminergic cells. However, the combination of bFGF with heparin showed a nearly threefold increase in the density of the outgrowing dopaminergic fibers, as noticed semi-quantitatively. In addition the transplants were more extensive and contained more dopaminergic neurons. The outgrowth of these transplants seemed to be more diffuse and extend over a longer distance. These results demonstrate that bFGF in combination with heparin is likely a trophic factor for fetal dopaminergic neurons. (bFGF was supplied by Calbio, USA)

NEUROPEPTIDES AND BEHAVIOR

288.1

GALANIN FRAGMENTS RETAIN BIOLOGICAL ACTIVITY ON DELAYED ALTERNATION IN RATS. J.N.Crawley, T.A.Podruchny*, M.Austin, S.DeMesquita, B.Martin*, G.Fisone*[1], T.Bartfai*[1]. Unit on Behavioral Neuropharmacology, Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892, and [1]Department of Biochemistry, University of Stockholm, Stockholm, Sweden.

Galanin (GAL) is a 29-amino acid neuropeptide which coexists with acetylcholine (ACH) in medial septal neurons projecting to the ventral hippocampus of the rat (Melander et al, Brain Res. 360:130-138, 1985). GAL inhibits the release of ACH (Fisone et al, PNAS 84:7339-7343, 1987), inhibits carbachol-stimulated phosphatidyl inositol turnover (Palazzi et al, Europ. J. Pharmacol. 148:479-480, 1988), and inhibits the ability of ACH to improve working memory in rats with basal forebrain lesions (Mastropaolo et al, PNAS 85:9841-9845, 1988). To identify the minimum sequence of amino acids containing the biological activity of GAL in rat brain, fragments of GAL 1-29 were tested on the food-reinforced t-maze delayed alternation paradigm, in rats with ibotenic acid lesions of the nucleus basalis of Meynert-medial septal area. Sequences 1-16, 17-23, and 24-29 were enzymatically cleaved from GAL 1-29; sequences 12-29, 18-29, and 21-29 were prepared by solid phase synthesis. Behavioral scores after intraventricular microinjection with equimolar concentrations of each fragment, in combination with ACH, indicated that C-terminal fragments actively inhibited ACH on delayed alternation in lesioned rats. Short sequences of C-terminal amino acids may be sufficient to convey the biological activity of GAL, and may be useful substrates for modifications to confer galanin antagonist activity.

MALE-FEMALE DIFFERENCES IN GRF-INDUCED FEEDING. P.R. Dickson and F.J. Vaccarino, Dept. of Psychology, Univ Toronto, Ontario, Canada, M5S 1A1.

We have previously shown that intracerebroventricular (icv) injection of growth hormone releasing factor (GRF) increases food intake in male rats. In males, GRF interacts with somatostatin to release growth hormone in regular 3 hour pulses; this pattern does not hold for females. In order to examine the possibility that males and females also differ with regard to central GRF actions, females were tested for GRF-induced feeding.

Food (Purina Rat Chow) and water intake of female Wistar rats with cannula implants aimed at the lateral ventricles were measured for a 90 minute period on 5 consecutive days following 60 minutes exposure to fresh food. On subsequent days, consumption was measured for the 90 minutes following icv GRF treatment. Vaginal smears were taken following manipulations every day. The following doses were tested in random order: 0.0, 10.0, 20.0, and 40.0 pmoles. rhGRF was dissolved in a 0.01% ascorbic acid vehicle and administered in a 2.0 ul volume over 1 minute. 1 no-drug day separated drug tests.

GRF had no consistent effect on food or water intake in female rats. Further, there was no clear relationship between response to GRF and phase of estrus cycle. This can be taken as tentative evidence for a sex difference in GRF effects on food intake. It remains to be seen how sex steroids may influence the GRF effects on food intake in both male and female rats.

This research was supported by a NSERC grant to F.J.V.

STRUCTURE-ACTIVITY RELATIONSHIP OF BOMBESIN(BBS)-RELATED PEPTIDES AS EXAMINED BY BEHAVIORAL IN VIVO STUDY. A.Masui*, T.Itoshima*, K.Tsunashima* and N.Kato (SPON:K.Satoh) Dept.of Psychiatry, Shiga Univ.Med.Sci.,Otsu 520-21 and Musashi Hosp. N.C.N.P., Tokyo 187, Japan.

BBS, a tetradecapeptide originally isolated from amphibian skin, has potent biological effects such as hypothermia and excessive grooming. In the present study, the contents of immunoreactive gastrin-releasing peptide (IR-GRP) in rat central nervous system and the behavioral effects of icv administered BBS-related peptides were examined. IR-GRP was widely distributed, but not BBS, in discrete brain regions. BBS elicited intense and long-lasting scratching behavior in a dose-dependent manner. Naturally occurring peptides such as neuromedin B and GRP-10 seemed to be short-acting. Leu-phyllolitorin was as potent as BBS and acted for a longer period than Phe-phyllolitorin. DesTrp anlogues seemed to have no biological potencies and the preliminary study indicates that pretreatment with these peptides appeared to inhibit phyllolitorin-induced scratching behavior. The possibility of antagonizing action of desTrp analogues is currently examined in terms of other behavioral indexes and compared with the BBS antagonists recently reported.

288.4

MICROINFUSION OF BOMBESIN INTO THE PREOPTIC AREA PRODUCES HYPOTHERMIA IN INSULIN TREATED RATS. A.M. Babcock*, and C. Barton* (SPON: R.R. Yeoman). Dept. of Psychology, Univ. of South Alabama, Mobile, AL 36688.

Bombesin (BBS) produces hypothermia in food-deprived, but not food-sated rats at normal ambient temperatures (Calisher et al., Neuropharm. 21:1059, '82). The role of food deprivation in this response has not been evaluated. The present experiment examined the effects of BBS microinfusion into the preoptic area of the anterior hypothalamus (POA) on food intake and core body temperature (T_b) under conditions of food satiation, food deprivation (18hrs), and insulin pretreatment (Regular Iletin I, 10U/kg). Bombesin (50 ng/.25 µl) produced a significant fall in T_b for food-deprived and insulin treated rats. However, no hypothermia was observed in food-sated rats. Bombesin also significantly reduced feeding in food-deprived rats. Our findings suggest that the POA is a sensitive region for BBS-induced hypothermia in food-deprived rats and that factors associated with the fasting state are important in the production of this response.

CYSTEAMINE-INDUCED SOMATOSTATIN DEPLETION AND WORKING MEMORY DEFICITS IN RATS.

G.R. Sessions, E. Demetriades*, L.L. Leber* and G.F. Koob. Walter Reed Army Institute of Research, Washington, D.C. 20307, U.S. Air Force Academy, Colorado Springs, CO 80840 and Scripps Clinic & Research Foundation, La Jolla, CA 92037.

Recent research revealing somatostatin depletions in the brains of patients with Alzheimer's Disease has focused interest in the functional role of this neuropeptide in learning and memory *(Roberts, et al., Nature, 1985, 314:92)*. Cysteamine HCl has been shown to temporarily deplete brain somatostatin in rats when administered intraventricularly (ICV) *(Bakhit, et al., 1983, Reg. Peptides, 6:169)*, and has been used in an experimental model for the study of the functions of the peptide in the mediation of behavior. The present study investigated the effects of cysteamine-induced depletions of central somatostatin on performance of an eight arm radial maze memory task in rats.

Animals received four daily post-trial ICV injections of cysteamine (250 µg, N=9) or saline (N=6) following extensive training on the task, then their performance was followed as they recovered from the effects of drug treatments. The drug-injected animals showed a small decrement in Working Memory without impairment of Reference Memory, and only while they received the drug. The alterations and recovery in Working Memory demonstrated by the injected animals followed closely the known course of somatostatin depletion after ICV injections of this drug. The results suggest that somatostatin depletion may produce selective deficits in neural processes underlying Working Memory.

288.6

LOW DOSES OF CENTRALLY ADMINISTERED SOMATOSTATIN INCREASES FOOD INTAKE IN RATS.

D. Feifel and F.J. Vaccarino. Department of Psychology, University of Toronto, Toronto, Canada, M5S 1A1.

Peripherally administered somatostatin (SRIF) has been consistently reported to attenuate feeding. The literature on centrally administered SRIF, however, is equivocal with some investigators citing a facilitation and others an attenuation of feeding.

To clarify the central feeding effects, if any, of SRIF, male Wistar rats were injected with 0, 0.4, 4.0 and 40 picomole SRIF in a 2µl vehicle (0.01% ascorbic acid) solution. The injections were administered via a chronically implanted cannula aimed at the lateral ventricle.

One hour post-injection measurements indicated that food intake was significantly increased with 0.4 and 4.0 picomole doses of SRIF. None of the doses tested had an effect on 24 hour intake. As well, locomotor activity, as measured by photocell activity cages, was unaltered. These results indicate that, in contrast to its peripheral anorexic effects, SRIF, in low doses, may act centrally to potentiate feeding.

This research was supported by a NSERC grant to FJV.

EFFECTS OF NEUROMEDIN B-32, NEUROMEDIN B-10 AND BOMBESIN ON INGESTIVE AND GROOMING BEHAVIORS.

H. Piggins[1], D. Lafreniere[1] and Z. Merali[1,2]. (SPON: T. Miliaressis) [1]Psychology and [2]Pharmacology, Univ. of Ottawa, Ont. Canada, K1N 9A9.

The functional significance of neuromedin B-10 (NB-10) and Neuromedin B-32 (NB-32), the newly isolated mammalian peptides, remains to be elucidated. This study comparatively assessed the behavioral effects of centrally administered NB-10 (0.31-6.2 nmol), NB-32 (0.062-3.1 nmol) and the amphibian structural analogue bombesin (BN; 0.0062-3.1 nmol). Rats implanted with 3rd ventricular cannulae were entrained on a schedule of 20 hr water deprivation. Following peptide administration, wet mash test meal and water intake as well as grooming behaviors were monitored. BN dose-dependently suppressed food and water intake and elicited intense grooming. The order of potency was grooming > anoretic > antidipsogenic. The order of relative effectiveness (potency and efficacy) on all the end points was: BN > NB-32 > NB-10. As compared to BN, NB-32 was 5X less potent for grooming effects and 6-10X less potent in suppressing ingestive behaviors. NB-10 was an order of magnitude less potent than NB-32. Thus in mammals, NB-32 and NB-10 may play a role in central mechanisms of grooming and ingestive behaviors. (Supported by NSERC).

NEUROBEHAVIORAL EFFECTS OF CALCITONIN GENE-RELATED PEPTIDE.

F.B. Jolicoeur[1], J.N. Michaud[1], D. Ménard[1], A. Fournier[2] and S. St-Pierre[2]. [1]Depts of Psychiatry and Pharmacology, Fac. of Med., Univ. of Sherbrooke, Sherbrooke, Québec, Canada, J1H 5N4. [2] INRS, Blvd. Hymus, Pointe Claire, Québec H9R 1G6.

CGRP-like immunoreactivity and putative receptors for the peptide have been reported to be widely distributed in brain of several animal species, including man, suggesting that CGRP might be implicated in a variety of neurophysiological processes. The purpose of the present study was to examine the profile of the neurobehavioral effects of CGRP following central administration. More specifically, the effects of various doses (0.312 -20.0µg) of human CGRP injected into the lateral ventricle of rats on spontaneous activity, muscular tone, body temperature, nociception, food and water intakes, as well as its potential for inducing catalepsy, were examined. hCGRP produced significant increases in body temperature, decreases in activity, nociception and muscular tone, and induced a strong catalepsy in animals. Threshold doses for these effects were : 0.625, 0.625, 5.0, 20.0 and 0.625 µg, respectively. *Ad libitum* food and water intakes were not affected by the peptide but, starting at a dose of 5.0 µg, both were significantly decreased in 22 hr food deprived animals. In a first structure-activity study, we have found that the pre-injection of 10 µg of the C-terminal fragment CGRP(8-37) significantly inhibited the hypophagic and hypodipsic, but not the hyperthermic effects of the same dose of hCGRP. A comparison of our dose effect relationships and our initial structure-activity study suggest that a heterogeneity of hCGRP central receptors might underlie various neurobehavioral effects of the peptide.

LOCAL INFUSION OF TRH OR CGRP IN THE CENTRAL NUCLEUS OF THE AMYGDALA ENHANCES ACOUSTIC STARTLE.

C.B. Sananes, K.R. Melia*, M. Davis. Psychiatry Dept., Yale Univ. Med. Sch., 34 Park St., New Haven, CT 06508.

The central nucleus of the amygdala (ACE) has been shown to be critical for fear-potentiation of acoustic startle as well as the delayed increase in startle observed after footshock. Because ACE has high receptor densities for both Thyrotropin releasing hormone (TRH) and Calcitonin gene related peptide (CGRP) and because local infusion of these peptides in the ACE have been shown to produce behavioral responses similar to amygdala stimulation, the present study evaluated the effect of local infusion of TRH and CGRP in the ACE on the acoustic startle reflex.

All drugs were infused bilaterally in the ACE of freely moving rats. Acoustic startle was measured 15 min prior to infusion and for 90 min immediately following it. TRH (2, 4 or 7 µg /0.5 µl), the TRH analog RX77368 (.01, .02 or .04 µg / 0.5 µl) and CGRP (2 µg /0.5µl) were used. Startle was markedly increased following administration of 7 but not 2 or 4 µg of TRH. This increase did not appear until 30-40 min after injection of the drug. This delay is probably not due to diffusion of the drug to a distant site because intracerebroventricular infusion of 40 µg/10µl TRH had no effect on acoustic startle. Administration of .04 but not .01 or .02 µg of RX77368 markedly enhanced startle with a delay of 30-40 min. Preliminary data suggest that 2µg CGRP also facilitates startle with a similar delay.

The delayed enhancement of startle following administration of TRH or CGRP is similar to the delayed increase in startle seen following footshock. It is thus possible that TRH and/or CGRP are released into the amygdala following footshock. Activation of the amygdala may represent an unconditioned response to shock relevant to fear conditioning and TRH and CGRP may be the neurotransmitters necessary for this unconditioned effect.

THE EFFECT OF NEUROPEPTIDES IN ANIMAL MODELS FOR DEPRESSION INVOLVES DOPAMINE TRANSMISSION IN THE BRAIN.

F. Drago, F. Spadaro* and U. Scapagnini*. Inst. of Pharmacology, Univ. of Catania Medical Sch., Italy.

TRH and prolactin (PRL) stimulate various behaviors in the rat. In two animal models for depression, the despair test (DT) and the chronic unpredictable stress (CUS) procedure, TRH exerted "antidepressant" activity both after peripheral and icv administration, and potentiated the effect of desipramine in the DT. This effect was mimicked by the analogue RGH-2202, which is devoted of thyreotropic actions, but not by TSH, T3 or T4. The treatment with the D1 and D2 receptor antagonists, SCH23390 and sulpiride, inhibited the "antidepressant" effect of TRH. No change was found after prazosine or methysergide treatments.

Prolactin failed to exhibit a direct "antidepressant" effect in young rats but potentiated that of desipramine in the DT and CUS procedure. A clear effect, however, was found in old rats that show a spontaneous "depressive" actitude. Icv injection of rat PRL or endogenous hyperprolactinemia, as raised by pituitary homografts, were merely equipotent in this respect. Again, the block of dopamine receptors reduced this effect.

SIMILAR FEEDING RESPONSES FOLLOWING THE INTRAHYPOTHALAMIC INJECTION OF NEUROPEPTIDE Y (NPY) AND ITS HOMOLOGUES. T. Foley-Nelson, A. Balasubramaniam*, S. Sheriff*, J.E. Fischer* and W.T. Chance. Dept. of Surgery, University of Cincinnati Med. Ctr. and VAH, Cincinnati, Ohio 45267.

Although several peptides affect feeding, NPY appears to be the most potent enhancer of feeding yet described. To determine the generality of this feeding response, we assessed intake of rat chow for 1 hr following the injection into the paraventricular hypothalamic area of 2 μg NPY or the same dose of 3 NPY homologues found in fish pancreas: anglerfish peptide Y (aPY-NH_2), salmon pancreatic polypeptide (sPP) and daddy sculpin pancreatic polypeptide (dsPP). As a comparison, all rats (n=18) were tested initially for feeding following control injections (1 μl) of artificial CSF followed 60 min later by 2 μg norepinephrine (NE). The following week CSF injections were again given, with half of the rats being treated with NPY and the remaining rats receiving aPY-NH_2. Two days later, food intake was again assessed following the injection of sPP and dsPP counterbalanced across the previous treatments. As seen in the

CSF	NE	NPY	aPY-NH_2	sPP	dsPP
0.4±0.2	2.6±0.4	5.6±1.0*	6.2±0.6*	8.0±0.9*	8.6±1.1*

table, food intake following NPY was twice as great as that following NE (*$p<0.01$). Feeding to aPY-NH_2, sPP and dsPP was equipotent to NPY, suggesting a generality of feeding across these homologous peptides. The results show that homologous peptides are able to exhibit NPY-like feeding, possibly by interacting with NPY receptors in hypothalamus.

288.12

PERTUSSIS TOXIN INHIBITS NEUROPEPTIDE Y INDUCED FEEDING IN RATS. A. Balasubramaniam*, S. Sheriff*, T. Foley-Nelson, J.E. Fischer* and W.T. Chance. Dept. of Surgery, Univ. of Cincinnati Med. Ctr. and VAH, Cincinnati, OH 45267.

Neuropeptide Y (NPY) is one of the most potent stimulants of feeding behavior. Rats with 24 ga cannulae implanted into the paraventricular hypothalamic area (PVH) were used to investigate the mechanisms involved in the NPY-induced feeding. Consistent with previous reports, injection of NPY (2 μg in 1 μl of artificial CSF) into PVH significantly increased cumulative food intake over 1, 2 and 4 h periods. Injection of pertussis toxin (PT) (2 μg in 1 μl) had no immediate effect on basal or NPY-induced feeding. However, 4 days after PT injection, food intake following injection of NPY (2 μg) was reduced to control level and ad lib. feeding was decreased 18%. In vitro investigations revealed that isoproterenol-stimulated cAMP production in hypothalamus of control rats was inhibited by NPY. In PT-treated rats, however, no inhibition of cAMP production by NPY was observed.

Cumulative Food Intake (g ± SEM; *$p<0.01$ vs Control)

	Control	NPY	PT (Basal)	PT + NPY
1 h	1.9 ± 0.7	7.6 ± 0.7*	0.6 ± 0.5	0.8 ± 0.5
2 h	2.2 ± 0.7	9.8 ± 0.7*	0.6 ± 0.5	2.7 ± 1.1
4 h	2.4 ± 0.7	10.8 ± 0.7*	2.0 ± 0.7	2.5 ± 1.5

These results suggest that cAMP may mediate NPY-induced feeding and that a PT-sensitive G protein may be involved in this signal transduction.

288.13

BILATERAL ENUCLEATION CAUSES A DECREASE IN SUBSTANCE P IMMUNOREACTIVITY IN THE MATING BEHAVIOR PATHWAY OF THE MALE GOLDEN HAMSTER

J.M. Swann & N. Macchione*. Department of Biological Sciences, Rutgers, The State University, Newark, NJ 07102.

Mating behavior of the male Golden Hamster (*Mesocricetus auratus*) is mediated by three critical areas in the chemosensory pathway; Medial Nucleus of the Amygdala (M), Bed Nucleus of the Stria Terminalis (BNST), and the Medial Preoptic Area (MPOA). Neurons in these areas actively accumulate gonadal steroids. We have recently demonstrated that, 1) neurons in M, MPOA, and BNST display substance P immunoreactivity (SPIR), and 2) SPIR is decreased in castrated animals and restored with testosterone treatment. Mating behavior in the hamster is affected by photoperiod, therefore, we examined the effects of a short photoperiod on SPIR by bilateral enucleation.

Adult, male Golden Hamsters were either, 1) enucleated (n=6), 2) enucleated, castrated and treated with testosterone (n=6), 3) castrated and treated with testosterone (n=6), or 4) intact controls (n=6). After seven to ten weeks, each hamster was injected with colchicine into the lateral ventricle, and 48 hours later, perfused with 2% paraformaldehyde and 0.25% benzoquinone. Free floating sections (40μm) were processed for SPIR using the indirect method of Sternberger.

All groups showed similar SPIR in MPOA. Compared to intact controls, enucleated animals showed testicular regression and few, if any, SP containing neurons in BNST and M. Testosterone-treated castrates and testosterone-treated, enucleated castrates did not significantly differ from intacts for testicular regression or SP containing neurons in M and BNST. These results suggest that bilateral enucleation causes a decrease in SPIR in M and BNST that seems to be mediated by testosterone.

288.14

MOTIVATION AND ATTENTIONAL MEASURES FROM A TEMPERATURE REINFORCED CUED DISCRIMINATION TASK IN RATS. C.W. Simpson*, G.E. Regch* (SPON.: D. Justesen). Sch. Basic Life Sci., Univ. MO-KC, Kansas City, MO, 64108

Rats under cold stress are known to maintain core temperature physiologically and behaviorally. Rats were trained to a cued discrimination task for infra-red heat reinforcement (CD/IR) in a -4°C ambient temperature (Ta) environment. CD/IR was run in an interactive computer driven program that permitted the differential measurement of response parameters. To the best of the authors' knowledge this is the first report in which CD/IR has been used to show differential change in motivation and attention. The data show 1) discrimination of correct cues, 2) increased motivation at lowered colonic temperatures (Tc), and 3) PGE2-elicited increased attention shown by a decrease error rate. Discrimination of cues was shown by increases in % correct responding from a low point of 69% at the beginning of training to a final criterion of >85%. Rats trained to the 85% criterion showed consistent performance, ie. number, rates (bar press/min), and %, of responding between correct cue, inappropriate cue, and intertrial interval. Increased motivation was indicated by a comparable increase in all parameters when Tc was decreased below 38°C down to 30.5°C. Rats at Tc values of 26.5° to 30°C had a significant decrease in all parameters consistent with inability to perform in the task. Performance following injection of 1pg PGE2 into the MAHPOA showed 1) increased total, i.e. correct and incorrect, responding at Tc's <38°C and 2) a differential decrease of incorrect responding at Tc's >38° C. The data indicate that with the CD/IR paradim, motivation and attention were changed by central PGE2 microinjection. (Supported by USAFOSR-87-0297.)

NEUROPEPTIDES AND THE IMMUNE SYSTEM: PEPTIDERGIC NERVE FIBRES AND RECEPTOR BINDING SITES LOCALIZED IN THE BURSA OF FABRICIUS AND THYMUS. C.B. Lacey, V.S. Seybold, and R.P. Elde. Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

Several peptides have been implicated in the communication between the nervous and immune systems. In previous studies we have shown a sparse but generalized distribution of peptidergic innervation in the **bursa of Fabricius**, a dorsal diverticulum of the caudalmost portion of the GI tract, which is recognized as the site of B-cell development and differentiation in avian species. In the present study we noted numerous peptidergic nerve fibres in a region located close to the burso-cloacal duct. This area is believed to be functionally distinct and has been referred to as the diffusely infiltrated area (DIA). Vasoactive intestinal peptide (VIP)-, calcitonin gene related protein (CGRP)-, and substance P (SP)- immunoreactive (ir) fibres were localized in the DIA. Furthermore, VIP-ir cell bodies were observed within the outer smooth muscle surrounding the bursa, the DIA, and the burso-cloacal stalk. Immunoreactive nerve fibres were also demonstrated in both avian and mammalian **thymus**. VIP-, CGRP-, SP-, NPY-, and DβH- immunoreactive fibres were localized to blood vessels, interlobular connective tissue and the parenchyma of both thymic cortex and medulla in the rat and with less frequency in the chick.

In addition to peptidergic fibres, we have begun to investigate the presence of receptor binding sites in both lymphoid organs in the chick. *In vitro* autoradiographic localization of ^{125}I-VIP demonstrated specific binding associated with vascular elements in the interfollicular (bursa) and interlobular and trabecular (thymus) regions as well as in the DIA and the outer muscular layers of the bursa and the medullary regions of the thymus.

These results suggest that peptidergic nerve fibres and receptors may participate in the modulation of the immune response in lymphoid tissues responsible for the development of immunocompetency in both avian and mammalian species.

289.2

INNERVATION OF THE SPLEEN IN THE RAT: ABSENCE OF AFFERENT INNERVATION. D. M. Nance and J.Burns*. Dept. of Anatomy, Dalhousie University, Halifax, Nova Scotia, B3H 4H7, Can.

Catecholamine fibers in the spleen of the rat are believed to be an important source of modulation of the immune system. The presence of afferent feedback from the spleen has not been systematically investigated. We examined whether the spleen receives afferent innervation and assessed the sources of efferent innervation to the spleen. The tracers fluoro-gold (FGo), fast blue (FB), WGA-HRP and HRP were used. The effects of cutting the splenic nerve on labeling of ganglion cell bodies and on catecholamine fibers in the spleen were assessed. The results showed that the celiac-mesenteric plexus provides a major efferent input to the spleen. Also, thoracic sympathetic chain ganglia provide an additional efferent supply to the spleen. Cutting of the splenic nerve prevented labeling of cell bodies in the sympathetic ganglia and eliminated catecholamine fibers in the spleen. In terms of afferent labeling, the results with FGo indicated that there were no cell bodies labeled in any sensory ganglia following splenic injections. Injections of WGA-HRP and exposing the cut end of the splenic nerve to HRP substantiated the observations based upon FGo. In contrast, FB produced faintly labeled cell bodies in the dorsal root ganglia irrespective of their spinal levels and this was not eliminated by cutting the splenic nerve. FB produced false positive labeling of afferent cell bodies following splenic injections. Thus, the spleen receives virtually no afferent supply but rather, receives an extensive efferent innervation from both the celiac-mesenteric and sympathetic chain ganglia. The effects of nerve section indicate that all of the efferent fibers to the spleen travel in the splenic nerve. Supported by MRC of Canada.

INTERLEUKIN-1 IMMUNOREACTIVE NERVE FIBRES IN THE RAT BONE AND ADJOINING TISSUES. A. Bjurholm*, A. Kreicbergs*& M. Schultzberg, Dept. of Orthopaedic Surgery, Karolinska Hospital, Dept. of Pathology, Karolinska Institute, Huddinge Hospital, Stockholm , Sweden.

The 17kD protein interleukin-1 (IL-1) was isolated from human monocytes and recognized as an endogenous pyrogene and lymphocyte activating factor. Among a number of actions IL-1 has been implicated in the regulation of bone physiology and in the pathophysiology of rheumatoid arthritis. The present study was carried out to analyze the occurrence of IL-1 in intraosseal nerves, since IL-1 like immunoreactivity was previously demonstrated in nerves in many peripheral organs.Substance P-, CGRP-, NPY- and VIP-immunoreactive and noradrenergic nerves have previously been shown to occur in the rat femur and tibia. The rats were perfused with para-formaldehyde and picric acid, and the bones, freed from muscles, were demineralized for approximately 3 weeks in buffered ethylene-diaminotetraacetic acid (4%). Following soaking in 10% sucrose, the tissue was cut and processed for indirect immunohistochemistry using an antiserum raised against a synthetic peptide corresponding to the amino acid sequence 169-194 of the murine IL-1alpha precursor protein. IL-1 immunoreactive fibres were observed almost exclusively in connection to blood vessels. A few fibres were seen along periosteal blood vessels, but the majority of the IL-1 immunoreactive fibres occurred in the bone marrow of the epiphysis. The latter fibres were localized around blood vessels in the marrow, and sometimes in connection to the epiphyseal plate. The IL-1 immunoreactive fibres were more sparse in the diaphysis, and none could be seen in the bone or cartilage tissue itself. Blood vessels surrounded by IL-1 immunoreactive fibres could also be seen in the synovial membrane.

In conclusion, IL-1 immunoreactive nerve fibres were found in the rat femur, tibia and knee joint, predominantly around blood vessels, and were most numerous in the epiphysis. The importance of this source of IL-1 in normal bone physiology and in the pathophysiology of bone and joint disease remains to be elucidated. The distribution pattern was similar to that of NPY- and TH-positive fibres suggesting coexistence of the two proteins in noradrenergic fibres.

289.4

SUBSTANCE P (SP) AND CALCITONIN GENE-RELATED PEPTIDE (CGRP) INNERVATION OF THE RAT SPLEEN. D. Lorton, D.L. Bellinger, S.Y. Felten, and D.L. Felten. Department Neurobiology & Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

Numerous investigators have demonstrated measurable levels of SP in 1° and 2° immune organs, SP receptors on immune cells, and alteration in a variety of immune parameters following administration of SP agents. Further, CGRP is co-localized within SP nerve fibers in gut-associated lymphoid tissue and other peripheral organs. In the present study, we investigated the distribution of SP+ and CGRP+ nerve fibers in the spleen of adult male Fischer 344 rats with immunocytochemistry. SP+ varicose plexuses entered the spleen with the splenic artery in the hilar region. The fibers distributed mainly along trabecular systems and venous sinuses. A few fine fibers extended away from the trabeculae and venous sinuses into the outer zone of the periarteriolar lymphatic sheath (PALS). These fibers were associated with vascular plexuses in the marginal zone (MZ); a few varicose fibers extended into the parenchyma of the MZ. An occasional fiber wandered through the PALS in sites where T cells predominate. Numerous individual linear SP+ fibers were observed in the red pulp. Few, if any, SP+ profiles were associated with the capsule or the central arteriolar system of the white pulp.

CGRP+ profiles showed a similar density and pattern of distribution in the spleen. CGRP+ immunoreactivity was found in varicose fibers along trabeculae, venous sinuses, MZ, PALS, and red pulp. The similarity in the innervation of SP+ and CGRP+ fibers support the hypothesis that these peptides may be co-localized in the spleen. The presence of SP+ and CGRP+ immunoreactivity in discrete compartments of the spleen, coupled with the presence of SP receptors on lymphocytes and evidence for a modulatory role for SP in both cell-mediated and humoral immunity, suggest that neurally derived SP in the spleen may act as a neurotransmitter with immune cells as targets. Whether or not these SP+ and CGRP+ fibers are sensory axons remains to be demonstrated. (Supported by R37 MH4207, R01 NS25223, and N00014-84-K-0488 from ONR)

289.5

SUBSTANCE P (SP) INNERVATION OF THE RAT THYMUS. S.Y. Felten, D.L. Lorton, D.L. Felten. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Experimental evidence suggest that SP modulates both cellular and humoral immune responses through interactions with specific receptors on lymphocytes, and measurable levels of SP have been reported in both 1° and 2° immune organs. We undertook the present study to look for a possible neural source of SP in the thymus that could provide neuromodulator signals for such interactions in vivo in this organ. SP innervation of the thymus in adult male Sprague Dawley rats was examined using immunocytochemistry. SP+ immunoreactivity was present in fine varicose neural-like profiles localized in specific regions of the thymus. SP+ varicose fibers were associated with the septa of interlobular connective tissue, and appeared to be present in regions where high densities of mast cells were observed. From the interlobular septa, SP+ fibers were observed entering the thymic cortex, where immature thymocytes reside. In the medullary region, numerous tangles of fine delicate SP+ fibers which resembled sensory nerve endings were noted. We are undertaking double label studies to ascertain the cellular associations of these fibers. We do not yet know whether these SP+ fibers are sensory or autonomic: however, regardless of the source of these fibers, it is likely that they can release SP and make it available for interactions with lymphocytes or accessory cells possessing receptors for SP. If the SP+ nerve are sensory axons, then an additional role can be hypothesized for possible immune-neural signaling using primary sensory axons for communication into the CNS. (Supported by R37 MH 4207, R01 NS25223, and N00014-84-K-0488 from ONR)

289.6

EFFECTS OF AGE ON SUBSTANCE P (SP)+ NERVE FIBERS IN THE SPLEEN OF FISCHER 344 RATS. D.L. Bellinger, D. Lorton, S.Y. Felten, and D.L. Felten. Department of Neurobiology & Anatomy, University of Rochester, School of Medicine, Rochester, NY 14642.

Immunocytochemistry was used to demonstrate SP+ nerve fibers in the spleen of Fischer 344 rats at 3, 8, 12, 17, 21, and 27 months of age. In young adult rats, SP+ nerve fibers entered the spleen with the vasculature, and penetrated the parenchyma as vascular and trabecular plexuses. Within the spleen, SP+ nerve fibers were found in nerve bundles along the large venous sinuses, and extended from these sinuses along trabeculae. Varicose SP+ profiles exited the venous plexuses into the surrounding red pulp and were present abundantly in this compartment. SP+ fibers were not observed around the central artery of the white pulp; however, occasional varicose linear fibers were found in the periarteriolar lymphatic sheath. In addition, SP+ vascular plexuses and long linear fibers were present in the marginal zone.

With normal aging, no apparent loss in the density of SP innervation of the spleen was observed; however, the distribution of SP+ nerve fibers was altered. SP+ nerve fibers retained their compartmentation, but appeared to regress toward the hilar region of the spleen, the site of entry of these nerve fibers. By 17 months of age, a progressive gradient loss of SP+ nerve fibers was observed with increasing distance from the hilus, continiuing thoughout 27 months of age. The presence of SP-containing nerve fibers in the spleen, coupled with other reports of chemical measurements of SP, the presence of SP receptors on immunocytes, and functional studies demonstrating alterations in immune parameters to administered SP and denervation with capsaicin, suggest that SP may modulate the immune system through direct "hardwired" communication channels from the central nervous system. Age-associated regression and redistribution of SP+ nerve fibers resembles some aspects of age-related NA and NPY+ fiber changes, suggesting that degenerattive or compensatory mechanisms may contribute to gradual alterations in the microenvironment of the spleen that accompany loss of immune competence. Supported by R37 MH4207, R01 NS25223, and N00014-84-K-0488 from ONR.

289.7

AGE-RELATED ALTERATIONS IN THE DISTRIBUTION OF NEUROPEPTIDE Y (NPY)-POSITIVE NERVE FIBERS IN THE RAT SPLEEN. D.L. Felten, D.L. Bellinger, and S.Y. Felten. Department of Neurobiology & Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

With light microscopic immunocytochemistry (ICC), NPY+ nerve fibers distribute in the rat spleen with a pattern remarkable similar to that of noradrenergic (NA) sympathetic innervation (Olschowka etal. 1988, Soc. Neurosci. Abstr. 14: 1288). Preliminary studies indicate that NPY may co-localize within NA nerve fibers in the spleen. Recent studies from our laboratory have reported that NA innervation in the spleen declines with age (S. Felten etal., 1987 Neurobiol Aging 8: 159-165). In the present study, we investigated whether a similar decline in splenic innervation occurs with NPY+ terminals.

ICC was used to demonstrate age-related changes in NPY+ nerve fibers in the spleen of F344 rats at 3, 8, 12, 17, 21, and 27 months of age. In young adult rats, an abundance of NPY+ nerve fibers distributed to specific compartments of the spleen. NPY innervation resembled the distribution pattern of splenic NA nerve fibers, but appeared to be slightly more robust. NPY innervation of the spleen remained constant through 12 months of age. By 17 months of age, a decline in density of NPY+ nerve fibers was apparent, and continued to diminish through 27 months of age. The depletion of NPY+ nerve fibers occurred with the same general pattern and time course observed for NA innervation; however, the loss of NPY+ nerve fibers did not appear to be as severe. These findings suggest that NPY co-localizes within NA nerve fibers that distribute to the spleen of F344 rats, and also may be present in non-NA nerve fibers. Further, based on previous findings that NPY can potentiate NE responses in some vascular beds (Beckner and Farrar), we suggest that NPY may interact with NE on the surface of immune cell targets to possibly potentiate the NA signal. Age-related loss in NPY+ and NA nerve fibers in the rat spleen may play a role in the decline of immunocompetence that occurs with age, or may occur secondary to age-related change in the immune system. Support by R37 MH4207, R01 NS25223, and N00014-84-K-0488 from ONR.

289.8

NEUROPEPTIDE-Y INVOLVEMENT IN NEURAL-IMMUNE INTERACTIONS IN THE RAT SPLEEN. T.A. Romano, J.A. Olschowka, S.Y. Felten and D.L. Felten. Dept. of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

It has been demonstrated at the light microscopic (LM) and electron microscopic (EM) levels that noradrenergic nerve fibers in addition to innervating the splenic capsule, trabeculae, and vasculature, enter into specific immune compartments of the spleen, contacting specific lymphoid cells. In addition to norepinephrine (NE) containing nerve terminals, there is evidence demonstrating neuropeptide-Y (NPY) containing nerve fibers innervating immune compartments of the spleen, such as the periarteriolar lymphatic sheath where contacts with T lymphocytes are probable, and the marginal sinus where contacts with B lymphocytes or macrophages may occur.

Evidence from our laboratory suggests that NE and NPY are colocalized in the same nerve fibers in the rat spleen. Chemical sympathectomy induced by 6-hydroxydopamine injections in rats results in destruction of noradrenergic nerve terminals, and hence noradrenergic denervation of the spleen. Immunocytochemistry was performed to determine the presence of NE and NPY after chemical sympathectomy. Not only were NE containing nerves destroyed, but NPY-positive nerve fibers were no longer present after sympathetic denervation, suggesting possible colocalization of NE and NPY. Colocalization of NE and NPY is currently being investigated with double labeling immunocytochemistry at the LM and EM level. Furthermore, the localization of the NPY receptor in spleen is being investigated.

These results suggest that in addition to norepinephrine's role in modulating or regulating immune phenomena, NPY may have a direct effect on the immune cells of the spleen and other lymphoid organs, or alternatively may have an indirect effect on immune activity by modulating and regulating norepinephrine. Supported by PHS NS24761, RO1 NS25223 and N00014-84-K-0488 from ONR.

THE IMMUNE RESPONSE EVOKES CHANGES IN LUTEINIZING HORMONE-RELEASING HORMONE RECEPTORS. M.C. Morale*, V. Guarcello*, F. Raiti*, G. Palumbo* and B. Marchetti*. (SPON: C. Bard). Dept. of Pharmacology, School of Medicine, University of Catania, 95125 Italy.

Evidence for the existence of a bidirectional network between neuroendocrine and immune systems involving the hypothalamic-pituitary-gonadal-thymic axis, is well documented and recent evidence indicates that the hypothalamic neuropeptide luteinizing hormone-releasing hormone (LHRH), is involved in this circuitry. In the present study we have investigated whether the immune response can evoke changes in LHRH receptor (R) function both in immune and neuroendocrine cells. Groups of rats were then immunized with sheep red blood cells (10 x 10^6, i.p.) and boosted again 7 days later. Rats were killed at different time intervals and the number of plaque-forming cells was measured in the spleen. Present results show that the antigen challenge is accompanied by a marked increase in the number of LHRH-R within the thymus gland. Furthermore, significant changes in LHRH-R were observed in neuroendocrine cells, indicating a reciprocal modulation of immune and reproductive axes, with LHRH serving as channel of communication.

EXPRESSION OF INTERLEUKIN-1 AND I-ASSOCIATED ANTIGEN IN RAT BRAIN. J.M. Dopp and J.A. Olschowka. Depts. of Microbiology and Immunology, and of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

Microglial cells and astrocytes have been shown to secrete interleukin-1 (IL-1) in vitro when cultured with lipopolysaccharide (LPS) and/or gamma-interferon (IFNγ) (Giulian, et al., 1986, J. Exp. Med., 164). The purpose of the present experiment was to determine if LPS and/or IFNγ injected into the brain could attract and stimulate endogenous phagocytic cells.

Male Sprague-Dawley rats were anesthetized and given 100-250 nl microinjections of IFNγ (1 U/nl) , LPS (2 ng/nl), an IFNγ /LPS mixture, or 9% saline into caudate putamen or hippocampus. Two to four days later, rats were anesthetized and perfused with 4% paraformaldehyde (PF) (for light-microscopy), or 4% PF plus 2.5% acrolein (for electron-microscopy). Brains were removed, cut into 30-µm sections, and stained immunocytochemically for IL-1ß, major histocompatibility (MHC) class II I-associated (Ia) antigen, glial fibrillary acidic protein (GFAP), or MAC-1.

Light microscopy results indicated that IFNγ or LPS alone induced minimal IL-1ß or Ia expression, and that this expression was enhanced by physical injury to the cortex during surgery. In contrast, the IFNγ /LPS mixture induced pronounced expression of IL-1ß and Ia regardless of cortical injury. Cell morphology indicated that the stained cells were microglia or astrocytes. Collectively the results indicate that expression of IL-1ß and Ia by these cells during the initiation of an immune response parallels that seen in peripheral macrophages. Supported by PHS NS24761.

INTERLEUKIN 1β-LIKE IMMUNOREACTIVE INNERVATION IN THE HUMAN CENTRAL NERVOUS SYSTEM. C.D. Breder and C.B. Saper. Depts. of Pharm. & Physiol. Sci., Neurology and Comm. on Neurobiology, The University of Chicago, Chicago, IL 60637.

Interleukin-1β is a cytokine secreted by macrophages in response to infection. It is thought to mediate several components of the febrile response. We have used immunohistochemistry to examine the hypothesis that, like other peripheral hormones, neurons in the brain may use IL1β as a neuromodulator in the central control of the immune system. We stained sections through six human basal forebrains and brainstems with polyclonal antisera raised against recombinant human (rH)-IL1β. Staining with these antisera was blocked with rH-IL1β but not with rH-IL1α, nor was it affected by preincubation with several neuropeptides found in the hypothalamus. IL1β-like immunoreactive (-ir) cell bodies were mainly found in the hypothalamus in the arcuate nucleus and retrochiasmatic area. IL1β-ir fibers were widely distributed in the hypothalamus, including the paraventricular, dorsomedial, ventromedial and arcuate nuclei and the medial preoptic and lateral hypothalamic areas. IL1β-ir fibers were also prominent in the central nucleus of the amygdala, the bed nucleus of the stria terminalis, and in the midline thalamic nuclei. In the brainstem, IL1β-ir innervation was observed in the periaqueductal gray matter, the locus coeruleus, the parabrachial nucleus, and in the nucleus of the solitary tract, amongst the cell bodies of the A2 noradrenergic neurons. IL1β-ir innervation of the brainstem and basal forebrain may participate in autonomic, endocrine and behavioral responses that underlie the febrile response.

DIURNAL GLUCOCORTICOID RECEPTOR BINDING AND CORTISOL SECRETION IN POST-TRAUMATIC STRESS DISORDER. R. Yehuda,* M.T. Lowy, S.M. Southwick,* D. Shaffer, * and E.L. Giller. VAMC-Yale University, West Haven, CT 06516 and Case Western Reserve University, Cleveland, Ohio 44106.

A dysregulation of the HPA axis in chronic post-traumatic stress disorder (PTSD) is suggested by our previous work showing lower mean 24-hr urinary cortisol excretion in combat veterans with PTSD compared to other psychiatric patients and normal controls. To further characterize HPA abnormalities in PTSD, basal AM and PM plasma cortisol and lymphocyte glucocorticoid receptor (GR) concentrations were measured in 10 PTSD patients and 10 normal controls. Both groups showed the normal AM to PM decline in plasma cortisol. However, the decline was significantly steeper in the PTSD group. Patients started out with a 20% higher mean cortisol concentration at 8:00 AM which fell to 25% below controls by 4:00 PM. GR concentrations also decreased significantly from AM to PM in both groups. Paralleling the cortisol findings, PTSD patients showed a steeper decline in GR number from AM to PM. In this case, AM GR number was 65% higher ($p<.05$) and remained 15% higher by the PM in the PTSD group. GR number was also positively correlated with overall depression and anxiety (assessed by Hamilton scales) as well as with PTSD symptoms measured by the Figley. The results further support the notion of a dysregulation of the HPA axis in PTSD.
Supported by Veteran Administration funds.

Effects of photoperiod on brain glucocorticoid receptors and the stress response in the golden hamster (Mesocricetus auratus). L. Krey*, E. Ronchi*, R.L. Spencer, A. Danielsson, B. McEwen. The Rockefeller University, New York, NY 10021

Hippocampal and hypothalamic Type I glucocorticoid receptor levels increase when male golden hamsters are maintained in short daylengths. Receptors were quantified with ^{3}H-cortisol single point binding assay on tissues from acutely adrenalectomized intact and castrated T-replaced male hamsters exposed to a long-day (LD 14:10) or a short day (LD 10:14) photoperiod for 4-8 weeks. The increase in receptor binding was associated with an elevation in Type I receptor steady state mRNA levels as measured by in-situ hybridization with the recently characterized mineralocorticoid receptor cDNA (Arriza et al., Science 237:268,1987). These changes in receptor biosynthesis occured along with modifications of the stress response to 1min exposure to ether. Serum glucocorticoid levels, as measured by RIA, showed that short day hamsters recover more efficiently, since they "reset" serum corticosterone/cortisol secretion to basal values at 60min after stress. However, in hamsters exposed to long photoperiods serum cortisol levels were still increased at 60min. The changes in the secretory dynamics of the brain-adrenal axis and the increase in receptor biosynthesis may be of adaptative value in a photoperiodic species like the hamster, presumably to shut down metabolic rate during torpor and hibernation.

290.3

ONTOGENY OF MINERALCORTICOID (MR) AND GLUCOCORTICOID RECEPTOR (GR) GENE EXPRESSION IN THE RAT BRAIN J.A.M. van Eekelen*, M.C. Bohn# and E.R. de Kloet (SPON: Dr. H. Rigter) * Rudolf Magnus Institute, University of Utrecht, Vondellaan 6, 3521 GD Utrecht, The Netherlands; # Dep. of Neurobiol. and Anat., Univ. of Rochester, Rochester NY, USA.

The cellular localization of MR and GR-mRNA in the developing rat brain was studied by in situ hybridization. The 35S-labeled cRNA, as well as cDNA-probes, were transcribed from either a 513 bp cDNA fragment encoding for the rat brain MR or a 500 bp cDNA fragment encoding for the rat liver GR (courtesy of J.L. Arriza and K.R. Yamamoto resp.). At all ages (pnd 2-16), MR-mRNA was mainly restricted to and evenly distributed over the hippocampal CA1-4 cell fields, the dentate gyrus (DG) and the pyriform cortex, which is in agreement with radioligand binding to MR during ontogeny. Hybridization to GR-mRNA was distributed more widespread. Moreover, with maturation, the pattern of GR-gene expression in hippocampus and hypothalamus changed, parelleling the developmental pattern of GR-immunoreactivity in CA1-2 neurons, DG and specific hypothalamic nuclei (PVN; Van Eekelen et al., B.Res. 436, 120, 1987/J.Neurosc.Res. 21, 88, 1988; Rosenfeld et al., Dev.B.Res. 42, 119, 1988).

290.4

EFFECTS OF HIPPOCAMPAL TYPE 1 AND TYPE 2 GLUCOCORTICOID RECEPTOR ANTAGONISTS ON ACTH LEVELS IN THE PM. M. Bradbury* and M. Dallman* (SPON: J. LaVail) Dept. of Neuroscience, Univ. of California, San Francisco, CA 94143

The hippocampus contains high concentrations of both type 1 and type 2 glucocorticoid receptors (GCR). Their effects on the hypothalamic-pituitary-adrenal cortical (HPA) axis in the PM have not been examined directly. To address this question, 26 gauge cannulae containing either GCR antagonists or cholesterol as a control were implanted into the anterior portion of the the hippocampus in 250-300 gram male rats. All rats were adrenalectomized and given subcutaneous pellets delivering plasma corticosterone doses of 3 to 6 ug/dl. Animals with cholesterol implants had ACTH levels in the PM similar to those in animals with no head surgery. Implants containing RU 38486, a type 2 GCR antagonist, dramatically increased the ACTH levels in the PM. The type 1 GCR antagonist, RU 26752, had a similar, although weaker effect. Effective implants were those penetrating the CA1 layer of the hippocampus. Preliminary diffusion experiments suggest that the spread of the steroids is restricted to the area immediately surrounding the cannulae. The data demonstrate the limbic system is involved in or may initiate negative feedback control of the HPA axis at the peak of the system's circadian rhythm in a GC dependent manner.

290.5

CHRONIC BUT NOT ACUTE IMIPRAMINE ADMINISTRATION DECREASES HIPPOCAMPAL TYPE I AND II CORTICOSTEROID RECEPTORS. M.T. Lowy and H.Y. Meltzer, Department of Psychiatry, Case Western Reserve University, Cleveland, Ohio 44106.

Depression is associated with increased cortisol secretion and alterations in lymphocyte glucocorticoid receptor regulation. Antidepressants may normalize some of the cortisol abnormalities in depressed patients. The present study assessed the effect of chronic and acute administration of the antidepressant drug, imipramine, on type I (mineralocorticoid) and type II (glucocorticoid) corticosteroid receptors in the hippocampus as well as type II receptors in other tissues. Chronic administration of imipramine (10 mg/kg x 2 x 14 days) significantly decreased both type I and II hippocampal corticosteroid receptors. Chronic imipramine had no effect on type II receptors in other brain regions such as the frontal cortex, hypothalamus or striatum. Acute imipramine administration (10 mg/kg x 2 x 1 day) had no effect on type I or II hippocampal corticosteroid receptors. The imipramine-induced decrease in hippocampal corticosteroid receptors may serve to minimize the effects of elevated glucocorticoid levels.

290.6

AGE-RELATED CHANGES IN TYPE II GLUCOCORTICOID RECEPTOR mRNA LEVELS IN PITUITARY AND SELECTED BRAIN REGIONS IN THE RAT. A. Peiffer, N. Barden & M.J. Meaney. Ontogénèse et Génétique Moléculaires, Laval Univ. Hospital Research Ctr., Ste-Foy, Québec G1V 4G2 and Douglas Hospital Research Ctr., McGill Univ. Montreal, H4H 1R3, Canada.

We have measured type II glucocorticoid receptor (GCR) mRNA and GCR binding in pituitary and brain of the aging rat to determine whether changes in receptor binding with age are reflected in altered gene expression for the GCR mRNA. Anterior pituitary, hypothalamus, amygdala, hippocampus and frontal cortex were dissected from intact Long Evans rats 6, 12, or 24 months of age. Type II, GCR binding was measured using [^{3}H]RU 28362. Total RNA was isolated by the guanidium isothiocyanate method and purified on CsCl gradients followed by phenol/chloroform extraction. Northern blots were hybridized with [^{32}P]-labelled Riboprobe corresponding to a 2.2Kb fragment of GCR mRNA, quantified by densitometry, and the data expressed as a ratio of ß-actin mRNA.

By 24 months there was a highly significant (40-50%) decrease in Bmax for [^{3}H] RU 28362 binding and a moderate (20-30%) decrease as early as 12 months in hippocampus. No other region examined showed any significant variation in [^{3}H] RU 28362 binding with age. Type II GCR mRNA was significantly elevated in all the regions at 12 months of age. At 24 months of age, GCR mRNA levels decreased in most regions and were not different from levels in 6 month-old animals. In the hippocampus, type II GCR mRNA levels also increased at 12 months of age, but, at 24 months of age and consistent with [^{3}H] RU 28362 binding, GCR mRNA levels were significantly decreased (40% and 74%, respectively) in comparison to both 6- and 12-month old animals.

In hippocampus, the loss of type II GCRs may involve a multi-step process, with compensatory increases in receptor mRNA levels at 12 months of age and decreases in both the receptor and its mRNA by the 24th month of life.

ESTROGEN MEDIATES SEX DIFFERENCES IN ADRENAL CORTICAL RESPONSES TO STRESS. A.A. Granberry*, B.N. Bunnell, E.H. Mougey and J.L. Meyerhoff. Dept. Psychology, Univ. GA, Athens, GA 30602 and Dept. Medical Neurosciences, Walter Reed Army Inst. Research, Washington, DC 20307

Several reports have indicated that corticosterone (CS) levels are higher in female than in male rats subjected to stress. To begin an examination of the role of estrogen in mediating such differences, we compared plasma CS and ACTH in males and females following acute exposure to stress. The subjects were 18 intact males, 18 intact females tested on their proestrous day, 18 ovariectomized (OVEX) females given 50µg estradiol benzoate in oil for 5 days before stress and 18 OVEX females that received only oil. Six rats in each treatment received 15 min of intermittent tailshock while they were restrained in small shock chambers, 6 were restrained but not shocked and 6 were home cage controls.

CS values were consistently higher in females than males across hormone treatments and stressor conditions. Females receiving tailshock did not differ as a function of hormone treatment, but under restraint stress, OVEX rats given estradiol were significantly higher than OVEX rats given oil. Restrained, intact females were intermediate. ACTH was highly variable, suggesting the presence of a complex interaction between stressor quality and hormone condition. We conclude that estrogen modulates the CS response to stress, possibly by acting directly on the adrenal cortex.

SEX DIFFERENCE IN TYPE I CORTICOID RECEPTORS IN RAT HYPOTHALAMUS. B.B. Turner and M.S. Ansari*. Dept. of Physiology, College of Medicine, East Tenn. State Univ., Johnson City, TN 37614.

We previously reported a sex difference in receptor affinity and number of the Type I corticoid receptor in rat hippocampus (Neurosci. Abstr. 14:443, 1988) and estrogen down-regulation of glucocorticoid receptor number in pituitary (Endocr. Soc. Abstr. 269, 1988). In the hippocampus, tissue from males exhibits greater affinity and receptor number. Here we ask whether a sex difference also exists in the hypothalamus with respect to affinity and receptor number.

In saturation plots with 3H-RU 28362 and 3H-DEX, males had greater affinity for the Type I receptor (0.70 $\pm$ 0.11 nM vs. 1.79 $\pm$ 0.24 nM), but the difference in receptor number was not significant; no sex differences were found in the binding of the Type II receptor. A series of single point studies also failed to demonstrate that the somewhat greater number of the Type I and Type II receptors found in males was significant. However, in vivo nuclear retention studies of 3H-corticosterone support the existence of functional differences in the occupation of Type I receptor system; at low dose (3 nmol/kg), but not at high dose (67 nmol/kg), retention of radioactivity was greater in males (3.26 $\pm$ 0.78 vs. 1.06 $\pm$ 0.37 nmols/mg protein, $p < 0.05$). These results suggest that in the female hypothalamus, they Type I system has less affinity than the male, and hence may not be fully occupied at all times. Supported by NIH grant NS-22158.

PRESENCE OF 11B-HYDROXYSTEROID DEHYDROGENASE IN THE HIPPOCAMPUS OF THE RAT. R.R. Sakai*, V. Lakshmi*, C. Monder*and B. S. McEwen. (SPON. L.J. Stein) Rockefeller Univ., Lab of Neuroendocrinology and The Population Council. New York, NY. 10021.

Corticosteroids circulate at levels 10^3-fold greater than aldosterone. Although they may cause local displacement of aldosterone from mineralocorticoid (type I) receptors, they do not do so in all tissues because 11B-hydroxysteroid dehydrogenase (11-DH) oxidizes cortisol (F) and corticosterone (B) to biologically inert 11-oxo metabolites which cannot compete with aldosterone for its receptor. We determined if this mechanism, which has been described in the kidney, applies to brain. Immunocytochemical analysis in adult brains showed 11-DH positive cells which correlated with the distribution of type I receptors. Highest 11-DH was found in hippocampus; lower levels were detected in other regions. The results were corroborated by enzyme activity using B as substrate in rat brain. No activity was found with F. These observations suggest a mechanism for specific aldosterone effects on brain physiology and behavior. Supported by grants DK 37094, MH 43787 and NS 08537.

CHARACTERIZATION OF GLUCOCORTICOID-INDUCED DECREASE IN GLUCOSE TRANSPORT IN FETAL RAT GLIAL CULTURES. H. Horner, C. Virgin*, R. Sapolsky. Dept. Biol. Sci. Stanford Univ., Stanford, CA 94305

Glucocorticoids (GCs), the adrenal steroids secreted during stress, impair the capacity of hippocampal neurons to survive hypoxia-ischemia, seizure and hypoglycemia. The cause of this effect is not known, but appears to involve energetic disruption, since the endangering effects of GCs can be reversed by supplementing the hippocampus with various energy substrates. As a possible mechanism, GCs inhibit glucose transport (GT) in peripheral tissues; we have found that GCs decrease GT in mixed cultures of neurons and glia from fetal rat hippocampus. In this study, we characterize a GC-induced inhibition of GT in hippocampal glia, since energy-dependent glial function (uptake of excitatory amino acids, of protons, etc.) can modulate neuronal function during neurological crises.

Hippocampi from Day-18 fetuses were dissected and dispersed. Cells were grown in flasks without poly-D-lysine pre-coating, and plated onto 48-well cluster dishes at 3 weeks of age; under such conditions, cultures are < 5% neuronal, as determined immunocytochemically. The specific transport of 14C-2-deoxyglucose was assessed 3 minutes after incubation with the sugar. 24-hour pretreatment with either corticosterone (CORT) or dexamethasone inhibited GT. Minimal effective doses were 1 uM and 10 nM, respectively, and maximal inhibition was approximately 15% ($p < .005$ in both cases). A minimum of 4 hours of steroid incubation was needed for the effect. Neither testosterone nor progesterone (1 uM, 24 hrs) were effective, whereas an equivalent treatment with estrogen caused a 15% increase ($p < .005$) on GT. CORT had no effect on GT in cultured glia from cortex or cerebellum, but caused a 40% ($p < .001$) inhibition in hypothalamus. The functional consequences of GT inhibition of these magnitudes in hippocampal and hypothalamic glia are under study. Supported by NIH RO1 AG06633.

SEROTONIN (5-HT) INCREASES GLUCOCORTICOID, TYPE II RECEPTOR BINDING CAPACITY IN CULTURED HIPPOCAMPAL CELLS. J.B. Mitchell, W. Rowe*, and M.J. Meaney. Douglas Hospital Research Center, McGill University, Montreal, Quebec, CANADA, H4H 1R3.

The hippocampus has been well established as a principle target region for the adrenal glucocorticoids (GCs), and corticoid activity at this site serves both neuroendocrine and behavioral functions. Thus, GC receptor regulation within the hippocampus is of considerable interest. In the work presented here, we have described the potent effects of serotonin (5-HT) on GC receptor binding in dispersed hippocampal cell cultures.

Primary cultures of dispersed hippocampal neurons from fetal (f19) rats were established and type II, GC receptor binding measured using [3H]RU 28362 as radioligand. Type II, GC receptor binding in hippocampal cells was dramatically increased (~ 190%) by nanomolar concentrations of 5-HT (ED50 = 4.3 nM). The effect of 10 nM 5-HT on type II, GC receptor binding was completely blocked by the 5-HT2 antagonists ketanserin and mianserin, and partially mimicked by the 5-HT2 agonist, ±DOI ((±)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane). There was no effect of agonists or antagonists of the 5-HT1 and 5-HT3 binding sites.

The change in type II, GC receptor binding required 4 days of exposure to 10 nM 5-HT, indicating that the effect probably involves regulation of protein synthesis. Interestingly, changes in type II, GC receptor binding persisted 1 week following the removal of 5-HT, with no decrease in the magnitude of the effect. Preliminary data also suggest that the effect of 5-HT is selective for the type II, GC receptor binding site, since [3H]aldosterone, a ligand for the type I, mineralocorticoid-like receptor, was not affected by similar exposure to 5-HT.

These data suggest that variations in 5-HT activity might influence type II, GC receptor binding in the hippocampus and that this effect involves, at least in part, 5-HT2 receptor sites. The temporal characteristics of this effect indicate that 5-HT might be involved in the induction of type II, GC receptors during early periods of postnatal development.

290.12

GLUCOCORTICOID RECEPTOR(GR) EXPRESSION IN PRIMARY HIPPOCAMPAL NEURONAL CULTURES. G. Bing, U. Vielkind*, and M.C. Bohn. Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642.

Hippocampus is a major target tissue for glucocorticoid action in the central nervous system. The actions of glucocorticoids are mediated by binding to specific intracellular receptors. Previous studies have demonstrated high levels of GR and GR mRNA in the rat hippocampus *in vivo*. The present study was undertaken to determine whether glucocorticoid receptors are expressed in rat hippocampal neurons grown in serum-free, and defined conditions.

Hippocampus from embryonic day 18-19 rat were dissociated, cultured in modified MEM plus 10% horse serum for 4 hrs. and then, grown in serum-free medium for 7 days. Various serum-free media were used including medium conditioned by C6 glioma cells or astrocytes from hippocampus or cerebrum. Defined media were modified MEM-N1 and DMEM-F12-N1. Neurons survived well in glia-conditioned media, and in modified MEM-N1, but most neurons died in DMEM-F12-N1. Immunocytochemistry using a monoclonal antibody against the rat liver GR, combined with an antibody against neuron specific enolase (NSE), demonstrated the presence of GR in the majority of pyramidal shaped neurons. GR immunoreactivity was predominantly nuclear, although light cytoplasmic staining was observed. This primary hippocampal neuronal culture serves as an excellent system to study GR regulation at the cellular and molecular levels.

Supported by NIH grant NS20832.

GLIAL CELLS EXPRESS GLUCOCORTICOID RECEPTORS. U. Vielkind[1*], A. Walencewicz[2*], J. M.Levine[2] and M.C. Bohn[1]. [1]Dept. of Neurobiology and Anatomy, Univ. of Rochester Medical Center, Rochester, N.Y. and [2] Dept. of Neurobiology and Behavior, State Univ. of New York, Stony Brook, N.Y.

The effects of glucocorticoids on gene expression are mediated via cytoplasmic glucocorticoid receptors (GR) which are translocated to the nucleus in the presence of steroid. In the nervous system, glucocorticoids are known to be involved in the regulation of neuropeptide and neurotransmitter-related genes, and presence of GRs has been demonstrated in neurons and adrenal chromaffin cells. Glucocorticoids also affect gliogenesis and regulate the expression of glial-specific enzymes. To determine whether specific types of glial cells express GRs, mixed glial cultures from rat cerebrum and cerebellum, as well as purified astrocytes and oligodendrocytes, were stained with a monoclonal antibody raised against the rat liver GR and double stained for glial-specific markers.

Astrocytes, both Type 1 and 2, contained GR-immunoreactivity (IR). Distinct granular staining was observed in the nucleus in the presence of dexamethasone, while light staining was observed in both the nucleus and cytoplasm in the absence of steroid. Nuclear GR-IR was also observed in oligodendrocyte nuclei, however the staining was less intense than in astrocytes. Glial cell lines, C6 glioma and JScl1 Schwannoma, also had GR-IR in nuclei. These studies demonstrate that all classes of glial cells express GRs which can translocate to the nucleus, suggesting that glia are a major target for glucocorticoid action in the nervous system.

Supported by NIH grants NS20832, NS21198 and the Medical Research Council of Canada.

IN VITRO BINDING OF ^{3}H-ALDOSTERONE IN BRAIN SECTIONS. B.G. Yongue, H. Coirini, & B.S. McEwen, N.Y.S. Psychiatric Inst., Columbia Univ., & Rockefeller Univ. New York, 10032

Receptor autoradiography provides anatomical resolution and precise binding localization. Type I corticosteroid receptors have been labelled in vitro, in slide mounted brain sections, using ^{3}H-corticosterone (CORT; Sarrieu, et al, 1985). However, the determinants of type I receptor specificity for either endogenous ligand, aldosterone (ALD) or CORT, are not clear. Hence, the need to develop brain ALD autoradiography. Sections (12um) of a tissue mash of hippocampus from 3-day-ADX rats were incubated (room temp) in 50mM TRIS pH 7.4 buffer containing 2mM EGTA, 6mM molybdate, 5mM ATP, 10mM dithiothreitol, 5% glycerol, and 0.5uM RU28362. Non-specific was assessed using 2.5uM cold CORT. Different washing conditions were tested by varying either buffers or the number and duration of the washes. Specific binding was reduced by inclusion of DTT or ATP and also by more than two washes or more than 6 min total wash duration. Two three-min washes with TEM buffer provided the best ratio total/non-specific binding. Highest specific binding was found at 30 to 60 min of incubation. Concentrations of ^{3}H-ALD from 0.2-10nM produced binding saturation between 2.5 and 10nM, with a K_d=1.2nM estimated by Scatchard analysis. This technique may provide insights into differential regulation of ^{3}H-ALD binding to type I receptors by ALD and CORT as previously found in this lab, using cytosolic assays of tissue punches (Coirini, 1988, SN Abst, 528.15). THE ORGANUM VASCULOSUM LAMINAE TERMINALIS (OVLT) IS CRITICAL FOR FEVER INDUCED IN GUINEA PIGS BY BLOOD-BORNE CYTOKINES. C.M. Blatteis, N. Quan, and R.D. Howell.* Dept. of Physiol. Biophys., Univ. of Tenn., Memphis, TN 38163.

The peripheral injection of various cytokines produces fever, a centrally mediated effect. We have suggested previously that the OVLT may be a site where cytokines could interact with the brain, because its electrolytic ablation prevents the febrile response to ip-injected lipopolysaccharide (LPS). We report now that such a lesion also attenuates the fevers produced by iv-injected LPS (2 ug/kg), recombinant human interleukin-1β (IL1, 100 ng/kg), tumor necrosis factor-α (TNF, 20 ug/kg), and interferonα_2 (IFN, 1x10^7 U/kg). IL1 and IFN evoked unimodal fevers in intact animals but no response in lesioned animals 11 d post-op. LPS and TNF caused bimodal febrile rises before lesion; after lesion, the first rise was unchanged, but the second was suppressed. These data suggest that the first peak of LPS fever may be mediated by TNF and the second by IL1/IFN, but the integrity of the OVLT is pivotal for the full febrile response to circulating pyrogens. EFFECTS OF MICROIONTOPHORETICALLY APPLIED INTERLEUKIN-1 AND NOREPINEPHERINE ON SINGLE UNIT ACTIVITY RECORDED FROM THE RAT HYPOTHALAMUS IN VIVO. W. McVaugh* and N. Dafny. Dept Neurobiology and Anatomy, Univ. Texas Med. Sch. at Houston, TX 77225.

Interleukin-1 (IL-1), in addition to its role as a regulator of immune function, has been implicated in the modulation of neuroendocrine processes. The present study was designed to explore the effects of iontophoretically applied IL-1 on the electrical activity of single neurons recorded from the anterior hypothalamus/periventricular area in the anesthetized rat. Male Sprague Dawley rats (280-320g) were anesthetized with urethane (1.2g/kg bw ip) and placed in a stereotaxic instrument. The skull was bared, a 5mm hole drilled in the cranium and the dura reflected. IL-1 and norepinepherine (NE) were iontophoresed onto individual neurons in the hypothalamus by means of a multibarrel micropipette assembly with a recording microelectrode attached. Neuronal activity was measured as spikes per unit time. Preliminary results indicate that the percentage of neurons responding to IL-1 with a change from baseline activity increased with dose (44, 50 and 70%, respectively) and that roughly half the neurons were excited while half were inhibited. NE resulted in between 50% and 60% of the neurons showing a change from baseline for all three doses administered. As the dose of NE increased, so did the number of responders demonstrating an inhibition of firing. The intermediate doses of IL-1 and NE, when applied comcomitantly, resulted in the majority (79%) of the neurons showing a change in activity with 82% of those responders being excited and 18% inhibited. These results suggest that IL-1 may exhibit dualistic effects: i.e. direct effects on hypothalamic neurons and modulatory properties affecting noradrenergic regulation.

EFFECTS OF THE NEUROPEPTIDE, α-MSH (1-13), ON DELAYED-TYPE HYPERSENSITIVITY REACTION IN MICE. M.E.Hiltz* and J.M.Lipton. (SPON:W.G.Clark) Dept. of Physiology, U.T. Southwestern Medical Center, Dallas, Texas 75235

The neuropeptide α-melanocyte stimulating hormone, α-MSH (1-13), has antipyretic and anti-inflammatory activities. α-MSH (1-13) as well as a C-terminal fragment of α-MSH [α-MSH (11-13)] was recently found to inhibit the acute inflammatory reaction induced by picryl chloride solution; however, the influence of α-MSH peptides on cell-mediated host responses, e.g. delayed-type hypersensitivity, is unknown.

To assess the effect of α-MSH on such a response, mice were sensitized with 0.5% 1-fluoro -2,4-dinitro-benzene (DNFB) solution. The ears were challenged 96 hrs later with a 0.15% DNFB solution to induce a delayed-type hypersensitivity reaction. The thickness of both ears was measured initially and at 24, 48 and 72 hrs after challenge to quantitate the degree of swelling. α-MSH (1-13) (30 μg/mouse) or saline was injected i.p. 3 hrs prior to the 24-hour ear measurement. There was a significant ($p < 0.001$) inhibition of swelling at 24 hr in animals treated with α-MSH, when compared with controls, but not at 48 and 72 hr after challenge. The results indicate that α-MSH, in addition to inhibiting fever and acute inflammation, can inhibit delayed-type hypersensitivity reactions. Funded by Texas Advanced Technology Program.

EFFECTS OF BROMOCRIPTINE AND HALOPERIDOL ON IMMUNE FUNCTION AND TUMORIGENESIS. J.L. Bussiere*, J.H. Exon* and C.A. Johnston (SPON: R.C. Speth). Dept. Veterinary Science, University of Idaho, Moscow, ID 83843 and College of Pharmacy, Washington State University, Pullman, WA 99164.

The effects of prolactin (PRL) levels on various immune parameters were determined using the dopamine agonist, bromocriptine (BCR) and antagonist haloperidol (HALO) in male Sprague-Dawley rats. Natural killer cell activity, delayed-type hypersensitivity, antibody production, and interleukin 2 (IL2), interferon and prostaglandin E2 (PGE2) production were assessed following two weeks of daily s.c. injections of BCR or HALO. Both HALO and BCR increased natural killer activity. However, IL2 and PGE2 production were differentially affected by HALO or BCR treatment: BCR increased both IL2 and PGE2, while HALO decreased IL2 and had no effect on PGE2. The effect of decreased PRL (with BCR) was then determined in a chemical-induced tumor model using 3-methylcholanthrene, which causes the formation of an in situ fibrosarcoma. Daily injections of BCR during the first two weeks following exposure to the carcinogen resulted in a significant increase in tumor incidence and decrease in tumor latency. The data demonstrate the potential importance of the anterior pituitary hormones in immune homeostasis and tumorigenic response to chemical carcinogens.

LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS AND THE MEDIAL SEPTUM: EFFECTS ON IMMUNE AND ENDOCRINE FUNCTIONS. W. Mayo, J. Cherkaoui, K.W. Kelley, R. Dantzer, P.J. Neveu, P. Mormède, M. Le Moal and H. Simon. INSERM U.259, Domaine de Carreire, 33077 Bordeaux Cedex FRANCE.Dept. Animal Sciences, University of Illinois, Urbana, IL61801, USA.

A large body of literature has demonstrated the important role of neural and endocrine influences in regulating immune functions. The effects of selective lesions (quisqualic acid -15μg/0.6μl) of two major cholinergic pathways of the central nervous system, the nucleus basalis magnocellularis (NBM)- cortical pathway and the septo-hippocampal pathway were examined on immune and endocrine functions. These two cholinergic pathways are severely damaged in some neurodegenerative diseases, particularly in the senile dementia of the Alzheimer type.

The lesion of the NBM induced an important increase of T-lymphocyte proliferation in response to mitogens (a two fold increase as compared to control, $p<0.01$) and an increase in interleukine-2 production. However antibody production was not modified. In contrast, lesion of the septal area led to a depression of the lymphoproliferation. No differences between experimental groups was observed in the plasma levels of stress hormones (ACTH, corticosteroids, prolactin).

These preliminary results clearly show that the cholinergic system has modulatory influences on T-lymphocyte functions. Characterization of both brain structures involvement in immunoregulatory functions and immunological targets of cholinergic influence are currently under studies in relation to immunodeficiencies in Alzheimer's disease.

291.6

TISSUE BIOGENIC AMINE CONCENTRATIONS FOLLOWING ENDOTOXIN ADMINISTRATION AND NEUROTRANSMITTER ALTERATION. H.M. Brown-Borg and F.W. Edens*. Dept. of Poultry Science, North Carolina State Univ., Raleigh, NC 27695-7635.

Catecholaminergic and serotonergic systems have been implicated in the modulation of immunity and disease. The effects of drug-induced sympathectomy and neutrotransmitter injection on monoamine and corticosterone (CORT) levels following endotoxin (E) injection are reported. In each of 3 studies, 3-wk-old chicks (Gallus domesticus) were divided into groups: control (C); drug [reserpine (R), propranolol (P), norepinephrine (NE), serotonin (5HT)]. In study 1, R (0.25 mg/kg, i.v.) was administered 16 and 12 hr before E injection (100 ug/kg 00127:B8 E. coli). In study 2, P (30 mg/kg, i.a.) was given 10 and 1 hr prior to E administration. In study 3, 30 min. prior to sampling, NE (.25 mg/kg, i.v.) or 5HT (.50 mg/kg, i.v.) was administered. Control groups in each study were bled and tissues (spleen and left ventricle) removed at time of E injection. Three hr post E injection control and treated birds were sampled. In study 1, C birds exhibited lower splenic NE levels when compared to E and RE groups (79.4+5.3 vs 114+10.4 and 148.64+10.24 ng/g; $P<.05$, respectively). Birds treated with P had increased splenic NE levels compared to C but lower levels than birds in the PE group ($P<.01$). Plasma CORT increased both the E and drug-E groups over that of controls in all 3 studies ($P<.05$). Our data indicate that peripheral neuronal activity is altered in this model of acute bacterial infection in Aves.

291.7

A MODEL FOR THE BEHAVIORAL EFFECTS OF INTERFERON: MOUSE INTERFERON ALPHA IN DBA/2J MICE Mark Segall* and Linda Crnic, Univ. of Colorado School of Medicine, Denver, CO 80262. (SPON: M. Reite)

Clinical use of interferon causes fatigue, anorexia, and impaired cognition. DBA/2J mice and mouse interferon-alpha (IFN-α; Lee Biomolecular) were used to model these effects. EXP.1 To determine the time course and effective dose, male mice, continually housed in the test chamber, were monitored 24 hours a day. Stable baselines were established between i.p. injections of 400, 800, and 1600 U/gm of mouse IFN-α. The 1600 U/gm dose decreased horizontal activity for 8 hours, and food pellets obtained for6 hours, after injection. All doses decreased the number of water licks 2 to 6 hours after injection. EXP.2 Interferon-induced nausea is not the likely cause for the decreased food consumpton: a 1600 U/gm injection of mouse IFN-α did not elicit a conditioned taste aversion. EXP.3 Short term studies compared types of interferon and routes of injection. As in Exp.1, i.p. injections of 1600 U/gm of mouse IFN-α decreased horizontal activity and food pellets obtained while i.p. injections of mock interferon or human IFN-α, or s.c. injections of mouse IFN-α had no effect. Thus the decreased activity and food intake in mice, seen only with mouse IFN-α, parallels the effects of interferon in humans. Therefore it is important to use species-appropriate interferon in an animal model. Supported by MH44453, MH09718, and MH00621.

CORRELATION OF TRH STIMULATION OF IN VITRO PRODUCTION OF TSH BY LYMPHOCYTES WITH IN VIVO TRH PITUITARY TESTING. W. J. Meyer, III, D.V. Harbour, R. Gardner, A. Wassef, and E. M. Smith, Dept. of Psychiatry and Behavioral Sciences, University of Texas Medical Branch, Galveston, TX 77550.

We examined the correlation between the pituitary TSH production after standard in vivo stimulation TRH testing and the mononuclear leukocyte's TSH production after in vitro TRH exposure. Twenty euthyroid individuals were given 200 ug TRH IV in vivo, and plasma TSH was measured over 60 min. The TSH response to TRH of freshly isolated mononuclear leukocytes from each individual was measured in vitro by incubating them with either plain media or TRH for 48 hours. The cell supernatants were analyzed by RIA for TSH. The fourteen individuals with a normal (peak TSH value > 10 uIU/ml) in vivo TRH test had a mean in vitro leukocyte TSH difference of 0.7±0.6 uIU/ml, whereas the 6 individuals with a blunted in vivo test had a significantly less in vitro TSH difference of 0.0±0.2 uIU/ml, ($p < 0.006$). Individuals with a blunted in vivo test had a normal leukocyte receptor Kd but lower Bmax (44±42 vs. 89±89 fmoles/mg membrane protein). Blunted pituitary response to TRH is correlated with decreased leukocyte TSH in vitro response to TRH and decreased TRH leukocyte receptor number. The mononuclear TSH production offers an enticing model of pituitary hormone secretion control and may provide insight into pituitary function abnormalities associated with psychiatric disease.

INFLUENCE OF THE CORPUS CALLOSUM ON IMMUNE FUNCTION

E. Fride*, P. Skolnick and P.K. Arora*. Lab of Neuroscience, NIDDK/NIH, Bethesda, MD 20892, USA.

Recent data from our laboratory indicate that communication between the left and right cerebral hemispheres may influence immune function (Fride et al. subm.). Nearly 70% of 129/J mice and 30% of BALB/c mice either lack or possess only a rudimentary Corpus Callosum (CC). In this study, several immune parameters (mixed lymphocyte reaction, MLR; cytotoxic T-lymphocyte activity, CTL; mitogen-stimulated T and B cell proliferation, MS) were measured and compared with control mice (CC^+). Degree of behavioral asymmetry was determined using a paw-preference test (Collins 1985). Callosal presence was scored under a microscope using toluidine blue stain. In both BALB/c and 129/J strains, CC^+ mice had a higher degree of paw preference than CC^- mice. The no. of spleen cells was lower in CC^- mice of both strains. CTL, MLR and MS were all significantly lower in CC^- than in CC^+ BALB/c mice.

BALB/c	CTL	MLR	ConA	PHA	LPS
	(% Lysis)		(Stimulation Index)		
CC+ (7)	81±5.2	2.7±.4	18.0±3.1	11±1.6	65±15.7
CC- (8)	65±3.0*	1.3±.1*	6.6±1.3*	6± .6*	29± 7.0*

(*p<.05)

The influence of the CC on immune function in 129/J mice is under investigation. These data suggest that inter-hemispheric communication is important in modulating the immune response.

291.10

EFFECTS OF THE PLATELET ACTIVATING FACTOR RECEPTOR ANTAGONIST BN-52021 ON CRH AND ADRENOCORTICOTROPIN SECRETION IN THE RAT.

R. Bernardini, A.E. Calogero+, Y.H. Ehrlich^, T.C. Kamilaris*, S.J. Listwak, G.P. Chrousos+ and P.W. Gold. Clinical Neuroendocrinology Branch, NIMH, and +Developmental Endocrinology Branch, NICHD, NIH, Bethesda, MD 20892; ^Developmental Neuroscience, CUNY, Staten Island, NY 10131.

Platelet activating factor (PAF), a naturally occurring alkyl-ether phospholipid, and a major participant in the anaphylactic/immune response, strongly stimulates the rat hypothalamic-pituitary-adrenal (HPA) axis in vivo. This effect appears to be mediated by direct stimulation of both hypothalamic CRH and, to a lesser extent, pituitary ACTH secretion. To examine the specificity of the PAF effect on the HPA axis we investigated the ability of a specific PAF receptor antagonist, the Ginkgo Biloba derivative BN 52021 (BN), to antagonize this effect. BN (10 mg/kg i.p.) injected 30 min prior to PAF was able to prevent the increase in plasma ACTH levels induced by PAF (500 ng/100 g of body weight i.v.). In addition, the effect of PAF on hypothalamic CRH secretion in vitro was inhibited by pretreatment of the tissue culture system with 1 μM BN, confirming the specificity of the response.

Our data suggest that PAF and its receptors may play a role in the activation of the hypothalamic-pituitary-adrenal axis during the defense response. Thus, PAF may represent another biochemical link between the immune and the endocrine systems.

291.11

PHARMACOLOGICAL MODULATION OF BETA-ENDORPHIN IN LYMPHOCYTES. A.E.Panerai and P.Sacerdote Dept. Pharmacology, Univ.of Milano, Milano, 20129 Italy.

Beta-endorphin (BE) is present in unstimulated human and rat lymphocytes. In order to investigate whether BE could be pharmacologically modulated similary to what observed for the hypotalamic or pituitary peptide, we treated rats and human subjects with drugs affecting the dopaminergic, serotoninergic and GABAergic systems. The results obtained show that both in rats and humans, lymphocyte BE was depressed after acute and/or chronic treatment with dopaminergic, GABAergic and anti-serotoninergic compounds. Consistently with this results, treatment with antidopaminrgic and serotoninergic drugs increased the lymphocyte concentrations of BE. These data show that: 1) BE in lymphocytes can be pharmacologically modulated; 2) lymphocyte BE seems to be modulated similarly to hypotalamic and intermediate pituitary BE, and not like the anterior pituitary peptide; 3) therapy with psychoactive drugs might affect the Immune System through changes in neuropeptides.

291.12

AGE AND CIRCADIAN CHANGES OF BETA-ENDORPHIN IN LYMPHOCYTES. P.Sacerdote and A.E.Panerai Dept. Pharmacology, Univ. of Milano, Milano, 20129, Italy.

Beta-endorphin (BE) concentrations were measured in lymphocytes from 6 and 18 month old rats, normal volunteers aging 20-30, 31-50, 51-70, 71-99 years, and at different times during the day in volunteers in the 20-30 and 51-70 years range. BE was significantly higher in 6 vs 18 month old rats. Similarly, BE concentrations increased from 20±3 pg/10^6 cells in the youngest group and remained higher up to the oldest group. In the youngest group, but not in the older, BE showed a circadian rhithm with nadir at A.M. and maximal concentrations at 1 P.M.. HPLC showed that most of BE in human lymphocytes is the N-acetylated sequence, at difference with what observed in plasma. These results show that 1) BE is present in unstimulated human and rat lymphocytes and concentrations are age related; 2) BE in human lymphocytes has a circadian rhithm; 3) N-acetyl-BE is the prevalent BE in lymphocytes.

291.13

EFFECTS OF ETHANOL ON TUMOR GROWTH AND NK CELL CYTOTOXICITY. R. Yirmiya, S. Ben-Eliyahu, R. P. Gale, Y. Shavit, H. Weiner, J. C. Liebeskind and A. N. Taylor. UCLA and West LA VAMC/Brentwood Division, Los Angeles, CA 90024.

The effects of chronic and acute ethanol administration on metastatic tumor growth were studied *in vivo*, using the MAD-B106 tumor cell line, previously shown to be controlled by natural killer (NK) cells. Additionally, the cytotoxic activity of NK cells against this tumor was measured *in vitro*. In the chronic experiments, Fischer 344 rats were fed a liquid diet containing ethanol or a control diet. After three weeks on the diet, animals were injected with MAD-B106 tumor cells. Two weeks later, lungs were removed and surface metastases were counted. In a second experiment, animals were sacrificed after three weeks on the diet and their splenic NK cell cytotoxic activity against MAD-B106 cells was assayed. In the acute experiments, animals were injected with either saline or ethanol (1.5-3.5 g/kg). One hour later, animals were either injected with MAD-B106 tumor cells and surface lung metastases were counted twelve days later, or sacrificed in order to assess the cytotoxic activity of their splenic NK cells. In another study, splenic and MAD-B106 cells were incubated in solutions containing various concentrations of ethanol. Ethanol treatment significantly increased the number of metastases in both the chronic and the acute study. However, in neither condition was there an effect of ethanol on NK cell cytotoxicity. In contrast, incubation of effector and target cells in physiologically relevant concentrations of ethanol significantly suppressed NK cell cytotoxicity. These results suggest that ethanol increases tumor growth, possibly by a direct effect on the interaction between NK and tumor cells. Supported by grants NS 07628 (J.C.L.), AA 06744 and VA Medical Research Service (A.N.T).

291.14

CENTRAL CATECHOLAMINE VARIATIONS ASSOCIATED WITH ANTIGEN ADMINISTRATION. S. Zalcman*, N. Shanks and H. Anisman. Dept Psychology, Carleton University, Ottawa, Ontario K1S 5B6, Canada.

Administration of sheep red blood cells (SRBC; 10^6 cells, ip) to CD-1 mice reduced norepinephrine (NE) concentrations and increased the accumulation of the NE metabolite, MHPG, in hypothalamus, hippocampus and locus coeruleus. Likewise, decreased dopamine (DA) levels and increased accumulation of the DA metabolite, DOPAC, were evident in the nucleus accumbens, while nigrostriatal DA activity was unaffected. These effects corresponded with the peak immune response to SRBC (i.e., 4 days after inoculation). At other intervals (1, 2, 3, 5, 6 days) amine changes were minimal, except for NE reductions in the locus coeruleus, which were also evident 3 days after immunization. These findings are consistent with the proposition that central amine variations may be related to immune activity. Since stressors provoke a similar neurochemical profile, the possibility exists that the antigen-induced immunological changes are interpreted as one component of a stress response.

291.15

EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS: EFFECT OF INTRACISTERNAL INJECTION OF COMPOUND 48/80 E.L. Orr, F.L. Jackson*, N.C. Stanley*. (SPON. D. Barker) Dept. of Anatomy. Texas College of Osteopathic Medicine. Ft. Worth, TX 76107.

Mast cells have been shown to release bioactive compounds which mediate increased vascular permeability and cellular inflammation in response to various immune or non-immune stimuli. A similar release of these compounds can be induced by treatment with Compound 48/80, a recognized mast cell degranulating agent. The development and expression of autoimmunity relative to the nervous system requires that specific autoimmune mediators exit the blood vascular system and enter the cerebrospinal fuid (CSF). Experimental autoimmune encephalomyelitis (EAE) is a model for CNS associated autoimmune disease (eg., multiple sclerosis). Our laboratory uses a recurrent model for EAE based on the ability of female Lewis rats to exhibit predictable primary and secondary occurrences of disease. To examine the hypothesis that nervous system-associated mast cells may modulate the disease process in animals with EAE, the following experimental paradigm was employed. Adult female Lewis rats were inoculated to induce EAE and assessed for behavioral symptoms beginning on day 7 postinoculation (pi). Immediately prior to the initial onset of the disease, animals were injected intracisternally with Compound 48/80 (10μg/20μl/5min). Control animals received vehicle alone. Our results indicate Compound 48/80 caused a significant reduction in the severity of the secondary occurrence of EAE with a lesser reduction observed in the primary occurrence of EAE relative to controls. Similar treatment prior to the secondary occurrence of EAE failed to elicit a similar effect indicating a functional difference in sensitivity to mast cell manipulations between the two occurrences. Based on the response of the animals to Compound 48/80, mast cells either directly or indirectly via other CNS tissues are likely able to regulate the disease process. Supported by a Grant from the NMSS #PP0053.

GLIOSIS IN DISEASES WITH NEURODEGENERATION AND IMMUNE SUPPRESSION. W.S.T. Griffin, L.C. Stanley*, J.S. Johnson* and R.C. Woody*. Departments of Pediatrics and Anatomy, UAMS, Little Rock, AR 72205.

Neurodegeneration can result from a variety of insults to the brain; apparently, without regard to the cause, gliosis ensues. In addition, several neurodegenerative diseases are associated with depressed immunity and have decreased expression of immune-response-generating, macrophage-derived interleukin-1 (IL-1) perhaps via induction of corticotrophin releasing factor (CRF). Moreover, with trauma-induced neurodegeneration, increases in glia-derived IL-1 can stimulate astrogliosis. To test the hypothesis that the gliosis of human neurodegenerative diseases of diverse cause is associated with increased expression of glial IL-1, we examined formalin-fixed, paraffin-embedded postmortem temporal lobe sections from 10 Alzheimer's (AD), 8 Down's, 6 AIDS, and age-matched-controls using antibodies to GFAP, S100, IL-1, and α/β-tubulin. Reactive astrocytes filled with GFAP and S100 immunoreactive product were present in each disease as were reactive glia filled with IL-1 immunoreactive product. The levels of IL-1, S100, and GFAP, but not tubulin, were elevated in homogenates of AD temporal lobe compared to controls. Therefore, although macrophage-derived IL-1 is decreased in the diseases studied, we conclude that elevation of glial-derived IL-1 may induce astrogliosis and contribute to immune suppression if glial IL-1, like macrophage IL-1, can stimulate CRF release.

291.17

ANALYSIS OF IMMUNOGLOBULIN A (IgA) IN CEREBROSPINAL FLUID (CSF) OF PATIENTS WITH NEUROINFLAMMATORY DISEASE A.H. Woo*, P.M. Knopf*, and H.F. Cserr (SPON: J.T. Parmelee) Physiology & Biophysics, Brown Univ., Providence, RI 02912

Elevated levels of CSF IgA appear in several neuro-inflammatory diseases and cannot be solely attributed to serum leakage across damaged blood-brain barrier (BBB) membranes. IgA is secreted across mucosal membranes by a specific receptor called secretory component (SC) which is found in high concentrations in mucus, colostrum, etc. If SC were detected in patient CSF, it would provide evidence for a secretory immune system in the brain.

CSF and sera from patients with amyotrophic lateral sclerosis, CNS Lupus, encephalitis, Guillain-Barré, meningitis, and multiple sclerosis were analyzed for IgA and SC using an Enzyme Immunoassay. Albumin (Alb) concentrations were determined by Radial Immunodiffusion. Normal and Parkinson's disease patients were used as negative controls. Purified colostrum SC, bile, and saliva were used as positive controls. An IgA index was used to evaluate CSF IgA with respect to BBB integrity where Index = [CSF IgA/serum IgA] / [CSF Alb/serum Alb]. 11 of 21 neuroinflammatory patients exhibited an elevated IgA index (>log mean + 2 SD of controls) but no CSF SC was detected. There does not appear to be a secretory IgA immune system in the CNS. Supported by NS-11050.

IMMUNOLOGICAL DYSFUNCTION IN GENETICALLY EPILEPSY-PRONE RATS. R.R.R. Rowland*, D.Y. Tso-Olivas*, S. Tokuda*, G.K. Weiss* and D.D. Savage. (SPON: E.H. Uhlenhuth). Depts. Microbiology, Physiology and Pharmacology, Univ. New Mexico Sch. Med., Albuquerque, NM, 87131.

Lymphocyte function has been shown to be regulated by a variety of lymphokines, hormones and neurotransmitters. The ability of the central nervous system and the endocrine system to regulate the immune system predicts that developmental defects in neuroendocrine function could produce alterations in the immune system. Genetically Epilepsy-Prone (GEPR-9) rats have been inbred for a genetic predisposition for acoustic stimulus-induced seizures. These rats possess deficits in brain norepinephrine and serum thyroid and growth hormones. Given these neuroendocrine deficits, we investigated immune function in GEPR rats.

Adult GEPR-9 and non-epileptic control Sprague-Dawley rats were immunized with sheep erythrocytes (SE), a T cell dependent antigen. Spleens were removed on day 5 or 7 and the anti-SE plaque-forming cell (PFC) responses were measured. The direct PFC response (IgM, day 5) of the GEPR group was 30% of control and the indirect PFC response (day 7, IgG) was 13% of control, indicating significant immunosuppression in the GEPR rat. Immunocompetence of GEPR rats was further evaluated by stimulating spleenocytes *in vitro* with concanavilin A (Con A) and pokeweed (PWM) mitogens. GEPR rats exhibited a 6 fold greater response than controls when stimulated with 5 μg/ml Con A, a T cell mitogen. The GEPR response to 5 μg/ml of PWM, a T cell-dependent B cell mitogen produced a proliferative response that was 19 times greater than controls. In contrast to the PFC data, the mitogen data suggest *immunoenhancement* in GEPR rats, presenting an interesting paradox. The inability of a hyperresponsive T cell population to participate in the response to a specific antigen challenge (*e.g.* SE) suggests a breakdown in the normal modulation of T cell function. The specific cause of this immune dysfunction is not known, but may be due to the inability of neuroendocrine systems in GEPR rats to modulate T cell activity. (Supported by NS24008 and RR08139)

REGIONAL CEREBRAL CORTICAL DEFICITS IN THE IMMUNE-DEFICIENT MOUSE. G.O. Gaufo*, S. Cronin*, and M.C. Diamond. Depart. of Physiology-Anatomy, Univ. of Calfornia, Berkeley, CA 94720.

The purpose of our investigation is to identify the cerebral cortical representation of an important aspect of the immune system, the T-cell mediated immunity. Bizière et al. (*Neurosci. Abstr.*, 6:31, 1980) found that ablation of the left dorsal and lateral aspects of the frontal, parietal, and occipital cortices resulted in decreased T-cell and NK activities as compared to ablation of the same areas on the corresponding hemisphere. This experiment inspired us to examine the thickness of the cortex of the genetically athymic nude mouse, a T-cell deficient animal. Among thickness measurements in frontal, somatosensory, and occipital areas, the frontal and lateral parietal cortices showed the greatest deficiencies. Surprisingly, in many other areas, the thickness of the cerebral cortex of the nude mouse did not differ significantly from the BALB/c mouse, an immune-competent animal. In addition, we found a significant reduction in the number of oligodendrocytes per unit area in left area 18 of the cerebral cortex compared to the immune-competent mouse (Diamond et al., *Exp. Neurol.*, 92:311, 1986).

We are presently investigating the effects of neonatal thymectomy on development of the cerebral cortex in the BALB/c mouse. By removing the thymus neonatally, we deprive the animal of the primary lymphoid organ responsible for producing T-cells. At 2 days of age, male and female BALB/c mice are assigned to one of three conditions: (i) thymectomy (ii) sham-operated and (iii) non-operated. There are 12 mice per group. Animals are placed back with their lactating mothers and weaned at 21 days of age. On day 41, the mice are anesthesized, perfused and brains removed. Twenty micra, transverse, frozen sections are taken of the frontal, somatosensory, and occipital cortex. On thionine stained sections, cortical thickness measurements of 9 different regions are made on microslide projected images (22.5X). In addition, the cortical cell morphology is analyzed in these brain sections.

Our hypothesis is that reduction of the source of T-cell production might localize a specific cortical region related to the control of T-cell mediated events. This approach refines the work of other investigators who created widespread lesions of the cortex and found modulatory effects on the immune system as a result.

DRAINAGE OF INTERSTITIAL FLUID (ISF) INTO DEEP CERVICAL LYMPH FROM DIFFERENT REGIONS OF RABBIT BRAIN. S.Yamada* and H.F.Cserr. Physiology and Biophysics, Brown University, Providence, RI 02912.

50% of ISF from rabbit caudate nucleus (CN) drains into cervical lymph. The route involves flow via perivascular spaces, along olfactory nerve sheaths, and into nasal submucosa (Bradbury et al., Am.J.Physiol., 240:F329, 1981). This study examines ISF flow in anesthetized rabbits from two additional brain regions, internal capsule (IC) and midbrain (MB). Lymph from both jugular lymph trunks was collected for a period of 2 to 5 hours, between 1/2 and 25 hours after microinjection of ^{125}I-albumin into brain. ISF drainage rates ($\mu l \cdot g\ brain^{-1} \cdot min^{-1}$), estimated from rates of tracer efflux from brain, were 0.10 and 0.17 for IC and MB as compared to 0.11 for CN. High tracer activity was associated with the ipsilateral middle cerebral artery after forebrain injection (IC or CN) and with the ipsilateral superior cerebellar artery after MB injection, consistent with efflux via perivascular spaces surrounding arteries supplying the injection site. Tracer drained preferentially to ipsilateral lymph and nodes after forebrain injection in contrast to lack of laterality after MB injection, suggesting complete mixing of ISF draining from ipsilateral and contralateral MB. Drainage into lymph accounted for 25% of tracer cleared from IC and 34% from MB. Supported by NIH Grant NS-11050.

NEUROENDOCRINE REGULATION: PROLACTIN

292.1

INFLUENCE OF SEROTONIN (5HT) ON THE DIURNAL AND NOCTURNAL SURGE OF PROLACTIN (PRL) IN THE PREGNANT RAT. A. Mistry* and J.L.Voogt. Dept of Physiology, Univ of Kansas Med Ctr, Kansas City, KS 66103.

5HT has been implicated in PRL control during various physiological states. This study evaluated the role of 5HT in the nocturnal and diurnal surges of PRL seen during early pregnancy. On day 8 of pregnancy, blood samples were withdrawn between midnight and 600h from previously implanted intracarotid catheters. Rats were sacrificed by decapitation, brains were frozen on dry ice and stored at -70C until later determination of biogenic amines using HPLC with electrochemical detection. Administration of parachlorophenylalanine (PCPA 250mg/kg ip), an inhibitor of 5HT synthesis did not affect the nocturnal PRL surge although it reduced 5HT content in the medial basal hypothalamus (MBH) to 20% of controls. PCPA also reduced dopamine (DA) but to a much lesser extent. Ketanserin (Ket 10mg/kg ip) and LY-53857 (5mg/kg ip) two selective 5HT2 receptor blockers were effective in greatly reducing the nocturnal PRL surge when injected at midnight. It is not clear whether the failure of PCPA to block the PRL surge is due to its inhibitory effect on DA or whether Ket and LY-53857 have effects separate from their 5HT2 antagonism. To test whether 5HT may have some role in the diurnal surge (Endocrinol 124:878,1989) rats were decapitated at 1800h on day 7 of pregnancy. Pretreatment with PCPA (24h) or Ket (2h) or LY-53857 (2h) greatly reduced plasma PRL levels to 3-7% of controls. Similar to results in the nocturnal study, PCPA greatly reduced MBH content of 5HT and also reduced DA. It is concluded that 5HT plays a significant role in the diurnal PRL surge during pregnancy. Its role during the nocturnal surge is unclear because of the contradictory effects of PCPA and the receptor blockers. (Supported by grant HD 24190)

SEX-RELATED ALTERATIONS OF TYROSINE HYDROXYLASE (TH) ACTIVITY AND IMMUNOSTAINING IN THE STALK-MEDIAN EMINENCE (SME) AFTER NEONATAL MONOSODIUM GLUTAMATE (MSG) TREATMENT. L. A. Arbogast and J. L. Voogt, Physiology Dept., Kansas Univ. Med. Ctr., Kansas City, KS 66103.

Neonatal MSG-treatment causes a loss of hypothalamic dopamine (DA) perikarya. The TH-containing nerve terminals are located in the SME. DA serves as a PRL inhibiting hormone. The aims of this study were: 1) to evaluate MSG toxicity on the amount and activity of TH in the SME of male and female rats, and 2) to relate changes in DA neuronal function to serum prolactin (PRL) levels. Male and female rats were injected with 4 mg/kg MSG or 10% NaCl (controls) on days 2,4,6,8 and 10 of age. Females were ovariectomized on day 45 and all rats were used on days 60-80. The TH protein was evaluated immunocytochemically in coronal brain sections using an avidin-biotin immunoperoxidase method. The number of hypothalamic DA perikarya was reduced in both males and females after MSG-treatment as compared to controls. TH quantity in the SME was less in male vs. female controls, but was markedly reduced in females and only modestly reduced in males after MSG-treatment. *In vitro* TH activity was assessed by incubating hypothalamic explants with brocresine, a decarboxylase inhibitor. Dihydroxy phenylalanine (DOPA) accumulation in the SME was measured by HPLC with electrochemical detection. TH activity was 3-fold higher in female than male controls. TH activity in the SME was 5-fold greater in control than MSG-treated females, but was unchanged in males. Serum PRL levels were 4-fold higher in male than female controls, but was not altered by MSG treatment in either sex. Conclusions: 1) the effects of MSG toxicity on the postnatal development of hypothalamic DA neurons is more profound in female than male rats, and 2) alterations in DA neuronal function are not always related inversely to circulating PRL levels. Supported by NIH grant HD 24190.

292.3

CONTRIBUTION OF ARACHIDONIC ACID METABOLITES TO BASAL AND TRH-INDUCED PROLACTIN RELEASE. M.P. Junier*, J.M. Israel*, F. Dray, J.D. Vincent, INSERM U176 BORDEAUX, INSERM U207, Institut Pasteur, PARIS, FRANCE

The contribution of arachidonic acid (AA) metabolites to basal and TRH-induced release of Prolactin (Prl) was investigated using perifusion of enriched cultures of lactotroph cells derived from pituitary glands of lactating female rats . Inhibition of AA lipoxygenase (LPX) and epoxygenase pathways by 10 uM Nordihydroguaiaretic acid (NDGA) decreased Prl release to ~35% of control values. In contrast, 10uM indomethacin, an inhibitor of AA cyclooxygenase pathway, was without effect. Of the LPX metabolites tested only 15-HPETE and 15-HETE induced Prl release with a maximal effect at 10-7 and 10-6 M respectively. In the presence of 10uM NDGA the absolute amount of Prl released by TRH was markedly decreased. However, because NDGA decreased basal Prl release, the relative increase induced by TRH over basal Prl levels was not markedly different between the two groups (% of Prl increased by TRH / % of Prl increased by TRH+NDGA = 0.81+0.07). In contrast, inhibition of the protein kinases A and G by H8 (10 uM) failed to alter basal Prl release but strongly inhibited the effect of TRH (% of Prl increased by TRH / % of Prl increased by TRH+H8 = 0.58+0.10). These results suggest that : a) AA LPX metabolites are involved in the maintenance of basal Prl release from enriched lactotroph cells in culture, b) the availability of TRH to stimulate Prl release is mainly independant of LPX activity, c) TRH-induced Prl release involves the participation of protein kinases A and/or G.

STIMULATION OF GH AND PRL SECRETION AND GENE EXPRESSION BY GH-RH IN A HUMAN PITUITARY CELL LINE. L. Dufy-Barbe*, D.W. Schmid* and B. Dufy., Lab. Neurophysiologie, CNRS UA 1200, Université de Bordeaux II, F-33076 Bordeaux Cedex, France.

From a somatotropic tumor, we have isolated human pituitary adenoma cells which behave *in vitro* as a cell line and could be maintained in culture up to passage 25. Immunocytochemical identification revealed that it was multihormonal and contained prolactin (PRL), growth hormone (GH), and the glycoprotein α chain immunoreactive cells. Measurement of basal hormone secretion showed that basal PRL and GH release declined rapidly with time in culture after passage 5 but still remained detectable.

The effects of exposure to 5 nmol/l GH-RH in a chemically defined medium significantly increased the secretion of GH (2.1 ng GH/96h/10^5 cells vs 0.6 in controls) and PRL (parallel increase). In addition, GH-RH stimulated protein synthesis significantly (6.1 µg/well vs 3.7 in controls).

In order to demonstrate GH-RH effects on gene expression of GH and PRL, Northern blot hybridization with RNA isolated from control and GH-RH treated cells was carried out. Synthetic oligonucleotide probes corresponding to different parts of the coding region for GH (Seeburg et al. 1977) and PRL (Martial et al. 1977) were used. These probes detected a single RNA species the size of which corresponded to published values (Murdoch et al. 1983). Moreover, we could detect differences in RNA abundance related to the GH-RH treatment.
This GH-RH responsive human pituitary cell line is presently used for the study of human GH and PRL gene expression.

EFFECT OF PROLACTIN ON THE NUMBER OF TUBEROINFUNDIBULAR DOPAMINE NEURONS IN AMES DWARF MICE. W.W.Morgan and K.C.Besch*,Univ.Texas Hlth.Sci.Ctr.,San Antonio,TX 78284.

Ames dwarf mice do not produce growth hormone (GH) or prolactin (PRL), and dopamine (DA) is virtually absent in the median eminence (ME). PRL replacement partially restores DA synthesis but not DA levels in the ME suggesting that the tuberoinfundibular dopaminergic (TIDA) neurons are very underdeveloped in Ames dwarfs. An antibody to tyrosine hydroxylase (TH; Eugene Tech) and an advin-biotin-peroxidase procedure were used to immunohistochemically determine if the number of TIDA neurons is also reduced in Ames dwarfs. TH-immunoreactive neurons were marked fewer in number in the arcuate nuclei but not the substantia nigra of Ames dwarfs compared to phenotypically normal mice of the same strain. Replacement of PRL by the implantation of a normal female pituitary under the kidney capsule or by the administration of ovine PRL (250ug/day) for two weeks increased the number of TH-positive neurons in the arcuate nuclei of male or female dwarfs to a level comparable to that seen in normal mice. Sham surgery or the administration of the sodium bicarbonate vehicle were ineffective. These data suggest that Ames dwarfs possess a nearly normal number of TIDA neurons, but most are very inactive due to the absence of circulating PRL. Supported by NIH # 22141.

HYPERPROLACTINEMIA (HyperPRL) INCREASES PROOPIOMELANOCORTIN GENE EXPRESSION IN THE ARCUATE NUCLEUS OF OVARIECTOMIZED RATS. K. Scarbrough[1], R.A. Steiner[2] and P.M. Wise[1], [1]Dept. Physiology, University of Maryland School of Medicine, Baltimore, MD 21201 and [2]Dept. Physiology and Biophysics University of Washington, Seattle, WA 98195.

HyperPRL can suppress LH release in ovariectomized (OVX) rats through hypothalamic mechanisms. To determine whether hyperPRL inhibits LH secretion by influencing opiate tone, we measured proopiomelanocortin (POMC) gene expression in the arcuate nucleus of OVX and OVX prolactin-treated rats. Rats were OVX and 4 days later half the rats received a subcutaneous injection of ovine prolactin (4 mg/kg body weight) every 8 hours for 2 days. Controls received an injection of vehicle (0.01M $NaHCO_3$, pH 8.6) at these times. The rats were killed one hour after the last injection, brains were removed and frozen at -70°C. Trunk blood was assayed for LH by RIA. A ^{35}S-labeled riboprobe complementary to POMC mRNA was prepared according to the methods of Chowen-Breed et al. (Endocrinol. 124:1697, 1989). 20μm sections were fixed in 4% paraformaldehyde, washed, acetylated and hybridized to the riboprobe at 45°C. After RNase treatment, stringent wash, and dehydration, slides were first exposed to x-ray film and then dipped in emulsion. Both film and emulsion-coated slides were developed using conventional photographic methods. Experimental conditions were optimized for probe concentration and exposure to film and emulsion. Films and slides were analyzed using a computerized image analysis system. HyperPRL significantly suppresses serum LH (OVX: 5.64 ± 0.60 HyperPRL: 3.80 ± 0.44 ng/ml). HyperPRL rats show a significant ($p < .05$) increase in POMC mRNA expression in the arcuate nucleus when compared to OVX controls. These data suggest that hyperPRL may increase the activity of opiatergic neurons in the arcuate nucleus and thereby inhibit LH secretion.

292.7

DIHYDROTESTOSTERONE (DHT) INHIBITS ESTROGEN (E) INDUCED HYPERPROLACTINEMIA IN THE MALE RAT. P.C. Doherty, and A.J. Carrillo, Dept. of Anatomy, N.E. Ohio Univ. Coll. of Med., Rootstown, OH 44272.

Prolonged treatment with E causes pituitary cell hypertrophy, hyperplasia and hypersecretion of prolactin (PRL). Similar treatment with testosterone (T) does not. The present experiments were performed to determine if coincubation of in situ and ectopic pituitaries in vivo with both DHT and E, the principal metabolites of T, could inhibit E-induced increases in pituitary weight and serum PRL. Adult male Fischer 344 rats were castrated and treated with subcutaneous implants of crystalline T, DHT, E, or E+DHT. Two additional groups were given four ectopic pituitary grafts and steroid capsules containing E or E+DHT. Six weeks later, the animals were sacrificed, the pituitaries were

	E	DHT	E+DHT	T
pit. wt.(mg)	22.0± 2.0	7.0±0.2	16.0±1.0	9.0± 0.4
prl (ng/ml)	212.7±102.0	16.2±3.2	12.7±3.2	45.8±24.0

removed and weighed, and trunk blood was collected for the PRL RIA. The E-induced increase in pituitary weight was inhibited by treatment with DHT but not to the levels seen in T-treated animals. In contrast, serum PRL levels were greatly inhibited in the E+DHT group. No inhibitory effects of DHT were observed in pituitary grafted male rats (1480±290 vs 1280±178 ng/ml). These results suggest that DHT can inhibit the effects of E but that hypothalamic input is necessary for these effects to occur. In addition, the differential effects of E+DHT on serum PRL levels and pituitary weight suggest that the primary mode of DHT action is on secretion. DIRECT FEEDBACK ACTIONS OF GONADAL STEROIDS ON IN VIVO LH SECRETION BY THE ISOLATED PITUITARY GLAND: EFFECTS OF HYPERPROLACTINEMIA F.J. Strobl*, J.M. Meredith*, and J.E. Levine (SPON: B. Menco). Dept. of Neurobiology & Physiology, Northwestern University, Evanston, IL 60208

We investigated whether hyperprolactinemia modulates the feedback actions of gonadal steroids exerted on the anterior pituitary (AP). Hypophysectomized, ovx rats (n=20) received 2 AP under the kidney capsule. Each rat was then fitted with an atrial catheter for infusion of LHRH (250ng/5min/h) and blood sampling. Blood samples were obtained at 2h intervals from 1600h on Day 5 of LHRH infusions to 2400h on Day 6. Rats received 1 Silastic capsule containing estradiol (E) (150μg/ml) at 1800h on Day 5 and 2 capsules containing oil or progesterone (P) (50mg/ml) at 1200h on Day 6. To prevent AP transplant-induced hyperprolactinemia a group of steroid-treated rats received the dopamine agonist CB-154 daily (1mg sc). Plasma LH and PRL levels were determined by RIA. LH levels in all control rats decreased from 0.79±0.09 to 0.36±0.03 ng/ml ($p < .01$) within 4h following E treatment. Thereafter, LH levels increased to 1.23±0.11 ng/ml by 2000h on Day 6. P had no additional effect on LH secretion ($p > .05$). Although CB-154 did not alter the pattern of LH responses to steroid treatment, it enhanced overall mean levels of LH by 48% ($p < .01$). These data suggest that hyperprolactinemia results in continued inhibition of LH secretion by direct actions on the AP, and that this action appears to be independent of the direct feedback effects of gonadal steroids.

THE PROLACTIN SECRETORY RESPONSE TO IMMOBILIZATION STRESS AND SEROTONERGIC STIMULATION DURING LACTATION. P. Callahan, Leslie Besecke, J. Janik, and J. Rabii. Zoology Dept., Miami University, Oxford, OH 45056 and Department of Biological Sciences, Rutgers University, Piscataway, NJ 08855.

We have previously reported an altered sensitivity in the prolactin secretory response to morphine and methadone during lactation. The purpose of this study was to determine the sensitivity of the lactating model to other prolactin secretory stimuli, namely immobilization stress and serotonergic stimulation. The immobilization stress was chosen since it has been reported to increase prolactin levels by decreasing tuberoinfundibular dopaminergic (TIDA) neuronal activity. The effects of serotonergic stimulation were also determined since serotonin appears to be involved in the suckling induced prolactin increase.

Non-lactating and lactating female rats (day 6-10 post-partum) were implanted with chronic jugular cannula 24 hours prior to the experiment. On the day of the experiment, pups were removed from the postpartum females prior to any treatment or drug administration. Animals were subjected to 10 minutes of immobilization stress. Serotonergic stimulation was accomplished by administering fluoxetine (FLX; 10 mg/kg, ip) followed one hour later by 5-hydroxytryptophan (5HTP; 30 mg/kg, ip).

The lactating female rats did not exhibit a prolactin secretory response to either of these stimuli. This was in marked contrast to the effects in the non-lactating female which clearly showed a significant increase in circulating levels of prolactin. These results support the notion that the lactating female exhibits an altered sensitivity to prolactin secretory stimuli. The mechanism(s) for this altered sensitivity is not known, however, we have previously reported a lack of sensitivity of the TIDA neurons to morphine induced inhibition (Callahan, et al., Life Sci., 43:49 '88). This may be one possible mechanism since TIDA neuronal inhibition seems to be required for a prolactin secretory response during lactation (Grosvenor, et al., Endo, 106:481, '80).

OPIOID NEURONS SYNAPSE ON TUBEROINFUNDIBULAR DOPAMINE NEURONS IN THE ARCUATE NUCLEUS OF JUVENILE MONKEYS. P.C. Goldsmith, J.E. Boggan* and K.K. Thind. Reproductive Endocrinology Center and Dept. of Ob/Gyn & Repro. Sci., Univ. Calif., Sch. Med., San Francisco, CA 94143.

Opioid (OP) neurons in the arcuate nucleus (ARC) synaptically inhibit nearby gonadotropin-releasing hormone (GnRH) neurons in monkeys (Thind and Goldsmith, *Neuroendocrinology* 47:203, 1988). Corticotropin-releasing factor neurons innervate periventricular dopamine (DA) neurons but not ARC OP neurons (Thind and Goldsmith, *Neuroendocrinology*, in press). To determine how these systems might interact, we investigated whether DA and OP elements form synapses in the cynomolgus monkey ARC. Tuberoinfundibular (TI) neurons in 4 juveniles were retrogradely labeled from the median eminence prior to aldehyde perfusion (see *Soc. Neurosci. Abstr.* 14:439, 1988). Frontal vibratome sections were immunostained for tyrosine hydroxylase with PAP for DA neurons, and for adrenocorticotropin with 15 nm gold for OP neurons. In the ARC, 63% of the DA neurons, but none of the OP neurons, were TI. Many DA neurons were contacted by OP axons, in agreement with results in the rat (Morel and Pelletier, *Peptides* 7:1197, 1986). In contrast to that report, symmetrical synapses were found between OP axon terminals and TI DA cell bodies. Small clear synaptic vesicles but no dense OP secretory granules were present at presynaptic sites, perhaps indicating tonic neurosecretion. The results suggest that OP neurons inhibit TI DA neurons in the ARC, where OP can act to increase prolactin secretion. Since both OP and DA neurons are steroid responsive, their interaction represents a sensitive control point in the neuroendocrine regulation of prolactin and perhaps also GnRH secretion in primates. (Supported by NIH HD10907).

292.11

ACETYLCHOLINE, MORPHINE, SEROTONIN AND DOPAMINE REGULATE THE IN VIVO RELEASE OF PROLACTIN THROUGH A COMMON PATHWAY.

C. M. Flores*, B. A. Hulihan-Giblin*, S. R. Wheeler*, L. R. West-Johnsrud* and K. J. Kellar. Department of Pharmacology, Georgetown University, Washington, D.C. 20007.

Nicotinic cholinergic, opiate and serotonergic agonists as well as dopaminergic antagonists release pituitary prolactin. The present studies were undertaken to explore the anatomical relationship and interdependence of the synapses utilized by such drugs. Consequently, we have characterized a common pathway employed by nicotine, morphine, 8-hydroxy dipropylaminotetralin (8-OH-DPAT) and haloperidol to release prolactin in conscious, freely moving, male rats implanted with jugular cannulae 24 hr prior to experimentation. In saline pretreated rats, the sequential administration (30 - 60 min apart) of nicotine (100 μg/kg), morphine (3 mg/kg), 8-OH-DPAT (100 μg/kg) and haloperidol (0.5 mg/kg) resulted in significant increases (3 - 10-fold) in plasma prolactin levels. Mecamylamine (3 mg/kg) antagonized the nicotine induced prolactin release only. Naltrexone (4 mg/kg) prevented the release by morphine and by nicotine, but not by 8-OH-DPAT or haloperidol. Methysergide (5 mg/kg) blocked the prolactin releasing effects of nicotine, morphine and 8-OH-DPAT but not haloperidol. Finally, bromocriptine (0.5 mg/kg) blocked the prolactin increases induced by all three agonists as well as by haloperidol. These data indicate that a poly-synaptic pathway regulating the in vivo release of prolactin is subserved, in series, by nicotinic cholinergic, opiate, serotonin and dopamine receptors, respectively.

292.12

SEROTONIN-1A RECEPTORS MEDIATE PROLACTIN RELEASE IN THE RAT.

B.A. Hulihan-Giblin[1]*, C.M. Flores1*, M.D. Lumpkin[2]*, and K.J. Kellar[1] (SPON: A.R. Raines). Dept. of Pharmacology[1] and Physiology[2], Georgetown Univ. School of Medicine, Washington, D.C. 20007.

Serotonin (5-HT) agonists stimulate prolactin secretion, probably by acting within the basal hypothalamus to influence the activity of tuberoinfundibular dopamine neurons. The type of 5-HT receptor involved in mediating prolactin release is not yet resolved. Although the 5-HT-1A agonist 8-OHDPAT has been found to stimulate prolactin release in some studies, other studies have found it to be ineffective or that the effect is not dose-related. We have examined the effect of 8-OHDPAT on prolactin release in rats in which an indwelling jugular cannula allowed intravenous injection of drugs and multiple sampling of blood over time. The effect of 8-OHDPAT (100 μg/kg) on prolactin release is rapid and relatively brief, with prolactin levels peaking at 8 times baseline within 10 min and returning to baseline within 40 min. 8-OHDPAT is a potent releaser of prolactin, with an ED_{50} of 20 μg/kg. The effect of 8-OHDPAT is completely blocked by pretreatment with methysergide 1 hr before. Another 5-HT-1A agonist, 5-methylurapidil is also a potent releaser of prolactin, reinforcing the idea that these responses are mediated by 5-HT-1A receptors. The prolactin response to 8-OHDPAT appears to desensitize rapidly; and 90 min after a single injection of 8-OHDPAT, the response to a second injection is diminished. The ED_{50} for this desensitization by 8-OHDPAT is approximately 200 μg/kg. This desensitization by 8-OHDPAT appears to be specific because the prolactin response to thyrotropin releasing hormone is unaffected by prior injection of 8-OHDPAT.

292.13

SUCKLING AND 5-HYDROXY-L-TRYPTOPHAN STIMULATE GROWTH HORMONE SECRETION VIA CHOLINERGIC MECHANISMS IN THE NEONATAL RAT.

B. Kacsoh* and C.E. Grosvenor. Dept of Molecular and Cell Biology, Penn State University, University Park, PA 16802.

The present experiments investigated the mechanisms underlying the high circulating growth hormone (GH) levels occurring in neonatal rats. Separation of 2-day-old rat pups from their mothers decreased, while a subsequent suckling period increased, serum GH levels in the pups. The serotonin antagonist cyproheptadine (1 or 10 mg/kg, s.c.) decreased serum GH values in separated pups (i.e. decreased basal secretion), but failed to inhibit the suckling-induced release of GH. Similarly, the serotonin precursor 5-Hydroxy-L-Tryptophan (5-HTP, 5 mg/kg, s.c.) increased serum GH levels in separated pups, and further stimulated the GH release induced by suckling. Atropin (10 mg/kg, s.c.), a blocker of the cholinergic muscarinic receptors, decreased serum GH levels in separated pups, and prevented the suckling-induced release of GH. Further, atropin prevented the GH-releasing effect of 5-HTP in separated pups. The alpha 2 receptor blocker yohimbine (10 mg/kg, s.c.) did not reduce serum GH values in separated pups, yet it prevented the suckling-induced release of GH. Rat GH-releasing hormone (rGHRH) did not stimulate GH secretion either in separated or in suckled rat pups. These findings suggest that 1) the mechanisms stimulating GH secretion by suckling or by 5-HTP, are arranged in a parallel (rather than serial) fashion, 2) while serotonin regulates basal secretion, the alpha 2 system mediates the suckling-induced release of GH, 3) both suckling and 5-HTP stimulate GH secretion via cholinergic mechanism(s), and 4) neither suckling nor 5-HTP induce GH release via rGHRH. (Supported by HD-04358 to CEG).

292.14

EFFECT OF CENTRAL INJECTION OF CRF ON CORTISOL AND PROLACTIN SECRETION IN THE SHEEP.

DWF Porter*, AM Naylor & DW Lincoln* (SPON: QJ Pittman). MRC Reproductive Biology Unit, 37 Chalmers Street, Edinburgh, UK.

Stress evokes a response characterized by activation of the hypothalamo-pituitary-adrenal axis with release of CRF and/or AVP, ACTH and cortisol. As well as its role in stimulating ACTH release from the pituitary, there is evidence that CRF can act via central pathway(s) to modify other neuroendocrine systems. The following studies were therefore undertaken to investigate whether central administration of CRF can alter the secretion of two hormones under different regulatory control and known to be released during stress in the sheep, namely cortisol and prolactin.

Scottish Blackface ewes were ovariectomized and implanted with a cannula directed towards the third cerebral ventricle. Plasma cortisol and prolactin concentrations were measured in 20min blood samples taken over a 12h sampling period. Intracerebroventricular injection of saline (50μl) or CRF (0.12nmol and 1.2nmol) was made at 4h and naloxone injected intravenously at 4h, 5.5h, 7h and 8.5h as required.

Injection of CRF (1.2nmol) into the third ventricle resulted in a significant increase in both plasma cortisol and prolactin concentrations. At the lower dose, CRF (0.12nmol) increased cortisol levels by enhancing pulsatility, but had less consistent effects on prolactin secretion. Intravenous injection of naloxone blocked the CRF-induced increase in prolactin but did not alter the ability of CRF to increase plasma cortisol. Neither saline nor naloxone alone affected plasma cortisol or prolactin levels.

In conclusion, central administration of CRF increases both cortisol and prolactin secretion in the sheep. In the case of prolactin, this increase was reversed by naloxone, suggesting a central action mediated by endogenous opioids. With respect to cortisol, it is possible that centrally injected CRF acted directly on the pituitary gland following leakage of the higher dose into the pituitary portal circulation. However, the lower dose of CRF increased pulsatile secretion of cortisol, providing evidence for a central component in the response. At present, the relative contribution of each remains to be investigated. In addition, these data demonstrate that basal cortisol and prolactin secretion in the ovariectomized ewe is not under tonic opioid inhibition.

292.15

CENTRAL INVOLVEMENT OF EXOGENOUS AND ENDOGENOUS CRF IN REGULATING PROLACTIN SECRETION IN THE SHEEP.

A.M. Naylor. MRC Reproductive Biology Unit, 37 Chalmers Street, Edinburgh, EH3 9EW UK.

Central administration of CRF to sheep stimulates the release of prolactin from the pituitary gland. This effect of CRF is prevented by the opioid antagonist naloxone, suggesting that the stimulatory effect of CRF on prolactin secretion is mediated by endogenous opioid peptides and is central in origin. Several observations indicate that central CRF may participate as a neurotransmitter in the brain regulating neuroendocrine responses to stress. The following studies were undertaken in sheep to investigate further this hypothesis using prolactin, a hormone which is released during stress in this species. Specifically, the effect of a CRF antagonist (αCRF9-41) on prolactin secretion was investigated under basal and stimulated conditions.

Scottish Blackface ewes were ovariectomized and implanted with a cannulae directed towards the third cerebral ventricle. Half of the sheep were implanted s/c with silastic implants containing estradiol. Plasma prolactin was measured in either 10 or 20min blood samples taken over an 8-11h sampling period. Intracerebroventricular injection of sterile saline (50μl), CRF (1.2 nmol) or αCRF9-41 (15.5 nmol) was made 4h into the sampling period. Introduction of a ram was used as a stimulus to evoke prolactin release where nesessary.

Injection of CRF (1.2 nmol) evoked a significant release of prolactin which was antagonized by prior treatment with αCRF9-41 (15.5 nmol). In contrast, injection of saline or αCRF9-41 alone did not alter prolactin secretion. Introduction of a ram evoked an increase in plasma prolactin to about 3x control levels. When introduction of the ram was preceded by a central injection of αCRF9-41 (15.5 nmol), the elevation in prolactin was reduced in 5/6 of the animals when compared with the saline controls.

In conclusion, these data indicate that central CRF releases prolactin via a central mechanism involving CRF receptors. However, under basal conditions there is no tonic stimulatory control by endogenous CRF of prolactin secretion. Under stimulated conditions (ie. in the presence of a ram), there is evidence to suggest that endogenous central CRF may be responsible for the elevation in plasma prolactin.

292.16

PITUITARY AND HYPOTHALAMIC ACTIONS OF ADENOSINE ON PROLACTIN SECRETION.

J. G. Ondo, M. W. Walker*, and K. Boackle*, Dept. of Physiology, Medical University of S. C., Charleston, S.C. 29425

This study examined the effects of the purine nucleoside adenosine on prolactin (PRL) secretion both at the level of the anterior pituitary and hypothalamus. Adenosine is present in the hypothalamus and affects cellular processes through interaction with two classes of plasma membrane receptors which are coupled to adenylate cyclase. Anterior pituitaries from male rats were dispersed and cultured for 48 hours. The cultured cells (150,000/well) were first preincubated then subjected to a two-hour incubation containing medium plus adenosine or specific receptor agonists. Adenosine ($5x10^{-5}$M), phenylisopropyladenosine (PIA, 10^{-5}M), or N-ethylcarboxyamide adenosine (NECA, 10^{-5}M) did not influence PRL secretion. However, the addition of adenosine deaminase (AD, 0.3-0.5 U/ml) to the medium increased PRL significantly. AD is responsible for metabolizing adenosine; the results suggest that pituitary cells release adenosine which tonically inhibits PRL secretion. Administration of PIA (10^{-5}-10^{-10}M) with 0.33 U/ml AD reduced PRL levels significantly. Combining dopamine (DA, 10^{-7}M) with PIA or NECA also resulted in inhibition of PRL greater than with DA alone. In contrast, intracerebral infusion of adenosine (100-200 nmoles) or PIA (10-50 nmole) stimulated PRL release in unanesthetized females. NECA or PIA (2.5 nmole) increased PRL 10 fold 15 min. after infusion into the third ventricle, an effect blocked by theophylline (25 nmole). LH levels measured in all animals were unaffected. These results support a biphasic action for adenosine on PRL secretion, a central stimulatory effect in the hypothalamus and an inhibitory, possible paracrine, effect directly on the pituitary lactotroph.

292.17

LACTATIONAL INFERTILITY IS SHORTENED BY A BRIEF INTERRUPTION IN NURSING IN ADOLESCENT MONKEYS. M.E Wilson* & T.P. Gordon* (SPON: F.A. King). Yerkes Primate Res. Ctr., Emory Univ., Atlanta, GA 30322

Lactational infertility is prolonged in adolescent rhesus monkeys (Macaca mulatta) following first parturition due to an apparent increased sensitivity to nursing (Biol. Reprod.,38:163, 1988). This study tested the hypothesis that a brief interruption in nursing shortens the period of lactational infertility in adolescent mothers. Nursing was prevented for a two week period by placing a primate vest on a female, preventing nursing but allowing other mother-infant contact. After nursing restriction, infants nursed ad libitum. Nursing restriction occurred when infants were actively suckling but able to maintain normal growth by eating solid food (140 d postpartum). Following the nursing restriction, total time infants spent nursing did not differ between groups: adolescent nursing restricted (AP: n=4), adolescent nursing unrestricted (AU: n=5), multiparous nursing restricted (MP: n=6), and multiparous nursing unrestricted (MU: n=6). Prior to the manipulation, serum estradiol (E2) was similar (~20 pg/ml) in all mothers, whereas following nursing restriction levels were lower ($p<.05$) in AU (17 ± 5 pg/ml) compared to AR (39 ± 10 pg/ml) who were similar to both MR (42 ± 7 pg/ml) and MU mothers (45 ± 11 pg/ml). Differences in E2 were associated with increased luteinizing hormone (LH) pulse amplitude. The interval from parturition to ovulation was shorter ($p<.05$) in AR (186 ± 13 d), MU (193 ± 4 d), and MR (183 ± 8 d) vs AU mothers (226 ± 15 d). These data indicate that adolescent rhesus monkeys are exquisitely sensitive to the suppression of reproduction by nursing, as a brief removal of the nursing stimulus advanced postpartum ovulation in adolescent but not adult mothers. This enhanced sensitivity may be due to the inhibitory effects of suckling on a developing neuroendocrine sytem. Supported by HD18120 & RR00165.

AN ENDOGENOUS STIMULATORY RHYTHM REGULATES PROLACTIN RELEASE IN LACTATING RATS. B.J. Arey*, B. Kanyicska* and M.E. Freeman. Dept. of Biological Sciences, Florida State Univ., Tallahassee, FL 32306.

Prolactin (PRL) secretion in female rats is regulated by an endogenous stimulatory rhythm that corresponds to the periods of mating-induced surges of PRL (Arey et al, Endocrinology 1989 124:119). Oxytocin (OT), vasoactive intestinal peptide and serotonin are hypothalamic stimulatory regulators of this endogenous rhythm (Arey and Freeman, Endocrinology 1989 124:878). In this study we investigated the role of this endogenous rhythm in lactating rats. On the day following birth, litters were adjusted to eight pups. On day 9 of lactation dams were fitted with chronic, indwelling intraatrial cannulae. The following day, pups were separated from their mothers for six hours before being reunited with their dams at either 0300, 1200 or 1700 h. Blood samples were taken from the atrial cannulae just prior to pup separation, and again at 0 (immediately before reuniting pups), 15, 30, 60 and 120 min following reuniting pups and dams. Serum samples were assayed for PRL, OT and growth hormone (GH) by RIA. Regardless of the time of suckling, 0-time samples contained significantly less PRL and OT as compared to their pre-separation levels. GH levels were not significantly different between 0-time and pre-separation levels. In all rats studied, PRL and OT concentrations were increased within 15 min of reuniting pups. Dams suckled at either 0300, or 1700 h demonstrated significantly greater PRL secretory profiles than rats suckled at 1200 h. Rats suckled at 0300 h and 1700 h had approximately a 40-fold maximum increase in PRL levels, whereas rats suckled at 1200 h showed only a 20-fold increase. OT levels rose steadily throughout the entire blood sampling period to an approximate 2-fold increase in OT by 120 min. However, there was no significant difference in secretory profiles of OT between time periods tested. GH levels also increased steadily throughout the blood sampling period and achieved approximately a 2-fold increase in concentration as compared to 0-time. There was no difference in secretory profiles of GH between time periods tested. These results suggest that the endogenous stimulatory rhythm regulating PRL release in ovariectomized rats, is also present in the lactating rat. (NIH, HD-11669).

EVIDENCE THAT VASOACTIVE INTESTINAL PEPTIDE (VIP) ANGIOTENSIN II (AII) AND LHRH MODULATE THE RELEASE OF PROLACTIN INDUCED BY DOPAMINE BLOCKADE. T. Inoue* and A. Negro-Vilar (SPON: M. Ching) Reprod. Neuroendoc. Sect., LMIN, NIEHS, NIH, Research Triangle Park, NC 27709.

The peptides VIP, AII and LHRH are among a number of substances that can stimulate prolactin (PRL) secretion by neuroendocrine, paracrine and/or autocrine mechanisms. We and others have shown that the stimulatory effect on PRL release of endogenous factors can best be observed when the tonic dopaminergic inhibitory activity is eliminated. In this study, we evaluated the PRL response to domperidone (DOM), a dopamine receptor antagonist, in male rats that were pretreated with specific receptor antagonists for the above peptides. Prior to DOM injection (0.1 mg/kg, i.v.) groups of male rats received one of the following: VIP antagonist ([4Cl-D-Ph^6-Leu^{17}]VIP); AII antagonist (Sarthran); LHRH antagonist ([D-pGlu^1, D-Phe^2, D-Trp^{3,6}]LHRH); oxytocin antagonist ([d(Ch$_2$)$_5$,Tyr(OMe)^{2}Orn^8]vasotocin) or saline vehicle given by constant infusion for 60 minutes. Blockade of VIP receptors reduced the DOM-induced PRL release in a dose-dependent manner. Blockade of AII and LHRH receptors also significantly attenuated the release of PRL after DOM. Oxytocin antagonist or LHRH agonist infusion had no effect on the stimulated PRL release. None of the analogs affected basal PRL levels. These results suggest that VIP, AII and LHRH are involved in the modulation of PRL secretion occurring after the removal of dopamine inhibition.

292.20

IN VIVO STUDIES ON THE PARACRINE ACTIONS OF PITUITARY ANGIOTENSIN II (AII) IN STIMULATING PROLACTIN (PRL) RELEASE FROM THE ANTERIOR PITUITARY GLAND OF RATS. M.K. Steele, L.S. Myers*. Physiology Dept., Univ. of Calif., San Francisco, CA 94143

In rats, pituitary gonadotrophs contain AII, and AII receptors are found on lactotrophs and corticotrophs. *In vitro*, both LHRH and AII stimulate PRL and ACTH release. The present studies investigated whether LHRH released pituitary AII to affect PRL and/or ACTH secretion in conscious rats. In male rats, intravenous LHRH (IV, 100 ng) stimulated LH but failed to alter PRL and ACTH secretion (Ganong and Shackelford, unpublished data). However, in ovariectomized rats treated with estradiol and progesterone, LHRH increased both LH and PRL release. The PRL response to LHRH was reduced by saralasin (12 μg/kg/min IV) and abolished by sarthran (5 μg/kg/min IV) infusion. In proestrous rats, neither saralasin nor sarthran had any effect upon the midcycle PRL surge. In addition, in other female rats, saralasin did not affect the increase in LH or PRL induced by 10 min of restraint stress. Taken together, these data show that exogenous LHRH stimulates PRL by releasing AII from the gonadotrophs. However, under physiological conditions where LH and PRL (and presumably endogenous LHRH) are elevated, pituitary AII does not appear to be involved in the PRL rise.

BIOLOGICAL RHYTHMS AND SLEEP: OTHER II

293.1

ABLATION OF THE SUPRACHIASMATIC NUCLEI DISRUPTS HIBERNATION AND BODY MASS RHYTHMS OF GROUND SQUIRRELS IN THE COLD. J. Dark, T.S. Kilduff, H.C. Heller* and I. Zucker, Dept. of Psychology, Univ. of California, Berkeley, CA 94720, and Dept. of Biological Sci., Stanford Univ., Stanford, CA 94305

Circannual rhythms of hibernation and body mass were studied in golden-mantled ground squirrels maintained in an LD 12:12 photoperiod at 6°C. Hibernation rhythms were disrupted by complete or partial suprachiasmatic nuclei (SCN) lesions. Several animals progressed through 4 hibernation cycles over the course of 2 years. One squirrel underwent two unusually long hibernation seasons, and another failed to hibernate for almost 2 years. Squirrels without SCN lesions had normal hibernation rhythms with a period of 11.5 ± 0.3 months. Hibernation normally coincides with the weight loss phase of the cycle but this association was absent in animals with SCN lesions. The SCN may be essential for normal circannual organization of hibernation and body mass rhythms at low temperatures.

BRAIN PROTEIN SYNTHESIS IN GROUND SQUIRREL BRAIN DURING HIBERNATION AND EUTHERMIA. T. S. Kilduff, R. Castro*, W.C. Dement, and H.C. Heller*. Depts of Psychiatry and Biol. Sci., Stanford University, Stanford, CA 94305.

Changes in arousal state such as sleep and hibernation may be mediated by production of endogenous substances which facilitate the state transition. To evaluate whether change in the proteins synthesized occur in the hibernating brain, in vivo labelling and detection of incorporated amino acids by autoradiography was utilized. Ground squirrels (Citellus lateralis), chronically implanted with cannulae in the left lateral ventricle, were injected with 0.5mCi of [^{35}S] methionine in a volume of 2.0ul while euthermic (T_b = 37°) or hibernating (T_b < 12°C) in a cold room. The label was allowed to incubate for 2hr in the euthermic animals and 2d in the hibernating animals. At the end of the incubation period, squirrels were sacrificed by pentobarbital overdose, the brain removed and dissected into 13 subregions, and proteins extracted. Proteins were separated by 2-dimensional gel electrophoresis and the gels exposed to X-ray film. In this procedure, three or four brain regions per animal (hypothalamus, basal forebrain, septum and striatum) incorporated enough [^{35}S] methionine to provide an adequate autoradiographic exposure in 3 weeks or less. Initial results suggest a surprisingly high number of proteins being synthesized during hibernation.

293.3

THE EFFECTS OF TEMPERATURE AND pH ON THE FIRING RATE OF SUPRACHIASMATIC (SCN) NEURONS IN HIBERNATORS AND NON-HIBERNATORS. J.D. Miller, V.H. Cao*, and H.C. Heller*. Dept. of Biological Sciences, Stanford University, Stanford, CA 94305-5020

The firing rates of SCN and non-SCN neurons from rats, euthermic ground squirrels, and hibernating ground squirrels were observed in the hypothalamic slice preparation. Bath temperature was varied between 10°C and 37°C and pH was continually monitored. Multiple regression analysis was performed to examine the contributions of temperature and pH to changes in firing rate. Standardized thermal coefficients, firing cutoff temperatures, and Q_{10}'s were calculated. Preliminary results indicate that the average Q_{10} for SCN cells in hibernating squirrels was significantly greater ($p < .01$) than that for euthermic squirrels or rats (which did not differ significantly from a Q_{10} of 2.0). Temperature accounted for at least twice as much of the variance in rate as did the effects of pH. The results are consistent with the hypothesis that the circadian clock may be greatly slowed in hibernation, possibly accounting for the multi-day temporal organization of hibernation bouts.

293.4

TRANSPLANTATION OF FETAL SCN INTO 3RD VENTRICLE OF ADULT HAMSTER SPARES DISRUPTION OF CIRCADIAN LOCOMOTOR RHYTHM FOLLOWING SCN LESION. A. Philpot*, M-T. Romero and R. Silver, Barnard College of Columbia University,New York, NY 10027.

We previously reported that transplants of fetal SCN into the 3rd ventricle of SCN-lesioned adult hamsters restores circadian locomotor rhythmicity (Lehman et al.,J. Neurosc 7:1626,1987). In the present study we report that if the host adult SCN is lesioned about 40 days following transplantation of fetal SCN into the 3rd ventricle, there is no disruption of circadian locomotor rhythmicity. Immunohistochemical verification of VIP- and NP-like immunoreactivity verified SCN transplantation and extent of lesion. The results suggest that donor SCN contributes to circadian rhythmicity prior to or immediately upon lesioning of the endogenous SCN. Given the evidence that fetal donor tissue requires a denervated target to establish synaptic connections, the results imply a non-synaptic mechanism mediating maintenance of locomotor rhythmicity following SCN lesions in these grafted animals and raises the possibility that a similar mechanism occurs in the SCN *in situ*.

293.5

SUPRACHIASMATIC NUCLEUS (SCN) TRANSPLANTS: COMPUTERIZED IMAGE ANALYSIS OF NEUROPEPTIDE DISTRIBUTION. J. Buggy, J. Ding, and P.J. DeCoursey*. Depts. of Physiology and Biology, Univ. of South Carolina, Columbia, S.C. 29208.

In transplants of fetal hypothalamic tissue, neuropeptide immunohistochemistry (IHC) characteristic of the normal SCN is observed. To better understand why these transplants to arrhythmic SCN-lesioned hosts restore free-running circadian rhythm in some instances but not others, computerized image analysis was used to analyze neuropeptide distribution. Videoscans of IHC sections stained sequentially for neuropeptide Y (Y), neurophysin (N), vasoactive intestinal polypeptide (V), and somatostatin (S) were fiducially aligned, digitized, and stored as image files. Areas outside the transplant were masked and a pixel intensity threshold selected for presence or absence of (IHC) stain. The percent of transplant area with IHC stain was determined individually for each neuropeptide and then, using superimposed images, for areas of neuropeptide overlap. VIP and N IHC in transplants were clustered as plexus aggregates, adjacent or with considerable overlap; S IHC was less clustered but often adjacent to N IHC. In transplants to lateral ventricle which did not restore rhythmicity, Y IHC was extensive and diffuse except for conspicuous absence in V and N aggregates, suggesting that normal Y innervation to SCN from geniculate leaflet did not occur. Circadian transplant function may require appropriate reinnervation with host brain which becomes less probable at transplant sites distant from the hypothalamus.

293.6

CONTROL OF PHASE AND LATENCY TO RECOVER CIRCADIAN LOCOMOTOR RHYTHMICITY FOLLOWING TRANSPLANTATION OF FETAL SCN INTO LESIONED ADULT HAMSTERS. M-T. Romero and R. Silver. Barnard College of Columbia University, New York, New York, 10027

Transplant of fetal hypothalamic tissue into SCN-lesioned (SCN-X) hamsters is followed by recovery of circadian locomotor rhythmicity with latencies ranging from 1-10 (X= 3.7) weeks (Lehman et al J. Neurosci., 7:1626, 1987). In the present study we gave melatonin (M) injections (75ug SC in sesame oil) at two different phase points. M treatment entrained the phase of the recovered free-running locomotor response and shortened the latency to restore rhythmicity following transplantation of fetal SCN into the 3rd ventricle of adult hamsters. Control animals including 1) SCN intact adult hamsters, 2) SCN-X adult hamsters, and 3) SCN-X hamsters bearing implants that did not restore rhythmicity, showed no entrainment to M injections. The results suggest that exogenously administered M can synchronize oscillators within the CNS resulting in rapid reinstatement of locomotor rhythmicity following transplantation of fetal SCN in adult lesioned hosts.

293.7

GONADAL RESPONSES TO PROGRAMMED MELATONIN INFUSIONS IN THE SYRIAN HAMSTER: EFFECTS OF INFUSION FREQUENCY AND SUPRACHIASMATIC LESIONS. E.Maywood*, R.Buttery*, G.Vance*, J.Herbert*, M.H.Hastings* (SPON:J.T.Clark). Dept. of Anatomy, Univ. of Cambridge, CB2 3DY, U.K.

The pineal melatonin signal mediates the effects of photoperiodic stimuli upon the neuroendocrine axis. The brain is able to identify and time the duration of its nocturnal exposure to melatonin although the location and mechanisms of action of the timer are unknown. The circadian system may provide a neural substrate for this timing process; the central oscillators of the suprachiasmatic nuclei (SCN) bind melatonin and regulate other neuroendocrine responses to timed hormonal stimuli, e.g. the LH surge. The involvement of the circadian system in reading the melatonin signal was tested in two ways. Pinealectomized Syrian hamsters received 35 programmed infusions of saline vehicle (SAL) or melatonin (MEL, 250 ng in 500 µl) via subcutaneous cannulae. The infusions varied in duration (4h or 10h) or frequency (20h to 48h). In a second experiment, animals received partial or complete lesions of the SCN, and were then given 35, 10 h infusions at a frequency of 24h. Paired testes weights (PTW) were recorded as an index of gonadal response.

Infusions of SAL or MEL for 4h daily had no effect on gonadal condition (PTW, Sal 2.93+0.23, Mel 4h 3.56+0.14g). MEL infusions for 10h induced significant gonadal involution (1.32+0.25). SAL infusions delivered every 20h or 25h had no effect (3.05+0.17) as did infusions of MEL for 10h every 28h and 48h (3.35+0.2; 3.20+0.3). However, MEL every 25, 23 or 20h induced gonadal regression (1.63+0.19; 0.75+0.48; 0.28+0.05), indicating that non-24h signals can be read by the brain. MEL induced gonadal atrophy in animals bearing partial (SAL 3.00+0.17, MEL 1.14+0.26) or complete SCN lesions (SAL 3.35+0.16; MEL 1.27+0.35). These data suggest that the photoperiodic gonadal response to MEL is not dependent upon the circadian clock of the SCN.

293.8

INTRACEREBRAL MELATONIN ENTRAINS RAT RUNNING WHEEL ACTIVITY Karen L. Brugge,* Harry Klemfuss, Daniel F. Kripke* SPON J. Christian Gillin, San Diego VAMC and M-003, UCSD, San Diego, CA 92093

Melatonin may entrain hormonal and behavioral rhythms by a direct action on the suprachiasmatic nucleus (SCN). Daily systemic melatonin injections entrain activity rhythms in rodents. This effect can be abolished by SCN lesions. We attempted to extend the results of Cassone's group (1986) by injecting melatonin intracerebrally rather than systemically to determine its entrainment effects on running wheel activity (RW).

Rats with cannulae placed into the region of the SCN were initially entrained to a L:D 12:12 cycle (lights off at 6 pm), and upon commencement of daily microinjections at 7-7:30 pm of melatonin (500 ng melatonin in 0.2 u L) or vehicle, the L:D schedule was changed to continuous red dim light (RR). RW activity was monitored. Four control rats receiving vehicle all free ran, whereas 6 of 9 rats receiving melatonin were synchronized with activity onset at the time of injection ($p<.05$). These results support the hypothesis that melatonin entrains RW activity by a direct effect on the SCN.

MELATONIN DECREASES THE REENTRAINMENT RATE OF LOCOMOTOR ACTIVITY FOLLOWING AN 8 HR ADVANCE OF THE LIGHT/DARK (LD) CYCLE IN C3H/HeN MOUSE. J. M. Fang* and M. L. Dubocovich (SPON: S.F. Holloway). Dept. Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

Melatonin receptor sites have been localized in the suprachiasmatic nucleus of the mammalian hypothalamus, which is considered to be the central component of circadian organization. The aim of this study was to determine the role of melatonin in the reentrainment of the circadian rhythm of locomotor activity in the C3H/HeN mice after a phase shifts of the LD cycle. Baseline data on locomotor activity of C3H/HeN mice (5-6 week) were recorded for 2 weeks in a 12:12 hr LD cycle. An 8-hr advance of the LD cycle was applied by advancing dark onset. Vehicle or melatonin (10 mg/kg, i.p.) were injected for a total of two week just before the time of the pre-phase shift dark onset. A significant difference in the latency to reach reentrainment between vehicle-injected [7.66±1.08 (6) days] and melatonin-injected mice [12.6±1.77 (5) days, $p<0.05$] was observed suggesting that melatonin decreases the rate of reentrainment following an 8-hr advance of the LD cycle. The involvement of brain melatonin receptor sites modulating the circadian rhythm of locomotor activity will be further investigated by administration of luzindole (N-0774), a competitive melatonin receptor antagonist. Supported by MH 42922.

IN VIVO MICRODIALYSIS OF AMINO ACIDS IN THE SUPRACHIASMATIC NUCLEI. M.A. Rea, J.L. Blank*, S. Ferreira*, D. Terrian and J.D. Glass*., USAF Sch. of Aerospace Med., Brooks AFB, TX 78235, and Dept.Biol.Sci., Kent State Univ., Kent, OH 44242

Microdialysis probes were stereotaxically implanted in the suprachiasmatic nuclei (SCN) of male Siberian hamsters maintained under LD 16:8. Dialysate was collected every 20 min for 24-26 hrs and assayed for amino acids by HPLC. Pronounced diurnal rhythms were observed in glutamate (GLU) content of dialysates from two animals whose probes were located along the lateral border of the SCN. GLU rose during the latter half of the dark phase to peak within 2 hours after lights-on. Peak values were 1.56 and 0.87 nmol/ml and represent increases of 164% and 168%, respectively, over the mean concentration for the total sampling period. In one animal, a similar rhythm in glycine content was observed which peaked at lights-on. These rhythms were absent in a third animal whose probe was located 0.8 mm lateral to the SCN. Glutamine content fell steadily thoughout the collection period in dialysates from all animals. Aspartate content did not show rhythmicity and GABA was not detected. Supported by AFOSR-2312W6 (MAR) and BRSG SO7-RR-07208 (JDG).

293.11

N-ACETYLASPARTYLGLUTAMATE: A TRANSMITTER CANDIDATE FOR THE RETINOHYPOTHALAMIC TRACT? J.R.Moffett, L.Williamson, +M.Palkovits, and M.A.Namboodiri. Dept. Biology, Georgetown Univ., Washington, DC 20057 and +Lab. Cell Biology, NIMH, NIH, Bethesda, MD 20892.

The retinohypothalamic tract (RHT) is the neural pathway mediating the photic entrainment of circadian rhythms in mammals. The neurotransmitters which operate in this projection system have not yet been determined. Utilizing affinity purified antisera to N-acetylaspartylglutamate (NAAG), a neuron specific dipeptide which may act as an excitatory neurotransmitter, we have examined the levels of this peptide in the retinohypothalamic projection system. NAAG was found to be localized extensively in the RHT and all of its target zones including the suprachiasmatic nuclei. Optic nerve transections resulted in significant reductions in NAAG immunoreactivity in the suprachiasmatic nuclei and supraoptic nuclei. In addition, transection of the optic nerve resulted in a 55% decrease in NAAG levels in the suprachiasmatic nuclei as measured in tissue micropunches by a soluble RIA utilizing the same affinity purified antibodies (assay specificity: IC50 for NAAG = 2.5 nM, IC50 for NAA = 100 uM; assay sensitivity: 1-2 pg/assay). To date, no saturable high affinity binding sites for NAAG have been found in the nervous system raising the possibility that NAAG derived glutamate may be the neuroactive agent binding to postsynaptic receptors following release and enzymatic breakdown of the peptide within the synaptic cleft. The data presented are consistent with the idea that NAAG, or NAAG derived glutamate as opposed to free vesicular glutamate, may act as one of the neurotransmitters involved in retinohypothalamic communication. (Work supported by NIH Grant DK 37024).

NEUROTENSIN: LOCALIZATION IN THE HUMAN SUPRACHIASMATIC NUCLEUS. **E.T. Koh*, J. C. King, B. Tate-Ostroff, H.E. Albers and E. G. Stopa, (Spon: Lester Adelman) Dept. of Anesthes., U. Mass. Med. Ctr, Worcester, MA; Depts. of Anat. and Cell Bio, and Neurosurg., Tufts U. Sch. of Med, Boston, MA; Mailman Res. Ctr., McLean Hosp, Belmont MA; Dept. of Bio, Georgia State U., Atlanta, GA; and Dept. of Path, SUNY Health Sci. Ctr, Syracuse NY.**

The distribution of neurotensin-like immunoreactivity (N-LI) was examined in the human suprachiasmatic region.

Human hypothalami(n=12) were fixed by immersion in either 5% Acrolein (12-14 hours) or 10% NBF (7-10 days). The immunocytochemical procedures were performed on unmounted serial coronal sections (40-80 um) using a modified PAP technique.

Analysis of the distribution of reaction product observed by light microscopy was accomplished using Dr. Dean Hillman's Cellmate system. Comparisons made between computer-generated maps of alternate sections stained with Nissl, vasopressin antiserum, vasoactive intestinal peptide antiserum and neurotensin antiserum, confirmed that a large subpopulation of N-LI-containing cell bodies was present within the human SCN.

These data indicate that neurotensin-containing neurons are a major constituent of the human SCN and suggest that neurotensin may be an important mediator of human circadian rhythmicity. **(AG00295, AG02126, 1S10RR03442)**

293.13

PEPTIDE CO-LOCALIZATION: FUNCTIONAL SIGNIFICANCE WITHIN THE CIRCADIAN TIMING SYSTEM. H.E. Albers, S.Y. Liou* & R.T. Zoeller. Lab. Neuroendocrinol. & Behav., Depts. Biol. & Psychol., Georgia State Univ., Atlanta, GA 30303 & Dept. Anat., Univ. Missouri Med. Sch., Columbia, MS 65212.

Neurons within the suprachiasmatic nucleus (SCN) that contain both vasoactive intestinal peptide (VIP) and peptide histidine isoleucine (PHI) have been implicated in the control of circadian rhythms. VIP/PHI SCN neurons may also contain a third biologically active peptide, gastrin releasing peptide (GRP). The present study localized the mRNA encoding VIP/PHI and GRP within the SCN and examined the SCN function of these peptides. In situ hybridization studies revealed that VIP/PHI and GRP mRNA distribution within the SCN was nearly identical. Combined microinjection of VIP, PHI and GRP into the SCN region (N=39) phase delayed the circadian locomotor rhythm by >1.5 hrs when administered around the time of activity onset, but had no effect on circadian phase at other times of the circadian cycle. In the hypothalamic slice, VIP, PHI and GRP provided individually (10^{-7} M) produced a small excitatory response in SCN single units. In contrast, when all three peptides were provided together (10^{-7} M) a four fold greater excitation was observed. VIP, PHI and GRP appear to be co-localized in the SCN, and this co-localization may be functionally significant in the control of circadian rhythms. (Supported by ONR N00014-89-J-1640).

RUBIDIUM FUSES SPLIT CIRCADIAN RHYTHMS IN HAMSTERS. J.D. Hallonquist and N. Mrosovsky. Depts. of Psychiatry & Zoology, U. of Toronto, Toronto, Ont. M5S 1A1, Canada.

Abnormal circadian rhythms are reported in patients with mood disorders. Demonstration that an antidepressant normalizes atypical circadian function in animals would suggest that its clinical efficacy might reflect a similar mechanism. When hamsters are housed in bright constant light, the normally intact portion of a free-running circadian rhythm may split into 2 components which then stabilize at an abnormal phase relationship 12hr apart. Spontaneous fusing of split rhythms is extremely rare.

Male hamsters with split circadian activity rhythms were used as an assay for the chronotypic properties of the experimental antidepressant rubidium (Rb). The Rb group had RbCl (100mM) added to the drinking water for a period of 10wk, after which normal water was returned. The Control group received only normal water. Seven of the 12 hamsters that received Rb showed fusing of split rhythms, vs. none of the 7 Control hamsters ($p = 0.016$, Fisher Exact).

Rubidium may normalize atypical coupling between circadian rhythms by acting directly on the suprachiasmatic nuclei (SCN) or by reducing photic input to the SCN via the geniculo-hypothalamic tract. This first demonstration that an antidepressant drug can normalize a circadian anomaly in animals is consistent with a circadian dysfunction hypothesis of the etiology of some mood disorders.

293.15

EFFECTS OF ALCOHOL AND TRIAZOLAM ON THE CIRCADIAN ACTIVITY RHYTHM OF THE GOLDEN HAMSTER. J.E.Joy and F.W.Turek. Dept. Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Several reports in the literature have suggested that chronic ethanol can alter circadian rhythmicity in animals. In hamsters, single injections of the benzodiazepine, triazolam, cause phase advances or phase delays, depending on the time of injection. Since many of the neuropharmacological effects of ethanol appear to be mediated through the GABA-Benzodiazepine receptor complex, we decided to explore the effects of ethanol on circadian activity rhythms in the golden hamster, and further whether ethanol treatment influences the effect of triazolam on circadian rhythms. In Expt I, adult male hamsters were given 25% ethanol in their drinking water. All animals showed an increase in the period of their free-running activity rhythm (mean increase = 0.11 h +_ 0.03; n=8). Control animals, provided with tap water, did not show a significant increase in period (mean increase = 0.02 h + _ 0.02; n=11). In Expt II, a separate group of male hamsters was given 25% ethanol for 10d, after which they were injected with a sub-maximal dose of triazolam (0.5 mg/animal) at times that typically cause phase advances (CT 6) or at times that cause phase delays (CT 21). Chronic ethanol treatment lowered the sensitivity of the animals to triazolam for both injection times. This pattern is consistent with cross-tolerance observed in the behavioral effects of ethanol and benzodiazepines.

293.16

DIURNAL VARIATION IN BRAIN SEROTONIN IS DRIVEN BY THE PHOTIC CYCLE AND IS NOT CIRCADIAN IN NATURE. J.S. Ferraro and R.W. Steger*. Physiology Dept, Southern IL Univ, Sch of Medicine, Carbondale, IL 62901.

In an effort to determine the driving force of the diurnal variation of serotonin (5-HT) in the brain, over 500 Syrian hamsters were exposed to long photoperiods (LD14:10), short photoperiods (LD10:14), constant dark (DD) or constant light (LL) for 12 weeks. Hamster in LD conditions were sacrificed at three hour intervals; those in constant conditions were sacrificed around the clock. The circadian time (CT) of tissue collection, in the animals in constant conditions, was determined from the onset of locomotor activity (defined as CT12; the beginning of the subjective night). Following decapitation, the brains were removed and the median eminence were rapidly dissected free and frozen on dry ice. The remaining brain was also frozen and stored at -70°C. Within several weeks, the brains were allowed to thaw partially and the medial basal hypothalamus (MBH); anterior hypothalamus (AH) and olfactory bulbs (OB) were dissected from the brain and weighed. Tissue samples were homogenized and N-methylserotonin was added to each sample as an internal standard with which procedure-related amine losses could be estimated. 5-HT levels were determined by HPLC with electrochemical detection. In LD14:10 and LD10:14, 5-HT levels displayed significant diurnal variation in the MBH, AH and OB (ANOVA; $P<0.05$). The sine waves of the 5-HT rhythm were of similar amplitude and phase with relation to lights on (i.e., high 5-HT content during the day and low content at night, with a sharp rise occurring just after lights on). This variation, however, was not apparent in animals exposed to DD or LL; 5-HT content did not display a significant diurnal oscillation. Since 5-HT failed to oscillate in the absence of environmental time cues, the rhythm must be driven by the environment and not an internal circadian clock. Supported by NIH grant NS23128 (JSF) and NSF grant DCB-8619702 (RWS).

293.17

SEROTONIN AGONISTS ALTER PHOTIC RESPONSES OF NEURONS IN THE DORSAL AND VENTRAL LATERAL GENICULATE NUCLEI OF HAMSTERS. D.X. Zhang and B. Rusak, Dept. of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1.

Neurons in portions of the lateral geniculate nucleus (LGN) receive a retinal projection and project in turn to the suprachiasmatic nucleus, which functions as a pacemaker in the circadian system. This mechanism contributes to the regulation of circadian rhythms by photic cues. The LGN also receives a serotonergic projection from the raphe nuclei; we asked whether serotonergic agonists would affect the responses of LGN neurons to retinal illumination.

Neural activity was recorded using a multibarrel micropipette in the LGN of urethane-anesthetized Syrian hamsters. Responses to long light pulses were recorded extracellularly from single neurons in the dorsal and ventral LGN (including the intergeniculate leaflet) under baseline conditions and while serotonin (20 mM, 20-40 nA, 20-40 sec) or the serotonin type 1A receptor agonist, 8-OH-DPAT (2 mM), was iontophoresed onto the cell. Most cells showed reduced responsiveness to retinal illumination during drug applications. Some cells were also suppressed by the drug in darkness, but others that showed reduced responses to photic cues showed no change, or even an increase in baseline rates. The results indicate that the effects of serotonin agonists on LGN neurons are complex, and that the serotonergic raphe projection may modulate photic responses relevant to rhythm entrainment.

ORGANIZATION OF THE CAT INTERGENICULATE LEAFLET DEMONSTRATED BY NEUROPEPTIDE Y-IMMUNOREACTIVITY. J.C. Speh and R.Y. Moore, Depts. of Neurology and Neurobiology, SUNY, Stony Brook, NY 11794.

The intergeniculate leaflet (IGL) in rodents is a lateral geniculate component which receives a distinctive pattern of retinal innervation by retinal afferents (Hickey and Spear, 1976) and contains a population of neuropeptide Y-immunoreactive (NPY+) neurons. These neurons project via the geniculohypothalamic tract (GHT) to the suprachiasmatic nucleus of the hypothalamus and participate in circadian rhythm regulation. The terminals of the GHT have been demonstrated in the cat (Cassone et al, 1988) but the location and organization of the IGL has not been reported. In this study the IGL was demonstrated using NPY immunohistochemistry. NPY+ neurons are present in the lateral geniculate complex and adjacent thalamus. As the VLG forms rostrally, NPY+ neurons and axons are in the medial portion of the VLG adjacent to the DLG. A few NPY+ cells extend along the DLG border and the border of the VLG with the optic tract. These NPY+ cells are present in essentially the same location throughout most of the extent of the VLG. The major component of the IGL, however, is represented by a long band of neurons that extends from the medial VLG dorsally and rostrally along the lateral border of the diencephalon, medial to the optic tract and lateral to the internal capsule, extending into the zona incerta. Thus, the cat IGL is organized in a pattern that is very similar to rodents. Supported by NIH grant NS-16304.

PREVENTION OF LIGHT-INDUCED DISSOCIATED WHEEL-RUNNING ACTIVITY BY IGL LESIONS OF CHRONIC CLORGYLINE-TREATED SYRIAN HAMSTERS W. Duncan*, E. Sutin, W. Orem*, B. Gao*, P.G. Sokolove, T.A. Wehr* (SPON: O. Takahashi) Clinical Psychobiology Branch, NIMH, Bethesda, Md. 20892 & Dept. of Biological Sciences, U. of Maryland, Baltimore, Md.

In humans, chronic treatment with the antidepressant drug clorgyline (CLG), a type A monoamine oxidase inhibitor (MAOI), often results in a temporal disorganization of the sleep-wake cycle. We previously observed dissociated patterns of wheel-running in clorgyline-treated hamsters housed in continuous light (LL) but not in saline-treated controls. In order to identify the visual pathway that contributes to this light-induced disruption of running activity, CLG-treated hamsters were given sham (n=8) or bilateral (n=4) intergeniculate leaflet lesions (IGLx). Saline-treated (SAL) hamsters received sham (n=4) or bilateral (n=4) IGLx. All hamsters were tested in LL (40 μW cm-2). Two CLG-treated hamsters received complete IGLx as documented by the absence of immunohistochemical staining for the presence of neuropeptide Y (NPY) cell bodies in the IGL. These two animals exhibited intact patterns of wheel-running with tau=24 hours. Two CLG-treated hamsters received partial IGLx as evidenced by NPY-immunoreactivity in the IGL. One partially lesioned, CLG-treated animal exhibited an intact pattern of wheel-running; the other exhibited rhythm dissociation. All hamsters that received sham+CLG-treatment exhibited dissociated wheel-running. All sham+SAL-treated hamsters exhibited intact wheel-running patterns with tau>24 hours. All IGLx+SAL-treated hamsters received complete IGL lesions; these animals exhibited intact running patterns with tau=24 hours. The failure to dissociate seen in CLG-treated IGLx hamsters housed in LL suggests the retinogeniculohypothalamic tract (RGHT) participates in the dissociation response. We speculate that some of the sleep-wake cycle disturbances reported in depressed humans treated with MAOIs may be related to the interaction of MAOIs and light within or post-synaptic to the RGHT.

ALTERED PROTEIN EXPRESSION IN PERIOD MUTANT HAMSTERS. G.Johnson[1], J.E.Joy[1], M.R.Ralph[2], M.Menaker[2], and C.Merril[1]. [1]NIMH-St.Elizabeth's Hospital, Washington D.C. 20032, and [2]Dept.Biology, Univ. of Virginia, Charlottesville, VA 22901.

A genetic mutation that dramatically shortens the period of the circadian locomotor rhythm of golden hamsters has recently been reported (Ralph,M.R. and Menaker,M. Science 241:1225,1988). Wild-type animals have rhythms whose freerunning periods average about 24 hours, animals heterozygous for the mutant trait have periods of about 22 hours, while homozygous animals have rhythms with periods close to 20 hours. The pattern of inheritance of this mutation suggests that it has occurred at a single, autosomal locus.

Using high resolution two-dimensional gel electrophoresis, we have asked whether the expression of the mutant allele can be detected at the protein level. We have discovered a protein (Mr ~40 kd, pI ~6.5) that is present in brain samples of wild-type hamsters and undetectable in mutant animals. This protein is found in SCN tissue, as well as tissue from other areas of brain in wild-type hamsters. We are now in a position to characterize this protein, which may provide a new, molecular approach to the study of mammalian rhythmicity. (Supported in part my MH09483 to MRR and HD13162 to MM.)

AGE AT HEAD INJURY AND AGE AT FOLLOW-UP TESTING INDEPENDENTLY PREDICT LATER COGNITIVE DECLINE. T. J. Rosen* and S. Corkin (SPON: J. H. Growdon). Dept. of Brain and Cognitive Sciences, and Clinical Research Center, Mass. Institute of Technology, Cambridge, MA 02139.

Veterans of World War II with penetrating head injury (HI) incurred in young adulthood showed increased cognitive decline in later years relative to subjects with peripheral nerve injury (Corkin et al., in press). Aging increased exacerbated decline, but the prior paper did not determine whether the controlling factor was age at HI (range 18 to 33 years) or age at follow-up testing (range 54 to 72 years). The present report used multivariate analyses of the HI subjects' data ($N = 57$) to separate the consequences of age at injury from those of age at follow-up. A procedure analogous to factor rotation transformed the original, highly correlated age variables ($r = .90$) to new variables with a substantially lower correlation ($r = .26$). Multiple linear regression analyses predicting exacerbated decline from the new variables revealed that greater age at injury and greater age at follow-up testing separately contributed to exacerbated decline on a measure of general intelligence and on a block counting subtest. The association between greater age at injury and cognitive decline suggests that the characteristics of the brain at the time of injury affect repair processes, and that limited restorative processes in subjects who were older at injury make them more vulnerable to degeneration with the onset of old age. The association between greater age at follow-up testing and cognitive decline suggests that cognitive decline is a specific response to aging rather than a general response to the passage of time since the injury occurred.

IMPAIRED BODY PARTS LOCALIZATION WITH PRESERVED BODY REFERENCE SYSTEM A. Sirigu, J. Grafman, K. Bressler, T. Sunderland, (Spon. J. Grafman). Cognitive Neuroscience Unit, NINDS, NIH, Bethesda, MD 20892.

We studied body schema disturbances in a 62-year-old woman with diagnosis of Alzheimer's disease. She was severely impaired in tasks requiring her (1) to point at parts of her own body on verbal command, even though she correctly named the same parts when pointed at by the Examiner (Ex), or (2) to point on Ex's body (or a picture, or a doll) the corresponding part touched by the Ex on the patient's body. Performances were nearly normal in variations of these tasks, in which small objects attached to the patient's and Ex's bodies served as pointing targets. When tested for recall several days later, she pointed at the exact position of the objects. Yet, when we again attached the objects on her body, while requiring her to ignore their presence and point at different body parts, she performed very poorly.

The fact that the same point in "body space" is localized correctly when identified as an external object and erroneously when identified as a body part contradicts the idea of the body schema as a unitary function. Learning the position of objects on the body surface requires an intact body coordinate system on which to map this information. Why then, can't such a body reference system be used to localize the position of its component body parts? The paradox raised by this dissociation suggests that different processing and/or representational systems, with possibly distinct neural correlates, may contribute to orientation towards one's own body.

294.3

TEMPORAL ORDER INFORMATION IN NORMAL SUBJECTS AND PATIENTS WITH DEMENTIA OF THE ALZHEIMER'S TYPE. J. Madsen* and R.P. Kesner (SPON: B. Grosser). Department of Psychology, University of Utah, Salt Lake City, Utah 84112.

The purpose of the study was to evaluate the efficacy of temporal processing in college students, normal, older adults and older adults with mild to moderate dementia. A test for order memory was administered on a MacIntosh computer. There were 56 trials with two phases within each trial. During the study phase, a series of eight X's appeared on the screen. During the test phase, two X's from the study phase sequence appear simultaneously in their original locations. The subjects were asked to make a recency judgment. On a random basis the number of items between test items (lag) was varied. Lags from 0-6 were selected for the test. Results indicate that college students performance improves as lag increases. The performance of older adults is similar but slightly less accurate. Mildly demented subjects performed at chance levels for all lags but 5 and 6. Moderately demented subjects were chance levels for all lags. It is believed that at the time of the study phase, contextual cues are not encoded with much flexibility by the mildly demented subjects, hence, their inability to discriminate between contexts at the time of the test except for the longest lags.

294.4

FROM COVERT TO OVERT RECOGNITION OF FACES IN A PROSOPAGNOSIC PATIENT. J. Sergent & M. Poncet*. Montreal Neurological Institute, Montreal, Canada, and Hôpital La Timone, Marseille, France.

Prosopagnosia is an inability to recognize known persons as a result of a failure to access relevant memories through the inspection of their faces. The nature of this disturbance, and the fate of memories related to faces, were investigated in a long-standing prosopagnosic woman. An examination of her perceptual capacities indicated no major impairment at maching faces, including different views of the same faces, and multidimensional scaling analysis showed that she could achieve configurational representations of faces as do normal subjects. In spite of her inability to evoke memories of persons from their faces, she displayed clear evidence that she could use pertinent memories related to these faces in tasks that did not explicitly call for their evocation. This covert recognition of overtly unrecognized faces was observed in perceptual, learning, and cued-recognition tasks. Because these findings suggest preserved semantic knowledge about unrecognized faces, attempts were made at surmounting this blocked activation of pertinent memories. Some of these attempts were successful in inducing the patient into experiencing a sense of familiarity with the faces and identifying them on her own, for the first time since the onset of her illness more than 15 years ago. These findings suggest that (1) failure to recognize faces may occur in spite normal configurational encoding of facial representations, (2) covert recognition of overtly unrecognized faces requires the integrity of perceptual processes, (3) prosopagnosia may occur despite preserved knowledge related to faces, (4) this patient's failure of overt face recognition reflects a deficit in activating these pertinent memories about faces which thus remain meaningless.

A Self-Rating Scale for Both Poles of Affective Illness. Edward Dewees*, Mark Bauer, Paul Crits-Christoph*, William Ball, Thomas McAllister*, Jon Cacciola*, Peter Whybrow, Peter Alahi*. Dept. Psychiatry, Univ. Pennsylvania, Philadelphia, PA 19104

While many self-rating scales exist for the assessment of depressive symptoms, to our knowledge none have been well validated for the assessment of manic and hypomanic symptoms. The Internal State Scale (ISS) consists of 18 self-report visual analogue scale items based on the premise that a high energy, or activated, state comprises the core symptoms of mania, regardless of dominant subjective mood. The ISS has been given to 14 manics (M), 12 depressives (D), and 12 controls (C). Items were divided a priori into 3 subscales which exhibited good inter-item reliability (alpha=0.81-0.90) in M,D, and C, and good test-retest reliability in C. The mania subscale differs as expected across groups (M>D=C) and is well correlated with the clinician-administered Young Mania Scale (r= 0.62). The well-being subscale differs as expected across groups (D<M=C) and is well correlated with the Hamilton Depression Scale (r= -0.79). Discriminant function analysis using these two scales correctly classifies over 80% of M, D, and C.

PSYCHOTIC SYMPTOMS WITH LEFT HEMISPHERIC AND BITEMPORAL DYSFUNCTION IN EPILEPTICS. D. Lacroix and J.M. Saint-Hilaire*. Département de Psychiatrie et Service de Neurologie, Hôpital Notre-Dame, Université de Montréal, Montréal, Canada, H2L 4M1.

The object of this study was to determine if the presence of psychotic symptoms could be correlated to a specific localization of an epileptogenic focus (EF), of interictal spiking activity and of slow wave activity in epileptic patients who underwent EEG assessment of seizures using depth electrodes or prolonged scalp recordings. Psychotic symptoms were quantified using a modified Brief Psychiatric Rating Scale with the rater blind to the localization of dysfunctions.

Preliminary results indicate increased psychotic symptoms: 1- if slow wave or interictal spiking activity was localized in the left frontotemporal, temporal or bitemporal regions as opposed to the right hemisphere; 2- if the EF or slow wave activity was localized exclusively in the left hemisphere and 3- if the EF was localized in the left amygdala, hippocampus and adjacent T2 temporal cortex as opposed to an EF localized in the other brain areas, including a bitemporal EF. These results support the hypothesis of a left hemispheric and/or bitemporal dysfunction in psychosis.

294.7

TEMPORAL ORDERING DEFICITS IN SCHIZOPHRENIA. B. L. Schwartz*, L. H. Deutsch*, C. Cohen*, and S. I. Deutsch* (SPON:E. Parker). Psychiatry, Veterans Administration Medical Center, Washington, D.C. 20422

Several lines of evidence suggest that cognitive deficits in schizophrenia are associated with abnormalities in the frontal lobe. This study used the recency judgement task, which has been found to be sensitive to frontal lobe dysfunction, to compare 16 schizophrenic patients and 16 normal controls. Each subject viewed a list of word pairs. In the recency judgement task, the subject was shown a test pair containing two previously presented words and was asked to choose which word was presented more recently. In addition, recognition memory was tested with pairs containing one old word and one new word. Schizophrenic patients were impaired on the recency judgement task, but not on the recognition task. In particular, patients showed deficits in judging the recency of words that occurred on the immediately preceding trial, whereas they were not impaired in recognizing these words. A selective deficit in memory for temporal ordering may provide further evidence of frontal lobe dysfunction in schizophrenia.

D-AMPHETAMINE IMPROVES MENTAL PERFORMANCE & RAISES BODY TEMPERATURE AFTER 48 HOURS WITHOUT SLEEP. H. Sing*, D. Thorne*, M. Thomas*, N. Shepanek*, M. Rankin*, C. Galinski*, A. Schelling*, D. Penetar*, J. Fertig, P. Newhouse, & G. Belenky. Dept. of Behavioral Biology, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Thirty-six normal male volunteer humans subjects were given placebo, 5, 10, or 20 mg d-amphetamine sulfate after 48 hours of total sleep deprivation. d-Amphetamine produced dose-dependent increases in alertness (Multiple Sleep Latency Test & Stanford Sleepiness Scale), mental performance (serial add & subtract, choice reaction time, logical reasoning) and mood (Profile of Mood States). The high dose (20 mg) returned these parameters to baseline values. d-Amphetamine also produced a dose-dependent increase in body temperature. At the high dose, temperature significantly exceeded baseline values. d-Amphetamine's normalization of performance during sleep deprivation may be accompanied by hypermetabolism.

SHORT TERM CHANGES IN THE NEUROMAGNETIC EVOKED FIELD. G. W. Lewis, L. J. Trejo,* M. Inlow,* & M. H. Blankenship.* Navy Personnel Research and Development Center, San Diego, CA 92152.

We have been using neuromagnetic visual evoked fields (VEF) to assess brain processing with the goal of improved prediction of job performance. As compared to visual evoked potentials, short-term changes in the VEF are not clearly understood. We find that changes in average VEF amplitude occur within the first 18 trials of a series. Using a single channel DC SQUID system, VEF recordings were obtained from 15 male subjects (aged 21 +/- 2 yrs) at sites O1 and O2 (10/20 system). Checkerboard stimulus luminance averaged 34 nits, subtended 5 degrees and had spatial frequency of 1.3 c/degree. VEFs were averaged in 3 blocks of 6 epochs each for a total of 18. Inter-stimulus interval averaged about 1.75 sec. The VEF data were divided into 10 post-stimulus windows of 50 msec width, rms amplitude obtained, and submitted to analyses of variance. Substantial differences were observed between the first block and the last two blocks of trials. Site differences were significant during the first block, but were not significant during the second and third blocks. Differences between windows were significant during the first and second blocks, but were not significant during the third block. Variability was lowest in windows 3 and 4 (100-200 msec), where field reversals are often observed with these stimuli, and was highest later in the VEF (> 350 msec). These VEF changes, occurring over a few seconds, may reflect short term brain adaptive changes such as habituation, or may infer decay of an orienting response. This abstract does not necessarily reflect the views of the Navy Department.

294.10

EFFECTS OF VOLUME AND LOCUS OF BRAIN LESIONS ON NEUROPSYCHOLOGICAL PERFORMANCE IN HUMANS. E. Turkheimer*, R. A. Yeo*, Presty, S. K. and E. D. Bigler*. Dept. of Psychology, University of Virginia, Charlottesville, VA 22903.

In a common research design in human neuropsychology, brain-damaged patients are grouped according to location of lesion, and performance on a measure of functional deficit is compared among groups. Although it is widely recognized that lesion volume is an important determinant of severity of deficit, the absence of a model of how lesion volume combines with lesion locus to produce deficits has inhibited the development of methodological and statistical procedures for studying naturally occurring lesions in humans. We propose such a unified model, which predicts that the basic manifestation of localization of function is as a statistical interaction between lesion location and volume in the prediction of neuropsychological deficit. The model is then applied the neuropsychological performance of a sample of patients with naturally occurring unilateral lesions. Results demonstrate that the interaction between lesion volume and location is more important that the main effect of either in the determination of degree of deficit.

294.11

REACTION TIMES DIFFER WHEN HUMANS AND MONKEYS MAKE HAND MOVEMENTS IN RESPONSE TO VISUAL AS COMPARED TO VIBRATORY CUES. V. D. Douglas*, C. A. McCandlish and R. J. Nelson (SPON: M.E. Michel). Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, 875 Monroe Avenue, Memphis, TN 38163.

Reaction times were determined for Rhesus monkeys and human subjects who made identical wrist flexion and extension movements in response to either vibratory or visual cues. Vibratory cues consisted of palmar vibration (low-amplitude sine wave at 27, 57 or 127Hz) delivered to the control handle of the apparatus. Changes in the display that signaled the wrist position served as visual cues. Visual and vibratory-cued trials were presented randomly in blocks of ten trials requiring the same movement in response to the sensory cues. Human subjects initiated movements approximately 50-80 ms sooner in response to vibratory as compared to visual cues (Vib. Mean RTs= 187-294ms; Visual Mean RTs=212-345ms). The differences in reaction times for the same movements to these cues increased with subject age. These differences were correlated with improvements by the older subjects during vibratory-cued trials, as measured by a decrease in the reaction times, whereas the reactions times for visually cued trials remained consistent as a function of subject age. Monkeys also showed differences in reaction times for vibratory as compared to visually-cued trials, which were 80-100 ms less for the former (Vib. Mean RTs= 186-264ms; Visual Mean RTs=269-360ms).

These findings of the normal reaction times for movements made in response to different sensory stimuli provide a framework that may be used to assess the extent of motor dysfunctions in human subjects and primates. As well, these data suggest that vibratory stimuli may be optimally used in sensory processing, especially in instances when movements must be made as quickly as possible or when auditory or visual cues may interfere with ongoing communication or attentive visual fixation. This study met NIH animal utilization guidelines.

THE QUADRIMENTAL BRAIN MODEL AS A NEUROSCIENCE WORKING HYPOTHESIS. B.E.Morton. Dept. of Biochem. and Biophys., Univ. of Hawaii Sch. of Med., Honolulu, HI 96822.

This model extends MacLean's Triune Brain concept to produce a framework for structure-activity explanations accounting for human behaviors previously not understood.

THE REPTILIAN SYSTEM (includes striatum, cerebellum, stem, autonomic system, site of Id): Maintains internal homeostasis by using body to conquer territory for food, shelter, and reproduction. Striatum does same-difference matching of sensory data with cerebellar memory to identify self and external objects. Maximizes immediate survival.

THE LIMBIC SYSTEM (includes emotions, site of Ego): Searches memory for the survival outcome of earlier-similar encounter, concludes same will repeat, produces approach-avoidance emotion motivators and adaptive responses.

LEFT HEMISPHERIC SYSTEM (site of usual consciousness and Intellect): Does serial, reductionistic, abstract data analysis upon which "intelligence", language, science, and civilization depend. Mostly unaware of mental activities of the three other brain elements, rationalizes their behavior as if they were its own. It can confabulate.

RIGHT HEMISPHERIC SYSTEM (includes Superego): Makes parallel, space-time global projections of worst-best survival outcomes. These produce insight and creativity. It values cooperation and deferred rewards. From these come conscience, morality, and wisdom. In conflict with immediate, selfish reptilian drives within or from others.

294.13

RELATIONSHIP BETWEEN SERIAL AND PARALLEL VISUAL SEARCH AND TARGET DISCRIMINABILITY. B. S. Oken and P. Stern*. Dept. of Neurology, Oregon Health Sciences University, Portland, OR 97201.

Prior research has posited 2 models of visual search; a preattentive, parallel and a more attention-requiring, serial process (Treisman, A., Psych. Rev., 95:15-48, 1988; Julesz, B., Trends Neurosci., 7:41-45, 1984). The factors that determine which of the 2 processes predominates in a given visual search task were examined in a series of experiments. Two-choice reaction times were obtained following presentation of several series of visual stimuli to 24 subjects. The subjects were instructed to determine whether or not a given target image was present on a screen that contained 2, 6, 10, 20, or 30 distractor images. Target discriminability was operationally defined by creating distractors that differed by varying degrees from the targets in either color or shape. In some series, the target was a unique conjunction of the features.

Response accuracies did not vary significantly across tasks. In easy target discrimination series, the reaction time to detect the presence of a target did not increase with increasing numbers of distractor stimuli. The slope of the reaction time - number of distractors correlation gradually increased as the target-distractor discrimination was made more difficult. The slopes of the correlations between the reaction time to detection of no-target condition (distractors only) and the number of distractors were consistently greater than those in the target present condition, but similarly varied with difficulty. Lastly, the slopes were modifiable by task repetition. It is postulated that the major determinant of which visual search process predodominates in a given task relates to the difficulty of the target discrimination.

NEUROPSYCHOLOGICAL DIFFERENCES BETWEEN HOMOSEXUAL MALES AND HETEROSEXUAL MALES AND FEMALES. C.M. McCormick and S.F. Witelson, Dept. of Psychology and Dept. of Psychiatry McMaster University, Hamilton, Canada, L8S 4K1.

Studies of certain clinical populations exposed to atypical levels of prenatal sex hormones indicate these people to show atypical patterns of cerebral asymmetry, cognitive skills, and sexual orientation (e.g., higher prevalence of left-hand preference and homosexuality in CAH females). In a study of homosexuals, we reported a higher prevalence of left-hand preference in homosexual females and a trend in homosexual males compared to the general population (McCormick et al., 1987, Soc Neur, 13). We suggested an association among prenatal sex hormones, sexual orientation, and cerebral asymmetry. In the present study, we investigated other neuropsychological measures in homosexual males compared to matched groups of heterosexual males and females. Subjects completed tests of spatial and verbal ability, and a dichotic test of hemispheric asymmetry. Homosexual males showed significant differences on cognitive tests compared to heterosexual males, and their mean scores typically fell between those of heterosexual males and females. On the dichotic test, homosexual males of each hand preference group showed a different pattern of asymmetry. However, in each case the homosexual males were reversed compared to the heterosexual males. We interpret the associations among sexual orientation, cognitive skills, and cerebral asymmetry in terms of sexual differentiation of the brain.

THREE-DIMENSIONAL RECONSTRUCTION OF THE HUMAN BRAIN. J.S. George, P.S. Jackson,* D.M. Ranken * and E.R. Flynn. Neuromagnetism Laboratory, Life Sciences and Physics Divisions, MS M882, Los Alamos National Laboratory, Los Alamos, NM, 87545.

We have developed procedures for 3-dimensional reconstruction of the human brain from magnetic resonance imaging (MRI) data. The basic structure of the model is a discrete Cartesian space. Logical resolution within the space is typically 32 planes of 256x256 elements (i.e. the resolution of an MRI tomographic series). The thickness of a plane is set equal to the MRI slice interval. 12 or 16 bit data provided by the MRI system is first compressed to 8 bits per pixel for display and may be further compressed to 4 bits (16 grey levels). This allows a representation of the original image data to be stored within a single byte volume element (voxel) while allowing 16 anatomical tag values for the voxel. Voxels are classified using image processing routines. A seed point and tag value identifying a structure are specified by the user, and the system tags all contiguous points satisfying intensity or contrast criteria. Our algorithms extend this 2-D "flood" procedure throughout the volumetric data structure. For 3-D rendering of an anatomical unit, the system can interrogate the model to identify all voxels on the surface of a designated structure. Shaded 3-D images can be calculated from any viewing angle, using microcomputer resident software or high performance hardware systems. The use of a volumetric model will allow neuroelectric source models to incorporate realistic head geometry and model fitting procedures to employ anatomically constrained source configurations.

AUTOMATED PERFORMANCE TEST SYSTEM (APTS): ASSESSMENT OF ENVIRONMENTAL HAZARDS ON HUMAN BRAIN FUNCTION. W. Dunlap†, R. Kennedy*, N. Lane*, J. Turnage*, and C. Latimer. Essex Corporation, Orlando, FL 30803.

Recent efforts have focused on development of computer-based neurobehavioral tests for assessment of the effects of environmental hazards on sensory, cognitive, and neuromuscular performance in man and in animal models. The neuropsychological test battery developed for assessment of human brain function has been designated as "Automated Performance Test System" (APTS) and includes: (1) visual pattern comparison, (2) visual search and code substitution, (3) associative and visual-spatial recognition; manikin spatial transformation, (4) short-term memory, (5) grammatical reasoning, and (6) preferred and nonpreferred hand finger tapping. The specific aims of this study were to examine the effects of various concentrations of ethanol, radiation-chemotherapy, and doses of different drugs on neurobehavioral performance. Significant dose and treatment dependent differential decrements were observed in visual, perceptual information processing, memory, reasoning and neuromuscular performance. The neuropsychological assessment indicated that the transient, subtle, and differential decrements of environmental treatments on neurobehavioral performance can be evaluated by APTS with precision, reliability, and reproducibility.

EFFECTS OF ATTENTION ON THE DETECTION OF VIBROTACTILE STIMULI IN MAN. L.J. Post* and C.E. Chapman. Centre de recherche en sciences neurologiques and Ecole de réadaptation, Université de Montréal, Montréal, Canada.

It has long been known that attention exerts a significant effect on the perception of visual and auditory stimuli. When attention is directed towards a particular stimulus modality, detection abilities are enhanced and reaction times (RTs) are reduced. As little is known regarding the effects of attention on the perception of somatosensory stimuli, this study was conducted to determine the magnitude of effect that attention exerts on the ability to detect vibrotactile, as compared to visual, stimuli.

Subjects (N=11) observed a panel containing 3 LED arrays. In a correctly signalled trial, the illumination of the green or red array indicated to which modality (vibrotactile or visual) subjects should direct their attention in the upcoming trial. A "no" signal trial occurred when both indicator arrays were illuminated, instructing subjects to divide their attention equally between the two modalities. A few incorrectly signalled trials were also presented. Subjects were instructed to respond, with a foot pedal press, as quickly as possible to the stimulus. The vibrotactile stimulus consisted of any of 3 suprathreshold intensities, delivered via an Optacon, to the right index finger; the illumination of the third LED array served as the visual stimulus.

Pooled data indicated that for both vibrotactile and visual stimuli, RTs were significantly shorter when the subject's attention was directed to the correct modality ($p<0.01$). In addition, RTs were significantly longer with weak, as compared to strong, vibrotactile stimuli ($p<0.01$). These findings suggest that detection abilities are improved when attention is directed to the somatosensory stimulus and that the influence of attention is greater on weak, than strong, somatosensory stimuli. Supported by the Canadian MRC and the FRSQ.

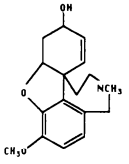
ANALYSIS OF FACTORS UNDERLYING UNILATERAL SPATIAL NEGLECT (USN). C.M. Butter, N. Kirsch* and G. Reeves*. Depts. of Psychology and Physical Medicine and Rehabilitation, University of Michigan, Ann Arbor, MI 48109.

Two factors thought to contribute to USN are deficient orienting to the neglected side and overactive orienting to the unneglected side due to disinhibition of the intact cerebral hemisphere. The contribution of the first factor was demonstrated by the finding that neglect shown by patients with right cerebral infarcts in a line-bisection task was consistently reduced by left-sided dynamic stimuli. We chose these stimuli because they activate the right superior colliculus, a component of the orienting system that is intact in these patients. Left-sided dynamic stimuli were more effective in reducing left USN than were the same stimuli presented in the center of the display (to control for their general alerting effects) or left-sided static stimuli. Furthermore, left-sided dynamic stimuli were as effective in reducing neglect in patients with left hemianopia as in those without this condition. The role of the second factor was shown by the beneficial effect on line-bisection of patching the right eye of patients with left USN, a procedure that blocks direct retinal input to the superior colliculus of the intact (left) hemisphere. This benefit was less consistent and smaller than that of dynamic left-sided stimuli. Combining the two procedures led to greater benefits than either procedure alone; thus, both deficient leftward orienting and overactivity of the left hemisphere appear to contribute to left USN.



295.1

THE EFFECTS OF GALANTHAMINE ANALOGUES ON CORTICAL ACETYLCHOLINESTERASE (AChE) ACTIVITY.

J. E. Sweeney, S-H Yeop*, M.M. Joullié* and J. T. Coyle. Depts. of Neuroscience and Pharmacology. Johns Hopkins Univ., Baltimore, MD 21205 and Dept. of Chemistry. Univ. of Pennsylvania, Philadelphia, PA 19104.

We have previously shown that galanthamine attenuates performance deficits in basal forebrain lesioned mice, inhibits AChE in cortical homogenates with an IC_{50} of 410 nM and increases cortical acetylcholine levels by 55% one hour after i.p. injections (Sweeney, J.E. *Pharmacol. Biochem. Behav.*, in press). Using structure-activity relationships, we now demonstrate which portions of the molecule are critical for galanthamine to bind competitively to the AChE molecule. Several structural analogues inhibit cortical AChE more potently than galanthamine.

GALANTHAMINE

Alterations of the allylic hydroxyl group result in a severe decrease in the drug's ability to inhibit cortical AChE. Conversion of the hydroxyl group to an acetoxy function, to a butyl or naphthyl carbamate group, or to a semicarbazone moiety (after oxidizing the hydroxyl to a ketone) severely reduces, by 1-2 orders of magnitude, the inhibitory activities of these compounds as compared to galanthamine. O-demethyl galanthamine is a considerably more potent inhibitor of cortical AChE than galanthamine with an IC_{50} of 80 nM. Benzyl bromide and methiodide salts of galanthamine are slightly more potent inhibitors of AChE than galanthamine.

These data indicate that the hydroxyl, tertiary N, and O-methyl are critical for binding to AChE. Furthermore, these findings have implications for the design of drugs which may be used for the treatment of Alzheimer's disease. Testing the behavioral effects of several of these analogues is currently in progress.

295.2

SPATIAL WORKING MEMORY ENHANCEMENT BY NICOTINE OF AGED LONG EVANS RATS IN THE T-MAZE

E. Cregan*, J.M. Ordy, E. Palmer, J. Blosser, T. Wengenack*, and G. Thomas, Fisons Pharmaceuticals, Rochester, NY 14623; Univ. Roch, Rochester, NY 14642.

Degeneration of basal forebrain cholinergic neurons has been correlated with memory dysfunction in senile dementia of Alzheimer's type, SDAT. Thus far, primary focus has been on loss of muscarinic receptors. Recent binding studies have shown loss of cortical and hippocampal nicotinic receptors in SDAT. Other studies have shown nicotine enhancement of memory dysfunction in SDAT and in monkeys. Nicotine enhancement of memory dysfunction has not been reported in aged animal models of SDAT. Specific aims of this study were to evaluate the effects of 0.1 and 0.4 mg.kg, s.c., of nicotine on spatial working memory and performance of 36-42 mo. old Long Evans (LE) rats in the T-maze. Compared to middle aged 24 mo. old LE rats, there was a significant impairment of memory of aged LE rats. Compared to saline, 0.1 and 0.4 mg/kg of nicotine significantly improved spatial working memory of aged LE rats, without effects on start, choice, and goal speed performance in the T-maze. The results indicated that nicotine enhanced memory impairments in aged LE rats serving as animal models of SDAT.

295.3

CHARACTERIZATION OF NOVEL MUSCARINIC AGONISTS, 1-OXA-8-AZASPIRO[4.5]DECANE DERIVATIVES IN BIOCHEMICAL AND BEHAVIORAL STUDIES.

F.Wanibuchi, S.Usuda, T.Konishi, M.Harada, M.Terai, K.Hidaka, S.Tsukamoto*and T.Tamura(SPON:K.Inoue) Central Res. Labs., Yamanouchi Pharmaceutical Co.,Ltd., Miyukigaoka 21 Tsukuba-city, Ibaraki 305, Japan.

A presynaptic cholinergic hypofunction with no change in the number of postsynaptic M_1 receptors (R) in Alzheimer's disease suggests that M_1 agonists are possible therapeutic agents. We synthesized novel muscarinic agonists, 1-oxa-8-azaspiro[4.5]decane derivatives, YM796 (2,8-dimethyl-3-methylene) and YM954 (2-ethyl-8-methyl-3-oxo). These compounds inhibited ^{3}H-pirenzepine binding to rat cerebral cortical membranes like putative M_1 agonists, RS86 and AF102B in the micromolar range and weakly inhibited ^{3}H-QNB binding to cerebellar membranes. YM796, YM954 and RS86 stimulated phosphoinositide (PI) hydrolysis in hippocampal miniprisms which is mainly linked to M_1-R but AF102B did not. YM796 (0.031 mg/kg,po) and YM954 (0.016 mg/kg,po) reversed the cognitive impairment in nucleus basalis magnocellularis-lesioned rats in a passive avoidance task, being more effective than RS86 and AF102B. YM796 was weaker than YM954 and RS86 in the induction of mouse tremor which are mainly mediated by M_2-R. These results show that YM796, YM954 and RS86 have M_1 agonistic activity and that YM796 has relatively weak M_2 agonistic activity. We are now carrying out further studies with (-)- and (+)-isomers of YM796.

295.4

EFFECTS OF TACRINE ON COGNITIVE PERFORMANCE IN MICE AND MONKEYS.

E. Schwam, G.P. Vincent, L. Rumennik and J. Sepinwall. Department of Neurobiology and Obesity Research, Hoffmann-La Roche Inc., Nutley, N.J. 07110.

Tacrine (THA), an anticholinesterase, is in clinical trials in Alzheimer's Disease. It enhanced cognitive performance in rodents (Fitten et al., In: Cur. Res. Alz. Ther. Ed.: Gaicobini and Becker, 1988) but produced equivocal effects in monkeys (Bartus and Dean, ibid.). In our Morris water maze procedure in mice, THA significantly improved acquisition by decreasing the latency to find a hidden platform (0.003-0.1 mg/kg, ip and 0.3-3 mg/kg, po using a 30 and 60 min pretreatment times (pts), respectively). The peak active doses of 0.01 mg/kg, ip and 1 mg/kg, po enhanced acquisition from 5-60 min and 5-90 min, respectively, but not at longer pts. In a subchronic study, a dose inactive after acute administration (0.001 mg/kg, ip) enhanced acquisition after 3 days of administration, with a duration of action of at least 48 hours. When proximal maze cues were removed and only distal room cues were available, the acquisition deficit exhibited by C57BL/10 mice was reversed by a dose of 1 mg/kg, po. In squirrel monkeys in repeated acquisition and short-term memory (delayed match-to-sample) procedures, 0.03-3 mg/kg, po, 20 min pt, failed to enhance performance, with deficits on some measures evident at 1 and 3 mg/kg. In conclusion, the cognition-enhancing effects of THA appear to be species and/or task specific.

295.5

NICOTINIC ENHANCEMENT OF DELAYED MATCHING BY MONKEYS IS SPECIFIC TO THE MOST DIFFICULT PROBLEMS.

W.J. Jackson and J.J. Buccafusco. Depts. Pharmacology & Toxicology and Physiology & Endocrinology, Medical College of Georgia and Veterans Administration Medical Center., Augusta, GA 30912

We previously reported that nicotine enhanced a delayed matching task specifically during trials involving long delays which were near the limit of performance capabilities in monkeys (Life Sci 43:277, 1988). The present study extends these observations by examining additional facets of matching performance. For example, we have demonstrated that in addition to length of delay, stimulus variables also contribute to the difficulty of individual trials. For each monkey, the order of difficulty represented by various stimulus configurations was determined. We observed the nicotine-mediated (2.5-10 μg/kg, i.m., 15 min prior to test session) enhancement to be greatest for those trials in which the longest delay and the most difficult stimulus configurations were coincident. The enhancement for these most difficult trials exceeded the enhancement associated with the overall session by a factor of almost 5. Nicotine also lengthened the latency of the choice responses, perhaps indicating that the monkeys were more "deliberate" about their choices when influenced by nicotine. This nicotine-induced apparent memory enhancement was still evident in several animals when tested on the day following the injection. These results support the concept of pharmacological exploitation of central nicotinic receptors in diseases involving memory deficits, e.g., Alzheimer's Disease. Supported by the Smokeless Tobacco Research Council.

295.6

FACILITATION OF HIPPOCAMPAL ACETYLCHOLINE SYNTHESIS BY GLUCOSE: CONTRIBUTION TO THE ACTION OF GLUCOSE ON MEMORY.

C. MESSIER, T. DURKIN, O. MRABET and C. DESTRADE. Lab. de Psychophysiologie, U.A. CNRS n° 339, Université de Bordeaux I, 33405 Talence CEDEX, FRANCE.

The effect of a 3 g/kg glucose injection on the velocity of the sodium-dependent high affinity choline uptake mechanism in the hippocampus was measured in resting mice or in mice immediately after training in an operant bar pressing task. Glucose did not significantly change high affinity choline uptake in resting animals. High affinity choline uptake in the hippocampus was increased by training in the operant bar pressing task. Glucose significantly reduced the increase of high affinity choline uptake observed in the trained animals. Similarly, a 3 g/kg glucose injection also reduced the high affinity choline uptake increase observed in animals injected with 1 mg/kg scopolamine. Finally, a 3 g/kg glucose injection significantly attenuated the amnesia produced by a post-training 1 mg/kg scopolamine injection in mice trained for an operant bar pressing task. These results provide additional evidence for an action of glucose on hippocampal cholinergic activity under conditions of high ACh demand. This action may be mediated via an increase in acetyl coenzyme A availability, one of the precursors of acetylcholine. This facilitative effect of glucose on hippocampal acetylcholine synthesis may constitute the physiological basis for its facilitative action on memory and its attenuation of scopolamine amnesia.

295.7

HOE 065, A COMPOUND STRUCTURALLY RELATED TO ACE INHIBITORS INCREASES ACETYLCHOLINE METABOLISM IN RAT BRAIN. G. Wiemer*, R. Becker*, H.J. Gerhards*, F.J. Hock and H. Urbach* (SPON: R. Hess). HOECHST AG, P.O.B. 80 03 20, 6230 Frankfurt/M. 80, FRG.

Previously we have reported that the lipophilic inhibitor of the dipeptidyl-carboxypeptidase (ACE) Hoe 288 improves cognitive functions in rodents. This effect is accompanied by an increased metabolism of acetylcholine (ACh; Usinger, P., Drug Develop. Res., 14: 315, 1988).

Although Hoe 065 - a prodrug of the ACE inhibitor Hoe 498 (Ramipril) - exerts no significant influence on plasma ACE or blood pressure in SHR the compound beneficially modifies performance in mice and rats as well as increases cholinergic transmission in different brain areas of the rat. 0.03 - 30 mg/kg i.p. or p.o. of Hoe 065 acutely caused a fall in brain ACh, increased the capacity of the high affinity choline uptake and the activity of the choline acetyltransferase without influencing the activity of the cholinesterase. An elevation of brain cyclic GMP was concurrently observed.

It is concluded that these effects are not necessarily related to an inhibition of the degradation of angiotensin I as can be assumed from the action of ACE inhibitors.

295.8

BEHAVIORAL EFFECTS OF HOE 065, A COMPOUND STRUCTURALLY RELATED TO ACE-INHIBITORS. F.J. Hock, H.J. Gerhards*, G. Wiemer*, W. Rüger* and H. Urbach*. HOECHST AG, P.O.B. 80 03 20, D-6230 Frankfurt/M. 80, FRG.

Over the past decade a large number of peptides has been detected in the CNS with putative function in motivational, memory and learning processes. Since the activity of dipeptidyl carboxypeptidase EC 3.4.15.1 (angiotensin converting enzyme, ACE) was found to be elevated in several brain regions of Alzheimer's disease patients we tested the behavioral effects in mice and rats of a compound which is structurally related to ACE-inhibitors. The new compound Hoe 065; n-octyl 2-/N-/(S)-1-ethoxycarbonyl-3-phenylpropyl/-L-alanyl/-(1S, 3S, 5S)-2-azabicyclo-/3.3.0/octane-3-carboxylate maleate salt was found to be highly potent in several behavioral tests.

In the up-hill avoidance test with rats Hoe 065 caused a significant enhancement of the up-hill response after scopolamine treatment. The reduction of the step-through latency after scopolamine in an inhibitory avoidance test with mice was tested. Hoe 065 caused a significant enhancement of the step-through latency with a minimal effective dose of 0.03 mg/kg i.p. In the 8-arm radial maze rats were required to find food pellets. Hoe 065 antagonized the impairment after scopolamine treatment significantly.

295.9

CHOLINERGIC MANIPULATIONS AND PASSIVE AVOIDANCE IN THE RAT: STATE DEPENDENCY AND ACQUISITION TO CRITERION. W. Jeffrey Wilson & Jennifer C. Hall. Dept. of Psychological Sciences, Indiana - Purdue University, Fort Wayne, IN 46805, & Dept. of Psychology, Emory University, Atlanta, GA 30322, USA.

In studies of the role of central cholinergic systems in learning and memory the effects of cholinergic manipulations (either pharmacological or surgical) on passive avoidance tasks are often assessed. Unfortunately, these studies rarely train subjects to criterion, so it is never clear whether or not learning has occurred during acquisition, and these studies rarely control for state-dependent (S-D) learning, so specific effects of the manipulations on memory storage or retention/recall cannot be ascertained.

In two experiments, rats were trained to criterion in a passive avoidance task, then were tested for retention 24 h later. In Experiment One, scopolamine (1 mg/kg) disrupted both the acquisition and retention/recall of the task. Initial step-through and escape latencies in the training session were unaffected, and S-D learning was not present. In Experiment Two, rats with lesions of the n. basalis magnocellularis (nbM) were compared to sham-operated controls, and the effects of pilocarpine (3 mg/kg) in conjunction with a peripheral muscarinic blocker (methyl scopolamine 1 mg/kg) were assessed. The lesion had no effect on the acquisition or retention/recall of the task, or on escape latency. nbM rats were slower to cross in training, especially when given pilocarpine. In both the nbM and sham rats, pilocarpine disrupted acquisition and retention/recall of the passive avoidance task, and it delayed entry to the dark side during training. An interaction between drug conditions in training and test revealed the presence of S-D learning in this experiment.

Although the nbM lesion had no effect, both drug manipulations disrupted acquisition (assessed via trials to criterion) and performance of the task. State-dependent learning was apparent in the effects of pilocarpine. [Supported in part by Purdue XL Grant to W. J. Wilson.]

295.10

MUSCARINIC CHOLINERGIC SYSTEMS & REPRESENTATIONAL MEMORY. W.S. Messer, Jr., J. Stibbe* and M. Bohnett*. Medicinal and Biological Chemistry, College of Pharmacy, Univ. of Toledo, 2801 W. Bancroft, Toledo, OH 43606

Representational memory is a form of working memory indicated when animals make discrminations based on cues not present at the time of choice. The role of muscarinic receptors in representational memory was examined using the selective antagonists pirenzepine and AF-DX 116. Rats were trained to perform a paired-run, alternation task in a T-maze to measure representational memory. Once animals learned the task, cannulae were implanted stereotaxically under general anesthesia for injections into the hippocampus. Following recovery from surgery, animals were retested in the maze to measure baseline performance and exhibited no impairment due to the surgical procedures. Bilateral injections of antagonists in 1 µl of saline were administered via cannulae 20 min. prior to testing. Rats receiving pirenzepine exibited an impairment of performance as measured by a reduction in the percentage of correct choices (79.2 ± 2.4 % with 10 µg; 70.8 ± 3.1 % with 70 µg). Animals receiving AF-DX 116 did not exhibit a significant impairment at any dose tested. The highest dose of AF-DX 116 (70 µg) produced a slight decrease in the percentage of correct choices (83.3 ± 0.0 %). The data suggest that M_1 receptors are involved in representational memory.

Dispositional memory is indicated when animals make discriminations based on cues present at the time of choice. To determine the role of cholinergic systems in both types of memory, animals were trained to perform two tasks in a modified T-maze. To measure dispositional memory, animals were required to perform a tactile discrimination in the stem of the maze in addition to the alternation task described above. Once animals learned both tasks they were injected bilaterally in the hippocampus with either saline or AF64A, a cholinergic neurotoxin. Testing was resumed one week following surgery. Rats receiving either saline or 1 nmole of AF64A were not impaired on either task, while animals receiving 2 nmoles of AF64A were impaired initially on both tasks. Animals with AF64A lesions showed a recovery of dispositional memory by the third session but still showed an impairment of representational memory. Animals with lesions were injected with pilocarpine to determine if muscarinc agonists could reverse the representational memory deficit. Pilocarpine (3.0 mg/kg) reversed the impairment associated with administration of AF64A, providing further support for the hypothesis that muscarinic receptors play an important role in representational memory. Supported by NS 23929 and NS 25765.

DISSOCIATIVE EFFECTS OF DIFFERENT TYPES OF BASAL FOREBRAIN LESIONS ON CORTICAL AChE-POSITIVE FIBER STAIN AND CYTOCHROME OXIDASE ACTIVITY. M. Sarter and P. Dudchenko*. Dept. of Psychology, The Ohio State University, Columbus, OH 43210.

Recent evidence suggests that the behavioral impairments produced by excitotoxic lesions of the basal forebrain are not primarily due to cortical cholinergic denervation. Robbins et al. (Neurosci., 28:337, 1989) reported a dissociation between the behavioral and the anticholinergic effects of quisqualate and ibotenate induced lesions.

The effects of different types of unilateral basal forebrain lesions (ibotenate, quisqualate, colchicine) on cortical acetylcholinesterase (AchE) positive fiber stain and cytochrome oxidase activity were compared in parallel sections. The rank ordering in terms of AchE-fiber loss was quisqualate > colchicine > ibotenate; however, in terms of cytochrome oxidase activity the reversed order was found. These data suggest that the reduction of cortical metabolic activity following ibotenate lesions is not primarily due to the loss of cholinergic input. From a behavioral point of view, cytochrome oxidase seems to represent a more valid histological correlate of the cortical effects of basal forebrain lesions than the loss of cholinergic activity.

296.1

EFFECTS OF CHOLINERGIC BLOCKADE IN THE AMYGDALA ON INHIBITORY AVOIDANCE AND REINFORCED ALTERNATION. A.H. Nagahara* and J.L. McGaugh. Department of Psychobiology and Center for the Neurobiology of Learning and Memory, Univ. California, Irvine, CA 92717.

Lesions of the nucleus basalis magnocellularis (NBM) in rats produce memory impairments on a wide variety of tasks. Such deficits have generally been interpreted as due to the loss of the cholinergic projection to cortex. However, NBM also sends a major cholinergic projection to the amygdala. We examined the role of this projection in memory by infusing scopolamine into the basolateral amygdala prior to or following training on two tasks sensitive to NBM lesions.

Sprague-Dawley rats were trained on an inhibitory avoidance task (IA). Each animal received an intra-amygdala injection, through implanted cannulae, of buffer or scopolamine (0.03, 0.1, or 1.0 μg/0.5 μl) either 5 min-pretraining or immediately posttraining. Retention was tested 48 hr after training. One week later, a subgroup of these animals was tested on a reinforced alternation (RA) task (15 consecutive trials, ITI=30s). Animals were tested under both conditions. Half received pretesting intra-amygdala injection of buffer on day 1 and scopolamine (0.1 μg/0.5 μl) on day 2, and the other half received the reverse order.

In the IA task, 0.1 μg scopolamine administered pretraining significantly impaired performance ($p<.01$); posttraining scopolamine injections did not. This finding suggests that the cholinergic system in the amygdala plays a role in the acquisition of the IA task. However, no effect on the RA task was found: The amygdala cholinergic system appears not to be essential for performance on this task. These data suggest that cholinergic blockade in the amygdala produces memory deficits on certain tasks and that some of the memory deficits observed in NBM-lesioned animals may be due to disruption of this NBM projection.

296.2

CHOLINERGIC-DOPAMINERGIC INTERACTIONS IN RADIAL-ARM MAZE PERFORMANCE: A LESION STUDY. S.R. McGurk, E.D. Levin, and L.L. Butcher. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563.

Accurate performance on the radial-arm maze is dependent on the integrity of nicotinic cholinergic, muscarinic cholinergic, and dopaminergic neurotransmitter systems, and is determined by complex interactions of these systems. It has been suggested that the basal nuclear complex is critical for the modulation of learning and memory.

We have examined the effects of lesions of the medial cholinergic pathway, arising from the basal nuclear complex and projecting to the cingulate and medial occipital cortices, on maze performance in rats. In Experiment I, we found that knife-cut lesions of the medial cholinergic pathway, but not similar lesions causing cortical damage but sparing this pathway, caused a robust but temporary disruption in radial-arm maze performance. In Experiment II, the effect of brain lesions on maze performance was eliminated by daily administration of the cholinergic agonist drug arecoline, suggesting that the performance deficit is due specifically to the loss of cholinergic innervation. In Experiment III, memory impairment caused by lesions of the medial cholinergic pathway were abolished by daily treatment with a D1 agonist (SKF 38393), diminished by daily treatment with a D2 agonist (LY 171555) or a D1 antagonist (SCH 23390), and not affected by a D2 antagonist (raclopride). Taken together, these data demonstrate the importance of the medial cholinergic pathway in maze performance and extend our previous observations that performance deficits due to cholinergic dysfunction can be reversed by modulation of dopaminergic systems. (NIH grant 10928 to L.L.B.)

296.3

CONCURRENT MUSCARINIC AND BETA-ADRENERGIC BLOCKADE IMPAIRS INHIBITORY (PASSIVE) AVOIDANCE AND MORRIS WATER MAZE PERFORMANCE. T. M. Gill*, M. W. Decker, and J. L. McGaugh (SPON: S. F. Zornetzer). Center for the Neurobiology of Learning and Memory and Dept. of Psychobiology, Univ. California, Irvine. CA 92717.

Cholinergic and noradrenergic (NA) deterioration is found in aging and Alzheimer's disease. Because experimental cholinergic disruption impairs performance on a variety of memory tasks but NA-depletion does not, cholinergic dysfunction is typically assigned a greater role in age-related memory decline than is NA dysfunction. However, NA-depletion enhances the disruptive effects of muscarinic cholinergic blockade on the radial maze (Decker and Gallagher, Br. Res., 417:59, 1987). The current study extends this finding by examining the effects of muscarinic cholinergic and ß-adrenergic blockade on two additional tasks.

Pretraining administration of either propranolol HCl (10 mg/kg ip) or scopolamine HBr (0.3 and 1.0 mg/kg ip) to rats had no significant effect on retention of step-through inhibitory avoidance training (0.5 mA, 2 s footshock) at a 1 day delay. However, concurrent administration of this dose of propranolol with either dose of scopolamine produced a profound amnesia ($p<.01$). Similarly, pretraining administration of either 10 mg/kg propranolol or 0.3 mg/kg scopolamine did not affect acquisition of the Morris water maze, but concurrent administration of these drugs increased escape latencies during training ($p<.001$) and impaired performance during a free swim probe trial conducted at the conclusion of training.

Thus, cholinergic/noradrenergic interaction is found in a variety of behavioral tasks and ß-adrenergic mechanisms play an important role in this interaction, suggesting a potential role for NA dysfunction in age-related memory decline.

LONG TERM SCOPOLAMINE TREATMENT DURING THE POSTNATAL PERIOD IMPAIRS SHORT-TERM MEMORY PROCESSES BUT NOT PLACE LEARNING IN YOUNG RATS. R. Paylor and J.W. Rudy, Psychology Dept., Colorado University, Boulder, CO 80309.

Long term scopolamine treatment causes an increase in the number of hippocampal muscarinic receptor binding sites in both neonatal and adult rats (J. Ben-Barak & Y. Dudai, Brain Res., 193, 309-313, 1980). Currently, however, it is not known what impact muscarinic receptor upregulation has on an animal's behavior. In the present study we looked at the effects of long term scopolamine treatment on short-term memory and place learning processes in the young rat.

Rat pups were injected once a day for 19 days starting at 1 day old. Forty-eight hours after the last injection subjects were tested on one of two tasks. The two tasks selected are known to be sensitive to hippocampal damage and cholinergic manipulations. In one group, subject's place learning processes were tested by training them to locate a hidden platform in the Morris water task. In the second group subject's short-term memory processes were tested by training them to solve a delayed conditional spatial alternation task in a water T-maze. The scopolamine treatment did not effect performance on the place-learning task, but significantly impaired subject's ability to learn the delayed conditional spatial alternation task. Additional experiments will be directed at understanding the nature of the behavioral impairment.

296.5

MICROINJECTIONS OF SCOPOLAMINE AND SULPIRIDE INTO RAT AMYGDALA OR THALAMUS: EFFECTS ON DELAYED NON-MATCHING TO SAMPLE AND VISUAL DISCRIMINATION IN A T-MAZE. G.N.O.Brito, S.P.Silva*,and L.S.O.Brito*. Lab.Neuropsicol.Exp.,Setor de Neurociencias,Univ. Fed.Fluminense, Niteroi, RJ, Brasil.

Recently, we demonstrated that microinjections of scopolamine(SCO), but not sulpiride(SUL), into prelimbic cortex interfered with the performance of delayed nonmatching to sample(DNMS).Injections of SCO or SUL had no effect on visual discrimination(VD). A large body of data indicate close anatomical links between prelimbic cortex, thalamus and amygdala. In the present study, rats were implanted with cannulae in either the amygdala(AMY) or thalamus(THA), and they were tested on either a DNMS or VD task in a T-maze after bilateral 1.0 ul injections of SCO(4.0 and 7.5 ug/ul) and SUL (10 ug/ul). The results demonstrated that the higher SCO dose injected into AMY or THA impaired the performance of DNMS and VD, whereas the lower dose interfered with the performance of DNMS only. Injections of SUL had no effect on performance of either task. We conclude that:(i)cholinergic, but not dopaminergic, mechanisms in AMY and THA are involved in memory processes; (ii)performance of a working/representational memory task(DNMS) is differentially sensitive to SCO injections in AMY and THA. Research supported by CNPq and FINEP.

296.6

THE IMPAIRMENT OF RADIAL-ARM MAZE CHOICE ACCURACY BY COMBINED MUSCARINIC AND NICOTINIC BLOCKADE AND ITS REVERSAL BY A D2 AGONIST. E.D. Levin, J.E. Rose*, S.R. McGurk and L.L. Butcher. Dept of Psychology, University of California, Los Angeles, CA 90024 and Dept of Psychiatry, Duke University, Durham, NC 27705.

Choice accuracy performance in the radial-arm maze is dependent upon both nicotinic and muscarinic acetylcholine receptors. In our previous study nicotinic and muscarinic blockers acted in at least an additive manner in disrupting radial-arm maze choice accuracy. In this study, it was found in rats (N=13) that mecamylamine (2.5 mg/kg) and scopolamine (0.04 mg/kg) provided a combined blockade which was greater than additive. The combination of subthreshold doses of these drugs caused a pronounced impairment. Previous studies have shown that the impairment caused by nicotinic blockade is reversed by the dopamine D2 agonist LY 171555 and that the impairment caused by muscarinic blockade is reversed by the D1 antagonist SCH 23390. In the current study LY 171555 (0.01 mg/kg) significantly ($p<.05$) attenuated the cognitive deficit caused by combined nicotinic and muscarinic blockade, however, SCH 23390 (0.01 mg/kg) was not found to be effective. Nicotinic and muscarinic blockade were found to have synergistic effects in producing cognitive impairment in the radial-arm maze. This deficit was treatable with the D2 agonist, LY 171555. This research was supported by NIH grants DA 02665 and NS 10928.

296.7

THE EFFECTS OF SCOPOLAMINE, METHYLSCOPOLAMINE, CHLORDIAZEPOXIDE AND D-AMPHETAMINE ON DELAYED MATCHING-TO-POSITION PERFORMANCE OF MALE AND FEMALE RATS. F. van Haaren[1], A. van Hest* and R.P.W. Heinsbroek* [1] Dept. of Psychol, Univ. of Florida, Gainesville, FL 32611 and Netherlands Institute for Brain Research, Amsterdam, The Netherlands.

Previous studies have shown that SCOP may differentially affect behavior in intact male and female rats (van Haaren, et al. Pharmacol Biochem Behav, 1989). The present experiment was designed to investigate whether or not SCOP treatment differentially affect memory functioning. Other pharmacological challenges were included to determine the specificity of the anticholinergic effects. Male and female rats were trained in a delayed matching to position procedure (delay 1, 5, 10 or 20 s) and treated (mg/kg) with SCOP, METHSCOP (0, .08, .16, .32), CDP (0, 2.5, 5, 10) and d-AMPH (0, .4, .8, 1.6). SCOP and d-AMPH disrupted matching behavior, CDP and METHSCOP did not. d-AMPH, but not SCOP disrupted matching more in females than in males. SCOP and d-AMPH produced a differential increase in the number of trials not initiated; attentional factors may play a role in disrupting matching behavior.

296.8

ANTAGONISM BY ATROPINE, SCOPOLAMINE, AND APROPHEN OF PHYSOSTIGMINE EFFECTS ON RATS' PERFORMANCE OF A RADIAL-MAZE LEARNING TASK. J. R. Leu, T. F. Elsmore, S. A. McBride. Division of Neuropsychiatry, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

Physostigmine (0.4 mg/kg) reduced the number of pellets earned in a 5-minute session by about 90%. Three anticholinergic drugs, atropine, scopolamine, and aprophen, all provided some degree of antagonism. Aprophen was the most effective, restoring performance to greater than 80% of control at doses of 3.2 and 6.4 mg/kg. Both atropine and scopolamine restored performance to only 45% of control at doses of 6.4 and 0.2 mg/kg, respectively. While the degree of antagonism produced by scopolamine was not as great as that of aprophen, it was somewhat effective over a wide range of doses.

296.9

MECAMYLAMINE ALTERS DYNAMIC COMPONENTS OF CENTRAL CHOLINERGIC SYSTEMS IN RAT BRAIN IN A DOSE PRODUCING LEARNING IMPAIRMENT. K. Elrod and J.J. Buccafusco. Dept. Pharmacology and Toxicology, Med. Coll. of GA and Vet. Adm. Med. Ctr, Augusta, GA 30912.

We previously demonstrated impairment of passive avoidance performance in rats following administration of the central nicotinic antagonist mecamylamine (M) but not the peripheral nicotinic antagonist hexamethonium (H). The present studies examined the effects of M and H on the dynamics of the cholinergic system in rat brain. Animals were pretreated s.c. with the behaviorally-deleterious dose of M in the rat (25mg/kg), a lower, behaviorally-ineffective dose of M (5mg/kg), H (25mg/kg) or saline prior to i.v. pulse, tracer injection of ^{3}H-choline. Pretreatment with M (25mg/kg) resulted in marked reductions of 38%-61% in newly formed ^{3}H-Ach in all 5 brain areas studied (frontal, limbic and parietal cortices, hippocampus and striatum). M (25mg/kg) did not, however, alter endogenous steady-state Ach levels. Estimates of Ach turnover revealed significant reductions of 59% and 64% in parietal cortex and hippocampus, respectively, of animals pretreated with M (25mg/kg). As with the behavioral studies, H or M (5mg/kg) was without effect on the same biochemical parameters. These drug-induced biochemical alterations may subserve the behavioral impairment observed following M (25mg/kg) administration. These results lend support to the hypothesis that presynaptic nicotinic receptors mediate a positive feedback mechanism for Ach release in that the centrally-acting antagonist produced a decrease in the release of Ach or firing rate of apparently tonically active central cholinergic neurons. Supported by the Smokeless Tobacco Research Council.

EFFECTS OF SCOPOLAMINE AND PYRITHIAMINE ON ALTERNATION BEHAVIOR IN RATS. A. S. Powers, D. V. Gutierrez,* & J. A. Hirsch.*(1) St. John's University, New York, NY 11439.

Hirsch & Gibson (Biochem. Pharmacol., 33, 1984) found that pyrithiamine (PY), a thiamine antagonist, stimulated the release of acetylcholine from rat cerebral cortex in vitro. The present experiment investigated the effects of the drug in vivo on an operant single alternation task in rats and compared its effects to those of scopolamine (SC), a muscarinic receptor blocker that is known to impair mnemonic processes.

Rats were trained in an operant chamber to alternate between two levers. Twenty reinforcements were given per day with an intertrial interval of 4s. Self-correction was allowed after an error. Errors per day were recorded.

After training to asymptote, the rats were given a series of intraperitoneal injections of PY (0.5 mg/kg) and SC (0.2 mg/kg), alone and in combination. Between injections, they were run without drug for at least 3 days. The sequence of injections was as follows: PY, PY, PY, SC, PY+SC, SC, SC, SC, PY, PY+SC. The injections were given 0.5 hr before testing.

Data were analyzed as difference scores between the previous drug-free day and the drug day. Although SC significantly disrupted performance ($p<.05$), PY had no significant effect. The results provide no evidence for a facilitatory effect of acute pyrithiamine on memory. (1)Present affiliation: Long Island Univ., Brooklyn, NY.

DIFFERENTIAL EFFECTS OF SCOPOLAMINE INJECTED INTO NEOSTRIATUM ON ACQUISITION, CONSOLIDATION AND RETRIEVAL OF CONDITIONED EMOTIONAL RESPONSES Marc D. Viaud and Norman M. White, Department of Psychology, McGill University, 1205 Dr. Penfield Ave., Montreal, Quebec, Canada, H3A 1B1

In previously published work we demonstrated that post-training micro-injections of amphetamine into the ventrolateral (VL) caudate nucleus improved retention of a conditioned emotional response (CER) with an olfactory conditioned stimulus (CS), but had no effect on retention of a CER with a visual CS; injections into the posteroventral (PV) caudate improved retention of a CER with a visual CS, but not with an olfactory CS. In the present experiment, using the same paradigm, we investigated the effects of the anti-cholinergic, scopolamine (1ug in 5uL), micro-injected 10 min before training (acquisition), 30 sec after training (consolidation) or 10 min before testing (retrieval). Compared to saline-injected controls, scopolamine prevented both acquisition and retrieval, but facilitated consolidation. All three effects were specific as to the relationship between injection site and CS modality. These findings are consistent with the hypothesis that the origin of the cortico-striatal input to areas of the dorsolateral striatum determines the content of the sensori-motor memory mediated in each area. The data are also consistent with other data suggesting that cholinergic function in the dorsolateral striatum is involved in the memory functions of this part of the brain.

RETROGRADE AMNESIA INDUCED BY SCOPOLAMINE: PRTOTECTIVE EFFECT PRODUCED BY OVERTRAINING. M. Durán*, and R. A. Prado-Alcalá. Psychophysiol. Lab., Anáhuac Univ. and Physiol. Dept., Med. Sch., Natl. Univ. of México, México, D. F.

Disruption of cholinergic activity of the striatum produces retrograde amnesia. When animals are submitted to overtraining such disruption is innocuous. Systemic application of anticholinergics also produces amnesia. We determined whether overtraining also has a protective effect against amnesia. Rats were trained, in one trial, to avoid the darker compartment of a two-compartment box; retention was tested 24 hr later. In Exp. I, a footshock of 3.0 mA was used, and the rats were injected (I.P., 5 min. posttraining) with 0, 2, 4, 8 or 12 mg/kg of scopolamine (SCOP). There was a dose-dependent amnesic state induced by SCOP. In Exp. II, rats were trained with 6.0 or 9.0 mA; there were three groups for each intensity: untreated, injected with 8 and with 12 mg/kg of SCOP. None of the groups showed amnesia. These results indicate that a) acetylcholine is involved in consolidation of normal training and b) acetylcholine is not involved in the consolidation of overtrained tasks. 296.13

COMPARATIVE EFFECTS OF SCOPOLAMINE TREATMENT AND FIMBRIA-FORNIX LESIONS ON MAZE PERFORMANCE IN RATS. J.C.Cassel*, C. Kelche* and B.E. Will. (SPON: J. Hirsch). D.N.B.C., Centre de Neurochimie du C.N.R.S., 12, rue Goethe, F-67084 Strasbourg Cedex, France.

Intact Long Evans rats were trained in a 8-arm radial maze and subsequently tested under systemic treatment with physostigmine (0.05mg/kg; I.p.), scopolamine methylbromide (Mbr) and scopolamine hydrobromide (Hbr; 0.5mg/kg). The effects of these drugs were compared to those of aspirative lesions of the fimbria-fornix pathways at 3 postoperative delays in different rats: 3, 7 and 12 months.

At each of these delays (1) rats with lesions showed impaired performance during predrug trials, (2) physostigmine had no effect in any group, (3) scopolamine HBr impaired performances of intact rats in a manner which closely paralleled the lesion-induced behavioral effects (errors, arms before first error, strategies). This impairment was not dependent on the strategies used by rats.

These results further support the involvement of cholinergic processes in spatial memory and suggest that scopolamine-induced disruption of central cholinergic functions may mimic the effects of fimbria-fornix lesions, at least under our test conditions.

296.14

THE EFFECTS OF SCOPOLAMINE AND FORNIX TRANSECTION ON ACTIVITY, EXPLORATION, EXTINCTION AND NAVIGATION IN RATS. K. Swanson* and B. Osborne (SPON: T. Root). Department of Psychology, Middlebury College, Middlebury, VT 05753.

Cholinergic manipulation disrupts many aspects of memory function and hippocampal damage results in a variety of deficits including increased activity and altered exploration, a greater tendency to exhibit previously effective behaviors and cognitive disruptions. A relationship between hippocampal lesions and cholinergic manipulation has been postulated. These experiments investigated the effects of both fornix transections and cholinergic blockade by examining three tasks; extinction of rewarded behavior, activity in an open environment, and the Morris swimming maze. Both cholinergic manipulation and fornix transection had behavioral effects across tasks. However, cholinergic manipulation was also effective in rats with fornix transection. From the results of these experiments, one would have to conclude that the two syndromes are different -- one dealing with hippocampal deficits and a broader one affecting memory and cognitive processing in general.

296.15

RHESUS MONKEY PERFORMANCE IN AN OPERANT TEST BATTERY (OTB): EFFECTS OF ATROPINE. Merle G. Paule and Michael P. Gillam.* Div. Reprod. & Dev. Tox., National Center for Toxicological Research, Jefferson, AR 72079-9502.

The involvement of the cholinergic system in a series of operant behaviors was studied using atropine sulfate (ATR, 0.01-0.56 mg/kg). Tasks included in the multiple schedule OTB and their durations were: Progressive Ratio (PR) 10 min, Conditioned Position Responding (CPR) 5 min, Incremental Repeated Acquisition (IRA) 35 min, Delayed Matching-To-Sample (DMTS) 30 min, and Temporal Response Differentiation (TRD) 20 min. These tasks are thought to engender responding associated with motivation, color and position discrimination, learning, short-term memory and attention, and time perception, respectively. Sessions lasted 50 min and began 15 min after iv ATR or saline. Endpoints monitored included response rates (rr), accuracies (acc), and percent task completed (ptc). Significant effects on IRA were noted at 0.01 mg/kg (increased rr) followed by a significant decrease in rr at ≥0.03 mg/kg. CPR ptc was significantly decreased at ≥0.03 mg/kg. DMTS acc, TRD ptc, and PR rr were all significantly decreased at ≥0.10 mg/kg. Thus, the sensitivities of these tasks to ATR were IRA>CPR>TRD=DMTS=PR. Of the 5 behaviors monitored, those thought to be associated with learning processes are the most sensitive to muscarinic cholinergic manipulation.

296.16

THE EFFECTS OF EXCITOTOXIC LESIONS OF THE MEDIAL SEPTAL NUCLEUS ON CONDITIONAL VISUAL DISCRIMINATION IN RATS. H.M.Marston* and T.W.Robbins. (SPON: Brain Research Association) Department Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB. UK.

The effects of quisqualic acid lesions to the septum were examined on acquisition and performance of an instrumental conditional visual discrimination in rats.

Lesions were made by infusing either 0.5ul of the excitotoxin (0.12M) or vehicle at four sites bilaterally. *Post mortem* biochemical and histological analyses revealed reductions in the level of choline acetyltransferase activity of approximately 60% in the hippocampal formation and 50% in the cingulate cortex. Reductions in the degree of acetylcholinesterase staining limited to these structures were also observed.

The behavioural paradigm involved a discrimination between fast and slow flashing lights. Following presentation of a stimulus two levers were introduced into the operant chamber, a response had then to be made either to the left or right, depending upon the frequency of the stimulus. Once an asymptotic level of performance had been attained, the animals were challenged with manipulations of the inter-trial interval and stimulus frequency and duration. In addition the effects of scopolamine(0.19, 0.38 mg/kg) methylscopolamine(0.24 mg/kg), physostigmine(0.05, 0.1 ,0.5 mg/kg), nicotine(0.08 ,0.23 mg/kg), d-amphetamine(0.4, 0.8 mg/kg) and chlordiazepoxide(5.0, 10.0 mg/kg) were investigated.

The lesion produced significant deficits on both the acquisition and performance of the task. The deficits in performance were ameliorated by lengthening the stimulus duration. In addition, the lesions attenuated the deleterious effect of scopolamine.

These results are compared with the lack of behavioural effects of excitotoxic lesions of the cholinergic projection to the anterodorsal frontal cortex on this task. A role for the cholinergic projections of the septum in the mediation of conditional instrumental learning is suggested, possibly as a result of disruption to attentional processes.

AF102B, A NOVEL M1 AGONIST, ENHANCED LEARNING AND MEMORY WITH A LONG DURATION OF ACTION. J. Sepinwall, G.P. Vincent and L. Rumennik. Neurobiology and Obesity Research, Hoffmann-La Roche Inc., Nutley N.J. 07110.

The cognitive deficit in Alzheimer's disease is associated with a presynaptic cholinergic deficit. Traditional muscarinic agonists lack receptor specificity and exhibit short durations of action (Bartus et al., In: Treat. Devel. Strat. For Alz's. Dis. Ed.: Crook et al., 1986), suggesting the need for a selective, long acting M1 agonist. AF102B (AF) in the Morris water maze improved acquisition in C57BL/10 mice by decreasing the latency to find the hidden platform (0.1 to 1.0 mg/kg, po, 60 min pretreatment [pt]). The peak active dose, 1.0 mg/kg, enhanced acquisition at 60 min and from 3 hr to 5 days pt following a single injection. It was inactive at 90 min thus suggesting a biphasic action. In another study, an inactive low dose after acute administration (0.03 mg/kg, po, 60 min pt) enhanced acquisition after a single injection with activity ranging from 3 hrs to 5 days pt. At shorter and longer pt times it was inactive. In squirrel monkeys AF improved the accuracy of retention on a delayed match-to-sample procedure by 8 and 10% (0.03 and 0.3 mg/kg, ig, 20 min pt, respectively). Thus AF enhanced cognition in both mice and monkeys with a duration of action longer than that reported for traditional muscarinic agonists.

296.18

EFFECT OF DM9384 ON DISCRIMINATION AVOIDANCE LEARNING DEFICIT INDUCED BY IBOTENIC ACID LESION OF THE FRONTAL CORTEX IN RATS. C. Hara and N. Ogawa. Dept. of Pharmacology, Ehime Univ. Sch. of Med., Ehime-ken 791-02, Japan.

Ibotenic acid (IBA) lesions of the dorsolateral frontal cortex (DFC) and medial prefrontal cortex (MPC) having cholinergic input from the nucleus basalis of Meynert (NBM) impaired retention of discrimination avoidance learning (DAL) similar to NBM lesion (Hara, C., Soc. Neurosci. Abstr., 14(2), 1224, 1988). In this study, effects of DM9384 (Daiichi Seiyaku Co.), a new pyrrolidone derivative, and tetrahydroaminoacridine (THA), a cholinesterase inhibitor, on the impairment were examined. Male Wistar strain rats (10 weeks old) which acquired DAL were injected IBA (7.5 μg) into the DFC, MPC or NBM under pentobarbital anesthesia. The rats which revealed the impairment of retention on Day 14 after the surgery were daily administered DM9384 (10 mg/kg, p.o.) or THA (0.5 mg/kg, i.p.) for 1 week. In the results, DM9384 and THA improved the impairment. Since DM9384 activates choline acetyltransferase and improves learning deficit induced by GABA antagonists, the learning deficit induced by the frontal cortex lesion may be involved in cholinergic as well as GABAergic neural systems.

296.19

NEONATAL INTRAVENTRICULAR INJECTION OF AF64A IMPAIRS PLACE LEARNING IN THE MORRIS WATER MAZE. J.N. Armstrong, S.J.E. Murtha, and B.A. Pappas. Unit for Behavioral Medicine and Pharmacology, Department of Psychology, Carleton University, Ottawa, Canada K1S 5B6.

Previous studies have demonstrated that intraventricular (i.v.) injections of AF64A into the adult rat impairs acquisition of place learning in the Morris Water Maze. In the present experiment, bilateral i.v. injection of 2 nmol/ul/side (but not 0.5 or 0.1 nmol) AF64A into Long-Evans rats 48-72 h after birth impaired acquisition of place learning when these animals were tested at 35 days of age. No group differences were found for cued navigation, suggesting that the impairment was specific to their ability to utilize external spatial cues rather than a primary performance deficit. The 2 nmol-injected rats were also more active than controls during exposure to the elevated plus-maze. However, they displayed avoidance of the open arm suggesting normal ability to process spatial cues. Neonatal i.v. injection of AF64A did not affect cortical or hippocampal choline acetyltransferase activity. The behavioral effects probably reflect the non-specific pathology caused by this drug.

TRANSMITTERS IN INVERTEBRATES IV

FMRFa INHIBITS THE AFTERDISCHARGE IN THE BAG CELL NEURONS OF APLYSIA. T.E.Fisher and L.K.Kaczmarek. Dept. of Pharmacology, Yale University Sch. Med., New Haven, CT 06510.

The bag cell neurons of Aplysia can be made to undergo a long-lasting afterdischarge of repetitive firing (mean of 25 minutes) by a brief electrical stimulation of an input from the head ganglia. An elevation of intracellular cyclic AMP contributes to this change in excitability. In this series of experiments we have examined the effects of phe-met-arg-phe-amide (FMRFa), a putative neurotransmitter in Aplysia, on the afterdischarge. Bath application of 10μM FMRFa rapidly suppresses firing during an afterdischarge (usually within 2-3 minutes) without otherwise altering membrane potential. This effect is reversible; when FMRFa is removed from the bath, the afterdischarge re-initiates either spontaneously or after brief electrical stimulation. Preincubation with FMRFa usually does not prevent an afterdischarge but results in a greatly reduced duration (1-5 minutes). Inhibition by FMRFa was not prevented by 8-parachlorophenylthio-cyclic AMP (pcpt-cyclic AMP; 500μM), forskolin/theophylline (50μM/1 mM) or tetraethylammonium ions (100mM). Experiments in single bag cell neurons in primary culture have identified two responses to FMRFa. Application of FMRFa elicits a rapid hyperpolarization of up to 20mV, likely due to the activation of a potassium current. This effect is prevented by pcpt-cyclic AMP, which may explain why it is not seen in afterdischarging cells. Under voltage clamp FMRFa also induces a modest decrease (10-30%) in voltage activated calcium currents. This decrease may be at least partly responsible for the suppression of the afterdischarge by FMRFa.

297.2

ACTIONS OF PEDAL PEPTIDE ON NEURON L5 IN *APLYSIA*. W. L. Pearson* & P. E. Lloyd, (SPON: R. McCrea) Comm. on Neurobiol. & Dept. of Pharmacol. & Physiol. Sci., Univ. of Chicago, Chicago, IL 60637.

Pedal peptide (Pep) is a neuropeptide synthesized predominantly in the pedal ganglia of *Aplysia*. Pep-immunoreactive varicosities have been observed throughout the periphery and the central nervous system, particularly on the left upper quadrant (LUQ) abdominal neurons. We have studied the effects of Pep on these cells, with emphasis on cell L5, using voltage clamp and current clamp techniques.

Under current clamp, bath application of Pep (10 μM) depolarizes LUQ cells as much as 20 mV and alters their firing pattern, eliciting tonic firing or bursting with shortened interburst intervals and decreased after-hyperpolarizations. Under voltage clamp, Pep evokes a net inward current associated with a conductance decrease. As measured at the peak of the net inward current, current-voltage (I-V) curves generated by digital subtraction of current records show that bath applied Pep in normal artificial sea water (ASW) produces an inward current that decreases near the potassium equilibrium potential, E_K. In low Ca^{++} and Ca^{++}-free, Co^{++}-containing ASW, this inward current is reduced. Altering the K^+ concentration of the bath shifts the I-V curve along the voltage axis in accordance with the shift in E_K. The Pep-evoked current can also be decreased by adding TEA to the bath or by filling the cell with Cs^+. These results suggest that Pep depolarizes LUQ neurons, particularly L5, by decreasing at least one K^+ conductance that is normally present in these cells at their resting potential or within their pacemaking voltage range. Supported by NS 23569.

297.3

INVOLVEMENT OF PEP-CONTAINING NEURONS IN LOCOMOTION IN *APLYSIA*. J. D. Hall* and P. E. Lloyd. (SPON: L. Minor). Dept. Pharm. Physiol. Sci. & Comm. on Neurobiol. Univ. Chicago, Chicago, IL 60637.

Pedal peptide (Pep) is a recently characterized very abundant neuropeptide in Aplysia. It is found throughout the CNS but is particularly concentrated in a band of large neurons in the pedal ganglia. Pep is transported in large amounts via peripheral nerves from the pedal ganglia to the foot. When exogenous Pep is applied to the foot via a cannulated artery, contractions of the foot produced by brief stimulation of a pedal nerve are modulated. Specifically, the amplitude and relaxation rate of each contraction increases during Pep application. These effects are seen with a threshold of ~10^{-8} M Pep.

A split-foot preparation was used to study the activity of Pep-neurons during locomotion and other behaviors. Pep-neurons have a low (~1 spike/sec) tonic activity when preparations are quiescent. During spontaneous or stimulus-induced locomotion, Pep-neurons fire more rapidly (3-4 spikes/sec), and in bursts which often coincide with the relaxation of each step. Also, Pep-neurons are strongly inhibited during sustained contractions of the foot.

The identity of Pep-neurons was confirmed after each experiment by microdissection and RIA. Pep-neurons in the pedal ganglia range from 100-200 μm in diameter (60-150 g animals) and contain from 0.8 to 3.8 pmol of Pep-like immunoreactivity. Since Pep modulates foot contractions and Pep-neurons are activated during locomotion, we propose that Pep has a modulatory role in peripheral regulation of foot muscle during locomotion. Supported by NIH NS23569.

297.4

IDENTIFICATION AND CHARACTERIZATION OF PUTATIVE DOPAMINE-CONTAINING NEURONS IMPLICATED IN THE CONTROL OF FEEDING BEHAVIOR IN *APLYSIA*. S. C. Rosen*, T. Teyke*, K. R. Weiss and I. Kupfermann. Cntr. Neurobiol. & Behav., Columbia Univ. and NYS Psychiatric. Inst. New York, N.Y. 10032

Application of 10^{-3} M dopamine (DA) to preparations consisting of isolated cerebral and buccal ganglia elicits a buccal motor program (BMP). In order to determine whether the DA effect can be accounted for by the actions of DA neurons, candidate neurons in the buccal and cerebral ganglia were impaled with electrodes for intracellular recording and stimulation. The neurons were subsequently marked with rhodamine and treated by the FaGlu method to reveal possible dopamine-like (DA-I) histofluorescence. A pair of bilaterally symmetrical DA-I buccal cells and a pair of DA-I cerebral cells were found to drive several cycles of a BMP. The buccal cells make direct connections to buccal motor neurons (e.g. B15s) and their activity is recruited into the BMP driven by the cerebral command element CBI-2. The cerebral DA-I cells are the previously identified CBI-1 cerebral-buccal interneurons. These cells are excited by mechanoafferent neurons in the cerebral ganglion (ICBMs) and provide direct inputs to numerous neurons in the buccal ganglion. The CBI-1s were found to receive strong excitatory input associated with movements of the lips or buccal mass. When the cerebral and buccal ganglia were isolated in separate chambers, a robust BMP was only elicited by application of the DA to the cerebral ganglion, and when the buccal mass was kept intact the evoked movements resembled swallowing. These data suggest that dopaminergic afferent input to the cerebral ganglion may elicit swallowing-like behavior, and that the dopaminergic CBI-1s may convey proprioceptive signals that modulate ingestive responses.

297.5

GLUTAMATE AS A PUTATIVE NEUROTRANSMITTER OF IDENTIFIED CEREBRAL GANGLION NEURONS OF THE SNAIL HELISOMA. R.L. Ridgway, J.E. Richmond, K. McKenney, K. Lukowiak, and A.G.M. Bulloch. Dept. of Medical Physiology, Univ. of Calgary, Calgary, Alberta, Canada T2N 4N1.

Glutamate has been shown to play a role in promoting neurite outgrowth of adult neurons of Helisoma trivolvis (Bulloch, J. Neurosci. Res., in press). The mechanism underlying this effect is unknown. We have sought here to determine if specific neurons of Helisoma use glutamate as a neurotransmitter. Autoradiographic visualization of ^{3}H-glutamate uptake in the CNS of Helisoma reveals labeled neurons in all central ganglia except the pedals. Of note is the labeling of two neurosecretory cell types of the cerebral ganglia: 1) the Mediodorsal Cells (MDCs), and 2) the Canopy Cells (CCs). Initial experiments using both HPLC analysis and antibodies specific to glutamate confirm that glutamate is localized in these cells. In addition, since these two cell types contain a somatostatin-like substance having putative neurotrophic properties (Bulloch, Brain Res. 412:6-17, 1987), we examined whether glutamate might feedback onto these cells to change their activity state. When glutamate is bath applied (at 300μM) or pressure-ejected (at 0.5M) onto MDCs of isolated ganglia, a 20-25 mV depolarization from resting potential is observed, implying that glutamate receptors are present. We conclude that glutamate is present in these identified cells and may function as an autoactive neurotransmitter.

297.6

ANALYSIS OF OCTOPAMINE-INDUCED INHIBITION IN AN IDENTIFIED EFFECTOR NEURON OF HELISOMA. F.H.Bahls Dept. of Physiology and Biophysics and Div. of Neurology,School of Medicine,University of Washington,Seattle, WA 98195

Patterned neuronal activity in the buccal ganglion of Helisoma can be modulated by a variety of neuroactive substances. Most recent investigations of neuromodulation in this system have focused on the effects of neurotransmitters on the interneuronal subunits responsible for generating patterned output (eg. Murphy,et al, Soc Neurosci Abs, 1988). However, many neurotransmitters also have direct modulatory actions on the effector neurons of the buccal ganglion. I have examined the response of an identified effector neuron (B5) to octopamine. Iontophoresis or bath perfusion with octopamine produces a sustained 15-20mV hyperpolarization, associated with an increase in input conductance. The minimal concentration of octopamine required to produce a detectable response is 10-7M. Prolonged exposure to octopamine produces no detectable desensitization. The reversal potential in normal saline is -84 (+/-15)mV. Doubling external potassium shifts the reversal potential to -69(+/-18)mV, while halving external potassium shifts the reversal potential to -102(+/-12)mV. The hyperpolarization is decreased in the presence of low concentrations of 4-AP (50μM). These results suggest that the hyperpolarization is due to an increase in potassium conductance. The response of B5 to octopamine is similar to that previously described to glutamate (Jones,et al, Brain Res 437:56-68,1987). The interaction between the responses produced by octopamine, glutamate and other neurotransmitters in B5 is currently under investigation. (Supported by NIH NS01167-01A1)

297.7

AN IDENTIFIED "DOPAMINERGIC" BUCCAL INTERNEURON ACTIVATES PATTERNED MOTOR ACTIVITY IN HELISOMA. E.M. McLean*, B. Behjatnia* and A.D. Murphy (SPON: M. Binder) Dept. of Biol. Sci., Univ. of Illinois at Chicago, Chicago, Illinois 60607.

The catecholamines, dopamine and octopamine, modulate the feeding central pattern generator (CPG) of Helisoma. The CPG consists of three subunits (S1-S3) which are independent interneuronal oscillators. Three octopamine immuno-reactive neurons (antibody provided by E. Kravitz and D. Valentine) were localized near the buccal commissure, in a similar position to the S3 interneuron, N3a. Approximately 50 "dopaminergic" neurons were localized in each of the paired buccal ganglia with a glutaraldehyde/formaldehyde histochemical technique. In some systems this technique produces yellow fluorescence in dopaminergic neurons and green fluorescence in serotonergic neurons. However, in Helisoma, this technique causes identified dopaminergic neurons to fluoresce but identified serotonergic neurons do not. The dopaminergic neuron N1a has been identified by combining electrophysiological recordings with co-staining of the soma by injection of the procion dye Reactive Red 4 (Sigma), and histochemical staining of the same preparation. Depolarization of neuron N1a or bath application of 10^{-6} M dopamine initiates the standard pattern of rhythmic activity (S1-S2-S3) in buccal neurons. Intracellular Lucifer Yellow injection revealed that N1a is a true buccal interneuron with a single axon that projects to the contralateral buccal ganglion and no processes occur in buccal nerve roots.

297.8

MODULATION OF CROP AND ESOPHAGEAL ACTIVITY BY THE FEEDING MOTOR PROGRAM, SCPS AND BUCCAL NEURON B1 IN THE TERRESTRIAL SLUG, Limax maximus. I.G. Welsford and D. J. Prior. Department of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia 19104-6084 and Dept. of Biological Sciences Northern Arizona Univ.,Flagstaff 86011-5640.

Activation of the feeding motor program (FMP) in semi-intact preparations of the terrestrial slug, Limax maximus, initiated rapid, high frequency contractions of the crop and esophagus. The FMP-induced increase in esophageal activity was mediated via the gastric nerves, while those of the crop were mediated via nerves N11 and N9. Application of SCP_A at concentrations of at least 10^{-7} M and SCP_B at concentrations of at least 10^{-9} M, similarly initiated rapid, high frequency crop and esophageal contractions. Unilateral stimulation of buccal neuron B1, which contains SCP-like immunoreactive material, initiated rapid high amplitude contractions of crop (but not esophagus) in a frequency-dependent manner (threshold 3-5 Hz). B1-induced increases in crop contractile activity were mediated via nerve N9. These data suggest that B1 may mediate FMP-induced alterations in crop activity in L. maximus, possibly via release of SCPs. Supported by Sigma Xi (IGW).

297.9

A PHYSIOLOGICAL AND IMMUNOCYTOCHEMICAL STUDY OF INNERVATION OF THE PENIAL COMPLEX IN THE SNAIL MELAMPUS BIDENTATUS. S.B. Moffett, Marine Biomedical Institute, Galveston, TX 77550.

Two clusters of neurons innervate the penial complex (sheath, penis, efferent duct and retractor muscles): one cluster is in the right cerebral ganglion and the other is in the right pedal ganglion. The transmitters utilized by cerebral neurons are not known, but serotonin-like and CARP (catch relaxing peptide)-like immunofluorescences are colocalized in the pedal neurons. A muscle preparation consisting of efferent duct, penis and sheath responds to brief stimulation of the penial nerve with twitch contractions. These increase in amplitude with increasing voltage until a plateau is reached and then, as the smaller pedal neurons are recruited, decrease to a stable lower plateau. Stimulation of the cerebropedal connective activates pedal neurons alone, producing a transient contraction sometimes followed by reduction in resting tension. The penial complex is also innervated by axons with buccalin-like and FMRFamide-like immunofluorescence and by peripheral neurons that exhibit CARP-like immunoreactivity. The muscle preparation responds to acetylcholine or FMRFamide with a prolonged contraction which is relaxed by serotonin. Effects of the other neuropeptides are under investigation. (Supported by NIH NS22896 to S.B.M. and NS27314 to J.E. Blankenship)

297.10

THE DISTRIBUTION OF SCP PEPTIDES IN MOLLUSCS. D.A. Price, D.M. Reed*, K.E. Doble*, T.D. Lee*,† and M.J. Greenberg. Whitney Lab, St. Augustine, FL 32086. †Div. of Immunol., Beckman Res. Inst. of the City of Hope, Duarte, CA 91010.

We have purified SCPs from various molluscan species using HPLC and RIA, and characterized them by FAB mass spectroscopy and, in some cases, micro-sequencing. We find that the SCPs are a fairly diverse group of peptides. For example, we found and sequenced an SCP analog from a clam (AMSFYFPRMamide) which had only its C-terminal tetrapeptide in common with the known SCPs. We have been unable to find any SCP-like immunoreactivity in chitons, so their SCPs may not react with our antisera. Within the gastropods all of the SCPs we have sequenced so far have a common heptapeptide core YLAFPRMamide, except for the mesogastropod Littorina irrorata which has an Ile for Leu substitution (SQPYIAFPRMamide). We found NYLAFPRMamide in one neogastropod, Thais haemastoma, but not in another, Busycon contrarium. One SCP, SGYLAFPRMamide, appears to be common to all pulmonates, but others are restricted to certain species. For example, SCP_B itself (MNYLAFPRMamide, identical to an SCP from Aplysia) is present in some (e.g., Helix, Siphonaria), but not others. Lymnaea has an 1120 dalton peptide with a blocked N-terminal which is absent from both Physa and Helisoma, and SQGYLAFPRMamide is found in both Biomphalaria glabrata and Helisoma. We are just starting to investigate the physiological significance of these structural variations.

EFFERENT NEUROTRANSMITTERS ONTO THE HAIR CELLS IN THE STATOCYST OF THE SQUID, *ALLOTEUTHIS SUBULATA*. R. Williamson.* (SPON: European Neuroscience Association) The Marine Laboratory, Citadel Hill, Plymouth PL1 2PB, U.K.

The squid statocyst has a sophisticated angular acceleration receptor system containing a strip of polarised secondary hair cells which make synaptic contact with underlying afferent neurones. The hair cells receive a very large efferent innervation which has been shown by histological methods to consist of cholinergic and catecholaminergic endings. Experiments were undertaken to establish whether the efferents had an effect on the statocyst output and if cholinergic and catecholaminergic agents were involved.

Electrical stimulation of the efferents was found to be able to decrease or increase the level of activity from the statocyst afferents. Bath application of gallamine could block the efferent induced decrease in afferent activity while phentolamine or haloperidol could block the efferent induced increase in activity. The spontaneous afferent activity could be decreased by bath applied acetylcholine and increased by dopamine or noradrenaline. Intracellular recordings from the secondary hair cells have indicated that they receive both inhibitory and excitatory efferent inputs and that, as with the afferent activity, the inhibitory input can be blocked by gallamine and the excitatory input by haloperidol.

These results support the view that the hair cells of the squid statocyst receive an efferent inhibitory input mediated by acetylcholine and an excitatory input which is catecholaminergic.

R.W. is a Wellcome Trust Senior Fellow.

297.12

LOCALIZATION AND CHARACTERIZATION OF 125I-α-BUNGAROTOXIN BINDING SITES IN COCKROACH BRAIN. G.L. Orr, N. Orr, R.M. Hollingworth*. Pesticide Res. Ctr., Mich. St. U., E. Lansing, MI 48824

Acetylcholine is an important neurotransmitter in the insect central nervous system and functional nicotinic acetylcholine receptors (nAChRs) in these tissues can be readily studied using α-bungarotoxin (α-BGT) as a receptor ligand. Nicotinic AChRs in cockroach brain membranes were characterized using ^{125}I-BGT in a filter binding assay and localized autoradiographically in 8 µm brain sections. Binding was saturable at α-BGT concentrations above 2 nM and Scatchard analysis of this data yields a linear plot with a K_d of 1.08 nM and a B_{max} of 8926 fmoles/mg protein with a Hill coefficient of 0.9. Displacement studies confirm the nicotinic nature of this site and demonstrate the high affinity of the Delphinium alkaloid, methyllycaconitine, and the antihelmintics, morantel and pyrantel. Kappa-bungarotoxin (k-BGT) displaces α-BGT in a biphasic manner and analyses of these data indicates that k-BGT is displacing ^{125}I-BGT from two sites which bind α-BGT with equal affinity. Autoradiographic studies show binding to be restricted mainly to neuropile regions of the brain and to be displaced by compounds showing high affinity in the binding assay.

297.13

CHARACTERIZATION OF A POTENT AGONIST OF OCTOPAMINE-SENSITIVE ADENYLATE CYCLASE. N. Orr, G.L. Orr, R.M. Hollingworth*. Dept. Zoology/Neurosci. and Pesticide Res. Ctr., Michigan St. Univ., E. Lansing, MI, 48824.

Octopamine (OA), a major biogenic amine in invertebtates, has been shown to function as a neuromodulator, neurotransmitter and a neurohormone. Many of these actions are mediated through the activation of octopamine-sensitive adenylate cyclase (OA-S-AC). The clonidine analogue, XAMI, was evaluated for effects on OA-S-AC in crude membrane preparations of neural and non-neural tissues in the cockroach, Periplaneta americana, and the tobacco hornworm, Manduca sexta. In cockroach nerve cord, XAMI was found to be a partial agonist with a V_{max} 87.9% of OA and a K_a= 36 nM which was 140 times less that that of OA. Additivity studies suggest that at a maximally stimulating concentration of 1 µM, XAMI interacts primarily with the OA-S-AC. The antagonist profile for XAMI mimics that of OA with mianserin being the best antagonist, followed by the α-adrenergic antagonist phentolamine. The β-adrenergic antagonist propranolol was ineffective. These data suggest that XAMI and related high-affinity analogues may be good ligands for studying the OA receptor and could have potential pesticidal activities with low vertebrate toxicity.

297.14

ISOLATION OF A PUTATIVE OCTOPAMINE RECEPTOR PROTEIN. James A. Nathanson and Edward J. Hunnicutt. Dept. of Neurology, Harvard Medical School, and Neuropharmacology Lab., Massachusetts General Hospital, Boston, MA 02114.

Despite recent advances in the isolation and cloning of vertebrate neurotransmitter receptors, little progress has been made in the isolation of invertebrate amine neurotransmitter receptor proteins. In the case of octopamine (OA) (thought by some to be the invertebrate analog to norepinephrine and epinephrine) progress has been hampered by the lack of high affinity or irreversible OA ligands. We now describe the isolation of a putative OA receptor protein from the firefly, Photinus pyralis using NC-5Z, a novel photoaffinity ligand for OA receptors. Under reversible conditions, NC-5Z stimulates light emission from intact firefly tails and, in membranes, activates OA-sensitive adenylate cyclase with a potency approximately 50-100 fold that of OA. Activation is non-additive with that due to OA and is blocked specifically by OA antagonists. When photolyzed with UV, NC-5Z irreversibly activates light organ adenylate cyclase, and such activation can be prevented by preincubation with an excess of OA. SDS-polyacrylamide electrophoresis and autoradiography of NC-5Z-labeled membranes reveals a 72±2 kD glycoprotein, the labeling of which can be displaced by mianserin and other OA antagonists. The identification of this putative OA receptor proteins may be useful in molecular biological studies of OA receptors.

5,7-DIHYDROXYTRYPTAMINE AFFECTS FEEDING BEHAVIOUR, SEROTONIN-LIKE IMMUNOREACTIVITY AND SEROTONIN CONTENT OF SELECTED TISSUES IN *RHODNIUS PROLIXUS*. H. COOK* and I. ORCHARD. Dept. of Zoology, Univ. of Toronto, Toronto, ON, Canada M5S 1A1.

5,7-dihydroxytryptamine (5,7-DHT), a neurotoxic analogue of serotonin, selectively lesions serotonergic neurons. In *Rhodnius prolixus*, 5,7-DHT treatment (1 µl of 10^{-3} M injected 24 hr previously) led to the enhancement of serotonin-like immunoreactive staining in the cell bodies and axons of 5 dorsal, unpaired, median (DUM) neurons in the mesothoracic ganglionic mass (MTGM). These neurons appear to be the major contributers to the serotonin-like immunoreactive neurohaemal areas of the ten abdominal nerves. The toxin-induced enhancement of immunoreactivity in the cell bodies and axons was accompanied by a severe depletion in the staining intensity of the neurohaemal areas. The serotonin-like immunoreactivity covering the salivary gland ducts also suffered a severe decrease in staining intensity. 5,7-DHT treatment resulted in a significant decrease in the serotonin content of the salivary glands and abdominal nerves, as measured by HPLC. No significant changes were noted in the brain, subesophageal ganglion, prothoracic ganglion or MTGM. In additon, bugs treated with 5,7-DHT ingested a blood meal which was significantly smaller than that of controls. These findings suggest that the depletion of peripheral serotonergic areas impairs feeding in *Rhodnius*.

297.16

EVIDENCE FOR NICOTINIC CHOLINERGIC AND FMRF-AMIDERGIC RECEPTORS IN BODY WALL MUSCULATURE OF A NEMERTINE WORM, *CEREBRATULUS LACTEUS*. W. R. Kem. Department of Pharmacology and Therapeutics, University of Florida College of Medicine, Gainesville, FL 32610.

Nemertines are a phylum of unsegmented carnivorous worms thought to have evolved from a turbellarian ancestor. The responsiveness of *Cerebratulus* longitudinal body wall muscle strips lacking nerve plexus to cholinergic compounds and various neuropeptides was investigated. ACh, nicotine, and several other nicotinoid compounds contracted the muscle, whereas four muscarinic agonists were without effect. Various nicotinic receptor antagonists, except for α-bungarotoxin, inhibited carbachol contractures, while muscarinic antagonists were inactive. The muscle was not irreversibly affected by either bromoacetylcholine or N-maleimidophenyltrimethylammonium after exposure to disulfide bond reducing agents. Histrionicotoxin did not block the carbachol response.

The contractural activity of a variety of FMRFa analogs was also tested. Although extensions at the N-terminus were tolerated without significant loss of activity, alteration of the RFa C-terminus always greatly reduced activity relative to FMRFa. Only one analog, FIRFamide, was more (3x) active than FMRFa. In collaboration with D. Price, two HPLC fractions immunoreactive with FMRFa antibody, but possessing different retention times, were detected in *Cerebratulus* extracts. This initial investigation indicates the presence of nicotinic cholinergic and FMRFa-like peptide receptors in longitudinal muscles of nemertines, a lower invertebrate phylum.

297.17

SEROTONIN REPRODUCES ASPECTS OF THE ALTERED BEHAVIOR INDUCED BY THE PARASITE *POLYMORPHUS PARADOXUS* (ACANTHOCEPHALA) IN *GAMMARUS LACUSTRIS* (CRUSTACEA). S.M. Helluy* and J.C. Holmes* (SPON: S. Wiener). Dept. of Zoology, Univ. of Alberta, Edmonton, Alberta, Canada, T6G 2E9.

Some larval helminths alter the behavior of their invertebrate intermediate hosts by changing the responses of the hosts to environmental stimuli. *P. paradoxus* induces in its intermediate host *G. lacustris* a shift in habitat towards zones of higher illumination and an altered escape behavior. Upon mechanical disturbance infected gammarids escape towards a light source, then cling firmly to any material and remain immobile in a flexed posture from minutes to hours. Uninfected gammarids escape away from a light source and do not cling (Bethel, W. M., and Holmes, J. C., *J. Parasitol.* 59:945, 1973).

Uninfected gammarids injected with serotonin (1 to 20 µg/50 mg) (but not other biogenic amines or GABA) responded to mechanical stimulation by clinging, but the response lasted for a shorter time than in infected gammarids. Octopamine (5, 10 µg/50 mg) suppressed the clinging response in infected gammarids for several hours. Also, serotonin elicited a photopositive behavior in uninfected gammarids in the hour following treatment, overriding the normal photic behavior of the animals. Octopamine did not affect the photic behavior of infected gammarids. The opposite actions of serotonin and octopamine on the clinging behavior of gammarids shared similarities with those obtained on the posture of lobsters and crayfish (Livingstone, M. S., et al., *Science*, 208:76, 1980), and on the escape behavior of crayfish (Glanzman, D. L., and Krasne, F. B., *J. Neurosci.*, 11:2263, 1983). (Supported by NSERC A-1444)

OBSERVATIONS ON THE MECHANISM OF THE STIFFENING ACTION OF ACh ON THE LIGAMENT OF THE SEA URCHIN SPINE. M. Morales*, J. Del Castillo* & D. S. Smith*. (Spon. C. Zuazaga). Institute of Neurobiol., UPR-MSC, 201 Blvd. del Valle, San Juan, Puerto Rico 00901 and Dept. of Zoology, U. of Oxford, Oxford OX1 3PS, U.K.

The spine-test articulation of the sea urchin is surrounded by a capsule or ligament which, in addition to collagen bundles, contains neurosecretory processes and thin muscle fibers. This structure exhibits rapid and reversible changes in viscosity under nervous control. Acetylcholine (ACh) (1-10 uM) stiffens the ligament rapidly. We tested the effect of ACh on: a) ligaments treated with saponin (0.1 mg/ml, 1 hour); b) ligaments immersed in sea water made 3 X hypertonic by the addition of sucrose, c) ligaments treated with Na azide and dinitrophenol [2 mM] and d) on frozen and thawed ligaments. As none of these treatments blocked the ACh effect, we concluded this is not likely to involve either cells or cellular membranes.

Calcium proved to be essential for the effect of ACh. Ca^{2+} ions in the medium could be replaced by Sr^{2+}, but the ACh effect was blocked by Mg, Ba, Co, Cd and La. In addition, the Ca channel blockers verapamil, bepridil and nifedipin [2 mM] prevented the effect of ACh. (Supported by NIH Grants No. NS-07464 and NS-14938).

PEPTIDES: ANATOMICAL LOCALIZATION III

298.1

ULTRASTRUCTURAL LOCALIZATION OF ENKEPHALINASE (E.C.3-4-24-11) IN RAT NEOSTRIATUM. D. Marcel*, H. Pollard*, P. Verroust*, J.C. Schwartz* and A. Beaudet (SPON: B.E. Jones). Neuroanatomy Laboratory, Montreal Neurological Institute, Montreal, Quebec, H3A 2B4, Canada.

The peptide degrading enzyme "enkephalinase" (enkase) was localized by light and electron microscopic immunocytochemistry in sections of rat neostriatum using a specific monoclonal antibody. The antibody was visualized using either radioautographic or PAP techniques. In the light microscope, both methods revealed a heterogeneous immunolabeling pattern characterized by the presence of dense patches prominent against a lighter matrix. These patches were concentrated in the dorsal aspect of the neostriatum and matched patches of mu opioid receptors detected by radioautography in adjacent sections. In the electron microscope, both techniques showed an ubiquitous distribution of the enzyme along neuronal plasma membranes. Immunolabeling was found with comparable frequencies along perikarya, dendrites, myelinated and unmyelinated axons and axon terminals and was most intense at the interface between two labeled elements. In rare instances, oligodendrocytes and thin glial leaflets also exhibited weak surface immunoreactivity. No obvious concentration of immunoreactive material was apparent at the level of synaptic junctions. The similarity between light and electron microscopic distributions of enkase and mu opioid receptor labeling supports a role of enkase in the inactivation of opioid peptides.

298.2

THE COEXISTENCE OF METHIONINE ENKEPHALIN- AND TYROSINE HYDROXYLASE-LIKE IMMUNOREACTIVITY IN COERULOSPINAL COMPLEX NEURONS: A THREE-COLOR IMMUNOFLUORESCENCE STUDY. H. Zhuo*, S.J. Fung, V.K. Reddy* and C.D. Barnes. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520

Previous studies have revealed the presence of spinally projecting methionine enkephalin- and tyrosine hydroxylase-containing neurons in the dorsolateral pontine tegmentum of the cat. Using a combined retrograde fast blue and immunofluorescence technique, the present study was designed to reveal the coexistence of methionine enkephalin and tyrosine hydroxylase in coerulospinal complex neurons.

In anesthetized cats, 5% fast blue was injected bilaterally into the lumbar spinal cord. After a two-week survival period, the animal received a colchicine injection intraventricularly 24 hr before sacrifice. The pontine brainstem was sectioned coronally at 20 um, and sections were first incubated with rabbit anti-methionine enkephalin and mouse anti-tyrosine hydroxylase antisera, and then reacted with anti-mouse IgG conjugated FITC and anti-rabbit IgG conjugated rhodamine, using the method of Staines et al. (J. Histochem. Cytochem. 36:145-151, 1988).

Under fluorescence microscopy, within one section, three-color fluorescence-labeled neurons were seen in the nucleus locus coeruleus, nucleus subcoeruleus, Kolliker-Fuse nucleus, and the medial and lateral parabrachial areas. The distribution of variously (triple-, double- and single-) labeled neurons of the dorsolateral pontine tegmentum were determined and morphometric measurements were performed. (Supported by NIH grant NS24388).

298.3

LOCALIZATION OF NEURONAL mRNA BY IN SITU HYBRIDIZATION USING A NON-RADIOACTIVE DETECTION METHOD. D.S. Grega, T.J. Cavanagh*, S. Grimme*, R. Martin, M. Lewis, E. Robbins* and F. Baldino, Jr. Boehringer Mannheim Corp., Indianapolis, IN. and Cephalon, Inc., West Chester, PA.

In situ hybridization (ISH) is a powerful tool for localizing mRNA's in specific cells. This is extremely valuable in studying the nervous system, where the presence of a specific cellular mRNA is determined in the context of the cell's unique location and function. This report describes a non-radioactive ELISA-based method for detecting digoxigenin-labeled oligonucleotide probes. Probe labeling procedures, determination of residue tail length, application of several probes to neuronal mRNA's in rat brain sections and a comparison with immunohistochemical detection for the end product is presented.

Oligonucleotide probes (20 to 40 base length) were 3'-end labeled with digoxigenin-labeled deoxyuridine triphosphate (Dig-dUTP) using terminal transferase. Tailing procedure modifications and tail length were assessed. Tail length varied between two and four Dig-labeled residues. Dig-labeled oligonucleotide probes were used to localize mRNA for arginine vasopressin, prosomatostatin, tyrosine hydroxylase and POMC in cryostat sections from appropriate brain regions using an alkaline phosphatase antibody-conjugate and subsequent color reaction. Immunohistochemical (IHC) detection of enzyme or neuropeptide was compared with ISH for the respective message.

Advantages of non-radioactive vs. radioactive detection methods for ISH include: rapid localization of mRNA's (days vs. weeks), increased cellular resolution, increased safety and ready comparison with conventional IHC.

298.4

VASOPRESSIN IMMUNOREACTIVITY IN THE BRAINS OF SEVERAL HAMSTER GENERA. T.P. Goodness, G.J. De Vries, C.F. Ferris, Neuroscience and Behavior, Univ. of Massachusetts, Amherst, Dept. of Physiology, Univ. of Massachusetts, Worcester.

Previous studies have shown similar patterns of vasopressin immunoreactivity (VP-IR) in the brains of rats, mice, gerbils, guinea pigs, and European hamsters. In all of these species, VP-containing neurons can be found in the paraventricular, supraoptic, suprachiasmatic, and medial amygdaloid nuclei, and in the bed nucleus of the stria terminalis . The VP content of the latter two nuclei is steroid dependent. In the rat, VP content decreases following castration and in European hamsters, VP content varies seasonally with testosterone levels. We compared the pattern of VP-IR in the Chinese hamsters (Cricetelus griseus), Armenian hamsters (Cricetelus migratorius), Djungarian hamster (Phodopus sungorus), and Syrian hamsters (Mesocricetus auratus). Although the pattern of VP-IR in the brains of Chinese, Armenian, and Djungarians was similar to that of other rodents, the steroid sensitive neurons were absent in the Syrian hamster. (Supported by NSF grant BNS-8809799 to GJD and NIH grant NS-23557 to CFF.)

298.5

COMPUTER-AIDED RECONSTRUCTION OF THE HYPOTHALAMO-NEUROHYPOPHYSIAL SYSTEM IN THE GOLDEN HAMSTER: EVIDENCE OF POPULATIONS OF NON-PROJECTING VASOPRESSIN MAGNOCELLULAR NEURONS AS REVEALED BY DOUBLE-STAINING. P.D. Mahoney*, E.T. Koh*, and C.F. Ferris. (Spon. A. Tischler) Dept. of Physiology, Univ. of Massachusetts Medical Center, Worcester, MA 01655.

In this study, we have mapped the hypothalamo-neurohypophysial system of the male Golden hamster, generating a 3-dimensional computer representation of the system in both a rotatable wire-frame model and a shaded and smoothed solid model. Three hamsters were micro-injected with HRP into the neurohypophysis, and 24 h later the hamsters were anesthetized and perfused, and their brains removed and sectioned (50 µm). The sections were first processed for HRP with TMB followed by nickel-conjugated DAB, and subsequently stained for vasopressin (AVP) using PAP with DAB. These double-stained sections were mapped using the PC-AT based software program Cellmate® (R&M Biometrics, Nashville, Tennessee). The average number of retrogradely labeled neurons, i.e. those projecting to the neurohypophysis, was 5773 ± 533. However, an average of 1110 ± 363 cells were immunoreactive to AVP but devoid of HRP. These neurons that did not project to the neurohypophysis were localized primarily in the medial supraoptic nucleus, paraventricular nucleus, and the nucleus circularis at the level of the anterior hypothalamus approximately 1000 µm caudal to the caudal border of the anterior commissure. Based on the distribution and localization of the non-projecting populations, it is speculated that these neurons may provide neurotransmitter for AVP-dependent flank marking in the Golden hamster. *This work was supported by NIH grant #NS23657.*

298.6

THE EXPRESSION OF MUTANT VASOPRESSIN PEPTIDE INCREASES THROUGHOUT LIFE IN BRATTLEBORO RATS. H.A. Griffioen*, F.W. van Leeuwen*, E.M. v.d. Beek* and R. Ivell**. (SPON: ENA) *Neth. Inst. for Brain Res., Amsterdam, The Netherlands, **Inst. for Horm. and Fert. Res., Hamburg, F.R.G.

The homozygous diabetes insipidus (HO-DI) Brattleboro rat is unable to synthetize a normal vasopressin (VP) precursor. A deletion in exon B of the VP gene results in a shift of the VP-mRNA reading-frame. As a consequence, a different non-glycosalated C-terminal mutant peptide is formed, which cannot be packaged in granules. An antiserum raised against the last fourteen amino acids of the mutant pwptide (CP-14) stained the supraoptic nucleus (SON) (e.g. Guldenaar et al., Cell Tiss. Res. 244: 431, 1986).

In the present study life-span changes in CP-14 immunoreactivity in the SON of male and female HO-DI rats are reported. Contrary to the report of Guldenaar et al., CP-14 immunoreactivity was also found in the PVN. During life the amount of CP-14 immunoreactivity in the SON slowly increases. In 16-day- and 6-week-old rats hardly any CP-14 immunoreactivity could be seen. This immunoreactivity slowly increased in 12- and 30-week-old HO-DI rats. In 44-, 52- and 83-week-old HO-DI rats a very intense staining is present. No sex differences were observed. The results indicate that during life the expression of the mutant VP-gene in HO-DI rats increases. Alternatively, the turn-over rate of m-RNA could be decreased.

298.7

EFFECTS OF COLCHICINE ON CGRP mRNA AND CGRP CONTENT IN RAT BRAIN STEM MOTONEURONS. M. Rethelyi*, C.B. Metz*, P. Petrusz* and P.K. Lund* (SPON: M.J. Sedivec). Depts. of Physiology and Cell Biology & Anatomy, Univ. of North Carolina, Chapel Hill, NC 27599.

In situ hybridization histochemistry and immunocytochemistry were used on adjacent sections to study the effect of colchicine on the expression of mRNA encoding CGRP in brain stem motoneurons. Vibratome sections were prepared from the brain stem of rats which received icv injections of colchicine (2x50 ug) 24 and 48 hours before sacrifice. Saline-injected and intact rats served as controls. Two oligomer probes of 23 and 32 bases in length were end-labeled with 32P. Autoradiography was performed on hybridized sections. - In the nucleus ambiguus and in the nuclei of the XIIth and VIIth nerves hybridization signal and immunoreaction (both of which were present in intact and saline injected controls) increased after colchicine injection. Hybridization signal and peptide immunoreaction could be detected in the neurons in the motor nuclei of the IIIrd, IVth, Vth and VIth nerves only after colchicine injection. (Supported by grants NS23804 and NS14899 from NINCDS, NIH.)

298.8

REGIONAL DISTRIBUTION AND CHARACTERIZATION OF THE BRAIN-GUT PEPTIDE: CALCITONIN GENE RELATED PEPTIDE (CGRP) IN PIG. D.R. Roddy*, L.D. Aimone, T.L. Yaksh, V.L.W. Go*. (SPON: J.A. Gilbert). Mayo Clinic, Rochester, MN 55905, Univ. of CA, San Diego, LaJolla, CA 92093, and Univ. of CA, Los Angeles, Los Angeles, CA 90024.

The presence of CGRP has been noted in tissues of the digestive, respiratory, urogenital, cardiovascular and central nervous systems where it appears by immunohistochemistry to be co-contained with tachykinins in primary sensory neurons (Neurosci 23:693, 1987). We used a specific radioimmunoassay (RIA) for CGRP to corroborate some of these findings. Tissues of gut, brain and spinal cord of pig (n=4) were dissected immediately postmortem, extracted in 0.1 N HCl and assayed by RIA. CRGP was least abundant in pig gut, where highest concentrations were noted in the small intestine (24 ng/gm). In brain, 115 ng/gm of CGRP was found in anterior hypothalamus and lateral medulla, 96 ng/gm in mammary body and 60 ng/gm in medial thalamus and substantia nigra. Notable amounts of CGRP were found throughout the dorsal horn of spinal cord (77-166 ng/gm) as well as in dorsal root ganglia, trigeminal ganglia and sciatic nerves (108-168 ng/gm). Thus, presence of CGRP in primary sensory neurons is confirmed by RIA.

298.9

CGRP PRIMARY AFFERENTS ARE PRESYNAPTIC TO GABA TERMINALS IN PRIMATE DORSAL HORN: A POST-EMBEDDING IMMUNOGOLD STUDY. Elizabeth Hayes* and Susan M. Carlton (SPON: J. Kitay). Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550.

A considerable amount of evidence supports the role of γ-aminobutyric acid (GABA) mediating primary afferent depolarization. This modulation is accomplished through axo-axonic interactions. Much of the anatomical data supporting this theory is based on degeneration studies following dorsal rhizotomy. It is difficult, however, to determine by structural criteria if a degenerating profile is a presynaptic or postsynaptic element. Therefore, in the following study, the interaction of GABA with calcitonin gene-related peptide (CGRP) containing primary afferents was analyzed at the electron microscopic level using the PAP immunostaining method combined with post-embedding immunogold labeling. Monkeys were perfused with mixed aldehydes and lumbar sections (25µm) immunostained for GABA using the PAP method. Following flat embedding in plastic, ultrathin sections were collected on formvar coated nickel slot grids. Osmicated sections were etched with $NaOI_4$ and $NaBH_4$ and immunostained for CGRP with 15nm IgG-gold (Janssen). In laminae I and II, GABA axon terminals, dendrites and cell bodies were observed postsynaptic to large glomerular type CGRP terminals. These findings challenge previous data which suggested GABA was presynaptic to primary afferents. (Supported by NIH grant NS 11255.)

298.10

DYNORPHIN A (1-8) PROFILES ARE POSTSYNAPTIC TO CALCITONIN GENE-RELATED PEPTIDE (CGRP) CONTAINING PRIMARY AFFERENTS IN MONKEY DORSAL HORN: A POST-EMBEDDING IMMUNOGOLD STUDY. Susan M. Carlton and Elizabeth Hayes*, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550

The upregulation of dynorphin (DYN) message and DYN peptide has been demonstrated in the dorsal horn following painful manipulations. It is hypothesized that increased DYN levels are a direct result of increased primary afferent input. In the present study we investigated the synaptic interactions between CGRP containing primary afferents and DYN A (1-8) profiles in the dorsal horn of Macaca fascicularis.

Monkeys were perfused with mixed aldehydes. Free floating lumbar sections (25µm) were immunostained for DYN using the PAP method, osmicated and then flat embedded in plastic. Ultrathin sections were collected on formvar coated nickel slot grids, etched with $NaOI_4$ and $NaBH_4$ and immunostained for CGRP with 15nm IgG-gold (Janssen). In laminae I and II, numerous CGRP-DYN interactions were observed with the CGRP terminal presynaptic to DYN containing cell bodies, dendrites and terminals. We hypothesize that CGRP effects both the manufacture and synaptic release of DYN A (1-8) in the dorsal horn. Furthermore, this structural relationship may play an important role in the processing of noxious input at the spinal cord level. Supported by grants from NIH (NS 11255) and the Bristol Myers Co.

298.11

THE DEVELOPMENT OF CHOLECYSTOKININ IN THE INTERPEDUNCULAR NUCLEUS OF RATS. M.P. Joyce* and G.A. Barr. Biopsychology Doctoral Program, Dept. of Psychology, Hunter College, CUNY, New York, N.Y. 10021 and Department of Psychiatry, Albert Einstein College of Medicine, Bronx, New York 10461.

The interpeduncular nucleus (IPN) contains distinctive subnuclei distinguished by their neurotransmitter content and synaptic and cellular morphology. The octapeptide, cholecystokinin (CCK) has been observed to be confined to well defined areas of the IPN. The presence of fiber staining with the absence of cell body labeling, indicates that the CCK content of the IPN is from un defined extrinsic sources. In order to elucidate the development of the distribution of IPN afferents, changes in the staining characteristics of CCK were studied in rat pups aged 1 to 35 days. Immunocytochemistry was performed with the Vectastain ABC Kit (Vector Labs). The primary antibody against CCK (Incstar) was diluted to 1:20,000. In the adult rat, substantial labeling is observed in the rostral, dorsal, lateral, and dorsal lateral subnuclei as other studies indicate. Staining is present but sparse in the central and ovoid areas of the rostral subnucleus. As development proceeds, staining in the rostral, central and dorsal subnuclei becomes more intense. In the lateral and dorsal lateral subnulcei, high staining densities are observed as early as 7 days of age with minor changes in density but not pattern of staining occurring thereafter. By 35 days of age, the localized areas of relatively dense fiber labeling described above is observed.

298.12

NEUROPHYSIN EXISTS IN A DIFFERENT CONFORMATIONAL FORM IN PARVICELLULAR NEURONS OF RAT HYPOTHALAMUS. G. Nilaver, L.C. Rosenbaum*, H.H.M. Van Tol*, and E.A. Neuwelt*. Depts. of Neurol., Biochem., Neurosurg., & Vollum Inst. Adv. Biomed. Res., Oregon Hlth. Sci. Univ., Portland, OR 97201.

Neurophysins (NPs) are carrier proteins associated with oxytocin (OT) and vasopressin (VP) neurons of the hypothalamus. We have previously demonstrated that a monoclonal antibody (mAb L6) raised to a surface antigen of human lung adenocarcinoma recognizes a cytoplasmic epitope in OT and VP neurons, identified as NP by immunohistochemistry and Western analysis (Neurology, 38:392,1988). We now report on the distribution of L6 immunoreactivity in control and adrenalectomized (ADX) rats, and in rats following intracerebroventricular injection of colchicine (COL) and tunicamycin (TX). Analysis of coronal sections (100 μm) of control rat hypothalamus demonstrated NP immunoreactivity to be exclusively confined to magnocellular OT and VP neurons and their projections to neural lobe. No staining was noted in the suprachiasmatic nucleus (SCN), the parvicellular paraventricular nucleus (p-PVN), or its projections to median eminence-zona externa (ZE-ME) and extrahypothalamic brain sites. The persistent absence of staining in p-PVN or ZE-ME of ADX rats, and in p-PVN and SCN of COL and TX rats suggests the existence of NP in a unique conformational form in these regions that is not recognized by mAb L6. (supported by PHS grants NIDDKD-37205 & NCI-31770; mAb L6 was provided by Drs. Hellström, ONCOGEN)

INNERVATION OF RAT HYPOTHALAMIC PARAVENTRICULAR (PVN) TRH-SYNTHESIZING NEURONS BY IMMUNOREACTIVE NEUROTENSIN. R. Toni, I.M.Jackson, S.E. Leeman, R.M.Lechan. Divs. of Endo., New England Med Ctr. Boston, MA 02111, R.I. Hosp., Providence, R.I. 02902 and Dept. of Physiology, Univ. Mass. Med. Sch., Worcester, MA 01605

Neurotensin (NT) exerts a number of effects in the CNS and when administered intraventricularly in the rat, inhibits TSH secretion from the anterior pituitary (Endocrinology,103,1903,1978).In addition,NT-immunoreactive (IR) neurons and fibers are richly distributed throughout parvocellular subdivisions of the rat PVN. To determine whether NT-IR axon terminals directly innervate TRH tuberoinfundibular (TI) neurons in the PVN, we performed double-immunolabeling studies at light and ultrastructural levels using antisera recognizing NT (HC#8, dil. 1:800) and a N-terminal sequence of the TRH precursor, preproTRH 25-50 (pYE-27, dil. 1:500)), as a marker of TRH neurons. After perfusion fixation of the rat brain, tissues were sectioned through the PVN and processed by the ABC technique using DAB as a chromogen. In the first step NT was identified by silver-gold or nickel ammonium sulfate to yeld a black or blue reaction product and in a sequential step, proTRH was identified using DAB alone or streptavidin-gold particles. NT-IR fibers were observed closely apposed to TRH-synthesizing neurons in anterior and periventricular parvocellular subdivisions of the PVN and to establish axo-somatic and axo-dendritic contacts, suggestive of functional synapses. Few NT-IR boutons were also observed presynaptic to unlabeled dendrites and juxtaposed to blood vessels. These data provide morphologic evidence to suggest a neurotensinergic innervation of TRH-synthesizing neurons in the PVN and indicate that at least some neurons of the TRH TI system may be under direct regulation by this neuropeptide.PHS 3F05TWO3924,grants NIH DK 37021 and CNR

GALANIN IMMUNOREACTIVITY IN PARASYMPATHETIC POSTGANGLIONIC NEURONS IN RAT SALIVARY GLANDS. F.A. Frierson*, L.M. Konopka*, and C.J. Forehand (SPON: I.J. Young). Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Neuropeptides coexist with classical transmitters in a variety of autonomic postganglionic neurons. For example, acetylcholine and functionally active vasoactive intestinal peptide (VIP) are colocalized in postganglionic neurons innervating cat salivary glands (Lundberg, J.M., et al., PNAS 77:1651, 1980). We have examined the distribution and source of galanin-like immunoreactive nerves in rat salivary glands.

Galanin-like immunoreactive fibers were observed throughout the submandibular, sublingual, and parotid glands in association with both inter- and intralobular ducts, and surrounding acini in the sublingual gland. The source of galanin-like fibers in the submandibular and sublingual glands was determined by denervation experiments. The glands were sympathectomized by severing the postganglionic branches from the superior cervical ganglion where they enter the glands. With sympathectomy, tyrosine hydroxylase immunoreactivity markedly decreased with no appreciable change in galanin-like immunoreactivity. Parasympathectomy, performed by severing postganglionic nerves from submandibular ganglia, resulted in a marked decrease in both VIP and galanin-like immunoreactivity. Moreover, galanin-like immunoreactivity was observed in submandibular ganglion cells.

These results indicate that galanin-like innervation of rat salivary glands is derived from parasympathetic nerves to the glands. Physiologic responses of individual gland cells to galanin application are described in the accompanying abstract (Forehand, C.J. and Konopka, L.M., Soc. Neurosci. Abstr. 15, 1989).

RAT SUBLINGUAL AND SUBMANDIBULAR GLAND CELLS DIFFER IN THEIR RESPONSES TO BOTH GALANIN AND BETHANECHOL. C.J. Forehand and L.M. Konopka. Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Rat sublingual glands contain largely mucous acini while rat submandibular gland acini are seromucous. In the previous abstract (Frierson, F.A., et al., Soc. Neurosci. Abstr. 15, 1989), we reported that a galanin-like peptide was present in the parasympathetic innervation to these glands, and that the acini of the sublingual, but not the submandibular, gland received dense galanin-like innervation. We have thus asked whether cells in these glands differ in their electrophysiologic responses to galanin and/or the muscarinic agonist, bethanechol.

Individual gland cells were impaled under visual control in wholemount preparations and maintained under single electrode current clamp. Resting membrane potentials ranged from -30 to -66 mv. Galanin (0.1mM) and bethanechol (10mM) were applied locally by pressure ejection. Agonist induced voltage shifts varied between the two glands: Most sublingual gland cells responded to bethanechol with biphasic voltage shifts, i.e., a short-lasting depolarization followed by a long-lasting hyperpolarization; a predominantly long-lasting depolarizing response was observed in the submandibular gland cells. Cells that responded to bethanechol with a biphasic response also responded to galanin. These results indicate a functionally different effect of the cholinergic and peptidergic inputs into the sublingual and submandibular salivary glands.

Supported by the American Heart Association and PHS grants K0401344 and R0125973.

GALANIN IMMUNOREACTIVE NEURONS IN THE HUMAN HYPOTHALAMUS. W.P. Gai*, L.B. Geffen*, and W.W. Blessing. Centre for Neuroscience, Flinders University of South Austrsalia, Bedford Park, SA 5042.

The localization of galanin (GA) immunoreactive neurons has been investigated by immunohistochemistry in the human hypothalamus. The coexistence of GA with arginine vasopressin (AVP), oxytocin (OXY) and tyrosine hydroxylase (TH) has also been examined in the supraoptic (SON) and paraventricular nuclei (PVN), in adjacent paraffin sections.

Somata and fibers positive for GA were found throughout the human hypothalamus. Major populations of GA-ir somata were seen in the preoptic area, intermediate, dorsal part of suprachiasmatic, SON, PVN, arcuate, dorsal and ventral part of the posterior hypothalamic, and the supramammillary nuclei. Scattered positive neurons were observed in the lateral part of the dorsomedial hypothalamic nucleus, lateral hypothalamic area and zona incerta. The number of GA-ir neurons in the intermediate nucleus was 10700; in the SON, 55900; and in the PVN, 43300. GA-ir fibers were more widely distributed than cell bodies and invaded most hypothalamic nuclei. The lateral tuberal nuclei and the SON (except the dorsomedial part) contained few GA-ir fibers. The mammillary complex contained almost no positive fibers. GA-ir axons were concenrated in the ventromedial part of the arcuate nucleus and formed a bundle travelling down the infundibular stem. In the median eminence the vascular plexus was wrapped by GA-ir fiber networks.

Neurons containing both GA and AVP were very common in the SON and also occurred in the PVN. These two nuclei also contained neurons positive for GA and OXY. Neurons positive for both GA and TH were rare.

The distribution of GA-ir neurons in the hypothalamus provides anatomical evidence for this neuropeptide being involved in endocrine and autonomic functions.

GALANIN/CHOLINERGIC INTERACTIONS IN THE HUMAN BRAIN: AUTORADIOGRAPHIC STUDIES OF GALANIN mRNA AND BINDING SITES USING in situ HYBRIDIZATION AND RECEPTOR AUTORADIOGRAPHY. J.M. Palacios[1], C. Bonnefond[1]*, G. Mengod[1]*, A. Probst[2]*, and P.H. Kelly[1]. 1) Precl. Res., Sandoz Ltd, 4002 Basle, 2) Dept.Neuropath., Inst.Pathol. Univ.Basle, 4000 Basle, Switzerland

Galanin, a 29 amino acid peptide, has been reported to colocalize with acetylcholine in certain regions of the rat brain. We have examined galanin-acetylcholine interactions in the human brain by using in situ hybridization, with synthetic oligonucleotides, and receptor autoradiography with ^{125}I-galanin. In both rat and human brain we observed high levels of galanin mRNA containing cells in several nuclei of the hypothalamus. However, in neither species were significant levels of galanin mRNA seen in the nucleus basalis of Meynert (nbM). Particularly high levels of galanin receptor binding sites were observed in the hypothalamus and some brainstem and bulbar nuclei. Neocortical areas were enriched in galanin binding, while intermediate levels were observed in the basal ganglia, the hippocampal formation and the nbM. In preliminary studies on the levels of ^{125}I-galanin binding in the nbM from senile dementia patients we did not observe significant differences in comparison with control cases. Unilateral lesions of the nbM in the rat also did not result in asymmetries of ^{125}I-galanin binding in any of the brain regions examined. These results are not consistent with a major direct anatomical interaction between galanin and acetylcholine in the human nbM.

ELECTRON MICROSCOPY OF THE 8TH NERVE AFTER IT'S TRAUMA IN THE RED-EARED TURTLE. R. H. Browner AND M. Nirenberg. Dept. Cell Biology and Anatomy, New York Med. Coll., Valhalla, N.Y. 10595.

Turtles were anesthetized with Sodium Brevital, placed on a stereotaxic apparatus and maintained with Halothane, Oxygen and Nitrous Oxide. The 8th nerves were crushed. The bony openings were closed with dental cement and the animals allowed to survive for 45, 50, and 80 days. Unoperated animals were used to determine the nerve's normal morphology. All animals were overdosed with Nembutal, the plastrons drilled open and the hearts exposed. The animals were transcardiaclly perfused with Reptilian Ringers and then 4% paraformaldehyde, 5% glutaraldehyde and 4% sucrose in phosphate buffer (0.15M, pH 7.4). The skulls were opened the heads were placed in the fixative overnight. The brainstem, 8th nerve and inner ears were removed, processed and embedded in Epon for EM analysis. Control 8th nerve fibers were myelinated and had normal elements. 8th nerve fibers in 50 and 80 day survivors were thinner with less myelin and fewer filaments. In both instances the 8th nerve were central nervous system tissue. (The Deafness Foundation).

AXONAL TRAJECTORIES OF TYPE-II SPIRAL GANGLION CELLS FROM VARIOUS COCHLEAR REGIONS IN MICE A.M. Berglund[1] and M.C. Brown[2]. Depts. of Anatomy and Cellular Biology[1], Cellular and Molecular Physiology and Otolaryngology[2], Harvard Medical School, Boston MA 02115; Eaton-Peabody Lab, Mass. Eye and Ear Infirmary, Boston MA 02114.

Most spiral ganglion neurons (type-I cells) provide the afferent pathway from inner hair cells, but a small population (5%; type-II cells) link outer hair cells with the cochlear nucleus (CN). Thin, unmyelinated axons of type-II cells from the basal region of the cochlea project to the CN, often forming terminal swellings in granule-cell regions (Brown et al., J. Comp. Neurol. *278*:581-590, '88). Our present objective was to determine if type-II axons from middle and apical cochlear regions shared these features. Extracellular HRP was deposited in the various turns of the spiral ganglion and the tissue was processed with DAB. Type-II axons (diameters < 1 um) from apical and middle regions were traced (9 fully and 17 partially) from their entrance in the nerve root to their terminals throughout the CN. These axons were compared with 6 basal axons of the previous study. Labeled axons from all cochlear regions followed labeled type-I axons and bifurcated in a cochleotopic manner, giving off ascending and descending branches. All type-II axons displayed many *en passant* (mean = 86), but only a few (mean = 5) terminal swellings on the ascending and descending branches. The type-II swellings were generally similar in morphology, regardless of their CN location and cochlear origin. Descending branches from all cochlear regions produced terminal swellings (20 of 37 total) in granule-cell regions. Unlike ascending branches from basal-region axons, however, those from apical-region axons produced terminal swellings primarily (37 of 39) near type-I terminals in magnocellular regions. We conclude: (1) Cochleotopic mapping of type-I and type-II axons onto the CN is similar for the bifurcation point and the general trajectory of the ascending branch; (2) Type-II axons, particularly descending branches, differ from type-I axons by their projection into CN granule-cell regions.

ACTIVATION OF THE AUDITORY BRAINSTEM OF DEAFENED GUINEA PIGS WITH COCHLEAR STIMULATION: A [14C]-2-DEOXYGLUCOSE STUDY. D.R. Schwartz*, J. Schacht, R.A. Altschuler, K. Frey and J. Miller. Kresge Hearing Research Institute, University of Michigan, Ann Arbor, MI 48109.

Profoundly deaf patients with remaining eighth nerve fibers are potential candidates for a cochlear prosthesis. However, after prolonged deafness, such implants have had variable success. The present study in guinea pigs used the 2-deoxyglucose (2DG) method to evaluate changes in the metabolic activity of the auditory brainstem with deafness and to determine the extent of reactivation with cochlear prosthetic stimulation.

Animals were deafened with kanamycin and ethacrynic acid. The following groups were compared: 1) unstimulated normal controls 2) sound-stimulated normal controls 3) unstimulated deafened animals 4) electrically stimulated (intrascalar electrode) deafened animals. The auditory brainstem (cochlear nucleus, superior olivary complex, lateral lamniscus and inferior colliculus) was evaluated.

In animals deafened for four weeks, auditory brainstem 2DG levels were reduced as compared to the sound-stimulated and unstimulated normal controls. Metabolic activity in the auditory brainstem was greatly increased with prosthetic stimulation but remained significantly below the level of either control group. These data show that auditory brainstem nuclei can be activated by cochlear prosthetic stimulation after 4 weeks of deafness. Future studies will examine the response after longer periods of deafness and with prolonged stimulation.

AUDITORY NERVE PROJECTIONS IN THE POSTNATAL OPOSSUM. F.H. Willard, Dept. of Anatomy, Univ. of New England, Biddeford Maine, 04005

The projection of auditory nerve fibers into the cochlear nucleus of the opossum, Monodelphis domesticus was investigated using the orthograde transport of HRP. These animals are born 14 days after conception. Opossums ranging from postnatal day 13 through 21 received placements of the HRP chips into the cochlea. All animals had cartilaginous temporal bones and ossicles as well as an epithelial plug in the external meatus. Tissue, sectioned frozen, was processed with BDHCl. Fibers, labelled with HRP, could be followed out of the cochlea, along the auditory nerve and into the cochlear nucleus. These fibers were arranged in a series of vertically oriented lamina extending throughout the rostrocaudal dimension of the cochlear nucleus. A topographic relationship was evident: placements in the apical region of the cochlea labelled fibers in the lateral aspect of the nucleus, while basal placements labelled medial fibers. Even at PND-13 labelled auditory nerve fibers were arranged in narrow lamina and exhibited little side branching. Evidently an adult-like, restricted distribution of auditory nerve fibers is established very early in development.

NEONATAL CONDUCTIVE HEARING LOSS AFFECTS COCHLEAR NUCLEI IN ALTRICIAL RODENTS BUT NOT IN PRECOCIAL RODENTS. D.B. Webster and N.A. O'Connell. Kresge Hearing Research Laboratory, Dept. of Otolaryngology, LSU Medical Center, New Orleans, LA 70112.

Unilateral conductive hearing losses of about 50 dB were initiated at 1 to 3 days of age by surgical removal of the external auditory meatus in CBA/J mice, cotton rats, spiny mice, and guinea pigs. At puberty, the animals were sacrificed with an overdose of anesthesia. Ears and brainstems were prepared for light microscopy and the cochlear nuclei were quantitatively studied. In CBA/J mice and cotton rats, who develop hearing postnatally, the volume of their ventral cochlear nuclei (VCN) and the size of VCN neurons were significantly smaller ($P<0.05$) on the experimental side than on the control side. In spiny mice and guinea pigs, who develop hearing prenatally, the volume of their VCN and size of VCN neurons were not significantly different ($P>0.05$) between experimental and control sides. The precocial rodents develop hearing in utero--essentially with a conductive loss--whereas the altricial rodents develop hearing postnatally with no conductive loss. Assuming that primitive mammals were altricial, the ability to develop normal cochlear nuclei with a conductive loss would be a derived character. [Supported by NIH grant NS 19238 and Kam's Fund.]

299.6

AGING AND THE MORPHOLOGY OF THE OCTOPUS CELL AREA OF THE COCHLEAR NUCLEUS IN C57BL/6J AND CBA MICE. J. F. Willott, L. S. Bross*, K. Jennings*, and J. Kelley*. Dept. Psychol., Northern Illinois Univ., DeKalb, IL 60115.

In C57 mice, which display progressive sensorineural cochlear pathology during middle age, volume of the octopus cell area (OCA) declines after 12-mo. of age, plummeting by 50% at 30 mo.; the number of neurons decreases, and the density of glial cells increases. Octopus cell size decreases only in the oldest mice. In CBA mice, which display minor sensorineural pathology late in life, a reduction in OCA volume and neuron density and increased glial density are dramatic after 24-mo.; octopus cell size is reduced by 24-mo. Golgi material indicates age-related changes including discontinuous dendrites, diminished size of arbors, and loss of some primary dendrites. However, normal-appearing octopus cells are found in extremely old mice of either strain.

While there are some differences in the profiles of age-related changes in the OCA between strains, the chronic sensorineural pathology in C57 mice does not appear to exacerbate the changes associated with aging.

MORPHOMETRIC ANALYSIS OF DEVELOPING ORIENTED DENDRITIC FIELDS IN THE DORSAL COCHLEAR NUCLEUS OF THE HAMSTER. L. Schweitzer. Dept. of Anatomical Sciences and Neurobiology, University of Louisville, Louisville, KY 40292.

We have demonstrated previously that the apical dendritic fields of fusiform cells in the dorsal cochlear nucleus become oriented parallel to the cochleotopic planes in the young hamster after the onset of hearing (Schweitzer & Cant, Neuroscience, 1985). These findings were based on comparisons between cells from different animals cut in different planes of section. With the use of a three-dimensional reconstruction system designed to analyze branching structures (Eutectic Electronics, Inc.), it has been possible to extend these initial observations by rotating the image of the cells and by analyzing each individual cell in different planes. In addition, detailed morphometric analyses of the dendrites of hamsters of various ages were performed in order to study the growth which underlies the formation of the oriented dendritic fields. The data indicate there is no change in the number of primary dendrites as a function of age. However, the dendrites do get longer in the dimension parallel to the cochleotopic planes as new branches are added to the existing dendrites. The distance between branch points remains remarkably constant with age.

These data from the normal hamster will be compared to the dendritic growth patterns in the neonatally-deafened hamster in which oriented dendritic fields fail to develop.

GLYCINE IMMUNOREACTIVITY IN THE COCHLEAR NUCLEUS: POSTEMBEDDING LIGHT AND ELECTRON MICROSCOPIC IMMUNOCYTOCHEMISTRY. J.M. Juiz, R.H. Helfert, J.M. Bonneau*, R.J. Wenthold+ and R.A. Altschuler. Kresge Hearing Research Institute, Univ. of Michigan, Ann Arbor, MI, 48109; +LMO, NIDCD, NIH.

An abundance of evidence supports a role for glycine as an inhibitory neurotransmitter in the cochlear nucleus (CN). To accurately identify glycine-like immunoreactivity in cells, fibers and terminals of the guinea pig CN, we used postembedding immunocytochemical techniques at both the light and electron microscopy levels.

Semithin and thin sections from aldehyde-fixed, plastic embedded CN were incubated with an affinity purified polyclonal rabbit antisera raised against glycine. The immunoreactivity was visualized using immunoperoxidase (for semithin sections) and immunogold (for ultrathin sections) techniques.

Immunoreactive cell bodies were found in all three subdivisions of the CN, with the greatest numbers located in the dorsal CN. These cells are currently being characterized ultrastructurally. Glycine immunoreactive terminals were abundant and contacted every major cell type in the CN. Two types of immunoreactive terminals have been identified, so far. The one more frequently observed contained oval/pleomorphic synaptic vesicles, while the other type possessed flat vesicles. Studies are in progress to further characterize these terminals with regard to shape, size, distribution and co-containment with other neurotransmitters.

CAVITATION IN THE ADULT GERBIL VENTRAL COCHLEAR NUCLEUS IS REVERSED BY COCHLEAR ABLATION. L. M. Kitzes and H. C. Moore* Depts. of Anatomy and Neurobiology and Surgery-Otolaryngology, University of California Irvine, Irvine, Ca 92717.

Round cavities are easily detectable in the ventral cochlear nucleus of the gerbil (Meriones unguiculatus) after 3 mo of age and increase in number and size thereafter. They have been taken as indicative of a neurodegenerative process (McGinn and Faddis, Hear. Res. 1987, 31: 235-244; Ostapoff and Morest, Hear. Res. 1989, 37: 141-162). McGinn and Faddis suggested that the initial formation of cavities was linked to afferent activity because they were reduced in gerbils subjected to a conductive hearing loss from 12 days of age.

To determine whether the appearance of cavities was reversible, the right cochlea of gerbils older than 7 mo of age was destroyed by inserting a probe through the round window. Following a survival period, the animals were sacrificed and the brainstem sectioned (15 or 30 μ thick) in the coronal plane. Alternate sections were stained with both thionin and eosin to visualize neuronal somata, cavities, and blood vessels. Cavities within the anteroventral (AVCN) and posteroventral (PVCN) cochlear nucleus were counted.

After 24 hr survival, the average number of cavities in the right PVCN and AVCN was reduced to 76% and 71%, respectively, of the numbers observed on the unablated side. After a survival period of 3 days, these percentages fell to 23% and 32%, respectively. The dimensions of PVCN and AVCN on the ablated and control sides did not differ significantly at this time. The relative number of cavities on the ablated side continued to decrease, although at a slower rate, after survival periods of 5, 7, and 11 days. These data suggest that the presence of cavities in the adult gerbil VCN depends upon the integrity of the primary afferent supply to this structure and that the maintenance of the cavities in the normal gerbil is a dynamic and reversible process. Whether the critical variable is pre- or postsynaptic remains to be determined.

NUMBER OF LESIONS IN MONGOLIAN GERBIL COCHLEAR NUCLEUS CAN BE PREDICTED FROM ANIMAL'S AUDITORY EXPERIENCE. K.D. Statler*, S. C. Chamberlain, R. L. Smith*, & N. B. Slepecky*, Institute for Sensory Research and Department of Bioengineering, Syracuse University, Syracuse, NY 13244

Under normal conditions, aging Mongolian gerbils develop an increasing number of microcystic lesions in the cochlear nuclei. The lesions form a contiguous area in the posteroventral cochlear nucleus and adjacent granular layer. The anteroventral and dorsal cochlear nuclei are spared. Ostapoff and Morest suggested that the lesions represent a progressive neurodegenerative disorder, possibly hereditary (Hearing Research, 37:141-162). McGinn and Faddis showed that auditory experience can affect the number of lesions that develop (Hearing Research, 31:235-244). By correlating the noise spectrum of the animals' environment with the tonotopic map of the cochlear nucleus, we have been able to show a relationship between the total driven afferent input and the number of lesions that develop. This has led to a predictive relationship between an animal's auditory history and the number of lesions occurring in its cochlear nuclei.

We have tested this relationship in two ways. We raised animals in a low noise environment different from that used to obtain the relationship. The number of lesions that developed in these animals was within 10% of our prediction and 20% lower than developed in the original environment. We have also raised animals from birth in a very low noise environment. We predict no lesions should develop until about age 50 days. Periodic samples up to age 39 days showed that no lesions developed, whereas gerbils raised in our normal environment develop about 25 lesions by age 38 days. If this correlation between the auditory experience of the animal and the number of lesions occurring in the cochlear nucleus holds, we may be able to use lesions as an activity marker in the posteroventral cochlear nucleus.

VOLTAGE-CLAMP STUDIES OF ISOLATED VENTRAL COCHLEAR NUCLEUS NEURONS. P.B. Manis and S.O. Marx*, Dept. Otolaryngology-HNS, Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

Neurons of the ventral cochlear nucleus (VCN) display a variety of responses to acoustic stimuli. Some features of these responses have been correlated with non-linearities in the membrane current-voltage relationship (Oertel, J. Neurosci. 3: 2043, 1983). We have investigated the nature of these nonlinearities in current and voltage-clamp recordings from neurons acutely isolated from the guinea pig VCN. In current clamp, isolated cells exhibited 2 types of responses (termed type I and type II) similar to those reported by Oertel (83). Type I cells discharged trains of action potentials in response to depolarizing current injections whereas type II cells discharged only 1-2 spikes and showed strong outward rectification above rest.

Outward currents evoked by voltage steps from -68 mV were studied in voltage clamp. A non-inactivating outward current in type I cells was activated near -20 mV (half-activation -5 mV). This current was blocked by 20 mM TEA and slightly reduced by 4 mM 4-AP. A non-inactivating outward current in type II cells was activated at -64 mV (half-activation -29 mV). This current was slightly reduced by 20 mM TEA, and could be substantially reduced by 4 mM 4-AP. Other currents, including a sustained inward current, a transient outward current, and a TEA and 4-AP resistant sustained outward current, were also observed in both cell classes. These results indicate that the outward rectification in type II VCN cells (presumed bushy cells) is mediated by a non-inactivating low threshold 4-AP sensitive outward conductance with rapid activation and deactivation kinetics. (Supported by Deafness Research Foundation and NIH T32 NS07283.)

3-DIMENSIONAL FREQUENCY MAPPING IN THE CAT DORSAL COCHLEAR NUCLEUS. G.A. Spirou*, B. May*, and D.K. Ryugo. Depts. Biomedical Engineering and Otolaryngology-HNS, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

We have been investigating the frequency representation of the dorsal cochlear nucleus (DCN) in decerebrate cats using single and multiple unit recordings. Characteristic frequencies (CFs) were determined in 100-200 μm steps in electrode penetrations oriented parallel to the strial axis and distributed in the caudal 2/3 of the nucleus. CFs were plotted onto histologically-reconstructed electrode tracks and analyzed using a computer-aided imaging system.

Typical tracks began in the 40-50 kHz region of the nucleus and terminated in the 0.5-1 kHz region. There was a systematic progression of CFs from high to low, with type II, III, and IV units interdigitated throughout. Frequency versus distance may be represented by two logarithmic functions, one with slope 1.08 ± 0.16 mm/decade at low frequencies and the other with slope 4.99 ± 1.5 mm/decade at high frequencies; the intersection occurred at 13.7 ± 4.4 kHz. The frequency organization of the nucleus is distinct from that of the cochlea in that there is an expanded representation of high CFs in the DCN.

Supported by grants from the NIH: NS20156; NS12524, and NS08333.

DEVELOPMENT OF DYNAMIC RESPONSE PROPERTIES OF COCHLEAR NUCLEAR NEURONS IN KITTENS. E.J. Walsh, J. Fitzakerley and J. McGee*. Depts. of Surgery and Pharmacology, Southern Illinois Univ. Sch. of Med., Springfield, IL 62794-9230.

It is widely accepted that dynamic response features of auditory neurons are important determinants of intensity coding in adults (Smith and Brachman, 1980; Moller, 1976). We have previously shown that the dynamic response ranges of cochlear nuclear (CN) neurons in kittens to long-duration stimuli are smaller than those observed in adult cats, suggesting that immature animals have a restricted ability to establish neural codes for intensity discrimination. We have extended the investigation of the development of intensity-dependent response properties of single CN neurons by examining dynamic range differences between the "onset" response (first 5 msec) and the "sustained" response (steady-state) to acoustic stimulation. Clear differences in dynamic response properties for both epochs were observed for each of the principal CN response types. Maximum driven discharge rates and sensitivities of neurons to changes in stimulus intensity (rate-intensity slopes) were higher during the onset response compared to the sustained response, regardless of age. Maximum driven rates generally increased during the first two weeks of development for both portions of the response. In contrast, rate-intensity slopes associated with onset responses decreased during development, while slopes for sustained responses increased. The development of dynamic response characteristics may reflect the final stages of neuronal differentiation, particularly with regard to membrane receptors. These results will be discussed in light of intensity-dependent responses of CN neurons during the microionophoresis of neuroactive amino acids. (Supported by NIH grant NS21171).

DISTRIBUTION OF PARVALBUMIN AND CALBINDIN IN THE AUDITORY SYSTEM OF BATS. K. Braun[1], M. Vater[2]*. [1]Otolaryngol. Dept., Univ. Wash., Seattle, WA. [2]Inst. Zool., Univ. Munich, FRG.

The distribution of the two neuron-specific Ca-binding proteins parvalbumin (PV) and calbindin-D-28K (CaBP) has been compared immunocytochemically in the auditory system of Rhinolophus rouxii. Similar to previous findings in the avian auditory system (Braun et al 1985 Cell Tissue Res 240,101) the neuron populations containing either protein show either a partially overlapping or a complementary spatial distribution, depending on the nucleus. In the cochlear nucleus all subdivisions contain PV+ cells, whereas only few CaBP+ cells are found in DCNd and DCNv. All nuclei of the sup. olivary and periolivary complex contain PV+ cells, whereas CaBP-immunoreactivity is found only in a rostral stripe of cells in LSO. In the lat. lemniscus many PV+ cells occur in VNLL, INLL and DNLL, but DNLL and INLL are void of CaBP+ cells. In the IC the central nucleus contains a heterogenous population of PV+ cells, while CaBP+ cells are found mostly in the dorso-medial and ventro-medial region. A subpopulation of large PV+ cells is clearly CaBP-. In the deep layers of the sup. colliculus many PV+ cells but only few CaBP+ cells are observed. In the MGB PV+ cells and neuropil are abundant in all subdivisions and show a clear regional specificity. All subdivisions of MGB contain numerous CaBP+ somata, in the dorsal MGB a subpopulation of medium to large oval cells are CaBP+ and PV-.

AUDITORY BRAINSTEM IN THE MOLE (Mogera): ANATOMICAL BASIS FOR POSSIBLE HEARING SPECIALIZATION OF THE UNDERGROUND DWELLER. M. Kudo*, Y. Nakamura, H. Tokuno*, Y. Kitao* and T. Morilzumi*. Department of Anatomy, School of Medicine, Kanazawa University, Kanazawa 920, Japan.

The cyto-, myelo- and chemo-architectures of the mole auditory nuclei were studied in Nissl, myelin and acetylcholinesterase stained materials, and then the origins of the ascending afferents to the inferior colliculus (IC) were identified using retrograde transport of wheatgerm agglutinin conjugated to horseradish peroxidase (WGA-HRP) injected into the unilateral IC. In all surgical procedures, moles were anesthetized with sodium pentobarbital and chloral hydrate. 1) In the cochlear nuclei, granule celled fields are very large in both the ventral (VCN) and dorsal (DCN) nuclei. Among several populations of neurons, fusiform cells in the DCN, multipolar cells in the VCN and DCN, and small spherical cells in the VCN project to the IC directly. 2) In the superior olive, the medial nucleus (MSO) is well developed in comparison with that in other similar body-sized mammals. Most strikingly, the projection from the MSO to the IC is bilateral in the mole. 3) The nuclei of the lateral lemniscus show a great development and differentiation of the dorsal (DLL), intermediate (ILL) and ventral (VLL) nuclei. Particularly the large ILL is comparable to that in the mustache bat.

INHIBITORY PATHWAY TO THE LATERAL SUPERIOR OLIVE FROM THE CONTRALATERAL VENTRAL COCHLEAR NUCLEUS STUDIED IN MOUSE BRAIN SLICE. S.H.WU* (SPON: T.P.Feng).Dept. of Cellular and Molecular Neurobiol., Shanghai Institute of Physiol., Shanghai, 200031 China

To study synaptic connection between the contralateral ventral cochlear nucleus(VCN) and lateral superior olive(LSO), intracellular recordings were made from neurons in the LSO and medial nucleus of trapezoid body(MNTB) of mouse brain slice. Neurons in the LSO usually give IPSPs with synaptic delays of 1.2-1.3 ms to electrical stimulation of the contralateral trapezoid body(TB). As the stimulating electrodes moved to the ipsilateral MNTB, the delays of the IPSPs shortened to about 0.7 ms. To the same stimulation neurons in the MNTB only give EPSPs with synaptic delays of 0.4-0.6 ms. These results indicated that the MNTB neurons are inhibitory neurons in the pathway between the contralateral VCN and LSO. Injection of a depolarizing current in the MNTB neurons elicited a single action potential and much smaller voltage change than a hyperpolarizing current of the same magnitude. The MNTB cells with such electrical properties seem to be well suitable for securing a one-to-one synaptic transmission.

A NOVEL PROJECTION OF THE VENTRAL NUCLEUS OF THE TRAPEZOID BODY IN THE RAT. W.B. WARR and K.M. SPANGLER. Center for Hearing Research, Boys Town National Institute, and Department of Anatomy, Creighton University School of Medicine, Omaha, NE 68131.

The ventral nucleus of the trapezoid body (VNTB) is a heterogeneous cell group situated within the ventral acoustic stria of most mammals. Various of its constituent neurons are known to have reciprocal connections with the ventral cochlear nuclei and the inferior colliculus, or to project to the cochlea by way of the olivocochlear bundle. In addition, experiments in the cat (Spangler et al., *J. Comp. Neurol.* 238:249-261, 1985) reveal a collateral projection from VNTB to parts of the periolivary zone which contain lateral olivocochlear neurons, but none to the lateral superior olivary nucleus (LSO) itself. Unfortunately, the methods were not capable of demonstrating inputs to lateral olivocochlear neurons. In the present study in rats, anterograde tract-tracing methods (tritiated leucine, PHAL and WGA-HRP injections into the VNTB) and retrograde methods (fluorogold and HRP injections into the LSO) revealed, among others, an unexpectedly strong, topographically organized, bilateral projection to the LSO proper, as well as to the lateral nucleus of the trapezoid body. Since in the rat, lateral olivocochlear neurons are situated clearly within the borders of the LSO, this novel, intrinsic projection may indeed represent inputs to lateral olivocochlear neurons.

DENDRITIC SPECIALIZATIONS IN THE MEDIAL AND LATERAL OLIVARY SYSTEM. J. K. Moore and M. Sakuma*. Depts. of Anatomical Sciences and Psychology, SUNY at Stony Brook, Stony Brook, NY 11794.

The medial and lateral olivary nuclei are composed of "bushy" or tufted neurons. Their dendritic morphology has been studied in the guinea pig by Golgi impregnation and by retrograde transport of a highly diffusable tracer (fluorogold) injected into the inferior colliculus. Both the Golgi technique and fluorogold cell labeling show that each stem dendrite terminates in a spray of thin, tortuous, varicose dendritic branches. The terminal dendritic tufts are identical to those of the cochlear nucleus bushy neurons which innervate the olivary nuclei. In both the medial and lateral nuclei, terminal tufts are intertwined with those of neighboring neurons, forming a shell of fine dendritic branches at the periphery of the nucleus. Electron microscopy of the peripheral dendritic zone reveals a meshwork of fine dendrites which are not contacted by synaptic boutons and which form numerous points of direct membrane apposition with surrounding dendrites. No gap junctions or other membrane specializations have been seen at these points of dendrodendritic apposition. The terminal dendritic tufts may be involved in some form of cell-cell coupling, but to date there is no evidence for either chemical or electrical synaptic junctions.

EXPERIMENTALLY INDUCED PROJECTIONS FROM THE VENTRAL COCHLEAR NUCLEUS OCCUR BEFORE THE ONSET OF HEARING. J. Kil*, F. A. RUSSELL* and L.M. KITZES (SPON: K. Spangler.) Dept. of Anatomy and Neurobiology, Univ. of California Irvine, Irvine, Ca 92717.

We have demonstrated previously that destruction of one cochlea in the neonatal gerbil (*Meriones unguiculatus*) induces the formation of new efferent projections from the ventral cochlear nucleus (VCN) on the non-ablated side to the superior olivary complex (SOC) bilaterally. These projections have been observed several months after the ablation using standard HRP procedures. We have used the fluorescent tracer Di-I to examine the developmental time course of these induced projections.

Age-graded series of normal gerbils and gerbils whose left cochlea was destroyed by aspiration at two days of age were sacrificed and perfused with saline followed by aldehyde fixatives. After post-fixation, a small crystal of Di-I was inserted into the right VCN. Two months later, 30 μm thick coronal sections of the brainstem were examined under a fluorescent microscope.

At 6 days of age efferent projections of the VCN are essentially adult-like. Heavy labeling occurs in the ipsi-LSO, along the lateral border of the ipsi-MSO, medial border of the contra-MSO, and in the dorsal hilus of the contra-LSO. This pattern is severely altered in neonatally ablated gerbils sacrificed at 14 days of age. In these animals, in addition to the normally observed efferent pattern, heavy labeling is observed on both sides of each MSO and within the primary limbs of the contra-LSO. In neonatally ablated animals sacrificed at 7 days of age, in addition to the normally observed efferent pattern, individual fibers, some with growth cones, are evident at or approaching the medial border of the ipsi-MSO and the lateral border of the contra-MSO. More extensive labeling within the contra-LSO is unclear at this time. As the onset of hearing in this species occurs at about day 12 or 13, it is evident that induction of these pathways does not depend upon acoustically driven, afferent activity.

COLLATERAL AXONS OF THE MEDIAL NUCLEUS OF THE TRAPEZOID BODY. N. Kuwabara, R.A. DiCaprio & J.M. Zook. Dept. of Zoological & Biomedical Sciences & OU-COM, Ohio University, Athens, OH 45701.

All mammals examined have a set of large diameter axons which arise from cells of the ventral cochlear nucleus, cross the midline, and end as calyces of Held upon principal cells of the medial nucleus of the trapezoid body (MNTB). The calyces are specialized terminals, each enveloping the soma of a single principal cell. The principal cells give off a large axon which projects to the lateral superior olive. In addition, each calyciferous axon and principal cell axon have many small, collateral branches, but the projections of these collaterals have not been well described.

We have characterized these collateral axons by intracellular labeling of calyciferous axons and principal cells with a tissue slice preparation of the auditory brainstem using two bat species: *Pteronotus parnellii*, *Eptesicus fuscus* and the mouse: *Mus musculus*. The collateral branches of calyciferous axons and principal cells have very similar projections, with branches to each, or most, of the following cell groups: the ventromedial and dorsomedial periolivary nuclei, the ventral and lateral nuclei of the trapezoid body, the medial olivocochlear bundle cell group and the ventral nucleus of the lateral lemniscus.

In a few cases, by injecting the dye Lucifer Yellow, we have been able to label both a single calyciferous axon and the principal cell that is immediately post-synaptic to the calyx. In these cases, two labeled collaterals, one from the calyciferous axon and one from the associated principal cell, were found to converge upon a single cell within one of the target nuclei.

MATCHING OF EXCITATION AND INHIBITION IN THE LATERAL SUPERIOR OLIVARY NUCLEUS OF THE F344 RAT. Finlayson, P.G., Yuscius, S.D.* and Caspary, D.M. Depts. of Pharmacology and Surgery, Southern Illinois University School of Medicine, Springfield, Illinois 62794-9230.

Age-related cell loss in structures which project to rat lateral superior olivary neurons (LSO) may be asymmetrical (Casey and Feldman, '82), suggesting a greater functional loss of glycinergic inhibition in LSO principal cells in aged animals. Recordings from LSO principal cells displaying EI (Excitation to ipsilateral stimuli / Inihibition by contralateral stimuli) responses were examined quantitatively in young adult (3 month) F344 rats. Measures of frequency matching and relative magnitude of excitation and inhibition were obtained by examining excitatory and inhibitory response areas, and families of rate-intensity (RI) curves. Seventy-six percent (32/42) of LSO neurons studied exhibited matched response areas including similar excitatory and inhibitory bandwidths and best frequencies. Excitatory and inhibitory thresholds were within 10dB in the majority of neurons. Families of RI curves were normalized by calculating interaural intensity differences (IID) and percent inhibition of ipsilaterally evoked activity. IID functions displayed a 10%-20% change in contralateral inhibition per 10 dB change in interauaral intensity. Binaural inhibition was maximal when the contralateral intensity was 10-40dB more intense than the excitatory stimulus. Twenty percent of rat LSO cells did not exhibit matched EI frequencies but exhibited inhibition at frequencies 1-2 octaves above the excitatory region. The present findings will enable data from the F344 rat LSO neurons to be compared with similar data obtained from cat and gerbil and also provide a baseline for studies of normal and pathologic changes in this species. PHYSIOLOGY AND ANATOMY OF PRINCIPAL CELLS IN THE CAT MNTB. P.H. Smith, P.X. Joris*, M.I. Banks* and T.C.T. Yin. Dept. of Neurophysiology, Univ. of Wisconsin, Madison.

We have recorded from principal cells of the cat medial nucleus of the trapezoid body (MNTB) using either metal electrodes or HRP-filled glass microelectrodes. These cells are believed to relay inhibitory input from the contralateral side to binaural cells in the LSO. We assumed that extracellular complex spike waveforms with a prominent prepotential recorded with metal microelectrodes were from principal cells. Prepotentials are thought to reflect synaptic potentials generated by the large calyces of Held arising from globular bushy cell axons originating in the contralateral AVCN. Prepotentials were never seen with high impedance glass electrodes where verification of recordings from principal cells was made by HRP injection and parent cell identification. Principal cells with low characteristic frequencies (CFs) showed good phase-locking. Those with high CFs usually showed primary-like with notch (PLn) response histograms. However, the response histograms of some cells were not PLn even at high stimulus intensities. There was a noticeable dip in the sustained portion of some of the responses. Mean first spike latencies of MNTB cells were slightly longer than the latencies typical for their major input, globular bushy cells axons with comparable CFs. In some instances the prepotential of the complex spike was absent when the spike occurred between stimulus presentations. The dendritic trees were not well filled in any of our axonally injected cells. Where distinguishable, the number of primary dendrites (2 or 3) corresponded to the number reported by others. The cell bodies were oval with asymmetric nuclei. The axon arose from the soma and headed laterally, passing close to or directly thru the MSO to innervate the appropriate frequency region of ipsilateral LSO. Some collaterals arising from the axon innervated the ipsilateral MSO, ipsilateral VNLL and the ipsilateral VNTB/VMPO region. At the EM level, terminals of MNTB axons contained non-round vesicles and could provide these regions with a source for contralateral inhibitory input.

SUPERIOR OLIVARY COMPLEX CYTOLOGY AND AUDITORY BRAIN STEM RESPONSES FOLLOWING NEONATAL COCHLEAR REMOVAL IN THE FERRET. David R. Moore and Lindsay M. Aitkin *, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, U.K.

Neonatal, unilateral cochlear lesions produce a sequence of degenerative and regenerative changes among neurons of the cochlear nucleus (CN) and their target nuclei, the superior olivary complex (SOC) and inferior colliculus (IC). A rapid degeneration of the CN on the lesioned side is followed by a gradual reinnervation of the IC and SOC by CN neurons on the unlesioned side. We have examined second order transneuronal degeneration in the SOC and obtained an overview of the functional consequences of cochlear removal at several levels of the auditory system. Cochlear removals were performed at postnatal day (P)5, P25, P40 or P180. Auditory brain stem responses (ABRs) were recorded at least weekly during the following three months. Brain tissue was paraffin-embedded, frontally sectioned at 10um and Nissl stained. ABRs to click stimuli first appeared at P28. Thresholds improved rapidly, reaching adult levels by P40. Neonatally lesioned animals underwent a second phase of ABR change, from P40 to P80, during which thresholds improved by around 10dB. Maximum sensitivity during this phase transferred from waves I and II to waves III and IV of the ABR. Cochlear removal at P5 produced marked degeneration (35% neuron loss) in the ipsilateral lateral superior olive, but not in other SOC nuclei. Removal at older ages did not markedly affect SOC cytology.

GENERATION OF AN AUDITORY SPACE MAP IN THE FERRET SUPERIOR COLLICULUS REQUIRES THE PRESENCE OF MONAURAL LOCALIZATION CUES A.J. King and S. Carlile*, University Laboratory of Physiology, Parks Road, Oxford OX1 3PT, U.K.

Spatially tuned auditory receptive fields of deep layer superior colliculus (SC) neurons are derived from a combination of monaural and binaural cues. To assess the capacity of the brain to synthesize a map of auditory space in the absence of normal monaural cues, we examined single unit responses from the SC of adult ferrets subjected to bilateral pinna removal at 28 days of age. The animals were anesthetized, paralysed and placed in an anechoic room, where recordings were made from units throughout the rostrocaudal extent of the SC. Within 10 dB of threshold, some units were sharply tuned around the contralateral interaural axis, while others responded equally well to noise bursts throughout this hemifield or exhibited a broad preference for frontally placed sounds. The receptive fields expanded with increasing sound intensity, becoming unselective for sounds in the contralateral and/or ipsilateral hemifields. A free-field impulse response analysis showed that the azimuthal location of the acoustic axis of the ear was constant from 1-28 kHz. In contrast to normal animals, azimuth spectral transformations were symmetrical, and therefore ambiguous, about the interaural axis. The lack of spatial tuning at high intensities suggests that, under these conditions, a map of auditory space based on binaural interactions has not been formed.

PARALLEL MONAURAL PATHWAYS TO THE MIDBRAIN IN AN ECHO-LOCATING BAT: THE VENTRAL LATERAL LEMNISCAL COMPLEX (VLL). E. Covey and J.H. Casseday, Department of Surgery, Duke University Medical Center, Durham, North Carolina 27710.

In echolocating bats, the VLL is hypertrophied and differentiated into three major cell groups. The cyto-architecture and connections of these cell groups suggest that VLL may be a complex system of parallel monaural pathways to the midbrain. We recorded the responses to sound of single neurons in the VLL of Eptesicus fuscus. The results confirm that VLL consists only of monaural pathways. Neurons in each division have very different response properties as would be expected if each cell group performs some different transformation of the auditory signal. These differences include: 1) breadth of tuning and 2) temporal pattern of response. For example, cells in one division (the columnar nucleus) are broadly tuned to frequency and respond with a single spike. These spikes are precisely locked to the stimulus onset; their latency is nearly identical for each stimulus presentation, with standard deviations as low as 0.02 ms. In addition, their latency remains virtually constant even in the face of large variations in stimulus intensity and frequency. Such "constant latency" neurons in the VLL could provide a precise marker of stimulus onset to higher levels involved with temporal analysis and thus represent an early stage in the neural circuitry for behavioral tasks such as echo-ranging. [Supported by NIH grant NS 21748]

AXONAL DOMAINS WITHIN THE DORSAL NUCLEUS OF THE LATERAL LEMNISCUS. Craig K. Henkel, Department of Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27103

Experiments were carried out to determine the organization and interrelationships of afferent axonal arbors within isofrequency domains in the dorsal nucleus of the lateral lemniscus. To stain axonal arbors PHA-L was injected into the superior olivary complex in cats anesthetized with sodium pentobarbital. The animals were allowed to survive for 5-7 days. Serially spaced, 50 µm thick sections were collected and the tissue processed for immunostaining with the ABC method (Vector). The results show that projections from the medial superior olivary nucleus to the dorsal nucleus of the lateral lemniscus have a very specific arborization pattern. First, the thickness of the arbor (perpendicular to the cochleotopic axis) varies but consists of a single tier. Then, secondly, the arbors end in isolated territories that are separated from one another. Finally, all of the axons reconstructed thus far arise as collaterals of thick axonal trunks that enter the central nucleus of the inferior colliculus where they also arborize extensively. The results suggest that the horizontal tiers of afferent fibers in the dorsal nucleus of the lateral lemniscus are a mosaic of restricted axonal arbors rather than uniform sheets from divergent axonal arbors.

RESPONSE PROPERTIES OF SINGLE NEURONS WITHIN CLUSTERS IN INFERIOR COLLICULUS AND AUDITORY CORTEX. G.K. Hui*, J.M. Cassady* and N.M. Weinberger (SPON: J.H. Ashe). Centr. Neurobiol. Learning and Memory and Dept. Psychobiology, Univ. of Calif., Irvine, California, 92717.

"Cluster" recordings ("multiple unit activity"), consisting of the discharges of several neurons, are widely employed. However, the extent to which individual cells within a cluster have the same response characteristics has received little study.

In barbiturate-anesthetized guinea pigs, the responses of clusters to contralateral tone stimulation were obtained using epoxy-insulated tungsten microelectrodes (tips 1-3 microns, impedances 1-2 megohms). On-line separation of single unit waveforms was achieved for 2-4 neurons per cluster (central nucleus of inferior colliculus [ICc]: 16 clusters, 38 cells; primary auditory cortex [ACx]: 25 clusters, 60 cells) using a computer algorithm that included waveform confidence limits. Response characteristics included best frequency (BF), bandwidth, intensity type (monotonic or non-monotonic) and discharge pattern. For both the ICc and ACx, differences in one or more characteristics were found in approximately 1/3 to 3/4 of the clusters, including BFs differing by at least 0.5 octaves.

These findings indicate that cluster recordings frequently consist of the discharges of single neurons for which one or more response characteristics differ. The possibility of such heterogeneity should be considered in the interpretation of neuronal cluster recordings.

NARROW BANDPASS FILTER NEURONS IN THE INFERIOR COLLICULUS OF AN FM BAT. J.H. Casseday, B.R. Johnson* and E. Covey. Depts. of Neurobiology and Surgery, Duke University, Durham, NC 27710

Neurons selectively tuned to a narrow frequency band (filter neurons) have been found in the central auditory system of bats that use constant frequency (CF) echolocation calls; however, filter neurons have not previously been reported in bats that use frequency modulated (FM) calls. We recorded responses from single neurons in the inferior colliculus (IC) of the big brown bat, Eptesicus fuscus. This bat navigates and locates prey using an FM echolocation call that sweeps from about 80 kHz to about 20 kHz. The majority of neurons in the IC respond vigorously to pure tones within this range and have frequency tuning curves that broaden as the sound intensity is increased. However, one population of neurons respond only to a very narrow band of frequencies regardless of stimulus intensity. For example, for most filter neurons the Q_{10dB} and Q_{40dB} were virtually identical, about 40. Although each filter neuron is selective for a narrow frequency band, different neurons have slightly different best frequencies (BF), but all are between 23 and 29 kHz. This is in contrast to CF bats where all filter neurons have about the same BF. Filter neurons in Eptesicus are located in a sheet about 700 um thick covering the dorsal and lateral surface. [Supported by NIH Grant NS-21748].

DIFFERENTIAL TIMETABLE OF PROJECTIONS INTO THE DEVELOPING INFERIOR COLLICULUS IN RAT. B. Maxwell* and J.R. Coleman (SPON: M. Welsh). Depts. of Psychology and Physiology, Univ. South Carolina, Columbia, SC 29208.

The sources of input to the inferior colliculus (IC) from the brainstem and cortex were examined in the postnatal S-D rat. Colliculi were iontophoretically injected with horseradish peroxidase (HRP) or a lectin conjugate in rat pups beginning at birth.

By postnatal day (PND) 7 all basic adult patterns of ascending and descending projections to IC are intact. At this age robust label appears in neurons of the cochlear nuclei, superior olive complex, lemniscal nuclei and auditory cortex. At PND 0 no label typically appears in the lateral superior olive (LSO), but at PND 1 the contralateral LSO is labelled along more medial sectors corresponding to the earliest generated LSO cells; few labelled neurons appear in the ipsilateral LSO. Heavy label subsequently appears throughout the contralateral LSO and moderate label in the ipsilateral LSO. Neurons from the cochlear nuclei, medial superior olive and superior paraolivary nucleus are retrogradely labelled from birth. The relative percentage of ipsilateral to contralateral labelled neurons in the dorsal cochlear nucleus increases after birth. Input from pyramidal cells of auditory cortex to the IC does not appear until after PND 3. Therefore, neurons from different levels of the auditory system neuraxis differentially invade the IC during postnatal life, although all input from auditory pathway structures clearly precedes functional responses to acoustic stimuli.

300.15

NEURAL GROWTH IN THE MEDIAL GENICULATE BODY OF THE POSTNATAL RAT. J.R. Coleman, W.J. Clerici, B. Maxwell* and M.C. Zrull*. Depts. of Psychology and Physiology, Univ. South Carolina, Columbia, SC 29208 and Neurotoxicology Progr., Johns Hopkins Univ., Baltimore, MD 21205.

The rat medial geniculate body (MGB) is subdivisible into ventral (MGv), dorsal (MGd) and medial (MGm) compartments and component nuclei. Neurons of these MGB sectors were studied in a series of Sprague-Dawley rats from birth to 80 days of age using thionin and rapid Golgi material.

At birth the nuclei of the MGB are discernable with MGv relatively larger than MGd and all cells small and darkly staining in thionin material. Golgi stains in newborn animals show substantial dendritic growth in cells in the MGv ventral nucleus and MGd dorsal nucleus when collicular afferents are just invading the MGB. Therefore, initial dendritic and somal growth of MGB neurons must largely be independent of ascending synaptic input. Somatic growth in neurons of all divisions of the MGB most sharply increases from postnatal days 3 to 7 which also parallels maximal postnatal expansion of auditory cortex. A second growth spurt in geniculate cells appears between postnatal days 11 and 16 at hearing onset. Neuron density most rapidly declines in geniculate nuclei from birth to postnatal day 7. These results suggest that epigenetic influences play the initial role in development of auditory forebrain structures, while further developmental events occur after onset of function. (Supported by NIH NS-20785).

ADULT-LIKE STRUCTURE OF FETAL TECTUM GRAFTED TO INFERIOR COLLICULUS. M.C. Zrull* and J.R. Coleman (SPON: S.J. Kelly). Dept. of Psychology, Univ. South Carolina, Columbia, SC 29208.

For comparison to suspension grafts, whole fetal tecta were grafted into the inferior colliculus (IC) of adult rats. Whole tecta were dissected from anesthetized Long Evans rat fetuses at 17 days of gestation (E17), bisected, trimmed to include the caudal half, and unilaterally injected to a lesion site in IC of adult conspecifics.

At 1 month post-implant, compared to suspension grafts, whole grafts were healthier with neurons exhibiting morphology and organization like the undamaged host IC. Dark stained multipolar and principal cells were more densely packed and often larger than host IC cells. Large grafted principal and multipolar neurons were sometimes aligned in rows similar to laminar gradients of corresponding cells in normal adult IC, although not always dorsomedial to ventrolateral due to graft orientation. Usually one interface between graft and host tissue was found across a border of small multipolar and glial cells.

Whole E17 tectal grafts were more viable, showed more mature features, and seemed more likely to aid repair of host IC than suspension grafts. (Supported by the Deafness Research Foundation).

GLUTAMATE AND ASPARTATE: LOCALIZATION AND COLOCALIZATION IN THE RAT INFERIOR COLLICULUS. M.R. Eyerly*, J.R. Coleman, M.C. Zrull* and A.J. McDonald (SPON: J.Freeman). Depts. of Psychology, Anatomy, and Physiology, Univ. South Carolina, Columbia, SC 29208.

The excitatory amino acids glutamate and aspartate have the same high-affinity uptake systems, but the distribution of these transmitter candidates according to neuron class may not be identical. The present study focuses upon morphological classification of glutamate and aspartate immunoreactive neurons of the midbrain inferior colliculus in S-D rats using the avidin-biotin procedure (Vector Labs.). Amino acids were colocalized by reaction of alternate sections in separate antibodies or in the same sections reacted sequentially by DAB and BDHC. Cells were categorized according to perikaryl shape and the digitized somal areas statistically analyzed with SAS.

In the central nucleus of inferior colliculus principal cells (usually ovoid) were immunoreactive for glutamate and aspartate in separate sections. The glutamate-reactive principal cells were statistically larger as a group than aspartate-reactive cells. Furthermore, neurons that colocalized glutamate and aspartate were typically among the largest of the principal cell population. Large multipolar cells were immunoreactive for glutamate, but not for aspartate. These results show that glutamate and aspartate immunoreactive neurons of the central nucleus of inferior colliculus constitute both separate and overlapping cell populations.

A NOVEL COINCIDENCE DETECTION MECHANISM BASED ON A NEURAL COMPARTMENTAL MODEL. W.E. Sullivan. Dept. of Biology, Princeton Univ., Princeton, N.J. 08544

A compartmental model was used to explore how intrinsic cellular properties can affect neural computations. Coincidence detection, in which spike output requires coincident synaptic input is thought to be involved in binaural time comparison. Conventional models assume rapidly decaying, near threshold synaptic inputs from each source, so that simultaneous arrival is needed to exceed spike threshold. Rapidly decaying inhibitory inputs, timed to occur 180 degrees out of phase with excitation may also contribute by suppressing non-synchronous excitatory inputs.

An alternative mechanism, based on the non-linear properties of spike initiation is suggested by simulations using the Hodgkin-Huxley model. The model contains passive electrical compartments designed to simulate soma and dendritic membrane and an active, spike initiating compartment. A low ratio of voltage sensitive sodium to potassium channels and a large conductance between active and passive compartments, produces models in which steady excitation at or near the soma causes a transient response for all suprathreshold stimuli. In the model, the lack of sustained firing is due to insufficient post-spike hyperpolarization under the influence of steady depolarizing current, which leads to insufficient removal of sodium channel inactivation.

This intrinsic transient response suggests a new mechanism for coincidence detection. The model can be driven by trains of excitatory pulses, but stops firing when excitation is constant. Thus, if two inputs are out of phase, so that e.p.s.ps from one source fill the gaps between those from the other, a steady input results and no output is produced. Since this is due to a refractory effect, inhibitory synapses can enhance the response by helping to remove sodium channel inactivation. In fact, the model can be driven by pulsatile inhibition combined with steady excitation, and also works well if pulsatile excitation is combined with steady inhibition. This is especially true for high frequency inputs where rapid recovery from spiking is needed. These results show how synaptic mechanisms may depend on intrinsic cellular properties in that both excitation and inhibition can contribute to either response enhancement or supression depending on the temporal context of their actions.

EFFECTS OF UNILATERAL INFERIOR COLLICULUS LESIONS IN THE FERRET ON MINIMUM AUDIBLE ANGLES FOR MIDLINE AND LATERAL FIELD SOUND LOCALIZATION. G.L. Kavanagh* and J.B. Kelly. Laboratory for Sensory Neuroscience, Carleton University, Ottawa, Canada, K1S 5B6.

Unilateral ablation of auditory cortex in the ferret results in an incapacity to localize brief sounds in the hemifield contralateral to the lesion. However, animals show no impairment in the ability to localize on midline and in the ipsilateral hemifield. In the present study the effects of inferior colliculus (IC) lesions were examined in eight ferrets to determine whether unilateral ablation of auditory midbrain results in a cortical pattern of sound localization deficits. The tectum was exposed by removing the dorso-posterior tip of visual cortex and the IC was aspirated. Minimum audible angles (MAA's) were obtained around 0°, -60° and +60° azimuth. Results indicate that unilateral ablation of the IC produces a profound contralateral sound localization deficit. With the largest lesions, postoperative performance was not above the level expected by chance, even with speakers separated to 60°. Also, animals showed substantial shifts in MAA's on midline and in the hemifield ipsilateral to the lesion. Deficits persisted despite repeated testing over several months. These results suggest that the representation of auditory space is not fully contralateralized at the level of the inferior colliculus.

DESCENDING TARGETS OF INFERIOR COLLICULUS EFFERENTS IN BUSH BABY (GALAGO CRASSICAUDATUS). G.C. Thompson and A.M. Thompson. Dept. of Otorhinolaryngology, Univ. of Oklahoma Health Sci. Cntr., Oklahoma City, OK 73190.

Efferent neuroanatomical projections descending from the bush baby inferior colliculus (IC) were labeled with the anterograde tracer, Phaseolus vulgaris leucoagglutinin (PHA-L). Small ionotophoretic injections were made into IC and, after survival times from 7-15 days, the animals were deeply anesthetized and intracardially perfused. Frozen brainstem sections (40 um thick) from the cochlear nucleus through IC were immunohistochemically processed with an antibody against PHA-L.

After injections into the central nucleus, PHA-L-labeled fibers could be observed streaming ventrally within the ipsilateral lateral lemniscus yielding numerous varicosities, presumptive terminal endings, throughout all three lemniscal nuclei. The labeled fibers continued ventrally and posteriorally and began to travel medially at the level of the pre-olivary region and entered the trapeziod body (TB). Some crossed within the dorsal half of the TB to the opposite side of the brainstem. Terminal varicosities and boutons, associated with the labeled fibers, were observed in the ventral nucleus of the trapezoid body (VTB) bilaterally. Additionally, some fibers continued to travel in the TB laterally and then dorsally to finally terminate within the anteroventral cochlear nucleus (AVCN).

Since the VTB is a source of input to the cochlea, our data suggests the existence of a two-synaptic pathway from the midbrain to the cochlea. Additionally, the presence of terminal endings within the AVCN suggests that the midbrain has the potential to modulate ascending auditory input via second order auditory neurons.

NEURONS OF ANTERIOR THALAMUS TRANSMIT SHORT LATENCY (S-L) AUDITORY SIGNALS SUPPORTING CONDITIONING OF A PAVLOVIAN EYEBLINK REFLEX IN CATS. C.D. Woody, E. Gruen*, V. Chizhevsky* and O. Melamed*. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA 90024.

Definition of primary (throughput) sensorimotor pathways underlying simple forms of conditioning has been a goal of research in this field. By defining such pathways a more complete understanding of the neural basis of conditioning can be obtained. In cats S-L eyeblink conditioning to a 70 db click CS obligatorily involves the motor cortex and facial nucleus, but not posterior cortical auditory areas. We therefore sought S-L unit activation in subcortical pathways that might support the S-L blink CR. Recordings (>80 units) from the parageniculate - lemniscal adjunct region failed to find such activity with onsets <10ms after the CS. Recordings from 200 anterior thalamic units (at the border of the reticular, lateral dorsal, ventroanterior, anteroventral, caudate and anterior intralaminar nuclei) found units activated at latencies 6-8 ms after the CS. The proportion of units responsive to the CS increased from 27% to 43% after conditioning ($p<.05$, Chi Sq 4.61). The CR formed by pairing click CS, glabella tap US and hypothalamic electrical stimulation (570-10ms ISI) was discriminatively elicited by the forward paired click CS as opposed to a backward paired hiss DS of comparable intensity, and so was the unit activity after conditioning. Cells of this region may transmit messages to the motor cortex supporting elicitation of the CR. (Supported by NS25510.)

CHEMICAL SENSES: PERIPHERAL OLFACTION

301.1

PATCH CLAMP STUDIES INDICATE THAT OLFACTORY RECEPTOR CELLS FROM IMPRINTED SALMON HAVE INCREASED RESPONSIVENESS TO AN IMPRINTED ODORANT. G. A. Nevitt. Dept. of Zoology, NJ-15, Univ. of WA, Seattle, WA 98195.

Coho smolts (*Oncorhynchus kisutch*) imprinted to the odorant phenyl ethyl alcohol (PEA), later specifically home to streams treated with PEA at concentrations as low as 10^{-7}M. I have used the cell attached patch clamp technique to show that ciliated olfactory receptor cells isolated from PEA imprinted fish respond to micromolar concentrations of PEA with a higher probability than cells isolated from nonimprinted salmon.

The cell attached mode was used to monitor cell responsiveness to PEA while minimizing disruption of the intracellular milieu required for odorant transduction. Brief (.5-2 sec) applications of PEA (10^{-6}M-10^{-8}M) were applied using a picospritzing pipet positioned far enough (~100 microns) from cilia to avoid cell movement during odorant application. Bursts of action potentials and/or rapidly activating bursts of inward current (5 pA) were observed in a significantly greater number of imprinted than nonimprinted cells (17/22 imprinted, 9/21 nonimprinted; $p<.05$). However, responsitivity of cells to a second, but behaviorally important odorant (L-serine) were not significantly different (10/18 imprinted, 13/19 nonimprinted; $p>.05$). For both odorants, cells responded in a dose dependant manner, but single channel activity was difficult to resolve even at nanomolar odorant application concentrations. These results suggest that exposure to PEA during smoltification may lead to selection of new PEA sensitive receptor cells, or alter sensitivity to PEA of preexisting cells. Supported by an NIH Neurobiology Training Grant and a Sigma XI Award to G. Nevitt, and by NIH grant HD17486 to W.J. Moody.

PATCH ELECTRODE STUDY OF FROG OLFACTORY RECEPTOR NEURON MEMBRANE PROPERTIES. R. Pun, S. Kleene* & R. Gesteland, Anatomy & Cell Biology, Univ. of Cincinnati Medical Center, OH 45267.

The effects of odors on the membrane properties of mechanically isolated receptor neurons were studied by whole cell tight-seal recording. Cells had a mean membrane potential of -36 mV (range -20 to -48 mV, n=9). At resting membrane potential, an off-spike followed a hyperpolarizing current pulse in most cells. The only spontaneous activity was long duration depolarizing shifts resembling Ca^{++} spikes (>200 msec) following stimulation. Cells were spritzed with a mixture of 10 odorous substances in Ringers each at a concentration of 1 μM. Four neurons responded unequivocally. Following a latency of up to 30 sec, hyperpolarization of the membrane (by current injection or spontaneously) was followed by oscillations which were enhanced by further hyperpolarization and which ceased with depolarization. Under voltage clamp conditions, a slow outward current was recorded after odor stimulation, which was followed by 1-2 sec duration spontaneous inward currents at regular intervals.

Current contributions of single cilia in isolated neurons were measured by drawing one of the several motile cilia into a small patch pipette and establishing a tight seal at the base of the cilium. With this cell-attached configuration and under voltage clamp conditions, cells were stimulated with 1-sec spritzes of the odor mixture. Most cells showed no response at any holding potential tested. In about 15% of the cells, stimulation resulted in current flow into the cilium. Current began to increase about 250 msec after stimulus onset, reached a peak in 100 msec and decayed in the next 2-10 sec. The maximum evoked current was 50 pA. Peak current amplitude and decay time increased with stimulus duration and when a hyperpolarizing potential was applied. In 4 out of 6 responding cells, no odorant-induced current was detectable in the absence of an applied potential.

Frog olfactory receptor membrane properties are apparently different from those measured in salamanders and mud-puppies. Supported by NIH NS23523 and NS23348.

301.3

OLFACTORY TRANSDUCTION IS MEDIATED BY THE DIRECT ACTION OF cAMP. S. Firestein and G.M. Shepherd. Section of Neuroanatomy, Yale University Medical School, New Haven CT.

The link between odor binding and ionic current generation in olfactory receptor neurons is presumed to be through a G-protein regulated second messenger cascade involving cAMP. However a direct measurement of an odor elicited current which is cAMP dependent has not been described. We now present such data as a direct demonstration of the role of cyclic nucleotides in olfactory transduction. Whole cell patch clamp recordings were obtained from isolated olfactory receptor neurons from tiger salamanders. Ionic currents elicited by brief pulses of odors were transformed from transient to sustained by IBMX, a phosphodiesterase inhibitor and by Forskolin, an adenylate cyclase activator. GTP-γ-S and GppNHp, both non-hydrolyzable GTP analogues, tonically activated the G-protein in a time dependent manner. The current was abolished by the GDP analogue GDP-β-S. The synthetic peptide analogue of the cAMP dependent protein kinase inhibitor (WIPTIDE) lengthened the response, suggesting that cAMP acts both directly on the channel and through a phosphorylation step affecting adaptation.

MOLECULAR CLONING AND LOCALIZATION OF NOVEL OLFACTORY-SPECIFIC ENZYMES POSSIBLY INVOLVED IN SIGNAL TERMINATION: A NEW ROLE FOR SUPPORTING CELLS. D. Lancet, J. Heldman*, M. Khen*, D. Lazard*, J. Lazarovits*, T. Margalit*, Y. Poria* and K. Zupko*. Department of Membrane Research, the Weizmann Institute of Science, Rehovot, Israel.

We recently cloned three enzymes that may play key roles in controlling olfactory signals. These are: (i) G_{s2} or G_{olf}, the olfactory-specific stimulatory GTP-binding protein, suggested to be important for chemosensory signal amplification; (ii) olfactory cytochrome P450 (P450olf1) and olfactory UDP glucuronosyl transferase (UDPGT), both likely to mediate olfactory signal termination. All three enzymes may serve as markers for specific cell types in olfactory tissue. We have produced antibodies against them, and are currently studying their tissue and subcellular localization. We hope to support our hypothesis that while signal reception and amplification occur in the most superficial layer of the chemosensory epithelium, i.e. the sensory neuronal cilia, enzymes that underlie odorant signal termination may be concentrated in a layer immediately below the cilia, i.e. the apical endoplasmic reticulum (ER) of the glia-like olfactory supporting (sustantacular) cells. We propose that olfactory cytochrome P450 and UDPGT in the highly enriched ER of supporting cells catalyse the biotransformation of lipophylic odorants to their respective membrane-impenetrable glucuronides. These undergo vectorial transport in secretory granules to the mucus layer at the epithelial surface, where they are cleared by mucociliary transport. Drug- or odorant-induced changes, or gentic differences, in the level of olfactory biotrans-formation enzymes could contribute to variations in olfacotry acuity.

OLFACTORY SENSORY NEURONS ARE TROPHICALLY DEPENDENT ON THE OLFACTORY BULB FOR THEIR PROLONGED SURVIVAL. J.E.Schwob and K.E.Szumowski*. Dept. Anatomy & Cell Biology, SUNY Health Science Center, Syracuse, NY 13210

Ablation of the olfactory bulb results in a chronic reduction in the number of mature olfactory sensory neurons (OSN's) on the operated side, despite some recovery from the acute effects of the lesion (Costanzo and Graziadei, 1983; Monti Graziadei, 1983). In rats studied one month or more after bulbectomy, TEM and SEM examination of the olfactory epithelium and a direct evaluation of the lifespan of OSN's were used to determine whether the olfactory bulb is required for prolonged OSN survival or promotes OSN differentiation without affecting lifespan. OSN's on the ablated side fail to elaborate the dense superficial ciliary mat characteristic of the normal epithelium, and most of the olfactory knobs bear no or only a few cilia. In addition, the fila olfactoria in the lamina propria contain large numbers of swollen and blown-out degenerating axons. An injection of bromodeoxyuridine (BrdU; 20 mg/kg, i.v.) was used to label newly postmitotic neurons on the chronically ablated and unoperated sides. The life cycle of these newly born neurons was assessed by sacrificing animals at 2 h, 5 d and 2 w after BrdU injection, and staining cryostat sections with anti-BrdU MAb. On the ablated side, basal cell proliferation is significantly stimulated by comparison with the unoperated side at 2 h after injection. At 5 d after BrdU, the number of labeled nuclei remains much higher on the ablated side, and the vast majority of the labeled cells are found in the neuronal zone of the epithelium. However, by 2 w, almost all of the labeled cells have disappeared from the ablated side, indicating that the life span of neurons born after bulbectomy is foreshortened. Therefore, in the absence of the olfactory bulb OSN's die before differentiating fully, i.e. they are trophically dependent on the bulb for prolonged survival. Supported by NIH NS19658 and NS 25958.

301.6

CHARACTERIZATION OF THE PRECURSOR POPULATION IN MOUSE OLFACTORY EPITHELIUM AFTER BULBECTOMY. M.A.Schwartz, D. M. Chikaraishi and J.S. Kauer. Neuroscience Program, Tufts NEMC, Boston, MA 02111.

The olfactory epithelium contains at least two types of basal cells; horizontal cells and more superficial globus cells, which may give rise to the sensory cells. Using immunocytochemistry and 3H-thymidine (TdR) autoradiography, we have studied how the mitotic index of these stem cell populations changes after turnover induced by bulbectomy (OBx). While both cell types show turnover as indicated by 3H-TdR uptake, cytokeratin antibody appears to label only the horizontal and not the globus basal cells. By determining the number of 3H labelled cytokeratin-positive and 3H labelled cytokeratin-negative cells at various intervals after OBx, the replacement elements for the olfactory receptor cells following induced turnover can be defined. Results indicate that approximately 90% of the 3H labelled cells 1-15 days after OBx are globus, cytokeratin-negative, cells. Although labelling is seen in the horizontal cells at all intervals after OBx, the number of labelled horizontal cells does not significantly change. Therefore, the increase in label index after OBx appears to be due to an increase in DNA synthesis in the globus basal cells which thus may be the replacement elements for the receptor cells during experimentally induced turnover. Supported by PHS Grants NS-20003, GM-33991 and the Dept. of Neurosurgery.

CULTURED RAT OLFACTORY NEURONS ARE EXCITABLE AND RESPOND TO ODORS. S.K. Pixley and R. Y. K. Pun. Dept. Anat. & Cell Biol. /Physiol. & Biophys., Univ. of Cincinnati Coll. Med., Cincinnati, OH 45267.

In order to study olfactory neurons and the poorly understood olfactory transduction mechanisms, we have developed dissociated, primary cell cultures of olfactory receptor neurons from nasal tissues of newborn Spraque-Dawley rats. An enriched culture medium increased neuron numbers by more than 20 fold. Neurons were immunostained for neuron-specific enolase, tau protein, synaptophysin and microtubule-associated protein 2. Neuron cell bodies averaged 10 um by 15 um, with two or more thin processes. Neurons could be found in 26 day old cultures, although at lower numbers than during the first 5-6 days. Electrophysiological studies performed on these cells after 3-5 days in culture, using the whole cell "tight seal" recording technique, indicated that they generate action potentials following stimulation. Some cells showed spontaneous inward currents. Application of an odorant stimulus resulted in depolarization or generation of an inward current. This is the first description of a monolayer culture system containing rat olfactory neurons which demonstrate biochemical and physiological maturity. (Supported by APA grant PB1-8803-1 (to SKP)).

301.8

CHARACTERIZATION OF PRIMARY CULTURES OF NEONATAL RAT OLFACTORY NEURONS. G.V. Ronnett, L.D. Hester* and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

We have developed a method for culture of rat neonatal primary olfactory neurons (Pevsner, J.P. et al., Soc. for Neurosci. Abst., 424, 1988). Greater than 98% of the cells in these cultures stained positively for anti-olfactory marker protein (OMP), a generous gift from Dr. Frank Margolis. In addition the same percentage of cells stained positively with anti-vimentin antibody, neuron specific enolase and chromogranin. Cell cultures were negative for glial fibrillary acidic protein and S-100 protein. The specificity of staining in all cases was confirmed by Western Blot analysis.

A number of substrates were tested, including laminin, heparan sulfate, polyornithine, collagen, collagen type IV, fibronectin and polylysine. The substrate which provides the highest yield of bipolar cell attachment as well as maintenance of bipolar morphology is laminin. Within 4 days after plating, in serum-free medium, cells withdrew their processes, suggesting that further nutrients/growth factors are needed. Therefore, we have tested the effects of growth factors, including NGF, TGF, FGF, BDNF, insulin, IGF-I and IGF-II on the cutures. In addition, endogenous levels of cAMP are measured in absence and presence of odorants.

301.9

CHARACTERIZATION OF A CONTINUOUS CULTURE OF OLFACTORY CELL LINES. F.F.Borisy[1], G.V.Ronnett[1], R.Hen[2*], S.H.Snyder[1]. [1]Dept. of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205, [2]Howard Hughes Medical Institute, Columbia University, New York, New York 10032.

Olfactory neuronal cell lines have been characterized immunocytochemically and levels of cyclic nucleotides have been studied in response to stimulation by a variety of odorants. Cell lines immortalized from olfactory epithelium have been grown continuously in culture for up to fifty generations. The cells stain immunopositive for 160 KD neurofilament, neuron specific enolase, 43 KD growth associated protein, and vimentin, but not for glial fibrillary acidic protein, S100, or keratin. Treatment with retinoic acid, dibutyryl cyclic AMP or isobutylmethylxanthine switches the cell morphology from epithelioid to neuronal. The treated cells have small refractile bodies and extended processes. Measurement of adenylate cyclase activity indicates a basal activity of 0.45 nmol/mg/min and a GTP S stimulated activity of 0.9 nmol/mg/min. Odorant stimulation produces a 20 - 30 per cent increase in adenylate cyclase activity.

301.10

OLFACTORY MECHANISMS: ROLE OF THE LATERAL NASAL GLAND. A.A. Khan and S.H. Snyder. Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med. Balt., MD 21205.

The lateral nasal gland (LNG) is the major source of odorant binding protein (OBP) which may be a carrier for odorants. The protein has been shown to bind odorants of various structural classes such as pyrazines, terpenoids, and aromatics. OBP is significantly homologous to a superfamily of proteins that are believed to transport hydrophobic ligands. This homology has suggested the possibility of a receptor binding site for the complex of odorants and OBP. Sagittal sections of the removed gland and olfactory epithelium indicate novel aspects of glandular anatomy: multiple ducts projecting from the gland anteriorly and posteriorly; a projection from the gland to the tear ducts; and regions of glandular tissue confluency with olfactory epithelium. Preliminary autoradiographic studies, with metabolically labelled [^{35}S]-met OBP, show a specific localization of OBP binding to olfactory epithelium and not to adjacent brain regions. These preliminary results indicate the existence of a binding site in olfactory epithelium for OBP.

301.11

OLFACTORY MARKER PROTEIN IN A SECOND CELL TYPE IN THE RAT OLFACTORY EPITHELIUM. E.W. Johnson*, P.M. Eller*, Bruce W. Jafek*, and D.T. Moran* (SPON: A. Martin). RMTSC and Univ. Colorado Hlth. Sci. Cntr., Denver, CO 80262. Supported by NS20486.

Immunocytochemical localization of olfactory marker protein (OMP) has been a reliable technique for identifying receptor cells in the mammalian olfactory epithelium (OE). Recently, we've demonstrated ultrastructural immunocytochemical localization of OMP (AChemS-XI Abstract #127, 1989) in the receptor vesicles and cilia of the olfactory bipolar neurons. The same techniques, using anti-OMP (courtesy of F. Margolis) with subsequent peroxidase conjugation and a DAB reaction, are used in the current study. A previous electron microscopic study in our lab suggested that a second cell type (termed "microvillar cell") in the mammalian OE may also be a receptor cell (Moran et al., Brain Res. 253:39, 1982). In the present study, we describe OMP labeling in the microvillar cell of the rat septal OE, at the light and electron microscopic levels. These scarce cells, with a central nucleus in an oval soma close to the epithelial surface, have microvilli that extend into the nasal cavity. The cytoplasm surrounding the nucleus and at the apical surface is immunocytochemically labelled with anti-OMP. These observations support the suggestion that there are two distinct cell types in the mammalian OE that contain OMP.

DISSOCIATED MOUSE OLFACTORY BULB CELL CULTURES. L. Guo*, R.M. Thompson*, S.P. Fracek Jr. and R. Schafer. Department of Biological Sciences, University of North Texas, Denton, TX 76203.

As part of a project to develop an *in vitro* model of the olfactory system using co-cultures of olfactory neuroepithelium and bulb cells from embryonic mice, we have compared the morphologies of intact adult tissue to cultured cells using light microscopy, scanning and transmission electron microscopy.

Cultured olfactory bulb cells are very similar to those found in the adult bulb, with both neurons and glial cells present. Cultured cells characteristically form clusters - heterogenic clumps of neurons with many neurites and fascicles of neurites that project to adjacent clusters. Many individual neurons are also present outside the clusters. Neuronal soma are spherical, oval, or pyramidal in shape and vary from less than 10 µm to more that 25 µm in diameter. The nuclei of these cells are spherical or oval, with few clusters of marginal heterochromatin and one or two nucleoli. The perikaryon is rich in organelles, especially endoplasmic reticulum (ER), mitocondria (MI), free ribosomes and Golgi. Microtubules (MT) and microfilaments (MF) predominate in the neurites.

Neurites of cultured olfactory bulb cells are well developed and some are several millimeters long and form a dense interconnecting network, especially around cell clusters. The diameter of the neurites ranges from 0.5 µm to 4 µm; fascicles can be up to 20 µm in diameter. Many MT, MI, and RER are found in In dendrite-like neurites. In axon-like neurites, only MT and an occasional MI are found. Presumed growth cones are found at the tips of some of the neurites.

Synapses are very prominent in these cultures, especially in a zone surrounding cluster areas. The terminals are often slightly swollen and may contain MI, in addition to synaptic vesicles. The vesicles can be divided into two types: 1) small, spherical and electron lucent vesicles of about 50 nm in diameter and 2) larger, spherical and electron lucent vesicles of about 90 nm in diameter. The large vesicles are more variable in size and have an electron dense core about 45 nm in diameter. Synaptic clefts are about 25 to 35 nm wide and contain an electron dense material. This research is supported by NSF Grant BNS-8719319 (to SPF).

301.13

BIOCHEMICAL PROPERTIES OF SENSILLA SPECIFIC PROTEINS IN SAND SCORPIONS. **D.A. Balseco* and P.H. Brownell (Spon: G. Ciment). Department of Zoology, Oregon State University, Corvallis, OR 97331-2914.**

The pectines of scorpions are large, mid-ventral, sensory appendages comprised of cuticular peg sensilla that contact the substrate. Behavioral and morphological evidence indicate that the pectines are chemosensory structures. In reducing SDS-PAGE, low molecular weight proteins (14-18 kd) have been localized to the pectinal sensilla of the sand scorpion, *Paruroctonus mesaensis*. These sensillar specific proteins (SSP) have species and sex specific molecular masses and are rapidly turned over. Incorporation of ^{35}S-methionine into SSP occurs within minutes when incubated *in vivo* or *in vitro* and is more rapid in males. Control tissues do not contain proteins with these characteristics. In non-denaturing PAGE, SSP occur as dimers (26-32 kd). These proteins are not glycosylated, and are easily extracted under mild conditions. Extraction with Triton X-114 results in the separation of aqueous and detergent phases with the SSP occurring in the aqueous phase. These results imply that SSPs are not integral membrane proteins.

The SSPs have similarities with a family of hydrophobic molecule binding proteins (15 kd pheromone binding protein in sensilla trichoidea of saturnid moths and 19 kd olfactory binding protein in rat nasal epithelia). The SSP of scorpions may function similarly and we are investigating the possible role of SSP in pheromone reception. **Support: BSF grant BNS 87-00990; PHS grant 07-32 NH-10002; Grant-in-Aid of Research from Sigma Xi.**

DETECTORS OF MAJOR AND MINOR FEMALE PHEROMONE COMPONENTS ON THE ANTENNAE OF MALE REDBANDED LEAFROLLER MOTHS. R. Patrick Akers* and Robert J. O'Connell. Worcester Foundation for Experimental Biology, 222 Maple Ave., Shrewsbury, MA 01545.

The pheromones of many insects are now proving to be complex blends of organic compounds. The biologically active components of the sex attractant pheromone of the female redbanded leafroller moth includes seven different compounds. Olfactory receptor neurons responsive to the two most abundant pheromone components are routinely observed within the long trichoid sensilla found abundantly on the proximal margins of male antennal subsegments. Here, we sought to determine if receptor neurons to the other components of the pheromone could be found in a systematic survey of the whole antenna. Extracellular single-sensillum recordings were obtained from 113 long sensilla trichodea broadly distributed on the antennae in response to the seven components of the female sex pheromone, presented both singly and in combinations. All of these sensilla contained two receptor neurons. The neuron with the larger impulse was specialized for *Z*-11-tetradecenyl acetate (Z11-14:Ac) and the companion neuron with the smaller impulse was specialized for *E*11-14:Ac. None of the receptor neurons found in these sensilla were responsive to any of the other components of the pheromone. A search was then initiated among the other sensillar types on the antenna. Olfactory receptor neurons responsive to stimulation with two of the minor components, *E*- and Z9-12:Ac, were found in separate sensilla. Standard SEM observations indicate that these neurons are housed within a shorter, narrower type of sensillum trichodeum than that which houses the receptor neurons responsive to the two major components. These neurons account for <10% of the number found to be responsive to major components of the pheromone, although they have similar sensitivities for their most effective stimuli. Supported by NS 23946.

301.15

PATCH CLAMP ANALYSIS OF MALE *MANDUCA SEXTA* OLFACTORY RECEPTOR NEURONS IN PRIMARY CELL CULTURE. M. Stengl, F. Zufall*[,1], H. Hatt*[,1], J. Dudel*[,1], and J.G. Hildebrand. ARL Div. of Neurobiology, Univ. of Arizona, Tucson, AZ 85721, & [1]Tech. Univ. of Munich, FRG.

Sex pheromones released by female moths *Manduca sexta* are detected solely by male-specific olfactory receptor neurons (ORNs). To investigate the transduction mechanisms underlying pheromone detection, we have established a primary culture system of male pupal antennal cells (Stengl & Hildebrand, *Neurosci Abs* 14:379,1988). Patch clamp studies showed that after only 2 days *in vitro*, most ORN-like cells (with resting potentials of -40 to -80 mV) exhibit (in whole-cell patch clamp experiments) a non-inactivating, voltage-dependent, outwardly rectifying K^+ current when the voltage is stepped from -70 to 0 mV. After about 2 weeks *in vitro*, these cells express a fast TTX-blockable inward Na^+ current. In cell-attached patches (with 150 mM NaCl and 2 mM KCl in the pipette), at least 2 different types of Cs^+-blockable K^+ currents could be distinguished: (1) a non-inactivating, voltage-dependent, outwardly rectifying K^+ current, which could be blocked by ATP or cGMP applied from the outside as well as from the inside of the cells; and (2) a rapidly inactivating, voltage-dependent K^+ current. In inside-out patches, we found a rapidly flickering Ca^{++}-dependent K^+ current. After 18 days *in vitro*, cells showed (at resting potential in cell-attached patches, with 150 mM KCl in the pipette to mimic the receptor lymph), very few, briefly opening K^+ channels, whose currents reversed around 0 mV cell potential and open-time probability (OTP) increased with depolarization. If these cells were stimulated with the female pheromone blend (prepared by washing the gland with DMSO), some of their responses changed: channel openings of longer duration and higher OTP appeared, while the OTP of the smaller-amplitude, briefly opening channels decreased. We now seek to learn whether these responses to pheromone underlie the depolarizing receptor potentials in the male-specific olfactory receptor cells.

acj6, A NEW *DROSOPHILA* OLFACTORY BEHAVIOR MUTANT WITH A DECREASED AMPLITUDE ELECTROANTENNOGRAM. R.K. Ayer, Jr.* and J. R. Carlson* (SPON: C. Sahley). Department of Biology, Yale University, New Haven CT. 06511.

The electroantennogram (EAG) was used to monitor the peripheral steps of olfactory transduction in both wildtype and mutant *Drosophila melanogaster*. The EAG, thought to represent the summed odorant response of all cells in the fly's antenna, is extracellularly measured as the voltage difference between a saline filled reference electrode inserted into the head capsule and a similar recording electrode placed on the anterior surface of the fly's antenna. A reflexive olfactory behavior assay developed in this laboratory was used to isolate a group of x-linked, *abnormal chemosensory jump* (*acj*) mutants on the basis of a decreased jump response to vaporous pulses of the odorant ethyl acetate (EA). One of these, *acj6*, is shown to have significantly reduced amplitude EAGs over a wide range of concentrations of EA and benzaldehyde (BZ). EAG amplitude is reduced to about 30% of wildtype levels for pulses of EA at a 10,000-fold dilution or BZ at a 100,000-fold dilution. The *acj6* jump response is reduced for odorant pulses of BZ as well as EA. Qualitative behavioral and quantitative physiological evidence has been used to assess whether the *acj6* mutation affects many functions of the fly or is specific to olfaction. While the general activity level of the *acj6* fly in the culture vial seems somewhat depressed, mating behavior and viability levels of flies carrying the mutant chromosome are similar to wildtype. The *acj6* electroretinogram appears normal, suggesting wildtype visual function. Genetic mapping experiments, presently in progress, may be useful in determining if a single mutational event on the x-chromosome is responsible for the behavioral and physiological phenotypes of *acj6*. Supported by NIH grant GM-36862 to J.C.

ECTONUCLEOTIDASE ACTIVITIES ASSOCIATED WITH THE OLFACTORY ORGAN OF THE SPINY LOBSTER: EFFECTS ON THE DETECTION OF EXOGENOUS AMP, ADP, AND ATP. H.G. Trapido-Rosenthal, R.A. Gleeson*, S.L. Wachocki* and W.E.S. Carr*. The Whitney Laboratory, University of Florida, St. Augustine, FL 32086.

The olfactory organ of the Florida spiny lobster, Panulirus argus, consists of aesthetasc sensilla on the lateral branches of the antennules. Within each sensillum are the dendrites of several hundred chemosensory neurons including those that respond to exogenous AMP, ADP, or ATP. Ectonucleotidase activities that dephosphorylate these nucleotides are also associated with these sensilla. Dephosphorylation of each of the nucleotides can be described by Michaelis-Menten kinetics. Maximum rates of dephosphorylation are variable; rates are half-maximal at micromolar substrate concentrations. While the product of sensillar 5'-ectonucleotidase is the electrophysiologically inactive nucleoside adenosine, the products of ATPase and ADPase activities are ADP and AMP, respectively; these compounds are themselves stimulants of their own classes of receptor cells, and are substrates for their respective ectonucleotidases. In addition, ADP, the initial product of ATPase activity, inhibits both ATP receptor cells and AMP dephosphorylation. We use the kinetic parameters of sensillar ectonucleotidase activities to estimate the effects that these perireceptor events may have on the olfactory detection of purine nucleotides by the lobster. Supported by NSF grants BNS-8607513 and BBS-8712420.

HIGH-RESOLUTION ELECTROCHEMICAL ANALYSIS OF AQUATIC ODOR SIGNALS. P.A. Moore[1,*], J.M. Parrish[2], J. Atema[1] and G.A. Gerhardt[2]. Boston University Marine Program[1], Marine Biological Laboratory, Woods Hole, MA 02543 and Depts. of Psychiatry and Pharmacology[2], Univ. of Colorado Health Sci. Ctr., Denver, CO 80262.

Odor signals are shaped by molecular diffusion and turbulent dispersal in the marine environment, and serve as important sources of information for sensory and neural systems of aquatic animals. However, the precise temporal, spatial and concentration dynamics of such signals remains unclear. In the present study, high-speed (10-200 Hz) electrochemical recording techniques utilizing miniature (30-150 microns) carbon-based electrodes were used to characterize the chemical dynamics of aquatic odor signals using dopamine as the odor tracer. Flume studies showed that odor signals consisted of bursts of concentration peaks; peaks had total time courses of 2-4 seconds and varied in amplitude, frequency and slope when electrodes were moved away from the source. Recordings at different depths along the shaft of the aesthetasc hairs in the lateral antennule of the lobster, Homarus americanus, demonstrated a major difference in the temporal and concentration parameters of signals that reached the deeper portions of the receptor structure. However, under the short impulse flow conditions that characterize the lobsters flicking behavior (i.e. odor sampling) the signals showed equally sharp onset slopes at all depths. These studies have contributed to a more detailed understanding of the temporal dynamics of odor signals as they are perceived by chemoreceptor structures in marine animals.

CHEMICAL SENSES: TASTE AND CAROTID RECEPTORS

302.1

SOLITARY EPIDERMAL CHEMORECEPTORS IN ANAMNIOTE AQUATIC VERTEBRATES: THE STATE OF THE ART. K. Kotrschal* (SPON: W. Hahn). Zool. Inst., Univ. Salzburg, A-5020 Salzburg, Austria & U. Colo. Med. Sch., Dept. Cellular and Structural Biology, Denver, CO 80262

Solitary epidermal chemoreceptor cells (SEC) innervated by spinal or cranial nerves are distributed across the epidermis of many aquatic vertebrates. Although SEC's are present in the agnathans, and in gnathostome fishes as well as in anuran tadpoles, our knowledge of this widespread sensory system used to be very limited. Due to research models such as rocklings (Gadidae: Teleostei), sea robins (Triglidae: Teleostei) and cyprinids (Cyprinidae, Teleostei) and the application of TEM, SEM, conventional and tracer neuroanatomy as well as electrophysiology, our knowledge of the fine structure (Whitear, M. and K. Kotrschal, 1988), innervation and central representation (Kotrschal, K. and M. Whitear, 1988), as well as the function of this system (Silver, W.L. and T.E. Finger, 1984; Peters, R. et al., 1987) has improved. The contemporary state of the art in SEC research will be surveyed.

The densities, distribution and innervation of SEC as compared to taste buds was studied with light and scanning electron microscopy in a variety of cyprinids and catfish. The density of SEC in many species appears to be one or two orders of magnitude greater than that of chemosensory cells organized in taste buds. Thus the SEC system appears to be a widespread, major sensory system in aquatic animals rather than a specialized system occurring in only a limited number of species. We may assume that SEC comprise a bulk-water sampling system of unknown biological roles. Whether SEC represent the morphological substrate for the "common chemical sense" as described by Parker remains doubtful.

PHOTOAFFINITY LABELING OF ALANINE TASTE RECEPTORS IN CATFISH. **B.P. Bryant, P. Shah, and K. Leftheris, Monell Chemical Senses Center, Philadelphia, PA, 19104**

To facilitate the isolation and ultra-structural localization of the alanine taste receptor we synthesized a photolabile analogue of L-alanine, the 4-azidobenzyl ester (AzB-Ala). Without photoactivation, AzB-Ala specifically and reversibly inhibited the binding of L-(3H) alanine to plasma membranes from taste epithelium following pre-exposure to AzB-Ala. L-(3H)arginine binding was unaffected. Used as an adapting stimulus, AzB-Ala caused differential inhibition of taste neural responses (Ala,87%; Arg,34%). Initial attempts to label membranes revealed that alanine but not arginine binding activity was labile to UV (254 nm). Using a filtered 350 nm lamp, it was possible to irradiate membranes without loss of alanine binding in controls. Specific, irreversible inhibition of the binding of L-(3H) alanine but not L-(3H) arginine was observed. Although protection against photo-activated inhibition using excess alanine has not been achieved, labeling appears to be specific to the alanine receptive pathway.

INTRACELLULAR RECORDING FROM *NECTURUS* TASTE CELLS IN LINGUAL EPITHELIAL SLICES Douglas A. Ewald & Stephen D. Roper Dept. of Anat. & Neurobiology, Colorado State Univ., Ft. Collins CO 80523 and Rocky Mountain Taste and Smell Center, Denver CO 80262

Taste buds in *Necturus* contain three morphologically distinct cell types: dark and light receptor cells with apical ends extending to the surface of the lingual epithelium and basal cells which are located at the base of the taste bud. Receptor cells exhibit generator potentials and action potentials in response to tastants (*cf.* Kinnamon & Roper, J. Physiol. **383** 601, 1987 and Chem. Senses **13** 115, 1988). In ultrastructural studies, chemical synapses have been identified in the basal region of the taste bud between taste cells and sensory axons and also between adjacent taste cells (Delay & Roper, J. Comp. Neurol. **277** 268, 1988). We have used transverse slices of epithelium (200 um in thickness) that contain taste buds to probe the electrophysiological properties of both receptor and basal cells *in situ* and to investigate the hypothesis that there are synaptic interactions among cells in the taste bud. The apical extremities of receptor cells were depolarized by focal application of brief pulses of high K^+ solution (140 mM) delivered from a micropipette (20 um tip diam.). Intracellular recordings from the **apical** processes of receptor cells showed large depolarizations (20 - 40 mV) with short latencies (100 - 150 ms). Recordings in the **basal** region of the taste bud revealed two classes of responses: i) large depolarizations (<40 mV) with short latencies (<150 ms) presumably representing electrotonic conduction of receptor potentials from apical to basal ends of receptor cells, and ii) smaller depolarizations (5 - 20 mV) with longer latency (>150 ms) which might represent synaptic transmission from receptor to basal cells. We are testing the latter hypothesis electrophysiologically (*e.g.* with pharmacological agents and by voltage dependence) and anatomically (with Lucifer Yellow dye injection). Supported by AG06657.

302.4

IMMUNOCYTOCHEMISTRY OF PUTATIVE NEUROTRANSMITTERS IN *NECTURUS* TASTE BUDS. S. B. Jain* and S. D. Roper. Dept. of Anat. and Neurobiology., Colorado State Univ., Ft. Collins, CO 80523 and the Rocky Mountain Taste and Smell Center, Denver, CO 80262.

Synaptic contacts have been identified at the ultrastructural level between taste cells and gustatory nerve fibers, and between adjacent cells in *Necturus* taste buds (Delay & Roper, 1988, *J. Comp. Neurol.* **277**, 268). The neurotransmitters released at these synapses are not known. Electron micrographs of synapses reveal small spherical electron-lucent vesicles at some sites, and large dense-core vesicles at other sites. We report here that GABA-like and glutamate-like (henceforth, GABA and glutamate) immunoreactivity, studied at the light microscopic level, has been localized in taste buds, especially in sensory fibers innervating taste cells in *Necturus*. Lingual epithelium was dissected from the animal and fixed in formaldehyde-glutaraldehyde. Thick (20 microns) sections were cut with a cryostat and treated with primary anti-GABA-BSA (rabbit serum) or anti-glutamate-KLH (monoclonal) antibodies. Controls included: (1) treating tissues with pre-immune rabbit serum (i.e. devoid of anti-GABA); (2) preadsorbing with 0.5 mM GABA, GABA-KLH, or glutaraldehyde conjugates (with BSA) of the following amino acids: GABA, taurine, glycine, beta-alanine, l-glutamate, l-glutamine or l-aspartate. Secondary antibody and biotinylated peroxidase (ABC kits) were obtained from Vector Laboratories and Pel-Freez. Control tissues showed non-specific, background staining in some taste cells and in numerous non-taste epithelial cells. Tissues treated with anti-GABA or anti-glutamate antibody showed strong immuno-reactivity at the base of the taste bud, especially in nerve fibers inner-vating the taste buds. These findings suggest that GABA and glutamate may be neurotransmitters in taste buds in *Necturus*. Supported by NIH grants NS20486 and AG06657.

302.5

A METHOD FOR ISOLATING INDIVIDUAL MAMMALIAN TASTE CELLS. A.I. Spielman , J.F. MacDonald, M. W. Salter, I. Mody, J.G. Brand* and G. Whitney*. Monell Chem. Sens. Ctr. Philadelphia., PA 19104 & Dept. Physiol., Univ. Toronto, Toronto, Ont. M5T 2S8.

Delination of the cellular mechanisms of taste reception in mammals has been limited by the difficulty of making electrophysiological recordings from individual taste cells. We present a method for acute isolation and voltage-clamp recording of single mammalian taste receptors.

Tongues were dissected from adult mice (SWR & CF1) which were killed by cervical transection. Individual folliate and vallate papillae were punched out of each tongue and pre-incubated for 1 hr in a well oxygenated divalent cation free buffer (mM): $NaHCO_3$ 26, NaH_2PO_4 2.5, NaCl 65, KCl 20, D-glucose 20, & EDTA 1, maintained at pH 7.4 & 32°C. This was followed by a 30 min incubation in 1.5 mg/ml pronase and 1 mg/ml elastase. The cells were then mechanically dissociated as previously described for CNS neurons (Mody et al, *Neurosci. Lett.*, 96: 70, 1989). Individual taste cells from the suspension attached to the bottom of plastic culture dishes. Whole cell patch clamp recordings were then made using conventional techniques. These cells demonstrated both a voltage-dependent transient inward Na^+ current and a sustained outward K^+ current (Delayed Rectifier).

In order to examine the responsiveness of these cells to taste stimuli we applied denatonium benzoate, the most "bitter" compound yet identified, to individual voltage-clamped taste cells. Pressure applications of denatonium (10 μM) produced a potent blockade of the Delayed Rectifier current in these cells.

This work was supported by BRSG (AIS), MRC of Canada (JFM, MWS & IM), NIH (JGB) & NINCDS (GW).

EVIDENCE FOR INS(1,4,5)P_3 AS A SECOND MESSENGER IN RAT TASTE RECEPTOR CELL SIGNAL TRANSDUCTION. P.M. Hwang, A. Verma, D.S. Bredt, D. Verma and S.H. Snyder. Depts. of Neuroscience, Pharmacology and Molecular Sciences, Johns Hopkins Univ. Sch. of Medicine, Balt., MD 21205.

Denatonium, a potently bitter substance, has been shown to mobilize intracellular Ca^{++} in isolated rat circumvallate (CV) taste receptor cells (Akabas, M.H., et. al., Science, 242:1047, 1988). We examined the energy-dependent sequestration of $^{45}Ca^{++}$ into 10 um frozen sections of rat CV via autoradiography. Accumulated $^{45}Ca^{++}$ was selectively localized to circumvallate papillae, which mediate bitter taste.The Ca^{++} taken up was taste bud cell-specific as demonstrated by lack of uptake post-denervation. In the presence of 100 nM Ins(1,4,5)P_3 there was a significant reduction in the amount of Ca^{++} uptake. This effect was IP_3 isomer-specific: Ins(1,4,5)P_3 = Ins(2,4,5)P_3 >> Ins(1,3,4)P_3. Other inositol phosphates such as IP_1 or IP_2 had no effect. The effect of IP_3 on Ca^{++} uptake was reversed with 100 ug/ml heparin, a known antagonist of IP_3 receptors. In preliminary experiments denatonium caused a rapid increase in mass levels of IP_3 as assayed by the IP_3 radioreceptor assay.

302.7

INNERVATION-DEPENDENT EXPRESSION OF NEURAL-RELATED ANTIGENS IN RAT TASTE CELLS. D. V. Smith, R. A. Akeson, M. T. Shipley and T. L. Belecky*. Depts. Otolaryngol. & Maxillofac. Surg., Pediatrics, Anat. & Cell Biol., Univ. Cincinnati Coll. Med. & Children's Hosp., Cincinnati, OH 45267.

Mammalian taste receptors are modified epithelial cells which are continually replaced throughout life. These cells are arranged within taste buds that are trophically dependent upon their innervation by gustatory nerves. Previous studies have reported the presence of growth-dependent neural membrane proteins on rat taste cells. Monoclonal antibodies (Mabs) directed against several neural membrane-related molecules were used for immunocytochemical study of taste buds in the rat vallate papilla. Mabs 2B8, 3F4, and 9OE recognize either neuronal cell adhesion molecule (NCAM) polypeptides or carbohydrate groups common to NCAMs and other molecules. In adult normal rats, vallate taste buds contained immunoreactivity for 2B8, 3F4 and 9OE, with a pattern of staining specific to each Mab. Subsets of taste cells were stained with 3F4 and 9OE, whereas 2B8, which also stains rat olfactory receptor neurons, appeared to be associated with all of the cells within each taste bud. Bilateral transection of the glossopharyngeal nerve resulted in the complete elimination of taste cell immunoreactivity to each of these Mabs after seven days. Earlier studies have shown that all morphologically detectable taste buds degenerate within this time. Studies are underway to determine the time course of this decline in antigenic expression, its recovery following reinnervation, and the role(s) of these antigens in the normal development of taste cells.

CALCIUM DEPENDENT ATPASE STAINING OF NORMAL AND DENERVATED FUNGIFORM TASTE BUDS. M.A. Barry and L.D. Savoy*. Dept. of BioStructure and Function, Univ. of Connecticut Health Center, Farmington, CT 06032.

These experiments are part of a study on the fate of denervated taste buds and the source of new taste bud cells following reinnervation in fungiform papillae of the golden hamster. Vallate and foliate taste bud cells show intense calcium dependent ATPase (Ca^{2+}-ATPase) activity, but fungiform papillae have not been previously examined. Ca^{2+}-ATPase activity was revealed histochemically in 10-20 μm sections of the tongue. Denervation was accomplished by cutting and devitalizing the combined chorda tympani-lingual nerve unilaterally. The normal fungiform taste bud and the connective tissue core (including nerve fibers) show intense activity relative to the remainder of the fungiform papilla and the filiform papillae. At 7 and 20 days following denervation, the taste buds are smaller than normal but still stain strongly for Ca^{2+}-ATPase. By 20 days, there are also fewer taste buds than normal on the denervated side. These results confirm recent findings that denervated fungiform taste bud cells persist rather than completely degenerate as previously thought. In addition, at least one property of taste bud cells, elevated Ca^{2+}-ATPase activity, is retained following denervation. Studies are in progress to localize Ca^{2+}-ATPase at the electron microscopic level. NS16993.

STIMULATION OF THE GERBIL'S GUSTATORY RECEPTORS BY INTENSE NATURAL SWEETENERS. W. Jakinovich Jr., Dept. of Biological Sciences, Herbert H. Lehman College and the Graduate School, City University of New York, Bronx, NY 10468; N.P.D. Nanayakkara*, R.A. Hussain*, and A. Douglas Kinghorn*, Program for Collaborative Research in the Pharmaceutical Sciences, College of Pharmacy, University of Illinois at Chicago, Chicago, IL 60612.

The purpose of this study was to determine if the gerbil responds to the INTENSE NATURAL SWEETENERS in the same manner as the human. The gerbil's chorda tympani nerve responses were obtained to each of the following sweeteners; hernandulcin (Hern), mogroside V (Mogro), periandrin III (Peri), rebaudioside A (Reb-A), stevioside (Stev) and sucrose (Suc). As stimuli, all of these compounds were more effective than Suc; Mogro>Stev=Reb-A>Peri>Hern>Suc. By comparison, in the human, the sweetness ranking of these compounds is Hern>Reb-A>Stev=Mogro>Peri>-Suc.

K+ CHANNEL BLOCKERS ATTENUATE IXTH NERVE RESPONSE TO QHCL BUT NOT UREA. P. E. Scott and J. Farley. Princeton Univ., Prog. Behav. Neurosci., Princeton, NJ 08541 and Indiana Univ., Prog. Neurosci., Bloomington, IN 47405.

Since K+ channels have been implicated in taste transduction processes, we sought to determine if K+ channels were involved in the rat IXth nerve response to bitter compounds. Concentration-response relations for QHCl (0.0001 M - 0.1 M) and urea (0.3 M - 4.0 M) were evaluated before and after treatment of the tongue with either the K+ channel blocker tetraethylammonium (TEA; 0.1 M) or 4-aminopyridine (4-AP; 0.01 M). TEA clearly reduced the response to QHCl but had little effect on the response to urea. The response to urea was also unaffected by treatment of the tongue with 4-AP. These results suggest that TEA and QHCl act at similar sites on primary taste neurons, presumably K+ channels. The fact that neither TEA nor 4-AP affected the IXth nerve response to urea indicates that the urea response is not mediated by TEA- or 4-AP- sensitive K+ channels. These results support a role K+ channels in the transduction of bitter taste and further support multiple receptor mechanisms for bitter taste.

302.11

ACTIONS OF HODULCIN: DYNAMICS AND KINETICS OF SUPPRESSION OF TASTE RECEPTOR CELL RESPONSES TO SUCROSE. L.M.Kennedy and D.E. Kolodny*. Dept. of Biology and Neuroscience Program, Clark Univ., Worcester, MA 01610.

Hodulcin (from Hovenia dulcis) selectively suppresses sweetness perception in humans and behavioral and receptor cell responses to sucrose in flies (Kennedy et al., Chem. Senses 13, 1988, 529; Kolodny & Kennedy, Chem. Senses 13, 545). We have been studying the effects of various concentrations of purified hodulcin (HDE) on fly (Phormia regina) receptor cell action potential responses to sucrose (in 50 mM NaCl) to determine the mechanisms of action. The concentration-effects (C-E) curve for responses to sucrose 50 mM is bell-shaped with suppression beginning at 0.025% HDE ($p<0.012$) and peaking at 0.075% HDE ($p<0.001$). While there is a significant decrease in effectiveness at 0.1% HDE ($p<0.000$), a small suppression remains ($p=0.01$)(Kruskal-Wallis,Mann-Whitney). Nonlinear regression fits for responses to sucrose 10, 20, 40, 80, 160, and 320 mM to the Michaelis-Menten equation ($r^2=0.75$-0.95, $p<0.0001$) show a decrease in Vmax (10.8-8.9- 7.4) and an increase in Km (19.6- 34.1- 48.3) as HDE concentration increases (0- 0.03- 0.07%) ($p\leq0.04$)(ANOVA). This analysis indicates that HDE concentrations on the rising phase of the C-E curve suppress sucrose responses by both competitive and noncompetitive mechanisms. Preliminary data suggest that primarily the noncompetitive mechanism acts at higher HDE concentrations ($\geq$0.1%). (Supported by NIH NS24159 to L.M.K.).

EFFECTS OF HALOPERIDOL ON BASAL AND STIMULUS EVOKED CATECHOLAMINE RELEASE FROM RABBIT CAROTID BODY. A. Gomez-Niño*, B. Dinger, C. Gonzalez and S.J. Fidone. Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, UT 84108

Previous experiments have established that the synthesis and release of dopamine (DA) are activated by natural and pharmacological stimulation of the carotid body. These data have suggested an important role for DA in chemotransmission between type I cells and afferent nerve terminals, both of which have been shown to possess DA receptors. However, the precise role of DA in chemotransmission has been confused by pharmacological experiments which demonstrate that DA can both excite and inhibit carotid sinus nerve discharge. In the present study, ^{3}H-catecholamine (^{3}H-CA; synthesized from ^{3}H-tyrosine) release was studied in carotid bodies superfused in the presence or absence of the DA receptor antagonist haloperidol (10^{-5} M). The introduction of haloperidol to carotid bodies superfused in media equilibrated with 100% O_2 increased the basal ^{3}H-CA release by 47% ($p<0.025$). Likewise, the evoked ^{3}H-CA release (stimulus-control) in the presence of hypoxic media (10% O_2-equilibrated) was elevated 5.2-fold ($p<0.001$) by haloperidol. These data suggest that DA autoreceptors, previously demonstrated to be present on type I cells, can modulate the basal and stimulus-evoked release of DA from the carotid body. Supported by USPHS grants NS12636 and NS07938.

EFFECTS OF HYPOXIC STIMULATION ON CYCLIC NUCLEOTIDE CONTENT IN THE RABBIT CAROTID BODY. W.-J. Wang*, B. Dinger and S.J. Fidone. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108.

We have initiated experiments designed to test the involvement of cyclic nucleotides in chemotransduction and chemotransmission in the arterial chemosensory tissue of the rabbit carotid body. Carotid bodies incubated in vitro in media equilibrated with 100% O_2 contained 5.4 ± 0.36 pmole/mg tissue ($\bar{X}$ ± SEM) of cAMP and 0.068 ± 0.007 pmole/mg tissue of cGMP (RIA measurements). Exposure to incubation media equilibrated with 5% O_2 (10 min) elevated the cAMP content (19.6 ± 3.9 pmole/mg tissue; $p<0.0005$) and depressed the level of cGMP (0.046 ± 0.005; $p<0.025$). Direct activation of adenylate cyclase by forskolin (10 µM; 10 min) increased the cAMP content by 47-fold, but decreased the amount of cGMP in the tissue by 49% ($p<0.01$), suggesting a reciprocal relationship between the two cyclic nucleotides. Incubation of carotid bodies in zero Ca^{++} media to prevent neurotransmitter feedback effects on adenylate cyclase resulted in increased levels of cAMP (13.2 ± 3.3 pmole/mg tissue) under resting conditions (100% O_2-media). Furthermore, hypoxic stimulation (5% O_2-media) in zero Ca^{++} media evoked an additional increase in the cAMP content (29.9 ± 7.3 pmole/mg tissue; $p<0.05$). Thus, processes independent of neurotransmitter action may initiate the generation of cAMP. Supported by USPHS grants NS12636 and NS07938.

IMMUNOCYTOCHEMICAL STUDIES OF CYCLIC GMP IN THE NORMOXIC AND HYPOXIC RAT CAROTID BODY. Z.-Z. Wang, B. Dinger, S.J. Fidone and L.J. Stensaas. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108

The cellular mechanism of chemosensory transduction in the carotid body remains obscure. The present study was undertaken to localize cGMP in the rat carotid body exposed in vitro to: 1) normoxic or hypoxic conditions, 2) to iso-osmolar 100 mM potassium, or 3) an activator of guanylate cyclase (sodium nitroprusside, SNP). Polyclonal antibodies to cGMP (obtained from Dr. De Vente) were used with the avidin-biotin peroxidase technique to immunostain frozen sections. Cyclic GMP immunoreactivity was present in about half of the type I cells of the rat carotid body in 100% O_2-equilibrated media. A dramatic increase in the number of cGMP-positive type I cells occurred following incubation in 100 mM K^+. Hypoxic stimulation (5% O_2, 10 min), and hypoxia combined with 100 mM K^+ greatly reduced both the number and intensity of cGMP immunostaining in type I cells. SNP (1.0 mM, 10 min) resulted in an elevation of cGMP, but mostly in vascular elements of the carotid body, and this effect was potentiated by hypoxic stimulation. These data indicate that cGMP may be involved in the transduction process by type I cells of the rat carotid body; they also provide evidence that cGMP-producing systems in type I cells and vascular elements are differentially sensitive to hypoxia and SNP. Supported by USPHS Grants NS12636 and NS07938.

EFFECTS OF HYPOXIA INDUCED BY Na-DITHIONITE ON GLOMUS CELLS IN CULTURE. L. Pang* and C. Eyzaguirre. Dept. Physiol. Univ. Utah Sch. Med., Salt Lake City, UT 84108.

The carotid body removed from 50-70 gm anesthetized rats was shredded in ice-cold Ham's F-12 saturated with O_2. The pieces were triturated with pipettes and plated on cover-glasses coated with polylysine (100 mg/l). After the cells attached to the glass (3-4 hrs), sodium selenite (1 mM), insulin (80 U/l) and $CaCl_2$ (100 mg/l) were added to the medium for incubation at 37° with 5% CO_2 in air. After 2-7 days the cultures were bathed in flowing rat saline (pH 7.43 at 31°) equilibrated with air, viewed with an inverted phase contrast microscope and impaled with microelectrodes for recording membrane potential (E_m) and input resistance (R_o). Glomus cell clusters (n=67) and isolated cells (n=34) were used. Cell diameter was 8.6±0.2 μ (SEM) and E_m -24.3±0.5 mv in both instances. R_o was 242.3±35.1 MΩ in clusters but 154.7±25.6 MΩ in isolated cells. After the controls, the preparation was bathed for 1-2 min with saline containing 1.25 mM Na-dithionite to lower saline PO_2 to 12 torr. Cells in clusters depolarized to -20.6±0.7 mV and R_o decreased to 160±33.7 MΩ. However, isolated cells hyperpolarized to -34.7±36.6 mV and R_o increased to 198± 36.6 MΩ. Differences may be due to destruction of enveloping sustentacular cells and/or intercellular communications in isolated cells. After fixation in 0.5% paraformaldehyde and 2% glyoxylic acid, glomus cells showed typical yellow-green fluorescence. Supported by grants AHA 860662, NS05666 and NS07938.

PROPERTIES OF DORSAL HORN NEURONS STUDIED INTRACELLULARLY AND THEIR RELATIONSHIP TO CHANGES SEEN AFTER LESIONS. L.M. Pubols, R.S. Dow Neurol. Sci. Inst., Good Samaritan Hosp. & Med. Ctr., Portland, OR 97210.

Previous work (L. Pubols et al., J. Neurophysiol. 60:1253, 1988) revealed that chronic dorsolateral funiculus (DLF) lesions increase the percentage of dorsal horn neurons responsive to sural nerve stimulation. The present study was designed to explore the hypothesis that strengthening of subliminal inputs is responsible for this change. To accomplish this, the response properties of 35 cat L_6 and L_7 dorsal horn cells were studied intracellularly, and the lesion data were reexamined in light of the findings.

Results of this study support the stated hypothesis in two ways: 1) Within broad limits the percentage of cells giving only EPSPs to sural nerve stimulation matched the postlesion increase in the percent of cells giving impulses to this stimulus. 2) Cells giving only EPSPs to sural nerve stimulation were predominantly those that had low threshold receptive fields on the proximal hindlimb. The postlesion increase in cells responding with impulses to sural nerve stimulation occurred primarily within this subpopulation.

No purely subliminal cutaneous receptive fields (RFs) were observed using natural stimuli. However, subliminal responses were commonly observed within the supraliminal RFs of these cells. (Support:NIH,NS19523)

DETERMINATION OF THE CENTRAL DELAY OF THE DORSAL ROOT REFLEX IN AN ISOLATED MAMMALIAN SPINAL CORD PREPARATION. J.BAGUST*, Y.CHEN* and G.A.KERKUT* (SPON: Brain Research Association), Dept. of Neurophysiology, Univ. of Southampton. U.K. SO9 3TU.

Dorsal root reflexes can be evoked in lumbar spinal roots by stimulation of adjacent dorsal roots or ascending branches of afferent fibres in the dorsal tracts of the cord. Changes in latency of the dorsal root reflex with distance between the site of stimulation and recording have been used to calculate the conduction velocity of those fibres responsible for evoking the reflex, and the central delay in the generation of the reflex. Isolated whole spinal cord preparations from adult golden hamsters were maintained at 25-27°C, and recordings made of evoked activity in lumbar dorsal roots following stimulation of dorsal tracts at 5mm intervals. The dorsal root response consisted of a directly conducted volley, followed by a synaptically generated reflex. Plots of distance against latency of these two components produced straight lines with similar gradients (mean conducted component 5.1 ±0.3m/s, reflex 4.5 ±0.2 m/s, n=7) but different intercepts on the time axis (mean 1.0 ±0.2ms for the conducted activity and 5.2 ±0.3ms for the reflex,n=7). This difference of 4.2ms represents the time for the generation of the dorsal root reflex within the cord, and indicates a polysynaptic connection between the stimulated fibres and those carrying the dorsal root reflex.

SERIAL-SECTION ELECTRON MICROSCOPE ANALYSIS OF AN ENTIRE Ia AFFERENT COLLATERAL IN THE CAT SPINAL CORD. M.J. Nicol* and B. Walmsley. Neural Research Laboratory, School of Anatomy, Univ. of N.S.W., Kensington, 2033, Australia

The present study was aimed at obtaining ultrastructural evidence concerning our previous proposal that there is considerable non-uniformity in the probability of quantal transmitter release among release sites arising from the same primary afferent fiber.

Serial-section electron microscopy was used to examine an entire HRP-labeled group Ia afferent collateral in Clarke's column of the cat spinal cord. A wide range of geometries and myelination patterns were found along the collateral, including: a) conventional nodes of Ranvier, b) nodes exhibiting a single synaptic bouton, c) nodes with two or more synaptic boutons connected by thin unmyelinated branches, d) terminal heminodes giving rise to one or more synaptic boutons separated by unmyelinated branches, e) complex arrangements of myelinated and unmyelinated branches giving rise to a number of boutons.

The afferent collateral gave rise to 35 synaptic boutons which contained synaptic specializations exhibiting a wide range of sizes and shapes, including perforations.

The geometry and myelination pattern of the presynaptic axon and its branches play an important role in determining the amplitude and duration of an action potential. The varied axonal geometries observed in the present study may contribute to non-uniformities in transmitter release from synaptic boutons along different branches. Morphological differences in the synaptic specializations located within synaptic boutons may also reflect intrinsic differences in the efficacy of transmitter release from different release sites.

SOMATOSENSORY INPUT FROM LUMBAR PARASPINAL TISSUES: ANATOMICAL TERMINATIONS AND NEURONAL RESPONSES TO MECHANICAL AND SYMPATHETIC STIMULI. W.J. Roberts, R.G. Gillette* & R.C. Kramis*, R.S.Dow Neurol. Sci. Inst., Good Samaritan Hosp. & Med. Ctr., Portland, OR 97209.

Chronic pain referred to deep tissues of the lower back is common in the human population. The physiological bases for low back pain are not well understood, partly because few studies have been done of somatosensory systems relating to paraspinal tissues. We have therefore undertaken studies in anesthetized cats - to anatomically determine the spinal projections from primary afferent fibers innervating paraspinal tissues and to record activity from dorsal horn neurons responsive to mechanical stimulation of paraspinal tissues.

Our preliminary studies using HRP labeling of populations of paraspinal afferent fibers indicate that: many afferents terminate bilaterally in lamina I, II, V & X; the rostro-caudal extent of the afferent terminals appears to be more extensive than that reported for afferents from the limbs; and a small percentage of these afferents have terminals in the cervical dorsal horn.

Preliminary recordings from dorsal horn neurons with paraspinal receptive fields have indicated that: many of the neurons receive convergent input from both skin and deep tissues; some have bilateral receptive fields; many have additional receptive fields in deep tissues of the hindlimb; and many are responsive to sympathetically-evoked afferent activity.

INTEGRATION OF THE SYNAPTIC POTENTIALS IN DORSAL HORN NEURONS EVOKED BY ELECTRICAL STIMULATION OF ADJACENT SPINAL ROOTS. S. Jeftinija, Department of Veterinary Anatomy, Iowa State University, Ames, Iowa 50011.

To study the integration of synaptic potentials in dorsal horn (DH) neurons, a horizontal spinal cord slice (400-500μm thick) and the functionally connected dorsal roots (DR) with the dorsal root ganglion (DRG) were prepared from 18-28 day old rats. Conventional intracellular recording from DH neurons using 3M K-acetate-filled electrodes was employed. Dorsal roots were electrically isolated from the spinal cord and stimulated with pulses of different duration and intensity.

Results are based on the recordings from 35 DH neurons located in the three most superficial laminae of the spinal DH. All of the neurons responded to the stimulation of both roots. In the majority of the cases the pattern of response of a particular neuron following the stimulation of one DR was identical or very similar to that following stimulation of the second DR. In a minority of cases, however, the response pattern evoked by stimulating one DR was different from that evoked by stimulating the neighboring DR. During the course of the experiments in which two adjacent DR were stimulated, the excitatory postsynaptic potentials (EPSP) recorded from single DH neuron did not summate. In several cases in which neuron responded differently to stimulation of the adjacent DR, a interaction was observed. An inhibitory postsynaptic potential evoked by stimulation of one DR induced a partial inhibition of excitatory transmission evoked by second DR stimulation. Supported by USDA Grant PL95-113.

PHYSIOLOGICAL STUDIES OF DORSAL HORN NEURONS IN LAMINAE I-IV OF ADULT CHICKENS. C. J. Woodbury* (SPON: A. Carlson), Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, N.Y. 11794.

The central projections of hindlimb cutaneous nerves of hatchling chickens were previously shown to form two somatotopic maps across the mediolateral axis of the superficial dorsal horn (DH) (Neurosci. Abst. 13:1387, 1987). The medial map fell within lamina III and the lateral map fell within lamina II of Brinkman and Martin (Br. Res. 56:43, 1973). These maps can be differentially labeled by choleragenoid- and WGA-HRP conjugates, respectively, which suggests that afferents segregate mediolaterally in chickens according to size and/or modality. In the present study I examined this possibility by investigating the conduction velocity (CV) and modality of cutaneous inputs to neurons in DH laminae I-IV of spinal, adult chickens anesthetized with α-chloralose. Glass micropipettes (2% Fast Green/2% NaCl) were used to record from units in segment LS8 that were activated by brief shocks (above C-fiber thresholds) applied to the posterior femoral cutaneous nerve. Multiunit recordings (1-2 MOhm electrodes) in lamina III-IV contained only a single, short latency response, regardless of stimulus intensity. Similar recordings in lamina I-II contained both a short and long latency component, the latter generated by afferents with a CV around 1 m/sec. Afferents to single neurons in lamina III-IV (12-18 MOhm electrodes) had CVs of 41 ± 16.6 m/sec, and most were briskly activated by light puffs of air across the receptive field (RF). In contrast, afferents to single neurons in lamina I-II had CVs of 10.8 ± 9.7 m/sec, and 24 % of these neurons were only activated by afferents with a CV below 2 m/sec. Further, most of the RFs of lamina I/II neurons could not be located by stimulating the skin with air or light touch; when the RF was found, a higher intensity stimulus (e.g., pressure or pinch) was usually required to activate the neuron. (Supported by an NIMH Predoctoral Training Grant, a Sigma Xi Grant-in-aid-of-research, and NSF and NIH grants to S. A. Scott.)

DORSAL HORN TERMINATION PATTERNS OF CUTANEOUS LOW THRESHOLD MECHANORECEPTORS. R. Sonty, J. Culberson, W. Gladfelter, R. Millecchia, and P. Brown. Physiology Dept., W. Va. Univ. Health Sci. Ctr., Morgantown, WV 26506.

A. G. Brown et al. (1981) reported that dorsal horn terminal distributions of hair afferents (HFA) and Pacinian corpuscles (PC) were rostrocaudally continuous; and rapidly adapting glabrous (RAG), slowly adapting type I (SA1), and slowly adapting type II (SA2) were rostrocaudally discontinuous. Only PCs and some SA1s and SA2s had projections ventral to lamina IV.

Cutaneous axons were impaled with horseradish peroxidase (HRP)-filled microelectrodes, and after determination of afferent type and receptive field location the axons were injected with HRP. The sample included 13 HFAs, 11 SA1s, 4 SA2s, 2 PCs, and 1 RAG. Although occasional rostrocaudal discontinuities were seen, they were irregular within axons and inconsistent across axons, and not correlated with afferent type. Projections ventral to lamina IV were seen in PC, SA1, SA2, and hair; these were generally wider than, and roughly in register mediolaterally and rostrocaudally with, more dorsal projections. The reasons for discrepancies between the two studies are not obvious.

303.9

CHARACTERIZATION OF SPINAL NEURONS CONTAINING A SELECTIVELY DISTRIBUTED NERVE TERMINAL PROTEIN. S.S. Kanekar, T.C. Ritchie and J.D. Coulter, Neuroscience Program and Dept. of Anatomy, The University of Iowa, Iowa City, IA.

NT75 is a neuron-specific 75kD protein recognized by the S-7B8 monoclonal antibody. NT75 is localized in select populations of nerve terminals and is not detectable in cell bodies and axons. The distribution of NT75 does not parallel that of any known neurochemical system, although this protein occurs in many putative excitatory amino acid pathways. In spinal cord, dense NT75 immunoreactivity in the superficial dorsal horn is contained in primary sensory nerve terminals. Nerve terminals of the corticospinal tract and other descending systems contribute to the moderate staining in the deeper dorsal horn and sparse staining in the ventral horn. The current study examines whether intrinsic spinal neurons contain NT75. After the lumbar cord is exposed to colchicine for 18-24 hrs, neurons of various morphological types and sizes within all spinal laminae exhibit NT75 labeling. Lamina I contains larger stained cells with horizontal processes, and small cells. Lamina II, however, contains only a few NT75-positive small cells. Large multipolar neurons containing NT75 are seen in the lateral spinal nucleus. Laminae III to VII contain numerous labeled small neurons, and a few larger neurons stain in the medial part of lamina VII. Laminae VIII and IX exhibit intensely labeled motorneurons, and a few small cells. Small NT75-positive neurons are clustered in Lamina X. The distribution of some NT75 cells suggests they may be ascending tract neurons, and dense NT75 staining occurs in the ventrobasal thalamus and the terminal fields of other ascending spinal systems. Further studies will characterize NT75 positive spinal neurons and will determine whether NT75 is a constituent of motor nerve terminals. Supported by NS23783.

SLOW EPSP IN CAT SPINAL NOCICEPTIVE NEURONES *IN VIVO* POTENTIATES VIBRATION-INDUCED INHIBITION: IMPLICATION OF NEUROKININS AND PURINES. Y. De Koninck and J.L. Henry. Departements of Physiology and Anaesthesia Research, McGill University, Montreal, Que.

We have suggested that exogenous application of tachykinins potentiates the purine-induced inhibition of dorsal horn neurones either by exogenous application of ATP or AMP (Salter & Henry, *Neurosci.*, 22:631, 1987) or by endogenous release in response to a peripherally applied vibration stimulus (Salter & Henry *Neurosci.*, 27:243, 1988; *Neurosci.*, 23:903,1987). In the present study we investigated the possibility that the endogenous release of a neurokinin may also potentiate the purine-mediated inhibition of dorsal horn neurones in the chloralose anaesthetised or decerebrated cat. Extracellularly, a prolonged excitation was obtained following a train (10-20Hz for 5-10s) of high intensity electrical stimulation to the afferent nerves. This excitation peaked 15-25s after the start of the train and decayed slowly over 1 to 6 min. The intensity-response relationship indicated the mediation of high threshold afferents in this response. Intracellular recording (KCl, K-Ac or K-CH_3SO_4) revealed a slow prolonged depolarization associated with an apparent increase in input resistance. This EPSP had the same time course as the excitation observed with extracellular recording and had similar characteristics to that reported by Urban & Randic (*Brain Res.*, 290:336, 1984) after a train stimulation of dorsal rootlets in the rat spinal slice and in which a neurokinin was implicated (Randic et al, *Brain Res.*, 383:15, 1986). Interaction between this slow EPSP and the inhibition obtained by peripheral vibration was studied. The inhibition was potentiated according to previously defined criteria (*Neurosci.*, 23:903,1987) when occurring during excitation following the train stimulation (n=7) as opposed to excitation by iontophoretic application of glutamate. In two cases, the response to vibration changed from excitation to inhibition during the post train EPSP. These results suggest that noxious stimulation induces the release of a neurokinin which may in turn increase the sensitivity of spinal nociceptive neurones to the purine-mediated, vibration-induced inhibition. Supported by MRC grant MA-5891 to JLH, YDK is a stagiaire de recherche of the FRSQ.

GLUTAMINASE IMMUNOREACTIVITY IN RAT SPINAL CORD. K.E. Miller, T. Kaneko, and A.T. Salvatierra. G.D.Searle R&D, Monsanto Co., St. Louis, MO 63198; Dept. Anatomy, Kyoto Univ., Kyoto 606, Japan; Dept. Neurol. Surg., Univ. Miami, Miami, FL 33136.

Glutamate is considered to be a neurotransmitter in sensory systems and glutamate-like immunoreactivity has been localized in the dorsal horn of spinal cord (Miller et al., Synapse 2:28,'88). To further understand the distribution of neurons that may use glutamate as a neurotransmitter, immunohistochemistry was performed on rat spinal cord using a monoclonal antibody against glutaminase, the enzyme that converts glutamine to glutamate (Kaneko et al., J.Neurosci. 7:302,'87). Rats (300g) were anesthetized and perfused with fixative. The spinal cords were dissected and frozen sectioned at 30um. The sections were processed for glutaminase immunoreactivity with avidin-biotin-peroxidase. Immunoreactive (IR) puncta were observed in the superficial dorsal horn. IR neurons were found most prominently in following locations: the marginal zone, lateral spinal nucleus, central gray region (lamina X), and intermediolateral cell column. These results support the hypothesis that glutamate is used as neurotransmitter in spinal sensory pathways. It also suggests that glutamate is important in regulating sympathetic activity. INTRATHECAL GALANIN SELECTIVELY BLOCKS THE FACILITATORY EFFECT OF SUBSTANCE P AND CALCITONIN GENE-RELATED PEPTIDE ON THE SPINAL CORD. Z. Wiesenfeld-Hallin[1], X-J. Xu[1]*, M.J. Villar[2]* and T. Hökfelt[2]*, Karolinska Institute, Huddinge[1] and Stockholm[2], Sweden.

Galanin (GAL), substance P(SP) and calcitonin gene-related peptide (CGRP)-like immunoreactivities coexist in some primary afferents. We examined the effects of intrathecal (i.t.) application of these peptides on spinal flexor reflex excitability in decerebrate, spinalized, unanesthetized rats.

I.t. SP or CGRP caused a brief facilitation of the flexor reflex. GAL, which by itself facilitated the reflex at the dose employed, was applied 2-4 min prior to SP or CGRP and reduced or totally blocked the facilitation evoked by these neuropeptides. In contrast, the facilitatory effect of i.t. somatostatin or vasoactive intestinal polypeptide, which do not coexist with GAL in primary afferents was not reduced by the preadministration of GAL.

These results may clarify the mechanisms underlying our previous observation that i.t. GAL inhibits the facilitatory effect of C-afferent stimulation on spinal excitability. It is concluded that i.t. GAL may exert a selective postsynaptic inhibitory effect on the spinal cord by blocking the facilitation caused by SP and CGRP, neuropeptides released at the central terminals of C-afferents.

303.13

NEUROPEPTIDES IN THE RAT SPINAL CORD: LOCALIZATION OF BN/GRP- AND FLFQPQRF-AMIDE-LIKE IMMUNOREACTIVITIES IN NEURONS. L. Kivipelto and P. Panula. Dept.Anat., Univ.Helsinki, 00170 Helsinki, Finland.

GRP_{18-27} and FLFQPQRF-amide-like peptides are found in the superficial laminae of the rat spinal cord, where they are probably involved in sensory neurotransmission. Most of the GRP_{18-27} is derived from the spinal ganglia, while there is no evidence of the presence of FLFQPQRF-amide-like peptides in the spinal ganglia. Biochemical and immunohistochemical studies after lesions have suggested that both peptides may be localized in spinal cord neurons, but direct evidence is lacking.

Adult rats treated with intraspinal colchicine were perfused with 4o/o paraformaldehyde. Cryostat sections of the spinal cord were incubated with antisera against GRP_{18-27} and FLFQPQRF-amide and the PAP method was applied. Immunoreactive neurons were seen with both antisera in laminae I-II and X. Preadsorption of the antisera with corresponding peptides abolished the immunoreaction, while unrelated peptides did not affect the staining. The results suggest that neurons in laminae I-II and X give rise to those nerve fibers immunoreactive for these peptides that remain after rhizotomy and transsection of the spinal cord.

SPECIFIC ANTAGONISM OF THE ANTINOCICEPTIVE EFFECTS OF INTRATHECAL DPDPE BY NALTRINDOLE IN RATS. E.J. Drower[1], A. Stapelfeld*[1], M.F. Rafferty[1], D.L. Hammond[2], K.C. Rice[3], and B. DeCosta*[3]. [1]G.D. Searle & Co.,Skokie, IL 60077; [2]Dept. of Anesthesia & Critical Care, Univ. of Chicago, Chicago, IL 60637; and [3]NIDDK/NIH, Bethesda MD, 20892.

Portoghese et al. recently reported the discovery of Naltrindole (NTI),a potent and selective delta opioid receptor antagonist in smooth muscle assays (Eur. J. Pharm.(1988)146:185). Although the authors indicated that NTI also selectively antagonized the in vivo effects of a delta agonist (DSLET), no experimental details were presented. In this study, we have evaluated the ability of NTI to antagonize the effects of intrathecal (i.t.) DPDPE, a highly selective delta agonist, and morphine on tail flick latency. (TFL) in rats. Intrathecal administration of 10 ug DPDPE produced a significant increase in TFL which was maximal at 10 min and persisted for up to 90 min. Administration of NTI (0.01-10 ug i.t.) 10 min after DPDPE dose-dependently antagonized the effect of DPDPE. The 1 ug dose completely reversed TFL to control levels within 30 min. NTI at a dose of 30 ug had no effect alone, nor did it antagonize the antinociceptive actions of i.t. morphine (1 ug). These data support the in vitro finding that NTI is a potent and selective antagonist of delta receptor-mediated responses, and indicate that the antinociceptive effects of i.t. DPDPE result from activation of delta receptors in the spinal cord.

PHYSIOLOGY OF SINGLE SPINAL CORD SENSORY NEURONS RESPONDING TO PENILE STIMULATION IN THE RAT. R.D. Johnson. Dept. of Physiological Sciences, University of Florida, School of Veterinary Medicine, Gainesville, FL 32610.

Normal erectile and ejaculatory events in the male rat are dependent on intact sensory pathways from the penis. Because little is known about the physiology of single dorsal horn neurons responding primarily to low threshold tactile stimulation of the penis, this study was undertaken to find these neurons and describe some of their physiological attributes.

Male Sprague-Dawley rats were anesthetized and maintained with I.V. urethane for the duration of the acute experiments. The spinal cord was transected at T7-8 to remove supraspinal inhibition. Following a thoracolumbar laminectomy, tungsten microelectrodes were advanced into the spinal cord to obtain extracellular recordings from single neurons responding primarily to penile stimulation.

Single neurons were isolated from the medial portions of the dorsal horn and intermediate zone from the T13-L1 junction to the caudal L6 spinal cord segments. The neurons had penile receptive fields that were at least 5 times bigger than single primary afferent fields suggesting a convergent input. Most of the neurons responded vigorously to slight indentation (60 mg von Frey hair) or stretch of either the ventral glans midline (frenulum) and the distal prepuce or the distal glans (cup). Some of the spontaneously firing neurons exhibited convergent excitatory and inhibitory effects from noxious stimulation of the perineal region or thigh. Some of the low threshold penile neurons also responded to noxious pinch and thermal stimulation of the penis.

The results of this study indicate that information from low threshold penile mechanoreceptors is distributed to sensory neurons throughout the lumbar spinal cord and their response patterns suggest they may play a role in the penile reflexes of the rat.

APPARENT SELECTIVE ANESTHETIC EFFECTS ON SPINAL DORSAL HORN NEURONS IN PHYSIOLOGICALLY INTACT, AWAKE, DRUG-FREE CATS

J.G. Collins, H. Iwasaki,* Y. Saito*, Dept. of Anesth., Yale Univ. Sch. Med., New Haven, CT 06510

Tonic inhibition of spinal dorsal horn neurons is known to exist and is likely to be influenced by general anesthetics. This study is part of a long-range project designed to evaluate the pharmacology of anesthetic effects on spinal dorsal horn neurons.

Extracellular single unit activity was recorded from the spinal dorsal horn of physiologically intact, awake, drug-free cats (IACUC approved protocol). Following baseline studies, general anesthetics (ketamine, 10 mg/kg, propofol, 7.5 mg/kg) were administered intravenously and stimulus response properties were re-evaluated. Interactions with methysergide (non-specific 5HT antagonist) were also evaluated.

Previous work demonstrated significant but at times different effects of pentobarbital and methysergide on both noxiously and non-noxiously evoked activity. Ketamine, at the dose studied, produced no such changes, but did alter the ability of methysergide to produce observed changes. Propofol produced changes in responses to noxious and non-noxious stimulation similar to those caused by both pentobarbital and methysergide. Although the observed changes were similar following propofol and methysergide administration, the two drugs did not always produce similar changes in the same neurons. These studies demonstrate the complex effects of anesthetics on tonic inhibition of spinal dorsal horn neurons, both in the selectivity of individual agents and each agent's specificity for particular neurotransmitter systems.

TUNING OF SPINAL NETWORKS TO TEMPORAL CHARACTERISTICS OF SPIKE TRAINS IN SINGLE PRIMARY AFFERENTS. H.R. Koerber, A.W. Seymour and L.M. Mendell, Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

Single primary afferents were impaled in the L7 dorsal root ganglia of α-chloralose anesthetized cats. Spike trains were recorded in response to natural stimulation of the fiber's receptive field (RF). Two such trains were chosen as standard test trains to study the ability of different central networks to process physiologically realistic frequency modulated afferent activity. One train was recorded in a hair follicle afferent fiber in response to a brief puff of air applied to the RF and consisted of 6 APs. The second was recorded in a slowly adapting type 1 (SA1) afferent fiber in response to a stroke across the RF using a small probe and consisted of 9 APs. These spike trains were delivered to impaled primary afferents (1 train/2s) while recording the central response as either cord dorsum field potentials (CDPs: see Koerber and Mendell, J. Neurophysiol. 60), extracellular single unit activity or intracellular EPSPs and APs. CDP recordings reveal that dorsal horn networks responding to stimulation of Aβ rapidly adapting afferents (e.g. Aβ hair follicle and RA pad afferents) are, with the exception of Pacinian corpuscles (PCs), tuned to respond preferentially to the first AP or pair of APs (interval <5ms) of the spike train. PC and Aδ-Down hair follicle afferent activated networks are also tuned to short intervals but require greater numbers of APs to activate them; single shocks or long interval (50ms) pairs of shocks usually either failed to or only weakly activated these networks. SA afferent networks tend to reproduce the afferent activity spike for spike as do Aβ HTMR afferent-supplied networks. Activity recorded in single dorsal horn neurons (extracellular spikes; intracellular EPSPs and APs) in response to these same spike trains in Aβ hair follicle afferents and SAs are consistent with these findings using CDPs. Supported by NS 23725 (HRK) and NS 16996; NS 14899 (LMM).

CROSSED DORSAL HORN CELL DENDRITES. W. Gladfelter, R. Sonty, J. Culberson, R. Millecchia, R. Ammar, and P. Brown. Physiol. Dept., W. Va. Univ. Health Sci. Ctr., Morgantown, WV 26506.

Receptive fields (RFs) in lateral or medial dorsal horn often span the dorsal or ventral body midline. Dermatomes are unilateral, so crossed RF components must be mediated by crossed afferent projections, cell dendrites, or internuncials. We have found crossed afferents. This study tested for crossed dendrites.

In anesthetized cats, sacrocaudal cells were penetrated with horseradish peroxidase (HRP)-filled microelectrodes, their RFs were mapped, and HRP was injected. Sections were processed with cobalt-enhanced diaminobenzidene.

All three cells with RFs spanning the dorsal midline had crossed dendrites; the one cell with a RF spanning the ventral midline had none. Of three cells with dorsal RFs not spanning the midline, one had crossed dendrites; all three with uncrossed ventral RFs had crossed dendrites. The one cell with a lateral RF had no crossed dendrites. Thus, there was a high correlation between crossed or uncrossed dorsal RFs and crossed or uncrossed dendrites (five out six). However, there was a perfect negative correlation for the four cells with ventral RFs.

303.19

BULBOSPINAL SEROTONINERGIC PATHWAYS IN THE FROG, *Rana Pipiens*. H. Tan* and V. Miletic. Dept. Comp. Biosci., Sch. Vet. Med., Univ. of Wisconsin, Madison, WI 53706.

We combined retrograde tracing and rhodamine immunofluorescence to identify the origin of serotoninergic (5HT) neurons with descending projections to the spinal cord of the frog. After spinal injections of Fluoro-gold, retrogradely-labeled 5HT neurons were detected in the caudal part of the brainstem. These doubly-labeled cells were distributed along the midline throughout the rostrocaudal extent of the dorsal portion of the raphe nuclear region.

The fluorescent tracer 1,1'-dioctadecyl-3,3,3,'3'-tetramethyl-indocarbocyanine perchlorate (DiI) was then placed in the middle and rostral raphe nuclear area. Labeled fibers could be traced bilaterally in the lateral portion of the dorsal funiculus and the lateral and ventral funiculi. These fibers were seen terminating in the dorsal and ventral horns, as well as the intermediate grey matter. After placement of DiI in the caudal raphe area, labeled fibers were found only in the intermediate grey and ventral horn.

These findings suggest that the organization of bulbospinal 5HT pathways in amphibians is similar to that of mammals, and that an isolated frog spinal cord preparation could be a useful model for pharmacological and physiological studies of the mechanisms of 5HT action in the spinal cord. (Supported by NS21278).

ORGANISATION OF EXCITATORY AND INHIBITORY CUTANEOUS INPUT TO POSTSYNAPTIC DORSAL COLUMN NEURONES IN THE ANAESTHETISED CAT. C.Pover and A.Kitchin* Dept. Preclin.Vet.Sci., Univ. Edinburgh, Summerhall, Edinburgh, EH9 1QH, U.K.

Postsynaptic dorsal column (PSDC) neurones relay cutaneous afferent information from the dorsal horn to the dorsal column nuclei; they respond to different types of stimuli applied to glabrous and hairy skin and may have complex receptive fields (RF) on discontinuous areas from the toe to the thigh. They may also be inhibited by mechanical stimulation adjacent to, overlapping or surrounding the excitatory field. (Noble & Riddell, J.Phys., 396: 497, 1988). Similar cutaneous evoked inhibition of neurones in the spinocervical tract (SCT) a parallel system linking other dorsal horn neurones with the lateral cervical nucleus via the ipsilateral dorsolateral funiculus has been shown to arise from both inside and outside the receptive field following air-jet or piezo-electric mechanical stimulation (Brown et al, pers.comm.) We are testing PSDC neurones in the same way and preliminary results indicate that conditioning and test stimuli applied within the RF produce inhibition which is related to both the spatial and the time separation of the two stimuli. It therefore seems likely that at least two sorts of peripheral inhibition may modify the responses of SCT and PSDC neurones to excitatory input and this could represent a system for refining or eliminating excess information. Supported by the Medical Research Council.

303.21

THALAMICALLY PROJECTING CELLS OF THE LATERAL CERVICAL NUCLEUS IN MONKEY, M.V. SMITH*, G.L. STANLEY*, and A.V. APKARIAN, (SPON: R.T. STEVENS), Dept. of Neurosurg., SUNY Hlt. Sci. Ctr., Syracuse, NY 13210.

The thalamic projection from the primate lateral cervical nucleus (LCN) was studied using retrograde transport of horseradish peroxidase injected into the thalamus. Four macaque and two squirrel monkeys were used. Retrogradely labeled LCN cells were examined in spinal tissue reacted with tetramethyl benzidine.

The size of the thalamic projection from LCN was found to be about 500 cells, unilaterally. 80 to 90% of labeled LCN neurons were located in the first two spinal segments. In the medulla and C1 LCN cells formed a distinct group off the tip of the dorsal horn, in C2 they were separated into two or more groups, and in C3 the cells were oriented along the axis of the dorsal horn. In two animals, the distance of the shortest and longest perpendicular axes of individual labeled cells were measured. This analysis revealed that thalamically projecting LCN cells become smaller in size, and more oblong in shape in caudal segments ($p<0.05$). In one additional macaque, all LCN cells were counted using Nissl stain. The estimated number of LCN cells in this monkey was 2,640 on one side. The smaller number of thalamically projecting LCN cells as compared to the total size of LCN indicates that only a fraction of LCN cells project to the thalamus in monkey.

GONADAL STEROIDS MAINTAIN DENDRITIC MORPHOLOGY OF NEURONS IN THE MEDIAL NUCLEUS OF THE AMYGDALA IN MALE SYRIAN HAMSTERS. D. M. Gomez, S. W. Newman. Dept. Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109

The adult male Syrian hamster is dependent upon both environmental chemosensory and internal hormonal signals for normal reproductive behavior. Because the medial amygdaloid nucleus (M) is the first area in the chemosensory pathway that contains gonadal steroid accumulating cells, we hypothesized that gonadal steroids maintain the dendritic length and arborization of neurons in this area and thereby maintain the integrity of this behaviorally essential pathway. Our previous studies demonstrated that neurons in caudal, but not in rostral, M were altered by castration. In the present study, we quantitatively analyzed the dendrites of Golgi stained neurons in caudal M from adult male Syrian hamsters in the following six groups of animals: reproductively intact animals (n=12), castrated animals immediately implanted with a blank silastic capsule (n=12), or a capsule filled with either testosterone (T,n=13), dihydrotestosterone (DHT,n=13), estradiol (E,n=12), or two capsules, DHT and E (n=8). Animals were tested for copulatory behavior to assess the effectiveness of the capsules. All animals were perfused at 12 weeks postcastration and the brains were processed using a Ramon Moliner modification of the Golgi technique. Neurons were analyzed using a digitizing tablet linked to a computerized measurement program. Two measures were recorded for each neuron: total dendritic length (TDL) and highest dendritic branch (HDB). Mean values of the treatment groups were compared using ANOVA. Consistent with previous findings, neurons from castrated animals without hormonal replacement had fewer distal dendritic branches than intact animals ($p<0.01$). These neurons also had shorter TDL, although the difference was not statistically significant ($p<0.06$). Total dendritic length and the dendritic branching pattern of castrates treated with DHT were not different from castrates but were significantly different from intacts (TDL $p<0.02$; HDB $p<0.02$). Neurons from T, E and the DHT+E groups were not different from intacts. These findings suggest that neurons in caudal M do not maintain their normal dendritic structure after long term castration or in the presence of DHT alone, whereas the presence of T, E or both DHT and E maintains the normal dendritic morphology. (Supported by NIH, NS#20629 to SWN)

304.2

THE UPTAKE OF MEDROXYPROGESTERONE ACETATE BY THE PRIMATE BRAIN: IN VIVO COMPETITION STUDIES. R.W. Bonsall*, H.D. Rees and R.P. Michael, Department of Psychiatry, Emory University School of Medicine, Atlanta, Georgia 30322, and the Georgia Mental Health Institute, Atlanta, Georgia 30306.

Medroxyprogesterone acetate (MPA) is a synthetic progestin that has been used in the treatment of sex-offenders. It has androgen-depleting actions and reduces the sexual activity of male macaques. To investigate its sites of action and the receptor systems that might be involved, we castrated 8 adult male cynomolgus monkeys and administered i.m. 40 mg progesterone (P)(2 males), 10 mg dihydrotestosterone propionate (DHTP)(3 males) or oil vehicle (controls)(3 males). Twenty-four hours after castration, all males were injected i.v. with 5 mCi ^{3}H-MPA, and killed 60 min later. Left halves of the brains were processed for thaw-mount autoradiography and right halves were analyzed by HPLC to measure the uptake of ^{3}H-MPA in nuclear fractions from 14 different brain regions. In control males, there were labeled neurons in the ventromedial nucleus (n.), arcuate n., medial preoptic n. and anterior hypothalamic area. In P-pretreated males, percentages of labeled neurons in these regions were reduced to 2-31% of control values ($P<0.05$), but in DHTP-pretreated males, percentages were not significantly different from those in controls. Nuclear concentrations of ^{3}H-MPA measured by HPLC were highest in the hypothalamus, preoptic area and amygdala of controls. Pretreatments with P reduced these levels to 15-42% of control values ($P<0.01$), but DHTP pretreatments had no significant effect. Pretreatments did not alter the concentrations of ^{3}H-MPA in blood and in tissue supernatants. The effects of MPA in the primate brain may be mediated mainly by progestin-target neurons.

A HORMONAL ROLE FOR A CHOLECYSTOKININ-LIKE PEPTIDE IN THE CONTROL OF THE GASTRIC MILL IN LOBSTER. G. Turrigiano* (SPON: A.I Selverston). Dept. of Biology, U.C.S.D, La Jolla, Ca 92093

The stomatogastric ganglion (STG) contains the gastric mill(GM) central pattern generator(CPG), which controls rhythmic contractions of the teeth. Previous work has shown that the stomatogastric nervous system contains a cholecystokinin(CCK)-like peptide, a CCK-like peptide can be released into the STG, and the output of the GM can be modulated by bath application of such peptides (Turrigiano, G., and A.I. Selverston, J. Neurosci, in press, 1989). The purpose of this study was to determine whether CCK-like peptides have a hormonal role in the control of the GM.

The pericardial plexus, a well-described crustacean neurosecretory organ, was found to be strongly immunopositive for CCK-like peptides. There were detectable levels of CCK-like peptides in the hemolymph, as determined by radioimmunoassay. When food-deprived lobsters were fed, there was on average a 4-fold elevation in the levels of CCK-like peptide in the hemolymph, with an average duration of 4 to 6 hours (n=7). The activity of the GM was monitored in freely moving lobsters using teflon-coated silver wires inserted into GM muscles; the GM was found to be strongly activated for the first 4 hours following ingestion, with a time-course similar to that of the elevation in levels of CCK-like peptides in the hemolymph. Finally, injections of CCK into the hemolymph were able to activate the GM (n=5). These data suggest that a CCK-like peptide in lobster has a hormonal role in the control of the gastric mill.

IMMUNOCYTOCHEMICAL CHARACTERIZATION OF PROJECTION - NEURONS IN THE VOCAL MOTOR SYSTEM OF CANARIES.
W.Zuschratter[1]*, M.Gahr[2], H.R. Güttinger[2], M.Sperl[1]*, H.Scheich[1].

[2]Univ. Kaiserslautern, Biology Department, Kaiserslautern, FRG.

In songbirds high levels of the calcium-binding protein parvalbumin (PV) have been found in the telencephalic vocal motor nuclei HVc, RA, Area X and MAN (Braun et al, Cell Tissue Res., 240:101, 1985). A subset of these PV containing cells was identified as GABAergic neurons (Zuschratter et al, Neurosci.Suppl.22: S114, 1987). The present study was done to determine 1. whether PV immunoreactive cells in HVc are projecting neurons, for instance to Area x and 2. whether these cells contain the estrogen receptors described in HVc (Gahr et al, Brain Res., 402:173, 1987). Adult male canaries were injected in Area X with rhodamine containing latex microspheres. Four days later sagittal sections including the retrogradly labeled HVc neurons were processed with a parvalbumin antiserum, using the ABC-method and FITC as chromogen. Afterwards sections were incubated with a monoclonal antiserum against estrogen receptors using the PAP technique and DAB as chromogen. In HVc most cells filled with the retrograde tracer showed moderate immunoreactivity for the calcium-binding protein. A second class of PV neurons which exhibited strong PV immunoreactivity and may be GABAergic cells did not contain microspheres. Double labeling experiments with PV and estrogen antisera revealed that some of the moderately stained PV projection neurons contained estrogen receptors. In conclusion PV immunoreactive cells could be devided into subpopulations by double labeling techniques. Partial co-localization of PV-immunoreactivity with estrogen receptors in neurons points to a special Ca buffering mechanism in steroid induced processes. (SPON: B. Hose)

FEMALE ZEBRA FINCHES GIVEN ONLY ESTROGENS PRODUCE MALE-LIKE VOCALIZATIONS. H.B. Simpson and D.S. Vicario. The Rockefeller University, New York, N.Y. 10021

Sex hormones administered early in development can have permanent effects on the behavior of both birds and mammals. We examined the changes estrogens alone can induce in the vocal behavior of female zebra finches. Song behavior is sexually dimorphic: females normally do not sing; adult males do and learn their song as juveniles. These behavioral differences are accompanied by differences in the neural structures serving vocal behavior.

Female zebra finches received estradiol-17β implants at three different ages: within the first week of hatching, at 20 days, or when adult (after 100 days). Between 100 and 150 days of age, we recorded vocalizations produced by treated females, focusing especially on song and the long call, a sexually dimorphic call.

We found that exogenous estrogens can cause female zebra finches to produce male-like song and male-like long calls, if given either in the first week after hatching or at 20 days of age. Some treated females produced song and long calls like those of normal adult males. Some learned from their male tutor. Others sang, but their song contained abnormal features. We correlated these behavioral changes with changes in the neural structures governing vocal behavior. Our data confirm earlier reports linking the masculinization of behavior to that of its neural substrate. These reports claimed that treated females sing only after receiving testosterone in adulthood. However, our data demonstrate that exogenous estrogens alone (either early or even at 20 days of age) can masculinize female vocal behavior. (NIH GMO-7739 and MH-40900)

SITES OF ACTION OF ANDROGEN AND ESTROGEN IN THE REGULATION OF MASCULINE SOCIOSEXUAL BEHAVIOR IN THE RAT. R.J. Barfield and J.A. Matochik. Dept. Biol. Sci. Rutgers Univ. New Brunswick, NJ, 08903.

It is well established that testosterone (T) acts in the brain in the regulation of male copulatory behavior; however, the precise identification of cellular targets for this action is lacking. In addition, although it is known that T regulates other aspects of sociosexual behavior such as signaling (scent marking and vocalization) and agonistic behavior, even less is known concerning the sites of hormonal action in these behaviors. In the present study, dilute estradiol (1-100 cholesterol) was used as a probe in the identification of sites of T action in the regulation of copulatory behavior in castrated males treated with systemic DHTP. In addition, we attempted to assess the role of the lateral septum and medial amygdala in the hormonal regulation of masculine copulatory behavior. Finally, we are currently attempting to clarify the role of androgen in the regulation of signaling behavior and to determine the location of target cells involved in this action. Results to date indicate that the rostral ventromedial preoptic area (and perhaps the diagonal band of Broca) are the sites upon which aromatized T acts. The central medial preoptic area does not appear to be particularly responsive. At present, a clear localization of the site of action of hormones in the regulation of other components of sociosexual behavior is not available.

NEUROENDOCRINE MODULATION OF MALE COURTSHIP BEHAVIOR IN THE BLUE CRAB (Callinectes sapidus) Debbie Wood, Charles D. Derby[1], Georgia State University, Barbara Beltz[2], Wellesley College, Richard A. Gleeson, Whitney Marine Laboratory
(SPON: M.-N. Girardot)

The male blue crab produces a sterotyped courtship display in response to a pheromone produced by the female. This behavior consists of both postural and rhythmic components. This system provides a good model for the study of neuromodulation of simple motor systems because of the rhythmic aspect of the behavior. Bioassays of neuromodulators have shown that the monoamine dopamine and the neuropeptide proctolin are capable of eliciting the postural and rhythmic behavioral components respectively. We have localized by used of immunocytochemistry potential neurosecretory cells which have proctolin-like and dopamine-like immunoreactivity. We are currently undertaking electrophysiological studies to detect changes in motor neuronal output in the presence of proctolin and dopamine.

STEROID MODULATION OF GABA RECEPTORS: NOVEL MECHANISM FOR REGULATION OF SEXUAL BEHAVIOR. M. Orchinik* and F.L. Moore. Oregon State Univ., Corvallis, OR 97331-2914

Previous studies reported that corticosterone (CS) and GABA rapidly inhibit amphibian (Taricha granulosa) sexual behaviors. We conducted radioligand binding studies using amphibian brain tissue, and have preliminary evidence that this rapid behavioral response to CS may reflect a direct modulation of the $GABA_A$ receptor. Binding of (^{35}S)-TBPS (specific for $GABA_A$ receptor) was inhibited by CS and related steroids. Conversely, specific binding of ^3H-CS to membranes was altered in opposite directions by GABA agonists and antagonists. We used in vitro receptor autoradiography to identify TBPS binding sites in an amphibian brain. The tectum and tegmentum contained the greatest density of putative $GABA_A$ receptors, with moderately high binding in lateral amygdala, striatum and medulla. TBPS binding in all brain regions was inhibited by steroids. Our findings suggest that CS may rapidly modulate behavior through the $GABA_A$ receptor, a non-genomic mechanism. STEROID MODULATION OF GABA-INDUCED ANALGESIA. M.M. McCarthy, M. Caba, C. Beyer, B.R. Komisaruk. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

GABA has been implicated in analgesia at the spinal cord level. Intrathecal (IT) infusion of GABA-A agonists increases pain thresholds whereas antagonists produce hyperalgesia. Steroid effects on GABA transmission are multiple and complex. We report here that steroids modulate nociception after IT infusion of the GABA-A agonist mucimol (MUS). A 1 ug dose of MUS given IT to ovx'd female rats has no effect on pain thresholds. Females in late estrus infused with the same dose of MUS are analgesic up to 30' post-infusion in the vocalization threshold to tail shock (VTTS) test ($p<.05$;MWU) but there is no effect on tail-flick latency (TFL). Females in late proestrus exhibited analgesia 10' after infusion of 1 ug MUS ($p<.01$;MWU) and females in diestrus were not analgesic at any time after 1 ug MUS 1T. Ovx'd females treated with EB (10ug for 2 days) and tested 40hr later exhibited analgesia after 1 ug MUS IT in the VTTS test. Ovx'd females injected with P (2mg) and infused with MUS 10' later exhibited analgesia in both the VTTS and TFL tests up to 30' after infusion ($P<.05$;MWU). Ovx'd females treated with EB+P (10ug 40hr prior; 1 mg 4hr prior) did not exhibit analgesia after 1 ug MUS IT. These data suggest E and P enhance GABA-induced analgesia thru different mechanisms which may be antagonistic. Supported by grant NIH1RO1NS 22948 (BRK) and Rutgers-CINVESTAV/CIRA Exchange Program.

EFFECTS OF CORTICOSTERONE IN THE FORCED SWIM TEST: EVIDENCE FOR EFFECTS ON CONSOLIDATION AND RETRIEVAL. L.J. Iny, J.B. Mitchell, S. Welner, and M.J. Meaney. Douglas Hospital Research Center, McGill University, Montreal, Quebec, CANADA, H4H 1R3.

Among the behaviors that have been reported to be affected by the presence or absence of corticosterone (B) is the amount of time that a rat is immobile in the Porsolt forced swim test. The Porsolt test, commonly used to screen antidepressants, consists of an initial 15 min forced swim and a 5 min test swim 24 h later. Rats spend progressively more time immobile during the 15 min training swim, and a high percentage of time immobile on the test.

Rats were tested in the Porsolt swim test 1 wk after adrenalectomy or sham adrenalectomy. Adrenalectomy significantly reduced time immobile during the test (from a mean of 206 s to 100 s), and this effect was completely reversed by B. In order to reverse the effect of adrenalectomy, it was necessary only to return plasma B levels to resting, basal levels; increasing plasma B to higher, stress levels did not further affect behavior. Adrenalectomized rats were also tested after administration of B before training, immediately after training, or prior to the test. Only B administration before, or immediately after the training session fully reversed the effect of adrenalectomy. When animals were tested repeatedly, at 1 wk intervals, it was found that if B had been present during training, performance depended, to some extent, on the presence of B during the test. That is, for animals trained with B, more time was spent immobile on tests with B than on tests without B. Adrenalectomized animals trained without B showed low levels of immobility on all tests.

In agreement with earlier studies (e.g. Jefferys et al., Eur. J. Pharmacol., 92:99, 1983), B appears to have a role in the incorporation or consolidation of information in the Porsolt swim test. The results of the experiments reported here indicate that B also plays some role in the manifestation, or retrieval of this information.

WKY RAT AS A MODEL FOR ANXIETY-INDUCED DEPRESSION. W.P. Paré* and E. Redei* (SPON: D. Brunswick), VA Medical Center, Perry Point, MD 21902 and U. Pennsylvania, Philadelphia, PA 19104

Wistar Kyoto (WKY) normotensive rats demonstrate a behavioral impairment in several behavioral tests, as well as an exaggerated plasma ACTH response to stress. In the open field test of emotionality, WKY's had longer response latency and lower ambulation scores as compared to spontaneously hypertensive rats, Fischer 344 and Wistar rats. Depressed ambulation by WKY's was also revealed in a learned helplessness paradigm; as compared to other strains, WKY's were significantly deficient in the acquisition of an avoidance/escape task following inescapable shock treatment the day before. Low open field ambulation and rearing scores and slow movement and freezing in the avoidance task suggested depressive behavior as a characteristic of WKY rats. WKY's were subsequently judged as more depressed in the Porsolt forced swim test. We hypothesized that the WKY's "depression" was anxiety-induced and reflected heightened activity of the hypothalamic-pituitary axis. Basal plasma ACTH levels did not differ between WKY's and Wistars, but the serial plasma ACTH response to 2-h restraint stress was significantly greater for WKY's. We propose that anxiety-induced depression is a characteristic of WKY rats and this strain is a valuable model for studying depression which may be induced by an exaggerated stress response.

CORTISOL IMPLANTS IN THE MEDIAL PREOPTIC-ANTERIOR HYPOTHALAMIC REGION (MPOA AH) INDUCE SUBMISSIVE BEHAVIORS IN GOLDEN HAMSTERS. D.M. Hayden-Hixson*[1] and C.F. Ferris[2] (SPON: M.K. Wolf). [1]Neurosci. & Beh. Prog., U. Mass., Amherst, MA 01003; [2]Dept. of Physiol., U. Mass. Med. Sch., Worcester, MA 01655.

Lesion, electrophysiological and glucocorticoid-implant studies have suggested involvement of the MPOA-AH in the expression of agonistic behaviors in a number of species. Also, recent immunocytochemical studies have described moderate to high densities of Type II glucocorticoid receptors in the hypothalamus, including the MPOA-AH. To examine the effects of elevated MPOA-AH cortisol levels on aggressive behaviors, male hamsters received 1mm (~25µg) implants of either hydrocortisone (N=30) or cholesterol (N=30) in the MPOA-AH.

In 15 minute paired-encounters, cortisol-treated animals were significantly ($p<.03$) more submissive than cholesterol-implanted controls. The effect was most pronounced 2 days postimplant, and disappeared by day 5. In contrast, cortisol- and cholesterol-treated animals were equally aggressive when juvenile males were placed in their home cages.

The results suggest cortisol inhibits the expression of aggressive behaviors in social, but not territorial, contexts through its action at specific sites in the medial preoptic-anterior hpothalamic region. (Work supported by NIH grant #NS23657).

DEXAMETHASONE INCREASES THE SPONTANEOUS YAWNING FREQUENCY IN MALE RATS. J.R. Eguibar *, A. Moyaho *, E. Zurita *, and B. Holmgren *. (SPON: R.M. Budelli). Depto. de Ciencias Fisiologicas, Instituto de Ciencias. Universidad Autonoma de Puebla, Mexico.

Yawning is an ubiquitous innate motor pattern among Vertebrates. It is well known that the administration of ACTH and related peptides into the brain ventricles produces a stretch-yawning syndrome (SYS) in different animal species . Although ACTH does not cross the blood-brain barrier, Gispen et al (1975) reported that a systemic injection of ACTH (0.5 mg/kg) in rats can induce yawning behavior, thus suggesting that a peripheral effect might be influencing yawning secondarily.

The purpose of these experiments was to explore the effect of dexamethasone (Dxm) on yawning behavior in adult male Sprague-Dawley rats. The animals were maintained under constant light and ad lib feeding to circumvent circadian variation of yawning. Intraperitoneal injection of Dxm (2-4 mg/rat) produced a significant increase in yawning from 6 h to about 24 h after administration ($p<0.05$, Mann-Whitney U test). Adrenalectomy was followed by a significant decrease in spontaneous yawning ($p< 0.05$). The administration of Dxm to adrenalectomized rats significantly increased their yawning rate ($p< 0.01$, Kruskal-Wallis test). These data suggest that glucocorticoids might exert a permissive effect on yawning, through central receptors participating in the regulation of this behavioral pattern.

This work was partially supported by a grant from SEP C88-01-0143 and a fellowship awarded to A. Moyaho by CECyT.

304.14

THE THYROID-ADRENAL AXIS AND THE ACQUISITION AND RETENTION OF THE IMMOBILE FLOATING RESPONSE. D. Jefferys and J.W. Funder. Medical Research Centre, Prince Henry's Hospital, Melbourne 3004, Australia.

We have previously shown that adrenalectomized (ADX), hypophysectomized (HPX) and ADX/HPX rats show indistinguishable levels of progressive immobility over a 15 min swimming test. Retested for 5 min 24 h later, HPX rats show immobility indistinguishable from control (~70%); ADX and ADX/HPX rats show only ~30% immobility, an effect reversed by glucocorticoids or kappa-selective opioids (Jefferys & Funder, Endocrinology, 121:1006, 1987). We have also shown that propylthiouracil (PTU) given daily for 21 days markedly inhibits the acquisition of the immobile response, which inhibition is reversed by T_4 given immediately before test (Jefferys & Funder, Soc. Neurosci., Abstract 41;11, 1988). We now report that T_4 given to PTU-treated rats up to 2 h after the initial test elevates immobility on retest to ~70%, further evidence for a role of T_4 in the retention, as well as the immediate performance, of the acquired response. Secondly, in a series of control studies, we have repeatedly shown that T_4 (15 µg) is equipotent with dexamethasone (6 µg) or ketocyclazocine (7.5 µg) in reversing the effect of adrenalectomy on retention of the behavioral response. The possible mechanisms, central or peripheral, of this unexpected effect of T_4 in adrenalectomized rats are currently under active investigation.

REM SLEEP IS INCREASED BY PROLACTIN, VIP, OR PHM TREATMENTS IN RABBITS. J.M. Krueger, F. Obal, Jr., M. Opp, A.B. Cady, and L. Johannsen. Dept. of Physiology and Biophysics, Univ. of Tennessee, Memphis, TN 38163.

These experiments were designed to study whether 1) vasoactive intestinal peptide (VIP) has effects on rabbit sleep similar to those reported for rats and cats; 2) peptide histidine methionine (PHM), a peptide structurally related to VIP, mimicks the somnogenic effects of VIP; and 3) prolactin (PRL), for which VIP and PHM act as releasing factors, has similar effects on sleep. Compared to control recordings, ICV injection of VIP or PHM (0.01, 0.1 or 1.0 nmol/kg) selectively increased rapid eye movement (REM) sleep during postinjection hours 2 to 6; the effects were not dose-dependent. A reduction in non-REM sleep was observed after the high dose of VIP and PHM. In response to SC injection of PRL (45 and 200 IU/kg), REM sleep increased in a dose-related manner. The results support the hypothesis that VIP is involved in the regulation of REM sleep. The VIP- and PHM-induced increases in REM sleep may be mediated via pituitary PRL release.

CENTRAL PROLACTIN ADMINISTRATION STIMULATES MATERNAL BEHAVIOR IN NULLIPAROUS FEMALE RATS. R.S. Bridges, M. Numan[1] and P.M. Ronsheim*. Dept. Anatomy & Cellular Biology, Harvard Medical School, Boston, MA 02115; [1]Dept. Psychology, Boston College, Chestnut Hill, MA 02167.

Previous studies in female rats have demonstrated a role for prolactin (PRL) in the induction of maternal behavior (Science 227:782, 1985). In the present report, the effects of both intracerebroventricular (ICV) and local neural infusions of PRL were assessed in an attempt to identify possible sites of PRL action. Adult nulliparous rats were ovariectomized and given a pregnancy-like steroid regimen (Silastic capsules) of progesterone (Days 1-11) and estradiol (Days 11-17). Endogenous pituitary PRL secretion was suppressed by s.c. injections of bromocriptine (Days 11-17). In the first study, ovine (O)-PRL (50 ug) or vehicle was infused twice daily on Days 11 and 12 and once on Day 13. Behavioral testing was conducted daily from Day 12 through 17. PRL-treated rats became maternal to foster young significantly faster than did controls. When separate groups of similarly treated rats were injected systemically with this dose of PRL, maternal behavior was unaffected. In a final study, infusion of O-PRL (5 ug) bilaterally into the medial preoptic area (MPOA) also stimulated maternal behavior more rapidly. Thus, PRL appears to act in the CNS, one site being the MPOA, to stimulate maternal behavior.

Supported by NIH HD19789 and NIMH MH00536 [RSB].

HIGH DOSES OF TESTOSTERONE INCREASE INTROMISSION RATES IN HYPERPROLACTINEMIC MALE RATS. M.A. Mroczynski* and P.C. Doherty. Dept. of Anatomy, N.E. Ohio Univ. Coll. of Med., Rootstown, Ohio 44272.

Chronic elevation of serum prolactin (PRL) levels, hyperprolactinemia (hyperPRL), inhibits male sexual behavior, including aspects of both sexual arousal and erectile function. To determine if the inhibition of sexual arousal and erectile function occur independently, the effects of hyperPRL were examined in animals given graded doses of testosterone (T). Groups of sexually experienced Fischer 344 male rats were castrated and given Silastic implants of T (group 1, 7.5mm; group 2, 15mm; group 3, 30mm; and group 4, 60mm). Two weeks later half the animals of each group were given four ectopic pituitary grafts and the remainder received sham surgery. Four weekly tests of copulatory behavior followed with repeated sampling for determination of serum levels of LH, PRL and T. A significant dose response effect of T was noted on mounting rates in standard tests of copulatory behavior. Hyperprolactinemia led to reduced mounting rates but this was significant only at the intermediate doses. Testosterone increased intromission rates in hyperprolactinemic males, but only in animals given the 60mm capsules. No effects of T on intromission rates were observed in the sham-operated controls. In mounting tests after genital anesthetization, T increased mounting rates in a dose response manner in the sham animals, but not in the grafted males. These differential effects of T on sexual arousal and erectile function during hyperPRL suggests that each of these measures of male sexual function is affected independently by the hyperprolactinemic state. Supported by a Research Challenge Grant from the Ohio Board of Regents.

304.18

EFFECTS OF PROLACTIN MICROINJECTIONS IN THE PREOPTIC AREA AND VENTROMEDIAL HYPOTHALAMUS ON FOOD INTAKE AND GONADAL CONDITION IN DOVES. J.D. Buntin and K.T. Foreman*, Dept. of Biol. Sciences, Univ. of Wisconsin, Milwaukee, WI 53201.

In ring doves, intracerebroventricular (ICV) injections of ovine prolactin (PRL) profoundly suppress plasma LH levels and testes weight (J.Endocr.,188:33,1988) and markedly stimulate food intake (Horm. Behav.,19:188,1985). In addition, PRL receptors are concentrated in several regions of the dove brain that have been implicated in the regulation of feeding behavior or gonadal activity (Fechner & Buntin, Br. Res.,in press). This study explored the role of two of these regions, the preoptic area (POA) and ventromedial hypothalamus (VMN), in mediating PRL-induced hyperphagia and gonadal suppression. Twice-daily unilateral injections of 25ng (1.1pmole) ovine PRL into either the VMN or POA of male ring doves resulted in a significant elevation of body weight ($p<.001$) and average daily food intake ($p<.05$) over a 5 day treatment period (n=8-10/group). However, VMN-injected birds showed a greater hyperphagic response than POA-injected birds (28% vs 17%, increase, respectively; $p<.05$). No significant changes in feeding occurred after POA or VMN injections of vehicle. Unlike the effects of ICV injections, reductions in testes weight did not accompany the hyperphagia induced by PRL injection at either site. These results implicate the VMN and POA as sites of PRL action in promoting hyperphagia.

ARE ALL AREAS OF THE SMALL INTESTINE ACTIVE IN INITIATING SATIETY OF SHAM-FEEDING RATS? V.E.Mendel and M.Palieschekey*. Dept. of Animal Physiology, Animal Science and Food Intake Lab.,Univ. of California, Davis,CA. 95616.

Cholecystokinin (CCK) has been identified by a number of laboratories as a possible mechanism for initiating satiety. Because the ileum of the rat does not contain CCK secreting cells infusion of nutrient into the ileum should not interrupt sham-feeding. In a preliminary study three male, Sprague-Dawley rats were surgically equipped with a stainless steel gastric cannula plus a silastic cannula in either the proximal duodenum, the jejunum, or the ileum. The animals were trained to drink a 20% (w/v) sucrose solution following a 16 hr. fast while housed in a restraining cage. Rats were allowed to sham-feed for 15 min before intestinal infusion began. Sucrose solution at 299.4 mOsm and 0.38 kcal/ml was infused at 0.3 ml/min (0.113 Kcal/min). The results are as follows.

	Duodenum	Jejunum	Ileum
Consumption (ml)			
Ga.Close	11.0 ±1.43	10.5 ±0.64	11.4 ±0.72
Sh-feed.	26.9 ±2.96	22.2 ±2.31	14.1 ±1.41
Infused	14.2	12.8 ±2.01	10.9 ±1.01

We conclude that all areas of the small intestine are active in initiating satiety and that satiety may not be initiated by CCK.

RECIPROCAL EFFECTS OF FASTING ON INSULIN BINDING IN DIFFERENT FRACTIONS OF RAT OLFACTORY BULB. J.L.Marks*, D. Porte Jr.*, and D.G.Baskin. Dept. Medicine, University of Washington, Seattle, WA,98195 and V.A. Medical Center, Seattle, WA, 98108.

Decreased insulin binding has been demonstrated in the plasma membrane (P2) fraction of olfactory bulbs(OB) from rats totally deprived of food, but not water, for 4 days (Marks and Eastman, Neurosci., in press, 1989). However, when quantitative autoradiography (QAR) was used to measure specific, OB insulin binding in fasted (n=4) vs. fed (n=4) animals, we found no change in insulin binding on the external plexiform layer: 142±20 vs. 146±17 or the granule cell layer: 54±9 vs. 61±15 dpm/sq mm (±SEM), even though these are the major sites of OB insulin receptors. This discrepancy was investigated by measuring specific insulin binding in brain homogenate, crude nuclear (P1), P2 and microsomal (P4) fractions prepared from the OB and amygdala of 3 day fasted (n=3) and free-feeding control (n=3) female rats. In both brain regions, the homogenate insulin binding, and in the amygdala, P1, P2 and P4 binding were similar in fed and fasted rats. However, in the OB, P2 insulin binding decreased from 49.0±2.1 to 41.1±1.5, P1 binding increased from 14.7±0.8 to 24.1±0.5 and P4 binding increased from 53.5±0.6 in the fed to 93.0±1.3 %/mg protein in the fasted rats, respectively(p values ≤ .05). The total insulin binding in the P1,P2 and P4 of fasted rats was added and was only 8% greater than that of fed controls.

We conclude that in the OB, total insulin binding is unaltered by a 3 day fast, when measured in tissue slices by QAR or in brain homogenates. However, there are reciprocal changes in binding in specific subcellular fractions, suggesting that insulin receptors may move between subcellular sites during food deprivation and this may be specific for the OB.

NMDA ANTAGONISTS INDUCE PATHOMORPHOLOGICAL CHANGES IN CEREBROCORTICAL NEURONS. J. Labruyere*, M.T. Price and J.W. Olney (SPON: A.I. Cohen) Washington University School of Medicine, St. Louis, MO.

Recent evidence implicating endogenous excitatory amino acids (EAA), such as glutamate and aspartate, in neurodegenerative disorders has stimulated interest in the use of EAA receptor antagonists as neuroprotective agents. Antagonists of the N-methyl-D-aspartate (NMDA) subclass of EAA receptor have received the greatest attention, especially non-competitive NMDA antagonists, such as PCP and MK-801, which freely penetrate blood brain barriers. Competitive NMDA antagonists, such as 2-amino-5-phosphonopentanoate (AP5) and 2-amino-7-phosphonoheptanoate (AP7), are also of potential interest, provided a means of increasing their blood brain barrier penetrance can be developed. In either case, a significant obstacle to the clinical use of these agents is their potential side effects. Recently, we found (Olney et al., Science, in press) that non-competitive NMDA antagonists (MK-801 > PCP > tiletamine > ketamine), when systemically administered in relatively low doses to adult rats, induce acute pathomorphological changes (extreme vacuolization of endoplasmic reticulum and dissolution of mitochondria) in large multipolar and pyramidal neurons (layers III and IV) of the posterior cingulate and retrosplenial cortices. To study whether this is an exclusive property of agents acting at the PCP site within the NMDA receptor channel, or might be reproduced by agents that block the NMDA receptor complex by other mechanisms, we micro-injected AP-5 and AP-7 unilaterally into a cerebrocortical locus immediately bordering on the posterior cingulate cortex. When thus injected, the corpus callosum and cingulum direct the spread of the compound toward both ipsilateral and contralateral cingulate neurons. We found that each agent induced PCP-like pathomorphological changes bilaterally in the same populations of cingulate neurons that are selectively affected by systemically administered PCP or MK-801. We conclude that if competitive NMDA antagonists could penetrate blood brain barriers as freely as non-competitive NMDA antagonists, they would mimic the latter in producing pathomorphological changes in cerebrocortical neurons when administered systemically. Supported by RSA MH 38894 (JWO) and DA 53568.

A COMPARISON OF THE EFFECTS OF MDL 27,266 WITH KNOWN NMDA ANTAGONISTS ON LONG TERM POTENTIATION IN THE IN VIVO AND IN VITRO RAT HIPPOCAMPUS . S.M. Sorensen, T.M. Humphreys*, and J.M. Zwolshen*, Merrell Dow Research Institute, Cincinnati, OH 45215.

MDL 27,266 is a novel triazole-3-one derivative which is being investigated as a broad spectrum anticonvulsant. It has been shown to protect against quinolinic acid seizures and hypoxic damage of the hippocampus in gerbils but it has no affinity for the NMDA receptor and only very poor affinity for the PCP binding site in vitro. In order to further characterize the activity of this compound we compared the activity of MDL 27,266 with MK-801 and CPP against long term potentiation (LTP) in the hippocampus; a phenomenon which has been shown to involve activation of the NMDA receptor. In the anesthetized rat MDL 27,266 (40 mg/kg) blocked LTP completely without altering the baseline population spike amplitude. This is in contrast to MK-801 (2 mg/kg i.p.) and CPP (10 mg/kg i.p.) which produced marked effects on basal population spike at doses which blocked LTP. Bath application of MDL 27,266 (100 uM) to the hippocampal slice caused a small decrement in the initial LTP which then further declined through the course of 60 minutes to 1/3 rd of control size. In similar experiments MK-801 (4 uM) completely blocked LTP and CPP (100 uM) had no effect on LTP. Implications of these differences in efficacy will be discussed.

305.3

CALCIUM-DEPENDENT AND -INDEPENDENT RELEASE OF ENDOGENOUS ADENOSINE FROM RAT CORTICAL SLICES BY K^+ AND EXCITATORY AMINO ACIDS T.D. White and K. Hoehn, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7

Adenosine, which inhibits neuronal firing and decreases glutamate release, may have a protective role in the CNS in situations of excess excitatory neurotransmission. Adenosine released from superfused rat cortical slices was measured by HPLC. When Ca^{2+} was omitted from the medium, K^+-evoked release of adenosine was decreased by about 50% whereas NMDA, kainate, and quisqualate-evoked release was not diminished, indicating Ca^{2+}-dependence of K^+ but not EAA-evoked adenosine release. In the absence of Ca^{2+}, adenosine release by K^+, kainate and quisqualate occurred earlier and was less sustained than control. In the presence of Ca^{2+}, adenosine release by a second K^+ or EAA stimulation was markedly diminished, suggesting depletion of a releasable pool of adenosine. Similarly, in the absence of Ca^{2+}, kainate-evoked release of adenosine was markedly diminished during a second stimulation. However, when Ca^{2+} was restored to slices previously stimulated in the absence of Ca^{2+}, release by a second exposure to K^+ or kainate was no different from initial control release. Restoration of Ca^{2+} did not restore quisqualate-evoked adenosine release and only partially restored NMDA-evoked release, possibly due to desensitization of these receptors. These findings suggest the existence of separate Ca^{2+}-dependent and -independent releasable pools of adenosine. (Supported by the MRC of Canada).

305.4

GLUTAMATE UPTAKE MEDIATES RELEASE OF ENDOGENOUS ADENOSINE FROM RAT CORTICAL SYNAPTOSOMES K. Hoehn and T.D. White, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7

We have previously shown that glutamate releases adenosine from rat cortical slices by acting at excitatory amino acid (EAA) receptors. To determine whether receptors mediating release are located on presynaptic terminals, we have studied release from cortical synaptosomes. Glutamate (30-1000μM) released adenosine from synaptosomes as detected by HPLC. Studies with EAA antagonists, DNQX, MK-801 and Mg^{2+}, and agonists, NMDA, kainate, and quisqualate, determined that glutamate-evoked release of adenosine from synaptosomes was not EAA receptor-mediated. Inhibition of glutamate uptake by dihydrokanate or replacement of Na^+ in the medium with Li+, choline, or sucrose blocked glutamate-evoked release of adenosine. Inhibition of ecto-5'-nucleotidase decreased adenosine release by glutamate, indicating that release was derived from extracellular metabolism of a released nucleotide. Glutamate did not release ATP or cAMP from synaptosomes, as determined by a firefly luciferin-luciferase assay and studies with IBMX respectively. Therefore, uptake of glutamate into presynaptic terminals releases a nucleotide (but not ATP or cAMP), which is converted extracellularly to adenosine. This adenosine, acting at A_1 adenosine receptors, may provide a negative feedback mechanism for decreasing glutamate release. (Supported by the MRC of Canada).

ADENOSINE-MEDIATED NEUROPROTECTION IN VITRO AND IN VIVO.
M.L. Weber, A.W. Probert, Jr., J.E. Goodrich*, M.A. Dominick* and F.W. Marcoux, Depts. of Pharmacology and Pathology and Experimental Toxicology, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The neuromodulator and cerebrovasodilator, adenosine, has been proposed to be neuroprotective. We have studied adenosine agonists in vitro and in vivo in models of hypoxic/ischemic neuronal injury in which vasodilators would be unlikely to be neuroprotective. Cortical neuronal cultures from fetal rat brain were subjected to hypoxia. Hypoxia-induced, NMDA-mediated intraneuronal accumulation of $^{45}Ca^{++}$ was measured in the presence of vehicle or either cyclopentyladenosine (CPA) or cyclohexyladenosine (CHA). In cultures showing a comparable degree of control $^{45}Ca^{++}$ accumulation during 4 hrs of hypoxia CPA and CHA inhibited this response in a concentration-dependent manner (IC-50s - 0.65 and 0.24μM). Gerbils were subjected to 10 mins of bilateral carotid occlusion under brief ether anesthesia. Twenty-four hrs later, ischemia-induced, CA1 neuronal injury-mediated increases in exploratory locomotor activity (LMA) were measured. While 0.1mg/kg had no effect on the ischemia-induced 128% increase in LMA observed in vehicle pretreated control gerbils, 0.3mg/kg CHA reduced the LMA increase by 50%. These findings suggest direct neuroprotective effects for adenosine agonists. In focal cerebral ischemia vascular effects of adenosine agonists may enhance or limit direct neuroprotective effects.

PRECLINICAL ANTICONVULSANT, ANXIOLYTIC AND NEUROPROTECTIVE PROFILE OF 8319, A NON-COMPETITIVE NMDA ANTAGONIST.
D.K. Rush, J.C. Wilker*, C.A. Wilmot, R. Corbett*, R.W. Dunn*, K. Locke*, L.L. Martin*, K.A. Rudolphi*[1] & S. Fielding. Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876 & [1]Hoechst-Werk Albert, Wiesbaden, FRG.

8319, ((±)-2-Amino-N-ethyl-alpha-(3-methyl-2-thienyl) benzene-ethanamine •2HCl), is a novel compound with the profile of a non-competitive NMDA antagonist. The compound displaced ^{3}H-TCP with high affinity (IC_{50}=43 nM), but was inactive at the NMDA, benzodiazepine and GABA sites; in vivo, 8319 showed good efficacy as an anticonvulsant, anxiolytic, and potential neuroprotective agent. It blocked seizures induced by NMDLA, supramaximal electroshock, pentylenetetrazol (PTZ), picrotoxin and thiosemicarbazide with ED_{50}'s of 1-20 mg/kg ip. In traditional operant conflict and the social interaction and elevated plus maze assays, 8319 showed anxiolytic activity at doses of 1-5 mg/kg ip. As a neuroprotectant, 8319 (30-100 mg/kg sc) presented the death of dorsal hippocampal pyramidal cells induced by direct injection of 20 nmol NMDA. At 15 mg/kg ip, the compound was also effective against hippocampal neuronal necrosis induced via bilateral occlusion of the carotid arteries in gerbils. In summary, 8319 is a non-competitive NMDA antagonist with good anticonvulsant and anxiolytic activity and may possess neuroprotective properties useful in the treatment of brain ischemia.

7-CHLORO-KYNURENATE BLOCKS NMDA RECEPTOR-MEDIATED NEUROTOXICITY IN CORTICAL CELL CULTURES.
D.M. Hartley, H. Monyer, S.A. Colamarino* AND D.W. Choi. Dept. of Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

Glycine strongly potentiates NMDA receptor-mediated neuroexcitation, and several investigators have reported that the glycine antagonist 7-chlorokynurenate (7-Cl Kyn) can block NMDA receptor-mediated neurotoxicity. We examined the neuroprotective actions of 7-Cl Kyn in murine neocortical cell cultures. Cultures exposed to 500 μM NMDA for 5 min in the absence of added glycine developed substantial neuronal cell loss over the next 24 h. The addition of 10 μM glycine did not increase submaximal neuronal injury, suggesting that endogenous glycine in the cultures was sufficient to achieve NMDA receptor saturation. Addition of 3-300 μM 7-Cl Kyn produced a concentration-dependent reduction in neuronal damage, with IC_{50} about 30 μM; some benefit was seen even if the drug was added after completion of the NMDA exposure. The protective effect of 100 uM 7-Cl Kyn was overcome by adding 10-1000 μM glycine, with ED_{50} about 100 μM. Furthermore, 10-300 μM 7-Cl-Kyn also produced concentration-dependent reduction in the neuronal damage induced by 4-60 min of combined glucose and oxygen deprivation. We concur with others that antagonists of the glycine receptor on the NMDA receptor complex may prove to be an effective means for combating stroke or other disease involving glutamate neurotoxicity.

305.8

BLOCK OF N-METHYL-D-ASPARTATE NEUROTOXICITY BY GLYCINE ANTAGONISTS IN CORTICAL CULTURES.
W.C. Zinkand*, J. Patel, and A.I. Salama (SPON: J.B. Malick). Dept. of Pharmacology, ICI Pharmaceuticals Group, ICI Americas Inc., Wilmington, DE 19897.

It is widely believed that the neurotoxic effect of glutamate, specifically as acting through the N-methyl-D-aspartate (NMDA) receptor subtype, causes the neuronal cell loss involved in many neurodegenerative diseases. Glycine, binding to strychnine-insensitive sites, is known to be a positive modulator of the NMDA responses in the CNS and is thought to be obligatory for these responses. We have shown that in primary cell culture from rat cerebral cortex, NMDA is a potent neurotoxin which is potentiated by glycine and D-serine. This toxic action is blocked by the putative glycine antagonists HA-966 and 7-chlorokynurenic acid even in the absence of added glycine. Block by these antagonists is reversed by adding glycine, unlike the block of NMDA toxicity by the NMDA antagonist 3-3(2-carboxypiperazine-4-yl)propyl-phosphonate (CPP), and the PCP analog MK-801.

305.9

DYNORPHIN-INDUCED NEUROTOXICITY IS BLOCKED BY PRE-TREATMENT OR POST-TREATMENT WITH MK-801.
Larry Isaac, Terri O'Malley*, Helen Ristic* and Peggy Stewart, Department of Pharmacology, Univ. of Ill. College Medicine, Chicago, 60612

Previously, we showed that dynorphin A (1-13)-induced neurotoxicity (DIN) in rats is mediated by the N-methyl-D-aspartate (NMDA) subclass of glutamate receptor (Brain Res. 443:329, 1988). The non-competitive NMDA antagonist, MK-801, blocks glutamate-induced calcium accumulation in rat cerebral cortical neurons in cell culture (Neurology and Neurobiology 46:563, 1988). Using MK-801 as a pre- and post-treatment to dynorphin injection in rats we determined whether the NMDA-associated ion channel participates in DIN and we estimated the time course of cell death. We pretreated rats, 30 min i.p., with 0.01-3 mg/kg MK-801 and we post-treated others, 15-90 min, with 3 mg/kg i.p. after dynorphin (25 nmoles i.t.).

Pretreatment with MK-801 provided a dose-dependent protection against DIN (loss of the tail-flick reflex) and at 1 mg/kg i.p. virtually prevented degeneration of spinal cord neurons assessed histologically 24 hrs later. Post-treatment with MK-801 at 15 min did not protect against DIN whereas 30 min post-treatment protected 50% of the rats against DIN. Post-treatment at 60 min protected 30% of the animals and 90 min post-treatment did not protect.

These data parallel our previous findings that DIN involves the NMDA supra molecular complex. In addition, neuroprotection by MK-801 suggests that dynorphin injection results in "opening" of the NMDA-associated ion channel which apparently permits a rapid and lethal accumulation of calcium into some neurons of the spinal cord central gray.

THE SELECTIVE κ OPIOID RECEPTOR AGONIST U50488H ATTENUATES NMDA INDUCED BRAIN INJURY IN THE NEONATAL RAT.
C.J.Hudson*, H.M.Scherch*, and E.D.Means. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

Enhanced activation of the NMDA-preferring glutamate receptor subtype seems to mediate hypoxic-ischemic brain injury in the immature brain. U50488H, a selective κ opioid receptor agonist, has been shown to exert cerebro-protective action, but has not been evaluated in a model of NMDA induced neuronal injury.

In this study, we examined the effects of U50488H on NMDA induced brain injury in the 7 day old rat pup. The injury was quantitated by assessing hemisphere weight reduction in pups that received unilateral NMDA injections. Rat pups (n=38) receiving peripallidal injection of NMDA (7.5 nmol/0.5 μl) showed a 17.5±0.7% reduction in the injected hemisphere dry weight compared to the non-injected hemisphere. U50488H (3, 10, 20 and 30 mg/kg, s.c.; 30" before, 1' after NMDA injection) significantly limited the hemisphere weight reduction at doses of 10,20 and 30 mg/kg, with maximal protection (50.4%, $p<.02$) at 20 mg/kg.

These results suggest that U50488H is effective in limiting NMDA mediated brain injury. Further work is needed to determine if this protective effect is due to antagonism of excitatory amino acids and/or induction of water diuresis with subsequent prevention of cerebral edema formation.

305.11

Depolarizing Conditions Protect Against Non-NMDA Mediated Glutamate Inhibition of Protein Synthesis in the Hippocampal Slice. J. J. Vornov* and J. T. Coyle (SPON: G. Capone), Depts. Neurology and Psychiatry, The Johns Hopkins School of Medicine, Baltimore, MD 21205

In some animal models of ischemia, NMDA receptor antagonists protect against neuronal degeneration, suggesting that glutamate causes injury by activating NMDA receptors. We have used inhibition of neuronal protein synthesis in the hippocampal slice as a method to localize acute, toxic effects of excitatory amino acids. Glutamate agonists at all three receptor subtypes (NMDA, quisqualate and kainate) produced a dose and time dependent inhibition of incorporation of TCA precipitable 3H-leucine into hippocampal slices. We confirmed that the effect is specific to neurons by autoradiography. NMDA was blocked by the specific antagonists MK-801 or ketamine and by the less selective antagonist kynurenate. Kynurenate antagonized the effects of quisqualate. In contrast to results reported in neuronal tissue culture, the inhibition caused by glutamate exposure was unaffected by antagonists.

Incubation of slices in high K^+ (120mM), low Na^+ (28 mM) medium produced a time-dependent decrease in protein synthesis which was partially mediated by NMDA receptor activation, since it was significantly decreased by simultaneous incubation with MK801. The effect of glutamate under depolarizing conditions was not significantly different from that in normal Krebs, but was significantly decreased by MK-801. There was no statistically significant effect of short exposures to glutamate when slices were depolarized in the presence of MK801. Substitution of choline for Na^+ had no effect on glutamate inhibition (choline 120mM, Na^+ 28 mM). When 60 mM KCl was added to normal Krebs without reducing Na^+, a small protection was observed. A larger protective effect was produced by veratridine (100μM), but still less than that of high K^+, low Na^+. It appears that under normal conditions, high concentrations of glutamate inhibit protein synthesis through non-NMDA sites not antagonized by high concentrations of kynurenate. When the Na^+ gradient is decreased, as occurs during energy failure, neurons appear sensitized to glutamate's NMDA effects and are at least partially protected against non-NMDA effects.

MORPHOLOGIC ALTERATIONS IN PRIMARY CULTURES OF RAT CEREBRAL ASTROCYTES AFTER EXPOSURE TO GLUTAMATE (GLU). L.J. Noble and P.H. Chan (SPON: R. Fishman). Dept. of Neurology, Univ. of California, San Francisco, CA 94143.

High extracellular concentrations of GLU, an excitatory neurotransmitter, are neurotoxic to the CNS. This toxicity was evaluated in astrocytes after exposure to 1mM GLU for 4 to 24 h. At the light microscopic level, GFAP-positive astrocytes in control cultures assumed varying, distinctive morphologies. The cytoskeleton of these cells was distributed in both a reticular pattern (usually associated with the soma) and in parallel arrays (identified primarily in processes). After exposure to GLU the heterogeneity of astrocytes was replaced by a predominance of cells in which the soma was swollen and angulated and processes appeared retracted. Cytoskeletal structures were not obvious and as a result the cytoplasm appeared homogenous. At the ultrastructural level, the normal compact appearance of the nucleolus was replaced by a structure which was irregular in shape and markedly dispersed, as evidenced by the prominence of intervening karyoplasm. Prominent dilated cisterns associated with endoplasmic reticulum contributed to the sparse appearance of the soma. In control cultures filaments in processes were distributed parallel to the axis. This linear organization was lost after exposure to GLU where filaments appeared disorganized and less numerous. Supported by NS23324 to LJN and NS14543 and 25372 to PHC.

REDOX STATE ALTERS NMDA RECEPTOR-MEDIATED NEUROTOXICITY. Daniel I. Levy and Stuart A. Lipton. Dept of Neurology, Children's Hosp & Harvard Med Sch, Boston MA 02115.

NMDA is lethal to postnatal rat retinal ganglion cells cultured in high Ca/low Mg medium (Hahn, Aizenman & Lipton *PNAS* 85:6556, 1988). Exposure to a reducing agent, such as dithiothreitol (DTT), selectively increases the electrophysiological response to NMDA in central neurons, including retinal ganglion cells; conversely, oxidizing agents reverse this effect (Aizenman, Lipton & Loring *Neuron* 2:1257, 1989). To investigate the effects of redox modulation on NMDA neurotoxicity, we studied retinal ganglion cell survival 24 hr after a 5-10 min exposure to DTT. Following dissociation, retinal cells were rinsed with control saline, DTT (0.5 - 2 mM), or DTT in the presence of the oxidizing agent DTNB (1 mM). Culture medium contained high Ca (10 mM), low Mg (50 μM), and micromolar concentrations of glutamate to induce neurotoxicity. To determine the degree of killing specifically related to activation of the NMDA receptor, APV (200 μM) was added to sibling cultures.

APV-preventable, glutamate-induced death was increased 70±9% with DTT treatment. This effect was totally blocked by the concomitant addition of DTNB. These findings suggest that the enhanced killing following reduction with DTT is mediated at the NMDA receptor site, and that the redox state of the NMDA receptor is crucial for the survival of neurons facing glutamate-related injury. Since a reducing state has been found in small and moderately-sized cerebral infarcts, these results may have implications for the treatment of stroke.

Supported by grants from NIH, the Sunny von Bulow Coma & Head Trauma Research Foundation, and the American Heart Association.

305.14

TURTLE CORTICAL NEURONS IN DISSOCIATED CULTURE ARE RESISTANT TO GLUTAMATE NEUROTOXICITY. A.M.Wilson*, A.R.Kriegstein (SPON: S.Ryan). Neurology Dept., Stanford Med. Ctr., Stanford, CA 94305.

The cerebral cortex of the pond turtle is resistant to ischemic injury. Because glutamate (Glu) neurotoxicity is an important mechanism of cell death in animal models of cerebral ischemia, we evaluated the sensitivity of cultured turtle neurons to Glu. Cortical neurons from the turtle, P. scripta, were prepared by a modification of the technique of Choi, Maulucci-Gedde, and Kriegstein (1987). Neurons were dissociated from the cortex of Stage 21 embryos, a week after the expression of NMDA receptors, and maintained at 30°C. Neurons appeared morphologically mature after 25 ± 3 days. Whole cell patch clamp recording of mature neurons showed spontaneous excitatory synaptic activity. Cultures were exposed to 3 mM Glu for 5 min at 22°C, washed free of Glu, and incubated for 24 hr at 35°C. Control cultures were not exposed to Glu but otherwise treated the same. The extent of cell death, as assayed by cellular morphology and trypan blue exclusion, was identical in Glu-exposed and control cultures. By contrast, murine cortical cell cultures treated with 3 mM Glu and incubated at 35°C showed >90% cell death (H. Monyer, pers comm). The remarkable difference between chelonian and mammalian neurons in susceptibility to Glu neurotoxicity may reflect differences in the timing or magnitude of receptor expression, circuit properties in culture, or intracellular mechanisms.

GLUTAMATE STIMULATED Ca_i ELEVATION IN CULTURED NEURONS MEASURED WITH Fluo-3 IN A 96 WELL MICROTITER FLUORIMETER J. Drejer[1*], P. Wahl[1,2*], A. Schousboe[2*], T. Honoré[1*]
[1]Ferrosan CNS-Division, Sydmarken 5, DK-2860 Soeborg
[2]Univ. of Copenhagen, Panum Institute, Blegdamsvej 3, DK-2200 Copenhagen, Denmark (SPON: ENA)

Fluo-3 is a new calcium chelator, which is non-fluorescent but undergoes a 40-fold enhancement of fluorescense on calcium binding. Fluo-3 is excited at 506 nm permitting the use of conventional non-quartz equipment. In the present model we have used Fluo-3-AM loaded mouse cortical neurons cultured in 96-well microtiter plates for measuring Ca_i with the use of a standard microtiter Fluorimeter (Fluoscan II, Labsystems). This setup allows the simultaneous measurement of a high number of identical cultures and may be used as a high throughout screening model for testing effects of compounds influencing Ca_i. Exposure of cortical neuronal cultures to excitatory amino acids such as glutamate, NMDA, kainate, quisqualate and AMPA lead to an immediate increase in Ca_i from a resting level of 70 nM to a maximum of 200-300 nM. The effect of NMDA could be antagonized potently by D-APV and MK 801. Non-NMDA responses induced by kainate, AMPA or quisqualate were blocked by CNQX. Responses to glutamate could only be blocked partially with PCP (60% inhibition). Cells exposed to low concentrations of glutamate (<20 μM) for up to 20 min were able to restore normal Ca_i levels after exposure. However, exposure to high concentrations of glutamate (>300 μM) for only a few min lead to irreversible calcium overload.

305.16

POTENCY OF GLUTAMATE AS A NEUROTOXIN IS GREATLY ENHANCED IN ASTROCYTE-POOR CULTURES OF RAT CEREBRAL CORTEX P. A. Rosenberg and E. Aizenman. Dept. of Neurology, Children's Hospital, Harvard Medical School, Boston, MA 02115.

Glutamate neurotoxicity has been proposed as a cause of neuronal death in a variety of illnesses, including stroke. An important element of the glutamate hypothesis is that under conditions producing neuronal death, glutamate, or a related agonist, attain concentrations in the extracellular space exceeding the toxic threshold for neurons. Since the presence of astrocytes might be expected to have a significant effect on the dose-response relationship for glutamate neurotoxicity (Garthwaite, Br. J. Pharmacol. 85: 297, 1985), we attempted to determine the sensitivity of neurons to glutamate in relative isolation from glia in cortical cultures. Astrocyte-poor (AP) cultures, containing approximately 50% neurons, demonstrated an EC50 to glutamate of 1.9±0.6 μM (n=8). In contrast, astrocyte-rich (AR) cultures, containing 6% neurons and approximately 15 times the number of astrocytes as AP cultures, demonstrated an EC50 to glutamate of 194±43 μM (n=3). These results suggest that central neurons are vulnerable to glutamate neurotoxicity at concentrations comparable to those that have been measured in normal hippocampus, using microdialysis. This work was supported by NS00993 and #P30-HD18655.

305.17

ULTRASTRUCTURAL RELATIONSHIPS BETWEEN NEURONS AND GLIA MODULATING GLUTAMATE TOXICITY IN CORTICAL CULTURES. K.M. Harris, D. Rulf, P.A. Rosenberg. Dept. of Neurol. Children's Hosp., Harvard Med. Sch., Boston, MA 02115

In a related study, Rosenberg et al. (this meeting) have shown that neurons in astrocyte-rich (AR) cortical cultures are significantly less sensitive to glutamate toxicity than neurons in astrocyte-poor (AP) cultures (1/15 the number of nonneuronal cells). We have compared AP and AR cultures with electron microscopy. Cultures were thin sectioned perpendicularly to the substrate thus, containing the full depth of culture in each section. In AR cultures, we have observed 2-4 overlapping astrocytic processes at the media surface; dense staining material occludes the inter-process space. The neuronal processes and synapses reside beneath the astrocytic sheet and thus, may be shielded from glutamate in the media. In contrast, AP cultures show neuronal processes and synapses exposed directly to the media. Portions of the neuronal somas in both AP and AR cultures are at the media interface; in AR cultures no axo-somal synapses have been observed here. These results suggest: 1) that the physical isolation of neuronal processes from media glutamate may render neurons in AR cultures less vulnerable to glutamate toxicity; and 2) that the primary target for glutamate as a toxin is likely to be dendritic. EXCITOTOXINS AND ANTIOXIDANTS IN REAGGREGATE CULTURES OF DEVELOPING RAT BRAIN. M. Halks-Miller, L. Toll, and M. F. Davies. SRI International, Menlo Park, CA 94025.

Reaggregate cultures of fetal rat brain contain neurons and glia that mature on schedule with their *in vivo* counterparts. Large aggregates can develop central neuronal degeneration. The relationship of this degeneration to the development of the NMDA-receptor in reaggregate cultures was examined by conducting ^{3}H-MK 801 saturation isotherms on *in vitro* days 8, 15, 19, and 23. Binding was greatest on days 8 and 15 (1,000 and 916 pmoles/mg protein), falling to 516 and 691 pmoles/mg protein on days 19 and 23 respectively. Addition of 500 µM NMDA to the cultures for one hour on day 14 *in vitro* caused an immediate swelling of cellular processes. One day later, approximately 50% of neurons were undergoing necrosis. By day 19 necrotic cells had been cleared by phagocytosis. The aggregates were reduced in volume and in protein content, but the remaining neurons appeared normal. This pattern of necrosis correlated with the release of the intracellular enzyme lactate dehydrogenase (LDH) into the culture medium. Peak levels of LDH were found 24 hr after exposure to NMDA. Both MK801 (10^{-5} M) and dextrorphan (10^{-4} M) prevented the release of LDH into the medium. Tocopherol, which has been shown to ameliorate neuronal necrosis in long-term cultures, had no effect in inhibiting the NMDA-induced release of LDH in short-term cultures.

305.19

MONOSIALOGANGLIOSIDES REDUCE NMDA NEUROTOXICITY IN NEONATAL RATS. M. Lipartiti*, S. Mazzari, A. Lazzaro*, R. Zanoni*, M.S. Seren* and A. Leon. Fidia Research Laboratories, 35031 Abano Terme, Italy.

We here report that systemic administration of monosialogangliosides is efficacious in limiting EAA-related neurotoxicity in vivo as already shown in vitro. Monosialogangliosides or saline were subcutaneously injected 1 hour prior and immediately following i.c.v. administration of NMDA (25 nmoles) in 7-day-old (P7) rats. At P12, the NMDA + saline treated group showed extensive brain damage as well as reduction in brain weight, whilst such neurotoxic effects were significantly reduced in the ganglioside treated groups. Interestingly, even though a similar effect was observed utilizing non-competitive NMDA antagonists, the monosialoganglioside effect, at least in vitro, occurs in the absence of any interference with specific EAA recognition sites or receptor operated calcium influx. This differentiates gangliosides from non-competitive NMDA antagonists. Furthermore, since EAA are most probably implicated in hypoxic-ischemic brain damage, the results here observed support the hypothesis that a similar effect underlies, at least in part, the ganglioside capability to ameliorate outcome following cerebral ischemia in adult rodents.

CONTINUOUS INTRATHECAL INFUSION OF THE GANGLIOSIDE GM-1 IN SHEEP. L.E. McCarthy* R.W. Colburn and D.W. Coombs. Dept. of Anesthesiology, Dartmouth Medical School, Hanover, NH 03756.

Implantable infusion pumps from 2 commercial sources (Shiley-Infusaid, Norwood, MA; Therex, Walpole, MA) are being used to administer intrathecal GM-1 or saline continuously to adult female sheep for up to 6 months. The main series of 11 animals is exposed for 12 weeks to 10 µg to 1 mg GM-1 per day, delivered via indwelling lumbar catheters. Infused volumes varied up to 3.5 ml/day. GM-1 infusions began 2 weeks after pump implantation or after complete recovery from surgical procedures. Animals were observed for signs of toxicity and spinal cords were harvested at term for histopathologic examination. Regardless of the dose of GM-1, no functional changes were observed which could be attributed to infusion. Histopathologic examinations of the spinal cords are currently underway. Thin layer chromatography of CSF samples showed that test animals had markedly elevated levels of GM-1 in lumbar and cisternal CSF samples compared to saline-infused controls. Measurements from one animal receiving 10 mg/day yielded concentrations of 120 and 12 µg/ml of CSF at the lumbar and cervical levels, respectively, suggesting that the CNS has the capacity for handling large amounts of GM-1. Pending histological examination, the chronic application of high concentrations of GM-1 directly to the lumbar cord, appears to be non-toxic.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY III

306.1

AMINO-OXYACETIC ACID PRODUCES EXCITOTOXIC LESIONS IN THE RAT STRIATUM. E. Urbanska‡, C. Ikonomidou‡, M. Siekluckaŧ and W.A. Turski‡ (SPON: M.S. Shahid Salles). ‡Dept. of Pharmacology, Medical School, PL-20-090 Lublin, Poland.

Amino-oxyacetic acid (AOAA) was microinjected into the striatum of adult (over 90 d of age) and 6-d-old Wistar rats and the resulting neuropathology was examined after a survival period of 30 min -30 days. AOAA (0.1, 0.25 and 1 µmol) produced neuronal degeneration in the adult rat striatum in a dose-dependent manner. In 6-d-old rats, AOAA caused no striatal damage up to the dose of 1 µmol. Neuronal injury produced by AOAA displayed excitotoxic characteristics, i.e. acute swelling of dendrosomatic elements with relative sparing of presynaptic axon terminals and glial cells. Prominent gliotic reaction was observed in the injured striatum within 4-5 days after microinjection of AOAA. Activity of L-glutamate decarboxylase (GAD) was decreased in the lesioned striatum 14 d after injection of AOAA (0.25 or 1 µmol) by 18 and 50% respectively. The neurotoxic effect of AOAA (0.25 and 1 µmol) in the adult rat striatum could be prevented efficiently by 2-amino-7-phosphonoheptanoic acid (AP7; 0.25 µmol) or kynurenic acid (KYN; 0.5 µmol). AP7 and KYN also prevented reduction in striatal GAD activity. These findings suggest that AOAA causes excitotoxic lesions in the adult rat striatum by excessive activation of N-methyl-D-aspartate (NMDA) receptors. AOAA however does not activate NMDA receptors by itself. This becomes evident in the failure of AOAA to damage the 6-d-old rat striatum, which reportedly is more susceptible to the neurotoxic action of NMDA. The mechanism by which AOAA activates striatal NMDA receptors seems to depend on the presence of intact corticostriatal pathways, since cortical ablation abolishes the excitotoxic reaction of striatal tissue to AOAA (1 µmol). AOAA is known to inhibit KYN-synthesis and it is thus tempting to speculate that this mechanism might partly underlie its neurotoxic properties. It is remarkable that striatal neurotoxicity of AOAA increases with age. This makes the mechanism of AOAA neurotoxicity a potential candidate for the pathogenesis of Huntington's disease, which starts in adult life and has been proposed to base on an excitotoxic process. In AOAA (0.25 and 1 µmol) lesioned rats, apomorphine HCl (0.5 mg/kg) produced circling ipsilateral to the lesioned striatum. Bilateral striatal lesion with AOAA (0.25 and 1 µmol) reduced catalepsy response to haloperidol (2 mg/kg) and increased that to morphine HCl (15 mg/kg) or arecoline HBr (15 mg/kg). This behaviour is similar to that observed in previously described rodent models for Huntington's disease. Supported by the Polish Academy of Sciences.

306.2

AN INDIRECT PRESYNAPTIC GLUTAMATERGIC MECHANISM IS INVOLVED IN STRIATAL EXCITOTOXIN LESIONS MEDIATED BY NMDA, KAINATE AND QUISQUALATE RECEPTORS

Kenton J. Swartz and M. Flint Beal

Department of Neurology, Mass. General Hosp. and Harvard Medical School, Boston, MA. 02114

Removal of the corticostriatal glutamatergic pathway protects against excitotoxic neuronal degeneration produced by kainic acid (KA), quinolinic acid (QA) and N-methyl-D-aspartate (NMDA). Decortication may protect against striatal excitatory amino acid (EAA) mediated toxicity by preventing presynaptic release of glutamate from corticostriatal terminals. We investigated the role of presynaptic glutamatergic afferents (corticostriatal) in striatal excitotoxin lesions caused by agonists acting at the three subtypes of EAA receptors. Rats were decorticated 14 days prior to intrastriatal injections of either NMDA (200 nmol), QA (240 nmol), KA (7.5 nmol), quisqualic acid (QUIS; 1000 nmol), (RS)-2'-amino-3-hydroxy-5-methyl-isoxazole-4-proprionic acid (AMPA; 22.5 nmol) or ibotenic acid (IBO; 200 nmol). Control (corticate) rats also received an equimolar dose of one of the above EAA agonists. The lesions were evaluated quantitatively by measuring the striatal content of GABA, substance P, neuropeptide Y and somatostatin. Consistent with previous reports, decortication totally blocked the excitotoxic effects of NMDA, QA and KA. In addition, we found that decortication totally blocked AMPA and QUIS striatal lesions. However, IBO, an EAA with agonist properties at both NMDA and QUIS (inositol phosphate linked) receptors, produced lesions that could only partially be blocked by prior deafferentation. These findings are consistent with the hypothesis that EAA mediated presynaptic glutamate release is involved in striatal excitotoxin lesions *in vivo*. The fact that decortication only partially blocked IBO lesions suggests that activation of the inositol phosphate linked QUIS receptor may play a role in EAA induced neuronal death. Agonists acting at other EAA receptors may activate this receptor by the presynaptic release of glutamate.

306.3

REGIONAL BRAIN QUINOLINIC ACID LEVELS AND NEUROCHEMICAL MARKERS OF TOXICITY: EFFECTS OF ACUTE VS CHRONIC TRYPTOPHAN FEEDING

Andrew Freese, Kenton J. Swartz, Matthew J. During, Melvin P. Heyes, M. Flint Beal and Joseph B. Martin

Department of Neurology, Mass. General Hosp., Boston, MA 02114 and Laboratory of Clinical Science, NIMH, Bethesda, MD. 20014

Quinolinic acid (QA), a metabolite of tryptophan (TRYP), is markedly responsive to acute TRYP loading. As an agonist of the NMDA receptor, QA is implicated in the pathogenesis of several neurological disorders, including Huntington's Disease (HD). Studies have suggested that an alteration of metabolism of TRYP into QA may in part be responsible for HD.

We have examined the effects of chronic and acute TRYP feeding in rats on plasma TRYP levels, brain QA levels and neurochemical markers of excitotoxin induced toxicity. Rats were fed chow with either 0.3 % (normal), 1.5 %, 3.0 % or 5.0 % TRYP. At the end of either 3 days or 2 months, rats were sacrificed between 5-7 AM, plasma was collected and tissue sections from striatum, hippocampus and cortex were dissected and frozen. Plasma TRYP levels were measured using high performance liquid chromatography (HPLC) with UV detection. Regional brain content of QA was measured using gas chromatography with negative ionization mass spec. detection. Neurochemical markers of toxicity (somatostatin, neuropeptide Y, substance P and GABA) were measured by radioimmunoassay and HPLC with electrochemical detection.

After 3 days of TRYP feeding (5.0 % vs 0.3 %), brain QA levels were increased 5 fold. However, after 2 months of TRYP feeding, brain QA levels did not significantly differ among the different doses of dietary TRYP. Plasma TRYP levels did remain markedly elevated in a dose dependent manner. Also at 2 months no sign of neurodegeneration (as measured by neurochemical markers of toxicity) was observed in any brain region examined. These results suggest that under chronic conditions of TRYP loading QA synthesis downregulates and is no longer precursor responsive.

306.4

GM_1 GANGLIOSIDE PRETREATMENTS REDUCE QUINOLINIC ACID INDUCED STRIATAL DAMAGE. G. Lombardi[1]*, G. Toffano[2] and F. Moroni[1]. [1]Dept. of Pharmacology, Univ. of Florence, [2]Fidia Res. Lab., Abano Terme (Padova), Italy.

A systemic treatment with GM_1 ganglioside has previously been found to reduce experimentally induced neuronal damage in dopaminergic, cholinergic and serotoninergic neurons, provided that the lesion is in proximity to the affected cell bodies (see Lombardi, G. et al., *Neuropharmacology*, 27: 1085,1988). Quinolinic acid (QUIN) and other excitotoxins typically cause neuronal damage only when applied near the affected cell bodies. In order to verify whether or not systemic GM_1 ganglioside administration could act by reducing the effects of endogenous excitotoxins, rats were unilaterally injected with 250 nmoles of QUIN (injection coordinates: AP=0; L=3.4; H=-4.2 from bregma, Koenig-Klippel, 1963). QUIN induced striatal lesions were evaluated both histologicallly on Nissl stained section and biochemically by measuring the striatal activities of choline acetyltransferase (ChAT) and L-glutamic acid decarboxylase (GAD). The intrastriatal injection of QUIN reduced GAD activity in the striatum of the injection side (from 11.1±0.5 to 7.14 ±0.4 nmol /h/mg of tissue) and ChAT activity (from 7.02±0.3 to 4.51±0.3 µmol/h/mg of tissue) by approximately 40 %. No changes were observed in the controlateral side. A treatment with intraperitoneal GM_1 ganglioside (10 or 30 mg/Kg/day) started immediately after the excitotoxin injection failed to modify QUIN toxicity. However, when GM_1 ganglioside was administered for 3 days before surgery at a dose of 30 mg/kg/day and its administration was continued for at least 12 days a significant reduction in QUIN toxicity was observed. Lower doses were inactive. Thus, appropiate doses of GM_1 ganglioside may reduce the excitotoxic damage in gabaergic and cholinergic neurons.

306.5

EFFECTS OF CHRONIC INTRASTRIATAL INFUSION OF QUINOLINIC ACID. Z. Susel*, T.M. Engber, S. Kuo* and T.N. Chase (SPON: J.R. Walters). Exptl. Therapeutics Branch, NINDS, Bethesda, MD 20892.

Acute injection of the excitotoxin quinolinic acid into the rat striatum has been reported to produce a pattern of neuronal degeneration similar to that seen in post-mortem striatal tissue from patients with Huntington's disease. However, if an endogenous excitotoxin is involved in the pathogenesis of Huntingtons's disease, exposure to such a compound is likely to occur over a prolonged period of time. We studied the effect of chronic infusion of quinolinic acid into the rat striatum on striatal choline acetyltransferase (ChAT) activity, glutamic acid decarboxylase (GAD) acitivity and somatostatin content. Infusions were conducted for 14 days at a rate of 0.5 µl/hr via an Alzet osmotic pump (Model 2002) connected to a stainless steel cannula implanted in the striatum. Quinolinic acid (dissolved in artificial CSF, pH adjusted to 7.4) was administered at doses of 9, 90, or 900 nmol/day. Control animals received infusions of artificial CSF vehicle. After 14 days, rats were sacrificed and the striata dissected for measurement of ChAT and GAD activity. Infusion of quinolinic acid significantly depleted ChAT activity at all 3 doses (69% of control values at 9 nmol/day; 61% of control at 90 nmol/day; 8 % of control at 900 nmol/day). Quinolinic acid infusion also significantly reduced GAD activity (73% of control at 9 nmol/day; 71% of control at 90 nmol/day; 12% of control at 900 nmol/day). Preliminary data showed a decrease in somatostatin content due to quinolinic acid infusion (69% of control at 9 nmol/day, 71% at 90 nmol/day, 20% at 900 nmol/day), but this decrease was statistically significant only at the highest dose of quinolinic acid. These findings indicate that chronic infusion of a low dose of quinolinic acid can cause excitotoxic damage in the striatum and may provide support for excitotoxic models of neurodegenerative diseases such as Huntington's disease.

306.6

NEURODEGENERATIVE EFFECTS OF CHRONIC INFUSION OF QUINOLINIC ACID INTO RAT HIPPOCAMPUS AND STRIATUM. A.Vezzani, R.Serafini*, M.Rizzi* and R.Samanin* Istituto di Ricerche Farmacologiche "Mario Negri", Via Eritrea 62, Milano 20157 (Italy).

The effect of chronic infusion of quinolinic acid (QUIN) into rat hippocampus and striatum was examined at light microscopic level on 40 µm cresyl-violet stained brain sections. Continuous infusion was done at constant speed (0.5 µl/h) for one or two weeks by osmotic minipumps (14 days-Alzet Model 2002) implanted subcutaneously and connected to an injection needle inserted in the dorsal hippocampus or striatum. No build up of 3H-QUIN occurred in the tissue during infusion as assessed by measuring radioactivity at various times (3h-1 week) after minipump placement. One-week intrahippocampal infusion of 6 nmol/h QUIN but not of its inactive analog nicotinic acid (n=6) caused complete degeneration of all pyramidal and granule cells; 2.4 nmol/h QUIN selectively affected pyramidal cells (CA1, CA3-4) while granule cells were generally spared (n=8). Neuronal loss was limited to a spherical area with a radius of approxymately 1 mm. The neurodegenerative effects induced by 2.4 nmol/h QUIN were antagonized by coinfusion of 7.2 nmol/h kynurenic acid (n=6), a tryptophan metabolite with anti-excitotoxic properties. One and two weeks-infusion of 1.2 nmol/h QUIN did not induce neurodegeneration except occasional loss of CA4 cells (n=6). One week-intrastriatal infusion of 10 nmol/h QUIN revealed an area of pronounced neurodegeneration extending approxymately 1 mm around the injection track; 4 nmol/h QUIN infused for one week were ineffective while two weeks-infusion caused cell loss less severe than 10 nmol/h (n=6-8). Possible implications for the pathogenesis of human neurodegenerative disorders will be discussed.

306.7

IBOTENIC ACID IS SIMILAR TO N-METHYL-D-ASPARTATE IN CYTOTOXICITY BUT SIMILAR TO QUISQUALATE IN PHOSPHOINOSITIDE HYDROLYSIS ENHANCEMENT IN RAT CORTICAL CULTURES. J. Patel , W.C. Zinkand*, W.C. Moore*, and A.I. Salama. Dept. of Pharmacology, ICI Pharmaceuticals Group, ICI Americas Inc., Wilmington, DE 19897.

Ibotenic acid (IBO) has been reported to interact with several systems associated with excitatory amino acids throughout the mammalian central nervous system. These include, but are not limited to, excitotoxicity and enhancement of phosphoinositide (PI) hydrolysis. We report that in primary neurocortical cultures, IBO, like N-methyl-D-aspartate (NMDA) is a potent neurotoxin as measured by release of lactate dehydrogenase (LDH). However, unlike NMDA, it enhances PI hydrolysis in a manner similar to quisqualate. IBO cytotoxicity, like that of NMDA, is potentiated by glycine and blocked by MK-801. Like quisqualate, the enhancement of PI hydrolysis by IBO is not modulated by glycine or blocked by NMDA antagonists. In neurotoxicity, IBO is about five-fold less potent than NMDA and roughly equipotent to quisqualate. In enhancement of PI hydrolysis, IBO is one hundred-fold less potent than quisqualate.

306.8

REGIONAL EFFECTS OF THE CHRONIC ADMINISTRATION OF THE EXCITOTOXIN B-N-OXALYLAMINO-L-ALANINE (BOAA) ON DOPAMINE AND SEROTONIN METABOLISM IN RAT BRAIN. V. Jackson-Lewis, J.L. Cadet, F. Suber, S. Fahn. Dept. Neurology, Columbia Univ., NY, NY 10032.

B-N-Oxalylamino-L-Alanine (BOAA), a potent excitotoxin, causes stereotypic behaviors when given acutely. Some of these behaviors have been related to catecholamine (CA) and serotonin (5-HT) metabolism. We investigated the effects of BOAA on regional CA and 5-HT metabolism in rat brain.

Rats received saline or BOAA (50ug x 1 day or 25ug x 5 days) icv and were sacrificed at 24 or 96 hours after treatment. DA, DOPAC, HVA, 5-HT and 5-HIAA levels were determined in the caudate (CN), accumbens (NAc), hippocampus (HIP), frontal cortex (FC) and brainstem (BS). Treated animals showed significant decreases in DA and to a lesser extent DOPAC and HVA levels in CN and NAc. While a single dose of BOAA was effective in decreasing DA and its metabolites, multiple dosage had a far greater effect. 5-HT and 5-HIAA levels decreased in all areas studied, the most marked effect being in HIP and FC. Decrements in 5-HIAA paralleled that of 5-HT. Multiple dosage was more effective in HIP whereas single dosage was equally as effective as multiple doses in FC. These data suggest that the excitotoxin, BOAA, given acutely or chronically, causes marked alterations in regional CA and 5-HT metabolism.

306.9

BOAA ENHANCEMENT OF L-GLUTAMATE RELEASE FROM GUINEA PIG HIPPOCAMPAL MOSSY FIBER SYNAPTOSOMES. R.L. Gannon and D.M. Terrian. Clinical Sci. Div., USAF Sch. Aerospace Med., Brooks AFB, TX. 78235.

The plant-derived amino acids Beta-N-oxalylamino-L-alanine (BOAA) and Beta-N-methylamino-L-alanine (BMAA) have been suggested to be environmental neurotoxins. Both BOAA and BMAA have been reported to possess similar neurotoxic properties, and appear to activate postsynaptic non-N-methyl-D-aspartate (NMDA) and NMDA receptors, respectively. We report here the effects of BOAA and BMAA on the basal and stimulated release of L-glutamate (Glu) and Dynorphin (Dyn) A(1-8)LI from guinea pig hippocampal mossy fiber synaptosomes. Fifteen minute applications of high (200 uM) but not low (30 uM) concentrations of BOAA significantly increased the basal release of cytosolic L-Glu by over 20 pmoles/min/mg protein. In contrast, BMAA (up to 1 mM), was without effect on basal L-Glu release. Depolarization of synaptosomes by a 30 mM KCl-containing medium in the presence of 200 μM BOAA significantly increased the evoked Ca^{2+}-dependent L-Glu release from 96 ± 7 to 136 ± 9 pmoles/min/mg protein. Lower concentrations of BOAA (30 uM) and BMAA (up to 1 mM), had no effect on KCl-stimulated release. Neither BOAA nor BMAA affected the basal or evoked release of Dyn A(1-8)LI. AFOSR 2312W3.

306.10

ENVIRONMENTAL NEUROTOXINS: A ROLE FOR DOMOIC ACID. A. Novelli, J. Kispert*, A. Reilly* and V. Zitko*. Lab. of Biophysics, International School for Advanced Studies, 34014 Trieste, Italy; Lab. Mol. Biology, NINDS, NIH,Bethesda, MD 20892, USA; Marine Chem. Division, Biological Station,St. Andrews, N.B., E0G2X0, Canada.

During the period from mid-November to mid-December 1987, more than 150 Canadians suffered from acute intoxication after eating cultured blue mussels. Their symptoms included disorientation, confusion and memory loss. The mussels were found to contain high amounts of domoic acid (DA), a peculiar excitatory amino acid (EAA), expected to act similarly to kainate. We used rat cerebellar granule cells in primary culture as an experimental system for the characterization of biochemical and neurotoxicological properties of DA. Exposure of the neuronal culture, for 1 min., to increasing concentrations of DA, resulted in a dose-dependent stimulation of cGMP formation (ED_{50}=5μM). Maximal stimulation (>100 times over basal levels) was achieved with 10μM DA. DA effect on cGMP formation was not reduced by physiological concentrations of Mg^{++}(1mM), by the NMDA-receptor antagonist amino-phosphonovalerate (APV) (1mM) or by the NMDA-receptor-associated channel blocker MK-801(1μM) and was dependent upon extracellular calcium. DA (50μM) did not affect intracellular cAMP levels. Neurotoxicity by DA (1.5μM) occurred within 30 min. of exposure to the drug when the neurons were in conditions of reduced cellular energy levels. However, DA toxicity was not potentiated in the absence of Mg^{++}, as occurred for NMDA agonists, and was not antagonized by APV or MK-801. Quisqualic acid (100μM), an agonist at the NON-NMDA type of EAAR, selectively antagonized DA's biochemical and toxicological effects.

In conclusion, DA appears to exert its neurotoxicity through the activation of the NON-NMDA subtype of EAAR, which is also involved in the stimulation of the formation of cGMP as a specific second messenger .

306.11

PHARMACOLOGY OF DOMOIC ACID FOLLOWING SYSTEMIC ADMINISTRATION: COMPARISONS WITH OTHER EAA AGONISTS. R.A.R. Tasker*, S.M. Strain* and B.J. Connell* (SPON: J.W. Downie). Dept. of Anatomy & Physiology, Atl. Vet. Coll., Univ. of PEI, Charlottetown, PEI, Canada C1A 4P3.

In Dec. 1987 a number of people suffered seizures and memory loss after ingesting cultured mussels containing Domoic acid (DA). To study the pharmacology of DA, female CD-1 mice (20-25 g) were injected (i.p.) with serial dilutions of toxic mussel extracts. Dose-related behaviours were recorded and subsequent data were based on cumulative scores over 60 min. according to a 7 point rating scale. Injections of DA in water or in acid extracts from DA-free mussels produced parallel ($p > 0.05$) sigmoidal dose-response curves (ED50 = 4.0 and 4.9 mg/kg, respectively). Injections of Kainic acid produced identical dose-related behaviours and a parallel ($p > 0.05$) dose-response curve (ED50 = 32.0 mg/kg). Injections of various doses of N-methyl-d-aspartate or Quisqualic acid failed to produce equivalent behaviours. DA-induced behaviours were not significantly antagonized by injections of 200, 400 or 600 mg/kg Kynurenic acid (before, simultaneously or after DA) or by prior injection of 40, 80 or 120 mg/kg Glutamic acid diethyl ester (GDEE). We conclude that systemically-administered DA produces excitotoxicity via activation of kainate receptors, and is not antagonized by either Kynurenic acid or GDEE. Supported by NSERC Grant STRGP 036 to R.T.

306.12

NEUROTOXICITY OF DOMOIC ACID-CONTAMINATED SHELLFISH: REVERSAL BY KYNURENIC ACID. **G.B. Glavin, C. Pinsky* and R. Bose. Dept. Pharmacol. and Dept. Surgery, Fac. Med., Univ. Manitoba, Winnipeg, CANADA R3E 0W3.**

The potent neuroexcitant amino acid (NEAA), domoic acid (DA), has been implicated as the major neurotoxin involved in the recent outbreak of amnesic shellfish poisoning (ASP), characterized by severe gastrointestinal bleeding and ulceration and protracted CNS disorders such as seizures, coma and death. An aqueous acidic extract from poisonous Atlantic mussels was injected in mice, yielding an LD_{84} of 40 ml/kg. Body-scratching, clonic convulsions and death occurred. Autopsy revealed antral and duodenal ulcers and alkaline peritoneal ascites. Protein content of the ascites correlated positively with pH. Pure domoic acid (0.5-8.0 mg/kg) produced similar findings. The broad-spectrum NEAA antagonist, kynurenic acid (KYN), 300 mg/kg, protected powerfully and significantly against DA-induced neuropathy and gastropathy. In other experiments, KYN showed anti-ulcerogenic and gastric anti-secretory effects. Optimal protection by KYN occurred 60 and 75 minutes after DA treatment, suggesting that KYN may show a form of use-dependent antagonism. We suggest that KYN would likely provide a significant measure of protection against DA neuro- and gastro-toxicity seen in humans at approximately 20 h after ingestion of contaminated shellfish. **(Supported by the MRC and Alzheimer Society of Canada).**

306.13

EXCITATORY AMINO ACID ANTAGONISTS (EAAA) PROTECT AGAINST AGONIST-INDUCED WILD RUNNING (WR) IN MICE. **J.T. Simmonds*, T.L. Sailer*, AND R.R. Notvest** (Spon: K.L. Keim). Wyeth-Ayerst Research, Princeton, NJ 08543-8000

In a previous report, it was shown that infusion of kainate into the colliculi induces WR in mice (Frye, G.D., Neurosci Abs, 13:510, 1987). This study examined the utility of the WR response as a pharmacological model. Intracollicular injections (1nmole) of kainate, AMPA or NMDA resulted in a rapid onset (<1 min) of WR. To examine the pharmacology, EAAA were co-administered with the agonists, and considered to protect if the delay to WR was >5 min. Co-administration of MK-801 (50 nmoles) protected only against NMDA WR. AP7 (25 nmoles) protected against NMDA and kainate but not AMPA WR. FG9065 (6 nmoles), FG9041 (14 nmoles) and GAMS (20 nmoles) protected against kainate; greater concentrations (50 nmoles) also protected against AMPA and NMDA WR. With the exception of AP7, the efficacy of these EAAA in the WR models is in agreement with their receptor selectivity. These WR models will be used to evaluate other known and novel EAAA.

306.14

THE KAINATE-INDUCED RELEASE OF AMINO ACIDS FROM CEREBELLAR GRANULE CELLS IS PARTIALLY PREVENTED BY QUISQUALATE AND 100 mM SUCROSE P.P. McCaslin and T.G. Smith Dept. Pharmacol. and Toxicol., UMC, Jackson, MS, 39216

Kainate is neurotoxic for cerebellar granule cells in primary culture. We have found that 25 *u*M quisqualate will prevent the rapid toxicity induced by 100 *u*M Kainate. Similarly, protection occurs by making the extracellular fluid hyperosmolar with 100 mM sucrose. The kainate-induced secretion of the excitatory amino acids, aspartate and glutamate, as well as several other amino acids were measured in granule neurons 18-22 day *in vitro* and the effects of quisqualate and sucrose on this kainate-induced release were examined. Neurons were washed with a balanced salt solution containing the following mM concentrations: 154 NaCl, 5.6 KCl, 2.5 $CaCl_2$, 10 glucose and 5 HEPES (pH 7.4, 37°C). Cells were left in this buffer to equilibrate for from 10 to 20 minutes. The release of several amino acids was then determined by placing a 0.25 ml drop of buffer (containing varying concentrations of kainate, quisqualate and/or 100 mM sucrose) on slides. After 3 min, the solution was collected and the amino acids (aspartate, glutamate, serine, threonine, glycine, alanine and GABA) secreted into the buffer were determined by 2-dimensional thin layer chromatography. Results indicate that kainate induces a large, apparently nonselective and calcium-independent, increase in the release of amino acids from granule cells. A significant release of most amino acids occurred with 10 *u*M kainate. While quisqualate and 100 mM sucrose protect against toxicity, they only partially prevent the release of amino acids induced by kainate.

306.15

CATECHOLAMINE CONTENT IN RAT CEREBRAL CORTEX AFTER KAINIC ACID INJECTION. Tzen-Kwan Chang, May J. Hsu, Wan-Lin Yang and Albert Y. Sun, Molecular and Cellular Neurobiology group, Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, ROC

Kainic acid (KA) is an excitotoxin that produces seizures by directly binding to glutamate receptors. We have used this potent glutamate agonist to study action of excitatory neurotransmitters and epileptogenesis. Sprague-Dawley rats (about 250 g. body weight) were given 24 mg of KA/Kg body wt. in buffered solution by intraperitoneal injection. Controls were given the same volume of vehicle solution. Rats were killed by decapitation at 3, 6 and 24 hours after injection and the cerebral cortices were dissected out for the analysis of norepinephrine (NE), dopamine (DA), adenine nucleotides and their metabolites. NE content decreased about 30% at 3 hrs after drug treatment and recovered to significantly higher than control level after 24 hrs while the DA content remained constant. Concomitantly, there was a decrease in ATP, ADP and AMP content while xanthine and hypoxanthine increased. We have also examined the high affinity uptake of NE by synaptosomes isolated from cerebral cortices of controls and drug-treated animals. There was a reduction in NE uptake activity at 3 hrs after KA treatment, and this reduction recovered after 24 hrs. It is postulated that KA causes excessive release of NE from noradrenergic neurons as well as reduction in NE-uptake. The reduction of NE uptake activity may be caused by damages in NEergic neurons due to the excitotoxic effect of KA.

RAT STRAIN DIFFERENCES IN KAINIC ACID NEUROTOXICITY II: DOSE RESPONSE. G.T. GOLDEN, G.G. SMITH*, J.H. KULP*, P.F. REYES and T.N. FERRARO. VA Medical Center, Coatesville, PA 19320 & Thomas Jefferson Med. Coll. Phila., PA.

It has been our observation as well as others that the use of kainic acid (KA), in particular as an animal model of status epilepticus, is complicated by excessive variability in the magnitude of the behavioral, EEG and neuropathological changes seen. Recently, a strain of rats has been reported (Neurosci Abstr, 1988, 14: 252) which reliably and consistently demonstrate electrographic and behavioral status epilepticus in response to a 10mg/kg sc injection of KA. In the present study we report dose response results in this strain (WF/NCR) and two other strains of rats.

Male WF/NCR (n=39), SD/BC (n=40) and LEH/CR (n=41) were administered sc, one of four doses of KA (6, 8, 10 or 12mg/kg) and were monitored for 240 min after KA injection. At doses greater than 6mg/kg, WF/NCR rats had the shortest, least variable latencies to onset of initial behavioral seizure and to behavioral status epilepticus. All WF/NCR rats exhibited behavioral seizures at 8, 10, and 12mg/kg doses of KA and 100% attained status epileticus at KA doses of 10 and 12mg/kg. All strains showed similar scores at the 6mg/kg dose, with the WF/NCR rats demonstrating the greatest dose dependent response in behavioral seizure score. WF/NCR rats had significantly more WDS at KA doses of 8, 10 and 12mg/kg than either SD/BC or LEH/CR rats. (Supported by VA funds)

306.17

Neurovisceral Toxic Syndrome (NVTS) from domoic acid-contaminated mussels: Toxicity profile, putative antidote and involvement of free radicals. R. Bose, G.B. Glavin and C. Pinsky*. **Depts. of Pharmacology & Therapeutics and Surgery, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, Canada R3E 0W3.**

The neuroexcitotoxin, domoic acid, which is kainate-like but of higher potency, has been implicated in a recent outbreak of NVTS from PEI mussels characterized by gastrointestinal diatheses, persistent memory disturbances and other symptomatology. We have discerned higher sensitivity to domoic acid in infant Swiss-Webster mice than in adults, and have characterized a behaviorotoxic profile which might be utilized for commercial screening of mussel products for the presence of excitotoxin contamination. In testing putative antidotes against domoic acid toxicity in mice, kynurenic acid, a nonselective antagonist at excitatory amino acid receptors was the most effective. Neuroexcitants and free radicals both have been implicated in neurodegeneration associated with aging and its related disorders as well as that following cerebral ischemia. Acute pretreatment of mice with toxic mussel extract (1 and 2 mg per kg domoic acid equivalents), at 60 min prior to sacrifice, resulted in significantly increased superoxide dismutase activity in brain with an associated decrease in thiobarbituric acid reactive lipid peroxidation products. These suggest an initial compensating phase of increased free radical activity. Chronic treatment with the toxin and tissue sampling after longer delays might reveal a failure in the brain's limited capacity to scavenge free radicals, leading to neuronal damage. **Support:** *MRCC, Alzheimer Soc Can.*

ACUTE FUNCTIONAL ACTIVITY AFTER EXCITOTOXIC LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS. L. Telford, B.J. Frost and †R.J. Boegman. Departments of Psychology, and †Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The nucleus basalis magnocellularis (nbM) is the site of origin of a major cholinergic projection to the cerebral cortex. Using the [^{14}C]2-deoxyglucose (2-DG) method, we examined regional functional activity in the brains of Sprague-Dawley rats following unilateral quinolinic (QUIN) (60 nmol) and ibotenic acid (IBO) (10 nmol) injections into nbM (according to the coordinates of Paxinos and Watson, 1986). 2-DG (125 μCi/kg) was infused into a femoral vein 20 minutes after injection of the excitotoxin. A slight decrease in functional activity occurred in ipsilateral visual cortex (QUIN, -18%; IBO, -26%), motor cortex (QUIN, -16%; IBO, -38%), and somatosensory cortex (QUIN, -23%; IBO, -38%) relative to contralateral cortex. Regions near the injection site displayed substantial functional activation relative to the contralateral side in QUIN-lesioned rats [substantia inominata (SI), 259%; globus pallidus (GP), 421%; caudate-putamen (CPu), 75%]. This asymmetry was less apparent after IBO injections (SI, 21%; GP, 122%; CPu, -16%). Intense labelling occurred in the medial forebrain bundle (MFB), 330%, and substantia nigra (SN), 121% after IBO, but not QUIN lesions (MFB, 14%; SN, 54%). We have demonstrated acute reductions in functional activity in ipsilateral cortex similar to those observed after chronic lesions. Additionally, massive ipsilateral functional activation occurred in several forebrain structures involved in motor control, which may correlate with the profound behavioral activation observed after excitotoxic lesions. Supported by MRC grants (MA 7244, MA 9118).

ANTAGONISTIC PHARMACOLOGY OF GLUTAMATE NEUROTOXICITY IN INFANT RAT BRAIN. C. Ikonomidou, J. Labruyere*, A. Benz* and J. W. Olney, Department of Psychiatry, Washington University, Medical School, St. Louis, MO

The antagonistic pharmacology of glutamate(Glu) neurotoxicity was studied in the infant rat brain. Glu (300-700 nmol), N-methyl-D-aspartate (NMDA) (3-8 nmol), kainic acid (KA) (2-6 nmol) and quisqualate (QA) (10-40 nmol) were microinjected into the head of the caudate nucleus of 2-d-old rats and the resulting neuropathology was quantitatively examined after a survival period of 4 hrs. All four excitatory amino acids produced a dose-dependent excitotoxic reaction which involved the head and tail of the caudate nucleus, the cingulate, frontal and parietal neocortices, the septum, several thalamic nuclei and the hippocampus. The damage produced by NMDA was more severe than that produced by KA, although in adult brain at these same doses, NMDA would produce no damage and KA would be severely neurotoxic. This corroborates prior reports that the infant rat brain, compared to the adult, is hypersensitive to NMDA and hyposensitive to KA. Systemic administration of the non-competitive NMDA receptor antagonist MK-801 (5mg/kg) totally prevented the excitotoxic reaction to NMDA (4 nmol) and substantially reduced the reaction to KA (3nmol, QA (20 nmol) and Glu (700 nmol). Similar results were obtained with the competitive NMDA-receptor antagonist APH (10 nmol), when co-injected with each agonist into the head of the caudate nucleus. The ability of MK-801 and APH to protect against KA and QA toxicity was unexpected. A possible explanation would be that KA and QA damage infant brain indirectly by release of endogenous Glu which then exerts excitotoxic action at hypersensitive NMDA receptors. This may be analogous to hypoxic/ischemic brain damage in the infant rat which, because it is effectively blocked by MK-801, is presumably caused by accumulation of endogenous Glu at NMDA receptors. Based on these and related findings, we propose that there may be a period during human ontogenesis when NMDA receptors are hypersensitive, rendering neurons hypervulnerable to the excitotoxicity of endogenous Glu, and that during this period, relatively minor disturbances in Glu homeostasis (e.g., due to hypoxia/ischemia, hypoglycemia, epilepsy, etc.) might cause brain damage that NMDA antagonists can prevent. Supported by RSA MH 38894 (JWO) and HD 24237.

POTASSIUM CYANIDE-INDUCED RELEASE OF GLUTAMATE FROM BRAIN SLICES: IMPLICATIONS FOR TOXICITY. M.N. Patel*, B.K. Ardelt*, G.K.W. Yim and G.E. Isom*. Dept. of Pharmacol. & Toxicol., Sch. of Pharm., Purdue U., W. Lafayette, IN 47907.

KCN produces a rapid onset of convulsions, tremors and subsequent generation of brain lesions. These manifestations are similar to those produced following activation of the glutamate excitotoxic transmitter system by acute brain hypoxia. Hence the interaction of KCN with the brain glutamate system was studied. Endogenous glutamate release from mouse cortical and hippocampal slices was monitored continuously through an enzyme-linked assay by fluorescence spectroscopy. Both a Ca-dependent and independent release of glutamate was evoked by KCN and KCl. In Ca^{+2} media, KCN (2mM), caused a release of glutamate from cortical (0.460μM/g/min.) and from hippocampal slices (0.708μM/g/min.) In EGTA-media it released 0.621μM/g/min glutamate from cortical slices and 0.577μM/g/min glutamate from hippocampal slices. Diltiazem (10^{-5}M), a Ca^{+2} channel blocker inhibited the KCN-induced Ca-dependent release of glutamate. It is concluded that KCN activates the glutamate excitotransmitter system in part by a calcium dependent process and these effects may contribute to the central actions of KCN. Additionally, the method employed to measure glutamate release gives a quantitative assessment of the different endogenous pools of the neurotransmitter in brain slices. (Supported by PHS Grant ES04140).

CYSTEINE PROTECTS BASAL FOREBRAIN CHOLINERGIC NEURONS FROM IBOTENIC, BUT NOT QUISQUALIC, ACID. G.L. Wenk. Department of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

Ibotenic acid (IBO) may inhibit the exchange of cysteine (CYS) and glutamate in the neuronal membrane. The lack of CYS within the neuron may decrease the formation of glutathione and lead to increased levels of free radicals. The toxicity of excitatory amino acids (EAAs), e.g. IBO and quisqualic (QUIS), may depend upon the formation of free radicals within the neuron. If IBO destroys cells by inhibition of the transfer of CYS into the cell, then excess amounts of extracellular CYS may inhibit the cytotoxicity of IBO. CYS may not prevent the cytotoxicity of other EAAs, e.g. QUIS, that do not affect the CYS-glutamate exchange system. IBO or QUIS, in the presence or absence of CYS, were injected into the basal forebrain of rats. Cortical choline acetyltransferase activity indicated the extent of cholinergic cell loss. The results show that CYS protects basal forebrain cholinergic cells from the cytotoxicity of IBO but not QUIS. These data indicate the extent to which a potential therapeutic intervention, CYS, can alleviate the biochemical and pathological results of excessive amounts of EAAs in the basal forebrain.

307.2

Immature Cortical Neurons in Culture are Uniquely Sensitive to Glutamate Toxicity by Inhibition of Cystine Uptake. T.H. Murphy, R.L. Schnaar, and J.T. Coyle Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore MD 21205.

Using the N18-RE-105 neuroblastoma X retina cell line, we previously demonstrated a mechanism of Ca++-dependent quisqualate (Quis)-type Glu toxicity which involves the inhibition of high-affinity cystine (Cys) uptake leading to glutathione depletion and an accumulation of cellular oxidants (*Neuron* 1989 in press). Similarly, primary cultures of immature cortical neurons (E17; 48-72 h in culture) were killed when exposed to culture medium with reduced Cys, with 50% cell death at 10 μM. Methionine-free medium was nontoxic. Toxicity was apparent within 2-6 h of substituting with low Cys medium. Immunohistochemistry indicated that non-neuronal cells (20% of the population) were less sensitive to Cys depletion. At this developmental stage no cytotoxicity was apparent with continuous exposure to 1 mM NMDA, quinolinate, aspartate, kainate, AMPA, or D-Glu for 24 h (100 μM Cys). However, compounds which significantly inhibit neuronal Cys uptake: Quis, Glu, homocysteate, BOAA, and ibotenate, killed greater than 50% of the neurons present (0.1-1.0 mM). The toxic potencies of Glu, Quis, and homocysteate were inversely proportional to the concentration of Cys in the medium.

Autoradiography of [35S]Cys uptake indicated that neurons and glia transport cystine by different mechanisms. Neurons used a high affinity uptake system which was Quis-sensitive, whereas non-neuronal cells used a low affinity system which was Quis insensitive, but potently blocked by D-Asp and Glu.

Exposure to Glu and homocysteate resulted in a time dependent depletion of cellular glutathione, which rendered cells vulnerable to endogenous oxidants. The centrally acting antioxidant idebenone at (1-3 μM), and vitamin E (30 μM) completely blocked the toxicity attributed to 1 mM Glu exposure.

In immature primary cortical cultures which lack NMDA toxicity, Glu toxicity results from the inhibition of Cys uptake leading to oxidant stress. The marked dependence of immature neurons on the uptake of Cys for viability may suggest a new mechanism of perinatal brain damage related to Glu.

307.3

Actions of Excitatory Amino Acids on Levels of Met-Enkephalin in Rat Brain. B.B. Ruzicka and K. Jhamandas, Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, K7L 3N6

To examine the sensitivity of striatopallidal enkephalinergic neurons to excitatory amino acids (EAA's), the effects of N-methyl-D-aspartate (NMDA) and quisqualic acid (QUIS) on the levels of methionine-enkephalin-like immunoreactivity (ME-i.r.) were evaluated following their focal injection into the right caudate-putamen of male rats. Levels of ME-i.r. were estimated by radioimmunoassay in the caudate-putamen and the globus pallidus 7 days after a single excitotoxin injection. NMDA (51-135 nmoles) produced no significant change in levels of ME-i.r. in the caudate-putamen, but it produced a dose-related (51-102 nmoles) increase in the ipsilateral and contralateral globus pallidus. The peak response, observed at 102 nmoles of NMDA, represented a 300% increase in ME-i.r. above baseline levels. QUIS produced a similar action and was more potent than NMDA. Thus, NMDA and QUIS elevated the levels of ME-i.r. in the terminal region of the enkephalinergic neurons. The functional significance of EAA-induced changes in the globus pallidus is currently under study, but it appears that the response characteristics of enkephalinergic neurons to EAA's differ from those of other striatal neurons.

FURTHER EVIDENCE THAT ACTIVATION OF N-METHYL-D-ASPARTATE (NMDA) RECEPTORS CONTRIBUTES TO METHAMPHETAMINE (METH)-INDUCED DAMAGE TO NIGROSTRIATAL DOPAMINERGIC NEURONS IN MICE. P.K. Sonsalla, W.J. Nicklas, and R.E. Heikkila, Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

The administration of METH to mice results in extensive damage to nigrostriatal dopaminergic nerve terminals as is evidenced by marked decreases in tyrosine hydroxylase activity, the number of dopamine (DA) uptake sites, and in the content of DA and its metabolites in the neostriatum. We previously reported that noncompetitive NMDA receptor antagonists including MK-801, phencyclidine, and ketamine protect against METH-induced damage. We now report that the competitive NMDA receptor antagonists, NPC 12626 (150 mg/kg) and CGS 19755 (80 mg/kg) administered s.c. 15 min prior to each injection of METH (3 or 4 i.p. injections of 10 mg/kg given every 2 h) also provided substantial protection against these METH-induced changes. Moreover, the intrastriatal infusion of NMDA (0.01 to 0.1 μmoles in 1 μl) produced a dose-dependent decrease in neostriatal DA content. In addition, the intrastriatal infusion of NMDA (0.1 μmole) produced a decrease in DA content which was potentiated by the systemic administration of a dose of METH (single s.c.injection, 30 mg/kg) which by itself did not alter DA levels (50% depletion of DA in NMDA plus METH treated mice. These data provide additional evidence which support a role for excitatory amino acids in mediating the toxic actions of METH on dopaminergic neurons in mice.

EXCITOTOXICITY OF N-METHYL-D-ASPARTATE IS MODULATED BY NIGRO-STRIATAL DOPAMINERGIC FIBRES. A.G. Chapman, N. Durmuller*, G.J. Lees* and B.S. Meldrum. Dept. of Neurology, Inst. of Psychiatry, London, SE5 8AF, U.K.

The excitotoxic effect of intrastriatal injection of N-Methyl-D-aspartate (NMDA) 300 nmol in 1.0μl in Wistar rats (wt 400 g) was assessed after 4 days by measurement of glutamic acid decarboxylase (GAD) and choline acetyltransferase (CAT) activity in the striatum. In some rats the nigrostriatal dopaminergic system was lesioned unilaterally by injecting 6-hydroxydopamineHBr (6-OHDA), 36 nmol in 2.0 μl in the substantia nigra, 7 days prior to NMDA injection. Striatal GAD activity was reduced by 79% following NMDA in control rats. A comparable reduction occurred on the non-lesioned side in 6-OHDA injected rats. The fall was only 45% on the lesioned side ($p < 0.01$ vs non-lesioned side).

CAT activity fell 54% after NMDA in unlesioned rats, and by 52% on intact side and 30% on lesioned side in 6-OHDA rats.

The excitotoxicity of NMDA appears to be enhanced by the nigrostriatal pathway. Involvement of excitotoxic mechanisms in ischemic brain damage may explain the protective effect of nigrostriatal lesions in fore-brain ischemia (Globus M.Y.T. et al Neurosci Lett 80:251, 1987).

DOPAMINE-RELATED SUBSTANCE ACTS AS A GLUTAMATERGIC AGONIST. E. Aizenman, W.F. White, R.H. Loring, and P.A. Rosenberg. Department of Neurology, The Children's Hospital and Harvard Medical School, and Department of Pharmacology, Northeastern University, Boston, MA 02115.

A structure-activity study of putative excitatory amino acids agonists (Biscoe et al., *Br. J. Pharmacol.* 58: 373, 1976) showed that 2,4,5-trihydroxyphenylalanine (TOPA, 6-hydroxydopa) and 3,4-dihydroxyphenylalanine (DOPA) had excitatory effects on neurons. Since TOPA was found by Biscoe et al. to be the most potent substance tested among the dopamine-related compounds, we studied the glutamatergic properties of TOPA in a variety of systems. TOPA (50-300 μM) produced excitatory responses in both rat cortical neurons in culture and in the isolated chick retina preparation. Whole-cell voltage-clamped responses to 50 μM TOPA recorded in cortical neurons were almost totally blocked by 10 μM CNQX, but only partially inhibited by 200 μM DL-APV. In binding experiments using the high affinity NMDA antagonist ^{3}H-CGS-19755 as a ligand, the addition of TOPA produced a dose-dependent decrease in binding with an IC_{50} near 20 μM. Finally, a 24 hour exposure of rat cortical cultures to media containing >200 μM TOPA produced extensive neuronal death. These studies suggest that TOPA, or an oxidation product, is a potent glutamatergic agonist, and may be related to an endogenously occurring excitotoxin derived from dopa, dopamine, or a metabolite. Our findings may help explain results from previous reports suggesting a role for dopamine in neurotoxicity (Preston et al., *Brain Res.* 338: 243, 1985; Globus et al., *Neurosci. Lettr.* 80: 251, 1987; Sonsalla et al., *Science* 243: 398, 1989). Supported by #P-30-HD18655 and NS00993.

307.7

NMDA RESPONSES ON HIPPOCAMPAL NEURONS CHANGE AFTER EXPOSURE TO ANOXIA AND HYPOGLYCEMIA. N. Hori*, S. Miyahara*, N. Doe*, Y. Shinoda* and D.O. Carpenter, Kyushu University, Fukuoka, Japan and New York State Department of Health, Albany, NY 12237.

Two to three days after transient forebrain ischemia neurons of rat hippocampus show characteristic changes in response to synaptic activation. Responses become prolonged and of a bursting nature, changes which may be associated with delayed neuronal cell death. We have found similar changes in a more acute preparation. In hippocampal slices we have studied the effects of low O_2 (5%) on the response of CA1 neurons to CA3 stimulation. With this protocal most neurons show a transient hyperpolarization followed by depolarization. Upon return to normal O_2 after 10-12 min the membrane potential recovers but after about 20 min the response to synaptic activation becomes a prolonged burst. This bursting response but not the fast initial excitation is blocked by 10^{-4}M APV, and thus appears to involve NMDA receptors. In other experiments we have examined the effects of low O_2 on ionophoretic responses to quisqualate, GABA and NMDA. Over the same period of time after return to normal O_2 the peak response to a constant ionophoretic application of NMDA increased, often by a factor of two, while quisqualate and GABA responses and membrane resistance did not change. Similar results were obtained with hypoglycemia (3 mM glucose). This preparation may be a good model of delayed neuronal death, and the preliminary observations suggest that anoxic and hypoglycemic insults may cause significant changes in the nature of responses to NMDA.

307.8

PERTURBATIONS OF METABOLISM AND ACUTE EXCITOTOXICITY. G. Zeevalk, S. Olynyk* and W.J. Nicklas. Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

An ex vivo preparation of chick neural retina was used to evaluate the effects of chemically-induced hypoglycemia or hypoxia and its relationship to acute excitotoxicity. Metabolism was evaluated by incubation of embryonic day 13 retina for 30 min with either an inhibitor of glycolysis (Iodoacetate, IOA), or electron transport (Rotenone, KCN), and in the presence or absence of a direct Krebs cycle substrate (pyruvate). The effects of this treatment on tissue ATP and phosphocreatine (PCr) and on lactate were measured enzymatically. Acute excitotoxicity was assessed by histology, by amino acid release, and with the use of antagonists MK-801 and CNQX. Results showed that the embryonic chick retina was very sensitive to hypoglycemia, the consequences of which were a reduction of tissue PCr and ATP which corresponded with a neuropathology exhibiting excitotoxic properties, predominately, but not entirely involving the NMDA receptor. Conversely, neural retina were fairly resistant to electron transport inhibition; ATP and PCr were only slightly reduced and excitotoxic damage could not be elicited except when mM concentrations of KCN were used ($\geq$2.5). Further, the decline in ATP and PCr elicited by IOA could not be prevented by pyruvate addition, suggesting that the reason for resistance to electron transport inhibition is that high energy phosphates are maintained predominately by glycolysis in this embryonic tissue.

CORTICOSTERONE ENDANGERS HIPPOCAMPAL NEURONS VIA THE NMDA-RECEPTOR. M. Armanini, C. Hutchins*, B. Stein, R. Sapolsky. Dept. Biol. Sci., Stanford Univ., Stanford, CA 94305

Corticosterone (CORT) is the rat adrenal hormone released during stress. CORT increases hippocampal vulnerability to excitotoxins, hypoxia-ischemia and metabolic poisons. Since these insults appear to damage via glutamate release and NMDA receptor activation, we examined whether CORT's endangerment might also be via the NMDA receptor. We sought a hippocampal toxin which, itself, does not work via the NMDA receptor, but whose toxicity is exacerbated by CORT; we would then determine if the CORT-induced exacerbation could be subtracted out with an NMDA receptor antagonist.

Rat hippocampi were bilaterally infused with 3-acetylpyridine (3AP), an electron transport uncoupler; one side was co-infused with the NMDA receptor antagonist APV. Damage induced by 220 ug 3AP was blocked by 7.5 ug APV, implying a component of 3AP toxicity mediated by the NMDA receptor. This is likely due to the 3AP-induced energy failure disrupting glutamate reuptake, as shown for other forms of energy depletion. 160 ug 3AP caused damage which was not sensitive to APV. Thus, this dose was used for the subsequent CORT experiment.

Rats were adrenalectomized (AD)Xed) and kept CORT-free 1 week before and after 3AP infusion, or were injected daily with 5mg CORT. The latter produces sustained circulating CORT levels in the range of major stressors. As previously reported, 3AP caused 75% more hippocampal damage in CORT-treated than in ADX rats. However, this CORT exacerbation of damage was entirely eliminated by 60 ug APV. This suggests that CORT endangers hippocampal neurons either by increasing the amount of glutamate reaching the NMDA receptor, and/or by increasing the sensitivity of the post-synaptic neuron to the NMDA receptor activation. The ability of CORT to disrupt glucose transport in hippocampal neurons and glia could potentially bring about either of these routes of dysfunction. Supported by NIH RO1 AG06633.

CALCIUM(Ca^{2+}) REGULATES QUISQUALIC ACID(QA) COUPLED PHOSPHOINOSITIDE(PPI) TURNOVER IN N-METHYL-D-ASPARTATE (NMDA) LESIONED BRAIN OF PERINATAL RATS. C.-K. Chen, F.S. Silverstein, M.V. Johnston. University of Michigan, Ann Arbor, MI 48104 & Johns Hopkins Univ, Baltimore, MD 21205

We previously reported that in NMDA lesioned brain, QA stimulated PPI turnover was enhanced in hippocampus and striatum. To explore the biochemical mechanisms underlying this response, we examined the influence of extracellular calcium levels on QA coupled PPI hydrolysis.

In 7-d-old rats, anesthetized with ether, unilateral intrastriatal injections of NMDA(17nmole/0.5ul) were done; rats were sacrificed 3 d later. QA coupled ^{3}H-IP1 formation was measured in hippocampal and striatal tissue slices prepared from the injected(I) or contralateral(C) hemisphere. ^{3}H-IP1 release was assayed after incubating myo-2-^{3}H-inositol labelled brain slices with QA(10^{-5} M) or carbachol(Carb, 10^{-2} M) for 2 h, in the presence of lithium, in buffers containing Ca^{2+}(2.2mM), without Ca^{2+}-{Ca(-)} or Ca(-) plus EGTA(0.5mM). In the presence of Ca^{2+}, QA coupled ^{3}H-IP1 formation(as % of contralateral basal) was enhanced in lesioned hippocampus(I vs C: 1212±192 vs 516±88, $p<0.05$). Stimulation was further enhanced in the Ca(-) buffer in the injected tissue{Ca(-) vs Ca(+): 1858±140 vs 1212±192, $p<0.05$}. ^{3}H-IP1 release was decreased significantly in Ca(-) plus EGTA(462±69). A similar trend was observed in striatal tissue. In contrast, Carb stimulated PPI turnover was not enhanced in Ca(-) buffer.

Intracellular Ca^{2+} levels have not been measured in NMDA lesioned brain slices, but elevated levels might be expected. These data may reflect improved Ca^{2+} homeostasis in lesioned tissue in Ca(-) buffer or alternatively suggest suppression of release of endogenous neurotransmitters that inhibit QA coupled PPI turnover.

307.11

CALCIUM-INDEPENDENT, NMDA-MEDIATED INJURY IN THE HIPPOCAMPAL SLICE. R.A. Wallis*, M.D. Fairchild*, K.L. Panizzon*, C.G. Wasterlain (SPON:R. Nishimura). Basic Neurophys. Lab., VAMC, Sepulveda, CA 91343 and Depts. of Neurology & Pharmacology and Brain Res. Inst., UCLA Sch. of Med., Los Angeles, CA 90024.

NMDA excitotoxicity is thought to be mediated by the opening of receptor-operated ionic channels resulting in calcium influx. We investigated the ionic dependence of NMDA-mediated cell injury in rat hippocampal slices perfused with artificial cerebrospinal fluid (ACSF) containing (mM) $CaCl_2$, 2.4 or 0; glucose, 4; and saturated with 95%O_2/5%CO_2. The extent of injury was judged by measuring the amplitude of the orthodromic population spike evoked in CA1 by stimulation of Schaeffer collaterals. Exposure to 50 uM NMDA for 40 minutes resulted in the complete loss (0% mean recovery) of the population spike after wash with ACSF. The non-competitive NMDA blocker MK-801 (32 uM) administered prior to NMDA exposure resulted in 89% (SD 2.83) recovery. When NMDA exposure was given in media without added calcium, 30% (SD 6.36) recovery was observed. NMDA exposure with MK-801 in media without added calcium, yielded 87% (SD 7.57) recovery. These data suggest the existence of a calcium-independent component of NMDA-mediated excitotoxicity in the hippocampal slice.

307.12

TIME COURSE OF NMDA-INDUCED DAMAGE AND RESULTING INFLAMMATORY RESPONSE IN RAT HIPPOCAMPUS. P.C.Harrison*, G.J.Patel*, N.Haynes*, L.Andrews*, R.E.Donaghy*, and L. G.Letts* (SPON: R. Anderson). Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT. 06877.

Excitatory amino acids have been demonstrated to produce neuronal degeneration in mammalian CNS tissue (Foster et al., *Neuroscience Let.*, 76:307, 1987). Extent of neuronal damage and time course of the inflammatory response following unilateral stereotaxic administration of NMDA (20 nm) into rat hippocampus was examined. Neuronal damage alone was assessed in perfusion fixed, frozen, cresyl violet stained sections. Both neuronal damage and inflammation were assessed in immersion fixed, paraffin-embedded, H&E stained sections. In frozen sections, acute unilateral hippocampal necrosis of the CA 1 and CA 3 regions appeared at 6 hr and was maximal between 30-48 hr post-NMDA (n=4/time point). In paraffin sections, a similar course of neuronal damage was observed followed by a localized inflammatory response consisting of a rapid increase in number of macrophages, capillaries and astrocytes beginning at 48 hr and peaking between 48-96 hr post-NMDA (n=4-6/time point). Neutrophils appeared to be a minor component of the NMDA-induced inflammatory response in contrast to what is known in models of stroke and CNS ischemia. Thus, injection of NMDA into rat hippocampus elicits neuronal damage and an inflammatory response which may differ from that associated with stroke and other disease states.

307.13

SELECTIVE ANTAGONISM OF EXCITATORY AMINO ACID EFFECTS ON STARTLE AND FIGURE-8 MAZE ACTIVITY IN MICE. J. Tizzano, D. Helton*, R. Tamura*, and J. Buelke-Sam. Tox. Div., Lilly Research Labs, Eli Lilly & Co., Greenfield, IN 46140.

Previously, it has been shown that the excitatory amino acids, N-methyl-D-aspartate (NMDA), L-glutamic acid (GLU), and L-aspartic acid (ASP) exhibit proconvulsive activity in the mouse maximal electroshock model (MES). Pretreatment with either a competitive (AP-4) or noncompetitive (MK-801) antagonist blocked the proconvulsive actions of NMDA and ASP but enhanced GLU proconvulsive activity. This study evaluated the interactions of effects produced by NMDA (1.56, 3.12, 6.25 mg/kg), GLU (250, 500, 1000 mg/kg), ASP (250, 500, 1000 mg/kg), alone or in combination with AP-4 (6.25, 12.5 mg/kg) or MK-801 (0.01, 0.10 mg/kg) on 1-hr activity or auditory and tactile startle. Male CD-1 mice (10/group) were injected ip 15 min prior to testing. Startle was measured in automated SDI chambers. Each 50-trial startle session was initiated with a 5-min adaptation period at a background noise level of 70 dBA, followed by alternating 5-trial blocks of auditory (120 dBA noise) and tactile (20 psi air puff) stimuli presented at 8-sec intervals. Activity was not altered by treatment. NMDA, AP-4, MK-801, and NMDA+MK-801 did not alter startle amplitudes compared to controls. NMDA(1.56)+AP-4 decreased auditory and tactile startle. GLU and ASP alone produced dose-related decreases in startle; however, only the decreases produced by GLU(250) were reversed by pretreatment with AP-4 or MK-801.

307.14

CHANGES IN MUSCARINIC ACETYLCHOLINE RECEPTOR DIFFERENTIAL BINDING IN RAT BRAIN AFTER MONOSODIUM GLUTAMATE TREATMENT. C. Beas-Zárate*, R. Schliebs*, A. Morales-Villagrán* and A. Feria-Velasco. Fac. Ciencias, Univ. Guadalajara; Paul Flechsig Inst. for Brain Res., Karl Marx Univ., Leipzig, G.D.R.; and Unidad Inv. Biomed. Occte., I.M.S.S. Guadalajara, Jal. MEXICO.

Systemic administration of monosodium L-glutamate (MSG) to rats results in neuronal degeneration in various brain regions and induces convulsions which might provide a useful model for studying partial status epilepticus of multifocal origin and general convulsive disorders. In a previous work it was shown that MSG-induced convulsions affect catecholaminergic neurotransmission in both, cerebral cortex and caudate nucleus of the adult rat. The present work was designed to reveal a possible involvement also of cholinergic mechanisms in MSG-induced convulsions. Because neurotransmitter receptors respond highly sensitive to changed neuronal activity at the synaptic level, muscarinic acetylcholine receptor binding using ^{3}H-quinuclidinyl benzilate (^{3}H-QNB) as radioligand, was applied as a biochemical marker. ^{3}H-QNB binding was measured in frontal, motor, and visual cortex, in caudate nucleus (CN) and hippocampus of rats treated with MSG. No alterations in receptor binding in either of the regions studied were found in adult rats which received a single dose of MSG. Repeated administration of MSG to adult rats for 4 days resulted in slight decreases of ^{3}H-QNB binding in the frontal cortex and CN as compared to control values. In contrast, neonatal MSG treatment led to a considerable increase in ^{3}H-QNB binding in CN, already detectable at the age of 7 days, persisting until adulthood. Data suggest that MSG-induced convulsions in adult rats, hardly affect cholinergic transmission in cerebral cortex, CN or hippocampus, while neonatal application of MSG has striking effects on the development of the cholinergic system, at least in the CN.

MONOSODIUM GLUTAMATE TOXICITY IS MASKED BY "ENRICHED" HOUSING ENVIRONMENT. K. Fisher*, J. Kleim*, R. Lloyd* and M. J. Saari, Neuroscience Research Unit, Nipissing University College, North Bay, Ontario. P1B 8L7.

We have recently demonstrated that neonatal monosodium glutamate (MSG) administration to male rat pups causes a severe performance deficit in the Morris water maze (Soc. Neurosci. Abstr., 14(2), 885, 1988). We have also shown that this deficit is partially masked by an "enriched" post-weaning housing environment. In two separate experiments we examined whether pre-weaning handling, like "enriched" housing, also protects against MSG induced behaviour deficits. Enrichment was found to significantly improve performance of the MSG treated in the Barne's maze, a recently developed task of spatial learning for rats, while pre-weaning handling did not. The platform dominance task also revealed the same pattern of behavioural results. We conclude that, unlike an "enriched" post-weaning environment, pre-weaning handling does not mask behavioural deficits induced by neonatal MSG administration. EXCITOTOXIC AMINOACIDS TOXICITY TO NERVE TERMINALS: MORPHOLOGICAL VS FUNCTIONAL ASPECT OF DEGENERATION. T. Moriizumi*, M. Takada and T. Hattori, (SPON: N. Miki), Dept. of Anatomy, Univ. of Toronto, Toronto, Ontario, M5S 1A8, Canada.

Fine structural analysis of the rat striatum injected with various excitotoxins unequivocally revealed axonal/terminal degeneration far too serious to be attributed only to damage of interneuronal populations. This led us to reinvestigate the feasibility of the so called axon-or terminal-sparing properties of these excitotoxins. Four to 28 days after an injection of either kainic acid (5 nmol) or quinolinic acid (200 nmol) into the striatum, nigrostriatal dopamine terminals were examined at injection sites by tyrosine hydroxylase (TH) immunohistochemical and 5-hydroxydopamine (5-OHDA) uptake studies. Injections of either toxin produced marked dilations of intensely TH-positive terminals with tremendous amounts of vacuoles. One hour after an intrastriatal injection of 5-OHDA, many labeled vesicles were clearly detectable in terminals which underwent dark type degeneration. These results indicate that both synthetic and uptake machineries of neurotransmitters could be retained in fine structurally defined degenerating terminals, and biochemical and retrograde tracing studies alone are not sufficient enough to claim that axons and terminals can be spared by toxic effects of these excitotoxins. Supported by the MRC of Canada.

307.17

CHARACTERIZATION OF CELL DEGENERATION, BLOOD-BRAIN BARRIER DISRUPTION AND BRAIN GLYCOGEN DEPOSITION FOLLOWING INTRAPERITONEAL ADMINISTRATION OF KAINIC ACID. S.A.L. Bennett*, Wm. Staines[1], and D.C.S. Roberts (SPON: G. Fouriezos[2]) Department of Psychology, Carleton University, Ottawa, Ont., K1S-5B6; [1] Department of Anatomy, [2] Department of Psychology, University of Ottawa, Ottawa, Ont., K1H-8M5.

Neuronal degeneration, blood-brain barrier (BBB) disruption, and glycogen deposition were correlated with kainic acid-induced (KA; 10 mg/kg) seizure activity using immunohistochemical and histochemical staining methods. Animals exhibiting loss of postural control, rearing, foaming at the mouth, and generalized limbic seizures were perfused at 2, 3, 4, 5, 24, and 30 hrs following KA administration. Immunoreactivity for rat IgG, HNK-1, GFAP, and C-Fos, and histochemistry using cresyl violet, PAS-Dimedone, acridine orange, and cytochrome oxidase were carried out on adjacent sections. Chromatolysis and simple neuron atrophy were evident in pyramidal neurons of the hippocampal CA fields, select thalamic and hypothalamic nuclei, specific cortical layers, habenular nucleus, and entorhinal cortex. Neuronal degeneration, in some regions, was anticipated at early time periods by enhanced C-fos immunoreactivity. BBB disruption, determined by the extent of rat IgG leakage into brain tissue, was correlated with regions showing neurodegenerative damage but was also prominent in regions showing no neural lesions. Glycogen depositions were found to surround, but not overlap, regions of marked BBB disruption.

307.18

PROTECTION OF DENTATE HILAR CELLS FROM THE EFFECTS OF PROLONGED AFFERENT STIMULATION BY INTRACELLULAR INJECTION OF A CALCIUM CHELATOR. H.E. Scharfman and P.A. Schwartzkroin. Dept. of Neurological Surgery, RI-20, Univ. of Washington, Seattle, WA 98195.

Prolonged afferent stimulation of rat dentate gyrus *in vivo* leads to degeneration only of those cells that lack parvalbumin and calbindin (CaBP $D_{28}K$) (Olney *et al.*, 1983; Sloviter, 1983, 1987, 1989). To test the hypothesis that calcium binding proteins (CaBPs) play a protective role against the effects of prolonged stimulation, we have recorded intracellularly from cells that lack immunoreactivity for CaBPs (CaBP-negative cells) in the hilus of the fascia dentata of hippocampal slices with microelectrodes containing the calcium chelator BAPTA (200 mM in 4 M KCH_3COOH), and allowed BAPTA to diffuse into the cells. CaBP-negative cells impaled with electrodes without BAPTA showed electrophysiological signs of deterioration during prolonged stimulation, such as depolarization and decrease in input resistance. CaBP-negative cells that were impaled with BAPTA-containing electrodes did not show signs of deterioration. Electrophysiological deterioration of CaBP-negative cells was also prevented by raising extracellular [Mg^{2+}] to 2 mM or by perfusing slices with the NMDA receptor antagonist aminophosphonovaleric acid (DL-APV, 100 μM).

These observations suggest that regulation of intracellular levels of free calcium by CaBPs plays a crucial role in protecting cells from calcium-mediated damage, and that differential concentrations of intracellular CaBPs is one factor that determines selective vulnerability of subpopulations of mammalian CNS neurons. Critical rises in intracellular calcium appear to be mediated by NMDA receptors.

ALTERATION OF ACTIVITY AND AMMONIA INHIBITION OF PHOSPHATE-ACTIVATED GLUTAMINASE FROM AGED RAT BRAIN. D.R. Wallace and R. Dawson Jr., College of Pharmacy, University of Florida, Gainesville, Florida 32610.

Phosphate-activated glutaminase (PAG: L-glutamine amidohydrolase, EC 3.5.1.2) is the enzyme responsible for the formation of glutamate and ammonia from the hydrolysis of glutamine. PAG is bound to the inner membrane of the mitochondrial matrix in nerve terminals and is enriched in synaptosomal fractions. The aim of this study was to examine possible age-related alterations in either the activity, or regulation, of PAG. The data indicate a trend towards increased activity in aged rats. Thirty month old rats displayed a higher Km (0.95±0.20 vs. 0.81±0.19mM)when compared to adults, and a higher Vmax (104.00±15.90 vs. 77.00±9.60 nMole/mg/min) when compared to adult rats. There was no age-related difference in phosphate activation, interference by aspartate, or pH optimum, although aged rats had a pH optimum slightly higher than adults. Ammonia concentrations of 100uM-5mM produced a significant ($p<0.02$) reduction in PAG activity in both age groups. At physiological (100-500uM) concentrations of ammonia there was a significant ($p<0.02$) attenuation of inhibition in aged rats when compared to adults. This change in ammonia regulation may be detrimental to the aging brain, resulting in increased production of glutamate and ammonia, both of which are neurotoxic in elevated concentrations.

307.20

U-54494A SELECTIVELY PROTECTS AGAINST KAINATE TOXICITY IN RAT CEREBELLAR GRANULAR CELLS. J.S. Althaus and P.F. VonVoigtlander. Central Nervous System Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

U-54494A (an analogue of the selective kappa opioid agonist U-50488H) is a selective anticonvulsant that lacks the analgesic, sedative and diuretic activity typical of kappa agonists. To understand its mechanism of action, U-54494A was tested as a protectant against excitotoxicity in rat cerebellar granular cells. The basic method used was reported previously (Novelli, A., Brain Research, 451:205, 1988), however we used the uptake of 3H-AIB (a selective system A amino acid uptake substrate) as a measure of cell viability instead of fluorescein diacetate staining. Dose-excitotoxic responses showed that glutamate, kainate and quisqualate were equipotent (LC50 = 3 μM) and that NMDA was 10 times less potent (LC50 = 30 μM). In this paradigm, U-54494A was found to be a selective antagonist of kainate toxicity. The selectivity profiles of other excitatory amino acid antagonists will be presented.

307.21

THE STEREOTAXIC INJECTION OF KAINIC ACID INTO THE STRIATUM OF RATS INDUCES UNCREASED PRODUCTION OF mRNA FOR HEAT SHOCK PROTEIN 70. J.B. Uney P.N. Leigh S. Thomas and B.H. Anderton. Department of Immunology, St George's Hospital Medical School, Cranmer Terrace, London. (SPON: BRA)

We have found that the injection of kainic acid into the striatum causes an increase in the synthesis in mRNA coding for heat shock protein 70 (Uney et al, FEBS Lett., 235:215). We have further shown that C1300 cultured neuroblastoma cells treated with Fe also show an increase in the levels of mRNA to the heat shock protein ubiquitin. This shows that degenerating neurones exhibit a stress response. Therefore the results may be seen to suggest that in human neurodegenerative diseases (eg.Parkinson's and Alzheimer's, where there is labelling of intracellular inclusions with antibodies to ubiquitin) free radical damage and production of heat shock proteins may play a part in the neurodegeneration process.

REGIONAL LOCALIZATION OF RECEPTORS AND NEUROTRANSMITTERS III

308.1

DISTRIBUTION OF GAMMA-AMINOBUTYRIC ACID-LIKE IMMUNOREACTIVE NEURONS IN THE MIDBRAIN PERIAQUEDUCTAL GREY OF THE RAT. J.C. Pearson and V.R. Roettger. Depts. of Anatomy and Physiology and Biophysics, Wright State University, Sch. of Med., Dayton, OH 45435.

Antiserum against GABA-glutaraldehyde-keyhole limpet hemocyanin was used to localize GABA-like immunoreactive (GABA-LI) neuronal somata in the midbrain periaqueductal grey (PAG) of the rat. Rats were intraventricularly colchicinized two days prior to perfusion with 4% paraformaldehyde and 0.5% glutaraldehyde in 0.1M phosphate buffer (pH 6.5). Vibratome sections (50um) were processed by the avidin-biotin-peroxidase method. GABA-LI somata show a heterogeneous distribution pattern within the subdivisions of the PAG. GABA-LI cells are concentrated in the ventral parts of the ventral lateral (VL) and medial (M) subdivisions of the PAG. The dorsal parts of the VL and M subdivisions contain only a few, scattered GABA-LI somata. GABA-LI cell bodies are present in the dorsal and dorsal lateral subdivisions of the PAG, but are fewer in number and more widely scattered when compared to GABA-LI neurons in ventral areas of the PAG. GABA-LI somata are present within the dorsal raphe (DR) and dorsal tegmental nuclei. Measurements of cell body area indicate that GABA-LI somata in the VL and DR are larger than GABA-LI somata in other PAG subdivisions.

308.2

IMMUNOGOLD LOCALIZATION OF PROBABLE GABA-B RECEPTOR SITES BY MONOCLONAL ANTI-BACLOFEN ANTIBODIES. G.R. Holstein, G.P.T. Martinelli*, E.D. Reis* and P. Pasik. Depts. of Neurology, Anatomy & Surgery, Mount Sinai Sch. Med., CUNY, New York, N.Y. 10029.

The immunolocalization of baclofen by the colloidal gold technique was utilized to identify the regional and ultrastructural distribution of potential GABA-B receptor sites. Mouse monoclonal antibodies were raised against the L-enantiomer of gamma-amino-beta-(p-chlorophenyl)butyric acid (baclofen) conjugated to keyhole limpet hemocyanin (KLH) by glutaraldehyde. Two culture supernatants and one ascites generated by monoclonal hybridomas were selected for (a) reactivity against baclofen conjugated to human albumin, (b) binding inhibitability by baclofen-HCl, and (c) lack of reactivity against GABA, histamine and monoethanolamine conjugates to bovine albumin. Pre- and post-embedding immunocytochemical studies were conducted on several structures of the rat brain. Experimental rats received an i.m. injection of the L-enantiomer of baclofen-HCl (5 mg/kg), while control rats received an equal volume of saline. Rats were sacrificed 90 min. later under ether anesthesia by cardiac perfusion. For pre-embedding studies, 50 μm vibratome sections were exposed to the monoclonal antibodies for 16 hr. The sections were further treated with biotinylated goat anti-mouse IgG preabsorbed with normal rat serum, followed by immunogold application using 1 nm gold particles and silver enhancement. Postembedding studies using 15 nm gold particles were performed on serial sections mounted on formvar-coated gold slot grids.

Electron microscopic observations suggest the presence of immunoreactive elements in discrete brain regions of the baclofen-injected rats. Distinct immunogold-labeled elements are present in the molecular layer of cerebellar cortex only in sections from the baclofen-injected animals. Identically processed sections from the uninjected animals showed no immunoreactivity. Also, sections from the baclofen-treated rats incubated in culture medium instead of primary antibody showed no immunostain. Preliminary observations in structures of the basal ganglia and thalamus suggest similar specificity.

Aided by NIH Grants # NS-24656, NS-22953 and NS-11631.

308.3

3D GLIOMA IMAGES USING PERIPHERAL BENZODIAZEPINES-IMPLICATIONS FOR PET

K. Ikezaki*, K.L. Black, S.T. Grafton*, A.W.Toga, and D.P. Becker. Div. of Neurosurgery, Brain Research Institute, Nuclear Medicine and Neuro Imaging Lab. UCLA , Los Angeles, CA 90024

Three dimensional comparison of peripheral benzodiazepine binding and histology in an experimental glial tumor, time course of binding and the effect on binding of labeling a positron emittor to the ligand were studied to evaluate their potential utility in positron emission tomography (PET). Time course studies of ^{3}H-flunitrazepam revealed high densities of peripheral benzodiazepine binding in C6 glioma with a constant tumor/cortex ratio within the first 60 min. Fluorodiazepam had similar ability as diazepam to displace ^{3}H-flunitrazepam binding *in vitro* and ^{3}H-diazepam demonstrated high specific bindings to tumors. However, 3-^{18}F-diazepam did not show high tumor binding. For three dimensional studies, images were generated from thionin stain sections and autoradiograms. ^{3}H-flunitrazepam, was superior in showing normal anatomical structure surrounding the tumor, whereas ^{3}H-PK11195 was superior in revealing high tumor/brain contrast. We conclude that specific peripheral-type ligands may prove more useful in PET in identifying the tumor boarders. However, positron labelling of these ligands can significantly alter binding characteristics, illustrating the necessity for *in vivo* animal binding studies prior to studies in man.

308.4

RADIOTRACER STUDIES IN HUMAN BRAIN WITH AN MRI-REGISTERED DUAL DETECTOR SYSTEM

K.J. Jeffries,* C.A. Tamminga, H.L. Loats, D.F. Wong,* L.T. Young,* H.H. Holcomb, R.F. Dannals,* and H.N. Wagner* (SPON. G. Thaker). Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore, MD 21228; Loats Associates Inc. Westminster, MD; and Johns Hopkins Medical Institutions, Baltimore, MD 21225.

A dual-detector probe makes possible certain positron studies of CNS at much reduced radiation dose and cost. The device consists of two sodium iodide scintillators which detect positron annihilation by coincident detection of 511 keV gamma-ray pairs. The probe lacks the imaging capability of PET, providing instead, a composite measure of activity within a volume of brain tissue. The scintillators, placed on opposite sides of the head, delineate a 5 cm diameter cylinder through the brain. A method using multiple fields-of-view and simultaneous linear equations has been developed in order to increase the specificity of measurements. Studies of the correlation between probe measurements and PET ROI data in humans are currently being carried out in order to test the instrument. In these studies, subjects are scanned with the probe immediately following a PET scan. Multiple studies are performed on each subject with varied doses of neuroleptic drugs. Blockade of ^{11}C-N-methylspiperone binding is used as a measure of occupancy of D-2 receptors in the caudate nuclei by these drugs. Probe measurements of the degree of blockade in specific brain regions are found to be within 5% of PET measurements.

308.5

A MODIFIED EMULSION-COATED COVERSLIP TECHNIQUE FOR COMBINED RECEPTOR AUTORADIOGRAPHY AND HISTOCHEMICAL STAINING OF LARGE TISSUE SECTIONS.

Kenneth J. Rhodes and Douglas L. Rosene. Dept. of Anatomy, Boston Univ. Sch. Med., Boston, MA 02118.

Autoradiograms generated using tritium sensitive films (e.g. Ultrofilm) generally suffer from limited resolution due to the comparatively large size of their silver grains. Furthermore, since the physically separated autoradiogram and underlying tissue section must be manually aligned for analysis, it is difficult to maintain areal and laminar relationships. These two technical problems can be overcome with the coverslip technique (Young and Kuhar, Brain Res., 179:225, 1979) in which an emulsion-coated coverslip is superglued to one end of a slide. This "sandwich" must then be pried open to allow autoradiographic development and subsequent tissue staining. However, chemical reactions near the glued end of the slide are often uneven and exposing the unfixed tissue section to developer interferes with many histological procedures. Thus we modified this technique to obtain high resolution autoradiograms of whole monkey brain sections (50 x 50mm). Sections were cut from two unfixed rhesus monkey brains on a Hacker-Brights cryostat and thaw mounted onto subbed slides. Muscarinic and benzodiazepine receptors were labeled using standard procedures. Glass coverslips (73 x 47mm; Surgipath) were coated with Kodak NTB-2 emulsion and permanently coupled to the microscope slide using a rectangular piece of adhesive-coated 3 mil aluminum foil (Cole Parmer). Using this method the coverslip could swing 180° away from the slide, allowing the coverslip autoradiogram to be developed without having the tissue section contact the harsh photographic chemicals. Similarly, the underlying tissue sections can be fixed and then processed using standard histological and histochemical staining procedures. Subsequently, the autoradiogram is permanently and precisely re-apposed to the tissue with mounting medium. This technique optimizes both autoradiographic and histological procedures so that the distribution of receptor sites can be directly compared with many other markers. (Supported by NIH grants NS19416, AG04321 AND PO1AG00001).

308.6

DIFFERENTIAL QUENCHING BETWEEN FETAL AND ADULT BRAIN IN RECEPTOR AUTORADIOGRAPHY WITH TRITIUM LABELLING.

J.D.E.Barks*, J.Bertlik* (SPON: U.Tuor) Department of Pediatrics, Univ. of Toronto, Toronto General Hospital, The Hospital for Sick Children, Toronto, Ont. M5G 1X8.

The purposes of this study were: (a) determine the need for separate calibration of autoradiography (AR) standards for fetal brain (FB), and (b) determine if white-matter quenching is important in human FB. Pastes were made from (i) whole 20 day Wistar rat FB (ii) dissected adult Wistar rat brains and (iii) dissected fetal (19 wk) and premature infant (33 wk) human brain. Increasing amounts of [3H]-lysine were added to tissue aliquots which were frozen, sectioned and apposed to film. From each aliquot sections were weighed, solubilized and dpm/mg tissue measured.

For rat tissue there was quenching from fetal to adult grey matter (GM) to adult white matter (WM) in plots of optical density (OD) vs tissue concentration (TC), shown by decreasing slope of regression lines ($P<.001$ F vs GM, $P<.001$ GM vs WM). In human FB there was no evidence of quenching between GM and WM. Plots of OD vs TC for human fetal and premature infant brain were best fit by quadratic equations and their 95% confidence intervals overlapped.

Conclusion: (a) AR studies of receptor ontogeny must use age-appropriate standards before firm conclusions can be made about maturational decreases in regional receptor expression. (b) Unlike adult brain, WM quenching is not seen in fetal brain.

308.7

LOCALIZATION OF [^{3}H]-L-GLUTAMATE BINDING SITES IN GOLDFISH BRAIN.

R.E. Davis, G.R. Wilmot* and J.J. Cha. Mental Health Research Institute and Neuroscience Program, University of Michigan, Ann Arbor, MI 48104-1687 (USA).

Previous studies have found specific binding sites for excitatory amino acids in membrane fractions of goldfish brain (Francis, A *et al.* [1981] *Brain Res.* **216**, 375; Henley, JM and Oswald, RE [1988] *J. Neurosci.* 8, 2101). For a more detailed anatomical study, we used autoradiography to investigate the distribution of [^{3}H]-L-glutamate ([^{3}H]glu) binding sites in 20 µm frozen sections of goldfish brain.

Binding was most prominent in the molecular layer of the valvula of the cerebellum, nucleus torus lateralis, and the nucleus diffusus and nucleus centralis of the inferior lobe. Moderate binding occurred in the optic tectum, torus semicircularis, and dorsal tegmentum. N-methyl-D-aspartate decreased [^{3}H]glu binding in the torus semicircularis, dorsal tegmentum, and optic tectum other than the fascicular layer of the periventricular grey zone (PGZ-f). In contrast, both kainate and kynurenate blocked binding in PGZ-f but not other layers of the tectum. Kainate and kynurenate also decreased binding in nucleus torus lateralis, nucleus diffusus, and nucleus centralis. Quisqualate strongly displaced [^{3}H]glu binding in the valvula and to a lesser extent in the torus semicircularis, dorsal tegmentum, and layers of the optic tectum superficial to PGZ-f. The nonuniform distribution of specific subtypes of [^{3}H]glu binding sites suggests that excitatory amino acids are widespread neurotransmitters in goldfish brain. (Supported by NIH NRSA 5T32.)

308.8

QUANTITATIVE AUTORADIOGRAPHY REVEALS NMDA RECEPTOR-COUPLED CHANNELS ARE LOCATED POSTSYNAPTICALLY.

J.W. Bekenstein, E.W. Lothman, G.F. Wooten, and J.P. Bennett, Jr., Dept. Neurology, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

In vitro quantitative autoradiography with [^{3}H]MK-801 was used to determine K_d and B_{max} values for the NMDA receptor-coupled channel in subregions of the rat hippocampal formation. A single form of the channel with an apparent K_d in the 15-20 nM range was found for [^{3}H]MK-801 binding in the presence of both 1 µM glutamate and 1 µM glycine. Specific binding was highest in the molecular layer of the dentate gyrus, followed by CA1 stratum radiatum and CA1 stratum oriens. Fewer binding sites were observed in the hilus of the dentate gyrus, cerebral cortex, CA1 stratum pyramidale, CA3 subregion (stratum oriens, stratum pyramidale, stratum radiatum), and thalamus. Selective destruction of dentate granule cells by colchicine microinjections reduced the number of [^{3}H]MK-801 binding sites by 40-60% in the molecular layer of the dentate, compared to intact tissue. [^{3}H]MK-801 binding did not change in other hippocampal subregions as a consequence of colchicine injection. Electrolytic entorhinal cortical lesions produced no changes in regional MK-801 binding site density in any of the regions under study. More detailed analysis revealed no change in the number of MK-801 binding sites per unit length of dendrite in the molecular layer of the dentate gyrus. These findings indicate that NMDA receptor-coupled channels are confined to a postsynaptic location in the adult rat hippocampus, with the highest concentration on dentate granule cells.

308.9

Distribution and ultrastructure of glycine-immunoreactive (GLY-ir) terminals in the rat dorsal vagal complex (DVC). L. Modarressi*, W.T. Talman and M.D. Cassell.* (Spon. H. Damasio) Depts. of Neurol. and Anat., Univ. of Iowa, Iowa City, IA 52242.

Microinjections of glycine into the rat DVC produce site-specific changes in blood pressure and heart rate. The distribution of GLY receptors in this region has been described, yet there is little information available concerning the regional distribution of endogenous GLY-containing terminals in the dorsal medulla. We have therefore examined the distribution and ultrastructure of GLY-terminals in the DVC using a specific anti-glycine antibody (gift of R. Wenthold, NINCDS). Serial 10 μm sections through the brainstem were obtained from 8 adult Sprague-Dawley rat brains fixed with 3% glutaraldehyde/0.5% paraformaldehyde. Binding of anti-glycine was detected using avidin-PAP immunocytochemistry. GLY-ir terminals were present in all subdivisions of the DVC except the dorsolateral part of the nucleus tractus solitarius (NTS) and the dorsal vagal motor nucleus. High densities of GLY-ir terminals were additionally present in the gracile, cuneate and hypoglossal nuclei. The highest densities of GLY-ir terminals in the DVC were found in the ventrolateral and intermediate subnuclei of the NTS, with low to moderate densities in the medial, commissural and interstitital subnuclei. Ultrastructurally GLY-ir terminals formed mainly axo-dendritic contacts, usually without pre- or post-synaptic densities. Two forms of GLY-ir terminals were observed: one type containing large spherical vesicles, the other containing densely packed pleomorphic vesicles. The presence of glycine terminals within the medial, ventrolateral and commissural subnuclei - all of which are related to cardiac, chemo- and baroreceptor afferents - is consistent with a role for glycine in medullary cardiovascular reflexes. (Support: VA Merit Review, HL32205, HL14388, NS24261).

LEARNING AND MEMORY: PHYSIOLOGY III

309.1

PINEAL AND LEARNING: EFFECTS OF BOTH IMPLANTATION AND REMOTION OF PINEAL GLAND ON PASSIVE AVOIDANCE TASK. G. G. Cobos-Zapiaín,* E. B. Naranjo-Rodríguez* and B. Barrera Mera. (SPON: Solano-Flores LP), ENEP. Iztacala, U.N.A.M. & Departamento de Fisiología, Facultad de Medicina,U.N.A.M. México, D. F.

This experiment examined the effect on memory of pnealectomy, and of a second pineal gland implanted on the brain. Under nembutal anesthesia rats, were surgically intervened. These animals were allowed 21 days to recover from the surgical procedures befores trainingwas initiated. A group of intact rats was also studied. Rats were trained with a footshock (0.2 in a 5 sec) in a one-trail inhibitory (passive) avoidance task. On a retention test 24 hours after training, animals with pinealectomy had retention performance which was not significantly different than that of control animals.

Rats with a second pineal gland implanted on the brain were impaired on retention performance as compared with the former groups (p's < 0.05). These findings indicate that implanting a second pineal gland interferes with memory processes.

309.2

CELIAC GANGLION LESIONS BLOCK THE MEMORY-IMPROVING EFFECTS OF POST-TRAINING GLUCOSE AND FOOT-SHOCK Norman M. White, Claude Messier and Barry Connell, Department of Psychology, McGill University, 1205 Dr. Penfield Ave, Montreal, Quebec, Canada, H3A 1B1

Previous experiments have demonstrated that post-training consumption of sucrose or injection of glucose (2g/Kg) improve retention in several memory tasks. The finding that fructose, a sugar that does not enter the brain, improves retention at the same doses as glucose suggests that this effect may be peripherally mediated. Previous experiments also suggest that the effect is not mediated by insulin or by the adrenal medulla. In the present experiments we found that lesions of the celiac ganglion, through which passes most of the sympathetic and parasympathetic innervation of the liver, eliminated the memory-improving action of post-training glucose injections on memory for a conditioned emotional response (CER). We have also shown that post-training foot-shock, a stressful event, one of the sequelae of which is an increase in blood glucose, improves memory. In the present experiment we found that lesions of the celiac ganglion also eliminate the effect of post-training foot-shock on memory for a CER. These findings suggest that some glucose-related function of the liver may initiate a neural signal which acts in some as yet unknown way on a memory substrate in the brain. This mechanism may mediate the effects on memory of a wide variety of normally occurring events.

309.3

AMYGDALA LESIONS PRODUCES DISRUPTION OF CONDITIONED TASTE AVERSIONS THROUGH DECREASED GASTRIC ACID CONCENTRATION. S. Alvarez*, G. Ortiz*, and F. Bermúdez-Rattoni (SPON: R. Salceda). Instituto de Fisiología Celular, UNAM, Apdo. Postal 70-600, 04510 México, D.F.

Several studies have shown, that permanent lesions of amygdala disrupt conditioned taste aversions (CTA) induced by a variety of unconditioned stimuli, such as lithium chloride and cupper sulfate. Other authors have reported that amygdala stimulation produces gastric ulcers and significant increments on gastric acid concentration (GAC). In the present study we assess the role that GAC by amygdala electrolytical lesions have on the acquisition of CTA. Two groups of rats; one with amygdala lesions and other of unoperated controls were trained in a CTA procedure. On the acquisition day animals received .1% of saccharin followed by i.p.injection LiCl(190 mg/kg). Two days later the saccharin was presented again and the volume consumption was measured. After the test trial animals were rapidly killed and the gastric pH was determined. Result showed that lesioned animals did not acquire the CTA and their GAC were significantly decreased as compared with the controls ($t=8.7; p < 0.001$). In addition, similar results were obtained when the GAC was decreased through an i.p. injection of 100 mg/kg of cimetidine (histamine H2 blocker receptor); i.e. blockade of CTA and enhanced gastric pH. These results suggest that the GAC plays an important role on the acquisition of CTA.

309.4

THE 5-HT_{1A} AGONIST, 8-OH-DPAT PREVENTS THE EXPRESSION BUT NOT THE DEVELOPMENT OF A CONDITIONED TASTE AVERSION. G.A. Hunter, G.P. Mark and B.G. Hoebel. Department of Psychology, Princeton University, Princeton, NJ 08544-1010

This experiment examined the involvement of serotonin (5-HT) in the development and expression of a conditioned taste aversion (CTA). Twenty-four male, Sprague-Dawley rats were subjected to a CTA paradigm in which the taste of 2.5 mM sodium saccharin (conditioned stimulus, CS) was paired with lithium chloride-induced malaise. Control animals received the same saccharin taste followed by saline injections. During conditioning, one group (A) was pretreated with 8-OH-DPAT (75 mg/kg, i.p.) 15 min prior to saccharin exposure and saline on the test day. A second group (B) received saline during conditioning and 8-OH-DPAT before testing. Development of the taste aversion was unaffected by 8-OH-DPAT pretreatment (group A). However, subjects in group B exhibited a pronounced attenuation of the CTA. The results suggest serotonergic involvement in the expression but not the learning of a conditioned taste aversion.

Supported by USPHS grant DA-03597.

CONDITIONED TASTE AVERSION REVERSES DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS. G.P. Mark, D.S. Blander* and B.G. Hoebel. Department of Psychology, Princeton University, Princeton, NJ 08544-1010

Extracellular dopamine (DA) as measured by microdialysis, has previously been shown to be increased in the nucleus accumbens (NAC) following ingestion of food, water or salt and by pharmacological means, e.g. local nicotine, cocaine and amphetamine administration. This suggests that accumbens DA release is related to the reward value of a stimulus. If so, stimuli with aversive qualities may attenuate DA release. To test this hypothesis, the microdialysis technique was used to determine the extent to which DA output in the NAC could be manipulated by development of a conditioned taste aversion (CTA) in which the taste of intraorally infused saccharin was paired with LiCl-induced malaise. Small but statistically reliable *increases* (26%, $p<0.05$) in DA were observed when animals tasted saccharin for the first time. After CTA, the same dose of infused saccharin caused a 50% *decrease* in accumbens DA ($p<0.05$). This effect was absent in pseudo-conditioned controls. These results suggest that the positive and negative reinforcement effects of a taste stimulus may involve increased and decreased mesolimbic DA output, respectively.

CONDITIONED RESPONSES TO INSULIN IN MAN. G. Fehm-Wolfsdorf, U. Beermann*, H. L. Fehm*. Depts. of Medical Psychology and Internal Medicine I, University of Ulm, D 7900 Ulm, F.R.G.

Classically conditioned changes in blood glucose levels have been repeatedly demonstrated. Till now the direction of the conditioned response is not clarified. Flaherty et al. (Physiol. Behav., 33: 587, 1984) described conditioned hypoglycemia as well as hyperglycemia depending on the nature of the CS. Eikelboom & Stewart (Psychol. Rev.,. 89: 507, 1982) have argued that direct vs. indirect central nervous system effects of insulin could lead to opposite peripheral physiological changes, and the temporal relationships between the drug effects and CS exposure may be decisive for direction of CR. We studied 24 male volunters in a differential conditioning procedure. Injection of 0.04 I.U./kg body weight of insulin or saline served as the UCS, two different odours were the CS. Sequence and combinations of the different UCS and CS were totally counterbalanced across subjects during four days. Insulin injections provided marked hypoglycemia which, however, was not always noticed by the subject. During the course of hypoglycemia mood state and cognitive performance of the subjects were checked. Levels of endogenous free cortisol were repeatedly measured to rule out a conditioned stress response as a mediator of blood glucose changes. Blood glucose levels on test day five did ot differ between CS^+ and CS^- groups, i. e. no differential conditioning was obtained, possibly due to unclear temporal S-R relationships.

EXTINCTION OF A CLASSICALLY CONDITIONED ODOR PREFERENCE IN INFANT RATS: NEUROBEHAVIORAL CONSEQUENCES. Regina M. Sullivan and Donald A. Wilson. Developmental Psychobiology Laboratory, Dept. Psychology, University of Oklahoma, Norman OK 73019.

The preweanling rat olfactory bulb demonstrates a modified response to odors which have acquired value through classical conditioning. The present study examined how these learning-associated neural changes are influenced by extinction of the conditioned behavioral response.

Wistar pups received daily conditioning sessions from PN1-PN17. Experimental pups received daily 10 min, forward pairings of odor and tactile stimulation (Odor-Stroke). Control pups received daily random presentations of odor and stroking (Random) from PN1-PN17. On PN18-PN19, half of the pups from each training condition underwent extinction which consisted of 10 min exposures to odor without stroking, 3 times each day. ON PN20, all pups were tested for response in one of two tests: behavioral preference in a two-odor Y-maze or olfactory bulb 2-DG uptake in response to the conditioned odor.

The results of the behavior test suggest that odor preferences classically conditioned early in life can be extinquished. Work currently in progress is assessing the neural consequences in the olfactory bulb of behavioral extinction. (supported by NS26100 to RMS and BNS8606786 to DAW)

OLFACTORY CLASSICAL CONDITIONING IN INFANT RATS WITH MEDIAL FOREBRAIN BUNDLE STIMULATION AS UCS: NEUROBEHAVIORAL CONSEQUENCES. Donald A. Wilson and Regina M. Sullivan. Developmental Psychobiology Laboratory, Dept. Psychology, University of Oklahoma, Norman OK 73019.

Early olfactory learning can induce a long-term change in olfactory bulb function. A major difficulty in the search for neural mechanisms of this change has been the diverse nature of the UCS. The present study examined the possibility of avoiding this problem by using medial forebrain bundle (MFB) stimulation as the UCS.

On PN12, Wistar rat pups had bipolar stimulating electrodes chronically implanted unilaterally in the MFB, under Ketaset/Rompun anesthesia. One hour after recovery from anesthesia (3-4 hr post-implant), experimental pups received 50 forward pairings of odor (5 sec) and MFB stimulation (300 ms, 200 Hz), with an ITI of 30-60 sec. Control pups received 50 random presentations of odor and MFB stimulation. On PN13, pups were either given a two-odor choice test or tested for olfactory bulb 2-DG uptake in response to the conditioned odor.

The results of the behavior test suggest that an odor preference can be classically conditioned using MFB stimulation as the UCS. Work currently in progress will determine the effects of this conditioning on olfactory bulb function.

COMPARISON OF LEARNING ABILITIES IN INBRED AND RECOMBINANT INBRED STRAINS OF MICE. M. Le Moal, J.L. Martinez, Jr., C. Berman*, and G.F. Koob (SPON: R. Emeson). INSERM Unite 259, Bordeaux, France; University California, Berkeley, CA 94720; Research Institute of Scripps Clinic, La Jolla, CA 92037

Acquisition of a one way active avoidance and an operant appetitive task was characterized in inbred mice as a prelude to studying the molecular basis of learning. The current used as the unconditioned stimulus (UCS) for active avoidance was the amount needed to cause 75% of the mice to jump in a flinch/jump test. Forty-five trials were given over 5 days . The rank ordering of learning in inbred mice as measured by mean number of avoidances was as follows: 1) DBA/2J and C57L/J. 2) AKR/J, and 3) C57BL/6J. The performance of BXD recombinant inbred mice did not indicate that the differences observed between the C57BL/6J and the DBA/2J was due to a single-gene mode of inheritance. In the operant task, animals were required to make a spatially discriminated nose-poke for a food reward on a fixed ratio 2 schedule in a 10 min training session for 8 days. The total number of rewards received differed between the C57BL/6J and DBA/2J with the C57 being superior. Here, four recombinant strains (BXD-8, -15, -18, -24) were like the C57, while one (BXD-30) was like the DBA progenitor. This strain distribution pattern is consistent with a single-gene mode of inheritance. These strain differences may reflect basic differences in learning but differences in motivation cannot yet be ruled out as an explanation. (Supported by NS 20912).

SELECTIVE LOSS OF HIPPOCAMPAL CA1 CELLS CAUSES DEFICIT IN PLACE NAVIGATION BUT NOT IN T-MAZE ALTERNATION IN RATS

M. Carli* and R. Samanin.* (sponsored by M.Tacconi)
Dept. Neuropharmacology, "Mario Negri" Institute, 20157 Milan, Italy

It is not known whether selective damage to hippocampal CA1 field, a region particularly affected by cerebral ischemia, disrupts spatial and/or working memory. To get information on this issue, a selective loss of pyramidal CA1 cells was obtained by injecting bilaterally 5µ/1µl (30nM) quinolinic acid (QUIN) into the stratum radiatum of the dorsal hippocampus in rats. Ten days after QUIN injection, lesioned, sham operated and intact animals were required to learn the spatial location of a hidden platform in the Morris swim maze. Lesioned rats were impaired in learning the place task, particularly at the beginning of the training period. When lesioned animals reached an escape latency similar to controls (19 days post-lesion), they showed a severe impairment in the transfer test. Cue learning in the water maze was not significantly affected by QUIN treatment.

Separate groups of animals with QUIN induced-lesion of the pyramidal CA1 cells, tested ten days after surgery as in the previous experiments, showed no impairment in learning response alternation in a T-maze.

The results suggest that rats with selective loss of hippocampal CA1 cells are impaired in learning a spatial task but are able to learn a non-spatial test of working memory.

RADIAL-ARM MAZE DEFICITS IN RATS WITH VESTIBULAR DYSFUNCTION FOLLOWING INTRATYMPANIC INJECTIONS OF SODIUM ARSANILATE. E.L. Hargreaves and K.-P. Ossenkopp. Dept. Psychology, Univ. of Western Ontario, London, Ontario, CANADA N6A 5C2.

Vestibular dysfunction was induced in Long-Evans rats by intratympanic injections of sodium arsanilate (atoxyl). Following a 1 week recovery period the animals were tested for labyrinthine integrity and their spontaneous locomotor behavior was analyzed (See: Ossenkopp, Prkacin & Hargreaves, this Volume).

Following this procedure the animals were reduced to 85% of their normal body weight. They were then run on an eight-arm radial maze over a period of 10 days (1 trial/day). Each arm of the maze was baited with a single sunflower seed, such that an optimal foraging strategy would dictate every arm to be entered only once, during a single trial.

Results indicated that the animals with vestibular dysfunction exhibited specific maze-running patterns such as more sequential re-entry of arms ($p=.01$) and less response stereotypy (sequential entry of adjacent arms) ($p=.02$). They did not show improvements on the learning measure of number of arms entered to complete the maze. They did however, show improvements on the measure of running-time ($p=.03$). These improvements may be accounted for by a gradual decrease in stress related behaviors, which disinhibits a characteristic hyperactivity (See: Ossenkopp et al., Above). Overall the animals with vestibular dysfunction show a deficit in performing the radial-arm maze. (Supported by NSERC).

QUANTAL ANALYSIS OF SYNAPTIC STRENGTH AND SHORT-TERM FACILITATION AT HIPPOCAMPAL CA1 SYNAPSES T. C. Foster and B. L. McNaughton. Department of Psychology, University of Colorado, Boulder, CO 80303.

Intracellular EPSPs were evoked in CA1 pyramidal cells either by the discharge of isolated CA3 cell spikes (SP) or by minimal stimulation of Schaffer afferents (MS). Quantal parameters ($m,n, p, v1$) of the response distribution were compared for paired pulse facilitation. At least 150 response pairs (50 msec ISI) were collected and noise deconvolution used to find the optimal quantal parameters of the response distributions. Most (SP: 7/9; MS 14/14) could be described by Poisson or binomial statistics at $P < .01$. Mean EPSP size (SP: 218 mV; MS: 244 mV) and quantal parameters for SP and the MS conditioning responses were not significantly different (means SP: $m = 1.17$, $n = 5.1$, $p = 0.23$, $v1 = 225$ mV; MS: $m = 0.98$ $n = 5.6$, $p = 0.18$, $v1 = 274$ mV). Mean EPSP amplitude was significantly correlated with m values but not with $v1$. Statistical comparisons confirmed ($P < .01$) that MS facilitation (206 $\pm$ 64%) resulted from increased release probability ($p = 0.33 \pm 0.14$). We conclude that 1) responses to minimal stimulation are drawn from a population with the same characteristics as the spike triggered responses; 2) transmission at this synapse can be described by Poisson or binomial statistics; 3) the 5-fold range of differences in mean synaptic efficacy between synapses (under these conditions) is due to differences in m and not $v1$; 4) facilitation is largely due to increased probability of transmitter release. RECOVERY OF SPATIAL LEARNING FOLLOWING DECAY OF EXPERIMENTAL SATURATION OF LTE AT PERFORANT PATH SYNAPSES. C. A. Castro, L. H. Silbert*, B. L. McNaughton, and C. A. Barnes, Department of Psychology, University of Colorado, Boulder, CO 80309.

Long-term enhancement (LTE/LTP) of hippocampal synapses is viewed by many to represent the underlying mechanism for storage of spatial information. Saturation of the LTE mechanism at perforant path synapses was previously shown to be accompanied by a severe deficit in the acquisition of spatial information (McNaughton et al., J. Neurosci 6:563-571, 1986). While this was consistent with conceptual models of distributed associative memory (McNaughton and Morris, TINS 10:408-415, 1987), the caveat could still be raised that the behavioral effect may have been due to some secondary effect of the stimulation, rather than to the saturation of LTE *per se*. Experimentally-induced LTE in the fascia dentata is not permanent, but decays with a time constant of one to several weeks (depending on stimulus parameters and other variables). Thus, if the learning impairment is actually an effect of the LTE saturation, then spatial learning should recover as LTE decays. Two groups of animals were implanted bilaterally with perforant path stimulating electrodes and electrodes for recording the synaptic and postsynaptic field responses in FD. One group (HF) received 14 days of high-frequency stimulation which produced a 50% increase in the field EPSP and a 150% increase in the population spike. The other group (LF) received only low-frequency stimulation. Both groups were then tested in the Morris water-pool task. While the LF group was able to use spatial cues to locate the escape platform, the HF group was completely unable to do so, showing no differential quadrant search during probe trials in which the submerged platform was removed. Neither group was impaired in escaping to a visible platform. Following the recovery of the field EPSP and population spike back to baseline (17 days after the last HF stimulation), the HF group was now just as proficient in using spatial cues to locate the escape platform as the LF group. The responses of the LF group remained stationary throughout the decay of LTE in the HF group, indicating that the decay was not an artifact of deterioration of the recording situation. These findings support the view that it is indeed the saturation of the synaptic connections produced by LTE that interferes with the acquisition of spatial information. DIFFERENTIAL TIMECOURSES OF EPSP AND POPULATION SPIKE GROWTH IN RAT FASCIA DENTATA RESULTING FROM SPATIALLY COMPLEX HOUSING. L. H. Silbert*, C. A. Castro, C. A. Barnes, and B. L. McNaughton (Spon: C. E. Dixon) Dept. Psychology, Univ Colorado Boulder, CO 80309.

Previous studies from this laboratory have demonstrated persistent changes in perforant path evoked field potentials in the fascia dentata resulting from prolonged exposure of normally cage-housed animals to complex spatial environments (Sharp et al , Br. Res.,1985; Sharp et al., Exp. Aging Res., 1987). A substantial increase in the population spike component developed gradually over several days of this treatment. Changes in the epsp component were smaller and apparently less reliable. The spike increments persisted, with gradual decay following termination of the enrichment treatment. In the present studies, we have used daily recording and a larger sample size to gain a better understanding of the quantitative relationship between the epsp and population spike changes. Nineteen hemispheres from 11 animals were studied in the complex housing group and compared to 9 hemispheres from 5 control animals. Responses were collected daily between 0900 and 1100. After 5 days of baseline recording, during which both groups remained singly cage-housed, the experimental group was transferred daily between the hours of 1700 and 0730 to large (0.8 m sq) plexiglas boxes filled with junk objects which were rearranged and/or changed daily. Both epsp and population spike exhibited significant progressive growth over the first five days, reaching asymptotes of 16% and 55%, respectively. Interestingly, over the next five days of complex housing, the epsp increments decayed back to baseline, whereas the spike increments persisted. This suggests that at least two independent physiological processes are activated by complex housing and reemphasizes the point that population spike measures alone are not good indices of *synaptic* plasticity. LONG-TERM ENHANCEMENT DOES NOT PRODUCE A CHANGE IN THE SPONTANEOUS FIRING RATE OF DENTATE GYRUS BASKET AND GRANULE CELLS. L. L. Chen, B. L. McNaughton, and S. J. Y. Mizumori. Department of Psychology, University of Colorado, Boulder, CO 80309

The relationship between the spontaneous firing of dentate gyrus granule and basket cells and induction of long-term enhancement (LTE/LTP) was studied in Nembutal-anesthetized rats. Identification of basket and granule cells was based upon the paired-pulse synaptic inhibition test described by Mizumori et al. (1989). The main differences between electrophysiologically defined granule and basket cells were that the latter were not inhibited during inhibition of the population spike, were activated by perforant path stimulation at short latency and at intensities below the threshold for a population spike, discharged multiple spikes, and showed high spontaneous firing rates. Stereotrode recording (McNaughton et al, 1983) of spontaneous unit activity was collected for 10 min before and 10 min after high-frequency perforant path stimulation. Eleven granule cells and 24 basket cells were recorded from 22 rats. High-frequency stimulation of the perforant path increased the EPSP slope (33.7% $\pm$ 2.7%) and population spike amplitude. Of those tested, 11/21 basket cells and 5/6 of granule cells showed a reduced threshold to perforant-path activation following high frequency stimulation (in agreement with Buszaki et al.,1982). However, apart from an occasional very transient (<1 min) elevation, there was no statistically significant change in the mean spontaneous rate of either granule or basket cells measured in the presence of LTE. These apparently contradictory results lead to the suggestion that the entorhinal cortical layer II cells of origin of the perforant path have very low spontaneous rates under these conditions and contribute little to the average spontaneous activity of dentate neurons. It remains to be determined whether the same is the case in conscious animals. Supported by Grant NS-20331 to B. L. M. and AG-05375 to S. J. Y. M.

EFFECTS OF MEDIAL SEPTAL LESIONS ON EXPLORATION-RELATED SYNAPTIC EFFICACY INCREASES IN RAT FASCIA DENTATA. E. J. Green, B. L. McNaughton, and C. A. Barnes. Department of Psychology, University of Colorado, Boulder, CO 80309.

Exploratory behavior in rats is accompanied by several moderately persistent alterations in the components of perforant path evoked synaptic responses in the fascia dentata (Sharp et al.,1989; Green et. al, 1989). These include a substantial increase in population EPSPs, and a decrease in both the amplitude and onset latency of population spikes. These changes have a gradual onset and decay, and long outlast exploration and its associated hippocampal theta activity. Thus, they are distinguished from the momentary "gating" effects of behavioral state described by Winson and colleagues. Neither locomotion nor hippocampal theta activity is sufficient to produce these efficacy changes, an observation consistent with the possibility that the effects are related to alterations in spatial sensory input.

The foregoing data, together with evidence indicating that an intact septo-hippocampal pathway is necessary for efficient performance of certain spatial tasks, prompted us to assess exploration-related alterations in perforant path evoked synaptic responses prior and subsequent to lesioning the medial septum. Transportation of animals from their home environment to a different location was accompanied by: 1) an increase in the incidence of exploratory behavior (and EEG theta), 2) substantial (20-70%) elevation in the initial slope of the field EPSPs, and 3) reduction in spike amplitudes and latencies to spike onset. Electrolytic lesions of the medial septum/diagonal band sufficient to attenuate theta rhythm severely or to abolish it were made through an indwelling septal electrode. Preliminary results indicate that these lesions were not sufficient to prevent the exploration dependent response changes (peak EPSP growth pre-lesion: 44 $\pm$ 5.5 %, post-lesion: 35 $\pm$ 3.3%). These results further dissociate hippocampal theta activity from the synaptic alterations associated with exploration and suggest that the information critical for such changes does not depend exclusively upon neural pathways which originate in or pass through the medial septal region. A COMPARISON OF PLACE AND CUE LEARNING FOLLOWING REVERSIBLE INACTIVATION OF THE MEDIAL SEPTUM. S. J. Y. Mizumori, G. M. Perez, M. C. Alvarado, C. A. Barnes, and B. L. McNaughton, Dept. Psych., Univ. Colo., Boulder, CO 80309.

Injection of a local anesthetic (tetracaine) into the medial septum produces a reversible working memory deficit in rats performing a radial maze task (Mizumori et al., *J. Neurosci.*, in press). During this period of behavioral impairment, the hippocampal θ-rhythm is abolished, CA3 place fields are disrupted, and the specificity of CA1 place fields remains unchanged. The purpose of the present experiment was to: 1) examine whether this behavioral deficit involved disruption of acquisition, maintenance, or retrieval aspects of spatial information processing, and 2) determine the extent to which the performance deficit was uniquely spatial.

Fischer 344 rats (9 mo old; n=8) were trained to perform one standard working memory trial daily on an 8-arm radial maze. A 30-min delay was interposed between choices 4 and 5. The first four (forced) choices comprised the sample phase of the experiment, while (free) choices made after the delay constituted test responses. When rats achieved criterion performance, bilateral hippocampal EEG electrodes and a medial septal guide cannula were implanted. Tetracaine injection into the septum (0.5 μL) reduced the θ-rhythm for about 20 min. When tetracaine was injected either before the sample phase or just before the test phase, a significant increase in errors was observed during the test phase ($p<.02$). Saline injections, or tetracaine given at the beginning of the delay, had no effect on choice accuracy. These findings indicate that normal cellular activity in the septohippocampal system is required for accurate acquisition and retrieval, but not maintenance, of spatial information. This suggests that this information is stored as a distribution of synaptic weights rather than as specific patterns of neural activity. The same rats were subsequently trained to perform a nonspatial task on the radial maze by selecting one of eight distinct (intramaze) cues presented simultaneously. The identity of the correct goal cue remained constant across days but varied in its spatial location from trial to trial. The rats performed four trials per day. Preliminary results (n=2, *thus far*) indicate that tetracaine-treated rats readily learn new nonspatial information when hippocampal θ is absent. That place, but apparently not cue, learning was disrupted by septal inactivation is consistent with the hypothesis that this treatment does produce a selective, rather than general, learning deficit. Supported by Grants AG-05375, AG-03376, and NS-20331.

309.18

A COMPARISON OF "THETA-ON" AND "THETA-OFF" CELLS RECORDED IN THE RAT HIPPOCAMPAL FORMATION DURING RADIAL MAZE PERFORMANCE. B. L. McNaughton, S. J. Y. Mizumori, C. A. Barnes, Dept. Psych, Univ Colorado, Boulder, CO 80309.

Most hippocampal formation single units in freely behaving rats fall into one of two categories (Ranck '73). CS cells have low average firing rates and sometimes fire complex spikes when the hippocampal EEG exhibits large irregular activity (LIA) associated with awake immobility. Theta (θ) cells fire simple spikes, have higher mean rates, and show substantially increased firing in phase with the EEG θ rhythm associated with Vanderwolf's Type I behaviors (e.g., walking, exploration). CS and θ cells almost certainly correspond to pyramidal and basket cells respectively (Fox and Ranck '75). CS cells are usually highly spatially selective (O'Keefe and Dostrovsky '71), whereas spatial selectivity of θ cells, while demonstrable, is marginal at best (McNaughton,Barnes and O'Keefe '83); Colom and Bland ('87) described, in urethane anaesthetized animals, a class of non-CS cell which was inactive in the presence of EEG θ and discharged continuously during LIA. They called these "θ-off" cells and used the term "θ-on" to refer to the classical "θ" cell. Others (e.g , Fox and Ranck '75, Buzsaki et al '83) have reported occasional encounters with such cells (which they called "anti-θ" cells) in conscious animals. We have studied the behavioral correlates of 14 θ-off cells encountered in CA1 (1), Hilus FD (4), Subiculum (6), and Entorhinal Cortex (3). Mean rates for θ-on and θ-off were 8.7 Hz and 6.5 Hz, respectively. Maximum rates were 114 Hz and 104 Hz, respectively. Some cells of *both* types showed 6-8 Hz modulation. Whereas firing rate for θ-on cells increased smoothly with running velocity, it decreased smoothly for θ-off cells. Whereas no θ-on cell exhibited clear spatial selectivity, two θ-off cells (in FD) did. When EEG θ rhythm was temporarily abolished by local injection of tetracaine into the medial septum (Mizumori et al '87), a θ-off cell was observed to fire continuously at high rate irrespective of behavior, with a pronounced 18-20 Hz rhythmic modulation. Under these circumstances, θ-on cells decrease their rates. Possible candidates for θ-off cells are the parvalbumen negative GABA interneurons (Kosaka et al '87) or those containing somatostatin (Kohler and Chan-Palay '82; Bakst et al '86). COMPACT SPATIAL REPRESENTATIONS ARE FORMED IN HIPPOCAMPUS BUT NOT PASSED BACK TO CORTEX. C. A. Barnes, B. L. McNaughton, S. J. Y. Mizumori, B. W. Leonard, L.- H. Lin*. Department of Psychology, University of Colorado, Boulder, CO 80309.

Pyramidal cells in the CA1 and CA3 subfields of the rodent hippocampus exhibit a remarkable selectivity for both location and (in most environments) orientation of the animal in space (O'Keefe, 1976). This study addresses the questions of whether this compact spatial representation is constructed in the hippocampus itself, and whether it is passed on to other cortical structures via the return pathway through the subiculum. Accordingly, single units were studied in 34 rats using the stereotrode method, in entorhinal cortex (n = 44), hippocampal subfields CA3 (n = 220) and CA1 (n = 121), and the subiculum (n = 194), while rats performed on a radial 8-arm maze for chocolate milk reinforcement. Based on a measure of the tendency of firing to be restricted to one maze arm, entorhinal units exhibited little if any spatial specificity (mean specificity index = 1.94; a score of 1 indicates no specificity by this measure). As found in many other studies, hippocampal cells were highly specific, with CA3 exhibiting significantly more specificity than CA1 cells (mean specificity index CA3 = 7.45, CA1 = 4.33). This strongly suggests that spatial specificity is constructed in hippocampus from relatively unspecific inputs (a finding supporting Quirk and Ranck, 1986, Soc. Neurosci. Abst). Surprisingly, subicular cells also exhibited little if any spatial specificity by this measure (mean = 1.53), although some indication of a dispersed but consistent specificity was found in some cells. This suggests that sparsely coded, highly localized spatial representations are necessary for some operations performed within the hippocampus itself (e.g., efficient event storage) and that the information is recoded into a much more distributed form before transmission back to other cortical areas. Supported by AG-03376 and NS-20331.

RESPONSIVENESS TO GLUTAMATE IS STABLE WITH AGE IN RAT HIPPOCAMPUS. G. Rao, C. A. Barnes, and B. L. McNaughton. Dept. of Psychology, Univ. of Colo., Boulder, CO 80309.

Age-related changes in rat hippocampal formation include a partial deafferentation of the dentate gyrus and a presumably compensatory increase in excitability of senescent hippocampal pyramidal and granule cells. Changes in basal neurotransmitter release and mitochondrial uptake have also been reported in aging brain. In this context, we investigated whether the sensitivity of hippocampal CA1 and dentate granule cells to glutamate applied iontophoretically near the cell body remains stable or changes with age. Slices were taken from a young (8 mo) and an old (27 mo) F344 rat each day (n=8 animals in each age group) to counterbalance any variability in the preparation. Recording pipettes (6-8 m tips) were filled with a .2 M glutamate in slice Ringer's solution. Units between 400-600 mV were recorded in stratum pyramidale and the granule cell layer (n=20: old CA1, 198 yg Ca1, 197 old FD, 193 yg FD). Glutamate application consisted of an ascending series of current pulses (10 sec off, 5 sec on) of amplitudes 0, 2, 4, 6, and 8 nA. The series was delivered 4 times, with a 30 second delay in between. No significant difference in unit firing rate to glutamate at any current amplitude was detected between the old and the young groups in either CA1 or FD. At least to the extent that it can be assessed at the level of the cell body, glutamate sensitivity appears to be neither enhanced nor compromised in senescent hippocampus. Supported by AG-03376 to C.A.B.

POST-MORTEM RECOVERY AND VIABILITY OF CENTRAL NERVOUS SYSTEM TISSUE SUBSEQUENTLY MAINTAINED IN VITRO. B.W. Leonard, C.A. Barnes, G. Rao, J. Meltzer, & B.L. McNaughton. Dept. of Psychology, Behavioral Neuroscience Area, Univ. Colorado, Boulder 80309.

The influence of post-mortem delay on the recovery and viability of in vitro brain slices has not been systematically studied. To explore the feasibility of gaining meaningful data about pre-mortem electrophysiological function from tissue that is not immediately available upon death, we have examined the effects of post-mortem delay on evoked field potentials in the in vitro rat hippocampal slice preparation. Brains were kept in situ at room temperature for delays of zero (n=1), 30 (n=7) or 120 min (n=4) before dissection and slicing of the tissue. Using standard in vitro conditions, tissue viability was assessed by recording Schaffer-collateral evoked field potentials in the CA1 pyramidal layer at 2, 4, and 8 hr after slicing. At 8 hr the percentage of slices displaying responses with the zero or 120 min post-mortem delay was 50% and 33%, respectively. At a fixed constant current stimulus the average spike amplitude of viable slices in these conditions was 16.6 mV and 8.2 mV, respectively. These results indicate that the processes responsible for the maintenance of electrochemical gradients across neuronal membranes can recover from a period of severe anoxia when the tissue is subsequently maintained in vitro , and suggests that meaningful information about synaptic and cellular function may be inferred from brain tissue available only at relatively long post-mortem delays. Supported by AG-03376.

Potentials recorded 8 hrs. after 30, or 120 min. post-mortem delays.

A SIMPLE MODEL FOR HIPPOCAMPAL PLACE CELLS IN WHICH DIRECTIONAL TUNING OF PLACE FIELDS DEPENDS ON ENVIRONMENTAL COMPLEXITY. W. E Skaggs and B. L. McNaughton, Dept Psychology, Univ Colorado, Boulder, CO 80309.

Many cells in the rat hippocampus are "place cells," firing preferentially when the animal is in a particular small portion of the space available to it. The "place fields" of these cells can appear on first exposure of the animal to the preferred location in an environment. They vary widely in size and shape, and in susceptibility to manipulations of the environment. We have programmed a simple computer model of place cells, using two layers of units. The units of the input layer form a value-coded representation of selected features of the environment as seen by the animal. The units of the second layer each receive randomly weighted excitation from the first layer, and are subject to a variable "inhibition" such that only the five receiving the most input become active (fewer if less than five exceed a predetermined threshold). These second layer units exhibit the sort of spatially localized firing characteristic of hippocampal place cells. As in the hippocampus, some units fail to be active at all in a given environment, and the sizes and shapes of the place fields vary widely.

With certain plausible but unproven assumptions, the model is capable of reproducing an apparently perplexing effect. On a radial eight-arm maze, the firing of place cells depends strongly on the direction the animal faces [McNaughton et al ,1983]; in a small grey cylinder in which the only "polarizing" cue is a single white card covering 100° on the wall the directional dependence of place fields is very much weaker [Bostock, Taube, and Muller, 1988]. Reasoning that the difference may arise from the greater complexity of the radial-maze environment, we set up the model so that the input layer contains 110 units, 22 associated with each of five "objects." The activity of each input unit depends either on the distance or on the direction from the animal to the associated object; also a unit becomes inactive if its object drops out of the animal's roughly 300° visual field. When only the two objects representing the edges of the cue card are present, the directional tuning of place cells is very broad. When all five objects are present and widely scattered, the directional dependence becomes much stronger. Although these results are preliminary, they do suggest that the differences in directional tuning of place cells in different environments may plausibly be explained in terms of environmental complexity without having to invoke the concept of place cells representing points in some abstract coordinate framework. HEBBIAN SYNAPSES AS CROSS-CORRELATION FUNCTIONS IN DELAY LINE CIRCUITRY. D. C. Tam[1] and T. A. McMullen*[2]. Dept. of Physiology and Biophysics, University of California[1], Irvine, CA 92717 and Dept. of Biomedical Engineering, Boston University[2], Boston, MA 02215.

Hebbian learning has long been proposed to be a plausible mechanism for synaptic plasticity. Artificial neural networks using the Hebbian rule have exhibited some aspects of learning. Analysis of the mathematical operation performed by Hebbian synapses in such networks indicates that for continuous signals the synaptic weight after learning has occurred is a representation of the cross-correlation between the input and output signals. Therefore, during learning, the synapse computes the correlation between input and output signals by accumulating weight changes. When the input signal is time shifted by τ, along a delay line, the final weight of the synapse represents the value of the cross-correlation coefficient at lag time τ. When the input and output are discrete time series such as spike trains, the final synaptic weight represents the probability, estimated from the learning sequence, that the output neuron fires at time lag $\tau = k - \Delta t$ after the input neuron has fired. The final synaptic weight is given by:

$$w(k\Delta t, n\Delta t) = w(k\Delta t, 0) + \sum_{h=1}^{n} x(h\Delta t - k\Delta t)\, y(h\Delta t) \quad (1)$$

where $w(k\Delta t, n\Delta t)$ is the synaptic weight at lag time $k\Delta t$ after n learning steps, $y(h\Delta t)$ is the output at time $h\Delta t$ and $x(h\Delta t - k\Delta t)$ is the input, time shifted by $k\Delta t$. It can be shown that the correlation coefficient is given by:

$$R(k\Delta t) = \lim_{\Delta t \to 0} \lim_{n \to \infty} [w(k\Delta t, n\Delta t) - w(k\Delta t, 0)]/n. \quad (2)$$

Equation (1) can be generalized such that x and y are replaced by x_i and x_j, any two inputs to the same target neuron. The operation of correlation may occur during learning or development in structures with delay line architecture such as cerebellar cortex, hippocampus and dorsal cochlear nucleus.

EPILEPSY: KINDLING II

310.1

MK-801 IS NEUROPROTECTIVE, BUT NOT ANTICONVULSIVE, DURING PILOCARPINE-FACILITATED STATUS EPILEPTICUS IN KINDLED RATS. G.M. Hudson* and G. G. Buterbaugh. (SPON: J.W. Ferkany). Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201.

Male amygdala kindled rats were subjected to 3 hours of pilocarpine facilitated status epilepticus (SE). Rats were treated with MK-801 (1 mg/kg i.p.; N=7) or vehicle (V; N=5) after 10 min of SE. In V treated rats, power spectral analysis of neocortical EEG revealed a 60 - 65% decrease in mean frequency (MF) and 97% edge frequency (EF) after 3 hrs of SE. Two weeks later, severe bilateral neuropathology was found in thalamic and septal regions, substantia nigra reticulata (SNr), amygdala, posterior & ventral hippocampus and entorhinal, piriform and frontal cortices. In MK-801 treated rats, MF and EF decreased by 20% and 21%, respectively, during the 3 hrs of SE. Neuropathology was limited to thalamic regions and the SNr. Rats treated with MK-801 (0.5 mg/kg; N=3) showed additional mild damage within entorhinal and piriform cortices. In ventral hippocampal kindled rats (N=3), similar MK-801 protection against SE-induced brain damage was found in spite of high-frequency spiking activity induced by MK-801 in the ventral hippocampus. These results demonstrate neuroprotective effects of MK-801 during prolonged SE and suggest that seizure mechanisms may be dissociated from mechanisms of seizure-induced brain damage in some brain regions. (Supported by PHS Z SO7 RR 05770)

310.2

STATUS EPILEPTICUS INDUCED NEUROPATHOLOGY RELATED TO KINDLING SITE AND DURATION OF STATUS. G. G. Buterbaugh and G. M. Hudson*. Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201.

Rats were kindled by daily stimulation of the piriform cortex, frontal neocortex, ventral hippocampus (VH) or dorsal hippocampus (DH) and subjected to 3 hours of pilocarpine facilitated status epilepticus (SE). Two weeks later, a bilateral pattern of damage was found within thalamic, septal, amygdala, substantia nigra reticulata (SNr), and posterior & ventral hippocampal regions. Mild to moderate bilateral cell loss was also observed within the entorhinal and piriform cortices. Rats kindled by amygdala (Am) stimulation and subjected to 2-3 hours of SE showed a similar qualitative regional pattern of damage with the exception of a more regionally extensive bilateral pattern of near complete degeneration of much of the entorhinal and piriform cortices. DH kindled rats surviving up to 6 hrs of SE showed damage similar to Am kindled rats after 2-3 hrs of SE. Moreover, four distinct kindling-site dependent patterns of SNr damage were observed ranging from blade necrosis (AM and DH) to "ring" necrosis (VH). These results suggest that the focal origin of kindled epileptogenesis is a determinant of susceptibility to seizure-induced damage within some brain regions. In particular, amygdala kindling results in a greater sensitivity to damage within paliolimbic structures. (Supported by PHS Z SO7 RR 05770 and NS 20670)

310.3

PHARMACOLOGICAL ALTERATION OF 2-DG UPTAKE DURING STATUS EPILEPTICUS. B.E. Jones and G.G. Buterbaugh. Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201.

The uptake of 2-DG was used to study the relative sensitivity of brain regions to anticonvulsant drugs during pilocarpine facilitated status epilepticus (SE) in amygdala kindled rats. Pentobarbital (Pent) or diazepam (Dz) were administered after 10 min of SE, followed within 10 min by [^{14}C]2-DG (100 uCi/kg; iv); rats were decapitated 45 min later and brains rapidly removed and frozen sectioned for contact autoradiography. Pent (18 mg/kg; iv) produced marked behavioral depression and suppression of EEG discharge in the neocortex and hippocampus, but not the amygdala. Uptake of 2-DG was decreased in all regions except the amygdala and piriform and entorhinal cortices. Pent (9 mg/kg; iv) had little effect on behavior, EEG or 2-DG uptake. Dz (4 mg/kg; iv) resulted in marked behavioral depression and little change in EEG seizure discharge. However, 2-DG uptake was selectively and bilaterally decreased in parietal cortex and the entire extent of the hippocampal formation. Diazepam (1 mg/kg; iv) had little effect on behavior, EEG discharge or 2-DG uptake. These results indicate that the amygdala and piriform-entorhinal cortices are relatively resistant to drug effects during SE and suggest that 2-DG uptake may not be a reliable index of seizure activity. Additional drugs are being studied to further assess this possibility.

310.4

ROLE OF ADENOSINE IN LIMITING STATUS EPILEPTICUS ENTRY AND SEVERITY IN THE ELECTROGENIC LIMBIC STATUS MODEL. D.M. Treiman* and A. Handforth (Spon: K. Syndulko) VAMC Wadsworth, Dept. of Neurology, ULCA, Los Angeles, CA 90024

In a limbic model of status epilepticus (SE) amygdala stimulation induces continuous spiking associated with exploratory behavior. Functional mapping studies indicate that the anatomic substrate is usually unilateral extensive limbic (Handforth, A. and Ackermann, RF, Brain Res 460:94, 1988). We hypothesized that an endogenous adenosine mechanism limits SE entry and severity. Rats had intracerebral electrodes implanted in both amygdalae and epidural electrodes over frontal and parietal cortex. In blinded experiments saline, 2-chloroadenosine (2CA, 20mg/kg), or aminophylline (AP, 100 mg/kg), 7/group, was given IP 15 min prior to stimulation of left amygdala with successive 5 min sessions of current; 15 sessions without achieving 5 min of post-current spiking constituted failure to enter SE. All saline animals entered exploratory SE, whereas entry was blocked or delayed by 2CA. AP accelerated SE entry and the resulting SE was generalized convulsive. In preliminary experiments, these treatments were administered after subjects had already entered SE (3/group). Whereas saline subjects remained in exploratory SE, AP resulted in worsening to generalized convulsive SE, and 2CA resulted in sedation with partial or complete spiking suppression. These results support a role for adenosine in limiting status entry and severity.

310.5

STRUCTURAL DAMAGE OF THE BRAIN TRIGGERS KINDLING AND SPONTANEOUSLY RECURRENT SEIZURES. E.A. Cavalheiro†, J.P. Leite†, Z.A. Bortolotto†, W.A. Turski, C. Ikonomidou† and L. Turski. Department of Neurology and Neurosurgery, Laboratory of Experimental Neurology, Escola Paulista de Medicina, Sao Paulo, SP, Brazil and Department of Pharmacology, Medical School, Lublin, Poland.

Structural damage of the human brain may lead to chronic epilepsy in survivors. Epidemiologic analyses show that a considerable time-delay occurs between the exposition of the brain to injury and the appearance of seizures. Such seizures are usually partial or mixed in type, may develop at any age, and are difficult to treat. We now show that in adult male Wistar rats, 240-280 g in weight, subjected to structural damage of the brain induced by means of sustained convulsions triggered by systemic administration of a cholinergic agent pilocarpine HCl (380 mg/kg; ip), spontaneous seizures may develop after a mean latency of 14-15 days. The mean number of spontaneously recurrent convulsions remains constant for several months. The evolution of such seizures proceeds through several electrographic and behavioural stages resembling kindling. Kindling may be otherwise induced in rodents by repeated systemic administration of convulsants or by repeated electrical stimulation of sensitive brain regions. These observations demonstrate that structural damage of the brain may lead to spontaneously recurrent convulsions (chronic epilepsy) in the rat and that kindling may be engaged in the evolution of such a condition. This finding suggests that kindling mechanisms underlie the development of epileptic foci from structural brain lesions. Such mechanisms may be involved in the etiology of some forms of epilepsy in humans. Supported by CNPCT, FAPESP, FEP and Polish Academy of Sciences.

310.6

SPATIO-TEMPORAL MAPPING OF CORTICAL EEG DURING AMYGDALOID ELECTRICAL KINDLING IN THE CAT. R. Fernández-Mas* A. Fernández-Guardiola, A. Martínez*, L. Rocha* and R. Gutiérrez. Instituto Mexicano de Psiquiatría, México 14370 D.F.

Time- and frequency-domain topographic maps of the EEG activity of frontal, parietal, temporal and occipital cortices were daily computed during amygdaloid kindling. A 16 epidural electrode array (matrix) was used in 4 cats, two implanted in the left amygdala and two in the right one. The EEG maps were obtained using a specifically designed program (RBEAM). Sixteen-channel EEG ink recordings, the stimulated amygdala activity and the behavioral responses were sampled and stored. The frequency-domain (FFT) maps computed for specific high EEG frequency bands (8-16Hz) revealed a clear pattern of ipsilateral ectosylvian and contralateral frontal high spectral density areas during behavioral stages 2-4. Stages 5 and 6 were characterized by parieto-rolandic and ectosylvian contralateral propagation. The historial layout (time-domain mapping) of the cortical projection of isolated AM/AD spikes, that was computed for a specific AD latency and during different behavioral stages, also showed the contralateral propagation of ectosylvian ADs to the frontal lobe.

RBEAM allows the averaging of several AD maps during Kindling, showing the constancy of the contralateral frontal focus, expressed in terms of a standard deviation.

310.7

KINDLING ANTAGONISM IS AGE SPECIFIC. K. Haas* and E.F. Sperber (SPON: S.L. Moshé). Depts. of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY

Burchfiel et al have demonstrated that, in adult rats, stimulations alternating between two limbic sites suppress the development of kindling in one or both sites. We report kindling antagonism is an age-specific phenomenom not present early in life.

Adult rats and 16 day old rats received alternating stimulations between amygdala and hippocampus. Another group of pups was stimulated at one site - either amygdala or hippocampus. Adults were stimulated three times daily while the pups were stimulated every 20 minutes.

Six adult rats kindled only from the amygdala. In two adults mutual suppression occured. The suppression of generalized motor components of kindled seizures was not due to lack of afterdischarges (ADs) since stimulation of the suppressed sites produced ADs as long as the ADs from kindled sites.

In pups alternating stimulations did not lead to suppression of kindled seizures from either site. Furthermore there was no difference in the total number of stimulations required for the completion of kindling compared to controls.

Our results in the adult continue the original observations of Burchfiel et al. The lack of kindling antagonism in rat pups may underly the propensity of the immature CNS to develop multifocal seizures.

310.8

SUBREGIONAL CHANGES IN HIPPOCAMPAL THYROTROPIN-RELEASING HORMONE (TRH) AFTER AMYGDALOID KINDLING IN RATS. S.M. Knoblach*, S. Durbin*, and M.J. Kubek. Indiana Univ. & VA Medical Centers, Indianapolis, IN 46223.

We have previously shown that hippocampal TRH levels are increased after kindling. To examine TRH increases at the subregional level, we kindled rats with a 200 ua, 1 msec pulse daily, until five successive Stage 5 seizures occurred. Later, animals were stimulated once and killed either 24 or 48 h afterward. Hippocampi were dissected into dorsal and ventral CA1, CA3, CA4/Hilus (CA4), Dentate (D) and Subiculum (S) subregions, frozen, extracted, and analyzed via specific TRH radioimmunoassay.

Baseline TRH content (pg/mg wet wt) in ventral subregions was: CA3, 4.17 +/-0.76; CA1, 3.24 +/-0.21; D, 1.93 +/-0.36; S, 1.66 +/-0.22; CA4, 1.39 +/-0.15. In dorsal subregions, TRH content was: CA3, 2.09 +/-0.37; CA1, 1.31 +/-0.24; D, 1.11 +/-0.16; S 0.95 +/-0.16; CA4, 3.57 +/-0.86. TRH levels 24 h after convulsion were significantly increased in ventral subregions: CA4 22x, D 9x, CA3 4x, CA1, S, 3x. TRH content was also significantly increased in dorsal subregions: D 18x, CA4 10x, CA3 8x, CA1 4x. Values for the 48 h timepoint were not significantly different from those at 24 h. This report is the first to show subregional changes in hippocampal TRH after kindled convulsion. We suggest that the large increase in CA4 and D represent changes in intrinsic TRH synthesis stimulated mainly by perforant path input, and note that the degree of TRH increase observed in the various subregions parallels the sequence of the hippocampal transsynaptic loop. Supported by VA and NIH NS-25661 (MJK).

310.9

EFFECT OF A 12 WEEK INTERVAL ON PERMANENCE OF 'PARTIAL' AND 'FULL' KINDLING. Z. Dennison, G.C. Teskey and D.P. Cain, Dept. Psychology, University of Western Ontario, London, Ontario, CANADA.

Kindling is considered a permanent change, and animals kindled to a stage 5 seizure are often referred to as 'fully' kindled, while animals kindled to a lesser stage are referred to as 'partially' kindled. We were interested in examining the implications of this distinction by comparing the permanence of electrographic and behavioral development due to amygdala kindling between rats kindled to stage 3 (unilateral convulsion) and rats kindled to a stage 5 (bilateral generalized convulsion).

Rats were implanted with bipolar stimulating-recording electrodes in the amygdala. After kindling to either stage 3 or stage 5, the rats were left in their home cages for 12 weeks and then restimulated. The preliminary results suggest the degree of permanence might not be as great as previously thought. Both duration of afterdischarge and behavioral stage attained had decayed, and a range of 2-7 restimulations were needed to restore the previous behavioral stage. Secondly, approximately equivalent numbers of restimulations between groups indicated that the degree of permanence was similar in 'fully' and 'partially' kindled animals. These terms may be misleading if they are interpreted to mean greater or lesser degrees of permanence.

310.10

SPONTANEOUS HIPPOCAMPAL INTERICTAL SPIKES INDUCED BY LOCAL KINDLING: RELATIONS TO SEIZURES AND PHYSIOLOGY. K. BOON*, E. SZCZUTKOWSKI* AND L. STAN LEUNG(SPON:S. BRUDZYNSKI). DEPT. CLIN. NEUROL. SCI. AND PHYSIOLOGY, UNIV. WESTERN ONTARIO, LONDON, CANADA N6A5A5.

Spontaneous interictal spikes (SISs) were recorded in the hippocampus in freely behaving rats following hippocampal CA1 kindling. SISs emerged after 2-10 daily kindling stimulations, and persisted until behavioral convulsions. However, seizures may be accompanied with a high or low SIS rate. After fully kindled, interruption of kindling for 4-8 days resulted in the decline of SIS rate to near-zero, but seizure susceptibility, as tested by the ability to evoke seizures, remained unchanged. The increase in SIS rate was time-locked to the tetanic stimulation or afterdischarge (AD), after which SIS rate declined with two time constants of approximately 80 min and 1.5 days. The long time constants suggest the participation of some form of long-term potentiation. Preliminary experiments suggest that the increase of SIS rate following an AD was resistant to intraventricular injection of 10-40ug of the NMDA antagonist APV. Supported by NS25383 and NSERC A1037.

310.11

HIPPOCAMPAL MOSSY FIBER ZINC IN WSP AND WSR MICE. D.J. Feller, J.C. Crabbe, D. Tso-Olivas*, C. Meshul, D.D. Savage, Oregon Health Science University and VA Medical Center, Portland, OR 97201, University of New Mexico School of Medicine, Albuquerque NM 87131

Alcohol withdrawal-seizure prone (WSP) and withdrawal-seizure resistant (WSR) mice have been selectively bred for differences in susceptibility to handling-induced convulsions (HIC) during withdrawal from chronic ethanol exposure. The basis for enhanced susceptibility to HIC in WSP mice is unknown. A deficit in hippocampal mossy fiber zinc (HMZ) has been observed in rats with a genetic predisposition to audiogenic seizures. Given this observation, HMZ was measured in naive WSP and WSR mice by quantitative histofluorescence using zinc-TSQ. HMZ was 72% lower in WSP than in WSR mice. Serum, hippocampal and whole brain zinc levels were identical for both lines suggesting that the decrease in mossy fiber zinc was not due to differences in zinc bioavailability. Ultrastructural analysis of mossy fibers in the CA3 region showed higher synaptic vesicle density in WSP compared to WSR mice. These data suggest that WSP mice may be producing more vesicles as a compensatory response to lower HMZ. The reduction in HMZ in WSP mice is a correlated response to selection, suggesting that the mossy fiber zinc deficit may contribute to seizure susceptibility in WSP mice. These studies were supported by Grants AA05828, AA06243, AA06498, NIDA Contract 271-87-8120, AA06548 and RR08139.

310.12

DECREASE IN HIPPOCAMPAL MOSSY FIBER ZINC IN RATS KINDLED TO SPONTANEOUS SEIZURES. DD Savage, D Corwin* and LL Paxton*, Dept. Pharmacol., Univ. New Mexico Sch. Med., Albuquerque, NM, 87131.

We have observed striking reductions in hippocampal formation (HPF) mossy fiber zinc in two different genetic models of epilepsy: 1) the Genetically Epilepsy-Prone (GEPR) rat and 2) the Alcohol Withdrawal Seizure Prone (WSP) mouse. This observation has prompted an investigation of mossy fiber zinc in other animal models of epilepsy. Using a computer-automated kindling system to facilitate the production of rats exhibiting spontaneous seizures, we tested the hypothesis that mossy fiber zinc is decreased in kindling-induced spontaneously epileptic rats.

Male Sprague-Dawley rats received angular bundle kindling stimulations (700 μampere biphasic square wave pulses at 60 Hz for 2 sec.) eight times a day at 3 hour intervals. Stimulations were discontinued after each rat had exhibited a minimum of five spontaneous forelimb clonic motor seizures. Four weeks later, each kindled rat and its matched unstimulated control were sacrificed and their brains frozen. Coronal sections of dorsal HPF and horizontal sections of ventral HPF were collected from ten epileptic and ten control rats. Quantitative zinc:TS-Q histofluorescence, expressed as femtograms zinc/100 μm^2, was measured in HPF CA_3 *stratum lucidum* and adjacent *stratum radiatum*. Specific mossy fiber zinc was defined as the difference in zinc:TS-Q fluorescence between these two regions. Specific mossy fiber zinc was reduced by 55% in dorsal HPF and 62% in ventral HPF of spontaneously epileptic rats compared to the unstimulated controls. This reduction parallels the mossy fiber zinc reductions observed in GEPR rats and WSP mice. This similarity in three different animal models of epilepsy suggests that a decrease in HPF mossy fiber zinc may be a contributing factor in the manifestation of a seizure prone state in epileptic rodents. Alternatively, the mossy fiber zinc reduction may be a consequence of spontaneous epileptic seizure activity. (Supported by NIH-NS23461).

310.13

EFFECT OF AMYGDALA KINDLING ON THE SEIZURE RESPONSE OF THE OLFACTORY BULB AND DORSAL HIPPOCAMPUS. M.E. Kelly, C. Dufresne* and D.C. McIntyre. Psychology Dept., Carleton Univ., Ottawa, Ontario, Canada K1S 5B6.

Previous amygdala kindling affected the dorsal hippocampus by raising its afterdischarge threshold (ADT) and/or shortening its AD duration. Such amygdala pretreatment had no effect on the olfactory bulb ADT, while enhancing its provoked AD and, in most cases, triggering stage-5 seizures. Subsequent 60 min stimulation of the kindled amygdala produced several generalized seizures but no status epilepticus. Twenty-four hours later, brief amygdala stimulation produced neither an electrographic nor behavioural response, while stimulation of the olfactory bulb produced only local AD. On the other hand, dorsal hippocampal stimulation showed increased responsiveness, reflected by lowered ADT's, longer AD durations and, in many cases, full generalized seizures. One week later, the amygdala re-acquired its stage-5 response, as did the olfactory bulb, while the hippocampus regressed to its previous short AD durations with no behavioural responses. These data suggest a facilitative relationship between the amygdala and olfactory bulb, possibly related to their shared neurology in the pyriform cortex. Conversely, a more antagonistic relationship between the amygdala and dorsal hippocampus is evident.

310.14

ASTROCYTIC RESPONSE TO IN VIVO KINDLING OF THE HIPPOCAMPUS. N. Hawrylak, F.-L. Chang, W.T. Greenough. Neur. & Beh. Biol. Prog., Depts. Psych. & Cell & Struc. Biol., Univ. IL, Champaign, IL 61820

Kindling of the dorsal hippocampus was employed to assess the possible morphological plasticity of astrocytes in response to epileptiform activity. Five pairs of adult rats with chronically implanted electrodes were stimulated twice a day via the Schaffer collateral pathway and responses monitored in the CA1 region. Kindling was performed with 2 msec pulses @ 60 Hz for 2 sec at a current intensity that initially induced at least 10 sec of afterdischarge (AD). Control animals were stimulated with parameters that did not induce AD (.2 msec pluses @ .2 Hz for 10 min.) at an intensity that elicited 50% of the maximal response. Following the induction of five stage 5 seizures, matched pairs were prepared for electron microscopy.

Astrocytic processes were identified in the middle third of the CA1 s. rad. 400 microns from the recording electrode. Kindled animals had a 45% increase in the volume fraction (v/v) of astrocytic processes compared to controls ($p < .01$). The increased astrocytic v/v may relate to either a general ionic, neurotransmitter or cellular metabolic adjusment or to synaptogenesis or other kindling phenomena. (Supported by Epilepsy Foundation of America and ONR N00014-89-J-1556)

310.15

THE LEVELS OF AMINO ACIDS DURING KINDLING DEVELOPMENT IN EIGHT REGIONS OF THE BRAIN M.Pless*, M.Pintor*, N.S.Nadi. (SPON:M.S.Kafka). Emory Un., Atlanta, Ga.,and and NINDS, Bethesda, Md. 20892

The levels of the putative transmitter amino acids, glutamate (GLU), aspartate (ASP), glycine (GLY), GABA and taurine (tau) were measured in microdissected hippocampus, temporal cortex, frontal cortex, entorhinal cortex, amygdala, thalamus and striatum in rats at stages i,ii,iii,iv and v of seizure development.The levels of the amino acids were compared to those measured in the same brain regions of sham operated but unkindled rats. In rats at stage i the levels of ASP, GLU, GABA and GLY were unchanged in all brain regions studied. In stages ii and iii the levels of GLU and ASP were significantly elevated when compared to controls (1.9 to 2.4X increased) in all regions except the entorhinal cortex. The levels of GABA were elevated in all regions examined 2X at stages ii, iii and iv. At stage v the levels of GLU, ASP, GABA were not significantly different from the controls. The levels of GLY and TAU were not altereed in any of the stages examined.

310.16

THE LEVELS OF SOMATOSTATIN IN EIGHT BRAIN REGIONS OF THE RAT DURING THE DEVELOPMENT OF KINDLING. N.S.Nadi, M.Pless* and M.Pintor*. NINDS, Bethesda, MD, and Emory University Atlanta, GA 30322.

The levels of the neuropeptide somatostatin (ST) were measured in microdissected hippocampus, temporal cortex (TC), frontal cortex (FC), entorhinal cortex (EC), occipital cortex (OC), amygdala, thalamus and striatum in rats at stages I,II,III,IV and V of the kindling development. The levels of ST were compared to those measured in the same brain regions of sham operated but unkindled rats. The levels of ST were decreased in all brain regions from rats in stages II,III (ranging from 25% to 80%) and V. The EC, TC and hippocampus, which are known to be involved in the origin and the spread of the epileptic discharge, showed the major decrease in the above stages. The stage IV where the epileptic and electrographic seizures start to evolve from partial to generalized, showed an increase of ST levels compared to the previous stages, becoming significantly higher than controls. The role of ST in the kindling development and the significance of its changes in the five stages will be discussed.

310.17

SECOND MESSENGER COUPLING CHANGES IN THE KINDLED RAT BRAIN. V.E.Chee* and N.S.Nadi.(SPON: W.W. Alberts) NINDS, NIH, Bethesda Md. 20892.

The exact nature of the chemical changes in the central nervous system leading to seizures is unknown. One possible mechanism could be the alteration in the coupling of receptors to second messenger systems such as cyclic AMP or inositol phosphate. We investigated the effect of norepinephrine (NE), N-methyl D-aspartate(NMDA) alone, in combination and in the presence or absence of glycine (GLY) on cyclic AMP and inositol phosphate formation in hippocampal (HP) and cortical slices (CX) from stage V amygdala kindled rats(K) and sham operated (S) rats. In the presence of NMDA and GLY the formation of inositol phosphate was significantly higher in the H of the K when compared to the S ($p<0.01$). In the presence of NE the levels of cyclic AMP were significantly more elevated in the H of the K when compared to the S ($p<0.001$). Furthermore in the K H NE potentiated the effect of NMDA on the formation of cyclic AMP. This interaction was not detected in the S or the CX of the K. The results suggest that region selective plastic changes do occur in the kindled brain.

310.18

TETRAPHENYLPHOSPHONIUM(TPP) UPTAKE IN RESPONSE TO EXCITATORY AMINO ACIDS IN THE KINDLED AND SHAM OPERATED RAT BRAIN. K. Wayns*, V.E.Chee* and N.S.Nadi.(SPON:W.H.Theodore). NINDS, NIH, Bethesda, Md. 20892.

The nature of the chemical changes leading to kindling is not clearly understood. One possible mechanism could be the altered response of membrane potentials to neurotransmitters and/or modulators. In order to study this question we prepared synaptoneurosomes(SN) from amygdala kindled (K) and control (C) rats. The SN were incubated with TPP in the presence of NMDA, glycine (GLY), norepinephrine (NE) and GABA (all at 1 uM). In the presence of NMDA the SN from the K rats were depolarized significantly more than the C (45±5.6 mV vs 57±3.2 mV). The hyperpolarization in the presence of GABA was not significantly different in the K vs the C rats. When SN were incubated in the presence of NMDA and GLY the depolarization in the K brain was also significantly more than the C (39±4.5 mV vs 55±3.9 mV). The presence of NE in the incubation medium potentiated the effect of NMDA. This potentiation was significantly greater in the K rats when compared to the C. These observations suggest the occurrence of plastic changes in neural networks in the kindled brain.

310.19

ALCOHOL CONSUMPTION IN KINDLED RATS. W.M. Burnham, A. Penushkovich*, G.A. Cottrell and M.A. Linseman. Dept. of Pharmacology, Univ. of Toronto and Addiction Research Foundation, Toronto, Canada M5S 2S1.

Numerous biochemical and electrophysiological changes have been reported in kindled rats, but few long-lasting changes in behavior. The present abstract reports a kindled/control difference in alcohol consumption which is observed as long as one month after the last kindled seizure. RVH rats were implanted with unilateral amygdaloid electrodes, and kindled daily to 5 Stage 5 seizures (1 sec, 60 Hz, 400 uA). Three days after the last seizure, they were introduced to alcohol (increasing concentrations up to 12%) in a "limited access" paradigm (access: 1 hr/day over a period of 6 wks). Initially, kindled and control subjects drank similar (low) levels of alcohol, but, over days, the control subjects drank increasingly more while the kindled subjects drank significantly less. Subsequent experiments showed that the kindled subjects did not differ in their physiological response to alcohol (hypothermia test), and that they actually drank more when a dextrose solution was offered. The data from the limited access experiment are similar to the effects of repeated ECS on alcohol consumption reported by Pinel and Mucha (Physiol. Behav., 15:585, 1975). Thus it appears that repeated seizures modify BOTH brain and behavior. (Supported by MRC MA5611 and the Addiction Research Council Of Canada)

KINDLING A PURE SLEEP EPILEPSY IN KITTENS. M.N. Shouse* (SPON: M.B. Sterman). VA Med. Ctr., Sepulveda, CA 91343 and Dept. of Anatomy and cell Biology, UCLA Med. Ctr., Los Angeles, CA 90024.

Secondary generalized temporal lobe epilepsy (TLE) is most common pure sleep epilepsy in humans. The mechanism for sleep epilepsy is obscure, in part because convincing animal models are unavailable. We describe the kindling of spontaneous sleep epilepsy in kittens and a possible brain stem mechanism.

Nine kittens, aged 2.5 to 6 months, and 12 adult cats, aged > 12 months, were kindled from amygdala. Kittens had higher initial afterdischarge (AD) thresholds (mean= 6.1 vs. 1.2 mA in adults), but seizure manifestations and kindling rates were identical to adults. Only the five youngest kittens (2.5 to 5 months) developed spontaneous seizures. Partial seizures could occur in any sleep or waking state, but all GTCs occurred in slow-wave-sleep (SWS), usually in the transition from SWS to rapid-eye-movement sleep (REMS). Threshold tests in older kittens and adults revealed maximum susceptibility to elicited GTCs in the transition from SWS to REMS.

The timing of spontaneous and evoked GTCs in kindled kittens and adult cats thus resembles human TLE. Moreover, electrolytic lesions of locus ceruleus complex increased REM sleep transitions and seizure susceptibility, suggesting that reduced norepinephrine could be a factor in pure sleep epilepsy.

NEURAL PLASTICITY IN ADULT ANIMALS: MONOAMINES AND ACH

311.1

PLASTICITY OF 5-HT INNERVATION OF THE DORSAL HORN IN THE RAT SPINAL CORD AFTER CAPSAICIN TREATMENT, AS SEEN WITH LIGHT- AND ELECTRON-MICROSCOPE IMMUNOCYTOCHEMISTRY. L. Marlier*, F. Sandillon*, N. Rajaofetra*, P. Poulat* and A. Privat* (SPON: M.C. Calvet). Lab. Neurobiologie du Développement, CNRS UPR41 INSERM U.249, EPHE, Inst. de Biologie, 34060 MONTPELLIER, FRANCE.

The dorsal horn (DH) of the rat spinal cord contains a high density of 5-HT immunoreactive profiles (5-HT IR). Sprague Dawley rats were treated neonatally with capsaicin, in order to specifically destroy C afferent fibers. They were sacrificed as adult in order to evaluate the influence of the lesion on serotonergic innervation of the dorsal horn. The efficiency of capsaicin treatment was monitored with immunodetection of calcitonin-gene-related-peptide (CGRP) and substance P on vibratome sections. In control animals, 5-HT IR is present in layer I, outer part of layer II (IIo) where most of the profiles are non-synaptic, layers III and IV, leaving a "clear band" corresponding to the inner part of layer II (IIi). This pattern is disrupted in capsaicin treated animals, with the invasion of layer IIi by 5-HT IR profiles which are found to establish axo-spinous synapses. In conclusion, the topography of 5-HT innervation in the rat DH is modified after neonatal capsaicin treatment. Moreover, the nature of the interactions is shifted from a non-synaptic to a synaptic one, indicating that the target exerts a determinant influence on the shaping of 5-HT afferents. (Supported by INSERM, IRME and DRET).

311.2

TRANSNEURONALLY-MEDIATED DOWN REGULATION OF OLFACTORY BULB DOPAMINE PHENOTYPE INVOLVES A LOSS OF TYROSINE HYDROXYLASE MESSENGER RNA. D.M. Stone, T. Wessel, H. Paivarinta, T.H. Joh and H. Baker. Lab of Mol. Neurobiol., Cornell Univ. Med. Coll., White Plains, N.Y. 10605.

Previous studies in this and other laboratories have demonstrated that the maintenance of tyrosine hydroxylase (TH) expression in dopaminergic neurons of the main olfactory bulb (OB) is dependent upon intact afferent input from the peripheral olfactory receptor epithelium. Thus, chemical or surgical deafferentation of the rat OB, or interruption of afferent activity via neonatal unilateral closure of the nares, results in a gradual loss of dopamine phenotype in a population of OB juxtaglomerular cells ipsilateral to the lesion. This loss of neurotransmitter phenotype is evidenced by a decrease in OB dopamine content, and a reduction in the activity of, and immunocytochemical staining for, TH, the rate-limiting dopamine biosynthetic enzyme. To further characterize this transneuronal effect, TH messenger RNA (mRNA) content was measured in OB from rats sacrificed 1 month after neonatal unilateral cauterization of the nares. In situ hybridization of an ^{35}S-labelled 33-base oligonucleotide complementary to rat TH mRNA revealed a > 50% reduction in signal intensity in the ipsilateral (odor-deprived) vs. contralateral (control) OB glomeruli. Similarly, northern blot analysis of OB poly (A)$^+$ RNA revealed a reduction in TH message level in the odor-deprived side when compared to the contralateral side. These results suggest that the loss of juxtaglomerular cell TH expression following interruption of afferent activity can be attributed to a decrease in the enzyme message level, possibly reflecting a transneuronally-mediated reduction in TH gene transcription. Supported by Grants # NS 23103 and MH 44043.

311.3

RECOVERY TO NORMAL OF PINEAL MELATONIN CONTENT AND URINARY MELATONIN METABOLITES FOLLOWING UNILATERAL DENERVATION BUT NOT UNILATERAL DECENTRALIZATION OF THE PINEAL GLAND R.E.Zigmond[1], R.L.Sherman*[3] and G.A.Kuchel*[1,2] Dept. Biol. Chem. & Mol. Pharm.[1], Division on Aging[2], Harvard Medical School, Boston, MA 02115; Section Analytical Biochem., NIMH[3]

The rat pineal gland receives bilateral innervation from the two superior cervical ganglia via the internal carotid nerves (ICN). The ganglia are in turn innervated by the cervical sympathetic trunks (CST). Sympathetic stimulation at night results in increased serotonin N-acetyltransferase (NAT) activity and consequently increased melatonin synthesis. We have previously found that after unilateral denervation (UnilCNX), but not after unilateral decentralization (UniCSTX), nighttime NAT activity returns to normal within 1.5 days.

Recovery of function was studied further by measuring pineal melatonin content and melatonin metabolites in the urine after such lesions. Following UnilCNX, nighttime melatonin content measured by HPLC with electrochemical detection was similar to controls (43.7 ± 4.5 pmole/mg) at 1.5, 14 and 21 days. However, following UniCSTX, pineal melatonin content was decreased at all 3 time points (37%, 61% and 47% of control respectively). 6-OH melatonin, the main metabolite of melatonin, was measured in the urine using gas chromatography-mass spectroscopy. Measurment of this metabolite in an animal before and after the lesions also indicated a rapid recovery of pineal function by the second night after UnilCNX. However, function was impaired for at least 12 days after a UniCSTX lesion. Thus functional recovery after sympathetic nerve lesions depends on the specific site of the lesion. Together with previous data, our results suggest that decentralized nerves can adversely impact on the efficacy of nearby intact nerves. (NS17512, MH00162 and a fellowship from the Brookdale Foundation).

311.4

REMODELING OF NORADRENERGIC INNERVATION IN RAT CEREBRAL CORTEX INDUCED BY REPEATED STRESS.
T. Sakaguchi* and S. Nakamura. Dept. of Physiol., Fac. of Med., Kanazawa Univ., Kanazawa 920, Japan.

We have presented electrophysiological evidence for terminal sprouting of locus coeruleus (LC) noradrenergic (NA) neurons in rat cerebral cortex following repeated mild stress, recently. We now report that the stress-induced change of cortical NA terminals may depend on the intensity of stress. Adult male Sprague-Dawley rats were used. The stress groups, restrained in a small cage for 1 or 6 hours daily, received the treatment for 1 or 2 weeks. The percentage of LC neurons activated antidromically by stimulation to a given brain site (projection index, P-index) was examined to assess the amount of LC projection to the brain site. The P-indices for 7 points covering nearly the entire cortex were determined under urethane anesthesia. The P-index for each cortical point did not differ between the control and 1-week stress groups. In the animals stressed for 1 hour daily for 2 weeks, the P-index for a point in the medial frontal cortex was significantly higher than that in the control. In contrast, in the 6-hour stressed animals for 2 weeks, the P-index for each cortical point appeared to decrease rather than increase. The stress treatment did not change the excitability of cortical LC terminal axons. These results suggest that the occurence of the morphological changs of LC neurons (i.e. either an increase or decrease in the density of cortical NA terminals) following repeated stress depends on the intensity of stress.

311.5

BEHAVIORAL RECOVERY AFTER UNILATERAL 6-OHDA LESION IN THE SUBSTANTIA NIGRA RELATED TO NIGRO-STRIATAL NEUROPLASTICITY.
S. Morgan*, G. Nomikos* and J.P. Huston (SPON: R. Schwarting). Inst. of Physiol. Psychology I, Univ. of Düsseldorf, Universitätsstr. 1, D-4000 Düsseldorf, FRG.

We looked at the relationship between behavioral recovery after unilateral 6-OHDA lesion of the substantia nigra (SN) and the number of cells in the SN labeled by HRP deposited in the caudateputamen (CPU). After unilateral injection of 6-OHDA into the SN rats were tested for asymmetrical behavior either only on the day after the lesion (group L1) or on the day after the lesion plus every alternate day for the following 15 days (group L15). HRP was deposited in the CPU ipsilateral to the lesion and the SN ipsilateral and contralateral to the lesion were examined for labeled cells. L15 animals that showed recovery from asymmetrical behavior had more cells than those which did not in contralateral and ipsilateral SN. Recovered rats in group L15 had more cells in the ipsilateral SN than group L1, while non-recovered animals did not differ from group L1. Thus, one correlate of recovery after a neurotoxic lesion of the SN is an increase in HRP uptake by cells which give rise to the nigrostriatal system.

311.6

PLASTICITY IN TUBEROMAMMILLARY-STRIATAL AND NIGRO-STRIATAL PROJECTIONS RELATED TO RECOVERY FROM BEHAVIORAL ASYMMETRIES INDUCED BY HEMIVIBRISSOTOMY.
J.P. Huston, H.-T. Weiler* and H. Steiner*. Inst. of Physiol. Psychology I, Univ. of Düsseldorf, Universitätsstr. 1, D-4000 Düsseldorf, FRG.

Unilateral clipping of vibrissae (UCV) in rats induces an asymmetry in facial scanning which subsides after 3 days. We determined the time-course of neuronal plasticity in tuberomammillary-striatal (TMS) and nigro-striatal (NS) projections after UCV and compared it to behavioral recovery. After UCV for 1-3, or 4-20 days rats were injected with HRP into the striatum ipsilateral or contralateral to UCV. Labeled cells were counted in the caudal magnocellular and postmammillary caudal magnocellular subnuclei of the tuberomammillary nucleus and in the substantia nigra. In UCV4-20 rats an asymmetry in TMS projections from both subnuclei was found, with more HRP-labeling in the crossed and uncrossed projections to the CPU contralateral than ipsilateral to UCV. These asymmetries were in the same direction as those found in NS projections in UCV4-20 rats. UCV1-3 rats had no asymmetries in TMS projections, but in the NS system they exhibited an asymmetry opposite to that in the UCV4-20 rats. The changes in TMS+NS projections appeared when rats recovered from behavioral asymmetry, suggesting a functional role of these projections in behavioral recovery.

DISTRIBUTION OF GAP-43 mRNA IN THE BRAINSTEM OF ADULT RATS, AS EVIDENCED BY IN SITU HYBRIDIZATION: LOCALIZATION WITHIN MONOAMINERGIC NEURONS
C.Bendotti and R.Samanin Dept. Neuropharmacology" Mario Negri" Institute, 20157Milano, Italy

GAP-43 is a nervous tissue specific phosphoprotein associated with development, regeneration, and functional modulation of synapses. Using the in situ hybridization of GAP-43 mRNA we examined the distribution of the sites of synthesis of this presynaptic phosphoprotein in the brainstem of adult rats. GAP-43 was selectively expressed in certain cell populations, with the highest hybridization signal detected at the level of the n. raphe dorsalis and substantia nigra compacta. An intense grain density was also observed within the neurons of the locus coeruleus , n. raphe medialis, ventral tegmental area, n.raphe pontis and, at a lower degree in the interpeduncular nucleus. No significant signal was detected at the level of the substantia nigra reticulata, red nucleus and nucleus peduncular pontine. Selective lesions of serotonergic neurons by I.C.V.injection of the neurotoxin 5,7-DHT significantly reduced the hybridization signal at the level of n. raphe dorsalis and medialis, demonstrating that GAP-43 transcript is expressed in serotonergic cells. A complete overlapping of the hybridization signal of tyrosine hydroxylase mRNA and GAP-43 mRNA was observed at the level of the substantia nigra of adjacent sections indicating the presence of this phosphoprotein in dopaminergic neurons.
These results suggest that this protein is synthesized within the serotonergic and catecholaminergic neurons of adult rat brain. It remains to be elucidated whether this phosphoprotein plays a role in the functional plasticity and/or signal trasduction of these neurotrasmitters.

311.8

METHYLAZOXY-METHANOL INDUCED MICROENCEPHALY: EVALUATION OF PROTEIN KINASE C MEDIATED PHOSPHORYLATION PROCESSES.
M. Di Luca*, M.P. Abbracchio*, M. Cimino* and F. Cattabeni Inst. Pharmacol. Sci., Sch. of Pharm., Univ. of Milano, 20133-Italy.

The administration of the antimitotic agent methylazoxy-methanol (MAM) to rats at day 15 of gestation results in a microencephaly in the offspring characterized by a consistent loss of interneurons in cortex, hippocampus and striatum. Previous studies demonstrated that the altered neuronal circuitry in this animal model results in active processes of neuronal reorganization and plasticity.

Since a family of phosphoproteins (GAPs, B50/F1), which show an apparent MW between 43 and 47 Kd and are selectively phosphorylated by PKC, has been implicated in neuronal adaptive changes, we have evaluated the phosphorylation state of a 47 Kd MW protein band in synaptic membrane extracts obtained from cortex and hippocampus of control and MAM-rats. This protein band showed a marked reduction of ^{32}P-phosphate incorporation in MAM-rats. This reduced *in vitro* incorporation might be indicative of an increased *in vivo* phosphorylation mediated by PKC: indeed PKC activity resulted markedly enhanced in MAM-rats.

These results suggest that MAM induced microencephaly might represent an useful experimental model to study the role of these phosphoproteins in neuronal adaptive events such as synaptic remodeling following toxic insults.

311.9

L-DOPA AND D1-SELECTIVE AGONISTS ACTIVATE C-FOS EXPRESSION IN THE STRIATUM OF 6-HYDROXYDOPAMINE-LESIONED RATS.
Harold A. Robertson and George S. Robertson, Department of Pharmacology, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7.

Following unilateral destruction of neurons in the substantia nigra with the neurotoxin 6-hydroxydopamine, rats given dopamine agonists turn towards the unlesioned side (contralaterally). Recently, we reported that stimulation of brain can lead to activation of the nuclear proto-oncogene c-fos (Dragunow, M. & Robertson, H.A., Nature, 329: 441, 1987). Fos activation may also be utilized as a high resolution metabolic marker for polysynaptic pathways (Hunt, S. P., Pini, A. & Evan, G., Nature, 328: 632, 1987). Accordingly, we have studied the effects of L-Dopa-induced rotational behaviour on the expression of c-fos-like immunoreactivity (IR) in rat brain. Here we report that L-Dopa-induced rotation is accompanied by the expression of c-fos. In lesioned animals receiving L-Dopa or a D1 selective agonist, there was strong contralateral rotation accompanied by activation of c-fos in the striatum. D-amphetamine produced ipsilateral rotation and a strong activation of c-fos in the unlesioned striatum. In rats given pentobarbital to prevent rotation, SKF 38393 still activates striatal c-fos. Moreover, the D2 selective agonist LY 171555 produced rotation but no activation of c-fos. Thus turning itself does not result in activation of c-fos. It is possible that fos activation may play a role in long-term changes such as "priming" and tardive dyskinesia.

THE NMDA ANTAGONIST MK-801 REVERSES D-AMPHETAMINE-INDUCED ACTIVATION OF THE PROTO-ONCOGENE C-FOS IN RAT STRIATUM.
Krista Johnson* and Harold A. Robertson. (SPON. J. Fisk). Dept. Pharmacol., Dalhousie Univ., Halifax, N.S., Canada B3H 4H7.

Excess excitatory amino acid activity is frequently associated with pathophysiological changes in brain. Methamphetamine produces degenerative changes in the striatal terminals of dopamine neurons and this damage is prevented by NMDA antagonists (Sonsalla, P. et al., Science 243:398, 1989). Recently, we found that L-Dopa induced c-fos in 6-OHDA lesioned rats (Robertson, G.S. et al, Eur. J. Pharmacol. 159: 99, 1989). We have also found that brain damage can induce the proto-oncogene c-fos (Dragunow, M., Robertson, H.A., Brain Res., 455:295, 1988) and this induction of c-fos can be reversed by NMDA antagonists. It seemed possible therefore that c-fos could play a role in NMDA-dependent methamphetamine-toxicity in striatum. D-amphetamine (5 mg/kg, i.p.) produced a "patchy" increase in c-fos protein throughout the striatum which, in medial regions, was reversed by pre-treatment with the NMDA antagonist MK-801 (3 mg/kg, i.p.). However, while reversing the effects in medial regions, rats which received both MK-801 and D-amphetamine exhibited a dramatic increase in c-fos protein immunoreactivity in the dorso-lateral striatum.

LESIONS OF THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS PRODUCE LOSS OF BASAL FOREBRAIN CHOLINE ACETYLTRANSFERASE: EVIDENCE FOR CHOLINERGIC-CHOLINERGIC INTERACTIONS
Justin D. Oh*, Nancy J. Woolf, and Larry L. Butcher, Laboratory of Chemical Neuroanatomy, Dept. of Psychology, University of California, Los Angeles, CA 90024-1563, U.S.A.

The choline acetyltransferase (ChAT)-immunopositive neurons in the pedunculopontine tegmental nucleus were unilaterally lesioned in rats and the animals were sacrificed 3 days, 8 days, or 1 month later. Brain sections were processed immunohistochemically for ChAT and nerve growth factor receptor (NGFR). Although little or no immunocytochemical changes were seen 3 days following the ablation, a marked depletion of ChAT positive cells in various parts of the basal forebrain were observed ipsilateral to the lesion side at 8 days. The decreases were most apparent in the magnocellular preoptic area and rostral nucleus basalis and exhibited some topographic relationship to lesion placement. Staining for NGFR was still present in the ipsilateral cells, which in adjacent sections showed a loss of ChAT staining, suggesting that the decrease in ChAT-like immunoreactivity of basal forebrain cells in response to pedunculopontine lesions did not reflect neuronal degeneration. [Support: USPHS grant NS 10928 to L.L.B.]

311.12

THYROID HORMONE ALTERS CHOLINERGIC EXPRESSION IN ADULT BASAL FOREBRAIN.
Christopher W. Mathes*, Nancy J. Woolf, Charles Lee and Larry L. Butcher. (SPON: J. T. Beatty) Laboratory of Chemical Neuroanatomy, Dept. of Psychology, University of California, Los Angeles, CA 90024.

Chronic thyroid hormone treatment alters the morphology and histochemistry of choline acetyltransferase (ChAT) immunoreactive neurons in the basal forebrain during postnatal development [Gould et al., Dev. Brain Res. 46:297, 1989], but it has not been established if similar effects occur in the mature animal. In the present study, young adult rats (52 days) were made hyperthyroid by daily i.p. injection of L-thyroxine (2.5 µg/g) or hypothyroid by the addition of 0.4% propylthiouracil in the feed. One group of euthyroid controls received i.p. injections of saline and another no injections. All treatments lasted seven weeks. Tissue sections were immunohistochemically processed for ChAT, and morphologic analyses and cell counts were performed. Significantly more cells at selected rostral and caudal basal forebrain levels expressed ChAT in hyperthyroid rats ($\bar{X}$=509) than in hypothyroid ($\bar{X}$=356), vehicle injected euthyroid ($\bar{X}$=250), and non-treated euthyroid ($\bar{X}$=318) rats [$F(3,12)=6,33$, $p<0.01$]. Compared to neurons from euthyroid rats, ChAT positive cells in the basal forebrains of hyperthyroid and hypothyroid animals demonstrated aberrant morphologic profiles including hypertrophied or shrunken somata and alterations in cell shapes and dendritic patterns [Support: USPHS grant NS 10928 to L.L.B.]

311.13

CORTICAL DEVASCULARIZATION AND NGF TREATMENT AFFECT THE NUMBER OF AXO-SOMATIC SYNAPSES ON CHOLINERGIC NEURONS OF THE ADULT RAT NUCLEUS BASALIS MAGNOCELLULARIS.
M. Piotte, L. Garofalo* and A.C. Cuello. Dept. Pharmacology & Therapeutics, McGill Univ., Montreal (Quebec), Canada H3G 1Y6.

Cortical devascularization causes biochemical and morphological retrograde degenerative changes in cholinergic neurons of the rat nucleus basalis magnocellularis (NBM). In order to determine how this cortical lesion affects the synaptic input of these cells, choline acetyltransferase immunoreactive NBM neurons were examined at the ultrastructural level in intact and cortically devascularized adult rats. In animals examined 15 days after the lesion, the number of axo-somatic synapses was markedly higher than in controls. At 30 days post-lesion this number was still higher than in controls but lower than at 15 days post-lesion. When the neurotrophic factor NGF was administered intracerebroventricularly via an osmotic minipump (12 µg/day ; immediately after the lesion for a maximum of 7 days) the increase in the number of axo-somatic synapses seen at 15 days post-lesion was less pronounced than in lesioned untreated rats. The increase in axo-somatic synapses could be explained in part by the decrease in perikaryal volume resulting from the lesion. The contribution of cell shrinkage to the observed effect is now under investigation.

311.14

EFFECTS OF CARBAMAZEPINE ON RECOVERY AFTER CORTICAL DAMAGE.
R.L.Fulton* and T. Schallert (SPON: N. Lobaugh); Psychology Dept. & Institute for Neuroscience, U. of Texas, Austin, 78712.

Manipulation of gamma-aminobutyric acid (GABA) activity has been found to alter behavioral recovery after experimental cortical damage. We have found that diazepam, at anti-convulsant doses, can disrupt recovery following lesions to the anteromedial cortex (AMC). The purpose of this study was to assess whether carbamazepine, a commonly prescribed anti-convulsant, also disrupts recovery from cortical damage. Although the mechanisms of action of carbamazepine are not fully understood, it is not thought to work directly at GABA-ergic synapses. Male rats sustained unilateral electrolytic lesions to the AMC. Rats were injected for a 14 day period with carbamazepine (15mg/kg; anticonvulsant dose,ED-100) 3 times a day for 3 days post-operative and twice daily thereafter. Behavioral tests measuring sensorimotor asymmetries (bilateral tactile stimulation tests) were administered pre-operatively and for 28 days post-operatively. Both carbamazepine-treated and control rats exhibited a unilateral bias ipsilateral to the lesion immediately after surgery, and both groups showed near total recovery by day 10 to 14. Tentative conclusions are that carbamazepine does not disrupt recovery of function after AMC lesions.The data are consistent with the view that diazepam interferes with recovery via GABA-related mechanisms. (Supported by NIH grant NS 23964 awarded to T. Schallert.)

311.15

EFFECT OF DIAZEPAM ON CALCIUM UPTAKE IN STRIATAL SYNAPTOSOMES FOLLOWING UNILATERAL NEOCORTICAL DAMAGE. J.S. Sims, T. Schallert, R.D. Trent *, L.E. Shapiro*, and S.W. Leslie. Inst. for Neuroscience and Dept. of Psychology, Univ. of Texas at Austin, Austin, TX 78713.

Unilateral damage to the anteromedial cortex (AMC) produces a transient sensorimotor asymmetry quantified using a bilateral tactile stimulation test. Diazepam is capable of preventing this recovery. Evidence from behavioral, pharmacological, and metabolic studies suggests that changes occur in striatal function following cortical damage. Male Long-Evans rats sustained unilateral AMC lesions or sham surgery and were given daily doses of diazepam (5 mg/kg) or vehicle. Animals were sacrificed at 3, 7 or 14 days following surgery. Striatal synaptosomes were stimulated with potassium (30 mM; for 3 sec) and the entry of $^{45}Ca^{++}$ was measured. In addition, potassium-stimulated dopamine release and dopamine content were measured. When comparing the two striata of each animal, animals injected with diazepam had greater asymmetries in calcium influx relative to vehicle-injected rats. It is possible that the dysfunction in calcium entry was related to a change in the release of dopamine or other neurotransmitters in the striatum. Asymmetries in dopamine release will be discussed as related to the disruption of calcium uptake. Supported by NIH Grant NS-23964 to T. S. and NIAAA grants AA05809 and RSDA AA00044 to S.W.L. 311.16

ALPHA-2-ADRENORECEPTOR-MEDIATED DECREASE IN GABA OUTFLOW IN BRAIN SLICES DURING MORPHINE TOLERANCE. L.Beani, C.Bianchi, L.Ferraro, M.Morari, M.Simonato, G.P.Spalluto and S.Tanganelli. Dept. of Pharmacology, University of Ferrara, Italy.

The cholinergic neurones projecting to the cerebral cortex are inhibited by norepinephrine (NE) through alpha-2-receptors (a-2-rec), whereas the intracortical gabaergic neurones are stimulated through alpha-1-receptors (a-1-rec). Deep plastic changes are produced by chronic morphine treatment. In fact, in morphine tolerant guinea-pigs NE stimulates the cholinergic neurones through a-1-rec and inhibits the gabaergic neurones through a-2-rec (JEPT,247: 294,1988). The inverted response of the cholinergic structures to NE and to alpha-agonists has been confirmed in cortical slices (J. Neurochem., in press).

This report shows that the intracortical gabaergic neurons, too, undergo inverted response to NE during morphine tolerance. Under these conditions, the spontaneous efflux of endogenous GABA from cortical slices is reduced by NE 30 uM and by clonidine 1 uM (ineffective in naive animals). This inhibition is prevented by idazoxan 0.1 uM. Conversely, phenylephrine (which normally increases GABA outflow) is ineffective.

In conclusion, the appearance of this novel, non physiological a-2-rec mediated inhibition versus GABA replaces the normal a-1-rec-mediated stimulation. Further esperiments have been undertaken in synaptosomes in order to identify the site (pre- or postsynaptic) of these effects.

OCULOMOTOR SYSTEM II

312.1

TRANSLATIONAL VESTIBULO-OCULAR REFLEX (TVOR) RESPONSES OF MONKEY ARE A LINEAR FUNCTION OF THE INVERSE OF THE VIEWING DISTANCE. U. Schwarz and F. A. Miles. Lab. Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

The TVOR was investigated in 4 rhesus monkeys using a sled that moved on a linear track and accelerated the animals along the inter-aural axis. Movements of both eyes were recorded with the electromagnetic search coil technique and accommodation was recorded with an infra-red optometer. Transient sinusoidal jerks (period, 200ms; amplitude, 630cm/s^2/s) were applied after the animal had satisfactorily fixated an LED (one of 5 targets at distances of 16-150cm). The LED was extinguished immediately prior to the onset of acceleration, leaving the room dark throughout the period of movement. (To preclude "learning", animals never experienced sled motion in the light and were never reinforced for their responses to the sled.) Dependence on proximity would be appropriate for the TVOR, and peak compensatory eye speed achieved within 250ms of the onset of sled motion was a linear function (coef. determination >0.9) of the inverse of viewing distance (diopters, D), with a mean slope of 1.4°/s/D (range, 1.0-2.0°/s/D) and a mean intercept of 1.2°/s (range, 0.5-2.2°/s). Full compensation would require a slope of 2.3°/s/D with an intercept of zero. From this it can be shown that the gain *(measured response/required response)* exceeded unity with the most distant LED (mean, 1.4) and fell short of unity with the nearest (mean, 0.7). Data from 2 monkeys indicate that responses could be increased by selectively increasing *either* vergence (using base-out prisms with the most distant LED) *or* accommodation (using base-in prisms with the nearest LED) and, for both animals, these increases in response were similar in the 2 cases. We conclude that TVOR responses are not solely a function of the vergence state, and that accommodation and/or other cues for absolute distance must also affect the dependence on proximity.

312.2

ARE THE TWO COMPONENTS OF THE PRIMATE OPTOKINETIC RESPONSE CONCERNED WITH TRANSLATIONAL AND ROTATIONAL DISTURBANCES OF GAZE? F. A. Miles, U. Schwarz and C. Busettini*. (SPON: D.L. Robinson). Lab. Sensorimotor Research., NEI, Bethesda, MD 20892.

Canal-ocular reflexes and otolith-ocular reflexes compensate for the rotational and translational components, respectively, of head movements. We suggest that any residual disturbances of gaze are dealt with by 2 independent visual tracking systems that correspond to the *direct* and *indirect* components of primate OKN: the *direct* dealing with the translational component of optic flow and the *indirect* with the rotational component. The *indirect* component is assumed to be phylogenetically older and mostly subcortical, while the *direct* component is assumed to be a cortical addition that deals with the translational problems of frontal eyed animals. A summary of the major differences:

ROTATIONAL MECHANISM	TRANSLATIONAL MECHANISM
1. *Indirect* component of OKN:	*Direct* component of OKN:
- Long time-constant.	- Short time-constant.
- Strong after-nystagmus.	- Weak after-nystagmus.
- Responds to low slip-speeds.	- Responds to high slip speeds.
- Strong naso-temporal asymmetry?	- Weak naso-temporal asymmetry?
2. Helps to stabilize gaze against rotational disturbances.	Helps to stabilize gaze against translational disturbances.
3. Back-up to canal-ocular reflex.	Back-up to otolith-ocular reflex.
4. Organized in canal planes.	Organized in otolith planes?
5. Cannot utilize motion parallax?	Can utilize motion parallax.
6. Insensitive to proximity & disparity?	Sensitive to proximity & disparity.
7. In all animals with mobile eyes?	In some frontal-eyed animals only?
8. Mainly a subcortical system?	A cortical system?

INITIAL OCULAR FOLLOWING RESPONSES OF MONKEY ARE A LINEAR FUNCTION OF THE INVERSE OF THE VIEWING DISTANCE. C. Busettini* and F. A. Miles. Lab. Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

The dependence of ocular following on viewing distance was investigated in 2 rhesus monkeys. Positions of both eyes were recorded with the electromagnetic search coil. Visual stimuli were random dot patterns subtending 40° back-projected onto a screen facing the animal and moved at constant speed for 100ms starting 30ms after a 10° rightward saccade into the center. Animals were neither trained to track these stimuli nor reinforced for doing so: our interest was solely in defining the basic linkage between the visual and oculomotor systems that we assume helps to stabilize gaze with respect to the surroundings. Six viewing distances were used (range, 20-150cm), the visual stimulus being adjusted for each so as to have constant size and speed for the animal. Response latencies were about 50ms and insensitive to viewing distance. Response amplitudes, as indicated by the maximum eye speed achieved within 100ms of the onset of the stimulus, were a linear function of the inverse of the viewing distance (coefficient of determination >0.95). When each animal's data were normalized with respect to that same animal's highest response and plotted against the viewing distance in diopters (D), the mean slope was 14.4%/D (range, 12.8-16.2%/D) and the mean intercept, 30% (range, 21-40%). This dependence on proximity is similar to that reported for the translational vestibulo-ocular reflex (TVOR) in the previous Abstract. We suggest that the ocular following system and TVOR are synergistic and share a pathway whose efficacy is modulated by absolute distance cues. We further suggest that the initial ocular following response corresponds to the *direct* component of OKN and provides visual back-up for the TVOR (otolith-ocular reflex), in contrast with the *indirect* component of OKN, which we suggest provides visual back-up for the rotational VOR (canal-ocular reflex).

312.4

Smooth Pursuit and Vestibulo-ocular Reflex Cancellation during Unpredictable Visual and Vestibular Stimulation K. E. Cullen, R. A. McCrea and T. Belton Comm. on Neurobiology, Univ. of Chicago

The ability of squirrel monkeys to fixate a target during passive, unpredictable vestibular stimulation by cancelling their vestibulo-ocular reflex (VORc) was compared to their ability to follow an unpredictable moving target by generating smooth pursuit eye movements. Two types of unpredictable stimuli were used: 1) a sudden, jerk-like acceleration of head or target or 2) pseudorandom movement of the target or the vestibular turntable.

The ability of the monkeys to fixate a head stationary target when the turntable was rapidly accelerated was considerably better than their ability to pursue a rapidly accelerating target when the turntable was stationary. When the target was unexpectedly accelerated, a smooth pursuit eye movement was evoked at a latency of 110 - 150 msec. but when the turntable was unexpectedly accelerated during VORc, the VOR evoked by the turntable 'jerk' was suppressed 20 - 40 msec after the turntable jerk. The amplitude of the VOR generated by the jerk varied as a function of the head acceleration prior to the jerk.

The ability of the monkeys to fixate a target during pseudorandom turntable movement was also considerably better than their ability to pursue a target that was moving pseudorandomly. Gaze velocity during VORc of pseudorandom vestibular stimuli matched head velocity closely in phase and amplitude when the highest frequency components of the stimulus were less than 2 Hz. When higher frequency components were included in the vestibular stimulus, the gaze velocity gain re head velocity decreased as a function of frequency, although the reduction in gain was much less than the gain reduction observed either during smooth pursuit of pseudorandom target movement or during VOR cancellation of predictable (sinusoidal) turntable movement.

These results suggest that an alternate mechanism exists for suppressing the VOR that does not depend on visual feedback of target motion. Since the VOR evoked by unexpected head movements varied as a function of head acceleration, the non-visual mechanism for VORc may utilize vestibular afferent information.

312.5

EFFECT OF VIEWING AN EARTH-STATIONARY SURROUND ON TORSIONAL POST-ROTATIONAL NYSTAGMUS IN HUMANS. S.H. Seidman*, W.P. Huebner, and R.J. Leigh, Ocular Motility Lab, Cleveland VA Medical Center, University Hospitals and Dept. Biomedical Engineering, Case Western Reserve University, Cleveland, OH 44106.

We measured the gain and time constant (T_{vor}) of the torsional vestibulo-ocular reflex (VOR) in three subjects (ages 22-41) who were rotated about an earth-vertical axis with their necks extended and faces supine. After a 60-second period of rotation in darkness at 100 deg/s, followed by a rapid brake to 0 deg/s, the post-rotational responses (PRRs) in darkness had a mean gain of 0.47 and a mean T_{vor} of 4.0 s. In further trials, a one-second room illumination, to reveal a stationary visual surround, was presented 2 s after the onset of the PRR and caused slow-phase eye velocity to drop rapidly to 0 deg/s. Within 0.5-1.5 s following the return to darkness, torsional eye velocity rose to a value similar to that occurring in PRRs for which there had been no visual exposure. These results support the hypotheses that for this head orientation (1) velocity storage for torsional vestibular nystagmus is weak or absent, and (2) there is a suppression/cancellation mechanism present in the torsional system which acts independently of velocity storage. (Supported by NIH grant EY06717 and Veterans Administration).

312.6

COMPARISON OF OCULAR TORSION IN PRIMATES DURING HORIZONTAL PURSUIT VERSUS VOR MEASURED BY SCANNING LASER OPHTHALMOSCOPY. D. Ott and R. Eckmiller. Dept. Biophysics, Div. Biocybernetics, University of Düsseldorf, F.R.G.

Torsional eye movements (about the line of sight) were studied in humans by analyzing the rotation of the ocular fundus pattern monitored by Scanning Laser Ophthalmoscopy (SLO) during horizontal pursuit and VOR: (1) Ocular torsion during sinusoidal horizontal pursuit (±5 deg, 0.1-1.0 Hz) was sinusoidally modulated (up to 8 deg peak-to-peak) with varying phase relationship re. horizontal eye position (varying from 30 deg lead to 15 deg lag), showing intorsion (extorsion) during temporal (nasal) eye movements. (2) Static fixation at various horizontal positions revealed no significant eye position dependant ocular torsion but occasional torsional saccades of varying amplitudes and durations. (3) During VOR-light (subject fixates a stationary visual target while being sinusoidally rotated about the vertical body axis, ±5 deg, 0.1-0.8 Hz) ocular torsion was also clearly modulated. (4) During VOR-suppression (subject and visual target rotate both in the same direction, ±5 deg, 0.1-0.8 Hz) the sinusoidal modulation of ocular torsion was very small if at all measurable. These findings suggest that ocular torsion serves the maintenance of vision not only during target movements (pursuit) but also during head movements (VOR) and is actively controlled by both visual and vestibular signals. 312.7

ALTERATION OF LOAD CONDITIONS ON THE EYE DURING FIXATION AND TRAINED SACCADIC EYE MOVEMENTS J.G. McElligott, L.M.Eisenman, and C. M. Philips* (SPON: S. McElligott) Temple University School of Medicine, Dept. of Pharmacology and Physiology, Phila., PA 19140, and Thomas Jefferson School of Medicine, Dept. of Anatomy, Phila., PA. 19107

Various schemes have been developed to alter normal motor function as well as sensori-motor interaction during oculomotor behavior in order to investigate adaptive changes mediated by the central nervous system. These include tenectomy as well as alteration of vision during a variety of eye movements. However, these paradigms suffer from a number of deficiencies. They produce permanent changes that cannot be undone, or they alter only one aspect of the sensory feedback (e.g., only visual and not motor proprioceptive feedback) The procedure reported overcomes these difficulties by allowing a change in the loading conditions or a perturbation to the eye during normal eye movements without interfering with vision. The head of an animal is placed in field of a permanent magnet. A wire is threaded under the 4 ocular rectus muscles of a cat in the form of a coil. When a D.C. current is applied to the coil, a magnetic dipole is created that produces a force that tends to rotate and align the eye with the field of the permanent magnet. The direction and the magnitude of the force is related respectively to the direction and the magnitude of the current in the eye coil. With this schema, we have produced forces of several grams that can change the magnitude of a saccade during trained eye movements as well as displace the eye with respect to its conjugate partner. All these alterations were produced in a monocularly viewing animal. Eye movements in both eyes were measured by the standard electromagnetic ocular search coil technique. (Supported by a grant from NIH S07-RR05417)

312.8

CHANGES IN OCULAR ALIGNMENT AFTER SUSTAINED PASSIVE DISPLACEMENT OF ONE EYE. D.S. Zee, D. Nommay* and G.M. Gauthier*, Universite de Provence, Marseille, France

We measured eye alignment in two normal subjects before and after a sustained passive rotation of one eye. To quantify alignment we used the Lancaster test which gives relative eye position without disparity cues. Preadaptation measures were made after 10 min of monocular viewing. Subject 1 had a 1-2 deg exodeviation and subject 2 a 1-2.5 deg esodeviation.

Using a suction lens one eye was covered and pulled laterally 30 deg. After 10 min the lens was removed and alignment measured. For subject 1 alignment shifted in a divergent (exo) direction by 2-3 deg and then returned to baseline in 7-10 min. For subject 2 alignment also shifted by 2-3 deg in an exodirection but within 1-3 min changed direction to reach 4-5 deg of esodeviation. After 10 min alignment returned to normal.

These results indicate that after a passive rotation of one eye there is a change in ocular alignment that lasts for minutes. We suggest the sequence of alignment changes can not be accounted for by mechanical changes alone but that central mechanisms, based upon nonvisual orbital afference, are also important.

312.9

FLIGHT SIMULATOR SICKNESS: ADAPTATION EFFECTS. R.S. Kennedy, J.E. Fowlkes*, K.S.Berbaum*, G.O. Allgood*, and D.W. Gower*. Essex Corporation, Orlando, FL 32803.

Simulator sickness, like space motion sickness, is manifested by perceptual disturbances of visuomotor, vestibular, and neuroendocrine origin. Symptoms result from discordant visual, vestibular, and proprioceptive stimuli. With repeated exposure to a simulator, symptoms subside as neural comparisons of information from different sensory modalities are recalibrated. Symptoms may return during readaptation to the normal environment. Adaptation may reduce sickness which is experienced during simulated flight, but safety hazards may result as pilots readapt. Evidence for adverse readaptation effects include: 1) flashbacks, and 2) ataxia in aircrew after simulated flight. Pilots' retrospective accounts show that flashbacks are sudden, compelling experiences of self-motion. Ataxia was measured after simulator flights in aircrews using tests of standing and walking steadiness. In one study, 36 pilots were measured repeatedly across ten simulator flights. While there was a decrease in symptomatology experienced while in the simulator over the course of the ten flights, there was a systematic increase in postural instability upon egress from the simulator, suggesting readaptation. The paradox of favorable and unfavorable outcomes from adaptation is described using these and related data. In addition, the development of a biocybernetic device to predict in real time pilots' likelihood of developing simulator sickness is discussed.

312.10

EYE POSITION IS AFFECTED BY GRAVITY IN ANESTHETIZED, PARALYZED HUMANS. M. J. Steinbach and J. Lerman*, Depts of Ophthalmology & Anesthesiology, Hospital for Sick Children, Toronto, Canada M5G 1X8, and the York University Vision Group.

In order to determine if the the center of rotation of the eye coincides with its center of mass we have been photographing the eyes of patients undergoing surgery for non-paralytic strabismus. Patients were unpremedicated and anesthetized with IV thiopental, atropine and succinylcholine. After tracheal intubation, anesthesia was maintained with halothane, nitrous oxide, oxygen and atracurium, a non-depolarizing muscle relaxant. Five minutes after administration of the muscle relaxant and just prior to the onset of the surgery, the patients were photographed with the lids gently lifted and the head rotated so that the left ear, and then the right ear faced down, with this sequence repeated once again. The camera, an 8 mm video with close-up lens, was equippped with a plexiglas strut which allowed for accurate positioning of the camera in the patient's midline. The position of the eye was determined from the corneal reflex produced by the camera's spotlight. In 7 patients there was a change in corneal reflex which indicated that the patients' eyes were rotating upward (about 5 deg), against the direction of gravity, suggesting that the center of mass is behind the center of rotation. This finding complicates models of eye-head coordination because the position of the head with respect to gravity will alter the requirements of the extraocular muscles in maintaining gaze stability. It may also be a cause of the motion sickness astronauts frequently experience in microgravity.

312.11

3-DIMENSIONAL HUMAN EYE POSITIONS AS A FUNCTION OF HEAD ORIENTATION: D.Straumann*, J.van Opstal*, B.J.M.Hess*, V.Henn, K.Hepp*. Neurology Clinic, University Hospital, CH-8091 Zürich, Switzerland.

We measured human eye rotations in 3 dimensions while head position was systematically varied relative to the stereotaxically defined horizontal plane. Absolute rotational vectors of the viewing eye were measured with Robinson's 3D scleral induction coil (modified by Collewijn, manufactured by Scalar instruments). Typically, we recorded 2000 eye fixations in each subject for every given head position. For calibration we first determined in-vitro length and relative orientation of the two coil vectors in 3D space. For offset voltages observed in-vivo, correction was done by vertical fixation tasks in the sagittal plane, where we assumed absence of torsion. Periodical repetition of the in-vivo calibration checked for possible slips of the annulus. With the head erect, all eye positions could be described as rotations about axes lying in one plane, defined as Listings' plane, which reduces the degrees of freedom for eye fixations to a function of horizontal and vertical rotations. We are investigating to what extent eye rotations can still be described as lying in one plane when head position is varied relative to body and gravity, and whether this plane will stay head-fixed. VERTICAL VISUAL-VESTIBULAR INTERACTION (VVI) INDUCED BY TELESCOPIC SPECTACLES (TS) IN HUMAN ADULTS. J. L. Demer and R. W. Baloh*. Jules Stein Eye Institute and Department of Neurology, UCLA Medical School, Los Angeles, CA. 90024.

Although TS are known to induce a strong, immediate VVI during horizontal head movements, the effects of these devices on the vertical vestibulo-ocular reflex (VOR) are poorly understood. We investigated the immediate effects of normal vision and vision with 4X binocular TS on the vertical VOR in 6 adults. Subjects were trained to make active, vertical head movements (amplitude 5-10 deg) synchronously with an audible tone modulated sinusoidally at 0.4 or 1.6 Hz. Gaze and head movements were recorded using magnetic search coils; eye position in the orbit was reconstructed by electronic subtraction. Smooth pursuit of a projected laser target was also tested.

In darkness, VOR gain (eye vel./head vel.) was directionally symmetric and ranged from 0.8-1.3 at both frequencies tested. During magnified vision, gain was closer to the ideal value of 1.0 than in darkness. During wearing of TS, there was considerable inter-individual variability in gain, but all subjects exhibited increases with TS to as much as 4.0 at 0.4 Hz, and some exhibited increases to as much as 2.5 at 1.6 Hz. Vertical smooth pursuit, however, was poor at these frequencies.

These data indicate the presence of robust vertical VVI at frequencies previously believed to be above the range of the smooth pursuit mechanism.

312.13

SACCADIC EYE MOVEMENTS AND RAPID ARM MOVEMENTS IN A DOUBLE-STEP TRACKING TASK. G.K.Kerr. Univ. Lab. of Physiology, Parks Road, Oxford OX1 3PT, U.K.

The interdependence of visual and limb movement control processes during goal-directed movements was examined in 7 subjects who used a manipulandum to track a target displayed on an oscilloscope. After a random foreperiod the target stepped to the right (visual angle 15°;elbow angle 45°) followed, on 60% of trials, by a second target step (visual angle 10°;elbow angle 30°) at one of 10 different inter-stimulus intervals. The second target step occurred in one direction only (left or right) on each day of testing.

When the second target step occurred 100ms or more prior to onset of the initial saccadic eye or elbow movement their amplitude of movement was able to be altered. However, there was an increased delay in producing a second movement. This appeared to result from the interruption of early stages of response programming arising from the incorporation of new visual information into initial amplitude computations. These stages involve a greater interdependence of visual and motor processes, possibly due to the utilisation of a common coordinate system.

312.14

EYELID MOVEMENTS WITH VERTICAL SACCADES IN HUMAN SUBJECTS. K.A. Manning, P.A. Sibony, & C. Evinger. Depts. of Neurobiology & Behavior and Ophthalmology, SUNY Stony Brook, NY 11794.

The upper eyelid follows the trajectory of the eye in a similar, but not idential fashion, during vertical saccades. The mechanisms underlying lid saccades, however, are poorly understood. We examined the lid kinematics (magnetic search coil method) and orbicularis oculi (OO) muscle activity (skin electrodes) of saccadic lid movements and blinks in 9 normal human subjects. Subjects executed 100 saccades (3-38 deg) and > 20 each of voluntary blinks and reflex blinks (supraorbital nerve stimulation).

For upward lid saccades, peak lid velocity increased linearly with amplitude at the same rate as the up-phase of the blink. This supports the notion that a single mechanism produces upward lid saccades and the blink up-phase. In contrast, the increase in velocity with amplitude of downward lid saccades plateaus and reaches only half of that seen with the blink down-phase. Thus, lid lowering with saccades and blinks employs different mechanisms. Further evidence of this difference occurs following lid injection of botulinum toxin (Manning et al. 1989). This treatment for facial spasms significantly reduces the velocity of the blink down-phase, but not that of downward lid saccades.

In most subjects, upward lid saccades lasted longer (sometimes twice as long) as downward lid saccades. Upward lid saccades often undershot, and down ward lid saccades frequently overshot final lid position. A small 50-100 msec increase in OO activity commonly occurs near the start of lid saccades in both directions. This tendency for OO activity to accompany gaze changes could contribute to the downward lid saccade overshoot, upward lid saccade undershoot, and the overall faster speed of downward lid saccades.

NICOTINE TRANSIENTLY INCREASES THE LATENCY OF THE BLINK REFLEX. C. Evinger. Dept. Neurobiology & Behavior, SUNY, Stony Brook, NY 11794

Smoking a cigarette causes a transient, 50% increase in the latency of the blink reflex in humans (Evinger et al., 1989). This increased latency might result from the nicotine in cigarette smoke acting on nicotinic receptors in the trigeminal nuclei and medullary reticular formation and/or by binding to nicotinic receptors in the basal ganglia. Consistent with the latter possibility, Huntington's chorea causes a similar increase in blink latency. We investigated the effect of nicotine alone on blink latency and examined the relative contributions of the brainstem and more rostral regions to modification of blink reflex latency in the rat.

Air puffs or electrical stimulation of the cornea of urethane anesthetized rats elicited robust blinks. Monitoring the EMG activity of the lid closing orbicularis oculi muscle (OOemg) allowed measurement of blink onset and magnitude. Electrical stimulation of the cornea evoked a blink with a latency of 12 ms and a relatively constant magnitude over repeated trials. An I.V. injection of nicotine (.8 mg/kg), however, caused a transient (3-5 min) 15% increase in corneal blink reflex latency and a slightly larger blink. Air puffs evoked blinks with a latency of approximately 20 ms and injecting nicotine transiently increased (2-7 min) the latency of these blinks by 40%. These results support the conclusion of our human study that the nicotine in cigarette smoke alters the blink reflex. To investigate if the brainstem nicotinic receptors were responsible for this modification, precollicular decerebrate rats received IV injections of nicotine. In these animals, which exhibit robust blinks, nicotine failed to alter the OOemg latency. This result supports the hypothesis that nicotine transiently increases the blink reflex latency by its action on more rostral regions such as the basal ganglia. Supported by grant EY07391.

313.1

UNIT ACTIVITY IN THE PRIMATE POSTERIOR PARIETAL CORTEX DURING AN OCULOMOTOR DELAYED RESPONSE TASK. M. Chafee*, S. Funahashi, and P.S Goldman-Rakic (SPON: P. Rakic). Sec. of Neuroanatomy, Yale Univ. Sch. of Med., New Haven, CT 06510.]

Spatially-selective mnemonic activity recorded in the prefrontal cortex was recently shown to reflect the location of visual targets presented during an oculomotor delayed-response (ODR) task. (Funahashi et al. J. Neurophysiol. 61:331-349,1989). Although the prefrontal cortex (PFC) receives visual input from a number of cortical areas, the posterior parietal cortex (PPC) is a likely source of visuospatial information because of its known projection to prefrontal cortex and its involvement in visuospatial processing.

Unit activity was collected from the PPC during ODR performance. Of the 134 units collected from two hemispheres, 99 were related to the task, and were activated either during the cue (13%), delay (28%) or response (79%) periods. The directionality of these responses was described by a gaussian curve fit to the magnitude of the response observed in each cell as the target postion was varied. Roughly 1/2 of all cue, delay and saccade responses recorded in the PPC were directionally selective. Although prefrontal and posterior parietal neuronal populations appear grossly equivalent in that directionally-selective cue, delay and oculomotor units were encountered, visual activity appeared significantly earlier ($p < .01$) in the PPC (mean latency, 92 msec) than in the PFC (mean latency, 134 msec), consistant with a feedforward transmission of visual information during ODR performance. On the other hand, oculomotor activity collected from the two areas was remarkably similar: the majority of the responses were post-saccadic, and frequency distributions of saccade latencies ranged from 200 msec before to 350 msec following the eye movement with the modal latency value occuring between 0 and 50 msec after the initiation of the eye movement in both regions.

These data provide physiological evidence supporting the idea that the prefrontal and posterior parietal cortices are engaged in a common circuit dedicated to visuospatial memory. Supported by MH44866.

313.2

VISUAL AND MNEMONIC CODING IN THE PRIMATE PREFRONTAL CORTEX DURING OCULOMOTOR DELAYED-RESPONSE PERFORMANCE. S. Funahashi, C.J. Bruce, and P.S. Goldman-Rakic. Sec. of Neuroanatomy, Yale Univ. Sch. of Med., New Haven, CT 06510.

We have previously reported that many prefrontal (PF) neurons have "memory fields", i.e. show excitation or inhibition in the delay period for selected cue directions in an oculomotor delayed-response (ODR) task (Funahashi et al. J. Neurophysiol. 61:331-349, 1989). To understand how visual activity relates to mnemonic activity in PF cortex, in the present experiment we compared the activity of PF neurons during the delay period in the ODR task with their visual activation in the cue period of the ODR task.

Among 434 PF neurons studied, 74 had phasic visual response to the onset of the cue, 168 had delay activity, and among them, 43 displayed both activities. Of the PF neurons with visual responses, 96% showed directional selectivity; best directions for 66% of neurons were toward the contralateral visual field, and the remaining neurons had best directions in the ipsilateral field (20%) or along the vertical meridian (14%). Similarly, of PF neurons with delay activity, 77% showed directional selectivity, and among them, 62% had best directions toward the contralateral visual field. The average breadth of directional tuning for the visual and mnemonic cells were 46° and 43° respectively, and did not differ significantly.

Comparison of the directional selectivity of the visual response with that of the delay activity for the 43 neurons with both activities revealed positive correlations between the best directions (+0.69) and tuning specificity (+0.27).

These findings indicate that most particulars of the visual activity exhibited by PF neurons are consistent with a role in constructing "memory fields" which appear to hold visuospatial information "on-line" to direct subsequent behavior. This is of interest because many neurons with memory fields lack overt visual activity. Thus, the mnemonic process may involve several distinct types of neurons that communicate with each other locally, perhaps within a cortical column.

313.3

CELLS IN PARIETAL CORTEX OF MACAQUES INVOLVED IN OCULAR FIXATION AND GOAL-DIRECTED MOVEMENTS.
M.P. GUICHARD*, J.P. JOSEPH, and M. ARZI INSERM U 94, 16 av. doyen LEPINE, 69500 BRON, FRANCE

We have studied the properties of cells recorded from the Intra-Parietal Sulcus (IPS), which are activated by both fixation of spatial targets and arm movement towards these targets.There were two targets (R and L separated by 70°) and four possible starting positions of the hands. The animal was fitted with EOG electrodes.

About half of the cells were activated by fixation of the ipsilateral and the other half by fixation of the contralateral target (spatial selectivity). For most cells, the intensity of the discharge during fixation did not depend on the arm used for the movement, but on the relative position or distance (before movement) between the starting point of the hands and the fixated target.

The same cells were also activated during arm movements. Activation induced by movement of the ipsilateral arm was weaker but comparable in all aspects to that induced by the contralateral arm. About half of the cells were activated with movements towards one target only (primarily towards the target ipsilateral to the recording site) whichever starting position was used. In these cells, spatial selectivity for movement and for fixation were for the same target. In the other half, spatial selectivity for movement was less pronounced than for fixation.

These data suggest that a population of cells in IPS is implicated in visual control of goal-directed movements.

POSTERIOR PARIETAL CORTEX, THE OCULOMOTOR NEAR RESPONSE AND SPATIAL CODING IN 3-D SPACE. JW Gnadt and LE Mays. Dept. of Physiological Optics and Neurobiology Research Center, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Single unit recordings were performed in posterior parietal cortex and superior temporal sulcus during near response behavior in trained Rhesus monkeys. Vergence demand, accommodative demand, binocular disparity, vergence response, accommodative response and their time derivatives were independently manipulated and measured. The following types of neurons were found:

1) *Disparity-sensitive visual tracking cells* were related to ongoing binocular disparity during visual tracking in depth. 2) *Velocity-sensitive motor cells* reflected the velocity of either ocular vergence or lens accommodation, independent of stimulus parameters. The cells responded during pursuit trials or for movements to a stepped target. In some cases, the activity led the movements; in other cases, it followed. 3) *Visual fixation cells* modulated their firing rate during changes in conjugate *and* disjunctive eye position. The cells' activity lagged eye position by about 100 ms and was unaffected by accommodation. The cells did not require a visual target during fixation. 4) *Eye-position-dependent visual cells*. Some visually responsive cells were modulated by the conjugate *and* disconjugate position of the eyes, even though the stimulus fell on the same positions on the two retinae. This suggested that some visual cells in parietal cortex are tuned in a three dimensional coordinate frame of reference.

Histological reconstruction has shown that these cell types exist in both the lateral bank of the intraparietal sulcus and in the medial bank of the superior temporal sulcus, two cortical areas which are interconnected anatomically. *(Supported by F32 EY06089 and T32 EY07033 to JWG, EY03463 to LEM and CORE EY03039.)*

COMPARISON OF CELL ACTIVITY IN CORTICAL AREAS 6, 4, and 5 RECORDED IN AN INSTRUCTED-DELAY TASK. D.J. Crammond and J.F.Kalaska, Centre de recherche en sciences neurologiques, Université de Montréal, Montréal, Québec, Canada. H3C 3J7.

253 arm-related cells were studied in 2 hemispheres of 1 monkey trained to make whole arm reaching movements in two-dimensions, during both an INSTRUCTED-DELAY and a CONTROL task described previously (Crammond and Kalaska 1988, Neurosci. Abstr. 14:343). In the DELAY task, the activity of 153 cells changed significantly after presentation of the CUE signal and varied with the direction of the intended movement. DELAY period activity was more common in area 6 (95/120 cells) than in area 5 (56/101 cells) and was infrequent in area 4 (2/32 cells). There were three major patterns of DELAY period activity (short-duration phasic bursts, sustained tonic rate changes and ramp changes). Tonic responses predominated in area 5 (74%), while phasic (41%) and ramp responses (37%) predominated in area 6, suggesting separate roles for the two areas in motor preparation. Latencies of cell activity in the DELAY period were similar in areas 5 and 6.

DELAY period activity predicted the directionality of cell activity in the CONTROL task. In the CONTROL task, 43/98 area 5 cells discharged before the first sign of EMG activity compared to 93/117 in area 6 and 22/30 in area 4. However, the mean pre-EMG latencies of these cells (-57 ms in area 6, -50 ms in area 4, -38 ms in area 5) were similar. Most area 5 and 6 cells which were active prior to EMG activity in the CONTROL task also showed DELAY period responses, but the majority of pre-EMG area 4 cells did not. This suggests that pre-EMG activity in area 4 was almost entirely related to movement execution. Many cells with phasic DELAY responses were less active after the GO signal in the DELAY task, than in the CONTROL task. Thus, pre-EMG activity in these cells could be dissociated into response components related to movement preparation and execution. (Supported by MRC Group Grant in neurological sciences).

313.6

RECIPROCAL TEMPORAL TRENDS OF SENSORY- AND MOTOR-COUPLING IN PREFRONTAL UNITS DURING VISUAL DELAY TASKS.
J. Quintana* and J.M. Fuster. Department of Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The purpose of this work is to determine the degrees of sensory- and motor-coupling of prefrontal units in the monkey engaged in visuo-motor performance with interposition of time between discrimination stimuli and discriminant responses. A delay task is used in which stimuli and responses are not only dissociated in time but in space: A brief and central color-light stimulus (1) is followed by a delay and a second stimulus (2) --a pair of white or color lights-- prompting the manual response to one side (right or left). The contingencies of the task are as follows:

Stimulus 1	Delay	Stimulus 2	Response direction
Yellow or Green	12 s	White lights	Right
Blue or Red	12 s	White lights	Left
Red or Green	12 s	Red and Green	Matching color (random side).

Thus, the color of the stimulus 1 predicts the response direction with different probabilities (Yellow, 100% right, 0% left; Blue, 0% right, 100% left; Red, 75% left, 25% right; Green, 25% left, 75% right). Some prefrontal units (8%) are coupled differentially to sensory information, and some (17%) to response direction. A third group of units are both sensory- and motor-coupled. Direction-related reactions may appear at any time after stimulus 1, as long as this stimulus provides unambiguous information about response direction, or after stimulus 2 in the absence of that information. Within and between units, the amplitude of direction-related reactions tends to increase with the proximity of the response, whereas that of sensory-related reactions tends to decrease after stimulus presentation. A few prefrontal units show selective activities in relation with certainty or with uncertainty of impending response direction. The existence of units coupled to such a variety of factors stresses the role of prefrontal cortex in cross-temporal integration of visuo-motor contingencies and behavioral planning.

FORELIMB MOVEMENTS WERE INDUCED BY BICUCULLINE INJECTION IN THE MONKEY PREFRONTAL AREA 8 AFTER A GO/NO-GO TASK WAS LEARNED. T. Oishi* and K. Kubota. Dept. of Neurophysiol., Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, JAPAN.

In naive monkeys (Macaca mulatta, N=2), somatotopically organized movements were induced by local injection of bicuculline (BMI, 5-10 μg) in areas 4 and 6, and only eye movement (19 sites) and shoulder elevation (5 sites) were induced in area 8. In contrast, in monkeys well-trained for a GO/NO-GO task (N=4), BMI injection in area 8, in addition to eye and shoulder movements, induced forelimb movements (16 sites). To confirm this further, in the same sites of area 8 of the same monkeys (N=2, 19 sites), BMI effect was compared before and after the training. Only after the training, BMI injection induced contralateral forelimb movements, similar in temporal patterns to the lever release performance of the task. In ipsilateral area 8, no changes in BMI-induced movements were observed before and after the training. These data suggest that, during learning of the task, a structure responsible for learned forelimb movements may be formed within contralateral area 8 and that the GABA controls are involved in such a learning-associated structuring.

SPATIAL REPRESENTATION OF MOVEMENT DISTANCE AND DIRECTION IN THE PREMOTOR CORTEX. D. Karluk*, T.J. Ebner. Depts. Neurosurgery and Physiology, Neuroscience Grad. Prog., Univ. of MN, Mpls., MN 55455.

Our previous chronic unit recording studies described the existence of a "movement field" for premotor cortex cells, each neuron exhibiting a preferential movement direction and distance. This study examined whether these two movement parameters were topographically represented. Single neurons were recorded from the premotor cortex of Rhesus monkeys trained to move to targets within the horizontal plane. The targets were arranged in circles at 3 distances from a central start box. For each cell, the response profile was divided into a series of time intervals of the percent change in firing relative to background. The response profile for each cell was plotted for a specific target and time epoch relative to its location in the premotor cortex. Although preliminary, the results suggest that for the same direction, different populations of cells are recruited for different distances. In contrast, for a given distance roughly the same population is activated, the magnitude of the increase varying with direction. These findings suggest a premotor cortex topography in which the population activated varies with movement distance and the modulation within a population varying with direction. ABNORMALITIES OF SUPPLEMENTARY MOTOR AREA (SMA) NEURONAL ACTIVITY IN MPTP PARKINSONISM. R.L. Watts, A.S. Mandir, Depts. of Neurology & Physiology, Emory Univ., Atlanta, GA 30322; E.B. Montgomery, Jr., Dept. of Neurology, Washington Univ., St. Louis, MO 63110.

We recorded single unit activity in the SMA of a macaque during self-initiated, rapid right wrist movements in the normal state and following induction of MPTP hemiparkinsonism. The animal was trained to "self"-initiate a flexion or extension movement following a visual instruction by at least 1.5 sec. In the normal state 51 task-related units were recorded in the left SMA: 40% were pre-movement "preparatory set" cells, 35% were "movement onset" related cells and the remaining 25% were best related to achievement of final target or receipt of a juice reward. A mild-moderate degree of right hemiparkinsonism was induced with 4 injections of 1.25-1.5 mg of MPTP into the left carotid artery over 5 weeks. Movement time remained significantly prolonged 6 months after MPTP ($p < .0001$; 477±29 msec vs. 315±17 in normal state), and electromyographic (EMG) activity disorganized in a pattern characteristic of parkinsonism. Following MPTP directional specificity of SMA neuronal activity was lost, and normal timing characteristics of SMA pre-movement "preparatory set" cells were greatly altered. Based on preliminary results, we conclude that abnormal "set" cell firing in SMA may play a role in defective movement initiation caused by parkinsonism.

313.10

CHANGES IN MOTOR CORTEX NEURONAL ACTIVITY ASSOCIATED WITH INCREASED REACTION TIME IN MPTP PARKINSONISM. A.S. Mandir, R.L. Watts, Depts. of Physiology and Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322, and S.R. Buchholz*, E.B. Montgomery, Jr., Dept. Neurology, Washington Univ. Sch. Med., St. Louis, MO 63110.

We recorded motor cortex (MC) neuronal activity in macaques performing either self- or stimulus-initiated rapid wrist flexion and extension tasks. Preliminary data reflect 3 normal animals and 2 of the 3 following induction of MPTP parkinsonism. Neurons were judged best related to either "GO" signal ("GO" neurons) or movement onset ("MO" neurons) by criteria examining abruptness, magnitude and temporal consistency of changes of neuronal firing. The timing between behavioral events and onset of first significant neuronal activity change are reported [PRE/POST MPTP] for **9** pre- and **6** post-MPTP "GO" neurons and **23** pre- and **16** post-MPTP "MO" neurons: "GO" signal to movement onset (MO) [260/330; median values in msec], "GO" signal to "GO" neurons [80/140], "MO" neurons to MO [180/250], and EMG onset to MO [100/140]. EMG patterns were less organized following MPTP, and therefore inefficient in generating MO. We hypothesize that movement initiation is delayed in MPTP parkinsonism due to decreased MC responsiveness (possibly due to failed "set" function in supplementary motor area) and inefficient generation of EMG for MO.

313.11

LEARNING-DEPENDENT ACTIVITY IN PREMOTOR CORTEX OF RHESUS MONKEYS. A.R. Mitz, S.P. Wise, M. Godschalk, Laboratory of Neurophysiology, NIMH, Poolesville, MD 20837.

Single-unit activity was studied in the premotor cortex (PM) of two rhesus monkeys while they learned new visuomotor associations. On each trial, the animals were presented one of a set of 4 visual stimuli and used a joystick to respond either 'Left', 'Down', 'Right', or 'NoGo'. Each stimulus in the set was associated with one correct response. One to 3 s later the stimulus flashed to trigger the response. Only a correct response within 1 s was rewarded. A given stimulus was repeated after a failed trial until the monkey responded correctly. After all stimulus-response associations were learned for a given set of 4 stimuli (fewer than 1 error in 10 trials per stimulus), a new set of 4 stimuli was presented. Animals typically learned to criterion in 3 to 20 minutes (40 to 200 trials). Single-units were recorded during the entire learning process and during the presentation of a set of 4 well-known (overlearned) stimuli.

Neuronal activity patterns observed during the task were similar to those described previously, including movement-, set-, and signal-related activity. Response-specific activity was observed. Half (15/29, first monkey) of the neurons analyzed showed no change during the learning process: their activity during early trials, when the monkey could not know the proper response, was nearly identical to activity late in the learning process (as well as during trials with the corresponding overlearned stimuli). The other half (14/29) showed learning-dependent activity. These neurons typically showed disorganized unit discharge during the initial phase of learning, and well-organized firing later, when the stimulus-response association had been learned. This later, well-organized firing, was characteristic of the same unit during responses to the corresponding overlearned stimuli.

314.1

CODING OF TONGUE MOVEMENT DIRECTION BY NEURONES IN TONGUE REGION OF MOTOR CORTEX (MI) OF AWAKE MONKEYS (M. FASCICULARIS). G.M. Murray and B.J. Sessle. Fac. of Dentistry, Univ. of Toronto, Toronto, Ont., M5G 1G6.

Some neurones within limb MI change their activity with arm movement direction (Georgopoulos et al, Sci., 1986). The aim of this study was to see if neuronal activity in tongue MI varies with tongue movement direction. In 2 awake monkeys, extracellular recordings were made from 48 single tongue MI neurones firing in relation to the monkey's trained tongue protrusion task towards a force transducer. Each neurone's activity was recorded during 10 or more trials with the transducer fixed at each of 2 or 3 positions in front of the monkey's mouth: at 0^{o} or 30^{o} to left or right from the midline. The firing rates of 27 of the neurones (65%) varied significantly (ANOVA; $p<0.05$) with the direction of tongue protrusion; 24 of the 27 exhibited a single preferred direction for which firing rate was significantly greater than for any other direction. All 27 neurones were located at intracortical microstimulation-defined (≤ 20 μA) tongue MI sites; an intraoral mechanoreceptive field was identified for 14. Thus, many tongue MI neurones, some of which receive intraoral afferent inputs, show modulation of their activity in relation to the direction of a tongue protrusion movement. This suggests that, in accordance with recent findings in limb MI, neuronal population coding of movement direction may be a feature of tongue MI. Supported by Canadian MRC.

314.2

DISCHARGE PROPERTIES OF NEURONES WITHIN PRIMATE TONGUE SOMATOSENSORY CORTEX SI DURING TRAINED MOTOR TASKS. L.-D. Lin, G.M. Murray, E. Moustafa* and B.J. Sessle. Fac. Dentistry, Univ. of Toronto, Toronto, Ont., M5G 1G6.

Changes in activity of SI neurones during limb movements have been implicated in limb motor control mechanisms. The aim of this study was to see if neurones in tongue SI also alter their activity during orofacial movements. Extracellular single unit recordings were made in two awake monkeys (M. fascicularis) trained to perform tongue protrusion and jaw biting tasks. The activity of 17 of 40 neurones with a mechanoreceptive field on the dorsal surface of the tongue was analyzed during the trained tongue protrusion task. 15 of these neurones showed a significant change in activity during the task: 13 neurones showed an increase in activity and 2 a decrease in activity; 2 of the 15 neurones increased their activity before the onset of tongue muscle EMG activity associated with the task. Activity during the biting task was analyzed in 10 of the 15 neurones which altered their activity during the tongue task, but only 3 of these neurones showed a change in activity during the biting task. These data suggest that tongue SI neurones may selectively alter their activity in relation to different trained orofacial tasks(i.e., tongue protrusion vs biting) and different phases of the tasks, and that these activity patterns may be utilized in the sensorimotor integration of orofacial movements. Supported by Canadian MRC.

314.3

A MOVEMENT-SEQUENCE DELAY TASK FOR THE STUDY OF MOTOR CORTICAL ACTIVITY DURING ARM REACHING IN 3D SPACE TJ Gould and RE Kettner (SPON: GP Frommer) Department of Psychology, Program in Neural Science, Indiana University, Bloomington, Indiana 47405

Past studies in prefrontal, premotor, supplementary motor and primary motor cortex have established that single-neuron responses can be observed well before the initiation of simple movements. These early responses may be associated with the generation and/or storage of appropriate motor responses. The present work sought to develop a behavioral preparation which could be used to study the generation of a more complicated sequence of movements than has previously been studied. The task temporally separates neural responses related to sensory input, short-term "memory" storage, and movement output. It also allows the analysis of reproducible, multi-joint, arm movments which have reasonably complicated trajectories in time.

A rhesus monkey was trained to hold a center button when a cue light came on. While continuing to hold at the center button, two of four randomly selected target buttons were lit in sequence. A 2-3 s delay period, during which no target buttons were lit, was terminated by dimming the cue light. The monkey then moved from the center button to target button 1 to target button 2 and then back to target button 1 to receive a liquid reward. Behavior in this task was shaped slowly over a period of several months. Final performance was at the 82% correct level with 46% of the errors being center-button release errors. Behavioral analyses indicate stereotyped eye movements during this task with the eyes fixed upon the cue light during the delay period. Arm movements were rapid averaging 274 ms. Motor cortical activity recorded during performance in this task will be reported.

314.4

NEURAL MODEL OF MOTOR CORTICAL RESPONSES DURING REACHING IN 3D SPACE RE Kettner & TJ Gould, Department of Psychology, Program in Neural Science, Indiana University, Bloomington, Indiana 47405

In past work by Georgopoulos et al. [Science (1986) 233: 1416; J Neurosci 8: 2913] the response properties of neurons in the motor cortex of monkeys making arm movements in 3D space have been described. We find that a large class of multi-layered, linear, network models produce response properties which are very similar to those observed in the above mentioned recording studies. A specific model which works consists of a feed-forward network with three layers corresponding to: the retina, association cortex, and motor cortex. The neural population code proposed in the above mentioned studies is used to predict movement direction in 3D movement space from motor cortical responses. Neuron-like nodes in each layer receive feed-forward input from elements at the next lowest level, and send outputs to nodes in the next highest level that are linearly porportional to their summed inputs. It can be proven mathematically that this and other, linear, feed-forward models have the following properties:

1. Activity changes are maximal in a preferred direction.
2. Motor cortical tuning functions follow a cosine relationship.
3. The population code predicts movement direction well given certain statistical and uniformity conditions.
4. Sustained activity varies linearly with hold position.
5. The same activity changes occur for same-direction movements initiated from different points in space.
6. The population code predicts movement initiated at multiple points in space using a fixed set of parameters.

In sum, a class of linear models may provide a first step in the creation of more general models of motor cortex responses observed experimentally during arm reaching in 3D space.

RELATIONSHIPS BETWEEN PRIMATE CORTICOMOTONEURONAL CELLS AND THEIR TARGET FOREARM MOTOR UNITS DURING TORQUE TRACKING. P. A. Fortier, D. Flament and E. E. Fetz, Dept. Physiol. & Biophysics and Regional Primate Res. Center, Univ. of Washington, Seattle, WA 98195.

Previous studies have shown that primate corticomotoneuronal (CM) cells and single motor units (SMU) of forearm muscles can be classified according to their response patterns during ramp-and-hold wrist movements (e.g., phasic-tonic, tonic, decrementing, etc.), and by their discharge rates as a function of active torque. The present study sought to determine (a) the degree to which CM cells facilitate different SMUs in their target muscles and (b) whether particular types of CM cells and SMUs are preferentially interconnected. In a monkey performing an isometric torque tracking task about the wrist, CM cells were identified by the presence of post-spike facilitation of forearm multiunit EMGs and were recorded simultaneously with several SMUs. By leaving the electrode in place, the same CM cells could be recorded for several days with different SMUs. Cross-correlograms between CM cells and SMUs of facilitated muscles showed post-spike peaks for most, but not all SMUs of the target muscles. The proportion of SMUs facilitated by CM cells (71%) was comparable to the proportion (73%) reported by Mantel and Lemon (Neurosci. Lett. 77:113), but less that the proportion facilitated by single intracortical microstimuli (95%; Palmer and Fetz, J. Neurophysiol. 54:1194). In many cases single CM cells facilitated SMUs in different muscles, consistent with divergent effects. Preliminary results show that the cross-correlation peaks tend to be larger for CM-SMU pairs which had similar discharge patterns during the tracking task.

MOTOR CORTICAL IMAGES OF SINUSOIDAL TRAJECTORIES. Andrew B. Schwartz and Bryan J. Anderson.* Barrow Neurological Inst., 350 W Thomas Rd., Phoenix, AZ 85013.

Monkeys were trained to draw with their fingers on a computer touch screen. Two tasks were performed as single units in the motor cortex were recorded extracellularly. The animals in the first task were required to move their index fingers directly from a center start position to one of eight radially oriented targets. The discharge rates of the active cells recorded in this task were found to be maximal in a single preferred direction and to fit a cosine function when plotted against the direction of movement. Sine waves of different amplitude and spatial frequency were presented to the animals in the second task. The animals were trained to smoothly trace, with their index fingers, the sinusoid from one end of the screen to the other. 'Population vectors' representing the combined activity of the many cells active in the motor cortex during this task were constructed. The weight of each cell's contribution in its preferred direction was determined by that cell's discharge rate at 20 msec intervals throughout the task and a population vector was calculated for each interval by summing all the cells' contributions. The direction of the population vectors changed throughout the sinusoidal task, closely matching the smoothly changing direction of the finger path. The 'image' formed by connecting the population vectors was that of the actual sinusoidal trajectory. (NIH- NS26375)

MOVEMENT TRAJECTORY OR GOAL REPRESENTATION IN PRIMATE PREMOTOR AND PRIMARY MOTOR CORTEX. S. Hocherman and S.P. Wise, Lab. Neurophysiol., NIMH, Poolesville, MD 20837

Neuronal activity was examined in areas 4 and 6 of two rhesus monkeys operantly conditioned to execute curved vs. straight arm-projection movements. Movements began from a common origin point under the chin and ended at one of three 36 mm wide targets: 0°, -30°, or +30° in front of the monkey. Three paths were used to approach each target: straight, curved convex to the right or curved convex to the left. After an initial hold time, an instruction stimulus (IS), consisting of 2-4 LEDs indicating the final target and the approach trajectory, was presented for 120 ms. A trigger stimulus (TS) followed 350-1000 ms after the IS. Movement was not constrained in time, but the chosen path had to be followed within ± 8 mm.

Of the 324 task-related units analyzed, 76 were located in area 4, 73 in ventrolateral area 6, 115 in dorsomedial area 6, and 60 in mesial area 6. Unit activity was found immediately after the IS, between the IS and TS, immediately before movement, and during other task epochs. For most units, activity modulation took place during more than one epoch. We hypothesized that if neurons represented spatial goals, we should observe similar activity for all movements to a given target. Similarly, if movement trajectory was represented, modulation should be observed in relation to given path types, regardless of target location. Neurons representing trajectory outnumbered those representing target position. Curved trajectories were found to be represented more often than straight ones.

314.8

EFFECTS OF MOTOR CORTEX INACTIVATION ON FORELIMB MOTOR CONTROL IN THE CAT. S.E. Cooper*, J. H. Martin, E. Sybirska, J. Brennan* & C. Ghez, Ctr. for Neurobiol & Behav, Columbia Univ and NYS Psych Inst, New York, NY, 10032.

The present study analyzes deficits in forelimb motor control resulting from inactivation of motor cortex (MCx). Deficts were assessed in a prehension and a step-tracking task. In the prehension task, cats reached to a baited target to grasp a morsel of food. In tracking, cats made adjustments of elbow torque to match abrupt changes in a target level indicated by a compensatory display (reaction time, RT, ~ 100 ms). Motor cortex was inactivated by microinjection of the short-acting local anesthetic lidocaine (10-30μg) or the long-acting GABA agonist muscimol (1-2μg). We measured changes in limb kinematics in prehension, and in RT and force trajectories in tracking.

Inactivation of the forelimb area of MCx resulted in the loss of placing and changes in posture characteristic of MCx lesions. In prehension, animals exhibited (1) hypometria, (2) impairment in the normally fluid sequence of elbow flexion and wrist extension in reaching, and (3) a reduced ability to use the digits in grasping. In tracking, responses were modestly hypometric in 12 of 14 experiments, while increases in RT occured in only 5 of 14 experiments and were quite small.

Our data on prehension suggest that the motor cortex plays a role in the independent spatial and temporal control of proximal and distal components of the motor response. In tracking, the lack of RT prolongation in the presence of impaired force production, taken together with our earlier finding that reversible inactivation of the red nucleus can prolong RT without impairing force production, supports the hypothesis that response initiation and amplitude control are mediated independently. (Supported by NS19205)

314.9

TIME-RELATED COGNITIVE EVENTS ENTRAIN NON-LINEARLY COUPLED RHYTHMS IN HUMAN EEG.

Hilton Stowell. ERBP Laboratory, 120 Nature Creek, Milledgeville GA 31061.

When human subjects learn and attempt recall of the relative timing of acoustic rhythms their scalp-conducted EEG shows rhythmical activity around onset-time of the accented transient, which can account for the phenomena called sensory evoked potentials (EP). Selective frequency analysis of this activity in the time-domain shows it to consist of a subharmonic and higher harmonics of their predominant alpha rhythm, synchronized for sufficient successive trials to reach statistical significance of phase-angle and amplitude either for stimulated trials alone, for unstimulated ("silent recall") trials alone, or for both together. This global mixture of alpha sub- and higher-harmonics, which is reflected in the unanalyzed "vertex potential" of EP, is further evidence for non-linear coupling of oscillating neural networks seen in nonhuman brains [1]. 1. Boeijinga, P.H. & Lopes da Silva, F.H. Brain Res. 478 (1989) 257-268.

CEREBRAL POTENTIALS PRECEDING ORAL MOVEMENT. A. B. Wohlert* and C. R. Larson. Dept. of Communication Sciences and Disorders, Northwestern U., Evanston, IL 60208.

The "readiness potential" is an averaged EEG record which shows increasing negativity at vertex and sensorimotor scalp sites prior to voluntary limb movements. It becomes lateralized to the hemisphere contralateral to the movement, just before the movement's onset. In order to determine whether simple, midline oral movement engenders the same pattern, potentials preceding bilateral lip protrusion and right finger extension tasks were compared in 12 right-handed subjects. Prior to the finger movement, potentials were generally more negative over the dominant left hemisphere. Prior to the lip movement, there was no consistent pattern of lateralization, nor did the hemisphere showing greatest negativity always correspond to the side of the lip showing earliest onset or greatest amplitude of EMG activity. Results do not support left hemisphere dominance in the pre-movement control of coordinated midline oral gestures, at this simple level.

314.11

FOCAL STIMULATION OF CORTICOSPINAL NEURONS LOCATED DEEP IN PARASAGITTAL PRECENTRAL CORTEX WITH THE MAGNETIC COIL. Joan B. Cracco*, Roger Q. Cracco, Nassar F. Hassan*, Mahendra Somasundaram*, Vahe E. Amassian and Paul J. Maccabee* Departments of Neurology and Physiology, SUNY Health Science Center at Brooklyn, Brooklyn, N.Y. 11203.

Using ourselves as subjects, we have shown that lateral areas of the precentral motor cortex can be focally activated to elicit individual finger movements. For focal activation we used a small "figure of eight" stimulator composed of two magnetic coils, each 5.0 x 4.8 cm., optimal stimulation occurring under the junction. We also demonstrated that focal activation of precentral parasagittal cortex is possible. Movements limited to abduction or flexion of toes and plantar or dorsiflexion of the foot were elicited. Recordings of compound motor action potentials from muscles of the left leg showed that the threshold for activation for small foot muscles was lower than for more proximal muscles. Furthermore, at certain precentral parasagittal scalp locations the abductor hallucis could be activated nearly in isolation whereas at sites a short distance away only abductor digiti minimi and extensor digitorum brevis were activated. Thus focal activation of corticospinal neurons deep in parasagittal precentral cortex can be achieved with magnetic coil stimulation.

314.12

SPECTAMINE IMAGING OF CEREBRAL BLOOD FLOW DURING VOLUNTARY MOVEMENT AND FOCAL STIMULATION OF MOTOR CORTEX WITH MAGNETIC COIL. B. Shafran*, P.J. Maccabee*, V.E. Amassian, R.Q. Cracco, A. Strashun*, R. Vaquer*, R. Singman* (SPON: B.M. Altura). Dept. Neurol., Physiol. and Nuclear Med., SUNY Hlth Sc. Cntr, Bkln, NY 11203

Spectamine imaging (I^{123}) of cerebral activity was performed during voluntary finger flexion (VFF) and magnetic coil stimulation (MCS) of motor cortex resulting in contralateral finger flexion. A butterfly (MC) over motor cortex hand area was energized just above threshold to elicit the finger flexions. Movements occurred once/20s in both groups. Imaging revealed increased activity (13-19%) in motor and premotor cortex contralateral to VFF. With MCS, this difference was reduced (4%) or reversed i.e. motor cortex opposite the MCS side had higher scintillation counts (15%) than the stimulated cortex, but both were absolutely increased. Cerebellar hemispheres did not differ significantly with voluntary activity (1.7%), but was 18% greater contralateral to the side of MCS. Thus, activity in motor and premotor cortex increases contralateral to voluntary finger movement, but increases bilaterally in motor cortex with MCS. This bilaterality may reflect transcallosal responses. Cerebellar cortex contralateral to the side of MCS was selectively activated. Evidently, focal MCS may activate different pathways in human motor cortex.

314.13

FRONTAL CORTICAL CELLS OF RATS ARE ACTIVATED IN A DIVIDED ATTENTION TASK. K. Pang, D. Olton and H. Egeth. Dept. of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

The frontal cortex (FC) is critically involved in divided attention. FC lesions in rats disrupt divided attention, while leaving focussed attention intact. In the present study, the activity of FC neurons was examined in a temporal discrimination task. Rats were trained to two stimuli (light and tone), each associated with a different fixed interval. Focussed attention trials (single stimulus presented) and divided attention trials (two stimuli presented) were given randomly within a session. Recording electrodes were implanted into the FC in trained rats. Extracellular recordings of FC cells were taken while the rat was performing the discrimination task. Neuronal activity was correlated with the behavioral performance. Some cells had divided attention correlates; these cells selectively increased their firing rate to the second stimulus in divided attention trials, but not to the same stimulus in focussed attention trials. Several firing patterns were observed, suggesting that FC neurons may code different aspects of divided attention. The remaining cells had more complicated firing patterns, which seem to involve motor responses; these cells increased their firing rate with increasing bar press rate in both focussed and divided attention trials. The data provide evidence that the frontal cortex is involved in both divided attention and motor responses.

NEUROSCIENCE IN CHICAGO 50 YEARS AGO: CONCEPTS AND CHARACTERS I. L.H. Marshall, Brain Research Institute, University of California, Los Angeles, CA 90024-1761

The decade of the 1930s was unusually productive in biomedical subfields related to neuroscience. Subdisciplines that already had a foundation, such as the behavioral aspects of cerebral localization and the conduction of the nerve impulse, were flourishing. Others were about to emerge, for example, the neuroendocrinology of the hypothalamus and the biomathematics of nerve nets that led to cybernetics. Looking at the scene in Chicago, we find in the 1930s a powerhouse of activity in neuroscience-related fields situated in three localities: Northwestern University Medical School's Institute of Neurology, the neurophysiology laboratory of the University of Illinois Neuropsychiatric Institute, and the University of Chicago's department of physiology. At Northwestern, Stephen Walter Ranson (1880-1942) had moved into the tower of a new building and revived the stereotaxic approach to pinpointing cerebral loci for stimulation, recording, or making lesions. The notable results were discoveries on posture control and hypothalamic influences on the pituitary gland concerning feeding, drinking, and other vital behaviors. At Illinois's INI Percival Bailey (1892-1973) had assembled a remarkable group led by Warren Sturgis McCullock (1898-1971). Their experimental work was a continuation of neuronography using strychnine to explore cerebral association pathways. The third center was at the University of Chicago.

NEUROSCIENCE IN CHICAGO 50 YEARS AGO: CONCEPTS AND CHARACTERS II. H.W. Magoun and L.H. Marshall, Brain Research Institute, University of California, Los Angeles, CA 90024-1761

The University of Chicago, along the Midway on the southside, was home to several groups working in neuroscience fields in the 1930s. Nathaniel Kleitman's research on sleep was in full swing, with graduate students as subjects. The "iron wire" model of nerve conduction devised by Ralph Staynor Willie (1875-1952) was a source of debate. The largest research group was the laboratory of Ralph Waldo Gerard (1900-1974) in the physiology department, in which several candidates for the doctor of medicine were taking an additional year and earning the Ph.D. degree. During the 1930s Gerard's laboratory published the first evoked potentials from the central nervous system and perfected the capillary pipette electrode. Gerard's support services were exemplenary: the biochemistry lab under a Russian emigree was a model of industry and cleanliness, and expert "electronikers" were available. Other departments, especially anatomy, had well established investigators in neuroscience. Heinrich Kluver and Paul Bucy were analysing the syndrome that bears their name, and Paul Weiss and Roger Sperry in zoology were looking at neuronal specificity and regeneration. The constellation of important concepts under investigation during the decade of the thirties placed Chicago among the top centers for neuroscience.

DIFFERENCE IN THE PROCESSING OF MULTISENSORY AND MULTIPLE UNISENSORY CUES BY SINGLE SUPERIOR COLLICULUS NEURONS, M.A. Meredith, P.W. Archer and B.E. Stein, Deparments of Anatomy and Physiology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA, 23298-0709.

When two contiguous stimuli from different sensory modalities (e.g. auditory and somatosensory) excite a superior colliculus (SC) neuron, their combination results in a dramatic response enhancement. The object of the present experiments was to determine whether this multisensory integration differs in any significant way from the integration that would result from the combination of stimuli within the same modality. Therefore, the activity evoked in SC neurons (n=22) by pairs of stimuli from within the same modality was compared to that elicited by pairs of stimuli from different modalities in chronically prepared, anesthetized cats.

Simultaneously presented unimodal stimulus pairs failed to evoke responses that exceeded the sum of the impulses evoked by these stimuli individually. Usually the combined response was significantly less than the sum of the two responses independently. These 'occlusive' effects were exhibited even when the stimuli were presented at wide temporal disparities (25 - 800 msec). These results contrasted sharply with the effects induced by combining excitatory stimuli from different modalities simultaneously and at these temporal disparities (see Meredith et al., J. Neurosci. 7:3215, 1987), indicating a substantial difference in the manner in which unimodal and multisensory information is integrated in the same SC neurons.

315.2

THE EFFECTS OF GABA AND GLUTAMATE ON MULTISENSORY SUPERIOR COLLICULUS NEURONS: AN IONTOPHORETIC STUDY

D.D. Dunning and B.E. Stein. Department of Physiology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA, 23298.

We have begun investigating the neurochemical bases of multisensory integration in cat superior colliculus (SC) neurons by pharmacologically manipulating the responses of multisensory neurons. This was accomplished by presenting unimodal stimuli before, during and after the application of transmitter agonists and antagonists. Transmitter substances were applied by extracellular iontophoresis from multibarrel micropipettes and the responses of SC neurons were recorded from a carbon-fiber electrode in the central barrel.

Gamma-aminobutyric acid (GABA) and glutamic acid (GLU) affected all multisensory neurons tested: GABA (500mM) decreased spontaneous activity while GLU (500mM) increased spontaneous activity, regardless of the properties a given neuron exhibited. Responses were dose dependent, with the minimum effective dose in the 10-20nA range and the maximum effect at 50-100nA. GABA and GLU also affected responses to visual, auditory and somatosensory stimuli in the same fashion: GABA decreased evoked activity, while GLU increased evoked activity. The effects of GABA and GLU on both spontaneous and evoked activity were readily blocked by appropriate antagonists (bicuculline methochloride or methiodide for GABA; kynurenic acid or gamma-D-glutamyl glycine for GLU). However, when the natural sensory stimuli were presented without adding GLU, the neuronal responses they evoked were unchanged by administering GLU antagonists.

These results indicate that GABA and GLU probably function to modulate responses of multisensory SC neurons. An unexpected finding was that the quisqualate- and kainate-type GLU receptors do not appear to be involved in initiating the responses of these neurons to natural sensory stimuli.

THE RETINOTECTAL W-CELL PROJECTION IN THE CAT: EVIDENCE FOR TOPOGRAPHIC VARIATIONS IN DENSITY D.M. Berson, J. Lu*, and J.J. Stein* Div. Biol. & Medicine, Brown Univ., Providence, RI 02912.

Local magnification in central visual maps is widely thought to reflect the intraretinal density of afferent ganglion cells. This may imply that retinal terminal arbors are uniformly spaced and that afferent density is quite constant. In the cat's superior colliculus, therefore, one might expect the density of W-cell terminations to be fairly uniform because such afferents dominate the retinotectal pathway. We have tested this hypothesis.

Monosynaptic inputs from the main W-cell projection mediate the late negative potential (LNP), a collicular field potential elicitable from the optic pathway. Using a fixed stimulus, we measured the maximum amplitude of the LNP at 90 topographically identified tectal sites in 5 cats. LNP amplitude varied 5-fold over the map and was systematically related to the representation of azimuth. Amplitudes were smallest in the area-centralis and vertical-meridian representations (azimuths 0 - 3°), averaging 26% of the maximum amplitude in that colliculus and never exceeding 38%. Amplitudes were largest in the representations of the contralateral periphery (mean = 57% of max.; azimuths >10°) and of the ipsilateral visual field (mean = 54% of max.) There was little systematic variation as a function of elevation. Controls excluded artifactual sources of variation such as non-uniform afferent activation and drift in electrode properties.

The results imply that W-cell input weakens in the area-centralis representation, matching anatomical evidence for thinning of retinal input in this region. Although topographic gradients in afferent or cellular architecture may also be involved, a plausible explanation for these variations is that collicular magnification is not proportional to retinotectal W-cell density.

DISTRIBUTION AND ULTRASTRUCTURE OF NEURONS LABELED BY AN ANTIBODY TO GAMMA-AMINOBUTYRIC ACID IN THE SUPERIOR COLLICULUS OF THE RHESUS MONKEY. R.R. Mize, R.F. Spencer, and C.J. Jeon, Dept. of Anatomy and Neurobiology, Univ. of Tennessee Health Science Center, Memphis, TN, 38163 and Dept. of Anatomy, Medical College of Virginia, Richmond, VA, 23298.

Three classes of neuron labeled by antibodies to gamma-aminobutyric acid (GABA) have been identified in the cat superior colliculus (SC). It is not known whether these classes are found in other species. To study this, we examined SC sections from Rhesus monkeys which were labeled by antibodies raised directly against conjugated GABA. Labeled neurons were distributed throughout the monkey SC, but they were most heavily concentrated within the zonal and superficial gray layers. These cells were almost all small neurons and had variable morphologies. Both horizontal and small granule neurons were identified. At the electron microscope level, three types of labeled profile were found. Presynaptic dendrites (PDSs) contained pleomorphic vesicles and received input from other synaptic terminals. Putative axon terminals with flattened synaptic vesicles were also identified. A third type of profile was identified in a series of 26 sections reconstructed with the aid of a computer. This profile was a vesicle-containing dendritic spine. Both PSDs and the dendritic spine received input from the same retinal terminal. In addition, synaptic terminals with flattened vesicles contacted PSDs, revealing a synaptic circuitry which could support disinhibition. These results show that three basic GABAergic cell types can be found in the SC of both cats and monkeys and may represent an organization common to all mammals. Supported by USPHS grants EY-02973 (R.R.M.) and EY-02191 (R.F.S.).

315.5

TWO CLASSES OF AXON TERMINAL ARE LABELED BY AN ANTIBODY TO CHOLINE ACETYLTRANSFERASE IN THE SUPERFICIAL LAYERS OF THE CAT SUPERIOR COLLICULUS. C.J. Jeon*, R.F. Spencer, and R.R. Mize (SPON: S. Afsharpour) Dept. of Anatomy and Neurobiology, Univ. of Tennessee Health Science Center, Memphis, TN 38163 and Dept. of Anatomy, Medical College of Virginia, Richmond, VA, 23298.

The cat superior colliculus receives a dense cholinergic (ACh) input which is thought to arise from two brainstem sources, the pedunculopontine and lateral dorsal tegmental nuclei and the parabigeminal nucleus. The tegmental input projects densely to the intermediate gray layer and sparsely to the superficial layers. The parabigeminal input probably projects only to the superficial layers. We have examined fibers labeled by an antibody to choline acetyltransferase, the synthetic enzyme of ACh, to determine if they differ in morphology and synaptic ultrastructure. Two classes of fiber were found within the zonal and upper superficial gray layers - thin fibers with few varicosities and thicker fibers with numerous varicosities. When fiber diameter was measured with an image analyzer, a bimodal distribution was found. At the electron microscope level, we also found two classes of immunoreactive profile. The first was a small axon terminal containing round synaptic vesicles and forming asymmetric synaptic contacts. These terminals frequently synapsed onto other dendrites. The second class was a larger varicose profile which also contained round synaptic vesicles but rarely formed conventional synaptic contacts. When present, these contacts were symmetric. These results suggest that the two cholinergic inputs which innervate the superficial layers of the cat superior colliculus may differ in fiber diameter and synaptic ultrastructure. Supported by USPHS grants EY-02973 (R.R.M.) and EY-02191 (R.F.S.).

QUANTITATIVE DISTRIBUTIONS OF AMINO ACIDS AND RELATED ENZYME ACTIVITIES IN LAYERS OF RAT SUPERIOR COLLICULUS. C.D. Ross[1], J.A. Parli*[1], R.J. Ryder*[1], W.B. Farms*[2] and D.A. Godfrey[2]. [1]Dept. of Physiology, Oral Roberts University School of Medicine, Tulsa, OK 74171 and [2]Dept. of Otolaryngology, Medical College of Ohio, Toledo, OH 43699.

Samples microdissected from layers of the superior colliculus from 5 rats, albino and pigmented, were analyzed for concentrations of amino acids by HPLC (fluorescence of OPA derivatives) and for activities of glutaminase (GLNase), aspartate aminotransferase (total: t-AAT; cytosolic isoenzyme: c-AAT), and malate dehydrogenase (MDH) by fluorometric methods. (amino acids: mmol/kg dry wt; enzyme activities: mol/kg dry wt/hr @ 37°C, except MDH, @ 25°C)

Layer	Asp	Glu	Gln	Gly	Tau	GABA	GLNase	t-AAT	c-AAT	MDH
SGS(IIa)	12	29	37	9	22	38	8	50	25	20
(IIb)	12	27	31	6	14	37	8	47	23	16
SO (III)	10	25	23	5	9	24	6	40	20	13
SGI(IVa)	9	25	20	5	8	22	6	42	20	14
(IVb)	9	25	20	6	8	21	5	39	19	14
SAI (V)	9	25	21	7	8	21	5	38	20	12
SGP-SAP	9	25	20	7	8	20	5	36	17	12
rat brain	12	32	14	7	22	17	9	46	22	12

The greatest gradient was superficial to deep, with highest amino acid concentrations and enzyme activities being in SGS. A small caudal to rostral gradient was seen in some cases. No marked differences were noted between medial and lateral locations or strains of rats. (EY-03838)

315.7

ANATOMICAL ORGANIZATION AND FUNCTIONAL EFFECTS OF THE NORADRENERGIC INPUT TO THE HAMSTER'S SUPERIOR COLLICULUS. R.D. Mooney, C.A. Bennett-Clarke, N.L. Chiaia, N. Sahibzada and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Antiserum directed against dopamine-ß-hydroxylase (DBH) was used to demonstrate the noradrenergic (NE) input to the hamster's superior colliculus (SC). DBH immunoreactive fibers were present in all SC laminae, but they were most dense in the ventral one-half of the stratum griseum superficiale, the stratum griseum intermediale, and the stratum album intermedium. Combination of retrograde tracing with fluorogold and immunocytochemistry demonstrated that the source of the NE projection to SC was the locus ceruleus and that this projection was almost completely crossed. Iontophoretic application of NE generally reduced both the spontaneous and stimulus evoked discharges of SC cells. This effect was observed for both visual neurons in the superficial laminae and somatosensory cells in the deep layers. Application of NE generally did not enhance signal to noise ratios for SC neurons. The effects of NE upon the activity of SC cells were usually reduced or completely blocked by co-administration of the ß-antagonists propranolol and sotalol. In the few cells tested, the α-antagonist corynanthine enhanced the suppressive effects of NE upon the activity of SC neurons. With one exception, application of NE or ß-antagonists did not change the receptive field properties of SC neurons. Complex somatosensory cells in which noxious stimulation reduced spontaneous activity and/or the discharges evoked by low threshold stimuli did have their receptive field properties altered by application of ß-antagonists. During application of sotalol or propranol, application of noxious stimuli no longer suppressed the activity of these neurons.

THE SUPERFICIAL GRAY LAYER OF THE HAMSTER'S SUPERIOR COLLICULUS CONTAINS SEROTONIN IMMUNOREACTIVE NEURONS. L.L. Parsons, C.A. Bennett-Clarke, R.D. Mooney, N.L. Chiaia and R.W. Rhoades (SPON: M. Rayport). Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Two different polyclonal antisera (Inc Star and Accurate) were used to assay for serotonin immunoreactive (SI) cells in the superior colliculus (SC) of hamster and rat. No SI cells were observed in any portion of the rat's SC, although a dense meshwork of SI fibers were visible in all layers of the colliculus in this species. In addition to SI fibers, numerous SI neurons were observed throughout the depth of the stratum griseum superficiale (SGS) of the hamster's SC. Most SI cells in the hamster's SC had horizontally oriented dendrites, but a number of neurons with vertically oriented dendrites and marginal cells were also seen. Serotonin immunoreactive neurons were not observed in the stratum opticum or any of the deep SC laminae. Pretreatment of hamsters with colchicine and pargyline greatly increased the number, but did not alter the laminar distribution, of SI cells. This treatment did not result in the appearance of SI neurons in the rat's SC. Pretreatment with reserpine resulted in a complete loss of SI cells in the hamster's SC. Injection of fluorogold (FG) into the dorsal and ventral lateral geniculate nuclei (two targets of the SGS of the hamster's SC that contain SI fibers) and subsequent immunocytochemical processing for SI revealed numerous FG labelled cells, but no double labelled neurons, in the SGS. Double labelled cells were visible in nucleus raphe dorsalis. Ablation of the superficial SC laminae did not reduce the density of SI in any known targets of the colliculus. Both of these results suggest that SI cells in the hamster's SC may be interneurons.

315.9

TACHYKININ IMMUNOREACTIVE CELLS IN THE SUPERIOR COLLICULUS OF RAT AND HAMSTER PROJECT TO THE PARABIGEMINAL NUCLEUS. C.A. Bennett-Clarke, R.D. Mooney, N.L. Chiaia and R.W. Rhoades (SPON: H.Waller). Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

A combination of immunocytochemistry for tachykinins using a polyclonal antiserum directed against substance P (Inc Star), retrograde tracing with fluorogold (FG), and ablation techniques were used to demonstrate that tachykinin immunoreactive (TI) neurons in the stratum griseum superficiale (SGS) of the superior colliculus (SC) in both hamster and rat project to the ipsilateral parabigeminal nucleus and that axons arising from these cells appear to be the sole source of TI in that structure. Immunocytochemical experiments demonstrated a dense meshwork of TI fibers (probably of retinal origin) and numerous TI cells in the SC of both hamster and rat. Tachykinin-immunoreactive neurons were almost completely restricted to the SGS. Many had dendrites that were horizontally oriented, although some TI cells with vertically oriented dendrites and a small number of immunopositive marginal cells were also noted. Injections of FG into the parabigeminal nucleus labelled numerous superficial layer cells in the ipsilateral SC of both rat and hamster. A number of these neurons also contained TI. In both species, retrogradely labelled and double labelled cells could be seen in all portions of the SGS, but they were most numerous in the rostromedial part of the colliculus. Ablation of the superficial SC laminae in either hamster or rat resulted in a nearly complete loss of TI in the ipsilateral parabigeminal nucleus. Such lesions did not reduce TI in other targets of the superficial SC laminae such as the ventral lateral geniculate nucleus.

BILATERAL PROJECTIONS OF THE PARABIGEMINAL NUCLEUS IN MACAQUE. J.F. Whitney, J.S. Baizer, and D.B. Bender*. Dept. Physiology, School of Medicine, SUNY at Buffalo, Buffalo, NY 14226.

In many non-primates, the superior colliculus contains a representation of both visual hemifields. Each colliculus projects to the parabigeminal nucleus (Pbg) ipsilaterally, while the Pbg projects to the colliculus bilaterally. In the primate, each colliculus has a map of only the contralateral hemifield. Nonetheless, we have found that the parabigeminal nucleus projects to both ipsilateral and contralateral colliculi. We made injections of fluorescent retrograde tracers (fast blue and diamidino yellow) into the representation of the upper or lower quadrants in the colliculus of macaque monkeys. In the Pbg, labelled cells were found both ipsilateral and contralateral to the injection site. The ipsilateral projection was topographically ordered. Injections in the upper quadrant representation in the colliculus labelled cells in the posterodorsal half of Pbg, while injections in the lower quadrant representation labelled the anteroventral half of the Pbg. However, the contralateral projection arose mainly from the anterior part of the Pbg. Supported by EY02254 and MH42130.

Fine Structure of HRP Labelled Terminals Projecting to the Tectum from Two Sensory Pathways. R.M. Meszler, P.H. Hartline and R.V. Stirling. Anatomy Dept., Dental School, Univ. of Maryland, Baltimore, MD 21201 and Eye Research Institute, Boston, MA 02114.

The morphological substrate for dual sensory input to the tectum of the rattlesnake was studied using anterograde labelling with HRP. Iontophoretic injections of HRP were placed in the optic chiasma to label retinal projections and nucleus RC for the infrared receptor pathway. After 7-10 days survival, vibratome slices of the aldehyde fixed tecta were incubated with DAB and prepared for light and electron microscopy. In tecta in which both retinal and RC projections were labelled there was a clear separation between the two terminal fields with the boundary being in the middle of the stratum griseum centrale (SGC). The retinal projections consisted of fine axonal branches with numerous varicosities extending throughout the superficial layers and into the outer SGC. The synaptic boutons contain clear spherical vesicles and form asymmetrical contacts with dendritic processes. In contrast, the RC terminals come from large diameter axons which enter the stratum fibrosum centrale (SFC) and divide into progressively smaller branches which extend into the deeper portion of SGC. The terminals branches of these projections form asymmetrical contacts with small dendritic processes and contain clear spherical vesicles with an occasional granular vesicle. Supported by NIH grant #1R01 NS21989 and NSF grant #BNS8411566.

315.12

MULTIMODAL INTERACTIONS IN RAT SUPERIOR COLLICULAR CELLS. Kimberly M. Preucil* and Douglas A. Weldon. Department of Psychology, Hamilton College, Clinton, NY 13323.

In rats, as in other species, anatomical and physiological evidence indicates a convergence of inputs from several modalities in the deep layers of the superior colliculus (SC). Multimodal interaction effects in superficial layer cells have been demonstrated in some species but not in others. In the present study, we examined the influence of combined auditory and visual stimulation on 126 cells in the SC of Long-Evans rats anesthetized with urethane. Visual (light flash, 300 msec) and auditory (65 dB white noise, 100 msec) stimuli were presented either alone or in combinations, with the stimulus onsets either simultaneous or displaced in time by 100, 200, 300, or 400 msec.

The presentation of the auditory stimulus inhibited the response to visual stimuli in 12% of the neurons in the superficial layers of the SC. Of the 49 neurons in the deep layers, an interaction effect occurred in 33% of the bimodal cells responsive to both visual and auditory stimuli, and these effects were either facilitatory or inhibitory. In both the superficial and deep layers, the presentation of the auditory stimulus sometimes produced a sharpening of the response to the visual stimulus.

315.13

LAMINAR ANALYSIS OF A 3D RECONSTRUCTION OF THE SUPERIOR COLLICULUS

A.W. TOGA, B.A. PAYNE* & E.M. SANTORI,
Laboratory of Neuro Imaging, Department of Neurology, UCLA School of Medicine. Los Angeles, CA. 90024

Recent evidence points to the existance of lattices in the superior colliculus (SC) of acetylcholinesterase (AChE) and cytochrome oxidase. These lattices may reflect an organizational principle in the various layers of the SC. Wallace (1988) notes that the two lattices are not in spatial register, but occur at the same depth. We have developed a set of algorithms to examine and display spatial relationships within different brain laminae and have applied these techniques to the study of lattices within the rat SC.

Serial (coronal) sections of tissue alternately stained for cytochrome oxidase or AChE were digitally scanned, and aligned. Sections were reconstructed into three dimensional models. Two models were reconstructed, one for each stain. Lamina profiles were computed using one of three techniques. In the first, a volume showing distance from the surface of the SC was computed and used to "erode" the surface at various depths. This subsurface is equidistant from the surface of the stratum griseum superficial (SGS). Densitometric data representing cytochrome oxidase or AChE is then mapped upon this surface. In the second approach to identifying lamina, a ratio method was employed. A top and bottom surface are identified. These two levels are used to form a ratio for computing a surface below the SGS. In this way the subsurface is no longer equidistant from the surface of the SGS. The third method requires the investigator to manually identify the specific lamina upon which the densitometric data are mapped. All methods illustrate the spatial relationship between the two lattices for cytochrome oxidase and AChE.

315.14

IMMUNOHISTOCHEMICAL CHARACTERISTICS OF NEURONS IN THE SUPERIOR COLLICULUS OF ADULT HAMSTERS A. Jourdain, G.M. Bray and A.J. Aguayo. Center for Research in Neuroscience, The Montreal General Hospital and McGill University, Montréal, Québec, Canada, H3G 1A4.

Immuno-reactivity (i.r.) for GABA, substance P (SP), parvalbumin (PV) and calbindin (CB) in the superior colliculus (SC) of adult hamsters was analyzed for laminar distribution and for correlation with neuronal type. Neurons with PV or GABA i.r. were evenly distributed throughout the superficial SC and were also observed in the deeper strata. By contrast, CB-i.r. neurons tended to be concentrated in the stratum zonale, in the lower stratum griseum superficiale (SGS), and in the deeper strata where large, multipolar neurons were heavily labelled. Fewer neurons showed SP i.r. and most were located in the lower SGS and upper SO.

Within the superficial SC, each of the antibodies labeled more than one type of neuron. Many of the GABA and PV-i.r. cells appeared to be horizontal or pyriform neurons. CB and SP i.r. labeled marginal and vertical neurons as well as horizontal cells.

These different patterns of neuronal i.r. presumably reflect the complexity of neural circuitry in the SC. The extent to which the neurons immunohistochemically identified in this study represent post-synaptic targets of retino-collicular terminals remains to be determined.

315.15

STEADY DIFFUSE LIGHT DECREASES, FLASHING DIFFUSE LIGHT INCREASES, COLLICULUS METABOLIC ACTIVITY: CHANGE DETECTOR? R.M. COOPER, G.A. THURLOW, and A. GAFKA*. Behavioral Neuroscience Group, Psychology Dept., University of Calgary, Calgary, Alberta, Canada, T2N 1N4.

Past work demonstrated that exposure to steady diffuse light (eye covered with translucent mask) results in a strong depression in 2-deoxyglucose (2-DG) uptake in the hooded rat superficial superior colliculus relative to 2-DG uptake in darkness; metabolic activity of visual cortex remains similar under the 2 conditions. In the present study, rats were also exposed to diffuse light but it was flashed at 2, 5 or 8 hz. Again, effects were minimal in cortex but flashing diffuse light strikingly increased SC 2-DG uptake. The increase and decrease, respectively, in metabolic activity under the two spatially unstructured light conditions suggest that the SC is involved in more than receptor orientation and that it is peculiarly sensitive to visual change, perhaps functioning in some alerting capacity.

315.16

N-ACETYLASPARTYLGLUTAMATE IS RELEASED FROM CHICK RETINAL NEURONS AND OPTIC TECTUM UPON STIMULATION OF ACTION POTENTIALS IN THE OPTIC TRACT. D.A. Eagles, L.C. Williamson, and J.H. Neale. Dept. Biology, Georgetown Univ., Washington, D.C. 20057

N-acetylaspartylglutamate (NAAG) is found in high concentration in neurons throughout the nervous system including retinal ganglion cells in avian and mammalian species. We have developed a specific, highly sensitive (1-2 pg) radioimmunoassay (RIA) for NAAG to quantify peptide release in the central nervous system. The RIA was validated with HPLC and IC50 values were: NAAG, 2.5nM; NAA, 100uM; asp-glu, 1mM; and glu, >1mM. NAAG release was quantified in chick retina following depolarization.

To determine if this peptide is released under more physiological conditions electrophysiological stimulation was employed in the optic tract. Chick optic tecta and associated optic nerves were removed and placed in Tyrode's buffer A suction stimulating electrode was placed on the cut optic nerve ending and a recording electrode was inserted into the optic tectum to determine the optimal stimulation for eliciting action potentials in the optic tract. NAAG was released upon depolarization by high potassium in chick retina and by electrophysiological stimulation of the optic tract in the optic tectum. Supported by NIDA grant DA 02297.

GAD IMMUNOREACTIVITY IN THE CENTRAL VISUAL SYSTEM OF RANA PIPIENS. C. Tyler, K.V. Fite, and G.J. DeVries. Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Immunocytochemistry was used to assess the presence of glutamic acid decarboxylase (GAD), the synthesizing enzyme for gamma aminobutyric acid (GABA), in the primary visual nuclei and terminal visual fields of the frog central visual system. GAD localization was mainly confined to primary terminal zones of optic nuclei. GAD-like immunoreactivity appeared in all primary visual nuclei, with the most dense immunoreactivity occuring in the pretectal terminal fields (posterior thalamic neuropil, nucleus mesencephali, and uncinate). Less intense immunoreactivity was also detected in the basal optic root nucleus. In the optic tectum the 6th and 8th laminae of the superficial optic tectum showed heavy and less dense GAD-like immunoreactivity, respectively. Results from comparing GAD-like immunoreactivity in normal and unilateral enucleated frogs will be presented.

315.18

MORPHOLOGY AND ELECTROPHYSIOLOGY OF IDENTIFIABLE SUBSETS OF VISUAL NEURONS IN THE OPTIC TECTUM OF GOLDFISH. D.M.Chen* and S.C.Sharma. Dept. of Ophthalmology, New York Med. Col., Valhalla, New York 10595.

Goldfish tectal cells were intracellularly recorded with HRP-filled glass micropipettes (70-90MΩ,5%HRP in 0.5M Kcl-Tris buffer). Iontophoretic injections (6-10nA pluses for 40sec) in 19 identifiable cells and their subsequent histological localization revealed that when one tectal neuron was injected with HRP, one or sometimes more adjacent neurons (which were not penetrated by recording electrode) also showed HRP labeling. Sixteen of these twin or multiple labeled neurons have their somata localized in or near the Stratum periventricular . These cells extended their slender dendritic process towards the surface with lateral branches in Central grey zone and terminal dendritic ramifications in the Stratum opticum. Three somata of remaindering cells were localized in the Stratum Fibrosum et Griseum Superficiale with their apical dendrites ramifying in the Stratum marginale and Stratum opticum. Intracellular recording revealed that the impaled tectal neuron showed a changing response patterns. These patterns alternated in the neuron. Present data provides credence to the existance of synaptic contacts between somata and processes of desmosome-like junctions, as well as tight junctions amongst processes of neurons in the Stratum periventricular (Supported by NEI grant 01426).

VISUAL SYSTEM: DEVELOPMENT AND PLASTICITY IV

316.1

EFFECTS OF LONG-TERM VISUAL CORTEX DAMAGE ON SPATIAL AND TEMPORAL FREQUENCY PROCESSING BY NEURONS IN THE CAT'S POSTEROMEDIAL LATERAL SUPRASLYVIAN (PMLS) CORTEX. W. Guido, L. Tong, and P.D. Spear. Dept. of Psychology and Center for Neuroscience, University of Wisconsin, Madison, WI 53706.

Previous studies indicate that neurons in the cat's PMLS cortex show functional compensation (normal direction selectivity and ocular dominance) following neonatal but not adult damage to visual cortical areas 17, 18, and 19. The purpose of the present study was to examine spatial and temporal frequency processing by PMLS neurons after long-term neonatal or adult visual cortex lesions. Recordings were made from PMLS neurons in adult cats that had ipsilateral areas 17, 18, and 19 removed on the day of birth (54 cells), 8 weeks of age (40 cells) or as an adult (39 cells). Neurons were stimulated with drifting sine-wave gratings of various spatial frequencies, contrasts, and temporal frequencies, and the responses were Fourier-analyzed. There were no significant differences in the spatial or temporal properties of PMLS neurons among any of the three groups. Most neurons had optimal spatial frequencies from 0.05 to 0.4 c/deg, spatial resolutions from 0.1 to 1.6 c/deg, and contrast sensitivity from 3 to 100 (33% to 1.0% contrast). When tested at the optimal spatial frequency, most PMLS neurons had optimal temporal frequencies from 3 to 10 Hz and high temporal frequency cut-offs from 10 to 20 Hz. The results in cats with a long-term lesion are similar to those in normal cats and cats with acute (24 hr) visual cortex damage. Together, these findings suggest that: 1) Normal spatial and temporal processing by PMLS neurons is independent of inputs from ipsilateral areas 17, 18, and 19. 2) Long-term visual cortex damage in adult cats does not lead to progressive secondary changes in PMLS cortex. 3) Cats with a neonatal lesion do not show compensation for the spatial and temporal properties of area 17, 18, or 19 neurons that were removed.

316.2

LACK OF BINOCULARITY CHANGES THE SPATIO-TEMPORAL CHARACTERISTICS OF NEURONS IN VISUAL AREA 18 OF THE CAT. S. Bisti*, G.P. Biral* and C. Trimarchi*. (SPON: H. Hollander). Inst. of Neurophysiology CNR, Pisa, I-56100.

Area 18 neurons shift their spatial frequency tuning curves along the spatial frequency axis on changing the temporal frequency of drifting stimuli. The higher the velocity of stimuli the lower the preferred spatial frequency (Bisti et al. J. Physiol., 359: 259, 1985). This spatio-temporal coupling could be instrumental in mechanisms involved in the perception of movement in depth (normally condition associated with convergent eye movements). We tested whether a disruption of binocularity during development may affect the spatio-temporal properties of area 18 neurons. We recorded single unit activity of neurons from three types of preparation, all with disturbed binocular vision: monocularly deprived, strabismic and young split-chiasm cats. In all three models, the spatio-temporal selectivity of area 18 neurons were uncoupled: spatial selectivity was invariant with velocity. These results reinforce the suggestion that spatio-temporal coupling of area 18 neurones is associated with the perception of motion in depth.

316.3

MECHANISM OF ANOMALOUS RETINAL CORRESPONDENCE: ALTERATIONS OF RECEPTIVE FIELD POSITION IN THE LATERAL SUPRASYLVIAN (LS) AREA OF STRABISMIC CATS. N.E.J. Berman, S. Grant*, M. Wilkes*, S.D. Shipp*, and R.I. Wilson*. Dept. of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS 66103; Dept. of Anatomy, Medical College of Pennsylvania, Phila., PA 19129; Dept. of Anatomy, Univ. College London, London, UK WC1E 6BT.

Binocularity and binocular correspondence of receptive fields were determined in area 17 and LS of normal cats and of cats reared with convergent strabismus induced surgically at 3 weeks. Strabismus always caused a breakdown of binocularity in area 17, and the few remaining binocular neurons had receptive field positions arising from positions of normal retinal correspondence in the two eyes. A similar effect was seen in area LS in cats with pronounced strabismus (11° to 30° crossed). The group of cats with mild strabismus (<10°), however, showed nearly normal proportions of binocular neurons in area LS, and their receptive field locations arose from anomalous retinal positions which established visual correspondence of receptive fields in the two eyes. These receptive fields, which were of normal size, appeared to have shifted horizontally on the retina in an uncrossed direction, compensating for the degree of strabismus present. Similar processes could provide the basis of visual compensations that are common in humans with mild congenital strabismus. Supported by the MRC, Wellcome Trust and MH38399.

316.4

ORIENTATION-SELECTIVECELLS CAN EMERGE FROM A HEBBIAN MECHANISM THROUGH INTERACTIONS BETWEEN ON- AND OFF-CENTER INPUTS. K.D. Miller, Dept. of Physiology, UCSF, San Francisco, CA 94143.

A model of populations of ON-center and OFF-center geniculocortical inputs interacting via a Hebbian mechanism can yield orientation-selective cells. The receptive fields of the resulting cells consist of alternate bands of ON- and OFF- inputs. Oriented cells emerge when like-center inputs are correlated at near distances, and anti-correlated at further distances, while opposite-center inputs are anti-correlated at near distances, and correlated at further distances. Such correlations and anti-correlations at near distances have been observed in the retina (D. Mastronarde, 1983, *J. Neurophys.* **49**, 303). Those at further distances have not been observed, but could be present in the LGN or in non-oriented cortical input layers.

This model for the development of orientation selectivity is a variation of that of Linsker (1986, *PNAS* **83**, 7508). His model was biologically problematic in using both positive and negative synapses. While these could be implemented through two populations of synapses, one inhibitory and one excitatory, the "two populations" must be a single population in terms of the statistics of their activation. The current model instead uses two populations (ON- and OFF-center inputs) each of which makes only excitatory synapses but which are mutually anticorrelated.

Linsker's model suggests a form for the cortical organization of orientation selectivity. The current model leads to different constraints on the total synaptic strength supported by an individual cell than Linsker's, and therefore to differing cortical organization of orientation.

Mechanisms underlying direction selective adaptation in neurons of the cat striate cortex. Stuart G. Marlin*, R. M. Douglas, and M.S. Cynader (SPON: A. Billy), Depts. of Psychology and Ophthalmology, University of British Columbia, Vancouver, British Columbia, Canada, V5Z 3N9.

We have previously shown that prolonged unidirectional motion induces changes in the direction selectivity of neurons in the cat striate cortex. To understand the mechanisms by which these changes occur we examined the effects of prolonged unidirectional motion on responses to sequentially flashed light bar stimuli (apparent motion) a procedure which is widely used to elucidate mechanisms of direction selectivity. We obtained quantitative measurements of the optimal spatial (Dopt) and temporal (Topt) displacements for sequentially flashed light bar stimulation. We then presented the two stimuli at Dopt using either preferred (Topt) or nonpreferred (-Topt) direction sequences and compared these responses with those to single flashes at each position. Responses to simultaneous presentation, and smooth motion (both preferred and nonpreferred direction) were also obtained. We compared the preadaptation responses in each stimulus condition to those obtained after 1 min of prolonged smooth motion in either the preferred or the nonpreferred direction. Prolonged stimulation in the preferred direction decreased the direction selectivity of cortical neurons and, in addition to small decreases in the responses to single flashes, resulted in proportionately larger decreases in the direction selective interactions associated with sequentially flashed stimuli. Conversely, prolonged nonpreferred direction stimulation resulted in increases in direction selectivity, small increases in the responses to single flashes and a proportionately larger increase in the interactions associated with direction selectivity. These results suggest that adaptation induced alterations in direction selectivity result from alterations of the sequence specific interactions within the receptive fields of cortical neurons and do not result from adaptation of responsivity at a precortical locus. FORCED CO-ACTIVITY IN VISUAL CORTEX REVEALS COMPLEXITY IN SIMPLE RECEPTIVE FIELDS. D. Shulz *, D. Debanne * and Y. Frégnac *, (SPON: M.J. Friedlander). Lab. de Neurobiologie et Neuropharmacologie du Développement. Université Paris XI, Orsay, 91405, FRANCE.

Two types of of receptive fields ("Simple" and "Complex" RF) are classically distinguished in visual cortex of adult mammals, on the basis of the spatial overlap of their responses to the static presentation (ON) and extinction (OFF) of a visual stimulus. These exclusive classes are thought to result from separate stable connections. Previous studies in the anesthetized and paralyzed cat, using protocols of cellular conditioning, allowed us to show that forced co-activity can modify the functional selectivity of a cortical cell in response to moving stimuli (Frégnac et al. *Nature*, 333:367, 1988).

A similar differential pairing procedure was applied with static stimuli to study the role of temporal correlation between pre- and post-synaptic activity in the plasticity of the spatial organization of the RF. The ON and OFF responses to a slit of light, shown repeatedly in a f ixed position, were respectively increased and blocked by brief opposite iontophoretic actions. Spatial generalization of possible effects were quantitatively measured across the RF.

Seventy-seven cells were recorded in area 17 of kittens and adult cats, reared normally. 53 were used for control of temporal stability of the RF organization, and 24 cells were submitted to 51 pairings. Long-lasting modifications of the ON/OFF ratio were observed in 11 out of the 24 paired cells (46%). In 7 of the modified cells the change was selectively restricted to the "paired" zone of the RF. The relative ON/OFF preference shifted in most cases (10/11) towards the response (ON or OFF) associated with the imposed increase in responsiveness, which supports the prediction of our working hypothesis. Largest effects were observed during the critical period.

CORTICAL VISUAL EVOKED POTENTIALS IN RHESUS MONKEY INFANTS DEPRIVED OF DIETARY TAURINE. M.Neuringer and J.A.Sturman. Oregon Regional Primate Research Ctr., Beaverton, OR 97006 and Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10213.

We are examining visual system development in rhesus monkeys deprived of dietary taurine from birth. One group of monkeys was fed a taurine-free soy protein human infant formula, while a second group received the same formula supplemented with 70 umole/100 ml taurine. We previously reported impaired visual acuity development in the taurine-deprived infants and degenerative changes in retinal photoreceptors, particularly cones in the foveal region.

Cortical visual evoked potentials (VEPs) to full-field flashes showed no consistent differences between groups. However, differences were seen in the VEP to phase-reversed square-wave gratings recorded at 6 spatial frequencies at 4, 8 and 12 weeks of age. Taurine-supplemented infants showed clear spatial tuning, and a shift in peak amplitude to higher spatial frequencies with age. In the taurine-deprived infants, amplitude vs. spatial frequency functions were shallow and showed no shift in peak spatial frequency from 8 to 12 weeks. These findings were correlated with abnormalities in the morphology of striate cortex at three months of age, including poor laminar organization and poor differentiation of pyramidal neurons and astrocytes.

These results provide new evidence for the importance of dietary taurine in primate nervous system development.

CYTOCHROME OXIDASE ACTIVITY IN THE ADULT PRIMATE VISUAL SYSTEM AFTER RECOVERY FROM BILATERAL FOVEAL ABLATIONS A.A. Skavenski and R.W. Sikes (SPON: L.E. White Jr.) Departments of Psychology and Physical Therapy, Northeastern University, Boston, MA 02115.

Following bilateral foveal ablations, neurons in the foveal projection zone of area 17 lose their response to light. Within three months, about half of these cells begin to respond to visual stimuli presented to the intact peripheral retina. What alterations in cytochrome oxidase activity (cytox) accompany this physiological plasticity?

Bilateral lesions of about 3 deg arc diameter were made in the foveae of M. nemestrina monkeys. Following recovery, the brains were processed for cytox. The lateral geniculate nucleus (LGN) showed a clear reduction (45%) in cytox in the parvocellular layers of the foveal region as compared to the non-foveal region while magnocellular layers appeared normal. In the foveal region of area 17, a comparable reduction (42%) in cytox was seen mainly in layers 4A and 4Cb; the chief target layers of the parvocellular LGN. Thus, it appears the parvocellular stream does not underlie this physiological recovery.

EFFECTS OF APHAKIA, COMBINED WITH OCCLUSION, ON AREA 17 OF INFANT RHESUS MONKEYS. M. Tigges, J. Tigges, J.R. Wilson, and R.G. Boothe. Yerkes Reg. Prim. Res. Center, & Dept. of Anat. & Cell Biol., Emory Univ., Atlanta, GA 30322.

In 5 newborn rhesus monkeys, unilateral lensectomies were performed and the aphakic eyes corrected with contact lenses. In 2 monkeys, the fellow eye was occluded almost continuously with opaque occluder lenses up to 2 years. In 3 monkeys, the fellow eye was occluded partially for short periods per day. When the monkeys were between 19 and 42 months old, 1 eye was enucleated; 4-14 days later, area 17 was reacted for cytochrome oxidase (CO) as a marker for deprivation-induced changes in the ocular dominance system. In all monkeys, layer 4C in the representation of the central visual field of area 17 exhibited darkly and lightly reacted CO stripes. Preliminary measurements showed that in all partially occluded monkeys, stripes connected to the occluded eyes were wider than stripes connected to the aphakic eyes. After continuous occlusion, the dark and light stripes in one monkey appeared to be of approximately equal width. In the second monkey, stripes related to the aphakic eye were slightly wider. These data demonstrate that an occluded eye is capable of maintaining a considerable amount of cortical territory when competing against an aphakic eye. Care and use of the monkeys complied with NIH guidelines. Supported by grants EY 06001, EY 05975 and NIH RR-00165.

CYTOARCHITECTURE OF OCULAR DOMINANCE COLUMNS IN OWL VISUAL CORTEX. J.D. Pettigrew and I.C. Gynther. Vision, Touch and Hearing Research Centre, Univ. of Queensland, St. Lucia, Qld. 4067, Australia.

The physiology of binocular interaction in the owl's visual cortex is very similar to that found in the striate cortex of cat or monkey. In particular, monocular concentric LGN inputs are used for binocular processing so that feature extraction is delayed until after the pathways from both eyes converge. We have taken advantage of two unusual features of the owl's visual cortex which facilitate investigation of the circuitry underlying binocular interaction, viz;- 1. the owl's LGN is monocular so that anterograde monosynaptic labelling of the whole input array from one eye is possible with a variety of different markers; 2. ocular dominance columns are not normally present in the owl but appear as a result of deprivation. After monocular deprivation, reconstructed ocular dominance columns formed stripes running orthogonally to the vertical meridian; after reverse monocular deprivation, a similar pattern was seen but stripes were narrower and no longer in register in the magnocellular versus the parvocellular regions of the LGN input layers. The fine morphology of identified neurons, and their possible relationships to ocular dominance column boundaries, are being studied with Lucifer Yellow injections in the brain slice preparation after being labelled with retrograde fluorescent tracers from output target regions of the visual cortex such as tectum, LGN and peri-ectostriatum. In this way we hope to learn more about the post-synaptic changes which may accompany the marked presynaptic rearrangements following deprivation.

ANALYSIS OF THE PATTERN OF OCULAR DOMINANCE IN NORMAL AND VISUALLY DEPRIVED CATS.

K. M. Murphy, D. G. Jones*, & R C. Van Sluyters.*
School of Optometry, University of California, Berkeley CA.

In primary visual cortex, inputs from the two eyes are largely segregated in layer IV, forming the anatomical correlate of physiologically identified ocular dominance columns. We have qualitatively and quantitatively analyzed the 2D spatial array of cortical ocular dominance beads in both normal and monocularly deprived cats. The pattern of ocular dominance for one eye was visualized following intraocular injection of WGA-HRP and subsequent unfolding and flattening of the cortex. In normal cats, labelled regions serving one eye form an irregularly branching and beaded pattern. Inputs from an eye deprived of pattern vision from the time of natural eye opening form many isolated, unconnected ocular dominance beads. Yet, the deprived eye retains a large degree of territory in layer IV. Inputs from the nondeprived eye of monocularly deprived cats are less segregated, however, ocular dominance beads are discernible. Statistical analyses of the 2D arrangement of ocular dominance beads reveal that this pattern is similar for normal cats and both eyes of monocularly deprived cats. The arrangement is nonrandom, indicating regularity in the array of beads. The average spacing of ocular dominance beads is about 675 μm. Analysis using Voronoi polygons and Delaunay triangles demonstrates that the cat pattern has no overall orientation, whereas the pattern of cytochrome oxidase blobs for one eye of a monkey is clearly oriented. These analyses indicate that monocular deprivation in the cat does not perturb the overall spatial arrangement of ocular dominance beads.

CONCENTRATION-DEPENDENT SUPPRESSION BY LITHIUM OF EFFECTS ON MONOCULAR DEPRIVATION IN KITTENS. T.Ohashi* and T. Kasamatsu (SPON: K. Nakayama). Smith-Kettlewell Institute, San Francisco, CA 94115.

Lithium (Li) reduced effects of monocular deprivation on ocular dominance in kitten visual cortex and the Li's effect was variable depending on individuals (Ohashi et al., 1988). Here we examined whether there are correlations between plasma concentrations of Li and the effects of monocular deprivation. Fifteen kittens (4-7 weeks old) were i.p. injected with either 25mg/kg Li_2CO_3, 81.8mg/kg RbCl, or saline alone, twice a day for 3 weeks. Li in plasma was measured with ion potentiometry. The ocular dominance distribution (Hubel and Wiesel, 1962) was determined in area 17 after brief monocular deprivation.

We found that 1) Li had no discernible effects on receptive-field properties of recorded cells; 2) the expected shift in ocular dominance following monocular deprivation was blocked. There was a positive correlation between the Li content in plasm and the proportion of binocular cells. Three kittens with plasm Li higher than 1.0mEq/L at the end of monocular deprivation showed high binocularity (B=0.54, 180 cells) and 5 kittens with Li lower than 0.5mEq/L showed low binocularity (B=0.34, 300 cells); 3) 7 control kittens injected with either RbCl (N=3) or normal saline (N=4) showed the usual shift with low binocularity (RbCl,B=0.33, 210 cells; saline,B=0.22, 240 cells). We thus concluded that Li reduces ocular dominance plasticity in a concentration-dependent manner.

ANTISERUM AGAINST THE ASTROGLIAL S-100 PROTEIN INTERFERES WITH OCULAR DOMINANCE PLASTICITY IN KITTEN VISUAL CORTEX. C.M. Müller* (SPON: European Neuroscience Association), Max-Planck-Institute for Brain Research, 6000 Frankfurt 71, F.R.G.

During a restricted postnatal period the circuitry of the kitten visual cortex undergoes an experience-dependent modification. Previous studies show that cortical malleability is limited to periods where cortical astroglial cells are immature, and plasticity can be restored in adult animals by transplantation of young astrocytes cultured from kitten cortex. One possibility for a glial involvement in cortical plasticity is via biochemical signals released from astrocytes. As the S-100 protein can be detected in cortical astrocytes from the beginning of the critical period and has been shown to be involved in plastic changes in the CNS, I tested the influence of an antiserum against this protein on ocular-dominance (OD) shifts resulting from monocular deprivation (MD). Cannulas attached to osmotic minipumps (Alza 2002) containing antiserum against S-100 (1:10 or 1:20; Dakopatts), or non-immune-serum, were implanted into kitten visual cortex. This procedure was followed by one week of MD. Electrophysiological assessment of the OD distribution after this period revealed a concentration-dependent retardation of ocular-dominance shifts in the hemisphere infused with the antiserum. Normal OD-shifts were found in control hemispheres receiving infusion of non-immune-serum. The infused antiserum was immunocytochemically localized exclusively in the extracellular compartment after termination of the electrophysiological experiments. The data suggest that the S-100 protein may be a crucial factor in the mediation of ocular-dominance plasticity. This might be due to the known neuronotrophic action of this protein. Release of S-100 protein by astroglial cells may be one mechanism of a glia-neuron interrelation in cortical plasticity.

316.14

A NEUROCHEMICAL BASIS OF OCULAR DOMINANCE PLASTICITY MAINTAINED IN DARK-REARED CATS. T. Kasamatsu, T. Shirokawa and V.S. Ramachandran. Smith-Kettlewell Eye Res. Inst., San Francisco, CA 94115 and Dept. Psychol., Univ. Calif., San Diego, La Jolla, CA 92093.

Rearing newborn kittens in the dark has retarding effects on the normal maturation of receptive fields in visual cortex, effectively postponing the end of cortical susceptibility to abnormal visual experience beyond the usual age limit (Cynader and Mitchell, 1980).

We studied whether the brain noradrenergic (NA) system plays a role in this matter. One hemisphere of dark-reared cats(6-18 months) was directly infused with either 4mM 6-hydroxydopamine(6-OHDA), or 10mM D,L-metoprolol (β_1 adrenoreceptor antagonist, or 10mM D-metoprolol (biologically inert)dissolved in 0.4% ascorbate saline. The other hemisphere was infused with either the vehicle solution alone or 0.05mM L-NA. The microinfusion, together with monocular lid suture, lasted for the next 4 weeks after the cats were brought to light. We found that 1) an expected shift in ocular dominance was partially suppressed in the 6-OHDA-infused hemisphere, though the shift toward the open eye was obvious in the control hemisphere, 2) the blockade of the ocular dominance shift was seen in the cortex infused with D-metoprolol, and 3) the shift was more strongly expressed in the NA-infused cortex than control. We conclude that the NA-β_1 adrenoreceptor system is necessary for expression of cortical plasticity in visual cortex of dark-reared cats. (Supported by USPHS EY06733.)

316.15

PLASTICITY IN ADULT AND ADOLESCENT CAT VISUAL CORTEX. K. Fox, N. Daw, and H. Sato. Dept. Cell Biol, Washington Univ. Med. Sch., St. Louis, MO 63110

NMDA receptors and LTP are thought to be related to plasticity. Both occur in the cortex of adult cats, though visually activated NMDA receptors are restricted to superficial layers. If both attributes are sufficient for plasticity then layers II and III of adult visual cortex should be plastic. If both attributes are necessary for plasticity only layers II and III should be plastic. Monocular deprivation has become a standard test for experience dependent plasticity, but the literature contains results on just 6 adult cats and 7 adolescents, none of which were assayed for plasticity as a function of layer. We therefore re-examined ocular dominance (OD) plasticity in older animals as a function of layer. Three month monocular deprivations were imposed starting at 8 months (6 animals). Both hemispheres were assayed for ocular dominance over two days. In the 8-11 month group, 532 cells were tested for ocular dominance. A moderate but significant shift toward the open eye occurred in layers V and VI as well as in layers II and III. Thus, OD plasticity in adolescents can occur through mechanisms which do not involve NMDA receptors. The shift in layer IV was small, rather variable between animals and insignificant. We are now studying the effect of 3 month eye sutures in two older age groups; 15 months and adults of at least 7 years.

316.16

EFFECT OF NOREPINEPHRINE AND ACETYLCHOLINE DEPLETION ON PLASTICITY IN KITTEN VISUAL CORTEX. B. Gordon, B. Mitchell*, K. Mohtadi*, E. Roth*, Y. Tseng*, F. Turk* Inst. Neurosci., Univ. of Oregon, Eugene, OR 97403.

In 1985 Bear and Singer reported that depleting both norepinephrine (NE) and acetylcholine (ACh) decreased visual cortex plasticity assayed by the effect of monocular deprivation (MD). We have amplified this result. We depleted cortical NE and ACh in 35-42 day kittens by lesioning the white matter behind the cingulate gyrus. One eye was sutured on the day of the lesion. We recorded from the visual cortex 7 days later. NE content was measured by HPLC. ACh depletion was inferred from depletion of choline acetyltransferase (ChAT) activity. NE depletion averaged 53% in the successfully depleted animals. Depletion of ChAT activity was consistent with NE depletion. In the first group of animals (N=5) the lesion was contralateral to the deprived eye. Plasticity was decreased but only on the lesioned side where 70% of the cells were driven by the deprived eye. On the unlesioned side only 16% of the cells were driven by the deprived eye. In the second group (N=2) the lesion was also contralateral to the deprived eye, but it was unsuccessful; that is, NE was not depleted on the lesioned side. In these animals only 14% of the cells were driven by the deprived eye. In the third group (N=4) the lesion was ipsilateral to the deprived eye. In these animals only about 26% of the cells on the lesioned side were driven by the deprived eye. The fourth group (N=2) was lesioned but not visually deprived. Animals in this group had normal ocular dominance histograms. We conclude that depletion of NE and ACh does decrease plasticity; that is, it protects the deprived eye from losing its ability to drive cortical cells. Surprisingly, depletion protects only the normally dominant contralateral pathway; the ipsilateral visual pathway remains plastic.

IBOTENATE-STIMULATED PHOSPHOINOSITIDE TURNOVER: A BIOCHEMICAL CORRELATE OF THE CRITICAL PERIOD FOR SYNAPTIC PLASTICITY. S. M. Dudek and M. F. Bear. Center for Neural Science, Brown University, Providence, RI 02912.

One distinguishing characteristic of experience-dependent synaptic modifications in the kitten striate cortex is that they are primarily restricted to a finite period of postnatal development often refered to as the "critical period." Though estimates of the length of the critical period have varied, there is general agreement that sensitivity to lid closure begins in kittens at about 3 weeks of age, peaks during the fifth week, and gradually disappears between 12 and 16 weeks. We have discovered that this is precisely the developmental profile for stimulation of phosphoinositide (PIns) turnover by the excitatory amino acid ibotenate as measured in synaptoneurosomes prepared from kitten striate cortex.

Ibotenate stimulates PIns turnover at a novel site as neither NMDA, KA nor AMPA are effective. The transient rise in ibotenate-stimulated phosphoinositide hydrolysis at 5 weeks of age does not occur in the striate cortex of kittens raised in complete darkness. Unlike ibotenate, the muscarinic agonist carbachol stimulates PIns turnover in striate cortex at all postnatal ages and is unaffected by dark-rearing. Together, these data indicate that a novel type of excitatory amino acid (EAA) receptor mechanism linked to phospholipase C is transiently expressed in striate cortex during the second and third postnatal months, and that its expression is triggered by visual experience.

PIns turnover leads to the formation of two intracellular second messengers, inositol triphosphate and diacyl glycerol. Thus, these data suggest that excitatory synaptic transmission during the critical period is characterized by unique patterns of second messenger activity, and raise the possibility that PIns hydrolysis may play a central role in the experience-dependent modification of visual cortex. Theoretical considerations have led us to suggest that EAA stimulated PIns turnover may promote the weakening or elimination of synapses when input activation fails to coincide with target depolarization. GAP-43 LEVELS IN CAT STRIATE CORTEX PEAK AT THE HEIGHT OF THE CRITICAL PERIOD. L. I. Benowitz, W. R. Rodriguez*, G. T. Prusky and M. S. Cynader (SPON: J. M. Gilbert) McLean Hospital, Harvard Med. Sch., Belmont, MA 02178; Eye Care Center, Univ. British Columbia, Vancouver, B. C. V5Z 3N9

The maturation of feature detectors in the cat striate cortex normally occurs within the first two months of life. The effects of physiological manipulations in altering the underlying synaptic organization are maximal at around postnatal day 30, the peak of the so-called *critical period.* One molecule that may play a role in determining the critical period could be the neuron-specific phosphoprotein GAP-43, since this protein has been implicated in the development and restructuring of synaptic relationships in other systems. A monospecific antibody prepared in sheep against purified rat GAP-43 was used in the ABC-peroxidase method to stain free-floating sections derived from kittens aged 0, 15, 30, 45, and 60 days postnatal and from adult cats. In neonates, the protein was essentially absent from the cortical mantle outside of the marginal zone (i.e., layer I), but was heavily concentrated in the thalamocortical fibers in the submarginal layer. By day 15, the cortical neuropil began showing increasing levels of the protein, and by day 30 GAP-43 levels peaked in the striate area and in much of the rest of the cortex, particularly in layer I and secondarily in the IV-V boundary. Thereafter, levels declined, and in the adult visual cortex, only very low levels of the protein could be detected. Since GAP-43 appears to transduce physiological activity patterns to alter the functions and structure of the nerve terminal membrane, its presence at the peak of the critical period is consistent with the notion of this protein contributing to activity-dependent tuning processes in this system. *Support: NIH EY 05690 and MRC of Canada.*

316.19

PERSISTENT HIGH-LEVEL EXPRESSION OF GAP-43 FOLLOWING DARK-REARING THROUGH THE CRITICAL PERIOD. SM de la Monte*, GW Mower, K Rosen, MC Fishman, Howard Hughes Medical Institute, Massachusetts General Hospital, Children's Hospital Medical Center, Harvard Medical School, Boston, MA 02114.

GAP-43 is a neuron-specific growth-associated protein expressed at high levels during neuronal growth and regeneration. Recently we and others demonstrated GAP-43 expression to be developmentally regulated such that in the immature brain the levels are globally high, whereas in the adult the levels are generally low, save a few regions including the hippocampus and olfactory bulb, where active restructuring of synapses may continue throughout life. In the present study we examined GAP-43 expression in the visual cortex of cats reared in complete darkness throughout the critical period of visual development. Dark-rearing is known to prolong physiological plasticity of this region. Norther blot analysis of Area 17 demonstrated 7-fold higher levels of GAP-43 mRNA and in situ hybridization disclosed twice as many grains per neuronal cell body in the 10 day old kitten as compared with 5 month old cats. GAP-43 mRNA levels in dark-reared cats were 40% to 70% higher than light-reared cats, and neuronal cell bodies contained the same density of in situ hybridization grains as in the kitten. Similarly, higher levels of immunoreactive GAP-43 in both neuronal perikarya and neurites were present in the dark-reared visual cortex as compared with light-reared controls. The findings suggest: 1-GAP-43 expression is developmentally regulated in the cat visual cortex; and 2-the developmental regulation of GAP-43 gene expression can be modulated by visual experience.-

COEXISTENCE OF SOMATOSTATIN AND MAP-2 IN DEVELOPING RAT VISUAL CORTEX. S.C. Feldman Dept. of Anatomy, New Jersey Medical School, Newark, NJ 07103.

Perinatal visual cortex (VC) is characterized by large numbers of somatostatin (SRIF)-immunoreactive cells and fibers. Prior to the formation of the cortical layers, i.e., D6, two types of SRIF cells are seen: those which resemble typical neurons, and those which are relatively atypical. The former are present in small numbers distributed throughout the cortical plate. The latter are numerous, transient and limited to the ventral one-half of the plate. The identity of these has been questioned. To determine if these cells are neuronal, sections of VC from animals aged E20 and days 0 and 8 were stained for both SRIF and MAP-2. MAP-2 is a microtubule-associated protein limited to neuronal dendrites. Sections were first reacted for MAP-2 or SRIF using the peroxidase-anti-peroxidase technique; the sections were then reacted for the other protein using avidin-biotin and alkaline phosphatase. Preabsorption of the antibody with synthetic SRIF (10μM) gave the same results as MAP-2 alone. In all sections, both types of SRIF-positive cells were labeled with MAP-2, except on Day 8 when the atypical cells were no longer seen. No SRIF cells were labeled with the glial antigen S-100. These results suggest that the atypical cells may be neurons, and lend support to the hypothesis that these cells are immature, possibly migrating, neurons.

ELECTROPHYSIOLOGICAL AND NEUROCHEMICAL DIFFERENCES IN THE VISUAL CORTEX OF LIGHT/DARK-AND DARK-REARED RATS. B.W. Bakkum, J.D. Port*, R.S. Cohen and L.A. Benevento Dept. of Anatomy and Cell Biology, U. of Illinois at Chicago, Chicago, IL 60612 and Dept. of Anatomy, U. of Maryland Baltimore Coll. of Dental Surgery, Baltimore, MD 21201.

Sprague-Dawley rats were raised to the age of two months in either complete darkness (Dk) or a 14hr on-10hr off lighting schedule (Lt/Dk). Single units were recorded from area 17 during visual stimulation consisting of whole field flashes, light and dark moving slits or bars and moving checkerboards. The animals were recorded from immediately after removal from their Dk or Lt/Dk environment. 321 cells were recorded. 92% of the Lt/Dk cells, but only 66% of the Dk cells, were visually responsive. When compared to Lt/Dk cells, Dk cells had a higher rate of spontaneous activity characterized by either a high tonic discharge or bursts every 1-4 seconds in the absence of stimulation. Dk cells had less finely tuned responses. For example, 21% of Dk cells, but no Lt/Dk cells, responded only to flashes, while 23% of the Lt/Dk cells, but no Dk cells, responded only to a moving bar. Only Lt/Dk cells were found to be direction sensitive and capable of responding to fast rather than slow moving stimuli. Orientation selectivity was found in 30% of Lt/Dk cells but in only 5% of Dk cells. Based on these changes in inhibitory function, we investigated the effects of dark-rearing on the number of GABA and somatostatin immunoreactive cells in area 17 of three month old rats. In all six cortical layers of area 17, there was a decrease in GABA-positive cells in Dk versus Lt/Dk rats ($p<0.001$). No changes were detected in numbers of somatostatin cells. Taken together, these data suggest that dark-rearing affects the development of normal inhibitory connections in area 17 of the rat visual cortex. Supported by NIH grant NS 15889.

WEDNESDAY PM SYMPOSIA

318

SYMPOSIUM **MESOPONTINE CHOLINERGIC NEURONS: THE NEURONAL SUBSTRATE OF THE ASCENDING RETICULAR ACTIVATING SYSTEM?** PB Reiner, UBC (Chair); M Steriade, Laval; K Semba, UBC; SR Vincent, UBC; C Leonard, NYU. DA McCormick, Yale; RW McCarley, Harvard

The concept that there exists in brain one or more systems involved in control of arousal has long intrigued neurobiologists. The landmark studies of Shute & Lewis suggested that mesopontine cholinergic neurons might be the elusive cell group. In recent years, a great deal has been learned about the biology of these neurons, and this symposium serves as an opportunity to review the merits of the hypothesis that these cholinergic neurons constitute the neuronal substrate of the ascending reticular activating system.

Mircea Steriade will review the concept of the ARAS in both its historical and modern usages, and will present data on these neurons' physiological properties *in vivo*. *Kazue Semba* will discuss the afferent and efferent connectivity of mesopontine cholinergic neurons. *Steve Vincent* will present data on the various transmitter-candidates which have been identified in these neurons in mammals and other vertebrates. *Chris Leonard* will discuss the physiology of mesopontine cholinergic neurons *in vitro*, as well as their responses to transmitter candidates such as acetylcholine. *Dave McCormick* will discuss the effects of acetylcholine on membrane properties of thalamic and cortical neurons *in vitro*. *Bob McCarley* will discuss the projections of mesopontine cholinergic neurons to the the medial pontine reticular formation, and the effects of acetylcholine in the MPRF on both neuronal physiology and behavior.

319

SYMPOSIUM: HEBBIAN SYNAPSE: LEARNING RULES AND MECHANISMS. J. Lisman, Brandeis Univ. (Chairperson); T. Brown, Yale Univ.; T. Sejnowski, Salk Inst. & UCSD; R. Nicoll, UCSF

In a now classic treatise, Hebb proposed that active synapses are strengthened if their activity leads to firing of the postsynaptic cell. Tom Brown will give a historical overview of this concept and describe its applicability to long-term potentiation (LTP) in the CA1 region of hippocampus. The key role of the NMDA receptor in LTP will be described. Brown's talk will conclude with a review of both theoretical and experimental work suggesting that synaptic plasticity governed by the Hebb rule underlies aspects of learning and memory. Terry Sejnowski will describe a process complimentary to the Hebb process that decreases synaptic strength when pre-synaptic and postsynaptic activity do not occur together. Roger Nicoll will describe the involvement of Ca in triggering different phases of LTP and the role of non-NMDA receptors in the expression of enhanced synaptic efficacy. John Lisman will describe how the Ca/Calmodulin kinase molecules contained within the postsynaptic density could serve as a memory storage device capable of storing graded synaptic weights and controlling synaptic efficacy. To conclude this symposium, Terry Sejnowski will discuss the relationship between learning and neural development (some of which depends on the NMDA receptor), and identify important cellular and network aspects of these processes that remain to be investigated.

VISUAL CORTEX IV

320.1

SYNCHONOUS, COHERENT BURST-FIRING BY NEURONS IN LAMINA III OF RAT VISUAL CORTEX *IN VITRO*. R. B. Langdon, D. M. Kuhn*, and M. Sur, Dept. of Brain and Cognitive Sciences, Mass. Inst. of Tech., Cambridge, MA 02139, USA.

We have studied field potentials in isolated slices of rat area 17 to observe gross features of aggregate neuronal behavior in this neocortical circuit. The data indicate that the major route by which excitation ascends after white matter stimulation in our (coronal) slices is by direct retrograde activation of layer III pyramidal cells. These neurons often respond to low-amplitude single-shock stimulation of the white matter by firing in unison one short-duration (10 to 15 msec) burst at roughly 300 Hz. Individual spikes during such bursts are synchronous and phase-locked tightly to the stimulation ('coherent'). These bursts depend upon neurotransmission that is blocked by CNQX, but not APV. Foci of coherent bursting spread horizontally for up to 1.6 mm at roughly 0.1 m/sec. During this horizontal spreading, burst activity remains focused in layer III. Preliminary data suggest that burst amplitudes can be potentiated by stimulating with 35 msec trains at the natural burst frequency (12 trains, 5 sec apart).

The bursting somewhat resembles epileptiform activity in media that contain bicuculline or penicillin (e.g., Connors, ***Nature*** **310**:865, 1984), but occurs in normal, drug-free medium and is lamina-specific and stimulus-locked. Preliminary data suggest that similar bursts can follow optic chiasm or LGN stimulation in supragranular cat visual cortex *in vivo*. We conclude that lamina III neurons can burst at high frequencies and are interconnected in a way that renders them prone to fire coherently. Coherent firing of specific ensembles of lamina III neurons may play a role in the representation of features in visual space in area 17, and their transmission to other regions of cortex.

OCCURRENCE OF OSCILLATORY NEURONAL RESPONSES IN CAT VISUAL CORTEX DEPENDS ON STIMULUS COHERENCY. A.K.Engel*, P.König*, C.M.Gray* and W.Singer (SPON: European Neuroscience Association). Max-Planck-Institute for Brain Research, 6000 Frankfurt 71, F.R.G.

We have previously shown that a fraction of cells in cat area 17 exhibits an oscillatory firing behaviour in a frequency range of 40-60Hz (Gray and Singer, PNAS 86, 1698-1702). Currently we investigate the dependence of the oscillatory responses on various stimulus parameters. In particular, we attempt to test the influence of stimuli which do not consist of a single continous contour. To detect rhythmic firing patterns, we computed autocorrelograms of single and multiunit responses. The frequency and the amplitude of the modulation of the autocorrelograms were evaluated quantitatively.

Our results show (i) that both the frequency and modulation strength of the oscillatory responses are independent of stimulus orientation. (ii) The response frequency increases with stimulus velocity, but the relative modulation strength of the autocorrelogram is unchanged. Above a cut-off velocity of 5-7deg/sec, the oscillatory behaviour disappears. (iii) The strength of the oscillatory response depends on binocular stimulation. (iv) Stimulation with random-dot patterns eliminates the rhythmicity of the response. (v) Simultaneous presentation of two light bars with different orientations reduces the strength of the oscillation in a significant fraction of cases.

We conclude that if a continuous light-dark contour is applied as a stimulus, the cells of area 17 show a strong oscillatory modulation of their responses for a wide range of stimulus orientations and velocities. However, if the continuity of the stimulus is disturbed, the oscillatory modulation is attenuated. These results suggests that oscillatory responses are particularly susceptible to the coherency of the visual stimulus. In addition, cooperativity between inputs from the two eyes may also be encoded in the oscillatory firing behaviour of the neurons.

320.3

SYNCHRONIZATION OF OSCILLATORY RESPONSES IN CAT CORTICAL AREA 17 REFLECTS GLOBAL COHERENCY OF VISUAL STIMULI. P.König*, C.M.Gray*, A.K.Engel* and W.Singer. Max-Planck-Institute for Brain Research, 6000 Frankfurt 71, F.R.G.

We have previously shown that oscillatory neuronal responses in cat visual cortex can transiently synchronize (Gray et al., Nature 338, 334-337). It is our current working hypothesis that this synchronization serves to link features in different parts of the visual field and, in particular, encodes the coherency of an object. We currently test this hypothesis by recording with multiple electrodes from area 17 and subjecting the data to cross-correlation analysis.

Our data indicate that (i) stimulation of overlapping receptive fields with a continuous contour leads to highly synchronized oscillatory activity in most of the responsive cortical columns. Disruption of the stimulus coherency interferes with this synchronization. (ii) Cortical sites with spatially separate receptive fields and similar orientation preferences can strongly be synchronized if they are concurrently stimulated with a single long light bar. If a gap is inserted into this stimulus, synchronization becomes weaker. The interaction disappears completely, if the two stimulus fragments are moved in opposite directions. (iii) Cells with non-overlapping receptive fields and dissimilar orientation preferences tend to synchronize better if stimuli with identical orientations are presented on both fields. (iv) Binocular stimulation in appropriate retinotopic correspondence facilitates the synchronization of responses in spatially separate columns.

In conclusion, the data available are consistent with the hypothesis that phase-synchronization is sensitive to global stimulus features, such as spatial continuity, similiarity of orientation of contours, coherent motion and disparity. Commonality of these features among various parts of an object may thus be reflected in the synchronization of oscillatory cortical responses.

320.4

STIMULUS-SPECIFIC INTERCOLUMNAR INTERACTIONS OF OSCILLATORY NEURONAL RESPONSES IN THE VISUAL CORTEX OF ALERT CATS. C.M.Gray, A.Raether*, W.Singer (SPON:J.E. Skinner), Max-Planck-Institute for Brain Research,6000 Frankfurt/M,71, F.R.G.

Previously, we have shown that a subpopulation of cells in the cat visual cortex exhibit stimulus-specific oscillatory responses at a frequency near 50 Hz (Gray and Singer,PNAS,86, 1989). These oscillatory responses exhibit inter-columnar synchronization which depends on their spatial separation, similarity of orientation preference and the global properties of visual stimuli (Gray,et.al., Nature,338,1989). These findings suggest that the synchronization of oscillatory responses in different columns might be a way to establish relations between common features in different parts of the visual field. To substantiate this hypothesis we considered it crucial to demonstrate the occurrence of oscillatory responses and their intercolumnar synchronization in alert animals. We recorded neuronal responses from up to 8 floating micro-electrodes in the striate cortex of kittens and adult cats while the animals viewed a slowly drifting square wave grating, the orientation of which changed continuously through 360 degrees over a period of 20 sec. Auto- and cross-correlation analysis of the neuronal responses revealed that 1) a large fraction of neurons exhibit oscillatory responses to stimuli of optimal orientation at a frequency between 40-60 Hz, 2) neurons in spatially separate columns synchronize their respective oscillatory responses when their orientation tuning overlaps, and 3) the magnitude of the oscillatory responses and their synchronization is greater with binocular stimulation than with monocular stimulation. These findings closely resemble those obtained under anesthesia and thus provide support our hypothesis stated above.

320.5

NEURAL CONNECTIVITY AND PHASE COHERENCE IN THE FIRING PATTERNS OF STRIATE CORTICAL NEURONS. C. Koch, D. M. Kammen* and P. Holmes*†. (SPON: M. Nelson). Divisions of Biology and of Eng. and Applied Science, Caltech, Pasadena, CA, 91125. † Permanent address: Dept. of Theor. & Applied Mechanics, Cornell University, Ithaca, NY 14853.

Stimulus specific collective oscillations have been reported in olfactory (Freeman, W. J. Elect. Clin. Neurophys., 44:369, 1979) and more recently in visual cortical (Gray, C. M. *et al.* Nature, 338:334, 1989) areas. The oscillations observed in the striate cortex of anaesthetised cats (Area 17) are remarkable in that cells tuned to similar orientations but spatially widely separated on the cortical surface (up to 7mm) exhibit stimulus dependent frequency locking with no apparent phase delay.

We have developed an analytically tractable model for a population of cells that receive as feedback from a single comparator neuron a signal proportional to the average activity of the entire population. No direct connections between the excitatory neurons are present. This model exhibits the rapid onset of frequency and phase locking and robust noise tolerance that is consistent with the data from Area 17.

In circuits based on direct lateral connections between the excitatory cells (as is the case in the striate cortex) we find that coherent oscillations can be generated, however, frequency and phase coherence are exceptional rather than generic results. Furthermore the *onset latency* of oscillation is a strong function of the neural population size.

We can therefore conclude that while direct lateral connections are certainly crucial in the function of the visual cortex it is probably the feedback circuits that are central to the establishment of long range dynamic coherence in response to visual stimuli.

A DETAILED COMPUTER SIMULATION OF RECEPTIVE FIELD PROPERTIES IN PRIMARY VISUAL CORTEX OF CAT. U. J. Wehmeier, F. Wörgötter and C. Koch, Division of Biology, 216-76, Caltech, Pasadena, CA 91125.

Simple cells in mammalian visual cortex exhibit a number of salient receptive field properties such as orientation selectivity, direction selectivity, and contrast gain control. These cells also display a high degree of receptive field structure, including ON and OFF subfields which have been shown to be mutually antagonistic and usually non-overlapping. In our detailed computer simulation of a patch of cat visual system, we examine a number of possible circuits which produce behaviour consistent with electrophysiology.

Our simulation (Wehmeier & Koch, 1988) has been extended to model approximately 30,000 cells with passive integration and spiking behaviour comprising a 5° by 5° patch of visual angle from the retina, the LGN, and the early cortical layers. The retina is modelled by DOG units with both ON- and OFF- center receptive field profiles. The retinal activity is subsequently passed to two populations of geniculate cells (ON and OFF), and relayed to the cortical input layers (comprising excitatory pyramidal cells and inhibitory stellate and basket cells).

A number of classes of simple cell receptive fields have been synthesized by circuits combining inhibitory and excitatory interactions between ON and OFF subfields. Single unit responses to both moving and flashed stimuli have been produced and compared to experimental intracellular records (Ferster, 1988). A detailed analysis of circuits involving inhibitory feedback has been done to demonstrate how orientation and direction tuning may be simultaneously induced in cortical simple cells within the constraints of known tuning properties. Both long and short range asymmetrical inhibition are shown to be effective in creating direction specificity. The simulated cortical response patterns were tested by presenting moving bars and gratings to our retina and comparing tuning curves to extracellular responses of real cells.

320.8

RECIPROCAL CONNECTIONS WITHIN CAT VISUAL CORTEX (AREA 18). J. D. Boyd* and J. A. Matsubara (SPON: D. E. Mitchell). Depts. of Ophthalmology, Anatomy, and Neuroscience Group. Univ. of British Columbia, Canada, V5Z 3N9.

In visual cortex, columns of neurons interlink specifically with some, but not other, nearby columns. This pattern of intrinsic connections can be visualized by small, focal injections of tracers such as WGA-HRP and is exploited in models attempting to explain properties of visual cortical neurons such as receptive field size, center-surround antagonism, ocular dominance and orientation selectivity. We, and others, have assumed that the intrinsic connections in visual cortex are reciprocal, since WGA-HRP labeled patches contain both anterograde, terminal labeling and retrograde neuronal labeling. However, because it is often difficult to quantify or even distinguish the dust-like, anterograde reaction product from collateral transport or artifact, the exact nature of reciprocity among the intracortical networks remains uncertain.

We examined the spatial relationship of cells labeled with WGA-HRP to axonal terminal fields labeled with Phasaeolus vulgaris leucoagglutinin (Pha-L). A cocktail of 4% WGA-HRP and 2.5% Pha-L was iontophoresed through a micropipette placed stereotaxically in area 18 of the cat. Alternate sections were reacted for HRP histochemistry or Pha-L immunocytochemistry.

Most PHA-L labeled terminal fields were punctate, averaging 0.4 mm in diameter. Between 5 and 10 distinct fields, with an interfield spacing of about 1 mm, were present surrounding a single cocktail injection. While all patches of retrogradely labeled cells overlapped with PHA-L labeled terminal fields, we observed more punctate terminal fields than retrogradely labeled patches. The additional punctate fields of terminals interdigitated between patches of retrogradely labeled cells. These results suggest a far more complicated arrangement of local connectivity, comprising separate anterograde and reciprocal networks, than was previously known. (Funded by MRC MA-9150 to J.M.)

320.9

DISTRIBUTION OF GABA-IMMUNOREACTIVE NEURONS WITHIN THE INTRACORTICAL PATCHES IN CAT VISUAL CORTEX (AREA 18): A DOUBLE LABEL STUDY. J.A. Matsubara and J.D. Boyd* Depts. of Ophthal., Anatomy and the Neurosciences Group. Univ of Brit. Columbia. V5Z3N9 Canada.

The local, intracortical connections in visual cortex have been studied by using small, focal injections of the retrograde tracer, WGA-HRP. The pattern of labeling arising from such injections is columnar, patchy and periodic, exhibiting a repeat spacing of about 1 mm. Our earlier studies, combining physiological mapping with injections of WGA-HRP, revealed that the interconnections linked together sites with different preferred orientations, which led us to speculate that an inhibitory connection between such sites might serve to enhance orientation tuning in visual cortex.

We looked for anatomical evidence for a direct, inhibitory connection between interconnected sites by combining retrograde labeling using WGA-HRP and immunohistochemistry using an antiserum against GABA. Sections were first reacted using the TMB method, stabilized (Horn and Hoffman, 1987) and then processed for GABA immunohistochemistry. The resulting WGA-HRP labeled cells were filled with a black, granular precipitate while the GABA cells were light brown and opaque in color. Double labeled (dl) neurons contained both reaction products.

We found three populations of dl neurons. The dl cells in the first set were distributed randomly in all directions in the injection halo zone. These GABA-positive cells were likely filled with WGA-HRP by diffusion and not active transport. The second set of dl cells was found beyond the injection halo zone, usually in association with the WGA-HRP labeled cells comprising the intrinsic patches. There was a strong tendency for the dl cells in this set to be associated with some, but not all, of the patches within 1 mm of the injection site center; dl cells were never associated with the long range, or more distant patches. The third set consisted of dl neurons which were found outside of the patches. These cells were within 1 mm from the injection center in the superficial layers and spanned distances up to 2 mm in the deeper layers.

320.10

BICUCULINE INDUCED DISRUPTION OF OPTICALLY DETERMINED OCULAR DOMINANCE BANDS IN MACAQUE STRIATE CORTEX. G.G. Blasdel and M.M. Haglund*. Dept. of Neurobiology, Harvard Medical School, 220 Longwood Ave., Boston, MA 02115.

In Monkey striate cortex the transfer of visual information from layer 4C to overlying layers 2 and 3 is characterized by several transformations that appear to exchange spatially continuous maps in 4C for orientationally continuous ones above. The requirements of this exchange are at odds with the well known vertical alignment of ocular dominance through layers. And this conflict suggests the possible involvement of additional inhibitory mechanisms.

We tested this possibility in two macaque monkeys by examining how ocular dominance, visualized with optical techniques thought to reflect upper layer activity (Blasdel and Salama, 1986), is affected by the GABA blocker bicuculine. After the animals had been prepared and ocular dominance bands visualized, we superfused their cortices with solutions of bicuculine (10, 20, and 40μM in saline) and repeated the procedure. We found that bicuculine at concentrations of 20μM or more disrupts the expression of ocular dominance bands even though activity patterns associated with orientation are still apparent. The disruption persists for as long as bicuculine is present in the superfusate. And when it is removed, the original ocular dominance patterns return. This reversible disruption of ocular dominance is unlikely to derive from pathological changes associated with bicuculine (e.g., abnormal bursting, seizures, etc.) since single unit recordings (obtained after the optical recordings and in the presence of 20μM bicuculine) revealed normal numbers of visually responsive upper layer cells, many of which were orientation selective. Moreover, obvious bicuculine associated effects were never observed with concentrations below 40μM.

These results suggest that ocular dominance in the upper layers depends strongly on (and may even be established by) inhibitory mechanisms.

INTERACTIONS BETWEEN ADJACENT ACTIVE CORTICAL REGIONS IN MACAQUE V1 VISUALIZED BY OPTICAL IMAGING OF INTRINSIC SIGNALS. *R.D. Frostig, C.D. Gilbert, D.Y. Ts'o, A. Grinvald & T.N. Wiesel.* IBM Research Division & Lab. of Neurobiology, The Rockefeller Univ., NY 10021.

The existence of long range horizontal connections within area V1 suggests that the activity in one cortical site can be influenced by activity several millimeters away. Previous studies using real-time optical imaging with voltage sensitive dyes showed activation of cortical areas both within and outside the topographic representation of the visual field stimulated.

In this study we first explored the spread of activity measured by optical imaging of **intrinsic signals**. A comparison of a map of orientation columns resulting from a small visual stimulus (a drifting grating within a 0.4° stationary window) with an electrophysiological map obtained with electrode penetrations at a number of sites indicated a correspondence in the areas of activation measured by these two methods. Thus maps obtained from optical imaging using voltage sensitive dyes and intrinsic signals are different: the intrinsic signal images cortical regions in which many neurons are firing whereas the dye signal spreads beyond that region, possibly because it also detects subthreshold postsynaptic activation. (Lieke et al., Neurosci Abstr. 14:1122, 1988). Because the dye signal is also **fast**, it is useful to combine these two imaging techniques to investigate long range cortical interactions.

A second part of this study was to explore interactions between nearby cortical regions by comparing the pattern and magnitude of activation from a small visual stimulus alone to that resulting from a combination of the small stimulus and surrounding stimuli. We found that the addition of the surround attenuates the signal obtained from the small stimulus alone and are currently studying the dependency of these interactions on stimulus orientation. One may speculate that the horizontal connections may contribute to this type of interaction. (supported by IBM and NIH grants NS-14716, EY05253, the Rita Allen Foundation and NSF grant 8351738).

320.12

SYNAPTIC PHYSIOLOGY OF HORIZONTAL AND INTERLAMINAR CONNECTIONS IN SLICES OF THE CAT'S VISUAL CORTEX. *J.A. Hirsch and C.D. Gilbert.* Laboratory of Neurobiolgy, The Rockefeller University., New York, NY 10021.

Neurons in the cat's visual cortex are linked by fibers which extend for millimeters parallel to the cortical surface as well as by interlaminar connections. In order to examine the origins and influences of intrinsic cortical inputs to single neurons, we have made intracellular recordings from layer 2+3 in brain slices prepared from area 17 and compared synaptic responses to stimuli delivered to 2+3 at various distances from the impaled cell, or below it in layer 4. Synaptic responses were measured when the membrane potential was held near the threshold for spontaneous activity since IPSPs were indistinguishable at rest.

Electrical stimulation of layer 2+3 within about 150 μm of the impaled neuron, or in layer 4, evoked a mixture of EPSPs and IPSPs followed by a long slow IPSP of higher threshold. Weak shocks applied 0.7 to 2.5 mm away from the recording site, in the same lamina, typically evoked an EPSP or an EPSP followed by a brief IPSP; the magnitude of the potentials grew with increasing stimulus strength. At these longer distances, the long slow IPSP was not seen.

To localize further the origins of the observed synaptic potentials, we separated layer 2+3 from 4 by severing the connections between them; the effects of stimulating layer 2+3 in these preparations resembled those seen in intact slices. Currently we are applying small amounts of excitatory agents at varying distances from the impaled neuron to map the lateral distribution of cells which innervate it. This distribution will be compared to the arrangement of orientation columns revealed by retrograde transport of fluorescent label. (Supported by NIH EY06010, NS22789 and NSF BNS351738)

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION II

321.1

INDUCTION OF C-FOS GENE EXPRESSION IN RAT CORTEX DURING STRESS. J.C. Miller, E.A. Stone, D. Filer*, A.J. Friedhoff. Millhauser Laboratories of the Department of Psychiatry, New York University School of Medicine, 550 First Ave., N.Y., N.Y. 10016.

The proto-oncogene, c-fos, is a regulatory gene which encodes a nuclear protein that can be induced rapidly and transiently by a variety of extracellular factors, including agents affecting neuronal activity. Induction of c-fos is believed to be an initial event in signal transduction involving long term adaptive responses. Earlier, we studied the induction of c-fos mRNA in the cortex during restraint stress, but did not find a significant effect. Recently, two other groups reported that low levels of adventitious disturbance could also cause the effect in controls necessitating unusual precautions to prevent unintended stress. Using these precautions we subjected rats to restraint stress as described previously. Twenty four hours prior to the stress all animals were gently handled for 1 minute to reduce emotional reactivity. On the day of the experiment the control rats were rapidly decapitated (5 sec). The stressed animals were then subjected to restraint for 2 hours and killed 1 hour later. The c-fos mRNA in the cortex was assayed using Northern transfer and hybridization. A marked induction of c-fos mRNA in cortex of the stressed rats was found. Thus, induction of c-fos gene expression represents a sensitive method for investigating stress induced neuronal activation in the CNS.

321.2

ADRENALECTOMY INDUCES PROLONGED C-FOS EXPRESSION IN HYPOTHALAMIC CRF NEURONS. L. Jacobson[1],* F.R. Sharp[1,2] & M.F. Dallman[1]* (SPON: C. Van Dyke). Departments of Physiology[1] and Neurology[2], University of California, San Francisco, CA 94143.

Neuronal c-fos gene expression has been suggested to be a marker of neural activity (Science 237:192, 240:1348). To determine if Fos expression may be used to identify brain regions responding to removal of corticosterone (B) feedback by adrenalectomy (ADX), rat brains were processed for immunocytochemistry at 1,3 & 7 d after ADX or sham-ADX (SHAM) using a polyclonal antibody to Fos residues 132-154. All rats were perfused within 15 min of anesthesia & within 3 h of lights-on. All treatment groups exhibited basal Fos-like immunoreactivity (FLIR) in several areas, including the suprachiasmatic nucleus, cerebral cortex, and amygdala. FLIR did not differ between SHAM rats & rats not subjected to surgery. Only ADX rats exhibited strong FLIR in the parvocellular hypothalamic paraventricular nucleus; this FLIR was observed at 1,3 & 7 d after ADX, but was prevented by implantation at ADX of a sc pellet providing physiological B levels. Virtually all PVN neurons expressing FLIR double stained for CRF; some parvocellular neurons also expressed both FLIR and vasopressin. We conclude that neuronal FLIR correlates with known changes in neuroendocrine activity after ADX.

321.3

CIRCADIAN VARIATION OF NEUROPEPTIDE mRNA IN THE PARAVENTRICULAR NUCLEUS AND PITUITARY.

S.P. Kwak, E.A. Young, H. Akil and S.J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI. 48109.

Endogenous glucocorticoid levels in plasma of many mammals fluctuate in a cyclic pattern. The nadir and apex of the rhythm correlate with "sleeping" and "waking" hours of the animal, respectively, and is thus thought to be influenced by a central mechanism sensitive to the circadian clock. Corticotropin releasing hormone and proopiomelanocortin gene products in the hypothalamus and the anterior pituitary are well known for their involvement in mediating steroid release from the adrenals, as well as being the sites of negative steroid feedback. Therefore, we were interested in determining the regulation of these genes with respect to the glucocorticoid rhythm.

RNase protection assay was used to analyze mRNAs of CRF, type 1(MR), type 2(GR) glucocorticoid receptors, and dynorphin from the paraventricular nucleus, as well as POMC mRNA from the anterior pituitary. Rats were housed at 12 hour day/night cycle (lights on at 7AM) and were decapitated at various times of the day. Initial analysis yielded no profile change in POMC mRNA and ACTH content, while corticosterone in plasma rose at 4PM and peaked 2 hours after lights off (9PM at 15.5ug/dl). Steroids returned to low levels by 4AM. CRF mRNA increased slightly from 2AM to 6PM, but decreased sharply between 7-9PM and returned to baseline at 12AM. DYN, MR, and GR mRNAs did not show any change which coincide with steroid levels. It therefore appears that CRF mRNA may be influenced by the steroid flux. We are currently investigating critical time periods. (SJW supported by Grant # DA02265).

321.4

EXPRESSION AND REGULATION OF CORTICOTROPIN-RELEASING FACTOR MESSENGER RNA IN A PONTINE MICTURITION CENTER (BARRINGTON'S NUCLEUS).

T. Imaki*, J. L. Nahon*, P.E. Sawchenko, C. Rivier, and W. Vale, Peptide Biology Laboratories, The Salk Institute, La Jolla, CA 92037.

Corticotropin-releasing factor (CRF) is distributed in a number of extrahypothalamic cell groups that are involved in autonomic responses. Barrington's nucleus (pontine micturition center) has been reported previously to contain CRF-like immunoreactivity , suggesting a physiological role for CRF in micturition . To explore the regulation of CRF mRNA expression in this nucleus, we examined the changes of CRF mRNA levels after stress, by *in situ* hybridization histochemistry. Male albino rats were exposed to electric footshock (1.5 mA, 1 sec duration, 60 times/30 min) and sacrificed 2 and 24 h after stress. Another group was exposed to same paradigm twice daily for 3 days and sacrificed 24 h after the last shock session. Sections were hybridized with an ^{35}S-labeled prepro CRF cRNA probe. CRF mRNA was expressed mainly in Barrington's nucleus and parabrachial nucleus at the level of dorsal pons. Both the number of labeled cells and the mean grain density per cell in Barrington's nucleus was significantly increased at 2 and 24 h after acute stress, as well as after chronic stress. These results indicate that, as in the hypothalamus, CRF mRNA in Barrington's nucleus is positively regulated by stress, and suggest a role for CRF in stress-induced urination.

321.5

CIRCADIAN CHANGES IN THE preproCRH mRNA CONTENT WITHIN THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS OF RATS OF BOTH SEXES AS MEASURED BY *IN SITU* HYBRIDIZATION.

Alan G. Watts & Larry W. Swanson†, Neural Systems Lab, The Salk Institute & †Howard Hughes Medical Institute, La Jolla, CA 92037.

Secretion of adrenal corticosterone into plasma of the non-stressed rat is characterized by a regular daily surge found at the beginning of the activity phase. This surge is stimulated by increases in the secretion of ACTH from the anterior pituitary, which in turn is stimulated by the release of CRH from terminals in the median eminence into the hypophysial portal circulation. The origin of the CRH terminals is the medial parvicellular part of the hypothalamic paraventricular nucleus (PVH). In order to investigate the mechanisms involved in controlling circadian hypothalamo-hypophysial-adrenal function, we have measured both the plasma concentration of corticosterone, and (by *in situ* hybridization) the content of the mRNA coding for the precursor of CRH in the PVH, in male and female rats at different times of the day. We used rats of both sexes to investigate the possible effects of the greater fluctuation in plasma corticosterone concentrations found in female rats.

Male or ovariectomized-estrogen treated female rats were perfused at 00.00h, 07.00h, 13.00h or 19.00h with a 4% paraformaldehyde solution in which the pH was changed from 6.5 to 9.5. Sections through the PVH were hybridized for 20h with a cRNA probe derived from a cloned sequence of the preproCRH gene (kindly provided by Dr. K. Mayo). After post-hybridization washes, the slides were exposed to Cronex 4 X-ray film for 4 days, then dipped in autoradiographic emulsion, exposed and developed. For semi-quantitation, the integrated optical density of the PVH on the film sections from experimental animals was compared and expressed relative to that of adrenalectomized controls on the same film. Plasma corticosterone concentrations were measured at the same time points in different groups of similarly treated animals.

There was a decrease in the content of preproCRH mRNA in the PVH of rats of both sexes between midday and midnight. This decline was much more prominent in female rats, where the increase in plasma corticosterone was approximately twice that found in males. Our results suggest that changes in the content of preproCRH mRNA throughout the day contribute to the diurnal rhythm in hypothalamo-hypophysial-adrenal function, and that these changes may be inversely related to circulating corticosterone concentrations.

This work was supported by NIH grant NS16686.

321.6

CORTICOTROPIN-RELEASING FACTOR (CRF) CONCENTRATIONS EXHIBIT A CIRCADIAN RHYTHM IN BOTH HYPOTHALAMIC AND EXTRAHYPOTHALAMIC BRAIN REGIONS: DIFFERENTIAL SENSITIVITY TO CORTICOSTERONE.

M.J. Owens, J. Bartolome and C.B. Nemeroff. Depts. Pharmacol. & Psychiat., Duke Univ. Med. Ctr., Durham, NC 27710.

It has recently been reported that CRF concentrations in cerebrospinal fluid exhibit a circadian rhythm. We have measured the regional brain concentrations of CRF in rats killed in the early morning or late afternoon. The effect of chronic corticosterone administration on CRF concentrations was also studied.

Regional brain concentrations of CRF exhibited marked differences depending upon the time of sacrifice. When compared to rats killed at 0900 hrs, CRF concentrations in rats killed at 1530 hrs were elevated in a number of brain regions. The afternoon rise in CRF concentrations was generally insensitive to exogenous corticosterone administration in extrahypothalamic areas. In rats killed at 0900 hrs, corticosterone failed to alter CRF concentrations or CRF receptor, in extrahypothalmic brain areas, but decreased hypothalamic CRF concentrations and eliminated the observed circadian hypothalamic CRF increase in animals killed at 1530 hrs. These findings support a lack of effect of glucocorticoids on CRF neurons in extrahypothalamic brain areas. This is the first report of circadian changes in neuropeptide concentrations in extrahypothalamic brain areas. Supported by NIMH MH-42088.

321.7

SELECTIVE PLASTICITY OF VASOPRESSIN CONTAINING CRH AXONS DURING REPEATED DAILY STRESS.

M.H. Whitnall, R. Kvetnansky*, D.C.E. de Goeij*, F. Berkenbosch*, and F.J.H. Tilders*. LNC, NINDS, Bethesda, MD; Inst. Exp. Endocrinol., Ctr. Physiol. Sci., Slovak Acad. Sci., Bratislavia, Czechoslovakia; Dept. Pharmacol., Faculty of Medicine., Free University, Amsterdam.

CRH neurosecretory axons in the external zone of the rat median eminence consist of two types: vasopressin (VP) containing (VP+) and VP deficient (VP-). Several types of short term stress, including immobilization, cause selective activation of the CRH+/VP+ axons with no effect on the VP- axons. To examine the effects of repeated daily stress on this system, Wistar rats were handled or immobilized for 150 min daily for 9 days. Rats were studied 24 h after the last exposure, or were immobilized for 60 min immediately before fixation. Median eminences were immersed in glutaraldehyde, embedded in LR White, and serial ultrathin sections were immunoperoxidase labeled for CRH and a proVP derived peptide. Values are given as number of swellings per sample area of pericapillary zone ± S.E.M.

Condition	CRH+/VP+ axons	CRH+/VP- axons	N (# animals)
Handling (daily) + 24 h rest	11.1±2.8	34.5±3.9	6
Stress (daily) + 24 h rest	24.1±4.2	25.6±3.4	6
Handling (daily) + 60' immob.	6.8±2.5	31.5±2.5	5
Stress (daily) + 60' immob.	22.3±3.6	28.4±2.9	6

Two-way ANOVA showed that daily stress produced a significant effect, but only on the VP+ axons ($P<0.0005$), possibly due to increased production of secretory vesicles containing CRH and VP in those neurons.

EFFECTS OF FENFLURAMINE TREATMENT ON CORTICOTROPIN-RELEASING FACTOR (CRF) ACTIVITY IN RAT BRAIN.

E.B. De Souza, R. Zaczek, M. Owens, S. Culp*, N.M. Appel and C.B. Nemeroff. Neurobiology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224; Department of Psychiatry, Duke University Medical Center, Durham, NC 27710.

Fenfluramine is used clinically in the treatment of obesity. Its weight-reducing effects, through decreased food intake and altered autonomic metabolic parameters, are postulated to be mediated by brain serotonin neurons. CRF, a peptide with potent anorectic effects, has recently been reported to reduce body weight in obese rats through its well-characterized autonomic actions. Since serotonin potently stimulates hypothalamic CRF secretion, we addressed the hypothesis that the weight-reducing effects of fenfluramine are mediated, in part, through altered CRF release. Specifically, we examined the effects of subacute d,l-fenfluramine HCl treatment (1-24 mg/kg, s.c., b.i.d. 4 days) in rats on CRF content in discrete regions of brain and on corticosterone levels in plasma. Dose-dependent reductions in hypothalamic CRF-like immunoreactivity were observed; maximal effects (~60% reduction) were noted at doses of fenfluramine > 4 mg/kg. The decreases in hypothalamic CRF appeared to be a consequence of increased CRF release since plasma corticosterone levels were reciprocally increased in a dose-dependent manner. In contrast, high-dose fenfluramine treatment (24 mg/kg) produced significant increases in CRF content in hippocampus, midbrain and spinal cord with no significant alterations in peptide levels in cerebral cortex, striatum, thalamus, pons/medulla and cerebellum. These data, demonstrating selective fenfluramine-induced alterations in CRF activity, suggest that CRF may represent an important endogenous neurotransmitter mediating the weight-reducing effects of the drug.

HAMSTERS WITH ACTIVE CORONARY VASOSPASM ARE AT INCREASED RISK FROM STRESS. B. Natelson, W.N. Tapp, J. Ottenweller*, E. Grover*, T. Pritzel* & S. Drastal*. Neuro-behav. Unit, VAMC & Dept of Neurosci., NJ Med. Sch., E.Orange, NJ 07019

Cardiomyopathic hamsters (CMH) develop cardiac micronecrotic lesions due to small vessel spasm at 2-3 months of age. Then, although incidence of new lesions falls, CMHs' hearts fail. We have shown that CMHs in the lesion producing period of their lives succumb to stress (PB&B 3:331, 1989). Older CMHs only succumbed when their heart failure was severe (FASEB J 2:2268, 1988). So, we posited that the presence of the vasospastic process was a risk factor for CMHs of similar ages confronting stress. Outcome of cold-restraint stress was compared between 2.5 mo old and 5-6 mo old CMHs. When 5 daily 2 hr sessions were used, deaths occurred in both groups. But mortality rates tended to diverge after the 3rd stress session: 58% of the older CMHS survived while only 25% of the younger ones did ($p = .11$). A second experiment used a less intense stressor; hamsters were kept in the cold for only 1 of the 2 hr stress sessions: 54% of the older CMHs survived despite their having enlarged hearts while only 15% of the younger ones did ($p < .05$). This experiment shows that CMHs with coronary vasospasm are at increased risk of dying prematurely due to stress when compared to CMHs in which active vasospasm has been replaced by cardiac compensatory changes. This animal model may help understand the role of stress in human coronary vasospastic disease in the absence of arteriosclerosis.

STRESS AND IL-1-RELATED ELEVATIONS OF BRAIN TRYPTOPHAN ARE DUE TO AUTONOMIC ACTIVATION. A. J. Dunn.
Department of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Footshock or restraint stress cause elevations of the concentration of free brain tryptophan, in addition to the activation of cerebral catecholaminergic and serotonergic systems. Immune challenges (Newcastle disease virus) influenza virus infection, and interleukin-1 (IL-1) administration cause similar changes in brain norepinephrine metabolism and tryptophan. The increases of cerebral tryptophan caused by all these treatments were uniform across all brain regions studied. Footshock causes small increases in plasma tryptophan. The neurochemical effects of footshock or restraint are not altered by adrenalectomy, suggesting that adrenal hormones (corticosterone, epinephrine, norepinephrine) are not involved. However, pretreatment with the autonomic ganglionic blocker, chlorisondamine (2.5-mg/kg IP) prevented the increase in brain tryptophan that followed 20 min electric footshock, 30 min restraint, or IP administration of 200 ng human recombinant IL-1α. The chlorisondamine pretreatment did not prevent the changes of cerebral catecholamine catabolism associated with these treatments. This suggests that the increases in cerebral tryptophan are caused by activation of the autonomic nervous system. We presume that the autonomic activation in some way alters cerebral tryptophan uptake, which would explain the rather uniform regional distribution of the increase in cerebral concentrations. If so, then infection and IL-1 apparently cause activation of the autonomic nervous system.

SELECTIVE BREEDING OF RATS FOR SUSCEPTIBILITY TO THE EFFECTS OF UNCONTROLLABLE SHOCK. P.A. Scott*, M.A. Cierpial, & J.M. Weiss (SPON: G. Marsh). Dept. of Psychiatry. Duke Univ. Medical Center, Durham, NC 27710.

One effect of exposure to uncontrollable electric shock in rats is to decrease motor activity as measured in a swim test. However, not all animals within a given population show this effect. To investigate whether there is a genetic component to this variation, we attempted to selectively breed Sprague Dawley rats to be either susceptible (ie., affected) or resistant to this effect of uncontrollable shock. Initially, nine litters of animals were exposed to shock and given the swim test. Animals from both the most affected and the most resistant litters were then brother-sister inbred and the offspring tested for susceptibility to uncontrollable shock. Offspring from the same parents were divided into same-sex triplets, with one animal receiving 3 hrs of randomly-spaced uncontrollable shock (3-hr), one animal receiving 1 hr of randomly-spaced uncontrollable shock (1hr), and one control animal being placed in the shock apparatus for 3 hrs without exposure to shock (control). Heritability proved to be a factor in susceptibility to the effects of uncontrollable shock in that 3-hr animals from affected parents showed significantly less activity in the swim test compared to control animals from the same parents while 3-hr animals from resistant parents showed no decrease in activity compared to their control animals.

RESTRAINT-STRESS SELECTIVELY ENHANCES DOPAMINE AND ACETYLCHOLINE RELEASE IN LIMBIC STRUCTURES. ENDOCRINE-NEURAL INTERACTION. L. Angelucci*, S. Puglisi-Allegra°, P. Casolini*, A. Zocchi*° and A. Imperato* (SPON : M. Karobath). Institute of Medical Pharmacology, University "La Sapienza", I-00185 Rome. ° Institute of Psychobiology and Psychopharmacology (CNR), I-00185 Rome.

We have utilized brain dialysis to directly evaluate in vivo the effects of restraint-stress on dopamine (DA) and acetylcholine (ACh) release in the main dopaminergic and cholinergic areas. Restraint-stress, while not altering the release of DA and the output of DOPAC and HVA in the striatum, induced a significant increase in the accumbens. The enhancement of DA release is even more pronounced in the prefrontal cortex,field of termination of DA-ergic neurones exclusively arising from the VTA. In order to elucidate the role of the pituitary-adrenocortical-axis in the DAergic and cholinergic activation, the effect of restraint-stress in adrenalectomized rats, was investigated. In this case, the stress-induced changes in DA and ACh release were much less. Moreover systemic corticosterone, mimicking the increase of its plasma levels after stress, enhanced DA and ACh release. Our results suggest that stress activate DA and ACh release in limbic areas and the pituitary-adrenocortical-axis plays a role in that.

DRUGS OF ABUSE: COCAINE II

COCAINE-INDUCED TOXICITY AND BODY TEMPERATURE RESPONSES TO COCAINE IN SPONTANEOUSLY HYPERTENSIVE RATS. R.W. Rockhold, Y. Ishizuka, S. Carver, B. Hoskins and I.K. Ho. Dept. of Pharmacol. and Toxicol., Univ. of Mississippi Med. Ctr., Jackson, MS 39216.

Heterogeneity in rectal temperature (RT) responses to cocaine are expressed by restraint in SHR under ambient temperatures of 22-24°C. The maximal change in RT is positive (hyperthermia) in certain SHR (designated SHR_H) while others show only a lowering in RT (SHR_L). The magnitude and direction of this response in SHR correlated negatively with increases in the time-to-onset of convulsions (Tc) following i.v. cocaine infusion (1.25 mg/kg.min). Wistar-Kyoto (WKY) rats show only hypothermic responses. Freely moving SHR and WKY show hyperthermic responses. The influence of ambient temperature on RT responses to cocaine was examined further in restrained SHR. Hypothermic responses only were observed to i.p. cocaine (10 mg/kg) in SHR maintained for 2 hr at 4°C, while hyperthermic responses were seen in a 37°C environment. Decreases in RT were significantly ($p<0.05$) different between SHR_H and SHR_L, respectively (-1.10 $\pm$ 0.15, n=4 vs -2.16 $\pm$ 0.25, n=8), at 4°C. No difference was obtained between sub-groups in increases in RT observed in a 37°C environment. An involvement of dopaminergic receptors in the divergent RT responses seen to cocaine at 22-24°C was studied in restrained SHR and WKY. Pretreatment with the dopamine D-1 receptor antagonist, SCH23390 (50 ug/kg, s.c.), converted cocaine-induced RT responses to hypothermia in all SHR and WKY, but did not alter Tc. In contrast, a D-2 receptor antagonist, sulpiride (50 mg/kg, i.p.), produced hyperthermia in all SHR and WKY and decreased Tc only in SHR. Sulpiride and SCH23390 blocked all cocaine-induced RT responses in both strains but increased Tc in only WKY. The results indicate that dopamine receptors mediate RT responses in restrained SHR and that thermoregulatory systems interact with cocaine toxicity. (DA 04264).

COCAINE ANALGESIA IS MEDIATED BY CENTRAL NOREPINEPHRINE AND OPIOID SYSTEMS. L.C. Terry, K. Berger*, J.A. Kiritsy-Roy, J.L. McNulty*, R.D. Janke*. Neuroendocrine Lab., Univ. of Michigan and VA Med. Center, Ann Arbor, MI 48105.

Cocaine has recently been shown to produce central analgesia in rats by an action that is believed to occur at the supraspinal level (Lin et al., Brain Res. 479:306, 1989); analgesia was partially attenuated by dopamine D_1 or D_2 blockade but not naloxone (1 mg/kg ip). Because cocaine inhibits reuptake of catecholamines and serotonin, the purpose of this study was to determine the role of norepinephrine (NE), alpha and beta adrenergic receptors, serotonin (5HT) and opioids in cocaine analgesia. Analgesia was quantitated using the hot plate test at 52°C with a maximal exposure time of 45 sec to prevent foot pad tissue damage. Fasted, naive rats were used, and drugs were injected intraperitoneally (ip). For central administration, drugs were infused acutely or into chronic indwelling lateral cerebral ventricular cannulae (icv). Central administration of cocaine and its metabolite benzoylecgonine (BE) caused dose-related analgesia in the range of 38-250 ug icv. BE was approximately twice as potent and had a longer onset and duration of action than cocaine. The onset of analgesia was the same (5 min) after icv or ip cocaine, indicating it must cross the blood-brain barrier rapidly. Also, the NE reuptake blocker desmethylimipramine caused analgesia similar to cocaine. Cocaine analgesia was blocked by pretreatment with the selective NE neurotoxin DSP-4, but not by $alpha_{1 \text{ or } 2}$, beta or 5HT receptor blockade with corynanthine, yohimbine, propranolol or methysergide, respectively. Finally, a high dose of naloxone (10 mg/kg ip) blocked cocaine analgesia, and submaximal doses of cocaine and morphine acted synergistically to produce analgesia. These results indicate that cocaine and its metabolite benzoylecgonine act on the CNS to produce analgesia in the rat, and this analgesia is mediated by both the NE and opioid systems.

AUGMENTATION OF DOPAMINERGIC TRANSMISSION IN THE BASAL GANGLIA FOLLOWING ACUTE COCAINE ADMINISTRATION. S.P.Banerjee, A.M. Cosentino*, C.Manetto* and T.I.Lidsky. CUNY Med. Sch. NYC

Dopaminergic (DA) antagonists block self-administration of cocaine (Coc) by rats. This observation has suggested that increased DA transmission underlies cocaine self-administration. This suggestion, however, appears to be in conflict with the electrophysiological demonstration that Coc supresses the spontaneous activity of DA cells located in the substantia nigra (SN) and ventral tegmental area. In the present experiment, we assessed the functional effects of Coc, delivered intravenously, by analyzing somatosensory field potentials evoked in the striatum. Administration of Coc attenuated striatal responses in a dose-dependent fashion (1 - 6 mg/kg). These data suggest that the functional effects of cocaine are to enhance dopaminergic activity which, in turn, suppresses striatal sensory responses.

COCAINE BINDING IN THE HUMAN BRAIN WITH POSITRON EMISSION TOMOGRAPHY N.D. Volkow, J.S. Fowler, A.P. Wolf, S. Dewey, D. Schlyer, B. Bendriem, R. MacGregor, R. Hitzemann, J. Logan. Brookhaven National Laboratory, Upton, NY 11973

Animal studies investigating the binding of cocaine (C) in the brain have reported a high affinity binding site related to the dopamine transporter which has been implicated in the reinforcing actions of C. In order to investigate the binding characteristics of C in the human brain, we studied the distribution and kinetics of carbon-11 cocaine (C*) in 6 volunteers using PET. These studies showed fast uptake and clearance of C* by the brain, with maximum concentration occurring 4-6 min. postinjection and clearance of 50% of the radioactivity by 20 min. Maximal concentration of C* occurred in the striatum which showed a concentration twice that in cortex and cerebellum. Administration of desipramine, 60 min. prior to injection of C* did not affect the binding of C* suggesting that the binding of C* is mainly associated to the dopamine transporter. The time activity curve for uptake and washout of C* from the striatum corresponded to the reported time response to the subjective effects of intravenous C suggesting that the euphorigenic properties of C may be related to the rapid binding and clearance of C in the striatum. COCAINE EFFECTS ON SEXUAL BEHAVIOR IN THE MALE RAT. Scott D. Mendelson and Joan M. Lakoski, Dept. Pharmacol. & Tox., The University of Texas Medical Branch, Galveston, TX 77550

The effects of acute and chronic cocaine treatment on sexual behavior were addressed in sexually experienced male rats (Sprague-Dawley, 300-400 gm). Cocaine HCl (3.75, 7.5, or 15 mg/kg, i.p.) or saline (n=15, repeated measures) were given 10 min prior to evaluation of sexually motivated level searching behavior (LS) and 15 min prior to introduction of a receptive female rat; no significant effects on LS, mount, intromission or ejaculation latencies as well as post-ejaculatory intervals, and frequencies of the above were observed. Cocaine (15 mg/kg, i.p.) or saline (n=5) administered 1 min prior to LS and 6 min prior to introduction of the female revealed no significant effects on LS but a significant increase in the latencies to mount and intromission ($p<0.02$).

Repeated exposure to cocaine (15 mg/kg, 2X daily, 6 days) produced no alteration in LS evaluated at 1 min but increased mount latencies at 6 min ($p<0.005$) as compared to controls. Examination of sexual behavior 24hr following repeated cocaine revealed no significant differences between groups. As stimulation of catecholaminergic activity has been found to enhance and serotonergic function, in general, inhibit male sexual behavior, these data suggest that cocaine's effects may be mediated via serotonergic pathways. Supported by NIDA DA 04296.

A PROGRESSIVE-RATIO SCHEDULE FOR COCAINE ADMINISTRATION: EFFECTS OF COCAINE DOSE AND DIAZEPAM. S.I. Dworkin, A. D'Costa*, N.E. Goeders and E. Hoffman*. Dept. of Physiol. Pharmacol., Wake Forest University, Bowman Gray Sch. of Med., Winston-Salem, NC 27103 and Depts. of Psychiat. and Pharmacol. & Ther., LSU Sch. of Med., Shreveport, LA 71130

Male Fisher rats were prepared with chronic indwelling jugular catheters and trained on a progressive-ratio schedule of cocaine self-administration. The progressive-ratio factor was increased from 1 to 25 over the course of initial training. Sessions were terminated after 2 hours or whenever a response did not occur for 15 min. Responding maintained by two cocaine doses (0.33 and 0.67 mg/infusion) was evaluated using the progressive-ratio 25 schedule. The total number of infusions received during the session was not different for the two doses. However, the interinjection intervals maintained by the low dose were directly related to the size of the ratio, thus as the ratio was increased the inter-injection intervals also increased. The larger dose result in more consistent intervals between injections that were not dependent on ratio size. Both substitutions of diazepam (0.20 or 0.25 mg/infusion) and the co-infusion of diazepam with the low dose of cocaine markedly attenuated self-administration. However, the rate of responding did not appear to be affected by the drug combination. Thus it appears that diazepam can attenuate the reinforcing efficacy of cocaine as indicated by the progressive-ratio procedure. (Supported by NIDA 03628)

322.7

BLOCKADE OF THE DISCRIMINATIVE STIMULUS (DS) EFFECTS OF COCAINE IN RHESUS MONKEYS WITH THE D1 DOPAMINE ANTAGONIST SCH 39166. K.E. Vanover*, M.S. Kleven, R.E. Chipkin, and W.L. Woolverton. The Drug Abuse Research Center, The University of Chicago, Chicago IL 60637.

An increase in dopamine (DA) neurotransmission in the brain is thought to mediate many of the behavioral effects of cocaine. Recent research suggests that D1 DA receptors play an essential role in the DS effects of cocaine (Kleven, et al., Psychopharmacology, 95:427, 1988). The purpose of the present experiment was to determine whether the DS effects of cocaine could be blocked by the selective D1 DA antagonist SCH 39166 (Chipkin, et al., J. Pharmacol. Exp. Ther., 247:1093, 1988). Rhesus monkeys (N=3) were trained in a 2-lever, food-reinforced, drug discrimination paradigm to discriminate cocaine (0.2 or 0.4 mg/kg, i.m., 10 min pre-session) from saline. Before test sessions, in which responding on either lever was reinforced, the monkeys were injected with various doses of cocaine alone or in combination with SCH 39166. Administration of cocaine alone (0.025 - 0.2 mg/kg, i.m.) resulted in a dose-related increase (0 - 100%) in the percent of responses that occurred on the drug-appropriate lever. Administration of SCH 39166 (0.05 or 0.1 mg/kg, i.m.) 50 minutes before an injection of cocaine (0.05 - 3.2 mg/kg, i.m.) reduced drug-appropriate responding from 100% to 0% at least at one dose combination in all monkeys. In all monkeys, the blockade was overcome by increasing the dose of cocaine, resulting in an 8 - 32 fold parallel shift to the right in the cocaine dose-response function. The results are further evidence that D1 DA receptors are involved in the DS effects of cocaine. (Supported by NIDA Grant DA-00250).

322.8

EFFECTS OF THE D1 ANTAGONIST SCH 23390 ON BEHAVIOR MAINTAINED BY COCAINE OR FOOD. M.S. Kleven and W.L. Woolverton. Department of Pharmacological and Physiological Sciences, Drug Abuse Research Center, The University of Chicago, Chicago, IL 60637.

Recent evidence that the D1 antagonist SCH 23390 blocks the discriminative stimulus effects of cocaine suggests that D1 dopamine receptors play a necessary role in the effects of cocaine (Kleven et al., Psychopharmacology, 95: 427, 1988). The purpose of the present experiment was to determine whether SCH 23390 selectively decreases cocaine self-administration. Rhesus monkeys (N=4) were trained to press a lever in daily experimental sessions under a 3 component multiple schedule of cocaine or food reinforcement. In the first and third components, food was available under a fixed-ratio (FR) 30 schedule. In the second component cocaine (0.025 or 0.05 mg/kg/inj, i.v.) was available under a FR 30 schedule. A time-out was scheduled after the delivery of each reinforcer. When behavior was stable, monkeys received continuous infusions of several doses of SCH 23390 (0.4-6.4 mg/kg/day) for at least the same number of sessions (5-12) that were required for responding to decline to low levels when the monkeys were allowed to self-administer saline. Infusion of low doses of SCH 23390 (0.2-0.8 mg/kg/day) decreased responding maintained by cocaine with minimal effects on responding maintained by food. Higher doses (1.6-6.4 mg/kg/day) decreased both food- and drug-maintained responding. The effects of SCH 23390 on drug-maintained responding progressively diminished over several days of continuous infusion such that at the end of the infusion period responding approximated control rates. In sessions following termination of daily infusions of higher doses of SCH 23390 (3.2-6.4 mg/kg/day), responding for cocaine occurred at low rates (5-10% of control), and recovery to control rates took as long as 2 weeks. These results suggest that a D1 antagonist can decrease the reinforcing effect of cocaine at doses which have minimal effects on responding maintained by food. However, the effects of SCH 23390 diminish over time and exposure to SCH 23390 may result in long-lasting changes in the effects of cocaine. (Supported by NIDA Grant DA-00250).

322.9

CHRONIC COCAINE IN VIVO MODIFIES PROLACTIN RELEASE IN THE PRESENCE OF DOPAMINE IN VITRO. NS Pilotte, RL Johnson*, EM Dax*. Neuroendocrinology Laboratory, Addiction Res. Ctr., Nat'l Inst. Drug Abuse, Baltimore, MD 21224.

Circulatory concentrations of prolactin (PRL) are reduced shortly after the administration of cocaine to rats treated chronically with the drug. In contrast, PRL increases 22 hr after cocaine. To determine if cocaine alters PRL release directly at the anterior pituitary gland (APG), we infused male Lewis rats with cocaine (1 mg/kg IV) or 0.15 M NaCl (0.1 ml/kg IV) every 12 min for 2 hr for 10 days. After the last session, the APGs were removed and prepared for use in a reverse hemolytic plaque assay (RHPA). PRL secretion was observed from single cells during a 1 hr incubation using a RHPA 24 hr later.

There were more plaque-forming cells from cocaine-treated rats but plaques with diameters > 0.10 mm occurred more often in APGs of saline-infused rats. Application of 3.3 μM cocaine to the AP cells did not alter basal or thyrotropin-releasing hormone-stimulated PRL-mediated plaque formation. The application of 10^{-6} to 10^{-11} M dopamine (DA) suppressed plaque development in a dose-related manner in both groups. However, plaques were smaller and occurred less frequently from cells of cocaine-treated rats at each concentration of DA. Chronic cocaine appears to increase the sensitivity of lactotropes to DA. One mechanism by which cocaine affects PRL release may be by an alteration in the density of DA receptors.

322.10

[^{3}H]CFT: A NOVEL HIGH AFFINITY LIGAND FOR COCAINE RECEPTORS. B.K. Madras, M.A. Fahey*, R.D. Spealman*. Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772.

The cocaine analog, 2β-carbomethoxy-3β-(4-fluorophenyl)-tropane (CFT also designated WIN 35,428) is 3-10 times more potent than (-)-cocaine both in vivo and in vitro. [^{3}H]CFT was evaluated as a radioligand probe for cocaine receptors in caudate-putamen membranes of monkeys (M. fascicularis). Kinetic, saturation and competition studies indicated that [^{3}H]CFT, in a manner analogous to [^{3}H]cocaine, bound to at least two components but with affinities 5-10 times those of [^{3}H]cocaine and with dissociation rates at least 10 times slower. In competition studies, the IC_{50} values of cocaine congeners and other monoamine uptake inhibitors at [^{3}H]CFT binding sites correlated highly with their IC_{50} values at [^{3}H]cocaine binding sites. All cocaine congeners displaced [^{3}H]CFT fully and recognized both binding components of [^{3}H]CFT. In contrast, several monoamine uptake inhibitors structurally unrelated to cocaine displaced only about 90% of specifically bound [^{3}H]CFT and appeared to recognize only one [^{3}H]CFT binding component. [^{3}H]CFT and [^{3}H]cocaine appear to bind to a similar spectrum of sites. However, because of its higher affinity and slower dissociation rate, [^{3}H]CFT is a superior radioligand probe for cocaine receptors.

CHRONIC COCAINE-INDUCED ALTERATIONS IN DOPAMINERGIC PRE- AND POSTSYNAPTIC MARKERS. L. M. Terry, E. Keran *, L. Hearn*, J. Sanchez-Ramos, J. Pablo, M. Basile and D. C. Mash. Departments of Neurology and Pharmacology, University of Miami School of Medicine, the Dade County Medical Examiner's Office and the College of Health, Department of Medical Laboratory Science, Florida International University, Miami, FL., 33101.

Repeated cocaine administration leads to a variety of behavioral and neurochemical effects. We have examined the effect of chronic administration of cocaine on dopaminergic uptake sites and D1 and D2 receptor subtypes in the rat brain using quantitative in vitro autoradiography. Sprague Dawley rats were implanted with Alzet minipumps containing cocaine (30 mg/kg/day) or saline. At the time of sacrifice, heart blood levels of cocaine were determined by Gas/Liquid chromatography. Dopaminergic receptor subtypes (D1 and D2) were labeled in slide-mounted sections of the rat brain with [^{3}H]-SCH23390 and [^{3}H]-raclopride, respectively. Dopaminergic uptake sites were labelled by differential [^{3}H]-mazindol uptake site autoradiography. Both D1 and D2 receptor subtypes were downregulated in the striatum by chronic cocaine administration. Dopaminergic uptake sites appeared to be unchanged in either the mesolimbic or striatal terminal fields. The density of D2 receptors in the substantia nigra and ventral tegmental area was unchanged, while the number of D1 receptors was markedly reduced in the substantia nigra. These results suggest that chronic cocaine administration may differentially regulate pre- and postsynaptic dopaminergic markers in cell body and terminal regions.

322.12

Binding Characteristics of Cocaine and Tropococaine to Muscarinic and Sigma Receptors in the Human Brain. D. C. Mash, A. J. Ruttenber*, C. V. Wetli*, W.J. Weiner, Y. Itzhak, and J. Pablo. Depts. of Neurology, Biochemistry and Pathology, University of Miami School of Medicine and the Dade County Medical Examiner Dept., Miami, FL. 33101 and the Center for Environmental Health, CDC, Atlanta, GA. 30333

Complications from cocaine abuse include acute psychiatric disturbances, such as dysphoria, agitation, assaultiveness, paranoia, psychosis and hallucinations. Although the precise mechanisms underlying these behavioral disturbances are not known, they may be related to the targeted effects of cocaine at specific neurotransmitter systems and receptors. Fatal excited delirium has been reported in recreational cocaine users having significantly lower blood levels of cocaine than those usually associated with fatal cocaine toxicity (Wetli, C.V. and Fishbain, D.A., J. Forensic Sci. 30:873, 1985). The reinforcing property of cocaine is attributed to its ability to block the reuptake of dopamine. We report here that cocaine exhibits high affinity for muscarinic and sigma receptor sites labelled in human brain membranes. Competition of cocaine with radiolabelled muscarinic agonists and antagonists gave Ki values in the low micromolar range (~ 5 μM). Putative sigma receptor sites in the human brain were labelled with [^{3}H]-ditolylguanidine (DTG). Competition of cocaine with [^{3}H]-DTG in human brain cerebellar membranes resulted in complex inhibition curves that were best fit by a two site model (IC50 values of 1 x 10-5 M and 5 x 10-4 M). Tropococaine, a 'street' contaminant of cocaine, had a ten-fold higher potency than cocaine at both muscarinic and sigma receptors. The direct action of cocaine at muscarinic and sigma receptors may contribute to the dysphoria and delirium experienced by some cocaine abusers. These observations further suggest that chronic cocaine abuse may lead to multiple receptor site alterations in the human brain and thereby contribute to the pathogenesis of cocaine-induced psychosis and the phenomenon of sudden death.

ISCHEMIA

323.1

EFFECTS OF THE 21-AMINOSTEROID U74006F ON POST-ISCHEMIC BRAIN LIPID PEROXIDATION AND RECOVERY OF EXTRACELLULAR CALCIUM E. D. Hall, K.E. Pazara* and J.M. Braughler. CNS Diseases Research, The Upjohn Co., Kalamazoo, MI 49001

The effects of U74006F, shown previously to improve neuronal survival in gerbils following a 3 hr. period of unilateral carotid occlusion (UCO), has been examined on post-ischemic lipid peroxidation (depletion of brain vitamin E) and recovery of cortical extracellular calcium (Ca++)e. Male gerbils were treated with vehicle (0.05 N HCl) or U74006F (10 mg/kg) i.p. at 10 min. before UCO and again immediately after UCO. Brain vitamin E was decreased at 2 hrs. after reperfusion in the vehicle treated animals by an average of 60%. In U74006F treated gerbils, the 2 hr. post-ischemic loss was only 39.7% ($p<0.002$ vs. vehicle). UCO also produced a drop in (Ca++)e from 1.05 mM before ischemia to 0.11 mM by the end of 3 hrs. in both vehicle and U74006F treated gerbils. By 2 hrs. after reperfusion, (Ca++)e recovered to only 0.22 mM in the vehicle animals compared to 0.56 mM in the U74006F group ($p<0.03$ vs. vehicle). Cortical blood flow, mean arterial pressure and pCO2 were the same in both groups. The results indicate that U74006F inhibits post-ischemic lipid peroxidation and that perhaps secondary to this membrane protective effect, the processes responsible for the reversal of the ischemia-induced intracellular Ca++ accumulation are preserved.

^{45}CALCIUM ACCUMULATION AND INTRACELLULAR CALCIUM DURING IN VITRO "ISCHEMIA". M.P. Goldberg, M.C. Kurth*, R.G. Giffard and D.W. Choi. Dept. of Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

We explored the relationship between Ca^{++} influx and neuronal injury in an in vitro model of cerebral ischemia. Dissociated murine neocortical cell cultures were exposed to medium lacking both oxygen and glucose, resulting in widespread neuronal death 24 hr later. With 30-60 min oxygen + glucose deprivation, cellular accumulation of media $^{45}Ca^{++}$ quantitatively paralleled resultant neuronal injury. No $^{45}Ca^{++}$ accumulation was observed in glial cultures under similar conditions. Such "ischemic" $^{45}Ca^{++}$ accumulation was increased by removing either Mg^{++} or Na^{+} from the exposure medium, and blocked by addition of the NMDA antagonists 1 mM APV, 100 μM dextrorphan (DX), or 100 μM CGS-19755. In contrast, neither $^{45}Ca^{++}$ accumulation nor neuronal death was significantly altered by addition of 100 μM nifedipine, a concentration sufficient to block $^{45}Ca^{++}$ accumulation evoked by KCl depolarization. In cultures previously loaded with the intracellular free Ca^{++} indicator fluo-3, intense fluorescence was observed in neurons (but not glia) immediately following deprivation of oxygen + glucose; and this high Ca^{++} signal could be blocked by NMDA antagonists. Present observations provide further evidence linking Ca^{++} influx via NMDA channels to ischemic neuronal injury.

EFFECTS OF CAFFEINE ON ISCHEMIC NEURONAL INJURY STUDIED USING MAGNETIC RESONANCE IMAGING AND HISTOPATHOLOGY. R.M. Brownstone, G.S. Sutherland*, J. Peeling*, F. Dai*, H. Lesiuk*, and J.K. Saunders*. Depts. Physiol. and Surgery, Univ. Manitoba, Winnipeg, R3E OW3; and the National Research Council of Canada.

The phenomena of post-ischemic selective neuronal vulnerability and ischemic maturation have led to the suggestion that intrinsic neuronal properties are in part responsible for eventual cell death (see Siesjö & Bengtsson, J. Cereb. Blood Flow Metab. 9:127, 1989). Adenosine may mediate a common underlying mechanism in ischemic neuronal damage (Hagberg et al, J. Neurochem 49:227, 1987). To test this hypothesis, the effects of caffeine on neuronal damage were assessed in rats subjected to forebrain ischemia. Six rats were given intravenous caffeine (20 mg/kg) 30 minutes prior to the ischemic insult ("Acute"), whereas 8 control rats received equivalent quantities of i.v. normal saline. Eleven rats were fed increasing oral doses of caffeine over a 3 week period (up to 90 mg/kg/d; "Chronic"). Post-ischemic high resolution (100 um) multi-slice, multi-echo magnetic resonance images were obtained daily for 3 days. All animals were then sacrificed via perfusion-fixation, and the brains studied histologically.

The control rats demonstrated MRI changes indicative of neuronal damage primarily confined to the striatum at 24 hours, with hippocampal damage evident at 48 hours. By 72 hours, the changes were beginning to resolve. Three of six of the "acute caffeine" rats showed significantly more pronounced neuronal damage in both the striatum and the hippocampus by 24 hours. The rest were similar to control. In the "chronic caffeine" rats, the neuronal injury was significantly less pronounced than in the control group. The histopathologic findings were consistent with these MRI changes.

These results support the hypothesis that adenosine plays an important role in reducing the neuronal damage following forebrain ischemia. It is suggested that the accelerated neuronal injury seen in the rats treated with an acute dose of caffeine was secondary to the direct antagonism of adenosine by caffeine, whereas in the rats chronically fed caffeine, there was an upregulation of adenosine receptors which resulted in a decrease in the neuronal damage.

MK-801 INCREASES CEREBRAL BLOOD FLOW IN A RAT MODEL OF TEMPORARY FOCAL CORTICAL ISCHEMIA. A.M. Buchan, D. Xue*, A. Slivka*, C. Zhang*, J. Hamilton* and A. Gelb*. Laboratory of Cerebral Ischemia, Robarts Research Institute, London, Ontario, Canada.

The NMDA antagonist MK-801 has been reported to have potent cytoprotective properties in the face of both global and focal cerebral ischemia. Pre and post treatment with MK-801 lessens the volume of cortical infarction in a variety of models. These experiments were performed to test the hypothesis that this effect is related to increased regional cerebral blood flow (rCBF) rather than NMDA antagonism.

Male Wistar rats, anaesthetized and monitored physiologically had both common carotids (RCCA,LCCA) and the right middle cerebral artery (RMCA) exposed. Right cortical rCBF was monitored with a laser Doppler flowmeter. Prior to occlusion rCBF was 106 ± 29 ml/100g/min (± SD) (N=28) with a tandem occlusion of the RCCA and RMCA this fell to 27 ± 7% of baseline (N=11) but no infarcts occurred unless the LCCA was also occluded. With both CCA and RMCA occlusion rCBF was 5.3 ± 1.8% (N=18). Prior to baseline measurements a further group of animals were given saline or MK-801, 5mg/kg i.p., baseline rCBF obtained and temporary clips (2-4 hrs) placed on the LCCA and RMCA, RCCA was permanently occluded.

Time	Saline	MK-801
Baseline rCBF(±SD)	92.9 ± 27	106 ± 32
% ±SD (N)	100 ±0% (8)	100 ±0% (10)
RMCA,RCCA,LCCA occluded	5.8 ±0.5% (8)	17.6*** ±2.3% (10)
LCCA/RMCA reperfused	63 ±13% (7)	80 ±10% (7)
At 24 hours	92 ±12% (7)	121 ±30% (4)

*** = p<.001 (Mann-Whitney U) MK-801 vs. Saline

Animals treated with MK-801 received 2 further doses of 2.5mg/kg at 6 hours and 12 hours. Cortical infarcts at 24 hours were smaller for MK-801 than for saline treated animals, but as can be seen in the table rCBF was significantly higher in drug treated animals. These in vivo findings are supplemented by our studies of canine basilar artery strips. MK-801 in clinically relevant dilutions (10-100 μ Mol) produced dose dependant but endothelium independent vasodilation of artery contracted with KCl and 5HT.

We conclude that the protective effects of MK-801 in focal cerebral ischemia are at least in part related to increased rCBF rather than NMDA antagonism.

EFFECTS OF NORMO- AND HYPERGLYCEMIA ON REVERSIBILITY AND EXACERBATION OF OUTCOME AFTER CLIP RELEASE AFTER MCA OCCLUSION IN CATS. G.M.de Courten-Myers*,R.E.Myers,M. Kleinholz * and K.R.Wagner(SPON:T.Mandybur).Dept. of Path.,UC College of Med.,and Res.Serv.,Cincinnati VAMC, Cincinnati,OH 45220.

Factors influencing the effects of restoring blood flow to areas of focal brain ischemia remain poorly defined but have come of interest because of fibrinolytic stroke treatment. We investigated pathologic outcome after temporary (4 and 8 hours) middle cerebral artery (MCA) occlusion in anesthetized cats rendered hyper- (20 mM for 6 hrs) or normoglycemic (6mM), respectively. Surviving animals were killed 2 weeks survival to assess infarct size (% MCA territory). Acute deaths resulted from total MCA territory edema with infarction.

Duration occlusion	Glycemia (mM)	Edema death	Infarct	Size mean±SE	Intact
4 hrs	20	7/13(54%)	0/13(00%)	0	6/13(46%)
8 hrs	20	4/9 (44%)	4/9 (44%)	9±3.0%	1/9 (11%)
4 hrs	6	1/12(08%)	5/12(42%)	2±0.3%	6/12(50%)
8 hrs	6	2/10(20%)	6/10(60%)	12±0.2%	2/10(20%)

Hyperglycemia at and following occlusion affected outcome negatively, causing more frequent edema deaths ($p<0.02$). In surviving animals of both glycemia groups, longer occlusion increased infarct frequency and size and decreased intact survival.

323.6

CARRIER MEDIATED TRANSPORT OF LACTIC ACID IN CULTURED NEURONS AND ASTROCYTES. M. Nedergaard*, S.A. Goldman, S. Desai*, and W.A. Pulsinelli (SPON: F. Plum) Dept. of Neurology, Cornell Univ. Medical College, N.Y., 10021.

Lactic acid is a key intermediate in the process of ischemic brain infarction, but the mechanism by which lactic acid crosses brain cell membranes is not well defined. As a measure of lactate transport, we examined neuronal and glial rates of intracellular acidification to lactate exposure at constant extracellular pH (pH_e) using microspectrophotometry and the pH sensitive dye BCECF. Cells were obtained from trypsin-dissociated E16 embryonic rat forebrain. Intracellular pH (pH_i) in CO_2-free HEPES buffered solution was 7.12±0.18 (n=42) in neurons, and 7.01±0.13 (n=36) in astrocytes. Exposure to L-lactate (1-80 mM) at constant pH_e (7.3) caused a reversible decrease of pH_i by 0.1-0.2 in both cell types. The absolute magnitude of intracellular acidification of neurons and glial cells with D-lactate was significantly less than with L-lactate. The initial rate of acidification was a saturable function of L-lactate concentration; K_m was below 1 mM, the maximum acidification rate was~0.3 pH units/min. The rate of acidification was not affected by lowering pH_e to 6.5. Thus under physiological concentrations of lactate and H^+ ions this carrier is saturated. During cerebral ischemia the net effect of this carrier may be the rapid equilibration of transmembrane lactic acid concentrations.

323.7

EXTRACELLULAR ACIDOSIS PROTECTS CULTURED NEURONS FROM INJURY INDUCED BY EITHER COMBINED OXYGEN-GLUCOSE DEPRIVATION, OR GLUTAMATE. R.G. Giffard, H. Monyer and D.W. Choi. Depts. of Anesthesia and Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

Brain ischemia in vivo is accompanied acutely by extracellular acidosis, a derangement considered to contribute to resultant neuronal injury. We examined the effect of pure acidosis upon the neuronal injury induced by oxygen and glucose deprivation in vitro. Murine cortical cell cultures subjected to combined hypoxia and glucose deprivation ("ischemia") for 45 - 60 min at pH 7.4 developed widespread neuronal degeneration over the next day. If the bathing medium pH was lowered to 6.0-6.4, resultant neuronal injury was markedly reduced. The basis for this protective effect of acidosis may be downmodulation of NMDA receptor activation (Morad et al., Soc. Neurosci. Abstr. 14:791, 1988), reducing glutamate neurotoxicity. We previously reported that the addition of 500 μM glutamate to the cultures for 5 min at pH 7.4 was sufficient to destroy most of the neuronal population; lowering pH to 6.0-6.4 also attenuated this direct glutamate-induced neuronal degeneration. Acidosis in vivo is indisputably associated with increased severity of infarction; however present observations raise the interesting possibility that acidosis per se may actually reduce the intrinsic vulnerability of neuronal cells to ischemic damage.

323.8

TISSUE LACTATE AND pH AS MARKERS OF INFARCTS FROM CEREBROVASCULAR OCCLUSIONS IN CATS. R.E.Myers,K.R.Wagner,M. Kleinholz* and G.M.de Courten-Myers.Res.Serv.,Cincinnati VAMC and Dept.Path., UC College Med., Cincinnati,OH 45220

Lactate accumulation in tissue >17-20 umoles/g correlates with brain injury in anoxia. We presently test whether a similar relation exists in infarction from middle cerebral artery (MCA) occlusion. We compared hyper- (20 mM) and normoglycemic (6 mM) animal groups in parallel biochemical and pathologic studies and determined lactate and pHi topographically after 0.5 and 4 hrs of occlusion. The % of lactate >17 umoles/g within the ischemic territory in 14 sample sites was correlated with infarct sizes also expressed as % of MCA territory derived from groups with the same durations of occlusion with clip release or with permanent occlusion with 2 wks survival for pathologic study. Acute deaths resulted from total territory infarction and edema.

The % high lactate sites after 0.5 and 4 hrs of occlusion correlated well with permanent occlusion infarct probability and with 4 hr occlusion-clip release outcome in normo- and hyperglycemic groups. However, hyperglycemic 0.5 hr occlusion lactate markedly overestimated 0.5 hr release infarction. pHi determinations revealed significantly less acidosis with similar lactate concentrations after 0.5 than 4 hrs occlusion indicating 1) the accompanying marked acidosis and not lactate most consistently correlates with brain damage and 2) intracellular buffering early after occlusion may protect against injury with early restoration of blood flow.

HYPOXIA ISCHEMIA INDUCES HEAT SHOCK PROTEIN IN NEONATAL RAT BRAIN. Donna M. Ferriero, Hernani Q. Soberano*, Roger P. Simon, Frank R. Sharp, Manual Gonzalez. Department of Neurology, UCSF, San Francisco, CA 94143-0870

The expression of heat shock protein in rat brain was evaluated in a model of neonatal hypoxia-ischemia. One week old rats were subjected to left carotid artery coagulation and exposure to 8% O_2/92% N_2 for 2 h (moderate injury) or 3.5 h (severe injury). Animals were sacrificed at 1, 12 and 24 h after the hypoxic insult. Immunoreactive cells containing a 70 kD heat shock protein (HSP 70) were seen in regions of the ipsilateral cortex as early as 1 h after the complete insult. After 12 h, neurons of the ipsilateral hippocampus and cortex stained intensely for HSP 70 in the moderately injured group. In the severely injured brains, bilateral staining was observed in neurons and vessels of hippocampus and cortex. Therefore, HSP 70 immunocytochemistry may serve as an early marker for neuronal injury from hypoxia-ischemia in the neonatal rat brain and more importantly may identify previously unrecognized areas of central nervous system vulnerability.

PAF-ACETHER PRODUCTION IN SPINAL CORD AFTER ISCHEMIA-REPERFUSION **Lindsberg P J*, Yue T-L*, Frerichs K U*, Hallenbeck J M*, Feuerstein G. (SPON:M CARPENTER). Dept. of Neurology USUHS, Bethesda, MD 20814.**

PAF-acether is a potent mediator of inflammatory responses and modulates cardiovascular functions in systemic and microvascular circulation. PAF has been shown to decrease blood flow in the central nervous system (CNS), to induce blood-brain barrier (BBB) damage and has therefore been suggested to play a role in ischemic CNS injury. However, no evidence of PAF-production in injured CNS-tissue has been reported. Lumbar spinal cord ischemia (10 min) was produced in six rabbits with an inflatable balloon-tipped Swan-Ganz catheter and verified by on-line laser-Doppler flowmetry through a laminectomy (L5). Spinal cord samples were obtained after 2 hours of reperfusion for PAF-assay and edema measurement. PAF was extracted by the method of Bligh-Dyer, isolated by TLC and assayed by measuring the release of ^{3}H-serotonin from washed rabbit platelets. Serotonin-release was higher in all ischemic samples than in controls ($p<.05$), suggesting PAF-like activity in CNS injured by ischemia-reperfusion. Coincidently, the water content of ischemic samples was increased by 3.1 ±.7 % ($p=.01$) indicating postischemic edema formation. Our data suggest that PAF exists in injured CNS tissue and may have a role in the pathophysiology of postischemic edema and delayed neuroinjury after ischemia-reperfusion.

POSTISCHEMIC NEURONAL FLOODING WITH IgG: AN EARLY PREDICTOR OF RAT HIPPOCAMPAL CELL DEATH. C. Williams*, L. Jenkins, and J. Povlishock (SPON: J. Astruc), Depts. of Anatomy & Surgery, Med. Coll. of VA, Richmond, VA 23298.

Previous studies of transient cerebral ischemia (TCI) have demonstrated neuronal populations, notably Hippocampal CA1 neurons, that show little or no initial post-ischemic change, yet die within several days. Biphasic local blood-brain barrier dysfunction and late neuronal flooding with exogenous and endogenous protein tracers thought to be associated with cell death, have also been described with TCI. We studied the possibility that neuronal flooding with endogenous circulating immunoglobulins might be an early and definitive marker of impending cell death by subjecting rats to global TCI and evaluating them after postischemic survivals of 4h to 72 h. Brain tissue was reacted for the immunocytochemical visualization of IgG at the electron microscopic level. In all animals, the insult produced early hippocampal interstitial labeling, indicating increased vascular permeability to IgG. Initially, this presence was not associated with neuronal flooding, despite some neurons displaying modest ultrastructural change. By 24h post-ischemia, however, neurons showing progressive changes all flooded with IgG, and by 48h, these innundated neurons demonstrated dramatic changes consistent with the onset of cell death. Thus, it appears that early intra-neuronal flooding with IgG is an indicator of impending cell death. Supported by NS-20193 and T32 NS-07288.

ANATOMY OF PENUMBRA IS MODIFIABLE WITH NMDA ANTAGONISTS AND PREDICTS REGION OF INFARCTION R Simon, F Sharp, K Shiraishi* Dept Neurol, UCSF, SF, CA 94143-0870

The pattern and time course of metabolic alterations in cortex and basal ganglia of rat have been studied using 2-deoxyglucose (2-DG) administered 5, 30, 60, 120, 140 min and 24 and 72 hrs following permanent MCA occulsion (N=5 per time point); the effect of the potent NMDA antagonist CGS 19755 (10mg/Kg) administered 5 min prior to,5 min or 60 min following MCA occulsion was then studied. In MCA occlusion rats a pattern of increased 2-DG was reproducibly seen: by 5 min 2-DG was decreased in lateral but increased in medial caudate-putamen (CP) and lateral neocortex; over the subsequent 30 min in CP and 120 min in cortex increased 2-DG uptake preceded decreased 2-DG uptake and infarction. The regional anatomy of the altered 2-DG uptake predicted the anatomy of the eventual infarct (defined on H&E sections at 72 hrs s/p MCA occlusion). Although alternate explanations for increased 2-DG preceding infarction are numerous, excitatory amino acid -induced hypermetabolism which preceeds and predicts the region of infarction is possible. This hypothesis was tested by studying the pattern of 2-DG uptake and resultant infarct in the same rat MCA model in the setting of CGS 19755. Total infarct size was decreased 64%, 50% and 0% in 5 min prior, 5 min post and 60 min post MCA occlusion respectively. 2-DG images showed altered metabolism corresponding closely to the regions of ultimate infarction. These data 1) support a role for excitation-induced hypermetabolism in the pathogenesis of ischemia; 2) suggest that attenuation of hypermetabolism may contribute to the neuroprotective effect of NMDA antagonists; and 3) suggest that the time window of effectiveness of NMDA antagonists may be dictated by the time course of the metabolic changes described above.

323.13

POSTISCHEMIC HIPPOCAMPAL GLUCOSE UTILIZATION AFTER LONG-TERM RECOVERY T. Beck*, A. Wree*, A. Schleicher* (SPON:D.J. Ennulat). Dept. Pathology, Columbia University, New York, NY 10032; Anat. Inst. Univ. Würzburg, FRG; Anat. Inst. Univ. Köln, FRG

Previously we showed local cerebral glucose utilization (LCGU) to be increased in CA1 sector 1 week postischemia (Beck et al., JCBFM 9 Suppl, 1989, in press).

In the present report, hippocampal glucose utilization was determined in male Wistar rats 2 and 3 weeks as well as 3 months after a 10 min forebrain ischemia induced by clamping of the carotid arteries and lowering blood pressure to 40 mmHg.

Despite severe neuronal damage as assessed by histological techniques, local cerebral glucose utilization (LCGU) was significantly increased in the pyramidal and radiatum layers of the CA1 sector up to 3 weeks postischemia, while in other hippocampal areas, and dentate gyrus decreases in LCGU prevailed compared to non-ischemic controls. At 3 months postischemia LCGU in CA1 sector was reduced compared to controls, while staining for GFAP was pronouncedly increased.

The increases in LCGU are suggested to either reflect long-lasting postsynaptic hyperexcitation of pyramidal cells or to point to ongoing presynaptic hyperactivity. Metabolism of glial cells is unlikely to contribute to these effects.

Vision calibrates the map of head movement in the optic tectum of developing barn owls. S. du Lac and E.I. Knudsen. Dept. Neurobiology, Stanford University, Stanford Ca 94305.

The optic tectum contains mutually aligned maps of visual and motor space: the size and direction of orienting movements that result from microstimulation at any given site in the tectum match the position of visual receptive fields recorded at that site. We tested whether visual experience is required for normal visuo-motor registration by comparing tectal maps in normal barn owls with those in owls raised with both eyelids sutured closed. Microstimulation with standard parameters was applied to the optic tectum and the resulting head movements were measured with a skull mounted search coil. As expected from a previous study, visual deprivation resulted in strabismus in 4 of 5 owls; when visual receptive fields were adjusted by the amount that the eye deviated from normal orientation, the visual map of space in the tecta of blind reared owls was essentially normal. In contrast, the topography of the motor map was conspicuously abnormal. Stimulation-induced head movements, although kinetically normal, rarely corresponded with visual receptive field locations measured at the site of stimulation. Movements elicited from different sites in a single tectum could be either hypo- or hypermetric relative to the movement predicted from the receptive field location. In addition, the direction of evoked movements tended to be inaccurate. A motor map, albeit degraded, did develop in the tecta of blind-reared owls: movements changed from small and ipsilateral to large and contralateral as the stimulation site moved from rostral to caudal, and from upward to downward as the site moved from dorsal to ventral. Thus, the tendency to form a systematic representation of movement vector does not depend on vision. However, vision is required for the motor map to attain the precise topography and accurate alignment with the visual map that exists in the tecta of adult owls.

324.2

EFFECTS OF VISUAL-AUDITORY EXPERIENCE ON SACCADIC LOCALIZATION OF AUDITORY STIMULI. D.D. Kurylo, P.H. Hartline and R.L.P. Vimal*. Eye Research Institute, Boston, MA, 02114.

Cats can be trained to look towards auditory targets, as reported previously (Hartline and Northmore, Soc Neurosci Abstr, 12:1277, 1986). It was also reported that when brief (50 msec) visual and auditory stimuli were presented simultaneously, though at different locations, cats often oriented their eyes to a location between the two stimuli (Vimal, Kurylo, and Hartline, Soc Neurosci Abstr, 14:957, 1988). We now describe how pairing of stimuli in this way influenced subsequent localization of auditory test stimuli that were presented alone. For example, when visual stimuli were offset to the left of auditory stimuli during paired visual-auditory presentations, subsequent localization of auditory alone stimuli was shifted to the left, compared to localization of auditory alone stimuli before pairing. Localization of auditory stimuli could be displaced in this way both horizontally and vertically. This effect occurred after as few as 50 pairings. Even when visual-auditory discrepant pairing occurred at only three spatial positions, subsequent changes in auditory localization generalized to regions in space previously unpaired. Similar changes in localization of auditory stimuli also occurred when cats were in the dark, or when a novel visual background was used during post-pairing auditory test trials. This eliminates the possibility that during paired trials cats learned to associate visual landmarks with each speaker and looked at those landmarks after auditory test stimuli. This effect suggests that the localization of auditory stimuli by adult cats may be continuously altered by experience.

324.3

MULTISENSORY INTERACTIONS IN CAT SUPERIOR COLLICULUS DURING ACTIVE FIXATION

C.K. Peck and J.A. Baro. School of Optometry, University of Missouri-St. Louis, St. Louis MO 63121

In the intermediate and deep layers of the superior colliculus (SC), visual and auditory receptive fields are in alignment when the eyes and ears are directed straight ahead. However, during normal orienting behavior, the eyes and ears can move independently and the consequent misalignment of visual and auditory receptive fields might be expected to reduce the probability of appropriate behavioral responses to multisensory targets. Passive displacement of the ears not only shifts the optimal location for auditory targets (Middlebrooks and Knudsen, J. Neurophysiol. 57: 672, 1987) but also depresses the response of SC neurons to multisensory stimulation at a given location in space (Meredith and Stein, Soc. Neurosci. Abstr. 12: 1034, 1986).

We have examined the effects of misalignment of receptor organs on the responses of visual-auditory neurons in SC while cats made active fixating eye movements to targets at different spatial locations. Under conditions of active, voluntary realignment of the eye, most multisensory neurons exhibited strong enhancement of responses to multisensory stimuli at a given spatial location when the eyes were deviated up to 20 deg. The effects of larger deviations could not be assessed due to the limitations of the cat's oculomotor range. Because passive displacements of visual and auditory targets by 10 deg. have previously been shown to suppress multisensory interactions in cat SC (Meredith and Stein, Brain Res. 365: 350, 1986), the present results suggest that active and passive misalignments of receptor organs are processed differently by the nervous system. Thus, misalignment of sensory maps during active fixation does not invariably degrade or suppress interactions among multisensory targets. Supported by NS-21238.

324.4

AUDITORY AND VISUAL STIMULUS INTERACTION IN THE GENERATION OF HUMAN SACCADIC EYE MOVEMENTS. C.J.Lueck*, I.J.Crawford*, C.J.Savage*, C.Kennard. Dept. of Neurology, The London Hospital, London E1 1BB, U.K.

The hypothesis that auditory and visual spatial representations move with respect to each other during eye movements (Sparks, D.L., Brain Beh. Evol. 31:49, 1988) was tested in man. Four normal subjects were studied using the magnetic scleral search coil technique. Auditory targets were arranged horizontally at 0°, -15°, and +15°. Visual interference was provided by simultaneous onset of one of twelve light emitting diodes arranged horizontally between -25° and +25°.

When starting with head and eyes pointing straight ahead, primary saccades showed shorter latency if the lights were on the same side of the midline as the target buzzer than if they were on opposite sides. Saccade amplitude was reduced equally by a light anywhere in the opposite hemifield. A light in the same hemifield affected saccade amplitude in a linear manner depending upon its position. Final eye position was affected in the same way as primary saccades. When the eyes started from an eccentric position, the relation between light position and saccade amplitude suggested that visual and auditory spatial representations do not remain in fixed relationship to each other during eye movements.

324.5

OBLIQUE GAZE SHIFTS IN HEAD FREE CATS. M.Crommelinck*, E.Olivier*, P.Monteyne*(SPON: M.Meulders). Lab. de Neurophysiologie, Louvain Univ. Sch. of Med., B-1200 Brussels, Belgium.

It has been shown, in head fixed cats and monkeys, that the duration of the smaller component of oblique saccades is increased, as compared to pure horizontal or vertical saccades, to match the duration of the largest component. Is this phenomenon also present when the head is free to move?

Eye and head movements were recorded by the search coil technique in alert cats trained to fixate visual targets. Preliminary results obtained from 640 oblique movements clearly show a stretching of the duration of the smaller component of eye movements, related to the amplitude of the other one. For saccades, the angle of which lies within 25 deg from either the horizontal or the vertical, however, one of the components is too small to be adapted. As far as gaze is concerned, there is no significant effect of one component on the duration of the other. The same is observed for the horizontal and vertical components of head movements, which seem to be independent of each other. These observations suggest that the vestibulo-ocular reflex is not operating with a unitary gain during these head free movements. Indeed, if this was the case, the effect of head rotation on gaze would be compensated for and, like the saccade, the gaze components would be adapted. The fact that head trajectories are not rectilinear (both components are not adapted in duration) does not mean that their amplitude is not precisely controlled. Indeed, the head takes a constant part in the gaze displacement (a mean of 77 and 82% for horizontal and vertical components respectively).

324.6

GAZE CONTROL IN THE HEAD-FREE CAT. I. COMPENSATION FOR STIMULATION-INDUCED PERTURBATIONS IN GAZE POSITION. D. Pélisson*, D. Guitton and D.P. Munoz. (SPON: L. Wolfe) Montreal Neurol. Inst. and McGill Univ., Montreal, H3A 2B4, Canada.

It is thought that saccades are controlled by signals representing target and instantaneous eye positions coded with respect to the head. To determine the frame of reference relevant to gaze (= eye + head) control, we extended to the cat whose head is unrestrained the original study of Mays and Sparks (Science, 208: 1163, 1980). We stimulated the superior colliculus (SC) to perturb initial gaze position before the onset of a gaze shift made in the dark to a flashed target. Gaze shifts compensated for this perturbation and reached the target with normal accuracy, despite the absence of visual feedback. This result indicates that gaze shifts were coded in either a body-centered or spatial frame but we could not distinguish between these 2 alternatives because the cat's body was fixed. When we perturbed an ongoing gaze shift by briefly stimulating a SC during the movement, the deviated gaze shift did not stop but compensatory adjustments to the trajectory occurred "on-line" so as to assure gaze accuracy. This experiment suggests that coordinated eye-head orienting movements are controlled by a feedback system which compares desired and actual gaze positions.

324.7

GAZE CONTROL IN THE HEAD-FREE CAT. II. SPATIO-TEMPORAL VARIATIONS IN THE DISCHARGE OF SUPERIOR COLLICULUS OUTPUT NEURONS. D.P. Munoz, D. Guitton and D. Pélisson*. Montreal Neurol. Inst. and McGill Univ., Montreal, H3A 2B4, Canada.

When a cat, whose head is unrestrained (head-free), orients to a target of interest, the following events occur in the crossed tecto-reticular (TR) pathway. 1) An ensemble of TR neurons (TRNs), centered at the site in the superior colliculus (SC) that will generate the gaze (= eye + head) shift, displays first a low frequency preamble discharge. 2) The TRNs composing this active zone then discharge a burst which precedes the gaze displacement by 15-20ms. 3) At the termination of the movement the initial active zone is silenced and fixation-related TRNs, located in the rostral poles of both SCs, begin to discharge. We have reported this information during the past five years. Here, we present the results of experiments in which we recorded simultaneously from 2 or more TRNs located at different sites in the SC between the initial active zone and the rostral fixation area. The results show that these TRNs are sequentially activated during a head-free gaze shift, indicating that the zone of TRN activity moves across the SC map, away from the initial site, towards the fixation zone, such that the instantaneous location of this zone reflects current gaze motor error.

324.8

MODULATION OF GAZE VELOCITY PURKINJE (GVP) CELLS DURING VESTIBULO-OCULAR REFLEX (VOR) WITH NEAR AND FAR VISUAL TARGETS. L.H. Snyder* and W.M. King. Department of Physiology, University of Rochester, NY 14642.

GVP cells, located in the cerebellar flocculus, modulate with the sum of eye and head movements (gaze) and have been implicated in control of the VOR, an oculomotor reflex that counter-rotates the eyes to stabilize images on the retina during head rotation. During rotation about a vertical axis, compensatory eye velocity is increased when near targets are viewed (Blakemore and Donaghy 1980). We investigated the role of horizontal GVP cells in such "near enhancement" of the VOR. Monkeys equipped with binocular scleral search coils were trained to fixate near (10 cm) or far (220 cm) LED targets. Brief pulses of whole-body rotation (25 d/s for 175 ms) were applied immediately after extinguishing all lights, including the LED target. Averaged eye velocity traces showed that the enhanced near target VOR response diverged abruptly from the far target response ~11 ms after the onset of eye movement. Averaged GVP cell discharge also diverged, but no earlier than 2 ms before the eye velocity divergence (28 observations on 11 cells), suggesting that these GVP cells are outside the pathways that drive near enhancement.

Eight of 11 cells did increase their tonic discharge rate with fixation of near compared to far targets (70 versus 40 hz, mean of 11). This change in firing rate may modulate the sensitivity of cells in more direct VOR pathways, and thereby alter the eye movement response to a given vestibular input.

THE LATENCY AND GAIN OF THE HORIZONTAL VESTIBULO-OCULAR REFLEX IN GOLDFISHES DETERMINED BY VESTIBULAR POSITION AND VELOCITY STEPS DURING LEARNING AND MEMORY. R. Baker, A. M. Pastor*, M. Weiser* and J. McElligott. Dept. Physiol. & Biophys. NYU Med. Ctr., New York, NY 10016, and Dept. of Pharmacol., Temple Univ. School of Med., Phil. PA 19140.

In goldfishes with symmetrical VOR gains (eye velocity/head velocity) in the dark of 0.9-1.0 for each eye, vestibular position and velocity steps were utilized to evaluate the latency and profile of horizontal eye movements before, during and after adaptive gain modification. Although electrical stimulation of the vestibular nerve initiated eye velocity at 12-14 msec the latency for both position and velocity steps ranged from 14-21 msec. Differences in latency, time to peak velocity and amplitude could sometimes be observed between movement of the two eyes. Utilizing vestibular frequencies from 0.125-0.5 Hz and amplitudes of 8-32°/sec, goldfishes were trained toward gains of 2.5, 0 or -1.0 with sinusoidal vestibular and visual stimuli for 3-6 hours and then re-trained to 1.0. In all experimental paradigms, irrespective of the extent of learning and memory, the VOR gain measured with vestibular velocity and position steps paralleled that found with sinusoidal stimuli. The latency for increases in VOR gain appeared to follow the earliest detectable eye velocity response for both position and velocity steps. In goldfishes trained to either perfect suppression or inversion (eye gain of 0 and -1.0), latency for the gain modification also followed onset of eye velocity. The initial unaltered eye velocity response was always of small amplitude and short time course, reaching the new gain setting within 0.1-0.2 sec. These data are similar to studies showing an early un-modifiable eye velocity response; however, given the magnitude of change in vestibular sensitivity the goldfish data suggests possibly only one, modifiable, vestibulo-ocular pathway underlying learning and memory. Supported by EY 02007 and NS 13742.

MONOCULAR ADAPTIVE GAIN CONTROL OF THE VESTIBULO-OCULAR REFLEX IN THE GOLDFISH, *Carassius auratus*. M. Weiser*, A. M. Pastor* and R. Baker Dept. Physiol. & Biophys., NYU Med. Ctr., New York, N.Y. 10016.

Sinusoidal vestibular and visual stimuli were used to study normal VOR and OKN performance as well as adaptive VOR gain control. In eight goldfish with VOR gain (eye velocity/head velocity) of 0.9-1.0 in the dark and 1.0 in the light, presentation of full field optokinetic stimuli produced nearly symmetrical (left eye vs. right eye) horizontal eye movement gain (eye velocity/world velocity) equal to 0.6-0.8 at 0.125 Hz and 16°/sec peak velocity. When one eye viewed the moving stimulus and the other eye the stationary stimulus, optokinetic gain was 0.2-0.3 and <0.1, respectively. When each eye was trained simultaneously towards a visual/vestibular gain of 0 and 2.0 initial performance ranged from 0.5-0.8 to 1.2- 1.5. After learning for 3-6 hours the eye movement gains stabilized near 0.2 and 1.8. The VOR memory tested in the dark was always biased more towards the gain of 0 than 2.0 with an average final value of 0.2 and 0.9 for each eye. Thus in all experiments the eye velocities were 25°/sec disparate during learning and about 12°/sec different during the subsequent test of VOR memory. Although the rapid re-setting eye movements were of markedly different amplitude and even direction, they occurred synchronously. Vestibular sensitivity for the eye training towards a higher gain actually decreased by 1-5°/sec; however, the gain was always the same in the eye trained towards 0 for the VOR both in light and dark. Ablation of the cerebellum showed that it was not necessary for establishing and maintaining the direction of the gain changes, but it was important for attaining larger gain amplitudes. Therefore, connections between the vestibular nuclei play a role in determining gain bias and the velocity difference between the two eyes. We conclude that the brainstem-cerebellar circuitry in the goldfish can produce significantly greater differences between individual eye velocities than is the case in mammals. Supported by EY02007 and NS13742.

ACTIVITY OF MEDIAL RECTUS MOTONEURONS IN GOLDFISH DURING VESTIBULAR AND VISUAL EVOKED EYE MOVEMENTS. A. M. Pastor* and R. Baker. (SPON: J. O'Neill). Dept. Physiol. NYU Med. Ctr., N Y, N.Y. 10016.

Goldfish were implanted with intracranial bipolar electrodes placed bilaterally on both oculomotor and vestibular horizontal canal nerves. Movements of both eyes were recorded with scleral search coil techniques and identified medial rectus motoneurons were studied during spontaneous saccades, fixations, and sinusoidal visual-vestibular stimulation producing VOR gains from 0 to 2.5. Electrical stimulation of the medial rectus nerve in the orbit and the whole IIIrd nerve showed that medial rectus motoneurons activated from the orbit were surrounded by vertical motoneuronal pools . All medial rectus motoneurons exhibited a discharge correlated with both eye position and eye velocity during every oculomotor behavior. The vertical oculomotor motoneurons that were antidromically identified showed no relationship to any horizontal eye movement or spontaneous tonic activity, except during 'blinks'. Single electrical shock stimulation of the horizontal canal nerve at 2xThr produced contralaterally directed twitch-like changes in the position of both eyes. Latency for the adducting (medial rectus) and abducting (lateral rectus) eye averaged 14 and 16 msec, respectively. Since IIIrd and VIth cranial nerve stimulation produced eye movements at the same latency (7 msec) the observed 2 msec difference in the evoked VOR latency indicates a differential central processing time for the two horizontal canal vestibulo-ocular pathways. Peristimulus time histograms of medial rectus motoneuronal activity triggered by threshold stimulation of the vestibular nerve clearly showed ipsilateral increases and contralateral decreases in excitability at a short latency. The data suggests a reciprocal vestibular inhibitory and excitatory regulation of the medial rectus subdivision as has been found for goldfish abducens motoneurons. Given the differences in eye movements induced by electrical stimulation of the vestibular nerve we conclude that the neural circuits underlying horizontal eye movements are structurally and, to a large extent, functionally separated; however, their behavior is well co-ordinated for visual and vestibular stimuli producing symmetrical eye movements. Supported by EY02007 & NS13742.

CENTRAL VELOCITY STORAGE: CONVERGENT EVOLUTION IN SOME TELEOSTS AND REPTILES? N. Dieringer* and W. Graf (Sponsor: E.E. Brink). Physiol. Inst., Univ. Munich, Munich, FRG and The Rockefeller Univ., New York, NY 10021

OKAN and VOR time constants longer than that of vestibular afferents are behavioral expressions of the function of a velocity storage mechanism. Differences in the ocular reflex responses of goldfish (Carassius auratus) and toadfish (Opsanus tau) suggest the presence and absence of a functioning velocity storage network, respectively. Lack of velocity storage was also found in other bottom living teleosts (e.g. northern sea robin, Prionotus carolinus, catfish, Ictalurus spec.) as well as in amphibians (urodeles and anurans) as described earlier (Dieringer et al., J. Comp. Physiol. 153, 1983). A non-functioning velocity storage mechanism appears to be concomitant with absence of an inhibitory vestibular commissure at the neuronal level (as in frog and toadfish) and, furthermore, with a reduced role of locomotor capabilities for feeding and escape at the behavioral level. Presence of a storage mechanism can thus be considered a physiological mechanism for behavioral strategies requiring stabilizing reflexes at rapid changes of speed of locomotion. In view of the poor locomotor capabilities of fish-like ancestors of modern amphibians and reptiles, a convergent evolution of a velocity storage mechanism in some teleosts and in reptiles appears to be likely. DISTRIBUTED PARALLEL PROCESSING IN THE VERTICAL VESTIBULOOCULAR REFLEX. T.J. Anastasio* and D.A. Robinson. Dept. of Ophthalmology, Johns Hopkins Univ. Sch. of Med., Baltimore, Maryland, 21205.

Rather than bearing any simple relationship to semicircular canal (SC) or extraocular muscle (EM) geometry, as predicted by vector analysis, the sensitivity-vectors (SVs) of vestibular nuclear neurons (VNNs) in the cat are dispersed in various directions (Baker et al., Brain Res. 294: 133-137, 1984). We constructed neural network models of the vertical VOR that can simulate this diversity.

Vertical VOR networks had three layers of units, input, hidden and output, representing vertical SC afferents, VNNs and cyclovertical EM motoneurons, respectively. Hidden-to-output connections were fixed in a reciprocal pattern; adaptable input-to-hidden connections were randomized prior to learning. Networks were trained to make compensatory responses to rotations about horizontal axes using the back-propagation learning algorithm.

Following training, the SVs of output units matched those desired (to 1 deg). SVs of hidden units in four-hidden-unit networks lined-up near those of the outputs, as expected from vector analysis. In contrast, those in 40-hidden-unit networks were divergent, as for cat VNNs. This similarity suggests that VNNs encode orientation information in a distributed manner, and that learning networks may be more helpful than vector analysis in predicting the behavior of VNNs.

MORPHOGENESIS AND DIFFERENTIATION

325.1

THE SALAMANDER BRAIN AS A PAEDOMORPHIC VERTEBRATE BRAIN. G. Roth[1]*, C. Naujoks-Manteuffel[1]*, K.C. Nishikawa[2], A. Schmidt[1]*. [1]Brain Res. Inst., Univ. of Bremen, F.R. Germany; [2]Sch. of Biol. Sci., Univ. of Kentucky, Lexington, KY 40506.

The salamander brain is usually considered primitive in view of the absence of multiple lamination and distinct nuclei, as compared to anurans and other vertebrates. However, there is evidence that the salamander brain is paedomorphic, i.e., secondarily simplified; (i) essentially the same morphological and functional types (projectivity, response properties) of tectal, pretectal and thalamic neurons are found in salamanders and frogs; (ii) the distribution of AChE and neuropeptides (BOMB, LENK, SP) in the visual system is similar to that found in frogs; (iii) the basic pattern of nerve cell migration is the same as in frogs, but migration is retarded in salamanders; the most derived salamanders (Bolitoglossini) show the least degree of cell migration; (iv) radial glial cells involved in cell migration are present, but seem to fail tc transform into astrocytes, as happens in other vertebrates. In general, late ontogenetic processes are retarded or fail to occur.

325.2

RETINAL REGENERATION IN GOLDFISH: USE OF CELL SPECIFIC MONOCLONAL ANTIBODIES TO ASSESS THE REESTABLISHMENT OF NORMAL CYTOARCHITECTURE. P.A. Raymond and L.K. Barthel*. Dept. Anat.& Cell Biol., Univ. Michigan, Ann Arbor, MI 48109.

We have generated a panel of monoclonal antibodies (Abs) that recognize specific cells or layers in goldfish retina, and we have used these reagents, and other Abs, to follow the degeneration and subsequent regeneration of the retina in adult goldfish following a neurotoxic lesion. Ouabain, injected intravitreally (5 to 20 μM), completely destroys neural retina, which regenerates in several months. Retinal sections (1 day to 10 months after ouabain injection) were processed for immunocytochemistry with:

Antibody	Specificity
ROS-1, ROS-2	rod outer segments
PLEX-1, PLEX-2	certain plexiform/fiber layers
RET-1, RET-2	amacrine & ganglion cell layers
NN-1, NN-2	microglia, pigment cells & other
MUL-2	Müller glia
ENDO-1	endothelial cells

and with rhodopsin Abs (RET-P1, rho4D2) and Müller Abs (CAC, GS). Double labeling with BrDU (or with ^{3}H-Tdr) proved that the neurons had regenerated. Restoration of cytoarchitecture was remarkably accurate. Supported by EY-04318.

GOLGI STUDY OF LAYER I THREE-DIMENSIONAL ORGANIZATION IN THE HUMAN CEREBRAL CORTEX. Miguel Marin-Padilla. Department Pathology, Dartmouth Medical School, Hanover, NH 03756.

The combined study of rapid Golgi preparations of layer I, cut parallel, perpendicular and tangential to the long axis of the gyrus, has permitted for the first time, the visualization and reconstruction of its three-dimensional organization. The autopsy material used included the cerebral cortex of 29,30,31,32,34, and 36 week old premature infants. Based on the observations made, the morphology and orientation of the Cajal-Retzius (C-R) cell is herein redefined in new terms. C-R cells are flat stellate neurons with several short and long primary dendrites radiating in all directions within a plane parallel to the pial surface. Dendrites may reach lengths up to 300 micrometers. Most C-R cells are located in the upper third of layer I. They have a descending axon that give off several fine collaterals that also radiate in all directions within the middle third of layer I. Axonic collaterals may reach lengths up to 500 micrometers. The main axon descends toward the lower third of layer I where it becomes a long and thick tangential fiber. The main axon can be followed for a long distance without reaching its termination. They also radiate in all directions. Together they constitute a prominent axonic band in the lower third of layer I. These axons are among the first to undergo myelinization in the cortical grey matter. Thus, dendrites, axonic collaterals and the main axon of C-R cells radiate in all directions and occupy distinct planes within layer I.

LIVE OBSERVATION OF DYNAMIC EVENTS IN THE FORMATION OF RAT CEREBRAL CORTEX BY LASER MICROSCOPY. M.W. Cooper*, A.B. Waxman and S.J. Smith*. (SPON: P. Forscher) Section of Molecular Neurobiology, Howard Hughes Medical Institute, Yale Medical School, New Haven, CT 06510.

We are using laser confocal microscopy to observe cellular proliferation, migration, differentiation and synapse formation events in tissue slices acutely isolated from cerebral cortex of rat embryos at days E14 to E19. Subcellular resolution is obtained by using the fluorescent, cationic membrane probe Di-I $C_{18}(3)$ as a vital stain. Selective staining of discrete subpopulations of neurons and glia results from localized application of the fluorescent stain. In 768 x 480 pixel images created with incident energy densities of less than 3×10^{-2} Joules/cm^2 at 514 nm, we are able to obtain signal-to-noise ratios adequate to resolve individual filopodia and other very fine cellular processes at depths of 50 to 100 microns into cortical slices. At these energy levels, we are able to record time-lapse video sequences at frame intervals of 15 to 30 seconds for periods of hours with little or no evidence of phototoxicity.

Growth cones observed within embryonic cortical slices exhibited cyclic extension and retraction of filopodia similar to those previously observed under cell culture conditions. Putative immature neurons exhibited migration along radial processes, as inferred in previous studies of fixed tissues. Migration velocities were observed to vary as a function of radial position, being slowest in the cell-dense ventricular zone and fastest in the distal imtermediate zone and cortical plate. One surprising observation was the free and rapid (> 1 um/sec) migration of macrophage-like cells within immature cortical volumes. On occasion, these rapidly migrating cells were observed to adhere to and cause rearrangement of neural or glial processes. (Supported by the HHMI and NIH grant NS16671 to SJS).

SPONTANEOUS INTRACELLULAR CALCIUM FLUCTUATIONS OCCUR IN NEURONS OF THE EMBRYONIC HIPPOCAMPUS. A.B. Waxman, M.W. Cooper*, and S.J. Smith*. Section of Molecular Neurobiology, Howard Hughes Medical Institute, Yale Medical School, New Haven, CT 06510.

We are using a scanning laser microscope and the fluorescent Ca indicator fluo-3 to measure changes in cytosolic Ca in embryonic hippocampal neurons. Parallel studies are being carried out in intact hippocampi explanted from day E17 to E19 rat embryos and on cultured cells dissociated from similar tissues. Use of the laser microscope in a confocal mode allows measurement of indicator fluorescence with excellent spatial resolution and signal-to-noise ratio at depths of 50 to 100 microns into the explanted hippocampus. The same laser microscope is used with a wider detector aperture setting for very efficient fluorescence measurements on the cultured cells in monolayer. In both cases, 768 x 480 pixel images are collected with energy densities below 3×10^{-2} Joules/cm^2, energy levels where little or no cellular photodamage is evident.

Spontaneous elevations of intracellular Ca occur at irregular intervals both in cultured neurons and in neurons within explants. The Ca elevations last between 1 and 10 sec, and occur at intervals on the order of hundreds of seconds. These Ca transients may reflect membrane electrical activity and opening of voltage dependent Ca channels, but we have not yet investigated this possibility directly. Multiple cells within either cultures or explants often exhibit closely synchronized Ca elevations, which may indicate that the Ca transients are synaptically driven, but some form of gap junctional signalling is also a possibility, given the early developmental stages involved. We have also observed that these Ca-increase events occur more frequently as cells make their initial intercellular contacts. (Supported by the HHMI and NIH gram NS16671 to SJS).

EVIDENCE THAT POSTNATAL DEVELOPMENT OF THE MOUSE OLFACTORY BULB PROCEEDS BY GRADUAL ADDITION OF NEURAL ELEMENTS. S.L. Pomeroy, A.-S. LaMantia and D. Purves, Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

We have undertaken a quantitative analysis of the mouse olfactory bulb from birth until maturity in order to ask whether the development of the mammalian brain proceeds by gradual construction or by selection from an initial excess of neural elements.

The brains of CF1 male mice of known age (up to 24 weeks postnatal) were removed and prepared for light and electron microscopy. An assessment was made of: (1) olfactory bulb size; (2) glomerular size and number in cresyl violet-stained serial sections; (3) the extent of mitral cell dendrites visualized by confocal microscopy after retrograde labeling with dil; and (4) the number of glomerular synapses in electron microscopical sections. Serial sections of the olfactory mucosa were also examined to evaluate the size of the sensory epithelium and the density of receptor cells.

We found that the size of the olfactory bulb and mucosa, the number of glomeruli, the complexity of mitral cell dendrites, and the number of glomerular synapses all increase from birth to maturity. These results indicate that neuronal assemblies such as glomeruli and their constituent elements are gradually added during development. Whether the increasing number of glomeruli in postnatal life represents simple addition of these neuronal ensembles, or the net effect of concurrent addition and elimination, cannot be determined from these observations in fixed tissues. The work in the following two abstracts addresses this issue directly by following the natural history of identified glomeruli in living animals. (Supported by USPHS Grant 11699, Training grant 07027, and Javits Center Grant).

325.7

OBSERVATION OF THE OLFACTORY BULB OVER TIME IN LIVING MICE. A.-S. LaMantia, S.L. Pomeroy and D. Purves, Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

We have developed a technique to examine directly the development and adult plasticity of neuronal ensembles in the brain of an individual animal over weeks to months. To obtain images from living animals, CF-1 mice of various ages were anesthetized, and the right olfactory bulb exposed surgically. After briefly superfusing the intact dura with hypertonic NaCl (1.6M), the bulb was stained topically with the styryl dye RH414. Within several minutes an extensive pattern of fluorescently labeled glomeruli appeared. This pattern was then recorded using a laser-scanning confocal microscope with a 10% transmittance neutral density filter (MRC Lasersharp-500, BIO-RAD). Confocal microscopy is superior to standard epifluorescence microscopy for this purpose because of its ability to attenuate out of focus fluorescence from the overlying dura and afferent fiber layer.

Examination of bulbs imaged in vivo and then immediately fixed and stained en bloc with Sudan Black showed that all of the glomeruli seen in the histological preparation are also apparent in the living animal. Light and electron microscopical examination of bulbs fixed acutely or several weeks after imaging showed the architecture and synaptic organization of the bulb to be unaffected by these procedures.

Therefore, a normal pattern of neural elements may be seen at least twice in the brain of a living animal without compromising the integrity of the tissue examined. This method of in vivo brain imaging can be used in mice from birth through maturity with similar effectiveness. In the following abstract we describe the use of this approach to monitor the development and stability of olfactory glomeruli.

325.8

ADDITION OF FUNCTIONAL NEURONAL ASSEMBLIES VISUALIZED IN THE OLFACTORY BULB OF LIVING MICE. D. Purves, A.-S. LaMantia, and S.L. Pomeroy, Dept. of Anatomy & Neurobiology, Washington Univ. School of Med., St. Louis, MO 63110

The arrangement of olfactory glomeruli was visualized in the same developing mouse on two separate occasions to assess the developmental plan in this part of the mammalian central nervous system.

Neonatal mice (4-7 days postnatal) were anesthetized by hypothermia and the olfactory glomeruli visualized by confocal microscopy after vital fluorescent staining, as described in the previous report. The pups were then allowed to recover and returned to the litter. One to three weeks later, the juvenile mice were perfused transcardially with 1% glutaraldehyde and their brains removed. After postfixation overnight, the olfactory bulbs were stained with Sudan Black and the final pattern of glomeruli compared with the earlier in vivo image.

In animals whose olfactory bulbs were re-examined after a week, the pattern was generally similar to that seen initially, although glomerular growth was apparent and some new glomeruli had been added. After 2 weeks, further additions to the initial population were seen with little or no evidence of glomerular deletion. After 3 weeks the additions were so substantial that comparison with the original image was often difficult. In contrast, the pattern of glomeruli was quite stable over intervals of several weeks in a series of adult animals.

Evidently the basis for the overall increase in glomerular number cited in the first of these three reports is the gradual construction and subsequent persistence of new functional units as the animal matures. These observations in living animals, taken together with histological counts of glomeruli in animals of different ages, indicate that this process continues up until about the time of sexual maturity and then ceases.

CELL REARRANGEMENT AND DIVISION IN SHAPING OF THE AVIAN NEURAL PLATE. G. C. Schoenwolf and I. S. Alvarez.* Univ. of Utah School of Med., Salt Lake City, UT 84132 and Univ. of Extremadura, Badajoz, Spain.

Shaping of the neural plate, one of the most striking events of neurulation, involves rapid craniocaudal extension. In this study, we determined the roles of two processes in neural plate extension: neuroepithelial cell division and cell rearrangement. Quail epiblast plugs of constant size were grafted either just rostral to Hensen's node or paranodally and the resulting chimeras were examined at selected times postgrafting. By comparing the size of the original plug, the number of cells it contained, and the distribution of cells within it to those same features of the grafts in developing chimeras, we were able to ascertain that during transformation of the flat neural plate into the closed neural tube (a period requiring 24h), the graft undergoes a maximum of 3 rounds of craniocaudal extension. Such extension is accompanied by 2 rounds of mediolateral cell rearrangement and 2 rounds of cell division, some of which occurs in the transverse plane of the neural plate and some in its longitudinal plane. Thus, craniocaudal extension during neural plate shaping is mediated by both mediolateral cell rearrangement and cell division, with the former playing a greater role in extension than does the latter. In addition, widening of the cranial part of the future brain occurs during neural plate shaping. Our results suggest that cell division in the transverse plane plays a major role in this process. Supported by NIH grant no. NS18112.

CELL TRANSPLANTATION IN THE ZEBRAFISH EMBRYO: IS THE *SPT-1* MUTATION CELL AUTONOMOUS? ROBERT K. HO*, DONALD A. KANE*, & CHARLES B. KIMMEL (SPON: W. ROBERTS). INSTITUTE OF NEUROSCIENCE; UNIVERSITY OF OREGON; EUGENE, OR. 97403

In the zebrafish gastrula, laterally positioned involuting cells converge dorsally to form mesodermal structures in the trunk. The mutation *spt-1* (spadetail) changes the direction of this movement: In *spt-1* homozygotes the same cells move caudally to the tailbud and eventually form mesodermal tissues of the tail. The mutation does not appear to affect ectodermal precursors.

We wish to know if *spt-1* acts in a cell autonomous manner in prospective trunk mesodermal cells and if the anomalous cell movements at gastrulation are specific only to mesodermal precursors. We have labeled mutant and wildtype cells so they can be distinguished from each other, co-transplanted the mixture of labeled cells into unlabeled sibling hosts, and followed the migration patterns and fate of these cells. Our results show that, irrespective of host genotype, cells transplanted to the prospective trunk mesoderm position of the gastrula migrate incorrectly (caudally) if they are mutant and correctly (dorsally) if they are wildtype. Cells placed in prospective ectoderm positions migrate correctly irrespective of their genotypes. We suggest that the *spt-1* mutation specifically and cell autonomously perturbs convergence of the mesoderm. Supported by NIH HD22486 and the Helen Hay Whitney Foundation.

CRANIAL MUSCLES AND MOTONEURONS THAT INNERVATE THEM ORIGINATE FROM THE SAME AXIAL LEVELS IN THE ZEBRAFISH

T.F. Schilling*, R.M. Warga* and C.B. Kimmel. (spon. D. Kimble) Inst. of Neuroscience, U. of Oregon, Eugene, OR 97403.

Do particular mesodermal and ectodermal structures in the vertebrate head both develop from single head segments? In the zebrafish, the positions of muscles of the eye, jaw, and series of gill arches do not correspond in any clear way to those of the motoneurons innervating these muscles, that are present in a series of brain segments. Differences in the two patterns could arise if mesodermal cells that contribute to a muscle originate at the same axial level as the corresponding motoneurons, and later move to new positions. Such a movement occurs in the chick embryo.

We made fate maps for head mesoderm in 12 and 24 hour zebrafish embryos in which muscle progenitors were labeled with lineage tracer, and correlated these positions with those of brain segments at the same stages, derived from antibody staining patterns. At 12 hours, cranial muscles mapped at approximately the same axial levels as the motoneurons that innervate them. In contrast, by 24 hours, the progenitors of all of the cranial muscles had moved rostrally, and certain of them had inverted their relative positions along the axis. These movements distorted the earlier map and brought the mesodermal cells into positions where they differentiated a day later, out of register with the corresponding neural segments.

We conclude that neural segments and their mesodermal targets are aligned early in cranial morphogenesis. Subsequent movements distort this original simple relationship to establish a complex pattern of cranial innervation.

SYNAPTIC INTERACTIONS BETWEEN SUBSTANCE P TERMINALS AND DOPAMINERGIC NEURONS IN THE RAT SUBSTANTIA NIGRA: AN ULTRASTRUCTURAL DOUBLE LABELLING IMMUNOCYTOCHEMICAL STUDY I. Mendez*, K. Elisevich, and B.A. Flumerfelt. Depts. of Anatomy and Clinical Neurological Sciences, University of Western Ontario, London, Canada, N6A 5C1.

Evidence that substance P (SP) immunoreactive striatal neurons project to the substantia nigra and influence the nigral dopaminergic output has been provided mainly by physiological, biochemical and pharmacological studies. However, the synaptology of SP-dopaminergic interactions in the substantia nigra is less clear. SP immunoreactive terminals and tyrosine hydroxylase (TH) immunoreactive neurons were simultaneously colocalized with the PAP method using two different chromogens with distinct reaction products easily differentiated at the light and electron microscope levels. SP immunoreactive structures were first localized with 3'3-diaminobenzidine, then TH immunoreactivity was localized using benzidine dihydrochloride. SP immunoreactive terminals made symmetrical and asymmetrical synaptic contacts on TH-positive dendrites in the substantia nigra pars compacta and reticulata. The present results give direct morphological evidence that substance P immunoreactive neurons, likely located in the striatum, provide a direct input to dopaminergic neurons in the substantia nigra, in support of the view that substance P acts as a modulatory neurotransmitter in the striato-nigral loop. (Supported by MRC of Canada)

326.2

ULTRASTRUCTURAL BASIS FOR INTERACTIONS BETWEEN OPIOID PEPTIDES AND DOPAMINE IN RAT STRIATUM. V.M. Pickel and J. Chan. Div. Neurobiology, Dept. Neurology and Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021.

We examined the cellular substrate for known functional interactions between neurons containing opioid peptides and dopamine, the principal catecholamine in the dorsolateral striatum of adult rat brain. Single, vibratome sections were dually labeled using a rat monoclonal antibody against leucine-enkephalin and a rabbit polyclonal antiserum against the catecholamine synthesizing enzyme, tyrosine hydroxylase (TH). Ultrastructural analysis of dually labeled sections unequivocally established the direct synaptic input from TH-immunoreactive terminals to neurons containing leucine enkephalin-like immunoreactivity (LE-LI), as suggested by more indirect analysis of adjacent sections (Kubota et al., *Brain Res.* 367:374, 1986). Additionally, we demonstrated that striatal terminals containing LE-LI and TH (1) form symmetric synapses on common spiny dendrites both with and without detectable LE-LI and (2) show appositions with each other and with unlabeled axon terminals. We conclude that in the dorsal striatum opioid and non opioid spiny neurons are directly inhibited by terminals containing dopamine and/or opioid peptides and that additional presynaptic interactions may account for functional relationships between these transmitters. (Supported by NIH grant DA-04600)

326.3

CCK/DOPAMINE /GLUTAMATE INTERACTIONS IN THE HIPPOCAMPUS/ NUCLEUS ACCUMBENS/VENTRAL TEGMENTAL AREAS.
De Witte Ph., Heidbreder C.* & Gewiss M.* Lab. Psychobiology, Univ. of Louvain, Belgium.

Neurons with co-localized cholecyctokinin (CCK-8) and dopamine are present predominantly in the ventral tegmental area and project mainly to the caudal part of the medial nucleus accumbens. The nucleus accumbens also received excitatory glutamatergic neurons coming from the hippocampus via the fimbria. This dopamine system may have different influence depending on the activity of the hippocampal formation and originating particularly from the subiculum. The hippocampal formation also contains excitatory CCK-8 interneurons innervating pyramidal cell bodies. The intracranial self-stimulation (ICSS) with electrodes implanted into the mesolimbic system can be modulated by intracerebral injection of CCK-8.
A decrease in ICSS is observed following injection of CCK-8 into the ventricle (150 picomoles), into the rostral part of the accumbens (150 picomoles) and into the subiculum (300 femtomoles). Glutamate injected in the same dosage gave raise to the same depressive effect of ICSS. Since CCK-8 inhibits ICSS at a dose 500 time lower into the subiculum than in the cerebral ventricles and since CCK-8 interneurons are present in this hippocampal formation it is thus tempting to relate the inhibitory CCK-8 action on ICSS by a stimulatory pathway coming from the subiculum to the accumbens via the fimbria.

CELLULAR LOCALIZATION AND EXPRESSION OF MAO IN CNS: QUANTITATIVE ENZYME RADIOAUTOGRAPHY AND IN SITU HYBRIDIZATION HISTOCHEMISTRY. J. Saura Marti*, N.C. Lan, J.C. Shih, M. Da Prada* and J.G. Richards. (SPON: W. Haefely). Pharma Research CNS, F. Hoffmann-La Roche AG., CH-4002 Basel, Switzerland.
Monoamine oxidase (MAO), a flavin-containing enzyme located in the outer membranes of neuronal and glial mitochondria, exists in two forms, MAO-A and MAO-B, which are identified by their inhibitor sensitivity and by their substrate selectivity. Both forms are important for neurotransmitter regulation. Fluctuation in functional MAO activity may be associated with neurological disorders such as depression and Parkinson's disease.
Ro 41-1049 [N-(2-aminoethyl)-5-(m-fluorophenyl)-4-thiazole-carboxamide. HCl] and Ro 19-6327 [N-(2-aminoethyl)-5-chloro-2-pyridine-carboxamide. HCl] are novel reversible and selective inhibitors of MAO-A and -B respectively. As radioligands they have been used to map the distribution and density of the enzymes in microscopic regions of rat CNS, peripheral organs and human brain. Extremely good correlations between binding and enzyme activity were obtained for various parameters, e.g. tissue selectivity, IC_{50} values for inhibitors, age-related changes and species-related differences. Furthermore, the distribution, density and selectivity of binding sites *in vitro* and *in vivo* were very similar, e.g. MAO-A: locus coeruleus, paraventricular thalamus, solitary tract nucleus, inferior olive, raphé nucleus; MAO-B: ependyma, circumventricular organs, hypothalamus, hippocampus, cerebellar Bergman glia cells, inferior olive, posterior pituitary. Using [^{35}S]cRNA probes, e.g. for human MAO-B, it was possible to identify the cellular localization of enzyme synthesis in 5-HT raphé neurones.
The possible role of MAO-A and MAO-B in the aetiology of depression and Parkinson's disease might be elucidated by studying their distribution and expression in diseased human brain using these selective, quantitative and high resolution techniques.

MODULATION OF ^{3}H-NOREPINEPHRINE (^{3}H-NE) RELEASE FROM THE URINARY BLADDER (UB) OF RAT: EFFECT OF IMIPRAMINE. G.T. Somogyi*, J.M. Perel and W.C. de Groat (SPON: A. Mallinger) Clinical Pharmacol. Program, Western Psychiatric Inst. and Clinic and Dept. Pharmacol., Univ. of Pittsburgh, Pittsburgh, PA 15213.

Cholinergic modulation of ^{3}H-NE release was studied in rat UB strips prelabelled with ^{3}H-NE. ^{3}H-NE uptake was very prominent in the UB base where the noradrenergic innervation is most dense. Electrical field stimulation (30V, 2 HZ, 240 shocks) markedly increased ^{3}H-NE outflow from the superfused tissue. The quantity of ^{3}H-NE released was approximately equal during three consecutive periods of stimulation. Activation of presynaptic muscarinic receptors by 0.1 uM oxotremorine (OXO) led to a 46% reduction of the ^{3}H-NE release. Either 1 uM atropine (ATR) or 1 uM imipramine administered with OXO increased the release above the control (147% and 158% respectively). Both 1 uM ATR and 1 uM yohimbine (YOH) increased the release of ^{3}H-NE (167% and 311% of the control respectively). ATR given after YOH had a smaller facilitatory effect than YOH given after ATR (176% and 366% respectively). We conclude that the release of ^{3}H-NE is modulated via endogenous transmitters acting on both muscarinic and alpha$_2$ adrenergic presynaptic receptors and that the latter provide the most prominent control. Imipramine, a drug that is used to treat hyperactive UB conditions exerts a strong antagonistic effect on muscarinic presynaptic receptors and thereby increases the release of NE; an action which very likely contributes to the therapeutic effects of the drug. Supported by USPHS Grant MH 30915, NSF BN-82-08348, NIH AM 316 888.

SIGMA ANTAGONIST MJ 14802 INCREASES NEUROTENSIN CONCENTRATION IN THE RAT NUCLEUS ACCUMBENS AND CAUDATE NUCLEUS. B. Levant, G. Bissette, and C.B. Nemeroff. Depts. Pharmacol. and Psychiat., Duke Univ. Med. Ctr., Durham, NC 27710.

Treatment with typical antipsychotic drugs, such as haloperidol, selectively increases the concentration of neurotensin (NT) in the nucleus accumbens and caudate nucleus of the rat. These increases in NT concentration may mediate the therapeutic and side effects, respectively, of antipsychotic drugs. Many antipsychotic drugs have been shown to posess high affinity for the sigma receptor. This study evaluated the effects of selective blockade of sigma and D_2 dopamine receptors on regional brain NT concentrations. NT concentrations in discrete brain regions of adult, male, S-D rats were measured by a sensitive and specific radioimmunoassay. Acute treatment with the selective sigma antagonist MJ 14802 (3 - 60 mg/kg, i.p.) increased the concentration of NT in the nucleus accumbens and caudate nucleus in a dose-related manner ($P<0.01$ at 35 mg/kg). Chronic treatment with MJ 14802 (21 days, 35 mg/kg/day) produced similar increases in NT concentration in these brain regions ($P<0.01$). Neither acute nor chronic treatment with the selective D_2 antagonist sulpiride (100 mg/kg, i.p.) produced the pattern of NT alterations observed after administration of haloperidol. Thus, sigma receptors, rather than dopamine receptors, may mediate the effects of typical antipsychotic drugs on regional NT concentration. Supported by NIMH MH-39415.

THE MELATONIN RECEPTOR IS COUPLED TO A G-PROTEIN. J.T.Laitinen and J.M.Saavedra., Lab. Clin. Sci., NIMH,Bethesda, MD 20892.

We used quantitative autoradiography to characterize 2-iodo-melatonin binding sites in the rat suprachiasmatic nuclei (SCN) and area postrema (AP) and compared them with those in the chick retina (Dubocovich, FASEB J., 2:2765,1988).

In all three areas, saturation studies revealed high affinity binding sites (K_d ~50 pM) with varying binding capacity (B_{max} ~10, ~30 and ~70 fmol/mg protein for SCN, AP and chick retina, respectively). Displacement studies gave similar results. At least in the SCN, melatonin binding exhibited a diurnal rhythm, a likely reflection from the oscillation of the receptor between two affinity states (Laitinen et.al.,Endocrinol.,124:1585, 1989). To clarify this further, we studied the effect of guanyl and adenyl nucleotides on melatonin binding. Only the guanyl nucleotides dose-dependently inhibited melatonin binding in the three areas. Preliminary data also suggests partial shift of the receptor from high to low affinity state in the presence of 50 μM GTP-gamma-S.

Thus, GTP-binding protein(s) likely participates in melatonin signal transduction. Moreover, our data might explain the discrepancy in affinities reported for the receptor in rat brain.

326.8

IMMUNOCYTOCHEMICAL DEMONSTRATION OF MUSCARINIC ACETYLCHOLINE RECEPTOR PROTEINS IN RAT AND HUMAN NEOCORTEX. INTERACTION WITH CORTICAL PROJECTIONS FROM THE MAGNOCELLULAR BASAL NUCLEUS. P.G.M.Luiten, Gy.Gaál*, R.P.A.Gaykema*, A.D.Strosberg* and H.Schroeder*. Dept. of Animal Physiology, University of Groningen, Groningen, The Netherlands.

Earlier we investigated the projection patterns from the magnocellular basal nucleus (MBN) to the cortex in the rat employing anterogradely transported Phaseolus vulgaris lectin (PHA-L). These projections were analyzed with LM and EM methods and match with cholinergic marker enzyme distribution. Presynaptic labeling with the tracer raised our interest in postsynaptic cholinergic receptors which we investigated with a monoclonal antibody (M35) raised against purified muscarinic receptor proteins.

Application of M35 to rat and human cortical tissue revealed basically identical patterns of immunoprecipitate. At LM level staining of predominantly pyramidal cell types occurred in layer V and somewhat less frequent in layers II/III showing immunoreactive perikaryal cytoplasm and basal and apical dendrites. At the EM level the subcellular distribution revealed the presumed pathway of receptor protein synthesis in the soma, dendritic transport system and postsynaptic membrane incorporation. Double-label pre and postsynaptic staining by peroxidase methods combined with the use of electron-dense particles in the EM indicate PHA-L labeled MBN terminals making symmetric and asymmetric synaptic contacts with M35 labeled neurons.

ANTI-PEPTIDE ANTIBODIES TO m1 MUSCARINIC RECEPTORS SPECIFICALLY LABEL CORTICAL NEURONS. P. F. Strang, D. C. Mash and D. D. Flynn. Depts. of Pharmacology and Neurology, University of Miami School of Medicine, Miami, FL., 33101.

Muscarinic receptor subtypes (M1 and M2) have been postulated on the basis of pharmacological evidence. While recent molecular biological data have demonstrated five distinct primary sequences of the muscarinic receptor, the pharmacological and biochemical properties attributed to each receptor subtype remains unclear. In the present study, monoclonal antibodies (mcabs) were produced against a peptide corresponding to a unique portion in the i3 cytoplasmic loop of the porcine m1 receptor sequence (Kubo et al., *Nature* 323: 411, 1986). Anti-peptide mcabs were screened by ELISA, immunoblot, immunoprecipitation and immunohistochemical procedures. Immunocytochemical localization studies were performed on paraformaldehyde fixed sections of the rat brain. The sections were processed to identify bound primary antibody by either the PAP (double bridge procedure) and/or biotin-avidin methods. Control sections were obtained by eliminating the primary antisera or by adding a nonspecific IgG instead of the mcabs. Sagittal sections reacted with mcabs revealed distinct labelling of pyramidal cells and apical dendrites throughout the cerebral cortex. Scattered neurons were also visualized in the olfactory tubercle and parasubiculum. No cell or fiber labelling was observed in the thalamus, pons or medulla. These results suggest that the m1 mcabs may recognize a subpopulation of the pharmacologically-defined M1 receptor subtype in the rodent brain. Supported by NS19065 and NS 25785.

SUBSTANCE P IMMUNOREACTIVITY IN THE RAT INTERPEDUNCULAR NUCLEUS AND SYNAPTIC INTERACTIONS WITH CHOLINE ACETYLTRANSFERASE AND GLUTAMIC ACID DECARBOXYLASE. M.D. Kawaja*, B.A. Flumerfelt, S.P. Hunt and A.W. Hrycyshyn. Dept. of Anatomy, University of Western Ontario, London, Canada & MRC Molecular Neurobiology Unit, Cambridge, U.K.

Habenular projections of the fasciculus retroflexus (FR) contain substance P (SP) or choline acetyltransferase (ChAT) activity, and provide two prominent topographically organized afferent inputs to the interpeduncular nucleus (IPN) of the ventral midbrain. The IPN also possesses neurons which stain immunohistochemically for SP or glutamic acid decarboxylase (GAD). In the present study the cellular and synaptic distribution of SP-immunoreactive profiles in the rat IPN were examined to determine their synaptic relations with either ChAT-positive FR axons or GAD-positive neurons. Both single and double antigen immunohistochemistry were employed using the chromogens diaminobenzidine and benzidine dihydrochloride. SP-positive axons and terminals were found throughout the nucleus, and SP-positive dendrites and somata were confined to the rostral portion. SP-positive FR terminals in several subnuclei formed contacts with dendritic processes solely, including those of GAD-positive neurons. Terminals of ChAT-positive FR axons contacted SP-positive dendrites. These results provide evidence for synaptic interactions between putative excitatory SP- and ChAT-positive FR axons and IPN neurons possessing GAD or SP activity. (Supported by the MRC of Canada)

PARADOXICAL INCREASE IN INTRACELLULAR CALCIUM (Cai) IN RESPONSE TO GABA IN CULTURED CHICK BRAIN CORTICAL CELLS. M.K. McMillian, L.G. Miller, S. Chesley,* F. Lopez,* A. Schatzki,* Div. of Clinical Pharmacology, Tufts-New England Medical Ctr., Boston, MA.

GABA acts as an inhibitory neurotransmitter in many neuronal systems, increasing Cl^- conductance through the $GABA_A$ receptor channel, and inhibiting Ca^{2+} currents and cAMP accumulation through the $GABA_B$ receptor. In dissociated 8 day old chick embryo cortical cells, cultured for 2-10 days on collagen-coated plates, activations of excitatory amino acid receptors (by glutamate, NMDA, quisqualate or kainate) produce large increases in Cai as measured by changes in Fura 2 fluorescence (ratio method). Surprisingly, GABA also increased Cai in these cells, but not in glial cultures. The increase in Cai was smaller than that obtained with glutamate analogs, but was similar to that obtained with acetylcholine, norepinephrine and ATP. Muscimol (1-50 μM) increased Cai and this effect was blocked by picrotoxinin, suggesting that the $GABA_A$ receptor was involved. The $GABA_B$ antagonist phaclofen (10 μM) did not block. While an indirect effect of GABA on Cai is possible, muscimol effects were observed after exposure to all other aforementioned agonists and their antagonists, and after naloxone. Depolarization of these cells with 40 mM KCl produced a larger effect on Cai than GABA and blocked a subsequent GABA effect.

CARDIOVASCULAR REGULATION III

327.1

INTRACELLULAR ANALYSIS *IN VIVO* OF CARDIOVASCULAR NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA. A.R. Granata and S.T. Kitai, Dept. of Anat. and Neurobiol., College of Medicine, The Univ. of Tenn., Memphis, TN 38163.

Neurons located in the rostral ventrolateral medulla (RVL) at the level of the C1 adrenergic neurons, which project to the intermediolateral nucleus (IML) in the spinal cord, provide an important excitatory drive to sympathetic preganglionic neurons. The purpose of this study was at first to identify these neurons and to characterize the changes in membrane potential occurring during the cardiac cycle. We used a conventional technique to record intracellular potentials. Rats were anesthetized (urethane plus ketamine), paralyzed, and ventilated and arterial blood pressure and EKG monitored. RVL neurons were antidromically activated following IML stimulation (axonal conduction velocity of 2.6-12 m/sec). After penetration, the majority of these neurons discharge at high regular frequencies. Hyperpolarizing currents injected through the recording electrode reduced the frequency of discharge and then action potentials fired at a regular time with respect of pulsatile arterial wave. Further hyperpolarization (current above 1nA) completely suppressed spike potentials but underlying depolarization remained (700-1100 uV; 200 sweeps averaged). The depolarizing potentials always preceeded the pulsatile arterial wave and their amplitude increased with hyperpolarizing current. A second group of neurons were antidromically activated from the IML (axonal conduction velocity of 20-34 m/sec) and monosynaptically activated from the NTS. The recorded neurons were intracellularly injected with biocytin and visualized under avidin-Texas red fluorescent microscopy. After that, the tissue was processed for phenylethanolamine N-methyltransferase (PNMT) immunoreactivity. All the injected neurons were located in C1 area of the RVL. We can conclude that a population of bulbospinal neurons in the RVL discharge spike potentials arising from EPSPs. These EPSPs are synchronized with the cardiac cycle. (Supported by AMER. HEART ASSOC. GRANT #861294 to A.R.G. and NIH GRANT NS20702 to S.T.K.).

ANESTHETIC-DEPENDENT CONTRIBUTIONS OF ROSTRAL LATERAL TEGMENTAL FIELD (rLTF) NEURONS TO SYMPATHETIC NERVE DISCHARGE (SND). M.J. Kenney, S.M. Barman and G.L. Gebber. Dept. Pharmacol., Mich. St. Univ., E. Lansing, MI 48824.

The LTF of the caudal medulla (0-4 mm above obex) contains many neurons whose basal discharges are correlated to the 2- to 6-Hz rhythm in SND of barbiturate-anesthetized cats (Gebber and Barman, J. Neurophysiol. 54: 1498, 1985). In contrast, few such neurons were found in the rLTF (4-7 mm above obex) in these preparations. The current study shows that the concentration of rLTF neurons with sympathetic nerve-related activity is dramatically increased under α-chloralose anesthesia. Unit spike-triggered averaging of inferior cardiac SND revealed that the discharges of ~50% of rLTF neurons were synchronized to an aperiodic sharp spike-like event in SND. On occasion, LTF unit activity was correlated to both the aperiodic event and the 2- to 6-Hz rhythm in SND. Microstimulation at rLTF unit recording sites elicited an increase in SND with temporal characteristics similar to that following spontaneous unit activity. Importantly, rLTF neurons with sympathetic nerve-related activity could not be found following midcollicular decerebration in chloralose-anesthetized cats. These results support the view that an aperiodic spike-like component of SND in chloralose-anesthetized cats is mediated by rLTF neurons that are driven by inputs from the forebrain. (Supported by NIH Grants HL33266 and HL13187.)

327.3

VISCEROTOPIC ORGANIZATION OF AFFERENTS OF NUCLEUS TRACTUS SOLITARII TO VENTROLATERAL MEDULLA. R.E. Gomez*, D.A. Ruggiero, S.L. Cravo*, E.P. Mtui*, and D.J. Reis. Div. of Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021. (SPON: J.E. LeDoux)

The nuclei reticularis rostroventrolateralis (RVL) and caudoventrolateralis (CVL) integrate cardiorespiratory (C-R) reflexes and receive afferents from nucleus tractus solitarii (NTS). Yet, the precise viscerotopic organization of the projection is unknown. Sprague-Dawley rats (300-350 g; n=20) were anesthetized with chloral hydrate (0.5 g/kg). *Phaseolus vulgaris* leucoagglutinin (PHA-L) was iontophoresed (7 µA anodal, 7 sec on/off, 15 min) into the caudal two-thirds of NTS. PHA-L labeled varicosities outlined the pyramidal and columnar organization of RVL and CVL. In other experiments, retrograde tracers, Fluoro-Gold, rhodamine-microbeads or WGA-HRP were deposited into RVL and CVL and the distribution of backfilled cells were mapped in medulla. RVL deposits labeled cells in n. retroambiguus (nRA), RVL, n. reticularis dorsalis (RD) and NTS. In NTS, cells were concentrated in dorsal (lateral), medial (parvicellular and subpostremal), intermediate and medial commissural subnuclei. Fewer cells were labeled in lateral and interstitial nuclei. CVL deposits labeled RVL, n.RA, RD and NTS. In NTS most neurons were in ventral, ventrolateral, interstitial, intermediate and lateral commissural subnuclei; few cells were labeled in dorsal or medial divisions. Control injections adjacent to RVL or CVL labeled few cells in NTS. Double-labeled NTS cells followed injections into regions transitional between RVL and CVL. In conclusion, cells of origin of NTS afferents to RVL and CVL are distributed viscerotopically, in a dorsomedial to ventrolateral direction. Single cells projecting to both RVL and CVL and 'interreticular' connections suggest anatomical substrates for C-R integration.

327.4

AFFERENTS FROM VENTROLATERAL MEDULLA TO NUCLEUS TRACTUS SOLITARII AND SPINAL CORD. E.P. Mtui*, R.E. Gomez*, D.A. Ruggiero, M. Anwar* and D.J. Reis. Div. Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021. (SPON: D.A. Fischman)

Neurons in the ventrolateral medulla (VLM) synthesize catecholamines (CA) and neuropeptides; maintain vasomotor tone and modulate cardiopulmonary reflexes relayed by the nucleus tractus solitarii (NTS). Sprague-Dawley rats (300-350g) were anesthetized with chloral hydrate (0.5 g/kg). We first sought to determine whether neurons in nucleus reticularis rostroventrolateralis (RVL) project to the NTS and spinal cord. *Phaseolus vulgaris* leucoagglutinin (PHA-L) iontophoresed into RVL (7 µA anodal, 7 sec on/off, 15 min) labeled terminals in NTS (dorsal-lateral, ventral, intermediate and commissural) subnuclei and intermediolateral cell columns (IML). Projection neurons in VLM were defined by injecting Fluoro-Gold (FG) and rhodamine microbeads (Rhod) into the thoracic cord and NTS. Cells throughout VLM contained FG or Rhod and were admixed with double-labeled cells in RVL. In the caudal VLM, prespinal cells in nucleus retroambiguus were dorsomedial to NTS-projection cells. In order to determine the contribution of CA neurons to the projections, single- and double-retrogradely labeled cells were photographed and tissues processed immunocytochemically (PAP) for tyrosine hydroxylase (TH). TH-immunoreactive backfilled cells were restricted to RVL, whereas most double-labeled (FG/Rhod) cells were immunonegative. To confirm the VLM projection to NTS, WGA-HRP was injected into NTS and tissues were processed for both retrograde transport and TH. Cells containing WGA-HRP and TH were skewed medially in the C1 adrenergic area of RVL; most projection neurons were immunonegative. In conclusion, adrenergic and primarily non-adrenergic projection neurons in VLM may modulate both cardiopulmonary reflex excitability and sympathetic vasomotor tone.

327.5

ANATOMICAL SUBSTRATES OF VENTRAL SURFACE CHEMORECEPTOR REFLEX. D.A. Ruggiero, T.A. Milner, M. Anwar and D.J. Reis. Div. Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021.

Structures integrating cardiopulmonary responses to chemoreceptor and pharmacologic stimulation of the carotid body (CB) and ventral medullary surface (VMS) are unknown. We sought to determine by light and electron microscopy (EM) the anatomical substrates integrating chemoreceptor functions of the CB and VMS. Sprague-Dawley rats (300-350 g) were anesthetized with halothane (2% in 100% O_2). (1) Transganglionic transport of wheat germ agglutinin-horseradish peroxidase (WGA-HRP) injected into CB labeled punctate varicosities in caudal divisions of nucleus tractus solitarii (NTS). (2) *Phaseolus vulgaris* leucoagglutinin (PHA-L) iontophoresed into NTS labeled terminals in a) nuclei reticularis rostroventrolateralis (RVL) and caudoventrolateralis (CVL) and b) along a thin sheet lining the glutamate sensitive area of the rostral VMS subjacent to RVL. (3) PHA-L deposits in RVL labeled terminals in CVL and along a similar strip of VMS. (4) Histochemical demonstration of transport of solid WGA-HRP (in tygon rings, 0.4mm i.d.) applied onto VMS combined with immunocytochemical labeling for serotonin or the adrenaline-synthesizing enzyme, phenylethanolamine N-methyltransferase (PNMT) backfilled monoaminergic and non-monoaminergic perikarya in RVL and areas of NTS which received CB afferents. (5) EM revealed that within 0.5μm of the VMS a) PNMT-immunoreactive (ir) terminals formed synapses with unlabeled dendrites and b) PNMT-ir dendrites were ensheathed by astrocytic processes. These data suggest that cardiopulmonary portions of the NTS link chemoreceptors of the CB and VMS via monoaminergic neurons in the nucleus RVL. (Supported by NIH 18974 and an AHA Established Investigator Award (DAR)).

CONTRIBUTION OF ADRENALINE SYNTHESIZING NEURONS IN THE VENTROLATERAL MEDULLA TO CIRCULATORY CONTROL. J. Ciriello and T.-X. Zhang. (SPON: R. McLachlan) Department of Physiology, University of Western Ontario, London, Canada N6A 5C1.

We have recently described an asymmetric distribution of phenylethanolamine N-methyltransferase (PNMT) containing neurons in the rostral ventrolateral medulla (VLM) of the Wistar Kyoto (WKY) rat. On the basis of this observation we investigated the contribution of PNMT neurons of the C1 region to the cardiovascuar responses elicited during chemical stimulation. The VLM was systematically explored in alpha-chloralose anesthetized and atropine treated WKY rats for pressor and cardioacceleratory sites using microinjections (12-25nl) of L-glutamate. At the end of each experiment the animal was perfused with Zamboni's fixative and transverse brain stem sections were processed immunocytochemically for the demonstration of PNMT. It was found that in 16 of 24 (66%) WKY rats studied, glutamate injections elicited increases in arterial pressure on one side of VLM only, whereas increases in heart rate were elicited from both sides. The pressor sites were found only in those areas containing PNMT neurons. These data support the hypothesis that adrenaline neurons in VLM are involved in vasomotor control, and suggest that an alternate population of neurons in the same VLM region provides an excitatory input to spinal cardioacceleratory neurons. (Supported by MRC of Canada)

327.7

Activation of 5-HT_2 Receptors at the Intermediate Area of the Ventrolateral Medulla Leads to Changes in Cardiorespiratory Activity. A.K. Mandal, K.J. Kellar, and R.A. Gillis. Department of Pharmacology, Georgetown University School of Medicine, Washington, D.C. 20007.

Recently, we proposed that serotonin (5-HT) may have a dual effect on cardiorespiratory activity at the intermediate area (IA) of the ventrolateral medulla (JPET 248(2):851-857). Specifically, we have shown that activation of 5-HT_{1A} receptors at the IA results in hypotension, bradycardia, and respiratory stimulation as caused by an increase in respiratory rate (f). Application of 5-HT to the IA also causes hypotension and bradycardia. These effects of 5-HT are intensified by prior blockade of 5-HT_2 receptors. The greater responses obtained by 5-HT after blockade of 5-HT_2 receptors may have been due to 5-HT's activating 5-HT_2 receptors, leading to increases in blood pressure (BP) and heart rate (HR). To test this hypothesis, a specific agonist for 5-HT_2 receptors, 1-(2,5-dimethoxy-4-iodophenyl)-2-amino-propane or DOI, was applied bilaterally to the IA of chloralose- anesthetized cats in a dose of 30 ug/side. DOI significantly increased BP (39±7 mmHg, $p<0.05$) and decreased f (-5±0 breaths/min, $p<0.05$) (n=8). Pretreatment with the 5-HT_2 antagonist, ketanserin (25 ug/side), prevented the cardiorespiratory effects of DOI (n=7). N-methyl-D-aspartate (NMDA) applied to the IA (11 ug/side) produced a similar increase in BP as observed with DOI; however, ketanserin did not counteract the hypertensive effect of NMDA. Ketanserin by itself caused a significant decrease in BP (-18±5 mmHg, $p<0.05$). These observations indicate that 5-HT_2 receptors and 5-HT_{1A} receptors located at the IA have oppposing effects on cardiorespiratory activity. Furthermore, since ketanserin by itself produced a decrease in blood pressure, we suggest that 5-HT_2 receptors at the ventrolateral medulla are under tonic activation.

327.8

AFFERENT SOURCES OF SUBSTANCE P-LIKE IMMUNO-REACTIVITY IN THE ROSTRAL VENTROLATERAL MEDULLA. R. Giuliano, T.A. Milner and D.J. Reis. Div. of Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021

Functional (*Brain Res.* 245:279, 1982) and anatomical (*Neurosci. Lett.* 55:255, 1985) evidence implicates the undecapeptide substance P (SP) in the cardiovascular functions of the rostral ventrolateral medulla (RVL). Terminals containing SP-like immunoreactivity (SPLI) form synapses with neurons of the C1 adrenergic group (C1 area) in the RVL (*J. Comp. Neurol.* 270:427, 1988). We sought to determine the sources of SP innervation of this major circulatory control region. Immuno-peroxidase labeling of a polyclonal antiserum against SP was combined with histochemical identification of wheat germ agglutinated horseradish peroxidase (WGA-HRP) in colchicine-treated rats. Unilateral pressure injections of WGA-HRP were made into the C1 area. In single sections processed for immunocytochemical localization of SP and retrograde labeling of WGA-HRP several afferent sources of SPLI to the RVL were detected. Dual-labeled neurons were seen primarily in the laterodorsal tegmental nucleus, lateral and medial divisions of the parabrachial nucleus and raphe nuclei of pons and medulla. Other dual-labeled neurons were distributed in the perifornical area, bed nucleus of the stria terminalis, lateral and dorsal hypothalamic areas and periaqueductal central gray. Single dual-labeled cells occurred scattered in the RVL contralateral to the injection site, the nucleus tractus solitarii and A1 area. In several regions (including periaqueductal central gray, central amygdaloid nucleus and various hypothalamic nuclei) cells con-taining SPLI were surrounded by anterograde label from the RVL. We conclude that (1) nerve terminals containing SPLI which innervate the RVL may derive from both local and extrinsic sources and that (2) RVL neurons may influence neurons with SPLI in certain brain areas.
